Globally, hepatocellular carcinoma (HCC) is a major cause of mortality<sup>[1,2]</sup>. It is the commonest primary liver cancer and accounts for 80%-90% of this class of malignancy. HCC is characterized by a very poor prognosis and is associated with high mortality. Annual mortality from HCC is virtually the same as its annual incidence, attesting to its rapid course and grave prognosis. Moreover, although HCC is the fifth most common cancer worldwide, it is the third most common cause of cancer-related mortality<sup>[3]</sup>. Recent observations have shown that incidence and mortality from liver cancer in the United States is the fastest growing of all cancers<sup>[2]</sup>. This is despite a decline in the overall cancer mortality rate that has occurred during the past 20 years. Currently available treatments of HCC are largely inadequate. However, with better understanding of the molecular pathogenesis of the cancer and significant advances in gene silencing technology, improved approaches are being devised to counter the malignancy. In particular, harnessing the RNA interference (RNAi) pathway to inhibit expression of genes that are implicated in transformation of hepatocytes is an exciting new approach to treating HCC. Therapeutic gene silencing technology is however at an early stage of development and there are several important hurdles that need to be overcome before this approach becomes a reality for treating HCC. In this review, we summarize HCC molecular pathogenesis as a background to discussing the interesting prospects of RNAi-based drugs for treating HCC.

## CAUSES AND MOLECULAR PATHOGENESIS OF HCC

There are several etiological agents and risk factors that

have been implicated in causing HCC<sup>[2]</sup>. Typically, HCC arises within a diseased liver and chronic liver injury *per se*, usually cirrhosis is thought to be causative of HCC. Thus, agents that result in chronic liver disease, although perhaps not directly carcinogenic, may be risk factors for HCC. Liver cancer is not evenly distributed throughout the world and is a consequence of unequal prevalence of major causative factors of the malignancy<sup>[2]</sup>. HCC has a particularly high incidence in sub-Saharan Africa, East and South East Asia where chronic hepatitis B virus (HBV) infection is common. Of the factors that have been identified to cause HCC, persistent HBV infection has the strongest association with the malignancy<sup>[1]</sup>. The long term risk of HCC in HBV carriers has been reported to be in the range of 25%-40%. Infection with hepatitis C virus (HCV) is also directly causative of liver cancer<sup>[4]</sup>. The long-term risk for HCC in HCV-infected individuals is estimated to be 1%-3% after 30 years, although in cases of established HCV-related cirrhosis, the annual rate of HCC development may be as high as 7%. Globally it is estimated that there are 387 million carriers of HBV<sup>[1,5]</sup> and 170 million people persistently infected with HCV<sup>[6]</sup>. These enormous numbers make HBV and HCV chronic infections the major HCC-predisposing factors. A primary focus of preventing HCC is thus aimed at eliminating these viruses.

Several other hepatocarcinogenic factors, which may cause transformation directly or indirectly, have been identified<sup>[2]</sup>. These include excessive alcohol intake, aflatoxin ingestion, vinyl chloride exposure, obesity, diabetes mellitus, dietary iron overload, cigarette smoking and use of oral contraception. Regardless of the study population, males have a higher risk for the malignancy than females. The male to female ratio of HCC varies between 2:1 and 4:1. A reason for this gender bias is a higher risk for exposure to HCC-causing agents such as alcohol and tobacco amongst males. Additionally, androgens *per se* may contribute to hepatocarcinogenesis.

### HBV

HBV is the prototype member of the hepadnaviridae family of hepatotropic viruses. It is a small, non-cytopathic, enveloped partly double stranded or relaxed circular DNA (rcDNA) virus with a genome size of 3.2 kb<sup>[7-9]</sup>. Viral rcDNA is converted to covalently closed circular DNA (cccDNA) within an infected hepatocyte. cccDNA then serves as template for expression of viral genes, formation of pregenomic RNA and ultimately the production of progeny viruses. The viral genome is remarkably compact and encodes four overlapping open reading frames (ORFs): core (C), polymerase (P), envelope (surface, S) and X (HBx), which collectively encompass the entire genome. Viral cis elements that control transcription and aspects of replication are thus embedded within protein coding sequences. This remarkably economical use of the small genome limits HBV sequence plasticity and the virus is thus a good target for therapy that is based on nucleic acid hybridization.

The exact mechanism of HBV-mediated hepatocarcinogenesis is not completely understood. Integration of viral DNA into the host cellular genome with resultant

effects on chromosome stability and surrounding genes may play a role. Several lines of evidence also implicate HBx in the transformation of hepatocytes. This protein has wide ranging effects on cellular processes that are involved in regulating cell differentiation, apoptosis and proliferation. The mechanism of action includes indirect transcriptional activation of cellular *cis* elements, effects on cell signalling pathways as well as modulation of apoptosis<sup>[10]</sup>.

### HCV

HCV is a member of the Flaviviridae family. The virion is enveloped and has an RNA genome comprising 9.6 kb of uncapped RNA with sense polarity<sup>[11]</sup>. The internal ribosomal entry site (IRES), which is located within the 5' NTR of the HCV genome, initiates translation of a large precursor polyprotein. This precursor is processed by cellular and viral proteinases to form 10 viral proteins, namely core, E1, E2, p7, NS2, NS3, NS4A, NS4B, NS5A and NS5B. E1 and E2 encode the envelope proteins and the viral core is derived from the C sequence. Non-structural proteins are responsible for assembling the viral proteinase machinery (NS2, NS3 and NS4A), forming the specialized membrane compartment for viral replication (NS4B) and RNA-dependent RNA polymerase (NS5B). The hydrophobic p7 protein, required for the late stages of viral assembly, is thought to function as a viroporin. The frameshift (F) protein, which is expressed during natural HCV infection, is yet to be fully characterized<sup>[12-14]</sup>. The entire HCV lifecycle is cytoplasmic and involves the formation of minus RNA and dsRNA intermediates within the membranous web. HCV dsRNA activates the innate immune response, but cellular antiviral effects are inhibited by the E2, NS3 and NS5A proteins<sup>[15-17]</sup>. Unlike with HBV, sequence heterogeneity and rapid evolution of quasispecies are characteristic of HCV infection. However, structural characteristics of the 5' NTR, which determine its function as an IRES impart sequence conservation in this region<sup>[11]</sup>.

Research suggests that HCV exerts its oncogenic effect through the actions of its viral proteins. The amino terminal of the NS3 protein<sup>[18]</sup> and the core protein<sup>[19]</sup> have been shown to influence various cellular functions including the enhancement<sup>[20-22]</sup> or inhibition<sup>[23-25]</sup> of apoptosis. The core protein may activate transcription of the proto-oncogene *c-myc* and also has an effect on apoptosis through effects on Fas, tumor necrosis factor (TNF-)<sup>[26]</sup> and a mitogen activated protein kinase or extracellular signal regulated kinase (MAPK/ERK) signaling cascade. In addition, the NS4B protein functions as a transcriptional activator of intracellular signals that play roles in cell proliferation and inflammation. NS3 and NS5A proteins may also contribute to hepatocarcinogenesis by blocking the action of p53<sup>[27,28]</sup>.

### Aflatoxin and ethanol

Aflatoxin exposure and excessive alcohol intake are important causes of liver cancer, which may have synergistic action when occurring together with chronic HBV and HCV infection<sup>[29]</sup>. Aflatoxins are mycotoxins generated by certain *Aspergillus* species and are potent natural carcinogens<sup>[30]</sup>. When converted to exo-8,9-epoxides in

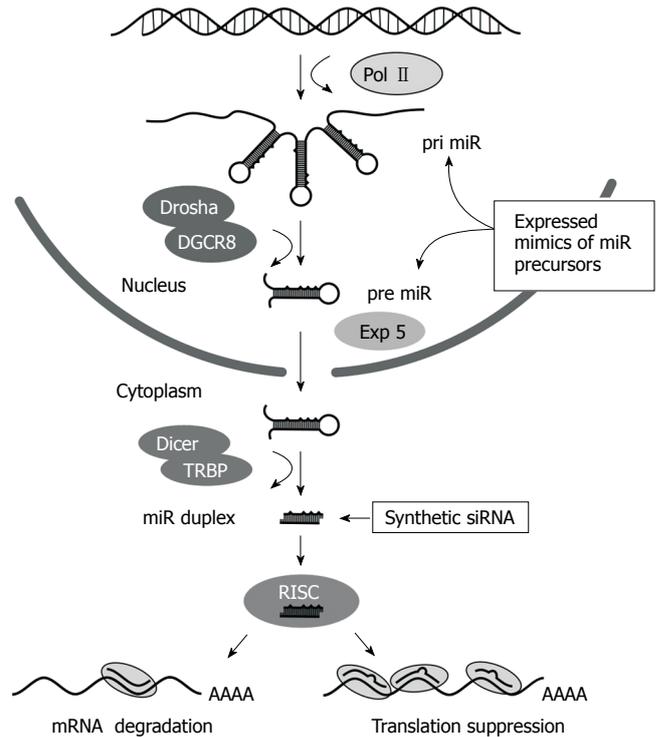

the liver they are capable of damaging guanine nucleotides in hepatocytes DNA to form mutagenic and potentially carcinogenic DNA adducts. Importantly, aflatoxin-induced mutation hot spots in the liver include a transversion that occurs in the third position of codon 249 of the p53 tumor suppressor gene<sup>[31,32]</sup>. Alcohol metabolism in the liver has also been implicated in mutagenesis and hepatocarcinogenesis<sup>[33]</sup>. The mechanism is through generation of reactive oxygen species (ROS) and increasing hepatic oxidative stress. Acetaldehyde accumulation also contributes to the formation of protein and DNA adducts which result from ROS generation. Excessive alcohol intake is also a cause of chronic liver injury and cirrhosis, which is itself indirectly hepatocarcinogenic.

**CURRENT TREATMENT OF HCC**

Although there have been advances in the detection of HCC, improvement in the management of the disease has not been significant<sup>[34]</sup>. Inadequacy of current therapy and presentation of patients with advanced disease have meant that the prognosis of individuals with HCC remains poor. Available treatment modalities include surgical intervention, percutaneous and arterial attempts at tumor ablation as well as drug-based treatment. If patients have well localized malignancies and good underlying liver function, surgical resection does have some success in eradicating tumors. However, this is clinically atypical, and patients with HCC usually present with cancers that have spread extensively within the liver and to distant sites. Treatment in these cases is palliative and the prognosis is extremely grave. Very early tumor detection and novel effective therapy are important objectives for improving management of patients with HCC. The potent targeted gene silencing that can be achieved by activation of RNAi has prompted investigations that apply this approach to direct treatment of HCC as well as through eliminating risk factors for the malignancy (e.g. HBV and HCV).

**HARNESSING RNAI TO TREAT HUMAN DISEASE**

RNAi is a powerful gene silencing mechanism that operates in most eukaryotic cells<sup>[35]</sup>. The effector molecules comprise short duplex RNA sequences of 21-23 bp that direct inhibition of homologous genes (Figure 1). Naturally, the pathway is important for processing of regulatory micro RNAs (miRs)<sup>[36,37]</sup>. These non-coding cellular sequences have roles in several pathways such as cell differentiation, metabolism, proliferation and malignant transformation. The miR processing pathway is initiated by transcription of miR-encoding cellular genes by RNA polymerase II (Pol II) to produce hairpin-containing primary miRs (pri miRs). These pri miRs may be derived from intronic sequences and may be polycistronic. Within the nucleus, pri miRs are processed to form precursor miR (pre-miR) hairpins of 60-80 nt in length. This step is catalyzed by the microprocessor complex, which contains Drosha and di George Critical

**Figure 1** Schematic illustration of the RNAi pathway showing the essential steps, with nuclear or cytoplasmic location, involved in micro RNA processing. Exogenous activators of the pathway, which may be synthetic siRNA or expressed mimics of miR precursors, are shown.

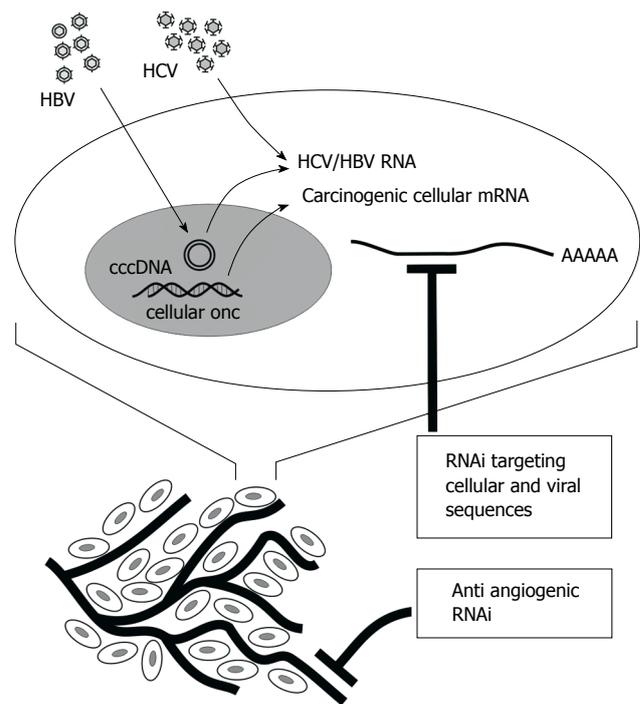

Region 8 (DGCR8) proteins. Drosha functions as an RNase III enzyme and DGCR8 is its double stranded RNA binding protein partner. Pre-miRs are exported from the nucleus to the cytoplasm by the RanGTP-dependent Exportin 5 transporter. Pre-miRs are then processed by Dicer with associated TAR RNA-binding protein (TRBP) to form a staggered RNA duplex of 21-24 bp with 2 nt 3' overhangs. This duplex is handed on to the RNA induced silencing complex (RISC), which includes several components such as Argonaute 1 (AGO1), Argonaute 2 (AGO2) and Fragile X proteins. One strand of the RNA duplex, which is designated the passenger strand, is cleaved within RISC and is then released from the complex. The remaining intact single stranded guide RNA activates RISC to direct target-specific silencing. Mature cellular miRs are usually not entirely complementary to their targets and bind to the 3' untranslated regions of cognate mRNA to induce translational suppression. Hybridization between target and nucleotides 2-8 from the 5' end of the guide strand, termed the seed sequence, are all that is required to cause translational suppression<sup>[38]</sup>. When base pairing between entire guide and target is perfectly matched, the AGO2 component of RISC exerts silencing through site-specific cleavage ('slicing') of the guide complement<sup>[39,40]</sup>.

Exogenous activators of RNAi may be used for therapeutic application by silencing specific pathology-causing sequences. These activators are typically expressed or synthetic sequences and they activate RNAi at different stages of the pathway (Figure 1). Exogenous small interfering RNAs (siRNAs) are usually synthetic mimics of the dsRNA duplexes that are formed after Dicer

processing, whereas expressed RNAi effectors are typically designed to simulate pri miR or pre miR sequences. The commonest form of expression cassette comprises a short hairpin RNA (shRNA)-encoding sequence that is inserted downstream of a Pol III promoter. When introduced into a cell, the shRNA acts as a mimic of pre miR and is processed by Dicer to form a siRNA. Synthetic or expression cassette-derived siRNAs are structurally symmetrical molecules but stability at the 5' ends of the siRNA duplex has an influence on the bias of guide strand selection<sup>[41]</sup>. The strand which is less tightly paired (A/U rich) to its complement at its 5' end is preferentially incorporated into RISC. Other factors that influence the effectiveness of siRNAs against their cognate targets have been described and have been incorporated into predictive algorithms used for design of exogenous silencing sequences. The U6 and H1 Pol III promoters have commonly been used to generate expressed shRNAs and they are capable of efficient transcription of short defined sequences. Importantly, Pol III promoters are usually constitutively active, which means that regulation of intracellular concentration of shRNAs is difficult to achieve<sup>[42]</sup>. Related to this, recent demonstration that U6 Pol III-expressed shRNAs may saturate the endogenous miR pathway to cause serious toxicity *in vivo* is an important concern<sup>[43]</sup>. Since naturally occurring pri miRs are expressed from Pol II promoters<sup>[44]</sup>, shuttle cassettes incorporating features of pri miRs may improve the efficiency of Pol II-expressed RNAi sequences.

## HCC AND MIRS

There are several studies that have implicated disruption of miR expression in carcinogenic mechanisms<sup>[45,46]</sup>. miR concentrations may be elevated or depressed in HCC, which suggests that by interacting with their cognates, these sequences may act as oncogenes or suppressors of hepatocyte transformation. Recent studies using miR microarrays, showed high expression of miR-21<sup>[47]</sup> and low levels of miR-122a<sup>[48]</sup> in HCC. miR-21 contributes to hepatocyte transformation, growth and spread by inhibiting phosphatase and tensin homolog (PTEN) tumor suppressor. Modulation of cyclin G1, a cell cycle modulator, is the mechanism by which decreased miR-122a expression was reported to be hepatocarcinogenic. Another study analyzing the role of peroxisome proliferator-activated receptor alpha (PPARalpha) in hepatocarcinogenesis showed that this protein is an important regulator of hepatic miRNA expression<sup>[49]</sup>. Of particular significance was PPARalpha inhibition of let-7C-mediated signaling and *c-myc* induction, which leads to hepatocyte proliferation and transformation. Other studies have implicated different alterations in miR expression that may be important for HCC<sup>[50,51]</sup>. A recent study, which analyzed sequence variation of 59 miRs in HCC and adjacent non-malignant tissue, revealed four variations in three microRNAs<sup>[52]</sup>. These miRs included miR-106b, miR-192 and let-7a-2. The significance of the variations for hepatocarcinogenesis was however not clear as the same sequence differences were found in non-malignant cells but not in eight liver cancer-derived cell lines. The

**Figure 2** RNAi targets that may be silenced to counter HCC. In addition to HBV and HCV genes, cellular sequences that are involved in hepatocyte transformation may be silenced to inhibit growth of malignant liver cells. Growth of HCC is also dependent on angiogenesis and inhibition of this process is expected to limit tumor growth.

conclusion from this study was that miR mutation is a rare event in HCC and is unlikely to represent the main mechanism of hepatocarcinogenesis. Collectively the data show considerable heterogeneity in HCC-related altered miR expression. This complicates developing a generic approach to HCC treatment that is based on modulation of miR expression.

## RNAI TARGETS TO COUNTER HEPATOCARCINOGENESIS

Suitable targets for development of RNAi-based treatment of HCC include cellular oncogenic sequences, angiogenic factors, as well as HBV and HCV genes (Figure 2). Studies to date, which have mainly demonstrated proof of principle, are summarized below. A difficulty of assessing usefulness of RNAi against HCC, HBV and HCV has been the lack of convenient small animal models. Advances have recently been made in addressing this obstacle. HCV replicons<sup>[11]</sup>, cells in culture that are permissive for HBV<sup>[53]</sup> and HCV<sup>[54]</sup> infection, the hydrodynamic injection procedure<sup>[55]</sup>, transgenic mice and xenografted mice<sup>[56]</sup> have, and will be, particularly useful.

### HBV

As with most investigations aimed at developing RNAi-based therapy, synthetic and expressed sequences have been used to activate RNAi and counter replication of HBV. Most studies to date have provided proof of principle in cell culture and small animal models of HBV replication. Recently however, FDA approval has been

granted for an investigational new drug license to test the use of expressed RNA sequences against HBV ([http://www.nucleonicsinc.com/news/pdfs/FDAClearanceHepB\\_Trial\\_may2007.pdf](http://www.nucleonicsinc.com/news/pdfs/FDAClearanceHepB_Trial_may2007.pdf)).

One of the first studies aimed at assessing efficacy of RNAi-activating sequences against HBV tested a panel of six U6 promoter cassettes that encoded shRNAs<sup>[57]</sup>. Profound inhibition of HBV surface antigen secretion from transfected cultured cells and *in vivo* in the murine hydrodynamic injection model was observed. Inhibitory effects were found to be due to a direct effect that is not dependent on an antigen-dependent immune response. Others have recently demonstrated varying degrees of inhibition of HBV replication by expressed shRNA sequences<sup>[58-64]</sup> and one study showed antiviral synergy between lamivudine and shRNA sequences in a cell culture model<sup>[61]</sup>. To address concerns about the emergence of RNAi escape mutants, Weinberg and colleagues<sup>[65]</sup> used long hairpin RNA (lhrRNA) expression cassettes to target the *HBx* ORF of HBV. These sequences were designed to generate multiple siRNAs from the 62 bp duplex region of the hairpin. Although impressive knockdown was achieved, the efficacy was not equal across the span of the duplex. siRNAs generated from the stem base were produced more efficiently and effected better silencing than the loopside siRNA template. Limited processivity by Dicer, which initiates its RNase III activity at the hairpin stem base, is thought to be the cause of this effect. Using an approach that obviates this problem by cleavage of hairpin RNA *in vitro*, endoribonuclease-prepared siRNAs (esiRNAs) targeting all four HBV ORFs were recently used to inhibit HBV replication with high efficiency<sup>[66]</sup>.

Since there is no convenient small animal model of HBV infection, transgenic mice have been used in some studies as a stringent model to simulate virus replication that occurs in HBV chronic carriers. Expressed shRNAs have been tested in 4 studies on HBV transgenic mice<sup>[43,62,63,67]</sup>. Hepatotropic recombinant adenovirus vectors expressing shRNAs from Pol III promoters caused sustained inhibition of viral replication over a 2-4 wk period after administration of a single dose of the vector<sup>[62,63]</sup>. The importance of optimizing the dose of expressed anti HBV shRNA sequences was highlighted in a recent study that showed fatality in HBV transgenic mice that were treated with recombinant adeno-associated virus (AAV) type 8 vectors that over expressed shRNAs<sup>[43]</sup>. Recombinant vectors expressing a 25-mer anti-HBV shRNA consistently caused death of treated mice, whereas low dose of a 19-mer shRNA vector efficiently suppressed markers of viral replication. These studies provide important evidence that HBV is susceptible to RNAi-based gene silencing in a model that simulates established ongoing replication that occurs in HBV chronic carriers.

Effective knockdown of HBV replication by synthetic siRNA has also been shown *in vitro* and *in vivo*. A siRNA duplex that targeted sequences immediately upstream of the surface ORF initiation codon was found to be particularly effective against HBV without a requirement for HBV DNA synthesis<sup>[68]</sup>. This property is distinct from anti-HBV nucleoside or nucleoside analogues, which act on

the viral DNA polymerase to have their therapeutic effect. Efficacy of *surface* ORF-targeted siRNAs was reported in other studies<sup>[69,70]</sup>. Improved knockdown by repeated siRNA transfection of cells in culture was also observed<sup>[71]</sup> as well as effectiveness against a HBV target that includes the sequences encoding the lamivudine-resistance YMDD *polymerase* gene mutation<sup>[72]</sup>. Recently, Morrissey and colleagues showed that chemically modified siRNAs caused potent and persistent anti-HBV activity *in vivo*<sup>[73]</sup>. Sequences were administered intravenously within a stable nucleic acid lipid particle (SNALP) formulation. Efficiency of the complexes is likely to be a result of increased stability *in vivo* and also diminished non specific immunostimulatory effects. Apolipoprotein A-1-derived nanoparticles have also been used successfully *in vivo* to deliver synthetic anti HBV sequences<sup>[74]</sup>. Importantly, these vectors are liver specific and are efficient at low doses. As well as being developed as an independent therapy, RNAi effectors may be used in combination with established licensed drugs to improve efficacy. Such synergy, which is likely to result from different mechanisms of drug action, has been demonstrated when using anti-HBV sequences in conjunction with lamivudine<sup>[61]</sup>.

### HCV

Since it is an RNA virus that replicates in the hepatocyte cytoplasm, HCV is considered a prime candidate for RNAi-based treatment. However, a high degree of heterogeneity of viral sequences has been a particularly significant obstacle to developing antiviral RNAi effectors. For this reason, the 5' NTR has been the favored HCV target of several studies<sup>[75-79]</sup>. Also, the lack of suitable models of HCV reproduction *in vivo* has hampered development of RNAi-based approaches to therapy. Extensive use of subgenomic replicon systems has been used successfully to study efficacy of antiviral therapeutic agents in cell culture and this approach has provided valuable insights<sup>[80,81]</sup>. Currently available models of HCV infection *in vivo* are limited and include the chimpanzee<sup>[82]</sup> and chimaeric immunodeficient mice that are grafted with human hepatocytes<sup>[83]</sup>.

In an early study that employed RNAi against HCV<sup>[79]</sup>, both synthetic and expressed RNAi effectors against the 5' NTR caused significant reduction of markers of HCV replication in a replicon model. Subsequent investigations targeting the 5' NTR showed suppression of viral gene expression by naked shRNAs<sup>[78]</sup> and also synthetic siRNAs<sup>[84]</sup>. Domain IV regions were found to be a particularly good target for RNAi-based HCV gene silencing<sup>[79]</sup>. However, a report by Takigawa and colleagues<sup>[77]</sup> showed that expressed shRNAs targeted to NS3-1 and NS5B were more effective than sequences against the 5' NTR. Other studies using both synthetic and expressed siRNAs also achieved significant inhibition of virus gene expression when targeting NS3 and NS5B sequences<sup>[85,86]</sup>. Although good efficacy against HCV has been demonstrated, a major concern remains the ability of the virus to accumulate evading nucleotide sequence mutations. Not surprisingly, emergence of resistant HCV replicons has been shown in cultured cells after repeated treatments with siRNA targeted against the

NS5B coding region<sup>[87]</sup>. Point mutations within the siRNA target sequence were observed, but resistant replicons were sensitive to a siRNA that targets another part of the genome. As with HBV<sup>[65]</sup>, vectors that express lhrNAs have been shown to be effective against HCV<sup>[88,89]</sup>. Although these sequences have the theoretical advantage of generating multiple siRNAs, the approach may be limited by incomplete Dicer processing of the hairpin (see above and<sup>[65]</sup>). Although approaches that produce polycistronic miR shuttles or esiRNAs may be preferable, a concern of using multiple siRNAs for therapy is the increased likelihood of silencing non-targeted genes as well as disruption of the endogenous miRNA pathway.

Other studies have aimed to circumvent the problem of viral escape by targeting host genes that are required for HCV replication<sup>[90-92]</sup>. Synthetic siRNA and adenovirus-delivered effectors specific for La autoantigen (La), polypyrimidine tract-binding protein (PTB), cyclophilins and human VAMP-associated protein of 33 kDa (hVAP-33) substantially blocked HCV replication. Endogenous hepatic miR-122 has recently been shown to suppress haem oxygenase-1 (HO-1) and facilitate HCV replication<sup>[93,94]</sup>. Upregulation of HO-1 or suppression of miR-122 thus represents an interesting strategy to counter HCV infection. Caspase 8 and the Fas cell death receptor, which mediate T-cell hepatocyte toxicity caused by viral infection, were efficiently silenced using RNAi<sup>[95,96]</sup>. Although promising, it remains to be established whether silencing of these endogenous genes causes toxicity.

### Cellular oncogenic sequences

As the molecular mechanism of hepatocarcinogenesis becomes better understood, so the number of potential targets that can be inhibited using RNAi improves. There are many oncogenes that have been described, which are implicated in the disruption of control of normal hepatocyte proliferation. Although this is encouraging, the targeting of specific cellular sequences is hampered by two main factors: (1) heterogeneity of gene expression in liver cancer cells from different sources, and (2) difficulty of achieving sufficient transfer of RNAi effectors to be of therapeutic benefit against the malignancy. The possibilities for therapeutic application are nevertheless intriguing.

A recent study aimed to analyze the effect of silencing the pituitary tumor transforming gene (PTTG) family on hepatocarcinogenesis<sup>[97]</sup>. PTTG is a recently discovered group of oncogenes that plays a role in the genesis of several types of cancer through effects on cell division, apoptosis and DNA repair<sup>[98]</sup>. PTTG1, but not PTTG2 and PTTG3, is frequently over expressed in patient liver cancer tissue as well as in established HCC lines<sup>[97]</sup>. Infecting cells with a recombinant adenovirus expressing an anti PTTG1 RNAi effector depleted cells of PTTG1 and resulted in the activation of p53 with consequent increased p21 expression and apoptosis. Inhibition of tumor growth in a nude mouse xenograft model of HCC further supported the notion that PTTG1 is a good candidate for RNAi-mediated HCC therapy.

Other studies aimed at silencing the serine protease urokinase-type plasminogen activator (u-PA) demonstrated

similar proof of principle efficacy<sup>[99,100]</sup>. Signalling through u-PA and its receptor (uPAR) have been implicated in cell invasion, survival, and metastasis of a variety of cancers<sup>[101,102]</sup>. Silencing of u-PA using RNAi-based approaches has been used successfully in tumor models of prostate cancer<sup>[103]</sup> and gliomas<sup>[104]</sup>. To assess efficacy of RNAi-based u-PA silencing on HCC, Salvi and colleagues<sup>[100]</sup> demonstrated that stable expression of a shRNA effectively knocked down u-PA. Moreover, silencing of u-PA resulted in attenuation of malignancy-associated cellular properties, such as migration, invasion and proliferation. In a follow up study, the effects of stable inhibition of u-PA on xenografted tumor cells were assessed<sup>[99]</sup>. Cells that stably produce silencing sequences targeted to u-PA were injected subcutaneously into nude mice. Knockdown of both u-PA protein and mRNA concentrations was observed, which lasted for a period of 11 weeks. A delay in xenografted tumor growth was observed in cells expressing anti u-PA sequences, which indicates that u-PA silencing may be beneficial for HCC therapy.

A further study aimed at developing RNAi-based HCC therapy, assessed inhibition of function of human gankyrin gene product (p28GANK)<sup>[105]</sup>. This novel oncogenic protein is ubiquitously over expressed in HCC and plays a role in cell cycle progression in normal hepatocytes and liver regeneration<sup>[106-109]</sup>. After screening for susceptible target sites, a shRNA expression cassette was incorporated into an adenoviral vector. This was used to determine silencing of p28GANK and assess antitumor properties of the viral vectors<sup>[105]</sup>. Effective silencing of approximately 80% was achieved. This depletion of p28GANK enhanced dephosphorylation of Rb1 decreased transcriptional activity of E2F-1 in cultured liver-derived cells and inhibited cell growth. Moreover, tumor cell growth was retarded in xenografted nude mice, which was thought to be a result of increased caspase-8- and caspase-9-mediated apoptosis caused by p28GANK inhibition.

RNAi-based approaches to the inhibition of vascularization of tumors has recently received attention<sup>[110-115]</sup>. HCC growth is dependent on neovascularization and inhibition of factors that are required for angiogenesis should therefore be effective in countering the growth of this cancer. Most work has focused on the silencing of vascular endothelial growth factor (VEGF) to reduce the formation of new vessels that are required for tumor development. RNAi-based inhibition of VEGF in cases of the wet form of macular degeneration has reached an advanced stage of clinical trial (<http://www.agingeye.net/maculardegen/maculardegennewdevelopments.php>). Although this disease is not a malignancy, demonstration that VEGF can be inhibited successfully *in vivo* using RNAi indicates that this target may also be suitable for clinical application to HCC therapy. Alnylam and Inex Pharmaceuticals, leaders in the field of developing RNAi-based human therapy, have recently advanced a combination systemic drug for the treatment of liver cancer (<http://www.alnylam.com/therapeutic-programs/programs.asp>). The therapeutic, which is a liposomal formulation termed ALN-VSP-1, contains siRNAs that

target VEGF and kinesin spindle protein (KSP). siRNA-mediated inhibition of KSP production leads to cell cycle arrest and death in malignant hepatocytes.

## CHALLENGES FACING USE OF RNAI-BASED THERAPY FOR TREATMENT OF HCC

Although the studies summarized above indicate that RNAi could be used for preventative or curative HCC treatment, there are several important hurdles that need to be overcome before clinical application. These include activation of the innate immune response, limitation of unintended interaction of RNAi effectors with cellular sequences, dosage regulation and optimizing delivery methods. These topics are briefly summarized below.

### **Innate immune response activation**

Duplex RNA within cells is sensed as unwanted gene activity and may result in unintended harmful effects caused by activation of inflammatory cytokines and the interferon (IFN) response<sup>[116-118]</sup>. Stimulation of cytoplasmic pattern recognition receptors, such as dsRNA dependent protein kinase (PKR), retinoic acid inducible gene- I (RIG- I) and Toll-like receptors (TLRs), leads to a cascade of events, which culminates in activation of transcription factors such as NF- $\kappa$ B, IRF3 and IRF7. This in turn causes increased expression of genes that include inflammatory cytokines and interferons. The response may be further amplified by autostimulatory positive feedback that involves JAK-STAT pathway activation. IFN pathway activation may also lead to inhibition of protein synthesis and degradation of cellular mRNA with consequent programmed cell death (apoptosis). The type of effector sequence that is used to activate RNAi also has a bearing on immunostimulation<sup>[119]</sup>. Synthetic siRNAs that are longer than 30 bp<sup>[120]</sup>, possess 5' triphosphates<sup>[121]</sup> and lack 2 nucleotide 3' overhangs<sup>[122]</sup> stimulate the innate immune system. Also, 'danger' motifs (e.g. GU rich sequences, 5'GUCCUCAA3' and 5'UGUGU3') may activate endosomal TLR3, TLR7 and TLR8<sup>[123]</sup>. RNAi effectors derived from expression cassettes that are transcribed from the nucleus do not pass through the endosomal compartment to activate these TLRs. However, unmethylated CpG islands within RNAi-activating DNA expression cassettes may be immunostimulatory. Recently, chemical modifications of siRNAs have been shown to attenuate immunostimulatory effects<sup>[124]</sup>, and this has been used successfully *in vivo* to counter HBV replication without release of interleukins and inflammatory cytokines<sup>[73]</sup>.

### **Non-specific interaction of silencing molecules with cellular sequences**

Cross-hybridization of siRNAs with transcripts that have partial sequence identity<sup>[125]</sup>, particularly in the seed region of the intended target, may contribute to non-specific silencing effects. An interesting recent observation has been that 2' O-methyl ribosyl modification at position 2 of the siRNA guide strand reduces off target silencing at the seed site<sup>[126]</sup>. This effect was independent of the

target and did not influence knockdown efficiency of perfectly matched sequences. Incorporation of HCC-specific transcriptional regulatory elements (e.g. the alpha fetoprotein promoter) may be helpful to improve specificity of expressed RNAi effector by limiting transcription to malignant hepatocytes. This approach has been used successfully to accomplish tumor-specific transgene expression<sup>[127-129]</sup>. In the long term, to address the problem of off-target silencing it is likely that detailed microarray analysis of cellular transcripts will need to be undertaken as part of developing RNAi-based HCC therapy.

### **Optimizing delivery vectors**

One of the most difficult challenges impeding the advancement of RNAi-based HCC therapy is efficient and safe delivery of effector sequences. Ideally, vectors should deliver silencing molecules selectively to most if not all the malignant hepatocytes. Synthetic siRNAs are smaller than DNA expression cassettes. They do not require delivery to the nucleus and activate RNAi within the cytoplasmic compartment. This makes regulated non-viral vector (NVV)-mediated delivery of synthetic siRNAs easier to achieve than it is for larger DNA expression cassettes. Viral vectors incorporate expression cassettes of necessity, and are generally more efficient vehicles *in vivo* than NVVs. Ease of scalable synthesis and chemical modification to influence biological properties are important properties of NVVs that, with improved delivery efficiency, are likely to contribute to their gaining favor for clinical application.

Recombinant adenoviruses and adeno-associated viruses (AAVs) are capable of transducing liver cells with high efficiency and have been used successfully to deliver sequences that silence HBV or HCV gene expression<sup>[43,62,63,90]</sup>. Despite recent concerns<sup>[130]</sup>, recombinant AAVs are attractive vectors as they appear to be safe and capable of long-term gene expression. They are also relatively easy to propagate and capsid sequences from naturally occurring hepatotropic AAV serotypes have been used to confer liver-targeting properties on the recombinant viruses<sup>[131]</sup>. Although efficient delivery vehicles, adenoviruses are strong stimulators of innate and adaptive immune responses. This may cause toxicity and limit repeated administration<sup>[132]</sup>. An added problem is that malignant hepatocytes may be refractory to infection with recombinant adenovirus vectors<sup>[128]</sup>. To modify tropism and reduce immune responses, recent studies have used surface modified<sup>[133]</sup> or helper-dependent 'gutless' vectors<sup>[134]</sup>. Surface modification of adenovirus vectors with synthetic polymers such as poly-N-(2-hydroxypropyl) methacrylamide (poly-HPMA) and polyethylene glycol (PEG) has been used to facilitate tissue targeting and diminish immunostimulatory protein-protein interactions. Helper dependent and chemically modified vectors may have an improved safety profile that could be better suited to clinical application. An interesting effect of adenoviruses on miR biogenesis, which may have an influence on their suitability of use as vectors for RNAi-based therapy, is mediated by the virus associated RNA (VA1)<sup>[135]</sup>. This RNA sequence of approximately 160 nt

folds into a structure that mimics miR and has the effects of reducing nuclear export of pre miRs by saturating exportin 5 and acting as a competitive inhibitor of Dicer.

NVV nanoparticles have been used effectively to target HCC cells and also to deliver anti-HBV/HCV sequences. Modifications to confer HCC specificity include incorporation of HBV L protein<sup>[136]</sup> as well as epidermal growth factor (EGF)<sup>[137]</sup> into the complexes. Proof of principle has been demonstrated in xenografted models of HCC, but efficiency of these vectors may not yet be adequate for therapeutic gene transfer. SNALPs containing synthetic siRNAs have been used successfully to inhibit HBV replication in a murine model of virus replication<sup>[73]</sup> and also to silence endogenous hepatic gene expression in primates<sup>[138]</sup>. A recent study investigated the use of a lactosylated cationic liposome 5 (CL-LA5) vectors to deliver anti HCV siRNAs to cultured cells and *in vivo*<sup>[139]</sup>. The complexes accumulated in the liver and specifically suppressed intrahepatic HCV gene expression in transgenic mice. SNALP technology, CL-LA5 vectors and the recently described siRNA Dynamic PolyConjugates<sup>[140]</sup> are interesting new vectors that offer exciting possibilities for future clinical application to HCC treatment.

### Regulating dose

Lethal toxicity *in vivo*, which was caused by saturation of the endogenous hepatocyte miRNA pathway has come as an important warning for the development of RNAi-based treatment<sup>[43]</sup>. Grimm *et al* showed that expressed shRNA sequences disrupted essential endogenous miRNA-mediated cell functions by saturating the rate limiting activity of exportin-5. Synthetic siRNAs should bypass this step and this has recently been shown to be the case<sup>[141]</sup>. Dosage and intracellular copy of shRNAs is difficult to achieve with the commonly used constitutively active Pol III promoters, such as U6 and H1. Use of tissue-specific and inducible Pol II promoters may go some way to refining transcription control and improving dosage of expressed RNAi sequences.

### CONCLUSIONS AND PROSPECTS

The enormous therapeutic potential of RNAi-based specific gene silencing has prompted enthusiasm for advancement of novel therapies for difficult to treat diseases, such as HCC. Developments have been exciting, and clinical trials are now in progress for treating a variety of diseases<sup>[142]</sup>. However, use of gene silencing technology to treat established HCC faces major difficulties. These include identification of optimal targets, efficient and safe delivery of RNAi sequences and limitation of unintended off target effects. Hepatocarcinogenesis is a multistep process and because of the considerable heterogeneity underlying the molecular mechanisms of hepatocyte transformation, identification of ideal RNAi targets to treat the malignancy is complicated. HCC also often presents as a disseminated cancer and safe delivery of RNAi effectors to all malignant cells will require improvement of currently available vectors. Good progress has been made with silencing of HBV and HCV

replication using RNAi. It is likely that treatment of these virus infections, as an HCC preventative measure, will be the first RNAi-based therapies to counter the malignancy. Currently, early diagnosis of HCC is critical for its effective treatment. Success of RNAi against HCC is also expected to be dependent on identifying the malignancy in its early stages before tumor bulk becomes excessive. In the near future, it seems that silencing technology may well be used as an adjunct to other liver cancer treatments. Thus, the utility of RNAi-based therapy is also likely to be reliant on improvement of existing treatment and diagnostic modalities. Despite these difficulties, intensive efforts from several quarters have given momentum to development of RNAi-based HCC therapy. It is difficult to anticipate technological advancements, but the field is likely to see considerable progress during the coming years.

## Abstract

Before the positive results recently obtained with multitarget tyrosine kinase inhibitor sorafenib, there was no standard systemic treatment for patients with advanced hepatocellular carcinoma (HCC). Sex hormones receptors are expressed in a significant proportion of HCC samples. Following preclinical and epidemiological studies supporting a relationship between sex hormones and HCC tumorigenesis, several randomized controlled trials (RCTs) tested the efficacy of the anti-estrogen tamoxifen as systemic treatment. Largest among these trials showed no survival advantage from the administration of tamoxifen, and the recent Cochrane systematic review produced a completely negative result. This questions the relevance of estrogen receptor-mediated pathways in HCC. However, a possible explanation for these disappointing results is the lack of proper patients selection according to sex hormones receptors expression, but unfortunately the interaction between this expression and efficacy of tamoxifen has not been studied adequately. It has been also proposed that negative results might be explained if tamoxifen acts in HCC *via* an estrogen receptor-independent pathway, that requires higher doses than those usually administered, but an Asian RCT conducted to assess dose-response effect was completely negative. Interesting, preliminary

results have been obtained when hormonal treatment (tamoxifen or megestrol) has been selected according to the presence of wild-type or variant estrogen receptors respectively, but no large RCTs are available to support this strategy. Negative results have been obtained also with anti-androgen therapy. In conclusion, there is no robust evidence to consider HCC a hormone-responsive tumor. Hormonal treatments should not be part of the current management of HCC.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the sixth most common cancer worldwide in terms of incidence (626 000 new cases per year, representing 5.7% of new cancer cases). Due to its very poor prognosis, the number of deaths is almost the same (598 000), representing the third most common cause of death from cancer<sup>[1]</sup>. The overall sex ratio (male:female) is around 2,4. HCC causes more deaths in men (416 882 deaths in 2002, ranking third cause of cancer death) than in women (181 439 deaths, ranking sixth)<sup>[1]</sup>.

Treatment options and prognosis of patients diagnosed with HCC largely depend not only on tumor characteristics, but also on the severity of the underlying chronic hepatic

disease, which affects most of the patients<sup>[2]</sup>. Prognosis is relatively better for the subset of patients eligible for surgical treatments (tumor resection, liver transplantation) or other loco-regional treatments with potentially curative aim (e.g., percutaneous ethanol injection, radiofrequency ablation). A worse outcome is expected in those patients who can be treated only with palliative loco-regional treatments (e.g., transarterial chemo-embolization) or who are not suitable for any of the above options.

Recently, sorafenib, a multi-target tyrosine kinase inhibitor targeting both the tumor cell and the tumor vasculature, has shown significant efficacy in the treatment of advanced HCC<sup>[3]</sup>. Before the publication of these encouraging results, there was no systemic treatment that could be considered standard for advanced HCC<sup>[2,4]</sup>. Cytotoxic drugs does not play a significant role in these patients: HCC cells show intrinsic resistance to chemotherapy, and treatment with these drugs is often associated with unacceptable toxicity, due to the often compromised liver function.

Normal human liver is morphologically and functionally modulated by sex hormones. Epidemiological studies in humans suggest that long-term use of oral contraceptives and anabolic androgenic steroids can induce both benign (hemangioma, adenoma, and focal nodular hyperplasia) and malignant (HCC) hepatocellular tumors<sup>[5]</sup>. Animal models of experimental liver carcinogenesis suggest a relationship between exposition to sex hormones and development of HCC, with some evidence that these hormones may play a relevant role as inducer and promoter in the process of liver carcinogenesis<sup>[6]</sup>. In typical animal models of hepatic tumor initiation and promotion following repeated estrogen stimulation, the estrogen induction of microsomally activated catechols by aryl hydrocarbon hydroxylase and estrogen 2-/4-hydroxylase causes excess free radicals and unrepaired DNA adducts and strand breaks, that produce a mutagenic and irreversible DNA damage. Several months after this tumor-initiating DNA damage, steroid receptors - estrogen receptor (ER), progesterone receptor (PgR), androgen receptor (AR) - increase well above normal levels, suggesting the relevance of sex hormones mediated pathways in cell growth and proliferation.

In the last decades, moving from this epidemiological and preclinical evidence, several clinical trials have tested the efficacy of hormonal treatment in patients with HCC. In this review, we summarize the evidence about the use of hormonal treatment in HCC, trying to understand if, in the era of target-oriented therapies, this disease can still be considered a potentially hormone-responsive tumor.

## **HORMONAL TREATMENT SHOULD BE STUDIED AS A TARGET-ORIENTED APPROACH**

In addition to oncogenes, tumor-suppressor genes, and other genetic factors, a number of growth factors involved in cell signaling pathways have been shown to play a role in liver carcinogenesis<sup>[7,8]</sup>. Angiogenic stimuli are also required for the growth of HCC, which is usually a hypervascular tumor.

Sex steroids are known to be able to stimulate cell growth directly in several cancer types. When the cellular mechanisms underlying autonomous tissue growth are linked to the growth-promoting effects of sex steroids, the clinical result is a *hormone-responsive* (also called *hormone-sensitive*) tumor. Hormonal treatment plays an established role in several solid tumors, like breast cancer and endometrial cancer in women and prostate cancer in men. As a matter of fact, hormonal treatment represents the first form of target-oriented cancer therapy, acting by disruption of growth factor (in this case, sex hormones) - receptor interactions. For example, binding of estrogen to ER induces activation of the receptor. In fact, ER, that resides in the cytosol, upon occupation by estradiol, dissociates from heat shock proteins and undergoes conformational changes, dimerization and phosphorylation<sup>[9]</sup>. The activated ER is transported to the nucleus, where it binds to estrogen response elements that are located upstream of estrogen-regulated genes, including those encoding molecules involved in cell proliferation.

The potential role of a target-oriented approach in the treatment of a human tumor can be adequately evaluated only if three relevant points are properly considered: (1) the molecular epidemiology of the target in the proposed study population; (2) the role of the target in patho-physiology of the tumor; (3) the effectiveness of the available target-oriented drug on target inhibition. If we consider hormonal treatment of HCC as a target-oriented treatment, the three relevant points to be taken into account are: (1) presence of sex hormones receptors expression in HCC cells; (2) relevance of stimulation by sex hormones in human HCC proliferation; (3) effectiveness of available drugs on inhibiting hormonal receptors activation.

As for the last point, there is no doubt that very effective drugs are available. In the last decades, the anti-estrogen tamoxifen has been a mile-stone treatment for patients with hormone-sensitive breast cancer. Tamoxifen inhibits the growth of tumor cells by competitive antagonism of estrogen at its receptor site, and levels of estrogen receptor expression are the best predictor of benefit from tamoxifen<sup>[10]</sup>. The real problem is that tamoxifen has been tested in patients with HCC, based on suggestive preclinical and epidemiological evidence, without an adequate evaluation of the first two points, that are even more important than the third one to enable the success of a target-oriented strategy: the target expression in HCC cells and the relevance of the sex hormones mediated pathways in HCC cell growth and proliferation mechanisms.

Expression of sex hormones receptors (ER, PgR and AR) - can be detected in a variable proportion of HCC<sup>[11-19]</sup>. Table 1 shows the proportion of ER+, PgR+ and AR+ HCC in the studies analysing the expression of these receptors by different techniques, mostly enzyme immunoassay or immunohistochemistry. In the recent study by Vizoso *et al*, sex hormones receptors expression was determined in 31 HCC patients by immunohistochemistry using tissue micro-arrays<sup>[19]</sup>. Their results demonstrate a wide variability in the immunohistochemical values for steroid receptors among HCCs: 67.7% of tumors stained positively for AR, 51.6%

for ER and 83.8% for PgR, but, among the positive cases, immunostaining score values for each protein were largely variable.

As for ERs, normal liver expresses almost exclusively wild-type ERs derived from the full-length transcript of the gene. Actually, there are two different ERs, ER-alpha and ER-beta, that are produced by distinct genes. During progression of liver disease to HCC, variant forms of ERs have been demonstrated<sup>[20]</sup>. Peritumoral cirrhotic tissue of patients with hepatocellular carcinoma, especially males, expresses a variant form of ER with an exon 5 deletion. This variant lacks the hormone-binding domain of the receptor but, being intact in the DNA-binding domain, maintains constitutive transcriptional activity. In HCC, variant ER largely predominates and sometimes becomes the only form expressed<sup>[20]</sup>. The occurrence of variant ER alone is limited almost exclusively to males, and this suggests that it could be one of the molecular events that eventually lead to the preferential development of hepatocellular carcinoma in males. In addition, variant ER is more frequent in patients infected with the hepatitis B virus. The growth rate of HCC in patients with variant ER is also significantly higher than that in patients with tumors expressing wild type ER. These tumors with variant ER, that are a significant percentage of HCC, are characterized by a worse prognosis, with significantly shorter survival<sup>[21]</sup>.

### EVIDENCE-BASED SUMMARY OF TAMOXIFEN EFFICACY IN HCC: RANDOMIZED CLINICAL TRIALS AND META-ANALYSES

Although only a limited percentage of HCC are ER+ and there is no robust evidence about the relevance of sex hormone-dependent pathways in HCC proliferation, in the last decades there has been great interest in the potential usefulness of tamoxifen for patients with HCC. Tamoxifen is characterized by a favourable tolerability profile, that, together with the easy oral administration, makes this drug an interesting candidate for treatment of solid tumors potentially responding to hormonal manipulation.

A number of randomized controlled trials have tested the efficacy of tamoxifen, with conflicting results (Table 2). Many of these studies were characterized by several methodological drawbacks, and by a really small sample size. Median survival in the control group was very variable, emphasizing the extreme variability in prognosis of patients with HCC.

With the aim of clarifying the benefit associated with tamoxifen and with other treatment strategies producing conflicting results in HCC, several systematic reviews have been conducted and published. Systematic reviews of health-care interventions are an attempt to collate information from all relevant studies and, if deemed appropriate, combine their results using meta-analysis. There have been four systematic reviews with meta-analysis of randomized clinical trials of tamoxifen in HCC<sup>[34-37]</sup>.

The two earlier reviews<sup>[34,35]</sup> were conducted and published about ten years ago, when only small-randomized

trials were available. Both reviews showed a marginal increase in overall survival with the use of tamoxifen in advanced HCC, suggesting that the preclinical rationale supporting the use of hormonal therapy in HCC patients could translate in to some clinical benefit.

The systematic review by Simonetti *et al* identified and considered seven trials: two trials<sup>[22,24]</sup> evaluated the addition of tamoxifen to chemotherapy, and the other five trials<sup>[23,25-27,29]</sup> were designed to compare tamoxifen versus no treatment or placebo. In these latter studies, pooled odds ratio of surviving at 1-year for patients receiving tamoxifen was 2.0, with 95% confidence intervals (CI) 1.1-3.6. This means a statistically significant result favouring tamoxifen. However, considering the limited quality of the evidence, the authors of the meta-analysis suggested a note of caution in considering these results definitive, calling for a large randomized controlled trial to definitely address the issue of the efficacy of tamoxifen in HCC.

Similarly, also the authors of the other review noted that further large, well-designed trials were needed to definitely answer this question, because controversy persisted about tamoxifen efficacy<sup>[33]</sup>. In fact, their meta-analysis, considering seven trials, showed a borderline survival benefit, but, in sensitivity analysis, the survival benefit of tamoxifen was no longer significant.

Two years before the publication of the first systematic review, in 1995, the Cancer of the Liver Italian Program (CLIP) Investigators started the CLIP-1 large randomized trial, with the aim of verifying whether earlier interesting but conflicting data on tamoxifen effect were confirmed in a larger study<sup>[31]</sup>. A pragmatic approach was chosen for the conduction of the trial. Eligibility criteria were broad, and all HCC patients with a life expectancy longer than 3 mo were eligible. Overall survival was the only endpoint of the intent-to-treat analysis, no placebo was used in the control arm and follow-up was conducted according to the usual clinical practice of participating centers. Patients assigned to the experimental arm received oral tamoxifen, 40 mg daily, until death or inability to assume the drug. Overall, 496 patients were randomized. Patients were predominantly males, with underlying viral cirrhosis. About half of them had a well compensated liver function. The results of the trial, published in 1998, showed no

overall survival advantage deriving from the administration of tamoxifen<sup>[31]</sup>. Median survival was 15 and 16 mo in the tamoxifen and the control arm, respectively. One-year survival probability was similar in the two arms, 55% and 56%, respectively. After adjustment for known prognostic factors, the relative hazard of death for patients receiving tamoxifen was equal to 1.07 (95% CI, 0.83-1.39). Considering that the sample size of the CLIP-1 trial was much higher than that of all the previous studies, it is not surprising that the results of this trial changed the results of the meta-analysis. The addition of the CLIP-1 data to the four previous trials considered in the review by Simonetti *et al* comparing tamoxifen alone versus no active treatment produced a pooled odds ratio of being alive at 1 year for patients receiving tamoxifen of 1.19 (95% CI, 0.88-1.61), and there was no more statistically significant advantage for tamoxifen.

After the publication of the CLIP-1 trial, two systematic reviews with meta-analysis have been published<sup>[36,37]</sup>. Both did not show any survival benefit for patients assigned to tamoxifen.

In the systematic review conducted by the Barcelona-Clinic Liver Cancer Group, and published in 2003, seven RCT were considered eligible for meta-analysis of tamoxifen effect<sup>[36]</sup>. Tamoxifen showed no survival benefit [odds ratio (OR), 0.64; 95% CI, 0.36-1.13,  $P = 0.13$ ], and the authors noted that only the low-quality trials showed any benefits.

Similar results are described in the Cochrane meta-analysis<sup>[37]</sup> that considered nine randomized trials (one testing two doses of tamoxifen) for a total of 1709 patients. Tamoxifen *versus* placebo/no intervention had no significant effect on overall survival [hazard ratio

(HR), 1.05; 95% CI, 0.94-1.16;  $P = 0.4$ ], without statistical heterogeneity between the trials. Trials were classified according to the adequacy or inadequacy of three methodological components: generation of the allocation sequence, allocation concealment and blinding. Subgroup analysis showed that a trend in reduction of mortality with tamoxifen was limited to trials with one or less adequate/three methodological components (HR 0.82; 95% CI 0.60-1.12;  $P = 0.2$ ), whilst tamoxifen showed no significant effect in trials with two adequate/three methodological components (HR, 1.00; 95% CI, 0.84 to 1.18;  $P = 0.98$ ) and tended to increase mortality in trials with three adequate/three methodological components (HR, 1.15; 95% CI, 0.99-1.34;  $P = 0.06$ ).

## ARE THERE ANY SUBGROUPS OF PATIENTS WHO RECEIVE BENEFIT FROM TAMOXIFEN?

Almost ten years ago, Mathurin *et al* discussed the conflicting results obtained with tamoxifen in their systematic review, stating that one of the main objectives in the future should have been to identify, using clinical and biological factors, the subgroups of patients responding to tamoxifen<sup>[35]</sup>.

### Clinical factors

As for the identification of clinical subgroups, updated results of the CLIP-1 study, published in 2002, confirmed the original negative result obtained in the overall study population, both in the subgroup of advanced patients and in those eligible for potentially curative loco-

regional treatments<sup>[38]</sup>. In a more recent RCT, conducted in France, 420 patients with HCC and a prevalence of alcohol-related liver cirrhosis were randomized to receive tamoxifen or supportive care alone<sup>[33]</sup>. Despite the negative result in the overall population, following a post-hoc unplanned subgroup analysis, French authors suggested that tamoxifen might be effective in a population of Okuda stage I or II, i.e. those patients without major hepatic insufficiency, and that new trials on tamoxifen are still warranted, at least in this subset of patients. It should be noted that subgroup analyses carry a relevant risk of false positive results, and their results should be always considered with great caution. However, we tried to validate the hypothesis generated by the French trial using updated data from the CLIP-1 randomised trial, but tamoxifen still resulted not effective both in patients with Okuda stage I - II and in patients with Okuda stage III disease or Okuda unknown<sup>[39]</sup>. We also tested the same hypothesis in subgroups defined according to the CLIP score. CLIP score is actually the most widely accepted and validated prognostic score for HCC<sup>[40-42]</sup>, and it takes into account liver function measured by Child-Pugh category, portal vein thrombosis, and level of alpha-fetoprotein and tumor size. In the patients of the CLIP-1 study, results were negative again both in patients with good CLIP score (0-1) and in those with worse or unknown CLIP score<sup>[39]</sup>.

### **Biological factors**

Hormonal treatment can be considered the first form of target-oriented cancer treatment. Greater emphasis should be probably given, when planning a clinical trial and interpreting its results, to the great impact that the molecular heterogeneity of tumors, affecting sensitivity to the experimental treatment, may have on the results of the trial<sup>[43]</sup>. This concept has been seldom taken into account in the planning and the analysis of clinical trials with cytotoxic agents, but in our opinion it should be necessarily applied in clinical trials with molecular targeted agents and, similarly, with hormonal treatment. We can imagine the whole population of potentially eligible patients as divided in to two distinct groups: one characterized by sensitivity to hormonal treatment, that will potentially produce in these patients an outcome better than the control, and the other, on the contrary, characterized by insensitivity to hormonal manipulation, that will translate in the absence of difference in efficacy between hormonal treatment and control. The higher the proportion of the latter patients in the study sample, the lower the power of the clinical trial to show a potentially positive result.

In particular, even in the case of solid tumors that are definitely considered hormone-sensitive, or hormone-dependent, not all the patients will derive benefit from hormonal treatment. In breast cancer, the disparity in clinical response to tamoxifen between women with hormone receptor-positive disease and those with receptor-negative tumors clearly established the utility of hormone receptor status in identifying those likely and, equally important, those unlikely to benefit from endocrine therapy<sup>[10]</sup>. In fact, it is now well established that the efficacy of hormonal treatment is relevant, but it is limited to patients with tumors expressing hormonal receptors.

This principle became the basis on which current clinical practice guidelines were established for the application of this treatment in breast cancer.

If we try to transfer these simple considerations to the hormonal treatment of HCC, it seems reasonable that a possible explanation of the negative results obtained with tamoxifen could stay in the lack of proper selection of the patients. In our opinion, it is really disappointing that none of the RCTs testing the efficacy of tamoxifen in HCC did select eligible patients according to hormonal receptors expression. The expression of these receptors is not so frequent in HCC, and the levels of expression in positive cases are largely variable. This might have diluted the positive effect of tamoxifen, potentially limited to a small subgroup of patients.

The only attempt of correlating target expression and efficacy of hormonal treatment in HCC patients comes from a secondary analysis of a Chinese randomized trial comparing tamoxifen versus no treatment for patients with advanced and otherwise untreatable HCC<sup>[18]</sup>. Immunohistochemical tests for ER and PgR were performed on the tumor tissues obtained from a subgroup of patients enrolled in the study. Disappointingly, in that series, the tumor expression of sex hormones receptors did not seem to affect the efficacy of tamoxifen<sup>[18]</sup>. However, it should be noted that, in that trial, (1) patients were not prospectively selected or stratified according to qualitative or quantitative hormonal receptors expression, (2) immunohistochemical determinations were performed only on a subgroup of 66 patients with adequate tissue specimen, out of 119 enrolled patients, and (3) the prognosis of the patients enrolled in that study was really dismal, with a median survival of 44 d *versus* 41 d, in the tamoxifen and control group, respectively. Adequately powered prospective phase III trials assessing the efficacy of tamoxifen in patients selected or stratified (prospectively or retrospectively) for ER expression have never been conducted.

Another intriguing hypothesis about the possibility that tamoxifen could be effective only in a selected subgroup of patients with HCC is related to the presence of variant estrogen receptors (vER)<sup>[20]</sup>. Tamoxifen could not be effective in tumors with vER, because of its inability to bind the receptor, and this could contribute to justify tamoxifen lack of efficacy, considering that a relevant proportion of HCC patients have predominant vERs<sup>[44]</sup>. In a small experimental experience<sup>[45]</sup>, anti-hormonal therapy of HCC was tailored according to the presence of wild-type or exon 5-deleted vER transcripts, limiting the administration of tamoxifen (at a daily dose of 80 mg) to patients with wild-type ER, and treating patients with vER with megestrol acetate, at the daily dose of 160 mg. Interestingly, tumor volume in all patients with wild-type ERs was halved after 9 mo of tamoxifen treatment, and the investigators concluded that choosing anti-hormonal treatment according to the presence of wild-type or variant ERs in the tumor definitely improves the response rate to tamoxifen.

Of course, in our opinion, these intriguing results are not sufficient to definitely claim the efficacy of tamoxifen in a selected subgroup of HCC patients. These preliminary

results still lack confirmation in adequately powered and designed randomized controlled trials, prospectively selecting patients with wild-type ER and randomizing them to receive tamoxifen or no treatment.

## SUPPOSED MECHANISM OF ACTION OF TAMOXIFEN IN HCC: ER-DEPENDENT VS ER-INDEPENDENT PATHWAYS

Some years ago, it has been proposed that the positive results obtained in some of the early small trials with tamoxifen in HCC and the negative results of the majority of the other trials might be explained if activity of tamoxifen in HCC could be related to an ER-independent pathway<sup>[46]</sup>. Several mechanisms have been proposed by which tamoxifen could act on HCC cells independently from the expression of ER: the interaction of tamoxifen and 4-hydroxy-tamoxifen with membrane phospholipids, with decrease in cell membrane fluidity and inhibition of adenylate cyclase, the inhibition of Protein Kinase C activity, the inhibition of calmodulin-dependent cAMP phosphodiesterase and the increase in Transforming Growth Factor beta1 levels, that can be obtained also in ER- cells<sup>[46]</sup>.

Interestingly, these mechanisms, potentially interfering with cellular pathways relevant to HCC proliferation, require much higher doses of tamoxifen than those used in most of the clinical trials conducted so far. In fact, tamoxifen is known to have therapeutic actions independent of ER status at higher doses (4-8 times higher than the dose established for ER-positive breast carcinoma)<sup>[46]</sup>. Thus, high-dose tamoxifen would potentially have therapeutic actions on both ER-positive and ER-negative HCC. Although correlation between sex hormone receptor expression and efficacy of tamoxifen in HCC has never been adequately studied, Tan *et al.*, in 2001, called for a “paradigm shift” to dissociate the action of tamoxifen from the expression of ERs<sup>[46]</sup>. They suggested that future trials with tamoxifen in HCC should have used higher doses of tamoxifen, at least four to eight-fold that of the dose intended to be efficacious in an ER-dependent mechanism. Moving from this intriguing hypothesis, a double-blind RCT was conducted in the Asia-Pacific region with 329 HCC patients, comparing tamoxifen versus placebo<sup>[32]</sup>. Tamoxifen was given at two distinct doses (120 mg daily and 60 mg daily), in order to assess possible dose-response effect. Quite disappointingly, rather than indicating a dose-response effect in favor of tamoxifen, the analysis showed a significant detrimental effect for the higher dose of tamoxifen. Three-month survival rates were 44%, 41%, and 35%, respectively for the placebo, tamoxifen at 60 mg, and tamoxifen at 120 mg groups, with a statistically significant trend difference in survival across the 3 arms. There was a significantly higher risk of death in the tamoxifen 120 mg group compared with the placebo group (HR, 1.39; 95% CI, 1.07-1.81). The detrimental effect of tamoxifen seemed not to be related to a higher toxicity of the higher dose. The trial, indeed, was unable to identify significant toxicity due to tamoxifen, and the rate of reported treatment toxicity (3%) was extremely low,

without significant differences among the arms; however, the Authors cautiously postulated that the general rapid decline of patients with inoperable HCC could make it difficult to identify treatment toxicities.

Although the mechanism by which higher doses of tamoxifen seems to have a negative impact on the prognosis of HCC patients is not completely clear, the unexpected findings of the Asian trial are confirmed by the results of the Cochrane meta-analysis<sup>[37]</sup>. In fact, with increasing dose of tamoxifen, there was an overall survival trend favouring the arm without tamoxifen. Namely, the HR for overall survival was lowest for trials of tamoxifen given at 20 mg daily (HR 0.88; 95% CI, 0.69-1.44;  $P = 0.71$ ), higher in trials of tamoxifen given at 40 mg daily (HR 1.00; 95% CI 0.85-1.19;  $P = 1.0$ ), even higher in trials of tamoxifen given at 60 mg daily (HR, 1.03; 95% CI, 0.81-1.31;  $P = 0.8$ ), and highest in the single trial of tamoxifen given at 120 mg daily (HR, 1.29; 95% CI, 1.04-1.6;  $P = 0.02$ ).

According to these results, we believe that, unfortunately, neither further trials are warranted with tamoxifen in HCC, nor any use in clinical practice should be considered because of its clear lack of efficacy.

## EVIDENCE WITH OTHER HORMONAL TREATMENTS: MEGESTROL ACETATE AND ANTI-ANDROGENS

Megestrol acetate exerts its action on ER-pathways at post-receptorial level. Efficacy of megestrol acetate has been tested in HCC with vER, according to the hypothesis that in these tumors a progestin drug might work better than tamoxifen<sup>[45,47]</sup>. A small prospective, randomized study assigned patients with advanced HCC characterized by variant liver ER to receive megestrol or placebo<sup>[47]</sup>. Out of 133 patients diagnosed with HCC and screened for eligibility, 45 patients (33.3%) had variant ER transcripts demonstrated in the tumor and were enrolled in the study. Twenty-four patients were randomized to no treatment and 21 to megestrol at the daily dose of 160 mg. Median survival in untreated patients was 7 mo (95% CI, 3.01 mo -10.99 mo) versus 18 mo (95% CI, 13.47 mo-22.53 mo) in patients treated with megestrol ( $P = 0.009$ ). According to the comment of the investigators, megestrol was associated with a remarkable increase in overall survival in patients with HCC characterized by variant ERs, who usually show a rapidly progressive disease, making a trial with this drug more than warranted. We believe that no firm conclusions on the effectiveness of megestrol acetate in that selected subgroup of HCC patients should be drawn, in the absence of adequately powered randomized trials. Such trials should select patients according to the presence of variant ER, randomizing patients to receive megestrol or no treatment.

Similarly to estrogens, there is some preclinical evidence supporting a positive influence of androgens on HCC growth, with a potential role of treatment with anti-androgens for patients with HCC. In tumor cells, androgen receptors seem to be present more frequently and in greater concentrations than estrogen receptors<sup>[48]</sup>. Furthermore, experimental studies have suggested a

promoter effect of androgens on tumor growth<sup>[49]</sup>, which may be suppressed via anti-androgen treatment<sup>[50]</sup> or castration<sup>[51]</sup>.

A randomized trial conducted in unresectable HCC by the European Organization for Research and Treatment of Cancer tested the efficacy of anti-androgen therapy<sup>[52]</sup>. The trial was conducted according to a factorial two-by-two design: patients were randomized to receive pure anti-androgen (nilutamide 300 mg daily for 1 mo, then 150 mg daily), luteinizing hormone-releasing hormone (LHRH) agonist (goserelin acetate at 3.6 mg or triptorelin at 3.75 mg administered monthly by subcutaneous injection), both treatments or control. Unfortunately, neither pure anti-androgen nor LHRH agonist showed significant efficacy in terms of survival. Another randomized phase III trial, designed with the aim of assessing the effect of anti-androgens in patients with advanced HCC, was conducted by the French collaborative group GRETCH<sup>[53]</sup>. Male patients with advanced HCC were randomized into 2 arms. Patients assigned to the experimental arm received leuprorelin (3.75 mg/mo subcutaneously), flutamide (750 mg orally daily), and tamoxifen (30 mg orally daily). Patients assigned to control arm received tamoxifen alone, considered as a standard treatment at the time of study planning. Between February 1994 and January 1998, 376 male patients were included. Median survival time was 135.5 d and 176 d in combination and tamoxifen groups, respectively ( $P = 0.21$ ). Adjusted relative risk of death in the treated group was estimated 1.08 (95% CI, 0.87-1.33). In conclusion, no benefit in survival was found with anti-androgenic treatment in male patients with advanced HCC.

## MOVING TOWARD OTHER SYSTEMIC TREATMENTS

In the last decades, although supported by weak and conflicting results, use of tamoxifen in patients with advanced HCC has been probably encouraged by the absence of other active systemic options.

In recent years, with the development of new drugs targeting growth factor receptor pathways or other cellular pathways potentially relevant to tumor cell proliferation, research efforts have been focused on targeted therapies. Recently, sorafenib, that is a small molecule tyrosine kinase inhibitor acting against Raf kinase, VEGF, PDGFR- $\beta$ , c-KIT and Flt has shown efficacy compared to placebo in a randomized controlled study conducted in 602 patients with advanced HCC, in the setting of Child-Pugh A cirrhosis<sup>[3]</sup>. A planned interim analysis concluded that the trial met its primary end point, demonstrating a statistically significant and clinically relevant better survival in the sorafenib arm, without striking difference in the incidence of serious adverse events. Most recently, a planned interim analysis found similar results favouring sorafenib in an Asia-Pacific regional Phase III trial of patients with advanced HCC, enrolling 226 patients from sites in China, Korea and Taiwan. Based on these results, sorafenib has been the first drug approved for treatment of HCC, by both US Food and Drug Administration and European Medicines Agency.

On the contrary, disappointing results of clinical trials that have tested the efficacy of hormonal treatment in HCC raise serious doubts about the real relevance of sex hormones mediated pathways in the clinical course of HCC. Hormonal treatments should not be part of the current standard management of patients affected by hepatocellular carcinoma.

## Abstract

Constitutive activation of the insulin-like growth factor (IGF)-signaling axis is frequently observed in human hepatocellular carcinoma (HCC). Especially the over-expression of the fetal growth factor IGF- II, IGF- I receptor (IGF-IR), and cytoplasmic downstream effectors such as insulin-receptor substrates (IRS) contribute to proliferation, anti-apoptosis, and invasive behavior. This review focuses on the relevant alterations in this signaling pathway and independent *in vivo* models that support the central role IGF- II signaling during HCC development and progression. Since this pathway has become the center of interest as a target for potential anti-cancer therapy in many types of malignancies, various experimental strategies have been developed, including neutralizing antibodies and selective receptor kinase inhibitors, with respect to the specific and efficient reduction of oncogenic IGF- II /IGF-IR-signaling.

## INTRODUCTION

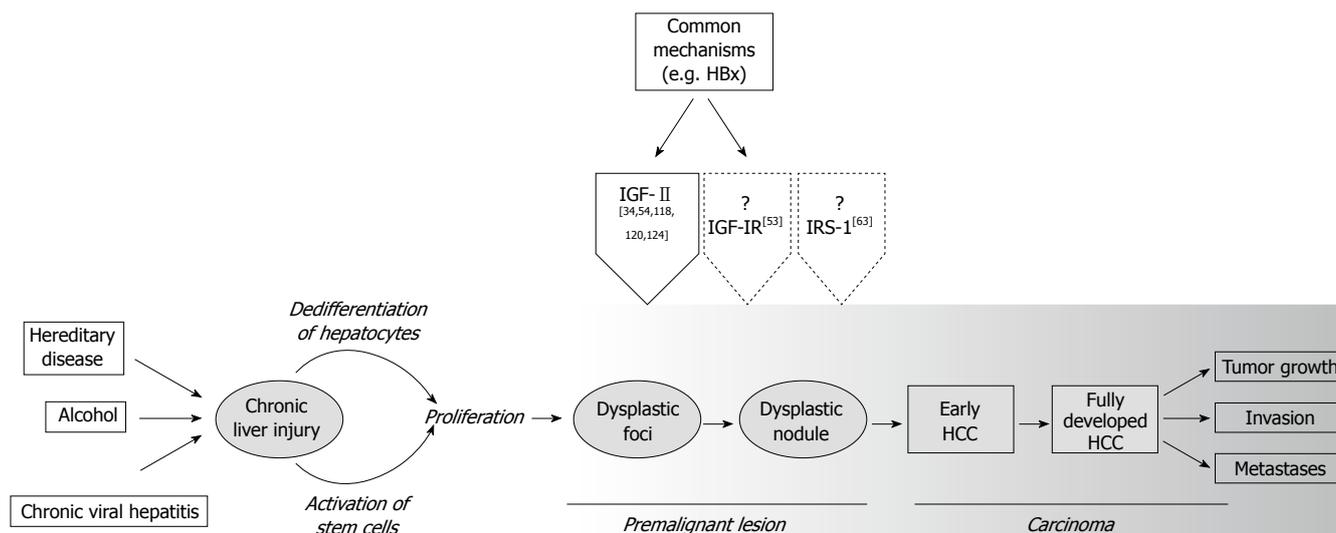

Human hepatocellular carcinoma (HCC) is considered the fifth most frequent malignancy worldwide and the third most common cause for cancer mortality with an increasing incidence in Asia and Africa, but also in industrial countries<sup>[1]</sup>. In more than 80% of cases, a well-defined etiology such as viral infection with hepatitis B- and C-viruses (HBV and HCV), aflatoxin B1 intoxication, chronic alcohol abuse, or hereditary diseases is associated with its development (Figure 1); however, clinical diagnosis of HCC is difficult due to the lack of reliable serum markers. Moreover, the therapeutic options for HCC patients are sobering due to the high angioinvasive capacity of the tumor.

Although the underlying molecular mechanisms responsible for the development and progression of HCC have not been completely delineated, it has become clear that aberrant activation of growth factor signaling pathways is a pivotal event in hepatocarcinogenesis. Besides the hepatocyte growth factor (HGF)/MET, Wnt/frizzled/ $\beta$ -catenin), transforming growth factor  $\alpha$  (TGF $\alpha$ )/EGF-R, and transforming growth factor  $\beta$  (TGF $\beta$ )/T $\beta$ R-signaling, dysregulation of the evolutionary highly conserved insulin-like growth factor (IGF) pathway is critically involved in proliferation and anti-apoptosis of HCC cells associated with uncontrolled tumor growth and chemoresistance<sup>[2]</sup>. In fact, based on its central regulatory position in tumor cell homeostasis, this signaling axis is considered a promising therapeutic anti-cancer target in many human malignancies. This review focuses on the molecular changes of IGF-signaling detected in human HCC, animal model systems that underline the central role of IGF- II -signaling in hepatocarcinogenesis, as well as resulting therapeutic strategies for the treatment of human liver cancer.

## COMPOSITION OF THE IGF-PATHWAY

The key molecules in this pathway are the ligands IGF- I and IGF- II, IGF-binding proteins (IGFBP1-6), membrane-associated receptors [IGF- I receptor (IGF-IR), mannose-6-phosphate receptor/IGF- II receptor (IGF- II R)], and insulin receptor substrates (IRS-1-6).

IGF- I and IGF- II are small, secreted molecules that are predominantly produced by the liver and which stimu-

**Figure 1** Schematic representation of human hepatocarcinogenesis. Human HCC usually develops on the background of a chronic liver disease (e.g. hepatitis, alcoholic liver disease, hemochromatosis). Dysplastic foci and dysplastic nodules are regarded as premalignant lesions preceding the development of HCC. In addition, “early” HCCs (< 2 cm, highly differentiated, non-invasive) are distinguished from fully developed HCCs (fast growing, invasive). However, human hepatocarcinogenesis represents a developmental continuum where a clear cut classification of a given lesion is often impossible. Increasing evidence suggests that aberrant IGF- II expression represents an early event in hepatocarcinogenesis; however, comparable data are currently not available for IGF-IR, and IRS. Nevertheless, reactivation of the IGF- II /IGF-IR signaling pathway seems to be a progression step in human liver cancer.

late different cell types in both an autocrine and paracrine manner. These factors display differing expression kinetics as the expression of IGF- II declines while the bioavailability of IGF- I increases shortly after birth. Besides the transcriptional regulation (e.g. genomic imprinting of the *igf-II* gene promotor), ligand bioavailability is further influenced by the presence of IGF-BPs in tissues and serum<sup>[3]</sup>. Secreted IGF-BPs bind extracellular IGFs with affinities comparable to IGF-IR and therefore modulate ligand bioactivity. For instance, 70% of IGF- II is bound to IGFBP-3, which is the most abundant BP in serum<sup>[4]</sup>; however, depending on the cellular context, both inhibitory as well as stimulatory effects of IGF-BPs on IGF-signaling have been described. All IGF-BPs are substrates for proteases and their bioavailability/bioactivity is regulated by limited proteolytic cleavage with an impact on IGF-dependent physiological processes<sup>[5]</sup>. However, IGF-independent biological effects under pathophysiological conditions have also been described for several IGF-BPs<sup>[6]</sup>.

The signaling of IGF- I and IGF- II is mediated by IGF-IR, a heterotetrameric protein (two  $\alpha$ - and  $\beta$ -chains), which consists of an extracellular ligand binding site and an intracellular tyrosine kinase domain. IGF-IR binds IGF- I with 15- to 20-fold higher affinity than IGF- II<sup>[7]</sup>. Ligand binding and receptor tyrosine kinase (RTK)-dependent phosphorylation of intracellular substrates such as IRS and Src homology collagen (Shc) then lead to the activation of the phosphatidylinositol 3-kinase (PI3-kinase)/protein kinase B (PKB/AKT)-axis and the Ras/mitogen activated protein kinase (MAPK)-pathway<sup>[8]</sup>. IRS proteins are a family of six (IRS-1 to IRS-6) related adaptors that integrate and coordinate signaling of the insulin receptor (IR) and also the IGF-IR. They are responsible for most of the biological activities of IGF-IR<sup>[9]</sup>.

In addition, IGF- II (but not IGF- I) efficiently binds and activates a distinct isoform of the insulin receptor lacking exon 11 (IR-A)<sup>[10-12]</sup>. IR and IGF-IR are highly homologous RTKs (up to 84% in the tyrosine kinase domain and 100% at the ATP-binding site)<sup>[13]</sup>, but there are substantial functional differences between both molecules: while both receptors exert metabolic effects, IGF-IR is anti-apoptotic, mitogenic, and it facilitates a malignant phenotype<sup>[14]</sup>. However, IR-A plays a central role not only in metabolic processes, but also in IGF- II-induced migration in cells lacking IGF-IR<sup>[11]</sup>. These different biological effects are possibly based on ligand/receptor abundance, protein turnover or currently undiscovered peculiarities of the distinct signaling axes. In addition, recent findings show that structural features in the domain governing ligand specificity do distinguish IGF-IR from IR<sup>[15]</sup>.

In contrast, IGF- II R which is structurally unrelated to IGF-IR, does not exhibit cytoplasmic kinase activity<sup>[16]</sup>. Although this receptor does not directly contribute to IGF-signaling, it regulates IGF- II turnover and bioavailability through receptor-mediated endocytosis and subsequent degradation<sup>[17]</sup>. IGF- I and insulin cross-react very weakly with IGF- II R and therefore are not regulated by its (inhibitory) activity<sup>[18]</sup>.

## IGF-SIGNALING IN HEPATOCARCINOGENESIS

Alterations in the IGF-signaling pathway have been described in several adult and pediatric human tumors such as Wilms tumors<sup>[19]</sup>, as well as colon<sup>[20,21]</sup>, lung<sup>[22]</sup>, breast<sup>[23,24]</sup>, and prostate cancer<sup>[25]</sup>. The reactivation of IGF-

signaling in HCC predominantly occurs at the level of IGF-II expression, which is secreted by the tumor cells themselves, which is suggestive of autocrine mechanisms of stimulation<sup>[26,27]</sup>. This growth factor is highly expressed in the fetal liver and early after birth, but its expression is strongly reduced in adulthood in humans, mice and rats<sup>[28-30]</sup>. Several studies have shown elevated expression levels for IGF-II in preneoplastic lesions (Dysplastic Nodules) and very high levels in HCC (Table 1, Figure 1), which is mainly based on aberrant activation of the epigenetically regulated *igf-II* promoters P1-P4<sup>[31]</sup>. Indeed, HCCs showing high level of expression of IGF-II exhibit reconstitution of the fetal type transcription pattern due to a loss of promotor-specific imprinting and hypomethylation<sup>[26,32-35]</sup>. Furthermore, viral proteins have been reported to facilitate IGF-II overexpression in HBV- and HCV-associated HCCs. For example, the HBV-derived HBx protein and the HCV-derived core gene product induce IGF-II expression through interaction with transcription factors activity such as Sp1 and Egr1<sup>[36,37]</sup>. In addition, the inactivation of tumor suppressor genes such as p53 by aflatoxin-induced mutations in codon 249 increases IGF-II expression through the formation of transcriptional complexes<sup>[38]</sup>.

Besides the direct transcriptional induction of IGF-II expression, additional mechanisms may contribute to elevated IGF-II bioavailability in HCC cells. Firstly, reduced levels of IGFBP-1, -2, -3, and -4 in HCCs were found to be associated with IGF overexpression<sup>[39,40]</sup>. These IGFBP-based effects on IGF-concentration may be even more complex, since a reduced degradation of IGFBPs by matrix-metalloproteinases (MMPs) was regulated by tissue inhibitors of MMPs (TIMPs). The regulation of TIMP-1, which is repressed in many HCCs, is associated with changes in IGF-II abundance<sup>[41,42]</sup>. Secondly, the downregulation or inactivation of IGF-II R theoretically leads to increased concentrations of IGF-II based on insufficient internalization and degradation. Here, the reduced expression of IGF-II R, the loss of heterozygosity (LOH) at the *igf-II* gene locus, homozygous deletions, and missense mutations with an impact on ligand binding have been described with respect to HCCs<sup>[43-49]</sup>. However, other studies did not detect any genetic alterations at the *igf-II* locus, which may be due to methodological and population-based differences<sup>[50-52]</sup>. Moreover, few studies described elevated IGF-II R levels in HCCs<sup>[53,54]</sup>. Independent of the underlying molecular mechanism, IGF-II overexpression denominates a group of HCCs with fewer tumor infiltrating lymphocytes, a lower apoptosis rate<sup>[55]</sup> and extrahepatic metastasis<sup>[56]</sup>. Thus, serum IGF-II availability was proposed as a tumor marker discriminating HCC from cirrhosis<sup>[57]</sup>.

IGF-I - and IGF-II-mediated signaling may occur through IGF-IR and IR holoreceptor dimers as well as through IGF-IR/IR hemireceptor complexes<sup>[58,59]</sup>. Particularly IGF-II has been shown to efficiently activate both IGF-IR and IR-A. However, our own results suggested that the presence of IR was not essential for IGF-II-mediated oncogenic properties in liver tumor cells, since efficient siRNA-dependent inhibition of IR (all isoforms) did not lead to changes in proliferation, apoptosis, or migration in HCC cells (unpublished data). Therefore, in HCC cells IGF-IR is the relevant receptor for protumorigenic IGF-II

**Table 1 Expression of IGF-(II) signaling axis constituents in human HCC**

Signaling constituent	Dysregulation (%)
IGF-II	9.2 <sup>[117]</sup>
	22.5 <sup>[26]</sup>
	25.6-60 <sup>[118]</sup>
	66.7 <sup>[54]</sup>

	100 <sup>[122]</sup>
IRS-4	53.3 <sup>[53]</sup>
	86 <sup>[123]</sup>
	46.7 <sup>[53]</sup>

signaling. This finding is supported by the fact that IGF-IR is highly expressed in many human malignancies and that only IGF-IR-signaling is crucial for oncogenic transformation and tumor cell survival<sup>[60]</sup>. Indeed, while IGF-IR levels were constitutively low in normal hepatocytes, IGF-IR was overexpressed in HCC and HCC cell lines (Table 1). Just as it was observed for elevated IGF-II expression, viral-based molecular mechanisms and mutational inactivation of tumor suppressor genes caused IGF-IR overexpression: HBV-derived HBx protein as well as p53 mutations in codon 249 induce IGF-IR<sup>[61,62]</sup>, suggesting that these protumorigenic events modulate several IGF-pathway constituents such as IGF-II and IGF-IR to reach maximal (oncogenic) signaling efficiency.

Lastly, IRS-1, -2, and -4 are overexpressed in most HCCs (Table 1). So far, most analyses are reported for IRS-1, showing that elevated IRS-1 levels mediate anti-apoptosis<sup>[63]</sup>, tumor cell growth<sup>[64]</sup>, and mitosis<sup>[65]</sup>. Further, it has been found that the HCV-derived core protein reduced IRS-1 expression in HCC cell lines<sup>[66]</sup>. To our knowledge, no molecular mechanisms responsible for the elevated IRS-1 expression (e.g. other viral proteins) have been described so far. Whether other IRS family members serve identical functions in HCC cells has not yet been analyzed.

In summary, several lines of evidence suggest a ‘multi-hit’ model for the oncogenic activation of IGF-II signaling in HCC. Firstly, the sum of protumorigenic events detected in HCCs (e.g. increased IGF-II, IGF-IR, and IRS bioavailability) indicates the potential for multiple hits in one single tumor. Secondly, viral proteins and the inactivation of tumor suppressor genes induce several IGF-II pathway constituents. Although increased bioavailability of IGF-II appears to be the dominant mechanism in human hepatocarcinogenesis, many hits in this pathway may be necessary to obtain full malignant competence.

## ANIMAL MODELS

The pivotal oncogenic function of IGF-II-signaling

in hepatocarcinogenesis is supported by several animal models. Transgenic mice expressing IGF-II (20-30-fold increased levels in serum) develop hypoglycemia and many types of malignancies, which are most frequently HCC<sup>[67]</sup>. In contrast, overexpression of IRS-1 is associated with increased DNA-synthesis, but liver tumor development was not detected<sup>[68]</sup>. In knockout model systems the disruption of the *igf-II* gene leads to elevated IGF-II levels; but since these animals exhibit lethal organ abnormalities (e.g. organomegaly), no further studies concerning liver tumor development have been carried out<sup>[69-71]</sup>.

In addition to these IGF-pathway-specific transgenic and knockout animals, additional models, initially not intended for the examination of the IGF-axis, supported the functional relevance of especially dysregulated IGF-II in hepatocarcinogenesis. Both mice with liver-directed expression of SV40T-Ag or HBV presurface gene products (preS1 and preS2) developed HCCs, which is associated with a high level of IGF-II expression<sup>[72]</sup>. Moreover, transgenic mice overexpressing the woodchuck hepatitis virus/c-MYC<sup>[73]</sup>, c-MYC<sup>[74]</sup>, and TGF $\alpha$ <sup>[75]</sup> developed HCCs accompanied by elevated IGF-II expression in the tumors. Equally, liver tumors in p53-null animals exhibited increased amounts of IGF-II as compared to normal littermates after delivery of polyoma virus middle T antigen (PyMT)<sup>[76]</sup>.

Cross-breeding experiments underlined the importance of IGF-II-signaling in hepatocarcinogenesis. Interbreeding of IGF-II knock-out mice with SV40T-Ag animals resulted in a reduced frequency (up to 15-fold) and size of liver tumors as compared to animals only expressing the oncogene<sup>[77]</sup>, suggesting an important role of IGF-II-signaling in tumor progression. This anti-tumorigenic effect for IGF-II-deficiency in tumor models was supported by similar results in animals expressing SV40T-Ag in Langerhans cells showing widely identical results<sup>[30]</sup>. In a more indirect approach, TIMP1 overexpression reduced IGF-II-driven HCC development in SV40T-Ag transgenic animals based on reduced tumor cell proliferation and vascularization<sup>[41,78,79]</sup>. However, it is also noteworthy that mice expressing the c-MYC oncogene and which are deficient for IGF-IR only showed a marginally reduced HCC incidence compared to animals expressing the oncogene alone<sup>[74]</sup>.

The functional connection between the viral infection of hepatocytes and IGF-II abundance was supported by studies utilizing the woodchuck model system. After woodchuck hepatitis virus (WHV) infection, a high level of IGF-II expression was detected in precancerous woodchuck liver and in up to 45% of HCCs, which correlates with repressed viral DNA replication and n-MYC expression in early precancerous lesions<sup>[34,80]</sup>. Further studies revealed that IGF-II availability protected from n-MYC-induced apoptosis especially under serum-free conditions<sup>[81]</sup>. Therefore, the selection for cells with high IGF-II levels may rescue a more unfavorable tumor phenotype and therefore promote tumor progression. Lastly, a reactivation of IGF-II expression in experimentally induced liver tumors using different chemical substances (3<sup>2</sup>-Me-DAB, 2-AAF, DENA) has been described in rats<sup>[82-84]</sup>.

These data clearly show that IGF-II overexpression and intactness of the IGF-II/IGF-IR pathway is also a common event in murine liver tumor development, independent of the underlying molecular mechanisms (e.g. oncogene activity, regeneration processes, chemically induced carcinogenesis)<sup>[72]</sup>.

## THERAPY

IGF-II is highly expressed during prenatal development and early after birth but levels rapidly decline in adulthood<sup>[28,29]</sup>. Since IGF-II signaling is frequently reactivated in human hepatocarcinogenesis, inhibition of this pathway unlikely affects normal liver function under physiological conditions and therefore represents a favorable therapeutic strategy. Several techniques have been developed to modulate the activity of IGF-(II) signaling in different tumor cell types<sup>[85]</sup>. Many approaches, such as neoexpression of dominant-negative receptor mutants (dnIGF-IR) or transfection of IGF-IR-specific antisense oligodeoxynucleotides, attained convincing inhibitory effects on IGF/IGF-IR signaling *in vitro* and *in vivo*<sup>[85]</sup>. However, neutralizing antibodies binding IGF-IR and IGF-IR-specific small inhibitory molecules are currently the most promising therapeutic and clinically relevant approaches<sup>[60]</sup>.

### Neutralizing antibodies

Recently, numerous blocking antibodies recognizing different membrane-bound RTKs such as EGF-R/HER1 (Cetuximab/Erbitux) and HER2 (Trastuzumab/Herceptin) have been developed<sup>[86]</sup>. Besides IGF-II-binding antibodies that physically inhibit ligand/receptor interaction<sup>[87,88]</sup>, many neutralizing antibodies specific for IGF-IR have been described such as alpha-IR3<sup>[89]</sup>, mAb391<sup>[90]</sup>, scFv-FC<sup>[91]</sup>, CP-751,871<sup>[92]</sup>, IMC-A12<sup>[93]</sup>, 7H2HM<sup>[94]</sup>, EM164<sup>[95]</sup>, h7C10<sup>[96]</sup>, 4G11<sup>[97]</sup>, 19D12<sup>[98]</sup>, R1507<sup>[60]</sup>, AMG479<sup>[60]</sup>, and 19D12<sup>[60]</sup>. Reduced IGF/IGF-IR signaling is presumably based upon lysosome-dependent degradation of IGF-IR<sup>[90,91]</sup>. Since proteasome inhibitors (e.g., Brefeldin) as well as protein synthesis inhibitors (e.g., cyclohexamide) did not affect antibody-dependent downregulation of the receptor<sup>[90,91]</sup>, it has been speculated that anti-IGF-IR antibodies hampered steady-state protein turnover based on endosomal accumulation of antibody/receptor complexes<sup>[99]</sup>. Although the anti-tumor effects of these antibodies were tested for several different cell types in preclinical studies, no comprehensive analyses regarding the anti-tumorigenic impact on HCC cells have been published to date. However, it is noteworthy that for other tumor entities, clinical trials for antibodies targeting IGF-IR have been launched such as CP-751, 871 (Pfizer), IMC-A12 (ImClone Systems), R1507 (Roche), and AMG479 (Amgen)<sup>[60]</sup>.

### Tyrosine kinase inhibitors

In addition to neutralizing antibodies, small molecule inhibitors targeting RTKs such as EGF-R/HER1 (Gefitinib/Iressa), BCR/ABL fusion product (Glivec/Imatinib), or cellular kinases (the multi-kinase inhibitor Sorafenib/Nexavar recognizing VEGF-R, PDGF-R, c-kit, Raf, and

RET) have been developed. Since IGF-IR and the IR are structurally related, highly specific IGF-IR inhibitors are necessary to prevent diabetogenic effects in patients. Published IGF-IR-selective RTK-inhibitors are tyrosine kinase inhibitors (AG538<sup>[100,101]</sup>, AG1024<sup>[102]</sup>, AG1034<sup>[102]</sup>), cyclolignans (picropodophyllin<sup>[103,104]</sup>), 6-5 ring-fused compounds<sup>[105]</sup>, pyrrole derivatives (NVP-AEW541<sup>[106,107]</sup>, NVP-ADW742<sup>[108,109]</sup>), PQQP<sup>[110]</sup>, BMS536924<sup>[111]</sup>, and BMS-554417<sup>[112]</sup>. Anti-tumorigenic effects of some inhibitors on HCC cells have been demonstrated. The application of NVP-AEW541<sup>[113]</sup> and picropodophyllin (Nussbaum *et al*, unpublished data) was shown to reduce tumor cell proliferation and increase apoptosis. Equally, IGF- II induced tumor cell motility was reduced by picropodophyllin (Nussbaum *et al*, unpublished data). In addition, the inhibition of IGF-IR-signaling by a combination of AG1024 and EGF-R-signaling by RTK-inhibitors or blocking antibodies synergistically reduced tumor growth<sup>[114,115]</sup>. However, NVP-ADW742 affects the viability of hepatocytes in a concentration-dependent manner. This RTK-inhibitor potentiated bile acid-induced cell death in normal hepatocytes, suggesting liver toxicity in patients with aberrant bile flow<sup>[116]</sup>. Because IGF-IR signaling is almost absent in normal hepatocytes, it is questionable whether these effects were IGF-dependent or independent. Thus, the effects of IGF-IR-specific inhibition on normal and diseased liver have to be analyzed carefully.

Although the anti-tumorigenic effects of IGF-IR-specific small molecules have been analyzed in numerous tumor cell types in preclinical setups<sup>[60]</sup>, to our knowledge, no clinical trials have been initiated to date.

## CONCLUSION

Several components of the IGF-signaling axis, such as IGF- II, IGF-IR and IRS, are frequently dysregulated in human hepatocarcinogenesis. The oncogenic reactivation of IGF- II-signaling has been verified in several *in vivo* models and supports the therapeutic relevance of this pathway. However, aberrant growth factor bioactivity involved in tumor development cannot be understood in a mono-dimensional manner since an intense cross-talk between IGF-IR signaling and other oncogenic pathways have been described<sup>[2]</sup>. Indeed, first functional studies revealed the necessity for multi-modal approaches for optimal anti-tumorigenic results and dose reduction. Therefore, it is questionable whether the highest specificity is the 'gold standard' for efficient treatment of malignancies, especially with respect to the development of (IGF-IR specific) RTK inhibitors. Thus, inhibitors targeting IGF-IR and other RTKs or combinations of different specific substances targeting distinct pathways might be attractive therapeutic approaches in the future.

### Abstract

In many parts of the world hepatocellular carcinoma (HCC) is among the leading causes of cancer-related mortality but the underlying molecular pathology is still insufficiently understood. There is increasing evidence that activins, which are members of the transforming growth factor  $\beta$  (TGF $\beta$ ) superfamily of growth and differentiation factors, could play important roles in liver carcinogenesis. Activins are disulphide-linked homo- or heterodimers formed from four different  $\beta$  subunits termed  $\beta$ A,  $\beta$ B,  $\beta$ C, and  $\beta$ E, respectively. Activin A, the dimer of two  $\beta$ A subunits, is critically involved in the regulation of cell growth, apoptosis, and tissue architecture in the liver, while the hepatic function of other activins is largely unexplored so far. Negative regulators of activin signals include antagonists in the extracellular space like the binding proteins follistatin and FLRG, and at the cell membrane antagonistic co-receptors like Cripto or BAMBI. Additionally, in the intracellular space inhibitory Smads can modulate and control activin activity. Accumulating data suggest that deregulation of activin signals contributes to pathologic conditions such as chronic inflammation, fibrosis and development of cancer. The current article reviews the alterations in components of the activin signaling pathway that have been observed in HCC and discusses their potential significance for liver tumorigenesis.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the predominant form of primary malignancy of the liver and accounts for more than half a million deaths per year<sup>[1]</sup>. In some geographical regions it is the most prevalent form of malignancy and the most common cause of death from cancer<sup>[2]</sup> making its containment a top priority. Chronic infection with the hepatitis B or C virus (HBV, HCV), dietary exposure to the hepatocarcinogen aflatoxin B1 (AFB1), ethanol abuse, and obesity are among the main risk factors for liver cancer<sup>[3]</sup>. Despite recent advances, the molecular pathology of the disease is not well understood and the therapeutic possibilities are largely limited to surgical procedures including resection, liver transplantation, or local tumor ablation<sup>[4]</sup>. A consistent pattern of changes comparable to the sequential mutations in tumor suppressor genes and oncogenes, like the one identified in colon carcinogenesis during adenoma to carcinoma progression<sup>[5,6]</sup>, has not been defined for HCC. Nevertheless, multiple genetic alterations including mutations of p53, inactivation of the Rb pathway, and activation of the Wnt/ $\beta$ -catenin pathway have been linked to HCC development and progression<sup>[3,7]</sup>. In addition deregulated expression of growth factors and their cognate receptors has been described in HCC for both, positive regulators of hepatocyte growth, such as insulin-like growth factor 2 (IGF-2), hepatocyte growth factor (HGF), and transforming growth factor  $\alpha$  (TGF $\alpha$ ), as well as for negative regulators like TGF $\beta$ <sup>[8]</sup>.

In recent years activins, a subgroup of the TGF $\beta$  family of growth, differentiation, and death factors which share part of their signaling mechanisms with TGF $\beta$ , have gained attention with respect to their role in tumor development in several organs<sup>[9]</sup>. Activin subunits, their receptors and several antagonistic proteins are expressed in the normal liver. Deregulation of this balanced expression

appears to contribute to hepatic dysfunctions like impaired regeneration, fibrogenesis and tumorigenesis<sup>[10]</sup>. The current knowledge about the role of activins and activin antagonists in HCC is discussed in this review.

## ACTIVINS-STRUCTURE AND SIGNALING

Activins are secreted polypeptides and represent a subgroup of the TGF $\beta$  superfamily of growth and differentiation factors. Additional members of this superfamily include TGF $\beta$ 1-3, bone morphogenetic proteins (BMPs), growth and differentiation factors (GDFs), myostatin, Mullerian inhibiting substance (MIS), nodal and several others<sup>[10,11]</sup>. Activins are homo- or heterodimers composed of four different  $\beta$  subunits ( $\beta$ A,  $\beta$ B,  $\beta$ C,  $\beta$ E), each encoded by a single gene. The  $\beta$  subunits can either form activins by dimerization with a second  $\beta$  subunit, or alternatively can form inhibins by dimerizing with a single  $\alpha$  subunit encoded in mammalian genomes<sup>[12]</sup>. Activin terminology is dependent on the dimer configuration with a single letter designating homodimers (activins A, B, C, and E) and two letters designating heterodimers according to their subunit composition (activins AB, AC, AE, BC *etc.*). With respect to tissue expression, transcripts of the  $\beta$ A and  $\beta$ B subunits were found to be detectable in almost all tissues analyzed with especially high expression in reproductive organs<sup>[13,14]</sup>. The  $\beta$ C and  $\beta$ E subunits, in contrast, are predominantly expressed in the liver and at lower levels in a limited number of additional organs<sup>[14-18]</sup>.

Activin  $\beta$  subunits are synthesized as precursor molecules with 350-426 amino acids and molecular weights between 38 kDa and 50 kDa<sup>[19]</sup>. The prodomains are removed in the ER and in the early Golgi by members of the protease family of subtilase-like pro-protein convertases (SPC)<sup>[20]</sup> to release mature peptides with either 115 ( $\beta$ B,  $\beta$ E) or 116 ( $\beta$ A,  $\beta$ C) amino acids. The amino acid sequences of the mature peptides are approximately 50% conserved among the four human  $\beta$  subunits, whereas the sequence homology in the prodomain is only about 20%. Analysis of the phylogenetic relationship of the mature human peptides groups together  $\beta$ A and  $\beta$ B on the one and  $\beta$ C and  $\beta$ E on the other hand<sup>[21]</sup>.

Like other members of the TGF $\beta$  family, the activin  $\beta$  subunits contain nine conserved cysteines in the mature peptides. The sixth is used for dimerization, whereas the other eight form intramolecular disulfide bonds which determine the three-dimensional structure of the peptides<sup>[22]</sup>. While all cysteines in the mature chain of activin  $\beta$ A are necessary for biosynthesis of activin A dimers or for their full biological activity, four additional cysteines in the prodomain are dispensable for dimerization and secretion. Protein folding and dimerization take place in the lumen of the ER and are catalyzed by members of the protein disulfide isomerase (PDI) family<sup>[23,24]</sup>. Unlike TGF $\beta$ , which is secreted as a latent complex consisting of the TGF $\beta$  homodimer, its prodomain (also termed latency-associated propeptide, LAP), and the latent TGF $\beta$  binding protein (LTBP)<sup>[25]</sup>, activins are secreted as dimers of the mature peptides and need no further processing in the extracellular space to gain bioactivity. Activin A signals are transduced *via*

two types of single-pass transmembrane serine threonine kinase receptors, termed activin receptors type I and type II<sup>[26]</sup>. Activin A first binds to the type II receptors which in turn recruit and phosphorylate the type I receptors<sup>[27]</sup>. Two type II receptors for activin A (ActR-II (A) or ACVR2 (A) and ActR-II B or ACVR2B) have been identified. The main type I receptor for activin A is ALK (Activin Receptor-Like kinase) 4, also designated as ActR-IB or ACVR1B, whereas activins B and AB have a preference for ALK 7 (ACVR1C) as type I receptor<sup>[28]</sup>. Receptors for activins containing  $\beta$ C or  $\beta$ E subunits have not been identified so far. Activin C, however, did not compete with activin A for receptor binding<sup>[29]</sup> and a chimeric activin construct in which the receptor binding sequence (amino acids 46-78) of  $\beta$ A was replaced by the corresponding region of  $\beta$ C retained type II receptor binding but was unable to recruit the type I receptor ALK 4<sup>[30]</sup>.

Inhibins have been shown to form a complex with type II receptors via their  $\beta$  subunits and with betaglycan also known as TGF $\beta$  type III receptor. The  $\alpha$  subunit, however, is unable to bind type I receptors and consequently activin receptor signaling is inhibited<sup>[31,32]</sup>. There is in general a considerable degree of promiscuity in receptor usage by different TGF $\beta$  superfamily members. In addition to activin A, for instance, myostatin, and several BMPs were shown to signal *via* ActR-II B<sup>[33]</sup>.

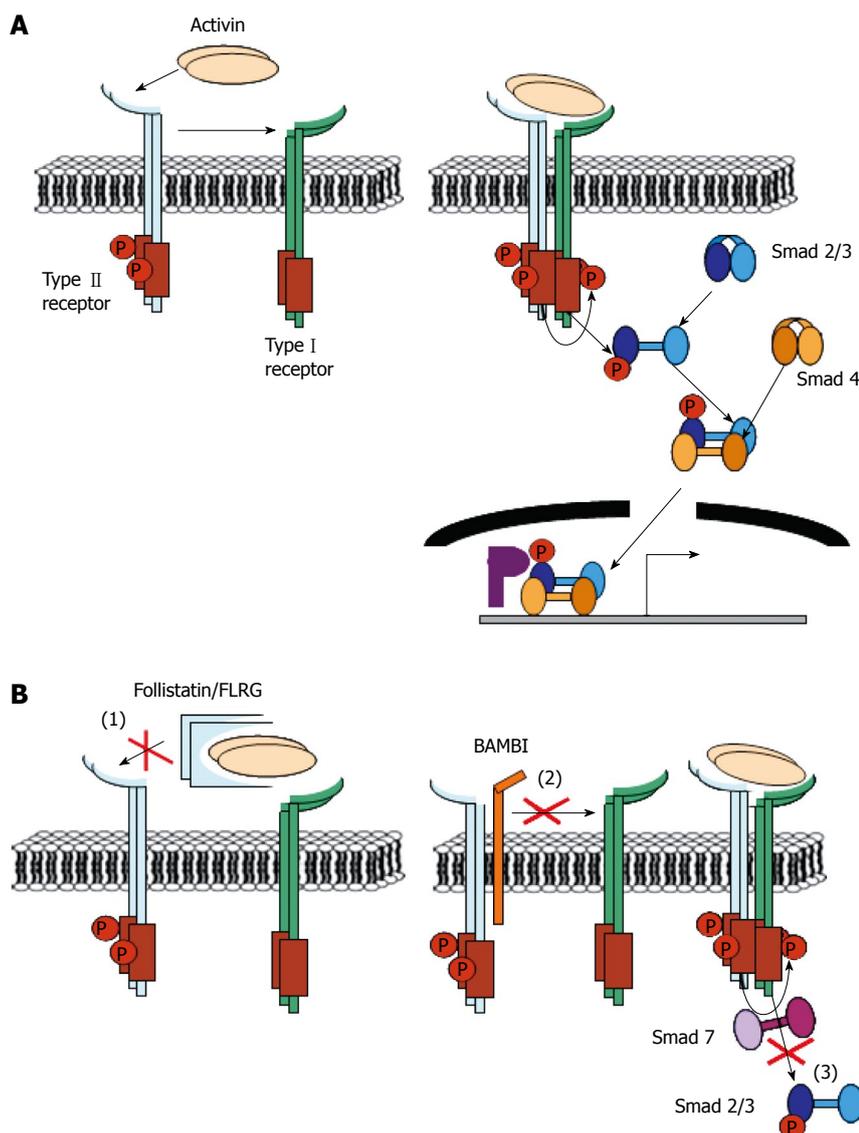

Phosphorylated TGF $\beta$  family receptors recruit intracellular mediators called Smads, which transduce activin signals to the nucleus<sup>[26]</sup>. Smads can be divided into receptor Smads (Smads 1, 2, 3, 5 and 8), a common mediator Smad (Smad 4) and inhibitory Smads (Smads 6 and 7). Activin A receptors, as well as TGF $\beta$  receptors, recruit and phosphorylate the receptor Smads 2 and 3, whereas receptor Smads 1, 5, and 8 are recruited by BMP receptors but not activin receptors<sup>[34]</sup>. Recent evidence suggests that-similar to TGF $\beta$ -additional Smad-independent signaling pathways may contribute to activin A signaling, as for instance, RhoA, MEKK1, JNK, and p38 were found to be involved in activin-induced cytoskeleton reorganization and cell migration in keratinocytes and in promoter activation of the transcription factor Pit-1 in pituitary lactotrope cells<sup>[35,36]</sup>.

Activin signals are tightly regulated on the one hand by a spatially and temporally restricted production of activin subunits and on the other hand by the expression of several extra- as well as intracellular antagonists of activin signaling. An overview of activin-mediated signaling events and the corresponding interaction points with endogenous activin antagonists is presented in Figure 1.

## ACTIVIN SUBUNITS AND ACTIVIN ANTAGONISTS IN LIVER CANCER

### Activin $\beta$ A

Activin A, the homodimer of two  $\beta$ A subunits, is by far the most extensively investigated activin. Multiple biological functions of activin A in a variety of cells and tissues have been described. Activin A has been implicated for instance in mesoderm induction<sup>[37]</sup>, stem cell biology<sup>[38]</sup>, reproductive biology<sup>[39]</sup>, erythroid differentiation<sup>[40]</sup>, systemic inflammation<sup>[41]</sup>, cell death induction<sup>[42]</sup>, wound healing<sup>[43]</sup>,

**Figure 1** Graphic representation of activin signaling and interaction points with activin antagonists. **A:** Activin dimers first bind the type II activin receptors, which then recruit and phosphorylate type I receptors. These in turn phosphorylate receptor-activated Smads, which subsequently form a complex with Smad 4 and are translocated to the nucleus, where they regulate the transcription of target genes; **B:** Activin antagonists can block activin signals by: (1) Binding activins in the extracellular space like follistatin or FLRG and thereby blocking their access to activin receptors; (2) Acting as inhibitory co-receptors, which prevent ligand receptor interactions (Cripto) or receptor dimerization (BAMBI); (3) Competing with receptor-activated Smads 2 and 3 for binding sites on activin receptors (Smad 7).

and fibrosis<sup>[44]</sup>. Knock-out mice for  $\beta A$  have severe defects in craniofacial development and die shortly after birth<sup>[45]</sup>. Concerning the liver, activin A potently inhibits mitogen-induced DNA synthesis and induces apoptosis in hepatocytes *in vivo* and *in vitro*<sup>[46-48]</sup>. Activin  $\beta A$  antisense oligonucleotides stimulated cell proliferation in the human hepatoma cell line HLF suggesting a growth inhibitory function of endogenous activin A<sup>[49]</sup>. In regenerating liver, activin  $\beta A$  gene expression was reduced at time points when hepatocyte replication took place and was increased at later periods when liver regeneration terminated<sup>[50]</sup>. Increased expression of  $\beta A$  at earlier time points after partial hepatectomy, however, has also been described<sup>[51,52]</sup>. Besides the effects on DNA synthesis and cell growth, activin A also regulates restoration of liver architecture after partial hepatectomy by stimulating collagen production in hepatic stellate cells (HSC) and tubulogenesis of sinusoidal endothelial cells<sup>[53,54]</sup>. Stimulation of HSC may also contribute to liver fibrosis and several investigations have found elevated levels of activin  $\beta A$  in fibrotic and cirrhotic rat livers<sup>[55-58]</sup>. Elevated levels of circulating activin A were found in patients suffering from chronic viral hepatitis or alcohol induced liver cirrhosis and in HCC patients<sup>[59-61]</sup>.

Reduced expression of activin  $\beta A$  transcripts in contrast, was observed in tumor tissue from chemically-induced rat liver tumors and in 5 of 11 HCC specimens<sup>[62]</sup>. In addition to a pro-apoptotic effect on the parenchymal cells and a pro-fibrotic effect on HSC, activin A has also been linked to neoangiogenesis *via* stimulation of VEGF expression in human hepatoma cells<sup>[63]</sup>.

### Activin $\beta B$

Like activin  $\beta A$ , the  $\beta B$  subunit is expressed in multiple tissues and organs<sup>[13,14]</sup>. Despite a considerable overlap in tissue expression and in some biological activities, important differences exist<sup>[64]</sup>. Knock-out mice for  $\beta B$  are viable but have defects in eyelid development and female reproduction<sup>[65]</sup>. When the coding region of the mature peptide of the  $\beta A$  subunit gene was replaced with the corresponding region of the  $\beta B$  subunit gene the developmental defects of the  $\beta A$  knock-out mice were only partially rescued<sup>[66]</sup>. Concerning the liver, the role of the  $\beta B$  subunit is not well characterized. In the normal rat liver the  $\beta B$  subunit was the only activin subunit undetectable by RNase protection assay<sup>[14]</sup>. Weak positive immunoreactivity for  $\beta B$  was, however, detected in hepatocytes of normal

rat livers and in connective tissue septa in fibrotic livers when analyzed by immunohistochemistry<sup>[55]</sup>. Activin  $\beta$ B mRNA was induced in stellate cells of CCl<sub>4</sub> treated rat livers<sup>[55]</sup>. Exposure to the peroxisome proliferator di-n-butyl phthalate led to a transient surge of  $\beta$ B mRNA expression 6 h after treatment in rat livers<sup>[67]</sup>. With respect to biological activities, recombinant activins A and AB but not activin B inhibited EGF induced DNA synthesis in primary rat hepatocytes<sup>[68]</sup>. In normal human liver the  $\beta$ B transcript is readily detectable by RT-PCR (M.G. unpublished observation), but no data with regard to expression changes of the  $\beta$ B subunit in liver tumors compared to normal liver have been reported yet.

### Activin $\beta$ C

The activin  $\beta$ C subunit was cloned from liver cDNA and demonstrated to be predominantly expressed in hepatocytes by Northern blot analysis and RNase protection assays<sup>[14,18,52,69]</sup>. By immunohistochemistry significant activin  $\beta$ C expression has been detected in cells from additional organs including the prostate, ovary, testes, and pituitary gland<sup>[15,70]</sup>. Formation of homodimeric activin C as well as heterodimeric activins AC, BC, CE, as well as inhibin C has been demonstrated by ectopic expression of the respective subunits in different cell models<sup>[14,70,71]</sup>. After partial hepatectomy a transient down-regulation of activin  $\beta$ C expression was observed by several studies<sup>[50,52,72,73]</sup>. A decrease of activin  $\beta$ C expression has also been observed in HepG2 and Hep3B hepatoma cells versus normal liver tissue<sup>[74]</sup> and in rat hepatocytes during primary culture with and without EGF treatment<sup>[52]</sup>. In contrast, increased activin  $\beta$ C expression was reported in the rat liver during the development of CCl<sub>4</sub> induced cirrhosis<sup>[56,75]</sup> and in response to treatment with the peroxisome proliferator bi-n-butyl phthalate<sup>[67]</sup>. The functions of the activin  $\beta$ C subunit are controversial. Activin  $\beta$ C knock-out mice developed normally and liver regeneration after partial hepatectomy proceeded similarly in knock-out animals and wild-type littermates<sup>[76]</sup>. Ectopic expression of activin  $\beta$ C induced apoptosis in human (HepG2, Hep3B) and rat (H4 IIEC3) hepatoma cells and delayed liver regeneration in mice<sup>[74,77]</sup>. In AML12 cells, an immortalized mouse hepatocyte cell line in contrast, and in primary rat hepatocytes, activin  $\beta$ C increased DNA synthesis<sup>[29]</sup>. Adenovirus-mediated expression of activin  $\beta$ C accelerated liver regeneration after partial hepatectomy in rats<sup>[78]</sup>. A specific association of activin  $\beta$ C immunoreactivity with mitotic hepatocytes was observed in regenerating liver after partial hepatectomy<sup>[50]</sup>. It was shown that activin C does not activate activin A-responsive promoters, and it was suggested that the  $\beta$ C subunit regulates the levels of bioactive activin A *via* the formation of signaling-incompetent activin AC heterodimers in PC3 human prostate cancer cells<sup>[79,80]</sup>. Data regarding the expression of the  $\beta$ C subunit in human liver tumors are not available yet.

### Activin $\beta$ E

Similar to activin  $\beta$ C, the  $\beta$ E subunit is predominantly expressed in hepatocytes but has also been detected in human heart, testis, peripheral blood leucocytes, placenta, and skeletal muscle<sup>[14,16,21,81]</sup>. Formation of homodimeric

activin E as well as heterodimeric activins AE and CE has been demonstrated after ectopic co-expression of the respective subunits<sup>[14,16]</sup>. Activin  $\beta$ E mRNA expression was transiently up-regulated after partial hepatectomy or portal vein branch ligation<sup>[73,76]</sup> and in response to lipopolysaccharide treatment<sup>[81]</sup>. Increased  $\beta$ E expression has also been observed in hepatic fibrosis induced by CCl<sub>4</sub><sup>[75]</sup>. Recently, induction of  $\beta$ E expression has been described as a marker for phospholipidosis in HepG2 hepatoma cells<sup>[82]</sup>. Similar to  $\beta$ C,  $\beta$ E subunit knock-out mice and double knock-outs lacking both  $\beta$ C and  $\beta$ E expression developed normally and had no defects in liver function<sup>[76]</sup>. When ectopically expressed in HepG2 or Hep3B hepatoma cells or in the murine hepatocyte cell line AML12, activin  $\beta$ E reduced cell number and increased apoptosis rates<sup>[74,83]</sup>. Transient overexpression of  $\beta$ E by non-viral gene transfer in the mouse liver inhibited regenerative DNA synthesis<sup>[77]</sup>. These observations suggest that activin E may have a growth-limiting function similar to activin A, however, the two subunits show a reciprocal pattern with respect to diurnal variations of expression<sup>[10]</sup>. In line with a growth-limiting function of activin E, transgenic mice overexpressing  $\beta$ E in the pancreas showed reduced proliferation of pancreatic exocrine cells<sup>[84]</sup>. Regarding liver cancer, reduced expression of the  $\beta$ E subunit was found in human HCC specimens as well as in N-nitroso morpholine-induced rat liver tumors<sup>[62,85]</sup>. Interestingly, activin  $\beta$ E expression was found to be regulated by the tumor suppressor gene RASSF1A<sup>[86]</sup>, a gene frequently inactivated by promoter hypermethylation in HCC<sup>[87,88]</sup>.

### Inhibin $\alpha$

The inhibin  $\alpha$  subunit is part of inhibins but not activins and in many biological systems activins and inhibins have antagonistic effects<sup>[89]</sup>. Historically activins received their name from the fact that they activated follicle stimulating hormone (FSH) secretion from the pituitary, whereas the previously described inhibins represented the long sought-after gonadal feed-back inhibitor of pituitary FSH secretion<sup>[12]</sup>. Knock-out mice for the inhibin  $\alpha$  subunit developed gonadal sex-cord stromal tumors suggesting a tumor suppressive function of the inhibin  $\alpha$  subunit<sup>[90]</sup>. In several human tumor types including some types of ovarian carcinoma and adrenal tumors, in contrast, overexpression of inhibin  $\alpha$  has been demonstrated, and inhibins have been used as serum markers for early detection of ovarian germ cell tumors and monitoring of recurrence<sup>[9]</sup>. With regard to liver cell growth, treatment with inhibin A *per se* had no effect on DNA synthesis of HepG2 hepatoma cells but antagonized the inhibitory effect of activin A<sup>[91]</sup>. In normal and fibrotic rat liver absence of inhibin  $\alpha$  subunit immunoreactivity has been reported<sup>[55]</sup>. Immunostaining for inhibin  $\alpha$  has been used to distinguish adrenal cortical tumors, which are positive in about 70% of cases, from HCC and renal cell carcinoma, which are mostly negative<sup>[92,93]</sup>.

### Follistatin

Follistatin is a secreted, monomeric glycoprotein lacking homology to the TGF $\beta$  superfamily. The biological

activities described for follistatin, however, seem to depend entirely on its interaction with activins and other members of the TGF $\beta$  family. Follistatin is expressed in most of the organs, that also express activin<sup>[13,94]</sup>, and it binds mature secreted activin A with very high affinity (Kd 50-680 pmol/L)<sup>[95-97]</sup>. Complex formation with follistatin completely abolished receptor binding of activin A, thus blocking activin signaling<sup>[96,98]</sup>. Two follistatin molecules embrace one activin dimer and bury one-third of its residues and its receptor binding sites<sup>[99]</sup>. Three major forms of secreted follistatin exist, resulting from alternative splicing and protein processing of a single follistatin gene and containing 288, 303 and 315 amino acids, respectively<sup>[95]</sup>. All forms of follistatin contain three homologous follistatin domains<sup>[100]</sup> of which the first two, but not the third, are necessary for activin A binding<sup>[97,101]</sup>. Follistatin 288 binds to heparan sulfates, whereas this binding is blocked by an acidic tail in follistatin 315<sup>[95]</sup>. In addition to binding activins A, B, AB, and E, follistatin was also shown to bind and antagonize myostatin as well as BMPs 2, 4, 6 and 7<sup>[16,102-105]</sup>. Follistatin administration by intraportal infusion or adenovirus-mediated overexpression caused DNA synthesis and liver growth in normal rat livers presumably by antagonizing tonic inhibition of liver growth by activin A<sup>[106,107]</sup>. Following partial hepatectomy follistatin expression was up-regulated after 24-48 h, the time period in which hepatocyte replication was increased<sup>[50]</sup>. Under similar conditions administration of follistatin accelerated liver regeneration but led to impaired restoration of normal tissue architecture and compromised liver function<sup>[108-110]</sup>. Administration of exogenous follistatin in CCl<sub>4</sub> treated rats attenuated the formation of liver fibrosis<sup>[111]</sup>. These results likely reflect the ability of follistatin to antagonize both growth-inhibitory and pro-fibrotic activities of activin A.

In human liver cancer and also in animal models follistatin expression was increased in about 60% of tumor tissues. Increased follistatin levels were also found in the blood of patients with liver cirrhosis and HCC<sup>[60,62,112]</sup>. Administration of follistatin stimulated DNA synthesis in preneoplastic rat hepatocytes in an *ex vivo* system, whereas hepatoma cell lines were unresponsive to exogenous follistatin possibly due to autocrine production of follistatin or other activin antagonists<sup>[62,112-114]</sup>.

### FLRG

Follistatin-related protein, encoded by follistatin-related gene (FLRG), also designated as follistatin-like 3 (FSTL-3) has a high similarity to follistatin and shares its ability to bind TGF $\beta$  family proteins, but contains only two instead of three follistatin domains<sup>[115]</sup>. Several other proteins, containing 1-10 follistatin domains, like the extracellular matrix-associated proteins SPARC and agrin, on the other hand were not able to bind TGF $\beta$  family members<sup>[100,116]</sup>. The FLRG gene was originally identified as a target of chromosomal rearrangement in leukemia<sup>[117]</sup>. The highest tissue expression of FLRG was found in placenta, whereas highest follistatin expression was found in ovary, testis, and pituitary<sup>[115,118]</sup>. In HepG2 hepatoma cells, expression of both FLRG and follistatin was induced in response to activin A treatment suggesting that they participate

in a feedback loop to restrict activin A signals<sup>[119]</sup>. FLRG mRNA is up-regulated in rat livers in response to a necrogenic dose of CCl<sub>4</sub> (M.G. unpublished observation) but otherwise the role of FLRG in liver regeneration has not been characterized. Elevated expression of FLRG was found in chemically induced rat liver tumors and H4 II E rat hepatoma cells but not in human liver tumor specimens<sup>[62]</sup> indicating species-specific differences with respect to FLRG regulation or differences between liver tumors of different etiologies.

### Activin receptors

The type II activin receptors ActR-II (A) and ActR-II B and the type I activin receptors ALK4 and ALK7 are expressed in multiple cell types and tissues including the liver. Adenovirus-mediated overexpression of a dominant-negative type II activin receptor caused DNA synthesis and liver growth in normal rat livers<sup>[120]</sup>. During liver regeneration after partial hepatectomy, no change of ActR II was observed while ActR II B was transiently decreased<sup>[50]</sup>. During CCl<sub>4</sub> induced rat liver cirrhosis, ActR II A was reduced after 5 wk but returned to control levels after 10 wk<sup>[56]</sup>. Ectopic overexpression of ActR-IB (ALK4) and ActR- II B or of ALK7 induced apoptosis in hepatoma cells<sup>[121,122]</sup>. In HCC tissue specimens, expression of activin receptors (ActR-I, ActR-IB, ActR- II, and ActR- II B) was demonstrated by immunohistochemistry<sup>[63]</sup>. Inactivating mutations of activin receptors have been found in microsatellite instable colon cancer, pancreatic cancer and prostate cancer, but have not been investigated in HCC so far<sup>[123-126]</sup>.

### Regulators of activin receptor activity

Several membrane-associated proteins exist which regulate activin-induced receptor activation. Cripto/TDGF1 is a member of the EGF-CFC (epidermal growth factor-Cripto/frl/cryptic) family of growth factor-like molecules. This secreted protein can attach to the outer cell membrane via a glycosylphosphatidylinositol anchor and functions as a co-receptor for nodal signaling during embryogenesis. Cripto has been found overexpressed in high percentages of several human malignancies including breast, pancreas, lung, colon and bladder cancer<sup>[127]</sup>. Cripto inhibits ligand receptor interactions of activins and TGF $\beta$ <sup>[128-130]</sup> and this has been suggested to contribute to its pro-tumorigenic activity. However, an additional activin receptor-independent signaling pathway for Cripto involving Glypican-1 and c-Src has also been described<sup>[127]</sup>. Expression of a shorter Cripto variant was observed in colon cancer including liver metastases, as well as in colon cancer and hepatoma cell lines<sup>[131,132]</sup>. Expression of this short variant is driven by Wnt signaling which is frequently constitutively activated in colon cancer and HCC. Based on these findings, a more extensive investigation on the role of Cripto in HCC is certainly warranted.

BAMBI (bone morphogenetic protein and activin membrane-bound inhibitor) also known as nma (non metastatic gene A) is a pseudoreceptor related to the type I receptors of the TGF $\beta$  family. It lacks an intracellular kinase domain and inhibits activin A, TGF $\beta$ , and BMP signaling by stably associating with TGF $\beta$  family

Table 1 Overview of described alterations of activins and activin antagonists in HCC and HCC-derived cell lines

Activin subunits and activin antagonists	Proposed function in activin signaling	Alterations observed in HCC and hepatoma cells
Activin $\beta$ A subunit	Activates activin receptors	Increased activin A in circulation of HCC patients <sup>[60,61]</sup> Decreased expression in rat and human liver tumors <sup>[62]</sup> Loss of expression in hepatoma cells <sup>[74,114]</sup>
Activin $\beta$ E subunit	Induces apoptosis by as yet undefined mechanisms	Decreased expression in rat and human liver tumors <sup>[62,85]</sup>
Follistatin	Binds activins and blocks their interaction with receptors	Increased in circulation of HCC patients <sup>[60]</sup> Increased expression in human mouse and rat liver tumors <sup>[62,112]</sup> Expressed in hepatoma cells <sup>[112,114]</sup>
FLRG	Binds activins and blocks their interaction with receptors	Increased in rat but decreased in human liver tumors <sup>[62]</sup>
BAMBI	Binds TGF $\beta$ -family type II receptors and blocks type I receptor activation	Increased in HCC and colon cancer <sup>[135]</sup>
Cripto	Blocks interaction of activins (and TGF $\beta$ ) with their receptors	Overexpressed in hepatoma cells <sup>[132]</sup>
Smad 7	Inhibits activation of Smads by activin (and TGF $\beta$ ) receptors	Increased expression in HCC <sup>[146,147]</sup>

receptors<sup>[133]</sup>. A recent study links LPS/Toll-like receptor 4-induced downregulation of BAMBI in hepatic stellate cells to hepatic fibrosis<sup>[134]</sup>. In contrast, elevated BAMBI expression driven by the Wnt/ $\beta$ -catenin pathway was found in HCC and CRC specimens<sup>[135]</sup>.

ARIPS 1 and 2 (activin receptor-interacting proteins) are PDZ (PSD-95/Discs-large/ZO-1) protein-protein interaction domain-containing proteins that were described to interact with type II activin receptors and inhibit or augment activin signaling, depending on the isoforms expressed<sup>[136-138]</sup>. ARIP 2 was recently shown to be induced by activin A in the mouse hepatoma cell line Hepa1-6 and to decrease activin-mediated collagen IV expression, suggesting that it participates in a negative feedback regulation of activin-induced liver fibrosis<sup>[139]</sup>. Data with regard to a role of ARIPS in HCC or other tumor types are missing so far.

#### Intracellular inhibitors of signal transduction

Downstream from activin receptors, signals are transduced by receptor Smad 2 and Smad 3 and the common mediator Smad 4, the same set of Smad proteins also used by TGF $\beta$  receptors. Mutations of Smad proteins are frequent in pancreatic and colorectal cancer and have also been detected in HCC<sup>[140-142]</sup>. Smads 6 and 7 associate with TGF $\beta$  family receptors but are not phosphorylated and thus inhibit signal transduction<sup>[143,144]</sup>. Smad7 has been demonstrated to inhibit activin signaling and to protect hepatocytes from activin A-induced growth inhibition<sup>[145]</sup>. Increased expression of Smad7 has been observed in HCC tissue compared to adjacent tissue<sup>[146]</sup> and in advanced HCC compared to early HCC or dysplastic nodules<sup>[147]</sup>. No mutations of either Smad 6 or Smad 7 were found in 52 HCC samples<sup>[148]</sup>.

Smurf-type ubiquitin E3 ligases, Smad anchor for receptor activation (SARA), and transcriptional co-activators and co-repressors such as CBP, p300, c-Ski, and SnoN, control Smad activation by TGF $\beta$ -family receptors or shuttling of activated Smads into the nucleus as well as transcriptional activity of Smad-containing complexes<sup>[42]</sup>. Their role in the link between activin signals and liver carcinogenesis has yet to be defined.

In summary, increasing evidence suggests that deregulation of activin signals frequently occurs in and contributes to HCC development and progression. An

overview of alterations in activin subunits and activin antagonists described in liver tumors and hepatoma cells is presented in Table 1.

#### THERAPEUTIC PERSPECTIVES

Activin signaling is complex. At least three features of the activin signaling cascade contribute to this complexity. First, four activin  $\beta$  and one inhibin  $\alpha$  subunit can give rise to multiple homo and heterodimers with different receptor binding capabilities. Secondly, a number of different extracellular activin-binding and receptor-interacting proteins can modulate ligand receptor interactions not only of activins but also of TGF $\beta$ , BMPs and GDFs. Thirdly, there is a considerable degree of promiscuity with respect to usage of receptors and intracellular signaling molecules between different members of the TGF $\beta$  superfamily<sup>[149]</sup>. For instance, activins and TGF $\beta$  use different type I and type II receptors but rely on the same Smad proteins for intracellular propagation of their signals. This makes it a difficult task to dissect their specific contribution to biological activities, especially in tissues such as the liver, where both activins and TGF $\beta$  are expressed. In addition, BAMBI, Cripto and Smad7 have all been shown to interfere with signal transduction of activins as well as of TGF $\beta$ .

TGF- $\beta$ 1 has a well recognized dual role in carcinogenesis<sup>[150]</sup>. It acts as a tumor suppressor in early stages of hepatocarcinogenesis by inducing apoptosis and eliminating precursor lesions<sup>[151,152]</sup>. At a later stage, however, liver tumor cells often become resistant to its proapoptotic effect, and produce large amounts of TGF $\beta$  themselves<sup>[153]</sup>. From the available data on both loss of expression in tumor cells and apoptosis induction<sup>[74,114,154]</sup>, one would postulate that activin A, and possibly activin E, may have a similar tumor suppressive function in the liver as TGF $\beta$ . Whether also activins may shift to a pro-tumorigenic function during tumor progression is little explored. For activin A, a contribution to liver fibrosis, enhanced expression of the angiogenic factor VEGF in hepatoma cells, and stimulation of growth and invasiveness of esophageal squamous cell carcinoma cells has been demonstrated<sup>[158,63,155]</sup>.

Despite all the complexity, however, a general theme

in HCC and in other tumor types seems to be the elevated expression of activin antagonistic proteins in the tumor cells, as observed for follistatin, BAMBI, Cripto, and Smad7<sup>[62,127,135,146,147]</sup>. These may serve to block the growth inhibitory and pro-apoptotic activity of activin A on hepatocytes. Similar observations have been made in additional tumor types, for instance for Cripto in multiple epithelial tumors, BAMBI in colon carcinoma, follistatin in melanoma and FLRG in breast cancer<sup>[127,135,156,157]</sup>.

Consequently, a targeted inhibition of activin antagonists might restore sensitivity to activin-induced growth inhibition and apoptosis, and may thus represent a feasible strategy to inhibit tumor growth. In line with this hypothesis, it has recently been shown that siRNA-mediated silencing of FLRG inhibited breast tumor cell growth *in vitro*, and that monoclonal antibodies to Cripto inhibited growth of testicular and colon cancer cells in xenograft models<sup>[128,156]</sup>. Future studies will have to clarify whether such approaches may offer new therapeutic opportunities for combating liver cancer.

## Abstract

Hepatocellular carcinoma (HCC) has a decisive influence on the prognosis of cirrhotic patients. Although  $\alpha$ -fetoprotein (AFP) is a known and specific tumor marker for HCC, it is not suitable for the screening and surveillance of HCC because of its poor predictive value and low sensitivity. The use of imaging modalities is essential for the screening, diagnosis and treatment of HCC. Ultrasound (US) plays a major role among them, because it provides real-time and non-invasive observation by a simple and easy technique. In addition, US-guided needle puncture methods are frequently required for the diagnosis and/or treatment process of HCC. The development of digital technology has led to the detection of blood flow by color Doppler US, and the sensitivity for detecting tumor vascularity has shown remarkable improvement with the introduction of microbubble contrast agents. Moreover, near real-time 3-dimensional US images are now available. As for the treatment of HCC, high intensity focused ultrasound (HIFU) was developed as a novel technology that provides a transcutaneous ablation effect without needle puncture. These advancements in the US field have led to rapid progress in HCC management, and continuing advances are expected. This article reviews the current application of US for HCC in clinical practice.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is increasing worldwide and is one of the most common carcinomas in the eastern part of Asia<sup>[1]</sup>. As the prognosis of cirrhotic patients depends on the occurrence and progression of HCC, management of this neoplasm is a major issue in clinical practice. The recent popularization of periodic surveillance and the development of diagnostic capabilities have resulted in the discovery of increasing numbers of patients with small HCC nodules<sup>[2,3]</sup>. Although tumor markers may be helpful for the diagnosis of HCC, imaging modalities are essential for finding and characterizing this neoplasm<sup>[4,5]</sup>.

On the basis of the continuing development of digital technologies, ultrasound (US) has also shown significant improvements within the last decade<sup>[6]</sup>. As for grey-scale imaging, tissue harmonic imaging (THI) has improved both lateral resolution and contrast resolution by narrowing the width of the US beam, with the reduction of reverberation and side-lobe artifacts. Since the margin and structure of tumor nodules have become clear, with distinct delineation<sup>[7-10]</sup>, THI has become popular as part of the routine work of grey-scale US examination.

Color Doppler imaging provides real-time evaluation of the hemodynamics in liver tumors, and power Doppler mode has contributed to a better detectability of blood flow<sup>[11-15]</sup>. However, limitations in the detection of slow flow and vessels located deeply from the skin surface have prevented the wider application of Doppler mode in the evaluation of tumor hemodynamics<sup>[16-18]</sup>. Furthermore, artifacts caused by respiratory or cardiac motion sometimes affect the precise evaluation of hemodynamic information.

With these backgrounds, US contrast agents have been expected to improve the detectability of blood flow in liver tumors, since the first report about a US contrast agent by Gramiak *et al*<sup>[19]</sup>. From the late 1980s to the 1990s, grey-scale contrast-enhanced US with carbon dioxide gained broad attention as an echo-enhancing technique, with

high sensitivity for detecting tumor vascularity and high performance for the characterization of liver tumors<sup>[20,21]</sup>. However, this method requires an arteriography procedure because carbon dioxide is easily soluble in blood. The development of microbubble contrast agents together with peripheral venous injection was expected for practical use. In the late 1990's, a galactose-based US contrast agent (SHU 508, Levovist) was made available by Schering, Germany<sup>[22,23]</sup>. It was a long-awaited material that could provide a stable enhancement effect in abdominal organs with a peripheral injection. Subsequently, many microbubble contrast agents have been produced or are currently under development. At present, the application of Doppler mode alone for detecting tumor blood flow is rare, as contrast-enhanced US with microbubble contrast agents provides details of the hemodynamics that are useful for the detection and characterization of liver tumors. Additionally, three-dimensional US images are now easily available due to the development of advanced digital technologies<sup>[24,25]</sup>, and high intensity focused ultrasound (HIFU) was developed as a novel treatment method for tumors<sup>[26]</sup>. This article reviews the current development and application of US for the diagnosis and treatment of HCC.

## SURVEILLANCE FOR HCC

Viral-related and/or alcoholic chronic liver disease is a high-risk factor for developing HCC that limits the prognosis. There is no question about the importance of periodic surveillance for HCC in these high-risk patients<sup>[27-29]</sup>. Some serum markers are known for HCC, and  $\alpha$ -fetoprotein (AFP) is widely used for its diagnosis<sup>[30-32]</sup>. Ishii *et al* reported that sensitivity and specificity of AFP was 13.8% and 97.4% at a cut-off value of 200 ng/mL, respectively, and 62.1% and 78.3%, at a cut-off value of 20 ng/mL, respectively<sup>[31]</sup>. They added that when AFP and another tumor maker, protein induced by vitamin K absence or antagonist II (PIVKA-II), were combined with cut-off values of 40 ng/mL for AFP and 80 mAU/mL for PIVKA-II, sensitivity was 65.5% and specificity was 85.5%. The study by Tong *et al* showed that the positive predictive value for AFP to detect HCC was only 12% or less for all AFP cut-off values, and the maximum joint sensitivity and specificity as determined by receiver operator characteristic (ROC) analysis were approximately 65% and 90%, respectively. Meanwhile, the positive predictive value for US to detect HCC was 78%, while sensitivity and specificity were 100% and 98%, respectively<sup>[33]</sup>. They concluded that AFP should not be used as the only test for screening and surveillance for HCC because of its poor predictive value and low sensitivity. Larcos *et al* also mentioned that US screening was superior to AFP assay for detection of HCC<sup>[34]</sup>. Novel serum markers with improved sensitivity are awaited for screening tests for HCC.

US is the most common method for the screening of HCC because of its advantages - simple, non-invasive and real-time observation<sup>[4,5]</sup>. However, there has been a variety of results in the application of US for HCC surveillance (Table 1). Sherman *et al* reported that US

<sup>1</sup>Sensitivity of radiologic procedures in the diagnosis and staging of known HCC before liver transplantation. <sup>2</sup>The higher value was presented from two data obtained between two observers.

showed a sensitivity of 71.4%, a specificity of 93.8%, with only 14% of positive predictive value, as a screening test in chronic HBsAg carriers<sup>[35]</sup>. Chalasanani *et al* compared the sensitivity in a screening program between US and computed tomography (CT), and the sensitivity of US (59%) was much lower than that of CT (91%)<sup>[36]</sup>. Two other studies in the diagnosis of HCC before liver transplantation resulted in similar sensitivity between US and CT, 79.4% for US and 81.6% for CT<sup>[37]</sup>, 58% for US and 53% for CT<sup>[38]</sup>, respectively, with the latter claiming that US is preferable to CT for routine screening of HCC before liver transplantation because of its lower cost. Meanwhile, Teeffey *et al* mentioned that the sensitivity of US (89%) was much higher than CT (67%) and magnetic resonance imaging (MRI, 56%)<sup>[39]</sup>. Evaluation of the actual sensitivity of US and other imaging techniques from the published studies on screening and surveillance is quite difficult because of the lack of a defined gold standard, as was also noted in the review article by Bolondi<sup>[28]</sup>. In addition, Chalasanani *et al* described in their study that the lesser steatosis to change liver echogenicity in Asian patients with predominantly viral cirrhosis, leaner body habitus in Japanese patients resulting in better visualization of the liver by US, and differences in US technique between physicians (Japan) and technologists (USA) were the causes for the high detection rates by US in Japanese reports<sup>[4,36,40]</sup>. Although it is natural that US results depend on the physical size of the patients and the operator's skill, medical staffs and engineers who engage in US should not accept the current situation. Further technical and technological improvements are required to overcome these problems.

Tumor detectability between US without enhancement and contrast-enhanced spiral CT has been compared in some previous studies. The comparison may not be on an equal footing, as US has now acquired collaboration with microbubble contrast agents. The application of contrast-enhanced CT for screening of HCC would be expensive and invasive, and MRI has the limitation of a low availability rate of the equipment. Although contrast-enhanced US may not be cheap, it is much less invasive and more convenient than contrast-enhanced CT. The

establishment of surveillance based on both non-contrast US and contrast-enhanced US may be necessary for the screening procedure of HCC.

According to clinical studies concerning the doubling time of tumor, median days were reported as 117 d (29-398 d) by Sheu *et al*<sup>[27]</sup> or 171.6 d (27.2-605.6 d) by Barbara *et al*<sup>[41]</sup>, and the former study called for a suitable screening interval for the early detection of HCC of 4-5 mo. Solmi *et al* reported that the percentage of detected unifocal tumors with a diameter less than or equal to 3 cm was significantly higher in the group followed-up every six months by both US and AFP than the group without this follow-up protocol<sup>[42]</sup>. Depending on the risk factors, a score based on certain clinical findings may be predictive for the doubling time of HCC<sup>[41,43]</sup>. The latter report recommended a regular US follow-up of a 3- or 6-mo interval according to the risk of HCC development, sex (male), alkaline phosphatase, AFP,  $\gamma$ -glutamyltransferase and albumin<sup>[43]</sup>. The study by Izzo *et al* also supported the 6-month surveillance by AFP and US for patients with severe chronic active hepatitis or liver cirrhosis<sup>[44]</sup>. However, Fasani *et al* reported that screening with US every six months may be inadequate for early detection of liver cancer in patients with multiple risk factors because multinodular HCC was under detected by US<sup>[45]</sup>. A tailor-made surveillance interval may be required according to the risk of HCC development.

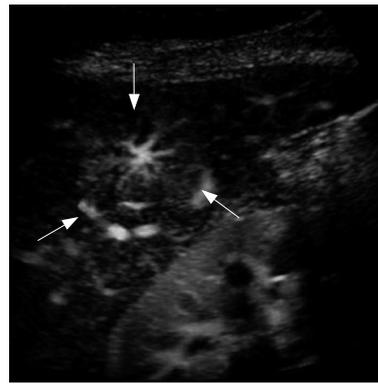

Bolondi *et al* examined their surveillance program based on US and AFP at six-month intervals in 313 cirrhotic patients, reporting that the cumulative survival of the 61 patients with liver tumors detected by the surveillance program was significantly longer than that of controls not participating in any specific surveillance program, with incidentally detected HCC, and multivariate analysis showed an association between surveillance and survival<sup>[46]</sup>. Other studies showed that surveillance based on US and AFP every 6-12 mo improved the survival of patients<sup>[47,48]</sup>.

As described above, the method and appropriate interval of surveillance have been discussed from the aspect of growth speed of HCC, detected number and size of HCC, and the risk of developing HCC. Furthermore, the significance of surveillance is well-supported by the improved survival rate. US should play a main role in the screening procedure of HCC.

## DIAGNOSIS OF HCC

Imaging diagnosis of HCC is based on the presentation of characteristic hypervascular appearances in nodules. The European Association for the Study of the Liver (EASL) has documented the diagnostic criteria for HCC in a report for the clinical management of HCC<sup>[49]</sup>. Nodules larger than 2 cm with an arterial hypervascular pattern by two imaging techniques or by one imaging technique associated with an AFP level higher than 400 ng/mL was considered to be HCC in cirrhotic patients without needing confirmation by a positive biopsy. Four imaging modalities, US, spiral CT, MRI, and angiography, were recommended for evaluation of the vascularity of hepatic nodules in that article.

The advantages of US imaging consist of the simple

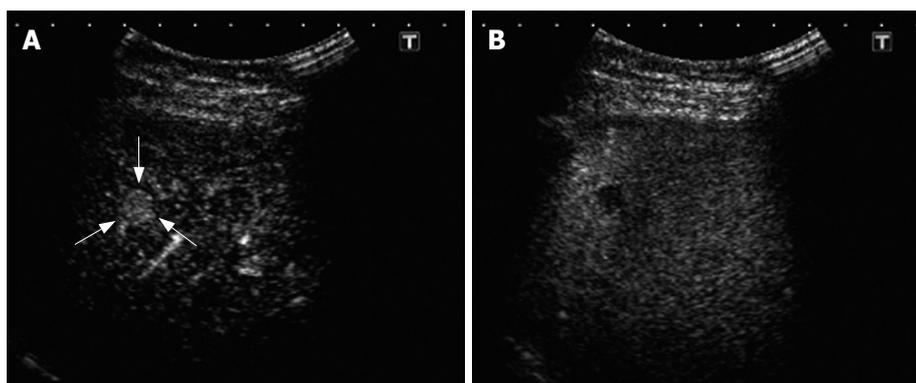

**Figure 1** Contrast-enhanced harmonic imaging with Sonazoid in focal nodular hyperplasia (FNH). The centrifugal blood flow appearance like "spoke-wheel sign" was clearly demonstrated in the center of the nodules (arrows).

and non-invasive demonstration of blood flow by real-time observation. US is a unique method that can evaluate blood flow direction under physiological condition. In contrast to focal nodular hyperplasia (FNH) with a centrifugal blood flow appearance (Figure 1), HCC has a characteristic hypervascular appearance with centripetal blood flow, and a basket pattern is one of the typical findings of HCC by color Doppler imaging<sup>[50-52]</sup>. The clinical application of microbubble contrast agents has resulted in remarkable improvement in blood flow detection by US examination. It was reported that the same enhancement pattern was found between contrast-enhanced harmonic grey-scale imaging with Levovist and contrast-enhanced helical CT in 53 of 61 (87%) HCC nodules<sup>[53]</sup>. Other studies have also shown over 80% concordance of tumor vascularity<sup>[54,55]</sup> between contrast-enhanced US with SonoVue (Bracco Diagnostics, Princeton, NJ, USA) and contrast-enhanced helical CT. Thus, the application of Doppler mode alone for detecting tumor blood flow is rare, as the more recent availability of microbubble contrast agents has assisted in overcoming the limitations of Doppler methods.

The diagnostic performance of contrast-enhanced US is not limited to the demonstration of tumor vascularity. Some microbubble contrast agents have a characteristic property of organ-specific accumulation<sup>[56-59]</sup>. Although the precise mechanism remains unclear, the reticuloendothelial system (i.e., phagocytosis by Kupffer cells) may be involved in this phenomenon. Both Levovist and Sonazoid (Nycomed-Amersham, Oslo, Norway) accumulate in the liver, and sonograms in this phase (late liver-specific parenchymal phase) are frequently used for the detection or characterization of liver tumors. In contrast, Definity (Bristol-Myers Squibb, N. Billerica, MA, USA) and SonoVue do not accumulate in the liver. The characterization of liver tumors by contrast-enhanced US has been carried out using accumulation images as well as vascular enhancement images (Figure 2A and B).

Concerning the discrimination of malignant versus benign liver lesions by contrast-enhanced US, recent literature has reported sensitivity of 98% to 100% and specificity of 63% to 93% with Levovist<sup>[60-63]</sup>, and sensitivity of 98% and accuracy of 92.7% with SonoVue<sup>[64]</sup>. Furthermore, in a clinical study with two independent image reviewers, Kim *et al*<sup>[65]</sup> described that contrast-enhanced US (agent detecting imaging mode with Levovist) provided a specific diagnosis in 75%-79% of 75 patients with focal hepatic lesions, and that the technique

**Figure 2** Contrast-enhanced harmonic imaging with Sonazoid in small HCC (9.8 mm, arrows). **A:** Early-phase image (22 s after the injection); **B:** Late-phase image (10 min after the injection). The early-phase image showed positive enhancement and the late-phase image showed negative enhancement in the nodule. These findings could easily diagnose this lesion as HCC.

was successful as a confirmatory imaging technique in 63%-72% of the patients.

Hypervascular hepatic lesions do not always reflect the fact that the final diagnosis of the nodule is HCC in heavy drinkers<sup>[66]</sup>, since benign hypervascular nodules sometimes occur in their liver. A recent report has shown that the ring-shaped appearance on liver-specific contrast-enhanced sonograms with Levovist may be a useful sign for the differential diagnosis of benign nodule from HCC in heavy drinkers<sup>[67]</sup>. Since contrast-enhanced CT hardly differentiates these benign nodules from HCC, this characteristic finding may prevent unnecessary treatments under misdiagnosis. Moreover, it could be expected to lead to a reduction in the application of percutaneous needle biopsy, an invasive procedure, for the precise diagnosis.

#### **Non-hypervascular and/or small (< 2 cm) nodules**

Well-differentiated HCC, dysplastic nodule (DN) and regenerative nodule (RN) do not always reveal the specific hypervascular pattern on contrast-enhanced CT such as typical HCC<sup>[68-71]</sup>. The characterization of such non-hypervascular nodules is very important in clinical practice<sup>[72,73]</sup> because high-grade DN are considered potentially pre-malignant lesions. However, as these non-hypervascular nodules have Kupffer cell distribution<sup>[74,75]</sup>, observation of the superparamagnetic iron oxide-enhanced (SPIO) MR images or liver-specific images on contrast-enhanced US could not easily characterize them.

According to the EASL report, percutaneous needle biopsy has until now been a standard method for the diagnosis of non-hypervascular hepatic nodules or small hepatic nodules of 1 cm to 2 cm<sup>[49]</sup>, because characterization of these nodules by imaging modalities alone is difficult<sup>[76-79]</sup>. As for nodules smaller than 1 cm, EASL recommended repeated US observation every 3 mo until the lesion grows to 1 cm, at which point additional diagnostic techniques can be applied<sup>[49]</sup>.

Thanks to the establishment of US-guided needle puncture technique<sup>[80]</sup>, percutaneous needle biopsy has a quite high diagnostic accuracy. Caturelli *et al* found that the typing accuracy of fine-needle aspiration biopsy was 88.6% for nodules with diameters < 10 mm, 86.2% for nodules with diameters of 11-15 mm, and 91.3% for nodules with diameters of 16-20 mm<sup>[81]</sup>. Durand *et al* reported that US-guided FNB diagnosed HCC nodules with a sensitivity of 91%<sup>[82]</sup>. However, liver biopsy for small nodules always has the possibility of sampling error, and a negative biopsy of

a nodule visible with imaging techniques in a cirrhotic liver can never be taken as a criterion to rule out malignancy<sup>[83]</sup>. Additionally, as rapid progression is rare in these kinds of nodules, repeated observations in their clinical course would determine their management. Therefore contrast-enhanced US can be expected to be an effective diagnostic tool for these non-hypervascular lesions because of its high resolution and non-invasive procedure.

## **TREATMENT SUPPORT AND EVALUATION OF THERAPEUTIC EFFECT**

### **US-guided treatment**

Since the majority of HCC patients have poor liver function and recurrence is not rare, surgical treatment is not always an appropriate choice<sup>[2,3,49]</sup>. With such backgrounds, percutaneous ethanol injection (PEI)<sup>[84-86]</sup> and radio-frequency ablation (RFA)<sup>[87,88]</sup> were developed and came to be widely used in clinical practice as minimally invasive methods<sup>[89]</sup>. They are now a first-line, favored approach with an efficient therapeutic effect on HCC<sup>[90-93]</sup>.

### **Treatment for recurrent lesions**

Although percutaneous US-guided treatments provide sufficient therapeutic effect, recurrence often plagues many HCC patients. According to long-term study results, cumulative recurrence rates of the treated site of post-PEI lesions were 3.4% at 1 year, 7.1% at 2 years, and 10% at 3 years, and those of the untreated sites in liver were 18.7% at 1 year, 62.1% at 3 years, and 81.7% at 5 years, respectively<sup>[94]</sup>. Thus, many HCC patients have to receive repeated treatments during their clinical course. In order to minimize adverse effects to the liver, less invasive treatment such as PEI or RFA is preferable for these patients. However, localization of lesions on sonograms is sometimes problematic in patients with cirrhotic liver and/or repeated treatment history<sup>[95,96]</sup>. Although percutaneous treatment under CT guidance is a well-established technique and a useful method for lesions undetected by US, the method lacks convenience and exposes both patients and physicians to radiation<sup>[97-100]</sup>. Microbubble contrast agents are also useful in such a case. A recent study showed that contrast-enhanced US with Levovist could localize 24/32 (75%) of HCC lesions that were invisible by non-contrast US<sup>[101]</sup>. Application of the next-

generation US contrast agents, SonoVue and Sonazoid, is expected to improve the localization result.

**Evaluation of therapeutic effect**

US examination is eligible for the evaluation of the therapeutic effect after percutaneous treatments such as PEI and RFA, because they are usually performed under US guidance. In fact, contrast-enhanced US has come to be frequently applied for evaluation of the therapeutic response in HCC nodules with improved sensitivity and specificity for detecting tumor blood flow (Table 2). According to the results by Bartolozzi *et al*, color Doppler US with Levovist showed sensitivity of 92%, specificity of 100%, and accuracy of 98% compared to the results of spiral CT and biopsy, in the detection of residual tumor tissue in 47 HCC lesions after PEI<sup>[102]</sup>. Wen *et al* examined the efficacy of coded harmonic angio mode with Levovist for detecting residual tumor in 91 HCC nodules about one week after RFA in comparison with contrast-enhanced CT, and they found that sensitivity, specificity, and diagnostic accuracy of US were 95.3%, 100%, and 98.1%, respectively<sup>[103]</sup>. Meloni *et al* reported that sensitivity and specificity of pulse inversion harmonic imaging with Levovist were 83.3% and 100%, respectively, for detecting residual non-ablated tumor at 4 mo after treatment in 35 patients with 43 HCC nodules, compared with helical CT findings<sup>[104]</sup>. Immediate evaluation of the therapeutic effect is often desirable after RFA for the management of HCC, and Choi *et al* mentioned that diagnostic agreement between power Doppler with Levovist about half or one day after ablation therapy and CT just after ablation was achieved in 100% of the 45 HCC nodules in 40 patients<sup>[105]</sup>. Another study showed that diagnostic concordance between agent detection imaging with Levovist performed within 24 h after RFA and 1-mo follow-up CT was 99% in 90 patients with 97 HCC nodules<sup>[106]</sup>. Thus, estimation of the therapeutic response in HCC after percutaneous treatments would become more efficient on the basis of this non-invasive imaging method. Although artificial signals caused by the RFA procedure affect an early detailed observation<sup>[105-107]</sup>, monitoring by contrast-enhanced US during RFA would likely be applied to the assessment of the therapeutic effect as well as the detection of viable tumor.

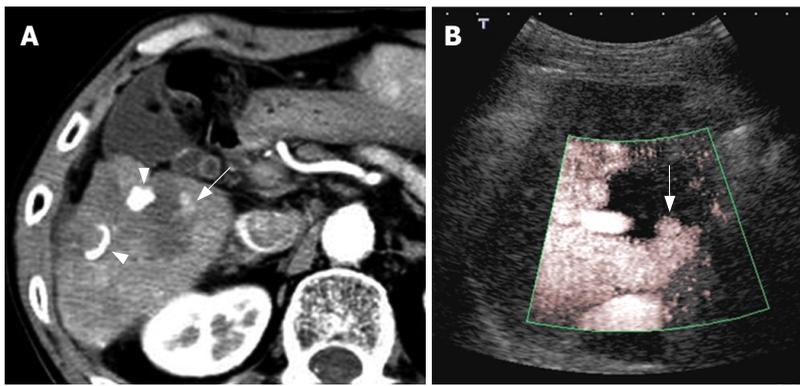

It is well known that contrast-enhanced CT can hardly evaluate intratumoral contrast enhancement when partial retention of iodized oil is present in the tumor after transcatheter arterial chemoembolization (TACE). Therefore, the therapeutic effect of TACE is usually assessed by the distribution of iodized oil in the tumor on non-contrast CT images, though these findings are an indirect presentation. As MRI findings are not affected by the presence of iodized oil, contrast-enhanced MRI is favorable for the assessment of the therapeutic effect after TACE. However, the equipment has not yet come into wide-spread use, the procedure is not convenient, and evaluation of the findings in small lesions is sometimes difficult due to the low resolution and influence of motion artifacts. Contrast-enhanced US has the advantage of not being limited by iodized oil deposition that affects

**Table 2 Assessment of therapeutic response after percutaneous treatment for HCC using contrast-enhanced US**

Author	Treatment	No. of patients/ No. of lesions	Results <sup>1</sup> (contrast agent)

the evaluation of contrast-enhanced CT findings. Some clinical studies have shown the magnitude of contrast-enhanced US for evaluation of the therapeutic effect after TACE<sup>[108,109]</sup>. According to the report by Pompili *et al*, contrast-enhanced US with SonoVue resulted in diagnostic agreement in 53/56 cases (94.6%), with 87.0% sensitivity and 98.4% specificity compared with contrast-enhanced CT findings, after non-surgical treatments for HCC<sup>[110]</sup>. Another study showed that contrast-enhanced US resulted in considerably higher sensitivity in detecting residual tumor blood flow after TACE than dynamic CT or dynamic MRI<sup>[111]</sup>. Meanwhile, Lim *et al* described that a reliable assessment of intratumoral blood flow by contrast-enhanced US may not be possible in many instances, particularly in small lesions or in lesions located deep within the liver parenchyma<sup>[112]</sup>. They concluded that CT is the standard imaging technique for monitoring the effectiveness of TACE and RFA, and contrast-enhanced US and MRI can complement CT in evaluating the therapeutic response. Although the performance of the US examination may depend on the operator's skill, location of the tumor and system capability, quite a few radiologists and hepatologists may believe that contrast-enhanced US plays a major role in evaluation of the therapeutic effect after TACE. The recent developments in this technology would allow contrast-enhanced US to be positioned as the standard method for evaluation of the therapeutic effect in many HCC patients (Figure 3A and B).

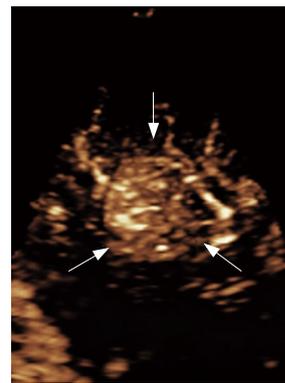

**Figure 3** Assessment of therapeutic response after PEI for HCC. **A:** Contrast-enhanced CT with dynamic study; **B:** Contrast-enhanced US (Advanced Dynamic Flow with Levovist). Contrast-enhanced CT showed enhancement appearance which needed additional treatment within the treated area (arrow), and contrast-enhanced US could demonstrate a similar finding. Arrow heads: Lipiodol.

## ADVANCED TECHNOLOGY

Recent US systems have provided three-dimensional visualization of the combined tissue structures and color blood-flow appearance under easy handling<sup>[24,25]</sup>. Additional anatomical information of the tumor with tumor-associated vessels is available at any plane from multiple directions<sup>[113-116]</sup>. With the remarkable progress in microelectronic technology, the US transducer has achieved full digital specification (Matrix transducer, iu22, Philips) with 3000 elements<sup>[117,118]</sup>. Including built-in micro-beamforming composed of a 150-computer board, it can visualize “Live 3D”, which presents real-time three-dimensional anatomical views visible from any angle with volume rendering for pyramidal volume (90°×70° angles). Contrast-enhanced 3D or 4D ultrasonographies using microbubble contrast agents might become a standard method for the characterization and/or evaluation of the therapeutic effect on liver tumors (Figure 4)<sup>[119]</sup>.

HIFU is a novel technology that enables transcatheter ablation effect without needle puncture<sup>[120,121]</sup>. While controlling the energy and focusing of US, successful HIFU results in necrosis of the tumor in the focal area with less damage of surrounding tissues. A number of clinical studies have been carried out using HIFU for the treatment of liver tumors as well as breast cancer and myoma uteri. In regard to liver tumors, it was reported that the anti-tumor effect and survival time by HIFU combined with TACE were superior to those by TACE alone in 50 patients with advanced HCC<sup>[122]</sup>. Although some of the subjects seemed to have a complete ablation effect, the precise effect for complete tumor necrosis by HIFU was not clear in this study. Furthermore, as the background of the HCCs showing sufficient ablation effect was not fully analyzed, it remains to be solved whether HIFU is valuable as a reliable method for curative treatment of small HCC. Nonetheless, this non-invasive method is really expected to be used for HCC treatment, as an alternative to PEI or RFA, because needle puncture is an invasive procedure for cirrhotic patients.

Normal ventilation is one of the serious problems in the completion of HIFU treatment for liver tumor, as movement of the liver may cause ablation failure that results on non-tumor tissue damage and/or incomplete therapeutic effect for the tumor. Wu *et al* reported that three-dimensional US images were used as a monitor to localize the tumor during HIFU treatment, and changes

**Figure 4** Real-time three-dimensional imaging of HCC (contrast-enhanced LIVE 3D with Sonazoid, iu22, Philips). Abundant tumor vessels were dramatically demonstrated in the HCC nodule. (Arrows: HCC nodule).

in echogenicity of the tumor just after the treatment were evaluated by US<sup>[122]</sup>. Advances in imaging technology for real-time 3D sonography would help the improvement of the therapeutic ability of HIFU.

In conclusion, US has made amazing strides in the last decades because of digital technology progress, and it will continue to grow. The advancement of imaging methods is expected to support the clinical management of patients with HCC.

## Abstract

A few signaling pathways are driving the growth of hepatocellular carcinoma. Each of these pathways possesses negative regulators. These enzymes, which normally suppress unchecked cell proliferation, are circumvented in the oncogenic process, either the over-activity of oncogenes is sufficient to annihilate the activity of tumor suppressors or tumor suppressors have been rendered ineffective. The loss of several key tumor suppressors has been described in hepatocellular carcinoma. Here, we systematically review the evidence implicating tumor suppressors in the development of hepatocellular carcinoma.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common form of primary hepatic tumor and is one of the most common cancers worldwide. HCC usually develops in patients with cirrhosis. Cirrhosis may be caused by viral hepatitis (primarily hepatitis B and C), alcohol, hereditary

haemochromatosis, autoimmune liver diseases and actually any disease that results in chronic inflammation of the liver. In order to understand how chronic inflammation and cirrhosis lead to initiation and progression of HCC extensive research on molecular events has been undertaken. Several intracellular signaling pathways have been closely associated with HCC: p53 pathway and DNA alteration, retinoblastoma (Rb) pathway and regulation of cell cycle, transforming growth factor-beta (TGF- $\beta$ ) and inhibition of cellular growth, and Wnt/beta-catenin pathway and cellular adhesion and signal transduction<sup>[1]</sup>. Deregulation in these different pathways favors the development of liver tumor. Conceptually, hepatocarcinogenesis is based on two main principles: (1) the activation of genes such as oncogenes (c-myc,  $\beta$ -catenin), growth factor (IGF-II, TGF- $\alpha$ ) and telomerase enzyme inducing cellular immortalization and (2) the inactivation of genes called tumor suppressor genes (for example p53 and Rb) Their expressions can be affected by different modifications such as promoter methylation, mutations, biallelic loss and loss of heterozygosity (LOH). In liver cancer, chromosomal aberrations are frequently observed on chromosome 1, 4, 5, 6, 8, 9, 10, 11, 13, 16, 17, 20 and 22 sharing the complexity of hepatocarcinogenesis. Moreover, if some mutations are associated with initiation of carcinogenesis, other genetic alterations promote progression and clone divergence in tumors<sup>[2,3]</sup>.

This review addresses the various tumor suppressors, which have been implicated in HCC (Table 1). Specifically, we discuss their function and involvement in the initiation or progression of HCC as well as their mechanisms of inactivation.

## p53 AND ITS PATHWAY

### p53

TP 53 gene, located on chromosome 17p13.1, encodes a 53 kDa DNA-binding transcription factor. The protein p53 is implicated in the control of cell cycle, apoptosis, DNA repair and angiogenesis. p53 activation has been related to various cellular and environmental changes including: (1) DNA damage (induced by UV light, gamma rays, X rays, and inhibition of topoisomerases), (2) cellular stress (hypoxia, disruption of cell adhesion) independent of DNA damage and (3) activation of growth signaling pathways<sup>[4,5]</sup>. p53 gene is a haploinsufficient tumor suppressor gene<sup>[6,7]</sup>. The loss of p53 activity has been described in many types of human tumors, particularly

Table 1 Summary of tumor suppressor regulated in HCC

Symbol	Name	Location	Haplo-insufficiency	Downregulation in HCC	Mechanism of regulation				Etiology

in 30%-60% of HCC. In many cases, these alterations contribute to progression and not to initiation of HCC<sup>[8]</sup>. In terms of prognosis, p53 alterations are generally associated with larger, less differentiated tumors and poor survival<sup>[9]</sup>. Recently, Lowe and its team observed that senescence program in correlation with the innate immune system turn off the tumor development after restoration of p53 expression in liver tumor cells<sup>[10]</sup>. Different studies described that p53 is regulated by methylation of its CpG islands in HCC<sup>[11,12]</sup> but its expression is mainly regulated by genetic mutations. Mutations affecting p53 are diverse by their nature and position. The p53 gene is altered by allelic deletion and punctual mutation concentrated between exons 4 and 9 of the coding region containing the DNA binding domain. Amongst these mutations, the transversion in codon 249 (G→T), which causes an

arginine to serine (R→S) substitution is present in 50% of HCCs. This genetic alteration can be a consequence of exposure to aflatoxin B1 (AFB1) which is a mycotoxin found in contaminated foods (like corn, rice, and peanuts) particularly in African and Asian countries<sup>[13,14]</sup>. Kirk have proposed the use of p53 mutant DNA as a biomarker for AFB1 exposure<sup>[15]</sup>. Mutated R249S p53 protein expression may induce (1) an inhibition of apoptosis<sup>[16]</sup>, (2) inhibition of p53 mediated transcription<sup>[17]</sup> and (3) stimulation of liver cell growth *in vitro*<sup>[18-20]</sup>. Like AFB1, the hepatitis B virus (HBV) affects the activity of p53 by inducing DNA damage and mutating the p53 gene. Synergism between AFB1 and HBV has been described<sup>[21,22]</sup>. The X gene of HBV (HBx) encodes a protein of 154 amino acids, which is a viral transcriptional co-activator capable of activating the expression of several proteins such as oncogenes

(c-myc, c-fos), cellular growth factors and cytokines. Protein X inactivates various functions of p53<sup>[3,23]</sup> such as apoptosis<sup>[17,24-27]</sup> and transcriptional activation<sup>[28]</sup>. Concerning HCV, the non-structural protein NS2-5 seems to deregulate the actions of factors controlling hepatocellular proliferation by inhibiting p21<sup>WAF</sup> and sequestering p53<sup>[29]</sup>. In transgenic mice, HCV core protein has been found *in vivo* to stimulate the initiation and development of tumor with the same histological characteristics of human HCC<sup>[30]</sup>. HCV core protein may interact directly with p53 and p73<sup>[31-33]</sup>.

In HCC, p53 level and activity are modulated by different proteins such as MDM2 (murine double minute 2) and p14<sup>ARF</sup> (Alternative Reading Frame). Oncogenic MDM2 protein contains a p53-DNA binding site and induces p53 degradation by ubiquitination and proteolysis<sup>[34,35]</sup>. However, auto-regulatory feedback loop of MDM2-p53 controls the function and expression of p53 and MDM2, respectively<sup>[36]</sup>. However, the activity of MDM2 is inhibited by ARF tumor suppressor protein<sup>[37]</sup>. This protein is encoded by INK4a/ARF locus on chromosome 9p21, which is frequently affected by hypermethylation and mutations in HCC<sup>[38]</sup>. In the clinical treatment strategy of HCC, the reactivation of p53 protein is focused on stabilization of p53 activity, over-expression of ARF protein and inactivation of MDM2-p53 interaction<sup>[39]</sup>. In animals, different small molecules such as nutlins and PRIMA-1 inactivate MDM2 and increase p53 activity<sup>[40,41]</sup>. Loss of cell cycle check-point control by mutation of p53 has been suggested to stimulate the metastatic potential of HCC via over-expression of L2DTL<sup>[42]</sup>. Ubiquitination and protein stability of p53 are regulated by a complex regrouping L2DLT, CDT2 and PCNA<sup>[43]</sup>. In contrast, TIP30, which is known to inhibit cell proliferation and tumorigenesis, may act as a hepatocarcinogenic tumour suppressor<sup>[44]</sup>. This protein diminishes Bcl2/Bcl-x expression and augments p53 expression<sup>[45]</sup>. TIP30 mutants inhibited the expression of tumor suppressor genes such as p53 and E-cadherin whereas they induced positive regulation of oncogenic genes expression such as N-cadherin and c-Myc<sup>[46]</sup>. Immunohistochemical analysis of HCC and normal liver showed that a 33 kDa protein called ING1 (inhibitor of growth-1, p33 (ING1)) is expressed at a lower level in HCC. Lower ING1 protein level was associated with enhanced cyclin E kinase activity<sup>[47]</sup>. Recently, Zhu and co-workers proposed that p33 (ING1b) and p53 work in tandem to enhance apoptosis, cell cycle arrest and to inhibit cell growth in HCC. Combined expression of p33 and p53 augments p21 (WAF1/CIP1) protein causing an arrest of cell cycle at stage G0/G1 and enhancing apoptosis<sup>[48]</sup>. The p53 pathway is intercrossing with other tumor suppressors as p21, p27 and p16, which are described below.

### p21

p53 directly controls a gene encoding for a protein named p21WAF/CIP1 (p21). This protein, whose gene is located on chromosome 6p21.2, acts as haploinsufficient tumor suppressor gene<sup>[49]</sup>. It functions as an inhibitor of cyclin-dependent kinases (cyclin-CDK2, CDK4) and interacts with proliferating cell nuclear antigen

(PCNA), a DNA polymerase accessory factor. This protein has a regulatory role in the cell cycle, S phase DNA replication and DNA damage repair. p21 has also been described to activate the caspase 3 protein and thus induce apoptosis. A reduction of p21 expression was observed in HCC<sup>[50]</sup>. Moreover, tumor progression and poor outcome of HCC were associated at disruption of p53-p21/WAF1 cell cycle pathways<sup>[51]</sup>. In a study addressing p53 expression and apoptosis, high p53 expression was associated with cell cycle arrest and apoptosis whilst a lower level of p53 induced only cell cycle arrest. However, p21 expression could activate only cycle arrest but not apoptosis in HCC as well as in the presence of high p53 as low p53 expression<sup>[52]</sup>. The transcription of p21 gene was found to be repressed by HBV X protein (HBx) and HCV core protein<sup>[53]</sup>. In addition, the stress due to the inflammation and fibrosis of HCV-associated chronic liver diseases induced up-regulation of p21<sup>[54]</sup>. Huether and co-workers analyzed the effect of cetuximab (Erbix), a chimeric human/mouse antibody directed against the Epidermal Growth Factor Receptor (EGFR), with or not in combination with other drugs on human hepatocellular carcinoma cell lines. The expression of the cyclin-dependent kinase inhibitors p21 and p27 (Kip1) was increased whereas the expression of cyclin D1 was decreased by cetuximab treatment. A synergistic antiproliferative effect was observed following a treatment with cetuximab combined with doxorubicin, tyrosine kinase inhibitors (erlotinib or AG1024) or the HMG-CoA-reductase inhibitor fluvastatin<sup>[55]</sup>. The expression of different proteins such as p53, p21 cyclin D implicated in enhancement of the apoptosis pathway and cell proliferation have been analyzed after treatment with antiangiogenic agent TNP-470 in a rat model of hepatocellular carcinoma. The augmentation in these angiogenic factors induced by HCC was prevented whereas a cell-cycle inhibition was generated by activation of p21 and reduction of the cyclin D-Cdk4 and cyclin E-Cdk 2 expression following animals' treatment with TNP-470. These results suggest that TNP-470 may be efficient for anti-angiogenic therapy and treatment of human HCC<sup>[56]</sup>.

### p27

The p27 (p27 Kip1), whose gene, a member of haploinsufficient tumor suppressor gene family<sup>[57]</sup>, locates on chromosome 12p13.1-p12, is a cyclin-dependent kinase inhibitor. Cell cycle progression at G1 and cyclin E-CDK2 and cyclin D-CDK4 complexes are regulated by p27. Different studies have been executed to understand the role of p27 in development of tumor and particularly in HCC. The comparison of hepatocellular HCC with adjacent non-tumoral and normal liver tissues found that the weak expression of p27 was strongly associated with infiltration, metastasis and poor prognosis in patients affected by HCC. Moreover, cytoplasmic sequestration of p27 was observed more in HCC leading a diminution of p27 expression and was particularly characterized in early steps of hepatocarcinoma development<sup>[58]</sup>. Philipp-Staheli and co-workers have already suggested that the p27 protein might be a check point for tumor suppression and

an important prognostic marker because its loss favors tumor growth<sup>[59]</sup>. Expression of p27 was lower in patients having liver cirrhosis and HCC in comparison to those without HCC level<sup>[60]</sup>. This group explained the loss of p27 expression by high level of methylation of its promoter. The high and low levels of p27 expression have been associated with prolonged survival and poor prognosis, respectively<sup>[61,62]</sup>. A study proposed that functional inactivation of p27 is strongly associated with methylation of p16 and loss of its expression<sup>[63]</sup>.

### **p16**

The p16 (P16INK4) gene, located on chromosome 9p21, encodes a protein that inhibits proliferation of normal cells by binding strongly with cdk4 and cdk6. This binding prevents cdk4 and cdk6 from interacting with cyclin D and inactivation by phosphorylation of the retinoblastoma protein (Rb). In 1998, post-transcriptional regulation was found to inactivate the p16 activity in HCC and this inactivation appeared to take place during the early-stage of hepatocarcinogenesis<sup>[50]</sup>. The loss of expression of p16 and inactivation of Rb represent major events in hepatocarcinogenesis<sup>[64]</sup>. Analysis of different hepatocyte cell lines revealed that increased p16 expression is associated with decreased phosphorylation of pRB. Reciprocally, phosphorylation of Rb and increase of cell growth were associated with silencing of p16 by promoter methylation<sup>[65]</sup>. The p16 gene is silenced by hypermethylation of 5' CpG islands in its promoter<sup>[66,67]</sup>. In addition to hypermethylation-induced transcriptional repression of the p16 gene, expression is also affected by mutation and deletion, although these modifications are less common<sup>[38]</sup>. As described above, aflatoxin inactivates p53. The concentration of aflatoxin B1 albumin adducts has been correlated not only with p53 mutation but also with p16 methylation stressing the importance of environmental factors in the development of HCC<sup>[68]</sup>.

## **WNT PATHWAY**

Many different proteins have been described in the Wnt pathway which function either as oncogenes (e.g beta-catenin) or as tumor suppressors (e.g E-cadherin, APC, Axin 1 and 2 proteins). About 50% of the HCC exhibited alteration of the Wnt pathway<sup>[69]</sup>.

### **E-cadherin**

E-cadherin protein, encoded by a gene located on chromosome 16q22.1, belongs to the cadherin superfamily and is a calcium dependent cell-cell adhesion glycoprotein. Loss of function induced by mutations was associated with proliferation, invasion and metastasis. Many investigations with animal models and human HCC tissues have been performed and show that E-cadherin gene expression is regulated by promoter methylation. Hypermethylation was associated with decreased E-cadherin expression but also with microvascular invasion and recurrence of HCC<sup>[70,71]</sup>. HBV and HCV affect this pathway. The presence of the HBx protein was associated with hypermethylation of the E-cadherin promoter, loss of its expression and beta-

catenin accumulation<sup>[72]</sup>. In HCV-associated HCC the probability of recurrence could be linked to depressed E-cadherin expression<sup>[73]</sup>.

### **Axin1/ axin2**

Axin1 and axin2 proteins, encoded by genes located on chromosome 16p13.3 and 17q23-q24, respectively, act as negative regulators of the Wnt signaling pathway and can induce apoptosis. Axins interact with different proteins such as beta-catenin, adenomatosis polyposis coli (APC) and glycogen synthase kinase 3-beta. Mutations in the Axin1 gene have been associated with different human cancers including HCC and hepatoblastomas. Satoh and co-workers identified mutations in the axin1 gene as well as in cell lines as in HCCs and they reported that wild type protein stimulates apoptosis leading to suppression of tumor growth. The gene coding for Axin1 protein is affected by loss of heterozygosity and small deletions, mutations and by missense mutations (1 bp deletion and 12 bp insertions)<sup>[74]</sup> which most of the time target the gene in a biallelic manner<sup>[75]</sup>. Combination of loss of heterozygosity and mutation induced the inactivation of Axin1 in HCC<sup>[76]</sup>. The loss of heterozygosity also frequently affects the Axin2 gene due to its chromosomal localization and has been associated with different tumors like breast cancer and neuroblastoma<sup>[77]</sup>. The percentage of Axin1 and Axin2 mutations in HCC remains controversial. In presence of Axin mutations, the Wnt-signaling pathway is the altered leading to the accumulation of beta-catenin<sup>[78-80]</sup>. Beta-catenin mutations were associated with over-expression of G-protein-coupled receptor (GPR) 49, glutamate transporter (GLT)-1 and glutamine synthetase (GS) while this correlation was not found with Axin1 mutations. These results suggest that Axin1 function might affect other signaling pathway than Wnt pathway<sup>[76]</sup>.

### **APC**

A gene located on chromosome 5q21-q22 encodes a tumor suppressor protein named adenomatosis polyposis coli (APC). This protein has many intracellular functions including nuclear export and degradation of beta-catenin. A small region designated the mutation cluster region regroup mutations associated to diseases. To determine the role of APC protein in hepatocyte carcinogenesis, Colnot and co-workers generated a knock-out mouse model targeting exon 14 of the APC gene. They observed that 67% of analyzed mice developed HCC while Wnt/beta-catenin pathway activation was demonstrated by accumulation of different genes regulated by beta-catenin (leukocyte cell-derived chemotaxin 2, ornithine aminotransferase and glutamine synthetase, glutamate transporter 1)<sup>[81]</sup>. The disruption of APC gene in liver induces hepatocyte hyperplasia, marked hepatomegaly and rapid mortality. Like other tumor suppressor genes, APC is hypermethylated in HCC relative to non-tumor liver. Hepatitis C virus/hepatitis B virus-negative HCC showed less methylation on APC gene than in hepatitis C virus-positive HCC<sup>[82]</sup>. Methylation status of APC and other tumor suppressor genes was associated with the epigenetic instability dependent HCCs<sup>[83]</sup>. Recently, bi-

allelic inactivation and nonsense mutation at codon 682 of APC gene in sporadic nodule-in-nodule-type HCC were observed using high-density array-based comparative genomic hybridization (aCGH) and direct sequencing, respectively. Both alterations lead to inactivation of APC binding to beta-catenin which may enhance the evolution of sporadic HCC<sup>[84]</sup>.

## RAS/JAK/STAT PATHWAY

### SOCS

The suppressor of cytokine signaling (SOCS), also known as STAT-induced STAT inhibitor (SSI) protein family comprises several members including SOCS1, SOCS2 and SOCS3 which are encoded by genes located in 16p13.13, 12q, 17q25.3, respectively<sup>[85,86]</sup>. These proteins function as negative regulators of cytokine signaling. SOCS1 as well as SOCS2 and SOCS3 are stimulated by cytokines and act in negative feedback loop to regulate cytokine signaling. SOCSs inhibit by direct binding the kinase activity of Janus Kinases (JAKs) proteins and so block the JAK/STAT pathway<sup>[87]</sup>. The role of SOCS1 in negative regulation of interferon-gamma and in T-cell differentiation was determined by generating a knock-out mouse model lacking the expression of SOCS1 gene. In the same way, SOCS2 and SOCS3 were demonstrated to be involved in regulation of postnatal growth and regulation of fetal liver hematopoiesis, respectively<sup>[87]</sup>. The SOCS1 gene promoter is enriched with CpG dinucleotides<sup>[88]</sup>. The decrease of SOCS1 expression was associated with aberrant methylation in CpG islands and 5' non-coding region of SOCS1 promoter and loss of heterozygosity<sup>[89,90]</sup>. A significant relationship between SOCS1 methylation level and HCC transformation of cirrhotic nodules was established confirming that SOCS might act as a tumor suppressor<sup>[91]</sup>. The suppression of cell growth and activation of JAK2 was observed after recovering of SOCS1 expression by gene therapy in cells having SOCS1 silenced by hypermethylation<sup>[92]</sup>. SOCS3 promoter can also be methylated resulting in diminution of SOCS3 expression<sup>[93,94]</sup>. Restoration of its expression blocks the phosphorylation of STAT3 and inhibits the proliferation. Cell growth and migration were negatively regulated by inhibition of JAK/STAT signaling pathway by SOCS3 protein in HCC<sup>[93]</sup>. The enhancement of proliferation and development of hepatic tumor, activation of STAT3 and inhibition of apoptosis were observed in absence of SOCS3 expression obtained using a conditional knockout mice approach under carcinogenic condition. These results confirmed that SOCS3 acts as tumor suppressor gene<sup>[95]</sup>. Leong and co-workers found that SOCS2 and SOCS3 were both up-regulated in hepatic cells following estrogen treatment *via* estrogen receptor (ER) alpha providing a mechanistic explanation for the rare cases of HCC responding to this treatment<sup>[96]</sup>.

### RASSF1A/NORE1

Members of the RAS superfamily are plasma membrane GTP binding proteins that modulate intracellular signal transduction pathways. A subgroup in this family contains

a Ras-association domain and takes part in RAS signaling pathway<sup>[97-101]</sup>. A gene located on chromosome 3p21.3 encodes a protein identified as human RAS effector homologue (RASSF1). Alternative splicing and promoter usage of this gene generates three different transcripts: RASSF1A, RASSF1B and RASSF1C. RASSF1A contains a Ras Association Domain (RA) and binds Ras in a GTP-dependent manner to affect apoptosis. The presence of CpG-islands in the promoter of the RASSF1 gene was associated with high methylation level and the loss of expression of RASSF1A. The reduction of RASSF1A expression was found in lung carcinoma and these results indicate that RASSF1A might act as a tumor suppressor<sup>[102]</sup>. Additionally, RASSF1A role is associated with the cell cycle given that it blocks the accumulation of cyclin D1 and G (1)/S-phase cell cycle progression<sup>[103]</sup>. Hypermethylation of RASSF1A induced the inactivation of RASSF1A but also correlated with environmental carcinogens such as AFB (1) and with inactivation of p16INK4a protein in hepatocellular carcinoma<sup>[104]</sup>. The high frequency of hypermethylation of RASSF1A promoter could be detected not only in tumor<sup>[83,105]</sup> but also in matched plasma of patients affected by HCC<sup>[105]</sup>. Methylation level of RASSF1A was proposed as a potential marker to diagnose HCC<sup>[100,106,107]</sup>. Recently, a strong association was identified between CpG island methylation phenotype (CIMP) and serum concentration of alpha-fetoprotein (AFP) and inactivation of many genes involved in process of tumor suppression such as RASSF1A. Thus CIMP might be used as molecular marker of late-stage HCC development<sup>[12]</sup>.

Among the subfamily of RAS effectors, the NORE1 proteins encoded by a gene located on chromosome 1q32.1 were described as a regulator of Ras dependent apoptosis. In the same manner as the RASSF1 gene, three different isoforms were identified (NORE1Aalpha, NORE1Abeta and NORE1B). NORE1A and NORE1B, which are separated by CpG islands spanning their first exons, share the Ras-association (RA) domain but the diacylglycerol (DAG) binding domain was only present on NORE1A<sup>[99]</sup>. Analysis of methylation found that NORE1A promoter was methylated whereas NORE1B was unmethylated in breast, colorectal and kidney tumor cell lines<sup>[97,99]</sup>. Comparative analysis showed that NORE1 gene was not altered by methylation whereas RASSF1A gene promoter was increasingly methylated from regenerating liver to hepatocellular carcinoma nodules<sup>[107]</sup>. In another study, expression of NORE1A and SOCS 3 was inhibited by high methylation level of their promoters and their inactivation associated with a subclass of poor prognosis HCC<sup>[94]</sup>. It appears that NORE1 could be considered as tumor suppressor gene in hepatocarcinogenesis<sup>[108]</sup>.

## OTHER PATHWAYS

### KLF6

Krüppel-like factors (KLFs) are highly related zinc-finger proteins that are important components of the eukaryotic cellular transcriptional machinery. Among this protein family, Krüppel-like factor 6 (KLF6) is a ubiquitously expressed zinc finger transcription factor

encoded by a gene located on chromosome 10p15<sup>[109]</sup>. The KLF6 protein binds DNA on guanine-rich core promoter elements and regulates the transcriptional activation process *via* its zinc fingers domains and central acidic N-terminal domain. Due to its regulatory role in transcription, different studies have been conducted to define the role of KLF6 in tumor development and has been described as a tumor suppressor in different cancer such as colon and prostate<sup>[110-112]</sup>. Reduction of KLF6 expression and methylation of KLF6 promoter have been associated with human cancers<sup>[111,113-115]</sup> but the incidence of KLF6 variation on HCC has been described for first time by Friedman's group<sup>[116]</sup>. They determined that loss of heterozygosity induces a loss of KLF6 expression in 50% of analysed HCC samples. In same samples, they identified several missense mutation associated with presence of HBV or HCV. Moreover, *in vitro* analyses of KLF6 mutations showed that only KLF6 wild type inhibits the cell growth of HepG2 cell lines by p21 protein activation whereas the different mutants did not induce any changes indicating regulatory effects of mutations on KLF6 activity. The process leading to the activation of p21 and reduction of cell proliferation by KLF6 necessitates the acetylation of KLF6 by histone acetyltransferase activity of either cyclic AMP-responsive element binding protein-binding protein or p300/CBP-associated factor. This process can be abrogated by a single mutation of lysine-to-arginine (K209R), point mutation already described in prostate cancer<sup>[117]</sup>. In recent work carried out on ovarian cancer, E-cadherin level variation was found to be mediated by direct action of KLF6 on its promoter<sup>[118]</sup>. Furthermore, induction of cellular differentiation and inhibition of cell proliferation was observed in KLF6 overexpressing HepG2 cell lines and associated with augmentation of E-cadherin and albumin expression and reduced cyclinD1 and beta-catenin expression. In the same study, the authors demonstrated also inhibitory effects of HBV and HCV infection on KLF6 expression<sup>[119]</sup>. The stability of KLF6 is modified by ubiquitination after induction of apoptosis by drugs (cisplatin, adriamycin) or UVB irradiation but not by apoptotic-dependent extrinsic/death-receptor pathway. The effects of KLF6 on tumor suppression and enhancement of chemotherapeutics response might be affected by the speed of its degradation and deregulation of its stability<sup>[120]</sup>. Apoptosis induced by upregulation of p53 and diminution of Bcl-xL expression was enhanced following KLF6 knockdown. Additionally, the arrest of cell cycle in G1 phase and expression of cyclin-dependent kinase 4 and cyclin D1 were weakened or suppressed in KLF6 silenced cells. These results bring a new perspective for the link between of KLF6 and apoptosis<sup>[121]</sup>.

### **PTEN**

This haploinsufficient gene located on chromosome 10q23.3 encodes a phosphatidylinositol-3,4,5-trisphosphate 3-phosphatase<sup>[122]</sup>. This protein dephosphorylates phosphoinositide substrates and acts as a negative regulator for intracellular levels of phosphatidylinositol-3,

4, 5-trisphosphate. PTEN is inactivated in many cases of breast, endometrial, prostate cancers. Many mutations affect PTEN gene such as missense mutations in exon 5 (K144I) and exon 7 (V255A) or silent mutations in exon 5 (P96P) in HCC from Taiwan<sup>[123]</sup>. In HBV infected liver cells, PTEN expression is also deleted following the genome integration of HBV<sup>[124]</sup>. In this Asiatic subset of HCCs, both mRNA and protein levels of PTEN were weaker in tumor than in paired para-carcinoma tissues<sup>[125,126]</sup>. Moreover, a point of mutation induced a weak level of PTEN which is inversely linked with FAK phosphorylation<sup>[127]</sup>. In 47% of HCC analyzed by Sieghart and co-workers, they observed a decrease or absent of PTEN which is inversely correlated with expression of phosphorylation proteins in mTOR pathway<sup>[128]</sup>. HCC development might be susceptible to inhibition of mTOR<sup>[129]</sup>. The lessening of PTEN expression was associated with loss of promoter activity<sup>[130]</sup>. Wang and collaborators confirmed that PTEN inactivation seems resulting not only of mutation and promoter methylation but also possible other epigenetic mechanisms which remain to be defined<sup>[131]</sup>. Reduction of PTEN expression in HCC was associated with poor prognosis and progression of HCC<sup>[132]</sup>. This might be due to the inverse correlation between PTEN expression and VEGF expression<sup>[133]</sup>.

### **HINT protein**

**Hint1:** Hint1 is encoded by gene located on chromosome 5q31.2 and is member of the The Histidine Triad (HIT) protein family characterized the His-X-His-X-His-XX motif. Hint1 forms homodimers and each subunit can bind a nucleotide. Hint1 acts as an adenosine 5'-monophosphoramidate (AMP-NH<sub>2</sub>) hydrolase<sup>[134]</sup>. Spontaneous immortalization and enhancement of cell growth were observed in cells lacking Hint1. Squamous tumors (both papillomas and carcinomas) of the forestomach developed after treatment with chemical carcinogen N-nitrosomethylbenzylamine (NMBA) showed a greater volume and a more severe degree of malignancy in Hint1-/- mice<sup>[135]</sup>. Accordingly, the hypothesis of Hint1 role as tumor suppressor was developed and work was carried out to elucidate which signaling pathway is involved. Weiske and co-workers determined an interaction between Hint1 and pontin and reptin<sup>[136]</sup>. Pontin and reptin are often found in complexes and they possessed single-stranded DNA-stimulated ATPase and ATP-dependent DNA helicase activity but with opposite action<sup>[137,138]</sup>. Moreover, both proteins interact with beta-catenin by modulating its transcriptional activity in Wnt pathway<sup>[139]</sup>. Hint1 was identified as a part of the LEF-beta-catenin transcription complex and function as a negative regulator of TCF-beta-catenin transcriptional activity, repressing expression of Wnt signaling target genes such as axin2 and cyclin D1<sup>[136]</sup>. The same authors reported that p53-induced apoptosis was influenced by Hint1, which up-regulated Bax and down-regulated Bcl-2. The pro-apoptotic activity of Hint1 was not related to its enzymatic AMP-NH<sub>2</sub> hydrolase activity<sup>[140]</sup>. Treatment of non small cell lung cancer (NSCLC) cell line with DNA demethylating agent, 5-aza-2'-deoxycytidine up-regulated of Hint1, and this correlated with growth inhibition and reduction of

tumorigenicity<sup>[141]</sup>. Weinstein's group described Hint1 is a novel haploinsufficient tumor suppressor gene and is able to repress the cell growth and tumor progression by inhibition of AP-1 transcription factor activity in mammary tumor and colon cancer cells, respectively<sup>[142,143]</sup>. The role of Hint1 in hepatocarcinogenesis remains to be explored.

**Hint2:** Hint2 is a mitochondrial HIT protein. This protein is encoded by a gene located on chromosome 9p13.3. Tissue profile expression of Hint2 showed that this protein is predominantly expressed in the liver and pancreas. Like its cytoplasmic homologue Hint1, Hint2 acts as an adenosine monophosphate hydrolase enzyme and this enzymatic activity was lost when the second histidine of the HIT motif is mutated. The sensitivity of cells to apoptosis was increased when Hint2 was over expressed whereas Hint2 knockdown was coincident with reduced caspase 3 expression. Subcutaneous injection of HepG2 cells over-expressing int2 in SCID mice resulted in smaller tumours, which displayed more apoptosis in comparison to mice, injected with control HepG2 cells. Microarray analyses carried out on human tissues found a significant reduction of HINT 2 mRNA in HCC compared with surrounding liver tissue. This diminution of Hint2 expression was associated with a poor prognosis<sup>[144]</sup>.

## FRAGILE CHROMOSOMAL SITE GENES AND HCC

### FHIT

The FHIT protein is encoded by a haploinsufficient tumor suppressor gene<sup>[145]</sup>, located on chromosome 3p14.2 a place known to be one of the most fragile sites in human genome. This protein, a member of the histidine triad gene family, is a diadenosine triphosphate hydrolase. In numerous tumor types such as lung, stomach, breast, colon, aberrant forms of FHIT protein were found due to rearrangements and deletions in region of FHIT locus<sup>[146-148]</sup>. Aberrant FHIT transcripts with deletions of exons and fusion of remaining exons and loss of heterozygosity were observed in HCC tissues in comparison with non-tumoral tissues and lead to the lack of FHIT protein expression. So FHIT was frequently altered in liver and might be implicated in liver tumorigenesis<sup>[149-151]</sup>. FHIT has also been described as a pro-apoptotic agent. Restoration of Fhit expression activated caspase 8 and induced apoptosis in Fhit-negative cell lines<sup>[152]</sup>. Sard reported a 2-fold increase in the apoptosis-related protein Bak and in the cell cycle inhibitory protein p21, but not in Bcl-2, Bcl-X, Bax and, p53<sup>[153]</sup>. Inactivation like by promoter methylation was associated with progression and poor prognosis of HCC<sup>[154,155]</sup>. In 2004, a study performed on HCC cohort from the US found over-expression of modified FHIT transcripts<sup>[156]</sup>. Fusion between exon 5 and 7 and between exon 7 and 9 were frequently observed in HCV-related<sup>[157]</sup>. Apoptosis was weaker in early HCC with negative FHIT expression than in advanced HCC with positive expression of FHIT. So, the absence of FHIT protein influencing the

balance between apoptosis/proliferation may play a role in formation of HCC<sup>[158]</sup>.

### WWOX

WWOX (WW-domain containing oxidoreductase) gene located on another fragile site on chromosome 16q23.3-q24 encodes a 46 kDa protein having 2 WW domains, which mediate the protein-protein interaction, and a short-chain dehydrogenase/reductase domain (SRD). The WW domain-proteins are expressed in all eukaryotes and act as regulator of a wide variety of cellular functions such as RNA splicing, transcription and protein degradation. Different forms of WWOX transcripts were observed following deletions or alternative splicing in frameshift leading to the total or partial loss of different domains. Diverse missense mutations and single nucleotide polymorphisms (SNP) within the WWOX have been identified in many tumor cell lines and conduct to consider this protein as a tumor suppressor<sup>[159]</sup>. No mutations leading to WWOX abnormal transcript were found in HCC cell lines. However, loss of heterozygosity on chromosome 16q at the fragile site FRA16D was found in 29% of HCC and an association between 16q lack and R249S mutation affecting the p53 gene was determined in HCC samples from patients exposed to aflatoxin B1<sup>[160]</sup>. Decreased or absent expression of WWOX was observed in cell lines derived from human HCCs<sup>[161]</sup>. WWOX protein is able to interact with other proteins, in particular with p73 protein<sup>[162,163]</sup>. The association of WWOX with p73 redistributes p73 from nucleus to cytoplasm blocking p73 transcriptional activity and enhancing the pro-apoptotic potential of WWOX<sup>[164]</sup>. A recent study performed on mouse models treated with carcinogen drugs found that the same down regulation profile for FHIT and WWOX in the liver<sup>[80]</sup>. This result completes the association between FHIT and WWOX expression observed in breast and gastric cancer<sup>[164-167]</sup>.

### Parkin (PARK2)

Like WW domain-containing oxidoreductase gene (WWOX; 16q23) and fragile histidine triad gene (FHIT; 3p14.2) parkin is also located on fragile and unstable chromosomal region (FRA6), which can be targeted by mutational rearrangement (duplication or deletion). Parkin is a member of RBR protein family implicated in ubiquitin related-proteolytic pathway<sup>[168-170]</sup>. This protein was involved in neurodegenerative diseases<sup>[171]</sup>. Parkin protects neurons and autosomal recessive juvenile parkinsonism is associated with mutations affecting this gene. Parkin seems to play a role in tumor suppression<sup>[172]</sup>. Analysis of HCC samples has been performed by Wang and collaborators. They determined that the expression of parkin was lower in HCC compared with normal liver. Transfection of Hep3B cells with parkin increased their sensitivity to apoptosis and negatively regulated their cell growth. These results prompt speculation that the absence of parkin expression may favor the development of HCC<sup>[173]</sup>. Down-regulation and loss of parkin expression was correlated with methylation of its promoter in acute lymphoblastic leukemia and chronic myelogenous leukemia (CML) in lymphoid blast crisis<sup>[174]</sup>.

## NEW POTENTIAL PATHWAYS IN TUMOR SUPPRESSION

### DNA methyltransferase

A family of protein called DNA methyltransferase catalyses the methylation process on CpG islands leading to regulation of gene expression. Two distinct gene families: DNMT1 gene and DNMT3 gene family which regroups two related genes: DNMT3a and DNMT3b are known to maintain and induce the methylation. The function of DNMT2 is still to be clarified<sup>[175-177]</sup>. High mRNA levels of DNMT1 and DNMT3 were observed in HCC in comparison of normal or non-tumoral tissues but only cytoplasmic DNMT3 expression was decreased in HCC. The first studies proposed that these proteins act during early stage of hepatocarcinogenesis and might take a part in progression of HCC<sup>[178-180]</sup>. Excepted for a correlation between DNMT3a immuno-reactivity and p53 methylation levels, Park and co-worked did not observed a correlation between DNMT expression and methylation levels of different tumor suppressor genes described in HCC<sup>[11]</sup>. It seems that not only DNMTs protein but also other mechanisms are engaged in methylation changes of tumor suppressor genes in HCC. In liver cell line infected by HBV and HBV-infected HCC samples, HBVx proteins induced a change of transcription of DNMTs proteins leading to regional methylation of tumor suppressor genes<sup>[181]</sup>. The lack of two other proteins: O6-Methylguanine-DNA Methyltransferase (MGMT) and human Mut L homologue (hMLH) implicated in DNA repair system have been associated with poor prognosis and advanced stages of HCC<sup>[182]</sup>. The expression of MGMT in HCC is altered by hypermethylation of its promoter and DNA integration of HBV near to FRA10F chromosome fragile site<sup>[183,184]</sup>.

### miRNA and HCC

Small non-coding RNAs 19 to 25-nucleotide-long RNA called microRNAs (miRNA) define a new family of regulatory molecules. They recognize and bind the complementary sequences in 3' untranslated regions (3'-UTR) of diverse target mRNAs<sup>[185]</sup>. By their role in control of diverse cellular processes such as proliferation, differentiation and apoptosis, miRNAs appear as new actor of regulation of tumorigenesis. However, miRNAs are themselves the target of regulation and their expressions are down- or up-regulated in various human cancer types and they can act as tumor suppressors or oncogenes<sup>[186-192]</sup>. Murakami and collaborators identified five mRNAs (miRNA 199a, 199a\*, 200a, 125a and 195) and three (miRNA 224, 18, p18) with lower and higher expression in HCC than in adjacent non-tumoral tissues, respectively<sup>[184]</sup>. Kutay and Gramantieri observed that miR-122a, the most represented miRNA in liver, is down regulated in HCC<sup>[193,194]</sup>. Moreover, Gramantieri and collaborators showed a reverse correlation between miR-122a and cyclin G1. This miRNA appears to block the tumor growth through the inhibition of cyclin G1 expression<sup>[194]</sup>. miR-122a has been also described to facilitate the replication of HCV RNA in HCC<sup>[195]</sup>. The genomic integration of HBV

in region of fragile site alters the expression of miRNA<sup>[196]</sup>. In fact, the genome integration of HBV in particularly in fragile site alters the expression of different miRNA. The expression of let-7e is lower in HCC than in non tumor liver and this inhibition is a consequence of HBV integration in FRA11B, FRA11G and FRA19A fragile sites<sup>[184,187,196]</sup>. miRNA-195 which modulates the expression of Bcl-2 like protein, SKI oncogenes and methyl-CpG binding protein-2 in HCC, is altered by integration of HBV in FRA17A<sup>[184,196]</sup>.

## CONCLUSION

Numerous proteins involved on the control of different cellular processes such as cell proliferation, apoptosis and DNA replication are described as tumor suppressor. The deregulation of expression of these proteins by mutations and/or methylation of their promoter and viral-dependent-action contributes to the progression of hepatic cancers. Comprehensive understanding of the functions of these tumor suppressors is a prerequisite to devise innovative treatments of HCC.

## DEFINITIONS

### Tumor suppressor

Cell fate is controlled by division, differentiation and death. The balance between these commitments is determined by negative and positive regulations mainly through two classes of genes: the tumor suppressor genes and the proto-oncogene genes, respectively. In normal condition, tumor suppressor genes repress the formation and development of tumor but damage in their expression or function conduct to uncontrolled cell growth or cancer. Their function is impaired by mutations, loss of chromosome region or silencing by promoter methylation. Tumor suppressor genes are important targets in the quest to develop clinical therapies based on the restoration of gene function to reverse the carcinogenesis process.

### Haploinsufficiency

The majority of tumor suppressor genes follow the "two-hit hypothesis". The loss of function is associated with a damage of both alleles. In case of haploinsufficiency, the missing of only one allele is sufficient to inactivate the synthesis of gene product and to confer in a dose-dependent manner tumor sensitivity. Haploinsufficiency is associated with a few tumor suppressor genes such as p53 and PTEN.

### Methylation state

Expression of genes can be regulated by methylation of their promoter. DNA methylation is the conversion of cytosine to 5-methylcytosine, which is catalyzed by DNA methyltransferase. It occurs on CpG sites mainly located in promoter region of genes. In case of cancer, aberrant methylation affects several tumor suppressor genes such as E-cadherin and SOCS1 leading to gene silencing and loss of protein function. The simultaneous methylation of CpG islands of multiple genes defines a new biomarker

named CpG island methylator phenotype (CIMP). CIMP has been recognized as an important mechanism of gene regulation.

### Loss of heterozygosity (LOH)

Loss of heterozygosity (LOH) refers to the loss of a single allele of a gene due to mutation, deletion of large chromosome segment and epigenetic regulating events such as methylation. LOH frequently affects tumor suppressor genes because most of them are located in chromosome fragile site. Losses in regions 1p, 4q, 6q, 8p, 13q, 16q, and 17p have been related to HCC and induce the lack of gene such as E-cadherin, WWOX, FHIT or p53.

Molecular mechanism underlying the functional loss of cyclindependent kinase inhibitors p16 and p27 in hepatocellular carcinoma. *World J Gastroenterol* 2008; 14(11): 1734-1740 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1734.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1734>

## Abstract

Hepatocellular carcinoma (HCC) is one of the most common human cancers, and its incidence is still increasing in many countries. The prognosis of HCC patients remains poor, and identification of useful molecular prognostic markers is required. Many recent studies have shown that functional alterations of cell-cycle regulators can be observed in HCC. Among the various types of cell-cycle regulators, p16 and p27 are frequently inactivated in HCC and are considered to be potent tumor suppressors. p16, a G1-specific cell-cycle inhibitor that prevents the association of cyclindependent kinase (CDK) 4 and CDK6 with cyclin D1, is frequently inactivated in HCC *via* CpG methylation of its promoter region. p16 may be involved in the early steps of hepatocarcinogenesis, since p16 gene methylation has been detected in subsets of pre-neoplastic liver cirrhosis patients. p27, a negative regulator of the G1-S phase transition through inhibition of the kinase activities of Cdk2/cyclin A and Cdk2/cyclin E complexes, is now considered to be an adverse prognostic factor in HCC. In some cases of HCC with increased cell proliferation, p27 is overexpressed but inactivated by sequestration into cyclin D1-CDK4-containing complexes. Since loss of p16 is closely related to functional inactivation of p27 in HCC, investigating both p16 and p27 may be useful for precise prognostic predictions in individuals with HCC.

## INTRODUCTION

The liver is a remarkable organ, since it can regenerate after significant tissue loss. When liver tissue is partially lost or injured, residual hepatocytes immediately enter the cell cycle from a quiescent (G0) state through pre-replicative (G1), DNA synthesis (S) and mitosis (M) states. Significantly, once the original volume of the liver is achieved, the hepatocytes revert to their quiescent state and restore the tissue volume to a physiological condition. This exquisite regenerative potential of the liver has been regarded as potentially being governed by sequential activation of a series of positive and negative cell-cycle regulators in hepatocytes. Briefly, cell-cycle entry is mainly promoted by cyclins A, D and E with cyclin-dependent kinase (CDK) 2 and 4 and the activities of these CDKs are negatively regulated by the cyclin-dependent kinase inhibitors (CDKIs) p16 and p27 to avert excessive hepatocellular replication. Therefore, it is understandable that many oncologists have sought to elucidate the molecular mechanism underlying cell-cycle regulators during hepatocarcinogenesis<sup>[1,2]</sup>.

To date, many studies have reported genetic and epigenetic alterations of cell-cycle regulators in hepatocellular carcinoma (HCC). In particular, both p16 and p27 are frequently altered in HCC, suggesting that they are potent tumor suppressors. Of note, epigenetic alterations of p16 in liver cirrhosis have recently been reported<sup>[3-5]</sup>, supporting the idea that p16 may be involved in the early stage of hepatocarcinogenesis. Moreover, we and others have found a close relationship between p16 and p27 during the progression of HCC<sup>[6-8]</sup>, indicating that comprehensive analyses of these CDKIs may

be valuable for further understanding of the clinical significance of cell-cycle regulators in HCC. In this review, an overview of the molecular mechanism underlying p16 and p27 inactivation in HCC is presented, and the clinical significance of the relationship between these CDKIs in individuals with a high risk of HCC is described.

## FREQUENT INACTIVATION OF p16 IN HCC

p16 is a specific inhibitor of CDK4 and CDK6 and potentially blocks G1 cell-cycle progression *via* dephosphorylation of Rb through its inhibitory effect on CDK4/cyclin D1 complex activity<sup>19,10</sup>. The *CDKN2/MTS1* gene encoding p16 is frequently deleted or inactivated by 5'-CpG island hypermethylation in various types of cancer cells, and p16 is considered to be a potent tumor suppressor<sup>10,11</sup>. Many studies have focused on searching for the genetic/epigenetic status of p16 in HCC with a view to investigating the molecular mechanism of hepatocarcinogenesis. Biden *et al* reported that p16 was frequently mutated or deleted in human HCC in an Australian population<sup>12</sup>, while Chaubert *et al* reported germline mutations of p16 in a subset of familial HCC in Switzerland<sup>13</sup> and Piao *et al* reported the presence of a homozygous deletion of p16 in 61% of HCC cases in a Korean population<sup>14</sup>. On the contrary, we examined the genetic status of p16 in 60 HCC cases in Japan but did not find any homozygous loss of *p16*<sup>15</sup>. Only 4 of 60 (6.6%) HCC cases showed intragenic mutations in exon 2 of *p16*, and no hotspots for amino acid changes were detected in our study. Significantly, however, we found that the p16 gene promoter was methylated in 27 of 60 (45%) HCC cases. A close relationship between loss of p16 immunostaining and hypermethylation of the p16 gene was found, indicating that epigenetic alterations induced loss of p16 protein expression in HCC<sup>15</sup>.

Interestingly, 24 of 60 (40%) HCC cases showed high levels of methylation in the p16 gene promoter region, ranging from 60%-85% of the CpG islands as assessed by methylation-sensitive single nucleotide primer extension<sup>16</sup>. The reason why the patterns of p16 inactivation differ among the studies is unclear. It should be noted that Li *et al* reported that HCCs with *p16* methylation were only found in individuals with hepatitis B virus (HBV) or hepatitis C virus (HCV) infection and not in virus-negative individuals<sup>4</sup>. Since many other studies have found rare homozygous deletions and infrequent mutations of *p16* in HCCs<sup>17-19</sup>, epigenetic changes may be the main reason for p16 inactivation in hepatitis virus-associated HCC, while genetic mutations of p16 may occur in specific geographical conditions and pedigrees.

## MOLECULAR MECHANISM OF p16 DNA METHYLATION IN HCC

The molecular basis of the aberrant hypermethylation of CpG islands of p16 observed in many cases of HCC is unknown. One possible mechanism is upregulation of DNA (cytosine-5)-methyltransferase (DNMT), which is widely assumed to be responsible for most of

the methylation of the human genome. Unfortunately, however, the relationship between DNA methyltransferase and gene methylation in cancer cells is controversial. For example, Eads *et al* reported that deregulation of DNA methyltransferase gene expression in human colorectal cancer cells did not play a role in establishing tumor-specific abnormal DNA methylation patterns<sup>20</sup>. Furthermore, Rhee *et al* reported that the p16 gene remained fully methylated and silenced in colorectal carcinoma cells lacking DNMT1, while genetic disruption of both DNMT1 and DNMT3b nearly eliminated methyltransferase activity and reduced genomic DNA methylation by more than 95%, indicating that cooperation of these two enzymes may be essential for maintaining DNA methylation in cancer cells<sup>21,22</sup>. In contrast, Robert *et al* reported that specific depletion of DNMT1, but not DNMT3a or DNMT3b, markedly potentiated the ability of the demethylating agent 5-aza-2'-deoxycytidine to reactivate silenced tumor-suppressor genes<sup>23</sup>, suggesting that DNMT1 may be sufficient for maintaining CpG island methylation in human cancer cells.

Histone deacetylation is another possible mechanism of p16 methylation, since DNA methylation and repressive chromatin characterized by histone deacetylation appear to act as synergistic layers for the silencing of global genes. However, the molecular relationship between p16 and histone deacetylation is not clear. Cameron *et al* reported that hypermethylated genes, including p16, cannot be transcriptionally reactivated with trichostatin A (a specific inhibitor of histone deacetylase)<sup>24</sup>. Zhu *et al* reported that p16 repressed in human lung cancer cells was induced by synergistic cooperation of depsipeptide (an inhibitor of histone deacetylase) and 5-aza-2'-deoxycytidine<sup>25</sup>. Interestingly, however, they also reported that cells treated with higher concentrations of 5-aza-2'-deoxycytidine and depsipeptide showed decreased p16 expression together with significant suppression of cell growth<sup>25</sup>. These lines of evidence indicate that the molecular mechanism of p16 DNA methylation in cancer cells may vary among different types of cancer cells.

It is noteworthy that Guan *et al* reported a close relationship between K-ras mutations and p16 methylation in colon cancer, by showing that a K-ras-transformed colon cancer cell line exhibited increased DNA methyltransferase activity and p16 gene methylation<sup>26</sup>. In HCC, Weihrauch *et al* reported that frequent K-ras mutations and p16 methylation were found in vinyl chloride-induced HCC<sup>27</sup>, suggesting that K-ras mutations may be important events in p16 inactivation in chemically-induced HCC. Although there have been no reports of the relationship between hepatitis virus infection and K-ras mutation, these reports may shed new light on why p16 is inactivated in many cases of HCC. A thorough examination of the relationship between p16 methylation and K-ras mutations in HCC is awaited.

## p16 GENE IS METHYLATED DURING THE EARLY STEPS OF HEPATOCARCINOGENESIS

Several recent studies have revealed that *p16* is methylated in some sets of individuals with non-HCC liver tissues

associated with chronic hepatitis virus infection. Kaneto *et al* reported that *p16* methylation was detected in 5 of 17 (29.4%) cirrhosis patients and 4 of 17 (23.5%) chronic hepatitis patients, all of whom were associated with HBV or HCV infection, but not in normal liver and other non-viral liver diseases<sup>[3]</sup>. Similarly, Li *et al* reported that the *p16* gene was methylated in 6 of 38 (16%) HBV-infected or HCV-infected chronic hepatitis and cirrhosis patients bearing HCC<sup>[4]</sup>. We found that *p16* was methylated in 4 of 112 (4%) liver cirrhosis patients<sup>[5]</sup>, all of whom were infected with HCV (personal communication). Although the ratio of *p16* DNA methylation in non-HCC liver tissues observed in our study was low compared with previous studies, these lines of evidence suggest that hepatitis virus infections may play roles in the induction of *p16* promoter methylation. Very recently, Jung *et al* reported that HBV X protein induced DNA hypermethylation of the *p16* promoter to repress its expression and led to transcriptional activation of DNMT1 *via* the cyclin D1-CDK4/6-pRb-E2F1 pathway<sup>[28]</sup>, suggesting a close relationship between hepatitis virus infections and aberrant methylation of the *p16* gene. Therefore, examinations of the degree of *p16* DNA methylation in non-HCC liver tissues with hepatitis virus infections, by bisulfate sequencing for example, may be of use for further elucidating the roles of hepatitis viruses in *p16* inactivation in the liver.

### CLINICAL SIGNIFICANCE OF p16 IN HCC

To investigate the clinical significance of *p16* inactivation in HCC, we evaluated the labeling index (LI) of *p16* in HCCs by immunohistochemical staining and found that the proportion of tumors with negative staining increased as the histopathologic grading of the tumors tended to become more poorly differentiated. Similarly, Ito *et al* reported that the *p16* LI was significantly decreased in cases with advanced-stage HCC<sup>[29]</sup>. However, regarding the prognosis of individuals with HCC, *p16* does not seem to be an independent risk factor. Tannapfel *et al* reported that they were unable to establish alterations of the *p16* locus as an independent prognostic factor for HCC<sup>[30]</sup>. Anzola *et al* found no associations between *p16* inactivation and clinicopathological characteristics or prognosis<sup>[31]</sup>, and suggested that this may arise because *p16* potentially plays an important role in hepatocarcinogenesis and is frequently altered from the early stages of HCC. As described later, we recently found that the status of *p16* affects the prognosis of HCC with *p27* overexpression<sup>[6]</sup>, indicating *p16* may become a supportive prognostic factor in HCC when combined with other prognostic factors. In other words, *p16* may become an important therapeutic target for HCC. Although there have been little studies of the relationship between the level of CDK4/6 activities and *p16* inactivation in HCC patients, the fact that *p16* is widely inactivated in HCC does give us the idea that a clinical trial of CDK4/6-selective inhibitor in patients with HCC may be hopeful.

### REGULATORY MECHANISM OF p27

*p27* is a member of the KIP family of CDKs<sup>[32,33]</sup>, which negatively regulates the G1-S phase transition by inhibiting

the kinase activities of CDK2/cyclin A and CDK2/cyclin E complexes. During the cell cycle, the *p27* protein level is highest at G0/G1 phase and lowest at S phase, and is mainly regulated by protein degradation *via* a Skp1-Cullin-F-box protein (SCF)-type ubiquitin ligase complex that contains Skp2 as the substrate-recognizing subunit<sup>[34,35]</sup>. It has also been found that Skp2 acts as the main rate-limiting regulator for *p27* degradation<sup>[36-38]</sup> and that cyclin kinase subunit 1 (Cks1) is essential for efficient Skp2-dependent destruction of *p27*<sup>[39,40]</sup>.

### p27 IS AN ADVERSE PROGNOSTIC FACTOR IN HCC

It is noteworthy that *p27* is widely regarded as an adverse prognostic indicator in many types of cancers, since decreased or absent expression of *p27* is frequently observed in cell nuclei in various types of human cancers with poor prognoses<sup>[41]</sup>. In HCC, many studies have reported that decreased *p27* expression is closely associated with clinical invasiveness of the tumors. Ito *et al* reported that the *p27* LI was significantly decreased in cases with portal invasion, poor differentiation, larger size and intrahepatic metastasis among 104 HCC cases examined<sup>[29]</sup>, and suggested that *p27* can act as an independent predictor of HCC recurrence among several types of G1-S cell-cycle regulators (e.g., pRb, p21, p16, p53, cyclin D1 and cyclin E). Fiorentino *et al* examined 54 HCC cases and reported that high expression of *p27* was a favorable independent prognostic parameter<sup>[42]</sup>. Tannapfel *et al* reported that *p27* was decreased in advanced cases in a series of curatively resected HCCs<sup>[43]</sup>. Qin *et al* reported that longer disease-free survival rates were observed in patients whose tumors had higher *p27* (KIP1) expression<sup>[44]</sup>. Armengol *et al* reported that *p27* constituted an independent predictor of recurrence after surgical resection in 46 cirrhotic patients with small HCCs<sup>[45]</sup>. Zhou *et al* reported that the LI of *p27* was associated with differentiation, invasiveness and metastasis of tumors among 45 HCC cases examined<sup>[46]</sup>. Similar to these previous reports, we found that HCCs expressing low levels of *p27* (low-*p27* expressers; *p27* LI of < 50% in the tumor cells), as evaluated by immunohistochemical staining, showed significantly favorable prognoses compared with individuals with HCCs showing high *p27* expression (high *p27* expressers; *p27* LI of > 50%). Kaplan-Meier survival curves revealed that the 5-year survival rates of the low-*p27* and high-*p27* expressers were 62% and 93%, respectively, and log-rank tests revealed that low *p27* expression was associated with a higher relative risk of dying from HCC than high *p27* expression<sup>[6]</sup>. Taken together, *p27* can be regarded as a powerful clinical indicator for prognosis prediction in individuals with HCC.

### p27 IS OVEREXPRESSED IN SOME SETS OF AGGRESSIVE HCCS

As described above, many studies have suggested that decreased *p27* expression can be regarded as a risk factor in individuals with HCC. Recently, however, extensive

studies have unraveled a novel aspect of the role of p27. Sganmbato *et al* reported that the levels of p27 were significantly increased in some breast cancer cell lines that exhibited exponential growth and high levels of cyclin D1 and cyclin E<sup>[47]</sup>. Fredersdorf *et al* reported that p27 expression was increased in some cases of highly proliferative breast cancer cells overexpressing cyclin D1<sup>[48]</sup>. Interestingly, Ciaparrone *et al* reported that a subset (35%) of colorectal carcinomas displayed diffuse cytoplasmic staining for p27 by immunohistochemical staining<sup>[49]</sup>, and Singh *et al* reported that cytoplasmic localization of p27 was associated with decreased survival in Barrett's associated adenocarcinoma<sup>[50]</sup>.

To comprehensively investigate the clinical significance of p27, we thoroughly examined the p27 status in HCC by immunohistochemical staining and found that the Ki-67 LI, a proliferation marker, varied from low to high among the high-p27 expressers (p27 LI of > 50%). Our results indicated that the tumors could be categorized into two groups according to a Ki-67 LI threshold of 20%, revealing that 26 of 40 (65%) high-p27 expressers had a Ki-67 LI of < 20% (2%-13%), while the remaining 14 (35%), including all 7 cases with cytoplasmic p27 immunostaining, had a Ki-67 LI of > 20% (22%-42%)<sup>[6]</sup>. To address the reason for the different cell proliferation status among high-p27 expressers, the kinase activity of CDK2 was analyzed in HCC samples from the high-p27 expressers. The results revealed that the CDK2 activities were low in 8 of 12 (67%) tumors with a Ki-67 LI of < 20%, but 5-8-fold higher in the remaining 4 cases. In contrast, the kinase activities in all 8 HCC cases in a subgroup with a Ki-67 LI of > 20% were significantly higher (20-fold-50-fold higher than their matched non-tumorous liver samples). Heating the tumor sample lysates effectively reduced the CDK2 activities, indicating that p27 *per se* was functional and not inactivated by either DNA mutations or genetic loss, since p27 is heat-stable. These lines of evidence indicate that p27 does not simply act as a tumor suppressor in some types of cancer cells, and that a thorough examination of the biological status of p27 should be performed.

### **FUNCTIONAL INACTIVATION OF p27 IS CLOSELY ASSOCIATED WITH SEQUESTRATION TO CYCLIN D1-CDK4-COMPLEXES**

To understand the molecular mechanism of the different levels of kinase activities among the high-p27 expressers, examination of the components of p27-containing complexes may be useful, since it has been reported that sequestration of p27 from CDK2 to cyclin D1-containing complexes results in a blockade of p27 functions as well as stabilization of active cyclin D1-CDK4/CDK6 complexes<sup>[51,52]</sup>. Therefore, we performed immunoprecipitation assays using 20 tissue sample lysates from high-p27 expressers and found that, in 12 tumors with low levels of kinase activities (< 8-fold relative to the levels in adjacent non-tumorous tissues), p27 was closely

associated with CDK2 in 8 samples and faintly associated with cyclin D1-CDK4 complexes in 4 samples. In contrast, in all 8 HCC samples with high levels of kinase activities (20-fold-50-fold higher relative to the levels in adjacent non-tumorous tissues), high levels of cyclin D1-CDK4-bound p27 were detected. These pieces of evidence strongly indicate that compositional changes in the complexes containing p27 may be an alternative reason for the increased cell proliferation in p27-overexpressing HCC.

### **THE COMPOSITIONS OF COMPLEXES CONTAINING p27 VARY AMONG HIGH p27 EXPRESSERS**

Several cell-cycle regulatory factors are known to influence the compositional status of p27-containing complexes. For example, cyclin D1 and CDK4 mobilize p27 from cyclin E-CDK2 complexes to cyclin D-CDK4 complexes, while p15 and p16 shift p27 to associate with cyclin E-CDK2 complexes<sup>[53,54]</sup>. We examined the expressions of these cell-cycle regulatory factors in high-p27 expressers, and found that p16 was closely correlated with the status of complexes containing p27, while CDK4 and cyclins D1, D3 and E were not. Our results revealed that p16 was expressed in 9 of 12 high-p27 expressers in which p27 was predominantly associated with CDK2, but was undetectable in all 8 HCCs in which p27 was closely associated with cyclin D1-CDK4 complexes<sup>[6]</sup>. Although there have been no other reports of the molecular relationships between p16 and p27-containing complexes, it is noteworthy that Sanchez-Beato *et al* reported a close relationship between p16 loss and anomalous p27 expression in aggressive B-cell lymphomas<sup>[55]</sup>. Further studies are needed to address whether the status of p16 influences any clinicopathological characteristics in human tumors expressing high levels of p27.

### **p16 DETERMINES THE PROGNOSIS OF HCCS WITH p27 OVEREXPRESSION**

To further investigate the functional role of p16 in the cell proliferation status of high-p27 expressers, we examined the LIs of p16 and Ki-67 in HCCs and found that the p16 LI was inversely correlated with the Ki-67 LI in high-p27 expressers. Immunohistochemical analyses revealed that p16 staining was positive in all 26 (100%) high-p27 expressers with a Ki-67 LI of < 20%, but negative in 12 of 14 (85%) high-p27 expressers with a Ki-67 LI of > 20%. Interestingly, methylation of the *p16* gene promoter was not detected in all 26 (100%) samples with positive p16 immunostaining, but was detected in 10 of 12 (83%) samples with negative p16 immunostaining. Therefore, we surmise that epigenetic changes of the *p16* gene may be the main cause of the p27 inactivation in HCCs that express considerable amounts of p27. Since we also found that loss of p16 expression was an independent prognostic factor for a poor outcome in high-p27 expressers compared with standard prognostic variables<sup>[6]</sup>,

assessment of the *p16* status may be useful for precise prognostic prediction in individuals with HCCs expressing high levels of p27.

## FORKHEAD TRANSCRIPTION FACTORS AND p27

Recently, Forkhead box M1B (Foxm1b), a ubiquitously expressed member of the Forkhead Box (Fox) transcription factor family, has been focused upon as another regulatory factor of p27 expression. Foxm1b expression is restricted to proliferating cells and mediates both hepatocyte entry into DNA synthesis and mitosis during liver regeneration<sup>[56,57]</sup>. Wang *et al* showed that regenerating livers in aged mice exhibited diminished Foxm1b expression with significant reductions in hepatocyte proliferation and increased levels of p27 expression<sup>[58]</sup>, thereby providing new evidence that Foxm1a regulates p27 at the protein level. Kalinichenko *et al* reported that Foxm1b was essential for the development of a rodent HCC model, and its mechanism was associated with reduced expression of p27 and increased expression of the CDK1-activator Cdc25B phosphatase<sup>[59]</sup>. More significantly, they also showed that Foxm1b was a novel inhibitory target of the p19 (ARF) tumor suppressor, and that a peptide containing p16 may represent a potential therapeutic agent toward Foxm1b overexpressing cancer cells. Since FoxM1 is essential for transcription of *Skp2* and *Cks1*<sup>[60]</sup>, which are specificity subunits of the SCF ubiquitin ligase complex that targets p27, examining the relationship between Foxm1b and p27 in human HCC may help toward understanding of the molecular mechanism of hepatocarcinogenesis.

## CONCLUSION

HCC is one of the most common human cancers, and its incidence is still increasing in civilized countries. HCC represents the fifth most-common malignant disease in the world and is the third most-common cause of cancer-related death worldwide<sup>[61,62]</sup>. The etiology of HCC is unique in that most HCC cases are associated with liver cirrhosis or chronic hepatitis attributable to HBV or HCV infection, chronic alcohol abuse and, more recently, non-alcoholic steatohepatitis<sup>[63]</sup>. Since the prognosis of HCC patients remains poor, identification of useful molecular prognostic markers for HCC is required. As described in the present review, coordinated examination of the p16 and p27 statuses may become a more accurate tool for predicting the prognosis of HCC. Further studies of cell-cycle regulators will provide better insights into the mechanism of hepatocarcinogenesis.

### Abstract

As for many other tumors, development of hepatocellular carcinoma (HCC) must be understood as a multistep process with accumulation of genetic and epigenetic alterations in regulatory genes, leading to activation of oncogenes and inactivation or loss of tumor suppressor genes (TSG). In the last decades, in addition to genetic alterations, epigenetic inactivation of (tumor suppressor) genes by promoter hypermethylation has been recognized as an important and alternative mechanism in tumorigenesis. In HCC, aberrant methylation of promoter sequences occurs not only in advanced tumors, it has been also observed in premalignant conditions just as chronic viral hepatitis B or C and cirrhotic liver. This review discusses the epigenetic alterations in hepatocellular carcinoma focusing DNA methylation.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common cancer worldwide. It shows a wide geographical variation with low incidence areas in North America and Europe and high incidence areas in Africa and Asia.

70%-80% of hepatocellular carcinoma occurs in cirrhotic liver. In high incidence areas, such as Asia and Africa, HCC is strongly associated with chronic viral hepatitis B and C and liver cirrhosis. Nutritional factors, toxins and metabolic diseases contribute also to hepatocarcinogenesis<sup>[1,2]</sup>.

As for many other tumors, development of HCC is due to a multistep process with accumulation of genetic and epigenetic alterations in regulatory genes, leading to activation of oncogenes and inactivation or loss of tumor suppressor genes (TSG).

In the last three decades, cancer has been understood as a summary of altered genetic and epigenetic events. The epigenetic pathway is, in contrast to genetic events, a reversible alteration and characterized by three main mechanisms: (1) DNA hypermethylation leading to inactivation, (2) DNA hypomethylation causing genomic instability, (3) histone modifications affecting chromatin conformation.

These processes, especially aberrant DNA methylation and histone modifications, are closely linked with each other by a protein complex of transcript activators and repressors and alter mRNA transcript expression of affected genes<sup>[3]</sup>.

Characteristically, DNA methylation does not change the genetic information. It just alters the readability of the DNA and results in inactivation of genes by subsequent mRNA transcript repression.

In humans and other mammals, CpG island methylation is an important physiological mechanism. The inactivated X-chromosome of females, silenced alleles of imprinted genes or inserted viral genes and repeat elements are inactivated through promoter methylation<sup>[4,5]</sup>.

### DNA HYPERMETHYLATION

#### Promoter hypermethylation

Hypermethylation of CpG islands in promoter sequences is associated with silencing of tumor suppressor genes and tumor-related genes by subsequent downregulation of mRNA transcript expression. Epigenetic silenced genes are involved in important molecular pathways of carcinogenesis e.g., cell cycle regulation, apoptosis, DNA repair or cell adhesion.

According to other types of malignant tumors, in hepatocellular carcinomas, aberrant methylation of several TSG and tumor-related genes such as *RASSF1A*, *bMLH1* or *SOC31* was frequently observed<sup>[6]</sup>.

CpG island hypermethylation is not only seen in HCC

Table 1 Methylation in hepatocellular carcinoma

Gene	Location	Function	Methylation frequency (%)	Ref.
p16 <sup>INK4a</sup>	9q21	CDK inhibitor	17-83	[10,11]
p14 <sup>ARF</sup>	9q21	MDM2 inhibitor	25-30	[7,12]
CASP8	2q33	Apoptosis	72	[17]
TMS1/ASC	16p11.2	Apoptosis	80	[23]
E-Cadherin	16q22.1	Cell adhesion	33-67	[28-30]
M-Cadherin	16q24.1	Cell adhesion	55	[34]
H-Cadherin	16q24.2-3	Cell adhesion	21	[17]
TIMP3	22q12	MMP inhibitor	13-19	[37-39]
hMLH1	3p21.3	Mismatch repair	18-44	[47-50]
hMSH2	2p21-22	Mismatch repair	68	[47,49,50]
hMSH3	5q11-12	Mismatch repair	75	[47,49,50]
MGMT	10q26	DNA repair	22-39	[53-55]
GSTP1	11q13	Detoxification	41-58	[53,58-61]
SOCS-1	16p13.13	Cytokine inhibitor	60	[67]
SOCS-3	17q25.3	Cytokine inhibitor	33	[68]
RASSF1A	3p21.3	Apoptosis	54-95	[71,75,76]
BLU	3p21.3	Unknown	20	[71]
SEMA3B	3p21.3	Apoptosis	80	[71]
FHIT	3p14.2	histidine triad protein	71	[86]

tumor tissue. Even in premalignant conditions such as dysplastic nodules or cirrhotic liver, promoter methylation of several kinds of TSG, e.g. E-cadherin, *GSTP1* or *p16<sup>INK4a</sup>* was demonstrated (Table 1 shows promoter methylation of different tumor-related genes in HCC).

### Proliferation and apoptosis

One of the most important pathways affected in HCC are the Rb (Retinoblastoma) gene and INK4a-ARF pathway<sup>[7]</sup>. The INK4a-ARF locus is coding two cell-cycle regulatory proteins, *p16<sup>INK4a</sup>* and *p14<sup>ARF</sup>*, acting through the Rb-CDK4 and p53 pathways. *p16<sup>INK4a</sup>* binds to cyclin-dependent protein kinase 4 (CDK4) and inhibits the ability of CDK4 to interact with cyclin D1. *p14<sup>ARF</sup>* prevents the *p53* degradation through its binding to MDM-2 and induces cell cycle arrest<sup>[8,9]</sup>.

*p16<sup>INK4a</sup>* is one of the most altered tumor suppressor gene in human cancer. In HCC, loss of *p16<sup>INK4a</sup>* is mainly caused by aberrant promoter methylation, whereas deletions and mutations of this gene locus are infrequently seen. CpG island promoter methylation was reported from 55% to 73%, but aberrant methylation occurred also in non-cancerous liver tissue with cirrhosis in 29% or chronic hepatitis B and C up to 23%<sup>[10,11]</sup>. Compared to *p16<sup>INK4a</sup>* methylation, *p14<sup>ARF</sup>* promoter methylation was observed less frequently in 8% to 20% of HCC. It was demonstrated that inactivation of *p14<sup>ARF</sup>* is due to homozygous deletions. No correlation was found between *p53* mutations and promoter methylation of *p16<sup>INK4a</sup>* or *p14<sup>ARF</sup>*<sup>[7,12]</sup>.

Caspase 8 (CASP8) is a key apoptotic gene that is involved in death receptor and the mitochondrial pathways and acts as initiator CASP<sup>[13]</sup>. *CASP8* is silenced by aberrant hypermethylation of its promoter in childhood neuroblastomas<sup>[14,15]</sup>. In HCC, *CASP8* aberrant promoter methylation was reported by Yu *et al*<sup>[16]</sup> with a frequency up to 72%.

*TMS1/ASC*, another proapoptotic gene, functions as a negative regulator of nuclear factor kappaB (NF-κB) and

blocks transcription of survival signals<sup>[17]</sup>. First, *TMS1* was identified as a target of methylation-induced silencing in cell lines overexpressing DNMT1. Epigenetic inactivation of *TMS1* was demonstrated in human glioblastomas, ovarian cancer, human melanoma, colorectal carcinomas or in lung cancer and breast cancer<sup>[18-22]</sup>. In HCC, *TMS1* promoter methylation was observed in 80%<sup>[23]</sup>.

In hepatocellular carcinoma cell lines, restoration of *TMS1* transcript was induced by demethylating agent 5'-AZA and trichostatin, a histone deacetylase inhibitor. Furthermore, in these cell lines *TMS1* DNA methylation was associated with histone H3 lysine 9 hypoacetylation and trimethylation<sup>[24]</sup>.

### Cell adhesion and invasion

**E-cadherin (CDH1):** E-cadherin, a member of calcium-mediated membrane glycoproteins, is expressed in all epithelial cells acting as an adhesion molecule. Inactivation of E-cadherin induces loss of adherens junctions and impairment of cell adhesiveness and cell proliferation signalling pathways. In tumours, reduction of E-cadherin expression results in tumour progression, cell invasion and formation of metastasis<sup>[25,26]</sup>.

Downregulation of E-cadherin, caused by genetic and epigenetic mechanism, is a frequent event in most type of epithelial carcinomas. In poorly-differentiated breast and gastric cancer, somatic mutations of E-cadherin are frequently found. Further, in all cases of familial gastric cancer, loss of E-cadherin is mainly caused by germline mutations<sup>[27]</sup>. In other types of tumors, mutations are infrequent events and repression of E-cadherin is mainly caused by aberrant promoter methylation.

In according to CC, mutations of E-cadherin are rare events in HCC. Reduced or loss of E-cadherin expression is mainly caused by aberrant CpG island methylation with a detectable frequency from 33% to 67%<sup>[28-30]</sup>. Wei *et al*<sup>[31]</sup> described, that loss of E-cadherin was closely associated with loss of heterozygosity (LOH) of E-cadherin and CpG hypermethylation. In precancerous conditions just as dysplastic nodules or liver tissue with chronic hepatitis or cirrhosis, aberrant E-cadherin methylation was detected in 8% and 46%, respectively<sup>[29,30]</sup>.

Other factors, except epigenetic inactivation or mutations, leading to inactivation of E-cadherin include transcriptional repression by binding of transcriptional factors, e.g. the repressors Snail or Sip-1 to CDH1-E box elements<sup>[32,33]</sup>.

But not only E-cadherin, as a member of cadherin genes, is epigenetically altered in HCC. Yamada *et al*<sup>[34]</sup> reported the highest methylation frequency of M-cadherin with a frequency to 55% among seven elucidated cadherin genes. Methylation-induced silencing of H-Cadherin (CDH13) was observed by Yu *et al*<sup>[17]</sup>, reaching 21%.

**TIMP-3:** Tissue inhibitor of metalloproteinase-3 (*TIMP-3*) leads to inhibition of cell migration and angiogenesis. In human carcinoma cell lines, overexpression of *TIMP-3* suppresses cell growth and induces apoptosis by stabilization of TNF-alpha receptors on the cell surface<sup>[35,36]</sup>. A *TIMP-3* downregulation was demonstrated

in different kinds of tumors, mostly mediated by CpG island promoter methylation<sup>[6]</sup>.

In HCC, *TIMP-3* methylation is an infrequent event reaching 13% to 19%. No methylation was found in normal liver tissue. Lü *et al.*<sup>[37]</sup> demonstrated *TIMP-3* methylation in 25% of hepatocellular cancer emboli in portal veins. The aberrant promoter methylation is accompanied by loss or reduced *TIMP-3* mRNA and protein expression<sup>[37-39]</sup>.

**TFPI-2:** *TFPI-2* is a Kunitz-type serine protease inhibitor that represses cellular invasion in several kinds of tumors, e.g. in lung cancer or pancreas carcinomas, by suppressing plasmin-mediated activation of MMP-1 and MMP-3 or inhibition of plasmin and trypsin activity<sup>[40-43]</sup>.

Wong *et al.*<sup>[44]</sup> observed *TFPI-2* downregulation with reduced or loss mRNA transcript expression in HCC with a frequency of 90%. In 47% of the observed HCC, aberrant CpG methylation was seen, but not in normal liver tissue. In HCC cell lines with epigenetically induced silencing, a *TFPI-2* mRNA transcript re-expression was induced by combined treatment with the demethylating agent 5'-AZA-DC and the histone deacetylase inhibitor TSA.

#### DNA repair

**Mismatch repair system:** Defects in DNA repair mechanisms may result in accumulation of mutations and genomic instability. The mismatch repair system (MMR) is one of the most important DNA repair mechanisms correcting errors in DNA replication. Defects of the MMR leading to microsatellite instabilities (MSI) have been observed in approximately 15% of sporadic colorectal and gastric carcinomas<sup>[45,46]</sup>. Promoter methylation of MMR genes in HCC occurred with a frequency of 5% to 13% for *bMLH1*, 68% for *bMSH2* and 75% for *bMSH3*. A high methylation frequency of *bMSH2* and *bMSH3* was observed in HCC corresponding non neoplastic liver tissue, especially in cirrhotic liver tissue, reaching 55 % and 70%, but not in normal liver tissue. No correlation was found neither to viral hepatitis nor to MSI status and DNA methylation of analyzed MMR genes<sup>[47-50]</sup>.

#### MGMT (O6-methylguanine DNA methyltransferase):

O6-methylguanine DNA methyltransferase (*MGMT*) is another important DNA repair gene with the highest activity in the liver<sup>[51]</sup>. *MGMT* protects cells from DNA damage caused by mutagenic and cytotoxic agents leading to alkylation at O6-guanine. Loss or reduced *MGMT* expression due to CpG islands methylation was detected in several kinds of human cancers<sup>[52]</sup>. In HCC, aberrant methylation occurred with a frequency of 22% to 39%, whereas the *MGMT* promoter shows higher methylation levels in chronic viral hepatitis associated HCC<sup>[53-55]</sup>. Interestingly, Su *et al.*<sup>[53]</sup> reported that *MGMT* promoter methylation occurred to a similar extent in non neoplastic liver tissue compared to HCC.

**GSTP1 (Glutathione S-transferase P1):** The detoxifying glutathione S-transferase P1 (*GSTP1*) gene protects cells from cytotoxic and carcinogenic influences

in due to inactivation of electrophilic carcinogens by conjugation with glutathione. Promoter methylation of *GSTP1* is best analyzed in prostate cancer. *GSTP1* methylation is an early event in prostatic carcinogenesis, because in high-grade prostatic intraepithelial neoplasia loss of *GSTP1* expression is caused by DNA methylation. Many other tumor types including breast cancer and cholangiocarcinoma showed a *GSTP1* hypermethylated promoter<sup>[56,57]</sup>. In HCC, methylation of the *GSTP1* gene occurred in 41% to 85%<sup>[53,58-61]</sup>. Zhang elucidated *GSTP1* methylation in HCC in presence of environmental chemical carcinogens. A significant correlation was observed with higher aflatoxin B<sub>1</sub> (AFB<sub>1</sub>)-DNA adducts in tumor tissue in contrast to tumor tissue without or lower levels of AFB<sub>1</sub>-DNA adducts. However, no association was found between *GSTP1* methylation and polycyclic aromatic hydrocarbon-DNA adducts<sup>[59]</sup>. So far, aberrant methylation of *GSTP1* is not only detectable in tumor tissue, Wang *et al.*<sup>[62]</sup> observed a *GSTP1* hypermethylation in serum of HCC patients.

**Suppressors of cytokine signaling (SOCS):** Suppressors of cytokine signaling 1 and 3 (SOCS-1 and SOCS-3) are intracellular proteins that act as negative regulators of Janus kinase (JAK) and signal transducer and activators of signaling pathways (STAT). The JAK/STAT signaling pathway plays an important role in cell growth and differentiation or immune reaction mediated by cytokines. Cytokines activate JAK's by binding to membrane receptors that leads to phosphorylation of STAT's and activates target genes. *SOCS1* and *SOCS-3* bind direct and indirect to JAK's and inhibit the phosphorylation of STAT's and activation of target genes<sup>[63,64]</sup>.

Aberrant methylation of *SOCS-1* and *SOCS-3* promoter sequence has been reported in several kinds of human cancer. *SOCS-1* and *SOCS-3* CpG island hypermethylation is an early event in human carcinogenesis. Recently, we have shown methylation-induced downregulation of *SOCS-1* and *SOCS-3* in precursor lesions of Barrett's adenocarcinomas and precursor lesions of squamous carcinomas of head and neck<sup>[65,66]</sup>. In HCC, aberrant promoter methylation of *SOCS-1* and *SOCS-3* occurred with a frequency of 60% and 33%, respectively<sup>[67,68]</sup>. Methylation of the *SOCS-1* gene was detected in HCV-induced chronic hepatitis and liver cirrhosis, reaching 45%, whereas the methylation frequency increased with fibrosis stage with the highest proportion in liver cirrhosis<sup>[69,70]</sup>.

#### Methylation hot spot 3p

The short arm of human chromosome 3 belongs to regional methylation hot spots in addition to chromosomal locus 11p and 17p. Alterations of the genetic information on chromosome 3 are one of the most frequent and earliest steps in the carcinogenesis of several types of tumors. LOH of chromosome 3p occurred in about 30% of hepatocellular carcinomas<sup>[71]</sup>.

In different kinds of human cancer, epigenetic inactivation *via* promoter methylation of several genes located on 3p, including *RASSF1A* on 3p21.3, *bMLH1* at 3p21.3, *RARB* 2 at 3p24.2, was shown.

One of the most frequent observed and most

epigenetically inactivated genes of 3p is *RASSF1A*, a multifunctional tumor suppressor gene that protects cells from genomic instability and transformation by stabilizing the microtubules<sup>[72,73]</sup>. An aberrant promoter methylation was detected in about 50% of malignant tumors. In renal cell carcinoma and small cell lung cancer, the highest prevalence was observed, reaching about 91%<sup>[74]</sup>. In HCC, hypermethylation occurred in approximately 54% to 95%, whereas HBV-associated HCC showed higher levels of *RASSF1A* methylation compared to HCC without risk factors. *RASSF1A* methylation occurs not only in HCC, methylation is even observed in non-neoplastic precancerous conditions like cirrhotic liver and chronic hepatitis<sup>[71]</sup>.

Semaphorin 3B (*SEMA3B*) and *BLU* are two other putative tumor suppressor genes located on 3p21.3, whereas the function of *BLU* still remains unclear. In lung cancer, *BLU* overexpression inhibits tumor colony formation efficiency. Qiu *et al*<sup>[77]</sup> reported that *BLU* might function as an environmental stress-responsive gene, regulated by E2F, at least in nasopharyngeal carcinomas. However, *BLU* methylation is a rare event in human cancer. We detected *BLU* promoter methylation in about 20% of our examined HCC<sup>[71,78]</sup>.

*SEMA3B*, a member of the Semaphorin family, suppresses tumor formation in lung cancer and induces apoptosis. It has been demonstrated that *SEMA3B* induced apoptosis is antagonized by *VEGF*<sup>165</sup> in due to an interaction with NP-1 receptor<sup>[79,80]</sup>.

Aberrant methylation of *SEMA3B* was detected in lung cancer and gliomas<sup>[81,82]</sup>. We reported a high prevalence of *SEMA3B* methylation in HCC, reaching 80%. In contrast, the tumor surrounding non-neoplastic liver exhibited an unmethylated *SEMA3B* promoter. Further, *RASSF1A* and *SEMA3B* expression was restored by treatment with the demethylating drug 5-AZA-C in HCC cell lines, suggesting that promoter hypermethylation is responsible for silencing transcript expression<sup>[71,72,81]</sup>.

The fragile histidine triad (*FHIT*) gene, located to 3p14.2, embraces FRA3b, the most actively fragile site in humans<sup>[83,84]</sup>. Functional and structural alterations of *FHIT* were identified in several kinds of human cancer. Methylation induced silencing was described in lung and breast cancers<sup>[85]</sup>. In HCC, promoter methylation of *FHIT* is a frequent and early event. Sun *et al*<sup>[86]</sup> observed *FHIT* hypermethylation with a frequency of 71% in HCC, 64% in non neoplastic liver tissue and 14 % in normal liver.

### CpG island methylator phenotype (CIMP)

Carcinomas with high rates of accumulated aberrant promoter methylation of tumor-related genes are characterized as CIMP<sup>+</sup> (CpG island methylator phenotype). CIMP<sup>+</sup> was first described for colorectal and gastric cancer by Toyota and Issa in 1999<sup>[87,88]</sup>. Shen *et al*<sup>[89]</sup> reported that CIMP<sup>+</sup> is associated with environmental exposures in HCC. HCC from patients without precancerous conditions or risk factors, respectively, showed significantly lower levels of methylation than HCC arising from patients with chronic hepatitis B and C or patients with cirrhosis.

CIMP positive HCC (tumours with five genes that

are concordantly methylated) showed a significantly association with methylation of the TSG *p14*, *p15*, *p16 ER*, *RASSF1A* or *WT1* and elevated serum alpha-fetoprotein (AFP) levels. Further, CIMP<sup>+</sup> was commonly seen in HCC with increased serum AFP levels<sup>[90,91]</sup>.

### DNA-methyltransferases (DNMT)

DNA hypermethylation is catalyzed by the family of DNA methyltransferases (DNMT) including DNMT1, DNMT3a and DNMT3b. DNMT1 is required for maintenance of DNA methylation whereas DNMT3a and DNMT3b function as de novo DNA methyltransferases<sup>[92-94]</sup>. DNMT2 was former described as DNMT because of its strong similarity with m5C methyltransferases of pro- and eukaryotes. But it was recently shown that DNMT2 does not methylate DNA. It's the first described RNA cytosine methyltransferase that methylate position 38 in Aspartic acid transfer RNA<sup>[95]</sup>.

In human cancer just as in HCC, an upregulation of DNMT activity is seen in contrast to global hypomethylation. Park *et al*<sup>[96]</sup> described a significantly overexpression of DNMT1 and DNMT3b in HCC compared to non-neoplastic liver tissue. DNMT3a showed similar or higher expression levels. Saito *et al*<sup>[97]</sup> observed higher expression levels of all three DNMTs in HCC and cirrhotic liver than in normal liver. Increased DNMT1 and DNMT3a expression was also reported in dysplastic nodules<sup>[98]</sup>.

According to other tumors, no correlation was seen between DNMT upregulation and promoter hypermethylation-induced inactivation of tumor-related genes. The certain mechanisms of DNMT upregulation remains still unclear, but it is suggested that aberrant DNMT activity, especially of DNMT1, is due to rapid proliferation of cancer cells because DNMT1 binds to proliferating cell nuclear antigen (PCNA)<sup>[99-101]</sup>.

DNA hypomethylation on pericentromeric satellite regions results in chromosomal instability. During hepatocarcinogenesis, DNA hypomethylation of these regions was reported in HCC and precancerous conditions. The splice variant of DNMT3b, DNMT3b4 that may lack DNA methyltransferase activity is associated with DNA hypomethylation on pericentromeric satellite regions. Saito *et al*<sup>[102]</sup> reported that overexpression of DNMT3b4 was seen in cirrhotic liver, chronic hepatitis and HCC whereas increased DNMT3b4 levels correlated with DNA hypomethylation on pericentromeric satellite regions.

### DNA HYPOMETHYLATION

In human cancer, global DNA hypomethylation leads to genomic instability, affects repeated DNA sequences, tissue-specific genes and proto-oncogenes or causes loss of imprinting with a biallelic expression, just as in case of *IGF2*. Further, the level of DNA hypomethylation increases with tumor progression<sup>[103,104]</sup>. In recent years, DNA hypomethylation was shown in several human cancer and some premalignant alterations, i.e. colorectal adenomas and carcinomas, adenocarcinoma of prostate, breast cancer or intestinal type of gastric carcinoma and hepatocellular carcinoma, respectively<sup>[105-108]</sup>.

Lin *et al.*<sup>[109]</sup> observed 5-methylcytosine (m5C) content in hepatocellular carcinogenesis by comparing hepatocellular carcinoma with non neoplastic liver, including cirrhotic livers. In all cancer tissues, 5-methylcytosine was significantly reduced. No difference of the m5C content was detected in cirrhotic and non cirrhotic liver tissue. The reduced 5mC level was associated with large tumor size and poorly histopathological grade.

It is suggested that (re-)activation of retroposons might be associated with global hypomethylation because approximately 90% of all m5C lies in these elements. An association between hypomethylation and transposon activation, especially of LINE-1 transposons, has been observed in human testicular carcinoma cell lines, urothelial carcinoma cell lines and teratocarcinoma cell lines<sup>[110-112]</sup>. But in HCC, an activation of transposable elements just as LINE-1 retrotransposons *via* hypomethylation could not be detected yet<sup>[109]</sup>.

## HISTONE MODIFICATION

Histone modifications are strongly associated with formation of the nucleosome structure and are closely linked to CpG island methylation by interacting with Methyl-CpG-binding proteins (MBD's) and DNA methyltransferases (DNMT's). Modifications including methylation, acetylation or phosphorylation of certain position of the histone tails. Whereas histone methylation is associated either to activation or to repression, histone hypoacetylation mediated by histone deacetylases leads mostly to DNA relaxation and subsequent accessibility for transcriptional factors with repression of transcription.

Lee *et al.*<sup>[113]</sup> reported that HCC with low survival expressed higher levels of genes involved in histone modifications just as PTMA and SET, two proteins that are members of inhibitors of histoneacetyltransferases complex.

p73, a member of the TP53 family represses AFP expression during normal hepatic development by chromatin structure alterations. In hepatoma cells, transactivated p73 suppresses endogenous AFP transcription via reducing of acetylated histone H3 lysine 9 and increasing dimethylated histone H3 lysine 9<sup>[114]</sup>.

## CONCLUSION

In hepatocarcinogenesis, aberrant methylation of tumor related genes occurs not only in advanced tumour stages, it's a frequent and early event. Promoter methylation of different kinds of tumor suppressor genes including *p16*, *SOC31* and *SOC33* or *RASSF1A*, has been demonstrated in premalignant conditions just as chronic hepatitis or liver cirrhosis. Moreover, the frequency of aberrant promoter methylation increases during the progression from precancerous lesion to HCC. In HBV or HCV-associated chronic hepatitis, methylation frequency of detected genes is significantly higher than in non-neoplastic non-viral liver tissue. Therefore, epigenetic changes in preneoplastic or early neoplastic stages may serve as indicator or "biomarker" for screening of patients with an increased risk for HCC.

Further, HCC is one of the most common causes of cancer death worldwide with a poor prognosis. Only few therapeutic interventions exist. It was demonstrated that re-expression of tumor suppressor genes that are epigenetically silenced is possible by using demethylating and histone modifying agents. In the next years, this might be a possible therapeutic approach analogue to other malignant diseases, e.g. myelodysplastic syndrome, but the used therapeutic agents that influence DNA hypermethylation are toxic and lead to genome wide alteration of the methylation pattern with possible activating of oncogenes or imprinted genes. Another possible aspect of chemotherapy might be to modulate the epigenetically involved pathways by using small molecules that are more specific. But further investigations in clinical trials are needed to prove and integrate epigenetic pathway modulating agents.

### Abstract

**AIM:** To look at a comprehensive picture of etiology-dependent gene abnormalities in hepatocellular carcinoma in Western Europe.

**METHODS:** With a liver-oriented microarray, transcript levels were compared in nodules and cirrhosis from a training set of patients with hepatocellular carcinoma (alcoholism, 12; hepatitis C, 10) and 5 controls. Loose or tight selection of informative transcripts with an abnormal abundance was statistically valid and the tightly selected transcripts were next quantified by qRTPCR in the nodules from our training set (12 + 10) and a test set (6 + 7).

**RESULTS:** A selection of 475 transcripts pointed to significant gene over-representation on chromosome 8 (alcoholism) or -2 (hepatitis C) and ontology indicated a predominant inflammatory response (alcoholism) or changes in cell cycle regulation, transcription factors and interferon responsiveness (hepatitis C). A stringent selection of 23 transcripts whose differences between

etiologies were significant in nodules but not in cirrhotic tissue indicated that the above dysregulations take place in tumor but not in the surrounding cirrhosis. These 23 transcripts separated our test set according to etiologies. The inflammation-associated transcripts pointed to limited alterations of free iron metabolism in alcoholic vs hepatitis C tumors.

**CONCLUSION:** Etiology-specific abnormalities (chromosome preference; differences in transcriptomes and related functions) have been identified in hepatocellular carcinoma driven by alcoholism or hepatitis C. This may open novel avenues for differential therapies in this disease.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is a primary liver cancer, the main causes of which are viral hepatitis (HBV; HCV), alcoholism or aflatoxin B1 intoxication. In most instances HCC develops in the setting of chronic hepatitis and/or cirrhosis. Numerous HCC-associated genomic and/or epigenomic alterations result in a dysregulated expression of genes and proteins<sup>[1,2]</sup>. Liver transcriptome analysis by microarray has resulted in the identification of numerous genes with an aberrant expression in HCC as compared to the surrounding cirrhosis<sup>[2-6]</sup>. Although mRNA down-regulation predominates in this context<sup>[7]</sup>, HCC-associated gene expression profiles largely vary between patient

subgroups<sup>[6,8]</sup>. This feature is of prognostic interest as different profiles are associated with the evolution rate or the occurrence of metastasis and relapse<sup>[2,4,9-11]</sup>. However, a comprehensive picture of altered gene regulation in HCC remains elusive<sup>[2,5,12]</sup>. Notably, the variety of etiologies with their associated abnormalities at the genome level is likely to promote distinct gene dysregulations and hence creates further complexity. For instance, the HBV- or HCV-induced genetic alterations are known to be different<sup>[9]</sup> and the associated transcriptomes have proven to vary significantly<sup>[13,14]</sup>. Therefore, deciphering the transcriptome patterns as a function of HCC etiology is of critical importance. However, the gene dysregulations in the context of alcohol abuse are poorly understood<sup>[15]</sup> and the associated transcriptome has seldom been studied. *A fortiori*, a comparison of liver transcriptomes in HCV virus- vs alcoholism-associated HCC has never been done. We now report that, among various findings, these transcriptomes differ in the cancerous nodules whereas, unexpectedly, they remain similar in the surrounding cirrhosis. This points to etiology-dependent mechanisms that take place at a relatively late stage of tumoral transformation.

## MATERIALS AND METHODS

### Human subjects and RNA sources

Liver fragments were obtained under strict anonymity from the digestive surgery unit of Charles Nicolle Hospital (Rouen, France). A fragment of a cancerous nodule as well as distant cirrhotic tissue were taken whenever an HCC resection was performed. In multinodular livers, only 1 nodule was studied, provided the tumor grade of this nodule was known. Control human livers were non-tumorous tissue from patients operated for benign liver tumor. Histopathology was carried out by a trained pathologist (AF). According to the current French rules and ethical guidelines, neither an informed consent nor advice from an ethical committee are requested prior to analysis of RNA in resected tissues that would otherwise be disposed off. Tissue storage and RNA extraction were done as described<sup>[16]</sup>.

### HCV- vs HBV-infection vs chronic alcohol abuse

Chronic alcohol abuse was defined as a regular, daily consumption of > 80 g or > 60 g ethanol in men or women, respectively, as estimated from three cumulated criteria, namely: (1) alcohol consumption, as indicated by the patient, (2) alcohol dependency, as evaluated from a specific interview and (3) blood level of several hepatic proteins (alanine aminotransferase, aspartate aminotransferase, gammaglutamyl transpeptidase). HBV infection was serologically assessed with the HBs antigen and anti-HBc antibodies (AxSYM kits from Abbott Laboratories). HCV infection was serologically determined by enzyme immunoassay (AxSYM HCV-3.0 kit from Abbott Laboratories). Both infections were further searched at the nucleic acid level in all patients of this study. HBV DNA was detected as described<sup>[17]</sup> in genomic DNA extracted from paraffin-embedded liver samples (DEXPAT Kit from TaKaRa Laboratories). HCV RNA

was detected in 2 µg hepatic RNAs with the Abbott real-time HCV kit (Abbott Laboratories, France). Serological and genomic determinations were consistent in all cases.

### Transcriptome analysis and real-time qRT-PCR

Our set of human cDNA probes dubbed *Liverpool* that is tailored to a complete coverage of the human transcriptome in healthy or cancerous liver (*ca.* 10<sup>4</sup> genes), the associated *LiverTools* database, as well as the procedures from array preparation to final data handling have all been detailed<sup>[16]</sup>. In brief, every RNA sample was subjected to 3 hybridization replicates. The resulting, normalized values were used for selection of significantly up- or down-regulated mRNA in cirrhosis vs paired nodule, using a statistically validated, funnel-shaped confidence interval ( $P < 0.05$ ) calculated from every mRNA detected per hybridization. This resulted in a false discovery rate (FDR) that is below 10% of the total number of regulated mRNAs, in agreement with an FDR estimate obtained from other, cumulated analyses in liver<sup>[5]</sup>. Abnormal mRNA ratio in cirrhosis vs paired nodule was defined from a statistically different abundance in at least 2 out of 3 replicates. A control of every cDNA probe was done by DNA re-sequencing with an ABI3100 capillary sequencer (Applied Biosystems). Real-time qRT-PCR of mRNAs was done as described<sup>[16]</sup> with primers designed with the Primer3 software (<http://frodo.wi.mit.edu>), and normalized with the 18S RNA level. The primers were: *AGXT*, forward CGCTGGCTATGACTGGAGAG, reverse GTCACGCGGTCCACATTCT, amplicon size 150 bp; *APCS*, TGGGAGAGATTGGGGATTTG, CCACACCAAGGGTTTGATGA, 158 bp; *APOC3*, ACTGAGCAGCGTGCAGGAG, TCACGGCTGAAGTTGTCTGA, 154 bp; *ATP6-V0D1*, TACCTCAACCTGGTGCAGTG, GTCTAGGAAGCTGGCCAGTG, 198 bp; *C4A*, TTGATC-ATGGGTCTGGATGG, CCTGGAGGA-AGTCGT-TGAGC, 157 bp; *CES1*, GGGTGCCTCAGAAG-AGGAGA, CTGGGTGTTGGCACC AATCT, 154 bp; *CLU*, ATGTTCCAGCCCTTCCTTGA, TCGTCGCCT-TCTCGTATGAA, 112 bp; *COBL*, TGGCATCCTCTGCTTCTGAG, CGTCTTGGTGCAGAGAGAG, 161 bp; *CRP*, TCGTATGCCACCAAGAGACA, CTTCTGCCCCACAGTGTAT, 235 bp; *CYP2E1*, TCAAGCCATTTTCACAGGA, CGATATCCTTTGGGTCAACGA, 129 bp; *FGL1*, GAAATTCAG-CACGTGGGACA, CCATGTCTGTTTTAGCCGTGT, 150 bp; *HP*, AACTGCGCACAGAAGGAGAT, TGGTGGGAAACCATCTTAGC, 202 bp; *HPR*, AGGGCGTGTGGGTTATGTTT, TTCTTTTCGGGGACTGTGCT, 141 bp; *HPX*, TGTGGATGCGGCCTTTATCT, GGCCAAGGGACTTTTCATA, 167 bp; *IDH2*, AAAGATGGC-AGT-GGTGTCAAG, TCATGTACAGCGGCCATTTCT, 151 bp; *MAGI1*, GGCAATGCATGTGTGGCTAT, CATCCATTTACTGCCAAGATCC, 113 bp; *NNMT*, CCCTCGGGATTACCTAGAAAAA, AGAGCCGATGTCAATCAGCA, 145 bp; *PDI A3*, AGAACTCACGGACGACA ACTTC, GCAGTGCAATCAACCTTTGC, 177 bp; *PSMD10*, GCATCCACA-AACATCCAAGA, TACTTGCTCCTTGGGACACC, 106 bp; *RBP4*, GATGGCACCTGTGCTGACA, TCGCAGTAACCGTTGTGGAC, 149 bp; *SAA*,

### Data mining

Our raw data are deposited in the GEO repository (GSE3632). The TIGR Multiexperiment viewer (Tmev version 2.2, <http://www.tm4.org>) was used for (1) unsupervised hierarchical clustering (UHC) using the average dot product and complete linkage options, (2) evaluation of sample re-assignment by a jackknife procedure (1000 iterations), and (3) supervised classification with the Significance Analysis of Microarrays (SAM) tool that selects discriminating transcripts<sup>[18]</sup> (our parameters were adjusted to an FDR < 1%). Supervised classification by Support Vector Machine (SVM) was done as indicated (<http://svm.sdsc.edu/>). The Onto-Express program (<http://vortex.cs.wayne.edu>) and the FatGO program set to level 4 or more (<http://fatgo.bioinfo.cnio.es/>) were used to categorize mRNA/protein function(s) by ontology. Detailed protein functions were retrieved with the SOURCE (<http://genome-www5.stanford.edu/cgi-bin/source/sourceSearch>) and/or OMIM (<http://www3.ncbi.nlm.nih.gov/entrez/query.fcgi?db=OMIM>) tools, and protein networks were identified with Bibliosphere ([www.genomatix.de](http://www.genomatix.de)). Gene locations on chromosomes were found in Onto-Express. Statistical analysis was carried out with the GraphPad InStat software, version 3 (<http://www.graphpad.com/>). Differences in transcript levels between groups were evaluated with Mann and Whitney's non parametric test. Significant differences in the numbers of functionally-related mRNAs that were differently regulated in tumor *vs* cirrhosis as a function of etiology were evaluated from 2 × 2 tables (number of mRNAs in a given functional subset *vs* number of all other mRNAs with other functions, in HCV *vs* alcoholic patients) by Chi square test (with Yates' correction, when required). Likewise, significant differences in the chromosomal locations of dysregulated genes as a function of etiology were evaluated from a 2 × 2 table per chromosome (number of dysregulated genes on this chromosome *vs* total number of other dysregulated genes, in HCV *vs* alcoholic patients) or arm (number of dysregulated genes on this arm *vs* number of all other *Liverpool* genes on this arm, in HCV *vs* alcoholic patients).

## RESULTS

### Some genomic and functional features of HCC/cirrhosis are etiology-dependent

In Table 1 various features are detailed for 35 patients with HCC (18 alcoholic patients A2-A34; 17 HCV patients V1-V35; no HBV-positive patients), and 5 HCC-free controls (C1 to C5). No clinical parameter differed between our alcoholic *vs* HCV groups. These groups were randomly separated into training (V1-A22) and test set (V23-A34). The number of mRNAs detected by microarray in the training set was 7617 ± 1270 (mean ± SD in controls), 7225 ± 1586 (tumors), or 6955 ± 1644

(cirrhosis), in keeping with a trend to down-regulation in HCC<sup>[7]</sup>. A comparison of transcript levels between tumor and surrounding cirrhosis selected a number of transcripts that could separate 3 major clusters by UHC, namely tumors, cirrhosis, and controls, as expected<sup>[2,4,6,10]</sup> (Figure S1, available on the wjg website).

We sought for transcripts with etiology-associated differences and this was first done regardless of the source, i.e. tumor *vs* cirrhosis. Using a pair-wise ratio (transcript level in tumor/transcript level in cirrhosis) resulted in 2730 transcripts with an abnormal ratio in at least 1 patient. Dysregulated transcripts were then limited to those with an abnormal ratio in at least 3 patients from at least 1 etiology group. This empirically determined cut-off was a compromise between a lower figure that provided many non-informative transcripts of a higher figure that selected too few transcripts (not detailed), and this resulted in 475 dysregulated transcripts. Because clusters of tissue-dependent genes can be co-regulated by chromosomal co-localization<sup>[19]</sup>, we investigated whether some of these 475 genes were co-localized on given chromosome(s). Indeed, a higher number of dysregulated genes on chr.2 along with a lower number of dysregulated genes on chr.8 (supplemental Table S1 available on the wjg website) were found in HCV *vs* alcoholic patients (Figure 1). These etiology-dependent differences in gene location were still found when separately considering the p arm ( $P < 0.01$ ) or q arm ( $P < 0.01$ ) of chr.2 and -8. Remarkably, abnormalities on chr.2 and -8 have been previously associated with HCC (see Discussion), which indirectly supports our cut-off above and etiology-dependent findings.

Within the above 475 transcripts we next searched for prominent protein functions as identified by ontology, and 283 transcripts with such functional information could be retrieved (further details in Table 2, footnote 3). As shown in Table 2, a significantly increased frequency and expression [(tumor/cirrhosis) ratio] of dysregulated transcripts coding for cell cycle regulation or transcription factors was found in the HCV patients. Proteins of the cell cycle were mainly activators of cyclin-dependent kinase phosphorylation (CDC37, CKS2), microtubule-associated proteins (CCT4, MAPRE1), a negative regulator of the G1/S transition (CUL1), a proliferation-associated c-myc activator (NME1) and a tumor suppressor (TSC1). Several transcription factors were directly relevant to a defence of the tumoral hepatocyte following HCV infection. Although the difference between tumor and cirrhosis was not always significant, in HCV patients the tumor/cirrhosis ratios for IRF3 and SPIB, two interferon alpha and beta activators, were increased whereas the ratio for IRF6, an as yet unclear regulator of interferon production, was decreased and that of IRF2, a repressor of interferon synthesis, remained close to 1. Also, the ratio for the repressor ATF3 that targets many viral promoters was increased.

On the opposite, an increased frequency of dysregulated transcripts for plasma proteins of the acute phase response was found in the alcoholic patients. In these patients, the tumor/cirrhosis ratio of these transcripts was indicative of an inflammatory condition as it was increased (CRP, ORM1, SAAs) or decreased

<sup>1</sup>V1 to A34, patients with cirrhosis and HCC, A or V refers to the alcoholic or viral etiology. C1 to -5, control patients. Patients V1 to V21 and A2 to A22 were first studied by microarray, and next used as a training set for SVM. <sup>2</sup>HCV: Hepatitis C virus infection; ALC: Alcohol abuse; -: None. <sup>3</sup>Differentiation grade; nd: Not determined. <sup>4</sup>In multinodular HCCs, only 1 nodule was studied. <sup>5</sup>Nodular infiltration; semi-quantitative appraisal done by a trained anatomopathologist (AF). <sup>6</sup>Histologically normal liver taken away from a benign adenoma (AD) or a focal nodular hyperplasia (FNH).

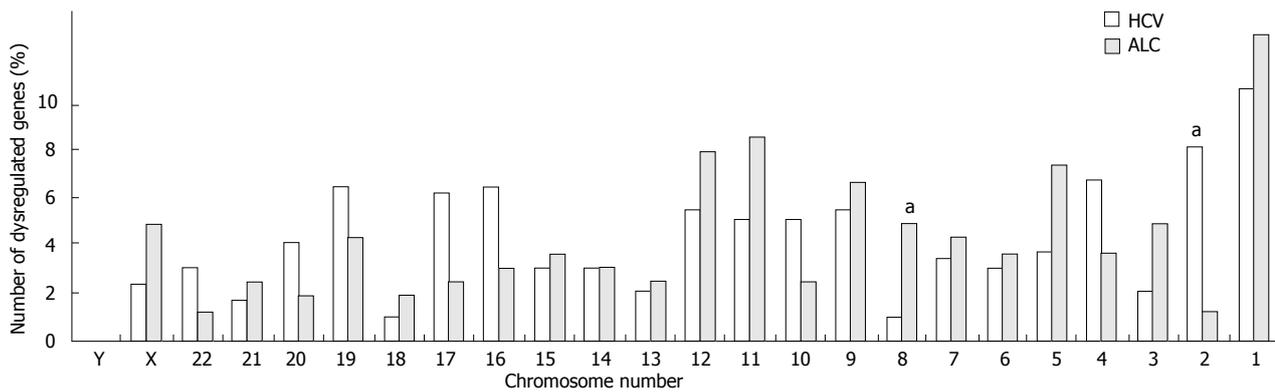

(AHSg) in keeping with known regulation in an acute phase response<sup>[16]</sup>. Surprisingly, the ratio for the anti-inflammatory glucocorticoid receptor NR3C1 was concomitantly increased, possibly as an attempt to limit the extent of this inflammation. Conversely, in HCV patients the ratios for APCS and CRP (acute phase plasma proteins), FOSL2 (a member of the Jun/Fos family that regulates some acute phase genes) and ETS2 (an up-regulator of inflammation) were decreased and the ratio for DSIPI (an anti-inflammatory transcription factor) was increased. Taken together, our data argued for a significant inflammatory condition in tumor as compared to adjacent cirrhosis in alcoholic but not HCV patients.

Finally, a tight SAM selection made from the 2730 transcript ratios above identified 23 non-redundant transcripts (29 probes) whose higher ratio in alcoholic vs HCV patients was statistically significant (red dots in Figure 2A). No transcript with a decreased ratio could be

identified, but such an imbalance in informative transcripts is not unusual with SAM<sup>[18]</sup>. Using these 23 transcripts in UHC separated the 22 HCV and alcoholic patients into two etiology-associated groups (Figure 2B). Only 2 patients were misclassified (A18, V15) which was further evaluated by a jackknife procedure (Figure 2B legend).

**The etiology-dependent transcriptomes are found in the HCC nodules**

We next investigated whether the etiology-associated differences in transcript levels depended on the transcript source, i.e. tumor vs cirrhosis. When using the (transcript level in tumor/mean transcript level in controls) ratio in nodules, a total of 2641 transcripts had a significantly abnormal ratio in at least 1 of our patients 1-22 (black and red dots in Figure 3A). SAM identified 18 non-redundant transcripts whose (tumor/controls) ratio was significantly higher in alcoholic vs HCV patients (red dots in Figure 3A).

**Figure 1** Etiology-dependent location of dysregulated genes. A total of 475 genes (HCV, 301 genes; alcoholism, 174 genes) with a dysregulated transcript were studied. Dysregulated transcripts were defined by an abnormal (tumor/cirrhosis) ratio in at least 3 patients of at least one etiology group (see details in Table 2, footnote 3). The number of dysregulated genes per chromosome is expressed as a percentage of the total number of dysregulated genes per etiology. Significant differences of gene frequency on a given chromosome in HCV vs alcoholic patients are: chr 2,  $P = 0.004$ ; chr 8,  $P = 0.02$  (Chi square test with Yates' correction),  $^aP \leq 0.02$ .

<sup>1</sup>Average ratio of mRNA levels in tumor and cirrhotic tissue in patients with a detectable expression of this mRNA. The number of such patients is indicated in brackets and a significant difference between tumors and paired cirrhotic tissues per etiology is indicated (<sup>a</sup> $P < 0.05$ ; <sup>b</sup> $P < 0.01$ ; Wilcoxon's non parametric, paired test). <sup>2</sup>Subset of mRNAs coding for proteins with a shared function as identified by Gene Ontology (GO) number. <sup>3</sup>Dysregulated mRNAs, as defined by an abnormal tumor/cirrhosis ratio found in at least 3 patients of at least one etiology group (total 475 mRNAs; HCV, 301; alcoholism, 174). The dysregulated mRNAs with an ontology-defined function (HCV, 183; alcoholism, 100) were a subset of the 475 mRNAs. <sup>4</sup>Hs. number as a unique mRNA identifier. <sup>5</sup>Only 5 of the 23 mRNAs listed in Figure 2B appear herein because the other mRNAs in Figure 2B belonged to functional classes in which the number of mRNAs was not different in alcoholic vs HCV patients.

As shown in Figure 3B, UHC of our 22 patients as based upon these 18 ratios provided two major clusters of HCV- or alcohol-associated HCCs. Only 2 samples were

misclassified (V-TU14, V-TU15), which was confirmed by a jackknife procedure (Figure 3B legend). Interestingly, all controls were clustered with the alcoholic tumors (right

**Figure 2** Etiology-dependent clustering of patients with (tumor/cirrhosis) ratios. **A:** Selection of transcripts with a significantly abnormal ratio of abundance in (tumor/paired cirrhosis). Black + red dots: 2730 transcripts with an abnormal ratio in at least 1/22 patients. Red dots: 23 informative transcripts (29 probes) with a significantly increased ratio in alcoholic vs HCV patients as selected by SAM with an FDR < 1%; **B:** UHC of 22 HCC patients with the above 23 transcripts. Note that the misclassification of two samples (A18, V15) was further evaluated by a jackknife procedure (1000 iterations) which supported cluster assignment to a variable extent (A18, < 50%; V15, 100%). Note that several transcripts were each detected with 2 or more different cDNA probes. Bottom scale bar: decreased (green), increased (red) or identical ratio (black). Gray squares are missing values. All data given on a log<sub>2</sub> scale.

side of Figure 3B), thus suggesting that alcoholism may alter expression of these 18 transcripts to a lesser extent than HCV infection.

Because the etiology-dependent transcripts identified from (nodule/cirrhosis) ratios (Figure 2) or from (nodule/controls) ratios (Figure 3B) largely overlapped (15/18 transcripts; 83%; stated in Figure 3B), this suggested that the nodules could be responsible for transcript abnormalities. Indeed, SAM made with the ratios from cirrhotic samples, i.e. (transcript level in cirrhosis/mean transcript level in controls), failed to identify a series of etiology-discriminant transcripts (no red dots in Figure 3C). Moreover, and as shown in Figure 3D, no etiology-

dependent clustering of patients V1-A22 was obtained when using the (cirrhosis/controls) ratios for these 18 stated transcripts. We concluded that such transcript levels now appear to be an etiology-dependent variable in nodules, but not in cirrhosis.

Taken together, our data indicated that a subset differently dysregulated following HCV infection vs alcoholism can be identified in cancerous nodules whereas it cannot be detected at an earlier stage of hepatic dysplasia, namely the surrounding cirrhosis.

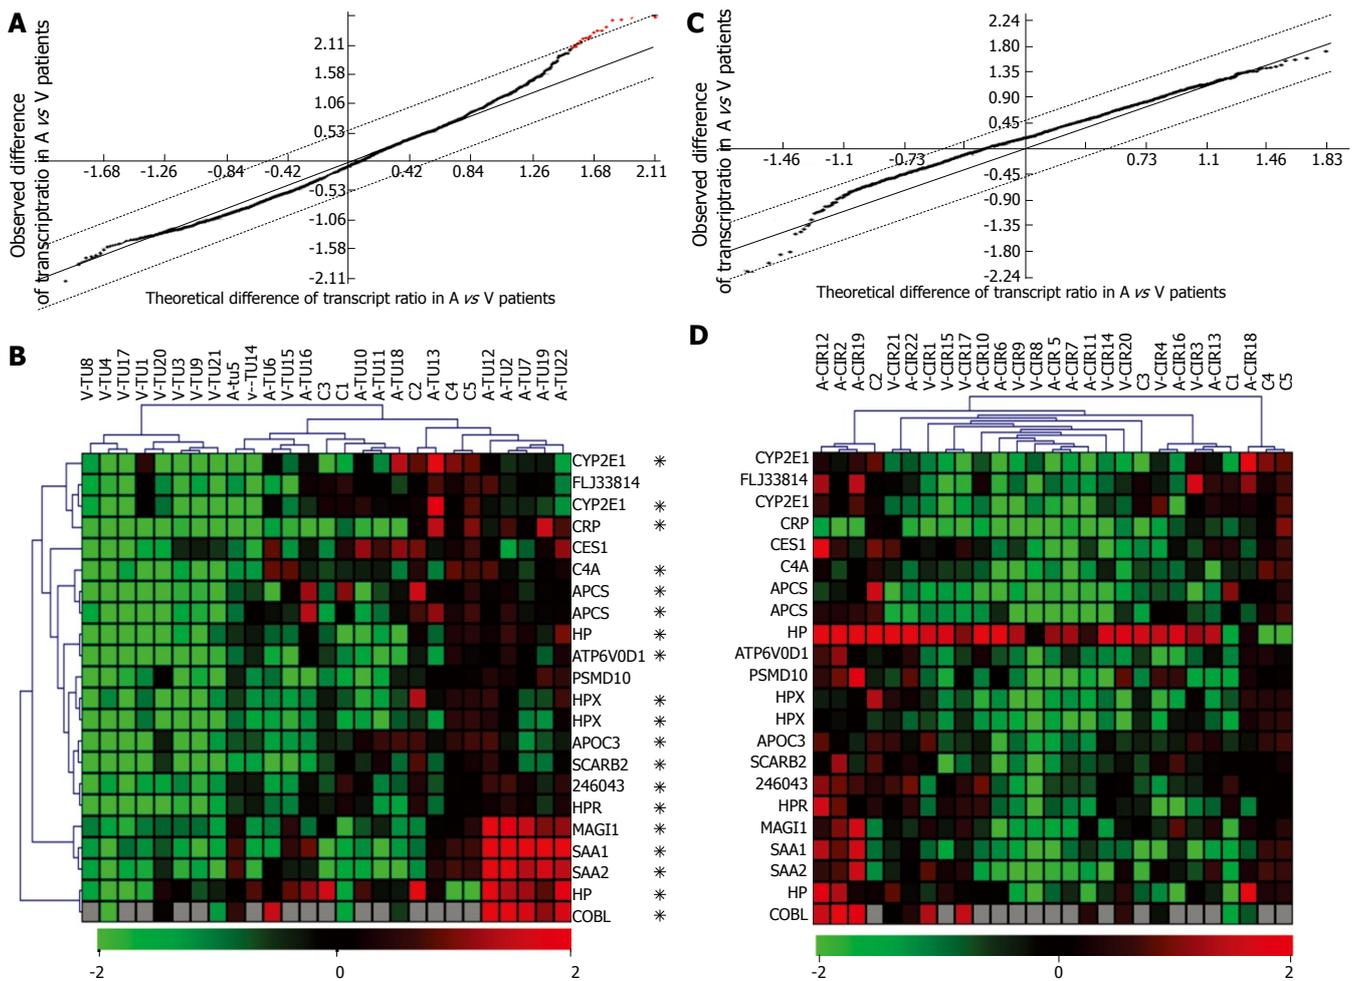

**Data validation**

Our data above were validated with a conceptually different tool (qRT-PCR). After excluding 3 transcripts whose gene structure was unknown (AC022706, FLJ33814, 246043) all transcripts previously found to vary significantly with etiology (i.e. cumulated lists from Figure 2B and 3B, total 23 transcripts) were quantified in every HCC patient in this study. Given our previous observation that cirrhotic samples were not informative, these transcripts were measured in tumors only. First, the informativeness of each of the above 23 transcripts was tested in our entire population of 35 HCC samples. As shown in Figure 4A, most transcripts (18/23, 78%) were significantly overexpressed in alcoholic tumors, as expected from Figure 3A. Next, UHC reproducibly resulted in a perfect and etiology-dependent separation of our test set (V23-V35 and A29-A34) (Figure 4B). Finally, a classification algorithm generated with qRT-PCR data from the training set (V1-A22) by SVM separated our test set into etiology-dependent groups with 2 misclassifications (V23, V24).

As for protein functions the increased level of CYP2E1 transcript in alcoholic patients fits its known up-regulation by ethanol<sup>[20]</sup>. Most other proteins in alcoholic patients were associated with the inflammatory response, as inferred from a comparison with our earlier data<sup>[16]</sup> as well as putative protein relationships retrieved with Bibliosphere (data not shown). They included acute phase proteins (APCS, APOC3, C4A, CRP, HP, HPX, NNMT, RBP4, SAAs) whose directions of variations indicated a stronger inflammatory condition of the tumor in alcoholic vs HCV patients. Remarkably, most of these acute phase proteins are scavengers of endogenous toxicants or protect against membrane peroxidation (CRP, HP, HPX, RBP4, SAAs). Among them, heme detoxicants include two hemoglobin transporters (HP, HPR) and one heme scavenger (HPX), whose variations suggested a higher iron metabolism in alcoholic vs HCV tumors. In alcoholism-associated tumors, only two proteins were associated with cell proliferation (FGL1) and apoptosis limitation (CLU).

**DISCUSSION**

Transcriptome-wide analysis in alcoholism-induced HCC has seldom been studied, which has prevented its detailed comparison with other etiologies. Indeed, transcript alterations in alcoholism-associated HCC have been reported but they focused on a limited number of transcripts or they did not differentiate between cirrhotic and cancerous tissues<sup>[21,22]</sup>. In contrast, we have now compared transcripts in tumor vs paired cirrhosis

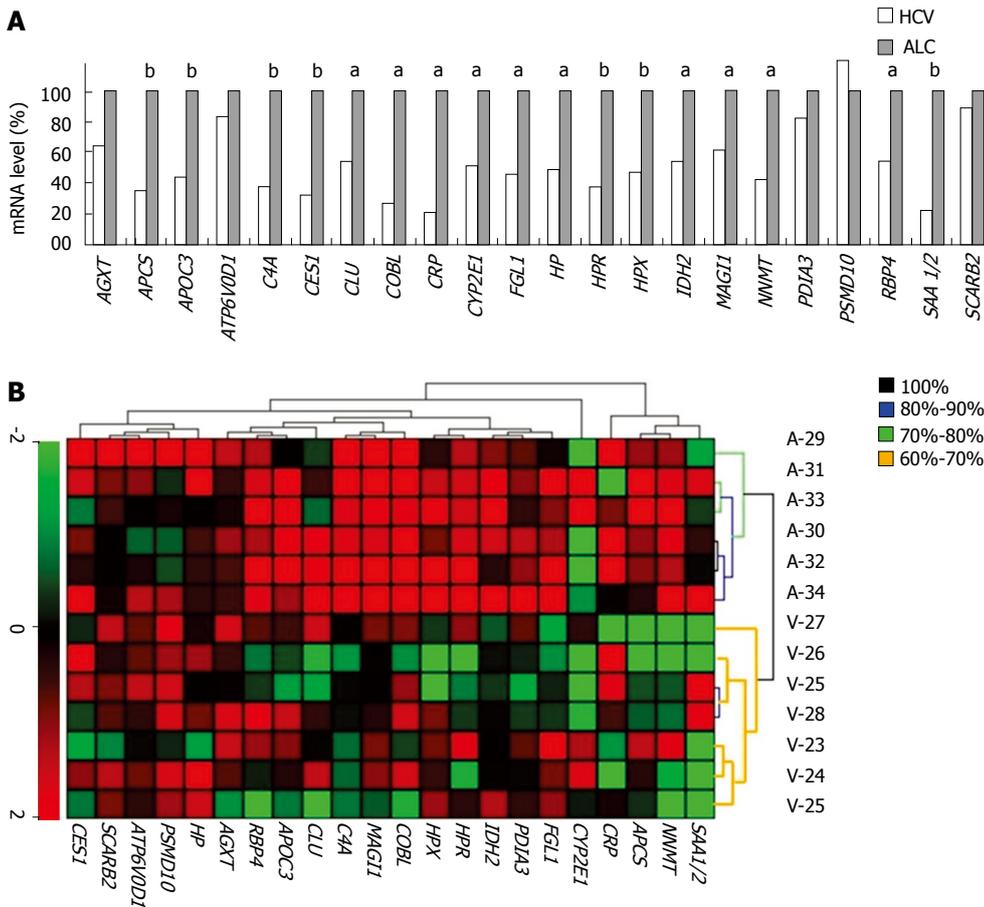

**Figure 3** Etiology-dependent clustering of tumors only, with (tumor/controls) ratios. **A:** Selection of transcripts with a significantly abnormal (level in tumor/mean level in controls) ratio. Black + red dots: 2641 transcripts with an abnormal ratio in at least 1/22 patients. Red dots: SAM selection of 18 informative transcripts (22 probes) with a significantly increased (tumor/controls) ratio in alcoholic vs HCV patients. SAM parameters as in Figure 2; **B:** UHC of 5 control livers and 22 tumors from 22 HCC patients, as done with the data of the 18 informative transcripts selected in **A**; The stars point to 15 transcripts (19 probes) that also belonged to the set of 23 transcripts previously selected in Figure 2; **C:** Selection of transcripts with a significantly abnormal (level in cirrhosis/mean level in controls) ratio. Black dots: 2037 transcripts with an abnormal ratio in at least 1/22 patients. No informative transcript was selected by SAM (no red dot); **D:** UHC of 5 control patients and 22 HCC-associated cirrhotic samples from 22 HCC patients, as done with the list of 18 transcripts used in **B**. Other details as in Figure 2.

by searching for abnormal (tumor/cirrhosis) ratios at a genome-wide level. We used a non-stringent selection of 475 transcripts whenever wide groups of transcripts were required (chromosomes; ontology) but we used SAM with a tight FDR to identify a total of 23 transcripts with strong etiology-associated variations. Second, we compared tumors (or cirrhosis) *vs* controls, which identified 18 transcript alterations in tumors only. The combined levels of these 18 transcripts in tumors but not in paired cirrhosis could classify the patients by etiology. Interestingly, most of these transcripts were previously associated with cirrhosis and HCC, this including, for instance, APCS, APOC3, CLU, CRP, CYP2E1, FGL1, HP, HPX, NNMT, RBP4, SAAs, and their down-regulations, mainly seen in an HCV context, were consistent with our present data<sup>[14,23-25]</sup>. The present lack of an etiology-dependent transcriptome in the cirrhosis surrounding HCC indicates that some etiology-dependent mechanisms take place at a relatively late stage of tumoral transformation. Further analysis of HCC-free cirrhosis will clarify this stepwise process.

As inferred from ontology, cell cycle regulation and a response to interferons appear to predominate in HCV-associated tumors. Our observation that over-expression of interferon-responsive genes in tumor *vs* cirrhosis is restricted to HCV patients also fits this viral etiology, as well as the ethanol-induced down-regulation of interferon gamma signalling in hepatoma cells<sup>[26]</sup>. HCCs with an alcoholic or viral origin have been subgrouped by others as a function of activation or repression of interferon-regulated genes but etiology influence was not documented<sup>[6]</sup>. The potent response of the normal hepatocyte to interferons is repressed by an HCV infection<sup>[27]</sup>. Therefore, the over-expression of interferon-responsive genes in nodule *vs* cirrhosis, as seen herein, suggests that a repression of these genes occurs in cirrhosis but escapes, at least partly, this viral mechanism in nodules.

The iron overload/HCC association is well established. Non transferrin-bound, free iron is carcinogenic and facilitates tumor growth *via* the production of ROS and free radicals, and subsequent lipid peroxidation<sup>[28]</sup>. Free iron and ROS in hepatocytes are a side effect of chronic

**Figure 4** Data validation by qRTPCR of tumor mRNAs. The levels of 23 transcripts (listed from Figures 2A and 3A; SAA1 and -2 are counted as 2 transcripts) were determined in tumors and normalized with the 18S RNA level. **A:** Every histogram depicts the mean transcript level in all patients from Table 1 ( $n = 35$ ) and is expressed as a percentage of the mean level in alcoholic patients (100%). Mann and Whitney's test ( $^aP < 0.05$ ;  $^bP < 0.01$ ). **B:** UHC made with qRTPCR data from our test set ( $n = 13$ ). The colors in dendrogram indicate the percentage of iterations reproducibly providing the same separation. Note the significant separation of 2 major, etiology-related branches (black branches found in 100% of  $10^3$  iterations).

alcoholism<sup>[29]</sup>. Our ontology-based data, up-regulations and functions of SAM-selected transcripts indicated that in alcoholic nodules an acute phase response is a prominent event. Therefore, a high extent of inflammation could participate in an etiology-dependent antitumoral response of the hepatocyte. However, this view is now challenged when considering (1) the induction of an inflammatory response in liver following both alcoholism and HCV infection<sup>[6,30,31]</sup>, (2) the similar extent of lymphocyte infiltration in both etiologies in our patients, (3) the limited apoptosis in alcoholic tumors and, most importantly, (4) the restricted functions of the afore mentioned set of acute phase transcripts. Indeed, in alcoholic patients the up-regulated levels of acute phase transcripts point to acceleration of iron metabolism (HP, HPX), a detoxication mediated by the haemoglobin degradation pathways (HP, HPR, HPX), and a protection against membrane peroxidation (CLU, CRP, RBP4, SAAs), and hence they strongly suggest accelerated exchange of free- *vs* bound iron in nodules. If so, the increase in proteins that prevent membrane peroxidation (CLU, CRP, RBP4, SAAs) represents a concomitant against free iron. Overall, we propose a set of transcripts as indicators of a detrimental iron metabolism whose extent and control are etiology-dependent. Alteration of this metabolism in alcoholism-induced tumors, as now suggested by the high levels of relevant transcripts, could participate in the free iron limitation noticed in HCC nodules<sup>[32]</sup>.

An increasing number of chromosome amplifications, mutations, deletions and transpositions develop during the transition from preneoplasia to HCC<sup>[1]</sup>. Such events on

chr.8 have allowed discrimination of patients with beta-catenin mutations and an allelic loss of chr.8p only from patients with a heterogeneous series of gains/losses of various other chromosome segments<sup>[9]</sup>. In contrast, chr.2 abnormalities are infrequent in HCCs<sup>[9]</sup>. Our present work now establishes a link between etiology and an abnormal expression of various genes on chr.2 (HCV) or -8 (alcoholism). This conclusion based upon transcript levels will require further investigations of etiology-dependent structural or epigenomic alterations on these chromosomes. As our data indicate that abnormal gene expressions are spread on both arms of chr.2 and -8, aberrant methylation of a series of promoters along a chromosome segment, long range epigenetic silencing and/or abnormal copy numbers of a chromosome<sup>[33-35]</sup> could explain our observations.

Overall, our data point to major etiology-associated differences in HCC. Given that HCC therapies have not yet considered any etiology-dependent mechanisms of carcinogenesis, our observations open new avenues for therapies that should take into account HCC etiology.

## COMMENTS

### Background

Chronic hepatitis C virus (HCV) infection and alcoholism are two important causes for hepatocellular carcinoma (HCC). Liver transcriptome analysis has resulted in the identification of genes with an aberrant expression according to different physiopathological states. In the present work, we performed a comparison of liver transcriptomes in HCV virus- vs alcoholism-associated HCC.

The genes shown here are those located on the significant chrs in Figure 1. They are referred to by an Hs. number as a unique identifier. Every such gene had an mRNA level that was significantly altered in tumor vs cirrhosis in at least 25% of the patients within at least one etiology.

The hepatitis B virus (HBV)- or HCV-induced genetic alterations are known to be different and the associated transcriptomes have proven to vary significantly. Therefore, deciphering the transcriptome patterns as a function of HCC etiology is of critical importance. However, the gene dysregulations in a context of alcohol abuse are poorly understood and the associated transcriptome has seldom been studied. *A fortiori*, a comparison of liver transcriptomes in HCV virus- vs alcoholism-associated HCC has never been done.

### Applications

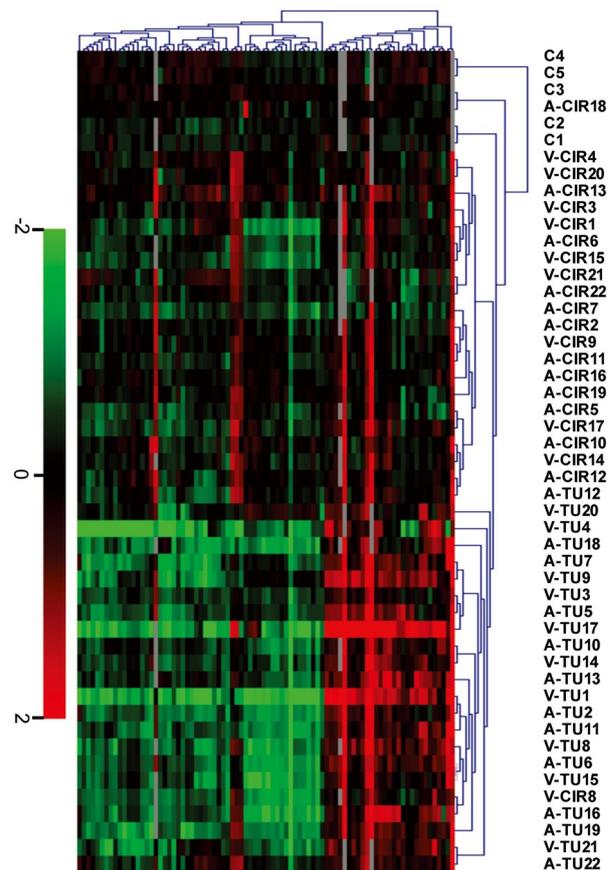

Given that HCC therapies have not yet considered any etiology-dependent mechanisms of carcinogenesis, our observations open new avenues for therapies that should take into account HCC etiology.

### Peer review

The manuscript by Derambure *et al.* describes a study that compared microarray data from hepatocellular carcinoma as a result from alcohol or hepatitis C. Interestingly, the authors found etiology-specific alterations in gene expression between the two HCC. These data would lead to a better understanding of the molecular basis of these disease states.

### Abstract

**AIM:** To investigate the role of nuclear factor of activated T cell 2 (NFAT2), the major NFAT protein in peripheral T cells, in sustained T cell activation and intractable inflammation in human ulcerative colitis (UC).

**METHODS:** We used two-dimensional gel-electrophoresis, immunohistochemistry, double immunohistochemical staining, and confocal microscopy to inspect the expression of NFAT2 in 107, 15, 48 and 5 cases of UC, Crohn's disease (CD), non-specific colitis, and 5 healthy individuals, respectively.

**RESULTS:** Up-regulation with profound nucleo-translocation/activation of NFAT2 of lamina propria mononuclear cells (LPMC) of colonic mucosa was found specifically in the affected colonic mucosa from patients with UC, as compared to CD or NC ( $P < 0.001$ , Kruskal-Wallis test). Nucleo-translocation/activation of NFAT2 primarily occurred in CD8+T, but was less prominent in CD4+ T cells or CD20+B cells. It was strongly associated with the disease activity, including endoscopic stage ( $\tau = 0.2145$ ,  $P = 0.0281$ ) and histologic grade ( $\tau = 0.4167$ ,  $P < 0.001$ ).

**CONCLUSION:** We disclose for the first time the nucleo-translocation/activation of NFAT2 in lamina propria mononuclear cells in ulcerative colitis. Activation of NFAT2 was specific for ulcerative colitis and highly associated with disease activity. Since activation of NFAT2

Aberrant activation of nuclear factor of activated T cell 2 in lamina propria mononuclear cells in ulcerative colitis. *World J Gastroenterol* 2008; 14(11): 1759-1767 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1759.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1759>

### INTRODUCTION

Inflammatory bowel disease (IBD), which includes the two components of Crohn's disease (CD) and ulcerative colitis (UC), is a chronic, relapsing and debilitating idiopathic inflammation of the gastrointestinal tract. UC is characterized by crypt abscesses and ulceration of the colon, which rarely extend beyond the muscularis layer. In comparison, CD is characterized by granulomatous inflammation involving the whole layer of bowel wall and, by its extension, any portion of the gastrointestinal tract. Although the exact etiologies remain uncertain, there is compelling evidence suggesting the implication of environmental risk factors<sup>[1]</sup>, including commensal bacteria<sup>[2,3]</sup>, genetic predisposition<sup>[4-9]</sup>, and disturbance of the immune reaction<sup>[10-12]</sup>.

In both UC and CD, the inflamed tissue is heavily infiltrated with inflammatory cells, mainly T lymphocytes<sup>[11,13,14]</sup>. These cells are thought to be activated and secrete large amount of cytokines, which in turn play a primary role in the pathogenesis of the diseases<sup>[15]</sup>. In addition, based on

studies of human tissue and animal models, it has been shown that UC and CD have distinct profiles of cytokine production. UC predominantly presents with type 2 helper T cell (TH2) cytokine profiles, such as IL-4, IL-5, and IL-13, while in DC, there is primarily a secretion of type 1 helper T cell (TH1) cytokines, including IL-12, IL-23, IFN- $\gamma$  and TNF- $\alpha$ <sup>[12,15-20]</sup>. Recently, de-regulation of innate immunity, including defects in the mucosal barrier and in innate effector cells such as neutrophils, monocytes, and dendritic cells, has been proposed to initiate early events and perpetuate the inflammatory state in CD<sup>[21]</sup>. However, the underlying mechanisms that initiate and promote the diverse immune perturbation in IBD remain to be determined. Moreover, elucidating the mechanisms that lead to aberrant immune activation of the colonic mucosa will contribute not only to understanding disease pathogenesis but also to the development of new therapies<sup>[22-29]</sup>.

Recently, we have used proteomic approaches to identify 19 differentially expressed proteins in the colonic mucosa of UC patients<sup>[30]</sup>. Of these, up-expression of the nuclear factor of activated T cells c1 (NFATc1 or NFAT2) is of particular interest, since NFAT proteins play pivotal roles in the development of the cardiovascular system and the regulation of immune function. Herein, we report results demonstrating nuclear translocation and activation of NFAT2 in infiltrating lymphocytes of UC diseased colonic mucosa.

## MATERIALS AND METHODS

### *Patients and tissue processing*

Colonic tissue sections were obtained from 107 cases of UC, 15 cases of CD, 48 cases of non-specific colitis, and 5 cases of normal controls. All UC patients, CD patients and non-specific colitis patients who underwent colonic endoscopic biopsy or surgical resection from April 1984 to September 2004 at our hospital were retrospectively included in the study in accordance with the clinical and pathologic diagnosis of UC, CD, or excluding the diagnosis of UC or CD, respectively. Those who had a tentative diagnosis of UC or CD, with a course of clinical symptoms less than three months, were excluded in this study. Seventy out of the 107 UC patients who had been regularly followed-up or were deceased by the end of the follow-up period (October, 2006) were included in the association studies between NFAT2 activation and clinical presentations. Disease activity was assayed on the basis of endoscopic observation of the mucosal pattern and histological grading<sup>[31,32]</sup>.

For proteomic assays using two-dimensional gel-electrophoresis, colonic biopsy samples were taken from the inflamed mucosa in four UC patients (all males; age range 25-42 years, average age 33 years), 3 cases of non-specific, infectious colitis (males, aged 21, 28, and 43 years), and 5 individuals without obvious colonic disease (all males; age range: 24-44 years, average age 33 years). The duration of the disease for the four UC patients was 6, 4, 6, and 10 years, respectively. No patient received immunosuppressive or steroid treatment for at least three weeks before the beginning of the study. All biopsy

samples were collected from the distal portion of the sigmoid colon (15-25 cm from the anal verge) and were then cut into two parts. One was immediately frozen at -80°C for subsequent proteomic assays, while the other was fixed in fresh 4% paraformaldehyde and embedded in paraffin for histologic and immunologic staining. Diagnosis of UC was made in accordance with standard criteria. The institutional ethics committee approved all of the protocols and all enrolled patients gave their informed consent, except those whose tissue samples had been collected and stored in the tissue bank of Chang Gung Memorial Hospital before 2000.

### *Two-dimensional gel electrophoresis and analysis*

The methods used for two-dimensional gel electrophoresis have been described previously<sup>[11]</sup>. In brief, frozen tissue samples (200 mg) were homogenized in 2 mL homogenization buffer (50 mmol/L Tris-HCl, pH 7.2) containing a protease inhibitor cocktail (1 mmol/L 4-(2-aminoethyl) benzenesulfonyl fluoride hydrochloride, 0.8 mmol/L aprotinin, 21 mmol/L leupeptin, 36 mmol/L bestatin, 15 mmol/L pepstatin A, 14 mmol/L E-64) using a homogenizer (IKA Labortechnik, Staufen, Germany) at 25 000 r/min. Samples containing 120  $\mu$ g protein were subjected in isoelectric focusing using the IPG strips in Protean IEF Cell (BioRad) in accordance with the manufacturer's instructions. Separation in the second dimension of 12.5% polyacrylamide gel slabs was carried out using Protean II electrophoresis equipment (BioRad).

The gels were initially fixed in 10% methanol and 7% acetic acid, and then stained for 3 h in a commercially available SYPRO Ruby buffer (Molecular Probes, Eugene, OR). Protein patterns in the gels were recorded as digitalized images using a high-resolution scanner (GS-710 Calibrated Imaging Densitometer, Bio-Rad). Gel image matching was done with Progenesis software (Progenesis Discovery, Nonlinear Dynamics, Durham, NC).

### *Protein identification by mass spectrometry*

Protein spots of interest were manually excised from the sypro Ruby stained 2D gels, de-stained using 50 mmol/L NH<sub>4</sub>HCO<sub>3</sub> in 50% acetonitrile and dried. The protein was digested by overnight incubation at 37°C with trypsin at 5 ng/mL in 50 mmol/L NH<sub>4</sub>HCO<sub>3</sub>, pH 7.8, followed by extraction in 1 volume 0.1% TFA and being eluted in 1.5  $\mu$ L matrix (5 mg  $\alpha$ -cyano 4-hydroxycinnamic acid/mL in 50% acetonitrile/0.1% TFA) for MALDI-TOF MS and MS/MS analysis. Both MS and MS/MS spectra were searched against the NCBI database, using the mascot software from matrix science (www.matrixscience.com) to identify the proteins.

### *Immuno-histochemical, double immunofluorescence and confocal microscopic studies*

For immuno-histochemical studies, after being de-waxed and rehydrated, the tissue sections were incubated with mouse anti-human NFAT2 as primary antibodies (diluted 1:500 in PBS; Abcam, Cambridgeshire, UK) for 2 h at room temperature, followed by rinsing with PBS and incubation by an HRP-conjugated rabbit anti-mouse IgG, or Rhodamin-conjugated anti-mouse IgG

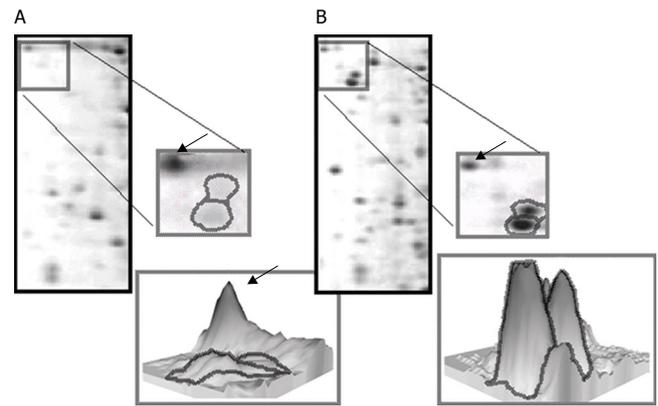

as the second antibody. HRP activity was detected using diaminobenzidine tetrahydrochloride (DAB) as substrate for 3 min in accordance with the manufacturer's instructions (BioGenex, San Ramon, CA 94583 USA).

To determine the relationship between the expression of NFAT2 and the cell types of LPMCs, we performed double immunofluorescence staining for NFAT2 and CD3 (BD, Franklin Lakes, NJ USA), CD4 (DAKO, Glostrup, Denmark), CD8 (Hytect, Turku Finland), and CD20 (DAKO, Glostrup, Denmark) on the same sections using Envision Doublestain System (DAKO, Glostrup, Denmark). Deparaffinization and microwave antigen retrieval were performed as described above. After quenching the endogenous peroxidase activity with peroxidase blocking reagent (DAKO, Glostrup, Denmark), tissue sections were incubated with mouse monoclonal anti-CD antibodies for one hour at room temperature, followed by rinsing with washing buffer and were incubated with HRP-conjugated anti-mouse antibodies (Jackson ImmunoResearch Laboratories, West Grove, PA) for 30 min at room temperature with detection of peroxidase activity. Then the tissue sections were subjected to the second staining for NFAT2 with the sequential steps of quenching the endogenous phosphatase, incubation with anti-NFAT2 antibodies, incubation with anti-goat IgG antibodies and detection of the phosphatase activity in accordance with the manufacturer's instructions (Envision Doublestain System, DAKO, Glostrup, Denmark).

For confocal microscopy, tissue sections were de-waxed using xylene twice and rehydrated with PBS followed by blocking with goat serum (BioGenex, San Ramon, CA 94583 USA) for 10 min at room temperature. The tissue sections were then incubated for 2 h with the specific antibody against NFAT2 (1:50, ab25916, Abcam, plc), rinsed extensively three times with PBS, incubated with secondary antibody (1:200 Jackson ImmunoResearch) for 30 min at room temperature in the dark, and then counterstained with 2-(4-Amidinophenyl)-6-indolecarbamidine dihydrochloride (DAPI, Sigma-Aldrich). The sections were rinsed successively with PBS, distilled water, and ethanol, and mounted with a drop of Mowiol on a micro slide. Confocal microscopy was performed using a laser scanning spectral confocal microscope (Leica PCS ST2, Leica Microsystems, Wetzlar, Germany).

### Statistical analysis

The degree of nucleotranslocation of NFAT2 was classified into five grades (I: 0%; II: < 10%; III: 10%-50%; IV: 50%-90%; V: > 90% of LPMC with nucleotranslocation of NFAT2) or low (< 50%) or high (> 50%). Comparing the degree of nucleo-translocation of NFAT2 among UC, CD and non-specific colitis patients, we used Kruskal-Wallis test (for UC, CD and NC three groups) or Mann-Whitney test (for any two unpaired groups). Associating the onset age with the degree of NFAT2 nucleo-translocation (< 50% *vs* > 50%) in UC patients, we used an unpaired two-sample *t* test. Examining the association of gender, sex, and disease duration before sampling with the degree of NFAT2 nucleo-translocation (< 50% *vs* > 50%), we used a corrected  $\chi^2$  test. To test association of the degree of nucleo-translocation of NFAT2 (< 50% *vs* > 50%) to the clinical outcome of

**Figure 1** Two-dimensional gel electrophoresis identifying increased amounts of NFAT2 in UC colonic mucosa tissue. Tissue protein lysate was prepared from normal (A) and UC affected colon tissues (B) and separated using two-dimensional gel electrophoresis (2-DE). Spot identification and matching across the gels and determination of the relative amount for each corresponding protein spot were conducted using the software, Progenesis workstation (non-linear). Proteins were identified using mass spectrometry as previously described<sup>[30]</sup>. The representative results of 2-DE are shown. The inserts are the close views along with the 3-dimensional pictures of NFAT2 and the reference protein spot on the 2-DE. Arrows indicate the reference protein spots across gels. The grey lines outline the NFAT2 spots.

UC patients, we used a two-side tailed Fisher's exact test. Correlating the degree of NFAT2 nucleo-translocation (grade I -V) to the disease activity (endoscopic grade 1-4 and histological grade 1-4) of UC patients, we used Kendall's -rank correlation coefficient.

## RESULTS

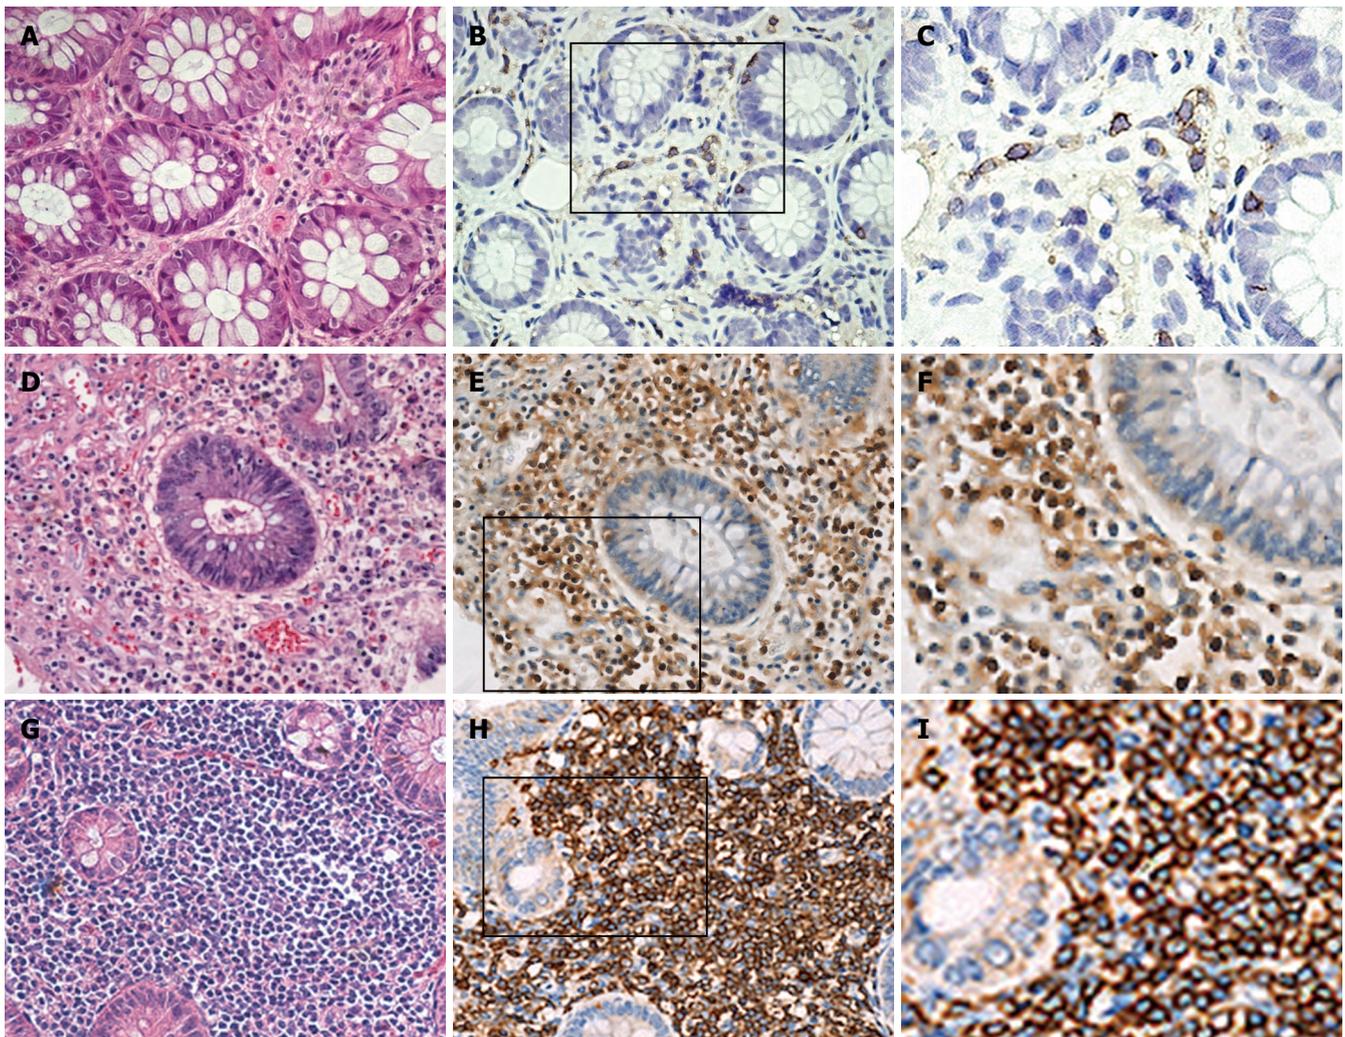

### Up-expression of NFAT2 in the proteomes of UC colonic mucosa

To identify the de-regulated proteins in colonic mucosa of UC, two-dimensional gel electrophoresis was used to compare the colon-mucosa proteomes between four UC patients and three healthy controls. Of interest is the up-expression of NFAT2 in UC colonic mucosa (Figure 1), because of its potential role in regulating immune function.

### Nucleo-translocation/activation of NFAT2 in the mucosa infiltrating lymphocytes in UC colonic tissues

To validate the up-expression of NFAT2 in UC diseased colonic mucosa, immuno-histochemistry was used to examine the relative number of cells specifically expressing NFAT2 in colonic mucosal tissue sections obtained from healthy controls and UC and CD patients. As shown in Figure 2, NFAT2 was detected in LPMCs obtained from the UC (Figure 2 D-F) and CD patients (Figure 2 G-I), as well as from the healthy controls (Figure 2 A-C), indicating that the up-expression of NFAT2 in UC was primarily due to the increase in the number of mucosa infiltrating lymphocytes as well as the up-regulation of NFAT2 in each infiltrating lymphocyte.

However, high magnification view showed differential distribution of NFAT2 inside the mucosa infiltrating lymphocytes among UC, CD, and controls. NFAT2 was restricted in the cytoplasm of lymphocytes in normal

**Figure 2** Immunohistochemical analysis of the expression of NFAT2 in colon mucosa tissues. **A-C** are derived from a case of normal control, **D-F** from a case of UC, and **G-I** from a case of CD. **A, D, G** are the results of H&E stain in 100 × magnification. **B, E, H** are the results of immunohistochemistry for NFAT2 counter-staining with hematoxylin for nuclei, 100 × magnification. **C, F, I** are the close view of **B, E, H** respectively. Of note, NFAT2 was exclusively located in cytoplasm of LMPCs of normal colon mucosa as well as LMPCs of CD affected colonic mucosa, whereas NFAT2 was primarily located in the nuclei of LMPCs of the UC affected colonic mucosa.

colonic mucosa (Figure 2B and C), while it was primarily located in the nuclei of infiltrating lymphocytes in UC colonic mucosa (Figure 2E and F). NFAT2 was also restricted in the cytoplasm of infiltrating lymphocytes in CD colon tissue (Figure 2H and I), although there was a heavy infiltration of lymphocytes (Figure 2G-I). Nucleo-translocation of NFAT2 within the infiltrating lymphocytes in UC colonic mucosa, but not in CD affected or normal colonic mucosa, was further validated by confocal microscopy, in which the subcellular distribution of NFAT2 was co-localized with chromosomal DNA within the nuclei of LMPCs in UC colon mucosa (Figure 3).

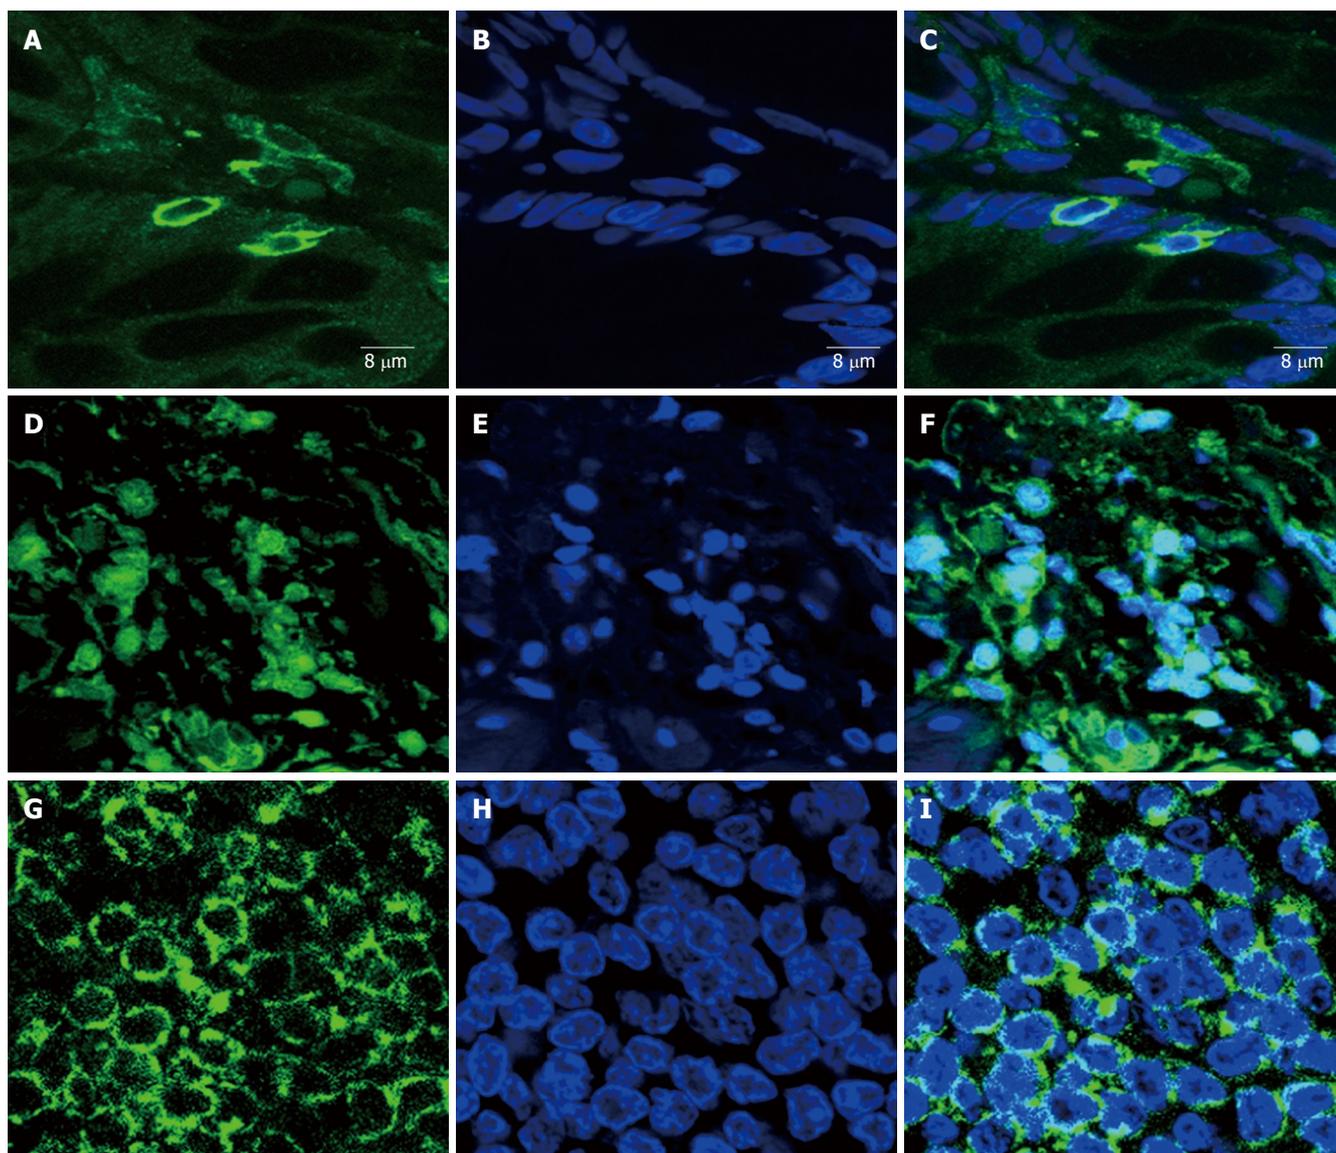

The cell-types of LMPC with NFAT2 nucleotranslocation/activation in the UC affected colonic mucosa were determined by double-staining using monoclonal antibodies against either CD3, CD4, or CD20, with those against NFAT2. The studies revealed that that nucleotranslocation of NFAT2 primarily occurred in CD8+ T cells and less prominent in CD4+ T cells (data not shown). NFAT2 was also expressed in some of the CD20+ B cells and translocated into nuclei, but mainly localized in the peripheral region of the nuclei (data not shown).

#### **Nucleo-translocation/activation of NFAT2 specifically in UC**

To further examine whether nucleotranslocation of NFAT2 of LMPCs in UC, we compared the degree of nucleotranslocation of NFAT2 in LMPCs in UC, DC and non-specific colitis. Diseased colonic tissue sections were obtained from 107 UC cases, 15 CD cases, and 48 cases of non-specific colitis. As shown in Figure 4 and summarized in Table 1, 76%, 26.7% and 8.3% of UC, CD and NC patients had high degree (Grade IV and V) of nuclear translocation of NFAT2, whereas 12%, 60% and 83% of UC, CD and NC patients had low degree (Grade I and II) of nucleotranslocation of NFAT2. Obviously, nuclear translocation of NFAT2 within LMPCs was specific for ulcerative colitis ( $P < 0.001$  for all three groups, *via* Kruskal-Wallis statistic test;  $P < 0.001$  for UC *vs* CD;  $P < 0.001$  for UC *vs* NC;  $P = 0.023$  for CD *vs* NC, *via* Mann-Whitney test).

#### **Nucleo-translocation/activation of NFAT2 and endoscopy, histologic grading, and clinical outcome**

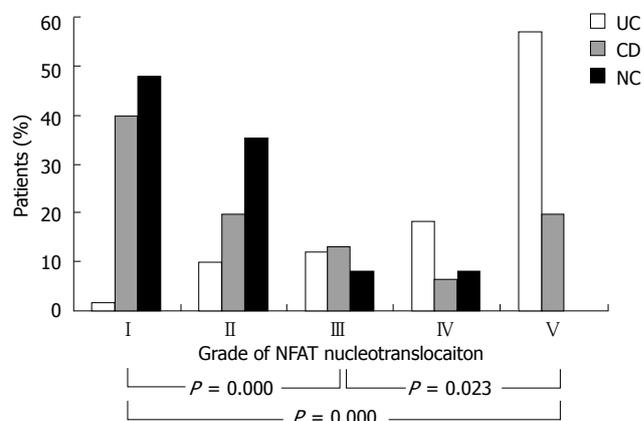

The degree of nucleotranslocation of NFAT2 in LMPCs was correlated to the clinical presentations of the cases

**Figure 3** Confocal microscopy demonstrating the subcellular distribution of NFAT2 in LMPCs of colon mucosa. **A-C** are derived from normal colon mucosa, while **D-F** from UC affected mucosa, **G-I** from CD affected mucosa. **A, D, G** represent the detection for NFAT2; **B, E, H**: The nuclei using DAPI; **C, F, I**: the merged images for **A, B, D, E, G** and **H, I**, respectively. Of interest, co-localization of NFAT2 with nuclei is noted in the colonic mucosa of UC (**F**), but not in CD (**I**), though there is a heavy infiltration of LMPCs in the CD affected colonic mucosa.

of UC, including gender, age at onset, disease duration before sampling, mucosal pattern (endoscopy grading), histologic grading, and outcome (Table 2). The degree of nucleo-translocation/activation of NFAT2 was not related to patients' gender, onset age, and disease duration. It was, however, highly associated with endoscopic grade (correlation coefficient,  $\tau = 0.2145$ ,  $P = 0.0281$  *via* Kendall's-rank correlation coefficient), and the histologic grade (correlation coefficient,  $\tau = 0.4167$ ,  $P = 0.000$  *via* Kendall's-rank correlation coefficient) and vice versa. There was no significant association between the degree of nucleotranslocation of NFAT2 and long-term clinical outcome of UC including requiring surgical intervention ( $P = 0.164$  *via* Fisher's exact test) and survival ( $P = 0.081$ , *via* Fisher's exact test) (Table 2).

On the other hand, the outcome of long-term follow-up was strongly associated with disease duration before sampling ( $P = 0.000$  *via* Kendall's-rank correlation

**Figure 4** Nucleo-translocation of NFAT2 in UC, CD, and non-specific colitis. Nucleo-translocation of NFAT2 was assayed using immuno-histochemical staining and the tissue sections were obtained from a total of 107 cases of UC, 15 cases of CD and 3 cases of non-specific colitis (NC). Overall  $P$  value  $< 0.001$  (determined *via* Kruskal-Wallis statistic).

**Table 1 Comparison of the degree of NFAT2 nucleo-translocation in LPMCs in patients of UC, CD and non-specific colitis**

Grades of NFAT2 nucleo-translocation in LPMCs (%)	Ulcerative colitis (cases) (%) <sup>1</sup>	Crohn's disease (cases) (%) <sup>1</sup>	Non-specific colitis (cases) (%) <sup>1</sup>
I (0)	2 (01.9)	6 (40.0)	23 (47.9)
II (< 10)	11 (10.3)	3 (20.0)	17 (35.4)
III (10-50)	13 (12.1)	2 (13.3)	4 (8.3)
IV (50-90)	20 (18.7)	1 (06.7)	4 (8.3)
V (> 90)	61 (57.0)	3 (20.0)	0 (0.00)
Total cases	107	15	48

<sup>1</sup>*P* = 0.000 amongst UC, CD and NC groups, *via* Kruskal-Wallis statistics; *P* = 0.000 for UC *vs* CD, *via* Mann-Whitney's test; *P* = 0.000 for UC *vs* NC, *via* Mann-Whitney's test; *P* = 0.023 for CD *vs* NC, *via* Mann-Whitney's test.

**Table 2 Correlation of NFAT2 nucleotranslocation to clinical presentations**

	<i>P</i> value	Statistic methods
Degree of NFAT2 nucleotranslocation <sup>1</sup>		
Onset age (yr, mean ± SD) <sup>1</sup>	0.9484	<i>t</i> -test
Gender (M <i>vs</i> F) <sup>1</sup>	0.651	χ <sup>2</sup> test
Disease duration (< 3 m <i>vs</i> > 3 m) <sup>1</sup>	0.507	χ <sup>2</sup> test
Outcome (survived <i>vs</i> non-survived) <sup>3</sup>	0.081	Fisher's exact test
Outcome (colectomy <i>vs</i> non-colectomy) <sup>1</sup>	0.164	Fisher's exact test
Degree of NFAT2 nucleotranslocation <sup>2</sup>		
Endoscopic grade (1-4) <sup>2</sup>	0.0281	Kendall's-rank correlation coefficient τ = 0.2145
Histological grade (1-4) <sup>2</sup>	0	Kendall's-rank correlation coefficient τ = 0.4167

<sup>1</sup>The degree of NFAT2 nucleo-translocation is divided into < 50% *vs* > 50% of LPMCs. <sup>2</sup>The degree of NFAT2 nucleo-translocation is categorized into 0%, < 10%, 10%-50%, 50%-90%, > 90% of LPMCs. <sup>3</sup>Non-survived: Died of complications of UC.

coefficient), endoscopy grade (*P* = 0.000 *via* Kendall's-rank correlation coefficient) and histologic grade (*P* = 0.031 Kendall's-rank correlation coefficient), but not associated with the degree of nucleo-translocation/activation of NFAT2 (*P* = 0.185 *via* Kendall's-rank correlation coefficient), age (*P* = 0.406), or sex (*P* = 0.369).

## DISCUSSION

Though many studies and reports have addressed the role of cytokines in the development of IBD, there is still a great gap between the increase of the putative initiating cytokines, such as IL-4 and IFN-γ (around 3 fold), and the downstream profound cascade of pro-inflammatory cytokines that include TNF-α, IL-1β and IL-6 (around 10-20 folds), which are directly implicated in the inflammatory process<sup>[10-12,33,34]</sup>. Indeed, the mechanisms that multiply downstream signaling and cause intractable inflammatory events remains completely unclear.

We report here the nucleo-translocation/activation of NFAT2 of lamina propria mononuclear cells (LPMCs) in UC affected colonic mucosa. The nucleo-translocation/activation of NFAT2 of LPMCs is specific for UC

because it is relatively rare in CD and is rarely found in non-specific colitis. Of interest, it has been shown that the activation of NFAT2 primarily leads to the commitment of Th2 differentiation<sup>[35-37]</sup>. Our findings of the nucleo-translocation/activation of NFAT2 specifically in UC is consistent with the general notion that UC is primarily driven by a Th2-like immune activation that is different from the major roles of Th1 immune activation in CD<sup>[10-14]</sup>. In addition, we show that the degree of nucleo-translocation/activation of NFAT2 of LPMC has been strongly associated with disease activity, such as clinical and histological grading, indicating its direct implication in the pathogenesis of UC. Our findings are reminiscent of that reported by Neurath *et al*, in which activation of T-bet, a transcription factor directing Th1 cell development and regulating T cell function, in the LPMCs was specifically found in CD patients but not in UC patients<sup>[38]</sup>. In addition, over-expression of T-bet was found to be essential and sufficient to promote Th1-mediated colitis in an experimental mouse model of CD<sup>[38]</sup>.

NFAT proteins, which are originally identified in T cells as inducers of cytokine gene expression, play a variety of biological roles in the differentiation of many cell types, including effector T cells, osteoclasts, and muscle cells<sup>[36,37,39-41]</sup>. The NFAT family contains five transcription factors, four of which (NFAT1-4) are regulated by the calcium/calcineurin signaling pathways that are essential for the regulation of lymphocyte function. The only non-calcium-regulated NFAT protein, NFAT5, is expressed in response to osmotic stress by almost all cells<sup>[40,42]</sup>.

Activation of NFAT1-4 proteins is tightly regulated by calcium-dependent phosphatase calcineurin. Calcineurin signaling was first defined in T lymphocytes as a regulator of nucleo-translocation and activation of NFAT proteins. In resting cells, NFAT proteins reside in the cytoplasm and are heavily phosphorylated. Upon engagement of cell surface receptors, the membrane component phosphatidylinositol-4,5-bisphosphate is converted to inositol-1,4,5-trisphosphate (IP3) and diacylglycerol. IP3 sequentially induces the calcium release from the intracellular store and triggers the opening of calcium-release-activated calcium channels in cytoplasm membrane, thereby maintaining the increased levels of intracellular calcium. This, in turn, forms a complex with calmodulin that activates the Ser/Thr-phosphatase activity of calcineurin so as to de-phosphorylate NFAT proteins resulting in nucleo-translocation of NFAT proteins and the induction of NFAT-dependent gene transcription<sup>[40,43,44]</sup>.

NFAT1 and NFAT2 are the major NFAT proteins in peripheral T cells; they overlap in function but differ remarkably in mode of expression. NFAT1 is constitutively synthesized in T cells, whereas NFAT2, the most prominent NFAT proteins in peripheral T cells, is expressed upon following T-cell receptor and co-receptor stimulation and maintained by an auto-regulation mechanism<sup>[40,45]</sup>. Activation of NFAT proteins, together with other transcription factors (such as T-bet, STAT1, 4, 6, GATA3, and FOXP3), determines the TH1/TH2/Treg lineage choice, particularly the development of TH2 immune response that is dependent on the nature of the stimulus and the signals that are received

from specific cytokines<sup>[34,40,45,46]</sup>. Upon the engagement of TCR, for example, NFAT2 cooperates with MAT to induce the expression of IL-4, IL-5 and TH2 lineage specific transcription factors (such as NFAT2, STAT6 and GATA3) to commit to TH2 cell differentiation<sup>[36,37,40,47-49]</sup>.

Of interest, there are two NFAT binding sites in each of the two promoter regions of the NFAT2 gene. Mutations abolishing NFAT binding result in a profound decrease in the transcription of NFAT2. Obviously, there is a positive auto-regulation of NFAT2 expression in TCR activated T cells<sup>[43,50,51]</sup>. Taken together, nucleo-translocation/activation of NFAT2 inflames an auto-regulatory positive feedback loop in amplifying downstream pro-inflammatory signaling. Our findings of specific nucleo-translocation/activation of NFAT2 in LPMCs in UC might imply the answer to the long term enigma of the mechanisms leading to the ultimate cascade of intractable inflammatory process of UC<sup>[52]</sup>.

The strong association of aberrant nucleotranslocation/activation of NFAT2 in LPMCs with the disease activity of UC further supports our hypothesis of direct implication of the calcium-calcineurin/NFAT pathways in the pathogenesis of UC. Blocking the positive-feedback loops initiated by the activation of NFAT2 would not only achieve an instant anti-inflammatory effect but might also lead to a long term remission of the disease. The calcium-calcineurin/NFAT pathways can therefore be the therapeutic targets for UC treatment. Indeed, targeting the calcium-calcineurin/NFAT pathways in the treatment of other chronic immune-mediated and intractable auto-immune diseases has been well documented<sup>[53]</sup>. For the treatment of UC, cyclosporin A, a specific inhibitor of calcineurin activity, has also been reported to be a successful treatment in cases with severe or steroids intractable UC<sup>[22,54-59]</sup>. Cyclosporin A has also been suggested as the consensus treatment for patients with severe UC in whom standard therapy has failed, or for those who are candidates for colectomy<sup>[60]</sup>. Nevertheless, the clinical use of the potent immunosuppressants, such as cyclosporin A (CsA) and tacrolimus (FK506), the fungal metabolites blocking the phosphatase activity of calcineurin, and consequently inhibiting the de-phosphorylation and nucleo-translocation of NFAT proteins, can cause severe side effects and, as such, their prolonged use in many chronic inflammatory or autoimmune diseases has been restricted. Recently, there has been a merging of peptide sequences that more specifically interfere with the interaction between calcineurin and NFAT, as well as small organic molecules that modulate NFAT function as the potential new immunosuppressive drug with improved specificity and reduced toxicity. Application of similarly newly developed drugs to the treatment of UC and some of CD will open the new era of IBD therapy in the near future<sup>[22-29,61-63]</sup>.

In summary, since the activation of NFAT is implicated in an auto-regulatory positive feedback loop of sustained T-cell activation, our findings of specific nucleo-translocation/activation of NFAT2 in LPMCs of UC not only indicate the pivotal roles of activation of NFAT2 pathways in the intractable inflammatory process of UC for the first time, but also open a window for the future development of new strategies for UC therapy.

## ACKNOWLEDGMENTS

The authors are grateful to Miss Yen-Ting Chen, Mr. Yu-Chih Lin and Professor Chee-Jen Chang at the Research Institute for Clinical Research, Chang Gung Memorial Hospital, Taoyuan, Taiwan, for their valuable comments and assistance on biostatistics analysis.

## COMMENTS

### Background

We used two-dimension gel electrophoresis comparing the proteome difference between the ulcerative colitis (UC). Affected and unaffected colonic mucosa. Of the up-regulated proteins in the UC affected colonic mucosa, nuclear factor of activated T cell 2 (NFAT2) was particularly interesting, since NFAT2 is not only the major NFAT proteins in peripheral T cells but also playing key roles in regulating T cell differentiation and functions. We aimed to investigate the role of NFAT2 in the development of UC.

### Research frontiers

Although T cells play pivotal roles in the pathogenesis of ulcerative colitis, the mechanisms causing sustained T cell activation and intractable inflammation remain unknown. It has been shown that activation of NFAT2 is implicated in an auto-regulatory positive feedback loop leading to a sustained T-cell activation. However, the role of NFAT in the pathogenesis of UC has never been addressed.

### Innovations and breakthroughs

This is the first study addressing the strong association of nucleo-translocation/activation of NFAT2 of the lamina propria lymphocytes in the UC affected mucosa with the disease activity and severity. More interestingly, nucleo-translocation/activation of NFAT2 of the lamina propria lymphocytes in the colonic mucosa was specific for UC, since it was less prominent in Crohn's disease (CD) and rarely detected in non-specific colitis, suggesting the roles of NFAT2 activation in the pathogenesis of UC.

### Applications

Because NFAT proteins are regulated by the calcium/calcineurin signaling pathways, our findings suggest direct implication of the calcium/calcineurin signaling pathways in the pathogenesis of UC. Blocking the positive-feedback loops initiated by the activation of NFAT2 would not only achieve an instant anti-inflammatory effect but might also lead to a long term remission of the disease. The calcium-calcineurin/NFAT pathways can therefore be the therapeutic targets for UC treatment.

### Terminology

NFAT proteins originally identified in T cells as inducers of cytokine gene expression play a variety of biological roles in the differentiation of many cell types, including effector T cells, osteoclasts, and muscle cells. NFAT2 is the most prominent NFAT proteins in peripheral T cells. Activation of NFAT2 determines the TH1/ TH2/Treg lineage choice, particularly the development of TH2 immune response.

### Peer review

In this study, the authors demonstrated for the first time the strong association of activation of nuclear factor of activated T lymphocytes with the disease activity and severity of UC. This work adds significant information regarding the mechanisms of sustained T cell activation and intractable inflammation of UC, and opens a new window for future development of anti-UC therapy.

### Abstract

**AIM:** To investigate endoscopic and histopathological findings in the duodenum of patients with *Strongyloides stercoralis* (*S. stercoralis*) hyperinfection.

**METHODS:** Over a period of 23 years (1984-2006), we investigated 25 patients with *S. stercoralis* hyperinfection who had had an esophagogastroduodenoscopy before undergoing treatment for strongyloidiasis. The clinical and endoscopic findings were analyzed retrospectively.

**RESULTS:** Twenty-four (96%) of the patients investigated were under immunocompromised condition which was mainly due to a human T lymphotropic virus type 1 (HTLV-1) infection. The abnormal endoscopic findings, mainly edematous mucosa, white villi and erythematous mucosa, were observed in 23 (92%) patients. The degree of duodenitis including villous atrophy/destruction and inflammatory cell infiltration corresponded to the severity of the endoscopic findings. The histopathologic yield for identifying larvae was 71.4% by duodenal biopsy. The endoscopic findings of duodenitis were more severe in patients whose biopsies were positive for larvae than those whose biopsies were negative (Endoscopic severity score:  $4.86 \pm 2.47$  vs  $2.71 \pm 1.38$ ,  $P < 0.05$ ).

**CONCLUSION:** Our study clearly demonstrates that, in addition to stool analysis, endoscopic observation and biopsies are very important. We also emphasize that *S. stercoralis* and HTLV-1 infections should be ruled out before immunosuppressive therapy is administered in endemic regions.

### INTRODUCTION

*Strongyloides stercoralis* (*S. stercoralis*) is an intestinal nematode which is a parasite of humans. About 100 million people are infected by this parasite in tropical and subtropical areas<sup>[1]</sup>. Infections are acquired when larvae penetrate the skin and migrate to the duodenum and upper jejunum to mature. An internal autoinfective cycle allows the parasite to reside within a human for years. Clinical syndromes of *S. stercoralis* vary widely. Chronic infection with *S. stercoralis* is most often asymptomatic. Hyperinfection describes a syndrome of accelerated autoinfection which results from immunosuppression. Detection of an increased number of larvae in stool, sputum and/or tissue is a hallmark of hyperinfection<sup>[2]</sup>. Gastrointestinal and pulmonary symptoms are common but non-specific, and include abdominal pain, diarrhea, vomiting, adynamic ileus, small bowel obstruction (SBO) and protein-losing enteropathy, as well as pneumonia. Disseminated infection is the migration of larvae to organs beyond the range of the autoinfective cycle (lungs and gastrointestinal tract) and is often complicated by Gram-negative sepsis. Such organs include the skin, liver, central nervous system as well as virtually every other organ. An immunocompromised condition consists of immunosuppressive drug therapy (e.g., corticosteroids, cyclosporine and anti-cancer drugs), hematologic malignancies, organ transplants, human T lymphotropic virus type 1 (HTLV-1) infection, and human immunodeficiency virus (HIV) infection<sup>[1,2]</sup>. As *S. stercoralis* colonizes in the duodenum where the larvae

mature, endoscopic evaluation has been recognized as an important tool for diagnosing strongyloidiasis. Although there have been several reports demonstrating endoscopic findings of strongyloidiasis, most of these are case reports or small case series<sup>[3-19]</sup>. This study aims at investigating the relationship of endoscopic markers to clinical and histopathological findings of the duodenum in patients with *S. stercoralis* hyperinfection in an endemic region.

## MATERIALS AND METHODS

### Patients

Over a 23-year period from 1984 to 2006, we identified 25 patients (15 males and 10 females; mean age =  $63.0 \pm 14.1$  years) with *S. stercoralis* hyperinfection who had had an esophagogastroduodenoscopy (EGD) before undergoing treatment for strongyloidiasis at Ryukyu University Hospital and other affiliated hospitals in Okinawa, Japan. The diagnosis of *S. stercoralis* hyperinfection was based on gastrointestinal, pulmonary and/or systemic symptoms along with the identification of an increased number of *Strongyloides* larvae or ova in the stool, sputum, gastroduodenal drainage and/or tissue. The clinical and endoscopic findings of the patients were investigated retrospectively. The study was conducted and carried out in accordance with the Helsinki Declaration.

### Endoscopy and histopathology

EGD was performed with forward-viewing endoscopes (Olympus, Tokyo, Japan) at the second portion of the duodenum. Since the endoscopic severity scoring system of the duodenum has not been established, we created the scoring system, which was determined by the total number of points for duodenitis. One point was given for a mild form (edema, erythema and white villi), two points for a moderate form (erosion, fine granule and hemorrhage) and three points for a severe form (ulcer, dilatation, dilatation and pseudopolyps). At endoscopy, biopsy specimens were obtained from the duodenal mucosa in a routine fashion using standard forceps. The specimens were stained with hematoxylin and eosin for histopathological evaluation. Duodenal pathology was assessed as described elsewhere<sup>[20]</sup>.

### Statistical analysis

Mann-Whitney *U*-test was used, when appropriate, to compare any differences among the groups. Statistical comparisons were analyzed using SPSS for Windows version 15 (SPSS Inc., Japan). *P* values less than 0.05 were considered statistically significant.

## RESULTS

### Clinical features

The clinical features of the patients are summarized in Table 1. The main symptoms and/or illnesses complicated by the hyperinfection were as follows: vomiting in 13 (52.0%), abdominal pain in 10 (40.0%), diarrhea in 8 (32.0%), SBO in 8 (32.0%), weight loss in 7 (28.0%), bacterial meningitis in 3 (12.0%), sepsis in 3 (12.0%), pneumonia in 2 (8.0%), and gastrointestinal bleeding in 2

(8.0%) patients. Most patients had more than one clinical symptom or illness. Six patients had disseminated infection (bacterial meningitis and/or sepsis) and the outcome of 2 patients was fatal. Twenty-four (96%) patients were under immunocompromised conditions resulting from HTLV-1 infection, administration of corticosteroid, diabetes mellitus, alcoholism, liver cirrhosis and chronic renal failure. Of note, 18 (72.0%) patients were HTLV-1 carriers. The diagnostic samples used for identifying *Strongyloides* were as follows: stool samples from 17 (68.0%) patients, duodenal biopsy from 15 (60.0%) patients, gastroduodenal drainage from 9 (36.0%) patients and sputum from 3 (12.0%) patients. Most patients were treated with thiabendazole or ivermectin alone and 2 patients needed a combination of the two drugs.

### Endoscopic and histopathological findings

The endoscopic findings of the patients are summarized in Table 2. Gross abnormal findings were observed in 23 (92.0%) patients and normal findings in 2 (8.0%) patients. A broad range of endoscopic findings included edematous mucosa in 16 (69.5%) patients, white villi in 13 (56.5%), erythematous mucosa in 9 (39.1%), erosion in 6 (26.0%), stenosis in 4 (17.3%), fine granule in 4 (17.3%), hemorrhage in 3 (13.0%), dilatation in 3 (13.0%), and ulcer in 2 (8.6%) patients (Figure 1). Most patients had more than one finding. Strongyloidiasis was diagnosed histopathologically in 71.4% (15/21) of patients who had duodenal biopsies. According to the endoscopic severity score of the duodenum, the endoscopic findings of duodenitis were more severe in patients whose biopsies were positive for larvae than in those with negative biopsies ( $4.86 \pm 2.47$  vs  $2.71 \pm 1.38$ ,  $P < 0.05$ , Figure 2). Representative endoscopic images of white villi and edematous mucosa (Figure 3), white villi and stenosis (Figure 4), and ulcer and pseudopolyps (Figure 5) are shown along with the histopathological findings. As shown together with the endoscopic and histopathological images, the degree of duodenitis, including villous atrophy/destruction and inflammatory cell infiltration, was associated with the severity of the endoscopic findings. In 6 cases whose stool was not obtained due to SBO or larvae were not identified in the stool, strongyloidiasis was diagnosed only by duodenal biopsies.

## DISCUSSION

This study was conducted in the Okinawa islands, a subtropical region of Japan, where both *S. stercoralis* and HTLV-1 are endemic and epidemiological studies have been thoroughly conducted<sup>[21-24]</sup>. There is an increasing body of evidence regarding the strong association between *S. stercoralis* and HTLV-1 co-infection and hyperinfection syndrome<sup>[21-26]</sup>, which has been further strengthened by our striking result that a majority (72%) of the patients with hyperinfection were co-infected with HTLV-1. We also confirmed the well-described role of corticosteroids in triggering hyperinfection regardless of the presence of HTLV-1 co-infection. Corticosteroids not only have a well-known effect impairing human immunity but also directly affect the female larvae to increase output of infective

Table 1 Clinical characteristics of patients with *S. stercoralis* hyperinfection

larvae with a structural similarity to larval ecdysteroids<sup>[1,27]</sup>.

Enteritis by *S. stercoralis* has been studied since the early 1960's before the endoscopic era. de Paola *et al*<sup>[28]</sup> classified the histopathological changes in fatal cases into three forms: catarrhal enteritis, edematous enteritis and ulcerative enteritis. Catarrhal enteritis is a minor form characterized by mild mucosal congestion with larvae restricted to the mucous membrane. Edematous enteritis is a moderately serious form characterized by edematous thickening of the wall, swelling folds and villous atrophy. Larvae occupy lymph-vessel spaces. They also observed that mucosal edema was not only a result of inflammation and protein deficiency but also an effect of larval invasion in the lymph vessels and lymphangiectasia. Ulcerative enteritis is a serious form characterized by ulcers and fibrosis. Larvae are encountered in the entire wall. In the endoscopic era, there have been several case reports describing endoscopic findings of the duodenum in strongyloidiasis, including normal mucosa, edema, erythema, erosion, swollen folds, fine granule, tiny ulcer, polyps, hemorrhage, megaduodenum, deformity, and stenosis (Table 3). To our knowledge, the present retrospective study represents the largest endoscopic experience with *S. stercoralis* hyperinfection. In the histopathological studies, Coutinho *et al*<sup>[29]</sup> reported that duodenal villous atrophy and crypt hyperplasia were proportional to the degree of clinical severity of strongyloidiasis. Suarez and Sanchez<sup>[19]</sup> confirmed that plasma cell infiltration, villous atrophy

and severe duodenitis were the characteristics of severe strongyloidiasis. A recent study clearly demonstrated that strongyloidiasis disrupted epithelial kinetics in the human small intestine by the induction of apoptosis and inhibition of cell proliferation, thereby resulting in villous atrophy and impaired barrier function<sup>[17]</sup>. Our observations disclosed that endoscopic findings of duodenitis were more severe in the patients whose biopsies were positive for larvae than in those with negative biopsies. Considering the fact that increased numbers of larvae are strongly associated with the progression to hyperinfection, our result supports their findings.

Prior reports have indicated that findings frequently include edematous mucosa, swollen folds and erythematous mucosa. However, pathognomonic findings are apparently not evident<sup>[3-19]</sup>. Our present study confirmed the aforementioned frequent findings. In addition, we noticed that an endoscopic feature of duodenal white villi seemed to be a frequent finding. The findings of tiny white spots<sup>[9]</sup> and white punctuate dotting mucosa<sup>[11]</sup> appear to be similar in appearance. The endoscopic finding of white villi is well-known in intestinal lymphangiectasia with protein-losing enteropathy. It represented markedly dilated lymphatics in the stroma of the villi and fats, including fat droplets in the absorptive cells from the impaired transport of fats from intestinal epithelial cells to intestinal lymphatics<sup>[30,31]</sup>. Considering the fact that larvae invade the lymph vessels and that there

is subsequent lymphangiectasia in edematous enteritis as reported by de Paola *et al*<sup>[28]</sup>, the appearance of white villi may reflect villous atrophy/destruction and mucosal edema similar to intestinal lymphangiectasia. We, therefore, emphasize that white villi can be a good endoscopic marker for strongyloidiasis in endemic regions.

There have been very few reports regarding the histopathologic yield by endoscopy for strongyloidiasis. In a study by Thompson *et al*<sup>[13]</sup>, a minimum of six biopsies were obtained from each lesion, resulting in a 100% histopathologic yield from the 6 patients. The reason for our low yield (71.4%) may be due to the fact that our study is a retrospective study conducted at multiple hospitals and only one to three biopsies were taken from each lesion. Obtaining multiple biopsy specimens might increase the histopathologic yield. However, looking at our study from another point of view, only duodenal biopsies were able to establish a diagnosis when the stool analysis was negative in 6 (24%) patients, which lead to the avoidance of a fatal outcome.

In conclusion, *S. stercoralis* hyperinfection can rapidly become fatal, so early diagnosis and treatment is very important. Although diagnosis is usually made by stool analysis, our results clearly demonstrate that endoscopic observation and biopsies, in addition to gastroduodenal drainage analysis, are important tools for diagnosing strongyloidiasis. We also emphasize that infection with *S. stercoralis* and HTLV-1 should be ruled out before

**Figure 1** Frequency of abnormal endoscopic findings in the duodenum**Figure 2** Comparison of endoscopic severity of the duodenum between the patients with larvae present and larvae absent in the duodenal biopsy ( $P < 0.05$ , Mann-Whitney *U*-test).

immunosuppressive therapy is administered for patients living in or coming from endemic regions.

## COMMENTS

### Background

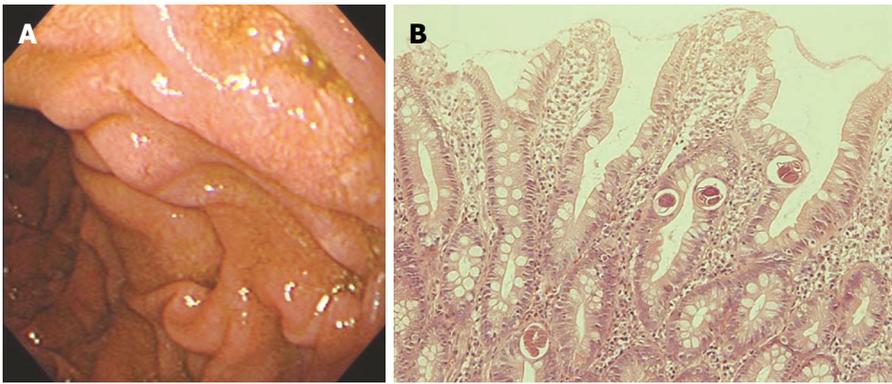

*Strongyloides stercoralis* (*S. stercoralis*) is an intestinal nematode that infects about 100 million people worldwide. As *S. stercoralis* colonizes in the duodenum, endoscopic evaluation has been recognized as an important tool for diagnosing strongyloidiasis. Although there have been several case reports demonstrating endoscopic findings of strongyloidiasis, the relationship of endoscopic markers to clinical and histopathological findings have not been intensively studied.

### Research frontiers

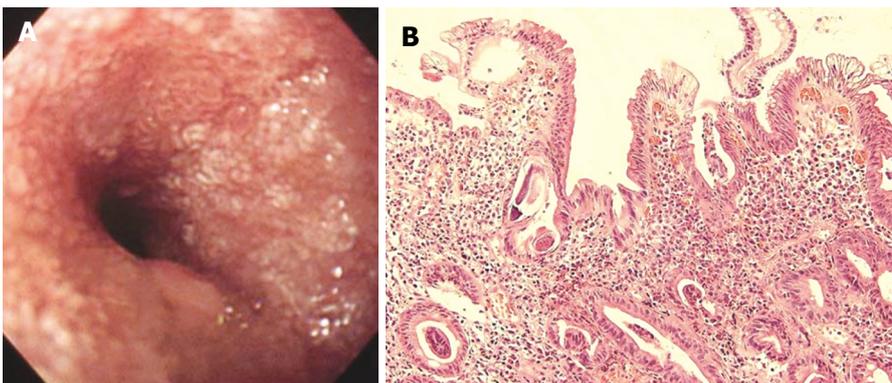

There is an increasing body of epidemiological evidence regarding the association between *S. stercoralis* infection and HTLV-1 infection. Studies of molecular mechanism of this association have become one of the hot spots at present. For the diagnostic purpose, detection of *S. stercoralis* in clinical samples has been improved by the agar plate culture method which was invented recently.

### Related publications

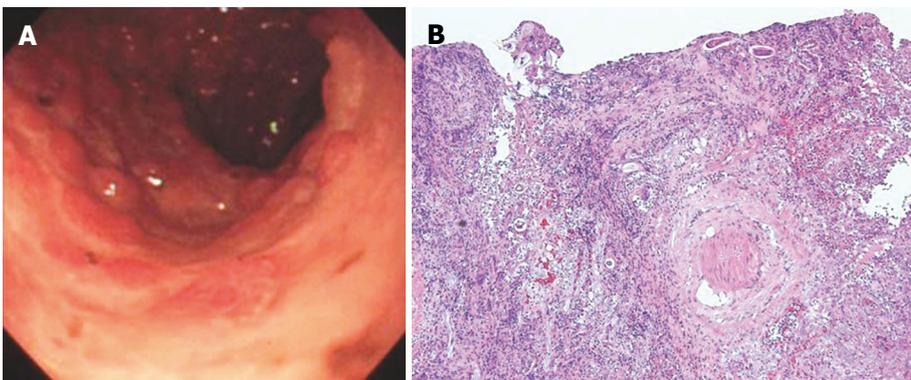

Nakada *et al*<sup>[21]</sup> clearly disclosed the first evidence of the association between *S. stercoralis* infection and HTLV-1 infection. Hirata *et al*<sup>[24]</sup> conducted a large

scale epidemiological study which strengthened this association and showed the impairment of host immune response against *S. stercoralis* by HTLV-1 infection.

### Innovations and breakthroughs

This study clarified the strong association between *S. stercoralis* hyperinfection and HTLV-1 infection. Moreover, presence of white villi can be a good endoscopic marker for the duodenal strongyloidiasis. Endoscopic biopsy helped early diagnosis of strongyloidiasis.

### Applications

Early endoscopic diagnosis of strongyloidiasis can have a marked impact on disease outcome. Co-infection with *S. stercoralis* and HTLV-1 should be ruled out to prevent hyperinfection before immunosuppressive therapy (e.g., corticosteroids) is administered for patients living in or coming from endemic regions.

### Terminology

Hyperinfection is a syndrome of accelerated larval autoinfection which results from immunosuppression. Disseminated strongyloidiasis is the migration of larvae to organs beyond the range of the autoinfective cycle and is often complicated by Gram-negative sepsis which results in high mortality rates.

### Peer review

This is a well conducted study clarifying the strong association between *S. stercoralis* hyperinfection and HTLV-1 infection.

### Abstract

**AIM:** To determine factors affecting the outcome of patients with cirrhosis undergoing surgery and to compare the capacities of the Child-Turcotte-Pugh (CTP) and model for end-stage liver disease (MELD) score to predict that outcome.

**METHODS:** We reviewed the charts of 195 patients with cirrhosis who underwent surgery at two teaching hospitals over a five-year period. The combined endpoint of death or hepatic decompensation was considered to be the primary endpoint.

**RESULTS:** Patients who reached the endpoint had a higher MELD score, a higher CTP score and were more likely to have undergone an urgent procedure. Among patients undergoing elective surgical procedures, no statistically significant difference was noted in the mean MELD ( $12.8 \pm 3.9$  vs  $12.6 \pm 4.7$ ,  $P = 0.9$ ) or in the mean CTP ( $7.6 \pm 1.2$  vs  $7.7 \pm 1.7$ ,  $P = 0.8$ ) between patients who reached the endpoint and those who did not. Both mean scores were higher in the patients reaching the endpoint in the case of urgent procedures (MELD:  $22.4 \pm 8.7$  vs  $15.2 \pm 6.4$ ,  $P = 0.0007$ ; CTP:  $9.9 \pm 1.8$  vs  $8.5 \pm 1.8$ ,  $P = 0.008$ ). The performances of the MELD and CTP scores in predicting the outcome of urgent surgery were only fair, without a significant difference between them (AUC =  $0.755 \pm 0.066$  for MELD vs AUC =  $0.696 \pm 0.070$  for CTP,  $P = 0.3$ ).

**CONCLUSION:** The CTP and MELD scores performed

equally, but only fairly in predicting the outcome of urgent surgical procedures. Larger studies are needed to better define the factors capable of predicting the outcome of elective surgical procedures in patients with cirrhosis.

### INTRODUCTION

Patients with cirrhosis who undergo surgery under general anesthesia are at an increased risk of surgery and anesthesia-related complications<sup>[1]</sup>. The underlying liver dysfunction makes patients with cirrhosis particularly susceptible to bleeding and infection, two common post-surgical problems<sup>[2]</sup>. Moreover, the effect of surgery and anesthesia on the liver may be significant. Whereas the exact hemodynamic effect of different anesthetics on the hepatic circulation can be variable<sup>[3-5]</sup>, the net result is usually a reduction in hepatic perfusion<sup>[6]</sup>, thereby exposing the liver to the risk of ischemic injury. In addition, a number of anesthetic agents have a potential for direct, drug-induced hepatotoxicity<sup>[7-9]</sup>. Blood loss during surgery may result in hepatic hypoperfusion as well. Post-operative hypotension, sepsis and the subsequent use of medication with potential hepatotoxicity further increase the risk of liver injury<sup>[10]</sup>. A number of case series of patients with cirrhosis undergoing specific surgical procedures suggest a worse than expected outcome<sup>[11-15]</sup>. A review of

733 patients with cirrhosis undergoing various surgical procedures revealed a perioperative mortality rate of 11.6% and a postoperative complication rate of 30%, which is significantly higher than what would be expected in patients without liver disease<sup>[16]</sup>.

The significant perioperative risks associated with surgery in patients with cirrhosis highlight the importance of preoperative assessment and appropriate patient selection for surgery. The Child-Turcotte-Pugh (CTP or "Child") classification was initially designed to evaluate the risk of surgical portosystemic shunt procedures, and was subsequently found to predict long-term survival in patients with cirrhosis<sup>[17]</sup>. Interestingly, the more recently devised prognostic scoring system used in patients with cirrhosis, namely the Model for End-stage Liver Disease (MELD) score was also originally designed for the purpose of selection of cirrhotic patients for a portosystemic shunt procedure—the transjugular intrahepatic portosystemic shunt (TIPS)<sup>[18]</sup>. Whereas the CTP class has traditionally been used in preoperative risk stratification in cirrhotic patients undergoing surgery, the MELD score was found to be superior to the CTP score and class in predicting three-month survival in patients with cirrhosis<sup>[19]</sup>.

There has been a recent interest in evaluating the role of the MELD score in preoperative risk assessment, with a number of recent publications on the subject<sup>[20–24]</sup>. The purpose of our study is to determine factors affecting the outcome of patients with cirrhosis undergoing surgical procedures under general anesthesia and to compare the capacities of the CTP and MELD scores in predicting that outcome.

## MATERIALS AND METHODS

### Patient selection

We conducted a retrospective review of the charts of patients with cirrhosis undergoing surgical procedures under general anesthesia between January 1999 and December 2004 at two teaching hospitals, Emory University Hospital and Emory Crawford Long Hospital.

We used the computerized medical record system to screen charts for "liver cirrhosis" and "general anesthesia" using billing codes and International Classification of Diseases-9 codes. Patients in whom the chart review did not reveal documented cirrhosis were excluded. Patients were considered to have documented cirrhosis if they had a liver biopsy confirming cirrhosis, an intraoperative finding of a cirrhotic liver during laparotomy or laparoscopy, or a combination of imaging and laboratory profiles consistent with cirrhosis. Patients undergoing surgical procedures directly involving the liver, such as liver transplantation, hepatectomy and transjugular intrahepatic portosystemic shunts were excluded. Patients for whom the preoperative CTP or MELD score could not be computed because of insufficient data were also excluded. Approval of the protocol by the Institutional Review Board of Emory University was obtained prior to the conduction of the study. The protocol conforms with the provisions of the declaration of Helsinki as revised in Edinburgh in 2000.

### Data collection

Preoperative history, physical examination and laboratory values were used to calculate the CTP and MELD scores. Surgical procedures were classified by organ system and by whether the procedures are urgent or elective. Surgery was considered to be elective if the procedures could reasonably have been scheduled at a later date without the need for hospitalization in the interim. Procedures not satisfying this criterion were classified as urgent procedures. Patients were followed up for 30 post-procedure days.

The primary endpoint for the purpose of our study was the occurrence of death or hepatic decompensation during the follow-up period. Hepatic decompensation was defined as the occurrence of both clinical decompensation and biochemical evidence of worsening liver function. Occurrences of new or worsening ascites, new or worsening encephalopathy, or variceal bleeding during the follow-up period were considered to be an evidence of clinical decompensation. A rise in the international normalized ratio (INR) or bilirubin in combination with clinical decompensation was required for the endpoint to be reached.

### Statistical analysis

Patient characteristics were tallied both overall and by achievement of the endpoint of death or hepatic decompensation, and descriptive statistics were calculated. Two-sample *t*-tests were used to compare means of the continuous measures between the endpoint groups. To compare categorical summaries, the chisquare test of independence was used. Where expected counts were too low, Fisher's exact test was employed. The Cochran-Armitage Test for Trend was used to examine the score system and endpoint relationships across ordinal Child classifications (A, B, C) and MELD tertiles.

These tests revealed that both score systems and procedure urgency were important factors in predicting death or decompensation. In order to more precisely quantify the roles of these variables in predicting the endpoint, a logistic regression was performed with urgency and classification score (either MELD or CTP) as independent variables, and the combined endpoint as a dependent variable. To avoid multicollinearity, the CTP and MELD scale were included in separate models.

To further characterize the relationships between score, urgency and the endpoint, we used a two-factor analysis of variance (ANOVA) to compare mean CTP and MELD scores for a model which included urgency, endpoint achievement, and their interaction.

These analyses showed that the scores significantly differed only within the urgent patient population. This directed our use of receiver-operating characteristic (ROC) plots to examine the relationship between score and patient outcome for the urgent-procedure population only. Predictive values for each scale were assessed by measuring the area under the curve (AUC). The AUCs for the CTP and MELD systems were compared using the method proposed by DeLong *et al*<sup>[25]</sup> for two correlated ROC curves. All analyses were performed using SAS software version 9.1 (SAS Institute Inc., Cary, NC). The correlated

CTP: Child-Turcotte-Pugh; MELD: Model for end-stage liver disease.

AUC test was implemented using the ROC SAS macro provided by DeLong *et al*<sup>[26]</sup>.

## RESULTS

A total of 617 patients were identified on initial screening. Of the initial group of patients, 258 had documented cirrhosis. Forty-five patients were excluded for undergoing liver-related surgery, and 18 patients were excluded because of insufficient data. A total of 195 patients were included in the study.

Patients were mostly white with a male predominance. The mean patient age was 57.1 years. Hepatitis C was the leading etiology of cirrhosis, followed by cryptogenic cirrhosis and alcoholic cirrhosis. Most patients were CTP class B, with a mean ± SD CTP score of 8.0 ± 1.9. The mean ± SD MELD score was 14.2 ± 6.3 (Table 1). The most commonly performed procedures were

gastrointestinal. A total of 138 procedures were classified as elective and 57 as urgent. The procedures performed are detailed in Table 2.

Seventeen (8.7%) patients died during follow-up and 28 (14.4%) patients had evidence of hepatic decompensation. Among the 17 patients who died, 13 (76.5%) had evidence of hepatic decompensation as well. A total of 32 patients (16.4% of the total, 21/57 patients in the urgent surgery group and 11/138 patients in the elective surgery group) reached the study endpoint of death or decompensation in the postoperative period. The causes of death were sepsis in 47.1% (8/17), gastrointestinal bleeding in 23.6% (4/17), and sudden cardiac arrest in 5.9% (1/17) cases. The cause of death was unknown in 4 patients. New or worsening hepatic encephalopathy was observed in 20 (10.3%) patients, new or worsening ascites in 9 (4.6%) patients, and variceal bleed in 8 (4.1%) patients.

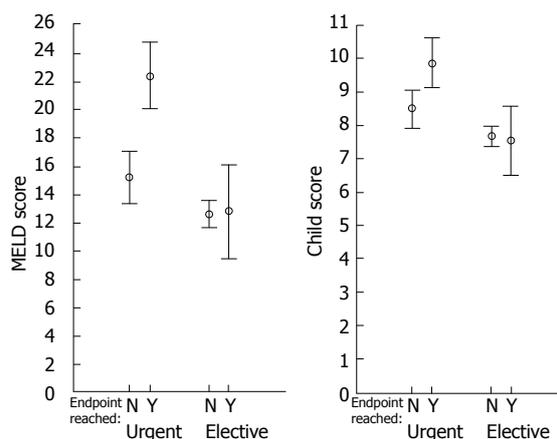

Bivariate analyses revealed a significantly different

**Table 3** Logistic regression analysis: odds ratio of death or decompensation in the postoperative period using the parameters of procedure urgency and the MELD score (A) or the CTP score (B)

	Odds ratio	95% CI	P
A: MELD model			
MELD (1 unit increase)	1.1	[1.03-1.17]	0.0044
MELD (5 unit increase)	1.58	[1.16-2.19]	
Elective (no vs yes)	4.34	[1.81-10.71]	0.0011
B: CTP model			
CTP (1 unit increase)	1.25	[1.00-1.57]	0.0554
Elective (no vs yes)	5.18	[2.20-12.22]	0.0002

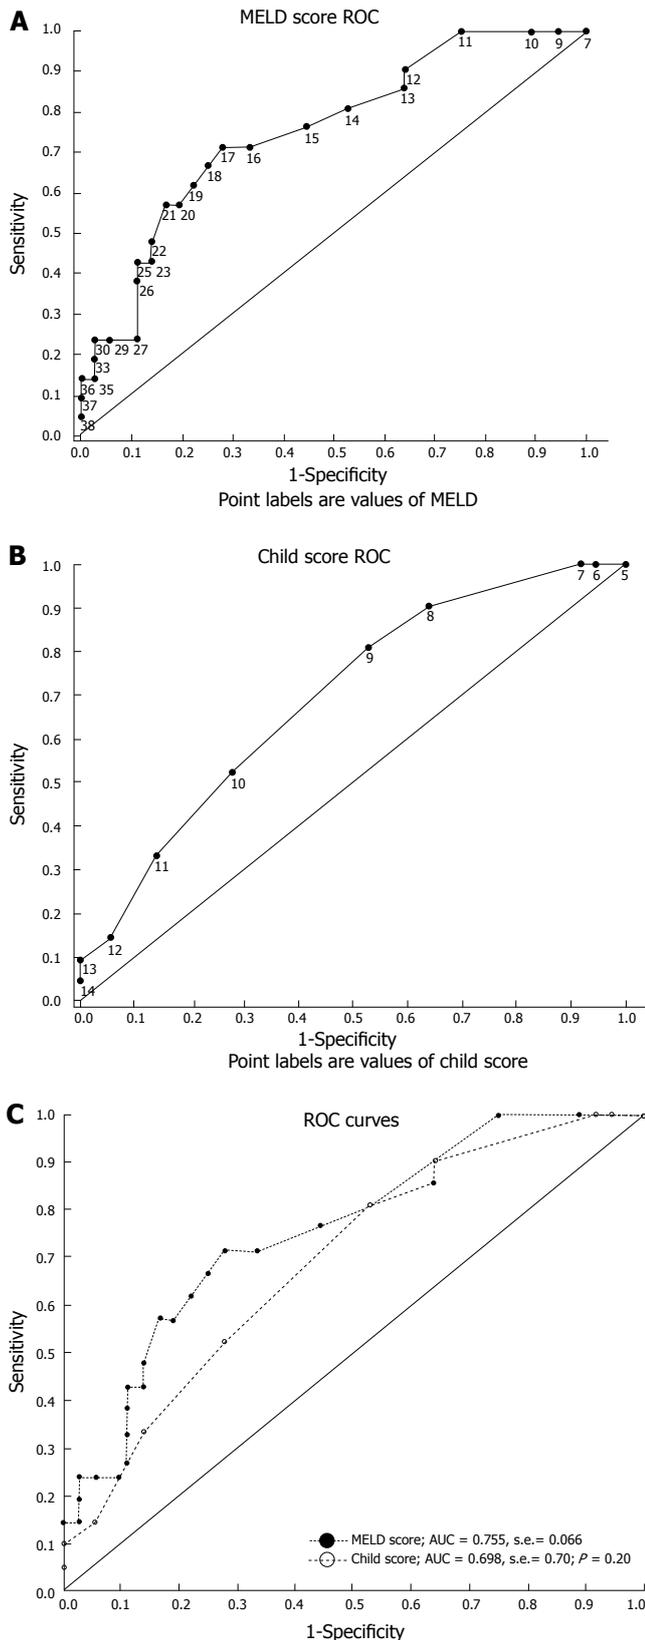

**Figure 1** Mean MELD and Child scores with 95% confidence intervals, stratified by procedure urgency. A significant difference was observed in means between the patients who reached the endpoint and the patients who did not in the case of urgent surgery, but not in the case of elective surgery.

trend between the proportion of patients that reached the study endpoint in each MELD tertile, as well as each CTP class ( $P = 0.0008$  for MELD,  $P = 0.0018$  for CTP). Those who experienced death or decompensation tended to be in the higher score classifications. Patients who reached the endpoint were also more likely to have had an urgent procedure ( $P < 0.0001$ ). No inter-group difference was found in the other baseline characteristics (Table 1). Logistic regression analyses revealed that the MELD score, CTP score and the urgency of the procedure were significantly associated with the study endpoint (Table 3).

Among patients undergoing elective surgical procedures, no statistically significant difference was noted in the mean  $\pm$  SD MELD score ( $12.8 \pm 3.9$  vs  $12.6 \pm 4.7$ ,  $P = 0.9$ ) or in the mean  $\pm$  SD CTP score ( $7.6 \pm 1.2$  vs  $7.7 \pm 1.7$ ,  $P = 0.8$ ) between patients who reached the endpoint and patients who did not. Conversely, both the mean  $\pm$  SD MELD score and mean CTP score were higher in patients reaching the endpoint in the case of urgent procedures (MELD:  $22.4 \pm 8.7$  vs  $15.2 \pm 6.4$ ,  $P = 0.0007$ ; CTP:  $9.9 \pm 1.8$  vs  $8.5 \pm 1.8$ ,  $P = 0.008$ , Figure 1).

When evaluating the capacities of the CTP and MELD scores to predict the occurrence of the study endpoint in the 57 patients undergoing urgent surgical procedures, the performances of both scoring systems were found to be fair: the area under the receiver operating characteristics curve (AUC) for MELD was  $0.755 \pm 0.066$ , the AUC for CTP was  $0.696 \pm 0.070$  (Figure 2A and B). No statistically significant difference was found between the AUC for MELD and the AUC for CTP for these patients ( $P = 0.20$ , Figure 2C). A MELD score of 17 had a sensitivity of 71% and a specificity of 72% in predicting the outcome of death or decompensation in urgent surgical procedures. A CTP score of 9 had a sensitivity of 81% and specificity of 47% in predicting the outcome. Among the patients undergoing urgent surgical procedures, none of the 15/57 patients with a preoperative MELD score of  $\leq 11$  and none of the 15/57 patients with a preoperative

**Figure 2** Receiver operating characteristics (ROC) curves for MELD score (A) and CTP score (B) as predictors of death or hepatic decompensation in the postoperative period in 57 cirrhotic patients who underwent urgent surgical procedures under general anesthesia. Panel C shows a comparison of the two curves.

CTP score of  $\leq 7$  had any evidence of death or hepatic decompensation in the post-operative period.

## DISCUSSION

Gastroenterologists and hepatologists are often asked to evaluate patients with cirrhosis prior to undergoing non-liver-related surgical procedures for an opinion about the perioperative risk entailed and potential ways to reduce that risk. Unfortunately, the available evidence to support answers to these questions is relatively limited and is uniformly based on retrospective data.

Early studies addressing preoperative evaluation in cirrhosis identified the Child-Pugh score as a useful preoperative parameter in predicting surgical risk in patients undergoing abdominal surgery with a mortality rate of 10% for Child class A patients, 30%-31% for Child class B, and 76%-82% for Child class C patients<sup>[27,28]</sup>. Compared to the Child score, the MELD score has an advantage of relying entirely on objective parameters for its computation, since it does not require an evaluation of the degree of ascites and the degree of encephalopathy. Also, the MELD score is a variable with a wider range of possible numeric values (6 to 40 for MELD compared to 5 to 15 for Child), thereby potentially allowing a better discrimination between patients with different degrees of hepatic dysfunction. Perkins *et al*<sup>[22]</sup> did not find a difference in the performances of the MELD score and the Child score in predicting the morbidity of cholecystectomy in 33 patients with cirrhosis. The authors favored the use of the MELD score because it is more objectively defined, and suggested a MELD score of 8 as a cut-off point that predicts an increased morbidity. Data about the urgency of the procedure was not provided<sup>[22]</sup>. In evaluating the outcome of 66 patients with cirrhosis undergoing predominantly elective cardiac surgery, Suman *et al*<sup>[21]</sup> found that the Child score and the MELD score were comparable in predicting the occurrence of hepatic decompensation in the postoperative period. The Child score cut-off point of 7, however, had a higher sensitivity in predicting mortality than a MELD cut-off of 13. In reviewing their experience with cardiac surgery in 27 patients with cirrhosis, Filsoufi *et al*<sup>[29]</sup> noted that the Child score was a better predictor of hospital mortality than the MELD score. On the other hand, Befeler *et al*<sup>[23]</sup> found the MELD score to be a better predictor of poor outcome than the Child class in 53 cirrhotic patients undergoing abdominal surgery, although in this case the MELD score was compared to Child class categories, and not to the numeric value of the Child score.

Our study included 195 patients with documented cirrhosis undergoing various surgical procedures under general anesthesia. The patients included in our study had fairly advanced liver disease with 57.4% of patients having a MELD score  $\geq 12$  and 79% being Child class B or C. The operative mortality (8.7%) that we observed is similar to the mortality observed in a large series of patients with cirrhosis undergoing surgery<sup>[16]</sup>.

We found the urgency of the procedure to be a powerful predictor of the outcome, with the occurrence of the combined endpoint of death or hepatic decompensation being observed more than 4 times more often in the patients undergoing urgent surgery compared to the patients undergoing elective surgery. This effect

persisted when controlling for the MELD or Child score in multivariate analysis (Table 3). Furthermore, when the data was stratified by the urgency of the procedure, neither the MELD nor the Child score was able to predict the outcome of elective surgery. This may be due to the lower event rate in patients undergoing elective surgery, as might be expected. It is conceivable as well that if a larger number of patients were included, the MELD score and Child score might have had a better discriminatory ability in predicting the outcome of elective surgery. This finding emphasizes, however, the importance of making a distinction between elective procedures and urgent procedures when studying the effect of variables on surgical outcome in patients with cirrhosis. In prior similar studies addressing predictors of operative outcomes in cirrhotic patients, this important distinction was not always made.

In the group of patients undergoing urgent surgery, the MELD score and Child score performed equally in predicting the occurrence of death or hepatic decompensation in the postoperative period. The performance of both scoring systems was only fair in that regard, with an AUC of 0.755 for MELD and 0.696 for Child, which is reflected in the lack of a cut-off point with both a high sensitivity and a high specificity in predicting the outcome for either scoring system. This is unlike the case of other studies where higher AUCs were noted<sup>[21,22]</sup>. Studies with higher AUC values had studied specific surgical procedures, and the reason for the lower AUC in our study is likely to be the fact we studied a variety of procedures with different inherent risks to the patient. This problem could be circumvented by devising a classification system of surgical procedures by their inherent risk to patients with liver dysfunction, similar to the established system used in the case of perioperative risk assessment in cardiovascular disease<sup>[30]</sup>. In their seminal study on perioperative risk in patients with cirrhosis, Ziser *et al*<sup>[6]</sup> provided some useful guidance in this direction; however, this remains an area in need of further study.

We noted that among patients in our study undergoing urgent surgery with either a MELD score  $\leq 11$  or a Child  $\leq 7$ , none had evidence of death or decompensation postoperatively. Patients falling into this low-risk category represented a substantial proportion (20/57, 35.1%) of the total number of patients undergoing urgent surgery, suggesting that these cut-off points may be useful in practice.

It is likely that the role of preoperative evaluation in patients with cirrhosis is more critical in the case of elective surgical procedures than it is in the case of urgent procedures. In many instances, patients undergoing urgent surgery may have no reasonable alternative to surgery, and may have little time for any preoperative intervention that could potentially reduce the risk of complications. Therefore, the best opportunity for Gastroenterologists or Hepatologists to intervene in a manner that may reduce surgical risk or to provide useful guidance as to whether or not to proceed with surgery is probably in the case of elective surgery rather than urgent surgery. We could not demonstrate that MELD score and Child score were helpful in determining the outcome of elective surgery.

Furthermore, larger studies are needed to better define the roles of the Child and MELD scores in predicting the outcome of surgical procedures in patients with cirrhosis, particularly in the case of elective surgery.

## COMMENTS

### Background

Patients with cirrhosis who undergo surgeries under general anesthesia are at an increased risk of complications. The Child-Turcotte-Pugh (CTP) class has been used to assess the risk of surgery in patients with cirrhosis. The model for end-stage liver disease (MELD) score is a more recently devised tool to assess the severity of liver disease.

### Research frontiers

Previous studies comparing the CTP score and the MELD score in predicting the outcome of surgery in cirrhosis yielded variable results, generally pointing in the direction of both scoring systems being good predictors of the outcome of non-hepatic surgery in cirrhosis. Only few studies made the distinction between elective and urgent surgery.

### Innovations and breakthroughs

The urgency of the surgical procedure was found to be a major predictor of the outcome, with the complication rate of elective procedures being generally low. In elective procedures, the CTP score and MELD score were not predictive of the outcome. In urgent procedures, the MELD score and CTP score performed equally in predicting an adverse outcome.

### Applications

The MELD score and CTP score could be used alternatively in evaluating the risk of an urgent surgical procedure. Studies are needed to assess the risk of elective procedures in patients with cirrhosis.

### Terminology

The CTP and MELD scores are both measures of the severity of liver disease in cirrhosis. The MELD score is computed entirely using objective laboratory data. The computation of the CTP scores requires an assessment of non-objective parameters, including the severity of ascites and of encephalopathy.

### Peer review

In this retrospective study, the authors determined the factors affecting the outcome of surgeries under general anesthesia in patients with cirrhosis and compared the capacities of the CTP and MELD scores to predict that outcome. They concluded that CTP and MELD scores performed equally, but only fairly in predicting the outcome of urgent surgical procedures.

Short-term overlap lamivudine treatment with adefovir dipivoxil in patients with lamivudine-resistant chronic hepatitis B. *World J Gastroenterol* 2008; 14(11): 1781-1784 Available from: URL: <http://www.wjg-net.com/1007-9327/14/1781.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1781>

### Abstract

**AIM:** To evaluate the efficacy of short-term overlap lamivudine therapy with adefovir in patients with lamivudine-resistant and naïve chronic hepatitis B, we compared patients receiving overlap therapy with those receiving adefovir alone.

**METHODS:** Eighty patients who had received lamivudine treatment for various periods and had a lamivudine-resistant liver function abnormality were enrolled. Forty of these patients received adefovir treatment combined with lamivudine treatment for  $\geq 2$  mo, while the other 40 received adefovir alone. We assessed the levels of hepatitis B virus (HBV) DNA at 0, 12 and 48 wk and serum alanine aminotransferase (ALT) levels after 0, 12, 24 and 48 wk of adefovir treatment in each group.

**RESULTS:** We found serum ALT became normalized in 72 (87.5%) of the 80 patients, and HBV DNA decreased by  $\geq 2$  log<sub>10</sub> copies/mL in 60 (75%) of the 80 patients at the end of a 48-wk treatment. HBV DNA levels were not significantly different between the groups. The improvements in serum ALT were also not significantly different between the two groups.

**CONCLUSION:** These findings suggest short-term overlap lamivudine treatment results in no better virological and biological outcomes than non-overlap adefovir monotherapy.

### INTRODUCTION

Hepatitis B virus (HBV) infection is the main cause of various liver diseases, such as acute and chronic hepatitis, cirrhosis and hepatocellular carcinoma<sup>[1,2]</sup>. To prevent progression into end stage liver diseases, effective and reliable treatment of chronic hepatitis B has been urgently needed. Five regimens have been used for the treatment of chronic hepatitis B. The approved drugs are interferon (conventional and pegylated), lamivudine, adefovir dipivoxil and entecavir. Lamivudine has been effective and tolerable in chronic hepatitis B, but grave drug-resistant mutations developed up to 65% after 5 years of treatment<sup>[3]</sup>. Unlike conventional interferon, pegylated interferon treatment could lead to similar or more efficient virological responses than lamivudine, but unwillingness to injection and a number of side effects have prevented its further active usage. However, recent reports showed more optimizing results than ever<sup>[4]</sup>.

Adefovir dipivoxil is a nucleotide analogue which has been shown to have potent anti-viral activity and side effects similar to those of lamivudine. It also has anti-viral effects against both naïve and lamivudine-resistant cases<sup>[5,6]</sup>. Because of provisions in Korean national medical insurance which restrict the use of adefovir to 'rescue' treatment in cases of lamivudine resistance, adefovir dipivoxil is generally prescribed to patients with lamivudine-resistant HBV in Korea<sup>[7,8]</sup>.

Peter *et al*<sup>[9]</sup> suggested the biological and virologic responses were comparable between combinations and adefovir monotherapy in patients with lamivudine-resistant HBV. However, aggravation of hepatitis is more common in patients receiving adefovir monotherapy. Therefore, an overlap period of 2-3 mo was recommended due to the risk of aggravation of liver function during the transition time.

We analyzed the differences between short-term overlap therapy with lamivudine and adefovir and adefovir monotherapy based on viral and blood chemical studies to elucidate the effectiveness of overlap.

## MATERIALS AND METHODS

### Clinical characteristics of the patients

From March 2004 to May 2006, 80 chronic hepatitis B patients were sequentially enrolled from admission and/or outpatient department and/or the Daejeon St. Mary's Hospital in the Medical College of the Catholic University of Korea. All patients gave written informed consent to participate in this study. All patients had been prescribed lamivudine for chronic hepatitis B and had developed lamivudine-resistant YMDD mutant HBV. YMDD mutation was confirmed by polymerase chain reaction (PCR) in our clinical pathology department. Prior to enrollment, all patients had a serum HBV DNA concentration above 10<sup>5</sup> copies/mL and elevated serum ALT above 80 IU/L. The exclusion criteria were as follows: Patients showing serologic and/or radiological evidence of alcoholic hepatitis or cirrhosis; patients who did not comply with a regular check up of serological and/or virological markers; patients with drug histories, such as herb medications.

Patients received 10 mg adefovir dipivoxil (Hepsera<sup>TM</sup>) orally once a day after enrollment, for 48 wk. Forty patients also received 100 mg lamivudine (Zeffix<sup>TM</sup>) for 2 mo.

### Virological and chemical assays

Serum ALT levels were assessed at intervals of 3 mo and HBV DNA levels were also assessed at 0, 24 and 48 wk. HBeAg and anti-HBe (HBeKit, Beijing North Institute of Biological Technology, Beijing, China) (Quantum Cobra Series II, Packard Inst. Co. Meriden, CT, USA) were assayed at 0, 12 and 48 wk. Serum HBV DNA was examined using an HBV DNA PCR instrument (Covas Amplicor<sup>TM</sup>, Roche Diagnostics systems, Mannheim, Germany).

### Statistical analysis

Data were recorded as mean ± SD and analyzed by paired *t*-tests. A *P* value of < 0.05 was considered to be statistically significant.

## RESULTS

### Baseline characteristics of patients

The baseline characteristics of the enrolled patients are shown in Table 1. There were no significant differences in clinical, virological and chemical characteristics between the groups. All enrolled patients completed the 48-wk adefovir treatment schedule.

Table 1 Baseline characteristics of patients in each group

	Overlap	Non-overlap
Age (yr)	43.3 ± 8.9	43.7 ± 13.0
Male/female ratio	32/8	29/11
Baseline ALT (IU/L)	188.4 ± 74.1	209.6 ± 130.6
Baseline HBV DNA (log <sub>10</sub> copy/mL)	6.9 ± 0.6	6.9 ± 0.7
Median lamivudine treatment (mo)	21.5	20.3
HBeAg positive/negative	22/18	25/15

Table 2 Comparison of mean serum ALT levels in each group

	wk after adefovir treatment (IU/L)				
	0	12	24	36	48
Overlap	188.4 ± 74.1	77.3 ± 53.9	78.3 ± 90.2	34.2 ± 13.4	25.9 ± 9.9
Non-overlap	209.6 ± 130.6	78.9 ± 40.8	43.6 ± 24.9	34.2 ± 8.7	24.0 ± 8.7
<i>P</i> -value	NS	NS	NS	NS	NS

NS: Not statistically significant.

Table 3 Comparison of median serum HBV DNA levels in each group

	wk after adefovir treatment (Log <sub>10</sub> copies/mL)		
	0	12	48
Overlap	6.9 ± 0.6	5.5 ± 1.4	3.8 ± 1.0
Non-overlap	6.9 ± 0.7	4.2 ± 1.2	3.4 ± 1.4
<i>P</i> -value	NS	NS	NS

NS: Not statistically significant.

### Comparison of ALT and HBV DNA levels between overlap and non-overlap

At the end of the study schedule, serum ALT level was normalized in 72 (87.5%) of the 80 patients. Overall, the HBV DNA level was decreased by more than 2 log<sub>10</sub> copies/mL in 60 (75%) of the 80 patients. HBeAg became negative in 6 (12.7%) of the 47 baseline HBeAg-positive patients. HBeAb seroconversion developed in none of the baseline HBeAg-positive patients.

Serum ALT levels at intervals of 3 mo showed no statistically significant difference between the groups, and ALT level flare up after adefovir monotherapy was seen in only 4 (10%) of the non-overlap patients (*vs* 7.5% of the overlap patients) (Table 2). HBV DNA levels at noted schedules also showed no specific statistically significant difference between the groups (Table 3).

## DISCUSSION

There are many suggestions and debates about the management of patients with lamivudine-resistant mutant HBV. However, no obvious consensus has emerged so far. Due to the reported high resistance to lamivudine treatment, many patients who received lamivudine as a therapy for chronic hepatitis B in Korea have had their prescription changed to other anti-viral agents, especially adefovir<sup>[7]</sup>. Adefovir has a similar potency and side effects,

but is associated with lower resistance than lamivudine<sup>[5,6]</sup>. Whether lamivudine should be prescribed for short-term treatments in combination with adefovir has been a matter of controversy<sup>[9,10]</sup>. Thus, we performed a prospective study to elucidate the efficacy of a short-term overlap lamivudine treatment. Although a short-term overlap lamivudine therapy was recommended due to the acute flare ups in serum ALT level reported by Peter *et al*<sup>[9]</sup>, similar ALT levels were seen in the two groups in our study.

All patients enrolled in our study had compensated chronic liver diseases and no patients had decompensated liver functions after a 48-wk follow up. HBV DNA levels and serum ALT levels were decreased sequentially by adefovir treatment with or without short-term overlap. Therefore, adefovir dipivoxil treatment was effective against lamivudine-resistant chronic hepatitis B.

Hadziyannis *et al*<sup>[11]</sup> recently reported adefovir monotherapy for HBeAg-negative chronic hepatitis B for up to 5 years was well tolerated, increasing improvement in the fibrosis of the liver, durable suppression of HBV DNA, and up to 29% resistance. Because of good results following long-term therapy with adefovir with or without short-term overlap lamivudine treatment, adefovir monotherapy without overlap lamivudine therapy might be validated.

Recently, Liu *et al*<sup>[12]</sup> reported that an overlap of lamivudine and adefovir treatments for more than 2 mo leads to better virological but not biochemical outcomes in patients with lamivudine-resistant HBV than adefovir treatment alone. However, their study population was smaller than ours and comprised non-randomized cases. Our data showed short-term overlap lamivudine therapy was not superior to non-overlap adefovir monotherapy group with regard to virological and/or biochemical laboratory data. HBeAg loss and HBeAg seroconversion rates were similar to those reported in previous studies by Locarinni *et al*<sup>[13]</sup>. Both HBeAg loss and HBeAg seroconversion were no better than lamivudine.

Akyildiz *et al*<sup>[14]</sup> also recently reported there was no significant difference between patients with lamivudine resistant chronic hepatitis B treated with adefovir alone and those treated with adefovir in combination with lamivudine for three mo. Therefore, the authors asserted it was not necessary to continue lamivudine treatment while switching to adefovir dipivoxil monotherapy. These results are consistent with ours, although it is not perfectly obvious to assert that switching to adefovir dipivoxil monotherapy with an instant cessation of lamivudine. Our study also has several limitations, such as an insufficient study population and/or non-randomized with blinded state. Moreover, follow up longer than 48 wk is ongoing state.

In summary, our results suggest there is no greater benefit of short-term overlap lamivudine treatment than non-overlap adefovir monotherapy. An overlap of more than 2 mo showed no better virological and/or biochemical results. Therefore, starting adefovir monotherapy immediately instead of applying a short-term overlap might be an efficient choice in cases of lamivudine-resistant HBV. Furthermore, new anti-viral agents with higher potency, durability and/or HBV seroconversion rate should be devised in the near future.

## COMMENTS

### Background

To prevent progression into end-stage liver diseases, effective and reliable treatment for chronic hepatitis B has been urgently needed. Adefovir dipivoxil is effective in patients with lamivudine-resistant and naive chronic hepatitis B. The efficacy of short-term overlap treatment with lamivudine and adefovir is not well known. We compared patients who received short-term overlap therapy with those who received adefovir only to evaluate the efficacy of short-term overlap lamivudine therapy.

### Research frontiers

Peter *et al* suggested the biological and virologic responses were comparable between combinations of adefovir and lamivudine therapies and adefovir monotherapy in patients with lamivudine-resistant Hepatitis B virus (HBV). However, aggravation of hepatitis was more common in patients receiving adefovir monotherapy. Therefore, an overlap period of 2-3 mo was recommended due to the risk of aggravation of liver function during the transition time. Liu *et al* reported an overlap of lamivudine and adefovir for longer than 2 mo leads to better virological but not biochemical outcomes in patients receiving adefovir for lamivudine-resistant HBV. Akyildiz *et al* reported there was no significant difference between patients with lamivudine-resistant chronic hepatitis B receiving adefovir alone and those receiving adefovir in combination with lamivudine for three months. Therefore, the authors asserted it was not necessary to continue lamivudine treatment while switching to adefovir dipivoxil monotherapy.

### Innovations and breakthroughs

Our study has a larger study population and a more objective differentiation of liver function than other studies. However, our study also has several limitations, such as an insufficient study population and/or non-randomized with blinded state.

### Applications

There are needs for longer and larger scales of study in this field. Although the recent article from Hadziyannis *et al* showed the superiority of combination therapy, more studies are needed to study the comparison between switching with or without overlap and combination therapy of adefovir and lamivudine.

### Terminology

Overlap of lamivudine and adefovir: Use of two regimens at the same time for several months to avoid viral flare up; Switching: When mutant HBV strains resistant to lamivudine develop, other regimens (such as Adefovir, Entecavir and Clevudine) can be substituted for lamivudine.

### Peer review

This study evaluates the efficacy of short-term overlap of lamivudine and adefovir in patients with lamivudine-resistant chronic hepatitis B. Compared with non-overlap adefovir monotherapy, short-term overlap lamivudine treatment show no better virological and biological outcomes. This can be interesting for the gastroenterologists and may represent a potentially efficacious approach to the clinical management of acute HBV infection.

Cyclooxygenase 2 polymorphism and colorectal cancer: -765G>C variant modifies risk associated with smoking and body mass index. *World J Gastroenterol* 2008; 14(11): 1785-1789 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1785.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1785>

### Abstract

**AIM:** To explore whether cyclooxygenase 2 (*COX-2*) -765G>C polymorphism is associated with susceptibility of colorectal cancer (CRC) and to evaluate the risk of colorectal cancer in relation to environmental exposures and polymorphism.

**METHODS:** We conducted a case-control study of 137 patients with colorectal cancer and 199 cancer-free controls in northeast China. Multivariate logistic regression analysis was performed to calculate the adjusted odds ratio (OR) and 95% confidence interval (95% CI).

**RESULTS:** The -765G>C polymorphism was not independently associated with CRC risk. However, risk associated with the polymorphism differed by smoking and body mass index (BMI). Smoking and BMI associated risks were stronger among those with -765GG genotype, showing that smokers had a 2.682-fold greater risk of CRC than nonsmokers (51/43 vs 68/126,  $P = 0.006$ ). Compared to those with a normal body mass index (BMI 18.5-22.9), those with overweight (BMI 23-24.9) had a 3.909-fold higher risk of CRC (OR = 3.909, 95% CI = 2.081-7.344;  $P < 0.001$ ), while those with obesity (BMI > 25) had a 2.031-fold higher risk of CRC (OR = 1.107, 95% CI = 1.107-3.726;  $P = 0.022$ ).

**CONCLUSION:** Although *COX-2* -765G>C polymorphism

### INTRODUCTION

Cyclooxygenases (COXs) are rate-limiting enzymes for prostaglandin production<sup>[1]</sup>. Two isoforms were described, the constitutively expressed *COX-1* and the inducible isoform *COX-2*<sup>[2]</sup>. *COX-2* is expressed at low levels in most tissues but high in inflammatory states<sup>[3]</sup>, and is induced by a variety of stimulators including cytokines<sup>[4]</sup>, growth factors<sup>[5]</sup>, as well as tumor promoters<sup>[6]</sup>. Prostaglandin synthesis by the *COX-2* is regulatory compounds that play major roles in the inflammatory response<sup>[2]</sup>. Chronic inflammation is responsible for the development and progression of many common cancers. It is well established that patients with inflammatory bowel disease are at increased risk of developing colorectal cancer (CRC)<sup>[7,8]</sup>.

*COX-2* promoter region contains multiple regulatory elements, such as nuclear factor- $\kappa$ B (NF- $\kappa$ B) binding site, nuclear factor interleukin-6 (NF-IL6)/CCAAT/enhancer-binding protein (C/EBP) binding site, cyclic AMP-response element (CRE) and activation protein 1 (AP-1). The regulation of *COX-2* gene expression could involve complex interaction among them<sup>[9]</sup>. Growing evidences indicate that genetic variants in the promoters of *COX-2* gene may modulate risk for breast cancer<sup>[10]</sup>,

gastric adenocarcinoma<sup>[11]</sup>, prostate cancer<sup>[12]</sup> and colorectal adenoma<sup>[13]</sup>. A common promoter variant, -765G>C (rs20417), a G to C transversion resulting in significantly lower promoter activity, and reduced levels of C-reactive protein (CRP), a systemic marker of inflammation<sup>[14]</sup>.

In this study, we explored the association between the *COX-2* promoter variant (-765G>C) and the risk for CRC. In view of that the environmental exposures are associated with an increased risk of CRC, we investigated interactions between the polymorphism and the environmental factors such as smoking status, intake of alcohol and BMI.

## MATERIALS AND METHODS

### Study population

Unrelated subjects from Shenyang of China were enrolled for case-control studies of risk factors for CRC. The trial recruited 137 CRC patients and 199 healthy control subjects. Cases were patients with a histologically confirmed diagnosis of CRC in the First Affiliated Hospital of China Medical University and Shenyang Hospital of Anal Diseases, between 2005 and 2006. The CRC patients included 71 men and 66 women, and their median age was 61.29 years. The patients were grouped according to the TNM-classification (UICC) based on the postoperative histopathology evaluation.

Control subjects were randomly selected among the people admitted to the same hospital during the same period. There were 104 men and 95 women; the median age was 60.65 years. They had no histories of cancer.

All subjects were consent to participate in the study, and allow their blood samples to be analyzed. Detailed information on risk factors including tobacco and alcohol consumption and higher BMI were obtained with a baseline questionnaire. This study used the suggested WHO BMI cutoff points for Asians to assess several variables, respondents whose BMI was less than 23 kg/m<sup>2</sup> were categorized as having normal weight, and respondents whose BMI was 23 kg/m<sup>2</sup> or higher were categorized as being overweight and obese).

### Genotyping

**DNA extraction:** Five mL of venous blood was collected from each subject. Genomic DNA was extracted using proteinase K digestion followed by a salting out procedure.

**SNP genotyping:** The *COX-2* -765G>C genotypes were determined by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) assay. The primers were 5'-GGCTGTATATCTGCTCTATATGC-3' (forward) and 5'-CCGCTTCCTTTGTCCATCAG-3' (reverse). The target sequence was amplified in a 20  $\mu$ L volume containing 20 ng DNA template, 2.0  $\mu$ L 10  $\times$  PCR buffer, 0.5 U Taq-DNA-polymerase, 20 pmol of each primer and 1.6  $\mu$ L 2.5 mmol/L dNTP. Amplification was performed for 1 min at 94°C and followed by 35 cycles of 30 s at 94°C, 30 s at 59°C, and 30 s at 72°C, and with a final step at 72°C for 1 min. The PCR products were then digested with *Aci*I (New England BioLabs) and separated on 8% polyacrylamide gel electrophoresis. After electrophoresis, homozygous C allele was represented by a DNA band sized at 306 bp, whereas homozygous G allele

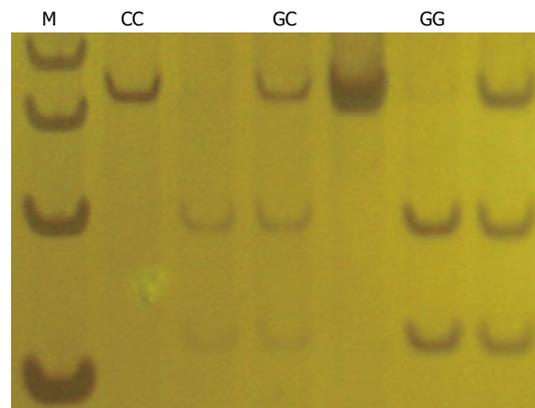

Figure 1 Genotyping of *COX-2* -765G>C polymorphism by PCR-RFLP.

was represented by a DNA band sized at 118 bp and 188 bp, and heterozygotes sized at 306 bp, 118 bp and 188 bp (Figure 1).

### Statistical analysis

Odds ratios (ORs) and 95% confidence intervals (CIs) were estimated by logistic regression analyses based on the comparison of genotypes between CRC patients and healthy controls using SPSS version 13.0, adjusting for the potential confounders such as age, gender, tobacco use, alcohol use, and BMI. The asymptomatic Pearson's  $\chi^2$  test was used to assess Hardy-Weinberg equilibrium. Data were considered significant when  $P < 0.05$ .

## RESULTS

Characteristics of the study population and the association with CRC are presented in Table 1. There were no significant differences in terms of distributions in age and gender between the cases and controls ( $P = 0.325$  and  $0.951$ , respectively), but the cases tended to have a higher body mass index ( $P < 0.001$ ) and more likely to smoke cigarettes ( $P < 0.001$ ).

Distribution of the *COX-2* -765G>C polymorphism genotypes in CRC patients and control subjects is shown in Table 2. Distribution of genotypes in controls was in good agreement with Hardy-Weinberg equilibrium ( $P = 0.838$ ), so did in cases ( $P = 0.651$ ). Overall, there was no association between CRC risk and *COX-2* -765G>C genotype. Similarly, no significant association was observed between -765G>C polymorphism and clinicopathological parameters among CRC patients (Table 3).

Risk associated with the *COX-2* -765G>C variant differed by smoking and BMI (Table 4). There was a positive association between cigarette smoking and development of CRC in the study population. The -765GG genotype in smokers was associated with a relatively increased risk of colorectal cancer compared to non-smokers (OR = 2.682, 95% CI = 1.336-5.385;  $P = 0.006$ ). The intake of alcohol was not positive for CRC development in this study. The effect of -765GG genotypes on CRC development was observed when individuals were stratified by BMI status. Compared with a normal BMI (18.5-22.9), those overweight (BMI 23-24.9)

had a 3.909-fold higher risk of CRC (OR = 3.909, 95% CI = 2.081-7.344; *P* < 0.001), while the obese (BMI > 25) had a 2.031-fold higher risk of CRC (OR = 1.107, 95% CI = 1.107-3.726; *P* = 0.022).

## DISCUSSION

Numerous studies suggest that *COX-2* plays an important role in the development of CRC<sup>[15]</sup>. However, the results of this study indicated that *COX-2* -765G>C polymorphism was not associated with CRC in this study population, but smoking and BMI may modify the risk of CRC in *COX-2* -765GG genotype.

Although the over-expression of *COX-2* is closely related to the metastasis and invasion of CRC<sup>[16]</sup>, and the *COX-2* -765G>C polymorphism located in the putative Sp1 binding site may reduce promoter activity responsible for increasing susceptibility to CRC, our study failed to detect an association between this polymorphism and CRC.

Our null findings are consistent with the previous report of an absence of an association between -765G>C polymorphism and CRC in Spaniards<sup>[17]</sup>. Similarly, a study in Singapore Chinese suggests that the -765G>C genotype distribution in CRC patients and healthy controls was comparable, but a significant association between genotype and risk was observed among consumers of higher n-6 PUFAs<sup>[18]</sup>.

23-24.9	32/46	3.909 (2.081-7.344)	6/8	5.128 (0.867-30.320)
> 25	51/42	2.031 (1.107-3.726) <sup>d</sup>	9/6	6.281 (0.864-45.631)

<sup>b</sup>P = 0.006 *vs* non-smoker group, <sup>d</sup>P < 0.001 *vs* normal BMI group (All estimates are multivariate adjusted for age, gender, smoking status, alcohol consumption and body mass index).

In contrast, Tan *et al.*<sup>[19]</sup> obtained contradictory positive results that the increased risk for CRC was associated with the *COX-2* -765GC genotype in Chinese population. To explain this discrepancy, several points should be considered. Firstly, the different result in association between *COX-2* -765G>C polymorphism and CRC may be due to the different study population. All our subjects were unrelated Han Chinese subjects, and drawn from a population pool in the northern part of China. Secondly, as the *COX-2* -765C allele has lower promoter activity than the G allele, the over-expression of the *COX-2* may lead to a higher risk of CRC and the G allele may be protective for CRC. In addition, the small sample size in the present study could not detect minor effect of the polymorphism on the development of CRC.

Substantial evidences indicate that significant exposure to cigarette smoke is associated with an

elevated risk for CRC and could be a factor of an early onset of CRC<sup>[20,21]</sup>. Cigarette smoke extract could promote tumor growth directly on colon cancer cells, the effect could likely be mediated by activation of COX-2 and up-regulation of the expression of VEGF, resulting in the induction of cellular proliferation and angiogenesis<sup>[22]</sup>. In our analysis, the COX-2 -765GG genotype in smokers was associated with a significant increase in the risk of CRC compared to non-smokers.

Obesity is also a risk factor for CRC<sup>[23,24]</sup>, and it has been shown that body mass index was independent significant predictors of CRC<sup>[25]</sup>. In this study, a significant association was observed for interactions between the polymorphism and BMI and CRC risk, a BMI of > 23 kg/m<sup>2</sup> was associated with an increase in the risk of CRC among -765GG genotype carriers. These findings support the hypothesis that smoking and BMI are significant risk factors for CRC. A stronger gene-environment interaction in CRC is expected.

The main limitation of our study is the lack of information on use of COX-2 inhibitors, which may cause bias in the effect of COX-2 on CRC. Another weakness of our study is the relative small study size, which may result in less precise estimation of gene-environment interaction.

In summary, our study found no association between COX-2 -765G>C polymorphism and CRC. However, our findings suggest that individuals with the -765GG genotype may be more sensitive to cigarette smoking and a higher BMI (> 23 kg/m<sup>2</sup>), perhaps attributable to the increased enzymatic activity of COX-2, and increased risk of CRC. This result is consistent with the observation that environmental factors were associated with development of CRC and that the association with smoking and BMI may differ by COX-2 -765G>C polymorphism.

## COMMENTS

### Background

Genetic and environmental factors are important in determining the susceptibility to colorectal cancer (CRC). COX-2, which is an enzyme responsible for the formation of prostaglandin H<sub>2</sub> from arachidonic acid, regulates angiogenesis and plays a critical role in tumor progression and aggressiveness. To investigate the role of COX-2 in CRC development, the authors conducted a case-control study of CRC in northeast China.

### Research frontiers

Single nucleotide polymorphisms of COX-2 gene may affect the risk of cancer formation in humans, and cancer is a complex process involving genetic as well as environmental factors. The authors conducted this study to investigate the association between COX-2 polymorphism and CRC and to evaluate the potential interaction with exposures to smoking and BMI.

### Innovations and breakthroughs

There are several reports on the association between COX-2 polymorphisms and CRC. In this study, although there was no association between CRC risk and COX-2 -765G>C genotype, risk associated with the COX-2 -765G>C variant differed by smoking and BMI. A stronger gene-environment interaction in CRC was observed.

### Applications

In the present study, COX-2-765GG genotype appears to be associated with an increased risk in the presence of smoking and higher body mass index (BMI). The results can be used to the etiological studies and prevention of colorectal cancer.

### Terminology

Single nucleotide polymorphisms or SNPs (pronounced "snips") are DNA sequence variations that occur when a single nucleotide (A, T, C or G) in the genome sequence is altered. Restriction fragment length polymorphism (RFLP) is a technique by which organisms may be differentiated by analysis of patterns derived from cleavage of their DNA.

### Peer review

The relationship between a polymorphism in cyclooxygenase-2 (COX-2) promoter region and the risk of colorectal cancer was studied in this manuscript. Although the studied polymorphism failed to show an association with colorectal cancer risk, the authors argued for positive association between this polymorphism and the risk of colorectal cancer in addition to tobacco use, alcohol intake, and obesity.

Herbal compound 861 regulates the mRNA expression of collagen synthesis- and degradation-related genes in human hepatic stellate cells. *World J Gastroenterol* 2008; 14(11): 1790-1794 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1790.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1790>

### Abstract

**AIM:** To identify the role of herbal compound 861 (Cpd 861) in the regulation of mRNA expression of collagen synthesis- and degradation-related genes in human hepatic stellate cells (HSCs).

**METHODS:** mRNA levels of collagen types I and III, matrix metalloproteinase 1 (MMP-1), matrix metalloproteinase 2 (MMP-2), membrane type-1 matrix metalloproteinase (MT1-MMP), tissue inhibitor of metalloproteinase 1 (TIMP-1), and transforming growth factor  $\beta$ 1 (TGF- $\beta$ 1) in cultured-activated HSCs treated with Cpd 861 or interferon- $\gamma$  (IFN- $\gamma$ ) were determined by real-time PCR.

**RESULTS:** Both Cpd 861 and IFN- $\gamma$  reduced the mRNA levels of collagen type III, MMP-2 and TGF- $\beta$ 1. Moreover, Cpd 861 significantly enhanced the MMP-1 mRNA levels while down-regulated the TIMP-1 mRNA expression, increasing the ratio of MMP-1 to TIMP-1 to (6.3 + 0.3)-fold compared to the control group.

**CONCLUSION:** The anti-fibrosis function of Cpd 861 may be mediated by both decreased interstitial collagen synthesis by inhibiting the transcription of collagen type III and TGF- $\beta$ 1 and increased degradation of these collagens by up-regulating MMP-1 and down-regulating TIMP-1 mRNA levels.

**Key words:** Herbal Compound 861; Human hepatic

### INTRODUCTION

Hepatic fibrosis, a wound-healing response to a variety of chronic liver injuries, is characterized by the increased deposition of remodeled extracellular matrix (ECM). Hepatic stellate cells (HSCs), the major source of ECM in liver, play a central role in the progress of fibrogenesis<sup>[1-4]</sup>. After acute or chronic injury, HSCs are activated by autocrine and paracrine mediators and have greater fibrogenic, contractile and migration activities than "resting hepatic stellate cells" accompanied with expressing activation markers (e.g.,  $\alpha$ -smooth muscle actin,  $\alpha$ -SMA). In addition to the synthesis of greater amounts of ECM components (predominantly collagen types I and III), activated HSCs also show altered expression/activity of matrix metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs), thereby leading to increased deposition of extracellular matrix and formation of scar tissue in the fibrotic liver<sup>[6-8]</sup>. Thus, the activated HSCs are considered a therapeutic target for antifibrotic drugs<sup>[2-5]</sup>.

Herbal compound 861 (Cpd 861) is an extract of mixed Chinese herbs that have been used for liver disease treatment in traditional Chinese medicine (TCM). Randomized double-blinded clinical studies have verified that Cpd 861 could significantly improve clinical manifestations and biochemical parameters of chronic HBV-related liver fibrosis patients, as well as regression of hepatic fibrotic change<sup>[9-11]</sup>. Our preliminary data show that Cpd 861 could inhibit HSC proliferation and reduce the expression of  $\alpha$ -SMA in culture-activated HSCs<sup>[12]</sup>. The aim of the present study was

to identify the role of Cpd 861 in the regulation of collagen synthesis and degradation in culture-activated HSCs and to define its antifibrosis molecular mechanisms of action on the expression of collagens, MMPs, and TIMP-1 in human hepatic stellate cells.

## MATERIALS AND METHODS

### Subjects

Human hepatic stellate cell line LX-2 used in this study was kindly provided by Dr. Friedman SL of the Mount Sinai School of Medicine. The cells express  $\alpha$ -SMA under all culture conditions and therefore are regarded as at least partially activated even after immediate replating<sup>[13]</sup>. The cells were cultured in Dulbecco's modified Eagle's medium (DMEM; Gibco, Invitrogen, Carlsbad, CA), supplemented with 5% heat-inactivated fetal bovine serum (FBS; Hyclone, USA), 200 mmol/L L-glutamine (Gibco, Invitrogen, Carlsbad, CA), 100 000 U/L penicillin (Sigma, USA) and 0.1 g/L streptomycin (Gibco, Invitrogen, Carlsbad, CA) in an atmosphere containing 50 mL/L CO<sub>2</sub>.

### Compound treatments

Cells were cultured in DMEM containing 5% FBS in an atmosphere containing 50 mL/L CO<sub>2</sub>. The medium was carefully removed before compound treatment. The fresh medium containing Cpd 861 (0.01 g/L, in this concentration Cpd 861 had no effect on the proliferation of LX-2 cells)<sup>[12]</sup> and IFN- $\gamma$  (1 000 000 U/L, Fosun Pharma, Shanghai, China) was added. IFN- $\gamma$ , which can reduce HSC activation both *in vivo* and *in vitro* associated with reduced extracellular matrix deposition in animal hepatic fibrosis progression<sup>[14-17]</sup>, was used as the positive control. The changes in mRNA expression of collagen types I and III, matrix metalloproteinase 1 (MMP-1), matrix metalloproteinase 2 (MMP-2), membrane type-1 matrix metalloproteinase (MT1-MMP), tissue inhibitor of metalloproteinase 1 (TIMP-1), and transforming growth factor  $\beta$ 1 (TGF- $\beta$ 1) were detected by quantitative real-time PCR.

### RNA isolation and reverse transcription

Total RNA was extracted from LX-2 cells as previously described<sup>[12]</sup>. The concentration of total RNA was determined spectrophotometrically with ND-1000 spectrophotometer (NanoDrop, USA) and the integrity of samples was confirmed by visualizing 28 S and 18 S ribosomal RNA bands under ultraviolet light after agarose gel electrophoresis. One  $\mu$ g of RNA was added to each reaction tube and converted to complementary DNA (cDNA) using oligo (dT)<sub>15</sub> primers (Promega, USA) and SuperScript™ II reverse transcriptase (Invitrogen, CA).

### Quantitative real-time PCR using SYBR green I

Real-time PCR reaction was performed (10 min at 95°C for activation, 15 s at 95°C and 60 s at 60°C for 40 cycles of amplification) on the Applied Biosystems 7300 Real Time PCR System using SYBR® Green PCR Master Mix (Applied Biosystems, USA). Standard curve method and/or comparative CT method were used to quantify

the mRNA expression levels<sup>[18,19]</sup>. Standard curves were generated using 10<sup>3</sup>-10<sup>9</sup> copies of plasmids containing cDNA of each target gene, and results were normalized for RNA input using glyceraldehyde-3-phosphate dehydrogenase (GAPDH). Samples and standards were analyzed in triplicate for each set of primers (Table 1).

After PCR, the melting curves of all final PCR products were analyzed as previously described<sup>[12]</sup>. To ensure that the correct products were amplified in the reaction, all samples were also separated on 2% agarose gel electrophoresis. All PCR conditions and primers were optimized to produce a single product of the correct basepair size.

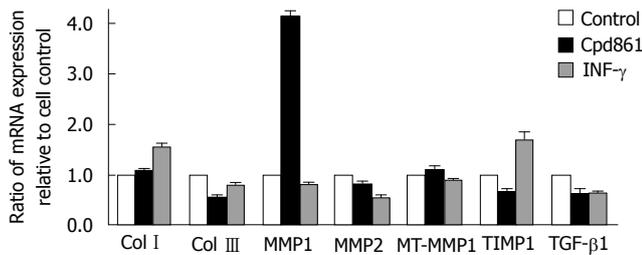

### Statistical analysis

Data were expressed as mean  $\pm$  SE. Statistical analysis was performed using GraphPad Prism software (version 3.0). *t*-test was used for comparison between the groups. *P* < 0.05 was considered statistically significant.

## RESULTS

Cpd 861 regulated the mRNA expression of hepatic fibrosis related genes.

To detect the effects of Cpd 861 on collagen synthesis and degradation in LX-2 cells, the mRNA levels of collagen types I and III, MMP-1, MMP-2, MT1-MMP, TIMP-1, and TGF- $\beta$ 1 in cultured-activated HSCs after 48 h of treatment with Cpd 861 (0.01 g/L) or interferon- $\gamma$  (1 000 000 U/L) were determined by real-time PCR. The data were normalized by GAPDH. As shown in Figure 1, both Cpd 861 and interferon- $\gamma$  reduced the mRNA levels of collagen type III, MMP-2 and TGF- $\beta$ 1. Moreover, Cpd 861, but not interferon- $\gamma$ , significantly enhanced the MMP-1 mRNA levels, but at the same time inhibited the TIMP-1 mRNA expression which increased the ratio of MMP-1 to TIMP-1 to (6.3  $\pm$  0.3)-fold compared to the control group. In our study, the mRNA levels of collagen type I and MT1-MMP in LX-2 cells did not change much after 48 h of treatment with Cpd 861. To further understand the mechanisms of Cpd 861, the change over time was also detected. As shown in Figure 2, after 24 h of

**Figure 1** mRNA expression changes of collagen types I and III, MMP-1, MMP-2, TIMP-1, and TGF- $\beta$ 1 in LX-2 cells after 48 h of treatment with Cpd 861 (0.01 g/L) or interferon- $\gamma$  (1000 000 U/L). The levels of mRNA were determined by real-time PCR and normalized by GAPDH. Results are expressed as fold inductions compared to each control group. The data represent mean  $\pm$  SE of triplicate for each treatment.

treatment with Cpd 861, the MMP-1 mRNA expression progressively increased significantly, while the expression levels of collagen type III, MMP-2, and TIMP-1 decreased significantly after exposed to Cpd 861 for 48 h or 72 h.

## DISCUSSION

The altered balance between the synthesis and degradation of matrix proteins is the major pathogenic feature in the hepatic fibrosis process, which leads to the quantitative and qualitative change of composition in hepatic ECM. In advanced liver fibrosis, the total components of ECM increase accompanying a decrease in the normal low density basement membrane-like matrix (collagen type IV) being replaced by interstitial type matrix (mainly collagen types I and type III), leading eventually to the net deposition of fibrillar matrix<sup>[20]</sup>.

The extracellular matrix synthesis is mediated at both transcriptional and post-transcriptional levels, while its degradation is predominantly regulated by MMPs, which can degrade almost all ECM components. For example, MMP-2 (gelatinase A), one of the major MMPs during liver fibrogenesis, degrades type IV collagen, and this function can enhance the normal basement replacement by fibril-forming collagen which contributes to the pathogenesis of liver fibrosis. MMP-2 is secreted as a pro-enzyme, and its activation involves a membrane type MMP (MT1-MMP) expressed on the cell surface<sup>[21,22]</sup>. In contrast to MMP-2, interstitial collagenases (MMP-1 in humans, MMP-13 in rats) are involved in the degradation of interstitial type matrix by cleaving such substrates at a specific Gly-Ile/Leu site<sup>[6]</sup>. The activities of MMPs are inhibited by TIMPs (a family of tissue inhibitors of metalloproteinases, TIMP-1 and TIMP-2 especially in the liver)<sup>[6]</sup>. The combination of MMPs and TIMPs plays a critical role in the remodeling of hepatic ECM during liver fibrogenesis. When liver fibrosis progresses, in addition to increased matrix synthesis, the enhanced expression and release of MMP-2 and MT1-MMP as well as TIMP-1 are also the striking features, while the expression of MMP-1 decreases or remains unchanged, which serves to promote progression of liver fibrosis by preventing degradation of interstitial collagens<sup>[6,23]</sup>.

In the liver, HSCs are the key cell type involved both in the synthesis and in the degradation of matrix

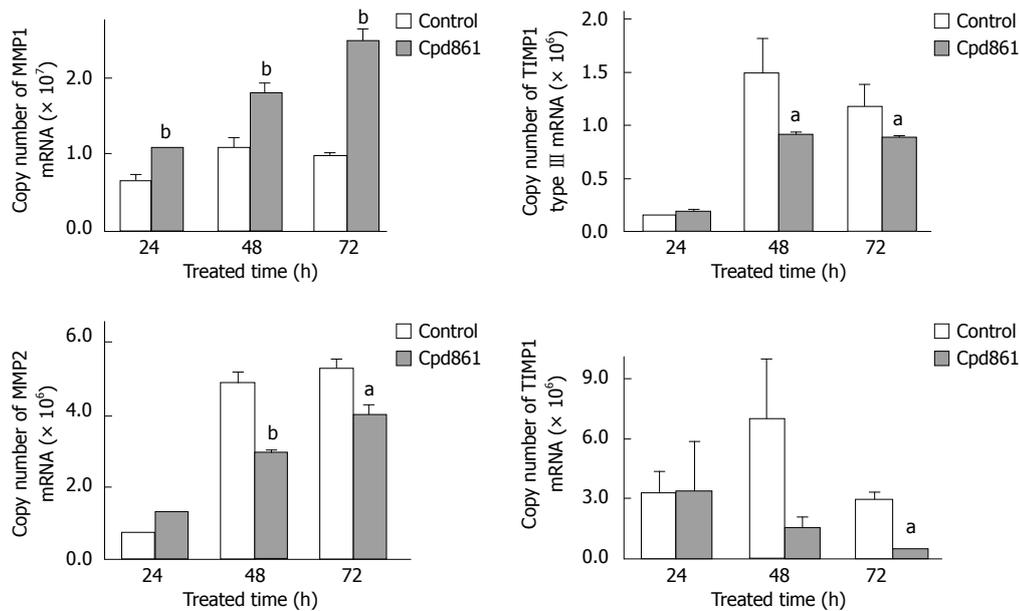

proteins. These cells are the major fibrogenic cell type that contributes to collagen accumulation in the liver. In a normal liver, HSCs in the space of Disse are maintained in a quiescent, nonfibrogenic phenotype. When the liver is injured, these cells are activated and transformed to myofibroblast-like cells characterized by fibrogenesis, contractility, and migration, production of much larger amounts of the majority components of extracellular matrix, particularly collagen types II and III. Moreover, satellite cells also express almost all the key components required for matrix degradation such as MMP-1, MMP-2 and TIMP-1<sup>[1,24]</sup>. Changes in the activity of MMPs and TIMPs lead to the remodeling of hepatic ECM during injury to the liver, which in turn directly and indirectly accelerates stellate cell activation.

LX-2 cells, a human hepatic stellate cell line, were used in our study. LX-2 cells retain features of HSCs and express key proteins involved in matrix remodelling<sup>[13]</sup>. The cells express  $\alpha$ -SMA under all culture conditions and are regarded as, at least, partially activated even after immediate replating. Furthermore, during growth on a plastic surface, the cells undergo further activation as defined by the increase in  $\alpha$ -SMA<sup>[25]</sup>. In our study, the collagen type III and MMP-2 mRNA expression increased, while MMP-1 mRNA expression was down-regulated when these cells were further activated on a plastic surface (data not shown), consistent with those seen in clinical or animal studies<sup>[6,23]</sup>. Thus, LX-2 cells provide a valuable tool in our anti-fibrotic drug research.

Cpd 861 formulated by one of the authors (Bao'en Wang)<sup>[10]</sup> according to Chinese medical theory, is comprised of *Salvia miltiorrhiza*, *Astragalus membranaceus* and *Spatholobus suberectus* as its chief components. This herbal compound has been proven to be effective for the treatment of patients with hepatic fibrosis and its therapeutic effectiveness in making hepatic fibrosis regress has been confirmed by several random clinical tests with paired liver biopsies and animal model studies<sup>[10,11,26,27]</sup>. Our previous study demonstrated that Cpd 861 can significantly inhibit cell proliferation in a dose-dependent manner and reduce the mRNA expression level of  $\alpha$ -SMA in LX-2 cells<sup>[12]</sup>. In this study, we used real-time PCR to identify mRNA expressions of collagens, MMPs, and TIMPs in culture-activated HSCs. The data show both Cpd 861 and positive control IFN- $\gamma$  inhibited the mRNA expressions of TGF- $\beta$ 1, MMP-2, and collagen type III, while there was no difference in the mRNA expression of MT1-MMP and collagen type I observed in LX-2 cells treated with either Cpd 861 or IFN- $\gamma$  alone.

As the dominant stimulus of ECM production by HSCs, the increasing expression of TGF- $\beta$ 1 has been demonstrated in both culture-activated HSCs and *in vivo* studies, and the autocrine expression in activated HSCs is its most important resource<sup>[28-30]</sup>. Besides direct transcriptional down-regulation of collagen type III, the restraining of mRNA expression of TGF- $\beta$ 1 may also play an important role in both Cpd 861 and IFN- $\gamma$  anti-collagen-synthesis functions.

As discussed above, the degradation of basement membrane by HSC-derived MMP-2 is critical to further activation of HSCs and scar formation during liver

**Figure 2** Time course of Cpd 861 on mRNA expressions in LX-2 cells. LX-2 cells were incubated with Cpd 861 (0.01 mg/mL) for 24, 48 and 72 h. The absolute copy number of mRNA for collagen type III, MMP-1, MMP-2, and TIMP-1 was determined by real-time PCR. The data represent mean  $\pm$  SE of triplicate for each treatment. <sup>a</sup> $P < 0.05$  and <sup>b</sup> $P < 0.01$  vs LX-2 cell controls.

wound remodeling. The transcriptional down-regulation of MMP-2 by both Cpd 861 and IFN- $\gamma$  may protect the normal basement membrane from being replaced by fibrillar matrix and indirectly inhibit the activation of HSCs.

It is particularly interesting that, in contrast to IFN- $\gamma$ , Cpd 861 also can significantly enhance the mRNA level of MMP-1 and decrease the TIMP-1 mRNA expression, indicating that Cpd 861 can directly (enhancing the expression of MMP-1) and indirectly (inhibiting the expression of TIMP-1) enhance the degradation of collagens. The data from the time course study indicate that the up-regulation of MMP-1 expression preceded the changes in MMP-2, TIMP-1, and collagen type III mRNA levels, suggesting that the fibrillar matrix degradation has already enhanced before its synthesis is inhibited by Cpd 861. In addition to their role in inhibiting extracellular matrix degradation, there is increasingly recognized that TIMPs play a significant role in regulating apoptosis of some cell types<sup>[6]</sup>. Thus, the down-regulation of TIMP-1 mRNA levels by Cpd 861 may also contribute to pro-apoptosis function in the HSCs due to its mechanism underlying anti-fibrosis.

In conclusion, the anti-fibrotic function of Cpd 861 may be attributed to both the decreased interstitial collagen synthesis by down-regulating the mRNA levels of collagen type III and TGF- $\beta$ 1 as well as increased degradation of these collagens by up-regulating MMP-1 and down-regulating TIMP-1, accompanying protection of the normal basement membrane from destruction by MMP-2, and perhaps at some points associated with the apoptosis of activated HSCs. Further work is required to accurately analyze the relative roles of these different functions in detail, and this will be important in the development of novel antifibrotic therapies.

## ACKNOWLEDGMENTS

The authors thank Dr. Friedman SL of Mount Sinai School of Medicine for providing the LX-2 cell line.

## COMMENTS

### Background

The altered balance between the synthesis and degradation of matrix proteins is the major pathogenic feature in the hepatic fibrosis process. The purpose of this study was to identify the role of herbal compound 861 (Cpd 861) in the regulation of mRNA expression of collagen synthesis- and degradation-related genes in human hepatic stellate cells (HSCs).

### Research frontiers

Although remarkable progress has been made in understanding the mechanisms underlying hepatic fibrosis and plenty of agents have been studied, few effective "anti-fibrogenic" drugs have been approved for use in humans.

### Innovations and breakthroughs

The study not only verified the clinical anti-fibrotic effect of the herbs, but also explored the multiple action sites of the herbal compound which is evidently different from that of the purified ingredients in Western drugs.

### Applications

The results of this study could allow for developing the effective anti-fibrogenic drugs from the Chinese herbs.

### Peer review

This is an interesting paper, describing the effect of plant extract Cpd 861 on the levels of mRNAs encoding collagens (types I and III, metalloproteinases (MMP-1 and MMP-2), and various other factors (TIMP-1 and TGF- $\beta$ 1) in LX-2 cells of stellate cell origin. The plant extract appeared to regulate the mRNA levels of collagen synthesis- and degradation-related genes, thus demonstrating an anti-fibrotic effect.

### Abstract

Diagnosis and treatment of common conditions in morbidly obese patients still pose a challenge to physicians and surgeons. Sometimes too much reliance is put on investigations that can lead to a misdiagnosis. This case demonstrates an obese woman admitted under the medical team with a presumed diagnosis of pneumonia, who was later found to have an acute abdomen and raised amylase, which led to an assumed diagnosis of pancreatitis. She died within 24 h of admission and post mortem confirmed the cause of death as systemic sepsis due to perforated appendicitis, with no evidence of pancreatitis. Significantly elevated serum amylase level may occur in non-pancreatic acute abdomen.

Forster MJ, Akoh JA. Perforated appendicitis masquerading as acute pancreatitis in a morbidly obese patient. *World J Gastroenterol* 2008; 14(11): 1795-1796 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1795.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1795>

### INTRODUCTION

Obesity is an increasing problem in the western population and the proportion of morbidly obese people who present with non-obesity problems is increasing. An important

consideration in dealing with such patients is the difficulty of diagnosis. We present a patient with acute abdomen and morbid obesity and discuss the unusual finding of markedly elevated serum amylase due to a non-pancreatic cause.

### CASE REPORT

The patient (AE) was a morbidly obese (BMI 59) 60-year-old woman with type 2 diabetes, asthma and previously diagnosed gallstones, who was referred by her general practitioner to hospital with breathlessness and a provisional diagnosis of pneumonia. Upon admission, she complained of abdominal pain, which was worse on coughing. She had pyrexia (39.4°C) tachycardia (pulse 125/min) and hypotension (90 mmHg systolic blood pressure). There were fine crepitations in both lung fields and vague right upper abdominal tenderness. A chest X-ray was requested and she was transferred to a respiratory ward.

AE was seen 3 h later by a medical Senior House Officer who thought the chest X-ray was normal, although this was reported later by a radiologist to show diffuse infiltrative shadowing consistent with acute respiratory distress syndrome (ARDS). Investigations revealed renal impairment, normal bilirubin, but raised plasma liver enzyme levels, a serum amylase level of 1029 IU/L and neutrophilia. AE was started on antibiotics as she was presumed to have acute pancreatitis and referred to the surgical team.

AE was assessed by a surgical registrar 8 h after her admission and was found to be systemically unwell, with a systolic blood pressure of 100 mmHg, pulse of 120/min, and pyrexia of 39°C. Further history taking revealed generalized abdominal pain of 5 d duration. Abdominal examination was deemed ineffective to elicit meaningful signs, due to extreme truncal obesity. The diagnosis of pancreatitis was confirmed and because of her progressive deterioration, resuscitative measures were commenced and she was referred to the High Dependency Unit (HDU). In the HDU, she had non-invasive positive pressure ventilation, invasive monitoring, and measures adopted to achieve glycemic control.

On the post take surgical ward round, the consultant on call confirmed the difficulty and unreliability of abdominal examination in such a morbidly obese patient, but given the diagnosis of acute pancreatitis, he/she advised continuation of supportive care. Shortly after AE was reviewed, she suffered a cardiac arrest and,

despite resuscitation, died. The post mortem confirmed death from generalized peritonitis and septicemia due to ruptured appendicitis. The pancreas was normal with no evidence of inflammation.

## DISCUSSION

This case highlights the difficulty in making accurate diagnosis in a morbidly obese patient. It is entirely understandable why a patient referred by her general practitioner with a provisional diagnosis of pneumonia, and who upon general examination had a vague upper abdominal tenderness would be presumed to have just a chest infection. Whether the ARDS picture on her chest X-ray was missed due to extreme obesity or not is unclear. Routine blood analysis in this patient showed deranged liver function tests which necessitated the request for serum amylase analysis. Given the high level of serum amylase, it was reasonable to make a diagnosis of acute pancreatitis. However, further enquiries revealed AE had had pain for > 5 d. In retrospect, this should have raised doubt about the diagnostic value of the elevated serum amylase level. It would appear there was an over reliance on the serum amylase result by all the teams involved in her care. Serum amylase can be raised in many acute peritonitis conditions, such as perforated duodenal ulcer, appendicitis<sup>[1]</sup> or small bowel ischemia<sup>[2]</sup>. What makes this case unique are the history of gallstones and an excessively high level of serum amylase- both of which contributed to the misdiagnosis. Furthermore, as indicated above, serum amylase usually falls within the first 48 h of the onset

of pancreatitis<sup>[3]</sup>. Liver enzymes may also rise in sepsis<sup>[4]</sup>. The main obstacle to a proper and thorough physical examination in this patient was her body habitus. Given the acknowledged difficulty with examination, there is a strong case for an even more detailed history and an early recourse to the use of ancillary investigations. A computed tomography (CT) scan of the abdomen in this case might have revealed a normal pancreas and the possibility of a potential life saving laparotomy. However, it is debatable whether emergency surgery in the presence of morbid obesity, medical comorbidities and systemic sepsis syndrome would have produced a different outcome. Another consideration is that this large patient might not have fitted into the CT scanner.

In conclusion, morbidly obese patients who present with acute medical or surgical problems require detailed and thorough history taking, coupled with early and appropriate investigations, in order to avoid diagnostic pitfalls. Significantly elevated serum amylase level may occur in the non-pancreatic acute abdomen.

### Abstract

Fibro-muscular dysplasia (FMD) is a rare but well documented disease with multiple arterial aneurysms. The patients, usually women, present with various clinical manifestations according to the specific arteries that are affected. Typical findings are aneurysmatic dilations of medium-sized arteries. The renal and the internal carotid arteries are most frequently affected, but other anatomical sites might be affected too. The typical angiographic picture is that of a "string of beads". Common histological features are additionally described. Here we present a case of a 47-year-old woman, who was hospitalized due to intractable abdominal pain. A routine work-up revealed a liver mass near the portal vein. Before a definite diagnosis was reached, the patient developed massive upper gastrointestinal bleeding. In order to control the hemorrhage, celiac angiography was performed revealing features of FMD in several arteries, including large aneurysms of the hepatic artery. Active bleeding from one of these aneurysms into the biliary tree indicated selective embolization of the hepatic artery. The immediate results were satisfactory, and the 5 years follow-up revealed absence of any clinical symptoms.

Hemobilia due to hepatic artery aneurysm as the presenting sign of fibro-muscular dysplasia. *World J Gastroenterol* 2008; 14(11): 1797-1799 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1797.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1797>

### CASE REPORT

A 47-year-old woman was admitted to the emergency department (ED) with epigastric abdominal pain, nausea, and vomiting for 2 d. The patient denied fever or changes of bowel habits. The pain did not subside following a medication with antacids and H<sub>2</sub> blockers prior to admission.

Physical examination revealed a soft abdomen with epigastric tenderness and the absence of jaundice and peritoneal irritation signs. It revealed no further findings.

Upon admission, white blood count, liver function test, bilirubin levels, and amylase activity were within the normal range. Abdominal X-ray was within normal limits. Abdominal ultrasound (US) demonstrated a cystic structure near the hepatic hilum. Gastro-duodenoscopy was performed without revealing any pathology. An abdominal CT scan demonstrated a soft tissue mass encapsulating the portal vein and hepatic artery causing intra-hepatic biliary tree dilatation (Figure 1A). Following an increase of the total bilirubin level of up to 0.39 g/L, endoscopic retrograde cholangio-pancreaticography (ERCP) was performed. ERCP revealed a common hepatic duct stricture with proximal biliary dilatation (Figure 1B). A stent was inserted without complications. Biliary brush biopsy was taken and turned out to be normal. With the working diagnosis of a neoplastic process, endoscopic ultrasound (EUS) guided biopsy was scheduled. While awaiting the procedure, the patient's condition stabilized, the pain resolved, and she was discharged. A few days later she presented with complaints of severe abdominal pain accompanied by jaundice and hematemesis. Upon arrival to the ED her pulse was non-palpable and systolic blood pressure was 70 mmHg. After aggressive fluid resuscitation and blood transfusion emergent gastro-duodenoscopy was performed, once again without any pathologic finding. Abdominal US revealed the described soft tissue mass which had doubled in size and appeared to be pulsating. With the working diagnosis that the tissue mass was of vascular origin, angiography was carried out. The hepatic, renal, and iliac arteries had a radiographic appearance of a

**Figure 1** Clinical examination results. **A:** Abdominal CT scan showing a soft tissue mass encapsulating the portal vein and hepatic artery (arrow); **B:** ERCP showing a common hepatic duct stricture (arrow) with proximal biliary tree dilatation; **C:** Selective angiography of the renal artery demonstrating the classic appearance of "string of beads"; **D:** Selective angiography of the hepatic artery revealing multiple aneurysms.

"string of beads" (Figure 1C and D), which characterizes fibro-muscular dysplasia (FMD). In order to prevent further bleeding from hepatic artery aneurysms to the biliary system, embolization of the proper hepatic artery using a thrombogenic coil was performed. Elevated levels of bilirubin indicated concurrent ERCP which revealed a clogged stent, obstructed by blood clots, and which thus was replaced. After the procedure the patient did not suffer from gastrointestinal bleeding, and elevated liver enzyme levels gradually resolved. The patient was discharged 52 d after her first admission.

Today, 5 years after the first symptoms, the patient has no clinical signs or symptoms related to hepatic artery embolization, and no laboratory or radiographic changes are evident.

## DISCUSSION

FMD is a disorder which leads to arterial stenosis and most commonly affects the renal and internal carotid arteries in 60%-75% and 25%-30% of cases, respectively<sup>[1,2]</sup>. It is double as common among females and most cases are diagnosed in patients younger than 50 years.

The pathogenesis is not well understood and might include a genetic predisposition, hormonal influences, mechanical factors, or ischemia. All of the above mentioned parameters might contribute to deposition of fibrous lesions, which are classified into five categories according to the affected arterial layer and the histological pattern<sup>[3]</sup>.

Clinical manifestations result from ischemia (due to arterial stenosis), hemorrhage (due to ruptured aneurysms), and embolization of intravascular thrombi formed within the aneurysms. Thus, they may vary widely depending on the arteries involved<sup>[4]</sup>.

A common manifestation of FMD is reno-vascular

hypertension due to renal artery stenosis. The clinical presentation of an affected carotid artery may vary from headache and lightheadedness to cerebrovascular accident.

The gold standard imaging technique for the diagnosis of FMD is angiography, which demonstrates several features such as beading of the vessel and concentric stenosis. The classical appearance in the most common of the five pathological subtypes is a "string of beads"<sup>[2]</sup>. Other diagnostic modalities include duplex-ultrasound, CT-angiography, and MR-angiography<sup>[5]</sup>.

Treatment of FMD depends upon the arteries involved and the clinical presentation. In cases of regional ischemia, revascularization (by either endovascular or surgical approach) is the preferred treatment. Hemorrhagic complications are treated by ligation or embolization of the affected artery. Hemobilia is a rare clinical condition which may be fatal if not treated promptly. It was first described in 1948 following abdominal trauma<sup>[6]</sup>. Since then, many patients suffering from hemobilia were described, most of them were treated surgically<sup>[7]</sup>. Endovascular embolization of ruptured hepatic artery aneurysms have been described<sup>[8,9]</sup> but not in the context of FMD.

FMD of the hepatic artery is only one of many etiologies that might cause hemobilia and it mandates treatment even if asymptomatic<sup>[10]</sup>. Only one case in which FMD was the underlying cause for hemobilia was described in the English literature<sup>[11]</sup>. That patient was treated surgically by ligation of the common hepatic and gastroduodenal arteries. The patient we report was the first who was treated with a minimally invasive endovascular technique for FMD related hemobilia.

In some cases of controllable gastrointestinal bleeding due to FMD related hemobilia, if the patient's hemodynamic status permits, selective angiography and embolization of ruptured hepatic artery aneurysms may

be highly effective. The endovascular approach holds less morbidity and mortality than surgery and serves both as a diagnostic and a therapeutic tool. Success in treating such a patient is dependent upon good communication and cooperation between the surgeon and the interventional radiologist.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1224 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Inappropriate references**

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

**Editorial Office**

**World Journal of Gastroenterology**

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

**Language evaluation**

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

**Copyright assignment form**

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

**Responses to reviewers**

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

**Proof of financial support**

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

**Links to documents related to the manuscript**

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

**Science news releases**

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

**Publication fee**

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## Abstract

Obesity has reached epidemic proportions particularly in western countries. Most non-surgical treatments of this condition are disappointing. Since 2005, several studies evaluating the effect of Botulinum Toxin type A (BT-A) in gastric antrum by means of endoscopy for the treatment of obesity have been published. This treatment modality was based on the observation that gastric injection of BT-A in laparatomized rats induced a significant reduction of food intake and body weight. Nowadays, 6 studies have been published yielding conflicting results. Differences in selection of patients, doses of BT-A, method of administration of the toxin and instruments of evaluation of some parameters among these studies may be the cause of divergent results. We discuss herein some important features of these studies pointing out on differences among them. At the same time, based on the knowledge of physiological characteristics of normal and abnormal gastric function related with feeding, we discuss the probable causes of failure observed in these trials. Finally, we give some guidelines concerning the way that future research in this field may follow, not without calling attention to disadvantages of this treatment.

**Key words:** Botulinum toxin; Obesity; Gastric emptying; Gastric motility; Gastroparesis

**Peer reviewers:** Yvan Vandenplas, Professor, Department of Pediatrics, AZ-VUB, Laarbeeklaan 101, Brussels 1090, Belgium; Andrew Ukleja, MD, Assistant Professor, Clinical Assistant Professor of Medicine, Director of Nutrition Support Team, Director of Esophageal Motility Laboratory, Cleveland Clinic Florida, Department of Gastroenterology, 2950 Cleveland Clinic Blvd., Weston, FL 33331, United States

Garcia-Compean D, Maldonado Garza H. Intragastric injection of botulinum toxin for the treatment of obesity. Where are we? *World J Gastroenterol* 2008; 14(12): 1805-1809 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1805.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1805>

## INTRODUCTION

The prevalence of obesity has increased in western countries in the last few decades, reaching epidemic proportions<sup>[1]</sup>. It affects more than 30% of general population in the US. In this country, the costs attributed to obesity amounts to 100 billion dollars per year<sup>[2]</sup> and the number of deaths attributed to obesity is approximately 280 000 annually<sup>[3]</sup>. Obesity increases the risk of morbidity and mortality, since some disorders such as diabetes, arterial hypertension, cardiovascular and cerebral illnesses, as well as hepatobiliary disorders, are particularly frequent in obese individuals<sup>[2]</sup>.

The dietetic, pharmacological and behavioral treatments have demonstrated to have limited effect and duration<sup>[4]</sup>. The intragastric balloon applied by endoscopy has equally given partial and transitory results<sup>[5]</sup>. Surgical treatments (gastric banding and gastric by-pass), even if they are the most effective in some patients, particularly those with morbid obesity, are invasive procedures and may have complications, some of them fatal<sup>[6]</sup>. In view of the above, the search for new methods for weight reduction is completely justified.

In the year 2000, Gui *et al* published a pioneering study in which they show that intra-muscular injections of Botulinum Toxin type A (BT-A) in the gastric wall of laparatomized normal-weight rats significantly reduced their food intake and body weight<sup>[7]</sup>. Subsequently, such findings were confirmed in 2005, by Coskun *et al* in obese rats. This group also observed a significant delay of gastric emptying in rats that had received BT-A<sup>[8]</sup>; therefore, they attributed body weight reduction to an effect of early satiety probably induced by the pharmacologically induced gastroparesis.

## BOTULINUM TOXIN

Botulinum Toxin is produced by the bacterium *Clostridium botulinum*. There are several serotypes from A to G. When this toxin is ingested by the human being it can produce a form of food poisoning known as botulism. The BT-A

has a powerful inhibiting effect of long duration on the muscular contractions of smooth and striated muscles<sup>[9]</sup>. This pharmacological property has been used in the treatment of some digestive illnesses characterized by muscular spasm, particularly achalasia and anal fissure<sup>[10,11]</sup>. BT-A binds with high affinity to cholinergic nerve endings and selectively inhibits their activity. Acetylcholine is considered the most important stimulating agent both in intrinsic (myenteric) and extrinsic (vagal) nervous systems<sup>[12]</sup>.

## SATIETY AND GASTRIC MOTILITY

Additionally, the mechanisms that induce the gastric satiety are complex and they are related to the motor function of the stomach as well as to endocrine and paracrine effects acting in interrelated form. It is known that several mechanisms are involved in the induction of satiety such as distension and accommodation of the stomach, as well as hormones such as cholecystokinin (CCK), glucagon-like peptide (GLP-1), bombesin, liberating-gastrin peptide and somatostatin. It has also been observed that ghrelin, which is a peptide produced in the stomach, has orexigenic effect that probably controls the appetite at a central hypothalamic level. Other factors also intervene for the control of appetite as glycemia and some hormones such as insulin, leptin and enterostatin. It has been observed, for example, that duodenal infusion of fat induces a delay of gastric emptying and sensation of satiety<sup>[13]</sup>. Additionally, gastric banding increases the cholecystokinin plasma levels<sup>[14]</sup>, the Roux-en Y gastric by-pass inhibits basal and postprandial ghrelin plasma levels and increases peptide YY (PYY) concentrations<sup>[15]</sup>. The jejunoileal by-pass increases cholecystokinin, motilin, GLP-1 and PYY<sup>[16]</sup>, delays gastric emptying and reduces hunger sensation. As cholecystokinin, ghrelin and PYY also influence the gastrointestinal motility, it may be possible that a mechanism related to modifications of the gastric emptying is responsible for the early satiety and reduction of body weight observed in these operated patients.

Also the patterns of the gastric motility are well known. The fundus and proximal portion of the gastric body relax during the prandial and postprandial period; therefore, the intra gastric pressure is not modified in a significant form at the beginning of food ingestion. This phenomenon is known as "gastric accommodation", a term which was introduced almost 100 years ago<sup>[17]</sup>. It consists of a receptive relaxation induced by the bolus deglutition and an adaptive relaxation influenced by the increase of the intragastric pressure due to food accumulation into the stomach. The impairment of the gastric accommodation seems to be initially responsible for the sensation of fullness and satiety<sup>[18]</sup>. Meanwhile, gastric antrum muscles contract in concentric form by means of rings of distal displacement impelling the gastric content to the duodenum. Nevertheless, the pylorus in postprandial period contracts preventing the early passage of solid meals to the duodenum. Thus, meals are returned to the gastric body in repeated form<sup>[19]</sup>. The speed with which the stomach empties depends on the nature of meals (the solids retain more time than the liquids), of the

osmolarity (the isosmotic meals retain less time than the hypo-osmotic and hyper-osmotic) and of the chemical composition (the fats retain the most time). The hormonal mediators previously mentioned are produced by means of chemical and mechanic stimuli triggered by meals in the stomach and the proximal intestine and their main function is regulation of the gastrointestinal motility.

## GASTROPARESIS

Gastroparesis is a gastric disorder characterized by a delay in the gastric emptying. The etiology is very diverse. The typical clinical manifestations are eructation, early satiety and sensation of gastric fullness, epigastric discomfort, nausea and vomiting and reduction of body weight<sup>[20]</sup>. It has been found that the patients with anorexia nervosa have a significant delay of gastric emptying compared to normal individuals or those with bulimia<sup>[21]</sup>.

## CLINICAL STUDIES OF BT-A FOR TREATMENT OF OBESITY

In accordance with all mentioned above, the clinical use of the BT-A injected into the gastric antrum in obese patients for inducing gastric emptying delay and body weight reduction seemed logical.

This idea was reinforced from the report of Rollnik *et al*, of a patient in whom the injection of BT-A in the gastric antrum by endoscopy was associated with a reduction of 9 kg of body weight and 32.5% of the caloric daily intake 4 mo after treatment<sup>[22]</sup>.

In the last two years, 6 studies evaluating this novel treatment have been published<sup>[23-28]</sup>. Three were open pilot and 3 were randomized double blind controlled trials (one of them performed by our group<sup>[23]</sup>) of which in only one, beneficial effect of BT-A on body weight reduction was observed<sup>[27]</sup>. Nevertheless, important differences among these studies deserve to be discussed in detail (Table 1).

### The dose of BT-A

The dose of BT-A used in all the studies was highly variable. It ranged from 100 UI to 300 UI. However, in the study in which the maximum dose was used no effect on body weight reduction was observed. Perhaps more important than the dose of BT-A was the method of application.

### Method of application of BT-A

In all the studies, BT-A was administered by means of endoscopic antral injections in a number of punctures that ranged from 8 to 24 in circular disposition. Probably, it was expected that the more the punctures performed the more intra muscular diffusion of the toxin might have been obtained. Nevertheless, this factor was not crucial since in the study in which the greatest number of punctures was done, (24 punctures) the results were negative.

It is important to point out that BT-A were injected both into the antrum and the gastric fundus in the only study in which positive results were obtained (in the rest of the studies only antral injections were done). If we remember, the gastric fundus does not have a propulsive

Table 1 Description of the results of 6 studies in which intra-gastric injection of Botulinum Toxin type A was administered to obese patients for treatment of obesity

Reference	n	Design	Dose (UI)	Follow-up (wk)	Results
Garcia-Compean <sup>[23]</sup>	12	Pilot	100 antrum	12	Reduction of body weight: No Gastric emptying: Negative
Albani <sup>[24]</sup>	8	Pilot	100 antrum	16	Reduction of body weight: No
Cardoso <sup>[25]</sup>	12	Pilot	200/300 antrum	12	Early satiety: Yes Reduction of body weight: No Gastric emptying: Negative
Gui <sup>[26]</sup>	14	RCT <sup>1</sup>	133/200 <i>vs</i> saline antrum	8	Early satiety: Yes Reduction of body weight: No Gastric emptying: Negative

Mittermaier <sup>[28]</sup>	10	RCT	200 <i>vs</i> saline / antrum	24	Max. gastric capacity for liquids: Positive Early satiety: No Reduction of weight: No

<sup>1</sup>RCT: Randomized controlled trials.

effect as the antrum, injections in this place to cause gastric emptying delay would not seem to have justification. Notwithstanding, the existence of other mechanisms related to satiety that might have origin in the fundus must be considered as we will discuss later.

### Early satiety

Of 4 studies in which early satiety was evaluated after therapy, a positive effect was observed in 3 (two of them were randomized double blind controlled trials). However, only in 1 of these 3 studies a significant body weight reduction was observed. This incongruousness between early satiety and absence of weight reduction observed in some studies may be due to the difficulties of measuring a subjective parameter like this, or perhaps the intensity of the early satiety was not enough to produce significant body weight loss.

### Gastric emptying

In only 1 of 5 studies in which gastric emptying after therapy was evaluated a significant delay was observed. Notwithstanding, diverse methods were used for measuring this parameter: octanoic acid breath test, gastric emptying scintigraphy for solids and liquids labeled with Technetium 99 and Indium 111, respectively. It is well known that results of these procedures can be affected by several factors (type of test meals, chemical composition and osmolarity of the test meals, quantity of liquid, *etc.*). For this reason these procedures must be carefully standardized in every laboratory. In regards to the above mentioned, presently highly sensitive and specific procedures for measuring gastric emptying are not available<sup>[29]</sup>.

## HOW TO EXPLAIN THE DIFFERENCES OF RESULTS BETWEEN THE ONLY POSITIVE AND THE 5 NEGATIVE STUDIES?

In the only positive study performed by the Italian group,

8 injections of BT-A were done in the gastric fundus in addition to the injections in gastric antrum. Conversely in the other studies, injections in the antrum were only done. In this positive study a significant modification of all the evaluated parameters were observed after treatment: presence of early satiety, a delay in gastric emptying, a reduction of the maximal gastric capacity for liquids and more importantly: a significant reduction of body weight. As authors of this study pointed out, gastric fundus is the principal source of ghrelin<sup>[30]</sup> and it also has sensory activity that regulates the total gastric capacity<sup>[31]</sup>. Ghrelin is a 28 amino acids peptide produced by the stomach with orexigenic effect acting on the arquate nucleus of the hypothalamus. Ghrelin plasma levels increase during periods of fasting and reduce after a meal, in other words, this peptide seems to have a regulatory effect of hunger. However, published studies have shown that ghrelin expression in gastric mucosa, measured by histochemistry, increased one year after gastric banding in obese patients who maintained body weight loss; this would discard the physio-pathogenic role of ghrelin in body weight loss of these patients<sup>[32]</sup>. Similarly, in another study, high ghrelin plasma levels did not predict a minor loss of body weight in patients with gastric banding compared to patients with normal plasma ghrelin levels<sup>[33]</sup>. Conversely, Roux-en-Y gastric by-pass inhibits basal and postprandial ghrelin plasma levels<sup>[15]</sup>. Additionally, ghrelin increases gastric emptying and stimulates gastric motility during fasting<sup>[34]</sup>. For all the above mentioned, it is difficult to clarify the role of ghrelin in body weight reduction of the patients in the positive study, particularly when plasma levels of this peptide were not measured.

The reduction of the maximal capacity for liquids after BT-A treatment may be explained by impairment of the gastric fundus accommodation inducing early satiety. Nevertheless, the test of gastric maximal capacity for liquids has poor reproducibility for measuring gastric accommodation. Recently, a novel scintigraphic method for simultaneously assessing gastric accommodation and emptying has been developed using dual-isotopes,

either ( $^{99m}\text{Tc}$ -pertechnetate intravenously and ( $^{111}\text{In}$ -diethylenetriaminepentaacetic acid in a liquid nutrient drink or an ( $^{111}\text{In}$ -oxine-labeled egg sandwich meal. Emptying and accommodation were measured using single positron emission computer tomography (SPECT) every 20 min and up to 240 min<sup>[35]</sup>.

On the other side, the mean delay of gastric emptying observed in patients after BT-A, although significant, was short. Therefore, it makes it difficult to attribute early satiety and body weight reduction to this mechanism.

Finally, treated and untreated patients were given reductive diets of 1200 kcal/day. This may explain the reason why non treated patients also had a significant body weight reduction. Therefore, it is very probable that in treated patients a combined effect of reductive diet and toxin was observed.

## FUTURE OF BT-A IN THE TREATMENT OF OBESITY

In the context of all the above discussed, the following question arises: What is the future of the endoscopic gastric injections of BT-A for the treatment of obesity?

In our opinion the method of antral injections has a very uncertain future. If we take into account that this drug is expensive (100 UI cost about 350 Euros or \$530 dollars), the performance of a study on a major scale is very difficult to achieve given the present circumstances.

Notwithstanding, it remains to be clarified if BT-A injections in the gastric fundus have better results in body weight reduction in obese patients. Perhaps the mechanism of action would be more difficult to explain. Modifications of gastric accommodation inducing early satiety may be an attractive hypothesis. Nevertheless, the measurement of this parameter in future studies by means of reliable tests will be the obstacle to overcome.

If gastric injections of BT-A demonstrate to be effective for the treatment of obese patients in the future, there is another disadvantage that must be considered: the limited duration of its effect (3 mo-6 mo). Therefore, for long-term administration by repeated administration of this drug, the cost-benefit relation has to be taken into account.

In medical science, it is frequent to find an agent that works and less frequent to know how it works. Consequently, we considerably learn from the test error method.

### Abstract

There is recognized increased risk for colorectal cancer in patients with inflammatory bowel disease, particularly in long-standing and extensive ulcerative colitis. There also appears to be an increased rate of intestinal cancer in Crohn's disease, including both colon and small bowel sites. In Crohn's disease, evidence suggests that detection of colorectal cancer may be delayed with a worse prognosis. Some risk factors for cancer in Crohn's disease include the extent of inflammatory change within the colon and the presence of bypassed or excluded segments, including rectal "stump" cancer. In addition, the risk for other types of intestinal neoplasms may be increased in Crohn's disease, including lymphoma and carcinoid tumors. Earlier detection of colorectal cancer based on colonoscopy screening and surveillance may be achieved but, to date, this has not translated into a positive survival benefit. Moreover, newer staining methods and evolving micro-endoscopic techniques show promise, but have not significantly altered management. Future research should focus on development of molecular or other bio-markers that might predict future dysplasia or cancer development in Crohn's disease.

### INTRODUCTION

Previous studies documented that patients with inflammatory bowel disease, particularly those with extensive and long-standing ulcerative colitis, have an increased risk of later colorectal cancer development. This data, however, was largely based on investigations conducted in tertiary care settings, especially from the United States and the United Kingdom. Later studies, particularly from similar geographic locations in the United States, demonstrated that the magnitude of this increased risk may not be so significant in a private or community practice setting<sup>[1,2]</sup>. In contrast, others have suggested that the risk of colorectal cancer in patients with colitis is not universally increased<sup>[3]</sup>. In part, this may be influenced by the underlying colorectal cancer risk related to individual inherited, geographic or other environmental factors, rather than inflammatory bowel disease *per se*.

### CROHN'S DISEASE AND CANCER RISK

In Crohn's disease, specifically, precise cancer risk data are very limited. If colorectal cancer does develop, however, the prognosis is recognized to be poor with reduced survival<sup>[4]</sup>. Several studies, again from tertiary care centers, have suggested that patients with Crohn's disease have an increased risk of colorectal cancer<sup>[5,6]</sup> and an excess overall mortality attributed to digestive tract tumors, including small bowel carcinoma<sup>[7]</sup>. The latter occur at a younger age, usually in males compared to those with small bowel carcinoma unrelated to Crohn's disease<sup>[8]</sup>.

Weedon *et al*<sup>[5]</sup> reported colorectal cancer in 8 of 449 patients with Crohn's disease, or about 1.2% (i.e., an estimated 20 times greater risk than a control population). Similarly, Gyde *et al*<sup>[6]</sup> described an approximately 4-fold increased risk in patients with Crohn's disease. More recent cohort and population-based studies from Canada, where reporting of malignant disease is legally mandated<sup>[7,9]</sup>, are also consistent with an increased intestinal cancer risk in Crohn's disease. In Europe, north-south differences in intestinal and extra-intestinal cancers have also been recently noted<sup>[10]</sup>. Interestingly, in Asia, with Crohn's disease now dramatically increasing, there is a high rate of colorectal cancer, particularly in the lower rectum and anal area<sup>[11]</sup>. A recent and extensive meta-analysis has also recently confirmed the increased colorectal and small bowel cancer risk in Crohn's disease<sup>[12]</sup>. Moreover, other malignancies have been reported in Crohn's disease, including myeloid and lymphoid malignancies<sup>[13]</sup>, possibly related, in part, to wider use of immunosuppressants or biological agents (e.g., infliximab)<sup>[14,15]</sup>. Finally, carcinoid tumors may be increased

in Crohn's disease<sup>[16]</sup>, and this has recently been estimated as a 15-fold risk<sup>[17]</sup>.

## RISK FACTORS

In a cohort-based study of Crohn's disease followed over more than 2 decades, 1% had intestinal cancers detected<sup>[13]</sup>. The clinical features of the intestinal cancers included: a long history of Crohn's disease, often (but not exclusively) over 20 years predating cancer development; a relatively young age of intestinal cancer diagnosis in Crohn's disease; and, the appearance of other histopathological types, including mucinous adenocarcinoma. Most cancers occur in the distal colorectum, often in the presence of extensive inflammatory disease. Cancers were also detected in bypassed or excluded segments of intestine, including rectal "stump" cancer, a potentially important and independent risk factor for later cancer development following colonic resection. The prognosis has also been disconcerting as disease is often detected late and mortality has been significant<sup>[8]</sup>. Even though epithelial dysplasia (thought to be a neoplastic intestinal marker for later or concomitant invasive cancer) has been defined in both small and large intestine supporting the concept of a dysplasia-carcinoma sequence in Crohn's disease, most cases of intestinal cancer, even in large tertiary care centers, are discovered incidentally at the time of surgical resection for treatment of the Crohn's disease.

## FUTURE RESEARCH

To date, specific recommendations for screening and surveillance colonoscopy, even in chronic and extensive Crohn's colitis, have been supported by only very limited data in older patients<sup>[18]</sup>. Indeed, it can be anticipated that the focal nature of dysplasia (as occurs even in extensive ulcerative colitis) may make detection of dysplasia even more difficult in Crohn's disease, a disorder generally characterized by patchy or segmental inflammatory change. As a result, establishing a productive screening program for epithelial dysplasia or focal cancers in Crohn's disease can be expected to prove difficult, even with dye staining or the intriguing potential of newly evolving technologies, such as confocal microendoscopy. Even in extensive colitis, a recent report found that colonoscopy surveillance may not improve survival, but only detect cancers at an earlier stage<sup>[19]</sup>. Other tools that might predict later cancer development in Crohn's disease, employing molecular or genetically-based markers<sup>[20]</sup>, are still desperately needed and should be aggressively pursued.

### Abstract

Patients older than 65 years are the fastest growing segment of the cancer population. It is estimated that within 20 years over 75% of cases and 85% of deaths from colorectal cancer (CRC) will be in this setting. Concerns about cancer treatment in the elderly relate to comorbidities, which increase proportionally with age, physiological changes associated with aging which may influence drug metabolism and toxicity, and diminishing life expectancy, which particularly impacts decisions surrounding the benefits of adjuvant therapies. Over the last 10 years, significant improvements in the treatment of advanced CRC with combination therapy have been made. The randomized trials which have defined these improvements did not exclude elderly patients. However, the median age of patients in these trials has generally been approximately 60 years. Thus, it appears that some degree of selection is involved with younger and presumably fitter patients being the subjects in most of the pivotal trials. The availability of new molecularly targeted agents and newly improved existing agents has expanded the range of treatment options available. This variety gives greater flexibility in dealing with different subsets of patients, such as the elderly. However, some fit elderly patients seem to tolerate combination therapy reasonably well, while studies on unfit elderly subjects are needed.

### INTRODUCTION

Advancing age is often associated with an increase in cancer diagnosis. Malignancies represent the second cause of death in the elderly population in the Western countries, and this age group represents more than half of all diagnosed cancers. Due to a continuous increase in life expectancy, we may expect a higher rate of older patients with malignant disease in the future, and a growth in health expenses. However, to date few data are available in the literature about the treatment of this group of patients. Elderly patients have been under-represented in or excluded from clinical studies, mainly because older age is chosen to be an exclusion criterion<sup>[1]</sup>. Very often, these patients are not treated because many believe the cancer growth potential to be lower in older subjects than in younger ones. Thus, many elderly cancer patients receive general supportive care. If this choice is a valid option for that group of patients defined as “frail”, this is not justifiable for all elderly patients. Often, oncologists fear heavy toxicities or suffer the patients and their relatives prejudice toward collateral effects resigning chemotherapy. However, in the Royal Marsden Hospital, no statistically significant difference in the overall or severe toxicity between the population aged 70 or older or the younger cohort was observed during adjuvant treatment for colorectal cancer (CRC) with a 5-fluorouracil (5-FU)-based chemotherapy<sup>[2]</sup>. The only exception was stomatitis, which was more frequent in the older age group (19% vs 11%,  $P = 0.01$ ). Regardless, when one plans a chemotherapy treatment in an older patient it is necessary to take into consideration the incidence and severity of myelosuppression, mucositis, nausea and vomiting, cardiomyopathy and peripheral neuropathy can increase above 70 years of age. On this basis, it is necessary to individualize a strategy to better tailor the treatment plan at the individual level. The assessment of the functional status by means of the widely used Karnofsky or Eastern Cooperative Oncology Group (ECOG)

Table 1 Comprehensive geriatric assessment

Measure	Description
Function	Activities of daily living (ADL) Instrumental activities of daily living (IADL) Performance status (PS)
Health	Number of co-morbid conditions
Socio-economic status	Income, education, living conditions, caregiver
Geriatric syndromes	Dementia (Mini-mental state examination, MMSE) Delirium Depression (Geriatric depression scale, GDS) Incontinence, failure to thrive, neglect and abuse
Pharmacy	Polypharmacy (other medications being taken)
Nutrition	Mini nutritional assessment

does not seem as effective in older patients as in the adult population, because comorbidities in the elderly may interfere with the measurement of the performance status (PS)<sup>[3]</sup>. Several instruments have been proposed to monitor comorbidities, although none has been validated or widely accepted by the oncologic community<sup>[4]</sup>. A Comprehensive Geriatric Assessment (CGA) scale was thus developed and validated by the Italian Group for Geriatric Oncology (GIOGer) (Table 1)<sup>[5]</sup>. The functional, emotional and cognitive status, comorbidities number, and the numbers of those with depression and geriatric syndromes may help to better define populations that may or may not benefit from various therapeutic approaches (Table 2). Another problem is the definition of “elderly” patient. There is a widely variable perception of the age at which a patient is considered elderly, and this is based on chronological rather than physiological age. In studies of the treatment of acute myeloid leukaemia, patients over 60 were considered elderly while patients with solid tumors had to be over 70<sup>[6]</sup>. These differences make data comparison among clinical studies more difficult. Besides these factors, changes in the elderly also occur in terms of the functions of several organs. Noteworthy are alterations in kidney and liver functions as well as the apparent bone marrow reserve. In addition, elderly patients very often have additional medication, which may significantly influence the *p450* cytochrome function. For this and other reasons clinicians are unwilling to treat an elderly patient. This paper will review the current therapeutic armamentarium suitable for CRC patients and its applicability to elderly subjects both in the adjuvant setting and in advanced disease.

## ADJUVANT CHEMOTHERAPY

Patients with newly diagnosed CRC have a median age of 70 years. Local recurrence or distant metastases are frequent within the first two years. The mean life expectancy of a 65-year-old man is approximately 13 years and for a 65-year-old woman the mean life expectancy is estimated to be nearly 19 years. Thus, an effective reduction in the occurrence of a disease relapse due to an adjuvant chemotherapy may be of major importance for these patients, as their life expectancy exceeds the time in which the appearance of metastatic disease would compromise their sur-

Table 2 Classification of patients into 3 treatment categories based on CGA

Group	Description	Treatment
1	Healthy, good PS	Standard cancer treatment
2	Partially dependent, ≤ 2 comorbidities Life expectancy shortened by cancer	Standard cancer treatment
	if can tolerate treatment	Palliation
	if cannot tolerate treatment	Palliation
	Life expectancy not shortened by cancer	Palliation
3	Frail patients who are totally dependent with ≥ 3 comorbidities or 1 geriatric syndrome	Palliation

vival. On the other hand, a pooled analysis of individual patient data from seven phase III randomised trials (involving 3351 patients) in which the effects of postoperative 5-FU plus leucovorin (LV) or levamisole were compared with the effects of surgery alone in patients with stage II or III colon cancer has demonstrated a benefit in terms of overall survival (OS) in each age group<sup>[7]</sup>. The patients were grouped into four age categories of equal size, and analyses were repeated with 10-year age ranges (≤ 50, 51 to 60, 61 to 70, and > 70 years). OS and the time to tumor recurrence were significantly longer in patients treated with 5-FU-based therapy than in patients who did not receive adjuvant treatment ( $P < 0.001$ ). No significant interaction was observed between age and treatment effect for OS or freedom from tumor recurrence, regardless of how age was included in the analysis. The survival curves for the patients who were older than 70 years of age converged slightly after five years, probably because of deaths from other causes. Analyzing the toxicities according to age for the two treatment regimens, the authors found age was not significantly related to the rate of grade 3 or higher nausea or vomiting, stomatitis or diarrhea among patients treated with either 5-FU plus LV or 5-FU plus levamisole. Although increased age was associated with higher rates of severe leukopenia in patients treated with 5-FU plus levamisole ( $P \leq 0.001$ ), this relationship was of borderline significance in patients who received 5-FU plus LV ( $P = 0.05$ ). However, this analysis denotes some critical aspects. The principal limitation of this study concerns its potential applicability to the general population of elderly patients. As a result of exclusion criteria and screening, elderly patients who enter clinical trials are a select group, with good PS, easy access to transportation and limited numbers of comorbidities. How co-existing conditions, malnutrition and poor social support might affect the efficacy and tolerability of 5-FU-based chemotherapy is unknown. It will be up to further studies to explain the decision to treat an elderly patient who has several other problems involving physician, patient and family. Moreover, only 23 of the 3351 patients (0.7%) in the trials were over the age of 80 years. Caution is therefore advised in extrapolating these findings to octogenarians.

Capecitabine is being investigated for the treatment of elderly patients with CRC. The X-ACT trial, comparing

oral capecitabine monotherapy (1250 mg/m<sup>2</sup> twice daily for 2 wk on/1 wk off) with the Mayo Clinic regimen (bolus 5-FU 425 mg/m<sup>2</sup> days with LV 20 mg/m<sup>2</sup> days 1-5 every 4 wk) in the adjuvant setting among 1987 patients with Dukes' C colon cancer, reported significantly superior relapse-free survival with capecitabine ( $P = 0.041$ ), and fewer adverse events than with 5-FU plus LV ( $P = 0.001$ )<sup>[8]</sup>. As a result, capecitabine monotherapy is now approved for adjuvant therapy of Dukes' C colon cancer. Diaz-Rubio *et al* provided a retrospective safety analysis on a subpopulation of patients  $\geq 70$  years of age (capecitabine:  $n = 186$ ; 5-FU/LV:  $n = 205$ ) from the X-ACT trial database<sup>[9]</sup>. With respect to all-grade non-hematologic adverse events, elderly patients treated with single-agent capecitabine had significantly less diarrhea (52% *vs* 68%,  $P = 0.002$ ), stomatitis (23% *vs* 67%,  $P < 0.001$ ), and nausea (33% *vs* 47%,  $P = 0.005$ ) than patients treated with bolus 5-FU/LV. Only all-grades hand-foot syndrome (HFS) was seen significantly more frequently with capecitabine (63% *vs* 8%,  $P < 0.0001$ ). With respect to grade 3 or 4 hematologic adverse events, elderly patients had significantly less neutropenia with capecitabine than 5-FU/LV (4% *vs* 31%,  $P < 0.00001$ ). Grade 3 or 4 hyperbilirubinemia was significantly greater with capecitabine than 5-FU/LV, when measured by NCI Common Terminology Criteria for Adverse Events. Although these results are promising, additional efficacy, quality of life (QoL), and cost data, particularly from the X-ACT trial, are needed to assess the usefulness of capecitabine for the treatment of elderly patients with CRC in the adjuvant setting.

A recent retrospective, age-based ( $<$  or  $\geq 70$  years), pooled analysis including 3742 CRC patients (614 age  $\geq 70$ ) was conducted extrapolating data in the Sanofi-Aventis database from four clinical trials testing the combination of oxaliplatin plus 5-FU/LV administered bimonthly (FOLFOX4) in the adjuvant, first-, and second-line settings<sup>[10]</sup>. End points included grade  $\geq 3$  adverse events, response rate (RR) (in advanced disease), progression or relapse-free survival, dose-intensity, and OS in the studies with mature survival data. The advantages of FOLFOX4 have been demonstrated in stage III patients<sup>[11]</sup>. The four trials formed the basis for the US Food and Drug Administration approval of FOLFOX4 in the treatment of metastatic CRC (first- and second-line settings) in stage III patients (after complete surgical resection). There was no difference in efficacy derived between younger and older patients enrolled into these trials with respect to RR, relapse/progression-free survival or OS. The analysis showed similar toxicity patterns in the two age groups. Increased rates of neutropenia (43% *vs* 49%;  $P = 0.04$ ) and thrombocytopenia (2% *vs* 5%;  $P = 0.04$ ) were observed in the older patients. However, efficacy outcomes were not different between the two age groups. In addition, drug delivery doses did not differ significantly by patient age and there was no difference in the incidence of treatment-associated deaths or neuropathy as a consequence of age. However, older patients who enrolled in these trials clearly are a select group, suggesting that generalizations derived from this study must be applied cautiously to individual older patients.

## CHEMOTHERAPY FOR ADVANCED DISEASE

### 5-FU

Treatment of patients with metastatic disease is palliative. As for any other age group of patients, concern may be raised whether an elderly patient might benefit most from general supportive care rather than from toxic treatments. If one considers that patients with a new diagnosis of CRC have a median age of 70 years, the first endpoint remains symptoms palliation or clinical benefit, and not the objective response (OR) or OS time. Renal elimination of 5-FU after its catabolism in the liver and mucosa is limited and estimated to account for no more than 10% of excreted drug<sup>[12]</sup>.

Therefore, 5-FU dose reduction in patients with renal dysfunction (possible in the older population) is usually not considered necessary. On the other hand, a large amount of 5-FU has to be metabolized by extrahepatic tissue. On this basis, a mild decrease in renal or hepatic function related to age is not a sufficient reason to reduce a 5-FU dose. A study examined the potential influence of gender and age on 5-FU-clearance<sup>[13]</sup>. Both factors are considered to have potential roles in the pharmacokinetic variability of drugs. There was no evidence that age modified 5-FU-clearance when it was adjusted for sex and dose. Female sex turned out to be a major determinant for increased toxicity, while age was not. These data quite justify the use of this drug in elderly patients. A large number of clinical trials confirm these assumptions. An Italian Group treated patients with a median age of 75 (range 70 to 85 years) with best supportive care or a weekly 5-FU bolus and LV regimen<sup>[14]</sup>. Interestingly, the median survival of the patients receiving chemotherapy was prolonged by 2 mo, indicating a potential benefit of chemotherapy in the elderly, and so confirming data from studies in the younger population. Adverse events were reversible and of limited impact. The study did not show any grade 4 toxicity, while grade 3 toxicity was verifiable in only 16.4% of cases. Similar encouraging results were reported in trials employing 5-FU continuous infusion (c.i.), which decreases the hematological toxicity. Two Italian phase II experiences evaluated the efficacy and safety of the "de Gramont" schedule in patients aged 70 years or older<sup>[15,16]</sup>. Both these trials reported ORs in 20% of patients and median survivals of about 12 mo, but demonstrated the feasibility of chemotherapy in elderly patients without quality of life worsening and with improvement of symptoms. In an attempt to anticipate the risks and benefits of chemotherapy, the authors applied the geriatric assessment scales (ADL and IADL) to patients. Unfortunately, neither of these scales was useful to these aims. However, these studies were carried out on a very small sample and there was a high risk of false-negative results. Regarding side effects, gastrointestinal and hematological toxicities were common, but rarely severe. A recent pooled retrospective analysis of data regarding 3825 patients (629 aged 70 years or older) included in 22 European phase II and III trials analyzed the role of 5-FU in the treatment of advanced disease<sup>[17]</sup>. The majority

of elderly patients were aged 70 to 74 years. They were generally treated with bolus 5-FU and its modulation by LV, methotrexate or interferon and less with 5-FU c.i. The results indicated 5-FU-based chemotherapy had the same activity in elderly patients compared with younger subjects, in terms of ORs (23.9% *vs* 21.1%, respectively;  $P = 0.14$ ), progression-free survival (PFS) (5.5 *vs* 5.3 mo, respectively;  $P = 0.01$ ) and OS (10.8 *vs* 11.3 mo, respectively;  $P = 0.31$ ). The 5-FU c.i. allowed a small improvement in these results. Although no significant differences were observed between age and treatment efficacy, the number of subjects over the age of 75 years was only 3.8%. Moreover, elderly patients who entered clinical trials were a select subgroup, with limited comorbidities, and probably not representative of the general older population. Totally absent were the toxicities data in this analysis. Reports on the efficacy and toxicity of 5-FU-based-chemotherapy for that group of patients defined as “frail” are lacking in literature.

### Raltitrexed

Raltitrexed is a nonfluoropyrimidine thymidilate synthase inhibitor that has shown efficacy and tolerability in the treatment of CRC. A randomized trial for metastatic disease demonstrated equal efficacy of raltitrexed compared with a conventional 5-FU-bolus regimen in terms of OR and OS<sup>[18]</sup>. However, leukopenia and mucositis were more frequent in the 5-FU-based arm than in the experimental arm. The once-every-3-wk dosing, tolerability profile and ease of administration advocated for further investigation in elderly population. However, 50% of raltitrexed is excreted by the kidney. In the case of renal dysfunction and creatinine clearance decreasing, the dose of drug has to be adapted. The higher rate of therapy-associated deaths due to a failure to adapt the raltitrexed dose in patients with renal dysfunction accounts for the premature closing of the Pan-European Trial on Adjuvant Colon Cancer (PETACC 1)<sup>[19]</sup>. The use of raltitrexed may be justified in subjects with 5-FU-associated cardiotoxicity<sup>[20]</sup>. As older patients are more likely to have a cardiovascular disease, and patients with pre-existing cardiovascular disease are more likely to experience 5-FU-associated cardiotoxicity, the use of raltitrexed in this age group may be of potential benefit. Two studies have evaluated the efficacy, safety and toxicity of raltitrexed in patients aged 70 years and older<sup>[21,22]</sup>. Treatment with raltitrexed resulted in clinical improvement of tumor-associated symptoms in 38% of cases and was associated with an acceptable toxicity profile. In particular, a risk group for nausea-vomiting and diarrhea was females between 70 to 75 years old, and a risk group for liver toxicity was males aged > 75 years. On the basis on these results the authors suggested raltitrexed was a suitable option in elderly patients.

### UFT

UFT combines the dihydropyrimidine dehydrogenase (DPD) inhibitor uracil with the 5-FU prodrug tegafur in a 4:1 molar ratio. Uracil competes with 5-FU for DPD and inhibits the degradation of the 5-FU generated by tegafur<sup>[23]</sup>. Compared with 5-FU alone, administration of UFT results in higher concentrations of 5-FU in tumors<sup>[24]</sup>.

Two large, multinational phase III trials compared UFT plus LV *versus* the Mayo regimen of 5-FU and LV in patients with previously untreated advanced CRC. A regimen of UFT (300 mg/m<sup>2</sup> per day) plus oral LV (75 or 90 mg per day) for 28 d every 5 wk was compared with 5-FU (425 mg/m<sup>2</sup> per day) plus LV (20 mg/m<sup>2</sup> per day) intravenously for 5 d every 4 wk or 5 wk<sup>[25,26]</sup>. The larger study with 816 patients reported similar OR rates (12% for UFT plus LV *vs* 15% for 5-FU plus LV) and no statistically significant difference in survival times. In the second study, which included 380 patients, the two regimens demonstrated similar times to disease progression, median survival times and RRs. However, in both studies, the UFT plus LV regimen showed significantly lower toxicity, with a lower incidence of grade 3 mucositis, myelosuppression, febrile neutropenia, and infections, and no notable hand-foot syndrome. These advantages make this form of oral therapy suitable for elderly patients. So, two Spanish groups reported good tolerability and efficacy for the use of UFT in elderly patients with metastatic CRC<sup>[27,28]</sup>. A recent ECOG trial evaluated the RR and toxicity profiles of elderly subjects, defined as those  $\geq 75$  years of age, treated with UFT and LV<sup>[29]</sup>. Treatment was administered as UFT (100 mg/m<sup>2</sup>) plus LV (30 mg) every 8 h for 28 d with 7 d of rest. Fifty-eight patients were enrolled with a median age of 81 (range, 75-89). Fifty-seven patients were evaluable for toxicity with grade 3-4 as follows: Gastrointestinal 20 (34%), neutropenia 4 (7%), no hand-foot syndrome. There was only one case of grade 4 diarrhea reported. In six cases (10%), a dose reduction for gastrointestinal toxicity was required, while there were 2 fatalities with gastrointestinal bleeds. The RR was 19%, median time to progression (TTP) was 19 wk, and OS was 11.8 mo. Thus, UFT + LV was well tolerated in this study with an incidence of grade 3-4 toxicity similar to phase III reports in younger patients. Activity was comparable to intravenous 5-FU/LV. This oral fluoropyrimidine is well tolerated and very active in elderly patients.

### Capecitabine

Capecitabine, an oral formulation of 5-FU, was developed as an alternative to intravenous 5-FU. Compared with the parenteral compound, capecitabine provides greater tumor selectivity while minimizing systemic exposure. The drug is well absorbed via the gastrointestinal tract and is catabolized to active drug by a series of three enzymes. Over 70% of the metabolites are excreted by the kidney. This makes one cautious when it is necessary to treat an elderly subject. A moderate restriction in liver function does not appear to alter the pharmacokinetic of this drug in a clinically relevant fashion<sup>[30]</sup>. A large, randomised, open-label phase II trial conducted in Europe, North America and Australia evaluated three schedules of capecitabine (continuous, intermittent and intermittent with oral LV) in patients with metastatic CRC<sup>[31]</sup>. The addition of LV seemed to increase the incidence of side-effects without any benefit to RR or survival times. The RR for the three schedules ranged from 21% to 24%; the median time to disease progression ranged from 127 d to 230 d, with the longest TTP being seen in the capecitabine intermittent arm (with-

out LV). This schedule, which consists of twice-daily dosing for 14 d followed by 7 days' rest, was further evaluated in two phase III trials. Each of these large trials included more than 600 patients. In the trial conducted in 61 centers in the USA, Brazil, Canada, and Mexico, a total of 605 patients were randomized to receive either 2500 mg/m<sup>2</sup> per day capecitabine in divided daily doses for 14 d followed by 7 days' rest or the Mayo regimen described above<sup>[32,33]</sup>. Capecitabine was more active than 5-FU in the induction of a tumor response, and the two groups showed similar times to tumor response and response durations. TTP and OS times were comparable between the two regimens, but the toxicity of capecitabine was less than that of 5-FU, with a substantially lower incidence of diarrhea, stomatitis, nausea and alopecia. However, capecitabine was associated with a higher incidence of palmar-plantar erythrodysesthesia. While capecitabine was shown to be tolerated by fit elderly patients, until a short time ago information on dosing and scheduling for older patients with impaired organ function was not available. Recently, a multicentre phase I / II trial of capecitabine (2000 mg/m<sup>2</sup> per day for 14 d every 3 wk) was conducted in 214 patients aged  $\geq 65$  years and/or with an ECOG PS  $\geq 1$ <sup>[34]</sup>. In the 192 patients evaluable for toxicity, there were no grade 3-4 hematological toxicities. Grade 3-4 toxicity occurred in 22% of patients during the first 3 cycles (8.9% HFS, 6.3% diarrhea, 2.6% lethargy, 2.6% dehydration, 1% abdominal pain, 0.5% stomatitis). Dose reductions were required in 14% and dose delays in 21% for medical reasons. In the 151 evaluable for activity, a response was seen in 13%, median PFS was 5.1 mo, and median OS was 16.3 mo. The authors demonstrated lower dose capecitabine was tolerable and active in less fit patients. This study provides valuable information on possible outcomes in these under-studied patients for whom combination chemotherapy may not be preferred. Oral therapies avoided central access devices, with their attendant costs, inconvenience to patients and potential for costly and morbid complications. These factors, along with patient preference for an oral regimen, have contributed to the development of oral 5-FU preparations.

### Irinotecan

Irinotecan (CPT-11) is a semisynthetic derivative of the natural alkaloid camptothecin, and belongs to a new class of antineoplastic agents called topoisomerase I interactive compounds. Since its introduction into the clinic, CPT-11 has undergone a comprehensive evaluation as a single agent and in combination chemotherapy in first-line as well as in second-line therapy of CRC. In two studies using either infusional or 5-FU bolus regimens, CPT-11 was able to improve the objective RR as well as the median survival of patients receiving 5-FU plus LV and CPT-11 combination therapy<sup>[35,36]</sup>. However, the inclusion criteria of both trials prevented patients over 75 years of age from being treated within the protocol. CPT-11 used as a single agent is associated with equal toxicity in younger and fit older patients (above 65 years of age)<sup>[37]</sup>. Pharmacokinetic studies have demonstrated equivalent drug pharmacological parameters in patients below or above 75 years of age<sup>[38]</sup>. A retrospective analysis compared toxic-

ity and survival according to age during a CPT-11-based treatment of 339 patients with fluoropyrimidine-resistant advanced CRC. All patients commenced CPT-11 at 350 mg/m<sup>2</sup> once every 3 wk and of the 339 patients, 72 (21%) were aged  $\geq 70$ <sup>[39]</sup>. There were no differences in the proportions of patients developing toxicities by age ( $< 70$  vs  $\geq 70$ : 37.8% vs 45.8%;  $P = 0.218$ ). Patients aged  $\geq 70$  had similar ORs (11.1% vs 9%;  $P = 0.585$ ) and survival (median 9.4 vs 9 mo;  $P = 0.74$ ) compared with younger patients. These data suggest elderly patients derive the same benefit without experiencing more toxicity with second-line CPT-11 treatment for advanced CRC, and do not support the recommendations to give reduced starting doses to elderly patients. Although in a phase II study older patients were twice as likely (38.6% vs 18.8%;  $P < 0.008$ ) to develop grade 3-4 diarrhea compared with younger patients<sup>[40]</sup>, and although clinicians often reduce the dose of CPT-11 from 350 mg/m<sup>2</sup> to 300 mg/m<sup>2</sup> when administered in a three-weekly schedule or from 125 mg/m<sup>2</sup> to 100 mg/m<sup>2</sup> in the weekly schedule, this is rather a precaution than an evidence-based indication. Moreover, a recent small retrospective study has demonstrated irinotecan (80 mg/m<sup>2</sup>) is active and tolerable when administered once a wk for 2 wk, followed by a wk rest in pretreated CRC patients aged 70 years or more<sup>[41]</sup>. The most frequently observed severe toxicities were diarrhea (grade 3, 13%) and neutropenia (grade 3, 30.4%; grade 4, 8.6%). Only one case of neutropenic fever occurred. Other hematological and non-hematological toxicities were mild and manageable. Objective partial responses (PR) were observed in 13% of cases and an additional 43% of patients reported a stable disease (SD). Just the lack of exhaustive data in literature has justified some recent trials evaluating the efficacy and safety of CPT-11 in combination regimens in elderly patients. In an Italian phase I / II trial accepting pretreated older patients, irinotecan in combination with oxaliplatin (OXIRI) were evaluated through a weekly schedule<sup>[42]</sup>. Twenty-one patients were enrolled at the second dose level with the maximum tolerated doses of 40 mg/m<sup>2</sup> for oxaliplatin and 60 mg/m<sup>2</sup> for CPT-11. The obtained results demonstrated the feasibility of chemotherapy with a good toxicity profile and acceptable efficacy (RR 28%). A Spanish phase II study evaluated the combination of CPT-11 and 5-FU 48 h c.i. as a first-line chemotherapy for patients older than 72 years<sup>[43]</sup>. Inclusion criteria such as Karnofsky  $> 70$ , adequate hepatic and renal function, normal blood cell counts and absence of geriatric syndromes were required. Although treatment delay was observed in 39.7% of cases, particularly for hematological toxicity, and dose reduction was required in 19% of subjects both for hematological and non-hematological toxicity, grade 3-4 toxicities appeared in about 20% of cases. Peripheral venous thrombosis was reported in 4 cases, central venous catheter thrombosis in one case and pulmonary embolism in yet another one. There were 2 toxic deaths, one due to grade 4 diarrhea and acute renal failure and the other due to a pulmonary embolism reported as unrelated to the treatment. Forty-four patients were assessable for efficacy with a RR of 31.8%. Thirty consecutive, previously untreated patients (76 years median age) with metastatic CRC, were

enrolled in another phase II trial evaluating the FOLFIRI regimen<sup>[44]</sup>. Although this combination appeared manageable (grade 3-4 neutropenia 20%; grade 3 thrombocytopenia 3.3%; grade 3 asthenia 10%; grade 3-4 diarrhea 17%), one treatment-related death due to neutropenic sepsis was registered. Overall, RR was 36.6% and the median TTP was 7 mo. After a median follow-up period of 17 mo, the median OS was 14.5 mo. A combined analysis of 2691 patients included in randomized trials has been recently presented to compare the efficacy and toxicity in older ( $\geq 70$  years) and younger ( $< 70$  years) subjects receiving first-line 5-FU/FA with or without irinotecan<sup>[45]</sup>. There was no imbalance regarding risk factors (ECOG PS, WBC, number of tumor sites, alkaline phosphatase and LDH) between elderly and younger patients. Older and younger patients had significantly improved RRs and PFS with combination therapy than with 5-FU/FA. Younger patients had significantly longer OS with irinotecan and 5-FU/FA ( $P = 0.0003$ ), while older patients had a trend to longer OS with this combination therapy ( $P = 0.15$ ). The combination was associated with more grade  $\geq 3$  toxicity in the general population, but there were no significant differences regarding toxicity between older and younger patients. Although this analysis has considered patients aged over 70 years who were selected for inclusion in phase III trials, it has demonstrated elderly patients derive similar benefits from irinotecan-containing chemotherapy, and with similar risks of toxicity, compared with younger patients. Two studies reported preliminary data on the efficacy and tolerability of CPT-11 in combination second-line regimens in patients aged  $\geq 66$ <sup>[46,47]</sup>. The first of these was conducted adopting a weekly schedule of CPT-11 and bolus 5-FU in 10 patients who had relapsed or had progressive disease after oxaliplatin-5-FU/LV combination. Three of the 10 patients showed a PR. The median TTP and median survival time were 4.5 and 12 mo, respectively. However, the toxicity profile was burdened with these percentages of grade 2-3 adverse events: Neutropenia 50%, thrombocytopenia 22%, anaemia 33%, diarrhea 33%, nausea 44% and fatigue 39%. The second trial evaluated the safety and efficacy of CPT-11 plus capecitabine. The 26 enrolled patients received first-line chemotherapy with FOLFOX4 in 16 cases, FOLFIRI in 4, and 5-FU/LV/methotrexate in 6 cases. Eight of 24 evaluable patients (33%) showed a response to treatment, median TTP was 5.5 mo, and OS was 11.5 mo. The most common grade 3 side effects were diarrhea (40%), nausea and vomiting (20%), and hand-foot syndrome (10%). Grade 3-4 neutropenia was seen in 40% of patients. No treatment-related death was reported. Nevertheless, more data on the use of CPT-11 in elderly patients would be reassuring.

### Oxaliplatin

Oxaliplatin is a novel platinum derivative and the first platinum compound to demonstrate significant efficacy in the treatment of advanced CRC. *In vitro* and *in vivo* preclinical studies on CRC have shown oxaliplatin is active against colorectal cell lines and is synergistic with 5-FU<sup>[48]</sup>. In one randomized trial, accepting patients below the age of 75 years, the role of oxaliplatin in combination with 2-d

administration of high-dose LV plus 5-FU bolus and low-dose infusional 5-FU in the first-line therapy of advanced CRC was evaluated in 420 patients<sup>[49]</sup>. The objective RRs in elderly and younger patients treated with infusional 5-FU/LV (22.2% *vs* 21.4%, respectively) were not different from those treated with infusional 5-FU/LV plus oxaliplatin (50% *vs* 50%;  $> 65$  years,  $n = 160$ ) as compared to younger patients, respectively. In general, compared with younger patients, this group of elderly patients did not experience increased toxicity except for grade 3-4 diarrhea (18% *vs* 8%,  $P = 0.34$ ). The combination regimens employing oxaliplatin plus infusional 5-FU/LV have less hematological toxicity, in particular for FOLFOX2 and FOLFOX6. Thus, clinicians have had a preference for oxaliplatin compared with CPT-11 when they have considered possible the evaluation of a polychemotherapy for elderly patients in several recent phase II studies. An Italian study assessed the tolerability and efficacy of FOLFOX2 in the treatment of pretreated and metastatic elderly patients in comparison to a series of patients  $< 65$  years<sup>[50]</sup>. The preliminary data suggested FOLFOX2 had comparable activity between the two groups (RR 30%) and this schedule was well tolerated in the elderly group. The main toxicities, albeit of short duration, were neutropenia, mucositis, diarrhea, and neurotoxicity. A tailored regimen including capecitabine and oxaliplatin (XELOX) for treating elderly patients with metastatic CRC was planned on September 2001<sup>[51]</sup>. Thirty-five patients aged 70-81 years were treated with an alternated dose escalation for both drugs over the first 3 cycles for each patient in the absence of WHO grade  $\geq 2$  toxicity on previous cycle. Starting doses were 85 mg/m<sup>2</sup> for oxaliplatin on d 1, and 2000 mg/m<sup>2</sup> for capecitabine, which was taken orally, twice a day, from d 2 to d 15. Dose escalation was performed in 51% of patients for oxaliplatin, and in 11% of cases for capecitabine. No grade 4 and 10 (29%) cases of grade 3 toxicity of any type were reported. Abdominal symptoms (pain, nausea or vomiting) affected 66% of patients, but they were of grade 3 in only 2 patients. Grade 3 diarrhea occurred in 9% of patients. The overall RR was 40%, while PFS and OS time were 6.9 and 14.1 mo, respectively. The authors reported compliance was fairly good considering only one patient went off for refusal in this study. Another three studies have investigated the XELOX regimen as first-line treatment for elderly patients with CRC<sup>[52-54]</sup>. Even if there was one treatment-related death for diarrhea in two of these trials, the authors emphasized the tolerability of this regimen for elderly patients. Thus, in the Feliu *et al* experience, reporting a median relative dose intensity of 92% for oxaliplatin and 98% for capecitabine with a RR of 36% and a TTP of 6.9 mo, the more frequent grade 3-4 toxicities per patient were: Diarrhea 22%, asthenia and vomiting 14%, nausea 10%, and anorexia 8%<sup>[53]</sup>. In the Comandone *et al* trial employing the same combination, 27 patients, 8 of whom were pretreated with chemotherapy, entered the study<sup>[54]</sup>. Following the RECIST criteria the authors observed a RR of 19.2%, while the median TTP and OS were 6.1 and 14.2 mo, respectively. The grade 1-2 toxicities were: Peripheral neuropathy 40%, nausea-vomiting 18%, neutropenia 26%, and asthenia 35%. In

one only case was the treatment interrupted for grade 3 neuropathy after one course of therapy. We have tested the oxaliplatin plus oral UFT/LV combination as a first-line therapy in patients with advanced or metastatic CRC aged 70 or older<sup>[55]</sup>. Forty-seven patients aged  $\geq 70$  were treated with oxaliplatin 65 mg/m<sup>2</sup> as an intravenous 3-h infusion on d 1 and 8 plus UFT 300 mg/m<sup>2</sup> and LV 90 mg in three divided doses given orally on d 1-14 for each 3-wk cycle. Patients were followed by a geriatric and a QoL assessment with specific scales and EORTC-QLQ-C30 questionnaire. All patients were assessable for toxicity and 45 for response to treatment. The overall RR was 51%, and the median duration of response was 8 mo (range, 3-19+ mo). After a minimum follow-up of 17 mo, the median TTP and the median OS were 8.0 and 14.1 mo, respectively. Regimen safety was manageable. Most adverse events were mild to moderate, and this did not result in QoL impairment. The most common grade 3-4 treatment-related adverse events were diarrhea (17%), neutro- and thrombocytopenia (2%), laryngeal spasm (2%), and peripheral neuropathy (12.7%). No treatment-related death occurred. In addition, early phase II data for modified FOLFOX4 are available<sup>[56,57]</sup>. Masscesi *et al* examined 78 patients aged  $\geq 70$  years and ECOG performance status  $\leq 2$ . Their schedule was: Oxaliplatin 45 mg/m<sup>2</sup> + 5-FU bolus 400 mg/m<sup>2</sup> + 5-FU infusional 600 mg/m<sup>2</sup> + LV 200 mg/m<sup>2</sup>, d 1 and 2, every 2 wk. Responses and geriatric scales ADL and IADL were assessed every 6 cycles. The overall RR was 50.5%, the median duration of response was 9 mo and second-line chemotherapy was delivered to 47% of patients. With a median follow-up time of 12.5 mo, the median TTP and OS were 8.1 and 20.1 mo, respectively. The main grade 3-4 toxicities were: Neutropenia 32%, diarrhea 10%, mucositis 4% and fatigue 4%. Grade 2 and 3 sensory neuropathy occurred in 17% and 6% of cases, respectively. Bi-fractionated FOLFOX4 was highly active and it demonstrated reduced neurotoxicity<sup>[56]</sup>. In the Kim *et al* experience to minimize toxicity and improve compliance of chemotherapy in elderly patients, reduced dose intensity (mini-) FOLFOX4 regimen was used as a first-line palliative chemotherapy. The schedule was: Oxaliplatin 65 mg/m<sup>2</sup> on d 1 + 5-FU bolus 300 mg/m<sup>2</sup>, 5-FU infusional 450 mg/m<sup>2</sup>, and LV 150 mg/m<sup>2</sup> on d 1 and 2, every 2 wk. Twenty-seven patients older than 70 years of age were enrolled. The overall RR was 31.8%, median PFS and OS were 7.1 and 13.5 mo, respectively. The main side effect was grade 1-2 anemia and neutropenia, observed in 24.3% and 13.5% of patients, respectively. There were no grade 4 toxicities and only one patient suffered from grade 3 neuropathy and vomiting. The authors recommended mini-FOLFOX4 in elderly patients with advanced CRC being well tolerated with acceptable toxicity without compromising objective RR or survival<sup>[57]</sup>.

## NOVEL BIOLOGICAL AGENTS

### Cetuximab

Cetuximab is a monoclonal antibody against the epidermal growth factor receptor (EGFR), which is expressed in many patients with CRC. Addition of cetuximab to

chemotherapy improved outcomes both in previously treated and in untreated patients<sup>[58-60]</sup>. Only one study has evaluated the activity and safety of cetuximab as a single agent in the first-line treatment of elderly patients<sup>[61]</sup>. Forty-one patients  $\geq 70$  years old with confirmed metastatic CRC, Karnofsky PS  $\geq 80$ , and adequate renal, hepatic and bone marrow function were included. Cetuximab (400 mg/m<sup>2</sup> as initial dose and 250 mg/m<sup>2</sup> weekly thereafter) was administered until progressive disease, unacceptable toxicity or consent withdrawal. Only two patients required dose reduction of cetuximab due to toxicity, and there was a dose delay of one wk in 12 cases (29%), achieving a median relative dose intensity of 80%. The main toxicities were those expected for cetuximab: Acne-like rash grades 1-2 (54%), grade 3 (10%), nail toxicity grades 1-2 (7%) and infusion related toxicity grades 1-2 (5%). Thirty-nine patients were evaluable for efficacy: One showed a complete response (CR), 5 showed a PR, 15 showed SD and 18 showed progressive disease (PD), resulting in an overall RR of 15.4% and tumor growth control of 54%. Cetuximab monotherapy is feasible in elderly patients as a first-line treatment for metastatic CRC with a favourable safety profile. Response and disease control rates remain in the range observed in pretreated patients. Further research with cetuximab in combination therapies is warranted in this population, as it could improve the efficacy of chemotherapy without jeopardizing its toxicity.

### Bevacizumab

Bevacizumab is the recombinant humanized version of a murine antihuman vascular endothelial growth factor (VEGF) monoclonal antibody A4.6.1<sup>[62]</sup>. One randomized phase III trial utilized a regimen of irinotecan, bolus 5-FU, and FA with or without bevacizumab in patients with a good ECOG PS (PS 0 or 1)<sup>[63]</sup>. This study demonstrated statistically significant and clinically relevant improvements in RR, TTP and survival in the bevacizumab-containing arm. Median survival was increased by 4.7 mo (15.6 *vs* 20.3 mo;  $P < 0.001$ ). However, retrospective analyses suggested the benefit derived from irinotecan in chemotherapy combination regimens might be limited to patients with a PS of 0<sup>[64]</sup>. Also, certain subgroups, including elderly patients, may experience significant toxicities when adding irinotecan to 5-FU/FA regimens. So, a second, supportive, placebo-controlled, randomized, phase II trial was conducted concurrently with the above-mentioned trial in patients deemed non-optimal candidates for first-line irinotecan-containing regimens<sup>[65]</sup>. Patients had a median age  $\geq 70$  years, ECOG PS 0 or 1, serum albumin  $\leq 35$  g/dL, or prior abdominal/pelvic radiotherapy. Subjects were randomly assigned to 5-FU/FA/placebo or 5-FU/FA/bevacizumab. When compared with patients treated with 5-FU/FA alone, the addition of bevacizumab prolonged median survival by 3.7 mo, PFS by 3.7 mo, response duration by 2.4 mo, and increased the RR by 11%. Despite this higher-risk population, the regimen of 5-FU/FA/bevacizumab seemed to be well tolerated. Grade 3 hypertension was more common with bevacizumab treatment (16% *vs* 3%), but was controlled by oral medication and did not cause study drug discontinuation. No increase in grade 3 or 4 bleeding

or venous thrombotic events was seen in bevacizumab-treated patients. The authors also reported an imbalance in the incidence of arterial thrombotic events: 10% in the 5-FU/FA/bevacizumab group compared with 4.8% in the 5-FU/FA/placebo group. The more advanced age of the population may have contributed to a higher overall incidence of this adverse event.

However, additional research is needed to clarify the appropriate dosing and scheduling of various combination chemotherapy regimens (containing specifically irinotecan or oxaliplatin) plus bevacizumab in older patients.

## CONCLUSION

Almost half of the CRC cases diagnosed occur in patients over the age of 70. In spite of the fact systemic chemotherapy is beneficial for patients with metastatic disease in terms of survival prolongation, symptomatic improvement and QoL, there is clear evidence that elderly patients are under-treated and under-represented or even excluded from clinical studies. Among the relevant trials for the treatment of CRC patients, probably no more than 20% of cases belong to the over 70 age-group. Nevertheless, elderly CRC patients have been shown to tolerate chemotherapy as well as younger patients in palliative settings with similar RRs. New studies are mandatory to establish particularly the safety of various combinations plus or minus biological agents in older patients. In this context, the results of a randomized phase II study evaluating the activity and safety of capecitabine in combination with oxaliplatin (CAPOX) or with irinotecan (CAPIRI) in patients  $\geq 70$  years could be of interest<sup>[6]</sup>. Preliminary data from this trial confirm both combinations are active (RR 38.4% for CAPIRI and 32.2% for CAPOX) with median response durations of 8.2 mo for CAPIRI and 6 mo for CAPOX. The most frequent severe toxicities were diarrhea (CAPIRI: 19.3%; CAPOX: 14.2%) and neutropenia (CAPIRI: 22.5%; CAPOX: 2.8%). No treatment-related death occurred. These findings seem to suggest the employment of capecitabine given in doublet combination is feasible in elderly patients apart from specimen of the above-mentioned regimens.

Even though the data reported in this review have to be interpreted with caution as these results apply to patients who fulfilled the protocol requirements, age alone is not a sufficient reason to reduce the dose of drugs or to withhold adjuvant or palliative treatment from an elderly patient. The PS is probably not the best mean to estimate the conditions of elderly patients and they need more attention regarding their functional, social and mental status. The main problem which remains to be solved is the applicability of these results to all in the elderly population. Until now, specific studies on unfit older patients are very few or lacking in the literature.

## APPENDIX

The information was gathered from extensive PUBMED searches (no limits to publication period were applied, but only English language papers are referenced). Additional

references, including congress abstract presentations, are included where appropriate and in particular when there are no published studies on a discussion topic.

## Abstract

Invasion and metastasis are the deadly face of malignant tumors. Considering the high rate of incidence and mortality of colorectal cancer, it is critical to determine the mechanisms of its dissemination. In the parallel investigation of the invasive front and tumor center area of colorectal cancer (CRC), observation of heterogeneous  $\beta$ -catenin distribution and epithelial-mesenchymal transition (EMT) at the invasive front suggested that there might be a crosstalk between tumor cells and the tumor microenvironment. Wnt signaling pathway is also involved in the cancer progression due to its key role in CRC tumorigenesis. Moreover, in recent years, there is increasing evidence that the regulators of microenvironment, including extracellular matrix, growth factors and inflammatory factors, are associated with the activation of Wnt pathway and the mobility of tumor cells. In this review, we will try to explain how these molecules trigger metastasis *via* the Wnt pathway.

## INTRODUCTION

Colorectal cancer (CRC) is one of the major malignancies worldwide and the second leading cause of cancer death in the United States<sup>[1]</sup>. In the past decades, many researches in tumorigenesis and progression of CRC have focused on genes and epigenetic changes. Recently, increasing attention has been paid to cellular signal transduction in CRC, especially Wnt pathway which regulates cell growth, differentiation and death in embryogenesis and tumor development, attributing to the presence of an activating mutation of the canonical Wnt signaling pathway in about 90% of all CRCs<sup>[2-6]</sup>. Activation of the Wnt signaling pathway is characterized by the accumulation of  $\beta$ -catenin in nuclei<sup>[7]</sup>. It was reported that nuclear  $\beta$ -catenin is detectable in colorectal tumors and its amount is increased from early adenomas to adenocarcinomas<sup>[8]</sup>. However, the distribution of  $\beta$ -catenin within an individual tumor is very heterogeneous. Immunohistochemical analysis of moderately- and well-differentiated colon adenocarcinomas reveals that accumulation of nuclear  $\beta$ -catenin is observed in dedifferentiated tumor cells at the invasive front and scattered in the adjacent stromal compartment. Contrarily, in central differentiated area, it is detectable on the membrane and its translocation is not found<sup>[9,10]</sup>. Consequently, there is considerable interest in finding the means to explain such dynamic changes. Recent researches highlight the role of tumor microenvironment in cancer dissemination where cells located at the invasive front are exposed to cytokines, such as growth factors, chemokines, inflammatory factors, and extracellular matrix, which may interact with the Wnt signaling pathway resulting in the heterogeneous intracellular distribution of  $\beta$ -catenin<sup>[11-13]</sup>. Therefore, this review will concentrate on the relationship between microenvironment and Wnt pathway in invasion and metastasis of CRC.

## WNT PATHWAY IN CRC

The Wnt signaling pathway is involved in various differentiation events both in embryogenesis and in tumor formation when aberrantly activated. Molecular studies demonstrated that constitutive activation of Wnt/ $\beta$ -catenin signaling occurs in nearly all colorectal tumors due to mutations either in *APC* gene or in less frequently  $\beta$ -catenin<sup>[14,15]</sup>. Therefore, understanding the role of this pathway in CRC carcinogenesis is important.

In the absence of Wnt signaling, intracellular  $\beta$ -catenin levels are regulated by multiprotein complex encompass-

Modified from Fodde and Brabletz, *Curr Opin Cell Biol*, 19, 152, (2007)

**Figure 1** Schematic illustration of the canonical Wnt/ $\beta$ -catenin signaling pathway. **A:** In the absence of Wnt ligands, destruction complex phosphorylates  $\beta$ -catenin for ubiquitination and proteolytic degradation; **B:** In the presence of Wnt ligands, formation of destruction complex is not accomplished, resulting in nuclear translocation of  $\beta$ -catenin.

ing the adenomatous polyposis coli (APC) protein, axin, and glycogen synthase kinase 3 $\beta$  (GSK3 $\beta$ ). The complex phosphorylates  $\beta$ -catenin making it for subsequent ubiquitination and degradation (Figure 1A). In the stimulated cells, Wnt ligands bind to one of the Wnt receptors, co-activating low-density lipoprotein receptor-related proteins (LRP). Binding of Wnts leads to phosphorylation of the cytoplasmic protein Dishevelled (Dsh) and consequently Dsh binds to axin resulting in dissociation of the complex and stabilization of  $\beta$ -catenin (Figure 1B). Intracellular  $\beta$ -catenin accumulation results in its nuclear translocation, nevertheless the molecular mechanism is still unclear. In nuclei,  $\beta$ -catenin works as a cofactor for transcription factors of the T-cell factor/lymphoid enhancing factor (TCF/LEF), modulating the expression of a broad spectrum of target genes (Table 1), which affects stemness, proliferation and differentiation.

In 85% familial and sporadic CRCs, the APC gene mutations lead to loss of  $\beta$ -catenin degradation of the complex function and intracellular  $\beta$ -catenin accumulation and translocation, which is the mark of active Wnt signaling<sup>[4]</sup>. Accordingly, constitutive activation of this Wnt- $\beta$ -catenin-TCF pathway, also called canonical Wnt pathway, is blamed for carcinogenesis in CRC.

The non-canonical Wnt pathway independent of  $\beta$ -catenin includes the planar-cell-polarity (PCP)-like pathway that guides cell movements during gastrulation<sup>[14]</sup> and the Wnt/Ca<sup>2+</sup> pathway<sup>[4]</sup>. Up to now, how these pathways are involved in tumorigenesis or cancer progression is still unknown. However, there is evidence that Wnts acting through the non-canonical pathway can promote tumor progression<sup>[16-19]</sup>. Experiments have been carried out by co-culture of breast tumor cells with macrophages, revealing that a canonical pathway in tumor cells is a necessary

**Table 1**  $\beta$ -catenin target genes related to cancer

Function	Target gene
Cell proliferation	C-myc; Cyclin D1
Inhibition of apoptosis	MDR1/PGP; COX-2; PPAR $\delta$
Tumor progression	MMPs; uPAR, Upa; CD44; Laminin $\gamma$ 2; Nr-CAM
Growth factors	c-met; VEGF; WISP-1; BMP-4

Negative feedback targets	Conductin; Tcf-1; Nkd

prerequisite. However, non-canonical pathway *via* Wnt5a is critical for macrophage-induced invasiveness<sup>[19]</sup>.

## $\beta$ -CATENIN IN CRC PROGRESSION

The capability of invasion and metastasis is the hallmark of malignant tumors. The progression of tumor cellular dissemination leading to invasive growth includes the detachment from primary cancer, migration, access to blood or lymphatic vessels and development of secondary tumors. Cellular dissemination is characterized by disordered cell-cell interactions and cell adhesion. Disintegration of cell adhesion molecules, especially  $\beta$ -catenin, has been implicated in this process. However, only  $\beta$ -catenin in the membranes, a stable subcellular localization, forms an adherent complex with  $\alpha$ -catenin and E-cadherin which is regulated by tyrosine phosphorylation. Phosphorylated  $\beta$ -catenin is dissociated from the adherent complex and transferred to the cytoplasm, where  $\beta$ -catenin can be degraded or translocated into nuclei, triggering dysregulation of Wnt pathway. Importantly, cooperative effects on tumor development of defects in E-cadherin-mediated cell adhesion and activation of  $\beta$ -catenin-mediated signal transduction are observed in human CRC<sup>[20]</sup>. Moreover, a tissue microarray-based analysis of a large number of cases, performed by Lugli *et al*<sup>[21]</sup> demonstrated that increased nuclear  $\beta$ -catenin expression and loss of membranous E-cadherin are two independent, adverse prognostic factors in sporadic CRC, suggesting that the role of  $\beta$ -catenin in tumor invasion and metastasis is not just attributed to interaction with E-cadherin, therefore other mechanisms may be involved, such as Wnt/ $\beta$ -catenin signaling pathway.

Furthermore, as the downstream effector of canonical Wnt pathway, nuclear  $\beta$ -catenin cooperating with TCF/LEF initiates expression of target genes (Table 1), some of which can improve tumor progression. MMP-7, a target of  $\beta$ -catenin/TCF signaling, is expressed in up to 90% of CRCs and its expression in the invasive front as well as in urokinase plasminogen activator (uPA) and urokinase plasminogen activator receptor (uPAR) is related to unfavorable outcome in CRC<sup>[22,23]</sup>. Fascin, a novel target of  $\beta$ -catenin/TCF signaling, is expressed at the invasive front of human colon cancer, suggesting that it plays a potential role in the development of colon cancer metastasis<sup>[24]</sup>. It was reported that intratumorous heterogeneity in CRC correlates with differential expression of 510 genes between the central tumor region and the invasive front, isolated by laser-microdissection in the same tumor samples<sup>[24]</sup>. This *in vivo* analysis shows over-expression of known Wnt/ $\beta$ -catenin target genes either in the entire

tumor tissue or specifically at the invasive front. Whether these target genes expressed at the front are involved in the tumor invasive process still needs to be further studied. Furthermore, the concomitant high expression in 2 groups of Wnt/ $\beta$ -catenin target genes, inflammation- and tissue repair-related genes, at the invasive front supports the hypothesis that inflammation-activated microenvironment may trigger selective Wnt/ $\beta$ -catenin target gene expression and contribute to the progression of CRC<sup>[25]</sup>. Accordingly, similar in tumor initiation, Wnt pathway activation (detectable by nuclear accumulation of  $\beta$ -catenin and expression of some target genes) might be functionally associated with cancer dissemination.

In modestly- and well-differentiated tumor, membranous expression of  $\beta$ -catenin in tumor center retains whereas nuclear  $\beta$ -catenin is observed in dedifferentiated tumor cells localized in the invasive area<sup>[10]</sup>. Since tumor cells in an individual tumor harbor APC mutations, this alteration alone cannot lead to the heterogeneous distribution of  $\beta$ -catenin, but its translocation has to be explained by additional events<sup>[26]</sup>. Whether nuclear  $\beta$ -catenin accumulation is the sign of motility enhancement of tumor cells and what initiates  $\beta$ -catenin heterogeneous distribution, are two questions arising from these observations.

## EPITHELIAL-MESENCHYMAL TRANSITION IN CRC DEVELOPMENT

In the majority of sporadic CRCs, well-, modestly-, and well-differentiated adenocarcinomas, tumor cells at the invasive front lose their epithelial characteristics and take on the properties that are typical of mesenchymal cells, which require complex changes in cell architecture and behavior. Such transition from epithelial- to mesenchymal- cells, dubbed as epithelial-mesenchymal transition (EMT), is considered a fundamental event in the metastatic cascade. The essential features of it are the disruption of intercellular contacts and the enhancement of cell motility, thereby leading to release of cells from the parent epithelial tissue. The resulting phenotype is suitable for migration and, thus, for tumor invasion and dissemination, allowing metastasis progression to proceed. Although the molecular bases of EMT have not been completely elucidated, several interconnected transduction pathways and a number of potentially involved signaling molecules, including  $\beta$ -catenin, have been identified<sup>[27,28]</sup>.

Activated  $\beta$ -catenin is directly linked to EMT. The activation of Wnt signal pathway results in the activation of  $\beta$ -catenin/TCF transcriptional regulators such as snail<sup>[29,30]</sup> and slug<sup>[31]</sup>, which regulate the changes in gene-expression patterns underlying EMT. Similarly, in the study of breast cancer cells, Yook *et al* demonstrated that canonical Wnt pathway engages tumor cell dedifferentiation and tissue-invasive ability through an axin-2-dependent pathway to identify a new mechanistic  $\beta$ -catenin-TCF-regulated axin2-GSK3 $\beta$ -Snail1 axis, thus gaining insight into cancer-associated EMT program<sup>[32]</sup>. It was reported that Wnt/ $\beta$ -catenin signaling pathway plays a pivotal role either in gastric cancer formation or in tumor invasion and dissemination<sup>[33]</sup>. In cell culture experiments, cells with  $\beta$ -catenin activation

lose their polarity and disrupt cell-cell contacts and EMT morphologically<sup>[34,35]</sup>. Moreover, immunohistochemical stains demonstrate alternations of the actin cytoskeleton in these cells, indicating that nuclear  $\beta$ -catenin accumulation is functionally related to EMT in budding tumor cells at the tumor-host interface.

## MICROENVIRONMENTAL REGULATION IN $\beta$ -CATENIN TRANSLOCATION AND EMT INDUCTION

The dynamic changes in the above non-random distribution of  $\beta$ -catenin and EMT of tumor cells at the invasive front of CRC, can be at least partially explained by interactions with the tumor environment. A micro-ecosystem exists at the invasive front of tumor where the stromal cells interact with parenchymal cells by producing extracellular matrix and secreting cytokines that directly or indirectly promote cell invasion<sup>[14,36]</sup>. Moreover, it also appears that inflammatory cells are involved in the formation of tumor metastasis<sup>[25,37]</sup>.

Epithelial-mesenchymal interactions are essential for intestinal development. Thus, more investigations should be focused on mesenchymal factors, particularly the components of extracellular matrix, because they have a potent regulatory effect on tumor cells. Recent studies demonstrated that Wnt ligands are expressed in both mesenchymal and epithelial cells of the colon<sup>[38]</sup>. It was also reported that local regulation by Wnt signals of diverse cell signaling pathways in fibroblasts could have multifaceted consequences for tissue microenvironments *in vivo*, including the balance between cell differentiation and proliferation, as well as between cell migration and adhesion<sup>[36]</sup>. Mesenchymal forkhead transcription factors, *Foxf1* and *Foxf2*, can limit paracrine Wnt signaling and promote extracellular matrix production in gut, and deletion of *Foxf1* and *Foxf2* is accompanied with increased mesenchymal expression of Wnt5a and  $\beta$ -catenin nuclear accumulation in epithelial cells, indicating that there is a crosstalk between stromal cells and parenchymal cells involving Wnt signaling<sup>[39]</sup>. There are extensive data to support the relation between extracellular matrix and signal pathway in tumorigenesis. Tsuboi K *et al*<sup>[40]</sup> investigated the relationship of galectin-3 expression, a component of extracellular matrix, to the clinicopathological factors, and found that reduced galectin-3 expression is related to invasion and metastasis of CRC. In contrast to  $\beta$ -catenin, the expression of galectin-3 is lower at the invasive front of a tumor. Whether  $\beta$ -catenin regulates galectin-3 expression or other signaling pathways are involved in the process is still controversial.

In addition, cell culture experiments have also revealed a role of cytokines, such as growth factors, in the intracellular  $\beta$ -catenin distribution, as well as in the induction of EMT<sup>[41]</sup>. One of the related growth factors is the hepatocyte growth factor (HGF), which is found in CRC. It was reported that HGFR and  $\beta$ -catenin physically interact in a complex, which is disassembled after HGF treatment<sup>[42]</sup>. Moreover, HGF treatment promotes  $\beta$ -catenin/TCF transcriptional activity in CRC cells. HGF also stimulates

cells leading to cell scattering. Therefore, a self-amplifying positive feedback loop between HGFR and  $\beta$ -catenin in CRC promotes tumor growth and invasion<sup>[42]</sup>. Like HGF, Platelet-derived growth factor (PDGF) also can activate EMT in CRC cells by enhancing Wnt signaling. A recent study has shown a novel Wnt-independent pathway that enhances  $\beta$ -catenin signaling to nuclei<sup>[12]</sup>. PDGF promotes tyrosine phosphorylation of p68, which binds to  $\beta$ -catenin and inhibits its phosphorylation by GSK3 $\beta$ <sup>[12]</sup>. A new EMT pathway from PDGF and another route to nuclear  $\beta$ -catenin signaling have been identified<sup>[43]</sup>. Similarly, the epidermal growth factor (EGF) and transforming growth factor  $\beta$  (TGF $\beta$ ) can also enhance Wnt/ $\beta$ -catenin signaling by phosphorylating p68<sup>[12]</sup>.

It has been widely accepted that inflammatory cells in colorectal tumors are associated with the progression to malignancy. Brown *et al*<sup>[44]</sup> reported that non-steroidal anti-inflammatory drugs (NSAIDs) can decrease the number and size of intestinal polyps in Apc-mutation mice by inhibiting cyclooxygenase-2 (COX-2), one of the main enzymes in prostaglandin biosynthesis. To investigate the mechanism, a recent study by Castellone and collaborators<sup>[37]</sup> indicate that COX-2 and its proinflammatory metabolite prostaglandin E2 (PGE2) enhance colon cancer progression *via* its heterotrimeric guanine nucleotide-binding protein (G protein)-coupled receptor, EP2. This signaling route involves the activation of PI3K and protein kinase A by free G protein and is directly associated with the G protein signaling (RGS) domain of axin, thus leading to GSK3 $\beta$  inactivation, relief of inhibitory phosphorylation of  $\beta$ -catenin and activation of Wnt signaling pathway<sup>[37]</sup>. Therefore, these findings suggest that COX-2 and inflammation can promote the progression of colon cancer. It was recently reported that co-culture of tumor cells and macrophages leads to up-regulation of Wnt5a in the latter and that non-canonical signaling *via* Wnt5a in cancer cells is critical for invasion<sup>[19]</sup>. However, whether a similar interaction between cancer cells and tumor-associated macrophages occurs in CRC is still unknown.

## SUMMARY

Since tumor cells at the invasive front display nuclear accumulation of  $\beta$ -catenin and EMT features associated with local activation of Wnt signaling pathway, dissemination of cancer cells is not due to gene mutation alone. The importance of tumor microenvironment where extracellular matrix, growth factors and inflammatory factors play a key role in tumor invasion cannot be overlooked. A complex network, which is orchestrated by Wnt pathway and other signaling pathways, may be involved in the regulation of tumor-microenvironment crosstalk. Further study is needed to investigate the specific role of tumor cells and the microenvironment of tumor in invasiveness. Although recent researches have illuminated the involvement of Wnt pathway in cancer development, a more comprehensive view of how cancer spreads will likely emerge in the future, allowing us to provide new potential therapeutic targets for the treatment of aggressive and recurrent CRC in clinical practice.

### Abstract

**AIM:** To characterize cytogenetic alterations in esophageal squamous cell carcinoma (ESCC) and its metastasis.

**METHODS:** A total of 37 cases of primary ESCC and 15 pairs of primary ESCC tumors and their matched metastatic lymph nodes cases were enrolled from Linzhou, the high incidence area for ESCC in Henan, northern China. The comparative genomic hybridization (CGH) was applied to determine the chromosomal aberrations on the DNA extracted from the frozen ESCC and metastatic lymph node samples from these patients.

**RESULTS:** CGH showed chromosomal aberrations in all the cases. In 37 cases of primary ESCC, chromosomal profile of DNA copy number was characterized by frequently detected gains at 8q (29/37, 78%), 3q (24/37, 65%), 5p (19/37, 51%); and frequently detected losses at 3p (21/37, 57%), 8p and 9q (14/37, 38%). In 15 pairs of primary ESCC tumors and their matched metastatic lymph node cases, the majority of the chromosomal aberrations in both primary tumor and metastatic lymph node lesions were consistent with the primary ESCC cases, but new candidate regions of interest were also detected. The most significant finding is the gains of chromosome 6p with a minimum high-level amplification region at 6p12-6q12 in 7 metastatic lymph nodes but

only in 2 corresponding primary tumors ( $P = 0.05$ ) and 20p with a minimum high-level amplification region at 20p12 in 11 metastatic lymph nodes but only in 5 corresponding primary tumors ( $P < 0.05$ ). Another interesting finding is the loss of chromosome 10p and 10q in 8 and 7 metastatic lymph nodes but only in 2 corresponding primary tumors ( $P < 0.05$ ).

**CONCLUSION:** Using the CGH technique to detect chromosomal aberrations in both the primary tumor and its metastatic lymph nodes of ESCC, gains of 8q, 3q and 5p and loss of 3p, 8p, 9q and 13q were specifically implicated in ESCC in Linzhou population. Gains of 6p and 20p and loss of 10pq may contribute to the lymph node metastasis of ESCC. These findings suggest that the gains and losses of chromosomal regions may contain ESCC-related oncogenes and tumor suppressor genes and provide important theoretic information for identifying and cloning novel ESCC-related oncogenes and tumor suppressor genes.

### INTRODUCTION

Advances in diagnostic and therapeutic modalities for malignancies have improved the survival of cancer patients. However, the mortality rate of patients with esophageal squamous cell carcinoma (ESCC) is still very high due to its highly invasive nature and potential to metastasize to lymph nodes and distant organs. ESCC is one of the leading causes of cancer-related death

in Linxian, Henan Province in northern China, with a mortality rate of 161/100 000 for male and 103/100 000 for female. Recent studies by us and other authors have indicated multiple genetic alterations underlying the multistage carcinogenesis of ESCC, such as p53-Rb pathway<sup>[1]</sup>. However, the mechanisms of human esophageal multistage carcinogenesis in this area, especially the difference in genetic changes between primary ESCC and lymph node metastasis, are largely unknown.

Comparative genomic hybridization (CGH) analysis can provide comprehensive information about relative chromosomal losses and gains in malignant tumors *in vitro*<sup>[2]</sup>. This technique can detect the changes of recurrent copy number and may highlight chromosomal regions containing genes that contribute to cancer development and/or progression. In this study, we used CGH analysis to examine 37 primary ESCC and 15 pairs of primary ESCC tumors and their corresponding metastatic lymph nodes, to elucidate the genetic pathway of carcinogenesis and to clarify the metastatic mechanisms of genetic aberrations in ESCC.

## MATERIALS AND METHODS

The 37 primary tumor samples and 15 pairs of primary ESCC and their matched lymph node metastasis in this study were all from Linzhou, Henan, the high incidence area for ESCC. The primary specimen for each patient was collected at the time of surgical resection at the Department of Surgery, Yiaochun Hospital and Linzhou Hospital. All the patients underwent esophagectomy without preoperative radiotherapy and/or chemotherapy. Tumor tissue specimens were frozen in liquid nitrogen and kept in a freezer at -80°C until use.

### Microdissection and DNA extraction

Tumor tissue was selected by histopathologic examination on the basis of estimated more than 80% cancer cells. The metastatic lymph nodes were embedded in OTC and cryosected into 15 µm serial slides under -20°C. For DNA extraction, we cut 22 serial 15 µm sections. The first and last ones were used for hematoxylin-eosin (HE) staining, and the remain 20 were lightly stained with hematoxylin. Under microscopic (MZ 12, Leica, Bensheim, Germany) observation, tumor tissues were microdissected manually from surrounding stromal tissues and normal cells with a disposable fine needle, and tissue fragments were collected and transferred into a microtube.

Genomic DNA was extracted from tumor specimens by proteinase K/sodium dodecyl sulfate digestion followed by phenol/chloroform/alcohol extraction. Normal reference DNA was prepared from peripheral blood lymphocytes of healthy donors.

### Slide preparation

Metaphase chromosome spreads were prepared from peripheral blood leukocytes of healthy donors. Blood cells were cultured for 72 h in RPMI1640 containing 15% fetal bovine serum and penicillin-streptomycin (PHA 5 µg/mL). Blood cells were harvested by arresting with Colcemid

(0.05 g/L) for 1h, followed by hypotonic treatment in KCl (0.075 mmol/L) for 20 min on ice and fixation in cold methanol: acetic acid (3:1).

### Comparative genomic hybridization(CGH)

CGH was performed essentially as described previously<sup>[2]</sup>. Briefly, genomic DNA from a tumor sample and a sex-matched normal reference was labeled directly with Spectrum Green-dUTP and SpectrumRed-dUTP (Vysis, Downers Grove, IL, USA) by nick translation. Two hundred nanograms of labeled tumor DNA and normal DNA probes were used in a 10 µL hybridization mixture (containing 55% formamide, 2 × SSC), and 10 µg human CotI DNA, which was denatured at 75°C for 5 min. The slide containing normal metaphase spreads was treated with RNase (100 mg/L) at 37°C for 1 h and then denatured at 75°C in 70% formamide, and 2 × SSC for 5 min. Hybridization with probes was then carried out at 37°C in a moist chamber for 72 h. The slide was then washed in 0.4 × SSC/0.3% NP-40 at 75°C for 2 min and then in 2 × SSC/0.1% NP-40 at room temperature for 2 min. After washing, the slide was counterstained with 1 mg/L DAPI in an antifade solution.

### Digital image analysis

The hybridized metaphase chromosomes were analyzed using a digital image analysis system containing a Zeiss Axiophot microscope equipped with a Metachrome II cool-charged device camera (Photometrics, AZ). Three images of each metaphase were captured using filter wheel-mounted, single band excitation Rhodamine, FITC, and DAPI filters. The image analyses were carried out using Quips CGH Analysis software (Vysis). Five metaphases were analyzed to generate fluorescence ratio profiles in each case. Interpretation of the profiles was performed according to the program guidelines. The thresholds used for interpretation of gains and losses of a DNA sequence copy number was defined as a tumor/reference ratio greater than 1.25 or less than 0.75, respectively, by both the standard and the reverse hybridization methods.

### Statistical analysis

We analyzed the genetic aberrations of ESCC using the Fisher exact test for independence. Differences with a *P* value less than 0.05 were considered statistically significant.

## RESULTS

### CGH analysis

A total of 230 DNA copy number gains and 212 DNA copy number losses were found in 37 ESCC samples, with an average of DNA copy number gains of 6.22 and DNA copy number losses of 5.73 per patient. In ESCC, the gain was most frequently detected on chromosome arms 8q (29/37, 78%), 3q (24/37, 65%) and 5p (19/37, 51%), (the chromosomal aberrant frequency on chromosome 6q, 7p and 7q was similar, all 38%), which was followed by (from high to low) 18p (12/37, 32%), 1q (11/37, 30%), 11q (10/37, 27%), 20q (10/37, 27%), 12p (9/37, 24%), 13q (6/37, 16%) and 18q (6/37, 16%). There were 20 cases

with high copy number amplifications (tumor/reference ratio > 1.5), which were located on chromosome 1pter-1p31, 1p11-1q22, 3q22-qter, 4p13-4q31, 5p, 6p12-6q14, 8q, 9p, 11q12-11q23, 11q13-11q23, 16p11-16q21, 18pter-18q12, 18p and 20p. The chromosomal profile of DNA copy number losses was characterized as follows: the most frequently detected loss was on 3p (21/37, 57%), which was followed in turn (from high to low) by 8p (14/37, 38%), 9q (14/37, 38%), 11q (13/37, 35%), 13q (13/37, 35%), 5q (12/37, 32%), 1p (12/37, 32%), 4p (11/37, 30%), 18q (11/37, 30%), 16q (10/37, 27%), 17p (10/37, 27%) and 19p (10/37, 27%). A summary of genetic aberrations detected by CGH in ESCC is provided in Table 1 and Figure 1.

#### Differences in copy number alterations between 15 pairs of primary ESCC and their matched lymph node metastasis

A total of 102 gains and 90 losses were found in 15 primary ESCC samples, with an average of gains and losses per patient of 6.8 and 6.0, respectively, and 110 gains and 142 losses were found in 15 lymph nodes metastasis samples, with an average of gains and losses per patient

of 7.4 and 9.5. More genetic changes (252) were found in lymph nodes metastasis than in the corresponding primary lesions (192), especially the losses (9.5/case *vs* 6.0/case). The copy-number changes for the entire genome detected in these 15 primary ESCC and their corresponding metastatic lesions are summarized in Table 2 and Figure 2. In primary tumors, the most frequently detected sites of chromosome gain were 3q (15 of 15, 100%), 8q (11 of 15, 73%), 1q (11 of 15, 73%), 12p (8 of 15, 53%), 18p (6 of 15, 40%), 5p (7 of 15, 47%), 6p (7 of 15, 47%), 20p (11 of 15, 73%). In metastatic lymph nodes, the most frequently detected sites of chromosome gain were 3q (14 of 15, 93%), 8q (10 of 15, 67%), 1q (11 of 15, 73%), 12p (8 of 15, 53%), 18p (6 of 15, 40%), 5p (7 of 15, 47%), 6p (7 of 15, 47%), 20p (11 of 15, 73%). High copy-number amplification with a minimum gain 3q24-qter was detected in two primary tumors and six metastatic lymph nodes. The other three high copy-number amplifications of 6p21-6q12 were detected only in metastatic lymph nodes but not in their corresponding primary tumors. The high copy-number amplification of 20p was detected in metastatic lymph node lesions but not in their corresponding primary tumor. In primary tumors, the chromosomal profile of

**Figure 1** Copy number alterations of 37 ESCC cases analyzed by CGH. Chromosomal regions of gain are on the right side of the chromosome ideograms, and regions of loss are on the left side.

DNA copy number losses were 3p (10 of 15, 67%), 10p (2 of 15, 13%), 10q (2 of 15, 13%), 4q (6 of 15, 40%), 4p (7 of 15, 47%), 19p (8 of 15, 53%), 13q (4 of 15), 1p (7 of 15), 17p and 18q (4 of 15, 27%). In metastatic lymph nodes, the chromosomal profiles of DNA copy number losses were 3p (12 of 15, 80%), 10p (8 of 15, 53%), 10q (7 of 15, 47%), 4q (10 of 15, 67%), 4p (9 of 15, 60%), 19p (10 of 15, 67%), 13q (8 of 15, 53%), 1p (7 of 15, 47%), 17p and 18q (7 of 15, 47%).

Statistically, in DNA copy number gains on chromosome 6p and 20p, there were significant differences between primary ESCC lesions and their corresponding lymph nodes ( $P < 0.05$ ). In DNA copy number losses on chromosome 10pq, differences were significant between primary ESCC lesions and their corresponding lymph nodes ( $P < 0.05$ ), (Table 3).

## DISCUSSION

We have identified a genome-wide map of genetic alterations in ESCC, and compared primary tumor and metastatic lymph nodes in this study. The majority of the

chromosomal aberrations in both primary tumor and metastatic lymph node lesions were consistent with the previous reports. For example, the gains of 3q, 5p, 8q23-ter and 20q and deletions of 3p25, 4p, 6q21, 9q22.3-q31, 9p, 11q22-qter, 13q12-13, 18q22.3, and 19q had been detected as frequent chromosomal alterations in ESCC in at least one of the previous CGH studies<sup>[3-6]</sup>. By comparing the primary ESCC with metastatic lymph nodes, we did detect new candidate regions of interest, such as 6p, 20p and 10pq, which may harbor the genes involved in lymph node metastasis.

The highest frequency of DNA gain in ESCC occurred at chromosome 8q (78%), the chromosomal region at 8q harbors MYC gene (8q24.1) which has been identified with a high frequency of amplification in ESCC<sup>[7,8]</sup>. Gains of 3q were commonly seen in ESCC<sup>[9]</sup>. Possible candidate genes involved in tumor development include the genes for ribosomal protein L22 (RPL22), butyrylcholinesterase (BCHE), glucose transporter 2 (SLC2A2), transferring receptor (TFRC), thrombopoietin (THPO) and the phosphatidylinositol-3 kinase catalytic  $\alpha$ -polypeptide (PIK3CA). Deletion of 9p and gain of 5p were seen

commonly in CGH studies of patients with ESCC<sup>[3-5,9]</sup> and both are related to the progression of ESCC<sup>[10,11]</sup>. hTERT on 5p is associated with the prognosis of patients with carcinomas of the breast, lung and ESCC as reported previously<sup>[10,12,13]</sup>. One of the potential candidate genes in the region includes JS-1 and JK-1<sup>[13]</sup>.

Deletion of chromosome 3p is one of the most frequent allelic imbalances in ESCC detected by CGH<sup>[3,4]</sup>. In our study, loss of 3p was detected in 65% in ESCC. Possible candidate tumor suppressor genes on these region were FHIT (fragile histidine triad)<sup>[15]</sup>, catenin (CTNNB1)<sup>[16]</sup>, and von Hippel-landau gene<sup>[17]</sup>. Our results of proximal 3p loss mainly in ESSC may indicate a specific tumor suppressor gene at this locus involved in ESSC in high-risk areas. Loss of 8p was found in 38% of ESCC cases. Deletion of 8p22-pter has been reported in patients with ESCC<sup>[5]</sup>. Mutations of the Fasciculation and elongation protein zeta-1 (FEZ1) gene at 8p22 were found in patients with ESCC<sup>[18]</sup>, and mutations of two other genes in these regions, tumor necrosis factor-

related apoptosis-inducing ligand receptor 1 (TRAIL-R1) and receptor 2 (TRAIL-R2), were found in patients with metastatic breast carcinoma<sup>[19]</sup>. Loss of 17p was detected in 37% of ESCC. One potentially relevant gene at 17p is TP53, whose product contributes to the control of cell proliferation and malignant transformation. Inactivation of TP53 is the most common defect found in human cancer including ESCC from Henan, China. Loss of 1p occurred in 32%. The minimal common region of deletion encompasses the most distal band 1p36-pter in ESCC. Loss of chromosome band 1p36 is frequently found in many malignancies, including gastric cardia carcinoma, colon cancer, and ESCC<sup>[20]</sup>.

In 15 pairs of ESCC and their corresponding metastatic lymph nodes, the most interesting finding in this study is the gain of 6p12-6q21 detected in seven metastatic lymph node lesions but only in two corresponding primary tumors (13% vs 47%;  $P = 0.05$ ). This suggests that 6p may harbor a putative oncogene that plays an important role in the ESCC progression, especially in the lymph

**Figure 2** Copy number gains and losses in ESCC by CGH. Chromosomal localization of gains is on the right side of chromosome ideograms and that of losses are on the left side. Thick lines indicate amplified regions. Straight lines indicate lymph nodes metastasis. Conversely primary tumors are indicated by dotted lines.

node metastasis. One study shows that regions 6p12-q14 harbor the *CCND3* gene, which shares 53.1% homology to *CCND1*. The *CCND1* gene is amplified in 30% of ESCC<sup>[21]</sup>. Regions of 6p12 are found to harbor runt-related transcription factor (*RUNX*) gene, which is associated with cell migration and invasion<sup>[22]</sup>. The gain of 6p is frequently detected in CGH studies in other tumors including uveal melanoma and Barrett's adenocarcinoma<sup>[23,24]</sup>. Most interestingly, in three cases, the high-level amplification of 6p12 was detected only in metastatic tumors. This implies that the overexpression of an oncogene(s) at 6p12 confers a selective advantage in ESCC. Moreover, this finding provides a candidate minimum amplification region at 6p12 for further studies and gene cloning. Another interesting finding in this study is the gain of 20p that was detected in 11 metastatic lymph node lesions but only in five corresponding primary tumors. The difference is significant in 20p gain between primary tumors and their metastatic lymph node lesions of ESCC (40% *vs* 73%,  $P = 0.03$ ). This suggests that 20p may harbor an oncogene and play an important part in ESCC progression especially in lymph node metastasis. Little is known about the relationship between 20p and the lymph node metastasis

**Table 3** Chromosomal aberrations with primary ESCC and lymph node metastasis

Chromosomal changes	Primary tumor (%)	Lymph node metastasis %	<i>P</i> value
Gain of 6p	2/15 (13)	7/15 (47)	0.05
Gain of 20p	5/15 (40)	11/15 (73)	0.03
Loss of 10p	2/15 (13)	8/15 (53)	0.05
Loss of 10q	2/15 (13)	7/15 (47)	0.05

of ESCC. Heselmeyer *et al* demonstrated that gains of 6p and 20p were connected with advanced-stage cervical carcinomas<sup>[25]</sup>. Hu *et al* demonstrated the over-expression of *CDC25B* gene in ESCC<sup>[26]</sup>. Possible candidate gene on 20p includes *CDC25B* and proliferating cell nuclear antigen (PCNA), each of which plays an important role at specific stages of cell cycle progression.

Loss of 10p was seen in eight metastatic lymph nodes but only in two corresponding primary tumors. The difference between primary tumors and their metastatic lymph node lesions of ESCC was significant (13% *vs* 53%  $P = 0.05$ ). Loss of 10q was detected in seven metastatic lymph nodes but only in two corresponding primary

tumors. The difference between primary tumors and their metastatic lymph node lesions of ESCC was significant (13% vs 47%  $P = 0.05$ ). These alterations had also been found in other carcinoma metastases, such as the head-neck squamous cell carcinoma (HNSCC)<sup>[27]</sup> and Spitzoid malignant melanoma<sup>[28]</sup>. A role of the 10q deletion in tumor progression is however conceivable since additional germline mutations in the PTEN gene (on chromosome 10q23) have been shown to be present in Crowden's disease<sup>[29]</sup>.

In this study, more genetic changes were found in lymph node metastasis than in their corresponding primary lesions, especially the losses (9.5/case vs 6.0/case). Previous studies showed that DNA copy number losses were more common in the metastases than in the primary larynx tumors and HNSCC<sup>[30,31]</sup>. In ESCC, DNA losses seem to be more closely associated with metastases than DNA amplification.

In conclusion, using the CGH technique to detect chromosomal aberrations in both the primary tumor and its metastatic lymph nodes of ESCC, gains of 8q, 3q, 5p and losses of 3p, 8p, 9q and 13q were specifically implicated in ESCC in Linzhou population. Furthermore, gains of 6p, 20p and loss of 10pq may contribute to the lymph metastasis of ESCC. These findings suggest that the gains and losses of chromosomal regions may contain ESCC-related oncogenes and tumor suppressor genes. The gains and losses of chromosomal regions identified in this study provide important theoretic information for identifying and cloning novel ESCC-related oncogenes and tumor suppressor genes. Finally, this study provides a practicable model to detect specific genetic change related to tumor metastasis by comparing the primary tumor with its corresponding metastatic tumor using the CGH technique.

## COMMENTS

### Background

Esophageal squamous cell carcinoma (ESCC) is one of the leading causes of cancer-related death in Linxian, Henan Province in northern China, with a mortality rate of 161/100000 for male and 103/100000 for female. However, the mechanisms of human esophageal multistage carcinogenesis in this area, especially the difference in genetic changes between primary ESCC and metastatic lymph nodes are largely unknown.

### Research frontiers

In this study, the authors applied comparative genomic hybridization (CGH) to ESCC to elucidate genetic aberrations in carcinogenesis and lymph node metastasis. To the knowledge of the authors, though CGH analysis of ESCC has been reported, no information is available concerning the relationship between genetic changes and the biologic characteristics of ESCC. The gains of 3q, 5p, 8q23-ter and 20q and deletions of 3p25, 4p, 6q21, 9q22.3-q31, 9p, 11q22-qter, 13q12-13, 18q22.3, and 19q had been detected as most frequent chromosomal alterations in ESCC. Our CGH results are generally consistent with other CGH studies.

### Innovations and breakthroughs

The present CGH study provides the first record of chromosomal imbalances occurring in ESCC tumors and corresponding lymph nodes in Linxian, Henan Province in northern China. The major findings of this paper are that gains of 8q, 3q, 5p and losses of 3p, 8p, 9q and 13q were specifically implicated in ESCC in Linzhou population, and gains of 6p, 20p and loss of 10pq may contribute to the lymph metastasis of ESCC. These loci may harbor the genes in the development and/or progression of ESCC.

### Applications

These loci provide important theoretic information for identifying and cloning novel ESCC-related oncogenes and tumor suppressor genes. Further studies are necessary to identify specific genes of these chromosomal regions and their functions. The target tumor susceptibility genes will be further characterized by mutation analysis. Single strand conformation polymorphism (SSCP) and sequencing analysis will be used to screen the mutation.

### Terminology

Comparative genomic hybridization (CGH); Single strand conformation polymorphism (SSCP).

### Peer review

This is a nicely written and presented paper with 37 cases of primary esophageal cancer and matched metastatic tissues. Although the number of studied cases is small, it is a useful contribution to the literature.

Effects of two novel nucleoside analogues on different hepatitis B virus promoters. *World J Gastroenterol* 2008; 14(12): 1836-1841 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1836.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1836>

### Abstract

**AIM:** To explore the effects of the nucleoside analogues  $\beta$ -L-D4A and  $\beta$ -LPA on hepatitis B virus (HBV) promoters.

**METHODS:** Four HBV promoters were amplified by polymerase chain reaction (PCR) and subcloned into the expression vector pEGFP-1. The four recombinants controlled by HBV promoters were confirmed by restriction analysis and sequencing. Human hepatoma HepG2 cells transfected with the recombinant plasmids were treated with various concentrations of  $\beta$ -L-D4A and  $\beta$ -LPA. Then, enhanced green fluorescent protein (EGFP)-positive cells were detected by fluorescence microscopy and using a fluorescence activated cell sorter (FACS).

**RESULTS:** Four HBV promoters were separately obtained and successfully cloned into pEGFP-1. Expression of EGFP under the control of the surface promoter (Sp) and the X promoter (Xp) was inhibited by  $\beta$ -L-D4A in a dose-dependent manner, while expression of EGFP under the control of the core promoter (Cp) and Xp was inhibited by  $\beta$ -LPA in a dose-dependent manner.

**CONCLUSION:** The two novel nucleoside analogues investigated here can inhibit the activities of HBV promoters in a dose-dependent manner. These findings may explain the mechanisms of action by which these two novel compounds inhibit HBV DNA replication.

### INTRODUCTION

Hepatitis B virus (HBV) is the leading cause of chronic hepatitis in the world<sup>[1]</sup>. According to the World Health Organization, over 350-million people (5% of the world population) are chronically infected with HBV. Although safe and effective vaccination for HBV is available in developing countries<sup>[2-4]</sup>, there is still no effective treatment for the millions of chronically infected individuals<sup>[5]</sup>. Consequently, long-term infection with chronic HBV could lead to cirrhosis and hepatocellular carcinoma<sup>[6,7]</sup>. In light of these facts, it is evident the discovery and development of novel antiviral agents for the treatment of HBV is an extremely important undertaking.

The number of formally approved anti-HBV drugs is limited. The necessity for new compounds acting on a variety of molecular targets within the viral replicative cycle is crucial. Thus, it remains important to discover new antiviral drugs, and to investigate new potential targets such as uncoating, transcription, packaging, excretion, or synthesis of cccDNA<sup>[8,9]</sup>.

In our previous work<sup>[10-13]</sup>, we synthesized two novel nucleoside analogues,  $\beta$ -L-D4A and  $\beta$ -LPA (Figure 1), and studied their inhibitory actions against HBV as well as their cytotoxicities.  $\beta$ -L-D4A and  $\beta$ -LPA possess potent inhibitory effects on the replication of HBV ( $EC_{50} = 0.2$  and  $0.01 \mu\text{mol/L}$ , respectively) with little cytotoxicity ( $IC_{50} = 200$  and  $50 \mu\text{mol/L}$ , respectively) or mitochondrial toxicity. Their TI values are 1000 and 5000, respectively. Therefore, they are expected to be developed as new clinical anti-HBV drugs. Our previous work also showed these two compounds possessed significant anti-HBV effects at the transcription level by inhibiting the

production of HBV RNA. Therefore, we supposed the two compounds might act by inhibiting the activities of HBV promoters.

Complementary DNA for the *Aequorea victoria* green fluorescent protein (GFP) produces a fluorescent product when expressed in prokaryotic or eukaryotic cells. Because exogenous substrates and cofactors are not required for this fluorescence, GFP expression can be used to monitor gene expression and protein localization in living organisms<sup>[14-16]</sup>. pEGFP-1 is a promoterless EGFP vector, which can be used to monitor transcription from different promoters and promoter/enhancer combinations inserted into the Multiple Cloning Site located upstream of the EGFP coding sequence<sup>[17,18]</sup>. Hence, we chose pEGFP-1 as an expression vector to monitor the activities of HBV promoters. In this study, we explored the effects of our two novel nucleoside analogues on HBV promoters to uncover the mechanism underlying their anti-HBV effects.

## MATERIALS AND METHODS

### Materials

$\beta$ -L-D4A and  $\beta$ -LPA were synthesized by ourselves with the help of the Pharmaceutic College of Wuhan University, and identified by infrared, mass spectra, and nuclear-magnetic resonance. Lamivudine was provided by Professor Cheng YC (School of Medicine, Yale University, New Haven, CT, USA). These compounds were dissolved in phosphate-buffered saline (PBS). The expression vector pEGFP-1 was purchased from BD ClonTech. Plasmid p3.6II was a kind gift from Prof. Wang Yuan (Institute of Biochemistry and Cell Biology, Shanghai Institute for Biological Sciences, Chinese Academy of Sciences). *E. coli* (Dh5 $\alpha$ ) and human hepatoma HepG2 cells were preserved by our institute. Fetal bovine serum (FBS) and Dulbecco's modified Eagle's medium (DMEM) were purchased from Hyclone Corp. All other reagents used were of analytical grade.

### Polymerase chain reaction (PCR)

The desired four fragments were HBV preS gene promoter (preSp), Sp, Cp (including enhancer II) and Xp (including enhancer I)<sup>[19-23]</sup>. PCR was employed to amplify the four fragments from p3.6II, a plasmid containing the HBV complete genome (adr subtype). Specific primers were designed by us and synthesized at Sangong Company (Shanghai, China). The primers used are listed in Table 1. The lower-case nucleotides indicate the recognition sites for restriction endonucleases Acc65 I and Age I (Fermentas, USA). PCR products were separated by agarose gel electrophoresis. Fragments of interest were withdrawn and directly ligated into pGEM-T vector (Promega, USA). Positive clones were then screened by virtue of a blue/white screening system and sequenced after small-scale extraction. The four positive plasmids were cleaved by Acc65 I and Age I, and fragments containing the HBV promoters were purified.

### Construction of EGFP expression vectors controlled by HBV promoters

The expression vector pEGFP-1 was digested by Acc65 I

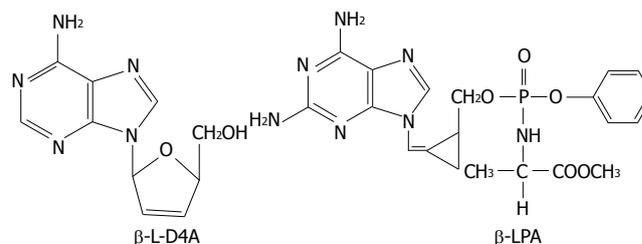

Figure 1 Structures of  $\beta$ -L-D4A and  $\beta$ -LPA.

	R5'-ACGTAAACAccggtCGTCCCGCGC-3'	

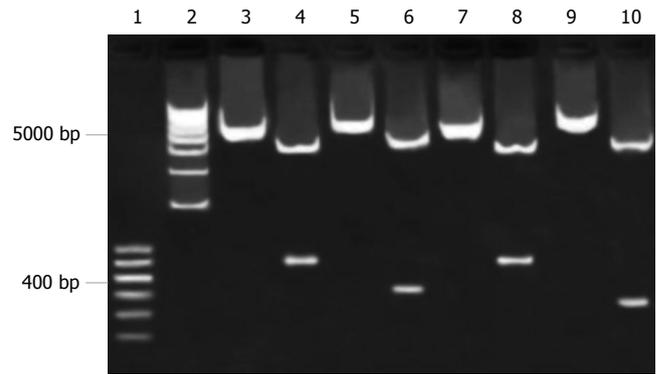

and Age I and vector fragments were collected. Then, the fragments containing HBV promoters were mixed with vector fragments at a ratio of 5 to 1, and these fragments were ligated using T4 DNA ligase (Promega, USA) at 16°C overnight. The ligated products were used to transform *E. coli* (Dh5 $\alpha$ ). Plasmids extracted from *E. coli* were analyzed by restriction enzymes and sequencing, and finally, the four promoter-controlled EGFP expression vectors pEGFP-Sp, pEGFP-preSp, pEGFP-Cp and pEGFP-Xp were produced.

### Expression assays

HepG2 cells were incubated in DMEM medium with 10% (vol/vol) FBS at 37°C in a moist atmosphere containing 5% CO<sub>2</sub>/95% air. The cells were inoculated at a density of  $3 \times 10^5$ /mL per well in 24-well tissue culture plates. Twenty-four hours after plating, the four expression vectors were transfected into HepG2 cells (1  $\mu$ g DNA per well) on different plates using Lipofectamine2000 (Invitrogen), according to manufacturer's instructions (one well was left as a negative control group, which was needed as reference for FACS). After a 6 h incubation, the transfected cells were treated with various concentrations of  $\beta$ -L-D4A (0.08  $\mu$ mol/L in 4 wells, 0.4  $\mu$ mol/L in 4 wells, 2  $\mu$ mol/L in 4 wells, 10  $\mu$ mol/L in 4 wells). Four wells of cells were treated with lamivudine at 1  $\mu$ mol/L as a comparative group, and 3 wells were not treated with any drug as a positive control group (that is, a blank control). The cells were grown in the presence of drugs for 42 h. EGFP-positive cells were detected using an inverted fluorescence microscope (ZEISS, Axiovert40) with an excitation wavelength of 488 nm. Then, all cells were digested with 0.25% trypsin; digestion was terminated by FBS and the cells were re-suspended in 500  $\mu$ L of PBS per well before being subjected to flow cytometry (Becton Dickinson) analysis. The same experiments were performed with  $\beta$ -LPA.

**Figure 2** The HBV promoters obtained from PCR were separated by agarose gel electrophoresis. Lane 1: Marker; Lane 2: preSp; Lane 3: Sp; Lane 4: Cp; Lane 5: Xp.

**Figure 3** Restriction analysis of recombinant vectors. Lanes 1, 2: Marker; Lanes 3, 4: pEGFP-Sp before and after being digested by Acc65 I and Age I; Lanes 5, 6: pEGFP-Cp before and after being digested by Acc65 I and Age I; Lanes 7, 8: pEGFP-Xp before and after being digested by Acc65 I and Age I; Lanes 9, 10: pEGFP-preSp before and after being digested by Acc65 I and Age I.

### Statistical analysis

Data are expressed as mean  $\pm$  SD. Each experiment was repeated at least three times. Differences were considered statistically significant when  $P < 0.05$ , as analyzed by one way analysis of variance and Tukey's post-hoc test. The analysis was conducted using the SPSS12.0.

## RESULTS

### Validation of cloning

After ligation of promoter fragments into pGEM-T vector, PCR products (Figure 2) were sequenced by Bioasia (Shanghai, China). Using BLAST searches of Entrez (NCBI), the sequencing results were proved to be consistent with the template (p3.6 II). The four recombinants pEGFP-Sp, pEGFP-preSp, pEGFP-Cp and pEGFP-Xp were identified by restriction enzymes (Figure 3).

### Detection of EGFP-positive cells

EGFP-positive cells could be seen by fluorescence microscopy among HepG2 cells transfected with pEGFP-Sp, pEGFP-Cp and pEGFP-Xp, but few could be seen among HepG2 cells transfected with pEGFP-preSp (Figure 4). These findings suggested HBV promoters could control the expression of EGFP.

### FACS analysis

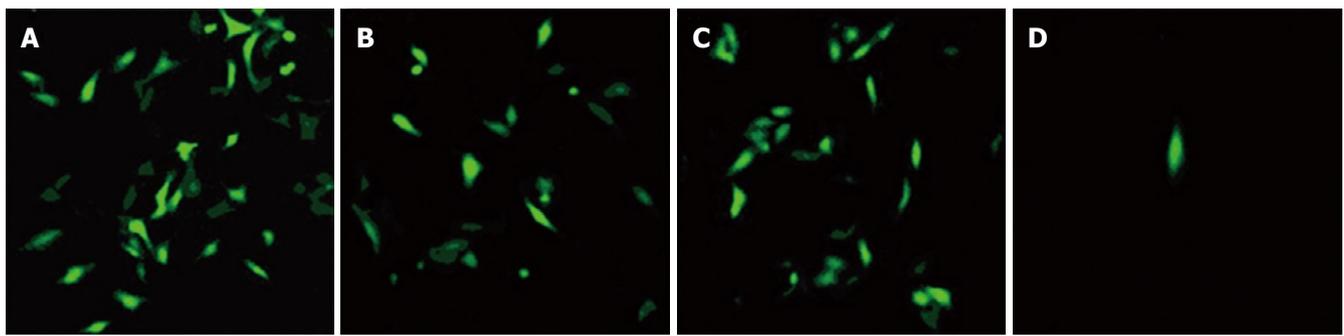

The percentage of EGFP-positive cells in each well was obtained by FACS.  $\beta$ -L-D4A inhibited the expressions of EGFP under the control of Sp (Figure 5, one representative picture was chosen from each group) and Xp in a dose-dependent manner, but had no effect on the expression of EGFP under the control of preSp and Cp; by contrast,  $\beta$ -LPA inhibited the expression of EGFP under the control of Cp and Xp in a dose-dependent manner, but had no effect on the expression of EGFP under the control of preSp and Sp; lamivudine could not inhibit the expression of EGFP under the control of any HBV promoter. The results are summarized in Tables 2 and 3.

## DISCUSSION

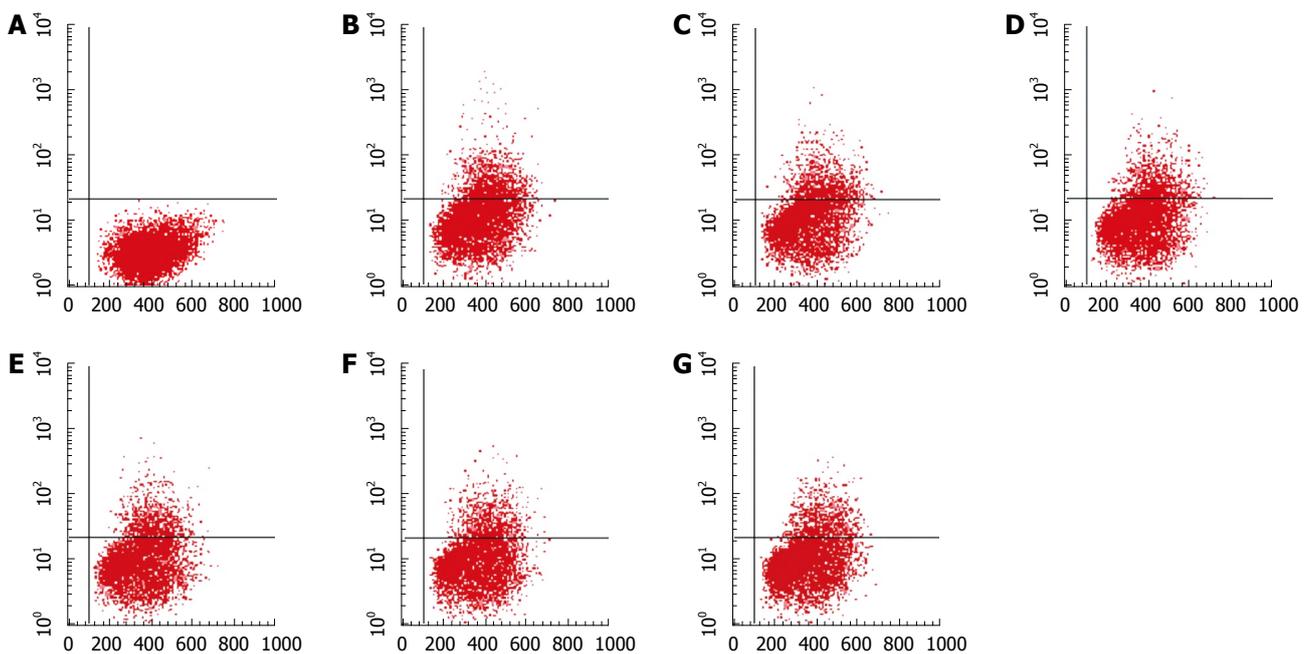

HBV infection remains a major public health problem

worldwide. Antiviral treatment of chronic Hepatitis B currently relies on immune modulators such as interferon alpha and its pegylated form, and viral polymerase inhibitors which belong to the nucleoside and nucleotide analog family<sup>[24]</sup>. Unfortunately, interferon alpha therapy is associated with several side effects, and the response rate for those receiving treatment has been unsatisfactory<sup>[25,26]</sup>. Because of the slow kinetics of viral clearance and spontaneous viral genome variability, viral mutants resistant to nucleoside analogs may be selected<sup>[27,28]</sup>. Thus, drugs targeting other unique viral targets are needed.

Our results indicate  $\beta$ -L-D4A and  $\beta$ -LPA can inhibit the activities of HBV promoters in a dose-dependent manner. On the other hand, expression of EGFP was not inhibited by lamivudine. This shows lamivudine has no effect on HBV promoters and suggests the anti-HBV effects of the two novel nucleoside analogues are mediated by mechanisms different from those used by lamivudine. HBV, a causative agent of hepatitis and hepatocellular carcinoma, contains a 3.2-kb partially double-stranded DNA genome. Upon infection of a host, the viral genome is transcribed to generate a 3.5-kb pregenomic RNA used as a template for viral replication. The pregenomic/core promoter is responsible for the synthesis of this 3.5-kb pregenomic RNA; therefore, regulation of this promoter is important in the viral life cycle<sup>[29]</sup>. The 3.5-kb RNA also serves as a template for the synthesis of polymerase and nucleocapsid core protein. In addition to the 3.5-kb RNA, three more transcripts are generated from the HBV genome. The large surface antigen is synthesized from a 2.4-kb RNA, and the major and middle antigens are synthesized from 2.1-kb transcripts. The X-gene product (HBx) is synthesized from the smallest 0.8-kb RNA<sup>[29]</sup>. The transcriptions of these RNAs are governed by the pre-S, surface, and X promoters, respectively<sup>[30,31]</sup>. Thus, HBV promoters are crucial for HBV transcription and play an important role in the HBV replicative cycle. Our previous study shows that  $\beta$ -L-D4A and  $\beta$ -LPA possess potent inhibitory effects on the replication of HBV *in vitro* with little cytotoxicity or mitochondrial toxicity, and can inhibit the expression of HBV antigens at high concentrations<sup>[10,13]</sup>; these findings can be explained by a model in which the two compounds inhibit

**Figure 4** Forty-eight hours after transfection, EGFP positive cells were detected by fluorescence microscopy ( $\times 100$ ). **A:** HepG2 cells transfected with pEGFP-Sp; **B:** HepG2 cells transfected with pEGFP-Cp; **C:** HepG2 cells transfected with pEGFP-Xp; **D:** HepG2 cells transfected with pEGFP-preSp.

**Figure 5**  $\beta$ -L-D4A inhibited the expression of EGFP in HepG2 cells transfected with pEGFP-Sp, as determined by FACS analysis. **A:** HepG2 cells not transfected with pEGFP-Sp, not treated with drug, the percentage of EGFP-positive cells was 0; **B:** HepG2 cells transfected with pEGFP-Sp, not treated with drug, the percentage was 21.42%; **C:** HepG2 cells transfected with pEGFP-Sp, treated with Lamivudine at 1  $\mu$ mol/L, the percentage was 21.14%; **D-G:** HepG2 cells transfected with pEGFP-Sp, treated with  $\beta$ -L-D4A at various concentrations (0.08, 0.4, 2, 10  $\mu$ mol/L), the percentages were 18.76%, 17.31%, 15.53%, 13.65% respectively.

the activities of HBV promoters, as shown in the present study. Thus, HBV promoters may be molecular targets of these two compounds. To confirm this, DNase I footprint-

ing assays should be performed in the future. Two main points are worthy of mention here. First, although HBV promoters are crucial to the HBV life cycle, no research on

anti-HBV drugs using promoters as molecular targets has been reported to date. Therefore, our effort to explore the effects of these two novel nucleoside analogues on HBV promoters is valuable and necessary. Second, four EGFP expression vectors containing different HBV promoters were successfully constructed by us. These vectors offer us the ability to monitor the activities of HBV promoters and provide an effective way to detect the effects of novel anti-HBV drugs on HBV promoters. Compared with the chloramphenicol acetyltransferase (CAT) reporter gene, the EGFP reporter gene has more advantages. Analysis of EGFP expression easier and there is no pollution from radiation. In summary, we have shown that  $\beta$ -L-D4A can inhibit the activities of Sp and Xp promoters, and that  $\beta$ -LPA can inhibit the activities of Cp and Xp promoters, in dose-dependent manners. These findings may help us to explain the mechanisms of action of these two novel compounds.

## COMMENTS

### Background

Hepatitis B virus (HBV) infection remains a global health problem. Currently, antiviral treatment of chronic Hepatitis B relies on interferon alpha and nucleoside analogs that inhibit viral polymerase. However, interferon alpha therapy has many side effects, while the use of nucleoside analogs can lead to the emergence of resistant viral mutants. Thus, development of novel antiviral agents against HBV is an extremely important undertaking.

### Research frontiers

All of the approved chemotherapeutic drugs for the treatment of HBV hepatitis are nucleoside analogs targeting HBV DNA polymerase. Drugs targeting other unique viral targets are needed.

### Innovations and breakthroughs

Although HBV promoters are crucial to HBV's life cycle, research on anti-HBV drugs targeting HBV promoters has not yet been reported. Therefore, our efforts to explore the effects of two novel nucleoside analogues on HBV promoters are valuable and necessary.

### Applications

This work may help to explain the mechanisms underlying the anti-HBV actions of  $\beta$ -L-D4A and  $\beta$ -LPA, which possess potent inhibitory effects on the replication of HBV, with little cytotoxicity or mitochondrial toxicity. Therefore, they are expected to be developed as new clinical anti-HBV drugs.

### Terminology

Green fluorescent protein (GFP) was firstly used as a marker of gene expression by Chalfie (*Science* 1994; 263: 802-805), and later developed as an EGFP reporter gene, which uses GFP to monitor gene expression and protein localization in living organisms.

### Peer review

The authors explored nucleoside analogues  $\beta$ -L-D4A and  $\beta$ -LPA's effects on HBV promoters.

### Abstract

**AIM:** To promote the development of improved tumor vaccination strategies relying on the intratumoral expression of viral fusogenic membrane proteins, we elucidated whether the size of syncytia or the way tumor cells die has an effect on the therapeutic outcome.

**METHODS:** In two syngeneic subcutaneous murine colon cancer models we assessed the anti-neoplastic effect on vector-treated and contralateral untreated tumors.

**RESULTS:** Intratumoral injection of a replication-defective adenovirus encoding respiratory syncytial virus fusion protein (RSV-F) alone (Ad.RSV-F) or together with the attachment glycoprotein RSV-G (Ad.RSV-F/G) led to a significant growth reduction of the vector-treated and contralateral untreated tumors. The treatment response was associated with a strong tumor-specific CTL response and significantly improved survival with medians of 46 d and 44 d, respectively. Intratumoral injection of Ad.RSV-G or a soluble RSV-F encoding adenovirus (Ad.RSV-F<sub>sol</sub>) had no significant anti-neoplastic effect. The median survival of these treatment groups and of Ad.Null-treated control animals was about 30 d.

**CONCLUSION:** Although *in vitro* transduction of colon cancer cell lines with Ad.RSV-F/G resulted in about 8-fold larger syncytia than with Ad.RSV-F, the *in vivo* outcome was not significantly different. Transduction of murine

colon cancer cell lines with Ad.RSV-F or Ad.RSV-F/G caused apoptotic cell death, in contrast to transduction with Ad.RSV-G or Ad.RSV-F<sub>sol</sub>, suggesting an importance of the mode of cell death. Overall, these findings provide insight into improved tumor vaccination strategies relying on the intratumoral expression of viral fusogenic membrane proteins.

### INTRODUCTION

For a potent and long-lasting tumor therapy it is desirable to eradicate the primary tumor and also to induce an anti-tumor immunity to prevent the spread and recurrence of tumor cells. Recent advances in tumor immunology have identified various tumor-associated antigens, and this has facilitated the development of vaccine strategies for cancer. However, the use of tumor-associated antigens as a vaccine component is limited to cancer patients with a known tumor antigen<sup>[1]</sup>. To circumvent this limitation, some cancer vaccination strategies use killed tumor cells or lysates delivered in combination with adjuvants or cytokines, which probably include both known and unknown antigens<sup>[2,3]</sup>. Furthermore, gene transfer of cytokines, MHC molecules, costimulatory molecules or tumor antigens to tumor cells has been used to enhance the visibility of tumor cells to immune effector cells<sup>[4,5]</sup>.

In 1994, Polly Matzinger presented a new theory called the danger model, suggesting a specific immune

response develops as a result of danger detection rather than discrimination between self and non-self antigens<sup>[6,7]</sup>. According to the danger model, the immune surveillance system fails to detect tumor antigens because transformed cells do not send any danger signals<sup>[7]</sup>. Danger signals are thought to act by stimulating dendritic cells to mature so that they can present foreign antigens and stimulate T cells<sup>[8-11]</sup>. During infections, microbial components provide signals that alert the immune system to danger and promote the generation of immunity<sup>[8,12]</sup>. Dying mammalian cells have also been found to release danger signals<sup>[13-16]</sup>. In the absence of such signals there is often no immune response or tolerance may develop.

Linardakis *et al* demonstrated in a syngeneic murine B16 melanoma model that the expression of fusogenic membrane protein G from vesicular stomatitis virus (VSV-G) can enhance the efficacy of a weak allogeneic vaccine<sup>[17]</sup>. Fusogenic membrane glycoproteins were introduced as a new class of therapeutic genes for cancer gene therapy by Bateman *et al*, who demonstrated that expression of these proteins alone resulted in a significantly greater tumor growth control than suicide prodrug systems<sup>[18]</sup>. The fusion of viral envelopes with cellular membranes is an essential step mediating the entry of enveloped viruses into host cells. This process is mediated by specific viral proteins such as the fusion (F) protein of paramyxoviruses<sup>[19-21]</sup>. A member of this virus family, human respiratory syncytial virus (RSV), encodes three envelope glycoproteins, namely the major attachment glycoprotein (G)<sup>[22]</sup>, the small hydrophobic (SH) protein, which blocks TNF- $\alpha$  mediated apoptosis<sup>[23]</sup>, and the fusion glycoprotein (F), which mediates virus-cell and cell-cell fusion<sup>[24]</sup>, creating the characteristic syncytia for which the virus is named.

Previously, we demonstrated in a syngeneic bilateral subcutaneous MC38 and Colon26 colon cancer model in immunocompetent mice that the injection of one tumor with a replication-defective adenovirus encoding RSV-F resulted not only in tumor growth reduction of the treated tumor, but also of the second, untreated contralateral tumor<sup>[25]</sup>. We observed qualitatively similar effects with fusogenic membrane proteins of measles virus (MV-H/F)<sup>[26]</sup>. The effects were associated with a tumor-specific cytotoxic T cell (CTL) response and a pronounced infiltration of tumors with natural killer cells and macrophages.

In an attempt to promote the development of improved tumor vaccination strategies that rely on intratumoral expression of viral fusogenic membrane proteins, in this study we elucidated factors that might influence the induction of a systemic anti-tumor response. Using the same bilateral subcutaneous tumor models we demonstrated that treatment of one cutaneous tumor with a replication-defective adenovirus encoding RSV-F alone (Ad.RSV-F) or in combination with RSV-G (Ad.RSV-F/G) resulted in improved survival and the induction of a systemic anti-tumor immune response. Although *in vitro* transduction of tumor cells with Ad.RSV-F/G resulted in significantly larger syncytia compared with transduction of tumor cells with Ad.RSV-F, the *in vivo* treatment

outcome was not significantly influenced by the size of cell-cell fusion. Treatment of animals with an adenovirus encoding a soluble, non-fusogenic form of RSV-F (Ad.RSV-F<sub>sol</sub>) or RSV-G (Ad.RSV-G) had no anti-neoplastic effect, indicating that the anti-neoplastic effects are not primarily mediated by intrinsic immunological properties of RSV envelope glycoproteins. In both tumor models we observed the induction of a systemic anti-tumor response only when RSV glycoprotein expression in the tumor cells caused syncytium formation and apoptosis, independent of the size of syncytia.

## MATERIALS AND METHODS

### Cells and cell culture

The murine colon adenocarcinoma cell line MC38 was obtained from Steven A. Rosenberg, NCI, NIH, Bethesda, MD. The murine adenocarcinoma cell line Colon26 was purchased from CLS (Heidelberg, Germany). The human embryonic kidney cell line 293 was obtained from Microbix Biosystems, Inc. (Toronto, Canada). The T-REx-293 cells, which stably express a tetracycline-dependent repressor, were purchased from Invitrogen (San Diego, CA, USA). Cell lines were propagated in Dulbecco's modified Eagle medium with high glucose (Invitrogen, Karlsruhe, Germany), supplemented with 10% heat-inactivated fetal bovine serum and 50  $\mu$ g/mL gentamicin. All cell lines were routinely tested for *Mycoplasma* and found to be free of contamination.

### Viruses

The replication-defective Ad5-based vector Ad.GFP, which encodes enhanced green fluorescent protein (GFP) driven by the CMV-IE promoter, has been described previously<sup>[27]</sup>. As a vector control we used Ad.Null, a replication-defective adenovirus generated with the Ad-Easy-1 system<sup>[28]</sup> that does not encode a transgene.

The adenovirus vector Ad.RSV-F, which carries a codon-optimized cDNA for native RSV-F<sup>[29]</sup>, has been described previously<sup>[25]</sup>. The vector Ad.RSV-F<sub>sol</sub> encodes a non-fusogenic soluble form of RSV-F, which lacks the transmembrane domain and cytoplasmic tail ( $\Delta$ 524-574). The vector Ad.RSV-G encodes the RSV (ATCC VR26) major attachment protein G, which was codon optimized for expression in human cells (GeneArt, Regensburg, Germany). In all adenovirus vectors, the RSV envelope glycoproteins were under the transcriptional control of the TetO2 promoter<sup>[30]</sup>. The vector Ad.RSV-F/G encodes the RSV-F and RSV-G proteins under the transcriptional control of a bi-directional TetO2 promoter. All RSV glycoprotein encoding adenovirus vectors were generated using the Ad-Easy-1 system<sup>[28]</sup>, and are Ad5-based and E1-, E3-deleted. Infectious vectors were rescued using T-REx-293 cells in the absence of tetracycline.

All vectors were purified using the Vivapure AdenoPACK 100 kit (Vivascience, Hannover, Germany). Vector particle concentration was determined by spectrophotometry as described previously<sup>[31]</sup> and expressed as viral particles (VP)/mL. The particle-to-PFU ratios of all vector preparations were about 30:1.

### Analysis of cell-cell fusion

About 95%-100% confluent MC38 or Colon26 cell monolayers were transduced with equal amounts of Ad.GFP to enhance syncytium visibility and Ad.Null, Ad.RSV-F, Ad.RSV-F/G, Ad.RSV-G, or Ad.RSV-F<sub>sol</sub>, at a multiplicity of infection (MOI) of 1000 VP/cell. Forty-eight hours after vector transduction, cells were analyzed by inverse fluorescence microscopy. Digital images were captured using a high-resolution still camera (Olympus DP50, Tokyo, Japan) attached to a fluorescence microscope (Olympus BX51, Tokyo).

### Analysis of apoptosis

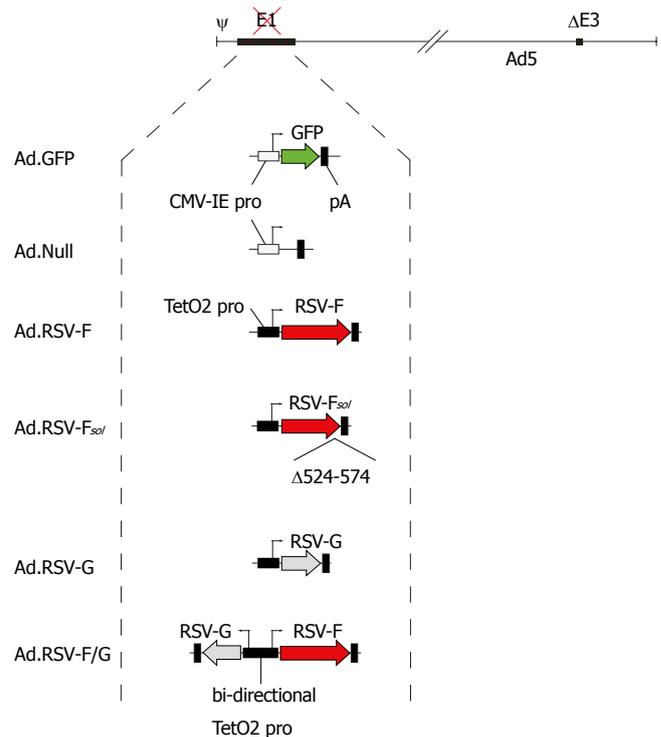

Fourteen hours after treatment, the annexin V binding and caspase-3/7 activity of MC38 and Colon26 cells was analyzed using the Annexin V-FITC Apoptosis Detection Kit I (BD Biosciences, San Jose, CA) or Caspase-Glo™ 3/7 assay (Promega, USA), respectively, as described previously<sup>[32]</sup>. Changes in mitochondrial membrane potential ( $\Delta\Psi_m$ ) were analyzed by flow cytometry using the BD MitoScreen Kit (BD Biosciences), as described previously<sup>[32]</sup>.

### In vivo studies

The Animal Care and Use Committee of the Ruhr-University Bochum approved all described studies. Six- to eight-week-old female C57BL/6 and BALB/c mice were obtained from Janvier (Le Genest-St-Isle, France). To generate the syngeneic bilateral subcutaneous syngeneic tumor model, C57BL/6 or BALB/c mice received subcutaneous injections of  $1 \times 10^5$  MC38 or Colon26 cells, respectively, in 100  $\mu$ L into the right hind flank and  $1 \times 10^4$  cells in 100  $\mu$ L into the left hind flank. Animals were randomly assigned to treatment groups ( $n = 5$  for each tumor model) when the tumor on the right hind flank reached a volume of about 200 mm<sup>3</sup> and the tumor on the left side was palpable. On day 0 and 2, animals received  $6 \times 10^9$  VP of Ad.Null, Ad.RSV-F, Ad.RSV-F/G, Ad.RSV-G, or Ad.RSV-F<sub>sol</sub> in 100  $\mu$ L of PBS into the tumor on the right flank. Tumor growth was monitored at least once a week, minimum and maximum perpendicular tumor axes were measured using vernier calipers, and tumor volume was calculated using the simplified formula of a rotational ellipse ( $l \times w^2 \times 0.5$ ). The skin thickness of 0.4 mm was subtracted from the measurements. To generate effector cells, mice were sacrificed and spleens were harvested and weighed 28 d after virus inoculation. When animals seemed to be in distress or the tumor weight exceeded 10% of the body weight, animals were euthanized by CO<sub>2</sub> asphyxia.

### CTL assay

We analyzed the CTL response to tumor cells, using the lactate dehydrogenase (LDH)-based CytoTox 96 (Promega) assay according to the manufacturer's instructions. In brief, target cells (MC38 or Colon26) were plated at a density of  $5 \times 10^3$  cells per well in round-bottomed 96-well plates. Target cells were then mixed with effector cells at the indicated ratios and co-incubated for 4 h. LDH release was determined measuring absorbance at 490 nm with a plate reader, and the specific lysis was calculated from triplicate samples as follows:

**Figure 1** Adenovirus vector design. All adenovirus vectors used in this study are E1- and E3-deleted and Ad5-based. The vector Ad.GFP encodes green fluorescent protein and the vector Ad.Null served as an adenovirus vector control. The RSV glycoprotein encoding vectors carried the transgene under the transcriptional control of the doxycycline-repressible TetO2 promoter. The vector RSV-F<sub>sol</sub> encodes a soluble form of the RSV fusion protein F without the transmembrane domain and cytoplasmic tail ( $\Delta 524-574$ ).

$$\text{Specific lysis (\%)} = \frac{\text{Experimental } A_{490} - \text{Effector spontaneous } A_{490} - \text{Target spontaneous } A_{490}}{\text{Target maximum } A_{490} - \text{Target spontaneous } A_{490}} \times 100.$$

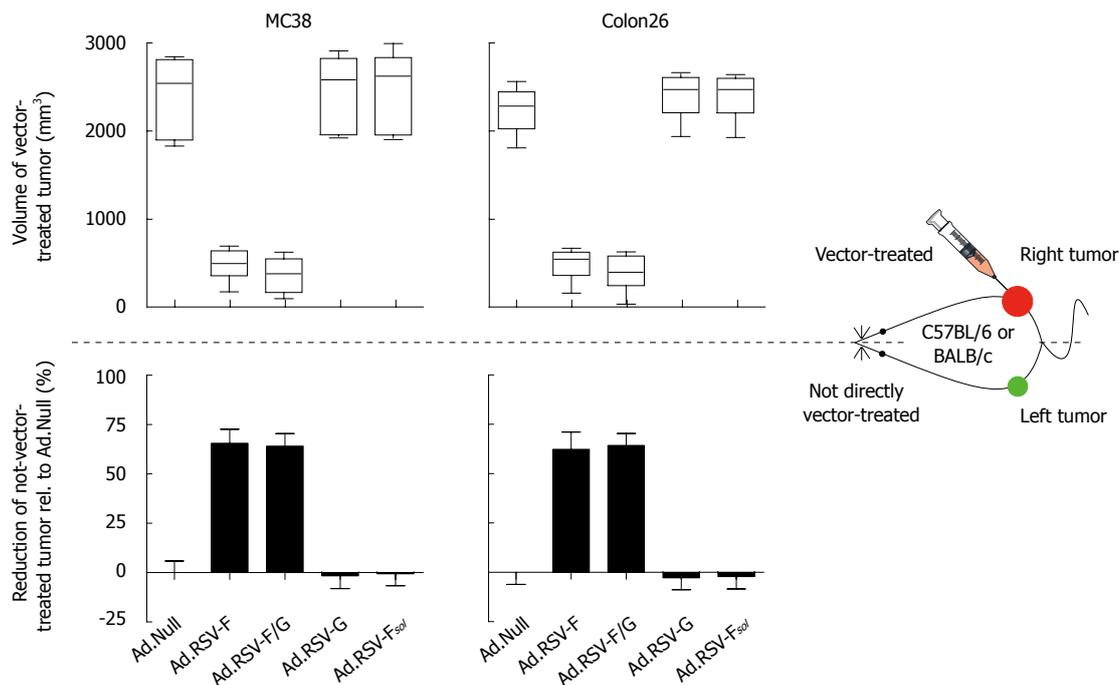

### Statistical analysis

The statistical software package SPSS 15 (SPSS Inc., Chicago, USA) was used for data analysis. For comparative analysis of survival rates across treatment groups, Kaplan-Meier analysis with the log-rank test was used. Tumor volumes and spleen weights were analyzed by one-way analysis of variance (ANOVA) followed by the Tukey's honestly significantly different (HSD) test. The sizes of syncytia were determined with the image analysis software ImageJ 1.38 (<http://rsb.info.nih.gov/ij>). The calculated areas of 30 syncytia in each treatment group were compared using the Mann-Whitney Rank Sum Test.

## RESULTS

### Intratumoral expression of RSV-F alone or in combination with RSV-G induces an antineoplastic effect on the treated tumor as well as on the untreated contralateral tumor

In the subcutaneous syngeneic bilateral MC38 and Colon26 colon cancer model we analyzed in more detail factors that are necessary to induce a systemic anti-tumor response by intratumoral expression of RSV envelope glycoproteins encoded by replication-defective adenovirus vectors (Figure 1). To analyze whether enhanced syncytium formation improves the tumor vaccination effect, animals were treated with Ad.RSV-F or an adenovirus encoding

**Figure 2** Intratumoral expression of RSV-F or RSV-F/G induces an anti-neoplastic effect. In a bilateral subcutaneous syngeneic MC38 or Colon26 colon cancer model, the indicated adenovirus vectors were inoculated on d 0 and d 2 into the tumor on the right flank. No viral vectors were inoculated into the tumor on the left flank. **A:** The volume of the tumor on the right flank was measured at d 28 and presented as box-and-whisker plots, showing minimum, 25th percentile, median, 75th percentile, and maximum tumor volume; **B:** The volume of the tumor on the left flank, which did not receive direct viral vector injections, was measured at d 28 and the volume reduction relative to Ad.Null-treated control animals is presented as bar graphs (mean  $\pm$  SD).

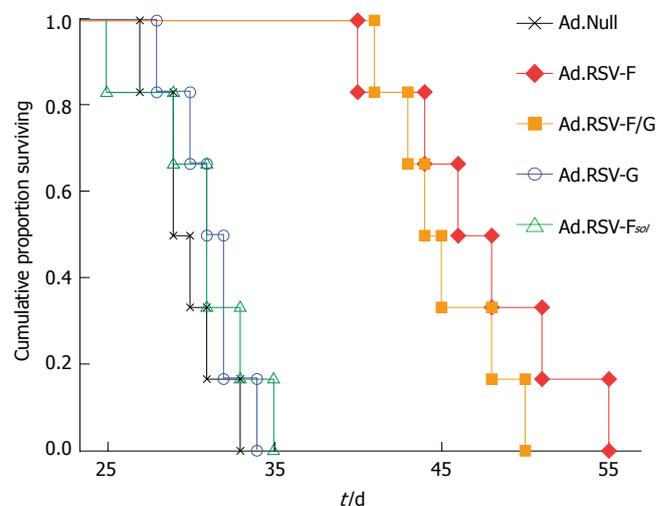

RSV-F as well as RSV-G (Ad.RSV-F/G). Furthermore, we elucidated whether syncytium formation is necessary to induce a systemic anti-tumor response or whether this effect is mediated by intrinsic immunological properties of RSV envelope glycoproteins. Animals were treated with an adenovirus encoding a soluble, non-fusogenic RSV-F without the transmembrane domain and cytoplasmic tail (Ad.RSV-F<sub>sol</sub>). Treatment of animals with Ad.RSV-G served as a control. In addition we analyzed whether the tumor cells needed to undergo apoptosis to induce a systemic anti-tumor response.

As shown in Figure 2, injection of Ad.RSV-F or Ad.RSV-F/G into the right tumor resulted in about 80% and 87% reduction, respectively, in the size of vector-treated tumors at day 28 ( $P < 0.001$ ). Importantly, treatment of the right tumor with Ad.RSV-F or Ad.RSV-F/G also resulted in about 60% reduction of the left, untreated tumor compared with Ad.Null-treated animals ( $P < 0.001$ ). By contrast, treatment with Ad.Null, Ad.RSV-G or Ad.RSV-F<sub>sol</sub> had no significant anti-neoplastic effect on either vector-treated or contralateral tumors ( $P > 0.05$ ).

To assess whether these results are unique to MC38 cells and C57BL/6 mice (H-2<sup>b</sup>), we repeated the syngeneic bilateral tumor model under identical conditions with Colon26 cells in BALB/c mice (H-2<sup>d</sup>), which have contrasting susceptibilities to certain intracellular pathogens<sup>[33,34]</sup>. As shown in Figure 2, the results were qualitatively similar to that obtained with MC38 cells.

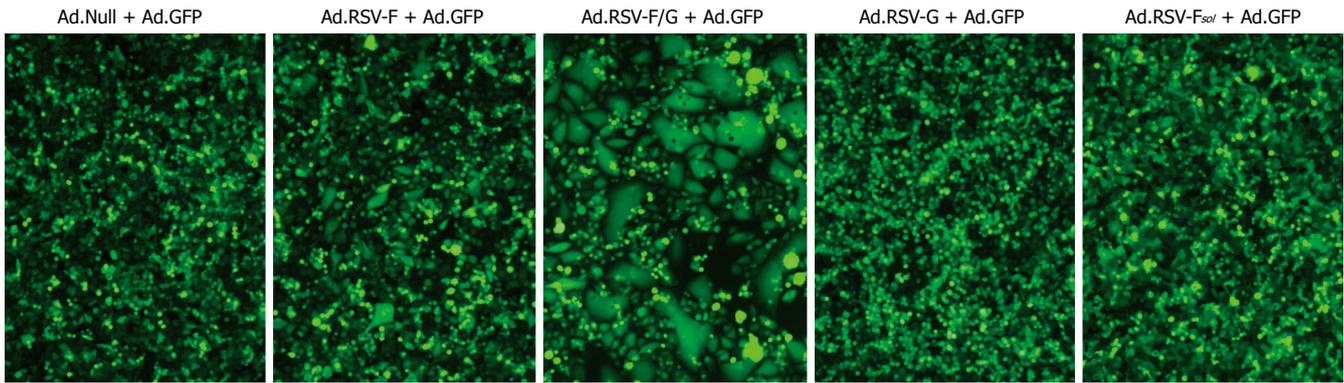

#### **Intratumoral expression of RSV-F alone or in combination with RSV-G results in enhanced survival**

Next, we analyzed in the syngeneic bilateral MC38

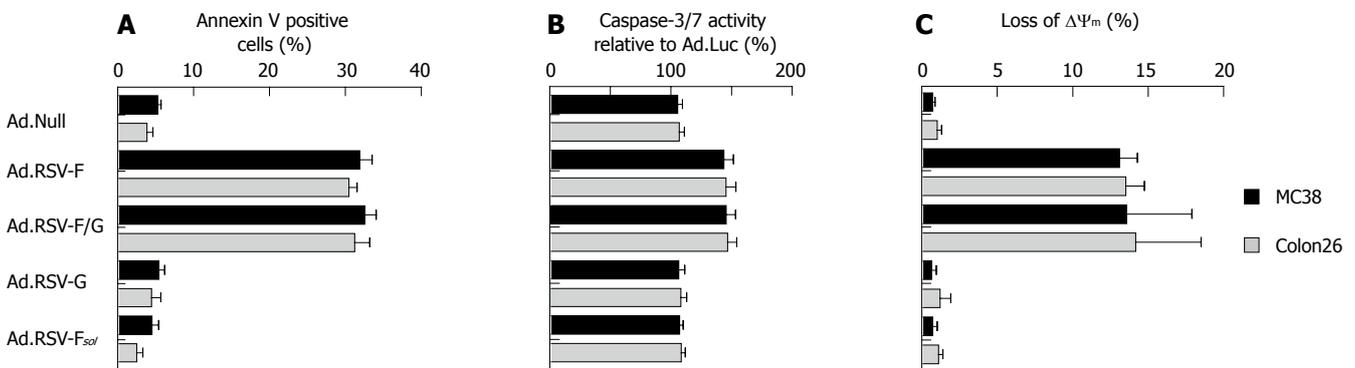

**Figure 3** Kaplan-Meier survival analysis. In the bilateral subcutaneous syngeneic MC38 colon cancer model described in Figure 2, one tumor was treated with the indicated adenoviral vectors, and survival time was monitored up to d 55.

subcutaneous colon cancer model whether intratumoral expression of RSV envelope glycoproteins also results in improved survival. Kaplan-Meier survival analysis revealed that animals treated with Ad.Null had a median survival of 29 d (Figure 3). Animals that received intratumoral injections of Ad.RSV-G or Ad.RSV-F<sub>sol</sub> had a median survival of 31 d ( $P > 0.05$ ). Treatment of mice with Ad.RSV-F or Ad.RSV-F/G resulted in a significantly improved outcome with median survivals of 46 d and 44 d, respectively ( $P < 0.001$ ).

**Figure 4** Fluorescence micrographs. MC38 cells were transduced *in vitro* with indicated RSV glycoprotein encoding adenoviruses and an adenovirus encoding GFP. Transduction with Ad.GFP enhanced the visibility of syncytia. Representative pictures 48 h after transduction are shown ( $\times 200$ ). Similar data were obtained with the Colon26 cells (data not shown).

**Figure 5** Analysis of apoptosis. **A:** MC38 or Colon26 cells were transduced *in vitro* with indicated adenovirus vectors and early apoptotic events were analyzed by flow cytometric measurements of phosphatidylserine translocation to the outer membrane by annexin V binding; **B:** Because apoptosis is essentially executed by proteases of the caspase family, we analyzed caspase-3/7 activity. Relative caspase activities are given as means  $\pm$  SD of three independent experiments; **C:** To measure mitochondrial alterations we determined the mitochondrial membrane potential  $\Delta\Psi_m$ . Ad.Null served as a control.

### Expression of RSV-F alone or in combination with RSV-G results in syncytium formation in MC38 and Colon26 cells

Next, we determined whether the size of syncytium formation correlates with the treatment outcome. As shown in Figure 4, no cell-cell fusion was detectable in MC38 cells transduced with Ad.Null, Ad.RSV-G or Ad.RSV-F<sub>sol</sub>. The median syncytia area of monolayers transduced under identical conditions with Ad.RSV-F or Ad.RSV-F/G was about 3 times and 25 times larger than the median area of single MC38 cells transduced with Ad.Null. Transduction of cell monolayers with Ad.RSV-F/G resulted in significantly larger syncytia than Ad.RSV-F ( $P = 0.001$ ). Similar data were obtained with Colon26 cells (data not shown).

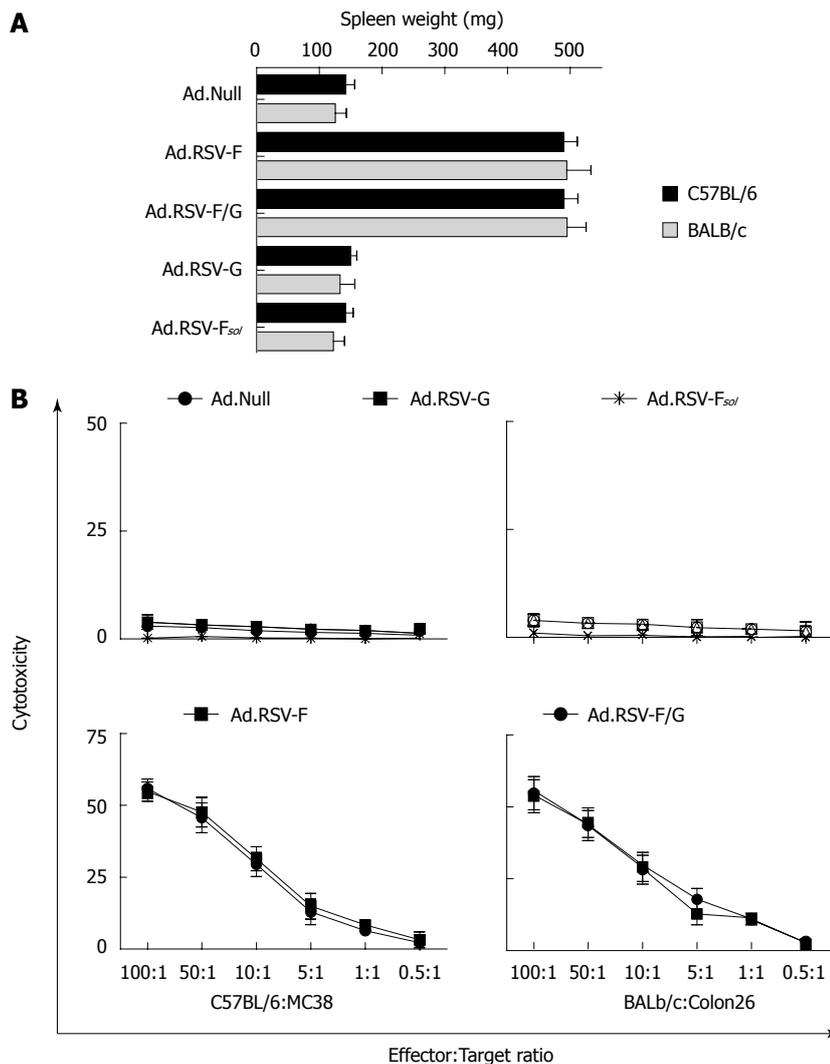

### Expression of RSV-F alone or in combination with RSV-G results in apoptosis

To examine whether the cells need to undergo apoptosis after expression of RSV envelope glycoproteins to induce a systemic anti-tumor response, we analyzed early and late events of programmed cell death. We first analyzed the binding of annexin V-FITC to externalized phosphatidylserine, which reflects reversible membrane damage, as a marker for the early stages of apoptosis in combination with vital staining<sup>[35]</sup>. As shown in Figure 5A,

there was no significant annexin V binding to MC38 or Colon26 cells transduced with Ad.Null. Fourteen hours after transduction with Ad.RSV-G or Ad.RSV-F<sub>sol</sub>, the median percentage of annexin V-positive cells was about 6%. Transduction of the tumor cell lines with Ad.RSV-F or Ad.RSV-F/G resulted in about 32% annexin V-positive cells.

Induction of apoptosis is essentially executed by the activation of caspases in response to extrinsic or intrinsic stimuli. Activation of initiator caspases results in the downstream activation of effector caspases that cleave key cellular proteins leading to controlled cell death<sup>[36]</sup>. To assess the involvement of caspases, we measured the proteolytic activity of the effector caspases-3/7 using a luminogenic substrate assay. The caspase-3/7 activity of untreated MC38 or Colon26 cells was normalized to 100%. As shown in Figure 5B, 36 h after transduction of MC38 or Colon26 cells with Ad.RSV-G or Ad.RSV-F<sub>sol</sub>, the median caspase-3/7 activity was about 107%. Treatment with Ad.RSV-F or Ad.RSV-F/G resulted in about 142% caspase activity.

In addition, we analyzed the mitochondrial membrane potential  $\Delta\Psi_m$ , an important parameter of mitochondrial alterations, 36 h after transduction of the cells with the

**Figure 6** Effects of indicated treatments on the spleen weight and cytotoxic T cell induction. **A:** In the bilateral subcutaneous syngeneic MC38 and Colon26 tumor model described in Figure 2, animals were euthanized at day 28 and spleen weight was determined (mean  $\pm$  SD); **B:** In addition, we determined the cytotoxic activity of spleen-derived T cells against target MC38 or Colon26 tumor cells in these animals using an LDH release assay. Data of all animals were expressed as the average percentage of specific LDH release from three independent experiments (mean  $\pm$  SD).

adenoviral vectors, by staining with the cationic dye JC-1, which selectively enters into mitochondria and reversibly changes color from green to red as the membrane potential increases. In healthy cells with high mitochondrial  $\Delta\Psi_m$ , JC-1 spontaneously forms complexes with intense red fluorescence. In apoptotic or unhealthy cells with low  $\Delta\Psi_m$ , JC-1 remains in the monomeric form, which shows green fluorescence. As shown in Figure 5C, transduction of MC38 or Colon26 cells with Ad.RSV-F or Ad.RSV-F/G resulted in a clearly stronger loss of  $\Delta\Psi_m$  compared with cells transduced with Ad.Null, Ad.RSV-G or Ad.RSV-F<sub>sol</sub>.

#### **Treatment of animals with Ad.RSV-F or Ad.RSV-F/G but not with Ad.RSV-G or Ad.RSV-F<sub>sol</sub> results in significantly increased spleen weight**

Splenomegaly is often associated with a cellular immune response. To elucidate whether the anti-neoplastic effect on the untreated contralateral tumor is immune-mediated we determined the spleen weights of the animals on d 28 (Figure 6A). We observed about a 245% increase in median spleen weights in the MC38 and Colon26 cancer model animals treated with Ad.RSV-F or Ad.RSV-F/G, compared to Ad.Null-treated animals. Treatment of animals with Ad.Null, Ad.RSV-G or Ad.RSV-F<sub>sol</sub> had no significant effect on spleen weight.

#### **Intratumoral expression of RSV-F or RSV-F/G but not of RSV-G or RSV-F<sub>sol</sub> induces a tumor cell-specific CTL response**

As the splenomegaly suggests the induction of a cellular immune response, we next determined whether there is a tumor-specific CTL response mediating the observed anti-neoplastic response against the untreated tumor. As shown in Figure 6B, in an LDH release assay we observed no cytotoxicity of splenocytes derived from Ad.Null-treated mice with or without tumors against the MC38 or Colon26 target cells. Splenocytes from animals treated with Ad.RSV-F or Ad.RSV-F/G showed a cytotoxicity of about 55% at an effector to target ratio of 100:1. By contrast, we observed only a slight lysis of target cells by splenocytes from animals treated with Ad.RSV-G or Ad.RSV-F<sub>sol</sub>.

## **DISCUSSION**

We demonstrated previously in syngeneic murine tumor models that intratumoral expression of viral fusogenic membrane proteins can induce a systemic anti-tumor response associated with a tumor-specific CTL response<sup>[26,37]</sup>. In this study we analyzed whether *in situ* tumor vaccination by intratumoral expression of RSV envelope glycoproteins is influenced by the efficiency

of cell-cell fusion, the mode of tumor cell death, or whether the effect is mediated by intrinsic immunological properties of the RSV-F protein.

The key findings of our current study were as follows. First, despite the limited intratumoral spread and transduction efficiency of the replication-defective adenovirus vectors<sup>[38]</sup>, intratumoral injection of Ad.RSV-F or Ad.RSV-F/G resulted in significantly improved tumor growth reduction of both vector-inoculated tumors and contralateral untreated tumors. The improved anti-neoplastic treatment efficacy also resulted in a significantly improved survival. The effect was not mediated by an adenovirus vector viremia, as we did not observe this effect in nude mice (data not shown) and we did not detect adenovirus vector beyond d 1 in the serum of vector-treated C57BL/6 mice<sup>[39]</sup>. This indicates that the systemic anti-tumor response depends on an intact immune system. This is supported by our demonstration of the induction of a tumor-specific CTL response and a massively increased spleen weight. This qualitatively confirms our data obtained in a bilateral subcutaneous colon cancer model using HSV-1 or adenovirus vectors encoding the fusogenic membrane proteins F and H of measles virus or RSV-F, showing that the expression of viral fusogenic membrane proteins can serve as a tumor vaccination platform<sup>[25,26,37]</sup>. Furthermore the data are in concert with previous studies demonstrating that expression of VSV-G encoded by a plasmid vector can enhance the immunogenicity of tumor cells<sup>[17,40,41]</sup>.

Second, we demonstrated that transduction of tumor cells with Ad.RSV-F/G resulted in clearly larger syncytia than transduction with Ad.RSV-F. This result is in concert with a previous observation<sup>[42]</sup>. However, as we used codon-optimized cDNA for the expression of the RSV glycoproteins<sup>[29]</sup>, we observed cell-cell fusion also after transduction of the tumor cells with Ad.RSV-F alone. In other paramyxoviruses, expression of the fusion protein alone is not sufficient to mediate cell-cell fusion<sup>[43]</sup>. Transduction of the murine colon cell lines with Ad.RSV-G or Ad.RSV-F<sub>sol</sub> did not cause detectable cell-cell fusion.

Third, there was no significant difference in the local and distant anti-tumor effect in animals that were treated with Ad.RSV-F or Ad.RSV-F/G, although the syncytia of cells transduced with Ad.RSV-F/G were clearly larger *in vitro*. This indicates that the treatment outcome was not significantly influenced by the size of cell-cell fusion.

Fourth, our data indicate that only RSV envelope glycoproteins which cause syncytium formation (RSV-F or RSV-F/G) are able to induce apoptosis, in contrast to RSV-G or RSV-F<sub>sol</sub>. Importantly, in our experimental setting, only membrane proteins which are able to induce apoptosis are associated with a local and distant anti-tumor effect. Because the expression of RSV-F<sub>sol</sub> did not induce a distant anti-tumor response, this effect is most likely not mediated by intrinsic immunological properties of RSV-F. This supports previous data indicating the mechanisms by which tumor cells are killed may be critical for the induction of a specific anti-tumor immunity<sup>[44,45]</sup>. However, because we did not include a fusion-disabled RSV-F, we cannot rule out the possibility that the transmembrane

domain of RSV-F *per se* is responsible for the observed effects.

In an earlier study we elucidated by Western blot analysis some of the molecular pathways leading to cell death by expression of viral fusogenic membrane proteins. We demonstrated that induction of apoptosis was independent of functional p53 and was mediated *via* a mitochondrial death pathway triggered by modulation of Bcl-2 family proteins<sup>[32]</sup>. In addition, we demonstrated increased protein levels of the heat shock proteins (HSP) 60, 70 and 90 $\alpha$ <sup>[46]</sup>.

According to the danger model, growing tumors do not provide a danger signal to dendritic cells, and thus, do not activate the immune system. Therefore, any tumor antigen-specific T cell will have its first antigen encounter with tumor cells or resting dendritic cells. Because there is no co-stimulation, either situation will drive the T cells into anergy or apoptosis and, eventually, tumor tolerance<sup>[47]</sup>. A conceivable mechanism for the induction of tumor-specific immunity is that expression of the viral fusogenic membrane proteins, apoptotic cells or exosomes of fused cells<sup>[48,49]</sup> might release danger signals resulting in a more efficient presentation of tumor antigens and activation of T cells. This is in concert with recent reports demonstrating that apoptotic tumor cells, but not malignant cells in necrotic tumors, can provoke an anti-tumor immune response<sup>[50]</sup>, if the tumor cells were killed in a caspase-3-dependent manner<sup>[51]</sup>. In addition, the xenogenization of tumor cells by presentation of viral antigens on the cell surface in conjunction with MHC class I molecules might contribute to the induction of a tumor-specific immune response<sup>[52,53]</sup>.

In this study we demonstrated that enhanced fusion function of RSV-F by co-expression of RSV-G does not significantly enhance *in situ* tumor vaccination in the two tested syngeneic tumor models. However, our data indicate that the vaccination effect critically depends on tumor cell apoptosis, which can be further enhanced by combination with chemotherapy and viral oncolysis<sup>[32,37]</sup>. Overall, these findings provide insight into improved tumor vaccination strategies relying on the intratumoral expression of viral fusogenic membrane proteins.

## ACKNOWLEDGMENTS

The authors are grateful to Steven A Rosenberg (Surgery Branch, NCI, National Institutes of Health, Bethesda, MD) for the MC38 cells. The authors would like to thank Klaus Überla for providing support and Cathrin Walter (West German Cancer Center University of Duisburg-Essen, Essen, Germany) for critical review of this manuscript.

## COMMENTS

### Background

In 1994, Polly Matzinger presented a new theory called the danger model, suggesting that a specific immune response develops as a result of danger detection rather than discrimination between self and non-self antigens. According to the danger model, the immune surveillance system fails to detect tumor antigens because transformed cells do not send any danger signals. Danger

signals are thought to act by stimulating dendritic cells to mature so that they can present foreign antigens and stimulate T cells. Dying mammalian cells have also been found to release danger signals. In the absence of such signals there is often no immune response or tolerance may develop.

### Research frontiers

Linardakis *et al* demonstrated in a syngeneic murine B16 melanoma model that the expression of fusogenic membrane protein G from vesicular stomatitis virus (VSV-G) can enhance the efficacy of a weak allogeneic vaccine. Hoffmann *et al* demonstrated previously that expression of viral fusogenic membrane proteins can induce apoptosis in tumor cells.

### Innovations and breakthroughs

In two syngeneic subcutaneous murine colon cancer models we demonstrated that intratumoral injection of a replication-defective adenovirus encoding respiratory syncytial virus fusion protein (RSV-F) alone (Ad.RSV-F) or together with the attachment glycoprotein RSV-G (Ad.RSV-F/G) leads to a significant growth reduction of both the vector-treated and contralateral untreated tumor. Treatment response was associated with a strong tumor-specific CTL response and significantly improved survival. Intratumoral injection of Ad.RSV-G or a soluble RSV-F encoding adenovirus (Ad.RSV-F<sub>sol</sub>) had no significant anti-neoplastic effect, suggesting the therapeutic effect is not mediated by intrinsic immunological properties of the viral proteins. Although *in vitro* transduction of colon cancer cell lines with Ad.RSV-F/G resulted in about 8-fold larger syncytia than with Ad.RSV-F, the *in vivo* outcome was not significantly different. Transduction of murine colon cancer cell lines with Ad.RSV-F or Ad.RSV-F/G caused apoptotic cell death, in contrast to Ad.RSV-G or Ad.RSV-F<sub>sol</sub>, suggesting an importance of the mode of cell death. Our results provide insight into improved tumor vaccination strategies relying on the intratumoral expression of viral fusogenic membrane proteins.

### Applications

This strategy might be applicable for the treatment of human cancer.

### Peer review

This is a good study designed to elucidate the relevance of the size of syncytia or the way tumor cells die on the therapeutic outcome after tumor vaccination using intratumoral expression of viral fusogenic membrane proteins. The results are informative and potentially helpful for human cancer treatments.

### Abstract

**AIM:** To evaluate the effect of Chinese traditional medicinal prescription, JIANPI HUOXUE decoction (JHD) on cytokine secretion pathway in rat liver induced by lipopolysaccharide (LPS).

**METHODS:** Twenty-four male SD rats were divided into normal group ( $n = 4$ ), model group ( $n = 10$ ) and JHD group ( $n = 10$ ) randomly. Rats in model group and JHD group were administrated with normal saline or JHD *via* gastrogavage respectively twice a day for 3 d. One hour after the last administration, rats were injected with LPS *via* tail vein, 50  $\mu\text{g}/\text{kg}$ . Simultaneously, rats in normal group were injected with equivalent normal saline. After LPS stimulation for 1.5 h, serum and liver tissue were collected. Pathological change of liver tissues was observed through hematoxylin-eosin (H.E.) staining. Tumor necrosis factor alpha (TNF- $\alpha$ ) in serum were assayed by enzyme linked immunosorbent assay (ELISA). The protein expression of TNF- $\alpha$ , phosphorylated inhibit- $\kappa\text{B}$  (p-I $\kappa\text{B}$ ) and CD68 in liver were assayed by Western blot. The distribution of CD68 protein in liver was observed through immunohistochemical staining. The mRNA expression of TNF- $\alpha$ , interleukin-6 (IL-6), CD14, toll-like receptor 2 (TLR2) and TLR4 in liver were assayed by real-time RT-PCR.

**RESULTS:** Predominant microvesicular change, hepatocyte tumefaction and cytoplasm dilution were observed in liver tissues after LPS administration as well as obvious CD68 positive staining in hepatic sinusoidal. After LPS stimulation, serum TNF- $\alpha$  ( $31.35 \pm 6.06$  vs  $12225.40 \pm 9007.03$ ,  $P < 0.05$ ), protein expression of CD68 ( $1.13 \pm 0.49$  vs  $3.36 \pm 1.69$ ,  $P < 0.05$ ), p-I $\kappa\text{B}$  ( $0.01 \pm 0.01$  vs  $2.07 \pm 0.83$ ,  $P < 0.01$ ) and TNF- $\alpha$  ( $0.27 \pm 0.13$  vs  $1.29 \pm 0.37$ ,  $P < 0.01$ ) in liver and mRNA expression of TNF- $\alpha$  ( $1.96 \pm 2.23$  vs  $21.45 \pm 6.00$ ,  $P < 0.01$ ), IL-6 ( $4.80 \pm 6.42$  vs  $193.50 \pm 36.36$ ,  $P < 0.01$ ) and TLR2 ( $1.44 \pm 0.62$  vs  $4.16 \pm 0.08$ ,  $P < 0.01$ ) in liver were also increased significantly. These pathological changes were all improved in JHD group. On the other hand, TLR4 mRNA ( $1.22 \pm 0.30$  vs  $0.50 \pm 0.15$ ,  $P < 0.05$ ) was down-regulated and CD14 mRNA increased but not significantly after LPS stimulation.

**CONCLUSION:** JHD can inhibit cytokine secretion pathway induced by LPS in rat liver, which is probably associated with its regulation on CD68, p-I $\kappa\text{B}$  and endotoxin receptor TLR2.

Effect of JIANPI HUOXUE decoction on inflammatory cytokine secretion pathway in rat liver with lipopolysaccharide challenge. *World J Gastroenterol* 2008; 14(12): 1851-1857 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1851.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1851>

### INTRODUCTION

When activated under physiologically challenging

conditions, such as endotoxemia or immune reactions, macrophages release large amounts of cytokines, interleukins and prostanoids, which may result in organ damage. Tumor necrosis factor alpha (TNF- $\alpha$ ) is a potent inflammatory cytokine which can exert a variety of effects on cells ranging from mitochondrial damage and oncotic or apoptotic necrosis to cell proliferation<sup>[1]</sup>. TNF- $\alpha$  may also prompt the accumulation of neutrophils (PMNs) by activating endothelial cells<sup>[1,2]</sup>. It can indirectly promote toxicity by priming PMNs to release reactive oxygen and nitrogen species and proteases that damage nearby cells<sup>[2,3]</sup>. An overproduction of TNF- $\alpha$  is associated with the development of alcoholic liver injury<sup>[4-6]</sup>. Kupffer cells, the resident macrophages in the liver, are the major producers of TNF- $\alpha$  following exposure to lipopolysaccharide (LPS), the bacterial endotoxin<sup>[7]</sup>, and play an important role in alcohol-induced liver damage<sup>[8]</sup>. It has been demonstrated that Kupffer cell-derived cytokines induced by intestinal-derived LPS involves in the mechanism of alcoholic liver disease (ALD)<sup>[8-11]</sup>.

Multiple mammalian receptors for LPS have been identified, including two glycoproteins: LPS-binding protein (LBP) and CD14. CD14 binds to the LPS-LBP complex and interact with a transmembrane toll-like receptor (TLR) responsible for signal transduction<sup>[12]</sup>. TLR4 is a specific receptor for gram-negative bacterial LPS<sup>[13]</sup>. Several observations indicate that TLR2 is also involved in LPS signaling<sup>[14-19]</sup>.

JIANPI HUOXUE decoction (JHD) consists of eight Chinese herbs. Previously, JHD was found to inhibit endotoxin levels and intestine or liver injury in ALD rats induced by Lieber-DeCarli ethanol liquid diet<sup>[20,21]</sup>. In the present study, we have isolated the LPS-induced cytokine secretion pathway from the complex conditions of ALD by employing the LPS challenging model described previously<sup>[22]</sup> to further explore the effects of JHD on this pathway. This might provide a new point of view on the mechanisms of JHD anti-alcoholic liver injury.

## MATERIALS AND METHODS

### JHD preparation

JHD consists of *Altractylodes macrocephala* Koidz., *Salvia miltiorrhiza* Bge., *Citrus aurantium* L., *Paeonia lactiflora* pall., *Pueraria lobata* (willd.) Ohwi, *Alisma orientalis* (Sam.) Juzep, *Schisandra chinensis* (Turcz.) Baill. and *Curuma longa* L. *Altractylodes macrocephala* Koidz., *Citrus aurantium* L. and *Curuma longa* L. were distilled with ethanol to get the volatilizable components for three times, each lasting 1-2 h. *Schisandra chinensis* (Turcz.) Baill. was also extracted with ethanol twice, independently, 1-2 h for each time. The other herbs were boiled with water for three times after being marinated in water for 1 h. The final density of the water-extraction was 1.08-1.12 (80°C) and the water-extraction was purified with ethanol. Finally, the volatilized components, ethanol-extraction of *Schisandra chinensis* (Turcz.) Baill. and water-extraction were mixed as the JHD. The concentration of 0.9 g crude drug/mL was used in experiments.

### Animal and treatment

Twenty-four female SD rats weighing 200 g were divided randomly into normal group ( $n = 4$ ), model group ( $n = 10$ ) and JHD group ( $n = 10$ ). Rats in model group and JHD group were administrated with normal saline or JHD *via* gastrogavage respectively, 5 mL/kg, twice a day, for 3 d. One hour after the last administration, rats in these two groups were injected with LPS (*Escherichia coli* 0111: B4, Sigma-Aldrich Co., USA) *via* tail vein, 50  $\mu$ g/kg body weight as described previously<sup>[21]</sup>. Simultaneously, rats in normal group were injected with equivalent volume of normal saline. After LPS stimulation for 1.5 h, serum and liver tissue were collected for assay.

### Histological examination

Sections of the liver sample (4  $\mu$ m thick) were stained with hematoxylin-eosin (H.E.) and examined under light microscope (Olympus Medical Systems Corp., Tokyo, Japan).

### Immunohistochemical assessment of CD68

Specimens were fixed in a 40 g/L solution of formaldehyde in 0.1 mol/L phosphate-buffed saline (pH 7.4) and embedded in paraffin wax from which 4  $\mu$ m thick sections were taken on a slide coated with poly-L-lysine (Dingguo Ltd., Beijing, China) for immunohistochemical assessment. Antigen retrieval was performed with 0.6% pepsin (Dingguo Ltd., Beijing, China) at 37°C for 10 min. The specimens were treated with 0.6% hydrogen peroxide-methanol, following 30 min of endogenous peroxidase blockage at 37°C. After blockage with 0.2% bovine serum albumin (BSA, Sino-American Biotechnology Company, Shanghai, China) for 20 min at room temperature, the samples were incubated at 4°C overnight, with a 1:100 dilution of anti-CD68 primary antibody (monoclonal anti-rat CD68, AbD Serotec, NC, USA). Following the processing of the samples incubated with a 1:250 dilution of horseradish peroxidase (HRP)-linked goat anti-mouse IgG (sc-2031, Santa Cruz Biotechnology Inc. Santa Cruz, CA) for 1 h at 37°C, diaminobenzidine (DAB) was applied as a chromogen and hematoxylin was used for floor staining.

### Measurement of serum TNF- $\alpha$ by ELISA

Serum levels of TNF- $\alpha$  were determined using a commercially available enzyme linked immunosorbent assay (ELISA) kit (Biosource International Inc., Camarillo, CA) according to the manufacturer's instruction. TNF- $\alpha$  was determined from a standard curve for the combination of these cytokines. The concentrations were expressed as pg/mL.

### Determination of CD68, phosphorylated inhibit- $\kappa$ B (p-I $\kappa$ B) and TNF- $\alpha$ level in liver tissue by Western blot

As described previously<sup>[23]</sup>, total protein was extracted from liver tissue and analyzed with bicinchoninic acid (BCA) protein concentration assay kit (Beyotime Inst. Biotechnology, Jiangsu, China). Sample protein was separated by electrophoresis in 10% SDS-PAGE separating gel with Bio-Rad electrophoresis system (Bio-

Rad Laboratories, Hercules, CA, USA). The primary antibodies (mouse anti-rat glyceraldehydes-3-phosphate dehydrogenase, GAPDH antibody, 1:5000 dilution, KANGCHEN Bio-Tech Inc., Shanghai, China; mouse anti-rat CD68 antibody, 1:100 dilution, AbD Serotec, NC, USA; mouse anti-rat p-I $\kappa$ B antibody, 1:500 dilution, Cell Signaling Technology Inc., Boston, USA; goat anti-rat TNF- $\alpha$  antibody, 1:500 dilution, R&D Systems Inc., Minneapolis, USA) were incubated at 4°C overnight. The corresponding horseradish peroxidase-conjugated secondary antibodies (goat anti-mouse IgG, peroxidase-linked antibody, 1:5000 dilution, Santa Cruz Biotechnology Inc., Santa Cruz, CA, rabbit anti goat-IgG, peroxidase-linked antibody, 1:5000 dilution, Jackson ImmunoResearch Laboratories Inc., PA, USA) were incubated at room temperature. The ECL kit (Pierce Biotechnology Inc., Rockford, USA) and the Furi FR-980 image analysis system (Shanghai Furi Co., Shanghai, China) were employed for revealing and quantitative analysis of the blots. GAPDH protein was used as the internal control.

#### Determination of TNF- $\alpha$ , interleukin-6 (IL-6), TLR2, TLR4 and CD14 mRNA levels by real-time RT-PCR

Total RNA was extracted from liver tissues of each group with the tissue/cell total RNA isolation kit (Watson Biotechnologies Inc., Shanghai, China) according to the manufacturer's protocol. The quantity and purity of RNA were detected by determining absorbance at 260/280 nm using a spectrophotometer (Unico Co., USA). Total RNA was reversely transcribed into complementary DNA (cDNA) using the cDNA synthesis kit (Fermentas Life Sciences Inc., Maryland, USA) according to the manufacturer's protocol. The Rotor Gene-3000 PCR machine (Gene Co., Hong Kong) and real-time PCR kit (SYBR<sup>®</sup> Premix Ex Taq<sup>™</sup>, TaKaRa Bio Inc., Japan) were employed based on the manufacturer's instruction. The specific primers for the target genes and  $\beta$ -actin (synthesized by Shanghai Shenggong Co.) used are described in Table 1.

Two-step PCR procedure was recommended as follows: pre-denaturation for 10 s at 95°C, 1 cycle; 95°C for 5 s and 59°C for 20 s, 40 cycles. The final products were identified by electrophoresis in 1.5% agarose gel and melt curve analysis. Two-standard curve method was employed in relative quantification analysis. Briefly, after the target gene products were emendated with internal control  $\beta$ -actin, the relative fluorescence values of target products in normal group were analysed and compared with other groups. The final results were described with the relative values. The calculation and analysis were performed by the software in the Rotor-Gene RG-3000 (Gene Co., Hong Kong).

#### Statistical analysis

All values were expressed as mean  $\pm$  SD. Comparisons were analyzed by one-way ANOVA using the SPSS 10.0 statistical package. Differences were considered statistically significant if the  $P < 0.05$ .

## RESULTS

### Effect of JHD on pathological changes of liver tissue in rats

Table 1 Primers for the target genes and  $\beta$ -actin used in real-time PCR

Target gene	Primer	Target fragment length (bp)
$\beta$ -actin	5'-TGACGAGGCCAGAGCAAGA-3'(F) 5'-ATGGGCACAGTGTGGGTGAC-3'(R)	331
TNF- $\alpha$	5'-GGCAGCCTTGTCCTTGAAGAG-3'(F) 5'-GTAGCCCACGTCGTAGCAAACC-3'(R)	171
IL-6	5'-CCACTTCACAAGTCGGAGGCTTA-3'(F) 5'-GTGCATCATCGCTGTCATACAATC-3'(R)	108
TLR4	5'-CTCACAACITCAGTGGCTGGATTTA -3'(F) 5'-TGTCTCCACAGCCACCAGATTC-3'(R)	178
TLR2	5'-GGCCACAGGACTCAAGAGCA-3'(F) 5'-AGAGGCCTATCACAGCCATCAAG-3'(R)	102
CD14	5'-GAATCCCAGTCGGAGGCGTA-3'(F) 5'-GGAGCAAAGCCAAAGTTCCTGA-3'(R)	94

H.E. staining showed predominant microvesicular change, hepatocyte tumefaction and cytoplasm dilution after LPS stimulation in the rat liver tissues. After JHD administration, those pathological changes of liver tissues were ameliorated obviously (Figure 1 A1-A3).

#### Effect of JHD on CD68 protein expression and distribution in liver tissue

CD68 immunohistochemical staining indicated that a spot of positive staining existed in hepatic sinusoidal of normal rats and obvious positive staining in the sinusoidal where hepatic microvesicular change was predominant after LPS stimulation. After JHD administration, the CD68 positive staining in the sinusoidal was lightened (Figure 1 B1-B3).

#### Effect of JHD on serum TNF- $\alpha$ level of rats

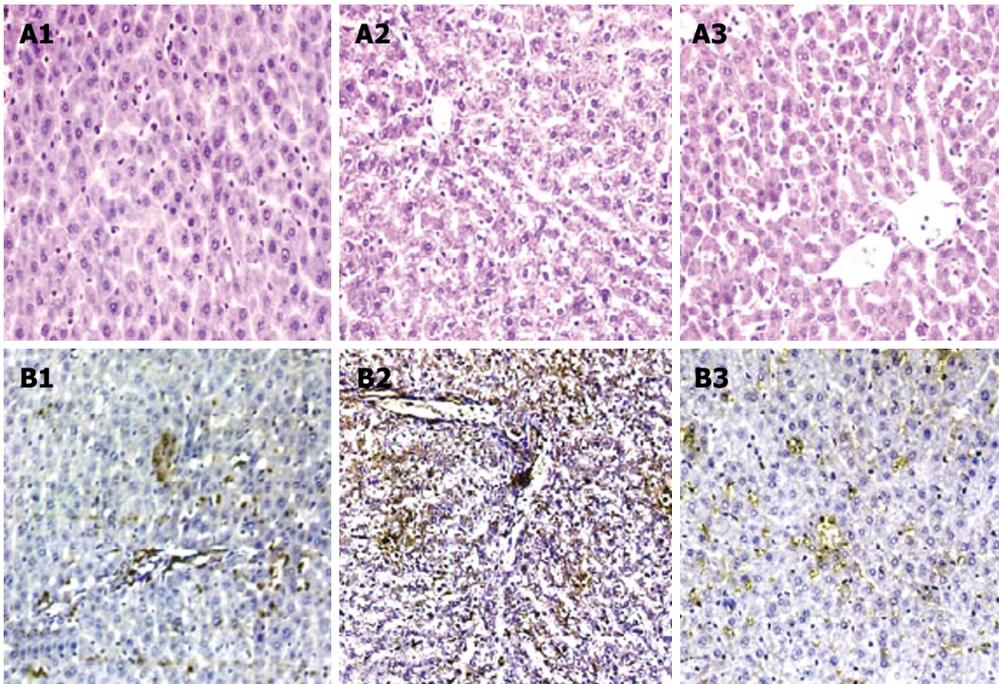

After stimulation with LPS for 1.5 h, serum TNF- $\alpha$  increased significantly ( $31.35 \pm 6.06$  vs  $12225.40 \pm 9007.03$ ,  $P < 0.05$ ) and decreased obviously in JHD group ( $12225.40 \pm 9007.03$  vs  $6031.70 \pm 2296.56$ ,  $P < 0.05$ ) (Figure 2).

#### Effect of JHD on protein expression of CD68, p-I $\kappa$ B and TNF- $\alpha$ in liver tissues

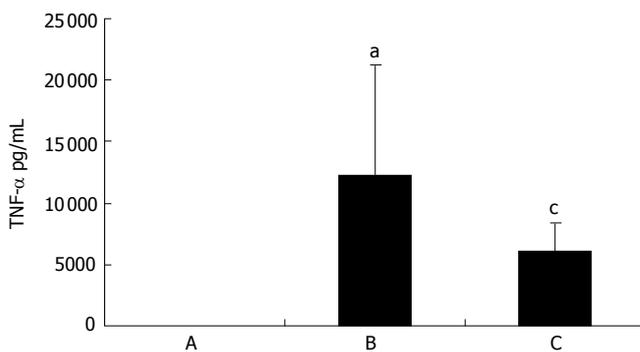

After stimulation with LPS for 1.5 h, protein expression of CD68, p-I $\kappa$ B and TNF- $\alpha$  in liver tissues were increased significantly (CD68:  $1.13 \pm 0.49$  vs  $3.36 \pm 1.69$ ,  $P < 0.05$ ; p-I $\kappa$ B:  $0.01 \pm 0.01$  vs  $2.07 \pm 0.83$ ,  $P < 0.01$ ; TNF- $\alpha$ :  $0.27 \pm 0.13$  vs  $1.29 \pm 0.37$ ,  $P < 0.01$ ) and decreased significantly (CD68:  $3.36 \pm 1.69$  vs  $0.76 \pm 0.45$ ,  $P < 0.05$ ; p-I $\kappa$ B:  $2.07 \pm 0.83$  vs  $0.87 \pm 0.83$ ,  $P < 0.01$ ; TNF- $\alpha$ :  $1.29 \pm 0.37$  vs  $0.67 \pm 0.36$ ,  $P < 0.01$ ) in JHD group (Figure 3).

#### Effect of JHD on mRNA expression of TNF- $\alpha$ , IL-6, TLR2, TLR4 and CD14 in liver tissues

After stimulation with LPS for 1.5 h, mRNA expression of TNF- $\alpha$ , IL-6 and TLR2 in liver were increased significantly (TNF- $\alpha$ :  $1.96 \pm 2.23$  vs  $21.45 \pm 6.00$ ,  $P < 0.01$ ; IL-6:  $4.80 \pm 6.42$  vs  $193.50 \pm 36.36$ ,  $P < 0.01$ ; TLR2:  $1.44 \pm 0.62$  vs  $4.16 \pm 0.08$ ,  $P < 0.01$ ) and decreased obviously in JHD group (TNF- $\alpha$ :  $21.45 \pm 6.00$  vs  $11.99 \pm 2.28$ ,  $P < 0.01$ ; IL-6:  $193.50 \pm 36.36$  vs  $76.12 \pm 32.16$ ,  $P < 0.01$ ; TLR2:  $4.16 \pm 0.08$  vs  $3.11 \pm 0.53$ ,  $P < 0.01$ ).

**Figure 1** Effects of JHD on pathological changes and CD68 protein expression and distribution in liver tissue. **A:** HE stain ( $\times 400$ ); **A1:** Liver tissue in normal group; **A2:** Liver tissue in model group; **A3:** Liver tissue in JHD group; **B:** CD68 immunohistochemical stain ( $\times 200$ ); **B1:** Liver tissue in normal group; **B2:** Liver tissue in model group; **B3:** Liver tissue in JHD group.

**Figure 2** Effect of JHD on serum TNF- $\alpha$  level of rats. **A:** Normal group; **B:** Model group; **C:** JHD group. <sup>a</sup> $P < 0.05$  vs A; <sup>c</sup> $P < 0.05$  vs B.

On the other hand, TLR4 mRNA expression was down-regulated ( $1.22 \pm 0.30$  vs  $0.50 \pm 0.15$ ,  $P < 0.05$ ) and mRNA expression of CD14 was increased but not significantly after LPS stimulation for 1.5 h (Figure 4).

## DISCUSSION

Gut-derived LPS is the primary endogenous endotoxin of gram-negative bacteria<sup>[9]</sup>. Extended ethanol exposure can lead to gut leakage<sup>[26]</sup> and the gut-derived LPS consequently enter the circulation. Previous researches have confirmed that LPS promoted the phosphorylation of inhibit- $\kappa$ B ( $\kappa$ B), transferred the NF- $\kappa$ B into nuclear, consequently promoted cytokines production in Kupffer cells, which was involved in the pathogenesis of ALD<sup>[9-12,24,25]</sup>.

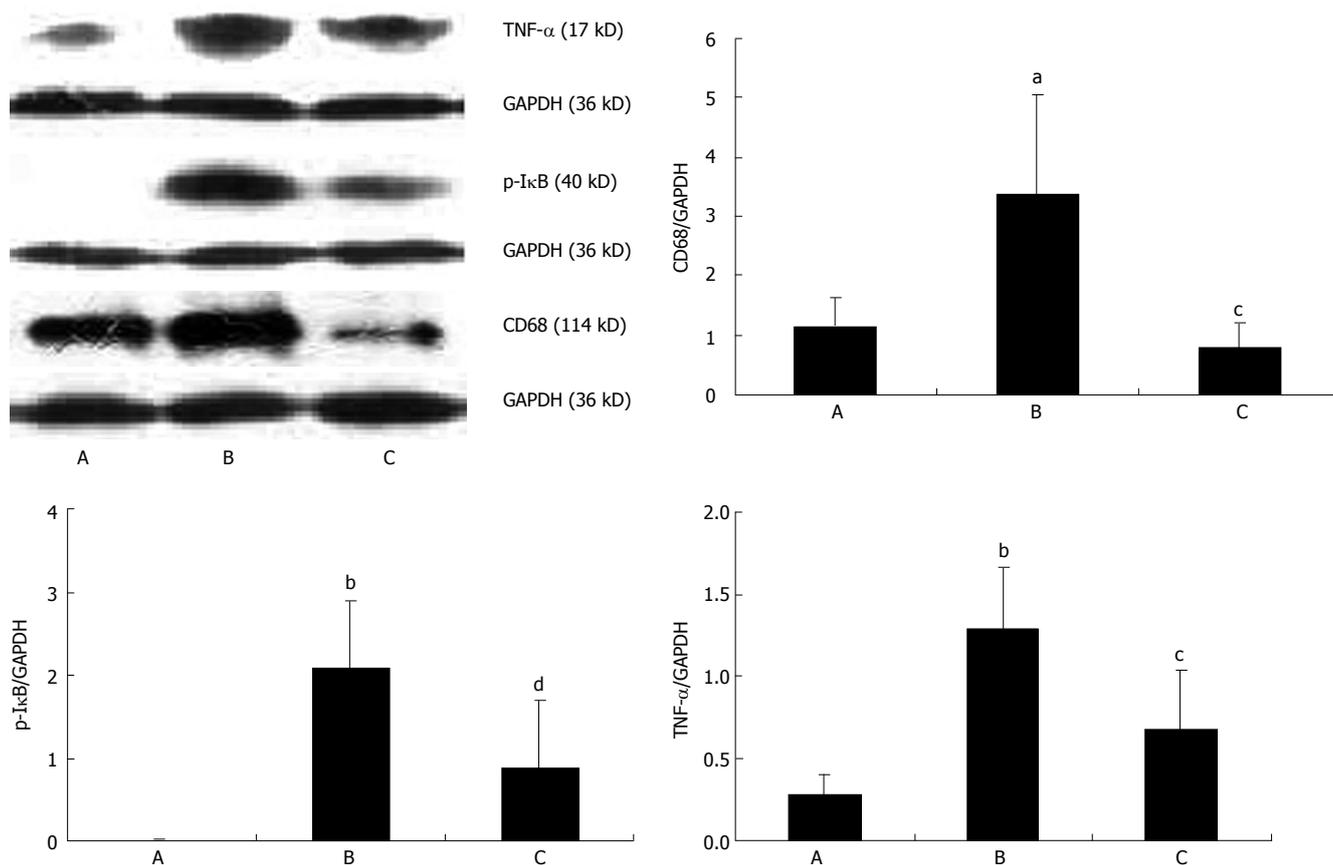

In the present research, the predominant microvesicular change, hepatocyte tumefaction and cytoplasm dilution were observed in liver tissues after LPS stimulation, and simultaneously, CD68, the specific antigen-molecule on the macrophage, was identified predominantly in the sinusoidal. The protein and/or gene expression of

inflammatory factors, such as TNF- $\alpha$  and IL-6, and the protein expression of CD68 and p-I $\kappa$ B were also increased by LPS stimulation. On the contrary, JHD inhibited the pathological changes significantly.

The endotoxin receptors are necessary for LPS signal transferring. CD14, TLR4 and TLR2 have been identified as the main endotoxin receptors<sup>[12-19]</sup>.

Soluble CD14 (sCD14) exists in blood and membrane CD14 (mCD14) anchors on the membrane of peripheral or liver resident macrophage (Kupffer cell) through glycosylphosphatidylinositol (GPI). LPS-LBP complex combines with mCD14 and activated cells through TLR-4<sup>[27]</sup>. CD14 has also been found to bind lipoteichoic acid (LTA) and peptidoglycan (PGN) from the cell wall of gram-positive bacteria and activate cells through TLR2<sup>[27]</sup>. The expression of CD14 stimulated by LPS was reported as a dynamic process. C Fearn's *et al*<sup>[28]</sup> found that 1 h after intraperitoneal injection of LPS, CD14 mRNA was induced in the liver of mice but not significantly, and peaked at 8-16 h. By 24 h, the level of CD14 mRNA returned to the basal level. In the present study, we also found that 1.5 h after injection of LPS *via* tail vein, the level of CD14 mRNA increased but not significantly, which might suggest that at this time point, CD14 gene level did not reach the peak in this model.

TLR4 has been proved to be the specific receptor for the LPS of gram-negative bacteria<sup>[11,29]</sup>. The reports on TLR4 mRNA expression stimulated by LPS were not consistent. Matsumura T *et al*<sup>[18]</sup> found when mice were administered LPS, TLR4 mRNA was decreased in the brain, increased in the heart and lung and not affected in the liver, kidney, and spleen. In the study by Choda Y *et al*<sup>[30]</sup>, TLR4 mRNA level was increased 0.5 h after intraportal LPS administration, but decreased thereafter. Liu XW *et al*<sup>[31]</sup> found that 3 h after intraperitoneal injection LPS in

**Figure 3** Effect of JHD on protein expression of CD68, p-I $\kappa$ B, TNF- $\alpha$  in liver tissue. A: Normal group; B: Model group; C: JHD group. <sup>a</sup> $P < 0.05$  vs A; <sup>b</sup> $P < 0.01$  vs A; <sup>c</sup> $P < 0.05$  vs B; <sup>d</sup> $P < 0.01$  vs B.

mice, *TLR4* mRNA was down-regulated in liver and failed to be detected by 6-12 h, but resumed to the basal level by 24 h. In our research, significant decrease of *TLR4* mRNA expression was observed in liver 1.5 h after LPS administration, which was consistent with the report by Y Choda.

The primary ligands of TLR2 are gram-positive bacteria-derived lipoteichoic acid (LTA), peptidoglycan (PGN) and mycobacterial lipoarabinomannan<sup>[32]</sup>. Previous reports suggested that neither human nor murine TLR2 plays a role in LPS signaling<sup>[15,33]</sup>. But the subsequent research<sup>[34]</sup> found that phenol repurified LPS did not activate cells from TLR2-mediated signaling, but the commercially prepared LPS contained low concentrations of highly bioactive contaminants described previously as endotoxin protein activated TLR2-mediated signaling. On the other hand, myeloid differentiated protein-2 (MD-2) which is necessary for TLR4-mediated LPS signaling was also proved to enable TLR2 to respond to endotoxin protein-free LPS and enhance TLR2-mediated responses to both gram-negative bacteria and their LPS<sup>[16]</sup>. Furthermore, the cytokines induced by LPS, such as interleukin-1 beta (IL-1 $\beta$ ) or TNF- $\alpha$ , also up-regulate *TLR2* mRNA of rat hepatocyte *in vivo* and *in vitro*<sup>[17]</sup>. As a result, LPS from gram-negative bacteria does not induce TLR2 expression directly, but induced the commercial LPS containing endotoxin protein indirectly. LPS-derived

cytokine and MD-2 can induce TLR2 expression greatly. Our results also suggested that *TLR2* mRNA was up-regulated significantly in liver after LPS administration. And as expected, *TLR2* mRNA in JHD group decreased significantly.

In conclusion, the present study confirmed that the inhibitory effects of JHD on cytokines (TNF- $\alpha$ , IL-6) protein or gene expression induced by LPS in liver is associated with its inhibition on the LPS-activated Kupffer cell signal pathway, including CD68 and p-I $\kappa$ B protein expression and *TLR2* mRNA expression.

## COMMENTS

### Background

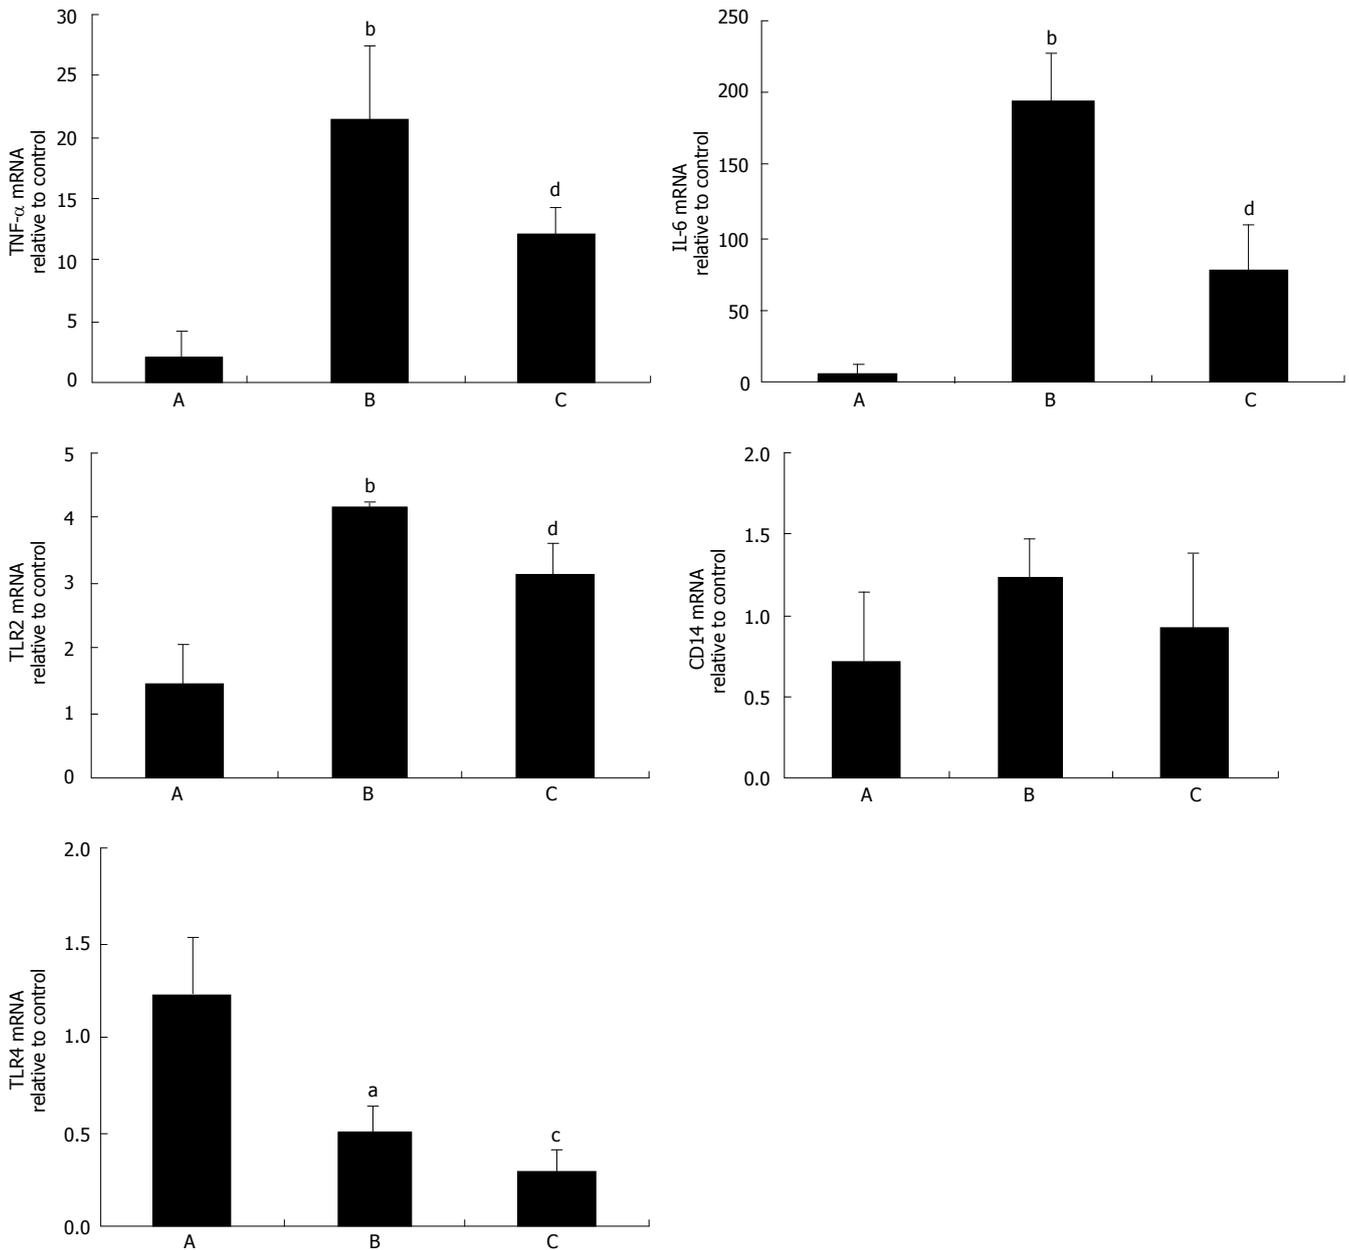

The "two-hits" theory brought about great advancement in pathogenesis research of alcoholic liver disease (ALD). Attention has been attracted in the mechanism of endotoxin or lipopolysaccharides (LPS) signal pathway involved in ALD. The resident macrophage in liver, Kupffer cells, is an important target cell of LPS and secreting cytokines. The endotoxin receptors, identified as CD14, toll-like receptor (TLR) 4, are essential for LPS signaling.

### Research frontiers

In this study, the expression of endotoxin receptors, CD14, TLR4 and TLR2 was observed after LPS or LPS + JHD administration. The difference of endotoxin receptors expression under similar challenge conditions is interesting, especially, TLR4 and CD14.

### Innovations and breakthroughs

This study confirmed one of the possible mechanisms of JHD, a Chinese

**Figure 4** Effect of JHD on mRNA expression of TNF- $\alpha$ , IL-6, TLR2, TLR4, CD14 in liver tissue. A: Normal group; B: Model group; C: JHD group. <sup>a</sup> $P < 0.05$  vs A; <sup>b</sup> $P < 0.01$  vs A; <sup>c</sup> $P < 0.05$  vs B; <sup>d</sup> $P < 0.01$  vs B.

herbs decoction, on anti-alcoholic liver injury, inhibiting some targets in LPS-activated cytokine secretion pathway, such as CD68, the specific molecular marker of macrophage, phosphorylated inhibit- $\kappa$ B ( $p$ -I $\kappa$ B) and TLR2, the endotoxin receptor.

### Applications

The present study provides a new experimental evidence of JHD inhibition alcoholic liver injury. To further evaluate the effects of JHD on Kupffer cell activation and endotoxin receptors expression induced by LPS, the multiple-time point observation and isolated Kupffer cells should be employed in the subsequent experiments.

### Terminology

Lipopolysaccharide (LPS), the major composition of gram-negative bacterial wall, can excite intensive inflammation reaction.

### Peer review

This is an interesting paper, describing the effects of a traditional Chinese medicine on the LPS activated Kupffer cells of murine liver. Methodology used is sound, results are well presented and analyzed, and conclusions are documented

by the findings of the study.

Over-expressed and truncated midkines promote proliferation of BGC823 cells *in vitro* and tumor growth *in vivo*. *World J Gastroenterol* 2008; 14(12): 1858-1865 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1858.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1858>

### Abstract

**AIM:** To determine whether midkine (*MK*) and its truncated form (*tMK*) contribute to gastric tumorigenesis using *in vitro* and *in vivo* models.

**METHODS:** Human *MK* and *tMK* plasmids were constructed and expressed in BGC823 (a gastric adenocarcinoma cell line) to investigate the effect of over-expressed *MK* or *tMK* on cell growth and tumorigenesis in nude mice.

**RESULTS:** The growth of *MK*-transfected or *tMK*-transfected cells was significantly increased compared with that of the control cells, and *tMK*-transfected cells grew more rapidly than *MK*-transfected cells. The number of colony formation of the cells transfected with *MK* or *tMK* gene was larger than the control cells. In nude mice injected with *MK*-transfected or *tMK*-transfected cells, visible tumor was observed earlier and the tumor tissues were larger in size and weight than in control animals that were injected with cells without the transfection of either genes.

**CONCLUSION:** Over-expressed *MK* or *tMK* can promote human gastric cancer cell growth *in vitro* and *in vivo*, and *tMK* has greater effect than *MK*. *tMK* may be a more promising gene therapeutic target compared with *MK* for treatment of malignant tumors.

### INTRODUCTION

Midkine (*MK*), a heparin-binding growth factor, was discovered through screening for factors that mediate retinoic acid-induced cell differentiation by Kadomatsu in 1988<sup>[1]</sup>. *MK* is a cysteine- and basic amino acid-rich protein, which is composed of two domains, i.e., N- and C-terminal half domains. The two domains are linked by a flexible linker region. Although the precise relationship between structural features and biological activities remains to be elucidated, it is interesting that only the C-terminal half domain of *MK* retains biological activities<sup>[2,3]</sup>. *MK* gene maps to band 11p11.2<sup>[4]</sup> and consists of five exons. Exon 1 does not encode amino acid sequence. Exon 2 encodes the hydrophobic leader sequence, which constitutes the beginning of gene translation. The signal peptide cleavage site lies toward the 3' end of exon 2<sup>[2]</sup>. A truncated form of *MK* (*tMK*), which lacks exon 3 encoding the N-terminal half, was found in pancreatic carcinoma cell lines by Kaname in 1996<sup>[5]</sup>. Recently two novel truncations of the *MK*, *tMKB* and *tMKC*, were found in a number of tumor cell lines, including A549 cells (lung adenocarcinoma), SGC-7901 cells (gastric cancer), 8910 cells (ovarian tumor) and MG-63 cells (osteosarcoma)<sup>[6]</sup>.

Many evidences showed that *MK* is expressed at higher levels in various tumors, such as digestive, lung, liver and breast cancers, neuroblastoma and Wilms' tumor<sup>[7-10]</sup>. *tMK* was found in pancreatic, gastric, Wilms', colorectal, bile duct and breast tumors, but not in non-cancerous and normal tissues<sup>[5,11-14]</sup>. *MK* can promote Wilms' tumor cell proliferation and tumor angiogenesis<sup>[7,10,15]</sup>, inhibit tumor cell apoptosis, induce transformation of NIH3T3 cells, and protect patocellular carcinoma (HCC) cells

against TRAIL-mediated apoptosis<sup>[16-19]</sup>. *MK* and *tMK* are correlated positively with metastasis of HCC, prostate carcinomas, Lewis lung carcinoma, gastric cancer<sup>[20-23]</sup> and gastrointestinal carcinomas<sup>[24]</sup>. They can induce the transformation of SW-13 cells and shorten the latency of tumor formation in nude mice<sup>[25]</sup>.

Our previous study also showed that *MK* highly expressed in gastric cancer tissues of Chinese patients, and the expressions of *MK* mRNA and protein were both associated with the clinical stage and distant metastasis of gastric cancer<sup>[26]</sup>. Therefore, it is necessary to determine the roles of *MK* and *tMK* in both tumorigenesis and tumor development in gastric cancer. BGC823 cell is a poorly differentiated gastric adenocarcinoma cell line and is an idea *in vitro* model for studying the tumorigenic activity. In the present study, we obtained human *MK* and *tMK* cDNA from gastric carcinoma tissues, constructed *MK* or *tMK* over expression plasmids (Figure 1), and then transfected the plasmids into BGC823 cell to study the effect of *MK* and *tMK* on tumorous characteristics *in vitro* and *in vivo*.

## MATERIALS AND METHODS

### Plasmids construction

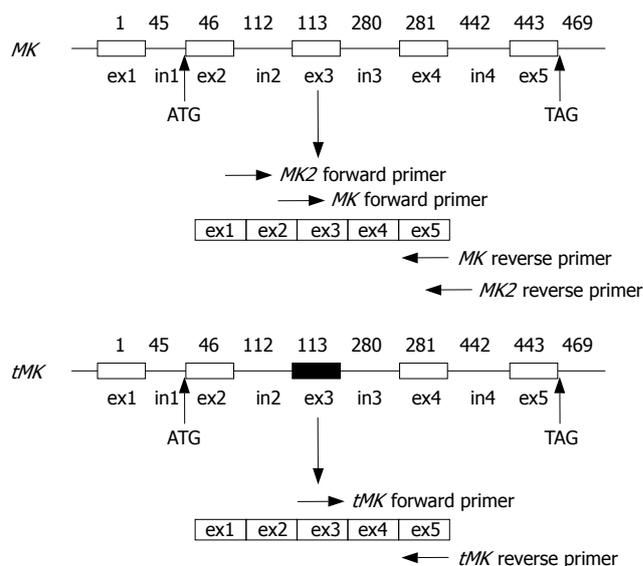

Plasmids with *MK* and *tMK* eukaryotic expression were constructed<sup>[2,5,13]</sup> (Figure 1). In our previous work, we designed pMD18-T-*MK* and pMD18-T-*tMK* vector<sup>[27,28]</sup>, and prepared the human *MK* and *tMK* DNA fragments by PCR using *MK-1* and *tMK* primers, (Table 1). The products of PCR digested with *Hind*III and *Eco*R I were inserted into the eukaryotic expression plasmid vector pcDNA3.1 (+) (Invitrogen, Carlsbad, CA, USA), which resulted in the formation of pcDNA3.1/*MK* and pcDNA3.1/*tMK*. The resultant recombinant plasmids were characterized by detailed restriction digestion (Figure 2).

### Cell culture and transfection

BGC823, a poorly differentiated gastric adenocarcinoma cell line, was cultured in RPMI medium 1640 (Gibco/BRL) supplemented with 10% fetal calf serum (Si Ji Qing, China) at 37°C under 5% humidified CO<sub>2</sub> and 100 µg/mL each of streptomycin and penicillin G (Amresco, USA). The plasmid was transfected using Lipofectamine 2000 reagent (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's instructions. Briefly, approximately 0.8 × 10<sup>5</sup> cells/well were grown overnight in 24-well plates. When the cells reached 90%-95% confluence, they were transfected with 0.8 µg of pcDNA3.1/*MK* or pcDNA3.1/*tMK* or pcDNA3.1 in serum-free medium using Lipofectamine 2000. After 4 h incubation at 37°C, 400 µL RPMI 1640 with 10% FBS was added. Stable transfectants were selected in the presence of 400 mg/L G418 (Amersco) during 2 wk of culture.

### RNA extraction and RT-PCR

Total RNA was extracted using the TaKaRa RNAiso Reagent (TaKaRa, Japan) according to the manufacturer's instructions. RNA concentrations were quantified by spectrophotometer at 260 nm. One µg total RNA was reverse-transcribed using Revert Aid™ First Strand cDNA Synthesis Kit (Fermentas, USA). Subsequently, 2 µL

**Figure 1** Illustration of *MK* and *tMK* gene DNA structures. Arrowheads indicate the sites of primer complemented with *MK* or *tMK* mRNA.

of the incubation mixture was used as the template for the following PCR using 2 × Taq enzyme mix kit (Tian Gen, China). Primers were synthesized by Bioasia (Shanghai, China) and are listed in Table 1. PCR was carried out for 28 or 30 cycles of denaturation (30 s at 94°C), annealing (40 s at 55°C), and extension (30 s at 72°C). The PCR products were then detected on 1% agarose gel containing 0.5 mg/L ethidium bromide. The gel was put on an UV-transilluminator and photographed. The *MK* signal was measured by a densitometer and standardized against the β-actin signal using a digital imaging and analysis system (SmartSpec™ Plus, BIO-RAD, USA).

### Western blot analysis

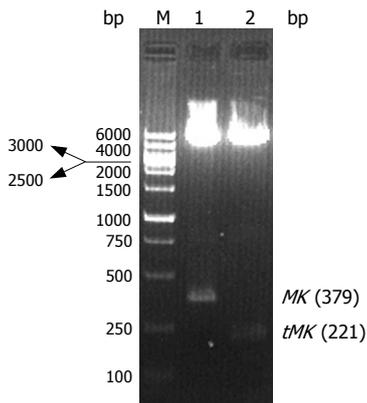

Cells (1 × 10<sup>7</sup>) were lysed in a buffer containing 50 mmol/L Tris-Cl, pH8.0, 150 mmol/L NaCl, 0.02% NaN<sub>3</sub>, 0.1% SDS, 100 mg/L phenylmethylsulfonyl fluoride (PMSF) and 1 mg/L Aprotinin, 1% Triton. After centrifugation, cell lysates (75 µg/lane) were subjected to 15% SDS-PAGE and transferred onto polyvinylidene difluoride membranes (Millipore, USA). The membranes were blocked for 1 h in PBST (10 mmol/L Tris-HCl, pH 7.4, 150 mmol/L NaCl, 0.05% Tween-20) containing 2% nonfat dried milk. Antibodies specific for *MK* (1:400, BA1263, Boster, China), β-actin (1:400, BA0410, Boster) and HRP-conjugated goat anti-rabbit secondary antibody (1:2000, BA1054, Boster) were used. Protein bands were detected by the enhanced chemiluminescence (ECL) reaction (Kibbutz Beit Haemek, Israel).

### Proliferation analysis

Cell viability was assessed with a Cell Counting Kit (Dojin Laboratories, Kumamoto, Japan). Briefly, BGC823 cells transfected with pcDNA3.1/*MK*, pcDNA3.1/*tMK*, or pcDNA3.1 and parental BGC823 cells were plated onto 96-well plates in RPMI 1640 supplemented with 10% FBS at a density of 3 × 10<sup>3</sup> cells/well. After 4 h, the medium

was changed to serum-free medium, and the cells were cultured  $\leq 2$  d. Ten microliter of a solution containing 4-[3-(2-methoxy-4-nitrophenyl)-2-(4-nitrophenyl)-2H-5-tetrazolio]-1,3-benzene disulfonate sodium salt (WST-8) was added to each well. Following incubation of an additional 4 h, the absorbance was measured at 450 nm with a multi-detection microplate reader (Hynergy<sup>TM</sup> HT, BIO-TEK, USA).

### Colony formation in soft agar

To perform the soft agar assay, a base layer of 0.5% (w/v) agar was prepared by adding autoclaved 1% (w/v) agar solution to 2x RPMI-1640 supplemented with 20% fetal calf serum at a 1:1 ratio. Stable transfectants or parental cell suspension containing  $2 \times 10^5$  cells were prepared in a 1:1 mixture of 0.7% (w/v) agar solution and 2x RPMI-1640 supplemented with 20% FCS. Cell suspension was added to the top of the base layer, allowed to solidify, and the plate was incubated at 37°C in a humidified 5% CO<sub>2</sub>. The plates were incubated for 10-15 d. The number of colonies was determined by direct counting under microscopy. Counts were expressed as number of colonies per plate on average from three independent experiments.

### Wound healing assay

The transfected BGC823 cells with pcDNA3.1/MK, pcDNA3.1/tMK or pcDNA3.1 and parental cells were plated onto 6-well plates in RPMI 1640 supplemented with 10% FBS at a density of  $2 \times 10^5$  cells/well. After 4 h, the medium was changed to serum-free medium. After 24 h, a plastic cell scraper was used to make an approximate 0.6 mm gap on the cell monolayer. Migration was quantitated by determining the distance between the cell edges at 0, 24 h and 48 h at the four marked locations on each well, using

an inverted microscope with a scale in the eyepiece<sup>[29]</sup>. The results of the four readings from each well were averaged. Experiments were repeated three times.

### Tumorigenicity study in vivo

Female BALB/c nude mice (5-6 wk old) were obtained from Vital River Lab Animal Co, Ltd, Beijing Laboratory Animal Research Center (Beijing, China). Cultured cells were harvested by trypsinization, washed and suspended in PBS at  $10^7$  cells/mL. One hundred  $\mu$ L cell suspensions were injected subcutaneously into the flank of female nude mice (seven mice per cell line). Tumor diameters were measured on d 14, 21 and 28, and tumor volume in mm<sup>3</sup> was calculated by the formula: Volume = (width)<sup>2</sup>  $\times$  length/2. Tumor growth rates were calculated by the formula: TGR = (V<sub>28th</sub> - V<sub>21th</sub>)/7 d. Data were presented as mean  $\pm$  SE. Twenty-eight days after injection, nude mice were sacrificed, and the tumors were removed, photographed and weighed.

### Immunohistochemistry

Immunostaining was performed on 6- $\mu$ m tissue sections using strept-avidin-biotin staining kit (Boster). For antigen retrieval, slides were heated by microwave in 0.01 mol/L Tri-sodium citrate buffer. Nonspecific binding sites were blocked with 5% BSA for 30 min and endogenous peroxidase activity was suppressed by treatment with 3% H<sub>2</sub>O<sub>2</sub> in methanol for 30 min. Sections were exposed to rabbit polyclonal anti-MK antibody (1:250, Boster) overnight at 4°C. 3,3'-diamino-benzidine was used as chromogen (Boster). Counterstaining was done with hematoxylin. Negative control sections were incubated with PBS instead of anti-MK antibodies. In each step, samples were washed with PBS.

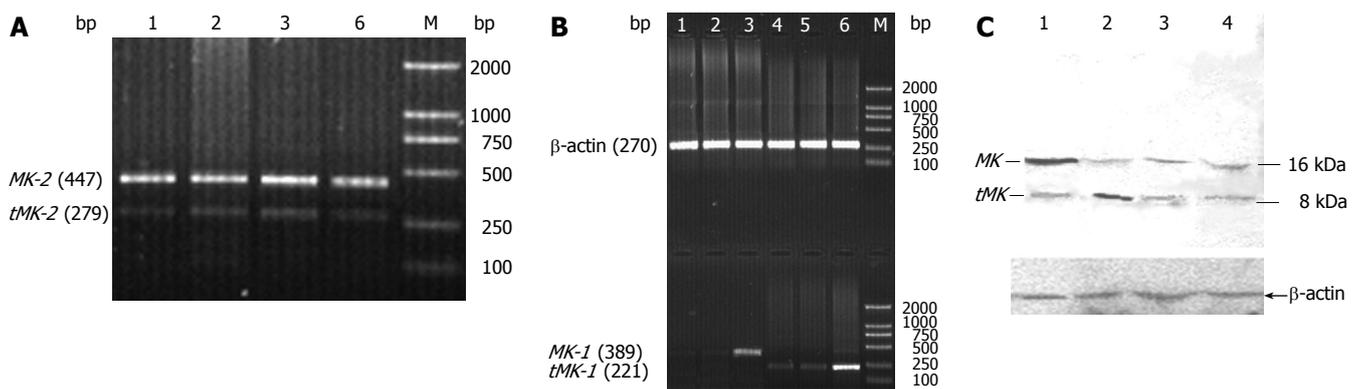

### Statistical analysis

Results were presented as mean  $\pm$  SE. Statistical significance between groups was analyzed by one-way ANOVA followed with the Student-Newman-Keuls multiple comparison tests. A *P* value of  $< 0.05$  was considered significant. Frequency of tumorigenesis in nude mice was calculated by Fisher's exact test.

## RESULTS

### Expression of MK and tMK

To evaluate the roles of MK and tMK in gastric tumorigenesis, we used transfection assay to obtain a

**Figure 3** RT-PCR (**A**, **B**) and Western blotting (**C**) analysis of the expression of *MK* or *tMK* in BGC823 after transfection. **A** and **B**, M: DNA molecular weight standards, DL2000 (TaKaRa); Lane 1 and 4: BGC823; Lane 2 and 5: BGC823/vector; Lane 3: BGC823/*MK*; Lane 6: BGC823/*tMK*. **C**, Lane 1: BGC823/*MK*; Lane 2: BGC823/*tMK*; Lane 3: BGC823/vector; Lane 4: BGC823.

*MK* or *tMK* over-expressed gastric cell line. RT-PCR and Western blotting were performed to determine *MK* or *tMK* expression level in the transfected gastric carcinoma cells. Compared with the parental cells and pcDNA3.1 transfected cells, transfection of BGC823 cells with pcDNA3.1/*MK* or pcDNA3.1/*tMK* resulted in significant enhancement of *MK* or *tMK* expression in BGC823 cells. These results indicated that transfection of pcDNA3.1/*MK* and pcDNA3.1/*tMK* was successful (Figure 3B and C).

#### Effect of over-expression of *MK* or *tMK* on BGC823 cells

To determine whether over-expression of *MK* and *tMK* could affect the BGC823 cell growth, cell proliferation activity was detected using Cell Counting Kit. The transfection of pcDNA3.1/*MK* or pcDNA3.1/*tMK* to BGC823 significantly increased the proliferation of BGC823 cells compared with the control. This showed that over-expressed *MK* or *tMK* could accelerate the cellular proliferation at 12 h, 24 h, 36 h and 48 h. Moreover, *tMK* exhibited stronger stimulatory effect than *MK* (Figure 4A). No difference between BGC823/vector and BGC823 was detected (Figure 4A). Furthermore, colony-forming assay was conducted in BGC823, BGC823/vector, BGC823/*MK* and BGC823/*tMK* (Figure 4B and C). The results showed that the colony number of BGC823/*MK* and BGC823/*tMK* cells was increased by 2- to 3-fold compared with BGC823 and BGC823/vector (Figure 4C). In addition, the wound healing assay also showed that over-expressed *MK* or *tMK* could induce significant migration of the cell at 24 h and 48 h, about 1.5-fold over BGC823 and BGC823/vector cells, and *tMK* showed stronger effect than *MK* (Figure 4D). These results demonstrated that over-expression of *MK* and *tMK* significantly enhanced the malignant state and invasive ability of BGC823 cells.

#### Tumor growth promoted by *MK* or *tMK* in vivo

As the over-expression of *MK* or *tMK* significantly changed the behavior of BGC823 cells *in vitro*, it is necessary to analyze the tumorigenicity of the stable transfectant *in vivo*. The time and frequency of visible tumor in nude mice treated with BGC823, BGC823/vector, BGC823/*MK* and BGC823/*tMK*, respectively, are

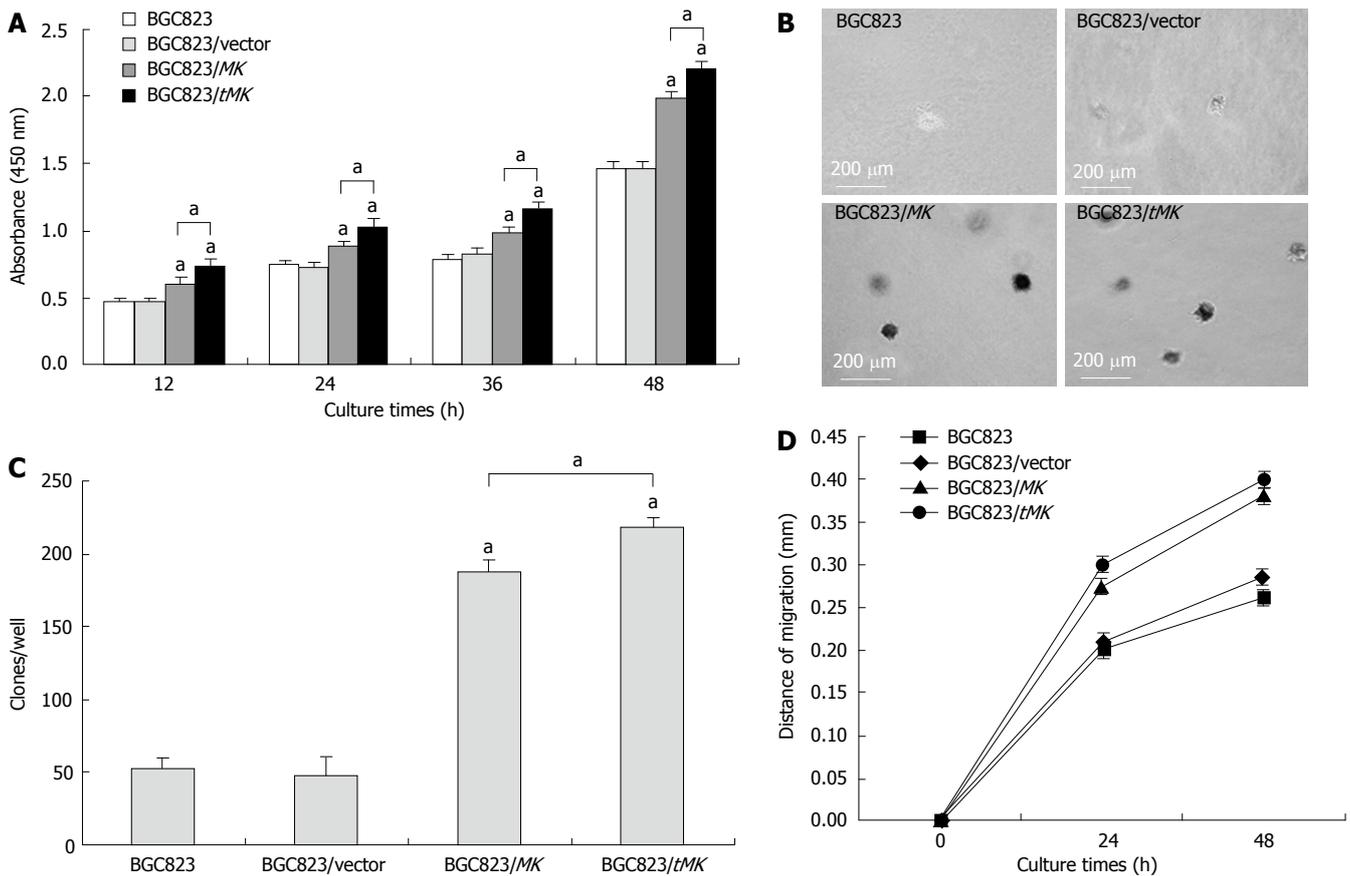

presented in Table 2. Tumor was clearly observed in most BGC823/*MK*- and all BGC823/*tMK*-injected mice at d 7, whereas visible tumor formed in about half of BGC823/vector and BGC823 injected mice until d 14. Furthermore, tumor diameters and volume were subsequently measured at d 14, 21 and 28. The results showed that tumor volumes of mice injected with BGC823/*MK* or BGC823/*tMK* cells were significantly larger than the control at d 21 and 28 (Figure 5C). Tumor growth rate (TGR) from d 21 to 28 showed that the TGR of nude mice injected with BGC823/*MK* or BGC823/*tMK* was significantly higher than the control mice (Figure 5D). At d 28 after inoculation, the tumors were removed, photographed and weighed. The tumor in mice injected with BGC823/*MK* and BGC823/*tMK* cells was 2-fold of that of the control (Figure 5B), and tumors in two mice injected with BGC823/*tMK* cells had erosive appearance (Figure 5A). Apparently, BGC823/*MK* or BGC823/*tMK* transfected cells could multiply and grow earlier and more rapidly than the BGC823 and BGC823/vector control cells in nude mice.

#### Immunohistochemical analysis

To detect whether BGC823/*MK*- or BGC823/*tMK*-transfected cells can stably express *MK* or *tMK* in nude mice for an extended period and the association between tumor growth and *MK* or *tMK* protein levels, immunohistochemical staining was conducted. *MK* was detected in cytoplasm and nucleus of tumor cells from different treatment groups of mice. The number and density of the positive points in tumor tissues induced with BGC823/*MK* and BGC823/*tMK* cells were evidently higher than the cells treated with BGC823 and BGC823/vector (Figure 6).

## DISCUSSION

To determine whether *MK* and *tMK* contribute to gastric tumorigenesis and tumor development, BGC823 cells that over-expressed *MK* and *tMK* genes, and nude mice inoculated with the BGC823 cells over-expressing either *MK* or *tMK* were used as model systems *in vitro* and *in vivo*, respectively. To show that the upregulated *MK* and *tMK*

**Figure 4** Effects of over-expressed *MK* or *tMK* on BGC823 cells *in vitro*. **A**: The cell proliferation determined by Cell Counting Kit ( $P < 0.05$ ); **B**: Colony formation in soft agar observed under light microscope; **C**: Comparison of colony numbers. **D**: Analysis of cell migration.

were exogenous in the transfected cells, we designed another pair of primers for *MK-2* sequence (Table 1)<sup>[5]</sup>. The forward primer of *MK-2* was complemented with the start section of exon 2, and the reverse primer was complemented with exon 5 and several base pairs of 3'-untranslated regions. *tMK* lacks exon 3, so *MK* (448 bp) and *tMK* (296 bp) DNA were obtained at the same time by RT-PCR using primers for *MK-2*. There was no significant difference in the expression of *MK* and *tMK* between transfected cells and parental cells. The state in those cells transfected with or without *MK* and *tMK* genes can imitate *MK* and *tMK* expression from initial to metastatic stages of tumor formation.

Previous studies showed that the over-expression of *MK* in S462 cell (malignant peripheral nerve sheath tumor cell line) could increase the cell viability and protect the cells from apoptosis under serum deprivation, but did not induce the proliferation of S462 cells to promote xenograft tumor growth in nude mice<sup>[16]</sup>. *MK* and *tMK* can induce the transformation of SW-13 cells (adrenal carcinoma cell line) and shorten the latency of tumor formation in nude mice, but SW-13/*MK* and SW-13/*tMK* showed no difference in tumor growth rate from the control<sup>[25]</sup>. However in our study, the growth of BGC823 cells which over-expressed *MK* and *tMK*, was increased significantly compared with the control cells. The tumor formation time was shortened in nude mice injected with BGC823/*tMK* or BGC823/*MK* cells. Tumor growth rate of was significantly higher than the control, and tumor volume and weight were higher than the control, indicating that the idiographic effect of

BGC823/ <i>MK</i>	7	5 (71.43) <sup>a</sup>	6 (85.71) <sup>a</sup>	7 (100)	
BGC823/ <i>tMK</i>	7	7 (100) <sup>b</sup>			

*P* value was calculated by Fisher's exact test. 7 d: BGC823/*MK* vs BGC823 or BGC823/vector,  $P = 0.0105$ ; BGC823/*tMK* vs BGC823 or BGC823/vector,  $P = 0.0003$ . 14 d: BGC823/*MK* vs BGC823,  $P = 0.0174$ ; BGC823/*MK* vs BGC823/vector,  $P = 0.0489$ . <sup>a</sup> $P < 0.05$ ; <sup>b</sup> $P < 0.01$ .

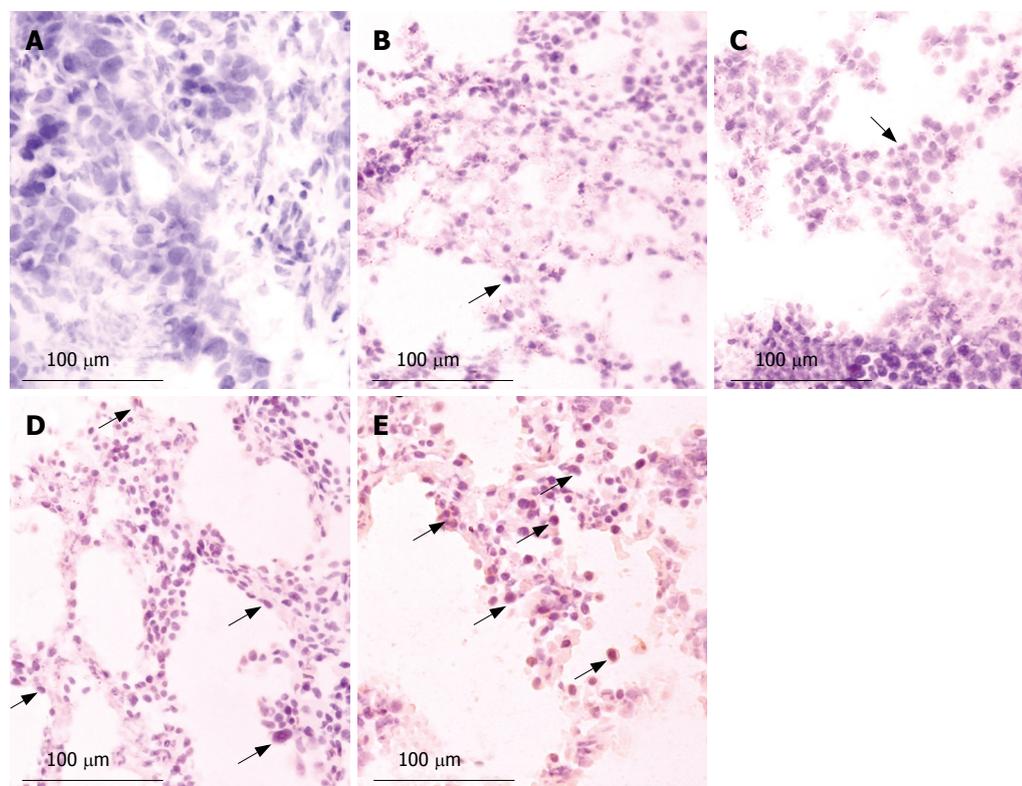

*MK* and *tMK* on tumorigenesis and tumor development may be related to types of tumors.

*MK* and *tMK* are heparin-binding growth factors. They play fundamental roles in the regulation of cell differentiation and development. Their aberrant expressions are usually associated with tumorigenesis<sup>[30-33]</sup>. In our study, *tMK*, which was only found in cancer tissues, had stronger effects than *MK* on tumor cell proliferation, and tumors from two mice injected with BGC823/*tMK* cells had erosive appearance. This result was in agreement with the previous studies. The differential activities of *MK* and *tMK* in promoting tumor proliferation may be attributed to the difference of the tertiary structure between these two proteins<sup>[34]</sup>.

In conclusion, over-expressed *MK* or *tMK* could promote tumor development of human gastric cancer

and tumorigenesis *in vitro* and *in vivo*. *tMK* had greater effect than *MK* in promoting the tumor formation. *tMK* might become a more promising gene therapeutic target compared with *MK* for treatment of tumors.

## COMMENTS

### Background

Midkine (*MK*), a heparin-binding growth factor, and its truncated form (*tMK*), were found expressing at higher levels in various tumors, and involve the growth and metastasis of some carcinomas. The expressions of *MK* mRNA and the protein

are both associated with the clinical stage and distant metastasis of gastric cancer in the Chinese patients. But few studies were conducted on the roles of *MK* and *tMK* in both tumorigenesis and tumor development in gastric cancer. In this article, the effect of *MK* and *tMK* on the growth and metastasis of BGC823 (a poorly differentiated gastric adenocarcinoma cell line), and tumorigenesis in nude mice was investigated.

### Research frontiers

Many studies of *MK* and *tMK* expression in various tumors including gastric cancer, have been reported. It has been found that *MK* can promote Wilms' tumor cell proliferation and tumor angiogenesis, inhibit tumor cell apoptosis, induce transformation of NIH3T3 cells, and protect hepatocellular carcinoma cells against TRAIL-mediated apoptosis. However, there has been no investigation about the effect of *MK* and *tMK* on the characteristics of gastric carcinoma.

### Innovations and breakthroughs

This article suggests that over-expressed *MK* and *tMK* can promote BGC823 cell growth, colony formation, wound healing and tumorigenesis in nude mice. *tMK* had greater effect than *MK*, and it might become a promising gene therapeutic target for treatment of malignant tumors.

### Applications

This observation might be of potential value in gene therapy for gastric cancer.

### Peer review

The manuscript describes that over-expressed *MK* and *tMK* can promote BGC823 cell growth, colony formation, wound healing and tumorigenesis in nude mice. The results were found important for *MK* and *tMK* as gene therapeutic target in gastric cancer.

## Abstract

**AIM:** To analyze the clinical and endoscopic features of Chinese patients with reflux esophagitis (RE).

**METHODS:** A total of 1405 RE patients were analyzed retrospectively. Data on gender, age, presence/absence of *H pylori* infection and associated esophageal hiatal hernia were collected. Esophagitis was divided into different grades according to Los Angeles Classification.

**RESULTS:** Of 18823 patients, 1405 were diagnosed as RE. The ratio of male to female patients was 1.75:1 ( $P < 0.01$ ). The mean age of male and female patients was significantly different ( $P = 0.01$ ). The peak age at onset of the disease was 40-60 years. According to Los Angeles Classification, there were significant differences in the age of patients with grades A and B compared to patients with grades C and D ( $P < 0.01$ ). Two hundred and seventy-seven patients were infected with *H pylori*, the infection rate was low ( $P < 0.01$ ). Complication of esophageal hiatal hernia was found to be significantly associated with the severity of esophagitis and age in 195 patients ( $P < 0.01$ ). Esophageal mucosa damages were mainly located at the right esophageal wall.

**CONCLUSION:** The peak age of onset of RE is 40-60 years and higher in males than in females. The mean age of onset of RE is lower in males than in females. The infection rate of *H pylori* is significantly decreased in patients with esophagitis. Old age and esophageal hiatal hernia are associated with more severe esophagitis. Right esophageal mucosal damage can occur more often in RE patients.

## INTRODUCTION

Gastroesophageal reflux disease (GERD) is described as a chronic symptom and/or tissue damage caused by abnormal gastric content refluxing up into the esophagus. GERD is a common disease, with associated typical symptoms of heartburn and regurgitation<sup>[1]</sup>. In recent years, the questionnaire survey among 5000 subjects in Beijing and Shanghai revealed that 10.19% and 7.76% of the subjects have associated reflux symptoms and it is, thus, speculated that GERD has a prevalence of 5.77%<sup>[2]</sup>. A community-based investigation in Guangdong Province showed that heartburn and/or regurgitation occurs at least one week in 6.2% of the community population<sup>[3]</sup>. It was reported that the prevalence of GERD varies greatly, from 7% to 15% and even to over 20%<sup>[4]</sup>. Patients with GERD have manifestations of esophageal mucosal damages, such as reflux esophagitis (RE), non-erosive GERD (reflux disease) or negative endoscopy reflux disease (NERD)<sup>[5-7]</sup>. As a common gastrointestinal disease, RE has attracted widespread attention at home and abroad. To further understand RE and summarize its clinical and endoscopic features, a total of 1405 patients with RE undergoing endoscopic examination in the Digestive Endoscopy Center of our hospital were retrospectively analyzed in the present study.

## MATERIALS AND METHODS

### Ascertainment methods

A total of 18823 patients underwent endoscopic

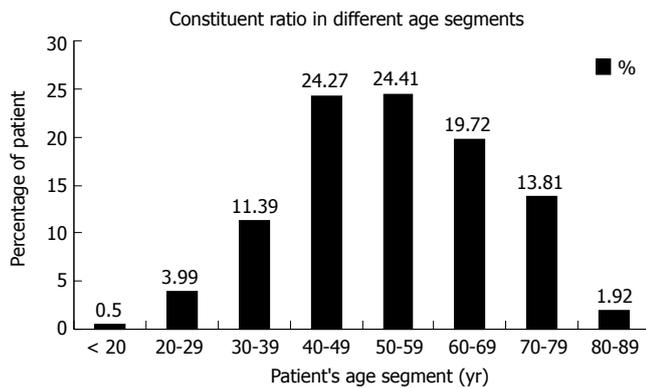

Figure 1 Percentage of patients at different age stages.

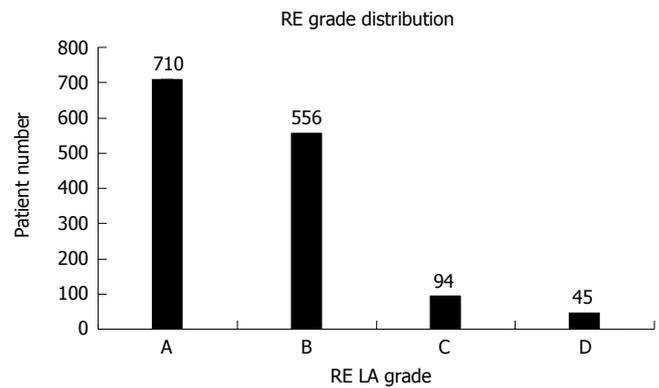

Figure 2 Distribution of disease grades in patients with reflux esophagitis.

examinations in the Digestive Endoscopy Center of Beijing Friendship Hospital between September 2004 and January 2007. The unified questionnaire was established and carefully filled in by specialists mainly based on endoscopic diagnosis. The general items included in the questionnaire for RE cases were gender, age, *etc.* The diagnostic data about the patients with RE included endoscopic staging, presence of associated *H pylori* infection and esophageal hiatal hernia (EHH), *etc.*

### General data

A total of 18823 patients (9800 males and 9023 females) underwent endoscopic examinations in the Digestive Endoscopy Center of Beijing Friendship Hospital between September 2004 and January 2007. Of them, 1405 patients (895 males and 510 females) were diagnosed as reflux esophagitis. Their age was 15- 89 years.

### Diagnostic criteria

Esophagitis was divided into different grades according to Los Angeles Classification in patients with RE. Patients with upper gastrointestinal operation-induced lumen structural changes, upper gastrointestinal obstruction, esophageal varices, achalasia of cardia, and patients undergoing esophageal stenting and those with combined reflux esophagitis following three-cavity catheter or gastric tube implantation were excluded.

*H pylori* infection was evaluated based on the diagnosis by rapid urease staining, C<sup>13</sup> breath test or pathological silver staining. Esophageal hiatal hernia was diagnosed when dentate line shifted 2 cm or more upward under endoscope, and hernia sac was seen under intra-gastric reversal endoscope. Mucosa within the hernia sac was diagnosed as gastric mucosa. Furthermore, esophageal hiatal hernia could be definitely diagnosed according to the upper gastrointestinal contrast.

A 1:00-12:00 location mark of esophageal mucosa damage similar to the index dial was established by setting the midpoints of anterior, posterior, left and right esophageal walls as 12:00, 6:00, 9:00 and 3:00, respectively. The location of mucosal damage was expressed as the corresponding location mark.

### Statistical analysis

$P < 0.05$  was considered statistically significant.

Table 1 Comparison of age in patients with different grades of reflux esophagitis

	LA-A	LA-B	LA-C	LA-D
Mean age	53.35 <sup>b</sup>	54.53 <sup>b</sup>	60.50	61.44
SD	13.90	14.19	13.68	14.97

<sup>b</sup> $P < 0.01$  vs the age of patients with grades C and D of RE. LA-A: Los Angeles Classification grade A; LA-B: Los Angeles Classification grade B; LA-C: Los Angeles Classification grade C; LA-D: Los Angeles Classification grade D.

## RESULTS

### Reflux esophagitis, age and grade

A total of 1405 patients were diagnosed as reflux esophagitis, accounting for 7.46% of the 18823 patients undergoing gastroscopic examinations. The diagnosis rate was 9.13% in 895 male patients and 5.65% in 510 female patients. The ratio of male to female patients was 1.75:1 ( $P < 0.01$ ). The age of onset of RE was 15-89 years (mean age:  $54.56 \pm 14.19$  years). The mean age of male and female patients was  $53.82 \pm 14.19$  years and  $55.85 \pm 14.08$  years, respectively ( $P = 0.01$ ). From the age of 20 to 90 years, 10 years were identified as one age stage. The number and percentage of patients in each stage were 56 and 3.99%, 160 and 11.39%, 341 and 24.27%, 343 and 24.41%, 277 and 19.72%, 194 and 13.81%, and 27 and 1.92%, respectively. There were 7 patients at the age of less than 20 years, accounting for 0.5% (Figure 1). According to Los Angeles Classification, there were 710 patients with grade A (mean age  $53.35 \pm 13.90$  years), 556 with grade B ( $54.53 \pm 14.19$  years), 94 with grade C ( $60.50 \pm 13.68$  years) and 45 with grade D ( $61.44 \pm 14.97$ , Figure 2). Patients with grades A and B accounted for 90.1% of all the patients. There was no difference in the age of patients with grades A and B ( $P = 0.138$ ) or with grades C and D ( $P = 0.712$ ). However, there were significant differences in the age of patients with grades A and B compared with those with grades C and D ( $P < 0.01$ , Table 1).

### Reflux esophagitis and *H pylori* infection

Of the 18823 patients undergoing endoscopic examination, 7190 were infected with *H pylori*, the infection rate was 38.2%. Of the 1405 patients with reflux esophagitis, 277 were infected with *H pylori*, the infection rate was 19.7%,

Table 2 Relationship between reflux esophagitis and *H pylori* infection

	Patients (n)	RE patients (n)	Male	Female	LA-A	LA-B	LA-C	LA-D
<i>H pylori</i> +	7190	277	188	89	137	116	15	9
<i>H pylori</i> -	11633	1128	707	421	576	440	79	36

Total	18823	1405	895	510	710	556	94	45

<sup>b</sup> $P < 0.01$  vs *H pylori* infection rate in all patients undergoing endoscopic examination. RE: Reflux esophagitis; LA-A: Los Angeles Classification grade A; LA-B: Los Angeles Classification grade B; LA-C: Los Angeles Classification grade C; LA-D: Los Angeles Classification grade D; *H pylori*+: Infected with *H pylori*; *H pylori*-: Not infected with *H pylori*.

Table 3 Relationship of reflux esophagitis and esophageal hiatal hernia

	RE patients (n)	Mean age	Male	Female	LA-A	LA-B	LA-C	LA-D
EHH+	195	62.03 ± 14.11	122	73	48	74	48	25
EHH-	1210	53.35 ± 13.83 <sup>b</sup>	773	437	662	482	46	20
Percentage (%)	13.9		13.63	14.31	6.76 <sup>a</sup>	13.31 <sup>a</sup>	51.06 <sup>a</sup>	55.56 <sup>a</sup>
Total	1405	54.56 ± 14.19	895	510	710	556	94	45

<sup>b</sup> $P < 0.01$  vs the age of patients with esophageal hiatal hernia; <sup>a</sup> $P = 0.717$  (no difference in the detection rate of grades C and D of RE;  $P < 0.01$  (significant differences in the detection rate of esophageal hiatal hernia among the other patients; EHH+: Associated esophageal hiatal hernia; EHH-: No esophageal hiatal hernia).

which was significantly lower than that (38.2%) of all patients undergoing endoscopic examinations during the same period. Of the 277 patients infected with *H pylori*, 188 were males and 89 were females. There was no gender difference in *H pylori*-infected patients with esophagitis ( $P = 0.109$ ). Of the 277 *H pylori*-infected patients with esophagitis, 137 had grade A, 116 had grade B, 15 had grade C and 9 had grade D, respectively. The severity of esophagitis was not associated with *H pylori* infection ( $P = 0.71$ , Table 2).

### Reflux esophagitis and esophageal hiatal hernia

Of the 1405 patients with reflux esophagitis, 195 had esophageal hiatal hernia (EHH+), accounting for 13.9%. Their mean age was 62.03 ± 14.11 years. There was a significant difference in the age between patients with and without esophageal hiatal hernia ( $P < 0.01$ ). No statistical significance was found in 122 male and 73 female patients ( $P = 0.722$ ). Of the 195 patients with esophageal hiatal hernia, 29 were infected with *H pylori*. The occurrence of esophageal hiatal hernia was not associated with the presence of *H pylori* infection ( $P = 0.08$ ). In the 195 patients with esophagitis and esophageal hiatal hernia, 48 had grade A, 74 had grade B, 48 had grade C and 25 had grade D, respectively. There was no difference in the detection rate of esophageal hiatal hernia between patients with grades C and D ( $P = 0.717$ ), while there were significant differences in the detection rate of esophageal hiatal hernia among the other patients ( $P < 0.01$ , Table 3).

### Esophageal mucosal damage in reflux esophagitis patients

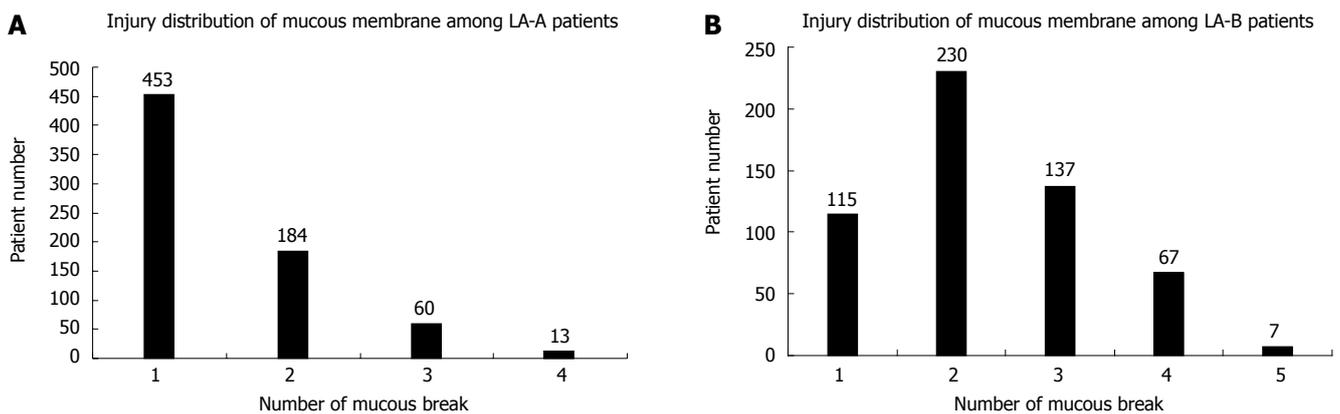

In the present study, the number and location of esophageal mucosal damages in patients with grades A and B reflux esophagitis were analyzed. In the 710 patients with grade A, 453 had only a mucosal damage, 184 had 2 damages, 60 had 3 damages and 13 had 4 damages (Figure 3A and B). In the

556 patients with grade B, 115 had only a mucosal damage, 230 had 2 damages, 137 had 3 damages, 67 had 4 damages, and 7 had 5 or more damages (Figure 3), indicating that a mucosal damage occurred mainly in patients with grade A and two or more mucosal damages occurred mainly in patients with grade B.

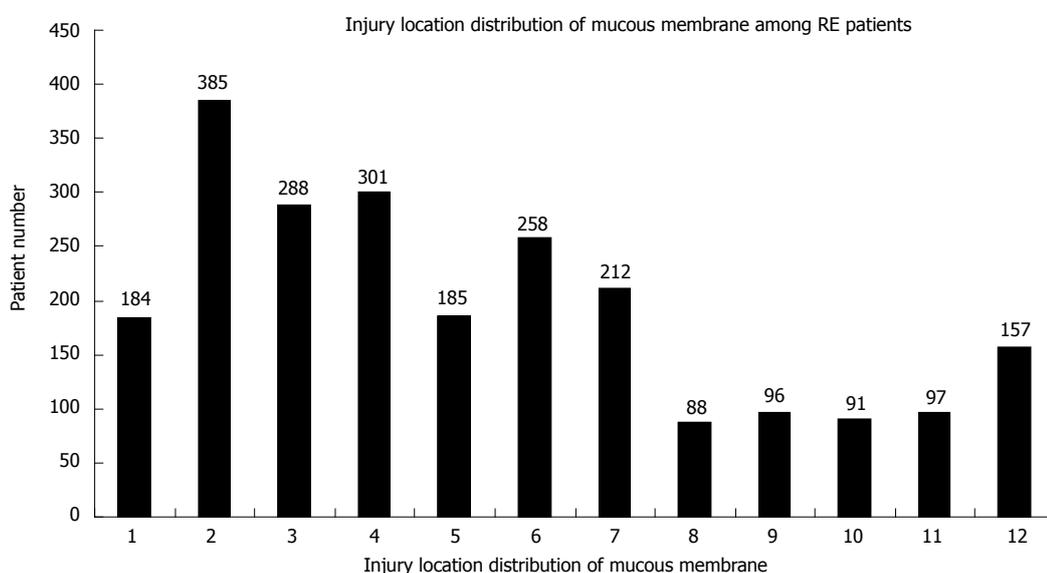

A 1:00-12:00 location mark similar to the index dial was established by setting the midpoints of anterior, posterior, left and right esophageal walls as 12:00, 6:00, 9:00 and 3:00, respectively. The location of mucosal damage was expressed as the corresponding location mark. The number of mucosal damages at the corresponding location of 1:00-12:00 was 184, 385, 288, 301, 185, 258, 212, 88, 96, 91, 97 and 157, respectively (Figure 4). The esophageal mucosa damages were mainly located at the right esophageal wall.

## DISCUSSION

Population-based studies suggest that GERD is a common condition with a prevalence of 10%-20% in Western Europe and North America<sup>[8,9]</sup>. The prevalence rates in South America (10%) and Turkey (11.9%) are similar to those in European countries<sup>[10,11]</sup>. In Asia, the prevalence is generally lower<sup>[12]</sup>. Chen *et al*<sup>[3]</sup> reported that the prevalence of heartburn occurring weekly is 6.2% while Wong *et al*<sup>[13]</sup> have found a lower prevalence of 2.3%. With the deepening of studies and understanding of gastroesophageal reflux disease, the number of such patients is increased in clinical practice. The significantly decreased quality of life in RE patients has increasingly attracted extensive attention<sup>[14-16]</sup>. It was reported that the quality of life deteriorates as the severity of GERD increases<sup>[17]</sup>. In the present study, all the patients undergoing endoscopic examinations in our hospital between September 2004 and January 2007 were analyzed. The detection rate of reflux esophagitis was 7.46%, which

**Figure 3** Distribution of mucosal damage in patients with Los Angeles Classification grade A (A) and grade B (B).

**Figure 4** Distribution of location of mucosal damage in patients with reflux esophagitis.

was higher in males than in females. The ratio of male to female was 1.75:1, suggesting that males have a higher susceptibility to RE than females. In comparison to the Italian general population, the prevalence of over-weight and obesity is increased in female RE patients but not in male RE patients<sup>[18]</sup>. Furthermore, RE tends to occur at a younger age of male patients, which may be related to the differences in life style between males and females. A study demonstrated that the prevalence increases linearly with age among women, and peaks among men at the age of 50-70 years and thereafter declines<sup>[19]</sup>. In the present study, the patients with grades A and B of RE accounted for 90.1%, suggesting that the disease is mild in most patients. Although reflux esophagitis can occur at all age stages, most patients are 40-60 years old. Esophagitis aggravates with the age of patients with reflux esophagitis. In this study, no statistical difference was found in items such as onset age and gender between patients with grades A and B of RE. Endoscopic examination is difficult to assess the length of esophageal mucosal damage. The esophageal mucosal damage in patients with grades A and B of RE was extended along the long axis of esophagus, which was different from transversal and vertical extension of damages in patients with grades C and D of RE.

These results suggest that grades A and B of RE can be considered a same grade. According to the standards set at Yantai Meeting, reflux esophagitis can be divided into grade 0 = normal mucosa (histological changes may be observed), grade 1 = punctiform or strip redness and erosion without integration, grade 2 = punctiform or strip redness and erosion with integration but non-entire pattern, grade 3 = extensive lesions, redness, erosion integration with entire pattern or ulcers. Grade 1 is equivalent to grades A and B in Los Angeles Classification. It was reported that changes in esophageal motility and response to PPI therapy are similar between patients with grades A and B of RE<sup>[20,21]</sup>. Therefore, we believe that the standards set at Yantai Meeting are more practical.

In the present study, the *H pylori* infection rate was significantly decreased in patients with reflux esophagitis. *H pylori* infection had no clear relationship with gender, age and severity of reflux esophagitis. There is evidence that *H pylori* infection is not associated with gastroesophageal reflux disease and *H pylori*-related inflammation does not affect sphincter motility, namely *H pylori*-positive patients have normal LES pressure and the normal frequency of transient LES relaxation<sup>[22]</sup>. Long-term PPI therapy can aggravate atrophic gastritis in patients infected with *H*

*pylori*. For *H pylori*-positive patients with gastroesophageal reflux disease, long-term PPI therapy should be preceded by the eradication of *H pylori*. During the long-term PPI therapy for GERD, *H pylori* infection can speed up the progress of gastric atrophy. Some investigators have proposed that *H pylori* should be eradicated in these patients. Nevertheless, eradication of *H pylori* does not have a clear effect on reflux symptoms in some GERD patients. A study by Spanish scientists showed that treatment of non-erosive gastroesophageal reflux disease with lansoprazole has no effect on *H pylori* infection<sup>[23]</sup>. According to the randomized controlled trial by Schwizer *et al*<sup>[24]</sup>, symptoms of *H pylori*-positive GERD patients occur earlier than *H pylori*-negative patients and those on eradication therapy for *H pylori* infection, suggesting that *H pylori* increases the sensitivity of esophagus and accelerates recurrence of symptoms. In contrast, Moayyedi *et al*<sup>[25]</sup> have not found any significant differences in the recurrence after eradication of *H pylori* in a large sample of patients. It was also reported that the infection rate of *H pylori* is higher in Chinese than in white Americans<sup>[26,27]</sup>.

Esophageal hiatal hernia is diagnosed mainly based on the upper gastrointestinal contrast. Although no recognized standards are available for endoscopic diagnosis of EHH, we can find some specific changes in EHH at endoscopic examination, including upward shift of the dentate line, hernia sac under intra-gastric reversal endoscope and gastric mucosa appearance within hernia sac. In the present study, the detection rate of esophageal hiatal hernia in those with reflux esophagitis was 13.9%. Esophageal hiatal hernia in patients with reflux esophagitis was not associated with *H pylori* infection or gender. The age of patients with reflux esophagitis and esophageal hiatal hernia was higher than that of those with simply reflux esophagitis. Esophagitis in patients with associated esophageal hiatal hernia was more serious. It was reported that hiatal hernia (HH) is closely associated with GERD, and isolated distal esophageal reflux is seen more in patients with HH than in patients without HH<sup>[28]</sup>. Hiatal hernia, in combination with other reflux conditions and symptoms, is associated with the risk of esophageal adenocarcinoma<sup>[29]</sup>. It was reported that no single factor or combined factors are capable of predicting mucosal damage with clinically sufficient certainty<sup>[30]</sup>.

In the present study, most patients with grade A of RE had one mucosal damage while those with grade B of RE had 2 or more mucosal damages. It was found that the most frequent location of mucosal damages in reflux esophagitis patients was the right esophageal wall, especially at the points of 2:00 and 4:00. This pathological change may be due to the anti-reflux role of oesophagogastric angle (His angle) and Gubaroff valve, which makes the left esophageal wall suffer from less gastric acid erosion. In contrast, the right esophageal wall is eroded and damaged by gastric contents more easily because of its direct connection with cardia ventriculi and the lack of valvar protection. Katsube *et al*<sup>[31]</sup> reported that the circumferential location of esophageal mucosal breaks differs significantly among different grades of esophagitis, suggesting that reflux of gastric contents into the esophagus can be effectively improved after a valve is added to cardia ventriculi by means of endoscopy or surgical technique.

In conclusion, the peak age of RE onset is 40-60 years and higher in male than in females. The mean age of RE onset is lower in males than in females. The infection rate of *H pylori* is significantly lower in patients with esophagitis, but the severity of esophagitis is not associated with *H pylori* infection. Old age and combined esophageal hiatal hernia are associated with more severe esophagitis. Right esophageal mucosal damage can occur more often in patients with reflux esophagitis.

## COMMENTS

### Background

Gastroesophageal reflux disease (GERD) affects at least 5%-7% of the global population. The characteristics of GERD of white and yellow race are different. The characteristics of GERD in white people have been described, but the characteristics of GERD in Chinese are not sufficiently described.

### Research frontiers

The clinical and endoscopic features of Chinese patients with reflux esophagitis (RE) were analyzed. The relationship between RE and patient's gender and age, between RE and *H pylori* infection, between RE and hiatal hernia (HH) was discussed. The main location of esophageal mucosa damages to esophageal wall was found.

### Innovations and breakthroughs

The clinical and endoscopic features of Chinese patients with reflux esophagitis (RE) were analyzed. The peak age of RE onset was 40-60 years and higher in males than in females. The mean age of RE onset was lower in males than in females. The infection rate of *H pylori* was significantly lower in patients with esophagitis, but the severity of esophagitis was not associated with *H pylori* infection. Old age and combined esophageal hiatal hernia were associated with more severe esophagitis. Right esophageal mucosal damage can occur more often in patients with reflux esophagitis.

### Applications

The characteristics of Chinese patients with RE were compared to those of people in other countries. Based on the fact that "right esophageal mucosal damage can occur more often in patients with reflux esophagitis", new methods to cure GERD with endoscopy or surgery should be recommended.

### Peer review

In this manuscript, the authors analyzed the clinical and endoscopic features of Chinese patients with reflux esophagitis (RE) and described the low infection rate of *H pylori* in RE patients, the association of hiatal hernia with the severity of RE, as well as the prevalence of right-sided esophageal mucosal damage. The study was well designed and the conclusion was reliable. It should be noted the distribution of mucosal damage locations in patients with RE was not similar.

hemofiltration as an alternative therapy for SAP remains controversial. However, we propose that early use of short-term high-volume veno-venous hemofiltration would have a beneficial impact on the management of SAP.

Cost-effectiveness analysis of early veno-venous hemofiltration for severe acute pancreatitis in China. *World J Gastroenterol* 2008; 14(12): 1872-1877 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1872.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1872>

### Abstract

**AIM:** To determine the most cost-effective hemofiltration modality for early management of severe acute pancreatitis (SAP) in China.

**METHODS:** We carried out a search of Pub-Medline and Chinese Biomedical Disk database. Controlled clinical trials on Chinese population were included in the analysis. The four decision branches that were analyzed were: continuous or long-term veno-venous hemofiltration (CVVH/LVVH), short-term veno-venous hemofiltration (SVVH), SVVH plus peritoneal dialysis (PD), and non-hemofiltration control group. The effectiveness of the technique was determined by survival rate, complications prevention and surgery preservation. The total cost of hospitalization was also assessed.

**RESULTS:** The SVVH only technique was the least costly modality, \$5809 (44449 RMB), and was selected as the baseline treatment modality. SVVH only arm achieved the lowest C/E ratio in terms of overall survival, complications prevention and surgery preservation. In incremental cost-effectiveness analysis, the CVVH/LVVH only and the control arms were inferior to other techniques. Sensitivity analysis showed SVVH only and SVVH plus PD arms overlapped in C/survival ratio.

**CONCLUSION:** The role of early veno-venous

### INTRODUCTION

Severe acute pancreatitis (SAP) is a grave illness associated with serious pancreatic and systematic disease. SAP is seen in nearly 20% of all patients with acute pancreatitis<sup>[1]</sup>. Despite advances in the understanding of the pathophysiology and management of acute pancreatitis over the past several decades, the mortality rate of SAP has not shown a substantial decrease, varying from 8%-15% to more than 30% in some studies<sup>[1-4]</sup>. The main factors that influence the poor outcome include systematic inflammatory response syndrome (SIRS) in the early stages ( $\leq 14$  d) and infection of pancreatic and peri-pancreatic necrotic tissue in the late stages ( $> 14$  d), both of which can precipitate secondary multi-organ deficiency syndrome (MODS)<sup>[5]</sup>. As some reports indicate, at least 50% of deaths in the early stage of SAP are related to MODS, and when three or more organs fail, the mortality rate increases to 95%<sup>[5,6]</sup>. Thus, efficient management during the early stages of the illness is important in improving the prognosis.

Since 1991, veno-venous hemofiltration (VVH) has been used in the initial management of SAP<sup>[7]</sup>. Several studies have indicated that hemofiltration removes from the circulation small and medium sized molecules that stimulate the inflammatory cells. Alternatively, VVH

may directly inhibit the cells that contribute to the systematic response<sup>[8]</sup>. The use of continuous veno-venous hemofiltration (CVVH) has been assessed in a animal model of SAP and was found to significantly improve the survival time, when used both for therapeutic and prophylactic treatment, especially the latter<sup>[9]</sup>. However, the efficiency of treatment decreased with continuing use of CVVH, suggesting that the filter membranes were compromised by long-term application<sup>[9]</sup>. The current consensus in Japan is to start CVVH soon after the onset of SAP, and to use it continuously for 3-14 d, because reduction in the chemical mediators, and improvement in the respiratory function and the incidence of MODS were more obvious if the treatment was started early rather than at a late stage<sup>[10]</sup>. However, there is no consensus on how long CVVH should be used and when it should be stopped. Therefore, early short-term veno-venous hemofiltration (SVVH) modalities have been examined, including the use of repeated SVVH (RSVVH), intermittent SVVH (ISVVH) and single SVVH (SSVVH). The time interval of hemofiltration plays an important role in the treatment of SAP during its early stage. A comparison of SVVH with prolonged time interval VVH, and long-term veno-venous hemofiltration (LVVH) in the treatment of SAP did not improve the prognosis further but was associated with more side-effects<sup>[11]</sup>. Therefore, in the decision making process the benefits of CVVH/LVVH and SVVH continue to be controversial. In addition, it should be noted that peritoneal dialysis (PD) is another approach to the treatment of SAP as it removes dialyzable toxins and reduces severe metabolic disturbances<sup>[12]</sup>. In China, PD has also been used as an additional therapy with early SVVH. Clinical studies in China have reported that the use of early SVVH plus PD results in better prognosis of SAP, since cytokines such as TNF, IL-6 and IL-8 can be removed effectively from the circulation by these techniques<sup>[13]</sup>.

In China, which is a developing country with a huge population and relatively low income, the use of early CVVH/LVVH carries a great economic burden because of its high cost. For this reason, early SVVH may be more acceptable. However, which one of these therapeutic modalities provides reasonable effectiveness at a lower cost needs to be further explored. The present cost-effectiveness analysis is based on a review of the literature, with a view to determine as to which approach is the most cost-effective treatment of SAP in China.

## MATERIALS AND METHODS

### The model

The cost-effectiveness analysis was based on a decision tree designed to simulate a simplified clinical course of SAP treated with or without early VVH (Figure 1). In the general structure of the tree, there were four intervention decision arms: conventional therapy without hemofiltration (control arm), conventional therapy combined with early CVVH or LVVH (CVVH/LVVH only), SVVH only, and SVVH plus PD. All the hemofiltration modalities were started in the early stage of SAP, generally 3-5 d after onset of the disease.

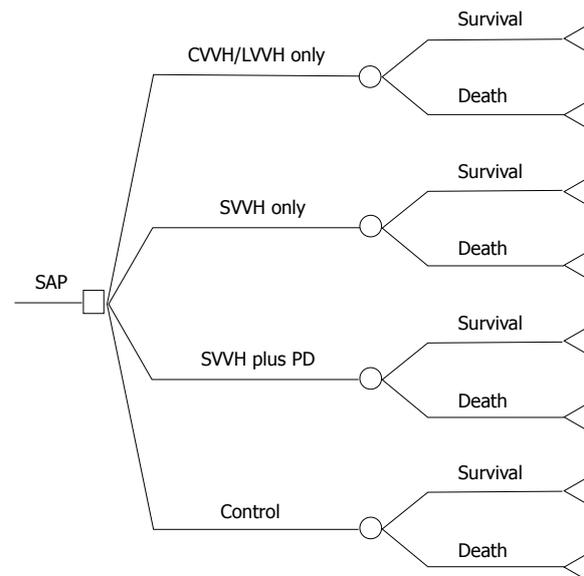

Figure 1 Decision tree of early hemofiltration for SAP.

### Effectiveness data

The primary effectiveness variable was overall survival rate. The secondary effectiveness variables were the overall complication prevention rate and overall surgery preservation rate since complications and surgery were the factors most likely to increase the cost of hospitalization. The complications analyzed included severe local and systematic infections, and MODS. Surgery was mainly performed for necrosectomy. Thus, the primary clinical outcome measure was survival (alive = 1, death = 0), while the secondary outcome measures were complications (none = 1, occurrence = 0) and surgery (no = 1, yes = 0). The specified probabilities were retrieved from our previous systematic review (Table 1)<sup>[14]</sup>.

### Cost data

The direct health care cost, i.e. total cost of hospitalization (currency, RMB), was calculated as mean  $\pm$  SD obtained from each of the studies, and the weighted costs were combined by the formula  $\frac{\sum(\chi_i n_i)}{\sum(n_i)}$ , of which  $\chi$  = total cost of hospitalization,  $n$  = number of assigned patients in any of the intervention arms, and  $i$  = number of included studies. All the costs were converted to the price index as of 2005, taking into account the annual increase in the Chinese prices, i.e. 1.0% in 1999-2000, 2000-2001, 2001-2002 and 2002-2003, 1.2% in 2003-2004, and 3.9% in 2004-2005<sup>[15]</sup>. One RMB was converted to 0.130688 U.S. dollars.

### Literature search and selection

We searched Pub-Medline and Chinese Biomedical Disk (CBMdisc) database from 1990 to 2006. The search strategy was combining the subheading and text words hemofiltration and pancreatitis. The studies based on Chinese population were selected regardless of the language. All patients were diagnosed to have SAP based on the Atlanta classification, APACHE II score > 8, Ranson score > 3, or Balthazar CT grading of D or E. All clinical studies which assessed cost comparing

**Table 3 Weighted total hospitalization costs**

Modalities	Cost (C) <sup>1</sup>			Incremental cost (ΔC) <sup>2</sup>
	WM	Max	Min	
CVVH/LVVH only	\$18826 (144051 RMB)	\$33254 (254455 RMB)	\$4397 (33647 RMB)	\$13017 (99602 RMB)
SVVH only	\$5809 (44449 RMB)	\$9359 (71613 RMB)	\$2259 (17286 RMB)	
SVVH plus PD	\$7868 (60205 RMB)	\$10622 (81279 RMB)	\$5114 (39130 RMB)	\$2059 (15756 RMB)
Control	\$11317 (86597 RMB)	\$17006 (130128 RMB)	\$5628 (43066 RMB)	\$5508 (42148 RMB)

<sup>1</sup>All the costs were converted to 2005 price before combination. <sup>2</sup>SVVH only, the least costly arm, was selected as common baseline for other arms to reference to. WM: Weighted mean; WMD: Weighted mean difference; CVVH: Continuous veno-venous hemofiltration; LVVH: Long-term veno-venous hemofiltration; SVVH: Short-term veno-venous hemofiltration; PD: Peritoneal dialysis.

hemofiltration with either a control group or another treatment modality were eligible for inclusion in the analysis.

**Statistical analysis**

TreeAge Pro Healthcare 2006 software was used in modeling and analyses. Both the cost-effectiveness analyses and the incremental cost-effectiveness analyses were examined, with C/E ratio and incremental C/E (ΔC/ΔE) ratio calculated separately. The treatment arm with the lowest cost was selected as the common baseline for comparison with other treatment arms. If there was uncertainty with regard to decision making, sensitivity analysis was carried out by alternating the variables to maximal and minimal limits (two-way), including the total cost of hospitalization and overall survival rate.

**RESULTS**

Our previous systematic review analyzed 10 randomized controlled trials and 6 clinical controlled trials comprising of a total of 891 Chinese patients<sup>[14]</sup>. The meta-analysis

showed that the overall mortality rate was significantly reduced in the hemofiltration group [RR = 0.49, 95% CI (0.32, 0.74), P = 0.0008]<sup>[14]</sup>. The specified probabilities of the clinical outcomes of each treatment arm were retrieved based on the sub-group analysis of the systematic review. The overall survival rates improved in the CVVH/LVVH only, SVVH only and SVVH plus PD arms by diverse extent (Table 1). Five controlled studies from 4 Chinese medical institutions which provided the data on cost were included in the present analysis<sup>[11,13,16-18]</sup>, and the detailed data were extracted and combined (Tables 2 and 3). Interestingly, both SVVH only and SVVH plus PD reduced the total cost of hospitalization compared with the control arm, while the CVVH/LVVH only approach was the most costly. By contrast, the SVVH only approach was the least costly arm, and was therefore selected as the baseline for the purpose of comparing the cost-effectiveness and incremental cost-effectiveness with the other treatment arms.

**Cost-effectiveness analysis**

In the cost-effectiveness analysis, the lowest ratios C/

survival rate, C/complication prevention rate and C/surgery preservation rate were \$6167 (47 186 RMB), \$7334 (56 122 RMB) and \$5903 (45 172 RMB) respectively in SVVH only arm. These findings indicate that a patient treated with SVVH would pay an additional \$62 (472 RMB), \$73 (561 RMB) and \$59 (452 RMB) respectively to gain 1% higher probability of each benefit. To summarize, the cost-effectiveness analysis can be ranked in the order of superior to inferior as SVVH only, SVVH plus PD, control and CVVH/LVVH only (Table 4).

In incremental cost-effectiveness analysis, the CVVH/LVVH only, SVVH plus PD and control arms were inferior to SVVH only arm in outcomes of overall survival and overall surgery preservation, while the CVVH/LVVH only and control arms were inferior to SVVH only and SVVH plus PD arms in the aspect of overall complication prevention (Table 4, Figure 2). The incremental C/complication prevention ratio of SVVH plus PD arm was \$40 385 (30 894 RMB), which suggest that a patient treated with SVVH plus PD will pay an additional \$404 (3089 RMB) compared to SVVH only to obtain a 1% higher probability of preventing complications.

### Sensitivity analysis

SVVH plus PD was the closest to SVVH only in both cost and effectiveness. Therefore, we performed sensitivity analysis to compare SVVH only and SVVH plus PD arms by changing the survival rate and cost in their ranges (Figure 3). The variable range of survival rates of SVVH only and SVVH plus PD arms were 0.900-1.000 and 0.853-1.000 respectively, which were retrieved from our previous meta-analysis<sup>[14]</sup>. The range of cost is listed in Table 3. It is clear that there is overlapping in the variable areas of the two modalities. The minimal and maximal C/survival rate ratios were \$2259 (17 286 RMB) - \$10 399 (79 570 RMB) and \$5114 (39 130 RMB) - \$12 453 (95 286 RMB) in SVVH only and SVVH plus PD arms respectively. If in area A, SVVH only was superior to SVVH plus PD modality, the ratio of C/survival rate was less than \$5114 (39 130 RMB). By contrast, if in area B, SVVH plus PD was inferior to SVVH only, the ratio of C/survival rate was more than \$10 399 (79 570 RMB).

## DISCUSSION

Persistent SIRS, which is an early sign of SAP, is associated with MODS and even death<sup>[19]</sup>. About 50% of deaths in patients with SAP occur in the early stage of the disease; these patients experience a severe initial attack and develop an exaggerated SIRS with the development of MODS and death<sup>[20]</sup>. Therefore, several treatment modalities which target the inflammatory response in patients with SAP have been under consideration<sup>[21]</sup>.

The onset and subsequent rapid deterioration seen in SAP is likely due to the over-production of pro-inflammatory cytokines, which are considered critical to the pathogenesis of the disease<sup>[14]</sup>. Thus, cytokines derived from macrophages are believed to play an integral role in the evolution of acute pancreatitis<sup>[22]</sup>. It has been suggested that the local pancreatic lesion activates macrophages to release pro-inflammatory cytokines<sup>[14,23]</sup>. This results in an

CVVH: Continuous veno-venous hemofiltration; LVVH: Long-term veno-venous hemofiltration; SVVH: Short-term veno-venous hemofiltration. SVVH only, the least costly arm, was selected as common baseline for other arms to reference to; PD: Peritoneal dialysis.

imbalance between pro- and anti-inflammatory cytokines, resulting in the development of SIRS. Some mediators, such as TNF-alpha, phospholipase, and kinin, are increased greatly in animal models of SAP<sup>[9]</sup>, and some studies have shown that there is a significant correlation between the serum levels of IL-1-beta, IL-6, IL-8, IL-10 and IL-11 and the severity of acute pancreatitis<sup>[24-27]</sup>. Animal studies have shown that early blockade of the cytokine cascade at the level of the IL-1 receptor significantly decreases the severity of pancreatitis and intrinsic pancreatic damage, as well as the mortality from SAP<sup>[28,29]</sup>. Several antagonists of the inflammatory mediators have been used successfully in the laboratory setting and are currently being examined in prospective randomized trials<sup>[30]</sup>. The effectiveness of any antagonist depends not only on its ability to block the effects of the inflammatory mediators but also on its administration early enough in the course of the disease, before pancreatic necrosis and organ dysfunction sets in<sup>[30]</sup>. Thus, the inhibition of the cytokine cascade should potentially alleviate the pancreatic and systematic inflammation and improve the outcome of SAP.

The present cost analysis was carried out to determine the most economical and effective hemofiltration modality in China. CVVH has been considered as a potentially effective approach in the management SAP for nearly a decade. However, in China, both CVVH and LVVH are too costly for the common public. Thus, the less costly approach, SVVH was analyzed. Several clinical studies of SVVH administrated to patients with SAP in the early stage of the disease have been carried out in various institutions in China. However, these studies had limited scale of participation, were methodologically of poor quality (only a few studies were randomized) and very few discussed the cost outcomes. Therefore, our results may be biased by these confounding factors.

Our previous meta-analysis, based on controlled trials carried out in China indicated that early SVVH was effective and safe for SAP, but the efficacy of CVVH/LVVH could not be proven<sup>[14]</sup>. Our initial findings inspired us to explore further the role of other treatment modalities in decision making. The results of the present analysis showed that SVVH is the most suitable approach

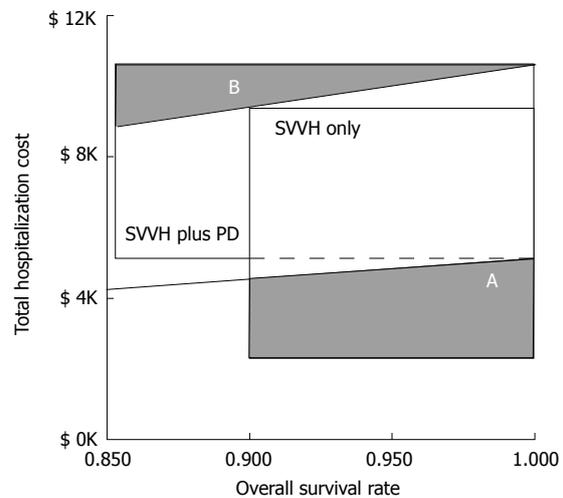

**Figure 2** Cost-effectiveness analysis plots. **A:** Cost-survival ratio; **B:** Cost-complications prevention ratio; **C:** Cost-surgery preservation ratio.

in the treatment of SAP in China. The use of SVVH only would result in the best clinical outcome with reduction in the overall mortality, and prevention of complications and surgery. Furthermore, SVVH only modality is the least costly compared to other treatment options, including CVVH/LVH only, SVVH plus PD and non-hemofiltration modalities. The CVVH/LVH only and non-hemofiltration modalities were surpassed by SVVH only. The SVVH plus PD modality was fairly close to SVVH only in efficacy and cost, but SVVH was superior. However, the sensitivity analysis showed overlapping of the cost-effectiveness ratio between SVVH only and SVVH plus PD modalities. These findings suggest that SVVH is not entirely superior to SVVH plus PD, and SVVH plus PD should be considered as a suitable alternative option in China, and requires further investigation about its cost-effectiveness.

The timing of hemofiltration is considered as a critical factor in the outcome of patients with SIRS or sepsis. The subset of patients with these complications may benefit from the use of early short-term pulse hemofiltration<sup>[31]</sup>. The use of LVVH did not improve the prognosis but was associated with more side-effects than SVVH<sup>[11]</sup>. Another factor which may influence the outcome of patients with SIRS or sepsis is the ultrafiltration rate. It has been noted that the beneficial effects are greater with “very high” ultrafiltration rates ( $\geq 100$  mL/kg per hour)<sup>[31]</sup>.

The benefit of VVH remains to be defined as an alternative therapy for SAP with SIRS or sepsis. A definite conclusion cannot be drawn because the studies have been small, are of poor quality and are heterogeneous in nature. Thus, there is no evidence in humans to recommend the use of VVH as an adjuvant therapy in patients with SAP. There continues to be uncertainty about the absolute indication, timing interval, dosing volume and the type of membrane required. Therefore, more randomized clinical trials are required before definite recommendations can be made about the clinical management of SAP. However, based on the present cost-effectiveness analysis in China, we suggest that the use of early short-term high-volume VVH is likely to play an important role in the management severe acute pancreatitis accompanied with SIRS, sepsis or organ failure.

**Figure 3** Two way sensitivity analysis of C/E ratio between SVVH only and SVVH plus PD modalities.

## COMMENTS

### Background

Nearly 50% of deaths in severe acute pancreatitis (SAP) occur during the early stage of the disease. These patients experience a severe initial attack and develop an exaggerated systemic inflammatory response syndrome (SIRS), with the development of multiple organ dysfunction syndrome (MODS) and death. Therefore, the role for therapy targeting the inflammatory response in SAP has been under much consideration recently.

### Research frontiers

The onset and the poor outcome of SAP is likely due to the over-production of pro-inflammatory cytokines, which is considered as the critical factor in this condition. Inhibition of the cytokine cascade should potentially alleviate the pancreatic and systemic inflammatory response, and improve the outcome of SAP. Thus, veno-venous hemofiltration which can effectively eliminate the cytokines, has been used in the early management of SAP. Several different modalities of hemofiltration are available, but their effectiveness is controversial. In particular, expensive treatments should be used with much discretion in China, a developing country.

### Innovations and breakthroughs

Based on our previous meta-analysis, early veno-venous hemofiltration may significantly reduce the overall mortality compared to no treatment. Analysis of different modalities showed that continuous or long-term veno-venous hemofiltration (CVVH/LVVH) and short-term veno-venous hemofiltration plus peritoneal dialysis (SVVH + PD) do not reduce the mortality significantly, whereas short-term only modality (SVVH only) was superior to other treatments in this

respect. A cost-effectiveness analysis based on the Chinese literature showed that SVVH only was the most cost-effective modality in reducing mortality, and in preventing complications and surgery. It can be implied that the timing of veno-venous hemofiltration should be regarded as a critical factor in the outcome of patients with SIRS or sepsis.

### Applications

Early veno-venous hemofiltration is considered as an effective alternative therapy for SAP, although it is expensive for the general population in China. Based on the current evidence, hemofiltration can control to a certain extent SIRS and even MODS, if used during the early stage of the disease, with SVVH only the most cost-effective modality in China. We believe that early short-term high-volume veno-venous hemofiltration will play an important role in the management of SAP with SIRS, sepsis or organ failure.

### Terminology

Severe acute pancreatitis (SAP) is a serious disease with intense pancreatic and systematic inflammation, seen in about 20% of patients with acute pancreatitis. Veno-venous hemofiltration removes waste products including cytokines by passing the blood through extracorporeal filters in the veno-venous access, which is categorized as continuous, long-term and short-term modalities based on the duration of hemofiltration.

### Peer review

It is a well written article dealing with the cost-effective of veno-venous hemofiltration in the early treatment of SAP.

### Abstract

**AIM:** To study the virological and host factors influencing hepatitis C infection outcomes in heroin users in southern China.

**METHODS:** HCV RNA and associated factors were analyzed among 347 heroin users from Guangxi Zhuang Autonomous Region, southern China who were hepatitis C virus (HCV) EIA positive for two or more consecutive visits.

**RESULTS:** Using the COBAS AMPLICOR HCV TEST, a remarkably low HCV RNA negative rate of 8.6% was detected. After multivariate logistic regression analysis, HCV RNA clearance was significantly associated with the presence of HBsAg (OR = 8.436,  $P < 0.0001$ ), the lack of HIV-1 infection (OR = 0.256,  $P = 0.038$ ) and age younger than 25 (OR = 0.400,  $P = 0.029$ ).

**CONCLUSION:** Our study suggests HCV infection among Chinese heroin users results in high levels of viral persistence even amidst factors previously found to enhance viral clearance. Prospective studies of a possible genetic component within the Chinese population and the pathogenicity of non-genotype 1 HCV infections are needed.

Factors influencing a low rate of hepatitis C viral RNA clearance in heroin users from Southern China. *World J Gastroenterol* 2008; 14(12): 1878-1884 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1878.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1878>

### INTRODUCTION

The hepatitis C virus (HCV) epidemic now affects over 200 million people worldwide. HCV is a single-stranded RNA flavivirus that is responsible for the majority of non-A-non-B hepatitis infections<sup>[1,2]</sup>. Natural history studies have found that 15%-59% of people who are infected with HCV will undergo spontaneous viral clearance with no further liver disease due to HCV<sup>[3-11]</sup>. The remaining will develop chronic HCV infection that can lead to cirrhosis, hepatocellular carcinoma and the need for a liver transplant.

The exact mechanism of HCV RNA clearance is not well understood although recent studies have shown that clearance is associated with strong, broad cellular immune responses<sup>[12-19]</sup>. Other factors such as younger age<sup>[3,20]</sup>, female gender<sup>[21,22]</sup>, presence of hepatitis B surface antigen (HBsAg)<sup>[3,23]</sup>, certain HLA alleles<sup>[6,24-29]</sup>, and low viral quasispecies diversity<sup>[30]</sup> have been linked to increased HCV RNA clearance. While African American ethnicity<sup>[3,25]</sup>, HCV genotype 1<sup>[31-33]</sup> and co-infections with human immunodeficiency virus-1 (HIV-1)<sup>[3]</sup>, Human T-Lymphotropic Virus-1<sup>[34]</sup> and *Schistosoma mansoni*<sup>[35]</sup> have been associated with lower HCV RNA clearance and higher HCV RNA levels. Understanding why and how individuals clear HCV is the key to developing new drugs and an effective vaccine<sup>[21]</sup>.

Studies of heroin users from Guangxi Zhuang Autonomous Region in southern China have attributed the appearance and spread of HIV, HCV and other infectious agents to the change in heroin using patterns from smoking to injection<sup>[36]</sup>. In Guangxi, two separate emerging HIV epidemics have sprung from different

heroin trafficking routes into the province<sup>[37,38]</sup>. It is not clear how widespread the HCV epidemic is in China. Little seroprevalence data exists, mostly from the major cities of Beijing, Shanghai and Hong Kong and to our knowledge; no studies on HCV RNA clearance in China have been done. Studies in Yunnan Province, which borders Guangxi Zhuang Autonomous Region in the west, have found high HCV co-infection rates in HIV-1 positive drug users<sup>[39]</sup>. Previous epidemiological studies in Guangxi not only found similar high rates of HCV co-infection in HIV-1 positive drug users, but a high HCV prevalence (72%), incidence (37.8 per 100 person years) in all heroin users enrolled in the study<sup>[40]</sup>. To determine the clearance rate of HCV RNA and study factors that influence clearance, serum from a large cohort of heroin users from Guangxi Zhuang Autonomous Region, southern China was qualitatively tested for HCV RNA.

## MATERIALS AND METHODS

### Study participants

Heroin users over the age of 18 in Guangxi Zhuang Autonomous Region, China are currently being followed in a study of behavioral and virological features of HIV-1 in injection drug users conducted at the Guangxi Provincial Health and Anti-Epidemic Center. Over 600 participants are being followed at study sites in Pingxiang and Binyang City in the Guangxi Zhuang Autonomous Region. Study participants from Pingxiang have been followed since September 1999 while participants from Binyang have been followed since January 2000. The informed consent procedure was described previously<sup>[40]</sup>. Briefly, at each visit, participants underwent blood draw and personal interviews and were counseled on the results of their serological tests. Baseline and follow-up questionnaires entailed a brief medical history including sexually transmitted diseases, history of drug use, sexual history, ethnic and economical backgrounds. Blood was collected and centrifuged and the serum either underwent serological assays or was stored at -70°C. Samples were then shipped from Guangxi to our laboratory in Baltimore, MD for HCV RNA testing and further analysis.

### Serologic assays

At the Guangxi Health and Anti-Epidemic Center in Nanning, the presence of HIV-1 antibody was determined by enzyme-linked immunosorbent assay (ELISA) using the Vironostika HIV-1 Microelisa System (Organon Teknika). All ELISA-positive samples were not considered HIV-positive until confirmation by HIV-1/2 Western blot immune assay manufactured by Gene Lab (Singapore). Positivity for Hepatitis B surface antigen (HBsAg) and antibody to Hepatitis B surface antigen (HBsAb) were determined by HBV ELISA (Xiamen Xinchung Scientific, Xiamen, China). Hepatitis C antibody was analyzed by the Ortho HCV Version 3.0 ELISA Test System (Ortho Diagnostic Systems, Raritan, NJ).

### HCV RNA detection and determination of HCV serotypes and genotypes

Available sera from 347 participants who were HCV

antibody positive for two consecutive visits (> 6 mo apart) were qualitatively tested for Hepatitis C RNA by the COBAS AMPLICOR HCV TEST KIT, sensitivity > 50 IU/mL (Version 2.0, Roche Diagnostics). Hepatitis C serotypes were determined for samples found HCV RNA negative using the Murex HC03 ELISA (Abbott Diagnostics, England). RNA for HCV genotyping was extracted from 100 µL of serum using the QIAamp Viral RNA kit (QIAGEN Inc, Valencia, CA). Reverse transcription and nested PCR was performed using primers to conserved regions of Core and E1 as previously described<sup>[41]</sup>. After purification with the QIAquick PCR Purification kit (QIAGEN Inc, Valencia, CA), samples were sequenced using the inner forward primer on an automated sequencer (PRISM, version 2.1.1; ABI, Foster City, CA). Sequences were compiled using the BioEdit program, version 4.7 (T. Hall, North Carolina State University, Raleigh) and genotypes were assigned after alignment with known HCV genotypes as previously described<sup>[41]</sup>.

### Statistical analysis

Univariate logistic regression analyses were first performed to explore the crude associations between the clearance of HCV and related factors, including age, length of drug use, frequency of drug use, injection drug use, HIV-1 Ab, HBsAb, HBsAg, study site, ethnicity and gender. Variables with a  $P < 0.1$  in the univariate model were then put into a multiple logistic regression model<sup>[42]</sup>. Those that ceased to be significant in the multivariate model,  $P > 0.05$ , were eliminated in a stage-wise manner, yielding a final model in which all variables were independently associated with the clearance of HCV.  $P$ -values reported are two-sided. The age, frequency of drug use and length of drug use closest to the overall sample mean within a factor of five were used in the model.

## RESULTS

A total of 347 study participants who were HCV EIA positive for two or more consecutive study visits were included in this study, 127 from Pingxiang City and 220 from Binyang City. Pingxiang City is in southern Guangxi and borders Vietnam while Binyang City is centrally located within the province. Survey and serology results from the study visit of HCV RNA analysis are listed in Table 1. This subset of the Guangxi cohort is predominantly male (96.25%) with a mean age of 27 (range 19-50). Two main ethnic groups are present in Guangxi, Han and the Zhuang minority. Approximately 67% of the study group is Han and 29% Zhuang. Less than half of the participants are married (32%). Over 90% of the participants have a middle school or lower level of education.

Approximately 93% of the heroin users admit to injection drug use (Table 1). Over half admit to sharing needles (data not shown). The participants have been injection drug users for an average of about 5 years (Table 1). The study group uses heroin at an average frequency of 74 times per month. Along with being HCV EIA positive, 25.94% of the study participants are also HIV Ab positive,

SD: Standard deviation; HCV: Hepatitis C virus; HIVAb: HIV-1 antibody; HBsAg: Hepatitis B surface antigen; HBsAb: Antibody to hepatitis B surface antigen.

13.26% are HBV surface antigen positive (HBsAg) and 42.65% are antibody positive for the HBV surface antigen (HBsAb). Of the 347 consecutively HCV EIA positive samples tested, only 30 had undetectable levels of HCV RNA (less than 50 IU/mL) resulting in an HCV RNA clearance rate of 8.6% (Table 1).

Results of univariate logistic regression analyses and final multivariate logistic regression analyses for Hepatitis C Viral RNA clearance are shown in Table 2. Univariate analysis revealed HCV RNA clearance to be associated with age younger than 25 (OR = 0.472), lack of HIV-1 infection (OR = 0.294), presence of HBsAg (OR = 7.793), lack of HBsAb (OR = 0.308), female gender (OR = 3.411) and acknowledgement of injection drug use (OR = 0.441). In the final model, only three factors were independently associated with HCV RNA clearance; being HBsAg

positive (OR = 8.436,  $P < 0.0001$ ), lacking HIV-1 infection (OR = 0.256,  $P = 0.038$ ) and age younger than 25 (OR = 0.400,  $P = 0.029$ ).

A comparison of previously published HCV RNA clearance rate can be found in Table 3. Our HCV RNA clearance rate is most similar to African American injection drug users in the Baltimore ALIVE cohort<sup>[3]</sup>, but remarkably less than the remaining studies listed.

## DISCUSSION

Injection drug practices in Guangxi Zhuang Autonomous Region, China continue to efficiently spread HCV, HIV and HBV resulting in large numbers of co-infections and multi-infections, the full impact of which has yet to be determined. Analysis of this cohort found a very low spontaneous HCV clearance rate (8.6%) among heroin users who have been HCV EIA positive for two or more consecutive study visits. The natural history of HCV in Chinese individuals has not been studied to this extent before.

Hepatitis C viral clearance was strongly associated with co-infection by the hepatitis B virus, specifically participants currently HBsAg positive. Other cohorts have seen trends between HBsAg positivity and HCV clearance<sup>[3,23]</sup>, but none with an association as convincing as is shown in our cohort. Previous studies of HBV and HCV co-infections have revealed viral interference between these hepatotropic viruses resulting either in one dominant virus<sup>[43]</sup> or in some cases resolution of both infections<sup>[44]</sup>. The exact mechanism of this interference is not known, although data suggest it is the result of inhibition of replication by viral proteins<sup>[45,46]</sup>. It is also plausible that the existing activation of non-specific immune responses within the liver during the current HBV infection enhances the clearance of the HCV infection.

HCV is now a major opportunistic infection for those with co-infected HIV-1<sup>[47]</sup>. Previous studies have shown that co-infections with HIV and HCV do not increase the progression to AIDS<sup>[48]</sup>, but do increase the HCV viral load and progression to end-stage liver disease (ESLD)<sup>[49,50]</sup>. Two separate subtypes of HIV, A/E and a B/C recombinant, were likely to enter Guangxi Zhuang Autonomous Region in 1996<sup>[38]</sup>. With high HCV prevalence and incidence rates, almost all injection drug users in Guangxi who become HIV-1 positive will be co-infected with HCV. This study found a significant association between HIV co-infection, defined by the presence of HIV-1 antibody, and the inability of the individual to clear HCV RNA. Only 3/90 HIV-1 antibody positive individuals were able to clear their HCV RNA. Two of these participants were new HIV-1 seroconverters and the third was HBsAg positive (data not shown). The mechanism of how HIV-1 infection inhibits HCV RNA clearance is likely due to immune suppression caused by HIV-1. It is less likely that the two HIV-1 seroconverters who cleared HCV RNA were immunocompromised (data not shown). Thomas *et al* did not see a significant association between HIV-1 co-infection and HCV clearance in the ALIVE cohort until HIV-1 infected people were broken down by CD4 levels<sup>[3]</sup>.

**Table 2** Factors associated with hepatitis C viral clearance among 347 consecutively HCV antibody positive heroin users from Guangxi Zhuang Autonomous Region, China

OR: Odds ratio; CI: Confidence Interval; HCV: Hepatitis C virus; HIVAb: HIV-1 antibody; HBsAg: Hepatitis B surface antigen; HBsAb: Antibody to hepatitis B surface antigen.

Age of the individual also affected the HCV clearance rate in our cohort. A meta-analysis by Mathei *et al* found a linear relationship between mean age and HCV RNA clearance rates<sup>[20]</sup>. The higher prevalence of HCV RNA in older individuals was suggested as a result of continuous re-exposure to HCV for a prolonged period of time. The ages found in our cohort are much younger than previous HCV studies where HCV RNA clearance rates were less than 15%<sup>[3,20]</sup>. We attempted to address whether our high levels of HCV RNA persistence were due to the length and frequency of drug use, but these factors proved non-significant.

HCV genotype 1 has been considered a more aggressive genotype, associated with lower clearance rates, decreased susceptibility to current treatments<sup>[32-34]</sup> and in a few cases, associated with a faster progression of HIV disease<sup>[51]</sup>. Many HCV cohort studies, including the ALIVE cohort in Baltimore are primarily genotype 1 infections<sup>[5]</sup>. Examination of our cohort found three major HCV subtypes present in chronic infections, genotypes 6a (38%), 3b (37%) and 1a (19%)<sup>[52]</sup>. It is unclear whether HCV genotypes in our cohort are responsible for the low HCV RNA clearance rate.

Age, HBsAg positivity and lack of HIV-1 co-infection were the most significant factors resulting in HCV RNA

clearance. In comparison with the ALIVE cohort<sup>[5]</sup>, our lower age, lower prevalence of HIV-1 and higher prevalence of HBsAg, would predict higher rates of HCV RNA clearance than was seen. After removing HIV-1 and HBsAg positive individuals, only 15 of the remaining 221 participants underwent HCV clearance, at a rate of 6.8% (data not shown). This suggests that other host and viral factors are present in the Guangxi cohort resulting in high rates of HCV persistence. Studies of the ALIVE cohort by Thomas *et al* found the lower HCV RNA clearance levels in African American injection drug users to be linked to differences in certain HLA-frequencies<sup>[3,25]</sup>. There is also speculation of differences in TH1/TH2 cytokine balances between Caucasian and African Americans<sup>[53]</sup>. Whether HLA or cytokine profiles of Chinese individuals account for the low HCV RNA clearance rates has yet to be seen.

Injection heroin use in China is rapidly distributing HCV, HBV and HIV. The natural history of HCV in Chinese heroin users results in little spontaneous clearance of HCV RNA. Current HIV infection further debilitates the individual's ability to control HCV infection. And although HBV is endemic in China and viral interference between HBV and HCV may eliminate one of the hepatropic viruses, it may not decrease the possibility for further liver disease. Further studies within the Guangxi

cohort and other Chinese Provinces will better define the pathogenesis of HCV in Chinese ethnicities and non-genotype 1 infections. In order to decrease the spread of HIV-1 and HCV, education on safe-needle practices and the illnesses transmitted by injection drug use is urgent in China.

## ACKNOWLEDGMENTS

We would like to thank Lara Sanders at Abbott Diagnostics for her assistance in performing the HCV serotyping.

## COMMENTS

### Background

Hepatitis C virus (HCV) is quickly spread through injection drug use. A proportion of individuals infected with HCV undergo viral clearance while the remaining individuals develop a chronic infection which can lead to cirrhosis, hepatocellular carcinoma and the need for a liver transplant. Injection drug use is a major risk factor for HCV infections. This research studies the rate of HCV clearance in injection drug users from Southern China and the potential associated factors for clearance.

### Research frontiers

This research studies HCV clearance in Chinese ethnicities with non-genotype 1 infections.

## Innovations and breakthroughs

A low rate of HCV clearance was found in injection drug users of Chinese ethnicities. The majority of HCV infections were non-genotype 1 and many of the participants had current or previous co-infections with Hepatitis B viruses. Together these factors have previously been found to increase the level of viral clearance, suggesting other factors in the cohort are driving the low rate of viral clearance.

## Applications

This research highlights the need for further studies of HCV infections in Chinese ethnicities which concentrate on the immunogenetics of the host.

## Peer review

This paper describes the rate of hepatitis C viral RNA clearance in heroin users from south China and analysis of factors associated with it. The authors found a remarkably low rate of hepatitis C viral RNA clearance in the cohort and some possibly relating factors. The data presented are epidemiologically important, and the authors discussed the results appropriately.

Effect of infliximab on small bowel stenoses in patients with Crohn's disease. *World J Gastroenterol* 2008; 14(12): 1885-1890 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1885.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1885>

### Abstract

**AIM:** To assess prospectively small bowel stenoses in Crohn's disease (CD) patients treated with infliximab using Small Intestine Contrast Ultrasonography (SICUS).

**METHODS:** Twenty patients (M 12, age,  $42.7 \pm 11.8$  years), 15 of whom showed obstructive symptoms indicating the presence of small bowel stenosis, and 5 without stenosis, were treated with infliximab (5 mg/kg at wk 0, 2, 6 and 5 mg/kg every 8 wk thereafter) for steroid refractoriness, fistulizing disease, or to avoid high-risk surgery. SICUS was performed at the induction phase and at regular time intervals during the follow-up period of  $34.7 \pm 16.1$  mo (range 7-58). Small bowel stenoses were detected by SICUS, endoscopy and MRI.

**RESULTS:** In no case was progression of stenoses or the appearance of new ones seen. Of the 15 patients with stenosis, 5 stopped treatment after the induction phase (2 for no response, 3 for drug intolerance, one of whom showed complete regression of one stenosis). Among the remaining 10 patients, a complete regression of 8 stenoses (1 stenosis in 5 patients and 3 stenoses in one patient) was observed after 6-22 infliximab infusions.

**CONCLUSION:** In patients with CD treated with infliximab we observed: (a) No progression of small bowel stenosis and no appearance of new ones, (b) Complete regression of 1/22 stenosis after the induction phase and of 8/15 (53.3%) stenosis after 6-22 infusions

### INTRODUCTION

The effect of infliximab on symptomatic Crohn's intestinal stenosis is controversial and, even though there is no direct evidence indicating anti-TNF $\alpha$  antibodies therapy enhances stricture formation, it is usual practice to withhold infliximab therapy in patients with intestinal stenosis. Indeed, two retrospective studies have reported intestinal obstructions as a possible adverse event<sup>[1,2]</sup>. Such obstructive events have been interpreted as the outcome of an accelerated healing process that may trigger fibrosis within the inner layers of the gut wall. Conversely a review of large clinical studies concluded infliximab treatment did not increase the risk of developing strictures in patients with Crohn's disease (CD)<sup>[3]</sup>.

Because of the lack of non-invasive, radiation-free, techniques to assess transmural small bowel lesions, previous studies were retrospective and relied on assessments of the obstructive symptoms rather than of the stenotic lesion itself<sup>[4-7]</sup>. Small intestine contrast ultrasonography (SICUS), performed after the ingestion of oral contrast, enables measurement of the wall thickness and luminal diameter of the small bowel<sup>[8,9]</sup>. This technique can accurately assess the presence, size, and number of small bowel lesions in CD patients<sup>[10,11]</sup>.

In the present study, SICUS was used to assess the time course of small bowel stenosis in CD patients treated with infliximab, in a prospective follow-up investigation.

## MATERIALS AND METHODS

### Patients

As a part of a long-term prospective follow-up study, twenty patients (12 males and 8 females, age  $42.7 \pm 11.8$  years) with CD of the small bowel received infliximab therapy because of the presence of fistulae (11 patients) and/or steroid dependence (7 patients) and/or azathioprine intolerance (5 patients) and/or extra-intestinal manifestation (1 patient with ankylosing spondylitis). Fifteen had small bowel stenoses and obstructive symptoms (6 had previously received extensive small bowel resections).

Diagnosis of CD was based on the criteria adopted in the EC-study<sup>[12]</sup>. Medical history, including abdominal and extra-abdominal complaints, associated disease, CD behavior and CDAI at the first and last assessment of the follow-up, smoking status at diagnosis and at follow-up, family history, location of CD, duration of the disease, past surgery and endoscopic dilatation, and current and previous medical treatment were enquired and reported. Informed consent was obtained from each subject.

### Protocol of the study

Patients were scheduled to receive an infusion of infliximab (5 mg/kg) at wk 0, 2 and 6 (induction phase) and 5 mg/kg every 8 wk thereafter (maintenance therapy). Each patient was prospectively evaluated with SICUS. SICUS was performed during the infliximab induction phase and at six-month intervals thereafter. Each patient was initially subjected to a standardized clinical interview and a physical examination, performed by one of two certified and experienced gastroenterologists (FB, EC). After an overnight fast, patients were consecutively submitted to SICUS and, on different days and in random order, to an endoscopic examination, with multiple mucosal biopsies, of the entire large bowel and terminal or neoterminal ileum. When deemed necessary additional investigations, including biochemistry, upper GI endoscopy, abdominal CT or MRI, were performed. The sonologist was aware of the diagnosis and clinical data, including bowel surgery, but was blinded to the results of endoscopy and of other investigations, and did not review the results of the previous SICUS examinations at each follow-up assessment.

At the end of the US investigation small bowel abnormalities were reported on a standardized form, with particular reference to presence, anatomical site and extension in centimeters of intestinal wall, and lumen alterations. Fistulas and abscesses were looked for and reported.

### Small intestine contrast US (SICUS)

Real-time US was performed using Toshiba Tosbee (Tokyo, Japan) equipment with 3.5 MHz convex and 5 MHz linear array transducers. The sonologist (NP) had experience exceeding 7000 sonographic examinations of the whole abdomen and 4000 examinations of SICUS.

SICUS was performed according to a previously published<sup>[8]</sup> method. Briefly, after the ingestion of 375 mL of macrogol contrast oral solution (Promefarm, Milan,

Italy) and after the contrast was seen to flow through the terminal ileum into the colon, a retrograde follow-through assessment of the entire small bowel was performed visualizing, in a caudo-cranial sequence, the contrast-filled ileal and jejunal loops. The body positions of patients were changed and abdominal compression with the US transducer was used whenever required to improve visualization of any single loop and detection of intestinal abnormalities after the ingestion of the oral contrast. All examinations were recorded on VHS to be re-examined at will.

Wall thickness and lumen diameter were measured at several sites (proximal, middle and distal) of the small bowel at the level of the maximally distended, and not contracting, intestinal loops.

The criteria for presence of CD ileal lesions were as follows<sup>[10]</sup>: (1) Increased wall thickness (more than 3 mm) and lack and/or distortion of the intestinal folds; (2) presence of bowel stenosis defined as a lumen diameter of less than 1 cm, measured at the level of maximally distended loop, independent of the presence of pre-stenotic dilatation; and (3) bowel dilatation defined as lumen diameter more than 2.5 cm<sup>[8,9]</sup>. The extension of the stenoses was expressed as the length of the segment with a lumen diameter of less than 1 cm<sup>[8,9]</sup>. To distinguish a stenosis from a dynamic reversible reduction of luminal diameter due to intestinal contraction, multiple and prolonged, more than 15 min, observations of the narrowed tract were performed. Furthermore the presence of stenoses located in the terminal and neoterminal ileum were confirmed at endoscopy based on their inability to pass an 11 mm caliber endoscope; those in the more proximal small bowel segments were confirmed on at least two consecutive follow-up observations at SICUS and MRI.

For each detected lesion, site, number and length were reported on the record chart. Regression of intestinal stenosis was defined as an intestinal lumen with a diameter more than 1 cm as assessed by at least 2 follow-up SICUS evaluations, and confirmed at endoscopy for the lesions located in the terminal ileum, and at MRI for those located in the more proximal small bowel segment.

## RESULTS

### Induction phase

Fifteen patients had one or more stenosis of the small bowel; five patients did not have stenoses. In two female patients with penetrating CD behavior, infliximab therapy was discontinued for intolerance after the first i.v. administration. In an additional 2 female patients, one with entero-enteric fistulae and one with recto-vaginal fistula, treatment was discontinued after the induction period owing to a lack of response to the treatment. After the first 3 induction infusions there was a complete regression of one of the three upper GI stenoses in one male patient, who discontinued treatment owing to intolerance.

### Maintenance phase

Fifteen patients then received maintenance therapy with

infliximab. The main characteristics of patients receiving maintenance therapy are reported in Table 1 and Figure 1. During the follow-up period of  $34.7 \pm 16.1$  mo (range 7-58 mo, median 38 mo), SICUS and, when required, endoscopic and imaging investigations, were performed at  $10.7 \pm 3.7$  mo intervals in all but 3 patients who were assessed at induction and regularly subjected to follow-up starting at 21, 24 and 28 mo after the induction phase. Three patients were referred for surgery as they did not respond to maintenance therapy; one for entero-cutaneous fistulas after 3 infusions, one for severe recurrence after 12 infusions and one who previously received surgical operations and endoscopic dilatations for recurrent obstructive episodes after 6 infusions. Thirteen patients remained on maintenance therapy.

#### Patients with small bowel stenosis

Nine patients had 1 or more small bowel stenoses (1 patient with 4 jejunal stenoses; 1 patient with 1 stenosis at the level of proximal ileum; 1 patient with 3 stenoses at the level the distal and terminal ileum; 1 patient with 1 stenosis at the level of distal ileum; 2 patients with 1 stenosis at the level of terminal ileum; 3 patients with 1 stenosis at the level of neo-terminal ileum). Complete regression of 8 stenoses, 3 of which showed prestenotic dilatation, was observed in 6 patients; in 2 of these, the stenosis was at the level of the neo-terminal ileum. In one patient with three stenoses, the most proximal one regressed after 9 cycles of therapy, whereas the remaining two regressed after 22 cycles (Figure 2). Regression of all stenoses was confirmed in subsequent observations performed during the follow-up from a minimum of 1 mo to a maximum of 42 mo. In 3 patients, there was no variation in the pre-existing 6 stenoses, all with pre-stenotic dilatation, but the obstructive symptoms disappeared.

#### Patients without small bowel stenosis

Among the 5 patients without stenoses, none developed stenosis or obstructive symptoms and in one patient a regression of terminal ileum alteration was observed (Table 1). On average, CDAI improved during infliximab maintenance therapy, but no relationship was found between CDAI at time of induction or at last follow up observation and regression of stenoses.

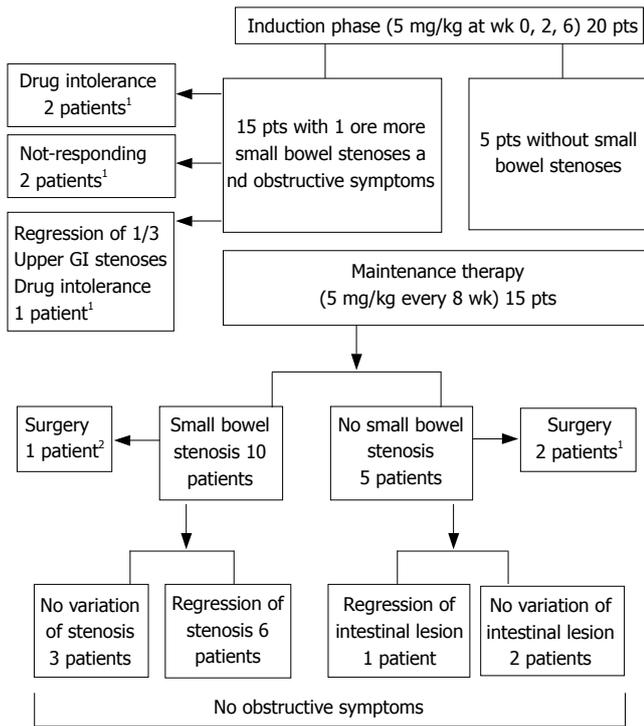

## DISCUSSION

The most relevant finding of the present study is the observation that during therapy with anti-TNF alpha antibodies there was no progression of pre-existing stenoses, no appearance of new ones, and complete regression of 1/22 (4.5%) small bowel stenoses after the induction phase and 8/15 (53.3%) small bowel stenoses after 6-22 maintenance infusions. In addition, despite the long duration of CD, no stenosis progressed to require surgery and in the presence of stenosis obstructive symptoms disappeared during infliximab treatment.

The limitations of this study are the small size of the population and the observational type of assessment. Confirmation in an *ad hoc* randomized controlled study performed in a larger sample size is required.

The strengths of this study are the prospective collection of data, the morphological assessment of CD stenosis with description of intestinal wall and lumen diameter and in comparison with previous reports, the relatively long duration of the follow-up in patients with small bowel stenosis treated with infliximab therapy.

A previously published review<sup>[3]</sup> of prospectively collected data in the TREAT registry and from the ACCENT I trial concluded long-term treatment with infliximab was not associated with increased risk of

**Figure 1** Table showing follow-up of patients on therapy with infliximab. <sup>1</sup>Stopped treatment; <sup>2</sup>In maintenance treatment after surgery.

development of stenosis. These conclusions were based on clinical judgment, as radiological and endoscopic evaluations were performed at the discretion of the investigators, and not systematically in patients without obstructive symptoms. In addition, because patients with symptomatic stenosis were excluded from the study, the effect of infliximab on high-grade stenosis could not be assessed.

The present study refers to patients with CD of the small bowel treated with infliximab and belonging to a larger CD patient population assessed in a long-term prospective follow-up study, in which SICUS is used to evaluate the time course of small bowel lesions.

SICUS has enabled the normal values of wall thickness and luminal diameter of the small bowel and the reproducibility of measurements in healthy control subjects to be defined<sup>[9]</sup>. Furthermore, the accuracy of SICUS in the assessment of the number, site and extension of small bowel lesions has been validated with intraoperative findings<sup>[10]</sup>.

In the present study, patients with symptomatic stenosis, some of whom have indications for surgery, and patients without stenosis, were prospectively followed up.

The observations obtained progressively in this case series indicate anti-TNF antibody therapy did not cause intestinal stenosis or obstructive symptoms. This finding is in contrast with previous reports of retrospective studies<sup>[1,2]</sup>, in which obstructive adverse events occurred after infliximab administration. However, retrospective analysis of these observations did not reveal whether the obstructive complication was due to a previously existing symptomatic stenosis and refractory to other therapies leading up to the use of infliximab. In the present study,

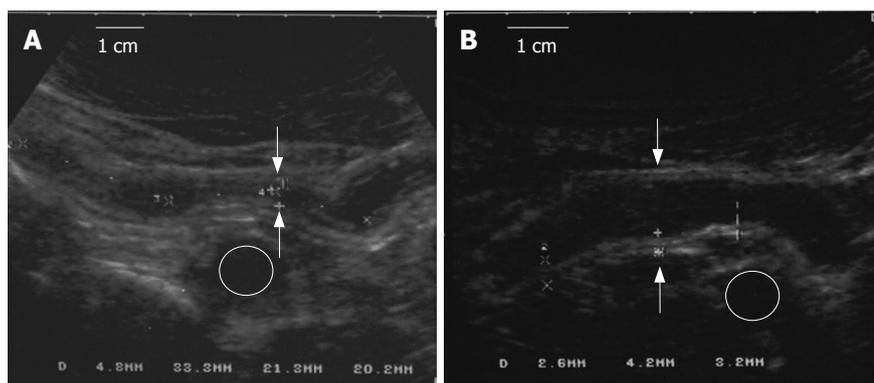

three patients received surgery during maintenance therapy. In one, who received stricturoplasty for stenosis, the lesion was already present and had surgical indications before infliximab treatment. Infliximab was administered in an attempt to avoid surgery in a patient with a previous history of intestinal resection and at risk of developing short bowel syndrome. After surgery, infliximab maintenance therapy was continued and after 2 years of follow-up no new stenosis has appeared and the patient shows no obstructive symptoms. In the second patient, who received surgery for enterocutaneous fistula, there was a temporary improvement after infliximab treatment and a symptomatic recurrence after the induction phase plus 3 cycles of maintenance therapy drug administration. In the third patient with entero-enteric fistulas, after an initial improvement of symptoms there was a severe recurrence after one year of maintenance therapy.

In three additional patients, despite the stenoses not changing after treatment, there was a disappearance of obstructive symptoms, and surgery was not required in the follow-up period. In the remaining six patients, there was complete regression of stenoses, irrespective of the CD type, whether stenosing or fistulizing, the site of the lesion, age of the patient, smoking status at follow-up, type and number of previous operations and pharmacological treatment, or the duration of CD.

It is reasonable to interpret the regression of the stenotic lesions as due to the anti-inflammatory effect of infliximab treatment.

A retrospective study evaluating the symptomatic response of obstructive symptoms for up to 18 mo reported a favorable response in 9 of 11 patients treated with infliximab and concomitant immunosuppressive drugs<sup>[13]</sup>. In the present study, only two patients of the 9 with stenoses receiving maintenance infliximab therapy received azathioprine concomitantly, indicating the favorable response was obtained after treatment with the biological agent, irrespective of the immunosuppressive drugs. In addition, regression of stenoses and obstructive symptoms was confirmed at all subsequent follow-up assessments. Such a favorable long-term effect could be a result of the maintenance treatment with infliximab that, when started immediately after endoscopic dilatation of small bowel stenosis, has been reported to prevent stenotic progression and obstructive complications in a 2-year follow up study<sup>[14]</sup>.

Tissue inflammation and fibrosis in the gut wall are regulated by cytokines with opposite effects. TNF has both a pro-inflammatory and anti-fibrotic action in the intestinal mucosa<sup>[15]</sup>. Anti-TNF agents induce endoscopic<sup>[16]</sup> and histological<sup>[17]</sup> mucosal healing, but it is not known how they act in the deeper layers of the gut wall and whether, and how, they affect fibrosis at this level<sup>[18]</sup>. The regression of stenotic lesions after administration indicates anti-TNF agents may act as antifibrotic agents in the deeper layers of the gut wall. It is also of relevance that 3 stenotic lesions with prestenotic dilatations regressed during infliximab treatment. A prestenotic dilatation is usually considered to be the result of a long-term stabilized and non-compliant luminal stricture due to circumferential fibrotic thickening of the gut wall. The intimate texture of this increased gut

**Figure 2 A:** Before infliximab therapy: A stenotic lesion of the terminal ileum, with narrow lumen (white arrows) and increased thickness of the intestinal wall. The markers assess the length. The iliac vessel is indicated (circle); **B:** After infliximab therapy (22 cycles): The same ileal segment with an increased lumen diameter (12 mm) and reduced thickness of the intestinal wall. The iliac vessel is indicated (circle).

wall thickness cannot be ascertained with SICUS. It seems, however, that Infliximab treatment can remodel it<sup>[18]</sup>. This event is possible because, in CD, fibrosis is mainly produced by mesenchymal cells, myocytes, interstitial cells of Cajal, and fibroblasts, all of which can proliferate and transform in fibrogenic cells or, under favorable conditions, redifferentiate into non-fibrogenic cells<sup>[19-27]</sup>. Several pro- and anti-fibrogenic factors and intestinal fibroblasts participate in the development of intestinal fibrosis<sup>[28]</sup> and should be antagonized to prevent fibrosis. In a murine model, chronic inflammation-induced intestinal fibrosis could be prevented by means of antisense NF- $\kappa$ B<sup>[29]</sup>. In the present study, it would appear that infliximab acts on the Crohn's lesion of the gut wall by either stopping or reversing the evolution of the stenotic process. However, in the patients investigated, no relevant clinical factors with high inter- and intra-individual variability predicted the response of the stenotic lesions to infliximab, indicating the degree of reversible inflammation and fibrosis may differ from one subject to another and may differ from one stenosis to another in the same subject.

Complete or partial regression of the stenotic lesions did occur early after induction, or late after several, up to 22, cycles of infliximab administration.

The great time and cycle response variability in the non-progression and regression of the stenoses may imply the effect of infliximab on the lesion may depend on at which stage of the CD fibrogenetic process infliximab is administered. Supportive of this hypothesis is the experimental evidence infliximab downregulates basic fibroblast growth factor and vascular endothelial growth factors involved in the process of intestinal fibrogenesis in CD<sup>[30]</sup>. Theoretically, the earlier in the process of fibrogenesis infliximab is administered, the greater the probability to prevent stricture formation. Indeed, in two operated patients with early therapy after postsurgical recurrence there was a prompt regression of stenotic lesion, and in one of them, complete disappearance of pretreatment endoscopic and SICUS alterations were observed.

In conclusion, within the time-limit of the follow-up, it would appear infliximab is able to modify the expected time course of the disease in a relevant number of treated patients by stopping further development of, or causing regression of, stenotic lesions, thus being helpful to postpone or avoid surgical interventions.

Longer follow-up studies and properly structured

clinical trials are needed to assess whether infliximab loses its response over time and whether the potential risks of infliximab therapy outweigh the possible benefits.

## COMMENTS

### Background

Strictures are common features in Crohn's disease (CD). Several studies suggest that, in CD, fibrosis is mainly produced by mesenchymal cells, myocytes, interstitial cells of Cajal and fibroblasts, all of which can proliferate and transform into fibrogenic cells or, under favorable conditions, redifferentiate in non-fibrogenic cells. Anti-TNF agents induce mucosal healing. Concerns have been raised that rapid healing of narrowed segments induced by anti-TNF agents may further narrow the lumen. Several differing studies support the concept of an antifibrogenic role for infliximab, possibly down-regulating collagen production restoring migration and reducing collagen production of CD myofibroblasts.

### Research frontiers

Follow-up studies based on the use of available imaging techniques to investigate, from different points of view, *in vivo*, the CD-involved intestinal wall and the response to different treatments.

### Innovations and breakthroughs

The strengths of this study are: (1) The prospective collection of data; (2) the morphological assessment of CD stenosis; (3) the relatively long duration of the follow-up of patients with small bowel stenosis who had been treated with infliximab therapy; and (4) the study was not supported by any pharmaceutical company and the authors have no conflicts of interests.

### Applications

These data suggest the presence of stenosis in patients with severe CD does not contraindicate anti-TNF treatment. If these data can be confirmed in an ad hoc randomized controlled study performed in a larger sample size, treatment with infliximab: (1) Could be indicated in patients with stenotic lesions requiring surgery; (2) may delay or even remove the need for surgery, and thus, favorably change the natural history of CD in patients with stenotic lesions of the small bowel.

### Terminology

Small intestine contrast ultrasonography (SICUS) was not different from other structures (i.e bladder, gallbladder, stomach). Filling the small intestine with fluid enables visualization of the intestinal wall and lumen. Macrogol links to water that remains in the intestinal lumen. After the ingestion of 375 mL-500 mL of macrogol solution, it is possible to visualize the entire small intestine from the Treitz to the ileo-cecal valve.

### Peer review

This is an interesting small series showing infliximab does not appear to have the major adverse effect on Crohn's strictures that was at one time feared.

### Abstract

**AIM:** To study the association of the frequency and pattern of KIT and PDGFRA mutations and clinicopathological factors in a group of patients with gastrointestinal stromal tumors (GIST).

**METHODS:** Thirty patients with GIST were examined. Exons 9, 11, 13, and 17 of the KIT and exons 12 and 18 of the PDGFRA gene were analyzed for the presence of mutations by PCR amplification and direct sequencing.

**RESULTS:** KIT or PDGFRA mutations were detected in 21 of the 30 patients (70%). Sixteen patients had mutations within KIT exon 11, three within KIT exon 9, and two within PDGFRA exon 18. GISTs with KIT exon 9 mutations were predominantly located in the small intestine, showed a spindle cell phenotype, and were assessed as potentially malignant. GISTs with KIT exon 11 mutations were located in the stomach and intestine, showed mainly a spindle cell phenotype, and were scored as potentially malignant ( $P < 0.05$ ). Tumors with KIT exon 11 codon 557/558 deletion/insertion mutations were found to be associated with a potentially malignant clinical behaviour ( $P < 0.003$ ). GISTs with PDGFRA mutations located in stomach showed a mixed

cell phenotype and were classified as of very low or low moderate malignant potential.

**CONCLUSION:** Determination of KIT and PDGFRA mutations should be additional parameters for the better prediction of GISTs clinical behaviour. Tumors with deletion/insertion mutations affecting codons 557/558 of the KIT gene seem to represent a distinct subset of malignant GISTs.

KIT exon 11 codon 557/558 deletion/insertion mutations define a subset of gastrointestinal stromal tumors with malignant potential. *World J Gastroenterol* 2008; 14(12): 1891-1897 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1891.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1891>

### INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are the most common primary mesenchymal tumors of the gastrointestinal tract. Their biological behaviour is difficult to predict. GIST prognosis is largely dependent on the size, mitotic index, and presence or absence of metastases<sup>[1-3]</sup>. We now know that GISTs may have either a well-developed or an incomplete myoid, neural, autonomic nerve, or mixed phenotype, or may remain undifferentiated<sup>[2]</sup>. Typically, GISTs are immunohistochemical positive for KIT tyrosine kinase receptor which is perhaps their single best defining feature<sup>[4,5]</sup>.

Some GISTs are benign tumors and most of these are found incidentally. Other GISTs metastasize to liver or disseminate in the peritoneal cavity. Most of the latter type GISTs do not respond to chemotherapy and

ultimately kill the hosts. The pharmaceutical development and therapeutic implications of protein tyrosine kinase inhibitors has refocused the attention on GIST. Until now, the treatment with selective tyrosine kinase inhibitors, such as imatinib mesylate, for patients with GISTs has hinged on the KIT positive immunostaining tumors<sup>[6]</sup>. Although the KIT positivity by immunohistochemistry becomes invaluable in the diagnosis of GISTs, some authors believe that a small subgroup of these tumors fulfill the clinical and morphological criteria of GISTs, and lack KIT expression<sup>[7,8]</sup>. Studies in the last decade have established that activating mutations of KIT are present in 40% to 92% of GISTs and likely play an essential role in the development of these tumors<sup>[9]</sup>. The subset of GISTs that lack detectable mutations could be divided into a group that has activating mutations in the related tyrosine kinase platelet-derived growth factor receptor alpha (PDGFRA) and a group without identified kinase mutations<sup>[10,11]</sup>.

A proportion of GISTs shows mutations in the regulatory juxtamembrane domain of the c-kit gene. These KIT mutations have been shown to represent gain-of-function mutations leading to ligand independent activation of the tyrosine kinase and the phosphorylation cascade that leads into mitogenic activation<sup>[12,13]</sup>. Benign and malignant GISTs carry mutations in KIT and PDGFRA gene, but although these mutations vary among GISTs the definitive genotype/phenotype correlations are still under consideration<sup>[9-11,14]</sup>. Moreover, currently it is not clear whether mutations are independent prognostic factors<sup>[15-18]</sup>.

In this study we examined a series of 30 patients with primary GISTs defined by different types of KIT and PDGFRA mutations, to investigate whether mutations' type and distribution are associated with GISTs clinical behaviour.

## MATERIALS AND METHODS

### *Clinical and pathological data*

Using the database of Surgery and Pathology Departments of Areteion University Hospital and Evangelismos General Hospital, we collected records with a pathologic diagnosis of stromal tumor within the GI tract. Thirty patients' records with the diagnosis of GIST between 2001 and 2005 were reviewed. Patients' age and gender, clinical manifestations, tumor size, pathological characteristics including cell type, cellularity, nuclear atypia, the number of mitoses, the presence of necrosis, or hemorrhage were recorded.

Formalin-fixed and paraffin-embedded samples were used for immunohistochemical examination. Tumors were divided according to their morphologic profile into four histological categories: epithelioid (Ep), spindle cell (Sp), mixed spindle cell with focal epithelioid component (mixed type 1), and tumors with mixed epithelioid and focal spindle cell component (mixed type 2). Mitoses were counted in 5 separate groups of 50 HPFs, a total area of 5 mm<sup>2</sup>, and the highest of these 5 counts was recorded. Mitotic activity was scored as low (< 5/50 HPF), intermediate (5-10/50 HPF), or high (> 10/50 HPF). Tumors were as-

signed to risk assessment categories based on size, mitotic index, and location according to published criteria<sup>[17]</sup>.

### *Immunohistochemistry*

Immunohistochemical staining was performed using the following primary antibodies: KIT (CD 117 antigen, polyclonal, Dako, USA; 1:50 dilution), PDGFRA (polyclonal, Santa Cruz, California, USA, 1:400), a-smooth-muscle actin (clone asm-1, Dako; 1:200), desmin (clone DE-R-11, NovocastraLabs; 1:100), S-100 (clone S1/61/69, Novocastra Labs; 1:40), CD34 (clone QBEnd/10, Novocastra Labs; 1:50), Ki-67 (clone MM1, Novocastra Labs; 1:200) by a standard three step immunoperoxidase procedure (APAAP, DAKO, Glostrup, Denmark). Appropriate positive controls were run in parallel for all antibodies tested. According to the proportion of tumor cells showing an immunopositive reaction, tumors were classified as negative (< 10%) or positive (> 10%).

### *DNA sequencing*

Exons 9, 11, 13, and 17 of the KIT and exons 12 and 18 of the PDGFRA gene were evaluated for the presence of mutations by PCR amplification and direct sequencing. DNA was extracted from formalin-fixed, paraffin embedded tissue samples using the PUREGEN DNA Purification System (Gentra Systems, Minneapolis, USA). The primer pairs used for PCR amplification and direct sequencing are given in Table 1.

Annealing temperature for the KIT exon 9 and 13 and for the PDGFRA primer sets was 53°C and for the KIT exon 13 and 17 primer sets 56°C, respectively. Amplification products were separated by 2% agarose ethidium bromide gel electrophoresis to confirm correct amplification. Products were purified with NucleoSpin Extract II kit (Macherey-Nagel, Duren, Germany) and applied to bi-directional sequencing on an ABI130 sequencer using the Big Dye Terminator v.1.1 KIT (Applied Biosystems, Foster City, CA).

### *Statistical analysis*

Data were analyzed using Statistical software SPSS Version 13.0. Fisher's Exact Test of Independence was used to evaluate the statistical significance of associations in two-way contingency tables to determine whether KIT and PDGFRA gene mutations are independent of clinicopathological parameters. Statistical significance would be inferred at a two-tailed  $P < 0.05$ .

## RESULTS

### Types and distribution of KIT and PDGFRA gene mutations among GISTs

All detected mutations, irrespective of whether involving single nucleotide substitutions or insertion/deletions, preserved the open reading frame. KIT or PDGFRA mutations were detected in 21/30 GIST patients (70%). Nine patients had no detectable mutations with the methods used. Sixteen patients had mutations within KIT exon 11 (Figure 1), three patients within KIT exon 9, and two patients within PDGFRA exon 18. No mutations were found in KIT exons 13, 17, or PDGFRA exon 12. The mutations within KIT exon 11 were heterogeneous and consisted of 10 simple deletions, 4 point mutations, and 2 insertions (Figures 1 and 2A). Codons 557 and 558 deletion/insertion mutations were found in 8 samples (50%) of the KIT exon 11 mutations followed by codon 560 (3 cases) and codon 559 (2 cases). Six of the mutations affecting codons 557/558 were deletions of various sizes and two were 3nt insertions.

KIT exon 9 mutations were all 6 bp insertions resulting in tandem duplication of the amino acids 502Ala-503Tyr (2 out of 3) (Figure 2B) or the amino acids 501Ser-502Ala. PDGFRA mutations affecting exon 18 consisted of a D842V substitution and a simple 12 bp deletion.

### Clinicopathologic profile of patients with GISTs

The clinicopathological and molecular findings of the GIST patients are summarized in Table 2. Sixteen of the patients (53.3%) were male and 14 (46.7%) were female. Patients with KIT mutation exon 9 GISTs were exclusively male. Patient age ranged from 46 to 82 years with a median of 63.4 years. Sixteen tumors (53.3%) were located in the stomach, 9 (30%) in small intestine, and 5 (16.7%) in large intestine. Two out of three GISTs with KIT exon 9 mutations were located within the small intestine. GISTs with KIT exon11 mutations were located in the stomach

(6/16) and within the small and the large intestine (10/16). GISTs with PDGFRA mutations were exclusively located in the stomach (2/2). The majority of GISTs with no detectable mutations in KIT or PDGFRA (77.8%) were located in stomach.

Tumor size ranged from 0.7 cm to 19 cm (mean: 8, std: 5.2). The mean tumor size of GISTs with KIT exon 9 mutations was 6.7 cm (std: 8.1), and that of GISTs with KIT exon 11 mutations 7.8 cm (std: 8.2). The mean tumor's size of GISTs with KIT exon 11 codon 557/558 mutations was 11.3 cm, while 4.4 cm in GISTs without 557/558 mutations ( $P = 0.025$ ) (Table 3). The mean size of GISTs with PDFGRA mutations was 11 cm (std: 7.8).

Grossly, most tumors were presented as circumscribed or lobulated masses. Cystic change was recognized in several cases. Histologically, the majority of tumors (66.7%) showed spindle cell phenotype, another 10% epithelioid, 13.3% mixed type 1, and 10% mixed type 2 phenotypes.

Deletions in KIT exon 11 were frequently found to be associated with a spindle cell phenotype, substitutions in KIT exon 11 were exclusively found to be associated with a mixed type 1 phenotype, while insertions in KIT exon 11 that affect codons 557/558 exclusively showed an epithelioid phenotype ( $P < 0.05$ ) (Table 4). The majority of GISTs with KIT exon 9 mutations showed a spindle cell phenotype, whereas GISTs with PDGFRA exon 18 mutations were both of mixed type morphology. The mitotic count ranged from 0 to 22/50 HPF ( $\times 400$ ) (mean: 4.8). The majority of tumors (70%) contained less than 5/50 HPF mitoses, 23.3% of tumors contained mitoses between 5 and 10/50 HPF, while only 6.7% of tumors contained mitoses  $> 10/50$  HPF. GISTs with KIT exon 9 and exon 11 mutations exhibited a mean value of 5/50 HPF mitoses (std: 4.7) and 4.8/50 HPF mitoses (std: 4.7), respectively. In GISTs with PDGFRA mutations, mitotic activity was low with 2 to 4/50 HPF.

Low malignant potential	7.1	12.5	37.5	
Low moderate malignant potential	14.3			
Malignant potential	21.4	87.5	25	

no necrosis. Absence of necrosis was present in 2/3 of GISTs with KIT exon 9-11 mutations, and in all GIST patients with PDGFRA mutations. A high proportion of GISTs with codon 557/558 mutations (50%) was found to be necrotic. The majority (66.6%) of the tumors showed no hemorrhage. Hemorrhage was found in all cases of GISTs with PDGFRA mutations ( $P = 0.038$ ), but to be absent in most of the GISTs with KIT mutations. The majority (80%) of the tumors showed no ulceration. All the tumors with ulceration were positive for KIT exon 9 or 11 mutations.

Immunohistochemically, 28 tumors were positive for KIT expression. All GISTs with KIT and PDGFRA mutations showed weak to strongly and diffuse positive staining for the KIT gene. PDGFRA expression was immunohistochemically detected in 18 cases (60%). Alpha-smooth muscle actin, desmin, and S-100 protein were positive in 12 (40%), 3 (10%), and 4 (13.3%) cases, respectively. A-SMA was positive in 47.6% of GISTs with KIT mutations. CD34 expression was positive in 20 (67%) cases. Ki-67 expression was strongly positive (5%) in 13 cases (43%). Applying the clinical behaviour (risk assessment) of primary tumors according to Miettinen and Lasota (2006) 6.7% of GISTs were benign, 30% of very low malignant, 16.7% of low malignant, 6.7% of low moderate malignant, and 40% of malignant potential. 57.9% of GISTs with KIT mutations were associated with malignant potential ( $P = 0.003$ ) whereas none of the GISTs with PDGFRA mutations was assessed as of malignant potential. 66.7% of the GISTs with exon 9 KIT mutations and 56.3% of those with exon 11 KIT mutations were assessed as of malignant potential ( $P = 0.036$ ) (Tables 4 and 5). Tumors with KIT exon 11 codon 557/558 mutations showed a statistically significant correlation with malignant potential scoring (87.5% *vs* 25% of the non 557/558,  $P = 0.003$ ).

**Table 4** GIST phenotypes according to the presence and type of KIT mutations

## DISCUSSION

In the late 1990s it was shown that GISTs share morphological, immunohistochemical, and genetic characteristics with the interstitial cells of Cajal (ICCs). Most GISTs express strongly and specific the tyrosine kinase KIT oncoprotein that it was claimed to be required for the diagnosis<sup>[4,5]</sup>. It is now clear that a small but significant group of GISTs (5%-10%) are KIT negative<sup>[7,8]</sup>. It seems that GISTs probably do not constitute a homogenous group of tumors. Until now the prediction of their biological behaviour depended on classic clinicopathological characteristics as size and mitotic activity or location. Moreover, in the last years a significant correlation has been suggested between these pathological parameters and molecular alterations<sup>[11]</sup>.

It has been suggested that tumors' location were associated with mutations. GISTs with KIT exon 9 mutations were predominantly located in the small intestine whereas GISTs with PDGFRA mutations represent gastric tumors<sup>[10,15,17]</sup>. Other studies failed to find a significant association between KIT exon 11 mutation status and tumor location<sup>[18,19]</sup>.

With regard to the primary tumor location, our results indicated that KIT exon 9 mutations were almost always detected in GISTs of intestinal origin, whereas PDGFRA mutations were associated with GISTs of gastric origin. The incidence of exon 11 KIT mutations did not appear to be related to tumor location.

The mutation type in GISTs has been reported to

be associated with the phenotype<sup>[20,21]</sup>. With respect to histological phenotype, KIT exon 11 mutations were strongly associated with spindle cell phenotype GISTs. Deletions in KIT exon 11 have been mostly associated with spindle cell phenotype, substitutions in KIT exon 11 were associated exclusively with mixed cell phenotype, whereas insertions in KIT exon 11 affecting codons 557/558 were exclusively associated with epithelioid cell phenotype GISTs. PDGFRA mutations, in this study, were exclusively associated with mixed type phenotype and low risk assessment GISTs.

An association between the occurrence of KIT exon 9 and 11 mutations in GISTs and malignancy was suggested by previous studies<sup>[14,22]</sup>. Our data support this notion by showing a significant association between KIT exon 11 and exon 9 mutations and malignant GISTs. Moreover, in our data this association remains significant when only the exon 11 mutations affecting codons 557/558 were analysed. This observation is in agreement with previous studies that indicate an association of 557/558 deletions with poor prognosis and metastatic behaviour<sup>[23]</sup>. In addition to deletions it is possible that insertions affecting the 557/558 codon, although rare, are also associated with malignant phenotype as suggested by previously published data<sup>[24-26]</sup>. Codons 557/558 have been also found to represent significant a/a residues either for inhibitory role in the control of the receptor tyrosine kinase activity (Tryp557) or in constitutive receptor phosphorylation (Lys558)<sup>[27,28]</sup>.

In conclusion, in this study we have analyzed the frequency and pattern of KIT and PDGFRA mutations in a group of GISTs, and we presented evidence that tumors defined by KIT codon 557/558 deletion/insertion mutations represent a subgroup of GISTs with malignant clinical behaviour. These findings underline the need for a new classification system that would integrate specific molecular alterations to the pathological criteria.

## COMMENTS

### Background

In the late 1990s it was shown that most gastrointestinal stromal tumors (GISTs) share morphological, immunohistochemical, and genetic characteristics with the interstitial cells of Cajal (ICCs). Most GISTs express strongly and specifically the tyrosine kinase KIT oncoprotein that it was claimed to be required for the diagnosis. GISTs are the most common primary mesenchymal tumors of the gastrointestinal tract. Their biological behaviour is difficult to predict. GISTs prognosis is largely dependent on the size, mitotic index, and presence or absence of metastases. We now know that GISTs may have either a well-developed or an incomplete myoid, neural, autonomic nerve, or mixed phenotype, or may remain undifferentiated. Typically, GISTs are immunohistochemical positive for KIT tyrosine kinase receptor which is perhaps their single best defining feature. Studies in the last decade have established that activating mutations of KIT are present in 40% to 92% of GISTs and likely play an essential role in the development of these tumors. The subset of GISTs that lack detectable mutations could be divided into a group that has activating mutations in the related tyrosine kinase platelet-derived growth factor receptor alpha (PDGFRA) and a group without identified kinase mutations. A proportion of GISTs shows mutations in the regulatory juxtamembrane domain

of the c-kit gene. These KIT mutations have been shown to represent gain-of-function mutations leading to ligand independent activation of the tyrosine kinase and the phosphorylation cascade that leads into mitogenic activation.

### Research frontiers

Benign and malignant GISTs carry mutations in KIT and PDGFRA gene, but although these mutations vary among GISTs the definitive genotype/phenotype correlations are still under consideration. Moreover, currently it is not clear whether mutations are independent prognostic factors. It has been suggested that tumors' location was associated with mutations in GISTs. KIT-MT exon 9 GISTs were predominantly located in small intestine whereas GISTs with PDGFRA mutations represent gastric tumors. Others studies failed to find a significant association between KIT exon 11 mutation status and tumor location. The mutation type in GISTs has been reported to be associated with the phenotype. With respect to histological phenotype, KIT exon 11 mutations were strongly associated with spindle cell phenotype GISTs. Deletions in KIT exon 11 have been mostly associated with spindle cell phenotype, substitutions in KIT exon 11 were associated exclusively with mixed cell phenotype, whereas insertions in KIT exon 11 affecting codons 557/558 were exclusively associated with epithelioid cell phenotype GISTs.

### Innovations and breakthroughs

In addition to deletions it is possible that insertions affecting the 557/558 codon, although rare, are also associated with malignant phenotype as suggested by previously published data. Codons 557/558 have been also found to represent significant a/a residues either for inhibitory role in the control of the receptor tyrosine kinase activity (Tryp557) or in constitutive receptor phosphorylation (Lys558). We presented evidence that tumors defined by KIT codon 557/558 deletion/insertion mutations represent a subgroup of GISTs with malignant clinical behaviour.

### Applications

These findings underline the need for a new classification system that would integrate specific molecular alterations to the pathological criteria.

### Peer review

This is a nice study which analysed the frequency and pattern of KIT and PDGFRA mutations in a group of patients with GISTs and the association of these mutations with other clinicopathological factors.

### Abstract

**AIM:** To evaluate portal hypertension parameters in liver cirrhosis patients with and without esophageal varices (EV).

**METHODS:** A cohort of patients with biopsy confirmed liver cirrhosis was investigated endoscopically and with color Doppler ultrasonography as a possible non-invasive predictive tool. The relationship between portal hemodynamics and the presence and size of EV was evaluated using uni- and multivariate approaches.

**RESULTS:** Eighty five consecutive cirrhotic patients (43 men and 42 women) were enrolled. Mean age ( $\pm$  SD) was 47.5 ( $\pm$  15.9). Portal vein diameter ( $13.88 \pm 2.42$  vs  $12.00 \pm 1.69$ ,  $P < 0.0005$ ) and liver vascular index ( $8.31 \pm 2.72$  vs  $17.8 \pm 6.28$ ,  $P < 0.0005$ ) were found to be significantly higher in patients with EV irrespective of size and in patients with large varices ( $14.54 \pm 1.48$  vs  $13.24 \pm 2.55$ ,  $P < 0.05$  and  $6.45 \pm 2.78$  vs  $10.96 \pm 5.05$ ,  $P < 0.0005$ , respectively), while portal vein flow velocity ( $13.25 \pm 3.66$  vs  $20.25 \pm 5.05$ ,  $P < 0.0005$ ), congestion index (CI) ( $0.11 \pm 0.03$  vs  $0.06 \pm 0.03$ ,  $P < 0.0005$ ), portal hypertensive index ( $2.62 \pm 0.79$  vs  $1.33 \pm 0.53$ ,  $P < 0.0005$ ), and hepatic ( $0.73 \pm 0.07$  vs  $0.66 \pm 0.07$ ,  $P < 0.001$ ) and splenic artery resistance index (RI) ( $0.73 \pm 0.06$  vs  $0.62 \pm 0.08$ ,  $P < 0.0005$ ) were significantly lower. A logistic regression model confirmed spleen size ( $P = 0.002$ , AUC 0.72) and portal hypertensive index ( $P = 0.040$ , AUC 0.79) as independent predictors for the occurrence of large esophageal varices (LEV).

**CONCLUSION:** Our data suggest two independent situations for beginning endoscopic evaluation of

Tarzamni MK, Somi MH, Farhang S, Jalilvand M. Portal hemodynamics as predictors of high risk esophageal varices in cirrhotic patients. *World J Gastroenterol* 2008; 14(12): 1898-1902 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1898.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1898>

### INTRODUCTION

The most common clinical manifestations of portal hypertension in patients with liver cirrhosis are esophageal varices (EV). Bleeding EV are of the most apprehensive complications of portal hypertension contributing to the estimated 32000 deaths annually attributed to cirrhosis<sup>[1]</sup>. Reducing morbidity and mortality of EV remains a challenge for physicians managing patients with chronic liver disease.

The incidence of EV in patients with cirrhosis ranges from 35% to 80%. Approximately one third of the patients with EV experience variceal bleeding, which in up to 70% of the survivors is followed by repeated bleeding episodes<sup>[2]</sup>. Esophageal variceal bleeding might be a deadly complication in liver cirrhosis patients with portal hypertension<sup>[3,4]</sup>. A screening is indicated in patients with newly diagnosed cirrhosis. Medical treatment must be considered as soon as varices are detected to prevent a first bleeding<sup>[5]</sup>.

It has been shown that the risk of EV bleeding is related to its size<sup>[6]</sup>. Large esophageal varices (LEV) are at a greater risk, which is possibly due to a higher variceal wall tension<sup>[7]</sup>. Availability of non-invasive methods for detection of LEV may help limit the number of endoscopic procedures.

The estimation of blood flow volume with Doppler sonography is non-invasive and allows physiologic measurements that were impossible to obtain in the past. It was widely used to explore the relationship between EV hemodynamics associated with portal hypertension and liver cirrhosis<sup>[8,9]</sup>. Main characteristics of portal hypertension like a decrease in portal flow velocity or an increase in portal vein diameter are detectable by this means<sup>[10,11]</sup>. However, no consistent alternative has been reported to replace endoscopic assessment of such patients through time yet. In this study, we investigated the hemodynamic features of the portal vein in two groups of patients with liver cirrhosis, namely those with and those without EV, as well as considering large varices with an advanced risk of bleeding.

## MATERIALS AND METHODS

Consecutive newly diagnosed cirrhotic patients who were visited at our institute participated in a prospective study from May 2006 to August 2007 prior to treatment. The diagnosis of cirrhosis was based on a liver biopsy evaluation. Patients on diuretic or vasoactive treatment, with previous gastrointestinal bleeding, hepatorenal syndrome during the past 3 mo, evidence of portal vein thrombosis on ultrasonography, and patients with clear signs of portal hypertension (ascites, porto-systemic shunts or hepatic encephalopathy) were excluded.

All patients underwent endoscopy after color Doppler-ultrasonic examination by the same gastroenterologist blinded to the results of duplex Doppler. They were evaluated for the presence and grade of EV, the presence of gastric varices, and portal hypertensive gastropathy (PHG). In the presence of EV, size was graded as I-IV using the Paquet grading system<sup>[12]</sup>. Moreover, patients were classified either as having LEV (grade III-IV) or not (no varices or grade I - II).

All patients were kept fasting overnight prior to the procedure at our institution. They were examined in the supine position during quiet respiration. The following main Doppler factors were always taken by the same equipment (with a 3.5- MHz linear - array transducer, EUB-525 Hitachi) and by the same operator ( $k = 0.80$ ): (1) Portal vein flow velocity as time average maximal velocity in cm/s and portal vein diameter<sup>[13]</sup>; (2) hepatic artery resistance index (RI) measured in the intrahepatic main branches<sup>[14]</sup> [ $RI = (\text{systolic velocity} - \text{end diastolic velocity})/\text{systolic velocity}$ ]; (3) splenic artery RI measured intraparenchymally near to hilum<sup>[15]</sup>; (4) spleen size (length of its longest axis); and (5) presence of portal-systemic collaterals.

The following indices were calculated: (1) The liver vascular index as the ratio of portal venous velocity to hepatic arterial pulsatility index; (2) congestion index (CI) of the portal vein with dividing portal vein cross-sectional area by portal blood velocity<sup>[16]</sup>; and (3) portal hypertensive index as  $(\text{hepatic artery RI} \times 0.69) \times (\text{splenic artery R} \times 0.87) / \text{portal vein mean velocity}$ .

Data were analyzed with SPSS for windows version 13. Descriptive statistics including means, standard deviations, and frequencies were computed. The chi square test was used to compare differences, and student's *t* test was

**Table 1** Baseline characteristics of 85 cirrhotic patients [as *n* (%) or mean  $\pm$  SD]

Gender	
Male	43 (50.6)
Female	42 (49.4)
Etiology	
Hepatitis B virus (HBV)	40 (47.0)
Hepatitis C virus (HCV)	12 (14.1)
Cryptogenic	14 (16.5)
Autoimmune hepatitis (AIH)	17 (20.0)
Alcohol	2 (2.4)
Wilson's disease	1 (1.2)
Size of esophageal varices	
None	16 (18.8)
Small (grade I-II)	50 (58.8)
Large (grade III-IV)	19 (22.3)
Size	7.9 ( $\pm$ 3.4)
Gastric varices	11 (12.9)
Portal hypertrophic gastropathy	75 (88.2)
Portal vein diameter (mm)	13.5 ( $\pm$ 2.4)
Splenic axis (cm)	15.7 ( $\pm$ 3.1)
Portal vein flow (cm/s)	14.6 ( $\pm$ 4.8)
Splenic artery resistance	0.7 ( $\pm$ 0.1)
Hepatic artery resistance	0.7 ( $\pm$ 0.1)

used to compare means of variables. Values were considered significant if  $P < 0.05$  (95% CI). A logistic regression equation was developed to predict presence and grade of EV. The sensitivity and specificity of the prediction rule were estimated by means of a receiver operating characteristic (ROC) curve and area under the curve (AUC) was reported for independent predictors.

## RESULTS

Eighty five consecutive cirrhotic patients (43 men, 42 women) were enrolled in the study. Mean age ( $\pm$  SD) of the study population was 47.5 ( $\pm$  15.9) years. Table 1 shows the patients' baseline characteristics. Hepatitis B virus (HBV) infection was the only cause of cirrhosis in most of our patients.

Thirteen patients had EV grade 1, 37 grade 2, and 19 grade 3. Gastric varices were detected in 11 patients (ten type 1 and one type 2).

Univariate analysis showed that most of the echo-Doppler parameters were related to presence of EV (Table 2). Portal vein flow velocity and liver vascular index was significantly higher in patients with EV while they had lower portal vein diameter, CI, portal hypertensive index, and hepatic and splenic artery RI. Presence of LEV was related to all of the echo-Doppler parameters described in Table 3.

Portal hypertensive index ( $P = 0.002$ ) and congestive index ( $P = 0.002$ ) were significantly higher, and portal vein flow velocity ( $P < 0.0005$ ) and liver vascular index ( $P \leq 0.0005$ ) were significantly lower in patients with PHG. Liver vascular index was independently correlated with PHG ( $P = 0.018$ ). Portal PHG was present in 94.2% of the patients with EV ( $P = 0.002$ ) and in all of the patients with gastric varices.

A logistic regression model showed that the parameters were not a good predictor of the presence of esophageal or gastric varices. However, spleen size and portal hyper-

EV: Esophageal varices; AUC: Area under the curve.

tensive index were reported as predictors of LEV as presented in Table 4. We examined threshold values for these independent predictors of LEV for achieving a sensitivity > 75%. Portal hypertensive index > 2.08 and spleen size > 15.05 cm reached a sensitivity of 79% for detecting LEV.

## DISCUSSION

Variceal gastrointestinal bleeding is one of the most common life-threatening complications of portal hypertension with significant morbidity and mortality. Variceal size is identified to be one of the most important factors responsible for first variceal hemorrhage<sup>[17]</sup>. 10% to 20% of small varices progress in size during one year<sup>[18]</sup> which is close to 20% to 30% risk of bleeding in first 2-year after first detection<sup>[19]</sup>. It seems that recognizing patients with elevated risk of bleeding for on time interventions will reduce morbidity and cost in initial diagnosis or periodic intervals thereafter.

Consensus based guidelines recommend endoscopic screening of all cirrhotic patients for the presence of varices at the time of diagnosis<sup>[20]</sup>. Relatively low risk of bleeding in compensated cirrhotic patients and a need to avoid invasive and avoidable procedures, suggests performing an upper gastrointestinal endoscopy only on those patients with clinical evidence of portal hypertension<sup>[21]</sup>.

Even though, the available data are insufficient to determine a reliable non-invasive predictive tool to categorize cirrhotic patients along with significant risk for bleeding. Researchers have designed studies based on clinical, biochemical, and radiographic measurements as to when one should begin endoscopic screening for the presence of EV with cirrhosis. Such attempts have been made to identify non-invasive procedures for either reducing or eliminating the need for screening endoscopy. Researchers support non-invasive methods (duplex Doppler sonography) in measurement of functional hepatic flow in cirrhotic patients, which can estimate hepatic reserve function<sup>[22]</sup>.

Our study, based on information achieved from newly diagnosed compensated liver cirrhosis patients demonstrated a correlation of portal hemodynamics with the presence of LEV and with a higher diagnostic accuracy with LEV on univariate analysis. However, on multivariate analysis, only increased spleen size and portal hypertensive index were found to have an independent predictive value

**Table 3** mean  $\pm$  SD of the primary and derivative echo-Doppler factors according to presence of large esophageal varices

	With LEV	Without LEV	P value	AUC
Portal vein flow velocity (cm/s)	12.13 $\pm$ 2.59	15.26 $\pm$ 5.06	0.001	0.715
Portal vein diameter (mm)	14.54 $\pm$ 1.48	13.24 $\pm$ 2.55	0.037	0.748
Hepatic artery resistance index	0.80 $\pm$ 0.06	0.70 $\pm$ 0.06	0.003	0.820
Splenic artery resistance index	0.76 $\pm$ 0.11	0.69 $\pm$ 0.06	< 0.0005	0.656
Spleen size (cm)	17.62 $\pm$ 3.05	15.21 $\pm$ 2.99	0.003	0.724
Liver vascular index	6.48 $\pm$ 2.78	10.96 $\pm$ 5.05	< 0.0005	0.817
Congestion index	0.14 $\pm$ 0.04	0.09 $\pm$ 0.03	< 0.0005	0.797
Portal hypertensive index	3.18 $\pm$ 0.90	2.14 $\pm$ 0.77	< 0.0005	0.791

LEV: Large esophageal varices; AUC: Area under the curve.

**Table 4** Logistic regression model to predict the presence of large esophageal varices in newly diagnosed patients with compensated cirrhosis

	P value	Odds ratio	95% CI
Congestive index	0.252	0	-
Portal hypertensive index	0.040	4.83	1.08-21.65
Liver vascular index	0.151	0.72	-
Spleen size	0.002	1.77	1.23-2.55

which has been the most consistently identified predictors in previous studies. Our data suggests two independent situations for beginning endoscopic evaluation of compensated cirrhotic patients: Portal hypertensive index > 2.08 and spleen size > 15.05 cm; restraining the need for upper gastrointestinal endoscopy of compensated cirrhosis.

It may be explained according to the issue that palpable spleen as well as LEV may both be related to the presence of a higher portal pressure. Different factors found to be important for this purpose included splenomegaly<sup>[23-28]</sup>, thrombocytopenia<sup>[25-30]</sup>, ascites<sup>[25,27]</sup>, hepatic encephalopathy<sup>[25]</sup>, serum albumin concentration<sup>[30]</sup>, serum bilirubin levels<sup>[30]</sup>, and Child-Pugh score<sup>[27,28]</sup>. Thus, the results of our study are consistent with those of the previously published data.

Echo-Doppler parameters like splenic artery RI and portal hypertensive index have been reported to have a specificity > 70% (for most thresholds) when comparing portal hypertensive patients with CLD patients without clinically relevant portal hypertension<sup>[8]</sup>.

Esophagogastric varices exactly reflect the presence of portal hypertension. But the correlation between esophagogastric varices and PHG is obscure<sup>[31]</sup>. Our study revealed a correlation between EV and the presence of gastropathy, and all of the patients with LEV had gastropathy.

Our study group represented a selected group of patients with liver cirrhosis attending a tertiary care center, but criteria for excluded patients (clear signs of portal hypertension) and preferring patients without history of GI bleeding achieved a better sample. Results would be best applied in patients attending large hospitals and further studies will be necessary regarding this aspect. Such studies may be particularly indicated because of

differences in the etiology of liver disease in dissimilar populations. The most common etiologies of cirrhosis in our population are either cryptogenic or HBV infection<sup>[32]</sup>.

Our data indicate that using non-invasive tools for estimating spleen size and portal hypertensive index allows predicting the presence of LEV with a fairly high accuracy. Values for the non-invasive indicators from this study and comparables need to be validated in a prospective study. Selecting patients for an upper GI endoscopy may be cost effective and, on the other hand, will define patients who need a critical management.

## COMMENTS

### Background

Bleeding esophageal varices (EV) are of the most apprehensive complications of portal hypertension in patients with liver cirrhosis. EV bleeding is a potentially deadly complication in such patients and is considered as an indication for screening in patients with newly diagnosed cirrhosis.

### Research frontiers

Availability of non-invasive methods may help limit the number of endoscopic procedures performed for detection of large esophageal varices (LEV) which hold the higher risk for bleeding.

### Related publications

Researchers have mentioned relations between portal hemodynamic situation and risk of EV or bleeding of them but available data are still insufficient to determine a reliable non-invasive predictive tool to categorize cirrhotic patients along with significant risk for bleeding.

### Innovations and breakthroughs

This study evaluates newly diagnosed patients with no complications who may benefit from non-invasive procedures. Etiology of liver cirrhosis in our study population is different from Western community.

### Applications

Using non-invasive tools for estimating spleen size and portal hypertensive index makes it possible to predict the presence of LEV. These values should ultimately be validated in a prospective study before being used to determine which patients should undergo esophageal variceal screening endoscopy.

### Terminology

Size of the spleen and portal hypertensive index are measured by ultrasonography. Portal hypertensive index in details is (Hepatic artery RI\*0.69)\*(splenic artery RI\*0.87)/portal vein mean velocity.

### Peer review

It is a nice study to evaluate and compare the differences in the parameters of portal hypertension in liver cirrhosis patients with and without esophageal varices.

### Abstract

**AIM:** To examine the characteristics of colonic polyps, where it is difficult to distinguish adenomatous polyps from hyperplastic polyps, with the aid of acetic acid chromoendoscopy.

**METHODS:** Acetic acid spray was applied to colonic polyps smaller than 10 mm before complete excision. Endoscopic images were taken before and 15-30 s after the acetic acid spray. Both pre- and post-sprayed images were shown to 16 examiners, who were asked to interpret the lesions as either hyperplastic or adenomatous polyps. Regression analysis was performed to determine which factors were most likely related to diagnostic accuracy.

**RESULTS:** In 50 cases tested by the 16 examiners, the overall accuracy was 62.4% (499/800). Regression analysis demonstrated that surrounding colonic mucosa was the only factor that was significantly related to accuracy in discriminating adenomatous from hyperplastic polyps ( $P < 0.001$ ). Accuracy was higher for polyps with linear surrounding colonic mucosa than for those with nodular surrounding colonic mucosa ( $P < 0.001$ ), but was not related to the shape, location, or size of the polyp.

**CONCLUSION:** The accuracy of predicting histology is significantly related to the pattern of colonic mucosa surrounding the polyp. Making a histological diagnosis of colon polyps merely by acetic acid spray is helpful for colon polyps with linear, regularly patterned surrounding colonic mucosa, and less so for those with nodular, irregularly patterned surrounding colonic mucosa.

### INTRODUCTION

The management of neoplastic and non-neoplastic colonic polyps is quite different<sup>[1]</sup>. Therefore, it is of great interest for a colonoscopist to distinguish them during colonoscopic examination without having to take a biopsy sample. In addition, it takes a few days to establish a histological diagnosis from a biopsy sample, and there is no assurance that the pathological result of the biopsied specimen represents the lesion as a whole<sup>[2]</sup>. The accuracy of conventional colonoscopy in distinguishing neoplastic from non-neoplastic lesions is reported to be between 68% to 84% even in the hands of experienced colonoscopists<sup>[3,4]</sup>. Therefore, several methods are usually required to make the distinction between hyperplastic and adenomatous colonic polyps colonoscopically, such as special techniques like high-resolution chromoendoscopy, magnifying colonoscopy, or narrow band imaging magnification<sup>[5-9]</sup>. However, these techniques are not used routinely in clinical practice for various reasons, for example. (1) lack of the appropriate equipment, (2) time restrictions, and (3) additional cost not covered by the insurance company.

Acetic acid enables a detailed examination of colonic neoplasms during colonoscopic examination by breaking the disulfide bonds of mucus, thus revealing the detail of the mucosal surface and allowing an analysis of the pit

pattern of the colonic polyps<sup>[10]</sup>. Acetic acid is a cheap, efficient, safe and convenient tool<sup>[11,12]</sup>. Therefore, once its accuracy in distinguishing between neoplastic and non-neoplastic polyps is established, its use might allow a one-stage colon polypectomy. Unfortunately, there are only few published data on the accuracy of acetic acid chromoendoscopy in the diagnosis of colonic polyps, and most of the previous studies were performed in conjunction with other methods such as magnifying endoscopy or with indigo carmine spraying<sup>[12]</sup>.

It would be helpful to colonoscopists if the factors affecting the accuracy in distinguishing between adenomatous and hyperplastic colon polyps were established. In the present study we examined the characteristics of colonic polyps in relation to the surrounding mucosa with the aid of acetic acid chromoendoscopy.

## MATERIALS AND METHODS

### Patients

From April to June 2006, 35 patients, in whom colonic polyps were revealed out of 299 routine colonoscopic examinations, were included in the study. Only 35 patients were included in the study since 258 examinations revealed no polyp and 6 revealed polyps only greater than 1 cm. Polyps greater than 1 cm were not included due to the higher probability of associated malignancy requiring removal regardless of the acetic acid chromoendoscopic finding. Colonoscopy was performed by one of the two colonoscopists (JH Kim and SY Lee) at the Digestive Disease Center of Konkuk University Hospital (the colonoscope Olympus CF260, Olympus Corp., Tokyo, Japan, was used). All patients provided written informed consent prior to colonoscopy. None of the 35 patients refused acetic acid chromoendoscopy. This prospective study was approved by the institutional review board of Konkuk University School of Medicine, which agreed that the study was in accordance with the ethical guidelines of the Helsinki Declaration.

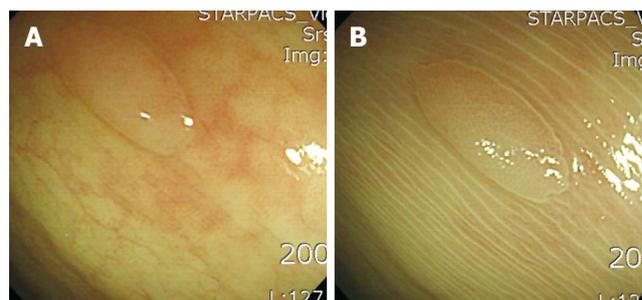

### Acetic acid chromoendoscopy

When a colon polyp smaller than 1 cm was found, 5-10 mL of 1.5% acetic acid was sprayed onto the lesion from a side channel of the colonoscope. On full air inflation, several endoscopic images were taken before and 15-30 s after spraying. Once the images were taken, the polyps were completely resected either by polypectomy or by cold biopsy sampling. The resected specimens were examined by pathologists, who were unaware of the endoscopic findings.

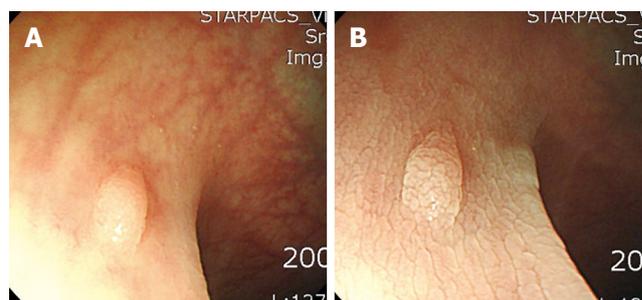

Size and location of the polyps were recorded. With respect to shape, the polyps were classified as either sessile or non-sessile. After being sprayed with acetic acid, the patterns of colonic mucosa surrounding the polyps were classified as having either (1) a linear and regular pattern (Figure 1) or (2) a nodular and irregular pattern (Figure 2).

### Selection of cases for the blind test (primary analysis)

After the final pathology report, colon polyps other than adenomatous or hyperplastic polyps were excluded

**Figure 1** Linear and regularly patterned colonic mucosa surrounding a polyp. On endoscopic removal, pathology revealed a hyperplastic colon polyp. **A:** Before spraying with acetic acid a sessile polyp is seen; **B:** After spraying with acetic acid the colonic mucosa surrounding the polyp has a linear and regular pattern.

**Figure 2** Nodular and irregularly patterned colonic mucosa surrounding a polyp. On endoscopic removal, pathology revealed a hyperplastic colon polyp. **A:** Before spraying with acetic acid a sessile polyp is seen; **B:** After spraying with acetic acid the colonic mucosa surrounding the polyp has a nodular and irregular pattern.

from the study. In our 35 patients, a total number of 54 colonic polyps smaller than 10 mm were detected during the colonoscopic examination. However, four cases were excluded since three were inflammatory polyps and one was a leiomyoma. The endoscopic images were selected by the colonoscopist who was not scheduled for the blind test (Lee SY). Finally, endoscopic images of 50 polyps, both pre- and post-sprayed, were collected.

### Blind test by 16 examiners (secondary analysis)

A total of 100 endoscopic images, pre- and post-acetic acid sprayed images of each of the 50 colonic polyps, were shown to 16 examiners (6 gastroenterologists who were not familiar with the colonic pit patterns, 5 residents, and 5 medical students) at the same time in the same place. Before the blind test, a short, 10-min lecture on colonic pit patterns, that included presentation of 24 PowerPoint slides, was given by the colonoscopist who had selected the images for examination (SY Lee). Typical images of mucosal pit patterns in hyperplastic colon polyps (star-like or papillary-like pattern) and adenomatous colon polyps (tubular or gyrus-like pattern) were shown during the lecture<sup>[13]</sup>. In addition, 10 cases of acetic acid sprayed images of colon polyps were shown to the 16 examiners. None of these images were included in the blind test and all of them were taken in Konkuk University Hospital only colonoscopically without using any other method.

The blind test was performed by showing the PowerPoint slides to the examiners. After examining two images

**Table 1** Relationship between the colon polyp and the pattern of colonic mucosa surrounding the polyp *n* (%)

	Linear and regular ( <i>n</i> = 34)	Nodular and irregular ( <i>n</i> = 16)	<i>P</i> value
Size of the polyp (mm, mean ± SD)	5.29 ± 2.18	4.75 ± 2.27	NS
Shape of the polyp			0.023
Sessile	20 (58.8)	15 (93.7)	
Non-sessile	14 (41.2)	1 (6.3)	
Location of the polyp			NS
Cecum	2 (5.9)	0 (0.0)	
Ascending colon	5 (14.7)	2 (12.4)	
Hepatic flexure	3 (8.8)	0 (0.0)	
Transverse colon	1 (2.9)	1 (6.3)	
Splenic flexure	0 (0.0)	1 (6.3)	
Descending colon	4 (11.8)	1 (6.3)	
Sigmoid colon	12 (35.3)	8 (50.0)

(one pre-acetic acid sprayed image and one post-acetic acid sprayed image) of each of the cases, the examiners were required to record their interpretation as either hyperplastic or adenomatous polyps. After the blind test, the responses were collected, transcribed, and analyzed for raw data associations.

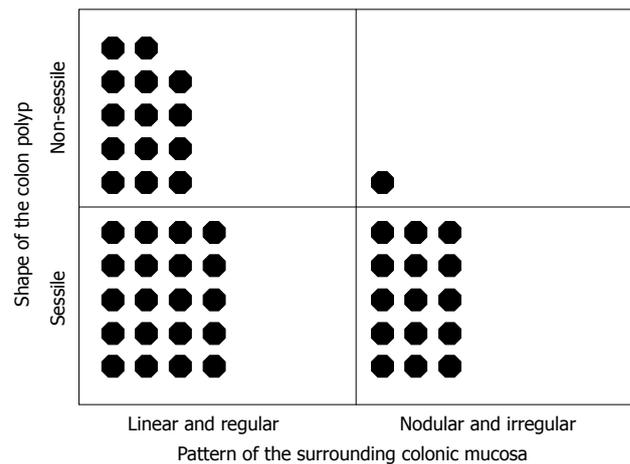

### Statistical analysis

A *P*-value of less than 0.05 was considered statistically significant. Differences between the groups were analyzed using the chi-square tests and Student's *t*-tests. Regarding age and polyp size, results were expressed as mean ± SD. Regression analysis was performed to assess the accuracy of predicting pathology (adenomatous polyp versus hyperplastic polyp). Binary logistic regression analysis was performed with the factors which colonoscopists can notice during the colonoscopic examination, i.e., (1) shape of the polyp, (2) size of the polyp, (3) location of the polyp, and (4) surrounding colonic mucosa.

## RESULTS

In the 50 cases tested by 16 examiners, the overall accuracy was 62.4% (499/800). There was no significant difference in test scores between the gastroenterologist group (30.3 ± 2.0, mean ± SD), the resident group (32.4 ± 5.4), and the medical student group (31.0 ± 5.6). Sensitivity, specificity, positive predictive value, and negative predictive value of acetic acid spray for adenomatous polyp were 81.8%, 41.2%, 73.0%, and 53.8%, respectively.

By regression analysis, the pattern of the surrounding colonic mucosa (*P* < 0.001) was the only factor predicting pathology (i.e. adenomatous polyp versus hyperplastic polyp). In 34 cases (68%), the colonic mucosa surrounding the polyp was linear and regular (Figure 1), and in 16 cases (32%) nodular and irregular (Figure 2). In contrast, the accuracy of distinguishing between hyperplastic and

**Figure 3** Diagnosis according to the shape of the colon polyp and the pattern of its surrounding colonic mucosa. Each black dot indicates a polyp. Most of the non-sessile colon polyps revealed linear and regular patterned surrounding colonic mucosa (*P* = 0.02).

adenomatous colon polyps was not related to the shape, location, or size of the polyp.

Neither age nor sex of the patient was related to the pattern of colonic mucosa surrounding the polyp (Table 1). The only related factor was the shape of the polyp (*P* = 0.02; Figure 3). Whereas size and location of the polyp were irrelevant.

## DISCUSSION

To the best of our knowledge, this study is the first to evaluate the significance of the type of colonic mucosa surrounding a colon polyp for distinguishing between adenomatous and hyperplastic polyps during acetic acid chromoendoscopy. Our findings revealed that linear and regularly patterned surrounding colonic mucosa enables a higher accuracy in predicting the pathology of the associated polyp when compared to those surrounded by nodular and irregularly patterned colonic mucosa.

Although the reasons for these two different surrounding colonic mucosal patterns are unclear, the nodular pattern seems to be similar to that seen in acetic acid sprayed gastric mucosa, which is considered to be indicative of chronic mucosal damage induced either by *H pylori* infection or by acid irritation (unpublished data). In the present study, the pattern of the mucosa surrounding a polyp was associated with the shape of the polyp, the non-sessile type being found more frequently in linear patterned surrounding colonic mucosa. However, this should be evaluated further by a large-scale study in conjunction with pathological analysis.

Most of the previous studies on acetic acid chromoendoscopy have examined the significance of detecting sessile polyps or analyzed polyp pit patterns<sup>[5,10-12]</sup>. In the present study, we did not classify colonic adenomas according to their degree of dysplasia, but simply assessed the accuracy of acetic acid chromoendoscopy, which is a cheap, easy, convenient, safe and fast procedure, in distinguishing between adenomatous and hyperplastic

colon polyps. We therefore analyzed only the mucosal pit patterns, and not the microvascular pattern, which is automatically masked by spraying with acetic acid.

It has been reported that residents are able to safely and effectively screen for colorectal neoplasms with a flexible sigmoidoscope when supervised<sup>[14]</sup>. Interestingly, there was no significant difference in the blind test scores between the gastroenterologists, residents, and medical students. This indicates that the results achieved using acetic acid chromoendoscopy are easy to interpret, even for those who have no experience in gastrointestinal endoscopy. However, it also indicates that although uniform descriptions of colonic mucosal pit patterns in hyperplastic colon polyps (star-like or papillary-like pattern) and in adenomatous colon polyps (tubular or gyrus-like pattern) are useful, they are not completely visualized merely by acetic acid chromoendoscopy.

The limitation of our study is that this was the data from 16 examiners, who were not familiar with the colonic pit patterns, predicted the pathology only on the basis of 2 pictures (pre- and post-sprayed images) not by full colonoscopic examination. Moreover, no additional methods such as magnifying endoscopy or indigo carmine spray were used. Therefore, the overall diagnostic accuracy for distinguishing between neoplastic and non-neoplastic lesions was lower than previous studies which were done by experienced colonoscopists<sup>[3,9,15]</sup>.

In conclusion, acetic acid chromoendoscopy can be used to distinguish between hyperplastic and adenomatous polyps without magnifying endoscopy with an accuracy of 62.4%, and the accuracy is significantly related to the pattern of colonic mucosa surrounding the polyp. In addition, we have found that making a histological diagnosis of colon polyps merely by acetic acid spray is helpful for colon polyps with linear, regularly patterned surrounding colonic mucosa, and less so for those with nodular, irregularly patterned surrounding colonic mucosa.

## ACKNOWLEDGMENTS

The authors would like to thank to Professor Soo Nyung Kim for his assistance in statistical analysis.

## COMMENTS

### Background

The management of neoplastic and non-neoplastic colonic polyps is quite different, and it is of great interest for a colonoscopist to distinguish them during colonoscopic examination without having to take a biopsy sample. Acetic acid is a cheap, efficient, safe and convenient tool which enables a detailed examination of colonic neoplasms during colonoscopic examination by breaking the disulfide bonds of mucus. Acetic acid chromoendoscopy is effective in revealing the detail of the mucosal surface and allowing an analysis of the pit pattern of the colonic polyps.

### Research frontiers

Recently, several endoscopic methods that help to make the distinction between hyperplastic and adenomatous colonic polyps colonoscopically have been introduced. Special techniques such as high-resolution chromoendoscopy, magnifying colonoscopy, or narrow band imaging magnification are being innovated.

## Innovations and breakthroughs

This is the first study that evaluated the significance of the type of colonic mucosa surrounding a colon polyp for distinguishing between adenomatous and hyperplastic polyps during acetic acid chromoendoscopy. Our findings revealed that linear and regularly patterned surrounding colonic mucosa enables a higher accuracy in predicting the pathology of the associated polyp when compared to those surrounded by nodular and irregularly patterned colonic mucosa.

## Applications

Through this study, we showed a new way to distinguish between neoplastic and non-neoplastic polyps by acetic acid chromoendoscopy which is a cheap, easy, convenient, safe and fast procedure. The patterns of surrounding colonic mucosa will help colonoscopists in distinguishing between adenomatous and hyperplastic colon polyps.

## Terminology

Acetic acid chromoendoscopy is a method done by spraying 5-10 mL of 1.5% acetic acid onto the lesion from a side channel of the colonoscope. Endoscopic images are usually taken before and 15-30 s after spraying.

## Peer review

This study interpreted the lesions as either hyperplastic or adenomatous polyps after acetic acid chromoendoscopy, and proved that making a histological diagnosis of colon polyps merely by acetic acid spray is helpful for colon polyps with linear, regularly patterned surrounding colonic mucosa, and less so for those with nodular, irregularly patterned surrounding colonic mucosa.

### Abstract

**AIM:** To study the hemodynamic effects of spironolactone with propranolol *vs* propranolol alone in the secondary prophylaxis of variceal bleeding.

**METHODS:** Thirty-five cirrhotics with variceal bleeding randomly received propranolol ( $n = 17$ : Group A) or spironolactone plus propranolol ( $n = 18$ : Group B). Hemodynamic assessment was performed at baseline and on the eighth day.

**RESULTS:** Spironolactone with propranolol caused a greater reduction in the hepatic venous pressure gradient than propranolol alone (26.94% *vs* 10.2%;  $P < 0.01$ ). Fourteen out of eighteen patients on the combination treatment had a reduction in hepatic venous pressure gradient to  $\leq 12$  mmHg or a 20% reduction from baseline in contrast to only six out of seventeen (6/17) on propranolol alone ( $P < 0.05$ ).

**CONCLUSION:** Spironolactone with propranolol results in a better response with a greater reduction in hepatic venous pressure gradient in the secondary prophylaxis of variceal bleeding. A greater number of patients may be protected by this combination therapy than by propranolol alone. Hence, this combination may be recommended for secondary prophylaxis in patients with variceal bleeding.

Hemodynamic effects of propranolol with spironolactone in patients with variceal bleeds: A randomized controlled trial. *World J Gastroenterol* 2008; 14(12): 1908-1913 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1908.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1908>

### INTRODUCTION

Variceal hemorrhage is one of the serious complications of portal hypertension in cirrhotics. About 70% of the survivors of variceal bleeds re-bleed within a year<sup>[1,2]</sup>. Of the various treatment modalities, pharmacotherapy is one of the more attractive avenues, as it is simple and safe and can be applied outside the hospital.

Beta-blockers like propranolol are the treatment of choice for primary prophylaxis of variceal hemorrhage<sup>[3]</sup>. Reduction of the hepatic venous pressure gradient (HVPG) to  $\leq 12$  mmHg is protective, while reduction by greater than or equal to 20% of the baseline value is also safe<sup>[4,5]</sup>.

However, only about one-third of patients taking propranolol alone achieve such reductions among bleeders<sup>[4,6]</sup>. Thus, a considerable number of patients are not protected by propranolol alone, particularly for secondary prophylaxis.

Hence drug combinations have been advocated for prevention of variceal re-bleeding. Recently, a combination of isosorbide mononitrate with propranolol has been tested for the prevention of variceal re-bleeding, with some benefit<sup>[7]</sup>. There have been a few studies showing efficacy of spironolactone (a drug that is commonly prescribed in cirrhotics with ascites) in the reduction of portal pressure among cirrhotics without ascites<sup>[8-11]</sup>. We evaluated the hemodynamic effects of a combination therapy of propranolol with spironolactone and found the combination had greater efficacy than propranolol alone, in propranolol-resistant cases<sup>[12]</sup>. Considering these facts, we have examined the portal hemodynamic effects of propranolol alone and propranolol in combination with spironolactone among cirrhotics who have bled at least once.

## MATERIALS AND METHODS

Forty-two consecutive liver cirrhosis patients with variceal bleeding were enrolled from the Liver Clinic of Medical College and Hospital Calcutta. This study was carried out from June 2005 to March 2007. Hemodynamic studies were undertaken in the catheter laboratory of The Institute of Cardiovascular Sciences, RG Kar Medical College and Hospital, Calcutta, which is situated close to Medical College Calcutta. The institutional ethics committees of both the hospitals approved the study protocol. Only those patients who had experienced at least one episode of variceal bleeding within the previous week were considered. After admission to hospital due to upper gastrointestinal bleeding with clinical features of chronic liver disease, patients underwent upper gastrointestinal endoscopy on the following day. Those patients who came with acute bleeding were initially treated with vasoconstrictors (like terlipressin), plasma expanders or blood transfusions, as and when necessary, and endoscopy was performed twenty-four hours after their hemodynamic stabilization. In the event of re-bleeding, endoscopic banding was performed. Only those patients with evidence of active variceal bleeding or clots or oozing from the varices were included. In addition, those patients with upper gastrointestinal bleeding who had esophageal varices in the absence of any other source of upper gastrointestinal bleed were also included. Patients were excluded for any of the following reasons: Asthma, congestive cardiac failure, severe diabetes, severe hypertension, any severe co-morbid states, age less than 15 years or more than 70 years, or previous treatment with endoscopic sclerotherapy, variceal ligation, porto-systemic shunt surgeries, beta-adrenergic blocking agents, spironolactone or nitrates. The procedures to be employed were explained to the patients and, after obtaining informed written consent, patients remained hospitalized for the duration of the study. All patients underwent blood tests to evaluate the liver chemistry (liver function tests, prothrombin time) and to establish the etiology of chronic liver disease (viral markers, anti-nuclear factor, ceruloplasmin). They also underwent routine investigations (complete hemogram, urea, creatinine, random sugar, electrolytes), ultrasonography with Doppler study and liver biopsy (as and when necessary) to establish the diagnosis. Variceal grading was adopted as per the Japanese Research Society<sup>[13]</sup>. Thereafter, the patients were transferred to The Institute of Cardiovascular Sciences, RG Kar Medical College for hemodynamic assessment. The first hemodynamic study was performed within a week of the last variceal bleeding episode.

### Hemodynamic study

All patients received a normal hospital diet, without any sodium restriction. Hemodynamic studies were carried out in all cases within a week of variceal bleeding after an overnight fast using a standard technique<sup>[14]</sup> in the catheter laboratory of the Institute of Cardiovascular Sciences RG Kar Medical College, Calcutta. Under local anesthesia in the supine position, a venous introducer was placed in the right femoral vein by the Seldinger technique. Under fluoroscopic guidance (Axiom Artis; Siemens, Munich Germany), a 7F balloon-tipped catheter (USCI; CR Bard Ire-

land, Galway, Ireland) was introduced into the main right hepatic vein through the inferior vena cava (IVC). Free (FHVP) and wedged (occluded) (WHVP) hepatic venous pressures were measured using a hemodynamic monitor (Axiom Sensis Germany) with pressure transducers (SIEMENS HEMOMED). Thereafter, we also measured the pressures in the IVC, right atrium (RA), mean pulmonary arterial pressure (MPAP) and pulmonary capillary wedge pressure (PCWP) in the similar fashion, wherever possible. Hepatic venous pressure gradient (HVPG) was calculated as the difference between WHVP and FHVP. All measurements were made in triplicate and means were obtained (data were recorded from the tracer curves).

After the baseline readings, the patients were divided into two groups by a computer-generated randomized table. One group (Group A) received propranolol (Inderal; ICI Pharmaceuticals, Chennai) at a dose of 40 mg twice daily and a placebo tablet in place of spironolactone, and the other group (Group B) received propranolol (40 mg twice daily) with spironolactone (Aldactone; 100 mg once daily; Searle: India, Mumbai). The dose of propranolol was gradually increased until a twenty percent reduction from the baseline pulse rate, or a pulse rate of 60 was achieved, whichever came earlier. Hemodynamic studies were repeated on the eighth day, after the morning dose. The patients, the investigators, the cardiologist and the statistician conducting the hemodynamic study were blinded to the nature of the treatment given.

Responders were defined as those individuals showing a reduction of HVPG to  $\leq 12$  mmHg and/or greater than a 20% reduction in HVPG from the baseline (primary outcome)<sup>[5]</sup>.

Forty-two patients with clinical features of chronic liver disease were initially considered and had upper gastrointestinal endoscopy. Of these, thirty-eight patients were considered for hemodynamic assessment. Of the four patients excluded, two had chronic obstructive lung disease, one had uncontrolled diabetes mellitus and the last was a case associated with peptic ulcer disease. Of these thirty-eight patients, thirty-five patients were included in the final analysis. Three more patients were excluded, as one of them had severe re-bleeding for which emergency endoscopic therapy was performed before hemodynamic assessment could be undertaken and the other two declined the second reading.

### Statistical analysis

Results are expressed as mean  $\pm$  SD. Chi-square tests, correlation and regression, paired *t* test and single factor ANOVA were used as required.  $P < 0.05$  was considered statistically significant.

## RESULTS

Thirty-five cirrhotics with variceal bleeding were included in the final analysis. The clinical and biochemical profiles of the included patients are given in Table 1. No subject had varices less than grade II. Sixteen of our cases (45.71%) were alcoholics; nine (25.71%) were of viral etiology, in eight patients (22.86%) no etiology was found, and there was one each of Wilson's and autoimmune liver disease.

Dose of propranolol (mg/d)	92.94 ± 23.39	88.89 ± 20.83	0.59

Values are shown as mean ± SE,  $P < 0.05$  considered statistically significant. Group A: Propranolol; Group B: Propranolol and Spironolactone; ALT: Alanine aminotransferase.

There was no statistically significant difference in the clinical and biochemical profiles between Group A (only propranolol) and Group B (propranolol with spironolactone), as shown in Table 1.

In Group A, there was a significant reduction in HVPG after therapy, as compared with the baseline ( $P < 0.01$ , Table 2). The differences in other hemodynamic parameters before and after propranolol administration were not statistically significant. Interestingly, in Group A, there was a paradoxical rise in HVPG in 5 patients (45.45%) among the non-responders (11 patients). We also observed a rise in FHVP in 10 out of the 17 patients on propranolol.

In Group B, there were significant reductions in both WHVP and HVPG after therapy compared with the baseline ( $P < 0.001$ , Table 2). None of the patients showed an increase in HVPG after drug therapy in contrast to five patients in Group A. We also observed an increase in FHVP among 9 of the 18 patients on propranolol with spironolactone.

Comparing Group A with Group B, 6 of the 17 patients (35.29%) in Group A and 14 of the 18 patients (77.78%) in Group B showed an HVPG reduction to either  $\leq 12$  mmHg or at least a 20% reduction from the baseline (responder) ( $P = 0.011$ ). Interestingly, 6 of the 17 patients (35.29%) in Group A and 13 of the 18 patients (72.2%) in Group B showed a 20% reduction in HVPG from the baseline ( $P = 0.0283$ ). Among these, 5 patients

(29.41%) in Group A and 11 patients (61.11%) in Group B had an absolute reduction in HVPG to  $\leq 12$  mmHg ( $P = 0.0599$ ).

The percent reductions in HVPG from baseline after a seven-day therapy were 10.2% and 26.94% in Group A and Group B, respectively, which was also statistically significant ( $P < 0.05$ , Table 2).

Compared with the baseline, post-drug right atrial pressures increased significantly among the responders (5.2 mmHg *vs* 6.1 mmHg,  $P < 0.05$ ) in contrast to the non-responders (4.73 mmHg *vs* 5.87 mmHg,  $P = 0.12$ ).

Interestingly, analyzing the baseline hemodynamic parameters in responders, we observed a strong inverse correlation between HVPG and MPAP ( $r = -0.58$ ) and a moderate inverse correlation between PCWP ( $r = -0.48$ ) and RA pressures ( $r = -0.30$ ). However after drug treatment, these relationships ceased to exist. By contrast, among non-responders, no correlation was observed between the baseline HVPG and any of MPAP ( $r = -0.141$ ), PCWP ( $r = -0.069$ ) and RA pressures ( $r = -0.0007$ ).

## DISCUSSION

For pharmaco-prophylaxis of variceal bleeding, most drugs act by vasoconstriction to reduce portal pressure. Increased blood volume, a common feature in decompensate cirrhosis, has a contributory effect in increasing portal pressure. It has been found acute expansion of blood volume by transfusion increases the chances of re-bleeding in a bleeder<sup>[15]</sup>. Moreover, increased blood volume maintains the hyperdynamic state of portal hypertension<sup>[16]</sup>. Thus, a reduction in plasma volume may reduce portal pressure. Spironolactone, a mineralocorticoid-blocking agent is used for its ability to reduce portal pressure as measured by HVPG<sup>[8-10]</sup>. Thus, the combination of spironolactone with a beta-blocker may reduce the portal pressure in a better way. The rationality behind the use of combination therapy is that effects acting through different mechanisms may be additive or even synergistic<sup>[17]</sup>.

In this study, a significantly larger number of patients responded to combination therapy than responded to propranolol alone (14/18 *vs* 6/17,  $P < 0.05$ ).

A better response with spironolactone was observed in a subset of eight non-ascitic patients who did not respond to propranolol for primary prophylaxis<sup>[11]</sup>. Variceal pressure was measured by endoscopy in that study. We also observed in our previous study that spironolactone when combined with propranolol reduced portal pressure in propranolol-resistant cases (measuring HVPG)<sup>[12]</sup>.

Studies have shown spironolactone does not further reduce portal pressure in patients already on low-dose transdermal nitroglycerine<sup>[18]</sup> or beta-blockers like nadolol<sup>[19]</sup> for primary prophylaxis.

The most important observation in our study is the significantly larger number of patients on combination therapy showing either an absolute reduction in HVPG to  $\leq 12$  mmHg or at least a 20% reduction from the baseline (responder) compared with those on propranolol alone ( $P = 0.011$ ).

A landmark paper by Feu *et al*<sup>[5]</sup> observed for the first time that a reduction in HVPG of more than 20% of

Table 2 Hemodynamic parameters at baseline and on d 8 of therapy

Characteristics	Group A (n = 17)			Group B (n = 18)			Group A vs Group B P-value

RAP (mmHg)	4.88 ± 2.87	6.25 ± 2.57	0.007	5.11 ± 2.59	5.78 ± 2.39	0.27	0.81	0.58
MPAP (mmHg)	17.46 ± 3.91	19.58 ± 4.8	0.32	18.11 ± 4.43	18.80 ± 4.29	0.60	0.76	0.82
PCWP (mmHg)	14.54 ± 6.78	14.33 ± 6.82	0.94	15.50 ± 4.53	14.40 ± 4.95	0.48	0.69	0.98

All the values are shown as mean ± SE.  $P < 0.05$  considered statistically significant. SBP: Systolic blood pressure; IVCP: Inferior vena cava pressure; FHVP: Free hepatic venous pressure; WHVP: Wedge hepatic venous pressure; HVPG: Hepatic venous pressure gradient; RAP: Right atrial pressure; MPAP: Mean pulmonary artery pressure; PCWP: Pulmonary capillary wedge pressure; Group A: Propranolol; Group B: Propranolol and Spironolactone.

baseline, even if not reaching the 12 mmHg target, is associated with almost complete protection against variceal re-bleeding. Eight studies<sup>[5,20-26]</sup>, either RCTs or prospective consecutive series, have shown the pharmacologic (or spontaneous) reduction of HVPG to less than 12 mmHg, or by as much as or more than 20% of the baseline value, virtually abolishes the risk of re-bleeding.

As mentioned earlier, one study demonstrated that addition of isosorbide mononitrate improved the efficacy of propranolol in the prevention of variceal re-bleeding on long-term follow up<sup>[7]</sup>.

The combination of spironolactone with propranolol showed a significantly greater percent reduction of HVPG from the baseline, as compared with propranolol alone (26.94% vs 10.2,  $P < 0.05$ ). This greater reduction in HVPG with combination therapy may in part be explained by a paradoxical rise in FHVP with a concomitant significant reduction in WHVP, in contrast to only a rise in FHVP without a significant post treatment reduction in WHVP in patients on propranolol alone. However, propranolol alone also significantly reduced HVPG from the baseline after 7-d therapy ( $P < 0.05$ ).

Since ascites does not alter HVPG or the gradient between portal venous pressure and intra-abdominal pressure<sup>[27,28]</sup>, reduction of HVPG by the addition of spironolactone is likely to be due to a true reduction in portal venous pressure and not due to a reduction in intra-abdominal pressure consequent to control of the ascites. Moreover, spironolactone, by reducing plasma volume, may reduce both WHVP and FHVP; thus, it should not influence HVPG. The efficacy of spironolactone in the reduction of portal pressure in patients without ascites has already been demonstrated<sup>[17]</sup>. Reduction of plasma volume and associated vasoactive mechanism may underlie the effects of spironolactone on portal pressure<sup>[11]</sup>. However, some evidence suggests spironolactone may have a direct effect on the vasculature, independent of its anti-aldosterone effect<sup>[29]</sup>. Spironolactone also has a unique property of inhibition of hepatic stellate cell activation and Na/H exchange isoform-1 (NHE-1) protein expression<sup>[30]</sup>. Spironolactone was shown to have a mineralocorticoid receptor-independent suppressive effect on immuno-active and inflammatory cytokines<sup>[31]</sup>. An anti fibrotic property

has also been evidenced experimentally in rats<sup>[30]</sup>. Recent studies have also demonstrated the aldosterone antagonist eplerenone prevents epithelial cell growth and stiffening of venous and arterial endothelia<sup>[32]</sup>.

Although most studies evaluated the effects of spironolactone over a longer period of time (4-8 wk), we completed our second hemodynamic reading after a week, considering that chance of re-bleeding after the index bleeding is maximal during the first two weeks. Moreover, one of the major active metabolites of spironolactone is canrenone, which has a slow clearance and a half-life of 10-35 h. Thus, to reach a steady state plasma concentration it would take a period of between 2-7 d.

Incidentally we observed a significant rise in right atrial pressures only among the responders of both groups following drug therapy. Moreover, there was a moderate to strong inverse correlation between the baseline HVPG and the baseline MPAP, PCWP and RA pressures, only among the responders. The significance or role of this observation needs further evaluation.

Hence, spironolactone, a drug commonly prescribed in cirrhotics for the reduction of ascites, has a potential independent portal pressure-reducing effect, and its impressive reduction of HVPG in combination with propranolol may pave our way to recommend this combination for secondary prophylaxis in variceal bleeding.

## COMMENTS

### Background

Variceal bleeding is one of the potentially life threatening complications of portal hypertension. About 70% of the survivors of variceal bleeds re-bleed within one year. Beta-blockers like propranolol have been the treatment of choice for prevention of variceal bleeding. However, only about one-third of the patients taking propranolol achieve a significant reduction in the hepatic venous pressure gradient to be considered risk free. Hence, drug combinations have been advocated for the prevention of variceal bleeding.

### Research frontiers

Various drug combinations have been tested for the prevention of variceal bleeding; for example, propranolol with isosorbide mononitrate. However, the problem with drug combinations is an increased incidence of side effects, which leads to discontinuation of therapy. The challenge is to find a drug combination that is not only effective but also safe and easy to administer over long periods of time.

### Innovations and breakthroughs

Spirolactone, a drug commonly used in cirrhotics with ascites to reduce fluid overload, has been found to have an independent portal hypotensive effect. The drug has been in use for a long period of time and has been found to be safe and free of side effects except for occasional gynaecomastia. The idea was to study the hemodynamic changes induced by the combination of spironolactone with propranolol, and compare it with propranolol alone, the gold standard drug. The significantly better response of patients receiving this combination pharmacotherapy (spironolactone plus propranolol) for secondary prophylaxis of variceal bleeding may be considered as a breakthrough.

### Applications

We found the combination of spironolactone with propranolol resulted in a significantly greater reduction in HVPG than propranolol alone, and this reduction was significant enough to cause patients to be relatively risk free from recurrence of variceal bleeds. However, long-term prospective studies are needed in a larger number of patients to actually observe the recurrence of variceal bleeding, if any.

### Terminology

The hepatic venous pressure gradient (HVPG) is measured by the introduction of a balloon-tipped catheter into the hepatic vein. HVPG is a very strong marker of the degree of portal hypertension.

### Peer review

This is a very interesting study dealing with a significant clinical problem. It is well conducted and most significant issues are addressed.

Received: October 24, 2007 Revised: December 30, 2007

### Abstract

**AIM:** To investigate the relationship between *H pylori* infection, blood ammonia concentration and hepatic encephalopathy (HE), and the effect of *H pylori* eradication in cirrhotic patients.

**METHODS:** From July 2003 to January 2005, 457 cirrhotic patients in five regions of Zhejiang Province were enrolled. Patients were evaluated for demographics, number connection test, *H pylori* infection, liver impairment, blood ammonia concentration and HE. Patients with *H pylori* infection were given 1 wk therapy with omeprazole plus clarithromycin and tinidazole. <sup>14</sup>C urea breath test was performed and mental symptoms and blood ammonia level were reassessed after bacterium eradication.

**RESULTS:** Overall *H pylori* infection rate was 60.6%, and HE occurred in 47.5% of cirrhotic patients. Subclinical HE (SHE) was detected in 55 of 117 cirrhotic patients. Blood ammonia concentration in *H pylori* negative ( $n = 180$ ) and positive ( $n = 277$ ) cirrhotic patients was  $53.8 \pm 51.4$  and  $78.4 \pm 63.6$   $\mu\text{mol/L}$ , respectively ( $P < 0.01$ ), which was significantly reduced to  $53.5 \pm 37.7$   $\mu\text{mol/L}$  after bacterium eradication ( $n = 126$ ) ( $P < 0.01$ ). Blood ammonia was  $97.5 \pm 81.0$   $\mu\text{mol/L}$  in *H pylori*-positive cirrhotic patients, and this did not significantly change in those with persistent infection after *H pylori* eradication ( $n = 11$ ). HE was more frequently observed in patients with *H pylori* infection than in those without (58.5% vs 30.6%,  $P < 0.01$ ). HE rate significantly dropped to 34.1% after *H pylori* eradication ( $P < 0.01$ ). *H pylori* prevalence significantly differed among cirrhotic patients with HE (74.4%), SHE

(69.1%), and those without HE (53.2%) ( $P < 0.05$ ). Blood ammonia level was significantly different among cirrhotic patients with HE ( $94.5 \pm 75.6$   $\mu\text{mol/L}$ ), SHE ( $59.9 \pm 49.2$   $\mu\text{mol/L}$ ), and without HE ( $47.3 \pm 33.5$   $\mu\text{mol/L}$ ) ( $P < 0.05$ ). Logistic regression analysis showed that blood ammonia concentration, Child-Pugh stage, upper gastrointestinal bleeding, electrolyte disturbance, and urea nitrogen were risk factors for HE.

**CONCLUSION:** *H pylori* infection is an important factor for inducing high blood ammonia concentration and HE in cirrhotic patients. *H pylori* eradication may be helpful for treatment and prevention of HE.

Effect of *H pylori* infection and its eradication on hyperammonemia and hepatic encephalopathy in cirrhotic patients. *World J Gastroenterol* 2008; 14(13): 1914-1918 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1914.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1914>

### INTRODUCTION

Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis. Although the pathogenesis is unclear, ammonia is one of the key factors involved. Recently, it has been suggested *H pylori* contributes to hyperammonemia in cirrhosis, and bacterium eradication decreases blood ammonia concentration in these patients<sup>[1-8]</sup>. However, the literature contains conflicting data, with several other studies showing ammonia levels do not significantly differ between cirrhotic patients with and without *H pylori* infection. Ammonia production in the stomach by *H pylori* urease appears to be inadequate to clinically affect ammonia disposal in the majority of cirrhotic patients<sup>[2,9-13]</sup>. The possible role of *H pylori* in the pathogenesis of HE deserves further investigation.

## MATERIALS AND METHODS

### Subjects

From July 2003 to January 2005, 457 cirrhotic patients in 18 hospitals from five regions of Zhejiang Province in China were enrolled in this prospective study. Diagnosis of liver cirrhosis was carried out by history, clinical examination, laboratory findings, and radiological findings according to the principles established by Chinese Hepatology Association in 2002. The main exclusion criteria included: (1) Severe cardiac, pulmonary, cerebral and renal disorders; (2) severe HE of grades III and IV; (3) currently receiving *H pylori* eradication therapy; (4) currently undergoing surgery, (5) active gastrointestinal bleeding where non-surgical therapy is ineffective; (6) psychological disorders other than HE; and (7) current alcohol or sedative-drug abuse.

Patients were evaluated for demographic checklists, number connection test (NCT), *H pylori* infection, liver impairment (according to Child-Pugh classification, including the total score of HE, ascites, prothrombin time, albumin concentration and bilirubin level, which ranked as Child-Pugh class A, B and C), blood ammonia concentration, and HE status. All patients received a low-salt, low-protein diet, and lactulose was given to all patients to induce two to four bowel movements a day. Protein intake was restricted to about 20-40 g daily. One hundred and thirty-seven patients with *H pylori* infection were given 1 wk eradication therapy. Mental symptoms and blood ammonia levels were reassessed 1 mo after eradication therapy.

### Detection of *H pylori* infection

Gastric specimens were taken from the antrum when performing endoscopic biopsies, which were assessed by rapid urease test, histology (Giemsa staining) or *H pylori* culture. The presence of *H pylori* was detected by <sup>14</sup>C urea breath test in those who did not undergo biopsy. Subjects who had *H pylori* were identified by at least one of the above tests showing a positive result.

### Ammonia measurement

Fasting venous blood samples were obtained from each patient to measure ammonia concentration ( $\mu\text{mol/L}$ ), according to the manufacturer's instructions.

### NCT

The NCT (part A) was performed to detect subclinical HE. Subjects were required to connect numbers printed on paper consecutively from 1 to 25, as quickly as possible. NCT abnormality was defined as taking > 66 s to fulfill this task.

### HE stage

HE stage was established by clinical characteristics, electroencephalography (EEG) and NCT results. Patients were classified as cirrhotic without HE, with subclinical HE (SHE), and with HE. SHE was characterized by normal traditional clinical evaluation with definite and quantifiable neuropsychological defects (NCT abnormality).

Table 1 Clinical characteristics of *H pylori*-positive and -negative patients

	<i>H pylori</i> (+)	<i>H pylori</i> (-)	P value
Sex (male/female)	196/81	141/39	0.045
Age (yr)	57.6 $\pm$ 12.7	56.9 $\pm$ 13.4	0.604
Child-Pugh class			
A/B/C	67/124/86	55/77/48	0.309
Upper gastrointestinal hemorrhage	155	95	0.263
Hepatorenal syndrome	19	11	0.448
Ascites	197	136	0.208

### *H pylori* eradication therapy

The 137 cirrhotic patients with *H pylori* infection received 7 d dual eradication therapy (omeprazole 20 mg b.i.d plus clarithromycin 500 mg b.i.d plus tinidazole 500 mg b.i.d). One month after completion of treatment, a <sup>14</sup>C-urea breath test was performed to reassess *H pylori* status.

### Statistical analysis

Statistics were calculated using SPSS ver. 11.0. Qualitative variables were expressed by means of frequency and percentiles, and were analyzed using the  $\chi^2$  test. Quantitative results are expressed as means  $\pm$  SD. Groups were compared by using Student's *t* test or ANOVA. Risk factors for HE were analyzed using logistic multiple regression. Odds ratio (OR) values were calculated from 95% CI, and OR > 1.00 was considered a significant risk factor. Statistical significance was established at *P* < 0.05.

## RESULTS

### Effect of *H pylori* infection on blood ammonia and HE

Overall *H pylori* infection rate was 60.6% (277/457). There were 137 *H pylori*-positive patients who received eradication therapy, among whom the eradication rate was 91.4% (126/137). HE occurred in 47.5% of cirrhotic patients (217/457), and SHE was detected in 47.0% (55/117) of those without HE. There was no significant difference in liver impairment (Child-Pugh class), and complications (upper gastrointestinal bleeding, hepatorenal syndrome, and ascites) between *H pylori* positive and negative groups (Table 1). Blood ammonia concentration in *H pylori* negative and positive cirrhotic patients was 53.8  $\pm$  51.4 and 78.4  $\pm$  63.6  $\mu\text{mol/L}$ , respectively (*P* < 0.01). Blood ammonia was 78.4  $\pm$  63.6  $\mu\text{mol/L}$  in *H pylori*-positive cirrhotic patients before treatment (*n* = 137), and 97.5  $\pm$  81.0  $\mu\text{mol/L}$  in those with persistent infection after treatment (*n* = 11). Blood ammonia was significantly reduced to 53.5  $\pm$  37.7  $\mu\text{mol/L}$  (*P* < 0.01) in the *H pylori* eradication group (*n* = 126). HE was more frequently observed in patients with *H pylori* infection than in those without (58.5% *vs* 30.6%, *P* < 0.01). HE rate significantly dropped to 34.1% after *H pylori* eradication (*P* < 0.01). Data are shown in Table 2.

### Relationship between HE and *H pylori* infection and blood ammonia

*H pylori* prevalence differed significantly between cirrhotic patients with HE (74.4%), those with SHE (69.1%), or

**Table 2** Effect of *H pylori* infection on blood ammonia concentration and HE

<i>H pylori</i> infection	<i>n</i>	Ammonia concentration (μmol/L)	HE rate
<i>H pylori</i> (-)	180	53.8 ± 51.4 <sup>bd</sup>	55 (30.6%) <sup>bd</sup>
<i>H pylori</i> (+)	277	78.4 ± 63.6	162 (58.5%)
Eradicated	126	53.5 ± 37.7 <sup>bd</sup>	43 (34.1%) <sup>bd</sup>
Failed to eradicate	11	97.5 ± 81.0	6 (54.5%)

<sup>b</sup>*P* < 0.01, vs failed to eradicate (+) group; <sup>d</sup>*P* < 0.01, vs *H pylori* (+) group.

**Table 3** Relationship between HE and *H pylori* infection and blood ammonia

	HE ( <i>n</i> = 217)	SHE ( <i>n</i> = 55)	Cirrhotic ( <i>n</i> = 62)	<i>P</i> value	χ <sup>2</sup>
<i>H pylori</i> infection	74.4%	69.1%	53.2%	< 0.01	9.999
Child-Pugh class				< 0.01	29.154
A/B/C	27/100/90	9/30/16	22/33/7		
Ammonia concentration (μmol/L)	94.5 ± 75.6 <sup>b</sup>	59.9 ± 49.2	47.3 ± 33.5		

<sup>b</sup>*P* < 0.01, vs SHE group (*t* = 4.117); vs cirrhotic (*t* = 1.601).

without HE (53.2%) (*P* < 0.05). Blood ammonia level differed significantly between cirrhotic patients with HE (94.5 ± 75.6 μmol/L), those with SHE (59.9 ± 49.2 μmol/L), or without HE 47.3 ± 33.5 μmol/L) (*P* < 0.05). Liver impairment of Child-Pugh class B and C in patients with HE and SHE were 87.6% and 83.6%, respectively. Child-Pugh class A and B accounted for 88.7% of cirrhotic patients without HE (Table 3).

### Risk factors for HE

Through logistic multiple regression analysis, we found blood ammonia concentration (*P* = 0.000, OR = 4.701), Child-Pugh class (*P* = 0.000, OR = 3.416), *H pylori* infection (*P* = 0.007, OR = 2.113), gastrointestinal hemorrhage (*P* = 0.048, OR = 1.798), electrolyte disturbance (*P* = 0.045, OR = 1.875), and blood urea nitrogen (*P* = 0.041, OR = 1.854) were risk factors for HE. Sex, age, ascites, spontaneous bacteria peritonitis infection, hemoglobin, white blood count, platelet count and creatinine were not significantly associated with HE (Table 4).

## DISCUSSION

Most currently available therapies for prevention of HE focus on reducing blood ammonia concentration<sup>[14,15]</sup>. *H pylori* is known to produce copious amounts of ammonia due to its strong urease activity. Ammonia produced by *H pylori* has a role in the pathogenesis of hyperammonemia when this organism is widely distributed and present in large numbers in the stomach, particularly in the presence of liver cirrhosis<sup>[16-19]</sup>. We did not find a significant difference in age, liver impairment and complication rate (upper gastrointestinal bleeding, hepatorenal syndrome and ascites) between *H pylori*-positive and -negative groups. However, blood ammonia concentration in *H pylori*-positive patients was significantly higher than that in *H pylori*-negative patients

**Table 4** Risk factors for HE analyzed by logistic multiple regression

	<i>P</i> value	OR value	95% CI
Sex	0.341	0.751	0.416-1.354
Age	0.881	0.959	0.555-1.657
Etiology	0.125	1.564	0.883-2.769
<i>H pylori</i> infection	0.007	2.113	1.222-3.654
Blood ammonia level	0.000	4.701	2.773-7.970
Child-Pugh class	0.000	3.416	1.823-6.398
Ascites	0.277	1.395	0.765-2.541
Hemorrhage	0.048	1.798	1.004-3.218
Infections	0.934	1.027	0.546-1.932
Electrolyte disturbance	0.045	1.857	1.015-3.398
Leukocyte count	0.840	1.056	0.625-1.782
Hemoglobin	0.592	1.192	0.626-2.270
Platelet count	0.430	1.279	0.694-2.356
Creatinine	0.489	0.768	0.364-1.621
Blood urea nitrogen	0.041	1.854	1.025-3.353

(*P* < 0.01). This suggested that *H pylori* infection was associated with hyperammonemia in cirrhotic patients. It has previously been shown ammonia concentration in portal and venous blood significantly increased after the instillation of 10<sup>10</sup> CFU/L *H pylori* in the stomach of cirrhotic rats<sup>[20]</sup>. Oral administration of acetohydroxamic acid significantly reduced blood ammonia levels in cirrhotic patients with *H pylori* infection, compared with those without infection<sup>[21]</sup>. We have previously reported that ammonia level in portal vein blood of cirrhotic patients with *H pylori* infection is significantly higher than that in patients without infection<sup>[22]</sup>.

In the present study, HE was more frequently observed in patients with *H pylori* infection than in those without (58.5% vs 30.6%, *P* < 0.01), which was consistent with that reported elsewhere<sup>[23-25]</sup>. The hypothesis that *H pylori* infection plays a pathogenic role in HE was initially devised by Gubbins *et al*<sup>[26]</sup>. In their study, seroprevalence for *H pylori* was detected in 78.6% of 117 alcoholic liver disease patients with HE, and in 62% of 71 patients without (*P* = 0.013). *H pylori* was detected only by serology, which has been reported to be inaccurate in cirrhotic patients. Therefore, the results of that study should be interpreted with caution. In a study of 55 cirrhotic patients, Dasani *et al*<sup>[17]</sup> detected *H pylori* infection more frequently in those with HE compared with those without (67% vs 33%, *P* = 0.004). However, conflicting data are available in the literature. Several studies have shown that ammonia levels do not significantly differ between cirrhotic patients with and without *H pylori* infection, which suggests that although *H pylori* infection is able to generate ammonia in the stomach, the amount appears to be too small to affect arterial ammonia levels in patients with cirrhosis<sup>[2,9,14,31]</sup>. The contribution of ammonia produced by *H pylori* to HE may depend on the number of bacteria and their distribution in the stomach, gastric pH, gastric membrane permeability to ammonia, liver impairment, and portal vein branch circulation. We suppose *H pylori* may increase blood ammonia concentration and induce HE when the bacterium is widely distributed in the stomach, and in the presence of severe liver impairment (Child-Pugh class B or C) with abundant portal vein branch circulation.

Through logistic multiple regression analysis, we found blood ammonia, Child-Pugh class, upper gastrointestinal bleeding, electrolyte disturbance, and urea nitrogen were significantly associated with HE. Dasani *et al.*<sup>[17]</sup> have documented that risk factors associated with HE include older age ( $P = 0.001$ ), lower albumin ( $P = 0.001$ ), *H pylori* infection ( $P = 0.004$ ), greater ascites score ( $P = 0.01$ ), and greater Child-Pugh class ( $P = 0.001$ ).

In view of the association of *H pylori* infection with hyperammonemia and HE, bacterium eradication may theoretically reduce ammonia concentration in cirrhotic patients<sup>[27-29,32]</sup>. Ito *et al.*<sup>[30]</sup> initially gave *H pylori* eradication therapy to cirrhotic patients, and found reduced ammonia concentration and recovery from HE after eradication, without relapse in the following 5 mo. In our study, blood ammonia concentration in *H pylori*-positive cirrhotic patients was significantly reduced by bacterium eradication ( $P < 0.01$ ). HE rate significantly dropped to 34.1% after *H pylori* eradication ( $P < 0.01$ ). However, several investigators have questioned whether the effect of eradication therapy on hyperammonemia is due to the non-specific effect of antibiotic therapy on the ammonia-producing gut flora. In Miyaji and Ito's study<sup>[16]</sup>, all patients were given lactulose, branched-chain enriched amino acid solution, low-protein diet, and kanamycin for 2 wk before *H pylori* eradication therapy, to reduce the effect of the gut flora on hyperammonemia. The blood ammonia concentration in patients with diffuse distribution of *H pylori* in the stomach was significantly reduced after bacterium eradication compared with the concentration after conventional treatment to reduce the gut flora. The ammonia concentration at 12 wk after eradication treatment was still significantly lower than that before. Therefore, eradication of *H pylori* to reduce bacterial ammonia production in the stomach is effective in patients with hyperammonemia with diffuse *H pylori* infection in the stomach, even after conventional therapy with a low-protein diet, antibiotics, lactulose and branched-chain enriched amino acid solution<sup>[1,16,17]</sup>. *H pylori* eradication may be helpful for the treatment and prevention of HE. However, further studies are warranted to evaluate the arguments for and against the role of *H pylori* in the pathogenesis of HE.

## COMMENTS

### Background

Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis. Although the pathogenesis is unclear, ammonia is one of the key factors involved. Recently, it has been suggested *H pylori* contributes to hyperammonemia in cirrhotic patients and bacterium eradication decreases blood ammonia concentration. However, several other studies have shown ammonia levels do not significantly differ between cirrhotic patients with and without *H pylori* infection. The possible role of *H pylori* in the pathogenesis of HE merits further investigation.

### Research frontiers

Recent research has focused on determining the relationship between *H pylori* infection, blood ammonia concentration and HE status in prospective and multicenter studies, and on investigating the effect of *H pylori* eradication on blood ammonia level and HE in cirrhotic patients.

### Innovations and breakthroughs

We designed this prospective study to evaluate the effects of *H pylori* infection

and eradication on hyperammonemia and HE in 457 cirrhotic patients in five regions of Zhejiang Province, China. We observed blood ammonia concentration was significantly higher and HE was more frequent in patients with *H pylori* infection than in those without. Moreover, eradication of *H pylori* infection resulted in reduction in both blood ammonia concentration and frequency of HE.

### Applications

*H pylori* infection is an important factor for inducing high blood ammonia concentration and HE in cirrhotic patients. *H pylori* eradication may be helpful for treatment and prevention of HE.

### Terminology

SHE is characterized by normal, traditional clinical evaluation with definite and quantifiable neuropsychological defects.

### Peer review

This study evaluated the relationship between *H pylori* infection, blood ammonia concentration and HE, and determined the effect of *H pylori* eradication on blood ammonia level and HE in cirrhotic patients. This study is of important clinical significance and should be of interest to readers of the journal.

### Abstract

**AIM:** To characterize changes in ghrelin levels in response to oral glucose tolerance test (OGTT) and to correlate changes in ghrelin levels with changes in insulin and glucose following OGTT in Chinese obese children of Tanner I and II stage with insulin resistance.

**METHODS:** 22 obese children with insulin resistance state were divided into four groups according to their Tanner stage and gender: boys of Tanner I (BT-I), boys of Tanner II (BT-II), girls of Tanner I (GT-I), girls of Tanner II (GT-II). Ghrelin, insulin and glucose were measured at 0, 30, 60 and 120 min following OGTT. The control children with normal BMI were divided into control boys of Tanner I (CBT-I,  $n = 6$ ), control boys of Tanner II (CBT-II,  $n = 5$ ), control girls of Tanner I (CGT-I,  $n = 6$ ), control girls of Tanner II (CGT-II,  $n = 5$ ). Fasting serum ghrelin levels were analyzed.

**RESULTS:** Ghrelin levels were lower in obese groups. Ghrelin levels of control group decreased in Tanner II stage (CGT-I vs CGT-II  $t = -4.703$ ,  $P = 0.001$ ; CBT-I vs CBT-II  $t = -4.794$ ,  $P = 0.001$ ). Basal ghrelin levels in BT-II decreased more significantly than that in BT-I group ( $t = 2.547$ ,  $P = 0.029$ ). Ghrelin levels expressed a downward trend after OGTT among obese children. The decrease in ghrelin levels at 60 min with respect to basal values was 56.9% in BT-I. Ghrelin concentrations at 0 min correlated directly with glucose level at 0 min in BT-I ( $r = 0.898$ ,  $P = 0.015$ ). There wasn't a significant correlation of ghrelin changes with glucose changes and insulin changes during OGTT in obese children with insulin resistance.

**CONCLUSION:** In conclusion, in obese children with insulin resistance, ghrelin levels decreased with

advancing pubertal stage. Ghrelin secretion suppression following OGTT was influenced by gender and pubertal stage. Baseline ghrelin levels and ghrelin suppression after OGTT did not significantly correlate with the degree of insulin resistance and insulin sensitivity.

### INTRODUCTION

Ghrelin is a novel GH-releasing peptide involved in the regulation of feeding behavior and energy homeostasis<sup>[1]</sup>. Ghrelin secretion is up-regulated under conditions of negative energy balance and down-regulated in the setting of positive energy balance. Coexpression of GH secretagogue receptor and ghrelin in the pancreas suggests that this peptide is involved in glucose metabolism<sup>[2]</sup>. Nutritional state is a determinant of plasma ghrelin in humans and rats<sup>[3,4]</sup>. Endogenous ghrelin in islets acts on beta-cells to restrict glucose-induced insulin release at least partly via attenuation of  $Ca^{2+}$  signaling, and that this insulinostatic action may be implicated in the upward control of blood glucose<sup>[5]</sup>.

Though ghrelin concentrations in healthy children and adolescents and animals have been investigated<sup>[6,7]</sup>. The role of ghrelin in childhood obesity, a state associated with hyperinsulinism and insulin resistance, is not fully understood. Previous reports demonstrated that plasma ghrelin levels decrease after oral glucose tolerance test (OGTT) in obese children and adults<sup>[8-10]</sup>. To date, there no data are available on ghrelin levels after oral glucose administration in Chinese obese children. Similarly, ghrelin

levels with respect to puberty stage and obesity severity have never been investigated. Based on this background, the aims of the present study were to characterize changes in ghrelin levels in response to OGTT, and also to correlate changes in ghrelin levels with modifications in insulin and glucose in Chinese obese children of Tanner I and II stage with insulin resistance.

## MATERIALS AND METHODS

### Patients

The pubertal stages were determined by visual inspection, using Tanner's criteria<sup>[11]</sup>. Children included in this study were ranging from Tanner I stage (aging 8.1 to 9.0 years) to Tanner II stage (aging 10.1 to 11.0 years) of pubertal development. Exclusion criteria were the presence of other endocrine disorders and the use of medication that could change the suggested laboratory evaluation at the time of the study. Age- and sex-specific body mass index (BMI) cut-off values can be used to identify adolescents with clustering of cardiovascular risk factors<sup>[12-14]</sup>. The BMI of obese group varied from 25.4 to 29.7 kg/m<sup>2</sup>. Twenty-two obese children with insulin resistance were divided into four groups according to their Tanner stage and gender: boys of Tanner I (BT-I, *n* = 6), boys of Tanner II (BT-II, *n* = 5), girls of Tanner I (GT-I, *n* = 6), girls of Tanner II (GT-II, *n* = 5). The control population was 22 healthy children with normal BMI (varied from 19.3 to 21.7 kg/m<sup>2</sup>), who were divided into control boys of Tanner I (CBT-I, *n* = 6), control boys of Tanner II (CBT-II, *n* = 5), control girls of Tanner I (CGT-I, *n* = 6), control girls of Tanner II (CGT-II, *n* = 5). Fasting serum ghrelin levels were analyzed in the control group, and the age of control group was matched to obese group in different puberty stage.

The human investigation committee of Zhejiang University School of Medicine approved the study. All subjects were informed about the purpose of this study and parents or guardians gave written consent.

### Methods

All obese subjects were given 0.75 g/kg (maximum 75 g) of glucose solution orally after overnight fasting. Glucose was dissolved in about 200 mL of water and sipped over about 10 min to prevent nausea. Blood samples were collected at 0, 30, 60 and 120 min. Glucose concentrations were examined immediately after withdrawal. Blood samples were kept in chilled tubes containing EDTA (1 mg/mL) plus aprotinin (500 U/mL) for measuring ghrelin and insulin. The tubes were centrifuged at 3000 rpm/min and the plasma was stored at -80°C until assayed.

Insulin resistance was measured by the homeostasis model assessment (HOMA). The HOMA formulas are as follows:

- Homeostasis model assessment-insulin resistance index (HOMA-IR) = [fasting blood glucose (FBG, mmol/L) × fasting blood insulin (FINS, mIU/L)]/22.5. HOMA-IR ≥ 2.8 represents insulin resistance state<sup>[13]</sup>.
- HOMA insulin sensitivity index (HOMA-ISI) = 1/(FINS × FBG).

Plasma ghrelin levels were determined by a commercial

radioimmunoassay (Phonex Pharmaceutical, Inc, Belmont, CA, USA), using a polyclonal antibody that recognizes octanoylated and non-octanoylated ghrelin and <sup>125</sup>I-ghrelin as a tracer molecule. The intra- and interassay coefficients of variation were 5.0% and 10.7% respectively. Assay sensitivity was 12 pg/mL.

Plasma glucose concentrations were determined by the hexokinase method using an analyzer (Hitachi System 717; Roche Diagnostics, Basel, Switzerland).

Insulin was analyzed by Micro-particle enzyme immunoassay (IMMULITE system, Diagnostic Products Corporation, Los Angeles, USA).

### Statistical analysis

The data were expressed either as mean ± SD or as 95% confidence intervals (95% CI). Normal distribution parameters were compared by independent-samples *t*-test or one-way ANOVA test. Non-normal distribution parameters were analyzed by Mann-Whitney *U* test. *P* < 0.05 was chosen as the level of significance. Linear regression analysis was performed to determine the overall interaction of different parameters, followed by partial correlation analysis.

## RESULTS

### The clinical features of obese I children

There were no differences in parameters such as insulin resistance, BMI, systolic blood pressure, *etc.*, among obese groups. A significant difference in insulin sensitivity was found (BT-I *vs* GT-II, *P* = 0.006; BT-I *vs* GT-II, *P* = 0.000; BT-I *vs* GT-II, *P* = 0.026, GT-II *vs* GT-I, *P* = 0.049) (Table 1).

### Basal ghrelin levels in obese children and control group

Fasting serum ghrelin levels were analyzed. Compared with controls of the same gender and same Tanner stage, basal ghrelin levels were lower in obese groups, and there was significant difference in ghrelin levels between CGT-I group and GT-I group (*t* = 4.415, *P* = 0.02). Ghrelin levels of control group decreased in Tanner I stage (CGT-I *vs* CGT-II *t* = -4.703, *P* = 0.001; CBT-I *vs* CBT-II *t* = -4.794, *P* = 0.001). Basal ghrelin levels in BT-II decreased significantly than that in BT-I group (*t* = 2.547, *P* = 0.029). There were no differences in ghrelin levels between GT-I and GT-II (*t* = -1.743, *P* = 0.112) (Table 2).

### Glucose, insulin and ghrelin levels after OGTT in obese children with insulin resistance

Ghrelin levels expressed a downward trend after OGTT among obese children (Table 3). Total ghrelin values (ghrelin 0 min plus ghrelin 30 min plus ghrelin 60 min plus ghrelin 120 min) were higher in BT-I than BT-II (*t* = 2.485, *P* = 0.032). At 0, 30, 60, 120 min during OGTT, GT-II group had no lower ghrelin levels than GT-I (*t* = 1.496, *P* = 0.169; *t* = -0.574, *P* = 0.580; *t* = -0.067, *P* = 0.968; *t* = 0.471, *P* = 0.649 respectively). The decrease in ghrelin levels at 60 min with respect to basal values was 56.9% in BT-I. This was the maximum ghrelin decrease following glucose administration, in parallel with maximum insulin levels. The maximum ghrelin decrease of GT-I occurred

Table 1 The clinical features of obese I children

	BT- I (n = 6)	BT- II (n = 5)	GT- I (n = 6)	GT- II (n = 5)

BT- I : Boys of Tanner I ; BT- II : Boys of Tanner II ; GT- I : Girls of Tanner I ; GT- II : Girls of Tanner II . Data are expressed as mean ± SD for Gaussian variables and as the median with lower and higher quartiles for non-Gaussian variables. <sup>a</sup>*P* < 0.05 vs BT- II ; <sup>b</sup>*P* < 0.05 vs BT- II ; <sup>c</sup>*P* < 0.05 vs GT- I .

at 30 min during OGTT, reaching approximately 39%, and it preceded the maximum increase in glucose levels. The maximum ghrelin decrease of BT- II and GT- II happened at 120 min, but it only reached 31% ± 10% and 9.8% ± 3% respectively. There were differences in ghrelin changes at 60 min from baseline levels between BT- I and BT- II (*F* = 8.402, *P* = 0.016), ghrelin value of GT- II at 60 min decreased more significantly than that of GT- I (*F* = 5.627, *P* = 0.041). However, the difference in terms of ghrelin changes between BT- II and GT- II happened at 30 min (*F* = 7.946, *P* = 0.020).

Ghrelin concentrations at 0 min during the oral glucose tolerance test correlated directly with glucose level at 0 min in BT- I (*r* = 0.898, *P* = 0.015) (Table 4). Although ghrelin values varied during OGTT, we could not demonstrate a significant correlation of ghrelin changes with glucose changes and insulin changes during OGTT in obese children with insulin resistance.

## DISCUSSION

Ghrelin plays a role in meal initiation and satiety in an inverse pattern to that of insulin<sup>[2,3]</sup>. Previous reports demonstrated that ghrelin levels were significantly decreased in obese children<sup>[8,15]</sup>. However, the secretory dynamics of ghrelin have not been characterized in obese children with insulin resistance. In this study, obese children with insulin resistance were divided into different groups by gender and pubertal stage to observe the effects of gender and puberty on ghrelin levels. In control children, basal ghrelin levels of Tanner II group were lower than those of Tanner I group. In obese children with insulin resistance, basal ghrelin levels in BT- II group decreased significantly than that in BT- I group, however, there were no differences in ghrelin levels between GT- I and GT- II. This result indicates that basal ghrelin levels differ depending upon the pubertal stage and gender. The increase in sexual hormones is associated with a marked decline in circulating levels of ghrelin in

Table 2 Basal ghrelin levels in obese children and control group (pg/mL)

	Boys		Girls	
	Tanner I	Tanner II	Tanner I	Tanner II

	872.3-1424.2	220.2-809.6	772.3-1220.3	182.6-1027.4
Control children	1009.6	244.5 <sup>e</sup>	412.9 <sup>a</sup>	222
	741.4-1777.7	165.7-323.3	134.8-691.1	113.1-359.0

Data are expressed as mean (95% CI). <sup>a</sup>*P* < 0.05 vs control group of the same gender and same Tanner stage; <sup>b</sup>*P* < 0.05 vs subgroup of the same gender and different Tanner stage within the control group; <sup>c</sup>*P* < 0.05 vs subgroup of the same gender and different Tanner stage within the obese group.

boys, serum testosterone are the major determinants of serum ghrelin<sup>[16]</sup>. Different estrogen and testosterone levels influence the body weight homeostasis of growth hormone secretagogue receptor (GHSR) -/- mice, which lack the orexigenic ghrelin signaling<sup>[17-19]</sup>. Contrary to what is expected in physiologic puberty, where ghrelin is progressively reduced, in central precocious puberty (CPP), ghrelin secretion seems to be independent from pubertal development. Concomitant estrogen suppression during treatment may play a potential role in the regulation of ghrelin secretion in CPP girls<sup>[20]</sup>. With advancing pubertal stages, ghrelin levels may be prone to be influenced by sexual hormones and growth hormone, so they display gender differences.

The rapid fall in plasma ghrelin concentration after glucose load suggests its involvement in the control of appetite and in the regulation of energy homeostasis<sup>[21]</sup>. The maximum decrease in ghrelin levels happened at 60 min in simple obesity adults (BMI, 26.3-40.5)<sup>[22,23]</sup>. OGTT-induced absolute suppression in ghrelin was approximately 50% less in overweight versus normal weight children, resulting in a similar percent suppression from baseline in the two groups<sup>[24,25]</sup>. In this study, the entity of ghrelin suppression during OGTT differed with gender and pubertal stage in obese children with insulin resistance.

<sup>a</sup>P < 0.05 vs 0 min in the same group; <sup>c</sup>P < 0.05 vs 30 min; <sup>e</sup>P < 0.05 vs 60 min.

The maximum decrease in ghrelin levels was about 57%, at 60 min in Tanner I boys. However, the maximum ghrelin decrease of GT- I occurred at 30 min, reaching approximately 39%. The maximum ghrelin decrease of BT- II and GT- II groups happened later, and the entity of the decrease lessened. This result demonstrated that the ghrelin secretion pattern of obese children with insulin resistance was different from simple obesity adults and overweight children. Gender differences in ghrelin suppression after OGTT in obese children with insulin resistance were also noted; further studies are needed to elucidate the mechanism underlying this phenomenon.

Fasting ghrelin levels were mainly influenced by insulin sensitivity independently from adiposity<sup>[26]</sup>. Ghrelin is substantially decreased during pregnancy, but glucose-induced ghrelin suppression is preserved at a lower level. There is apparently no relation to the degree of insulin resistance<sup>[27,28]</sup>. Plasma ghrelin concentrations in obese children with insulin resistance were lower than those of control children in our study, which were in accordance with previous reports. In this study, the correlation between baseline ghrelin levels and basic factors involved in glucose homeostasis were further analyzed, Baseline ghrelin levels of obese children with insulin resistance have

**Table 4** The correlation of baseline ghrelin levels with some baseline indexes involved in glucose homeostasis

Group	Vs FBG r (P)	Vs FINS r (P)	Vs FBG/FINS r (P)	Vs HOMA-IAI r (P)	Vs IR r (P)	Vs IS r (P)	Vs BMI r (P)
BT- I	0.898 (0.015) <sup>a</sup>	0.488 (0.326)	0.35 (0.947)	0.297 (0.568)	0.552 (0.269)	0.435 (0.338)	0.737 (0.095)
BT- II	0.045 (0.859)	0.1 (0.693)	0.929 (0.007) <sup>a</sup>	0.896 (0.016) <sup>a</sup>	0.772 (0.072)	0.85 (0.032) <sup>a</sup>	0.672 (0.114)

<sup>a</sup>P < 0.05.

not correlations with some clinic indexes as reported in patients with type 2 diabetes and overweight children<sup>[29,30]</sup>. Baseline ghrelin levels correlated with insulin sensitivity and β-cell function only in BT- II group. Baseline ghrelin concentrations in BT- I group correlated with fasting blood glucose. There were no relationships between baseline ghrelin levels and baseline glucose, insulin concentrations and insulin sensitivity in BT- II and GT- II

groups. There was no correlation between baseline ghrelin and dynamic glucose and insulin data.

Alterations in ghrelin suppression in overweight children may be yet another manifestation of the insulin resistance of obesity<sup>[26]</sup>. Ghrelin parameters were inversely associated with fasting insulin, HOMA-IR in adolescent girls with anorexia nervosa<sup>[31]</sup>. However, we could not demonstrate a significant correlation between ghrelin level changes, glucose and insulin concentrations after OGTT in obese children with insulin resistance. Ghrelin suppression after OGTT is modulated by insulin sensitivity. Whether ghrelin suppression in obese children with insulin resistance is a manifestation or an outcome of insulin resistance requires additional investigation.

In conclusion, in obese children with insulin resistance, ghrelin levels decreased with advancing pubertal stage. Ghrelin secretion suppression following OGTT was influenced by gender and pubertal stage. Baseline ghrelin levels and ghrelin suppression after OGTT did not significantly correlate with the degree of insulin resistance and insulin sensitivity.

## ACKNOWLEDGMENTS

We thank all the children and their parents for participating in this research project. We also thank You-Jun Jiang, Chun-Lin Wang, and Hong Shen for their exceptional patient care and organization.

## COMMENTS

### Background

Ghrelin plays a role in the regulation of energy balance and attenuates leptin-induced reduction in food intake and body weight. Ghrelin levels were found decreased in obese individuals and influenced by the pubertal stage. However, the relationship between ghrelin secretion and insulin resistance, pubertal stage are not completely understood.

### Research frontiers

Obesity increases the risk of developing type 2 diabetes, hypertension, stroke, and heart attack. Insulin resistance has a central role in above chronic diseases. A reciprocal relationship exists between ghrelin and insulin, suggesting that ghrelin regulates glucose homeostasis. However, the secretory dynamics of ghrelin have not been characterized in obese children with insulin resistance.

### Innovations and breakthroughs

In obese children with insulin resistance, ghrelin levels decreased with advancing pubertal stage. Ghrelin secretion was influenced by gender and its suppression following OGTT differed with gender and pubertal stage.

### Applications

Taken gender and puberty into consideration, alterations in ghrelin suppression in obese children may be another manifestation of the insulin resistance.

### Terminology

Tanner's pubertal staging of the secondary sexual characteristics that identify pubertal progression are a cornerstone for both clinicians and those involved in clinical research of children and adolescents. This staging has served as the foundation for the study and understanding of the maturation of the hypothalamic-pituitary-gonadal axis, adrenarache, and the physiological processes that initiate and facilitate progression of sexual maturation. According to Tanner's description, progression of sexual maturation is divided in to Tanner's stage I, II, III, IV and V stage.

### Peer review

This study investigated plasma ghrelin changes in response to OGTT, and also

to correlate changes in ghrelin levels with modifications in insulin and glucose in Chinese obese children of Tanner and stage with insulin resistance. It is of particular importance to obese children with insulin resistance.

**Key words:** Cystic fibrosis transmembrane conductance regulator gene; Gene polymorphism; Poly-T; TG-repeats; M470V

**Peer reviewer:** CS Pitchumoni, Professor, Robert Wood Johnson School of Medicine, Robert Wood Johnson School of Medicine, New Brunswick, NJ D8903, United States

### Abstract

**AIM:** To investigate the three important cystic fibrosis transmembrane conductance regulator (*CFTR*) haplotypes poly-T, TG-repeats and the M470V polymorphisms in the Chinese population, and to compare their distribution with that in Caucasians and other Asian populations.

**METHODS:** Genomic DNA was extracted from blood leukocytes. Exons 9 and 10 of the *CFTR* gene were obtained through polymerase chain reaction (PCR). Exon 9 DNA sequences were directly detected by an automated sequencer and poly-T and TG-repeats were identified by direct sequence analysis. Pure exon 10 PCR-amplified products were digested by *Hph* I restriction enzyme and the M470V mutation was detected by the AGE photos of digestion products.

**RESULTS:** T7 was the most common (93.6%) haplotype and the (TG)11 frequency of 57.2% and (TG)12 frequency of 40.9% were dominant haplotypes in the junction of intron 8 (IVS-8) and exon 9. The frequency of T5 was 3.8% and all T5 allele tracts (10 alleles) were joined with (TG)12. Four new alleles of T6 (1.5%) were found in three healthy individuals. In exon 10, the V allele (56.1%) was slightly more frequent than the M allele (43.9%), and the M/V (45.5%) was the dominant genotype in these individuals. The three major haplotypes T7-(TG)11-V470, T7-(TG)12-M470 and T7-TG11-M470 were related to nearly 86.0% of the population.

**CONCLUSION:** The polymorphisms of poly-T, TG-repeats, and M470V distribution were similar to those in other East Asians, but they had marked differences in frequency from those single haplotype polymorphisms or linkage haplotypes in Caucasians. Thus, they may be able to explain the low incidence of CF and CF-like diseases in Asians.

### INTRODUCTION

The cystic fibrosis transmembrane conductance regulator (*CFTR*) gene on chromosome 7q31 spans approximately 250 kb of DNA and encodes 27 exons encodes<sup>[1]</sup>. The *CFTR* gene encodes a cAMP- and ATP-dependent chloride channel that is present in the apical membrane of the epithelial cells that line most exocrine glands<sup>[2]</sup>. Phosphorylation of the regulatory domain by protein kinase A, followed by binding and hydrolysis of ATP at both nucleotide-binding domains, regulates the transport of chloride ions through the channel<sup>[3]</sup>. Absence, reduced levels, or malfunction of the *CFTR* protein results in cystic fibrosis (CF), and CF-like diseases such as congenital bilateral absence of the vas deferens (CBAVD)<sup>[4,5]</sup>, bronchiectasis<sup>[6]</sup> and chronic pancreatitis<sup>[7]</sup>. Since the discovery of the *CFTR* gene, more than 1000 mutations and 200 polymorphisms have been identified<sup>[8]</sup>. CF is one of the most common autosomal recessive disorders in Caucasians, with an incidence of approximately 1 in 2500 Caucasian births and a carrier frequency of approximately 1 in 25. However, in Asians, the prevalence of CF is very low, with an incidence of approximately 1 in 100000, and in particular, the severe mutations, such as  $\Delta F508$ , G542X and N1303K, are rarely found in Asians. Previous studies have demonstrated that polymorphisms outside the *CFTR* gene<sup>[9,10]</sup>, as well as within the gene, may affect transcription or function of the *CFTR* protein and modify the phenotype of some CF mutations. It has been mentioned that poly-T, TG-repeats and M470V polymorphisms play a role in the development of CF-like diseases. The poly-T tract located at the junction of intron

8 (IVS-8) and exon 9 influence transcription, and thereby reduce the amount of normal CFTR protein. The number of T residues present, five, seven or nine, affects the splicing efficiency of exon 9. If the T5 allele is present, a proportion of CFTR transcripts will lack exon 9, which produces a non-functional protein and variable CF symptoms<sup>[11]</sup>. The TG-repeats, 5' of the poly-T, also influence splicing of exon 9<sup>[12]</sup>, and when present on the same allele as a 5T repeat, the longer the TG-repeats, the higher the proportion of CFTR transcripts that will lack exon 9. On the other hand, the M470V polymorphism on exon 10 affects the intrinsic chloride activity, and thereby affects the function of the CFTR protein<sup>[12,13]</sup>.

Although mutations and polymorphisms of CFTR have been extensively studied in Western populations, their importance is less well studied in East Asia because of the rare presentation of classical CF. There are just a few data on CFTR in Asia, especially in China. No reports on CFTR genetic background among the normal Chinese population have been published, except for sporadic reports on CFTR mutations in CF-like patients. To explore polymorphic backgrounds of CFTR in the Chinese population, we analyzed polymorphisms of poly-T, TG repeats and M470V in 132 healthy individuals among the general population in Jiangsu Province.

## MATERIALS AND METHODS

### Subjects

A total of 132 healthy unrelated subjects were randomly selected from the population of Jiangsu Province (78 males, 54 females; mean age 44 years, range 16-85 years). Four milliliters of blood were collected for genotyping. The blood was mixed with EDTA and stored at -80°C.

### DNA analysis

Genomic DNA was extracted from blood leukocytes using the QiaAmp DNA Blood Mini kit (Qiagen, Hilden, Germany). Polymerase chain reaction (PCR) was carried out using Ex Taq Polymerase (Takara, Japan). The PCR used a GeneAmp PCR system (Model PTC-200, Bio-Red, Foster City, CA, USA). Cycling for both reactions was performed as follows: 94°C for 5 min for preheating, 35 cycles at 94°C for 30 s, 60°C for 60 s, and 72°C for 30 s, followed by one cycle at 72°C for 10 min for extension. The oligonucleotide primers used were: Intron 8 and exon 9 junction, sense 5'-CCATGTGCTTTTCAAATAAT TGT-3', anti-sense 5'-TAAAGTTATTGAATGCTCGC CATG-3'; and exon 10, sense 5'-TTGTGCATAGCAG AGTACCTGAAA-3', anti-sense 5'-GCTTCTTAAAGC ATAGGTCATGTG-3'. The sequences of exon 9 PCR-amplified products were sequenced by Shanghai Invitrogen Company using an automated sequencer (ABI 737). Exon 10 PCR-amplified products were purified using the High Pure PCR Product Purification Kit (Roche Diagnostics, Mannheim, Germany). The M470V mutation was detected by *Hpa*I restriction enzyme digestion.

### Haplotype analysis

Haplotypes consisting of three loci were investigated,

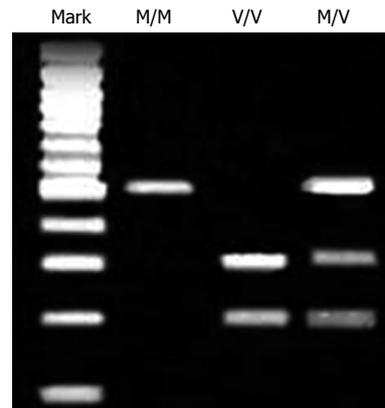

Figure 1 M470V polymorphism in exon 10.

Table 1 Allele frequency of poly-T tract

Number (n)	Number (frequencies) of poly-T tract			
	T5	T6	T7	T9
2n = 264	10 (0.0379)	4 (0.0152)	247 (0.9356)	3 (0.0114)

that is, poly-T, TG-repeats, and the M470V. The M470V polymorphisms were estimated by the AGE photos of pure PCR products after *Hpa*I restriction enzyme digestion (Figure 1). Poly-T and TG-repeats are continuous in sequence, hence their haplotypes were identified by direct sequence analysis (Figure 2). The frequency of each haplotype of TG-repeats and M470V ( $P_m$ ) was estimated by the following equation derived from the Hardy-Weinberg law:  $(P_1 + P_2 + P_3 + P_m)^2 = 1$ , where  $P_1 + P_2 + P_3 + P_m = 1$ , and  $P_1^2, P_2^2, P_3^2, P_m^2$  are the frequencies of homozygous for either locus or both loci.

## RESULTS

### Poly-T

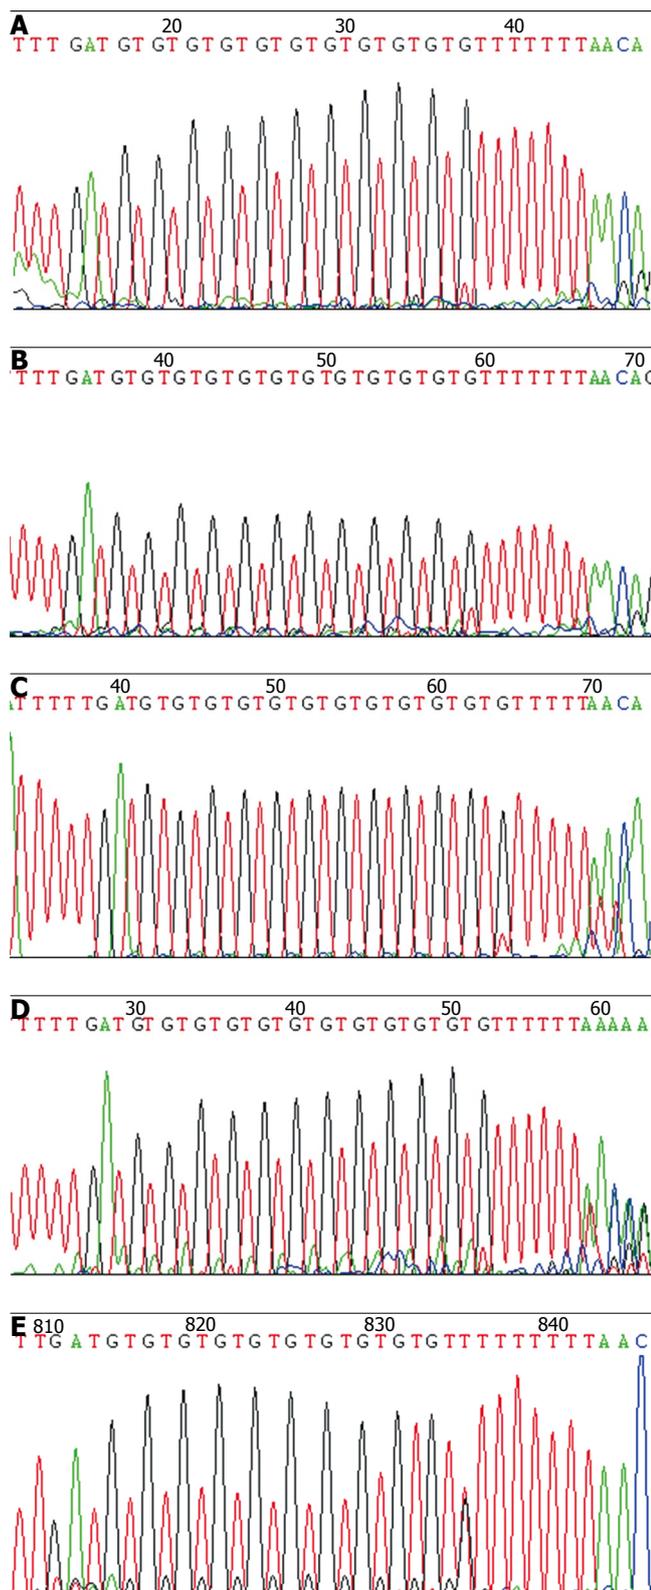

T7 was the most common haplotype (93.6%), hence, T7/T7 was a dominant genotype in Chinese individuals (Table 1). Four alleles of T6 were newly found in the normal subjects. Ten alleles of T5 with a frequency of 3.8% were found. The T9 alleles were very rare at just 1.1%. The sequence analysis indicated that four alleles of T6 probably resulted from a T deletion from T7.

### TG-repeats

(TG)11 and (TG)12 were the dominant haplotypes in the Chinese population, with a frequency of 57.2 and 40.9%, respectively. The frequency distribution of genotypes (TG)11/(TG)11, (TG)11/(TG)12 and (TG)12/(TG)12 was 46.2, 21.2 and 29.6%, respectively (Table 2). The relative ratio of the (TG)11/(TG)11, (TG)11/(TG)12 and (TG)12/(TG)12 was roughly 2:1:1.

### M470V

The V allele was slightly more frequent than the M allele in the Chinese population, and the frequencies were 56.1 and 43.9%, respectively. The dominant genotype was M/V, followed by V/V and M/M (Table 3).

**Figure 2** The polymorphisms of TG-repeats and Poly-T haplotype in IVS-8. A: TG11-T7; B: TG12-T7; C: TG12-T5; D: TG12-T6; E: TG10-T9.

### Three-locus haplotype analysis

T7-TG11-V470 was the dominant linkage haplotype in the Chinese population, and the frequency was 47.4%, which was almost half of all the types of linkage. Other frequencies were: T7-TG12-M470, 29.2%; T7-TG11-M470, 9.9%; and T7-TG11-M470, 6.8%, and others

**Table 2** Allele frequency of TG-repeat polymorphisms

Number (2n)	Number (frequencies) of TG-repeats				
	TG10	TG11	TG12	TG13	
264	3 (0.0114)	151 (0.572)	108 (0.4091)	2 (0.0076)	
TG-repeat number (frequencies) in individuals with alleles					
	11/11	11/12	12/12	11/13	10/12
132	61 (0.4621)	28 (0.2121)	39 (0.2955)	2 (0.0152)	2 (0.0152)

**Table 3** Genotypes and allele frequencies at M470V polymorphic site

Number (2n)	Number (frequencies) of individuals with genotypes			Number (frequencies) of individuals with alleles	
	MM	MV	VV	M	V
264	28 (0.2121)	60 (0.4545)	44 (0.3333)	116 (0.4394)	148 (0.5606)

**Table 4** Linkage of poly-T, TG-repeats and M470V

Linkage haplotypes	2n (frequencies) (2n = 264)
T7-TG11-V470	125 (0.4735)
T7-TG12-M470	77 (0.2917)
T7-TG11-M470	26 (0.0985)
T7-TG12-V470	18 (0.0682)
T5-TG12-M470	8 (0.0303)
T5-TG12-V470	2 (0.0076)
T7-TG13-M470	2 (0.0076)
T9-TG10-M470	1 (0.0038)
T9-TG10-V470	1 (0.0038)
T6-TG12-M470	2 (0.0076)
T6-TG12-V470	1 (0.0038)
T6-TG11-V470	1 (0.0038)

were very rare (Table 4). The T5 alleles were all linked with (TG)12, and its distribution ratio at M470 and V470 loci was 4:1.

## DISCUSSION

The present study is believed to be the first comprehensive report on the functional polymorphisms of CFTR in the Chinese population. Analysis of three polymorphic loci with frequent alleles in the general population showed the poly-T, TG-repeats and M470V distributions were similar to those reported for other East Asians<sup>[14-16]</sup>. T7 was the most common haplotype (93.6%), and (TG)11 and (TG)12 were the dominant haplotypes in the junction of intron 8 (IVS-8) and exon 9. In exon 10, the V allele was slightly more frequent than the M allele, and the M/V genotype was the dominant genotype. The three major haplotypes T7- (TG)11-V470, T7- (TG)12- M470 and T7-TG11-M470 were found in nearly 86.0% of the population.

Similar to other populations, the T7 allele was the most common haplotype (93.6%) in IVS-8, and T7/T7 was the dominant genotype in Chinese individuals. The T6 allele, in addition to the well-known T5, T7 and T9 alleles, was

found. It has not been reported in Caucasians, but it has been reported in Asians, including Vietnamese<sup>[14]</sup>, Japanese<sup>[15]</sup> and Koreans<sup>[16]</sup>. However, its functional transcript and disease association is uncertain at this time. Four T6 alleles (1.5%) were found in three normal individuals, and the frequency was higher than that in Japanese (1.2%)<sup>[15]</sup> and Vietnamese (0.1%)<sup>[14]</sup>. The T9 allele was found in three alleles, and its frequency of 1.1% was higher than that in Japanese (0.6%-1.0%)<sup>[14,15]</sup>, Vietnamese (0.6%)<sup>[14]</sup> and Koreans (0.52%)<sup>[16]</sup> but lower than in Caucasians (7.0%)<sup>[14]</sup>. It is known that polymorphisms in IVS-8 Tn tract affect the RNA splicing of exon 9, and the T9 allele is associated with the most efficient usage of the IVS-8 splice acceptor site<sup>[11]</sup>. This efficiency decreases with shorter poly-T tract T5, which results in a lower than normal level of full-length CFTR mRNA, and presumably a decrease in mature, functional CFTR protein. T5 may be the most common atypical CF mutation worldwide. Prior studies have demonstrated that some individuals who carry T5 with a severe CF-causing mutation may have non-classic CF; others may have male infertility due to CBAVD<sup>[5,17-20]</sup>, lung disease such as bronchiectasis<sup>[6,21,22]</sup> and chronic pancreatitis<sup>[23,24]</sup>; and approximately 40% may be healthy and fertile as a consequence of incomplete penetrance<sup>[5,17]</sup>. In our study, the frequency of the T5 allele in the Chinese population was 3.8%, which is similar to the Vietnamese (3.7%)<sup>[14]</sup>, but lower than that in Caucasians (7.0%)<sup>[5,13]</sup>, and higher than in Japanese (0.6-1.0%)<sup>[14,15]</sup> and Koreans (1.7%)<sup>[16]</sup>.

The main TG-repeat was (TG)11/11, with 61 (46.21%) individuals having the (TG)11/11 haplotype. (TG)11 was the dominant haplotype in the Chinese population, with a high frequency of 57.2%. This was higher than in Vietnamese (41%)<sup>[14]</sup> and Japanese (51%-54%)<sup>[14,15]</sup>, but lower than in Caucasians (67%)<sup>[14]</sup>. The main dominant haplotypes were (TG)11 and (TG)12 in the Chinese population, as well as other Asian populations, however, in Caucasians, after the (TG)11 haplotype, the most common was the (TG)10 haplotype<sup>[14,25]</sup>. As previously reported, the TG-repeats that join with poly-T tracts also influence splicing of exon 9<sup>[12]</sup>, and when present on the same allele as a T5 tract, the longer the TG-repeats, the higher the proportion of CFTR transcripts that will lack exon 9. T5 allele adjacent to either (TG)12 or (TG)13 repeats is more likely to exhibit an abnormal phenotype than T5 adjacent to (TG)11<sup>[26]</sup>. In our study, all T5 allele tracts (10 alleles) were joined with (TG)12 repeats. The TG repeat number also exerts an effect on a T7 background. Compared with (TG)10 allele, TG (11) increases almost threefold the proportion of CFTR transcripts that lack exon 9<sup>[12]</sup>.

At the M470V locus on exon 10, similar to other Asian populations and Caucasians, the V allele (56.1%) was more frequent than the M allele (43.9%) in the Chinese population. The M470V polymorphism is a missense mutation caused by a particular amino acid alteration in the exon 10 M470V locus. It has been shown the M470 allele causes a delay in CFTR protein maturation and gives rise to a chloride channel with an increased probability of being open, compared with the V470 CFTR protein<sup>[12]</sup>. It has also been shown that the variability of European random CFTR genes is almost completely restricted to those who carry the M allele of the M470V polymorphic site<sup>[27]</sup>.

Table 5 Frequencies of TG-repeats and M470V haplotypes

M470V	(TG) n	n/frequencies (n = 132)
V/V	11/11	35 (0.2625)
M/M	12/12	27 (0.2045)
M/V	11/11	26 (0.1970)
M/V	11/12	20 (0.1515)
M/V	12/12	11 (0.0833)
V/V	11/12	8 (0.0606)
M/V	11/13	2 (0.0152)
V/V	12/12	1 (0.0076)
M/M	10/12	1 (0.0076)
M/V	10/12	1 (0.0076)

However, interestingly, the M allele has been reported for some CF mutations, and particularly for  $\Delta F508$ <sup>[28-30]</sup>, most mutations have been found to be associated with the M470 allele, while the V470 allele shows an extended haplotype homozygosity<sup>[27,31,32]</sup>.

The T7 allele tracts were combined with (TG)11 and (TG)12 repeats, but the T7-(TG)10 haplotype was not found in our study. In the T7 background, the (TG)11/(TG)11-V/V, (TG)12/(TG)12-M/M, (TG)11/(TG)11-M/V and (TG)11/(TG)12-M/V were the four main haplotypes and almost equally distributed in the Chinese population (Table 5). We found that TG-repeats and M470V had a linkage distribution in that V/V was combined with (TG)11/(TG)11, and M/M was combined with (TG)12/(TG)12 haplotype. The major haplotypes were T7-(TG)11-V470 and T7-(TG)12- M470, similar to Japanese and Vietnamese, but in the Chinese and Japanese, the main haplotype was T7-TG11-V470. Conversely, T7-TG12- M470V was the main haplotype in Vietnamese. However, in Caucasians, two main haplotypes, T7-(TG)11- V470 and T7-(TG)10-M470 are predominant<sup>[14,25]</sup>. As previously reported, TG-repeats also influence the function of CFTR protein, and longer TG repeats increase the proportion of CFTR transcripts that lack exon 9<sup>[12]</sup>. Therefore, the two major (TG)11/(TG)12-bearing haplotypes may have a corresponding low CFTR activity in Asian populations compared with the dominant (TG)11/(TG)10-bearing haplotypes in Caucasians. This may explain the low incidence of CF and CF-like diseases in Asians.

This report provides evidence for a poly-T, TG-repeat and M470V haplotype background in the Chinese population. We found polymorphisms of poly-T, TG-repeats and M470V were similarly distributed in other East Asians, and have marked differences from the frequencies of single haplotype polymorphisms or linkage haplotypes in Caucasians. Further study of the relationship between polymorphisms of poly-T, TG repeats and M470V haplotypes in CF and CF-like diseases in the Chinese population should be undertaken.

## ACKNOWLEDGMENTS

We thanks Dr. S Naruse (Department of Internal Medicine, Nagoya University, Nagoya, Japan) for his excellent technical guidance.

## COMMENTS

### Background

The cystic fibrosis transmembrane conductance regulator (*CFTR*) gene encodes a cAMP- and ATP-dependent chloride channel that is present in the apical membrane of the epithelial cells that line most exocrine glands. Absence, reduced levels, or malfunction of the *CFTR* protein results in CF and CF-like diseases, such as CBAVD, bronchiectasis and chronic pancreatitis. It has been reported that poly-T, TG-repeats and M470V polymorphisms play a role in the development of CF-like diseases. The present study is believed to be the first comprehensive report on functional polymorphisms of *CFTR* in the Chinese population.

### Research frontiers

The *CFTR* gene is a cAMP- and ATP-dependent chloride ion transport channel. The three haplotypes poly-T, TG-repeats and M470V polymorphisms play a role in the development of CF-like diseases. Although mutations and polymorphisms of *CFTR* have been extensively studied in Western populations, their importance is less well-established in East Asia. The present study is believed to be the first comprehensive report on functional polymorphisms of *CFTR* in the Chinese population. This study provides evidence for poly-T, TG-repeat and M470V haplotype backgrounds in the Chinese population.

### Innovations and breakthroughs

There are just a few data on *CFTR* in Asia, especially in China. No reports on *CFTR* genetic background among the normal Chinese population have been published, except for sporadic reports on *CFTR* mutations in CF-like patients. The present study is believed to be the first comprehensive report on functional polymorphisms of *CFTR* in the Chinese population. This study provides evidence for poly-T, TG-repeat and M470V haplotype backgrounds in the Chinese population.

### Applications

Comparative analysis of common *CFTR* polymorphisms in poly-T, TG-repeats and M470V in the healthy Chinese population sheds light on the situation of *CFTR* gene mutations and polymorphisms in the Chinese population. This study provides a polymorphic background of *CFTR* in the Chinese population, and helps to understand CF-like diseases such as CBAVD, bronchiectasis and chronic pancreatitis in China.

### Terminology

*CFTR* gene on chromosome 7q31 spans approximately 250 kb of DNA and encodes 27 exons. The *CFTR* gene encodes a cAMP- and ATP-dependent chloride channel that is present in the apical membrane of the epithelial cells which line most exocrine glands.

### Peer review

This interesting study investigated three important *CFTR* haplotypes, poly-T, TG-repeats and M470V polymorphisms in the Chinese population. The results may explain the low incidence of CF and CF-like diseases in Asians.

Prognostic significance of S100A4 and vascular endothelial growth factor expression in pancreatic cancer. *World J Gastroenterol* 2008; 14(12): 1931-1935 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1931.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1931>

### Abstract

**AIM:** To investigate the expression of vascular endothelial growth factor (VEGF) and calcium-binding protein S100A4 in pancreatic cancer and their relationship to the clinicopathological parameters and prognosis of pancreatic cancer.

**METHODS:** Expression status of VEGF and S100A4 was examined in 62 surgical specimens of primary pancreatic cancer by immunohistochemistry. Correlation between the expression of VEGF and S100A4 and clinicopathological parameters was analyzed.

**RESULTS:** Thirty-eight of 62 (61.3%) specimens of primary pancreatic cancer were positive for S100A4. Thirty-seven (59.7%) specimens showed positive expression of VEGF. The positive correlation between S100A4 and VEGF expression was significant in cancer tissues ( $P < 0.001$ ). S100A4 expression was significantly correlated with tumor size, TNM stage and poorer prognosis. VEGF expression had a significant correlation with poorer prognosis. The prognosis of 17 S100A4- and VEGF-negative cancer patients was significantly better than that of other patients ( $P < 0.05$ ). Distant metastasis ( $P = 0.001$ ), S100A4- ( $P = 0.008$ ) and VEGF-positive expression ( $P = 0.016$ ) were significantly independent prognostic predictors ( $P < 0.05$ ).

**CONCLUSION:** Over-expression of S100A4 and VEGF plays an important role in the development of pancreatic cancer. Combined examination of the two molecules might be useful in evaluating the outcome of patients with pancreatic cancer.

### INTRODUCTION

Each year there are more than 170 000 new cases of pancreatic cancer in the world. Pancreatic cancer accounts for up to 2.1% of all cancer cases and is the 5th leading cause of cancer death. The survival rate of patients at all stages of the disease is poor. The overall median survival time is 3-5 mo with a 12 mo-survival rate of 10% and a 5-year survival rate less than 5%<sup>[1]</sup>. Because of lacking of methods for the early diagnosis and limited knowledge on the biological features of pancreatic cancer, the majority of patients are not diagnosed properly until the advanced stage<sup>[2]</sup>.

The S100 protein family is a large family of soluble calcium-binding proteins, first isolated from bovine brain by Moore in 1965<sup>[3]</sup>. The S100 family members are involved in a variety of physiological functions, such as cell motility, cell proliferation and differentiation, cell cycle control, regulation of enzyme activity, and calcium-dependent transcriptional regulation<sup>[4-7]</sup>. The S100A4 protein, which was once named as mts1 or p9Ka, belongs to the S100 family and is classified as a 'metastasis-related gene'<sup>[8]</sup>. It was reported that over-expression of S100A4 is significantly correlated with tumor invasion and metastasis<sup>[9-11]</sup>. A number of studies suggested that over-expression of S100A4 is correlated with poor clinical outcomes in a variety of human cancers, such as bladder, colorectal, ovarian, and esophageal carcinoma<sup>[12-15]</sup>. VEGF plays an important role in tumor angiogenesis and correlates significantly with tumor invasion and metastasis<sup>[16]</sup>. Elevated levels of VEGF correlate with a poor prognosis of various cancers, including pancreatic cancer<sup>[17,18]</sup>.

This study was to examine the expression status of S100A4 and VEGF in 62 surgical specimens of primary pancreatic carcinoma by immunohistochemistry and study the role of these two molecules in progression and metastasis of pancreatic cancer.

## MATERIALS AND METHODS

### Specimens

Specimens obtained from 62 patients (36 males, 26 females) with primary pancreatic cancer admitted to Department of Surgery, 6th Affiliated Hospital of Shanghai Jiaotong University in 2002-2005, were formalin-fixed and paraffin-embedded. The age of these patients ranged 30-84 years (mean age of 64.8 years). All cases were diagnosed as primary pancreatic ductal adenocarcinoma by histopathology (well differentiated in 17 cases, moderately differentiated in 15 cases, and poorly differentiated in 30 cases). No patient received any radiotherapy or chemotherapy. The size of tumor was analyzed by maximum diameter. The patients were staged according to the international TNM system by International Union against Cancer (UICC).

### Immunohistochemistry and evaluation criteria

Rabbit anti-human S100A4 polyclonal antibody and mouse anti-human VEGF monoclonal antibody were purchased from NeoMarkers. Two consecutive sections of each specimen were incubated. Immunohistochemistry staining was performed according to the manufacturer's instructions. The tissue used as a negative control was incubated with PBS instead of primary antibody. The tissue known to highly express VEGF and S100A4 was used as positive control.

For each slide, cells positive for VEGF or S100A4 were counted and evaluated under 5-10 fields at 200 × magnification (cells counted: 100-200), and the percentage of positive cells was calculated. Cells were considered positively immune stained when nuclei and cytoplasm were stained. The distribution of stained S100A4 was evaluated with the percentage of stained cells scored as 0: < 5%, 1: 5%-25%, 2: 26%-50%, 3: 51%-75%, 4: > 75% and staining intensity scored as 1: buff, 2: buffy, 3: puce. When the multiplication of the two scores was greater than or equal to 2, S100A4 was considered positively stained. VEGF was considered positively stained when brown-stained granules were observed in cytoplasm and the percentage of positive cells was greater than 10%.

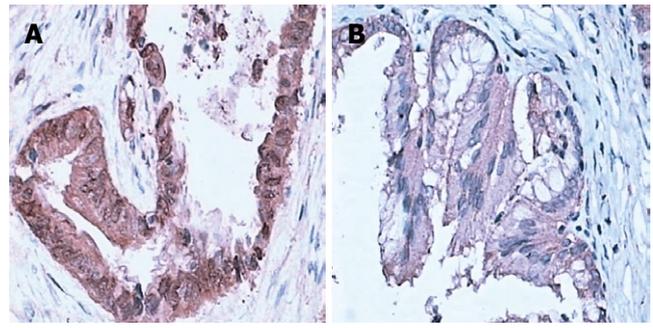

### Statistical analysis

The correlation between S100A4/VEGF expression and clinicopathological parameters was evaluated by chi-square ( $\chi^2$ ) test or Fisher's exact test. Survival curves were plotted using the Kaplan-Meier method. Survival rates for different groups were compared using the log-rank test. Predictors for prognosis of the patients were assessed using Cox multiple hazards regression analysis. Statistical analysis was carried out using the SPSS 13.0.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Expression of S100A4 and VEGF

S100A4 was immunoreactive in cytoplasm and nuclei (Figure 1A). VEGF was immunoreactive mainly in cytoplasm (Figure 1B). Of the 62 pancreatic cancer patients, 38 (61.3%) had positive S100A4 expression and 24 (38.7%) negative S100A4 expression. Thirty of the 38 (78.9%)

**Figure 1** Positive expression of S100A4 (A) and VEGF (B) in pancreatic cancer ( $\times 200$ ).

**Table 1** Correlation analysis of S100A4 and VEGF expression in pancreatic cancer

S100A4	VEGF		P value
	(+)	(-)	
(+)	30	8	< 0.001
(-)	7	17	

Significance was estimated with  $\chi^2$  test.

patients with positive S100A4 expression had positive VEGF expression. Seventeen of the 24 (70.8%) S100A4-negative patients had negative VEGF expression. The positive correlation between expression of S100A4 and VEGF was statistically significant ( $P < 0.0001$ ) (Table 1).

The correlation between S100A4/VEGF expression and clinicopathological parameters was analyzed (Tables 2-3). Tumors with their maximum diameter greater than 4 cm had a higher S100A4 expression than those with their maximum diameter less than 4 cm. Tumors at III + IV stage had a higher S100A4 expression than those at I + II stage. The correlation between S100A4 expression and tumor size and TNM stage was statistically significant. VEGF expression was not significantly related with the clinicopathological parameters.

### Correlation between expression of S100A4 and VEGF and prognosis of patients

The 62 patients were followed up till December 2006 and their median survival time was 290.6 d. The 1-, 2-, and 3-year survival rate was 37%, 14%, and 7%, respectively. The median survival time of the S100A4 positive and negative patients was 232.8 d and 535.5 d, respectively, while the median survival time of the VEGF positive and negative patients was 229.7 d and 541.6 d, respectively. The survival curve was better for patients with S100A4-negative cancer than for those with S100A4-positive cancer ( $P < 0.001$ ; log-rank test) (Figure 2A). The survival curve was better for patients with VEGF-negative cancer than for those with VEGF positive cancer ( $P < 0.001$ ; log-rank test) (Figure 2B).

According to the expression of S100A4 and VEGF, pancreatic cancer patients were subdivided into four groups: (1) S100A4(+)/VEGF(+), (2) S100A4(+)/VEGF(-), (3) S100A4(-)/VEGF(+), (4) S100A4(-)/VEGF(-). Patients in the S100A4(-)/VEGF(-) group had a significantly

better prognosis than those in the other three groups, and their median survival time was 678 d. Patients in the S100A4(+)/VEGF(-) group had a poorer prognosis than those in the S100A4(-)/VEGF(+) and S100A4(-)/VEGF(-) groups (*P* < 0.05; log-rank test). However, there was no

**Figure 2** Survival curves for group of pancreatic cancer patients according to S100A4 expression (A), group of pancreatic cancer patients according to VEGF expression (B), and four subgroups of pancreatic cancer patients according to the expression of S100A4 and VEGF (C).

significant difference between the S100A4(+)/VEGF(-) and S100A4(+)/VEGF(-) groups (Figure 2C).

The prognostic value of following parameters was analyzed, including age, differentiation of tumor, size of tumor, lymph node metastasis, distant metastasis, TNM stage and expression of S100A4 and VEGF. The influence of these parameters was evaluated by the Cox proportional hazards model. The results of these analyses showed that distant metastasis, expression of S100A4 and VEGF were significant independent prognostic predictors (Table 4).

## DISCUSSION

In this study, the expression of S100A4 and VEGF was evaluated in relation to the clinicopathological parameters

**Table 4** Cox multivariate regression analysis of clinicopathological features as a prognostic predictor

	B	SE	Wald	df	P value	OR (95% CI)
Distant metastasis	1.101	0.345	10.163	1	0.001	3.006 (1.528, 5.914)
S100A4	0.893	0.338	6.989	1	0.008	2.443 (1.260, 4.736)
VEGF	0.821	0.340	5.815	1	0.016	2.272 (1.166, 4.426)

of pancreatic cancer. Of the 62 pancreatic cancers patients, 61.3% were positive for S100A4 expression. Pancreatic cancer with a large size and high TNM stage had a higher S100A4 expression. Over-expression of S100A4 was significantly correlated with tumor size, TNM stage and a poor prognosis. These results suggest that over-expression of S100A4 might enhance cell motility and invasiveness.

It was reported that expression of S100A4 is significantly correlated with lymph node metastasis in several types of cancer, such as breast, colorectal, stomach, lung, and thyroid carcinoma<sup>[19-23]</sup>. Our results show that positive S100A4 expression was higher in patients with lymph node metastasis than in patients without lymph node metastasis. However, there was no significant difference in S100A4 expression between the two groups, suggesting that expression of S100A4 is not closely related to lymph node metastasis. Further study is needed to confirm our findings.

S100A4 protein may modulate cell cycle, cell motility, invasiveness and adhesion. In cancer cells, S100A4 protein regulates protein kinase C phosphorylation of the heavy chain of nonmuscle myosin in a calcium-dependent manner, resulting in enhanced cell motility and invasiveness<sup>[24,25]</sup>. Merzak *et al*<sup>[26]</sup> reported that expression of S100A4 is closely correlated with *in vitro* invasiveness of glioma cells. Moreover, increased levels of S100A4 confer metastasis of non-metastatic epithelial cell line *in vivo*<sup>[27,28]</sup>. Ambartsumian *et al*<sup>[29]</sup> reported that S100A4 induces tumor progression by stimulating angiogenesis. All these findings demonstrate that S100A4 plays an important role in tumor growth, invasion, metastasis and angiogenesis.

VEGF is a mitogen and motor of vascular endothelial cells and also an important factor for angiogenesis. It can induce proliferation and migration of vascular endothelial cells, and formation of blood capillary lumens. VEGF increases vascular permeability and stimulates vascular endothelial cells to secrete proteinase and small molecules. In 1993, Brown *et al*<sup>[30]</sup> firstly reported the high expression of VEGF in pancreatic cancer specimens, which is closely correlated with the growth and invasion of pancreatic cancer. In our study, S100A4 and VEGF expression in pancreatic cancer was detected, showing that expression of S100A4 and VEGF is closely correlated. The mechanism of S100A4 and VEGF expression and their relationship with the development and progression of pancreatic cancer deserve further study at molecular level.

In conclusion, expression of S100A4(-)/VEGF(-) cancer can be used as a marker to predict the survival of patients. Distant metastasis, positive S100A4 and VEGF are highly independent prognostic predictors. Expression of S100A4 and VEGF can be used as an indicator of prognosis in patients with pancreatic cancer. Exploitation

and application of S100A4- or VEGF-targeted tumor inhibitors can decrease the recurrence or metastasis rate of pancreatic cancer and improve the prognosis of patients.

## COMMENTS

### Background

The prognosis of pancreatic cancer is very poor. Many patients are not diagnosed until at its advanced stage. Current treatment for the disease is surgery in combination with radiotherapy or chemotherapy. Growth and metastasis of pancreatic cancer were studied in order to improve its prevention and treatment.

### Research frontiers

S100A4 protein expression in different kinds of cancer is closely correlated with the growth, invasion and metastasis of pancreatic cancer. The mechanism of S100A4 protein underlying the growth, invasion and metastasis of tumor is a hot topic in recent researches.

### Innovations and breakthroughs

The expression of S100A4 and VEGF in pancreatic cancer and their correlation with prognosis of pancreatic cancer patients were studied. Our results show that expression of S100A4 and VEGF is positively correlated with pancreatic cancer.

### Applications

By detecting tumor-associated proteins S100A4 and VEGF, we evaluated the biological characteristics and prognosis of pancreatic cancer, which can improve our understanding of pancreatic cancer and provide scientific basis for the application of S100A4 and VEGF inhibitors in treatment of pancreatic cancer.

### Terminology

S100 protein: a member of the large family of soluble acid calcium-binding proteins, first discovered and designated by Moore in 1965. S100 protein can be completely dissolved in saturated ammonium sulfate, and the family consists of 21 members, like S100A1-A13, S100B, S100P, Profilaggrin, Trichohyalin and Reperin, etc. S100 protein regulates interaction between Ca<sup>++</sup> and target-protein, and is involved in a variety of physiological functions, such as cell proliferation and differentiation, cell cycle control, regulation of enzyme activity, and calcium-dependent transcriptional regulation.

### Peer review

In this nice research, the authors investigated the expression of S100A4 and VEGF in pancreatic cancer and discussed the prognostic significance and clinical pathological features of S100A4 and VEGF. The research may offer certain contribution to the treatment of pancreatic cancer. The design of the study is scientific and the results are reliable and have clinical application values.

Double-balloon enteroscopy reliably directs surgical intervention for patients with small intestinal bleeding. *World J Gastroenterol* 2008; 14(12): 1936-1940 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1936.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1936>

### Abstract

**AIM:** To evaluate preoperative double-balloon enteroscopy for determining bleeding lesions of small intestine, thus directing selective surgical intervention.

**METHODS:** We retrospectively reviewed 56 patients who underwent double-balloon enteroscopy to localize intestinal bleeding prior to surgical intervention, and compared enteroscopic findings with those of intraoperation to determine the accuracy of enteroscopy in identifying and localizing the sites of small intestinal bleeding.

**RESULTS:** Double-balloon enteroscopy was performed in all 56 patients in a 30-mo period. A possible site of blood loss was identified in 54 (96%) patients. Enteroscopy provided accurate localization of the bleeding in 53 (95%) of 56 patients, but failed to disclose the cause of bleeding in 4 (7%). There was one case with negative intraoperative finding (2%). Resection of the affected bowel was carried out except one patient who experienced rebleeding after operation. Gastrointestinal stromal tumor (GIST) was most frequently diagnosed (55%).

**CONCLUSION:** Double-balloon enteroscopy is a safe, reliable modality for determining bleeding lesion of small intestine. This technique can be used to direct selective surgical intervention.

### INTRODUCTION

Small intestinal bleeding is uncommon, accounting for only 2%-10% of gastrointestinal bleeding cases<sup>[1]</sup>. Localization of the bleeding site in small intestine is critical to planning appropriate therapy. But small intestine is roughly three meters in length and tortuously folded in the peritoneal cavity, which poses a challenge for endoscopies, computed tomography, scintigraphy and angiography to pinpoint the bleeding sources. Gastrointestinal hemorrhage is described as “obscure” if the bleeding site is not identified by these methods<sup>[2]</sup>. Double-balloon enteroscopy was first introduced in 2001 as an important advance in the exploration of the small intestine<sup>[3]</sup>. Compared with other methods, it has the advantage of direct visualization of the intestinal lumen, permitting biopsy<sup>[4]</sup>. However, it is unclear whether enteroscopy alone is accurate enough to be used to direct appropriate surgical intervention. To evaluate preoperative double-balloon enteroscopy in determining bleeding focus of small intestine, we reviewed the results of enteroscopy in 56 patients who had small intestinal bleeding and underwent surgery.

### MATERIALS AND METHODS

#### Patients and methods

We reviewed retrospectively the records of 56 consecutive patients who underwent surgery from June 2003 to December 2005 for small bowel bleeding in whom preoperative double-balloon enteroscopy was performed. The group of patients consisted of 26 females and 30 males with a mean age of 58 years (range from 14-75 years). The bleeding history ranged from 1 wk to 10 years. The main presenting features were melaena or maroon stool. The mean hemoglobin level was 65 g/L

**Table 1** Summary of diagnostic studies in 56 patients with small intestinal bleeding prior to enteroscopy and surgery

	No. of patients	No. of procedures
Barium enema	29	29
Gastroscopy	56	72
Colonoscopy	52	54
Angiography	9	9
CT	56	63
Tc <sup>99m</sup> -labeled red blood cells scintigraphy	5	5
Capsule endoscopy	7	7

(range from 35-98 g/L). The mean number of packed red blood cell unit transfused to each patient prior to surgery was 10 U. Coagulation parameters were normal in all patients. Each patient received an extensive diagnostic evaluation with 4 diagnostic procedures including esophagogastroduodenoscopy, colonoscopy, computed tomography, scintigraphy and barium enema, as well as angiography, and capsule endoscopy in some patients, but all failed to elucidate a possible bleeding site. The diagnostic workup for the patients prior to referral is summarized in Table 1. Two patients underwent surgery previously for bleeding.

### Small bowel enteroscopy

Double-balloon enteroscopy was performed with a Fujinon EN450P5 video enteroscope (Fujinon, Saitama, Japan) with a working length of 2.0 m. EN450P5 is a thinner endoscope with an external diameter of 8.5 mm, and forceps channel diameter of 2.2 mm. The instrument is forward-viewing with a 120° angle of view.

The endoscopy can be used both from the mouth (anterograde approach) and anus (retrograde approach). It is highly possible that the entire small intestine can be observed by the endoscopy using the combination of both routes. The anterograde approach was used in 50

**Figure 1** Enteroscopy identified a polyp 1.5 cm in diameter in jejunum.

patients, the retrograde approach in 2 patients, and both in 4 patients.

## RESULTS

Small bowel enteroscopy was performed in all 56 patients. A possible site of blood loss was identified in 54 (96%) patients. Neoplastic lesions were visualized in 43 patients, vascular malformation in 5, Meckel's diverticulum in 3, Peutz-Jeghers syndrome in 1, Crohn's disease in 1, polyp in 1 and negative finding in 2 patients.

All patients were surgically explored immediately after the enteroscopy. Thirty-six patients underwent laparoscopic surgery and 20 patients laparotomy. The final diagnoses of all patients are summarized in Table 2. GIST was the most frequent diagnosis in our study group (Figure 1). Thirty-one (55%) patients had GIST (19 located within 1.0 m distal to the ligament of Treitz). Other diagnoses included adenocarcinoma in 7 (13%) patients (Figure 2), Meckel's diverticulum in 4 (7%), vascular malformation in 3 (5%), adenoma in 2 (3%), ulceration in 2 (3%), Peutz-Jeghers syndrome in 1 (2%), lymphoma in 1 (2%), Crohn's disease in 1 (2%), leiomyosarcoma in 1 (2%), hemangioendothelioma in 1 (2%), inflammatory polyp in 1 (2%), pheochromocytoma in 1 (2%), and negative findings in 1 (2%) patient.

In 53 of 56 patients, enteroscopy provided accurate localization of bleeding, but it failed to disclose the causes of bleeding in 4 patients. Three patients were diagnosed with vascular malformation with preoperative enteroscopy, but the surgical specimen revealed Meckel's diverticulum, GIST and ulcer respectively. In two patients who had a normal small bowel at total enteroscopic examinations, ulcer was found in 1 patient and GIST in the other by surgery. One patient had a jejunal a polyp with enteroscopy, but no visualized lesion was found in surgery (Figure 3).

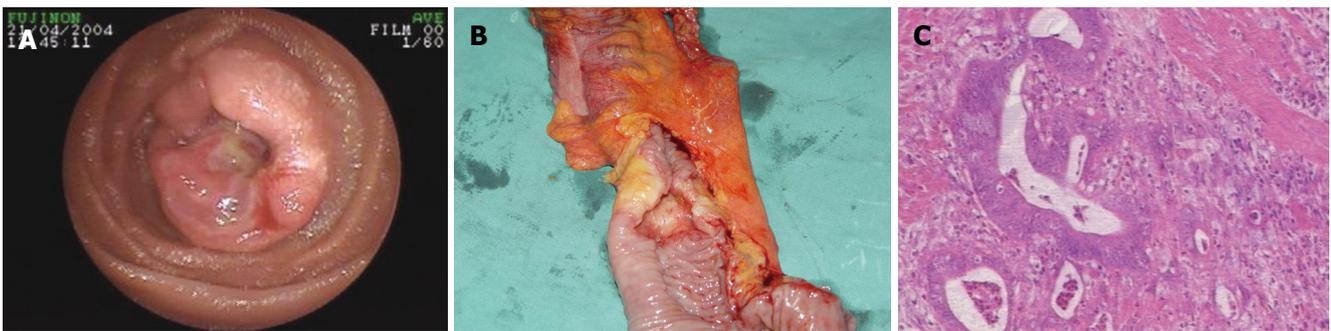

The mean follow-up period for the series was 29.6 mo. One patient had rebleeding during the follow-up period.

## DISCUSSION

Vascular lesions are the most common cause of intestinal bleeding, accounting for 70%-80% in the Western world<sup>[5]</sup>, but in China are neoplasms, accounting for 22.2%-60.9%<sup>[6]</sup>. Other causes include Meckel's diverticulum, ulcerative

**Figure 2** Stromal tumor of small intestine. **A:** Preoperative enteroscopy; **B:** Surgical exploration; **C:** Photomicrograph of the lesion (HE,  $\times 100$ ).

**Figure 3** Adenocarcinoma of small intestine. **A:** Preoperative enteroscopy; **B:** Surgical exploration; **C:** Photomicrograph of the lesion (HE,  $\times 100$ ).

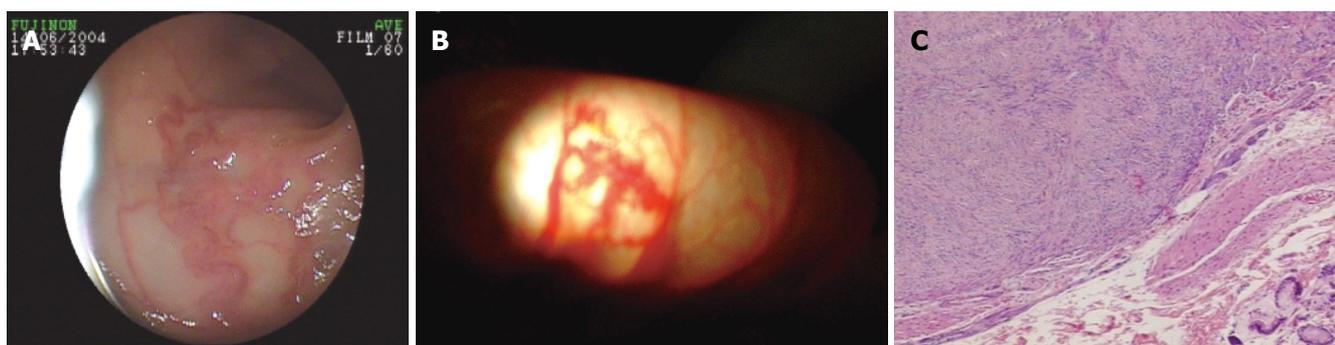

disease, and Crohn's disease<sup>[7]</sup>. Neoplasm was the most frequent diagnosis in our study group, accounting for 80%. The relative high rate was not reported previously. Small bowel bleeding always occur chronically and intermittently. Its intermittent and self-limiting nature may render correct diagnosis more difficult. In about 5% of patients, even multiple diagnostic modalities are unable to localize the source of bleeding<sup>[8]</sup>. This causes a management problem as therapy depends on locating the site of blood loss. Double-balloon enteroscopy is an important advance in the exploration of the small bowel, especially for lesions discovered beyond the reach of standard endoscopy<sup>[9]</sup>. The advantage of the technique over push enteroscopy is that extend portions of the small bowel can be viewed. It has been reported that push enteroscopy successfully identified the source of bleeding in 24%-75% of patients<sup>[10-13]</sup>. Recently, Zhong reviewed 20 patients undergoing double-balloon enteroscopy for obscure gastrointestinal hemorrhage and reported a correct diagnosis in 80% cases<sup>[14]</sup>. Although the diagnostic efficiency varies in different series, the indications and diagnostic yield of enteroscopy have yet to be fully defined. As shown by our experience, the indications for enteroscopy were classified into four groups: (1) Unexplained disease of small bowel such as digestive bleeding, abdominal pain and diarrhea. (2) Incomplete intestinal obstruction. (3) Diagnosis was made but the extension of small bowel lesion needs assessment. (4) Follow-up after treatment for small bowel disease. Of the 56 patients in this series, histopathologic examination confirmed the endoscopic findings in 52 (93%) cases. Though enteroscopy failed to disclose the causes of bleeding in 4 patients, surgery revealed that enteroscopy

provided the accurate localization of bleeding in 53 of 56 patients. Therefore, enteroscopy is a reliable modality for accurately localizing the site of small bowel bleeding. These enable surgeons confidently provide appropriate surgical intervention.

The small intestine represents approximately 75% of the total length of the gastrointestinal tract and more than 90% of the mucosal surface, but fewer than 2% of all gastrointestinal malignancies originate in the small bowel<sup>[15]</sup>. It has been estimated that 35%-50% of the small bowel tumors are adenocarcinomas, 20%-40% are carcinoids and about 14% are lymphomas<sup>[16,17]</sup>. GIST is uncommon mesenchymal tumors, accounting for approximately 0.1%-0.3% of all gastrointestinal neoplasms<sup>[18]</sup>. However, in this group of patients, the most common histological type is GIST. Among all the 42 patients with small bowel tumors, 31 patients had GIST. The high proportion of GIST has not been found in other studies. About 32% of gastrointestinal GIST have been found in the small bowel<sup>[19]</sup>. GIST comprises a spectrum of variable malignancies ranging from benign to aggressive forms<sup>[20]</sup>. Histologically, the distinction between benign and malignant tumors is not evident. Two of the strongest pathologic predictors of malignant behavior are size and mitotic count<sup>[21]</sup>. According to Shiu, GIST  $> 6$  cm in diameter should be considered a potential malignance<sup>[22]</sup>. GISTs usually arises from or between the muscularis propria and the muscularis mucosa of the bowel wall and extends primarily toward the serosa<sup>[23]</sup>. But small bowel enteroscope is limited in its mucosal visualization and can only detect the lump within the bowel lumen. Therefore, preoperative enteroscopy has little value in predicting

**Figure 4** Diverticula was visualized as angioma by preoperative double-balloon enteroscopy. **A:** Preoperative enteroscopy, angioma between jejunum and ileum; **B:** Diverticula 80 cm proximal to ileocecum. **C:** Photomicrograph of the lesion (HE,  $\times 100$ ).

**Figure 5** Vascular malformation of small intestine. **A:** Preoperative enteroscopy; **B:** Surgical exploration; **C:** Photomicrograph of the lesion (HE,  $\times 100$ ).

benign or malignant behavior of GIST. However, to this kind of patients, enteroscopy can accurately localize the site of hemorrhage. The rate of rebleeding after surgery is very low. Interestingly, 19/31 stromal tumors arise within 1.0 m distal to the ligament of Treitz. Similar result was reported by Soderman<sup>[24]</sup>. The main surgical complication in this area is prolonged gastroparesis and ileus. Four of 19 patients of our group had such complications.

Although most vascular lesions appear endoscopically similar, they consist of various pathological identities such as angiodysplasia (vascular ectasia), venous ectasia, telangiectasia, hemangiomas, arteriovenous malformation (AVM) and caliber -persistent artery (Dieulafoy's lesion)<sup>[25]</sup>. Small bowel barium may not detect mucosal-based lesions such as vascular ectasias. <sup>99m</sup>Tc-labelled red blood cell scintigraphy and angiography are seldom useful in identifying the bleeding site in patients with chronic and moderate blood loss<sup>[26]</sup>. Moreover, pooling of blood in the intestine may result in false localizations. One patient in this group had previously undergone a segmental resection based on angiographic findings. But reoperation revealed that the lesion identified by angiography is 2.0 m distal to the real bleeding lesion. At present, small bowel enteroscopy is not capable of marking the site of bleeding, so the areas of vascular malformation must be endoscopically reidentified by intraoperative enteroscopy so that the surgeon can precisely determine their location and the extent of surgical resection. Three cases of vascular lesions in our group underwent intraoperative enteroscopy and similar findings were described to that of preoperative enteroscopy (Figure 4).

Peutz-Jeghers syndrome (PJS) is an autosomal dominant inheritance characterized by hamartomatous gastrointestinal polyps and mucocutaneous pigmentation, and 70%-90% of patients have polyps in the small bowel<sup>[27]</sup>. As the polyps are located diffusely throughout the small intestine, resection of the entire affected intestine may lead to short-bowel syndrome<sup>[28]</sup>. The main advantage of enteroscopy is that surgeon can identify and resect the segment concentrating polyps. Endoscopic procedure allows effective snare of the residual polyps so as to avoid the risk of developing short-bowel syndrome<sup>[29]</sup>.

It is highly possible that entire small intestine can be observed by the double-balloon enteroscopy using the combination of both antegrade and retrograde routes<sup>[30]</sup>. We agree with Pennazio M that identification of a single lesion is often enough for both diagnostic and therapeutic purposes<sup>[31]</sup>. In our group, only 4 patients underwent both approaches and only one patient experienced rebleeding. Total small bowel enteroscopy identified a polyp 1.5 cm in diameter in this patient (Figure 3), but exploratory laparotomy with intraoperative endoscopy failed to find a source of blood loss. The reason may be that the manipulation of endoscopy can lead to the shedding of polyp, but the patient had rebleeding 3 mo after operation.

As the technology continues to evolve, the endoscopy will provide more valuable information. But the findings by enteroscopy has not been clarified, especially in the vascular lesion. For example, one patient in our group was diagnosed with hemangioma in the jejunum by preoperative enteroscopy (Figure 5A), the surgical specimen revealed Meckel's diverticulum (Figure 5B). In

conclusion, double-balloon enteroscopy is a safe, reliable modality in determining bleeding lesion of small intestine. As such, this technique can be reliably used to direct selective surgical intervention. Further studies should focus on analyzing and refining the clinical implications of endoscopic results.

## COMMENTS

### Background

Current techniques for detecting the source of bleeding in the small intestines have low diagnostic yields. The source of bleeding can be identified by colonoscopy, arteriography, scintigraphy, and barium radiology, but no bleeding sites are found in about 5%-10% of cases. Compared with other methods, double-balloon enteroscopy has the advantage of direct visualization of the intestinal lumen, permitting biopsy and treatment in some cases.

### Research frontiers

Localization of the bleeding site in small intestine is critical to planning appropriate therapy.

### Innovations and breakthroughs

In this retrospective study, the diagnostic yield of enteroscopy in identifying the source of bleeding was higher than the overall diagnostic yield of the conventional modalities. The results suggested that enteroscopy provided accurate localization of the bleeding in 53 (95%) of 56 patients.

### Terminology

Gastrointestinal bleeding (OGIB) is generally defined as recurrent bouts of chronic bleeding for which no definite source has been discovered by routine investigations.

### Applications

Double-balloon enteroscopy is a safe, reliable modality for determining bleeding lesion of small intestine. This technique can be used to direct selective surgical intervention.

### Peer review

This is an interesting retrospective review of a significant number of cases. And the patients after double enteroscopy were subsequently subjected to surgery, and histological confirmation was done. The authors evaluated the use of double-balloon enteroscopy in identifying the source of small intestinal bleeding. Double-balloon enteroscopy can reliably direct surgical intervention for patients with small intestinal bleeding.

Comparison of esomeprazole enteric-coated capsules vs esomeprazole magnesium in the treatment of active duodenal ulcer: A randomized, double-blind, controlled study. *World J Gastroenterol* 2008; 14(12): 1941-1945 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1941.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1941>

### Abstract

**AIM:** To evaluate the efficacy and tolerability of two different preparations of esomeprazole in healing duodenal ulcers.

**METHODS:** A total of 60 patients with active duodenal ulcers were enrolled and randomized to receive esomeprazole enteric-coated capsules (40 mg) or esomeprazole magnesium (40 mg), once daily, for 4 consecutive wk, with ulcer healing being monitored by endoscopy. Safety and tolerability were also assessed.

**RESULTS:** Fifty seven patients completed the whole trial. The ulcer healing rates at the end of wk 2 were 86.7% and 85.2% in the esomeprazole enteric-coated capsules and esomeprazole magnesium groups, respectively ( $P = 0.8410$ ), and reached 100% at the end of wk 4 in both groups. Symptom relief at the end of wk 2 was 90.8% in the esomeprazole enteric-coated capsules group and 86.7% in the esomeprazole magnesium group ( $P = 0.5406$ ); at the end of wk 4 symptom relief was 95.2% and 93.2%, respectively ( $P = 0.5786$ ). Adverse events occurred in 16.7% of the esomeprazole enteric-coated capsules group and 14.8% of the esomeprazole magnesium group ( $P = 1.0000$ ).

**CONCLUSION:** The efficacies of esomeprazole enteric-coated capsules and esomeprazole magnesium in healing duodenal ulcer lesions and relieving gastrointestinal symptoms are equivalent. The tolerability and safety of both drugs were comparable.

### INTRODUCTION

Esomeprazole, the stereospecific S-isomer of omeprazole, is the first proton pump inhibitor (PPI) to be developed as a single isomer for use in the treatment of acid-related diseases<sup>[1,2]</sup>. This optical isomer is subject to less first-pass metabolism and lower plasma clearance than omeprazole, thereby offering higher systemic bioavailability<sup>[3,4]</sup>. Early studies have shown esomeprazole achieves greater and more sustained acid control than omeprazole, with a similar tolerability and safety profile<sup>[5,6]</sup>. Furthermore, esomeprazole shows a more rapid onset of acid-suppression effect than omeprazole, and less inter-individual variation in acid control<sup>[7,8]</sup>. Additionally, a recent crossover study demonstrated that esomeprazole at a standard dose of 40 mg once daily provides more effective control of gastric acid at steady state than standard doses of pantoprazole, lansoprazole and rabeprazole in patients with symptomatic gastroesophageal reflux disease (GERD)<sup>[9,10]</sup>. In addition, esomeprazole treatment yields higher erosive esophagitis healing rates and provides sustained resolution of heartburn in more patients than any other currently available PPI<sup>[11]</sup>.

The current study investigated whether esomeprazole enteric-coated capsules (40 mg; synthesized by Chongqing Lummy Pharmacy, China) provides effective duodenal ulcer healing compared with esomeprazole magnesium (40 mg; Nexium, AstraZeneca Inc), when administered once daily for 4 wk, in a Chinese population.

## MATERIALS AND METHODS

### Patients

A randomized, double-blind, double-dummy, parallel-controlled study was conducted in accordance with the ethical principles of the Declaration of Helsinki and internationally accepted guidelines for clinical trials in patients with duodenal ulcer disease. Each protocol was approved by an independent ethics committee prior to study commencement. All patients provided written informed consent before entry into the study. The randomization scheme was computer generated. A centralized allocation method was used to assign patients to a treatment group.

Men and women aged 18-65 years, with no more than two active endoscopically confirmed duodenal ulcers (less than 2 cm in diameter), were recruited into the study from April 2006 to July 2006. Major exclusion criteria included: Pregnancy or lactation, any clinically significant abnormal laboratory values at entry, multiple drug allergies, prior gastric surgery, and concurrent treatment with corticosteroids or non-steroidal anti-inflammatory drugs. Discontinuation of any previous PPI therapy was required at least 7 d before randomization. No antisecretory drugs, including H<sub>2</sub>-receptor antagonists, or any other agents known to alter the pharmacokinetics of PPI, were allowed during the study or within 1 wk before entry. In addition, patients were excluded from the study if they had esophageal erosions or ulceration, esophageal and/or gastric varices, gastric ulcer, pyloric stenosis, endoscopic evidence of active gastrointestinal bleeding or Zollinger-Ellison syndrome. Other exclusion criteria concerned concurrent renal or hepatic insufficiency, treatment for cancer and any history of drug or alcohol dependence.

Of the 60 patients enrolled in the study, 30 in the treatment group received esomeprazole enteric-coated capsules and 30 in the positive control group received esomeprazole magnesium, and 95% of patients completed the study. Three patients (5%) discontinued the study, all in the esomeprazole magnesium group, and were excluded from the evaluable cohort because of consent withdrawal. The baseline demographic and clinical characteristics of the 57 patients in the evaluable cohort, gender, age, height, blood pressure, heart rate, duration of disease, pre-entry score and initial ulcer size and number, were not different between the two groups (Table 1). Overall, the population was predominantly male (70.2%) and most patients were less than 55 years of age (80.7%). Approximately one-third of patients smoked and consumed alcohol, and this proportion was comparable between the two groups. Compliance with study medication was high during 4-wk treatment period, with more than 90% of the patients in each treatment group taking over 75% of the prescribed drugs.

### Study procedures

Eligible patients were randomly assigned in a double-blind fashion to one of the two groups: The treatment group received esomeprazole enteric-coated capsules (40 mg; Chongqing Lummy Pharmacy, China) and an esomeprazole magnesium-matching placebo, and the other group received esomeprazole magnesium (40 mg; Nexium,

Table 1 Baseline demographic and clinical characteristics (% mean  $\pm$  SD)

Characteristics	Esomeprazole enteric-coated capsules (n = 30)	Esomeprazole magnesium (n = 27)	Statistics	P value

AstraZeneca Inc) and an esomeprazole enteric-coated capsule-matching placebo as a positive control group. The study began within 3 d of baseline endoscopy. Patients were administered the medicine once daily in the morning, 30 min before breakfast, for up to 4 wk. All medications were packaged and labeled identically to maintain blinding. Treatment allocation for each patient was provided in individually sealed and blinded randomization envelopes which were collected and checked by the monitor at the end of the study to ensure the integrity of the blinding.

Ulcer healing was determined by sequential endoscopies performed after 2 wk of therapy, and again after 4 wk if the ulcer was not healed. The primary efficacy variable was the rate of ulcer healing, defined as complete regeneration of the mucosa (re-epithelialization) with no visible mucosal breaks at the site of all ulcers identified during the study. An erosion at the original site of any ulceration was considered to be evidence of incomplete healing (Figure 1). Whenever possible, endoscopic examinations in individual patients were performed by the same endoscopist.

The secondary end-points of the frequency and intensity of epigastric pain, heartburn, regurgitation, flatulence, belching, nausea and vomiting were assessed at baseline and at the endoscopy visits. Gastrointestinal symptoms were graded on a four-point scale: 0 = none; 1 = mild (aware of symptoms, but easily tolerated); 2 = moderate (discomfort sufficient to cause interference with normal activities); and 3 = severe (incapacitating, with inability to perform normal activities). The patients recorded all of these items in diary cards on a daily basis. The investigator used the diary card information to complete the study case report forms and obtained the total score of all recorded symptoms. The relief of gastrointestinal symptoms was calculated as [(baseline total score-post-treatment total score)/(baseline total score)]  $\times$  100%.

### Assessment of adverse events

The safety and tolerability of the medication were assessed using physical examination at final visit, review

**Figure 1** Comparison of Esomeprazole enteric-coated capsules treated group (left column) and Esomeprazole magnesium treated group (right column) in duodenal ulcer under endoscopy. **A:** Baseline duodenal ulcer under endoscopy; **B:** Duodenal ulcer under endoscopy at wk 2; **C:** Duodenal ulcer under endoscopy wk 4.

of adverse events as reported by patients at wk 4, and clinical laboratory evaluations at baseline and at the final visit. Clinical laboratory tests included serum chemistry, hematology and urine analysis. The causal relationship of an adverse event to the study drug was classified as being probable, possible or unlikely, and the intensity of the adverse event was rated as mild, moderate or severe. The action taken with study drug in response to the adverse event (none, treatment temporarily stopped, treatment discontinued) was also recorded.

### Statistical analysis

Data were analyzed using SAS for Windows, version 6.12; the null hypothesis was rejected if  $P$ -values were  $\leq 0.05$ . The primary analysis was carried out on the per-protocol (PP) population, which included all randomized subjects who completed a full course of each treatment, had no appreciable loss of data, and had no major protocol violations. The significance of differences in categorical data was determined using the Pearson  $\chi^2$  or Monto-Carlo's exact test. The Student's  $t$  test and Mann-Whitney  $U$  test were used when appropriate. Results are reported as means and standard deviations.

## RESULTS

### Ulcer healing

The duodenal ulcer healing rates at wk 2 and 4 were compared between the two treatment groups (Figure 1). At wk 2, the healing rate was 86.7% in the esomeprazole enteric-coated capsules group compared with 85.2% in the esomeprazole magnesium group ( $P = 0.8410$ ). At wk

**Table 2** Adverse events during 4-wk therapy

Adverse event	Esomeprazole enteric-coated capsules ( $n = 30$ )	Esomeprazole magnesium ( $n = 27$ )
Dizziness	2	2
Diarrhea	1	0
Constipation	0	1
Face puffiness	1	0
Other	1 (cough)	1 (palpitation)
Total	5	4

4, 100% ulcer healing was documented in all patients. As shown in Figure 1, case 223 received esomeprazole enteric-coated capsules and case 181 received esomeprazole magnesium. Both patients had much improved duodenal ulcers at wk 2 and had complete ulcer healing at wk 4.

### Relief of gastrointestinal symptoms

Assessment of gastrointestinal symptoms showed significant improvements in the frequency and intensity of epigastric pain, heartburn, regurgitation, flatulence, belching, nausea and vomiting at wks 2 and 4, and the two groups demonstrated comparable efficacy. At wk 2, the rate of symptom relief was 90.8% in the esomeprazole enteric-coated capsules treatment group compared with 86.7% in the esomeprazole magnesium positive control group ( $P = 0.5406$ ). At wk 4, the rates of symptom relief in the two groups were 95.2% and 93.2%, respectively ( $P = 0.5786$ ).

### Safety and tolerability

Of the 60 patients with duodenal ulcers who were randomized with respect to medication, 57 patients received either esomeprazole enteric-coated capsules ( $n = 30$ ) or esomeprazole magnesium ( $n = 27$ ) for four wk, and were included in the safety and tolerability analysis. Only a few adverse events were documented with the following distribution: 5/30 patients (16.7%) in the esomeprazole enteric-coated capsules treatment group, and 4/27 patients (14.8%) in the esomeprazole magnesium positive control group (Table 2). There was no difference between the two groups ( $P = 1.0000$ ). The reported adverse events during the trial were minor and did not require treatment interruption. There were no clinically relevant changes in blood pressure, heart rate or laboratory values during the study.

Of the 3 patients who withdrew from this study, one patient moved to another city because of a change in work place, and the other two patients rejected the gastroscopic operation because of complete symptom relief.

## DISCUSSION

There are stereoselective differences in the metabolism of PPIs by the cytochrome P450 (CYP) isoenzymes 2C19 and 3A4, and this is the basis of the observed pharmacodynamic and clinical efficacy differences between esomeprazole and omeprazole<sup>[12-15]</sup>. A study in which these enzymes were expressed from cDNAs suggested that CYP2C19 is responsible for 40% and 87% of the total intrinsic clearance of S- and R-omeprazole, respectively<sup>[16]</sup>,

indicating esomeprazole would be cleared more slowly *in vivo*<sup>[16,17]</sup>. Several pharmacological studies using intragastric pH monitoring conducted in either healthy subjects or GERD patients have consistently established the superiority of standard dose esomeprazole over all other currently available standard PPI regimens<sup>[18-22]</sup>. Recently, another S-isomer of pantoprazole has been used to investigate the efficacy in the treatment of acid-related disease; it has shown better efficacy in the control of GERD symptoms than its racemic mixture of pantoprazole<sup>[23]</sup>.

Miner *et al*<sup>[9,10]</sup> demonstrated that, in a five-way crossover study, oral esomeprazole (40 mg) increased intragastric pH more rapidly and maintained intragastric pH above 4.0 longer than lansoprazole (30 mg), omeprazole (20 mg), pantoprazole (40 mg) and rabeprazole (20 mg) did in 34 *H pylori*-negative patients with symptoms of gastroesophageal reflux disease. In addition, a recent study showed that esomeprazole (20 mg) was more effective at maintaining gastric pH above 4 for longer than lansoprazole (15 mg), pantoprazole (20 mg) and rabeprazole (10 mg)<sup>[24]</sup>.

Two randomized multicenter trials<sup>[25,26]</sup> which used esomeprazole to treat DUs demonstrated that in *H pylori*-positive patients with duodenal ulcer, 1 wk of esomeprazole (20 mg twice daily) triple therapy followed by placebo for 3 wk provides the same effective ulcer healing, *H pylori* eradication and symptom control when compared with 1 wk of omeprazole (20 mg twice daily) triple therapy followed by a 3-wk period of omeprazole monotherapy (20 mg once daily). The authors concluded that 1 wk of esomeprazole-based triple therapy is sufficient to ensure high rates of ulcer healing without the need for follow-on PPI monotherapy in patients with uncomplicated duodenal ulcer disease. Besides, in GERD patients, esomeprazole demonstrated significantly higher healing rates at 4 and 8 wk than other standard dose PPIs, and the magnitude of the benefit that esomeprazole offers increases with the severity of the underlying reflux esophagitis<sup>[11]</sup>.

The present study investigated the efficacy and safety of esomeprazole enteric-coated capsules (synthesized by Chongqing Lummy Pharmacy, China) in the treatment of active duodenal ulcer disease, with esomeprazole magnesium (Nexium, AstraZeneca Inc)-treated patients used as a positive control group. Patients with active duodenal ulcers received esomeprazole (40 mg) once daily for four wk in both groups. At the end of second wk, duodenal ulcer healing was 86.7% in the treatment group and 85.2% in the positive control group ( $P = 0.8410$ ), and at the end of fourth wk duodenal ulcer healing was 100% in both groups (Figure 1). In the improvement of gastrointestinal symptoms caused by active duodenal ulcer, the esomeprazole enteric-coated capsules treatment group showed 90.8% relief, which was greater than that of the esomeprazole magnesium positive control group (86.7%,  $P = 0.5406$ ) at the end of the second wk; at the end of the fourth wk, 95.2% and 93.2% symptom relief was seen in the esomeprazole enteric-coated capsules treatment group and the esomeprazole magnesium positive control group, respectively ( $P = 0.5786$ ).

Since the first PPI, omeprazole, was launched on the market in 1988, it has been widely used to treat acid-

related disorders and has demonstrated good efficacy and safety. Treatment with omeprazole over the mean period of 6.5 years causes histologic changes in the stomach which can be detected only by biopsy, but with no specific symptoms<sup>[27]</sup>. Meanwhile, esomeprazole, the S-isomer of omeprazole, which had increased plasma concentrations and better clinical efficacy than omeprazole, should not be associated with any increase in unwanted effects. In studies involving large numbers of patients, the adverse event rates of esomeprazole have been proven to be similar to those recorded for omeprazole and placebo<sup>[28,29]</sup>. Our data showed the adverse event rates were 16.7% in the esomeprazole enteric-coated capsules treatment group and 14.8% in the positive control group ( $P = 1.0000$ ). The results of the current study are consistent with the findings of Richter *et al*<sup>[30]</sup>, who showed that in the 8-wk treatment of reflux esophagitis, the adverse event rates were 15.3% in the esomeprazole group and 15.1% in the omeprazole group. However, the adverse event rate was much lower in the study by Maton *et al*<sup>[28]</sup>. In that study the adverse event rate of esomeprazole was about 3% compared with placebo, in 12-mo treatment for reflux esophagitis. The difference between these studies could be due to variations in therapy duration. Furthermore, in the current study, 3 patients in the esomeprazole magnesium group withdrew from this study, but none of these discontinuations were related to adverse events.

In conclusion, the results of this study indicate treatment with esomeprazole enteric-coated capsules (40 mg) is equivalent to treatment with esomeprazole magnesium (40 mg) in the healing of active duodenal ulcers and improving gastrointestinal symptoms, and that these treatments have similar safety and tolerability profiles.

## COMMENTS

### Background

Proton pump inhibitors (PPI) were introduced in the late 1980s and have emerged as the drug class of choice for the treatment of most acid-related disorders. Omeprazole was the first PPI on the market, followed by lansoprazole, rabeprazole, pantoprazole and esomeprazole, in that order. Conversely from the other available PPIs, which are all racemic mixtures, esomeprazole, the S-isomer of omeprazole, is the first PPI to be developed as a single isomer and demonstrates pharmacological and clinical benefits beyond those seen with racemic PPIs.

### Research frontiers

Studies have shown esomeprazole at a standard dose of 40 mg once daily achieves greater and more sustained acid control than standard doses of any other currently available PPI, with good safety.

### Innovations and breakthroughs

This study was designed to evaluate the efficacy and tolerability of two different preparations of esomeprazole, esomeprazole enteric-coated capsules and esomeprazole magnesium, in the healing of active duodenal ulcers.

### Applications

This study indicates treatment with esomeprazole enteric-coated capsules is equivalent to treatment with esomeprazole magnesium in healing duodenal ulcer lesions and relieving gastrointestinal symptoms, and could be an alternative in the treatment of acid-related diseases.

### Terminology

Isomers are compounds which have the same molecular formula but different

chemical structures. Depending on the types of differences there are between the structures, it is possible to classify isomers into various sub-types. Stereo-isomers contain the same functional groups and differ only in the arrangement of atoms in space.

### Peer review

The study is performed well and carefully written.

### Abstract

Accessing the bypassed portion of the stomach via conventional endoscopy is difficult following Roux-en-Y gastric bypass surgery. However, endoscopic examination of the stomach and small bowel is possible through percutaneous access into the bypassed stomach (BS) with a combined radiologic and endoscopic technique. We present a case of obscure overt gastrointestinal (GI) bleeding where the source of bleeding was thought to be from the BS. After conventional endoscopic methods failed to examine the BS, percutaneous endoscopy (PE) was used as an alternative to surgical exploration.

### INTRODUCTION

Bleeding from the bypassed stomach (BS) in patients following Roux-en-Y gastric bypass surgery (GBS) is uncommon and can be a challenging diagnostic and therapeutic task. When the BS is not reachable by conventional ap-

proaches or more novel methods (e.g. double balloon endoscopy), surgical exploration may provide the only access to the BS and small bowel. Percutaneous endoscopy (PE) provides an opportunity to examine the BS and bowel and could be considered a practical alternative to surgical exploration.

### CASE REPORT

#### Patient

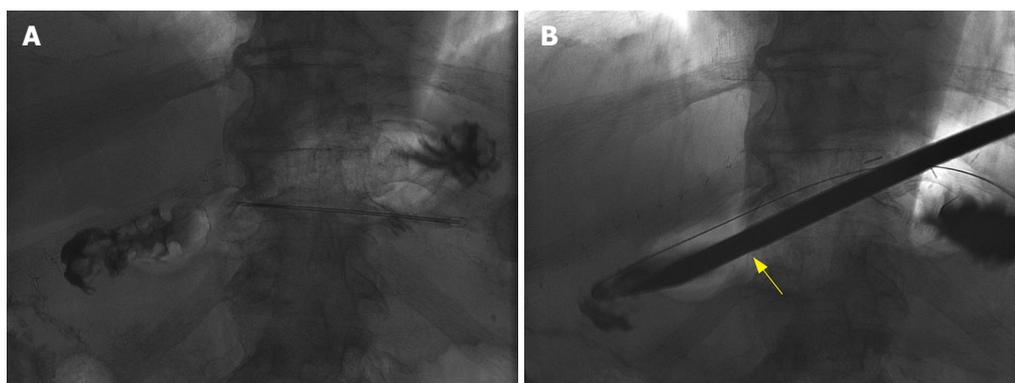

A 66-year-old man status post Roux-en-Y GBS for morbid obesity 6 years prior presented to an outside institution with melena and hemodynamic instability. His hemoglobin (Hgb) was 10 gm, a drop from baseline Hgb of 15 gm. The patient was taking aspirin 81 mg daily. Upper endoscopy revealed expected post-surgical changes, and colonoscopy showed diverticulosis with no bleeding. A tagged RBC scan revealed a focus of activity in the right upper quadrant. Aspirin medication was stopped and the patient was discharged following cessation of clinical bleeding and a stable Hgb. He was readmitted 5 d later with recurrent melena and an Hgb of 8.5 gm. Repeat bleeding scan was negative, but CE revealed bleeding at 4 h into the recording (suspected jejunum). The Roux-en-Y anastomosis was not identified.

The patient was transferred to our institution for DBE, but the Roux-en-Y anastomosis was not reached, and no proximal source of bleeding was identified. Based on the suspicion that bleeding was coming from the BS, diagnostic and therapeutic alternatives including open or laparoscopic surgical exploration with gastroscopy and possible gastrectomy were considered. Surgery was considered high risk because of patient's obesity and other comorbid conditions. As an alternative to surgical exploration, we endeavored to examine the BS using a combined approach with interventional radiology and endoscopy.

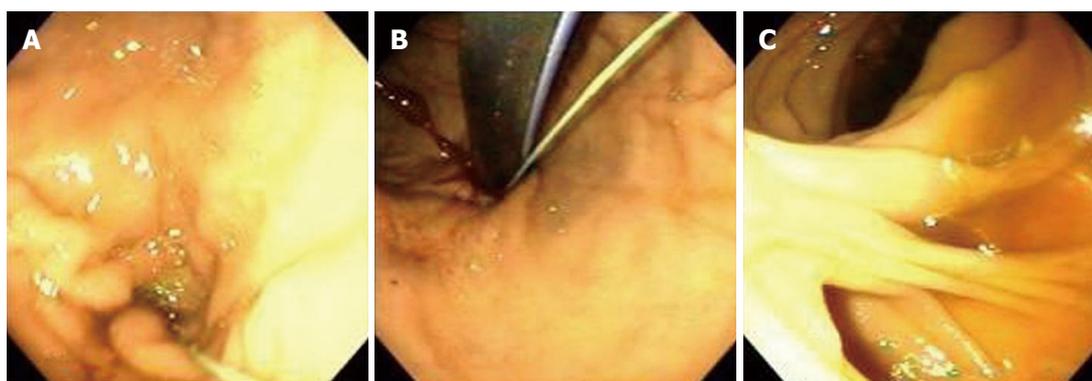

#### Technique

After a thorough discussion of potential risks and benefits, informed consent was obtained. One milligram of intravenous glucagon was administered to prevent gastric peristalsis. Once the BS was identified with real-time trans-abdominal ultrasonography, a 19-gauge needle was passed into the collapsed lumen of the BS under sterile conditions. The stomach was then inflated with air while progress was monitored with fluoroscopy (Figure 1A).

Three gastric anchors were inserted into the central portion of the BS, pulling the gastric wall to the abdominal

**Figure 1** Fluoroscopic images of percutaneous endoscopy. **A:** Inflated bypassed stomach with air; **B:** Trochar (arrow) used to dilate the percutaneous track.

**Figure 2** Endoscopic images by percutaneous endoscopy. **A:** Antegrade views of bypassed stomach; **B:** Retrograde views of bypassed stomach; **C:** Roux-en-Y anastomosis.

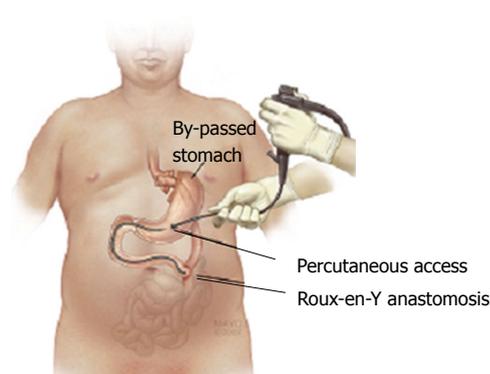

wall. A trochar was inserted, the tract was dilated, and a 30 French sheath was placed under fluoroscopic guidance (Figure 1B).

Through the sheath, a standard Olympus endoscope was introduced into the BS and examination was performed in antegrade and retrograde fashion (Figure 2A and B). The endoscope was advanced through the stomach and small bowel to the Roux-en-Y (Figure 3) anastomosis, where the two additional limbs of small bowel were examined for a distance of approximately 10 cm (Figure 2C). No source of bleeding was identified. After completion of the endoscopy, a 22 French gastrostomy tube (PEG) was placed in the BS for future access in the event of rebleeding. The patient experienced no clinical bleeding and had a stable Hgb, so he was discharged with the PEG (later changed to a button PEG) in place. As no bleeding occurred after 3 mo, the gastrostomy tube was removed.

## DISCUSSION

The prevalence of obesity in the United States is reaching epidemic proportions. An estimated 30% of individuals met the criteria for obesity in 1999-2002<sup>[1,2]</sup>. The increasing numbers of obese individuals have led to intensified interest in GBS. The estimated numbers of bariatric surgical procedures in United States have increased from 13 365 in 1998 to 72 177 in 2002<sup>[3]</sup>. GBS is an effective and safe procedure; however, gastrointestinal (GI) bleeding after GBS can occur with an incidence of 0.8% to 4.4%<sup>[4,5]</sup>.

Bleeding after GBS has been classified as early (< 48 h) and late (> 48 h)<sup>[6]</sup>. Late bleeding usually indicates luminal bleeding, whereas early bleeding may apply to bleeding intraluminally or into the abdominal cavity. The most com-

**Figure 3** Illustration of the percutaneous endoscopy.

mon etiology of bleeding from BS is peptic ulcer disease (PUD), but the true incidence of bleeding from the BS is not known. One series reported only 8 of 3000 (0.26%) patients experienced GI bleeding from PUD involving the BS<sup>[7]</sup>.

Endoscopic examination of the BS is a challenge in this patient population as it is difficult to reach the BS with conventional endoscopy. Flickinger and colleagues described the use of a pediatric colonoscope in 1985. In that series of 78 procedures, 68% of the attempts to pass through the jejunostomy for retrograde evaluation of duodenum and BS were successful<sup>[7]</sup>. Later, Sinar *et al* evaluated the BS by retrograde endoscopy and reported a successful procedure in 65% (33/51) of their patients<sup>[8]</sup>.

Percutaneous examination of the BS with contrast was first described by McNeely *et al* in 1987<sup>[9]</sup>. In a series of 14 patients (11 nausea/pain, 3 GI bleeding), the radiocontrast

examination was successful in 13/14 patients. However, the specificity of the findings was low as only 20% (1/5) of the patients had confirmation of the suspected diagnosis. Endoscopic examination through percutaneous access with a bronchoscope was first reported in 1998<sup>[10]</sup>. Since then, only a few case reports have been published utilizing PE to evaluate suspected pathology in the BS<sup>[11,12]</sup>.

New noninvasive techniques like virtual endoscopy have been evaluated for examination of BS in a small series<sup>[13]</sup>. However, more studies are needed to define the utility of the technique. Recently a case series utilizing DBE reported successful examination of the BS in 83.3% (5/6) of the cases<sup>[14]</sup>. The BDE technique enjoys several advantages over the more invasive percutaneous approach, but examination with DBE may be limited by difficult access, as with our patient, necessitating alternative approaches.

In this case no identifiable source of bleeding was found and hence the gastrostomy tube was left in place for future access. This is an advantage of the percutaneous approach as the stomach can be flushed and assessed in the event of bleeding. The access also allows a portal for endoscopy (requiring standard equipment and no special training). Fortunately, our patient had no further bleeding, so the gastrostomy tube was removed after 3 mo of observation.

In conclusion, this case highlights the value of PE to examine the BS after Roux-en-Y GBS. Advantages of this technique include direct access to the BS and the ability to leave an access point in the event of recurrent bleeding. Moreover, less endoscopic expertise is required compared to DBE, and the procedure is less invasive than surgery particularly in patients with multiple comorbidities.

### Abstract

Duodenal diverticula are a relatively common condition. They are asymptomatic, unless they become complicated, with perforation being the rarest but most severe complication. Surgical treatment is the most frequently performed approach. We report the case of a patient with a perforated duodenal diverticulum, which was diagnosed early and treated conservatively with antibiotics and percutaneous drainage of secondary retroperitoneal abscesses. We suggest this method could be an acceptable option for the management of similar cases, provided that the patient is in good general condition and without septic signs.

### INTRODUCTION

Duodenal diverticula are a relatively common condition.

Usually asymptomatic, they may become clinically evident when complicated, for example, with inflammation, bleeding or perforation. Perforation is the rarest complication and carries a high mortality. As this is exceptional, there are no well defined management recommendations. Below, we describe one approach to conservative management.

### CASE REPORT

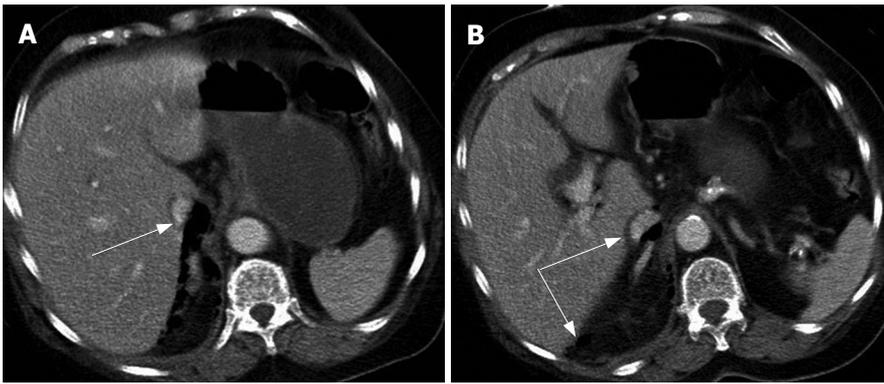

An 85-year-old female, with arterial hypertension as the only antecedent, arrived at the Emergency Department with an intense thoracic pain radiating to the upper abdomen, accompanied by cold sweating, which occurred suddenly while she was out walking. A few minutes later, she experienced nausea and vomiting. General exploration demonstrated arterial hypotension and epigastric pain on palpation. Blood analysis only showed leukocytosis ( $15\,000/\text{mm}^3$  with 82% neutrophils). Thoracic and abdominal radiographs were normal. Due to a suspicion of dissecting aorta aneurism, a thoraco-abdominal computed tomography (CT) was performed, revealing perihepatic-free liquid, pneumoperitoneum and retroperitoneum next to the cava vein, secondary to perforation of a hollow viscus, probably of the duodenum (Figure 1).

In the initial hours following the patient's admission to hospital she improved with only intravenous fluid resuscitation, presenting with remittent fever and abdominal pain. It was decided to maintain conservative management with nasogastric decompression and intravenous Meropenem, which was then administered.

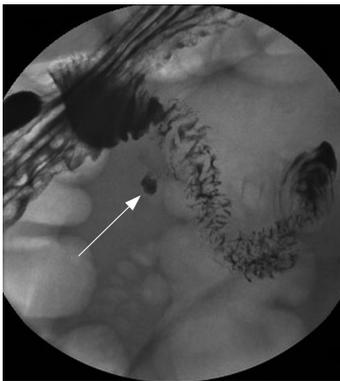

The nasogastric tube was retrieved on the fourth day, but she remained nil-by-mouth and continued to receive intravenous antibiotherapy. She had an uneventful evolution; on the sixth day, a Gastrografin swallow examination revealed a duodenal diverticulum in the second portion, without leakage of contrast at this time (Figure 2). A new abdominal CT showed an abscess surrounding the duodenal diverticula and another one, which was retrohepatic and subdiaphragmatic, containing air. Both were drained percutaneously. The patient was discharged on the twentieth day. Six months later she is asymptomatic.

### DISCUSSION

The incidence of duodenal diverticula is estimated to be 5%-22% in a healthy population<sup>[1,2]</sup>. Most of these are located along the pancreatic or mesenteric border,

**Figure 1** Abdominal CT showing perihepatic free liquid, pneumoperitoneum and retroperitoneum next to the cava vein.

**Figure 2** Gastrografin swallow examination revealing a duodenal diverticulum in the second portion without leakage of contrast.

mainly in the second part of the duodenum, and are really pseudodiverticula, as they do not involve all of the intestinal layers<sup>[2-4]</sup>. Many of them are near the ampulla of Vater, and these are known as perivaterian or periampullary diverticula<sup>[4]</sup>.

They are asymptomatic until they develop complications. Many possible complications have been reported. The most frequent are inflammation, haemorrhage, pancreatitis and common bile duct obstruction. Perforation is considered to be the rarest complication, and is also the most serious, with a mortality of up to 20%<sup>[5,6]</sup>. Only about 100 cases have been reported over the past two decades<sup>[2]</sup>.

Diagnosis is difficult, because the clinical presentation is non-specific, without pathognomonic signs or symptoms, and requires imaging. However, the most frequent presentation is acute pain in the right upper abdomen or epigastrium, associated with nausea and vomiting.

As the perforation is usually open to the retroperitoneum, it is possible there will be no signs of peritonism. Diverticulum perforation usually leads to retroperitoneal abscess formation and sepsis. It may also lead to the development of duodenocolic fistula with steatorrhea or gastrointestinal bleeding if perforation gets into the aorta<sup>[6]</sup>. It is important to make a differential diagnosis with other right upper abdomen pathologies such as cholecystitis, cholangitis, pyelonephritis, perforated duodenal ulcers or even bottom right pneumonia.

In most instances plain abdominal radiographs or ultrasounds are used as the first imaging techniques with subtle findings, and preoperative diagnosis is usually incorrect<sup>[2]</sup>. CT is the modality of choice<sup>[7]</sup>, usually demonstrating a thickened bowel wall, mesenteric fat inflammation

and an extraluminal collection of air and fluid, often retroperitoneal<sup>[7-9]</sup>. It is frequently possible to identify the diverticulum itself.

The most common approach is surgical, although there exist only a few reports of conservative management with antibiotics and percutaneous drainage<sup>[8,10-13]</sup>. Surgical intervention will depend on the clinical situation and intraoperative findings. If inflammation permits, the treatment of choice is, after Kocherizing the duodenum, diverticulectomy with single or double-layer duodenal closure. It is important to place drainage tubes, especially in the retroperitoneum if affected<sup>[2,4,7]</sup>. A tongue of the greater omentum can be patched over the closure. Injury to the pancreatic or distal common bile duct can be avoided by placing a tube into the ampulla of Vater before dissecting the diverticulum.

When there is substantial inflammation of the duodenum, a diversion should be performed by a subtotal gastrectomy followed by Billroth II reconstruction, or a Roux-en-Y gastroenteroanastomosis. Only patients who are mildly affected are likely to benefit from non-operative management. In these patients, the perforation has probably already sealed spontaneously, or will do so within a short period of time.

Non-operative management consists of nasogastric decompression and wide spectrum antibiotics. It may be advisable to perform radiographic studies with water-soluble contrast between the fifth and seventh day, before starting oral alimentation with fluids. Formation of abscesses is likely, so percutaneous drainage must be easily accessible if conservative management is implemented. If a patient's condition worsens, conservative management must be abandoned in favour of surgery.

In conclusion, duodenal diverticulum perforation is a very rare but serious complication with a difficult diagnosis, normally requiring a CT. Very few cases which have been treated conservatively, for example, using antibiotics and posterior percutaneous drainage, have been reported. This option must only be tried in patients who are in a generally good condition with no septic signs. This must of course be replaced by surgery if the patient deteriorates.

### Abstract

We review the case of a 74-year-old patient with advanced colon cancer who suffered recurrent bouts of hypoglycemia. A state of inappropriate, non-suppressed hyperinsulinism in the presence of severe hypoglycemia was diagnosed. We finally discuss the known mechanisms behind fasting hypoglycemia in patients with advanced cancer, the diagnosis, and possible treatments of this rare paraneoplastic endocrine complication.

### INTRODUCTION

Non-islet cell tumour hypoglycemia (NICTH) is a rare association between spontaneous hypoglycemia and tumours derived from tissues other than the pancreatic

islets<sup>[1]</sup>. It was initially associated with abdominal soft tissue sarcomas, although other tumour types have been described. The most consistent finding is the overproduction of insulin or especially insulin-like growth factors by the tumour. We review the case of a patient with a sigmoid carcinoma with ectopic production of insulin and secondary hypoglycemia and the clinical diagnosis and management of this rare condition.

### CASE REPORT

A 74-year-old male patient was diagnosed in September 2004 with a sigmoid cancer with advanced hepatic and pulmonary metastases. He had no previous medical history of interest. The primary tumour was surgically removed. The pathologic study showed a moderately differentiated adenocarcinoma; the TNM staging was pT4 N2 (12/15) M1, stage IV. After surgery, his performance status (PS) was 1. There were no baseline laboratory abnormalities. His CEA and CA 19.9 levels were 270.9 ng/mL and 1257.3 UI/mL, respectively.

Between November 2004 and April 2005, he received 1st line chemotherapy with 12 fortnightly cycles of infusional 5-fluorouracil and oxaliplatin (FOLFOX regimen). A radiologically stable disease was achieved after the 6th and 12th infusion, with a lowering of the CEA and CA19.9 levels. Overall tolerance to chemotherapy was good; however, treatment was finally stopped due to persistent grade 2 chronic neurotoxicity (CTC version 3) secondary to oxaliplatin. At that moment, he began follow-ups in our clinic.

In July 2005, the patient suffered a loss of consciousness in the early hours of the morning. The capillary blood glucose at that moment was low (45 mg/dL) and he was brought to the Emergency Room (ER). There were no other basic laboratory abnormalities. The electrocardiogram was normal, as was a CT brain scan. With further questioning, the patient referred in the last weeks similar episodes of poor sleep, frequent nightmares, dizziness and blurred vision, although with no loss of consciousness, in the early hours of the morning, which improved with the ingestion of food. The patient had also gained weight in the last weeks, as he had a craving for sweet foods; he also had learnt to avoid these episodes of dizziness during the day with the increased food ingestion.

The patient was admitted for further study. His PS was 2 and it had deteriorated in the last few weeks. He was overweight, although there were signs of muscular atrophy. There were signs of peripheral oedema and ascitis and a

palpable hepatomegaly of 4 cm of size. A more complete laboratory study only showed mild anemia (hemoglobin of 10.7 g/dL) and hypoalbuminemia (serum albumin of 2.2 g/dL), with no ionic abnormalities. The CEA and CA 19.9 levels had risen (448.2 ng/mL and 2155.9 UI/mL, respectively). A CT scan showed hepatic and pulmonary progression of disease; there were also signs of peritoneal carcinomatosis and ascitis and a sigmoid mass.

During his admission, the patient suffered recurrent bouts of hypoglycemia in the early morning hours which needed the use of nocturnal intravenous 10% glucose hypertonic fluid for adequate control. No thyroid or adrenal axis abnormalities were found.

An overnight fasting test was performed under close medical supervision. It was stopped at 6:00 am when hypoglycemic symptoms appeared. In that moment, the glucose level was 20 mg/dL, the insulin level was 15.5  $\mu$ UI/mL (not suppressed), the C-peptide was 5.61 ng/mL (elevated) and IGF-I was less than 2 ng/mL (suppressed). All these data were compatible with fasting hypoglycemia secondary to hyperinsulinism. Neither a pancreatic arterial and venous-phase CT scan or an octotide scan revealed signs of a primary pancreatic  $\beta$ -cell tumour.

Diazoxide was begun, which partially improved the hypoglycemia and the need for hypertonic fluids, at the cost of worsening of the peripheral oedemas. Due to the paraneoplastic nature of the hypoglycemia, 2nd line chemotherapy was begun with infusional 5-FU and irinotecan (FOLFIRI regimen) and a first infusion was given. However, the patients' general state quickly deteriorated and an intestinal occlusion secondary to the peritoneal carcinomatosis developed, which did not improve with medical treatment. A multiorgan failure appeared and the patient died 3 wk after the original admission. The patients' family refused an autopsy.

## DISCUSSION

NICTH is a rare clinical entity. In almost half of cases it has been linked to large pleural or abdominal mesenchymal tumours<sup>[1-3]</sup>, retroperitoneal fibrosarcoma being the classic prototype. Other tumour types implicated have been hepatocarcinomas, adrenal carcinomas, and in a few cases gastrointestinal tumours, genitourinary tumours and lymphomas<sup>[1,2,4,5]</sup>. In many cases instances the tumour is already known to be present, usually in an advanced stage<sup>[1]</sup>. However, diagnosis can be difficult in those cases where it is the first clinical manifestation.

The pathogenesis of hypoglycemia in NICTH may involve a variety of mechanisms, including excessive consumption of glucose by what is typically a large tumour, inadequate production of counter regulatory hormones, such as growth hormone or cortisol, or ectopic or abnormal secretion of insulin or insulin-like growth factor-2 (IGF- II) and IGF-binding proteins. This last mechanism seems to be the most frequent and best characterized in patients with typical NICTH<sup>[3-7]</sup>. Insulin secretion by the non- $\beta$ -cell tumour, as in our case, is extremely rare and most cases published are secondary to secretion of an incompletely processed IGF- II by the tumour ("big IGF- II", which can be measured with specialized assays) which acts

as an insulin-like factor in the insulin receptors, causing hypoglycemia<sup>[8]</sup>. The fasting suppression state can differentiate between both conditions, as in the setting of hypoglycemia, insulin levels will be non-suppressed in the former and suppressed in the latter. In both cases, however, IGF-I levels will be suppressed, which can be a useful marker in these patients<sup>[9]</sup>.

The clinical presentation is usually severe fasting hypoglycemia, which is persistent and requires intravenous glucose administration for reversal. Because the onset of fasting hypoglycemia is often gradual, autonomic signs are minimal or absent in most cases and neuroglycopenic symptoms predominate. They are most common in the early morning, after the overnight fast. The differential diagnosis includes all other conditions which can produce fasting hypoglycemia in adults and includes renal or hepatic failure, adrenal insufficiency, sepsis,  $\beta$ -cell pancreatic tumours, ethanol ingestion or drugs (usually insulin or sulfonylureas)<sup>[9,10]</sup>. Most are easily ruled out and the differential usually only includes  $\beta$ -cell pancreatic tumours, adrenal insufficiency or factitious hypoglycemia secondary to exogenous administration of insulin or sulfonylureas<sup>[10]</sup>.

In our case, there were no adrenal axis abnormalities. The patient was in close medical supervision, with no contact with hypoglycemic drugs and so factitious hypoglycemia was ruled out. An overnight fast revealed a severe hypoglycemia, alongside a non-suppressed insulin and an elevated C-protein, which seemed to show an autonomous secretion of insulin. However, there were no radiological signs of a concomitant  $\beta$ -cell pancreatic tumour. The hypoglycemia also behaved like a paraneoplastic phenomena; its appearance was quite sudden and it coincided with the tumour progression, both radiologically and in the elevation of the tumour markers.

Treatment of this infrequent condition can be difficult. These patients often require continuous glucose infusions to control their symptoms. In some cases, diazoxide, a potent inhibitor of insulin secretion, has been useful<sup>[1]</sup>. Debulking surgery may bring relief to the hypoglycemia, especially in those with slow-growing mesenchymal tumours<sup>[1-3,11]</sup>. Specific treatment should be instituted if possible (e.g, imatinib in gastrointestinal stromal tumours)<sup>[12]</sup>. In most cases, however, the outcome is often poor due to the size and advanced stage of the tumour.

### Abstract

We report a case of gastric penetration caused by accidental ingestion of a chicken bone in a 42-year old woman with a partially wearing denture. Three days ago, she accidentally swallowed several lumps of poorly-chewed chicken. Physical examination disclosed mild tenderness in the periumbilical area. Abdominal Computed tomography (CT) showed a suspicious penetration or perforation of the stomach wall measuring about 3 cm, by a linear radiopaque material at the lesser curvature of the antrum. The end of a chicken bone was very close to but did not penetrate the liver. Endoscopic examination revealed a chicken bone that penetrated into the prepyloric antrum. The penetrating chicken bone was removed with grasping forceps. Five endoscopic clips were applied immediately at the removal site and the periumbilical pain resolved promptly. After removal of the chicken bone, the patient was treated with conservative care for three days, after which she was completely asymptomatic and discharged without complication. To treat gastric penetration by a foreign body, endoclipping can be a useful method in patients with no signs or symptoms of peritoneal irritation.

Extraction and clipping repair of a chicken bone penetrating the gastric wall. *World J Gastroenterol* 2008; 14(12): 1955-1957 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1955.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1955>

### INTRODUCTION

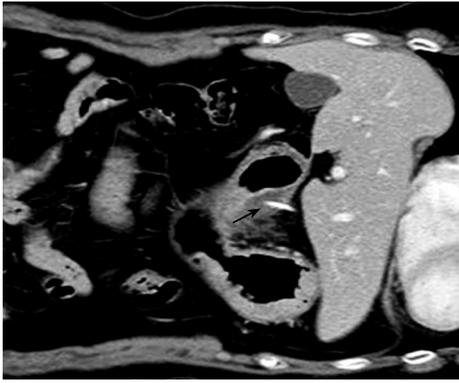

Ingestion of a foreign body is a frequent cause of injury associated with a significant morbidity and mortality. Most ingested foreign bodies pass spontaneously through the gastrointestinal tract, but some patients need endoscopic or surgical management<sup>[1,2]</sup>. Gastric penetration by a chicken bone has been reported rarely in cases of foreign body ingestion<sup>[3,4]</sup>.

Gastrointestinal penetration by a bone fragment carries some problems in diagnosis because simple radiography is not a reliable method despite the bony calcification. Both surgical and endoscopic management are available treatments<sup>[3-6]</sup>. The endoscopic clip, which is often used as a hemostatic procedure, has been used recently to repair perforation and close an endoscopic mucosal resection site<sup>[7-9]</sup>, and some reports on the use of a hemoclip to repair foreign body perforation are also available<sup>[10,11]</sup>.

Herein, we describe a patient with gastric penetration caused by accidental ingestion of a chicken bone, which was diagnosed using CT. The patient was treated conservatively and endoscopically by removing the chicken bone and using clipping to close the penetration site.

### CASE REPORT

A 70-year old woman visited the emergency room complaining of epigastric pain for three days. She accidentally swallowed several lumps of poorly chewed chicken. She had a partially wearing denture because of teeth extraction one month ago. Physical examination disclosed mild tenderness in the periumbilical area without surgical signs including rebound tenderness. Her blood pressure was 100/60 mmHg, heart rate was 80/min, and body temperature was 36.6°C. The patient had an acute ill appearance but no history of nonsteroidal anti-inflammatory drug use, peptic ulcer, or liver disease. Laboratory studies

**Figure 1** 2.8 cm linear density (arrow) penetrating into the thickened gastric wall (CT).

**Figure 3** Follow-up endoscopy revealing near closure of the ulcer at the penetration site.

**Figure 2** Endoscopic management. **A:** A chicken bone penetrating into the prepyloric antrum; **B:** The whole chicken bone was removed using a grasping forceps; **C:** Clip placement was performed at the removal site; **D:** The length of removed chicken bone was about 3.0 cm.

revealed hemoglobin concentration of 132 g/L, hematocrit 38.6%, white blood cell count of  $11.7 \times 10^9/L$ , and platelet count of  $222 \times 10^9/L$ . Her serum urea nitrogen concentration was 3.2 mmol/L, creatinine 50.4  $\mu\text{mol/L}$ , AST 283 nkat/L, ALT 233 nkat/L, sodium 138 mmol/L, potassium 3.8 mmol/L, and chloride 104 mmol/L. Chest and abdomen X-ray images were negative for any abnormalities, but abdominal CT showed a suspicious penetration or perforation of the stomach wall measuring about 3 cm, by a linear radiopaque material at the lesser curvature of the antrum. The end of a chicken bone was very close to but did not penetrate the liver, and no major vessel injury was seen in the abdomen CT (Figure 1). Endoscopic examination revealed a chicken bone that penetrated into the prepyloric antrum (Figure 2A). The penetrating chicken bone was removed gently with grasping forceps (Figure 2B). No bleeding or other complications occurred after removal of the penetrating chicken bone. Five endoscopic clips were applied immediately at the removal site (Figure 2C) and the periumbilical pain resolved promptly. The removed bone fragment measured 3.0 cm in length (Figure 2D). Chest and flat abdomen X-ray imaging was performed serially after removal of the bone

and revealed no abnormalities, such as free air. After removal of the bone fragment, the patient was treated with conservative care (nothing taken by mouth, intravenous hyper-alimentation, intravenous omeprazole, and antibiotics) for 3 d, after which she was completely asymptomatic and discharged without complication. Follow-up endoscopy was performed 7 d later and showed near closure of the ulcer at the penetration site (Figure 3).

## DISCUSSION

Foreign body ingestion and food bolus impaction occur commonly. Although most foreign bodies will pass out spontaneously, 10%-20% require nonoperative intervention, and 1% or fewer require surgical procedure<sup>[1,2]</sup>. The incidence of accidental chicken bone ingestion is 6%-6.4% in Asian countries<sup>[12,13]</sup>. There are several reports on colon wall perforation by a chicken bone treated endoscopically. Tarnasky *et al*<sup>[14]</sup> have reported colonoscopic removal of a chicken bone impacted in the sigmoid colon without complication. Rex *et al*<sup>[5]</sup> have reported that two patients had their chicken bones impacted in the sigmoid removed successfully by colonoscopy. However, to our knowledge, no reports are available on patients with chicken bone penetration of the gastric wall treated endoscopically with clipping and conservative care.

In adults, foreign body ingestion occurs commonly among those with prison inmates, psychiatric patients, alcoholics, children, selected professions (carpenters and dressmakers), and people wearing dentures<sup>[15]</sup>. In our patient, the foreign body ingestion seemed to have resulted from poor dentition and an artificial denture.

Foreign bodies induce various clinical manifestations, such as perforation, bleeding, bowel obstruction, and even ureteral colic<sup>[16,17]</sup>. A foreign body that perforates the bowel wall may take several possible courses, including lying in the bowel lumen at the site of perforation, like this patient, or passing through the gastrointestinal wall to migrate to a distal organ<sup>[18]</sup>.

In the diagnosis of nonmetallic foreign bodies (especially fish or chicken bones), CT scanning is superior to plain X-ray radiography. Plain radiography is unreliable, even with bony radiopacity, because of the masking effect of the soft tissue mass, fluid collection around the penetrated bone, and the absence of free gas in the abdomen<sup>[6,19]</sup>. Also In this patient, CT scanning was a more reliable diagnostic method than X-ray. CT scanning showing the

calcified foreign body with a thickened intestinal segment, localized pneumoperitoneum, regional fatty infiltration, and associated intestinal obstruction is definite for diagnosis of nonmetallic foreign body perforation<sup>[19]</sup>. However, the accuracy of CT is limited by the lack of observer awareness, and a high index of suspicion must be maintained for the correct diagnosis<sup>[20]</sup>. Immediate surgical intervention is a traditional treatment of choice for frank gastrointestinal perforation. However, it was reported in recent years, that endoscopic clip placement, as used in a hemostatic procedure, can be used in treatment of anastomotic leaks after esophagogastric surgery and gastrointestinal perforation<sup>[7-9]</sup>. Clipping has been used to treat foreign body removal (e.g., gastric toothpick penetration)<sup>[11]</sup>. We decided to perform endoscopic removal of the chicken bone penetrating into the gastric wall and to use the clip to close the penetration site because CT scanning showed no peritoneal irritation and no complication associated with the bone penetration. The pain and symptoms relating to the foreign body disappeared immediately after removal of the penetrating bone fragment. However, serious complications could have occurred if the penetrating bony fragment stuck to a vessel, or if a peritoneal abscess pocket resulted from the bone penetration. Thus, it is necessary to closely observe the patient's status before and after such a procedure.

In conclusion, endoclipping can be a useful method to treat gastric penetration by foreign bodies, such as a chicken bone, in patients with no signs or symptoms of peritoneal irritation.

### Abstract

This report describes serial observations of the growth process of a small invasive ductal carcinoma (IDC) of the pancreas from imaging studies. Histopathological studies showed IDC with macroscopic retention cysts proximal to an intraductal papillary-mucinous adenoma with mild atypia of the branch duct type in the pancreatic body, with no relation between the two lesions. IDC was demonstrated as an extremely low-echoic mass resembling a cyst with an unclear margin on the initial endoscopic ultrasonography. We misinterpreted the low-echoic mass as a benign intraductal mucinous-papillary neoplasm (IPMN) based on findings of other imaging studies, and the patient was followed-up. The mass increased from 7 mm to 13 mm in diameter over 22 mo, and remained smaller than 10 mm in diameter for about 420 d. The tumor volume doubling time was 252 d. The Ki67 labeling index was 15.9%, similar to that described in previous reports. Hence, IDC may grow slowly while remaining small.

### INTRODUCTION

Invasive ductal carcinoma (IDC) of the pancreas has the worst prognosis of all digestive carcinomas. Its histogenesis and natural progression are unknown, and small IDCs are still difficult to detect. This is an extremely rare case of a small IDC in which the growth process was observed on imaging studies for 22 mo.

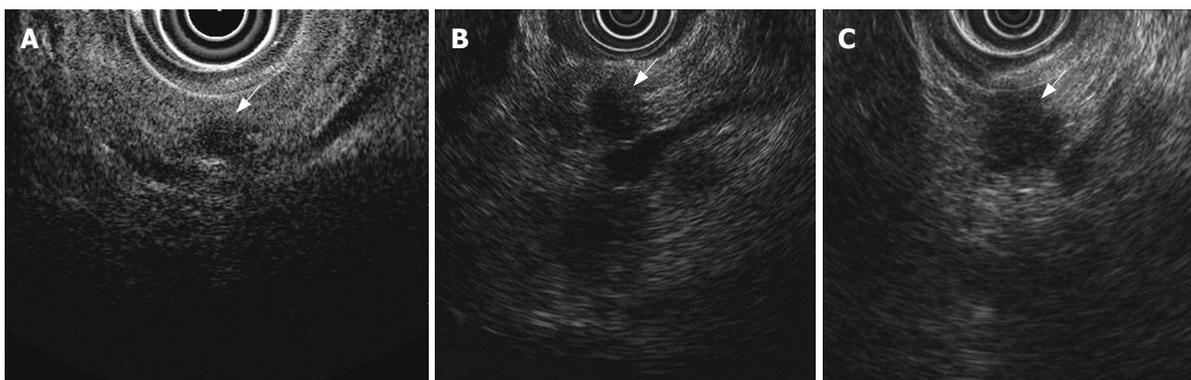

### CASE REPORT

A 77-year-old man, who was being followed-up for chronic Hepatitis C infection, was referred to our department for evaluation of a pancreatic mass on screening transabdominal ultrasonography (US). US showed a low-echoic mass, 7 mm in diameter, in the pancreatic body, without distal dilatation of the main pancreatic duct (MPD) (Figure 1A). Endoscopic ultrasonography (EUS) demonstrated an extremely low-echoic mass with posterior echo enhancement, which appeared to be a cyst (Figure 2A). Contrast-enhanced computed tomography (CT) scan and magnetic resonance cholangiopancreatography (MRCP) revealed a grape-like cyst in the pancreatic body. Endoscopic retrograde pancreatography (ERP) indicated mucus in the MPD and a dilated branch pancreatic duct in the pancreatic body without mural nodules (Figure 3A). We misinterpreted the low-echoic mass in US/EUS images as a benign intraductal mucinous-papillary neoplasm (IPMN) of the branch duct type, and observed the lesion by US/EUS every 6 mo (Figures 1B and 2B).

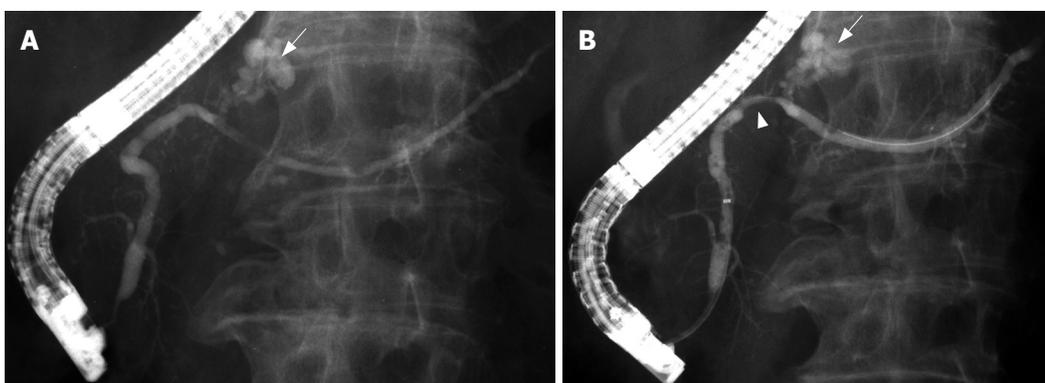

Twenty-two months after the initial diagnosis, US/EUS showed the low-echoic mass had increased in diameter to 13 mm (Figures 1C and 2C). Then, for the first time, we detected a grape-like cyst distal to the lesion on US/EUS (Figure 1D), and recognized the low-echoic mass being followed was not identical to the initially diagnosed IPMN. A contrast-enhanced CT scan revealed a hypovascular area proximal to the grape-like cyst. On MRCP, the cyst did not show any change, but MPD in the pancreatic body became unclear. ERP demonstrated slight compression of the MPD proximal to a dilated branch duct (Figure 3B), and

**Figure 1** Chronological changes in US findings. **A:** Initial US showed a low-echoic mass, 7 mm in diameter, in the pancreatic body (arrow); **B:** After 10 mo, the diameter of the low-echoic mass had increased to 9 mm (arrow); **C:** After 22 mo, the diameter of the low-echoic mass had increased to 13 mm (arrow); **D:** After 22 mo, a grape-like cyst distal to the low-echoic mass was detected for the first time (arrow).

**Figure 2** Chronological changes in EUS findings. **A:** Initial EUS demonstrated an extremely low-echoic mass with partial posterior echo enhancement, 7 mm in diameter, in the pancreatic body (arrow); **B:** After 14 mo, the diameter of the low-echoic mass had increased to 9 mm (arrow); **C:** After 22 mo, the diameter of the low-echoic mass had increased to 13 mm (arrow).

**Figure 3** Chronological changes in ERP findings. **A:** Initial ERP revealed a dilated branch duct in the pancreatic body (arrow), and the MPD was mildly dilated by mucus; **B:** After 22 mo, the dilated branch duct did not show any marked change (arrow). Proximal to it, the MPD was slightly compressed (arrow head).

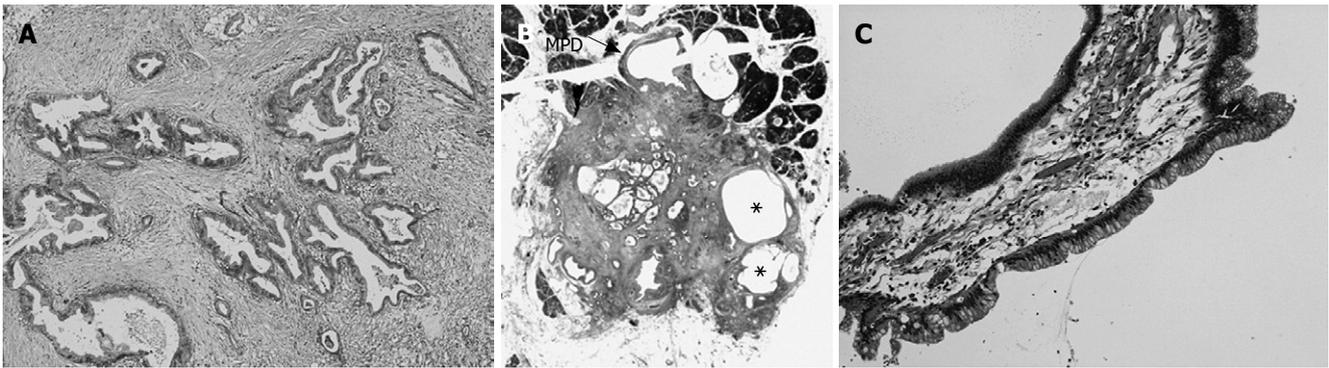

brush cytology did not detect any malignant cells.

Distal pancreatectomy was performed under a diagnosis of IDC concomitant with IPMN. The cut surface of the resected specimen showed a white, irregular-shaped mass with a clear margin in the pancreatic body, and a dilated branch pancreatic duct distal to the mass. Microscopic examination showed that the 13 mm × 12 mm mass was composed of moderately differentiated tubular adenocarcinoma with desmoplastic fibrosis limited to the pancreas, and included macroscopic retention cysts (Figures 4A and B). This mass was diagnosed as an ordinary IDC, not derived from IPMN, and minimal intraductal extension of IDC was seen in the MPD compressed by the mass.

A dilated branch pancreatic duct distal to the IDC was lined with low-papillary columnar cells with intracellular mucus; this was diagnosed as intraductal papillary-mucinous adenoma with mild atypia (Figure 4C). The IDC and IPMN were unrelated and were separated by normal epithelium in the MPD. After follow-up for 32 mo, our patient has shown no evidence of recurrence.

## DISCUSSION

This patient demonstrated small IDC concomitant with synchronous IPMN. A branch duct type IPMN without mural nodules is a candidate for regular follow-

**Figure 4** Histopathological findings. **A:** The mass is composed of moderately differentiated tubular adenocarcinoma with desmoplastic fibrosis, resulting in a diagnosis of IDC (HE, original magnification  $\times 20$ ); **B:** The tumor mass includes macroscopic cystic components (\*) lined by normal ductal epithelium, suggestive of retention cysts in carcinoma (HE, original magnification  $\times 1$ ); **C:** The lining of the dilated branch duct is composed of low-papillary columnar cells with copious intracellular mucin, resulting in a diagnosis of branch duct type intraductal papillary-mucinous adenoma with mild atypia (HE,  $\times 40$ ).

up<sup>[1-3]</sup>. Because IPMN is sometimes superimposed on synchronous/metachronous IDC, the entire pancreas should be included in follow-up examinations for IPMN<sup>[2,4]</sup>. In our case, a low-echoic mass seen at the initial US/EUS was misinterpreted as being identical to a cystic dilated branch pancreatic duct seen in other imaging studies, and was clinically diagnosed as a benign IPMN. Therefore, short-term observation and repeated examination were selected.

Although a small IDC is usually depicted as a solid, low-echoic mass on EUS<sup>[5]</sup>, the initial EUS in this case showed an extremely low-echoic mass resembling a cyst with an unclear margin. Histopathologically, the IDC included macroscopic retention cysts. Therefore, we considered the cyst-like mass seen at the initial EUS reflected IDC with retention cysts. It is difficult to diagnose IDC on initial imaging examination, although it is unknown whether transpapillary cytology would indicate malignant cells. However, EUS-guided fine-needle aspiration biopsy (EUS-FNAB) should be performed with caution, because cases of seeding after EUS-FNAB have been reported<sup>[6,7]</sup>. Retrospectively, we ought to have noticed the low-echoic mass that we were following was slowly increasing in diameter, and should have selected surgical resection sooner.

In our case, the tumor volume doubling time of the IDC on US/EUS was 252 d. Furukawa *et al*<sup>[8]</sup> have reported the tumor volume doubling time of IDC on CT scan was  $159 \pm 67$  (median, 144) d, shorter than that in our patient. The reason for this difference may be that the initial diameter of IDCs in their study ranged from 13 to 47 mm, with a mean of 19 mm, and because the final diameter ranged from 15 to 47 mm with a mean of 30 mm, larger than that in our patient. More interesting is the fact the tumor remained smaller than 10 mm in diameter for about 420 d. The Ki67 labeling index in the present case was 15.9%, while that of the previous reports ranged from 14.5% to 29.3%<sup>[9,10]</sup>. Hence, an IDC may grow slowly

while remaining small, although the accumulation of more cases is necessary.

### Abstract

Peliosis hepatis is a rare benign vascular disorder of the liver that may be associated with malignancy, infection and drugs. The imaging manifestation of this disorder is often variable and nonspecific making its diagnosis difficult. We describe a rare case of peliosis hepatis and gummatous syphilis of the liver with emphasis on CT findings. Image characteristics of our patient included pseudotumoral appearance of peliosis hepatis, isodensity to the adjacent liver parenchyma on unenhanced and dual-phase scanning. To our knowledge, peliosis hepatis associated with syphilis and unique enhancement pattern has not been reported. Considering the imaging features of peliosis hepatis, it should be considered in the differential diagnosis of atypical focal hepatic lesion.

### INTRODUCTION

Peliosis hepatis is a rare kind of benign vascular disorder characterized by widespread blood-filled cystic cavities in the liver<sup>[1]</sup>. Occasionally, the lesion mimics tumor. The imaging manifest of this disorder is variable and

nonspecific, making its diagnosis and differential diagnosis difficult. To our knowledge, no study is yet available on peliosis hepatis associated with syphilis. We report a rare case of focal peliosis hepatis and gummatous syphilis, their computed tomography (CT) and ultrasonography (US) findings along with the features of histopathology.

### CASE REPORT

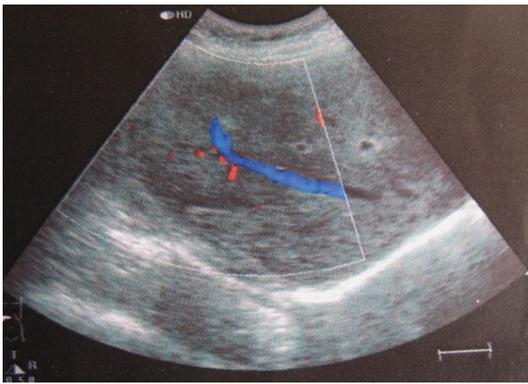

A 44-year-old woman had upper right abdominal pain for 4 months with no hemorrhagic tendency. Physical examination revealed no icteric skin and sclera, no abdominal mass, hepatosplenomegaly and superficial lymph nodes. On admission, treponema pallidum antibody test was positive,  $\alpha$ -fetoprotein (AFP) was normal (1.74 ng/mL, normal range 0-8), routine blood chemistry and serum transaminase values were within the normal limits.

Abdominal ultrasonography showed a heterogeneous hypoechoic mass in the right lobe of the liver and the right hepatic vein was observed crossing the lesion with a normal shape (Figure 1). The hepatic veins, portal veins and other abdominal organs did not show any abnormalities. Unenhanced and contrast-enhanced dual-phase CT examination of the upper abdomen was performed with a 16 channel spiral CT scanner. There was an ill-defined isodensity area measuring 70 mm × 65 mm with punctate calcification in segments V and VI (Figure 2A). The attenuation of contrast in the mass was identical to that in the adjacent liver parenchyma during arterial and portal-venous phase. The center of this area was not enhanced. The right hepatic vein crossed the lesion with a normal shape (Figure 2B and C). Meanwhile, there was a hypo-attenuated lesion (10 mm in diameter) in segment VIII without enhancement at arterial and portal-venous phases (Figure 3). The spleen was normal and no lymphadenopathy was observed in the upper abdominal cavity and retroperitoneal space.

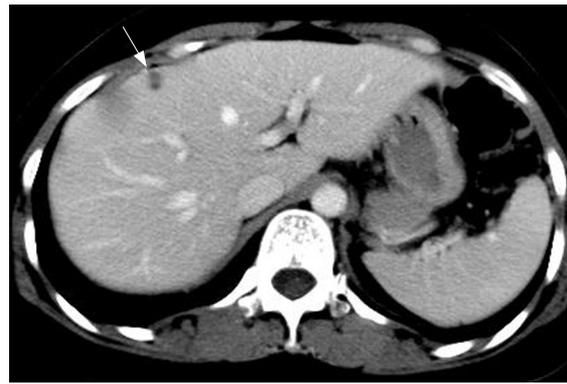

After lobectomy of the right lobe of liver was performed and the resected hepatic specimen was split, a dark violet mass was located in segments V and VI. Histopathology showed a mass with multifocal and irregular blood-filled cystic spaces and ectatic adjacent sinusoids. The histopathological diagnosis was peliosis hepatis (Figure 4), while the hypodensity lesion within segment VIII was a gumma (Figure 5).

### DISCUSSION

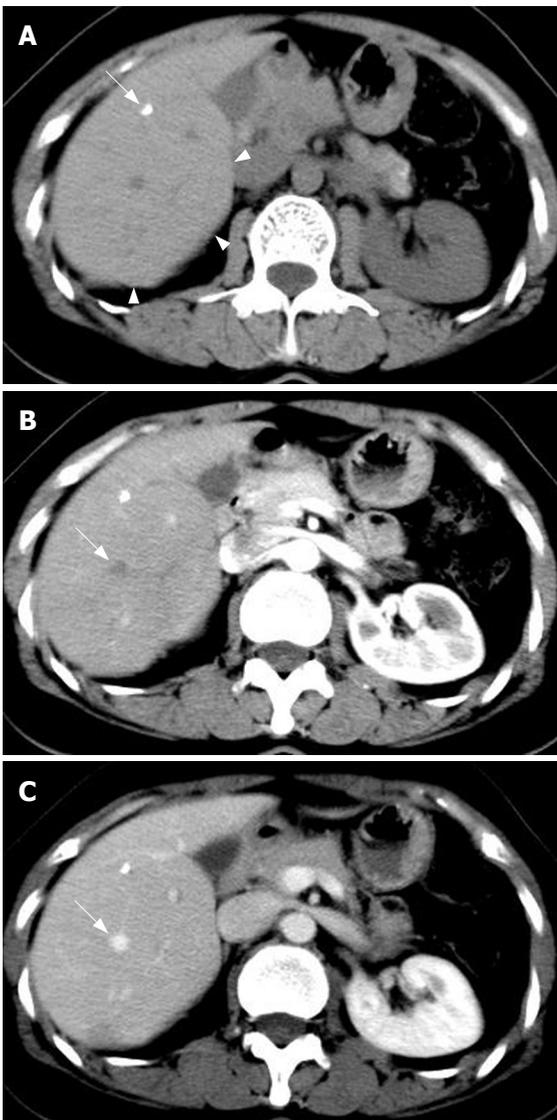

Peliosis hepatic, first described by Wagner and named by Schoenlank, is a rare benign vascular disorder. The lesion

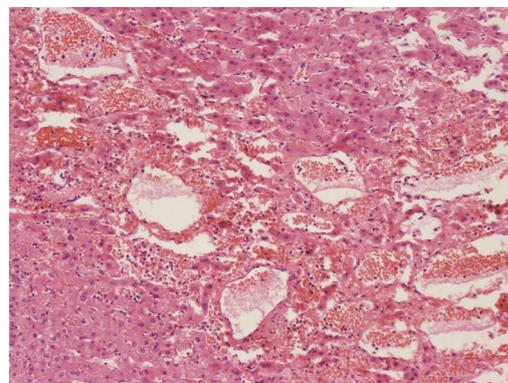

**Figure 1** Doppler sonographic image showing a slightly heterogeneous hyperechoic lesion in the right lobe of liver without mass effect on the right hepatic vein.

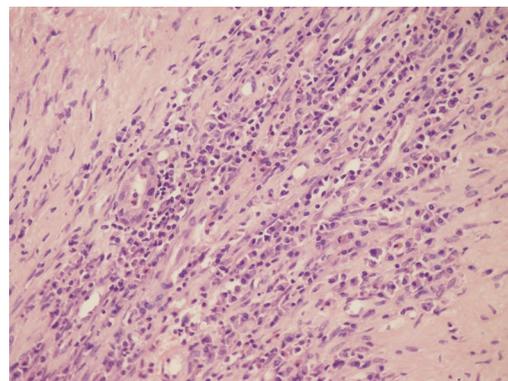

**Figure 3** Portal phase image showing a hypo-attenuated lesion (10 mm in diameter) within segment VIII (arrow). Histopathology proved it to be a gumma.

**Figure 2** Transverse unenhanced CT image showing the protrudent visceral surface which hints a local iso-attenuated lesion (arrowheads) with punctate calcification (arrow) (A), identical density of the lesion to the adjacent liver parenchyma at arterial phase (B) and portal phase (C). The right hepatic vein with a normal shape and location crosses the lesion (arrow).

**Figure 4** Histology of specimens (HE,  $\times 50$ ). Microscopy reveals multiple blood-filled cystic spaces and ectatic sinusoids.

**Figure 5** Gumma on segment VIII characterized by multifocal coagulation necrosis and significant infiltration of plasma cells mixed with lymph cells (HE,  $\times 100$ ).

varies from 1 mm to several centimeters with multiple blood-filled cavities<sup>[2,3]</sup>. The lesions typically involve the

whole liver, but local peliosis hepatis (also called peliosis hepatis pseudotumor) has also been reported<sup>[4]</sup>, like our case. Yanoff and Rawson<sup>[5]</sup> have reported two types of the disease: parenchymal and phlebotactic. The irregularly-shaped blood spaces of the parenchymal type, usually associated with hemorrhagic parenchymal necrosis, are not lined with endothelium. The blood spaces of the phlebotactic type, based on aneurismal dilatation of the central vein, are covered with endothelium and have no hemorrhagic parenchymal necrosis.

The causes for peliosis hepatis are unknown. However,

peliosis hepatis is associated with drugs (anabolic steroids, oral contraceptives, *etc*), malignant tumor (particularly hepatocellular carcinoma), and chronic infections (pulmonary tuberculosis, leprosy and HIV infections)<sup>[2-4]</sup>. Peliosis hepatis accompanying syphilis infection has not, to our knowledge, previously been reported. Syphilis infection may be one of the causes for peliosis hepatis, but their relationship needs to be further investigated.

The clinical manifestations and laboratory examinations of peliosis hepatis are not specific and the imaging features of US, CT and MRI may be helpful for its diagnosis. The imaging findings of peliosis hepatis are variable depending on the pathologic patterns, lesion size, extent of communication with sinusoids, and complications such as thrombosis or haemorrhage within the lesion and concomitant hepatic steatosis<sup>[2-4]</sup>. Conventional gray-scale sonography shows hyperechoic lesions in patients with a healthy liver, homogeneous hypoechoic lesions in patients with hepatic steatosis and heterogeneous hypoechoic lesions if complicated by hemorrhage. Absence of a mass effect on peripheral blood vessels is considered characteristic of a peliosis hepatis pseudotumor<sup>[3,4]</sup>. On unenhanced CT, peliotic lesions usually have multiple areas of low attenuation, calcifications and hemorrhage within the lesions have also been described<sup>[2]</sup>. On MR imaging, the signal intensities of the lesions largely depend on the stage and status of the blood component. On T1-weighted sequence, the lesions are hypo-intense or heterogeneous hypo-intense if complicated by hemorrhage. On T2-weighted sequence, peliotic lesions are usually hyper-intense compared to liver parenchyma. On contrast-enhanced imaging, the lesions show a predominantly central enhancement at the arterial phase and slow centrifugal progression at the portal-venous and delayed phases (the so-called target sign) or an unusual centripetal enhancement pattern similar to hemangioma, from the periphery to the centre. Hemorrhagic parenchymal necrosis and thrombosed cavities manifest as a non-enhancing area. In some instances, small (< 2 cm) peliotic lesions also show hyper-attenuation on both arterial and

portal venous phase images<sup>[2]</sup>. As imaging appearances and laboratory examinations are not specific, biopsy is the only way to make its diagnosis. The lesion of our case showed isodensity and was ill-defined on unenhanced scanning and synchronous enhancement with the liver parenchyma on enhanced CT. The enhancement pattern was different from previous reports. It may be due to the difference in the severity of sinusoids dilatation.

In conclusion, our case is unusual in several respects: (1) peliosis hepatis with syphilitic gumma of the liver, (2) isodensity to the adjacent liver parenchyma on unenhanced and dual-phase scanning, (3) pseudotumoral appearance. Awareness of the imaging features of peliosis hepatis is important to make its diagnosis. Peliosis hepatis should be considered in the differential diagnosis of atypical local hepatic lesion.

## ACKNOWLEDGMENTS

The authors thank Dr. Zhu HB for her valuable advice regarding the pathology of peliosis and gummatous syphilis of the liver and Dr. Song QL for help in the preparation of this manuscript.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1224 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Electronic journal (list all authors)**

Morse SS. Factors in the emergence of infectious diseases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

**Patent (list all authors)**

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Inappropriate references**

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/15.doc>

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

**Editorial Office**

**World Journal of Gastroenterology**

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

**Language evaluation**

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

**Copyright assignment form**

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

**Responses to reviewers**

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

**Proof of financial support**

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

**Links to documents related to the manuscript**

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

**Science news releases**

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

**Publication fee**

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

### Abstract

Wireless capsule endoscopy is a new technique that allows complete exploration of the small bowel without external wires. Its role has been analyzed in many small bowel diseases such as obscure gastrointestinal bleeding, Crohn's disease and gastrointestinal polyposis syndromes with promising results. Studies on other pathologies (i.e. small bowel tumour, celiac disease) are under evaluation to define the role of this technique.

Mata A, Llach J, Bordas JM. Wireless capsule endoscopy. *World J Gastroenterol* 2008; 14(13): 1969-1971 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1969.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1969>

The need and wish to perform endoscopic examination of the small bowel have led to the development of an ingestible miniature camera device capable of obtaining images of the whole small intestine.

Wireless capsule endoscopy is a new type of radiotelemetry video system which is small enough to be swallowed and has no external wires, fiberoptic bundles or cables. It measures 11 mm × 26 mm and weighs 3.7 g. By using a lens of a short focal length, images are obtained as the optical window of the capsule sweeps past the gut wall, without requiring air insufflation of the gut lumen. The capsule is propelled by peristalsis through the gastrointestinal tract and does not require a pushing force to propel it

through the bowel. Up to 2002, more than 250 000 capsule explorations had been performed<sup>[1]</sup>, and nowadays this number has increased significantly.

The M2A capsule [Mouth to (2) Anus] initially, and Pillcam SB (Small Bowel) later, from GIVEN (GastroIntestinal Video Endoscopy, Given Imaging Limited, Yoqneam, Israel), and endocapsule from Olympus are the capsules that have been approved for use in the clinical setting. Each capsule contains a lens, light emitting diodes (LEDs), a color camera, 2 batteries, a radio frequency transmitter and an antenna. The camera takes 2 images per second and transmits these by means of radio frequency to a sensor array in a belt placed around the patient's abdomen and from there to a recording device in the belt. Once the study is completed (between 6 and 8 h), the recording device is removed and the images are downloaded to a computer workstation with software that displays the video images on a computer monitor.

Capsule endoscopy can be performed as an outpatient procedure. Small bowel preparation is still a controversial issue. Some groups used fasting or clear liquids for 10 to 12 h (or even for 24) before the study, although some studies suggest that bowel preparation (with 2 or 4 litres of polyethylene glycol based electrolyte solution or oral sodium phosphate preparation) improves the visualization of the small intestine<sup>[2,3]</sup>. A recent Spanish prospective multicenter trial published in abstract form, has shown that all three strategies have similar results<sup>[4]</sup>.

The role of wireless capsule endoscopy has been analyzed in patients with obscure gastrointestinal bleeding and in comparative studies with endoscopic<sup>[5]</sup> or radiographic methods<sup>[6]</sup>. Capsule endoscopy has shown a diagnostic yield of 71% compared to 29% of push enteroscopy, in a recent analysis of 7 prospective studies<sup>[7]</sup>. Another study has shown that the detection rate of capsule endoscopy is higher in patients with ongoing overt bleeding than in those with anemia or prior overt bleeding<sup>[8]</sup>. In a comparative study with intraoperative enteroscopy, the sensitivity, specificity, positive and negative predictive value of capsule endoscopy were 95%, 75%, 95% and 86%, respectively<sup>[9]</sup>. For obscure gastrointestinal bleeding, capsule endoscopy has shown better results than radiographic studies, which have a low diagnostic yield in detecting small bowel lesions<sup>[6,10]</sup>.

Capsule endoscopy has also shown its usefulness in the evaluation of the small intestine in patients with suspected or known Crohn's disease<sup>[11]</sup>, and is superior to small bowel follow-through<sup>[12-14]</sup>, enteroclysis<sup>[15,16]</sup>, push enteroscopy<sup>[16]</sup> and CT enteroclysis<sup>[17]</sup> for identifying small intestinal dis-

ease. The sensitivity and specificity of capsule endoscopy have recently been estimated to be 89.6% and 100%, respectively<sup>[18]</sup>.

However, the diagnostic criteria of capsule endoscopy for Crohn's disease have not yet been defined. Mucosal breaks and aphthous ulcers or erosions are also seen in asymptomatic healthy volunteers, and small bowel ulcers and strictures have been associated with the use of nonsteroidal anti-inflammatory agents, making it, at times, difficult to differentiate these findings with the presence of a Crohn's disease<sup>[9]</sup>.

Capsule endoscopy has been performed in patients with gastrointestinal polyposis syndrome, and several studies have suggested that it may be useful in the detection of small bowel polyps<sup>[19,20]</sup>. A comparative prospective study showed that capsule endoscopy can detect more polypoid lesions than small-bowel follow through in these patients<sup>[21]</sup>. Nevertheless, more prospective studies with longer follow-up are required, to define the role of capsule endoscopy findings in the outcome of patients with gastrointestinal polyposis syndrome.

Capsule endoscopy in the pediatric population and esophageal capsule endoscopy (Pillcam ESO) have shown promising results but larger prospective trials are needed to define their role in these patients.

Other possible indications for capsule endoscopy, such as celiac disease, HIV positive patients with gastrointestinal symptoms, mal-absorption or small bowel transplantation, have not been defined so far, and more prospective trials assessing the use of capsule endoscopy in these groups of patients are still needed.

The main contraindication of performing the capsule endoscopy procedure is the suspicion or knowledge of a gastrointestinal obstruction, stricture or fistula. Other former contraindications such as implanted cardiac pacemakers or other electro-medical devices and patients with swallowing disorders have been excluded since some studies showed no interference between capsule endoscopy and pacemaker or implantable defibrillators functioning<sup>[22,23]</sup> and endoscopic placement of the capsule into the gut<sup>[24]</sup>.

The capsule retention rate varies with the indication of the examination, being reported of 1.5% in patients with obscure gastrointestinal bleeding<sup>[25]</sup> and 5% in patients with suspected Crohn's disease<sup>[26]</sup>, who are usually asymptomatic<sup>[10,25]</sup> and may require endoscopic removal or surgery. How to prevent capsule retention has yet to be defined since neither radiologic studies nor the "patency capsule" has shown conclusive results so far. The clinical setting of each patient, as well as some features related to intestinal strictures (previous small bowel surgery, NSAIDs, suspected small bowel Crohn's disease), have to be analyzed prior to the study. Patients should be informed about the possibility of capsule retention and further treatment.

### Abstract

Although the aetiology of inflammatory bowel disease (IBD) remains unknown, the pathogenesis is gradually being unravelled, seeming to be the result of a combination of environmental, genetic, and immunological factors in which an uncontrolled immune response within the intestinal lumen leads to inflammation in genetically predisposed individuals. Multifactorial evidence suggests that a defect of innate immune response to microbial agents is involved in IBD. This editorial outlines the immunopathogenesis of IBD and their current and future therapy. We present IBD as a result of dysregulated mucosal response in the intestinal wall facilitated by defects in epithelial barrier function and the mucosal immune system with excessive production of cytokines growth factors, adhesion molecules, and reactive oxygen metabolites, resulting in tissue injury. Established and evolving therapies are discussed in the second part of this editorial and at the end of this section we review new therapies to modulate the immune system in patients with IBD.

### INTRODUCTION

The intestinal mucosa constitutes an immunologic system in which oral tolerance and defence against harmful organisms develop<sup>[1]</sup>. The mucosal immune system, which plays a pivotal role in host defence, is continuously exposed to large amounts of exogenous (i.e., dietary) and endogenous (e.g., bacterial) antigens<sup>[2]</sup>. Activation of lamina propria (LP) T cells by lumen antigens may lead to the production of inflammatory cytokines and subsequent mucosal inflammation and tissue damage<sup>[3,4]</sup>. Dysfunctions of the intestinal immune system and cross-reactivity against host epithelial cells have been implicated as major mechanisms by which inflammation occurs<sup>[5]</sup>. In addition to immune factors as leukocytes, macrophages, polymorphonuclear cells, mast cells, B and T lymphocytes, other potential mediators of inflammation are involved in the disease: eicosanoids, biological amines, cytokines, nitrogen- and oxygen-reactive metabolites, platelet-activating factor have been noted to influence inflammatory processes<sup>[6]</sup>. Among environmental factors, antigens to intestinal bacteria play an important role. The loss of tolerance to intestinal bacterial flora is manifested as an abnormal immune response<sup>[7]</sup>. Accordingly, inflammatory bowel disease (IBD) could be considered to be an imbalance between pro-inflammatory and anti-inflammatory mediators<sup>[3]</sup>. The following editorial summarizes the current view of the immunopathogenesis basis of IBD in relation to barrier disruption, immune deregulation genetic epidemiology and susceptibility to environmental dysregulation, triggers and its implications for therapies.

### EPIDEMIOLOGY AND CLINICAL FEATURES

IBD like ulcerative colitis (UC) and Crohn's disease (CD), comprises a group of multifactorial intestinal disorders with high incidence throughout the human population<sup>[8]</sup>. The highest incidence rates and prevalence have been reported in northern Europe and North America. The disease is characterized by cycles of clinical exacerbation and remission, with periods of improvement followed by relapse, and appears to be immunologically mediated<sup>[12]</sup>. UC and CD show some overlapping clinical features, and in 10%-15% of cases it is not possible to differentiate between the two diseases. But also, differences exist in the nature and location of the lesion damage between UC and CD. While UC is restricted to the large intestine and is associated with continuous mucosal inflammation, including crypt abscesses as well as ulcers, which typically

**Table 1 IBD immunopathogenesis**

Reactive oxygen species (ROS)
Antioxidant defence system

spread from the most caudal part of the rectum, CD can affect any part of the gastrointestinal tract and is characterized by segmental and transmural inflammation, fistulas, oedema and granulomas in whole intestinal wall<sup>[13]</sup>.

At the histological level, various abnormalities have been observed in patients with IBD and in experimental models of intestinal inflammation including the presence of a significant number of neutrophils within the lamina propria and the crypts, where micro-abscesses can form, the depletion of goblet cell mucin, induced by disturbed transformation of undifferentiated cells in an environment exposed to inflammatory cytokines, damage to the nervous system<sup>[13,14]</sup> and hypertrophy of smooth muscle cells<sup>[15]</sup>. Intestinal inflammation alters the contractile activity of intestinal smooth muscle, and the motility disorders induce abnormal growth of the intestinal flora, resulting in disturbance of the intestinal flora that can aggravate the pathogenesis of mucosal inflammation<sup>[16]</sup>.

## GENETIC FACTORS

The discovery of susceptibility genes to IBD have shown the importance of (1) dysregulation of the innate immune response to enteric microflora or pathogens; (2) increased permeability across the epithelial barrier, and (3) defective regulation of the adaptive immune system of epithelial barrier function in disease pathogenesis. IBD is considered a complex polygenic disease and its susceptibility genes could interfere with the disease and with the response to different therapies.

Strong evidence for genetic factors has been reported contributing to IBD susceptibility<sup>[17]</sup>. IBD is thought to be caused by the mutual reactions among host susceptibility genes (CARD15/NOD2, CARD4/NOD1, HLA, TLR4, DLG5, NF- $\kappa$ B1), environmental factors including enteric flora and food antigens, and abnormal immune balance<sup>[9-11]</sup>. The genetic contribution may be more important in CD than UC with multiple gene products contributing to risk<sup>[18]</sup>. Identifying NOD2 as a susceptibility gene in CD and additional susceptibility loci have been implicated in IBD such as IBD5, IL23R and ATG16L1 among other loci<sup>[19-21]</sup>. The number of potential gene continues to increase, additional novel loci map to chromosomes 16q24.1, TNFSF15, NKX2-3 and the intergenic region on chromosome 10q21.1 might contribute to the IBD<sup>[22]</sup>. Future genetic research may include focus on phenotypes, control for environmental variables and gene-gene interactions.

## PATHOGENESIS OF IBD

There is compelling evidence that dysregulation of the

mucosal immune system is a major factor contributing to the pathogenesis of IBD<sup>[13]</sup>. The pathogenesis of these diseases is understood to represent the outcome of three essential, interactive cofactors: host susceptibility, enteric microflora and mucosal immunity<sup>[12,13]</sup>. The basis of IBD is the presence of genetically determined alterations that result in a mucosal immune system that overreacts to normal intestinal microflora. These immune responses may be induced by defects in the epithelial barrier, and increased intestinal permeability, adherence of bacteria, and decreased expression of defensins<sup>[12]</sup>.

The mucosal immune system senses and interprets the local microenvironment, recognizing and avoiding reactions to commensal flora (tolerance), whilst retaining its capacity to respond to episodic challenge from pathogens<sup>[1,2]</sup>. Increased synthesis and release of pro-inflammatory mediators such as cytokines, chemokines, eicosanoids, platelet activating factor, reactive oxygen and nitrogen metabolites, as well as other abnormalities have been in IBD<sup>[6]</sup>. We described IBD as a result of dysregulated mucosal response in the intestinal wall facilitated by defects in epithelial barrier function and mucosal immune system with excessive production of cytokines growth factors, adhesion molecules, and reactive oxygen metabolites, resulting in tissue injury (Table 1).

## DYSREGULATED IMMUNITY

### Cytokines

Alterations in the production of many cytokines have been described in patients with active IBD<sup>[23]</sup>. The significance of these findings in the pathogenesis of IBD remains poorly understood and controversy has continued as to whether these changes really represent a primary defect in the regulation of the immune system or are a secondary consequence of immune activation<sup>[6]</sup>.

The nature of the immune response and the cytokine profile generated are under genetic control and determine the features of the inflammatory process in IBD. In active IBD the balance of regulatory and effector cells is disturbed, predominating effector T cells (Th1, Th2) over regulatory T cells (Th3, Tr). CD has been associated with type 1 helper T-cell cytokines (Th1), such as interferon- $\gamma$ , TNF- $\alpha$  and IL-12<sup>[24,25]</sup>. In ulcerative colitis, the pattern of cytokine is less clear; there is a modified Th2 response associated with cytokines such as IL-15 and IL-10<sup>[25,27]</sup>. Among the cytokines involved, Interleukin-10 is a regulatory cytokine which plays a crucial role in the balance of the mucosal immune system, promoting physiological activation and preventing the pathological inflammation that characterizes the inflammatory bowel diseases<sup>[26]</sup>. The immuno-regulatory activity of IL-10 is based upon its ability to inhibit both cytokine synthesis and antigen presentation, with maintenance of intestinal immunoregulation and tolerance to components of intestinal flora, controlling the inflammatory responses to intestinal antigens<sup>[26]</sup>.

This pathophysiological concept for IBD is changing as a result of recent advances with the description of another type of effector immunologic response CD4+ Th pathway, namely interleukin-23/interleukin-17 axis. IL-23

is produced by antigen-presentation cells and promotes a population of T lymphocytes that produce IL-17, IL-6 and TNF- $\alpha$  (Th17 cells)<sup>[27,28]</sup>. These IL-23-driven CD4+ T cells are highly inflammatory and elicit IL-17-dependent autoimmunity. IL-17 is an inflammatory cytokine expressed by activated CD4+ T cells and triggers the NF- $\kappa$ B signalling cascade and MAP kinase pathway, leading to T cells proliferation and up-regulation of inflammatory molecules<sup>[29]</sup>. Recent publications have reported that the IL-23/IL-17 pathway may have a pivotal role in intestinal inflammation<sup>[30,31]</sup>. These findings demonstrate that IL-23, but not IL-12, is essential for the development of intestinal inflammation in IBD. In addition, levels of expression of IL-23 and IL-17 are increased in patients with CD<sup>[32]</sup>. Recently, the study of Duerr *et al*<sup>[33]</sup> reported a significant association between CD and a gene on chromosome 1p31 that encodes a receptor for IL-23 (*IL-23R*) that is highly expressed by memory T cells.

Also, the interesting works of Bamias *et al*<sup>[34]</sup> and Prehn *et al*<sup>[35]</sup>, respectively, have described a novel TNF-like cytokine co-stimulator of IFN- $\gamma$ , namely TL1A that play an important role in mucosal inflammation and in experimental ileitis. TL1A is expressed in dendritic cells and acts on CD4+ cells and provides co-stimulation for proliferation of IFN- $\gamma$  and is up-regulated in patients with active IBD. A single nucleotide polymorphism in the gene encoding TL1A (*TNFSF15*) confers susceptibility to CD<sup>[36]</sup>.

### **Mucosal epithelial barrier function**

The polarized epithelial cells provide a crucial barrier function, with high concentrations of dietary and bacterial antigens at the apical surfaces in the mucosa and with high concentrations of lymphoid cells at the basolateral surface<sup>[37]</sup>. The intestinal epithelium is considered a constitutive component of the mucosal immune system. Intestinal epithelial cells (IECs) are connected by tight junctions, which are dynamically regulated in response to cytokines and are down-regulated by the junctional complexes in human IBD (E-cadherin and  $\beta$ -catenin)<sup>[38]</sup>. The epithelium is in constant communication with luminal flora and the underlying network of innate and adaptive immune cells, and IECs constitutively express or can be induced to express costimulatory molecules<sup>[39]</sup> and components of the human major histocompatibility complex (MHC)<sup>[40]</sup>, toll-like receptors (TLRs)<sup>[41]</sup>, NOD proteins<sup>[42]</sup>, inflammatory cytokines<sup>[43]</sup>, as well as antimicrobial peptides<sup>[44]</sup>.

IECs contribute to the initiation and regulation of innate and adaptive defence mechanisms by interacting with lamina propria dendritic cells (DC), lamina propria lymphocytes (LPL), intraepithelial lymphocytes (IEL) and mediators of the immune and the enteric nerve system<sup>[45]</sup>. IECs such as non-professional antigen-presenting cells might interact with naïve T cells (Th0) through MHC II receptors, and produce co-stimulatory signals suppressing or inducing anergy in mucosal T cells<sup>[46]</sup>. The epithelial barrier is leaky in IBD and has a lower epithelial resistance and increased permeability that enables the proliferation of non-pathologic organisms (normal microflora) in close juxtaposition to elements of the mucosal immune system.

Also, IBD have disturbed innate immune mechanisms of the epithelial layer and mucosal epithelial cells have a different pattern of TLR expression<sup>[47]</sup>. Also, an up-regulation of NOD2 in IECs and disturb in antigen recognition and processing by antigen-presenting cells are present in patients with IBD<sup>[48]</sup>.

Paneth cells secrete antimicrobial peptides, including  $\alpha$ -defensins that play an important role in innate intestinal defences. The Paneth cell deficiency in  $\alpha$ -defensins increases the risk of CD and polymorphism in the defensin gene associated with CD<sup>[49]</sup>.

Goblet cells are also an important component of the epithelium and are responsible for defence and epithelial mucosal repair in colitis. Defects in mucus production have been reported in IBD<sup>[50,51]</sup>.

The adaptive immune response in IBD failure to balance, and the DCs might be responsible for a dysregulated innate immune response<sup>[52]</sup>. DCs are the primordial cells in controlling immunity against pathogens and tolerance towards commensals and are dominant subsets of antigen-presenting cells in the intestinal lamina propria<sup>[53]</sup>. DCs penetrate their dendrites between epithelial cells to sample luminal antigens without altering the mucosal barrier and they contain components of commensal bacteria. Depending upon the nature of the antigen and the activation state of DCs, the end result may be immune activation or tolerogenic action<sup>[54]</sup>. DCs also have an important role in mucosal inflammation through the production of cytokines, resulting in persistent activation of effector T cells<sup>[55]</sup>.

An increase in intraepithelial lymphocytes (IEL) appeared in IBD and the activation of these IELs could be responsible for: (1) defending the mucosal barrier against intraluminal microorganisms, (2) modulation on epithelial cells of the expression of MHC antigens, or (3) non-MHC as well as MHC-restricted cytotoxicity<sup>[56]</sup>. The increase of IELs is known to be associated with an abnormal expression of class II MHC molecules on surface and crypt colon epithelial cells. Helper T cells could trigger an MHC-restricted immune mechanism.

### **Oral tolerance**

In an antigenic environment like intestine, the mucosal immune system must maintain tolerance to commensal bacteria, food and self antigens and must be able to initiate defence responses to pathogens. Studies have suggested that IBD is a consequence of the breakdown of mucosal tolerance and tolerance to normal flora is broken<sup>[57]</sup>. DCs in conjunction with antigen-specific T lymphocytes trigger the maintenance of immune tolerance. Activation of intestinal NKT cells by CD1d-expressing IECs and professional antigen presenting cells (DC cells) may contribute to induction of oral tolerance<sup>[58,59]</sup>.

In IBD, atypical antigen-presenting cells become potent effector-T-cell activators, and the IECs can act as antigen-presenting cells capable of stimulating primed T cells which acquire an activated phenotype with increased histocompatibility molecule expression in the presence of inflammatory cytokines<sup>[60]</sup>. IECs might also activate T cells *via* non-classical MHC. Our research group has previously shown that intestinal epithelial cells expressing HLA-G at

the apical surface of the epithelial layer and at crypt level in ulcerative colitis, but not in CD<sup>[61]</sup>. HLA-G is a non-classical major histocompatibility complex class I, which is selectively expressed at the maternal-foetal interface of cytotrophoblast cells and protects the foetus from maternal rejection and creating a general state of tolerance<sup>[62]</sup>.

Non-typical antigen-presenting cells, as epithelial cells, might acquire an activated phenotype with increased expression of HLA-G in the presence of inflammatory cytokines as IFN-gamma and TNF-alpha and might activate T cells *via* non-classical MHC molecules as HLA-G<sup>[61]</sup>. In UC the specific expression of HLA-G, considered as a molecule implicated in tolerance immunity will be of great importance in the maintenance of the tolerance to fed antigens and of gut microflora and support the notion that it may serve as a regulator of mucosal immune responses to antigens of undefined origin.

## REACTIVE OXYGEN SPECIES (ROS)

The intestinal mucosa is vulnerable to oxidative stress from constant exposure to reactive oxygen species (ROS) generated by the lumen contents such as oxidized food debris, transition metals such as iron and copper, bacterial metabolites, bile acids and salivary oxidants<sup>[63]</sup>. A balance is maintained between oxidant and antioxidant systems under physiological conditions, but it is impaired in pathological success. Oxidant-mediated injury plays an important role in the pathophysiology of IBD<sup>[64]</sup>. It has been suggested that intestinal damage in IBD is related to increased free radical production and to impaired antioxidant defence systems<sup>[65]</sup>. There are an increased number of activated inflammatory cells in lamina propria of IBD releasing reactive oxygen radicals that are highly produced by neutrophils, macrophages and DCs<sup>[63]</sup>, and exceeds the limited intestinal antioxidant defence system, contributing to intestinal oxidative injury in IBD<sup>[64]</sup>.

Our research group has undertaken to determine whether the small intestine is subjected to oxidative damage during experimental IBD induced by administration of TNBS, as well as, to examine the accompanying changes in antioxidant status, in order to understand its role in the pathogenesis of disease.

TNBS may be metabolized to yield superoxide anion (O<sub>2</sub><sup>-</sup>), and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), suggesting that TNBS-induced intestinal inflammation may be partially mediated by cytotoxic reactive oxygen metabolites generated by the oxidative metabolism of TNBS<sup>[66]</sup>. We evaluated the activity of the antioxidant enzymes catalase (CAT), glutathione peroxidase (GPX), glutathione reductase (GR), glutathione transferase (GT) and superoxide dismutase (SOD), as well as the levels of total glutathione (GSH). We found that GSH levels and SOD activity decreased in animals administered TNBS. These result are in agreement with studies in human IBD, that have been reported a decreased superoxide dismutase activity, as well as low total glutathione levels.<sup>[67]</sup> Decreased GSH in gut epithelial cells may increase susceptibility to oxidative injury and exacerbate degeneration of the intestinal mucosa<sup>[28]</sup>. Therefore, the elevated activities of glutathione peroxidase (GPX) and catalase (CAT) enzymes observed suggest that TNBS led to the formation of high levels of peroxides, including H<sub>2</sub>O<sub>2</sub>, increasing tissue injury<sup>[68]</sup>.

Nutritional deficiencies have been reported in IBD, such as lower levels of vitamins A, E and C, important natural antioxidants for the organism, as well as a decrease in trace elements such as zinc and selenium, which are crucial components of several antioxidant enzymes such as SOD<sup>[69]</sup>.

## MEDICAL MANAGEMENT BASED ON PATHOGENESIS

The main goal of therapy for IBD is to induce a clinical remission and then maintain it for a long period of time, in order to realize the best attainable quality of life. Choice of therapy depends on the severity and location of disease, as well as side effects and other adverse events. Although 5-aminosalicylates, corticosteroids and immunosuppressive drugs are generally used in the treatment of IBD, there are an important numbers of the patients who are not controlled by these conventional therapies<sup>[70]</sup>, indicating a considerable need for develop new and more effective therapy. Treatment with anti-diarrhoeal agents, proper nutrition, antagonistics of activation platelets factors, flavonoids, probiotics and prebiotics can be efficient, but also, a growing number of new biological agents are under investigation, as monoclonal antibodies to antisense mRNA products, peptides and vaccines among others. In Table 2 we summarised medical management based on pathogenesis.

### Dietary nutrients

Dietary management of IBD may be an interesting alternative to drug therapy if it proves to be effective without side effects and can be used as a remission induction and maintenance therapy<sup>[71]</sup>. Nutrients may be involved in the modulation of the immune response, thus, as components of cell membranes, nutrients can mediate the expression of proteins involved in the immune response, such as cytokines, adhesion molecules, *etc*<sup>[71]</sup>.

A potential relationship between components of the

diet and disease pathophysiology has been considered, and immunologic mechanisms have been postulated to link food antigens and the development of intestinal inflammation. Some reports have suggested that consumption of refined sugar might be a risk factor for CD, but not UC<sup>[72]</sup>. Fat intake has been reported to be positively associated with UC, whereas fruit, vegetables, and fiber consumption seem to decrease the risk of IBD<sup>[73]</sup>.

### **Polyunsaturated fatty acids (PUFAs)**

The composition of lipids in the cell membrane is modified by dietary changes and can influence cellular responses. Dietary lipids are one of the most active nutritional substrates modulating the immune response. The link between fatty acids and inflammation is that the eicosanoid family of inflammatory mediators is generated from PUFAs<sup>[74]</sup>. Long chain n-3 PUFAs decrease the production of inflammatory eicosanoids, cytokines and adhesion molecules, inhibiting the arachidonic acid metabolism and altering the expression of inflammatory genes across effects on transcription factor activation and intraluminal bacterial content<sup>[75]</sup>.

Several studies have shown that patients with IBD had an abnormal plasma phospholipids fatty acid profile<sup>[76,77]</sup>. The loss of the omega-3 fatty acids which increases the n-6. n-3 ratio, would lead to a predominance of proinflammatory eicosanoids. In an experimental model of IBD induced by rectal administration of TNBS when the animals received dietary n-3 PUFAs, they showed beneficial effect by competing with n-6 PUFAs for the production of lipid inflammatory mediators such as leukotrienes (LTB<sub>4</sub>), thromboxane (TXA<sub>2</sub>), Prostaglandins (PGE<sub>2</sub>) and cytokines<sup>[77]</sup>. The restoration of GSH levels after administration of the n-3 PUFAs demonstrated the decrease in oxidative stress. It was suggested that dietary PUFAs could affect mucosal adhesion sites for gastrointestinal bacteria by modifying the composition of the intestinal wall and as a result, the dietary PUFAs could modulate the probiotics action<sup>[78]</sup>.

Although LC-PUFA may be of interest in the dietary management of IBD, these fatty acids are highly susceptible to peroxidation, and indeed they may influence the antioxidant defence system. To overcome lipid peroxidation by products and cell damage from diets supplemented with PUFAs, appropriate antioxidants should be provided.

### **Dietary fiber**

Several studies have shown that dietary fiber actively contributes to the intestinal anti-inflammatory effect, supporting its potential role in the treatment of IBD. Their therapeutic effect is associated with an increased production of short-chain fatty acids, mainly acetate, propionate and butyrate in the colonic lumen and with the promotion the use of these fatty acids, specifically butyrate by colonic epithelial cells<sup>[79]</sup>. The result is the restoration of the metabolic function of the intestinal cells by aerobic ATP production after butyrate oxidation by epithelial cells that accelerate the intestinal repair preserving the integrity of the intestinal mucosa and downregulating the exacerbated immune response presented in IBD<sup>[80]</sup>.

The dietary fiber associated with the production of short-chain fatty acids, also can contribute to the inhibition of the production and release of proinflammatory cytokines, including IL-6, IL-8, TNF-alpha, and other mediators of inflammation as reactive oxygen and nitrogen metabolites (NO production)<sup>[81]</sup>.

### **Probiotics and prebiotics**

IBD represent a malfunction of tolerance to the commensal microbiota, for this reason attention is focused on this relationship as a potential therapeutic action. Therapies such as prebiotic and probiotics that selectively manipulate the gastrointestinal microbiota present an attractive treatment in IBD with maintenance of remission and without major side effects. Some evidences support that the use of probiotics and prebiotics in IBD need to use standardized methodology to confirm their utilization as therapy<sup>[82]</sup>.

### **Probiotics**

The human intestine contains different bacterial species, named intestinal microflora that plays a critical role in maintaining intestinal health. This intestinal microflora protects against pathogens and maintains the epithelial barrier integrity<sup>[83]</sup>. The functions of these bacteria include control of proliferation and differentiation of IECs and development and balance of the immune system.

Probiotics are living microorganisms that upon ingestion in specific numbers have beneficial effect and exert their therapeutic effects to modulate the barrier function, the inhibition of pathogenic bacteria, the intestinal production of cytokines, with anti-inflammatory properties and enhancement of the digestion and absorption of food<sup>[83,84]</sup>.

### **Prebiotics**

Prebiotics are selectively fermented short-chain carbohydrates that allow specific changes in the composition and activity of the microbiota in the gastrointestinal tract and confers health benefits, these include fructo-oligosaccharides and galacto-oligosaccharide<sup>[85,86]</sup>. Prebiotics have been shown to enhance the immunoregulatory bacteria of lumen, to reduce the activity of pro-inflammatory transcription factors and attenuate the inflammation. In this sense prebiotics produce butyrate and acetate that inhibit, mucosal inflammation, acting on epithelial and DCs function<sup>[87]</sup>.

### **Flavonoids**

Flavonoids are polyphenolic compounds that occur ubiquitously in foods of plant origin and exert antimicrobial, antiviral, antineoplastic, antihepatotoxic, hypolipidemic, antiallergic and anti-inflammatory features<sup>[88]</sup>. Biochemical investigations of flavonoid mechanisms have demonstrated that these compounds inhibit a wide variety of enzymatic systems. Variations in the heterocyclic ring C give rise to flavonols, such as morin.

Morin (2',3,4',5,7-pentahydroxyflavone, flavonol) is a yellowish pigment extractable from the wood of *Chlorophora tinctoria* and acts as a broad-spectrum and non-toxic antioxidant<sup>[89]</sup>. Our laboratory analyzed the effects of morin on experimental TNBS-induced IBD

in rats. Oral administration of morin, at doses ranging from 10 to 200 mg/kg, significantly reduced the mucosal damage by 20%-40% induced by the TNBS experimental model of IBD, although these beneficial effects were not dose-related. Morin reduced the enzymatic activity of myeloperoxidase (MPO) (marker of neutrophil infiltration) and can be interpreted as a manifestation of this anti-inflammatory property<sup>[89]</sup>. Also, significantly inhibited LTB<sub>4</sub> synthesis, and this inhibition was maximal at the highest dose of morin assayed (200 mg/kg). Also, morin reduces colon oxidative stress induced in the TNBS model. This reduction may be explained on the basis of its ability both to inhibit free-radical production and to scavenge free radicals once they have been released and by inhibition of colon LTB<sub>4</sub> synthesis.

### **Antagonistic platelet-activating factor**

Sulphasalazine, a diazo compound with 5-aminosalicylic acid (5-ASA) linked to sulphapyridine that acts as a carrier, has been used as therapy for IBD. This agent is useful in maintaining remission by prevention of relapses in patients with IBD<sup>[90]</sup>. Unfortunately, long-term administration of sulphasalazine is accompanied by a considerable number of side-effects, either dose-dependent such as nausea, vomiting, headache, *etc.*, or allergic such as cutaneous rashes, exanthema, fever, *etc.*

Several mechanisms have been postulated as being involved in the intestinal anti-inflammatory effect exerted by 5-ASA derivatives, including antioxidant and/or radical scavenging properties, inhibition of leukocyte chemotaxis and inhibition of IL-1 synthesis<sup>[91]</sup>. It has been shown that colon mucosa from patients with IBD produces high levels of platelet-activating factor (PAF) with an important role in the pathogenesis of IBD, its inhibition by specific antagonists may have a potential therapeutic benefit in the treatment and management of these inflammatory diseases<sup>[91]</sup>.

UR-12746 is a compound which combines 5-ASA and UR-12715 through an azo link, and possesses antagonist PAF activity. We demonstrate the therapeutic efficacy of UR-12746 when administered orally at doses of 50 and 100 mg/kg in acute and chronic stages of the TNBS model of IBD<sup>[92]</sup>. The intestinal anti-inflammatory effect of UR-12746 was associated with a decrease in leukocyte infiltration in the colon mucosa and with a reduction in myeloperoxidase activity. This effect was higher than that seen with sulphasalazine, when assayed at the same doses and in the same experimental conditions. This result suggests that the intestinal anti-inflammatory activity of UR-12746 by inhibition of leukotriene B<sub>4</sub> synthesis in the inflamed colon, improvement of the altered colon oxidative status, and reduction of colon IL-1 $\beta$  production. Treatment with UR-12746 was able to ameliorate the altered colon oxidative status by significantly increasing glutathione content and by reducing the colon malonyldialdehyde levels<sup>[92]</sup>.

### **Future in therapy: Modulation of the immune response and biologic therapies**

Advances in the understanding of IBD pathogenesis have allowed the development of novel therapies, which at least

theoretically represent a more specific management of the disease with fewer side effects. The real future in therapy should be to develop an approach to prevention of the initiation and perpetuation of the inflammatory status before tissue damage success, involving the induction of tolerance, commensal flora, generation of regulatory T cells and gene transfer, among others. Between these therapeutics factors, the immunosuppressors like calcineurin inhibitor (tacrolimus and cyclosporine), that suppresses pro-inflammatory cytokine production and T-cell activation, have been used to treat inflammatory bowel disease, especially in refractory ulcerative colitis, and to treat an extra-intestinal manifestation of IBD<sup>[93]</sup>. Understanding the role of cytokines has been an important advance in IBD therapies, along with the monoclonal antibody technology, which made possible the targeted inhibition of specific disease related cytokines. Also, it has been possible to give inhibitory cytokines as therapeutic agents<sup>[94]</sup>. The blockage of proinflammatory cytokine TNF-alpha (anti-TNF- $\alpha$  monoclonal antibody) serves as a model for development of new therapy<sup>[94]</sup>. In this sense, the use of infliximab inhibits the bioactivity of TNF-alpha by directly binding to the cytokine and also modulates the function of TNF-alpha-producing cells<sup>[95]</sup>. Many case reports have been published on the use of infliximab for treating patients with extraintestinal manifestations of IBD<sup>[96]</sup>.

Other potential modes of therapeutic actions in IBD include the induction of the anti-inflammatory cytokines IL-10 or TGF-beta *via* retrograde signalling or induction of a certain subset of regulatory T cells<sup>[97]</sup>. The IL-23 pathway has been a target of antibody blockade<sup>[40]</sup>. Further research is needed to know how the *IL-23R* gene and the IL-23/IL-17-mediated inflammatory axis contribute to disease susceptibility and will lead to therapeutic interventions.

The process of T-cell activation, by enhancing regulatory T cells as opposed to inhibiting effector T cells could be considered to be effective for the treatment of IBD. Various populations of T cells exert a downregulatory effect on immune responses, including Tr1 cells (IL-10 secretion), Th3 cells (TGF-beta) and CD4+CD25+ T regulatory cells, in which inhibition is through direct cell contact. The earliest work of this therapy may involve the selection and engineering of T cells delivering IL-10<sup>[98]</sup>.

Lymphocyte-endothelial interactions mediated by adhesion molecules are important in leukocyte migration and recruitment to sites of inflammation in IBD, a selective inhibition of these adhesion molecules offers many potential targets for specific intervention against inflammation<sup>[99]</sup> to treat CD. In the next years, the role of anti-CD3 drugs (visilizumab), which induces apoptosis in activated T cells, the epithelial repair, and autologous hematopoietic stem cell transplants<sup>[100]</sup> will be established.

Ultimately, the future therapy for IBD should be individualized and directed at induction of remission over a long period of time with the avoidance of important side-effects and maintaining the patient's quality of life.

## **CONCLUSION**

Relevant advances in the understanding of the molecular

pathogenesis of IBD have been made, discovering susceptibility genes, identification of environmental factors implicated, and dysregulation of immunity in disease pathogenesis. Although the precise mechanisms underlying the development of IBD are not known, sufficient data have been collected to suggest interplay between genetic predispositions, accompanied by the importance of epithelial barrier function, and innate and adaptive immunity. Current therapies generally involve combinations of pharmacologic agents such as aminosalicylates, azathioprine, steroids, with dietary manipulation. Newer agents including monoclonal antibodies targeted to specific proinflammatory cytokines, to adhesion molecules, and the induction of anti-inflammatory cytokines and T-cell activation, have emerged and provided clinical benefit in the treatment and relapse of IBD.

Received: December 4, 2007 Revised: January 27, 2008

## Abstract

Colonic diverticulosis is one of the most common causes of lower gastrointestinal bleeding. Endoscopy is not only a useful diagnostic tool for localizing the bleeding site, but also a therapeutic modality for its management. To date, haemostatic methods have included adrenaline injection, mechanical clipping, thermal and electrical coagulation or combinations of them. The results of all published data are herein reviewed.

Pilichos C, Bobotis E. Role of endoscopy in the management of acute diverticular bleeding. *World J Gastroenterol* 2008; 14(13): 1981-1983 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1981.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1981>

Forty percent of lower gastrointestinal bleeding (LGB) is due to colonic diverticulae. Inversely, bleeding complicates only 5% of all cases of colonic diverticulosis<sup>[1]</sup>. In most of cases, hemorrhage ceases spontaneously; however, in 20% it persists, thus imposing an emergency treatment<sup>[2]</sup>.

Endoscopic hemostasis is a proven therapy in some indications of LGB, such as in the post-polypectomy bleeding and the post-radiation rectitis<sup>[3,4]</sup>. Nevertheless, any attempt of endoscopic treatment presupposes either a certain diagnosis or a strong presumption of the bleeding

lesion, which may not always be evident. Since the end of 1980's, the benefit of an emergency colonoscopy in this setting has been investigated, but yielded contradictory conclusions (Table 1). After adequate bowel preparation urgent colonoscopy is incomplete in 0%-45% of cases and the risk of complications does not exceed 11%. The method allows positive diagnosis in approximately two thirds of cases and hemostasis in one third and may result in a shorter duration of hospitalization<sup>[5-13]</sup>. The timing of colonoscopy has little or no impact on the diagnostic yield, but when it is performed early (within 24 h following admission) it seems associated with a better clinical outcome<sup>[12-14]</sup>.

The criteria proposed by Zuckerman for attributing LGB to diverticulosis are inspired by the Forrest classification of bleeding gastro duodenal ulcers<sup>[15]</sup>. They include typical endoscopic stigmata such as active bleeding, visible vessel and adherent clot and presumptive findings, such as presence of fresh blood within one or more bowel segments and diverticular erosions. Using these criteria, a lower bleeding could undoubtedly be attributed to diverticulosis in only 20% of cases. In all other cases, the diverticular origin of bleeding is either presumed indirectly by the absence of any other lesion or considered as incidental<sup>[16]</sup>.

Endoscopic treatment aims to stop active bleeding, reduce the risk of recurrence, diminish transfusion needs and avoid surgery. To date, haemostatic methods have included adrenaline injection, mechanical clipping, thermal and electrical coagulation or associations of them. All of them are of similar efficacy, but mechanical clipping also offers the theoretical advantage of marking the bleeding site, which might be useful in case of relapse<sup>[17]</sup>. Beyond these traditional techniques, Farrell, based on the previous work of Witte *et al*, has reported 4 cases of diverticular bleeding treated by elastic band ligation and suggested that this might be a promising method not only for the hemostasis, but for diverticular reversion as well<sup>[18,19]</sup>. Concerning APC, despite its excellent results in vascular malformations, it has never been tested in the setting of diverticular hemorrhage, to our knowledge.

Apart of three original studies including only one prospective trial, all other published data are limited to some case reports. In the first study, Jensen *et al* compared 10 endoscopically managed patients with certain diverticular bleeding to 17 non-treated historical controls. Endoscopic treatment included diluted adrenaline injections in cases of active bleeding, bipolar coagulation in cases of visible vessel and association of

both methods in cases of an adherent clot. None of the treated patients relapsed during a 30 mo observation period, whereas 9 of the 17 controls (52%) presented a recurrence within 3 years and 6 of them (35%) failed to avoid surgery<sup>[16]</sup>. In the study of Bloomfeld, although the haemostatic methodology was similar to the previous study, results were less encouraging. Of 13 patients with active diverticular bleeding endoscopically treated, 5 and 3 presented an early or a late recurrence (up to 35 mo), respectively, thus a success rate of 46%<sup>[20]</sup>. Finally, in the most recent study of Smoot *et al*, endoscopic haemostasis carried out in 7 patients actively bleeding, was proven both effective and free of complications<sup>[14]</sup>. The methodology and the results of all relevant studies and reports are presented in Table 2. Summarizing the above data, one could say that out of 63 patients endoscopically managed, 6 (9.5%) presented an early relapse of bleeding and none a method-related complication. However, the long-term efficacy of endoscopic therapies is not demonstrated and randomized trials including larger number of patients are needed to make safe conclusions.

Thus, based on the above data one can conclude that in cases of lower GI bleeding, urgent colonoscopy after an adequate bowel preparation should be attempted. Endoscopic hemostasis might help patients to avoid at

least emergency surgery, if a diverticular origin seems certain or highly probable.

## Abstract

Endoscopic mucosal resection (EMR) is a technique used to locally excise lesions confined to the mucosa. Its main role is the treatment of advanced dysplasia and early gastrointestinal cancers. EMR was originally described as a therapy for early gastric cancer. Recently its use has expanded as a therapeutic option for ampullary masses, colorectal cancer, and large colorectal polyps. In the Western world, the predominant indication for EMR in the upper gastrointestinal tract is the staging and treatment of advanced dysplasia and early neoplasia in Barrett's esophagus. This review will describe the basis, indications, techniques, and complications of EMR, and its role in the management of Barrett's esophagus.

## INTRODUCTION

Endoscopic mucosal resection (EMR) is a technique used

to locally excise lesions confined to the mucosa. Its main role in therapeutic endoscopy is the treatment of advanced dysplasia and early gastrointestinal (GI) cancers<sup>[1-4]</sup>. Tada *et al* published the first case report of EMR in 1984 as a treatment option for early-stage gastric carcinoma<sup>[5]</sup>. Since then, EMR has been used diagnostically and therapeutically in both the upper and lower GI tracts, and has significantly lower morbidity and mortality compared to surgical management<sup>[6]</sup>.

EMR is most commonly used to locally treat early gastric and esophageal dysplasia/cancer. However, there are several reports describing EMR as a therapeutic option for ampullary masses, colorectal cancer, and large colorectal polyps<sup>[7-10]</sup>. In the Western world, the predominant indication for EMR in the upper GI tract is the staging and treatment of early neoplasia in Barrett's esophagus. This review will describe the basis, indications, techniques, and complications of EMR, and its role in the management of Barrett's esophagus.

## BASIS OF EMR

The GI wall is comprised of 5 layers: mucosa, deep mucosa, submucosa, muscularis propria, and serosa or adventitia. The two major components are the mucosal and the muscular layer. The submucosa consists of loose connective tissue that attaches the above layers together. The mucosal and muscular layers can be separated from each other by injection of fluid into the submucosal layer. This allows for safe resection of mucosal lesions without causing damage of the deeper muscle layer<sup>[11]</sup>.

EMR has become standard practice because of its following distinct advantages: (1) advanced dysplasia and most early neoplastic lesions are free of lymph-node metastases, and can be treated with curative intent simply by local resection<sup>[12]</sup>; (2) EMR provides tissue specimen for histology and staging<sup>[13]</sup>; (3) EMR is minimally invasive and carries lower morbidity and mortality compared to traditional surgical approaches<sup>[14]</sup>; and (4) surgery can be performed after EMR if advanced neoplasia or incomplete resection is detected on histologic evaluation of the EMR specimen.

EMR also has some disadvantages: (1) EMR is labor intense, time consuming, and requires advanced endoscopic skills; (2) larger lesions can only be resected in piecemeal fashion which precludes evaluation for completeness of the resection at the lateral margins; (3)

there is uncertainty regarding the long term outcome of patients treated with EMR due to the lack of randomized trials directly comparing EMR with surgery; and (4) EMR is poorly reimbursed in the US.

## TECHNIQUES OF EMR

Once a mucosal lesion is identified, it is helpful to perform chromoendoscopy  $\pm$  endoscopic ultrasound to further define the size and borders of the lesion, and determine its depth of invasion<sup>[15-17]</sup>. Both chromoendoscopy and narrow band imaging can help improve detection of dysplastic lesions, and further delineate the borders of the lesion. Additionally, computer tomography (CT) imaging can help determine the size of the lesion and rule out distant metastatic disease prior to proceeding with EUS. Although it can be challenging to determine intramucosal from submucosal neoplasias, the risk of pre-existing lymph node metastases must be discussed with the patient prior to pursuing EMR. Ultimately, histopathologic evaluation of the EMR specimen is the most important predictor of lymph node metastasis. Surgical management of early esophageal/gastric malignancies should be based on the histological analysis of the EMR specimen (i.e. depth of invasion) as well as each patient's surgical morbidity and mortality risks.

Several EMR techniques have been described in the literature. Multiple EMR techniques are available: (1) strip-off biopsy; (2) "inject, lift, and cut" method; (3) the "cup and suction" or EMR-cap technique; and lastly (4) EMR with band ligation<sup>[18]</sup>. Prior to pursuing any of the above methods, it is recommended that the periphery of the lesion be marked with either a needle knife, electrocautery, or argon plasma coagulator (APC). This allows for distinct identification of the borders of the lesion that is being excised. The absence of all markings assists in determining if the resection is complete.

Depending on the EMR technique used, lift injection may be required. No standardization of the type of injection solution exists. Various injectates that have been used include normal saline, normal saline plus epinephrine solution, 50% dextrose in normal saline, 10% glycerine/5% fructose in normal saline, hyaluronic acid, and a mixture of methylene blue and normal saline<sup>[18,19]</sup>. Injection of these various solutions can help lift the mucosa from the submucosa, and theoretically decrease the risk of perforation and reduce the risk of hemorrhage<sup>[20]</sup>. An additional advantage of injecting prior to EMR is identification of lesions that do not successfully lift, which generally suggests involvement of the submucosal layer, and thus are not candidates for resection<sup>[15]</sup>.

Multiple electrosurgical currents are used during EMR, including blend, cut, and coagulation settings, depending primarily on operator preference. The electrosurgical setting most commonly used in the esophagus at Leeds is the ERBE "endo-cut mode" with a power setting of 45 watts<sup>[21]</sup>. In a recent editorial by Seewald *et al.*, a pure coagulation current with the Erbotom at a setting 3- and 60-W output was used for electrosurgical resection<sup>[22]</sup>.

(1) The strip biopsy is the least complex EMR technique, but is often limited to polypoid or nodular

lesions only<sup>[23]</sup>. It is similar to standard polypectomy. Injection into the submucosa is not done. A diathermy snare is tightened around a lesion, which is subsequently removed with the application of an electrical cutting current. The strip biopsy technique can be applied to flat lesions by using either a barbed snare or ultra stiff snare<sup>[24]</sup>.

(2) The "inject, lift, and cut" method is similar to the strip-off method. A two channel upper endoscope is needed. Prior to snaring the lesion, a submucosal injection is used to effectively lift the mucosa from the submucosa, thereby potentially reducing the risk of perforating the muscular layer. The lesion is then lifted by forceps and situated into a snare (*via* the second channel of a dual-channel endoscope), such that the lesion is resected at the base by applying electrocautery<sup>[20]</sup>.

(3) The "cup and suction" or EMR-cap technique is the most frequently used method of EMR in the esophagus<sup>[25]</sup>. This technique was first described by Inohue *et al* in 1993<sup>[26]</sup>. This method requires a transparent plastic cap be attached to the distal tip of a single-channel endoscope. This is followed by injection of approximately 20 mL of lifting solution into the submucosa. A designated "duck bill" small-diameter snare is then placed within the rim of the transparent cap. Following this, the lesion is sucked into the cap as the snare is closed at the base of the lesion. Once suction has been released and it has been determined that the entire lesion is contained within the snare, the lesion is removed using electrocautery<sup>[27]</sup>.

The advantages of the EMR-cap technique are that a standard single-channel endoscope can be used, and only one endoscopy assistant is required. In addition, it appears that there is a lower risk of bleeding compared to the strip-off method<sup>[21,25]</sup>. The disadvantage is that it may be difficult to ensure that the entire lesion has been aspirated into the cap, and occasionally, visualization of the lesion can be obscured by the cap itself. Furthermore, the snare tends to lose its shape after a single use and thus a new snare is usually required for each piece of tissue removed. This can quickly add to the cost of the procedure, particularly if a large surface area needs to be removed (e.g. long segment Barrett's esophagus).

(4) EMR with ligation is similar to the EMR-cap technique, in that suction of the lesion is required. However, unlike the EMR-cap technique, the lesion is suctioned into a ligation cylinder without prior submucosal injection. A rubber band is then deployed at the base to create a pseudopolyp. The pseudopolyp is subsequently removed at its base by tightening a snare just below the level of the rubber band<sup>[28]</sup>. The standard band ligator can be used, but a designated ligator that fits the single channel therapeutic upper scope is available (Duette, Cook Medical, Winston-Salem, NC). The main disadvantage of this technique with the standard ligator is that the endoscope must be withdrawn to remove the ligation cylinder before reinsertion for resection<sup>[29]</sup>. The Duette system, on the other hand, allows the passage of a snare *via* the therapeutic channel of the scope and multiple resections can be carried out sequentially without the need of removing the scope.

The EMR-cap and EMR with ligation techniques have been prospectively compared to each other in a single-

center study performed by May A *et al.* In this study, 50 EMR-cap resections were compared to 50 EMR with ligation resections of early stage esophageal cancer. No significant difference in the maximal diameter of the resection specimen area was noted between the two groups. In addition, only one minor episode of bleeding was seen in each group, with no severe complications in either group. Therefore, it was concluded that both techniques are similar in efficacy and safety<sup>[30]</sup>.

## ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD)

ESD, one of the more recently described techniques, has been developed to perform single en-block resections of large mucosal lesions<sup>[31]</sup>. This technique involves the use of an electrocautery knife to dissect out mucosal lesions. Several knives have been developed for ESD, including triangle-tip knives, hook knives, insulation-tip knives, and flex knives<sup>[32-34]</sup>. In ESD with use of a triangle-tip knife, the borders of a mucosal lesion are marked by electrocautery and then injection of an epinephrine-saline solution into the submucosa is performed. This is followed by marginal cutting circumferentially, *via* electrocautery, around the previous markings. At this point, a high-viscosity solution (such as hyaluronic acid) is injected to provide a longer period of mucosal lifting to allow for actual submucosal dissection. Dissection is carried out by electro cauterization using the tip of the triangle-tip knife to free the mucosal lesion from the submucosa. Once completed, the freed mucosa is removed<sup>[27]</sup>. At present, the various knives used for ESD are not available in the US.

## EMR COMPLICATIONS

As with any endoscopic procedure, complication rates are operator dependent and diminish with increased experience. The Japanese Society of Gastrointestinal Endoscopy calculated a complication rate of 0.5% based on all upper GI EMR's performed between 1993 to 1997<sup>[35]</sup>. A lower overall complication rate of 0.17% was reported by Kaneko *et al* in 1995. The mortality rate calculated by Kaneko *et al* was 0.0001%<sup>[36]</sup>.

The risks of EMR include bleeding, pain, perforation, and stricture formation. Bleeding can occur at the time of the procedure, or be delayed for up to 12 h. Bleeding rarely occurs beyond 24 h after the procedure. Venous oozing is more common following esophageal EMR, whereas brisk bleeding is more common after gastric EMR of large and fundic lesions. Bleeding is most commonly treated endoscopically *via* electrocauterization, APC, or placement of metallic clips<sup>[37-40]</sup>.

Dull pain following EMR generally results from denudation of the mucosa and subsequent exposure to gastric acid. This pain can often be controlled by proton-pump inhibitors. Sudden sharp pain, especially during or at the completion of the procedure, should raise suspicion of a perforation<sup>[41]</sup>. The risk of perforation following EMR of gastric lesions is 0.06%-5%<sup>[42]</sup>. Upper GI tract perforation can be managed conservatively with the combination of

clipping, nasogastric tube suction, and broad-spectrum antibiotics<sup>[43]</sup>.

Patients are at an increased risk of developing strictures if circumferential resections of the esophagus or gastric pylorus are performed<sup>[29,44,45]</sup>. These strictures are often responsive to dilation. To date, animal studies have not identified that prophylactic balloon dilation, esophageal stenting, or deep mural steroid injections prevent the formation of strictures<sup>[44]</sup>.

## INDICATIONS FOR EMR IN THE UPPER GI TRACT

### Gastric malignancy

Per the Japanese literature, the indications for EMR in resection of superficial gastric cancers applies to well- or moderately differentiated adenocarcinoma and/or papillary carcinoma. Gastric cancers that penetrate the submucosa are at increased risk of lymph node metastases. Gastric cancer confined to the mucosa has a 0%-5% risk of lymph node metastases, compared to 10%-20% risk if the cancer involves the submucosa<sup>[46-49]</sup>. Thus, gastric lesions must meet the following criteria to be candidates for EMR: confined to the mucosa, < 2 cm for elevated lesions, < 1 cm for flat or depressed lesions, cannot be associated with an ulcer or ulcer scar, and cannot have venous or lymphatic involvement<sup>[50]</sup>.

### Esophageal squamous cell carcinoma

Currently, EMR is generally indicated for superficial well- or moderately differentiated squamous cell carcinoma without venous or lymphatic involvement that is limited to the lamina propria. This is based on a 0% risk of metastasis when the neoplasia is limited to the epithelium, compared to the 12% and 26% risk of metastasis when the neoplasia involves the muscularis mucosa and submucosa, respectively<sup>[51]</sup>. There is no consensus on the maximum size of the lesion that can be resected. EMR is not recommended for circumferential lesions secondary to the risk of subsequent stricture formation<sup>[15]</sup>.

### High-grade dysplasia and early adenocarcinoma in Barrett's esophagus (BE)

BE is associated with a 30-fold increased risk of esophageal adenocarcinoma, which remains one of most rapidly rising cancers in the Western world<sup>[52-54]</sup>. Although EMR has a clear role in squamous cell carcinoma, its role in BE is not clearly defined, although studies have determined that EMR is effective in removing visible lesions in BE<sup>[24,30,55]</sup>. In fact, current evidence suggests that EMR of high-grade dysplasia (HGD) and early cancer (EC) has similar success rates as surgical treatment<sup>[56-60]</sup>. According to Ell *et al*, the indications for EMR in the setting of Barrett's neoplasia include the following: lesions limited to the mucosa that are macroscopically flat, tumor size between 20-30 mm, and good to moderate differentiation on histology<sup>[56]</sup>. Additionally, research suggests that EMR has better diagnostic reproducibility compared to mucosal biopsies alone, implying a possible role in routine surveillance<sup>[61]</sup>. Certainly, the cost-effectiveness and availability of EMR

would need to be considered prior to pursuing EMR as a primary tool in the surveillance of BE.

In one of the largest studies evaluating the efficacy of EMR for treatment of HGD and EC, 97% complete remission was achieved in resection of “low-risk” lesions and 59% complete remission in resection of “high-risk” lesions. “Low-risk” lesions were defined as macroscopic lesions measuring up to 20 mm and limited to the mucosa. However, at an average 12 mo follow-up period, the combined recurrence and metachronous cancer rate was 14%<sup>[56]</sup>. In an Italian study, EMR was found to be an effective method of treating HGD and intramucosal cancer in 34 patients that did not have submucosal involvement, with all patients remaining in remission at a median follow-up of 34.9 mo. In addition, EMR changed the pretreatment diagnosis in 25.6% of the studied patients<sup>[62]</sup>.

Recurrence of neoplastic disease after EMR is a potential limitation<sup>[56,59]</sup>. Therefore, circumferential resection, in which the targeted dysplastic lesion and the surrounding Barrett’s mucosa are removed, has also been studied<sup>[63]</sup>. In two separate studies from 2003 and 2006, no recurrent or metachronous lesions were reported. This is in stark contrast to an 11% recurrence rate with circumferential resections at a mean follow-up of 18 mo in a study by Giovannini *et al.*<sup>[24,29,55]</sup>.

In addition to EMR, multiple ablative techniques have been evaluated in the management of HGD and EC in BE. These include photodynamic therapy (PDT), argon beam coagulation therapy, lasers, radiofrequency ablation, and yttrium-aluminum-garnet laser therapy<sup>[64-68]</sup>. In fact, a recently-published multicenter, randomized controlled trial has shown that photodynamic therapy with Photofrin is superior than omeprazole alone in eliminating HGD at 5 years follow-up (77% *vs* 39%, respectively)<sup>[69]</sup>. To improve eradication of neoplastic tissue and decrease recurrence rates, the combined use of EMR with ablative techniques have been described<sup>[59,70]</sup>. Theoretically, recurrence rates are expected to be much lower with combined modalities, because both visible and non-visible lesions would be eradicated.

Combined modality has been evaluated by the Wiesbaden group in two separate studies. In the first study, 28 patients underwent EMR, 13 underwent PDT, 3 underwent APC, and 6 patients received a combination of these therapies for the treatment of HGD or EC. Metachronous or recurrent lesions were seen in 23% of the patients at a mean follow-up period of 34 ± 10 mo. Amongst the patients treated with EMR alone, 6/28 patients (21.4%) developed metachronous or recurrent lesions, compared to 1/6 patients (16.6%) treated with combined modalities<sup>[59]</sup>. In a follow-up study of a total of 115 patients (EMR = 70, PDT = 32, APC = 3, EMR + PDT = 10) undergoing endoscopic treatment for HGD or EC, there was a 31% rate of metachronous or recurrent lesions over an average follow-up time of 34 ± 10 mo. Individually, the metachronous or recurrence rate was 30% (21/70) in the EMR group *vs* 37.5% in the EMR + PDT group<sup>[70]</sup>. It is important to note that the number of patients treated with the combined modality is markedly less than that treated with EMR alone.

## CONCLUSION

Since its introduction as a potential treatment option of GI mucosal cancers in 1984, the indications for EMR are continuing to expand. Today, EMR has become an integral part of the therapeutic endoscopy armamentarium. Although there are no specific guidelines for EMR as a treatment option for HGD or early cancer in Barrett’s esophagus, the literature indicates that EMR is similar to surgery in efficacy, but has less morbidity and mortality. As newer techniques of EMR, including circumferential mucosectomy, are developed, the potential of reducing recurrence and metachronous rates are inviting.

Received: August 29, 2007 Revised: January 3, 2008

analysis demonstrated that the mean survival time and 5-year survival rate were lower in the cases with low expressions of syndecan-1 and E-cadherin and high expression of integrin  $\beta 3$  ( $P < 0.01$ , in all cases). COX multivariate analysis showed that the expression level of syndecan-1 could be an independent prognostic index of gastric carcinoma ( $P < 0.01$ ), whereas E-cadherin and integrin  $\beta 3$  could not be independent indexes ( $P > 0.05$ ,  $P > 0.05$  respectively).

**CONCLUSION:** The low expression of syndecan-1 and E-cadherin and the high expression of integrin  $\beta 3$  are significantly correlated with the invasion and metastasis of gastric carcinoma, and they are highly correlated with each other. Therefore they may serve as important prognostic markers of gastric carcinoma.

Relationship between cell adhesion molecules expression and the biological behavior of gastric carcinoma. *World J Gastroenterol* 2008; 14(13): 1990-1996 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1990.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1990>

### Abstract

**AIM:** To evaluate the relationship between the expression of cell adhesion molecules (CAMs) and the biological behavior of gastric carcinoma.

**METHODS:** Expression of syndecan-1, E-cadherin and integrin  $\beta 3$  were evaluated by immunohistochemical study in a total of 118 gastric carcinomas and 20 non-tumor gastric mucosas.

**RESULTS:** The expressions of syndecan-1 and E-cadherin were significantly lower in gastric carcinoma compared to non-tumor gastric mucosa, and the low expression rates were positively correlated to the tumor invasion depth, vessel invasion, lymph node metastasis and distant metastasis ( $P < 0.01$  in all cases). However, the expression of integrin  $\beta 3$  was significantly higher in gastric carcinoma compared to non-tumor gastric mucosa, and the high expression rates were positively correlated to the tumor invasion depth, vessel invasion, lymph node metastasis and distant metastasis ( $P < 0.01$  in all cases). In addition, the three protein expressions were correlated to the tumor growth pattern ( $P < 0.01$ ,  $P < 0.01$ , and  $P < 0.05$  respectively), but not correlated to tumor differentiation ( $P > 0.05$ ,  $P > 0.05$  and  $P > 0.05$  respectively). Positive correlation was observed between the expressions of syndecan-1 and E-cadherin, but they which were negatively correlated to the expression of integrin  $\beta 3$  ( $P < 0.01$  in all cases). Univariate

### INTRODUCTION

Gastric carcinoma is the most common malignant tumor of the digestive system. Two of the most important causes for the high mortality are invasion and metastasis. However, the mechanism of invasion and metastasis of gastric carcinoma is still not definitely clear at present<sup>[1]</sup>. Cell adhesion is one of the important steps in metastasis. Syndecan-1, E-cadherin and integrin  $\beta 3$  make up cell adhesion molecules (CAMs) and participate in the adhesion between the cell and the extracellular matrix<sup>[2]</sup>. Syndecan-1 is a set of transmembrane heparitin sulfate glycoproteins (HSPGS), which is present at the surface of most epithelia cells and take part in the adhesion between the cell and the extracellular matrix. The expression of syndecan-1 was augmented during epithelial regeneration and rearrangement in the stomach and other tissues<sup>[3,4]</sup>. E-cadherin is a calcium dependent intercellular

adhesion molecule and it is present in normal cells to maintain the normal structure of tissues which has special biological characters and is highly related to invasion and metastasis of cancer cells<sup>[3]</sup>. Studies show that the reduction or absence of syndecan-1 and E-cadherin expressions could induce the growth, invasion and metastasis of tumors<sup>[5]</sup>. Integrin is a heterodimer consisting of a group of  $\alpha$  and  $\beta$  polypeptide chains which can be divided into three groups based on the difference of a common  $\beta$  chain ( $\beta 1$ ,  $\beta 2$  and  $\beta 3$ ). By identifying the extracellular matrix such as laminin, fibronectin and immunoglobulin superfamily on the cell membrane (I-CAM for example) *etc.*, mediating adhesive reaction of cell-extracellular matrix and cell-cell and receiving and conducting cascade signals, Integrin regulates the survival, apoptosis, movement, proliferation and inflammatory reaction of cells<sup>[6]</sup>. To our knowledge, the co-expressions of syndecan-1, E-cadherin and integrin  $\beta 3$  in gastric carcinoma and their clinical significances have not been reported before. We thus studied the expressions of CAMs in gastric carcinoma patients to find out the relationship among three of them using the immunochemical S-P method and to explore the correlation in their expression and pathological indexes of gastric carcinoma and survival time.

## MATERIALS AND METHODS

### Specimen

One hundred and eighteen specimens were collected from gastric carcinoma patients (91 men, 27 women, average age 56.3 years, range 25-79 years). They received the radical operations in our hospital from October 1986 to November 2002. Follow-up period was up to 5 years and the survival period was calculated from the day of surgery to the end of the follow-up or to the day of death. The censored value was zero. Of 118 gastric carcinomas, 70 were highly or moderately differentiated, while 48 were poorly or undifferentiated. According to the tumor, lymph node, and metastasis (TNM) standard stadiation, 47 were in T1-T2 stages and 71 were in T3-T4 stages. Eighty nine cases had vascular invasion and 29 without. Eighty three had lymph node metastasis and 35 without; distant metastases of carcinoma were found in 55 cases, while no distant metastasis in 63 cases. Twenty gastric mucosa specimens were collected 5 cm away from the cutting edges of radical operation as normal controls, which were detected as non-tumor mucosa.

### Main reagents

Mouse anti-human syndecan-1, E-cadherin and integrin  $\beta 3$  were purchased from ZYMED Company. SP kit was purchased from Maixin Biotect Company, Fuzhou, China. Streptavidin peroxidase staining was performed according to the kit instruction. Normal gastric mucosa was used as a positive control and PBS was used to replace the first antibody as a negative control.

### Immunohistochemistry

Immunohistochemistry was made according to the streptavidin peroxidase (SP) methods. The staining step followed the routine process. In order to examine the

specificity of immunostaining, both positive and negative controls were run at the same time in each experiment. The normal gastric mucous was used as the negative control.

### Results evaluation

Based on the proportion of positively stained cells in the sections, the criteria of syndecan-1 and E-cadherin were set as follows<sup>[7]</sup>: (1) if more than 90% of the tumor cells exhibited intense membranous staining similar to that of normal cells, the result was considered as positive (++); (2) if the staining intensity was demonstrably reduced relative to that of normal cells and/or the staining pattern was heterogeneous (10%-90% positive), the result was deemed to be weakly positive (+); (3) if its expression was completely lost or positive in less than 10% of cells, the result was defined as negative (-). In statistical analysis,  $\pm$  were classified as the low expression group and ++ were set as the high expression group. In addition, the criteria for integrin  $\beta 3$  were classified into four grades<sup>[8]</sup>. Briefly, -, no staining in fewer than 10% of tumor cells; +, weak staining in only 10%-50% of tumor cells; ++, moderate staining in 50%-75% of tumor cells; and +++, strong staining of more than 75% of tumor cells. The sections for integrin  $\beta 3$  were judged as a high expression group when more than 50% of cancer cells (++ or +++) were stained; others were judged as a low expression group.

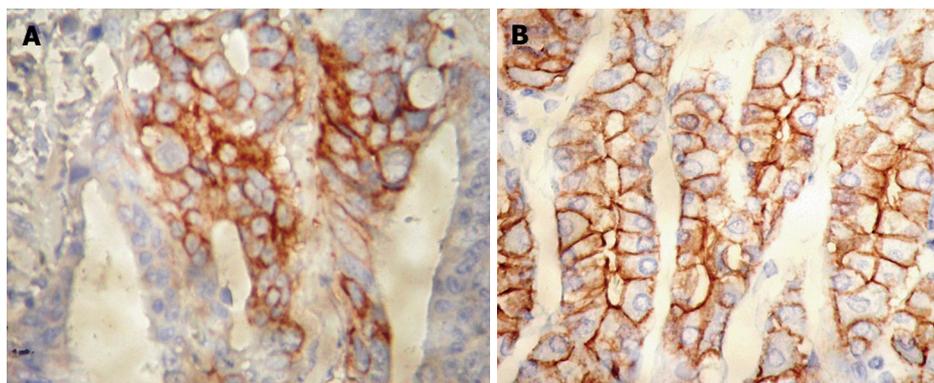

### Statistical analysis

SPSS 11.5 software package was used in data processing. Non-parameter Spearman rank correlation analysis was used to determine the relationship between the expressions of syndecan-1, E-cadherin and integrin  $\beta 3$  and the pathological indexes of the progression of gastric carcinoma. The survival rate was estimated by the Kaplan-Meier method and analyzed by the long-rank test. Fisher's exact test was used to differentiate the rates of different groups. Univariate analysis and Cox-multivariate analysis were used to analyze the effect of the pathologic parameters (differentiation level, invasion depth, vessel invasion and lymph node metastasis), the expression of syndecan-1, E-cadherin and integrin  $\beta 3$  on the total survival.

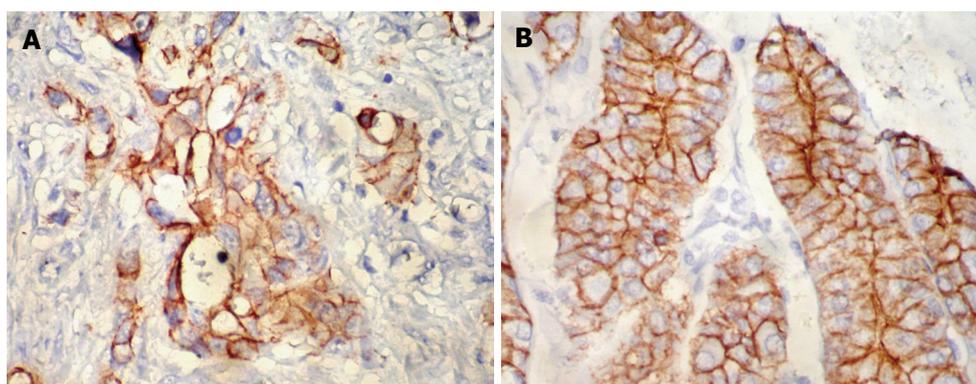

## RESULTS

### The expressions of syndecan-1, E-cadherin and integrin $\beta 3$ in gastric carcinoma and non-tumor gastric mucosa

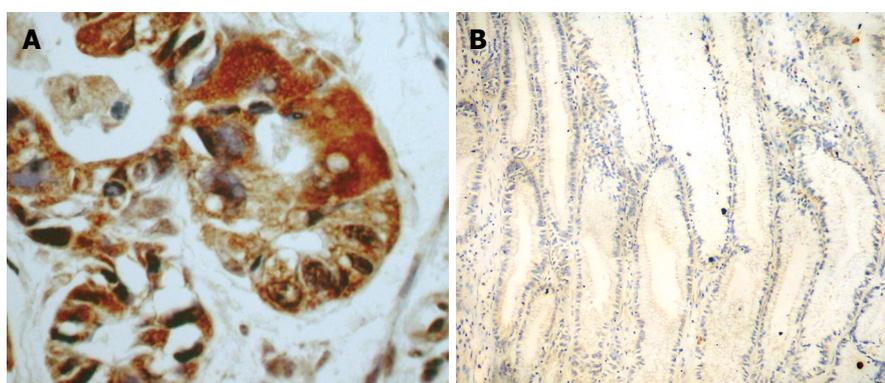

Of a total of 118 gastric carcinomas the following was found: syndecan-1 low expression 57.6% (68/118) (Figure 1A) and high expression 42.4% (50/118); E-cadherin low expression 57% (68/118) (Figure 2A) and high expression 42.4% (50/118); and integrin  $\beta 3$  low expression 50% (59/118) and high expression 50% (59/118) (Figure 3A). However, of 20 non-tumor gastric mucosa, syndecan-1 high expression (Figure 1B) 90% (18/20) and low expression 10% (2/20); E-cadherin high expression 85% (7/20) (Figure 2B) and low expression 15% (3/20); and integrin  $\beta 3$  high expression 15% (3/20) (Figure 3B) and low expression 85% (17/20). Compared to normal tissues, the gastric carcinoma tissues showed lower syndecan-1 expression ( $\chi^2 = 15.5$ ,  $P < 0.01$ ), lower E-cadherin expression rate and density with

**Figure 1** Syndecan-1 expression. **A:** Syndecan-1 was negatively (+) expressed in gastric carcinoma. *Sp method.* ( $\times 250$ ); **B:** Syndecan-1 was highly expressed (++) in non-tumor gastric mucosa ( $\times 250$ ).

**Figure 2** E-cadherin expressions. **A:** E-cadherin was negatively (+) expressed in gastric carcinoma (Magnification  $\times 250$ ); **B:** E-cadherin was highly expressed (++) in non-tumor gastric mucosa ( $\times 250$ ).

**Figure 3** Integrin  $\beta 3$  expression. **A:** Integrin  $\beta 3$  was highly expressed (+++) in gastric carcinoma ( $\times 250$ ); **B:** Integrin  $\beta 3$  was negatively (+) expressed in non-tumor gastric mucosa ( $\times 250$ ).

the increase of invasive depth of cancer cells ( $\chi^2 = 12.4$ ,  $P < 0.01$ ) and higher integrin  $\beta 3$  expression ( $\chi^2 = 8.5$ ,  $P < 0.01$ ). There are significant differences in the expressions of these three proteins in gastric carcinoma and non-tumor gastric mucosa.

#### **Relationship between the expression levels of syndecan-1, E-cadherin and integrin $\beta 3$ and the pathological indexes of progression of gastric carcinoma**

The low expressions of syndecan-1 and E-cadherin were positively correlated with the gastric carcinoma growth mode ( $\chi^2 = 12.47$ ,  $P < 0.01$ ;  $\chi^2 = 15.27$ ,  $P < 0.01$ ), invasion depth ( $\chi^2 = 32.95$ ,  $P < 0.01$ ;  $\chi^2 = 28.73$ ,  $P < 0.01$ ), vessel invasion ( $\chi^2 = 46.22$ ,  $P < 0.01$ ;  $\chi^2 = 40.52$ ,  $P < 0.01$ ), lymph node metastasis ( $\chi^2 = 43.49$ ,  $P < 0.01$ ;  $\chi^2 = 38.28$ ,  $P < 0.01$ ) and distant metastasis ( $\chi^2 = 63.30$ ,  $P < 0.01$ ;  $\chi^2 = 51.98$ ,  $P < 0.01$ ). Additionally, the gastric carcinoma growing in invasive style had low expressions of syndecan-1 and

E-cadherin which were not correlated to the differentiation level of gastric carcinoma ( $\chi^2 = 1.60$ ,  $P > 0.05$ ). The high expression of integrin  $\beta 3$  protein was positively correlated with gastric carcinoma growth modes ( $\chi^2 = 5.83$ ,  $P < 0.05$ ), invasion depth ( $\chi^2 = 29.74$ ,  $P < 0.01$ ), vessel invasion ( $\chi^2 = 33.33$ ,  $P < 0.01$ ), lymph node metastasis ( $\chi^2 = 29.61$ ,  $P < 0.01$ ) and distant metastasis ( $\chi^2 = 41.72$ ,  $P < 0.01$ ). The gastric carcinoma growing in invasive style had high expressions of integrin  $\beta 3$  protein, which was not correlated to the differentiation level of gastric carcinoma ( $\chi^2 = 0.14$ ,  $P > 0.05$ ) (Table 1).

#### **Relationship among the expressions of syndecan-1, E-cadherin and integrin $\beta 3$ in gastric carcinoma**

There was significant positive correlation between the expression levels of syndecan-1 and E-cadherin. Both of them had negative correlation with integrin  $\beta 3$  expression (Table 2).

**Table 1** Correlation between expressions of syndecan-1, E-cadherin and integrin  $\beta 3$  and pathological parameters in 118 gastric carcinoma patients

**Factors that affect the survival rate of gastric carcinoma**

Univariate analysis showed that the patients with high syndecan-1 expression had a 5-year survival rate of 91.66%, while it was 12.8% in those with low syndecan-1 expression. There was significant difference between the rates ( $\chi^2 = 53.13, P < 0.01$ ). The patients with high E-cadherin expression level had a 5-year-survival rate of 93.59%, which was significantly different from that of the patients with low E-cadherin expression with the rate of 12.8%. There was significant difference between the rates ( $\chi^2 = 43.36, P < 0.01$ ). The patients with high integrin  $\beta 3$  protein expression had a 5-year-survival rate of 13.85% and the patients with low integrin  $\beta 3$  expression had the rate of 72.75%. There was significant difference between the rates ( $\chi^2 = 35.11, P < 0.01$ ). Kaplan-Meier analysis indicated that the patients with low syndecan-1/E-cadherin protein expression level and high integrin  $\beta 3$  expression level had poor prognosis (Table 3, Figure 4A-C).

COX-multivariate analysis showed that syndecan-1 expression could be used as a prognostic marker of gastric

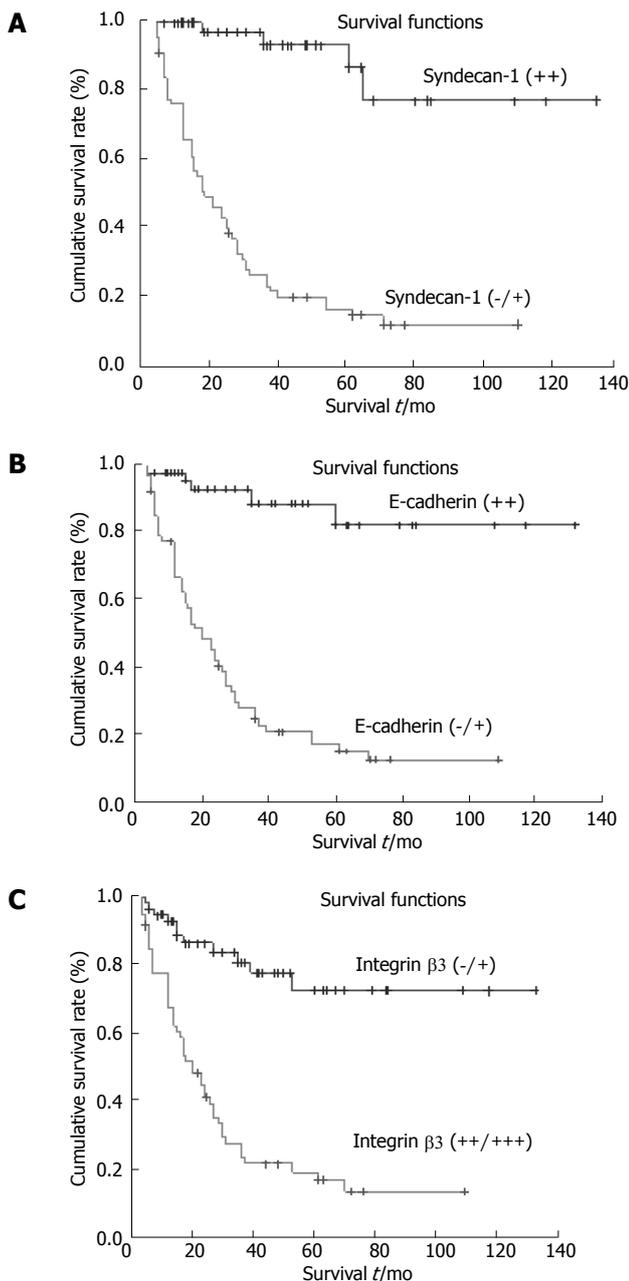

**Table 3** Relationship between the expressions of syndecan-1, E-cadherin and integrin  $\beta 3$  and the prognosis of gastric carcinoma patients

Groups	n	Mean survival time (mo)	5-yr survival rate (%)	$\chi^2$	P
Syndecan-1 expression

cancer patients ( $P < 0.01$ ). However, E-cadherin and integrin  $\beta 3$  could not be used as independent prognosis markers ( $P > 0.05$  and  $P > 0.05$  respectively). (Syndecan-1: B = 3.447, SE = 0.988, Wald = 12.183,  $P < 0.01$ ; E-cadherin: B = 0.019, SE = 0.686, Wald = 0.001,  $P > 0.05$ ; integrin  $\beta 3$ : B = 0.098, SE = 0.364, Wald = 27.711,  $P > 0.05$ ).

**DISCUSSION**

Gastric carcinoma is highly malignant and usually results in a poor prognosis. Although the achievement in early diagnosis and treatment of gastric cancer has improved the patients' outcome, it is still one of the leading causes of mortality in countries such as China and Japan. Currently, about 39% of gastric cancer cases occur in the Chinese population, ranking the leading cause of cancer-mortality in China, particularly in rural areas<sup>[9]</sup>. The overall 5-year survival rate for patients who undergo curative surgical resection for gastric carcinoma ranges from 47% to 60.4%<sup>[10]</sup>. The typical characteristics of malignant tumor are invasion and metastasis, which are the main cause for their lethality. Tumor progression is considered to be

**Figure 4** Correlation between syndecan-1, E-cadherin and integrin  $\beta 3$  expressions and the survival time. **A:** Survival curves by the Kaplan-Meier method. Long-rank test revealing a significant difference between negative and positive expression of Syndecan-1 ( $P < 0.05$ ); **B:** Survival curves by Kaplan-Meier method. dynamic, complex, and a multi-step process, where the essential steps are the breakdown of cell-cell adhesion and degradation of basement membrane (BM)<sup>[11]</sup>. The cellular and molecular steps required for metastases of neoplastic cells are starting to be elucidated. The metastatic cascade starts with a downregulation of the epithelial bonds which enables tumor cells to leave epithelial structures, to invade the stroma, to enter the blood stream or the lymphatics, to extravasate, and to colonize the target organs. Interestingly, invasive growth and metastases often recapitulate embryonic development and are greatly influenced by

the stromal microenvironment<sup>[12]</sup>. Thus, carcinoma cells interact bidirectionally with neighboring fibroblasts, endothelial cells, and lymphocytes through growth factors, chemokines, cell adhesion molecules, and extracellular matrix proteases.

Loss of cell adhesion may contribute to loss of contact inhibition of growth, which is an early step in the neoplastic process. It has been shown that various cell adhesion molecules expressed on carcinoma cells play crucial roles. However, the mechanisms of invasion and metastasis are still under investigation. Until now there is no satisfactory tumor marker for predicting its evolution.

Syndecan-1, E-cadherin and integrin  $\beta 3$  make up CAMs together<sup>[2]</sup> to participate in adhesion between cell and extracellular matrix. Experimental studies show that changes in cell-cell and cell-matrix adhesion are central to the conversion from premalignant lesions to early invasive carcinoma<sup>[13]</sup>.

Syndecan-1 (CD138) is a member of the transmembrane heparin sulfate proteoglycan (HSPG) family, taking part in and improving adhesion between cell and extracellular matrix<sup>[14]</sup>, improving cell proliferation, maintaining the differentiation phenotype of cells and inhibiting the growth of tumor cells<sup>[15]</sup>. Wiksten *et al*<sup>[16]</sup> reported that abatement or loss of syndecan-1 expression is highly correlated to the focal size, lymphatic metastasis, invasion depth, TNM stage and prognosis of gastric carcinoma. It is reported that the expression of syndecan-1 increases gradually from large intestine adenoma to carcinoma, then to invasive carcinoma<sup>[17,18]</sup>.

E-cadherin is a calcium dependent transmembrane glycoprotein and has the functions of mediating the adhesion of homogeneous cells among epithelia and of maintaining the integrity and polarity of tissue structures<sup>[19]</sup>. The abatement or loss of E-cadherin expression may induce the decrease of adhesion among cells and thus make cancer cells disunite, grow invasively toward peripheral tissues and leave original focal to form metastasis once the necessary conditions are met<sup>[20,21]</sup>. Documents indicate that in gastric carcinomas, the reduction in E-cadherin expression activation of E-cadherin gene varies from 17% to 92%<sup>[22,23]</sup>. This phenomenon has been confirmed in many kinds of tumors such as lung cancer, breast cancer, large intestine cancer, liver cancer and gastric cancer<sup>[24-27]</sup>.

Integrins belong to the family of transmembrane glycoprotein hetero-dimer. They mediate adhesion of neighboring cells and participate in the growth and repair of cells and vascular proliferation *etc* as important receptors of extracellular matrix protein<sup>[28]</sup>. Molecular biological studies on melanoma, colon and rectal cancer and other carcinomas in the past few years showed that the dissociation from or penetration through BM of tumor cells, caused by the adhesion of  $\alpha 3\beta 1$ ,  $\alpha 5\beta 1$ ,  $\beta 3$  and other Integrins on tumor cell surface to extracellular matrix, is the initial step for the invasive growth and remote metastasis of malignant tumor. Moreover the high expression of integrin  $\beta 3$  in malignant melanoma and malignant ovarian tumor cells is positively correlated to invasion and metastasis of cancer cells<sup>[29]</sup>.

Documented data shows that these three proteins, syndecan-1, E-cadherin and integrin  $\beta 3$ , cooperate with

each other for expressions and functions; moreover their expression levels are correlated with the progression of gastric carcinoma. Experimental studies show that syndecan-1 and E-cadherin are all present in epithelia and both can form immunoprecipitation with transcription regulatory factor  $\beta$ -cadherin and this indicates that they are materially and functionally correlated with each other<sup>[30]</sup>. The expression of syndecan-1 and E-cadherin in gastric carcinoma is low and their expression levels are positively correlated<sup>[31]</sup>. The abatement or loss of E-cadherin expression is involved in lymph node micro-metastasis of gastric carcinoma<sup>[32]</sup>. Sun *et al.*<sup>[33]</sup> proposed the following point of view based on different studies: the decrease of *in vitro* syndecan-1 expression inhibits E-cadherin expression, and/or lowers E-cadherin expression at the same time as the beginning of epithelium-stroma transformation and induces effective and timely epithelium-stroma transformation<sup>[33]</sup>.

Signal conduction mediated by syndecan-1 needs the cooperation of integrin  $\beta 3$ <sup>[34]</sup>. Mammary glandular epithelia short of syndecan-1 show rearrangement of integrin  $\beta 3$  and markedly low expression of E-cadherin at the same time<sup>[35]</sup>. Wound healing theory indicates that E-cadherin activates the migration of integrin  $\beta 3$ -transfected cells and constrains them to separate from wound margin. The study of Ohta *et al.* shows that over expression of the homeobox gene HOXD3 promotes the non-expression of E-cadherin and increased expression of integrin  $\beta 3$ , which plays an important role in the quick migration and isolation of tumor cells<sup>[29]</sup>. Zhang *et al.*<sup>[11]</sup> reported that E-cadherin loss in epithelial tumor progression was not only related to severing cell-cell adhesion but also associated with increased integrins expression, which induced cell-matrix adhesion of these cells<sup>[13]</sup>.

The results of this study indicate that the expressions of syndecan-1 and E-cadherin in gastric tumor tissues are low and their levels are significantly correlated. This suggests that syndecan-1 and E-cadherin play a positively cooperative role in the genesis and development of gastric carcinoma. They are negatively correlated to the level of integrin  $\beta 3$  expression and this suggests that Integrins have different effects on the progression of gastric carcinoma. The functional consequence of enhanced cell-matrix adhesion is the initial attachment and retention of these cells at the epithelial-stromal interface, thus providing the appropriate microenvironmental conditions for incipient tumor cell invasion<sup>[13]</sup>.

Basing on the biological characters of syndecan-1, E-cadherin and Integrins, on relevant documents and on the results of this study, the correlation of CAMs with the progression of gastric carcinoma can be summarized as follows: (1) at the early stage of gastric carcinoma, tumor cells have low E-cadherin and syndecan-1 expression, adhesion between cells is weak and tumor cells are isolated from primary tumor, which is the initial step of invasion and metastasis of gastric carcinoma; (2) the decrease of the expressions of E-cadherin and syndecan-1 reduces adhesion between tumor cells and BM or extracellular matrix mediated by them and this is propitious to local growth and dispersion of tumor. At the same time, various hydrolytic enzymes will be released, after the adhesion of

cancer cells to BM or extracellular matrix, to degrade the BM or extracellular matrix which tumor cells adhere to. Thus cancer cells may enter into the blood circulation. Experimental studies show that Integrins are the main receptors for cells adhesion to extracellular matrix and syndecan-1 increases the combination of them; (3) the increase of Integrin expression, after that cancer cells enter the blood circulation, is in favor of adhesion of tumor cells to endothelia to induce invasive growth and remote metastasis of gastric carcinoma. In these processes, adhesion of tumor cells to endothelia and the BM under endothelia is the key process for the invasion and metastasis.

The pathological indexes and survival analysis results confirm that gastric cancer tissues with low syndecan-1 and E-cadherin protein expressions and high integrin  $\beta 3$  protein expression have deeper invasion depth, higher occurrences of vascular invasion, lymph node metastasis and remote metastasis, shorter average survival time and lower 5-year survival rate, which is consistent with the study results of Wiksten *et al.*<sup>[16]</sup>, Trikh *et al.*<sup>[36]</sup> and other researchers.

In conclusion, low expressions of syndecan-1 and E-cadherin protein and high expression of integrin  $\beta 3$  protein are significantly correlated to invasion of gastric carcinoma. As intracellular adhesion molecular complexes, these three proteins are highly correlated with each other. Therefore, the results of co-examination of them can be important indexes for prognosis of gastric carcinoma.

## COMMENTS

### Background

Cell adhesion is one of the important steps in invasion and metastasis. Syndecan-1, E-cadherin and integrin  $\beta 3$  make up intercellular adhesion molecules (CAMs) and participate in the adhesion between cell and extracellular matrix. One or two of them in gastric carcinoma has been reported before; however, in order to better understand the coordinated regulation of cell-cell and cell-matrix interactions during malignant transformation, we study the coexpression of E-cadherin, syndecan-1 and integrin  $\beta 3$  by immunohistochemical study in gastric carcinomas.

### Research frontiers

Recent investigations have suggested that frozen tissue-based molecular classifications effectively predict prognosis of gastric cancer, prognostic classification on formalin-fixed tissue is needed. Therefore additional markers are required in the prognosis of patients with gastric cancer.

### Innovations and breakthroughs

In this article, we identified that syndecan-1, E-cadherin and integrins were highly correlated with each other as intracellular adhesion molecular complexes. We suggest that the results of co-examination can be important indexes for prognosis of gastric carcinoma.

### Applications

The results from the study confirm the correlation between expressions of CAMs and gastric cancer. It suggests that the coexpression of them can be used to identify the prognosis of gastric carcinoma.

### Terminology

CAMs are proteins located on the cell surface involved in the binding with other cells or with the extracellular matrix in the process called cell adhesion.

### Peer review

This report analyzed that advanced gastric cancer including with/without distant

metastases. Prognostic factor of each stage of gastric cancer about CAMs should be analyzed and author should speculate other factors too.

### Abstract

**AIM:** To evaluate long-term follow-up of minimum-sized hepatocellular carcinoma (HCC) treated with percutaneous ethanol injection (PEI).

**METHODS:** PEI was applied to 42 lesions in 31 patients (23 male and eight female) with HCC < 15 mm in diameter, over the past 15 years.

**RESULTS:** Overall survival rate was 74.1% at 3 years, 49.9% at 5 years, 27.2% at 7 years and 14.5% at 10 years. These results are superior to, or at least the same as those for hepatic resection and radiofrequency ablation. Survival was affected only by liver function, but not by sex, age, etiology of Hepatitis B virus or Hepatitis C virus,  $\alpha$ -fetoprotein levels, arterial and portal blood flow, histological characteristics, and tumor multiplicity or size. Patients in Child-Pugh class A and B had 5-, 7- and 10-years survival rates of 76.0%, 42.2% and 15.8%, and 17.1%, 8.6% and 0%, respectively ( $P = 0.025$ ).

**CONCLUSION:** Treatment with PEI is best indicated for patients with HCC < 15 mm in Child-Pugh class A.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the major malignancies worldwide<sup>[1-4]</sup>. With recent advances in diagnostic imaging, particularly in ultrasound (US), an increasing number of small or early-stage HCCs have been detected. In patients with early-stage HCC, percutaneous ethanol injection (PEI) has been a second choice when surgical techniques have been precluded, although PEI has been used as a first-line treatment option in some centers in Italy and Japan. Over the past few years, several methods for thermal tumor destruction through localized heating or freezing, including radiofrequency ablation (RFA), laser ablation, microwave ablation, and cryoablation, have been developed and clinically tested. Among these, RFA has recently emerged as a real competitor to PEI.

At this point, there are no unequivocal data to back up percutaneous ablation as a replacement for resection as first-line treatment for patients with early-stage HCC. Therefore, whether percutaneous ablation replaces resection as first-line option for very early HCC will be resolved by launching a large international randomized controlled trial.

In this study, early-stage HCC (< 15 mm diameter) is referred to as minimum-sized HCC<sup>[5]</sup>. The present study is a long-term follow-up of minimum-sized HCC treated with PEI.

### MATERIALS AND METHODS

#### Subjects

We analyzed the clinical features of consecutive patients treated with PEI in the 1990s at Kobe Asahi Hospital. The diagnosis of HCC was made by imaging, including US and computed topography (CT) and confirmed by

tumor-targeted biopsies. Thirty-one patients with liver cirrhosis and HCC were treated with PEI as the first-line anticancer treatment. The characteristics of the patients are summarized in Table 1. The criteria for treatment with PEI were as follows: (1) Uninodular HCC  $\leq 15$  mm in diameter, or multinodular HCC lesions  $\leq 15$  mm in diameter (in one or both hepatic lobes); (2) absence of portal vein thrombosis and extra-hepatic metastases; (3) age  $< 75$  years; (4) liver cirrhosis of Child-Pugh class A or B; and (5) prothrombin time ratio (normal/patient)  $> 40\%$  and platelet count  $> 40\,000/\mu\text{L}$ . The number of tumorous nodules and portal vein patency were established by US and CT. Maximum tumor diameter was measured by US. The absence of extrahepatic metastases was ascertained by chest X-ray, and abdominal CT and US.

Liver cirrhosis was diagnosed histologically, radiologically or clinically. Serum hepatitis B surface antigen (HBsAg) was positive in two patients, and anti-hepatitis C virus antibody (anti-HCV) was positive in 29. Arterial blood flow was confirmed by CO<sub>2</sub> US-angiography or CT during arteriography (CTA); portal blood flow was confirmed by CT during arterial portography (CTAP) (Table 1). Surgery was contraindicated in most patients because of liver dysfunction, presence of lesions in locations that made hepatic resection inappropriate, advanced age, coexistence of another disease, or a combination of these factors. However, during the past few years, some patients, including possible candidates for surgery, were treated with PEI. Informed consent was obtained from all patients after the nature of the procedure had been fully explained.

The diameter of the tumors ranged between 8 and 15 (mean  $11.9 \pm 2.4$ ) mm. The diagnosis of HCC was established by histological biopsy with the needle guided by sonography in 31 patients.

#### Treatment schedule and follow-up protocol

PEI<sup>[6]</sup> was administered to each patient (3-6 sessions; once or twice weekly) by one or two injections of 95% sterile ethyl alcohol (1.6-73.9 mL, mean  $17.6 \pm 16.7$  mL) delivered to each lesion with a multiple-side-hole 21-gauge needle (Et-hanoject, TSK, Tokyo, Japan), depending on the size of the lesion and the distribution of the injected ethanol within the tumor.

One month after the end of PEI treatment, the  $\alpha$ -fetoprotein (AFP) level was measured, CT was repeated, and multiple percutaneous biopsies of the treated lesions were carried out to evaluate treatment outcome. Lesions appearing as hypoattenuated, non-enhanced areas on CT scans were diagnosed as necrotic, whereas enhanced areas were suspected of being persistent tumors. The biopsies under US guidance were carried out by placing the needle in the enhanced areas of the tumor. Histological samples were obtained from all of the patients.

The treatment was terminated and the patients entered the follow-up protocol in the absence of residual tumors, confirmed by CT and biopsies, and of suspected persistent tumors, confirmed by AFP levels. Such patients were given additional PEIs targeted in areas where viable tumors had previously been observed, and were examined again by CT

and biopsies after 1 mo. The follow-up protocol included clinical assessment, measurement of hepatic functional serum indexes and AFP levels, and US examinations conducted at 3-mo intervals. The duration of the follow-up was calculated from the beginning of PEI and lasted for 2-167 (mean  $\pm$  SD,  $57.5 \pm 37.7$ ) mo.

#### Statistical analysis

Student's *t* test and  $\chi^2$  test were used to identify differences in patient characteristics in the various subgroups with prognostic factors. The Kaplan-Meier method was used to analyze the factors associated with post-PEI survival of patients with HCC and distant intrahepatic recurrence of HCC, and the difference was determined by log rank test. Stepwise regression analysis was used to identify factors that affected the survival rate of post-PEI patients.  $P < 0.05$  was considered to indicate a statistically significant difference.

## RESULTS

All patients completed the planned treatment course. No major treatment-related complication had occurred by the end of the study. Overall survival rate was 74.1% at 3 years, 49.9% at 5 years, 27.2% at 7 years and 14.5% at 10 years. The longest survival period was 13 years 11 mo, and three patients lived longer than 10 years after PEI treatment. Up to December 2003, 23 post-PEI patients died: Four from cancer (17.4%), 15 from hepatic failure (65.2%) and four from other causes (17.4%). According to the Child-Pugh classification, two (20%) died from cancer and seven (70%) from hepatic failure (class A), and

two (15.3%) from cancer and eight (61.5%) from hepatic failure (class B) (Table 2).

### Prognostic factors

The influence of patient- and tumor-related factors on survival is shown in Table 3. Survival was affected by liver function, but not by sex, age, etiology of cirrhosis (HCV or non-HCV), AFP level, arterial blood flow, portal blood flow, histological characteristics, and tumor multiplicity or size. The final step of stepwise variable showed function was significantly associated with survival rate. Child-Pugh class A patients showed a higher survival rate than Child-Pugh class B ( $P = 0.011$ , Table 4). The 5-, 7- and 10-years

survival rates of 76.0%, 42.2% and 15.8%, respectively, for patients in Child-Pugh class A were significantly higher than those for patients in Child-Pugh class B (17.1%, 8.6% and 0%, respectively) ( $P = 0.025$ , Figure 1). Patient characteristics by Child-Pugh classification showed that prognosis of class A and class B patients was affected by sex and not by any other patient- and tumor-related factors (Table 5). The two groups were similar with respect to the other patient- and tumor-related factors.

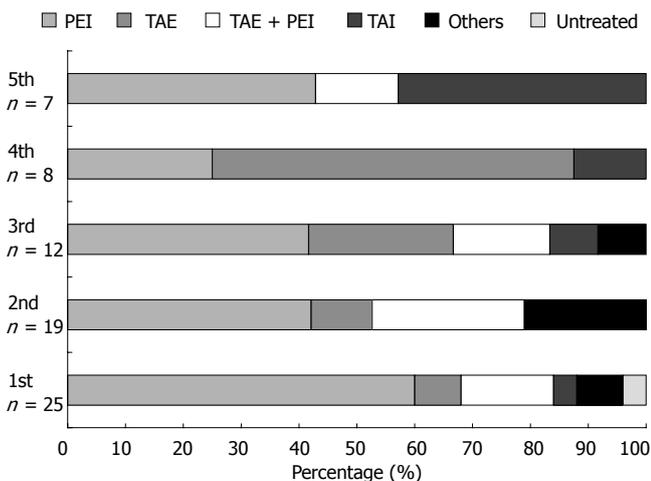

Lesions in intrahepatic areas other than the site treated by PEI were observed in 25 patients (81.8%), and cumulative recurrence rates at 1, 3, 5, 7 and 10 years after PEI were 47.0%, 73.4%, 87.7%, 87.7% and 87.7%, respectively (Figure 2). The frequency of initial recurrence according to segment was 32.0% in segments other than the initially treated segment (other segments), 32.0% in the same segment as the initially treated segments, and 28.0% in both the same and other segments. The tumor diameter of recurrent lesions was < 20 mm in 84.0% of cases, 21-30 mm in 8.0%, and no tumor was > 30 mm at detection (Table 6). The recurrent lesions that occurred in 25 post-PEI patients after initial treatment were managed as follows: PEI in 15

**Figure 1** Survival of patients with HCC treated by PEI according to Child-Pugh classification.

**Figure 2** Recurrence of HCC treated by PEI at remote site from initial treated site.

**Figure 3** Treatment for repeated recurrences in patients with HCC initially treated by PEI.

(60.0%); transcatheter chemoembolization (TACE) in two (8.0%); TACE + PEI in four (16.0%); transcatheter arterial infusion chemotherapy in one (4.0%); and other methods in two (8.0%). One patient (4.0%) was untreatable because of severe liver dysfunction or poor general condition. Second, third, fourth and fifth recurrent lesions were treated with PEI in eight (42.1%), five (41.6%), two (25.0%) and three (42.8%) patients, respectively (Figure 3).

## DISCUSSION

In a multicenter trial conducted in Italy<sup>[7]</sup>, the 3-, 5- and 7-years survival rates after PEI in patients with a single

**Table 6** Recurrence of HCC initially treated by PEI ( $n = 25$ )

Location of recurrence

Others	2 (8.0%)

<sup>1</sup>In two cases, tumor thrombus was seen in portal vein and HCC metastasizing to distant site (sacrum and lumbar vertebra), respectively.

HCC ≤ 30 mm in diameter have been reported as 78%, 54% and 28%, respectively; those in patients with a single HCC 30.1-50 mm as 61%, 32% and 16%, respectively; and those in patients with multiple lesions as 51%, 21% and 0%, respectively. In a series of 270 patients in Japan with fewer than three small lesions (≤ 30 mm in diameter) of HCC, overall 3- and 5-years survival rates after PEI were 81.6% and 60.3%, respectively, but the rates were higher, 87.3% and 78.3% in Child-Pugh class A patients with a solitary tumor ≤ 20 mm in diameter<sup>[8]</sup>. The overall 3-, 5-, 7- and 10-years survival rates after PEI in the present study were 74.1%, 49.9%, 27.2% and 14.5%, respectively, in our population with minimum-sized HCC. Patients of Child-Pugh class A had 5-, 7- and 10-years survival rates of 76.0%, 42.2% and 15.8%, respectively. The outcome in this study was superior, or at least equal to that reported in other studies.

The superiority or equality of our results, including those for multinodular HCC, compared with other studies can be explained by tumor size alone. Generally speaking, the therapeutic effect of PEI is largely dependent on tumor size<sup>[9]</sup>. Strictly speaking, the difference between tumors 15 and 16-20 mm in diameter is very important. Pathological events identified in 106 small resected HCCs < 20 mm in diameter have demonstrated local metastases (located ≤ 10 mm from the nodule), and microscopic portal invasion among the most frequently occurring tumors (the so-called distinctly nodular types). The frequency of portal invasion has been reported as significantly higher in HCC 16-20 mm in diameter (40%) than in HCC 11-15 mm in diameter (25%,  $P < 0.01$ )<sup>[9,10]</sup>. In the current study, survival was not influenced by sex, age, HBsAg positivity, anti-HCV positivity, AFP levels, arterial blood flow, portal blood flow, histological characteristics, tumor multiplicity, or tumor size. However, a statistically significant difference was observed in long-term survival probability attributed only to liver dysfunction.

PEI-treated patients of Child-Pugh class A had longer survival than those of class B, which was comparable with the Italian and Japanese studies<sup>[7,8,11]</sup>. Generally speaking, in treating HCC, prognosis depends not only on the grade of cancer spread (tumor stage)<sup>[12]</sup>, but also on the grade of residual liver function (liver disease stage). Kudo *et al*<sup>[13]</sup> have proposed a prognostic staging system for HCC called

the Japan Integrated Staging Score (JIS score), and have suggested that the prognosis of stage I HCC (solitary, < 20 mm in diameter, no vascular invasion) depends on liver function. Here, the long-term results of PEI were equivalent to those achieved with patients treated by hepatic resection. According to the Liver Cancer Study Group of Japan<sup>[14]</sup>, the 5- and 7-years survival rates among 3674 patients with single, clinical stage I HCC lesions < 20 mm in diameter, treated by hepatic resection, reached 65.4% and 47.1%, respectively. In our study, the respective rates of 77.3% and 43.0% were obtained by restricting the final analysis to a selected group of 20 patients with single or multiple HCC nodules  $\leq$  15 mm in diameter and with Child-Pugh class A cirrhosis. Hence, although no prospective randomized trials comparing PEI versus surgery have been conducted, the long-term results of the two treatments seem to be quite similar.

Recently, new thermal therapeutic techniques for HCC have been developed, including RFA, laser microwaves and cryotherapy. Among these, RFA has attracted much international interest and is now widely used in clinical practice. In a comparison of PEI and RFA in 86 patients with 112 HCCs<sup>[15]</sup>, a complete response was reached in 90.3% by RFA and 80% by PEI, with an average of 1.2 sessions for RFA and 4.8 sessions for PEI. However, more complications arose by RFA: one severe (hemothorax that required drainage) and four minor (intraperitoneal bleeding, hemobilia, pleural effusion and cholecystitis), compared with none by PEI.

Recently, three randomized studies which compared RFA versus PEI for first-line treatment of early-stage HCC have been published<sup>[16-18]</sup>. European groups have failed to show a statistically significant difference in overall survival between patients who received RFA and PEI<sup>[16]</sup>. On the other hand, survival advantages have been identified in studies in Japan and Taiwan<sup>[17,18]</sup>. In Japan, Shiina *et al.*<sup>[17]</sup> have described 232 patients, 118 treated by RFA and 112 by PEI. Four-year survival rate was 74% (95% CI: 65-84) for RFA and 57% (95% CI: 45-71) for PEI. RFA had a 46% smaller risk of death [adjusted relative risk, 0.54 (95% CI: 0.33-0.89),  $P = 0.02$ ], a 43% smaller risk of overall recurrence [adjusted relative risk 0.57 (95% CI: 0.41-0.80),  $P = 0.0009$ ], and an 88% smaller risk of local tumor progression [relative risk, 0.12 (95% CI: 0.03-0.55),  $P = 0.006$ ] than PEI. Similarly, benefits in survival were also suggested in a subgroup analysis of a trial in Taiwan<sup>[18]</sup>.

Most trials comparing RFA and PEI for treatment of small HCC have yielded better survival, local efficacy, local recurrence and duration of treatment in favor of RFA; the only advantage in favor of PEI being a slightly lower rate of complications<sup>[16]</sup>. In the present study, the frequency of HCC recurrence was considered to be high, with new lesions appearing in 25 of the 31 patients. However, after PEI, almost all recurrence was caused by the emergence of new nodular lesions in hepatic segments other than at the locations of the treated tumors, and were therefore probably unrelated to the original tumor. Repeat PEI alone was feasible for recurrence in 60.0%, 42.1%, 41.6%, 25.0% and 42.8% of these cases at detection of the first to fifth recurrence, respectively. As the number of lesions also

increases whenever a tumor recurs, local treatment such as PEI is of limited value, and PEI must be replaced by another form of treatment such as TACE or transcatheter infusion chemotherapy.

All the studies mentioned above confirm the high efficacy of PEI in the treatment of minimum-sized HCC. In conclusion, to achieve the best possible prognosis in its treatment, early detection of HCC < 15 mm in diameter by imaging and histological diagnoses, and early treatment by PEI are essential.

## COMMENTS

### Background

In treatment of hepatocellular carcinoma (HCC), only 20%-30% of patients are candidates for surgery. Thus, various non-surgical therapies, such as percutaneous ethanol injection (PEI), microwave coagulation and radiofrequency ablation (RFA) have been widely used for small HCC. Although PEI was used as first-line treatment in some Japanese and Italian centers in the 1980s and 1990s when surgical techniques were precluded, RFA has recently emerged as a real competitor to PEI. At this time, there are no unequivocal data to back up PEI as a replacement for resection as a first-line treatment for patients with early-stage HCC.

### Research frontiers

PEI is a standard therapy. However, there has been a drastic shift from PEI to RFA since the introduction of the latter into clinical practice, because efficacy seems more reproducible in RFA than in PEI and microwave coagulation. Most trials comparing RFA and PEI for the treatment of small HCC have yielded not only local efficacy but also survival in favor of RFA. In addition, RFA requires shorter hospitalization than PEI, which improves quality of life. However, severe complications arise with RFA, such as hemothorax, intraperitoneal bleeding, liver abscess, liver infarction and diaphragmatic hernia, compared with none with PEI.

### Innovations and breakthroughs

PEI can be safely performed. In fact, severe complications such as intraperitoneal bleeding, liver abscess, liver infarction and diaphragmatic hernia did not occur in our study. After PEI however, almost all recurrence was caused by the emergence of new nodular lesions in hepatic segments other than at the locations of the treated tumors. In those cases, PEI was used not only for the initial treatment of small HCC, but also for recurrent lesions at untreated sites after treatment. The post-PEI survival rates in our patients with Child-Pugh class A cirrhosis were at least equal to those in the post-surgery group. Tumor size (< 15 mm in diameter) and liver function (Child-Pugh class A cirrhosis) were significant survival predictors, and such patients were the best candidates for percutaneous ablation. PEI is considered not to compete with but to be complementary to RFA in the treatment of small HCC, because of its excellent safety and efficacy.

### Applications

RFA is superior to PEI in the treatment of small HCC from the viewpoint of treatment response and long-term survival. PEI however, seems feasible, efficacious and is very safe. RFA is difficult with tumors located near the gall bladder, bile ducts and diaphragm. Therefore, the usefulness and importance of PEI for HCC, especially for small-sized (< 15 mm in diameter) HCC, should be emphasized. Early detection of HCC < 15 mm by imaging and histological diagnosis and early treatment by PEI are essential.

### Terminology

Small HCC: < 15 mm in diameter. Local ablation therapy: non-surgical imaging-guided therapy (using US and/or CT) such as PEI, microwave coagulation and RFA. PEI: absolute ethanol is injected directly into lesions through 21-22-G needles, which are inserted under US guidance. It can destroy a considerably large volume of tissue in one session. RFA: electrodes are inserted into the tumor under imaging guidance. Radiofrequency energy is emitted from the exposed portion of the electrode, which is converted into heat and causes necrosis of the tumor. Child-Pugh class A liver cirrhosis: Cirrhosis with relatively good liver function (bilirubin < 2 mg/dL, albumin > 3.5 g/dL, and prothrombin time > 80%), without ascites and encephalopathy.

**Peer review**

This study reported a small cohort of 31 patients with HCC < 15 mm in diameter treated by PEI. Overall survival of the patients was equal or possibly slightly superior to that with treatment by hepatic resection or radioablation. Although a small number of patients was analyzed, it represents an interesting and potentially important clinical finding.

### Abstract

**AIM:** To determine the effect of tetrahydrocurcumin (THC) on tumor angiogenesis compared with curcumin (CUR) by using both *in vitro* and *in vivo* models of human hepatocellular carcinoma cell line (HepG2).

**METHODS:** The 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT) assay was used for testing the anti-proliferating activities of CUR and THC. In male BALB/c nude mice,  $2 \times 10^6$  human HepG2 cells were inoculated onto a dorsal skin-fold chamber. One day after HepG2 inoculation, the experimental groups were fed oral daily with CUR or THC (300 mg/kg or 3000 mg/kg). On d 7, 14 and 21, the tumor microvasculature was observed using fluorescence videomicroscopy and capillary vascularity (CV) was measured.

**RESULTS:** Pathological angiogenic features including microvascular dilatation, tortuosity, and hyper-permeability were observed. CUR and THC could attenuate these pathologic features. In HepG2-groups, the CV were significantly increased on d 7 (52.43%), 14 (69.17%), and 21 (74.08%), as compared to controls (33.04%,

$P < 0.001$ ). Treatment with CUR and THC resulted in significant decrease in the CV ( $P < 0.005$  and  $P < 0.001$ , respectively). In particular, the anti-angiogenic effects of CUR and THC were dose-dependent manner. However, the beneficial effect of THC treatment than CUR was observed, in particular, from the 21 d CV (44.96% and 52.86%,  $P < 0.05$ ).

**CONCLUSION:** THC expressed its anti-angiogenesis without any cytotoxic activities to HepG2 cells even at the highest doses. It is suggested that anti-angiogenic properties of CUR and THC represent a common potential mechanism for their anti-cancer actions.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is a highly malignant tumor characterized by active neovascularization<sup>[1]</sup>. Since HCC recruit new blood vessels to support tumor growth, an anti-angiogenic agent is one of the goal drugs to treatment of HCC. Cancer cells have a very high rate of mutation in contrast to endothelial cells, which are the main components of blood vessels and have a lower rate of mutation. Because of this genetic stability, anti-cancer treatment inducing tumor-induced angiogenesis is expected to be less vulnerable to such drug tolerance. Moreover, it may work on a broad spectrum of solid tumors because all these tumors need to induce angiogenesis for their processes. It is of great interest to apply the idea of anti-angiogenesis treatment to the prevention of cancer. If

food factors that can inhibit angiogenesis were to be found, such factors could be used to stop small cancers from progression. Curcumin (CUR) is considered to be among such candidates. Curcumin (diferuloylmethane) is a phenolic compound from the plant *Curcuma longa*. A variety of pharmacological effects of curcumin have been reported, including anti-inflammatory<sup>[2]</sup>, anti-oxidant<sup>[3,4]</sup>, and anti-carcinogenic activities<sup>[5-7]</sup>. Recently, it has been shown that the anti-cancer property of curcumin is mediated in part by its anti-angiogenic activity<sup>[8-11]</sup>. As the active metabolite of curcumin obtained in gastrointestinal tract, tetrahydrocurcumin (THC) is a reduced analog of curcumin with phenolic and  $\beta$ -diketo moieties as well as curcumin (Figure 1). Sugiyama *et al*<sup>[12]</sup> demonstrated that THC exhibited similar physiological and pharmacological properties, in particular, THC has possessed strong anti-oxidant action than curcuminoids including curcumin, demethoxycurcumin, and bisdemethoxycurcumin<sup>[13]</sup>. Although the role of THC in anti-cancer activity has been implicated<sup>[13]</sup>, its possible mechanism(s) and efficacy related to curcumin anti-cancer responsibility are still controversial. For instance, THC has been reported to be a less effective chemopreventive agent in mouse skin than curcumin<sup>[14]</sup>. In contrast, 0.5% THC mixed diet showed a stronger inhibitory effect on 1,2-dimethylhydrazine induced mouse colon carcinogenesis than curcumin<sup>[15]</sup>. Therefore, the present study was aimed to determine the effect of THC on tumor angiogenesis in comparison with curcumin by using both *in vitro* and *in vivo* models of human hepatocellular carcinoma cell line (HepG2).

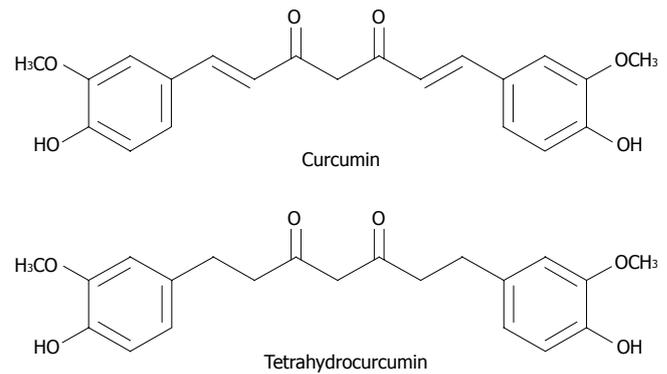

## MATERIALS AND METHODS

### Preparation of curcumin and THC

The curcuminoid mixture obtained from the rhizomes of *Curcuma longa* was subjected to silica gel column chromatography, using hexane-dichloromethane, dichloromethane and dichloromethane-methanol as eluents to afford curcumin (CUR) as the major constituent. Recrystallization was accomplished by dissolving the evaporated eluate with a small quantity of dichloromethane and ethanol was then added. CUR crystallized out as yellow needles, melting point (m.p.) 181-183°C. THC was synthesized from CUR by catalytic hydrogenation reaction, with palladium on charcoal as a catalyst. The product was purified by silica gel column chromatography followed by recrystallization with dichloromethane-hexane to give 75% yield of THC as colorless needles, m.p. 93-94°C. The spectroscopic (IR, <sup>1</sup>H-NMR and mass spectra) data of the synthesized THC were consistent with the reported values<sup>[16]</sup>.

### In vitro study of anti-proliferation assay

The effects of CUR and THC on the growth and survival of human hepatocellular carcinoma cell lines were measured using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT) assay. Briefly, HepG2 cells ( $7.5 \times 10^4$  per well) were plated in 0.2 mL medium containing 10% FBS in triplicate in 96 well plate after 24 h medium was removed and then treated with 0.2 mL medium containing the indicated concentrations of CUR or THC at 37°C

**Figure 1** Chemical structures of CUR and THC. CUR and THC have similar  $\beta$ -diketo and phenolic moieties.

for 24 h. At the end of incubation, 0.050 mL of MTT solution (5 mg/mL) was added to each well. After 20 min incubated at 37°C, 0.030 mL of isopropanol was added to dissolve the formazan crystals. The absorbance of the MTT formazan was determined at 570 nm in an enzyme-linked immunosorbent assay (ELISA) reader. Cell growth index was defined as a percentage of the absorbance of treated cells to untreated cells.

### Animal preparation

The experiments were performed in BALB/c-nude mice (b.w. 20-25 g;  $n = 90$ ). The animal experiment was conducted according to the guideline of experimental animals by The National Research Council of Thailand (1999). The mice were bred and maintained in a specific pathogen germ-free environment.

The mice were divided into four groups: (1) normal (control) mice with vehicle treatment (Con,  $n = 15$ ), (2) HepG2-induced tumor mice (HepG2,  $n = 15$ ), (3) HepG2-induced tumor mice with CUR treatment (HepG2-CUR,  $n = 30$ ) and (4) HepG2-induced tumor mice with THC treatment (HepG2-THC,  $n = 30$ ). In order to implant HepG2 a dorsal skin-fold chamber (7 mm diameter)<sup>[16]</sup> was used. After the anesthetization by sodium pentobarbital (50 mg/100 g BW, i.p.), 30  $\mu$ L of  $2 \times 10^6$  HepG2 cells were inoculated in the middle area of dorsal skin-fold chamber and then covered with 7 mm glass slip. All surgical procedures were performed under aseptic conditions. The animals were then housed one animal per cage with free access to sterile water and standard laboratory chow.

In the CUR and THC treated groups (HepG2-CUR and HepG2-THC groups), the mice were daily oral treated by 2 mL of 300 and 3000 mg/kg BW CUR and THC dissolved in 0.1% dimethyl sulfoxide (DMSO; Sigma, USA). These treatments were started twenty-four hours after the inoculation. In the control group (Con and HepG2), the mice received vehicle (0.1% DMSO) instead.

### Intravital fluorescence videomicroscopy study

The experiments were performed d 7, 14 and 21 after vehicle, CUR or THC treatments. The mice were anesthetized with an intraperitoneal injection of sodium pentobarbital (50 mg/kg BW). A catheter was inserted into

**Figure 2** An example of 5 windows selected for measurement of capillary vascularity (CV) from the video-image at a low magnification ( $\times 10$ , Bar = 100  $\mu\text{m}$ ).

a jugular vein for application of fluorescence tracers. Then, the dorsal skin-fold chamber was removed and skin area around the chamber was fixed with modeling wax on a plate.

The microcirculation within a studied area was observed under an intravital fluorescence microscope using a  $10\times$  objective. During the experiment, a videocamera (Sony, Japan) was used to project the image onto a monitor (Sony, Japan) and to record the interested areas within the tumor-bearing chambers by using a video-recorder (Sony, Japan). The videotape of each experiment was then analyzed off-line using digital image processing software (Global Lab II).

For visualization of the microvascular lumen, a bolus of 0.1 mL of 5% fluorescein isothiocyanate-labeled dextran (FITC-dextran) was injected into the jugular vein 5 min prior to the recording. The recorded videoimages were analyzed and calculated for capillary vascularity, using digital image processing software (Global Lab II) and then expressed in percentage as described previously<sup>[9]</sup>. The capillary vascularity (CV) level was used as an index of angiogenesis.

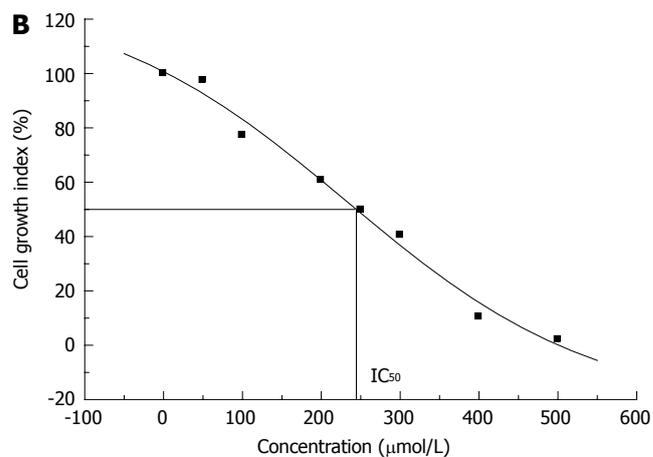

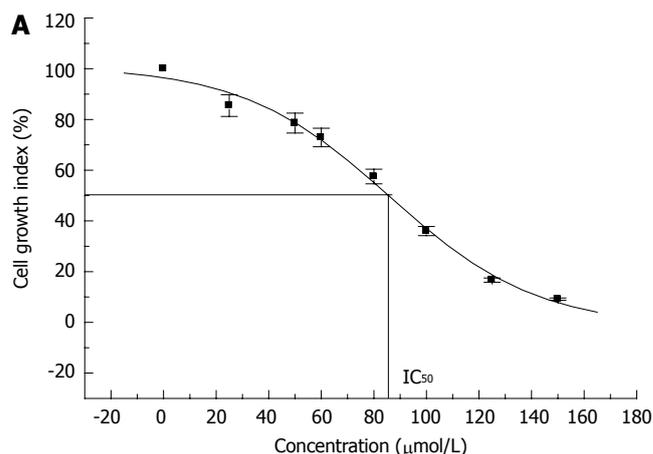

### Measurement of capillary vascularity

Based on the recorded video image, we measured capillary vascularity (CV) defined as follows:  $\text{CV} = (\text{number of pixels within the capillaries}) \times 100 (\%) / \text{total number of pixels within the selected window area}$ .

In each mouse, we observed and recorded at 5 positions on the surface of tumors by moving the microscopic stage. Figure 2 shows an example of 5 windows selected on one low-magnified image. Each window (video frame of  $100 \times 100$  pixels) was selected so as to cover any no large vessel. By determining both minimum and maximum intensities of pixels, we counted the total number of pixels over all capillaries in each window, using digital image processing software (Global Lab II) and expressing the CV as percents of capillary area to total area. Averaging the CV's ( $\text{CV}_i, i = 1-5$ ) measured over 5 video-frames (positions), we calculated the mean CV in one mouse:  $\text{Mean CV} = (1/5) \sum \text{CV}_{(1-5)}$ .

### Statistical analysis

Results were shown as mean  $\pm$  SE. One-way ANOVA was used to evaluate the difference of means. The statistical differences were considered at the probability level ( $P$  value) of less than 0.05.

**Figure 3**  $\text{IC}_{50}$  and cell growth index by MTT assay. **A:** Effects of CUR on cell proliferation of HepG2 cell; **B:** Effects of THC on cell proliferation of HepG2 cell. Values given represent the mean  $\pm$  SE of three independent experiments carried out in triplicate. The  $\text{IC}_{50}$  value was required to decrease viability from 100% to 50%.

## RESULTS

### Anti-proliferation effects of curcumin and its analog on HepG2 cells

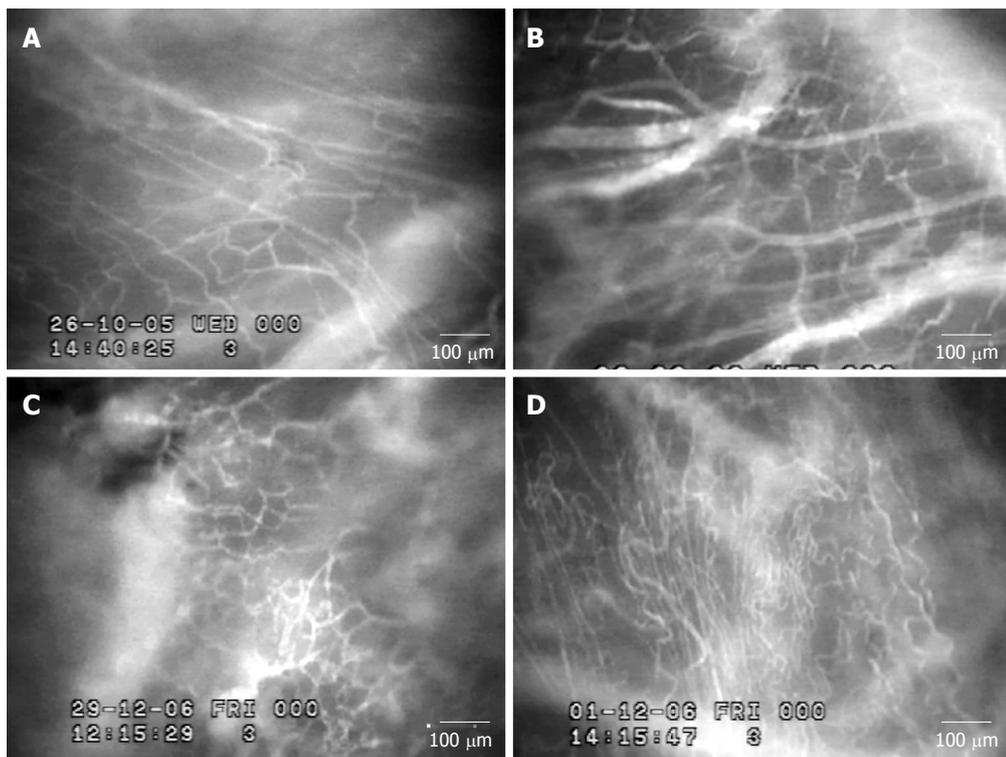

The anti-proliferation activity of CUR and its analog, THC, were examined in HepG2 cell lines by MTT assay. It was found that CUR is a more potent anti-proliferative agent than THC. The  $\text{IC}_{50}$  of CUR and THC were 85.98 and 233.12  $\mu\text{mol/L}$ , respectively (Figure 3).

### Tumor angiogenesis in HepG2-implanted nude mice

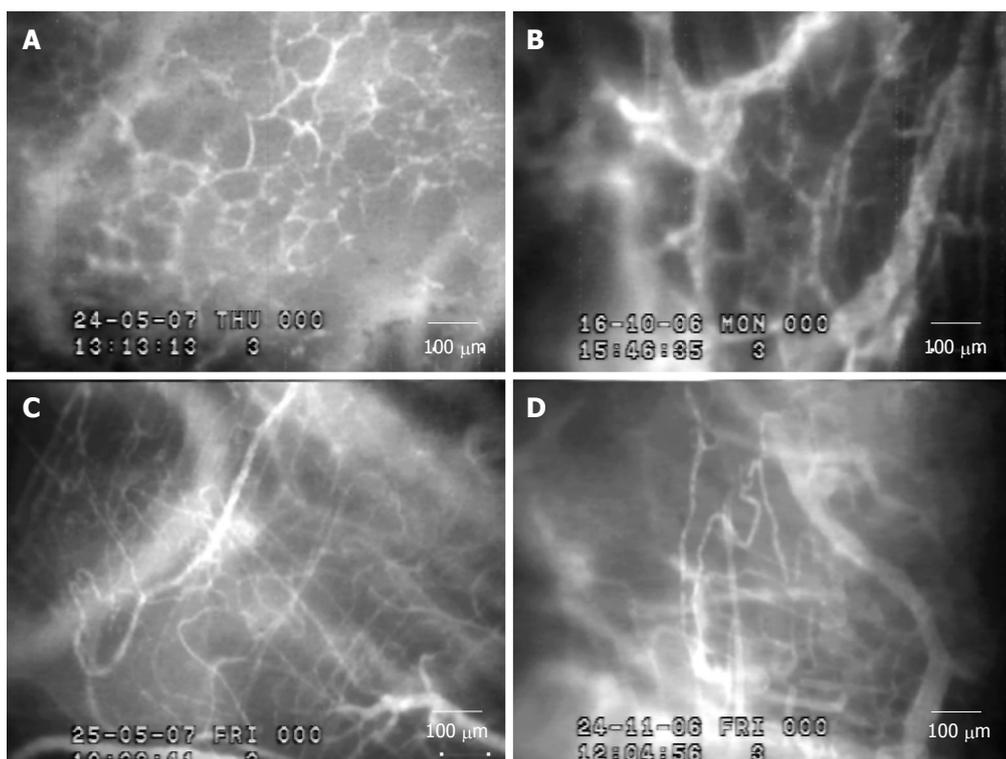

Intravital fluorescence microscopic observation demonstrated a number of neocapillaries in HepG2 groups. Figure 4 shows fluorescence videoimages of the microvasculature for control and HepG2 groups on d 7, 14 and 21 after tumor cells implantation. In addition, pathological angiogenic features including abrupt changes in the diameter, tortuosity, and hyper-permeability were also observed in HepG2 groups.

### Effects of curcumin and its analog on tumor angiogenesis in HepG2-implanted nude mice

Figure 5 demonstrated the intravital fluorescent microscopic observation of tumor angiogenesis affected by CUR and THC treatment. The result showed that the appearance of

**Figure 4** A: Fluorescence videomicroscopy image of the microvasculature for control; B: Fluorescence videomicroscopy image of the microvasculature for 7 d HepG2 groups; C: Fluorescence videomicroscopy image of the microvasculature for 14 d HepG2 groups; D: Fluorescence videomicroscopy image of the microvasculature for 21 d HepG2 groups ( $\times 10$ , Bar = 100  $\mu\text{m}$ ).

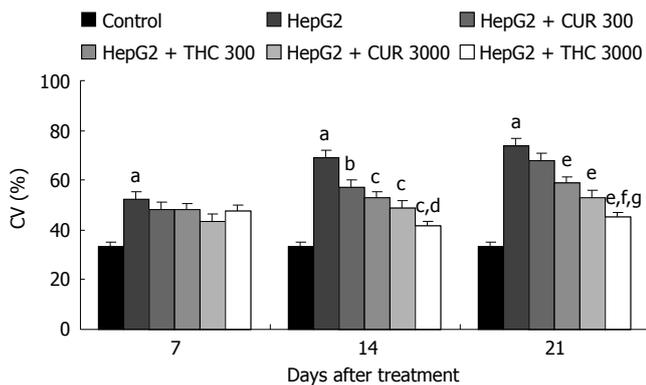

**Figure 5** A: Fluorescence videomicroscopy image of capillary vascularity on 14 d after the implantation of tumor cells with treatment of CUR (3000 mg/kg); B: Fluorescence videomicroscopy image of capillary vascularity on 14 d after the implantation of tumor cells with treatment of THC (3000 mg/kg); C: Fluorescence videomicroscopy image of capillary vascularity on 21 d after the implantation of tumor cells with treatment of CUR (3000 mg/kg); D: Fluorescence videomicroscopy image of capillary vascularity on 21 d after the implantation of tumor cells with treatment of THC (3000 mg/kg,  $\times 10$ , Bar = 100  $\mu\text{m}$ ).

neocapillaries induced by HepG2 was markedly reduced on 14 and 21 d after treatment of CUR and THC (3000 mg/kg BW). In addition, the abnormalities of neocapillary network pattern were attenuated after both treatments.

#### **Capillary vascularity of tumor tissue in HepG2-implanted nude mice**

For analysis of microvascular parameters, CV in the surface

area of tumor was calculated at different periods after tumor cell inoculation. Figure 6 shows CV of 7, 14 and 21 d after vehicle, CUR or THC treatment in control and HepG2 groups. In HepG2-group, the percentage of CV was significantly increased on d 7 (52.43%), 14 (69.17%), and 21 (74.08%), as compared to age-matched controls (33.04%,  $P < 0.001$ ). Treatment with CUR and THC showed significant decrease in the percentage of CV ( $P < 0.005$

**Figure 6** Capillary vascularity (mean  $\pm$  SE) of 7 d, 14 d, and 21 d after vehicle (0.1% DMSO), CUR or THC (300 and 3000 mg/kg BW) treatment in control and HepG2 groups. <sup>a</sup> $P < 0.001$ , vs control group with vehicle; <sup>b</sup> $P < 0.005$ , vs 14 d HepG2 group with vehicle; <sup>c</sup> $P < 0.001$ , vs 14 d HepG2 group with vehicle; <sup>d</sup> $P < 0.01$ , vs 14 d HepG2-THC 300 group; <sup>e</sup> $P < 0.001$ , vs 21 d HepG2 group with vehicle; <sup>f</sup> $P < 0.001$ , vs 21 d HepG2-THC 300 group; <sup>g</sup> $P < 0.05$ , vs 21 d HepG2-CUR 3000 group.

and  $P < 0.001$ , respectively). In particular, the anti-angiogenic effects of CUR and THC were dose-dependent manner. However, the beneficial effect of (3000 mg/kg) THC treatment than CUR was suggested, in particular, from the 21 d percent of neocapillaries density (44.96% and 52.86%,  $P < 0.05$ ).

## DISCUSSION

By using MTT assay, the anti-proliferation properties of CUR and THC were examined in HepG2 cell lines. It was found that CUR has more potent anti-proliferation properties than THC. The  $IC_{50}$  of CUR and THC were 85.98 and 233.12  $\mu\text{mol/L}$ , respectively. CUR has been shown to inhibit cell proliferation in a wide variety of human cancer cell lines *in vitro*<sup>[18]</sup> and in various xenotransplant and orthotopic models of human cancer in rodent<sup>[18,19]</sup>. CUR suppresses the activation of several transcription factors that are implicated in carcinogenesis<sup>[18]</sup>, including nuclear factor kappa B (NF- $\kappa$ B)<sup>[20]</sup>, activator protein 1 (AP-1)<sup>[21]</sup>, and at least two of the signal transducer and activator of transcription proteins (STAT3, STAT5), and modulates the expression of early growth response protein 1 (Erg-1), peroxisome proliferators-associated receptor gamma (PPAR- $\gamma$ )<sup>[22]</sup>. It also suppresses the expression of cyclin D1<sup>[23]</sup> and induces apoptosis of tumor cells<sup>[24,25]</sup>. According to the inhibitory effects of CUR on these cell signaling pathways, CUR may mediate its anti-proliferation by inhibiting either expression or activation of proteins that required for cell survival or cell proliferation. Furthermore, it might imply that THC could be able to suppress these key factors of signaling pathways at lesser efficacies than CUR.

By using intravital fluorescence videomicroscopy, the results showed that: (1) there was a significant increase in the numbers of CV with the heterogeneous network in HepG2 groups as compared to controls as which consistency with our previous reports<sup>[9,10]</sup>. (2) In this study, it was confirmed that more neocapillary density was observed as a time-dependent manner during tumor

progression (CV of 21 d  $>$  CV of 14 d  $>$  CV of 7 d). (3) THC is a stronger anti-angiogenic agent than CUR.

Therefore, in the present study, CUR and THC could exert both *direct* and *indirect* actions by inhibiting tumor cell proliferation and by inhibiting tumor angiogenesis, respectively. Although the precise mechanisms that lead to tumor angiogenesis are not fully understood, several studies have shown that tumor angiogenesis which is the common process necessary for every tumor types requires the expressions of cyclooxygenase-2 (COX-2), vascular endothelial growth factor (VEGF), and matrix metalloproteinase-9 (MMP-9). Similar to our findings, CUR has been shown to suppress the proliferation of human vascular endothelial cells *in vitro*<sup>[26]</sup> and to abrogate angiogenic response *in vivo*<sup>[10]</sup>. It has also been shown that CUR inhibited Akt activation and down-regulated the expression of 5-lipoxygenase<sup>[20]</sup>.

The significant finding initiated from the current study is that THC has efficacy in anti-angiogenic activity than CUR. Although THC is shown to be less anti-proliferative activity than CUR, several studies agreed to demonstrate that THC is a more potent anti-oxidant than CUR<sup>[12,27]</sup>, and the mechanism could be implied by its  $\beta$ -diketo moiety<sup>[12]</sup>. A number of evidence also suggested that tumor-mediated inflammatory response could generate an intensive local accumulation of reactive oxygen species (ROS). ROS may play a role as the mediator for the consequence of tumor induced the expression of tumor biomarkers involved tumor angiogenesis. The activation for VEGF and angiopoietin-1 induced EC migration and/or proliferation through an increase in ROS mainly proposed by a number of researchers<sup>[28,29]</sup>. It was found that ethanol stimulated actin cytoskeletal reorganization, cell motility and tube formation in a ROS-dependent manner in ECs<sup>[30]</sup>. Furthermore, Leptin, a circulating adipocytokine, upregulated VEGF mRNA and stimulates cell proliferation through an increase in ROS in ECs<sup>[31]</sup>.

Based on the idea of ROS, several other antioxidants such as green tea catechins, vitamin E, and natural polyphenols from red wine have been documented as the inhibitors of tumor angiogenic responses<sup>[32]</sup>. According to the more potent anti-oxidant activity of THC, the more potent anti-angiogenic activity of THC than CUR could be used to describe the different anti-angiogenic results.

Finally, it was concluded that both CUR and THC have shown to produce both anti-proliferation and anti-angiogenesis at different manner. More potent tumor anti-angiogenesis was observed for THC, and it might be due to its higher anti-oxidant activity than CUR. It is implied that THC might be a promising candidate for tumor anti-angiogenesis in the near future.

## COMMENTS

### Background

Anti-angiogenesis, the postulated mechanism of anti-cancer activities of tetrahydrocurcumin (THC) and curcumin (CUR), was examined using hepatocellular carcinoma cells (HepG2)-implanted nude mice. CUR has been found to be an angiogenic inhibitor. However, THC, a potent anti-oxidative agent is responsible for the reported effect is still to be determined. The present study was aimed to determine the effect of THC on tumor angiogenesis in comparison with CUR by using both *in vitro* and *in vivo* models of HepG2.

## Research frontiers

THC contains both a phenolic moiety and a  $\beta$ -diketone moiety in the same structure. THC exhibits many of the same physiologic and pharmacological activities as CUR and in some systems may exert greater anti-oxidant activity than CUR. Therefore, the role of THC in preventive and therapeutic of cancer is gain interest. Anti-angiogenic therapy is one of the most promising strategies for cancer treatment. In this study, anti-angiogenic activity was investigated by evaluating the density of neovascularization induced by Hepatocellular carcinoma cell (HepG2) in nude mice, using intravital fluorescence videomicroscope. The results showed that THC exerts significant anti-angiogenic activity. Therefore, THC might be a promising candidate for tumor anti-angiogenesis in the near future.

## Innovations and breakthroughs

The present study showed the anti-cancer and anti-angiogenic activities of CUR and THC. CUR and THC have shown to produce both anti-proliferation and anti-angiogenesis at different manner. More potent tumor anti-angiogenesis was observed for THC, and it might be due to its higher anti-oxidant activity than CUR.

## Applications

The findings from this study support the idea that anti-oxidative substances can be a therapeutic target for treating cancer.

## Peer review

In this study, THC, a novel type of anti-oxidant showed anti-angiogenic activities without any cytotoxic effect. Importantly, our results have provided originally an *in vivo* evidence for anti-angiogenic activity of THC, in particular by using hepatocellular-carcinoma inoculated skin-chamber model.

### Abstract

**AIM:** To investigate the relationship of changes in expression of marker genes in functional categories or molecular networks comprising one functional category or multiple categories in progression of hepatic fibrosis in hepatitis C (HCV) patients.

**METHODS:** Marker genes were initially identified using DNA microarray data from a rat liver fibrosis model. The expression level of each fibrosis associated marker gene was analyzed using reverse transcription-polymerase chain reaction (RT-PCR) in clinical biopsy specimens from HCV-positive patients ( $n = 61$ ). Analysis of changes in expression patterns and interactions of marker genes in functional categories was used to assess the biological mechanism of fibrosis.

**RESULTS:** The profile data showed several biological changes associated with progression of hepatic fibrosis. Clustered genes in functional categories showed sequential changes in expression. Several sets of clustered genes, including those related to the extracellular matrix (ECM), inflammation, lipid metabolism, steroid metabolism, and some transcription factors important for hepatic biology showed expression changes in the immediate early phase (F1/F2) of fibrosis. Genes associated with aromatic amino acid (AA) metabolism, sulfur-containing AA metabolism and insulin/Wnt signaling showed expression changes in the middle phase (F2/F3), and some genes related to glucose

metabolism showed altered expression in the late phase of fibrosis (F3/F4). Therefore, molecular networks showing serial changes in gene expression are present in liver fibrosis progression in hepatitis C patients.

**CONCLUSION:** Analysis of gene expression profiles from a perspective of functional categories or molecular networks provides an understanding of disease and suggests new diagnostic methods. Selected marker genes have potential utility for biological identification of advanced fibrosis.

### INTRODUCTION

Liver fibrosis is caused by liver disorders such as hepatitis C, hepatitis B, alcoholic hepatitis and non-alcoholic hepatitis. Fibrosis progresses gradually and finally disrupts liver structure and function over several decades, leading to fatal diseases such as cirrhosis and hepatocellular carcinoma (HCC). Classification of fibrosis progression is usually based on histological criteria using the METAVIR scoring system<sup>[1]</sup>, which includes five stages: F0 (no fibrosis), F1, F2, F3, and F4 (cirrhosis). Such a classification is essential in decisions regarding treatment of liver fibrosis. Prominent subjective symptoms do not occur from F1 to F3, but patients begin to be aware of symptoms after F4. However, the F4 stage of cirrhosis is almost incurable and diagnosis of fibrosis at an earlier stage is desirable. The biology after F4 (cirrhosis) has been well studied, due to the interest in diagnosis and therapy for hepatocellular carcinoma (HCC),

but progression to HCC may begin in the early stage of fibrosis in hepatitis C<sup>[2]</sup>.

Prevention of HCC and inhibition of fibrosis in the early phase is important, but the detailed hepatic biological changes corresponding to the F stage are unclear. To understand the background of the early stage of fibrosis, we previously identified genes that can be used as markers of biological changes in progression of hepatic fibrosis and diagnosis of fibrotic progression; these data were obtained from DNA microarray data from an experimental DMN (dimethylnitrosamine)-treated rat model of hepatic fibrosis<sup>[3]</sup>. This work led to marker genes that were arranged in functional categories related to fibrosis, based on genes associated with hepatic cell types such as Kupffer cells, hepatic stellate cells, and hepatocytes.

These marker genes give information on cell-specific and time-dependent behavior of each hepatic cell in fibrogenesis. In the current work, the behavior of marker genes associated with a particular F stage was analyzed using RT-PCR in clinical biopsy specimens from hepatitis C patients. This profile data revealed several biological changes in progression of hepatic fibrosis. Since many functionally clustered genes showed similar changes in expression, we propose serial expression changes in molecular networks associated with liver fibrosis progression in hepatitis C patients. Many functionally clustered genes showed large changes in expression in the early stage of fibrosis, suggesting the importance of therapy at this early stage. Alteration of gene expression also suggested qualitative changes in biological status in the transition from F3 to F4, which is a suspected risk factor for development of HCC. We conclude that analysis of gene expression profiles from a perspective of molecular networks provides improved understanding of disease and indicates potential methods of diagnosis.

## MATERIALS AND METHODS

### *Patients in the clinical study*

All patients were recruited from the Osaka City University Hospital (Osaka, Japan). Sixty-one patients with seropositive results in diagnosis using the third-generation hepatitis C virus enzyme-linked immunosorbent assay (Lumipulse II Ortho HCV, Ortho-Clinical Diagnostics, Tokyo, Japan) and positive serum HCV-RNA were included in the study. Informed consent was obtained from all patients. Liver biopsies were performed on all patients enrolled in the study, and the histological features of the liver specimens were analyzed and graded using the METAVIR scoring system<sup>[1]</sup>. The liver fibrotic stage (F stage) and inflammatory activity (A grade) were determined histologically: at least four subjects were found to be in each F stage classification. Determination for chymase 1 exceptionally has been done with three subjects in F4 stage due to the lack of appropriate samples.

Part of the biopsy sample from each patient was immediately immersed in RNAlater (QIAGEN, The Netherlands) to inhibit RNAase and then kept at 4°C overnight before being transferred to another tube and frozen at -80°C.

### *RT-PCR analysis*

Total RNA was extracted from liver biopsy samples using

an ISOGEN kit (Nippongene) and reverse transcribed using a High Capacity cDNA Archive Kit (ABI, Foster City, CA), in each case according to the manufacturer's instructions. The total RNA in the final reaction mixture was 10 ng/ $\mu$ L. Real-time PCR was performed on an Applied Biosystems 7500 Real-Time PCR System (ABI) data collection system, and analyses were performed using the accompanying software. RT-PCR was performed using 0.8  $\mu$ L cDNA in each well, with a final concentration of 1X the probes of the TaqMan<sup>®</sup> Gene Expression Assay and 1X the Taqman Universal PCR Master Mix (ABI). The final reaction volume was 20  $\mu$ L. Each sample was analyzed in duplicate. The thermal cycler conditions were 2 min at 50°C and 10 min at 95°C, followed by 40 cycles of 15 s at 95°C and 1 min at 60°C.

Data were analyzed using the comparative CT method, in which the expression level of a target gene is normalized relative to an endogenous reference. GAPDH was used as the endogenous reference in all experiments. The target CT and endogenous control CT were calculated for each sample, and the target gene expression level was then calculated using the formula  $2^{(34-CT)}$ . The average of duplicate measurements was obtained, and the relative expression of each gene in a sample was calculated by setting the expression of GAPDH equal to 1000. PCR fluorogenic probes for all the target genes and the endogenous reference were purchased as TaqMan<sup>®</sup> Gene Expression Assays (ABI).

### *Statistical analysis*

A Kruskal-Wallis test was applied to select marker genes with statistically significant changes ( $P < 0.05$ ) in expression level during the fibrosis progression. This calculation was performed using SPSS (SPSS Inc., IL, USA). The gene expression data were subjected to hierarchical clustering analysis using Genowiz<sup>™</sup> software (Ocimum Biosolutions).

### *Pathway analysis of PCR data*

The behavior and relationships of marker genes in pathways associated with lipid metabolism were analyzed with bioSpace Explorer, a system for analysis of expression profile data. This system was produced collaboratively by Pharmafrontier Co. Ltd. and World Fusion Co. Ltd. to examine molecular interactions in expression profile data, using both manual and computational text mining.

## RESULTS

### *Expression behavior of marker genes*

All marker genes determined in this study are listed in Table 1. For each gene, since the quantitative limitation of biopsy specimens resulted in a difference in sample number for each probe, the type of samples, indicating the number of biopsy specimens, is listed in Table 2. Marker genes were selected as representative members of functional categories or molecular networks based on their expression changes in an experimental hepatic fibrosis model<sup>[3]</sup>. Marker genes with statistically significant changes in expression are listed in Table 1. Genes that showed statistically insignificant changes in expression are listed with the gene name only in Table 1. Marker genes that showed statistically significant changes by *t* test during a

Liver biopsy samples were analyzed by RT-PCR using a TaqMan® Gene Expression Assay probe, as described in the Materials and Methods. The genes were selected from DNA microarray data from a rat fibrosis model presented in a previous paper 3. Genes in the ECM category (or other HSC markers) were selected as marker genes for HSC. Genes in the inflammation category were selected as markers of inflammatory cells in liver. Other genes were selected as markers of hepatocytes. Expression profiles of marker genes that showed statistically significant changes during fibrosis by a Kruskal-Wallis test are listed. Genes that showed statistically insignificant changes in expression are listed with the gene name only in Table 1. Columns from left to right indicate functional category, gene description, gene name, expression intensity at F1 stage, group classification (expression of marker genes in group 1 decreased almost linearly along with the F stages, expression of marker genes in group 2 increased almost linearly along with the F stages, and expression of marker genes in group 3 had a peak in the middle of the F stages), expression ratio between neighbouring F stages (a decreased ratio is shown in light gray and an increased ratio in deep gray), serial gene number and types of samples, which indicates the number of biopsy specimens, as shown in the Table 2. Actual alteration behavior of some characteristic genes are shown in Figure 1.

Table 2 Types of samples indicating the number of biopsy specimens

Type of sample	Number of samples			
	F1	F2	F3	F4
1	25	13	14	9
2	23	13	14	8
3	22	12	14	8
4	12	6	9	4
5	7	4	5	4
6	6	4	4	3
7	5	4	5	5

Quantitative limitation of biopsy specimens resulted in a difference in sample number for each probe, according to the interest in the particular gene.

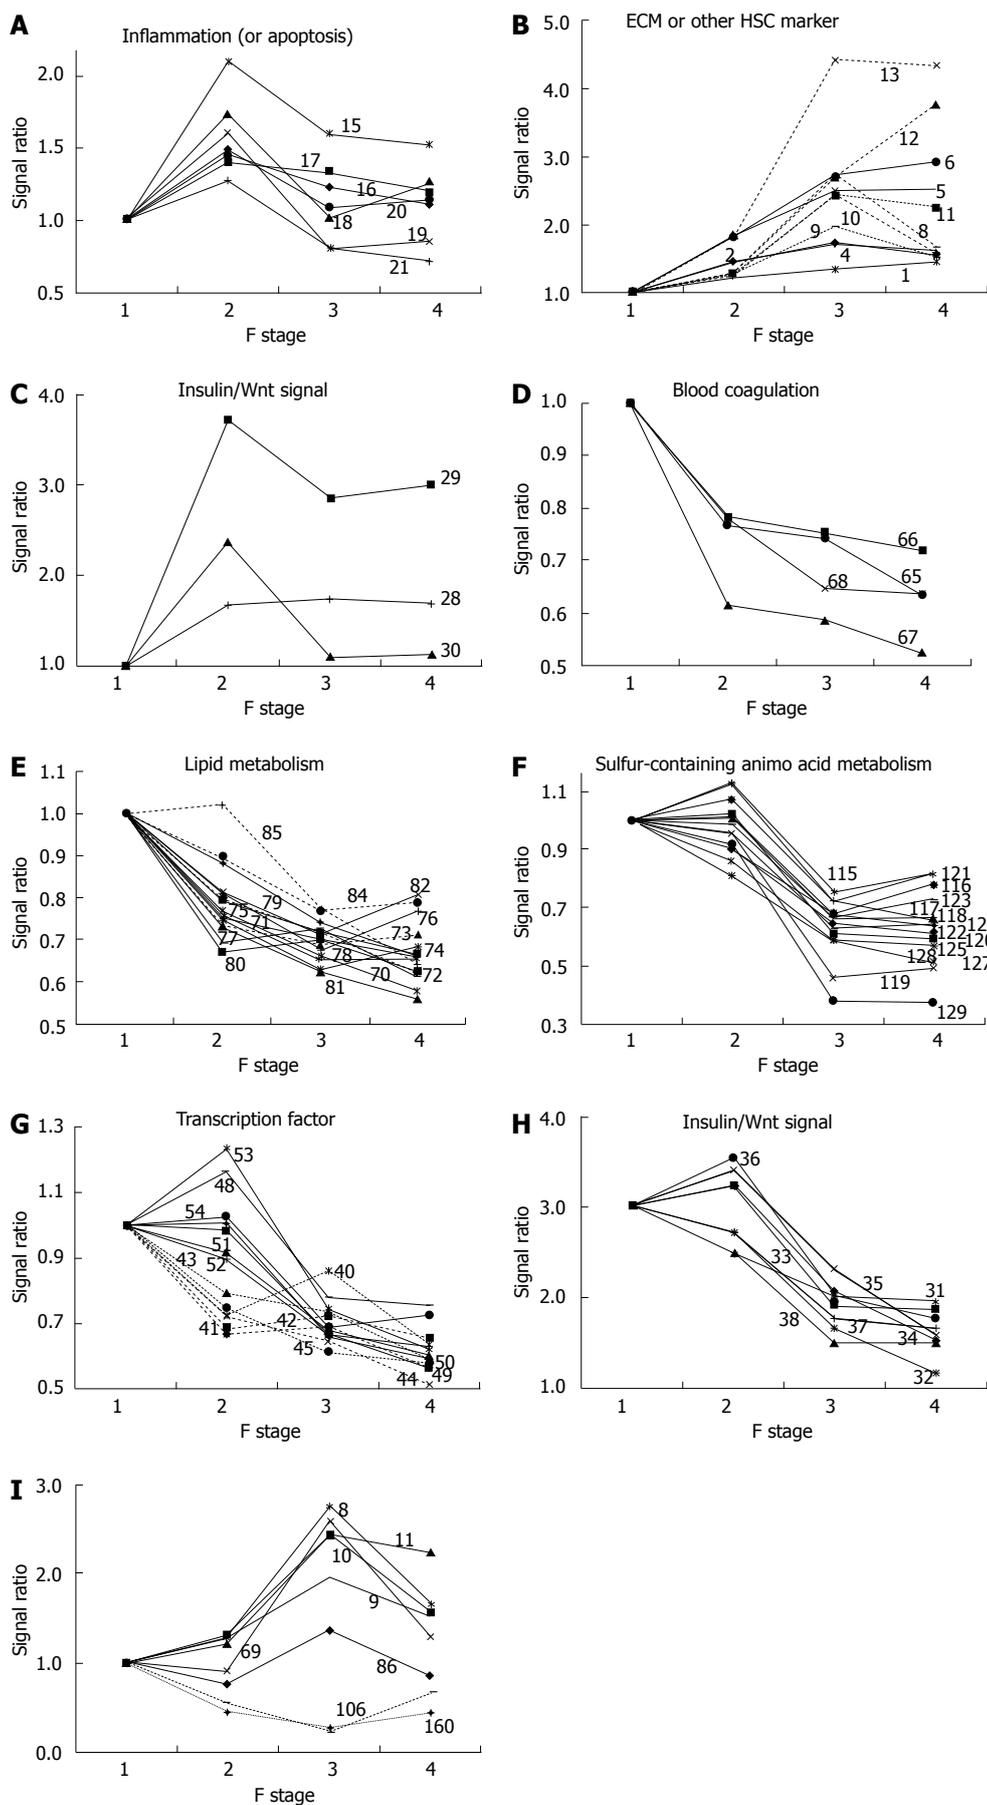

transition to an adjacent F stage are similar to the selected genes in Table 1. An additional four marker genes selected in the *t* test analysis were added to the genes in Table 1. Over half of the selected marker genes from the DNA microarray data from the animal model showed statistically significant changes in the human samples, showing the effectiveness of the animal model for selection of genes

of significance in humans.

Genes showing changes in expression were roughly divided into three groups: genes in group 1 showed an almost linear decrease in expression along with an increase in F stage; genes in group 2 showed an almost linear increase with an increase in F stage; and genes in group 3 showed a peak in the middle of the F stage scale. Almost all genes in one category belonged to one or two groups, suggesting that genes in one category showed similar changes in expression during progression of fibrosis. The expression ratio between F stages is also shown in Table 1, with the peak ratio shown in bold. The peak for almost all genes in a given category occurred at the transition to the same F stage, again suggesting that genes in one category underwent changes in expression under similar mechanistic control.

### Expression changes in gene clusters in the early phase (F1 to F2) of fibrosis

The functional categories showing a peak change in expression ratio in the early phase of fibrosis were inflammation, ECM, blood coagulation, lipid metabolism, half of the

**Figure 1** Clusters of genes in functional categories. The characteristic behavior of gene clusters for each functional category is shown separately in Figure 1A-I. The numbers in each figure refer to the serial number of genes in Table 1. The expression ratio relative to the F1 stage is plotted in each graph. **A:** Inflammation gene cluster with a peak at F2; **B:** ECM gene cluster showing increased expression along with fibrosis progression; **C:** Insulin/Wnt signaling gene cluster with increased expression in the early phase of fibrosis; **D:** Blood coagulation factor gene cluster showing decreased expression along with fibrosis progression; **E:** Lipid metabolism gene cluster showing decreased expression along with fibrosis progression; **F:** Sulfur-containing amino acid metabolism gene cluster showing a synchronous decrease in expression from F2 to F3; **G:** Two transcription factor gene clusters showing sequential decreases in expression; **H:** Insulin/Wnt signaling gene cluster showing decreased expression from F2 to F3; **I:** A gene cluster showing a peak or bottom at F3.

genes in steroid metabolism, half of those in energy source amino AA metabolism, and half of transcription factors.

Expression of marker genes in the inflammation and ECM categories started to increase in the early phase. Expression

**Table 3** Classification of gene clusters based on serial alteration of gene expression along with the fibrosis progression

F1-F2	F2-F3	F3-F4
Inflammation		
Wound-healing (ECM)		
Blood coagulation		
Transcription factors (cluster 1)	Transcription factors (cluster 2)	
	Insulin/Wnt signal	
Lipid metabolism		
Steroid metabolism (cluster 1)	Steroid metabolism (cluster 1)	
	Bile acid metabolism	
Energy source AA metabolism (cluster 1)	Energy source AA metabolism (cluster 1)	
	Aromatic AA metabolism	
	Sulfur-containing AA metabolism	
	Glucose metabolism (cluster 1)	Glucose metabolism (cluster 2)

Gene clusters are indicated under the name of gene category. The pattern of serial alteration for gene cluster was determined based on the maximum changing point of the expression ratio shown in Table 1.

of marker genes related to inflammation, such as LYZ, GZMB, IL1B, TNF and TGFB1, occurred in clusters and reached a peak at fibrotic stage F2, as shown in Figure 1A, suggesting that inflammatory events are particularly active at the F2 stage. However, histological classification of inflammatory activity shows a tendency for an increase in inflammation that is correlated with an increase in F stage; therefore, the conclusion regarding inflammatory events based on expression of marker genes appears to differ from that based on histological classification. Gene expression in the ECM category also increased until F3 or F4, as shown in Figure 1B; expression of such genes might indicate an inflammatory response for wound healing. Increased expression of some clustered genes related to the cell cycle, CCND1, FOXM1 and GJA1 (Connexin 43), was also found at an early stage, as shown in Figure 1C, and might reflect a response to hepatic cell injury.

Almost all other genes were linearly down-regulated. Several genes related to blood coagulation, i.e. F10, AGT, FGA and PLG, were down-regulated as a cluster in the early phase, as shown in Figure 1D; this down-regulation may be linked to prolongation of the blood coagulation time in cirrhosis. An early response of many clustered genes associated with lipid metabolism was also found, as shown in Figure 1E. Expression of these genes decreased consecutively during fibrosis and the early response of genes affecting lipid metabolism is of interest.

### Expression changes in gene clusters in the middle phase (F2 to F3) of fibrosis

The peak change in the expression ratio of marker genes in metabolism of sulfur-containing AA and aromatic AA was delayed, compared to genes associated with other kinds of metabolism. Marker genes for sulfur-containing AA metabolism decreased remarkably as a cluster in the phase from F2 to F3, as shown in Figure 1F. Decreased expression of marker genes for steroid metabolism, energy

source AA, and transcription factors were separable into two groups: early-response and middle-response genes.

All the down-regulated transcription factors, including TCF1 (HNF-1), HNF4A (HNF-4), CEBPA (C/EBP alpha), CEBPB (C/EBP beta), PPARA (PPAR alpha), RXRA (RXR alpha), NR1H3 (LXRA), NR1H2 (LXRB), NR1H4 (FXR), USF-1, USF-2, and NR0B2 are important in hepatic metabolism and other regulatory mechanisms. Alteration of expression of these genes might be related to abnormal expression of metabolic enzymes. Two clusters of transcription factors were clearly distinguishable based on their expression pattern, as shown in Figure 1G: the first cluster, including HNF-4, C/EBPA, RXR, TCF1 (HNF1), PPARA, and NR0B2, which showed altered expression in the early phase, might influence expression of the second cluster, including CEBPB, NR1H2(LXRB), NR1H3(LXRA), NR1H4(FXR), ESRRA and USF2, which showed altered expression in the middle phase of fibrosis.

A cluster of genes associated with insulin/Wnt signaling were down-regulated, as shown in Figure 1H, suggesting a common regulatory mechanism. These expression changes are likely to be related to changes in expression of transcription factors and genes in metabolic networks. The down-regulated genes included GSK3B and CTNNB1 (catenin beta 1), which participates in Wg/Wnt signaling for regulation of cell proliferation and differentiation<sup>[4]</sup>; GJA1 (connexin 43), which forms gap junctions and is regulated by Wg/Wnt signaling<sup>[5]</sup>; and FOXM1, which is associated with cell proliferation<sup>[6]</sup> and liver regeneration<sup>[7]</sup>. All of these genes had peak expression at F2 in a clustered manner, as shown in Figure 1C and G. Enhancement of cell proliferation for wound healing might be linked with a peak of inflammation at F2, and expression of genes such as CCND1, GJA1 and FOXM1 in the downstream part of the insulin/Wnt pathway were altered ahead of genes involved in insulin/Wnt signaling. The relationship between these genes requires further study.

### Expression changes in gene clusters in the late phase (F3 to F4) of fibrosis

Few genes showed altered expression in the late phase of fibrosis, but a cluster of genes in the glucose metabolism category showed decreased expression. It was also of interest that expression of several genes reversed direction or abruptly altered in the late phase, as shown in Figure 1I. These results suggest different biological changes from the start of the late stage in the transition from F3 to F4.

Serial expression changes for the functional categories are summarized in Table 3 and these data indicate associations between clustered genes in one category and inter-category relationships.

### Down-regulated individual marker genes (group 1)

Regeneration of hepatic cells is suppressed during fibrosis and such suppression is thought to then cause further fibrosis. IGF1, GHR and IL6R (inflammation) support the regeneration of hepatocytes and down-regulation of the expression of these genes may be linked directly to formation of fibrosis. Down-regulation of PON1, which associates with HDL (high-density lipoprotein)

and regulates the cellular redox state, and PPT, which is known as a lysosomal hydrolase of long chain fatty acyl CoA and has a role in maintenance of synaptic function, may be related to mitochondrial damage, as we and others have suggested<sup>[3,8,9]</sup>. RGN, a calcium-binding protein that plays a pivotal role in maintaining cell homeostasis and function, was also down-regulated. Down-regulation of these genes may impair liver function. TRIB3 inhibits Akt/PKB activation by insulin<sup>[10]</sup>, and this gene was suddenly down-regulated from the F3 to F4 phase, suggesting new conditions in the insulin signaling pathway in the transition from F3 to F4.

### **Up-regulated individual marker genes (group 2)**

Most inflammatory marker genes showed peak expression in the middle phase of fibrosis, as shown in Figure 1A, but CMA1 (chymase 1), which is produced by mast cells, underwent a linear increase in expression with progression of fibrosis. This is of note, since chymase has been reported to be involved in chronic hepatic fibrosis in autoimmune hepatitis and primary biliary cirrhosis<sup>[11]</sup>, and mast cells may have a special role in fibrogenesis. The role of mast cells in chronic inflammation, however, deserves further study, because of the shortage of determined sample and low expression of CMA1.

### **Individual marker genes with peak expression in the middle phase of fibrosis (group 3)**

The only hepatic stellate cell (HSC)-specific marker gene to show peak expression at the F2 stage was PRNP, which is reported to be a marker for the early phase of HSC activation. The amino acid transporters SLC38A2 (ATA2), SLC6A6 (TAUT) and SLC7A1 (CAT-1) showed peak expression at F2, which may also suggest enhancement of cell proliferation at this stage of fibrosis. Increased expression of SLC38A2, which preferentially transports alanine, has been reported in regeneration of hepatocytes<sup>[12]</sup>, since hepatocytes require alanine as an energy source<sup>[13]</sup>. Based on our results, down-regulation of SLC38A2 in the late phase of fibrosis suggests that utilization of alanine as an energy source decreases at this stage of fibrosis. Up-regulation of SLC6A6, a taurine transporter, in the early phase of fibrosis can be understood as protective behavior against injury of hepatocytes<sup>[14]</sup>. FASN, a marker gene for fatty acid metabolism, showed peak expression at the F3 stage of fibrosis. We have observed suppression of biosynthesis and degradation of fatty acids in the liver in a CCl<sub>4</sub>-induced cirrhotic rat model, and clinical results show temporal enhancement of fatty acid biosynthesis before subsequent suppression in an advanced phase of fibrosis; this may be a compensative action related to suppression of other forms of energy metabolism in fibrosis, as we have previously suggested<sup>[5]</sup>.

### **Candidate marker genes for diagnosis of fibrosis and discrimination of fibrotic stages**

Diagnosis in the early stage of fibrosis may be important for monitoring progression of fibrosis and hepatic biological changes. Candidate marker genes at each step of fibrosis were selected based on an expression change

ratio > 1.5 and an intensity > 10. Up-regulation of LYZ and down-regulation of FGA, OAT and AGXT2 were noteworthy in the transition from F1 to F2, and up-regulation of genes in the ECM category and down-regulation of genes in metabolism of energy source AA, aromatic AA, steroids and sulfur-containing AA occurred in the transition from F2 to F3. Diagnosis of the late stage of fibrosis (the transition from F3 to F4) is important because of the risk of tumorigenesis. Some genes showed a reversal of expression in the F3 to F4 transition, suggesting that biological changes in the stage from F3 to F4 are qualitatively different from those at earlier stages. Remarkable down-regulation of TRIB3, which inhibits insulin signaling and NF $\kappa$ B signaling, was noteworthy in the F3 to F4 transition. The reversal in expression of FASN in this phase may indicate changes in lipid metabolism and that of OAT indicates changes in ornithine metabolism or the urea cycle. The early increase in collagen expression began to decline in the F3 to F4 stage and the similar decline of SERPINE1 (Pai1) expression may reflect increased fibrolysis. Consecutive analysis of marker molecules in plasma will be important for monitoring progression of fibrosis at each step, and the data in this paper provides useful information for the selection of serum markers and interpretation of changes in the levels of these markers.

### **Coordinated regulation of functional categories**

All genes in Figure 1 were subjected to hierarchical clustering analysis. Statistical clustering of the expression ratio between neighboring F stages for the genes in Table 1 was combined with functional categories, as shown in Figure 2. Functional categories clearly corresponded to the statistical clusters, suggesting coordinated regulation of genes in one functional category. Overlap of functional categories in statistical clusters suggested that these categories might be regulated by correlated mechanisms. In contrast, separation of members of a category into multiple positions of a statistical cluster suggests that the functional category may be divided into subgroups with respect to regulation.

## **DISCUSSION**

### **Biological interpretation of changes in gene expression**

Changes in expression of hepatic cell-specific marker genes reflects biological changes in the progression of hepatic fibrosis. Shimizu *et al.*<sup>[15]</sup> reported co-localization of chymase with fibrotic tissue, and we have reported increased expression of marker genes for mast cells, including chymase, in progression of fibrosis in a DNM-induced rat fibrosis model. The results reported here also show correlation of the expression of chymase with the stage of fibrosis. Therefore, these results suggest that a certain cell population producing chymase has an important role in the pathogenesis of fibrosis.

Many marker genes related to inflammation showed peak expression at F2. Inflammation has been reported to induce activation of HSCs<sup>[16]</sup>, and we have shown a peak in activated inflammatory cells in a DMN-induced fibrosis model. These results suggest that a temporal

of HNF-4 in human cirrhosis<sup>[21]</sup> and of PPARs in hepatitis C virus genotype 3<sup>[22]</sup> have been reported. C/EBP alpha and C/EBP beta regulate proliferation of hepatocytes<sup>[23]</sup> and glucose and lipid homeostasis<sup>[24-27]</sup>, and HNF-1 and HNF-4 broadly regulate hepatic functions such as carbohydrate metabolism<sup>[28]</sup>, lipid metabolism<sup>[29]</sup>, bile acid metabolism and HDL-cholesterol metabolism<sup>[30]</sup>; expression of HNF-1 is also regulated by HNF-4<sup>[31]</sup>. USF1 and USF2 have been reported as glucose signals<sup>[32,33]</sup>, and the USF1 and USF2 homodimers and the USF1-USF2 heterodimer regulate expression of liver-specific genes such as apolipoprotein A2 and pyruvate kinase. HNF-4 and USF2a bind to the enhancer sequence cooperatively<sup>[34]</sup>. HNF-4 also regulates PPAR alpha<sup>[35]</sup>, which in turn regulates glucose<sup>[36]</sup>, lipid<sup>[37]</sup> and cholesterol metabolism<sup>[38]</sup>. RXR alpha regulates lipid, bile acid and cholesterol homeostasis<sup>[39]</sup>, and LXR alpha, LXR beta and FXR are associated with lipid<sup>[40,41]</sup>, bile acid and cholesterol homeostasis<sup>[40,42]</sup>. RXR and FXR form heterodimers with other transcription factors, including other members of the same family or with PPAR alpha<sup>[40,43,44]</sup>. NR0B2 (SHP) regulates cholesterol metabolism<sup>[45]</sup>, glucose metabolism<sup>[45]</sup> and bile acid synthesis<sup>[46]</sup>, and interacts with LXR<sup>[47]</sup>. AKT1 and AKT2 are important kinases in the pathway of insulin regulation of glucose homeostasis<sup>[48]</sup> and in fatty acid synthesis<sup>[49]</sup>. Hence, the altered expression of these transcription factors may relate to altered expression of metabolic enzymes in glucose and lipid metabolism in the fibrotic liver of hepatitis C patients.

The continuous increase in expression of cyclin D1 (CCND1) correlated with F stage, as shown in Figure 1C, and appears to be important for hepatic tumorigenesis. The association of Wnt signaling<sup>[50,51]</sup> and cyclin D<sup>[52]</sup> with tumorigenesis is well known. Catenin beta 1 (CTNNB1) regulates cyclin D expression<sup>[53]</sup> and is itself regulated through phosphorylation by GSK3B<sup>[54]</sup> or other kinases<sup>[55]</sup>. Down-regulation of expression of CTNNB1 occurred in advanced fibrotic stages, as shown in Figure 1H, and beta interacting protein 1 (CTNNBIP1), which is a negative regulator of CTNNB1, was also down-regulated, as also shown in Figure 1H. From this perspective, it was interesting that alterations in expression of genes associated with insulin signaling, including GSK3B, CTNNB1, CTNNBIP1 and downstream genes such as CCND1 and GJA1 (connexin 43), were clustered, as shown in Figures 1C and H. Suppression of insulin signaling has been reported in cirrhosis<sup>[56]</sup>; however, the response of downstream genes in this pathway was inconsistent with suppression of the insulin signal. Therefore, further studies will be necessary to clarify whether this inconsistency arises from differences between expression levels and the activity of the protein products of these genes, or if another signal<sup>[57]</sup> is involved in the Wnt and insulin signaling pathways.

The bioSpace Explorer is a system for analysis of DNA microarray data that may allow an understanding of the molecular relationships underlying the above results. The network of genes from previous reports revealed integral relationships among insulin/Wnt signal, CEBPA, PPARA, RXRA, glucose metabolism, lipid synthesis and lipid metabolism. An initial version of bioSpace Explorer was constructed based on molecular networks related to lipid metabolism, with entries showing relationships between

molecules *via* a line between the molecules. This bird's eye view of the pathway including lipid metabolism with the input PCR data is illustrated in Figure 3; molecules related to inflammation were up-regulated and many genes related to lipid metabolism were down-regulated.

### **Hypothetical causes of biological changes in progression of fibrosis**

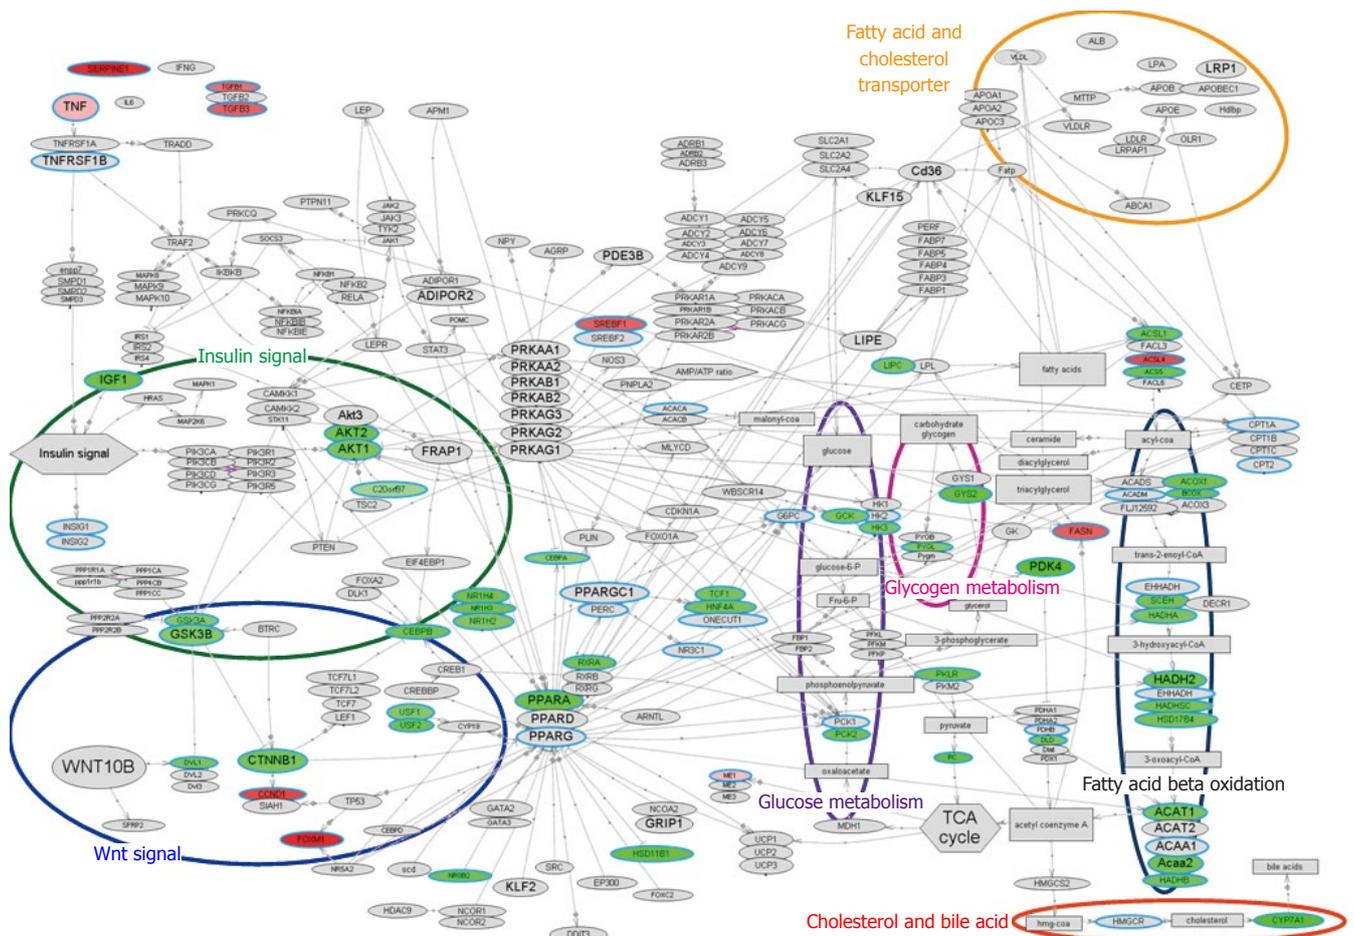

Biological changes in fibrosis can be summarized as follows. Initially, Kupffer cells or other inflammatory cells are activated in the transition from F1 to F2. This event immediately influences production of ECM and cell cycle genes for wound-healing<sup>[58]</sup>. Blood coagulation is quickly suppressed in moving from F1 to F2, as shown by down-regulation of coagulation factor genes and up-regulation of the inhibitor, PAI-1. Several transcription factor genes are also immediately influenced, probably due to inflammation, as shown by the down-regulation of CEBPA, HNF4A, TCF1 and NR0B2. Expression of many genes associated with lipid metabolism also changed quickly in the transition from F1 to F2. Down-regulation of these genes may be controlled by down-regulation of the transcription factors, especially RXRA, PPARA, LXRs and FXR. Some genes related to steroid metabolism also responded quickly for control of inflammation.

Expression of genes associated with sulfur-containing AA metabolism and aromatic AA metabolism changed simultaneously in the transition from F2 to F3. The first type of metabolism relates to the redox state<sup>[59]</sup> and the second is associated with production of active metabolites such as catecholamines and serotonin. Such important biological states are controlled to maintain homeostasis through several mechanisms<sup>[60]</sup> and this may explain the delayed change in expression of these genes. The expression of many genes related to intracellular signaling, including insulin/Wnt signaling, also changed simultaneously in the transition from F2 to F3. This delayed change may also reflect compensative action for hepatic cellular defects on metabolism for energy supply and/or hepatic cellular proliferation. The main molecules in fibrosis, such as collagens, increase in expression from F2 to F3 and cause development of fibrosis through activation of HSCs through a stimulatory cycle involving inflammatory cells, HSCs and hepatocytes, as described previously<sup>[61]</sup>.

Some quantitative biological changes started in the transition from F3 to F4. Down-regulation of genes associated with sugar metabolism and fatty acid synthesis at this stage might induce persistent defects in energy storage and supply to the liver. The liver transits into an inescapable negative cycle between this defect in the hepatic energy state and mitochondrial damage in cirrhosis. This negative cycle will be discussed in a future paper describing DNA microarray analysis of an animal model of cirrhosis.

### **Coordinated regulation of functional categories**

Statistical cluster analysis showed coordinated regulation of functional categories in liver fibrosis. These regulatory mechanisms can be examined prospectively using bioSpace Explorer, and these results will be discussed in a future paper. In the current work, the clinical gene expression profiles assembled using RT-PCR, using genes

**Figure 3** Molecular network associated with lipid metabolism. Gene expression changes in pathways related to lipid metabolism, illustrated with bioSpace Explorer (a system for analysis of DNA microarray data for lipid metabolism; Pharma Frontier Co. Ltd / World Fusion Co. Ltd.; see texts for details). The bird's-eye view of the lipid metabolism is displayed. The up-regulated and down-regulated gene expression ratios at F3 vs F1 in Table 1 are displayed in red and green, respectively, with the color gradation proportional to the ratio. Genes in Table 1 that did not show a statistically significant change in expression are indicated with a blue circle with gray background. An entry with a gray background only indicates no input data. Most of the entity names in Figure 2 are the same as the gene name in Table 1, but the names "C20orf97", "SCEH", "Acaa2", and "ACS5" in Figure 2 refer to "TRIB3", "ECHS1", "ACAA2", and "ACSL5", respectively, in Table 1. These differences are due to the software used in bioSpace Explorer.

originally selected based on DNA microarray data from an experimental animal model, provided an improved understanding of disease and suggested new methods of diagnosis. Therefore, statistical analysis and functional clustering or network analysis of the transcriptome, alone or in combination, can provide an overview of a dynamic biological system.

## ACKNOWLEDGMENTS

We thank Ms. Tomoko Kobayashi of Pharmafrontier Co. Ltd. and Mr. Ken Osaki of World Fusion Co. Ltd for statistical analysis and operation of the bioSpace Explorer for analysis of DNA microarray data for lipid metabolism.

## COMMENTS

### Background

Information from clinical specimens is very important, but there is a limitation in sample preparation. With DNA microarray, it is difficult to determine gene expression profile from a small amount of sample such as a clinical needle biopsy sample. RT-PCR with TaqMan probe can make it possible with high quality. We have to get maximum information with a minimum number of TaqMan probes

because the amount of samples is limited and probes are expensive. Selection of probes is a key factor. We extensively determined gene expression profiles from animal models of liver fibrosis with DNA microarray (WJG 2006; 12: 6473). The gene marker sets were arranged to show the change of gene expression of a molecular network or functionally clustered gene sets. In this paper, the selected gene marker sets effectively showed the dynamic behavior of global gene network change during liver fibrosis.

### Research frontiers

Dynamic behavior of genome-wide genes expression is now measured with DNA microarray. This technology must be applied to clinical samples. Such information can greatly advance the study of disease pathogenesis, diagnosis and therapy. One problem is the interpretation of huge expression profile data from DNA microarray. Advanced technology of computational text-mining has recently shown the genome-wide molecular networks or functional molecular clusters. This genome-wide network is going to be applied to the analysis of DNA microarray data. When expression profile data are arranged as a change in their networks of functional clusters, these huge data are expected to suggest effectively the biological meaning in terms of broad aspects of research interest. Therefore, we are developing an analysis system genome-wide molecular network which was made possible by a combination system based on both computational and manual text-mining. This system was partially applied on the interpretation of gene expression profile in this paper. Prevention therapy for individual patients at an early stage is required because genomic polymorphism is going to reveal the personal risk of diseases. The biological background of progression to disease onset must be understood for development of prevention therapy. Prediction of liver cancer risk is going to be tried in the early

stage of liver fibrosis before cirrhosis. The accumulation process of hepatic stress which leads to onset of liver cancer has to be elucidated. For example, there is a question why BCAA (branched chain amino acids), which improves hepatic metabolism, reduces onset of liver cancer.

### Innovations and breakthroughs

We have already prepared the gene marker sets which can show the change of molecular networks or functionally clustered genes by DNA microarray experiment on liver fibrosis of animal models. The gene marker sets were linked to biological events in each hepatic cell such as hepatocytes, immune cells and stellate cells. Application of gene marker sets and RT-PCR with TaqMan probe technology on clinical specimens successfully showed the serial change of gene expression in molecular network or functionally clustered gene sets in the progression of liver fibrosis. It was proved that network analysis is a powerful tool for biological research. Our sequential approach (animal model/DNA microarray → selection of appropriate gene marker sets in molecular networks → clinical samples/RT-PCR → analysis functionally clustered gene markers in molecular networks → analysis of the relation between molecular networks) can effectively advance clinical research. Serial change of clustered gene expression during liver fibrosis progression, which was made clear in this paper, will reveal the molecular mechanism of many symptoms before and after the onset of cirrhosis and liver cancer.

### Application

Gene marker sets and RT-PCR on clinical specimens as well as analytical methods with genome-wide gene networks can be applied to get the information of dynamic biological progression on various diseases. Serial change of clustered gene expression during liver fibrosis progression can provide a method of diagnosis and therapy in liver fibrosis. For example, the question why BCAA, which improves hepatic metabolism, reduces onset of liver cancer, will be solved.

### Terminology

Text-mining: all published information about molecular interaction and their function are collected and arranged to make new valuable information such as gene-wide molecular networks; TaqMan-PCR probe: Applied Biosystems offers more than 700,000 TaqMan® Gene Expression Assays, the most comprehensive set of pre-designed Real-Time PCR assays available. All TaqMan® Gene Expression Assays have been designed using validated bioinformatics pipeline of Applied Biosystems, and run with the same PCR protocol, eliminating the need for primer design or PCR optimization.

### Peer review

This paper revealed that metabolic deficiency occurs before the onset of cirrhosis. It had already been found in animal models with hepatic toxic substances in the preceding paper. Metabolic deficiency in hepatitis which was caused by a virus was found to be the same as animal models in this paper. Gene marker sets, selected from analysis of animal models, and analysis methods using molecular networks can lead to success in finding the serial change of functionally clustered genes expression during liver fibrosis progression. A set of appropriate gene markers in each network was a key to analysis. The sequential approach (animal model/DNA microarray → appropriate gene marker sets in molecular networks → clinical samples/RT-PCR → analysis functionally clustered gene markers in molecular network → analysis of the relation between molecular networks) is useful to elucidate the molecular mechanism of disease.
