Our patient did not display any symptoms. He only had an iron deficiency anemia. Six months after beginning low-dose methotrexate (15 mg/wk), a iron deficiency anemia developed. He showed no signs or symptoms of mucositis, or symptoms of bone marrow toxicity, or of renal or liver impairment. No diarrhea, nausea or other gastro-intestinal symptoms were present. We believe he had an iron malabsorption, secondary to duodenal atrophy, which slowly resolved after removing methotrexate, with clinical, analytical, endoscopical and microscopical confirming the healing.

This drug is frequently used in patients with rheumatological, gastroenterological and oncological illnesses. At high doses, and without folic acid supplementation, mucositis is a side-effect in which experimental studies have tried to understand[4,5] for prevention[6-7]; however, not many human cases have been described. Its presentation is usually symptomatic (weight-loss, diarrhea, nausea, general malaise, *etc*) and tends to appear with high doses.

The pathogenesis of the sprue-like syndrome is unclear. Two mechanisms might be involved, local antimetabolite toxicity and genetic predisposition[3].

Our case might allow other clinicians to think of an underlying sprue-like syndrome when a iron deficiency anemia appears when taking methotrexate, even if, like in our case, the patient is taking low doses of the drug and is completely asymptomatic.

This methotrexate-induced sprue-like syndrome is of clinical interest because of its singularity in the clinical presentation (only iron deficiency anemia), its origin (a duodenal atrophy induced by low-dose methotrexate, with no myelosuppression), and its complete resolution after withdrawal of the drug, which has been confirmed both through the periodical analysis and through the endoscopical study.

Abstract

A small subset of patients with active ulcerative colitis is non-responsive to major known non-biological therapies. We reported 5 patients with positive serum proteinase-3 antineutrophil cytoplasmic antibody (PR3-ANCA) and tried to (1) identify the common clinical features of these patients; (2) investigate the efficacy of a novel therapy using a Chinese medicine compound; and (3) attract more gastroenterologists to be engaged in further study of this subset of patients. The common manifestations of disease in these 5 patients included recurrent bloody diarrhea and inflammatory lesions involving the entire colorectal mucosa. Initial treatment with intravenous methylprednisolone successfully induced remission. Four of these 5 patients were steroid-dependence, and immunosuppressants, such as azathioprine and cyclophosphamide, were ineffective. In 3 patients, only the particular Chinese medicine compound could induce and maintain remission. One patient underwent colectomy. No vascular inflammatory lesions were found by histopathological examination. Although more cases are needed for confirmation, our study indicates that ulcerative colitis with positive PR3-ANCA may belong to a subtype of refractory ulcerative colitis. The particular Chinese medicine compound used in our study is by far the most effective in the management of these patients, with additional advantages of having no noticeable side-effects and less financial burden.

INTRODUCTION

Ulcerative colitis (UC) is a disease of chronic inflammation of colon, which is diagnosed by a combination of clinical, colonoscopic, histopathological, radiological findings and therapeutic response. Infectious and non-infectious colorectal diseases such as Crohn's disease, ischemic colitis, collagenous colitis, lymphocytic colitis and colorectal cancers should be excluded. The principle therapy is 5-aminosalicylic acid for mild to moderate disease, and corticosteroids for moderate to severe disease. If both are ineffective, cyclosporin A is considered as a salvage therapy[1]. Colectomy has to be used in those who fail on medical treatment. Either 5-aminosalicylic acid or azathioprine is recommended for maintenance of remission[2]. In clinical practice, some patients would prefer to die rather than have a colectomy as this can impair quality of life. These patients are the challenge for gastroenterologists who are trying their best to seek promising medicine.

In 2006, a refractory UC patient treated in the Division of Gastroenterology, Shanghai Renji Hospital was unexpectedly found to be serum proteinase-3 antineutrophil cytoplasmic antibody (PR3-ANCA)

positive. Therefore, all UC patients admitted from Jan 2003 to Dec 2007 were screened and the PR3-ANCA positive patients were studied and analyzed.

CASE REPORT

The clinical data of 180 UC patients admitted from Jan 2003 to Dec 2007 were analyzed, 65 patients were investigated for ANCA and only 5 patients were positive for PR3-ANCA. Their demographic and clinical characteristics are summarized in Table 1. The disease activity of UC was evaluated according to Truelove & Witts criteria. Serum myeloperoxidase (MPO)-ANCA was negative (< 1.4) and PR3-ANCA was positive (> 1.4) in all 5 patients. The common disease manifestations in these 5 patients included recurrent bloody diarrhea and inflammatory lesions involving the entire colorectal mucosa (Table 2).

Remission was initially and successfully induced in all 5 patients by treatment with iv Methylprednisolone (Table 3). Four of them relapsed when the prednisone dosage was reduced. In accordance with the principle of UC therapy, azathioprine was prescribed in 3 patients. As 75 mg/d or 100 mg/d could not be tolerated, 50 mg/d was adopted for more than 3 mo but remained without effect. Cyclophosphamide 0.6 g iv was also ineffective. Case 1 had tried cyclosporin A, but this was discontinued because of vomiting. Her life was threatened by bloody diarrhea more than twenty times per day, a high temperature of 40℃, and venous thrombosis of the left leg. She was persuaded again and again, and at last reluctantly accepted colectomy. One patient (case 2) had bloody diarrhea more than ten times per day and a high temperature when prednisone was reduced in dosage from 40 mg/d. She visited a traditional Chinese medicine physician and successfully withdrew the prednisone by taking a Chinese medicine compound prescribed by that physician. Remission was successfully maintained for more than 1 year. She discontinued the Chinese medicine compound by herself because she thought the disease was cured but bloody diarrhea recurred within 2 mo. She started to take the Chinese medicine compound again and her bloody diarrhea quickly disappeared. She returned to her work without any side effects caused by the Chinese medicine, but refused to undergo colonoscopy again.

As a result of this outcome, cases 3 and 4 were recommended to visit the same traditional Chinese medicine physician. They were able to reduce the dose of prednisone gradually after taking the Chinese medicine compound and successfully maintain the remission.

Repeat colonoscopies were performed in 4 of these 5 patients because of recurrent bloody diarrhea. Case 1 showed severe inflammatory lesions involving the entire colorectal mucosa with bleeding and many large deep irregular ulcers before therapy. After prednisone treatment, scars in the cecum and ascending colon, pseudopolyps in the transverse colon, and scattered erosions in the rectosigmoid colon were observed. When bloody diarrhea relapsed 20 times per day, colonoscopy revealed severe inflammatory lesions of entire colorectal mucosa. Case 2 initially showed inflammatory lesions involving the entire colorectal mucosa. When bloody diarrhea relapsed during the maintenance therapy with sulphasalazine 1.5 g/d, colonoscopy revealed again inflammatory lesions from the hepatic flexure to the rectum. Case 3 revealed severe inflammatory lesions involving the entire colorectal mucosa initially and limited lesions were found in the rectosigmoid colon with several ulcers after treatment with prednisone. Case 4 initially showed inflammatory lesions involving the entire colorectal mucosa. Once bloody diarrhea was alleviated, ulcers in the rectosigmoid colon were observed. However, colonoscopy showed inflammatory lesions involving the entire colorectal mucosa again when she was taking prednisone 15 mg/d. Case 5 showed mild inflammatory lesions involving the entire colorectal mucosa with scattered erosions but no ulcers. He was the only patient who did not relapse during nearly 1 year follow up.

Table 1 Demographic data of the five patients

Case	Gender	Age (yr)	Date of admission[1]	Date of initial diagnosis
1	Female	57	Dec 2006	Nov 2006
2	Female	48	Feb 2007	Jun 2006
3	Male	67	Jun 2007	May 2007
4	Female	33	May 2006	May 2004
5	Male	55	Jul 2007	May 2007

[1]Patients were admitted to Division of Gastroenterology, Shanghai Renji Hospital.

The colonoscopic biopsies of 4 patients (cases 1, 2, 3 and 5) and the surgical colon resection specimen of case 1 were examined by 2 experienced pathologists. No vascular inflammatory lesions were found.

Constituents of the particular Chinese medicine compound were: Fllase Asiabell Root Tangshen, Garden Burnet Root, Milkvetch Root, Largehead Atractylodes Rhizome, Lignum et Radix Cudraniae, White Peony Root, Whiteflower Patrinia Herb, Herba Violae, Common Bletilla Tuber, Japanese Pagodatree Flower-bud, Lalang Grass Rhizome, Whipformed Typhonium Rhizome, Folium Isatidis, Hairyvein Agrimonia Herb and Bud, *etc*.

DISCUSSION

ANCA is a group of antibodies directed against certain proteins in the cytoplasm of neutrophils. There are 2 major categories of ANCA that can be determined by immunofluorescence staining. Perinuclear ANCA (pANCA) refers to the more localized perinuclear or nuclear staining pattern; cytoplasmic ANCA (cANCA) refers to the diffuse, granular staining pattern. It has been shown that ANCA is associated with small-vessel vasculitis. MPO-ANCA is related to polyangiitis or allergic granulomatous angiitis, and PR3-ANCA is a specific and sensitive marker of Wegener's granulomatosis[3,4]. Wegener's granulomatosis is a systemic and necrotizing granulomatous vasculitis. The main manifestations of Wegener's granulomatosis are lung nodular infiltration, upper respiratory tract diseases and proteinuria/

Table 2 Common manifestations of disease in the five patients

Case	Bloody diarrhea	Abdominal pain	Relapse	Activity	Colonoscopy	Histological examination	Other colorectal inflammation
1	20 times/d	Yes	Yes	Severe	Entire colorectum erosion, ulcer	Mucosa inflammatory	No
2	4 times/d	Yes	Yes	Moderate	Entire colorectum erosion, ulcer	Mucosa inflammatory	No
3	6 times/d	Yes	Yes	Severe	Entire colorectum erosion, ulcer	Mucosa inflammatory	No
4	7 times/d	Yes	Yes	Severe	Entire colorectum erosion, ulcer	Mucosa inflammatory	No
5	5 times/d	Yes	No	Moderate	Entire colorectum erosion	Mucosa inflammatory	No

Table 3 Treatment of the five patients

Case	Induction of remission	Immunosuppressant		Maintenance of remission
		Azathioprine	Cyclophosphamide	
1	Methylprednisolone 40 mg/d, iv	50 mg/d, po	0.6 g, iv	Colectomy
2	Methylprednisolone 40 mg/d, iv Chinese medicine compound			Chinese medicine compound
3	Methylprednisolone 40mg/d, iv + prednisone 20 mg/d, po Chinese medicine compound	50 mg/d, po	0.6 g, iv	Chinese medicine compound
4	Methylprednisolone 40 mg/d or 80mg/d, iv	50 mg/d, po	0.6 g, iv	Chinese medicine compound
5	Methylprednisolone 40 mg/d, iv			Sulphasalazine 2 g/d

hematuria. Kidney, nasal mucosa or lung biopsies reveal granulomatous lesions. If the disease involves the colon, the patient may have bloody diarrhea. The principle treatment of vasculitis is to use prednisone or cyclophosphamide to induce remission and then use cyclophosphamide or azathioprine for the maintenance of remission. Three to 6 mo therapy is usually needed for inducing remission, but the relapse rate is high. Long-term morbidity and mortality are high[5,6].

The 5 patients reported here did not meet the criteria of Wegener's granulomatosis (case 2 had a nasal polyp but CT scan showed no lung lesion, and biopsies of the nasal polyp and kidney did not show any granuloma). Also, histopathological studies of the 4 patients examined did not reveal any vascular inflammation in either biopsy or surgical specimen of the colon.

It was reported that UC had a high pANCA positivity, which was further identified as MPO-ANCA, LF-ANCA, and BPI-ANCA, *etc*[7,8]. The presence of pANCA combined with anti-Saccharomyces cerevisiae mannan antibodies was recommended as a way to distinguish UC from Crohn's disease[9]. PR3-ANCA belongs to cANCA, which is not a deep concern with UC because of its low positivity. Liu et al reported 5 of 58 UC patients had positive PR3-ANCA, but the significance of this finding was not mentioned[10]. In Elzouki's report, 17 of 141 UC patients were PR3-ANCA positive, but no relationship was found between PR3-ANCA and the severity of UC[11]. In the 5 patients reported here, inflammatory lesions involving the entire colorectum were seen. The probable reason for the difference is that our patients were naive, while corticosteroids could lessen the extent of the lesion. Although corticosteroids could induce remission temporarily, maintenance of remission and recurrence are problems that are hard to solve. What is the effective treatment for UC with positive PR3-ANCA?

Azathioprine was employed in 3 steroid-dependent patients. In the 3 patients, 50 mg/d had been used for more than 3 mo, but bloody diarrhea relapsed when the dose of prednisone was reduced to 30 mg/d. Azathioprine has been recommended for maintenance therapy of both UC and ANCA-associated vasculitis[4,6], but was ineffective in our UC patients. Recurrence of bloody diarrhea suggested that azathioprine was ineffective.

Cyclophosphamide has been recommended for the management of active vasculitis, and it was also reported that it could successfully induce remission in Crohn's disease and indeterminate colitis[12]. Cyclophosphamide had been given in our 3 steroid dependent patients; however it was ineffective. Anti-tumor necrosis factor-α antibody has been reported to be effective for refractory UC patients[13]. However, it is too expensive and could not be afforded by ordinary Chinese patients. In our 3 patients, the Chinese medicine compound successfully induced and maintained remission. (Case 1 had a colectomy and did not have a chance to try the Chinese medicine compound). It is suggested that the Chinese medicine compound might be one of the best treatments for UC with positive PR3-ANCA.

Our preliminary study indicates that UC with positive PR3-ANCA may belong to a subtype of refractory UC. The Chinese medicine compound prescribed is not only more effective than Methylprednisolone but also has the merit of being without noticeable side-effects. However, more evidence is needed. We hope more gastroenterologists can be attracted and more cases will be accumulated. The particular Chinese medicine compound

is worthy of further study and the effective constituents should be identified.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

The limited efficacy of cytotoxic therapy for advanced biliary tract and gallbladder cancers emphasizes the need for novel and more effective medical treatment options. A better understanding of the specific biological features of these neoplasms led to the development of new targeted therapies, which take the abundant expression of several growth factors and cognate tyrosine kinase receptors into account. This review will briefly summarize the status and future perspectives of antiangiogenic and growth factor receptor-based pharmacological approaches for the treatment of biliary tract and gallbladder cancers. In view of multiple novel targeted approaches, the rationale for innovative therapies, such as combinations of growth factor (receptor)-targeting agents with cytotoxic drugs or with other novel anticancer drugs will be highlighted.

INTRODUCTION

Biliary tract cancers (BTC) originate from the intra- or extrahepatic bile duct epithelium[1]. They were first described by Durand-Fardel in 1840[2,3]. The extrahepatic type (cholangiocarcinoma), primarily cancers involving the confluence of the right and left hepatic ducts, accounts for 80%-90%, and the intrahepatic type (cholangiocellular carcinoma) for the remaining 10%-20% of all biliary tract cancers. Hilar BTC as a specific sub-entity was first reported by Klatskin in 1965, hence their designation as Klatskin tumors[4]. BTC have been considered rare malignancies comprising only 3% of gastrointestinal tumors. However, interest in BTC is growing due to a rising worldwide incidence and associated mortality especially in intrahepatic BTC[5-8].

BTC is notoriously difficult to diagnose and is usually fatal because of its late clinical presentation and the lack of effective non-surgical treatment modalities[9]. Surgical resection or liver transplantation remain the only potentially curative therapeutic options. Unfortunately, most patients have unresectable disease at presentation and die within 12 mo. Liver failure and recurrent sepsis, secondary to biliary obstruction, also contribute to the high mortality[10]. Overall survival rate is poor, with less than 5% of BTC patients surviving to 5 years, a rate which has not changed significantly over the past 30 years[11]. Similar to BTC, there is currently no standard chemotherapy regimen for patients with advanced gallbladder cancer.

Therefore, innovative drugs are urgently needed for effective medical treatment of biliary tract and gallbladder cancers. This review will provide a perspective overview of selected agents, which are currently in development, or under consideration or testing for a more effective, targeted treatment of BTC (Table 1; Figure 1)[12-24]. Moreover, we will discuss promising approaches, which

Table 1 Current status of clinical trials with agents that target growth factor receptors and related signaling pathways for treatment of biliary tract and gallbladder cancers

Name	Target	Mechanism	Cotreatment	Status	Clinical trials
Bevacizumab	VEGF	VEGF-neutralizing antibody	Erlotinib	Phase Ⅱ	NCT00350753[17]
			Erlotinib	Phase Ⅱ	NCT00356889[18]
			Radiation	Phase Ⅰ	NCT00426829[21]
			Floxuridine, dexamethasone	Phase Ⅱ	NCT00410956[20]
			Gemcitabine, oxaliplatin	Phase Ⅱ	NCT00361231[19]
Cediranib (AZD2171)	PAN-VEGFR, PDGFR, c-KIT	Tyrosine kinase inhibitor	AZD-0530	Phase Ⅰ	NCT00475956
Cetuximab	EGFR	Monoclonal antibody	Gemcitabine, oxaliplatin	Phase Ⅱ	NCT00552149 (BINGO)[22]
Erlotinib	EGFR	Tyrosine kinase inhibitor		Phase Ⅱ	NCT00033462[12]
			Gemcitabine	Phase Ⅰ b	
			Oxaliplatin, gemcitabine, radiation	Phase Ⅰ	NCT00266097[16]
Lapatinib	EGFR, erbB2	Tyrosine kinase inhibitor		Phase Ⅱ	NCT00107536[14]
Sorafenib	VEGFR, PDGFR, c-Raf, B-Raf	Tyrosine kinase inhibitor	Oxaliplatin,	Phase Ⅱ	NCT00238212[15]
			Capecitabine	Phase Ⅰ / Ⅱ	NCT00634751[23]
			Gemcitabine	Phase Ⅰ / Ⅱ	NCT00661830 (GEMSO)[24]
Bortezomib	Proteasome	Proteasome inhibitor		Phase Ⅱ	NCT00085410[13]
			Docetaxel	Phase Ⅰ	

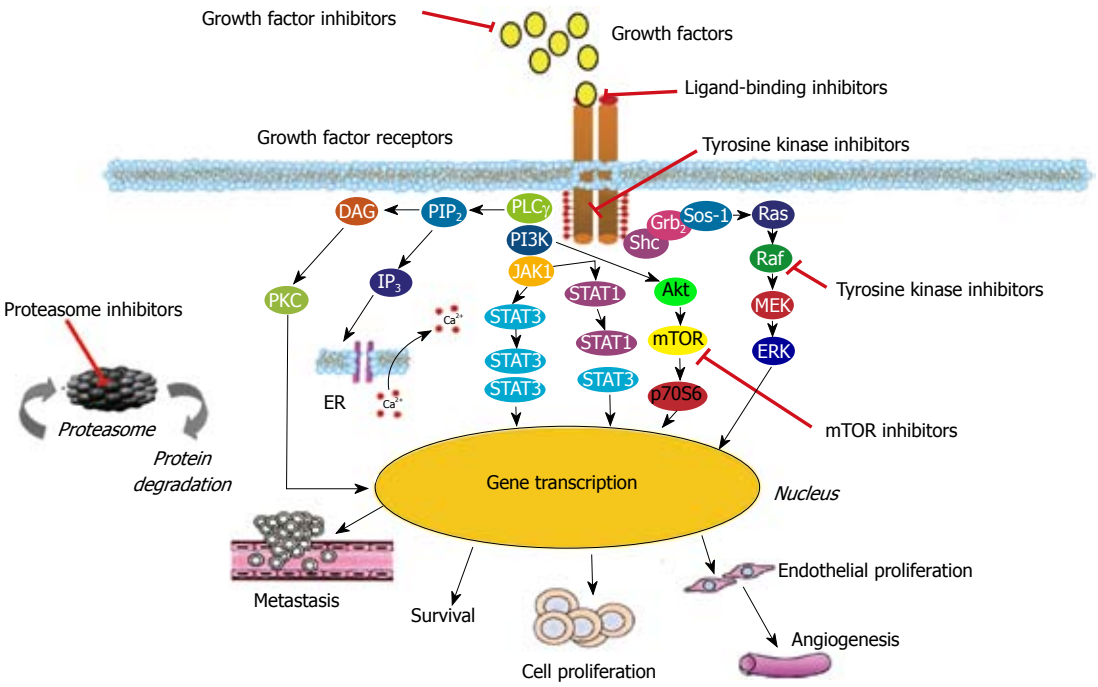

Figure 1 Major growth factor receptor signaling pathways. TK: Tyrosine kinase; P: Phosphorylation; MEK: Mitogen-activated protein kinase; ERK: Extracellular signal-regulated kinase; PI3K: Phosphatidylinositol-3 kinase; mTOR: Mammalian target of rapamycin; JAK: Janus kinase; STAT: Signal transducer and activator of transcription.

have not yet been tested in BTC or gallbladder cancer, but warrant future evaluation.

ANTIANGIOGENIC TREATMENT STRATEGIES

Angiogenesis plays a central role in tumor growth and progression, and its implications have been extensively investigated and described in the literature for various cancers[25,26]. In the early 1970s, Folkman J[27] was the first to develop the concept of angiogenesis-dependent tumor growth and postulated that the specific blocking of blood flow to the tumor should be a promising strategy for cancer treatment.

Among the angiogenic factors/receptors described so far, the vascular endothelial growth factor (VEGF) and VEGF receptor family including the secreted glycoproteins VEGF-A, VEGF-B, VEGF-C, VEGF-D, VEGF-E, the placental growth factors (PlGF-1,-2), and their cognate receptors VEGFR-1 (Flt-1) and VEGFR-2 (Flk/KDR) play major roles in not only physiological but also in pathological angiogenesis. VEGF-A which binds to both VEGFR-1 and -2 is a key regulator of the development of the vascular system and is commonly

overexpressed in a variety of solid tumors[28].

In addition, elevated levels of circulating VEGF-A are correlated with progression and metastasis of gastrointestinal cancers. A recent study confirmed that elevated VEGF expression correlated with increased metastasis of intrahepatic cholangiocarcinoma[29]. Here upregulated VEGF-C, which plays an important role in the lymph node metastasis of intrahepatic cholangiocarcinoma, was the best independent factor for a poor prognosis[30].

In this vein VEGF protein is overexpressed in cholangiocarcinomas[31], which is paralleled by VEGFR-1, -2 expression in the surrounding endothelial cells[32,33]. Therefore the VEGF/VEGFR system is an attractive target for the treatment of these almost chemoresistant cancers.

ANTIBODY-BASED ANTIANGIOGENIC THERAPY

Anti-VEGF treatment

Bevacizumab is a humanized murine monoclonal anti-VEGF antibody, which when combined with standard cytostatic treatment significantly increased survival in patients with metastatic colorectal cancer as compared to standard treatment alone[34]. This positive phase Ⅲ clinical trial led to approval of bevacizumab for the treatment of advanced colorectal cancer in 2005. Comparable results were obtained in a recent phase Ⅲ clinical trial of bevacizumab in non-small cell lung cancer. This study was interrupted prematurely because of an obvious survival advantage in the antibody treated patients[35].

The first clinical data on the successful treatment of cholangiocarcinoma with bevacizumab were reported in 2006, and described a patient whose metastasis from cholangiocarcinoma resolved after salvage therapy with 3 cycles of bevacizumab (5 mg/kg) combined with cisplatin (75 mg/kg) and high-dose fluorouracil and leucovorin over a period of 2 wk[36].

Currently, several studies using bevacizumab for combination therapy of cholangiocarcinoma are ongoing. An ongoing phase Ⅱ trial explores the combination of systemic bevacizumab with floxuridine and dexamethasone given as a hepatic arterial infusion in patients with unresectable hepatocellular carcinoma or intrahepatic cholangiocarcinoma (NCT00410956). In this trial, patients undergo placement of the hepatic arterial infusion (HAI) pump and a cholecystectomy and receive floxuridine and dexamethasone by HAI continuously for 2 wk. Bevacizumab is concomitantly given for 30-90 min iv at the beginning and end of each cycle. Outcome measure of the study trial is to determine the antitumor efficacy (complete and partial response, stable and progressive disease) as well as toxicity as measured by Common Toxicity Criteria (CTC), which is a standard set by the National Cancer Institute to provide standard language for reporting adverse events which occur in cancer clinical trials[37].

Two other Phase Ⅱ trials are currently determining the safety and efficacy of bevacizumab in combination with the EGFR tyrosine kinase inhibitor erlotinib in patients with metastatic or unresectable gall bladder or bile duct cancers and other advanced upper gastrointestinal carcinomas, which are refractory or intolerant to standard chemotherapy (NCT00350753[17]; NCT00033462[12]). This particular combination was chosen because dual targeting of cancer cells (EGFR) and their nutrient supply (anti-VEGF) will likely have synergistic antitumoral effects[38]. Synergy has been shown at the molecular level, since inhibition of the EGFR suppressed the release of VEGF from tumor cells *in vitro*[39,40]. Moreover, high levels of VEGF have been shown to promote resistance to anti-EGFR treatment in squamous cell carcinoma[41]. Recent clinical trials for refractory non-small-cell lung cancer and advanced renal cell carcinoma proved that this particular combination is highly effective[42-44].

The combination of bevacizumab with radiation therapy is currently being studied in inoperable hepatocellular carcinoma and cholangiocarcinoma in a non-randomized, open label phase I trial (NCT00426829[21]). In rectal cancer patients, bevacizumab was shown to enhance tumor blood flow, to reduce tumor interstitial pressure, and to decrease mean vessel density. These physiologic changes enhanced the efficacy of radiation therapy in a neoadjuvant setting[45]. It is most probable that antiangiogenic preconditioning to normalize the tumor vasculature in primary liver tumors will equally create a "therapeutic window" whereby improved blood flow with enhanced exposure to radiosensitizing oxygen is achieved.

Anti-PlGF treatment

The use of a neutralizing anti-PlGF monoclonal antibody in VEGF-inhibitor resistant tumors is an attractive alternative antiangiogenic strategy. A proof of concept study has been performed in an animal study with melanoma or pancreatic adenocarcinoma bearing mice[46]. The antibody specifically inhibits the binding of PlGF to its receptor VEGFR-1, present on tumor-associated endothelial cells and macrophages. The underlying idea of using this approach was derived from gene inactivation studies showing that endogenous PlGF is redundant in vascular development and physiological vessel maintenance, but an important contributor to the "angiogenic switch" in solid tumor growth. This led to the hypothesis that unlike VEGF inhibitors, PlGF inhibition might reduce pathological angiogenesis, without disturbing physiological blood vessel homeostasis and reduce concomitant unwanted side effects. Hence, anti-PlGF treatment could perhaps substitute for anti-VEGF therapy in the future. Moreover, as PlGF levels increase in the circulation of cancer patients receiving anti-VEGF treatment[47-49], anti-PlGF should also counteract this potential downside of anti-VEGF therapy. Accordingly, anti-PlGF-treatment inhibits angiogenesis, lymphangiogenesis, tumor growth and motility in anti-VEGF-resistant tumor bearing

mice. Here, it blocks the so-called rescue-angiogenesis, a major problem in current antiangiogenic approaches, and showed excellent treatment tolerability. In addition, anti-PlGF treatment may permit long-term treatment of cancers in children, pregnant women, or patients at risk for thrombotic, cardiac or other complications for whom the adverse effects of other VEGF/VEGFR-inhibitors may be excessive and prohibitive.

ANTIANGIOGENIC THERAPY WITH SMALL MOLECULE INHIBITORS

Several agents which inhibit the tyrosine kinase activity of angiogenic growth factor receptors like the VEGFR or PDGFR, have been synthesized by combinatorial chemistry. These tyrosine kinase inhibitors are small molecules which occupy the ATP binding site of the tyrosine kinase domain of the intracellular portion of the receptor. Because of their effects on downstream signaling, these inhibitors interfere with a number of key biologic functions associated with VEGFR activation. Although drugs that are targeted to specific VEGFR kinases have shown clinical efficacy, the redundancy in the angiogenesis pathways necessitates broad spectrum inhibitors that address multiple (VEGFR) targets[50].

AZD2171

AZD2171 is a highly potent small molecule with pan-VEGFR-tyrosine kinase inhibiting activity (50% inhibitory concentration of < 0.002 μmol/L for VEGFR-2 and 0.005 μmol/L for VEGFR-1, respectively). AZD2171 also inhibits VEGFR-3, PDGFR-β and c-Kit at nanomolar concentrations[51]. The antineoplastic potency of AZD2171 has been demonstrated in several tumors, including lung, hepatocellular, colorectal and prostate cancer and in all cases the antitumor effect was associated with strong inhibition of VEGF signaling and angiogenesis[52-54]. A phase I dose-finding study was conducted in 83 patients with advanced solid tumors[52]. The study was divided into parts A and B, with 36 patients on a dose-escalation schema, in which 3 to 8 patients received a single oral dose of AZD2171 ranging from 0.5-60 mg. After a wash-out period of 2 to 7 d, the patients continued with daily treatment at the same dose level. AZD2171 was generally well tolerated at < 45 mg/d with common side effects of fatigue, nausea, diarrhea, and vomiting. In part B, an additional 47 patients were enrolled at 20, 30 or 45 mg orally daily. All patients had liver metastases and six patients had NSCLC. The major toxicities and side-effects included hypertension, headache, diarrhea, and voice hoarseness. Three patients in the 60 mg cohort each experienced one serious adverse event (grade 4 cerebral hemorrhage, grade 4 hypoglycemia, and grade 3 hypertension). Of the 83 patients enrolled, two partial responses were observed, while stable disease was seen in 23 patients.

At present AZD2171 is being evaluated in three different studies (Horizon Ⅰ-Ⅲ) in patients with advanced colorectal cancer. In Horizon Ⅲ, which is a phase Ⅱ/Ⅲ study, AZD2171 is tested as a combination partner for FOLFOX compared to a combination of FOLFOX and bevacizumab in patients with previously untreated metastatic colorectal cancer. AZD2171 has shown encouraging signs of antitumor activity in a clinical development program, which has included over 700 patients to date. Based on the generally encouraging findings, AZD2171 is currently also being investigated in cholangiocarcinoma. A pending phase I trial (NCT00475956) explores the effects of AZD2171 in combination with AZD0530, a dual-specific inhibitor of Src and Abl. Src and Abl are protein tyrosine kinases which are overexpressed in malignancies such as chronic myeloid leukemia (CML), where AZD0530 has already been proved to be an effective anticancer agent[55]. The idea for using this particular combination for the treatment of cholangiocarcinoma may have arisen from observations that the Abl- and Src-inhibitor imatinib (Gleevec) showed apoptosis-inducing and growth-reducing effects in cholangiocarcinoma cells *in vitro*[56]. However, imatinib also inhibits other tyrosine kinases, such as c-kit and PDGFR-β. Thus it is not clear, whether the effects of imatinib on cholangiocarcinomas are related to Src-inhibition. This is doubtful as s-src expression, which is highly correlated with the indices of early stage hepatocellular carcinoma phenotype, is not likely to be involved in the cholangiocarcinoma phenotype, as no s-src activation could be detected in cholangiocarcinoma[57].

STRATEGIES TARGETING THE EGFR

The central role of the epidermal growth factor receptor (EGFR) in the proliferation of tumor epithelia and its overexpression in several solid tumors have provided the rationale for targeting this key signaling network. EGFR blockade with monoclonal antibodies and tyrosine kinase inhibitors has already translated into clinical benefit in gastrointestinal tumors, including primary liver cancer[58,59].

Over the past few years, three EGFR-specific agents have received regulatory approval: (1) The monoclonal anti-EGFR antibody cetuximab for metastatic colorectal cancer, and squamous cell carcinoma of the head and neck; (2) The tyrosine kinase inhibitor erlotinib for advanced or metastatic pancreatic cancer and NSCLC; and (3) The EGFR tyrosine kinase inhibitor gefitinib for advanced or metastatic NSCLC. However, the general FDA approval for NSCLC treatment with gefitinib was recently withdrawn after it failed to demonstrate a survival benefit either alone or with chemotherapy in three phase Ⅲ trials[58,60].

Several reports indicate that the EGFR is frequently (over-)expressed in cholangiocarcinoma. Additionally, sustained EGFR activation due to defective receptor internalization has been reported for cholangiocarcinoma cells[61]. Of note, bile acids activate EGFR-signaling *via* a TGF-alpha-dependent mechanism, thereby contributing to the growth characteristics of cholangiocytes and cholangiocarcinoma cells[62]. Clinicopathologically,

EGFR overexpression was shown to be associated with macroscopic tumor type, lymph node metastasis, tumor stage, lymphatic vessel invasion, and perineural invasion in extrahepatic cholangiocarcinoma. High levels of EGFR expression and activation increased the risk for tumor recurrence in intrahepatic cholangiocarcinoma[29]. EGFR-inhibitors inhibited cholangiocarcinoma cell growth *in vitro* and *in vivo*[33,61,63].

These encouraging preliminary findings on the general suitability of anti-EGFR-based-approaches for the treatment of cholangiocarcinoma spawned several clinical trials. In a cohort composed of 24 chemotherapy-refractory patients and 18 chemotherapy-naive patients administered oral erlotinib (150 mg/d) as monotherapy, the progression free survival at 6 mo was determined[64,65]. Seventeen percent of the patients achieved this primary end point, while disease control was obtained in 50% of patients with a median duration of 5.1 mo. Seven percent of the patients showed a partial response of 4 to 14 mo duration. The results suggest an astonishing therapeutic benefit for EGFR blockade with erlotinib in patients with advanced biliary cancer, however, this has to be confirmed in future larger controlled trials and in trials which use erlotinib in combination with other targeted agents.

An ongoing multicenter phase Ⅱ trial in patients with advanced BTC (BINGO; NCT00552149) evaluates the efficacy of the EGFR-antibody cetuximab (Huether *et al*, 2006), combined with gemcitabine-oxaliplatin chemotherapy (GEMOX). Patients will be randomized 1:1 to receive GEMOX (1000 mg/m² gemcitabine; 100 mg/m² oxaliplatin) alone or GEMOX + cetuximab (500 mg/m²) every other week. The BINGO trial also comprises ancillary basic research and functional imaging studies, in order to identify markers that predict treatment efficacy of bile duct cancer. The primary outcome measure of the study is progression-free survival at 4 mo. Secondary outcome measures are the feasibility and toxicity of the treatments, and an evaluation of the degree and duration of objective tumor response or tumor control in a time frame of one year.

A third study used cetuximab in combination with GEMOX in a small number of nine GEMOX resistant patients with advanced, metastatic and unresectable intrahepatic cholangiocarcinoma[66]. Patients received cetuximab 400 mg/m² on day 1, then 250 mg/m² weekly, combined with gemcitabine 1000 mg/m² on day 1 and oxaliplatin 85 mg/m² on day 2, every 3 wk. Results of the study were encouraging. Cetuximab was well tolerated and provided good palliative effects in advanced cholangiocarcinoma. Moreover, adding cetuximab bypassed tumor resistance to GEMOX[67].

Taken together, anti-EGFR-based therapies for treating BTC appear to have their greatest potential when given in combination either with conventional cytostatics or with other targeted agents. The rationale for using combination therapies is the existence of multilevel receptor cross-stimulation or of redundant signaling pathways which lead to neoplasia. Blocking only one of these pathways allows others to act as salvage or escape mechanisms for cancer cells. Preclinical evidence of synergistic antitumor activity achievable by combining targeted agents that block multiple signaling pathways has recently emerged[68-70]. The multi-target approach can be accomplished by using either combinations of selective agents or single agents, which address various targets[71].

IGF/IGFR-BASED STRATEGIES

Activation of the insulin-like growth factor (IGF) receptor 1 (IGF-1R) by IGF-Ⅰ and IGF-Ⅱ plays a pivotal role in tumor cell proliferation and spread, by promoting cell cycle progression, preventing apoptosis, and by regulating and maintaining the metastatic tumor phenotype[70,72-75]. A wide variety of tumors show abnormal or enhanced expression of IGFs and IGF-1R, which leads to auto- and paracrine growth stimulation, and which has been correlated with enhanced proliferation, tumor de-differentiation, disease stage, development of metastases and reduced patient survival. Enhanced expression of IGF-1R has also been demonstrated in BTC, and the IGF/IGFR system was shown to be centrally involved in proliferation and suppression of apoptosis of cholangiocarcinoma cells[76], making the IGF/IGFR-signaling system an attractive target for the treatment of BTC. Thus IGF-1R blocking antibodies, IGF-1R antisense oligonucleotides, or IGF-1R siRNA have all been shown to effectively interfere with IGF-1R mediated signaling *in vitro* and with tumor growth and spread *in vivo*[76-80].

We and others validated the selective IGF-1R tyrosine kinase inhibitor NVP-AEW541 as a promising novel agent for the therapy of several cancers[81-85]. Moreover, we showed that a combination of IGF-1R inhibitors together with the multi-kinase inhibitor sorafenib, offer additive antitumoral efficacy for cholangiocarcinoma *in vitro*[86]. The antineoplastic properties of NVP-AEW541 and related compounds such as NVP-ADW742 have been demonstrated in preclinical studies on Ewing's sarcoma-bearing mice, fibrosarcoma, breast cancer and musculoskeletal sarcoma[81-83].

Specific IGFR-antibodies potently suppressed prostate and breast cancer cell growth *in vitro*[87]. The clinically most advanced anti-IGFR antibody is CP-751871, which is currently being tested in three phase Ⅱ trials for advanced breast cancer, NSCLC and prostate cancer (www.clinical-trials.gov). Importantly, the preliminary clinical data indicate that IGFR-inhibition is well-tolerated[88-90]. Safety is important, since IGFR-based inhibition has long been regarded as a high-risk intervention, because of the high homology of the IGF-1R receptor with the related insulin-receptor, and the fear that IGF-1R tyrosine kinase inhibitors may lead to insulin resistance and overt diabetes[91]. However, the current *in vivo* data do not support this assumption, resulting in a growing interest in anti-IGFR-based therapies[92].

Crosstalk between the signaling of the IGF/IGFR

system and other growth factor receptors will likely attenuate the antineoplastic effect of monotherapeutic approaches, necessitating combinations of IGF/IGFR-targeting therapies with other therapies to enhance efficacy[93,94]. This can be achieved by dual-targeting the IGF-1R and the EGFR, since the EGFR is activated by the IGF/IGFR-system leading to mito-oncogenic EGFR-tyrosine kinase activity without ligand stimulation of the EGFR[95]. In this line IGFR- combined with EGFR-inhibition can over-additively enhance the antineoplastic effect of the respective monotherapies in gastrointestinal cancers[96-98].

DUAL-TARGETING SMALL MOLECULE INHIBITORS

The use of dual-targeting small molecule inhibitors, simultaneously blocking less related kinases such as VEGFR and EGFR tyrosine kinases, may also be promising for the future treatment of BTC. These agents inhibit both tumor cell proliferation/survival by blocking mito-oncogenic EGFR signaling of the tumor cells and angiogenesis by inhibiting endothelial VEGFRs. Recent *in vivo* studies of non-cholangiocarcinoma models (colon, prostate, NSCLC) demonstrated that the dual-targeting tyrosine kinase inhibitor NVP-AEE788 displayed significant antineoplastic efficacy[99-101]. NVP-AEE788 was recently also shown to be a potent inhibitor of cholangiocarcinoma cell growth[33], further emphasizing the possible suitability of EGFR/VEGFR-dual targeting agents for the treatment of cholangiocarcinoma.

ZD6474 (Zactima) is another EGFR/VEGFR tyrosine kinase inhibitor with potent antineoplastic properties in phase Ⅱ/Ⅲ trials on NSCLC and thyroid cancer. In these trials response rates of 30% in patients with locally advanced medullary thyroid cancer[102] as well as significant prolongation in the progression-free survival of NSCLC patients[103,104] were observed.

Clinical studies on BTC using these dual target kinase inhibitors have not yet been conducted. Nevertheless, the idea of simultaneously inhibiting these two growth factor receptor systems is currently under clinical investigation using a combination of EGFR-inhibiting erlotinib together with VEGF-neutralizing bevacizumab (see before). Indeed, the University of Colorado together with Astra Zeneca only recently started a phase I trial (NCT00551096) to determine the highest dose of Zactima that can be safely given as a single agent or in combination with gemcitabine and capecitabine in advanced solid tumors. This study is explicitly planned with an expanded cohort of patients with biliary cancers (BTC and gallbladder cancer), who will be treated at the highest determined dose in further studies.

OTHER STRATEGIES

Targeting the AKT/mTOR pathway

The activated PI3K/AKT/mTOR pathway has emerged as a novel contributor to BTC development[105]. PI3K associates with the intracellular domain of several growth factor receptors. Upon receptor activation, PI3K triggers the generation of phosphatidylinositol 3,4,5-trisphosphate (PIP3), which provokes the subsequent activation of AKT, a serine/threonine kinase that activates multiple cellular target proteins, such as the mammalian target of rapamycin (mTOR) subfamily. mTOR is a serine-threonine kinase that downregulates apoptosis, and *via* stimulation of cell cycle progression enhances proliferation and cell growth. Specifically, mTOR is involved in the activation of mRNA-translation into proteins, which are necessary for cell cycle progression from G1 to S-phase, including the E4-binding protein (E4-BP1), and $p70^{S6}$ kinase[106]. In nontransformed cells the PI3K/AKT/mTOR pathway is controlled by the phosphatase and tensin homolog deleted on chromosome ten (PTEN), a tumor suppressor which inhibits this pathway by reversing PI3K and subsequent AKT activation. Mutation or silencing of the PTEN gene leads to activation of the mTOR pathway and promotion of carcinogenesis.

AKT-inhibition

The tricyclic nucleoside VQD-002 (triciribine phosphate monohydrate, TCN-P, Vioquest Pharmaceuticals) is a small molecule inhibitor of AKT signaling. Identified by the Moffitt Cancer Center through screening the NCI diversity set, VQD-002 was shown to be highly selective for Akt without affecting the activation of other related kinases, such as PI3K, PKC, phosphoinositide-dependent kinase-1, serum and glucocorticoid-inducible kinase, PKA, STAT-3 or ERK1/2. Accordingly, AKT-inhibition by VQD-002 resulted in suppression of cell growth and induction of apoptosis in human cancer cells and in tumor xenograft mouse models, with high selectivity for those tumors with aberrant Akt[107]. An ongoing phase Ⅰ/Ⅱa trial (NCT00363454) on metastatic solid tumors overexpressing AKT, such as pancreatic, breast, ovarian and colorectal cancer is promising, as preliminary results indicate that VQD-002 was well tolerated and prolonged the stable disease period of patients (http:www.vioquestpharm.com). VQD-002 is already earmarked for combination with the EGFR antagonist erlotinib, since preclinical studies showed that coadministration of VQD-002 can help to overcome resistance to EGFR-antibody therapy in breast cancer patients with PTEN-deficiency[108].

mTOR-inhibition

The natural antibiotic rapamycin (sirolimus) is a potent inhibitor of mTOR[109]. Recently, three analogues of rapamycin with superior pharmacokinetic and biological properties have emerged. The cell cycle inhibitor-779 (CCI-779, temsirolimus) is a soluble ester analogue. RAD001 [40-O-(2-hydroxyethyl)-rapamycin, everolimus] is a derivative of rapamycin with high oral bioavailability, and AP23573 is a non-pro-drug analogue of rapamycin. These agents have been successfully tested for their antineoplastic potency and/or tolerability in various malignancies in early clinical trials (e.g. CCI-779 in renal, breast and lung cancers),

or are currently being studied in open clinical trials for the treatment of colorectal, endometrial, and brain tumors (RAD001, everolimus)[110-112]. AP23573 has been successfully tested in a phase Ⅱ trial in sarcomas[113], and two phase I studies in patients with refractory or advanced solid tumors showed partial responses and disease stabilization in individual patients[114]. In preclinical investigations, the antiproliferative, antimigratory and anti-invasive potency of rapamycin in cholangiocarcinoma cells has recently been described[115]. Activated mTOR was also demonstrated to be a negative prognostic factor for patients with BTC, and patients with activated mTOR are likely to benefit from targeted therapy with mTOR inhibitors in the future[116]. However, so far no trials exploring mTOR-inhibitors for BTC have been initiated.

Targeting the Ras/Raf/MARK pathway

The proliferative Ras/Raf/MEK/ERK pathway is one the key signaling cascades that underlies the development and maintenance of cancers. This pathway transduces extracellular signals from the various growth factor receptor tyrosine kinases (e.g. EGFR, IGFR, VEGFR and PDGFR) to the nucleus with a series of specific phosphorylation events, resulting in the expression of proteins for cell cycle progression, apoptosis resistance, extracellular matrix remodeling, cellular motility, angiogenesis or drug resistance[117]. Dysregulation of this crucial pathway occurs due to oncogenic transformation of Ras and Raf isoforms, or to overexpression and/or overactivation (*via* phosphorylation) of the Ras and Raf genes[118,119]. Activating B-Raf mutations are relatively common in cholangiocarcinomas and disruption of the Raf/MEK/ERK (MAPK) kinase pathway, either by B-Raf or Ras mutations, is detected in more than 60% of all BTC, which is therefore one of the most frequent defects in cholangiocellular carcinogenesis[120].

Sorafenib

The bi-aryl urea derivative sorafenib (Nexavar™) is an oral multi-kinase inhibitor, which targets kinases of wild-type B-Raf, mutantV559E B-Raf and C-Raf, and importantly receptor tyrosine kinases involved in angiogenesis, including VEGFR-2, and -3, and PDGFR[121]. Sorafenib has been approved by the FDA for the treatment of advanced renal cell carcinoma and of inoperable hepatocellular cancer.

The effect of sorafenib on several molecular targets in addition to the Raf isoforms makes it difficult to determine which of its targets contributes most to its antitumor activity in a given tumor type. For instance, a recent HCC trial suggested that inhibition of the Raf/MEK/ERK pathway was central to sorafenib's mode of antitumor action[122], whereas in other cancers, such as renal cell carcinoma or NSCLC, the antineoplastic activity was attributed mainly to its antiangiogenic activity[121,123].

Sorafenib alone or in combination with conventional cytostatics (5-fluorouracil, gemcitabine, doxorubicin) or IGF-1R inhibition induces a potent growth suppression of cholangiocarcinoma cells *in vitro*[86]. Antitumor efficacy was even higher when sorafenib was combined with the histone deacetylase inhibitor MS-275[124,125]. These encouraging findings have resulted in an ongoing phase Ⅱ trial which evaluates sorafenib monotherapy in patients with unresectable or metastatic gallbladder cancer or BTC (NCT00238212). In an intermediate evaluation of this study, sorafenib was well tolerated, but as a single agent it did not lead to a clinically significant response rate in these patients, while its impact on survival was comparable to commonly used chemotherapy regimens. These promising results of sorafenib monotherapy will likely facilitate novel therapeutic strategies which will combine multikinase inhibition with conventional cytostatic therapy or with unrelated pathway inhibitors, such as histone deacetylase or proteasome inhibitors (see below) for enhanced and well tolerated medical treatment of advanced BTC[126].

Targeting the proteasome

Another interesting therapeutic approach for innovative cancer treatment is the inhibition of the 26S proteasome, which is a large protease that is present in both the nucleus and the cytoplasm of eukaryotic cells. The proteasome functions as an identifier and proteolytic graveyard for proteins branded for destruction by the ubiquitin system. The so-called ubiquitin-proteasome pathway (UPP) is the major non-lysosomal proteolytic system in eukaryotic cells and triggers degradation of proteins involved in cell cycle progression, apoptosis, nuclear factor kappa B (NF-κB) activation, and angiogenesis. UPP also degrades mutant, damaged, and misfolded proteins[127]. Since these signaling pathways are critical for cell survival and proliferation, especially in cancer cells, inhibition of the proteasome has emerged as an attractive target for cancer therapy.

Bortezomib

Bortezomib (Velcade™) is a proteasome inhibitor, which blocks multi-ubiquitinated protein degradation by reversibly and competitively inhibiting the active site threonine residue of the 26S proteasome[128]. Antineoplastic activity of bortezomib has already been shown in several *in vitro* and *in vivo* studies[129,130]. Only recently we and others showed the potent apoptosis inducing and growth inhibiting features of bortezomib in cholangiocarcinoma cells[125,131]. Bortezomib is the first proteasome inhibitor to be approved for cancer therapy and based on the results of a phase Ⅱ trial[127] has recently been approved by the FDA for the treatment of mantle cell lymphoma[132,133]. Other cancers, including neuroendocrine tumors, RCC, NSCLC, or metastatic sarcomas have also been evaluated in recent phase Ⅱ clinical trials. In some of these studies a significant antineoplastic effect with bortezomib monotherapy was observed, while in other studies no or only marginal responses were found[134-136]. However, in the latter cases further investigation on the role of bortezomib in combination with other antitumoral drugs was recommended, since proteasome

inhibition will likely sensitize cancer cells to other therapeutic agents. Combinations with encouraging results have been reported in two studies of lung cancer and lymphoma[137,138]. In another phase I trial, bortezomib was tested in combination with the cytotoxic agent docetaxel in advanced solid tumors, including cholangiocarcinoma, where it showed generally good tolerability[13]. A phase Ⅱ trial exploring bortezomib as first-line systemic therapy of patients with unresectable or metastatic adenocarcinoma of the bile duct or gallbladder is currently ongoing (NCT00085410). A comparable study in HCC was recently reported to have resulted in disease stabilization in some patients, with generally good tolerability. Here it was again suggested that the focus should next be on combinations of bortezomib with HCC-relevant cytostatics such as doxorubicin[139]. In the *in vitro* studies on cholangiocellular carcinoma cells we found that bortezomib shows over-additive antitumoral effects when combined with multikinase inhibitors like sorafenib or histone deacetylase inhibitors, such as MS-275[125].

CONCLUSION

Targeted-therapies, which specifically inhibit growth factor receptors and their related signaling pathways, are promising approaches for the innovative medical treatment of biliary tract and gallbladder cancers. In particular, antiangiogenic strategies as well as combination treatments with cytostatics have proved particularly efficient, as they leave fewer mechanisms of escape for the tumor cells. Combinations of these targeted drugs are especially intriguing, and in the future multi-kinase inhibitors such as sorafenib will be combined with other growth factor receptor inhibitors, proteasome inhibitors, histone deacetylase inhibitors, farnesyltransferase inhibitors or cytostatics to effectively control advanced biliary tract or gallbladder cancers. The advantage of such novel combination therapies is their higher tumor cell specificity and higher efficacy, combined with acceptable toxicity and side effects. These novel combination treatments will widen the therapeutic spectrum for biliary tract and gallbladder cancers; the results of (ongoing) clinical studies are eagerly awaited.

Abstract

Aberrant expression and signaling of epidermal growth factor receptor (ErbB) family receptor tyrosine kinases, most notably that of ErbB2 and ErbB1, have been implicated in the molecular pathogenesis of intrahepatic cholangiocarcinoma. Constitutive overexpression of ErbB2 and/or ErbB1 in malignant cholangiocytes has raised interest in the possibility that agents which selectively target these receptors could potentially be effective in cholangiocarcinoma therapy. However, current experience with such ErbB-directed therapies have at best produced only modest responses in patients with biliary tract cancers. This review provides a comprehensive and critical analysis of both preclinical and clinical studies aimed at assessing the role of altered ErbB2 and/or ErbB1 expression, genetic modifications, and dysregulated signaling on cholangiocarcinoma development and progression. Specific limitations in experimental approaches that have been used to assess human cholangiocarcinoma specimens for ErbB2 and/or ErbB1 overexpression and gene amplification are discussed. In addition, current rodent models of intrahepatic cholangiocarcinogenesis associated with constitutive ErbB2 overexpression are reviewed. Select interactive relationships between ErbB2 or ErbB1 with other relevant molecular signaling pathways associated with intrahepatic cholangiocarcinoma development and progression are also detailed, including those linking ErbB receptors to bile acid, cyclooxygenase-2, interleukin-6/gp130, transmembrane mucins, hepatocyte growth factor/Met, and vascular endothelial growth factor signaling. Lastly, various factors that can limit therapeutic efficacy of ErbB-targeted agents against cholangiocarcinoma are considered.

INTRODUCTION

Intrahepatic cholangiocarcinoma, also known as peripheral cholangiocarcinoma, is a primary epithelial cancer that arises within liver and which exhibits differentiation markers of biliary epithelial cells or cholangiocytes[1-3]. This rare, but highly malignant hepatobiliary cancer accounts for approximately 10%-15% of all primary liver cancer[3,4]. More than 90% of intrahepatic cholangiocarcinomas are classified histologically as well-to-moderately differentiated tubular adenocarcinomas, although other rare histological variants, including papillary, adenosquamous, and intestinal-type carcinoma also occur[1,2,5-7]. Typically, a desmoplastic reaction of variable degrees is a common histological feature and in some cases may be the most prominent characteristic of the tumor[1,2].

Morphologically, intrahepatic cholangiocarcinomas have been further classified as either having a mass-forming, periductular infiltrating, or intraductal growth pattern[1,2,8-10]. Of these morphological types, the intraductal growing cholangiocarcinoma is the least common, but has a more favorable prognosis than either

the mass-forming or periductular infiltrating types. Some tumors may also manifest a combination of growth patterns (i.e. mass-forming and periductular infiltrating), thereby precluding an absolute morphology-based classification system based solely on a single type of growth pattern.

Intrahepatic cholangiocarcinoma typically carries a very poor prognosis and the challenges posed by this cancer are formidable. Most notably, early diagnosis of intrahepatic cholangiocarcinoma is problematic, with a vast majority of patients being diagnosed at first presentation with advanced malignant disease. Thus, treatment options are limited and prospects for long-term survival are for the most part dismal. Current epidemiological data have further indicated a global increase over the past two to three decades in the age-adjusted incidence and mortality rates of intrahepatic cholangiocarcinoma[4,11-14], whereas the age-adjusted incidence and mortality rates for extrahepatic cholangiocarcinoma have been reported to be declining over a comparable time period[4,12]. It is of further interest that the most significant rise in intrahepatic cholangiocarcinoma incidence was noted among the older ($\geqslant$ 65 years of age) rather than younger age groups analyzed[4,12].

It has recently been reported that only about 10% of patients with intrahepatic cholangiocarcinoma have been found to have a known established risk factor, such as primary sclerosing cholangitis, hepatolithiasis, infestation with the liver flukes *Opisthorchis viverrini* or *Clonorchis sinensis*, and choledochal cysts[15]. Thus, a vast majority of patients presenting with intrahepatic cholangiocarcinoma do not have a history of these well-recognized risk factors and the cause for the rising incidence, particularly among older age groups, of this often fatal hepatobiliary malignancy remains unclear. However, in addition to the more well-established risk factors listed above, a number of chronic liver diseases, including alcoholic liver disease, hepatitis C and B, human immunodeficiency virus infection, unspecified cirrhosis, and diabetes have also been recently reported to be associated with the development of intrahepatic cholangiocarcinoma[12-14,16,17].

Common features of the few well-established risk factors and the more recently analyzed pre-existing chronic liver conditions seemingly predisposing for intrahepatic cholangiocarcinoma include chronic inflammation and bile duct cell injury often combined with cholestasis and altered bile composition. Molecular perturbations brought about by the mileau of cholangitis and cholestasis have been linked to the initiation, promotion and/or progression stages of cholangiocarcinogenesis[1,18-20]. Among the pathways affected and demonstrated to be playing a role in the molecular pathogenesis of intrahepatic cholangiocarcinogenesis are those mediated by the ErbB family of receptor tyrosine kinases, most notably involving the dysregulation of ErbB2 (HER2/neu) and/or epidermal growth factor receptor (EGFR) signaling. This review will critically evaluate the role played by the ErbB family receptor tyrosine kinases in the development and progression of intrahepatic cholangiocarcinoma. Specifically, the significance of aberrant ErbB2 and EGFR expression and genetic alterations in relation to the pathogenesis of human intrahepatic cholangiocarcinoma will be assessed. Experimental models linking constitutive overexpression of activated ErbB2 to intrahepatic cholangiocarcinoma development will also be described. In addition, relevant interactive relationships between ErbB2, as well as EGFR, with other key molecular pathways associated with intrahepatic cholangiocarcinoma development and/or progression and the effects of bile acids on ErbB receptor signaling in cholangiocarcinoma cells will be discussed. Lastly, the potential value of EGFR and/or ErbB2 as molecular targets in intrahepatic cholangiocarcinoma therapy will be assessed.

THE ERBB FAMILY OF RECEPTOR TYROSINE KINASES AND THEIR SPECIFIC LIGANDS

The ErbB family of class I receptor tyrosine kinases is comprised of four distinct receptors: EGFR (ErbB1), ErbB2, ErbB3 and ErbB4. Each of these plasma membrane receptors, in turn, is composed of an extracellular ligand-binding domain, a transmembrane lipophilic domain, and a conserved cytoplasmic tyrosine kinase domain[21-24]. All of these receptors, with the exception of ErbB2, bind receptor specific ligands belonging to the EGF-family of growth factors. These EGF-related growth factors have been divided into three groups[21,23]. The first group, which includes epidermal growth factor (EGF), transforming growth factor-α (TGF-α), and amphiregulin, binds specifically to EGFR. A second group, which shows dual specificity by binding to both EGFR and ErbB4, includes heparin-binding EGF, epiregulin, and betacellulin. Neuregulins (NRGs), compose the third group, with NRG1 and NRG2 (heregulins) being ligands for ErbB3 and ErbB4, and NRG3 and NRG4 binding only to ErbB4[21,23,25]. EGF-family growth factors are produced in cells as transmembrane precursors, which can then be shed as soluble active ligands through proteolysis catalyzed by cell surface acting proteases, most notably through the activity of matrix metalloproteinases (MMPs)[22,26,27]. This mechanism of cell surface growth factor shedding plays an important role in regulating ligand availability and receptor activation[22,27].

The binding of EGF-family ligands to the extracellular domain of ErbB receptors induces homo- or heterodimerization of the receptor proteins and activation of the intrinsic tyrosine kinase domain, resulting in the trans-phosphorylation of specific tyrosine residues within the receptor's cytoplasmic tail[21-23]. The phosphorylated residues then serve as docking or recruitment sites for a variety of signaling proteins[22,24,28,29], which in turn, initiate downstream signaling cascades and other molecular activities that

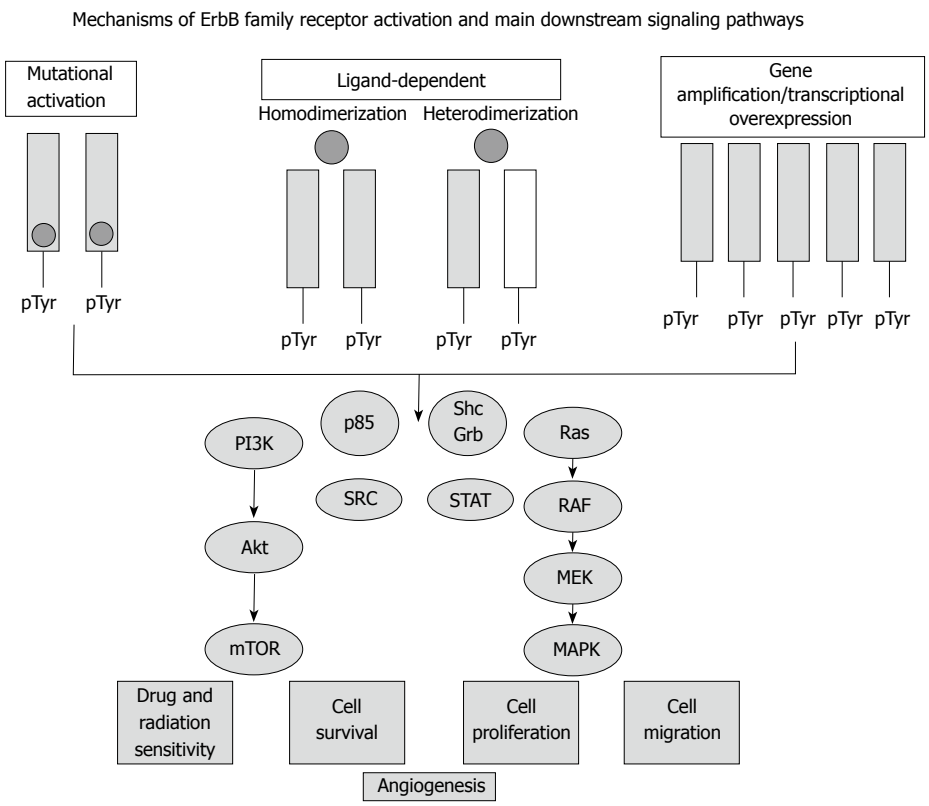

Figure 1 Simplified scheme depicting ErbB receptor tyrosine kinase activation and downstream signaling pathways relevant to intrahepatic cholangiocarcinogenesis.

regulate such fundamental biological responses as cell differentiation, cell proliferation, cell survival, cell migration, and angiogenesis (Figure 1). The type and amplitude of the downstream signaling pathways that are activated and their resulting biological effects are governed by the complexity and diversity of the ErbB network regulating these responses, and as such, are dictated in large part by which ErbB receptors are being expressed, the number of receptors being expressed and their dimerization and tyrosine phosphorylation profiles, the type and concentration of stimulating ligand, receptor stability at the cell surface, and the potential for receptor transactivation and/or cross-talk with other receptor-mediated signaling pathways[22,23,30-33].

ErbB2, because of the unique conformation of its ectodomain compared with the ectodomains of EGFR and ErbB3, is the only member of the ErbB receptor family that does not allow for the binding of any of the known soluble EGF-like ligands[21-23]. The crystal structure of a truncated ErbB2 ectodomain has further revealed a conformation that resembles that of an activated state poised to interact with other ErbB receptors[21,34]. This unique structure helps to explain why ErbB2 has an enhanced capacity for heterodimerization and is the preferred dimerization partner for all other ErbB receptors[23]. Moreover, by having a fixed conformation that resembles the ligand-activated state, it is not surprising that ErbB2 exhibits a constitutively high basal kinase activity and is closely linked to human oncogenesis[23,35]. It is also relevant that ErbB2 overexpression can result in ligand-independent homodimerization and that EGFR levels may be increased in tumors induced in association with the constitutive overexpression of ErbB2[23,36].

ErbB2-containing heterodimers (i.e. ErbB2/EGFR or ErbB2/ErbB3) are associated with a more robust signaling than that generated by homodimers[23]. In this context, it is notable that ErbB2/ErbB3 heterodimers are most potent in terms of stimulating cell mitogenesis and neoplastic transformation[21,23]. The dominant signaling capacity of ErbB2/ErbB3 heterodimers appears to be paradoxical since ErbB2 is a ligandless receptor for EGF family growth factors, while ErbB3 has an impaired kinase activity[21]. However, an allosteric mechanism for the activation of the kinase domain of ErbB3 by its interaction with ErbB2 has been predicted[24]. Furthermore, the potent signaling exhibited by ErbB2/ErbB3 heterodimers relates to their capacity to strongly activate both the *ras-raf*-MEK-p42/44 mitogen-activated protein kinase (MAPK)/extracellular regulated kinase (ERK) and the phosphatidylinositol 3-kinase (PI3K)-Akt pathways[23]. Activation of the *ras-raf*-MEK-MAPK (ERK) pathway involves the recruitment of select adaptor proteins (Grb-2 or Shc) to the receptor, and is a key pathway for driving cellular proliferation[22,23]. The PI3K-Akt pathway, which regulates cell survival and anti-apoptotic signals is activated by recruitment of the p85 adaptor subunit of PI3K to the receptor[22,23]. Specifically, ErbB3 (and ErbB4) activates PI3K through select p85 docking sites on the cytoplasmic tyrosine kinase domain. Additional factors contributing to potent signaling capacity of the ErbB2/ErbB3 heterodimers is their increased stability at the cell surface and their ability to evade downregulation mechanisms, thereby leading to prolonged signaling[23]. ErbB2 also acts to decrease the rate of ligand dissociation from ErbB2-containing

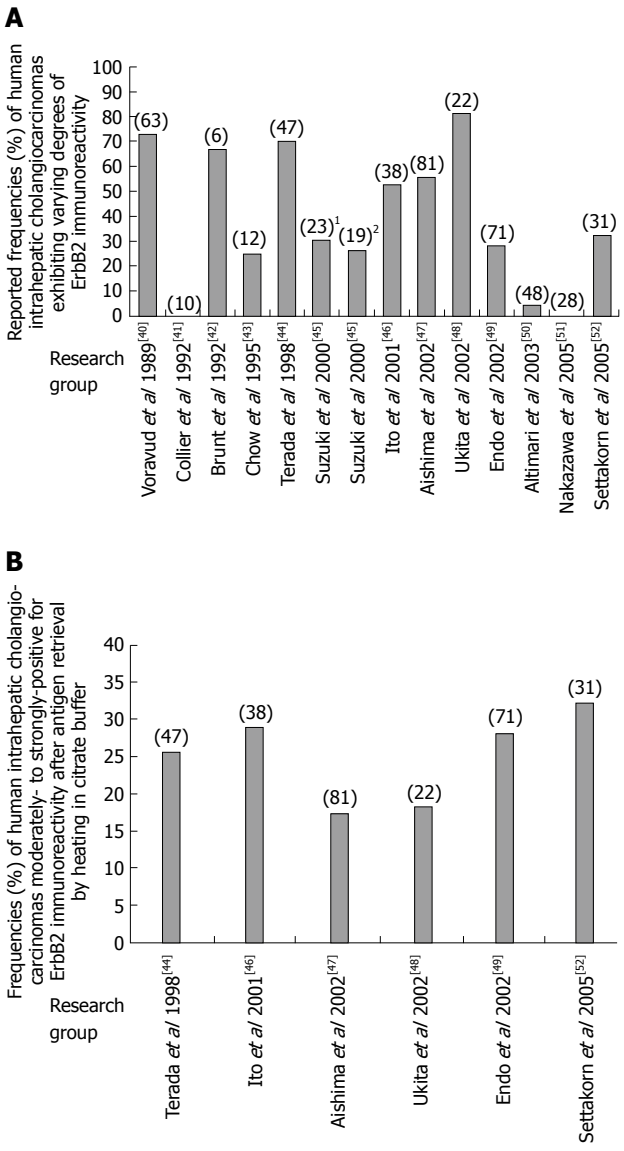

Figure 2 ErbB2 expression in human intrahepatic cholangiocarcinoma. A: Differences in overall reported frequencies of archival human intrahepatic cholangiocarcinoma specimens scored as being immunohistochemically-positive for ErbB2 expression using non-uniform experimental methods and criteria; B: Range of reported frequencies of archival human intrahepatic cholangiocarcinomas scored as being moderately-to-strongly positive (+2 to +3) for ErbB2 immunoreactivity following antigen unmasking by heating of tissue specimens in citric acid buffer, pH 6.0. Number in () = number of cases analyzed; number in [] = reference number; In A, [1]refers to Japanese cases analyzed; [2]refers to Thai cases analyzed.

heterodimeric complexes[23].

In addition to activating the intracellular *ras-raf*-MEK-MAPK and PI3K-Akt cascades, signaling through ErbB family receptors also activates other key cell regulatory molecules affecting cell differentiation, cell cycle progression, and malignant transformation and/or progression, including transcription factors such as *c-myc, c-Jun, c-fos,* Ets family members, signal transduction and activator of transcription (STAT) proteins, and nuclear factor-κB (NF-κB)[21-23,37-39]. Cyclin D1 is an important cell cycle regulator downstream of ErbB receptor signaling, which promotes G1/S phase cell cycle progression[23,30]. Moreover, preferential binding of phospholipase Cγ to the tyrosine kinase domain of the EGFR receptor mediates the generation of lipid second messengers diacylglycerol and inositol 1, 4, 5-triphosphate[21].

ErbB2 and/or EGFR together with EGF-like peptides are frequently found to be overexpressed in various epithelial cancers of both the human and experimental animal models. Mechanisms associated with the aberrant constitutive activation of ErbB2 or EGFR in malignant tumors include not only those associated with a persistent paracrine or autocrine production of growth factor ligands within the tumor, but also may occur as a result of receptor gene amplification and/or transcription-mediated protein overexpression, or by mutational activation. As ErbB2, and to a lesser extent EGFR, have been the most studied of the ErbB family receptor members in intrahepatic cholangiocarcinoma, much of the remainder of this review will focus on establishing their relevance to the molecular pathogenesis of intrahepatic cholangiocarcinoma and their potential as molecular targets for therapy against this lethal cancer.

ABERRANT ERBB2 EXPRESSION IN HUMAN INTRAHEPATIC CHOLANGIOCARCINOMA

The human ErbB2 receptor tyrosine kinase is a 185 kDa transmembrane glycoprotein encoded by the *c-erbB-2* proto-oncogene localized to chromosome 17q. Since 1989, several independent studies have been published describing the results of immunohistochemical analyses of ErbB2 oncoprotein expression in cancerous epithelium of human intrahepatic cholangiocarcinomas relative to that of normal bile ducts in adult liver[40-52]. In each of these studies, ErbB2 immunohistochemistry was performed on formalin-fixed, paraffin-embedded tissue samples from human intrahepatic cholangiocarcinomas of either Eastern and/or Western origin, which were mostly obtained from surgical files, but in some studies, also included specimens from autopsy files[44,48]. ErbB2 immunostaining was either not detected or only weakly detected in normal intrahepatic bile duct epithelium in adult and in fetal human livers[40,43,44,47,49]. On the other hand, reported incidences of intrahepatic cholangiocarcinoma cases overexpressing immunoreactive ErbB2 in their cancerous epithelium were found to vary considerably. Figure 2A highlights differences in the published frequencies (%) of analyzed cases of human intrahepatic cholangiocarcinomas that showed positive 1+ (weak) to ⩾ 2+ (moderate to strong) immunoreactivity for ErbB2. The obvious disparities among these published values are likely due, at least in part, to one or more of the following possibilities: (1) differences in tissue processing procedures used to optimize antigen availability, (2) use of different ErbB2 antibody preparations, (3) variations in the criteria or methods used to score and quantify positive cases of ErbB2 overexpression, and (4) in some studies, having too small of a sampling size of

intrahepatic cholangiocarcinoma specimens in the study to be meaningful[41,42].

Notable differences among the experimental approaches used in these various independent studies included the fact that antigen retrieval procedures involving heating tissue specimens in citrate buffer, pH 6.0, were employed in only some[44,46-50,52], but not all of the published studies. Moreover, in some of these studies, mouse monoclonal ErbB2 antibody preparations were used[41-46,48,49] whereas others were performed with rabbit polyclonal anti-ErbB2 antibodies[40,47,50-52]. Furthermore, while in some studies no distinctions were made between plasma membrane and cytoplasmic immunostaining when scoring tumors ostensibly positive for ErbB2 overexpression[40,47], others more appropriately relied largely on evidence of positive membranous immunostaining when classifying positive cases[43,44,48-52]. Also, the methods used in these studies to assess human intrahepatic cholangiocarcinomas for ErbB2 overexpression have been for the most part semi-quantitative, with no standard or uniform guidelines having been adopted to date for quantifying or validating ErbB2 overexpression in human cholangiocarcinogenesis. In this context, the results shown in Figure 2B are somewhat revealing, since they demonstrate that a greater degree of conformity among the reported frequency of expression values shown in Figure 2A can be achieved when the data are reevaluated in terms of (1) being derived only from those studies in which antigen unmasking was accomplished through heating of the tissue specimens in citric acid buffer, pH 6.0, and (2) when only those tumors scored as being moderately-to-strongly-positive ($\geqslant$ 2+) in their immunostaining reactions are used in calculating the overall frequencies of ErbB2-overexpressing tumors. It also follows that before further progress can be made in using immunohistochemistry to reliably and reproducibly assess cases of human intrahepatic cholangiocarcinoma for ErbB2 overexpression, there is a real need to establish rigorous clinical practice guidelines specific for this cancer, as were recently recommended by the American Society of Clinical Oncology and the College of American Pathologists for ErbB2 testing and validation in human breast cancer[53]. Less subjective and more analytical methods, such as the use of computer-assisted image analysis for quantifying immunostaining reactions are also needed to permit more objective measurements of ErbB2 immunoreactivity (as well as that of other marker proteins) in fixed tissue sections from human intrahepatic cholangiocarcinomas and related risk conditions. In this regard, utilizing microdensitometry measurements of immunostaining reactions, Endo *et al*[49] had demonstrated a strong positive correlation between levels of plasma membrane ErbB2 immunoreactivity and that of cytoplasmic cyclooxygenase-2 (COX-2) in human intrahepatic cholangiocarcinogenesis. The data generated from this quantitative immunohistochemical study are consistent with a growing body of experimental evidence that supports a strong positive relationship between ErbB2 receptor expression and signaling and COX-2 protein up-regulation and increased activity in the pathogenesis of intrahepatic cholangiocarcinoma (see below).

Not surprisingly, and likely for the same reasons described above for ErbB2, comparable immunohistochemical studies aimed at assessing EGFR overexpression in archival specimens of human intrahepatic cholangiocarcinomas from surgical files also yielded disparate results. For example, in five different published studies, the frequencies of intrahepatic cholangiocarcinomas exhibiting 2+ to 3+ immunostaining for EGFR were reported to be 10.7%[51], 21.1%[46], 21.6%[54], 47%[55], and 81%[50], respectively. In the positive tumors, EGFR immunostaining, with varying degrees of heterogeneity, was largely localized to the plasma membranes of the cancerous epithelial cells. Ito *et al*[46] further observed that 39.5% of their analyzed cases (n = 38) of human intrahepatic cholangiocarcinoma showed 2+-positive cytoplasmic immunostaining for ErbB3, with 10.5% of the total tumors analyzed also found to be 2+-positive for cytoplasmic ErbB4 immunostaining. In addition, these investigators reported that 21.1% of the cases of intrahepatic cholangiocarcinomas included in their study exhibited positive immunostaining for all four ErbB family members, while 36.8% of the tumors analyzed were found to exhibit positive immunostaining reactions for three of the four type I receptors. However, the purely descriptive nature of this study makes it impossible to predict specific receptor dimerization preferences that may be operative in these analyzed tumors.

While uncommon, activating mutations in the tyrosine kinase domain of ErbB2 have been recently described for a subset of lung cancer patients[56]. Likewise, a novel H878Y missense mutation in the tyrosine kinase domain of ErbB2 has also been recently demonstrated in 11% (2/18) of examined cases of human hepatocellular carcinoma[57]. However, in this same study, none of 22 analyzed cases of biliary cancer were found to harbor the *erbB2* H878Y mutation. All hepatocellular carcinoma and biliary cancer samples analyzed in this particular study were further observed to be negative for gain-of-function somatic mutations affecting the catalytic domain of the EGFR gene. In contrast, Leone *et al*[58] recently described somatic mutations in the tyrosine kinase domain of EGFR in a subgroup of patients with either cholangiocarcinoma or gallbladder carcinoma. Gwak *et al*[59] also recently reported that 13.6% (3/22) of examined cases of human cholangiocarcinoma exhibited EGFR mutations in the kinase domain. While still limited in scope, these collective findings suggest that mutations in the tyrosine kinase domain may be playing a role (albeit limited) in sustaining the activation of ErbB receptors, most particularly EGFR, in a subset of human biliary tract cancers, including some intrahepatic cholangiocarcinomas. Thus, identifying such activating mutations could conceivably contribute towards predicting a positive response of a few select biliary tract

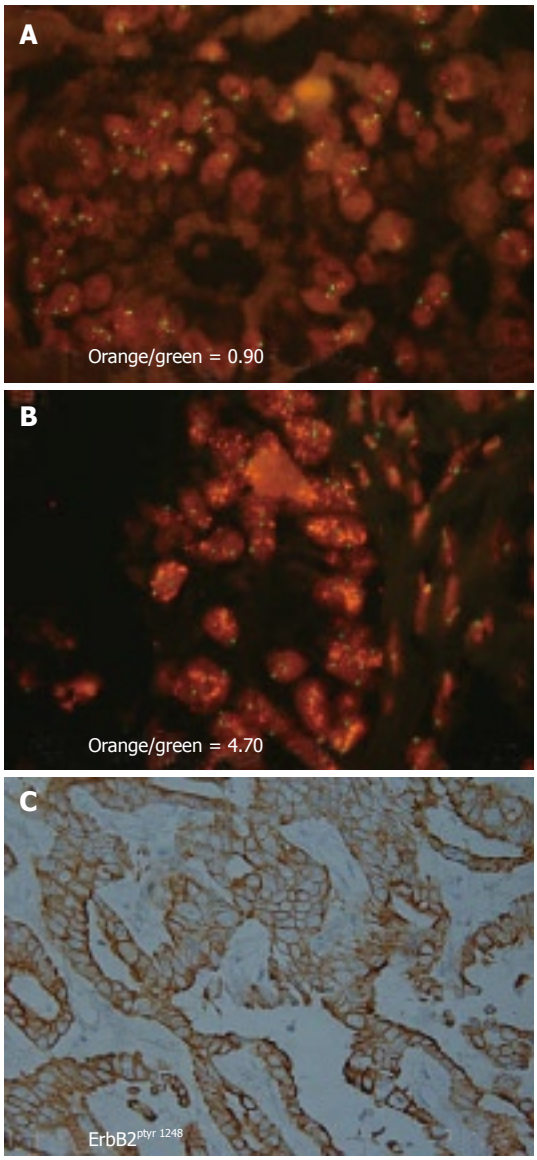

Figure 3 Representative photomicrographs demonstrating *c-erbB2* gene amplification and a corresponding strong positive immunoreactivity for activated ErbB2 oncoprotein in the neoplastic cholangiocytes of a human intrahepatic cholangiocarcinoma. A and B: Sections of two different intrahepatic cholangiocarcinomas with neoplastic cholangiocytes exhibiting FISH nuclear signals for *c-erbB2* (orange dots) and for CEP17 (centromeric region of chromosome 17; green dots). Orange/green values indicate *c-erbB2*/CEP17 signal ratio for each cholangiocarcinoma. An orange/green ratio of > 2.0 = a tumor with *c-erbB2* amplification (B), whereas a ratio value at or approximating 1.0 = a tumor without *c-erbB2* amplification (A). The neoplastic cholangiocytes in the intrahepatic cholangiocarcinomas depicted in A (immunohistochemical staining not shown) and in B (with corresponding immunohistochemical staining shown in C) were each found to exhibit strong positive immunoreactivity at the plasma membrane for activated ErbB2 oncoprotein, using an antibody directed against phosphotyrosine 1248 of ErbB2. Tyrosine 1248 is the main autophosphorylation site in the carboxy terminal domain of ErbB2 linked to downstream signaling through the *ras-raf*-MEK-p42/44 MAPK signal transduction pathway. Thus, activation of ErbB2 *via* autophosphorylation at tyrosine 1248 in neoplastic cholangiocytes of intrahepatic cholangiocarcinomas can be demonstrated either in the presence or absence of *c-erbB-2* amplification. (A, B × 330, C × 132).

cancers to ErbB targeted therapies (see below).

Presently, there have only been limited efforts to investigate *c-erbB2* gene amplification in human intrahepatic cholangiocarcinomas. Moreover, as has been the case with immunohistochemistry, current studies that utilized either fluorescence *in situ* hybridization (FISH), exemplified in Figure 3, or chromogenic *in situ* hybridization (CISH) analysis to evaluate *c-erbB2* amplification in cases of human cholangiocarcinoma have also produced variable and conflicting results. Shiraishi *et al*[60], employing two-color FISH using probes specific for *c-erbB2* and chromosome 17 centromere, did not detect evidence of *c-erbB2* amplification in six analyzed cases of human biliary tract cancers, including two peripheral and three hilar cholangiocarcinomas that showed a gain in 17q. In contrast, Ukita *et al*[48] employing FISH to evaluate gene amplification using only a *c-erbB2* probe reported increased *c-erbB2* signals in all 22 of their analyzed cases of intrahepatic cholangiocarcinoma. In this study, putative *c-erbB2* amplification was detected in the form of cluster signals in most of the tumors. On the other hand, there was a notable discordance between the immunohistochemical findings for ErbB2 overexpression and the FISH data for *c-erbB2* amplification. Furthermore, since Ukita *et al*[48] did not assess for changes in chromosome 17 copy number, it is not possible to determine from their results the extent to which aneuploidy or chromosome 17 polysomy alone may have contributed to their findings. More recently, Altimari *et al*[50] using CISH detected putative *c-erbB2* amplification in 4% of cases of human intrahepatic cholangiocarcinoma that were also found to be moderately to strongly immunoreactive for ErbB2 oncoprotein. However, this study also did not include an internal control for chromosome 17 copy number. On the other hand, Nakazawa *et al*[51] using two color FISH with probes for *c-erbB2* and chromosome 17 centromere reported no evidence of *c-erb2* amplification in 28 analyzed cases of human intrahepatic cholangiocarcinomas. Contrary to the findings of others (see Figure 2) Nakazawa *et al*[51] also reported that none of their analyzed cases of intrahepatic cholangiocarcinoma were immunohistochemically positive for ErbB2 overexpression.

The limited scope of these reported findings together with the fact that experimental variations and non-standardized criteria were used in assessing *c-erbB2* amplification in human intrahepatic cholangiocarcinoma clearly indicates the need for further studies in order to more definitively assess the extent to which gene amplification may be contributing to ErbB2 overexpression in these tumors. Universal and reliable standards need to be adopted for assessing *c-erbB2* amplification in biliary tract malignancies, including intrahepatic cholangiocarcinoma, leading to a more rigorously controlled assessment of *c-erbB2* gene amplification in relation to protein overexpression. It is also important to be able to more definitively assess if *c-erbB2* amplification might provide a more reliable and less variable indicator than immunohistochemistry for predicting favorable therapeutic responses of patients with intrahepatic cholangiocarcinomas to target-based treatments with ErbB2 inhibitors.

Another important deficiency in our current

understanding of ErbB2 and EGFR overexpression in human intrahepatic cholangiocarcinomas is the noticeable lack of mRNA data. *In situ* hybridization (ISH) has been used to investigate *c-erbB2* mRNA expression in the cancerous epithelium of archival formalin-fixed, paraffin-embedded specimens of human cholangiocarcinoma[48], but the staining pattern that was observed was seen to be diffusely intranuclear and to a much lesser extent cytoplasmic, suggesting some possibility of artifact. Regardless, these reported ISH results are descriptive and not quantitative, and have not been validated by more definitive analytical methods, such as real-time reverse-transcriptase polymerase chain reaction (real-time RT-PCR). Utilizing laser microbeam microdissection and cDNA microarray analysis, Obama *et al*[61] demonstrated a more than five-fold increase in *c-erbB2* expression in 3 (14%) and more than a two-fold increase in 6 (28%) of 21 cases of human intrahepatic cholangiocarcinomas analyzed. However, it was not evident if the microarray data for *c-erbB2* was validated by real-time RT-PCR. Here it may also be relevant that Endo *et al*[49], utilizing computer-assisted image analysis to evaluate plasma membrane ErbB2 immunostaining, have reported strongly-positive immunoreactivity for plasma membrane ErbB2 to be most prominent in the cancerous epithelium of well differentiated intrahepatic cholangiocarcinomas, whereas most of the tumors analyzed by Obama *et al*[61] were classified as being moderately to poorly differentiated. Settakorn *et al*[52], on the other hand, observed a low level of ErbB2 immunoreactivity in all (n = 9) of their analyzed archival cases of low grade human intrahepatic cholangiocarcinoma and strongly-positive ErbB2 immunoreactivity in 10 of 22 cases of the higher grade tumors. The fact that different commercial antibodies (monoclonal *versus* polyclonal) were used by Endo *et al*[49] and Settakorn *et al*[52], respectively, may account, at least in part, for the discrepancies in their reported immunohistochemical findings. Nevertheless, it is evident from the limited and conflicting results described above that further studies are needed to more clearly define the association between tumor grade and *c-erbB2* mRNA and protein expression in human intrahepatic cholangiocarcinoma.

A number of immunohistochemical studies have demonstrated increased expression of ErbB2 oncoprotein in variable percentages of noncancerous biliary proliferative disorders associated with human cholangiocarcinogenesis, including hepatolithiasis and PSC[44,47,49]. These findings suggest that ErbB2 overexpression associated with risk conditions characterized by cholangitis and partial biliary obstruction may represent a relatively early event linked to human intrahepatic cholangiocarcinogenesis. Interestingly, Su *et al*[62] also measured a higher mean level of ErbB2 oncoprotein in bile collected from patients with cholangiocarcinoma than in bile collected from patients with biliary tract infection, biliary stone disease, or normal controls. This study further supports ErbB2 as playing a role in human cholangiocarcinogenesis and suggests that elevated ErbB2 in bile might have some use in identifying individuals with high risk for developing biliary tract cancers. But again, these findings are limited in scope and need to be significantly expanded and substantiated before ErbB2 in bile can be accepted as a possible diagnostic test for predicting cholangiocarcinoma risk. Moreover, in none of the studies indicated in Figure 2, was the activation status (tyrosine phosphorylation) of the ErbB2 or EGFR receptors determined. In this regard, there is a further need to rigorously establish the tyrosine phosphorylation status of ErbB2 expressed in cholangiocarcinoma cells (i.e. see Figure 3C) compared with non-malignant cholangiocytes in liver, together with that of other ErbB receptor family members. Moreover, this should be done in conjunction with determining associated changes in receptor mRNA and protein expression levels. Such a comprehensive analysis of ErbB receptor family expression and activation would be more informative than that reflected in currently published studies, particularly when viewed in terms of contributing towards devising and tailoring specific strategies aimed at targeting ErbB signaling pathways for intrahepatic cholangiocarcinoma therapy.

ERBB2 AND RODENT MODELS OF CHOLANGIOCARCINOGENESIS

Neu is the rat homologue of human ErbB2. Table 1 lists experimental rodent models in which Neu overexpression has been demonstrated to be associated with the molecular pathogenesis of intrahepatic cholangiocarcinoma. Western and Northern blotting, together with immunohistochemistry and ISH have been used to demonstrate Neu protein and mRNA to both be significantly overexpressed in the cancerous epithelium of furan-induced intrahepatic intestinal-type cholangiocarcinomas when compared with hyperplastic bile ducts/ductules in the liver of bile duct-ligated rats and with normal adult rat liver[63,64]. In these tumors, *c-neu* was further determined not to be amplified nor to exhibit evidence of a key activating point mutation within its transmembrane domain[64]. In addition, Neu oncoprotein overexpressed in furan-induced rat cholangiocarcinomas was tyrosine phosphorylated, indicative of a constitutively activated signaling state. Here, it would seem that constitutive overexpression of activated Neu in furan-induced rat intrahepatic cholangiocarcinomas is the result of an altered transcriptional event rather than to mechanisms involving gene amplification or mutation. Similarly, Neu protein was further demonstrated by immunohistochemistry to be overexpressed in cancerous epithelium of intestinal-type cholangiocarcinoma induced in the livers of rats treated with thioacetamide when compared with normal cholangiocytes[65].

Hepatic cirrhosis and early formed cholangiofibrotic precursor lesions precede the development of intrahepatic cholangiocarcinoma in both furan- and thioacetamide-treated rats. Here it is interesting that Neu

Table 1 Rodent models of intrahepatic cholangiocarcinoma constitutively overexpressing ErbB2/Neu in cancerous epithelium

Model	Tumor			ErbB2/Neu			Tyrosine phosphorylation	Ref.
	Development time	Incidence (%)	Classification	c-erbB-2/neu	mRNA	Protein		
Furan rat model	> 1 yr	70-100	Intestinal-type cholangiocarcinoma	Wild-type/ non-amplified	Increased	Increased	Increased	[63,64]
Thioacetamide rat model	16-22 wk	100	Intestinal-type cholangiocarcinoma	NA	NA	Increased	NA	[65]
P53 deficiency/CCl_4 mouse model	≥ 16 wk	40	Ductal cholangiocarcinoma	NA	NA	Increased	NA	[66]
Rat BDEneu orthotopic cell transplantation model	4 wk	100	Ductal cholangiocarcinoma	Mutated	Increased	Increased	Increased	[68,69]

NA: Not assessed.

overexpression has also been observed in metaplastic/dysplastic glands within these early cholangiofibrotic lesions, as well as in the later developed invasive cholangiocarcinomas, compared with negative or marginal levels of Neu detected in normal or hyperplastic bile ductular epithelium[64,65]. More recently, CCl_4-induced hepatic fibrosis was shown to be associated with the promotion of intrahepatic cholangiocarcinoma in p53-deficient mice[66], with strong Neu immunostaining having also been seen in the cancerous epithelium of a majority of the mass-forming liver tumors, as well as in some metastatic lesions. Here too, Neu expression was detected in early intrahepatic cholangiocarcinomas as well, with only weak or undetected Neu immunostaining being observed in normal bile ducts and in small bile duct hyperplasia. Overall, these experimental results are consistent with previously described epidemiological and immunohistochemical findings for human intrahepatic cholangiocarcinogenesis, which support a role for hepatic cirrhosis as a potential risk factor in the pathogenesis of intrahepatic cholangiocarcinoma development[13,16]. They further suggest Neu overexpression to be a factor in both the early and later stages of intrahepatic cholangiocarcinogenesis.

More direct evidence for the involvement of Neu in the development of biliary tract malignancies, including intrahepatic cholangiocarcinoma comes from genetic-based animal and cell models. Transgenic mice (*BK5.erbB2* mice) generated to constitutively overexpress wild-type rat *c-neu* developed gallbladder adenocarcinoma at a 100% incidence and intrahepatic cholangiocarcinomas at 30% incidence by 8 mo of age[36]. No mutations in either *K-ras* or *p53* were detected in 16 of the murine gallbladder adenocarcinomas analyzed, with *p53* being found to be elevated in only one of these tumors. On the other hand, Neu and EGFR protein (but not ErbB3 or ErbB4) were found to be increased and hyperphosphorylated on tyrosine residues in gallbladder tissue from the *BK5.erbB2* mice. Increased heterodimer formation between Neu and EGFR and increased p42/44 MAPK activation were also observed in gallbladder from these transgenic mice when compared with that from control mice not expressing the rat *c-neu* transgene, further implicating increased Neu signaling in development of biliary tract cancers. Consistent with these transgenic mouse data, it has recently been demonstrated that when non-tumorigenic immortalized adult rat cholangiocytes (BDE1 cells)[67] were stably transfected with a constitutively expressed mutant rat *neu* gene, they became highly tumorigenic[68,69]. These malignant transformants, designated as BDEneu cells, overexpressed activated Neu[68,69], as well as EGFR (Sirica, A.E., unpublished data), and exhibited elevated levels of phospho-p42/44 MAPK and phospho-Akt when compared with both non-tumorigenic parent BDE1 cells and non-tumorigenic control BDEneo cells that were derived by stably transfecting BDE1 cells to only express the gene for neomycin resistance[68]. BDEneu cells transplanted *via* bile duct inoculation into the livers of isogenic rats rapidly formed large moderately differentiated mass-forming intrahepatic cholangiocarcinomas that recapitulated clinical, cellular, and molecular features of advanced human disease[68,69] (Figure 4). Notably, BDEneu tumors were found to be highly invasive and metastatic, to produce bile duct obstruction at the hepatic hilus, and to retain strong immunoreactivity in their cancerous epithelium for Neu constitutively phosphorylated at tyrosine 1248. Tyrosine 1248 is known to be a major autophosphorylation site at the cytoplasmic tyrosine kinase domain of Neu oncoprotein that reflects the activation status of the receptor and couples Neu to the *ras-raf*-MEK-p42/44 MAPK signal transduction pathway[70,71].

The C611B cell line is another novel rat cholangiocarcinoma cell line that constitutively overexpresses Neu when compared with hyperplastic rat intrahepatic bile ducts/ductules induced in bile duct-ligated rats[72-75]. This cell line was established from a transplantable mucin-producing cholangiocarcinoma expressing wild-type *neu* that was derived from the furan rat cholangiocarcinogenesis model[72]. Like BDEneu cells, C611B cells express Neu protein phosphorylated at tyrosine 1248, as well as activated Akt and p42/44 MAPK (Figure 5A). Inoculation of C611B cells into the inguinal fat pads or livers of isogenic rats also yields a 100% incidence of mass-forming adenocarcinomas that closely resemble in their histopathology well differentiated mucin-producing tubular intrahepatic cholangiocarcinomas of the human[72]. As exemplified by the RT-PCR data shown in Figure 5B, C611B

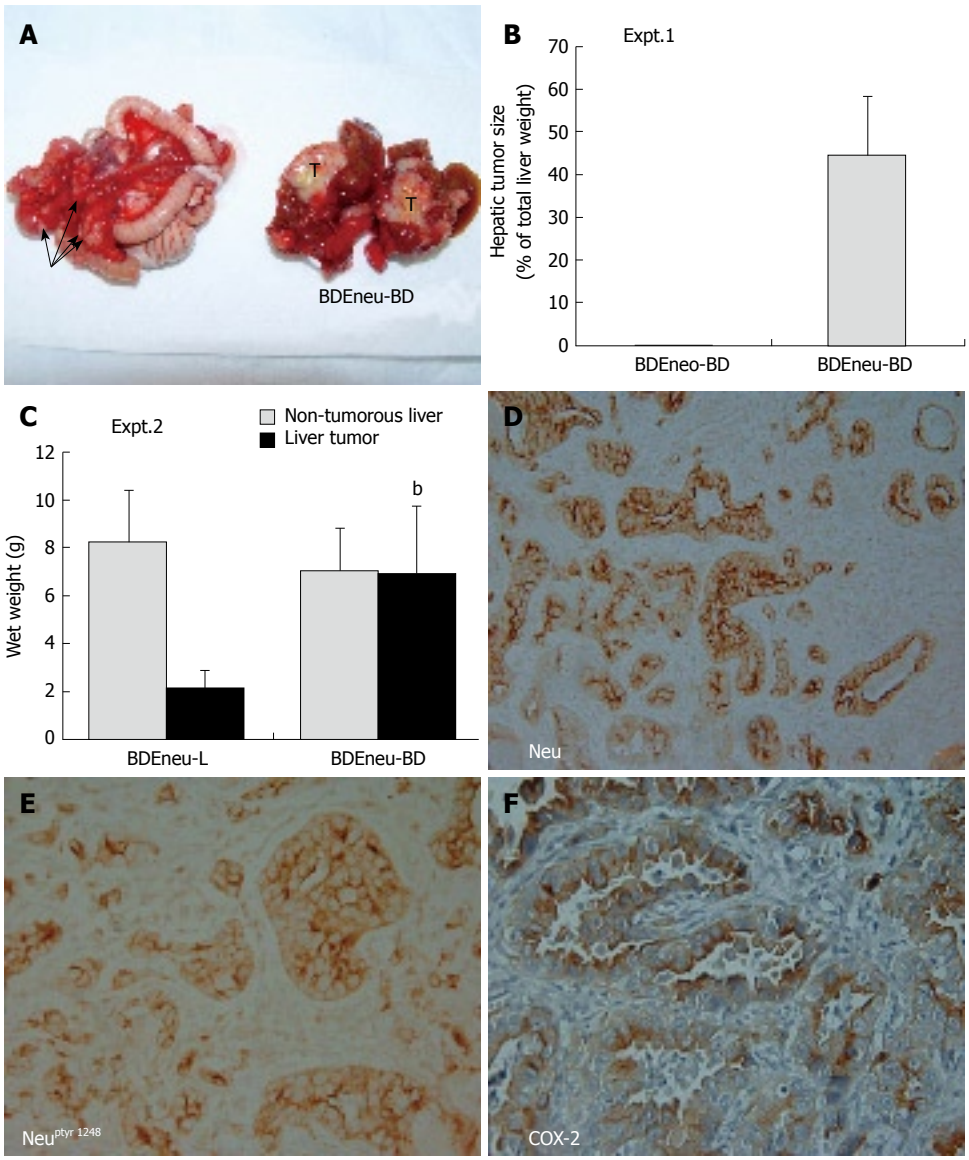

Figure 4 Rat BDEneu cell transplantation model of intrahepatic cholangiocarcinoma progression. A: Gross pathology of a bisected invasive hepatic tumor (T) formed in the liver of an isogenic Fischer 344 rat at 3 wk after bile duct inoculation of 4 x 10^6 tumorigenic rat BDEneu cholangiocytes overexpressing mutationally-activated Neu, together with associated peritoneal metastases (arrows); B: Expt 1. mean tumor size ± SD (as a % of total liver weight) of hepatic tumors that formed at a 100% incidence in isogenic rat livers at 3 wk after bile duct inoculation of 4 x 10^6 BDEneu cells (BDEneu-BD), compared with no tumors formed in rats comparably inoculated with control non-tumorigenic BDEneo cells (BDEneo-BD) transfected to stably express the neomycin resistance gene only, in the absence of oncogenic *neu* $n = 6$; C: Expt 2. Differences in mean wet weight ± SD of hepatic tumors (relative to that of corresponding non-tumorous liver) formed at 3 wk after bile duct inoculation of 4 x 10^6 BDEneu cells (BDEneu-BD) *versus* the mean wet weight of hepatic tumors that formed over the same time period following inoculation of the BDEneu cells directly into liver (BDEneu-L). $^bP \leqslant 0.001$ (BDEneu-BD tumor *versus* BDEneu-L tumor). $n = 4$; D: Representative low power photomicrograph demonstrating neoplastic cholangiocytes within a rapidly growing BDEneu-BD intrahepatic cholangiocarcinoma to be strongly immunoreactive for plasma membrane Neu; E: Photomicrograph showing malignant cholangiocytes within a BDEneu-BD intrahepatic cholangiocarcinoma to exhibit strong uniformly positive immunoreactivity for activated Neu phosphorylated at tyrosine 1248; F: Photomicrograph of a BDEneu-BD tumor demonstrating positive cytoplasmic immunostaining for COX-2 in the cholangiocytes of the neoplastic ducts. Positive immunostaining in D-F is indicated by brown reaction product. (See References 68 and 69 for a more complete description of rat BDEneu model). (D × 66, E, F × 132).

cholangiocarcinomas simultaneously express mRNA for ErbB growth factor ligands (i.e. TGF-α, heregulin) and for three of the four ErbB family receptors, with the exception of ErbB4, which is also not detected in normal rat liver[76]. These data, although limited, suggest that ligand-dependent activation of ErbB family receptors are likely operative in these tumors, and that cognate ligands, such as TGF-α, may be playing an important role in this process[26]. EGFR immunoreactivity has also been detected in the cancerous epithelium of 100% of analyzed specimens of rat cholangiocarcinomas induced by thioacetamide[55], further suggesting that signaling through EGFR may also be a relevant contributing factor to the genesis and progression of intrahepatic cholangiocarcinoma[77]. However, additional mechanism-based studies are needed to more fully substantiate this likely possibility.

It is surprising that there is a noticeable lack of published data on the use of well established hamster models of cholangiocarcinogenesis, such as those

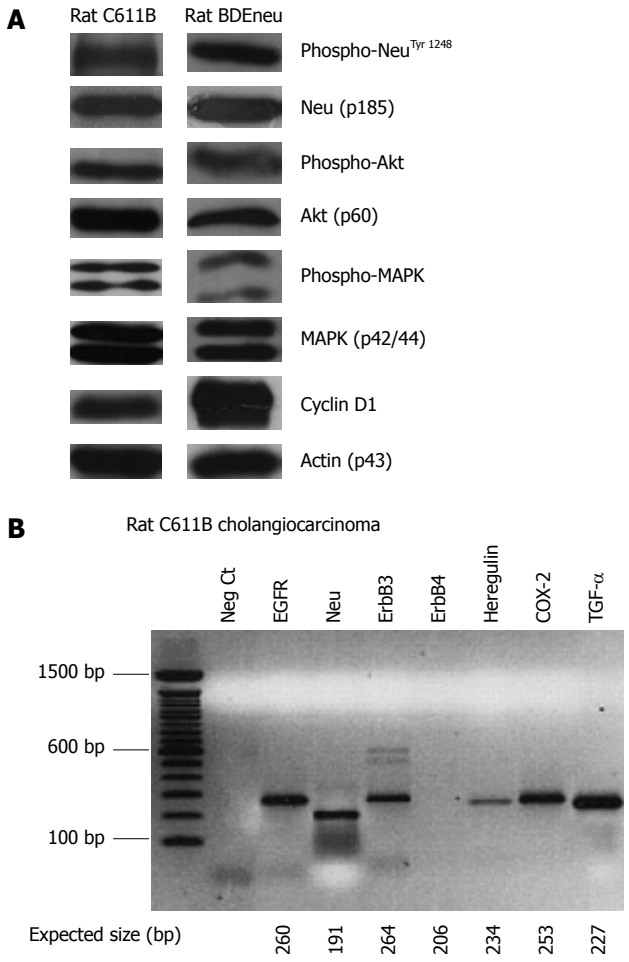

Figure 5 Western blot (A) and RT-PCR (B) analyses. A: Relevant protein and phosphorylation profiles associated with aberrant Neu expression in rat C611B and BDEneu cholangiocarcinoma cell lines. C611B overexpress the wild-type *c-neu* gene[64], whereas BDEneu cells overexpress mutationally-activated *neu* oncogene[68,69]. Note that both cell lines are positive for phospho-Neu, phospho-Akt, and phospho-p42/44 MAPK, as well as show prominent expression of cyclin D1; B: RT-PCR analysis of *c-erbB* family receptor together with heregulin, TGF-α, and COX-2 mRNAs detected in malignant neoplastic ducts obtained by laser capture microdissection from a hepatic tumor formed in an isogenic Fischer 344 male rat following cell transplantation of rat C611B cholangiocarcinoma cells directly into liver. Note that as expected, among the ErbB family receptors, only ErbB4 mRNA is not detected in the tumor ducts. Moreover, it is also significant that mRNA signals for both the EGFR ligand TGF-α and for COX-2, which is known to be up-regulated in response to EGFR and/or Neu signaling, are each shown to be prominently detected in C611B cholangiocarcinoma.

which combine tumor initiating doses of carcinogenic nitrosamines with *Opisthorchis viverrini* or *Clonorchis sinensis* infection[78-82] as a means to investigate the role of aberrant ErbB family receptor signaling in intrahepatic cholangiocarcinoma development and progression. This may be due to the fact that only very limited hamster-specific immunochemical and molecular reagents are currently available for such studies. Nevertheless, the establishment of novel rodent models as those described above and in Table 1 have proven to be valuable resources for investigating the role of ErbB-family receptors in intrahepatic cholangiocarcinogenesis. Clearly more studies are needed in this regard, but from the standpoint of clinical relevance, it is also apparent that some recently developed rodent models of intrahepatic cholangicarcinoma development and progression have the potential of serving as powerful preclinical platforms for rapidly testing novel ErbB targeted treatment strategies for cholangiocarcinoma prevention and therapy.

INTERACTIVE RELATIONSHIPS BETWEEN ERBB FAMILY RECEPTORS AND OTHER MOLECULAR PATHWAYS

The interplay between the EGFR and/or ErbB2 receptor tyrosine kinases with other diverse signaling pathways provides multiple functional links by which intrahepatic cholangiocarcinoma growth and/or progression may be promoted or potentiated. Furthermore, such interactive molecular relationships can have important implications with respect to devising novel molecular targeting strategies for cholangiocarcinoma therapy or chemoprevention[1]. EGFR and/or ErbB2 have been linked to other molecular pathways implicated in intrahepatic cholangiocarcinoma growth, apoptosis resistance, angiogenesis and/or invasion and metastasis. Each of these depicted interactions will be discussed separately, although it is important to keep in mind that they are likely functioning in concert.

Bile acids

Secondary bile acids, such as deoxycholic acid and its conjugated forms, which have been reported to be increased in the serum of cholangiocarcinoma patients[83], may be acting to promote cholangiocarcinogenesis in the biliary tract[20,84,85] through a mechanism involving bile acid-mediated activation of EGFR, leading to up-regulation of COX-2 and protein turnover inhibition of the potent antiapoptotic protein, myeloid cell leukemia 1 (Mcl-1). Werneburg *et al*[26] have demonstrated that bile acids like deoxycholic acid can act to activate EGFR in cultured human H-69 cholangiocyte and KMBC cholangiocarcinoma cell lines by a TGF-α-dependent mechanism mediated by bile acid stimulation of matrix metalloproteinase activity catalyzing TGF-α membrane release. Yoon *et al*[86] have further shown deoxycholic acid and conjugated forms, such as taurochenodeoxycholate, to significantly induce COX-2 expression in cultured human KMBC cholangiocarcinoma cells *via* EGFR transactivation and subsequent activation of p42/44 MAPK, p38 MAPK, and c-jun-N-terminal kinase (JNK). In addition, deoxycholic acid was found to prolong Mcl-1 protein turnover in cultured KMBC cholangiocarcinoma cells by an EGFR/Raf-1-dependent mechanism[87]. Comparable mechanisms have been reported for bile-acid mediated induction of COX-2 and Mcl-1 in human and rat hepatic stellate cells[88], suggesting that bile acids might also be playing a role in enhancing the survival and proliferation of myofibroblastic tumor stromal cells associated with the desmoplastic reaction typically characteristic of intrahepatic cholangiocarcinoma. It may also be of interest that deoxycholic acid, as well as

taurodeoxycholic, and taurochenodeoxycholic bile acids have recently been reported to regulate the expression of MUC4, a modulator of ErbB2 signaling (see below), in human esophageal carcinoma cells by a promoter-dependent mechanism involving activation of the PI3K pathway[89], and in the case of taurodeoxycholic and taurochenodeoxycholic bile acids, have also been found to be mediated by hepatocyte nuclear factor-1α[90].

Cox-2

Cox-2, the inducible form of prostaglandin endoperoxidase, has been reported to be commonly up-regulated in the malignant neoplastic epithelium of intrahepatic cholangiocarcinomas of both the human[49,91,92] and of experimental rodent models[68,69,73-75] (Figures 4F and 5B). Accumulating evidence over the past several years has further supported COX-2-derived prostaglandin signaling as playing an important role in cholangiocarcinogenesis as a mediator of mitogenesis, anti-apoptosis, and angiogenesis[93,94]. Moreover, a close relationship between COX-2-derived prostaglandin signaling and that of EGFR or ErbB2 overexpression and activation has been established in animal and cell models of biliary tract carcinogenesis[36,68,74].

Vadlamudi *et al*[95] were the first to demonstrate the regulation of COX-2 expression by heterodimeric ErbB2 signaling. Furthermore, the presence of a nuclear ErbB2 has been identified, which appears to act as a transcriptional regulator of COX-2[96]. Benoit *et al*[97] have further demonstrated that COX-2, through the production of its major enzymatic product prostaglandin E_2 (PGE_2), positively regulates ErbB2 expression, supporting a model in which ErbB2 and COX-2 regulate each other in a positive loop. Cross-talk between COX-2- derived PGE_2 and EGFR has also been demonstrated in human cholangio- and hepatocellular carcinoma cells[33,98], and EGFR kinase inhibitors were found to decrease COX-2 expression levels in cultured human cholangiocarcinoma cells[77], suggesting a similar positive regulatory loop for EGFR and COX-2. In addition, the recent findings of Zhang *et al*[99] have suggested that in human cholangiocarcinoma cells, PGE_2-enhanced phosphorylation of MAPK/ERK is, at least in part, mediated through EP1 receptors and EGFR phosphorylation that is associated with increased intracellular calcium concentration.

As previously noted in this review, a positive correlation between immunohistochemically-determined ErbB2 expression and COX-2 up-regulation has been described in human cholangiocarcinogenesis[49]. COX-2 up-regulation has also been determined to closely parallel constitutive *c-neu* protein and mRNA overexpression in cholangiocarcinoma cells and tumors derived from the furan rat model of intrahepatic cholangiocarcinogenesis[73,74]. Of particular interest are the findings of Kiguchi *et al*[36] who observed a prominent up-regulation of COX-2 protein and mRNA in gallbladder tissues and tumors from *BK5.erbB2* transgenic mice constitutively overexpressing wild-type rat *c-neu,* thereby adding more convincing support for the role of Neu (ErbB2) in COX-2 expression in biliary tract carcinogenesis. Consistent with the findings of Kiguchi *et al*[36], Lai *et al*[68] more recently reported COX-2 protein and mRNA, together with a concomitant overproduction of PGE_2, to be significantly induced in rat BDE1 cholangiocytes upon *in vitro* malignant neoplastic transformation of these cells with mutationally-activated rat *neu* oncogene. Neoplastic epithelium of tumors overexpressing mutationally-activated Neu formed from orthotopically transplanted *neu*-transformed rat cholangiocytes (BDEneu cells) were also found to be positively immunoreactive for cytoplasmic COX-2[68] (Figure 4F).

Interleukin-6 (IL-6)/gp130

The inflammatory cytokine IL-6 has been demonstrated to be frequently overexpressed in malignant neoplastic cells of human well differentiated intrahepatic cholangiocarcinomas[100] and to be increased in the serum and bile of cholangiocarcinoma patients[101-103]. IL-6 has been further shown to function as an autocrine growth factor for human cholangiocarcinoma cell lines[100,104,105], and to up-regulate Mcl-1 in malignant human cholangiocyte cell lines[106,107].

Gp130 is the signal transducing element of the IL-6 receptor. Current data support a mechanism whereby sustained IL-6-induced phosphorylation (activation) of gp130, leading to enhanced activation of STAT-3, contributes to cholangiocarcinoma cell mitogenesis and enhanced Mcl-1 up-regulation and resistance to apoptosis[106-109]. Isomoto *et al*[108] have further reported that sustained IL-6/STAT-3 signaling in human cholangiocarcinoma cells is due to epigenetic silencing of suppressor of cytokine signaling 3 (SOCS-3). Here, it is also noteworthy that COX-2-derived PGE_2 was recently found by Han *et al*[109] to induce IL-6 production through activation of the EP4 receptor and subsequent phosphorylation of gp130/STAT-3 in SG231 human cholangiocarcinoma cells, demonstrating the potential for cross-talk between the COX-2/PGE_2 and IL-6/gp130 pathways in cholangiocarcinoma. In this same study, it was also found that PGE_2 signaling in human CCLP1 human cholangiocarcinoma cells could activate STAT-3 through EP1 receptor-mediated intracellular activation of *c-Src* and EGFR[109].

Qiu *et al*[110], utilizing human prostate carcinoma cells, were the first to demonstrate that ErbB2 forms a complex with the gp130 subunit of the IL-6 receptor, thereby serving as a functional component of IL-6 receptor signaling activating the p42/44 MAPK pathway. Grant *et al*[111] subsequently reported gp130 to be constitutively associated with ErbB2 and ErbB3 in human breast cancer cells and found EGF to induce tyrosine phosphorylation of gp130 in these cells, further supporting a functional interaction between gp130 and the ErbB receptor family. Interestingly, IL-6 overexpression was recently reported to also decrease EGFR promoter methylation in human cholangiocarcinoma cells, leading to enhanced EGFR protein expression[112].

MUC1 and MUC4

Aberrant overexpression of the transmembrane mucins MUC1 and MUC 4 has been frequently observed in human intrahepatic cholangiocarcinomas[55,113-116], and both MUC1 and MUC4 have been reported as being independent prognostic factors for predicting poor outcomes in patients with mass-forming intrahepatic cholangiocarcinoma[113-115]. MUC1 overexpression has also been detected in rat intrahepatic cholangiocarcinoma[55], and more recently, MUC1 mRNA was demonstrated to be significantly increased in the highly tumorigenic rat BDEneu cholangiocarcinoma cell line[68] over that of non-tumorigenic parent BDE1 cholangiocytes, as well as of that expressed in a spontaneously transformed rat cholangiocyte cell line, designated as BDEsp, which was less tumorigenic than the BDEneu cell line[69]. MUC4 has also been cited as being overexpressed, as well as co-localized with Neu protein, in gallbladder adenocarcinoma formed in *BK5.erbB2* transgenic mice overexpressing the wild-type rat *c-neu* transgene[117].

The transmembrane mucins MUC1 and MUC4 interact by different mechanisms with ErbB family receptors and each can function to potentiate ErbB-dependent signal transduction[118-120]. The cytoplasmic tail of MUC1 harbors several tyrosine residues that when phosphorylated may provide critical docking sites for initiating downstream cytoplasmic signaling pathways relevant to cancer development and progression[118]. Notably, the MUC1 cytoplasmic tail has been shown to interact with all four members of the ErbB family of receptor tyrosine kinases[118,119]. EGFR-mediated phosphorylation of the MUC1 cytoplasmic tail at its YEKV motif has further been demonstrated to enhance its affinity for β-catenin, potentially favoring decreased cell adhesion and in the case of tumor cells, increased invasiveness[118,119]. Heregulin was also reported to enhance the formation of MUC1-ErbB2 complexes in tumor cells and to induce the binding of the MUC1 cytoplasmic domain with γ-catenin and targeting of the MUC1 cytoplasmic tail-γ-catenin complex to the nucleolus[121]. This latter finding also supports cross-talk between the ErbB2 receptor tyrosine kinase and MUC1. However, the role of a MUC1 cytoplasmic tail-γ-catenin complex in the nucleolus still needs to be elucidated, particularly in relation to malignant neoplastic cell transformation and progression.

MUC1's cytoplasmic tail, through its interaction with ErbB family receptor tyrosine kinases, has been demonstrated to potentiate ErbB signaling mediated through Grb2-Sos-activation of the Ras-p42/44 MAPK signaling cascade[118,119]. More recently, MUC1 has also been reported to modulate TGF-α-dependent cancer progression[122], as well as to regulate EGFR stability upon activation[123], thereby suggesting a possible alternative pathway whereby cancer development and progression may be promoted *via* a mechanism based on MUC1-mediated inhibition of EGFR degradation. MUC1's C-terminal subunit has further been reported to be translocated to mitochondria by a mechanism in which heregulin-induced tyrosine phosphorylation of ErbB receptors results in the activation of *c-Src*[124]. This interaction, in turn, stimulates binding of the MUC1 cytoplasmic domain to the molecular chaperone HSP90, thus forming a complex to transport MUC1 oncopeptide to the mitochondrial outer membrane, where it may then act to facilitate neoplastic development by blocking activation of the intrinsic apoptotic pathway[124].

In contrast to MUC1, MUC4 has been shown to function as a novel intramembrane ligand and modulator for ErbB2 receptor tyrosine kinase[118-120]. Specifically, it has been proposed that EGF-like domains on MUC4 interact with the cognate receptor portion of ErbB2[119]. However, the actual mechanism whereby MUC4 can signal through ErbB2 is complex and still not completely understood. Caraway and his associates[118,125] first reported that MUC4 alone was capable of inducing tyrosine phosphorylation of ErbB2 and up-regulation of $p27^{kip}$ (a cyclin-dependent kinase inhibitor), but did not produce activation of MAPKs or PI3K-Akt. On the other hand, these researchers found that in the presence of NRG1, MUC4 potentiated ErbB2/ErbB3 phosphorylation, as well as enhanced p42/44 MAPK and Akt activation and $p27^{kip}$ repression[118,125]. More recently, it was reported by Funes *et al*[126] that MUC4 potentiates NRG1 signaling by making more ErbB2/ErbB3 receptors available at the plasma membrane for interaction with the NRG1 ligand, without affecting the total quantity of receptors expressed by the cell. Interestingly, in this study, without NRG1, no evidence of MUC4-stimulated ErbB2 receptor tyrosine phosphorylation was detected. The basis for this difference with earlier reported results[118,125] is unclear, but it seems that MUC4 may be acting to stabilize the ErbB2/ErbB3-NRG1 complex at the plasma membrane by suppressing its internalization[119,126].

MUC 4 has also been reported to suppress apoptosis in cells in the presence or absence of NRG treatment[118]. Indeed, based on the cumulative data for MUC4 interaction with ErbB2, Carraway *et al*[118] have proposed that in polarized untransformed epithelium, the MUC4-ErbB2 complex in the absence of NRG1 receptor signaling would promote cell differentiation. In contrast, in unpolarized cancer cells, MUC4 and NRG1 could function simultaneously to augment ErbB2/ErbB3 signaling, leading to downstream activation of both the Ras-p42/44 MAPK and PI3K-Akt signaling pathways and transcriptional regulation of cyclin D1, promoting cancer cell growth, survival, and/or progression[119].

HGF/Met

Met, the heterodimeric tyrosine kinase receptor for hepatocyte growth factor (HGF), its cognate ligand, is commonly overexpressed in the neoplastic epithelium of intrahepatic cholangiocarcinomas of both human and rodent origin[47,64-66,72,127]. Positive immunoreactivity for Met was determined to be most prominent in well differentiated human cholangiocarcinomas and to be low in poorly differentiated tumors[47,127]. Rat models of intrahepatic cholangiocarcinoma overexpressing

Neu were further found to concomitantly overexpress Met[64,65,72]. In this context, it is noteworthy that like Neu, constitutive overexpression of tyrosine phosphorylated Met in the cancerous epithelium of furan-induced rat intrahepatic cholangiocarcinomas was determined not to be the result of gene amplification, but to correlate with increased Met mRNA expression[64]. Constitutively-activated Met has also been detected in intrahepatic cholangiocarcinomas formed in liver of p53-/- mice following CCl_4 treatment[66].

Typically, in epithelial cancers, Met activation occurs mainly through a paracrine mechanism with stromal cell-secreted HGF, although evidence supporting the existence of a HGF/Met autocrine growth control circuit in cholangiocarcinoma cell lines of both human[105] and rat[73,128] origin has been described. However, cross-talk between EGFR and Met has been demonstrated to also occur in malignant epithelial cell lines in the absence of HGF, but in the presence of TGF-α or EGF[31]. EGFR signaling has also been implicated in HGF-induced hepatocyte proliferation[129], and downstream signaling from HGF/Met has been demonstrated to synergize with ErbB2 to enhance malignant progression[130]. Furthermore, evidence has been provided indicating that EGFR can transactivate the Met receptor tyrosine kinase in human hepatocellular and pancreatic carcinoma cells[131]. PGE_2 generated by COX-2 has also been shown in human colon and hepatocellular carcinoma cells to transactivate the Met receptor in a manner dependent on functional EGFR[32,33]. Moreover, TGF-α and PGE_2, factors which are overexpressed in cholangiocarcinoma cells[74,132,133], may function as inducers of HGF production by tumor stromal fibroblasts[134]. Overall, these findings support interactive functional relationships between ErbB family receptors, HGF/Met, and COX-2 that are likely contributing in a major way towards regulating intrahepatic cholangiocarcinoma growth and progression.

VEGF

Moderate to strong expression of the angiogenic factor, vascular endothelial growth factor (VEGF or VEGF-A), as well as of the lymphangiogenic factor VEGF-C, has been detected in the cancerous epithelium of a significant percentage of human intrahepatic cholangiocarcinomas[135-139] and in human cholangiocarcinoma cell lines[135,140]. Increased VEGF expression has been reported to be associated with a significant vascularization of human intrahepatic cholangiocarcinomas, as assessed by microvessel density[135,136]. In comparison, hypovascularity of cholangiocarcinoma may be related to a down-regulation of VEGF together with an up-regulation of the angiogenesis inhibitor thrombospondin-1[136,141,142], although further studies are needed to validate the likelihood of this being a primary mechanism underlying the limited angiogenesis observed in cases of intrahepatic cholangiocarcinoma.

Cultured rat BDE1 cholangiocytes stably transfected with constitutively expressed rat neu oncogene overexpress VEGF[68]. Moreover, ErbB homo- and heterodimers have been demonstrated to increase VEGF expression in other tumorigenic cell types, with EGFR/ErbB2 and ErbB2/ErbB3 heterodimers determined to be the most potent inducers of VEGF mRNA expression when compared with various other paired combinations, such as EGFR/ErbB3 or ErbB2/ErbB4[143]. Interestingly, in both mouse and human cell models, thrombospondin-1 mRNA and protein were down-regulated *in vitro* and in tumors overexpressing specific paired combinations of ErbB receptors, compared with cells stably transfected to overexpress only single ErbB receptors[144].

ErbB2-mediated up-regulation of VEGF has been shown to involve activation of PI3K-Akt, mTOR and p70S6 kinase[145], as well as to be linked to increased expression of hypoxia inducible factor-1α (HIF-1α), an activator of VEGF transcription, *via* a PI3K-Akt-dependent mechanism[146]. In addition, targeting STAT3 was found to block HIF-1 and VEGF expression induced by ErbB2 and other oncogenic growth signaling pathways[147]. Moreover, EGFR tyrosine kinase inhibitors have been shown to decrease VEGF expression in cancerous epithelial cells by both HIF-1-dependent and HIF-1-independent mechanisms[148]. PGE_2 has also been reported to up-regulate VEGF in cancer cells *via* transactivation of EGFR[149]. Thus, aberrant ErbB receptor signaling in malignant cells, including cholangiocarcinoma cells, has important implications not only for promoting cancer cell growth and progression, but also for regulation of the tumor microenvironment.

THERAPEUTIC TARGETING OF ERBB RECEPTOR TYROSINE KINASES IN CHOLANGIOCARCINOMA CELLS

Conventional chemotherapy, which does not distinguish between cancer cells and normal healthy cells is of limited benefit in the treatment of unresectable or metastatic intrahepatic cholangiocarcinoma[183]. However, in recent years, the emergence of target-based cancer therapies has provided the option of developing and testing novel treatment strategies that have the potential of improving therapeutic efficacy against cancers like intrahepatic cholangiocarcinoma, which are typically refractory to conventional cancer chemotherapeutic modalities. Since ErbB receptor tyrosine kinases, most notably EGFR and/or ErbB2, are frequently overexpressed and/or constitutively activated in human cancers, including intrahepatic cholangiocarcinoma, agents that selectively target ErbB receptor family members have generated considerable interest among clinicians and researchers alike, with monoclonal antibodies (mAbs) and small molecule tyrosine kinase inhibitors (TKIs) having advanced the furthest in clinical development[155]. Table 2 lists mAbs and TKIs targeting ErbB family receptors that are currently approved and/or in phase clinical trials for the treatment of various

Table 2 Selected anti-cancer agents targeting ErbB family receptors

Agent	Class/Type	Target	Route of administration	Development stage	Ref.
Trastuzumab (Herceptin)	Recombinant humanized mAb	Extracellular domain of ErbB2	Intravenous infusion	Approved (ErbB2-positive breast cancer)	[150-152]
Pertuzumab (Omnitarg, $2C_4$)	Recombinant humanized mAb	Dimerization domain of ErbB2	Intravenous infusion	Phase Ⅱ/Ⅲ	[151,153,154]
Cetuximab (Erbitux, C225)	Recombinant human/mouse chimeric mAb	Extracellular domain of EGFR	Intravenous infusion	Approved (EGFR-positive metastatic colorectal cancer and squamous cell carcinoma head and neck cancer)	[151,155-157]
Panitumumab (ABX-EGF, Vectibix)	Fully human mAb	Extracellular domain of EGFR	Intravenous infusion	Approved (EGFR-positive metastatic colorectal cancer)	[157-159]
Matuzumab (EMI-72000)	Recombinant humanized mAb	Extracellular domain of EGFR	Intravenous infusion	Phase Ⅰ/Ⅱ	[157,159,160]
MDX-447	Humanized bispecific mAb	Extracellular domain of EGFR and high affinity IgG receptor CD64	Intravenous infusion	Phase Ⅰ/Ⅱ	[157,161]
Gefitinib (Iressa)	Anilinoquinazoline/Reversible TKI	EGFR tyrosine kinase	Oral	Limited approval (NSCLC)	[157,162-164]
Erlotinib (Tarceva)	Anilinoquinazoline/Reversible TKI	EGFR tyrosine kinase	Oral	Approved (NSCLC and pancreatic cancer)	[153,155,157,165,166]
Lapatinib (Tykerb, GW572016)	Thiazolylquinazoline/Reversible TKI	EGFR and ErbB2 tyrosine kinases	Oral	Approved (ErbB2-positive advanced metastatic breast cancer)	[157,166-169]
PKI-166	Pyrrolopyrimidine/Reversible TKI	EGFR and ErbB2 tyrosine kinases	Oral	Phase Ⅰ	[153,155,157,166,170]
BMS-599626	Pyrrolotriazine/Reversible TKI	EGFR and ErbB2 tyrosine kinases	Oral	Phase Ⅰ	[171,172]
EKB-569 (Pelitinib)	Cyanoquinoline/Irreversible TKI	EGFR tyrosine kinase	Oral	Phase Ⅰ/Ⅱ	[157,166,173]
BIBW-2992	Anilinoquinazoline/Irreversible TKI	EGFR and ErbB2 tyrosine kinases	Oral	Phase Ⅰ/Ⅱ	[168,174]
CI-1033 (Canertinib)	Anilinoquinazoline/Irreversible TKI	Pan-ErbB tyrosine kinases	Oral	Phase Ⅰ/Ⅱ	[153,157,164,168]
HKI-272	Cyanoquinoline/Irreversible TKI	Pan-ErbB tyrosine kinases	Oral	Phase Ⅰ/Ⅱ	[153,164,168,175]

mAb: Monoclonal antibody; TKI: Tyrosine kinase inhibitor; EGFR: Epidermal growth factor receptor; NSCLC: Non-small cell lung cancer.

human solid cancers.

Recent preclinical studies, summarized in Table 3, have demonstrated that select TKIs targeting either EGFR or ErbB2, as well as those producing dual inhibition of EGFR and of ErbB2, are capable of effectively suppressing cellular growth and inducing significant apoptosis in human and rodent biliary cancer cell lines *in vitro*, and in some studies were also found to significantly inhibit tumor growth in athymic nude mice that had been subcutaneously xenografted with select human biliary tract carcinoma cell lines. Orally active TKIs were also shown to exhibit both chemopreventive and therapeutic effects in the *BK5.erbB2* transgenic mouse model of gallbladder carcinoma[182]. These cumulative preclinical results provide a "proof of principal" for EGFR and/or ErbB2 targeting as being a promising strategy for the chemoprevention and/or adjuvant therapy of biliary tract cancers. Most importantly, select preclinical studies further indicated that dual targeting of EGFR and ErbB2 with TKIs, such as lapatinib[180] or NVP-AEE788[181], as well as treatments with EGFR or ErbB2 inhibitors administered in combination with other small drug inhibitors, such as the COX-2 inhibitor celecoxib[75], or the MEK inhibitor CI-1040[179], were found to be significantly more potent than corresponding treatments with the single targeting agents alone in suppressing cholangiocarcinoma or gallbladder carcinoma cell growth *in vitro* and/or the tumorigenic growth of biliary tract cancer xenografts *in vivo*. Consistent with previously described results obtained with other carcinoma cell types[169,184], growth suppression and induced apoptosis of cultured rat and human cholangiocarcinoma cell lines produced by *in vitro* treatments with the dual EGFR/ErbB2-TKI lapatinib or by single agent TKIs combined to simultaneously inhibit EGFR and ErbB2 tyrosine phosphorylation were also observed to be correlated with prominent dose-dependent inhibition of both p42/44 MAPK and Akt activation[180] (Figure 6). On the other hand, while the dual EGFR/ErbB2 inhibitor NVP-AEE788 was reported to suppress tumorigenic growth in nude mice subcutaneously implanted with human biliary tract cancer cell lines by mechanisms involving downstream blocking of p42/44 MAPK signaling, induction of apoptosis, and inhibition of angiogenesis, treatment with this agent had no apparent effect on reducing Akt activation in the tumor xenografts[181]. In contrast, the EGFR-TKI gefitinib, was determined to effectively

Table 3 Preclinical biological effects of ErbB RTK inhibitors alone or combined with other target-based treatments for biliary tract cancer cells

Agent	Target	Experimental condition	Biliary cancer cell line/ tumor	Biological effects	Ref.
Gefitinib	EGFR	Cell culture	HAG-1 human gallbladder adenocarcinoma cell line	Dose-dependent *in vitro* cell growth inhibition by arresting cells in G0/G1, followed by progressive cell apoptosis; inhibition of EGFR phosphorylation and of Erk1/2 and Akt activation; decreased cyclin D1 mRNA and induced accumulation of p27 protein, a negative cell cycle regulator	[176]
Gefitinib + Ionizing radiation	EGFR	Cell culture	HuCCT1 human intrahepatic cholangiocarcinoma cell line; TFK-1 human bile duct carcinoma cell line	Gefitinib induced increase in radiosensitivity of HuCCT1 and TFK-1 cells	[177]
Cetuximab + erlotinib	EGFR	Cell culture and subcutaneous tumor xenografts in athymic nude mice	HuCCT1 cell line	Combined treatment with cetuximab blunted erlotinib-induced EGFR up-regulation and regulated in HuCCT1 growth inhibition and apoptosis *in vitro* and HuCCT1 tumor growth arrest *in vivo*	[178]
Gefitinib + CI-1040	EGFR + MEK-Erk1/2	Cell culture and subcutaneous tumor xenografts in athymic nude mice	HuCCT1 cell line	Drug combination significantly more effective than single agent treatments in suppressing both *in vitro* and *in vivo* tumor cell growth; combination treatment dramatically decreased phosphorylation levels of EGFR and Erk1/2 in cultured cells and in xenografted tumors, whereas HuCCT1 cells were found to be resistant to treatments with gefitinib or CI-1040 alone	[179]
Lapatinib	EGFR/ ErbB2	Cell culture	Rat C611B and human HuCCT1 cholangiocarcinoma cell lines	Lapatinib was demonstrated to be a potent inhibitor of C611B and HuCCT1 cholangiocarcinoma cell growth *in vitro* by a mechanism involving inhibition of EGFR and ErbB2 activation, suppression of p42/44 MAPK and Akt phosphorylation, and induction of apoptosis	[180]
NVP-AEE788	EGFR/ ErbB2 and VEGFR-2	Cell culture and subcutaneous tumor xenografts in athymic nude mice	EGI-1, TFK-1, CC-SW-1, CC-LP-1 and SK-ChA-1 human extrahepatic bile duct cancer cell lines; MZ-ChA-1 and MZ-CA-2 human gallbladder adenocarcinoma cell lines	NVP-AEE788 more efficacious than the EGFR RTK inhibitors gefitinib and erlotinib in suppressing *in vitro* cell growth; EGI-1 tumors in mice treated with NVP-AEE788 had significantly reduced volume and mass compared with those in placebo-treated mice, while erlotinib was without effect in inhibiting *in vivo* tumor growth; main mechanisms of NVP-AEE788 drug action were suppression of Erk1/2 phosphorylation, induced apoptosis, and inhibition of tumor angiogenesis	[181]
Emodin + Celecoxib	ErbB2 +COX-2	Cell culture	C611B rat intrahepatic cholangiocarcinoma cell line	Emodin and celecoxib combined to synergistically suppress anchorage-dependent and anchorage-independent cell growth *in vitro* through a mechanism involving enhanced inhibition of ErbB2 activation, decreased phospho-Akt, and enhanced caspase-9 and -3 activation, resulting in significantly increased apoptosis	[75]
Gefitinib or GW2974	EGFR EGFR/ ErbB2	BK5.erbB2 transgenic mice constitutively expressing wild-type rat ErbB2	Gallbladder adenocarcinoma	Both agents produce significant chemopreventative and therapeutic effects in reducing gallbladder adenocarcinoma incidence, which was associated with prominent decreases in both the phosphorylation and protein levels of EGFR and ErbB2, with significantly decreased Erk1/2 acitivity and with a reduction in COX-2 protein levels in BK5.erbB2 mouse gallbladders	[182]

RTK: Receptor tyrosine kinase; EGFR: Epidermal growth factor receptor; VEGFR-2: Vascular endothelial growth factor receptor-2; COX-2: Cyclooxygenase-2.

block EGFR tyrosine phosphorylation and associated downstream activation of Akt, but had a minimal effect on inhibiting p42/44 MAP kinase activation in cultured human HuCCT1 cholangiocarcinoma cells[179]. This TKI also failed to block p42/44 MAP kinase phosphorylation and tumor growth *in vivo* in athymic nude mice subcutaneously transplanted with HuCCT1 cells. The fact that the HuCCT1 cholangiocarcinoma cell line expresses a mutant *Kras* may explain why upstream inhibition of EGFR by gefitinib was ineffective in blocking p42/44 MAPK activation in these cells[179]. However, gefitinib given in combination with the MEK inhibitor CI-1040 was associated with a profound inhibition of HuCCT1 tumor growth that appeared to be linked to either a greater p42/44 MAP kinase inhibition or to simultaneous inhibition of Akt and p42/44 MAPK signaling[179]. In comparison, gefitinib alone suppressed both the autophosphorylation of p42/44 MAPK and to a lesser degree that of Akt in the HAG1 human gallbladder carcinoma cell line[176].

Interestingly, the EGFR-TKI erlotinib was found to up-regulate EGFR in HuCCT1 cholangiocarcinoma cells, but combined treatment with the anti-EGFR antibody cetuximab or blockage of erlotinib-induced EGFR synthesis by a small interfering RNA abrogated this TKI effect, and resulted in an inhibition of cell proliferation and increased apoptosis in the HuCCT1 cells[178]. Moreover, in this study, cetuximab was shown to be equally effective when administered alone or in combination with erlotinib in partially suppressing

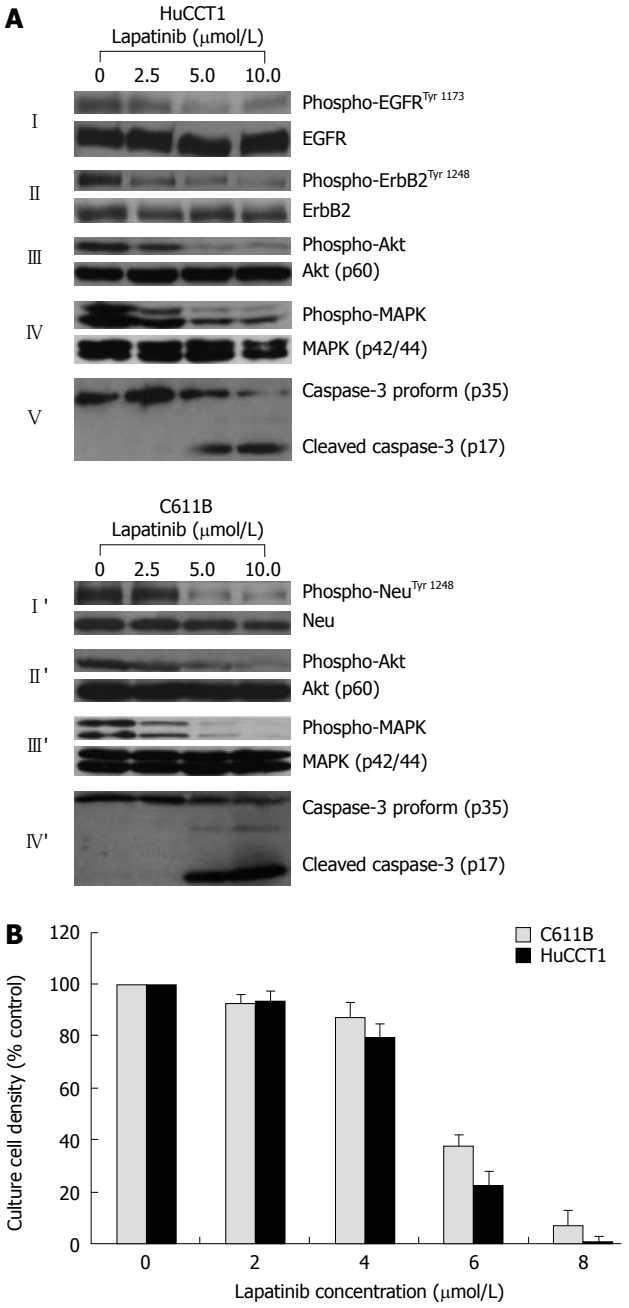

Figure 6 Dose-dependent inhibition test. A: Western blots demonstrating dose-dependent suppression by the dual ErbB1 (EGFR)/ErbB2 (Neu) inhibitor lapatinib of phospho-EGFR$^{Tyr\ 1173}$ and/or of phospho-ErbB2/Neu$^{Tyr\ 1248}$, together with concomitant downstream inhibition of phospho-Akt and of phospho-p42/44 MAPK expressed in cultured human HuCCT1 and in rat C611B cholangiocarcinoma cells, respectively. Note that the lapatinib treatment *in vitro* did not affect corresponding total protein levels, but in both cell lines induced a dose-dependent activation of the apoptotic enzyme, caspase-3; B: Dose response curves for lapatinib on suppressing anchorage-dependent growth of cultured rat C611B and human HuCCT1 cholangiocarcinoma cells. Each value represents the mean ± SD (n = 3). Note the close relationship between the lapatinib concentrations required to induce prominent suppression of EGFR and/or ErbB-2/Neu signaling ($\geqslant$ 5 μmol/L) and those associated with marked inhibition of *in vitro* cholangiocarcinoma cell growth ($\geqslant$ 6 μmol/L). Lapatinib-induced suppression of C611B and HuCCT1 growth *in vitro* correlated with both a down-regulation of cyclin D1 protein expression and with a prominent apoptosis being induced in these respective cultured cholangiocarcinoma cell lines (data not shown).

tumorigenic growth in HuCCT1 bearing mice, suggesting that antibody-induced down-regulation of EGFR may provide an effective strategy for circumventing resistance to specific EGFR-TKI inhibitors in cholangiocarcinoma and other EGFR-expressing cancer cell types.

In the *BK5.erbB2* transgenic mouse model, decreased gallbladder carcinoma incidence produced by chemopreventive or therapeutic treatments involving single targeting of EGFR with gefitinib or dual targeting of EGFR/ErbB2 with GW2974 were each demonstrated to not only reduce tyrosine phosphorylation levels, but also total protein levels of EGFR and ErbB2 in the gallbladders of responsive mice[182]. Of further note, these targeted treatments were also associated with decreases in COX-2 protein level and of MAPK activity in gallbladders from both the gefitinib and GW2974-treated *BK5.erbB2* mice, with GW2974 showing a greater inhibitory effect than gefitinib on the development of gallbladder carcinoma and also a strong reduction in the tyrosine phosphorylated forms of both EGFR and ErbB2. Interestingly, gallbladder adenocarcinomas refractory to the gefitinib treatment were reported to exhibit sustained activation of EGFR and ErbB2.

ErbB2-TKI emodin in combination with the COX-2 inhibitor celecoxib was further demonstrated to act synergistically to suppress anchorage-dependent and-independent growth of rat C611B cholangiocarcinoma cells overexpressing activated wild-type ErbB2 through a mechanism involving enhanced Akt inactivation leading to increased apoptosis[75]. From a clinical standpoint, targeted treatments, including the use of select EGFR- and/or ErbB2-TKIs combined with other agents that act to suppress the phosphorylation of Akt are likely to prove to be more effective than single agent treatments for the therapy of biliary tract cancers. In this context, it is noteworthy that both the EGFR-TKI gefitinib and the Akt inhibitor LY294002 were each determined in a preclinical study to increase the radiosensitivity of human HuCCT1 and TFK1 biliary carcinoma cell lines by suppressing Akt activation[177]. Thus, preclinical testing of various paradigms utilizing select targeting of aberrant EGFR and/or ErbB2 signaling affecting MAPK and/or Akt activation, in combination with other classes of agents that act to suppress Akt activation, would seem to be warranted as a potential strategy for developing new adjuvant therapies for biliary tract carcinomas, including cholangiocarcinoma.

As reflected in Table 4, there have been to date only a limited number of published clinical studies on EGFR and/or ErbB2 targeting in human biliary tract cancers. Unfortunately, while the various treatments described in these studies were determined in most cases to be well tolerated, the anti-tumor effects produced by such treatments in which ErbB receptor targeting was included as part of the therapeutic regimen, was at best modest, and mostly without effect in the vast majority of biliary tract cancer patients who presented with unresected or metastatic disease. Moreover, the extent of EGFR expression was reported not to be significantly associated with outcome[185]. In one case report, a patient with metastatic cholangiocarcinoma was described as having a response to cetuximab-based therapies; however, the patient's tumors were determined

Table 4 Outcomes of ErbB-targeted therapies in patients with advanced biliary cancer

Assessable patients	Tumor	ErbB status	ErbB inhibitor	Target	Administration	Response	Ref.
40	Unresected or metastatic biliary tract cancers (gallbladder, intra- and extrahepatic bile duct)	29/36 (81%) assessable tumor samples positive for EGFR expression	Erlotinib	EGFR	Single agent	PR-3 patients; SD-17 patients; median time to disease-progression of 2.6 mo	[185]
1	Metastatic cholangiocarcinoma	Negative EGFR expression in tumor	Cetuximab	EGFR	In combination with 5'flurouracil, folic acid, and radiotherapy	PR in intra-chemotherapeutic state	[186]
1	Unresected cholangiocarcinoma with peritoneal carcinomatosis	Positive EGFR expression in tumor	Cetuximab	EGFR	In combination with gemcitabine	PR with 30% reduction in hepatic mass and disappearance of peritoneal carcinomatosis as shown by computed tomography	[187]
9	Unresected cholangiocarcinoma with disease progression after at least 3 cycles of gemcitabine-oxaliplatin	9/9 (100%) tumor samples positive for EGFR expression, with all being negative for membranous ErbB2	Cetuximab	EGFR	In combination with gemcitabine-oxaliplatin	After 6 mo, CR-1 patient; PR-1 patient; SD-1 patient; progressive disease-6 patients; all patients relapsed, with a median time to disease progression of 4 mo	[188]
17	Unresected advanced biliary tract cancers (gallbladder, bile duct)	Not reported	Lapatinib	EGFR/ ErbB2	Single agent	No observed responses; 5 patients with SD; cohort closed due to no noted lapatinib activity	[189]
6 with biliary tract cancers out of a total of 34 with various types of solid tumors	Advanced cholangiocarcinoma (5) or gallbladder cancer (1)	Not investigated	Lapatinib	EGFR/ ErbB2	In combination with oxaliplatin/ 5-flurouracil/ leucovorin	PR-1 patient with cholangiocarcinoma and 1 patient with gallbladder cancer	[190]

CR: Complete response; PR: Partial response; SD: Stable disease.

by immunohistochemistry not to express EGFR[186]. Also, while immunohistochemistry was used in some of these clinical therapeutic studies to confirm a positive EGFR status[185,187,188] of the tumors prior to treatment, unlike some of the preclinical *in vivo* studies described above[179,181,182] (Table 3), no effort was made in any of the studies listed in Table 4 to investigate the effects of the ErbB-target agents being tested on markers of biological activity (i.e. suppression of EGFR tyrosine phosphorylation; inhibition of p42/44 MAPK and/or Akt activation, suppression of cyclin D1) in tumors of responsive *versus* non-responsive patients.

In view of the promising preclinical results obtained with ErbB-targeting agents against human and rodent biliary tract cancer cells, including cholangiocarcinoma cells *in vitro* as well as *in vivo* in tumor xenograft and transgenic models, it is disappointing that the current clinical experience with ErbB-directed therapies have resulted in only very limited anti-tumor activity having been demonstrated in select patients with biliary tract cancers. However, these (albeit limited) clinical findings are also quite consistent with an increasing body of data from different clinical trials demonstrating at best, only modest therapeutic responses of various other epithelial tumor types to single-drug treatments with ErbB inhibitors. In addition, the discrepancies between current preclinical and clinical data point out a real need to establish "patient-like" *in vivo* models of cholangiocarcinoma progression that would more closely mimic the advanced human disease, and which could better serve to more accurately predict the clinical efficacy of ErbB-directed therapies. In this context, it is noteworthy that very recent preliminary studies in the author's laboratory have demonstrated that when the dual EGFR/ErbB2-TKI lapatinib was administered to rats by gavage over a three week period, beginning at 2 d after bile duct inoculation of oncogenic *neu*-transformed rat cholangiocytes (BDEneu cells), this treatment produced an approximately 70% inhibition in mean intrahepatic tumor wet weight compared with that of tumors formed in the livers of vehicle control-treated rats. In contrast, when the lapatinib treatment was delayed and given to rats with more advanced tumors that resulted in bile duct obstruction, it was without any anti-tumor effect (Sirica AE, Zhang Z, and Campbell DJ, unpublished data). As already indicated above, a similar lack of clinical response was reported by Ramanathan *et al*[189] in a Phase Ⅱ study evaluating the anti-tumor efficacy of lapatinib as a single agent treatment in patients with advanced biliary tree cancer. Thus, the rat model of intrahepatic cholangiocarcinoma progression based on bile duct inoculation of highly tumorigenic BDEneu cholangiocytes[68,69] would appear to closely reproduce certain relevant clinical (i.e. bile duct obstruction, icteric liver, elevated serum bilirubin), pathologic (moderately differentiated invasive ductal cholangiocarcinoma with desmoplasia, peritoneal carcinomatosis), and key molecular features (i.e. overexpression of tyrosine

Table 5 Factors affecting ErbB-targeted therapies for intrahepatic cholangiocarcinoma and other biliary tract cancers

Factors
Patient selection and sampling size
Suboptimal drug dosing and/or scheduling
Tumor microenvironment and bioavailability
Intratumoral heterogeneity in receptor expression and activation
Receptor dynamic effects
Mutational effects
Different mechanisms of acquired resistance
Constitutive overexpression of ErbB family ligands
Co-activation of multiple receptor tyrosine kinases resulting in signaling redundancy and interplay
Lack of uniform biomarkers to effectively predict therapeutic response
Co-morbid disease and toxicity

phosphorylated p185^{neu}, COX-2, and MUC1) of the progressive human disease, as well as permit for a rapid preclinical assessment within a three-to-four week period of innovative molecular targeting strategies that include specific targeting of ErbB2 (and EGFR) regulated signaling pathways. Validating such target-based ErbB-targeting strategies in this "patient-like" model may prove to be most useful in developing new paradigms for adjuvant therapies for intrahepatic cholangiocarcinoma. However, more definitive basic and translational studies are now required to determine the significance of this preclinical rat model of intrahepatic cholangiocarcinoma progression for predicting the clinical efficacy of ErbB-directed therapies against the early *versus* advanced human malignant disease.

FACTORS AFFECTING THERAPEUTIC RESPONSES TO ERBB-TARGET AGENTS

Table 5 lists various factors that should be considered when devising strategies for ErbB-target-based therapies against intrahepatic cholangiocarcinoma. Obviously, patient selection is important and there is a real need now for clinical trials aimed at identifying biological markers that would better predict which of those with this malignant disease would best benefit from such ErbB-directed therapies. It also seems apparent from the limited clinical data that is currently available that single agent testing in cholangiocarcinoma patients with advanced disease that is refractory to conventional therapeutic modalities may not be the best way to assess the therapeutic value of agents that target ErbB receptor signaling pathways. Here again, it can be restated that preclinical models of intrahepatic cholangiocarcinoma that closely recapitulate clinical and molecular features of human disease progression are needed to test novel therapeutic paradigms that combine ErbB-targeted therapies with other target-based therapies in an effort to maximize the inhibition of redundant signaling pathways that aberrantly regulate malignant tumor growth and survival. In addition, preclinical testing of paradigms that combine ErbB target-based therapies with current conventional modalities could further lead to more rational approaches to developing new strategies for adjuvant management of tumor cell resistance, recurrence or progression. Because this cancer is relatively rare, it is also apparent that for the testing of ErbB-targeted therapies against intrahepatic cholangiocarcinoma to be statistically meaningful and rigorously controlled, multi-center trials set in well established treatment centers for hepatobiliary cancer located in both Eastern and Western countries would be needed to achieve appropriate patient selection. Furthermore, well controlled preclinical and multi-center clinical trials should also be directed towards evaluating the chemopreventative effects of ErbB-directed targeted treatments alone and/or in combination with other therapies in select patient populations with known high risk premalignant conditions for intrahepatic cholangiocarcinoma.

Data on optimum dosing and scheduling of ErbB-targeted agents alone and in combination with other target-based or conventional treatments against intrahepatic cholangiocarcinoma are severely lacking and need to be developed, both preclinically and clinically. Tumor microenvironment and bioavailability is also an important factor in determining the potential therapeutic effectiveness of ErbB-targeted therapies against intrahepatic cholangiocarcinoma. For example, intrahepatic cholangiocarcinomas are often hypovascularized[136,141,142,191], thereby limiting the possibility of ErbB-targeted agents of reaching the malignant cells in sufficient concentrations to be therapeutically effective. In addition, hypoxic tumor microenvironments inducing HIF-1α[192,193] and tumor extracellular matrix components, like laminin 5[194], may alter the effectiveness of ErbB directed antineoplastic therapies. Moreover, intratumoral heterogeneity of expression for tyrosine kinase growth factor receptors (i.e. EGFR and ErbB2) indicate that targeting of single ErbB family receptor tyrosine kinase receptors in adenocarcinoma types, including intrahepatic cholangiocarcinoma, may not in itself be sufficient to elicit a strong therapeutic response[195]. ErbB receptor dynamics have also been shown to influence response to ErbB-targeted agents. For example, as described above, exposure of HuCCT1 human cholangiocarcinoma cells to erlotinib was shown to induce EGFR protein and mRNA expression in these cells, leading to resistance to EGFR tyrosine kinase inhibition[178]. However, cetuximab or blockage of EGFR synthesis in HuCCT1 cells by small interfering RNA (siRNA) was found to abrogate erlotinib-induced EGFR up-regulation in these cells, suggesting that resistance and sensitivity to EGFR-targeted agents are dynamic events, and that combinations of more than one type of ErbB-directed therapy may be needed to elicit a positive therapeutic outcome.

Mutational events play a key role in mediating resistance or sensitivity to cell-based ErbB-targeted therapies[196-202]. The efficacy of EGFR-TKIs, such as gefitinib or erlotinib, has been linked to activating

mutations in lung cancer cell EGFR[199,201], whereas secondary mutations, such as EGFR T790M mutation, can also lead to resistance to EGFR-TKI therapy[197,201] and to lapatinib-mediated inhibition of receptor autophosphorylation[202]. *Kras* mutation has also been demonstrated to be an important predictor of resistance to therapy with ErbB-TKIs in some solid tumors[197,199,200]. In addition, tumor cells with ErbB2 mutations were reported to be resistant to EGFR-TKI treatment, but sensitive to ErbB2 inhibitors, both *in vitro* and *in vivo*[198,199].

In addition to secondary mutations, various other mechanisms of acquired resistance to ErbB-targeted therapies have also been described, including EGFR ubiquitination[203], signaling interplay between the EGFR and IGF-1 receptors[204], steric hindrance of ErbB2 by MUC4[205], and flexibility of the ErbB receptor family signaling system in the face of inhibition of a single member, such as EGFR[206]. Moreover, it has been hypothesized that co-activation of multiple receptor tyrosine kinases, (i.e. EGFR and/or ErbB2, Met, PDGFR, IL-6R) in solid malignant tumors results in redundant inputs that drive downstream signaling, therefore limiting the effectiveness of therapies that target just a single receptor tyrosine kinase[207]. For example, Met/*c-Src* signaling has been recently shown to mediate EGFR tyrosine phosphorylation and cell growth in cultured SUM229 breast cancer cells in the presence of EGFR-TKIs[208].

Presently, there is no uniform set of biomarkers that can be used to accurately predict a therapeutic response in solid tumors, including intrahepatic cholangiocarcinoma, to ErbB-directed therapies. TGF-α expression has recently been reported to drive constitutive EGFR pathway activation and sensitivity to gefitinib in human pancreatic cancer cell lines[209]. Elevated TGF-α also appeared to predict for a partial response to lapatinib in patients with advanced EGFR and/or ErbB2 solid malignancies[210]. However, Ishikawa *et al*[211] have also presented data to suggest that increased levels of TGF-α and of amphiregulin in serum may serve as predictors of poor response to gefitinib among patients with advanced non-small cell lung cancer. More recently, Jimeno *et al*[212], utilizing global gene expression profiling together with gene set enrichment analysis, defined an EGFR pathway-based signature that was predictive of a therapeutic response to erlotinib and cetuximab in a subset of xenografted human pancreatic cancers. Further studies are needed, however, to determine if this approach can be effective in a clinical setting as a means of defining biomarkers of ErbB-directed therapies.

Impaired liver function and cirrhosis, together with older age, genetic background, co-morbitities, such as cardiovascular disease, and immune-status all need to also be considered as factors that may affect the potential use and/or effectiveness of ErbB target-based treatments for intrahepatic cholangiocarcinoma therapy. Presently, only a very few clinical trials have investigated cardiotoxicities of the various ErbB target agents, using defined cardiac endpoints, such as left ventricular function[213], although it is now well established that herceptin when administered in combination with anthracyclines, can induce significant cardiotoxicity[153,213]. On the otherhand, treatments with small drug TKI, like lapatinib, erlotinib, and gefitinib, or with the anti-EGFR mAbs cetuximab and panitumumab, have been reported to be associated with low cardiotoxicity[213]. Skin rash is a classic adverse effect of ErbB-targeted therapy and diarrhea is relatively common in patients treated with EGFR antibodies, or with TKIs, including lapatinib, erlotinib, and gefitinib[153,213,214]. Interstitial lung disease, elevated hepatic transaminases, and nephritic syndrome have also been rarely reported to occur with small drug EGFR-TKIs[214], and a high prevalence of hypersensity reactions to cetuximab, including anaphylaxis, has been reported in some areas of the United States[215]. Thus, ErbB target-based therapies are not without risk, although the current clinical experience has indicated that such therapies are generally well tolerated.

FINAL REMARKS

While it now seems apparent that aberrant EGFR and/or ErbB2 expression and signaling is associated with the molecular pathogenesis of intrahepatic cholangiocarcinoma, there is still a significant gap in our knowledge as how to best exploit such alterations in terms of targeted therapies that can then be successfully translated into positive clinical outcomes. More definitive approaches, including cDNA microarray analysis, quantitative immunohistochemistry, and possibly proteomics, need to be evaluated in terms of their potential for profiling individual patient samples (cholangiocarcinoma tumor tissue and cytological specimens and corresponding serum and/or bile samples) for select molecular biomarkers that would be predictive of a therapeutic response to ErbB targeted therapies. In addition, there is a need to develop more effective drug delivery systems for these agents, in order to maximize their bioavailability. Preclinical animal platforms for rapidly testing target-based treatments of intrahepatic cholangiocarcinoma that closely mimic key clinicopathological and molecular features of the human disease also need to be more fully developed and assessed for their ability to more effectively predict therapeutic responses in human clinical trials. Furthermore, based on the complex interactive growth factor receptor signaling and microenvironment properties of solid tumors like intrahepatic cholangiocarcinoma, it seems evident that novel therapeutic strategies involving multiple targeted therapeutics aimed at both cancer and tumor stromal cell targets should be rigorously explored as a means of achieving more effective molecular therapies for this devastating cancer.

ACKNOWLEDGMENTS

The author thank Dr. Jorge A Almenara and Ms. Deanna

J Campbell for their helpful comments, and to express his gratitude to Ms. Jennifer L DeWitt for her valuable assistance in preparing the Figures and Tables for this review article.

Abstract

This review focuses on current knowledge on hepatocyte aquaporins (AQPs) and their significance in bile formation and cholestasis. Canalicular bile secretion results from a combined interaction of several solute transporters and AQP water channels that facilitate water flow in response to the osmotic gradients created. During choleresis, hepatocytes rapidly increase their canalicular membrane water permeability by modulating the abundance of AQP8. The question was raised as to whether the opposite process, i.e. a decreased canalicular AQP8 expression would contribute to the development of cholestasis. Studies in several experimental models of cholestasis, such as extrahepatic obstructive cholestasis, estrogen-induced cholestasis, and sepsis-induced cholestasis demonstrated that the protein expression of hepatocyte AQP8 was impaired. In addition, biophysical studies in canalicular plasma membranes revealed decreased water permeability associated with AQP8 protein downregulation. The combined alteration in hepatocyte solute transporters and AQP8 would hamper the efficient coupling of osmotic gradients and canalicular water flow. Thus cholestasis may result from a mutual occurrence of impaired solute transport and decreased water permeability.

INTRODUCTION

Bile secretion is the main function of the exocrine liver, and the maintenance of normal bile formation and delivery into the intestinal lumen is essential for physiological processes such as digestion and absorption of dietary lipids and elimination of endo- and xenobiotics. Cholestasis is a pathologic condition defined as an impairment of normal bile formation, bile flow obstruction or both[1]. There have been major advances in the understanding of the molecular mechanisms underlying bile secretion and cholestasis, and much of this work has been focused on the study of solute membrane transporters[2,3]. However, considering that bile is composed of more than 95% water, less attention has been paid to the molecular basis and regulatory mechanisms of water transport in hepatocytes during bile formation. The cloning and functional characterization of a family of proteins that works as membrane water channels, named aquaporins (AQPs)[4], challenged the former concepts of water transport and contributed to the better understanding of bile physiology. The aim of this work is to give a concise overview of the current knowledge and recent advances in the role of AQPs during bile formation as well as the significance of AQPs in the development of bile secretory failure.

AQUAPORINS OVERVIEW-GENERAL STRUCTURE AND FUNCTION

AQPs are small integral proteins which belong to a family of homologous tetrameric proteins widely

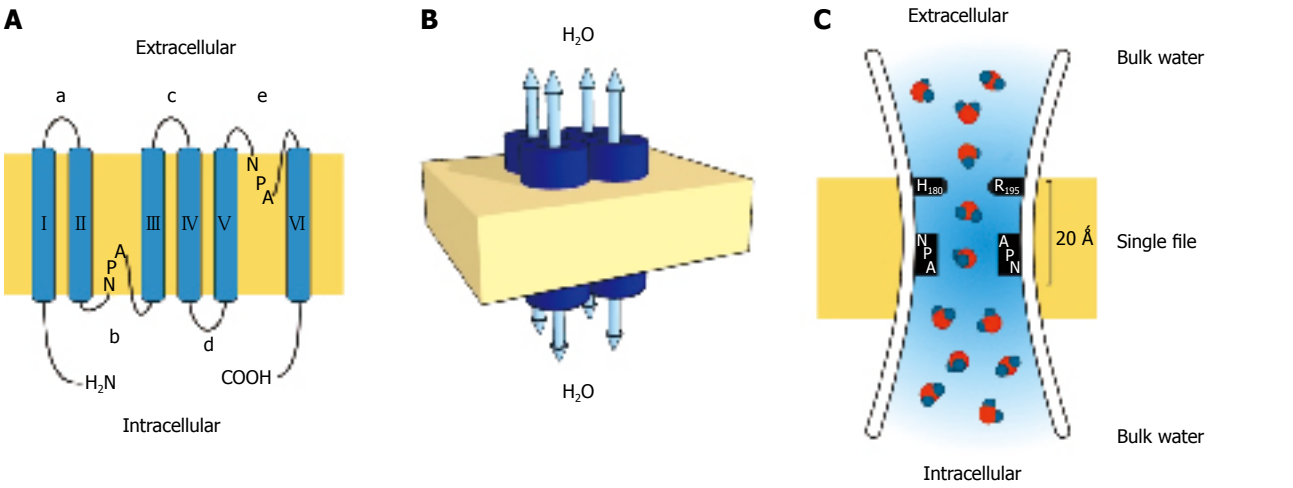

Figure 1 Topology, organization and functioning of the aquaporin water channel molecule. A: Each AQP monomer consist of six transmembrane domains (I -VI) connected by five loops (a-e) with two NPA boxes shaping the water pore, and the amino and carboxy termini oriented toward the cytoplasm; B: Aquaporins are arranged in tetramers. The water pore does not reside in the center of the molecule, but is formed by connecting loops b and e in each subunit that functions as a unique water pore allowing bidirectional water movement; C: The hourglass model for aquaporin structure. The channel consist of an extracellular and intracellular vestibule containing water in bulk solution joined in the center by a central constriction 20 Å in length where water molecules pass in single file. The a/R constriction delimited by arginine in the position 195 (R195) and histidine in the position 180 (H180) provides fixed positive charges which prevent proton passage. The second constriction is bounded by two asparagine residues from the highly conserved NPA motif. The single water molecule passes through the constriction with no resistance as it forms transient hydrogen bonds with the nearby asparagines.

distributed in mammals, plants, and lower organisms[4]. The first AQP was purified from human erythrocytes and was initially named CHIP28. Following expression studies in Xenopus oocytes the protein was functionally identified as a water channel and renamed AQP1[5]. The discovery of AQPs triggered an immense number of studies which advanced the current understanding of water permeation across biological membranes. At least 13 AQP isoforms have been identified from mammalian tissues (AQP0-AQP12)[4,6,7]. While AQPs function primarily as water-transporting channels, some of these proteins also exhibit permeability to certain small solutes such as glycerol, ammonia[8], hydrogen peroxide[9] and some gases such as carbon dioxide and nitric oxide[10].

AQP1 was the first member of the AQP water channel family to be identified[5]. The functional unit of AQP1 is a homotetramer, but in contrast to ion channels where the permeation site is placed in the center of the tetramer, each AQP subunit contains a distinct aqueous pore. The monomers, composed of approximately 270 amino acids, possess six transmembrane alpha-helix regions connected by five loops, with the amino- and carboxy-termini oriented towards the cytosol. Among the five connecting loops, two enclose the strictly conserved three-amino acid motif (asparagine-proline-alanine, NPA), which overlap in the center of the pore and are responsible for the water channel selectivity (Figure 1A and B).

Cryoelectron microscopy in combination with atomic force microscopy and X-ray analysis confirmed the so-called "hourglass model". It consists of a wide extracellular and intracellular vestibule, joined in the center by a narrow region of approximately 20 Å in length that shapes the filter responsible for water selectivity[11]. In the vestibules water exists in bulk solution, while in the center of the channel water transits in single file. Actually it has been identified as a two-stage filter in the central region of the pore: an outer barrier termed the aromatic/arginine constriction (ar/R), and the central constriction or NPA region. Both stages of the filter add to the remarkable efficiency and selectivity of the AQPs[12] (Figure 1C).

The filter selectivity appears to be based on size exclusion, as the central constriction of the filter is slightly wider than the water molecule (~2.8 Å) and represents a steric limit for bigger molecules through the channel. The ar/R constriction is composed of a highly conserved arginine residue in the 195 position and a nearby histidine residue in the 180 position. This filter provides supplementary criteria for solute selection, as the conserved residues have a strong positive charge that repels protonated water. In the NPA region, water-water interactions are distorted so water molecules remain isolated from their solvation shell in the bulk, a process essential for the filter selectivity[13]. As water molecules approximate to the constriction, the oxygen atom rotates towards the asparagine residues from the NPA motifs (asparagines 76 and 192) and creates new hydrogen bonds between the oxygen and the asparagine residues. The dipole reorientation breaks the hydrogen bonds among water molecules and avoids the passage of protonated water[13,14].

The hourglass model also explains the reversible inhibition caused by mercurial compounds. Mercury reacts with sulfhydryl groups from cysteine residues. Among the 4 cysteine residues present in AQP1, only that located in the 189 position reacts with mercurial compounds producing water transport inhibition[15]. This residue is located in the E loop, next to the NPA motif inside the pore[13].

HEPATOCYTE AQPS: EXPRESSION AND SUBCELLULAR LOCALIZATION

There has been much interest in the localization and

Table 1 Cellular and subcellular localization and permeability characteristics of hepatic AQPs

Cell type	Aquaporin	Subcellular localization	Permeability	Ref.
Hepatocytes	AQP0	ICV	Water	[16]
	AQP8	ICV-CPM-Mitochondria-SER	Water/NH_3/H_2O_2	[9,16-20,28,29,32]
	AQP9	BLM	Water/glycerol/urea/certain small uncharged molecules	[16,21,22,30,31]
	AQP11	ND	ND	[6]
Cholangiocytes	AQP1	APM-BLM-ICV	Water	[23,25,36]
	AQP4	BLM	Water	[26]
Gallbladder epithelia	AQP1	APM-BLM	Water	[27]
	AQP8	APM	Water/NH_3/H_2O_2	
Peribiliary vascular endothelia	AQP1	APM-BLM	Water	[24]

physiological role of AQPs in the liver. We and others have recently shown that rat hepatocytes express mRNA and protein for AQP0[16], AQP8[16-20], AQP9[16,21,22] and AQP11[6]. In addition, other cells of the hepatobiliary tract such as cholangiocytes, gallbladder epithelia and peribiliary vascular endothelia also express AQPs[23-27]. The cellular and subcellular distribution and permeability characteristics of AQPs in the hepatobiliary tract are summarized in Table 1. We will focus essentially on the hepatocyte AQPs that play a role in bile formation and secretory failure, i.e. AQP8 and AQP9.

Typically, AQP8 has a varied subcellular localization, which probably correlates with broad physiological roles in the hepatocyte. Accordingly, it was estimated that under basal (unstimulated) conditions most of the hepatocyte AQP8 (75%) reside in intracellular structures, while the remainder reside in the plasma membrane[19]. Detailed biochemical, confocal immunofluorescence and immunoelectron microscopy analyses revealed that the intracellular AQP8 is mostly located in transport vesicles[17,19], smooth endoplasmic reticulum[28] and in the inner membrane of some mitochondria[29]. The protein expression in the plasma membrane is specifically located in the canalicular domain[16,17] and it is regulated by cAMP. Based on immunoblot analysis it was found that hepatocyte AQP8 can be present in two forms of different molecular weight: a N-glycosylated protein of about 34 kDa, and a non-glycosylated protein of 28 kDa[19,29]. According to this, it can be assumed that hepatocytes exhibit two intracellular subpopulations of AQP8 with different physiological functions. A 34 kDa AQP8 in transport vesicles and canalicular plasma membrane domains involved in the formation and regulation of bile (see below); and a 28 kDa AQP8, located in the inner mitochondrial membrane with still uncharacterized functions[29]. Regarding AQP8 distribution in the liver, there is evidence that it has a differential lobular localization. Accordingly, immunohistochemical studies showed staining predominantly in the hepatocytes surrounding the central vein of rat liver[16]. Different results were shown in mouse hepatic lobules, where AQP8 seems to be predominantly distributed in the periportal and midlobular hepatocytes with some immunostaining in the pericentral region[28].

AQP9 is a water channel of approximately 32 kDa that allows the passage of water and a wide variety of neutral solutes such as urea, glycerol, purines and pyrimidines[30,31]. Immunolocalization studies performed in rodent liver revealed that AQP9 is exclusively restricted to the hepatocyte sinusoidal plasma membrane domain[21], with an expression pattern strongest around the perivenous zone[32].

Hepatocytes also express AQP0, formerly named major intrinsic protein[16]. AQP0 is mainly localized to intracellular vesicular compartments, but it is not responsive to cAMP and so far, there is no evidence that its trafficking is regulated[14]. The function of AQP0 in hepatocytes has not yet been determined.

The last member to be identified was AQP11[6]. However, the study showed protein levels in total liver membranes, thus the AQP11 cellular and subcellular localization remains to be elucidated.

REGULATION OF HEPATOCYTE AQP TRAFFICKING

Certain epithelia adjust their transport capacity in the short term (i.e. min) by rapid insertion of specific transporters in the secretory membrane. Therefore, the epithelial secretory or absorptive activity can be regulated by handling the number of transport molecules in the plasma membrane. AQP2 is the vasopressin-regulated water channel of the kidney collecting duct[33]. Accordingly, the vasopressin-induced exocytic insertion and endocytic retrieval into and out of the plasma membrane represents a rapid mechanism to regulate its water membrane permeability[34]. Likewise, AQP5 is the main AQP expressed in the acinar cells of the salivary gland. While the water channel is normally sequestered in intracellular vesicles, it redistributes to the apical plasma membrane upon stimulation by muscarinic agonists[35]. Furthermore, it was demonstrated in cholangiocytes that AQP1 is located in intracellular vesicles and undergoes secretin-induced exocytic insertion into the apical membrane[25,36]. Thus, fluid-transporting epithelia can regulate the rate of water transport across cell membranes by rapid relocalization of AQP molecules.

By using isolated rat hepatocytes, it was found that the water channel AQP8 is localized largely in intracellular vesicles and can be redistributed to the plasma membrane in a mechanism stimulated by cAMP. This was the first evidence that hepatocytes were able to regulate their membrane water permeability[19]. Furthermore, confocal immunofluorescence microscopy and functional studies in polarized isolated rat hepatocyte couplets showed that the insertion of AQP8 occurs specifically in the hepatocyte canalicular membrane domain, a mechanism that facilitates the osmotically-driven canalicular water secretion in response to a choleretic stimulus[16]. The microtubule blocker colchicine specifically inhibits the dibutiryl cAMP effect on both AQP8 translocation to plasma membrane and water transport, suggesting that the hormone-dependent AQP8 trafficking relies on microtubules[19].

Glucagon is a choleretic hormone, and its actions in hepatocytes are mostly mediated by cAMP-dependent protein kinase A (PKA). We found that glucagon induces the translocation of intracellular AQP8-containing vesicles to the canalicular domain in hepatocytes, and that this mechanism is dependent on the activation of PKA and the integrity of the microtubular network[37]. Because AQP8 lacks consensus PKA phosphorylation sites[38], we suggested that unidentified protein mediators might be involved in the vesicle trafficking induced by glucagon. The understanding of the precise mechanisms by which glucagon stimulates AQP8 translocation requires further investigation. Because AQP1 also lacks phosphorylation sites for PKA, the mechanisms involved in AQP8 translocation are probably similar to those involved in the secretin-mediated AQP1 trafficking in cholangiocytes[25,36,39].

It has been shown that glucagon is able to induce phosphatidylinositol-3-kinase (PI3K) activation in rat hepatocytes[40]. PI3K mediates several signaling transduction pathways in hepatocytes, including some involved in the regulation of vesicle trafficking and in the process of bile formation[41-44]. In fact, we showed that PI3K is involved in the hepatocyte trafficking of AQP8 stimulated by glucagon[45]. Thus our studies indicate that there is a dual requirement of PKA and PI3K for glucagon-induced AQP8 trafficking. The cross-talk between PKA and PI3K signaling pathways has already been suggested for the regulated translocation of Bsep to the hepatocyte canalicular membrane[46]. This may reflect the need for a cooperative action between PKA and PI3K on a single downstream effector. Consistent with this, it has been reported that in rat hepatocytes, cAMP can activate protein kinase B/Akt, a downstream PI3K effector[44,46]. Interestingly, it has recently been shown that cAMP-PKA mediated phosphorylation of the p85 regulatory subunit of PI3K which was suggested to be an important point of convergence of cAMP-PKA and PI3K signaling pathways[47]. Thus, the glucagon-induced AQP8 trafficking in hepatocytes seems to involve both the cAMP/PKA and PI3K signaling pathways in a cooperative manner.

Therefore, during active choleresis, hepatocytes rapidly increase their canalicular membrane water permeability by vesicle trafficking and thus modulate the abundance of AQP8 in the membrane.

PHYSIOLOGICAL SIGNIFICANCE OF HEPATOCYTE AQPS: BILE FORMATION

Hepatocytes are highly polarized epithelial cells characterized by two definite plasma membrane domains: a basolateral domain in contact with the sinusoidal blood and a bile canalicular domain, defining a sealed apical compartment. The asymmetric distribution of protein transporters to the apical and basolateral membrane domains is the basis of vectorial flux of solutes and water from blood into the bile canaliculi and therefore for the generation of bile[1-3]. Canalicular bile formation is an osmotic secretory process resulting from the inflow of water into the biliary space in response to osmotic gradients created by the active secretion of solutes. The excretion of bile salts via the bile salt transporter Bsep, glutathione via the organic anion transporter Mrp2, and HCO3- *via* the Cl-/HCO3- exchanger AE2 are known to be the major driving forces for water movement from the sinusoidal blood to the bile canaliculus[2]. While the generation of bile flow depends on the molecular and functional canalicular expression of the aforementioned solute transporters, the molecular route for water movement has been largely disregarded albeit the majority of canalicular bile is water.

Theoretically, water can flow through the hepatocyte epithelial barrier either across tight junctions between adjacent hepatocytes (paracellular route) or across hepatocyte plasma membranes (transcellular route). The paracellular route was traditionally proposed as the major pathway for water movement. Nonetheless, the experimental data supporting this view remained limited and largely indirect[48]. Experimental evidence supporting the transcellular pathway came from AQP inhibitory experiments in polarized rat hepatocyte couplets. Under choleretic stimuli, the AQP blockers prevented osmotically-driven water transport into the bile canaliculus[16]. Direct osmotic water permeability assessment by stopped-flow spectrophotometry in canalicular and sinusoidal plasma membrane vesicles revealed the presence of both lipid (non-channel) and AQP-mediated pathways for sinusoidal and canalicular water movement[49]. The study demonstrated that the canalicular plasma membrane domain has lower water permeability than the sinusoidal membrane, and thus it is rate limiting for transcellular water transport in hepatocytes. However, upon cAMP stimulus the intracellular AQP8 inserts to the canalicular domain and so this membrane becomes highly water permeable. Approximate estimations of transcellular hepatocyte water permeability suggest it to be similar to rat kidney proximal tubule, in which water flow seems to be largely transcellular[49]. Therefore, the transcellular pathway via water channels seems to account for most of the water entering the bile canaliculus.

As stated above, hepatocytes express AQPs in intracellular compartments as well as in the basolateral and canalicular plasma membrane domain. In the canalicular membrane, AQP8 was shown to be localized in lipid microdomains ("rafts") enriched with cholesterol and sphingolipids[50,51]. These rafts are thought to promote the assembly of specific proteins into definite regions of the plasma membrane. Because other canalicular transporters such as AE2 and Mrp2 are also localized in membrane microdomains[51], it seems plausible that in the apical membrane, AQP8 is clustered with functionally associated solute transporters, which would generate the driving force necessary for osmotic water transport mediated by AQP8.

The hormone glucagon is known to modulate canalicular bile formation[52]. Although the actual osmotic driving force involved in glucagon-induced choleresis is currently unknown, the solute gradients are thought to be created by active HCO3-excretion mediated by the canalicular transporter AE2[52]. In line with this, it was shown that glucagon (via cAMP) is able to stimulate the microtubule-dependent vesicle insertion of AE2 to hepatocyte plasma membrane[52]. This mechanism, in association with an increased activity of the exchanger, may account for the bicarbonate-rich choleresis induced by glucagon. Furthermore, recent immunofluorescence studies carried out in the hepatoma-derived hybrid cell line WIF-B, showed that AQP8 and AE2 are packaged in the same vesicle population, possibly conforming to a functional bile secretory unit[53]. Thus our findings provide evidence that AQP8 may improve the efficient coupling of canalicular water transport to the HCO3- secreted by AE2 during glucagon-stimulated hepatocyte bile formation.

Further evidence for the role of AQP8 in bile secretion comes from ontogenic expression studies during mice liver development. It was shown that at the time of weaning, there is a rapid increase in AQP8 mRNA and protein expression when the hepatobiliary transport systems complete their maturation, suggesting that AQP8 is necessary for canalicular bile formation[28].

Although the mentioned studies support a role for AQP8 in canalicular water secretion, conclusive evidence should come from studies performed in hepatocytes lacking AQP8 expression. With regard to this, experimental evidence against a role for AQP8 in canalicular bile formation came from data obtained from AQP8 knockout mice[54]. This study revealed that AQP8-null mice challenged with a high-fat diet did not show a significantly different phenotype when compared to their wild-type counterpart. The lack of dietary fat misprocessing could suggest that the excretion of bile salts required for proper lipid digestion was at least preserved. However, direct studies on bile formation in AQP8-null mice are mandatory, in order to determine if these animals develop cholestasis. On the other hand, as hepatocytes express several members of the AQP water channel family, the normal AQP8-null mice phenotype could result from a compensatory overexpression or functional modification of other genes.

Functional studies from our laboratory provided further evidence supporting the notion that canalicular water transport during bile secretion is AQP8-mediated. Indeed, we found that AQP8 gene suppression by RNA interference is able to inhibit osmotically-driven and cAMP-induced canalicular water secretion in the human hepatocyte cell line HepG2[55].

Therefore, while according to our model, AQP8 modulates the canalicular, rate limiting water flow, AQP9 would contribute to the sinusoidal uptake. In agreement with this, functional studies in rat hepatocyte basolateral membrane indicate that sinusoidal water transport is AQP-mediated[49]. As bile secretion requires the transcellular movement of water to the bile canaliculi and AQP9 is the only sinusoidal water channel described so far, it is logical to believe that water moves from the sinusoidal blood, at least in part, through AQP9.

PATHOPHYSIOLOGICAL SIGNIFICANCE OF HEPATOCYTE AQPS: CHOLESTASIS

Bile secretion failure is a consequence of several pathologic conditions with the risk of producing severe liver injury and systemic disease. There have been major advances in the understanding of the molecular pathogenesis of bile secretory failure[1-3]. It is well known that hepatocyte canalicular bile secretion results from the coordinated interaction of several solute membrane transport systems together with, as detailed above, AQP water channels. Hence, it is conceivable that defective AQP membrane expression may lead to alterations in normal bile physiology. The significance of liver AQPs in bile secretory failure are summarized in Table 2.

Extrahepatic cholestasis is a pathologic condition caused by a mechanical obstruction of the biliary tree secondary to a wide variety of acute and chronic conditions including gallstones, pancreatic carcinoma and cholangiosarcoma[56]. If uncorrected, the obstruction may lead to hepatocyte damage, secondary biliary cirrhosis and portal hypertension. The experimental model of bile duct ligation (BDL) in the rat has been extensively used to assess modifications in the molecular expression of hepatocyte membrane transporters in obstructive cholestasis. In a recent study, we examined the effect of BDL on the protein expression and subcellular localization of the hepatocyte water channel AQP8[57]. Biochemical and immunohistochemical studies determined that BDL-induced extrahepatic cholestasis caused downregulation of hepatocyte AQP8 at the protein level (Figure 2). In opposition, the AQP8 mRNA steady-state levels in BDL were increased, possibly as a compensatory mechanism in response to AQP8 protein reduction. The fact that AQP8 protein downregulation was not associated with reduced levels of the mRNA may indicate the involvement of posttranscriptional regulatory mechanisms. Additionally, the AQP8 translocation to the hepatocyte plasma membrane in BDL was found to be impaired. Hence it was concluded that the defective hepatocyte AQP8 functional expression as well as impaired translocation

Table 2 Molecular and functional expression of AQPs in cholestasis

Experimental model	AQP8			AQP9			Ref.
	Protein	mRNA	CPM P_f	Protein	mRNA	BLM P_f	
Obstructive cholestasis							
BDL	↓↓	↑	ND	↓↓↓	↓	↓	[57,58]
Intracellular cholestasis

CLP-induced cholestasis	↓↓↓	ND	ND	↔	ND	ND	[66]

Arrows depict significant protein and mRNA changes in treated rats compared with controls: ↑, increased; ↓, decreased; ↔, without change. ND: Not determined; P_f: Osmotic membrane water permeability; CPM: Canalicular plasma membrane; BLM: Basolateral plasma membrane; BDL: Bile duct ligation; EE: 17α-ethinylestradiol; LPS: Lipopolysaccharide; CLP: Cecal ligation and puncture.

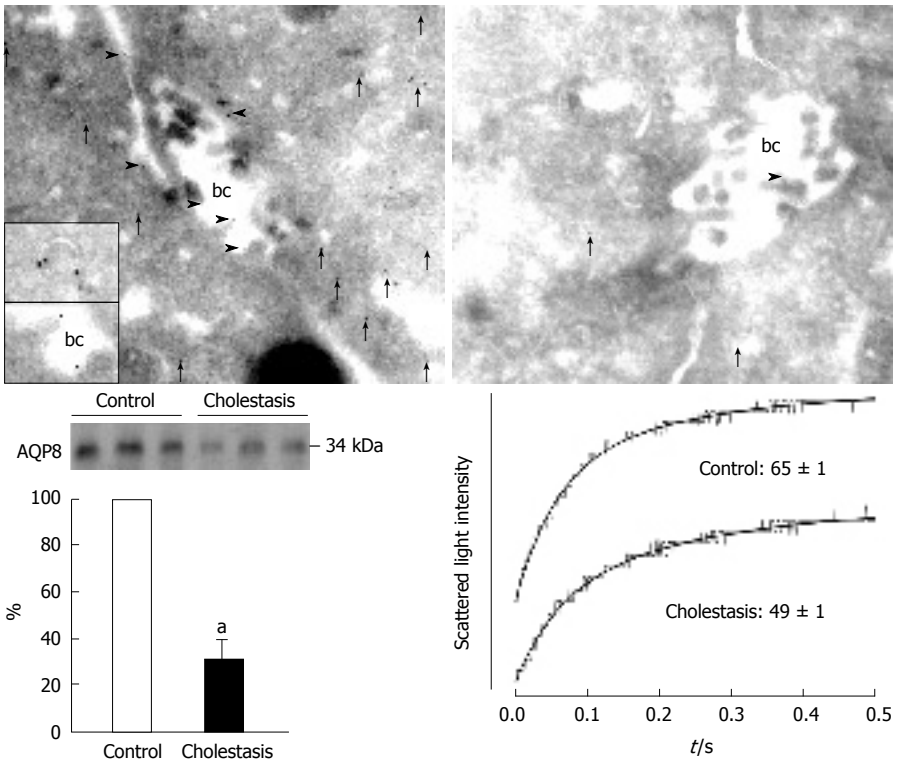

Figure 2 Functional expression of AQP8 in normal and cholestatic liver. Superior panel: Immunogold electron microscopy for AQP8 in liver from control (left) and 7-d BDL rats (right). Arrowheads indicate AQP8 in bile canalicular (bc) membranes. Arrows indicate AQP8 in the pericanalicular cytoplasm. The upper inset shows an AQP8-containing vesicle, and the lower insert shows AQP8 in the tip of a microvillus and in the intermicrovillar plasma membrane region. (Original magnification X 60 000) Modified and reproduced with permission[57]. Inferior panel: On the left, anti-AQP8 immunoblot of the canalicular plasma membranes from normal and LPS-induced cholestatic liver. On the right, water permeability assessment of canalicular membranes from LPS-induced cholestatic liver. Typical tracings of a time course of scattered light intensity (osmotic water transport), along with single exponential fits in canalicular plasma membrane vesicles in response to a 250 mosM hypertonic sucrose gradient. Calculated P_f values (μm/s) are shown under each curve. Data are mean ± SE from 3 independent vesicle preparations. $^aP < 0.05$ *vs* conrtol. Modified and reproduced with permission[64].

may contribute to the secretory dysfunction caused by obstructive cholestasis.

In addition, very recent work suggested a potential involvement of sinusoidal AQP9 in the pathogenesis of obstructive cholestasis. Detailed biochemical studies demonstrated that in BDL there is a decrease in AQP9 protein in basolateral membranes with a simultaneous intracellular increase of the protein[58]. In addition, functional studies performed in sinusoidal hepatocyte membrane found a close correspondence between the AQP9 decreased membrane protein levels and impaired osmotic water permeability. It was concluded that downregulation of AQP9 in the hepatocyte basolateral plasma membrane affects sinusoidal water uptake during bile formation, thus contributing along with AQP8 downregulation to the bile flow dysfunction in obstructive cholestasis.

Estrogens are known to cause intrahepatic cholestasis in susceptible women. The most common clinical features of this disorder are oral contraceptive-induced cholestasis and cholestasis associated with pregnancy or postmenopausal replacement therapy[2]. Experimental cholestasis induced by 17α-ethinylestradiol (EE) has been widely used to investigate *in vivo* alterations in the expression of hepatocyte membrane transporters in this pathological condition. In a recent work, we found that the protein expression of hepatocyte AQP8 is downregulated in estrogen-induced cholestasis possibly by posttranscriptional mechanisms, without significant changes in the sinusoidal AQP9[59]. In fact, complementary studies in primary cultured rat hepatocytes with protease inhibitors indicated that estrogen-induced AQP8 downregulation was mediated by increased lysosomal degradation. Of note, the canalicular AQP8 downregulation was correlated with a 22% reduction in the canalicular membrane water permeability. Previous reports have estimated that under basal conditions the AQP-mediated water

pathway contributes to approximately 30% of the total canalicular water transport[49]. For that reason, the 22% water permeability decrease caused by estrogens may be enough to impair the efficient canalicular coupling between osmotic solutes and water transport during bile formation. On the other hand, it is worth mentioning that the contribution of AQP8 in acute cholestasis appears to be less significant. A recent study showed that experimental acute cholestasis in rats caused by the estrogen metabolite estradiol-17-*d*-glucuronide ($E_2$17G) failed to cause endocytic internalization of canalicular AQP8[60], in contrast to that observed for Bsep and Mrp2[61,62]. Therefore the rapid retrieval of solute transporters, but not that of AQP8, seems to be the main cause of acute cholestasis induced by $E_2$17G.

It is well known that sepsis, a systemic inflammatory response secondary to bacterial infection, is frequently associated with intrahepatic cholestasis[62]. Lipopolysaccharides (LPS) are endotoxins released into the circulation from bacterial sites of infection and are responsible for the macrophage secretion of proinflammatory cytokines, primarily tumor necrosis factor α (TNF α), interleukin 1-β and interleukin-6. These cytokines are the principal mediators of bile secretory failure[63]. In a study performed using a rodent model of endotoxemia, we demonstrated that LPS reduced the functional expression of hepatocyte canalicular AQP8[64]. As shown in Figure 2, a decrease in canalicular AQP8 protein expression of approximately 70% was associated with a 25% decrease in water canalicular permeability measured by stopped-flow spectrophotometry. This result is in good agreement with the above-mentioned studies of estrogen-induced cholestasis. Thus, LPS-induced cholestasis may ultimately be caused by impaired transient osmotic gradients generated by defective canalicular expression of the solute transporters Bsep and Mrp2[65], together with reduced canalicular water permeability secondary to defective AQP8 expression. The impairment in AQP8 expression was found to be posttranscriptional and mediated by the cytokine TNFα. Indeed, the passive immunization *in vivo* with anti-TNFα antibody prevented LPS-induced cholestasis and AQP8 protein downregulation. These results were confirmed in cultured rat hepatocytes treated with recombinant TNFα. Complementary *in vitro* studies using lysosome and proteasome inhibitors showed that AQP8 degradation was mediated *via* both lysosomal and proteasomal pathways. It was concluded that LPS induces posttranscriptional AQP8 downregulation and an associated decrease in canalicular membrane water permeability, a mechanism that is likely to contribute to the molecular pathogenesis of LPS-induced cholestasis.

As clinical sepsis is commonly polymicrobial, the above-mentioned results were further confirmed in an animal model of peritoneal sepsis characterized by a focus of infection with mixed intestinal flora instead of an endotoxic challenge. Thus liver AQP8 expression was studied in rats with sepsis induced by cecal ligation and puncture (CLP)[66]. In agreement with the endotoxic model, immunoblotting and immunohistochemical studies revealed a significant decrease in AQP8 protein level in canalicular membranes, without any significant reduction in AQP9 expression. These results are in agreement with the findings in LPS-treated rats, and further support the notion that the defective expression of hepatocyte AQP8 contributes to the development of bile secretory dysfunction in sepsis.

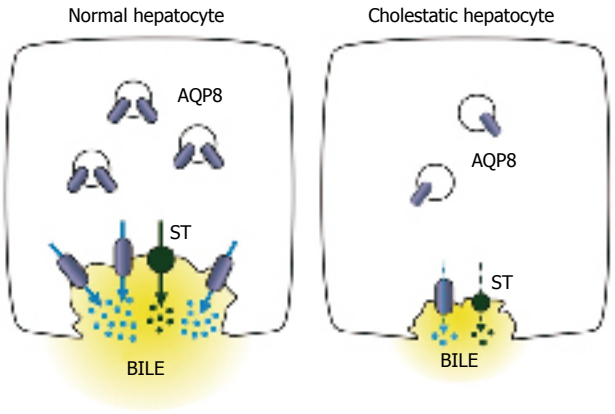

Figure 3 Proposed contribution of hepatocyte AQP8 to the development of cholestasis. On the left a normal hepatocyte is illustrated with AQP8 expressed at the canalicular membrane domain and in intracellular vesicles. Bile is formed by the active secretion of solute transporters (ST) such as Bsep and Mrp2, which generate the osmotic driving forces for water transport through canalicular AQP8. On the right, a cholestatic hepatocyte is illustrated with decreased expression and functioning of ST. AQP8 is downregulated at the canalicular domain, which impairs the water osmotic permeability thus contributing to decreased bile formation.

Based on the cumulative evidence described above, a schematic model for the hepatocyte AQP8 contribution to the development of bile secretory failure is depicted in Figure 3.

CONCLUSION

In conclusion, this review summarized recent progress in research and current available data on the expression and pathophysiological significance of AQP water channels in the hepatocyte. It has long been established that canalicular bile secretion is the result of a combined interaction of several solute transporters. However, in the last few years further insight has been provided on the molecular basis of water movement during bile secretion. The functional expression of AQP8 is impaired in several experimental models of cholestasis such as extrahepatic obstructive cholestasis, estrogen-induced cholestasis and sepsis-induced cholestasis. A combined alteration in solute transporters and AQP8 would hamper the efficient coupling of osmotic gradients and canalicular water flow. Therefore, the common association of impaired solute transport together with decreased water permeability would ultimately lead to bile secretory failure. Nevertheless, more research is needed to expand the current knowledge underlying AQP expression regulation and water transport in cholestasis.

Abstract

The canalicular membrane represents the excretory pole of hepatocytes. Bile is an important route of elimination of potentially toxic endo- and xenobiotics (including drugs and toxins), mediated by the major canalicular transporters: multidrug resistance protein 1 (MDR1, ABCB1), also known as P-glycoprotein, multidrug resistance-associated protein 2 (MRP2, ABCC2), and the breast cancer resistance protein (BCRP, ABCG2). Their activities depend on regulation of expression and proper localization at the canalicular membrane, as regulated by transcriptional and post-transcriptional events, respectively. At transcriptional level, specific nuclear receptors (NR)s modulated by ligands, co-activators and co-repressors, mediate the physiological requirements of these transporters. This complex system is also responsible for alterations occurring in specific liver pathologies. We briefly describe the major Class Ⅱ NRs, pregnane X receptor (PXR) and constitutive androstane receptor (CAR), and their role in regulating expression of multidrug resistance proteins. Several therapeutic agents regulate the expression of relevant drug transporters through activation/inactivation of these NRs. We provide some representative examples of the action of therapeutic agents modulating liver drug transporters, which in addition, involve CAR or PXR as mediators.

INTRODUCTION

Hepatocytes are polarized cells and represent 80% of the liver mass. The basolateral and canalicular membranes differ in their composition and functions and are separated by tight junctions that seal off the bile canaliculi. The basolateral membrane is in contact with the sinusoidal blood. The canalicular membrane represents the excretory pole of hepatocytes. Bile formation is largely dependent on active transport of solutes such as bile acids, glutathione and bicarbonate through the canalicular membrane followed by the passive movement of water. Canalicular excretion is the rate-limiting step of bile formation since biliary constituents are secreted into bile against concentration gradients. The canalicular primary bile is further modified by absorptive and secretory processes along the biliary tree. Considerable species specific differences in bile formation exist, including the contribution of ductular bile and bile acid composition[1]. In mammals, bile is essential for solubilization and digestion of dietary lipids.

The sinusoidal uptake and canalicular excretion of most biliary constituents is mediated by several transport systems expressed at the two polar surface domains of liver cells. Basolateral transport systems are responsible for the translocation of molecules across the sinusoidal membrane, whereas active canalicular transport systems are in charge of the biliary excretion. Numerous transport proteins involved in basolateral transport have been identified including the Na^+-taurocholate co-transporting

polypeptide (NTCP, SLC10A1), organic anion transporting polypeptides (OATPs: SLCO family), multidrug resistance-associated proteins 1, 3 and 4 (MRP1, 3 and 4; ABCC1, 3 and 4), and organic anion and cation transporters (OATs, OCTs: SLC22A family). Canalicular transport of osmotically active solutes, contributing to bile formation, is mediated by MRP2 (ABCC2), the bile salt export pump (BSEP, ABCB11), and the organic anion 2 (AE2, SLC4A2), which are involved in biliary excretion of glutathione and glucuronide conjugates, monoanionic bile salts, and bicarbonate, respectively[1-4]. Biliary elimination of drugs is mediated by the multidrug resistance protein 1 (MDR1, ABCB1), also known as P-glycoprotein, MRP2, and the breast cancer resistance protein (BCRP, ABCG2)[5-11]. Though they all belong to the superfamily ABC, in contrast to the majority of its members, BCRP is present as a monomer and consists of only one ATP-binding site and 6 transmembrane regions.

In this review we focus our attention only on the hepatic drug transporters and their regulation by nuclear receptors activated by compounds habitually used as therapeutic agents.

APICAL DRUG TRANSPORTERS AND NUCLEAR RECEPTORS

Drug transporters are constitutively expressed in several organs playing an important role in the efflux of xenobiotics and their metabolites; the apical membrane of epithelial secretory tissues, and particularly the liver, being the most relevant sites. Substrates recognized by P-glycoprotein, MRP2 and BCRP represent a wide spectrum of endo- and xenobiotics, including contaminants and therapeutic drugs, either neutral, cationic or anionic, and of hydrophobic or hydrophilic nature. P-glycoprotein is a member of the ABC superfamily of transporters originally described in cancer cell lines, conferring resistance to therapeutic agents. It was the first ABC transporter identified in canalicular membranes of normal hepatocytes. MDR1 functions as an efflux pump for a wide range of amphiphilic, bulky type Ⅱ cationic drugs together with other hydrophobic compounds, including endogenous and exogenous metabolites or toxins, steroid hormones, hydrophobic peptides and even glycolipids[12]. MRP2 mediates the biliary elimination of different organic anions, including glutathione-S-conjugates (e.g. of leukotriene C4), glucuronides (e.g. of bilirubin and estrogens), and oxidized glutathione[2,13]. MRP2 also mediates the canalicular transport of glucuronidated and sulfated bile salts[14]. In addition, MRP2 was found to transfer reduced glutathione, though with very low affinity. MRP1 but not MRP2 was the first member of the superfamily of ABC (ATP Binding Cassette) transporters dependent on ATP hydrolysis, and was initially identified in a human lung cancer cell line[15]. BCRP that was initially found to confer resistance to breast cancer treatment was more recently found to be expressed normally in epithelial tissues and transport sulfated metabolites of drugs with high specificity[16-18].

Expression of these canalicular drug transporters are subject to transcriptional and post-transcriptional regulation in response to endogenous and exogenous compounds and different pathologic situations. The short-term changes in transporter activity and expression are generated at post-transcriptional level. An intensive regulation mediated by second messenger and protein-kinases modulates the recruitment of the transporters from intracellular reservoirs to plasmatic membrane or alters the activity by phosphorylation-dephosphorylation and protein-protein interactions. All these factors act in association to regulate the functional state of drug transporters, which were found to be affected to different degrees by liver disease[1,4,19]. Particular interest has been given recently to proper localization of BSEP and MRP2 in the normal situation, which is disrupted in cholestatic disease as a consequence of their internalization and abnormal localization to subapical membrane. This was observed not only in experimental animals such as the rat, but also in humans[20,21].

At transcriptional level, a wide variety of nuclear receptors (NR)s activated by ligands, co-activators and co-repressors, mediate the physiological requirements of these transporters. This complex system is also responsible for alterations occurring in specific liver pathologies. The biotransformation systems (phase Ⅰ and Ⅱ reactions) that act in coordination with efflux proteins are also regulated by this same network of NRs[22,23]. Transcriptional regulation of drug transporters by NRs is a complex process involving: (1) ligand binding, (2) the association of NRs with regulatory sites in the genome through their DNA sites, (3) co-regulator recruitment, (4) the regulation of polymerase Ⅱ binding and activity at target promoters, and (5) the ending or attenuation of NR-dependent signaling[24-26].

Co-activators and co-repressors represent key factors in modulation of NR activity. Co-activators are implicated in chromatin relaxation due to their intrinsic histone acetyltransferase or methyltransferase activity. After binding to the activated (agonist-bound) NR, co-activators contribute to the full activation of expression of the target genes. Several co-activators were shown to cooperate with nuclear receptors: the p160 family (SRC-1, TIF-2, GRIP, ACTR), p/CIP and CBP/p300. On the other hand, co-repressors, such as NcoR and SMRT, preferentially bind to inactivated receptors (absence of ligand, antagonist-bound, reverse agonist-bound) and recruit various forms of histone deacetylases, thus leading to chromatin condensation and ultimately, to repression of the target gene expression[27].

As anticipated above, NRs comprise a superfamily of transcription factors activated by ligands which can both activate and repress gene expression. According to their dimerization and DNA binding properties, NRs can be classified into four groups. Class Ⅰ comprises the classical receptors of steroid hormones (estradiol, testosterone, progesterone, cortisol). These form homodimers before binding to response elements in the promoter regions of target genes. NRs belonging to Class Ⅱ, such as pregnane X receptor (PXR), constitutive androstane

receptor (CAR), and farnesoid X receptor (FXR), form heterodimers with the retinoid X receptor (RXR), prior to interacting with target genes. Since RXR is the obligated partner in the heterodimer formation, its low availability may result in a trans-repressive effect. Receptors with no ligand can exist, and have been found to bind DNA as homodimers. They belong to Class Ⅲ (e.g. RXR, and the nuclear hepatic factor 4, HNF4). Class IV consists of NRs that act as monomers, like the liver receptor LRH1[28].

We will focus on class Ⅱ receptors since they represent the best characterized. More specifically, we will briefly describe those receptors involved in regulating drug transporters, i.e. PXR and CAR. Originally, these NRs were identified as sensors able to respond to a wide variety of environmental xenobiotics to promote detoxification by phase I *CYP450* genes[29]. Lehmann *et al*[30] showed that hPXR receptor binds to the rifampicin/dexamethasone response element in the *CYP3A4* promoter region as a heterodimer with the 9-cis-retinoic acid receptor (RXR). They also reported that hPXR is activated by many *CYP3A4* inducers, including several steroids, lovastatin, clotrimazole, rifampicin and phenobarbital. Increasingly at present, data reveals the involvement of NRs in the regulation of Phase I and Ⅱ enzymes, along with the proteins effluxing their metabolites[31].

PXR

In 1998, Kliewer *et al*[32] identified a new member of the nuclear hormone receptor family activated primarily by pregnanes: PXR (NR1I2). It was principally cloned from mouse liver and later from rabbit, rat and human. PXR is predominantly expressed in liver and intestine, and to a lower extent, in lung and kidney[32,33]. PXR dimerizes with RXRα immediately after its activation by ligand binding. It was originally believed to be localized mainly at the nucleus, but later it was found that it is present at the cytoplasm, interacting with a protein complex and that, after activation, it translocates to the nucleus to regulate gene transcription[34]. One relevant feature of this receptor is that it recognizes a wide variety of xenobiotics such as ligands, dexamethasone, rifampicin, spironolactone, and pregnenolone 16α-carbonitrile being among the best characterized. It can also bind some specific bile acids such as litocholic, 3-ketolitocholic, cholic and deoxycholic acids[32-34]. PXR regulates genes involved in phase I metabolism (e.g. *CYP3A*) and several genes associated with drug transport such as *MDR1*, *OATP2*, *MRP2*, and *MRP3*[35-37]. PXR is remarkably divergent between species, with the rabbit, rat and human receptors sharing only approximately 80% of the amino acid identity in their ligand-binding domains. This feature is reflected by marked pharmacological differences in PXR activation profiles. PXRs from different species are differentially activated by specific compounds, thus correlating well with species-specific induction of *CYP3A* gene expression. For example, the hypocholesterolemic drug SR12813, the macrolide antibiotic rifampicin and the antidiabetic drug troglitazone are effective activators of the human and rabbit PXR but have modest activity on the rat and mouse PXR. On the contrary, pregnane 16α-carbonitrile is a more potent activator of the rat and mouse than the human and rabbit receptor[33]. In addition, PXR polymorphism has been described and it is assumed to contribute to the observed interindividual variability of gene expression and atypical responses to drugs or altered sensitivity to carcinogens[38,39].

CAR

Also known as NR1I3, this NR was identified in 1994 as a receptor interacting with a subset of retinoic acid response elements[40]. It was originally defined as a constitutively activated receptor since it forms a heterodimer with RXR and binds to retinoic acid response element in the absence of ligand[41]. It was demonstrated more recently that CAR activation is a multistep process. The initial step is translocation to the nucleus and interaction with RXRα, a process that can be independent of ligand binding[37,42]. It is known that CAR participates in regulation of transcription of drug transporter genes such as *MRPs* (*MRP2*, *3*, and *4*) and *Oatp2*[23,43,44].

CAR is found mainly in liver and it is also detected in certain extrahepatic tissues such as the intestine[40,45]. Pathophysiological conditions such as trauma, sepsis, inflammation[46] or drugs[47] can modify CAR expression. *In vivo*, CAR is sequestered in the cytoplasm forming a complex with proteins such as heat shock protein 90 (HSP90) and CAR cytoplasmic retention protein (CCRP)[48]. In addition, phosphatase 2A (PP2A) is recruited to the HSP90-CCRP-CAR complex[49]. Translocation of CAR to the nucleus, most likely dependent on the activity of PP2A, is followed by association with RXR and binding to the phenobarbital responsive enhancer modules (PBREM). Thus, CAR activation can imply direct binding of an agonist, recruitment of co-activators, dissociation of co-repressors, and the subsequent nuclear translocation and heterodimerization with RXRα[50], prior to DNA binding and induction of gene expression[51]. CAR co-activators so far identified are GRIP1/TIF2, PGC-1, SRC-1, Sp1, ASC-2 and SMC-1. CAR transcriptional activity correlates well with its concentration in the nucleus. The blockage of phenobarbital-mediated induction of *CYP2B* gene in rodents by okadaic acid, a protein phosphatase inhibitor, has provided an additional indication of the importance of CAR nuclear accumulation in the increase of transcription rate[52]. Some ligands of CAR like androstenol act as inverse agonists, affecting the protein in such a way that co-repressors instead of co-activators are recruited, and the transcriptional activity of the receptor is decreased[53]. Estrogen derivatives display both agonist and antagonist nature by inducing the recruitment of both SRC-1 and NcoR after binding to CAR[54]. Alternatively, some CAR activators are not ligands *in vitro*. Among others, phenobarbital and bilirubin can modulate CAR activity by indirect activation, promoting the nuclear translocation of the receptor without binding to the ligand domain, although the mechanism is not totally understood[49,55].

MODULATION OF DRUG TRANSPORTERS BY THERAPEUTIC AGENTS: ROLE OF NUCLEAR RECEPTORS

Synthetic drugs, natural products, endogenous substances, and environmental toxicants are chemicals known to modulate the activity of major Class Ⅱ nuclear receptors, CAR and PXR[56,57]. It is widely recognized that CAR and PXR are major determinants in the regulation of an extensive spectrum of genes involved in the metabolism and disposition of xeno- and endobiotics[37,58-60]. Thus, among other factors, drug exposure can influence the activity of these NRs, affecting the metabolism, toxicity and drug-drug interactions of many xenobiotics or endogenous substances. The following paragraphs describe some representative examples of the action of therapeutic agents modulating drug transporters and involving CAR or PXR as mediators.

Pharmaceutical agents that are agonists of PXR and CAR had been used for treatment of human diseases long before their mechanism of action was clarified. Rifampicin, a human PXR agonist, was found to be effective in the treatment of pruritus in cholestatic disorders[61,62]. Furthermore, administration of rifampicin to healthy human volunteers significantly induced UDP-glucuronosyltransferase 1A1 (UGT1A1), involved in bilirubin glucuronidation, and MRP2 expression, leading to reduction in serum bilirubin levels[63]. Certain traditional Chinese herbs are powerful CAR activators and have been used extensively for management of neonatal jaundice[64]. Phenobarbital, in addition to rifampicin, has been empirically used to treat hyperbilirubinemia[65,66] due to its inductive properties on UGTs. These compounds are activators of PXR and CAR and the identification of the UGT locus as a direct target for hPXR and hCAR has relevance in both xenobiotic/endobiotic metabolism and disposition in human disease. Simultaneous induction of biotransformation and transport systems by these same agents was also effective in increasing the disposition of a variety of carcinogens, as well as estrogen and thyroxin[67]. MRP2 is one of the best characterized drug transporters to act in coordination with biotransformation systems to increase drug elimination[22]. This is in part due to its universal capacity to respond to NR activators, which in turn activate a wide spectrum of phase I and Ⅱ reactions. Indeed, Kast *et al*[36] have reported that *MRP2/Mrp2* genes are modulated by PXR, FXR and CAR in human and rodents. Interestingly, these three distinct nuclear receptor signaling pathways converge on a common response element in the 5'-flanking region of these same genes.

Glucocorticoids are also well known inducers of several biotransformation and transport systems. In acute cholestasis, as well as in chronic cholestatic disorders such as primary biliary cirrhosis, the beneficial effects of steroids could be attributed not only to their anti-inflammatory and immune-modulatory actions but also to the effects mediated by alterations in biotransformation enzymes and transporters, these latter systems being regulated by NRs[68]. CAR seems to act as a primary glucocorticoid receptor (GR)-response gene, since the CAR gene promoter harbors a GR response element[69]. In addition, glucocorticoids such as dexamethasone induce CAR nuclear translocation. Glucocorticoids also induce PXR expression and nuclear translocation and thus induce target genes expression like *CYP3A4*, *BSEP* and *MRP2*. These latter findings explain the improvement of liver cholestatic diseases such as that induced experimentally by endotoxin administration[70].

As was demonstrated for the steroids pregnenolone 16α-carbonitrile, 5 β-pregnane-3, 20-dione and dexamethasone[71], spironolactone, widely used as a diuretic, also binds to PXR[72]. Rats treated with spironolactone, exhibit up-regulation of Mrp2 and P-gp in liver[73,74] along with increased phase Ⅱ biotransformation reactions[75,76]. Data on increased expression of Mrp2 (protein and mRNA) are consistent with transcriptional regulation of the target genes and with spironolactone-PXR interaction. The potentiality of spironolactone to counteract alterations in biliary secretory function emerges from studies demonstrating that this steroid was able to prevent the decrease in bile flow and biliary secretion of Mrp2 substrates induced by the cholestatic ethynylestradiol[77]. It is interesting to note that spironolactone also leads to up-regulation of PXR mRNA and protein levels (ML Ruiz, SSM Villanueva, MG Luquita, AD Mottino, and VA Catania, unpublished results), reinforcing a role for this nuclear receptor as a modulator of the action of spironolactone. This finding also suggests that an adaptive response to prolonged treatment with therapeutic drugs may result from changes in expression of the NR gene, and consequently from its availability for binding to the respective ligands. Clearly, the binding of an agonist or antagonist to NRs can directly translate physiological and pathophysiological requirements into alterations of gene expression[1,78,79]. These effects can be additionally modulated by transcriptional or post-transcriptional regulation of the transcription factor itself[80,81].

Acetaminophen is a widely used therapeutic drug which can produce hepatotoxicity when administered at high doses. CAR is a key regulator of acetaminophen metabolism and hepatotoxicity. CAR activators, as well as high doses of acetaminophen, induce expression of key drug metabolizing enzymes in wild-type but not in *Car*-/- mice, and administration of the inverse agonist ligand androstanol after treatment with acetaminophen blocks hepatotoxicity in wild-type but not in *Car*-/- mice[82]. In addition, *Car*-/- mice are resistant to acetaminophen hepatotoxicity. In contrast, mice deficient in Nrf2 are highly susceptible to acetaminophen hepatotoxicity and were unable to increase the hepatic basolateral drug transporters Mrp3 and Mrp4, as detected in wild type animals[83]. These transporters may represent an attractive target to reduce acetaminophen hepatotoxicity. Indeed, pretreatment of rats with acetaminophen was shown to increase Mrp3 expression, and thereby induced a shift from biliary to urinary elimination of acetaminophen glucuronide; the subsequent decreased enterohepatic recirculation was postulated to decrease exposure of the liver to acetaminophen and thereby protect against hepatoxicity[84]. Whether CAR

or PXR, in addition to NrF, are involved in modulation of key drug transporters regulating acetaminophen toxicity, at toxic or subtoxic doses, needs further exploration.

Whereas a number of drugs targeting different NRs, which form heterodimers with RXR, have been approved for treatment of metabolic diseases[85], finding new therapeutic compounds that could modulate drug efflux in a similar way still represents a major challenge. Our increasing understanding of the molecular regulation of transport and detoxification systems, including mediation of NRs, should help significantly.

CONCLUSION

Major drug transporters in the liver, either at the apical or basolateral level, are extensively regulated by therapeutic agents, and likely involve mediation of NRs. Targeting NRs such as CAR and PXR to improve liver diseases, particularly those involving alterations in biliary secretory function, represents a promising perspective. Most of the studies referenced in this current review, which clearly support this possibility, were performed either in rodents or in human cell lines. To what extent the results obtained in these experiments apply to humans is poorly known and needs further exploration.

Abstract

AIM: To investigate if an immune imbalance may account for the development and progression of chronic radiation enteritis. We analyzed the Th1/Th2 immune response profile early and 6 mo after fractionated colorectal irradiation.

METHODS: A rat model of fractionated colorectal γ-irradiation (4-Gy fractions, 3 fractions per week) was designed to investigate the effects of cumulative dose on inflammatory mediators (cytokines and chemokines) and immune response (Th1/Th2 profile and immunosuppressive mediator IL-10) during acute (early) response and 6 mo after the end of fractionated irradiation (chronic response). Analyses were performed 1 d after the cumulative doses of 16 Gy and 36 Gy and 1 d, 3 d, and 26 wk after the cumulative dose of 52 Gy.

RESULTS: Without causing histological damage, fractionated radiation induced elevated expression of IL-1β, TNFα, MCP-1, and iNOS in distal colonic mucosa during the early post-irradiation phase. At that time, a Th2 profile was confirmed by expression of both the Th2-specific transcription factor GATA-3 and the chemokine receptor CCR4 and by suppression of the Th1 cytokine IFNγ/IP-10 throughout the irradiation protocol. After 6 mo, despite the 2-fold reduction of iNOS and MCP-1 levels, the Th2 profile persisted, as shown by a 50% reduction in the expression of the Th1 transcription factor T-bet, the chemokine receptor CCXCR3, and the IFNγ/STAT1 pathway. At the same time-point, the immunosuppressive IL-10/STAT3 pathway, known to regulate the Th1/Th2 balance, was expressed, in irradiated rats, at approximately half its level as compared to controls. This suppression was associated with an overexpression of SOCS3, which inhibits the feedback of the Th1 polarization and regulates IL-10 production.

CONCLUSION: Colorectal irradiation induces Th2 polarization, defective IL-10/STAT3 pathway activation and SOCS3 overexpression. These changes, in turn, maintain a immunological imbalance that persists in the long term.

INTRODUCTION

During radiation therapy for pelvic or abdominal cancer, the intestines are a critical dose-limiting organ. Despite precautions in treatment planning (e.g. multiple fields) and delivery, patients develop radiation-induced bowel injury during and after therapy[1]. Radiation enteropathy therefore remains an important obstacle to the radiocurability of abdominal tumors and continues to impair patients' "quality of life". Symptoms of acute bowel toxicity occur among about 80% of these patients, and include vomiting, diarrhea, hemorrhages and ulcerations due to the direct effects of radiation on the intestinal mucosa[2]. Explanations based on recognition that irradiation induces changes in cellular functions have recently replaced the concept attributing the severity of acute intestinal radiation toxicity to disruption of the epithelial barrier and mucosal inflammation.

Acute (early) effects are those observed during the course of radiation therapy: they are usually transient

and cease shortly after its completion. In some patients, persistent acute damage causes consequential effects to appear later on, i.e. after radiation exposure[3]. These delayed effects, called chronic radiation enteritis, concern fewer patients (50%) but are important clinically because of their chronic progressive nature and their significant long-term morbidity. Delayed radiation enteropathy typically presents, from the clinical standpoint, 6 mo to 3 years after irradiation. It is characterized by dysmotility and malabsorption, sometimes developing into fibrosis and eventually, in some cases, bowel obstruction, years or even decades after radiation exposure. A latency period was previously thought to exist between the time of radiation treatment and the onset of radiation-induced damage, but many studies now show that this is not the case. Experimental evidence indicates that the onset of delayed radiation effects is a continuous process that starts immediately at irradiation[4]. The process includes the production of cytokines and reactive oxygen species (ROS), which cause responses in the surrounding tissue, including cell infiltration. These "waves" of response may be interpreted as the result of failed attempts at adaptation and then later as the evidence of dysregulated tissue response. Recent studies show that irradiation induces the synthesis of various cytokines in several tissues, including the intestines[5] and lungs[6]. These cytokines lead to cell infiltration and fibroblast stimulation, thus enhancing collagen synthesis[7]. In addition, cytokine production by immune cells is crucial to immune response to infectious agents and disease prevention.

Many diseases, including inflammatory bowel disease[8], are associated with imbalances between Th1 (T helper cell type 1) and Th2 (T helper cell type 2) cytokines. Because these cell subpopulations tend to function antagonistically towards each another, the persistence of disease susceptibility and resistance depends on the profiles of the cytokines that each type secretes. Several reports show that ionizing radiation induces the preferential differentiation of Th cells into Th2 cells in the spleen[9,10] and more recently, in the intestines[11], where this Th2 dominance is characterized by repression of IFNγ. Th2 cells play a critical role in the pathogenesis of radiation-induced pneumonitis, which precedes lung fibrosis[12].

Th1 and Th2 cells were originally distinguished from each other by their specific cytokine expression profiles. *In vivo* analysis of these polarized Th cells has revealed differential sets of molecular expression, including specific chemokine/chemokine receptors. Typically, the chemokine receptor CXCR3 is expressed exclusively on Th1 lymphocytes, which migrate to the inflammatory sites in response to CXCR3 ligands and interferon-inducible protein (IP)-10[13,14]. Likewise, CCR4 is preferentially expressed on Th2 cells[15]. Specific expression of transcription factors leads to differential expression of polarized Th cells. For example, T-bet, expressed specifically in Th1 cells, mediates IFNγ production, while GATA-binding protein 3 (GATA-3), which suppresses this production, is thought to be the most important factor associated with the development of the Th2 phenotype and inhibition of the Th1 phenotype[16]. Th1 cytokines can activate macrophages, regulate cell-mediated immune responses, and promote tumoricidal activity. Th2 cells, in contrast, promote humoral immunity. Each Th subset mutually inhibits the growth and function of the other one. Members of the suppressor of cytokine signaling (SOCS) family of proteins are described as feedback inhibitors of a broad range of cytokine signaling pathways, regulating the amplitude and duration of the polarization influenced by T-bet or GATA-3[17]. Notably, SOCS3 inhibits the signal transduction pathway implicating IFNγ[18].

Determining Th1/Th2 balance during the radiotherapy protocol and, in particular, its long-term balance requires a longitudinal study. In this study, a rat model of fractionated colorectal-irradiation was designed to investigate the effects of cumulative dose on the inflammatory mediators and the immune response. Our study suggests that the downregulation of Th1-type cells, induced by γ-irradiation, persists for at least 6 mo after the end of the irradiation protocol. This supports the hypothesis that the radiation-induced impairment of inflammation control mechanisms plays a critical role in both acute and late effects.

MATERIALS AND METHODS

Animals

Adult male Wistar rats (Elevage Janvier, France) weighing 200-250 g were housed (three per cage) with food and water *ad libitum*. All experiments were conducted in accordance with the French Ministry of Agriculture regulations for animal experimentation (No. 2001-464, May 2001).

Radiation schedule

Anesthetized rats were sham-irradiated or exposed to a γ-ray source (^{60}Co, 1 Gy/min). The radiation field was confined to the colorectum (field size: 2 by 2.5 cm). Radiation was delivered 3 times a week (4-Gy fractions) for a total dose of 16, 36, or 52 Gy. The cumulative doses of 16 and 36 Gy correspond nearly to one third and two thirds of the total fractionated dose (52 Gy), respectively. Radiation response was assessed on the first day after the cumulative dose of 16 and 36 Gy, and day 1 and day 3 of the cumulative dose of 52 Gy, and 26 wk after it reached 52 Gy.

Tissue isolation

After the rats were anesthetized, distal colon tissue in the irradiation field was excised and rinsed with saline. Whole-tissue samples were collected and fixed with 4% formaldehyde for immunostaining assays, while scraped mucosa layers were snap-frozen and then stored at -80℃ for RNA extraction.

PCR analysis

The mRNA levels of inflammation-related cytokines and chemokines and of the housekeeping gene hypoxanthine-guanine phosphoribosyltransferase (HPRT) were measured by real-time polymerase chain reaction (RT-PCR). Total RNA was extracted from the colon mucosa

samples with the RNeasy kit (Qiagen). RNA purity and integrity were checked by spectrophotometric analysis and agarose gel electrophoresis. In accordance with the manufacturer's instructions, 1 μg of total RNA was reverse-transcribed into cDNA with random hexamers and the SuperScript II RNase H (GibcoBRL) in a 20-μL reaction volume. SYBR chemistry (Applied Biosystems) was used to amplify PCR in the ABI-Prism 7000 detection system (Applied Biosystems), under the following conditions: 50℃ for 2 min, 95℃ for 10 min and 40 cycles at 95℃ for 15 s and 60℃ for 1 min. The primer sequences, designed with Primer Express software (Applied Biosystems), are listed in Table 1.

Immunoblot analysis

Total proteins were obtained by colon homogenization in a cold RIPA buffer (Sigma) containing a standard protease-inhibitor cocktail. Protein concentrations of cytoplasmic and nuclear extracts were measured with a modified Bradford method from Biorad Laboratories (Biorad, France). The samples were then stored at -80℃.

Proteins (25 μg) were boiled in SDS and mercapto-ethanol buffer and then separated on a 120 g/L polyacrylamide gel (NuPAGE gels; Invitrogen, France) and electroblotted. Polyvinylidene difluoride membranes were incubated with a blocking solution (50 g/L skimmed milk in TPBS containing 1 mL/L Tween 20), washed with TPBS and incubated with rabbit polyclonal STAT1 p84/p91 (1/700, Santa Cruz), STAT3 (1/300, Santa Cruz) and SOCS3 (1/200, Santa Cruz) for 1 h at room temperature. After washing, immunodetection was performed with the respective horseradish-linked secondary antibodies (1/1000; Santa Cruz). GAPDH protein was detected similarly with a rabbit anti-GAPDH polyclonal antibody (1/1000, Santa Cruz) to verify uniformity in gel loading. Chemiluminescence was detected according to the manufacturer's protocol (ECL, Biorad). Mean band densities were quantified with a Las 3000 apparatus (Fugifilm) and normalized to the total amount of protein in the control.

Immunostaining

Neutrophils and macrophages: Fixed distal colon specimens were dehydrated, embedded in paraffin and then sectioned into 5 μm thick slices. After dewaxing in xylene and rehydration by exposure to graded ethanols, sections were processed to reveal immunoreactivity to myeloperoxidase (MPO), a marker of neutrophils, or were prepared for macrophage detection. All sections were subjected to an endogenous peroxidase blocking solution (3% H_2O_2). For macrophage staining only, the slides were boiled in 10% citrate buffer for antigen retrieval. To reduce non-specific binding, all slides were pre-incubated with the protein blocker (Dako) before treatment for 1 hour at 26℃ with anti-rat MPO antibody (NCL-MYELOp; 1:300, Novocastra) or at 37℃ with an antibody binding the activated macrophage marker ED1 (MCA341; 1:50, Serotec). Secondary reagents were a secondary antibody, followed by the Vector Elite ABC kit (Dako) for neutrophil detection, and the LSAB 2 system HRP kit (Dako) for macrophages. Whenever necessary, slides were washed with a Tris buffer (50 mmol/L Tris-HCl; 0.3 mol/L NaCl; 0.1% Tween 20; pH 7.6). For both the primary and secondary staining, sections were treated with a NovaRED kit (Vector Laboratories Inc.) for color development, and then counterstained with Mayer's hemalum. For MPO staining, positive cells were counted under a light microscope in a blinded fashion and expressed as the mean number of marked cells per ten random crypts (100 crypts).

Apoptotic cell detection: Apoptotic cells were visualized by the terminal deoxynucleotidyltransferase (TdT)-mediated dUTP-biotin nick-end labeling assay (TUNEL) using the In Situ Cell Death Detection kit (Roche Molecular Biochemicals, France) according to the manufacturer's instructions. Briefly, deparaffinized and rehydrated tissue sections were incubated in proteinase K (20 mg/L in 10 mmol/L Tris-HCl, pH 7.6) for 10 min at 37℃. Sections were exposed to the TUNEL reaction mixture at 37℃ for 1 h. After washing in PBS buffer,

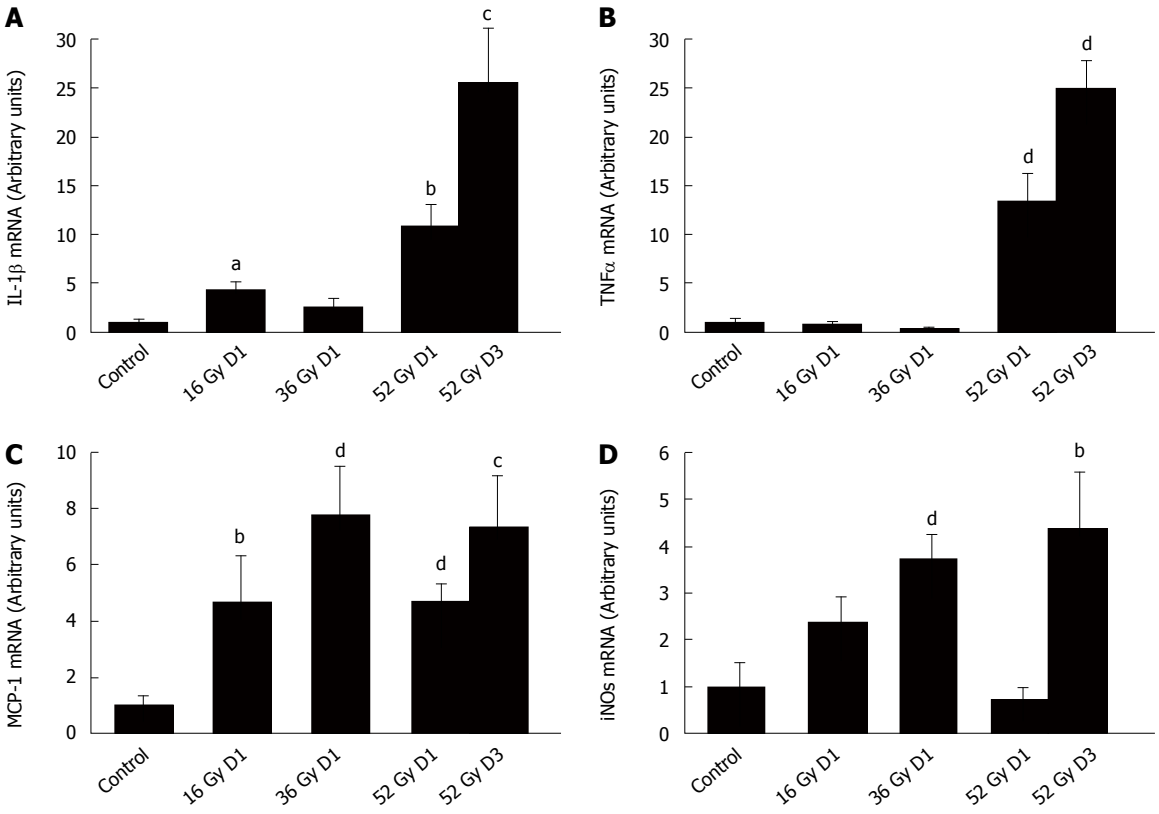

Figure 1 Effects of colorectal fractionated irradiation protocol on inflammatory mediator expression. Levels of IL-1β (A), TNFα (B), MCP-1 (C) and iNOS (D) mRNA were assessed in distal colon mucosa one day after cumulative doses of 16 Gy, 36 Gy, 52 Gy as well as 3 d after 52 Gy. The quantification of target genes was normalized to the reference gene HPRT. Data are mean ± SE, $^{a}P < 0.05$; $^{b}P < 0.01$; $^{c}P < 0.005$; $^{d}P < 0.001$ *vs* control.

POD (peroxidase) was added to react for 30 min at 37℃. For both stainings, the slides were treated with a NovaRED™ kit (Vector Laboratories Inc, Burlingame, CA) for colour development and counterstained with Meyer's hemalun.

Result expression and statistical analysis

For the real-time PCR, we used the comparative $\Delta\Delta C_T$-method for the relative mRNA quantification of target genes, normalized to the reference gene HPRT, and the relevant sham-irradiated sample. Specifically, we determined $2^{-\Delta\Delta CT}$, with $\Delta\Delta C_T$ the difference between $\Delta C_{T(\text{irradiated sample})}$ and $\Delta C_{T(\text{sham-irradiated sample})}$ and ΔC_T the difference between the mean $C_{T(\text{gene of interest})}$ and the mean $C_{T(\text{HPRT reference gene})}$. C_T is the threshold cycle of fluorescence intensity. Each experimental group consisted of 6 animals. Values of PCR and MPO-positive cell counts are expressed as the mean ± SE.

All data are expressed as the mean ± SE for 6 animals. Data were analyzed by one-way ANOVA followed by a Bonferroni test to determine the significance of the differences.

RESULTS

Pattern of inflammatory mediators during fractionated γ irradiation

Overexpression of pro-inflammatory cytokines is often a sign of the onset of inflammation and has been characterized as an early effect of intestinal radiation[5]. To test whether fractionated irradiation induces a persistent and progressive inflammatory process, we assessed the expression of inflammatory mediators, relative to the housekeeping gene HPRT, in rat colon mucosa on D1 in irradiated rats in all 3 dose groups (16, 36 and 52 Gy) and on D3 in the 52 Gy group. IL-1β expression increased by a factor of 4.5 ($P < 0.05$) on D1 after colorectal γ-irradiation to 16-Gy exposure, compared with controls. On the other hand, 24 h after the 36-Gy cumulative dose, IL-1β expression did not differ from that in the sham-exposed rats. Finally, after the 52-Gy dose, IL-1β mRNA rose to levels dramatically higher than in controls (11-fold, $P < 0.01$) on D1 and still higher (25-fold, $P < 0.005$) on D3 (Figure 1A). TNFα expression after the total 52-Gy dose was also 13.5 times higher than in controls on D1 ($P < 0.005$) and remained elevated at D3 ($P < 0.001$) (Figure 1B). Similarly, the level of MCP-1, known to recruit and activate monocytes and macrophages in tissue, increased significantly during the fractionated protocol (Figure 1C). In addition, the expression of iNOS, strongly secreted by macrophages, remained high throughout the protocol (Figure 1D).

Histology and assessment of inflammatory cell accumulation

Histological analysis of distal colons showed no distinct difference between the sham-irradiated group and the rats with cumulative doses of 16, 36, and 52 Gy.

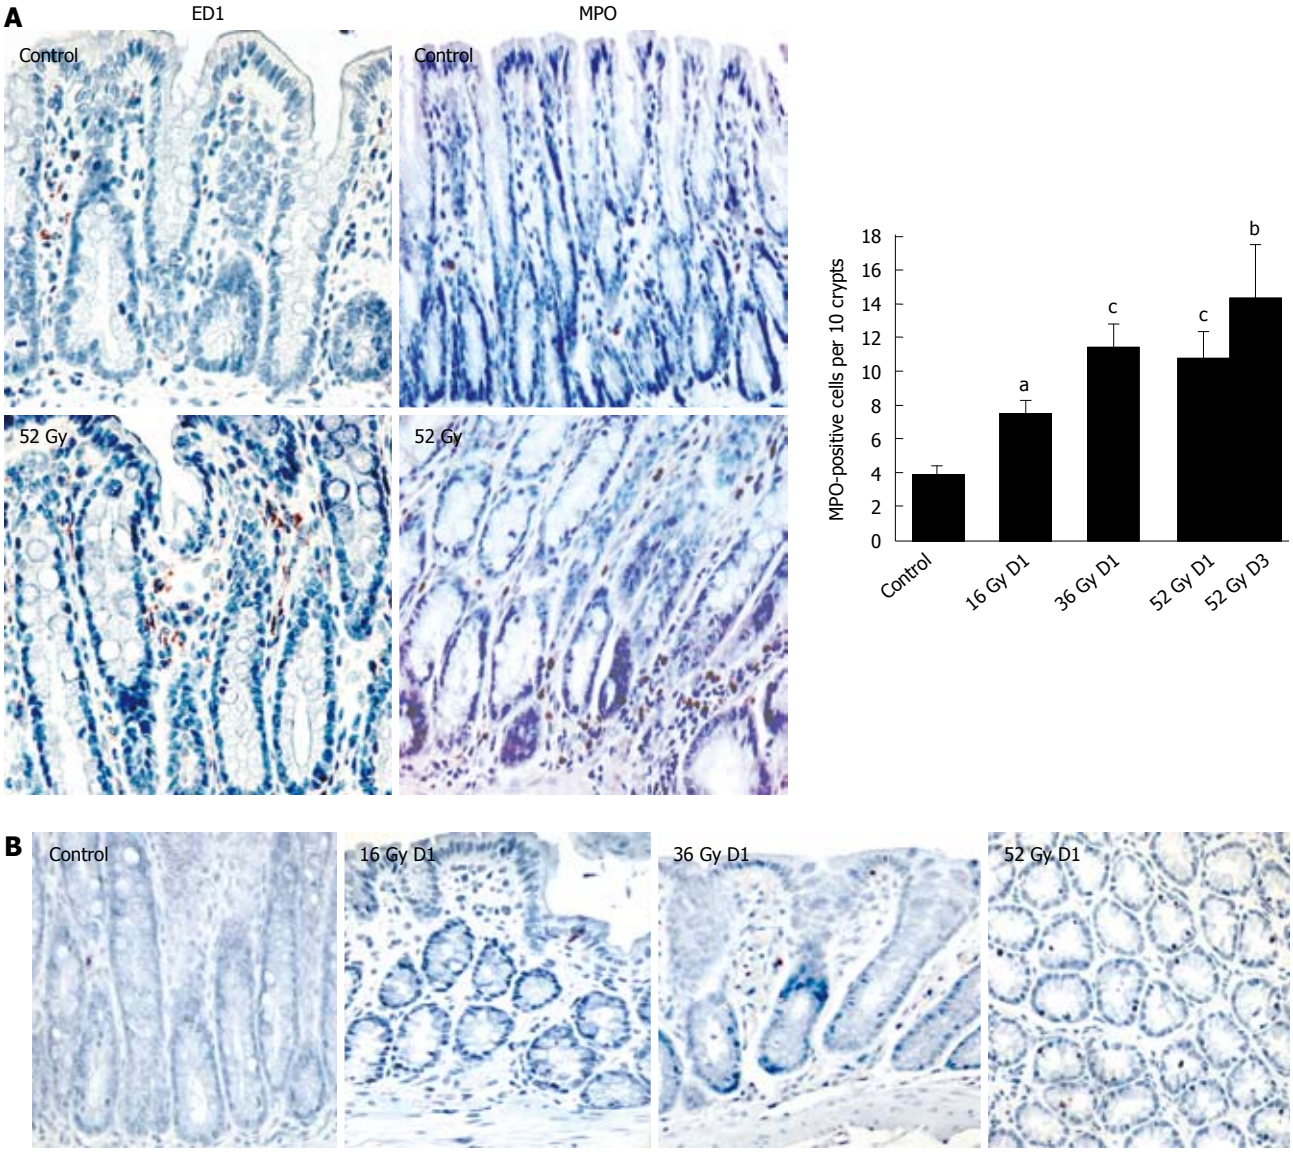

Figure 2 Effects of colorectal fractionated irradiation protocol on inflammatory cells and apoptotic cell presence. Recruitment of ED-1-positive and MPO-positive cells (A) was assessed in distal colon mucosa in the normal distal colon (control) and three days after cumulative doses of 52 Gy. MPO-positive cells were correlated with the average number of neutrophils one day after cumulative doses of 16 Gy, 36 Gy, and one day and three days after 52 Gy. The presence of apoptotic cells was confirmed by the terminal deoxynucleotidyltransferase (TdT)-mediated dUTP-biotin nick-end labeling (TUNEL) staining at each timepoint of the fractionated protocol (B). Data are mean ± SE, $^{a}P < 0.01$; $^{b}P < 0.005$; $^{c}P < 0.001$ *vs* control values. (× 20).

Immunostaining of macrophages showed an increase in ED1-positive macrophages in the lamina propria on D1 and D3 after the maximal cumulative dose of 52 Gy (Figure 2A). This macrophage accumulation may be related to the overexpression of TNFα, MCP-1 and iNOS. In addition, the number of MPO-positive neutrophils was nearly twice as high as in controls on D1 after the 16-Gy exposure ($P < 0.01$) and remained elevated throughout the protocol, about 3 times higher than in controls in the 36-Gy group ($P < 0.001$) and in the 52-Gy groups on D1 and D3 (Figure 2A). In addition, TUNEL assay showed no significant modification of the apoptotic cell number during fractionated irradiation (Figure 2B).

Imbalance of Th1/Th2-associated genes during fractionated irradiation

As previously reported[11], abdominal irradiation initiated a Th2-cell immune response characterized by suppression of IFNγ expression. Here too, we observed that fractionated irradiation induced a wave suppressing IFNγ expression, reducing it significantly (3-fold decrease, $P < 0.005$) (Figure 3A). This decrease was associated with reduction of IFN-inducible genes by the end of the protocol, including IFNγ-inducible 10 kDa protein (IP-10) ($P < 0.05$).

We measured Th cell populations present in the mucosa during the fractionated protocol more directly by taking into account the fact that activated Th cells acquire and maintain high levels of specific patterns of chemokine receptors: CXCR3 is thus a marker of Th1 and CCR4 of Th2[15]. Fractionated irradiation modified the chemokine receptor profile (Figure 3B). CXCR3 levels fell by 50% ($P < 0.05$) after a 16-Gy cumulative dose and 80% ($P < 0.01$) after a 36-Gy dose. The

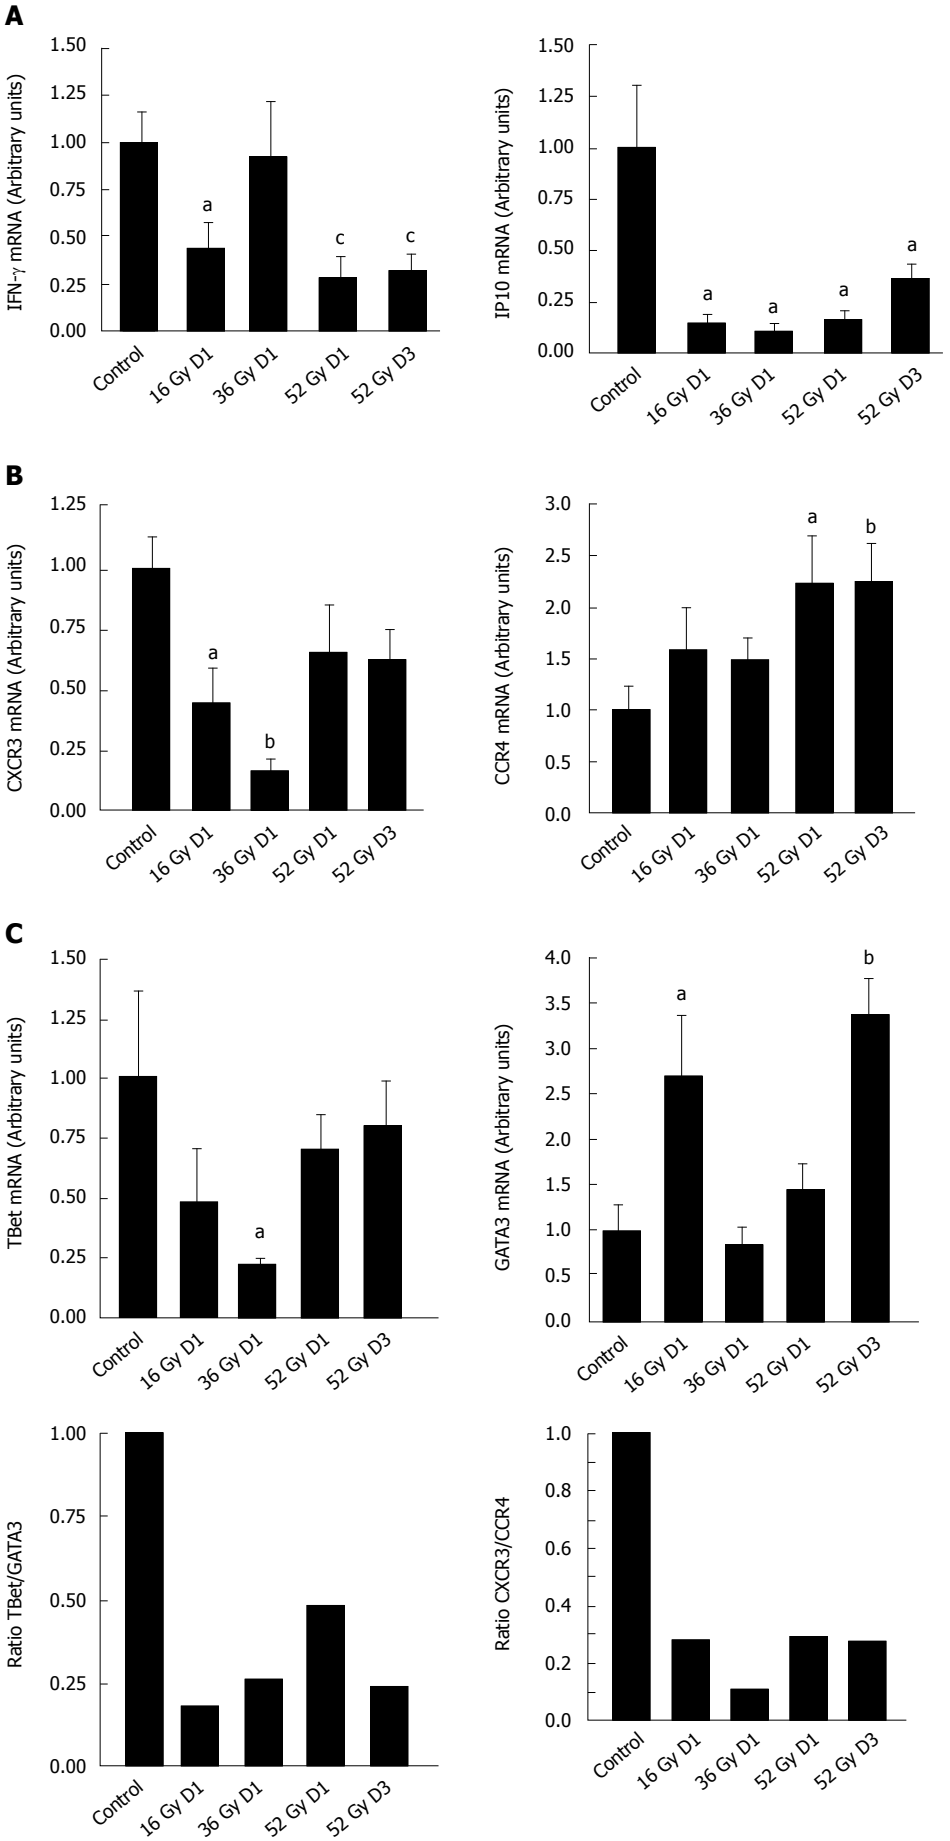

Figure 3 Early Th1/Th2 polarization by fractionated irradiation protocol within 1 and 3 d of irradiation. Colorectal fractionated irradiation protocol induced suppression of Th1 cytokines (IFNγ and IFN-inducible genes (IP-10)) (A). Gene expression of the chemokine receptors CXCR3 and CCR4 (B) and transcription factors T-bet and Gata3 (C) implicated in the Th1/Th2 balance was analyzed one day after cumulative doses of 16 Gy, 36 Gy, 52 Gy and 3 d after 52 Gy in colon mucosa. Data are mean ± SE, $^{a}P < 0.05$; $^{b}P < 0.01$; $^{c}P < 0.005$ *vs* control.

CXCR3 level remained low after a cumulative dose of 52 Gy, but CCR4 expression increased significantly ($P < 0.01$). The CXCR3/CCR4 ratio, which serves as an indicator of the Th1/Th2 balance[15], fell about

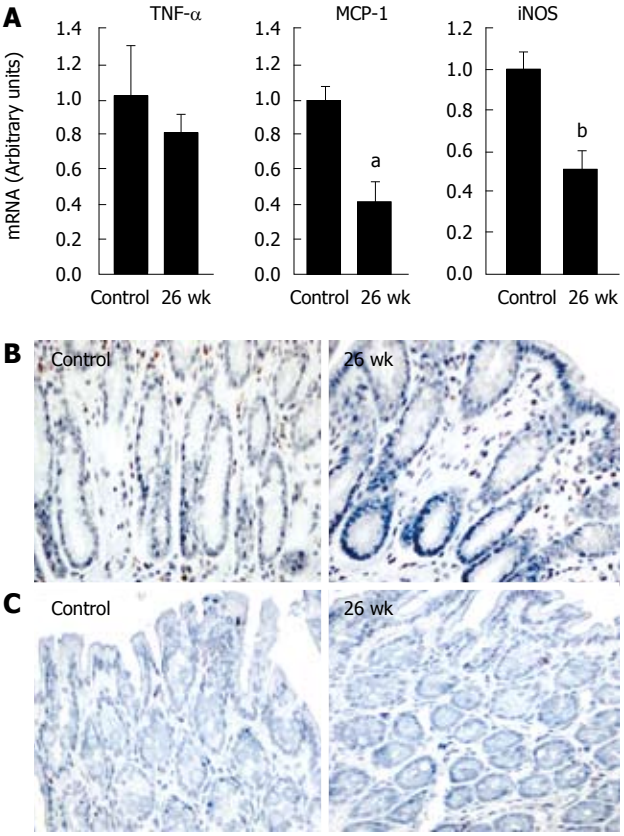

Figure 4 Long-term impairment of inflammatory response. Delayed effects of the radiation schedule on expression of TNFα, MCP-1 and iNOS in colon mucosa 26 wk after the end of cumulative dose of 52 Gy (A). The quantification of target genes was normalized to the reference gene HPRT. Immunostaining for macrophages (B) and apoptotic cells (C) in the colon: Fractionated irradiated group shows no intense ED1-positive macrophages in the lamina propria and no significant modification of the apoptotic cell number 26 wk post-irradiation. Data are mean ± SE, $^{a}P < 0.01$; $^{b}P < 0.005$ *vs* control.

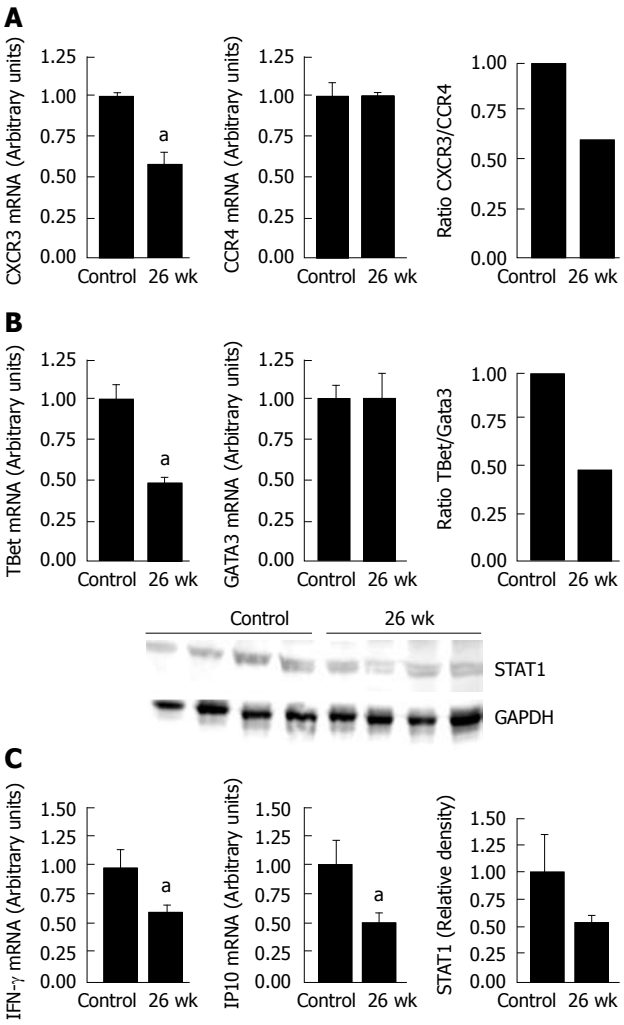

Figure 5 Persistence of Th2 polarization at 6 mo. Expression of chemokine receptors CXCR3 and CCR4 (A) and transcription factors T-bet and Gata3 expression (B) in colon mucosa was assessed 26 wk after the end of cumulative dose of 52Gy. Aspects of immune response that changed long after irradiation included IFNγ and IP-10 expression and downregulation of signal transducer and activator 1 (STAT1) (C). Immunoblot showing STAT1 in total protein extracts from mucosa colon. GAPDH levels are used as internal standards and relative densitometric data are analysed following normalization to the control. Dot plots of four experiments on different samples are shown. Data are the mean ± SE; $^{a}P < 0.05$ *vs* control.

70% during the course of treatment, thus confirming that irradiation induced Th2 dominance. Further confirmation comes from analysis of the transcription factors T-bet and GATA-3, respectively, selectively expressed in Th1 and Th2 cells. The T-bet profile closely resembled that of CXCR3 (Figure 3C). GATA-3 expression increased more than T-bet expression did at every period, and the ratio of T-Bet to GATA-3 ratio fell, decreasing 4-fold by the end of the protocol.

Long-term impairment of inflammatory response

Histological analysis of the colon 26 wk after the last delivered fraction showed no changes. To investigate the inflammatory response, we analyzed the expression of mediators related to macrophage infiltration. No change in TNFα expression was observed during this period. Surprisingly, however, expression of MCP-1 and iNOS decreased significantly, by 60 and 50% respectively. No increase in macrophage infiltration and no significant modification of apoptotic cell umber were observed at 6 mo (Figure 4).

Persistence of the imbalance in the immune response

The fractionated schedule may increase the probability that radiation-induced inflammation will become chronic and/or induce damage at intermediate times post-irradiation. No previous report has prospectively identified changes in the Th1/Th2 balance according to expression of chemokine receptors and transcription factors over time after irradiation. Analysis of the Th1 profile showed a significant 2-fold reduction ($P < 0.05$) in both CXCR3 and T-bet expression compared with the controls 26 wk after the end of the protocol (Figure 5A and B). Levels of CCR4 and GATA3 (both Th2 markers) did not change.

The consequence of the Th1/Th2 imbalance was seen in the significant reduction in IFNγ and IP-10 ($P < 0.05$): expression of both fell by half. Because IFNγ delivers signals through the STAT family of signal transducers, such as STAT1, we sought to determine if reduced IFNγ expression in irradiated mucosa was correlated with a reduction in STAT1. Western blot

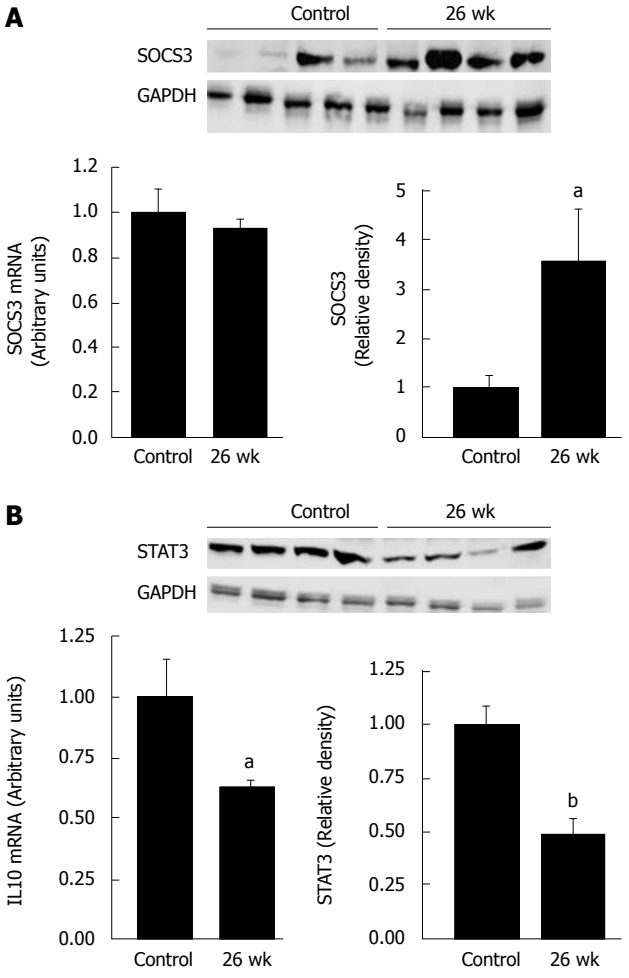

Figure 6 Fractionated irradiation-modified SOCS3, IL-10 and STAT3 expression. SOCS3 mRNA and protein (A), IL-10 mRNA and STAT3 protein (B) were measured in the colonic mucosa 26 wk after the end of cumulative dose of 52 Gy. Western blot analyses are showing SOCS3 and STAT3 in total protein extracts from mucosa colon. GAPDH levels are used as internal standards and relative densitometric data are analysed following normalization to the control. Dot plots of four experiments on different samples are shown. Data are expressed as the mean ± SE; $^{a}P < 0.05$; $^{b}P < 0.001$ *vs* control.

analysis showed that STAT1 immunoreactivity was also lower at 26 wk than in controls (Figure 5C). Taken together, these data indicate that the shift towards Th2 dominance is maintained 26 wk after irradiation.

Irradiation induced expression of SOCS3 and regulated expression of IL-10 and STAT3 in the long term

The relative decrease of STAT1 protein levels prompted us to investigate the possible role of the SOSC proteins, which inhibit STAT signaling. A particularly interesting candidate from this family is SOCS3, known to interfere with the IFNγ/Stat-1 pathway[19,20]. Western blot analysis showed the SOCS3 protein levels remained high at 26 wk after irradiation ($P < 0.05$) (Figure 6A). Because SOCS3 regulates production of the immunoregulatory cytokine IL-10 by modulating STAT3 signaling[21], we assessed IL-10 and STAT3 expression (Figure 6B). IL-10 expression ($P < 0.05$) 26 wk after the end of the protocol was half as much compared to the control rats and was correlated with a similar decrease in STAT3 protein levels ($P < 0.001$). These data show that elevated SOCS3 levels modify expression of IL-10 and STAT3.

DISCUSSION

The pathological process of radiation injury begins immediately after radiation exposure, but its clinical and histological features may not become apparent for weeks, months, or even years after treatment. In this study, we investigated whether fluctuations in cytokine levels after radiation treatment continue over a relatively long period 6 mo after the end of treatment, and whether they predict late effects. Identifying the critical factors could provide useful tools for selecting patients for treatment to prevent late damage or to reduce its severity. If we knew how early cytokine responses modify downstream late effects, we might be able to target cytokines for prevention. The results showed that each dose fraction influenced tissue inflammatory responses and led to long-term persistence of the immune imbalance.

Fractionated radiation produces a series of repeated insults to healthy tissues: these lead to inflammatory events that do not dissipate within 24 h, so that repetitive responses accumulate over the period of radiation therapy[22]. During our fractionated protocol in the rat, we identified inflammatory reactions in the colon induced by a cascade of inflammatory mediators, including IL-1β, TNFα, MCP-1, and iNOS, with levels and latency periods specific for each mediator. In addition, histological observations showed infiltration of inflammatory cells (macrophages and neutrophils). TNFα is known to be a key mediator of pathogenesis in a broad range of infectious and predominantly Th-mediated inflammatory diseases, possibly via macrophage induction of iNOS and thus NO synthesis. However, iNOS has also been shown to enhance induction of TNFα synthesis[23], contributing to local tissue destruction during the chronic inflammation that is one of the direct consequences of inflammatory processes. A previous study found a positive correlation between iNOS activity levels and disease severity in patients with ulcerative colitis, but this association is less clear in Crohn's disease[24]. The involvement of iNOS-derived NO in acute radiation syndrome is suggested by an increase in iNOS gene expression or enzyme activity in the intestines[25]. The present study revealed a biphasic pattern of iNOS expression: early overexpression during the fractionated protocol, followed by delayed suppression, seen at 6 mo. In particularly, iNOS regulates chemokine expression involved in leukocyte (especially neutrophil) trafficking: the absence of iNOS enhances lung inflammatory responses, associated with increased production of MCP-1 by endothelial cells and macrophages[26]. Reports about iNOS regulation of the production of this CC chemokine are contradictory. *In vitro* studies show that inhibition of endogenous NO synthesis by a NOS inhibitor increases MCP-1 levels in endothelial cells[27], whereas, in a rat model of pulmonary granulomatous inflammation, inhibition of NO production reduced MCP-1 expression[28]. Our results are consistent with the hypothesis that iNOS can regulate MCP-1 expression, because increased levels

of iNOS were associated with both increased neutrophil recruitment and MCP-1 expression during the fractionated treatment. Moreover, at a later phase, the expression of both iNOS and MCP-1 was cut in half. At this time, no explanation is given, but additional attention is being placed on macrophages, the essential iNOS producers that are inactivated with regard to inflammatory mediator production. A more general suppression is achieved with IL-10, but exposure to IL-4 or related cytokines initiates a so called "alternatively activated macrophage" or M2 macrophages[29]. These cells have distinct functional properties that integrate them into polarized type 2 responses, tissue remodeling and repair. These cells show diminished capacity to produced iNOS. Furthermore, the maturation stage of the macrophage population may be worth considering in the later phase.

The immunomodulatory activity of iNOS is reported to influence Th cell development and to downregulate the induction of Th1 responses, thereby promoting a Th2 response[30]. Multiple pathways appear to be involved in initiating the type 2 T-cell responses. Gu *et al*[31] reported an impaired Th2 response in MCP-1 knockout mice, thus demonstrating that MCP-1 is necessary for the generation of Th2 cells. A possible feedback loop for Th2 activation might be the production of IL-4 and IL-13 by Th2 cells: these cytokines stimulate MCP-1 production and lead to further recruitment of Th2 cells[13]. Our results corroborate previously published work reporting on the initiation of a Th2 response in the early phase of abdominal radiation[11]. In that study, we identified a Th2 response during the fractionated protocol. It included suppression of the Th1 cytokine profile, that is, of both IFNγ and the IFN-inducible gene IP-10. These are also identified by the specific pattern of chemokine receptors (CXCR3 and CCR4) and the specific transcription factors (T-bet and GATA-3), selectively expressed in Th1 cells and Th2 cells, respectively, that control the differentiation and the functions of these Th cell subsets. The correlation between the suppression of CXCR3 and T-bet observed in the present study also corroborates a previous report[32] that deletion of T-bet reduces CXCR3 expression: CXCR3 is both a direct transcription target of T-bet and the chemokine receptor of IP-10. IFNγ may act upstream of T-bet to drive CXCR3 expression[32]. Consequences of T-bet deletion include the failure of primary $CD4^+$ T cells generated under Th1 polarizing conditions to migrate to the site of inflammation because of defects in several specific mechanisms of the T-cell trafficking pathway. Surprisingly, suppression of CXCR3 and T-bet continued during the later phase, for reasons that we could not determine.

An essential role of STAT1 is the activation of Th1 production of T-bet and IFNγ. Analysis of the expression of IFNγ and STAT1 showed that the persistent suppression of the IFNγ/IP-10 was correlated with low STAT1 protein levels at 6 mo. Taken together, the low ratios of CXCR3/CCR4 and Tbet/Gata3, as well as the defective IFNγ/STAT1 expression, indicate a prolonged Th2 dominance 6 mo after irradiation. Experiments with STAT1 knockout mice have demonstrated the crucial importance of this protein for macrophage activation and NK cytolytic activity *in vivo*: as a consequence, these mice have elevated susceptibility to viral and bacterial infections[33,34]. The differentiation of the IFNγ-producing Th1 cells is crucial for the resistance to intracellular infections, notably by "alternatively activated macrophage" inactivation.

Some reports describe families of cytokines that induce inhibition of the STAT1 signal cascade, such as SOCS. SOCS3 impairs IFNγ-induced STAT1-dependent gene activation[35]. We recently showed that acute irradiation induces SOCS3 overexpression[36]. In this study, immunoblot analysis showed that the protein levels of SOCS3 remained high in the later post-irradiation phase. Berlato *et al*[37] reported that constitutive expression of SOCS3 diminishes the quantities of TNFα and NO produced by the transduced cells in response to LPS stimulation. Crespo *et al*[38] confirmed that SOCS3 inhibits transcription of the iNOS gene, apparently by suppressing interaction between STAT1α and IFNγ. SOCS3 might also block the signaling pathways required to activate the posttranscriptional mechanisms that regulate TNFα synthesis[39]. Thus, the low levels of MCP1 and iNOS and the unchanged amount of TNFα observed 6 mo after irradiation suggest a possible role for SOCS3 in the suppression of these genes.

Previous studies report discovered that IL-10 rapidly induces SOCS3 in a STAT3-dependent manner[40,41]. Because SOSC3 can negatively regulate responses to different activating cytokines and bacterial products, it is speculated that the anti-inflammatory action of IL-10 is due to induction of SOCS3[42]. Here, however, our analysis of the expression of IL-10/STAT3 signaling shows that the irradiation-induced SOCS3 overexpression was instead associated with suppression of IL-10 mRNA and STAT3 protein. Berlato *et al*[37] found previously that constitutive expression of SOCS3 can block the capacity of IL-10 to activate STAT3, and Kinjyo *et al*[43] showed that STAT3 is hyperactivated in SOCS3-deficient T cells during T cell differentiation.

The development and persistence of chronic inflammatory disorders such as inflammatory bowel disease can be induced by defects in IL-10 production or in STAT3 signaling molecules or by overexpression of SOCS3[44]. Accordingly, suppression of T-cell expression of SOCS3 and the identification of this protein intracellular target may be the mechanisms to introduce tolerance and thus prevent the immune dysregulation induced by radiotherapy protocols. These results raise the question whether the presence of Th2 immune cells in the intestines after irradiation (acute and delayed) may result from changes in the dynamics of lymphocyte recirculation, involving the alteration of the microvasculature and the presence of differential chemokines.

COMMENTS

Background

The use of radiation therapy to treat cancer inevitably involves exposure of normal tissues. Gastrointestinal symptoms after pelvic radiotherapy, which affect quality of life, are substantially more common than generally recognised and are frequently poorly managed. Patients may experience symptoms associated with damage to normal tissue during the course of abdominal therapy for a few

weeks after therapy or months or years later. In fact, it is not known what venet occurring at an early stage may predispose to significant changes later on.

Research frontiers

In this article, it is shown that immune mechanism alterations may assume greater importance during the early irradiation. Experimentally carried out in the rat model, fractionated irradiation modified the T helper cell polarization, as shown by Th1 cytokine (IFNγ) repression in the colon. This shift occurred *via* transcriptional regulation of the level of cytokine mediators, *via* modification of specific signal transducers of IFN signalling and a through the secretion of a feed-back inhibitor of Th1 polarization, thus potentiating the Th2 profile.

Innovations and breakthroughs

The major result is that the immunity alteration persisted in long term, i.e. after the end of the radiotherapy protocol. These data raise the question whether the post-irradiation Th2 polarization in the intestine (both acute and delayed) may result from changes in the dynamics of lymphocyte recirculation.

Applications

Although the irradiation-induced immune damage has not yet been studied in great detail, a good understanding of this immunity alteration and the relationship between acute and late effects may motivate clinicians to look more often at methods of decreasing tissue toxicity, thus contributing to ameliorate the patents' quality of life after radiotherapy. In radiotherapy, priority needs to be given to assessing simple methods of preventing bowel toxicity, without compromising the control of the tumor.

Peer review

The paper is technically well done and well written and presents novel data.

Abstract

AIM: To evaluate the use of web-based technologies to assess the learning curve and reassess reproducibility of a simplified version of a classification for gastric magnification chromoendoscopy (MC).

METHODS: As part of a multicenter trial, a hybrid approach was taken using a CD-ROM, with 20 films of MC lasting 5 s each and an "autorun" file triggering a local HTML frameset referenced to a remote questionnaire through an Internet connection. Three endoscopists were asked to prospectively and independently classify 10 of these films randomly selected with at least 3 d apart. The answers were centrally stored and returned to participants together with adequate feedback with the right answer.

RESULTS: For classification in 3 groups, both intra- [Cohen's kappa (κ) = 0.79-1.00 to 0.89-1.00] and inter-observer agreement increased from 1st (moderate) to 6th observation (κ = 0.94). Also, agreement with reference increased in the last observations (0.90, 1.00 and 1.00, for observers A, B and C, respectively). Validity of 100% was obtained by all observers at their 4th observation. When a 4th (sub)group was considered, inter-observer agreement was almost perfect (κ = 0.92) at 6th observation. The relation with reference clearly improved into κ (0.93-1.00) and sensitivity (75%-100%) at their 6th observations.

CONCLUSION: This MC classification seems to be easily explainable and learnable as shown by excellent intra- and inter-observer agreement, and improved agreement with reference. A web system such as the one used in this study may be useful for endoscopic or other image based diagnostic procedures with respect to definition, education and dissemination.

INTRODUCTION

The dissemination and teaching of image based medical technologies depend on adequate training. Mostly, medical doctors perform specific training by visiting experts. New information technologies, namely those based on the internet, may circumvent such difficulties at least at early phases of training.

Gastric cancer is the second most lethal cancer in the World. Early stages at diagnosis are related to better prognosis[1]. Minute flat non-invasive neoplastic lesions

(dysplasia)[2] may be found during screening programs (in Japan) or during the follow-up of patients with atrophic chronic gastritis (ACG) or intestinal metaplasia (IM)-the milieu where neoplastic changes develop[3-6]. However, for patients with lesions such as ACG or IM there is not a definite proposal for their management. The difficulty in proposing a guide of practice for the management of patients with atrophic chronic gastritis and intestinal metaplasia may be related to the fact that conventional endoscopy used in most studies shows a low reproducibility and poor relation with histology at diagnosing these diffuse mucosal changes and minute lesions of cancer[7,8]. For the last ten years, several studies considered magnification and high-resolution endoscopy in conjunction with chromoendoscopy for the diagnosis of precancerous[9-14] and neoplastic lesions[15-22], in the gastrointestinal tract. However, mostly authors focused on the validity assessment and rarely were reliability or the learning of each group description defined[16,17]. Furthermore, several classifications were defined and the need for standardization stressed[23]. In fact, aimed at improving the evaluation of patients with precancerous gastric conditions, our own group described a classification for the diagnosis of intestinal metaplasia and minute dysplastic lesions using magnification chromoendoscopy with methylene blue[17].

As part of a multicenter trial, the training of endoscopists and teaching of this classification was planned using a web-based system. This manuscript reports the feasibility of such a system for the learning and dissemination of endoscopic classifications.

MATERIALS AND METHODS

Study design

Three endoscopists (A, B and C), independently and blinded to other endoscopists' answers, were asked to prospectively classify 20 endoscopic videos of magnification chromoendoscopy using a web-based learning system, a hybrid system composed of a CD-ROM and a dynamic website connected to a database, aiming at classifying each video 6 times (1st to 6th time).

Endoscopic videos selection

Endoscopic videos were selected according to a modified version of a magnification chromoendoscopy pattern classification of gastric mucosa[17]. For video selection the records of magnification chromo-endoscopy with methylene blue (1%) using an Olympus Q240Z magnification endoscope (Olympus Corp., Tokyo, Japan), performed in a cohort of patients under follow-up at our institution, were used[6]. Videos were recorded using a S-Video interface wih a digital DVCAM Sony Recorder (DSR-20MDP, Sony, Tokyo, Japan). Endoscopic patterns were obtained using the maximum magnification power possible with this endoscope, defined according to differences in color and homogeneity: Group I definition was when the mucosa showed a regular mucosal pattern and no change in color after staining with methylene blue; Group Ⅱ if the mucosa presented a regular pattern and was stained in blue. Subgroup Ⅱ E, for areas of mucosa with blue irregular marks [initially (Dinis Ribeiro GIE 2003) called Ⅱ A] or blue round and tubular pits (Ⅱ B); and subgroup Ⅱ F when blue villi (formerly Ⅱ C) or blue small pits (Ⅱ D) were described in the observed mucosa; Group Ⅲ was the definition if neither a clear pattern nor a change in color (heterogeneous staining) were noticeable.

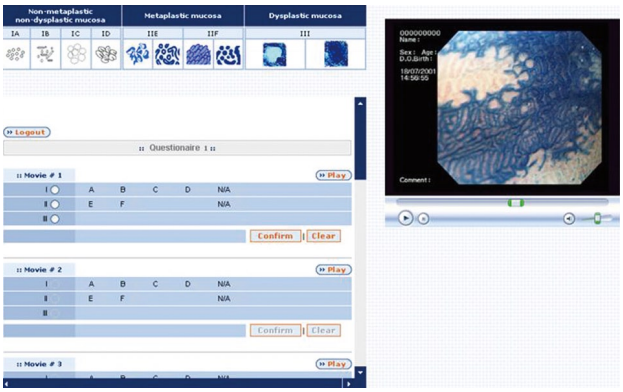

Figure 1 Graphical user interface for movie classification. The right frame is used to play a video clip loaded from the distributed CD; the left frame shows the patterns at the top and a form to retrieve user classifications.

Web-based learning system

The expected download time for each 5 s film (Windows Media Player video clips with 36 Mbytes) of about 120 min (at a 56 Kbits/s connection) and the user's physical location were instrumental in choosing the hybrid system architecture[24,25]. Using an Internet connection, a CD-ROM including all 20 selected endoscopic movies and an "autorun" file used to trigger a local HTML frameset (with two frames) referenced to the remote questionnaire on the classification of each film were developed for this project (on the left)[26]. The right frame was used to play the films stored on the CD-ROM (Figure 1). At the top, a schematic representation of each pattern was always visible.

Each endoscopist was asked to classify 10 videos randomly selected from the 20 videos included in the CD, with a minimum interval of 3 d. Before classifying each video, the user could run the film as many times as necessary before the decision was taken. After deciding, the user had to lock his answer in order to advance to the next question, not allowing subsequent videos to influence previous responses. After each questionnaire, ie for each 10 film sets classified, their answer or classification together with the proposed answer (to be used as reference, see below) was returned to participants. By this time, all videos included in that set could again be seen.

The HTML questionnaire was stored on an Oracle database using a PHP script. The web-server is run on RedHat Linux 7.2 (Enigma), Apache 1.3, PHP 4.0 compiled with GD Graphics Library 1.8 and Oracle 8 DBMS. Answers were centrally stored on an Oracle database using a Hypertext Pre-Processor (PHP) script.

Endoscopists

Endoscopists (M.A., P.A., R.S.) were invited to participate as they belonged to two different centers (POI

Table 1 Reproducibility for the classification in groups (Ⅰ *vs* Ⅱ *vs* Ⅲ) and in subgroups (Ⅰ *vs* ⅡE *vs* ⅡF *vs* Ⅲ) according to number of times observers (A, B and C) classified the films of magnification chromoendoscopy

Number of classification (nth)	Inter-observer agreement (95% CI)	
	Proportion of agreement	Weighted kappa
Classification in groups		
1st observation	0.60 (0.36-0.81)	0.52 (0.26-0.75)
2nd observation	0.85 (0.62-0.97)	0.73 (0.53-0.87)
3rd observation	0.85 (0.62-0.97)	0.71 (0.51-0.86)
4th observation	0.95 (0.75-1.00)	0.97 (0.94-0.99)
5th observation	0.80 (0.56-0.94)	0.71 (0.50-0.86)
6th observation	0.90 (0.68-0.99)	0.94 (0.89-0.98)
Classification in subgroups		
1st observation	0.45 (0.23-0.69)	0.49 (0.23-0.73)
2nd observation	0.55 (0.31-0.77)	0.69 (0.48-0.85)
3rd observation	0.45 (0.23-0.69)	0.66 (0.42-0.83)
4th observation	0.70 (0.46-0.88)	0.90 (0.81-0.96)
5th observation	0.60 (0.36-0.81)	0.66 (0.43-0.83)
6th observation	0.75 (0.51-0.91)	0.92 (0.84-0.96)

in Porto, and CUH in Coimbra) inclined to implement this technology, but with no previous experience of it or without previous participation in the development of the classification.

Statistical analysis

For each image, proposed classification (Group Ⅰ, Group Ⅱ, Subgroup ⅡE or ⅡF, or Group Ⅲ) was considered as if another observer would have classified it, and, also, as a reference classification or gold standard. This allowed us to consider both agreement and validity measures, respectively, in the evaluation of reproducibility and learning curve.

Inter-observer agreement and agreement with the reference agreement were estimated using different measures of agreement[27], simple proportions of agreement (Pa) and proportions of specific agreement, and quadratic weighted Cohen's kappa coefficient (Kc) (estimated by intra-class correlation coefficient)[28-33]. The confidence intervals for proportions of agreements were estimated with binomial distribution[33]. Strength of agreement was considered as follows: 0.01-0.2 slight, 0.21-0.4 fair, 0.41-0.6 moderate, 0.61-0.8 substantial, 0.81-1 almost perfect[34]. No bias was observed [McNemar test ($P = 1.0$); bias index (0.117, $P = 0.2891$)][35,36].

Estimates of sensitivity (Se), specificity (Sp) and validity were also calculated comparing the classification for each film against the proposed classified as reference. For classification in groups, true positives were defined if the observer correctly classified each film as group Ⅲ. For classification in subgroups, diagnostic positivity was considered in cases of Subgroups ⅡF and Ⅲ. These options and the decision to use weighted kappa coefficient were based upon the relation of these patterns with both dysplasia and incomplete intestinal metaplasia, named as being high-risk lesions for adenocarcinoma[4-6].

The learning curve was defined by visual analysis of a plot of both validity and agreement measures. Statistical estimates were performed with r-project v2.1.1, SPSS® and MedCalc®.

RESULTS

Reproducibility

Both classification in groups (Ⅰ *vs* Ⅱ *vs* Ⅲ) and subgroups (Ⅰ *vs* ⅡE *vs* ⅡF *vs* Ⅲ) showed substantial to excellent inter-observer agreement. In fact, at 6th observation, proportion of agreement is 0.90 and 0.75 respectively and weighted kappa is 0.94 and 0.94, respectively (Table 1).

As far as intra-observer agreement is concerned this was substantial in all observers, initially from first to second observation ($\kappa = 0.79$ to 1.00), and excellent from 5th to 6th observation (0.89 to 1) considering the classification in Groups (Ⅰ *vs* Ⅱ *vs* Ⅲ); and for classification in subgroups (Ⅰ *vs* ⅡE *vs* ⅡF *vs* Ⅲ), 0.74-0.85 to 0.75-1.00.

Specific proportions of agreement were also very high varying from 0.43, 0.79 and 0.82 (for groups Ⅲ, Ⅱ and Ⅰ, respectively) to 0.96, 0.92 and 0.92 (Ⅲ, Ⅱ and Ⅰ) at last classification. Concerning specific proportions of agreement, only a slight increase was observed from 0.50 and 0.50 (ⅡE and ⅡF) to 0.64 and 0.60 (at last observation).

Learning curve

An increase was observed in both proportions of agreement and kappa values, as far as agreement with original classification was concerned, from moderate to substantial/excellent in all observers (Table 2). Also inter-observer agreement varied from Kc = 0.52 or 0.49, respectively for groups and subgroups classification, from 1st to 6th classification (Figure 2). Excellent agreement was obtained by the 4th time for all observers irrespective of institution or time between classifications, by the time they had evaluated 80 videos.

Also, concerning validity measures, paired sensitivity and specificity of 100% were achieved at 4th classification for all observers, at 4th time for classification in groups and at 6th for classification in subgroups by observer A. Observers B and C achieved a validity of 0.85 and 0.90 at their 6th classification (Figure 2).

DISCUSSION

The concept of 'learning by doing' in invasive procedures such as endoscopy, even though current and acceptable, may be affected by the continuous research in this field leading to new endoscopes and gastrointestinal mucosal description availability.

In a preliminary form, we have described the feasibility of a hybrid approach of Internet and CD-ROM/DVD technology as a web-based education system[37]. Such desktop virtual reality systems[38] were described in several fields of knowledge[24,25] as recently in endoscopy by de Lange[39].

According to our study, the classification proposed is both easily explainable and learnable. The simplicity of this classification, the fact that it includes in the instrument description the phenomenon itself (i.e. intestinal metaplasia) and the feedback given to each observer at the end of a single classification[40,41] may

Table 2 Agreement with reference and validity measures for the classification in groups (Ⅰ *vs* Ⅱ *vs* Ⅲ) and in subgroups (Ⅰ *vs* ⅡE *vs* ⅡF *vs* Ⅲ) according to number of times observers (A, B and C) classified the films of magnification chromoendoscopy (95% CI)

justify the excellent results.

Learning curves for most procedures concern efficacy and time to achievement of such efficacy. For example, in surgical procedures how fast trainees achieve the ability to get surgery adequately performed without complications[42,43]. Also in endoscopy some reports use colonoscopy models[44] and endoscopic ultrasound fine needle aspiration[45] with similar methodology.

A single report exists on the learning curve for the diagnostic performance of endoscopy. Besides simplification of any visual categorization, Tung and Tagashi defined the need of a steep learning curve for magnifying colonoscopy. They used for that evaluation the evolution of validity measures, that is sensitivity, specificity and global accuracy. However, there is no one particular statistical procedure for learning assessment, to be named in diagnostic technologies outcomes as a measure of reality[46].

Diagnostic procedures are aimed at being both valid, ie to measure what they are supposed to. However, even though most studies concern validity assessment, reliability of a measure should be a condition to be verified before any other quality feature. For dichotomic, nominal or ordinal variables, proportion of agreement (Pa) or Kappa statistics may be used. Pa is easily acceptable and interpretable. However, it is not corrected to the amount of agreement that was expected by chance (Pe)[47]. With the aim of solving this problem, Cohen developed the named Kappa statistics (Kc); a method which takes into consideration the so-called agreement by chance. In ordinal variables, distance from total agreement may be weighted, either linearly or exponentially[48]. Therefore, kappa is a global index of agreement and easy to calculate. However, some concern has been raised by others[48,49]. Cohen's Kappa varies with the distribution of cases for each category, namely as far as the total number of cases or prevalence[50] and if unbalanced marginal totals is present. Additionally, bias can influence kappa's interpretation[51]. Therefore, some authors recommend the estimation of both prevalence

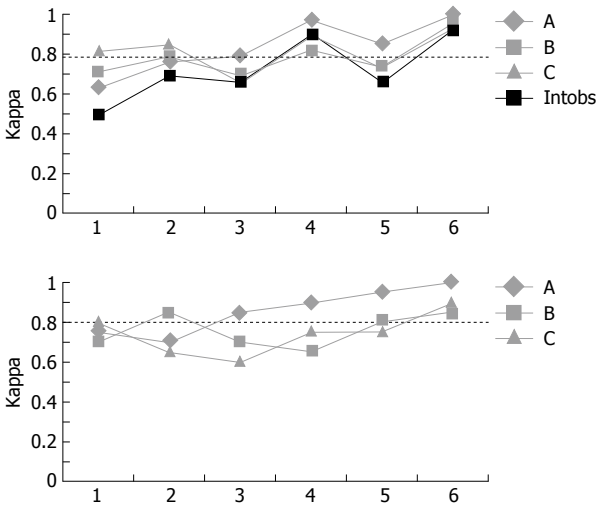

Figure 2 Variation of agreement with reference (Kappa) and inter-observer agreement (Black) (top graphic) and validity (bottom graphic) along sequential observations (1st to 6th) for the classification in subgroups [dashed line marks for 0.80 as the cutoff for almost perfect agreement (top graphic) and validity (bottom graphic)].

and bias adjusted kappa[35,36] and others advocate the use of either McNemar's test or the bias index (proportion of deviated ratings) to assess bias, following which Cohen's kappa could then be used. It seems reasonable to consider that both agreement measures (proportion of agreement and weighted Cohen's kappa) and validity measures. Thus, the proposed original classification could be considered either as the classification by a different observer and agreement with it by each observer would be evaluated for reliability or it may be considered as reference and common measures of validity would be used similarly to the paper of Tung and Tagashi.

In the present study, although 20 selected non-consecutive films were assessed, no observer bias was noticeable and the fact that all categories of classification groups were included for evaluation, may allow us, even though cautiously, to consider our classification of gastric mucosa both reliable and easily learnable.

The follow-up of patients with atrophic chronic gastritis and intestinal metaplasia[52,53] may lead to early diagnosis of gastric neoplastic lesions and improvement of patients' prognosis. Following the non-existence of distinctive symptoms[54-56], most authors based their studies (mostly) on morphologic evaluation through endoscopically performed multiple biopsies, because of the patchy characteristics of atrophic chronic gastritis and intestinalization of gastric mucosa[57-59]. However, with the exception of atrophic vascularization, most studies found that for conventional endoscopy, descriptions of 'gastritis' showed suboptimal validity[60-63] and unsatisfactory reliability[7,8,63].

New endoscopic methods are expected to optimise both the identification, in a (more) reproducible and valid measure for such lesions-'optic biopsy'. An increasing number of expert opinion texts, reviews and studies report the use of magnification chromoendoscopy through the gastrointestinal tract.

As far as colorectal lesions are concerned, in 1996 Kudo *et al*[15] defined a 7 patterns classification (type Ⅰ, Ⅱ, Ⅲs, ⅢL, Ⅳ, Vn, Vi) that showed consistently good sensitivity but highly heterogeneous results in its specificity[15,22]. Eight years have past and recently reproducibility was demonstrated[16], in an altered simplified three patterns classification with management consequences or prognosis implications: I and Ⅱ as non-neoplastic; ⅢL and IV as neoplastic; and Ⅲs and V as neoplastic possibly invasive.

However, in upper gastrointestinal tract, both for Barrett's mucosa and stomach mucosa, diverse classifications have been published and the need for their standardization stressed[23].

Endo *et al*[10] and Yagi *et al*[21] using methylene blue, Guelrud *et al*[12,14] and Toyoda *et al*[64] using acetic acid, and Sharma *et al*[13] using indigo carmine, described features of intestinal metaplasia and Sharma also reported endoscopic dysplasia. Good validity results were published by all authors, but Meining *et al*[11] showed a low inter-observer agreement, both for Endo and for Guelrud classifications (Cohen's kappa of 0.017 and 0.162).

In the stomach, our own group described the use of magnification chromoendoscopy with methylene blue for the diagnosis of intestinal metaplasia and gastric epithelial dysplasia in 2003. We subsequently found that a substantial agreement was observed on the classification of endoscopic images into groups (Ⅰ, Ⅱ, or Ⅲ), both for intra-observer (Pa = 0.91, Kc = 0.86) and for inter-observer agreement (Pa = 0.84, Kc = 0.74)[17]. Hereby, the stomach size and the presence of inflammation were considered limitations for chromoendoscopy and particularly for magnification[65].

However, concurrent results by others working in the field of gastric mucosa were consistent with ours. Recently, Yagi *et al*[66] described aspects for normal antral mucosa and for gastritis with H pylori similar to our group Ⅰ. Also Yang types A through D[67] and Kim types 1 through 3[18] may be compared with our group classification as Group Ⅰ. Furthermore, Kim's type 4 and Yang types D and E are very similar to Subgroups ⅡE and ⅡF. Tajiri *et al*[19,20] stressed that this procedure may have marked impact in the diagnosis of minute neoplastic flat 'gastritis-like' lesions and they described very similar features to our own research group's Group Ⅲ or pattern-less.

This means that, as with Kudo's classification in the colon, the existence of a unique and standardized classification for magnification chromoendoscopy (both in Barrett's and in the stomach) may have contributed to the dissemination of this technique and further use in even newer technologies.

In conclusion, a modified version of our classification for gastric mucosa diffuse changes and minute dysplastic lesions seems to be reliable and easily learnable. The web-based system hereby developed can be used for new diagnostic technology teaching and dissemination and for assessing the similarity between our own and other classifications, with the aim of the achievement of consensus.

ACKNOWLEDGMENTS

This project and preliminary results were presented in a Poster Session at the 8th Annual World Congress of the Internet and Medicine (MedNet), Geneva, Switzerland (2003), published as an abstract in the *Int J Health Care Engineering* 2003; 11: 371-372, in a Poster Session at Digestive Diseases Week in Chicago in May 2005 and published in Gastrointestinal Endoscopy as an abstract.

COMMENTS

Background

Dissemination and teaching of image-based medical technologies depend on adequate training. Mostly, medical doctors perform specific training by visiting experts. New information technologies, namely those based on the internet, may circumvent such difficulties at least at early phases of training.

Research frontiers

Concerning digestive endoscopy, several studies addressed and derived classifications for endoscopic descriptions of precancerous and neoplastic lesions in the gastrointestinal tract. Web-based systems could also be used in this setting for dissemination and training.

Innovations and breakthroughs

As part of a multicenter trial, the training of endoscopists and teaching of this classification were planned using a web-based system. This manuscript reports the feasibility of such a system for the learning and dissemination of endoscopic classifications.

Applications

Similar systems could be used in other areas of medical technologies based on image. Furthermore, similar methodologies could even go further by gathering clinical data, other technologies could be used in medical decision analysis.

Peer review

This manuscript specifically addresses a new evaluation of the reliability of a classification for magnification chromoendoscopy. It describes the feasibility of a web-based system to be used as part of endoscopists' training in learning new technologies.

Abstract

AIM: To investigate the molecular events involved in liver regeneration following subtotal hepatectomy (SH) as previous studies have largely focused on partial hepatectomy (PH).

METHODS: Male Wistar rats were subjected to 70% PH or 90% SH, respectively, and sacrificed at different times after surgery. Untreated and sham-operated animals served as controls. Serum and liver samples were obtained to investigate liver function, apoptosis (TUNEL assay) and transcription factors (NF-κB, Stat3; ELISA) or cytokines (HGF, TNF-α, IL-6, TGF-α, TGF-β; quantitative RT-PCR) involved in liver regeneration.

RESULTS: Serum levels of ALT and AST in animals with 70% PH differed significantly from sham-operated and control animals. We found that the peak concentration 12 h after surgery returned to control levels 7 d after surgery. LDH was increased only at 12 h after 70% PH compared to sham. Bilirubin showed no differences between the sham and 70% resection. After PH, early NF-κB activation was detected 12 h after surgery (313.21 ± 17.22 ng/mL), while there was no activation after SH (125.22 ± 44.36 ng/mL) compared to controls (111.43 ± 32.68 ng/mL) at this time point. In SH, however, NF-κB activation was delayed until 24 h (475.56 ± 144.29 ng/mL). Stat3 activation was similar in both groups. These findings correlated with suppressed and delayed induction of regenerative genes after SH (i.e. TNF-α 24 h postoperatively: 2375 ± 1220 in 70% and 88 ± 31 in 90%; IL-6 12 h postoperatively: 2547 ± 441 in 70% and 173 ± 82 in 90%). TUNEL staining revealed elevated apoptosis rates in SH (0.44% at 24 h; 0.63% at 7 d) compared to PH (0.27% at 24 h; 0.15% at 7 d).

CONCLUSION: The molecular events involved in liver regeneration are significantly influenced by the extent of resection as SH leads to suppression and delay of liver regeneration compared to PH, which is associated with delayed activation of NF-κB and suppression of proregenerative cytokines.

INTRODUCTION

Major hepatectomy is primarily used to treat malignant

liver disease and in living donor liver transplantation (LDLT). After resection the remaining liver can regenerate to a fully functional organ[1-3]. Tissue damage due to the surgical process further decreases the amount of healthy remnant liver tissue leading to an additional reduction in functional liver capacity in the postoperative period[4,5]. This situation can lead to liver insufficiency and, ultimately, to liver failure and death[6-8]. Therefore, patients have to fulfil certain criteria, such as the absence of end-stage liver disease, in order to be eligible for extended hepatectomy[1].

The same is true for donors in LDLT. While LDLT is a life saving procedure for the recipient, it is a potentially lethal operation for the donor. Therefore, very stringent criteria have to be fulfilled prior to hepatectomy to ensure donor safety[9-11]. For the donor, fast liver regeneration is imperative to reduce the probability of liver insufficiency[12,13]. Thus, an improvement in regenerative capacity would enhance donor safety and increase the possibility of including individuals who are not eligible for donation due to insufficient liver size[8,14].

As already stated the major concern in major hepatectomy or in the LDLT setting, is efficient regeneration of the remnant or transplanted partial liver, respectively. It has been demonstrated that graft size is of high importance in regenerative processes in the recipient[12]. Liver function parameters and regeneration are significantly better in patients undergoing a small resection than in patients undergoing a liver resection of more than 60%[15]. This effect exceeds a linear size correlation, which led to the conclusion that graft or remnant liver size influences regeneration. The underlying molecular mechanisms, however, are not well understood[16-19]. In particular, the role of proregenerative cytokines (e.g. IL-6 and TNF-α) and the role of transcription factors such as NF-κB are ambiguous[5,20-22].

While previous studies have largely focused on the molecular events after partial hepatectomy, the aim of this work was to investigate liver regeneration after subtotal hepatectomy. We analyzed whether the extent of liver resection has an impact on the activation of transcription factors and the expression of pro- and anti-regenerative cytokines using a rat resection model and compared 70% (partial hepatectomy, PH) and 90% resection (subtotal hepatectomy, SH), respectively.

MATERIALS AND METHODS

Resection

Six to eight-week-old male Wistar rats were anaesthetized with isoflurane. Seventy percent PH and 90% SH were performed under isoflurane anesthesia as described by Higgins *et al*[23] and Emond *et al*[24]. The rats were divided into 4 groups: control group (untreated), sham operation, 70% PH and 90% SH. Serum and liver tissue samples were obtained during surgery and 2 h, 12 h, 24 h, 48 h, 72 h and 7 d after resection (n = 4 at each time point, per group).

ALT, AST, LDH and bilirubin

Serum concentrations of liver related enzymes (ALT, AST, LDH and bilirubin) were assessed using commercially available enzyme activity tests [ALAT (GPT) FS (IFCC mod.); ASAT (GOT) FS (IFCC mod.); Bilirubin Auto Direct FS; LDH FS IFCC; DiaSys Diagnostic Systems; Holzheim, Germany].

Liver to body weight ratio

After the observation period, the remnant, regenerated liver was resected and weighed (A) and total body weight (B) was measured. The acquired data were expressed as a percentage of the ratio between the remnant liver weight divided by the total body weight multiplied by 100. Liver body weight ratio (LBW-r, %) = A/B × 100.

RNA isolation from liver tissue

Samples of liver tissue (approximately 2-5 g) were placed in 5 mL Trizol and homogenized with an Ultra Turrax (Janke & Kunkel, Staufen, Germany). One mL aliquots of the homogenized samples were used for RNA isolation using chloroform. RNA precipitation was performed using 100% isopropanol. The dry RNA pellet was resuspended in 100 μL Rnase-free water and purified with Rneasy® Mini Kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions. RNA concentration in the samples was measured by OD 260, purity was determined by OD 260/280.

Protein isolation

Samples of liver tissue (approximately 2-5 g) were placed in 3 mL lysis buffer (10 mmol/L HEPES, 10 mmol/L NaCl, 0.1 mmol/L EDTA, 1 mmol/L DTT, 0.4% NP-40) and homogenized with an Ultra Turrax. One mL aliquots of the homogenized tissue were centrifuged at 4℃, 800 *g* for 5 min. Supernatants were centrifuged again at 4℃, 20 000 *g* for 30 min and the protein concentration was measured using a Bradford assay (BioRad, Munich, Germany). This fraction was referred to as the cytosolic fraction. The pellet obtained by centrifugation was resolved in 350 μL extraction buffer (20 mmol/L HEPES, 400 mmol/L NaCl, 1 mmol/L EDTA, 1 mmol/L DTT, 0.2% NP-40) and repeatedly vortexed over a 30 min period. After centrifugation at 4℃, 20 000 *g* for 20 min, the supernatant was collected and the protein concentration measured with the Bradford assay. This fraction was referred to as the nucleic fraction. Proteinase inhibitors (Complete Mini EDTA free, Roche) were added to the extraction and lysis buffers 30 min prior to use.

Quantitative real-time PCR

Changes in mRNA expression were analyzed by quantitative real-time RT-PCR using the iCycler system (Bio-Rad, Munich, Germany). RT-PCR was performed with the QuantiTect SYBR Green RT-PCR kit (Qiagen, Hilden, Germany) to determine the cytokines involved in liver regeneration (TNF-α, IL-6, HGF, TGF-α, and TGF-β; Quantitect Primer Assays, Qiagen, Hilden,

Germany). Each PCR was performed using a total 30 μL volume of a mixture containing 2 μL of total RNA (20 ng to 200 ng). Beta-actin expression was chosen for normalization. The quantification was performed using the Pfaffl method[25] by calculating copy numbers from the ct-value for each gene per sample. Beta-actin mRNA levels were calculated in the same manner and the relation of target gene copies/100 000 copies of β actin are given. The data are shown as the mean of four separate experiments.

ELISA

NF-kappaB (NF-κB p65 ELISA KIT, BioSource™ CA, USA), and STAT3 [STAT3 (pY705) ELISA KIT, BioSource™, CA, USA] ELISAs were conducted according to the manufacturer's instructions. Negative and positive controls were included and a standard curve was determined for each assay. Sample size of the nucleic protein extract was 10 μL. Normalization was carried out by calculating relative protein concentrations.

TUNEL staining

Sections of paraffin-embedded tissue were dewaxed by heating to 60℃ for 30 min and subsequent washing in xylene. The slices were rehydrated through a grade series of ethanol (100%, 90%, 70%), permeabilized with permeabilization solution (0.1% Triton X-100, 0.1% sodium citrate) and washed twice in PBS. Positive controls were incubated with DNase I for 10 min at room temperature prior to labeling. TUNEL reaction mixture was prepared according to protocol (*In Situ* Cell Death Detection Kit, Fluorescein; Roche, Germany). Labeling was conducted as described in the assay manual, samples were subsequently embedded in ProLong® Gold antifade reagent with DAPI (Invitrogen, CA, USA). Labeled cells per 10 fields of vision were counted on a fluorescence microscope and absolute numbers were compared.

Statistical analysis

Data are shown as mean ± SE. Differences between any two groups were determined by the Wilcoxon test for ELISA, qrt-PCR, TUNEL-assay and bilirubin. $P < 0.05$ was considered to be statistically significant. For differences between any two groups regarding the serum parameters ALT, AST and LDH the variance test was used and $F < 0.05$ was considered statistically significant.

RESULTS

Liver regeneration

The overall mean LBW-r was 4.06% ± 0.35% in control and sham-operated animals. After 70% resection, animals showed a continuous increase in LBW-r over 7 d starting from 0.74% ± 0.06% at the time of surgery, and reaching 2.70% ± 0.15% 7 d postoperatively. The earliest significant increase in LBW-r occurred between 2 h (0.88% ± 0.15%) and 12 h (1.39% ± 0.07%) with $P = 0.006$ (Figure 1).

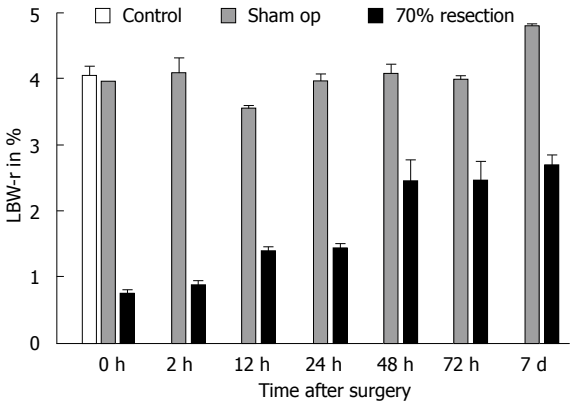

Figure 1 Liver-body-weight-ratio of control animals, sham-operated and 70% resected animals given in g per 100 g body weight. Controls had a LBW-r of 4.04% ± 0.15%.

Serum levels of liver enzymes

AST and ALT were significantly raised in the 70% resected animals compared to sham-operated rats (Figure 2A and B). Peak levels were found for both enzymes at 12 h postoperatively (AST, 12 h: 1055 ± 55 for 70% and 2204 ± 739 for 90%, $F = 0.011$; ALT, 12 h: 753 ± 110 for 70% and 1706 ± 725 for 90%, $F = 0.011$). Serum levels of both enzymes diminished over time, reaching control levels 7 d after surgery. LDH after 70% resection did not differ significantly from sham animals except at 7 d postoperatively (Figure 2C). LDH 7 d after 70% resection was 2060 U/I while the level in sham-operated animals was 890 U/I ($F = 0.033$). Seventy percent resection did not lead to a significant increase in bilirubin serum levels when compared to sham-operated animals (Figure 2D).

NF-κB activation

As described in the literature, NF-κB activation was observed after PH during the early phase of regeneration (0 h: 273.33 ± 24.45 pg, $P = 0.024$; 2 h: 285.34 ± 36.49 pg, $P = 0.009$) and 12 h postoperatively (313.21 ± 17.22 pg, $P = 0.001$). NF-κB remained activated until 7 d after surgery in this group. After SH, however, NF-κB activation was delayed until 24 h after the operation. NF-κB was significantly activated in the SH group 24h after surgery (475.66 ± 144.29, $P = 0.048$) with a peak at 48 h (747.18 ± 146.36 pg, $P = 0.02$). NF-κB activation was comparable in both groups at day 7 (Figure 3A).

STAT3 activation

Because we utilized a STAT3(pY705) ELISA, only phosphorylated STAT3 was measured in the assay.

Activation of STAT3 occurred during surgery in both the 70% (16-fold) and 90% (3-fold) resections. Two hours after surgery, STAT3 activation increased significantly in the PH (138-fold) and in the SH group (197-fold), decreasing thereafter and reaching preoperative levels 24 h after surgery. The differences between the two groups did not reach statistical significance (Figure 3B).

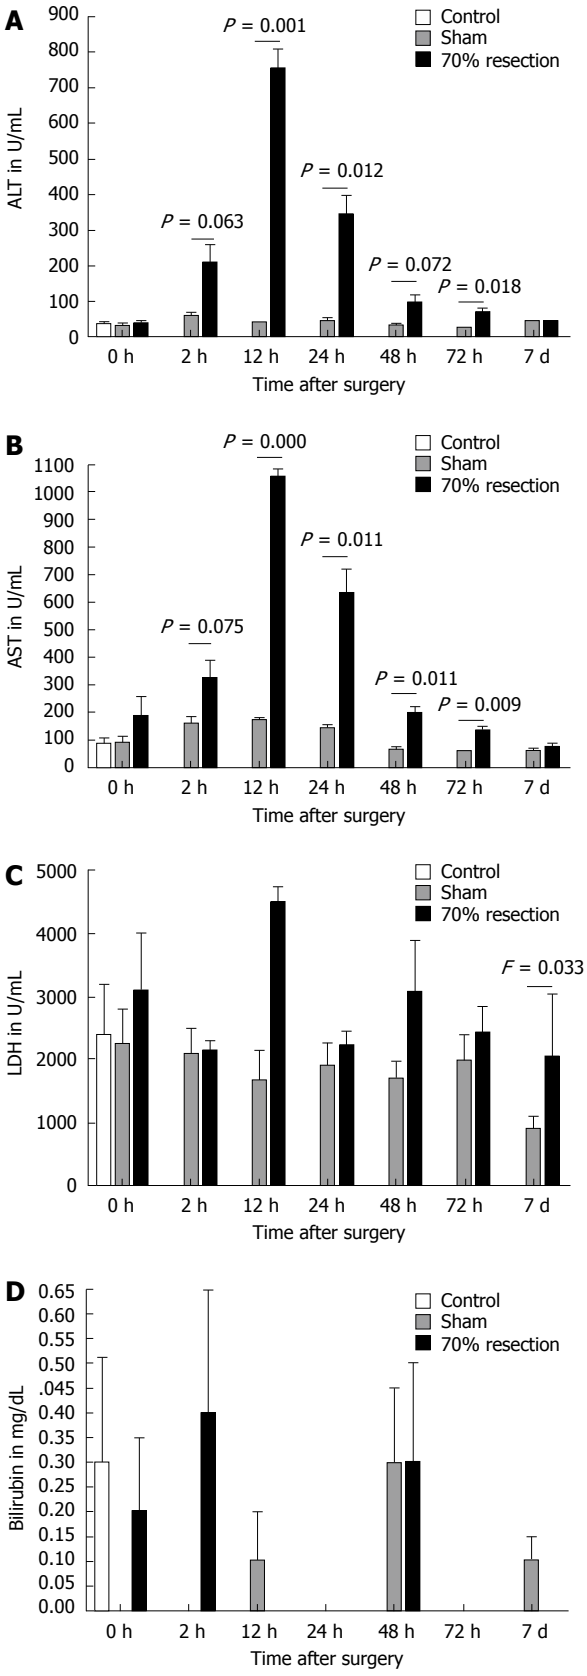

Figure 2 Serum levels of liver related enzymes, each given in U/L and mg/dL for bilirubin, respectively. A: ALT, base level in serum was 36.2 ± 5.2 U/mL; B: AST in controls was 84.0 ± 31.1 U/mL in serum; C: LDH, basal release of LDH into serum was 2416 ± 1088 U/mL; D: Bilirubin, with a baseline serum level of 0.3 ± 0.3 mg/dL.

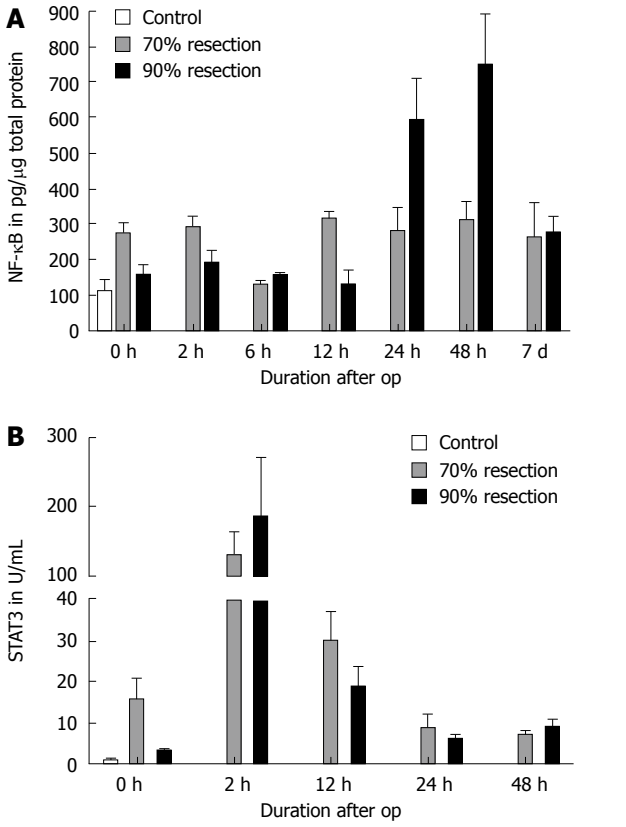

Figure 3 ELISA results of nucleic protein extracts. A: Active NF-κB. Baseline activation was 111 pg/μg total protein; B: Phosphorylated STAT3 (tyrosine 705) in total cellular protein. Activation in control animals was 4.5 U/mL. Protein was isolated from regenerating rat liver after 70% or 90% resection, respectively, at different time points after surgery. All data are normalized to an internal standard and are shown as mean values of four separate experiments. Significance is given *versus* control group.

Expression of pro- and anti-regenerative cytokines

In the group with 70% PH, 6 h after resection a rise in TNF-α expression was detected compared to controls, reaching a maximum after 24 h and decreasing thereafter to preoperative levels. In contrast, a significant rise in TNF-α expression was not detected after SH (Figure 4A). For IL-6, a biphasic expression pattern occurred in PH with high levels of expression at 2 h and 12 h postoperatively, while after SH a significant upregulation was only detected at 2 h after surgery (Figure 4B). Postoperatively, HGF expression increased steadily reaching a maximum at 12 h after surgery and returning to preoperative levels after 24 h in both groups (Figure 4C). A significant increase in early postoperative TGF-α expression was only detected after PH (12 h). At later time points, TGF-α expression was downregulated in this group while it increased up to 7 d after resection in SH (Figure 4D). We detected a slight upregulation in TGF-β expression in both resection groups at early time points (2 h, 6 h) with a strong peak at 12 h postoperatively which was detectable only in the PH group (8.25-fold compared to controls). Thereafter, TGF-β expression returned to control levels (Figure 4E).

Apoptosis

Control animals had a TUNEL index (percentage of TUNEL-positive cells) of approximately 0.12%. After PH, the rate of apoptosis reached a peak directly after surgery (0.44%), followed by a decrease to 0.27% at 24 h

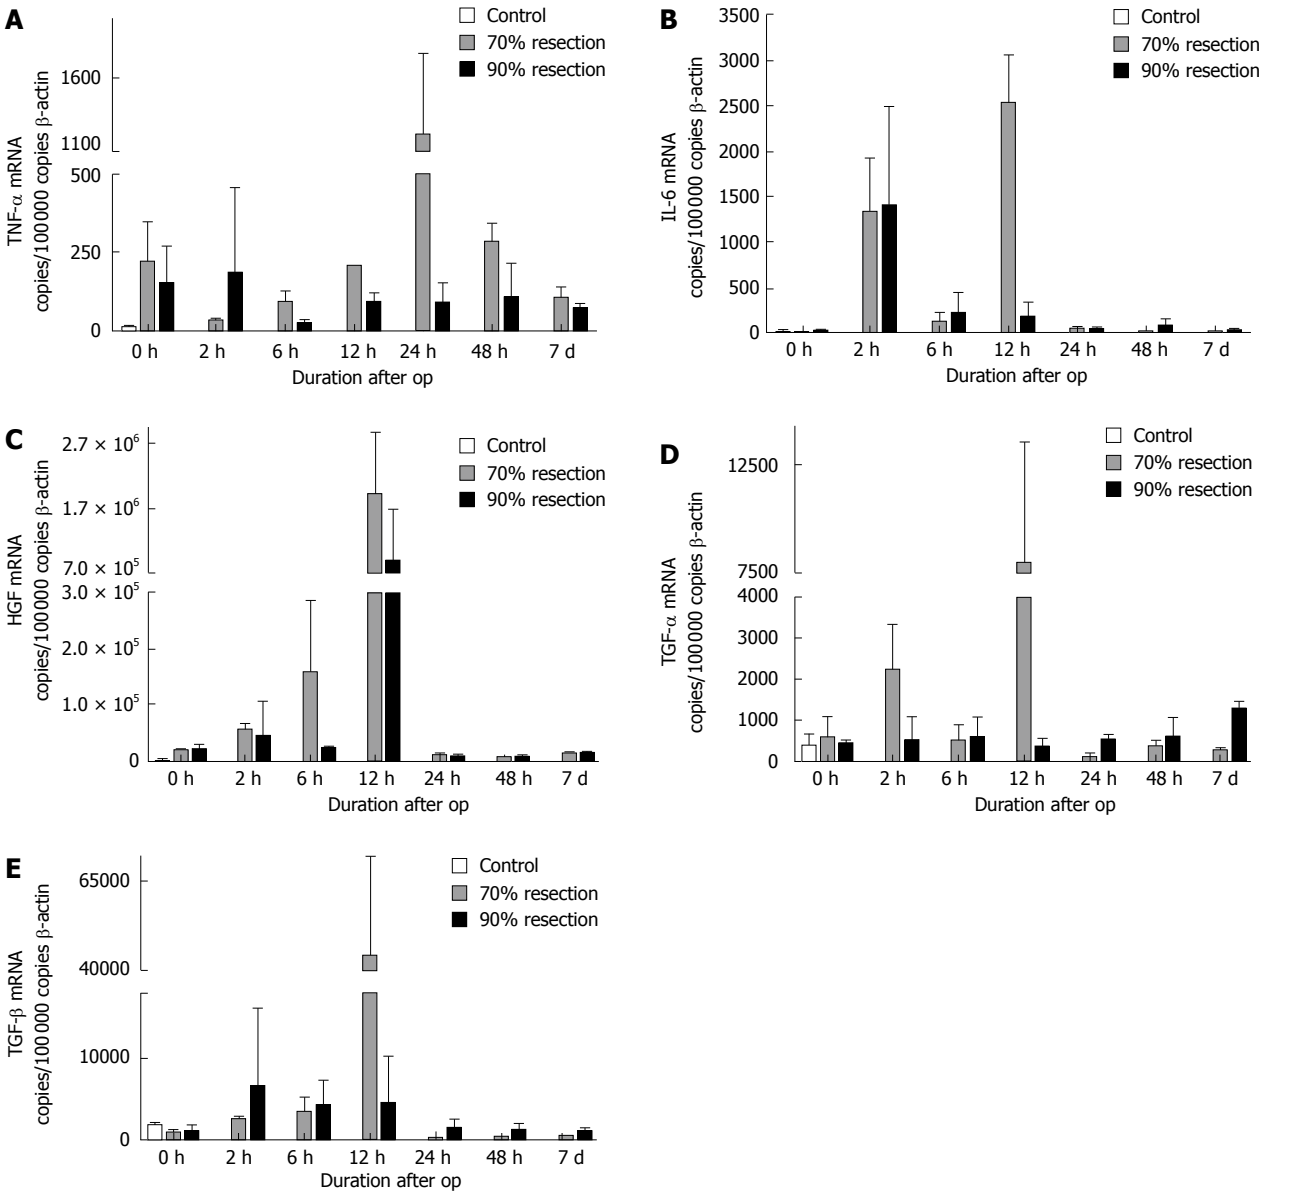

Figure 4 mRNA was isolated from regenerating liver tissue of rats at different time points after 70% or 90% resection, respectively. A: TNF-α (< 50 copies/100 000 copies β-actin); B: IL-6 (< 15 copies/100 000 copies β-actin); C: HGF (50 000 copies/100 000 copies β-actin); D: TGF-β (< 2500 copies/100 000 copies β-actin); E: TGF-β (< 5500 copies/100 000 copies β-actin). Measurement of cytokine and growth-factor expression was performed by quantitative real-time (rt) PCR. Copy numbers of each gene were calculated from ct values. Data shown are the mean of four separate experiments with standard error of mean. All statistical significances were calculated against control animals. Baseline expression of each gene is given in parentheses.

and to 0.20% at 48 h and returned to control levels at 7 d (0.15%). After SH, however, the apoptotic peak was delayed until 24 h after surgery, declining to 0.18% at 48 h. In contrast to PH, a second apoptotic peak (0.63%) was detected at 7 d in this group (Figures 5 and 6).

DISCUSSION

In this study, we analyzed the molecular events in liver tissue after subtotal hepatectomy (expression of proregenerative cytokines, activation of transcription factors and apoptosis) which are, in contrast to partial hepatectomy, not well understood. Our data indicate that activation of proregenerative genes like TGF-α and IL-6 is stronger after PH compared to SH. TNF-α which is also involved in liver regeneration, is induced by PH but not by SH. In addition, HGF expression was higher in PH than in SH. This was associated with stronger activation of NF-κB in PH during the early phase of regeneration. Finally, the apoptotic peak was delayed until 24 h after surgery and had a biphasic course in SH. In PH, apoptosis had a monophasic course and peaked directly after surgery.

These data are in accordance with other experiments from our group, in which we observed higher regenerative capacities and better liver function tests (ALT, AST, bilirubin) after 70% PH compared to 90% SH (Benkö *et al*, submitted). The time course of liver regeneration differed significantly between 70% PH and 90% SH. Animals with 70% resection showed a significant increase in LBW-r as early as 12 h after surgery. In the PH group, liver weight reached

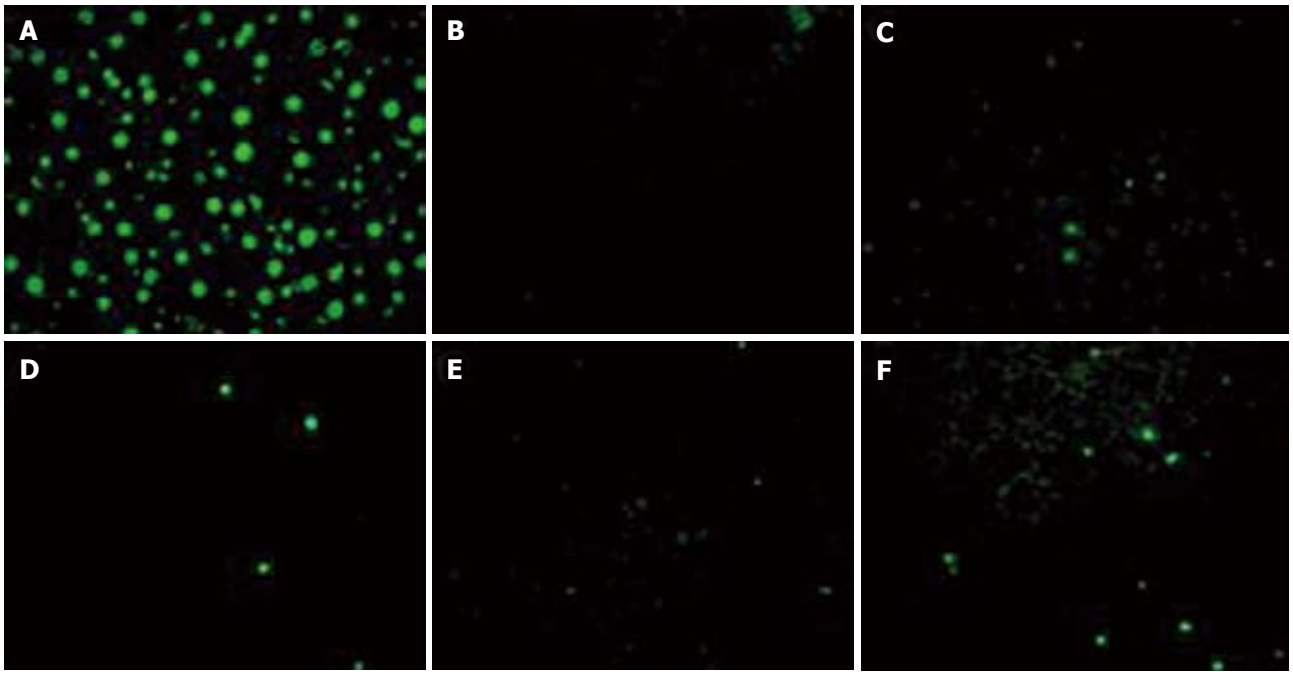

Figure 5 Representative images of TUNEL staining in liver tissue from the following groups. A: Positive control; B: Negative control; C: 70% resection, 24 h after surgery; D: 90% resection, 24 h after surgery; E: 70% resection 7 d after surgery; F: 90% resection, 7 d after surgery.

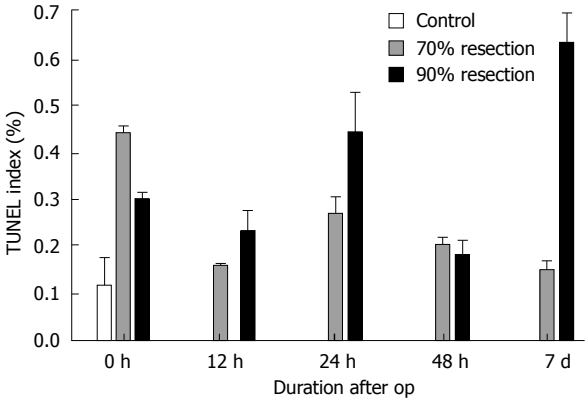

Figure 6 Results of TUNEL staining from paraffin embedded tissue sections. Paraffin embedded tissue slides from regenerating rat liver were dewaxed, washed and stained using the TUNEL method. The slides were covered in anti-fade medium with DAPI and analysed with a fluorescence microscope. False positive results were ruled out by comparison of the images with DAPI counterstaining (not shown). The TUNEL index is the number of TUNEL-positive cells divided by the total cell number. Cells were counted in ten fields of vision per section. Numbers shown are mean of four separate experiments in each group. TUNEL index for control animals (no resection) was approximately 0.12%.

65% of sham-operated controls 7 d after surgery. In contrast, after 90% resection, LBW-r started to increase 24 h after surgery and reached only 30% of the liver weight compared to controls at day 7. The time course in both groups for AST and ALT was similar although the release of both enzymes into serum was significantly higher after 90% SH, 12, 24 and 48 h postoperatively. LDH levels were similar in both groups until 12 h after surgery where the increase was more prominent in the 90% SH group than in the 70% PH group. At all later time points, LDH decreased in animals with 90% resection compared to controls and the 70% group. Serum bilirubin in the 70% resection group did not differ from the sham group. In animals with 90% resection we found a significant increase in bilirubin from 12 h to 72 h postoperatively. These findings show that damage to liver cells is increased after 90% hepatectomy compared to 70% resection.

Genes related to the initial phase of regeneration, such as TNF-α and IL-6, which prime hepatocytes into a state in which they are susceptible to growth factors[16,17], were expressed at later time points in our model. Nonetheless, both cytokines were expressed at lower levels or were delayed after SH compared to PH. As described previously[18,26-28], growth factors relevant to liver regeneration (HGF and TGF-β) were upregulated in PH, whereas no or only a reduced induction was observed after SH. This suggests that the expression of the factors relevant to the regeneration of liver tissue is influenced by the extent of resection.

For TGF-β we detected a distinct peak at 12 h after PH but not after SH. Since TGF-β has antiregenerative properties[18], high expression levels would be expected to counteract regeneration in this group. On the other hand, regeneration is a very tightly regulated process[19], which implies that high expression of TGF-β could lead to attenuation of ongoing regenerative processes in the PH group, whereas the regenerative stimuli which induce TGF-β expression are lacking in the SH group. This concept is supported by a very tight downregulation of TGF-β in the 70% hepatectomy group at later time points after surgery.

TUNEL indices were significantly raised directly after PH. Although we found a decrease in apoptosis over time, TUNEL indices remained elevated compared

to controls. Thus, the data indicate that apoptosis occurs earlier and in parallel with regeneration in animals with 70% resection. In contrast to this, animals with 90% hepatectomy showed slightly higher TUNEL indices at earlier time points and a strong increase in apoptosis 7 d after surgery. This could on the one hand, indicate that there was more tissue damage, which led to a higher number of apoptotic cells during the early postoperative phase. On the other hand, the significant rise in TUNEL indices 7 d after surgery leads to the conclusion that the main phase of remodelling occurs at later time points.

Our data suggest that liver regenerative processes after 90% SH are impaired by reduced or delayed activation of proregenerative factors compared to 70% PH. Activation of NF-κB as well as expression of important cytokines and growth factors depend on the amount of resected liver tissue. The underlying mechanisms are not yet clear, although they may be associated with the liver's ability to regenerate and to reduce tissue to fit current requirements[16,28].

It is still unclear, which role NF-κB plays during the regenerative process in the setting of extended hepatectomy. A continuous activation was detected at low levels after PH while a delayed and more pronounced activation could be seen after SH. While basal activation of NF-κB may be sufficient and important for regeneration and structural reformation after 70% resection[29], the strong NF-κB activation in animals with 90% hepatectomy may also favor inflammatory processes in the damaged tissue, which counteract the restoration of a functional liver[21,30,31].

In conclusion, our data suggest that the molecular events involved in liver regeneration are significantly influenced by the extent of resection, as subtotal hepatectomy leads to delayed activation of NF-κB and suppression of proregenerative cytokines compared to partial hepatectomy. Therefore, strategies to improve the activation of proregenerative transcription factors and the early production of proregenerative cytokines may improve clinical outcome after extended hepatectomy.

COMMENTS

Background

Liver resection is an important therapeutic measure to treat severe liver disease. Imperative for patient outcome is a timely regeneration of healthy liver tissue. Molecular events underlying liver regeneration are not completely understood but involve cytokines such as TNF-α and IL-6 to initiate and growth factors such as HGF and TGF-α to prolong regeneration.

Research frontiers

Although some hypotheses for the initiation of liver regeneration after tissue damage exist, it is not known which agents induce cell proliferation. Intrinsic LPS or contaminating bacteria have been discussed as initiating factors, activating TLR-systems in resident immune liver cells, known as Kupffer cells. One important factor in TLR-pathways is the transcription factor NF-κB, which regulates the expression of many genes including regenerative and anti-apoptotic effectors as well as proinflammatory cytokines. In this respect it is still unclear whether NF-κB activation promotes regeneration or contributes to further tissue damage by aggravating postoperative inflammation.

Innovations and breakthroughs

In our experiments we found a clear difference in regenerating liver after SH compared to PH regarding serum parameters and LBW-r. For the known cytokines and growth factors involved in liver regeneration, we detected reduced and/or delayed expression after SH. Furthermore, the SH group displayed a delayed activation of NF-κB. Until this work it was not known if the extent of liver resection had a direct influence on the regenerative capacity at a molecular and cellular level. Here, we demonstrated that the regenerative processes in the liver depend, at least partially, on the extent of resection.

Applications

A deeper insight into the molecular events underlying liver regeneration as well as into the relationship between the extent of resection and the regenerative processes may increase the possibility of enhancing regeneration pharmacologically. This would not only improve outcome for patients undergoing extensive hepatectomy but also make this therapeutic measure available for patients with severe liver tissue damage (i.e. cirrhosis), who otherwise would not be eligible for surgery.

Terminology

We used two models of liver resection. A 70% liver resection described as partial hepatectomy (PH) and a 90% liver resection model of extensive surgical intervention referred to as subtotal hepatectomy (SH).

Peer review

This manuscript focuses on the regulation of liver regeneration by the extent of resection. The authors of this study provide evidence that SH leads to delayed activation of NF-κB and suppression of proregenerative cytokines compared to PH. The manuscript is clearly written and findings are very interesting.

Abstract

AIM: To investigate the effects of resveratrol on liver ischemia/reperfusion (I/R) injury in rats.

METHODS: A total of 40 male Sprague-Dawley rats weighing 240-290 g were randomized into four groups of ten: (1) controls: data from unmanipulated animals; (2) sham group: rats subjected to the surgical procedure, except for liver I/R, and given saline; (3) I/R group: rats underwent liver ischemia for 45 min followed by reperfusion for 45 min; (4) I-R/Resveratrol group: rats pretreated with resveratrol (10 μmol/L, iv). Liver tissues were obtained to determine antioxidant enzyme levels and for biochemical and histological evaluation.

RESULTS: Plasma aminotransferase activities were higher in the I/R group than in the I-R/Resveratrol group. Malondialdehyde levels and the hepatic injury score decreased, while superoxide dismutase, catalase, and glutathione peroxidase levels increased in group 4 compared to group 3. In group 4, histopathological changes were significantly attenuated in resveratrol-treated livers.

CONCLUSION: These results suggest that resveratrol has protective effects against hepatic I/R injury, and is a potential therapeutic drug for ischemia reperfusion-related liver injury.

Resveratrol attenuates oxidative stress and histological alterations induced by liver ischemia/reperfusion in rats. *World J Gastroenterol* 2008; 14(46): 7101-7106 Available from: URL: http://www.wjgnet.com/1007-9327/14/7101.asp DOI: http://dx.doi.org/10.3748/wjg.14.7101

INTRODUCTION

Hepatic injury caused by ischemia/reperfusion (I/R) has been proposed as a key clinical problem associated with liver transplantation and major liver surgery[1]. Additionally, hepatic I/R injury also occurs in diverse situations, including heart failure, liver trauma, and blood occlusion to the liver[2,3]. The production of reactive oxygen species (ROS), including superoxide, hydrogen peroxide, and hydroxyl radical, has been demonstrated in reperfusion injury[4]. I/R activates Kupffer cells (KC), the resident macrophages in the liver, to generate ROS, proinflammatory cytokines, and chemokines and to upregulate inducible nitric oxide synthase[5].

Resveratrol (3,4,5 tri-hydroxystilbene) is a naturally occurring phytoalexin present in high concentrations in the skin and seeds of grapes[6]. It occurs naturally in a trans-or cis-isoform[7-9]. Resveratrol has been reported to have several biologic effects such as a potent antioxidative effect *via* prevention of lipid peroxidation[10,11], anti-platelet activity[12], an estrogenic activity[13], and anti-inflammatory activity attributed to cyclooxgenase inhibition[6,14]. Previously, it was suggested that resveratrol stimulated nitric oxide production in endothelial cells, has a vasodilatory effect on blood vessels[15], and improves the energy metabolism system after spinal cord trauma[16].

The aim of this study was to evaluate the possible protective effect of resveratrol against I/R-induced hepatic injury, using biochemical and histological parameters.

MATERIALS AND METHODS

Forty male Sprague-Dawley rats weighing 240-290 g

were used in the study. All of the experimental protocols were performed according to the guidelines for the ethical treatment of experimental animals.

Animals and experimental protocol

The rooms where the animals were housed were windowless and were under controlled temperature (22 ± 2℃) and lighting conditions. The rats were housed individually in cages, and allowed free access to standard rat chow and water before and after the experiments. The animals were fasted overnight before the experiments, but were given free access to water. They were anesthetized using 100 mg/kg ketamine and 20 mg/kg xylazine body weight (ip), The right femoral vein was cannulated to administer drugs and saline.

The animals were randomized into four groups (n = 10 in each group): (1) controls: Unmanipulated animals, rats not subjected to any surgical procedure or liver manipulation; (2) sham group: Rats subjected to the surgical procedures described below, except for liver I/R, and administered saline vehicle and maintained under anesthesia for an equivalent duration (i.e. 45 min plus 45 min); (3) I/R group: Rats subjected to the surgical procedures described below and underwent liver ischemia for 45 min followed by reperfusion for 45 min (n = 10); (4) I-R/Resveratrol group: Rats received resveratrol 10 mg/kg dissolved in 2 mL 50% alcohol (Sigma Chemicals, St. Louis, MO, USA) by infusion pump 15 min before liver reperfusion.

Liver ischemia/reperfusion

As described previously[17], the ligament attachments connecting the liver, diaphragm, abdominal wall, and neighboring organs were divided. After the organ was carefully isolated, the liver hilus was exposed to find the common hepatic artery and portal vein. A vascular microclamp was used to interrupt the blood supply to three-quarters of the liver for 45 min, and this was followed by 45 min of reperfusion. Other rats were subjected to a sham operation (sham-operated), which was identical to the surgical procedure used for the I/R group rats without clamping; the rats were kept under anesthesia for the same length of time. At the end of the experiments, the rats were killed with an overdose of sodium pentobarbital.

Measuring serum liver enzymes

The abdominal aorta was punctured and 5 mL of blood was taken and placed in heparinized tubes. Plasma was separated by centrifugation (3000 r/min for 10 min at room temperature) for biochemical studies. The activities of alanine aminotransferase (ALT, a specific marker for hepatic parenchymal injury), and aspartate aminotransferase (AST, a nonspecific marker for hepatic injury) in plasma were determined in units per liter using standard auto-analyzer methods on an Abbott Aeroset (Abbott Laboratories, Abbott Park, IL, USA). Just before the rats were sacrificed, the livers were removed for histopathological evaluation.

Histopathological study

The livers were divided into two pieces. One was immediately placed in 10% formalin solution, left overnight, and then embedded in paraffin blocks. The blocks were cut into 4-μm sections and stained with hematoxylin-eosin, using standard protocols. The severity of hepatic injury in the sections was evaluated using a point-counting method on an ordinal scale as follows: grade 0, minimal or no evidence of injury; grade 1, mild injury consisting of cytoplasmic vacuolation and focal nuclear pyknosis; grade 2, moderate to severe injury with extensive nuclear pyknosis, cytoplasmic hypereosinophilia, and loss of intercellular borders; and grade 3, severe necrosis with disintegration of hepatic cords, hemorrhage, and neutrophil infiltration[18].

Biochemical analyses

The other piece of liver was washed in ice-cold 0.9% saline solution, weighed, and stored at -70℃. Tissue homogenates were prepared as 0.1 g/mL in 250 mmol/L sucrose, 1 mmol/L EDTA, 1 mmol/L DL-dithiothreitol, and 15 mmol/L Tris HCl (pH 7.4), using an all-glass Potter Elvehjem homogenizer (Selecta, Barcelona, Spain). Each homogenate was centrifuged for 20 min at 800 r/min. The resulting supernatant fraction was used to determine enzyme activities. The protein concentrations in the supernatant were determined using the Bradford method[19].

Malondialdehyde determination

Liver malondialdehyde (MDA) levels were determined using the method of Wasowicz *et al*[20] based on the reaction of MDA with thiobarbituric acid at 95 to 100℃. Fluorescence intensity was measured in the upper n-butanol phase using fluorescence spectrophotometry (F-4010; Hitachi, Tokyo, Japan) adjusted for excitation at 525 nm and emission at 547 nm. The arbitrary values obtained were compared with a series of standard solutions (1,1,3,3-tetramethoxypropane). The results are given in nanomoles per gram of wet tissue.

Superoxide dismutase, catalase, and glutathione peroxidase determination

Superoxide dismutase (SOD) activity was measured using the xanthine-oxidase-cytochrome c method, as described by McCord and Fridovich[21]. The final concentrations in the cuvettes were 50 mmol/L potassium phosphate (pH 7.8), 0.1 mmol/L EDTA, 10 mmol/L cytochrome c, 50 mmol/L xanthine, 50 or 2 mmol/L cyanide, 1 U catalase (CAT), and 0.05-0.1 mg of tissue. The reaction was initiated by adding 1 U xanthine-oxidase. The inhibition of xanthine-oxidase was followed spectrophotometrically at 550 nm. One unit of SOD activity was defined as the amount of enzyme that produced 50% inhibition of the control rate of cytochrome c reduction.

CAT activity was assayed according to the method of Beers and Sizer[22]. The final concentrations in the cuvettes were 500 mmol/L potassium phosphate (pH 7), 100 mmol/L H_2O_2, and 0.05-0.1 mg of tissue. The decrease in the absorbance at 240 nm after adding the substrate was followed spectrophotometrically.

GSH activity was assayed using a coupled enzyme system in which oxidized glutathione (GSSG) reduction

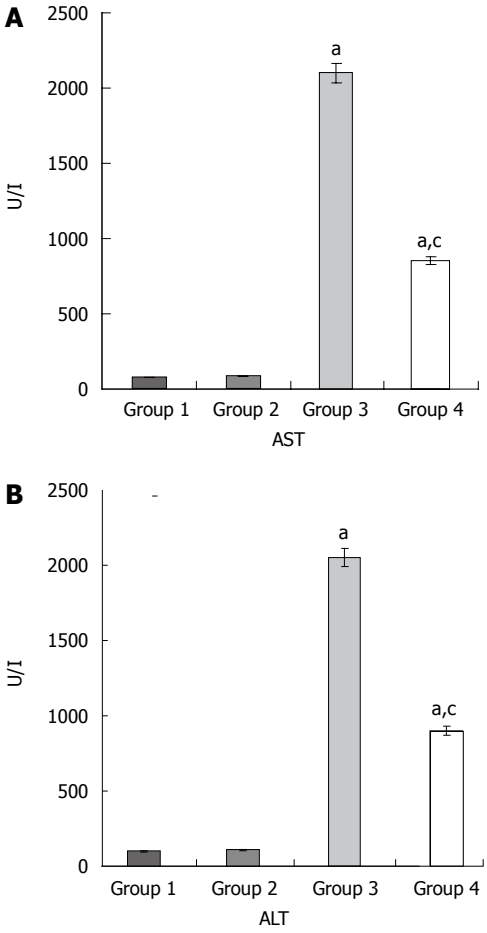

Figure 1 Effects of liver I/R and resvera-trol on liver function. A: The AST values; B: The ALT values $^{a}P < 0.05$ compared with Group 1 and 2; $^{c}P < 0.05$ compared with Group 3. The values are the mean ± SE. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase.

was coupled to NADPH oxidation by glutathione reductase[23]. The assay mixture contained 50 mmol/L potassium phosphate (pH 7.5), 1 mmol/L EDTA, 1 mmol/L NaN_3, 1 mmol/L reduced glutathione (GSH), 0.2 mmol/L NADPH, 1 U glutathione reductase, and tissue (0.05-0.2 mg). After a 5-min preincubation period (20-25℃), the reaction was initiated by adding 0.25 mmol/L H_2O_2. The decrease in absorbance at 340 nm was followed spectrophotometrically.

Protein assays

The protein content of the homogenates was determined using the procedure of Lowry *et al*[24].

Statistical analysis

Data were entered and analyzed on an IBM-compatible personal computer using SPSS version 9.0. All values were expressed as the mean ± SE. The significance of the data obtained was evaluated using analysis of variance (ANOVA). Differences between means were analyzed using the post-ANOVA test (Tukey's *b*). $P < 0.05$ was considered significant.

RESULTS

The ALT and AST levels were significantly increased in groups 3 and 4 in comparison with groups 1 and 2 ($P < 0.05$ in all cases). Moreover, the ALT and AST levels were significantly decreased in group 4 compared to group 3 ($P < 0.05$) (Figure 1).

The MDA, SOD, CAT, and GSH values for the different groups are shown in Figure 2. In group 3, MDA was significantly increased compared with groups 1, 2, and 4 ($P < 0.05$ in all cases). In addition, SOD, CAT, and GSH significantly decreased in group 3 compared with groups 1, 2, and 4 ($P <0.05$ in all cases).

The liver histopathological scores were 0.1 ± 0.2, 0.1 ± 0.2, 2.8 ± 0.1, and 1.1 ± 0.2 in groups 1 to 4, respectively. The histopathological scores were higher in groups 3 and 4 than in groups 1 and 2 ($P < 0.05$ in all cases). Moreover, the histopathological score was lower in group 4 than in group 3 ($P < 0.05$). Normal findings were obtained on histological examination of rats in groups 1 or 2 (Figure 3A and B). In group 3, focal necrosis with sinusoidal congestion and neutrophil accumulation were observed at the midzonal region (Figure 3C). In contrast, these changes were markedly attenuated in resveratrol-treated livers (Figure 3D).

DISCUSSION

Hepatic ischemia and reperfusion injury is observed following major liver surgery, transplantation, trauma and sepsis and may cause metabolic and structural hepatic damage[25,26]. This remains a significant problem in surgical procedures, and is a limitation of liver transplantation[27]. Several mechanisms have been considered to explain I/R injury of the liver. Activation of KC with enhanced formation of ROS and secretion of inflammatory cytokines and proteolytic enzymes are considered to play an important role in liver reperfusion injury[28,29]. Additionally, migration of activated polymorphonuclear leukocytes at the injury site may prolong the injury as a result of the production of inflammatory cytokines, adhesion molecules, and ROS[30,31]. The formation of ROS may initiate oxidative stress which can lead to lipid peroxidation[32]. Removal of oxidative stress is the primary intervention to decrease tissue injury. Superoxide dismutase, catalase, glutathione, α-tocopherol, and carotene are known endogenous antioxidants, but none of these endogenous antioxidants are sufficient to compensate oxidative stress. Several antioxidants have been studied and reported to decrease oxidative stress in hepatic and renal tissue in experimental obstructive jaundice, septic shock, and I/R models.

Resveratrol is a polyphenol phytoalexin (trans-3,5,4-trihydroxystilbene) that possesses diverse biochemical and physiological actions, including estrogenic, antiplatelet, and anti-inflammatory properties[33,34]. Recently, resveratrol was found to be a highly potent antioxidant which could inhibit free radical generation in brain, spinal cord, kidney, liver and red cell membrane[35-38]. It has been shown that resveratrol inhibits lipid peroxidation[39], and prevents apoptotic cell death induced by oxidative stress[40]. The end production of lipid peroxidation includes aldehydes, hydrocarbon gases, and MDA. MDA is a sensitive index of lipid peroxidation[18,41]. Bertelli *et al*[33] suggested that

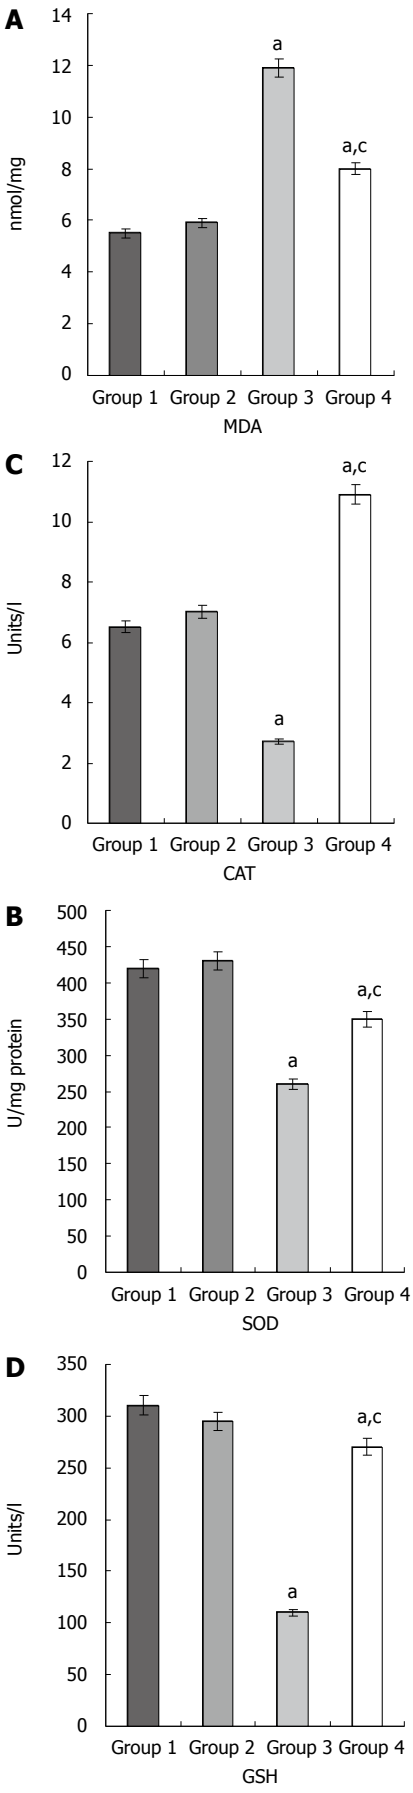

Figure 2 Effects of ischemia/reperfusion and resveratrol on the MDA (A), SOD (B), CAT (C), and GSH (D) levels in liver tissue. $^{a}P < 0.05$ compared with groups 1 and 2. $^{c}P < 0.05$ compared with group 3. The values are the mean ± SE. MDA: Malondialdehyde; SOD: Superoxide dismutase; CAT: Catalase; GSH: Glutathione peroxidase.

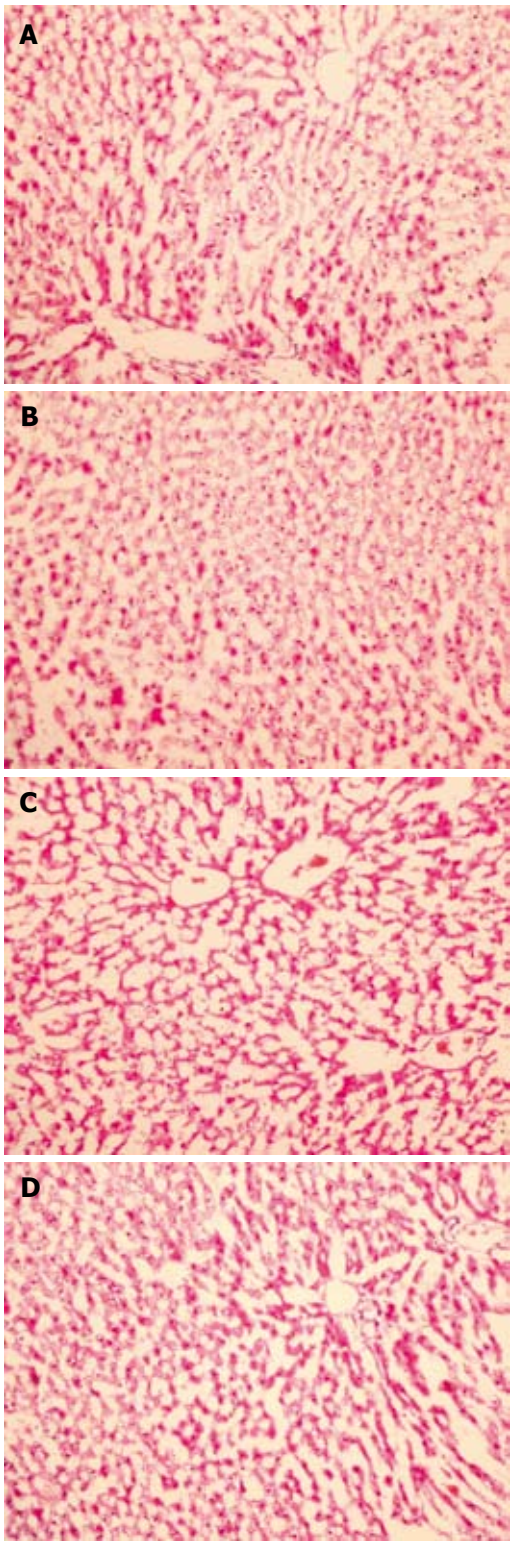

Figure 3 Effect of resveratrol on hepatic tissue injury after I/R evaluated by histological examination. In groups 1 and 2, normal findings were obtained on histological examination (A and B, respectively) (HE, x 200); C: In group 3, swollen hepatocytes with marked vacuolization and congestion were observed (HE, x 200); D: In group 4, the hepatocytes and sinusoids showed normal morphology, reflecting a well preserved liver parenchyma (HE, x 200).

MDA formation was reduced in the ischemic-reperfused myocardium of resveratrol-treated rats. In an experimental study by Kirimlioglu *et al*[42], MDA levels in liver tissue and plasma were higher in group B subjected to 70% partial hepatectomy than those of group A treated with

resveratrol before and after 70% partial hepatectomy. Although the exact mechanism is not known, it is thought that this was probably due to the antioxidant and inhibitory effects of resveratrol on ROS, which might be a biochemical mechanism related to the anti-inflammatory and anticarcinogenic properties of resveratrol[43]. To control the detrimental effects of ROS, organisms have developed a variety of antioxidant defense systems, especially the endogenous antioxidant enzymes system including SOD, CAT and GSH. The activities of these enzymes are higher in the liver than in other tissues. CAT is an oxidoreductase enzyme, which transforms H_2O_2 into H_2O and O_2. It can protect cells from damage induced by ischemia reperfusion by scavenging ROS[44]. GSH is considered to be the principal mitochondrial antioxidant and its depletion markedly enhances the sensitivity of mitochondrial structures to ROS-mediated injury[45]. A decrease in GSH level after reperfusion could reflect ROS-mediated consumption[46]. SOD catalyses dismutation of the superoxide anion (O_2^-) into H_2O_2; H_2O_2 can be transformed into H_2O and O_2 by CAT; GSH is a selenoprotein, which reduces lipidic or nonlipidic hydroperoxides as well as H_2O_2 while oxidizing GSH[47]. Plin *et al*[48] showed that resveratrol protects mitochondria and cells against cold preservation-warm reperfusion (CPWR)-induced injury. Resveratrol improved both mitochondrial coupling and ATP synthesis measured after CPWR as demonstrated by the increase in respiratory control ratio and ADP/oxygen values, respectively. These protective effects could be related to the antioxidant properties of the molecule which has been shown to be able to scavenge ROS[49].

In our study, liver tissue MDA levels in the I/R group increased compared with normal and sham groups. With resveratrol administration, liver tissue MDA levels decreased. Additionally, our results suggest that increased SOD, GSH and CAT activities may be attributed to reactive oxygen products such as superoxide anions and H_2O_2 in the resveratrol-treated group. These data indicate that resveratrol may provide protection to the liver during I/R injury, in part by improving activities of the endogenous antioxidant enzymes, which scavenge ROS and reduce their effects. Histopathologically, the resveratrol-treated group showed well preserved liver parenchyma with hepatocytes arranged radially around the central vein. In a study by Hassan-Khabbar *et al*[50], the effect of trans-resveratrol on liver injury induced by I/R was investigated. While Hassan-Khabbar performed measurements after 3 h of reperfusion, in the present study, measurements were performed after less than 1 h. Thus, the present study suggests that the protective effect of resveratrol may occur more rapidly than previously thought.

In conclusion, this study is the first to evaluate the hepatoprotective effects of resveratrol in hepatic I/R. The protective effects of resveratrol may be associated with its antioxidant activity and free radical scavenging activity which are released during the reperfusion period.

COMMENTS

Background

Hepatic injury caused by ischemia/reperfusion (I/R) has been proposed as a key clinical problem associated with liver transplantation and major liver surgery. Furthermore, hepatic I/R injury also occurs in diverse situations, including heart failure, liver trauma, and blood occlusion to the liver. The production of reactive oxygen species has been demonstrated in reperfusion injury. Resveratrol has been reported to have several biologic effects such as a potent antioxidative effect *via* prevention of lipid peroxidation. Therefore, the possible protective effects of resveratrol against I/R-induced hepatic injury were investigated.

Research frontiers

This study is the first to evaluate the hepatoprotective effects of resveratrol in hepatic I/R. The protective effects of resveratrol may be associated with its antioxidant activity and free radical scavenging activity which are released during the reperfusion period.

Innovations and breakthroughs

This study explained one of the possible mechanisms of the protective effects of resveratrol.This may be associated with its antioxidant activity and free radical scavenging activity released during the reperfusion period.

Applications

In this study, the implication of ROS in the pathology of hepatic I/R injury was explored. Protective effects of resveratrol were determined. This may represent a novel and attractive approach to determining the protective effects of resveratrol therapy on hepatic injury caused by ischemia/reperfusion

Peer review

In the present study, the authors tested the effect of Resveratrol on ischemia/reperfusion-induced liver injury in rats, and found a protective effect.

Abstract

AIM: To investigate the presence of human papillomavirus (HPV) in esophageal squamous papilloma (ESP) and determine p16, p53 and Ki67 expression in a Mexican cohort.

METHODS: Nineteen cases diagnosed as ESP, corresponding to 18 patients were reviewed; nineteen cases of normal esophageal mucosa were used as negative controls. HPV detection was performed by amplified chromogenic in situ hybridization (ACISH) using a wide spectrum-cocktail probe and PCR.

RESULTS: The average age at presentation was 46.3 years (range 28-72 years). Patients included four (22.22%) males and 14 (77.77%) females. The most frequent location was upper third (11 cases), followed by middle third (3 cases) and unknown site (5 cases). Immunohistochemistry (IHC) revealed basal and focal p53 expression in 17 cases (89%); p16 was expressed in eight cases (42.10%) and the Ki67 index ranged from 10% to 30%. HPV was detected in 14 out of 16 cases (87.5%) by ACISH: Twelve showed diffuse nuclear patterns and two showed granular patterns. HPV DNA was identified by PCR in 12 out of 14 cases (85.7%). Low-risk HPV types were detected in the most of the cases.

CONCLUSION: This study provides identification of HPV infection in almost 80% of ESP using either ACISH or PCR; overall, all of these lesions show low expression of cell-cycle markers. We suggest ACISH as an alternative diagnostic tool for HPV detection in ESP.

INTRODUCTION

Esophageal squamous papillomas (ESPs) are uncommon benign lesions, usually asymptomatic and often discovered as incidental findings. ESPs were first described by Adler in 1959[1-5]. The etiology and pathogenesis of ESP appear to be related to an inflammatory-reparatory type, such as chronic gastro-esophageal reflux, esophagitis, trauma, chemical irritants, and viruses[6,7]. Their malignant potential is still unclear, and it has been proposed that Human Papillomavirus (HPV) plays an etiopathogenic role; however, HPV is not consistently identified[8,9]. The detection of HPV in ESPs may have a great value, in terms of follow-up of lesions associated to genotypes implicated in the genesis of premalignant and malignant lesions in squamous epithelial-lined tissues, including nasal cavity, pharynx and the anogenital tract[7].

The Mexican population possesses a high prevalence of HPV-related cervical lesions. Previous studies have demonstrated high expression rates of $p16^{INK4a}$ in cervical lesions[10]; however, little is known on $p16^{INK4a}$ and the etiologic role of HPV in the development of ESPs. The purpose of this study is to investigate the presence of HPV through molecular techniques in a cohort of 19 ESPs cases and determine the relationship between HPV and the expression of cell cycle proteins.

MATERIALS AND METHODS

Nineteen specimens from 18 patients were retrieved from the Department of Pathology-UPAEP University

Table 1 Esophageal squamous papillomas: Clinical and pathological features

Age	Gender	Endoscopic indication	Location	ACISH	PCR	p16	p53	Ki67

NA: Not available; ACISH: Amplified chromogenic in situ hybridization; PCR: Polymerase chain reaction; [1]Same patient.

Hospital files during a 12-year period. Endoscopic reports and clinical charts were reviewed to obtain information about age, gender, symptoms, endoscopic location and past medical history. Clinical and endoscopic follow-up were available for sixteen patients.

Multiple 4-μm thick sections from formalin-fixed paraffin-embedded tissue (FFPET) blocks were obtained. In addition to hematoxylin and eosin (HE) staining, the following immunostains were performed, according to manufacture's instructions: $p16^{INK4a}$ (Clone EGH4; 1:25; DakoCytomation, Carpinteria, California, USA), p53 (Clone DO-7; 1:100 DakoCytomation, Carpinteria, California, USA) and Ki67 (Clone MIB-1; 1:150; DakoCytomation, Carpinteria, California, USA). Negative and positive controls were reviewed. Slides were independently evaluated by two pathologists (OB, SSS). Discrepancies were resolved by consensus examination.

Molecular techniques were applied depending of availability of tissue. In 16 out of 19 cases, detection of HPV was performed by amplified chromogenic in situ hybridization (ACISH) (GenPoint/DakoCytomation, Carpinteria, California, USA), using a HPV biotinylated DNA probe. Nineteen samples of normal esophageal mucosa were used as negative controls.

Fourteen FFPET out of 19 ESPs were examined for HPV by PCR-RFLP, as described previously[11,12]. DNA was extracted from FFPET blocks (cases and negative control samples). After DNA extraction, amplifications were performed using consensus primers MY09 and MY11. To determine HPV types 6/11, 16, 18 and 31, the PCR products were digested using restriction endonucleases and analyzed by agarose gel electrophoresis.

RESULTS

The clinical and pathological features of the patients and their tumors are shown in Table 1. The average age at presentation was 46.3 years (range 28-72 years). Patients included four (22.22%) males and 14 (77.77%) females. The most frequent indication for endoscopy was abdominal pain (15 patients), followed by reflux (seven patients). In all cases, ESPs were incidental findings, discovered during the endoscopic procedure. In none of the cases was Barrett's esophagus or respiratory-tract papillomatosis reported. Clinical data showed no history of HPV-related diseases, immunosuppression or radiotherapy. At endoscopy, some patients also presented with Helicobacter pylori infection, chronic gastritis, peptic ulcer disease, hiatal hernia, esophagitis and reflux esophagitis.

Endoscopically, the most frequent location of ESP was the upper third (11 cases), followed by the middle third (3 cases) and unknown site (5 cases). All except one case were present as a single lesion. Patients underwent total endoscopic excision. Clinical and endoscopic follow-up was done in sixteen of the patients, and no recurrences have been documented to the date.

Grossly, ESPs present as polypoid, soft, smooth, whitish-pink tumors, ranging from 3 to 7 mm at their largest dimension. Histological examination revealed exophytic lesions, composed of branched fibrovascular core, covered by acanthotic squamous epithelium. No other growing pattern was observed. Basal cell hyperplasia and koilocytosis were present in all cases (100%). Vacuolated cells in the upper layers were detected in all cases. Parakeratosis, papillomatosis and intraepithelial lymphocytes and some eosinophils were also noted. Ten cases (52.63%) showed a prominent epithelial granular layer and intraepithelial capillary loops were present in nine cases (47.36%). Dyskeratotic cells and multinucleated giant cells were absent and no dysplastic changes were found in any of the patients.

HPV was detected in 14 of 16 cases (87.5%) by ACISH: Twelve showing a diffuse and complete nuclear

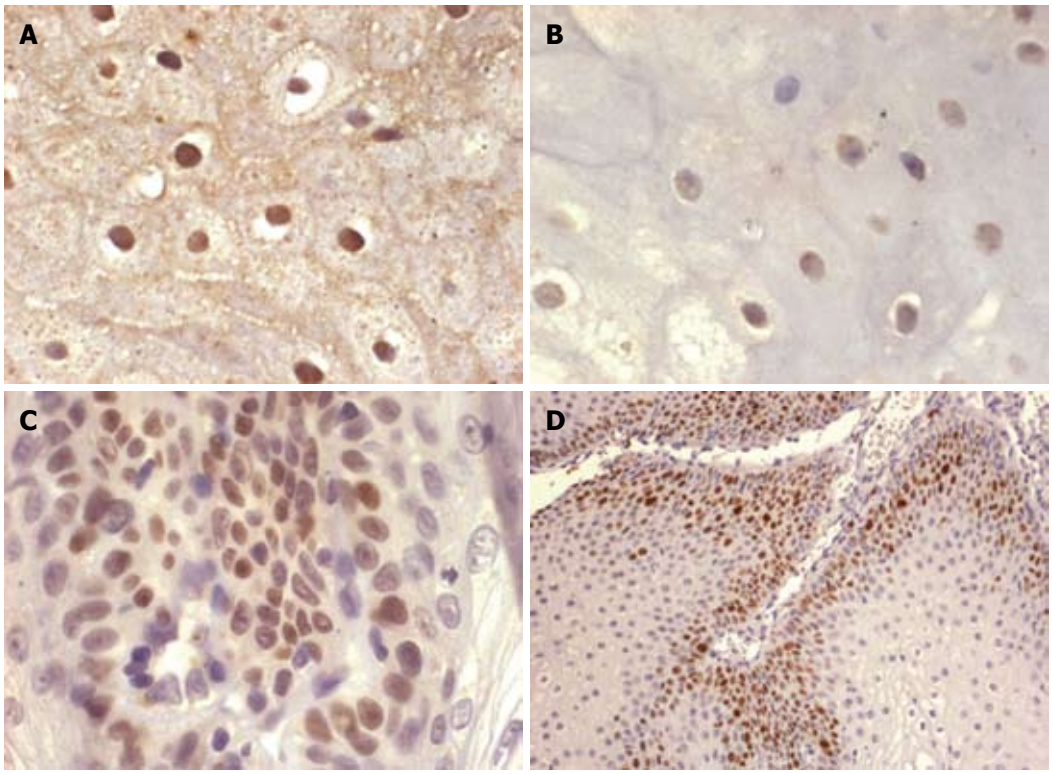

Figure 1 Esophageal squamous papillomas. A: Amplified chromogenic in situ hybridization, episomal infection with diffuse nuclear staining pattern; B: Amplified chromogenic in situ hybridization, nuclear granular staining pattern; C: p53 expression; D: Ki67 expression.

staining pattern (indicating the episomal state of the HPV viral genome, Figure 1A) and two a nuclear granular pattern (indicating the integrated form of the HPV viral genome, Figure 1B). HPV DNA was identified by PCR in 12 of 14 cases (85.7%). Infection by a low risk type HPV (6/11) was detected in 10 of 14 cases, whereas two of the 14 cases were infected by a high risk HPV type (16). Both high risk cases showed a granular staining pattern on ACISH, suggesting viral genomic infection. In two cases, ACISH demonstrated a diffuse pattern and HPV was not documented by PCR.

p53 was expressed in 17 cases (89%). The percent of p53-positive cells ranged from 10 to 15%, showing a basal and focal expression (Figure 1C). There was no difference between the p53 expression of non-infected and HPV-detected ESPs. In two cases, IHC for p53 was not performed (no tissue was present in the block). Eight cases (42.10%) expressed $p16^{INK4a}$ (both nuclear and cytoplasmic). Four of these cases were infected by 6/11 serotypes. In those cases, $p16^{INK4a}$ revealed a low rate of expression (< 20%), mostly at a basal layer location and focally extending into the medium third. Ki67 proliferative index in 17 cases ranged from 10 to 30% on basal cells (Figure 1D), and there was no difference on expression between non-HPV-related lesions and HPV high and low risk-related lesions.

DISCUSSION

This report of cases represents the first study performed in Mexico to determine the presence of HPV in an unusual esophageal lesion, whose relation with esophageal carcinoma is not completely understood. The etiology is still unclear, and the role of HPV in squamous cell lesions of the esophagus is difficult to establish. Since 1982, when Syrjanen *et al*[13] demonstrated the presence of HPV antigens in ESP, a certain percentage of ESPs have been reported as associated with HPV[2,7,14-16]; however, this relationship has not been consistently proven. Some authors hypothesize that mucosal injury, followed by regeneration, is the key role in the pathogenesis, supported by the coexistence of ESPs and gastro-esophageal reflux, esophagitis and hiatal hernia; also by the fact that most of the ESPs are located in lower level of the esophagus[7,17-18]. In a study, Talamini *et al*[9] found that in the Italian population, ESPs are located mostly in the middle third and secondarily, in the lower third; this study also reported a very low prevalence of cases associated with HPV and implied that alcohol intake and cigarette smoking were risks factors.

In contrast to previous reports, our study shows a female predominance, and a predominantly upper third location[8,9]. These findings raise the possibility that certain factors, including gastro-esophageal reflux, are unlikely to be the main etiological factors or are responsible for only a small proportion of cases. For that reason, some others conditions or perhaps, behavioral reasons, might be related in this specific population.

In our series of cases, we found that ten out of 11, were located in the upper third and were related to HPV-infection. In two of them, high grade serotypes (HPV 16) were detected. How does HPV get access to that location? This is still unknown. Jalal *et al*[19] have shown HPV DNA in the mouths of individuals with clinically normal oral mucosa. HPV is an epitheliotropic virus that requires the environment of a differentiating squamous epithelium for their life cycle. Peripheral blood mononuclear cells may serve as HPV carriers, spreading the virus *via* the blood[20]. The Mexican

population possesses a high prevalence of HPV-related cervical lesions, and some mechanism of infection probably exists, including viral transmission by direct contact (e.g. sexual) that might involve the infection of the upper third of the esophagus, but we could not confirm this hypothesis due to the non-availability of clinical information of the HPV-infection status in the patients' sexual partners.

According to Winkler *et al*[21], 31% of ESPs having histological findings of HPV infection, show positive reactions to HPV antigens by IHC; Odze *et al*[7] reported 50% positivity of HPV in 38 cases using PCR, mostly type 16, and proposed a multifactorial etiology including mucosal irritation and HPV association; Woo *et al*[18] also suggest a multifactorial cause and Poljak *et al*[8] believe that HPV DNA in ESPs is not the result of viral infection but the result of incidental HPV colonization which have been formed as result of other etiological factors; genetic association has also been mentioned[2]. In our study, we believe that presence of HPV-associated ESPs, reflects the high prevalence of the virus in developing countries, including Mexico, in contrast to western countries, and is in agreement with previous reports[22].

The malignant potential of ESPs has been described in some studies and is controversial[18]. According to Talamini *et al*[9], ESPs appear not to have a risk of development of malignancy or to be a marker of such risk. We found a predominance of HPV infection by low-risk serotypes and in two cases, high-risk serotype infection; however, no dysplastic changes, malignant transformation or recurrence was identified. Furthermore, we suggest that clinical and endoscopic follow-up should be recommended and performed on regular basis on patients with HPV high-risk serotypes lesions. These serotypes have been demonstrated by numerous epidemiologic and molecular studies to be the etiologic agents for an overwhelming majority of premalignant and malignant cervical cases[23] and in consequence, HPV might be related as a risk factor for esophageal carcinoma[7].

Previous reports have shown a correlation between $p16^{INK4a}$ expression in cases of cervical dysplasia HPV-related[10]. Although we did not find a relationship between HPV infection and protein expression of cell cycle markers, we believe that their utility will be mainly in the grading of dysplasia, and also in the evaluation of esophageal lesions when dysplasia or malignancy is suspected.

In summary, our study provides strong evidence that most ESPs are associated with HPV infection; however we believe that other pathogenetic mechanisms are related to the development of these lesions. PCR is currently considered to be the most sensitive method for the detection of HPV infection available[8] but is susceptible to false positives due to contamination. Although PCR is the gold-standard for HPV evaluation, PCR is not available in the pathological routine evaluation and ACISH might serve as a useful and alternative diagnostic tool for HPV detection.

COMMENTS

Background

Squamous papillomas are uncommon benign lesions of esophagus, of unknown etiology, and controversial malignant potential. Esophageal squamous papillomas (ESP) have been found to be associated with different conditions, including gastro-esophageal reflux, inflammation and trauma. Human papillomavirus (HPV) has been implicated in the genesis of malignant neoplasms in squamous epithelial-lined tissues, including the nasal cavity, pharynx and anogenital tract; however, previous studies have not consistently identified HPV in ESP.

Research frontiers

This study was designed to identify the presence of HPV in a series of 19 ESPs, from a population with high cervical HPV prevalence. Identification of HPV was performed by molecular techniques, and cell-cycle markers expression was assessed by immunohistochemistry.

Innovations and breakthroughs

Previous studies have not consistently identified HPV in ESP. To the best of our knowledge, this is the first study performed in Latin America to determine HPV infection in esophageal papillomas. In this Mexican cohort, we found that almost 80% of ESPs were associated with HPV infection.

Applications

Due to the well-known association of HPV with premalignant and malignant conditions, follow-up of patients with esophageal lesions with high-risk type of HPV and viral genomic infection should be implemented and guaranteed. Amplified chromogenic in situ hybridization (ACISH) can be used as an alternative diagnostic tool for routine HPV identification.

Terminology

HPV are a group of more than 100 viruses. Both high and low-risk types of HPV can cause the growth of abnormal cells, but only the high-risk types (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, 68, and 73) lead to malignant transformation.

Peer review

This manuscript shows that the ACISH method is as useful as the standard PCR method in detecting HPV in esophageal squamous papillomas. The manuscript would be improved and more useful to the clinician if the author's would include photographs of gross esophageal squamous papillomas samples as well as photomicrographs for the ACISH results. The study is well conducted and the data support the conclusions of the author's that the use of ACISH represents an acceptable alternative to detect HPV in esophageal squamous papillomas.

Abstract

AIM: To localize nestin positive cells (NPC) in pancreatic tissue of mice of different ages.

METHODS: Paraffin sections of 6-8 μm of fixed pancreatic samples were mounted on poly-L-lysine coated slides and used for Immunolocalization using appropriate primary antibodies (Nestin, Insulin, Glucagon), followed by addition of a fluorescently labeled secondary antibody. The antigen-antibody localization was captured using a confocal microscope (Leica SP 5 series).

RESULTS: In 3-6 d pups, the NPC were localized towards the periphery of the endocrine portion, as evident from immunolocalization of insulin and glucagon, while NPC were absent in the acinar portion. At 2 wk, NPC were localized in both the exocrine and endocrine portions. Interestingly, in 4-wk-old mice NPC were seen only in the endocrine portion, towards the periphery, and were colocalized with the glucagon positive cells. In the pancreas of 8- wk-old mice, the NPC were predominantly localized in the central region of the islet clusters, where immunostaining for insulin was at a maximum.

CONCLUSION: We report for the first time the immunolocalization of NPC in the pancreas of mice of different ages (3 d to 8 wk) with reference to insulin and glucagon positive cells. The heterogeneous localization of the NPC observed may be of functional and developmental significance and suggest(s) that mice pancreatic tissue can be a potential source of progenitor cells. NPC from the pancreas can be isolated, proliferated and programmed to differentiate into insulin secreting cells under the appropriate microenvironment.

INTRODUCTION

Diabetes results from an inadequate mass of functional pancreatic β-cells and such inadequacy can result from a lack of selective autoimmune destruction of pancreatic β-cells (type 1)[1,2] or a lack of compensation to overcome Insulin resistance (type 2)[3,4]. In addition, an intrinsic β-cell defect, fragility, or shortened life span may be other possible impairments underlying the pathophysiology of diabetes[5]. Recently, adult pancreatic tissue (exocrine/endocrine) has emerged as a promising source of pancreatic stem cells, which are capable of differentiating into functional insulin secreting cells (ISC) given an appropriate microenvironment[6,7]. The introduction of new methods for *in vitro* generation of

β-cells from pancreatic tissue will help to provide greater numbers of viable ISC.

The promise of using adult tissue stem cells are attributed to their wide distribution in almost all tissues, modulation of their plasticity, ability to be modified genetically or reprogrammed and they are safer for transplantation[8]. They can also be immortalized or multiplied in culture for a number of passages and the ethical constraints on their use are minimal as compared to the use of embryonic stem cells[9]. Nestin has been unequivocally identified as a marker of neural stem cells or progenitors[10,11]. It is abundantly expressed in neuroepithelial cells during embryogenesis but it is nearly absent from all mature central nervous system cells[12,13]. In addition, nestin has been demonstrated in rat bone marrow[14], human embryonic stem cells[15,16], human islet explants[17], human fetal pancreas[18], and adult rat pancreas[19]. The varied expression and characterization of nestin positive cells (NPC) in different cell types is thought to have considerable functional significance during the developmental process. Despite several studies documenting the potential of NPC as stem cells/progenitors to differentiate into ISC, some studies have reported that NPC may not function as progenitors for ISC[20,21]. Nestin is an intermediate filament protein and might play a key role in imparting cytoskeletal functions to the cell[22]. In support of these reports, ductal epithelial cells (DEC), which comprise 10% of the pancreatic cells expressing the intermediate filament proteins cytokeratin 7 and 19, have been demonstrated to function as pancreatic progenitors due to their ability to generate ISC[7]. NPC present in the pancreas, in addition to imparting the structural functions, also participate in developmental regulation as progenitors, similarly to DEC[23].

Therefore, exploring *in vitro* system(s) for the precise characterization and propagation of NPC would be a feasible approach to harness the potential of NPC as progenitors capable of differentiation into ISC. The present investigation has been undertaken to characterize NPC in the pancreas of mice at different ages (3 d to 8 wk), which has not been previously reported. Hence, understanding the localization of NPC at different ages would help in identifying the source of the progenitors and can further facilitate their differentiation into ISC under an appropriate microenvironment.

MATERIALS AND METHODS

Experimental design

All animal experimental procedures were approved by the Institutional ethical committee on animal research. Male Swiss albino mice aged 3 d, 1, 2, 4 and 8 wk were obtained from the National Center for Laboratory Animal Sciences (NCLAS), National Institute of Nutrition, Hyderabad, India.

Tissue preparation

The animals were ethically sacrificed using CO_2 asphyxiation and their pancreas were removed and washed with PBS. After removal of the adhered fat, the tissue was fixed overnight in Bouins solution at room temperature[24,25]. The fixed tissue was washed twice in 70% Ethanol and paraffin sections of 6-8 μm were cut using a microtome before being mounted on to poly-L-lysine coated slides. They were dried overnight at 37℃ before proceeding to immunolocalization.

Sample preparation and immunolocalization for nestin/insulin/glucagon

The pancreatic sections from all the age groups were processed under identical conditions. The samples were de-paraffinized by heating at 60℃ for 30 min. They were then dehydrated by passing through a series of decreasing concentration of ethanol (100%, 90%, 70%, 50%, and 30%). This was followed by washing for 2 min each with double distilled water and PBS. They were then blocked with 4% Horse serum at room temperature for 1 h. Subsequently they were incubated with primary antibody overnight at 4℃ (Mouse anti Rat Nestin 1:200 BD Biosciences, USA, anti mouse glucagon 1:200 Santa Cruz and anti mouse insulin 1:500 Sigma, USA). After repeated washing with PBS containing Ca^{2+} and Mg^{2+}, the slides were treated with a secondary antibody tagged with an appropriate fluorescent dye (Goat anti guinea pig alexa 488, Goat anti rabbit alexa 546, Goat anti mouse alexa 633, Molecular Probes, USA). The fluorescence images were captured using a confocal microscope (Leica SP5 series) and fluorescent intensities units (FIU) were corrected using appropriate controls (primary antibody controls). The FIU have been quantitated as relative fluorescent units (RFU) and the experiments have been carried out independently in three sets of mice.

Statistical test

Results are expressed as mean ± SE using three independent experiments. One-way analysis of variance (ANOVA) was used, followed by a post-hoc LSD test with SPSS software to determine the significance.

RESULTS

Immunolocalization of nestin in mice pancreases at different ages is shown in Figure 1. In the early phase of postnatal period (3-6 d pups), the NPC were localized more towards the periphery of the endocrine pancreas, as evident from the colocalization of insulin and glucagon with NPC and by the absence of NPC in the acinar fraction (Figure 1A and B). In the 2-wk-old mice, the NPC were seen both in the exocrine as well as the endocrine pancreas (Figure 1C). Interestingly, in the 4-wk-old mice, the NPC were confined to the endocrine pancreas and were located more towards the periphery along with the glucagon positive cells (Figure 1D). In the 8-wk-old pancreatic tissue, the NPC localized predominantly in the central region of the islets clusters, where immunostaining for insulin was also predominant (Figure 1E). The RFU for the localization of nestin is shown in (Figure 2) where the NPC showed predominance in the insulin enriched fraction by eight week.

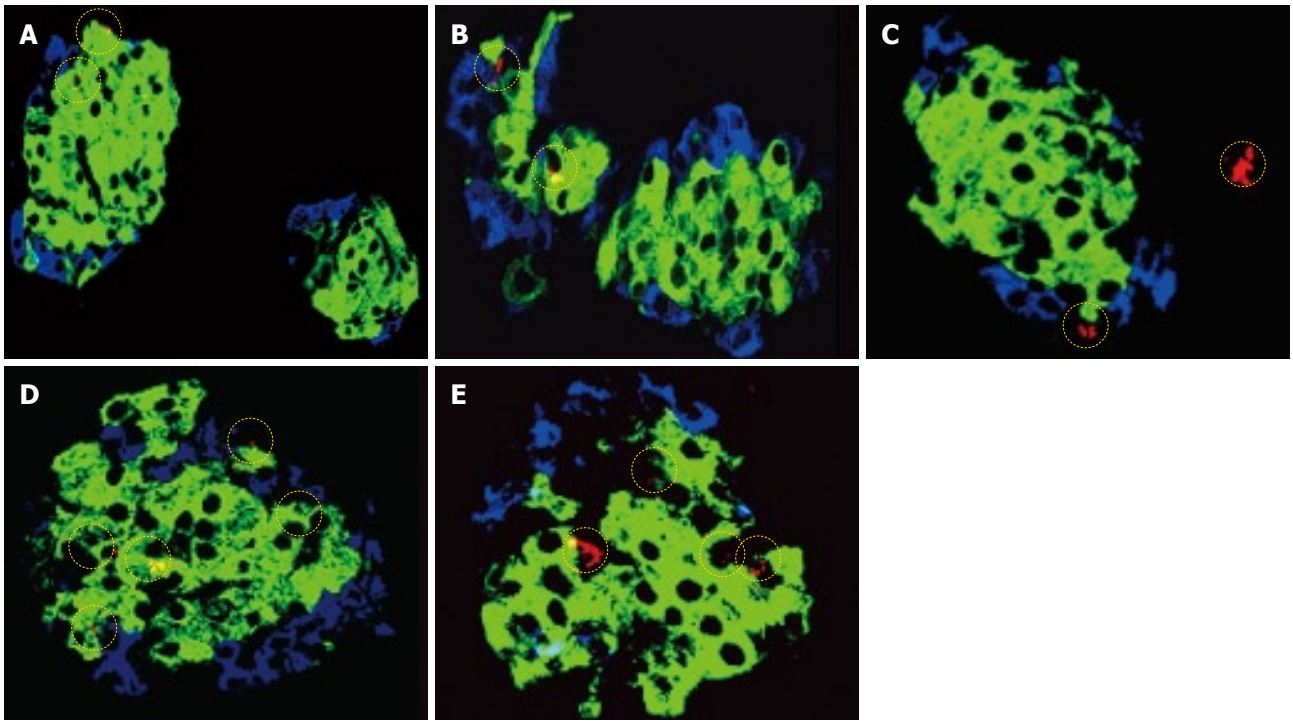

Figure 1 Immunolocalization of nestin in mice pancreases at different ages. A: Immunohistochemical localization of Nestin (red), Insulin (green), glucagon (blue) in three-day-old mouse pancreatic section, the presence of nestin is more towards the periphery of the endocrine fraction, magnification (x 400); B: One-week-old mouse pancreatic section, the presence of nestin is more towards the periphery of the endocrine fraction, magnification (x 400); C: Two-week-old mouse pancreatic section showing Nestin staining in both the exocrine as well as endocrine fraction, magnification (x 400); D: Four-week-old mouse pancreatic section showing Nestin staining only in the endocrine fraction confining more towards the periphery of the insulin stained cells, magnification (x 400); E: Eight-week-old mouse pancreatic section showing the Nestin localization predominant in the central region of the islets clusters where immunostaining for insulin was also significant, magnification (x 400).

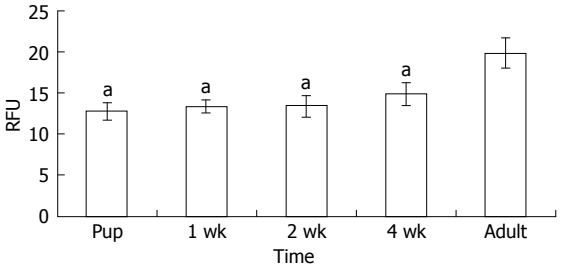

Figure 2 Quantitative relative fluorescence units of Nestin for different age groups performed in three different sections showing a higher level in the 8-wk-old pancreatic tissue. $^{a}P < 0.05$ in the adult as as compared to other four ages.

DISCUSSION

The present observations unequivocally suggest heterogeneity in the distribution of NPC within pancreatic tissue at different ages of mice (3 d to 8 wk) and this could be of functional and developmental significance. During embryogenesis, an increased expression of nestin has been reported in the neuroepithelial stem cells[26]. In line with these studies, the role of nestin has been demonstrated in the process of cellular rearrangements in the undifferentiated cells[27,28]. Studies in human islet explants, rat pancreatic tissue and embryonic stem cells have explored nestin as a marker of pancreatic progenitor stem cells, which have the renewal property and can be regulated to differentiate into insulin and glucagon positive cells[29,30].

The immunohistochemical localization of NPC (predominantly in the insulin-enriched fraction) has been depicted as RFU in Figure 2. These observations show that the endocrine portion of the pancreas serves as the primary enriched source of progenitors such as NPC, which, like DEC, can be expanded and differentiated into ISC with the appropriate growth factors in their microenvironment. In the present study, the application of reliable and specific immunocytochemical technique using specific antibodies and confocal microscopy has enabled the identification of NPC associated/colocalized with insulin and glucagon cells.

We report for the first time the significant localization of NPC (progenitors) in the endocrine pancreas at different ages of the mice. With increasing age of mice, the colocalization of NPC is more predominant in the insulin positive cells in the central region, unlike that seen at other ages. Identification of the sources and understanding the conditions and factors within the microenvironment of the pancreatic stem cells will be of therapeutic importance for the generation of ISC, which may be useful in the management of diabetes.

ACKNOWLEDGEMENTS

We thank Department of Biotechnology, Govt. of India, New Delhi for their financial support to carry out this work. We thank the Head of the Institutes of National Institute of Nutrition, Department of Health Research, Govt. of India, Hyderabad and National Center for

Cell Science, Department of Biotechnology, Govt. of India, Pune for extending their support to carry out this work. We acknowledge the help extended by Dr. Anandwardhan A Hardikar and his group towards the study and Dr. M Raghunath for manuscript correction.

COMMENTS

Background

The present study has been undertaken to investigate the precise localization and characterization of nestin positive cells (NPC) as a source of pancreatic progenitors that are capable of differentiating into insulin secreting cells (ISC). Nestin is an intermediate filament protein playing key role in imparting cytoskeletal functions to the cell and has been demonstrated as a progenitor in the neuronal tissue, bone marrow, embryonic stem cells, islet explants, fetal and adult pancreatic tissue.

Innovations and breakthroughs

This paper demonstrates the immunolocalization of NPC along with insulin and glucagon at different ages of mice for the first time.

Applications

Their data demonstrates the predominance of NPC in the insulin enriched fraction of 8-wk-old mice and these observations are significant due to the fact that NPC are one of the progenitors of adult pancreatic tissue. The NPC can be expanded and differentiated into ISC with the appropriate growth factors in its microenvironment.

Terminology

NPC standed for a pancreatic progenitor; ISC means the beta cells of islet that secrete insulin.

Peer review

The study investigates immunolocalization of nestin in the mouse pancreas. Nestin is a known marker of neural stem cells, which is also transiently expressed by many types of cells during development. Upon differentiation, nestin becomes downregulated. One best known instance of nestin expression in adult organisms, are the neuronal precursor cells of the subventricular zone. The study by Dorisetty *et al* suggests that nestin is localized to the endocrine pancreas. Based on this, the authors hypothesize that pancreatic endocrine tissue is a potent source of progenitor cells, which could be reprogrammed into insulin-producing cells and could be used for the treatment of diabetes. The idea of the study is interesting, and is supported by the literature data.

Abstract

AIM: To construct a noninvasive assessment model consisting of routine laboratory data to predict significant fibrosis and cirrhosis in patients with chronic hepatitis B (CHB).

METHODS: A total of 137 consecutive patients with CHB who underwent percutaneous liver biopsy were retrospectively analyzed. These patients were divided into two groups according to their aminotransferase (ALT) level. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), the likelihood ratio (LR) of aminotransferase/platelet ratio index (APRI) $\geqslant$ 1.5 or < 1.5 in combination with different hyaluronic acid (HA) cut-off points were calculated for the presence of moderate to severe fibrosis/cirrhosis (fibrosis stages 2 and 4) and no to mild fibrosis/cirrhosis (fibrosis stages 0 and 1).

RESULTS: The APRI correlated with fibrosis stage in CHB patients. The APRI $\geqslant$ 1.5 in combination with a cut-off HA cut-off point > 300 ng/mL could detect moderate to severe fibrosis (stages 2-4) in CHB patients. The PPV was 93.7%, the specificity was 98.9%. The APRI < 1.5 in combination with different HA cut-off points could not detect no to mild fibrosis in CHB patients.

CONCLUSION: The APRI $\geqslant$ 1.5 in combination with a HA cut-off point > 300 ng/mL can detect moderate to severe fibrosis (stages 2-4) in CHB patients.

INTRODUCTION

About 350 million individuals are chronically infected with hepatitis B virus (HBV) worldwide[1]. There are 30 million patients with chronic hepatitis B (CHB) in China, which will progress to cirrhosis or hepatocellular carcinoma (HCC) in 10%-30% of CHB patients. Although antiviral treatment with interferon or nucleoside analogues has been widely adopted, it has significant side effects. Liver biopsy can help decide the treatment modality for patients infected with HBV, especially for those whose alanine aminotransferase (ALT) is under 2 of the upper limit of normal (ULN) or normal, but its value is questioned because of its potential risk and the concern of sampling errors[2]. Therefore, there is a growing tendency to use noninvasive measures instead of histopathological analysis of liver tissue for the evaluation of disease progression in patients with chronic liver diseases. Up to date, several laboratory tests, scores, and indices have been proposed for noninvasive prediction of hepatic fibrosis in CHB patients[3,4]. However, the results of such tests are different in

different study populations[5]. Aminotransferase/platelet ratio index (APRI) is easy to calculate, but it can only predict the severe hepatic fibrosis (F3, F4). Kuroiwa *et al*[6] reported that HA can predict all fibrosis stages, but its sensitivity and specificity are not very high. We hypothesized that APRI in combination with different hyaluronic acid (HA) cut-off points would be a better predictor of fibrosis than individual parameters.

MATERIALS AND METHODS

Patients

A total of 137 consecutive patients with CHB who underwent percutaneous liver biopsy at Shanghai Public Health Clinical Center (China) from 2005 to April 2008 were included in this study. Real-time PCR showed that all patients were positive for HBV DNA and had no chronic liver disease confirmed by standard clinical, serological, biochemical, and radiological criteria. Additional exclusion criteria were antiviral treatment before liver biopsy, alcohol consumption in excess of 40 g/d. Liver biopsies were obtained by either blind or ultrasound-guided techniques using a 16-gauge Klatskin needle. The length of biopsy samples was longer than 1.5 cm. All biopsies were read by a pathologist who had no clinical information on the CHB patients. Formalin-fixed and formalin-embedded liver tissues were cut into 4-μm thick sections with a microtome. One section was stained with hematoxylin and eosin for assessment of hepatic inflammatory activity and the other sections were stained with Gomori stain for evaluation of hepatic fibrosis. Biopsy specimens with at least 4 portal fields were considered representative and scored by a pathologist unaware of the laboratory results. Fibrosis was staged as no (0), mild (1), moderate (2), severe (3), and cirrhosis (4), using the METAVIR score[7]. Hepatic inflammatory activity was also scored.

Serum aspartate aminotransferase (AST), ALT, HA and platelet count in all patients within 2 wk after liver biopsy were routinely determined. The ULN for ALT was 50 U/L, and transformed into ULN for further analysis. The reference range for platelet count was 100 $\times 10^9$-300 $\times 10^9$/L. HA was measured using the RIA and the reference range was 9-119 ng/mL. According to the ULN of ALT, we divided the patients into two groups with their ALT $\geqslant$ 2ULN and < 2ULN, respectively. APRI was calculated as previously described[8,9].

Statistical analysis

Baseline demographic data were evaluated for comparability of the two groups using Fisher's exact test for categorical variables and Student's *t* test for continuous variables. Student's *t* test or analysis of variance was used to compare the means of different stage groups when appropriate. Correlation was evaluated by the Spearman correlation coefficient. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and likelihood ratio (LR) of APRI $\geqslant$ 1.5 and APRI < 1.5 in combination with different HA cut-off points were detected for the presence of moderate to severe fibrosis/cirrhosis (fibrosis stages 2 and 4) and no to mild fibrosis/cirrhosis (fibrosis stages 0 and 1). $P < 0.05$ was considered statistically significant.

Table 1 Characteristics of patients included in this study

	ALT $\geqslant$ 2ULN	ALT < 2ULN
Number of patients	78	59
Age (SD)	35.2 (7)	38.7 (7.4)

Significant fibrosis ($\geqslant$ F2)	269.8 (214.1)	268.9 (187.1)

[1]APRI: (AST/ULN) × 100/PLT.

RESULTS

Characteristics of patients

A total of 137 patients with CHB who underwent percutaneous liver biopsy were included in this study. In order to adequately estimate the predictive model, the patients were divided into 2 groups with their ALT $\geqslant$ 2ULN and ALT < 2ULN, respectively. There was no significant correlation between age, gender, HA, APRI and disease stage. The characteristics of patients in the two groups are shown in Table 1.

Stages of fibrosis

The distribution of fibrosis stages in the two groups is shown in Table 1. Of the 137 patients, 57 (41.6%) had no or only mild fibrosis (stages 0 and 1), 46 (33.6%) had moderate fibrosis (stage 2), and 34 (24.8%) had severe fibrosis or cirrhosis (stages 3 and 4). As expected, the APRI and HA cut-off points increased with the stage of fibrosis, but there was no significant difference between the two groups. The mean APRI was $\geqslant$ 1.5 in patients with moderate to severe fibrosis or cirrhosis (stages 2-4) and < 1.5 in patients with no or mild fibrosis (stages 0 and 1).

Among the patients with their APRI $\geqslant$ 1.5, the Spearman correlation coefficient was $r = 0.312$ and 0.344 between APRI and fibrosis stage ($P < 0.05$, Figure 1), and $r = -0.717$ and -0.812 between HA and fibrosis stage

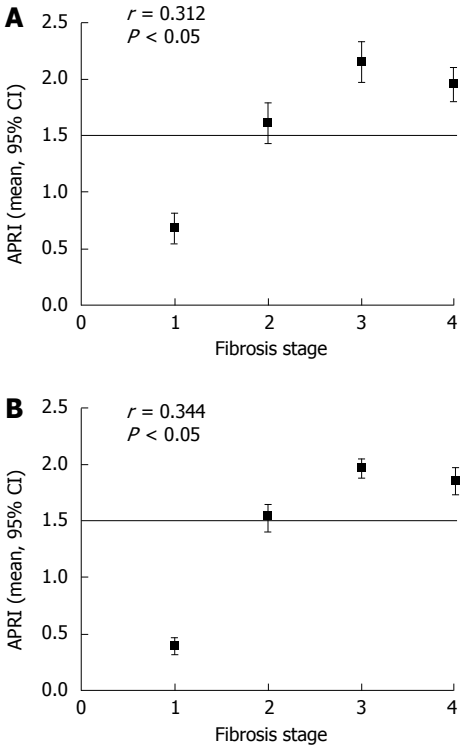

Figure 1 APRI and fibrosis stage in CHB patients with their ALT ⩾ 2ULN (A) or < 2ULN (B).

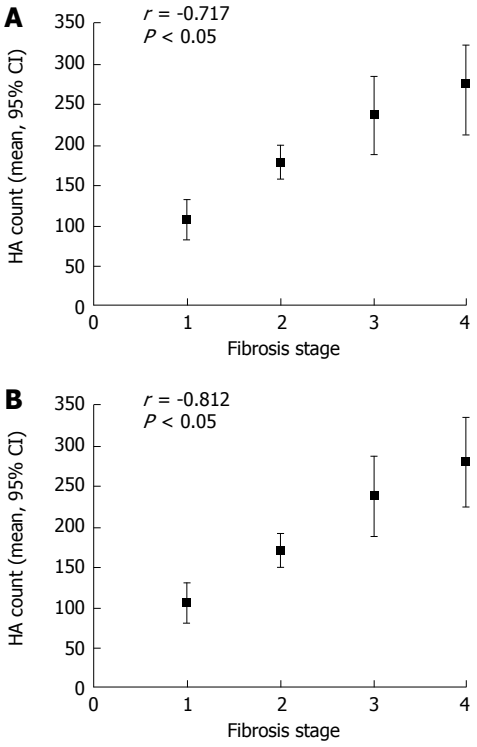

Figure 2 HA and fibrosis stage in CHB patients with their ALT ⩾ 2ULN (A) or < 2ULN (B).

Table 2 Sensitivity, specificity, PPV, and NPV of APRI > 1.5 in combination with different HA cut-off points for the detection of liver fibrosis (stages 2-4) in CHB patients

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	+LR	-LR
APRI ⩾ 1.5	44.7	84.3	41.3	84.7	2.80	0.66
+HA ⩾ 150	46.6	95.6	88.6	89.5	10.6	0.56
+HA ⩾ 200	46.8	97.8	90.2	89.9	21.3	0.54
+HA ⩾ 250	47.3	98.7	93.2	90.2	36.4	0.53
+HA ⩾ 300	45.3	98.9	93.7	91.3	41.2	0.55

Table 3 Sensitivity, specificity, PPV, and NPV of APRI ⩽ 1.5 in combination with different HA cut-off points for the detection of liver fibrosis (stages 0-1) in CHB patients

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	+LR	-LR
APRI < 1. 5	35.3	81.6	41.3	82.2	1.9	0.79
+HA < 300	45.7	86.2	44.6	83.1	3.3	0.63
+HA < 250	42.8	83.2	42.8	81.3	2.5	0.69
+HA < 200	38.5	80.8	40.8	80.3	2.0	0.76
+HA < 150	31.7	78.8	37.1	77.7	1.5	0.87

($P < 0.05$, Figure 2). However, there was no significant difference in patients with their APRI < 1.5 between APRI or HA count and fibrosis stage.

APRI ⩾ 1.5 in combination with different HA cut-off points could detect moderate to severe fibrosis (stages 2-4) in CHB patients (Table 2). The sensitivity, specificity, PPV, NPV, +LR and -LR were determined. APRI alone had a PPV of 41.3% and a specificity of 84.7%. When HA was added, the PPV and specificity increased significantly, indicating that APRI ⩾ 1.5 in combination with a HA cut-off point > 300 ng/mL can detect moderate to severe fibrosis or cirrhosis (stages 2-4) in CHB patients. In the present study, the PPV was 93.7% and the specificity was 98.9%. On the other hand, not all patients with moderate to severe fibrosis or cirrhosis could be correctly identified. The identification methods for patients with no or mild fibrosis (stages 0 and 1) using APRI < 1.5 in combination with different HA cut-off points are shown in Table 3. Since the sensitivity, specificity, PPV and NPV were low, mild fibrosis in CHB patients could not be detected using these laboratory parameters.

DISCUSSION

It is well known that the exact staging of liver fibrosis is crucial for the therapeutic decision and assessing the prognosis of CHB patients. The gold standard for fibrosis staging is liver biopsy. However, a simple noninvasive method for detection of fibrosis would be beneficial. Some studies have shown that APRI is only sensitive to F3-F4 stages of fibrosis[10,11].

HA, mainly metabolized in liver, is one of the important components of extracellular matrix, and can reflect the level of hepatic fibrosis in some degree. Guéchot *et al*[12] showed that the sensitivity and specificity of serum HA at a cut-off point of 110 μg/L for the diagnosis of hepatic fibrosis are 79% and 89%, respectively. Patel *et al*[13] reported that as a noninvasive valuable marker, serum HA concentration is correlated with hepatic fibrosis. Kuroiwa *et al*[6] showed that the

AUC value of HA for any fibrosis and cirrhosis is higher than 0.5. Montazeri *et al*[14] demonstrated that serum HA is a preferred marker of severe fibrogenesis and inflammation in CHB patients. HA at a cutoff point of 126.4 μg/L can detect severe fibrosis with a sensitivity of 90.9% and a specificity of 98.1%.

In this study, the APRI was correlated with fibrosis stage in CHB patients. The sensitivity, specificity, PPV, NPV, +LR and -LR of APRI in detecting were 35.3%, 81.6%, 41.3%, 82.2%, 1.9 and 0.79, respectively, for the detection of mild fibrosis (stage 1) in CHB patients. However, its sensitivity, specificity, PPV, NPV, +LR and -LR of APRI were 44.7%, 84.3%, 41.3%. 84.7%, 2.8 and 0.66, respectively, for the detection of moderate to severe fibrosis (stages 2-4) in CHB patients. The sensitivity, specificity, PPV, and NPV of HA were very low for the detection of fibrosis stages in CHB patients. APRI does not involve a complicated formula, thus allowing it to be quickly calculated. In addition, it uses 2 laboratory tests and is not associated with the added expense of a reference laboratory, and does not contain subjective parameters such as ethanol intake.

We established a noninvasive assessment model of liver fibrosis consisting of APRI and HA. APRI $\geqslant$ 1.5 in combination with different HA cut-off points was used to predict moderate to severe fibrosis (stages 2-4) in CHB patients. APRI alone had a PPV of 41.3% and a specificity of 84.7%. When different HA cut-off points were added, the PPV and specificity increased significantly, especially when a HA cut-off point was greater than 300 ng/mL, indicating that APRI $\geqslant$ 1.5 in combination with a HA cut-off point > 300 ng/mL can predict moderate to severe fibrosis (stages 2-4) in CHB patients. The PPV, specificity and LR of this model were 93.7%, 98.9% and 41.2, respectively. On the other hand, not all patients with moderate to severe fibrosis could be correctly identified. We want to know if serum ALT level is correlated with HA and APRI values. However, the APRI and HA increased with the stage of fibrosis, but there was no significant difference in patients with their ALT $\geqslant$ 2ULN or < 2ULN, respectively, which may be due to the small number of patients.

Since the rate of APRI < 1.5 in combination with different HA cut-off points for the detection of mild fibrosis (stage 1) in CHB patients was low in this study, liver biopsy was needed for the detection of mild fibrosis in CHB patients.

Finally, the model was established based on liver biopsy as the gold standard[15]. Since sampling error and inter-observer variability are known limitations of a liver biopsy, we should interpret the results of noninvasive tests for hepatic fibrosis with caution within a broader clinical context.

In conclusion, a predictive model for assessing the probability of significant hepatic fibrosis can be established in CHB patients. APRI $\geqslant$ 1.5 in combination with a HA cut-off point > 300 ng/mL can detect moderate to severe fibrosis (stages 2-4) in CHB patients.

COMMENTS

Background

Liver biopsy is the gold standard for hepatic fibrosis in chronic hepatitis B (CHB) patients, especially in those whose alanine aminotransferase (ALT) is under 2ULN or normal, but its value is questioned because of its potential risk and sampling error. Noninvasive markers of liver fibrosis have been recently proposed as substitutes for liver biopsy, but their reported accuracy is around 80%. They have been mostly validated in hepatitis C but not in hepatitis B. They applied their method in a cohort of patients with chronic hepatitis B.

Research frontiers

Since sampling error and inter-observer variability are known limitations of liver biopsy, some noninvasive methods for liver fibrosis have been proposed, but international guidelines still do not recommend a routine use of the markers due to lack of reproducibility and a misdiagnosis rate of 20%. Thus, a trusted method that avoids a number of liver biopsies by maintaining an excellent accuracy is urgently needed.

Innovations and breakthroughs

In this study, they established a noninvasive assessment model consisting of APRI and HA for the detection of liver fibrosis and cirrhosis in CHB patients. APRI $\geqslant$ 1.5 in combination with a HA cut-off point > 300 ng/mL could detect moderate to severe fibrosis (stages 2-4) in CHB patients. The PPV and specificity of this model were 93.7% and 98.9%, respectively, showing that it can be used as a non-invasive marker for the detection of liver fibrosis in CHB patients.

Applications

The predictive model can be used as a first line assessment of significant hepatic fibrosis in CHB patients, limiting liver biopsy to those who are unclassified or show a low predictive value. In the future, priority should be given to large scale validation studies and the most promising non-invasive markers in patients with all major etiologies of chronic liver disease and most frequent cofactors affecting the diagnostic performance of fibrosis markers.

Terminology

APRI: a simple test combining aspartate aminotransferase (AST) and platelet count for non-invasive prediction of significant fibrosis and cirrhosis in hepatitis C patients. It is a very simple and economic tool, but it is somehow less accurate than fibrotest.

Peer review

This is an interesting paper addressing a clinical problem in the management of chronic hepatitis B. The usefulness of this combination of non-invasive markers of fibrosis and its place in clinical practice needs to be further studied.

Abstract

AIM: To evaluate the efficacy and safety of Heller myotomy (HM) for recurrent achalasia, performed after different methods of first-line treatment.

METHODS: We searched for studies published in PubMed from 1966 to March 2008 on treatment of recurrent achalasia with HM after failure with different methods of first-line treatment. The efficacy of HM was assessed by a pooled estimate of response rate with individual studies weighted proportionally to sample size.

RESULTS: Sixteen studies were eligible and included in the review. The results showed that HM has a better remission rate for recurrent achalasia after failure of HM [weighted mean (SD)] of 86.9% (21.8%) compared with 81.6% (23.8%) for pneumatic dilatation (PD). One study evaluated the efficacy of HM after failure of PD combined with botulinum toxin injection (83%). The most common complications were perforation and gastroesophageal reflux.

CONCLUSION: HM has the best efficacy in patients with recurrent achalasia who were treated with HM as first-line treatment. Future studies should focus on how to increase the success rate and decrease the complications of HM.

INTRODUCTION

Achalasia is a severe neuromuscular disorder of the esophagus, characterized by the loss of peristalsis and an inability of the lower esophageal sphincter (LES) to reach optimal relaxation[1]. Although the etiology of achalasia remains elusive, the mainstay of therapy is directed towards reduction of LES pressure to improve esophageal emptying by gravity[2].

Treatment for achalasia includes drug therapy[3], botulinum toxin (BoTx) injection[4,5], pneumatic dilatation (PD)[6,7] and Heller myotomy (HM)[8-10]. Among these, PD and HM are the most common treatment methods for untreated achalasia[11]. However, none of the treatments reverses the underlying neuropathology of achalasia. There are still some patients who have persistent or recurrent dysphagia[12].

How to select an appropriate treatment for the patients of recurrent achalasia is a hot topic of debate. BoTx, PD and HM are the most popular options for recurrent achalasia. However, BoTx and PD do not achieve a good remission rate for recurrent achalasia in the long term. Moreover, perforation is a severe complication for patients treated with PD as second-line treatment. Therefore, HM is becoming increasingly popular for treatment of recurrent achalasia[13-16]. However, the efficacy of HM is very much dependent upon first-line treatment, for reasons of symptom relapse or failure, and age and co-morbidity of patients.

Therefore, our purpose was to compare the efficacy and safety of HM for patients with recurrent achalasia treated with different methods of first-line treatment, and to evaluate the influence of first-line treatment, including BoTx, PD and HM, on the efficacy of HM performed as second-line treatment.

MATERIALS AND METHODS

Literature search

A systematic review of the literature was conducted. Search tools included Elsevier Science Direct, Blackwell Synergy, Medline (OVID), Pub-Med and Springerlink. Search terms were "achalasia" combined with "treatment, Heller myotomy, pneumatic dilatation, botulinum toxin injection, recurrent, relapse, efficacy, or safety". We first reviewed the abstracts of all articles that reported the efficacy of HM for recurrent achalasia. Then, we retrieved the full articles when relevant. Additionally, reference lists of articles were checked for further relevant articles. We included studies that assessed the influence of first-line treatment methods for HM, in order to evaluate the efficacy and safety of HM as a second-line treatment for recurrent achalasia.

Study selection and data analysis

A study was considered eligible for inclusion if patients had undergone clinical, manometric, radiographic and endoscopic evaluation to confirm achalasia. The severity of symptoms was evaluated by a modified symptom score[17], which consisted of the sum of the scores for dysphagia, regurgitation and chest pain. Recurrent achalasia is defined as recurrence of severe symptoms of dysphagia, regurgitation or chest pain (symptom scores of 2 or 3), and the need for intervention again, or repeat HM[18-22].

Data regarding the first author, year of publication, first-line treatment, operation duration, median hospital stay, and symptoms remission rate, were extracted. Since there was no controlled trial to analyze efficacy and safety of HM for recurrent achalasia patients performed with different methods as the first treatment. There was no uniformity in assessment of efficacy among trials; therefore, we extracted the number of individuals with a good-to-excellent response, which was sustained until the end of the observation period without any further therapy after HM, regardless of criteria. These were considered HM treatment failures, when patients required further treatment or were converted to esophagectomy.

Statistical analysis

The efficacy of studies included in the review was assessed by a pooled estimate of response rate with individual studies weighted proportionally to sample size[23]. In calculating the weighted mean response for each treatment modality ($\hat{p}$), included studies were characterized by the number of subjects (n) and the response rate for those subjects (p). Ellipses represent scant data.

$$SE(\hat{p}) = [p_1(1 - p_1)/n_1 + p_2(1 - p_2)/n_2 + p_x(1 - p_x)/n_x]^{1/2}$$

$$\hat{p} = (n_1p_1 + n_2p_2 + n_xp_x)/(n_1 + n_2 + n_3)$$

RESULTS

Our literature searches identified 162 studies. Of these, 16 were eligible and included in the analysis. The clinical characteristics and efficacy of studies included in the review are shown in Table 1.

Study characteristics

There were five studies[24-28] and three studies[29-31] that assessed the efficacy of HM for failed PD as the first-line treatment. The remission rate was 77.8%-93%. Operation duration was 50-210 min. Median hospital stay was 2.6-8 d. One study[32] has reported the efficacy of HM for achalasia patients who failed combined treatment with PD and BoTx. The remission rate was 83%, operation duration was 156 min, and the hospital stay was 3.5 d. There were five[33-37] studies and two[38,39] studies that assessed the efficacy of HM for failed HM as the first-line treatment. The remission rate was 73%-100%. Operation duration was 90-128 min. Median hospital stay was 2-4 d. The reasons for recurrence of

HM were incomplete myotomy, myotomy fibrosis and fundoplication disruption.

Efficacy of HM for recurrent achalasia

Our review showed that HM has a better remission rate for recurrent achalasia performed with HM [weighted mean (SD)] is 86.9% (21.8%) effective versus 81.6% (23.8%) for PD as the first line treatment. Only one study evaluated the efficacy of HM for failed PD combined with BoTx (83%). We did not evaluate the efficacy of HM for failed BoTx injection because of the lack of data.

It is still controversial that prior treatment measures influence the efficacy of HM for the recurrent achalasia. Some researchers[40] consider that HM is easy to perform in PD patients, and the efficacy is as high as that in patients without any previous therapy. Good clinical results with HM are associated with a reduction of LES pressure to < 10 mmHg. Whereas, some studies[41-43] have shown that the technical difficulties of performing HM increase in some patients with previous dilatation. Preoperative PD represents a risk factor for laparoscopic HM. There was a trend toward a higher incidence of intraoperative esophageal perforation and recurrent dysphagia in patients with prior PD treatment. Moreover, some studies[44-47] have demonstrated that reoperative laparoscopic HM can be undertaken safely (in experienced hands), and can result in good outcomes, with a similar level of success as that seen after primary myotomy.

Complications of HM for recurrent achalasia

We did not evaluate the co-morbidity in patients with recurrent achalasia treated with HM after different methods of first-line treatment, because of a lack of detailed data. Therefore, we used a descriptive method. Patients who were treated with HM experienced intraoperative and postoperative complications. The most common intraoperative complication was gastrointestinal perforation, including gastric and esophageal perforation in 1.5%-20% of patients. Besides, some patients experienced pneumothorax (1.9%-6.7%). Early postoperative complications included pulmonary complications (1.3%-4%). Some patients experienced persistent and severe chest pain, which prolonged the time to hospital discharge. Gastroesophageal reflux is a frequent complication after HM, presenting at a rate of 2.6%-20%. Most patients could be controlled with medical therapy. Some patients presented with endoscopic esophagitis without reflux symptoms.

DISCUSSION

We have performed a review to analyze efficacy and safety of HM for recurrent achalasia performed after different methods of first-line treatment. Our results showed that HM has the best clinical efficacy in recurrent achalasia when performed after HM as first-line treatment (86.9%), followed by 83% for PD combined with BoTx and 81.6% for PD. Although the number of patients in this review was relatively small, it represents one of the largest series in the literature.

First, the efficacy of HM for recurrent achalasia depends on the method of first-line treatment. Traditionally, endoscopic therapies have been selected for first-line treatment over surgery, because of the morbidity associated with open or laparoscopic HM. In patients who have had prior endoscopic therapy, there is a notable difference in the submucosal dissection plane, especially near the squamocolumnar junction. Often the plane is obliterated, and it is very difficult to confidently and easily dissect down onto the mucosa, as can be accomplished in those who have not had prior therapy[48]. However, some studies have shown that previous PD does not determine a high failure rate or a high rate of complications with HM[49]. Therefore, it is urgent to build up a standard technique to decrease the risk of HM for recurrent achalasia.

Second, the efficacy of HM for recurrent achalasia depends on the reasons for symptom relapse or failure. Reasons for failure were incomplete myotomy (33%), myotomy fibrosis (27%), fundoplication disruption (13%), too tight fundoplication (7%) and a combination of myotomy fibrosis and incomplete myotomy (20%).

Third, the efficacy of HM for recurrent achalasia depends on the age and co-morbidity of patients. There is a strong association between age at which diagnosis of achalasia is first established and the requirement for HM[50]. For each year of increasing age, the odds ratio for the eventual requirement for myotomy decreases by 0.943 (95% CI: 0.90-0.98). As age increases, the need for surgical therapy progressively diminishes. The perioperative and postoperative morbidities also influence the efficacy of HM for recurrent achalasia.

Finally, the efficacy of HM for recurrent achalasia depends on the operative technique and postoperative management. In recent years, laparoscopic HM, with or without fundoplication, has increasingly been performed because of the lower morbidity and shorter recovery period associated with laparoscopic surgery[51]. Some surgeons[52] prefer a posterior partial fundoplication instead of an anterior hemifundoplication. It prevents reflux more effectively and keeps the edges of the myotomy separate. Whereas, some studies have shown that laparoscopic HM without fundoplication has the same or an even better effect on achalasia[53]. Finley *et al*[54] have reported that laparoscopic HM without anterior fundoplication shows significantly better upright esophageal clearance, with a trend toward improved dysphagia and regurgitation frequency, when compared with anterior fundoplication.

Recently, there have been some new methods to treat recurrent achalasia. Ponciano *et al*[55] have reported that the Serra-Dória procedure for the treatment of megaesophagus in patients who had already undergone cardiomyotomy, and whose symptoms recurred, has low morbidity and no mortality. It offered a significant relief of symptoms, with a decrease in the caliber of the esophagus in several patients. The patients also improved with regards to reflux esophagitis. Oelschlager

et al[56] have suggested that an extended gastric myotomy (3 cm) more effectively disrupts the LES, thus improving the results of surgical therapy for achalasia, without increasing the rate of abnormal GER, provided that a Toupet fundoplication is added. Postoperatively, LES pressure was significantly lower after extended gastric myotomy. There were no reoperations in the extended gastric myotomy and Toupet fundoplication group.

Our review suggests that HM has the best clinical efficacy in patients with recurrent achalasia who are treated with HM as first-line treatment. Future studies should focus on how to increase the success rate of HM and decrease the complications and adverse effects. It is necessary to promote and popularize the technique of HM in general hospitals.

ACKNOWLEDGMENTS

We are grateful to Professor Shi Yao Chen for his excellent assistance in statistical analysis.

COMMENTS

Background

None of the treatment measures reverses the underlying neuropathology of achalasia. Heller myotomy (HM) is the most used technique for recurrent achalasia. However, the efficacy of HM is largely dependent on the method of first-line treatment.

Research frontiers

Authors aimed to evaluate the efficacy and safety of HM for patients with recurrent achalasia treated with different methods of first-line treatment.

Innovations and breakthroughs

Previous studies support the hypothesis that the efficacy of HM is very much dependent upon first-line treatment. However, there have been no studies to compare the efficacy of HM in patients with recurrent achalasia treated with different methods of first-line treatment. In this study, they found that HM has the best efficacy in recurrent achalasia treated with HM as the first-line therapy.

Applications

The results may provide a systematic analysis of the efficacy of HM for recurrent achalasia and identify HM as having the best efficacy in patients with achalasia treated with HM as first-line treatment. They can also offer assistance with the best treatment choice for achalasia in the future.

Terminology

Achalasia is a primary motor disorder characterized by incomplete relaxation of the lower esophageal sphincter (LES) and aperistalsis of the esophageal body, secondary to loss of inhibitory ganglion cells in the myenteric plexus. The etiology of the disease is unknown, with genetic, autoimmune, infectious, and environmental factors being implicated.

Peer review

This study is a systematic review of HM for recurrent achalasia. The authors show that HM achieves the best efficacy in patients with recurrent achalasia who were treated with HM as first-line therapy. It is a very interesting study.

Abstract

AIM: To investigate whether bone marrow-derived dendritic cells pulsed with tumor lysates induce immunity against gastric cancer *ex vivo*.

METHODS: c-kit$^+$ hematopoietic progenitor cells were magnetically isolated with a MiniMACS separator from BALB/c mice bone marrow cells. These cells were cultured with cytokines GM-CSF, IL-4, and TNFα to induce their maturation. They were analysed by morphological observation, phenotype analysis, and mixed lymphocyte reaction (MLR). Bone marrow-derived DCs (BM-DCs) were pulsed with tumor cell lysate obtained by rapid freezing and thawing at a 1:3 DC:tumor cell ratio. Finally, cytotoxic T lymphocyte (CTL) activity and interferon gamma (IFNγ) secretion was evaluated *ex vivo*.

RESULTS: c-kit$^+$ hematopoietic progenitor cells from mice bone marrow cells cultured with cytokines for 8 d showed the character of typical mature DCs. Morphologically, observed by light microscope, these cells were large with oval or irregularly shaped nuclei and with many small dendrites. Phenotypically, FACS analysis showed that they expressed high levels of Ia, DEC-205, CD11b, CD80 and CD86 antigen, moderate levels of CD40, and negative for F4/80. Functionally, these cells gained the capacity to stimulate allogeneic T cells in MLR assay. However, immature DCs cultured with cytokines for 5 d did not have typical DCs phenotypic markers and could not stimulate allogeneic T cells. *Ex vivo* primed T cells with SGC-7901 tumor cell lysate-pulsed (TP) DCs were able to induce effective CTL activity against SGC-7901 tumor cells (E:T = 100:1, 69.55% ± 6.05% specific lysis), but not B16 tumor cells, and produced higher levels of IFNγ when stimulated with SGC-7901 tumor cells but not when stimulated with B16 tumor cells (1575.31 ± 60.25 pg/mL in SGC-7901 group *vs* 164.11 ± 18.52 pg/mL in B16 group, $P < 0.01$).

CONCLUSION: BM-derived DCs pulsed with tumor lysates can induce anti-tumor immunity specific to gastric cancer *ex vivo*.

INTRODUCTION

Dendritic cells (DCs) are professional antigen presenting cells (APCs) that both initiate and modulate the immune response[1]. DCs are cells in the pathway of antigen capture and presentation to T cells, with the unique

ability to directly prime naïve $CD4^+$ and $CD8^+$ T cells. They posses the ability to efficiently uptake, process, and present antigens on major histocompatibility complex (MHC) class I and Ⅱ molecules, together with co-stimulatory molecules such as B7 and CD40[2]. Therefore, DCs are believed to be essential for stimulating tumor-specific cytotoxic T lymphocyte (CTL) and inducing the protective and therapeutic anti-tumor immunity against cancer cells.

Gastric cancer is one of the most common cancers[3]. Although gastric cancer therapy has made great progress, it is still difficult to treat advanced gastric cancer, as it has spread to the lymph glands and metastasized. Currently, radical surgery represents the standard method of therapy. Adjuvant therapy such as chemotherapy and radiation therapy have been widely applied, but gastric cancer control at the advanced stage remains difficult[4,5]. A new adjuvant therapeutic method is needed in order to improve the 5-year survival rate of patients with gastric cancer. Currently, tumor immunotherapy for gastric cancer has potential.

Ishigami *et al*[6] examined 169 patients with gastric cancer by immunohistochemical staining of CD57 and S-100-protein and found that DCs infiltrate in the tissue of gastric caner, but cannot play an important role due to lacking Th cells in the tumor microenvironment. In addition, a poorer differentiation of gastric cancer corresponds to a the lower amount of DC infiltration in the tumor tissue. Patients with a high level of DCs infiltration had a lower positivity of lymph node metastases and lymphatic invasion than patients with lower level of DCs infiltration[7]. The 5-year survival rates of patients with many DCs infiltrated were 78% better than that of patients with fewer DCs infiltrated[6]. According to the function of DCs described above, we can state that the DCs are related to clinical stage, invasion, metastasis and prognosis of gastric cancer. Galetto *et al*[8] reported that T-cell memory against gastric carcinoma antigens can be triggered by tumor-loaded autologous DCs. Therefore, it is feasible that DCs-based tumor vaccines will become a new effective immunoadjuvant therapy for gastric cancer, which can decrease the incidence and recurrence rate after operation for gastric cancer[9].

In this study, we demonstrated that vaccination with bone marrow-derived DCs pulsed with tumor cell lysate induced tumor-specific CTL activity and anti-tumor immunity against SGC-7901 gastric cancer cell lines, suggesting promising strategy for gastric cancer immunotherapy.

MATERIALS AND METHODS

Animals

BALB/c and C57BL/6 (B6) mice (8-10 wk old) were purchased from the Shanghai Experimental Animal Center, Chinese Academy of Sciences (Shanghai, China). All mice were kept under pathogen-free conditions in the animal center of the Soochow University (Suzhou, China).

Cell culture

Gastric cancer cell line, SGC-7901, and melanoma cell line, B16, were purchased from the Shanghai Cell Biology Institutes, Chinese Academy of Sciences (Shanghai, China). Both cell lines were cultured in RPMI (Roswell Park Memorial Institute) medium 1640 (GIBCO, USA) containing 10% fetal calf serum (FCS), penicillin G (100 U/mL), and streptomycin (100 μg/mL) at 37℃ in a humidified incubator supplemented with 50 mL/L CO_2.

Major

Murine granulocyte-macrophage colony-stimulating factor (GM-CSF), IL-4, tumor necrosis factor-α (TNFα), IL-2, and IL-7 were purchased from Becton Dickinson (New Jersey, USA). Phenotypic analysis, fluorescein isothiocyanate (FITC)- or phycoerythrin (PE)-labeled monoclonal antibodies (Mabs), such as MHC I (Ia), DEC-205, CD11b, CD40, CD80, CD86, and F4/80, were provided by Pharmigen (CA, USA). Mitomycin C (MMC) was purchased from Jingmei Biothe (Shenzhen, China).

Generation of bone marrow-derived DCs

Primary bone marrow-derived DCs (BM-DCs) were obtained from mouse bone marrow precursors according to a previously established protocol[10]. BALB/c mice bone marrow obtained from tibia and femurs by flushing with media. Tissue was minced in a single-cell suspension through a nylon mesh. BALB/c mice bone marrow cells were stained sequentially with biotinylated anti-c-kit MAb and Streptavidm MicroBeads (Dynal, Norway). $c\text{-}kit^+$ hematopoietic progenitor cells were magnetically isolated with a MiniMACS separator (Milteyi Biotec, Auburn, CA) from the BALB/c mice bone marrow cells. The cells (6×10^6) were cultured for 5 d in fresh RPMI medium 1640 containing 10% FCS, GM-CSF (4 ng/mL), and IL-4 (10 ng/mL). Then immature DCs were further cultured in GM-CSF (4 ng/mL) and TNFα (5 ng/mL) for 3 d to induce their maturation. Bone marrow-derived mature DCs were observed by light microscope (Nikon, Japan).

Immunofluorescence staining

DCs immunofluorescence analysis was performed as previously described[11]. In brief, DCs cultured for 5 d or 8 d as described above (2×10^5-4×10^5 cells) were incubated with rat anti-DEC-205 MAb followed by FITC-labeled goat anti-rat IgG $(Fab')^2$ antibodies or directly with FITC-labeled MAbs against CD40, F4/80, CD11b, or CD80 and PE-labeled MAbs against Ia, or CD86 followed by FACS analysis. The instrument compensation was set in each experiment using two-color stained samples.

Mixed leukocyte reaction assay

The mixed leukocyte reaction (MLR) assay was performed in accordance with previously described methods[12]. Immature DCs or mature DCs derived from bone marrow $c\text{-}kit^+$ cells were incubated in RPMI

Medium 1640 containing 10% FCS and mitomycin C (MMC; 15 μg/mL) in six-well plates at 37℃ for 3 h to arrest their proliferation. After several washes with PBS, these stimulator cells were suspended in RPMI-1640 containing 10% FCS at concentrations ranging from 1×10^2 to 5×10^4 cells/mL. One hundred microliters of the above stimulator cells suspension were added to each well of 96-well plates that contained allogeneic $CD4^+$ T cells (3×10^5 cells/100 μL per well) that had been magnetically isolated from B6 mice using CD4 Microbeads. Five days later, T-cell proliferation was determined by using an MTT assay. Fifteen μL of MTT (5 μg/mL in PBS) was added to each well, and the plates were incubated at 37℃ for an additional 4 h. The resultant absorbance at 550 nm was read by a microplate immunoreader. PBS alone was used as the negative control. Results are expressed as the mean of three wells from three individual experiments.

Pulsing DCs with tumor cell lysates

BM-DCs were pulsed with freeze-thawed tumor lysate at a 1:3 DC:tumor cell ratio. SGC-7901 tumor cells (6×10^6) were lysed by rapid freezing (liquid nitrogen) and thawing in a 37℃ bath three times. BM-DCs (2×10^6 cells/mL) were incubated in six-well plates in the presence of SGC7901 tumor lysates (6×10^6 cell equivalents/mL) in RPMI Medium 1640 containing 10% FCS, GM-CSF (4 ng/mL), and IL-4 (10 ng/mL) for one day at 37℃ and 50 mL/L CO_2. These SGC-7901 tumor cell lysate-pulsed (TP) DCs were used for vaccination after one day. B16 TP DCs were used as control.

Assays for cytotoxic T lymphocyte activity ex vivo

To confirm that tumor-specific cytotoxic T lymphocytes (CTLs) can be generated *ex vivo*, splenic $CD3^+$ T cells (1×10^6 cells/mL) were magnetically isolated from naïve BALB/c mice using CD3 microBeads. These cells were cultured in RPMI medium 1640 containing 10% FCS, then primed *ex vivo* in the presence of cytokines including IL-2 and IL-7 (5 ng/mL) at day 0, 7, and 14 with SGC-7901 TP DCs or B16 TP DCs at a 1:20 stimulator to responder cell ratio. Unpulsed DCs and SGC-7901 tumor lysates were used as controls. Fresh medium containing IL-2 and IL-7 was exchanged every 4 d. The primed T cells were effector cells; SGC-7901 or B16 tumor cells were target cells. On day 21, target cell suspension was added into 96 well plates, and effector cells were titrated to dilutions of target cells by serial dilutions (E-T mix, E:T, 1:1, 5:1, 10:1, 20:1, 50:1, 100:1). Supernatant from each well was collected after 20 h and cytolytic activity against target SGC-7901 tumor cells and B16 tumor cells was measured with a Cytotoxicity Detection Kit (LDH; Boehringer Mannheim, Mannheim, Germany). IFNγ production was determined with the IFNγ ELISA kit (Endogen, Woburn, MA, USA.) at a stimulator to responder cell ratio of 1:20.

Statistical analysis

Differences were evaluated using Statistical Package for Social Science 11.0 (SPSS11.0). Statistical analysis was performed using Student's *t*-test. Statistical tests were two-sided. $P < 0.05$ were considered to be statistically significant.

RESULTS

Morphological character of DCs

c-kit^+ hematopoietic progenitor cells from the BALB/c mice bone marrow cells were cultured in presence of GM-CSF, IL-4, or TNFα for 8 d, then observed by light microscopy. Results show large cells with oval or irregularly shaped nuclei and many small dendrites (Figure 1).

Phenotypic markers of DCs analysis by FACS

The phenotypic profile of a representative population of bone marrow DCs was determined by FACS. BM-DCs cultured for 5 d expressed moderate levels of co-stimulatory molecule CD40, high levels of CD11b, and very low levels of Ia, DEC-205, CD80, CD86, and were negative for F4/80 (Figure 2). However, when these cells were cultured in the presence of GM-CSF, IL-4, or TNFα for 8 d, they differentiated into mature DCs that expressed high levels of Ia, DEC-205, CD11b, CD80 and CD86 antigen, moderate levels of the co-stimulatory molecule CD40, and were negative for F4/80 (Figure 2).

The capacity of BM-DCs to enhance allogeneic MLR

Allogeneic mixed-leukocyte reactions were performed using splenic T cells purified from B6 mice as responder cells. BM-DCs were treated with MMC to arrest cell proliferation and were used as stimulator cells. T cell proliferation was determined by using an MTT assay. Results show BM-derived mature DCs have the capacity to stimulate allogeneic T cells (Figure 3); however, BM-derived immature DCs and PBS did not simulate allogeneic T cells (Stimulator cells: 5×10^4 cells/mL, OD 550 nm: 1.74 ± 0.15 in mature DCs group *versus* 0.22 ± 0.05 in immature DCs group or 0.16 ± 0.04 in PBS group, $P < 0.05$, Figure 3).

Generation of tumor-specific cytotoxic T cells induced by BM-DCs

To study the potential of in anti-tumor immunity *in vitro*, BM-derived DCs were prepared by pulsing BM-DCs with tumor lysates after 5 d of culture in the presence of GM-CSF and IL-4. Naïve mouse splenic T cells were primed *in vitro* with SGC-7901 TP DCs or B16 TP DCs in the presence of IL-2 and IL-7 to elicit cytolytic reactivity against tumor cells. The results show that T cells *in vitro* primed with SGC-7901 TP DCs were able to lyse efficiently and specifically parental SGC-7901 tumor cells, but not B16 tumor cells, and T cells primed with B16 TP DCs, SGC-7901 tumor lysates or unpulsed DCs did not induce specific CTL against SGC-7901 tumor cells (E:T = 100:1, 69.55% ± 6.05% specific lysis in the SGC-7901 TP DCs primed T cell/SGC-7901 group *versus* 15.72% ± 2.9% specific lysis in the SGC-7901 TP DCs primed T cell/B16 group, 13.75% ± 3.14% specific lysis in the B16 TP DCs primed T cell/SGC-7901 group,

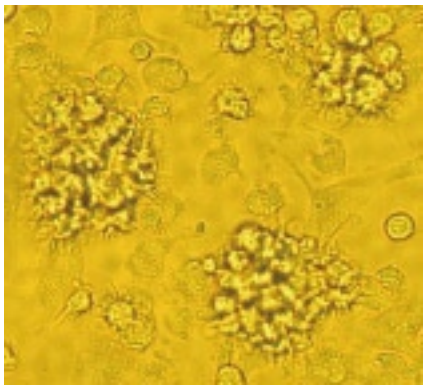

Figure 1 Morphological characteristic of BM-DCs. c-kit$^+$ hematopoietic progenitor cells from the BALB/c mice bone marrow cells were cultured in presence of GM-CSF, IL-4, or TNFα for 8 d, and then these cells were observed by light microscopy (× 200).

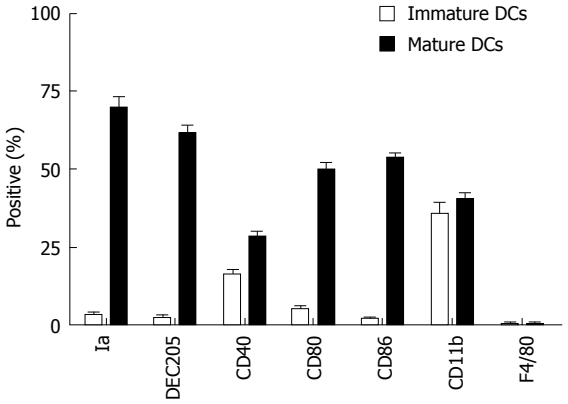

Figure 2 Immunophenotypic analysis of BM-DCs. BM-DCs (2×10^5-4×10^5 cells) cultured for 5 d or 8 d were incubated with FITC- or PE-labeled MAbs. The phenotypes of these cells were analyzed by immunofluorescence staining as described in the Materials and Methods. The results are representative of three independent experiments and the data are given as mean ± SE.

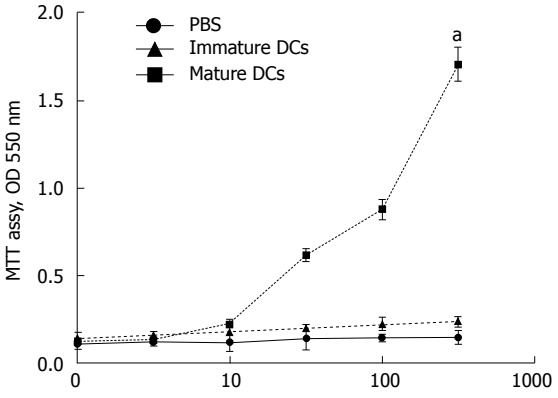

Figure 3 The capacity of BM-DCs to enhance allogeneic MLR. Allogeneic mixed-leukocyte reactions were performed using splenic T cells purified from B6 mice as responder cells. Immature or mature DCs were treated with MMC to arrest cell proliferation and were used as stimulator cells at the indicated cell numbers. PBS was used as a control. T-cell proliferation was determined by using an MTT assay after 5 d of culture. The results are representative of three independent experiments and the data are given as mean ± SE. $^aP < 0.05$, mature DCs group *versus* immature DCs group or PBS group.

10.6% ± 3.01% specific lysis in the SGC-7901 tumor lysates primed T cell/SGC-7901 group, or 8.75% ± 2.15% specific lysis in the unpulsed DCs primed T cell/SGC-7901 group, $P < 0.05$, Figure 4).

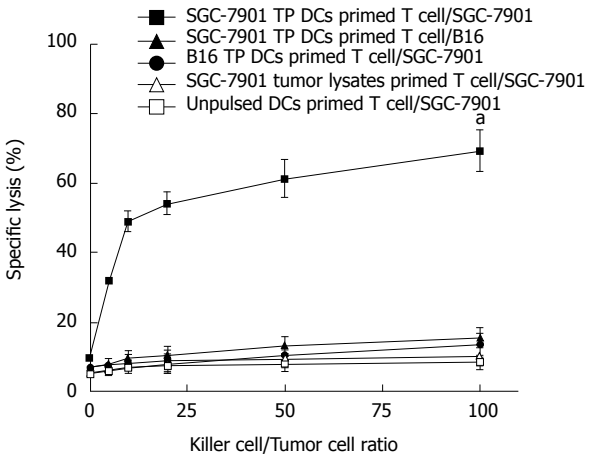

Figure 4 Generation of tumor-specific cytotoxic T cells *ex vivo*. Splenic CD3$^+$ T cells were isolated from naïve B6 mice with MACS. T cells were primed with SGC-7901 tumor cell lysate-pulsed BM-derived DCs as described in Materials and Methods. Unpulsed DCs and SGC-7901 tumor lysates were used as controls. The primed T cells (effector cells) were titrated by serial dilution (1:1, 5:1, 10:1, 25:1, 50:1, 100:1), and mixied with SGC-7901 or B16 target cells, and their lytic activity against SGC-7901 or B16 was assayed by a Cytotoxicity Detection Kit. Statistical analysis used the paired Student's *t* test. The results are representative of three independent experiments. Data are given as mean ± SE. $^aP < 0.05$, SGC-7901 TP DCs primed T cell/SGC-7901 group *versus* SGC-7901 TP DCs primed T cell/B16 group or other control groups.

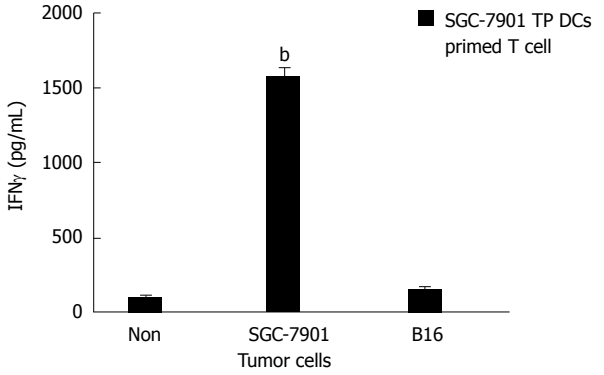

Figure 5 Assays for IFNγ secretion *ex vivo*. Splenic CD3$^+$ T cells were isolated from naïve BALB/c mice with MACS. T cells were primed with SGC-7901 tumor cell lysate-pulsed BM-derived DCs as described in Materials and Methods. The primed T cells (effector cells) were mixied and incubated with SGC-7901 or B16 target cells. Supernatant from each well was collected for measuring IFNγ production with the mouse IFNγ ELISA kit. Statistical analysis used the paired Student's *t* test. The results are representative of three independent experiments. Data are given as mean ± SE. $^bP < 0.01$, SGC-7901 *versus* B16 or Non.

Splenic CD3$^+$ T cells primed with SGC-7901 TP DCs produced higher levels of IFNγ *in vitro* when stimulated with SGC-7901 tumor cells; however, they did not produce higher levels of IFNγ when stimulated with B16 tumor cells (1575.31 ± 60.25 pg/mL in the SGC-7901 group *versus* 164.11 ± 18.52 pg/mL in the B16 group, $P < 0.01$, Figure 5).

DISCUSSION

In our experiments were obtained successfully from

BALB/c mouse bone marrow precursors. These BM-DCs were analysed by morphological observation, phenotype analysis, and mixed lymphocyte reaction (MLR). This study demonstrates the generation of an effective CTL response against gastric carcinoma cells by repeated *ex vivo* stimulation of T cells with tumor lysate-pulsed DCs.

DCs induce, sustain and regulate immune responses[13]. Four stages of their development have been delineated: (1) bone marrow progenitors; (2) precursor DCs, which patrol through the blood, lymphatics and lymphoid tissues; (3) tissue-resident immature DCs, which possess high endocytic and phagocytic capacity permitting antigen (Ag)-capture; and (4) mature DCs, present within secondary lymphoid organs, expressing high levels of co-stimulatory molecules permitting Ag-presentation[14].

Immature DCs are characterized by high capacity for antigen uptake but low T-cell stimulatory capacity. DCs mature because DC-mediated immune responses are more effective if DCs receive an activation signal. This signal can be microbial products such as lipopolysaccharide or unmethylated CpG motifs mimicking bacterial DNA[15,16], inflammatory mediators such as TNFα and IL-6[17,18], or T cell-derived signals such as CD40 ligand[19]. Matured DCs up-regulate co-stimulatory molecules, secrete the T-cell differentiation factor IL-12[20], and present antigens more effectively because of increased phenotypic stability and extended half-life of MHC class Ⅰ- and Ⅱ-molecules[21]. Furthermore, immature DCs bear the danger of inducing non-proliferating, IL-10-producing T cells, whereas mature DCs promote the development of Th1 cells[22].

In our experiment, c-kit$^+$ hematopoietic progenitor cells from mouse bone marrow cells cultured with GM-CSF, IL-4 or TNFα for 8 d showed the character of typical mature DCs. Morphologically, these large cells with oval or irregularly shaped nuclei and many small dendrites. Phenotypically, FACS analysis showed that they had typical mature DCs phenotypic markers, and expressed high levels of Ia, DEC-205, CD11b, CD80 and CD86 antigen, and moderate levels of CD40. Functionally, these cells gained the capacity to stimulate allogeneic T cells. However, immature DCs cultured with cytokines for 5 d did not possess typical DCs phenotypic markers and could not stimulate allogeneic T cells.

The use of a DC-based tumor vaccine as a cellular adjuvant to induce tumor-specific protective immunity holds great promise for cancer patients. This is important for advanced stage tumors with poor responsiveness to chemotherapy, such as gastric cancer. Currently, no defined tumor-specific antigen is available for many tumors, including gastric cancer. Now, DCs can be pulsed with synthetic peptides or proteins derived from known tumor associated antigens (TAA) such as MUC1, Her-2/neu, tyrosinase, CEA or Melan-A/MART[9].

In this study, tumor cell lysates were obtained by rapid freezing and thawing, and were regarded as tumor specific antigens. BM-derived DCs were pulsed with tumor lysates. Naïve mouse splenic T cells were primed *in vitro* with SGC-7901 TP DCs or B16 TP DCs to elicit cytolytic reactivity against tumor cells. The results showed that primed T cells *in vitro* with SGC-7901 TP DCs were able to induce specific CTL against SGC-7901 tumor cells, but not B16 tumor cells. Vaccination with DCs pulsed with tumor lysates has been shown to have efficient anti-tumor effects in many other tumor models and in clinical studies. Schnurr *et al*[23] report that T cells specific for pancreatic carcinoma cells can be generated *in vitro* by lysate-pulsed DCs and that the T-cell response can be enhanced by keyhole limpet hemocyanin (KLH). This *in vitro* model can be applied to compare different strategies in the development of DC-based tumor vaccines. Primary clinical studies were performed on melanoma patients using DCs pulsed with peptides or loaded with tumor cell lysates. Kono *et al*[24] report that tumor vaccination therapy with DCs pulsed with HER-2/neu-peptides may be a potential candidate for the novel treatment of gastric cancer patients. Nine gastric cancer patients with recurrent or unrescetable tumor were enrolled in the clinical trial. Vaccinations with DCs pulsed with HER-2 (p369) peptide were performed at 2-week intervals. In 3 of 9 patients, the tumor markers (CEA or CA19-9) were decreased after vaccination. Two patients had a tumor regression of more than 50%, and two presented a mixed response.

In summary, vaccination with bone marrow-derived dendritic cells pulsed with tumor cell lysates induced anti-tumor immunity specific to gastric cancer *ex vivo*. These results suggest that an evaluation of BM-DCs pulsed with tumor lysates against gastric cancer is an important next step *in vivo*. A trial evaluating this approach in mice is currently in preparation.

COMMENTS

Background

Dendritic cells (DCs) are professional antigen presenting cells (APCs) that both initiate and modulate the immune response. DCs are cells in the pathway of antigen capture and presentation to T cells, with the unique ability to directly prime naïve CD4$^+$ and CD8$^+$ T cells. Gastric cancer is one of the most common cancers. Although gastric cancer therapy has made great progress, it is still difficult to treat advanced gastric cancer, as it has spread to the lymph glands and metastasized. Currently, tumor immunotherapy for gastric cancer has potential. DCs are believed to be essential for stimulating tumor-specific cytotoxic T lymphocyte (CTL) and inducing the protective and therapeutic anti-tumor immunity.

Research frontiers

Currently, no defined tumor specific antigen is available for many tumors, including gastric cancer. Now, DCs can be pulsed with synthetic peptides or proteins derived from known tumor associated antigens (TAA) such as MUC1, Her-2/neu, tyrosinase, CEA or Melan-A/MART. Some studies have shown that it is feasible that DCs-based tumor vaccines will become a new effective immunoadjuvant therapy for gastric cancer, which can decrease the incidence and recurrence rate after operation for gastric cancer. Primary clinical studies were performed on melanoma patients using DCs pulsed with peptides or loaded with tumor cell lysates. Kono *et al*[24] report that tumor vaccination therapy with DCs pulsed with HER-2/neu-peptides may be a potential candidate for the novel treatment of gastric cancer patients.

Innovations and breakthroughs

c-kit+ hematopoietic progenitor cells from mice bone marrow cells cultured with GM-CSF, IL-4 or TNFα for 8 d showed the character of typical mature

DCs. Gastric cancer cell lysates were obtained by rapid freezing and thawing, and were regarded as tumor specific antigens. Vaccination with bone marrow-derived dendritic cells pulsed with tumor cell lysates induced anti-tumor immunity specific to gastric cancer *ex vivo*.

Applications

Vaccination with bone marrow-derived dendritic cells pulsed with tumor cell lysates induced anti-tumor immunity specific to gastric cancer *ex vivo*. These results suggest that an evaluation of BM-DCs pulsed with tumor lysates against gastric cancer is an important next step *in vivo*. A trial evaluating this approach in mice is currently in preparation.

Terminology

DCs means dendritic cells, BM-DCs indicates bone marrow DCs, APCs stands for antigen presenting cells, MHC is major histocompatibility complex, CTL is cytotoxic T lymphocyte, IFNγ means interferon gamma.

Peer review

Using an *in vitro* system, the authors suggest a specific anti-tumor effect based on immunological mechanisms. The fatal prognosis of cancer requires the development of novel therapeutic concepts. Unfortunately, various promising strategies have failed in the clinical practice. Therefore, suitable animal models are strongly needed to investigate the possible effectiveness of the shown *ex vivo* principle for an anti-cancer treatment.

Abstract

Hepatitis B virus (HBV) infection constitutes a serious global health problem. In countries with intermediate or high endemicity for HBV, exacerbations of chronic hepatitis B may be the first presentation of HBV infection. Some of these patients may be diagnosed mistakenly as having acute hepatitis B. Accurate diagnosis in these cases is very important for deciding whether to start treatment or not, because acute hepatitis B does not require therapy, while exacerbation of chronic hepatitis may benefit from it. Clinical and routine laboratory findings cannot help distinguishing between these two conditions. Therefore, several assays have been proposed for this purpose during the last few years. The presence of high levels of anti-HBe antibodies, HBsAg and HBV DNA are typical of chronic disease, whereas high titers of IgM anti-HBc, together with their high avidity index, characterize acute HBV infection. Starting from the description of a patient with acute hepatitis B-who recently came to our observation-we critically review the currently available assays that may help distinguishing between the different conditions and lead to the optimal management of each patient.

INTRODUCTION

Many parts of the world are endemic for the hepatitis B virus (HBV) infection. In these countries, especially those with intermediate or high endemicity rates, patients may frequently present with acute or chronic HBV infection. In fact, exacerbations of chronic hepatitis B are common, and may even be the first presentation of infection, including in cases with compensated, previously asymptomatic cirrhosis. Sometimes these patients may be diagnosed mistakenly as suffering from acute hepatitis B. At first glance, it is difficult to distinguish between these two clinical conditions, due to the similar clinical features and serological profile[1,2]. It is estimated that, in endemic areas, acute exacerbations of chronic hepatitis constitute about 50% of cases diagnosed as primary infections[2-5]. Distinguishing between these two conditions is extremely important, because antiviral therapy is not recommended in cases of acute hepatitis (except for very severe ones), whereas it is indicated in cases of chronic hepatitis. Therefore, simple, effective and reliable assays are required for differentiating between these conditions. Some methods for differentiating between chronic and acute infections have been suggested in the last few years, but no review summarized or compared them until now. Staring from the description of a case with acute hepatitis-who recently came to our observation-we shortly review these methods. Our aim is to provide practicing physicians with the basic knowledge and the tools useful for distinguishing between acute and chronic hepatitis B, for the benefit of the patients.

CASE REPORT

A 38-year-old male presented to our emergency room

complaining of weakness, vomiting, sore throat and dark urines during the past few days. Several years before he had been diagnosed as having mixed connective tissue disease (MCTD), based on arthralgias and positive serology for ANA, anti-SSA/Ro and anti-SSB/La antibodies. He had been treated with plaquenil (hydroxychloroquine) for the previous 6 mo, but this drug had been discontinued two weeks before admission. The patient also had Wolff Parkinson White (WPW) syndrome for which he had never been treated. On admission, physical examination was unremarkable, except for the presence of a mild jaundice. Blood tests revealed extremely elevated liver enzymes, mostly hepatocellular, with ALT levels of 3069 U/L (normal: 6-53 U/L) and AST of 1215 U/L (normal: 2-60 U/L), while the indices of cholestasis were only mildly elevated, with alkaline phosphatase at 207 U/L (normal: 40-130 U/L) and GGT at 376 U/L (normal: 10-80 U/L). The total bilirubin was 35 mmol/L (normal: 0-17 mmol/L) and the LDH was 1200 U/L (normal: 300-620 U/L).

The patient denied traveling abroad, having unprotected sexual contact or recent viral infections. He had never received blood or blood-derived products, had never used drugs and he was not drinking alcohol. He had no fever and his electrocardiogram (ECG) was normal, with no signs of WPW syndrome.

What is the differential diagnosis in this patient?

The clinical presentation and the results of the laboratory tests call for a differential diagnosis of hepatitis. Since the patient had a diagnosis of MCTD the possibility of autoimmune hepatitis as an additional manifestation of his disease was raised[6]. In many of these cases, anti-smooth muscle antibodies (AMA) are positive, while in our patient they were negative. Another possible diagnosis would have been hepatic toxic injury due to plaquenil consumption, which is a reversible and dose-related cause of acute hepatitis[7]. Our patient had received plaquenil for 6 mo with no evidence of liver injury, and the treatment had been stopped 2 wk before admission. Furthermore, despite the discontinuation of the medication, liver tests were still worsening, making the diagnosis of plaquenil hepatotoxicity very unlikely. Thus, we had to look for infectious causes of hepatitis.

What further investigations are needed?

An abdominal ultrasound showed a liver of normal size and echogenicity, with an enlarged spleen (14.6 cm). The search for markers of autoimmunity revealed the presence of antinuclear (+2 of +4) and anti-SSA/Ro antibodies, but anti-SSB/La antibodies were negative and C3 levels were normal. Assays for ENA, anti-nRNP, anti-parietal, anti-mitochondria and anti-smooth muscle antibodies were negative. Blood tests for detecting infectious agents revealed the absence of serological markers of HAV, HCV and toxoplasmosis. However, there were markers suggesting a previous exposure to CMV and EBV (IgG antibodies). HBsAg and anti-HBc antibodies were positive. Further investigations revealed the presence of HBeAg, the absence of anti-HBe antibodies, and 2.65×10^9 IU/L of HBV DNA.

What does this serologic profile implicate?

Our patient had positive serology for HBV infection. The possibility of acute hepatitis B was raised, but the patient denied having unprotected sexual relations, using intravenous drugs, undergoing dental procedures or being exposed to blood products. Although in up to 30% of cases the exact mode of transmission cannot be identified, the lack of any risk factor for a recent infection does not support the diagnosis of acute infection. Therefore, we raised the possibility of an acute exacerbation of a chronic HBV infection. The differentiation between these two conditions is important because in cases of acute hepatitis, except for very severe ones, antiviral therapy is not recommended, whereas this is indicated in the case of an exacerbation of a chronic hepatitis. In both conditions, patients may suffer from flu-like prodromic symptoms, together with jaundice, abdominal discomfort and pruritus. Hepatosplenomegaly is also common in both situations. In addition, there are no significant differences as to the biochemical assays, such as peak bilirubin serum level, PT prolongation and serum albumin level. A tendency for higher levels of serum transaminases is seen in acute infection[8]. Some methods of differentiating between chronic and acute infections have been suggested over the past few years. A short review of some of them is described below, together with a discussion regarding their relevance to the present case.

Role of HBeAg in the differential diagnosis: HBeAg is a secretory protein that is processed from the precore protein and considered as a marker of HBV replication and infectivity[9]. The presence of HBeAg is usually associated with high levels of HBV DNA in serum and higher rates of transmission of infection from carrier mothers to their offspring and from patients to health care workers[10-13].

Seroconversion from HBeAg carrier to anti-HBe antibodies occurs early in patients with acute infection, prior to HBsAg to anti-HBs seroconversion[14]. However, HBeAg seroconversion may be delayed for years in patients with chronic HBV infection. In such patients, the presence of HBeAg is usually associated with the detection of HBV DNA in serum and active liver disease (except for HBeAg-positive patients with perinatally acquired HBV infection, who may have normal serum ALT concentrations and minimal inflammation in the liver)[15,16]. Seroconversion from HBeAg to anti-HBe is usually associated with a decrease in serum HBV DNA levels and liver disease remission[17].

HBeAg has been found more frequently in patients with acute infection compared with those with chronic infection, but the difference is not statistically significant. On the other hand, anti-HBe was found more frequently among patients suffering from an acute exacerbation of chronic infection than in those with acute infection. Levels of anti-HBe antibodies and HBeAg/anti-HBe

immune complexes are significantly higher in patients with exacerbation of chronic hepatitis[8,18]. However, the presence of anti-HBe as a diagnostic tool for chronic infection was found to have low sensitivity, specificity, NPV and PPV[8].

Our patient had positive HBeAg and negative anti-HBe antibodies, which supports the diagnosis of an acute infection.

Role of HBcAg in the differential diagnosis: The viral core antigen is expressed within the infected hepatic cells and cannot be detected in serum. Its corresponding antibody, on the other hand, can be detected in serum at different phases of infection. IgM anti-HBc is a single serum marker of HBV infection within the period between the disappearance of HBsAg and the appearance of anti-HB antibodies. Identification of IgM anti-HBc is considered diagnostic for the acute phase of infection, but it has been reported that it can remain present in serum for two years from the initial infection. Moreover, the titer of IgM anti-HBc can also rise and become detectable in exacerbations of chronic hepatitis[18].

Recently, it has been suggested that the titer of IgM anti-HBc can be useful for differentiating between acute and chronic HBV infection. Kumar *et al*[8] demonstrated that high titers of IgM anti-HBc are more common in patients with acute infection, and titers above 1:1000 can be seen in up to 80% of these patients. In about 70% of patients with chronic hepatitis, IgM anti-HBc titers were lower than 1:1000 or negative. Differentiation between these two conditions by measuring the titers did not prove to have high sensitivity, specificity, NPV or PPV. Therefore another assay was proposed that enables the standardization between different laboratories, i.e. the sample/cutoff ratio (S/CO)[19]. A ratio > 10 indicates acute infection whereas a ratio < 10 indicates chronic infection. It appears that in cases of acute infection the mean ratio is 25.96, as opposed to an average ratio of 2.95 in chronic infection, a difference that is statistically highly significant. A S/CO > 10 had a sensitivity and NPV of 100%, a specificity of 99% and PPV of 99.3% for diagnosing an acute infection.

In our patient there were high titers (> 1:1000) of IgM anti-HBc, supporting the diagnosis of acute infection, but the S/CO (3.2/1.2) was < 10, suggesting a chronic infection.

Role of HBsAg in the differential diagnosis: HBsAg is an important marker of HBV infection. It has been reported that changes in quantitative measurement of this marker depend on the phase of infection[20-22]. A difference is found between the high levels of HBsAg that are detected in patients who are hospitalized during chronic or acute infection and the low levels observed in subjects with inactive, chronic infection. Moreover, recent data support the fact that high level of HBsAg are related to viral replication and disease activity[8]. In acute hepatitis, the levels of HBsAg are generally above 1×10^7 IU/L and decrease sharply in the recovery phase. In chronic anti-HBe-positive cases, HBsAg levels are generally lower than 1×10^7 IU/L (mean 2655), whereas in 5 HBeAg positive chronic hepatitis patients the mean value was reported to be 7.8756×10^8 IU/L, with 90% of cases exceeding 1×10^7 IU/L.

Our patient had HBsAg levels of 2.22×10^9 IU/L, which does not support an acute infection, but positive HBeAg and negative anti-HBe antibodies, which in chronic cases correlate with high levels of HBsAg.

Role of HBV DNA in the differential diagnosis: A quantitative measurement of the viral DNA enables the evaluation of the level of viral replication. There are many assays for measuring HBV DNA, their sensitivity being dependent on the assay used. Currently, there are some attempts to standardize the different measurements and express results in IU/L. Low or undetectable levels have been seen in patients suffering from acute hepatitis[21], and a significant decline in HBV DNA levels has been reported even before the appearance of the disease. It has also been suggested that an acute infection may be diagnosed by finding undetectable HBV DNA in serum by the time medical aid is sought or in the presence of ALT levels lower than 400 IU/L. HBV DNA levels become detectable during reactivation of chronic hepatitis[22]. Recently, it has been shown that HBV DNA levels can help differentiate an acute infection progressing to recovery from an exacerbation of chronic infection, which requires therapy[8]. In this study, low levels of HBV DNA (< 0.5 pg/mL, equal to 141 500 copies/mL) were found in about 96% of patients with acute infection, as opposed to 13% in those with exacerbation of chronic hepatitis. Higher HBV DNA levels were found in 87% of patients with chronic infection compared to only 4% in those with acute infection. The sensitivity and specificity of low levels of HBV DNA for identifying an acute infection are 96% and 86.6%, respectively. The combination of high levels of HBV DNA with low titers of IgM anti-HBc yielded sensitivity, specificity, NPV and PPV of 100%, 97.9%, 96.3% and 100%, respectively, for diagnosing an exacerbation of a chronic hepatitis.

Our patient had high levels of HBV DNA (2 650 000 copies/mL), which supports the diagnosis of exacerbation of chronic infection.

What is the patient's diagnosis?

Our patient had positive HBeAg, negative anti-HBe antibodies, and high titers of IgM anti-HBc, which support the diagnosis of an acute infection (Table 1). However, the presence of IgM anti-HBc S/CO < 10, low levels of HBsAg and high levels of HBV DNA suggest an acute exacerbation of chronic infection. In order to make a progress in the diagnosis, we decided to investigate his family. Familial analysis revealed positive anti-HBc in the patient's mother. She also recalled having icteric disease about 40 years earlier. Therefore, the possibility of perinatal transmission was raised and a diagnosis of acute exacerbation of a chronic HBV infection was made. The patient was treated with

Table 1 Comparison of the serological markers in acute HBV and in exacerbation of chronic HBV infections

Serological markers	Acute infection	Chronic exacerbation	Comments
HBeAg	-	+	Not different, and also not helpful in infections with HBeAg-negative strains
Anti-HBe	-	+	Low sensitivity and specificity, and also not helpful in infections with HBeAg-negative strains
Anti-HBe level, and complexes of HBeAg/anti-HBe	↓	↑	Not helpful in infections with HBeAg-negative strains
IgM anti-HBc	> 1:1000	< 1:1000	Low sensitivity, specificity, NPV and PPV
Sample/cutoff ratio for IgM anti-HBc	> 10	< 10	High sensitivity, specificity, NPV and PPV
Anti-HBc avidity index	< 0.7	> 0.7	High sensitivity, specificity, NPV and PPV
HBsAg	↓	↑	Useful in HBeAg-negative cases
HBV-DNA	< 0.5 pg/mL	> 0.5 pg/mL	Sensitivity: 96%
	≤ 141 500 copies/mL	≥ 141 500 copies/mL	Specificity: 86%

lamivudine, 100 mg per day, for 4 mo. After 2 mo of treatment the liver enzymes returned to normal values. After 4 mo of treatment, an HBeAg seroconversion was seen and anti-HBs antibodies appeared. The treatment was discontinued and after one year liver enzymes were still normal. The HBsAg/anti-HBs ratio indicated a complete recovery from the HBV infection.

DISCUSSION

HBV infection remains a global public health problem, despite the availability of an effective vaccine. In most cases, HBV infection occurs in patients at high-risk, such as intravenous drug users, homosexual men and in certain groups where HBV is endemic. HBV infection can lead to an acute or chronic hepatitis, liver cirrhosis and hepatocellular carcinoma.

Acute HBV infection has a variable course, ranging from asymptomatic infection to fulminant hepatitis. The incubation period lasts from one to four months. A serum sickness-like syndrome may develop during the prodromal period, followed by systemic symptoms, anorexia, nausea, jaundice and right upper quadrant discomfort. The symptoms and jaundice generally disappear after one to three months. Some patients will develop chronic infection. The proportion of patients progressing to chronic infection is much higher in the newborn (up to 90%) compared to 1% to 5% among adults and intermediate values in young children. Most patients with chronic HBV infection are asymptomatic. However, in some patients, chronic HBV infection may be associated with extrahepatic manifestations such as panarteritis nodosa and glomerulonephritis. The natural history of chronic HBV infection is variable, depending upon age, mode of acquisition and ethnicity. Children in non-endemic countries frequently clear HBeAg and HBV DNA from serum during the first two decades of life. Children who seroconvert spontaneously tend to have higher ALT levels early in life[23]. By contrast, children from endemic countries in whom HBV was acquired perinatally usually remain HBeAg-positive and have high levels of viral replication, although histologic injury is typically mild[16,24]. These patients may experience acute exacerbations of hepatitis. Therefore, it may be difficult for their physicians to differentiate between those who have an acute hepatitis B from those with an exacerbation of chronic HBV infection. The guidelines provided here may help solving this problem since the therapeutic approach toward these conditions is different. Antiviral therapy is recommended in case of acute exacerbation of chronic hepatitis B, whereas, in most cases, supportive treatment is sufficient in acute hepatitis B.

Key learning points: (1) In endemic areas, acute exacerbations of chronic HBV infection constitute about 50% of cases diagnosed as having acute HBV infection; (2) the proportion of patients progressing to chronic HBV infection is much higher in the newborn (up to 90%) compared with children or adults; (3) the therapeutic approach differs between acute hepatitis B and acute exacerbation of chronic hepatitis B, since treatment is usually not recommended in case of acute infection; (4) available laboratory tests can be helpful in the differential diagnosis, in order to provide a better management of patients.

Abstract

Metastatic palatine tonsil cancer is extremely rare, with nearly 100 such tumors reported in the English literature. The prognosis of metastatic palatine tonsil cancer is poor. A 53-year-old man presented with painless left palatine tonsillar swelling and a cervical mass following right hemicolectomy for an ascending colon adenocarcinoma. Physical examination showed an ulcerated mass located on the upper pole of the left palatine tonsil. A punch biopsy was taken for histological examination which showed a moderately-differentiated adenocarcinoma. The patient was treated with palliative radiotherapy and chemotherapy. He was still alive when we wrote this paper. Our case shows that immunohistochemical diagnosis of metastatic palatine tonsil cancer is essential.

INTRODUCTION

Metastatic palatine tonsil tumor is uncommon despite the palatine tonsil is rich in vasculature. It was reported that the incidence of metastatic palatine tonsil cancer is about 1%[1]. Metastatic palatine tonsil tumor generally occurs in lung[2], breast[3], stomach[4], and kidney[5,6]. Distant metastasis of palatine tonsil tumor in liver[7], brain[8], and lung[9] is usually found in colorectal cancer patients following a surgical resection. Metastatic palatine tonsil tumor is often accompanied with synchronous lesions in other organs, a sign needing aggressive palliative treatment[10].

It is often difficult to distinguish a metastatic tumor at an unusual site from a secondary cancer, especially after long-term complete remission. In this paper, we report a case of metastatic palatine tonsil tumor from an ascending colon carcinoma and reviewed the cases reported in the English literature.

CASE REPORT

A 53-year-old man with bellyache and changes in bowel habit was diagnosed having an adenocarcinoma of the ascending colon in January 2006. He underwent a right hemicolectomy, which showed a moderately-differentiated adenocarcinoma measuring 60 mm × 60 mm × 10 mm in size. The tumor invaded the subserosal layer (T_3) with three excised positive regional lymph nodes (N_1). The patient received 4 courses of adjuvant chemotherapy with fluorouracil and leucovorin and was regularly followed up, with physical examination, abdominal ultrasonography and detection of serum carcinoembryonic antigen (CEA) performed every 3 mo. One and a half years later, he was referred to our hospital due to painless left palatine tonsillar swelling and a cervical mass. He had no gastrointestinal and head symptoms. Physical examination showed an ulcerated mass located on the upper pole of the left palatine tonsil, about 2 cm in diameter. Several enlarged, fixed cervical lymph nodes were found in

This case	Male	53	A	Moderately	19	Left	Radiotherapy	13 alive

[1]A = ascending colon, T = transverse colon, R = rectum, nr = not referred; [2]Well = well differentiated adenocarcinoma, moderately=moderately-differentiated adenocarcinoma, poorly = poorly-differentiated adenocarcinoma, Signet-ring = signet-ring cell carcinoma; [3]Interval = the time between the diagnosis of colorectal carcinoma and the development of metastatic palatine tonsil tumor.

the left area. The rest findings of physical examination were unremarkable. The CEA, CA125 and AFP levels were within the normal range. Magnetic resonance image (MRI) revealed an enlarged left palatine tonsil narrowing the oropharyngeal airway. At the same time, a lesion in the left temporal lobe of the brain was found, about 3 cm in diameter. Chest X-ray and abdominal ultrasonography also showed no metastasis in lung and liver. A punch biopsy was taken for histological examination which showed a moderately-differentiated adenocarcinoma. Immunohistochemistry showed that the tumor cells exhibited immunoreactive CDX2 and villin, an immunomarker. These features were consistent with those of metastatic colorectal adenocarcinoma. The patient was treated with palliative radiotherapy and chemotherapy.

DISCUSSION

The palatine tonsil is one of the most common sites of head and neck cancer and squamous cell carcinoma in adults[11] as well as lymphoma in children[12]. Metastatic palatine tonsil cancer is extremely rare, with only 100 such tumors reported in the English literature. We present a case of metastatic palatine tonsil cancer manifested as a left palatine tonsil mass from a primary ascending colon adenocarcinoma.

Seven cases of metastatic palatine tonsil tumor from colorectal carcinoma have been reported in the English literature[13-19] (Table 1). The age of these cases ranged 36-81 years with a median age of 54 years, and the male and female ratio was 5:2. Of the 7 cases, 4 had a primary rectal cancer[13-16], 2 had a primary ascending colon cancer[17,18] and 1 had a primary transverse colon cancer[19]. Our case was a 53-year old male patient with primary ascending colon cancer. Metastatic palatine tonsil cancer is often unilateral, with the left side more commonly involved than the right side[20]. Lymphatic routes have been proposed as the possible pathways of metastatic palatine tonsil cancer from colorectal cancer. Of the 7 reported cases, 5 had primary lesions with metastatic regional lymph nodes, 2 had enlarged cervical lymph nodes when the palatine tonsil mass was found. Similar findings were evident in our patient. Metastatic palatine tonsil tumor from colorectal cancer is generally considered a systematic disease with a poor prognosis. No matter it is treated with radiotherapy or tonsillectomy, the survival time of such patients is 6-15 mo. Radiotherapy remains the choice of treatment for palatine tonsil tumor[21]. Tsubochi *et al*[22] have reported a successfully-treated metastatic lingual tonsillar tumor from bronchial adenocarcinoma after external radiotherapy, and the patient was still alive 8 years after the treatment. However, the beneficial effects of radiotherapy on patients with metastatic palatine tonsil tumor remain unclear and should be further studied.

It is difficult to determine whether palatine tonsil tumor is primary or secondary, especially after long-term complete remission. In our case, metastatic palatine tonsil tumor had a carcinoma origin, because it was very similar to a colorectal adenocarcinoma. Also, to make sure that metastatic palatine tonsil tumor is originated from an ascending colon cancer, immunohistochemical staining for its tissue was performed. Immumarkers, such CDX2 CK20 and villin, are useful in determining the primary site of adenocarcinoma. Suh *et al*[23] reported that nearly all colorectal adenocarcinomas can express CDX2 and villin, which are of diagnostic values in distinguishing primary from secondary colorectal carcinoma.

In conclusion, metastatic palatine tonsil tumor from colorectal cancer rarely occurs, and immunohistochemical diagnosis of metastatic palatine tonsil tumor is essential.

Abstract

5-aminosalicylic acid (mesalamine) rarely induces hypersensitivity reactions. If chest pain associated with atypical electrocardiographic changes are seen during its administration, one should always bear in mind type I variant of Kounis syndrome. This variant includes patients, of any age, with normal coronary arteries, without predisposing factors for coronary artery disease, in whom the acute release of inflammatory mediators from mast cells can induce either sudden coronary artery narrowing, without increase of cardiac enzymes and troponins, or coronary artery spasm that progresses to acute myocardial infarction, with elevated cardiac enzymes and troponins.

Kounis GN, Kouni SA, Hahalis G, Kounis NG. Mesalamine hypersensitivity and Kounis syndrome in a pediatric ulcerative colitis patient. *World J Gastroenterol* 2008; 14(46): 7141-7142 Available from: URL: http://www.wjgnet.com/1007-9327/14/7141.asp DOI: http://dx.doi.org/10.3748/wjg.14.7141

TO THE EDITOR

We have read with interest the article published recently in this journal[1] concerning a 12-year-old boy who developed severe chest pain after oral administration of 5-aminosalicylic acid (5-ASA, mesalamine). Electrocardiographic changes during the pain were not specific but inverted T-waves were present in the lateral chest leads. Additionally, cardiac enzymes, troponins, C-reactive protein and brain natriuretic peptide were normal. The authors concluded that this patient had suffered a rare hypersensitivity reaction to mesalamine.

It is known that mesalamine can, rarely, induce hypersensitivity reactions such as hypersensitivity myocarditis, hypersensitivity pneumonitis, angioedema, pericarditis, erythroderma, toxic epidermal necrolysis, palmar-plantar erythrodysesthesia, skin rashes and hypereosinophilia.

This case seems to be a characteristic case of type I variant of Kounis syndrome[2,3], the youngest reported so far. Another case of Kounis syndrome secondary to amoxicillin/clavulanic acid use has been recently reported in a 13-year-old child[4]. On the other hand, salicylate products such as aspirin are known to induce hypersensitivity reactions, and aspirin has been reported to induce Kounis syndrome[5].

Pathophysiologically, symptoms of salicylate hypersensitivity can be explained by over-production of leukotriene metabolites, since salicylate allergic patients who have come in contact with salicylates show a marked inhibition of cyclooxygenase (COX), which is continuously expressed in the human body. This leads to a diminished production of COX products such as prostacyclin and thromboxane, and can accelerate the metabolism of arachidonic acid towards lipoxygenase products such as leukotrienes. It is known that leukotrienes are powerful coronary arterial vasoconstrictors, and their biosynthesis is enhanced in the acute phase of unstable angina[2]. Atay *et al*[1] have correctly stated that arachidonic acid metabolites generated through both COX and lipoxygenase pathways are thought to be increased in patients with ulcerative colitis. Ideally, in this case, allergic screening with measurement of mast cell mediators such as histamine and arachidonic acid metabolites should have been carried out. However, this study shows that Kounis syndrome is not a very rare disease but a 'very rarely diagnosed' disease.

Abstract

Song *et al* have reported a 100% success rate of acellular extracellular matrix (AEM) anal fistula plug in low fistula-in-ano. The results with this product in high fistula-in-ano are keenly awaited.

To THE EDITOR

I read with great interest the work published by Song *et al*[1]. First of all, I congratulate the authors on achieving a 100% success rate with acellular extracellular matrix (AEM) anal fistula plug (AFP). This is an encouraging step to treat the notorious disease. However, there are few points that remain unanswered. First, the authors did not mention the source (origin) of the product and the company manufacturing the AEM. Second, how this product is different from the AFP (Surgisis, Cook Surgical Inc., Bloomington, Indiana, USA) is a matter of great interest. This assumes importance because various studies using Surgisis AFP have reported a success rate of 24%-87%[2,3]. Our study with Surgisis AFP in 21 patients with fistula-in-ano yielded a success rate of 71.4%. However, all of our patients had high fistulae[4]. Third, why did the authors specifically choose low fistulae in the study for which there are other effective treatment modalities available. Why high fistulae were not included in the study has not been explained in the paper. Fourth, the authors have pulled the plug from the secondary opening towards the primary opening. This is in contrast to the published studies with Surgisis AFP in which most of the authors pulled the plug from the primary opening to the secondary opening. Was there any specific reason for this variation or was it a random variation? Fifth, the authors did not explain as how did they use AEM material, like they rolled it and made a plug or they cut it into stripes and inserted those stripes into the fistula tract. The results reported are quite encouraging. However, the follow-up period of one month is too short to conclude anything convincingly. Further prospective studies with AEM plug in high fistulae would be required to substantiate these findings.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Patent (list all authors)

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

Chemokines produced in the liver during hepatitis C virus (HCV) infection induce migration of activated T cells from the periphery to infected parenchyma. The milieu of chemokines secreted by infected hepatocytes is predominantly associated with the T-helper/T-cytotoxic type-1 cell (Th1/Tc1) response. These chemokines consist of CCL3 (macrophage inflammatory protein-1α; MIP-1α), CCL4 (MIP-1β), CCL5 (regulated on activation normal T cell expressed and secreted; RANTES), CXCL10 (interferon-γ–inducible protein-10; IP-10), CXCL11 (interferon-inducible T-cell α chemoattractant; I-TAC), and CXCL9 (monokine induced by interferon γ; Mig) and they recruit T cells expressing either CCR5 or CXCR3 chemokine receptors. Intrahepatic and peripheral blood levels of these chemokines are increased during chronic hepatitis C. The interaction between chemokines and their receptors is essential in recruiting HCV-specific T cells to control the infection. When the adaptive immune response fails in this task, non-specific T cells without the capacity to control the infection are also recruited to the liver, and these are ultimately responsible for the persistent hepatic damage. The modulation of chemokine receptor expression and chemokine secretion could be a viral escape mechanism to avoid specific T cell migration to the liver during the early phase of infection, and to maintain liver viability during the chronic phase, by impairing non-specific T cell migration. Some chemokines and their receptors correlate with liver damage, and CXCL10 (IP-10) and CXCR3 levels have shown a clinical utility as predictors of treatment response outcome. The regulation of chemokines and their receptors could be a future potential therapeutic target to decrease liver inflammation and to increase specific T cell migration to the infected liver.

INTRODUCTION

The hepatitis C virus (HCV) is a hepatotropic non cytopathic virus very efficient in evading the host immune response. Hepatitis C infection is a major cause of chronic liver disease worldwide, affecting at least

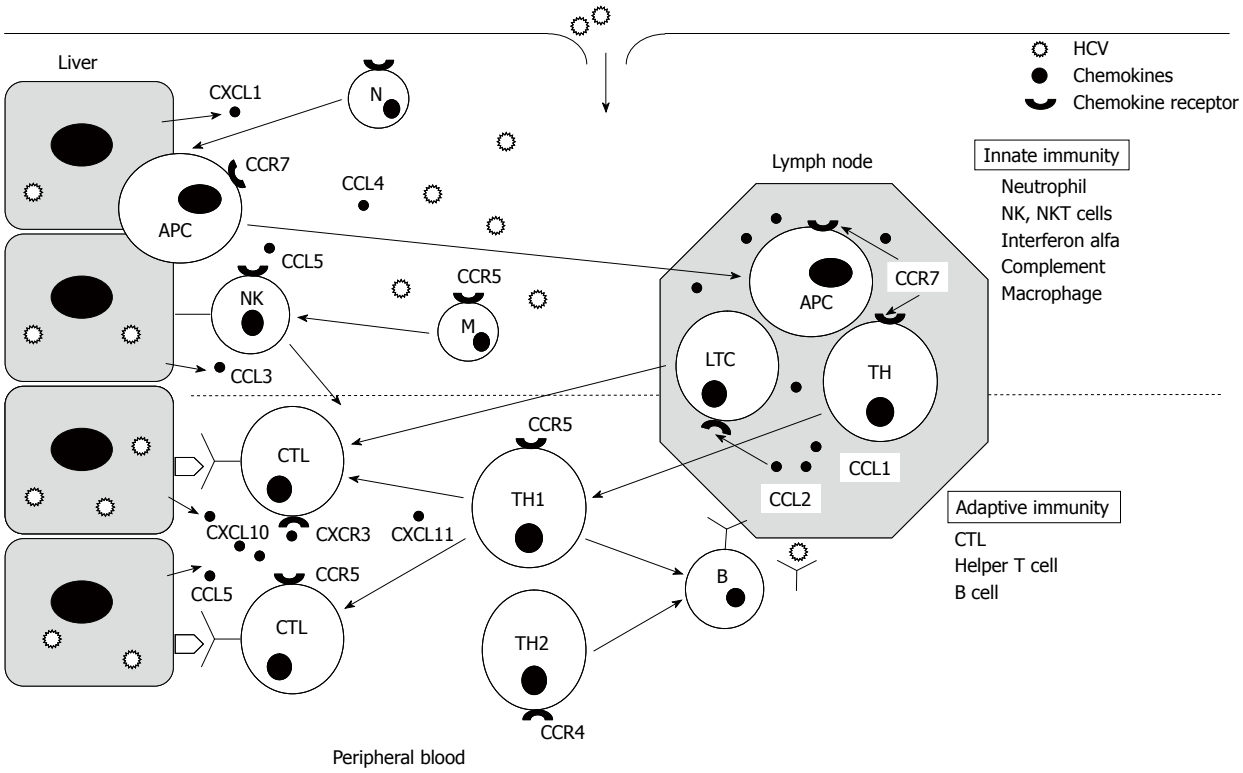

Figure 1 Innate and adaptive immune response. Importance of specific cytotoxic T cell response. In a non-cytopathic viral infection the development of a vigorous specific cytotoxic T lymphocyte (CTL) response is essential. Professional antigen presenting cells (APC) take up viral antigens and migrate from infected parenchyma to the lymph nodes to prime naive specific CTLs. These cells express the chemokine receptor CCR7 to reach the lymph nodes, attracted by CCL1 and CCL2 chemokines. After priming, specific CTLs lose CCR7 expression and up-regulate CCR5 and CXCR3 chemokine receptors, then migrate to the hepatic parenchyma to develop their effector function, attracted by the chemokines produced in the liver. During the early phase of infection, innate immunity is the first barrier for fighting against the virus. The cellular innate response is also recruited in the infected parenchyma by the interaction between chemokines and their receptors.

170 000 000 people[1]. Approximately three quarters of infected subjects develop a chronic infection, but only one third progress to cirrhosis, hepatocellular carcinoma and liver failure without treatment[2]. Nowadays around 50% of patients treated with pegylated-interferon plus ribavirin clear the virus[3,4]. To control HCV infection an adequate specific T cell response is necessary[5-7], with T cells that are able to migrate to the infected site to develop their effector functions (Figure 1). Nevertheless, specific T cells fail to remove the virus in the majority of patients[7,8], because often a non-specific T cell population is recruited to the infection site, and these cells are presumably responsible for the chronic damage[9] (Figure 2).

In both scenarios the attraction of leukocytes to the liver is controlled by chemokines, which are chemotactic cytokines secreted by infected cells and interact with their receptors expressed on the recruited leukocytes[10] (Figure 3). In an experimental model of influenza virus infection, the importance of appropriate chemotaxis to control viral infection was shown. In this model, cytotoxic specific CD8+ cells expressing inadequate chemokine receptors were not able to reach the infected site and clear the virus, while specific cytotoxic T cells expressing the correct chemokine receptors controlled the infection without tissue damage[11] (Figure 4). On the other hand, it has also been demonstrated that chemokines and their receptors can be involved in liver damage. In an animal model study it was reported that a massive hepatic infiltration by non-specific T cells, expressing chemokine receptors associated with the type-1 response, can cause acute liver failure[12] (Figure 5). Therefore, chemokines and their receptors are associated with viral control but are also associated with immune-mediated liver inflammation. Moreover, in a hepatotropic viral infection in humans, a huge intrahepatic non-specific mononuclear infiltrate during viral persistence was noticed, while this was not present in subjects with viral control[13] (Figure 2). In this last study, the intrahepatic chemoattraction of non-specific T cells perpetuated the liver damage. Consequently, also in humans, chemokines and their receptors develop an important role in viral clearance and in the development of chronic tissue inflammation. Obviously, the modulation of these pathways is important for generating an efficient immune response, and for participating in the inflammatory process during the chronic infection phase, but pathway modulation could also be a viral strategy used by HCV to escape from immune control[14]. This review introduces the advances obtained in the last decade on the role of chemokines and their receptors in chronic hepatitis C pathogenesis.

STRUCTURE AND FUNCTION OF CHEMOKINES AND THEIR RECEPTORS

Table 1 Chemokines and their receptors

	Chemokine receptor	Chemokine ligands	Target cells
Subfamily CC			
	CCR1	CCL3, CCL5, CCL7, CCL14	T cells, monocytes, basophils and eosinophils
	CCR2	CCL2, CCL8, CC7, CCL13, CCL16	Memory T cells, monocytes and dendritic cells
	CCR3	CCL11, CCL13, CCL7, CCL5, CCL8, CCL13	Eosinophils, basophils, mast cells, T helper 2 cells and platelets
	CCR4	CCL17, CCL22	T helper 2 cells, dendritic cells, basophils, macrophages and platelets
	CCR5	CCL3, CCL4, CCL5, CCL11, CCL14, CCL16	T cells, monocytes
	CCR6	CCL20	T cells, B cells and dendritic cells
	CCR7	CCL19, CCL21	T cells and dendritic cells
	CCR9	CCL25	T cells, plasma cells
	CCR10	CCL27, CCL28	T cells
Subfamily CXC			
	CXCR1	CXCL8, CXCL6	Neutrophils and monocytes
	CXCR2	CXCL8, CXCL1, CXCL2, CXCL3, CXCL5, CXCL6	Neutrophils, monocytes and vascular endothelial cells
	CXCR3-A	CXCL9, CXCL10, CXCL11	T helper 1 cells, mast cells and mesangial cells
	CXCR3-B	CXCL4, CXCL9, CXCL10, CXCL11	Neoplastic cells and vascular endothelial cells
	CXCR4	CXCL12	Expressed in multiple cells
	CXCR5	CXCL13	B cells and T helper cells
	CXCR6	CXCL16	CD8+ cells, natural killer cells and memory CD4+ cells
Subfamily CX3C			
	CX3CR1	CX3CL1	Macrophages and smooth muscle cells
Subfamily XC			
	XCR1	XCL1, XCL2	T cells and natural killer cells

Chemokines are small heparin-binding proteins that direct the movement of mononuclear cells through the body to contribute to the development of an adaptive immune response and to the pathogenesis of inflammation. These molecules also play a role in angiogenesis, haematopoiesis, lymphoid organ development, wound healing and regulation of embryonic development. These proteins are 8-10 kDa in size with 20%-70% amino acid sequence homology and are secreted by resident cells at the inflammatory site[10]. Around 50 chemokines have been described and are subdivided into four families according to the position of the two N-terminal cysteine residues: CXC, CC, XC and CX3C[15,16,17] (Table 1). The CXC family has also been subdivided into two groups depending on the presence of the ELR motif (Glu-Leu-Arg). A systematic nomenclature has been adopted in the past few years for chemokines and their receptors[18,19]. Chemokines induce cell migration and activation by binding to specific G-protein-coupled cell-surface receptors on target cells, called chemokine receptors[10] (Table 1). Receptor triggering leads to a cascade of cellular activation, including the generation of inositol triphosphate, the release of intracellular calcium, and the activation of protein kinase C[20]. Chemokine receptor signalling also activates small guanosine triphosphate binding proteins of the Ras and Rho families[21]. Rho proteins are involved in cell motility through regulation of actin-dependent processes such as membrane ruffling, pseudopod formation, and assembly of focal adhesion complexes[15]. All these mechanisms propel cells in the appropriate direction. In humans different chemokine receptors subdivided into four families have been described: XC, CXC, CC and CX3C chemokine receptors. These receptors are expressed on different types of leukocytes, and some are constitutively expressed while others are induced, depending on the degree of leukocyte activation and differentiation[15]. Polarisation of chemokine receptor expression on T cells depending on the cytokine production profile has been demonstrated[22]. Chemokine receptors, such as CCR5 and CXCR3, are associated with the type-1 response, while CCR3, CCR4 and CCR8 are associated with the type-2 response[23,24,25,26]. Due to the preferential Th1/Tc1 response of liver infiltrating T cells during chronic hepatitis C[27,28], this review focuses on these two chemokine receptors, which bind chemokines from the non-ELR-CXC and CC subfamilies. The ligands for CXCR3 are interferon (IFN)-γ-inducible protein 10 (IP-10, CXCL10), monokine induced by IFN-γ (Mig, CXCL9), and IFN-inducible T-cell α chemoattractant (I-TAC, CXCL11). CXCR3 is expressed on activated T cells and natural killer cells[29]. The CCR5 ligands comprise regulated upon activation, normal T-cell expressed and secreted (RANTES, CCL5), macrophage inflammatory proteins 1α (MIP 1α, CCL3) and 1β (MIP 1β, CCL4). CCR5 is expressed predominantly on activated and memory T cells. Hereafter the systematic nomenclature for chemokines will be used.

CHEMOKINE SECRETION AND CHEMOKINE RECEPTOR EXPRESSION IN CHRONIC HEPATITIS C

The migration of lymphocytes to the liver is a complex process involving adhesion, rolling, triggering, and transendothelial migration. Chemokines and their

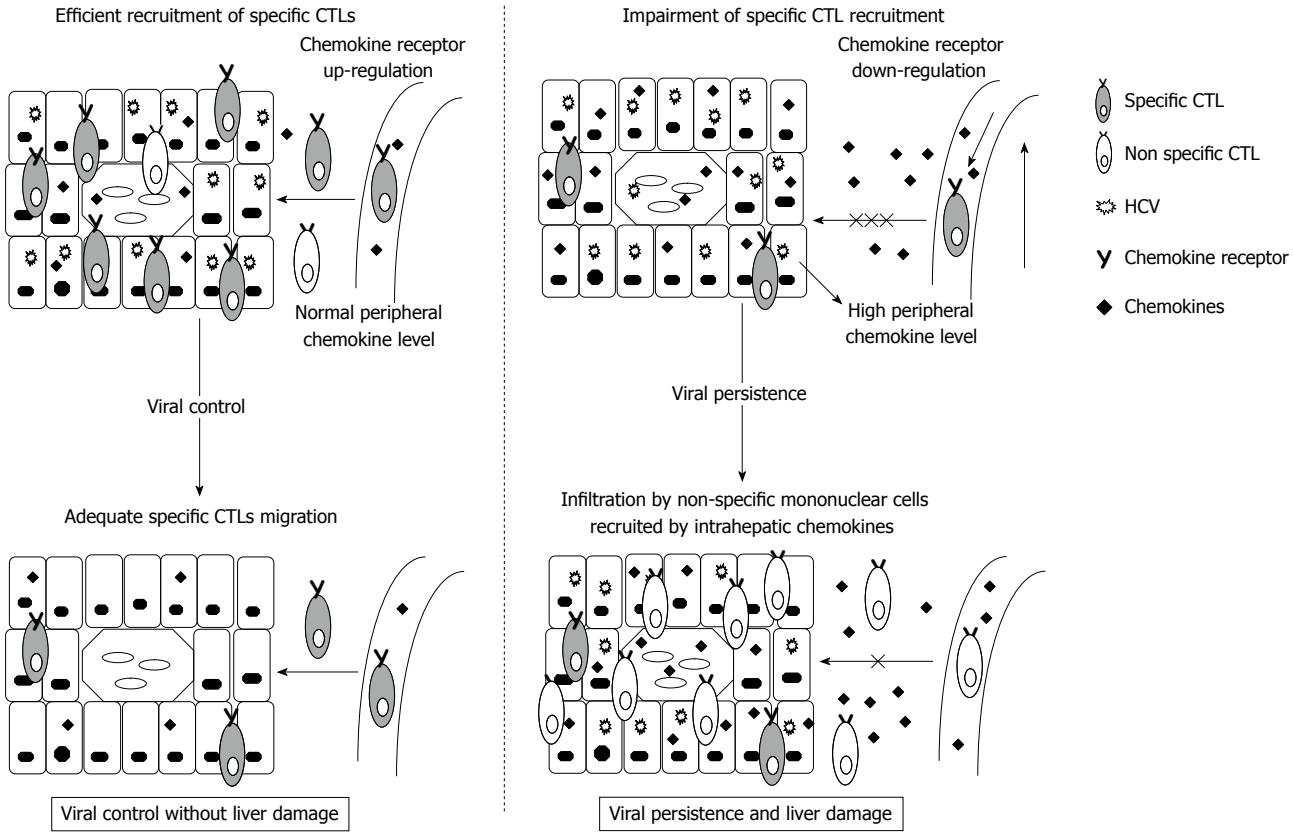

Figure 2 Different migration potential between resolved and persistent HCV infection. In a resolved infection HCV-specific cytotoxic T lymphocytes (CTL) migrate rapidly to the infected liver, attracted by the chemokines produced by hepatocytes, succeeding in controlling HCV infection without liver damage. In persistent infection the migration of T cells to the liver may be impaired. High chemokine levels during infection may induce chemokine receptor down-regulation on T cells by molecule internalization. This mechanism could impair the migration of specific T cells during primary infection, which could inhibit HCV clearance. During the chronic phase, the persistent presence of HCV in the liver could keep a long-standing chemokine production, which could attract non-specific mononuclear cells to the liver, and be responsible for chronic liver damage. The relative migration impairment due to chemokine receptor down-regulation on non-specific T cells could modulate inflammatory infiltration of the liver, inducing chronic low-grade liver damage, which could favour host and virus long-term survival.

receptors play an essential role in this multistep pathway[30,31]. In chronic hepatitis C, the expression of different chemokines in the liver has been described. CXCL10 is increased in the liver and peripheral blood during chronic hepatitis C[32,33,34,35]. This molecule is produced by hepatocytes and sinusoidal endothelial cells[33,34]. CXCL9 and CXCL11 are also increased in the serum and liver of subjects with chronic hepatitis C[33,36]. CXCL9 is detected primarily on sinusoidal endothelial cells, while CXCL11 is produced mainly by hepatocytes[33,37]. The intrahepatic expression of CCL5 is also elevated in chronic hepatitis C and it is produced by hepatocytes, sinusoidal endothelial cells and biliary epithelium[37]. Finally, several studies have reported an increased level of CCL3 and CCL4 either in the liver or in serum. These molecules are detected on endothelial cells, on some hepatocytes and on biliary epithelial cells[33,35,38]. The expression of all these chemokines in the liver can be induced directly by HCV. Previous reports have shown a high hepatocyte synthesis of CXCL10, CXCL9 and CCL5, induced by some HCV proteins such as NS5A and core[39], although a recent *in vitro* study suggests that HCV proteins could also decrease the expression of CCL5 and CXCL10 genes[40]. All these chemokines recruit T cells with a Th1/Tc1 phenotype expressing specific chemokine receptors such as CCR5 and CXCR3[24]. The non-ELR-CXC chemokine attracts CXCR3 expressing T cells while CC chemokine attracts CCR5 expressing T cells to the liver. Consequently, in chronic hepatitis C, an intrahepatic enrichment of CCR5 and CXCR3 expressing T cells, located in the hepatic lobule and portal tracts, has been shown while these populations are very infrequent in uninfected subjects[33,35,37] (Figure 6).

CORRELATION BETWEEN LIVER INFLAMMATION AND CHEMOKINE/ CHEMOKINE RECEPTOR

Persistent HCV infection is characterised by a non-specific inflammatory infiltrate in the liver, mainly composed of CD8+ cells[41,42], and responsible for liver damage[9]. These cells are attracted by the interaction between the intrahepatic secreted chemokines and the chemokine receptors expressed on T cells. Previous reports have shown a correlation between liver inflammation and liver infiltrating CXCR3/CCR5 expressing T cells[35,37] (Figure 7). The frequency of occurrence of these cells was positively correlated with portal and lobular inflammation but not with liver fibrosis. These data suggest that CCR5 and CXCR3

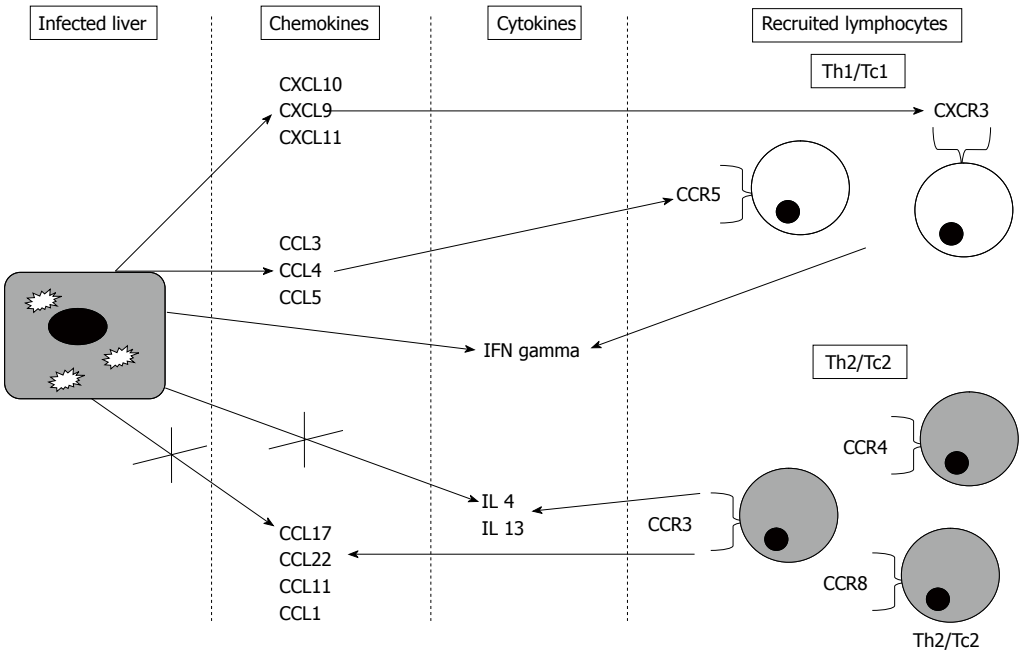

Figure 3 Chemokines and chemokine receptors related to chronic hepatitis C pathogenesis. In chronic hepatitis C, intrahepatic chemokines recruit Th1/Tc1 cells expressing CCR5/CXCR3 chemokine receptors. The X symbol indicates that chemokines and cytokines associated with a Th2/Tc2 response are not primarily produced in the HCV infected liver.

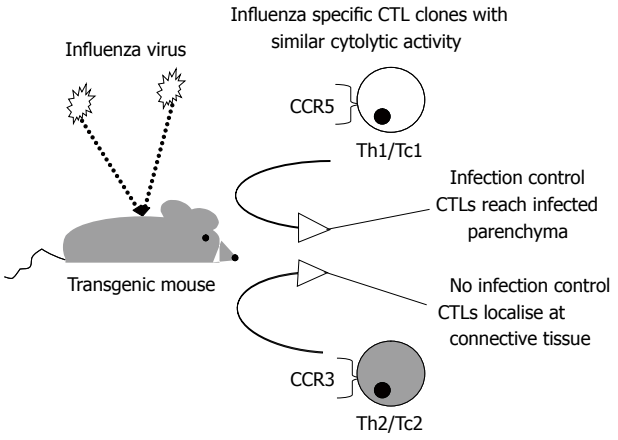

Figure 4 Adequate chemotaxis is necessary to control a viral infection. Specific cytotoxic T cells with active *in vitro* effector functionality are not able to control a viral infection if they do not express the appropriate chemokine receptor to reach the infected parenchyma. In a murine model of influenza virus infection, specific CCR5-expressing T cells were able to clear the virus while administration of specific CCR3-expressing T cells induced mouse death. CTLs: cytotoxic T lymphocytes.

could play an important role in chronic liver damage by means of recruitment of inflammatory T cells into the liver. Several previous studies have also shown a correlation between liver inflammation and chemokine levels. Intrahepatic CXCL10 mRNA levels are associated with intralobular inflammation[43]. Similarly, CXCL9 and CXCL11 correlate with the grade of liver inflammation[37,44]. Furthermore, CC chemokines are also correlated with intrahepatic inflammatory activity[45]. Clearly, intrahepatic CCL5-positive cells correlate with inflammatory activity but not with liver fibrosis[37]. The absence of correlation between liver fibrosis and liver infiltrating CXCR3/CCR5 expressing T cells and their ligands could be due to a statistical beta error, but also could suggest that it is necessary for something other than liver inflammation to occur in order to develop fibrosis, such as genetic and non-genetic factors[46]. Nevertheless, a recent study, examining a large sample of chronic hepatitis C patients, showed a positive correlation between CXCL9, CXCL10 and CXCL11 intrahepatic levels and the grade of fibrosis[47], indicating that persistent liver inflammation produced by the mononuclear cells attracted by these chemokines could finally induce the activation of a liver fibrosis cascade. Bearing in mind all the previous data, it is possible to speculate that chemokines are secreted in the infected liver to attract an adaptive immune response able to clear the virus. Unfortunately, when the specific response fails these chemokines also attract non-specific T cells, which are not able to remove the virus but produce liver inflammation (Figure 2). Therefore, as chemokines are nonspecific chemoattractants, the intrahepatic inflammatory infiltrate produced during chronic infection is mainly non-HCV-specific and consequently unable to eliminate HCV. It is, however, able to produce cytokines capable of initiating and perpetuating hepatic fibrogenesis[48]. The efficiency of this mechanism could play a role in determining why chronically infected individuals either do or do not progress to fibrosis. Certain polymorphisms in key chemokines known to be up-regulated in chronic HCV, such as CCL5, have been identified as correlates with the development of fibrosis[49].

MODULATION OF CHEMOKINE/CHEMOKINE RECEPTOR PATHWAY AS A VIRAL ESCAPE MECHANISM

HCV is usually able to evade the immune system efficiently. Several HCV escape mechanisms have been previously described, such as selection of escape mutations, induction of specific T cell anergy or resistance to the effects of α-interferon[5,50]. One

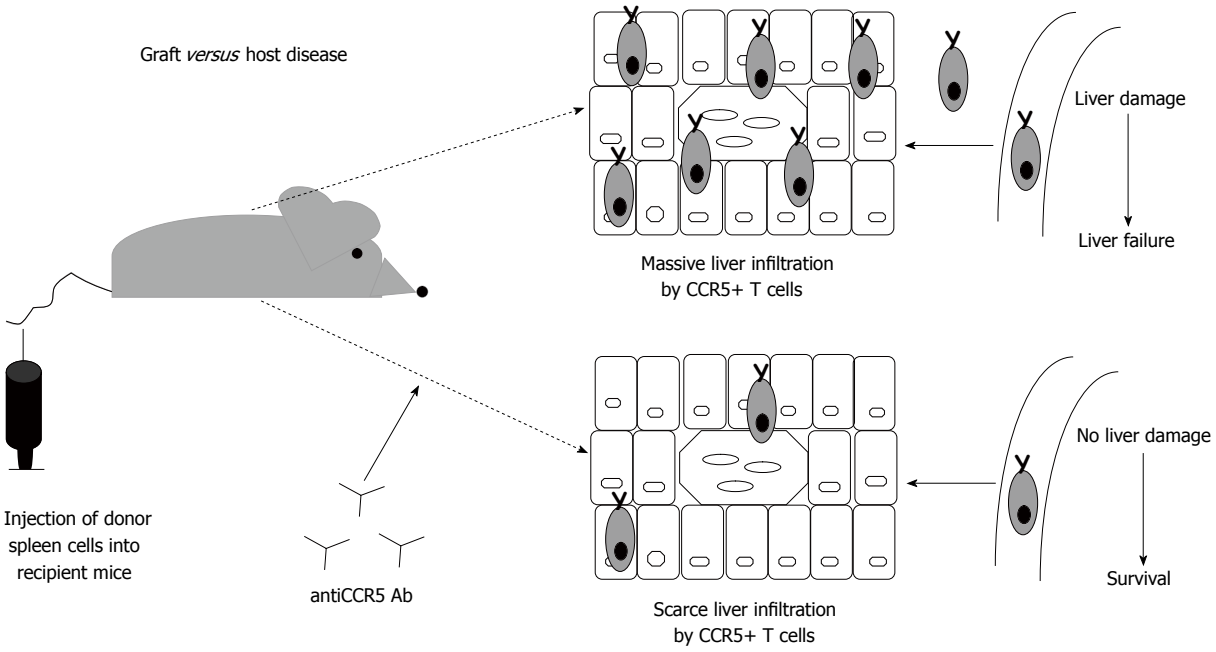

Figure 5 Intrahepatic chemoattraction of non-specific T cells causes liver damage. In a murine model of graft *versus* host disease the liver is infiltrated by CCR5-expressing T cells causing liver failure. This process can be blocked by using anti-CCR5 monoclonal antibodies.

hypothetical mechanism for HCV to survive could be to reduce hepatic chemotaxis of T lymphocytes to impair infection control during primary infection and also to decrease tissue damage during the chronic phase. The natural history of chronic hepatitis C means it can take up to three decades to develop liver cirrhosis[51]. This in turn means that the immunologically-mediated liver damage must be continuous but very light. For HCV it is essential to extend host survival as much as possible to assure its own viability. Considering these facts, it could be important for HCV to impair the expression of chemokine receptors associated with the type-1 response to improve its survival ability.

One mechanism to achieve this could be to reduce T cell migration into the liver through impairment of CCR5 and CXCR3 expression. To maximise the ability of the immune system to control the infection, a high frequency of HCV-specific CCR5+/CXCR3+ T cells should be expected during primary infection. Soon after HCV infection, prominent CD8+ cell responses are repeatedly observed and transient up-regulation of CCR5 and CXCR3 expression is seen[52,53]. During chronic hepatitis C, however, T cells show reduced surface expression of chemokine receptors associated with the Th1/Tc1 response while an intracellular increase of these molecules has been described[54]. This finding suggests the occurrence of HCV-mediated chemokine receptor internalization in chronically infected subjects. Moreover, a high serum concentration of CCL3 and CXCL10, associated with a normal or reduced peripheral frequency of CCR5- and CXCR3-positive T cells during chronic hepatitis C, has been also described[35,54]. During chronic HCV infection, the observed absence of an increase in the number of peripheral CCR5/CXCR3-positive T cells could be due to either an intrahepatic sequestration of CCR5/CXCR3 expressing T cells, caused by CCL3/CXCL10 attraction, or to a down-regulation of these chemokine receptors produced by the high serum concentration of their ligands.

It has been shown that GB virus C, a close relative of HCV[55], can reduce CCR5 expression on T cells by inducing CCL5 release[56,57]. This mechanism impairs the ability of HIV to infect CD4 T cells, thus extending host survival[57,58]. Another study into HCV infection described CCR5 down-regulation on CD8+ cells by receptor internalization[54]. It has been shown that the HCV-E2 protein, after binding to CD81[59], induces CCL5 secretion by CD8+ cells and the ensuing interaction between CCL5 and CCR5 is responsible for CCR5 down-regulation on these cells[60]. All these data suggest that HCV could modulate chemokine receptors associated with the Tc1 response to achieve a survival advantage. This mechanism could decrease HCV-specific T cell migration during acute infection, avoiding viral control, and could also impair non-specific T cell migration during persistent infection, modulating liver inflammation and fibrosis which could extend host and viral survival. If HCV is able to interfere with CCR5/CXCR3 expression, an increase in T cells expressing these chemokine receptors after viral load drop due to anti-viral treatment should be expected, together with a CXCL10/CCL3 decrease. To address this significant issue, a longitudinal analysis of CCR5/CXCR3 expressing CD8+ cells and CXCL10/CCL3 levels during treatment was performed[35]. In the majority of treated patients in this study, an increase in CCR5/CXCR3 expressing CD8+ cells was demonstrated. This finding was associated with a significant decrease in CXCL10 and CCL3 serum levels after 24 wk of treatment. A likely explanation for these data is that HCV control

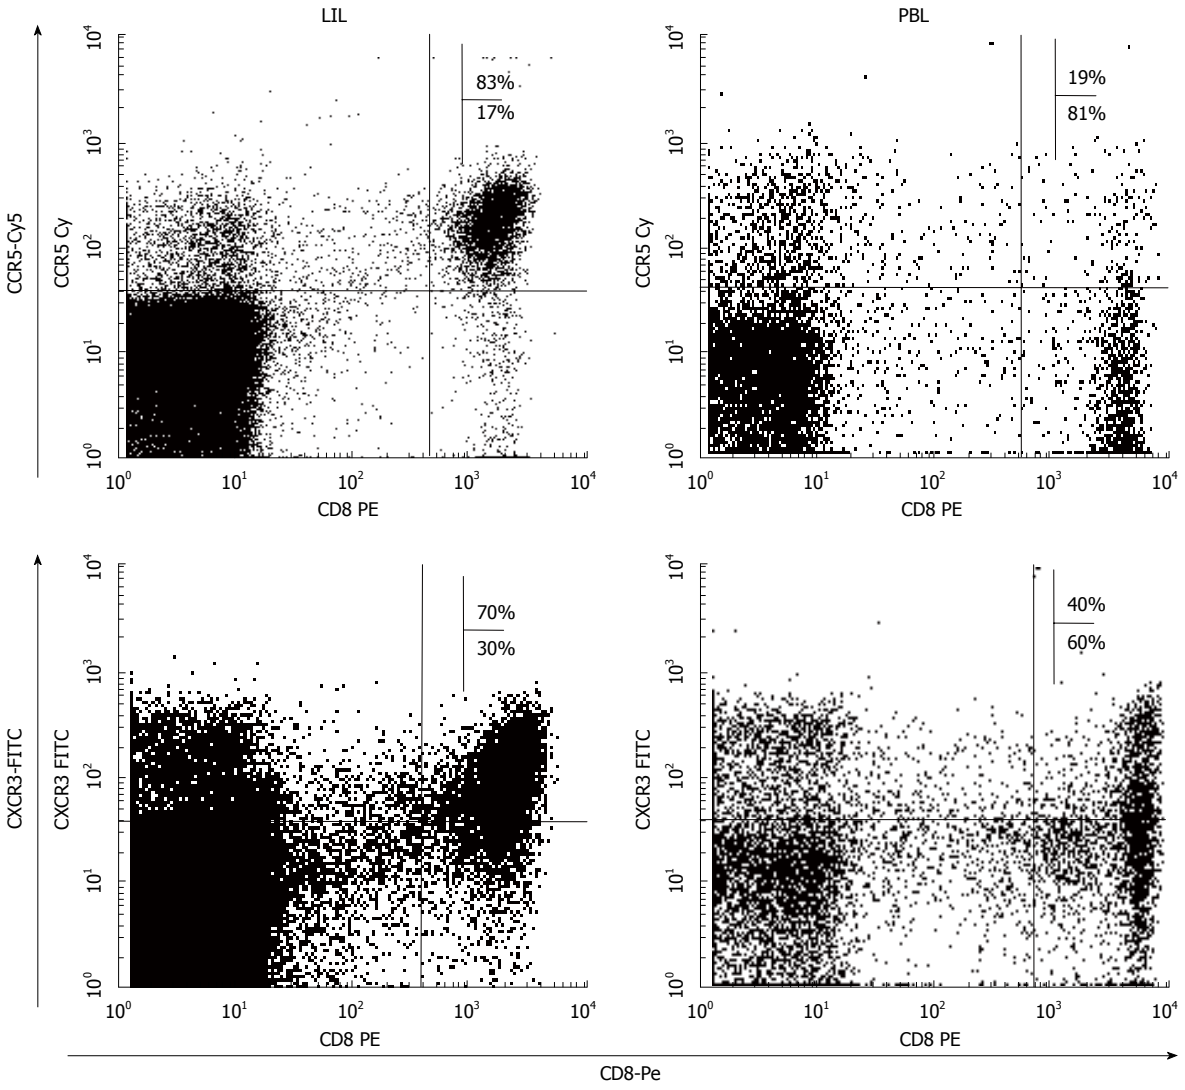

Figure 6 Intrahepatic enrichment of CCR5 and CXCR3 expressing T cells. FACScan® dot-plots of liver infiltrating (LIL), and peripheral blood (PBL) lymphocytes from a patient with chronic hepatitis C stained with labelled antibodies against CD8, CCR5 and CXCR3. The intrahepatic frequency of CCR5/CXCR3-expressing CD8+ cells is higher than in the peripheral blood.

during treatment could decrease CXCL10/CCL3 release, allowing CCR5/CXCR3 up-regulation on peripheral CD8+ cells. Actually, in this study a significant positive correlation between HCV viral load and CCL3 and an almost significant correlation with CXCL10 was shown. In summary, all these data taken together suggest that HCV could down-regulate CCR5 and CXCR3 expression on T cells by means of the secretion induction of their chemokine agonists. This strategy could favour HCV escape from immune control and could also decrease long-standing liver inflammation, allowing extended host and virus survival.

CHEMOKINE/CHEMOKINE RECEPTOR LEVELS AS TREATMENT RESPONSE OUTCOME PROGNOSTIC TOOL

As previously commented, Tc1/Th1 associated chemokines and their ligands can be modulated by HCV infection to impair the immune response. Therefore, the levels of these molecules may also influence treatment-mediated viral clearance. Previous studies have shown how baseline CXCL10 serum concentration is associated with the outcome of antiviral therapy in monoinfected[61-64] patients and in patients co-infected with HIV[65]. Elevated pre-treatment CXCL10 levels correlate with non-response to current therapy. Moreover, it was shown that the increase in CXCR3 expressing CD8+ cells during treatment is associated with SVR[35]. This suggests that for HCV, it is important to modulate the expression of this receptor not only to maintain liver viability but also to escape from immunological control. In addition, in this last study, a faster reduction in CXCL10 serum concentration was suggested in responders than in non-responders during the first 12 wk of treatment. Therefore, high CXCL10 may decrease the response of CXCR3 expressing T cells and have a negative influence on treatment outcome. Patients with either low base-line or rapid decrease of CXCL10 levels could promptly restore the response of CXCR3 expressing T cells which could assist in viral control. On the other hand, the absence of an increase in CXCR3

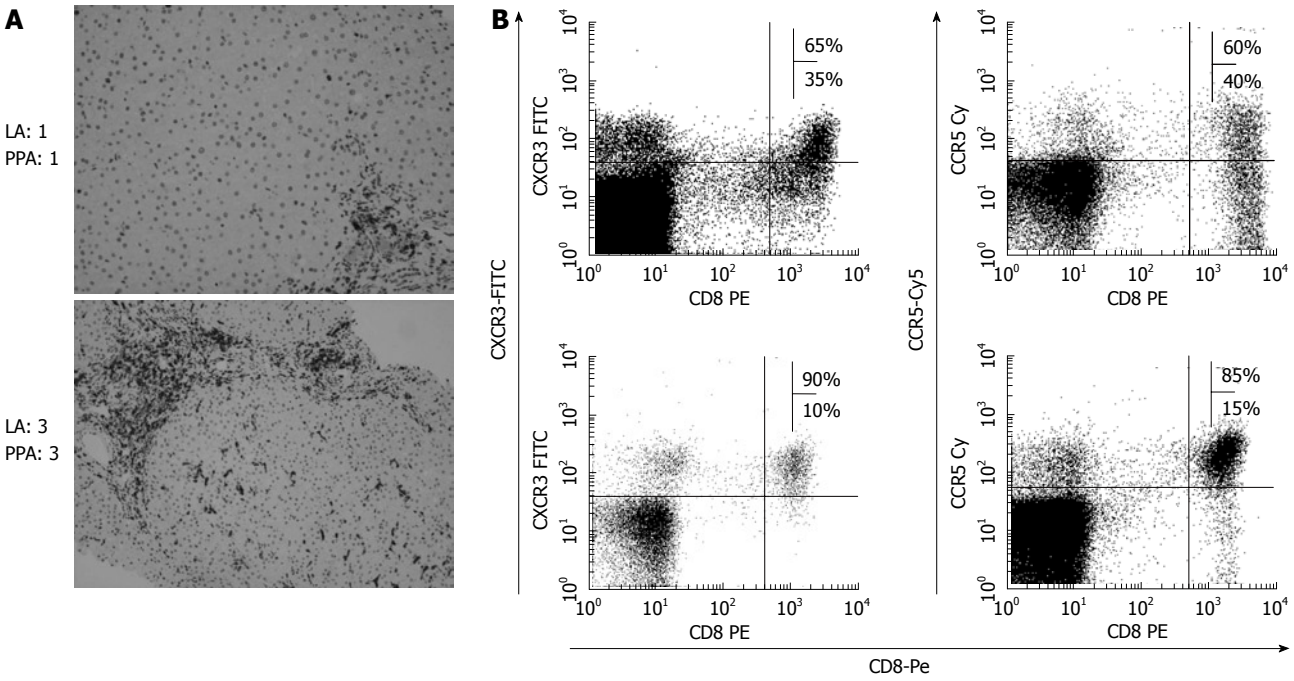

Figure 7 Correlation between liver inflammation and frequency of intrahepatic CCR5 and CXCR3 expressing T cells in chronic hepatitis C. A: Representative photomicrographs of liver immunostaining for CD8 from two chronic hepatitis C patients with different grades of inflammation. CD8 cells are stained in dark by the immunoperoxidase technique. Original magnification 400X. A patient with lobular activity (LA) 1 and porto-periportal activity (PPA) 1 showed little staining while a patient with LA 3 and PPA 3 presented intense CD8 staining; B: FACScan® dot-plots of intrahepatic lymphocytes from these two patients after staining with CD8-Pe and with either CCR5-Cy5 or CXCR3-FITC mAbs. In the upper right quadrant are represented the double positive cells. The frequency of CCR5/CXCR3 expressing CD8+ cells is higher in the patient with the higher histological liver inflammation.

expressing CD8+ cells after 24 wk of treatment is associated with a 100% negative predictive value of SVR[35]. This information may be clinically important in predicting non-response and allowing the termination of treatment in those patients with no increase in the frequency of CXCR3 expressing CD8+ cells after 24 wk of treatment. Nevertheless, with these data it is impossible to completely rule out the possibility that the observed change in chemokine patterns during treatment was an epiphenomenon due to a direct interferon effect[66]. This aspect could be clarified by studies based on patients treated with protease inhibitors. Finally, CCL20 and CXCL9 have also been suggested as tools to predict treatment outcome[61,67]. All these studies defined to predict treatment response provide preliminary information only since they are based on a very small number of patients. Therefore, these data should be re-confirmed by larger multivariate studies before applying these prognostic variables to daily clinical work.

ROLE OF CHEMOKINE/CHEMOKINE RECEPTOR POLYMORPHISMS

Several chemokine and chemokine receptor polymorphisms have been associated with different HCV infection outcomes. A CXCL11 polymorphism, defined by a 5-bp deletion in the CXCL11 promoter, has been associated with an increased risk of chronic HCV infection[68]. The distribution frequency of the allele was found to be significantly increased in a chronically HCV infected population compared to healthy controls. This deletion variant significantly reduced the transcriptional activity of the CXCL11 promoter in vitro in the presence of replicating HCV, which impaired T cell migration in vivo. Moreover, a CCR5 frameshift mutation, called CCR5-Δ32 that abrogates CCR5 expression also favoured HCV infection[69]. In this study an association between this homozygous mutation and an increased prevalence of HCV infection, as well as an increase in viral load, was documented. On the other hand, this mutation has also been associated with reduced liver inflammation[49,70,71]. These data suggest that the specific and non-specific T cell migration impairment due to the absence of CCR5 expression could favour HCV persistence and could also decrease liver damage. Similarly, a CCL5 deletion mutation which produces higher expression of CCL5 is associated with a lower grade of liver inflammation and fibrosis[70,71]. In this case the CCL5 over-expression may lead to CCR5 internalization and subsequent impairment of T cell migration. These mutations, which reduce chemokine receptor expression, are interesting proofs of the role of these molecules in the development of intrahepatic inflammation during chronic hepatitis C.

CHEMOKINE RECEPTORS AS A POTENTIAL THERAPEUTIC TARGET

Human monoclonal antibodies against CCR5, CXCR3 and their ligands have been used to treat different inflammatory and infectious diseases in humans and in animal models. CCR5 monoclonal antibodies have

been shown to be effective in avoiding T cell infection by CCR5-tropic HIV-1[72,73,74], and also in decreasing tissue inflammation in some animal models[75]. CXCL10 blocking is a successful treatment for experimental colitis[76,77]. Anti-CXCR3 monoclonal antibodies display an anti-inflammatory effect in an animal model of arthritis[78] and could also be a therapeutic target in inflammatory bowel disease[79]. These molecules have not been yet tested in chronic hepatitis C, due to the absence of an adequate animal model for proving their efficiency and safety. In the near future, an HCV permissive mouse model reconstituted with a human immune system will allow us to study mechanisms of chemokine/chemokine receptor immunopathogenesis[80]. Nevertheless, in a murine model of liver failure the administration of anti-CCR5 monoclonal antibodies has been shown to suppress intrahepatic liver inflammation, allowing mouse survival[12] (Figure 5). At least theoretically, all these previous data suggest that antibodies able to block the interaction between CCR5/CXCR3 and their ligands could decrease chronic liver inflammation in HCV infected subjects unable to clear the virus. Clearly, if the migration of non-specific T cells to the infected liver is impaired, liver damage will be reduced since HCV is not directly cytopathic. This strategy could be explored in patients without a sustained virologic response after current standard treatment. These future drugs could reduce liver fibrosis progression until new effective anti-HCV treatments are available. Obviously, the lessons learnt from HIV about the safety of these drugs should be the milestone for starting clinical trials in non-responder HCV patients[81].

In summary, the current knowledge about the role of chemokines and their receptors during chronic hepatitis C strongly suggests that they are implicated in persistent liver inflammation. Moreover, HCV seems able to modulate the expression of some chemokine receptors through the induction of their ligands. This strategy could be used by HCV as a survival mechanism. First of all, it could impair specific T cell migration to the infected liver during the primary infection, weakening HCV clearing. Later, the mechanism could interfere in non-specific T cell migration to the liver during the chronic phase of infection to extend host survival. From a practical point of view, some chemokines and their receptors have been shown to be prognostic tools in predicting anti-HCV treatment responses, and after new larger studies to re-confirm these data, these predictors could be added to daily clinical practice. Finally, the blocking of chemokines and chemokine receptor engagement is a therapeutic strategy that should be explored in the near future for non-responders to current anti-HCV therapy.

Abstract
The intestinal epithelial lining plays a central role in the digestion and absorption of nutrients, but exists in a harsh luminal environment that necessitates continual renewal. This renewal process involves epithelial cell proliferation in the crypt base and later cell migration from the crypt base to the luminal surface. This process is dependent on multi-potent progenitor cells, or stem cells, located in each crypt. There are about 4 to 6 stem cells per crypt, and these stem cells are believed to generate distinct end-differentiated epithelial cell types, including absorptive cells, goblet cells, enteroendocrine cells and Paneth cells, while also maintaining their own progenitor cell state. Earlier studies suggested that intestinal stem cells were located either in the crypt base interspersed between the Paneth cells [i.e. crypt base columnar (CBC) cell model] or at an average position of 4 cells from the crypt base [i.e. label-retaining cells (LRC +4) model]. Recent studies have employed biomarkers in the *in vivo* mammalian state to more precisely evaluate the location of these progenitor cells in the intestinal crypt. Most notable of these novel markers are *Lgr5*, a gene that encodes a G-protein-coupled receptor with expression restricted to CBC cells, and *Bmi 1*, which encodes a chromatin remodeling protein expressed by LRC. These studies raise the possibility that there may be separate stem cell lines or different states of stem cell activation involved in the renewal of normal mammalian intestinal tract.

INTRODUCTION

An improved understanding of stem cell biology and its possible application in the treatment of diseases has emerged as an important fundamental area in clinical medicine. The intestinal epithelial lining is relatively unique in its ability to rapidly regenerate. This has led to an ever increased focus on the crypt cell as a potential model of adult stem cell biology. The mammalian intestinal epithelial lining plays a critical role in digestion and in the absorption of nutrients and requires constant renewal due to the very harsh luminal environment. This renewal process involves rapid and continuous proliferation of epithelial cells in the crypt base with subsequent migration of these cells to the luminal surface. This process of epithelial cell renewal within the intestine appears to be entirely dependent upon a limited number of long-lived multi-potent intestinal progenitor cells or stem cells.

An intestinal epithelial stem cell may be broadly defined as a cell having at least 2 important properties: firstly, an ability to generate distinct differentiated epithelial cell types found in the intestine; and secondly, an ability to maintain itself as a progenitor cell over prolonged periods. It appears that each intestinal crypt contains approximately 4 to 6 stem cells. Each of these cells is believed to be capable of essential regenerative activity which is required to produce all the distinctive end-differentiated epithelial cell types found in the intestine. However, recent studies employing specific biomarkers for identification of stem cells have raised new and intriguing issues which have significant implications for the regenerative processes in the digestive tract involved in both health and disease.

INTESTINAL STEM CELL IDENTIFICATION

Over 30 years ago, Cheng and Leblond identified small cycling epithelial cells interspersed between the Paneth cells, or the so-called crypt base columnar (CBC) cells, using morphological methods in mammalian intestine[1,2]. Later, Bjerkness and Cheng provided additional information on these specialized cells using elegant clonal marking techniques[3].

These investigators theorized that the CBC cells located within the stem cell zone of the crypt base might represent the actual intestinal epithelial stem cells[3,4]. All of the end-differentiated intestinal epithelial cells were hypothesized to develop from these CBC cells including intestinal columnar cells, intestinal goblet cells, enteroendocrine cells and Paneth cells.

An alternative hypothesis has also suggested that intestinal stem cells were actually located elsewhere at a position that averaged +4 from the bottom of the crypts with the lowest three positions generally relegated to the terminally differentiated Paneth cells. Evidence supporting this hypothesis of the +4 stem cell model was provided by Potten *et al*[5,6]. These investigators, using the DNA-labeling reagents, bromo-deoxyuridine or (^{3}H)-thymidine, on radiation-sensitive, label-retaining cells (LRC) showed that the LRC were located specifically at the +4 position in the intestinal crypt region, precisely at the origin of the migratory epithelial cell column.

INTESTINAL STEM CELL SIGNALING

Intestinal stem cells, although compartmentalized into the crypt region, do not function in isolation independent of specific regulatory controls. Clearly, these cells play critical roles in the proliferation and differentiation of normal and neoplastic epithelial cells, However, the complex regulation of these cells involves a wide array of critical signaling pathways, recently well reviewed elsewhere[7]. These include Wnt, BMP, PTEN-controlled PI3K/Akt and Notch pathways. While studies are needed to further elucidate all of the specific mechanisms involved in each signaling pathway, recent reports focused on the elusive position of these progenitor cells have served to add a new dimension to the intricate biology of these cell processes.

INTESTINAL STEM CELL LOCALIZATION

In 2007, Barker and Clevers reported a highly restricted molecular marker for intestinal stem cells[8]. These investigators identified *Lgr5*, a gene encoding a specific G-protein-coupled receptor, which was expressed specifically in CBC cells. Later, using engineered mice, a DNA marker on *Lgr5*-positive cells was created which permitted subsequent tracing of their lineage into long-lived epithelial clones with all of the cell types in normal ratios. Interestingly, CBC cells were not quiescent (as might have been expected) but completed a cell cycle in about one day suggesting that these CBC cells would have to undergo many hundreds or thousands of cell divisions during the lifetime of the animal without loss of genetic information or malignant transformation. The *Lgr5* gene was also found to be expressed in the stomach and throughout the intestinal tract as well as in colon cancer cells leading to speculation that *Lgr5* might be a cancer stem cell marker. Moreover, as the *Lgr5* gene encoded a receptor on the cell surface, it was suggested that this might permit recognition with a monoclonal antibody and a means of eventually eradicating *Lgr5*-positive cancer stem cells[9].

In a recent 2008 report, another new stem cell marker was reported by Sangiorgi *et al*[10]. In their studies, *Bmi 1*, a Polycomb group protein known to play an important role in the renewal of hematopoietic and neural stem cells, characterized the progeny derived from *Bmi 1*-positive cells using a similar lineage tracing approach employed for Lgr5-positive cells. The *Bmi 1* locus marked long-lived cell clones by all intestinal cell types. Ablation of *Bmi 1*-positive cells resulted in depletion from the epithelium in entire intestinal crypts. Of note, *Bmi 1* was expressed in cells in the +4 position region, not at the location of the CBC cells, and primarily in the proximal small intestine, suggesting that a different stem cell population may have been characterized. Moreover, crypt *Bmi 1*-positive cells appeared to have slow turnover with relatively slow kinetics, another difference from *Lgr5*-positive cells which rapidly turnover[11].

FUTURE STUDIES

The possible relationship of these two apparently distinctive intestinal stem cell populations requires further definition. In addition, studies for other new stem cell markers are likely to already be in progress. Are these studies likely to indicate that there are multiple stem cell populations in the intestine similar to other stem cell organs, such as the epidermis, with distinctive stem cell populations? Or, alternatively, is this simply the expression of a single stem cell population in different proliferative states? Further definition of this issue is essential. The regenerative processes in the intestinal epithelial lining in health and disease are both fascinating and complex. More importantly, the possible implications for clinical medicine may be enormous. As clinicians caring for patients, close attention to this rapidly progressing fundamental investigative endeavour is needed.

Abstract

Colonic diverticulosis can either be asymptomatic or present with complications resulting in significant morbidity and mortality. A key presentation of complicated disease is abscess formation (Hinchey type Ⅱ). The natural course of this is unclear and therefore treatments range from conservative approach with antibiotics and percutaneous guided drainage (PCD) to surgery. There is no clear consensus on the exact management strategy. A Medline based literature search specifically looking at studies dealing with Hinchey type Ⅱ diverticulitis and its management was carried out. For comparison, five-year retrospective data of diverticular abscesses from our institution was collected and the outcome analysed. Various studies have looked into this aspect of the disease, elaborating on the significance of the size and location of the abscesses, the role of PCD, recurrence rates and the controversies regarding the need for elective surgery. Conservative treatment with antibiotics alone is effective in a majority of cases with a role for PCD in large safely accessible abscesses. Variable recurrence rates have been reported in literature and elective surgery should be planned for selected groups of patients.

INTRODUCTION

The prevalence of colonic diverticulosis has gradually yet steadily increased in the western world and ranges from 30%-50% of population over the age of 50 and more than two thirds over the age of 80[1].The sigmoid colon is the most common site to be involved. These diverticulae are primarily pulsion type of pseudo-diverticulae characterised by outpouching of mucosa and peritoneum through the sites of penetration of blood vessels in the colonic wall[2]. Though the exact aetiology is not known, abnormal colonic structure and motility along with genetic, dietary and changes in intestinal flora are considered to play a role in its patho-physiology[3].

There is lack of clarity about the natural course of the disease. Its different manifestations ranging from being completely asymptomatic to an array of complicated diverticular disease makes it vital to acquire a good understanding of this condition. Complicated diverticulitis (CD), accounting for 20%-30% of total prevalence of diverticulosis, causes significant morbidity and mortality in patients in addition to considerable healthcare costs in the western world[4]. This includes the gamut of diverticulitis either with or without phlegmon, abscess, fistula, obstruction, bleeding and perforation with purulent/faecal peritonitis[5,6].

The clinical presentation usually comprises of a triad of primarily left lower quadrant pain, fever and leucocytosis, although other associated features like nausea, vomiting, change in bowel habits, rectal bleeding and dysuria may be present. The clinical classification scheme[7] by the European association for endoscopic surgeons is based on the clinical severity and is detailed in Table 1. Other classifications do additionally incorporate the clinical and pathological aspects with the computerized tomography (CT) findings and aid in the planning of treatment strategies for this condition. The universally accepted is the Hinchey classification[8],

which descriptively characterises the various stages of diverticulitis and its acute complications. Type I and Type Ⅱ refer to inflammatory phlegmon and paracolic abscesses while type Ⅲ and Ⅳ refer to purulent and faeculent peritonitis respectively. This classification has been further modified as given in Table 2.

The sequence of pathological changes complicating a colonic diverticulum starts from a microperforation in its structure[9]. However the progression beyond this can be unpredictable either leading to a phlegmon or to frank faeculent peritonitis. The management is dictated by the stage of the disease at the time of its presentation and by the observed response to the initiated treatment[10]. Conservative measures characterised by bowel rest, antibiotics and clinical monitoring are usually effective in the treatment of early stages of diverticulitis especially modified Hinchey stage 0 and stage I a. There is also a clear consensus on open or laparoscopic surgical management of type Ⅲ and Ⅳ as these stages are unlikely to respond to conservative measures. However the exact management strategy for type I b and Ⅱ (specifically diverticular abscesses i.e. paracolic or pelvic) needs more clarity.

The general treatment option for these stages (I a & Ⅱ) starts from conservative management to CT guided percutaneous drainage (PCD) and then on to surgery based on progression of the disease with reliance on clinical and laboratory parameters. It is important to understand that this severe condition has an overall mortality of 5%-10% and higher rates in emergency surgery (> 25%)[13].

The problems associated with management of these stages relate to the difficulty in gauging if the condition will respond to conservative treatment, the exact indications for PCD and identifying the cohort of patients who will need early emergency surgery. Additional hurdles to management include problems with PCD, primarily the difficulty in access, documented failure rate and its associated complications. Most of the studies in literature have dealt with the different stages of CD and the main impetus has been on the various surgical approaches to the management of this condition and its impact on morbidity and mortality. This article has specifically reviewed the management of Hinchey Ⅱ diverticulitis associated with pericolic and pelvic abscesses.

MEDLINE BASED LITERATURE SEARCH

A Medline based review of the literature was performed specifically looking at studies which dealt with diverticular abscesses (Hinchey type Ⅱ diverticulitis) and its outcome. A five-year retrospective analysis of data of patients admitted with diverticular abscess (Hinchey type Ⅱ) admitted to our institution was also collected and analysed for comparison.

OUTCOME ANALYSIS

The rationale behind the use of antibiotics and PCD in the management of diverticular abscesses is based on the treatment of intra-abdominal sepsis and the reduction of the abdomino-pelvic inflammatory milieu to facilitate single stage operations. CT has revolutionised the approach to diverticulitis due to it's high sensitivity and specificity in the diagnosis[14] planning of management and also a therapeutic role in guided drainage of abscesses. Before the advent of PCD, 10%-15% of operations for diverticulitis was for drainage of abscesses[15] and multistage surgical procedures were being performed for diverticular abscesses[16,17]. The diagnostic findings on CT include inflammation of pericolic fat, colonic wall thickening, mesocolic and pelvic abscesses, perforation with free intraperitoneal air and bowel obstruction (Figure 1).

CT in addition enables to exclude other causes of acute abdomen, however, the reliable differentiation of acute diverticulitis from colonic malignancy can be difficult[18]. It has been reported that the findings such as pericolic stranding, involvement of more than 10 cm of the colon or the absence of pericolic nodes associated with colonic thickening and pericolonic inflammatory changes are likely to point to diverticulitis rather than cancer[18]. The CT classification by Ambrosetti[19] as shown in Table 3 is valuable in assessing the severity of the disease and planning optimal management.

The preferred approach is usually transabdominal, either anterior or lateral taking precautions to avoid the inferior epigastric and the deep circumflex iliac vessels, respectively[20]. Alternative approaches include transgluteal[21,22], transperineal[23,24], transvaginal and

Table 1 Clinical classification of diverticulitis (adapted from Köhler *et al*[7])

Grade	Clinical features	Symptoms
I	Symptomatic uncomplicated disease	Fever, abd pain, CT evidence of diverticulitis
Ⅱ	Recurrent symptomatic disease	Recurrence of above symptoms
Ⅲ	Complicated disease	GI bleeding Phlegmon Abscess Peforation-purulent/ faecal peritonitis Stricture Fistula Obstruction

Table 2 Modified hinchey classification (adapted from Wasvery *et al* [11,12])

Modified Hinchey classification	
0	Mild clinical diverticulitis
I a	Confined pericolic inflammation-phlegmon
I b	Confined pericolic abscess
Ⅱ	Pelvic, intrabdominal or retrocolic abscess
Ⅲ	Generalized purulent peritonitis
Ⅳ	Faecal peritonitis
Fistula	Colo-vesical/-vaginal/-enteric/-cutaneous
Obstruction	Large/small bowel obstruction

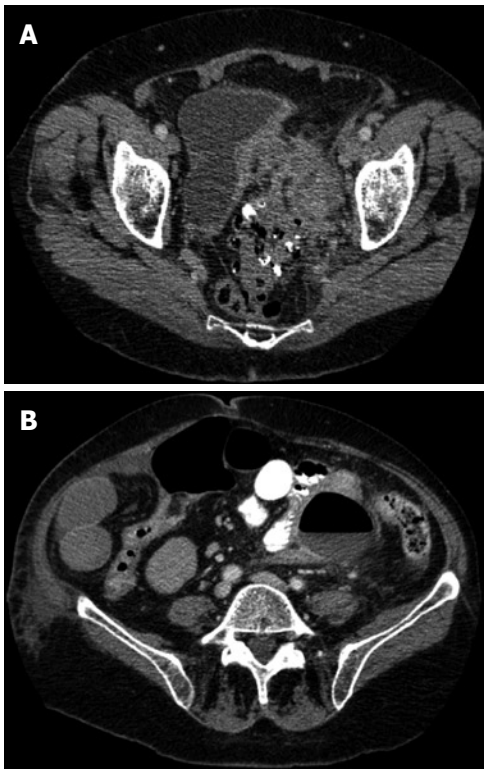

Figure 1 Abdomen and pelvis CT. A: Pelvic abscess secondary to complicated diverticulitis; B: Paracolic abscess secondary to complicated diverticulitis.

transrectal[25] for access. PCD primarily was used as a temporary measure and bridge to surgery though recent suggestions questioning the necessity of surgery after conservative treatment have generated further debates. Although it is presently acknowledged that CT plays a pivotal role in guided PCD, operator skill and the location of the abscess are paramount in determining success of the intervention. Guided PCD is the choice of intervention for simple uninoculated abscesses with success rate of more than 80%, but is known to have a high failure rate in cases of complex abscesses which are defined as abscesses with loculations, associated with fistulae and infected fluid collections whose drainage route traverses normal organs[20].

Despite innovative improvements in modalities, the response to conservative treatment of Hinchey Ⅱ is not consistently successful, as various unexplained factors seem to modify the clinical course. Based on deterioration in clinical parameters, patients undergo surgery preferably receiving a single stage colectomy or in some cases two stage procedures, a colectomy with diversion stoma. Attempts to identify the exact indications surrounding the modality of approach are currently ongoing and can be appreciated from the interesting literature on this issue. Tables 4 and 5 feature some of the important publications and their findings dealing specifically with diverticular abscesses.

Stabile *et al*[26] in his series of 19 patients with a follow up of 17.4 mo showed that PCD was successful in 14 patients who subsequently had elective single stage operations. The average size of the abscesses in this series

Hinchey type Ⅱ (*n*)	28
Average size of abscesses (cm)	5
Average size of abscess for PCD (cm)	7
Rate of surgical intervention (%)	46

was quite large at 8.7 cm. Meuller *et al*[27] also reported successful results with PCD and on retrospective chart review of 87 patients with diverticulitis prior to the use of PCD found that more than 50% of those who underwent two stage surgical procedures would have benefited from PCD. Similar studies by Neff *et al*[28] and Saini *et al*[29] have reinforced the contribution of PCD in facilitating single stage surgical procedures.

Ambrosetti *et al*[30] from his study of 73 cases of diverticular abscesses with a follow up of 43 mo found that 59% of total cases eventually needed surgery either during the acute admission or as an elective procedure. The rest of the group did not need any form of surgical intervention after conservative treatment either with or without PCD. In his study, antibiotics alone without PCD was effective in 30 patients and 19 out of 73 patients underwent PCD. The study also compared the prognosis of mesocolic abscesses with pelvic ones and revealed that pelvic abscesses exhibited an aggressive behaviour and therefore needed to be rapidly drained percutaneously and were likely to require surgery. In addition, it was stated that the indication for secondary colectomy after successful treatment of mesocolic abscess with or without drainage was not peremptory.

In a 10-year study and a mean follow up of 46.5 mo by Kaiser *et al*[11] CT guided PCD was found to be successful in 93% of cases. In this series of 99 cases, 16 (16.2%) of them were amenable for PCD. Out of 99 patients, 23 patients failed conservative treatment with antibiotics ± PCD and needed emergency surgery during the same admission. Overall recurrence rate for the entire group was 18.2 % with especially high rates for early stages (40% for stage I b + PCD, and stage Ⅱ ± PCD). Interestingly, the recurrence in the stage I b group after CT guided PCD was high at 40% when compared to the overall stage I b recurrence of 12.7%. The exact reason for this was not clear although the size of the abscesses in the drained group was significantly larger thus making the possibility of more severe disease in the drained group likely. The key finding of a high

Kumar *et al*[31]	30	12	17	5	-
Stabile *et al*[26]	19	19	-	3	14
Mueller *et al*[27]	24	21	1	6	12
Kaiser *et al*[11]	99	16	56	23	20
Ambrosetti *et al*[30]	73	19	30	18	25
Brandt *et al*[13]	66	34	21	15	28
Siewert *et al*[33]	30	4	17	-	13
Cinat *et al*[37]	13	13	-	5	-
Saini *et al*[29]	17	8	-	1	7
Alvarez[34]	59	-	33	26	-

incidence of recurrence in these groups highlighted the assertion that successful PCD should be considered as just a temporary measure rather than definitive treatment. The authors recommended that considering the high rates of recurrence, CT confirmed abscess was a strong indication for consideration of elective/semi-elective surgery.

There are several studies in literature detailing the role of PCD in diverticular abscesses but very few comparing treatment with antibiotics alone or antibiotics with PCD. Brandt *et al*[13] retrospectively looked at this issue comparing two groups with CT confirmed abscesses, one who had antibiotics alone and the other antibiotics with PCD. Interestingly, the results show that the patients treated with antibiotics alone achieved an outcome similar to patients treated with PCD. However the average abscess size was larger in the PCD group (4 cm in the antibiotic only group compared to 6 cm in PCD group). Failure rate of PCD in this series was 33% which was comparable to other series[35,36]. The results from this study showed that antibiotics alone were effective in more than 80% of patients presenting with Hinchey type Ⅱ diverticulitis.

A similar study by Siewert *et al*[33] reported that antibiotics alone was effective in resolving acute symptoms for abscess size less than 3 cm. In this study, the abscess size was comparatively smaller than in other studies as most patients presented early in the course of the disease and CT was performed on the day of presentation in the emergency department. Kumar *et al*[31] in his series of 30 patients with abscesses found that patients with an average abscess diameter of 4 cm improved on antibiotics alone.

In the series of 69 cases of CT confirmed diverticulitis (Table 4) from our institution over a period of 5 years (unpublished), we found comparable rates of abscesses to that in literature (28/69 patients with diverticular abscess). The average size of abscesses in our patients was 5.0 cm. Only a small percentage of abscesses were accessible for PCD (3/28 cases) in our series and the average size of the abscesses in these cases was 7 cm. The rate of acute surgical intervention during the initial admission was 46% in our series and was comparable to other series in literature.

As seen in Tables 5 and 6, in a majority of studies, the average size of abscesses for PCD intervention was more than 6 cm with an overall increased prevalence of paracolic abscesses over pelvic and distant abscesses. The percentage of PCD intervention ranged from about 13% to 51%, though in a few studies it was not clear whether all abscesses were taken into consideration or the only ones amenable to drainage were reported. Interestingly, conservative treatment using antibiotics with or without PCD was successful as definitive treatment in about 30% to 56% in a majority of studies while it was effective in tiding over the acute situation in a range of 56% to 76%. The collective data also suggests that more than 50% of cases may eventually need semi-elective or elective surgery due to recurrent symptoms.

Issues in management

Despite the wealth of literature detailing the management of this condition, certain aspects of decision making and

management have remained controversial, especially the indications for PCD, single stage operations and planning of elective surgery.

Size and location of abscesses

Significant parameters like the size and location of the abscesses do influence the success of conservative or PCD intervention. Most of the evidence in literature shows that the size of the abscess is directly proportional to the need for intervention. Some of the large series reported in literature are given in Table 4. It is generally observed in various studies that abscesses with a size of up to 4 cm seem to respond better to antibiotics alone[13,31,33]. In the context of PCD, as an average, size equal to or more than 5 cm with safe access seems to be an indication[11,30].

Regarding the significance of the abscess location, there has been emphasis on better prognosis with mesocolic and paracolic abscesses[30,34] though this has been disputed by some studies[31]. It is feasible that mesocolic abscesses are the result of early disease resulting in local colonic inflammatory changes with pus collection contiguous with the mesentery and therefore respond better to conservative treatment. Single stage surgical procedures are also sufficient in these circumstances as these abscesses can be removed en bloc with the specimen[27]. Pelvic abscesses are probably the result of a slightly larger perforation with potential to complicate further by exceeding the confines of the mesentery onto the surrounding pelvis and peritoneum. This may benefit by PCD but could further deteriorate to necessitate surgery or on resolution of the acute episode need elective surgery[30]. Therefore, the pelvic location of the abscess could be a potential indicator for further elective surgery.

Failure of conservative treatment with or without PCD

The early Hinchey stages like stage 0 or I a can also fail conservative treatment and progress to emergency surgery. Kaiser *et al*[11] in his series found that 6.8% of these stages needed surgical intervention during the first admission. In his series, 22.2% of stage I b and Ⅱ failed conservative treatment and PCD. The failure rate of PCD ranges from 15%-30% in different series[11,38,39]. Although there are no clear early indicators to potential failure of conservative treatment, large sized abscesses with systemic features of inflammation could predict failure. In this context, Kumar *et al*[31] found in his series that an abscess size more than 6.75 cm associated with leucocytosis of more than 14.8×10^9/L and fever more than 102°1 F could predict a failure in conservative treatment.

Complications

Complications with PCD have been reported in the range of about 5% in most series[31] and they include bleeding, perforation of viscus, solid organ injury and fistulation. High rates of mortality as much as 75% were seen in earlier series due to complications of PCD[40]. Although faeculent drainage from the catheters were reported in some series[26], a majority did show response to conservative treatment and did not cause any secondary problems[27]. Recurrent abscesses after PCD have been reported which can interfere with elective operation[6].

Recurrence and elective surgery

It is known that recurrence is a problem after conservative management of diverticulitis. The manifestations of recurrence may range from episodic cramps without CT evidence to complicated disease and about 30% are likely to develop recurrent diverticulitis[2,41,42].Variable recurrence rates ranging from about 7% to 35% have been reported in literature[42]. The potential to recurrence is high in these early Hinchey stages as the later stages would have had emergency surgery as definitive treatment[11]. Recurrent symptoms of diverticulitis have also been linked to the initial size of the abscesses[33] though there is no clear pattern in its presentation. High relative recurrence rates of 53.8% were seen in non-operated cases in some series[11,32]. Considering the high rates of recurrence and the low complication rates for elective surgery, it has been suggested that elective surgery should be undertaken to achieve relief of symptoms[43].

Questions regarding the indications for elective colectomy after conservative treatment remain unanswered. Resection is commonly recommended after two attacks of uncomplicated diverticulitis[44] in order to reduce the morbidity and mortality of complicated disease. However, the pattern of the first presentation of complicated disease can be very variable. Although pericolic abscesses and inflammatory phlegmon were found to be significantly associated with at least one prior episode of diverticulitis[5], studies have shown that previous history of diverticulitis was present in less than 20% of acute diverticulitis admissions[34]. Interestingly, Chapman *et al*[5] in her series on CD found that 53.4% of patients presented with CD as their first episode and 89.5% of patients who died due to diverticular perforation had no previous history of diverticulitis. Therefore, prophylactic colectomy to reduce morbidity and mortality from CD may not serve its intended purpose.

Studies have also shown that about 40%-50% of patients admitted with abscesses responded well to conservative treatment and eventually did not need surgery[30]. Therefore, elective surgery should be considered for patients who develop persistent or recurrent symptoms. Although there is no consensus on this issue, it is acknowledged that some subgroups may be at high risk and should be offered surgery especially young patients and patients with co morbidities such as diabetes, collagenous disorders and immunosuppressed[45-47].

CONCLUSION

Interpreting the results of various studies, the essential consistent finding is that about 20%-30% of the CD

cases present with abscesses out of which about a similar percentage (20%-30%) are amenable to PCD. In addition, the failure rate in PCD is about 20%-30%. Considering the whole spectrum of the Hinchey type Ⅱ diverticulitis, primary broad-spectrum antibiotics alone will remain the choice of primary therapy and interventions like PCD should be planned based on the abscess size and feasibility of drainage and also depend on the local expertise available to undertake the procedure. The role of PCD, though beneficial, will still be nominal. However, considering the large and increasing numbers of hospital admissions with this pathology, the contribution of PCD will remain paramount in terms of ameliorating the clinical picture. Considering the high rates of recurrent diverticulitis and its morbidity, assessment for elective surgery should be done on a case-by-case basis.

Abstract

A wide range of local thermal ablative therapies have been developed in the treatment of non resectable hepatocellular carcinoma (HCC) in the last decade. Laser ablation (LA) and radiofrequency ablation (RFA) are the two most widely used of these. This article provides an up to date overview of the role of laser ablation in the local treatment of HCC. General principles, technique, image guidance and patient selection are discussed. A review of published data on treatment efficacy, long term outcome and complication rates of laser ablation is included and comparison with RFA made. The role of laser ablation in combination with transcatheter arterial chemoembolization is also discussed.

INTRODUCTION

Surgical resection or transplantation have in the past been considered the gold standard for treatment of hepatocellular carcinoma (HCC). The overall resectability rate for such lesions is very low due to a combination of underlying chronic liver disease, lesion location and multifocal nature of HCC. Similarly, surgical resection carries a significant associated morbidity and mortality, as well as a disease recurrence rate of up to 75%[1,2]. Local thermal ablative techniques have gained popularity over the last decade proving to be an effective and safe alternative in many patients. These techniques are also cost effective in comparison to other treatments and are able to maximise the preservation of surrounding liver parenchyma whilst minimizing in-patient hospitalization[3]. Laser ablation (LA) represents one of a range of currently available loco-ablative techniques with the majority of reported data coming from Italy, Germany and the UK.

GENERAL PRINCIPLES & TECHNIQUES

The term laser ablation refers to the thermal tissue destruction of tissue by conversion of absorbed light (usually infrared) into heat and includes various technical variations on this theme including "laser coagulation therapy", "laser interstitial tumour therapy" and "laser interstitial photocoagulation"[4].

Infrared energy penetrates tissue directly for a distance of between 12-15 mm, although heat is conducted beyond this range creating a larger ablative zone[5]. Optical penetration has been shown to be increased in malignant tissue compared to normal parenchyma[6]. Temperatures above 60℃ cause rapid coagulative necrosis and instant cell death, but irreversible cell death can also be achieved at lower hyperthermic temperatures (> 42℃) although longer durations (30-60 min) are required[7]. Temperatures above 100℃ will cause vaporisation from evaporation of tissue water and above 300℃ tissue carbonisation occurs. Overheating is thus best avoided as carbonization decreases optical penetration and heat conduction and limits the size of lesion produced[6]. Local tissue properties, in particular perfusion, have a significant impact on the size of ablative zone. Highly perfused tissue and large vessels act

as a heat sink, as laser light is absorbed by erythrocytic heme and transported from the local area[8]. This phenomenon makes native liver parenchyma relatively more resilient to LA than tumor tissue and is the basis for the use of hepatic inflow occlusion techniques in conjunction with laser therapy such as local arterial embolization[9,10].

The most widely used device for LA techniques is the Nd-YAG (neodymium: yttrium-aluminium-garnet) laser with a wavelength of 1064 nm, because penetration of light is optimal at the near-infrared range of the spectrum[11]. More recently, more compact, less expensive diode lasers with shorted wavelengths (800-980 nm) have been used, although the lower tissue penetration produces a smaller volume of destruction.

Light is delivered *via* flexible quartz fibres of diameter from 300-600 μm. Conventional bare tip fibres provides a near spherical lesion of about 15 mm diameter at their ends, but have been largely replaced by interstitial fibres which are quartz fibres that have flat or cylindrical diffusing tips and are 10-40 mm long, providing a much larger ablative area of up to 50 mm[12,13]. The use of beam splitting devices allows the use of up to four fibres at once with corresponding increase in ablative volume, but requires multiple fibres to be placed and only works effectively at lower powers. Beam splitters are, therefore, rarely used with interstitial fibres. With increasing laser power, comes better light transmission and larger ablative zones. However, it also causes increased local temperature rise, risking overheating and carbonization of the adjacent tissue. The use of water cooled laser application sheaths allows a higher laser power output (up to 50 W compared with 5 W) while preventing carbonization[14]. Thus, the use of multiple water-cooled higher power fibres allows ablative zones of up 80 mm diameter. Water cooled sheaths do require wider bore cannulas, but are commonly placed *via* a coaxial dilation system from an 18 G puncture.

IMAGE GUIDANCE

A range of different imaging modalities have been used to guide percutaneous laser ablation techniques determined largely by local experience and resource availability. Ultrasound (US) guided needle placement has the advantage that it is quick, portable, and widely available, as well as being familiar to those used to performing US guided biopsies. The major disadvantage is that it offers little reliable indication of the temperature or extent of the ablative zone being created.

In contrast, magnetic resonance (MR) guided LA, often in conjunction with liver specific contrast agent, e.g. teslascan [mangafodipir trisodium (MnDPDP) Nycomed Imaging, Oslo, Norway], offers real time thermal mapping that allows the operator to visualise the size, location and temperature of the ablation zone[15,16]. This technique tends to be used in conjunction with the higher power water cooled laser systems as the increased energy (for example 40 000 J) can be delivered in a safe and controlled manner[17,18]. By contrast, US guided laser systems tend to use multiple lower power laser fibre with a lower total energy delivery[19]. However, MR guided LA is limited by machine availability and represents a longer procedure.

Thermal imaging can be performed on most MR systems, with thermal changes being easier to demonstrate as magnet field strength increases. There are several methods of measuring tissue temperature changes with MR. The simplest, and most widely used technique, is measuring alterations in T1 value of tissues which decreases in a linear relationship with increasing tissue temperature up to approximately 55℃[20,21]. Techniques that measure changes in the tissue diffusion coefficient are more accurate, up to ± 1℃, but require long acquisition times and, therefore, suffer from patient motion artifacts[22]. Another technique measures changes in the proton resonance frequency shift (phase shift). Again this measures temperature changes very accurately, but is not suitable for use in fatty tissue and is less suited to open MR units as it requires a homogenous magnetic field[23]. All of these techniques are best used in conjunction with subtraction techniques, i.e. pretreatment image subtraction from heating image, which allows very accurate assessment of lesion size, but is sensitive to motion and misregistration artifacts[24].

In addition to thermometry, the use of "open" MR magnets allows real time imaging of needle placement in a truly multiplanar manner [unlike computed tomography (CT)] and is not limited by the presence of bone or gas (unlike US) with the disadvantage that the inherent lower field and gradient strengths of open systems reduce image quality and increase scan time. Conventional closed magnets require fibre placement using CT or US with subsequent transfer into the MR scanner for thermal mapping. This has the disadvantages involved with patient transfer mid procedure, but provides faster imaging and thermal mapping than an open system. The use of MR guidance and thermometry is currently only feasible with LA systems, as it uses a completely metal free system and does not produce any radiofrequency (RF) interference. Most RFA systems are currently not suitable for MR usage, both because of steel within the electrodes and the degradation of image quality by extraneous RF noise produced by the RF generators. Although MR compatible systems have been developed in practice the RF noise remains problematic[16].

There is variation across the literature regarding patient analgesia during laser ablation with some groups providing conscious sedation and intravenous analgesia whilst others preferring general anaesthesia. General anaesthesia allows higher tolerable energy delivery and better control of respiration, but has significant resource implications, has its own associated morbidity rates and may affect patient inclusion/selection.

The use of local ablative techniques in combination with surgery has been explored using RFA and cryoablation[25]. While technically feasible, there is little recently published experience of LA usage at laparoscopy or laparotomy.

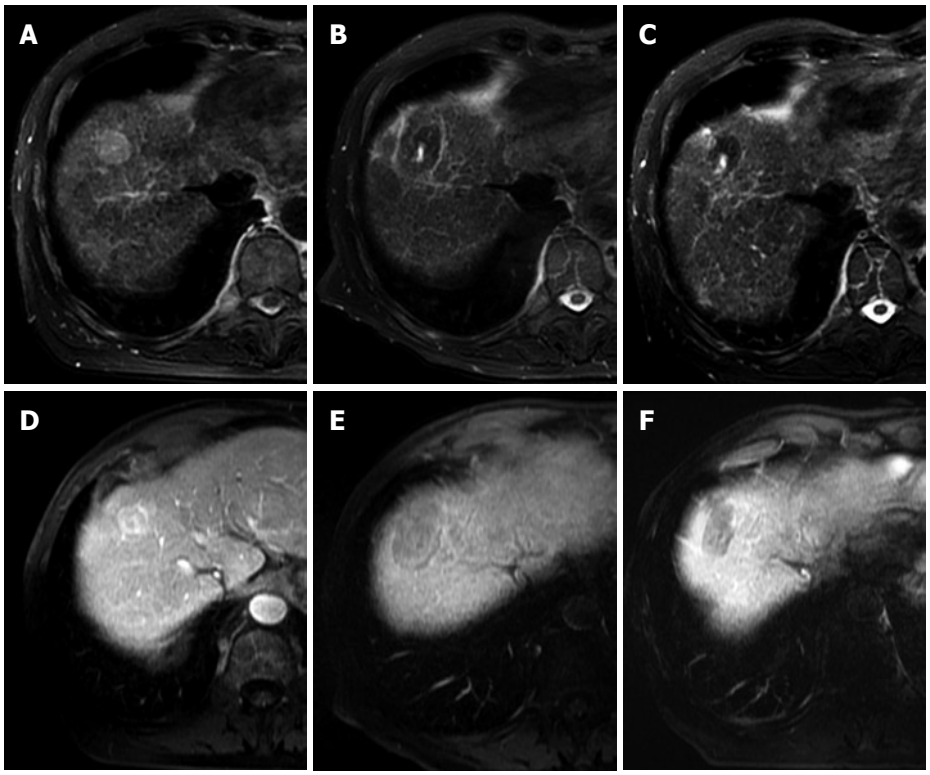

Figure 1 Typical MRI appearances pre and post laser ablation of a small HCC in a 73-year-old male patient with hepatitis C cirrhosis. T2-weighted axial images demonstrate a high signal 2.5 cm segment Ⅷ HCC (A). At one month post treatment (B) a typical low signal laser burn is demonstrated with high signal centre which has shrunk in size at 10 mo follow up (C). T1-weighted post contrast images of the same lesion demonstrate heterogeneous arterial enhancement pre-treatment (D), with non-enhancing scar at 1 mo (E) and persistent non-enhancement at 10 mo (F).

PATIENT SELECTION

Selection criteria vary from unit to unit dependant on the technique used and facilities available, but are broadly similar to those for other local ablative techniques and are based on size, number and site of HCC in patients who are deemed unsuitable for surgical resection or transplant. Laser ablation is also considered a valid interim treatment while awaiting transplant surgery. Patients are generally considered if there are less than 5 lesions of 5 cm or less. Lesions larger than this can be considered, particularly if using a high power system, though they may require more than one treatment. The ideal lesions are those less than 3 cm and deep within liver parenchyma. Lesions adjacent to major vessels, biliary ducts, bowel or diaphragm can be treated with caution. MR guided techniques allow confident ablation of anatomically more problematic lesions with the use of real time thermometry and multiplanar MR targeting. Severe liver disease (Childs C) and coagulopathy are relative contraindications to be considered in each individual patient and extra hepatic disease is generally considered an absolute contraindication.

EFFECTIVENESS

Several factors make interpretation of published outcome data difficult. While the majority of patients have HCC secondary to viral hepatitis, they represent a diverse cohort in terms of disease severity. Differing laser fiber systems with differing energy delivery levels make comparison of both efficacy and complication rates difficult to compare. Again, the range of imaging modalities used at follow-up, combined with a variety of definitions of treatment success, make comparison of data difficult.

Lastly, current guidelines suggest that formal tissue biopsy of HCC is not recommended in every case due to potential risks of tumour seeding. Many groups, therefore, assume the diagnosis of HCC based on history, imaging appearances and rising alpha fetoprotein (αFP) levels. The inevitable occasional inclusion of some lesions that are not in fact HCCs may, therefore, favorably skew outcome data.

When assessing the literature regarding efficacy of laser ablation, a clear distinction must be drawn between primary effectiveness rates and long term outcome rates. Primary effectiveness relates to complete lesion ablation as assessed by either CT or MR at a defined point post procedure and after a defined number of treatments. This does not necessarily correspond to improved long term outcomes. However, data regarding long term survival rates for LA is scarce and in part reflects the novelty of the treatment and the rapid advances in technology, particularly in relation to the laser fibres. Pacella *et al*[26] reported long term survival rates of 89%, 52% and 27% for 1, 3 and 5 years, respectively, in a series of 169 sub 40 mm lesions in 148 patients (144 biopsy proven HCC) treated with 239 sessions. They quote an overall 82% complete lesion ablation rate[26]. The same group reported an earlier series of 74 patients with 92 biopsy proven sub 4 cm HCCs with a complete ablation rate of 97% and survival rates of 99%, 68% and 15% for 1, 3 and 5 years, respectively[27] (Figure 1).

Results reported by those groups using water cooled higher power MR guided laser ablation have been promising. Eichler *et al*[28] reported mean survival rates of 4.4 years (95% CI: 3.6-5.2) in a series of 39 patients with 61 presumed HCCs with a complete ablation rate

of 97.5%. Although the same groups have provided compelling long term survival data for the ablation of hepatic metastases, no such data has to date been published for HCC ablation[29].

COMPARISON WITH OTHER ABLATIVE TECHNIQUES

A report by Ferrari *et al*[30] is the only randomized prospective study comparing LA with RF ablation. They treated 81 cirrhotic patients with 95 biopsy proven, sub 4 cm HCCs. Two matched groups were randomised to US guided RF or LA under general anaesthetic. LA was *via* multiple 5 W fibres delivering a maximum of 1800 J per fibre per treatment. Post treatment, lesions were evaluated with CT. They reported no significant difference overall in survival rates between the two techniques with cumulative rates of 91.8%, 59.0%, and 28.4% at 1, 3 and 5 years, respectively. They did, however, demonstrate a statistically significant higher survival rate for RFA over LA for Child A patients ($P = 0.9966$) and nodules $\leqslant$ 25 mm ($P = 0.0181$). They reported no significant complications[30]. This work added to the same groups' previous published improved survival rates in patients treated with LA, compared to those treated with either transcatheter arterial chemoembolization (TACE) or percutaneous ethanol injection (PEI)[31].

COMBINATION WITH TACE

The rationale of combining LA with TACE is attractive, particularly for large lesions. Pacella *et al*[19] described the use of LA followed by TACE in the treatment of 30 large (3.5-9.6 cm) HCCs. They achieved 90% ablation rate with survival rates of 92%, 68% and 40% at 1, 2, and 3 years, respectively. No significant complications were reported, leading the authors to conclude that combination therapy was a safe and effective palliative therapy in the treatment of large HCCs[19]. Ferrari *et al*[32] supported this suggestion demonstrating improved ablation rates and survival in patients with HCCs > 5 cm given combination treatment over LA alone.

COMPLICATIONS

Reported complication rates for laser ablation compare favourably to surgical rates.

Arienti *et al*[33] reported complication rates for 520 patients, with 647 presumed HCCs treated with 1004 laser sessions (local anaesthetic, US guided). They report 0.8% deaths and 1.5% major complication rate. An earlier report by Vogl *et al*[34] included 899 patients (of which 42 had HCC), with 2520 lesions treated with 2132 laser sessions (local anaesthetic, CT/MRI guided) and reported 0.1% mortality and 1.8% major complication rate. Included in the major complications were liver failure/segmental infarction, hepatic abscess/cholangitis, bile duct injury, and haemorrhage (intrahepatic/peritoneal/gastrointestinal). Both groups reported common side effects of asymptomatic pleural effusion (7.3% & 6.9%), post procedural fever (33.3% & 12.3%) and severe pain (7.5% & 11.5%). While tumor seeding after percutaneous biopsy and ablative therapies is well recognized, it has rarely been reported after laser ablation and neither of the above groups reported this complication.

CONCLUSION

LA of HCC remains a safe and effective local therapy for patients in which surgical resection is not possible or appropriate. Nevertheless, further data from randomized trials are required to establish long term survival rates, particularly for higher power water cooled systems before the treatment can be fully validated as a standard treatment. Further data is required to establish its role in combination therapy, either with other percutaneous treatments and/or surgery. At this stage, RFA remains the standard of care, but as the technology and experience progress the technique will be in a position to be randomised against RFA as an effective alternate primary treatment of HCC in an attempt to establish equivalent efficacy/long term survival.

Abstract

AIM: To investigate the expression pattern of gamma-aminobutyric acid A (GABAA) receptors in hepatocellular carcinoma (HCC) and indicate the relationship among gamma-aminobutyric acid (GABA), gamma-aminobutyric acid A receptor α3 subunit (GABRA3) and HCC.

METHODS: HCC cell line Chang, HepG2, normal liver cell line L-02 and 8 samples of HCC tissues and paired non-cancerous tissues were analyzed with semiquantitative polymerase chain reaction (PCR) for the expression of GABAA receptors. HepG2 cells were treated with gamma-aminobutyric acid (GABA) at serial concentrations (0, 1, 10, 20, 40 and 60 μmol/L), and their proliferating abilities were analyzed with the 3-(4, 5-methylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay, cell doubling time test, colon formation assay, cell cycle analysis and tumor planted in nude mice. Small interfering RNA was used for knocking down the endogenous GABRA3 in HepG2. Proliferating abilities of these cells treated with or without GABA were analyzed.

RESULTS: We identified the overexpression of GABRA3 in HCC cells. Knockdown of endogenous GABRA3 expression in HepG2 attenuated HCC cell growth, suggesting its role in HCC cell viability. We determined the *in vitro* and *in vivo* effect of GABA in the proliferation of GABRA3-positive cell lines, and found that GABA increased HCC growth in a dose-dependent manner. Notably, the addition of GABA into the cell culture medium promoted the proliferation of GABRA3-expressing HepG2 cells, but not GABRA3-knockdown HepG2 cells. This means that GABA stimulates HepG2 cell growth through GABRA3.

CONCLUSION: GABA and GABRA3 play important roles in HCC development and progression and can be a promising molecular target for the development of new diagnostic and therapeutic strategies for HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer and the third leading cause of cancer-related death worldwide[1]. Although liver resection and local ablation are regarded as potentially curative treatment[2], its prognosis is poor. Up to 40% of patients are diagnosed at an advanced stage, and only palliative treatment can be offered.

To change this situation, the development of new molecular therapies against good targets is an urgent issue. To this direction, we previously used a method by combining the *in silico* screen and experimental verification to identify genes that are differently expressed in cancers compared with their corresponding normal tissues. Among genes that are overexpressed in

HCC cells, we focused on the gene gamma-aminobutyric acid (GABA) A receptor α3 subunit (GABRA3). GABRA3 is a subunit of the GABAA receptors that may associate with other GABAA receptor subunits to form a functional chloride channel that mediates the inhibitory synaptic transmission in the mature central nervous system (CNS). GABA primarily functions as an inhibitory neurotransmitter in the mature CNS by activating the GABA receptor, but can also modulate the proliferation, migration and differentiation of neuronal cells during CNS development[3-5] and the proliferation of peripheral non-neuronal cells[6,7]. GABA and GABAA receptors are also present in peripheral tissues, including cancerous cells, but their precise functions are poorly defined.

This study demonstrates that GABRA3 overexpressed in HCC and GABA promoted the proliferation of cancer cells through GABRA3.

MATERIALS AND METHODS

Cell lines

HCC cell line Chang, HepG2 and normal liver cell line L-02 were maintained by our lab. All cell lines were cultured in DMEM supplemented with 10% FBS and antibiotics (100 units/mL penicillin and 100 μg/mL streptomycin). Cells were maintained at 37℃ in an atmosphere of humidified air with 5% CO_2.

Collection of tissues

All samples of HCC tissues and paired non-cancerous tissues (5 cm away from tumor) were obtained during surgical resection from the First Affiliated Hospital of Xiangya School of Medicine. Written consent was obtained from the patients, who agreed with the collection of tissue samples. The resected tissue samples were immediately cut into small pieces, and snap-frozen in liquid nitrogen until use. All tumor tissue and paired non-cancerous tissue samples were pathologically confirmed.

Semiquantitative polymerase chain reaction (PCR)

Total RNA from HepG2, Chang L-02 cell lines and liquid-nitrogen-frozen tissue samples were extracted using Trizol reagent (Invitrogen) according to the manufacturer's instructions. First-strand cDNAs were synthesized from 2 μg of DNase I -treated total RNA using oligo (dT) primer with SuperscriptTM Ⅱ reverse transcriptase (Invitrogen) for 60 min at 42℃. We prepared appropriate dilutions of each single-stranded cDNA for subsequent PCR amplification by monitoring β-actin as a quantitative control. The sets of primer for GABAA receptor subunits are shown in Table 1, 5'-AGCAAGAGAGGCATCCTCA-3' and 5'-TCAGGCAGCTCGTAGCTCT-3' for β-actin, 554bp. One μL of each cDNA product was amplified in a mixture containing 5 pmol primers, 200 μmol/L dNTPs, and 1 unit Taq DNA polymerase with reaction buffer in a final volume of 20 μL. PCR was performed using the following parameters: initial denaturation at 95℃ for 1 min, 30 cycles of 30 s at 95℃, 30 s at 60℃, and 1 min 30 s at 68℃, followed by a final 10 min extension at 68℃. Reaction products were separated on 1.5% agarose gels containing ethidium bromide and the level of amplification was determined using a Phosphor Imager.

RNA interference

To knock down GABRA3 expression, we used pGCsi-U6/Neo/GFP vector encoding a small hairpin RNA directed against the target gene in HepG2. The target sequences for GABRA3 were 5'-GCACTGACA ACATCACTAT-3' (Si-1), 5'-CTGAGACCAAGACCT

ACAA-3' (Si-2), 5'-GATCCTTCCACTGAACAAT-3' (Si-3). As a negative control, we used shRNA vector without hairpin oligonucleotides (Si-Mock). Human HCC cell line HepG2 was plated onto 6-well plates, and transfected with these small interfering RNA (siRNA) expression vectors using FuGENE6 (Roche) according to the instructions of the manufacturer, followed by 800 μg/mL of neomycin selection. The cells were harvested 10 d later to analyze the knockdown effect on GABRA3 by RT-PCR using the primers shown in Table 1 and by flow cytometry (FCM) using rabbit anti-human polyclone antibody against GABRA3 (Chemicon).

Cell proliferation test *in vitro*

Growth experiments of HepG2, HepG2/Si-1, and HepG2/Si-Mock were performed using the 3-(4,5-methylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay, cell doubling time test, soft agar cloning formation assay and were reconfirmed with cell cycle analysis, which was performed by flow cytometry.

In the MTT assay, cells were seeded with serum-free medium at a density of 10^3 cells/well in 96-well plates ($n = 6$), grown overnight, washed in PBS, and incubated with GABA (Sigma-Aldrich) at serial concentrations (0, 1, 10, 20, 40 and 60 μmol/L) in appropriate medium supplemented with 1% FBS. The samples were tested every 24 h for 6 d. MTT was added (50 μg/well) for 4 h. Formazan products were solubilized with DMSO, and the optical density was measured at 570 nm.

In the cell doubling time test, cells were seeded at a density of 10^4 cells/well in 24-well plates ($n = 3$), grown with serum-free medium overnight, and incubated with GABA at serial concentrations (0, 1, 10, 20, 40 and 60 μmol/L) in DMEM medium with 1% FBS. Cells were collected 6 d later, and cell densities were assessed by counting the cells in a hemocytometer. Cell doubling time (TD) was calculated with the following formula: TD=t × [lg2/(lgNt-lgNo)] [t: Period of culturing (hour); No: cell density when the cells were seeded; Nt: cell density when the cells were cultured "t" hours].

Soft agar colony formation assay was used to assess the anchorage-independent growth ability of cells. The cells were incubated with GABA at serial concentrations (0, 1, 10, 20, 40 and 60 μmol/L) in DMEM medium overnight. A total of 1000 single-cell suspension cells were resuspended in 1 mL growth media containing 0.3% low melting temperature agarose and GABA at different concentrations (0, 1, 10, 20, 40 and 60 μmol/L) respectively and were plated in triplicate on 6-well plates over a base layer of 1 mL growth media containing 0.6% low melting temperature agarose. Colonies > 50 μm were counted 14 d after plating.

For flow cytometry, cells were incubated with serum-free medium for 24 h, and then cultured in DMEM with 10% FBS in the presence or absence of 40 μmol/L of GABA for 48 h. Cells were harvested and resuspended in fixation fluid at a density of 10^6/mL, 1500 μL propidium iodide (PI) solution was added, and the cell cycle was detected by FACS Caliber (Becton Dickinson).

Tumor implanted in nude mice

Male 8-wk-old BALB/c nude (nu/nu) mice were purchased from Slac Laboratory Animal Co. Ltd (Shanghai, China). HepG2, HepG2/Mock and HepG2/Si-1 cells were treated with or without GABA (40 μmol/L) for 24 h first, and then the cells (3×10^6) were suspended in 0.2 mL of extracellular matrix gel and injected sc in the left back flank of these animals. The mice were divided into six groups: (a) the mice were injected with HepG2 and treated with 0.9% NaCl injection (150 μL) into the implanted tumor (HepG2, $n = 5$); (b) the mice were injected with HepG2 and treated with GABA injections (40 μmol/L in 150 μL of 0.9% NaCl) into the tumor (HepG2 + GABA, $n = 5$); (c) the mice were injected with HepG2/Mock and treated with 0.9% NaCl injection (150 μL) into the implanted tumor (HepG2/Si-Mock, $n = 5$); (d) the mice were injected with HepG2/Mock and treated with GABA injections (40 μmol/L in 150 μL of 0.9% NaCl) into the tumor (HepG2/Si-Mock + GABA, $n = 5$); (e) the mice were injected with HepG2/Si-1 and treated with 0.9% NaCl injection (150 μL) into the implanted tumor (HepG2/Si-1, $n = 5$); (f) the mice were injected with HepG2/Si-1 and treated with GABA injections (40 μmol/L in 150 μL of 0.9% NaCl) into the tumor (HepG2/Si-1 + GABA, $n = 5$). The same operator did the injections every other day starting from "day 0" when the tumors were implanted. Tumor variables were measured every three days by an electronic caliper, and volume was determined as tumor volume (mm^3) = length (mm) × width^2 (mm^2) × 0.523. The measurement started from the first week, when the tumor mass was well established. A third operator, in a coded and blinded fashion, evaluated the morphometric variables.

Statistics

Results were expressed as mean ± SD. Student's t test was used, and $P < 0.05$ was considered statistically significant.

RESULTS

Expression of GABAA receptors

We documented GABAA mRNA expression in 8 pairs of HCC and adjacent non-tumor tissues as well as HepG2, Chang, L-02 cell lines. The results of semiquantitative RT-PCR on a scale of + (limited expression) to +++ (highly expressed) are shown in Table 2.

GABAA-α3, β3, δ, ε, and θ receptor subunits were detected in HepG2 and α3, δ, ε, and θ in Chang liver cells by RT-PCR. In L-02, only ε subunit was detected. In tissues adjacent to HCC, GABAA receptor expression was limited to GABAA-β3, ε and π. In HCC tissues, although GABAA-ε expression remained largely unchanged, GABAA-α3 mRNA expression was consistently (6/8) and significantly increased, and GABAA-δ and θ isoforms were also detected.

Effect of GABRA3-siRNA on the growth of HCC cells

Table 3 Cell cycle of HepG2/Si-1 and HepG2/Si-Mock (mean ± SD)

	Si-1	Si-Mock
G1/G0%	56.1 ± 3.36	50.9 ± 3.14
G2/M%	14.3 ± 1.72	14.2 ± 1.43
S%[1]	29.5 ± 2.26	34.5 ± 2.37

[1]$n = 3$, $P < 0.05$.

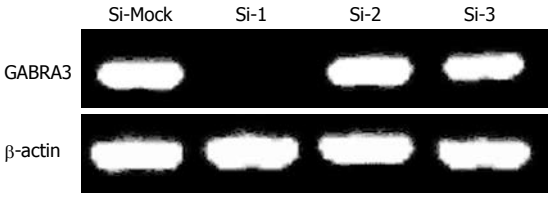

Figure 1 RT-PCR confirmed the knockdown effect on GABRA3 expression by Si-1, but not by Si-2, Si-3 and a negative control Si-Mock in HepG2 cells. β-actin was used to quantify RNAs.

overexpression in HCC cells, we constructed three siRNA expression vectors (Si-1, Si-2, and Si-3) specific to GABRA3 transcripts and transfected them into HepG2 cells that endogenously expressed high levels of GABRA3 as shown in Table 2. A knockdown effect was observed by RT-PCR when we transfected Si-1, but not Si-2, Si-3 or a negative control Si-Mock (Figure 1). MTT assays (Figure 2A) and colony formation (Figure 2B and C) revealed a drastic reduction in the number of cells transfected with Si-1 compared with Si-Mock for which no knockdown effect was observed. The cell doubling time of the cells transfected with Si-1 was 8.7 ± 0.183 d, while Si-Mock was 5.3 ± 0.125 d (n =3, $P < 0.05$). Cell proliferation detected by flow cytometry is shown in Figure 2D and Table 3. This result was consistent with the results above. The tumor size of the nude mice injected with HepG2/Si-1 (Group e) was significantly smaller than the mice injected with HepG2/Si-Mock (Group c) (Figure 2E).

Effect of GABA on the growth of HCC cells

To examine the effect of GABA on the growth of GABRA3-expressing HCC cells, we treated GABRA3-positive HCC cells HepG2 with GABA at several concentrations. As shown in Figure 3 and Table 4, the addition of GABA in the culture media enhanced the proliferation of HepG2 cells in a dose-dependent manner. The promoting effect on HCC cell proliferation was more evident with the GABA concentration from 1 μmol/L to 40 μmol/L. When the GABA concentration was up to 60 μmol/L, the promoting effect became insignificant. We also tried GABA at concentrations of 100 μmol/L, 200 μmol/L and 400 μmol/L, but there was no significant effect (data not shown). The effect of GABA persisted up to 5 d. The cell doubling times of HepG2 cells treated with 0, 1, 10, 20, 40 and 60 μmol/L were 5.1 ± 0.128, 2.73 ± 0.052, 2 ± 0.057, 1.51 ± 0.044, 1.3 ± 0.064 and 4.1 ± 0.085 d.

In the nude mice implanted with tumors (injected with HepG2 cells), a significant difference in tumor size was found in GABA-treated (at the concentration of 40 μmol/L) mice compared with mice injected with 0.9% NaCl only (Figure 3E).

and Table 5, GABA enhanced the growth of HepG2/Si-Mock compared with the HepG2/Si-Mock without GABA. On the other hand, the proliferating ability of HepG2/Si-1, which did not express GABRA3, was not enhanced but lowered by GABA. In the nude mice injected with HepG2/Si-Mock, the tumor size of the mice treated with GABA was much larger than the mice treated without GABA, while the result was opposite in the mice injected with HepG2/Si-1.

DISCUSSION

Although GABA and GABA receptors function as an inhibitory neurotransmitter in the mature CNS, abnormal levels of gene and protein expression of some GABA receptor subunits have been detected in many malignant tumors, such as π subunit in pancreatic cancer[8]. This indicates that GABAergic system may play an important role in the pathogenesis and development of malignant tumors, and their expression levels are important for prognosis. In this study, we found the overexpression of GABRA3 in more than half of the HCC tissues compared with the adjacent non-tumor liver tissues, and GABRA3 was expressed in malignant liver cell lines HepG2 and Chang, but not in normal cell line L-02, implicating that GABRA3 may be a good molecular target for the diagnosis of HCC.

GABAA-β3 receptor expression is absent in malignant hepatic cell lines, and the proliferating ability of Chang cells, which were stably transfected with GABAA-β3 receptor, was significantly decreased[9]. On the other hand, GABAB receptors were increased and GABAB receptor agonist promoted proliferation of hepatocytes[10]. It means that even in HCC, different GABA receptor subunits may have different functions. Functional analysis using siRNA of GABRA3 strongly supported its involvement in the development and progression of HCC. In our study, the proliferation rate of HepG2 cells after GABRA3 knockdown was significantly reduced, whereas proliferation of HepG2/Si-Mock cells was not inhibited. This result indicated that GABRA3 may increase the proliferating ability of

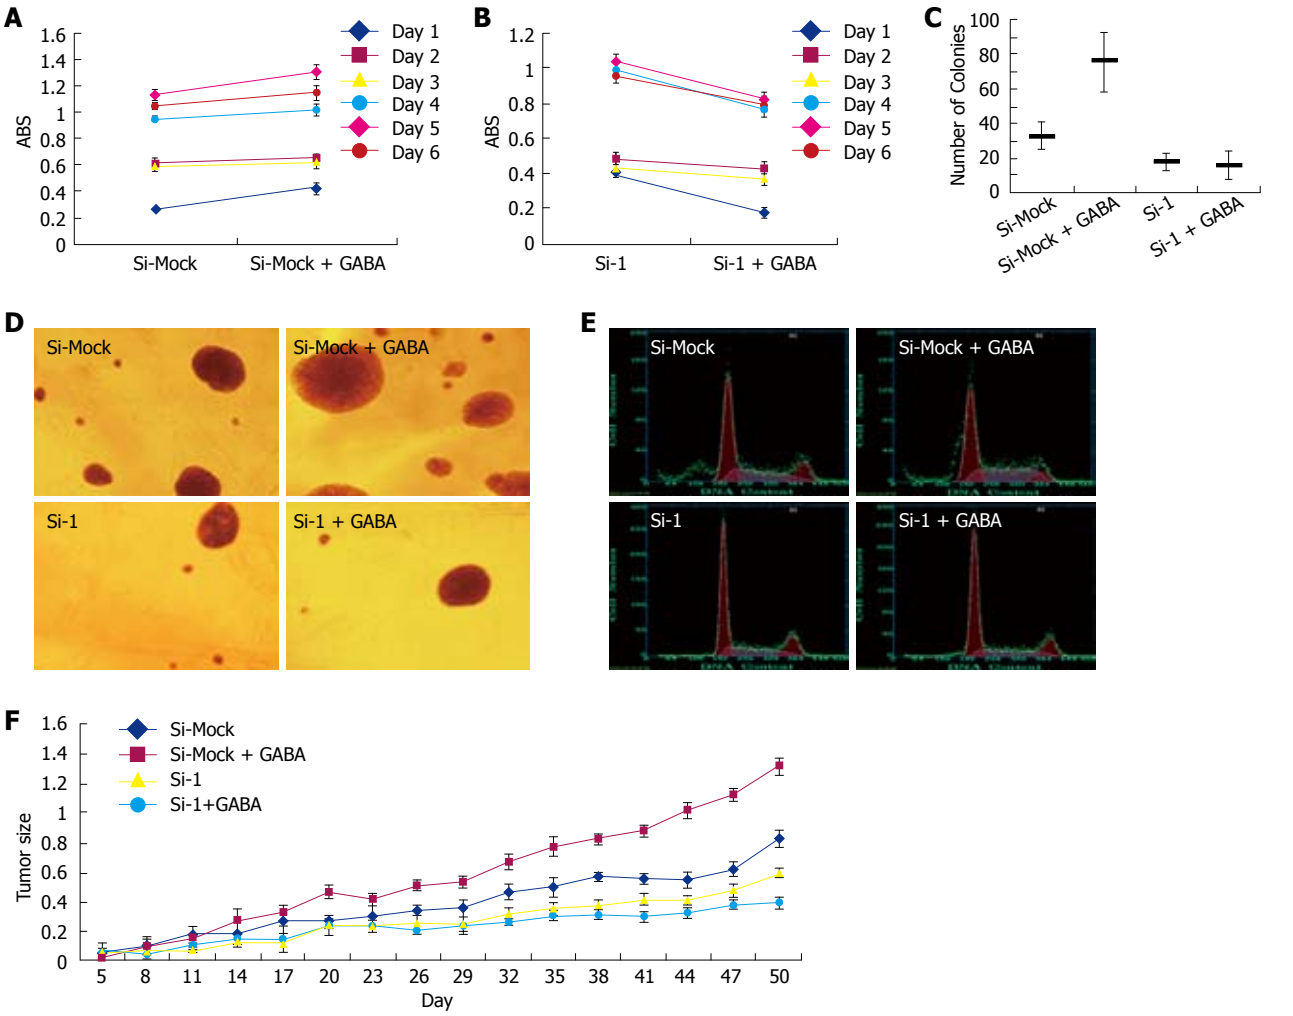

Figure 4 GABA stimulated HCC cell proliferation through GABRA3. HepG2/Si-1 and HepG2/Si-Mock cells were treated with or without GABA (20 μmol/L). hepatocytes.

Biju *et al* [10] reported that, in N-nitrosodiethylamine-induced neoplasia in the rat liver, GABAB receptors were increased and the GABAB receptor agonist baclofen increased EGF-mediated DNA synthesis in hepatocytes. Thus, GABA-associated pathways also could act positively in the regulation of cancer cell behavior. Our findings in this study also support the theory that GABA and GABRA3 promoted HepG2 cell proliferation *in vivo* and *in vitro*. Although GABA usually induces hyperpolarization in adult neurons, GABA has been shown to exert depolarizing responses in the immature CNS structures and CNS tumors[11,12]. And Minuk *et al*[13] reported that human HCC tissues were depolarized compared with adjacent non-tumor tissues. In particular, GABA increased the proliferation of immature cerebellar granule cells through the activation of GABAA receptors and voltage-dependent calcium channels[14]. Takehara *et al*[14] reported that GABA stimulated pancreatic cancer growth through GABRP by increased intracellular Ca^{2+} levels and activating the mitogenactivated protein kinase/extracellular signal-regulated kinase (MAPK/Erk) cascade[8]. From the results above, we deduce that GABA may promote the HepG2 cell proliferation through GABRA3 by voltage-dependent calcium channels. Interestingly, GABAA receptor antagonist bicuculline methiodide also could promote the proliferation of HepG2 cells (data not shown), indicating that it might activate some other signal transductions.

By comparing the proliferative activity of the GABRA3-knockdown HepG2 cells treated with GABA, we found that GABA stimulated HepG2 cell growth through GABRA3. The proliferating ability of the cells treated with GABA was not enhanced compared with the cells without GABA treatment. And interestingly, GABA inhibited the growth of the GABRA3-knockdown HepG2 cells. It indicates that GABA activates some other receptors to inhibit the proliferation without GABRA3, which is identical to some previous reports[15,16,17]. But GABA primarily activates GABRA3 if it exists.

Regarding the expression of other GABAA receptor subtypes/isoforms, the GABAA-δ expression detected

in the majority of HCC tissues has not been previously described, and the significance of this finding has yet to be elucidated. Although GABAA-α1 (1 case), α3 (1 case), β3, γ2 (2 cases), ε and π expression was also detectable, it is unlikely that expression of these isoforms results in the formation of functional GABA-gated receptors with GABRA3. The reason is that GABA could produce opposite effects on HepG2 cells with or without GABRA3 expression, which means that GABA could activate GABA receptors. Moreover, the detection of the subunits was not unexpected, because previous reports have documented that the spectrum of GABAA receptor isoform expression correlates with the state of cell differentiation[18,19].

In conclusion, relative to adjacent non-tumor tissues, HCC tissues have increased GABAA-α3 receptor expression. Knockdown of GABRA3 expression in receptor expressing malignant hepatocytes results in attenuated *in vivo* and *in vitro* tumor growth. Moreover, GABA promotes hepatocyte proliferation through GABRA3. These findings highlight the importance of elucidating the role of GABAergic activity in the pathogenesis of HCC. They also raise the potential for new therapeutic and diagnostic approaches to HCC in humans.

COMMENTS

Background

Gamma-aminobutyric acid A receptor α3 subunit (GABRA3) is a subunit of the gamma-aminobutyric acid A (GABAA) receptors that may associate with other GABAA receptor subunits to form a functional chloride channel that mediates the inhibitory synaptic transmission in the mature central nervous system (CNS). GABA functions as an inhibitory neurotransmitter for activating GABA receptors.

Research frontiers

Recently, abnormal levels of gene and protein expression of some GABA receptor subunits have been detected in many malignant tumors. This indicates that GABAergic system may play an important role in the pathogenesis and development of malignant tumors.

Innovations and breakthroughs

This study demonstrated the overexpression of GABRA3 in Hepatocellular carcinoma (HCC) tissues, which has not been previously described, and illustrated that GABA stimulated HCC cell proliferation through GABRA3.

Applications

The findings raise the potential for new therapeutic and diagnostic approaches to HCC in humans.

Terminology

GABA stands for gamma-aminobutyric acid, which is an inhibitory neurotransmitter. GABRA3 stands for gamma-aminobutyric acid A receptor α3 subunit.

Peer review

In this work, the authors have explored the expression pattern of GABAA receptors in hepatocellular carcinoma cells, identifying the overexpression of GABRA3 in HCC cells and tissues.They also demonstrate that GABA increases proliferation of GABRA3 positive cells, which is cancelled when GABRA-3 expression is knock-down. Results are new and show relevance to understand the molecular mechanisms that control hepatocarcinogenesis.

Abstract

AIM: To investigate if contrast-enhanced ultrasonography (CE-US) is useful for determining treatment efficacy and outcome in the early stages of pancreatic cancer chemotherapy by assessing changes in intratumor hemodynamics using CE-US with a contrast agent.

METHODS: The subjects were 34 patients with unresectable advanced pancreatic cancer treated by chemotherapy. CE-US was assessed after every treatment (course) completion under the same conditions, and patients were divided into two groups according to the intratumor enhancement pattern: Vascular rich (R) group and vascular poor (P) group.

RESULTS: After the second course of treatment, R group in intratumor hemodynamics had 18 patients, and P group had 16 patients. The reduction rates of serum CA19-9 level after chemotherapy which decreased to half or less of the baseline level were 2/15 (0.1%) in P group, but 11/16 (69%) in R group (P = 0.006). When the mean number of courses of chemotherapy and outcome were compared, P group had a mean number of courses of 4.9 (R group, 10.2) and mean survival time (MST) of 246 d (R group, 402 d), showing that outcome was significantly better in R group (P = 0.006).

CONCLUSION: CE-US revealed that the change in intratumor blood flow correlated with both serum CA19-9 level and outcome. Patients with serum CA19-9 that decreased to less than half the baseline level, and patients with an abundant intratumor blood flow, had a significantly better outcome. Thus, CE-US is potentially useful for evaluating treatment efficacy and outcome in the early stages of pancreatic cancer chemotherapy.

Usefulness of contrast-enhanced ultrasonography in determining treatment efficacy and outcome after pancreatic cancer chemotherapy. *World J Gastroenterol* 2008; 14(47): 7183-7191 Available from: URL: http://www.wjgnet.com/1007-9327/14/7183.asp DOI: http://dx.doi.org/10.3748/wjg.14.7183

INTRODUCTION

The yearly mortality due to pancreatic cancer exceeds 200 000[1] worldwide and is increasing. Even with recent advances in diagnostic image technology, most cases of pancreatic cancer are only discovered at an unresectable stage, when the prognosis is poor and the 5-year survival rate is no more than 1%[1]. To date, multimodality therapy consisting of chemotherapy with 5-fluorouracil (5-FU)[2-7] and radiotherapy[8-10] has been the standard treatment for unresectable pancreatic cancer. Since the results of this treatment have not been satisfactory, gemcitabine (GEM) (Eli Lilly Japan, Kobe, Japan) has recently become the standard chemotherapy medication

for unresectable pancreatic cancer, and GEM is expected to both increase antitumor efficacy[11-15] and improve clinical benefit response (CBR)[13].

The present study seeks to determine the antitumor effects of GEM in the early stages of treatment. To do so, we compared the enhancement patterns of pancreatic tumors visualized by contrast-enhanced ultrasonography (CE-US) using a microbubble contrast agent[16,17]. We investigated whether assessment of changes in intratumor hemodynamics by CE-US is useful for determining treatment efficacy and prognosis in the initial stages of chemotherapy for pancreatic cancer.

MATERIALS AND METHODS

Materials

The subjects were 34 patients (17 Stage Ⅲ and 17 Stage Ⅳ) with performance status 0-2 unresectable advanced pancreatic cancer that had visited this hospital and had undergone CE-US over the past 5 years. Staging of the disease was in accordance with The International Union Against Cancer (UICC) staging system (6th edition). The drugs and doses used were 1000 mg/m^2 for GEM and 10 mg/m^2 for cisplatin (CDDP). Seven patients showed adverse effects of GEM treatment, so the dose was reduced to 800 mg/m^2. One course of treatment consisted of the following: GEM alone given to 18 patients, GEM + CDDP given to 13 patients, and GEM + CDDP with radiotherapy (50-60 Gy) given to three patients once per week for three weeks followed by a one-week rest. In addition, a histological diagnosis by endoscopic ultrasonography-fine needle aspiration (EUS-FNA), which has been reported to be useful[18], was performed for all the subjects prior to the chemotherapy treatment. After the chemotherapy treatment of patients who had received four courses or more, re-biopsy was again performed for eight patients that gave informed consent to do so. All patients provided written informed consent before the study. Our Institutional Review Board reviewed and approved the entire study.

CE-US

The ultrasound equipment used was either a Sequoia 512 (Siemens-Acuson; Mountain View, CA, USA) or Aplio (Toshiba Medical Systems, Tokyo, Japan). Levovist R (2.5 g) (Shering; Tokyo, Japan) was prepared at a dose of 300 mg/mL, and a bolus of 7 mL was injected through the median cubital vein at a speed of 1 mL/s. After detailed observation of the lesion in B-mode, the vascular image was depicted for 60 s after injection of the contrast agent, at a speed of 5 frames/s (fps) with breath held, focusing on the blood flow dynamics in the lesion and surrounding pancreatic tissue. Thereafter, perfusion images were depicted for 180 s after injection with intermittent transmissions for periods of 2-10 s to observe the enhancement of the lesion. The color Doppler gain level was standardized as 50. We observed the blood vessels of the lesion in the vascular image, and the actual perfusion of the lesion through the capillaries in the perfusion image.

According to our previous report[16], both the vascular and perfusion images of the tumor blood flow signal were compared with the non-tumor regions of pancreas and classified depending on the signal intensities into the following three groups: hypervascularity (hyper), isovascularity (iso), and hypovascularity (hypo) (Figure 1).

Assessment of CE-US for chemotherapy

CE-US enhancement patterns after chemotherapy were classified into the following patterns according to our previous assessment prior to the present study. CE-US was assessed after every treatment (course) completion under the same conditions, and patients were divided into four types: an increased intratumor blood flow type (from hypo to iso, HI type); an abundant intratumor blood flow that remained the same before and after treatment type (from iso to iso; II type), a no increase in intratumor blood flow type (from hypo to hypo, HH type), and a decreased intratumor blood flow type (from hyper/iso to hypo, IH type). Furthermore, these four types were further divided into two groups; a vascular rich (R) group of the HI and II types with a high post-treatment intratumor blood flow, and vascular poor (P) group of the HH and IH types with a poor post-treatment intratumor blood flow. The assessment of intratumor blood flow luminance was performed at the same time as the analysis of luminance where the midline of the tumor, which was the region of interest (ROI), was compared over time with adjacent non-tumor regions using Adobe Photoshop (Adobe Systems; San Jose, CA). This was done to measure the amount of blood flow objectively. When the luminance score (LS) (luminance of tumor area divided by luminance of normal area) is 20% or less, there is the possibility of increased luminance due to artifacts. Therefore, a conclusion of increased blood flow was reached if the LS increased by 20% or more compared to the baseline value. The images for all the patients were recorded and luminance evaluated from the same images by three physicians (T.I., T.K., and F.M.) experienced in CE-US.

Endpoint

Treatment efficacy and outcome were evaluated from the viewpoint of serum CA19-9 level and CE-US enhancement pattern in the R and P groups. The definition of response to treatment was evaluated after the second course of chemotherapy.

Statistical analysis

Student's *t* test, Fisher's exact test, Wilcoxon's test, and the log-rank test were used for the statistical analysis. A P value < 0.05 was considered to indicate a statistically significant difference.

RESULTS

All the tumors were visualized in B-mode by CE-US, and mean tumor diameter was 39.4 mm (15-80 mm). When the CE-US enhancement patterns of the tumors before

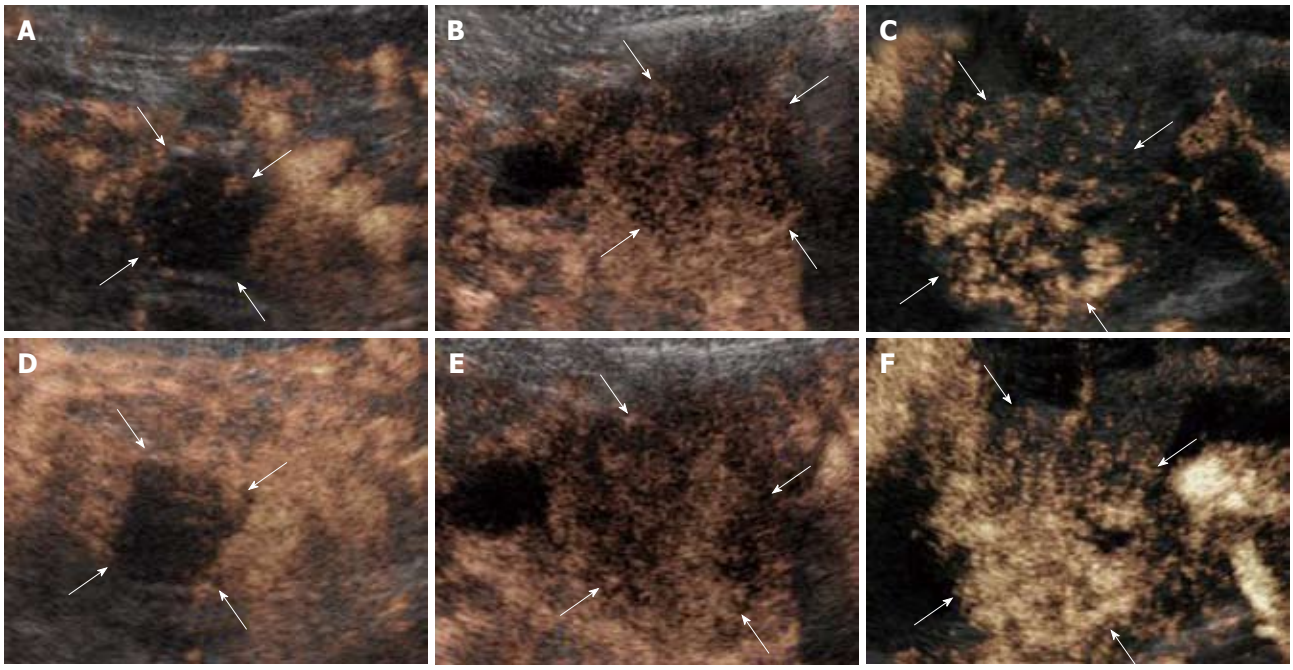

Figure 1 Enhancement pattern of CE-US in pancreatic cancer. A-C: Vascular image; D-F: Perfusion image; A, D: Hypovascularity; B, E: Isovascularity; C, F: Hypervascularity.

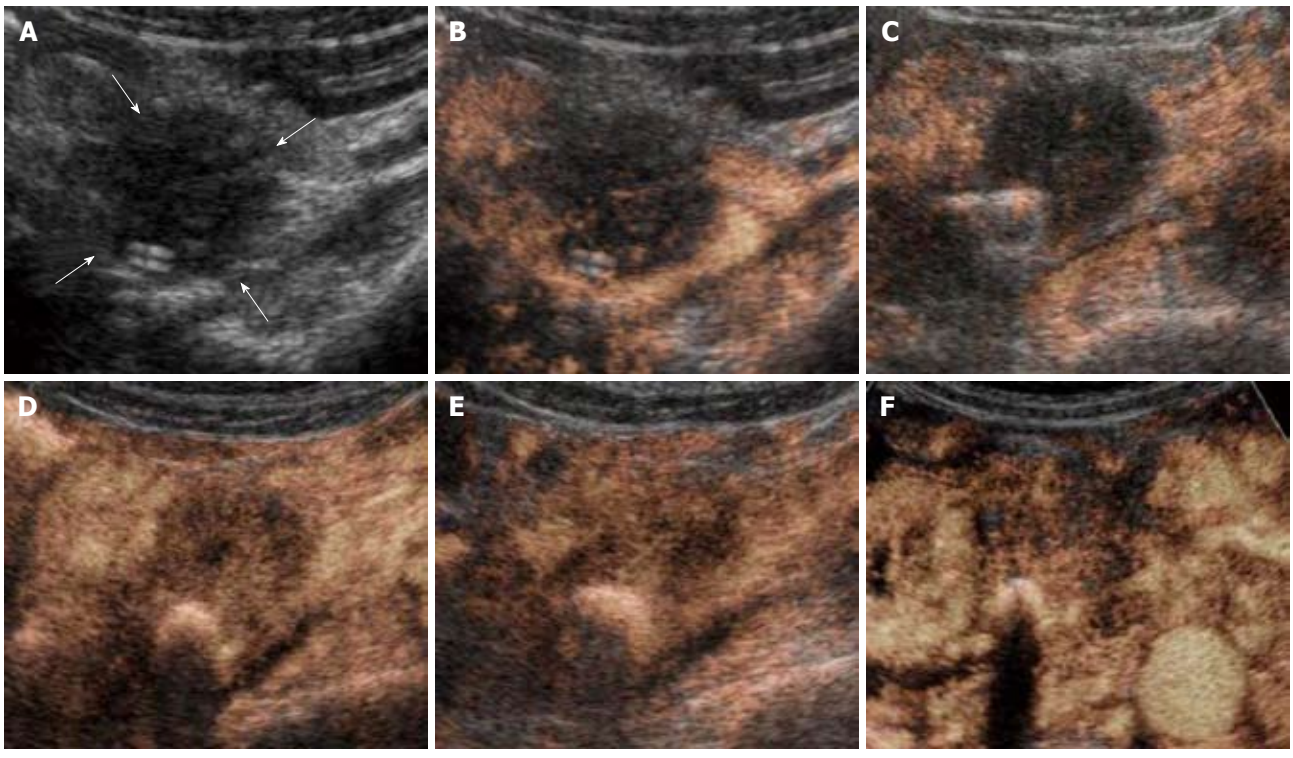

Figure 2 CE-US changes over time in the R (HI) group (luminance score). A: B-mode; B: Pre (0.30); C: Post 2 course (0.28); D: Post 4 course (0.78); E: Post 7 course (0.62); F: Post 16 course (0.46).

and after treatment were compared, intratumor blood flow before treatment was of the hypovascularity type in 28 (82%) patients and of the isovascularity type in 6 (18%) patients. After treatment, changes in intratumor hemodynamics after the second course were seen in 12 (35%) patients, all of whom had increased intratumor blood flow (HI type). There was no change in the hemodynamics in 22 (65%) patients (16 in the HH type and 6 in the II type). Blood flow did not decrease in any of the patients. Twelve patients in the HI type and 6 in the II type, making a total of 18 (53%) patients, were combined to form the R group. The CE-US changes over time in the R group are shown in Figures 2 and 4, and the CT changes in Figures 3 and 5. Similarly, for the P group (HH type), the CE-US and CT changes over time for 16 patients are shown in Figures 6 and 7. After

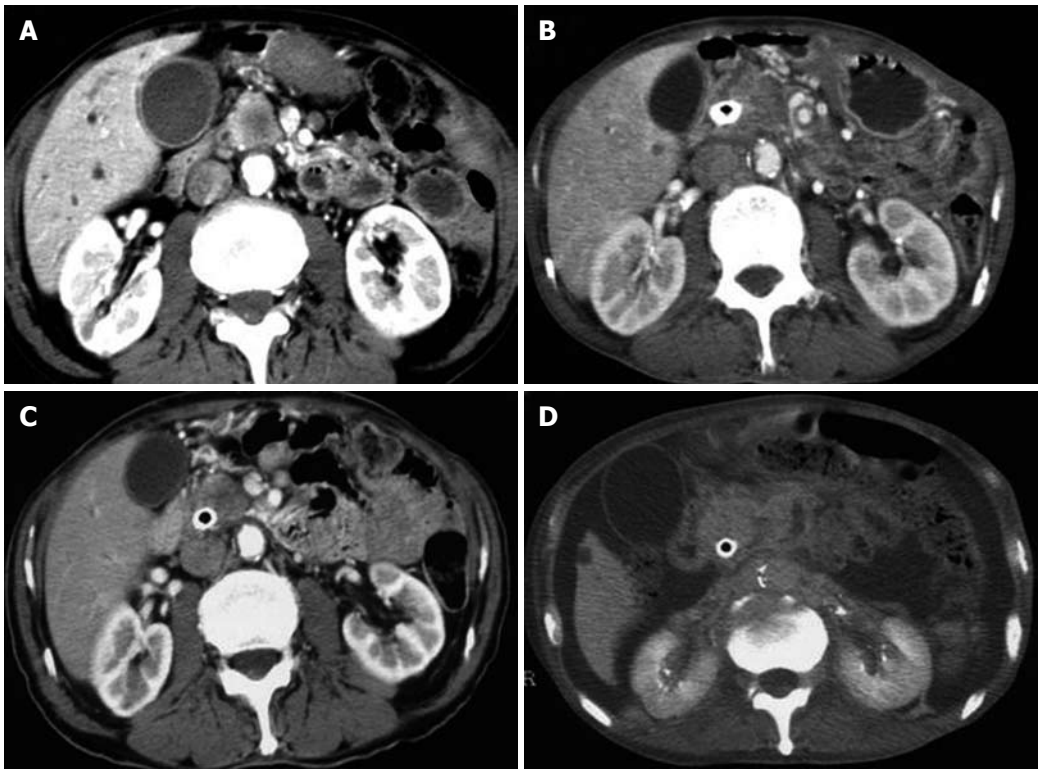

Figure 3 CT changes over time in the R (HH) group. A: Pre; B: Post 4 course; C: Post 7 course; D: Post 16 course.

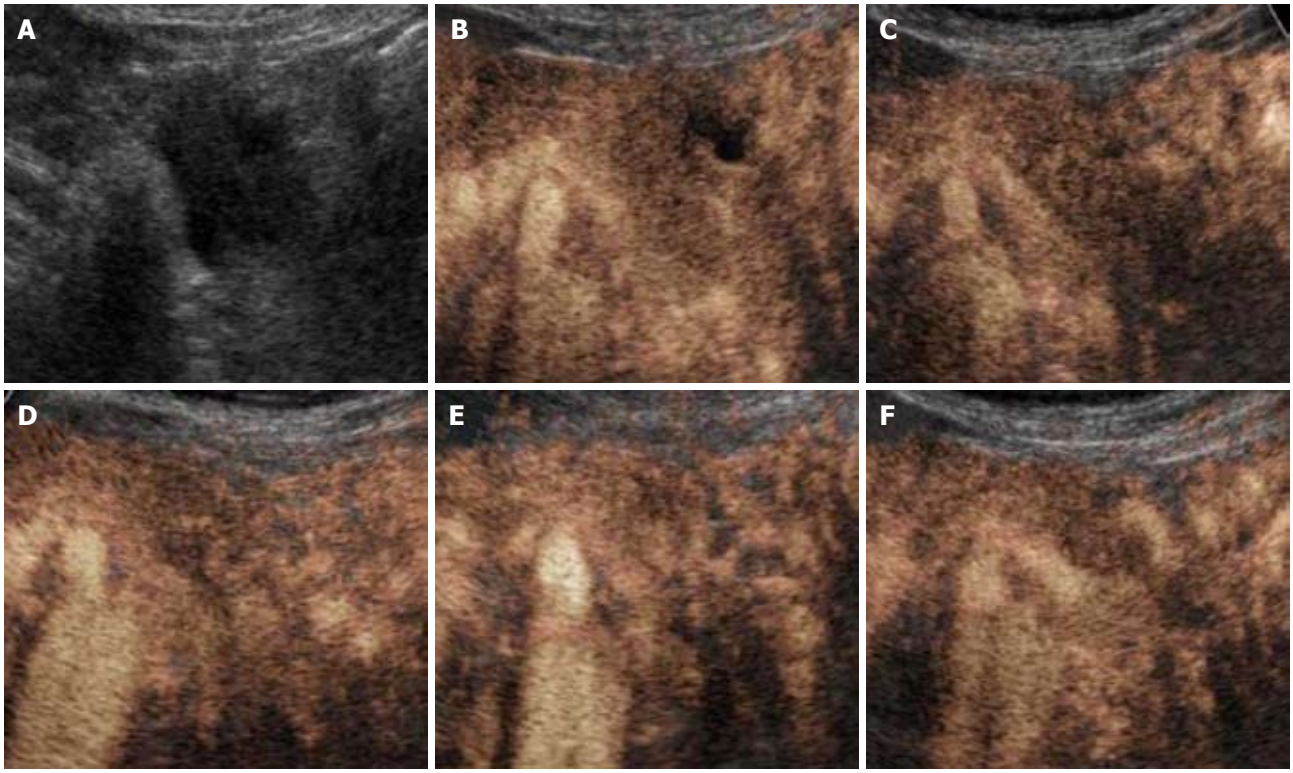

Figure 4 CE-US changes over time in the R (II) group (luminance score). A: B-mode; B: Pre (0.96); C: Post 2 course (0.99); D: Post 4 course (1.0); E: Post 7 course (0.93); F: Post 11 course (1.0).

treatment, there was increased imaging performance by both CE-US and CT in the HI type, in other words, the changes after treatment showed correlation in terms of images in 33% (4/12) patients. In addition, there was no significant difference in the tissue types.

There was no difference between the R and P groups in relation to performance status or chemotherapy regimen. When mean tumor diameter before and after treatment in the R and P groups were compared, the values before treatment were 37.2 mm *vs* 41.8 mm and after treatment were 31.9 mm *vs* 37.5 mm, with no significant difference between the groups ($P = 0.891$).

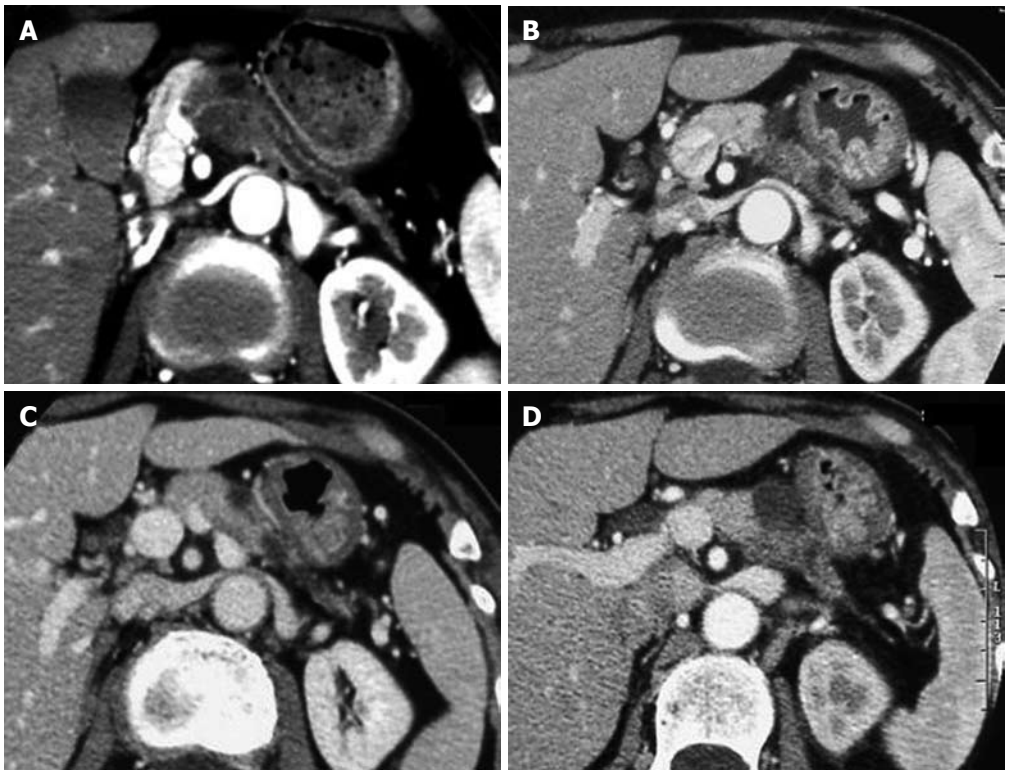

Figure 5 CT changes over time in the R (II) group. A: Pre; B: Post 2 course; C: Post 7 course; D: Post 11 course.

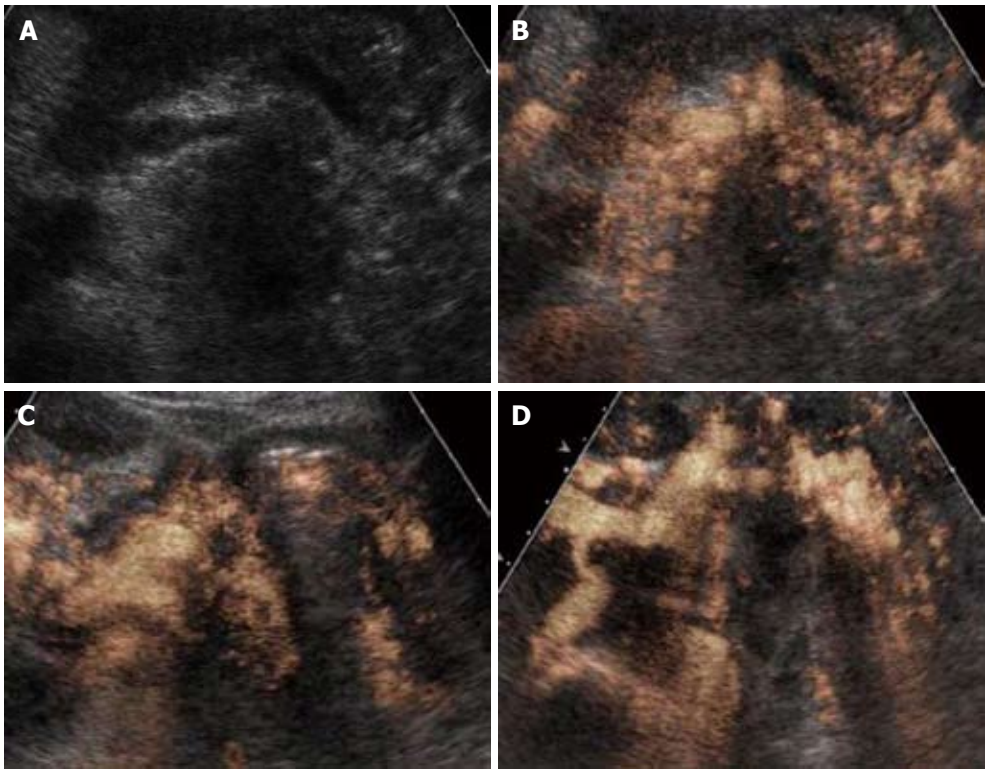

Figure 6 CE-US changes over time in the P (HH) group (luminance score). A: B-mode; B: Pre (0.29); C: Post 2 course (0.46); D: Post 3 course (0.29).

Tumor response based on Response Evaluation Criteria In Solid Tumors (RECIST) in the R group was rated as a complete response (CR) in one patient, partial response (PR) in 5 patients, stable disease (SD) in 10 patients and progressive disease (PD) in 2 patients. In the P group, results were PR in one patient, SD in 6 and PD in 9 patients. Although there was no significant difference between the groups, the response rate in the R group was high compared with P group (33% *vs* 6%, $P = 0.051$). These results are shown in Table 1. The grade of histological differentiation in the R group was well-moderately differentiated type in 12 patients, poorly differentiated medullary type in five patients and poorly differentiated scirrhous type in one patient. In the P group, it was well-moderately differentiated adenocarcinoma in 16 patients. There was no significant difference in grade of histological differentiation between the two groups ($P = 0.072$). In the 8 patients

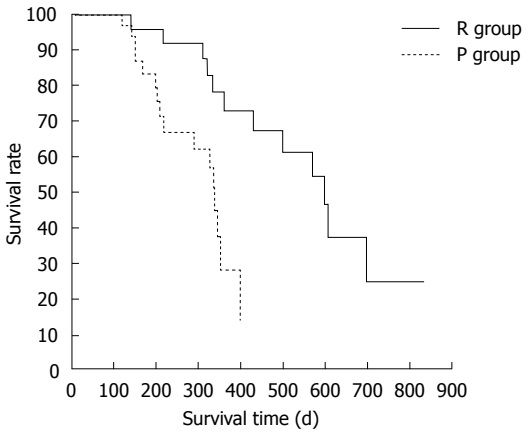

Figure 9 Kaplan-Meier survival curves by enhancement pattern of CE-US and outcome after chemotherapy.

(6 in group R and 2 in group P) that had post-treatment tissue biopsy, the histological findings revealed only necrotic tissue except in one R group case showing viable malignant tissue (Figure 8). The patients whose serum CA19-9 level decreased to half the baseline level or less were 2/15 (0.1%) in group P but 11/16 (69%) in group R, showing a significant decrease in group R [P = 0.006; 95% confidence interval (CI), 41-88]. When mean courses of chemotherapy and outcome were compared, group P had a mean course number of 4.9 (range, 1-12) and mean survival time (MST) of 246 d (range, 119-351 d), whereas group R had a mean course number of 10.2 (range, 1-27) and MST of 402 d (range, 109-831 d), showing that outcome tended to be significantly better in group R (P = 0.006, 95% CI, 48-265). These results are shown in Table 1. The correlation between CE-US imaging pattern and MST based on these results is presented as a Kaplan Meier survival curve (Figure 9).

DISCUSSION

In this investigation, we demonstrated that patients with abundant intratumor blood flow (the R group) had significantly better GEM treatment results than the P group with a poor intratumor blood flow (P group *vs* R group; mean number of treatment courses: 4.9 *vs* 10.2; MST: 246 d *vs* 402 d). Patients with increased intratumor blood flow were commonly seen after the second course of treatment. With regard to tumor response, the GEM

response rate in the R group was 33.3% while that in the P group was no more than 6.3%.

Halm[19] and Heinemann *et al*[20] reported good treatment efficacy in patients where serum CA19-9 level decreased by 20% or more of the baseline value. In the present study, serum CA19-9 level decreased to half the baseline value or less in 69% of patients in R group, where treatment efficacy was good. However, in P group, the decrease was only 0.1%. Serum CA19-9 is the sialylated Lewis blood group antigen that is expressed by the monoclonal antibody 1116 NS 19-9[21]. When this antigen is negative, an increase in serum CA19-9 level cannot be seen, making a clear interpretation difficult. These results suggest that changes in intratumor blood flow after treatment, as revealed by CE-US, are related to serum CA19-9 level and prognosis, and that prognosis is good in patients with serum CA19-9 levels that decrease to half the baseline level or less after treatment, and those with abundant intratumor blood flow.

GEM became commercially available in the late 1990s as a chemotherapy agent for unresectable pancreatic cancer, and is now positioned as a first-choice drug. We have used GEM as a primary chemotherapy agent but have sometimes experienced cases where the treatment has not been effective. Although the reason for that is not clear, recently there are reports that gemcitabine resistance has been associated with the ribonucleotide reductase subunit M2 (RRM2)[22]. If the status of treatment efficacy can be determined in the early stage of antitumor drug treatment, more effective chemotherapy can be selected. Physicians could then switch patients to other drugs, and select other treatment options such as concomitant therapy or combined treatment with radiotherapy. The burden that unnecessary anticancer drug treatments place on the body, as well as the time wasted, could thus be avoided.

Based on our previous investigations[16,17] of the CE-US imaging patterns of pancreatic tumor disease, it was assumed that the qualitative intratumor histological changes that were caused by treatment were reflected in the hemodynamics seen in CE-US. Therefore, CE-US could be applied to the evaluation of treatment efficacy after chemotherapy of pancreatic cancer.

The CE-US imaging patterns of pancreatic ductal cancer are basically classified into three types-hypo, iso, and hypervascular-with the most common pattern being hypovascularity[16]. Although the extent of the patterns in the tumors differed, a punctate or dendritical blood flow signal was seen in most patients. This indicates that the pancreatic tumor is an ischemic tumor, but demonstrates that much of the blood flow is at the capillary level. In the relationship between CE-US imaging pattern and histological differentiation, tissue type in the case of a hypovascularity pattern was moderately or poorly differentiated adenocarcinoma (scirrhous type). In the case of an isovascularity pattern, the tissue type was poorly differentiated adenocarcinoma (medullary type), whereas in the case of a hypervascularity pattern it was papillary adenocarcinoma[17]. These differences in imaging pattern are related to inflammatory changes, tumor development morphology and grade of histological differentiation, fibrosis and amount of interstitial connective tissue, vascular occlusion and degree of patency due to invasion of tumor vessels, and density.

Pancreatic cancers are generally anemic tumors and so respond poorly to anticancer treatment. It has become possible to visualize the microvascular flow in tumors by CE-US, and it is now evident that much of the intratumor blood flow is at the capillary level. With an abundant intratumor blood flow, more drugs will readily enter the tumor and thus increase treatment efficacy. The bubble diameter of the contrast agent is 2-3 μm, which is the same as the diameter of the capillaries that can be visualized. It is therefore preferable for the diameter of the particle system of anticancer drugs to be lower than that. According to the manufacturer (Eli Lilly Japan), the particle diameter of GEM is 0.2 μm or less. This is also important from the perspective of tissue transferability; GEM migrates up to the capillary level of tumors and so is assumed to show antitumor effect in tissues. The increase in intratumor blood flow in CE-US may be the reason for the intratumor histological changes and changes at the capillary level. The post-treatment results on EUS-FNA tissue showed that the tumor had changed into necrotic tissue and had decreased in volume. A reactive inflammatory change is triggered, causing disintegration of the tumor, which then becomes necrotic tissue. Furthermore, the volume of the tumor decreases and there is improvement in vascular occlusion and exclusion caused by tumor exclusion and vascular invasion. This is assumed to be the mechanism whereby intratumor blood flow improves. However, there was no significant difference between antitumor efficacy and grade of histological differentiation in this study, which suggests that antitumor efficacy not only correlates with the grade of histological differentiation, but also with other factors such as the amount of interstitial connective tissue and density.

In this study, the CT and CE-US imaging patterns before and after treatment were not always in concordance. The rate of concordance of the imaging patterns before treatment was 92% (31/34 patients), and after treatment it was 76% (26/34 patients). Moreover, in the R group, where treatment efficacy was good and CE-US revealed abundant blood flow, the CT imaging after treatment did not necessarily show change. In the HI type in particular, only 33% (4/12 patients) showed a correlation in imaging changes after treatment. The reasons for this include the fact that the contrast agents for CT and those for CE-US are different; the CT agents are predisposed to extravascular interstitial leakage, and there is a difference in the imaging time phase of the agents. There were some cases in which there was no change in tumor volume and enhancement pattern of CT after the treatment, but the outcome was comparatively good. The CE-US of such patients commonly revealed abundant intratumor blood flow, and also it showed that such patients were good outcome in our present study. Therefore, there was a difference of

assessment between CT and CE-US.

At present, although the UICC guidelines suggest that antitumor effects should be evaluated based on volume change as estimated by CT, such evaluation is sometimes questionable. The results of the present investigation demonstrated that, apart from volume change by CT, there is the possibility that the CE-US imaging pattern is also one important parameter in the evaluation of the post-treatment effect. It can at least be said that CT-based estimation of antitumor effect leaves much to be desired. Moreover, there will be a problem of radiation exposure related to CT in the future. However, the role of CE-US imaging in prognostic evaluation needs to be investigated further in a larger patient cohort.

In conclusion, CE-US revealed that the change in intratumor blood flow after GEM treatment was correlated with serum CA19-9 level and outcome. Patients with serum CA19-9 levels decreasing to less than half the baseline level, and patients with an abundant intratumor blood flow, tended to have a good outcome. Thus, CE-US is potentially useful for evaluating treatment efficacy and outcome in the early stages of pancreatic cancer chemotherapy.

COMMENTS

Background

The yearly mortality due to pancreatic cancer exceeds 200 000 worldwide and is increasing. Even with recent advances in diagnostic image technology, most cases of pancreatic cancer are only discovered at an unresectable stage, when the prognosis is poor and the 5-year survival rate is no more than 1%.

Research frontiers

To date, multimodality therapy consisting of chemotherapy with 5-fluorouracil (5-FU) and radiotherapy has been the standard treatment for unresectable pancreatic cancer. Since the results of this treatment have not been satisfactory, gemcitabine (GEM) has recently become the standard chemotherapy medication for unresectable pancreatic cancer, and GEM is expected to both increase antitumor efficacy and improve clinical benefit response (CBR).

Innovations and breakthroughs

The present study seeks to determine the antitumor effects of GEM in the early stages of treatment. We compared the enhancement patterns of pancreatic tumors visualized by contrast-enhanced ultrasonography (CE-US) using a microbubble contrast agent. We investigated whether CE-US is useful for determining treatment efficacy and outcome in the early stages of pancreatic cancer chemotherapy by assessing changes in intratumor hemodynamics using CE-US with a contrast agent.

Applications

CE-US revealed that the change in intratumor blood flow after GEM treatment was correlated with serum CA19-9 level and outcome. Patients with serum CA19-9 levels decreasing to less than half the baseline level, and patients with an abundant intratumor blood flow, tended to have a good outcome.

Peer review

It is an interesting paper. The study revealed that CE-US is potentially useful for evaluating treatment efficacy and outcome in the early stages of pancreatic cancer chemotherapy.

Abstract

AIM: To assess the role and mechanism of metformin in inducing apoptosis of pancreatic cancer cells.

METHODS: The human pancreatic cancer cell lines ASPC-1, BxPc-3, PANC-1 and SW1990 were exposed to metformin. The inhibition of cell proliferation and colony formation *via* apoptosis induction and S phase arrest in pancreatic cancer cell lines of metformin was tested.

RESULTS: In each pancreatic cancer cell line tested, metformin inhibited cell proliferation in a dose dependent manner in MTS (3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium assays). Flow cytometric analysis showed that metformin reduced the number of cells in G1 and increased the percentage of cells in S phase as well as the apoptotic fraction. Enzymelinked immunosorbent assay (ELISA) showed that metformin induced apoptosis in all pancreatic cancer cell lines. In Western blot studies, metformin induced poly-ADP-ribose polymerase (PARP) cleavage (an indicator of caspase activation) in all pancreatic cancer cell lines. The general caspase inhibitor (VAD-fmk) completely abolished metformin-induced PARP cleavage and apoptosis in ASPC-1 BxPc-3 and PANC-1, the caspase-8 specific inhibitor (IETD-fmk) and the caspase-9 specific inhibitor (LEHD-fmk) only partially abrogated metformin-induced apoptosis and PARP cleavage in BxPc-3 and PANC-1 cells. We also observed that metformin treatment dramatically reduced epidermal growth factor receptor (EGFR) and phosphorylated mitogen activated protein kinase (P-MAPK) in both a time- and dose-dependent manner in all cell lines tested.

CONCLUSION: Metformin significantly inhibits cell proliferation and apoptosis in all pancreatic cell lines. And the metformin-induced apoptosis is associated with PARP cleavage, activation of caspase-3, -8, and -9 in a time- and dose-dependent manner. Hence, both caspase-8 and -9-initiated apoptotic signaling pathways contribute to metformin-induced apoptosis in pancreatic cell lines.

INTRODUCTION

The incidence of pancreatic cancer has steadily increased year by year, however its prognosis is still dismal, despite of all efforts in early diagnosis and therapy. Even with a complete surgical resection, the 5-year survival rate is < 20%[1]. It is the fourth leading cause of cancer-related deaths in Western industrialized countries[2]. In 2006, it was estimated that more than 33 700 new cases of pancreatic cancer would be diagnosed in the United States, with virtually the same number of deaths (32 300) from this disease[3]. Conventional therapies associated with surgery and radiotherapy often in combination with chemotherapy show modest efficacy in local control and palliation and no real progress in patient survival[4-6]. Thus, novel approaches to human pancreatic carcinoma therapy are urgently needed.

Metformin (1,1-dimethylbiguanide hydrochloride) is the most widely prescribed anti-hyperglycemic agent in the world. It reduces blood glucose, is not associated with significant toxicity or hypoglycemia, increases insulin sensitivity and reduces serum insulin levels[7].

Population-based studies have shown that patients treated with metformin exhibit unexpected but beneficial reductions in both obesity and cancer of several subtypes[8]. We have studied the effects of metformin on pancreatic cancer and identified novel molecular mechanisms of metformin activity.

MATERIALS AND METHODS

Reagents

Metformin was purchased from Sigma Chemical Co., MO and dissolved in sterile water to make a 1M stock solution. Caspase-3 substrate, Ac-DEVD-pNA, caspase-8 substrate, Ac-IETD-pNA, and caspase-9 substrate, Ac-LEHD-pNA, were obtained from Alexis Biochemicals, San Diego, CA. Specific pan-caspase inhibitor, z-VAD-fmk, caspase-8 inhibitor, z-IETD-fmk, and caspase-9 inhibitor, z-LEHD-fmk, were obtained from BD Biosciences, San Jose, CA.

Antibodies for Western blot analysis were from following sources: caspase-8 mouse mAb (1C12), caspase-9 polyclonal antibody, and caspase-3 rabbit mAb (8G10), P-MAPK (Phospho-p44/42 MAP Kinase Thr202/Tyr204), Akt, and P-Akt (Phospho-Akt, Ser-473) (Cell Signaling Technology, Inc., Beverly, MA); MAPK (ERK2) (Santa Cruz, CA, USA); Poly (ADP-ribose) polymerase (PARP) mAb (C-2-10) (BIOMOL Research Laboratories Inc., Plymouth Meeting, PA); EGFR mouse mAb (clone F4), β-actin mouse mAb (clone AC-75) (Sigma Chemical Co.). All other reagents were purchased from Sigma Chemical Co. unless otherwise specified.

Cells and cell culture

The human pancreatic cancer cell lines SW1990 ASPC-1 BxPc-3 PANC-1 were obtained from the American Type Culture Collection (ATCC, Rockville, MD) and maintained in RPMI 1640 (Life Technologies). All cell lines were cultured at a 37℃ humidified atmosphere containing 95% air and 5% CO_2 and were split twice a week.

Cell proliferation assay

The CellTiter96™ AQ non-radioactive cell proliferation kit (Promega Corp., Madison, WI) was used to determine the cell viability. In brief, cells were plated onto 96-well plates with complete medium for 24 h incubation in a 37℃ humidified atmosphere containing 95% air and 5% CO_2. Cells were then grown in either 0.1 mL medium with 5% FBS as control, or 0.1 mL of the same medium containing a series of doses of metformin and incubated for another 72 h. After reading all wells at 490 nm with a micro-plate reader, the percentages of surviving cells from each group relative to controls, defined as 100% survival, were determined by reduction of MTS (3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium, inner salt).

Clonogenic assay

In brief, cells were seeded into 6-well plates in triplicates at a density of 100-500 cells/well in 2 mL of medium containing 10% fetal bovine serum (FBS). After 24 h incubation, cells were then cultured with medium with 5% FBS as control, or the same medium containing a series of doses of metformin for 14 d in a 37℃ humidified atmosphere containing 95% air and 5% CO_2. The cell clones were stained for 15 min with a solution containing 0.5% crystal violet and 25% methanol, followed by three rinses with tap water to remove excess dye. The colony numbers were counted with gel documentation system EAGLE EYETM Ⅱ (Stratagene, La Jolla, CA).

Flow cytometric analysis

Flow cytometric analyses were performed to define the cell cycle distribution for metformin treated and untreated cells. In brief, cells grown in 100-mm culture dishes were harvested by trypsinization and fixed with 70% ethanol. Cells were stained for total DNA content with a solution containing 50 μg/mL propidium iodide and 100 μg/mL RNase I in phosphate buffered saline (PBS) for 30 min at 37℃. Cell cycle distribution was then analyzed at the Flow Cytometry Core Facility of UCDHSC with a FACScan flow cytometer (Becton Dickinson, San Jose, CA, USA).

Caspase enzymatic activity assay

Caspase enzymatic activities were measured using a modified colorimetric assay kit from Clontech Laboratories, Inc. (Palo Alto, CA). The assay was based on spectrophotometric detection of the chromophore p-nitroanilide (pNA), which is cleaved from caspase-specific substrates by activated caspases (DEVD-pNA by activated caspase-3, IETD-pNA by activated caspase-8, and LEHD-pNA by activated caspase-9).

Quantification of apoptosis

An apoptosis ELISA kit (Roche Diagnostics Corp.) was used to quantitatively measure cytoplasmic histone-associated DNA fragments (mononucleosomes and oligonucleosomes). This photometric enzyme immunoassay was performed according to the manufacturer's instructions.

Western blotting analysis

Protein expression levels were determined by Western blot analysis. Briefly, cells were lysed in a buffer containing 50 mmol/L Tris, pH 7.4, 50 mmol/L NaCl, 0.5% NP-40, 50 mmol/L NaF, 1 mmol/L Na_3VO_4, 1 mmol/L phenylmethylsulfonyl fluoride, 25 g/mL leupeptin, and 25 g/mL aprotinin. The lysates were centrifuged at full speed in a microcentrifuge for 20 min and the supernatants were collected for protein concentration determination by the Coomassie Plus protein assay reagent (Pierce Chemical Co., Rockford, IL). Equal amounts of cell lysates were boiled in Laemmli SDS-sample buffer, resolved by SDS-PAGE, and Western blot analysis with specific antibodies as described in the Figure legends.

RESULTS

Metformin inhibits cell proliferation/survival in pancreatic cancer cells

In each pancreatic cancer cell line tested, metformin

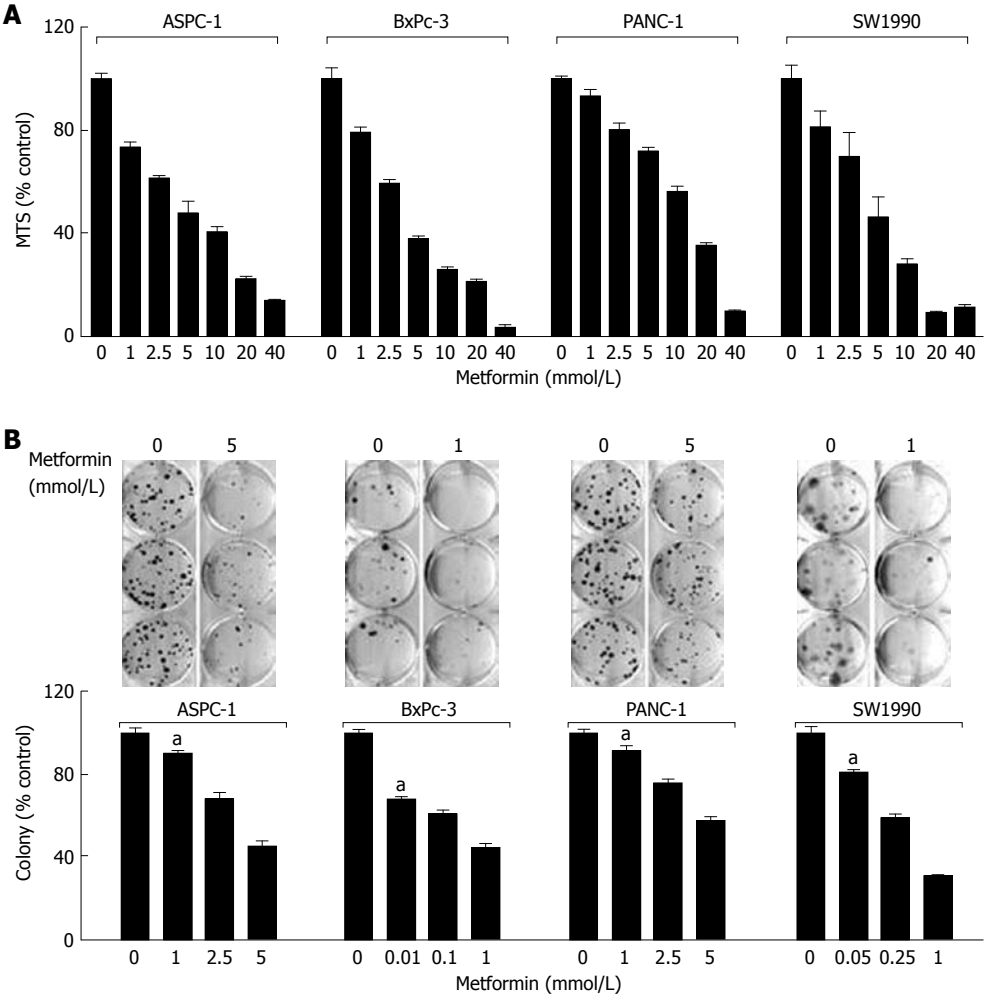

Figure 1 Metformin inhibits proliferation/survival in the basal-like subtype of pancreatic cancer cells. A: ASPC-1, BxPc-3, PANC-1 and SW1990 were plated onto 96-well plates with either complete medium or medium containing a series doses of metformin; B: ASPC-1, BxPc-3, PANC-1 and SW1990 were grown in triplicates in the absence or presence of metformin at different concentrations for 2-3 wk.

inhibited cell proliferation in a dose-dependent manner in MTS assays (Figure 1A). The MTS IC50 values for metformin activity were less than 5 mmol/L (in three of the four lines ASPC 1, BxPc 3, and PANC 1); while for SW1990 cells it was 10 mmol/L. To study the long- term effects of metformin on pancreatic cancer cells, we used clonogenicity assays. Metformin resulted in significantly fewer colonies at concentrations well below what was inhibitory using the 72 h MTS assay described above. The lowest inhibitory concentrations for the 4 cell lines ASPC 1, BxPc 3, and PANC 1, and SW1990 were 1 mmol/L, 0.01 mmol/L, 1 mmol/L, and 0.05 mmol/L, respectively (Figure 1B).

Metformin blocks cell cycle progression and induces apoptosis in pancreatic cancer cells

To study the effects of metformin on cell cycle distribution and progression, we used flow cytometric methods on metformin treated and untreated cells. Metformin reduced the number of cells in G1 and increased the percentage of cells in S phase as well as the apoptotic fraction (Figure 2). The percentages of apoptotic cells in all four pancreatic cancer cell lines were increased significantly in metformin-treated as compared with untreated cells (Figure 2). These data suggest that the effects of metformin on pancreatic cancer cells were distinct and, therefore, should occur through different molecular mechanisms.

Metformin selectively induces apoptosis via caspases activation in pancreatic cancer cells

ELISA specific assays for apoptosis were used to quantitatively evaluate metformin associated apoptosis in pancreatic cancer cell lines. Metformin induced apoptosis in all pancreatic cancer cell lines (Figure 3A). In Western blot studies, metformin also induced PARP cleavage (an indicator of caspase activation) pancreatic cancer cell lines (Figure 3A). Consistent with these data, protein levels of the pro-caspases-8, -9, and -3 were each reduced by metformin in the pancreatic cell lines (Figure 3A). Using these three assays (Western blot analyses of PARP cleavage, an apoptosis specific ELISA and caspase activity assays) the effects of metformin over a range of treatment intervals and drug concentrations were evaluated.

Activation of both caspase-8 and caspase-9 contributes to metformin-induced apoptosis

There are two well characterized caspase cascades in

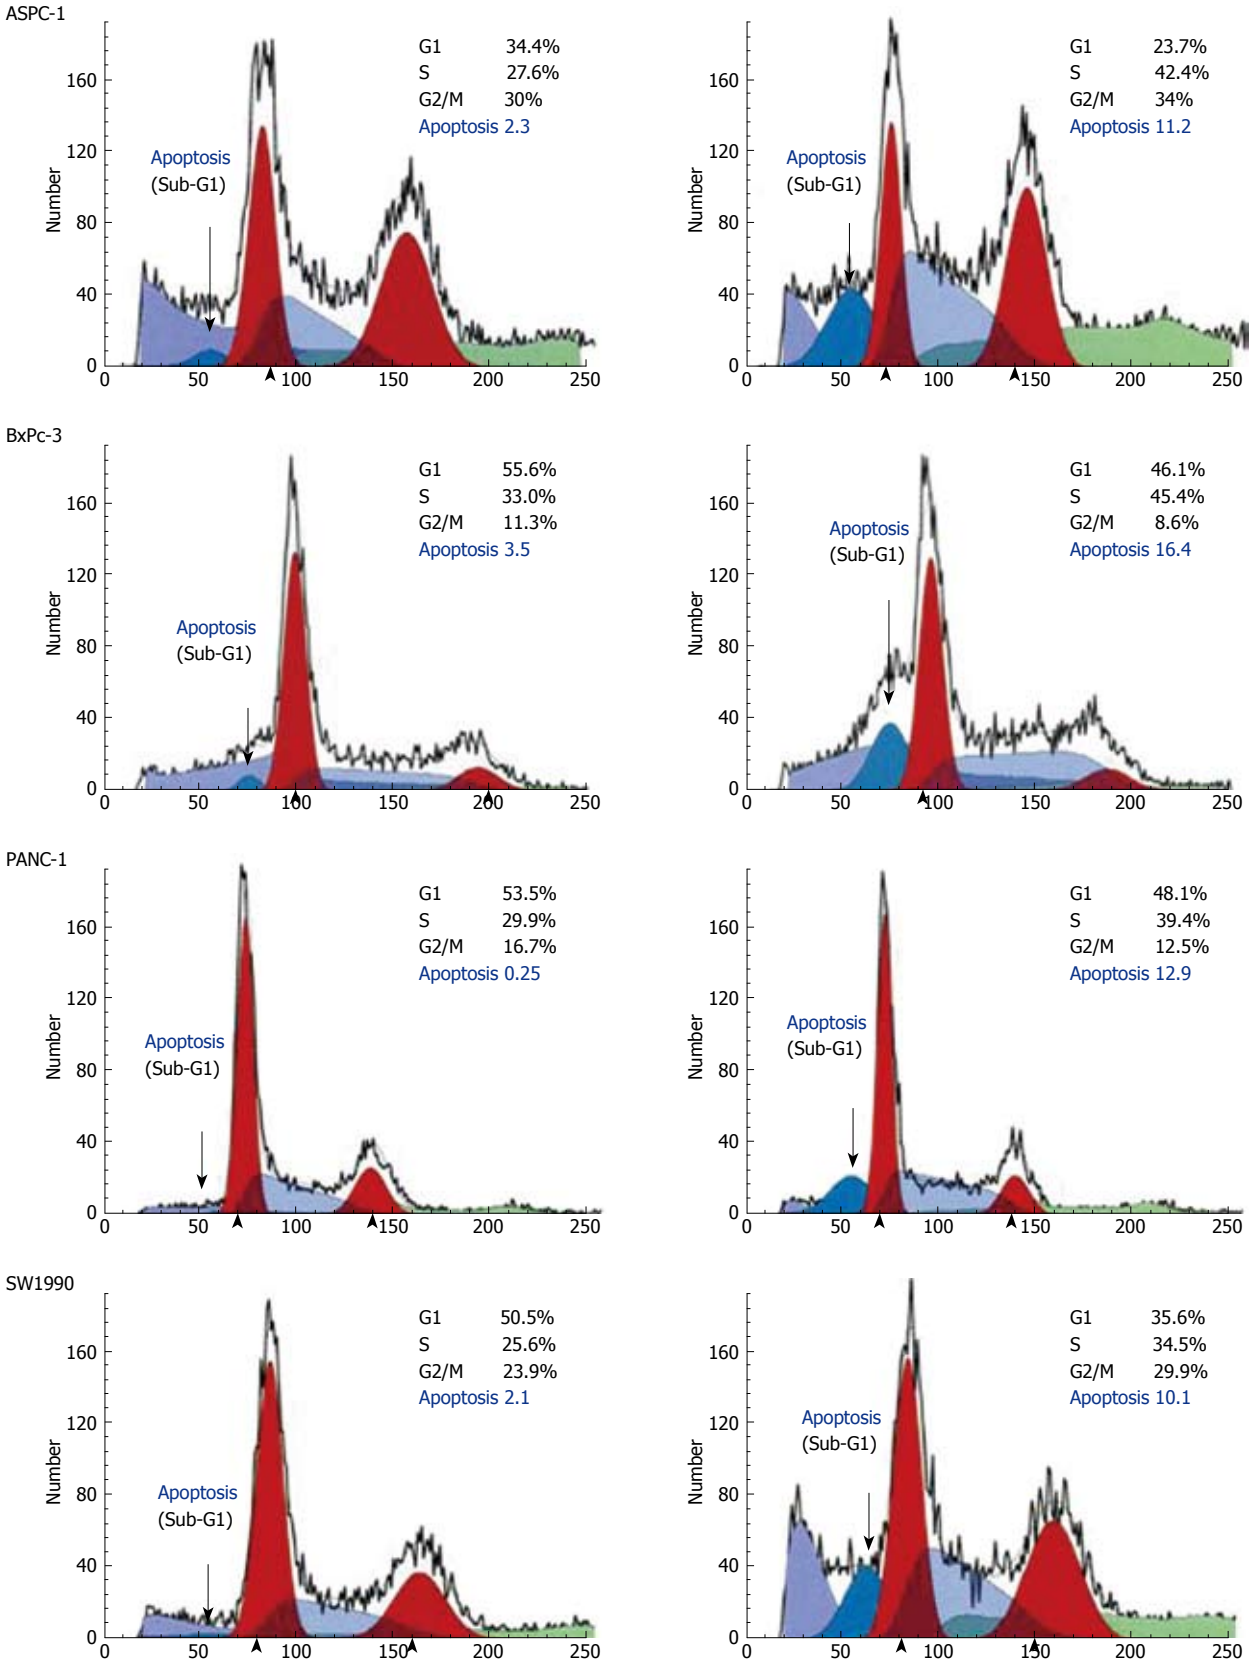

Figure 2 Metformin induces apoptosis and blocks cell cycle progression in the pancreatic cancer cells.

apoptosis: one initiated by cell surface death receptors (the so-called extrinsic pathway *via* caspase-8) and the other triggered by changes in mitochondrial integrity (caspase-9 activation, known as the intrinsic pathway)[9-11]. To further define the effects of metformin, we used specific caspase inhibitors to determine which might block metformin-induced apoptosis. The general caspase inhibitor, VAD-fmk completely abolished metformin-induced PARP cleavage and apoptosis in three cell lines (Figure 4). The caspase-8 specific inhibitor (IETD-fmk) and the caspase-9

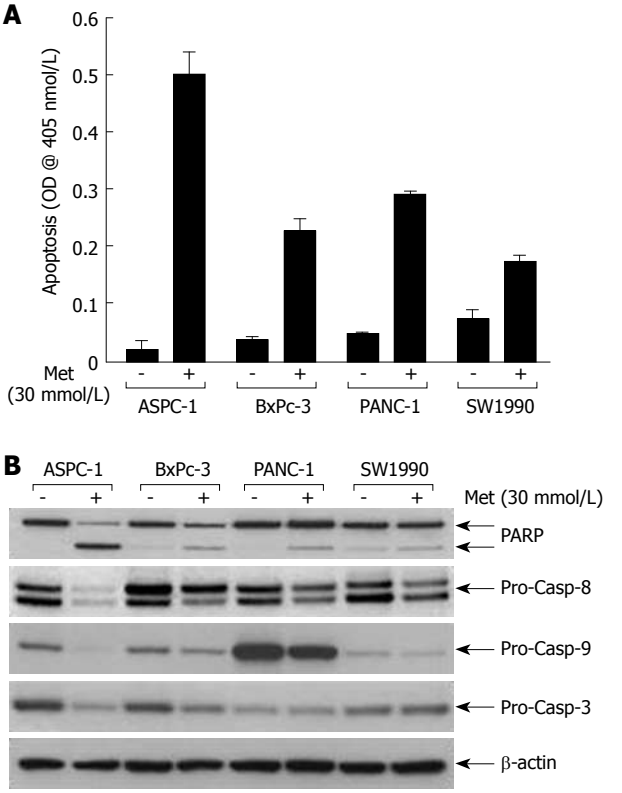

Figure 3 Metformin increases PARP cleavage, reduces levels of pro-caspase-8, -9, -3, and induces apoptosis in pancreatic cancer cells.

specific inhibitor (LEHD-fmk) only partially abrogated metformin-induced apoptosis and PARP cleavage in BxPc-3 and PANC-1 cells (Figure 4B and C), although IETD-fmk had a much greater effect than LEHD-fmk in ASPC-1 cells (Figure 4A).

Metformin reduces epidermal growth factor receptor (EGFR) and inhibits Akt and MAPK signaling

Pancreatic carcinomas were well known for EGFR overexpression, and they appear to utilize EGFR as an important pro-carcinogenic, pro-growth receptor. Using Western blot analyses, we observed that metformin treatment dramatically reduced EGFR and P-MAPK, in both a time- and dose-dependent manner in three cell lines tested (Figure 5). Of interest, short-term (8 h) treatment with metformin transiently raised P-MAPK levels. Early induction of MAPK signaling may reflect metformin's interaction with the insulin receptor[12]. P-Akt levels were also significantly lowered by metformin treatment in one cell line (ASPC-1; Figure 5A), although there were only minor changes of P-Akt in BxPc-3 cells (Figure 5B). P-Akt was undetectable and unchanged by metformin in PANC-1 cells (Figure 5C). This data suggests that apoptosis induced by metformin may be mechanistically driven by a reduced EGFR, with subsequent inactivation of downstream signaling involving MAPK and to a lesser extent Akt.

DISCUSSION

The development, continued growth and metastasis

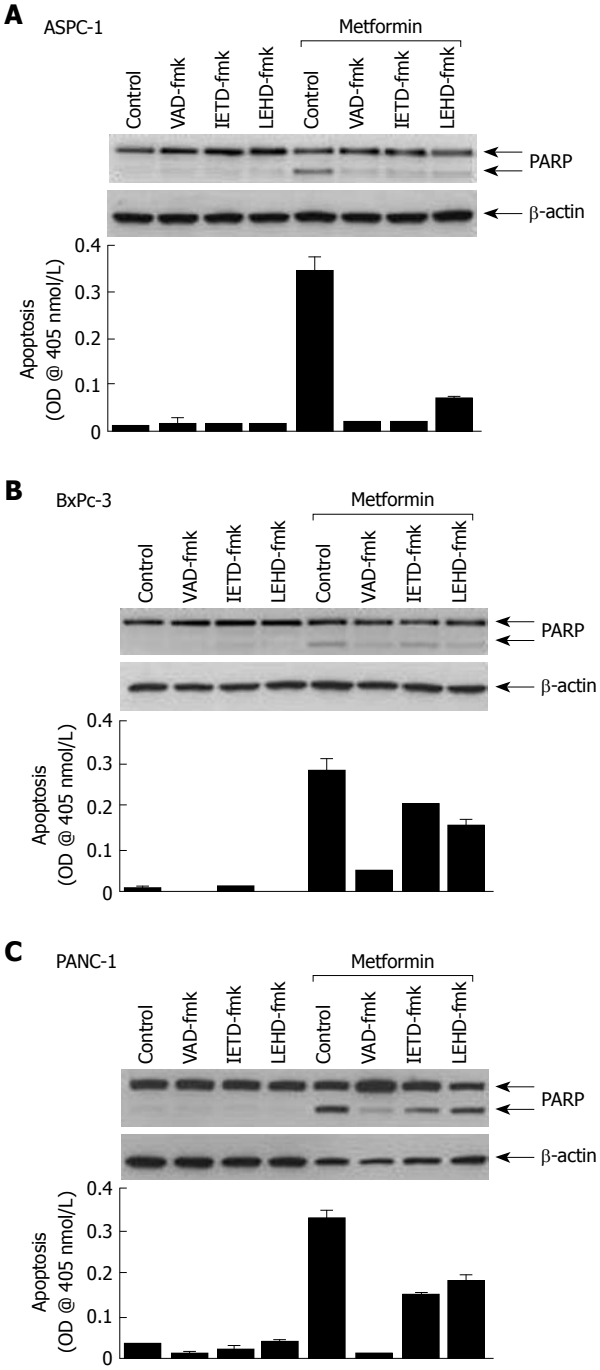

Figure 4 Activation of both caspase-8 and caspase-9 contributes to metformin-induced apoptosis in pancreatic cancer cells. A: ASPC-1; B: BxPc-3; C: PANC-1.

of pancreatic cancer are driven by multiple genetic and epigenetic changes, including inactivation of tumor suppressor genes and activation of proto-oncogenes[13]. Since the last decade, molecular biology and technology have contributed significantly to the development of therapeutic agents in medicine, and especially in oncology. The major areas include inhibition of tumor growth, inhibition of metastatic invasion, and inhibition of intercellular signal transduction and compensation of gene expression[14]. But it still needs a long time to treat pancreatic cancer patients. Up to now, only two combinations, Gem plus erlotinib and Gem plus

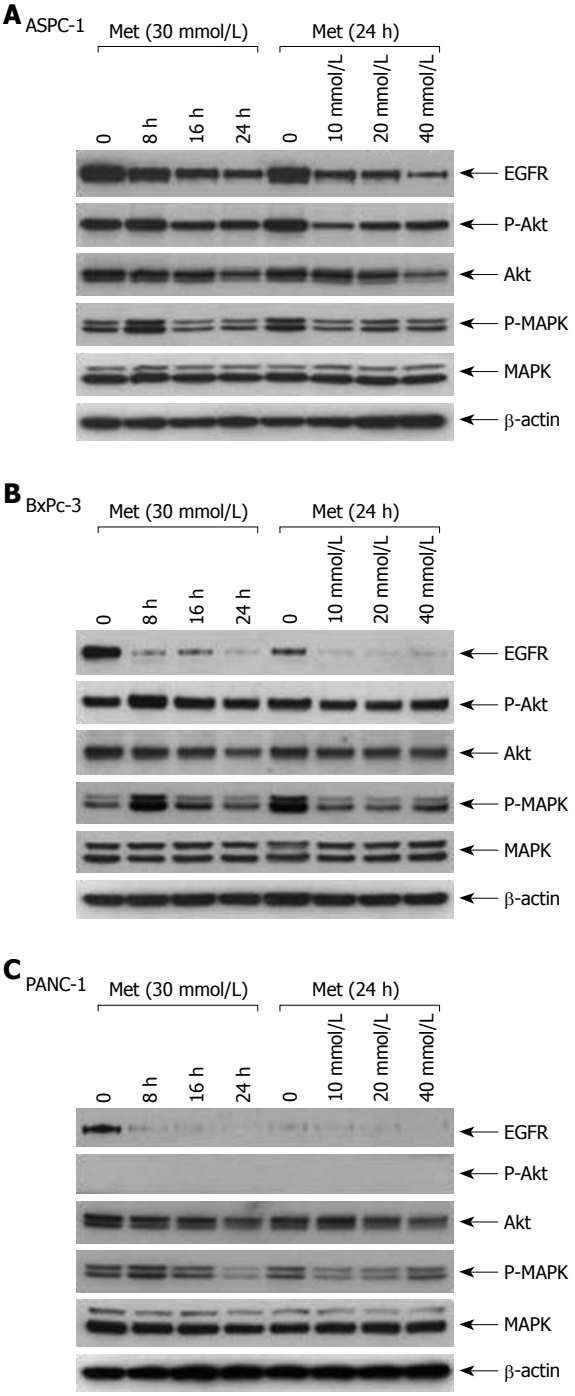

Figure 5 Metformin lowers EGFR expression levels and inhibits downstream signaling in pancreatic cancer cells. A: ASPC-1; B: BxPc-3; C: PANC-1.

capecitabine have achieved a slightly longer survival of the patients[15].

Metformin has a long track record of human use, with limited toxicity and it is relatively inexpensive. It might, therefore, be of great clinical benefit for pancreatic cancer treatment. According to our data, concomitant metformin therapy can enhance the response of patients to DNA damaging agents (chemotherapy and radiation therapy) because of their extended arrest in the S phase. Metformin should also enhance RTK inhibitor and anti-EGFR treatment response, because of its action on EGFR and P-MAPK effects. Finally, metformin might enhance treatment with apoptosis-inducing agents that inhibit PARP, for it induces PARP cleavage. Its usage in pancreatic cancer patients may also have additional benefits, including weight control, stabilization of pre-diabetic syndromes, regulation of glucose/insulin and adipogenesis pathways.

Two recent studies have indicated that EGFR was detected in more than 95% of patients with pancreatic cancer[16,17]. Also, co-expression of EGFR and its ligands is a common occurrence in pancreatic cancer and has been shown to function as an autocrine[13]. Real advancement towards individualized pancreatic cancer treatment will require understanding the molecular mechanisms underlying pancreatic cancer biology[18,19]. Early studies of basal carcinomas focused on EGFR as a molecular target, although EGFR inhibitors have not shown great efficacy in clinical trials[11,20]. The data we present here indicates that metformin may serve as a valuable treatment option for pancreatic cancer patients.

Metformin is widely used as a first-line treatment for pre-diabetic syndromes and type Ⅱ diabetes[21]. Of interest, some studies have shown that women treated with metformin have a lower overall incidence of cancer, including pancreatic cancer[8]. Metformin may therefore be useful as a preventative agent in selected patients to reduce, either directly through cell growth inhibition or indirectly through obesity and diabetes control. Further studies of metformin may provide more insights into its efficacy.

In summary, we have demonstrated that the anti-diabetic drug, metformin, selectively induces apoptosis through activation of the caspase cascade, abrogation of EGFR and downstream signaling in the basal subtype of pancreatic cancer cells. Metformin may be a low toxicity, novel therapeutic strategy for the difficult-to-treat pancreatic cancer patients.

COMMENTS

Background

Pancreatic carcinoma is one of the tumors with a high incidence rate. It is less sensitive to standard adjuvant chemotherapy. Metformin (1,1-dimethylbiguanide hydrochloride) is the most widely prescribed anti-hyperglycemic agent in the world. Population-based studies have shown that patients treated with metformin exhibit unexpected but beneficial reductions in both obesity and cancer. But no study about the therapeutic effect of metformin in pancreatic caner has been reported.

Research frontiers

There are many studies about the treatment of pancreatic cancer. Target therapy is the most popular part of pancreatic cancer research as well as the use of traditional medicine. Metformin is one of the traditional drugs which are thought to have anti-cancer effects.

Innovations and breakthroughs

This study showed that metformin significantly inhibited cell proliferation and induced apoptosis in all pancreatic cell lines, and the metformin-induced

apoptosis was associated with poly-ADP-ribose polymerase leavage, activation of caspase-3, -8, and -9 in a time- and dose-dependent manner.

Applications

Metformin is a common drug which has been used for many years. This study has suggested that it had a potential therapeutic effect for pancreatic cancer. Although further *in vivo* studies are needed, metformin may be a low toxicity, novel therapeutic drug for the difficult-to-treat pancreatic cancer patients.

Peer review

This is a very interesting study. Metformin, the commonly used anti-diabetic drug has been proven to have anti-cancer effect in pancreatic carcinoma in *in vitro* studies with pancreatic cancer cell line. The study was strictly done with standard molecular techniques. The result is of clinical implication in the treatment of pancreatic cancer.

Abstract

AIM: To rapidly detect molecular alterations in different malignancies and investigate the possible role of *Tp53*, C-*myc*, and *CCND1* genes in development of tumors in human organs and their adjacent normal tissues, as well as the possible relation between well- and poorly-differentiated tumors.

METHODS: A tissue array consisting of seven different tumors was generated. The tissue array included 120 points of esophagus, 120 points of stomach, 80 points of rectum, 60 points of thyroid gland, 100 points of mammary gland, 80 points of liver, and 80 points of colon. Expressions of *Tp53*, *C-myc*, and *CCND1* were determined by RNA *in situ* hybridization. 3′ terminal digoxin-labeled anti-sense single stranded oligonucleotide and locked nucleic acid modifying probe were used.

RESULTS: The expression level of *Tp53* gene was higher in six different carcinoma tissue samples than in paracancerous tissue samples with the exception in colon carcinoma tissue samples ($P < 0.05$). The expression level of *CCND1* gene was significantly different in different carcinoma tissue samples with the exception in esophagus and colon carcinoma tissue samples. The expression level of *C-myc* gene was different in esophagus carcinoma tissue samples ($\chi^2 = 18.495$, $P = 0.000$), stomach carcinoma tissue samples ($\chi^2 = 23.750$, $P = 0.000$), and thyroid gland tissue samples ($\chi^2 = 10.999$, $P = 0.004$). The intensity of signals was also different in different carcinoma tissue samples and paracancerous tissue samples.

CONCLUSION: Over-expression of the *Tp53*, *CCND1*, and *C-myc* genes appears to play a role in development of human cancer by regulating the expression of mRNA. *Tp53*, *CCND1* and *C-myc* genes are significantly correlated with the development of different carcinomas.

INTRODUCTION

Over-expression or amplification of a particular oncogene was first described in a tumor. Subsequently, other tumors were evaluated, mostly in the order of their perceived importance with rare tumors neglected. Therefore, it may take several years from the discovery of a potentially important molecular alteration to the definition of different primary tumors where this specific alteration may play a role in the development of such tumors. Tissue microarray has the potential to greatly facilitate analysis of alterations in different

tumors. *Tp53* is a specific protein produced by the most commonly mutated gene in human cancer that suppresses the growth of tumors[1]. Like other tumor-suppressor genes, *Tp53* normally controls cell growth. If *Tp53* is physically lost or not in effect (because of its inactivation), it may permit cells to divide without restraint[2]. The level of *Tp53* has a prognostic (predictive) value for tumors. For example, breast cancer patients with a high level of *Tp53* after mastectomy are at a higher risk for cancer recurrence than those with a low level of *Tp53*[3]. The buildup of *Tp53* within cancer cells is a sign that *Tp53* is not working properly to suppress the growth of tumors[4]. *CCND1* forms a holoenzyme with a cyclin-dependent kinase (CDK), either CDK4 or CDK6 that phosphorylates the retinoblastoma gene product of pRb. Since the phosphorylation of pRb results in the release of E2F transcription factors, freeing them to stimulate transcription of growth-promoting target genes, over-expression of *CCND1* promotes tumor progression through the G1 phase of cell cycle in cells grown on a substratum[5,6]. Over-expression of *CCND1* has been reported in a variety of human tumors including cancers of the lung, head, neck, and bladder[7]. It was reported the over-expression rate of *CCND1* is 30%-73% in patients with breast carcinoma[8,9]. Whether the expression of *CCND1* can serve as a prognostic indicator of tumors has also been investigated, but the conclusions are contradictory in breast carcinoma[10]. *C-myc* gene is an important member of the *myc* gene family, can translocate and regulate a variety of substances, enable an unlimited cell proliferation, immortalize cell life, and is involved in tumor development[11,12].

At present, studies about *Tp53*, *CCND1* and *C-myc* are mainly focused on Caucasian (white race) patients but not on Asians. Since the carcinogenesis of some organ carcinomas might show discrepancies among different races (Caucasian and Asian), detailed information on over-expression and amplification of the three genes in Chinese patients with carcinoma and its correlation with pathological parameters is needed. To more clearly address the importance of over-expression and expression of *Tp53*, *CCND1* and *C-myc* genes in human cancer, we used *in situ* hybridation technique, which can clearly distinguish stromal from carcinoma components, and decrease the loss of such components in RNA extraction procedure. This approach to the specific location of genes on chromosomes is a technique for the hybridization of DNA and RNA "*in situ*". This procedure can isolate or synthesize "*in vitro*" specific radioactive RNA or DNA (known as probes), and then anneal them to chromosomes treated in such a manner that their basic double stranded DNA has been "melted" or dissociated. The relation between *Tp53* and *CCND1*, *C-myc* mRNA expressions was also discussed in this study.

MATERIALS AND METHODS

Materials and microarray construction

A total of 620 primary tumor tissue samples from 7 different tumors and 20 normal tissue samples were snap-frozen and stored at -70℃. All patients were Chinese and underwent operation at Xiamen University Hospital during 2000-2006. Tissue blocks measuring approximately 1.5 cm × 1.5 cm × 0.3 cm of grossly apparent carcinoma and non-pathologic organs were fixed in phosphate-buffered saline (PBS) containing 4% paraformaldehyde (1‰ DEPC, pH 7.4) for 24 h, dehydrated through gradient ethanol, and embedded in paraffin. A hematoxylin and eosin (HE)-stained section was made from each block to define the representative tumor region. Representative areas in different lesions were carefully selected on HE-stained sections and marked on individual paraffin blocks. Tissue cylinders with a diameter of 1-mm were then punched from tumor areas in each "donor" tissue block and put into a recipient paraffin block using a custom-made precision instrument. Five-mm sections of the resulting multiple tumor tissue microarray blocks were transferred to glass slides using the paraffin sectioning aid system [adhesive-coated slides (PSA-CS4x), adhesive tape, and UV lamp; Instru-medics, Inc., Hackensack, NJ], supporting the cohesion of 0.6-mm array elements. The final TMA consisted of 640 1-mm diameter TMA cores each spaced at 0.8 mm between core centers. A section stained with HE was reviewed to confirm the presence of morphologically representative areas in the original lesions.

Preparation of digoxigenin-labeled probes for RNA in situ hybridization

Anti-sense probes matched the corresponding sequence. Locked nucleic acid (LNA) was modified to increase the stability and sensitivity of probes. The sequences of probes are 5'-CAGGACAGGCACAA ACACGCACCT*CAAAGCTGTTCCGTCCAGTA GATTAC-3Dig (*Tp53*), 5'-CCTCCTCGCACTTC TGTTCCTCGCAGACCT*CCAGCATCCAGGT GGCGACGATCTTCCG-3Dig (*CCND1*), 5'- CTTCCT CATCTTCTTGTTCCTCCTCAGAG T*CGCTGCTG GTGGTGGGCGGTGTC-3Dig (*C-myc*). The positive probe was 30T. Asterisk indicates that the LNA modifying site and 3' terminal were labeled with digoxigenin. All probes were synthesized by Sangon (Shanghai).

RNA *in situ* hybridization

Hybridization procedures were performed in this study based on the instructions of RISH kits (Cybrdi USA) with some modifications. The glassware was washed, rinsed in distilled deionized water, and autoclaved before use. Gloves were worn when the glassware and slides were handled to prevent RNase contamination on the tissue. Because of the differences in tissues and probes, we performed different pilot-experiments to achieve the best results (Table 1). Deparaffinized sections were mounted on Denhardt-coated glass slides and treated with pepsin (0.25 mg/mL in DEPC H2O-HCl) for 25-30 min in a 37℃ water bath. The treated sections were then processed for *in situ* hybridization at 42℃-45℃ for 36-48 h. The hybridization mixture contained the labeled

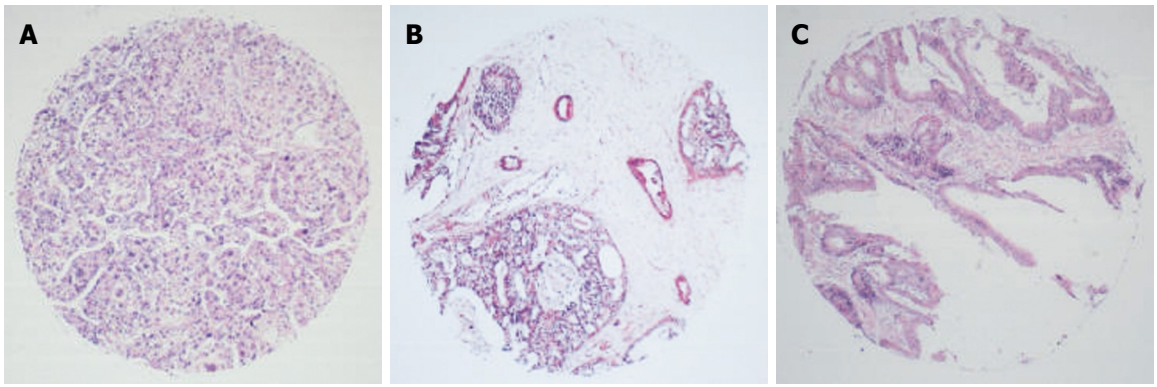

Figure 1 Over-expression of *CCND1* in hepatoma (A), breast cancer (B), and gastric cancer (C).

oligonucleotide probe, 50% formamide, 10 mmol/L Tris-HCl, 1 mmol/L vanadyl-ribonucleoside complex (Sigma 94740), 1 mmol/L CTAB (Sigma 855820, pH 7.0), 0.15 mol/L Nacl, 1 mmol/L EDTA (pH 7.0), 1 × Denhardt's mixture and 10% dextran sulfate. After hybridization, the slides were washed three times, 30 min each time, in 0.1 mol/L TBS at room temperature, then treated with TBS (100 mmol/L Tris, pH 7.5, 150 mmol/L NaCl) containing a 1% blocking reagent (Roche) and 0.03% Triton X-100 for 30 min at room temperature and incubated for 30 min with antidioxigenin alkaline phosphataseconjugated antibodies (Roche) diluted at 1:500 in TBS containing 0.03% Triton X-100 and a 1% blocking reagent. After washed three times, 15 min each time, in TBS and 0.05% Tween, the slides were rinsed in a DAP-buffer (100 mmol/L Tris, pH 9.5, 100 mmol/L NaCl, 50 mmol/L $MgCl_2$) and subsequently hybridization signals were visualized using nitroblue tetrazolium and 5-brom-4-chlor-3-indolyl phosphate as substrates [DAP-buffer in 10% PVA(Sigma 341584)].

Statistical analysis

All cases were first grouped to calculate the percentages of positive and negative cases. χ^2 contingency test was used to evaluate the differences among groups. Analyses were performed using the statistical package SPSS 10.0 (SPSS, Chicago, IL). $P < 0.05$ was considered statistically significant.

RESULTS

Technical considerations

The tissue micro-array technology is substantially different from the traditional multi-tissue blocks, which are often used in pathology laboratories for antibody testing. The most important advantages of tissue micro-array technology include increased capacity, negligible damage to the original tissue blocks, precise positioning of tissue specimens and possibility of automatic construction and analysis of arrays. In this study, we chose 4% paraformaldehyde in phosphate-buffered saline (1‰ DEPC PBS) as a fixation agent, which can decrease degradation of RNA and result in a good morphology. RISH analysis showed that 80%-95% of tumor samples were interpretable. RISH-related weak hybridization, background, and tissue damage were responsible for about one-sixth of the non-informative cases.

Expression of Tp53, C-myc and CCND1 gene in different organs

RNA *in situ* hybridization (RNA-ISH) was used to detect specific RNAs *in situ*. Most protocols using 4% paraformaldehyde as a fixation agent increased the probe permeability, and hybridization was performed in a buffer containing 50% formamide. The typical results of ISH were observed as amethyst dots on arrays, locating in cytoplasm or cytoblasts (Figures 1-3). RNA analysis and quantification required completely intact, non-degraded RNA samples to produce optimal results. Vanadium oxide ions and formation of complex nucleoside could protect RNA degradation from RNase. Cetyltrimethyl ammonium bromide (CTAB) could stabilize the Oligo probe and target sequence formation of double-stranded structures, thus improving the re-annealing speed.

Two major factors, probe accessibility and affinity to the targeted RNA molecules, were found to affect the hybridization efficiency. Poor probe hybridization efficiency was found to be one of the major drawbacks of RNA-targeted *in situ* hybridization. The monomer containing LNA greatly improved the stability and sensitivity of RNA-targeted *in situ* hybridization. The six array elements resulting in 640 points are shown in Figures 1 and 2.

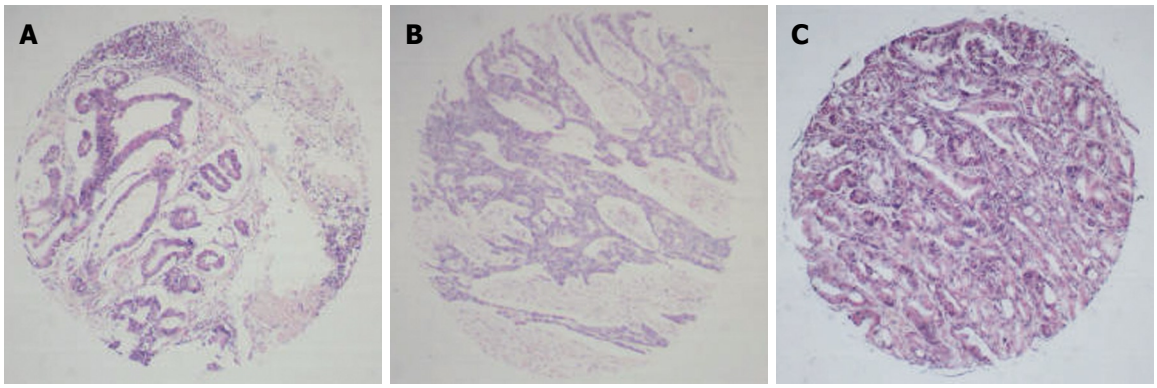

Figure 2 Over-expression of *C-myc* in esophageal carcinoma (A), esophageal squamous cell carcinoma (B), and colon cancer (C).

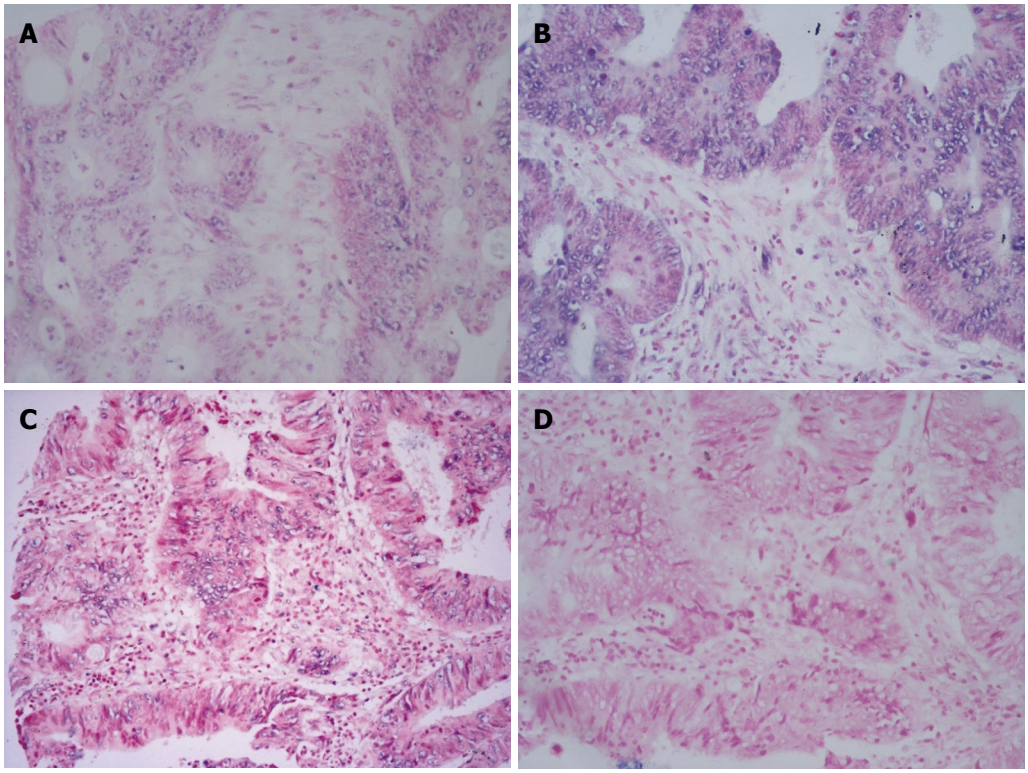

Figure 3 RISH showing expression of *CCND1* (A),*C-myc* (B),*Tp53* (C), and negative expression (D) in different tumor tissue samples. Deparaffinized sections mounted on denhardt-coated glass slides were treated with pepsin for 20, 25 and 30 min, respectively in a 37℃ water bath. The treated sections were then processed for *in situ* hybridization at 4℃, 42℃ and 44℃ for 36, 41.5 and 48 h, respectively. The hybridization mixture contained 10 ng of the labeled oligonucleotide probe. Post-hybridization, slides were treated with a 1% blocking reagent for 30 min at room temperature and then incubated for 45, 60 and 50 min, respectively, with antidioxigenin alkaline phosphatase conjugated antibodies diluted at 1:500 in TBS. After washed three times for 5 min in TBS, the slides were rinsed in a DAP-buffer and hybridization signals were visualized using NBT/BCIP as substrates (x 200).

Gene over-expression

A total of 640 samples were studied for *Tp53*, *CCND1* and *C-myc* mRNA expression, with non-radioactive *in situ* hybridization. ISH results were expressed as intensity and percentage based upon the signal intensity of positive staining and the number of stained cells within the sample, respectively. Tumor was graded according to the World Health Organization System. Normal tissues were also obtained from patients and a tumor free area in the same specimen served as a control. The presence of occasional tumor cells without detectable over-expression might be attributed to the truncated cells that had lost their genetic material during sectioning or tissue pretreatment before hybridization.

Tp53 was over-expressed in different tumors. The over-expression frequencies of *Tp53* in these tumors are shown in Table 2. A significant difference was observed in carcinomatous and paracancerous tissue samples, including those of esophagus, stomach, rectum, thyroid gland, liver, mammary gland. *Tp53* was over-expressed in almost all tumor cells within an array element. Our data indicate that expression of *Tp53* in tumor tissues may play a role in cell carcinomatous change. Intracellular levels of *Tp53* were elevated due to the increased stability and higher steady state of the protein, which may permit cells to divide without restraint. The positive

expression rate of *Tp53* was 48.9% (44/90) in carcinoma tissue samples and 20% (6/30) in normal adjacent tissue samples. In most cases, carcinomatous tissue samples had stronger signals than paracancerous tissue samples (Figures 4 and 5). Stronger positive dots (positive cells > 50%) were observed in carcinomatous tissue samples.

CCND1 ISH signals, located exclusively in nuclei, were variable in terms of staining intensity and proportion of positive nuclei among the cells in individual cases. The over-expression frequencies of all tumors are shown in Table 3. In this study, a significant difference was found in carcinomatous and paracancerous tissue samples, including those of stomach, rectum, thyroid gland, liver, and mammary gland. Our data indicate that *CCND1* expression was significantly associated with carcinomatous change. *CCND1* was expressed only in one paracancerous tissue sample of rectum, but in 4 carcinomatous tissue samples. In most cases, carcinomatous tissue samples had stronger signals than paracancerous tissue samples (Figures 4 and 5).

The over-expression frequencies of *C-myc* gene in all tumors are shown in Table 4. In this study, a significant difference was found in carcinomatous and paracancerous tissue samples, including those of esophagus, stomach, and thyroid gland. The expression of *C-myc* gene in carcinomatous and paracancerous tissues samples was not significantly associated with the histological grade of tumors. The expression of *C-myc* mRNA was heterogeneous in breast tumor tissue samples, with no predominant morphologic subtype in the high or low categories($\chi^2 = 7.062$, $P = 0.133$). However, breast carcinoma tissue samples had stronger signals (positive cells > 75 %) than normal adjacent tissue samples. The positive expression rate of *C-myc* mRNA was 62.5% (25/40) in carcinomatous tissue samples, 60% (12/20) in lobular hyperplasia samples, and 60% (12/20) in fibroadenoma tissue samples.

In our study, the positive expression rate of the three probes was not significantly different in colon carcinoma and paracancerous tissue samples, which was 58.3%, 75.0%, 66.7% and 65.0%, 65.0%, 50.0%, respectively (χ^2 =2.083, $P = 0.555$; $\chi^2 = 7.273$, $P = 0.064$; $\chi^2 = 3.627$, $P = 0.305$), suggesting that tumor grade is not related with the gene expression level. The signal intensity was different in colon. Hybridization signals (positive cells > 75%) were always observed both in *CCND1* and in *C-myc*. Carcinoma tissue was associated with weaker signals (positive cells < 50%). However, an opposite tendency was found in thyroid and mammary glands.

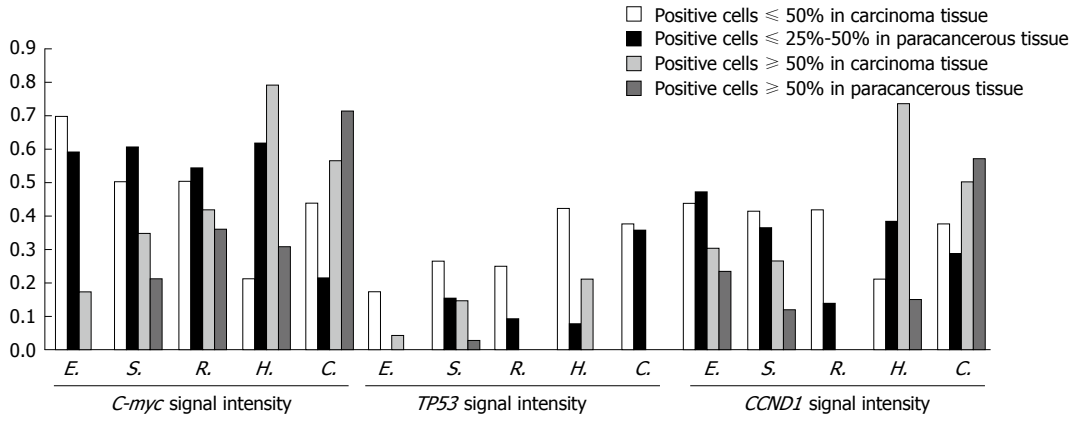

Figure 4 Signal intensity of *Tp53*, *CCND1*, and *C-myc* gene expression in different organs. E: Esophagus; S: Stomach; R: Rectum; H: Liver; C: Colon.

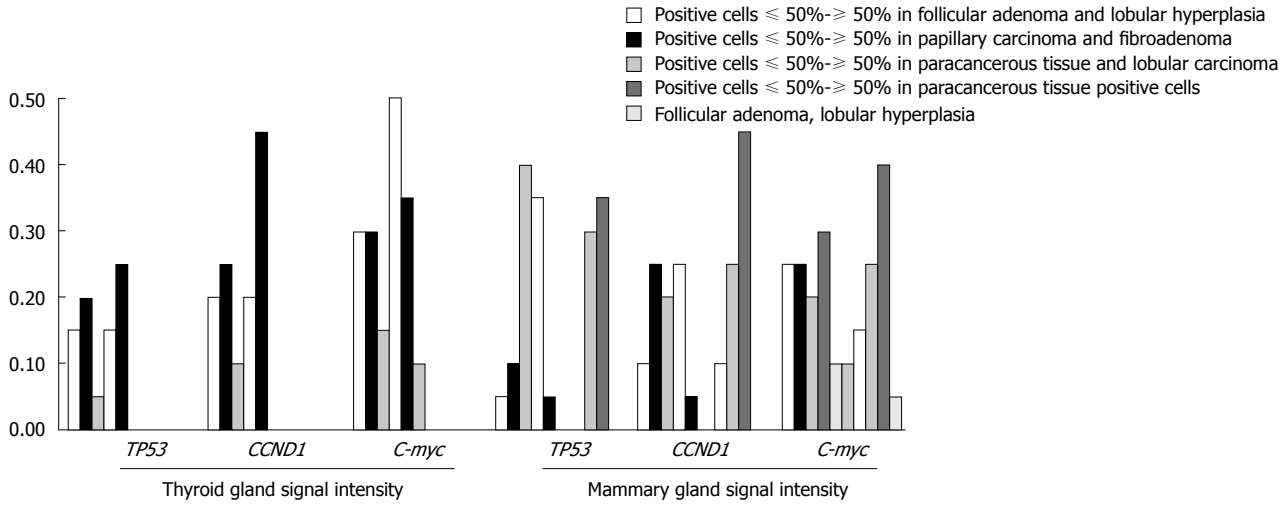

Figure 5 Signal intensity of *Tp53*, *CCND1*, and *C-myc* expression in thyroid gland and mammary gland.

The correlation coefficients of *Tp53-CCND1*, *CCND1-C-myc* and *Tp53-C-myc* were 0.653 (t = 3.76, P = 0.001), 0.737 (t = 4.753, P = 0.000) and 0.459 (t = 2.253, P = 0.036), respectively. If this finding was validated by an additional analysis in a larger population, these gene ratios could be used as prognostic markers in diagnostic biopsies.

DISCUSSION

In this study, we used the TMA technology because it allows analysis of a large number of samples and markers. A major concern for the TMA technique is the extent to which tumor heterogeneity may affect the validity of results. This issue has been addressed in TMA studies, which demonstrated that all previous findings from large sections could be fully reproduced[13,14]. The data on *Tp53*, *CCND1*, and *C-myc*, RNA *in situ* hybridization most commonly studied in associated tumors, are consistent with the reported findings[13,14]. In this study, the positive expression rates of *Tp53*, *CCND1*, and *C-myc* RNA were higher than those in previous reports[13,14], confirming the usefulness of the TMA approach. In our study, all tissue samples were fixed in phosphate-buffered saline (1‰ DEPC PBS) containing 4% paraformaldehyde that can prevent mRNA degradation from RNase and result in good morphology, indicating that tissue micro-array may be powerful in identification of different types of tumor with a particular molecular alteration.

Northern blot, dot blot or PCR-based approach has been used in detecting the expression of *Tp53*, *CCND1* and *C-myc* mRNA in different tumors, but just a few reports are available on *in situ* hybridization. Some normal tissuses are dominated by adipose cells, differing greatly from tumor tissue in its epithelial cellularity. Normal and tumor tissues cannot be rigorously compared using techniques involving RNA extraction from total tissue. Therefore, conclusions such as 'increased expression' may be more difficult to make from studies with Northern blot, dot blot and PCR-based techniques requiring RNA extraction from tissues not fastidiously microdissected for selection of tumor cells. In this study, a more sensitive hybridization mixture decreased RNA degradation, thus accelerating oligonucleotide probe-RNA annealing. The signal intensity can be increased and low abundance RNA can be detected using a locked nucleic acid modifier

to increase its stability and sensitivity[15-17]. The non-specificity signal can be decreased and the specificity can be increased using a different temperature and probe concentration. A strong hybridization signal appears in the transmitting tissue of pistil a few hours after 10% PVA (MW, 70-100 kDa) is used[18-20].

Our results reveal that the expression of *Tp53* was higher in six different carcinoma samples than in their adjacent normal adjacent tissue samples with the exception in colon tissue samples. In this study, the expression of *Tp53* was observed in 4 cases of lobular hyperplasia and in 20 cases of fibroadenoma. However, the positive expression rate of *Tp53* was 75% (30/40) in breast carcinoma samples and 75% (30/40) in lobular carcinoma tissue samples, suggesting that determination of *Tp53* gene by RISH contributes to the diagnosis of carcinoma and distinguishes DCIS from atypical hyperplasia. Moreover, carcinoma tissue often has a stronger signal than paracancerous tissue. In the present study, the signal (positive cells > 50%) was stronger in liver and thyroid gland carcinoma tissue samples than in follicular adenoma tissue samples. Originally, *TP53* was thought to be an oncogene because over 50% of cancer cells tested showed a high level of *Tp53* protein. However, all of them are mutated forms of *Tp53*. It was reported that the *Tp53* gene acquires frequent mutations during the development of human malignancies including cancer of colon, breast, and lungs[21]. As described earlier, intracellular regulation of *Tp53* expression can occur at the level of mRNA or *Tp53* protein. A recent study indicated that even a brief reactivation of endogenous *Tp53* in *Tp53*-deficient tumors can lead to a complete tumor regression[22].

At present, the expression of *CCND1* has been investigated in several differences tumors, showing that patients with positive expression of *CCND1* usually have a poor prognosis compared to those with negative expression of *CCND1* in lung cancer, head and neck squamous cell carcinoma, and bladder cancer[23]. Although positive expression of *CCND1* can serve as a poor prognostic factor or is associated with a worse prognosis, the expression of *CCND1* is not correlated with the prognosis of cancer patients[24]. Furthermore, intensive investigations have been done on the correlation between *CCND1* expression and patient survival in Caucasian females with breast carcinoma, but systematic investigations on alteration of *CCND1* in Asian females are rare[23,24]. Whether *CCND1* expression, clinicopathological parameters, survival rate and other prognostic markers are associated with cell cycle is not clear. In our study, a significant difference was found in positive expression rate of *CCND1* between different tumors except for tumors of esophagus ($\chi^2 = 7.500$, $P = 0.058$) and colon ($\chi^2 = 7.273$, $P = 0.064$). These results agree with the conclusions of other studies[23,24].

The expression of *CCND1* plays an important role in the early staging of carcinogenesis in Caucasian females with breast carcinoma. In the present study, 4 patients had lobular hyperplasia, 25 had breast carcinoma, suggesting that expression of *CCND1* also plays an important role in Chinese patients with breast carcinoma. *CCND1* was over-expressed in gastric adenocarcinoma tissue samples.

The *C-myc* oncogene is amplified or over-expressed in different human cancers. Experiments *in vivo* have also causally linked aberrant expression of this gene to the development and progression of cancer in different body sites[25]. However, several critical issues regarding the significance of *C-myc* in human cancer still remain obscure. *C-myc* is essential for tumor development, since it regulates factors necessary for the growth of tumors lending a new potential target to anti-angiogenic cancer therapies. Our study showed that the expression of *C-myc* was significantly different in carcinoma and its adjacent normal tissue samples. In our study, 18 patients had follicular adenoma and 16 had papillary carcinoma. The signal intensity of *C-myc* was also similar in follicular adenoma and papillary carcinoma patients with no strong signal occurred in paracancerous tissue samples, indicating that determination of *C-myc* gene by RISH can contribute to the diagnosis of carcinoma and distinguish carcinoma from follicular adenoma.

C-myc gene over-expression is associated with a poor

prognosis of breast cancer patients[26]. The abnormal expression of *C-myc* mRNA and over-expression of *C-myc* in tissue array are listed in Table 4. The prognostic value for the over-expression of *C-myc* mRNA or protein is inconsistent and conflicting[26]. In our study, c-myc gene expression had no significant difference in breast lobular hyperplasia, fibroadenoma, lobular and ductal carcinoma tissue samples and their adjacent normal tissue samples ($\chi^2 = 7.062$, $P = 0.133$), and *C-myc* mRNA was highly expressed in 50% (75%) of high grade breast carcinoma tissue samples.

Our data show that the three genes were not differently expressed in colon carcinoma tissue samples, which is not consistent with the data reported by Deming[27] using the relatively insensitive Southern blot technique, suggesting that the three genes are not important factors for colon carcinogenesis and not significantly correlated with DCC deleted in colon cancer (DCC) and mutated in colon cancer (MCC) genes.

In normal cells, *Tp53* gene is activated due to DNA damage and increases the transcription of p21 inhibiting the activity of cyclin/CDK complex and preventing cells from entering S phase. Mutation of *Tp53* gene reflected by positive expression of mutated type Tp53 protein is one of the main causes for malignant transformation. In this study, *CCND1* was correlated with *Tp53* expression. We believe that although *Tp53* could induce the expression of p21 and inhibit the function of *CCND1*/CDK complex in normal cells, abnormal expression of *CCND1* does not necessarily respond to the dysfunction of wild-type *Tp53* protein or positive expression of mutated type *p53* in carcinoma cells. A pathway independent of *Tp53* mutation may exist in carcinoma, which could also result in *CCND1* over-expression. Over-expression of *CCND1* may play an important role in the carcinogenesis of tumors without cooperation of *Tp53* mutation[28].

In conclusion, it is necessary to analyze the lower grade tumors and premalignant lesions with the same tools to determine whether the expressions of *Tp53*, *CCND1* and *C-myc* are different, and to compare the development and progression of tumors. Only a subtle deregulation of the expression of *C-myc* is sufficient to allow genomic instability. Whether gene expression precedes or follows its over-expression in the course of cancer needs to be further studied.

COMMENTS

Background

The *Tp53*, *CCND1* and *C-myc* oncogenes are amplified or over-expressed in many types of human cancer. Experiments *in vivo* have also causally linked aberrant expression of these genes to the development and progression of cancer in different body sites. However, several critical issues regarding the significance of *Tp53*, *CCND1* and *C-myc* in human cancer still remain obscure. The frequency of amplification, over-expression of mRNA and protein in breast cancer is about 50%-100%. Whether the expression of these genes is altered at the cytogenetic level in different types of human carcinoma remains unclear.

Research frontiers

The development and progression of cancer in different body sites are very intricate and involve the expression of multiple cytokines and oncogenes such as *Tp53*, *CCND1* and *C-myc*.

Innovations and breakthroughs

Few studies are available on the correlation of *Tp53*, *CCND1*, *C-myc* with seven kinds of tissue. To study the expression of oncogene during the development of cancer, we constructed tissue microarrays consisting of samples from 7 types of tumor. Using scrupulous *R* & *ISH* and LNA modifying probe, we achieved high expressions of these genes in different tumor tissues. *C-myc* mRNA was highly expressed in 50% of high grade breast carcinomas, which was much higher than the reported data (22%) by real-time RT-PCR.

Applications

The relationship between oncogene and tumor clarifies the mechanism of tumor and provides an important molecular basis for closer observation of the nature of tumor, which can be widely applied in the diagnosis, treatment, and prognosis of cancer.

Peer review

The authors studied the expression of *Tp53*, *C-myc*, and *CCND1* in different tumors using tissue microarrays. The study was well designed. The findings are reliable and can be widely applied in the diagnosis, treatment, and prognosis of cancer.

Abstract

AIM: To evaluate the safety and efficacy of vitamin E in children with chronic hepatitis B.

METHODS: We randomly assigned patients with chronic hepatitis B, positive for hepatitis B e antigen (HBeAg), to receive either vitamin E or placebo once daily for 6 mo in a 3:1 ratio and double-blind manner. The primary end point was HBeAg seroconversion, defined as the loss of HBeAg, undetectable levels of serum hepatitis B virus DNA, and the appearance of antibodies against HBeAg 12 mo after therapy.

RESULTS: At baseline visit, 49 patients had normal and 43 had increased serum aminotransferase levels. Twenty-nine patients did not respond to previous treatment with interferon-α or lamivudine. Seventy-six children completed the study; 16 were non-compliant (n = 7), lost to follow-up (n = 7), or started another antiviral treatment (n = 3). Intention-to-treat analysis showed HBeAg seroconversion in 16 children (23.2%) treated with vitamin E and two (8.7%) in the placebo group (P = 0.13). Vitamin E was well tolerated.

CONCLUSION: There is only a tendency that vitamin E may promote HBeAg seroconversion. Therefore larger studies are needed to clarify the role of antioxidants in the therapy of chronic hepatitis B.

INTRODUCTION

More than 350 million people worldwide are chronically infected with hepatitis B virus (HBV). Chronic HBV infection causes cirrhosis, hepatocellular carcinoma, and end-stage liver disease which accounts for approximately 1 million deaths each year. In most countries horizontal transmission of HBV is the main route of infection

during childhood[1-3]. In this age group the first stage of infection is characterized by the presence of hepatitis B s antigen (HBsAg) and hepatitis B e antigen (HBeAg) in serum, a high virus load, and low inflammatory activity. These parameters indicate a low or absent immune response against HBV which can persist for decades. The great majority of patients in this "immune tolerance" phase have no sustained response to current treatment[4]. However, it is known that chronic HBV carriers show spontaneous HBeAg seroconversion at approximately 10% per year[5]. Among patients with predictors of beneficial response such as high levels of serum transaminases and low levels of HBV DNA, only approximately one-third respond to interferon alpha[6-9] and about 20% respond to nucleoside analogues[10-12]. Furthermore, it has been shown that interferon alpha treatment simply accelerates anti-HBe seroconversion[13]. The question of whether it is worth treating a patient is further complicated by the significant side effects of interferon alpha treatment and the potential to develop resistance to nucleoside analogues. Therefore further treatment options are needed.

Since a defective immune response is likely to be one factor in the pathogenesis of liver damage caused by HBV, immunomodulatory substances have been tested for the treatment of chronic hepatitis B[14-19] but the results are conflicting. In a recent placebo controlled study, Andreone *et al*[20] tested vitamin E for chronic hepatitis B. In this pilot trial, the response rate was significantly higher in patients in the vitamin E group than in the placebo group.

Vitamin E is an antioxidant in the cell membrane which acts as a scavenger of free radicals. In patients suffering from various hepatopathies, it is able to protect against liver damage[21,22]. Vitamin E was also shown to enhance clinically relevant T-cell-mediated function[23].

The purpose of this study was to evaluate the safety and efficacy of a high-dose 6-mo course of vitamin E in a large number of chronically infected children. Our study included a 12-mo follow-up period, which allowed us to evaluate post-treatment effects and the durability of response.

MATERIALS AND METHODS

We conducted a prospective, randomized, double-blind, placebo-controlled study of patients with chronic hepatitis B in 22 German centers and one Austrian center. The dose of vitamin E depended on the patients' weight. Children below 20 kg received 200 IU of *RRR*-α-tocopheryl acetate concentrate once daily for 6 mo. Patients between 20 and 40 kg received 400 IU and patients of more than 40 kg received 600 IU once daily for 6 mo (Cognis, Nutrition&health, Düsseldorf, Germany). After the treatment period, patients were followed up for 12 mo. Placebo capsules were indistinguishable from vitamin E capsules and were produced by the same company. Eligible patients were randomized to receive either vitamin E or placebo in a 3:1 ratio. Patients were randomly assigned by a computer-generated program at the study center (Children's Hospital, Helios Klinikum Wuppertal, Germany).

The local ethics committee (Witten-Herdecke University, Germany) approved this study. Written consent was given from parents and also from the patient if older than 11 years.

Inclusion criteria

Inclusion criteria were: (1) age between 1 and 17 years; (2) presence of HBsAg and HBeAg for at least 6 mo; (3) presence of HBV DNA in serum for at least 6 mo (HBV-DNA > 10 000 copies/mL).

Exclusion criteria

Exclusion criteria were: (1) antiviral therapy within the 6 mo prior to the study; (2) concurrent participation in another clinical trial; (3) hepatic decompensation; (4) co-infection with hepatitis C, hepatitis D or human immunodeficiency virus; (5) pregnancy or breast feeding.

Monitoring

The following biochemical and virological data were examined at baseline visit and 2, 4, 6, 12 and 18 mo after starting therapy: vitamin E, aspartate aminotransferases, γ-glutamyl transferase, complete blood count, thromboplastin time, thyroid stimulating antibodies, HBV DNA, HBeAg, anti-HBe, HBsAg, anti-HBs. At each visit, the child underwent a physical examination and was interviewed regarding potential side effects and adverse reactions. Biochemical and serological markers of hepatitis B infection were tested in each center.

Evaluation of efficacy

The primary end point for efficacy was seroconversion to anti-HBe, loss of HBeAg and loss of HBV DNA at the end of follow-up (12 mo after treatment), defined as HBV-DNA level under 400 copies/mL or in other tests < 5 pg/mL.

Statistical analyses

The comparison of groups with respect to responses at 18 mo was done by Fisher's exact test.

RESULTS

Characteristics of patients

Ninety-two children and adolescents were enrolled in the study. Baseline characteristics of the patients are shown in Table 1. Vitamin E and placebo groups were similar with respect to demographic and clinical characteristics. Of the 76 patients completing the study, 18 (16 vitamin E and two placebo) responded to therapy as defined by HBeAg seroconversion, loss of HBeAg and HBV DNA (< 400 copies/mL) and normalization of alanine aminotransferase (ALT).

Exclusion of patients

Of the 92 patients enrolled, 16 were excluded (13 of the vitamin E and three of the placebo group). Seven patients

Table 1 Characteristics and results of 76 children who completed the study before and after treatment with vitamin E or placebo

	Vitamin E	Placebo
Total	56	20
Sex (%)		
Female	22 (39.3)	8 (40)
Male	34 (60.7)	12 (60)

were non-compliant as medication was taken only for a reduced period or was taken irregularly and one patient administered additional self-medication with vitamin E. Seven patients were lost to follow-up and three patients started treatment with interferon alpha or lamivudine.

Dosage

Twenty-six of the 69 (37.7%) patients in the vitamin E group received 600 IU, 30 (43.5%) 400 IU and eight (11.6%) 200 IU.

Levels of transaminases before treatment

Patients were classified into two groups: one with normal transaminase levels and the second with elevated transaminase levels. In the children who responded to therapy, eight patients had normal transaminase levels before treatment and eight patients had elevated transaminases, while all children with response in the placebo group had elevated transaminases (Table 2). Eighteen children seroconverted to anti-HBe and 15 of them showed ALT elevation before seroconversion (mean 3.2 times normal range). In three of these patients transaminases increased slightly only before seroconversion while the rest of them had a mild transaminase flare immediately before and during anti-HBe seroconversion. None of them showed acute exacerbation of hepatitis B.

Levels of HBV DNA

Patients were classified into two groups: one with low HBV DNA titers of less than 1000 pg/mL and one with high HBV DNA of more than 1000 pg/mL. Twelve (75%) patients with low and four (25%) with high viral DNA responded to vitamin E. In the two responders in the placebo group, one patient had high HBV DNA titers and one low.

18 mo	3	1

Route of infection

Thirty-four patients (49.3%) in the vitamin E group and 10 patients (43.5%) in the placebo group were likely to be infected by her mother, either perinatally or later in childhood. Of these, nine children responded to vitamin E treatment; none of the children in the placebo group responded. The route of infection was unknown in 21 children (30.4%) in the vitamin E group and nine (39.1%) in the placebo group. Eight and two children responded to therapy, respectively. The only patient with parenteral infection in the vitamin E group responded to therapy while the child in the placebo group did not.

Side effects

The therapy was well tolerated. Three children treated with vitamin E experienced self-limited gastroenteritis of 1-3 wk duration. Monitoring of the above-mentioned biochemical and clinical data did not reveal any other side effects or adverse events. No child had before or during follow-up abnormal TSH or thromboplastin time. There was no significant increase in the GGT-level and no pathological change of the whole blood count.

Time of HBeAg seroconversion

In the vitamin E group, six patients responded during vitamin E treatment, seven within the first year and three at 18 mo after the start of therapy. In the placebo group, both patients responded only during the follow-up period at 12 and 18 mo. During anti-HBe seroconversion and loss of HBeAg no child developed acute exacerbation of hepatitis B.

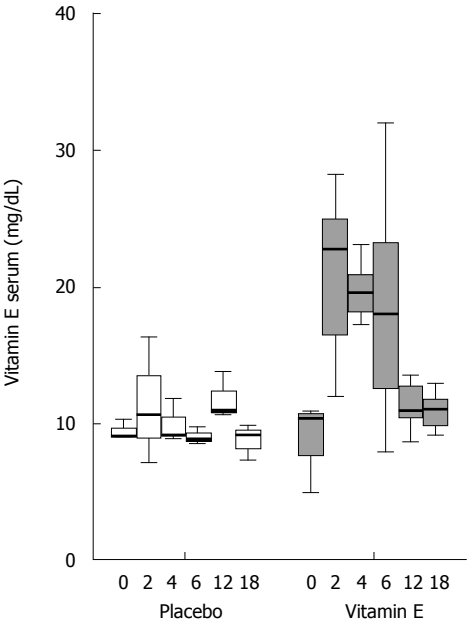

Figure 1 The significant vitamin E levels before, during and after treatment (mean ± SD) in patients treated with placebo or vitamin E.

Vitamin E levels

A significant increase in vitamin E levels was observed in the vitamin E group. Vitamin E levels doubled within 2 mo and fell to starting levels immediately after cessation of therapy. No significant change in vitamin E levels was found in the placebo group (Figure 1).

DISCUSSION

The results of this study suggest that vitamin E is well tolerated in children and adolescents with chronic hepatitis B and yields a higher HBeAg seroconversion rate than patients treated with placebo. Among 69 children treated with vitamin E, 23.2% became negative for serum markers of viral replication (HBeAg and HBV DNA). As expected, an 8.7% spontaneous rate of anti-HBe seroconversion and loss of HBeAg was found in the control group, in line with previous reports[5,8,24-26]. The response rate in vitamin E-treated-children was slightly worse than in patients treated with interferon alpha[5,8,24-26] and comparable with the treatment with nucleoside analogues[10-12]. This is surprising since the majority of children treated in our study had poor predictors of virological response. Among children who completed the study, approximately two-thirds had normal ALT levels and high levels of viremia, and one-third were resistant to one or two previous antiviral treatments. In the study of Andreone *et al*[20], 7 of 15 patients treated with vitamin E showed normalization of ALT levels, 8 of 15 became negative for HBV DNA, and 3 of 7 HBeAg positive patients achieved seroconversion which differed significantly from the placebo group. It is known that seroconversion of HBeAg may occur after years of treatment with interferon or lamivudine. In our study population, 19 children were treated with interferon or lamivudine before treatment with vitamin E (Table 1). Only one child was treated 7-12 mo before entering this study with interferon, and another three patients were treated 12-36 mo before starting this study. The remaining patients received antiviral therapy more than 2 years before the study. We therefore think that antiviral therapy prior to the study should not be a significant bias of the results of this study.

It is known that vitamin E improves the aminotransferase status in patients with various liver diseases such as hepatitis C, hemochromatosis and Wilson's disease[21,22]. This effect is probably based on its antioxidant properties, resulting in the protection of liver damage by oxidative stress. However, immunomodulatory effects are also documented. It was shown *in vivo* that vitamin E enhances T cell-mediated function, acts as a proliferative stimulator of lymphocytes and has natural killer cell activity[23,27,28]. Furthermore, T helper cells are polarized towards the T helper-1 phenotype which is known to be under-represented in chronic hepatitis B carriers[29]. It can be hypothesized that these effects of vitamin E may be a factor in the antiviral immune response seen in our patients.

According to current consensus statements on the treatment of HBeAg positive hepatitis B, only patients with ALT levels greater than double normal values, or moderate/severe hepatitis on biopsy should be considered for therapy[30-32]. In childhood, however, the majority of patients are immune tolerant to HBV, resulting in no significant liver inflammation. The results of this study suggest that vitamin E may be used for these patients; this is supported by the finding that half of the patients with HBeAg seroconversion had normal aminotransferases before treatment. Moreover, it may be useful for patients who have previously failed with interferon alpha or nucleoside analogues as re-treatment with the same drugs either as monotherapy or in combination[33,34]. The excellent safety of vitamin E found in this study and in many other reports, even in long-term treatment, further favors this therapy[35].

Although the HBeAg seroconversion rate was higher in the vitamin E group, our study population is too small to show a significant difference between the two groups. Our study is hampered by the relatively high number of patients who had to be excluded because of non-compliance or loss of follow-up. This may in part be due to the long follow-up period and the high number of treatment centers involved in this study. Furthermore, some patients may not have been convinced that vitamin E can be used as a "real" drug and can be effective against hepatitis B. The results of this study may, however, improve the motivation of such patients and lead to a bigger study population.

We conclude that treatment with high doses of vitamin E is well tolerated and may promote HBeAg seroconversion even in difficult to treat patients, but further studies are warranted to verify the effectiveness of vitamin E.

COMMENTS

Background

With an anual mortality of around 800 000 patients per year, chronic hepatitis B is one of the most serious worldwide health problems.

Research frontiers

Chronic hepatitis B can be regarded as a difficult to treat disease. Despite treatment options like interferon-alpha and nucleos(t)ide analogues, the majority of patients fail to respond to treatment. Moreover during the so-called immune tolerant phase of HBV infection, no treatment can be offered to the patient as the chance to respond to treatment is minimal.

Innovations and breakthroughs

Recent reports have demonstrated that treatment with vitamin E can normalize liver transaminases and may also lead to HBeAg seroconversion. In this report, studied for the first time in children, the effect of vitamin E was evaluated in a placebo-controlled trial. The overall effect in the vitamin E group was higher than in the placebo group but this effect did not reach significance.

Applications

In particular, children are often in the immune tolerant phase of infection and therefore no treatement is indicated. As vitamin E has an excellent side-effect profile, it may be used in otherwise not treatable children. This has however been evaluated in larger studies.

Peer review

Authors investigated the putative role of vitamin E in chronic hepatitis B. The study was conducted carefully and the double-blinded placebo-controlled trial reaches a high standard.

Abstract

AIM: To analyze the change of dimethylarginine plasma levels in cirrhotic patients receiving transjugular intrahepatic portosystemic shunt (TIPS).

METHODS: To determine arginine, asymmetric dimethylarginine (ADMA), symmetric dimethylarginine (SDMA), and nitric oxide (NO) plasma levels, blood samples were collected from the superior cava, hepatic, and portal vein just before, directly after, and 3 mo after TIPS-placement.

RESULTS: A significant increase in the arginine/ADMA ratio after TIPS placement was shown. Moreover, TIPS placement enhanced renal function and thereby decreased systemic SDMA levels. In patients with renal dysfunction before TIPS placement, both the arginine/ADMA ratio and creatinine clearance rate increased significantly, while this was not the case in patients with normal renal function before TIPS placement. Hepatic function did not change significantly after TIPS placement and no significant decline in ADMA plasma levels was measured.

CONCLUSION: The increase of the arginine/ADMA ratio after TIPS placement suggests an increase in intracellular NO bioavailability. In addition, this study suggests that TIPS placement does not alter dimethylarginine dimethylaminohydrolase (DDAH) activity and confirms the major role of the liver as an ADMA clearing organ.

INTRODUCTION

In 1977, Carnegie and co-workers[1] pointed out the potential role of the liver in the metabolism of asymmetric dimethylarginine (ADMA) by reporting an increased urinary excretion of ADMA in patients with liver disease. Later, it was shown in an organ balance study in rats that the liver takes up substantial amounts of ADMA, thereby suggesting a crucial role for the liver in regulating systemic ADMA concentrations[2]. These results were confirmed in patients undergoing hepatic surgery in whom it was also shown that the clearing of symmetric dimethylarginine (SDMA) was not only confined to the kidney, but the human liver also took up small amounts of SDMA from the portosystemic

circulation[3]. Elevated ADMA levels have been reported in patients eligible for liver transplantation[4,5], in postoperative patients undergoing major liver resection[6], in patients suffering from decompensated alcoholic cirrhosis[7], and in critically ill patients with hepatic dysfunction[8]. ADMA plays a regulatory role in the arginine-nitric oxide (NO) pathway by inhibiting the enzyme NO synthase[9] and by competing with arginine and SDMA for cellular transport across cationic amino acid transporters (CAT) of system y+[10]. Both ADMA and SDMA are removed from the body by urinary excretion. However, the main eliminatory route for ADMA is degradation by the enzyme dimethylarginine dimethylaminohydrolase (DDAH) which is highly expressed in the liver, but is also present in the kidney, and in endothelial cells[11,12].

Dimethylarginines may play an important pathophysiological role in liver cirrhosis because this disease is characterised by endothelial dysfunction and NO deficiency in the intrahepatic circulation (review article[13]). In fact, increased intrahepatic vascular resistance in cirrhosis is not only due to structural changes, but also due to a dynamic component. The latter has largely been attributed to a reduced intrahepatic endothelial NO-synthase activity in liver cirrhosis[14]. Indeed, it has been suggested that an alteration in hepatic DDAH expression and/or activity in liver disease leads to high intrahepatic ADMA levels along with resultant endothelial dysfunction and increased intrahepatic resistance[15]. In cirrhotic patients, elevated peripheral ADMA and NO levels have been reported[7,16] and it has been suggested that ADMA might oppose the peripheral vasodilation caused by excessive systemic NO production during liver cirrhosis[7]. In order to analyze the change of dimethylarginine plasma levels in cirrhotic humans, we studied patients receiving transjugular intrahepatic portosystemic shunt (TIPS).

MATERIALS AND METHODS

The study was approved by the institutional review board and medical ethical review committee of the University Hospital Regensburg in Germany. Before study entry, patients were informed on the purpose of the study and informed consent was obtained from all patients.

Patients

The study population consisted of 25 patients suffering from liver cirrhosis and undergoing TIPS-placement mainly because of refractory ascites or recurrent esophageal variceal bleeding. The etiology of liver cirrhosis was: alcoholic hepatitis (20), viral hepatitis (2), cryptogenic hepatitis (2), and myeloproliferative disease (1). All patients had severe portal hypertension (portal pressure > 12 mmHg) which was determined during TIPS-placement. The diagnosis of liver cirrhosis was based on clinical, biochemical, and ultrasonographic data. Severity of hepatic failure was scored according to the Child-Pugh Classification[17].

Blood sampling and analysis

Blood samples were collected just before TIPS-placement from the superior caval vein, hepatic vein, and portal vein. Directly after TIPS-implantation and -dilation to its final lumen (before ending the procedure and dismissing the patient to the ward), and 3 mo after placement of the stent (to investigate patency of the shunt), blood was drawn again from the superior caval vein, portal vein and from another hepatic vein to prevent sampling from the extended portal venous tract.

ADMA, SDMA, and arginine plasma concentrations were measured by high-performance liquid chromatography with fluorescence detection using monomethylarginine as internal standard, as previously described[18]. After sample cleanup by solid-phase extraction, the analytes were derivatized with ortho-phthaldialdehyde reagent containing 3-mercaptopropionic acid. Chromatographic separation of the fluorescent derivatives was performed on a monolithic column as recently described[19]. Intra-assay coefficients of variation (CVs) were < 1.2% for all analytes. Inter-assay CVs were < 3.0% for ADMA and arginine and < 4% for SDMA. Reference values for ADMA have been obtained from plasma of healthy laboratory personnel and medical students[18]. The concentration of ADMA in these individuals is normally distributed. These patients did not have liver or kidney diseases and had no diseases that influence ADMA levels.

NO_x concentrations were measured using the Nitric Oxide Analyzer from Sievers Instruments (Boulder, Colorado, USA), as described previously[20,21]. Briefly, this assay is based upon spectrophotometric analysis after chemiluminescent reaction between NO and ozone (detection limit < 1 μmol/L). Creatinine clearance rate was calculated from plasma and urinary concentrations in 24 h collected urine. Other biochemical parameters were determined by standard laboratory methods.

Statistical analysis

Differences between timepoints were tested with Wilcoxon signed ranks test. For each comparison, the overall α-level was set at 0.05. Relations between variables were investigated by Spearman's rho. Data are presented as medians and interquartile ranges (IQR). Statistical analyses were performed using SPSS (SPSS 11.0 for Windows).

RESULTS

Patients

Patient characteristics are presented in Table 1. Hepatic synthetic and clearing functions were slightly impaired as reflected by decreased factor V, antithrombin Ⅲ, albumin, and cholinesterase concentrations and slightly increased bilirubin levels. Three months after TIPS-placement, no significant improvement was seen in either laboratory parameters of hepatic function, hepatic enzyme concentrations, or Child-Pugh score (data not shown).

Although creatinine and urea levels were within the

[a]$P < 0.05$ *vs* just before TIPS-placement.

Concentrations of ADMA, SDMA, and arginine

The changes in ADMA, SDMA, and arginine concentrations in the systemic, portal, and hepatic vein are shown in Table 4. At all 3 three timepoints, median systemic ADMA and SDMA plasma levels were higher in cirrhotic patients compared to healthy volunteers[18] (ADMA: 0.42 μmol/L (0.37-0.47); $P < 0.05$, SDMA: 0.46 μmol/L (0.42-0.52); $P < 0.05$, respectively). In contrast, arginine concentrations were lower at baseline compared to healthy individuals (arginine: 88 μmol/L (76-113); $P < 0.05$), but did not differ anymore after TIPS-placement.

Although ADMA levels did not show a significant change due to TIPS-placement, SDMA concentrations were significantly lower 3 mo after TIPS-placement in comparison to baseline values. Placement of TIPS caused a significant increment of both arginine levels and arginine/ADMA ratios.

When an additional analysis was performed between patients with (creatinine clearance rate < 97 mL/min) and patients without (creatinine clearance rate > 97 mL/min) additional renal dysfunction before TIPS placement, arginine/ADMA ratio increased significantly ($P = 0.021$) in patients with renal dysfunction; before TIPS placement: 94 (81-135) and 3 mo after TIPS placement: 124 (99-174). This was also the case for creatinine clearance rate which improved significantly ($P = 0.036$) from 44 mL/min (27-70) before TIPS placement to 105 mL/min (73-146) 3 mo after TIPS placement. In patients with normal renal function, no significant changes in either creatinine clearance rate or arginine/ADMA ratio was seen.

NO_x plasma concentrations

Although NO_x plasma levels showed a decreasing

Table 5 Plasma concentrations of NO_x (μmol/L)

NO_x	Just before TIPS		Directly after TIPS		3 mo after TIPS	
	Median	IQR	Median	IQR	Median	IQR
Systemic vein	112	37-243	107	33-212	44	26-103
Portal vein	83	35-241	85	45-223	57	21-96
Hepatic vein	85	35-304	86	32-220	39	21-76

tendency after TIPS placement, changes did not reach statistical significance (Table 5).

SDMA concentrations were positively related to NO_x before and 3 mo after TIPS placement ($r = 0.53$; $P = 0.027$, and $r = 0.60$; $P = 0.025$, respectively). ADMA was also related to NO_x plasma levels 3 mo after TIPS placement ($r = 0.67$; $P = 0.009$). Neither significant relations were present between arginine/ADMA ratios and NO_x plasma levels nor between NO_x concentrations and portosystemic pressure gradient.

Relations between dimethylarginines and hepatic and renal function

ADMA was positively related to Child-Pugh score before and 3 mo after TIPS placement ($r = 0.44$; $P = 0.034$ and $r = 0.59$; $P = 0.028$, respectively). SDMA was positively related to Child-Pugh score 3 mo after TIPS placement ($r = 0.66$; $P = 0.011$).

SDMA was related to creatinine clearance rate before and 3 mo after TIPS placement ($r = -0.70$; $P < 0.001$, $r = -0.85$; $P < 0.001$, respectively). ADMA was also related to creatinine clearance rate 3 mo after TIPS placement ($r = -0.70$; $P = 0.007$).

Neither ADMA nor SDMA was related to porto-systemic pressure gradient.

DISCUSSION

The main finding in the present study was an increase of the arginine/ADMA ratio three months after placement of TIPS in cirrhotic patients. In addition, TIPS placement caused a decrease in SDMA levels which may be partially explained by an advantageous effect on renal function as reflected by an increase in creatinine clearance rate due to TIPS placement. Interestingly, when patients with and patients without renal dysfunction before TIPS placement were studied separately, both the arginine/ADMA ratio and the creatinine clearance rate improved significantly in patients with renal dysfunction before TIPS placement, while these changes were not seen in patients with normal renal function. The advantageous effect of TIPS placement on renal function is also reflected by the strong and significant correlation between SDMA plasma levels and creatinine clearance before and particularly after TIPS placement. The relation between dimethylarginines and creatinine clearance rate has already been shown in patients with renal insufficiency[22]. Interestingly, the clearing of SDMA is not only confined to the kidney, but the human liver also takes up substantial amounts of SDMA[3]. Indeed, we also found a relation between SDMA and Child-Pugh score, thereby underlining the reported SDMA clearing capacity of the liver. Thus, increased SDMA levels in our studied cirrhotic patients may be caused by a combination of renal and hepatic dysfunction. Also for ADMA, we observed increased plasma concentrations at baseline being also closely related to the severity of liver dysfunction. This is in accordance with the findings of Lluch and coworkers[7] who likewise reported a direct relationship with the Child-Pugh score of patients being evaluated.

The main metabolic route for ADMA is degradation *via* DDAH[23] and the liver, which has a high DDAH activity, has been shown to be an important regulator of plasma ADMA levels in both animals and humans[2,3]. In portal hypertensive conditions, a recent study of Mookerjee and coworkers[24] showed reduced DDAH expression and increased ADMA levels in liver tissue of patients with severe alcoholic hepatitis. In addition, they suggested that elevated dimethylarginines may serve as a marker of a deleterious outcome in patients with alcoholic hepatitis. Also, in patients undergoing liver transplantation, ADMA has been shown to be a potential marker of acute allograft rejection[4]. Moreover, in cirrhotic animals, significantly decreased hepatic clearance of ADMA has been demonstrated[25].

In our study population, systemic ADMA concentrations did not decrease after TIPS placement. This is not surprising considering the well-known TIPS-induced decrease in hepatic extraction capacity. In other words, we assumed ADMA levels to increase after TIPS placement due to shunting and thus less degradation by hepatic DDAH. However, this increasing effect on ADMA serum levels induced by the TIPS implantation may be offset by the observed increase in renal function and the most likely improvement in renal ADMA clearance. In fact, ADMA plasma levels strongly correlated with creatinine clearance 3 mo after TIPS placement. Moreover, these data are in accordance with the observation of unaltered liver function represented by the lack of significant changes in biochemical laboratory parameters indicating hepatic function nor in Child-Pugh score after TIPS placement. Because we did not measure arterial dimethylarginine concentrations nor organ blood flow of the liver and kidney, no definite conclusions can be drawn about hepatic and renal elimination of dimethylarginines. Nonetheless, renal dysfunction often develops in patients with severe liver disease and a causal role for ADMA has been proposed in the development of the hepatorenal syndrome[26]. Recently, Lluch and co-workers[16] studied dimethylarginine concentrations in cirrhotic patients with hepatorenal syndrome and confirmed this hypothesis. Moreover, they suggested that SDMA may be a marker of renal dysfunction in cirrhotic patients. Therefore, the lack of an increase in ADMA and actual decrease in SDMA levels may well contribute to the well-known beneficial effects of TIPS with respect to neurohormonal status and kidney function in liver cirrhosis.

In liver cirrhosis, Laleman and co-workers[25] substantiated the potential role of ADMA in the

pathogenesis of impaired intrahepatic NO production. The known decrease in intrahepatic NO synthase activity in rats with biliary cirrhosis was found to be associated with an increase in circulating ADMA concentrations. In addition, endothelium-dependent vasorelaxation, measured in a liver perfusion model, was reduced in bile-duct ligated rats and addition of ADMA to the perfusate further blunted this vasodilatory response. However, in our study no association between ADMA levels and the severity of portal hypertension could be detected. A potential explanation may be the mode of action by which TIPS lowers portal pressure being independent from ADMA. Moreover, also SDMA has been reported to interfere with NO synthesis by competing with arginine for transport across cell membranes[10]. Especially high levels of SDMA in combination with low arginine concentrations may decrease NO synthesis significantly and hemodynamical consequences may be the same as reported for ADMA[23,27].

The gut produces citrulline which is used by the kidneys to synthesize arginine. It can be hypothesized that a decrease in portal pressure will have an advantageous effect on blood flow and function of the intestines, thereby increasing citrulline production by the gut and possibly enhancing renal arginine synthesis. Arginine is degraded in the liver that contains large amounts of arginase which breaks down arginine into urea and ornithine. TIPS placement may lead to a decreased capacity to eliminate arginine in the liver because blood does not enter the hepatocyte, but shunts directly from a portal branch into the hepatic vein. This may explain the increase in arginine plasma levels after TIPS placement. As a precursor of NO, this increase in arginine concentrations may enhance renal blood flow, thereby stimulating glomerular filtration rate and clearing a larger amount of dimethylarginines from the systemic circulation. This compensatory increase in renal excretion of dimethylarginines in fact will prevent a rise in ADMA levels induced by TIPS-induced portal decompression.

Liver cirrhosis is characterized by excessive systemic and particularly splanchnic NO production representing the pathophysiological hallmark in the development of the hyperdynamic circulatory syndrome. This vascular NO overproduction is stimulated by an in increase in portal pressure[28] and is an attempt to open the portal circulation and to enhance collateral blood flow in the systemic circulation bypassing the hepatic circulation. Besides a rise in arginine levels, the arginine/ADMA ratio increased significantly after TIPS placement. Theoretically, an increase in the arginine/ADMA ratio leads to an elevation in NO bioavailability. In our study, nonetheless, NO_x plasma levels showed a decreasing tendency after TIPS placement. While no relationship was found between NO_x and the arginine/ADMA ratio, both ADMA and SDMA were positively related to NO_x levels. This finding substantiates the hypothesis that dimethylarginines might oppose the peripheral vasodilation caused by excessive systemic NO production during liver cirrhosis[7]. It can be hypothesized that after TIPS placement, portal pressure drops and thus the main stimulus for splanchnic NO overproduction is greatly attenuated. In addition, renal and probably also gut function improve, thereby causing arginine synthesis (*via* gut-derived citrulline) by the kidney to increase. Furthermore, ADMA slightly decreases due to enhanced function of the kidney causing the arginine/ADMA ratio to increase. This is advantageous for the y^+ pump that is now able to transport more arginine into the cell, where it is converted to NO. The increased arginine/ADMA ratio after TIPS may result in a better NO-availability on tissue level, while systemic (plasma) NO is decreased due to less splanchnic NO release.

In conclusion, the main finding of the present study was a significant increase in the arginine/ADMA ratio in cirrhotic patients 3 mo after TIPS placement. In addition, TIPS enhanced renal function and concomitantly significantly lowered systemic SDMA levels, but did not change hepatic function. In line with this unaltered liver function, no significant decline in ADMA plasma levels could be detected, thereby confirming the major role of the liver as ADMA clearing organ.

COMMENTS

Background

Asymmetric dimethylarginine (ADMA) plays a regulatory role in the arginine-nitric oxide (NO) pathway by inhibiting the enzyme NO synthase. In addition, dimethylarginines may play an important pathophysiological role in liver cirrhosis because this disease is characterised by endothelial dysfunction and NO deficiency in the intrahepatic circulation. In cirrhotic patients, elevated peripheral ADMA and NO levels have been reported and it has been suggested that ADMA might oppose the peripheral vasodilation caused by excessive systemic NO production during liver cirrhosis. In order to analyse dimethylarginine plasma levels in cirrhotic humans, authors studied patients receiving transjugular intrahepatic portosystemic shunt (TIPS).

Research frontiers

Elevated ADMA levels have been reported in patients eligible for liver transplantation in postoperative patients undergoing major liver resection, in patients suffering from decompensated alcoholic cirrhosis, and in critically ill patients with hepatic dysfunction. In fact, increased intrahepatic vascular resistance in cirrhosis is not only due to structural changes, but also due to a dynamic component. It has been suggested that an alteration in intrahepatic ADMA levels may lead to endothelial dysfunction and increased intrahepatic resistance. In cirrhotic patients, elevated peripheral ADMA and NO levels have been reported and it has been suggested that ADMA might oppose the peripheral vasodilation caused by excessive systemic NO production during liver cirrhosis.

Innovations and breakthroughs

This study shows an increase of the arginine/ADMA ratio after TIPS placement suggesting an increase in intracellular NO bioavailability. In addition, this study suggests that TIPS placement does not alter dimethylarginine dimethylaminohydrolase (DDAH) activity and confirms the major role of the liver as ADMA clearing organ.

Applications

TIPS placement is associated with an increased arginine/ADMA ratio suggesting an increased NO bioavailability which could have a positive effect on the microcirculation of important organs.

Peer review

In this study, the levels of ADMA, symmetric dimethylarginine (SDMA) and arginine in caval/portal and hepatic vein as well as the NO_x plasma levels in patients with cirrhosis were analyzed. Most of patients enrolled in this study suffered from alcohol-induced liver disease. The key finding of the manuscript is that arginine levels increase after TIPS-placement. The study is interesting and well performed.

Abstract

AIM: To assess the efficacy and advantages of 4-wk pegylated interferon α-2a (peg-IFN-α2a) monotherapy for chronic hepatitis C patients with strong predictors of sustained virologic response (SVR).

METHODS: Patients (n = 33) with genotype 2 and low viral load (< 100 KIU/mL), who became HCV RNA negative after 1 wk of IFN treatment, were randomly allocated to receive a 4- or 12-wk treatment course at a ratio of 2:1, respectively, with a subsequent 24-wk follow-up period. Peg-IFN-α2a was administered subcutaneously at a dose of 180 μg or 90 μg once weekly. SVR was defined as absence of serum HCV RNA at the end of the follow-up period.

RESULTS: All patients completed the treatment schedule, and more than half were symptom-free during the treatment. In the 4-wk treatment group, 20 of 22 (91%) patients achieved SVR. Two patients relapsed, but achieved SVR following re-treatment with peg-IFN-α2a alone. In the 12-wk treatment group, 11 of 11 (100%) patients attained SVR.

CONCLUSION: Our results show that a 4-wk course of peg-IFN-α2a monotherapy can achieve a high SVR rate in "IFN-sensitive" patients, without negatively affecting outcome.

INTRODUCTION

Pegylated interferon alpha (peg-IFN-α) in combination with ribavirin for 24 wk is currently recommended as a standard treatment for patients with hepatitis C virus (HCV) genotypes 2 and 3, because prolongation of treatment duration to 48 wk does not always provide a substantial gain in the sustained virologic response (SVR) rate[1-5]. In contrast, short-term combination treatment (i.e. less than 24 wk of duration) has been evaluated in genotype 2 and 3 patients with or without initial virological response[6-11]. Shorter treatment may lead to a substantial reduction in patients' burden and to the avoidance of premature termination of treatment without adversely affecting the outcome. Still, the pros and cons of a shorter treatment have not been conclusively defined and treating patients for less than 24 wk is still controversial.

A recent trend in the treatment strategy for chronic hepatitis C is the development of tailored or

individualized treatment regimens based on major strong predictors of SVR to IFN-based treatment, such as HCV genotype[2,3,12-17], pretreatment viral load[2,4,12,14,15,18], and initial virologic response to treatment[15,19-24]. Further subdivision or stratification of patients by combining these predictors may allow the development of more rational and optimal regimen without adversely affecting the outcome: e.g. treatment duration or combination with or without ribavirin. Specifically, a subgroup of genotype 2 patients with low viral load showed an excellent response even to conventional IFN monotherapy[12-14,18]. Furthermore, if initial virologic response is also taken into consideration in determining treatment regimen for the "IFN-sensitive" patient subgroup, even a shorter course of peg-IFN-α2a monotherapy might result in a high SVR rate without adversely affecting the outcome.

In the present study, we evaluated the efficacy and tolerability of a 4-wk peg-IFN-α2a monotherapy for "IFN-sensitive" patients with genotype 2 and low viral load, who became HCV RNA negative after 1 wk of treatment, in a pilot, randomized trial comparing a 4-wk *versus* a 12-wk treatment schedule. This study may allow us to substantially reduce the total dose and duration of peg-IFN-α treatment and to spare the use of ribavirin in the "IFN-sensitive" patient subgroup.

MATERIALS AND METHODS

Study population

Thirty-seven patients chronically infected with HCV genotype 2 and low viral load were consecutively enrolled in this pilot randomized study. They received short-term peg-IFN-α2a monotherapy at the Department of Gastroenterology and Hepatology, Kashiwa Hospital, the Jikei University School of Medicine, between August 2006 and July 2007. Eligible patients had anti-HCV antibodies, infection with HCV genotype 2 confirmed by polymerase chain reaction (PCR)-based method[25], serum HCV RNA levels < 100 kilo-international units (KIU)/mL by a quantitative PCR assay (Amplicor HCV Monitor Version 2.0, Roche Diagnostics, Tokyo, Japan; lower detection limit, 0.5 KIU/mL) (defined as 'low' viral load) at the enrolment, persistently abnormal serum alanine transaminase (ALT) concentrations (> 30 IU/L) during the preceding 24 wk, platelet counts ⩾ 50 × 10^3/μL, neutrophil counts ⩾ 750 /μL, and hemoglobin values ⩾ 10 g/dL. All patients were ⩾ 20 years of age and none had received prior IFN-containing treatment. Exclusion criteria were: liver cancer or decompensated liver cirrhosis; other forms of liver disease; coexisting serious psychiatric or medical illness; treatment with any other antiviral or immunomodulatory agent administered within the preceding 12 wk; hepatitis B surface antigen or hepatitis B core antibody; and pregnancy or lactation. The Local Ethics Committee of Jikei University School of Medicine approved the study. All patients provided informed consent before entry into the trial. Liver biopsy was performed between the enrolment and the beginning of treatment, and histopathologic evaluation was carried out using the ranking system for grading of necroinflammation activity and staging of fibrosis[26]. Steatosis was graded as mild (< 30% of hepatocytes contained lipid droplets in the cytoplasm), moderate (30%-60%), or severe (> 60%).

Study protocol

When patients showed virological response (VR) after 1 wk of treatment, patients were randomly allocated to receive a 4- or 12-wk treatment course at a ratio of 2:1 using a central randomization system, respectively, with a subsequent 24-wk follow-up period. Randomization was performed by means of sealed, opaque, numbered envelopes, each containing a sheet of paper assigning to either group, which were prepared independently by a medical statistician. The total sample size was estimated statistically (two-sided $\alpha = 0.10$, $\beta = 0.20$). Patients without VR after 1 wk were excluded from the trial, and all received a 12-wk treatment course. VR was defined as undetectable serum HCV RNA, using a qualitative PCR assay (Amplicor HCV version 2.0, Roche Diagnostics) with a lower detection limit of 50 IU/mL. Peg-IFN-alpha-2a (Roche, Nutley, NJ) at a dose of 180 μg (platelet count > 90 × 10^3/μL and neutrophil count > 1500/μL) or 90 μg (< 90 × 10^3/μL and < 1500/μL, respectively) was administered subcutaneously once weekly. During the treatment, the dose of peg-IFN was adjusted based on platelet and/or neutrophil counts determined before each administration: Peg-IFN was reduced from 180 to 90 μg when platelet or neutrophil counts fell below 90 × 10^3/μL and 1500/μL, respectively, and from 90 to 45 or 30 μg when platelet or neutrophil counts fell below 70% of the values observed the previous week. Peg-IFN was discontinued when the platelet count, the neutrophil count, or the hemoglobin value dropped below 25 × 10^3/μL, 500/μL, and 8.5 g/dL, respectively.

Clinical, laboratory and hematological data were assessed once weekly during the treatment and every 4 wk during the 24-wk follow-up period. Virological assessment was performed after 1 wk from the initiation of treatment, at the end of treatment, and every 4 wk during the follow-up period. Sustained virologic response (SVR) was defined as undetectable serum HCV RNA at the end of follow-up period. Safety was monitored clinically by careful interview and medical examination throughout the study.

Statistical analysis

The χ^2 test, Fisher's exact two-tail test, or Mann-Whitney test were used for statistical comparisons between groups, where appropriate. Treatment outcomes were analyzed on an intention-to-treat basis. All *P* values for statistical tests were two-tailed and values less than 0.05 were considered statistically significant. All calculations were performed using the SPSS 15.0 statistical package (SPSS, Chicago, IL).

RESULTS

Patient characteristics

Of 37 patients, 33 (89%) showed VR after 1 wk

Table 1 Characteristics of treatment-naïve chronic hepatitis C patients with genotype 2 and low viral load at the start of treatment (mean ± SD)

	4-wk treatment group (n = 22)	12-wk treatment group (n = 11)
Gender (M/F)	10/12	6/5
Age (yr)	57 ± 10	56 ± 12
Body weight (kg)	58.5 ± 10.7	60.6 ± 10.4
Body mass index (kg/m^2)	23.0 ± 2.9	21.8 ± 2.2
History of transfusion (yes/no)	10/12	3/8
Initial dosage (180 μg/90 μg)	20/2	9/2
Aspartate transaminase (IU/L)	53 ± 27	55 ± 32
Alanine transaminase (IU/L)	75 ± 35	77 ± 36
γ-glutamyl transpeptidase (IU/L)	52 ± 24	48 ± 30
Albumin (g/dL)	4.3 ± 0.3	4.2 ± 0.3
Total cholesterol (mg/dL)	169 ± 22	182 ± 35
Platelet count (× 10^3/μL)	157 ± 58	165 ± 62
Hemoglobin (g/dL)	13.3 ± 1.6	13.6 ± 1.8
Leukocyte count (/μL)	4700 ± 1500	5300 ± 900
Neutrophil count (/μL)	2490 ± 1140	2550 ± 613
Liver histology		
Stage (1/2/3/4)	9/5/5/0	5/4/2/0
Grade (mild/moderate/severe)	11/8/0	8/3/0
Steatosis (mild/moderate/severe)	15/4/0	9/2/0
Viral load (KIU/mL)	24 ± 21	24 ± 22

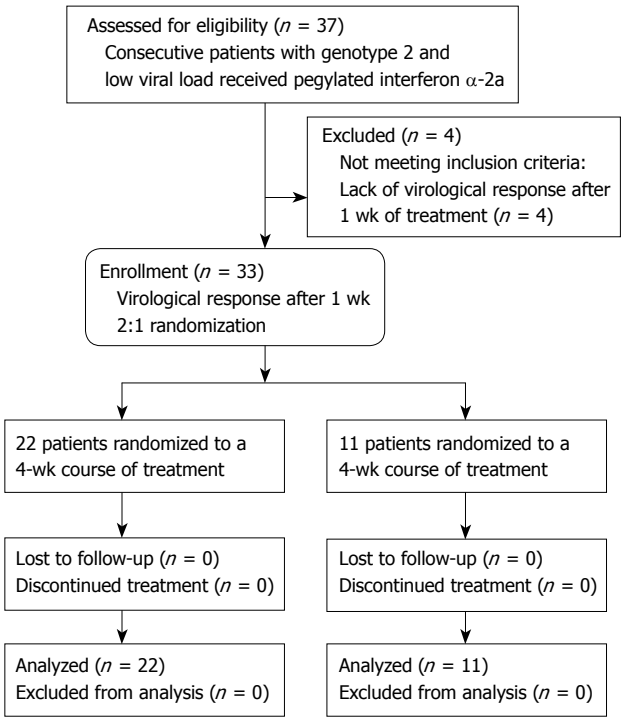

Figure 1 Flow diagram of patients included in the pilot study.

of treatment. The 33 patients were subsequently randomized to the 4-wk (n = 22) or the 12-wk (n = 11) treatment arms (Table 1, Figure 1). There was no statistically significant difference between the two groups as far as the baseline characteristics features were concerned. Irrespective of the treatment course, all 33 patients completed the treatment and were closely followed up as scheduled. None of the patients was lost to follow-up. None of the patients received growth factors for cytopenias, such as granulocyte-colony stimulating factor and erythropoietin. A liver biopsy was not available in 3 patients because of a bleeding disorder (n = 1, 4-wk treatment group) or because of patients' refusal (n = 2, both for the 4-wk treatment group).

Sustained virological response rates

In the 4-wk treatment group, 20 of 22 (91%) patients achieved SVR. Two patients relapsed 8 wk after the end of treatment. In the 12-wk treatment group, 11 of 11 (100%) patients attained SVR. No statistical difference was observed between both groups as to the SVR rates. The two patients who relapsed were offered re-treatment (4-wk and 12-wk regimens, respectively): both agreed and achieved SVR.

Predictors of sustained virological response or relapse

Univariate analyses failed to identify factors (including patients' age, body weight, and the presence of steatosis) associated with SVR or relapse.

Safety

Six patients in the 4-wk treatment group and five in the 12-wk treatment group complained of low-grade fever, headache, or malaise, but these symptoms were well tolerated during treatment. The dose of peg-IFN-α2a was reduced in three (all for thrombocytopenia) and four (two for neutropenia and two for thrombocytopenia) patients, respectively. Consequently, the cumulative dose of peg-IFN-α2a was 180 to 720 μg and 1350 to 2160 μg, respectively. All patients recovered completely from the adverse events after the completion of treatment.

Medication price

On the basis of current prices in Japan, the cost of medication (peg-IFN-α2a of 90 or 180 μg weekly) for 4-wk treatment course is between 536 and 1044 USD, and that for 12-wk treatment course is between 1608 and 3131 USD.

DISCUSSION

The results of this randomized pilot study suggest that a subgroup of patients could achieve a sufficiently high rate of SVR after only a 4-wk course of peg-IFN-α2a monotherapy. One of the most IFN-sensitive subgroups appears to include patients with genotype 2 and low viral load who exhibit VR after 1 wk of treatment.

Patients with genotype 2 or 3 are more sensitive to peg-IFN-α plus ribavirin treatment than those with genotype 1, and the current recommendation advocates a 24-wk treatment course, because more than 80% of the former group will attain SVR[3-5,7,11,27]. Recently, several studies suggested that the treatment duration could be shortened from 24 to between 12 and 16 wk without adversely affecting outcome in patients with genotype 2 or 3 who achieve VR after 4 wk of treatment[6-8,11]. In contrast, large trials indicated that shortening the treatment duration to 16 or 14 wk lessened the SVR rates[9,10]. It remains controversial whether the optimal

treatment duration is 24 wk or less than 24 wk for patients with genotype 2 or 3. A shorter treatment may not to be suitable for every patient with genotype 2 or 3. There may be a need to investigate whether the 4 wk timepoint from the beginning of treatment is appropriate to predict the therapy outcome after 24-wk treatment course.

There is ample evidence that peg-IFN-α plus ribavirin treatment is more beneficial in patients with genotype 2 than those with genotype 3[4,7-10]. This suggests that treatment regimens should be tailored or individualized for each genotype, with a special emphasis on the duration of treatment. As for patients with genotype 2 alone, even high-dose conventional IFN-α monotherapy for 24 wk produced an SVR rate of 78%[14]. Furthermore, the inclusion of baseline viral load and initial virologic response, as strong predictors of SVR independent of genotype[4,6,7,10,11,15,16,19-24,27], may identify patients suitable for shorter treatment in a more accurate way. In a small size study, an SVR rate of 100% was reported in patients with genotype 2a and low viral load (< 100 KIU/mL) treated with IFN-α for 6 wk[28]. In another study, 89.5% and 100% of patients, without genotype 1 and high viral load (> 100 KIU/mL), who showed VR after 2 wk of treatment, achieved SVR with 8-wk and 24-wk peg-IFN-α2a monotherapy, respectively[29]. Although the sample size was very small, this pilot randomized trial suggested that the duration of peg-IFN-α2a monotherapy may be further shortened while maintaining a high SVR rate by dividing patients according to the presence or absence of strong predictors of response.

Common or characteristic adverse events are more severe and frequent in the combination treatment with ribavirin than in IFN-α or peg-IFN-α monotherapy, especially with prolonged treatment duration, leading to frequent withdrawals from treatment, because ribavirin accumulates in various tissues as well as in erythrocytes[2,15,24]. Therefore, only a minority of patients in need of therapy actually receives peg-IFN-α plus ribavirin treatment. Before participation in this trial, IFN-based treatment has been withheld from some patients for a variety of reasons such as advanced age, or the relatively low hemoglobin level and/or platelet count. Symptoms recorded in this study were mild or few, supporting the view that a short treatment course is safer and associated with few adverse events and less frequent withdrawal from treatment[1,2,7,8,11,30]. Our trial demonstrated that a 4-wk peg-IFN-α2a monotherapy was safe for such patients, and suggested that the indication for treatment could be extended to include patients considered otherwise unsuitable for the peg-IFN-α plus ribavirin combination therapy.

The combination treatment is costly, and the longer the treatment duration, the higher the cost of treatment. Currently, the cost of treatment of a person weighing 65 kg who receives peg-IFN-α2a at 180 μg weekly and ribavirin at 800 mg daily for 24 wk is approximately 11253 USD in Japan. Thus, a 4-wk peg-IFN-α2a monotherapy would achieve a > 90% reduction in cost and drug exposure. When one adds the costs of medical consultation and laboratory tests, the 4-wk peg-IFN-α2a monotherapy provides a substantial saving in costs and inconvenience compared to the extended treatment.

In conclusion, the present study showed high SVR rates in genotype 2 patients with low viral load who had undetectable serum HCV RNA after 1 wk of treatment, treated with a 4-wk course of peg-IFN-α2a monotherapy. Tailoring or individualizing treatment to individual patients would considerably reduce both patients' and society burdens, without adversely affecting the clinical outcome.

COMMENTS

Background

Hepatitis C virus (HCV) genotype, pretreatment viral load and initial virologic response are major predictors of the treatment outcome in interferon (IFN)-based treatment for chronic hepatitis C. Patients infected with genotype 2 or 3 are currently recommended to receive a 24-wk course of pegylated IFN alpha (peg-IFN-α) plus ribavirin combination therapy. However, treatment regimens should be modified for those subgroups of genotype 2 patients with favorable predictors.

Research frontiers

To improve the treatment outcome while reducing the adverse effects and treatment costs, peg-IFN-α plus ribavirin combination treatment regimens for chronic hepatitis C are rationally tailored or reasonably individualized based on major predictors of response. The duration of combination therapy for genotype 1 or 4 patients is modified from 24 wk to 48 or 72 wk according to virological response after 4 wk, 12swk and 24 wk after treatment. In contrast, it remains controversial whether the treatment duration for genotype 2 or 3 patients could be shortened from 24 wk to 12, 14 or 16 wk according to the virological response after 4 wk of therapy.

Innovations and breakthroughs

This pilot, randomized study demonstrates that further stratification of patients by combining strong predictors may shorten the treatment duration and allow peg-IFN-α monotherapy without adversely affecting the outcome, leading to the substantial reduction in both patients' and society burdens. Moreover, this study questions whether the virological response at 4 wk after treatment is appropriate for efficiently discriminating the treatment outcome in a 24-wk treatment course for genotype 2 patients.

Applications

This randomized pilot study suggests that further stratification by combining strong predictors may be extended to individuals infected with other genotypes in tailoring or individualizing more rational and optimal regimens.

Terminology

Virological response is defined as undetectable serum HCV RNA (< 50 IU/mL). Treatment outcome means sustained virologic response, defined as undetectable serum HCV RNA at the end of the 24-wk follow-up period.

Peer review

This is an interesting and well-written manuscript describing an important issue in hepatitis C treatment.

Abstract

AIM: To evaluate the efficacy of pegylated interferon α-2b (peg-IFNα-2b) plus ribavirin (RBV) therapy in Japanese patients with chronic hepatitis C (CHC) genotype Ib and a high viral load.

METHODS: One hundred and twenty CHC patients (58.3% male) who received peg-IFNα-2b plus RBV therapy for 48 wk were enrolled. Sustained virological response (SVR) and clinical parameters were evaluated.

RESULTS: One hundred (83.3%) of 120 patients completed 48 wk of treatment. 53 patients (44.3%) achieved SVR. Early virological response (EVR) and end of treatment response (ETR) rates were 50% and 73.3%, respectively. The clinical parameters (SVR *vs* non-SVR) associated with SVR, ALT (108.4 IU/L *vs* 74.5 IU/L, $P = 0.063$), EVR (76.4% *vs* 16.4%, $P < 0.0001$), adherence to peg-IFN (≥ 80% of planned dose) at week 12 (48.1% *vs* 13.6%, $P = 0.00036$), adherence to peg-IFN at week 48 (54.7% *vs* 16.2%, $P < 0.0001$) and adherence to RBV at week 48 (56.1% *vs* 32.1%, $P = 0.0102$) were determined using univariate analysis, and EVR and adherence to peg-IFN at week 48 were determined using multivariate analysis. In the older patient group (> 56 years), SVR in females was significantly lower than that in males (17% *vs* 50%, $P = 0.0262$). EVR and adherence to Peg-IFN were demonstrated to be the main factors associated with SVR.

CONCLUSION: Peg-IFNα-2b plus RBV combination therapy demonstrated good tolerability in Japanese patients with CHC and resulted in a SVR rate of 44.3%. Treatment of elderly female patients is still challenging and maintenance of adherence to peg-IFNα-2b is important in improving the SVR rate.

INTRODUCTION

In Japan, annual mortality due to liver cancer exceeds 30 000 and 75% of liver cancer is associated with hepatitis C virus (HCV) infection[1]. The combination of pegylated interferon (peg-IFN) plus ribavirin (RBV) is one of the most effective therapies for chronic hepatitis C (CHC), and the effect of this combination is reported to be higher than conventional interferon[2,3]. However, the majority of Japanese CHC patients are infected with HCV genotype Ib and have a high viral load, and treatment with conventional interferon has its difficulties[4]. CHC patients in Japan tend to be older than CHC patients in other countries therefore, problems such as a higher incidence of liver cancer and lower tolerability to treatment have been observed[4,5]. The HCV strain and the efficacy of interferon treatment vary between races and countries[6,7]. Identification of the factors associated with treatment efficacy is extremely important, however, few studies involving large populations have reported on the treatment of Japanese CHC patients with pegylated interferon alpha-2b (peg-IFNα-2b) plus RBV[8,9]. In this study, we evaluated the efficacy and safety of peg-IFNα-2b plus RBV therapy in CHC genotype Ib patients with a high viral load. This treatment became available in Japan for health insurance approved treatment from December 2004. In addition, we attempted to identify predictive factors for treatment outcome.

MATERIALS AND METHODS

Study population

One hundred and thirty CHC genotype Ib patients with a high viral load, who received peg-IFNα-2b plus RBV therapy in our hospital or our affiliated institutions between December 2005 and November 2006 were enrolled in this study. The diagnosis of CHC was based on the following criteria; HCV antibody positive, HCV-RNA positive and elevation of serum alanine aminotransferase (ALT) activity (> 35 IU/L) within 6 mo of screening. Exclusion criteria were leucopenia [white blood cell (WBC) count < 3000/μL], neutropenia [neutrophil (ne) count <1500/μL], thrombocytopenia [platelet (PLT) count < 90 000/μL], anemia [hemoglobin (Hb) < 12 g/dL], cirrhosis, creatinine clearance < 50 mL/min, uncontrolled mental disorder, severe heart or lung disease, or autoimmune disease. The study was approved by the ethical committee of Tohoku University according to the Declaration of Helsinki. All patients gave written informed consent before enrollment.

Treatment regimen

The patients received peg-IFNα-2b (Pegintron®; Schering-Plough, Kenilworth, NJ, USA) at a dosage of 1.5 mg/kg every week subcutaneously for 48 wk. Daily RBV (Rebetol®, Schering-Plough) was given orally for 48 wk and the dosage was adjusted according to weight (600 mg for ⩽ 60 kg, 800 mg for 60 to 80 kg, 1000 mg for > 80 kg). Blood samples were obtained every four weeks and were analyzed for biochemical parameters including ALT and HCV RNA levels. The HCV genotype was determined using a kit. HCV genotype was determined by PCR using a mixed primer set derived from the nucleotide sequences of the NS5 region. HCV RNA levels were measured by quantitative RT-PCR (Amplicor, Roche Diagnostic Systems, CA, USA). HCV RNA negativity was evaluated by qualitative RT-PCR (Amplicor, Roche), which has a higher sensitivity than the quantitative method. The lower limit of the assay in the quantitative method was 5 KIU/mL (equivalent to 5000 copies/mL) and was 50 IU/mL (equivalent to 50 copies/mL) in the qualitative method. Early virological response (EVR) was defined as undetectable HCV RNA after 12 wk. Sustained virological response (SVR) was defined as undetectable HCV RNA at 24 wk after completion of treatment.

Statistical analysis

Fisher's exact test and the Mann-Whitney *U* test were used to evaluate the parameters [age, sex, weight, body mass index (BMI), EVR, peg-IFN adherence, RBV adherence, HCV RNA, ALT, WBC, Hb, and PLT] to determine SVR. Quantitative data were divided into two groups using the median to examine the differences. We conducted multivariate analysis using binary logistic regression on the parameters which achieved statistical significance ($P < 0.05$) using univariate analysis. All analyses were performed using a statistical software package (StatView-J version 5.0, SAS Institute Inc. Cary, NC, USA).

RESULTS

Patient characteristics

The details of clinical background, blood biochemistry and virological data on the CHC patients who received peg-IFNα-2b plus RBV therapy are shown in Table 1. Seventy of 120 patients (58.3%) were male, and 50 patients (41.7%) were female. The mean age was 54.8 years, and the median age was 56 years. The mean age of males was 54.1 years, and the mean age of females was 55.8 years. The median BMI was 23.6. Seventy seven patients (64.2%) had no previous history of IFN treatment and 41 patients (34.2%) had been treated with IFN previously. Of these previously treated patients, 8 were null-responders (patients who did not achieve a virological or biochemical response during IFN treatment), 15 were relapsers, and 18 patients had no available virological response.

Treatment efficacy

One hundred of 120 patients (83.3%) completed 48 wk of treatment and 24 wk of follow up. Using intention to treat (ITT) analysis, 53 patients (44.3%) achieved SVR. The rate of EVR was 50%. Response rate at the end of treatment was 73.3%. The transition rate of HCV RNA negativity with time is shown in Figure 1. Patients discontinued treatment due to depression in 3, neutropenia in 3, retinopathy in 2, anemia in 1,

Relationship between clinical parameters and SVR

The association between SVR rate and the baseline clinical parameters before treatment or treatment-related factors was examined using univariate analysis. The following baseline factors were analyzed: age, sex, BMI, HCV RNA level, ALT, WBC, Hb, and PLT. A summary of these results is shown in Table 2. The mean ALT level in patients who achieved SVR was 108.4 IU/L, which was significantly higher than the ALT level of 74.5 IU/L in the non-SVR group ($P = 0.0478$). The PLT level in patients in the SVR group was 1.73 ×10^5/μL, which was higher than the PLT level of 1.55 ×10^5/μL in the non-SVR group ($P = 0.063$). To determine the factors associated with treatment outcome, we examined the relationship between the SVR ratio and achievement of EVR or adherence to peg-IFN and RBV. A summary of these results is shown in Table 2 and Figure 2. As shown in Table 2, the ratio of patients who achieved EVR was

Overall (≥ 80%/< 80%)	35/41 (85.4%)	29/60 (48.3%)	0.0001
Cumulative exposure to RBV			
12 wk (≥ 80%/< 80%)	41/50 (82%)	44/63 (69.8%)	0.1882
Overall (≥ 80%/< 80%)	32/50 (64%)	25/63 (39.7%)	0.0138

ALT: Alanine aminotransferase; WBC: White blood cell; EVR: Early virological response; Peg-IFN: Pegylated interferon; RBV: Ribavirin.

Table 3 Multivariate analysis of association between sustained virological response and influential factors

Factor	Coefficient	χ^2	Odds ratio (95% CI)	*P*
EVR (not achieved)	-2.725	19.325	0.066 (0.019-0.221)	< 0.0001
Cumulative exposure to peg-IFN				
Overall (≥ 80%)	2.392	6.600	10.934 (1.763-67.82)	0.0102
Constant	1.294			

EVR: Early virological response; Peg-IFN: Pegylated interferon.

significantly higher in the SVR group than in the non-SVR group ($P < 0.0001$). The SVR rate in patients who achieved EVR was 76.4%, and this was significantly higher than the SVR rate in the non-EVR group which was 16.4% ($P < 0.0001$). The ratio of patients who received 80% or more of the scheduled dose of peg-IFN or RBV was significantly higher in the SVR group than in the non-SVR group. The SVR rate in patients who received 80% or more of the scheduled dose of peg-IFN was 48.1% (12th wk) and 54.7% (overall). The SVR rate in patients who did not receive sufficient peg-IFN was 13.6% (12th wk) and 16.2% (overall), and these were significantly lower than the group who had good adherence. The group with adequate adherence to RBV (overall) showed an SVR rate of 56.1%, which was significantly higher than the SVR rate of 32.1% in the poor adherence group ($P = 0.0102$). For the factors which were determined as statistically significant by univariate analysis, we subsequently conducted multivariate analysis. The results of this analysis are shown in Table 3. Using binary logistic analysis, EVR and adherence to peg-IFN were determined to be independent predictive factors for SVR.

We examined a group of patients who were older than the median age (56 years). From the baseline factors obtained before treatment, sex was determined

to be a parameter which may be associated with SVR (Table 4). The SVR rate in females was 17%, which was significantly lower than the SVR rate of 50% in males

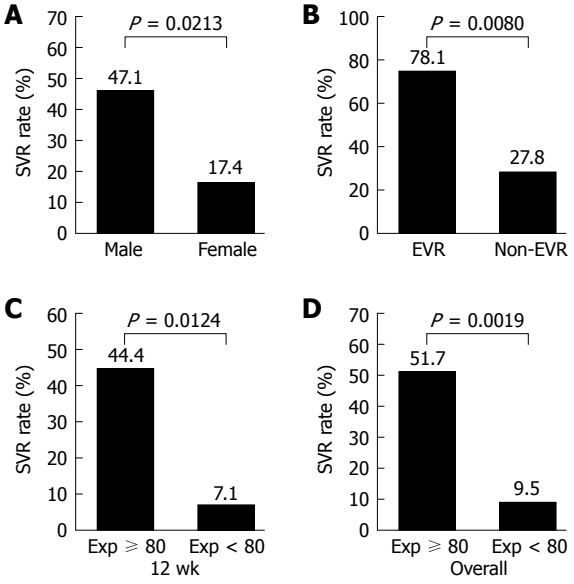

Figure 3 Clinical parameters in the older patient group (> 56 yr) associated with SVR rate using univariate analysis. A: The relationship between sex and SVR rate; B: The relationship between EVR and SVR. C and D: The relationship between cumulative exposure to peg-IFN and SVR.

(*P* = 0.0262) (Figure 3A). From the factors associated with treatment outcome, EVR and adherence to peg-IFN were demonstrated to be significant (Figure 3B). In particular, the SVR rate in the group with poor adherence to peg-IFN was 7.1% (1 of 14) at the 12th wk and was 9.5% (2 of 21) at the end of treatment. These rates were extremely low compared with the SVR rate of 44.4% (12th wk) and 51.7% (overall) in the group with good adherence to peg-IFN (Figure 3C and D).

DISCUSSION

One hundred of 130 patients completed peg-IFNα-2b plus RBV combination therapy in our hospital and related institutions. Treatment was discontinued in 13 patients (10.8%) due to adverse effects. The treatment showed good tolerability in Japanese patients. A study of peg-IFNα-2b plus RBV combination therapy in Caucasian and African American CHC patients reported a discontinuation rate of 21%[10]. Another study on Japanese CHC patients reported a 21% discontinuation rate[9]. Although we cannot compare these studies directly, it seems that tolerability in this study was satisfactory. At least in a clinical setting, peg-IFNα-2b plus RBV was well tolerated in our study of Japanese patients.

In this study, age, ALT level, EVR achievement, and adherence to Peg-IFN and RBV were associated with a high SVR rate using univariate analysis. After multivariate analysis, EVR and adherence to peg-IFN were demonstrated to be associated with SVR. Of the baseline factors assessed before treatment, age, sex, WBC, α-feto protein level, γ-glutamyl transpeptidase, and LDL-cholesterol have been reported to be associated with a high SVR rate following peg-IFNα-2b plus RBV therapy in CHC Japanese patients[8,11,12]. The results of this study were very similar to those of our

study. Davis *et al*[13] reported that EVR was considered to be associated with SVR in patients with CHC treated with IFN. As a result of this study, EVR was found to be one of the factors which most influenced SVR rate in Japanese patients treated with peg-IFNα-2b plus RBV combination therapy. In our study of older patients (older than the median), sex, EVR, and adherence to peg-IFN were associated with SVR rate. The SVR rate in older females was remarkably low at 17.4% compared to the SVR rate in all females included in the study which was 36.0% (data not shown).

Adherence to peg-IFN was found to influence the SVR rate as a treatment-related factor in this study. SVR rates were low in patients who did not receive 80% or more of the intended dose of peg-IFN. The effect of adherence to IFN on SVR has been reported previously[13-15]. In a study on peg-IFNα-2a/RBV therapy in patients with HCV genotype I, it was reported that the SVR rate in cases who had a reduction in RBV dosage before the 20th wk was remarkably low[15]. Furthermore, a reduction in RBV dosage and/or peg-IFNα-2a dosage after the 24th wk did not influence the SVR rate[15]. On the other hand, a study on African American patients with HCV genotype I reported that a reduction in peg-IFNα-2b dosage influenced the SVR rate more than a reduction in RBV dosage[14]. In the current study, adherence to RBV up to the 12th wk did not significantly influence the SVR rate, but overall adherence to RBV significantly influenced the SVR rate. Unlike the reports on Caucasian and African American patients, it may be that overall adherence to RBV is important in Japanese patients.

It was notable that adherence to peg-IFNα-2b significantly influenced SVR in this study. In the patients who did not receive 80% or more of the intended dose by the 12th wk, the SVR rate decreased markedly. Adherence to peg-IFNα-2b at the 12th wk may be critical in determining whether the treatment should be continued. It is often difficult to maintain adherence to peg-IFNα-2b simply to improve the SVR rate, because IFN dosage and the hematologic adverse effects of this drug are problematic[16,17]. Recently, a 72-wk treatment protocol for late virological responders was reported[18,19]. Further examination of the impact of prolonged administration in patients with poor adherence to peg-IFNα-2b is needed.

In conclusion, peg-IFNα-2b plus RBV combination therapy demonstrated good tolerability in Japanese patients with CHC, and resulted in a SVR rate of 44.3%. Treatment of older female patients and maintenance of adherence to peg-IFNα-2b are important factors in improving SVR rate.

COMMENTS

Background

Pegylated interferon α-2b (peg-IFNα-2b) plus ribavirin (RBV) is a standard treatment of chronic hepatitis C globally. However, the impact of this treatment in an ordinary clinical setting in Asian patients is still unclear.

Research frontiers

It is well documented that data from clinical practice is not comparable to those of clinical trials. This is believed to be derived from differences in recruited patients in phase Ⅱ and Ⅲ clinical trials and usual clinical settings (e.g. young *vs* elderly, highly motivated *vs* reluctant, *etc*).

Innovations and breakthroughs

The current study demonstrated that outcome is dependent on therapeutic adherence (> 80% of expected peg-IFN dosage). The overall treatment success [sustained virological response (SVR)] was 44.3%, almost equivalent to those in phase III clinical trials.

Applications

The total SVR rate was equivalent to clinical trials. The elderly, especially female patients showed a lower response to treatment. The reason for this is still unclear and future investigations are feasible in order to understand this observation.

Terminology

SVR indicates sustained virological response, which means sustained (more than 24 wk after treatment) viral clearance from the infected host.

Peer review

It is very important to describe the true clinical impact of global standard treatment in Asian races. Fortunately, the results were almost equivalent to those of other global regions. Although female patients seem to have a disadvantage with this treatment, these patients could have comparable results if adherence to both drugs is maintained.

Abstract

AIM: To investigate and identify prevalent hepatitis B virus (HBV) genotypes and to explore lamivudine-resistant mutations among treated and untreated patients in Jordan.

METHODS: A total of 107 cases with chronic hepatitis B were recruited from different medical centers in Jordan. Serological tests were preformed for all cases using a microparticle enzyme immunoassay. HBV Genotyping was performed for 70 cases using Line probe genotyping assay. The YMDD mutations were explored for 20 cases (4 were lamivudine naive) using the INNO-LiPA HBV DR assay.

RESULTS: Genotype D was the only detected genotype. A total of 6 YMDD mutations were detected in 5 treated patients (31%) while one mutation was detected in the naive patients. Seventeen percent of cases were positive for HBeAg and had statistically significant higher levels of serum aminotransferases.

CONCLUSION: HBV genotype D appears to be the only circulating type in Jordanian patients. The YMDD mutations were detected in 31% of lamivudine-treated cases with similar patterns to those found in the literature. We also found a relatively low prevalence of HBeAg expression among examined cases (17%). Awareness of these serologic, genotypic and resistance patterns might help in the formulation of management plans and for predicting clinical outcomes. Further larger scale studies are needed to confirm our results and to examine possible associations among clinical, serologic, and genetic patterns of HBV infections in Jordan.

INTRODUCTION

Infections with hepatitis B virus (HBV) continue to be a worldwide problem[1] and a considerable proportion of these infections usually progress to chronic infection and hepatocellular carcinoma[2]. In view of this significant diseases burden, vaccination against hepatitis B emerged as the most cost-effective prevention method[3]. The available treatments of HBV infections include interferon-alpha (IFN-α) and nucleoside analogue agents (lamivudine, adefovir, entecavir, telbivudine, and others)[4]. However, responses to these treatment regimens are variable and are still a long way from being perfect. Besides, treatment protocols are associated with considerable risks of evolving resistant mutants[5]. These hepatitis B mutants can appear in patients as a consequence of the constant selection pressure from either the immune response or treatment choice. In the meantime, classification of HBV has changed from the serologic subtype classification to a more precise genotype genetic classifi-

cation. Hepatitis B virus has been classified into the eight genotypes (A-H) on the basis of nucleotide sequence differences, and these genotypes have typical geographic distributions and may have different pathogenicity and epidemiology[6]. These genotypes are generated during replication of HBV DNA through an RNA reverse transcriptase intermediary step that lacks proofreading functions[7,8]. Lamivudine, as a potent nucleoside analogue, has been used for chronic HBV infections therapy. However, the need for long-term courses is associated with emergence of lamivudine-resistant mutations. The most common of these mutations affect HBV polymerase-reverse transcriptase. The most commonly reported mutations are the substitution of either valine (M204V) or isoleucine (M204I) for methionine in the tyr-met-asp-asp (YMDD) motif located in the polymerase active site (domain C), and substitution of methionine for leucine (L180M) in the active site (domain B)[9,10]. The present study aimed to identify prevalent hepatitis B genotypes and lamivudine-resistant mutations among treated and untreated HBV patients in Jordan.

MATERIALS AND METHODS

Patients and setting

In this cross-sectional study, we recruited 107 patients with chronic hepatitis B from different departments of King Abdullah University Hospital, Jordan University Hospital, and Princess Badea'h Hospital. All were positive for HBsAg. Genotyping and lamivudine-resistance mutation analysis were performed for 70, and 20 patients, respectively (budgetary restrictions meant we couldn't genotype all the patients). There was no recruitment discrimination made in respect to active or previous lamivudine treatment.

HBV serological markers testing

Twenty ml of peripheral blood were taken and serum samples were aliquoted and stored at -70℃ until used. Sera were tested for HBsAg, anti-HBc, anti-HBs, HBeAg, and anti-HBe using the microparticle enzyme immunoassay (Abbott diagnostic laboratories/AXSYM system, v2, 200, Ireland).

HBV DNA extraction

HBV DNA was extracted from the serum using a DNA-sorb-B kit (Sacace Sr biotechnologies company, Italy). DNA was re-suspended in a final volume of 30 μL of sterile, nuclease-free water and then stored at -20℃ till used.

HBV genotypes detection

HBV Genotyping was performed using the Line probe genotyping assay (INNO-LiPA HBV Genotyping assay; Innogenetics, Ghent, Belgium). It is a line probe assay designed to identify hepatitis B genotypes A to G by detection of type-specific sequences (328-619 nucleotides) in the HBV polymerase gene (domains B to C), which are overlapped with specific sequences in the HBV surface gene. In summary, the biotinylated PCR product (after amplification) was denatured by adding denaturation solution at room temperature. It was then hybridized with specific oligonucleotides probes immobilized as parallel lines on membrane based-strips in hybridization solution at 50℃ using a water bath. Stringency solution was then added to strengthen the binding between the probe and single stranded denatured DNA. Unhybridized DNA was washed from the strips by addition of rinse solution. Conjugate solution was then added to the strips at room temperature. Finally, a chromogenic substrate was added to the strips. A purple precipitate was observed in the lines, identifying stable hybrids formed between the DNA and the probes.

Amplification of HBV DNA and YMDD mutations detection

Amplification of HBV DNA was as described previously[9]. YMDD mutations were detected using a lamivudine resistance assay (INNO-LiPA HBV DR; Innogenetics, Ghent, Belgium). The amplified region of the HBV genome is common between the HBsAg gene and the polymerase gene, therefore the same protocol was followed for both amplification and hybridization processes. This assay detects mutations or polymorphisms at codons 180, 204 and 207 of the HBV polymerase gene, in addition to HBsAg-specific codons, due to the overlapping reading frame.

Statistical analysis

Data were processed using the statistical package for statistical science software (SPSS, version 10, Chicago. Inc). Statistical analysis was carried out using Fisher's exact test, Chi-square test, and *t*-test wherever appropriate. A P value of < 0.05 was considered significant.

RESULTS

Patients' demographics

We recruited 107 patients (31 female and 76 male). Mean age of cases was 34.1 years (SD = 13). Chronicity was confirmed in all cases with positive results for HBsAg, anti-HBcAg-IgG and negative results for anti-HBsAg-IgM. Sixteen patients had a history of receiving lamivudine (Twelve were actively receiving it, while 4 were off treatment at time of enrolment). None of HBeAg negative cases had hepatitis-related symptoms (jaundice, liver enlargement, and Ascites), while 33% of the HBeAg positive cases had such symptoms (Table 1).

Serological patterns

Most patients did not express HBeAg (83%). However, the mean levels of alanine aminotransferase (ALT), and aspartate aminotransferases (AST) were significantly higher in the HBeAg positive group (121 *vs* 38 and 143 *vs* 37, respectively) (Table 1) and these ALT and AST values were statistically significantly abnormal.

HBV genotyping

Surprisingly and interestingly, the 70 selected samples (positive-HBsAg) were all positive for genotype D. We

Table 1 Clinical and serological patterns of all 107 HBsAg positive patients *n* (%)

Criteria	HBeAg positive	HBeAg negative	*P*
Number of cases	18 (17)	89 (83)	< 0.0001
Hepatitis-related symptoms	6 (330)	0 (0)	< 0.0001
Positive HBeAb	0 (0)	89 (100)	< 0.0001
Abnormal ALT	18 (100)	35 (39)	< 0.0001
Abnormal AST	16 (89)	12 (13)	< 0.0001
Abnormal ALP	4 (22)	18 (20)	0.85

ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; ALP: Alkaline phosphatase.

did not detect any other genotypes. Detecting no other genotypes in our cohort made it impossible to compare between HBV genotypes and their effects on clinical course of disease or on response to antiviral drugs.

Lamivudine resistance mutations

Lamivudine resistant mutations were tested for 20 cases (4 were lamivudine naive and 16 with a history of lamivudine treatment) (Table 2). Six mutations were detected in 5 different patients with a history of lamivudine treatment (31%). Two mutations (M204Ile and L180M) were detected in one patient. On the other hand, one mutation only (M204V) was detected in a lamivudine naive patient. The mutation M204Ile was the most prevalent and durations of lamivudine treatment ranged from 1 to 13 years.

DISCUSSION

This is the first report from Jordan that investigates HBV genotypes and lamivudine resistance mutations. Our results showed that genotype D is at least the most (if not the only) prevalent genotype in Jordan. This genotype is also the most prevalent genotype worldwide, with more concentration in the Middle East and the regions around as Turkey, Egypt, and Gulf region. Recent studies have found that genotype D accounts for 81%-85% of all genotypes in Saudi Arabia and almost all genotypes in Egypt[11-13]. This finding might have potential impact on selection of antiviral drugs, prediction of disease courses and clinical responses. There is accumulating evidence that patients with genotype D might achieve higher sustained viral response rate than patients with genotype A[14], despite being less responsive to interferon treatment when compared to genotypes A and B[5]. It is also known that that genotype D has a higher likelihood of developing advanced cirrhosis compared to genotype A[15]. Furthermore, there is evidence that the rate of resistance to lamivudine is lower in patients infected with genotype D than in patients with genotype A[5]. In our study, the prevalence of lamivudine resistant mutations was 31%. It is difficult to compare this prevalence to other studies because our cases received variable durations of lamivudine treatment. However, this prevalence seems broadly similar to those in other reports showing that there is a 20% yearly chance for resistance

Table 2 Profile of detected YMDD mutations among tested cases

Mutation	Patients with history of lamivudine treatment	lamivudine naive patients
Patients tested	16	4
HBeAg Positive	3	1
M204Ile	4	0
M204V	1	1
L180M	1	0
Total	6	1

to emerge in lamivudine-treated patients. The mutation M204Ile was the most prevalent, followed by the M204V mutation, which is similar to cases reported previously[16]. We also detected a mutation in an apparently lamivudine-naive case. This might be due to transmission of the virus from a lamivudine-treated index case or, less likely, to a spontaneous mutation. In general, HBV mutations conferring drug resistance to lamivudine are rare in lamivudine naive patients but do exist[17]. In one of our patients, the M204V mutation was accompanied by the mutation L180M. This combination is also common and has been described before[18]. Our study has also found a relatively low rate of HBeAg positive patients (17%). This might be explained by the rapid clearance of HBeAg among patients with genotype D demonstrated in previous reports[12].

In conclusion, HBV genotype D appears to be the only circulating type in Jordanian patients. The YMDD mutations were detected in 31% of lamivudine-treated cases with similar patterns to those in the literature. We also found a relatively low prevalence of HBeAg expression among examined cases (17%). Awareness of these serologic, genotypic and resistance patterns might help in the formulation of management plans and in predicting clinical outcomes. Further larger scale studies are needed to confirm our results and to examine possible associations among clinical, serologic, and genetic patterns of HBV infections in Jordan.

COMMENTS

Background

Hepatitis B virus (HBV) infections continue to impose huge medical, social, and economic burdens on patients and countries all over the world. Chronic liver disease, cirrhosis, and hepatocellular carcinoma are serious consequences of such infections. These infections are possibly transmitted through transfusion of blood products, unprotected sex, vertical transmission from mothers, or other different risky behaviours. As of today, and despite tremendous medical advances, there is permanent cure for these infections.

Research frontiers

Individualizing the management of patients with hepatitis B infections is based on understanding the local prevalence of different genotypes of this virus. It is also affected by the patterns of resistance manifested by local strains. We addressed these issues in this article. We studied the genotype profiles and resistance patterns of hepatitis B strains among Jordanian patients.

Innovations and breakthroughs

Even though we expected genotype D to be the most prevalent one among Jordanian patients, it was surprising that no other genotypes were detected. With a small number of strains tested for YMDD resistance mutations, it was apparent that our YMDD lamivudine resistance profiles were similar to those encountered

in other surrounding countries and other different parts of the world. During the twentieth century, huge advancements in understanding the basics of this disease have been achieved. Researchers have focused on different frontiers including pathogenesis, diagnostic approaches, genetic profiling, antiviral therapy, resistance patterns, and vaccines development.

Applications

This study may give certain insights to Jordanian physicians managing hepatitis B patients. Genotypic profiles and resistance patterns might help in decisions regarding selection of antiviral therapy, duration of treatments, and expected responses to treatment. Knowing the genetic profiling of hepatitis B strains might reduce the cost of diagnostic testing.

Terminology

Lamivudine is a well-known antiviral drug used for treatment of hepatitis B and other viral infections. YMDD is a motif that is commonly mutated in hepatitis B virus lamivudine resistant mutants.

Peer review

In this article, the authors have described HBV molecular epidemiology in Jordan. The objectives were clearly stated and a respectable sample size (107 subjects) was studied. All subjects were HBsAg positive. Only 17% of cases were positive for HBeAg. 100% of cases were genotyped as HBV genotype D. YMDD mutations were observed in 31% of cases analyzed. Overall, the manuscript is well written and results are clearly presented. Interpretation of the findings is appropriate.

Abstract

AIM: To present our experience with tuberculous peritonitis treated in our hospital from 2002-2007.

METHODS: We reviewed the medical records of 9 children with tuberculous peritonitis.

RESULTS: Nine patients (5 boys, 4 girls) of mean age 14.2 years were diagnosed with peritoneal tuberculosis. All patients presented with abdominal distention. Abdominal pain was seen in 55.5% and fever in 44.4% of the patients. Four cases had coexisting pleural effusion and two had pulmonary tuberculosis with parenchymal consolidation. Ultrasonography found ascites with septation in 7 patients. Two patients had only ascites without septation. Ascitic fluid analysis of 8 patients yielded serum-ascite albumin gradients of less than 1.1 gr/dL. Laparoscopy and laparotomy showed that whitish tuberculi were the most common appearance. Adhesions were also seen in three cases. The diagnosis of peritoneal tuberculosis was confirmed histo-pathologically in 7 patients and microbiologically in two. Two patients had been diagnosed by ascitic fluid diagnostic features and a positive response to antituberculous treatment. All patients completed the antituberculous therapy without any complications.

CONCLUSION: Tuberculous peritonitis has to be clinically suspected in all patients with slowly progressive abdominal distension, particularly when it is accompanied by fever and pain. Laparoscopy and peritoneal biopsy are still the most reliable, quick and safe methods for the diagnosis of tuberculous peritonitis.

INTRODUCTION

Tuberculous peritonitis (TBP) is an uncommon presentation of tuberculosis (TB) especially in children without any other debilitating disease such as cirrhosis, diabetes and chronic renal failure on continuous ambulatory peritoneal dialysis[1]. It is estimated that TBP occurs in 0.1%-3.5 % of all patients with pulmonary TB and represents 4%-10% of all extrapulmonary TB[2,3]. Most of the cases are in their 30's or 40's and it is rarely seen in children[1,4]. It results from hematogenous spread or contagious spread from an abdominal focus or mesenteric lymph node[4,5]. Most patients have chronic abdominal complaints. Due to the protean nature of the manifestations, diagnosis is often delayed and the rate of complications and mortality increases. Therefore, clinicians should be aware of the disease for the early diagnosis. We aimed to review the clinical features of the TBP in children that were followed up in our center.

MATERIALS AND METHODS

In this retrospective study, we reviewed the medical records of 9 children with TBP followed by our Pediatric Department from 2002-2007. The presentation symptoms, history of TB exposure, biochemical tests, clinical and histological features of the patients were recorded. Other causes of ascite and chronic liver

diseases were ruled out in all patients. None of the patients had any other chronic disease.

The tuberculin skin test (TST) was evaluated 48-72 h after intradermal injection of 5 tuberculin units of purified protein derivative. It was considered to be positive when the induration was greater than or equal to 15 mm in previously vaccinated patients and greater than or equal to 10 mm in patients who had never been vaccinated.

Diagnosis of TBP was based on either typical laparoscopic appearance with tubercles and histological presence of caseating granuloma or diagnostic features of the ascitic fluid and response of the antituberculous therapy (in the absence of tissue samples being available). Patients were treated with isoniazide (10 mg/kg per day) and rifampin (15 mg/kg per day) for 9 mo and pyrazinamide (30 mg/kg per day) and streptomycin (20-40 mg/kg per day) for the first 2 mo. Metilprednisolone (2 mg/kg per day) was also given to four patients (patients 1-3 and 5) for the first 6 wk. The data were expressed as mean ± SD.

RESULTS

Nine patients were diagnosed with peritoneal tuberculosis. They were 5 boys and 4 girls with a mean age of 14.2 years (range 11-16 years). At presentation, abdominal distention was a common complaint in all patients (100%). In addition, five had abdominal pain (55.5%), four had fever (44.4%), three had coughing, three had weight loss, and three had night sweating (33.3%). The mean duration of symptoms was 41.5 ± 30.2 (7-90) d. Six patients had a history of tuberculosis within the family (for details see Table 1).

At admission, only four of the patients had two Bacillus Calmette-Guerin (BCG) scars. The tuberculin skin tests (TST) were positive in 6 patients with an induration ranging from 10-22 mm. Five cases had concomitant thoracic involvement (Table 1). Three patients had pleural effusion (Figure 1), one had parenchymal consolidation, and one (patient 4) had both of them. The most common abdominal ultrasonography (USG) findings were ascites with septation (found in 7 patients). Two had only ascites without septation (patients 1 and 6), one had hepatomegaly (patient 8) and two had intra-abdominal lymphadenopathies (patients 4 and 9) as well as ascites. In one patient (patient 1), peritoneal fluid could not be obtained. This patient had been previously operated on because of intestinal obstruction in another center, where they had seen multiple adhesions and whitish tuberculi on peritoneum. The patient was then referred to our center.

Ascitic fluid analysis was performed in 8 patients. All of the ascitic fluids were exudative, and the serum-ascite albumin gradient was less than 1.1 g/dL in all of them. Laboratory findings of serum and ascitic fluid are shown in Table 2. Direct examination of ascitic fluids revealed a predominance of lymphocytes. Acid fast bacilli (AFB) only found in one patient (patient 8). Positive cultures for M. tuberculosis were present in two patients. Three patients showed high adenosine deaminase activity (ADA)

Table 2 Laboratory findings of the patients at presentation

Parameter	Mean ± SD (range)
Hemoglobin (g/dL)	11.2 ± 1.3 (9.9-13)
White cell count (10^{12}/L)	6.4 ± 1.9 (4.1-9.0)
Erythrocyte sedimentation rate (mm/h)	42.3 ± 21.0 (10-72)
C-reactive protein (g/dL)	79.6 ± 63.7 (21-203)
Serum total protein (g/dL)	7.4 ± 0.7 (6.5-8.5)
Serum albumin (g/dL)	3.2 ± 0.5 (2.4-3.9)
Serum/ascites albumin gradient (g/dL)	0.6 ± 0.2 (0.3-1.0)
Ascites LDH (IU/L)	746.8 ± 327.1 (366-1331)
Ascites total protein (g/dL)	5.2 ± 0.6 (4.7-6.0)
Ascites albumin (g/dL)	2.6 ± 0.5 (1.9-3.4)
Ascites glucose (mg/dL)	71.7 ± 15.1 (49-89)
Ascites polymorphonuclear leukocyte (per mm^3)	1915 ± 1578 (520-5200)
Ascites lymphocyte (per mm^3)	3135 ± 3165 (602-9400)

LDH: Lactate dehydrogenase.

in their ascitic fluid. The clinical features of patients are shown in Table 1.

Laparoscopy was performed on 6 patients and laparotomy on one, and whitish tubercles were the most common findings in all. In three of the cases, adhesions were also seen. All biopsy samples obtained from 7 patients revealed caseating granuloma (Figure 2). The diagnosis of peritoneal tuberculosis was confirmed histopathologically in 7 patients, and two of these patients were also proved microbiologically. The remaining 2 patients had been diagnosed by ascitic fluid diagnostic features and a positive response to antituberculous treatment.

All patients completed the 9 mo course of therapy and recovered without any complications. Patients were followed for 6 to 15 mo after the end of therapy and all were in good health.

DISCUSSION

Tuberculous infection is still a significant cause of morbidity and mortality in the world. It is estimated that the incidence of TBP among all forms of TB varies from 0.1 % to 0.7 % worldwide and it is seen most commonly in patients between 35 and 45 years of age[4]. It is seen in children with a lower frequency. Recently, Forssbohm *et al*[6] reported that in Germany, only 5% of peritoneal TB cases were children under 14 years old. In the US, peritoneal TB accounts 0.3% of all TB cases in children less than 20 years and median age in children was 13 years[7]. Our review showed that TBP is also seen in lower frequency in our local area, the Black Sea region of Turkey. We have followed up only 9 children with TBP in a 5 year period. Mean age in this study was 14.2 years, in accordance with the literature. There was only one patient of 11 years old, the others were between 14-16 years. However, younger children with TBP have been reported in two studies from Turkey[8,9].

The initial symptoms of TBP cases are nonspecific, such as abdominal distention, pain, fever and weight loss and the occurrence of these events take a long time[5,8-10]. The clinical presentation of our patients was similar

Figure 1 Chest roentgenogram showing pleural effusion on both sides (patient 5).

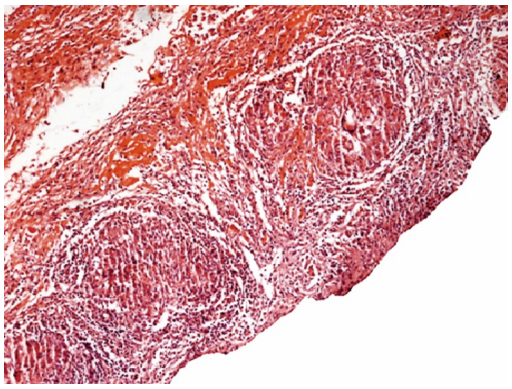

Figure 2 Histological appearance of caseating granuloma (patient 5, haematoxylin and eosin stain, original magnification x 10).

and ascites, causing abdominal distention was present in all cases. Constitutional symptoms of abdominal pain was seen in 55.5% of the patients, fever in 44.4%, and weight loss, night sweating and coughing were seen in 33.3% of the patients. One patient (patient 1) presented with small-bowel obstruction due to chronic peritoneal inflammation and adhesions. Intestinal obstruction developed in patients with TBP is also reported in the other studies[4,11-13].

Due to the nonspecific symptoms and physical findings, diagnosis is often delayed. The gold standard of diagnosis of TB in children is the triad of contact with a patient with active TB, positive TST and compatible physical and radiological findings. Clinicians must be aware of this serious health problem and inquire of familial history of TB. In our series, 66.7 % of patients have a contact history within the family and therefore we consider that family history is an important factor to take into account when making the diagnosis. In addition, TST is a helpful tool in diagnosis of TB and applied frequently. However, its diagnostic value in TBP can be variable. The frequency of TST positivity was higher (66.7%) in our study population than reported as 18%-27% in the other studies[8,14,15].

Chest radiographs are abnormal in 50-75% of patients with TBP[5]. It has been reported that 12%-63% of patients with TBP also had pleural effusion in different studies[8,16,17]. Similarly, in our study, 5 patients

(55.5%) had thoracic involvement, 4 of them had pleural effusion and 2 had consolidation. In most studies, direct examination of AFB and culture positivity of the peritoneal fluid are rarely seen[2,9,14,18]. In the present study, ARB were seen in only one case (patient 8) and culture of peritoneal fluid was positive in two cases (patients 2 and 5).

Analysis of ascitic fluid often shows exudative features with lymphocytic predominance and serum-ascite albumin gradient lesser than 1.1 gr/dL[18]. The ascite samples acquired from eight patients in our study had lymphocytic predominance and low serum-ascite albumin gradient, therefore we also suggest that the ascitic fluid features mentioned above might be a good indicator for diagnosis.

High levels of ADA in the ascitic fluid has been shown to be compatible with the diagnosis of TBP with high sensitivity (100%) and specificity (97%), but the analysis of ADA activity is expensive and may not be available everywhere[18-20]. We were able to assess ADA activity in ascitic fluid in only three patients and their values were high.

Bacillus can reach the peritoneum through the gastrointestinal tract *via* mesenteric lymph nodes or directly from the blood[5]. The most common form of disease is wet peritonitis, both visceral and parietal peritoneal layers are affected with the formation of multiple tuberculous nodules and ascites[21]. Abdominal USG is a non-invasive and easy available method of detecting abdominal fluid and lymphadenopathy. So it can be used for the diagnosis of TBP as a first step investigation. The most specific sonographic findings of TBP are ascites with fine septations and lymphadenopathy with hypoechogenic centers indicating caseating necrosis[18]. Abdominal USG of the present patients revealed ascites as the most common findings in all patients, also with fine septations in 7 of them, intra-abdominal LAP was seen in two patients, and hepatomegaly in one.

A thickened peritoneum, whitish tubercles and adhesions are the most common appearance of TBP in laparoscopy or laparotomy. Besides specific appearance, these procedures allow us to take a peritoneal biopsy, which is the gold standard for diagnosis[22]. In our series, 6 patients had undergone laparoscopy and one had a laparotomy and whitish tubercles on peritoneum were seen in all and adhesions in two. This pathognomonic appearance was proved by the observation of caseating granuloma on the histology. No complications were encountered in our patients.

Some authors suggest that corticosteroid administration combined with antituberculosis treatment can reduce the complications and morbidity rate, however, there is a controversy about the benefit[23-25]. In the present study, we added metilprednisolone to antituberculosis therapy in four patients, with positive results.

In conclusion, TB is still a major cause of mortality and morbidity worldwide. Although TBP is uncommon in childhood, it needs to be considered in all patients presenting with ascites, particularly when it is accompanied by fever and abdominal pain. Due to its high fatality rate, if not diagnosed in time, early diagnosis is very important. Laparoscopy and peritoneal biopsy are still the most reliable, quick and safe methods for the diagnosis of TBP.

COMMENTS

Background

Tuberculous peritonitis is an uncommon presentation of tuberculosis in children. Its diagnosis is more difficult in children because of nonspecificity of symptoms and difficulty in confirming the diagnosis.

Research frontiers

Tuberculous peritonitis is seen most commonly in adults and seen in children with a lower frequency. Due to the insidious nature of the manifestations, diagnosis is often delayed and the rate of complications and mortality increases. Chronic abdominal complaints, ascidic fluid investigations and laparoscopy are important in diagnosis.

Innovations and breakthroughs

Abdominal distention due to ascites was present in all of our cases and fever and abdominal pain were seen in almost half of them. In addition, serum-ascite albumin gradient less than 1.1 gr/dL, laparoscopic and histological findings were important in the diagnosis.

Applications

Although the clinical signs and symptoms suggest the disease, the laparoscopy and biopsy are still the most reliable methods for the definite diagnosis of tuberculous peritonitis and they are easy to apply.

Terminology

Low serum-ascite albumin gradient (< 1.1 gr/dL) is a better distinguishing marker for separating ascites related to non-portal hypertension origin from ascites with portal hypertension.

Peer review

Tuberculosis peritonitis (TP) even if it is rare in developed countries; it remains frequent in developing countries. This retrospective study includes 9 cases. Even if the number of cases is small, it is necessary to stay in touch with this disease since it still affects children. This study is well done even though is retrospective. The different observations are well documented. This study confirms that, regardless of enormous progress in imagery, laparoscopy is still the most reliable method for the diagnosis of TP.

Abstract

AIM: To investigate the effects of rosiglitazone (RGZ) on expression of interleukin-18 (IL-18) and caspase-1 in liver of non-alcoholic fatty liver disease (NAFLD) rats.

METHODS: Twenty-eight Sprague-Dawley (SD) rats were randomly divided into control, NAFLD, and RGZ treated NAFLD groups. A NAFLD rat model of NAFLD was established by feeding the animals with a high-fat diet for 12 wk. The NAFLD animals were treated with RGZ or vehicle for the last 4 wk (week 9-12) and then sacrificed to obtain liver tissues. Histological changes were analyzed with HE, oil red O and Masson's trichrome staining. Expressions of IL-18 and caspase-1 were detected using immunohistochemical staining and semi-quantitative reverse-transcription polymerase chain reaction (RT-PCR) analysis.

RESULTS: The expression levels of both IL-18 and caspase-1 were higher in the liver of NAFLD group than in the control group. Steatosis, inflammation and fibrosis, found in the liver of NAFLD rats, were significantly improved 4 wk after RGZ treatment. The elevated hepatic IL-18 and caspase-1 expressions in NAFLD group were also significantly attenuated after RGZ treatment.

CONCLUSION: RGZ treatment can ameliorate increased hepatic IL-18 production and histological changes in liver of NAFLD rats. The beneficial effects of RGZ on NAFLD may be partly due to its inhibitory effect on hepatic IL-18 production.

Inhibition of hepatic interleukin-18 production by rosiglitazone in a rat model of nonalcoholic fatty liver disease. *World J Gastroenterol* 2008; 14(47): 7240-7246 Available from: URL: http://www.wjgnet.com/1007-9327/14/7240.asp DOI: http://dx.doi.org/10.3748/wjg.14.7240

INTRODUCTION

Interleukin-18 (IL-18), previously called interferon-gamma (IFN-γ) inducing factor, is originally identified as a pro-inflammatory cytokine derived from Kupffer cells in animals with acute liver injury induced by endotoxin[1]. IL-18 is closely related to and acts synergistically with IL-12. However, its amino acid sequence and structure motifs resemble the IL-1 family. IL-18 expression has been demonstrated in a variety of cell types originated from both immune and non-immune systems, suggesting that IL-18 may have a wide range of cellular sources and functions apart from being a macrophage-derived inducer of IFN-γ production from type 1 T helper cells[2]. IL-18 is intracellularly synthesized as a non-functional precursor protein, pro-IL-18. Like pro-IL-1β, pro-IL-18 is then processed by caspase-1 into a bioactive mature form[3].

Non-alcoholic fatty liver disease (NAFLD), one of the most common causes of chronic liver diseases, represents a spectrum of liver disease extending from simple fatty liver through steatohepatitis to cirrhosis

in the absence of a history of significant alcohol use. NAFLD is considered one of the clinical features of metabolic syndrome in which insulin resistance plays a central role[4]. Several lines of evidence show that IL-18 may be important in the pathogenesis of inflammatory processes, which contribute to the development of insulin resistance. It has been shown that elevated serum IL-18 levels are associated with insulin resistance in obese subjects, women with polycystic ovary syndrome, and patients with type 2 diabetes mellitus[5-7]. Furthermore, hepatic IL-18 level is elevated in insulin resistance-related obese mice with NAFLD[8].

Rosiglitazone (RGZ), a selective ligand of peroxisome proliferator-activated receptor gamma (PPAR-γ), is an insulin sensitizer that has been used in a number of insulin-resistant conditions, including NAFLD. Several clinical studies showed that RGZ could improve liver enzyme levels and histological changes in NAFLD patients by increasing insulin sensitivity[9-11]. However, whether the beneficial effect of RGZ on NAFLD is associated with reduced IL-18 expression in the liver remains unclear. This study analyzed the expression of IL-18 and caspase-1 in the liver of NAFLD rats, and investigated the effects of RGZ on hepatic IL-18 production and liver histology.

MATERIALS AND METHODS

Animal and experimental protocol

Twenty-eight male Sprague-Dawley (SD) rats, weighing 140-160 g, were housed in individual cages at 22℃ with free access to food (standard chow diet) and water for 1 wk before initiation of the experiment. The study protocol was approved by the Animal Care and Use Committee of Peking University Health Science Center.

The rats were randomly divided into control group (n = 6), NAFLD group (n = 11), and RGZ-treated NAFLD group (n = 11). Rats in the control group were maintained on the standard chow diet for 12 wk. A rat model of NAFLD was induced by a high-fat diet (standard chow diet + 10% lard + 2% cholesterol) for 8 wk as previously described[12]. Subsequently, rats in the RGZ-treated NAFLD group were treated with RGZ maleate (Avandia®, 4 mg/kg per day) *via* gavage, whereas rats in the NAFLD group were given normal saline for another 4 wk. At the end of study, all rats were sacrificed after 12 h of fasting. Blood samples were collected for biochemical assays. The liver was removed and weighted after rinsed with ice-cold saline, and sampled for histological study and RNA extraction.

Biochemical analyses

Serum insulin concentrations were determined with a radioimmunoassay kit (Beijing Atom HighTech Co., Ltd., Beijing, China). Serum leptin and adiponectin levels were measured with an ELISA kit (Invitrogen, Carlsbad, CA, USA). Free fatty acid (FFA) concentrations were analyzed using a commercially available kit (Randox, Antrim, UK). Additional blood biochemical parameters, including glucose, triglycerides, total cholesterol, alanine aminotransferase (ALT), aspartate aminotransferase (AST) and alkaline phosphatase (ALP), were assayed using an automatic biochemical analyzer. Homeostasis model assessment (HOMA) was employed to estimate the insulin resistance index (HOMA-IR), which reflects both peripheral and hepatic insulin resistance[13]. Liver weight index (%) was calculated as liver weight/body weight × 100.

Histological studies

The sections of liver tissues from the center of the largest hepatic lobes were fixed in 10% buffered formaldehyde, and then embedded in paraffin. A 5 μm-thick section cut from a paraffin-embedded block was stained with HE and Masson's trichrome. To visualize the fat droplet accumulation, frozen liver tissue sections were stained with oil red O. Steatosis, necro-inflammatory grade and stage of fibrosis were assessed as previously described[14]. Liver histology was evaluated blindly.

Immunohistochemical staining

Goat IL-18 polyclonal antibody was obtained from Santa Cruz (Santa Cruz, CA, USA). Rabbit caspase-1 polyclonal antibody was purchased from Lab Vision (Fremont, CA, USA). Immunohistochemical staining of 5 μm-thick paraffin-embedded liver tissue sections was performed according to its manufacturer's protocol (Vectastain Elite ABC kit; Vector, Burlingame, CA, USA). Briefly, liver sections were deparaffinized in xylene and rehydrated in graded ethanol. After endogenous peroxidase and biotin were blocked, the tissues were pre-incubated with 3% horse serum for 30 min to prevent non-specific reactions. The sections were then incubated with primary antibodies diluted at 1:150 for 60 min. On negative control sections, the step with primary antibodies was omitted. Polyclonal antibodies were detected using a biotinylated anti-goat or rabbit IgG diluted at 1:200 in 5% bovine serum albumin for 30 min. The sections were incubated with R.T.U. Vectastain Elite ABC reagent for 30 min, stained with diaminobenzidine for 5 min and counterstained with hematoxylin before they were mounted.

Reverse-transcription polymerase chain reaction (RT-PCR) analysis

Total RNA was extracted from the liver tissues using a TRIzol reagent (Gibco, Carlsbad, CA, USA) according to its manufacturer's instructions. cDNA was prepared with the SuperScription First-Strand Synthesis System (Invitrogen) as previously described[15] and amplified by polymerase chain reaction (PCR). The sequences of primers used for PCR are 5'-GGCTCTTGTGTCAACT TCAAA-3' and 5'-TTATCAGTCTGGTCTGGGATT-3' (232 bp) for *IL-18*, 5'-TCCTGAGGGCAAAGAGGAA GC-3' and 5'-GGCAAGACGTGTACGAGTGGGT-3' (479 bp) for *caspase-1*, 5'-GCTCGTCGTCGACAACG GCTC-3' and 5'-CAAACATGATCTGGGTCATCT TCTC-3' (353 bp) for *β-acti*, respectively. Each semi-quantitative RT-PCR analysis was performed with a set

of *IL-18* or caspase-1 primers in combination with a set of primers for house-keeping gene *β-actin* as an internal standard. The conditions of PCR were as follows: 1 cycle at 94℃ for 5 min; 30 cycles at 94℃ for 30 s, at 60℃ for 30 s, at 72℃ for 45 s; 1 cycle at 72℃ for 5 min. The PCR products were separated on a 2% agarose gel which was dried and then scanned using an ultraviolet gel imaging system (BioRad, Hercules, CA, USA). Gene expression levels were represented as ratios of target gene to co-amplified internal standard.

Statistical analysis

Data are expressed as mean ± SE. Analysis of variance was used to compare the means of three groups, followed by Newman-Keuls test to determine the statistical significance between two groups. $P < 0.05$ was considered statistically significant.

RESULTS

Effects of RGZ on hepatic histology

The liver tissues from all groups were stained with HE and analyzed (Figure 1A-C). In contrast to the control group, typical steatosis and portal and lobular inflammation were observed in the NAFLD group after 12 wk of feeding with a high-fat diet (Figure 1A and B). In the NAFLD group, steatosis was observed in about 65% of hepatocytes (mean score: 3 *vs* 0 in the control group). Moderate infiltration of mononuclear and polymorphonuclear cells was also found (mean score: 2 *vs* 0). Fat droplet accumulation and fibrosis (mean score: 1 *vs* 0) were observed in sections stained with oil red O (Figure 1D-F) and Masson's trichrome (Figure 1G-I) in the NAFLD group (Figure 1E and H), but not in the control group (Figure 1D and G). These findings suggest that the animal model of NAFLD was successfully established. Furthermore, markedly attenuated steatosis (mean score: 0.6), inflammation (mean score: 0.5) and fibrosis (mean score: 0.2) were observed 4 wk after treatment with RGZ (Figure 1C and I).

Effects of RGZ on hepatic metrology and biochemistry

Increased liver weight and liver weight index observed in the NAFLD group were significantly improved after RGZ treatment (Table 1). The hepatic surface was smooth, red-brown, and soft in the control group, whereas the liver in the NAFLD group was enlarged in dimmer color with a moderate texture. The liver feature of the RGZ-treated NAFLD group was in between the above two groups (data not shown). Moreover, serum ALT, AST and ALP levels were significantly elevated in the NAFLD group and significantly reduced in the RGZ-treated NAFLD group compared with the untreated NAFLD group (Table 1).

Effects of RGZ on insulin resistance and metabolic parameters

Increased serum insulin, leptin, FFA, and HOMA-IR levels were observed in the NAFLD group, which were attenuated in the RGZ-treated NAFLD group. In contrast, decreased serum adiponectin levels were found in the NAFLD group, which were ameliorated in the RGZ-treated NAFLD group. Fasting blood glucose concentration was significantly elevated in the NAFLD group and decreased in the RGZ-treated NAFLD group. The levels of serum triglycerides were significantly higher in the NAFLD group, and reduced after RGZ treatment. Serum cholesterol levels were significantly higher in the NAFLD group, and tended to become lower in the RGZ-treated NAFLD group although the difference was not statistically significant (Table 1).

Table 1 Effects of RGZ on blood biochemistry and hepatic parameters (mean ± SE)

Parameters	Control (n = 6)	NAFLD (n = 11)	RGZ-treated NAFLD (n = 11)
Glucose (mmol/L)	6.48 ± 0.32	7.31 ± 0.20[a]	6.26 ± 0.16[c]
Insulin (mU/L)	20.41 ± 1.85	27.03 ± 1.48[a]	21.07 ± 1.19[c]

Effects of RGZ on IL-18 and caspase-1 expression in liver tissues

Immunohistochemical staining was used to analyze the expression of IL-18 (Figure 1J-L) and caspase-1 (Figure 1M-O) proteins in the liver tissues. Positive expression of either IL-18 or caspase-1 was rarely detected in liver tissues from the control group with very week staining in some Kupffer cells (Figure 1J and M). However, the NAFLD group exhibited a strong expression of both IL-18 and caspase-1 in the liver lobules. Hepatocytes and/or infiltrating inflammatory cells within the lobules were the major cell types expressing IL-18 and caspase-1 (Figure 1K and N). Compared to the untreated NAFLD group, the expression of hepatic IL-18 and caspase-1 was significantly inhibited 4 wk after treatment with RGZ (Figure 1L and O).

RT-PCR analysis further showed that constitutive *IL-18* or *caspase-1* mRNA expression was found in liver tissues from the control group. The mRNA levels of *IL-18* and *caspase-1* were significantly higher in liver tissues from the NAFLD group than in those from the control group. The mRNA expression of *IL-18* and *caspase-1* was significantly reduced in the RGZ-treated

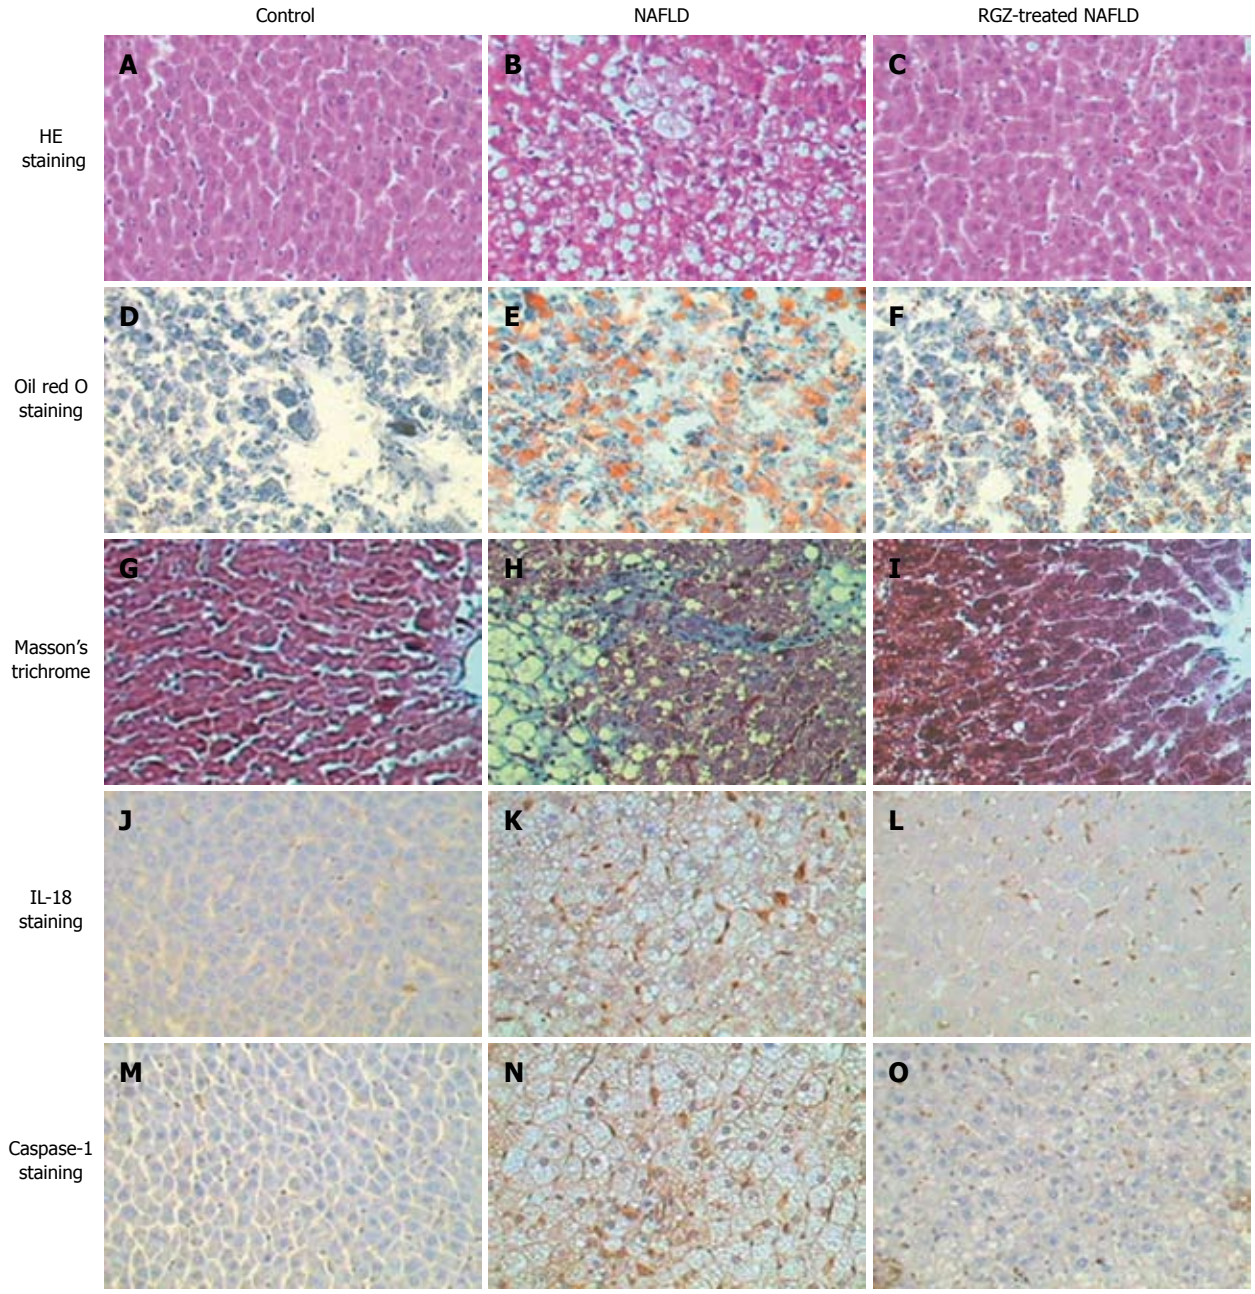

Figure 1 Histological studies of rat livers in normal control, NAFLD and RGZ-treated NAFLD groups (x 400). Liver tissue sections were stained with HE, A: Normal control group; B: NAFLD group; C: RGZ-treated NAFLD group. Liver tissue sections were stained with oil red O, D: normal control group; E: NAFLD group; F: RGZ-treated NAFLD group. Liver tissue sections were stained with Masson's trichrome, G: Normal control group; H: NAFLD group; I: RGZ-treated NAFLD group. Liver tissue sections were stained with immunohistochemistry for IL-18, J: Normal control group; K: NAFLD group; L: RGZ-treated NAFLD group. Liver tissue sections were stained with immunohistochemistry for caspase-1, M: Normal control group; N: NAFLD group; O: RGZ-treated NAFLD group. Histological changes in fatty liver disease and IL-18- or caspase-1-positive staining cells were rarely detectable in the control group. NAFLD rat liver showed steatosis and moderate inflammatory changes, fat droplet accumulation, mild fibrosis, strong IL-18- and caspase-1-positive staining. A significant improvement of steatosis, inflammation, fibrosis, and IL-18 and caspase-1 staining was observed in liver of the RGZ-treated NAFLD group.

NAFLD group compared to the NAFLD group, but remained higher in the RGZ-treated NAFLD group than in the control group (Figure 2).

DISCUSSION

Insulin resistance is closely associated with NAFLD, typically known as a part of the metabolic syndrome, and has been implicated as a contributing factor for the pathogenesis of NAFLD[4,16-18]. Treatment with RGZ, an oral anti-diabetic agent of the thiazolidinediones, leads to the improvement in insulin resistance with ameliorated histological and biochemical changes of liver injury in diabetic and non-diabetic patients with NAFLD[9-11]. Pioglitazone[19], another thiazolidinedione insulin-sensitizer, and metformin[20] exert similar effects in non-diabetic patients with NAFLD. These findings suggest that insulin resistance contributes to the development of NAFLD and that insulin sensitizers may represent important agents for the treatment of NAFLD. Furthermore, the beneficial effects of insulin-sensitizing agents, RGZ[21,22], pioglitazone[12] and

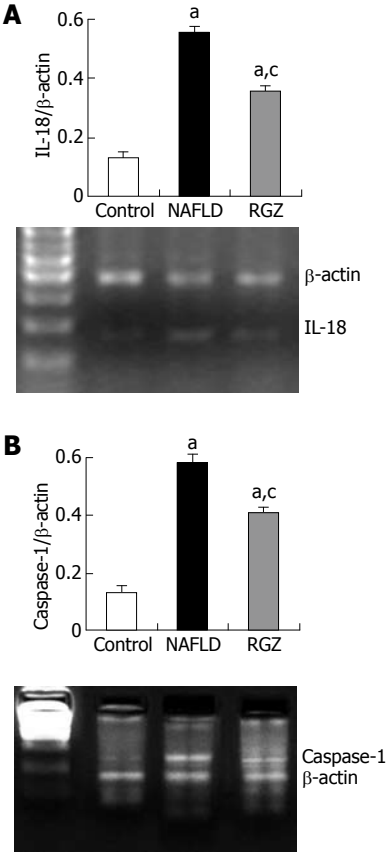

Figure 2 RT-PCR analysis of mRNA expression of *IL-18* (A) and caspase-1 (B) in liver tissues of the three groups. The histograms show the ratio of target gene expression to *β-actin*. Data are presented as mean ± SE from six independent experiments in the control group and eleven in the NAFLD and RGZ-treated NAFLD groups. $^{a}P < 0.05$ *vs* control group, $^{c}P < 0.05$ *vs* NAFLD group.

metformin[21], on hepatic steatosis and inflammation have been confirmed in various animal models of NAFLD. Compared to metformin, RGZ appears to be a better drug for improving hepatic steatosis[21]. In line with the above reports[12,21,22], our study showed that increased liver weight and liver weight index, elevated serum liver enzyme levels and altered liver histological conditions including steatosis, inflammation and fibrosis were observed in the NAFLD rats, which were significantly improved 4 wk after RGZ treatment. In agreement with previous reports[12,21], the present study also showed that the levels of serum insulin, leptin, FFA and triglycerides as well as HOMA-IR were significantly increased, whereas the levels of serum adiponectin remarkably decreased in the NAFLD group. Four weeks after RGZ treatment, these abnormalities were significantly improved, suggesting that insulin resistance may play an important role in the pathogenesis of NAFLD.

Overnutrition-induced chronic inflammation is a key component in the pathogenesis of insulin resistance and metabolic syndrome. Pro-inflammatory cytokines can cause insulin resistance in adipose tissue, skeletal muscle and liver by inhibiting the insulin signal transduction[23]. A role of IL-18 has been recently postulated in the development of insulin resistance based on the observation that elevated serum IL-18 levels are associated with insulin resistance and hypoadiponectinemia[5-7,24]. In obese women, circulating levels of IL-18 are increased and positively associated with body weight and visceral fat, which can be ameliorated by caloric restriction-induced weight loss over 1 year[25]. A recent report showed that plasma IL-18 is associated with changes in insulin resistance and reduced after weight loss with a 15-wk life-style intervention. In addition, the expression of IL-18 in adipose tissue is increased in obese subjects but not affected by weight loss[26], indicating that changes in plasma IL-18 are related to insulin resistance rather than to obesity. Notably, the fact that increased serum IL-18 levels are associated with increased serum liver enzyme concentrations suggests that IL-18 might contribute to the development of liver disease associated with insulin resistance[27,28]. The role of IL-18 in the development of insulin resistance-related NAFLD is further supported by a report showing that both serum IL-18 concentration and hepatic *IL-18* mRNA expression are elevated in lipopolysaccharide-treated *ob/ob* mice, an animal model of fatty liver disease[8]. Moreover, IL-18 may play an important role in liver injury caused by hepatitis B virus infection[29], hepatic ischemia/reperfusion[30], and endotoxin exposure[31] since the liver injury can be reversed by blockage of IL-18 *via* either gene knockout[31] or neutralizing antibody[30]. Importantly, exogenous administration of IL-18 with IL-12 to BALB/c mice induces fatty liver in an IFN-γ and nitric oxide dependent manner[32], suggesting that IL-18 plays a pivotal role in the inflammatory cascade leading to NAFLD associated with insulin resistance.

In the present study, the expression of IL-18 and caspase-1 was extremely low in liver tissues from the control animals. However, the expression of IL-18 and caspase-1 was significantly increased in liver lobules from NAFLD rats. Hepatocytes and inflammatory cells within the lobules are the major cell types expressing IL-18 and caspase-1. IL-18 is synthesized as a precursor molecule without biological activity and requires caspase-1 for cleavage into a mature peptide and subsequent release[3]. Increased expression of caspase-1 in hepatocytes and infiltrating inflammatory cells indicates that both cell types may produce and secrete mature IL-18. This finding is generally consistent with a previous report showing that IL-18 production can be originated from Kupffer cells as well as injured hepatocytes[29]. As noted above, RGZ improves the histological and biochemical changes in NAFLD along with the improvement in insulin resistance[9-11]. In addition, increased circulating levels of IL-18 are significantly decreased after RGZ therapy for patients with metabolic syndrome[33] or type 2 diabetes mellitus[34]. The present study showed that increased expression of IL-18 and caspase-1 in livers of NAFLD rats was reduced 4 wk after treatment with RGZ. Therefore, it is conceivable that hepatic IL-18 production may have a critical role in the development of NAFLD and that the beneficial effects of RGZ on NAFLD may be mediated by inhibiting IL-18 expression possibly *via* PPAR-γ activation[35].

The mechanism by which hepatic IL-18 production

contributes to the development of NAFLD remains to be elucidated. IL-18 is a pro-inflammatory cytokine with multiple functions including stimulation of IFN-γ production[1-3], enhancement of IL-1β, and IL-8 production *via* direct stimulation of tumor necrosis factor-α (TNF-α) production[36]. A previous study showed that intraperitoneal administration of IL-18 with IL-12 induces mouse fatty liver in an IFN-γ dependent manner[32]. Macrophage-derived TNF-α contributes to insulin resistance and development of hepatic steatosis in diet-induced obesity[37]. It was also reported that either IFN-γ or TNF-α up-regulates gene expression or posttranslational processing of *IL-18* in several tissue cell types[15,38,39], indicating that IL-18 may contribute to the development of insulin resistance-related NAFLD *via* a complex cytokine network of IL-18 and many other cytokines such as TNF-α, IFN-γ and IL-1β.

In summary, increased hepatic IL-18 production along with liver histological and biochemical changes can be ameliorated after RGZ treatment. The beneficial effects of RGZ on NAFLD may be due to its direct anti-inflammatory properties, possibly *via* PPAR-γ activation, or secondary to improved insulin resistance.

COMMENTS

Background

Interleukin-18 (IL-18), originally identified as a pro-inflammatory cytokine in endotoxin-induced liver injury, is an important mediator of innate and adaptive immunity. Recently, IL-18 has been reported to be associated with insulin resistance-related non-alcoholic fatty liver disease (NAFLD).

Research frontiers

Treatment with thiazolidinedione (TZD) leads to improvement in insulin resistance and ameliorates histological and biochemical changes of liver injury in patients with NAFLD. However, whether the beneficial effect of TZD on NAFLD is associated with reduced IL-18 expression in the liver remains unknown.

Innovations and breakthroughs

The data show that increased hepatic IL-18 and caspase-1 expression along with liver histological and biochemical changes can be ameliorated after rosiglitazone (RGZ) treatment in an animal model of NAFLD. Therefore, the beneficial effects of RGZ on NAFLD may be due to its direct anti-inflammatory properties or secondary to improved insulin resistance, *via* peroxisome proliferator-activated receptor gamma (PPAR-γ) activation.

Applications

IL-18 plays a pivotal role in the inflammatory cascade leading to NAFLD associated with insulin resistance. Therefore, blockage of hepatic IL-18 action may be a novel target for treatment of NAFLD.

Terminology

NAFLD represents a spectrum of liver disease extending from simple fatty liver through steatohepatitis to cirrhosis in the absence of a history of significant alcohol use. Low-grade inflammation, characterized by abnormal cytokine production, increased synthesis of acute-phase reactants and activation of inflammatory signaling pathways, is a key component in the pathogenesis of insulin resistance, obesity and steatohepatitis.

Peer review

This is an interesting paper. The authors showed that RGZ treatment can improve the increased hepatic IL-18 expression along with liver histological changes in a rat model of NAFLD.

Liver resection for benign hepatic lesions: A retrospective analysis of 827 consecutive cases. *World J Gastroenterol* 2008; 14(47): 7247-7251 Available from: URL: http://www.wjgnet.com/1007-9327/14/7247.asp DOI: http://dx.doi.org/10.3748/wjg.14.7247

Abstract

AIM: To analyze the operative and perioperative factors associated with hepatectomy of benign hepatic lesions.

METHODS: A total of 827 condecutive cases of benign hepatic lesion undergoing hepatectomy from January 1986 to December 2005 in the Chinese PLA General Hospital were investigated retrospectively according to their medical documentation.

RESULTS: The effect of operative and perioperative factors on the outcome of patients were analyzed. Of the 827 cases undergoing hepatectomy for more than 3 liver segments accounted for 22.1%, 316 (38.21%) required transfusion of blood products during operation. The average operating time was 220.59 ± 109.13 min, the average hospital stay after operation was 13.55 ± 9.38 d. Child-Pugh A accounted for 98.13%. The postoperative complication rate was 13.54% and the in-hospital mortality rate was 0.24%. Multivariate analysis showed that operating time (P = 0.004, OR = 1.003) and albumin value (P = 0.040, OR = 0.938) were the independent predictors of morbidity and indicated that operating time, blood transfusion, complication rate, and LOS had a trend to decrease.

CONCLUSION: Hepatectomy for benign hepatic lesions can be performed safely with a low morbidity and mortality, provided that it is carried out with optimized perioperative management and an innovative surgical technique.

INTRODUCTION

Hepatectomy is a dangerous and complex operation[1-6]. The choice of surgical treatment for benign hepatic lesion is controversial. Erdogan *et al*[7] reported that the indications for surgical resection of liver hemangioma are progressive abdominal pain and > 5 cm in diameter, which have been justified in patients with minimal or no symptoms, even in patients with giant hemangiomas. Yoon *et al*[8] performed 52 operations for 115 hepatic hemangiomas, enucleation was performed for 31 (60%) of the 52 patients who underwent surgical resection. Postoperative complications were found in 13 patients (25%) with no peri-operative death occurred. Of the 52 patients with symptoms before resection, 96% had resolution of their symptoms after operation. Chaib *et al*[9] suggested that hepatic adenoma should be removed in all cases, especially in female patients on oral contraceptives when their tumor was greater than 3 cm in diameter or when malignancy cannot be excluded. No postoperative death occurred in 24 patients with hepatic adenoma. Bile leakage occurred in 1 patient, intraperitoneal abscess in 1 patient, pleural effusion in 2 patients, venous thrombosis in 1 patient and wound infection in 1 patient. Ibrahim *et al*[10] suggested that indications for intervention in cases of benign liver tumors should include symptoms, suspicion of malignancy, or risk of malignant change. Liver resection for benign liver tumor is safe, but indications for

intervention must be evaluated carefully. The presence of chronic parenchymal liver disease does not increase the morbidity of benign hepatic lesions in these patients. This study retrospectively investigated the perioperative predictors by reviewing 827 consecutive cases of benign hepatic lesion undergoing hepatectomy from January 1986 to December 2005 in Chinese PLA General Hospital.

MATERIALS AND METHODS

Patients

A total of 827 consecutive cases (334 males, 493 females, the male and female ratio = 1:1.48) of benign hepatic lesion undergoing hepatectomy from January 1986 to December 2005 in the Chinese PLA General Hospital were included in this study. Their age was 5-79 years and mean age was 43.88 years. Of the 827 cases, 345 had hepatic hemangiomas, 245 had intrahepatic bile duct stones, 35 had hepatic cysts, 35 had hepatic focal nodular hyperplasia, 17 had strictures of intrahepatic bile duct, 17 had hepatic adenoma, 16 had hepatic angioleiomyolipoma, 16 had hepatic echinococcosis, 13 had hepatic inflammatory pseudotumor, 11 had hepatic trauma, 11 had congenital biliary duct cystic dilatation, 10 had other inflammatory diseases (including 4 cases of extrahepatic disease and hepatic adherence disease, 3 cases of hepatic focal necrosis, 1 case of liver calcification, 1 case of hepatic mycotic chronic granuloma, 1 case of sclerosing cholangitis), 7 had hepatic cystadenoma, 4 had hepatic atypical hyperplasia, 4 had hepatic parasitic diseases, 4 had hepatic phthisis, 4 had hepatic granuloma, 4 had hepatic spontaneous haematoma, 3 had hepatic hamartoma, 3 had hepatapostema, and 23 had other diseases (including 6 cases of chronic cholecystitis with suspected preoperative malignant diseases, 4 cases of nodular cirrhosis with suspected preoperative malignant diseases, 2 cases of hepatic hemangioma and intrahepatic bile duct stone, 2 cases of portal hypertension requiring partial liver resection, 1 case of hepatic purpura, 1 case of hepatic lipoma, 1 case of hepatic adenomatous hyperplasia nodus, 1 case of hepatic fibroangiolipoma, 1 case of hepatic leiomyoma, 1 case of benign hepatic occupying lesion with suspected preoperative malignant diseases, 1 case of giant hepatic regenerative nodus with suspected preoperative malignant diseases, 1 case of hepatic artery-portal vein fistula requiring partial liver resection, 1 case of Budd-Chiari syndrome requiring partial liver resection).

Diagnostic methods and preoperative hepatic functional evaluation

All the results were obtained based on pathological diagnosis. Child-Pugh A was scored in 736 out of 750 cases, accounting for 98.13% (Table 1).

Table 1 Preoperative Child-Pugh score of patients

Child-Pugh score	*n*	%
5	635	84.7
6	62	8.3
7	39	5.2
8	9	1.2
9	5	0.7

Surgical methods

Incisions below the right costal margin were routinely used and the lesions were resected after liver was liberated from the left or right side. Regular hepatectomy, focal hepatectomy, and enucleation were performed. Hepatic hemangioma was enucleated after the liver blood flow was occluded. The liver sections were sutured face-to-face to reduce errhysis. Hepatic lobectomy or segmental resection was performed to remove intrahepatic bile duct stones since irregular focal hepatectomy could not accurately remove them, usually leading to remnant pathological tissue and stone. Fifty lesions were resected under laparoscope, accounting for 6.0%. Fifty-one lesions underwent line precoagulation liver resection with a WBD-2 equipment, accounting for 6.2%.

Statistical analysis

SPSS10.0 statistical software was used to analyze the 827 cases of benign hepatic lesions. $P < 0.05$ was considered statistically significant.

RESULTS

Extent of hepatectomy

Hepatectomy for more than 3 liver segments was performed in 183 cases, accounting for 22.1%, including 10 Ⅱ segmentectomies, 19 Ⅲ segmentectomies, 81 Ⅳ segmentectomies, 34 Ⅴ segmentectomies, 42 Ⅵ segmentectomies, 37 Ⅶ segmentectomies, 27 Ⅷ segmentectomies, 22 Ⅰ segmentectomies, 2 extended right hemibepatectomies, 3 extended left hemibepatectomies, 5 multiple suffusions, 129 right hemibepatectomies, 94 right posterior lobectomies, 49 right anterior lobectomies, 5 right trilobectomies, 4 central hepatectomies, 134 left hemibepatectomies, 1 left trilobectomy, and 255 left external lobectomies. If the lesions were located in multiple discontiguous segments (lobes), the locations were separately described. If the lesions were suffused in several segments (lobes), the locations were described as multiple suffusions.

Perioperative outcome

Perioperative results: Of the 827 cases, 517 (62.52%) had a blood loss of less than 200 mL, 99 (11.97%) had a blood loss of 200-400 mL, 146 (17.65%) had a blood loss of 400-1000 mL, 65 (7.86%) had a blood loss of more than 1000 mL , 316 (38.21%) required transfusion of blood products during operation (range 150-8090 mL, mean 879.33 ± 834.64 mL), including whole blood transfusion in 210 cases, red blood cell transfusion in 38 cases, plasma transfusion in 7 cases, mixed transfusion in the remaining cases, auto-blood transfusion in 63 (6.62%) cases (ranged 200-7079 mL, mean 870.45 ± 862.31 mL).

The operating time was 20 to 975 min (mean 220.59 ± 109.13 min). Hospital stay ranged 1-174 d (mean 25.24 ± 15.59 d). Postoperative hospital stay ranged 1-151 d (mean 13.55 ± 9.38 d).

Complications: Postoperative complications occurred in 112 cases (13.54%). The most common complications were epigastric complications related to liver cirrhosis: pleural effusion in 53 cases, hydroperitonia in 20 cases and perihepatic hydrops in 17 cases, which resolved without any sequelae after transfusion of condensed human serum albumin, adjustment of water and electrolyte balance, and administration of diuretics. The main procedure-related complications were perihepatic abscess in 7 cases, cholangitis in 4 cases, incisional infection or liquification in 13 cases. Bile leakage was the most severe complication in 10 cases (1.21%).

Logistic regression analysis of complication-related risk predictor was performed. Multivariate analysis showed that the independent predictors were gender, laparoscope, microwave in line precoagulation liver resection, abdominal operation history, simple anatomical hepatectomy, type B hepatitis, blood loss, the number of segments resected, operating time, albumin value, Child-Pugh score, and age. Operating time (P = 0.004, OR = 1.003) and albumin value (P = 0.040, OR = 0.938) were the independent predictors of complication. Operating time was the risk predictor and increased albumin value was the protection predictor.

Mortality: Two patients died with a mortality of 0.24%. One was a cases of liver trauma combined splenic rupture, hemorrhagic shock, and pelvic fracture. The blood pressure was too low to be measured during emergency operation although tremendous blood products and liquid were transfused. The patient died of blood loss and DIC eventually. The other was a case of intrahepatic bile duct stone undergoing left external lobectomy, exploration of the common bile duct, and T-tube drainage. Postoperative procedure was uneventful. Unfortunately, 15 d after operation, the patient died due to a sudden short breath, chest distress, and ventricular fibrillation.

Changes of perioperative predictors for hepatectomy in the last 20 years

The past 20 years were stratified into 4 stages with 5 years as a stage. The predictors were compared. Multivariate analysis indicated that operating time, blood transfusion, complication rate, and hospital stay had a trend to decrease (Table 2).

Table 2 Changes of perioperative predictors for hepatectomy in the last 20 years

Predictors	Yr	95% confidence interval (mean)	*P*
Age (yr)	86-90	42.676-48.375 (45.525)	0.004
	91-95	41.298-45.938 (43.618)	
	96-00	40.298-43.499 (41.898)	
	01-05	44.288-46.570 (45.429)	
Operating time (min)	86-90	236.649-290.639 (263.644)	< 0.001

	91-95	37.6% (38/101)	
	96-00	47.8% (98/205)	
	01-05	41.8% (165/395)	

DISCUSSION

Liver is the largest parenchymatous organ in the body which is deep seated in the epigastrium and protected by the bony thorax[11-14]. Liver has abundant blood flow and is a blest and indispensable organ, known as the "forbidden zone" or a "noli me tangere-do not touch me" organ. Liver surgery became possible in the second half of the 20th century and a rapid progress in liver surgery has been achieved in the latest 20-30 years[15,16]. Liver surgery for benign and malignant lesions mainly involves partial liver resection[17].

In the initial stage of liver surgery, the mortality is rather high due to the wide excision of liver and hepatectomy is only suitable for selective malignant lesions and the expected outcome is not good. However, the current surgical techniques make it possible to perform operations on liver. The safety is not inferior to other large intraabdominal operations. It was reported that the mortality of patients with liver tumors could be lowered to the minimum, even to zero[17,18]. Nowadays, surgery is a routine treatment modality for benign hepatic lesions. Zhi-Qiang Huang has reported two cases of intrahepatic bile duct stone (the secondary common benign hepatic lesion in China) treated with left external

lobectomy or right hepatectomy since 1958, leading to wide application of hepatectomy for benign hepatic lesions in clinical practice[19-23].

In this study, retrospectively investigated 827 consecutive cases of benign hepatic lesions were retrospectively investigated in the Chinese PLA General Hospital, which provides some evidence-based data about the improved hepatectomy techniques.

In this series, the most common diseases were hemangioma and intrahepatic bile duct stone, accounting for 41.7 % (345/827) and 29.6% (245/827), respectively. It was reported that the incidence of intrahepatic bile duct stone is higher than hemangioma in China[24].

Hepatectomy can be divided into two categories: hepatectomy involving bile duct and hepatectomy not involving bile duct. Usually, hepatectomy involving bile duct has more complications. The operation procedure, mainly using regular segmental resection or lobectomy, therefore, has different characteristics. Intrahepatic bile duct stone is the representative of this kind of lesion. In 1958, our operation team first reported regular lobectomy for intrahepatic bile duct stone based on the theory that intrahepatic bile duct stone is a kind of segmental lesion with a strict distribution within the liver[25,26]. After more than 50 years, this conception has been well established and developed gradually[27]. In the present series, 202 cases of intrahepatic bile duct stone underwent anatomical hepatectomy, accounting for 82.4% of the total cases, with a complication rate of 16.3% (data not shown). Hepatectomy not involving bile duct is mainly for liver tumors. Hepatic hemangioma is the main representative of benign hepatic lesions[10,19,21,28], which grows slowly and recurs occasionally and can be radically resected. Because of the well-demarked border between the tumor and its normal liver tissue, enucleation is usually performed. In this series, the complication rate was 11.3%, lower than that of intrahepatic bile duct stone.

The postoperative complication rate of hepatectomy was 13.54% in this series. Multivariate analysis showed that operating time (P = 0.004, OR = 1.003) and albumin value (P = 0.040, OR = 0.938) were the independent predictors of morbidity of benign hepatic lesion. Operating time was the risk predictor and increased albumin value was the protection predictor. The study indicated that some surgical technical refining, for instance, optimizing surgical instruments, increasing the surgeon's proficiency and co-operation level, should be taken into account to decrease the operating time so as to reduce complications.

The albumin value should be emphasized on the preoperative liver functional reserve evaluation. In this series, two patients died with a perioperative mortality of 0.24%. One was a case of liver trauma complicated by splenic rupture, hemorrhagic shock, and pelvic fracture, and died of blood loss and DIC. The other case had a sudden death because of ventricular fibrillation 15 d after operation.

The Chinese PLA General Hospital have performed, 2008 hepatectomies for benign and malignant lesions with a total perioperative complication rate of 14.44% and a mortality rate of 0.55%[29]. In this series, the perioperative complication rate and mortality were lower than the total perioperative complication rate and mortality, indicating that hepatectomy is safer for benign hepatic lesion than for malignant lesions.

In addition, multivariate analysis revealed that operating time, blood transfusion, complication rate, and hospital stay had a trend to decrease, indicating that surgical quality is improved.

In conclusion, hepatectomy is a safe procedure for benign hepatic lesions. Benign hepatic lesions should undergo aggressive surgical management when clinical presentations, diagnosis, society factors, and progress in liver surgery are considered. Reducing operating time and preoperative liver functional reserve evaluation play an important role in improving the operation quality.

ACKNOWLEDGMENTS

The authors thank all who assisted us in collecting data from the Hepatobiliary Surgery Institute of the Chinese PLA General Hospital.

COMMENTS

Background

Hepatectomy is a dangerous and complex surgical procedure. The choice of surgical procedure for benign hepatic lesion is controversial.

Research frontiers

Operative safety and indication of hepatectomy for benign hepatic lesions at different sites are the key research frontier.

Innovations and breakthroughs

We analyzed the operative and perioperative factors associated with hepatectomy for benign hepatic lesions. Multivariate analysis showed that operating time (P = 0.004, OR = 1.003) and albumin value (P = 0.040, OR = 0.938) were the independent predictors of morbidity.

Applications

The postoperative complication rate of hepatectomy was 13.54% and in-hospital mortality rate was 0.24%, indicating that hepatectomy is a safe procedure for benign hepatic lesions.

Peer review

This is a very large series of hepatectomy for benign liver lesions. It is a publishable manuscript and very informative. The manuscript should provide more strong messages than "hepatectomy is a safe procedure for benign hepatic lesions". The authors advocated that benign hepatic lesions should undergo aggressive surgical management when clinical presentations, diagnosis, society factors, and progress in liver surgery are considered. Reducing operating time and preoperative liver functional reserve evaluation play an important role in improving the operation quality.

Abstract

Mucinous cystic neoplasms (MCNs) of the pancreas occur mostly in females and are potentially sex hormone-sensitive. However, a MCN occurring during pregnancy is quite rare. A 30-year-old woman in the tenth week of pregnancy was referred to us because of a rapid increase in left hypochondrial distending pain. On ultrasound, the patient had a large intra-abdominal cystic lesion. She was thereafter diagnosed with missed abortion and a computed tomography scan showed that the lesion was a cystic tumor 18 cm in diameter originating from the pancreatic tail. The patient subsequently underwent tumor resection with distal pancreatectomy, sparing the spleen. Histopathological analysis of the specimen revealed a pancreatic MCN with moderate dysplasia. Immunohistochemically, the tumor was positive for both estrogen and progesterone receptors. To our knowledge, this is the first reported case of pancreatic MCN with moderate dysplasia in association with pregnancy. Our case strongly indicates that pancreatic MCN is female-hormone dependent.

INTRODUCTION

Mucinous cystic neoplasm (MCN) of the pancreas is an uncommon tumor characterized by a proliferation of mucin-producing columnar epithelium supported by ovarian-type stroma[1,2]. MCNs are typically located in the pancreatic body or tail and rarely communicate with the pancreatic duct[1,2]. Pancreatic MCNs occur almost exclusively in females, and are potentially sex hormone-sensitive, according to the studies reported to date[2]. However, MCNs encountered in pregnancy are rare; only eight such cases have been reported in the English literature[3-10]. In this report, we describe a 30-year-old woman with a large pancreatic MCN that grew rapidly during the early stage of pregnancy.

CASE REPORT

A 30-year-old woman in the tenth week of pregnancy was referred to our hospital due to increasing distending pain in the left hypochondrial region over the last month. She had no notable medical history, but had complained of vague epigastric discomfort over the past several years. Physical examination suggested the presence of an elastic hard mass, approximately 20 cm in diameter, in the left upper quadrant. Laboratory tests showed slight anemia and normal levels of amylase, liver enzymes, and tumor markers. An abdominal ultrasound demonstrated a huge cystic lesion in the left upper abdomen. Soon after hospitalization, her pregnancy ended in missed abortion at 10 wk gestation, which was confirmed by clinical and ultrasound findings. Further evaluation by computed tomography (CT) scanning revealed a well-demarcated cystic mass, measuring 18 cm × 14 cm, probably originating from the distal pancreas (Figure 1). There were

Figure 1 Abdominal computed tomography scan showing a huge cyst measuring 18 cm in diameter.

Figure 2 Macroscopic view of the cystic tumor.

no septa or protruding lesions inside the cystic mass.

Ultrasound-guided percutaneous cyst aspiration was then performed to reduce the pain, and 2100 mL of dark-brownish mucinous fluid was aspirated, without spillage into the peritoneal cavity. The aspirated fluid showed an amylase level of 59 IU/L, a carcinoembryonic antigen (CEA) level of 32100 ng/mL, and a carbohydrate-associated antigen (CA) 19-9 level of 34500 U/mL. Cytological examination of the fluid was class Ⅱ with no malignant findings. Thus, a diagnosis of possible pancreatic MCN was made. After dilatation and curettage, the cystic mass was resected with distal pancreatectomy. Since invasive carcinoma was not suspected by preoperative images and intraoperative findings, the spleen was preserved. The tumor was unilocular, had thick walls, and was filled with tenacious mucoid material and necrotic debris (Figure 2). Histopathological analysis showed a mucin-producing columnar epithelium lining the inner wall of the cyst, with ovarian-type stromal tissue (Figure 3A). The epithelium had a focal papillary architecture without significant cytologic atypia, giving a diagnosis of pancreatic MCN with moderate dysplasia (Figure 3B). Immunohistochemical studies showed positive staining for both progesterone and estrogen receptors in the stromal cell nuclei (Figure 3C and D). The patient had an uneventful post-operative course, and she remained disease-free for 12 mo after surgery.

DISCUSSION

To our knowledge, eight cases of pancreatic MCN associated with pregnancy have been reported since the first report in 1968 by Smithers *et al*[7]. Four cases were histologically diagnosed as benign mucinous cystadenoma[3-6], while the other four were diagnosed as mucinous cystadenocarcinoma[7-10]. Our case might be the first case of pancreatic MCN with moderate dysplasia (also referred to as "borderline tumor"), in association with pregnancy.

Although cystic tumors of the pancreas often grow slowly and can remain indolent for many years[5,10], MCNs which develop during pregnancy tend to grow more rapidly and achieve extraordinary size. Kato *et al*[4] reported that a pancreatic MCN in a pregnant patient rapidly increased in volume from 2619 to 4950 mL over 46 d. Ganepola *et al*[3] also reported a case whose cyst increased in size from 5.5 cm to more than 12 cm within 4 mo. In a recent review, 344 MCNs defined by ovarian-type stroma had a mean size of 8.7 cm (range, 0.6-35 cm)[11], whereas in the review of reported cases and in our case, pregnancy associated-MCNs had a mean size of 15 cm (range, 10-22 cm).

These findings are consistent with the concept that pancreatic MCNs may be responsive to female sex hormones. One series reported that stromal cell nuclei were positive for estrogen receptors in 15 of 65 MCN cases (23%) and for progesterone receptors in 46 cases (71%)[2]. The predominantly female occurrence and the expression of female hormone receptors in MCNs has been the subject of much speculation. One possibility is that MCNs originate from primitive ovarian cells, which are incorporated into the embryonic pancreas when the left primordial gonad is in close proximity to the dorsal pancreatic anlage during embryogenesis[1]. The dorsal pancreatic anlage gives rise to the body and tail of the pancreas, and this hypothesis could explain the predilection of MCNs for the distal pancreas. Another possibility is that the neoplastic epithelial cells of MCNs might induce ovarian stromal differentiation in cells that normally reside in the pancreas. This concept is based on the fact that the stroma in the fetal pancreas is morphologically similar to that of MCNs[12]. However, direct evidence for these hypotheses has yet to be found.

Pancreatic MCN presents a clinical problem in that it always carries a malignant potential. Mucinous cystadenocarcinoma can be considered not only as a neoplasm arising de novo but also as an evolution of the benign form[8]. As large tumor size was reported to be one of the predictive factors of malignant MCNs[13], it is prudent to assume that the increased growth of MCNs during pregnancy brings with it some degree of increased risk for malignant transformation[9]. However, it remains unclear whether high levels of estrogen and progesterone in pregnancy accelerate the malignant transformation of a benign tumor into a malignant tumor. In fact, there is evidence that a decrease in progesterone receptor immunoreactivity was correlated with histological or cytological atypicality and a worse prognosis[2].

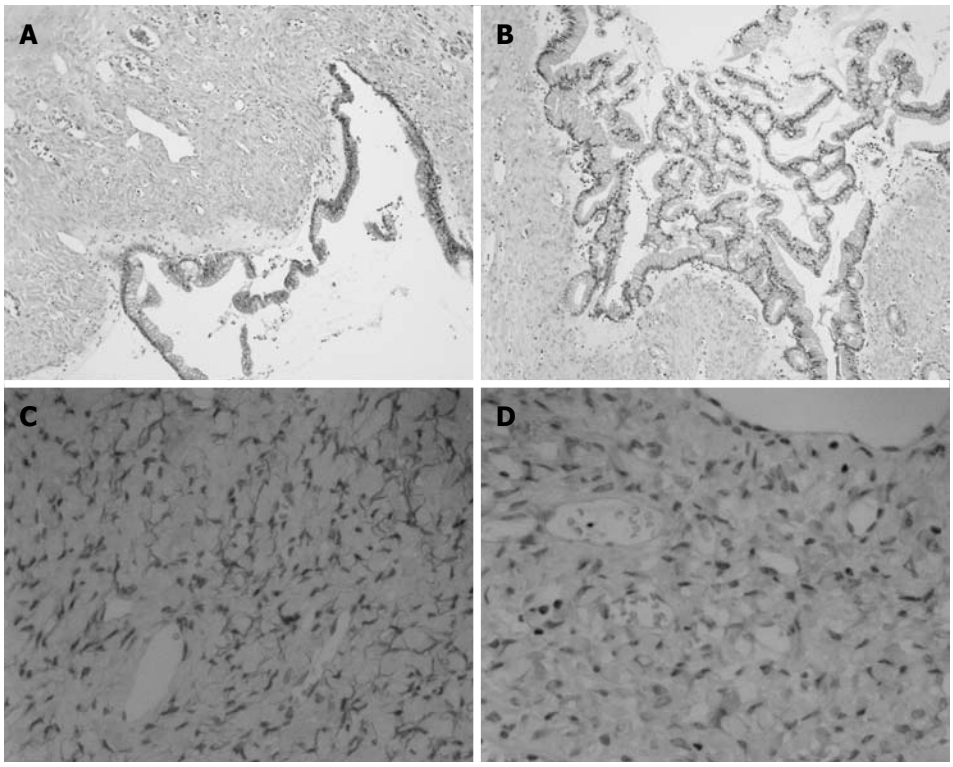

Figure 3 Microscopic findings of the cystic tumor. A: Columnar, mucin-producing epithelium with underlying ovarian-type stroma (HE, x 100); B: The epithelium had a focal papillary architecture (HE, x 100); C: Positive staining in the stromal cell nuclei for progesterone receptor (x 400); D: The estrogen receptor of stromal cell nuclei (x 400).

Pancreatic MCN detected during pregnancy requires special management considerations due to its large size and resultant risk for fetal growth restriction. So far, there have been four cases of successful antepartum resection of pancreatic MCN during pregnancy that later resulted in healthy infants[3-5,9]. These authors have recommended the second trimester as a safe period for surgery because this period provides enough time for fetal maturity. Since the tumor in the present case did not compress the uterus, there may be no direct correlation between tumor progression and miscarriage in our patient.

In the present case, successful cyst aspiration provided a basis for accurate diagnosis as well as symptom relief for the patient. Cyst fluid analysis has recently been utilized to differentiate pancreatic cystic neoplasms. van der Waaij *et al*[14] found that an amylase concentration below 250 U/L effectively ruled out pseudocyst. In addition, it has been reported that cyst fluid CA 19-9 level greater than 50000 U/mL had a sensitivity of 75% and a specificity of 90% for distinguishing mucinous tumors from other cystic lesions[15]. Furthermore, a recent series[16] revealed that cyst fluid CEA greater than 800 ng/mL had a sensitivity of 42.9% and a specificity of 95.2% for diagnosing pancreatic MCNs. When performing cyst aspiration, however, care must be taken to avoid spillage of cyst contents, which may result in the development of pseudomyxoma peritonei[4].

In summary, our report describes the ninth case of pancreatic MCN associated with pregnancy and the first such case of MCN with moderate dysplasia. Our case strongly indicates that pancreatic MCN is a hormone-dependent tumor that can grow dramatically during pregnancy. Considering the malignant potential of this tumor and adverse effects on the fetus, complete resection should be performed without delay.

ACKNOWLEDGMENTS

We acknowledge the contributions of Dr. Ohe to the diagnosis and management of this patient.

Abstract

The author reports a very rare case of sporadic primary multiple extragastrointestinal stromal tumors (EGISTs) of the omentum associated with different mutations of the exon 11 of the *c-kit* gene in a 75-year-old man with gastric cancer. During an operation for the cancer, two solid tumors (10 mm and 8 mm) were found in the omentum. Both tumors consisted of cellular spindle cells. Mitotic figures were two and three per 50 high power fields. The tumor cells were positive for KIT, CD34 and vimentin, but negative for desmin, S100 protein, α-smooth muscle actin and p53 protein. Ki67 labeling was 2% and 3%. The larger EGIST showed a deletion of codons 552-558 of exon 11 of the *c-kit* gene, while the smaller EGIST had a point mutation at codon 559 (GTT→GAT) in exon 11 of the *c-kit* gene. Exons 9, 13, and 17 of the *c-kit* gene, and exons 12 and 18 of the platelet derived growth factor receptor α genes showed no mutations. The case shows that sporadic multiple EGISTs can occur in the omentum.

Terada T. Primary multiple extragastrointestinal stromal tumors of the omentum with different mutations of *c-kit* gene. *World J Gastroenterol* 2008; 14(47): 7256-7259 Available from: URL: http://www.wjgnet.com/1007-9327/14/7256.asp DOI: http://dx.doi.org/10.3748/wjg.14.7256

INTRODUCTION

Gastrointestinal stromal tumors (GIST) were once thought to be smooth muscle or neurogenic tumors, but recent advances in the study of the *c-kit* gene and platelet derived growth factor receptor α (*PDGFRA*) gene have revealed that GIST are associated with gain-of-function mutations of the *c-kit* gene and the *PDGFRA* gene[1,2]. KIT is a transmembrane receptor tyrosine kinase whose ligand is stem cell factor[3]. GIST is believed to be derived from interstitial cells of Cajal (ICC) (pacemaker cells) which are present in the muscular layer of the gastrointestinal walls[3]. ICC expresses KIT protein (CD117) and CD34[3]. Immunohistochemical demonstration of KIT and/or CD34 is a hallmark in the pathological diagnosis of GIST[3].

Mesenchymal tumors resembling GIST and positive for KIT have been found in the soft tissue[4] and less frequently in abdominal organs such as the liver[5], gall bladder[6,7], pancreas[8,9], and serosa[10]. Such tumors are called extragastrointestinal stromal tumors (EGIST). The present study presents a case having two EGISTs in the greater omentum. According to Todoroki *et al*[11], 28 cases of EGISTs in the omentum have been reported in the literature. However, primary multiple GISTs in the omentum have been reported only once, by Kim *et al*[12]. The author here reports this case with a comparison with normal omentum.

CASE REPORT

A 75-year-old Japanese man complained of epigastralgia. The patient did not have neurofibromatosis, and denied any family history of mesenchymal tumors of the gastrointestinal organs. An endoscopic examination showed a depressed lesion of the stomach, and a biopsy showed well-differentiated adenocarcinoma. No tumor formations were noted by various imaging modalities including CT. A gastrectomy was performed, and during the operation two small solid tumors (10 mm and 8 mm in diameter, respectively) were found in the greater omentum. The both tumors were not attached to the gastrointestinal organs. Both tumors were diagnosed as EGISTs as described below, and treated by imatinib. No recurrence was seen one year after the operation.

Cases of EGIST were reviewed from 27659 surgical and biopsy specimens performed from 2000 to 2007, in my laboratory. As a result, thee cases of EGIST were found. One was a uterine EGIST, one was an omental

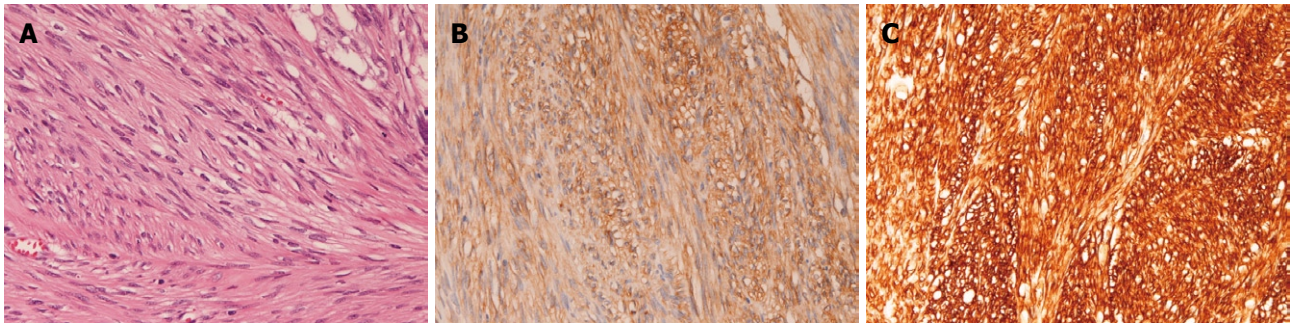

Figure 1 Histological and immunohistochemical findings of the tumors. A: Histology of the tumor. The tumor is composed of cellular spindle cells. Hematoxylin and eosin (x 200). B: KIT immunostaining of the tumor. KIT is diffusely and strongly positive in the tumor cells (x 200). C: CD34 immunostaining of the tumor. CD34 is diffusely and strongly positive in the tumor cells (x 200).

EGIST, and one was a mesenteric EGIST. In this case report, the author shows a case of omental EGIST. The patient's clinical records were obtained. As controls, three cases of normal omentum, which were resected in cases of ovarian cancer, were used. The materials were fixed in 10% formalin and embedded in paraffin. Several 3-μm sections were cut from each paraffin block, and stained with hematoxylin and eosin.

Immunohistochemical studies were performed by the DAKO's envision method as previously described[13]. The antibodies used were KIT (polyclonal, Dako Corp, Glustrup, Denmark), CD34 (QBEND10, Dako), vimentin (Vim 3B4, Dako), desmin (D33, Dako), α smooth muscle actin (1A4, Dako), S100 protein (polyclonal, Dako), p53 protein (DO7, Dako), and Ki-67 antigen (MIB1, Dako).

Genetic analyses for the *c-kit* gene (exons 9, 11, 13 and 17) and the *PDGFRA* gene (exons 12 and 18) were performed by direct sequencing of PCR products. The exons of both genes were selected because they are frequent mutation sites[3]. The primers are shown in Table 1. In brief, genomic DNA was extracted from the paraffin blocks by proteinase K digestion and phenol/chloroform extraction, and subjected to PCR for 40 cycles (94℃ for one minute, 52℃ for one minute, and 72℃ for one minute), using a thermal cycler (GeneAmp PCR system 9700, Applied Biosystems, ABI, CA). The annealing temperature was 53℃. The PCR products were then subjected to electrophoresis in a 2% agarose gel with ethidium bromide, and the PCR products were diluted 1:1 in loading buffer (94% formamide, 10mg bromphenol blue), denatured by heating at 98℃ for three minutes, and snap frozen, before being electrophoresed on a polyacrylamide gel. The products were extracted and sequenced on an ABI PRIZM 3100 Genetic analyzer (Applied Biosystems, ABI, CA).

Histologically, the both tumors showed almost the same morphologies. Both tumors consisted of cellular spindle cells (Figure 1A). Mitotic figures were two in the smaller tumor and three in larger tumor, per 50 high power field (HPF). No epithelioid pattern was recognized and no necrotic areas were present. Immunohistochemically, the tumor cells of both tumors were strongly positive for KIT (Figure 1B), CD34 (Figure 1C) and vimentin, but negative for desmin, S100 protein, α-smooth muscle actin and p53 protein. Ki67 labeling was 2% in the smaller tumor and 3% in the larger tumor. Both tumors were diagnosed as EGIST. The normal omentum showed scattered mesenchymal cells positive for KIT and CD34 in the surface of the omentum. The stomach lesion was an early well-differentiated adenocarcinoma confined to the mucosa. The stomach showed no GISTs.

Genetic analyses for the *c-kit* gene (exons 9, 11, 13 and 17) and the *PDGFRA* (exons 12 and 18) showed a deletion at codon 552-558 of exon 11 of the *c-kit* gene in the larger tumor (Figure 2). The small tumor showed a point mutation (GTT→GAT) at codon 559 of exon 11 of the *c-kit* gene (Figure 3). Other exons of the *c-kit* gene showed no abnormalities. Exons 12 and 18 of the

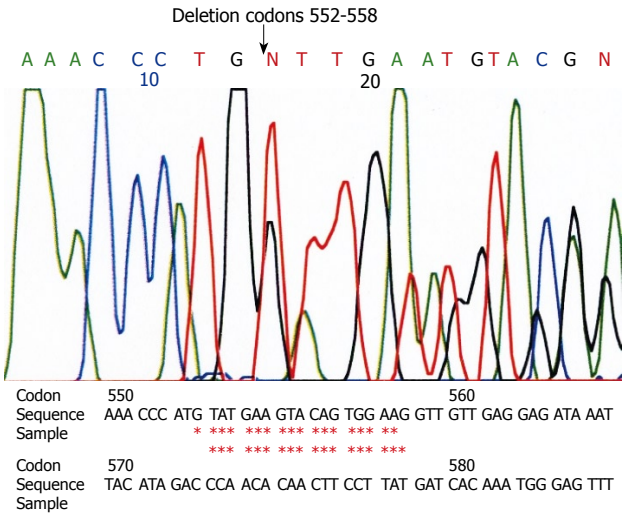

Figure 2 Computer analysis of a part of exon 11 of the *c-kit* gene in the larger tumor. Deletion of codons 552-558 is noted. Asterisks show the deletion.

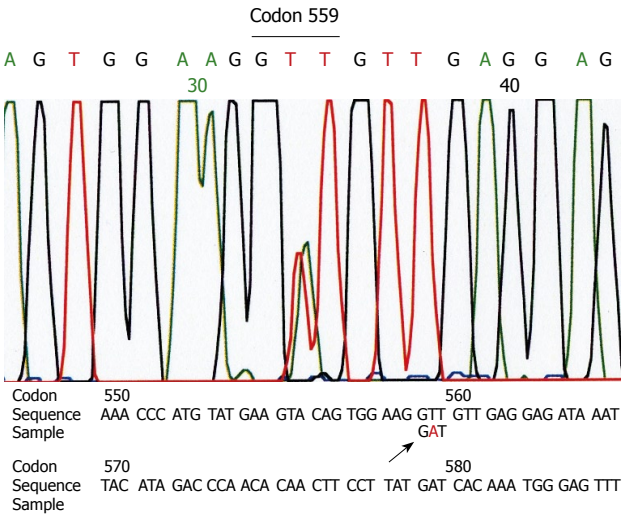

Figure 3 Computer analysis of a part of exon 11 of the *c-kit* gene in the smaller tumor. A mutation at codon 559 (GTT→GAT) is recognized (arrow).

PDGFRA gene also showed no abnormalities in both tumors. The normal omentum showed no abnormalities in either of the two genes.

DISCUSSION

According to Todoroki *et al*[11], there are 28 cases of EGIST of the omentum in the literature. Most of them are single EGIST[10,11], and multiple EGISTs of the omentum have been reported only once[12]. The present study reports a second case of primary multiple EGIST of the omentum. The diagnosis of EGIST of the present case was conclusive. The present study showed scattered KIT-positive ICC-like cells in surface of the omentum. Sakurai *et al*[14] also reported KIT-positive ICC-like mesenchymal cells in the omentum. Therefore, the present case may be derived from the ICC-like cells physiologically present in the omentum.

GIST is thought to be a potentially malignant tumor[3]. The malignant potential has been accessed by various parameters, such as tumor size, mitotic figures, necrosis, cell type, and Ki-67 labeling[15-17]. However, the parameters and the results varied from one observer to another. For example, Hasegawa *et al*[17] reported that tumor size of less than 5 cm was low risk, 5-10 cm posed an intermediate risk, and more than 10 cm posed a high risk. The present case is probably low risk due to the tumor size. GIST with mitotic figures less than 5 per 50 high power fields are low risk, 5-10 are intermediate risk, and more than 10 are high risk. The present case is low risk according to the mitotic count. The presence of necrosis is a high risk for malignancy, therefore the absence of necrosis in the present case also suggests it is low risk. Ki-67 labeling is also related to the GIST risk. In the present study, the Ki-67 was 2% and 3%, respectively, indicating low risk. Taken together, these data suggest that the present EGIST case has a low risk of malignancy.

The present study examined the *c-kit* and *PDGFRA* genes and found that the two EGISTs of the omentum had different mutations in exon 11 of the *c-kit* gene. It has been found that mutations ratio of the *c-kit* gene is 80% in exon 11, 15 % in exon 9, and less than 2% in exons 13 and 17[3]. Mutations ratio of the *PDGFRA* gene is 10% in exon 18 and less than 2% in exons 12 and 14[3]. Therefore, the present case showed a common mutation pattern. In addition, the present case shows that the two EGISTs are not identical tumors, but individual tumors with different pathogenesis.

Imatinib has been developed to treat GIST[3]. The present case also used Imanitib. Imanitib is effective in GIST cases with c-kit mutations in exon 11[3] and in present case it may have been be effective, because neither recurrence nor metastasis has been seen one year after the operation.

In summary, the author showed a very rare case of primary multiple EGISTs of the omentum with different mutations in exon 11 of the *c-kit* gene.

Abstract

Portopulmonary hypertension (PPH) is clinically defined as the development of pulmonary arterial hypertension complicated by portal hypertension, with or without advanced hepatic disease. Physical signs may be absent in mild to moderate PPH and only appear in a hyperdynamic circulatory state. Similar signs of advanced liver disease can be observed in severe PPH, with ascites and lower extremity edema. Pulmonary hypertension is usually diagnosed after anesthetic induction during liver transplantation (LT). We present intraoperative pulmonary hypertension in a 41-year-old male patient with hepatic cirrhosis. Since this patient had no preoperation laboratory data supporting the diagnosises of pulmonary hypertension and was asymptomatic for a number of years, it was necessary to send him to the intensive care unit after operation. Further study should be focued on the diagnosis and treatment of pulmonary arterial hypertension in order to reduce its mortality.

INTRODUCTION

Patients with liver disease are predisposed to develop histological changes in pulmonary vessels, which will cause pulmonary vascular disease, particularly pulmonary hypertension. Portopulmonary hypertension (PPH) is usually regarded as a severe complication of chronic liver disease with portal hypertension and occurs in 5%-10% of patients with advanced liver disease[1]. Direct measurement of pulmonary artery pressure (PAP) by right-heart catheterization (RHC) remains the gold standard for detecting pulmonary hypertension. Doppler echocardiography using trans-tricuspid valve gradient allows noninvasive estimation of pulmonary artery systolic pressure, and is mostly used for liver transplant candidates. However, echocardiography and electrocardiography are seldom performed in patients with mild or moderate PPH[2].

Patients with PPH may be asymptomatic at the time of diagnosis, and symptoms associated with advanced liver disease and portal hypertension may be indistinguishable from those of PPH of any causes[3]. The recognition of PPH requires a high degree of clinical suspicion. Treatment options for patients with PPH are few. Previous studies have shown that cirrhotic patients with moderate to severe pulmonary hypertension have a very high mortality. Patients with severe PPH who undergo liver transplant without vasodilator therapy have an extremely poor survival[4]. However, recent reports indicate that preoperative therapy can reduce pulmonary hypertension and right ventricle dysfunction, thus improving clinical status and making liver transplantation (LT) feasible[5-7]. However, pro-operative therapy is not efficient for portal hypertension (PHT). There

is no doubt that the occurrence of non-pulmonary manifestations of perioperative pulmonary hypertension presents management challenges. This report describes our new experience with the management of portal and pulmonary hypertension.

CASE REPORT

A 41-year-old male patient with end-stage liver disease secondary to alcohol and hepatitis B was referred to our department for LT. Over the previous 10 mo, the patient had ariceal bleeding, increasing jaundice, and ascites. Cutaneous spider naevi were present and his fingertips were clubbed. He refrained from smoke five years ago due to chronic active hepatitis B and denied to have prior pulmonary problems. Pulmonary and cardiac examinations were unremarkable. Chest radiography showed normal main and central pulmonary arteries. Electrocardiogram was within the normal range with no evident signs of pressure overload of the right atrium and ventricle. Lung function tests showed a mild restrictive pattern that was ascribed to ascites. Total lung capacity, FEV1 and FVC were in normal range. Urinalysis was negative. His liver function tests were as follows: 101 μmol/L total bilirubin with a direct fraction of 50 μmol/L, 113 U/L alkaline phosphatase, 112 U/L ALT and 83 U/L AST. The end-stage liver disease score was 24. PCR showed that His viral profile was HBsAg (+), anti-HBs (-), HBeAg (-), anti-HBe (+), anti-HBc (+) and HBV DNA < 10^3 copies/mL. He received 4 wk of lamivudine therapy.

Following our usual protocol for monitoring LT recipients, routine intraoperative transesophageal echocardiography was performed during LT[8]. The pulmonary artery was a moderately enlarged. His systolic PAP was higher than 53 mmHg, pulmonary capillary wedge pressure (PCWP) was 10 mmHg, cardiac output (CO) was 7.4 L/min), pulmonary vascular resistance (PVR, 201 dyn·s·cm^{-5}) was higher than the usual values observed in cirrhotic patients[9]. To reduce the increased PAP, the patient administrated nitric oxide (40 ppm) and epoprostenol (40 μg). However, no notable reduction was found in the mean PAP (mPAP). Epoprostenol therapy was continued with its dose increased from 6 to 20 ng/kg per min. One hundred percent of oxygen was then administered before liver dissection. Then the PAP came down slowly. LT was performed using the "piggyback technique", a standard procedure without venovenous bypass[8]. The anhepatic phase lasted 78 min and reperfusion was tolerated without any significant incident. Immediately after the liver was reperfused, PAP increased to a maximum of 75 mm Hg (60% of systemic level) and terribly reflow was present in the graft. About 10 min later, PAP decreased to less than 40% of systemic level (Table 1).The speed of dobutamine infusion was increased to 3-5 mg/kg per min for continuous inotropic and pulmonary vasodilator effect. The color of graft became normal after 30 min. PVR was only slightly increased, but the mean PAP was markedly increased due to a profound increase in cardiac output. After haemostasis, further surgery was completed uneventfully. At the end of surgery, haemodynamics of the patient was stable. The total operative time was 8 h. The estimated blood loss was 3346 mL, so that the patient was transfused 10 U of packed red blood cells and 30 U of fresh-frozen plasma. Immunosuppression was initiated with cyclosporin, mycophenolate mofetil, and steroid was withdrawn followed by maintenance of immunosuppression with cyclosporin and mycophenolate mofetil.

During the following 24 h in the intensive care unit (ICU), haemodynamics was mildly increased in PVR which was reduced when pulmonary vasodilators (nitroglycerin, isoprenaline, epoprostenol) were used. At this time, mPAP was 35 mmHg. The patient was extubated with dobutamine discontinued approximately 20 h after surgery. PaO_2 was 9.2 kPa, $PaCO_2$ was 6.2 kPa, and HCO_3^{-2} was 8 kPa (pH 7.36) after extubation. Graft function was remarkable following a continuous decrease in transaminases and prothrombin time (PT 50%). The post-transplant viral prophylaxis included HBIG (10 000 U/d) during the anhepatic period and lamivudine (100 mg/d) in the morning of postoperative day 1[10]. On the 7th postoperative day, the patient was transferred to the normal ward. Three weeks later, the liver function was recovered with normal transaminases and PT. In the follow-up, pulmonary function, chest X-ray and pulmonary angiography showed no evidence of pulmonary hypertension.

In January 2008, almost 2 years after LT, the patient was still in good condition and had no signs of pulmonary hypertension. A Doppler echocardiogram showed that the size right and left ventricles was normal. The viral profile of the patient was not good after transplantation with persistent positive HBsAg and negative anti-HBs and HBV DNA.

DISCUSSION

PPH is defined as mPAP ⩾ 25 mmHg and PCWP ⩽ 15 mmHg with evidence of portal hypertension. It was reported that 60% of patients with PPH are asymptomatic at the time of diagnosis, and symptoms associated with advanced liver disease and portal hypertension may be indistinguishable from those of PPH[3]. Therefore, the diagnosis of PPH is frequently established in the operating room before the transplantation procedure. Some of these patients may have mPAP exceeding 25 mmHg, but they do not have the associated pathological changes in the pulmonary vasculature that increase the mortality[11]. Some right heart catheterization information is derived from the operating room during general anesthesia[12]. Pulmonary pressure tends to increase during the initial stage of anesthesia. Our patient's pulmonary hypertension was atypical before operation and revealed pulmonary hypertension after inhaling anesthesia. Since inhalational anesthetic agents can independently increase venous return, central filling and cardiac output can be achieved in patients with portal hypertension[13].

Table 1 Intra- and post-transplantation cardiopulmonary hemodynamic data

Time	mPAP (mmHg)	PVR (dyn·s·cm^{-5})	Therapeutic agents
Before clamp	35	254	Epoprostenol, NO, 100% O_2
Anhepatic	40	340	Epoprostenol, 100% O_2
Reperfusion (15 min)	40	NA	Epoprostenol and milrinone, adrenaline
Enter ICU	30	NA	Epoprostenol
24 h-pro	35	240	Epoprostenol and isoprenaline
48 h-pro	30	211	Epoprostenol and isoprenaline

LT: Liver transplantation; mPAP: Mean pulmonary artery pressure; PCWP: Pulmonary capillary wedge pressure; PVR: Pulmonary vascular resistance; NO: Nitric oxide; NA: Not applicable.

Until now, the treatment options for patients with PPH are few, and the reported mean survival time of PPH patients after diagnosis is approximately 15 mo[14]. Nitric oxide, prostacyclin and isosorbide-5-mononitrate have been administered to improve PAP before and after LT[15]. Because of the association of portosystemic shunting with pulmonary hypertension, LT cannot cure both portal hypertension and PHT. LT is well tolerated in patients with only mild or moderate PPH. The mortality rates of patients with or without PPH after operation are comparable[16]. Since the risks in patients with severe PHT appear to be unacceptably high, and the affected patients deny LT, the marked reduction in PAP after epoprostenol therapy for patients with severe PPH may result in a marked decrease in perioperative mortality after LT[17]. PAP in this patient was steadily increased vasodilator therapy. This patient had a significant response to intravenous epoprostenol and the nitric oxide was also inhaled to test the reversibility of mPAP during operation. Continuous use of pulmonary vasodilators (isoprenaline, epoprostenol) reduced his PVR. Pulmonary hypertension may exacerbate after operation when patients receive no epoprostenol, and the patients may die of right ventricle failure[4]. Improvement in and de novo development of PPH may occur following LT[18-20]. The reason why transplant patients develop pulmonary hypertension following transplantation is unknown[13].

It was reported that transplant mortality is 36% (13/36) in patients with PPH[21]. Evidence from two studies suggests that preoperative mPAP is an independent predictor of mortality[6,22]. Another study showed that mPAP is not an accurate predictor of mortality and that pressure measurement does not serve as an independent surrogate of the severity of disease or outcome[23]. The marked difference in outcome suggests that single hemodynamic variables are not related with mortality in patients with PPH. In the literature, death of patients with PPH undergoing LT often occurs in the postoperative period due to cardiocirculatory stress or infectious complications[1,24,25]. Alternatively, defective hepatic metabolism and portosystemic shunting may expose the pulmonary vasculature to proliferating, vasoconstrictive, or inflammatory compounds that accelerate the progression of pulmonary arteriopathy or right ventricular failure[25]. Safer strategies for LT in patients with asymptomatic PPH can reduce the mortality rate. Our current strategies are as follows. (1) Right heart catheterization should be done pre-operation when PPH is suspected; (2) pulmonary vascular resistance should be decreased with intravenous epoprostenol therapy after diagnosis of PPH; (3) nitric oxide, epoprostenol, calcium channel blockers and other agents should be used during perioperation[26]; (4) venovenous bypass or piggy back technique that allows a more restrictive volume replacement during the anhepatic phase should be used.

In conclusion, asymptomatic PHT is not a contraindication to LT, and some of PHT patients may survive many years after LT. Patients with asymptomatic PHT who might benefit from LT need to be better characterized, and reliable screening methods to identify these patients need to be developed.

Abstract

The safety and feasibility of pregnancy following liver transplantation (LT) have been accredited in a series of LT center. The first case in mainland China is reported. The follow-up data of a 22-year-old pregnant patient with end-stage liver disease undergone orthotopic liver transplantation were analyzed retrospectively. After surgery, the patient was uneventfully recovered and became pregnant 33 mo after LT. The patient was closely monitored and treated with a standard and individualized triple-drug immunosuppressive therapy throughout her pregnancy. Caesarean section was performed in March 18, 2004, and a health live-born infant was delivered. After the delivery, a 4-year follow-up period indicated that the patient was satisfactory with her condition and her baby was healthy. Our case shows that a successful pregnancy following LT is possible and safe in women with end-stage liver diseases under close monitoring. Three factors including mother, baby, and transplanted liver function must be considered for the safety of high-risk pregnancies.

INTRODUCTION

Liver transplantation (LT) is now an acceptable therapy for patients with end-stage liver disease. Among patients undergoing LT, approximately 11% are women at the reproductive age[1]. Within one year after a successful LT, 97% of female patients at the childbearing age recover menstrual function owing to the restored hepatic estrogen metabolism, and the likelihood of conception and successful pregnancy is high[2]. The first known post-transplantation pregnancy in a LT recipient was reported in 1978. Since then, a series of cases have been reported worldwide[3,4]. We report the first case in mainland China.

CASE REPORT

A 22-year-old nulliparous woman, with a 4-year-history of persistent right upper quadrant pain, intermittent jaundice, and fever, was admitted to our hospital in September 2000. She had no particular family or genetic history, and underwent a cholecystostomy for acute cholangitis four months ago. The serum levels of total bilirubin (TB), direct bilirubin (DB), γ-glutamyl transferase (γ-GT) and alkaline phosphatase (ALP), and white blood cell (WBC) count were markedly increased. Microbiologic culture of blood demonstrated that *Escherichia coli* were the responsible bacteria in the patient. Alpha-fetoprotein (AFP) and viral markers for hepatitis A, B, and C were negative. B-type ultrasonography and computerized tomography (CT) showed a diffuse abscess and cirrhotic nodules in the shrunken liver. Therefore, she was diagnosed having primary biliary cirrhosis, sclerosing cholangitis, bacteremia, and bacterial liver abscess.

On September 28, 2000, after having been treated effectively, she underwent a successful orthotopic LT using conventional techniques with a veno-venous bypass. The donor was a 19-year-old brain-dead healthy female caused by head trauma and her family consented to her

organ donation. The overall length of the OLT procedure was 530 min. The duration of anhepatic phase and venous bypass was 97 min and 73 min, respectively. The anastomosis time for suprahepatic vena cava, infrahepatic vena cava, and portal vein was 23, 13, and 15 min, respectively. Standard proximal end-to-end anastomosis between donor's common hepatic artery and recipient's proper hepatic artery was performed under magnification, which lasted 22 min. Choledochojejunostomy was carried out with a 40-cm-long Roux-en-Y jejunal limb. A total of 3600 mL blood was transfused and the volume of blood loss was 1400 mL. Intraoperative findings correlated well with CT and B ultrasound findings. The postoperative pathological diagnoses were biliary cirrhosis, sclerosing cholangitis, and liver abscess.

The recipient had an uneventful recovery in the postoperative period. She gained complete consciousness 1 h after LT, received extubation 10 h later, and was discharged on post-LT day 22. Normal menstrual cycles were observed (restored) 3 mo later. After operation, the patient received a standard triple-drug immunosuppressive therapy, including cyclosporine A (CsA), mycophenolate mofetil (MMF), and prednisone. The dose of each agent was individualized according to the plasma drug concentration. Three months after operation, MMF was discontinued, and prednisone and CsA were maintained. One year later, prednisone was discontinued, and CsA was maintained alone. Twenty-six months later, she had a pregnancy and also an unstable graft. By agreement between the patient and physicians, pregnancy was terminated at 22 wk of gestation. Thirty months after LT, she became pregnant for the second time. During the first trimester of this pregnancy, she presumed to discontinue CsA because of serious pregnancy reaction without physicians' permission. The sharply increased serum levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), TB, DB, and ALP were suggestive of rejection. She was hospitalized then and treated with a daily regimen of 1 g of MMF, in addition to 450 mg of CsA. Despite the argument for MMF use during pregnancy, the patient and physicians decided to continue the pregnancy with regular ultrasound examinations. Two months later, she recovered with normal liver function and the fetus developed well. Her serum level of CsA remained within the normal limit (100-150 mg/L).

On March 18, 2004, the mother patient at 37 weeks' gestation gave birth by Cesarean section to a boy weighing 2000 g and measuring 42 cm in length. The patient's postpartum course was uneventful with normal liver and renal functions and she was discharged on the 12th d after Caesarean section. However, the newborn's 1- and 5-min agar scores were 5 and 7, respectively. Although without any congenital malformation, he was diagnosed having hypoxic ischemic encephalopathy and neonatal pneumonia. His immune functions were examined on the first and seventh days after birth, showing that the baby was in a severe immunosuppressive state. After proper and careful treatment, the newborn was discharged in good health on the 22nd d after birth. The child demonstrated normal growth and development during the 4-year follow-up period.

Once a major surgery like LT is performed, a lifelong follow-up is required. After the postpartum course, a series of investigations were followed for the mother patient and her male baby routinely according to the tentative protocol of West China LT center. Subsequent visits were scheduled at each month (the first six months after LT), every 2 mo (6-12 mo after LT), every 3 mo (the 2nd year) and every 3-6 mo (the 3rd year and thereafter). During these visits, routine blood, liver and kidney function, blood concentration of immunosuppressant, hepatitis B or C, and ultrasound scans and X-rays would be regularly undertaken. As an outpatient, she was recommended for a series of notices including self-examination of appetite, abdomen, stool, urine, skin, strength, energy, *etc*, self-protection from infection, house environment, working environment, keeping fine spirit and proper exercise, relation with the family members, sexual intercourse with her husband and use of contraception, self-examination of her baby's growth and development, necessary communications with doctors, and regular follow-up. The major content of follow-up at the late-stage post-LT included the monitoring of immunosuppressant concentration, new graft function, discovery of biliary and vascular complications, primary disease recurrency, rejection, and side effects of drugs. Currently, at 49 mo follow-up, the recipient and her son lived well with normal liver allograft function during the follow-up at 49 mo.

DISCUSSION

LT is considered an ultimate life-saving measure for patients with severe liver dysfunction and may provide patients with the best chance for long-term disease-free survival. Successful grafting offers the patient gross improvement in life quality, maximized rehabilitation, and restores the chance for parenthood to most recipients at their reproductive age. Reproductive function and sexuality, which are important components of quality of life, are commonly affected by end-stage liver disease. Shortly after successful LT, most female recipients at childbearing age normalize their menstrual function, thus leading to pregnancy[5].

The number of pregnancies following LT is increasing due to the greater survivals associated with constantly improved management and immunosuppressive regimens. Although pregnancy after LT does not seem to have obviously deleterious effects on allograft function or survival, complications can occur both in mothers and infants. Pregnancies in transplant recipients appear to be associated with increased health risks, including ectopic pregnancy, hypertension and pre-eclampsia, infection, and need for delivery by Cesarean section. The incidence of prematurity, intrauterine growth retardation and malformation is relatively high in newborns at the gestationalage age (SGA), irrespective of the type of immunosuppressive therapy used. The severe risks are mainly related to the fact that transplant recipients must continue immunosuppressive therapy throughout their pregnancy[6].

Most immunosuppressive agents (e.g. azathioprine, cyclosporine, and MMF) have been found to be teratogenic in animals. However, the frequency of birth defects in infants born to women receiving immunosuppressive agents is not statistically different from that in the general population[7]. Long-term or late-onset medical complications of immunosuppressive therapy for diseases (e.g. autoimmune disease, cancer, and infertility) are as yet unknown. Immunosuppressive agents can cross the placenta and result in a severe immunosuppressive state in the newborn. Right on the day of delivery, the concentration of CsA in the umbilical blood is 14.1 μg/L (75 -175 μg/L in adults). Cyclosporine is known to cause endothelial cell dysfunction and reduced nitric oxide production, which may be associated with cell dysfunction and hypertension. Tacrolimus-based immunosuppressive regimens are associated with a much lower incidence of new onset of hypertension and toxemia of pregnancy. Report from the National Transplantation Pregnancy Registry (NTPR) demonstrated that there was not any congenital malformation observed in the 5 off springs born to women receiving MMF[2]. So, during pregnancy, female recipients may continue their immunosuppressive medications to stabilize the allograft function. On the other hand, during pregnancy, increased plasma volume and adipose tissue and higher hormone concentrations lead to great changes in drug metabolism. Thus, the levels of immunosuppressive agents must be carefully monitored to individually establish therapeutic doses[3]. Our results are consistent with these findings.

Few data are available on breast-feeding by mothers taking immunosuppressive drugs. Whether the risks of exposure to immunosuppression through breast milk outweigh, the benefits of breast-feeding remain unknown. Our patient did not breast feed her baby because she was on CsA at a dose of 150 mg one day.

Pregnancy does not appear to increase the risk of graft rejection or impairment. In this case, a rejection episode occurred once at 8 wk gestation, and was believed to be related to the patient's willful discontinuation of immunosuppressive therapy. Reduction of immunosuppressive medications during pregnancy, based on the premise of natural nonspecific maternal immunosuppression, may lead to rejection of transplanted organs, which can be successfully managed with adjustment of immunosuppressive medications.

It was reported that the rate of Cesarean deliveries among LT recipients is higher than that of the general population[8]. In this case, Cesarean section was performed just for obstetric reasons, because we had not any experience with the management of such a patient.

All pregnancies in solid-organ-transplant recipients should be considered at high risk associated with hypertension, preeclampsia, intrauterine growth retardation and prematurity, and managed by a multidisciplinary team. The expectant mother should be closely monitored (at least every 2 wk) by her transplantation physicians and her prenatal care should preferentially be managed by a specialist in high-risk obstetrics (maternal-fetal medicine). Nagy *et al*[2] reported that the interval from transplantation to pregnancy was shorter in the group that had abortions and terminations (24.4 ± 24.3 mo) than in the group that had live births (47.8 ± 28.7 mo). NTPR has advised female organ transplant recipients to wait 1 or 2 years after transplantation before attempting to conceive to insure that the transplanted organ is functioning adequately and to allow for stabilization of the immunosuppressive regimen[7,9]. We strongly advocate delaying conception for at least 24 mo after LT. In reproductive-age women, who have undergone a liver transplant, physicians need to be proactive in discussing fertility issues and should counsel their patients regarding the timing of pregnancy, as well as the risks and alternatives. Moreover, physicians should respect the decision that each recipient makes about the risks and benefits. In this case, till now, the excellent maternal and neonatal outcome was a result of perfect communication and cooperation between the patient and the multidisciplinary team of our LT center. To the present, two hundred and two pregnancies and 205 outcomes have been reported in 121 LT recipients in NTPR[4]. To our knowledge, this present case is the first successful pregnancy of woman after LT in mainland China.

In conclusion, pregnancies among liver-transplanted female recipients are generally regarded at high risk, but do not seem to have a deleterious effect on graft function or survival. Mother, baby, and transplanted liver function must be considered for the safety of these high-risk pregnancies.

Abstract

The clinical characteristics of undifferentiated (embryonal) sarcoma of the liver (UESL) were investigated and the best treatment modalities were recommended. Both histology and immuno-histochemistry demonstrated the cellular features of this peculiar tumor. The tumor size was 12 cm × 9 cm × 8 cm in the right liver lobe. The patient underwent surgical resection of the tumor. The postoperative recovery was uneventful and she died eight months after diagnosis. The tumor showed mixed spindle and polygonal cells within the myxoid matrix. Some tumor cells contained eosinophilic hyaline globules that were positive for resistant diastase. Immunohistochemistry showed positive vimentin. Stellate and spindle cells were positively stained with alpha-1-antichymotrypsin (AACT) and CD68. This case indicates that UESL is not obviously differentiated in old-aged adults.

INTRODUCTION

Undifferentiated (embryonal) sarcoma of the liver (UESL), first documented in 1978, is a rare and highly malignant hepatic neoplasm of mesenchymal origin and shows a divergent differentiation[1,2]. Although UESL is considered a relatively major entity in pediatric liver malignancies, its frequency in the adult population is extremely low. In fact, few reports have focused on the general features of adult cases[3]. Given that the majority of the populations are under the age of 30 years, adult cases over the age of 40 years are quite exceptional. Furthermore, the detailed pathological characteristics of adult cases based on particular immunohistochemistry are not yet clear. To our knowledge, no study has described the systemic pathology features of UESL. In the present study, we describe a UESL patient at the age of 61 years with no obvious mesenchymal differentiation such as smooth muscle phenotype.

CASE REPORT

A 61-year-old woman was admitted in November 2007 to the Department of Hepatobiliary Surgery because of a huge abdominal mass, located in the right hypochondrium. Her major complaint was abdominal pain. An abdominal ultrasound showed a lesion in the right liver lobe, which was avascular on angiographic examination, and subsequently confirmed by CT scan (Figure 1). However, her serum alpha-fetoprotein (AFP) level was normal. No pulmonary metastases were detected by chest X-ray examination. Medical and family histories were unremarkable, and the patient reported

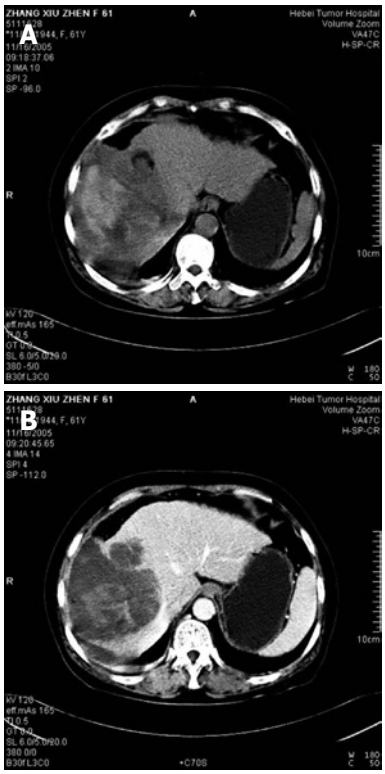

Figure 1 CT scan befor surgery showing a large mass (A) and a well-circumscribed and lowly-attenuated mass (B) in the right liver lobe.

no contact with any hepatitis virus carrier. Right hepatic lobectomy and cholecystectomy were performed at a laparatomy. The postoperative period was uneventful, no adjuvant irradiation or chemotherapy was administered. The patient died after 8 mo.

A mass measuring 12 cm × 9 cm × 8 cm was found in the right liver lobe. The tumor was well circumscribed and demarcated from the normal liver tissue. The cut surface revealed a white or yellowish soft mass with massive necrosis, hemorrhage and degeneration.

For light microscopy, fresh tissue was fixed in 10% formalin and embedded in paraffin. The tissue was cut into 4-μm thick sections which were stained with hematoxylin and eosin and periodic acid-Schiff (PAS) with and without diastase. The histopathological features of the neoplasm are presented in Figures 2 and 3. The primary tumor showed proliferation of atypical spindle cells mixed with stellated cells. These cells had obvious heteromorphism and were irregularly arranged. In some areas, the cells were differentiated into epithelium and had light eosinophilic cytoplasm. Cell membrane was fuzzy (Figure 2A). Some tumor cells contained eosinophilic hyaline globules, which were resistant to diastase and positive for PAS (Figure 2D, Figure 3B). Some ducts lined by a single layer of cuboidal cells resembling normal bile ducts were found in the tumor periphery (Figure 2B and C). Lymphocytes and plasma cells infiltrated around many thin-walled vessels in the background component of the tumor.

Immunohistochemical and alkaline phosphatase staining was performed using a labeled streptavidin biotin system. Primary antibodies such as broad-spectrum vimentin, desmin, alpha-smooth muscle actin (SMA), muscle-specific actin, neuronspecific enolase (NSE), HMB-45, CD68, CD34, factor Ⅷ, epithelial membrane antigen (EMA) and cytokeratins AE1/AE3 (Dako, Kyoto, Japan) were used. Immunostained sections were graded using a sliding scale of 1+ to 4+ according to the percentage of reactive cells (-: negative; 1+: < 10%; 2+: 10%-25%; 3+: > 25%-50%; 4+: > 50%). The immunohistochemical findings are summarized in Table 1. Most tumor cells were strongly reactive with vimentin (Figure 3A). Some stellate and spindle cells showed a granular cytoplasmic positivity for AACT and CD68. Lysozyme, alpha-sarcomeric actin, myoglobin, SMA, NSE, neurofilament, S-100 protein, HMB-45, CD34, factor Ⅷ, EMA, AE1/AE3 and AFP were negatively stained. The tumor was diagnosed as an undifferentiated embryonal sarcoma (malignant mesenchymoma).

Table 1 The immunohistochemical findings

Antibody	Expression
Vimentin	4+
AACT	1+
CD68	2+
Lysozyme	1+
α-sarcomeric actin	-
Myoglobin	-

HMB-45	-
S-100	-
CD34	-

DISCUSSION

UESL has a predilection for children and young adults in the first 2 decades of their life. To our knowledge, few cases have been reported in patients over the age of 40 years[3]. The overall clinical outcome is poor with a long-term disease-free survival rate of less than 30% in all series. In 2 other series, the outcome was better[4]. In the first series of 9 patients, 4 were alive with no evidence of disease, whereas in the second series, 3 out of 4 patients were alive with no evidence of disease[4]. In all series, the long-term survival was achieved only in those whose tumors could be resected completely.

According to the literature, the principal pathological features of UESL in children include an expansive intrahepatic growth with massive necrosis, hemorrhage, and occasional gelatinous appearance[1,2]. Laboratory evaluations including alfa-fetoprotein showed no specific abnormality. Radiologic characteristics of USL are characterized by enhanced peripheral rim, some solid portions at the periphery or adjacent to the septa, and discrepancy in internal architecture between computed tomography (CT) and ultrasound scan[5].

UESL is histologically surrounded by a fibrous

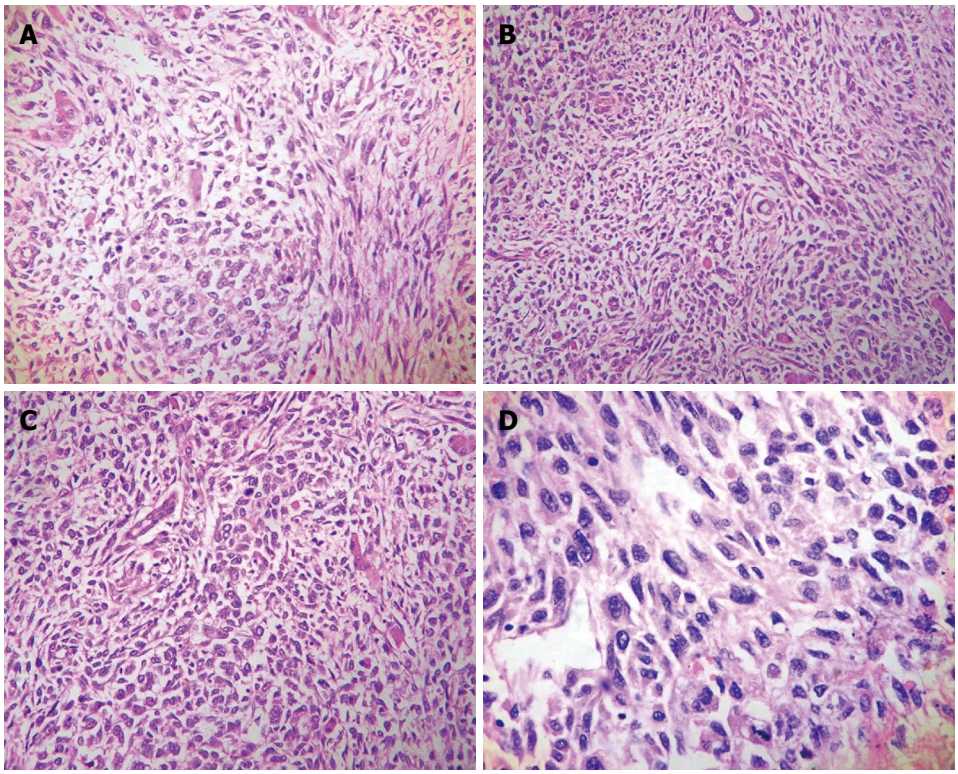

Figure 2 UESL. A: Atypical spindle cells mixed with stellated cells (HE, x 200); B: Normal bile ducts in the tumor (HE, x 200); C: Normal hepatic cells in the tumor (HE, x 200); D: Giant cells containing eosinophilic hyaline globules in the cytoplasm (HE, x 400).

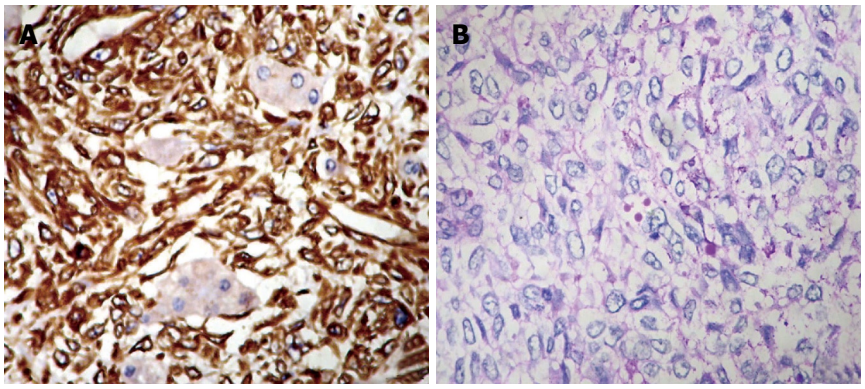

Figure 3 Immunohistochemical expression of UESL. A: Strong reactivity for vimentin in spindle and polygonal or round cells (streptavidin-biotin method, x 200); B: Tumor cells containing eosinophilic hyaline globules with positive PAS.

pseudocapsule with a slightly direct invasion of the adjacent hepatic parenchyma. The cellular component is composed of medium-large spindle or satellite cells with marked nuclear pleomorphism. At the periphery, trapped hepatocytes and abnormal bile duct cells are apparent[6]. In addition, there are prominent eosinophilic, PAS-positive, and diastase-resistant globules in the cytoplasm of tumor cells[1,7]. Generally, immunohistochemistry using various cell-specific markers reveals that UESL is highly positive for histiocytic markers such as AACT and CD68, and vimentin is commonly positive. A few case reports demonstrate that tumor cells are reactive to cytokeratin, S-100 protein, and NSE[1,7,8-11]. In our case, both vimentin and histiocytic markers were positive, whereas cytokeratins, S-100 protein, and NSE were negative. In some cases, the smooth muscle differentiation was confirmed by the positivity of desmin and alpha-SMA. However, our case did not exhibit any myogenic features. The differential diagnosis of UESL in old-aged adults includes malignant fibrous histiocytoma (MFH), leiomyosarcoma, liposarcoma, and angiomyolipoma (AML). MFH is characterized by fibroblastic, histiocytic, and pleomorphic tumor cells forming a storiform pattern. In the present study, the tumor was basically composed of primitive mesenchymal cells with a divergent differentiation toward fibroblastic, histiocytic lines. Although these cellular compositions are quite similar to those of MFH[7,12], it is possible to distinguish UESL from MFH on the basis of tissue pattern[13]. In our case, the diagnosis of leiomyosarcoma was inappropriate, because the tumor did not show any variable size of the foci and any fascicular pattern of the brightly eosinophilic spindle cells in hematoxylin, and SMA was negative. Lipoblastic differentiation has been suggested by some investigators on the basis of oil red O staining, and cells resembling lipoblasts seen at light microscopy[14]. However, no multivacuolated lipoblasts were observed in our case under light microscope, and the tumor cells were negative for S-100 protein. AML is characteristically composed of a varying heterogeneous mixture of 3 tissue components: blood vessels, smooth muscle cells, and adipose cells. However, the proportions

of the 3 tissue components vary markedly from case to case and from area to area within the same tumor[15]. AML with spindle cells and pleomorphic features may be misdiagnosed as various sarcomas, including MFH, leiomyosarcoma, dedifferentiated liposarcoma, and undifferentiated sarcoma[16-20]. Recent studies indicate that HMB-45 is a promising marker for AML and can facilitate differentiation of this tumor from other lesions[20-22]. In our case, the tumor cells were negative for HMB-45. Whenever pathologists encounter spindle cell tumors in the liver, immunostaining with HMB-45 should be performed to distinguish AML from other neoplasms.

The prognosis of UESL is poor. Even after complete resection of the tumor, few UESL patients can achieve a long-term, disease-free survival. Our patient died 8 mo after the tumor resection. Since 1990, long-term survivors after multiagent chemotherapy have been reported and their outcome appears to have improved substantially over the last decades[23,24]. The chance of cure depends on radical resection and vigorous multiple approaches including chemotherapy[23,24]. We hold that multiagent chemotherapy after resection can significantly improve the survival and the identified pathologic changes may offer important clues to the pathogenesis and development of UESL and other pediatric mesenchymal tumors.

Abstract

The differential diagnosis of Behcet's disease (BD) from inflammatory bowel disease (IBD) is sometimes difficult and challenging. Hereby, we suggested the utility of anti-saccharomyces cerevisiae antibody (ASCA) and anti-neutrophilic cytoplasmic antibody (p-ANCA) in the differential diagnosis of BD from IBD.

Key words: Anti-neutrophilic cytoplasmic antibody; Anti-saccharomyces cerevisiae antibody; Behcet's disease

Filik L, Biyikoglu I. Differentiation of Behcet's disease from inflammatory bowel diseases: Anti-saccharomyces cerevisiae antibody and anti-neutrophilic cytoplasmic antibody. *World J Gastroenterol* 2008; 14(47): 7271 Available from: URL: http://www.wjgnet.com/1007-9327/14/7271.asp DOI: http://dx.doi.org/10.3748/wjg.14.7271

TO THE EDITOR

The clinical diagnosis of Behcet's disease (BD) may pose considerable difficulties. Since the disease is multisystemic and does not have any pathognomonic symptom or laboratory findings, the diagnosis is based on a group of clinical features (oral, genital, skin or ocluar lesions)[1,2]. Gastrointestinal manifestation is relatively common in Japanese patients with BD (50%-60%), and the rate is significantly lower in Turkish and American population (5% and 8%, respectively)[3,4]. Similarly, accurate diagnosis of inflammatory bowel diseases (IBD) is very important. Also, because the treatment strategies in Crohn's disease (CD) and ulcerative colitis (UC) differ, especially when surgery is required, much effort has been expended over the years to distinguish some cases. Non-invasive tests are expected to display a crucial role in the differential diagnosis. The presence of a relatively specific laboratory marker can substantially facilitate the diagnosis of BD, and possibly support a diagnosis before all disease manifestations have occurred. Serum was obtained from 18 patients with BD whose diagnosis was fulfilled with the criteria of Behcet's Disease International Study Group[5]. Both anti-saccharomyces cerevisiae antibody (ASCA) and anti-neutrophilic cytoplasmic antibody (p-ANCA) were measured with indirect immunofluorescence assay. None of the patients was ASCA or p-ANCA positive.

ASCA is more frequently found in CD patients (50%-80%) compared to patients with UC (2%-14%)[6]. ANCA is present in the sera of 60%-80% of the patients with UC and approximately 10%-30% of patients with CD[6]. Since none of the patients in this study was ASCA or p-ANCA positive, we might conclude that both serologic tests may aid in the differential diagnosis of IBD and BD.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Patent (list all authors)

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

A variety of inflammatory diseases of the colon, which can be differentiated from inflammatory bowel disease (IBD) and infectious colitis by their clinical, endoscopic and histological characteristics, are reported as non-IBD and non-infectious colitis. These diseases include microscopic colitis, ischemic colitis, segmental colitis associated with diverticula, radiation colitis, diversion colitis, eosinophilic colitis and Behcet's colitis. The etiopathogenesis of most of these diseases remains obscure and the epidemiological data are rather limited. These conditions are often troublesome for the patient and are associated with diagnostic difficulties for the physician. In many cases the treatment is empirical and there is a need for future research using randomized controlled trials.

Koutroubakis IE. Spectrum of non-inflammatory bowel disease and non-infectious colitis. *World J Gastroenterol* 2008; 14(48): 7277-7279 Available from: URL: http://www.wjgnet.com/1007-9327/14/7277.asp DOI: http://dx.doi.org/10.3748/wjg.14.7277

This issue of *World Journal of Gastroenterology* contains a number of articles focusing on diagnosis and management of non-inflammatory bowel disease (IBD) and non-infectious colitis. This term includes a variety of inflammatory diseases of the colon, which can be differentiated from IBD and infectious colitis by their clinical, endoscopic and histological characteristics[1,2]. These diseases include microscopic colitides (collagenous and lymphocytic colitis), ischemic colitis, segmental colitis associated with diverticula (SCAD), radiation colitis, diversion colitis, eosinophilic colitis and Behcet's colitis. The etiopathogenesis of most of these diseases remains obscure. Clinical presentations include chronic, watery diarrhoea, abdominal pain and intermittent rectal bleeding. Constitutional symptoms are typically absent and laboratory data are often non-specific. Colonoscopic evaluation and mucosal biopsy are essential in establishing these diagnoses and to exclude IBD and infectious colitis. Prognosis and responses to treatment are variable. In general these conditions are often troublesome for both the patient and the physician. Most of these diseases are uncommon; therefore, epidemiologic data and data from controlled trials are not readily available.

Experts for these diseases were invited to write clinical guidelines for the diagnosis and management of the most common and more important of these diseases, although the scarcity of original data for the recently characterized forms of colitis make this task rather difficult.

Ischemic colitis is the most common form of gastrointestinal ischemia and accounts for 1 in 1000 hospitalizations. However, due to its mild and transient nature the incidence of IC is believed to be underestimated[3]. Although frequent in the elderly, younger patients may also be affected. The first two articles[4,5] deal with the diagnosis and management of ischemic colitis and the diagnostic approach of chronic GI ischemia.

Segmental colitis (or diverticular colitis) has been defined as the chronic mucosal inflammation associated with diverticular disease. This condition, which is usually called segmental colitis associated with diverticulosis (SCAD), is mainly characterized by the involvement of the sigmoid colon with sparing of the rectum and proximal colon. SCAD often mimics IBD at endoscopic and histological examination[6]. Freeman[7] has recently reviewed the clinical, pathogenetic and therapeutic features of this disease.

Collagenous colitis and lymphocytic colitis are the two major conditions that are characterized by chronic

watery diarrhoea, without endoscopic or radiological lesions, but with histological abnormalities and are therefore considered as "microscopic colitis". Recent data suggests that the incidence of microscopic colitis is slightly less than the incidence of chronic idiopathic inflammatory bowel diseases (IBD)[8,9]. In their review Tysk *et al*[10] provide the current concepts on the diagnosis and management of microscopic colitis.

Radiation colitis has been known for years as an insidious and progressive iatrogenic disease that frequently develops 6 months to 5 years after regional radiotherapy for malignancy. Although improvements have been made in radiotherapy delivery, the incidence of radiation colitis is increasing. Kountouras *et al*[11] present an extensive review on the recent advances in the management and prophylaxis of radiation colitis.

The articles cited in this review of non-IBD and non-infectious colitis hopefully serve to remind us that there are a variety of inflammatory diseases of the colon. The articles aid in early diagnosis of these diseases and provide us with current therapeutic options, as well as future prospects.

Other diseases that are rather rare and not included in these articles are diversion colitis, eosinophilic colitis and Behcet's colitis.

Diversion colitis is a non-specific colonic inflammation following surgical diversion of the fecal stream away from the colorectal mucosa. Such surgery may be necessary in cases of colon cancer, trauma or inflammatory diseases. Diversion colitis is characterized histopathologically by a chronic lymphoplasmacytic inflammatory infiltrate, and the existence of lymphoid follicular hyperplasia is considered to be a hallmark feature[12]. The development of diversion colitis is attributed to a lack of short chain fatty acids (SCFA), normally produced from the breakdown of complex carbohydrates by resident bacteria. SCFA are the preferred energy substrate for colonocytes and are necessary for normal metabolism. Although most patients are asymptomatic, common symptoms are rectal bleeding, tenesmus and mucous discharge. It is observed in up to 91% of adults following diversion and it is usually mild or moderate but rarely severe (only in 4% of cases). The restoration of fecal continuity is the treatment of choice and is curative. However, prolonged diversion causes involution and atrophy of the segment leading to a poor functional outcome. Other possible treatment options are SCFA enemas (or 5-ASA enemas)[13,14].

Eosinophilic colitis is an etiologically obscure and rare colonic inflammation which can be associated with involvement of other sections of the gastrointestinal tract from esophagus to rectum in a diffuse or segmentary manner. An infiltrate of eosinophilic granulocytes is found to varying degrees in all wall layers. Eosinophilic gastroenteritis may involve any part of the gastrointestinal tract, however colonic involvement is usually confined to the right colon. The common clinical symptoms are acute colicky pain, diarrhoea, rectal bleeding and weight loss. A history of food intolerance or allergy is present in most of the patients and peripheral eosinophilia is present in 80% of cases. Colonoscopy is usually inconclusive but histology reveals an inflammatory infiltrate by eosinophils in the mucosal and submucosal layers. Treatment includes initially dietary manipulation and avoidance of specific foods, but in refractory cases, corticosteroids, immunosuppressants and sodium cromoglycate are effective although the published data on treatment of eosinophilic colitis are rather limited[15,16].

Behcet's disease is a chronic inflammatory disease characterized by systemic manifestations such as recurrent oral and genital ulcerations, ocular and cutaneous lesions, arthritis and vascular disease. Gastrointestinal involvement is rare; its frequency has been reported to be 3%-25%, with geographical differences[17]. Cases of Behcet's disease cluster along the ancient Silk Road, which extends from eastern Asia to the Mediterranean basin. In cases with ileocolonic involvement, it is often difficult to distinguish Behcet's disease from other inflammatory bowel diseases. Intestinal Behcet's disease commonly accompanies ulcerative lesions in the small and large bowel. The diagnosis of intestinal Behcet's disease, therefore, often depends on clinical manifestations of systemic Behcet's disease and intestinal ulcerative lesions. Treatment options include corticosteroids, azathioprine, or cyclosporine thalidomide and infliximab[18,19].

In conclusion, there is a wide variety of rarer causes of colitis included in the term non-IBD non-infectious colitis. The etiopathogenesis of most of these diseases remains obscure and the epidemiological data are rather limited. In many cases the treatment is empirical and there is a need for future research using randomized controlled trials.

Abstract

Microscopic colitis, comprising collagenous and lymphocytic colitis, is characterized clinically by chronic watery diarrhea, and a macroscopically normal colonic mucosa where diagnostic histopathological features are seen on microscopic examination. The annual incidence of each disorder is 4-6/100 000 inhabitants, with a peak incidence in 60-70-year-old individuals and a noticeable female predominance for collagenous colitis. The etiology is unknown. Chronic diarrhea, abdominal pain, weight loss, fatigue and fecal incontinence are common symptoms, which impair the health-related quality of life of the patient. There is an association with other autoimmune disorders such as celiac disease, diabetes mellitus, thyroid disorders and arthritis. Budesonide is the best-documented short-term treatment, but the optimal long-term strategy needs further study. The long-term prognosis is good and the risk of complications including colonic cancer is low.

INTRODUCTION

Chronic diarrhea, reported in 4%-5% of individuals in Western populations, is a common cause for consulting a physician in general practice or in internal medicine, and for referral to a gastroenterologist[1]. Microscopic colitis (MC), previously regarded as rare, and certainly overlooked, has now emerged as a common cause of chronic diarrhea especially in elderly women. The condition is characterized clinically by chronic watery diarrhea, and a macroscopically normal or almost normal colonic mucosa, where microscopic examination of mucosal biopsies reveals characteristic histopathological changes[2]. MC comprises the two entities collagenous colitis (CC) and lymphocytic colitis (LC), which have indistinguishable clinical presentations but are separated by histopathological characteristics. This review will highlight epidemiology, clinical features, diagnosis and management of MC.

EPIDEMIOLOGY

CC and LC, first described in 1976[3] and in 1989[4], respectively, have mostly been reported from European or North American centers, but the disease is found worldwide[5-10]. Currently, epidemiological data have been reported from seven different regions (Table 1)[5,6,11-17]. Long-term epidemiological data from Sweden and US since the 1980s show a rising incidence, which seems to have levelled off during the last study periods in the Swedish study. Whether the increasing incidence figures are an artefact, reflecting an increased awareness and improved diagnosis of the condition, or in fact represents a true rise is at present unknown. MC may be diagnosed in 10%-20% of cases investigated for chronic

watery diarrhea[5].

CC mainly affects middle-aged women with a peak incidence around 65 years of age, and the female:male ratio is about 7:1 (Figure 1)[6,18]. However, the disease can occur in all ages, including children[19]. In LC, the peak incidence is in the same age group as CC, but the female predominance is less pronounced with a female:male ratio of 2-3:1 (Figure 1)[20].

CLINICAL PRESENTATION

The clinical symptoms of CC and LC are similar and the diseases cannot be differentiated on clinical grounds. Both disorders cause chronic or recurrent non-bloody, watery diarrhea, often associated with nocturnal diarrhea, diffuse abdominal pain, and weight loss, which may be substantial[18,20,21]. Although some patients may suffer from severe diarrhea, serious dehydration is rare. Fatigue, nausea and fecal incontinence are other associated symptoms and the disease may significantly impair quality of life in the affected patient[22,23].

The onset of disease can be sudden and mimic infectious diarrhea[18,20]. The clinical course is often chronic relapsing and benign. Severe complications are rare, although there are reports of colonic perforation in CC[24-26]. No increased risk of colorectal cancer has been reported in CC[27]. A few cases with concomitant lymphoproliferative disorders and CC have been presented but further studies are required to assess if there is an increased risk[28].

Some patients may have mild symptoms that may be misinterpreted as irritable bowel syndrome[29]. Morphological findings of LC have been reported even in constipated or asymptomatic patients[30]. The natural history of the condition in these patients is unknown.

Patients with MC often have concomitant autoimmune diseases[18,20,21]. The most common are thyroid disorders, celiac disease, diabetes mellitus and rheumatoid arthritis. The occurrence of such associations, reported in up to 40%-50% of patients in some cases, is variable depending on the study, and differences between LC and CC with respect to

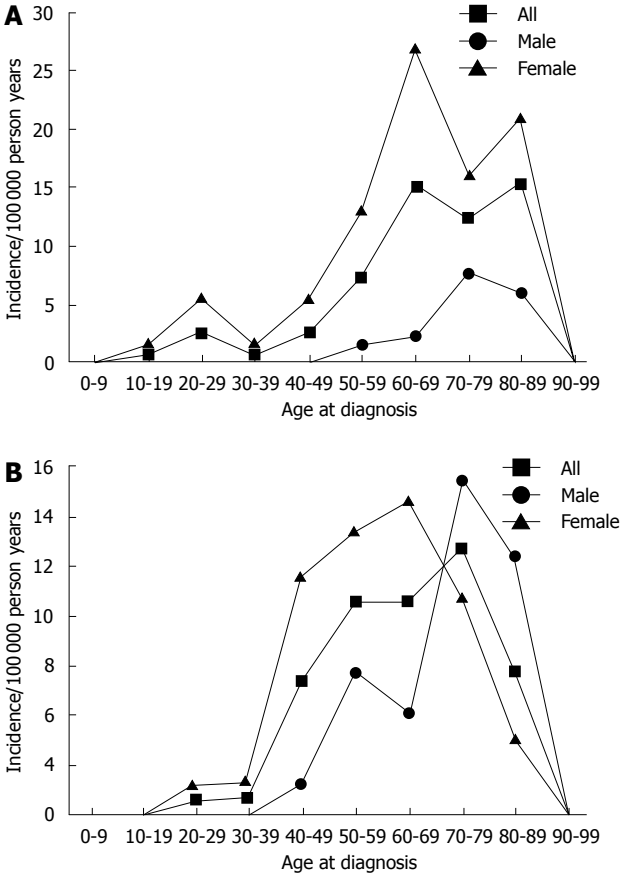

Figure 1 Age- and sex-specific incidence of CC (A) and LC (B). Reprinted with permission from *Gut* 2004; 53: 346-350[5].

associated conditions have been described[18,20,21,31]. Bile acid malabsorption can often co-exist with MC and lead to worsening of symptoms[32]. An interchange between ulcerative colitis or Crohn's disease and MC has been reported occasionally[33,34]. Whether this merely is a chance association of two fairly common disorders occurring in the same individual, or results from a common genetic predisposition or shared immunological pathways remains unknown.

ETIOLOGY AND PATHOGENESIS OF MUCOSAL INFLAMMATION

The cause of MC is multifactorial and largely unknown. CC and LC are presently considered to represent specific mucosal responses in predisposed individuals to various noxious luminal agents. As CC and LC have many clinical similarities and share histopathological features, except for the subepithelial collagen layer found in CC, it has been discussed whether LC and CC are in fact the same disease seen in different stages of development. Conversion of LC to CC or *vice versa* has been reported. However, conversion is seen infrequently and this fact, together with the observed difference in sex ratio, makes it more likely to consider CC and LC as two separate but related entities.

Data on the mucosal inflammation in MC are limited. In the epithelium, mainly CD8+ T lymphocytes are

found that carry the α/β form of the T-cell receptor, and in the lamina propria there are mainly CD4+ T lymphocytes[35]. By means of segmental colorectal perfusion, increased luminal levels of eosinophilic cationic protein (ECP), basic fibroblast growth factor (bFGF) and vascular endothelial growth factor (VEGF) have been found in CC[36-38]. By immunohistochemistry, others have verified increased mucosal levels of VEGF that are not affected following therapy with budesonide[39]. A study of cytokines in MC found a TH1 mucosal cytokine profile with interferon γ, tumor necrosis factor (TNF)α and interleukin-15 as the predominantly up-regulated cytokines[40]. Using Ussing chamber technology, transcellular and paracellular mucosal permeability has been found to be increased in patients with CC[41,42]. The excess subepithelial collagen in CC may be caused by an imbalance of collagen turnover. An increased collagen synthesis is supported by the finding of an increase in the number or the activity of myofibroblasts[43]. Among degrading enzymes, matrix-metalloproteinases (MMPs) have a central role that is regulated by tissue endogenous inhibitors of metalloproteinases (TIMPs)[44]. Impaired collagen degradation in CC is supported by the finding of restricted MMP-1 RNA expression and increased TIMP expression[45].

GENETICS

A familial occurrence of MC has been reported, but the role of genetic factors still remains largely unknown[46-49]. Human leukocyte antigen (HLA) studies have shown an association between MC and HLA-DQ2 or DQ1/3, and recently an association has reported between MC and HLA-DR3-DQ2 haplotype and with TNF2 allele carriage, irrespective of the presence of concomitant celiac disease[50,51]. Variants of the MMP-9 gene have been reported to be associated with CC[52]. No association with NOD2/CARD15 polymorphisms and susceptibility to CC has been found[53].

LUMINAL FACTORS

The mucosal inflammation with an increased number of intraepithelial T lymphocytes has suggested that MC may be caused by an immunological response to a luminal agent in predisposed individuals. This theory is supported by the observation that diversion of the fecal stream by an ileostomy normalizes or reduces the characteristic histopathological changes in CC[54]. After closure of the ileostomy, recurrence of symptoms and histopathological changes occur.

Drug-induced MC

There are several reports on drug-induced MC and a strong likelihood of association has been found with acarbose, aspirin, Cyclo3 Fort, non-steroidal anti-inflammatory drugs, lansoprazole, ranitidine, sertraline and ticlopidine[55]. Assessment of concomitant drug use in patients with MC is therefore important to identify and consider withdrawal of drugs that might cause or worsen the condition.

Infection

An infectious cause has been suspected, especially in patients with a sudden onset of disease. An association with MC and *Campylobacter jejuni, Yersinia enterocolitica* or *Clostridium difficile* has been reported occasionally[56-59]. LC shares many features with "Brainerd diarrhea", which refers to outbreaks of acute watery diarrhea with long duration, first reported among 122 residents of Brainerd, Minnesota, USA[60]. Colonic biopsies of these patients show epithelial lymphocytosis similar to LC, but no crypt distortion or epithelial destruction[61]. Investigations of several outbreaks of Brainerd diarrhea have established an incubation period of 10-30 d and median duration of illness of 16 mo[62]. Although an infectious agent is thought to be the cause of Brainerd diarrhea, no microorganism has yet been identified. Furthermore, a seasonal pattern of onset of LC[20,63] may support an infectious cause. However, in most cases of MC with a sudden onset, stool cultures remain negative.

Bile acids

Bile acid malabsorption can coexist with MC, which leads to worsening of symptoms. Concurrent bile acid malabsorption was found in 27%-44% of patients with CC and in 9%-60% of patients with LC[32,64,65]. These observations are the rationale for recommendations on bile acid binding treatment in MC. The treatment is especially effective in patients with concomitant bile acid malabsorption, but improvement has also been shown in patients without bile acid malabsorption.

Autoimmunity

The association with other autoimmune diseases such as thyroid disease, celiac disease, diabetes mellitus or arthritis has suggested an autoimmune process. However, no specific autoantibody or marker has been identified.

Nitric oxide (NO)

Colonic NO production is greatly increased in active MC caused by upregulation of inducible nitric oxide synthase (iNOS) in the colonic epithelium[66-69]. A major transcriptional inducer of iNOS gene expression is the transcription factor nuclear factor-κB (NF-κB). In active CC, colonic mucosal NF-κB has been found to be activated in epithelial cells but not in lamina propria macrophages, in contrast to ulcerative colitis[70]. The levels of NO are correlated to clinical and histological disease activity[67]. NO has been suggested to be involved in the pathophysiology of diarrhea in CC, as infusion in the colon of N^G-monomethyl-L-arginine, an inhibitor of NOS, reduced colonic net secretion by 70% and the addition of L-arginine, a precursor of NO synthesis, increased colonic net secretion by 50%[68]. Further

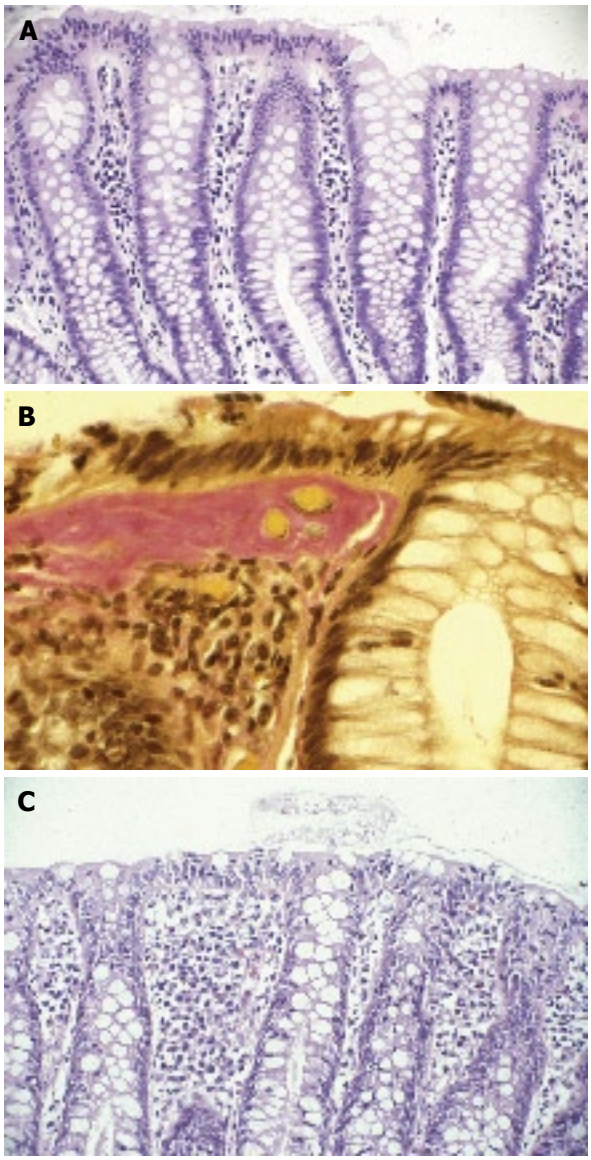

Figure 2 Biopsy from colon. A: normal colonic mucosa (H&E stain); B: typical findings of CC-increased subepithelial collagen layer, inflammation of lamina propria and epithelial cell damage with intraepithelial lymphocytes (Van Gieson's stain); C: typical findings of LC-epithelial cell damage with intraepithelial lymphocytes and inflammation in the lamina propria (H&E stain).

support for NO being involved in the pathogenesis of CC comes from therapeutic studies. Treatment with budesonide, in contrast to placebo, has resulted in a significant reduction of iNOS mRNA that is correlated with clinical and histopathological improvement[71].

Secretory or osmotic diarrhea

The exact mechanism of diarrhea in MC has not been clarified fully. In CC, diarrhea has been regarded as secretory and caused by reduced net absorption of Na^+ and Cl^- ions caused by epithelial cell lesions, and the thickened collagenous layer as a co-factor that causes a diffusion barrier, and by additional active Cl^- secretion[72]. Fasting, on the other hand, seems to reduce diarrhea, which indicates an osmotic component in some patients as well[73].

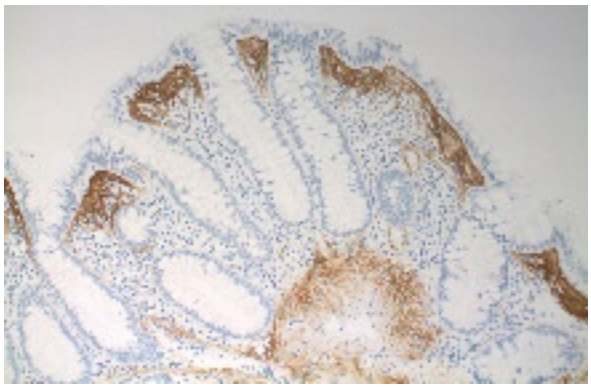

Figure 3 Tenascin immunostaining in CC.

DIAGNOSIS

Diagnosis of MC relies solely on typical microscopic changes seen in colonic mucosal biopsies[74]. In CC, a thickening of the subepithelial collagen layer is seen together with a chronic mononuclear inflammation in the lamina propria, and epithelial cell damage, with an occasionally increased number of intraepithelial lymphocytes (Figure 2). The thickened subepithelial collagen layer in CC is $\geqslant$ 10 μm in well-orientated sections, in contrast to a normal basal membrane of $<$ 3 μm. The thickening of the collagen layer may be variable and is most prominent in the ascending or transverse colon, and may be absent in biopsies from the sigmoid colon or rectum, which emphasizes the importance of obtaining biopsies from the proximal colon when diagnosing CC[75]. Generally, the histopathological changes are restricted to the large bowel, but a thickened collagen layer has infrequently been found in the stomach, duodenum or terminal ileum. In addition to conventional histological staining, the use of tenascin immunostaining has been suggested in uncertain cases of CC (Figure 3)[43,76].

The diagnostic features of LC (Figure 2) are an increased number of intraepithelial lymphocytes ($\geqslant$ 20/100 surface epithelial cells), in conjunction with surface epithelial cell damage and infiltration of lymphocytes and plasma cells into the lamina propria, but the collagen layer is normal, in contrast to CC[74]. In uncertain cases, immunostaining of CD3+ T lymphocytes facilitates the assessment of intraepithelial lymphocyte count (Figure 4).

Barium enema and colonoscopy are usually normal, although subtle mucosal changes can be seen such as edema, erythema and abnormal vascular pattern[18,20]. Tears of colonic mucosa have occasionally been seen during colonoscopy, which might be a sign of increased risk of colonic perforation during the procedure[26,77-79]. In the future, the use of confocal laser microscopy may enable *in vivo* diagnosis of MC[80-82].

Laboratory tests are non-diagnostic and only non-specific abnormalities such as moderately elevated C-reactive protein, erythrocyte sedimentation rate, or mild anemia are found. Stool tests reveal no pathological microorganisms, but fecal calprotectin can be slightly elevated[83].

Table 2 Data from four randomized, placebo-controlled trials of oral budesonide in CC and LC

Author year	Number of cases	Dosage	Clinical response budesonide *vs* placebo	Histological response budesonide *vs* placebo	Adverse events
Collagenous colitis					
Baert *et al*[91] 2002	28	9 mg/d Budenofalk 8 wk	Improvement: 8/14 *vs* 3/14 ($P = 0.05$)	Reduction of lamina propria inflammation in 9/13 *vs* 4/12 ($P < 0.001$) No difference in collagen layer	Mild No difference between treatment groups
Miehlke *et al*[93] 2002	45	9 mg/d Entocort 6 wk	Remission: 15/23 *vs* 0/22 ($P < 0.0001$)	Improvement in 17/23 *vs* 5/22 ($P < 0.01$) No difference in collagen layer	Mild 38% *vs* 12% $P = 0.052$
Bonderup *et al*[92] 2003	20	9 mg/d Entocort 8 wk	Response: 10/10 *vs* 2/10 ($P < 0.001$)	Reduction of overall inflammation ($P < 0.01$) and of collagen layer in sigmoid colon ($P < 0.02$)	None
Lymphocytic colitis					
Miehlke *et al*[95] 2007	41	9 mg/d Budenofalk 6 wk	Remission: 18/21 *vs* 8/20 ($P = 0.004$)	Response in 11/15 *vs* 4/12 ($P = 0.04$)	Mild No difference between treatment groups

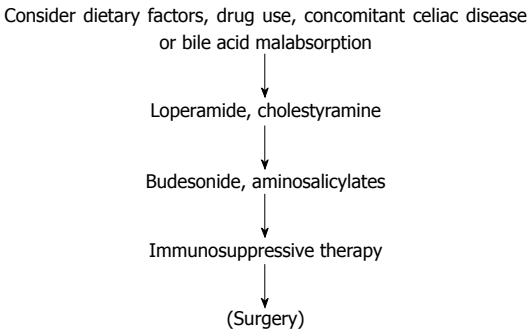

Figure 5 Treatment algorithm for MC.

ATYPICAL MC

In addition to CC and LC, other rare subtypes of MC have been described including MC with giant cells[84,85], paucicellular LC[86], cryptal LC[87], pseudomembranous CC[88], MC with granulomatous inflammation[89], and MC not otherwise specified[74]. The clinical features of these conditions are similar to those of classical MC, but histopathological appearance differs. Further studies are required to address the relationship and clinical significance of these atypical forms of MC[90].

THERAPY AND PROGNOSIS

A careful assessment of concomitant drug use and dietary factors such as excess use of caffeine, alcohol and dairy products that might worsen the condition is important. Concomitant bile acid malabsorption or celiac disease should be considered. In the patient with mild symptoms, loperamide or cholestyramine are recommended as the first step of treatment (Figure 5).

Budesonide is the best-documented treatment and significantly improves the clinical symptoms and the patient's quality of life. Three short-term, randomized controlled trials in CC have consistently shown that budesonide 9 mg daily for 6-8 wk is superior to placebo (Table 2)[91-93]. About 80% of patients responded to budesonide and had a decrease in the number of loose stools after 2-4 wk of therapy. In a Cochrane meta-analysis, the pooled odds ratio for clinical response with budesonide compared to placebo was 12.32 (95% CI 5.53-27.46), and the number needed to treat was two patients[94]. In a placebo-controlled trial including 41 patients, budesonide treatment was effective also in LC[95]. After 6 wk treatment, 18 of 21 patients (86%; 95% CI 65%-96%) in the budesonide group achieved a clinical response compared to eight of 20 patients (40%; 95% CI 22%-61%) in the placebo group, which yielded an odds ratio of 9.00 (95% CI 1.98-40.93; $P = 0.004$)[96]. The number needed to treat to achieve a clinical response with budesonide was three patients.

The relapse rate is high after cessation of successful short-term budesonide therapy in CC and 61%-80% of treated patients will have a recurrence of symptoms[91-93]. In clinical practice, tapering doses of budesonide to 3-6 mg/d have been used as maintenance therapy and may well control clinical symptoms. There is now evidence for such a strategy in CC, and two studies have proven maintenance therapy with budesonide 6 mg/d for 6 mo is well-tolerated and superior to placebo[97,98]. A total of 80 patients, who had responded to open-label budesonide, were randomized to budesonide 6 mg/d or placebo for 6 mo. Clinical response was maintained in 33/40 (83%) patients who received budesonide compared to 11/40 (28%) patients who

received placebo ($P = 0.0002$). Pooled odds ratio was 8.40 (95% CI, 2.73-25.81) with a number needed to treat of two patients for maintenance of clinical response with budesonide. Histological response was seen in 48% of patients who received budesonide compared to 15% of patients who received placebo ($P = 0.002$)[94]. However, 6 mo maintenance therapy did not alter the subsequent course, as the relapse risk after withdrawal of 24 wk maintenance treatment was similar to that observed after 6 wk induction therapy, and the median time to relapse was equal in the two groups (39 d *versus* 38 d)[97].

Other oral corticosteroids, such as prednisolone, are associated with more frequent side-effects, and the efficacy seems inferior to budesonide, although no formal comparative studies are available[99].

Bismuth subsalicylate has been shown to be effective in a small placebo-controlled study including nine patients with CC and five with LC[100]. This drug is not available in a number of countries because of concerns regarding drug toxicity.

Sulfasalazine or mesalazine have been extensively used in MC but not strictly evaluated in randomized placebo-controlled trials. In a recent trial, 64 patients with MC were randomized to mesalazine 2.4 g/d or mesalazine 2.4 g/d + cholestyramine 4 g/d for 6 mo. A high remission rate was seen in both treatment arms, and 85% of patients with LC and 91% of those with CC were in remission at study end. Combined therapy was superior in CC and induced an earlier clinical response in both diseases[101]. The benefit of mesalazine with or without cholestyramine needs to be confirmed in a placebo-controlled trial.

Antibiotics such as metronidazole or erythromycin have been used but not in a controlled fashion. Probiotic treatment shows uncertain results and need further evaluation[102]. *Boswelia serrata* extract has been tried in a placebo-controlled trial showing a non-significant trend in favor of active treatment[103].

In patients with unresponsive or steroid-resistant disease, immunosuppressive therapy may be considered, although the evidence is limited. An open study with azathioprine gave partial or complete remission in eight of nine patients with MC[104]. The efficacy of methotrexate has been assessed in a retrospective study[105]. Out of 19 patients with CC, a good response, generally seen within 2-3 wk of treatment, was seen in 16 and a partial response in two patients. The dose of methotrexate ranged from 5-25 mg/wk (median 7.5-10 mg/wk).

Surgical therapy may be considered for patients with severe unresponsive MC. Both split ileostomy and subtotal colectomy have been performed and reported as successful[54,106]. The indications for surgical therapy today are limited, considering the improvement of medical therapy.

The long-term prognosis of MC is generally good. In a follow-up study of CC, 63% of the patients had a lasting remission after 3.5 years, and in another cohort study, all 25 patients were improved 47 mo after diagnosis, and only 29% of them required ongoing medication[107,108]. A benign course was reported in 27 cases with LC, with resolution of diarrhea and normalization of histology in > 80% of patients within 38 mo[109]. Others have reported that 63% of patients with LC had a single attack, with a median duration from onset of symptoms to remission of 6 mo[20].

CONCLUSION

MC is a fairly common cause of chronic diarrhea, especially in elderly women, and may considerably impair the patient's quality of life. The correct diagnosis depends on the awareness of the condition by the clinician (referring the patient with chronic diarrhea to colonoscopy and not to barium enema), by the endoscopist (obtaining mucosal biopsies although the colonic mucosa is endoscopically normal) and by the pathologist (recognizing the histopathological features of MC). Treatment with budesonide is effective in the short term and improves the patient's symptoms and quality of life, but the optimal long-term therapy needs further study. The long-term prognosis is good and the risk of complications including colonic cancer is low.

Abstract

Radiation colitis, an insidious, progressive disease of increasing frequency, develops 6 mo to 5 years after regional radiotherapy for malignancy, owing to the deleterious effects of the latter on the colon and the small intestine. When dealing with radiation colitis and its complications, the most conservative modality should be employed because the areas of intestinal injury do not tend to heal. Acute radiation colitis is mostly self-limited, and usually, only supportive management is required. Chronic radiation colitis, a poorly predictable progressive disease, is considered as a precancerous lesion; radiation-associated malignancy has a tendency to be diagnosed at an advanced stage and to bear a dismal prognosis. Therefore, management of chronic radiation colitis remains a major challenge owing to the progressive evolution of the disease, including development of fibrosis, endarteritis, edema, fragility, perforation, partial obstruction, and cancer. Patients are commonly managed conservatively. Surgical intervention is difficult to perform because of the extension of fibrosis and alterations in the gut and mesentery, and should be reserved for intestinal obstruction, perforation, fistulas, and severe bleeding. Owing to the difficulty in managing the complications of acute and chronic radiation colitis, particular attention should be focused onto the prevention strategies. Uncovering the fibrosis mechanisms and the molecular events underlying radiation bowel disease could lead to the introduction of new therapeutic and/or preventive approaches. A variety of novel, mostly experimental, agents have been used mainly as a prophylaxis, and improvements have been made in radiotherapy delivery, including techniques to reduce the amount of exposed intestine in the radiation field, as a critical strategy for prevention.

INTRODUCTION

Radiation colitis is an insidious, progressive disease of increasing frequency. It is usually iatrogenic and unavoidable and frequently develops 6 mo to 5 years after regional radiotherapy for malignancy[1,2]. About half of all patients with malignancies undergo irradiation as part of their therapy. Considerable morbidity and mortality accompany radiation treatment because of the deleterious effects on adjacent normal tissues, mainly the colon and the small intestine. The type and extent of injury, depending on the dose of the radiation and the radiation sensitivity of the gut and the duration, is highly variable, ranging from 3 mo to 30 years[1,3]. Serious consequences may develop after years of gestation, and the disease, its treatment, and the disability produced are formidable. Apart from acute radiation colitis, manifestations of chronic radiation injury include proctitis, hemorrhages, fistulas, abscesses with signs of sepsis, perforations, strictures, and even cancer. Therefore, novel means to increase resistance of the intestine to radiation damage and effective therapeutic strategies are needed to prevent and manage this disease.

MANAGEMENT OF COLITIS CAUSED BY IRRADIATION

In general, prior to start, each treatment should be

individualized, and any predisposing factor should be identified during its course in order to early recognize and treat complications. Once complications have arisen, it is best to deal with the irradiated tissue by the most conservative modality, because the areas of intestinal injury do not tend to heal. This may require early diversion or resection as conservative therapy, because fistulas and bleeding will become recurrent and intractable. The effectiveness of non-surgical approaches remains far from desirable, and bleeding recurrence represents a major drawback that leads to a need for consecutive therapeutic sessions and combination of techniques[4]. If diversion fails to control bleeding, resection is necessary, even if it involves an abdominoperineal resection.

From another general viewpoint, there is a similarity in the activation of mucosal cytokines between inflammatory bowel disease (IBD) and radiation proctosigmoiditis. Indeed, as in the case of IBD patients, the mucosal levels of interleukin (IL)-2, -6, and -8 are significantly higher in both diseased and normal segments of colon in patients with radiation proctitis, compared with normal controls. In addition, IL-1β levels are significantly higher in diseased segments, compared with endoscopically normal-appearing segments in radiation proctitis. Tumor necrosis factor-alpha (TNF-α) levels are also significantly elevated in irradiated mice compared with non-irradiated controls[5]. These data may partially explain the beneficial effects of similar systemic and topical drugs including mesalamine compounds and steroids when used in radiation-induced proctosigmoiditis[6].

ACUTE RADIATION COLITIS (TABLE 1)

Empirical-experimental management

The majority of acute radiation colitis is self-limited, and only supportive management is required[7]. It must be emphasized, however, that acute radiation syndrome with a threshold dose of 8 Gy in man, represents a lethal clinical-pathological unit, enteritis and proctocolitis necro-hemorrhagica, with unknown causal therapy. In this respect, the detection of phospho-Elk-1, a protein acting as a transcription factor activating specific genes, might be considered as a suitable and very sensitive marker of acute radiation-induced injury of large and small intestine[8]. Whether Elk-1 inhibitors, such as the compound A (CpdA) or the protective agent U0126 [1,4-diamino-2,3-dicyano-1,4-bis(2-aminophenylthio)-butadiene], the effect of which probably results from the IL-1β mRNA reduction *via* the inhibition of ERK pathway, can be used in the management of this syndrome remains to be investigated[9,10].

Inflammatory cell infiltration of the colon is observed at an early stage of radiation-induced colitis. The migration of inflammatory cells from the circulation requires interactions between cell adhesion molecules on the vascular endothelium and molecules on the surface of leukocytes. Specifically, circulating leukocytes are recruited to sites of inflammation by a well-regulated and coordinated process that largely occurs in postcapillary venules. Adhesion molecules are expressed on the surface of endothelial cells, and leukocytes are involved in an orderly sequence of cell-cell interactions that include leukocyte adherence to vascular endothelium and the subsequent transendothelial migration into the inflamed tissue. Finally, reactive oxygen metabolites produced by activated leukocytes can induce damage to various cellular components, including structural and regulatory proteins, carbohydrates, lipids, DNA and RNA. In this respect, upregulation of intercellular adhesion molecule (ICAM)-1 and the accumulation of inflammatory myeloperoxidase-positive cells have been observed during acute radiation colitis prior to an overt radiation-induced ulcer, thereby playing important roles in the development of radiation-induced colonic ulcer[11]. Moreover, there is direct *in vivo* evidence that antioxidant mechanisms of the intestinal mucosa are not mobilized during the acute tissue radiation response; four days after exposure, during the inflammatory phase, superoxide dismutases (SOD) and catalase are decreased and glutathione peroxidases and metallothioneins are induced. Dexamethasone treatment modulates only glutathione peroxidase expression and does not influence either metallothionein or SOD expression. These experimental data indicate that during the radiation-induced acute inflammatory response, an imbalance of the antioxidant network of intestinal mucosa occurs[12].

In view of the aforementioned data, modulation of the leukocyte recruitment and activation pathway seems to be a potential therapeutic strategy against acute radiation colitis. Further supporting this consideration, experimental studies have demonstrated that leukocyte rolling is mediated by P-selectin and that firm leukocyte adhesion is supported by lymphocyte function antigen-1 in radiation-induced colitis. P-selectin-dependent leukocyte rolling is a precondition for subsequent leukocyte adhesion in radiation-induced intestinal damage. Therefore, targeting P-selectin and/or lymphocyte function antigen-1 might protect against pathologic inflammation in the colon induced by radiotherapy[13]. Moreover, Cu/Zn-SOD1 supplementation in an

Table 1 Management of acute radiation colitis

Management of acute radiation colitis
Supportive management
Anti-diarrheal medications and by reducing fat and lactose intake; In intractable cases hospitalization is required for parenteral feeding and elementary diet
Elk-1 inhibitors

Targeting P-selectin and/or lymphocyte function antigen-1
Cu/Zn-SOD1 supplementation
Synthetic somatostatin analog octreotide
Other measures
Antiemetics
Steroid-containing suppositories
Recombinant granulocyte colony-stimulating factor in neutropenia
Epidermal growth factor

experimental model of radiation-induced intestinal inflammation has also been shown to decrease oxidative stress and adhesion molecule upregulation in response to abdominal irradiation. Specifically, a significant increase in the flux of rolling leukocytes and number of firmly adherent leukocytes in intestinal venules is observed after irradiation. Although administration of SOD1 has no effect on leukocyte rolling, it decreases leukocyte adhesion to intestinal venules significantly and in a dose-dependent way. Treatment with SOD1, at doses that reduce leukocyte recruitment, abrogates the increase in hydroperoxides in intestinal tissue and ICAM-1 upregulation in intestinal endothelial cells. The inflammatory score, but not a combined histology damage score, is also significantly reduced by SOD1[14].

Diarrhea associated with acute radiation colitis frequently resolves with anti-diarrheal medications and by reducing fat and lactose intake. The diarrhea rarely requires discontinuation of treatment unless chemotherapy is given concurrently with radiation[15]. Intractable diarrhea during the combined treatment may require hospital admission for administration of parenteral feeding. Elementary diet may also be introduced as an alternative to parenteral nutrition[16].

Patients refractory to anti-diarrheal medications may benefit from administration of the synthetic somatostatin analog octreotide[7]. Specifically, it has been shown that subcutaneous octreotide administration (150 μg t.i.d.) for 5 d is apparently an effective, well-tolerated treatment modality for concurrent chemoradiotherapy-induced diarrhea refractory to loperamide[17]. Octreotide appears to be more effective than conventional therapy with diphenoxylate and atropine in controlling acute radiation-induced diarrhea and eliminating the need for radiotherapy interruptions[18].

Apart from anti-diarrheal medications, other measures of general management of acute radiation enteropathy include administration of antiemetics. Steroid-containing suppositories may be helpful in the treatment of patients with anorectal inflammation[7]. Severe neutropenia from chemotherapy might require growth factors, such as recombinant granulocyte colony-stimulating factor (G-CSF, filgrastim) or granulocyte-macrophage colony-stimulating factor (GM-CSF, sargramostim) to shorten the period of neutropenia, and avoid excessively delayed therapy from the bone marrow depression[19]. G-CSF is a cytokine known to activate neutrophils *in vivo* and GM-CSF mediates its effects on the neutrophil lineage through its effects on phagocytic accessory cells and its synergy with G-CSF[20,21].

Epidermal growth factor, an endogenous peptide, trophic to the gastrointestinal tract, significantly decreases the acute clinical manifestations of experimental radiation enteritis[22]. Therefore, it may be effective in human acute radiation colitis[23].

CHRONIC RADIATION COLITIS (TABLE 2)

Empirical-experimental management

Chronic radiation colitis is recognized as a frequent and clinically important sequel of abdominal and pelvic irradiation treatment for malignant disease. Since radiotherapy is now being used more than ever before in the therapy of solid organ neoplasms of the abdomen and the pelvis, the incidence of radiation colitis is likely to increase in the future[24-26]. Importantly, it is a precancerous lesion: Radiation-associated rectal cancer originates from dysplasia due to radiation colitis and has a tendency to be diagnosed at an advanced stage and to bear a dismal prognosis[27,28]. Therefore, management of chronic radiation colitis remains a major challenge owing to the progressive evolution of the disease that includes development of fibrosis, endarteritis, edema, fragility, perforation, partial obstruction, and even cancer. Patients with this condition are commonly managed conservatively. Because the obstruction is only partial, decompression is easily achieved by nasogastric suction and parenteral support. The patient is then often discharged on a liquid-to-soft diet. However, this therapeutic regimen does nothing for the underlying pathology. Although total parenteral nutrition corrects denutrition and facilitates deferred surgery in some patients, severe radiation enteritis remains a poorly predictable progressive disease with numerous relapses[29]. The problem, sooner or later, will return with the patient further depleted by the chronic radiation colitis. In a recent meta-analysis assessing the incidence and significance of malnutrition and examining the efficacy of therapeutic nutritional interventions used to manage gastrointestinal side effects in patients undergoing pelvic radiotherapy, it has been shown that there is no evidence favoring the use of nutritional interventions to prevent or manage bowel symptoms attributable to radiotherapy[30]. Regarding the underlying

Table 2 Management of chronic radiation colitis (IL; TNF-α)

Prostaglandin-inhibiting compounds
Oral steroids (for severe cases)
Probiotics (Lactobacillus bulgaricus)
Antioxidants
Colestyramine Balsalazide (in radiation-induced proctosigmoiditis)
Peroxisome proliferation-activated receptor activators
Sucralfate enemas
Short-chain fatty acids
Hyperbaric oxygen
Control of bleeding (by endoscopic cauterization using a heater, BICAP probe, Nd: YAG or argon laser)
Surgery (indicated in intestinal obstruction, perforation, fistulas, and severe bleeding)

pathology, vascular damage consisting of fibrin thrombi, fibrinoid necrosis and subintimal thickening of the arterioles leads to persistent local ischemia, which results in diffuse fibrosis of the lamina propria and submucosa. The diffuse fibrosis, in turn, accelerates vascular damage and further worsens local ischemia, forming a vicious cycle, finally leading to ulceration of the bowel wall and serious complications including massive gastrointestinal hemorrhages and perforations[31]. Therefore, surgical intervention appears to be appropriate when the diagnosis of chronic radiation colitis is confirmed[32].

Nevertheless, chronic changes in cytokine levels after abdominal irradiation in rodents have recently been documented[33]. Structural injury of the bowel wall and mesentery were scored and correlated with the levels of TNF-α, IL-6, transforming growth factor (TGF)-β1, -β2, -β3 and interferon (IFN)-γ mRNA in large and small bowel of mice 18-25 wk after whole abdominal irradiation with 12.5 and 13.5 Gy. Abdominal irradiation seems to induce considerable bowel damage associated with increased levels of all cytokines compared with sham-irradiated (0 Gy) mice. These experimental data demonstrate long-term cytokine expression changes in the bowel wall after irradiation that parallel the responses noticed in other tissues prone to radiation-induced fibrosis, such as cutaneous and pulmonary tissues, thereby having implications for the prediction, treatment and/or prevention of chronic radiation colitis. For instance, chronic IL-6 elevations, even prior to the start of irradiation, may predict patients at risk of radiation fibrotic bowel damage in the same way that IL-6 baseline elevations have been shown to identify patients with an increased risk of radiation pneumonitis and pulmonary fibrosis following thoracic irradiation[33]. Since studies in animal models of IBD have shown that various antibodies to pro-inflammatory cytokines and their receptors, such as IL-6 receptor (IL-6R) or TNF, appear to suppress chronic intestinal inflammation by inducing T-cell apoptosis[34], it is reasonable to assume that such antibodies (anti-IL-6R) might also be used to manage radiation colitis. In addition, reduction in cytokine expression with cyclooxygenase (COX)-2 inhibitors and small molecular inhibitors of TNF-α may reduce the frequency and severity of long-term bowel damage. There is some evidence that the COX-2 pathway is implicated in radiation-induced gut injury[31,35,36]. COX-2 and nuclear factor κB (NF-κB) expression have been associated with histopathological changes in the human colon and rectum following abdominal radiotherapy[31].

Besides, in radiation colitis involving aberrant glands, cellular proliferation increases and spotted oncogene p53 expression is noticed. Therefore, radiation colitis and aberrant glands with p53 overexpression might predict malignant potential of this condition[37].

Three typical phases of radiation proctitis are defined on histological grounds (acute damage, and early and late regenerative phases), essentially correlating with the time interval between radiotherapy and surgery. Such characteristics are mirrored by alterations in cadherin-catenin expression and localization in rectal crypts; morphology at both cellular and glandular levels in the large bowel is dependent to an extent on cell-cell adhesion mediated by cadherin-catenin complexes. In this regard, P-cadherin is highly expressed in the acute radiation damage and early regenerative phases, with a decreased level of expression during late regeneration. E-cadherin and associated catenins are translocated from the membrane to the cytoplasm in degenerating crypts, with return to normal membranous expression in regenerating crypts. Therefore, radiation-induced proctitis represents an *in vivo* model of mucosal damage and regeneration, thereby providing a valid model to study events during epithelial injury and repair: altered cadherin and associated catenins expressions appear to be predictive indicators closely associated with these processes[38]. On the other hand, because the E-cadherin-catenin complex plays a critical role in the maintenance of normal tissue architecture, mutation of any of its components is believed to result in loss of cell-cell adhesion, thereby contributing to neoplasia development. In this respect, adenomatous polyposis coli (APC) gene abnormalities, found to be the "gate-keeping" event for the initiation of colorectal neoplasia, may lead to a disruption of normal cell-cell adhesion through altered association with catenins and the cell adhesion molecule E-cadherin that binds catenins[39]. Translocation of the β-catenin protein, a key downstream effector of the Wnt signal transduction pathway, is frequently found in colorectal cancer. This protein is also observed in the cytoplasm and/or nucleus of non-neoplastic irradiated colonocytes. Nuclear translocation of β-catenin correlates with loss of APC and gain of cyclin D1 expression, suggesting the activation of the Wnt pathway during radiation-induced colorectal carcinogenesis. Because the translocation of β-catenin is found in irradiated-colonic mucosa as well as in colon cancer, the disruption of the β-catenin expression may be one of the early events in radiation-induced colonic oncogenesis[40]. Based on these data, interventions on cadherin-catenin complex pathways may also be used against chronic radiation colitis and radiation-induced colonic carcinogenesis. Finally, in a novel mouse model of radiation-induced colitis, a combination of high-dose γ-irradiation and lack of major histocompatibility complex (MHC) class Ⅱ expression on cells of hematopoietic origin results in the development of radiation colitis. Therefore, protection and/or inhibition from radiation-induced colitis seems to require MHC class Ⅱ antigen expression by cells of hematopoietic origin[41]. In this regard, administration of the recombinant pleiotropic human cytokine IL-11, which stimulates bone marrow stem cells to proliferate, has been shown to decrease intestinal mucosal injury produced by radiation in animals, thereby providing a potential therapeutic regimen for the treatment and/or prevention of chronic radiation colitis[42].

Diarrhea, with or without abdominal cramps, is the most common symptom of chronic radiation colitis[26]. The etiology of chronic radiation-induced diarrhea may be attributable to accelerated small and large

bowel transit, bacterial overgrowth, increased intestinal permeability, malabsorption of bile salts, lactose, fat and carbohydrate, and pancreatic insufficiency, all of which can exist with or without small bowel or large bowel strictures[43,44]. In case of colonic strictures, spurious diarrhea can occur. Moreover, the above mentioned microvascular changes in the bowel wall lead also to mucosal atrophy and a non-specific chronic inflammatory cell infiltrate, which has resulted in a mistaken diagnosis of celiac sprue[45]. However, in most cases, the pathophysiology of the diarrhea is uncertain. While changes in intestinal absorption and motility, unrelated to bacterial overgrowth, have been implicated in the etiology of diarrhea, there has been no comprehensive evaluation of gastrointestinal function in chronic radiation colitis. Perhaps partly as a result of this, present approaches to treatment have often been empirical. A low-residue diet (i.e. a low-fiber diet poor in foods that increase bowel activity) combined with bismuth subsalicylate or opiate drugs, such as loperamide or diphenoxylate, might be sufficient for mild diarrhea[1]; loperamide-N-oxide slows small intestinal transit, increases bile acid absorption, and is effective in the treatment of diarrhea associated with chronic radiation colitis[26]. Other antidiarrheal agents can be administered, including aminosalicylates and prostaglandin (PG)-inhibiting compounds[46,47]. In severe cases of radiation colitis, oral steroids have been tried with limited success[48]. Randomized controlled trials are not available, and all treatment regimens are based on evidence from small pilot studies, including the administration of sulfasalazine[49], glutathione (GSH)[50], and antioxidants[51]. Furthermore, antibiotics are indicated if there is small bowel bacterial overgrowth syndrome[52,53]. Preliminary results suggest that probiotics may also be useful for treatment of radiation bowel disease, although no robust data exist[54]. Other studies suggested that colestyramine, an agent that binds bile acids in the colonic lumen, might be effective in preventing radiation-induced diarrhea if administered in dosages of 4 g t.i.d. during radiation therapy[55]. In the presence of low serum magnesium levels, intravenous administration of magnesium sulfate, together with low residue diet and antidiarrheals, may also ameliorate the diarrhea[56].

Anti-diarrheal and bulk-forming agents have a role in the management of rectal urgency, frequency, and fecal incontinence, which might be induced by radiation damage of the myenteric plexus of the rectum and internal anal sphincter[57]. Sulfasalazine, 5-aminosalicylic acid (5-ASA) preparations and corticosteroid enemas have minimal or no effects on rectal tenesmus or bleeding[48].

However, recent pilot studies indicate that balsalazide, a new 5-ASA drug that yields a high concentration of active drug to the distal colon, is able to prevent or reduce symptoms of radiation-induced proctosigmoiditis[58]. In addition, irradiation-induced inflammatory response could be modulated pharmacologically based on the anti-inflammatory properties of 5-ASA, which is a peroxisome proliferation-activated receptor (PPAR) activator. PPAR agonists are now emerging as therapeutic drugs for various inflammatory diseases characterized by impaired PPAR expression: Irradiation drastically reduces mRNA and protein levels of PPAR-α and -γ. Specifically, 5-ASA treatment normalizes both PPAR-α and PPAR-γ during the post-irradiation period (after 7 and 3 d, respectively). By promoting PPAR expression and its nuclear translocation, 5-ASA interferes with the NF-κB pathway, both reducing irradiation-induced NF-κB p65 translocation/activation and increasing the expression of NF-κB inhibitor (IκB) mRNA and protein. Therefore, 5-ASA prevents irradiation-induced inflammatory processes as well as expression of TNF-α, monocyte chemotactic protein-1, inducible nitric-oxide synthase, and macrophage infiltration. In addition, 5-ASA restores the IFN-γ/signal transducer and activator of transcription (STAT)-1 and STAT-3 concentrations that were impaired at 3 and 7 d post-irradiation and are correlated with suppressor of cytokine signaling-3 repression. Collectively, these data suggest that PPAR agonists might be effective in the prevention of inflammatory processes and immune responses during and after pelvic radiotherapy[59].

Fecal incontinence appears to be a late complication that causes symptoms years after radiation treatment. The specific mechanisms that cause incontinence are changes in anal resting tone, squeeze pressure, and rectal volume or rectal compliance. Other aspects associated with incontinence include further disorders such as proctitis, colitis, and other disturbances involving the lower digestive tract. The therapeutic options mainly comprise management of associated aspects, such as proctitis or diarrhea; surgical intervention should be the absolute exception[60].

It has been reported that sucralfate treatment has a protective effect against experimental radiation colitis. Sucralfate enemas prior to radiation lead to reduction in: (a) the number of apoptotic colonic crypt cells; (b) the number of caspase-3 positive cells; (c) oncogene p53 accumulation and p21 expression; and (d) proapoptotic Bax/anti-apoptotic Bcl-2 ratio in rats. Therefore, the protective effects of sucralfate against radiation colitis might be partially due to the suppression of radiation-induced apoptosis in the colon and the protection of the colonic epithelial stem cell region[61]. Sucralfate administration may be also effective in human radiation proctocolitis[62]. In addition, when compared with oral sulfasalazine plus rectal prednisolone enemas, sucralfate enemas give a better clinical response in human proctosigmoiditis, are better tolerated, and, because of the lower cost, they might be the preferred short-term regimen[48]. Moreover, topical sucralfate induces a lasting remission in the majority of patients with moderate to severe rectal hemorrhage due to radiation proctosigmoiditis[63].

Clinically, short-chain fatty acids (SCFAs) have been proposed as possible therapeutic agents in several conditions including radiation proctitis. Although some promising effects have been observed in uncontrolled studies, a specific therapeutic role for SCFAs remains to be defined[64].

Hyperbaric oxygen

Hyperbaric oxygen application appears to be a very effective means of treatment of chronic radiation colitis and non-healing wounds in the involved anorectal region[65]. Hyperbaric oxygen therapy can be considered as a treatment option after failure of standard treatments in patients with severe radiation proctopathy[66]. The rationale for hyperbaric oxygen is the creation of an oxygen gradient in hypoxic tissue that stimulates the creation of new blood vessels. Neoangiogenesis improves the blood supply and reduces the ischemia and necrosis responsible for severe complications. In a retrospective study of patients with severe radiation colitis refractory to medical management, hyperbaric oxygen therapy provided clinical relief and can thus prove to be a useful alternative to conventional treatment in patients with chronic radiation-induced necrosis of the digestive tract[67]. Moreover, in a systematic review of the literature on the application of hyperbaric oxygen prevention and treatment of delayed radiation injuries, all but seven of the 74 publications analyzed reported positive results when hyperbaric oxygen was delivered as treatment for or prevention of delayed radiation injury. These results are particularly impressive in the context of alternative interventions[68]. Hyperbaric oxygen may also be helpful in management of bleeding due to chronic radiation colitis in patients not controlled with conservative measures such as formalin and laser therapy[69,70]. Hyperbaric oxygen treatment and infusion of PG E1 abolishes completely tarry stools and hematuria, and reverses the endoscopic findings of radiation colitis and cystitis[71].

Control of bleeding

Rectal bleeding due to radiation colitis usually results from telangiectasias. It is frequently minor, but blood transfusions may be required. Endoscopic cauterization using a heater, BICAP probe, Nd:YAG or argon laser can reduce bleeding.

Argon plasma coagulation therapy appears to be a simple, safe, and effective technique in the management of hemorrhagic radiation-induced proctosigmoiditis and is now generally accepted as the treatment of choice followed by local application of formalin if this fails[31,72,73]. Argon plasma coagulation, a non-contact thermal coagulation technique that reduces rectal bleeding in 80%-90% of cases, is applied endoscopically, with a probe passing through the endoscope that delivers a field of argon gas to the mucosal surface, where it is ionized by a high-voltage filament resulting in superficial mucosal heating and coagulation of friable blood vessels. Topical formalin therapy depends on direct application of a 4% concentration of the chemical soaked in gauze to the hemorrhagic areas under direct vision using a rigid sigmoidoscope. Thrombosis of the neovasculature and coagulation necrosis of the superficial mucosa ensues, with a complete response rate of 78%. While topical formalin appears to be slightly less effective than argon plasma coagulation therapy, formalin application alone or a combination of the two treatments has been advocated for severe cases of hemorrhagic radiation proctitis. Although formalin installation may be effective in controlling refractory bleeding due to radiation-induced proctitis, the procedure is not risk-free and may induce major complications such as acute colitis[74]. Preliminary results of a randomized study of the two therapeutic interventions, however, show equivalent efficacy but an absence of effect of either treatment on anorectal dysfunction.

Another approach to treat hemorrhagic radiation proctitis involves use of low-dose thalidomide, a potent inhibitor of (neo)angiogenesis, following a case report with successful outcome[75]. In addition, hormone therapy consisting of an estrogen-progesterone combination might provide a promising new additional symptomatic therapy for bleeding radiation colitis[76].

Rectal strictures should be managed initially non-operatively with a low-fiber diet, stool softeners, mineral oil enemas, and analgesics. Manual or endoscopic dilations of rectal strictures might be required. Short strictures with minimal angulation can be dilated by transendoscopic balloons or other dilators, albeit with considerable risk of perforation. Long, tortuous strictures should be managed operatively[77].

Surgery

About one third of patients with chronic radiation enteritis will need to be operated during follow-up. Surgical intervention is indicated in intestinal obstruction, perforation, fistulas, and severe bleeding. Surgery should be performed by an experienced team familiar with the treatment of radiation colitis. It is difficult to perform surgery for chronic radiation colitis because of the diffuse process of fibrosis and alterations in the gut and mesentery. The risk of anastomotic leak is high if the anastomosis is performed using irradiated tissue[78]. The risk can be lowered if at least one limb of the anastomosis did not receive prior radiotherapy[79]. It is difficult to distinguish between the normal tissue area and the irradiated area of the gut by gross evaluation during operation even when the fresh tissue is sent for frozen section. The accuracy in localizing injured intestine may be improved by intraoperative endoscopic evaluation, which can detect radiation-induced mucosal injury[80].

Resection of the affected intestine is significantly better than an enteric bypass procedure in overall outcome. However, extensive surgical resection of the diseased bowel may lead to short bowel syndrome and increase the need for total parenteral nutrition. Moreover, because of the progressive evolution of the fibrosis, the patient may require additional surgery. Surgical bypass of the damaged bowel is associated with a blind loop syndrome, and the patient may be still at risk of perforation, bleeding, abscess, and fistulae due to the persistence of the affected bowel. Bypass procedures should be performed when resection is not possible or as a temporary management before resection at a later date. Limited resection of the diseased intestine is the goal, but if the lesion is too diffuse, a bypass procedure

might be attempted.

Management of a pelvic fistula (e.g. vaginal or bladder fistula) is also complex and requires fecal diversion before the corrective surgery. Patients with fistulae frequently present with additional challenges such as electrolyte imbalance, malnutrition and infections. Many surgical techniques have been described to repair fistulae, but corrective surgery is best done when the patient is medically stable and enough time has elapsed after the surgical diversion. This permits the healing and decreased inflammation of the affected tissues[81,82].

In cases with severe fibrotic strictures, surgical intervention with establishment of a primary anastomosis may be required[83]. Strictureplasty may be an effective and safe tool to conserve intestinal length in certain highly selected patients with chronic radiation colitis and small-bowel strictures, namely those with limited intestinal reserve where strictures are located within long segments of diseased bowel which, if resected or bypassed, would have significant nutritional or metabolic consequences. Strictureplasty is not indicated for the treatment of perforation, hemorrhage, fistula, or short segments of disease in patients with adequate intestinal reserve[84].

Surgical complications of chronic radiation colitis such as intestinal obstruction, enterocutaneous fistula, intestinal stenosis, intestinal bleeding, severe proctocolitis and intestinal perforation should be managed operatively[85].

It is important to note that vigorous preoperative and postoperative nutritional support and evaluation are vital because of the poor healing qualities of the irradiated gut.

If conservative measures and local intervention to control bleeding prove unsuccessful, resection or ligation of the affected area(s) is preferred over a bypass procedure because the latter will allow the hemorrhage to continue and may lead to a higher mortality rate[86]. A promising surgical approach is small bowel transplantation, which may be considered in the pediatric population with radiation colitis.

PREVENTION OF RADIATION COLITIS

Based on the above data, it appears that the management of radiation bowel damage can be difficult and problematic; chronic radiation colitis is complex and rarely curable. Recent advances in the approaches to its prevention or amelioration are therefore particularly encouraging. Research to uncover the mechanisms of fibrosis and the molecular events underlying radiation bowel disease could lead to the development of new therapeutic and/or preventive approaches and provide the basis for predicting the risk of bowel damage and oncogenesis using levels and expressions of the mentioned cytokine IL-6, oncogene p53 or cadherin-catenin complexes, and for amelioration of bowel damage through inhibition, for example, of the COX-2 and Rho/Rho kinase pathways[33,87]. In this regard, the COX-2 inhibitor Rofecoxib® has been shown to suppress cytokine expression and to reduce acute bowel damage in rodents following abdominal irradiation[36]. In addition, piroxicam (a nonsteroidal anti-inflammatory agent) significantly decreases the incidence of colonic neoplasia in general and also delays the endoscopic appearance of colonic neoplasia in rats after pelvic irradiation[88]. Moreover, specific inhibition of Rho kinase is a promising approach for the amelioration of radiation fibrotic gut damage, as reported by a study investigating molecular pathways involved in the maintenance of fibrosis of the bowel wall of late radiation colitis patients[87]. Alterations in expressions of genes coding for Rho proteins was first established by molecular profile analysis of ileal biopsies. Primary cultures of gut smooth muscle cells derived from the ileal biopsies are associated with retention of fibrogenic differentiation *in vitro* and exhibit a typical cytoskeletal network, a high constitutive connective tissue growth factor level, increased collagen secretory capacity and altered expression of genes coding for the Rho family. Rho kinase blockade induces a simultaneous reduction in the number of actin stress fibers, α-smooth muscle actin and heat shock protein (Hsp) 27 levels. It also reduces connective tissue growth factor levels, the latter probably through NF-κB inhibition, leading to decreased expression of the type 1 collagen gene[87]. These observations show the involvement of the Rho/Rho kinase pathway in radiation fibrosis and intestinal smooth muscle cell fibrogenic differentiation, suggesting the potential role of Rho kinase inhibitors in ameliorating the radiation bowel damage.

Additional biomarkers potentially playing a role in the prediction, reduction or prevention of radiation colitis include genetic alterations of the cellular radiation response genes, such as the ataxia telangiectasia gene, and micronutrients, such as selenium and zinc. Genetic variants of the ataxia telangiectasia gene have been correlated with the risk of rectal hemorrhage associated with chronic radiation proctitis among prostate cancer patients who received the full brachytherapy prescription dose to defined volumes of the rectum[89]. The ataxia telangiectasia sequence alterations lead to an approximately sevenfold increase in mild to moderate (Radiation Therapy Oncology Group grades 1 and 2) radiation proctitis among patients who had received the full prescription dose to either low (< 0.7 mL) or moderate (0.7-1.4 mL) volumes of their rectum. Patients contemplating this increasingly popular radiation treatment modality for early prostate cancer should not only be better informed about the risks of bowel complications, but could also have their radiation dose prescriptions individualized based on genetic profiling.

Dietary supplementation of selenium and zinc may be useful in reducing anorectal sequelae after pelvic radiotherapy; an indirect relationship between baseline plasma levels of these micronutrients and abnormalities in anorectal function one year after radiotherapy for prostate cancer has been suggested. Notably, the heavy metal zinc induces Hsps, also known as stress proteins and molecular chaperones, which play a central role in protecting cellular homeostatic processes from environmental and physiologic insults by preserving the

structure of normal proteins and repairing or removing damaged ones. Lowering Hsps in cancer tissues can amplify the effectiveness of chemo- or radiotherapy[90].

Importantly, improvements in the delivery of radiotherapy, including techniques to reduce the amount of exposed intestine in the radiation field, also represent a critical strategy for prevention. The ideal radiation toxicity preventive therapy must have high efficacy, low toxicity, low cost, and not afford cancer protection. Unfortunately, the currently available therapy often does not fulfill all of these objectives and there is a need to identify patients who may truly benefit from preventive therapies. Specifically, the radiation therapy technique plays an essential role in reducing the rate of complications; particular attention should be paid to optimizing radiotherapy technique and dose prescriptions. The use of only anterior and posterior fields for pelvic radiation should be avoided, if possible, because of the high dose and large volume of intestine irradiated. A higher operative mortality was reported in trials using this technique preoperatively for rectal cancers[91,92]. The toxicity of radiation is directly related to the volume of small bowel being irradiated[93]. In many patients, therapy in the prone position with a special "belly" board allows the protrusion of the small intestine out of the radiation field[94,95]. Patients should be instructed to maintain a full bladder during the radiation session, which mechanically displaces the intestine out of the pelvis[96].

Modern radiation treatment techniques, such as three-dimensional treatment planning, also optimize the treatment technique by developing more accurate dose distributions. Notably, three-dimensional conformal radiotherapy techniques, including intensity-modulated radiotherapy, may not reduce late intestinal toxicity because margins around the cancer may not be able to be safely reduced and because of the prescription of higher radiation doses[97,98]. Brachytherapy, alone or as a supplement to external beam radiotherapy, is now increasingly being utilized to decrease normal tissue toxicity, without compromising treatment efficacy, in the management of prostate carcinoma[99,100]. Brachytherapy is a kind of radiotherapy whereby the source of radiation is located either within the malignant tissue (interstitial brachytherapy) or within a cavity in its immediate vicinity (intracavitary brachytherapy), rather than at a distance (typically 100 cm) from the center of the neoplasm target, as it is the case with external beam radiotherapy. Brachytherapy exploits the physical characteristics inherent with this modality of radiotherapy, whereby the high radiation dose is limited to the neoplasm target, while the surrounding normal tissues are spared from radiation by the rapid dose reduction (with the square of the distance). Brachytherapy alone, in the therapy of low-risk prostate carcinoma, is well tolerated, even in patients with a history of IBD[101].

Another related treatment, such as intensity-modulated radiotherapy (IMRT), uses sophisticated planning techniques to avoid critical structures. IMRT uses multiple segments of beams to shape the dose distribution to a desired result.

Operation, as a major risk factor, leads to the prolapse of the small intestine into the pelvis, exposing it to a full dose of radiation. Postoperative bowel adhesions also increase the volume of gut irradiated compared with normal intestine, usually mobile and able to move out of the radiation field. With gut adhesions, the intestine is trapped and is more likely to receive a high dose of radiation. If radiation therapy is anticipated after surgery, every attempt should be made at the time of surgery to displace the bowel outside of the radiation field[102]. One simple technique is the surgical placement of a polyglycolic, biodegradable mesh that moves the intestine out of the pelvis[103,104]. The procedure has negligible morbidity and it does not increase the operating time significantly. It also does not require a second operation to remove the mesh because it is absorbed 3 to 4 mo postoperatively. MRI can be used post-operatively to verify the position of the mesh, the small bowel, and its disappearance. Placement of a mesh during surgery allows a higher dose of radiation to be given postoperatively when indicated, thereby decreasing by 50% the volume of the small bowel exposed to the radiation[105,106]. Other techniques such as pelvic reconstruction, omentoplasty, and transposition of the large bowel also reduce the volume of gut at risk for radiotherapy up to 60%[106-109].

Amifostine (WR-2721) is an amino-thiol with well-established radioprotective effects. Recent studies have documented its effectiveness in protection of the salivary glands in patients receiving radiotherapy for head-and-neck cancer[110]. It has also been investigated for the prevention of chronic radiation colitis. According to preclinical studies, amifostine protects both the small and large intestine[111]. Specifically, it is converted intracellularly to an active metabolite, WR-1065, which in turn binds to free radicals and protects the cell from radiation damage[112]. In a randomized study, the late effects of radiation were significantly reduced in the group receiving parenterally administered amifostine. However, the median follow-up was quite short (24 mo), and longer follow-up is necessary to confirm the benefits of this medication because the incidence of late complications increases with time[113]. There is also evidence suggesting that intrarectal application of amifostine directly onto the rectum may reduce the risk of proctitis in patients undergoing radiotherapy for prostate cancer[114]; its intrarectal application is feasible and well tolerated. Systemic absorption of amifostine and its metabolites is negligible, and close monitoring of patients is not required after rectal administration[115]. Systemic administration of amifostine, used concurrently with radiotherapy in advanced rectal cancer, has been reported to reduce acute and late pelvic radiation toxicity[113]. Other investigators[116], however, were not able to demonstrate any protection afforded by amifostine.

Since cytotoxic effects of ionizing radiation on gastrointestinal epithelium may be related to oxidative stress, a number of agents have been used as a prophylaxis

treatment. Eicosanoids and free radicals release have been implicated in the pathogenesis. Selenium and/or vitamin E pretreatments are shown to improve post-irradiation disturbances in pro-oxidant-antioxidant balance, such as increased intestinal lipid peroxide and decreased GSH levels, increased intestinal SOD and GSH peroxidase activities and decreased glutathione transferase activity. This amelioration has been confirmed by histopathological findings[117]. In another study, the early side effects of radiation were suggested to be prevented by vitamin A supplementation[118].

PGs have been investigated as potential radioprotectors. PGE2 and the PG analogs enprostil and misoprostol (Cytotec®) display radiation protection in animal studies[119-122]. Misoprostol suppositories also reduced symptoms of acute radiation colitis in patients undergoing radiation therapy for prostate cancer[123]. With respect to the mechanism of action, PGE2 has pro-proliferative and anti-apoptotic effects on epithelial cells in gastrointestinal injury. PGE2 decreases radiation-induced apoptosis and increases crypt survival[124].

Experimental data indicate that in control animals, glucagon-like peptide-2 (GLP-2) induces an increase in intestinal mucosal mass, along with an increase in villus height and crypt depth. GLP-2 administration before and after irradiation completely prevents the acute radiation-induced mucosal ulcerations and strikingly reduces the late radiation damage. Microscopic observations show an improved organization of the intestinal wall and an efficient wound healing process, especially in the smooth muscle layers. This therapeutic effect is mediated through an increased mucosal mass before tissue injury and the stimulation of still unknown mechanisms of tissue response to radiation damage. Although these preliminary results still need to be confirmed, GLP-2 might be a way to limit patient discomfort during radiotherapy and reduce the risk of consequential late effects[125].

Irradiated intestine consistently exhibits increased immunoreactivity of transforming growth factor (TGF)-β1. It has been demonstrated that mucosal barrier breakdown is closely associated with increased TGF-β immunoreactivity in subsequent radiation enteropathy. The highly significant correlation between TGF-β expression levels and alterations in late-responding tissue compartments also suggest a role for TGF-β in primary radiation colitis. A recent preclinical study showed a role for possible anti-TGF-β1 interventions to reduce delayed radiation fibrosis and enteropathy[126].

Preliminary studies also suggest that IFN-γ may be effective in the treatment of patients with radiation-induced cutaneous fibrosis. IFN-γ should be considered in Phase Ⅰ-Ⅱ studies to assess its toxicity and efficacy in the treatment of patients with radiation colitis[127].

Many special diets and nutrients, such as the mentioned fiber, elemental diets, SCFAs and amino acids like glutamine, may reduce small-bowel radiation toxicity. Specifically, probiotics (*Lactobacillus bulgaricus* strain isolated from yogurt) added as substrates can be given by an oral or enteral route to patients who undergo radiotherapy to prevent radiation-induced colitis and related malnutrition[128].

Glutamine and arginine support the mucosal barrier in several ways. In experimental studies, a 7-d glutamine- or arginine-enriched diet administered both pre- and post-irradiation showed that they have protective effects on gut mucosa in the post-irradiation state. However, pre- and post-irradiation administration together do not provide superior protection compared to post-irradiation administration alone[129].

Administration of insulin-like growth factor (IGF)-I immediately following abdominal irradiation increases small-intestinal mass and improves indicators of mucosal integrity, suggesting acceleration of small-intestinal mucosal recovery from radiation injury[130]. More recently, growth hormone and IGF-I have been demonstrated to protect intestinal cells from radiation-induced apoptosis both *in vitro*, by inhibiting apoptosis of the cells and preserving the mucosal integrity[131], and *in vivo*[132], utilizing IGF- I transgenic mice.

Pancreatic enzymes can exacerbate acute intestinal radiation toxicity, and suppressing pancreatic secretion with synthetic somatostatin receptor analogs, such as octreotide, can reduce both early and delayed radiation colitis[133]. Of note, in an experimental model, irradiation significantly increased intestinal and pancreatic myeloperoxidase activities and intestinal malondialdehyde levels of intestinal tissues, and octreotide treatment improved this elevation. The histopathologic evaluation of the mucosal structure was also preserved in the octreotide-treated group. Inflammation of pancreatic tissue was also confirmed with histopathological examinations. Moreover, irradiation seems to induce NF-κB overexpression, and octreotide treatment decreases the end organ damage and inflammation of the small intestine. Thus, octreotide appears to have beneficial effects on intestinal and pancreatic damage in abdominal irradiation through the inflammatory process[134].

Despite the aforementioned promising agents used in acute and chronic radiation colitis, further understanding of the pathophysiological mechanisms involved in the pathogenesis of acute and chronic irradiation colitis and the interaction of the molecular events controlling mainly apoptosis and fibrosis may assist in the development and establishment of new therapeutic approaches.

Abstract

Ischemic colitis is the most common form of ischemic injury of the gastrointestinal tract and can present either as an occlusive or a non-occlusive form. It accounts for 1 in 1000 hospitalizations but its incidence is underestimated because it often has a mild and transient nature. The etiology of ischemic colitis is multifactorial and the clinical presentation variable. The diagnosis is based on a combination of clinical suspicion, radiographic, endoscopic and histological findings. Therapy and outcome depends on the severity of the disease. Most cases of the non-gangrenous form are transient and resolve spontaneously without complications. On the other hand, high morbidity and mortality and urgent operative intervention are the hallmarks of gangrenous ischemic colitis.

INTRODUCTION

Ischemic colitis (IC), first described by Boley *et al*, is the most common form of ischemic injury to the gastrointestinal tract representing more than half of the cases with gastrointestinal ischemia[1,2]. The incidence of IC is underestimated because it often has a mild and transient nature. Moreover, many cases are misdiagnosed as suffering from other diseases such as inflammatory bowel disease or infectious colitis.

An acute, self-limited compromise in intestinal blood flow which is inadequate for meeting the metabolic demands of a region of the colon is the underlying pathophysiology[3]. Colonic blood flow may be compromised by changes in the systemic circulation or by anatomic or functional changes in the local mesenteric vasculature. The original insult precipitating the ischemic event often cannot be established, but frequently occurs in the elderly patient with diffuse disease in small segmental vessels and various co-morbidities. Approximately 90% of cases of colonic ischemia occur in patients over 60 years of age although younger patients may also be affected[4].

IC presents either as an occlusive or a non-occlusive form. In most cases no specific occlusive lesion is recognized on angiography, and patients are referred to as suffering from non-occlusive colon ischemia.

The aim of this review is to transfer the current knowledge on diagnosis and management of ischemic colitis into daily clinical practice.

RISK FACTORS

A plethora of conditions may predispose to IC: Mesenteric artery emboli, thrombosis, or trauma may lead to occlusive vascular disease and impaired colonic perfusion[5]. Hypo-perfusion states due to congestive heart failure, transient hypotension in the perioperative period or strenuous physical activities and shock due to a variety of causes such as hypovolemia or sepsis can result in IC[3]. Mechanical colonic obstruction due to tumors, adhesions, volvuli, hernias, diverticulitis or prolapse may also infrequently cause IC[3]. There is a long list of medications that predispose to colon ischemia. Major classes of pharmacologic agents known to be associated with IC include the following[6]: antibiotics, appetite suppressants (phentermine), chemotherapeutic agents (vinca alkaloids and taxanes), constipation inducing medications, decongestants (pseudoephedrine), cardiac glucosides, diuretics, ergot alkaloids, hormonal therapies, statins, illicit drugs,

immunosuppressive agents, laxatives, nonsteroidal anti-inflammatory drugs, psychotropic medications, serotonin agonists/antagonists and vasopressors. Iatrogenic causes may result in IC. Ischemic colitis follows aortic reconstruction with an incidence of 2% to 3% and is higher after abdominal aortic aneurysm repair[7,8]. IC may be a complication of coronary artery bypass surgery or a rare complication of colonic surgery or colonoscopy[3].

A state of increased coagulability, although not extensively investigated, has been raised as a significant factor in the pathogenesis of IC. Some cases of IC have been reported to be associated with genetic defects such as deficiencies of protein C, protein S, and antithrombin Ⅲ[9-11], factor V Leiden (FVL) mutation[12,13], and prothrombin 20210G/A mutation[14], as well as acquired factors such as antiphospholipid antibodies[15]. Protein Z deficiency has also been reported in IC patients[16]. A thrombophilic tendency in the majority of patients was shown in a study of comprehensive thrombophilic screening in colon ischemia[17]. The most significant associations were found with the antiphospholipid antibodies and the FVL mutation[17]. These results were confirmed by another recent study in which thrombophilic disorders were found in 28% of patients studied[18].

IC might also spontaneously appear in apparently healthy individuals. In these cases no clear cause for the ischemia is identified. This idiopathic or "spontaneous" form is generally thought to be related to localized non-occlusive ischemia of the bowel[5]. In younger patients a predisposing cause is more easily recognized. Vasculitides, estrogens, cocaine and methamphetamine use, psychotropic drugs, sickle cell disease, long-distance running and heritable disorders of coagulation should be considered[19-24]. In a recent study[25], the frequency of the 506 Q allele of the factor V (FV) 506 RQ (Leiden) mutation and the mutant 4G allele of plasminogen activator inhibitor (PAI) polymorphism were found to be significantly higher in young patients with IC compared with healthy controls.

PATHOPHYSIOLOGY

The colon is predisposed to ischemia by its relatively low blood flow and its less developed microvasculature plexus compared with the small bowel. Two major arteries supply most of the blood to the colon: the superior mesenteric artery (which supplies the ascending and transverse colon) and the inferior mesenteric artery (IMA) (which supplies the descending and sigmoid colon). The internal iliac arteries supply the rectum.

The colon is protected from ischemia by a collateral blood supply *via* a system of arcades connecting the two major arteries. The anatomy is highly variable, however, and certain areas are more vulnerable in some people[26]. The splenic flexure and sigmoid colon are regions where two circulations meet each other (so-called watershed areas), have more limited collateral networks and therefore ischemic damage is more common in these areas. The marginal artery of Drummond is one of the collateral vessels supplying the splenic flexure; 5% of the population has a diminished or absent marginal artery of Drummond[27]. These patients are at particular risk of ischemia. The right colon may be vulnerable in systemic low-flow states, as the marginal artery of Drummond is poorly developed here in 50% of the population[28]. The vasa recta are smaller and less developed in the right colon compared to the left colon. Collateral flow between the IMA and the internal iliac arteries occurs *via* the superior and middle/inferior rectal (hemorrhoidal) vessels. Ischemic damage of the rectum is rare because of its dual blood supply from the mesenteric and iliac arteries.

Classification

Clinically, ischemic colitis may be classified into gangrenous and non-gangrenous forms. The latter can also be subdivided into transient and chronic forms.

According to the classification of Brandt and Boley the following types are suggested[29]: (1) Reversible ischemic colonopathy; (2) Transient IC; (3) Chronic ulcerative IC; (4) Ischemic colonic stricture; (5) Colonic gangrene; and (6) Fulminant universal.

The non-gangrenous form accounts for 80%-85% of cases[26]. The disease is transient, and reversible in about 50% of cases. Chronic forms, presenting either as chronic segmental colitis or strictures, occur in 20%-25% and 10%-15% of cases, respectively[26,29]. Predictive factors of the chronic form are older age, longer elapsed time from the onset of illness to the termination of subjective symptoms, and a prolonged period until normalization of the white blood cell count or the erythrocyte sedimentation rate[5]. Gangrene occurs in about 15% of patients and requires laparotomy as soon as possible[26]. Fulminant pancolitis is rare, occurring in only 1% of cases[26].

A worse prognosis has been reported in elderly patients. There are conflicting results with regard to the relationship between the medical history of patients and the severity of IC. High blood pressure, history of cancer, diabetes mellitus, aortic surgery, peripheral vascular disease and involvement of the right side of the colon have been suggested by some authors to be predisposing factors for a worse evolution of the disease[30-32]. In the study by Anon *et al*[33], factors predicting poor prognosis in ischemic colitis were the absence of hematochezia, tachycardia and peritonism, anemia, hyponatremia and colonic stenosis.

Any part of the colon may be affected but the left colon is the predominant location in approximately 75% of patients[5]. Splenic flexure is involved in approximately one-quarter of patients[5] and isolated right colon ischemia (IRCI) in about 10% of cases[29]. In a recent biopsy-proven study, IRCI accounted for 26% of cases[34]. Its clinical presentation was found to be different in patients who presented more commonly with abdominal pain without bloody diarrhea. IRCI has been reported to be associated with hemodialysis and chronic renal failure and in patients with shock. It is associated with severe colitis and patients have a worse outcome than those with colon ischemia involving other regions, including

a five-fold need for surgery and a two-fold increase in mortality[34]. Patients on hemodialysis who develop IRCI have a particularly unfavorable outcome[34]. Insufficient collateralization and blood flow to the right side of the colon is believed to be the reason for the poor prognosis in these patients. Alternatively, it is possible that the presence of an acute superior mesenteric artery occlusion and thus its outcome reflects that of acute mesenteric ischemia.

Clinical presentation

The clinical presentation varies, depending on the severity and extent of the disease. None of the symptoms and signs is specific. Most patients present with a sudden onset of crampy abdominal pain, diarrhea and an urge to defecate. The pain is mild, located over the affected bowel, usually to the left side of the lower abdomen and hypogastrium, followed by mild rectal bleeding within 24 h. The blood may be bright red or maroon, frequently mixed with the stools. Rectal bleeding is usually minimal. Significant hematochezia accompanied with hemodynamic instability or the need for blood transfusion suggests a different diagnosis. The presence of an associated ileus may be manifested by anorexia, nausea and vomiting.

Clinical examination of the abdomen reveals mild to moderate tenderness over the affected area of the colon. Rectal examination shows heme-positive stools. Fever is unusual while the white cell count is generally raised. In cases of severe ischemia with transmural infarction and necrosis, marked tenderness with peritoneal signs may be present on physical examination accompanied by metabolic acidosis and septic shock.

DIAGNOSIS

Given that the presentation of colon ischemia is not specific and is highly variable, diagnosis and management is clinically challenging. Diagnosis requires a high index of clinical suspicion. The chronology of symptoms and the clinical situations upon which these symptoms appear must be taken into account.

Special attention must be paid to the presence of conditions that predispose to the disease, such as strenuous physical activity, dehydration, illicit drugs, thrombophilic tendency, aortic surgery or cardiac bypass, vasculitis, major cardiovascular episode accompanied by hypotension or an obstructing lesion of the colon.

The presence of diarrhea, abdominal pain and tenderness as well as mild lower gastrointestinal bleeding, even in the absence of any risk factor, should prompt consideration of IC as a cause. Early and repeated clinical evaluation in addition to radiological and endoscopic assessment is necessary to avoid complications. Common clinical conditions should be excluded. The differential diagnosis includes infectious colitis, inflammatory bowel disease, pseudomembranous colitis, diverticulitis and colon carcinoma. Severe forms may be difficult to distinguish from acute mesenteric ischemia.

All patients with clinical suspicion of IC should have stool cultures for *Salmonella, Shigella, Campylobacter* and *Escherichia coli* O157:H7[35]. The latter organism has been implicated in causing colonic ischemia. Infection with parasites or viruses such as cytomegalovirus should also be excluded.

Laboratory tests

Various laboratory markers of ischemia have been investigated such as: lactate, LDH, CPK, amylase levels, leucocytes, alkaline phosphatase, inorganic phosphate, intestinal fatty acid binding protein and alfa-glutathione S-transferase[36]. These markers have been studied mainly in acute bowel ischemia, and none has been found to be sufficiently specific to diagnose IC. They are uncommon in mild ischemia and only increase with advanced and severe ischemic damage, late in the course of the disease.

Imaging techniques

Plain abdominal radiography can reveal nonspecific findings such as thumbprinting, air-filled loops, colonic aperistalsis, mural thickening and exhausted bowel in up to 21% of patients[3]. It is a useful examination for excluding colon infarction[37]. When intra-abdominal air secondary to perforation, air within the bowel wall, or air in the portal vein, is demonstrated by plain radiography, an emergency exploratory laparotomy is indicated.

Barium enema may suggest colon ischemia in up to 75% of patients with thumbprinting being the most common finding. Ulcers, ridges, edema, eccentric mural deformity, succulation and strictures may also be seen. Findings are non specific[38]. Barium enema should be avoided in cases where there is a suspicion of gangrene or perforation. Barium enema also makes the later use of angiography or endoscopy more difficult because of residual contrast agent.

Computed tomography (CT) is often used as the initial diagnostic test when assessing patients with nonspecific abdominal pain. It may suggest the diagnosis and location, exclude other serious medical conditions, narrow the differential diagnosis possibilities and illustrate the complications. Although intrinsic colonic abnormalities cannot be used to diagnose or predict the development of infarction[39].

In non-transmural IC, the initial bowel wall thickening, thumbprinting, and pericolonic stranding, with or without peritoneal fluid, can be seen on CT images. In these cases, CT usually demonstrates the double halo or target sign. After reperfusion of the ischemic bowel wall, the sign may be produced by edema in the submucosa and appear as low attenuation or by hemorrhage and appear as high attenuation. If there is total vascular occlusion without reperfusion (infarction), the colonic wall remains thin and unenhancing, associated with dilatation of the lumen. In these cases, CT may demonstrate a thrombus in the corresponding mesenteric vessel. If ischemia is transmural, strictures may form. Occasionally, a toxic megacolon develops. Pneumatosis and/or gas in the mesenteric veins are ominous signs when associated with bowel wall thickening and are due to bowel infarction.

Pneumatosis coli or pneumatosis intestinalis can be diagnosed by demonstrating air bubbles in the colonic or intestinal wall. The gas bubbles are arranged in a linear fashion and are best visualized with the window settings for bone or lung[40].

Mesenteric angiography usually has no role in the evaluation and management of IC because at the time of symptom onset, colon blood flow has returned to normal. Damage from hypoperfusion is often at the arteriolar level, whereas mesenteric vessels and arcades are patent. There are two exceptions where angiography may have some utility: when acute mesenteric ischemia is considered and cannot be clearly distinguished from IC by clinical presentation, or when there is isolated involvement of the right side of the colon, suggesting superior mesenteric artery occlusion.

Sonography is a sensitive technique for the early detection of changes in the colon wall resulting from ischemia, and it can suggest this cause in the appropriate clinical setting. Location and length of the involved colonic segment, colon wall thickening, bowel wall stratification and abnormal echogenicity of the pericolic fat and peritoneal fluid are some of the findings on sonography[41].

Color Doppler sonography may be useful in the differentiation between inflammatory and ischemic bowel wall thickening[42]. Sonography may provide data for identifying patients who will develop necrosis. In one study, altered pericolic fat or the absence of improvement in sonographic follow-up studies were factors associated with transmural necrosis[41]. Nevertheless, overlying bowel gas, operator-dependent quality and poor sensitivity for low flow vessel disease limit its use.

Scintigraphy has recently been used in the diagnosis of ischemic colitis. In-111 or Tc-99m-labeled leukocyte scintigraphy has been studied and has demonstrated successful imaging of bowel infarction while Tc-99m(V) DMSA was recently found to have no role in the detection and diagnosis of IC[43-45].

Colonoscopy

In recent years, colonoscopy has replaced barium enema as the most common diagnostic method and the gold standard for confirmation of IC. It is more sensitive and allows visualization of colonic mucosa and histological analysis of biopsies. However, with the exception of colonic gangrene, neither endoscopic nor histological findings are specific[29] and highly depend on the duration and severity of ischemic injury. Diagnosis requires early colonoscopy (< 48 h). Serial studies in connection with the clinical setting are necessary to establish the diagnosis.

Ischemic tissue damage to the colon is thought to be a result of both local hypoperfusion during the ischemic period and reperfusion injury when blood flow returns. When the ischemic period is brief, reperfusion may be significant and accounts for most of the histologic and endoscopic damage present in IC[2]. Reperfusion injury may be associated with the release of oxygen free radicals which cause lipid peroxidation within cell membranes, resulting in cell lysis and tissue damage.

When the ischemic period is of long duration, hypoperfusion deprives the involved bowel of oxygen and nutrients, leading to hypoxia and direct cell death[2]; damage progresses from the lumen outwards to the serosa (from the mucosa and submucosa to deeper layers).

In the early stages only the mucosa and the submucosa are involved. Hemorrhagic nodules may be seen at colonoscopy and represent bleeding into the submucosa. These findings parallel the "thumbprints" or "pseudotumors" found on barium studies[5]. The purple submucosal hemorrhages usually dissipate within 48 h or are followed by ulceration. Hence, the initial diagnostic study should be performed soon after the onset of symptoms. Focal areas of pale and edematous mucosa interspersed with areas of petechial hemorrhage or superficial ulceration may also be seen in mild cases[2,46]. Later, segmental erythema with or without ulcerations and bleeding may be observed. A single longitudinal ulcerated or inflamed colon strip represents the characteristic single-stripe sign[47]. In more severe ischemia when transmural infarction of the bowel wall occurs, the mucosa appears gray-green or black over a significant area. Pseudopolyps and pseudomembranes may also co-exist[5]. In chronic stages, weeks or months later, stricture, mucosal atrophy and granularity or a mucosal pattern suggestive of "segmental ulcerative colitis" may occur[2].

Histologic changes in IC include edema, distorted crypts, mucosal and submucosal hemorrhage, inflammatory infiltration in the lamina propria, granulation tissue, intravascular platelet thrombi and necrosis. In the phase of stricture, inflammation is minimal and fibrosis predominates[5].

Endoscopic findings which distinguish between IC and inflammatory bowel disease are the segmental distribution, rectum sparing and rapid resolution on serial examinations[3]. Special care should be taken during colonoscopy to avoid overinflation which can lead to the risk of perforation. Distention of the bowel with room air may cause a further reduction in intestinal perfusion. Using carbon dioxide as the insufflating agent which is rapidly absorbed, and has the benefit of vasodilation and direct improvement in colonic perfusion, may minimize these risks[26]. When signs of peritonitis are present, endoscopy should be avoided. When endoscopy reveals findings of gangrene, colonoscopy should be stopped and laparotomy performed as soon as possible.

Total colonoscopy when it is considered safe, is preferred because 30% of IC cases occur proximal to the left flexure[3]. Given the high morbidity and mortality of IRCI and the vague presenting symptoms, early diagnosis and aggressive management is critical.

TREATMENT

Treatment depends on acuteness and severity of presentation. Most cases of IC are transient and resolve

spontaneously. Such patients do not require specific therapy. Very mild cases can be managed on an outpatient basis with liquid diet, close observation and antibiotics. Patients with more severe symptoms must be hospitalized. In the absence of colonic gangrene or perforation, general measures of supportive care are recommended. Patients should be placed on bowel rest and given intravenous fluids to resuscitate extracellular volume and reduce intestinal oxygen requirements. Parenteral nutrition should be considered for patients who need prolonged bowel rest and have major medical contraindications to surgery[26]. Cardiac function and oxygenation should be optimized. Swan-Ganz catheterization may assist in guiding fluid status and cardiac function in hemodynamically unstable patients. Vasopressors or any medications which are associated with colon ischemia should be withdrawn if possible. Oral cathartics and bowel preparations should not be given because they can, in some cases, precipitate colonic perforation or toxic dilatation of the colon. Likewise, the use of systemic corticosteroids may potentiate ischemic damage and predispose to colonic perforation. Local corticosteroids may have a role in the treatment of patients with chronic IC although no published experience supports their use. A nasogastric tube should be placed if ileus is present. Decompression of a distended colon by use of a rectal tube may be useful. Empiric broad-spectrum antibiotics are given to cover aerobic and anaerobic bacteria and minimize bacterial translocation and sepsis which has been shown to occur with the loss of mucosal integrity[48]. The use of antibiotics is based on several experimental studies which showed a reduction in severity and extent of bowel damage when antibiotics were given before or during an ischemic event[2,49]. Antibiotics have resulted in prolonged survival after intestinal ischemia in rats[49]. Although there is a lack of substantial evidence in humans, this practice is justified because of the difficulty in predicting who will progress to gangrenous colitis. In experimental studies[5], substances such as papaverine, isoproterenol, bradykinin, histamine, serotonin, adenosine, vasoactive intestinal polypeptide and glucagon have been found to dilate colonic vasculature and improve local colonic blood flow and tissue oxygenation.

Frequent clinical follow up of the abdomen, careful monitoring of vital signs and serial radiographic and colonoscopic examinations are needed. Clinical suspicion of colonic infarction justifying an emergency laparotomy may arise if there are signs of clinical deterioration despite conservative therapy, such as sepsis, persistent fever and leukocytosis, peritoneal irritation, protracted pain, diarrhea or bleeding, protein-losing colopathy for more than 14 d, free intra-abdominal air, or endoscopically-proved extensive gangrene[26].

About 20% of patients with acute IC will require surgery with an associated mortality rate of up to 60%[31]. At laparotomy, the diagnosis is confirmed and all affected bowel resected. It is important to ensure normal surgical margins. The external appearance of the bowel may be normal during laparotomy since the serosa may be unaffected, despite extensive mucosal damage. The extent of resection should be guided by the distribution of disease seen on preoperative studies. Some authors have reported on intraoperative techniques such as Doppler ultrasonography, intraoperative colonoscopy, evaluation of the antimesenteric serosal surface by hand-held photoplethysmography, pulse oximetry or transcolonic oxygen saturation and intravenous fluorescein for assessment of colonic viability[49,50]. In general, the resected segment should be examined in the operating room for mucosal injury. If needed, additional colon should be removed. Questionably viable areas of colon are generally resected. A colectomy is followed by colostomy or ileostomy. Patients with left-sided IC undergo resection with a proximal stoma and a distal mucous fistula or Hartman pouch. Primary anastomosis is unusual. Rarely, an ileocolostomy may be performed in patients with right-sided IC and viable ileum and transverse colon. In a series by Longo *et al*[51], the stoma was closed in 75% of patients with IC who underwent segmental resection *vs* only a third of those with total colonic involvement.

Fortunately, in the majority of patients, signs and symptoms of the disease resolve within 24 to 48 h and complete clinical, radiographic and endoscopic resolution occurs within 2 wk. In these circumstances no further therapy is indicated. In severe but reversible injury, when segmental ulcerative colitis exists, the colon may take 1 to 6 mo to heal[29]. Asymptomatic patients should have frequent follow-up examinations to document healing or the development of strictures or persistent colitis. In such cases, the patient may have persistent diarrhea, rectal bleeding or repeated episodes of sepsis, which may lead to perforation. Chronic ischemia may respond to topical steroid preparations in addition to general conservative measures. Resection of the affected segment is curative and subsequent development of further ischemic disease is rare. Asymptomatic strictures should be observed, since some may return to normal within 12 to 24 mo with no specific therapy[31]. When a stricture produces symptoms of obstruction, segmental resection is adequate while endoscopic dilation has been proposed as an alternative to surgery[48].

CONCLUSION

The etiology of ischemic colitis is multifactorial and the clinical presentation variable. The diagnosis is based on a combination of clinical suspicion, endoscopic and histological findings. Therapy and outcome depend on the severity of the disease. Most cases of the non-gangrenous form are transient and resolve spontaneously without complications. High morbidity and mortality and urgent operative intervention are the hallmarks of gangrenous ischemic colitis.

Abstract

Splanchnic or gastrointestinal ischemia is rare and randomized studies are absent. This review focuses on new developments in clinical presentation, diagnostic approaches, and treatments. Splanchnic ischemia can be caused by occlusions of arteries or veins and by physiological vasoconstriction during low-flow states. The prevalence of significant splanchnic arterial stenoses is high, but it remains mostly asymptomatic due to abundant collateral circulation. This is known as chronic splanchnic disease (CSD). Chronic splanchnic syndrome (CSS) occurs when ischemic symptoms develop. Ischemic symptoms are characterized by postprandial pain, fear of eating and weight loss. CSS is diagnosed by a test for actual ischemia. Recently, gastro-intestinal tonometry has been validated as a diagnostic test to detect splanchnic ischemia and to guide treatment. In single-vessel CSD, the complication rate is very low, but some patients have ischemic complaints, and can be treated successfully. In multi-vessel stenoses, the complication rate is considerable, while most have CSS and treatment should be strongly considered. CT and MR-based angiographic reconstruction techniques have emerged as alternatives for digital subtraction angiography for imaging of splanchnic vessels. Duplex ultrasound is still the first choice for screening purposes. The strengths and weaknesses of each modality will be discussed. CSS may be treated by minimally invasive endoscopic treatment of the celiac axis compression syndrome, endovascular antegrade stenting, or laparotomy-assisted retrograde endovascular recanalization and stenting. The treatment plan is highly individualized and is mainly based on precise vessel anatomy, body weight, co-morbidity and severity of ischemia.

INTRODUCTION

In this review we will cover the current insights in splanchnic or gastrointestinal ischemia. This disorder is still rarely seen in daily practice, and randomized controlled trials are absent, therefore the view of this paper is highly personal and partly authority-based in its conclusions. The spectrum of ischemic bowel disease is broad, ranging from transient left-sided ischemic colitis (with a good prognosis) to full blown intestinal infarction, with a high death rate. We will focus on new developments in clinical presentation, diagnostic approaches, and treatment options. Splanchnic ischemia can develop during low-flow states in patients with patent vessels, and in subjects with varying degree of splanchnic artery stenoses or splanchnic venous thrombosis. The prevalence of significant splanchnic arterial stenoses, or chronic splanchnic disease (CSD) is high, ranging from 30% to 50%[1,2]. Chronic splanchnic syndrome (CSS) occurs when ischemic symptoms develop. The most characteristic ischemic symptoms consist of postprandial pain, with resultant fear of eating and weight loss. When epigastric bruit is included, these are the so-called classical triad of CSS. In most patients

with CSS, this triad is incomplete. The true incidence of CSS is currently unclear, but is rare compared to CSD due to abundant collateral circulation.

Two important developments occurred in the last decade. Firstly, validation of the gastric exercise tonometry, which is currently the only clinically available and validated diagnostic test to ascertain the presence of splanchnic ischemia[3,4]. Using an ischemia-specific test it should be possible (1) to identify patients with symptomatic vessel stenoses, or CSS, which can be treated, and (2) to make this diagnosis in time and thus prevent the disaster of acute intestinal infarction. Secondly, the increasing evidence that one vessel CSD may cause splanchnic ischemia resulting in one vessel CSS, and can be successfully treated with appropriate selection procedures[5]. An important difference in presentation, treatment and outcome has been shown to exist between single and multi-vessel disease[6]. In the latter group, the clinical presentation is often less typical, with diarrhea, unexplained gastric ulcers, or dyspepsia-like symptoms. These insights stem mainly from our work with tonometry.

An entirely different entity consists of patients suffering from splanchnic ischemia without splanchnic stenoses; the so-called non-occlusive mesenteric ischemia (NOMI). It can be seen as a consequence of physiological adaptation mechanisms during low-flow states were blood is dispersed from the gastrointestinal region to more vital organs[7]. This situation is very common in intensive care and operative units, but can also be seen in outpatients. Treatment consists of aggressive fluid resuscitation and medication. However, bowel infarction can still occur.

In the last decade a change in imaging of the splanchnic vessels occurred. Duplex ultrasound, although operator dependent and suitable for 80% of patients, is still the first choice. Visceral angiography has increasingly been replaced by CT and MR-based angiographic reconstruction techniques. The clinically important advantages and disadvantages of these techniques will be discussed. Whichever technique is used, it leaves the clinician with only anatomical information. To decide whether a given stenosis has caused the symptoms, information on actual ischemia is required. This information can be obtained using tonometry, which has a proven accuracy of 80%-90%. Other tests including, serological iFABP, endothelial progenitor cell measurement, or MR angiography (MRA)-based saturation measurements, may serve that purpose in the near future.

Treatment options have changed considerably over the last decade. Apart from the classical transabdominal vascular reconstructive surgery techniques, minimally invasive endoscopic treatment of the celiac axis compression syndrome, endovascular antegrade stenting, or laparotomy-assisted retrograde endovascular recanalization and stenting have broadened our therapeutic "armory" considerably. The main patient characteristics to guide therapy choice, which include anatomical considerations, as well as body weight, co-morbidity and severity of ischemia, will be discussed.

EPIDEMIOLOGY

The prevalence of CSD is not insignificant, and rises with increasing age. In a 30-year-old angiographic study of 713 patients, 5% of the splanchnic arteries were occluded and in 70% of these occlusions the IMA was involved[8]. In a retrospective study including 980 patients with a mean age of 68 years who underwent angiography for various indications, 8% had significant stenoses of at least one splanchnic artery[9]. In a screening study with duplex ultrasonography in 553 healthy elderly subjects with a mean age of 84 years, stenoses in the celiac artery (CA) or superior mesenteric artery (SMA) were found in 18%[10]. In patients with atherosclerotic disorders of aorta, iliac and femoral vessels the incidence ranged from 25% to 40%[11,12].

A minority of patients with CSD will develop CSS or acute splanchnic syndrome (ASS). A follow-up of the study in elderly subjects in whom duplex had shown CSD, revealed no CSD-related mortality after 6 years of follow-up[13]. This risk is increased in subjects with 2 and 3 vessel CSD. In the study by Thomas *et al* 4.5% of patients with three-vessel CSD developed CSS and another 1.5% died of ASS after a follow-up of an average of 2.6 years[9]. In the Detroit experience, of the 23 patients with severe acute intestinal ischemia studied between 1963 and 2000, 12 (52%) patients had undetected CSS symptoms well before presentation[14].

ANATOMY AND (PATHO)-PHYSIOLOGY

Anatomy

Three major arteries supply blood to the stomach, small intestine and colon. The first branch, the celiac artery (CA) supplies the stomach, proximal duodenum, liver and spleen. The second, the superior mesenteric artery (SMA) supplies the distal duodenum, small intestine and proximal colon. The third branch supplies the distal colon and the rectum. There is an abundance of collateral vessels to protect the gastrointestinal tract from ischemia. Branches of these arteries enter the serosa of the gut on the mesenteric side and form a vascular plexus around the gut. After penetration of the bowel wall, a dense submucosal plexus is formed. From this plexus, arterioles penetrate the muscularis mucosa to the superficial mucosal layers. At the mucosal tip they branch into an intense capillary network of capillaries and venules. Each villus has a single, central arteriole. This arteriole travels to the tip of the villus, then splits into a network of capillaries, which form a central venule at the base of the villus. This is why countercurrent exchange can take place[15]. The tip of the villus is quite susceptible to ischemia[16].

Blood flow

Under normal conditions, approximately 20% of the cardiac output goes through the splanchnic vessels. This splanchnic blood flow doubles after a meal to approximately 2000 mL/min. Blood draining from the bowel enters the splanchnic veins and finally drains into

the portal vein. The liver, therefore, receives its blood supply from two sources: venous blood from the portal vein and arterial blood from the hepatic artery, which branches from the CA in 75% and from the SMA in remaining 25%. This dual blood supply renders the liver relatively protected against ischemia. When the blood flow to the bowel decreases below a certain level (the critical O2 delivery level), the cells will switch to anaerobic glycolysis, resulting in lactate production[17]. In the gastrointestinal system this occurs when blood flow is reduced below 50% of the basal rate[18,19]. In most cases of splanchnic ischemia, the arterial lactate levels will remain normal despite increased lactate production by the gut. The reason for this discrepancy is the large lactate metabolizing capacity of the liver. Thus, systemic lactic acidosis is a late phenomenon in these patients, indicating severe transmural ischemia and probably liver involvement as well.

The regulation of the splanchnic blood flow involves both vasoconstrictive and vasodilating substances. The main vasoconstricting substances are the catecholamines and endothelin, especially endothelin-1[20,21]. The main splanchnic vasodilators are nitric oxide (NO) and prostaglandins. It is assumed that part of the gastrointestinal toxicity of NSAIDs can be attributed to vasoconstriction because of reduced mucosal prosta-glandin concentration[22].

During low-flow states, splanchnic vasoconstriction is an early and profound phenomenon[23], which may lead to blood flow reduction below the 50% threshold. Splanchnic ischemia develops well before systemic hemodynamic instability arises[24]. This splanchnic vasoconstriction may be triggered by shock states, including hemorrhage, sepsis, dehydration or cardiac failure, from vasoactive medications, nicotine and cocaine abuse, or even in strenuous exercise[19,25-27] or severe psychological stress[28]. This combination of ischemia despite normal vessel anatomy, has given rise to the term non-occlusive mesenteric ischemia (NOMI).

Ischemic and reperfusion damage

After the onset of ischemia, an ischemic and reperfusion phase can be distinguished. When this ischemia lasts for less than 6-8 h all processes are reversible; thereafter, transmural gangrene may be the result of completely interrupted blood flow. The ischemic phase starts when the energy-containing ATP is depleted due to lack of oxygen, leading to disruptions of the tight junctions. Also, membrane-bound enzymatic pumps stop functioning, leading to inflow of luminal electrolytes and water into epithelial cells resulting in cell death. Both effects lead to reduced intestinal epithelial barrier function, with bacteria and other luminal contents entering the blood stream[29]. At the same time, the mucosal enzyme xanthine dehydrogenase is converted to xanthine oxidase (XO), which at this stage is harmless. These early effects of the ischemic phase alone are localized and can remain clinically undetected for many hours. The reperfusion phase starts when oxygen-enriched blood re-enters the ischemic tissue. This reperfusion may begin after partial dissolution of an embolus or thrombus or after revascularization. This oxygen is transformed into reactive oxygen species (ROS) by the abundantly present XO. ROS are toxic to proteins and DNA[30], and diffuse into tissues, leading to intensification and spreading of the damaged area. This so-called ischemia-reperfusion cascade initiates an inflammatory and thrombotic response in the submucosal layer of the villus. In the future, antagonists of leukocyte vessel wall adhesions, an early event in the ischemia-reperfusion cascade, could attenuate these inflammatory and thrombotic responses[31]. Successful restoration of splanchnic blood flow, containing toxic products, from the ischemic area into the systemic circulation might trigger multiple organ failure.

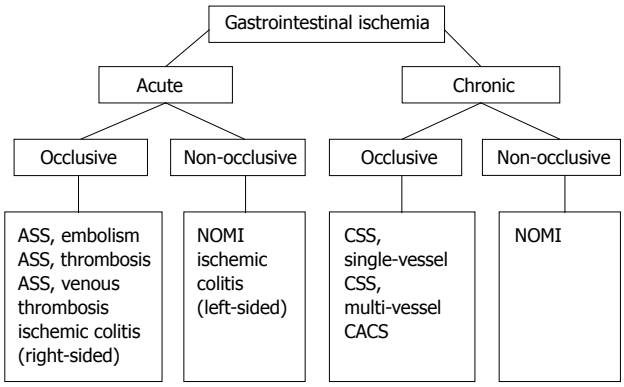

Figure 1 Classification of splanchnic, or gastrointestinal ischemia. ASS: Acute splanchnic syndrome; CSS: Chronic splanchnic syndrome; CACS, Celiac artery compression syndrome; NOMI: Non-occlusive mesenteric ischemia.

CLINICAL PRESENTATION

The naming of gastrointestinal ischemic syndromes is often confusing and requires a brief introduction. We will divide the different syndromes based on duration of complaints and vessel abnormalities (Figure 1). Acute splanchnic syndrome (ASS; synonym: acute mesenteric ischemia, acute bowel infarction) is characterized by a sudden onset of abdominal pain due to interrupted splanchnic circulation. It consists of occlusive disorders: acute splanchnic emboli, venous thromboses and end-stage arterial thrombotic occlusions, and the non-occlusive disorder, NOMI. Chronic splanchnic syndrome (CSS) is defined by a combination of chronic splanchnic disease (CSD) with ischemic symptoms. Celiac artery compression syndrome (CACS) is defined by the combination of eccentric celiac artery compression by the arcuate ligament of the diaphragm and chronic abdominal symptoms caused by ischemia. NOMI may be diagnosed with chronic or remittent splanchnic hypoperfusion, for example in heart failure[32] or in dialysis patients[33]. Finally, ischemic colitis is a separate entity and will be discussed separately.

Acute splanchnic syndrome

Acute splanchnic ischemia can result from arterial thrombosis, acute embolism, venous thrombosis or non-occlusive ischemia[34-39]. Most often the superior mesenteric

artery is involved. Clinically, it is recognized by an acute onset of abdominal pain, which might be accompanied by nausea, vomiting and hypotension. On physical examination and laboratory testing there are usually minimal abnormalities at first[40]. If left untreated, the pain often disappears. Without restoration of blood flow and depending on the collateral circulation, a full blown peritonitis follows within hours or days, with translocation of bacteria and SIRS, or systemic inflammatory response syndrome, and multiple organ failure. Mortality is high, ranging from 32%-80% depending on the etiology. In the last four decades a reduced mortality rate was observed for venous thrombosis and arterial embolism (now 32% and 51%), while the mortality of NOMI and arterial thrombosis remained unchanged at 73% and 77%[39]. Therefore, the most important factors for improvement of survival should be a high index suspicion, a proper diagnosis of CSS before ASS develops and an immediate restoration of blood flow.

Chronic splanchnic syndrome

Chronic splanchnic syndrome (CSS), a synonym for chronic mesenteric ischemia, gastrointestinal ischemia or intestinal angina, is a relatively rare disorder and may be under-diagnosed. After institution of a multidisciplinary approach team for the evaluation of insufficiently explained abdominal pain in the Medisch Spectrum Twente Hospital, the recognition of CSS increased from seven to 23 persons per million per year[41]. The major symptoms of CSS are outlined in Table 1. The most characteristic is postprandial pain, starting 15-30 min after a meal, and persisting for 1-3 h. Patients often report fear of eating, and take smaller meals, with less fat and proteins. Weight loss, the second characteristic finding in CSS, is almost always caused by reduced intake due to this fear of eating and not to malabsorption. Diarrhea, unexplained gastric ulcers or even gastroparesis can also be presenting symptoms.

This multidisciplinary team, with nationwide referrals, also found a differentiation between single- and multi-vessel disease[6]. Although the clinical presentation is quite similar, the course and outcome justifies separate discussion of both groups[42].

Single-vessel disease

The etiology of isolated stenoses of the splanchnic arteries, most often the celiac artery, is caused in most cases by splanchnic arteriosclerosis or external compression by the crux of the diaphragm[5]. Due to the presence of abundant collateral vessels, it was generally assumed that a single stenotic lesion rarely, if ever, causes complaints[43]. In 1972, Szilagyi *et al*[44] reviewed the entire literature on CA compression syndrome and found no proof of any abnormality of intestinal structure or function that could be attributed to this compression, nor proof that treatment had more than a placebo effect. However, several papers were published with good results for CA decompression operations[45-47]. These opinions were challenged recently by our group. We have shown that by using tonometry as a functional test, we could successfully distinguish patients that benefited from surgery from those who did not, and that the disappearance of symptoms after successful revascularization was associated with normalization of this functional test[5]. The prognosis of single-vessel CSS seems rather benign. In 50 patients with an isolated stenosis, no mortality and low post-operative morbidity were seen on follow-up, which contrasts sharply with multi-vessel CSS[6]. No difference in short-term outcome between patients with CACS or atherosclerotic lesions was observed. In our view, single-vessel CSS can be diagnosed when (1) there is a significant stenosis on duplex ultrasound or angiography (> 70%), (2) the clinical history fits CSS and (3) the functional test (gastric exercise tonometry) indicates splanchnic ischemia.

Table 1 Clinical picture in 107 CSS patients[6]

Patient characteristics in 107 CSS patients	
Age	Mean 55 years, range 18-85
Male:Female	26%:74%
Duration of symptoms	Mean 18 mo, range 3-192
Reported weight loss	78%
BMI	Mean 20.8 kg/m^2, range 12.0-33.2
BMI < 20 kg/m^2	35%
Weight loss (kg/mo)	Mean 1.3 kg/mo, range 0-8
Pain after meal	86%
Pain after exercise	43%
Abdominal buit	24%
Classical abdominal angina	22%
Cardiovascular history	40.20%
Nicotine use	45.80%

Multi-vessel disease

When 2 or 3 of the main splanchnic arteries have significant stenoses the ratio of CSS versus CSD increases to almost 90% in patients referred to our unit (unpublished data). Although the clinical presentation is in essence not very different from patients with single vessel disease, (postprandial pain and weight loss as the main symptoms) sometimes quite atypical presentations can be seen. Even experienced clinicians can miss an adapted lifestyle that masks a case of slowly progressive CSS. In multi-vessel CSS the clinical presentation can mimic simple dyspepsia with bloating and fullness, gastroparesis, unexplained diarrhea or simply lack of energy. When the disease progresses, the pain may be provoked by small triggers such as a simple drink, or even during rest. Abdominal vascular resting pain, persisting abdominal pain not related to a meal, are important prognostic indicators, and often indicate imminent or ongoing bowel infarction, or ASS. It should be remembered that the time to develop irreversible ischemic changes is about 6-8 h in end-stage 2- or 3-vessel CSS.

Ischemic colitis

There are two types of ischemic colitis: left-sided and right-sided ischemic colitis. Left-sided ischemic colitis usually presents with abrupt onset abdominal pain, followed by bloody diarrhea, which may persist for days

to weeks. It is often associated with low-flow states[48], coagulation disorders[49], cardiac abnormalities or after abdominal aortal surgery. Low-flow states may be induced by arrhythmias or cardiac dysfunction, drugs, dehydration or (aortic) surgery. Isolated right-sided ischemic colitis usually presents with abdominal pain, but rarely with bloody diarrhea[50]. Right-sided ischemic colitis is usually associated with SMA stenosis or occlusion. It should therefore be considered as part of CSS or ASS.

The late stages of ischemic colitis can be a clinical challenge, with clinical presentation and endoscopic findings mimicking both Crohn's disease and ulcerative colitis. In most cases isolated ischemic colitis will be transient, although persistent colitis, stricture formation and even gangrenous colitis have been seen to develop[48].

NOMI

NOMI has already been mentioned as cause of ASS in 20%-30% of patients. Most NOMI patients however, never develop ASS, and this condition is quite common due to the early splanchnic vasoconstriction with reduced circulating blood volume of any cause. Moreover, the bowel has limited capacity to preserve aerobic metabolism. NOMI is very common and widely recognized in intensive care and peri-operative medicine, where it is referred to as intramucosal acidosis or mucosal ischemia[7]. Here, the clinical signs of NOMI may range from abdominal tenderness, nausea, diarrhea, ulceration, bleeding and full thickness ischemia, and may lead to bowel wall necrosis and even death. In critically ill patients, this process can easily lead to translocation of bacteria and endotoxins, causing SIRS and multi organ failure[51].

We also distinguished a group of patients with 'abdominal migraine' characterized by symptoms compatible with splanchnic ischemia, abnormal functional tests (tonometry) indicating ischemia, splanchnic angiography without relevant pathology, and good response to vasodilators[4,52].

DIAGNOSTIC METHODS

Duplex ultrasound

Duplex-ultrasound is widely used as screening tool for detection of splanchnic stenosis. In experienced hands the CA and the SMA can be visualized in 80%-90% of patients. Proper visualization can be difficult because of the location behind the, often air-filled, stomach. First, vessel anatomy is established using the B-mode. This is followed by assessment of blood-flow pattern and velocity. The arterial blood-flow in the splanchnic vessels varies during the cardiac cycle. The normal CA has a biphasic signal. Retrograde flow in the common hepatic artery may indicate proximal CA stenosis or occlusion. The SMA normally has a triphasic signal. A biphasic signal in the SMA is normal after a meal or when the right, or rarely the common hepatic artery, comes from the SMA as an anatomic variant; it may indicate a proximal stenosis if it occurs in the fasting state. Blood-flow measurement is performed using a measurement angle of less than 60 degrees. A significant stenosis is characterized by areas of high velocity jets (small streaks of very high, sometimes turbulent flow) within the artery, and overall increased flow velocity. The widely accepted cut-off values, published by Moneta in 1993, are: for the CA a Peak Systolic Velocity (PSV) and End Diastolic Velocity (EDV) of 200 m/s and 55 m/s; and for the SMA, PSV and EDV of 275 and 45 m/s, respectively[53]. Using these threshold values, the sensitivity and specificity for stenoses > 70% were 89% and 44% for the inspiration CA, 89% and 62% for the expiration CA, 100% and 61% for the inspiration SMA, and 80% and 42% for the expiration SMA. One criticism of the "Moneta criteria" has been that he used a cohort from the general population with atherosclerotic disease, who did not necessarily suffer from chronic abdominal symptoms. In daily practice, duplex ultrasound is performed under fasting conditions. Some studies suggested measurement after test meals, because patients with ischemia had suppressed augmentation of blood-flow following a meal compared to subjects with normal vessels[54-58]. Until recently, post-test meal splanchnic duplex made no headway in daily practice. Duplex-derived flow velocities after splanchnic artery bypass grafting may be affected by graft diameter or type of reconstruction and are not equal to the preoperative criteria[59].

MRA

By using contrast, so-called contrast enhanced (ce)-MRA it is possible to identify splanchnic artery stenoses and even collaterals, for example Riolan's artery[60-62]. Surprisingly, we could identify only two studies that compared digital subtraction angiography (DSA) with MRA in 19[63] and 23 patients[61] with good correlation. In our own experience, with 25 patients in whom DSA and MRA were performed within 2 mo, the MRA had a 95% sensitivity and 90% specificity, compared to DSA as the "gold standard". We observed a significant inter and intra observer variation in grading of stenoses in 45% of the cases[64]. Although widely used, it can therefore not be considered a gold standard investigation for assessment of vessel anatomy. A potential advantage of MRA is its ability to measure actual flow through the splanchnic and portal circulation. The arterial flow is harder to measure than in veins, because of the smaller caliber and the pulsatile character of arterial flow[56]. However, a consistent relationship between flow in the arteries and veins was observed[65,66]. Several studies with healthy volunteers and patients have shown augmentation of flow after a meal and significant differences between patients with vessel stenoses and healthy volunteers[54,58]. These results may be promising for future use in diagnosing CSS.

CT angiography

With the introduction of the multi-slice CT scan, CT angiography of the abdominal arteries has become possible. There are several studies showing that CT angiography is an accurate way to image the splanchnic arteries, veins, and collaterals[67-70]. Surprisingly, studies focusing on CSD and comparing this technique to the gold

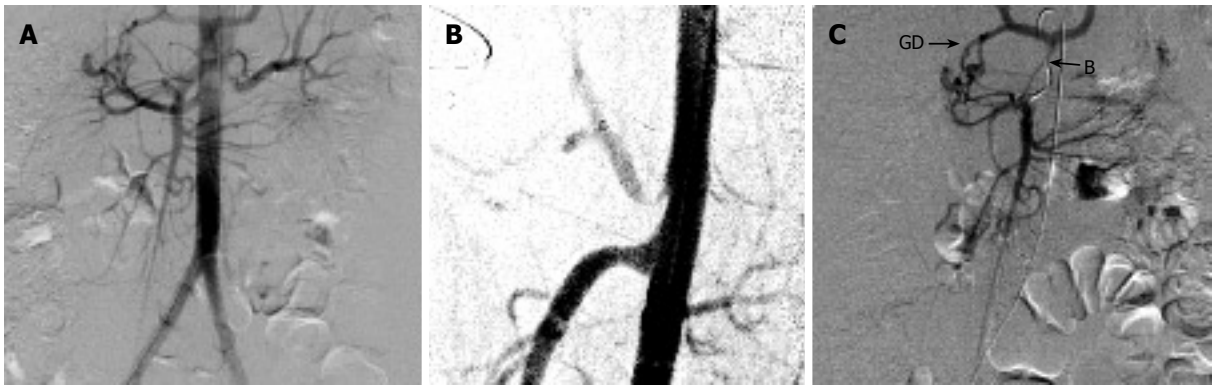

Figure 2 Collateral vessels: gastroduodenal (GD) artery and Buehlers artery (B). A: The gastroduodenal (GD) artery and Buehlers artery (B) are visible on non-selective aortography indicating stenosis of the origin of either the CA or SMA. The late filling of the CA points to a stenosis in its origin; B: Lateral aortography showing an asymmetrical stenosis of the CA; C: On selective cannulation of the SMA, both collaterals are more clearly visible.

standard (DSA) in a representative group of patients, are lacking to our knowledge. It is essential to use multi-slice scanners with slice thicknesses of 2 mm at most (preferably 1 mm) to allow accurate visualization of the arteries. With the state-of-the-art technology, CT-scanning in inspiration and expiration is possible and is a prerequisite when there is suspicion of celiac artery compression syndrome. The advantages of CT angiography are clear: in a patient with acute abdominal complaints it can show or exclude arterial and venous obstruction, bowel involvement (wall distention and thickening, presence or absence of contrast enhancement, pneumatics), as well as alternative diagnoses. Among these are perforations, pancreatitis, and abscesses. Similarly, in the setting of chronic unexplained postprandial pain, CT angiography may also show alternative diagnoses. In our experience, these include pancreatitis, pancreatic cancer, and retroperitoneal tumors. Adding the advantages of minimal invasiveness and lower costs, CT angiography can be a serious competition for conventional angiography[67,69,71,72].

Angiography

Intra-arterial digital subtraction angiography (DSA) of the splanchnic vessels can be used to perform endovascular therapeutic procedures in the same session, including infusion of papaverine and angioplasty or stenting of stenoses. The combination of high diagnostic accuracy and the possibility for intervention makes angiography the procedure of choice in patients suspected of symptomatic splanchnic stenoses, especially with imminent or ongoing infarction. In acute splanchnic infarction, angiography serves as guideline for endovascular or operative revascularization.

A state-of-the art visceral angiography involves three steps: (1) a non-selective anterior-posterior abdominal aortic angiography. When collaterals show in this stage, they indicate significant splanchnic artery stenosis and are considered pathological (Figure 2A and B); (2) a lateral aortography during maximal inspiration and expiration, for detection of external compression of the CA and/or, rarely, the SMA; and (3) selective angiography of all three splanchnic vessels to obtain a detailed view of the vascular anatomy, stenoses and anatomical variations[42]. Although CT and MR angiography are gaining ground as the principal investigative tools for splanchnic vessel anatomy, detailed angiographic information of anatomy, stenosis, collaterals and anatomical variations is, in our view, essential in the preparation of an optimal revascularization strategy.

Endoscopy

Although almost all patients with CSS underwent upper GI endoscopy during the work-up of their complaints, abnormalities were rarely noted. Reports on gastroparesis and gastric gangrene have been published, but are also rare. In our experience, 7% of patients with CSS presented with unexplained gastroduodenal ulcers (Helicobacter negative, no NSAID-use). In colonic ischemia endoscopy is the mainstay of diagnosis. The typical picture consists of superficial ulceration, mucosal friability, edema, and patchy areas of either bleached or cyanotic mucosa[73,74]. Colonic ischemia of longer duration may mimic ulcerative colitis or even Crohn's disease. Some papers have focused on endoluminal light spectroscopy oximetry. With this technique, mucosal hemoglobin oxygen saturation can be measured[75-80]. In a recent study it was shown that mucosal saturations are low in patients with chronic splanchnic ischemia, compared to healthy subjects. After successful treatment in these patients, mucosal oxygen saturations increased substantially[76]. There are a several potential limitations to this technique. Firstly, ischemia is patchy in nature, and can therefore be missed. Secondly, ischemia might be present in parts of the small bowel that are difficult to reach endoscopically. Thirdly, ischemia might only be present in a situation of increased oxygen demand (after a meal, or during exercise), especially earlier in the course of the disease.

Tonometry

Tonometry of the gastrointestinal tract has the unique potential to the detect ischemia, irrespective of flow or metabolism. Tonometry is based on a general physiological principle that during ischemia, anaerobic metabolism leads to increased production of acids, which are buffered locally by bicarbonate ions, leading to increased carbon dioxide tension (PCO_2) in the tissue. This relation between

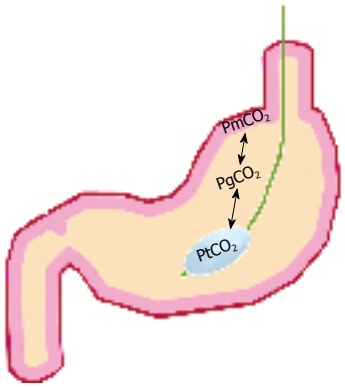

Figure 3 Tonometer balloon placed in the stomach nasogastrically. CO_2 diffuses rapidly over different membranes, therefore the tonometer PCO_2 ($PtCO_2$) will be in equilibrium with gastric luminal PCO_2 ($PgCO_2$) and mucosal PCO_2 ($PmCO_2$). The PCO_2 can be measured from the catheter either from injected saline using blood gas analyzers or by connection to a semi-automated Tonocap device. The underlying physiological principle is that ischemia is always associated with PCO_2 increase. Therefore, focal measurement of ischemia is possible for long periods *via* a minimally invasive technique.

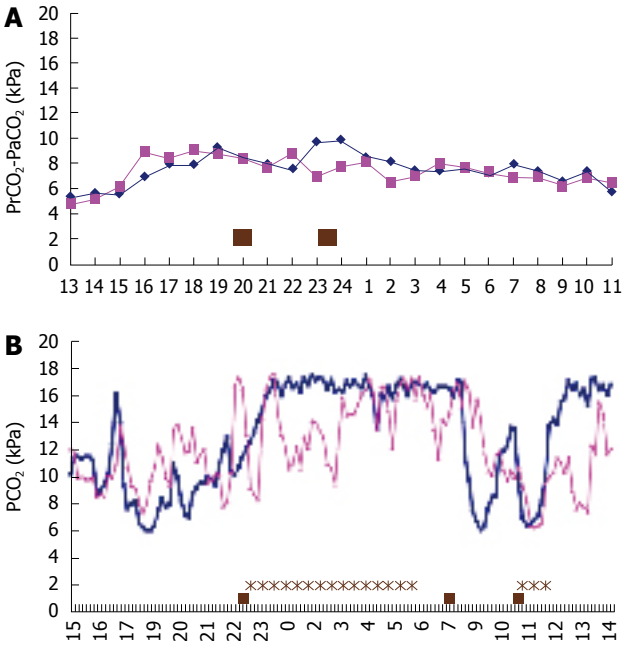

Figure 4 Imminent ASS and normal gastric and jejunal PCO_2 pattern. A: Normal 24 h PCO_2 pattern in the stomach (squares) and jejunum (diamonds) with variation in PCO_2, but no peaks above 11 kPa following meals; B: Imminent bowel infarction in a patient with severe 3 vessel CSS. After her evening meal she had pain for almost 6 h, and extreme ischemia with PCO_2 > 16 kPa for 7 h. She was treated with endovascular stent placement the day after this measurement, with immediate relief of complaints. She is still doing well, over 3 years later.

ischemia and increased PCO_2 has been observed in all ischemic models and animals studied. The most specific marker of ischemia is an increased difference between luminal and arterial CO2, the PCO_2 gradient, which is barely influenced by other systemic factors, including hyper- or hypoventilation. The luminal PCO2 can be measured conveniently using a nasogastric tonometry catheter and air tonometry (Figure 3). The unique property of tonometry in measuring ischemia *per se*[3] sets it apart from all other diagnostic methods. Indeed, when blood flow is gradually reduced, the PCO2 gradient remains normal until the blood flow decreases to < 50% of the basal flow and then increases sharply[18,19].

In patients with suspected chronic ischemia, gastric tonometry has been used initially using a test meal with variable, but overall disappointing, results[81-83]. The main methodological problems involved buffering effects by gastric acid and dilution effects of the ingested test meals[84]. We therefore developed a tonometric test involving 10 min of submaximal exercise, in order to provoke GI ischemia[19]. The diagnostic accuracy of the gastric exercise tonometry test (GET) was evaluated in a cohort of patients referred for suspected CSS. GET had a 78% sensitivity and 92% specificity for ischemia detection[4]. We have used GET to guide treatment in patients with single vessel stenoses. The main finding in this study was the tight relationship between normalization of GET and disappearance of symptoms after anatomically successful revascularization[5]. We also re-examined the potential use of a 24-h tonometry test, including test meals, with standardization of the test circumstances, including potent acid suppression and standard test meals[85]. In a pilot study in 33 patients referred for suspected CSS, the 24 h tonometry showed promising results, with a sensitivity of 76% and a specificity of 94%, comparable to those of exercise testing[86]. We are now analyzing a study comparing GET and 24-h tonometry. The preliminary data suggest that 24-h tonometry permits accurate measurement of postprandial and fasting PCO_2 levels; following meals, gastric and small bowel PCO_2 gradients may physiologically increase up to 10 kPa. During ischemia, gradients exceed 11 kPa (60 mmHg)[87]. Also, prolonged PCO2 increases for several hours (up to 7 h in one subject, Figure 4), especially in combination with abdominal pain during fasting, indicate imminent infarction, and thereby provide invaluable extra information.

Serological markers

Currently, there is no reliable marker to diagnose gastrointestinal ischemia. Studies have been performed using several markers, including (L and D)-lactate, LDH, D-dimer; however, none of these was proven to be sensitive or specific. In contrast, various animal models have successfully used markers like D-lactate and i-FABP (intestinal Fatty Acid Binding Protein) as an early marker of intestinal ischemia. This enzyme is present in the mature enterocytes of the small intestine, in the highest concentration at the villi[88,89], the region most susceptible to ischemia, and is released early after an ischemic insult. Therefore it seems a good candidate marker for early ischemia detection[90]. There are a few patient studies indicating its potential as marker for ASS[89,91], but also during pancreatitis[92] or inflammatory bowel disease[93]. We performed a pilot study comparing tonometric responses to a test meal and indeed found increased i-FABP in these subjects[94]. More studies are needed before the role of this and other promising plasma markers can be established.

WORK-UP AND TREATMENT

In the work-up of patients in whom splanchnic ischemia is suspected four questions should be addressed: (1) is the history compatible with splanchnic ischemia, (2) which of the three vessels are narrowed, to what degree and are pathological collaterals present, (3) is there (functional) evidence of actual ischemia, and (4) is the impairment of the splanchnic blood flow in the short-term threatening for the bowel.

Endovascular techniques have emerged allowing for stent placement in CA and SMA in most patients. The choice is between dilation or stent placement. Dilation alone has a low short-term success rate, and we currently use it only as diagnostic tool to distinguish between CSS and CSD. Although some vessels can be treated *via* the femoral artery; the sharp downward angulation (60 degrees) of the AMS and CA often necessitates brachial artery cannulation in many cases. In our center, both techniques are often combined, using the femoral catheter as a guide for the stent placed *via* the brachial catheter. Compared to operative revascularization, the main disadvantage of stent placement is the shorter long-term patency. The latter was shown in three recent studies, of which two compared endovascular and open repair. Atkins *et al* reported in a cohort of 80 patients with CSS primary patency at 1 year of 58% after endovascular and 90% after open repair and a primary assisted patency of 65% *vs* 96% respectively[95]. Bieble *et al* reported that in a cohort of 49 patients with CSS, 75% after endovascular and 89% after open repair were symptom free after 2 years[96]. The main difference in this study was the restenosis rate of 8% after open versus 25% after endovascular treated patients, with lower complication rates in the latter. Sarac *et al*[97] reported a primary, primary assisted and secondary patency of 65%, 97% and 99% in a cohort of 87 endovascular treated splanchnic arteries. The low short-term morbidity makes it an excellent choice in patients with limited life expectancy or those too weak or underweight for operative revascularization.

A variety of surgical techniques have been advocated for open repair of the splanchnic arteries, including reimplantation, transarterial and transaortic endarterectomy, antegrade and retrograde aortovisceral bypass using vein or arterial autograft bypasses and prosthetic bypass, with early success rates between 91% and 96% and late success rates between 80% and 90%[98]. The choice of technique is usually based on the preference and experience of the surgeon. However, the majority of centers with wide experience believe that antegrade autogenous revascularization techniques of both the CA and the SMA in selected cases offers the best long-term results. The disadvantage of major aortic surgery is the not inconsiderable burden for the patient. In general, we prefer antegrade two-vessel reconstruction for young patients with CSS and a body mass index above 19.5 kg/m^2, and endovascular or minimal invasive retrograde single or multi-vessel reconstructions for patients with relevant comorbidity or reduced life expectancy. Also endovascular repair could act as bridge to open repair after full recovery and weight gain in selected young patients with end stage CSS.

Acute splanchnic syndrome

The diagnosis of ASS begins with a high index of suspicion. Any patient with acute onset of abdominal pain that remains unexplained after proper investigation for two hours should be suspected to have ASS. An urgent investigation of vessel patency should be ordered. The choice is between an acute angiography and a CT scan. Simultaneously with the CT scan or DSA, the volume status should be aggressively restored to counterbalance the splanchnic vasoconstriction, which is almost always present in these patients. All necrotic bowel should be removed and blood flow restored as soon as possible. The latter will involve intravenous heparin in venous ASS, revascularization or embolectomy in arterial ASS, and in selected cases, intra-arterial vasodilation in ASS-NOMI[73]. In arterial ASS, the choice of revascularization, and whether it should be done before or after bowel resection, depends on local expertise. Bowel vitality can be hard to assess initially, therefore second- and third look operations to ascertain bowel vitality are often advised and seem prudent. It has been shown that aggressive treatment might be responsible for the modest improvement in outcome of ASS[39]. In cases of limited extent of severe bowel ischemia we advise immediate retrograde endovascular revascularization[99,100] and resection of the ischemic bowel to diminish the detrimental cascade of ischemia-reperfusion resulting in multi organ failure and high mortality.

Acute ischemic colitis

Isolated acute left-sided ischemia can usually be treated conservatively, as it is almost always non-occlusive in nature. Right-sided ischemic colitis should be considered as ASS and treated accordingly. Patients with left-sided ischemic colitis should be treated with intravenous fluid and bowel rest. Broad spectrum antibiotics are advised, which might reduce bowel damage[48,101], but there is no evidence to back this up. Left-sided ischemic colitis subsides in 2 wk[48] in most patients. About 20% of patients with acute ischemic colitis ultimately need surgery, either because the ischemic colitis persists or complications occur. A non-responsive left-sided ischemic colitis can manifest as ongoing sepsis refractory to medical treatment, persistent diarrhea, bleeding, or protein-losing enteropathy for more than 14 d. In some patients progressive peritonitis or gangrene of the colon develops, with a mortality rate of 30%-60%[48,102].

CHRONIC SPLANCHNIC SYNDROME

Single-vessel CSS and CACS

Patient selection is crucial in these patients. When single-vessel CSS is diagnosed by history, vessel anatomy and functional tests, treatment may help to relieve the symptoms. The prognosis quod vitam is good; therefore

treatment is aimed at relief of symptoms only. Some patients prefer conservative measures including small meals and proton pump inhibitors. When a revascularization is indicated, the choice of technique depends on vessel abnormalities as well as local experience.

In CACS patients primary stent placement is not an option because the repeated force by the diaphragm with each respiration will fracture the stent in the short-term. Different techniques are currently used to release the CA from compression by the diaphragm's crux. One potential complication is the development of reflux disease[5], which is related to the damage to the crux, which also plays an important role in the physiological anti-reflux barrier. Recently, we have performed the release by an endoscopic retroperitoneal technique with equally good results compared to the open approach in the short-term[103]. The problem of reflux seems to be reduced, although more studies with longer follow-up times are needed.

Multi-vessel CSS

Most patients with abdominal symptoms and multi-vessel stenoses have, in our experience, CSS. The risk of developing ASS is considerable[6], therefore the treatment goal is aimed at symptom relief as well as prevention of ASS. There are no prospective studies on the conservative treatment of CSS, but advice on diet and lifestyle have been described. Most patients have already changed their eating pattern, with smaller and more frequent meals that contain less fat and protein. It should be strongly advised to stop smoking because it causes strong splanchnic vasoconstriction. The use of proton pump inhibition is not evidence based, however, it makes sense as these drugs reduce the secretion of gastric acid, and thus gastric metabolic demand, while increasing the gastric blood flow[104]. Atherosclerosis is a generalized disorder; therefore the usual measures should be initiated including treatment of hypertension, hyperlipidemia, and diabetes.

Most multi-vessel CSS patients have an indication for revascularization. Whether patients with multi-vessel (asymptomatic) CSD should be treated to prevent ASS is uncertain. It may be considered in young patients in good health, but firm evidence is lacking. The choice of revascularization in multi-vessel CSS again depends on anatomy, experience, and comorbidity as discussed before.

NOMI

Chronic splanchnic ischemia due to NOMI comes in two different patient groups. The first group has severe underlying medical conditions, with reduced effective circulating volume and splanchnic vasoconstriction and ischemia. These include dialysis patients[33] and chronic heart failure[32] patients. Treatment is difficult because the treatment of their underlying disease requires reduction of intravascular volume, which may worsen their abdominal complaints. In our experience the use of nitrates, ketanserin and alpha-inhibitors may have a positive effect on the abdominal symptoms, whereas calcium channel blockers seemed to worsen these. A second group we encountered are patients with a clinical presentation similar to CSS, with normal microvasculature but functional tests indicating ischemia. As discussed earlier, in some of these we have observed vascular spasms during angiography, with onset of pain within minutes thereafter[4]. In a pilot study, we treated them with vasodilators, nitrates, ketanserin or nicorandil. Over 50% of patients show a reduction of abdominal pain of at least 50% on a visual analog scale, which is sustained for years in most cases[52]. Further studies are needed to assess the prevalence, precise mechanism and the best treatment options of this disorder.

Post-intervention care

After revascularization, severe reperfusion injury can occur. The exact risk factors for its development are unknown. In our experience it is more common in patients with serious and long-standing multi-vessel disease. The following pattern in reperfusion damage after revascularization is typical. The first 1-2 d after revascularization the patient has good clinical recovery. Most could start eating again without pain or special discomfort. After 2-3 d symptoms develop, in hours to days, consisting of nausea, abdominal pain, similar or even worse than before treatment, diarrhea and in extreme cases, protein-losing enteropathy with very low serum albumin levels. Massive ascites may develop during reperfusion.

It is crucial to distinguish reperfusion injury from vessel occlusion; therefore vessel patency has to be ascertained with CTA or DSA. This bowel reperfusion syndrome can persist for days to weeks. We therefore treat these patients with parenteral nutrition, intravenous fluids, and proton pump inhibitors. The end of the reperfusion syndrome is usually heralded by increased appetite, reduced pain and reduced diarrhea. Patients can restart oral intake, be taken off parenteral nutrition and generally have uneventful recovery within weeks thereafter. No long-term complications have been observed in these patients.

CONCLUSION

Splanchnic ischemia has developed into a broad spectrum of diseases. These are characterized by onset, vessel anatomy, and presence of ischemia. Each syndrome has different characteristics, outcome, and treatment options, therefore a state-of-the art vessel anatomy assessment and accurate functional test are crucial. Tonometry is the only validated test assessing the adequacy of the splanchnic blood-flow and consequently is crucial in proper patient selection. Treatment options, including noninvasive, minimal invasive and classical open vascular reconstructive techniques, are wide and require a multi-disciplinary team-approach for proper selection and follow-up.

Abstract

AIM: To study the growth inhibitory and apoptotic effects of *Scutellaria barbata* D.Don (*S. barbata*) and to determine the underlying mechanism of its antitumor activity in mouse liver cancer cell line H22.

METHODS: Proliferation of H22 cells was examined by MTT assay. Cellular morphology of PC-2 cells was observed under fluorescence microscope and transmission electron microscope (EM). Mitochondrial transmembrane potential was determined under laser scanning confocal microscope (LSCM) with rhodamine 123 staining. Flow cytometry was performed to analyze the cell cycle of H22 cells with propidium iodide staining. Protein level of cytochrome C and caspase-3 was measured by semi-quantitive RT-PCR and Western blot analysis. Activity of caspase-3 enzyme was measured by spectrofluorometry.

RESULTS: MTT assay showed that extracts from *S. barbata* (ESB) could inhibit the proliferation of H22 cells in a time-dependent manner. Among the various phases of cell cycle, the percentage of cells in S phase was significantly decreased, while the percentage of cells in G_1 phase was increased. Flow cytometry assay also showed that ESB had a positive effect on apoptosis. Typical apoptotic morphologies such as condensation and fragmentation of nuclei and blebbing membrane of apoptotic cells could be observed under transmission electron microscope and fluorescence microscope. To further investige the molecular mechanism behind ESB-induced apoptosis, ESB-treated cells rapidly lost their mitochondrial transmembrane potential, released mitochondrial cytochrome C into cytosol, and induced caspase-3 activity in a dose-dependent manner.

CONCLUSION: ESB can effectively inhibit the proliferation and induce apoptosis of H22 cells involving loss of mitochondrial transmembrane potential, release of cytochrome C, and activation of caspase-3.

INTRODUCTION

Scutellaria barbata D.Don (*S. barbata*) is a perennial herb, also known as Ban-Zhi-Lian (barbat sskullcap) in traditional Chinese medicine. It is mainly distributed in southern China and has been used as an antitumor agent for lung cancer, digestive system cancer, hepatoma,

breast cancer, and chorioepithelioma as well as an anti-inflammatory agent and a diuretic in China and Korea[1-9]. Extracts from *S. barbata* (ESB) have *in vitro* growth inhibitory effects on a number of human cancers including leukemia, colon cancer, hepatoma and skin cancer[4-10]. However, its antitumor mechanism still remains unclear.

It was reported that many Chinese herbs have anticancer properties and induce apoptosis[11]. Three apoptotic pathways have been addressed, including the mitochondrial pathway[12,13], death receptor pathway[14], and endoplasmic reticulum stress-mediated apoptosis pathway[15]. The mitochondrial pathway initiates apoptosis in most physiological and pathological situations. Permeabilization outside mitochondrial membrane plays the most important role in mitochondrial apoptosis. In the mitochondria-initiated pathway, mitochondria undergoing permeability transition release apoptogenic proteins such as cytochrome C or apoptosis-inducing factor from the mitochondrial intermembrane space into the cytosol[16]. Released cytochrome C can activate caspase-9, and activated caspase-9 in turn cleaves and activates executioner caspase-3. After caspase-3 activation, some specific substrates for caspase-3 such as poly (ADP-ribose) and polymerase (PARP) are cleaved, and eventually lead to apoptosis[17].

In this study, *S. barbata* extract showed anti-tumor activity *in vitro* and could inhibit the growth of mouse H22 hepatoma cells by inhibiting cell apoptosis and cytotoxic effects, demonstrating that the extract from *S. barbata* can strongly inhibit cell proliferation and induce apoptosis of H22 cells through the mitochondrial dysfunction pathway.

MATERIALS AND METHODS

Reagents and animals

New bovine serum (Gibco, USA), RPMI-1640 medium(Gibco, USA), propidium iodide (PI) (Sigma, USA), dimethyl sulfoxide (DMSO), ribonuclease (RNase A), rhodanmin123 (Rh123), and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenytetrazolium bromide (MTT) were purchased from Sigma Chemical (St. Louis, MO). Mouse monoclonal antibodies against caspase-3 and cytochrome C were purchased from Santa Cruz Biotechnology, Inc. (Santa Cruz, USA). Apoptotic cell Hoechst 33258 detection kit was purchased from Nanjing Kai-ji Biotechnology Development Ltd (China), and fluorescence probes Rhodamine 123 was purchased from Sigma (USA). Male SD rats weighing 220-250 g were purchased from the Experiment Animal Center, Medical School of Xi'an Jiaotong University (China).

Preparation of S. barbata extract and drug containing serum

S. barbata crude extract (ESB) was purchased from Xi'an Zhongxin Biotechnology Development Ltd (China). One kilogram of *S. barbata* was extracted three times with water as previously described[18]. Final qualification was 10:1. More specifically, stems of SB were cut into small pieces, boiled in water for 2 h, put into a filtrate, and concentrated by spray drying until the specific density reached 1.15-1.18.

"Serum pharmacology" was used to study the *in vitro* pharmacological activity of herb medicine as previously described[19]. ESB-containing serum was prepared as previously described[18,20]. Twenty male SD rats were randomly divided into control group, high ESB dose group, medium ESB dose group, and low ESB dose group (n = 5). Rats in the high, medium and low ESB dose groups received intragastric ESB of 6, 3 and 1.5 g/d per kg of body weight. Rats in the control group received normal saline, twice a day for 3 d. Two hours after the last administration, blood was immediately obtained from the heart and kept at room temperature for 4 h. The serum was separated by centrifugation at 2400 r/min for 10 min, collected following twice of filtration with a 0.22 μm cellulose acetate membrane, calefied in 56℃ water for 30 min, and stored at -20℃ for use.

Cell lines and culture

Mouse H22 hepatoma cells, purchased from Shanghai Institute of Cell Biology, Chinese Academy of Sciences (Shanghai, China), were cultured in RPMI-1640 medium (Gibco, USA) supplemented with 10% fetal bovine serum (Gibco, USA), 1×10^5 U/L penicillin and 100 mg/L streptomycin in an incubator containing a humidified atmosphere with 50 mL CO_2 at 37℃. The cells were subcultured until reaching logarithmic growth phase. The viability of H22 cells, stained with trypan blue, was above 97%.

Cell viability assay

Cell viability was assessed by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) dye reduction assay (Sigma, USA). H22 cells were seeded at a concentration of 5×10^3 cells/well in a 96-well plate, and grown at 37℃ until adherence. At end of the treatment, 50 μg/10 μL of MTT was added and the cells were incubated for another 4 h. Two hundred μL of DMSO was added to each well after the supernatant was removed. After the plate was shaken for 10 min, cell viability was detected by measuring the absorbance at 490 nm wavelength using an enzyme-labeling instrument (EX-800 type) in quintuplicate.

Cell viability (%) = the absorbance of experimental group/the absorbance of blank control group × 100%.

Detection of morphological apoptosis

Staining of cells with uranyl acetate and lead citrate was performed to detect morphological changes. Briefly, adherent H22 cells were treated with ESB at a high dose for 48 h. The treated cells were digested with pancreatin and fixed in 3% glutaraldehyde precooled at 4℃ for 2 h. To make ultra-thin sections of copper, cells were washed with PBS, fixed in 1% osmic acid for an additional hour, dehydrated in acetone and embedded in epoxide resin. After stained with uranyl acetate and lead citrate, the

sections were examined under a Hitachi-800 transmission electron microscope as previously described[21].

Nuclear staining

H22 cells were harvested by centrifugation, washed with PBS and fixed in 1% glutaraldehyde for 1 h at room temperature. The fixed cells were washed with PBS, stained with 200 μmol/L Hoechst 33258 for 10 min. Changes in nuclei after stained with Hoechst 33258 were observed under a fluorescence microscope (Olympus, BX-60, Japan).

Cell cycle analysis

H22 cells were incubated at 5×10^5 cells/well in 6-well plates, treated with a homologous drug for 48 h. The detached and attached cells were harvested and fixed in 70% ice-cold ethanol at -20℃ overnight. After fixation, cells were washed with PBS, resuspended in 1 mL PBS containing 1 mg/mL RNase (Sigma) and 50 μg/mL PI (Sigma), and incubated at 37℃ for 30 min in the dark. Samples of 10 000 cells were then analyzed for DNA content by FACScan flow cytometry (Beckman, USA), and cell cycle phase distributions were analyzed with the CellQuest acquisition software(BD Biosciences).

Detection of mitochondrial membrane potential

Mitochondria transmembrane potential ($\Delta\psi m$) was detected under laser scanning confocal microscope(LSCM) with Rhodamine 123 (Rh123) staining as previously described[22]. About 1×10^6 cells were harvested by trypsinization, washed twice with PBS, and incubated with Rh123 at the final concentration of 1 μL/mL for 20 min at 37℃ in the dark, centrifuged at 1000 r/min for 5 min, washed twice with a medium, resuspended in the medium, cultured at 37℃ in an incubator containing 50 mL CO_2 for 60 min. Fluorescence intensity was determined at an excitation wavelength of 488 nm, emission wavelength of 530 nm under a laser scanning confocal microscope (Olympus, FluoView™ FV300, Japan). The fluorescence intensity of Rhodamine 123 in cells represents the mitochondrial membrane potential[23].

Western blot analysis

H22 cells (2.5×10^7) were collected by centrifugation at 2000 r/min for 10 min at 4℃, washed twice with cold PBS (pH 7.2), centrifuged at 2000 r/min for 10 min. Protein content was determined using a Bio-Rad protein assay reagent with bovine serum albumin as the standard. Total proteins (30 μg/lane) were separated by 15% SDS-PAGE gel electrophoresis, and transferred to a 0.45 μm PVDF membrane (Amersham Pharmacia Biotech). The blots were incubated with the desired primary antibody overnight at the following dilutions: caspase 3 (1:1000), cytochrome C (1:1500), and β-actin (1:1500). Primary antibodies were purchased from Santa Cruz Biotechnology, Inc. (Santa Cruz, CA, USA). Subsequently, the membrane was incubated with appropriate secondary antibodies for 1 h at room temperature. The immunoblots were analyzed by densitometry on a GelDoc 2000 system (Bio-Rad Laboratories Inc. USA) as previously described[17,24].

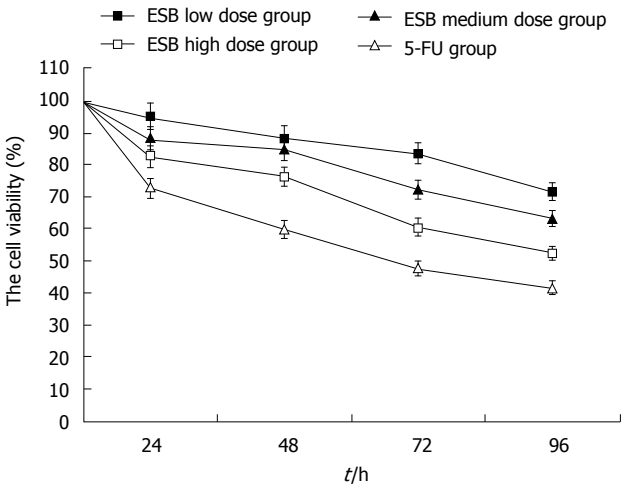

Figure 1 Inhibition of H22 cell proliferation by ESB. H22 cells were treated with different doses of ESB. The number of cells was determined at 0, 24, 48, 72, and 96 h, respectively. The viability of cells was detected by MTT assay. ANOVA analysis showed that the growth of H22 cells was inhibited by ESB in a dose- and time- dependent manner ($P < 0.05$).

Assay for caspase-3 activity

Caspase-3 activity was assayed using the caspase-3 activity assay kit (Nanjing Kai-ji, China) as previously described[25,26]. In brief, standard curve was plotted by detecting the absorbance of standard samples with terminal concentrations at each well, respectively. After 1 h incubation at room temperature, H22 cells were collected and lysed completely in a caspase assay buffer. The activity of caspase-3 was assayed in triplicate using a plate-reading luminometer (Turner Designs, Sunnyvale, CA) at the wavelength of 405 nm. Nkat was used to represent the activity measured[25].

Statistical analysis

All data were expressed as mean ± SD. Statistical analysis was performed with analysis of variance (ANOVA) using the statistical software SPSS 11.0. $P < 0.05$ was considered statistically significant.

RESULTS

Effect of ESB on proliferation of H22 cells

H22 cells were treated with different doses of ESB. The growth rate of H22 cells was evaluated after 0, 24, 48, 72, and 96 h, respectively. The cell viability of H22 cells in different ESB treatment groups was significantly higher than that in 5-FU treatment group (Figure 1). High and medium dose ESB inhibited the proliferation of H22 cells ($P < 0.05$), while low dose ESB could not obviously inhibit the proliferation of H22 cells ($P > 0.05$). MTT assay showed that high and medium dose ESB inhibited the proliferation of H22 cells *in vitro* in a time-dependent manner.

Morphological observation of apoptosis of H22 cells induced by ESB

High resolution transmission electron microscopy showed that normal H22 cells were round and regular in shape

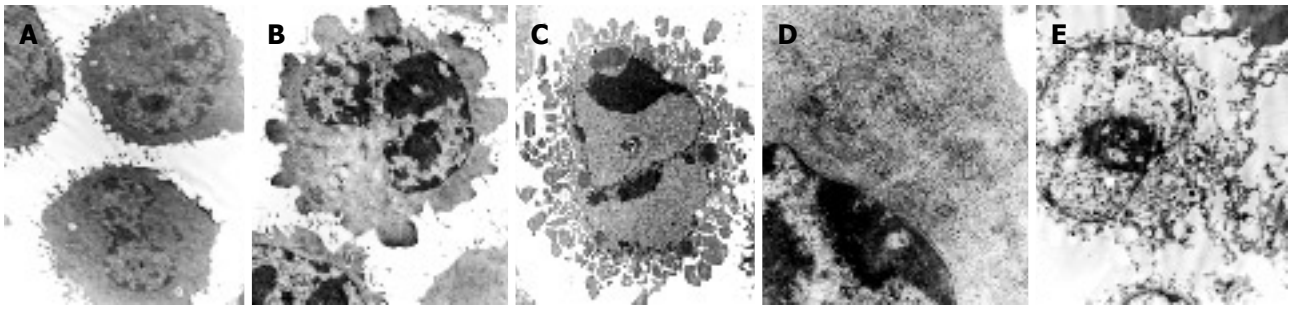

Figure 2 Morphological observation of H22 cells by EM after treatment. A: normal hepatoma H22 cells (5000 ×); B: karyopyknosis and chromatic agglutination in high ESB dose group (5000 ×); C: apoptotic body in high ESB dose group (5000 ×); D: chondriosome swelling in high ESB dose group (6000 ×); E: cellular swelling and necrosis in 5-FU group (5000 ×).

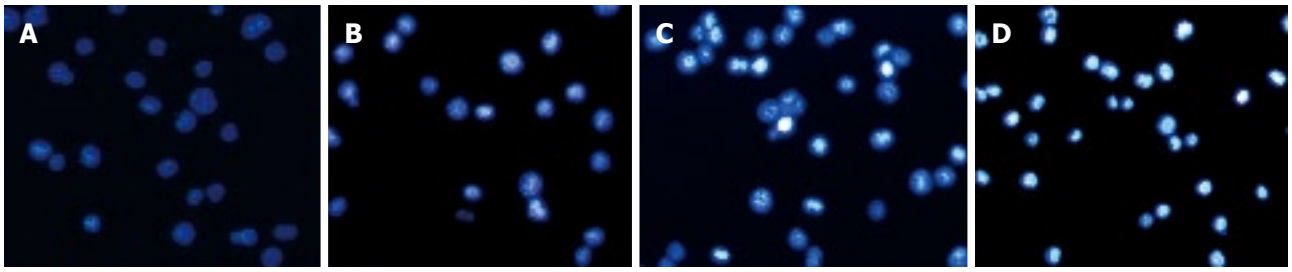

Figure 3 Cell apoptosis observed with Hoechst 33258 staining under a fluorescence microscope (× 200). After cells were treated with different doses of ESB for 48 h, Hoechst 33258 staining was used to observe apoptotic cells as described in MATERIALS AND METHODS. The number of apoptotic cells gradually increased in a dose-dependent manner with marked morphological changes found in cell apoptosis including condensation of chromatin and nuclear fragmentation. A: Control group; B: Low dose treated group; C: Medium dose treated group; D: High dose treated group.

with chromatin margination in few tumor cells (Figure 2A). After treatment with a high ESB dose for 48 h, a part of nuclear membrane domed outward with a sharp angle. The typical morphologies of apoptotic H22 cells such as chromatic agglutination and fragmentation of nuclei, chondriosome swelling, formation of apoptotic body, could be observed in high ESB dose group (Figure 2B-D), while in 5-FU group, cellular swelling and necrosis could be observed in many fields of vision.

Detection of apoptosis of H22 cells by Hoechst 33258 staining

After treatment with different doses of ESB for 48 h, H22 cells were stained with Hoechst 33258 and observed under a fluorescence microscope. The condensely stained chromatin of apoptotic cells was more bright than that of normal cells. The characteristics of apoptosis, such as nuclear shrinkage, DNA condensation and fragmentation, were found in ESB treatment group (Figure 3B-D), while no apoptosis occurred in blank control group (Figure 3A). The percentage of apoptotic cells in control group and low and high ESB dose groups was 3.36% ± 2.14%, 14.57% ± 4.28%, 43.15% ± 5.33%, 72.65% ± 6.52%, respectively. Furthermore, the number of apoptotic cells gradually increased in a dose-dependent manner.

Effect of ESB on cell cycle distribution by flow cytometry

The effects of ESB on cell cycles were analyzed by flow cytometry. The percentage of cells was significantly decreased at S phase and increased at G_1 phase in high ESB dose group.

Table 1 Effect of ESB on cell cycle and apoptosis of H22 cells by flow cytometry (mean ± SD)

Groups	*n*	G_0/G_1	S	G_2/ M	Apoptosis rate
Control	5	37.63 ± 2.12	32.73 ± 2.24	21.75 ± 1.52	0.51 ± 0.12
ESB low dose	5	39.35 ± 2.25	33.56 ± 3.12	21.20 ± 1.27	1.07 ± 0.15
ESB medium dose	5	45.91 ± 2.56[a]	30.65 ± 2.64	17.15 ± 1.34[a]	3.15 ± 0.27[a]
ESB high dose	5	56.05 ± 2.37[b]	21.33 ± 3.42[b]	12.30 ± 1.25[b]	7.83 ± 0.43[b]

Cell cycle distributions in control and ESB-treated cells were determined by PI staining and flow cytometric analysis. Results presented were representative of three independent experiments. [a]$P < 0.05$, [b]$P < 0.01$ *vs* control group.

The sub-G1 population indicated apoptotic-associated chromatin degradation. The ratio of cell apoptosis in blank control group, and low, medium, high ESB dose groups was 0.51%, 1.07%, 3.15%, 7.83%, respectively. There was significantly difference between the 4 groups ($P < 0.05$). These results suggest that high ESB dose can induce cell cycle arrest at G_0/G_1 phase and apoptosis in H22 cells (Table 1).

Effect of ESB on mitochondrial membrane potential

Mitochondria play an essential role in apoptosis. To assess whether ESB affects the function of mitochondria, mitochondrial membrane potential was detected under a laser scanning confocal microscope with Rh123 staining. The fluorescence intensity of Rhodamine123 in H22 cells of blank control group was the strongest (Figure 4).

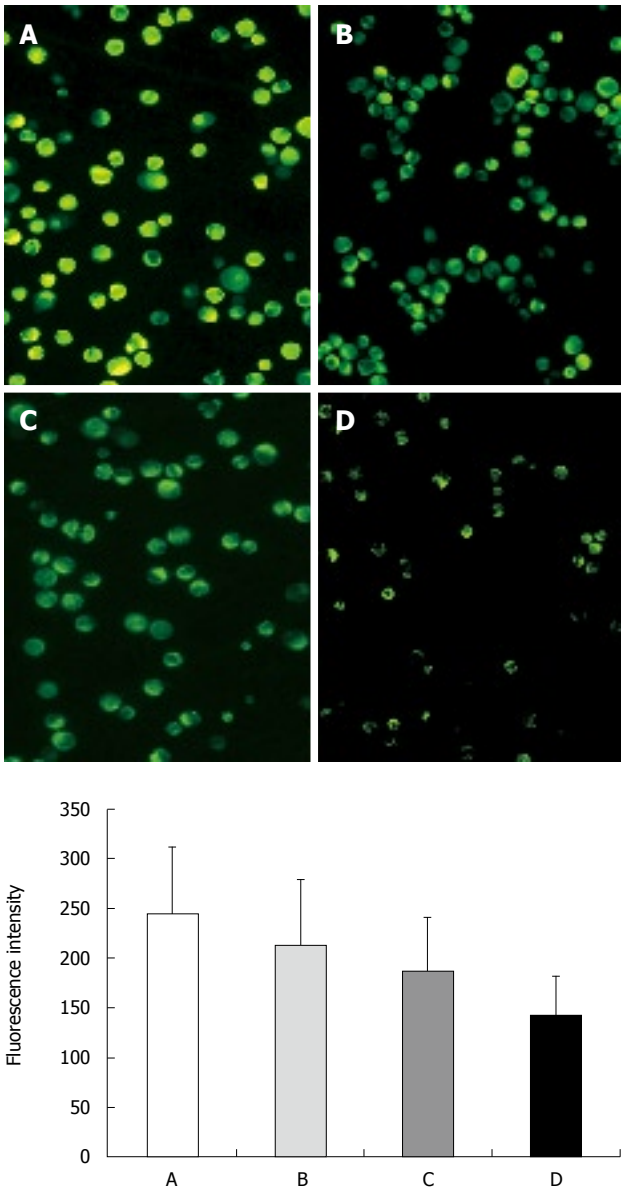

Figure 4 Effect of ESB on Δψm measured with laser scanning confocal microscope by staining with Rhodamine 123 (200 ×). A: Control group; B: Low ESB dose group; C: Medium ESB dose group; D: High ESB dose group. Fluorescence intensity (FI) indicates membrane potential of mitochondria in the cells. FI was decreased in a dose-dependent manner ($P < 0.05$, ANOVA analysis).

After treatment with different doses of ESB for 48 h, ANOVA analysis showed that the fluorescence intensity was decreased in a dose-dependent manner ($P < 0.05$).

Caspase-3 activity in ESB-induced apoptosis of H22 cells

Caspase-3, acting on downstream of the mitochondrial signaling pathway, is a major mediator of apoptosis. Dysfunction of mitochondria provoked us to detect the changes of caspase-3 activity in H22 cells following ESB treatment. The expression intensities of caspase-3 protein in the control and low-high ESB dose groups were 0.21 ± 0.02, 0.33 ± 0.04, 0.59 ± 0.03, and 0.85 ± 0.05, respectively (Figure 5). Western blot analysis revealed that there was a gradual increase in caspase-3 protein in low-high ESB dose groups ($P < 0.05$), indicating that

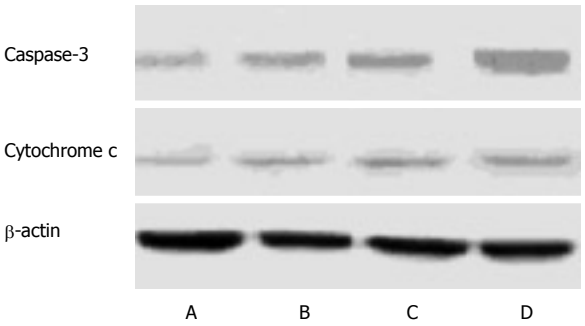

Figure 5 Protein level of caspase-3 and cytochrome C in H22 cells. A: Control group; B: Low ESB dose group; C: Medium ESB dose group; D: High ESB dose group. After treatment with different doses of ESB for 48 h, cellular proteins were detected by Western blot analysis.

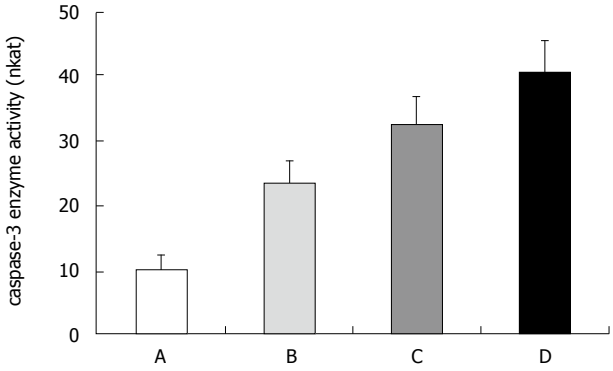

Figure 6 Effect of ESB on caspase-3 enzyme activity in H22 cells. A: Control group; B: Low ESB dose group; C: Medium ESB dose group; D: High ESB dose group. There was a dose dependent increase in activity of caspase-3 enzyme in ESB treated cells ($P < 0.05$). This assay was done triplicate, independently. Nkat was used to represent activity measured.

caspase-3 can be activated by ESB.

Caspase-3 activities were detected after treatment with different doses of ESB for 48 h, showing that caspase-3 activity was induced by ESB in a dose-dependent manner (Figure 6).

Release of cytochrome C from mitochondria in ESB-induced apoptosis

Cytochrome C release from mitochondria into cytosol is a critical step in the apoptotic cascade. The reduction of mitochondrial membrane potential may facilitate the release of cytochrome C, which will then activate the apoptotic pathway to trigger cell death. The protein level of cytochrome C in cytosol was measured in H22 cells treated with different doses of ESB by Western blot analysis with mouse monoclonal cytochrome C antibodies. As shown in Figure 5, the amount of cytosolic cytochrome C in the cytosolic fraction after ESB treatment was significantly increased in a dose-dependent manner ($P < 0.05$).

DISCUSSION

S. barbata, which has been traditionally used in treatment of inflammation, hepatitis, tumor and gynecological

diseases in China and Korea[1-9]. Studies have shown that *S. barbata* contains a large number of alkaloids and flavones, alkaloid, sterides, and polysaccharides[27,28]. However, the active site of chemical structure for antitumor activity has not been fully determined[29]. Recent studies indicate that *S. barbata* extract (ESB) is effective against hepatoma, lung and digestive system cancers, *et al*[4-10], and can be used in combination with other traditional Chinese medicines in treatment of other tumors.

In pharmacology study, crude Chinese drugs or their compounds are often added directly into the culture system of cells or organs *in vitro*[30]. However,, experimental results *in vitro* are often different from those *in vivo*. Serum pharmacology has been extensively used to study the effects and mechanisms of Chinese drugs *in vitro*[30]. It is believed that serum pharmacology is more scientific and beter for Chinese drugs than traditional pharmacology in which crude drugs are directly added into the culture system of cells or organs *in vitro*[19-20,30,31]. In this study, we investigated the effects of ESB on inducing apoptosis of H22 cells with serum pharmacology.

H22 cells were treated with different doses of ESB containing serum, and the growth rate of H22 cells was evaluated by MTT assay after 0, 24, 48, 72, and 96 h, respectively. High and medium ESB dose inhibited the proliferation of H22 cells, while low ESB dose could not obviously inhibit the proliferation of H22 cells. MTT assay showed high and medium ESB dose inhibited the proliferation of H22 cells *in vitro* in a time-dependent manner, which may provide useful information for development of anti-tumor drugs.

Morphological changes of apoptosis include membrane blebbing, cell shrinkage, chromatin condensation, DNA fragmentation and formation of apoptotic bodies[32]. These morphological changes were also observed in our study under transmission electron microscopy and fluorescence microscope after treatment with a high ESB dose for 48 h. Typical morphologies of apoptotic H22 cells, such as chromatic agglutination and fragmentation of nuclei, chondriosome swelling, formation of apoptotic body, were observed in ESB high ESB dose group (Figure 2B-D), but no apoptosis occurred in blank control group. Furthermore, fluorescence microscopy showed that the number of apoptotic cells gradually increased in a dose-dependent manner.

Blocking of cell cycle is one of the mechanisms of ESB by which the growth and proliferation of tumor cells are inhibited[33]. Flow cytometry showed that cell apoptosis was significantly decreased at S-phase, increased at G_1-phase, and reached its peak at subG_1-phase. The blocking of cell cycle may be one of the mechanisms of ESB by which the growth of H22 cells is inhibited and cell apoptosis is induced.

Mitochondria play a critical role in apoptosis induced by chemotherapeutic agents[12-14]. Many agents can induce, directly or indirectly, apoptosis by insult to the mitochondria[34,35]. Apoptosis could cause loss of $\Delta\psi m$ and release of cytochrome C into cytosol, and induce caspase-9-dependent activation of caspase-3[13]. In this study, the effect of ESB on $\Delta\psi m$ was examined using Rhodamine 123, a mitochondrial potential probe, showing that H22 cells lost $\Delta\psi m$ following ESB treatment. Forty-eight hours after ESB treatment, the cells exhibited significant alterations in $\Delta\psi m$, and the fluorescence intensity of disruption of $\Delta\psi m$ gradually decreased in a dose-dependent manner

One of the major apoptotic pathways is activated by the release of cytochrome C from mitochondria into cytosol[36], which is the hallmark of cells undergoing apoptosis. In this study, Western blotting analysis was performed to measure the protein level of cytochrome C in H22 cells after treatment with different doses of ESB. The amount of cytosolic cytochrome C in the cytosolic fraction after ESB treatment was increased in a dose-dependent manner (Figure 6).

Caspases are cystein proteases that play a key role in the execution phase of apoptosis[37]. Caspase-3, a member of the family of caspases, extensively studied as "the executor of apoptosis", plays a crucial role in cell death[38]. Apoptosis mediated by caspase-3 occurs in many cancer cells. In this study, Western blot analysis revealed that caspase-3 protein was gradually increased in the low-high ESB dose groups. At the same time, caspase-3 enzyme activity was increased in a dose-dependent manner. These results indicate that caspase-3 can be activated by ESB. ESB treatment resulted in loss of mitochondrial membrane potential, release of cytochrome C and caspase-3, demonstrating that ESB induces apoptosis and mitochondria are involved in apoptosis mediated by ESB.

In conclusion, ESB has antiproliferative activities against H22 cells by inducing apoptosis involving loss of $\Delta\psi m$, release of cytochrome C, and activation of caspase-3.

COMMENTS

Background

Medicinal plants have been used as traditional remedies for hundreds of years. Among them, *Scutellaria barbata D.Don* (*S. barbata*) has been traditionally used in treatment of hepatitis, inflammation, osteomyelitis and gynecological diseases in China. Studies indicate that extracts from *S. barbata* have growth inhibitory effects on a number of human cancers. Reports are available on the treatment of lung, breast and digestive system cancer, hepatoma, and chorioepithelioma with *S. barbata* extracts. However, the underlying mechanism of the antitumor activity of *S. barbata* extracts remains unclear.

Research frontiers

Studies have confirmed that many Chinese herbs have antitumor properties and induce apoptosis. In the process of signal transduction of cell apoptosis induced by drugs, mitochondria play a great role in promoting apoptosis signal and releasing caspase. Permeabilization of the outside mitochondrial membrane plays the most important role in mitochondrial apoptosis, during which loss of $\Delta\psi m$ and release of cytochrome C into cytosol, and caspase-9- dependent activation of caspase-3 occur sequentially.

Innovations and breakthroughs

There is no evidence that the mitochondrial pathway is involved in apoptosis induced by S. barbata. The present study was undertaken by culturing mouse liver cancer H22 cells treated with serum containing different concentrations of ESB. ESB containing serum induced apoptosis of H22 cells, and apoptosis was

involved in loss of mitochondrial transmembrane potential, release of cytochrome C, and activation of caspase-3.

Applications

This experimental study on the mechanism of the antitumor activity of S. barbata, may offer new evidence for S. barbata in the treatment of hepatoma in clinical practice.

Terminology

ESB is an extract from *Scutellaria barbata*; Δψm indicates mitochondrial transmembrane potential;1 nanokatal defined as the amount of enzyme required to increase the rate of reaction by 1 nmol/s under defined assay conditions.

Peer review

This study examined the anti-tumour effects of Scutellaria barbate. The authors used serum containing extract from *S. Barbata* (ESB) to determine its effect on proliferation of H22 hepatoma cells *in vitro*. ESB inhibited cell proliferation by inducing cell cycle arrest at Go/G1 phase and by increasing apoptosis with a reduction in mitochondrial membrane potential, release of cytochrome C and capase-3 activation. This work is novel and improves our understanding of the mechanisms of action of ESB.

Abstract

AIM: To detect the *MLH1* gene promoter germline-methylation in probands of Chinese hereditary non-polyposis colorectal cancer (HNPCC), and to evaluate the role of methylation in *MLH1* gene promoter and molecular genetics in screening for HNPCC.

METHODS: The promoter germline methylation of *MLH1* gene was detected by methylation-specific PCR (MSP) in 18 probands from unrelated HNPCC families with high microsatellite-instability (MSI-H) phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. At the same time, 6 kindreds were collected with microsatellite-stability (MSS) phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* genes as controls. The results of MSP were confirmed by clone sequencing. To ensure the reliability of the results, family H65 with nonsense germline mutation at c.2228C > A in *MSH2* gene was used as the negative control and the cell line sw48 was used as the known positive control along with water as the blank control. Immunochemical staining of *MLH1* protein was performed with Envision two-step method in those patients with aberrant methylation to judge whether the status of *MLH1* gene methylation affects the expression of MLH1 protein.

RESULTS: Five probands with *MLH1* gene promoter methylation were detected in 18 Chinese HNPCC families with MSI-H phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. Two of the five probands from families H10 and H29 displayed exhaustive-methylation, fulfilling the Japanese criteria (JC) and the Amsterdam criteria (AC), respectively. The other 3 probands presented part-methylation fulfilling the AC. Of the 13 probands with unmethylation phenotype, 8 fulfilled the JC and the Bethesda guidelines (BG), 5 fulfilled the AC. The rate of aberrant methylation in *MLH1* gene in the AC group (22.2%, 4/18) was higher than that in the JC/BG groups (5.6%, 1/18) in all HNPCC families with MSI-H phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. However, no proband with methylation in *MLH1* gene was found in the families with MSS phenotype and without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. No expression of MLH1 protein was found in tumor tissues from two patients with exhaustive-methylation phenotype, whereas positive expression of MLH1 protein was observed in tumor tissues from patients with partial methylation phenotype (excluding family H42 without tumor tissue), indicating that exhaustive-methylation of *MLH1* gene can cause defective expression of MLH1 protein.

CONCLUSION: Methylation phenotype of *MLH1* gene is correlated with microsatellite phenotype of *MMR* genes, especially with MSI-H. Exhaustive-methylation of *MLH1* gene can silence the expression of MLH1 protein. *MLH1* promoter methylation analysis is a promising tool for molecular genetics screening for HNPCC.

INTRODUCTION

Hereditary non-polyposis colorectal cancer (HNPCC), also known as Lynch syndrome, is characterized by an autosomal dominant inheritance of early-onset microsatellite instability (MSI)-positive colorectal cancer and an increased risk of other cancers, including cancers of the endometrium, stomach, ovary, urinary tract, pancreas, and small bowel. HNPCC accounts for 5%-10% of all colorectal cancers and is caused by a mutation in one of the following DNA mismatch repair (MMR) genes: *MLH1, MSH2, MSH6, PMS1* and *PMS2*[1-3]. Germline mutations in *MLH1* and *MSH2* account for > 90% of all known MMR mutations in HNPCC[4], and germline mutations in *MSH6* account for 5%-10%, whereas mutations in other genes are rare[3,5]. MSI has been observed in approximately 13% of sporadic colorectal cancers (CRC) and in virtually all CRC arising in patients with HNPCC. Germline mutations in *MMR* genes, high-frequency microsatellite instability (MSI-H) and loss of MMR protein expression are the hallmarks of HNPCC. Epigenetic silencing is usually considered a kind of somatic phenomenon and somatic *MLH1* promoter hypermethylation is generally accepted in the tumorigenesis of sporadic tumours. However, little is known about the maintenance of epigenetic state in the germline[6] and abnormal *MLH1* gene promoter methylation in normal body cells is controversially discussed as a mechanism predisposing patients to HNPCC. Recently, aberrant methylation in MMR genes, *MLH1* or *MSH2*, has been supposed as a basic factor for cancer[7]. Promoter hypermethylation in *MLH1* gene of colorectal tumors correlates well with loss of MLH1 protein in sporadic MSI-positive cases[8,9]. This study was to investigate the *MLH1* gene germline epimutation by methylation-specific PCR (MSP) in 18 Chinese HNPCC kindreds with MSI-H but without germline mutations in *MSH2, MLH1,* or *MSH* gene, in order to identify HNPCC families and provide experimental information for HNPCC database.

MATERIALS AND METHODS

Materials

From January 1998 to October 2005, 24 Chinese HNPCC families fulfilling different clinical criteria were registered at the Department of Abdominal Surgery in Shanghai Cancer Hospital/Institution. Germline mutations in *MLH1*, *MSH2* and *MSH6* genes were excluded by DNA-PCR-based sequencing in the probands of all Chinese HNPCC families[10-12]. Of them, 18 unrelated HNPCC probands were selected for the study objects with the phenotype of MSI-H, and the remaining 6 were for the control group with the phenotype of microsatellite stability (MSS). Each participant was asked to give 10 microliters of peripheral blood and consented for access to archival tumor tissue. The characteristics of the selected cases are listed in Tables 1 and 2. To ensure the reliability of the results, family H65 with nonsense germline mutation at c.2228C > A in *MSH2* gene was used as the negative control and the cell line sw48 was used as the known positive control for the methylation in *MLH1* gene as well as water as the blank control. This study was proved by the Medical Ethical Committee of Cancer Hospital, Fudan University. The procedures of the study were in accordance with the international rules and regulations.

DNA extraction

Genomic DNA from peripheral blood and the cell line sw48 was extracted with the QIAGEN (Hilden, Germany) DNA extraction kit following its manufacturer's introductions. Concentration of the genomic DNA was determined with an ultraviolet spectrophotometer (Beckman, DU640 type).

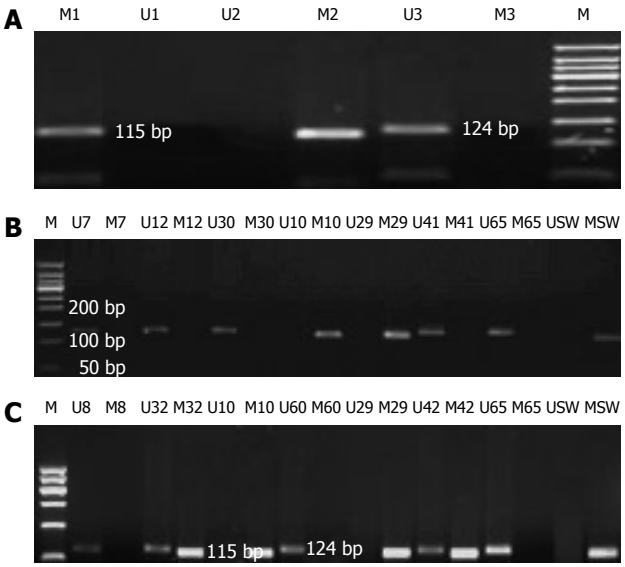

Figure 1 Results of *MLH1* MSP assay using primers that amplify methylated (M) or unmethylated (U) alleles (Lane M represents 100-bp DNA marker). A: MLH1 MSP assay in families H10, H65 and cell line SW48. M1, M2, U1and U2 indicate the methylated and unmethylated products of familiy H10, cell line SW48, and the methylaed band (115 bp); M3 and U3 indicate the methylated and unmethylated products in family H65; B: MLH1 MSP assay in families H7, H12, H30, H10, H29, H41, H65 and cell line SW48. U7, U12, U30, U41 and U65 indicate the unmethylated products of families H7, H12, H30, H41, and H65,respectively; M10, M29 and MSW indicate the methylated products of families H10, H29, and positive control SW48, respectively; C: MLH1 MSP assay in families H8, H32, H10, H60, H29, H42 H65 and cell line SW48. U8, U60 and U65 indicate the unmethylated products of families H8, H60 and H6, respectively; M10, M29 and MSW indicate the methylated products of families H10, H29, and positive control SW48, respectively; U32, M32 and U42, M42 are products of families H32 and H42, respectively.

PCR for methylation in MLH1

MSP exploits the effect of sodium bisulfite on DNA, which efficiently converts unmethylated cytosine to uracil with methylated cytosine unchanged. Consequently, after treatment, methylated and unmethylated alleles have different sequences that can be used to design allele-specific primers.

Genomic DNA was modified with sodium bisulfite as described previously[13,14]. The modified DNA was then subjected to MSP using primer pairs engineered to amplify either methylated or unmethylated DNA. Methylated and unmethylated primer pair sequences were also designed as previously described[15] and synthesized (Sangon, shanghai). PCR was carried out with HotstarTaq DNA polymerase (Cat. No. 203203): preheating at 94℃ for 10 min, followed by 40 cycles of denaturation at 94℃ for 45 s, annealing at 58℃ for 45 s and extension at 72℃ for 45 s, and a final elongation at 72℃ for 7 min. PCR products were subjected to 2% agarose gel electrophoresis. The products of exhaustive-methylation only indicated a methylated band of 124 bp and the unmethylated products only indicated an unmethylated band of 115 bp, while the partially methylated products indicated both of them. After observation of clear and expected bands, the products were purified using the QIAquick gel extraction kit (Qiagen) and sequenced on a 3700 DNA sequence system (ABI, USA) in order to check the correct bisulfite modification. Appropriate positive and negative reference samples were included. Each result of sequencing was analyzed by DNA Star 5.08 bioanalysis software.

Immunochemical staining for MLH1

A monoclonal antibody against MLH1 (Pharmingen, San Diego, CA, USA) was prepared at a 1:40 dilution and detected by the Envision two-step method to judge whether the status of methylation in *MLH1* gene would affect the expression of MLH1 protein. The expression of MLH1 was diminished in cancer tissues in the absence of detectable nuclear staining of neoplastic cells. Infiltrating lymphocytes and normal colonic crypt epithelium next to the tumor area served as internal positive controls.

RESULTS

Five probands with *MLH1* gene methylation were found in 18 unrelated Chinese HNPCC families with MSI-H phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. The rate of abnormal methylation in *MLH1* gene was approximately 27.8% (5/18). Among the 18 patients, 2 displayed exhaustively methylated phenotype and the other 3 presented partially-methylated phenotype. The exhaustive methylation accounted for 11.1% (2/18) in the HNPCC families with MSI-H but without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. Perhaps, the changes might be much lower in all unselected HNPCC families. Among the 13 probands with unmethylation phenotype, 8 fulfilled the Japanese criteria (JC)/Bethesda guidelines (BG), 5 fulfilled the Amsterdam criteria (AC). All probands with partially-methylated phenotype fulfilled the AC, whereas probands of families H10 and H29 displaying exhaustively-methylated phenotype fulfilled the JC and AC, respectively. The rate of aberrant methylation in *MLH1* gene in the AC group (22.2%, 4/18) was higher than that in the JC/BG groups (5.6%, 1/18) in all HNPCC families with MSI-H phenotype and without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. However, no proband with methylation in *MLH1* gene was found in HNPCC families with MSS phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. In our study, the expected size of bands was clear and specific. The study was repeated in triplicate to make sure all results credible (Figure 1A-C). Moreover, all exhaustively and partially methylated PCR products were purified and clone-sequenced in order to further substantiate the results of MSP (Figure 2). We believed that the methylation in *MLH1* gene might be related with microsatellite phenotype. No expression of MLH1 protein was observed in tumor tissues from two patients with exhaustively methylated phenotype, while positive expression of MLH1 protein was found in tumor tissues from patients with partially methylated phenotype (excluding family H42 without tumor tissue), suggesting that exhaustive-methylation in *MLH1* gene can cause defective expression of MLH1 protein and influence its function while the partial methylation in *MLH1* gene may have no impact on the expression of MLH1 protein.

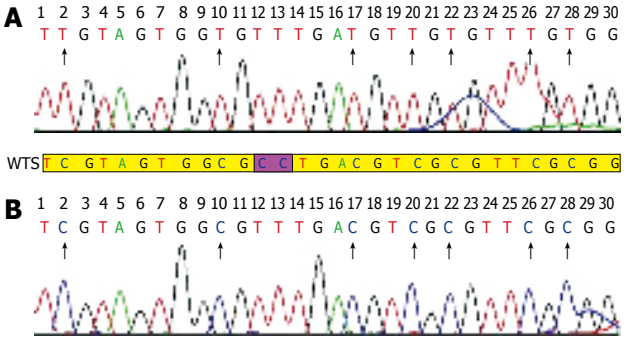

Figure 2 Methylation analysis of the promoter *MLH1* gene by clone sequencing. Arrow indicates CpG dinucleotide, WTS indicates the wild-type sequence of transcription start site. A: Unmethylated band presenting all unmethylated cytosines was converted to uracil after bisulfite modification; B: Methylated band presenting all unmethylated cytosines was unchanged after bisulfite modification.

DISCUSSION

HNPCC syndrome is the most common form of hereditary colorectal cancer. Predisposed individuals have a higher risk of developing cancer. The syndrome is primarily due to heterozygous germline mutations in *MLH1*, *MSH2*, *MSH6* and *PMS2* genes. The resulting mismatch repair deficiency leads to MSI which is the hallmark of tumors arising within this syndrome, as well as a variable proportion of sporadic tumors. Diagnostic guidelines and criteria for molecular testing of suspected families have been proposed and continuously updated. However, not all families fulfilling these criteria show mutations in MMR genes and/or MSI implicating other unknown carcinogenic mechanisms and predisposition genes. This subset of tumors is the focus of current clinical and molecular research.

Germline mutations in the coding regions of *MSH2* and *MLH1* genes are known to be responsible for up to 45%-64% of all HNPCC families[16], and those of *MSH6* account for 10% of HNPCC kindreds[17]. We have previously detected germline mutations in the entire coding regions of *MSH2, MLH1* and *MSH6* genes in 24 probands meeting the AC, 15 probands fulfilling the JC and 19 probands meeting the BG by PCR-gene-sequencing with 20 germline mutations detected including two mutations occurring in a same patient and three novel mutations[10,11]. Subsequently, 3 new mutations are found by mRNA-based PCR sequencing[12]. It was speculated that the remaining probands without mutations in *MSH2*, *MLH1*, and *MSH6* genes might be associated with other aberrant types of genes. It was reported that DNA methylation associated with transcriptional silencing of *MLH1* is the underlying cause of MMR defects in most sporadic colorectal cancers with a MSI+ phenotype[9,18]. Moreover, reversal of methylation with 5-aza-deoxycytidine not only results in reexpression of MLH1 protein, but also restoration of the MMR capacity in MMR-deficient cell lines[9]. These findings further substantiate that the promoter methylation in *MLH1* gene is another deficient mechanism of *MLH1* gene.

Hypermethylation of CpG island in the promoter sequence has been proved to be an important mechanism of gene silencing and is particularly associated with transcriptional silencing of tumor suppressor genes in sporadic cancers[19,20]. Germline mutations might occur in individuals with a well-characterized genetic disease but lack an identifiable mutation in known disease genes[21]. It was recently reported that monoallelic promoter hypermethylation in *MLH1* gene is observed in peripheral blood from a number of patients with early-onset colorectal cancer[7,22-24]. The above results indicate that *MLH1* promoter-germline mutation might be related to HNPCC.

Our study demonstrated 5 probands with *MLH1* gene methylation (including 2 exhaustive-methylations which fulfill the JC and the AC, respectively, and 3 part-methylations fulfilling the AC) in 18 unrelated Chinese HNPCC families with MSI-H phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. The rate of aberrant methylation in *MLH1* gene (22.2%, 4/18) was higher in probands fulfilling the AC than that (5.6%, 1/18) in those meeting the JC and BG. Of the 13 probands with unmethylated phenotype, 8 fulfilled the JC and BG (61.5%, 8/13), 5 fulfilled the AC (38.5%, 5/13). However, no proband was detected with the aberrant methylation in *MLH1* gene in the 6 suspected HNPCC families with MSS phenotype and without germline mutations in *MSH2*, *MLH1* and *MSH6* genes. These findings illuminate that the promoter methylation in *MLH1* gene is likely another underlying cause of MMR defect in HNPCC fulfilling the AC. In order to ravel whether the aberrant methylation in *MLH1* gene influences the expression of MLH1 protein, immunostaining of MLH1 protein was carried out in 5 probands with *MLH1* aberrant methylation in our study. No expression of MLH1 protein was found in 2 probands with exhaustively methylated phenotype, whereas positive expression of MLH1 protein was observed in 2 probands with partially methylated phenotype (excluding family H42 without tumor tissue) suggesting that exhaustive methylation in *MLH1* gene can cause defective expression of MLH1 protein and influence its function while partial methylation of *MLH1* gene may have no impact on the expression of *MLH1* gene, revealing that methylation in *MLH1* gene may be related with the microsatellite phenotype and influence the expression of MLH1 protein and its function, which is consistent with the reported findings in other studies[8,9].

In neoplastic cells, stable allele-specific loss of transcription due to aberrant methylation in an unmutated promoter region can identify hypermethylation as a direct mechanism of tumor suppressor gene inactivation[25]. Moreover, the promoter methylation can be passed in somatic mitosis, which is reversible. Persons with hypermethylation in *MLH1* alleles of somatic cells can predispose to the development of cancer in patterns with hereditary nonpolyposis colorectal cancer. It was reported that epimutation can be transmitted from a mother to her son[26], which is consistent with transgenerational epigenetic inheritance.

In the present study, the rate of aberrant methyla-

tion in *MLH1* gene was only 27.8% (5/18) in selected HNPCC with MSI-H phenotype but without germline mutations in *MLH1*, *MSH2* and *MSH6* genes. Among the probands with aberrant methylation, the rate of methylation in those fulfilling the AC accounted for 80% (4/5), which was significantly higher than that [20% (1/5)] in those meeting the JC and BG. Methylation analysis of the *MLH1* promoter should be performed for all early-onset or multiple colorectal cancer patients with MSI-H tumors or loss of MLH1 protein expression due to unknown causes in HNPCC probands fulfilling the AC.

There is evidence that aberrant methylation in the promoter region of *MLH1* alleles is functionally equivalent to a pathogenic *MLH1* germline mutation and mimics the clinical phenotype of Lynch syndrome. 'Sporadic' HNPCC-patients need to be treated Lynch syndrome patients. Individuals carrying *MLH1* germline epimutations are at a high risk of developing colorectal and other tumors and should be considered carriers of germline mutations. Inheritance should be discarded in each case, until more conclusive data are obtained. *MLH1* promoter methylation analysis should be performed at least for the first degree relatives with positive methylation to exclude the inheritance of a familial epimutation[27]. Identification of hypermethylation as an epigenetic defect has important implications for surveillance recommendations, since these patients should be treated like Lynch syndrome patients.The heritability of methylation needs to be further investiged.

ACKNOWLEDGMENTS

The authors are grateful to the patients who took part in this study and to Departments of Cancer Hospital for sending blood and tumor specimens. The authors also appreciate the help from Professor Sun MH, Wang CF and Cai Q for their detection of germline mutations in MSH2 and MLH1 genes of the probands of certain Chinese HNPCC cases and Professor Mo SJ for the supply of certain Chinese HNPCC cases.

COMMENTS

Background

Germline mutations in mismatched repair genes, such as MLH1, MSH2 and MSH6, lead to hereditary nonpolyposis colorectal cancer (HNPCC) and not all families fulfilling these criteria show mutations in mismatched repair genes. It is well known that MLH1 promoter methylation is related with sporadic colorectal cancer. However, MLH1 promoter germline-methylation in Chinese HNPCC patients has not yet been reported.

Research frontiers

Germline mutations in MMR genes, such as MSH2, MLH1 and MSH6 contribute to the early diagnosis of HNPCC and screening of HNPCC families. Few studies on MLH1 promoter germline-methylation are available.

Innovation and breakthroughs

Five patients with *MLH1* gene methylation were found in this study by methylation-specific PCR in 18 unrelated Chinese HNPCC probands with high microsatellite-instability phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* gene. The rate of abnormal methylation in *MLH1* gene was approximately 27.8% (5/18) and the rate (22.2%, 4/18) in probrands fulfilling the Amsterdam criteria, which was higher than that (5.6%, 1/18) in those meeting the Japanese criteria/Bethesda guidelines.

Applications

MLH1 promoter methylation analysis can be used for the microsatellite phenotype of mismatched repair genes and is a promising tool for molecular genetics screening of HNPCC.

Terminology

HNPCC is an abbreviation of hereditary nonpolyposis colorectal cancer; MSP is an abbreviation of methylation-specific PCR.

Peer review

In this study, MLH1 promoter germline-methylation was detected in 18 unrelated Chinese HNPCC probands with high microsatellite-instability phenotype but without germline mutations in *MSH2*, *MLH1* and *MSH6* gene. The rate of aberrant methylation in probands meeting theAmsterdam criteria was higher than that in those fulfilling the Japanese criteria/Bethesda guidelines. However, the function of MLH1 promoter germline-methylation should be further studied with a large of samples.

Abstract

AIM: To describe a quantitative analysis method for liver biopsy sections with a machine that we have named "Dioguardi Histological Metriser" which automatically measures the residual hepatocyte mass (including hepatocytes vacuolization), inflammation, fibrosis and the loss of liver tissue tectonics.

METHODS: We analysed digitized images of liver biopsy sections taken from 398 patients. The analysis with Dioguardi Histological Metriser was validated by comparison with semi-quantitative scoring system.

RESULTS: The method provides: (1) the metrical extension in two-dimensions (the plane) of the residual hepatocellular set, including the area of vacuoles pertinent to abnormal lipid accumulation; (2) the geometric measure of the inflammation basin, which distinguishes intra-basin space and extra-basin dispersed parenchymal leukocytes; (3) the magnitude of collagen islets, (which were considered truncated fractals and classified into three degrees of magnitude); and (4) the tectonic index that quantifies alterations (disorders) in the organization of liver tissue. Dioguardi Histological Metriser machine allows to work at a speed of 0.1 mm^2/s, scanning a whole section in 6-8 min.

CONCLUSION: The results are the first standardized metrical evaluation of the geometric properties of the parenchyma, inflammation, fibrosis, and alterations in liver tissue tectonics of the biopsy sections. The present study confirms that biopsies are still valuable, not only for diagnosing chronic hepatitis, but also for quantifying changes in the organization and order of liver tissue structure.

Metrically measuring liver biopsy: A chronic hepatitis B and C computer-aided morphologic description. *World J Gastroenterol* 2008; 14(48): 7335-7344 Available from: URL: http://www.wjgnet.com/1007-9327/14/7335.asp DOI: http://dx.doi.org/10.3748/wjg.14.7335

INTRODUCTION

The main purpose of this paper is to describe a rigorous method based on the fundamentals of measurement theory[1], which metrically defines the changes in magnitude of liver tissue prime basic structural elements that occurring during the course of chronic hepatitis B and C.

Each available score to evaluate hepatic lesions is characterized by some methodological inaccuracy[2-4]. In fact, transient elastography (Fibro-Scan)[5,6] is limited by the skill of the operator and because liver stiffness is not only dependent from fibrosis, and serological assays not directly involved in tissue evolution, but in patient diagnosis[7-11]. In addition to the inherent risks of excising a liver specimen[12], current morphometric analyses[13-17] are time-consuming, depend on subjective choices of the regions of interest, involve the interactive elimination of Glisson's capsule and staining artefacts, and use the International System (IS), which is unsuitable for measuring the irregular shapes found in histology[18-21].

The study concerning the status of the liver tissue affected by chronic viral hepatitis was suggested by three

main needs. The first was ethical because methodological accuracy and repeatability are essential. The second was clinical because many problems remain unsolved in hepatology, such as non-responders to therapy[3], and regression of cirrhosis[2]. The third need was economic, as the price of the metrical data supplied by the "Dioguardi Histological Metriser" analysis is relatively low, and the repeatable biopsy interpretation is obtained with a few minutes.

The lack of an appropriate geometry had prevented the real measurement of irregular liver structures, until Mandelbrot's fractal geometry[22] (also called the geometry of irregularity) offered a correct approach for obtaining reproducible and closer to reality metrical measurements of hepatocellular mass, inflammation, and fibrosis, and also provided a quantitative index for evaluating the organization of liver tissue tectonics. In order to apply these new measurements, we constructed a practical and fully-automated machine that we called the "Dioguardi Histological Metriser", which is capable of measuring 10 parameters to describe the status of the residual hepatocyte mass (including hepatocyte vacuolization), inflammation, fibrosis, and the loss of liver tissue tectonics in liver biopsy sections, at a speed of 0.1 mm^2/s. Hepatitis B and C virus infections do not usually affect the biliary system.

The study concerning the status of the liver tissue affected by chronic viral hepatitis B and C, was suggested by three main needs: (1) Ethical: methodological accuracy and reproducibility are essential; (2) Clinical: because many questions remain unsolved in hepatology, such as non-responders patients to therapy[3], and regression of cirrhosis[2]; (3) Economical: metrical data analysis supplied by the "Dioguardi Histological Metriser" is not expensive reproducible and is obtained within a few minutes.

MATERIALS AND METHODS

Case list

We studied 398 patients randomly collected (250 male) aged 52 ± 12 years with chronic hepatitis B or C, who were admitted to the hepatology departments of the Istituto Clinico Humanitas (ICH) IRCCS, Rozzano, and the University of Milan Department of Gastroenterology, Ospedale Maggiore IRCCS, Milan, Italy. The biopsies were performed in accordance with the guidelines of the Ethics Committees of ICH and Ospedale Maggiore IRCCS. All of the liver specimens were approximately 17 ± 12 mm^2.

The logarithmic curve of the ordered set according to the fibrosis data magnitude obtained from the 398 patients, can be interpreted as the trajectory (from α to ω)of the ideal dynamics of collagen deposition during the course of chronic hepatitis (Figure 1).

Histological methods

Three consecutive 2 μm thick sections were cut from formalin-fixed, paraffin-embedded biopsy specimens: the first was stained with hematoxylin and eosin for diagnostic purposes; the second was treated to identify inflammatory cells by using monoclonal antibodies raised against leukocyte common antigen (LCA: Dako, Milan, Italy) and a standardized immunoperoxidase method[23], and hepatocellular lipids vacuoles; and the third was stained with Sirius red to visualize fibrosis.

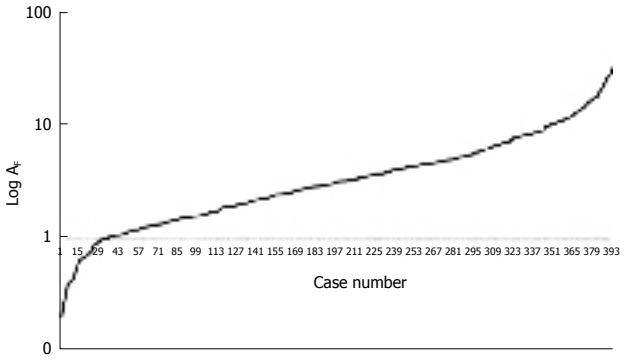

Figure 1 Markovian logarithmic curve obtained with the fibrosis content in each single biopsy section from 398 patients, ordered by increasing severity. A_F = area of fibrosis.

Semi-quantitative analyses

Expert hepatopathologists graded and staged the biopsy sections using the Knodell[24], Sheuer[25], Ishak[26], and METAVIR[27] semi-quantitative scoring systems.

Example of liver tissue geometric analysis

A specific example of the set of metrical parameters obtained by quantitatively evaluating liver residual parenchyma, inflammation, fibrosis, and disordered liver tissue tectonics is shown in Figure 2.

Methodology validations

Variations in the water bath temperatures used to distend the histological sections were tested at 41, 43, 45 and 47℃, (which accounted for 12% of the variations in fibrosis). Variations in paraffin section thickness were tested using five sequential thicknesses from 2-6 μm, (which accounted for 20% of the variations in fibrosis). Variations in staining times (tested using nine sequential sections stained with a freshly-made Sirius red solution for 15-135 min), (which accounted for 13% of the variations in fibrosis). Intra-sample variability in the tissue area covered with Sirius-red-stained collagen was assessed using three series of thirty 2 μm-thick sections obtained from three biopsies, two series of fifteen 4 μm-thick sections obtained from two further biopsies, and one series of ten 6 μm-thick sections obtained from a sixth biopsy. The results showed wide intra-sample variability, because of the highly irregular distribution of the collagen matrix. Also the loss of the thinner matrix components because of histological section processing might have play played a role in this result.

Statistical analysis

The results were analyzed using Statistica software (StatSoft Inc., Tulsa, OK, USA). Variability was evaluated using the coefficient of variation (CV) given by the formula CV = (SD/mean) × 100%. *P* values of less than 0.05 were considered statistically significant.

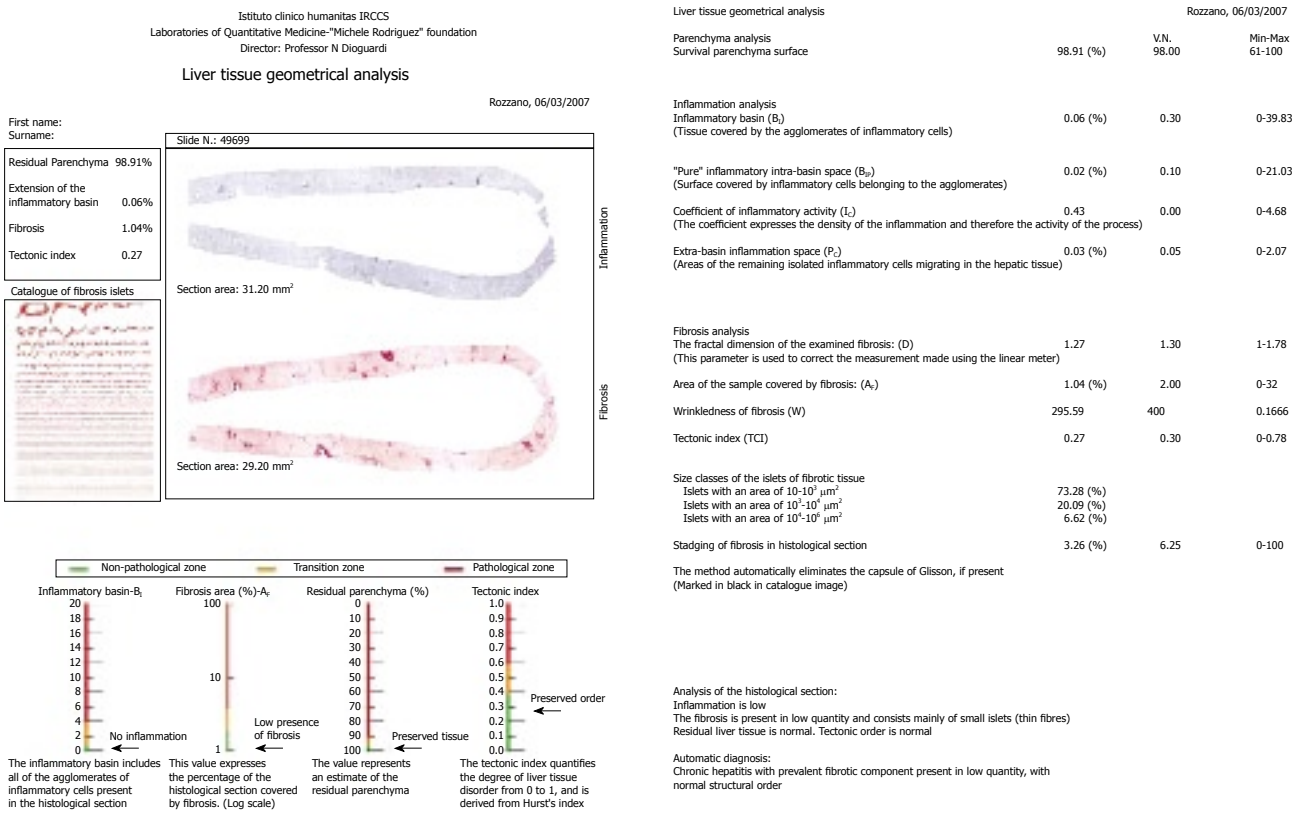

Figure 2 An example of LTGA. The machine completes the analysis by providing a common language description of the histological pattern and diagnosis.

The model and its pathological transformation

Our model for measuring the state of liver tissue is based on two canonical points: the choice of the prime structural elements of the tissue, and the most general kind of tissue organization[1].

Prime structural elements (determine property of the system) and are the most representative structural elements of an organ tissue insofar as they have the property of changing their shape and size over time, without losing their individuality.

Prime liver structural elements were considered: (1) the parenchyma (i.e. the *substantia jecuris*), which consists of the hepatocytic mass that, in this phase of the research, includes regenerative nodular hepatocytes; (2) the dispersed set of topical immunological cells; (3) the collagen scaffold that consists collagen fibers and included the portal spaces; and (4) the tectonic, defined by the Malpighi-Kiernan lobular organization of the liver. All of these elements were taken in their strictly structural form.

The most general kind of organization[1] of an organ tissue is the state of its prime structural elements defined by quantitative relationships. It determines tissue tectonics and the reference for every structural change in organ architecture which, in the case of the liver, is the lobular structure.

Pathological events occurring during the course of chronic viral hepatitis transform the shape and size of these prime physical structures, and consequently alter the most general organization of the liver system.

The main events altering the natural physical state of the prime structural elements and tectonics of liver tissue, are enlargement, reduction and "vacuolization". The pathological transformations determined by these events during the course of chronic viral hepatitis, can be interpreted as follows: (1) necrosis reduces lipid hepatocyte determines vacuolization increases the size of the parenchyma; (2) Increase in the number of dispersed cells generated by the topical general immune system determine inflammatory cell clusters; (3) Growth of septa that evolve into porto-portal or porto-central fibrotic bridges results in expansion of the collagen support network (which appears as Sirius-red-stained islets in a histological section). Taken together these individual transformations (in shape and size) generate a loss of the natural harmony in the inter-relationship of the prime elements. This loss of order is also measurable.

The Dioguardi Histological Metriser

We designed and built our own user-friendly Liver Tissue Geometric Analyser (LTGA or Dioguardi Histological Metriser; patent pending), which automatically ensures correct microscope focusing, metrically evaluates the image of an entire digitalized histological slide, and defines the areas covered by the residual parenchymal mass (including lipid vacuolization), inflammation and fibrosis; it also disregards any unfilled spaces (vascular and biliary cavities or sinusoidal spaces) and artifactual tissue-free spaces.

The Dioguardi Histological Metriser consists of two parts: a "client" (or dedicated microscope system) that captures and digitizes the images of the specifically stained histological section, and a central "server" that receives the images, automatically measures the parameters

Figure 3 Liver fibrosis. A: Prototypical examples of multifarious Sirius-red-stained collagen islets making-up the liver collagen network; B: the Metriser automatically selected and excluded Glisson's capsule (black islets) from the computation of fibrosis by means of an appropriate algorithm.

listed in Table 1, and sends the results back to the client.

In this study, the microscope system consisted of a Leica DMLA microscope (Leica, Milan, Italy) equipped with an X-Y translator table, a digital camera (QICam, QImaging, Surrey, Canada), and an Intel Pentium 4, 2.60 GHz computer. We used *ad hoc* built-in image analysis software that automatically filtered, selected, and marked the outlines of the images of interest using color thresholds based on the levels of red, green and blue. All of the measurements were made at 10 × objective magnification. The Dioguardi Histological Metriser automatically selected and excluded Glisson's capsule from the computation of fibrosis by means of an appropriate algorithm (Figure 3).

The minimum and maximum scalars obtained empirically on the basis of the Dioguardi Histological Metriser measurements of 398 biopsies are shown in Table 1.

Table 1 Quantitative parameters automatically obtained with the Metriser

Parameter	min	max
Residual hepatocellular set		
Residual hepatocellular set (%)	67.97	99.59
Inflammation		
Inflammatory cell cluster space (%)	0	8.71
Pure inflammatory cell cluster space (%)	0	3.67
Extra-basin inflammatory space (%)	0	1.14
Fibrosis		
Area of Sample covered by fibrosis (%)	0	32
Islets magnitude		
$10\text{-}10^3$ (%)	8.9	100
$10^3\text{-}10^4$ (%)	0	58.15
$> 10^4$ (%)	0	87.4
Wrinkledness	0	1666
Tectonic Index		
Liver tissue	0	0.78
Low or no disorder	0	0.4
Middle disorder	0.4	0.6
High disorder	0.6	1

Data are expressed as percentage of true liver surface. The value 0 is obtained when no cell clusters were recognized. Quantitative evaluation of steatosis. At this phase of the research this quantitative parameter is still obtained with an ad hoc software.

Measuring the pathological structures

We took as a reference for the following measurements the physical transformation average of the areas of the studied histological section.

Residual parenchymal mass: We consider the surviving hepatocellular set that remains after necrotic viral destruction, together with the nodular regenerated hepatocytes.

This surviving part of the hepatocellular set (residual mass) is expressed as a percentage of the reference area using the formula:

$H_S = 100\% - A_I - A_F$

Where H_S is the area of the residual hepatocellular set, A_I the sum of the area of the inflammation basin, and A_F the area covered by fibrosis. Vacuolization is due to the accumulation of lipids within hepatocytes (Figure 4). In this phase of the research we included lipid vacuoles in the residual parenchyma. The extension of these cytoplasmic enclaves was measured separately, to define the steatosis grade.

Inflammation basin: We called the inflammation basin (Figure 5A) the classic liver tissue pattern characterized by various sets of spatial immune-cell aggregates[23]. We consider three components. (1) Inflammatory cell clusters

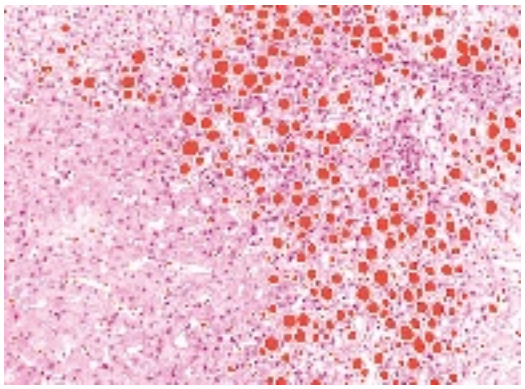

Figure 4 Computer-aided recognition of vacuolization, due to the accumulation of lipid vacuoles within hepatocytes. The image represents only a limited exemplificative area taken from the whole histological section (× 10).

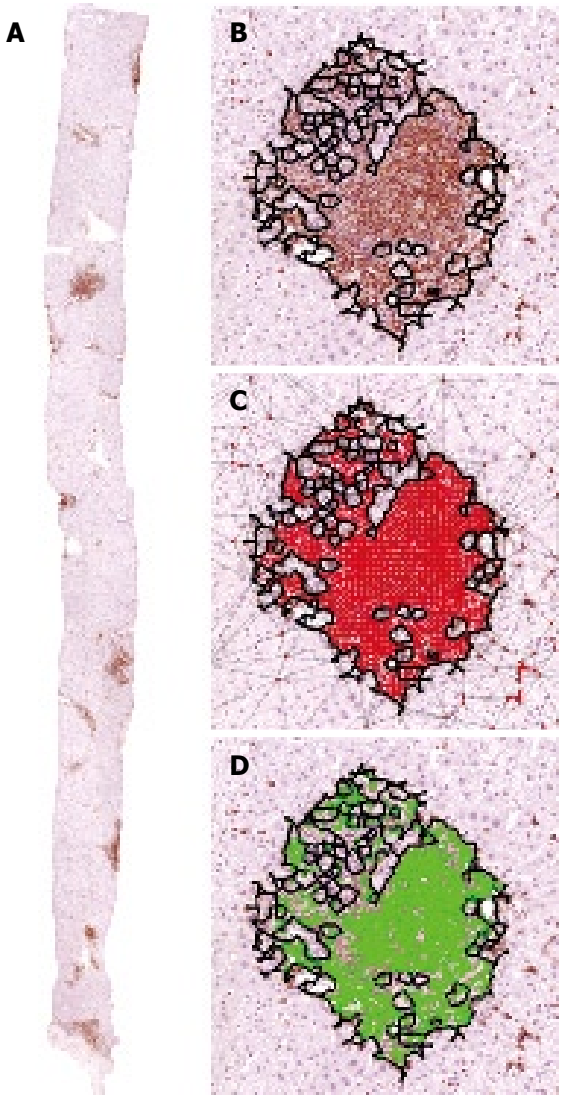

Figure 5 Liver inflammation (× 10). A: Morphological picture showing the inflammatory cell' clusters forming the inflammation basin; B: inflammatory cell cluster; C: discrimination of the cluster outline (black line) using the Delaunay' triangulation; D: pure intra-cluster inflammatory space covered by the inflammation cell bodies (green surface). The immunological staining was performed by treating the sections with monoclonal antibodies raised against LCA.

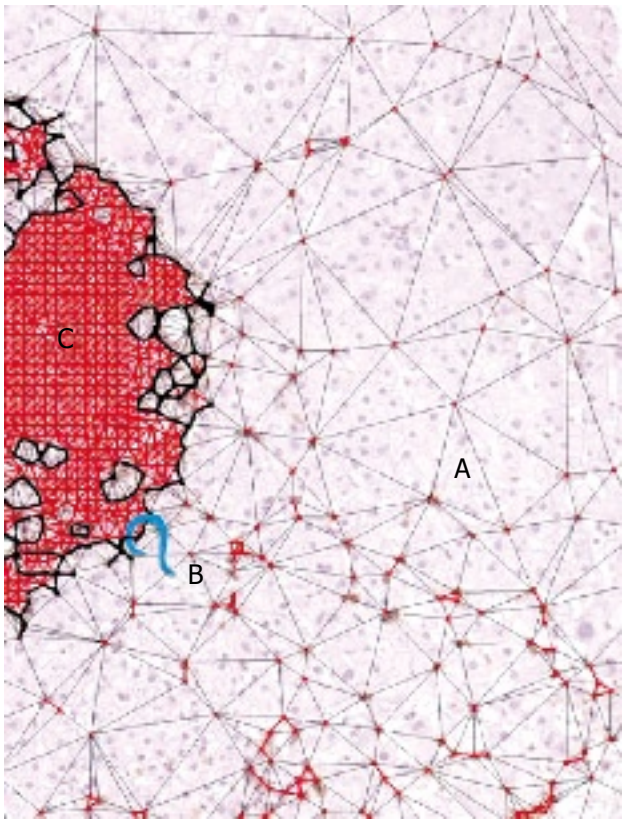

Figure 6 Liver inflammation (× 10). A: Extra-cluster inflammatory space, which is the sum of micro-areas covered by individual inflammatory cells represented by the nodes of the Delaunay' triangulation network; B: irregular outline (black line) in which lies the outermost cells distant each other no more than 20-μm; C: the irregular outline divided outermost cells from the inside resident cluster cells. The immunological staining was performed treating the sections with monoclonal antibodies raised against LCA.

structure are arbitrarily fixed using Delaunay's triangulation (Figure 5C), which defines their edges, as a continuous line, connecting the centers of the outermost cells (with a maximum distance of 20 μm)[23]. This line separates the intra-cluster inflammatory cells, from the immunologically evidenced parenchymal leukocytes throughout the tissue[23]. (2) Intra-cluster inflammatory space (Figure 5D), which is intra-cluster area covered by resident inflammatory cell bodies micro-areas[23]. (3) Extra-cluster inflammatory space, which is the sum of micro-areas covered by individual inflammatory cells that remain outside the clusters, within the liver tissue interstitium (Figure 6)[23].

Fibrosis: The fibrotic framework appears as a multifarious set of collagen islets (Figure 3). Three classes of collagen islets were arbitrarily identified on the basis of their area the first one included islets with an area of between 10 and 10^3 μm^2, the second are those with an area of between 10^3 and 10^4 μm^2, and the third are those with an area of > 10^4 μm^2[21] (Figure 7).

The wrinkledness of collagen islets is calculated using the formula:

$$W = \frac{P}{2\sqrt{\pi A}} - R$$

Where wrinkledness (W) is expressed as the ratio between the perimeter and area of an object[21], P is the frac-

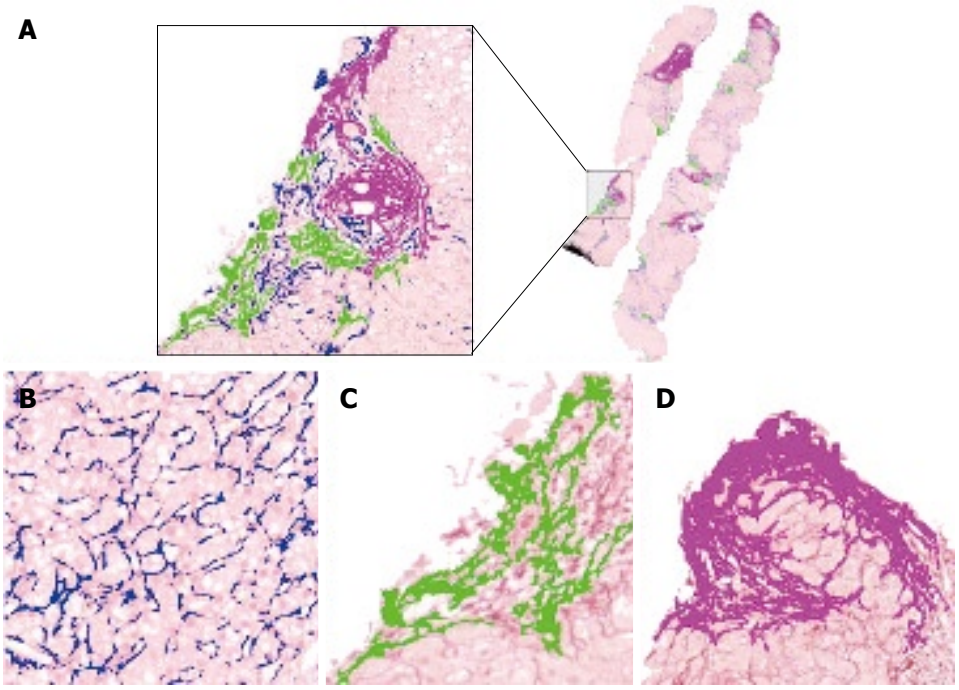

Figure 7 Liver collagen islets magnitude (× 10). A: The Histological Metriser Dioguardi distinguish and highlight with different colours three classes of Sirius-red stained collagen islets; B: islets with magnitudes arbitrarily fixed at 10-10^3 μm^2 (colored in blue); C: islets with magnitudes fixed at 10^3-10^4 μm^2 (colored in green); D: islets with magnitudes fixed at and > 10^4 μm^2 (coloured in pink).

tal-corrected perimeter of the collagen area, *A* the fractal-corrected collagen area, and *R* the roundness coefficient of the collagen islets[21].

Liver tectonics: Natural liver tectonics defines the organization of the intersecting elements of liver tissue. The tectonic order was quantitatively described by the Tectonic Index (*TCI*, which ranges from 0 to 1) obtained using the Euclidean and fractal dimensions and *TCI* was obtained from *H* using the conversion formula:

$TCI = 1 - H$

Where $H = D\gamma + 1 - D$, in which *D* is the fractal dimension and $D\gamma$ the Euclidean dimension.

TCI describes the loss of tissue organization or any deviation from natural order: a high *TCI* indicates a high degree of tissue disorder, and a low *TCI* indicates a low degree of tissue disorder. It can therefore be written:

$TCI = 1 - H = D - D\gamma$

Fractal dimension correction of the IS meter

The irregularity of collagen islets makes it impossible to measure them using IS linear units unless these units are corrected by means of fractal dimension[20,21]. This correction makes it possible to include details of shape that escape (or do not interact with) linear unit measurements at any given scale[20,21]. We derived the fractal dimension using the box-counting method[20,21,28,29]. Since the biological objects has been classified as "truncated fractals"[20,21,30] we used the fractal dimension to correct the reference units as a dilation factor[20,21].

Table 2 shows the differences between the uncorrected and fractal dimension-corrected IS measurements.

Table 2 Differences between the uncorrected and fractal-corrected IS measurements of fibrosis surface extension

n	Uncorrected fibrosis extension range (%)	Mean increase of fibrosis extension after IS meter correction (%)	min (%)	max (%)

49	10-40	4	2	6

n: Number of liver biopsy.

RESULTS

Dioguardi Histological Metriser resolution power

The Dioguardi Histological Metriser resolution was assessed by computing the surface area of liver fibrosis in 13 tissue sections, and repeating the measurements 10 times in order to define the instrument error. Two objects were considered distinct if, and only if, their values and 95% confidence intervals (twice the standard deviation of the experimental values) did not overlap. The Dioguardi Histological Metriser distinguished 68 different categories, as against the six of Ishak, the five of the METAVIR scoring system, and the four of Knodell's or Sheuer's methods. The mean distance between the data with no overlap was 0.786% (range: 0.056%-2.216%).

The selective power of the metrical quantifications defines the capacity of the method to distinguish small differences in magnitude.

Comparison of metrical and semi-quantitative data

A study a part, was performed to define differences of the metrical date concerning residual hepatocytic mass inflammation, fibrosis and liver tissue tectonics on the same patient. The digital images of 61 pairs of histological biopsies from patients with hepatitis C virus-dependent disease. The first measurement was made 4-15 years after of the interval (after the antiviral treatment). The aim was to study the date differences after a long and irregular time.

For each pair of biopsies, we studied: (1) the difference

Table 3 Residual parenchyma metrical and semi-quantitative case numbers

Δ metrical measure		Semi-quantitative evaluations				
		HAI	Scheuer	Ishak	METAVIR	Average
Increase	24	19	26	26	23	23.5

(Δ) between the scalar measurements performed with Dioguardi Histological Metriser; and (2) the changes of the semiquantitative evaluation with the four most widely used semi-quantitative methods (Knodell, Sheuer, Ishak, METAVIR).

Juxtaposing the quantitative variations in the metrical measurements with the time to the same parameters studied by means of the semi-quantitative methods in order to collate the results of the two scores, we found the following. (1) The metrical measurements of residual parenchyma gave, in comparison to semi-quantitative results, fewer indications of no change and more indications of decreases (Table 3). (2) The metrical measurements of inflammation gave more indications of increases, and fewer indications of no change than the semi-quantitative results (Table 4). (3) The metrical measurements of fibrosis gave more indications of increases and fewer indications of no change than the semi-quantitative results (Table 5). (4) The quantitative evaluations of the tectonic index of liver architecture gave more indications of increased disorder, and fewer indications of no change than the semiquantitative results (Table 6).

To compare the difference of the metrical scalars, with the ordinally numbered categories is not possible, because metrical measurements are *in continuum* (and thus additive with successive points separated by $\Delta = 0$), whereas semi-quantitative evaluations are discrete and not additive with intervals of $\Delta \neq 0$.

Differences between the metrical and semi-quantitative results

On the straight line of real numbers, we reported the value of the cases grouped by each category recognized with the current semi quantitative scoring systems.

The collate of the distribution of the data reported on the state shows the overlapping of the metrical measurements that correspond to patients classified in different semi quantitative categories (Knodell, Ishak, Sheuer, and METAVIR). This highlights the inadequacy of all four semi-quantitative methods in discriminating different states of liver fibrosis (Figure 8).

Classes of magnitude of collagen islets

Our method distinguished three classes of collagen islets with magnitudes arbitrarily fixed at 10-10^3 μm^2, 10^3-10^4 μm^2, and > 10^4 μm^2 (Figure 7). As the process of fibrosis is a progressive deposition of extracellular matrix that coalesces into islets that are subsequently thickened by matricial deposits, it can be speculated that thin islets indicate the initiation and persistence of inflammation.

Stad-ging and grading

Stad-ging indicates the part of the disease course already covered and the part that remains to be covered, before it reaches its end. It is established by placing the value of fibrosis (expressed as a scalar) on the ideal trajectory that indicates the phase of fibrosis, at the time of measurement (Figure 9)[21]. In brief, stad-ging indicates the tendency of the process to evolve in both senses from one state to another.

The staging and stad-ging of fibrosis are different insofar as the former indicates the current fibrotic state, and the latter indicates the phase of the process: i.e. the percentage of the course before collagen deposition reaches its maximum level of tolerance, which in our case, was empirically found to be 32% of fibrosis. The magnitude of inflammation defines the current status (grading) of the disease process.

DISCUSSION

The aim of this study was to test the means of rapidly

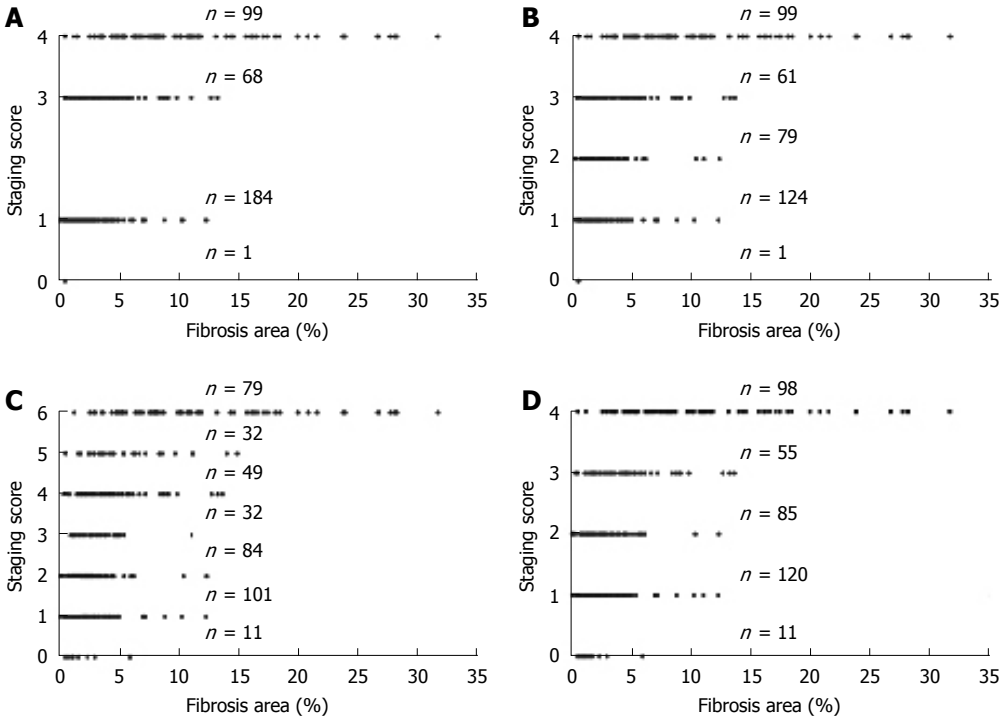

Figure 8 Comparison of the phase portraits obtained using the scalar values of fibrosis (%) calculated from each biopsy section, projected onto the state spaces. A: Knodell HAI; B: Sheuer; C: Ishak; and D: METAVIR categories (staging). All graphs highlight a considerable overlap of scalar data that corresponds to different categories. Forty-six cases for HAI, 34 for Sheuer, 10 for Ishak and 29 for METAVIR resulted uncertain to be classified in a unique category of severity.

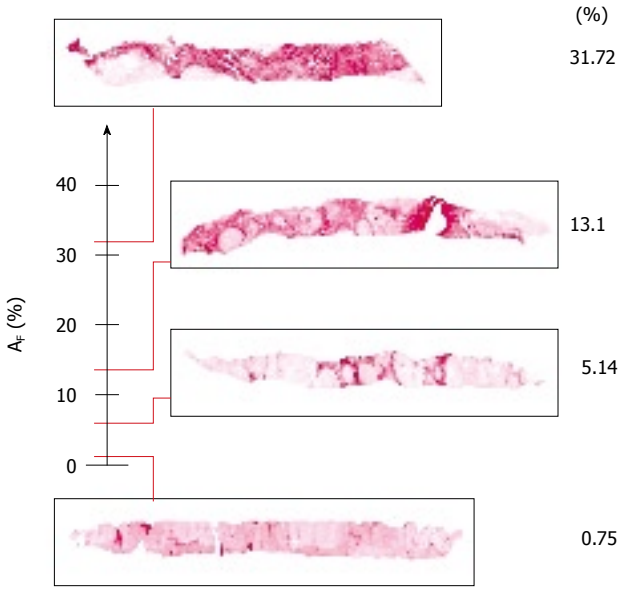

Figure 9 Stad-ging indicates the part of the disease course already covered and the part that remains to be covered before it reaches its end, and is established by placing the value of fibrosis (expressed as a scalar) on the ideal trajectory that indicates the phase of fibrosis at the time of measurement. A_F = fibrosis area (× 10).

making standardized and precise metrical measurements of pathological elements in a liver biopsy histological section using the rules of measurement theory.

The model used to make quantitative comparisons between the structural elements of the natural liver system and the same elements in liver tissue affected by chronic viral inflammation was constructed on the basis of a set of four observables, which were considered the prime structural elements of the system. Three of these (the hepatocyte sub-set, topical immune system and collagen support network) were taken as axioms for measuring the purely structural organized matter; the fourth (tissue tectonics) was taken as an axiom because it defines the harmony that orders the natural conformation of liver tissue. Recognizing these observables in their most strictly structural form makes it possible to define necrosis, the topical immune system, the collagen network and tissue tectonics in geometrical terms: (1) necrosis of the hepatocyte mass was considered a reduction, and steatosis an enlargement due to lipid deposition in the form of intercellular vacuoles; (2) inflammation was considered an enlargement of the topical immune cell system; (3) fibrosis an enlargement of natural liver collagen formed by the deposition of intercellular matrix; and (4) the transformations in liver tectonics as a reduction in the natural harmonic state of liver tissue that caused disorder in the organ's lobular structure.

This model allows the Dioguardi Histological Metriser to provide the following quantitative data: (1) the metrical extension of the residual hepatocellular set including the area of vacuoles pertinent to abnormal lipid accumulation; (2) the geometric measure of the inflammation basin (i.e. that part of the liver surface covered by inflammatory cell clusters), which distinguishes intra-basin space and extra-basin dispersed parenchymal leukocytes; (3) the magnitude of collagen islets, which were considered truncated or asymptotic planar fractals and classified into three degrees of magnitude; and (4) the TCI that quantifies alterations (disorders) in the organization of liver tissue.

To quantify these elements, the Dioguardi Histological Metriser uses three units of measurement. The first are the traditional IS units, which are used to measure the outlines of clusters and lipid vacuolization; the second are the traditional IS units corrected by the fractal dimension, which are used to measure irregular fractal collagen islets and the area of the residual hepatocellular set; and the third is the TCI, which is based on the inter-relationships between the Euclidean and fractal dimensions of liver tissue, and provides

Table 7 Side effects of liver biopsy sampling and other invasive techniques

a quantitative estimate of the loss of natural tectonic order.

On the basis of our results, it is difficult not to consider biopsies a rich source of information regarding the course of chronic liver inflammation, despite their undeniable limitations[31]. Our perseverance in studying biopsies should be seen in the light of the risks[32-36] currently accepted in many fields of medical practice[37-39] (Table 7). Quantifying liver lesions in a biopsy sample raises many questions concerning the status and organization of natural and pathological liver systems that do not seem to be merely subsidiary matters to be dealt with within the confines of a specific investigation[1].

Why adopt a new measuring method in hepatology?

One fundamental question is whether hepatology researchers or practitioners need to adopt a metrical method of tissue analysis in order to confront the everyday problems they already solve in a less precise but what they still consider to be a satisfactory manner. Viral inflammation is a dynamic process influenced by a variety of factors that generate changes in the shapes (wrinkledness) of liver tissue lesions. However, studying the evolution of liver tissue status can use no more than one biopsy, which must therefore be examined in as much detail as possible, and this makes any attempt to improve precision crucial. It is clear that the status of the organ cannot be defined quantitatively without an appropriate technology that is capable of: (1) discriminating the most representative observables; (2) eliminating imprecise identifications and measurements; (3) using a suitable metrical unit for measuring the irregularly shaped elements of the tissue; (4) standardizing the measurement of previously unavailable histological elements; and (5) considering the smallest foci of inflammation and fibrotic islets that cannot be observed through an optical microscope.

The problem of the most representative observables was solved by the model, and that of the linear IS unit was solved by correcting it by the fractal dimension of the measured object[20,21]. The problem of standardizing the measurements was solved by constructing an innovative and completely automatic instrument that excludes human error, provides objective and reproducible results, and eliminates the need for the tedious work of light microscopic analysis (the automated analysis of an entire histological section takes place at a speed of 0.1 mm^2/s).

The problem of the representativeness of a biopsy fragment (which accounts for only 1/40 000-1/60 000 of the whole liver)[12] cannot be directly solved by our method which, however, can ensure objective and mathematical precision in measuring elements that may or may not be visible through a microscope.

At this point it has to be stressed that, although our metrical measures are rigorous and reproducible, their scalars provide definitions of magnitude and not interpretations, which remain the responsibility of pathologists and clinicians.

However, our machine can already describe a histological picture in verbal and repeatable terms, and thus provide a strictly morphological diagnosis. We can also say that we have begun to consider it in terms that make it more comparable with an intelligent collaborator than a sophisticated desk computer. Finally, our data come from machine-made metrical measurements of the pathological observables in a histological pattern, and are not hypotheses based on semi-quantitative methods that can only continue to generate new hypotheses.

This paper is closed with a dedication to Robert Rosen.

ACKNOWLEDGMENTS

The authors are grateful to Professor Massimo Colombo and Dr. Guido Ronchi for their kind concession to study the specimens of the archives of Department of Gastroenterology of Ospedale Maggiore IRCCS, Milan, Italy and Dr. Rosalind Roberts, Dr. Giuseppe Peverelli and Dr. Kevin Smart for their language revisions of the manuscript.

COMMENTS

Background

Liver biopsy can be considered the gold standard for grading, staging and stad-ging the chronic liver disease. In addition, it remains a primary source for acquiring new knowledge about liver pathology.

Innovations and breakthroughs

This study introduced a new kind of liver biopsy measurement that bases the tissue state description on scalars, not with subjective interpretations (i.e. hypothesis). Furthermore, the Dioguardi Histological Metriser can describe a histological picture in verbal and repeatable terms, and thus provide a strictly morphological diagnosis.

Applications

The method, with opportune software, based on the same principles can be used for investigating also non-viral or inflammatory liver disease of other organs.

Peer review

This paper reports an impressive method for automated biopsy scoring.

Abstract

AIM: To study the mechanisms by which *Campylobacter jejuni* (*C. jejuni*) causes inflammation and diarrhea. In particular, direct interactions with intestinal epithelial cells and effects on barrier function are poorly understood.

METHODS: To model the initial pathogenic effects of *C. jejuni* on intestinal epithelium, polarized human colonic HCA-7 monolayers were grown on permeabilized filters and infected apically with clinical isolates of *C. jejuni*. Integrity of the monolayer was monitored by changes in monolayer resistance, release of lactate dehydrogenase, mannitol fluxes and electron microscopy. Invasion of HCA-7 cells was assessed by a modified gentamicin protection assay, translocation by counting colony forming units in the basal chamber, stimulation of mediator release by immunoassays and secretory responses in monolayers stimulated by bradykinin in an Ussing chamber.

RESULTS: All strains translocated across monolayers but only a minority invaded HCA-7 cells. Strains that invaded HCA-7 cells destroyed monolayer resistance over 6 h, accompanied by increased release of lactate dehydrogenase, a four-fold increase in permeability to [^{3}H] mannitol, and ultrastructural disruption of tight junctions, with rounding and lifting of cells off the filter membrane. Synthesis of interleukin (IL)-8 and prostaglandin E_2 was increased with strains that invaded the monolayer but not with those that did not.

CONCLUSION: These data demonstrate two distinct effects of *C. jejuni* on colonic epithelial cells and provide an informative model for further investigation of initial host cell responses to *C. jejuni*.

INTRODUCTION

Campylobacters are small (1.5-6.0 μm long and 0.2-0.5 μm wide) Gram-negative spiral rods. *Campylobacter jejuni* (*C. jejuni*), a foodborne organism contracted from untreated water, milk and meat, especially chicken, is one of the most important causes of bacterial diarrhea worldwide[1-4]. The clinical spectrum ranges from non-inflammatory watery diarrhea to an acute entero-colitis with neutrophilic invasion of the mucosa and bloody diarrhea mimicking ulcerative colitis.

Much work has been conducted on laboratory strains such as NCT11168, which has been completely geno-

typed. This has allowed a number of virulence factors to be identified, including a number of flagellar proteins, which not only enable chemotaxis towards mucus and amino acids and epithelial cell invasion[5-7], but also facilitate secretion of non-flagellar virulence proteins[6], O-linked glycosylation, which is required for optimal flagella function[7], proteins secreted *via* flagella that result in epithelial cell invasion and apoptosis[8-10], a cytolethal distending toxin (CLDT)[11] with DNAse activity[12], associated with apoptosis[13] and secretion of interleukin (IL)-8 and other chemokines[14,15] and a lipo-oligosaccharide that resembles human neuronal gangliosides, which may pre-dispose to autoimmune phenomena such as Guillain-Barre syndrome[16].

Clinical isolates vary in the extent to which they express these virulence factors. *C. jejuni* display heterogeneity in its ability to invade cells of the intestinal epithelial layer[17-21]. Estimates of the proportion of clinical isolates that are characterized by toxin production range from 12% to 100%[22]. Cell death may occur by a variety of mechanisms, not all involving CLDT[23]. Release of chemokines such as IL-8 seems to occur by CLDT-dependent and independent mechanisms[14], and it is unclear how far inflammatory responses to *C. jejuni* infection, such as secretion of chemokines, correlate with reported differences in the ability of the bacteria to invade epithelial cells, or how much this is due to responses of cells in the lamina propria, such as macrophages. Similarly, the extent to which secretory responses by epithelial cells can maintain a secretory diarrhea, which is characteristic particularly of childhood infection, is also unclear. One possibility is that *C. jejuni* induces synthesis of prosecretory compounds such as prostaglandins directly in epithelial cells[24-27]. An earlier study that failed to show this might have been flawed because it used CaCo2 cells, which do not readily express cyclo-oxygenases (COXs) or synthesize prostaglandins[28].

In order to investigate the direct effects of *C. jejuni* on colonic epithelial function *in vitro*, we therefore exposed the well-differentiated colonocyte line HCA-7, clone 29 to a panel of primary clinical isolates. Our data suggest two distinct patterns of interaction between *C. jejuni* and colonic epithelium, with a minority of strains invading colonic epithelial cells, which causes barrier destruction and induces elaboration of potentially pro-inflammatory mediators.

MATERIALS AND METHODS

Bacterial strains

Nineteen consecutive *C. jejuni* clinical strains from community patients with acute bacterial enteritis were isolated and characterized by the Laboratory of Public Health, University Hospital, Nottingham, UK. Of these, three fresh clinical isolates (strains 2801055, 2102011 and 1702030*)* were used for detailed studies along with the laboratory strain 12189 (a kind gift from Dr. J Ketley), originally isolated from a patient with diarrhea and passaged several times in the laboratory[28]. Strains were grown microaerobically for 48 h on chocolate agar plates prior to inoculation into tissue culture flasks containing liquid medium (RPMI 1640 supplemented with 4% Isosensitest broth and 5% FCS) (Sigma, UK). A stock of the original isolates was aliquoted and frozen at -80℃. For study of bacterial-epithelial cell interactions, bacteria were resuspended in 4% Isosensitest broth with 5% FCS. After static microaerobic incubation for 24 h, bacteria were pelleted, washed and resuspended in PBS.

The bacteria were diluted in Dulbecco's modified Eagle's medium (DMEM) (Sigma, UK) to different concentrations (10^5-10^8 bacteria/mL). Determination of the number of bacteria was standardized by optical density at a wavelength of 570 nm. Growth curves for the different strains and titration and culture of serial dilutions was used to establish the number of bacteria in culture. This was done by incubating the different strains grown on a chocolate agar plates in Isosensitest broth (5% FCS) overnight. After centrifugation (7000 r/min, 5 min) and washing in PBS, bacteria were resuspended in 1 mL PBS, and serial diluted. Each dilution was measured in a spectrophotometer at a wavelength of 540 nm. Each sample was then serially diluted in a 96-well plate and dilutions incubated on chocolate agar plates. After overnight growth, bacterial colonies were counted and plotted against absorbance. The results were used to establish bacterial numbers before incubating epithelial cells.

Cell culture

Tumor-derived colonic epithelial cells, HCA-7, colony 29 (a kind gift from Susan Kirkland) were cultured as described previously[29]. Briefly, cells were grown in DMEM with 10% FCS, glutamine (0.29 mg/mL), ampicillin (8 μg/mL), penicillin (40 μg/mL), streptomycin (368 μg/mL) and non-essential amino acids in an atmosphere of 5% CO_2 at 37℃. For studies of bacterial cell interactions, normal medium was replaced with antibiotic-free medium for at least 24 h. Tests for mycoplasma contamination were not performed. For electrophysiological studies, cells (10^5 cells/membrane) were seeded on Snapwell or Transwell filters (polycarbonate membrane, pore size 0.45 μm, surface area 1 cm^2; Costar UK Ltd) and formed confluent monolayers within 8-10 d, as assessed by an epithelial volt-ohmmeter (EVOM; World Precision Instruments, Stevenage, UK)[29].

Effect of C. jejuni on barrier function

Bacteria were grown and added to the apical side of monolayers grown on Transwell or Snapwell filters at a concentration of 10^4-10^8 bacteria/monolayer. Transepithelial resistance was measured with an EVOM at various timepoints up to 24 h after inoculation with different concentrations of bacteria. These data were supported by detailed studies of filter-grown monolayers voltage-clamped in Ussing chambers (World Precision Instruments) and by assessment of [^{3}H] mannitol flux[26].

Ussing chamber studies

Confluent HCA-7 cell monolayers were inoculated on the apical side with varying amounts of strains of *C. jejuni*. After different time periods, filters were

placed in an Ussing chamber and voltage-clamped by continuous application of a short circuit current (SCC)[30]. Resistance (Ω cm^2) was measured under basal conditions and the change in short circuit current (ΔSCC μA/cm^2) after basolateral stimulation by bradykinin (10^{-6} mol/L), and finally after similar stimulation by carbachol (10^{-4} mol/L).

Invasion assay

Invasion of epithelial cells was investigated using a gentamicin invasion assay[18]. Bacteria were grown in 4% Isosensitest broth and 5% FCS. After static microaerobic incubation for 24 h, bacteria were pelleted, washed and resuspended in PBS. Bacterial number was assessed spectrophotometrically and 10^6 organisms added to the cell monolayer. Infected monolayers were incubated for up to 6 h at 37℃, washed and covered with tissue culture medium containing gentamicin (100 μg/mL). After 90 min, the integrity of the monolayer was checked microscopically, then washed in PBS and flooded with 1 mL 10 mL/L Triton X-100 for 5 min, to release intracellular bacteria. Dilutions and viable counts were made of the bacteria within the lysed monolayer. Positive control was a *Yersinia enterocolitica* invasive strain 8081c, and the negative control was *Escherichia coli* non-invasive strain HB101. When it became clear that monolayer destruction occurred with some bacteria, we modified the assay to correct for the number of remaining cells per monolayer. We calculated the number of cells remaining per monolayer by using a hemocytometer, before lysing to obtain counts of intracellular protected bacteria.

Lactate dehydrogenase (LDH) release

HCA-7 cells were incubated with *C. jejuni* for 4 h. Media from the apical reservoir of bacterium-exposed and control monolayers were then collected and analyzed for spontaneous LDH using a colometric assay (Sigma)[31]. In addition, total intracellular LDH concentration from HCA-7 cells was determined by addition of 1 mL 0.1% Triton X-100 to wells of bacterium-exposed and control monolayers. After vigorous pipetting to ensure lysis of all cells, the homogenate was then collected from each well and was also assayed for LDH.

[^{3}H] mannitol flux

Mannitol flux studies were performed in an Ussing chamber[32]. Mannitol (final concentration 5 mmol/L) was added to both sides of the monolayer in Krebs solution. After equilibration of the epithelial monolayer, [^{3}H] mannitol (1 μCi/mL) was added to the apical side. Radioactivity was counted on samples from the basolateral compartment at 15-min intervals for 60 min. Basolateral chamber volume was maintained by replacing the sample aliquot with an equal volume of fresh Krebs buffer. Apical to basolateral flux, expressed as mol·h/cm^2, was calculated by relating the accumulation of tritium in the basolateral chamber compared to the apical.

Electron microscopy (EM)

Filters with HCA-7 cells inoculated with 10^7 bacteria for 6 h where fixed by immersion in 2.5% glutaraldehyde (in 0.1 mol/L cacodylate buffer, pH 7.4). Subsequent processing was performed as described previously[25].

Bacterial translocation

Translocation was measured by inoculating the apical side of monolayers with 10^7 bacteria/0.5 mL. Medium from the basolateral compartment was collected after 2, 4, 6 and 8 h inoculation, diluted 10-fold and cultured on agar plates[33,34]. After each collection, membranes were transferred to fresh wells to establish the number of bacteria translocating over each 2-h period. The number of bacteria was established by counting colony-forming units at each time interval to establish the total number of bacteria translocated. Colony forming units where counted after microaerophilic incubation for 24 h to assess the time course of bacterial translocation.

IL-8 measurement

Level of IL-8 in the basolateral supernatant after 6 h incubation with different strains of *C. jejuni* and of control monolayers was measured using a quantitative ELISA[14] (Amersham, UK). Samples were pipetted into wells coated with specific antibody for IL-8, followed by incubation with a biotinilated antibody reagent. After extensive washing, a streptavidin-horseradish peroxidase conjugate was added and developed with 3,3',5,5'-tetramethylbenzidine substrate. After terminating the reaction, the optical density was read at 450 nm. Detection level was 25-1000 pg/mL.

PGE2 measurement

Aliquots of supernatant were prepared in the same way as for IL-8 release. PGE2 levels were measured by ELISA (Amersham), based on competition between unlabeled PGE2 and a fixed quantity of peroxidase-labeled PGE2 for a limited amount of PGE2-specific antibody[35].

Statistical analysis

Analysis of variance was used in experiments where time or dose was varied, to investigate the influence of cellular invasive and non-invasive bacteria and the interaction with time. For simple comparisons, unpaired *t* tests were used. $P < 0.05$ was considered statistically significant. Statistical analysis was performed using PRISM (Graphpad, San Diego, CA, USA) or Statistical Package for the Social Sciences (SPSS, Chicago, IL, USA).

RESULTS

Transepithelial resistance

Fourteen of the 19 clinical strains tested, as well as the laboratory isolate 12189 had no effect on transepithelial resistance up to 24 h. In contrast, the other five fresh clinical isolates abrogated monolayer resistance entirely by 6 h. These differences did not correlate with rates of translocation. Detailed studies, with strain 2801055 which abrogated transepithelial resistance, showed that decrease in transepithelial resistance varied with bacterial load and was

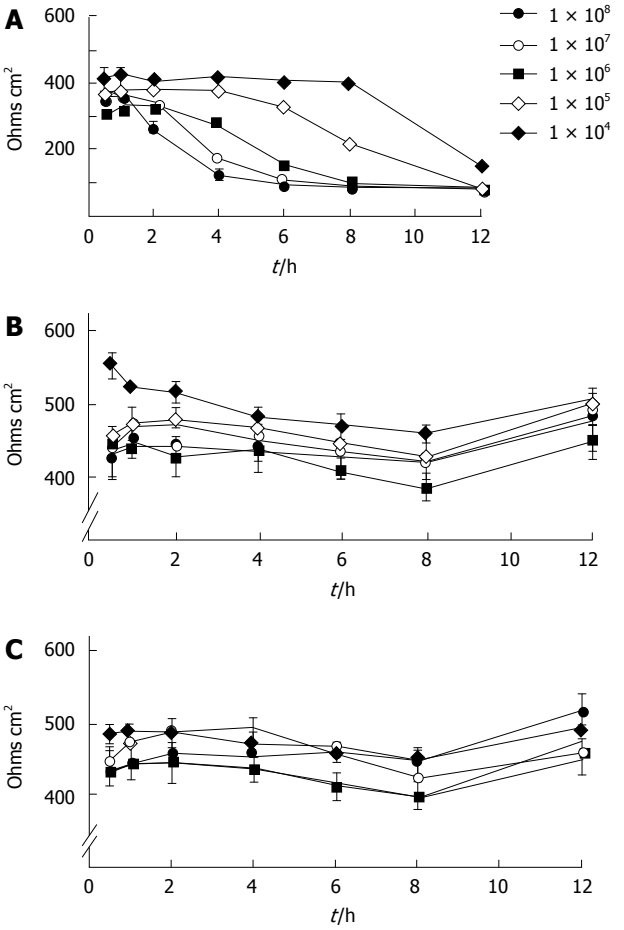

Figure 1 Time course and dose-response of changes in transepithelial resistance after inoculation of T84 cells with three different strains of C jejuni. A: Strain 2801055 reduced resistance to baseline over 6 h in a time- and dose-dependent manner [data are mean ± SE, n = 3 for each bacterial concentration; P < 0.05 compared with controls (uninfected monolayers)]. Baseline resistance across the filter membrane was 100 Ω.cm^2; B: Strain 12189 had no effect on resistance across the monolayer; C: Strain 2102011 had no effect on resistance across the monolayer.

time dependent, starting after 2 h of inoculation with 10^8 bacteria/0.5 mL (Figure 1). With strains 12189 or 2102011, no changes were seen at any time with any of the bacterial loads inoculated (Figure 1). Measurements in Ussing chambers mirrored those obtained with the EVOM with the different strain types. There was no significant difference in electrical resistance in monolayers infected with the strains 12189 and 2102011 at 4 and 8 h. However, strain 2801055 showed a time-dependent decrease in transepithelial resistance, with resistance falling to 71.3% and 17.7% of control at 4 and 8 h respectively (P < 0.05 *vs* control at 8 h).

Invasion of epithelial cells by C. jejuni

The standard gentamicin protection assay showed that 1.15% ± 0.05% of the positive control strain *Y. enterocolitica* invaded HCA-7 cells *vs* 0.0005% with the negative control strain *E. coli* HB101. Overall, *C. jejuni* showed levels of HCA-7 invasion that were intermediate between these values. Analysis of variance showed that the total number of *C. jejuni* per monolayer was higher for those that abrogated monolayer resistance compared to those that did not (P = 0.033), and that this increased with

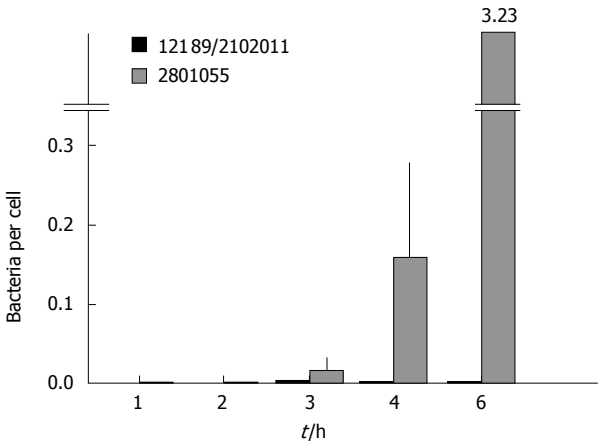

Figure 2 Invasion of monolayers of HCA-7 cells determined by a gentamicin protection assay, corrected for the number of cells remaining per monolayer. *C. jejuni* strain 2801055 invaded the cells of the monolayer in a time-dependent manner, while strains 12189 and 2102011 showed no cellular invasion. Data are mean ± SE, n = 4. Analysis of variance showed that the total number of *C. jejuni* per monolayer was higher for those strains that abrogated transepithelial resistance compared to those that did not (P = 0.033), and that this increased with time (P = 0.02).

time (P = 0.02). When the number of bacteria was related to the number of HCA7 cells remaining in the monolayer at the time of assessment, there was a substantial and highly significant difference between strains that destroyed and did not destroy the monolayer (Figure 2).

LDH release

LDH release from monolayers inoculated with the cell-invasive strain 2801055 was significantly increased after 24 h compared to inoculation with the non-invasive strains 12189 and 210211 (n = 4 per experiment, P < 0.05). LDH release with these strains did not differ from that seen with uninfected monolayers (Figure 3A).

Transepithelial mannitol flux

Cumulative flux data show that strains 12189 and 210211 did not change the flux of [^{3}H] mannitol, which indicated an intact paracellular resistance, whilst strain 2801055 increased the flux significantly (Figure 3B).

EM studies

In keeping with electrophysiological results, strains 12189 and 2102011 did not affect cellular morphology (Figure 4A and B). Monolayers infected with these strains showed close cell-to-cell contact, but bacteria were occasionally located in the pores of the filter membrane (Figure 4C). In contrast, strain 2801055 showed marked cellular and tight junction destruction at 6 h (Figure 4D). There was cell rounding and condensation of the plasma membrane (Figure 4E). In addition, cells were lifted off the filter membrane and multiple bacteria were seen between epithelial cells and the filter (Figure 4E and F).

Bacterial translocation

All strains tested translocated across the monolayer to become detectable after 2 h, with no obvious inter-strain differences.

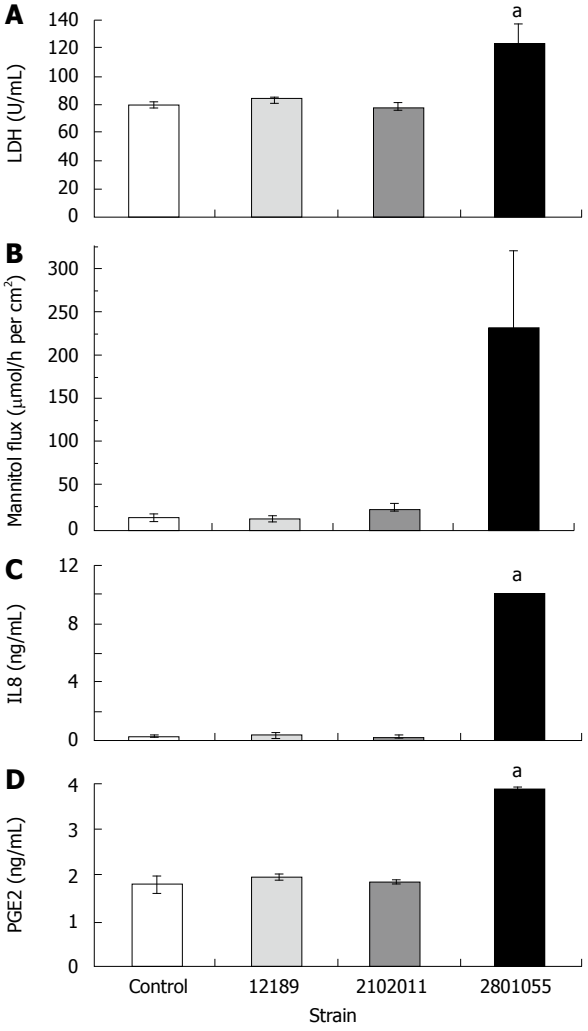

Figure 3 HCA-7 monolayer release of LDH, [^{3}H] mannitol flux and release of IL8 and PGE2 after inoculation with different strains of *C. jejuni*. All data are mean ± SE at 4 h, (n = 4). A: Strain 2801055 showed a significantly higher LDH release after 4 h ($^aP < 0.05$) incubation compared to the other two strains, which were similar to control values; B: Strain 2801055 induced a significantly higher flux rate across the monolayer after 4 h ($^aP < 0.05$) incubation compared to the other two strains, which were similar to control values; C: Strain 2801055 showed a significantly higher IL8 release after 4 h ($^aP < 0.05$) incubation compared to the other two strains, which were similar to control values; D: Strain 2801055 showed a significantly higher PGE2 release after 4 h ($^aP < 0.05$) incubation compared to the other two strains, which were similar to control values.

IL-8 production

IL-8 release from HCA-7 monolayers increased in response to inoculation with the invasive strain 2801055, whereas IL-8 release with the non-invasive strains 12189 and 210211 was not significantly different from that seen in uninfected monolayers (Figure 3C).

PGE2 release

There was a two-fold rise in PGE2 released after inoculation with the invasive strain 2801055 (n = 4, $P < 0.05$). By contrast, PGE2 levels for strains 12189 and 2102011 were similar to spontaneous PGE2 production in control monolayers (Figure 3D).

Bradykinin- and carbachol-induced secretion

Bradykinin 10^{-6} mol/L administered basolaterally induced a ΔSCC of 19.83 ± 3.25 μAmp/cm^2. ΔSCC responses to bradykinin were significantly enhanced by 30% compared with control (uninfected) monolayers at 4 h (n = 4, $P < 0.05$ for all 3 strains Figure 5A), but were lost at later time points, when there was a significant reduction with strain 2801055. The early increase was not seen in response to carbachol (Figure 5B), and at 8 h was significantly decreased with strains 2801055 and 2102011 (n = 4, $P < 0.05$).

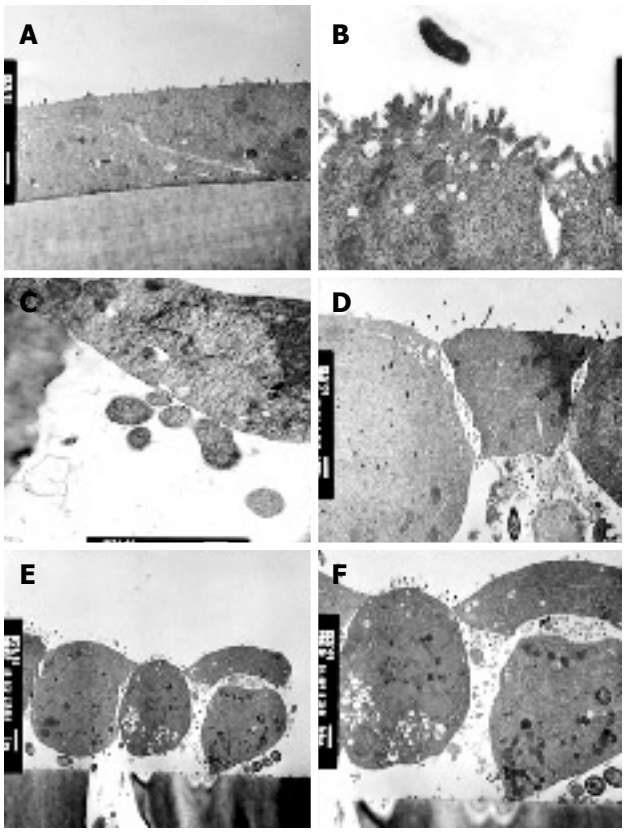

Figure 4 Comparison of the effects of strains 12189 and 2801055 on transmission electron micrograph appearance of monolayers of HCA-7 cells. A: Following inoculation of strain 12189, 10^7 bacteria/0.5 mL, on the apical side for 6 h, there was no disruption of monolayer integrity; B: There were normal tight junctions and normal apical microvilli; C: Close cell-to-cell contact is seen with occasional bacteria located in the pores of the filter membrane; D: Following inoculation of strain 12189, 10^7 bacteria/0.5 mL, on the apical side for 6 h, monolayer integrity was compromised with disruption of tight junctions; E: Monolayers showed condensation of the plasma membrane with lifting and rounding of cells off the supporting membrane. *C. jejuni* are also seen beneath a cell which is lifting off the membrane; F: Changes are seen at higher power.

DISCUSSION

In this study, we showed two distinct patterns of interaction between clinical isolates of *C. jejuni* and a colonic epithelial cell line. Strains that invaded epithelial cells were shown to destroy them, as demonstrated by a fall in transepithelial resistance and release of LDH. These processes were accompanied by release of IL-8 and PGE2. Strains that did not invade epithelial cells did not affect barrier properties or increase mediator production.

Translocation to the lamina propria[2,33] and a consequent interaction between bacterial antigens and antigen presenting cells, immunocytes and macrophages in the

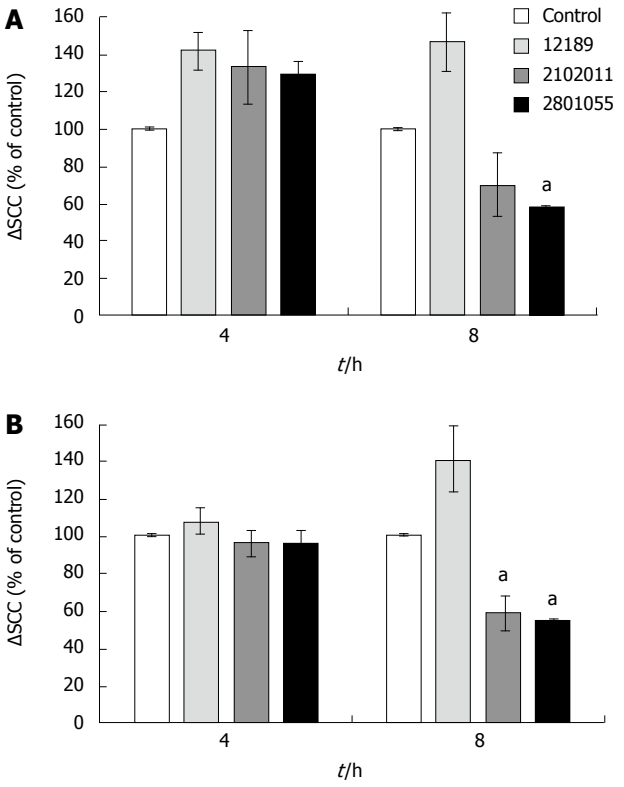

Figure 5 ΔSCC after stimulation with bradykinin (10^{-6} mol/L) and carbachol (10^{-4} mol/L) in monolayers inoculated with different strains of *C. jejuni*. Data are mean ± SE (n = 4) and are shown as percentage of control. A: Reduced chloride secretory response (represented by SCC) to bradykinin after 8 h inoculation with strain 2801055. $^aP < 0.05$; B: Reduced chloride secretory response to carbachol after 8 h inoculation with strains 2801055 and 2102011. $^aP < 0.05$.

lamina propria[36], is likely also to result in production of cytokines and chemokines. However our data show that epithelial cells can themselves be a source of mediators that could influence inflammatory and secretory processes in the case of strains that invade epithelial cells.

Although a paracellular route has been invoked to explain the ability of *C. jejuni* to invade the mucosa and achieve systemic infection, intracellular bacteria have been reported and a paracellular route of invasion inferred[37]. Using a modified gentamicin protection assay that allows for cell death, we were able to confirm cellular invasion by *C. jejuni*, and showed that this was associated with cytotoxicity and elaboration of pro-inflammatory and pro-secretory molecules. As yet it is uncertain whether intracellular invasion directly causes the associated release of IL-8 and PGE2, or whether this is a secondary consequence of cell death. A direct specific effect is possible since we have reported that IL-8 synthesis and PGE2 release from epithelial monolayers also occur in response to treatment with a boiled cell-free extract of *C. jejuni*[38], with induction of COX-2[39] and activation of nuclear factor-κB (NF-κB) and other relevant signaling pathways[40].

Enhanced release of IL-8 and other chemokines would play an important role in chemoattraction of neutrophils that characterizes some clinical infections with *C. jejuni*. Whether the increased prostaglandin synthesis that we observed with cellular invasion is sufficient under some circumstances to induce secretory diarrhea is more difficult to evaluate. We showed an early increase in bradykinin-induced secretion, as indicated by changes in SCC, with all strains tested, including non-invasive strains that did not stimulate prostaglandin synthesis. This increase in bradykinin-induced chloride secretion may therefore occur by prostaglandin-independent mechanisms. Direct epithelial action, *via* cAMP, cGMP, calcium mobilization, or induction of galanin or inducible nitric oxide are alternative mechanisms that are activated directly by bacterial enterotoxins or *via* signaling mechanisms that include NF-κB, which we and others have shown are upregulated by components of *C. jejuni*[24-27,40-43]. Destruction of the monolayer by strains that did invade epithelial cells and stimulate prostaglandin synthesis makes it difficult to evaluate whether enhanced prostaglandin synthesis by epithelial cells contributed to secretory diarrhea in these cases.

Campylobacter, like *Salmonella*, *Yersinia*, *Shigella* and *Listeria*, is an organism capable of translocation, as demonstrated by the current and previous monolayer studies and clinical features that include septicemia, Guillain-Barre syndrome and meningitis[16,33,34,41]. Previous studies have left unclear whether the main route is transcellular or paracellular. Both have been described. Our data suggest the translocation across the monolayer is common since all of the 19 clinical strains isolated from patients and one laboratory strain showed this property, regardless of whether they invaded epithelial cells and/or destroyed the monolayer. This suggests a dominant paracellular route of translocation, which is supported by our EM observations, which showed bacteria in the paracellular space. This appeared to occur efficiently, as judged by the rate of accumulation of bacteria on the basolateral side, and without gross disruption of tight or adherence junctions, as judged by the unchanged transepithelial resistance and mannitol permeability, seen with strains that translocated without epithelial cell invasion.

In the case of bacteria that invaded and destroyed the epithelial monolayer, translocation could be a crude consequence of its destruction, although bacteria that destroyed the monolayer did not appear to translocate faster than those that did not. Translocation results may differ according to the cell type used for epithelial monolayers. In previous studies that used differentiated CaCo2 cells, cellular invasion was not accompanied by the complete abrogation of monolayer resistance seen in our study and not all strains translocated[34]. We chose to use HCA7 cells in preference to CaCo2 cells because they have a differentiated large rather than small bowel phenotype and because they are capable of expressing COX-2 under induction conditions. Our data suggest that this is an informative model and cell line to study disease pathogenesis and signaling mechanisms[40].

COMMENTS

Background

Campylobacter jejuni (*C. jejuni*) is the commonest cause of bacterial diarrhea worldwide but its mode of pathogenesis is not clear.

Research frontiers

Since this work was done, the *Campylobacter* genome has been sequenced. Work following from the current study has investigated gene expression and has shown that chemokines play a central role.

Innovations and breakthroughs

The paper underlines the importance of allowing for cell destruction when doing gentamicin assays. Unlike many previous studies, this one used clinical isolates, which showed that there were two distinct patterns for the effect of *C. jejuni* on colonic epithelial cells. The cells themselves have the capacity to generate chemoattractant molecules, without necessary involvement of immune and other cells in the lamina propria.

Applications

Showing that *Campylobacter* spp. are cell invasive and stimulate production of chemoattractant mediators points to possible targets for treatment.

Terminology

Ussing chamber: Monolayers are grown on a permeable filter. When cells form tight junctions they cause resistance to an electrical current passed through the monolayer.

Peer review

The majority of previous studies regarding *C. jejuni* have been performed using a laboratory strain NCT11168. This manuscript is considered to contain attractive information for enhancing the understanding the mechanism of *C. jejuni* infection. It's an interesting paper.

Abstract

AIM: To investigate the protective effects of magnolol on sepsis-induced inflammation and intestinal dysmotility.

METHODS: Sepsis was induced by a single intraperitoneal injection of lipopolysaccharide (LPS). Male Wistar rats were randomly assigned to one of three treatment groups: magnolol prior to LPS injection (LPS/Mag group); vehicle prior to LPS injection (LPS/Veh group); vehicle prior to injection of saline (Control/Veh). Intestinal transit and circular muscle mechanical activity were assessed 12 h after LPS injection. Tumor necrosis factor-α (TNF-α), interleukin-10 (IL-10), monocyte chemoattractant protein-1 (MCP-1) and inducible nitric oxide synthase (iNOS) mRNA in rat ileum were studied by RT-PCR 2 h after LPS injection. Nuclear factor-κB (NF-κB) activity in the intestine was also investigated at this time using electrophoretic mobility shift assay. In addition, antioxidant activity was determined by measuring malondialdehyde (MDA) concentration and superoxide dismutase (SOD) activity in the intestine 2 h after LPS injection.

RESULTS: Magnolol significantly increased intestinal transit and circular muscle mechanical activity in LPS-treated animals. TNF-α, MCP-1 and iNOS mRNA expression in the small intestine were significantly reduced after magnolol treatment in LPS-induced septic animals, compared with untreated septic animals. Additionally, magnolol significantly increased IL-10 mRNA expression in septic rat ileum. Magnolol also significantly suppressed NF-κB activity in septic rat intestine. In addition, magnolol significantly decreased MDA concentration and increased SOD activity in rat ileum.

CONCLUSION: Magnolol prevents sepsis-induced suppression of intestinal motility in rats. The potential mechanism of this benefit of magnolol appears to be modulation of self-amplified inflammatory events and block of oxidative stress in the intestine.

Magnolol attenuates sepsis-induced gastrointestinal dysmotility in rats by modulating inflammatory mediators. *World J Gastroenterol* 2008; 14(48): 7353-7360 Available from: URL: http://www.wjgnet.com/1007-9327/14/7353.asp DOI: http://dx.doi.org/10.3748/wjg.14.7353

INTRODUCTION

Sepsis frequently occurs after trauma, burns, hemorrhage or abdominal surgery. It is a leading cause of morbidity and mortality in critically ill patients[1]. During sepsis, the most frequent complications within the gastrointestinal (GI) tract are ileus and mucosal barrier dysfunction[2]. Ileus plays an important role in the pathophysiology of sepsis by promoting bacterial stasis, bacterial overgrowth and bacterial translocation, which lead to the development of secondary infections and multiple organ failure[3].

Although common during sepsis, the etiology of ileus is still unclear. Current evidence supports the hypothesis that lipopolysaccharide (LPS) rapidly activates resident intestinal macrophages, which subsequently initiate a molecular and cellular inflammatory response that causes intestinal dysmotility[4-6]. Additionally, oxidative stress during sepsis may also be involved in this process[7]. Currently, there is no accepted pharmacological prevention or management of sepsis-induced intestinal

dysmotility. Blocking oxidative stress and modulating the inflammatory events might be helpful.

Magnolia officinalis, a traditional Chinese herb, is commonly used in the treatment of abdominal distention and vomiting associated with many clinical conditions. It has been reported to attenuate L-arginine-induced GI dysmotility in rodents[8], and to improve the electrical activity of GI smooth muscle during endotoxemia[9]. Recently, magnolol (5,5'-di-2-propenyl-1,1'-biphenyl-2,2'-diol), a principal constituent isolated from the bark of *Magnolia officinalis*, has been showed to attenuate peroxidative damage and to improve survival of rats with sepsis[10]. Treatment with magnolol after hemorrhagic shock can suppress the tumor necrosis factor-α (TNF-α) level and preserve interleukin-10 (IL-10) production in rats[11].

Thus, we have developed the hypothesis that through modulation of inflammatory cytokines during sepsis, magnolol may be helpful for treatment of sepsis-induced ileus. Therefore, the objective of the present study was to examine the capacity of magnolol pretreatment to prevent sepsis-induced intestinal dysmotility and to determine its effects on pro- and anti-inflammatory molecular responses in the local intestine.

MATERIALS AND METHODS

Animal preparation and experimental design

Male Wistar rats (250-300 g body weight) were obtained from the Academy of Military Medicine Sciences (Beijing, China). The rats were exposed to 12 h light and 12 h darkness each day, with free access to food and water. All experiments were performed in accordance with the institutional criteria for the care and use of laboratory animals in research. Sepsis was induced by a single intraperitoneal injection of LPS (*Escherichia coli*, O55: B5; Sigma, St Louis, MO, USA) at 20 mg/kg. Controls received intraperitoneal injections of saline.

Magnolol (National Institute for the Control of Pharmaceutical and Biological Products, China) was dissolved in 40% (v/v) propylene glycol and diluted to the desired concentration in normal saline. Final concentration of propylene glycol in the injected solution was < 4.0×10^{-3}% (v/v). The single dose used for the magnolol instillation was 10^{-5} g/kg, which was previously shown to be helpful for increasing survival of surgically induced sepsis[10]. Normal saline with 4.0×10^{-3}% (v/v) propylene glycol served as a vehicle.

Animals were randomly assigned to one of three treatment groups. LPS/Mag group: rats received magnolol (10^{-5} g/kg, intravenous bolus *via* the tail vein) 30 min before LPS injection; LPS/Veh group: rats received vehicle 30 min before LPS injection; Control/Veh: rats received vehicle 30 min before injection of saline. Preliminary results showed that intraperitoneal injection of LPS caused a profound suppression of intestine muscle contractile activity, which was both dose- and time-dependent. Furthermore, the effects of LPS are always rat strain specific and relate to the serotype of LPS[12]. In this study, we chose the 12-h time point for measurement of intestinal smooth muscle function. To elucidate the potential mechanism for magnolol preventing sepsis-induced ileus, we also evaluated changes in the chemokines and cytokines in the intestine 2 h after LPS injection, because the inflammatory response in the local intestine rapidly initiated by LPS is always responsible for GI dysmotility[4-6].

Intestinal transit

Twelve hours after LPS (or saline) was administered, the animals received an intragastric injection of 0.1 mL Evans blue (50 mg in 1 mL 0.9% NaCl). Then, the rats were killed by exsanguination 1 h later. Intestinal transit was determined by measuring the distance between the gastric pylorus and distal small intestine that was stained blue[13].

Measurement of muscle contractility

Circular muscle mechanical activity was assessed using full-thickness strips obtained from the ileum of each animal 12 h after LPS (or saline) injection. Muscle strips (2 × 10 mm) were placed in a mechanical organ chamber that was continuously perfused with pre-oxygenated Krebs-bicarbonate solution maintained at 37℃. One end of each strip was tied to a fixed post, and the other was attached to an isometric force transducer. After an equilibration period of 30 min, spontaneous mechanical contractions were recorded. The contractile responsiveness of muscle strips to the muscarinic receptor agonist bethanechol was also evaluated. Dose-response curves were generated by exposing the muscles to increasing concentrations of bethanechol (0.1-100 μmol/L) for 10 min; with intervening 20-min wash periods. Contractions were recorded, measured, and stored in a computer using a commercially available hardware and software package (TaiMeng Technology, Chengdu, China).

RT-PCR

To elucidate the potential mechanism of magnolol treatment blunting sepsis-induced intestinal dysmotility, mRNA for TNF-α, IL-10, monocyte chemoattractant protein 1 (MCP-1) and inducible nitric oxide synthase (iNOS) in rat ileum was assessed by RT-PCR.

Total mRNA was extracted with TRIZOL Reagent (GIBCO BRL, USA). Reverse transcription was performed using a Reverse Transcription System Kit (Promega, Madison, WI, USA) according to the manufacturer's protocol. Primers were designed and purchased from AuGCT Biotechnology (Beijing, China). β-actin was used as an endogenous control. The sequences of the RT-PCR primers are listed in Table 1. PCR was performed with 25 μL reaction mixture of 1 μL RT product, 2 mmol/L $MgCl_2$, 0.03 U/L Taq DNA polymerase, 0.4 mmol/L dNTP, 0.1 μmol/L primer (endogenous control, target genes), and 1 × Taq DNA polymerase magnesium-free buffer. Then, the reaction

Table 1 Primer sequences

Gene	Primer sequences	Product size (bp)
β-actin	F 5' GAAATCGTGCGTGACATTA 3' R 5' TAGGAGCCAGGGCAGTAA 3'	349
TNF-α	F 5' GTAGCAAACCACCAAGCAG 3' R 5' GGTATGAAATGGCAAATCG 3'	211
IL-10	F 5' GCTATGTTGCCTGCTCTT 3' R 5' ATGCTCCTTGATTTCTGG 3'	307
MCP-1	F 5' ACTTGACCCATAAATCTGA 3' R 5' TGGAAGGGAATAGTGTAAT 3'	168
iNOS	F 5' TTGGGTCTTGTTAGCCTAGTC 3' R 5' TGTGCAGTCCCAGTGAGGAAC 3'	264

mixture was overlaid with two drops of mineral oil and incubated in a thermocycler (Eppendorf, Germany) programmed to pre-denature at 94℃ for 2 min, denatured at 94℃ for 30 s, annealed at 55℃ for 30 s, and extended at 72℃ for 30 s for a total of 30 cycles. The last cycle was followed by a final incubation at 72℃ for 6 min and cooling to 4℃. PCR products were electrophoresed on a 1.2% agarose gel and saved as digital images. Relative quantities of target gene mRNA were analyzed by Quantity One software (Bio-Rad Laboratories, USA), normalized with β-actin expression.

Electrophoretic mobility shift assay (EMSA)

Nuclear protein of rat ileum was prepared by hypotonic lysis followed by high salt extraction[14,15]. Nuclear factor-κB (NF-κB) activity in the nuclear extract was analyzed using the EMSA kit according to the manufacturer's protocol (Gel Shift Assay System; Promega). In brief, an NF-κB oligonucleotide probe (5'-AGTTGAGGGGACTTTCCCAGGC-3') was end-labeled with [γ-32P] ATP and T4-polynucleotide kinase. Binding assays were performed in 10 μL binding reaction mixture that contained 10 μg nuclear proteins and [γ-32P]-labeled NF-κB oligonucleotides. The binding reaction mixture was incubated at room temperature for 20 min and then electrophoresed on 4% non-denaturing PAGE. After PAGE, the gels were dried and exposed to X-ray film. The autoradiograms were quantified by scanning densitometry, using Quantity One software (Bio-Rad US).

Detection of superoxide dismutase (SOD) and malondialdehyde (MDA) in ileum

To evaluate the antioxidative capacity of magnolol, MDA concentration and SOD activity in rat ileum were measured 2 h after LPS injection. Intestinal tissue samples were thawed, weighed and homogenized 1:9 (w/v) in 0.9% saline. The homogenates were centrifuged at 3000 r/min for 10 min at 4℃, and the supernatant was removed for the assay of MDA content, SOD activity and total protein.

Total intestinal protein concentration was determined using the Coomassie blue method, with bovine serum albumin as a standard. SOD activity and MDA level were detected with kits, according to the manufacturer's instructions (Jiancheng Bioengineering Ltd, Nanjing, China). Results were expressed as N/mg protein and nmol/mg protein, respectively.

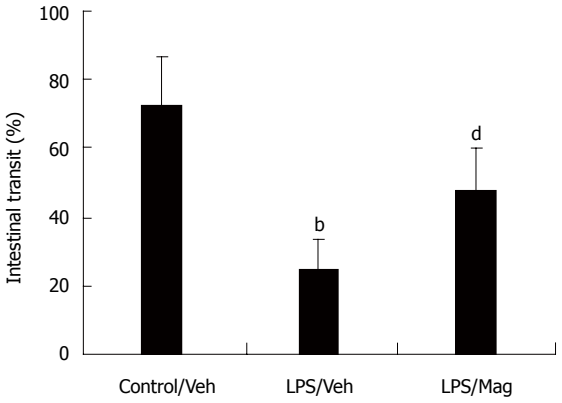

Figure 1 Magnolol prevents delayed small intestinal transit caused by LPS-induced sepsis. Data are shown as mean ± SE; $n = 6$. $^{b}P < 0.01$ (LPS/Veh *vs* Control/Veh); $^{d}P < 0.01$ LPS/Mag *vs* LPS/Veh, LPS/Mag *vs* Control/Veh.

Statistical analysis

Data were expressed as mean ± SE. Statistical significance was determined by one-way ANOVA using SPSS 11.0 (SPSS, Chicago, IL, USA). $P < 0.05$ was considered statistically significant.

RESULTS

Intestinal transit

As shown in Figure 1, LPS significantly delayed small intestinal transit from 74% ± 14% in control rats to 25% ± 9% in LPS rats. Pretreatment with magnolol significantly increased the transit in LPS animals, although this increase did not return to the control distribution pattern.

Changes in muscle contractility

The second series of experiments was designed to determine the effect of intravenous magnolol pretreatment on the intestinal musculature by measuring *in vitro* ileal circular muscle contractility from septic animals after LPS injection. Figure 2A shows the typical spontaneous contractility of circular muscle strips from three different animals. Analysis of the frequency of spontaneous contraction showed that muscle contractility in LPS-treated intestines was significantly lower than that in control tissues. Pretreatment with magnolol partly restored the spontaneous contractile pattern (Figure 2B).

Next, we evaluated the contractile response of muscle strips to the muscarinic receptor agonist bethanechol (0.1-100 μmol/L) using isometric force measurements.

As shown in Figure 3A, ileal circular muscle strips from LPS-treated animals showed significant impairment in the dose-response curve of bethanechol-stimulated muscle contraction. Magnolol treatment partly prevented LPS-induced impairment of ileal circular smooth muscle contractility. Figure 3B shows that, compared with

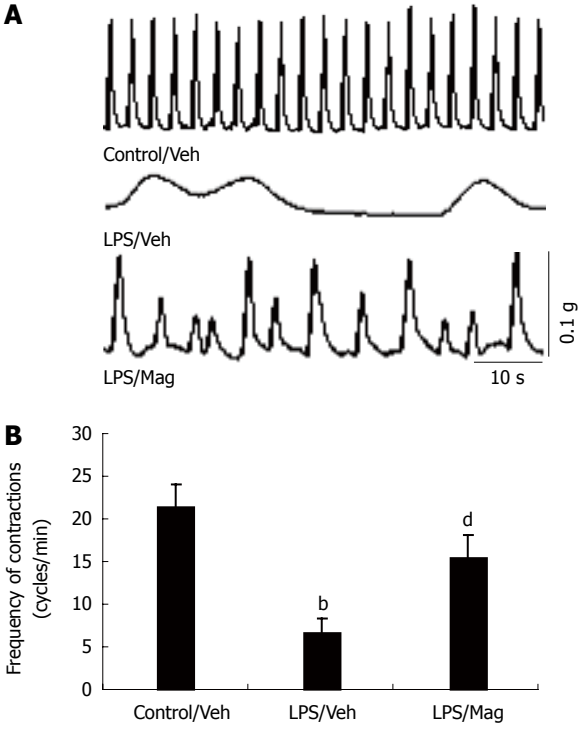

Figure 2 Change in spontaneous rhythmic contractions. A: Original traces of ileal circular muscle strip rhythmic contractions; B: Frequency of spontaneous rhythmic contractions. $^{b}P < 0.01$ (LPS/Veh *vs* Control/Veh); $^{d}P < 0.01$ (LPS/Mag *vs* LPS/Veh) ($n = 6$).

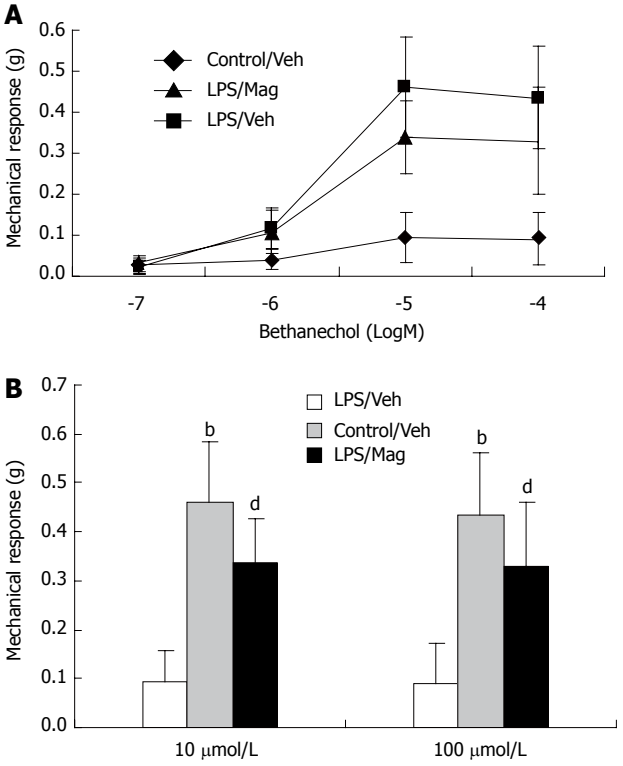

Figure 3 The contractile responsiveness of circular muscle strips to bethanechol. A: Bethanechol-stimulated dose-response curve; B: Circular muscle contractions at bethanechol concentration of 10 and 100 μmol/L. $^{b}P < 0.01$ (LPS/Veh *vs* Control/Veh); $^{d}P < 0.01$ (LPS/Mag *vs* LPS/Veh) ($n = 6$).

controls, LPS significantly suppressed bethanechol-induced circular muscle contractions at bethanechol concentrations of 10 and 100 μmol/L. Magnolol treatment significantly increased the mechanical response of ileal circular muscles in LPS-treated animals.

The effect of magnolol treatment on GI motility of control rats was also evaluated. Neither intestinal transit nor circular muscle strip contractility was altered by magnolol (data not shown).

Molecular inflammatory responses

As shown in Figure 4, LPS induced a significant increase in TNF-α, IL-10 and MCP-1 mRNA levels in the ileum. Magnolol treatment significantly decreased LPS-induced TNF-α and MCP-1 mRNA expression. As for the anti-inflammatory mediator IL-10, magnolol significantly increased IL-10 mRNA expression in the ileum of LPS-treated animals.

iNOS has been shown to be the most important mediator of smooth muscle contraction during sepsis. Therefore, we also explored the effect of magnolol on iNOS mRNA expression in the ileum. Magnolol significantly suppressed LPS-induced iNOS mRNA expression.

NF-κB activity in rat intestine

NF-κB comprises a family of transcription factors that act as regulators of pro-inflammatory mediators[16]. We hypothesized that magnolol could potentially produce the above beneficial effects through decreased expression of NF-κB. As shown in Figure 5, LPS significantly induced activated NF-κB above control levels, and as hypothesized, magnolol significantly suppressed this response.

SOD and MDA in the small intestine

As shown in Figure 6, the MDA concentration in rat ileum, an index of lipid peroxidation, was significantly increased after LPS challenge compared with controls. Pretreatment with magnolol significantly decreased the MDA concentration. SOD activity in intestinal tissue decreased markedly in LPS-treated animals. Magnolol pretreatment caused a significant increase in SOD activity in rat ileum.

DISCUSSION

This study demonstrated the ability of magnolol, an antioxidant isolated from a Chinese herb, to prevent intestinal dysmotility in LPS-induced septic rats. It also provided evidence that the potential mechanism of action of magnolol results from both attenuation of peroxidative damage and modulation of the inflammatory response during sepsis.

Sepsis-induced ileus after complicated abdominal surgery, hemorrhagic shock, trauma and burns still causes morbidity and mortality in critically ill patients. Accumulating evidence has indicated that overwhelming pro-inflammatory and oxidative stress responses combined with diminished anti-inflammatory pathways are responsible for GI dysmotility during sepsis[4-7]. Unfortunately, there is no accepted pharmacological

prevention or management of sepsis-induced ileus at present. The present study demonstrated that magnolol can partly restore the delayed intestinal transit caused by LPS. Additionally, magnolol treatment can prevent LPS-induced impairment of ileal circular smooth muscle contractility.

Numerous studies have demonstrated that exaggerated production of oxygen-derived free radicals in the face of defective antioxidative protection occurs in animals and humans with sepsis[17-19]. This

imbalance between pro- and anti-oxidants may produce oxidative stress, which ultimately leads to cellular injury and necrosis, *via* several mechanisms including lipid peroxidation, protein denaturation, and DNA damage. *Magnolia officinalis* has been used as a blood-quickening and stasis-dispelling agent in traditional Chinese medicine. Magnolol, a compound purified from the bark of *Magnolia officinalis*, has been shown to be 1000 times more potent than α-tocopherol in inhibiting lipid peroxidation in rat heart mitochondria[20], and 50 000 times more potent than glutathione, a well-known antioxidant. It can also exhibit free radical scavenging activity. Moreover, it has been reported to suppress superoxide anion production in myocardium exposed to ischemia and reperfusion[21]. In accordance with these studies, we found that magnolol significantly attenuated the intensity of lipid peroxidation and increased SOD activity in rat ileum during sepsis. The antioxidant properties of magnolol are proposed to underlie its beneficial effects during sepsis.

We considered that prevention of sepsis-induced intestinal dysmotility by magnolol was partly through interruption of the cycle of inflammatory events in the local intestine. To confirm this hypothesis, we performed semi-quantitative RT-PCR on ileal tissue for inflammatory cytokines TNF-α, MCP-1 and iNOS, which have been shown to participate in leukocyte recruitment and functional muscle impairment[4,5,22]. The anti-inflammatory mediator IL-10 was also evaluated in our experiment. We found that magnolol significantly suppressed the initial surge of TNF-α at the gene level and increased IL-10 expression in septic rat intestine. Pro-inflammatory cytokines, such as TNF-α, have been shown to be released early after an inflammatory stimulus[23]. The increase in pro-inflammatory cytokines is followed by an increase in anti-inflammatory cytokines, such as IL-10, which reflect the compensatory anti-inflammatory response syndrome[24]. It has been reported that IL-10 can inhibit cytokine production in monocytes by blocking LPS-induced NF-κB activation[25]. Additionally, IL-10 modulates the production of various chemokines (such as MCP-1) and prevents generation of NO by LPS-activated monocytes/macrophages[26-28].

MCP-1 is a potent chemoattractant that is capable of promoting monocyte recruitment into an inflammatory site, as well as activating monocytes and macrophages[29,30]. It has previously been shown that regulation of leukocyte recruitment and subsequent intestinal smooth muscle dysmotility during endotoxemia is mediated through MCP-1, and that a major source of MCP-1 is the dense network of resident muscularis macrophages[13]. In this study, we used MCP-1 mRNA as our marker of chemokine activity. As mentioned above, magnolol significantly reduced intestinal MCP-1 mRNA expression during LPS-induced sepsis.

NO is known to be the main inhibitory neurotransmitter of the GI tract, caused by the activity of the constitutive isoform of neural NO synthase (cNOS) within the enteric nervous system[31]. Besides, NO is produced at almost all sites of inflammation by leukocytes through the activity of iNOS[32]. Evidence indicates that NO from iNOS plays a pivotal role in mediating LPS-induced suppression of intestinal smooth muscle activity[4], and that up-regulation of iNOS activity is mediated by TNF-α and IL-1[5]. Additionally, NO and superoxide anions can join to form the toxic metabolite $ONOO^-$[33,34], which is also involved in the pathogenesis of sepsis-induced motility disturbances[7]. Magnolol has been reported to suppress the overproduction of NO and TNF-α in LPS-activated macrophages[35]. The results obtained in the present study provide support for this view. Pretreatment with magnolol significantly decreased iNOS mRNA expression in the intestine of the LPS-treated animals.

NF-κB is an inducible nuclear transcription factor that plays a central role in regulating the transcription of many pro-inflammatory cytokines[16], including TNF-α and IL-1β. Furthermore, intricate negative and positive feedback loops exist within NF-κB activation and cytokine expression. Pro-inflammatory cytokines activate NF-κB, but IL-10 deactivates NF-κB[36]. In the present study, we found that magnolol significantly suppressed NF-κB activation in the intestine of septic rats, which suggests that magnolol modulates inflammatory cytokines may be through intervention in the NF-κB signal transduction system. In addition, magnolol might also inhibit NF-κB activation through increasing IL-10 gene expression.

During sepsis, oxidative stress causes direct damage to cells and tissues and is involved with inflammatory cytokine production[17]. Suppression of cytokines by antioxidants has been demonstrated in previous studies. *N*-acetyl-cysteine has been shown to prevent the priming of increased expression of TNF-α mRNA after LPS[37]. Also, it has been reported that the free-radical-trapping compound phenyl *N-tert*-butylnitrone administered in LPS-induced sepsis promotes enhanced production of endogenous IL-10[38]. Additionally, the involvement of oxidative stress or oxygen free radicals in NF-κB activation has been suggested[39]. Therefore, we assume that magnolol modulation of cytokine synthesis may be related to its antioxidant properties. This is in agreement with previous studies that have shown that gut injury is partly prevented by antioxidants[40]. However, this has not been proven experimentally.

Although the findings of the present study predict a role for magnolol in a clinical setting, several problems should be mentioned. We did not use the cecal ligation and puncture (CLP) sepsis model in our study, which appears to be a reliable and clinically relevant animal model of the human septic condition, because abdominal surgery can also initiate an inflammatory cascade and ultimately lead to impairment of intestinal smooth muscle activity. More intricate pathophysiological mechanisms may be involved in the development of gut dysmotility in the CLP sepsis model[41]. Additionally, Zhang *et al*[42] previously reported that, *in vitro*, magnolol exerted an inhibitory effect on isolated ileum of guinea pigs. However, we found in our study that *in vivo,* magnolol treatment could prevent LPS-induced suppression of intestinal motility but had no

effect on control animals. These discrepancies suggest that the pharmacological properties of magnolol on GI motility might change when it is administered at different doses or *via* different routes. At the dose and route that we used in our study, the antioxidant effect of magnolol could be the important mechanism through which it ameliorates the severity of sepsis. Under other pathophysiological conditions, whether magnolol could exert a similar effect is still not known. Other well-designed experiments are needed to further determine the clinical usefulness and safety of magnolol.

In conclusion, the data presented in this study suggest a protective role of magnolol in preventing sepsis-induced suppression of intestinal motility. The potential mechanism of this beneficial effect of magnolol appears to be modulation of the self-amplified inflammatory events and block of oxidative stress in the intestine.

COMMENTS

Background

During sepsis, gastrointestinal (GI) dysmotility occurs frequently. Accumulating evidence has indicated that overwhelming pro-inflammatory and oxidative stress responses combined with diminished anti-inflammatory pathways are responsible. Recently, magnolol, an antioxidant isolated from a traditional Chinese herb, has been showed to attenuate peroxidative damage and to improve survival of rats with sepsis. It can also suppress the TNF-α level and preserve IL-10 production in hemorrhagic shock in rats. Thus, the authors presumed that through modulation of inflammatory cytokines during sepsis, magnolol might be helpful for treatment of sepsis-induced ileus.

Research frontiers

Sepsis-induced GI dysmotility is a major problem in critically ill patients. The pharmacological intervention is difficult for the clinician to handle. In addition, there is a lack of controlled studies on which to build an evidence-based treatment concept for critically ill patients.

Innovations and breakthroughs

Currently, there is no accepted pharmacologic prevention or management of sepsis-induced GI dysmotility. Therefore, management remains largely supportive. Insights gained in this preliminary study might be helpful in producing an effective pharmacological intervention strategy.

Applications

This study provides the evidence that pretreatment with magnolol could attenuate sepsis-induced GI dysmotility. The potential mechanism of this benefit of magnolol appears to be modulation of the self-amplified inflammatory events and block of oxidative stress in the intestine.

Terminology

Sepsis is defined as infection plus systemic manifestations of infection. Cytokines: non-antibody proteins secreted by inflammatory leukocytes and some non-leukocytic cells, which act as intercellular mediators. Magnolol (5,5' -di-2-propenyl-1,1'-biphenyl-2,2'-diol), a principal constituent isolated from a traditional Chinese herb. Lipopolysaccharides (LPS) are large molecules consisting of a lipid and a polysaccharide joined by a covalent bond; they are found in the outer membrane of Gram-negative bacteria, act as endotoxins and elicit strong immune responses in animals.

Peer review

This preliminary study provides us with a new insight into management of sepsis-induced GI dysmotility. However, the pharmacological properties of magnolol may change when it is administered at different doses or *via* different routes. Other well-designed experiments are needed to further determine its clinical utility and safety.

Abstract

AIM: To assess the safety of bismuth used in *Helicobacter pylori* (*H pylori*) eradication therapy regimens.
METHODS: We conducted a systematic review and meta-analysis. MEDLINE and EMBASE were searched (up to October 2007) to identify randomised controlled trials comparing bismuth with placebo or no treatment, or bismuth salts in combination with antibiotics as part of eradication therapy with the same dose and duration of antibiotics alone or, in combination, with acid suppression. Total numbers of adverse events were recorded. Data were pooled and expressed as relative risks with 95% confidence intervals (CI).
RESULTS: We identified 35 randomised controlled trials containing 4763 patients. There were no serious adverse events occurring with bismuth therapy. There was no statistically significant difference detected in total adverse events with bismuth [relative risk (RR) = 1.01; 95% CI: 0.87-1.16], specific individual adverse events, with the exception of dark stools (RR = 5.06; 95% CI: 1.59-16.12), or adverse events leading to withdrawal of therapy (RR = 0.86; 95% CI: 0.54-1.37).
CONCLUSION: Bismuth for the treatment of *H pylori* is safe and well-tolerated. The only adverse event occurring significantly more commonly was dark stools.

INTRODUCTION

Bismuth salts have been used for centuries in medicine. From a gastroenterology perspective these drugs have been used to treat peptic ulcer disease, dyspepsia, parasitic infections, microscopic colitis, and infectious diarrhoea[1]. The discovery of *Helicobacter pylori* (*H pylori*) in 1983 by Warren and Marshall revolutionised the management of peptic ulcer disease[2], and led to a renewed interest in bismuth compounds, largely because bismuth was found to inhibit the growth of *H pylori* and was effective in eradicating the organism (when combined with antibiotics or in combination with antibiotics and acid suppression therapy[3,4]).

The first randomised controlled trial (RCT) of bismuth in *H pylori*-positive individuals suggested that bismuth was superior to erythromycin monotherapy in eradicating the infection[5]. A further RCT of 6 wk of colloidal bismuth subcitrate versus cimetidine, in *H pylori*-positive duodenal ulcer patients, demonstrated that bismuth successfully eradicated the bacterium in up to 50% of patients[6]. Subsequently, an RCT of both colloidal bismuth subcitrate and cimetidine, alone or in combination with tinidazole, confirmed that colloidal bismuth subcitrate and tinidazole cleared the infection in almost 75% of patients[7]. With the addition of a second antibiotic, tetracycline or amoxicillin, eradication rates in later RCTs exceeded 80%[8-10]. However, there were some problems associated with bismuth-based triple therapy, which included the number of tablets patients were required to take, the duration of therapy, and side effects such as altered taste, nausea, and diarrhoea.

There are a variety of bismuth salts currently available on the market. All are inorganic, poorly soluble and therefore less than 1% is typically absorbed systemically[11]. Blood concentrations of bismuth do rise when these compounds are ingested however, and there is therefore the potential for toxicity, though levels less than 50 μg/mL are unlikely to be associated with any meaningful toxicity in man[11]. In the 1970s, high doses of bismuth salts were used for long periods and were associated with neurotoxicity. In France, there were almost 1000 cases of bismuth-associated encephalopathy of which 72 were fatal[1]. The doses of bismuth used in *H pylori* eradication are administered for a much shorter duration, typically 1 to 2 wk. In a recent bioavailability study, where bismuth salts were given in combination with omeprazole for 6 d[12], plasma levels of bismuth remained well below 50 μg/mL, but a review of their safety profile would provide additional evidence that such low doses of bismuth, given for a short period of time, do not expose patients to undue risks. We have therefore conducted a systematic review and meta-analysis of available published literature to assess the magnitude of the risk of adverse events experienced when bismuth salts are used, either alone or in combination with one or more antibiotics, to eradicate *H pylori*.

MATERIALS AND METHODS

Outcomes assessed

Primary outcomes: The primary aim of this systematic review and meta-analysis was to assess the total number of adverse events occurring following treatment for *H pylori* with bismuth compounds, either alone, or in combination with antibiotics and/or acid suppression therapy, compared to treatment with antibiotics alone, acid suppression therapy alone, a combination of the two, or no treatment/placebo.

Secondary outcomes: The secondary aims were to evaluate the number of specific individual adverse events occurring and the number of withdrawals of therapy due to adverse events, and to assess the effect of long-term (defined as 1 mo or more) therapy on number of adverse events (both total number and by specific category) and withdrawals due to adverse events.

Eligibility criteria

Types of studies: In order to best estimate adverse events that were directly attributable to the use of bismuth, studies were only eligible for inclusion in this systematic review if they were RCTs that compared bismuth monotherapy with either acid suppression therapy alone, placebo, or no treatment, or compared bismuth compounds in combination with either antibiotics, or antibiotics and acid suppression therapy as part of a recognised efficacious eradication regimen with an identical dose and duration of antibiotics either alone or in combination with acid suppression therapy. We defined an efficacious bismuth-containing eradication regimen as any one of: bismuth triple therapy (bismuth in combination with two antibiotics); bismuth quadruple therapy (as for triple therapy, but with the addition of acid suppression therapy); or ranitidine bismuth citrate dual (with one antibiotic) or triple (with two antibiotics) therapy.

Types of participants: Patients were required to be *H pylori*-positive adults (over the age of 16 years) taking any bismuth compound for more than 1 d with a comparison group of *H pylori*-positive patients who were not taking bismuth.

Types of assessment: Bismuth toxicity had to be assessed and recorded using one or more of the following methods: medical databases; face-to-face interviews; telephone interviews; symptom diaries; or questionnaire in order for studies to be eligible for inclusion. The questionnaire used was not required to be previously validated but, if there were sufficient studies using questionnaires, we aimed to assess the impact of this in a sensitivity analysis.

Types of outcome measures: The proportion of patients that reported any adverse event and the proportion experiencing specific individual adverse events were assessed wherever trial reporting allowed this.

Search strategy and identification of eligible studies

Search strategy: Two authors performed searches of the medical literature to identify articles from MEDLINE (from 1966 up to October 2007), EMBASE (from 1988 up to October 2007), and the Cochrane Library and Current Contents electronic databases. RCTs using bismuth salts were identified using the medical subject heading term "bismuth". These studies were combined using the set operator and with papers that used a variety of free text terms including "Denol", "Pepto-Bismol", "bismuth", "subsalicylate", "tripotassium dicitrato bismuthate", "subnitrate", "subgallate", "ranitidine bismuth citrate", "pylorid", "quadruple therapy", "pylera", and "bismuth subcitrate potassium". There were no language restrictions, and papers published in abstract form only were also eligible for inclusion in the review. The abstracts of all papers identified by the initial search were evaluated for appropriateness to the study question, and all potentially relevant studies were retrieved and examined in greater detail to determine whether or not they met all eligibility criteria. The bibliographies of identified studies were then used to perform a recursive search of the literature to identify other potentially eligible studies. In addition, Digestive Disease Week, United European Gastroenterology Week, and European *H pylori* Study Group conference abstract books between 2000 and 2007 were hand-searched.

Selection of studies: Two reviewers screened all titles and abstracts of trials that were identified by the search strategy as being potentially eligible for inclusion in the systematic review to confirm or refute eligibility. This was performed using pre-designed eligibility forms. A third reviewer adjudicated where any disagreements arose, and a consensus view was taken.

Assessment of study quality: The quality of studies was assessed according to the following pre-defined criteria: method of assessment of occurrence of adverse events (interview, diary, and questionnaire), generation of randomisation schedule, method of allocation of concealment, and blinding of assessor as to patient allocation to therapy.

Data extraction

Data concerning total number of adverse events and number of specific individual adverse events were extracted on to specially developed forms by two reviewers and all data extraction was checked by a third reviewer. These verified data were then entered onto a Microsoft Excel spreadsheet (XP professional edition; Microsoft Corp, Redmond, WA, USA), and again this was double-checked by a third reviewer. Trial characteristics including setting (population-based, primary care, secondary care), country of origin, number of centres involved, duration of bismuth therapy and dosage schedule, type of bismuth compound, mean age of included patients, and proportion of male patients were recorded to allow exploration of potential reasons for any heterogeneity detected between trial results.

Data synthesis and statistical analysis

Data were extracted as dichotomous outcomes and pooled using a random effects model[13], where sufficient data were available. The impact of bismuth therapy on the incidence of total and specific individual adverse effects *versus* comparison regimen was expressed as a combined relative risk (RR) with a 95% confidence interval (CI). The number needed to harm with bismuth therapy to cause one adverse event, and a 95% CI, were calculated as the reciprocal of the risk difference from the meta-analysis, and where this was statistically significant the results were reported.

Due to differences in methodology, patient populations, and outcome measures between eligible trials, the results of individual studies can be very diverse and therefore when they are included in the same meta-analysis this may affect the accuracy of the overall result. This inconsistency within a single meta-analysis can be quantified with a statistical test of heterogeneity, to assess whether the variation across trials is due to true heterogeneity, or chance. This quantity is termed I^2, and its value ranges from 0 to 100 percent, with 0 percent representing no observed heterogeneity, and larger values indicating increasing heterogeneity. A value below 25 percent is arbitrarily chosen to represent low levels of heterogeneity[14]. Where the degree of statistical heterogeneity is greater than this, clinical reasons within individual trials that may account for some of this inconsistency can be explored. Wherever statistically significant heterogeneity existed between trial results in this systematic review, possible explanations were investigated informally using sensitivity analyses. These are exploratory only, and may explain some of the observed variability, but the results should be interpreted with caution.

All statistical analyses were performed using Stats Direct version 2.2.4 (Stats Direct Ltd, Sale, Cheshire, UK), which was used to generate Forest plots of pooled relative risks for total adverse event rates and specific individual adverse event rates by category, as well as funnel plots to assess for evidence of publication bias.

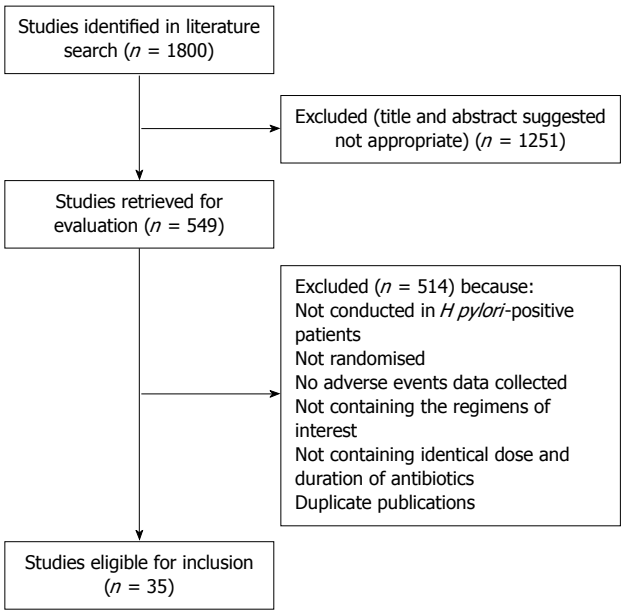

Figure 1 Flow diagram of assessment of studies identified in the systematic review.

RESULTS

Selection of eligible studies

The search strategy identified 1800 studies, of which 549 were possibly eligible. After reviewing the abstracts of these it became clear that 209 were RCTs of bismuth, and these were retrieved for further assessment. Of these, 35 were eligible for inclusion in the meta-analysis[7,15-48], reporting on 4763 *H pylori*-positive patients, 2435 of whom received bismuth or bismuth-based regimen, and 2328 received a comparison regimen (Figure 1). Thirty-three of the trials were found in fully published form, and two were only published as abstracts[29,44]. Seven of the RCTs used more than one bismuth-containing regimen[7,20,31,34,35,41,47].

Trial characteristics

Detailed trial characteristics are provided in Table 1. Nineteen of the trials were conducted in Europe[15-18,20,23-25,27-30,37,40,42-45,47], eight in the Far East[21,22,32,35,36,38,46,48], four in the USA[31,33,34,41], one in the Middle East[26], one in South America[19], one in Australia[7], and one was a multi-national study[39]. Eleven of the studies were multicentre RCTs[15,21,25,29,31,32,34,39,41,44,45]. Duration of bismuth therapy ranged from 7 to 56 d, with a total daily dose of between 400 mg and 2100 mg. Nineteen studies used ranitidine bismuth citrate[15,17,20,22,24,28-32,34,36,39-41,43,45,46,48], ten studies colloidal bismuth subcitrate[7,16,18,21,26,27,37,38,42,44], two studies tripotassium dictrato bismuthate[23,35], two studies bismuth subsalicylate[25,33], one study bismuth subnitrate[19], and one study both bismuth subnitrate and

colloidal bismuth subcitrate[47]. Comparison regimens were proton pump inhibitor or H_2-receptor antagonist (H_2-RA)-based eradication therapy in 23 studies[15,17-24,26-30,32,35,36,39,40,43,45,46,48], antibiotics alone in four studies[16,38,44,47], antibiotics or placebo in three studies[31,34,41], H_2-RA alone in two studies[25,37], placebo alone in two studies[33,42], and H_2-RA in combination with either one antibiotic or placebo in one study[7]. The mean age of individuals in included studies ranged from 36.7 years to 50.5 years, and the proportion of male patients varied between 32 percent and 78 percent. The number of participants in each RCT ranged from 20 to 530 individuals.

Trial quality

Thirteen of the trials were double-blind randomised studies[7,15,20,22,31,33,34,37-39,41,42,47], the remainder being either single-blind or open. Five of the single-blind trials specifically stated that assessors were blinded to treatment allocation[21,24,45,46,48]. Ten of the studies reported the method of generation of the randomization schedule[15,18,20,26,30,32,37,39,47,48], but only four the method of concealment of allocation[27,32,47,48]. Four of the studies recorded adverse events using a questionnaire[20,24,28,40], but only two of these stated that the questionnaire was validated[24,28]. Seven studies collected information concerning adverse events using a diary or diary cards[21,27,32,34-36,48], two *via* face-to-face interview[43,45], and one *via* telephone interview[46]. The remainder of trials did not state how they collected adverse events data.

Total number of adverse events with bismuth or bismuth-containing regimen versus comparison regimen

There were no serious adverse events such as death or neurotoxicity in either arm of any of the included

Table 2 Crude adverse event rates, and relative risk of adverse events

Adverse event	Number of trials	Total number of patients	Number of patients in bismuth arms	Number of patients in comparison arms	Number of adverse events in bismuth arms (%)	Number of adverse events in comparison arms (%)	Relative risk of adverse events with bismuth versus comparison regimen (95% CI)
Any	25	3180	1585	1595	431 (27.2)	419 (26.3)	1.01 (0.87-1.16)
Abdominal pain	13	2439	1221	1218	63 (5.2)	61 (5.0)	1.06 (0.64-1.74)

RCTs. Twenty-five trials reported the total number of individuals experiencing any adverse event with bismuth or bismuth-containing regimens *versus* comparison regimen[15-20,23-27,30,32,33,35-40,42,44,45,47,48]. Three of these studies utilized more than one regimen[20,35,47], allowing 28 comparisons to be made. The relative risk of an adverse event with bismuth or bismuth-containing regimens versus comparison regimen was 1.01 (95% CI: 0.87 to 1.16) (Figure 2 and Table 2). There was statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 30.3\%$). The Egger test did not suggest any trend for funnel plot asymmetry ($P = 0.16$). Sensitivity analysis according to trial setting, country of origin, dose of bismuth salt used, type of bismuth salt used, mean age of patients included in the study, and proportion of males included in the study failed to reveal any obvious explanation for the observed heterogeneity.

Number of specific individual adverse events with bismuth or bismuth-containing regimen versus comparison regimen

Abdominal pain: Thirteen trials reported the total number of individuals experiencing abdominal pain with bismuth or bismuth-containing regimens versus comparison regimen[17,18,20,21,24,26,28,30,34,39,40,46,47]. Three of these studies utilized more than one regimen[20,34,47], allowing 16 comparisons to be made. The relative risk of abdominal pain with bismuth or bismuth-containing regimens versus comparison regimen was 1.06 (95% CI: 0.64 to 1.74) (Table 2). There was no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 22.0\%$), and the Egger test did not suggest any trend for funnel plot asymmetry ($P = 0.15$).

Dark stools: Four trials reported the total number of individuals experiencing dark stools with bismuth or bismuth-containing regimens versus comparison regimen[17,42,46,48]. The relative risk of dark stools with bismuth or bismuth-containing regimens versus comparison regimen was 5.06 (95% CI: 1.59 to 16.12) (Figure 3 and Table 2). There was marginal statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 25.2\%$), but no obvious causes were found, and the Egger test did not suggest any trend for funnel plot asymmetry ($P = 0.28$). The number of patients needed to harm with bismuth or bismuth-containing regimen versus comparison regimen to cause one case of dark stools was 7.5 (95% CI: 4 to 71).

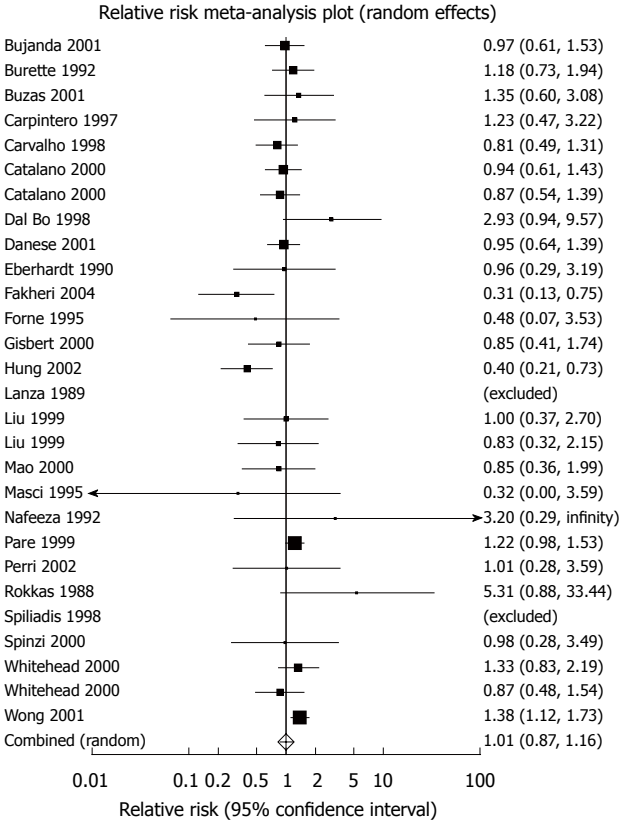

Figure 2 Forest plot of trials of bismuth or bismuth-containing regimens versus comparison regimen examining the effect on relative risk of any adverse event.

Diarrhoea: Twenty-two trials reported the total number of individuals experiencing diarrhoea with bismuth or bismuth-containing regimens versus comparison regimen[7,17,18,20,24-28,30-32,34,36,39-42,45-48]. Six of these studies utilized more than one regimen[7,20,31,34,41,47], allowing 28 comparisons to be made. The relative risk of diarrhoea with bismuth or bismuth-containing regimens versus comparison regimen was 1.01 (95% CI: 0.72 to 1.42) (Table 2). There was marginal statistically significant heterogeneity detected between trial results (heterogeneity

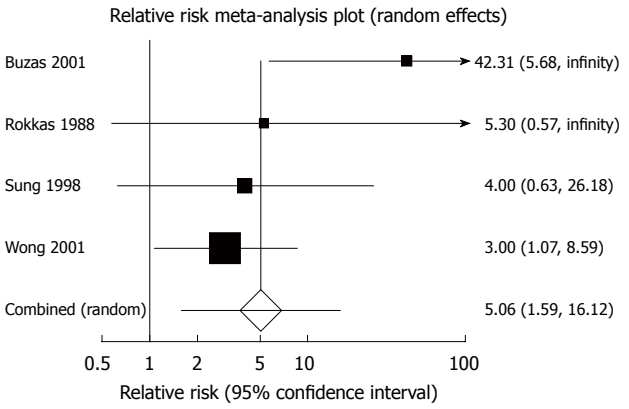

Figure 3 Forest plot of trials of bismuth or bismuth-containing regimens *versus* comparison regimen examining the effect on relative risk of dark stools.

test: $I^2 = 26.2\%$), but no obvious causes were found, and the Egger test did not suggest any trend for funnel plot asymmetry ($P = 0.75$).

Dizziness: Eight trials reported the total number of individuals experiencing dizziness with bismuth or bismuth-containing regimens versus comparison regimen[21,26,31,32,35,41,46,48]. Three of these studies utilized more than one regimen[31,35,41], allowing 11 comparisons to be made. The relative risk of dizziness with bismuth or bismuth-containing regimens versus comparison regimen was 1.18 (95% CI: 0.81 to 1.72) (Table 2). There was no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$), and the Egger test did not suggest any trend for funnel plot asymmetry ($P = 0.20$).

Headache: Fourteen trials reported the total number of individuals experiencing headache with bismuth or bismuth-containing regimens versus comparison regimen[17,18,20,24-26,30,31,34,39-41,46,47]. Five of these studies utilized more than one regimen[20,31,34,41,47], allowing 19 comparisons to be made. The relative risk of headache with bismuth or bismuth-containing regimens *versus* comparison regimen was 1.31 (95% CI: 0.81 to 2.11) (Table 2). There was no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$), and the Egger test did not suggest any trend for funnel plot asymmetry ($P = 0.83$).

Metallic taste: Fourteen trials reported the total number of individuals experiencing metallic taste with bismuth or bismuth-containing regimens versus comparison regimen[17,20,24,27,30,34,35,39-42,45,46,48]. Four of these studies utilized more than one regimen[20,34,35,41], allowing 18 comparisons to be made. The relative risk of metallic taste with bismuth or bismuth-containing regimens versus comparison regimen was 1.02 (95% CI: 0.81 to 1.28) (Table 2). There was no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$), though the Egger test suggested there was funnel plot asymmetry ($P = 0.01$).

Nausea and/or vomiting: Twenty trials reported the total number of individuals experiencing nausea and/or vomiting with bismuth or bismuth-containing regimens versus comparison regimen[17,18,20,21,24-28,30-32,34,35,39-42,46,47]. Six of these studies utilized more than one regimen[20,31,34,35,41,47], allowing 26 comparisons to be made. The relative risk of nausea and/or vomiting with bismuth or bismuth-containing regimens versus comparison regimen was 1.16 (95% CI: 0.89 to 1.52) (Table 2). There was no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$), and the Egger test did not suggest that there was any evidence of funnel plot asymmetry ($P = 0.85$).

Withdrawal of therapy due to adverse events with bismuth or bismuth-containing regimen versus comparison regimen

Twenty-eight trials reported the total number of individuals who terminated therapy due to experiencing adverse events with bismuth or bismuth-containing regimens versus comparison regimen[16-18,20,22-32,34-37,39-43,45-48]. Six of these studies utilized more than one regimen[20,31,34, 35,41,47], allowing 34 comparisons to be made. The relative risk of withdrawal of therapy due to adverse events with bismuth or bismuth-containing regimens versus comparison regimen was 0.86 (95% CI: 0.54 to 1.37) (Table 2). There was no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$), though the Egger test suggested that there was evidence of funnel plot asymmetry ($P = 0.05$).

Effect of duration of bismuth therapy on incidence of adverse events

The duration of bismuth therapy was one month or more in eleven of the included studies[7,18,25,31,34,37-39,41,42,47]. There were sufficient trials to pool data to examine the effect of duration of therapy on total number of adverse events, some of the specific individual adverse events (including diarrhoea, headache, and nausea and/or vomiting), and withdrawal of therapy due to adverse events.

Total number of adverse events: Seven trials provided data on total number of adverse events in 945 individuals (467 of whom were assigned to bismuth)[18,25,37-39,42,47], and one study utilized more than one regimen allowing eight comparisons to be made[47]. The relative risk of an adverse event with bismuth or bismuth-containing regimens used for one month or more versus comparison regimen was 1.20 (95% CI:1.00 to 1.44), with no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$).

Diarrhoea: Nine studies provided data on the incidence of diarrhoea with one month or more of bismuth in 1601 patients (859 of whom were assigned to bismuth)[7,18,25,31,34,39,41,42,47], with five of the studies utilizing more than one regimen allowing fourteen comparisons to be made[7,31,34,41,47]. The relative risk of diarrhoea with

bismuth or bismuth-containing regimens used for one month or more versus comparison regimen was 1.72 (95% CI: 1.14 to 2.60), with no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$).

Headache: Seven studies provided data on the incidence of headache with one month or more of bismuth in 1435 patients (778 of whom were allocated to bismuth)[18,25,31,34,39,41,47], with four of the studies utilizing more than one regimen allowing eleven comparisons to be made[31,34,41,47]. The relative risk of headache with bismuth or bismuth-containing regimens used for one month or more versus comparison regimen was 1.39 (95% CI: 0.76 to 2.53), with no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$).

Nausea and/or vomiting: Eight studies provided data on the incidence of nausea and/or vomiting with one month or more of bismuth in 1501 patients (810 of whom were allocated to bismuth)[18,25,31,34,39,41,42,47], with four of the studies utilizing more than one regimen allowing twelve comparisons to be made[31,34,41,47]. The relative risk of nausea and/or vomiting with bismuth or bismuth-containing regimens used for one month or more versus comparison regimen was 1.47 (95% CI: 0.87 to 2.48), with no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$).

Withdrawal of therapy due to adverse events: Nine studies provided data on the incidence of withdrawal of therapy due to adverse events with one month or more of bismuth in 1554 patients (837 of whom were allocated to bismuth)[18,25,31,34,37,39,41,42,47], with four of the studies utilizing more than one regimen allowing thirteen comparisons to be made[31,34,41,47]. The relative risk of withdrawal of therapy due to adverse events with bismuth or bismuth-containing regimens used for one month or more versus comparison regimen was 0.86 (95% CI: 0.47 to 1.57), with no statistically significant heterogeneity detected between trial results (heterogeneity test: $I^2 = 0\%$).

DISCUSSION

This is, to our knowledge, the first systematic review and meta-analysis to examine the safety profile of bismuth compounds used either alone or in combination with antibiotics for the treatment of *H pylori* infection, or *H pylori*-related diseases. This information is very important because there have been previous concerns surrounding the issue of potential for toxicity with use of the drug in some countries, particularly in France, where severe neurological adverse events related to the prolonged use of bismuth, given in large quantities, led to the complete withdrawal of all bismuth compounds. This is in contrast to much of the rest of the world, particularly North America, where these drugs are still available without prescription over the counter.

Serfontein *et al*[11], when reviewing blood bismuth levels in patients following administration of therapeutic bismuth formulations, concluded that levels less than 50 μg/mL were highly unlikely to be associated with any meaningful toxicity in man. The authors also reported site-specific toxicity issues depending on whether the complexes of bismuth were water or lipid soluble, the former being associated with renal toxicity, the latter with neurotoxicity. In both cases the doses used and the duration of treatment leading to such adverse effects were much greater than the ones used in the context of *H pylori* eradication therapy. When bismuth-based compounds are used in the treatment of *H pylori* they are usually only given for 1 to 2 wk at low doses, so it would be expected that in this situation the incidence of severe adverse events such as death or neurotoxicity would be lower. These data, with no reported deaths or neurotoxicity in any of the included RCTs, would support this hypothesis. Less serious adverse events are still important though, particularly from the patient's perspective. These may affect compliance with therapy, which is important as successful eradication of *H pylori* is likely to lead to successful ulcer healing and prevention of ulcer relapse[49], and may also improve symptoms in a small but significant proportion of those with functional dyspepsia[50,51]. In a previous analysis of factors that determine the likely success of *H pylori* eradication with bismuth-based triple therapies, patient compliance was shown to be the most important predictor of response[52].

No statistically significant difference was detected in the total number of side-effects between those receiving bismuth-based therapy and comparison regimen in this meta-analysis. In addition, there was no statistically significant difference detected in individual adverse events such as abdominal pain, diarrhoea, dizziness, headache, metallic taste, and nausea and/or vomiting with bismuth compounds versus comparison regimen. Finally, there was no statistically significant increase detected in the number of individuals requiring cessation of therapy as a direct result of adverse events with bismuth-based therapy versus comparison regimen. The number of individuals reporting dark stools with bismuth was significantly higher, though there were fewer studies reporting this adverse event, which probably explains the wider confidence interval. This is unlikely to have any serious consequences related to patient safety, but it is still important to warn patients that this is an expected side-effect of therapy. This observation also has implications for the successful blinding of patients allocated to bismuth therapy in double-blind RCTs.

Total number of side-effects did appear to increase slightly when only those trials that used one month or more of bismuth therapy were included in the meta-analysis, though this did not achieve statistical significance. Diarrhoea was significantly more common with bismuth compounds when only studies using more than one month of therapy were included, but no statistically significant difference was detected in the incidence of other adverse events reported, where there were sufficient trials to examine this issue. Again, there was no increase in cessation of therapy in individuals

assigned to bismuth-based therapy, even if treatment was for one month or more. As mentioned earlier, most current bismuth-based *H pylori* eradication regimens are given for 1 or 2 wk only, so these observations related to longer duration of bismuth therapy are unlikely to have any significant implications in the majority of patients.

The strengths of this systematic review and meta-analysis are that it has been conducted using rigorous methodology and contains a large number of RCTs, which have provided data from in excess of 2000 patients for most of the analyses. In addition, the fact that the data of interest to this meta-analysis were not the primary endpoint of any of the included trials means that the results of the current study are likely to be free from publication bias, as evidenced by the funnel plots for many of the outcomes we assessed. Disadvantages, as with any systematic review, arise from the methodology of the trials included. Many studies were not double-blind and few reported that assessors were blinded to the treatment allocation of the patients either, and this may have led to under-reporting of adverse events in those assigned to "active treatment" with bismuth therapy. Most studies also failed to report either the method of generation of the randomization schedule or the method of concealment of allocation. Finally, only four of the studies used a questionnaire to collect adverse event data, and only two stated that this questionnaire was validated. This may mean that adverse event data were inaccurate in many of the trials and we cannot exclude the possibility that this may have biased the results of the current meta-analysis towards the null hypothesis.

In summary, this systematic review and meta-analysis provides strong evidence that bismuth compounds used either alone, or in combination with antibiotics and acid-suppression therapy, for the treatment of *H pylori* are safe and well-tolerated. The only observation of note was that dark stools were significantly more common in those assigned to bismuth-based therapies.

COMMENTS

Background

Bismuth compounds are often used as part of eradication therapy for *Helicobacter pylori* (*H pylori*). There are concerns about toxicity of these compounds in some countries, particularly as a result of their potential neurological sequelae.

Research frontiers

Data concerning toxic effects of bismuth compounds are mainly derived from studies that have used these compounds at a high dose for a prolonged period of time. We conducted a meta-analysis of adverse events resulting from a 1 to 2-wk course of bismuth based *H pylori* eradication therapy.

Innovation and breakthroughs

The current study demonstrated that bismuth compounds, when used short-term for 1 to 2 wk in *H pylori* eradication therapy, are safe. The only adverse event that occurred more frequently in patients receiving bismuth was dark stools.

Applications

Potential adverse events from bismuth compounds in a 1 to 2-wk course of *H pylori* eradication therapy are now quantified. Gastroenterologists can be assured that these compounds are safe to use.

Terminology

The number needed to harm is the number of patients that would need to be treated with bismuth compounds for one patient to experience an adverse event.

Peer review

There are now problems in obtaining satisfactory eradication rates of *H pylori* with PPI-based triple therapies, so the use of bismuth containing regimens has been recommended as a potential first line therapy in the Maastricht guidelines. Furthermore, there are now new bismuth combinations commercially available. For these reasons it is important to be sure of the safety of bismuth compounds.

Abstract

AIM: To determine the seroprevalence of Hepatitis A (HAV) amongst Saudi children and compare it with previously reported prevalence data from the same population.

METHODS: A total of 1357 students were randomly selected between the ages of 16 and 18 years (689 males and 668 females) from three different regions of Saudi Arabia (Madinah, Al-Qaseem, and Aseer) and tested for anti-HAV-IgG.

RESULTS: The overall prevalence of anti-HAV-IgG among the study population was 18.6%. There was no difference between males and females but there was a significant difference in the seroprevalence (P = 0.0001) between the three different regions, with Madinah region showing the highest prevalence (27.4%). When classified according to socioeconomic status, lower class students had a prevalence of 36.6%, lower middle class 16.6%, upper middle class 9.6%, and upper class 5.9% (P = 0.0001). Comparing the current study results with those of previous studies in 1989 and 1997 involving the same population, there was a marked reduction in the overall prevalence of HAV from 52% in 1989, to 25% in 1997, to 18.6% in 2008 (P < 0.0001).

CONCLUSION: Over the last 18 years, there has been a marked decline in the prevalence of HAV in Saudi children and adolescents. The current low prevalence rates call for strict adherence to vaccination policies in high-risk patients and raises the question of a universal HAV vaccination program.

INTRODUCTION

Hepatitis A (HAV) is a major health problem worldwide and, like other enteric infectious diseases, is classically an infection of childhood. Although acute infection commonly passes unnoticed, a significant proportion of patients may have fulminant liver failure, especially patients with liver cirrhosis or immune deficiencies. Generally, its prevalence pattern varies from one population to the other and is closely related to the socioeconomic conditions of sanitation and hygiene. An improvement in sanitation and living standards in many areas of the world has caused the epidemiology of HAV to rapidly evolve. As such, with an improvement in living conditions, more clinical cases are being diagnosed owing to the increased age of those susceptible, which is paradoxical to childhood infection where the majority of infections are subclinical[1-5]. The availability of safe and efficacious vaccines against HAV has made it

increasingly important to understand the epidemiology of HAV in a given area before a strategy for the use of the vaccine is advised or implemented[6-8]. In particular, the epidemiological data from the previous decade may no longer be valid now.

Understanding the epidemiological shift in HAV seropositivity is of strategic importance to a nation's healthcare system. In countries that dramatically improve their socioeconomic status and standards of living, the susceptible pool may increase rapidly to such an extent that HAV becomes a major public health concern. The epidemiology of HAV in developed countries is characterized by low prevalence rates among children with a large group of susceptible adults being negative for anti-HAV.

Two decades ago, studies performed in Saudi Arabia indicated the HAV prevalence rate to be in the range of 90%-100% amongst the adult population[9-13]. However, later studies showed a consistent decline in anti-HAV prevalence rate[14,15]. In the years 1989 and 1997, community-based studies revealed that the overall prevalence rate of HAV infection among children of age 1-12 years had reduced dramatically from 52% (1989) to 25% (1997)[16,17].

We aimed to evaluate the epidemiological shift in HAV serostatus within the adolescent population of three predefined regions of Saudi Arabia and compare it to previously published data.

MATERIALS AND METHODS

Study population

We selected our sample from a population of 10-12th grade school students (corresponding to the age of 16-18 years) in three regions. These regions were as follows: (1) The Aseer region: school population of 25 512, 13 996 males and 11 516 females; (2) Madinah: school population of 23 852, 12 133 males and 11 719 females; and (3) The Al-Qaseem region: school population of 16 067, 7974 males and 8093 females. These regions were selected because they represented low, medium, and high prevalence rates in our previous studies. The sample was selected using a stratified random sampling technique where the Kingdom was stratified into three strata according to the previous endemicity of infection. The proportional allocation method was used to determine the recruited number of students in each stratum. Within the stratum, the sample was proportionally allocated according to gender. In every region, schools served as the sampling units. From the list of schools in the region, one or more male schools and one or more female schools that satisfied the required sample size were randomly selected.

A total of 1357 students (689 males, 668 females) from these three regions of the Kingdom of Saudi Arabia (KSU), were randomly selected. The socioeconomic status of this population was also stratified (low, middle and high class). King Abdulaziz City for Science and Technology approved the protocol of this study, and informed consent was obtained from the parents as well as from the students participating in the study.

Data collection, blood sampling and testing

Fieldwork for this study was undertaken in December 2007 and January 2008. Demographic data were recorded, and a venous blood sample (5-10 mL) was taken from each student. Serum was separated by centrifugation, coded, and stored at -70℃ until tested. Blood samples were tested for anti-HAV-IgG using EIA kits ADVIA Centaur system.

The socioeconomic status of each student was taken to be representative of that of the father and/or the mother and classified using a socioeconomic status 3-point scoring system derived according to the type of house (mud-built = 1, apartment or ordinary house = 2, villa = 3), number of rooms in the house (1-2 rooms = 1, 3-4 rooms = 2, 5 and more = 3), number of family members (4 or less = 3, 5 = 3, 6 = 2, 7 or more = 1), father and mother education (primary grade or less = 1, secondary/high school = 2, university or equivalent = 3), parent occupation (laborer = 1, farmer or office clerk = 2, trader = 3). An overall score of less than 10 from a maximum of 21 was classified as representative of a low socioeconomic status, 10-15 as low middle, 15-17 as high middle and above 17 as high class.

Statistical analyses

Data was entered in MS Excel and analyzed using SPSS Pc+ version 16.0 statistical software. Descriptive statistics (proportional) were used to summarize the categorical variables. χ^2 test followed by analysis of residuals was used to calculate the statistical association between two categorical variables. χ^2 test for trend was used to calculate the significance of proportions of categorical variables at different time points. P value of < 0.05 was considered statistically significant.

RESULTS

The blood samples of 1357 students (aged 16 to 18 years; 689 males and 668 females) were collected and analyzed. The overall prevalence rate of anti-HAV-IgG among the population study was 18.6%.

Association between anti-HAV-IgG values and gender

A significant association between gender and anti-HAV serostatus was seen. The proportion of males who were anti-HAV positive (21%) was significantly higher when compared with females (16.2%) ($P = 0.021$). The adjusted residuals of the frequencies were also statistically significant when compared with the 5% standard normal deviate value (1.96) (Table 1).

Association between anti-HAV-IgG values and regions

A significant association was observed between the area (Aseer, Madinah, and Al-Qaseem) and anti-HAV serostatus. The proportion of subjects from Madinah who were anti-HAV positive (27.4%) was significantly higher compared with samples from other areas (Aseer: 13.5% and Al-Qaseem: 13.9%; $P < 0.0001$). The adjusted residuals of the frequencies of Madinah area (6.2)

Table 1 Prevalence of anti-HAV within the study population and its association with gender

Gender	Anti-HAV (%)		*P* value
	Positive	Negative	
Male (*n* = 689)	145 (21)	544 (79)	0.021
Female (*n* = 668)	108 (16.2)	560 (83.8)

Socioeconomic status	Anti-HAV(%)		*P* value
	Positive	Negative	
Low class (*n* = 239)	88 (36.8)	151 (63.2)	< 0.0001
Lower middle class (*n* = 880)	146 (16.6)	734 (83.4)	
Upper middle class (*n* = 136)	13 (9.6)	123 (90.4)	
High class (*n* = 102)	6 (5.9)	96 (94.1)	

were also statistically significantly higher when compared with the 5% standard normal deviate value (1.96) (Table 2).

Association between anti-HAV-IgG values and socioeconomic status

A significant association between social status of the sampled population and anti-HAV status was found. The proportion of low class subjects who were anti-HAV positive (36.8%) was significantly higher compared with subjects of other classes (lower middle class: 16.6%; upper middle class: 9.6% and high class: 5.9%; $P < 0.0001$). The adjusted residuals of the frequencies of low class (7.9) were also statistically significantly higher when compared with the 5% standard normal deviate value (1.96) (Table 3).

Comparison of anti-HAV-IgG of previous studies performed in 1989[16] and 1997[17], with the present study

There was a high statistically significant trend for decreased prevalence of HAV infection in all three areas over the three time points. Among the three areas (Al-Qaseem, Aseer and Madinah), the Al-Qaseem area had a significantly decreased prevalence of HAV infection (61.1% in 1989, 31.5% in 1997 and 13.8% in 2007-2008). The decrease in prevalence of HAV infection in Aseer area from 1997 to 2007-2008 was only 5.4% and in Madinah for the same period was only 1.2%, whereas in Al-Qaseem the decrease was 17.7% during the same period (Table 4).

DISCUSSION

The results of this study show a marked decline in the endemicity of HAV within the Saudi population in the age range of 16-18 years. This trend is highlighted by the dramatic linear decline from 53% in 1987 to 25% in 1997 and finally to 18.6% in the present study. Other studies from the region have shown a similar trend.

Table 3 Prevalence of anti-HAV and its association with the region of study population

Region	Anti-HAV(%)		*P* value
	Positive	Negative	
Aseer (*n* = 532)	72 (13.5)	460 (86.5)	< 0.0001
Al-Qaseem (*n* = 332)	46 (13.9)	286 (86.1)	
Madinah (*n* = 493)	135 (27.4)	358 (72.6)	

Table 4 Prevalence of HAV infection in KSA over the last 18 years (1989[16], 1997[17], and 2008)

Region	1989 prevalence (%)	1997 prevalence (%)	2007-2008 prevalence (%)	*P* value
Al-Qaseem	126/201 (61.1)	71/225 (31.5)	46/332 (13.8)	< 0.00001
Aseer	212/476 (44.5)	78/411 (18.9)	72/532 (13.5)	< 0.00001
Madinah	208/350 (59.4)	83/317 (26.2)	135/493 (27.4)	< 0.0001
Total	546/1027 (53.1)	232/953 (24.3)	253/1357 (18.6)	

Al Muneef and colleagues found a hepatitis A seroprevalence of 28.9% in 2399 Saudi children two years ago[18]. However, the present study which was performed on the same population cohort three times over the past 18 years showed a graded but dramatic decline in prevalence. In addition, this study was performed in three areas of different endemicity within the country, representing different levels of socioeconomic development.

HAV endemicity is closely linked to improvements in sanitation and living conditions in the population. In the case of Saudi Arabia, the Saudi government's real-estate bank has helped to build 851 000 housing units through a government loan from 1974 to 2003[19].

According to the official human development report in 2003, the Saudi per Capita GDP increased from 1145 USD in 1970 to 10 853 USD in 2002 and the life expectancy at birth has changed from 53.9 years (1970-1975) to 70.9 in 2000[19].

We believe therefore, that the vast improvement in the socioeconomic status of the Saudi population is the factor most likely to be responsible for this decline. Furthermore, the overall reduction in illiteracy within the Saudi population from greater than 90% in the 1960s to 13.4% in 2007-2008 (7% in males and 19.8% in females)[20] is likely to have contributed to this decline.

A difference was also observed in the prevalence rates of anti-HAV between the three different regions of the KSA in our study, in effect reflecting the different stages of economic development of these regions. The role of socioeconomic status in the study population in determining the level of HAV prevalence was also demonstrated in this study (Table 3) similar to previous publications[16-17].

Previous community-based studies conducted in the Saudi population have shown differing gender-based results in HAV seropositivity. Al-Rashed showed no difference in the anti-HAV prevalence rates between male and female populations[17], while in another study, Khalil *et al*[21] showed a higher seropositivity for Saudi males. The dif-

ference between male and female prevalence rates among this age group is likely to be related to the greater exposure of the male population to HAV infection sources in the community. For instance, the eating habits of the Saudi male population are certainly more gregarious compared to the female population. Similarly, the local culture of less female co-habitation and social interaction may also play a role in reducing their exposure to infection sources.

Finally, this study indicated that more than 82% of the adolescent population of Saudi Arabia is susceptible to symptomatic HAV infection. This could occur either by exposure to infected persons, either where they live or upon travel to high endemic areas either within or outside the country. Outbreaks of symptomatic acute HAV infection have been recently reported within increasing pools of susceptible populations within the country[22-24]. This high susceptibility of the young population represents a continuous challenge to the healthcare system of the country.

Recently, an HAV vaccine has been introduced in many countries as part of an Extended Program of Immunization (EPI). Several studies have demonstrated the efficacy and safety of the vaccine[25-28] and some authorities have recommended its universal implementation in certain populations[29]. Therefore, the recent decision by the Saudi Ministry of Health to introduce the HAV vaccine as part of the EPI program starting from 2008, to children of 18-24 mo of age is certainly timely. The effect of this strategy needs to be studied in future community-based studies, where the results of the present study could well serve as a reference point for comparative analysis.

COMMENTS

Background

Hepatitis A (HAV) is a major health problem worldwide. Generally, its prevalence pattern varies from one population to the other and is closely related to the socioeconomic conditions of sanitation and hygiene. An improvement in sanitation and living standards in many areas of the world has caused the epidemiology of HAV to rapidly evolve.

Research frontiers

This research group took blood samples from school students aged 16-18 years in three different regions of the country after consent of the parents and students. It was found that the prevalence of hepatitis A in this population was 18.6% compared to 25% in 1997 and 52% in 1989. There was also a link between hepatitis A and socioeconomic status with children from a lower socioeconomic status having a higher prevalence.

Innovation and breakthroughs

This study confirmed the findings of other studies in Saudi Arabia and other developing countries showing a reduced rates of hepatitis A with improved socioeconomic status.

Applications

This study is important because it compares current prevalence rates with previous rates from the same community. The reported low rates in the current study calls for strict adherence to vaccination policies in high-risk patients and raises the question of a universal HAV vaccination program.

Peer review

HAV infection is an important topic, and continues to be a source of morbidity and mortality. Al Faleh elegantly describes how the HAV seroprevalance has decreased in Saudi Arabia, and appropriately raises concerns about an increasingly susceptible population.

Abstract

AIM: To determine the prevalence of celiac disease (CD) in children with idiopathic short stature (ISS) and the diagnostic value of immunoglobulin (Ig) A G antigliadin antibodies (AGA) and transglutaminase (TTG) antibodies for CD.

METHODS: A total of 104 children (49 male, 55 female) with ISS without a specific etiology were studied. Extensive endocrine investigations had shown no abnormalities in any subject. Anthropometric parameters and IgA AGA and IgA TTG antibodies were evaluated in this study group. These antibodies were measured by enzyme-linked immunosorbent assay. All patients were referred for an endoscopic intestinal biopsy. The biopsy samples were classified according to revised Marsh criteria (UEGW 2001).

RESULTS: We detected positive IgA TTG antibodies in 36 and IgA AGA in 35 of these patients. Thirty one IgA TTG antibody positive and 28 IgA AGA positive subjects showed histological abnormalities compatible with celiac disease (33.6%). Sensitivity, specificity, positive predictive value (PPV) and negative predictive value for IgA AGA were found to be 80%, 88.4%, 77.8% and 89.7%, respectively. Sensitivity, specificity and PPV for IgA TTG antibodies were 88.6%, 94.2% and 88.6%, respectively.

CONCLUSION: We conclude that the prevalence of celiac disease is high in patients with ISS and it is important to test all children with ISS for celiac disease by measuring serologic markers and performing an intestinal biopsy.

Prevalence of celiac disease in Iranian children with idiopathic short stature. *World J Gastroenterol* 2008; 14(48): 7376-7380 Available from: URL: http://www.wjgnet.com/1007-9327/14/7376.asp DOI: http://dx.doi.org/10.3748/wjg.14.7376

INTRODUCTION

Short stature is one of the most common causes for referrals to pediatric endocrinologists. Many of these patients have no identifiable medical abnormality and are classified as idiopathic short stature (ISS). For most of these patients, it is believed that genetic variations are the underlying cause. Short stature is a well-known feature of pediatric celiac disease (CD)[1]. In recent studies, CD was considered to be a more common cause of short stature in otherwise healthy children than growth hormone deficiency[2,3]. In other studies, CD has been found without typical gastrointestinal symptoms in some cases of short stature[4-26]. Moreover, some studies suggested an association between CD and growth hormone deficiency[27]. Diagnosis of CD depends on the demonstration of a flat or almost flat jejunal mucosa in biopsy specimens from the small intestine and regeneration of the mucosa after a gluten-free diet[5]. It has been suggested that patients with untreated CD have circulating antibodies against gliadin, and antiendomysium antibodies (anti-EMA) have proven to be a reliable screening test for CD, even in asymptomatic patients[6,7]. The immunofluorescence test is technically difficult to

interpret, with large interobserver variability. In addition, esophageal tissue from monkeys is a common substrate, and the testing is time consuming. Transglutaminase (TTG) antibodies are also highly sensitive and specific and since IgA antibodies to TTG can be examined by enzyme-linked immunosorbent assay (ELISA), they are easier to use as screening antibodies compared with EMA testing[9]. The purpose of the present study was to evaluate prospectively the clinical, laboratory and histologic features of CD and the sensitivity, specificity and positive and negative predictive values (PPV and NPV, respectively) of antibodies against gliadin and TTG in 104 children with a diagnosis of ISS but with no specific etiology.

MATERIALS AND METHODS

A total of 104 children (55 female, 49 male) with ISS and height less than the 2nd percentile adjusted for age and sex, but without specific etiology were enrolled in the study from November 1, 2003 to September 1, 2005 at Ahwaz Jundishapour University Hospitals. Ages ranged from 2 to 18 years. The height, weight and weight for height measurements had been recorded for all patients at presentation and the patients and their parents answered a CD-specific questionnaire used for data collection. All children were being followed at the Department of Endocrinology of Golestan Hospital and had undergone an extensive negative endocrine investigation which included: concentrations of serum electrolytes and glucose, sweat test, total proteins and albumin, determination of immunoglobulin A (IgA), assessment of liver and renal function (determined by standard methods), and hormonal evaluation through the measurement of thyroid-stimulating hormone, free-thyroxin, and growth hormone.

All etiologic factors known to produce growth retardation had also been excluded, e.g, diabetes mellitus, hematological and liver disease, renal failure, fetal growth failure, diseases of bone metabolism, and chromosomal abnormalities. When no cause of the short stature was found, additional investigations were performed by measuring the serum levels of IgA anti-TTG antibodies and IgA antigliadin antibodies (AGA). AGA was measured by a commercial ELISA assay (ELISA-Biosystem, Madrid, Spain). A serum dilution of 1:100 was used and the results were reported in terms of arbitrary units (AU/mL). An IgA AGA $\geqslant$ 20 AU/mL was considered positive. A commercial ELISA. (Orgentec) kit was used to measure anti-TTG antibodies and a titer of more than 1/10 was considered positive. Intestinal biopsies were obtained from all 104 patients with endoscopic grasp forceps (who had negative or positive results for anti-TTG antibody). Four to six biopsy specimens were taken from the second and third parts of the duodenum. Formalin-fixed biopsy specimens stained with hematoxylin and eosin were studied with the use of light microscopy. The slides were examined and confirmed by a pathologist experienced in CD. Mucosal lesions were classified according to the criteria of Marsh[8] as: (1) type 0, normal mucosa, pre-infiltrative lesions; (2) type 1, normal mucosal architecture with epithelial lymphocyte infiltration, infiltrative lesions; (3) type 2, hypertrophic crypts with epithelial lymphocyte infiltration, hyperplastic lesions; and (4) type 3, typical flat mucosa, destructive lesions. The research protocol was reviewed and approved by the Medical Ethics Committee of the Ahwaz Jundishapour University Hospitals. Written informed consent was obtained from the children's parents.

Table 1 The age, weight, height, short stature and BMI of patients (mean ± SD)

Group	Age	Weight	Height	Short stature (*n*)		BMI
				> 2 SD	> 3 SD	
Without CD	16.6 ± 6.5	38.7 ± 13.4	140 ± 17.1	54	15	19 ± 3.5
With CD	16.9 ± 7.1	37.9 ± 13.1	137.6 ± 13.1	30	5	19.1 ± 3.1
Total	16.8 ± 6.7	38.5 ± 13.2	139.2 ± 17.3	84	20	19.1 ± 3.5

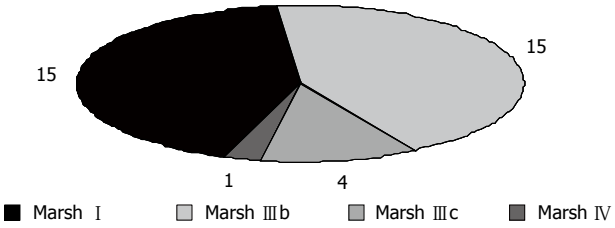

Figure 1 Histological findings of celiac disease.

Statistical analysis

The results are reported as mean ± SD. Statistical analysis was performed by the unpaired Student *t*-test (GraphPad Prism Software Incorporated), with the level of significance set at $P < 0.05$.

RESULTS

The most frequent symptom was diarrhea ($n = 13$) followed by abdominal pain and distention ($n = 3$) in patients with CD and the patients affected by CD did not differ from those without CD in any of the symptoms. A family history of CD was detected in two patients (5.7%). At diagnosis, in the CD patient group, mean weight was 37.9 ± 13.1 and mean height was 137.6 ± 13.1. In this group, short stature of > 2 SD and > 3 SD was found in 30 patients (85.7%) and 5 patients (14.3%), respectively ($P > 0.05$, Table 1).

Small intestine biopsies were performed in all 104 patients with ISS. Duodenal mucosal histopathology was normal in 69 patients. Histopathologic analysis showed evidence of abnormalities compatible with CD in 35 cases (33.6%).

The following histological findings were obtained: (a) 15 of 35 patients had normal mucosal architecture with epithelial lymphocyte infiltration and (b) 15 cases had hypertrophic crypts with epithelial lymphocyte infiltration and partial villous atrophy and (c) five cases showed subtotal or total villous atrophy (Figure 1).

Therefore, the prevalence of properly diagnosed CD

Table 2 Relationship between positive and negative IgA AGA, and IgA TTG antibodies and histological evidence of celiac disease (*n*)

Lab group	IgA AGA		IgA TTG antibodies	
	Positive	Negative	Positive	Negative
Without CD	8	61	4	65
With CD	28	7	31	4
Total	36	68	35	69

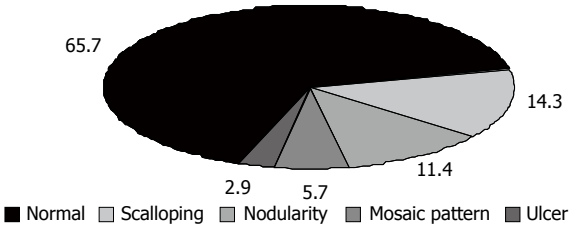

Figure 2 Endoscopic features.

among patients with ISS in this study was 33.6% (35 of 104 patients). IgA AGA, and I IgA TTG antibodies were found in 80% (n = 28), and 88.6% (n = 31) of patients with ISS, respectively. Specificity and the positive predictive value (PPV) for TTG antibodies were found to be 94.2% and 88.6% for CD in the group of patients with ISS in this study. Table 2 shows the relationship between positive and negative IgA AGA, and IgA TTG antibodies and histological evidence of CD. IgA AGA: sensitivity 80%, specificity 88.4%, PPV: 77.8%, negative predictive value (NPV) 89.7%; IgA TTG antibodies: sensitivity 88.6%, specificity 94.2%, PPV 88.6%, NPV 94.2%. The endoscopic features are summarized in Figure 2.

DISCUSSION

Screening for CD in the general population indicates a prevalence of 1:300 to 1:100. About 50% of these children are completely symptomless but because of these figures some experts suggest CD screening for all adults[28] and children[29]. In a British population-based study on short stature, where CD was not specifically investigated, the prevalence of CD was 2:180. In children with short stature and no gastrointestinal symptoms who were investigated for CD, the prevalence increased to 2%-8%. When other (endocrine) causes for short stature are excluded, the prevalence might rise as high as 59%[30,31]. Although CD was once thought to be rare in Iran, several recent reports have cleared this misconception[23,24]. Dr. Shahbazkhani reported that the minimum prevalence of gluten sensitivity among apparently healthy urban Iranian blood donors is 1/166[25]. However, all of these reports deal with typical presentation of CD.

We performed a prospective study on newly diagnosed cases of CD in a group of short stature patients in the south-West of Iran in 2003-2005. Despite the presence of clinical signs of CD during childhood in more than one-third of the patients, the disease remained undiagnosed for many years. This late diagnosis may lead to short stature and low female fertility.

In the last 20 years the clinical picture of CD has changed considerably. The classic form of CD now accounts for a small and systematically shrinking percentage of cases, while atypical forms that present with few or no symptoms are the majority[11]. Short stature is a well-recognized complication of CD[12] although Cacciari *et al*[13] found that adult height is normal in patients who experienced their first symptoms of CD during adulthood. Adult height was shorter only in patients who had symptoms during childhood. This study demonstrated the prevalence and clinical features of CD (n = 35) in a group of 104 patients with ISS. Ages ranged from 2 to 18 years and the mean age of diagnosis was 16.9 years, similar to the results of the study by Mäki *et al*[14]. The age at onset of symptoms appeared to modify the clinical picture. Patients with an earlier onset of CD have a typical clinical picture, whereas patients with delayed onset have atypical presentation, such as short stature.

According to our findings, the prevalence of biopsy-proven CD was 33.6% in the group of ISS children, thereby justifying screening for this disease in all children with short stature. The proportion of CD in cases with ISS ranged from 18.6% to 59.1% in other studies[15,16]. The mechanism of growth retardation is not clearly understood in patients with CD; nutritional deficiencies especially zinc deficiency, low serum somatomedin activity and defects in growth hormone secretion have been proposed as underlying mechanisms[17-19]. An association between CD and autoimmune disorders, such as type I diabetes, autoimmune thyroid disease, and Sjögren's syndrome, has been well documented in the literature[20]. These conditions were not detected in patients in the present study. Susceptibility to CD is determined by genetic factors, which is confirmed by the occurrence of multiple cases of CD in the same family. The prevalence of CD found among first degree relatives is approximately 10%[21]. Screening of siblings in the present study showed that only two siblings (5.7%) had CD. The tests used for CD in this study were IgAAGA and IgA TTG antibodies. The total IgA level was determined also, because CD is associated with IgA deficiency. Antiendomysial antibody and anti-TTG antibodies have been shown to have a high sensitivity and specificity for the diagnosis of CD and correlate well with villous atrophy in untreated patients[32], but false-negative results have been obtained for patients with IgA deficiency[22]. A jejunal biopsy remains the gold standard for the diagnosis of CD but both serologic and histopathologic parameters of CD were investigated in the patients in this study. The sensitivity and specificity of serologic tests were variable. The TTG antibody test has been shown to have a higher sensitivity and specificity for the diagnosis of CD in our patients. Our patients were also tested for IgA deficiency and all were found to have normal IgA values. However, negative results for these tests would not exclude CD. Shamir *et al*[10], using multiple serological strategies

to diagnose silent CD, demonstrated that using any serological marker alone, including EMA antibodies detected by immunofluorescence, would underestimate the prevalence of CD[10]. We found that seven cases with partial villous atrophy had normal AGA, and four of this subgroup had normal anti-TTG antibodies also. Anti-TTG antibodies seem to be more specific but both measurements had limitations in the diagnosis of CD. Our data support the view that there is no single test or measurement that can identify all subjects with CD and ISS. Histological findings of CD showed a spectrum ranging from type 1 mucosal lesions to total villous atrophy type 4 in our study. Fifteen of 35 CD patients (42.9% of CD cases) had mild mucosal abnormality without villous atrophy, 15 (42.9% of CD cases) had partial villous atrophy, four (10.3% of CD cases) had subtotal villous atrophy and one (2.9% of CD cases) had total villous atrophy. According to histological findings, if we limited the diagnosis of CD to cases with villous atrophy, only 20 of 106 ISS cases in our study would have CD (19.3% of all cases) which is obviously more common than the general population.

In conclusion, the possibility of CD should be kept in mind as the prevalence of CD is high in patients with ISS. The patients affected by CD did not differ from those without CD in any of the symptoms. Patients with ISS should be evaluated for CD even in the absence of typical clinical symptoms. It is important to test all children with ISS for CD by measuring anti-EMA IgA or anti-TTG antibodies and performing an intestinal biopsy.

Clinical bottom line: In 33.6% patients with idiopathic short stature, CD may be the underlying cause. Investigation of CD is recommended in the diagnostic assessment of a short child with no endocrinological abnormality.

ACKNOWLEDGMENTS

It is our greate pleasure to thanks Dr. SP Payami for referring of some cases and Dr. T Rajabi for revewing of pathologic slides and Mr SA Latifi for statistical analysis of data. We greatly appreciate the cooperation and assistance we received from the nursing staff of Emam and Golestan Hospitals. The authors sincerely thank the children and their parents for their participation in this study. The authors also thank Mrs Shahnaz Shahid Zadeh for her excellent assistance.

COMMENTS

Background

Short stature is one of the most common causes for referrals to pediatric endocrinologists. Many of these patients have no identifiable medical abnormality and are classified as idiopathic short stature (ISS). For most of these patients, it is believed that genetic variations are the underlying cause. Short stature is a well known feature of pediatric celiac disease (CD).

Research frontiers

The prevalence of CD is high in patients with ISS and it is important to test all children with ISS for CD by measuring serologic markers and performing an intestinal biopsy.

Peer review

This is a well written manuscript with a good abstract. In the text they mentioned jejunal biopsies as the gold standard for diagnosis.

Abstract

AIM: To determine the prevalence of gluten sensitive enteropathy (GSE) in a large group of patients with iron deficiency anemia (IDA) of obscure origin.

METHODS: In this cross-sectional study, patients with IDA of obscure origin were screened for GSE. Anti-endomysial antibody (EMA) and tissue transglutaminase antibody (tTG) levels were evaluated and duodenal biopsies were taken and scored according to the Marsh classification. The diagnosis of GSE was based on a positive serological test and abnormal duodenal histology. Gluten free diet (GFD) was advised for all the GSE patients.

RESULTS: Of the 4120 IDA patients referred to our Hematology departments, 206 (95 male) patients were found to have IDA of obscure origin. Thirty out of 206 patients (14.6%) had GSE. The mean age of GSE patients was 34.6 ± 17.03 (range 10-72 years). The female to male ratio was 1.3:1. Sixteen patients had Marsh 3, 12 had Marsh 2, and 2 had Marsh 1 lesions. The severity of anemia was in parallel with the severity of duodenal lesions. Twenty-two GSE patients (73.3%) had no gastrointestinal symptoms. Fourteen GSE patients who adhered to GFD without receiving iron supplementation agreed to undergo follow up visits. After 6 mo of GFD, their mean hemoglobin levels (Hb) increased from 9.9 ± 1.6 to 12.8 ± 1.0 g/dL ($P < 0.01$). Interestingly, in 6 out of 14 patients who had Marsh 1/2 lesions (e.g. no villous atrophy) on duodenal biopsy, mean Hb increased from 11.0 ± 1.1 to 13.1 ± 1.0 g/dL ($P < 0.01$) while they did not receive any iron supplementation.

CONCLUSION: There is a high prevalence (e.g. 14.6%) of GSE in patients with IDA of obscure origin. Gluten free diet can improve anemia in GSE patients who have mild duodenal lesions without villous atrophy.

INTRODUCTION

Gluten sensitive enteropathy (GSE) is an autoimmune enteropathy due to food gluten intolerance in genetically predisposed people[1]. While GSE was thought to be a rare disease in the past and was believed to be essentially a disease of Europeans[2-5], recent screening studies showed that GSE is one of the most frequent genetically based diseases which occurs worldwide, with a prevalence ranging from 1:85 to 1:500 in different populations[6-9].

Several categories of GSE have recently emerged, including: monosymptomatic, oligosymptomatic, atypical (without gastrointestinal symptoms), silent, potential and latent form[10,11]. Iron deficiency anemia (IDA) is a commonly observed sign in GSE and is the only abnormality in 40% of patients[12]. In fact, only a minority of GSE patients present with classical malabsorption symptoms of diarrhea and weight loss, whereas most patients have subclinical or silent forms in which IDA can be the sole presentation[13].

In an extensive evaluation of the gastrointestinal tract in patients with IDA in order to identify a source of bleeding, the origin of bleeding cannot be detected in a significant minority of patients. In some of these patients IDA could be the result of diseases that impair iron absorption in the absence of bleeding[14,15]. Gluten sensitive enteropathy is one of these disorders which causes chronic inflammation in the bowel surface, leading to infiltration of T-lymphocytes, hyperplasia of crypts, villous atrophy and reduction of the bowel absorption surface for various nutrients such as iron[16].

Considering the broad spectrum of clinical manifestations of GSE, including anemia, osteoporosis, dermatitis herpetiformis, neurologic disorders and life-threatening complications such as non Hodgkin's lymphoma, small intestinal adenocarcinoma, esophageal cancer, and melanoma, early diagnosis of GSE is essential[17-20].

The present study was conducted to estimate the prevalence of GSE in a large group of patients with IDA of unknown origin by use of two highly sensitive and specific serological tests. We also present the follow-up data of those GSE patients who adhered strictly to a GFD and agreed to undergo follow up visits.

MATERIALS AND METHODS

Subjects

In this prospective study we evaluated all 4120 patients with IDA referred to the Hematology departments of Shariati Hospital, and Firoozgar Hospital from April 2003 to September 2007. Iron deficiency anemia was defined as: hemoglobin concentration less than 13.5 g/dL in men and less than 11.5 g/dL in women; mean corpuscular volume (MCV) less than 80 fl; and ferritin level less than 30 ng/mL.

Methods

Patients were evaluated in 6 steps. In step 1, patients with the following conditions were excluded from the study: known malignancies, hematological diseases (hemolytic anemia, aplastic anemia, thalassemia and myelodysplasia), known chronic diseases (e.g. chronic renal failure, chronic infectious disease, severe cardiac and respiratory disease, collagen vascular disease and chronic liver disease), pregnancy, heavy menstrual flow (cycles $\geqslant$ 7 d), menometrorrhagia, drug addiction, alcoholism, gastric surgery, and obvious blood loss (e.g. melena, hematochezia, hematuria, recurrent epistaxis). In this step 3559 patients were excluded and 561 were entered into the next step.

In step 2, patients were offered the chance to participate in the study, and a questionnaire was completed by each patient. Ninety-four patients declined to enter the study, and 467 patients entered into the next step. Informed consent was obtained from each patient and documented under institutional guidelines and oversight.

In step 3 all patients underwent colonoscopy. Patients with likely sources of blood loss, including any mass lesions, polyps greater than 1.5 cm, five or more vascular ectasias, histologically-proven inflammatory bowel disease, ischemic colitis, or solitary rectal ulcer were excluded. In this step 108 patients were excluded, and 359 patients were entered into the fourth step.

In step 4, all remaining patients underwent upper gastrointestinal endoscopy to exclude sources of blood loss, including varices, peptic ulcer, mass lesions, polyps greater than 1.5 cm in diameter, five or more vascular ectasias, or erosive gastritis. If none of the above lesions were detected, three biopsy specimens were taken from the second part of the duodenum. One hundred and forty seven patients were excluded in step 4.

In step 5, the remaining 212 patients underwent small bowel barium study. Six patients with abnormal small bowel series were excluded in this step.

Thus, from the 4120 patients with IDA who entered the Hematology department, 206 patients were found to have IDA of obscure origin.

In step 6, venous blood samples for tissue transglutaminase antibody (tTG) and endomysial antibody (EMA) were obtained from the 206 remaining patients with IDA of obscure origin. The duodenal biopsy specimens were fixed immediately in formalin solution for 4-8 h at room temperature and were routinely processed for conventional histological evaluation. The biopsy specimens were read by one expert histopathologist and the histological damage of duodenum was expressed based on Modified Marsh classification[3]: 0: Normal mucosal structure without significant lymphocytic infiltration; 1: Lymphocytic enteritis (more than 30 lymphocytes/100 epithelial cells); 2: Lymphocytic enteritis and crypt hyperplasia; 3A: Partial villous atrophy; 3B: Subtotal villous atrophy.

The levels of antibodies against IgA tTG were determined by ELISA using human recombinant tTG as the antigen (Orgentec Diagnostika GmbH, Mainz, Germany). Serum samples were diluted to 1:100 with distilled water, incubated with antigen for 30 min at room temperature, washed three times, and subsequently incubated for another 30 min with antihuman IgA. Optical density was read at 450 nm. Results were expressed in arbitrary units (AU) according to the reference calibrator. The cut-off value for a positive outcome was considered to be 10 AU, according to the instructions on the kit. IgA EMA assay was performed using an indirect immunofluorescence technique. The result was considered positive when bright green reticular fluorescence of smooth muscle was detected by fluorescence microscopy. Total serum IgA was measured in patients with negative tTG and EMA results to exclude IgA deficiency as a cause of false-negative tTG and EMA.

Table 1 Hemoglobin (Hb), Mean Corpuscular Volume (MCV) and Ferritin in GSE patients as compared with other anemic patients

	GSE	Other IDA patients[1]
Hb (g/dL)	9.8 ± 1.7	9.3 ± 2.0
MCV	74.0 ± 9.2	69.1 ± 12.6
Ferritin (ng/mL)	12.4 ± 9.8	11.2 ± 24.2

[1]*P* value was not significant compared to GSE patients (independent *t*-test).

Table 2 Mean hemoglobin level among patients with various degrees of duodenal lesions

MARSH classification	No. of GSE patients	Mean Hemoglobin level
1	2	11.2 ± 1.6
2	12	10.9 ± 1.2[b]
3	16	8.68 ± 1.5[b,d]

[b]*P* < 0.001 compared to Marsh 1 group (independent t-test), [d]*P* < 0.001 compared to Marsh 2 group (independent *t*-test).

The presence of positive tTG or EMA plus abnormal duodenal histology (e.g. Marsh 1, 2 or 3) was defined as gluten sensitivity enteropathy (GSE). All GSE patients were referred to our nutrition clinic and advised to follow a strict gluten free diet, but iron supplementation was withheld. Patients were followed up after 6 mo. Adherence to GFD was assessed in the follow up visit.

Statistical analysis

Data are presented as mean ± SD or percentage. Statistical analysis was performed using SPSS software version 15 and *t*-test for comparison of the means of quantitative variables. $P < 0.05$ was considered statistically significant.

RESULTS

From the 206 patients with IDA of obscure origin, 95 were men with a mean age of 37.6 ± 19.8 years, and 111 were women with a mean age of 39.1 ± 14.4 years.

Serological findings

Serological screening tests showed 31 patients had one or two positive tests. Twenty eight patients had positive tTG, and 23 had positive EMA. In 20 patients both tests were positive. None of the patients with negative serological tests was IgA-deficient.

Biopsy findings

Thirty-eight patients had abnormal duodenal histology. Sixteen patients had Marsh 3, 15 had Marsh 2 and 7 had Marsh 1. Among 38 patients with abnormal duodenal histology, 8 patients (3 with Marsh 2, and 5 with Marsh 1) had negative serologic tests. Eight patients who had abnormal duodenal histology but negative serological tests were not considered to have GSE.

GSE patients

Thirty out of 206 (14.6%) of the patients had GSE. The mean age of these patients was 34.6 ± 17.03 (range 10-72 years). The female/male ratio was 1.3:1. Thirty-one patients were positive for one or two serologic tests, but one of the tTG-positive patients had normal duodenal histology. Among 30 GSE patients, three had negative tTG, and seven had negative EMA. The mean duration of anemia before the diagnosis of GSE was 3.6 ± 1.4 years. These patients had been treated with oral iron for a mean duration of 1.9 years. Anemia improved in only 8 patients (26.8%) treated with oral iron supplementation before GSE diagnosis. Four patients (13.3%) had a family history of prolonged anemia of unknown cause in first degree relatives.

Six patients (20%) mentioned flatulence, two (6.7%) had intermittent diarrhea and one (3.3%) had dermatitis herpetiformis. There were no gastrointestinal symptoms in 22 GSE patients (73.3%).

The mean age of the GSE patients was not significantly different from other IDA of obscure origin patients (34.6 ± 17.0 *vs* 39.3 ± 17.1 years, respectively).

In Table 1, mean Hb, MCV and ferritin in GSE patients are compared with other patients with IDA of obscure origin. There were no statistically significant differences between the patient groups.

In GSE patients, the decrement in hemoglobin level was parallel to the severity of duodenal lesion. Patients with Marsh 3 lesions had more severe anemia (Table 2).

Sensitivity and specificity of the serologic tests

We calculated the sensitivity and specificity of the serological tests based on our definition of GSE (e.g. positive tTG or EMA, plus abnormal duodenal histology). The sensitivity and specificity of IgA tTG-Ab for diagnosing GSE were 90% and 98.5% respectively. Also, the sensitivity and specificity of EMA for diagnosing GSE were 76.6% and 100%, respectively.

Follow up

All the GSE patients were referred to our Nutrition Clinic, and GFD was advised for all of them. Iron supplementation was not started in the patients. The patients were invited for a follow up visit 6 mo after the diagnosis.

Four GSE patients were lost to follow up. Seven patients did not strictly adhere to GFD. For five other patients, iron supplementation was started at other clinics during the follow up period. Thus, we present the follow up data of 14 patients who strictly adhered to GFD and did not use iron supplementation during the 6 mo follow up period.

Mean hemoglobin increased from 9.9 ± 1.6 to 12.8 ± 1.0 g/dL ($P < 0.001$), and mean serum ferritin level increased from 12.0 ± 6.0 to 22.1 ± 7.9 ng/mL.

Interestingly, in 6 patients with Marsh 1/2 lesions (e.g. without villous atrophy) mean Hb increased from 11.0 ± 1.1 to 13.1 ± 1.0 g/dL ($P = 0.002$), and mean serum ferritin level increased from 16.5 ± 4.3 to 25.9 ± 6.2 ng/ml ($P = 0.014$). Demographic and clinical data are presented in Table 3.

Table 3 Demographic and clinical data of the 6 patients with Marsh 1/2 lesions that adhered to GFD

Patient No.	Gender	Age	Marsh classification	Hb level before GFD (g/dL)	Hb level 6 mo after GFD (g/dL)	Ferritin level before GFD (ng/mL)	Ferritin level 6 mo after GFD (ng/mL)
1	Male	29	1	12.8	14.0	19	24.6
2	Male	10	2	10.5	13.5	13.7	34.0
3	Female	17	2	9.5	12.2	20	23.5
4	Male	22	2	11.5	13.0	18	31.0
5	Male	30	2	11.1	14.2	9	16.2
6	Female	38	2	10.4	11.8	19	26.0

DISCUSSION

In this prospective study, we found GSE as the cause of IDA of obscure origin in a significant proportion (14.6%) of patients. Various rates of prevalence of GSE in IDA patients have been reported among different studies[21-24]. This discrepancy may be explained by patient selection criteria in the different studies.

In our study, the prevalence of GSE is amongst the highest rates reported. One reason is that we evaluated GSE among highly selected patients in whom the cause of IDA could not be identified after extensive evaluation. Also, we considered patients with positive serological tests and milder degrees of duodenal mucosal lesions (e.g. Marsh 1 or 2) as having GSE.

Physicians may fail to consider GSE as a cause of IDA when gastrointestinal symptoms are absent or nonspecific. In this study, most GSE patients (73.3%) did not report any gastrointestinal symptoms. In our study, there were no differences in demographic characteristics or hematological indices between GSE patients and other patients with anemia of obscure origin to help to distinguish them (Table 1). In GSE patents, the hemoglobin level was inversely correlated with the severity of the histological injury. Patients with Marsh 3 lesions had the most severe anemia, consistent with the role of impaired intestinal absorption in the pathogenesis of IDA. We found marked improvement of anemia in 14 patients who adhered to GFD but did not use iron supplementation. Many authors consider the presence of villous atrophy (e.g. Marsh 3) as one of the major criteria for diagnosing celiac disease (CD)[25,26]. In order to avoid this controversy in the definition of CD, we used the term "gluten sensitive enteropathy" rather than celiac disease to describe patients with any degree of intestinal damage together with positive serologic tests. In this study, we showed a significant objective improvement in hemoglobin level with GFD alone in patients with positive serology but no villous atrophy (e.g. Marsh 1 or 2). Our study suggests that restriction of the diagnosis of CD to patients with overt villous atrophy will exclude some patients who might benefit from GFD.

In this study, we used a human recombinant protein-based tTG test, which has higher sensitivity and accuracy than a guinea pig protein-based tTG test[27]. However, neither tTG nor EMA was 100% sensitive. We found 7 patients with positive tTG, negative EMA and intestinal damage. On the other hand, we found 3 patients with negative tTG, positive EMA, and duodenal lesions. While some guidelines suggest that either EMA or tTG is sufficient for identifying patients with CD[27,28], our study provides evidence that both tTG and EMA should be used for diagnosing CD.

In this study we did not evaluate GSE in all patients with IDA. One may speculate that some patients who were excluded before step 5, may have had GSE as well as another cause of IDA. The prevalence of GSE in IDA has been reported in previous studies[21-23]. In fact, the aim of our study was to evaluate GSE in a large population of patients with IDA of obscure origin. In a population based study done in Iran, the female to male ratio of GSE was 1 to 1.1[9]. Thus, the female to male ratio found in our study represents the ratio of the disease found in the general population of the country.

In conclusion, celiac disease should be considered in any patient with unexplained IDA, even if they do not have any gastrointestinal symptoms. Furthermore, GFD can improve anemia in IDA patients who have positive tTG/EMA and mild duodenal lesions without villous atrophy.

We kindly thank Professor Detlef Schuppan from Harvard Medical School and Dr. E Scott Swenson from Yale School of Medicine for their valuable comments.

COMMENTS

Background

Iron deficiency anemia (IDA) is the only abnormality in 40% of patients diagnosed with gluten sensitive enteropathy (GSE). The majority of patients with GSE don't present with classical malabsorption symptoms such as diarrhea and weight loss. In this study we determined the prevalence of GSE in patients with IDA in Iran.

Research frontiers

Recent screening studies shows that GSE is one of the most commongenetic based diseases which occurs worldwide, with a prevalence of ranging from 1:85 to 1:500 in different populations. Various rates of prevalence of GSE in IDA patients have been reported among different studies probably due to different patient selection criteria in these studies.

Innovation and breakthroughs

Iron deficiency anemia is a common presentation of GSE and can be the sole presentation of the disease. Gluten free diet (GFD) might improve mild duodenal damage (e.g. Marsh 1 or 2) without villous atrophy.

Applications

According to our results, identification of anemic patients with underlying GSE is of great importance. Since IDA can be the sole manifestation of GSE, by diagnosing GSE and giving GFD to patients, we can both prevent the complications of GSE and probably cure IDA without iron supplementation.

Terminology

GSE is an autoimmune enteropathy triggered by the ingestion of gluten-containing grains in susceptible individuals.

Peer review

This is a well-written, well analyzed and scientifically accurate manuscript. The paper is balanced in every part, the reference list is adequate and the conclusions are clear.

Abstract

AIM: To discuss the expression of glactin-3 in liver metastasis of colon cancer and its inhibition by modified citrus pectin (MCP) in mice.

METHODS: Seventy-five Balb/c mice were randomly divided into negative control group (n = 15), positive control group (n = 15), low MCP concentration group (n = 15), middle MCP concentration group (n = 15) and high MCP concentration group (n = 15). CT26 colon cancer cells were injected into the subcapsule of mouse spleen in positive control group, low, middle and high MCP concentrations groups, except in negative control, to set up a colon cancer liver metastasis model. The concentration of MCP in drinking water was 0.0%, 0.0%, 1.0%, 2.5% and 5.0% (wt/vol), respectively. Liver metastasis of colon cancer was observed after 3 wk. Enzyme-linked immunosorbent assay (ELISA) was used to detect the concentration of galectin-3 in serum. Expression of galectin-3 in liver metastasis was detected by immunohistochemistry.

RESULTS: Except for the negative group, the percentage of liver metastasis in the other 4 groups was 100%, 80%, 73.3% and 60%, respectively. The number of liver metastases in high MCP concentration group was significantly less than that in positive control group (P = 0.008). Except for the negative group, the median volume of implanted spleen tumor in the other 4 groups was 1.51 cm^3, 0.93 cm^3, 0.77 cm^3 and 0.70 cm^3, respectively. The volume of implanted tumor in middle and high MCP concentration groups was significantly smaller than that in positive control group (P = 0.019; P = 0.003). The concentration of serum galectin-3 in positive control and MCP treatment groups was significantly higher than that in the negative control group. However, there was no significant difference between them. Except for the negative control group, the expression of galectin-3 in liver metastases of the other 4 groups showed no significant difference.

CONCLUSION: Expression of galectin-3 increases significantly in liver metastasis of colon cancer, which can be effectively inhibited by MCP.

INTRODUCTION

Liver metastasis is the main cause that impacts the therapeutic effect and postoperative prognosis of colorectal cancer. Inhibiting liver metastasis is beneficial to the therapeutic effect and postoperative prognosis of colorectal cancer[1]. Galectin-3, a carbohydrate-binding protein on tumor cell surface, is closely related to cell to cell adhesion, aggregation of cancer cells *in vitro*, tumor growth and metastasis *in vivo*[2,3]. Galectin-3 is highly expressed in a variety of metastatic cancer cells[4]. Galactosyl, a main component of modified citrus pectin (MCP), can specifically inhibit tumor growth and metastasis *in vivo* and galectin-3-mediated functions *in vitro*[5]. Few studies are available dealing with the inhibitory effects of MCP on cancer metastasis. The aim of this study was to discuss the inhibitory effect of MCP on liver metastasis in a rat colon cancer model.

MATERIALS AND METHODS

Cell lines

Mouse colon adenocarcinoma cell line (CT-26), preserved

and passaged in our biotechnology laboratory, was cultivated in RPMI-1640 culture medium containing 10% new born calf serum, penicillin G and streptomycin at 37℃ in an 5% CO_2 incubator containing 50 mL/L CO_2.

Animals

Seventy-five 6-8 wk old Balb/c female mice, offered by Guangdong Medical Laboratory Animal Center (certification No. 2006A019), weighing 20-25 g, were used in this study. The mice were free from specified-pathogens. Experiments were performed in the SPF Animal Laboratory.

Drugs and reagents

MCP was provided by Centraxinc International, Inc (Francisco, USA). Mouse galectin-3 ELISA kit was provided by R&D Company (Minneapolis, USA). Mouse galectin-3 affinity purified pol was purchased from Jingmei Biotech Co, Lid (Shanghai, China).

Main equipments

U.S Beecher tissue microarray meter, ST360 auto ELIASA were purchased from Kehua (Shanghai, China).

Establishment of mouse model of liver metastasis of colon cancer

Seventy-five Balb/c mice were randomly divided into negative control group, positive control group, low MCP concentration group, middle MCP concentration group and high MCP concentration group. The concentration of MCP in drinking water was 0.0%, 0.0%, 1.0%, 2.5% and 5.0% (wt/voL), respectively. CT26 cells in exponential growth with sufficient NS were used to mix up into a suspension (1×10^6/mL). The mice were anesthetized with 4% chloral hydrate (10 mL/kg) by injecting into their abdominal cavity and an abdominal wall incision paralleling the left subcostal margin was then made. Laparotomy was performed and 0.05 mL of CT-26 suspension was injected into the spleen. A same volume of NS was injected into the abdominal cavity of mice in the negative control group. The incision was closed with #1 suture. All mice continuously received MCP dissolved in drinking water from the 2nd d after operation, to the necropsy day 21. A same volume of distilled water was given in negative control group. All mice had free access to food and water during the experiment.

Observation

After a 3-wk observation, the eyeball of mice was removed to collect 0.5-1.0 mL peripheral blood. All mice were killed by decapitation. The abdominal cavity was opened to observe primary neoplasms of the spleen and record the volume and number of neoplasms (volume = $ab^2/2$, a = max diameter, b = min diameter). The total volume was recorded if there were more than 2 neoplasms. The number of liver metastases was calculated. All neoplasms were identified with HE staining. Liver metastasis was divided into 4 grades as previously described[6]: grade 0: no liver metastases; grade Ⅰ: 1-5 liver metastases; grade Ⅱ: 6-10 liver metastases; grade Ⅲ: more than 10 liver metastases.

ELISA analysis of galectin-3

Blood sample was centrifuged at 3000 r/min for 5 min to separate serum. The isolated serum was stored at ≤ -20℃. The serum sample was diluted in a diluent at 1: 20. In brief, 100 μL of a diluent was added into each well of a plate and incubated for 2 h at room temperature, and the plate was washed with a washing buffer. One hundred μL of detection antibody was added into each well of a plate, incubated for 2 h at room temperature, and the plate was washed with a washing buffer. One hundred μL of a working diluent of streptavidin-HRP was added into each well of a plate, incubated for 20 min at room temperature in the dark, the plate was washed. Finally, 100 μL of a substrate solution was added into each well of a plate, incubated for 20 min at room temperature in the dark, and 50 μL of a stop solution was then added into each well of the plate. A microplate reader was used to read the absorbance at 450 nm, then a standard curve was plotted and a formula was used to fit the OD of standard samples.

Liver metastasis tissue microarray

Liver tissue sections were stained with HE to select typical nidi, such as a region rich of neoplasms but lack of necrosed areas and bleeding. A tissue microarray meter was used to perforate into a paraffin block (25 mm × 25 mm × 20 mm). The diameter of each hole was 1.2 mm, and the distance between two holes was 1.0 mm. Fifty holes were arranged in 10 lines and 5 arrays. A 1.2-mm long puncture needle was used to draw out the marked typical tissue core and to transfer it to a certain location on the paraffin block. Forty-seven metastasis samples were arranged into 2 paraffin blocks. Each sample included 2 marked cores. The tissue array paraffin was kept on a 55℃ copper board for 30 min. The paraffin block was pressed gently to array the tissue cores and cooled at room temperature. The arrays were sliced quickly after pre-cooled at 4℃ for 4 h.

Immunohistochemistry analysis

The tissue sample sections were stained with galectin-3 immunohistochemistry following the instructions provided with galectin-3 affinity purified polyclonal antibody. The sections were deparaffined and hydrated. After washed with PBS, the sections were incubated with 3% hydrogen dioxide for 10 min at room temperature, with antibody for 10 min at room temperature, with EnVision for 30 min at room temperature, finally with DAB for color development. The results were judged double-blindly by 2 pathologists. The level of galectin-3 expression was classified into negative (-), weakly positive (+), positive (++) and strong positive (+++) as previously described[7].

Statistical analysis

All the data were analyzed by SPSS10.0 Software. Tumor

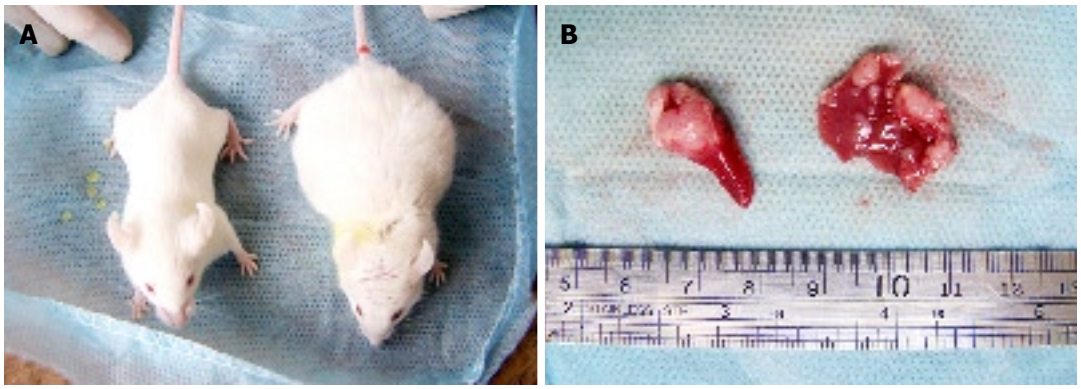

Figure 1 Mouse model of liver metastastic colon cancer. A: Tumor-bearing and healthy mice; B: Primary spleen tumor and liver metastasis.

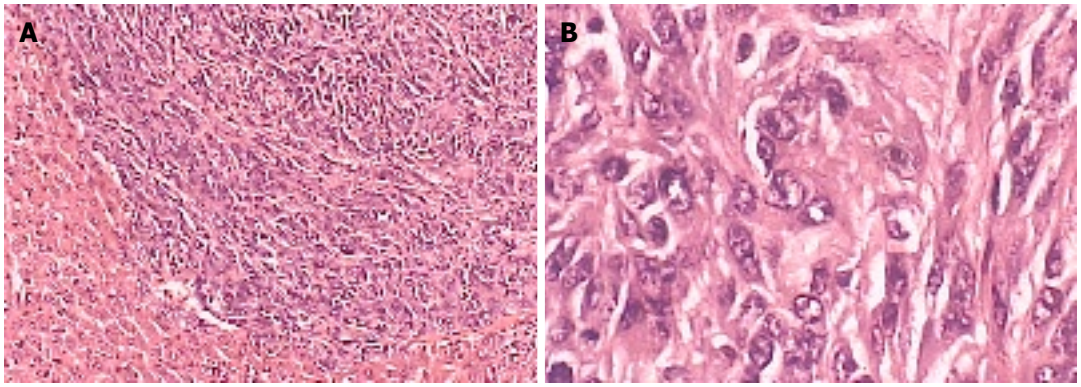

Figure 2 Liver metastastic colon cancer tissue sections stained with HE (A × 200, B × 400).

Table 1 Liver metastases

Groups	*n*	Numbers of liver metastases				χ^2	*P*
		0 (0)	I (1-5)	II (6-10)	III (> 10)		
Positive control group	15	0	2	7	6		
1.0% MCP group	15	3	6	2	4	3.996	> 0.05
2.5% MCP group	15	4	7	1	3	7.069	> 0.05
5.0% MCP group	15	6	4	2	3	8.052	< 0.05[1]

[1]The number of liver metastases in high MCP concentration (5.0%) group was significantly less than that in positive control group ($P = 0.008$).

Table 2 Volume of primary spleen tumor (cm^3)

Groups	*n*	*M*	mean ± SD	χ^2	*P*
Positive control group	15	1.51	1.71 ± 1.29		
1.0% MCP group	15	0.93	1.28 ± 0.68	2.955	> 0.05
2.5% MCP group	15	0.77	0.90 ± 0.55	8.083	< 0.05[1]
5.0% MCP group	15	0.70	0.76 ± 0.30	7.989	< 0.05[1]

[1]The volume of primary spleen tumor in middle and high MCP concentration groups was significantly smaller than that in positive control group ($P = 0.003$).

volume, number of liver metastases, concentration of galectin-3 in serum and tissue were analyzed by non-parametric test.

RESULTS

Mouse living status

No mouse died during the 3-wk experiment period. Some mice were found to have tumor mass bulging on the abdominal wall. Some of the cancer-carrying mice appeared signs of mental depression, such as reduced activity, slow response, gloomy hair color, loss of appetite (Figure 1).

Metastatic liver cancer

Except for the negative control group, the liver metastatic rate for the other 4 groups treated with high, middle and low MCP concentrations was 100%, 80%, 73.3% and 60%, respectively. The number of liver metastases in high MCP concentration group was significantly less than that in low and middle MCP concentration groups ($P < 0.05$) (Table 1).

Volume of primary spleen tumor

The median volume of implanted spleen tumor in high, middle and low MCP concentration groups was 1.51 cm^3, 0.93 cm^3, 0.77 cm^3 and 0.70 cm^3, respectively. No tumor was found in negative control group. The volume of tumor in high MCP concentration group was significantly lower than that in middle and low MCP concentration groups ($P < 0.05$) (Table 2, Figure 2).

Concentration of galectin-3 in serum

The concentration of galectin-3 in serum samples calculated according to the standard regression formula was (14.63 ± 10.08) ng/mL in negative control group, (91.01 ± 22.94) ng/mL in positive control group, (82.75 ± 20.33) ng/mL in low MCP concentration group, (79.01 ± 17.64) ng/mL in middle MCP concentration group and (85.94 ± 15.52) ng/mL in high MCP concentration

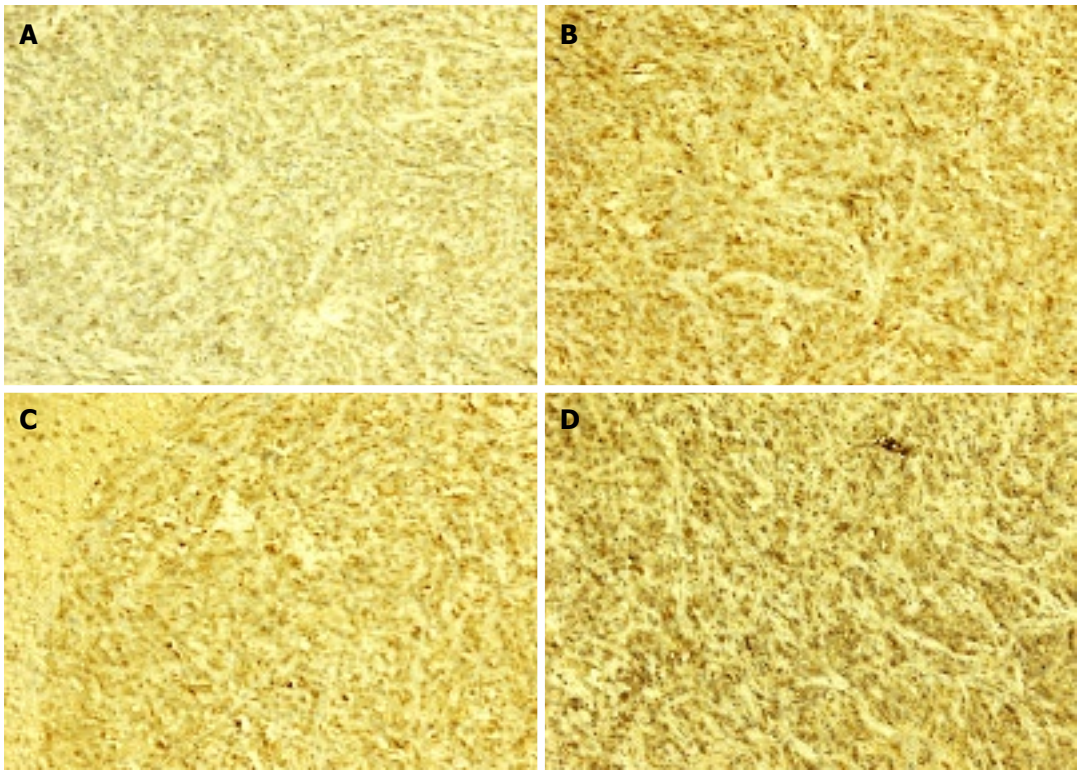

Figure 3 Expression of galectin-3 (× 200) in positive control group (A),1.0% MCP concentration (B), 2.5% MCP concentration group (C), and 5.0% MCP concentration group (D).

Table 3 Serum concentration of galectin-3 (μg/mL)

Groups	*n*	mean ± SD	*H*	*P*
Negative control group	15	14.63 ± 10.08	9.37	< 0.01[1]
Positive control group	15	91.01 ± 12.94		
1.0% MCP group	15	82.75 ± 20.33		
2.5% MCP group	15	79.01 ± 17.64	4.34	
5.0% MCP group	15	85.94 ± 15.52		

[1]The serum concentration of galectin-3 in negatives control group was significantly lower than that in positive control group ($P < 0.01$).

Table 4 Expression of galectin-3 in liver metastasis

Groups	*n*	Expression of galectin-3				*H*	*P*
		(-)	(+)	(++)	(+++)		
Positive control group	15	5	6	2	2	0.52	*P* = 0.170
1.0% MCP group	12	4	3	2	3		
2.5% MCP group	11	2	6	2	1		
5.0% MCP group	9	3	4	1	1		

group, respectively. The results indicate that the concentration of serum galectin-3 in positive control group and MCP treatment groups was significantly higher than that in negative control group ($P < 0.01$, Table 3).

Expression of galectin-3 in liver metastasis

Brown cells in cytolymph under microscope were considered positive cells. The percentage of positive cells in metastatic liver tissue showed that galectin-3 had no significant difference in liver metastases positive control and MCP treatment groups (Figure 3, Table 4).

DISCUSSION

Liver metastasis of colon cancer includes tumor cell infiltration, exfoliation, adhesion, aggregation and invasion, which involve carbohydrate-mediated recognition proteins, such as the galectins. Adhesion of tumor cells to tumor embolus and anchorage of tumor cells to blood vessel endothelium or basement membrane are the two crucial steps of liver metastasis of colon cancer. Different galectins expressed in different steps of metastasis cascade might play a crucial role in tumor progression[8]. Galectin-3, a member of the lectin family, is a multifunctional oncogenic protein which regulates cell growth, adhesion[9], proliferation and apoptosis, as well as cell-cell interaction and angiogenesis[10-13]. A large body of evidence has confirmed that metastatic cancer cells significantly express galectin-3, and high expression of galectin-3 can be detected in both primary and metastatic lesions[14], even in blood[15], showing a strong relation with cancer growth and metastasis[16-18]. Moreover, the expression of galectin-3 can be used as a diagnostic and prognostic marker of colorectal cancer[19-21]. Therefore, if the function of galectin-3 is blocked, the progression of adhesion and aggregation can be intercepted, which may stimulate the development of novel drugs for the targeted treatment of colorectal cancer and other cancers[22].

MCP is a non-digestible, water-soluble polysaccharide fiber derived from citrus fruits, and also a complex polysaccharide rich in galactosyl residues. MCP can specifically inhibit carbohydrate-binding protein as a high affinitive ligand[23]. When the concentration of MCP reaches an adequate level, galectin-3 protein on the surface of cancer cells would be almost completely blocked by MCP molecules. As a result, the procession of adhesion

and aggregation between cancer cells will be intercepted. In addition, MCP can inhibit morphogenesis of endothelial cells and angiogenesis by blocking galectin-3, thus intercepting cancer cells to absorb nutrition from vessels and cancer progression[24,25]. However, there is no evidence that MCP attacks cancer cells directly or indirectly with or without toxicity and side effects[26]. *In vitro* experiments have shown that MCP is able to inhibit adhesion of cancer cells to laminin and homotypic aggregation[27]. Animal experiments also showed that oral MCP can inhibit the growth and metastases of rat prostate cancer cells[28], human breast cancer[5] and melanoma cells[29-31].

The results of our study show that MCP could effetely inhibit the growth and metastasis of implanted colon cancer in mouse spleen. The number of liver metastases and tumor volume in high MCP concentration group were significantly less and smaller than those in control group, indicating that MCP can inhibit the growth and metastasis of colon cancer in a dose-dependent manner, which is consistent with the reported data[5,28-30]. In contrast, low MCP concentration group showed no significant difference in colon cancer growth and liver metastasis, which may be due to the lack of samples and the low sensitivity of non-parametric statistics. Further studies are needed to clarify the role of MCP concentration in this regard.

ELISA and immunohistochemistry analysis have shown that MCP does not impact glactin-3 concentration and expression in liver metastatic cancer cells, but inhibits liver metastasis *in vitro*[30]. The possible mechanism is that MCP only blocks out galectin-3 molecules on the surface of cancer cells, but does not intercept the expression or secretion of cancer cells. It was recently reported that galectin-3 can be used as a reliable diagnostic marker of colorectal cancer and is one of the target proteins in cancer treatment[22].

In conclusion, MCP can effectively inhibit the growth of colon cancer and liver metastasis by intercepting the adhesion and aggregation of cancer cells. MCP, as a natural polysaccharide derived from fruits and a nontoxic drug, may pave a new way in controlling the growth and metastasis of colon cancer and other cancers. The role of MCP and chemotherapy in controlling and curing liver metastatic colon cancer needs further study.

The authors thank the staff in Pathology Department and Biotechnology Laboratory for their technical assistance.

COMMENTS

Background

Galectin-3 is a carbohydrate-binding protein closely related with cancer growth and metastasis. Studies have shown that galectin-3 is over-expressed in different types of cancer. Dietary components play an important role in cancer progression and metastasis, carbohydrate-mediated recognition processes participate in cancer progression. Modified citrus pectin (MCP), a non-digestible and water-soluble polysaccharide fiber derived from citrus fruits, can inhibit galectin-3-mediated function *in vivo* and *in vitro*.

Research frontiers

The role of galectin-3 in cancer growth and metastasis is an important field in tumor research. Several experimental studies have reported the specific inhibitory effect of MCP on different cancer cells in xenograft models. The present study investigated the effect of MCP on colon cancer growth and liver metastasis *in vivo*. In addition, the expression of galectin-3 was also studied to describe the possible anticancer mechanism of MCP.

Innovations and breakthroughs

Few experiments have been conducted to observe the effect of MCP on preventing cancer growth and metastasis *in vivo*. This study showed the inhibitory effect of MCP on liver metastasis of colon cancer in a mouse model. Besides, the expression of galectin-3 in tumor tissue and serum was tested to describe the galectin-3 status during MCP treatment.

Applications

This study demonstrated that galectin-3 was over-expressed in liver metastasis of colon cancer and oral MC could inhibit cancer growth and metastasis in a mouse model. The results show that galectin-3, as a potential marker and therapeutic target of colorectal cancer, played an important role in prevention and treatment of cancer.

Terminology

Citrus pectin is a complex polysaccharide fiber derived from the pulp and peel of citrus fruits. Citrus pectin is rich in galactosyl, a ligand for galectin-3, when it is modified by high-pH and temperature. MCP inhibits galectin-3 function when citrus fruits are combined with galectin-3.

Peer review

In this manuscript, the authors studied the inhibitory effect of MCP on liver metastasis in a mouse colon cancer model. The study demonstrated that MCP inhibited liver metastasis by suppressing the function of galectin-3. The study is well designed and the results are reliable.

Abstract

AIM: To investigate the protective effect of melatonin on liver after intestinal ischemia-reperfusion injury in rats.

METHODS: One hundred and fifty male Wistar rats, weighing 190-210 g, aged 7 wk, were randomly divided into melatonin exposure group, alcohol solvent control group and normal saline control group. Rats in the melatonin exposure group received intraperitoneal (IP) melatonin (20 mg/kg) 30 min before intestinal ischemia-reperfusion (IR), rats in the alcohol solvent control group received the same concentration and volume of alcohol, and rats in the normal saline control group received the same volume of normal saline. Serum samples were collected from each group 0.5, 1, 6, 12, and 24 h after intestinal IR. Levels of serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were measured with an auto-biochemical analyzer. Serum TNF-α was tested by enzyme-linked immunosorbent assay (ELISA). Malondialdehyde (MDA) in liver was detected by colorimetric assay. Pathological changes in liver and immunohistochemical straining of ICAM-1 were observed under an optical microscope.

RESULTS: The levels of ALT measured at various time points after intestinal IR in the melatonin exposure group were significantly lower than those in the other two control groups ($P < 0.05$). The serum AST levels 12 and 24 h after intestinal IR and the ICAM-1 levels (%) 6, 12 and 24 h after intestinal IR in the melatonin exposure group were also significantly lower than those in the other two control groups ($P < 0.05$).

CONCLUSION: Exotic melatonin can inhibit the activity of ALT, AST and TNF-α, decrease the accumulation of MDA, and depress the expression of ICAM-1 in liver after intestinal IR injury, thus improving the liver function.

INTRODUCTION

Bowel transplantation is still the only definite therapy for bowel dysfunction although it is more difficult than other organ transplantations at the final stage of bowel dysfunction[1]. Small intestine with high immunogenicity has the highest reject reaction rate in all organ transplantations[2]. Although more and more powerful nonspecific immunosuppressive agents have been used in recent years, the rate of graft rejecting reaction is still higher than 50% in intestine[3]. Current clinical data show that combined liver and small intestine transplantation decreases both acute and chronic rejection compared with simple small intestine transplantation[4]. Small intestine transplantation, the best therapy for bowel dysfunction at present, cannot replace total parenteral nutrition (TPN) due to its severe rejecting reaction. Long term

TPN therapy may induce liver injury and some patients with intestinal dysfunction can accompany hepatic diseases. Since combined liver and intestine transplantation can prevent further liver injuries[5], systematic research should be done to identify the mechanism of hepatic injury caused by intestinal ischemia-reperfusion (IR) and detect the possible intervention which can lessen the injury. Melatonin can protect liver from intestinal IR injury due to its powerful ability to clear free radicals[6]. The objective of this study was to determine the possible protective effect and mechanisms of melatonin in intestinal IR models and provide evidence for its clinical application in spare-part surgery.

MATERIALS AND METHODS

Materials

One hundred and fifty healthy male Wistar rats, weighing 190 to 210 g, aged 6-7 wk, were randomly allocated into melatonin disposure group, alcohol solvent control group and normal saline (NS) control group. All rats were raised for at least 1 wk before operation in a 12 h dark and 12 h light cycle, with free access to food and water. One gram of melatonin (Sigma Company, USA) was dissolved in alcohol solvent (40%) and kept at a subambient temperature. Rats in the melatonin exposure group received 20 mg/kg intra-peritoneal melatonin diluted by NS to 1/10 of the incipient concentration 30 min before intestinal IR. Rats in the alcohol solvent control group received the same concentration of alcohol and NS. Thiopental sodium (40 mg/kg) was injected into biceps femoris of rats 45 min before the intestinal IR model was established. A model of pan-small intestinal IR injury was established by occlusion of the superior mesenteric artery (SMA) for 30 min. Serum samples were collected from rats in each group after reperfusion for 0.5, 1, 6, 12 and 24 h. A paraformaldehyde (PFA, 40 g/L) phosphate buffer (0.1 mol/L, pH = 7.3) was provided by Laboratory of Shengjing Hospital, China Medical University (Shenyang, China). Correlated biochemical agents were bought from Boehringer Mannheim Company in Germany. MDA kits were purchased from Nanjing Jiancheng Biological Engineering Research Center. TNF-α kit was bought from Shenzhen Jingmei Biological Engineering Limited Company (China). ICAM-1 kit was purchased from Serotech Company in UK. OLYMPUS-BX60 optical microscope and photograph system, HITACHI-7600A automatic biochemistry analyzer and SAKURA paraffin section cutter, were provided by Laboratory of China Medical University (Shenyang, China).

Methods

Blood was obtained by trans-diaphragmatic cardiac puncture, each sample was centrifuged for 5 min at 3000 r/min with the clear supernatant remained. ALT and AST were detected with an automatic biochemistry analyzer. Serum TNF-α was determined by ELISA. MDA in liver tissue homogenate obtained from the central part of medial lobes was assayed by colorimetry. ICAM-1 in liver cells was tested by immunohistochemistry and observed under an optical microscope. Cells (including endotheliocytes in liver sinusoid and hepatocytes) with fine yellow particles in cytoplasm were defined as positive. The number of ICAM-1 positive cells per one high power field was calculated, the mean value was expressed as mean ± SD. All parameters were analyzed by variance analysis and SNK test using SPSS 13.0.

RESULTS

Serum ALT

After reperfusion for 12 and 24 h, the levels of ALT in the exposure group at each time point were significantly lower than those in the alcohol solvent and NS control groups ($P < 0.05$), while there was no obvious difference between alcohol solvent and NS control groups (Table 1).

Serum AST

After reperfusion for 12 and 24 h, the levels of AST in the melatonin exposure group were significantly lower than those in the alcohol solvent and NS control groups ($P < 0.05$), while there was no obvious difference between the alcohol solvent and NS control groups (Table 1).

Serum TNF-α

After reperfusion for 12 and 24 h, the levels of TNF-α in the melatonin exposure group were significantly lower than those in the alcohol solvent and NS control groups ($P < 0.05$), while there was no obvious difference between the alcohol solvent and NS control groups (Table 1).

MDA in liver tissue homogenate

After reperfusion for 6, 12 and 24 h, MDA in the melatonin exposure group was significantly lower than that in the alcohol solvent and NS control groups ($P < 0.05$), while there was no obvious difference between the alcohol solvent and NS control groups (Table 1).

ICAM-1 stained cells in liver tissue

After reperfusion for 6, 12 and 24 h, the positive rate of ICAM-1-stained cells in the melatonin exposure group was significantly lower than that in the alcohol solvent and NS control groups ($P < 0.05$), while there was no obvious difference between the alcohol solvent and NS control groups. The positive cells were mainly liver parenchymal cells located near the sinus hepaticus and sinusoid endothelial cells of liver (Figure 1A-F). The number of positive cells in the alcohol solvent and NS control groups increased gradually and reached its peak at 12 h, and then decreased. The similar trend occurred in the melatonin exposure group, but the extent was much lower than that in the other two control groups (Table 1).

DISCUSSION

Serum ALT and AST levels are generally accepted as the most sensitive indexes of acute hepatic injury and AST appears at the later phase[7]. After reperfusion, the ALT levels in the three groups gradually decreased with the time and were lower in the melatonin exposure group than in the other two control groups ($P < 0.05$),

[a]$P < 0.05$ *vs* alcohol solvent and NS control groups.

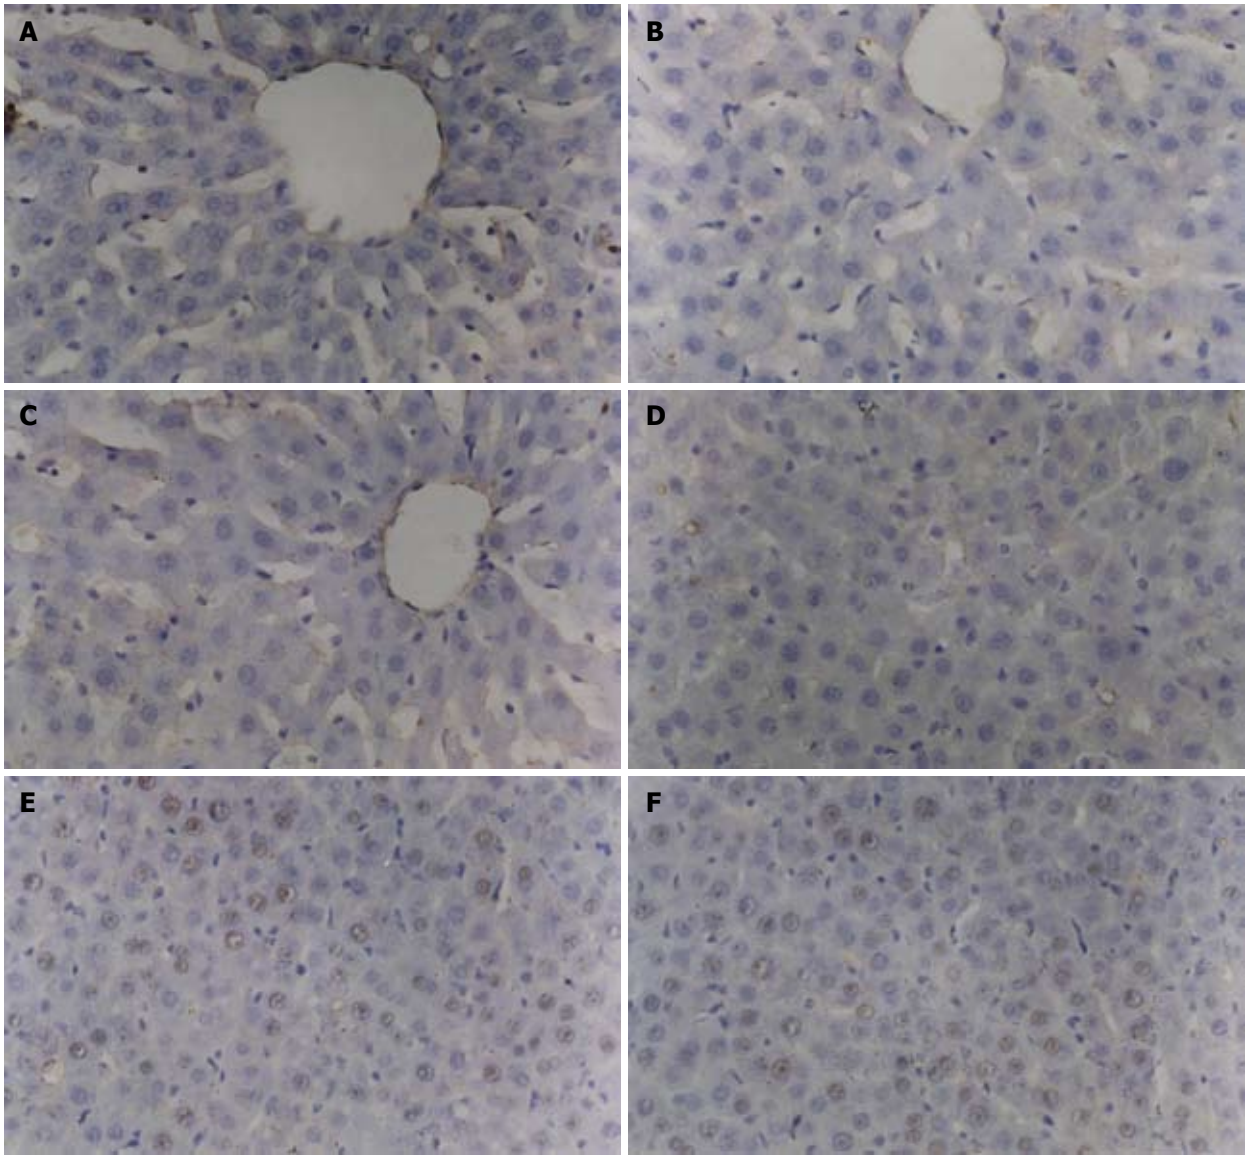

Figure 1 Positive cells are mainly hepatic parenchymal cells located near the sinus hepaticus and sinusoid endothelial cells of liver in melatonin exposure group (A, D), alcohol solvent control group (B, E), NS control group (C, F). The positive cell rate of two control groups increased gradually and reached its peak 12 h after reperfusion, then decreased. This condition also occurred in melatonin exposure group, but the extent was much lower than that in the control groups.

while AST level gradually increased with the time and maintained at its original level in the melatonin exposure group ($P < 0.05$, Table 1). Hepatic injury occurred at the early stage of pan-intestinal IR SMA was blocked for 30 min. The possible reason is that indirect clipping SMA reduced the portal blood flow. The accrescence of ALT indicates the hepatic injury, but the ischemic time is too short to lead to prominent AST changes. After the block of SMA was released, the hepatic injury due to reduced blood flow was ameliorated, but a great amount of active substances, such as free radicals, TNF-α, ICAM-1, *etc*, entered hepatic tissues *via* superior mesenteric and portal veins leading to secondary hepatic injuries, which can explain the variable curves of ALT and AST in the other two control groups. Compared with the other two control groups, exogenous melatonin could ameliorate the hepatic function after intestinal IR injury at the early or late phase. Recent studies about the protective effect of melatonin on IR injury in various organs showed that melatonin can eliminate free radicals, inhibit release of inflammatory media and apoptosis[8-10]. On the other hand, many factors can result in IR injury, such as free radicals[11], overload of calcium[12], inflammation of white blood cells and vascular endothelial cells[13] and apoptosis, *etc*[14]. Therefore, we detected serum TNF-α, MDA and ICAM-1-stained cells in liver tissues in this study. TNF-α gradually increased during the first 12 h after reperfusion and then decreased when it reached its peak between 12 and 24 h in the three groups. However, the TNF-α level was lower in the melatonin exposure group than in the other two control groups 12 and 24 h after reperfusion ($P < 0.05$), suggesting that TNF-α increases in systemic circulation after pan-intestinal IR, which can be effectively inhibited by exogenous melatonin[15-17]. Furthermore, TNF-α is generally accepted as an important inflammatory medium which has the same position as the interleukin family, and participates in almost all inflammatory reactions[18,19]. According to the curves of TNF-α and AST in the first 12 h systemic circulation after reperfusion, the secondary hepatic injury after pan-intestinal reperfusion is related to the concentration of TNF-α in systemic circulation. MDA is a final product of lipid peroxide, and its concentration in tissues can directly reflect the extent of lipid peroxide injury[20]. The concentration of MDA in each group gradually increased after reperfusion, which is generally considered the result of generous release of free radicals and accumulation of lipid peroxide products after pan-intestinal IR[21]. However, the concentration of MDA was obviously lower in the melatonin exposure group than in the other two control groups 6, 12 and 24 h after reperfusion, indicating that melatonin can relieve the IR injury by eliminating free radicals[22]. It was reported that ICAM-1 is directly correlated with the inflammation of white blood cells and vascular endothelial cells[23]. In this study, ICAM-1 gradually increased after reperfusion and decreased after reaching its peak between 12 and 24 h, which was in accordance with the concentration of TNF-α in systemic circulation. However, ICAM-1 was obviously lower in the melatonin exposure group than in the other two control groups. Analysis of the data showed that after clipping SMA for 30 min, (1) the first hepatic injury was relatively mild and reversible while the secondary injury was permanent and severe; (2) a large number of free radicals induced the expression of inflammatory factors such as TNF-α and ICAM-1 leading to hepatic injury through the portal vein, and free radicals directly caused peroxide injury after reperfusion; (3) exogenous melatonin protected liver from intestinal IR injury by inhibiting the production of free radicals, reducing the concentration of TNF-α in systemic circulation, and suppressing the expression of ICAM-1 in liver, *etc*. It has been recently shown that liver is the final metabolic place of melatonin and melatonin protects liver from intestinal IR injury[24-26]. Studies have shown that melatonin has no side effect when a large dose is used[27,28]. Intestine can absorb nutrients and has immune functions, and its vascular anatomy is specifically related with liver, the biggest digestive gland in human body. Since the blood in intestinal vein goes through the portal vein to the liver, intestinal IR inevitably affects the normal physical function of liver. During IR, a great amount of xanthic dehydrogenase in intestinal mucosa would change into xanthic oxydase, and xanthic oxydase can induce the production of free radicals which enhance the expression of adherence factors such as ICAM-1. These adherence factors are the main etiological agents of the secondary hepatic injury[29]. Up to now, rejecting reaction, graft-*versus*-host disease (GVHD) and infection are the restrained factors for intestine transplantation[30].

In conclusion, IR is the key mechanism underlying liver injuries at the early stage of organ transplantation.

ACKNOWLEDGMENTS

The authors thank Dr. Wei-Guo Zhang for his helpful discussion and proof reading.

COMMENTS

Background

Common intestinal ischemic diseases, intestinal resection caused by various etiologies, intestinal transplantation due to short bowel syndrome and long-term intravenous nutrition induce various hepatic injuries. On the other hand, combined liver and intestine transplantation has some immune dominance compared with simple intestinal transplantation, and acute or chronic rejecting reaction occurred in combined liver and intestine transplantation obviously decreases. Thus, it is necessary to study the mechanism of hepatic injury caused by intestine ischemia-reperfusion (IR) and discuss the injury relieving therapies.

Research frontiers

Melatonin is an effective free radical scavenger in liver, kidney, pancreas, digestive tract, *etc*. It is generally accepted that melatonin plays a role in protecting liver from intestinal IR injury by eliminating free radicals in cytoplasm. Thus, melatonin secreted by conarium is an endocrine hormone and has a very complicated mechanism of action and its receptors are distributed in almost all human organs. At present, researchers are paying their attention to the modulating function of melatonin in various inflammatory media.

Innovations and breakthroughs

Melatonin interferes with hepatic injury after intestinal reperfusion. The possible protective mechanism of melatonin by producing and releasing inflammatory agents was discussed. Melatonin was found to be able to reduce the concentration of serum TNF-α and inhibit the expression of ICAM-1.

Applications

Exogenous melatonin can protect liver from intestinal IR injury after intestinal

ischemic-reperfusion by eliminating free radicals, reducing the production and release of inflammatory media, *etc*. As an effective and safe clinical medicine, it can be extensively used in surgery.

Terminology

Melatonin is an endocrine hormone secreted by conarium. Endogenous melatonin plays an important role in organic biorhythm, developing cycle, internal environmental stabilization and anti-caducity. TNF-α is an important inflammatory medium and participates in almost all inflammatory reactions. ICAM-1 is a member of the adhesive molecule family and is closely related to adhesion of neutrophile granulocytes and vascular endothelial cells in inflammatory reaction.

Peer review

This is a well written and interesting manuscript. The authors demonstrated that melatonin can protect liver from intestinal IR injury by abating the concentration of serum TNF-α and inhibiting the expression of ICAM-1 in liver cells.

Abstract

We report a case of 30-year-old woman with Peutz-Jeghers syndrome (PJS). Because of small intestinal obstruction, she received the small intestinal polypectomy in 2001, and the pathological diagnosis was Peutz-Jeghers polyp canceration (mucinous adenocarcinoma, infiltrating full-thickness of the intestine). The patient did not feel uncomfortable after 6 mo of chemotherapy and other management. We kept a follow-up study on her and found that she suffered from cervical cancer in 2007, with a pathological diagnosis of cervical adenosquamous carcinoma.The patient presented with typical features of PJS, but without a family history. The PJS accompanied with both small intestinal and cervical malignancies has not been reported so far in the world.

INTRODUCTION

Peutz-Jeghers syndrome (PJS) is an autosomal dominant disease characterized by hamartomatous polyps in the gastrointestinal tract and mucocutaneous melanin pigmentation. Patients with PJS are at increased risk for common and unusual types of gastrointestinal and extra-gastrointestinal tumors[1].This report describes the clinicopathological characteristics of PJS complicating multiple organ neoplasms. It provides evidence not only for the risk of malignancy in this disorder, but also for a hamartoma-adenoma-carcinoma sequence.

CASE REPORT

We report here a case of a 30-year old woman who suffered from multiple organ neoplasms with PJS. The melanin pigmentation around lips appeared when she was 3 mo old, after that, melanin pigmentation increased and also appeared on the palm and planta. She presented with iterative abdominal pain and vomit in 1997, and was found having multiple polyps in colon by colonoscopy. The polyps had been resected several times, but the symptoms still existed.

The patient presented to us in April 2001. Physical examination revealed the pigmentation on the oral lips, the buccal mucosa (Figure 1A), and the hands and feet (Figure 1B), about 1-3 mm in diameter. Endoscopy and gastrointestinal tract contrast examination revealed multiple polyps in sinus ventriculi, small intestine and colon. Most polyps were resected and demonstrated hamartomatous polyps, some of which showed adenomatous changes (Figure 2A), and the one in small intestine revealed carcinomatous changes (mucinous adenocarcinoma, infiltrating full-thickness of the intestine) (Figure 2B). The patient received FOLFOX4 chemotherapy after surgery. Tumor markers and routine blood tests were mainly normal during the treatment. The patient gradually recovered, then we kept follow-up visit on her.

In November 2007, the patient complained of abnormal vaginal discharge for 2 mo, without vaginal

bleeding and abdominal pain. Gynecological B-mode ultrasonography found occupying lesion located between inferior segment of cervix and vagina. Gynecologic examination revealed thick cervix, and cervical scraping

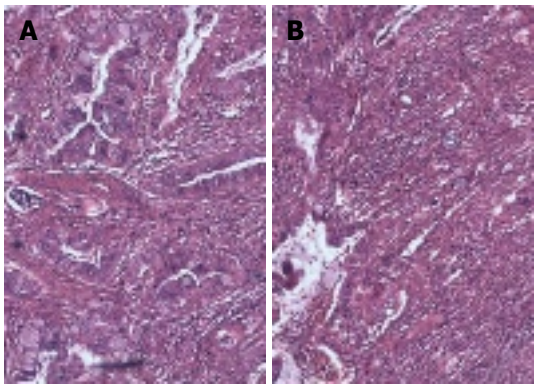

Figure 3 Cervical adenosquamous carcinoma. A: Moderately differentiated adenocarcinoma; B: Well-differentiated squamous carcinoma (HE × 100).

Figure 4 Endoscopic view of multiple polyps in sigmoid colon (12 mm in diameter).

smear confirmed cervical adenocarcinoma. After neoadjuvant chemotherapy (Paclitaxel 120 mg/dL, Carboplatin 350 mg/dL, one day per wk for 6 wk), total hysterectomy was performed in February 2008. Final pathological diagnosis was cervical adenosquamous carcinoma (Figure 3), and cancerometastasis of lymph nodes in left external iliac (1/1). The patient also received pelvic radiotherapy after surgery (50 GY in total).

The tumor markers (CA125, CA19-9, CEA) were normal when the patient paid a return visit in May 2008. She was found to have multiple polyps in her stomach, terminal ileum and sigmoid colon by endoscopy (Figure 4), polyps were resected and pathology still confirmed hamartomatous polyps. In addition, none of her lineal relations has the symptoms and physical signs of PJS, and no tumor patient was found in her family history.

DISCUSSION

PJS patients have an increased risk for several malignancies including small intestine, stomach, pancreas, colon, esophagus, ovary, uterus, lung, and breast cancer. PJS is associated with a markedly increased risk of malignancy that is not confined to the gastrointestinal tract. A metaanalysis found that,

compared with the general population, patients with PJS have a relative risk (RR) of 15 times higher than for developing many kinds of cancer. And the cumulative risk for all cancers was 93% from age 15 to 64. Very high RRs for the development of cancer were observed in the small intestine (520), stomach (213), pancreas (132), colon (84) and esophagus (57), and RRs are greater than 10 for the development of breast, lung and ovarian cancer[2]. Several gonadal malignancies occur in PJS patients. In female patients, sex cord tumors with annular tubes (SCTAT) are found in the ovaries of many individuals examined. Patients with these tumors can present with menoxenia, hyperestrogenism or sexual precocity[3]. Minimal deviation of cervical adenocarcinoma has been reported in PJS patients. Presenting symptoms include abnormal vaginal bleeding or a mucoid vaginal discharge. It is an extremely well differentiated adenocarcinoma of the cervix. It usually shows poor malignant behavior and poor prognosis with mucinous type of adenocarcinoma[4].

STK11/LKB1 was identified strongly relative to the PJS, which is a tumor-suppressor involved in intracellular signal transduction and cellular polarity[5]. Some studies provided molecular evidences of a hamartoma-adenoma-carcinoma sequence in PJS. The second hit in *LKB1* causing loss of heterozygosity (LOH) in adenomatous and carcinomatous lesions in PJS polyps was noted by several investigators[6,7]. In addition, LOH of *p53*, *K-Ras* and β-*catenin* mutations were found in adenomas developing in hamartomatous polyps, indicating that molecular alterations in these genes drive carcinogenesis in PJS as well[8]. However, the precise frequency of LOH of *LKB1* in PJS polyps in human remains unclear, and studies in mice showed that loss of the wild-type *LKB1* allele is not a prerequisite for the formation of hamartomatous polyps[9]. Therefore, the need for the second-hit in *LKB1* during polyp development in PJS, and the role of *LKB1* as a typical 'Knudson' two-hit tumor-suppressor gene, is questioned. One theory suggests mucosal prolapse as a pathogenic mechanism underlying the development of typical hamartomatous polyps in PJS. In this hypothesis, PJS hamartomatous polyps represent an epiphenomenon to the cancer-prone condition and the hamartoma-adenoma-carcinoma sequence as such does not exist[10]. The important role of *LKB1* in cellular polarity may provide new insights into the molecular mechanism of polyp and carcinoma development in PJS. Loss of polarity function may also affect asymmetric stem cell division in PJS and lead to expansion of the stem cell pool[11]. It could contribute to polyp formation and explain the increased cancer risk as well. A recent study found *STK11*-deficient mesenchymal cells produced less TGF-β, and defective TGF-β signaling to epithelial cells coincided with epithelial proliferation. TGF-β signaling defects in polyps of individuals with PJS, suggesting that the identified stromal-derived mechanism of tumor suppression is also relevant to PJS[12].

We report the unique case of a patient with the Peutz-Jeghers syndrome who developed intestinal malignancy and cervical cancer in 7 years. As far as we know, no similar case has been reported to date. The pathological changes of polyps would support the development of hamartoma-adenoma-carcinoma; and the carcinomatous change of cervix would add the risk of extra-gastrointestinal tumors in this disorder. However, the pathogenic mechanism of these changes is still unknown. It should be studied progressively on whether germline mutation of *STK11/LKB1* exists or other factors participate in the process of malignant changes. We also suggest that the patient and her family members should be followed up with endoscopy.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
