## Contents

<b>EDITORIAL</b>	1313	Efficiency of bowel preparation for capsule endoscopy examination: A meta-analysis <i>Niv Y</i>
<b>OBSERVER</b>	1318	Proton pump inhibitors and an emerging epidemic of gastric fundic gland polyposis <i>Freeman HJ</i>
<b>REVIEW</b>	1321	Feasibility of herpes simplex virus type 1 mutants labeled with radionuclides for tumor treatment <i>Mi YX, Long YH, Li YC</i>
<b>TOPIC HIGHLIGHT</b>	1326	Management of inflammatory bowel disease in the pregnant patient <i>Habal FM, Ravindran NC</i>
<b>GASTRIC CANCER</b>	1333	Isolation and bioinformatics analysis of differentially methylated genomic fragments in human gastric cancer <i>Liao AJ, Su Q, Wang X, Zeng B, Shi W</i>
<b>COLORECTAL CANCER</b>	1339	Increased hepcidin expression in colorectal carcinogenesis <i>Ward DG, Roberts K, Brookes MJ, Joy H, Martin A, Ismail T, Spychal R, Iqbal T, Tselepis C</i>
<b>VIRAL HEPATITIS</b>	1346	COOH-terminal deletion of HBx gene is a frequent event in HBV-associated hepatocellular carcinoma <i>Liu XH, Lin J, Zhang SH, Zhang SM, Feitelson MA, Gao HJ, Zhu MH</i>
<b>BASIC RESEARCH</b>	1353	Expression of tumor necrosis factor-alpha converting enzyme in liver regeneration after partial hepatectomy <i>Lin XM, Liu YB, Zhou F, Wu YL, Chen L, Fang HQ</i>
<b>CLINICAL RESEARCH</b>	1358	Prevalence of gastroesophageal reflux symptoms in a large unselected general population in Japan <i>Yamagishi H, Koike T, Ohara S, Kobayashi S, Ariizumi K, Abe Y, Iijima K, Imatani A, Inomata Y, Kato K, Shibuya D, Aida S, Shimosegawa T</i>
<b>RAPID COMMUNICATION</b>	1365	Absence of Na <sup>+</sup> /sugar cotransport activity in Barrett's metaplasia <i>Murray LJ, Tully O, Rudolph DS, Whitby M, Valenzano MC, Mercogliano G, Thornton JJ, Mullin JM</i>
	1370	Des-gamma-carboxy prothrombin as an important prognostic indicator in patients with small hepatocellular carcinoma <i>Hakamada K, Kimura N, Miura T, Morohashi H, Ishido K, Nara M, Toyoki Y, Narumi S, Sasaki M</i>
	1378	MK615 inhibits pancreatic cancer cell growth by dual inhibition of Aurora A and B kinase <i>Okada T, Sawada T, Osawa T, Adachi M, Kubota K</i>

- 1383** Management of cholelithiasis in Italian children: A national multicenter study  
*Della Corte C, Falchetti D, Nebbia G, Calacoci M, Pastore M, Francavilla R, Marcellini M, Vajro P, Iorio R*
- 1389** Liver histology in ICU patients dying from sepsis: A clinico-pathological study  
*Koskinas J, Gomas IP, Tiniakos DG, Memos N, Boutsikou M, Garatzioti A, Archimandritis A, Betrosian A*
- 1394** Clinical significance of loss of heterozygosity for M6P/IGF2R in patients with primary hepatocellular carcinoma  
*Jang HS, Kang KM, Choi BO, Chai GY, Hong SC, Ha WS, Jirtle RL*
- 1399** Intestinal permeability and its association with the patient and disease characteristics in Crohn's disease  
*Benjamin J, Makharia GK, Ahuja V, Kalaivani M, Joshi YK*
- 1406** Scintigraphic evaluation of gallbladder motor functions in *H pylori* positive and negative patients in the stomach with dyspepsia  
*Yaylali OT, Yilmaz M, Kırac FS, Değirmencioğlu S, Akbulut M*
- 1411** Relevance of MUC1 mucin variable number of tandem repeats polymorphism in *H pylori* adhesion to gastric epithelial cells  
*Costa NR, Mendes N, Marcos NT, Reis CA, Caffrey T, Hollingsworth MA, Santos-Silva F*
- 1415** Fatty liver disease in severe obese patients: Diagnostic value of abdominal ultrasound  
*Almeida AM, Cotrim HP, Barbosa DBV, Athayde LGM, Santos AS, Bitencourt AGV, Freitas LAR, Rios A, Alves E*
- 1419** Gastric motor effects of ghrelin and growth hormone releasing peptide 6 in diabetic mice with gastroparesis  
*Qiu WC, Wang ZG, Wang WG, Yan J, Zheng Q*
- 1425** Requirements for transfusion and postoperative outcomes in orthotopic liver transplantation: A meta-analysis on aprotinin  
*Liu CM, Chen J, Wang XH*
- 1430** Percutaneous cryosurgery for the treatment of hepatic colorectal metastases  
*Xu KC, Niu LZ, He WB, Hu YZ, Zuo JS*
- 1437** Activator protein-1 involved in growth inhibition by RASSF1A gene in the human gastric carcinoma cell line SGC7901  
*Deng ZH, Wen JF, Li JH, Xiao DS, Zhou JH*
- 1444** Genetic polymorphisms in cytochrome P4502E1, alcohol and aldehyde dehydrogenases and the risk of esophageal squamous cell carcinoma in Gansu Chinese males  
*Guo YM, Wang Q, Liu YZ, Chen HM, Qi Z, Guo QH*

**CASE REPORT**

- 1450** Cervical cellulitis and mediastinitis following esophageal perforation: A case report  
*Righini CA, Tea BZ, Reyt E, Chahine KA*
- 1453** A case of multiple intra-abdominal splenosis with computed tomography and magnetic resonance imaging correlative findings  
*Imbriaco M, Camera L, Mancinuria A, Salvatore M*
- 1456** Intrauterine midgut volvulus without malrotation: Diagnosis from the 'coffee bean sign'  
*Park JS, Cha SJ, Kim BG, Kim YS, Choi YS, Chang IT, Kim GJ, Lee WS, Kim GH*

**Contents**

- 1459 Transanal excision of a malignant fibrous histiocytoma of anal canal: A case report and literature review  
*Kim BG, Chang IT, Park JS, Choi YS, Kim GH, Park ES, Choi CH*
- 1463 Overlap of reflux and eosinophilic esophagitis in two patients requiring different therapies: A review of the literature  
*Molina-Infante J, Ferrando-Lamana L, Mateos-Rodriguez JM, Pérez-Gallardo B, Prieto-Bermejo AB*
- 1467 Complications of extrahepatic echinococcosis: Fistulization of an adrenal hydatid cyst into the intestine  
*Ruiz-Rabelo JF, Gomez-Alvarez M, Sanchez-Rodriguez J, Rufian S*

**ANNOUNCEMENT** 1470 The article published in *WJG* 2005; 11(7): 931-937 was partly duplicate an article previously published in *Critical Reviews in Eukaryotic Gene Expression* (2004; 14: 183-202)

**ACKNOWLEDGMENTS** 1472 Acknowledgments to Reviewers of *World Journal of Gastroenterology*

**APPENDIX** 1473 Meetings  
 1474 Instructions to authors

Niv Y. Efficiency of bowel preparation for capsule endoscopy examination: A meta-analysis. *World J Gastroenterol* 2008; 14(9): 1313-1317 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1313.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1313>

### Abstract

Good preparation before endoscopic procedures is essential for successful visualization. The small bowel is difficult to evaluate because of its length and complex configuration. A meta-analysis was conducted of studies comparing small bowel visualization by capsule endoscopy with and without preparation. Medical data bases were searched for all studies investigating the preparation for capsule endoscopy of the small bowel up to July 31, 2007. Studies that scored bowel cleanness and measured gastric and small bowel transit time and rate of cecum visualization were included. The primary endpoint was the quality of bowel visualization. The secondary endpoints were transit times and proportion of examinations that demonstrated the cecum, with and without preparation. Meta-analysis was performed with StatDirect Statistical software, version 2.6.1 (<http://statsdirect.com>). Eight studies met the inclusion criteria. Bowel visualization was scored as "good" in 78% of the examinations performed with preparation and 49% performed without ( $P < 0.0001$ ). There were no significant differences in transit times or in the proportion of examinations that demonstrated the cecum with and without preparation. Capsule endoscopy preparation improves the quality of small bowel visualization, but has no effect on transit times, or demonstration of the cecum.

### INTRODUCTION

Good preparation before endoscopic procedures is essential for successful visualization. It is also an important factor for patient safety, quality of care, and cost efficiency<sup>[1,2]</sup>. The small bowel is difficult to evaluate because of its length and complex configuration. The recently developed Given Diagnostic Imaging System (PillCam, Given Imaging Ltd., Yoqneam, Israel) for evaluation of pathologies of the small bowel<sup>[3-7]</sup> can identify lesions that cannot be detected by other techniques<sup>[8,9]</sup>. The preparation recommended by the manufacturer is a 12-hour fast after 24-hour intake of clear liquids.

Studies of the effect of bowel preparation for capsule endoscopy on optimal visualization, gastric and small bowel transit times, and rate of cecum demonstration have sometimes reached different conclusions<sup>[10-17]</sup>. Sood *et al*<sup>[18]</sup>, in MRI studies, found no significant difference in transit time between patients prepared with polyethylene glycol or standard methods. In our previous studies, the use of sodium phosphate preparation was not associated with a significant change over fasting in gastric or small bowel transit times, although it yielded a significantly better view of the mucosa<sup>[10,11]</sup>. Others reported that both polyethylene glycol and sodium phosphate have a marked accelerating effect on small intestinal transit time<sup>[19,20]</sup>.

In the present study, we performed a meta-analysis of studies comparing preparation with no preparation before capsule endoscopy of the small bowel. The primary endpoint was the quality of small bowel visualization. The secondary endpoints were gastric and small bowel transit times and proportion of examinations demonstrating the cecum.

### FORMULATION OF QUESTIONS

The primary question was: What is the contribution of bowel preparation to successful capsule endoscopy

examination? This raised the subsidiary question of a possible difference in the rates of excellent and good cleaning of the small bowel with and without preparation. In addition, we sought to determine the impact of preparation on gastric transit time, small bowel transit time, and arrival of the capsule to the cecum with the battery still functioning.

## CRITERIA FOR CONSIDERING STUDIES FOR THIS META-ANALYSIS

Our study was based on controlled studies of the quality of small bowel capsule examination with and without prior preparation. Two studies of our group were included in the meta-analysis<sup>[10,11]</sup>. There was no overlap between the patient populations in these two studies.

## SEARCH STRATEGY FOR IDENTIFICATION OF STUDIES

We conducted a bibliographic search of the PubMed (MEDLINE), EMBASE, COCHRANE LIBRARY (Cochrane Database of Systemic Reviews and the Cochrane Controlled Trial Register), CINAHL, and AMED databases up to July 31, 2007 using the following keywords: “capsule endoscopy”, “M2A” (mouth-to-anus), and “PillCam”. The search was directed at English-language medical journals. All papers identified by the electronic database search were examined and additional references were identified from the references listed in each paper.

## INCLUSION CRITERIA

Case-control studies investigating the preparation for capsule endoscopy of the small bowel which employed a scoring system for bowel cleanness and measured gastric and small bowel transit time and rate of cecum demonstration were included.

## EXCLUSION CRITERIA

Studies that focused on esophageal or colonic examination, did not directly compare preparations, had no control, or did not measure transit times were excluded from the analysis.

## STATISTICAL ANALYSIS

For each study, the following variables were extracted and entered into an Excel data sheet: author, journal, year of publication, number of participants, type of preparations, proportion of good bowel visualization, gastric transit time, small bowel transit time, and proportion of cecum demonstration. The meta-analysis was performed with the StatDirect Statistical software, version 2.6.1 (<http://statsdirect.com>). Heterogeneity was checked using  $\chi^2$  test (Q-statistics) with significance of  $P < 0.05$ . With the assumption that the studies are a random sample from a population of studies, we choose to use a random

effects model. Forest plots were constructed for visual presentation of the individual studies proportions and the pooled proportion<sup>[21]</sup>.

## RESULTS

Our search yielded 550 studies of capsule endoscopy, of which 8 investigated the preparation for small bowel capsule endoscopy and otherwise met the inclusion criteria<sup>[10-17]</sup>.

Five out of these studies compared the proportion of “good” scores between the groups<sup>[10-13,17]</sup>. The findings are shown in Table 1. A total of 237 patients were included, 130 with and 107 without preparation.

Seven out of these studies included a comparison of gastric and small bowel transit times and in proportion to examinations of cecum demonstration<sup>[10,11,13-17]</sup>. The findings are shown in Table 2. A total of 401 patients were included, 221 with and 180 without preparation.

A “good” score was similarly defined in the five papers found suitable for comparison of preparations. In our two papers<sup>[10,11]</sup> we used a score of 3 grades, where “good” was defined as a good mucosal visualization in more than 80% of the small bowel transit time. Albert and coworkers<sup>[12]</sup> used a score of 4 grades, and we used their scores 0 and 1 as “good”, when there was no limitation for interpretation. Viazis and coworkers used the term adequate when more than 90% of the small bowel transit time and the mucosa was clear<sup>[17]</sup>, and Ben-Soussan and colleagues, using a score of 4 grades, defined “good or excellent” when visibility was good in more than 75% of the small bowel transit time<sup>[13]</sup>. A “good” score was documented for 78% of the patients with preparation (95% CI, 65%-88%) compared to 49% of the patients without preparation (95% CI, 35%-62%;  $P < 0.0001$ ; Figure 1).

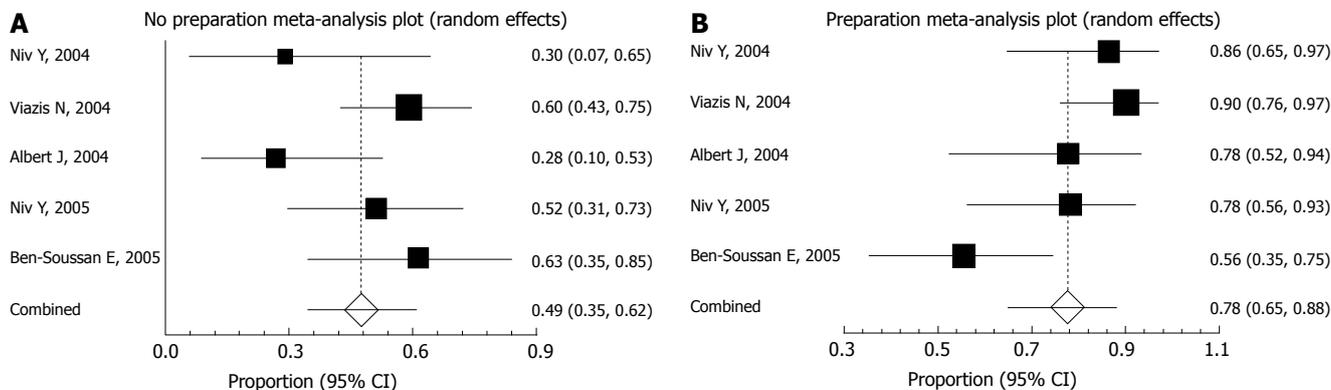

The capsule reached and visualized the cecum in 76% of the patients with preparation and 68% without. This difference did not reach statistical significance (Figure 2).

There was no statistically significant difference between the endoscopies performed with or without preparation in gastric transit time (pooled effect size, -0.054; 95% CI, -0.418 to 0.308) or small bowel transit time (pooled effect size, -0.327; 95% CI, -1.419 to -0.765; Figure 3A and B).

## CONCLUSION

Capsule endoscopy is a new technology, and there is still no consensus regarding the proper preparation. The manufacturer recommends only a 12-h fast after 24-h intake of clear liquids. It may be in the interest of the manufacturer to recommend such a simple preparation, so that the procedure will be easy to perform. However,

since the procedure is costly, time consuming, and not usually repeated, it is critical to optimize the quality of visualization, which may be impaired by secretions, bubbles or coating of the capsule with intestinal residue.

Few studies have compared different preparation strategies, using different approaches, designs, and methods. Two controlled studies by our group found that the sodium phosphate method provided better

**Figure 3** Differences in transit times in patients underwent preparation before the capsule examination and those who underwent the procedure without prior preparation, a meta-analysis of 7 papers and 401 patients. **A** = difference in gastric transit time, **B** = difference in small bowel transit time.

visualization than the standard method, with significantly less and later-appearing turbid fluid in the small bowel lumen, which could block the visual field of the capsule<sup>[10,11]</sup>. Our results were in agreement with the prospective, randomized, controlled trial of Viazis *et al*<sup>[17]</sup>, which demonstrated a significant advantage of preparation with polyethylene glycol over fasting alone. The findings in our control group were also similar to the control findings of Viazis *et al*<sup>[17]</sup> in terms of transit times, percentage of procedures in which the cecum was reached, and diagnostic yield (secondary endpoint). Taken together, the data from our nonrandomized comparison case-control studies<sup>[10,11]</sup> and the randomized study of Viazis *et al*<sup>[17]</sup> indicate that bowel preparation with either sodium phosphate or polyethylene glycol is superior to simple fasting for capsule endoscopy. Albert and colleagues used simethicone for bubble absorption and improved the visibility of the small bowel mucosa<sup>[12]</sup>. Thus their paper was added to this meta-analysis even though simethicone is not a classic preparation drug and may not be considered equivalent to polyethylene glycol or to sodium phosphate<sup>[12]</sup>.

Only 3 papers looked at the diagnostic yields as a secondary endpoint, since it would be much more useful to compare more definite outcomes such as number and type of lesions visualized in attempting to compare the effect of preparation and no preparation<sup>[11,13,17]</sup>. Ben-Soussan and colleagues found no association between preparation and diagnostic yield of the capsule examination<sup>[13]</sup>, while we and Viazis found a significant advantage of preparation for findings more lesions<sup>[11,17]</sup>. Thus, this point is still controversial.

The main weakness of the study is in the different preparation regimens, and different scores used by the individual centers, sometimes addressed to evaluate different aspects of the small bowel cleansing: amount of intraluminal fluid, gas or air bubbles, and percentage of "free" mucosal surface.

Our search yielded 8 studies comparing preparation with sodium phosphate, polyethylene glycol or simethicone in one group of patients with simple fasting in another group, before capsule endoscopy of the small bowel. The results of the meta-analysis clearly demonstrated that although preparation improves the quality of small bowel visualization, it has no significant effect on gastric transit

time, small bowel transit time, or cecum demonstration. The main limitation of our meta-analysis is the diversity of the methods used by the different trials. All the studies were controlled, but only one of them was randomized<sup>[17]</sup>. Two studies compared different strategies used by different centers, and 5 studies compared 2 different periods with changed strategies. Nonetheless, the study groups in every study were very similar in their demographic and clinical data. Most of the patients were referred for the capsule examination to evaluate occult gastrointestinal bleeding. Co-morbidity was also similar between the groups, and no significant alterations in transit times were anticipated. Thus, further studies are needed to definitively establish the association among motility factors, battery life-time, good visualization of the bowel, and completeness of the examination.

## Abstract

Fundic gland polyps are now commonly recognized during endoscopy. These polyps are benign, often multiple and usually detected in the gastric body and fundus. In the past, these polyps were sometimes associated with familial adenomatous polyposis. In recent years, it has become evident that increasing numbers of these polyps are being detected during endoscopic studies, particularly in patients treated with proton pump inhibitors for prolonged periods. In some, dysplastic changes in these polyps have also been reported. Recent studies have suggested that there may be no increase in risk of colon cancer with long-term proton pump inhibitor therapy. While temporarily reassuring, ongoing vigilance, particularly in those genetically predisposed to colon cancer, is still warranted.

## GASTRIC POLYPS

Gastric polyps and tumors have been classified into

mucosal, lymphoid, mesenchymal and stromal types<sup>[1]</sup>. Both neoplastic (adenoma, carcinoma, carcinoids) and non-neoplastic mucosal types occur. Most neoplastic epithelial polyps are asymptomatic and, usually, occur in the gastric antrum. Occasionally, these polyps bleed or present with an iron deficiency anemia. Rarely, gastric adenomas, particularly if large and pedunculated, cause symptoms from intermittent gastric outlet obstruction due to duodenal prolapse. Carcinoma may also complicate such adenomas. But, even these complex malignant polyps have been amenable to endoscopic resection<sup>[2]</sup>.

## FUNDIC GLAND POLYPOSIS

One of the most common types of gastric polyps, generally classified as non-neoplastic, is the sporadic fundic gland polyp. Usually, these are confined to the gastric body and fundus and rarely cause symptoms. Fundic gland polyps are typically detected during investigation for abdominal pain, dyspepsia or chronic reflux. Historically, it has been estimated that these polyps occur in up to 2% of all endoscopic studies. Although quite characteristic, they were only first described as a distinct pathological type in 1977<sup>[3]</sup>. Previously, these were reported to occur most often in females and were thought to be derived from the parietal cell- and chief cell-bearing region of the gastric mucosa<sup>[1]</sup>. Cystic dilation of pits deep in the mucous neck cells was observed with mucous cells, chief cells and parietal cells lining these mucosal cysts. Inflammatory changes in these polyps is usually minimal or absent. It has been reported that these polyps may resolve spontaneously<sup>[4]</sup>.

## FAMILIAL ADENOMATOUS POLYPOSIS (FAP)

Gastric polyps also occur in the majority of patients with FAP, screened with endoscopy<sup>[5-7]</sup>. FAP results from inherited germline mutations in the adenomatous polyposis coli (*APC*) gene, coupled with second somatic mutations. This leads to inactivation of both copies of the *APC* tumor suppressor gene<sup>[8,9]</sup>. Importantly, the most common gastric lesion in FAP is the syndromic fundic gland polyp, histologically similar to sporadic fundic gland polyps. Gastric and duodenal adenomas also occur in FAP, but are much less common. Fundic gland polyps are most often not associated with FAP and have little or no potential for malignant transformation<sup>[5,10]</sup>. However,

high-grade dysplasia and gastric adenocarcinoma have both been associated with fundic gland polyps in FAP<sup>[7,11-15]</sup>. As a result, colonoscopic surveillance has been suggested to determine if FAP or an attenuated form of FAP is present when fundic gland polyps are first detected<sup>[16]</sup>. Evidence strongly supporting this approach is not available. As fundic gland polyps are being increasingly recognized during endoscopic evaluations, added colonoscopic studies might be best reserved for those with concomitant gastric or duodenal adenomas.

## MOLECULAR GENETIC MARKERS

Since both sporadic and syndromic FAP-associated fundic gland polyps have similar histological appearances, genetic markers have been explored to determine if there are additional similarities or differences. Distinct disruptions in the Wnt signaling pathway with activating beta-catenin mutations occur with sporadic polyps, while FAP-associated polyps showed second, somatic mutations of the *APC* gene<sup>[17]</sup>. With chronic acid suppression therapy, multiple fundic gland polyps develop that are also histologically and genetically identical to single sporadic polyps<sup>[18]</sup>. In these, beta-catenin mutations were detected in most polyps. In addition, distinct mutations in different polyps from the same individual indicated a multifocal origin for the polyps<sup>[18]</sup>. Separate studies on fundic gland polyps in the absence of FAP have also failed to show *APC* gene deletions<sup>[19]</sup>. Interestingly, a very low prevalence of *H pylori* infection was also noted with these polyps<sup>[19]</sup>. In contrast, *APC* gene mutations were found in FAP with both syndromic fundic gland polyps and high grade dysplasia in gastric epithelium<sup>[20]</sup>. While these studies have served to elucidate molecular changes in sporadic and syndromic (FAP) gastric fundic gland polyps, more information is needed to determine if these markers could be used cost-effectively to predict risk in fundic gland polyps for eventual development of gastric cancer.

## PROTON PUMP INHIBITOR-ASSOCIATED GASTRIC POLYPS

Omeprazole was first introduced for clinical use as a proton pump inhibitor in 1988. Since then, worldwide sales figures for proton pump inhibitors have dramatically risen with estimated sales now totaling over \$10 billion and rising. Over 720 million prescriptions for proton pump inhibitors have been written worldwide, largely for long-term use, while large randomized clinical trials have confirmed the high efficacy and safety profile of long-term treatment<sup>[21]</sup>. In addition, however, substantial physiological changes occur with chronic acid suppression therapy. Increased levels of circulating gastrin occur. This hormone stimulates increased cell proliferation. Chronic ECL cell stimulation also results as reflected by increased levels of chromogranin A, an endocrine cell product<sup>[22]</sup>. In recent years, gastric fundic gland polyps have become increasingly detected in patients on long-term proton pump inhibitor therapy<sup>[23-26]</sup>. These fundic gland polyps are often multiple in this setting and localized in the gastric body and fundus.

No definite sex predilection has been defined. They appear to have similar histologic and genetic features to those developing without proton pump inhibitor use. Recent studies have defined a relationship between the length of drug use, especially after 12 mo, and increased polyp risk<sup>[26]</sup>. In addition, most patients with fundic gland polyps on proton pump inhibitors are *H pylori*-negative<sup>[26]</sup>, consistent with a previous report of fundic gland polyp regression following acquisition of *H pylori*<sup>[27]</sup>. Of concern, multiple fundic gland polyps have also been noted in some children on long-term omeprazole therapy<sup>[28,29]</sup>. Moreover, in a pediatric FAP population on proton pump inhibitors for more than 6 mo, dysplasia was reported in fundic gland polyps<sup>[29]</sup>. These studies imply that with increasing use of long-term proton pump inhibitors, an epidemic of fundic gland polyposis will be defined. Studies are needed to determine if further follow-up of patients on long-term therapy with proton pump inhibitors and fundic gland polyps is warranted. In spite of an early record of safety with long-term use, there remain concerns regarding the potential risk of cancer with long-term exposure, not only in those with FAP, but also in those genetically predisposed to cancer. This concern is reflected in the recently published studies on colon cancer risk with long-term proton pump inhibitor exposure. In these studies, no increased risk was shown<sup>[30,31]</sup>. While temporarily reassuring, ongoing vigilance will be required before the final chapter is written.

### Abstract

For over one hundred years, viruses have been recognized as capable of killing tumor cells. At present, people are still researching and constructing more suitable oncolytic viruses for treating different malignant tumors. Although extensive studies have demonstrated that herpes simplex virus type 1 (HSV-1) is the most potential oncolytic virus, therapies based on herpes simplex virus type 1 vectors still arouse bio-safety and risk management issues. Researchers have therefore introduced the new idea of treating cancer with HSV-1 mutants labeled with radionuclides, combining radionuclide and oncolytic virus therapies. This overview briefly summarizes the status and mechanisms by which oncolytic viruses kill tumor cells, discusses the application of HSV-1 and HSV-1 derived vectors for tumor therapy, and demonstrates the feasibility and prospect of HSV-1 mutants labeled with radionuclides for treating tumors.

### INTRODUCTION

Oncolytic virus<sup>[1]</sup>, a tumor-specific replicating virus, is

one of a number of natural or engineered viruses that can selectively replicate in and cleave tumor cells, but not kill normal somatic cells. There are six major mechanisms by which viruses can lyse tumor cells: (1) Viruses can replicate, package in and cleave tumor cells; (2) Similar to non structure protein (NS protein), some protein particles produced by virus replication can induce host cell apoptosis; (3) Both nonspecific and specific immune responses as well as immunoreactive sensitivity to cytokine (TNF- $\alpha$ , IFN- $\gamma$ ) associated with virus infection can accelerate tumor cell lysis; (4) Virus associated antigen can enhance MHC- I expression on tumor cells, and increase the ability of antigenic specific cytotoxic T cells to kill tumor cells; (5) Oncolytic virus can enhance the sensitivity of tumor cells to radiotherapy and chemotherapy; and (6) Oncolytic virus can carry and express cancer therapeutic genes.

At present, many engineered oncolytic viruses have been used in animal or human studies. Some of them have been or are ongoing into phase III clinical trials, especially adenovirus. ONYX-015<sup>[2,3]</sup>, a derivative of adenovirus with a deletion of the E1B-55KD gene, can kill p53-deficient tumor cells, but not cells with functional p53. Many limitations were found, however, in its phase II clinical trial; ONYX-15 could neither treat tumors sufficiently, infect secondary tumor metastases efficiently, nor spread sufficiently in solid tumors<sup>[2,3]</sup>. Nevertheless, evident organ impairment, toxicity and environmental events have not been found.

Several other oncolytic viruses (Newcastle disease virus, reovirus, retrovirus, rabies virus) have not been extensively used in research and clinical therapy, due to small genome size, limited host range, unclear replication mechanisms, etc.

### RESEARCH AND CLINICAL APPLICATIONS OF HERPES SIMPLEX VIRUS TYPE 1 FOR TUMOR TREATMENT

Compared with other viruses, herpes simplex virus type 1 (HSV-1) has a number of favorable properties for cancer treatment<sup>[4]</sup>. (1) In spite of its neurotropism, HSV-1 possesses a wide range of host cells, which is superior to adenovirus. (2) HSV-1 is able to infect dividing cells as well as nondividing cells. (3) Its DNA has been completely sequenced<sup>[5]</sup>, and the genome of 152 kb has exceeded adenovirus genome of 36 kb. Furthermore, transgenes can replace as much as 30 kb of the deleted HSV genome in replication-defective HSV-1 mutants, and

simultaneous delivery of multiple transgene and insertion of heterologous promoters are allowed. (4) Its genome will not integrate into the cellular genome, resulting in little insertional mutagenesis, which is the major concern in retrovirus and adeno-associated virus vectors. (5) The entire replication cycle is usually about 20 h in permissive cells<sup>[5]</sup>, and that of adenovirus is 48-72 h<sup>[6]</sup>. (6) Recombinant HSV-1 is easily engineered, and purified viruses with a high titer can be routinely prepared. (7) HSV-1 can efficiently infect different cells<sup>[7]</sup>, which is advantageous for the generalization from preclinical results to clinical trials. In contrast, the application of adenovirus vectors has been limited by few animal models. (8) HSV-1 infection is able to spread through both cell junctions and extracellular spaces and can penetrate into solid tumors with less systemic spread. (9) HSV-1 rarely causes life-threatening illness even in immune-competent adults. (10) HSV-1 infection can be treated using several anti-HSV-1 drugs (such as Acyclovir and Famciclovir)<sup>[8]</sup>.

Two main types of HSV-1 vectors are used in tumor therapy: replication-defective vectors and conditionally replication vectors. They can either terminate viral lytic infection or only confine themselves in certain types of cells.

Replication-defective vectors, in which either one of a few essential viral genes are deleted and then transgene expression cassettes are inserted in a viral genome, can effectively express transgene products, but are unable to replicate in cells unless host cells can supply the deleted viral functions. The HSV-1 mutant is used as a transgene in nerve cells. The HSV-1 thymidine kinase (TK) gene, a suicide gene encoded by UL23, is unique and most frequently used. TK protein can transform innocuous prodrugs such as GCV into cytotoxic drugs, resulting in termination of DNA synthesis in active cells, especially in tumor cells. Furthermore, bystander effects generated by TK/GCV systems are also toxic to tumor cells, but not towards neurons and quiescent glia<sup>[9]</sup>. Besides the TK gene<sup>[10]</sup>, other cancer therapeutic genes such as connexin-43<sup>[11]</sup>, p53<sup>[12]</sup>, IL-2<sup>[13]</sup>, granulocyte-macrophage colony-stimulating factor (GM-CSF)<sup>[13]</sup>, IL-12<sup>[14]</sup> and interferon (IFN- $\gamma$ )<sup>[15]</sup>, have also been delivered in the replication-defective HSV-1 vectors for treating malignant gliomas and other types of tumors, and an antitumor effect has been demonstrated by intratumoral injection in animal models. In addition, multiple therapeutic genes, for example, co-expressing TK and TNF- $\alpha$ <sup>[16]</sup>, TK, connexin-43 and TNF- $\alpha$ <sup>[17]</sup>, TK and IL-12<sup>[18]</sup>, have simultaneously been delivered in replication-defective HSV-1 vectors in extensive studies. As a result, tumor growth was significantly inhibited.

Conditionally replicating vectors, generated by deleting some nonessential viral genes, can preferentially infect, replicate in, and lyse tumor cells. Therapeutic transgenes can also augment the antitumor effect.

Recently, there have been many reports about HSV-1 mutants. In several animal tumor models, HSV-1 mutants with TK gene deletion were created and tested for oncolytic virotherapy, which could induce tumor regression following intra-neoplastic administration<sup>[19]</sup>. The UL39-

deleted virus, hrR3, efficiently replicates in malignant cells but proliferates less in normal cells<sup>[20]</sup>. It was demonstrated that hrR3 had produced significant antitumor effects and survival benefits in animal models such for brain, colon, pancreas and liver cancers. In animal studies, HSV1716<sup>[21]</sup>, R3616<sup>[22,23]</sup> and R4009<sup>[22,23]</sup>, which are the ICP34.5-deleted strains, are able to replicate when inoculated into neuron and other non-replicating cells. In contrast, in animal models of glioma, mesothelioma, melanoma, ovarian and lung cancer, HSV1716, R3616 and R4009 are replicated significantly. G207<sup>[24,25]</sup>, containing deletions of both copies of ICP34.5 gene and an insertion of *E. coli* lacZ gene in UL39 gene which encodes ICP6, had some favorable properties for cancer treatment. Competent replication in tumor cells, attenuated neurovirulence, GCV hypersensitivity, temperature sensitivity and the product of lacZ gene were easily detectable. G47 $\Delta$ <sup>[26]</sup>, a derivative of G207 with an additional ICP47 gene deletion, could more efficaciously inhibit tumor growth *in vivo* than its parent G207, while safety was unaffected<sup>[26]</sup>. Under the name of NV1020<sup>[27]</sup>, R7020<sup>[27,28]</sup> contained a 15kb deletion of ICP34.5, the deletions of UL24, UL55, UL56 and endogenous TK gene and the insertion of exogenous TK gene which was controlled by  $\alpha$ 4 promoter. Compared with R3616<sup>[22,23]</sup> (double ICP34.5-deletion mutant), R7020 was more efficacious in inhibiting the growth of tumors, and more sensitive to ACV and GCV. Myb34.5<sup>[29]</sup> had the deletion of both endogenous copies of the ICP34.5 gene and re-insertion of this gene into the ICP6 locus, with the new ICP34.5 gene under the control of the B-myb promoter. In contrast to hrR3, Myb34.5 was active in tumor cells, but was more attenuated in normal cells.

Although the usefulness of HSV-1 vectors for treating tumors have been confirmed, there are some limitations in their application. (1) It is more difficult to produce multiple gene deleted HSV-1 vectors than the wild-type virus, resulting in a lower yield. The opportunity of homologous recombination of wild-type HSV-1 with recombinant viral mutants is concerned. (2) It is particularly difficult to keep long-term stability (over 6-mo period) of HSV-1 derived vectors, either in aqueous solution or in lyophilized form. (3) The virus may rapidly spread in individuals with immunodeficiency. The efficacy may be reduced by immune response induced by antiviral or antitransgene products. (4) Attention must be paid to the safety in use of HSV-1 because HSV-1, a human pathogen, has broad cell type tropism and high replication capacity. So the safety and efficacy of HSV-1 mutants for tumor treatment are still a focus of future studies.

## **SUPERIORITY AND PROSPECT OF HSV-1 MUTANTS LABELED WITH RADIONUCLIDES FOR TUMOR TREATMENT**

HSV-1 mutants can selectively infect tumor cells, but not suppress the growth of normal cells. There may be a synergistic antitumor effect, when they are labeled with radionuclide. With the help of the viral vectors, radionuclide will be carried into tumor tissues and bring

about radiation damage to tumor cells. It is rarely reported whether HSV-1 can be labeled with radionuclide, whether viral bioactivity may be influenced by the virus labeled or radionuclide which will enter into tumor cells together with virus. We analyzed these issues in this overview.

HSV-1 has an enveloped double-stranded nucleic acid (dsDNA). Located in the core of the virus, dsDNA is surrounded by a protein shell called a capsid which consists of 162 capsomeres arranged in a  $T = 16$  icosahedral symmetry. The channels which are controlled by tegument proteins are contained in the capsid, controlling the transport of dsDNA through the channel. Surrounding the capsid, an amorphous tegument contains at least eight types of proteins that play an important role during HSV-1 infection. An outer envelope is composed of lipid bilayer with about 13 different viral glycoproteins.

It is well known that the HSV-1 envelope and tegument-capsid surrounding dsDNA consist of multiple proteins, about 60%-80% protein of the whole structure elements. However, HSV-1 mutants are generally constructed by modifying the dsDNA without altering their tegument-capsid. There are enough proteins, which well fit the labeling. Furthermore, the proteins such as monoclonal antibody, polypeptide and ligand, can all be labeled successfully<sup>[30,31]</sup>. As for radionuclide, there are <sup>125</sup>I, <sup>131</sup>I, <sup>32</sup>P, <sup>35</sup>S, <sup>99m</sup>Tc, <sup>188</sup>Re, <sup>186</sup>Re, <sup>90</sup>Y and so on. In a word, the proteins contained in HSV-1 structural elements are considerably suitable for radiolabelling.

During initial infection, HSV-1 attaches first to the host cell surface receptor, and fuses with the membrane of host cells, and the de-enveloped tegument-capsid is efficiently and rapidly transported to the nuclear pore complexes, where the viral dsDNA is released. The capsid with associated tegument structures can also be carried to the nuclear pore through the microtubules<sup>[32]</sup>. The transition from virtual attachment to penetration is very rapid and takes only several minutes<sup>[33]</sup>. At the early phase of virus infection, the viral envelope glycoproteins, gC and gB, bind to cell surface heparin sulfate<sup>[34]</sup>. Then, viral glycoprotein gD binds to certain cell surface receptor (e.g., nectin-1a, nectin-1b, 2a, 2d, HveA), contributing to virion-cell fusion<sup>[35]</sup>. Besides, three other viral envelope glycoproteins, gB, gH and gL, have been shown to be helpful for the HSV-1 penetration into host cells<sup>[36]</sup>. As a result, the viral proteins are delivered into different metastructures. So, it is feasible that HSV-1 vector mutants could carry radionuclide-labeled proteins into tumor cells.

Could radiation from radiolabeling of viruses destroy their structures and damage their biologic characteristics? A study<sup>[37]</sup> on the combination of gene therapy with radiotherapy for tumors revealed that the gene products in mice lung cancer cells had increased dose-dependently, when irradiated by gamma-ray at doses of 2-40 Gy followed by AdCMVlu transfection. The efficacy could be up to 24 times higher, and tumor growth was inhibited. Kanazawa<sup>[38]</sup> demonstrated that the number of replicative dsDNA of the laryngeal cancer cell line (HEp-2) and Henrietta Lacks (HeLa) strain of cancer cells had a significant enhancement in the combination of virus system and radiotherapy. The virus system was composed of adeno-associated virus (AAV) vectors,

the HSV-1 thymidine kinase (HSV-tk) and ganciclovir (GCV). The radiation dosage was 4Gy. These experiments *in vitro* suggested that the combination of AAVtk/GCV system with radiotherapy was significantly effective in the treatment of cancers. Weichselbaum RR<sup>[39]</sup> found radiation could induce the transcription of CarG elements in the Egr-1 promoter sequences which lies the upstream of TNF- $\alpha$  cDNA. At the same time, TNF- $\alpha$  obtained a high expression. Generally, radiotherapy would stimulate the virus replication, resulting in a higher HSV-1 antitumor activity<sup>[40]</sup>. Other studies had also indicated that ionizing radiation could enhance anti-cancer activity of hrR3 without altering its replication<sup>[40]</sup>. Similarly, a synergistic antitumor response, with more tumor regression and better survival rate, was induced by the combination of ionizing radiation and R3616 deleted ICP34.5<sup>[41]</sup>. So, radionuclide labeled to HSV-1 mutants does not damage the viral biological function, but can enhance the antitumor effect.

It is extremely important that compounds labeled with radionuclide should possess a good stability *in vivo*. The labeled compounds should stay in the tumor cell cytoplasm while the HSV-1 mutant dsDNA enters the nucleus. HSV-1 recombinant-labeled radionuclide should, therefore, have a favourable stability before penetration into the tumor cell nucleus. Of course, suitable radiolabeling methods which can keep labeled compounds stable should be well considered. Diethylenetriaminepentaacetic acid (DTPA) is known as one of the difunctional chelators. This kind of chelator has a stereochemical structure group which is found to tightly hold radionuclide and amino acids fragments active group by a covalent link. Thus, radionuclide (<sup>188</sup>Re, <sup>90</sup>Y) is indirectly linked up with protein molecule, and the compounds labeled with radionuclide is stable *in vivo*. Moreover, the biochemical activity of radiolabeled complex will not be influenced. As a chelating agent, DTPA has a potential and broad applicability<sup>[30,31]</sup>.

As far as radiolabeling and the structure of HSV-1 are concerned, the feasibility of labeling radionuclide to HSV-1 mutants is demonstrated by a plenty of animal experiments and clinical trials. Furthermore, once the radionuclide is introduced, nuclear medicine approaches may be employed in the clinic to monitor and assess the therapeutic efficacy *in vitro* in a non-invasive manner.

In order to increase the efficiency of HSV-1 mutants in killing tumor cells, we intend to construct HSV-1 GRT, by deleting ICP 47 gene and one copy of ICP 34.5 gene and inserting *E. coli* Z gene and TNF $\alpha$  gene in UL39 gene. Then HSV-1 GRT can be labelled with <sup>131</sup>I or <sup>188</sup>Re directly or indirectly. We will study the expression of HSV-1 GRT or radioactive compounds (<sup>131</sup>I-HSV-1 GRT, <sup>188</sup>Re-HSV-1 GRT and <sup>188</sup>Re-DTPA-HSV-1 GRT) in tumor cells and mechanism of inhibiting or killing tumor cells. In other words, our aim is to develop an ideal drug which can combine viral oncolysis with radionuclids therapy. With the help of the HSV-1 GRT, radionuclids (<sup>131</sup>I or <sup>188</sup>Re) can be carried into tumor tissues and bring about radiation damage to tumor cells.

## CONCLUSION

HSV-1 mutants provide a choice for oncolytic viruses

to selectively target and kill tumor cells, and they are also attractive vectors helping radionuclide get to focal tumor tissues. The combination of viral oncolysis with radionuclide therapy will achieve a synergistic anticancer effect, with more inhibition of tumor growth, less toxicity and fewer side effects than either HSV-1 mutants or radionuclide therapy. It is reasonably concluded that HSV-1 mutants labeled with radionuclide will be a potential focus for tumor treatment.

## Abstract

Inflammatory bowel disease (IBD) is a chronic disorder affecting young adults in their reproductive years. Many young women with IBD express concern about the effect their disease will have on fertility, pregnancy course and fetal development. This article presents an approach to management of IBD in the pregnant patient, including counseling and investigation, and summarizes existing data on the safety of medications used to treat IBD in pregnancy and breastfeeding.

## INTRODUCTION

Inflammatory bowel disease (IBD) is a chronic disorder affecting young adults in their reproductive years. Voluntary childlessness in patients with IBD is greater than in the

general population due to relationship difficulties, body image problems, fear of pregnancy and inappropriate medical advice that pregnancy might be dangerous<sup>[1-3]</sup>. Pregnancy planning should be discussed with the patient and her partner early on prior to conception. Education and open communication are important as patients may be reluctant to broach this topic on their own. Patient concerns often relate to fertility, impact of IBD on pregnancy and fetal development, and drug effects pre-conception, during pregnancy and while breastfeeding.

## FERTILITY

Women with ulcerative colitis (UC) who have not undergone surgery or those with inactive Crohn's Disease (CD) have fertility rates comparable with the rest of the population. In comparison, women with UC who have had surgery<sup>[4]</sup> or those with active CD<sup>[5,6]</sup> have increased infertility. Fertility appears to revert to normal after induction of remission in women with CD. Women who have their first pregnancy after the onset of IBD have fewer pregnancies than population controls, whereas women who became pregnant prior to onset of IBD have similar reproductive history<sup>[5]</sup>. In addition, women with CD have a delayed age of first pregnancy after being diagnosed<sup>[7]</sup> and have been shown to have fewer children than might be expected after diagnosis with a higher rate of failure to conceive<sup>[8]</sup>.

## IMPACT OF IBD ON PREGNANCY AND FETAL DEVELOPMENT

The initial impression looking at multiple, small observational studies of pregnancy in women with IBD was that the outcome was normal<sup>[6,9]</sup>. Fetal mortality risk (spontaneous abortion, stillbirth or neonatal death) is not higher for IBD patients<sup>[3]</sup>, but there is an increased risk of preterm delivery (< 37 wk) and low birth weight (< 2.5 kg) in mothers with IBD<sup>[10-14]</sup>. Still, the majority of women with IBD will have a normal outcome of pregnancy. Disease activity is the main adverse factor predisposing to prematurity and low birth weight babies<sup>[15]</sup>.

## DISEASE ACTIVITY

Approximately one-third of women with inactive IBD at conception will relapse during the pregnancy or puerperium.

This risk of a flare is no greater than any other year of the patient's life<sup>[3]</sup>. If conception occurs at a time when IBD is active, disease will settle only in about one-third of women with UC or CD<sup>[12,16]</sup>. One-quarter of patients with active IBD during pregnancy will experience chronically active disease and in about half of these patients, disease will worsen (45% UC, 33% CD)<sup>[15]</sup>. Active disease has been associated with miscarriage, stillbirth, prematurity and low birth weight<sup>[17]</sup>. Thus, conception is advised when IBD is in remission.

Maintenance therapy, if possible, should be continued throughout pregnancy and flare-ups of disease should be investigated and treated appropriately as in the non-pregnant patient. If conception occurs with active IBD, inducing remission with medical therapy carries less risk than continuing pregnancy without treatment.

### TNF- $\alpha$ AND PREGNANCY LOSS

Tumour necrosis factor is a pivotal pro-inflammatory cytokine in IBD<sup>[18]</sup>. Active IBD, more so CD than UC, is associated with elevated TNF- $\alpha$  levels<sup>[19,20]</sup>. In the past, TNF- $\alpha$  has been thought to be primarily involved in triggering immunological pregnancy loss. Newer evidence suggests that the possible essential function of TNF- $\alpha$  is to boost death signaling to kill the embryo if damages triggered by detrimental stimuli will result in birth of offspring with structural anomalies<sup>[21]</sup>. This theory seems more plausible from a clinical perspective since risk of pregnancy loss is higher with active IBD.

### COUNSELLING THE IBD PATIENT WITH POTENTIAL FOR PREGNANCY

#### *Preconception counseling*

As with all patient-physician interactions, the therapeutic alliance, education and communication are important components in assisting the patient with IBD to make decisions about conception and pregnancy. Early on in the patient-physician relationship, preferably prior to conception, the physician should address fertility, IBD impact on pregnancy outcomes, medication effects and importance of disease remission in minimizing fetal risk. Many women want to be drug free during pregnancy and should not feel guilty about making this choice as long as it is an informed decision. The patient, her partner and her physician should discuss the possibility of disease exacerbation during pregnancy while off treatment and the necessary courses of action in such an event. Treatment choices depend on individual preference, disease severity and potential for drug toxicity. Risks and benefits of maintenance therapies during pregnancy with the best available evidence should be addressed. In addition, breastfeeding should be presented as a favorable option since it confers numerous benefits to both mother and child. The likelihood of medication secretion in breast milk and impact on fetal wellbeing become essential topics.

#### *Alcohol*

Patients contemplating pregnancy should be educated about the adverse effects of alcohol on fetal development.

Maternal consumption of alcohol during pregnancy can result in fetal alcohol syndrome (FAS), a permanent birth defect clinically defined by growth deficiency, central nervous system damage and dysfunction, and a unique cluster of facial abnormalities. Although FAS is the most extreme and recognizable expression of the adverse effects of alcohol on the fetus, prenatal alcohol exposure can also cause less pronounced mental, learning and behavioral disabilities in the child, commonly termed as Fetal Alcohol Spectrum Disorders (FASDs)<sup>[22]</sup>.

#### *Smoking*

Tobacco smoking during pregnancy has been associated with placenta previa, placental abruption, premature rupture of membranes, preterm birth, intrauterine growth restriction and sudden infant death syndrome (SIDS)<sup>[22]</sup>. Smoking cessation should be encouraged in the patient prior to, during and after pregnancy.

#### *Dietary supplementation and nutritional therapy*

**Folic acid, calcium and vitamin D:** Folic acid supplementation is recommended for all pregnant women. Women with IBD may have folic acid deficiency or be taking medications that interfere with folic acid metabolism such as sulfasalazine<sup>[15]</sup>. Thus, pregnant women with IBD should be encouraged to take 5 mg of folic acid per day instead of 1 mg/d as recommended for the general population. Also, patients with IBD on steroid therapy should be encouraged to take calcium and vitamin D supplementation to prevent bone loss.

**Nutritional therapy:** The average weight gain during pregnancy is 11-16 kg. Early nutritional intervention is indicated in pregnant women with active IBD who may not be gaining weight. Enteral feeding has been anecdotally shown to be associated with normal pregnancy outcome<sup>[23]</sup> and total parenteral nutrition (TPN) may be required in very sick IBD patients.

#### *Mode of delivery*

In general, the decision to have a caesarean section should be made on purely obstetric grounds. Some surgeons advise elective caesarean section to avoid risk of anal sphincter damage<sup>[15]</sup>. Vaginal delivery and episiotomy may lead to development or worsening of perianal CD<sup>[24]</sup>. Current indications for caesarean section are active perianal disease and presence of an ileoanal pouch. There is no absolute contraindication to vaginal delivery in pregnant patients with inactive IBD.

### RADIOLOGIC AND ENDOSCOPIC INVESTIGATION OF IBD EXACERBATIONS DURING PREGNANCY

#### *Radiology*

Radiographic imaging should be avoided unless obstruction, perforation or toxic megacolon are suspected. Investigations that expose the patient to less radiation are preferable - specifically plain abdominal films rather than CT or barium studies. Ultrasound is the safest form

Table 1 Food and drug administration (FDA) classes in pregnancy

Class	Definition
A	Controlled studies in women fail to demonstrate a risk to the fetus in the first trimester (and there is no evidence of risk in later trimesters) and the possibility of fetal harm appears remote
B	Either animal reproduction studies have not demonstrated a fetal risk, but there are no controlled studies in pregnant women OR animal reproduction studies have shown an adverse effect (other than decrease in fertility) that was not confirmed in controlled studies in women in the first trimester (and there is no evidence of risk in later trimesters)
C	Either studies in animals have repeated adverse effects on the fetus (teratogenic, embryonic or other) and there are no controlled studies in women or studies in women and animals are not available. Drugs should be given only if the potential benefit justifies the potential risk to the fetus
D	There is positive evidence of human fetal risk but the benefits from use in pregnant women may be acceptable despite the risk (e.g. if the drug is needed in a life threatening situation or for a serious disease for which safer drugs cannot be used or are ineffective)
X	Studies in animals or human beings have demonstrated fetal abnormalities OR there is evidence of fetal risk based on human experience OR both, and the risk of the use of the drug in pregnant women clearly outweighs any possible benefit. The drug is contraindicated in women who are or may become pregnant

of radiologic imaging - it can be used to assess abscess formation and can provide information on bowel wall thickness. MRI studies are also safe and have been used to diagnose terminal ileal CD during pregnancy<sup>[17]</sup>. Since active disease in the mother has an adverse effect on the fetus, investigation for diagnostic and therapeutic purposes is warranted and should not be delayed.

### Endoscopy

Endoscopy does not increase risk of premature labor or fetal abnormalities. Colonoscopy and sigmoidoscopy are safe during pregnancy if indicated<sup>[25]</sup> and rigid sigmoidoscopy and rectal biopsy can be performed without fetal risk<sup>[16]</sup>. Fetal heart rate should be monitored closely during the procedure and if required, sedation for endoscopy is thought to be safe. Antispasmodics such as hyoscine butylbromide (Buscopan) are contraindicated<sup>[15]</sup>.

## MEDICAL/DRUG THERAPY

The most common medication classes used in treatment of IBD are presented below, along with US Food and Drug Administration (FDA) classifications for their use. Please refer to Table 1 for details of the FDA Drug Classification System and to Tables 2 and 3 for summaries of drug safety during pregnancy and breastfeeding respectively.

### 5-aminosalicylic acid preparations (FDA Class B)

This class of medications includes sulfasalazine, mesalamine, olsalazine and balsalazide. Aminosaliclates are used for maintenance therapy or induction of remission in IBD. All aminosaliclates are FDA category B except olsalazine which is FDA category C. Both sulfasalazine and mesalamine are safe in breastfeeding mothers.

Table 2 FDA classes of medications used to treat IBD

FDA class	Medications
B	5-Aminosalicylic acid preparations (sulfasalazine, mesalamine, balsalazide); metronidazole, amoxicillin/clavulanic acid; infliximab; adalimumab
C	5-Aminosalicylic acid preparations (Olsalazine); fluoroquinolones; corticosteroids; bisphosphonates; cyclosporin; tacrolimus
D	Azathioprine and 6-MP
X	Methotrexate; thalidomide

Table 3 Breastfeeding safety of medications used to treat IBD

Safe	Limited data, potential toxicity	Contraindicated
5-ASA preparations (sulfasalazine, mesalamine)	Metronidazole Fluoroquinolones	Thalidomide
Amoxicillin/clavulanic acid	Bisphosphonates	Methotrexate
Corticosteroids	Azathioprine 6-mercaptopurine (6-MP) Adalimumab Infliximab	Cyclosporine (CsA) Tacrolimus (FK506)

**Sulfasalazine:** Sulfasalazine competitively inhibits the brush border enzyme folate conjugase<sup>[17]</sup>. It is a folic acid antagonist that theoretically can cause neural tube defects, cardiovascular and urinary tract abnormalities, and oral clefts<sup>[26]</sup>. Clinical studies show no increase in incidence of congenital anomalies with sulfasalazine treatment<sup>[27]</sup>. Given the effect of sulfasalazine on folic acid metabolism, extra folic acid supplementation is recommended for all pregnant women on this medication during the course of their pregnancy. Sulphasalazine and its metabolite sulphapyridine both cross the placenta and are secreted in breast milk at levels approaching that of maternal levels<sup>[15]</sup>. Initial concerns about sulphasalazine in the neonatal setting were raised because a related sulfonamide (sulphisoxazole) could cause kernicterus in neonates<sup>[28]</sup>. Several studies have shown that there is no increased incidence of neonatal jaundice with sulfasalazine<sup>[9,30]</sup>. It is safe in breastfeeding mothers unless the fetus suffers from pre-existing hemolysis or if a rhesus incompatibility between mother and fetus is suspected<sup>[17]</sup>.

**5-ASA (Mesalamine):** Mesalamine is safe in pregnancy in conventional doses. Higher doses of greater than 3 g/d carry a potential risk of fetal nephrotoxicity, specifically interstitial nephritis<sup>[30]</sup>. There is no significant change in congenital abnormalities, abortions or fetal distress with conventional 5-aminosalicylic acid treatment<sup>[31-33]</sup>. Mesalamine is excreted in breast milk, but does not pose a significant risk to the baby<sup>[34]</sup>.

### Antibiotics

Metronidazole and the quinolones have limited benefit for long term treatment of IBD. Short courses of these medications in treatment of pouchitis and perianal disease are low risk in the pregnant patient.

**Metronidazole (FDA Class B):** Metronidazole is used for treatment of active CD as well as perianal disease. This medication does not increase risk of spontaneous abortion or congenital anomalies<sup>[35,36]</sup>, although infants of women exposed to metronidazole in the second to third months of pregnancy have shown higher rates of cleft lip with or without cleft palate<sup>[37]</sup>. Potential toxicity exists for long-term metronidazole use while breastfeeding<sup>[38]</sup>.

**Fluoroquinolones (e.g. Ciprofloxacin) (FDA Class C):** Human studies with fluoroquinolones have not shown increase in spontaneous abortion or congenital abnormality incidence<sup>[39]</sup>. However, animal studies demonstrate musculoskeletal abnormalities induced by this medication class<sup>[40]</sup>. Fluoroquinolones have a high affinity for bone tissue and cartilage, and may cause arthropathies in children. Although they are thought to have minimal risk overall, they should be avoided in the first trimester. Fluoroquinolones are likely compatible with breastfeeding, although data is limited.

**Amoxicillin/clavulanic acid (FDA Class B):** Amoxicillin/clavulanic acid is used as an alternative antibiotic for pouchitis. It does not confer increased teratogenic risk and is compatible with breastfeeding<sup>[41]</sup>.

### **Corticosteroids (FDA Class C)**

Corticosteroids come in parenteral, oral and topical formulations. They include prednisone, prednisolone, dexamethasone and budesonide, and are indicated in moderately to severely active disease<sup>[3]</sup>. Although corticosteroids cross the placenta, these agents pose a very small risk to the developing infant when used in the first trimester. This risk is often outweighed by the benefit of controlling the mother's IBD. Animal studies show increased frequency of cleft lip and cleft palate<sup>[42]</sup>. However, these findings do not correlate with human results. A prospective controlled study in 2004 did not demonstrate increased rate of congenital anomalies or oral cleft with corticosteroid treatment during pregnancy<sup>[43]</sup>. In addition, studies of corticosteroid use in pregnant patients with rheumatoid arthritis, antiphospholipid syndrome and SLE show no convincing evidence of teratogenesis<sup>[44-46]</sup> and steroid use in IBD patients is not associated with pregnancy complications<sup>[29]</sup>.

Although adrenal suppression among neonates born to mothers taking corticosteroids is a theoretical concern, it has not been an issue in practice. Rectal preparations can be used until the third trimester unless there are specific concerns regarding miscarriage or premature delivery<sup>[15]</sup>.

Corticosteroids are secreted into breast milk in low concentrations. The maternal: fetal ratio of steroid serum concentrations depends on which steroid the patient is taking. Fluorinated steroids, betamethasone and dexamethasone are less efficiently metabolized by the placenta compared to prednisolone, resulting in fetal levels 10%-12% of that in maternal serum<sup>[47]</sup>. While breastfeeding is safe with steroid use, mothers are encouraged to defer breastfeeding until 4 h after taking oral dosing of steroids to reduce neonatal exposure<sup>[48]</sup>.

There is no data on the safety of oral budesonide

in pregnancy. Inhaled or intranasal budesonide is not associated with adverse fetal outcomes. Budesonide effects on breastfeeding are unknown<sup>[38]</sup>.

### **Bisphosphonates (FDA Class C)**

IBD patients on long term corticosteroid treatment may be started on bisphosphonates to prevent bone loss or treat osteoporosis. Alendronate and risedronate are two common bisphosphonates used to this effect. Alendronate has been shown in animal studies to cross the placenta and incorporate into fetal bone<sup>[49]</sup>. Long-term effects of alendronate on human bone development are unknown and the half-life of alendronate is greater than 10 years. The concern with long-term bisphosphonate treatment is that the drug is slowly released from maternal bone and may result in continuous low-level exposure to the fetus during gestation. Thus, bisphosphonates should be used with caution in young women who have the potential for pregnancy.

### **Immunomodulators**

**Methotrexate (FDA Class X):** Methotrexate is used as an alternative to azathioprine in treatment of steroid dependent or resistant CD. It is a teratogen that interferes with folic acid metabolism and purine synthesis. In obstetrics, it is used therapeutically to abort ectopic pregnancies<sup>[50]</sup>. Fetuses exposed to methotrexate develop congenital anomalies collectively known as methotrexate embryopathy or fetal aminopterin syndrome characterized by intrauterine growth retardation, decreased ossification of the calvarium, hypoplastic supraorbital ridges, small low-set ears, micrognathia, limb abnormalities and sometimes mental retardation. Methotrexate is contraindicated in pregnancy and breastfeeding. Female and male patients on methotrexate must be using a reliable form of contraception and should avoid conceiving for 6 mo after stopping the drug. A woman who conceives on methotrexate and refuses therapeutic abortion should stop the methotrexate and immediately start high dose folic acid replacement<sup>[51]</sup>.

### **Azathioprine/6-mercaptopurine (6-MP) (FDA Class D):**

Azathioprine (a prodrug of 6-MP) and 6-MP are used in treatment of steroid-dependent or resistant IBD. Most evidence for safety of azathioprine in pregnancy comes from studies in transplantation. The fetus is protected from potential teratogenic effects of azathioprine and 6-MP since the fetal liver lacks the enzyme inosinate phosphorylase which is necessary to convert azathioprine and 6-MP to active metabolites. Both these medications when used in small doses in clinical practice do not affect human interstitial cell function or gametogenesis<sup>[52,53]</sup>. Renal transplant patients and SLE patients on treatment with azathioprine and 6-MP have had good outcomes<sup>[15]</sup>. Also, retrospective studies have also shown that these medications are safe in pregnant patients with IBD<sup>[54,55]</sup>. If a patient is established on azathioprine or 6-MP therapy and the drug is essential to maintain remission, the patient should continue treatment. Breastfeeding is not recommended by the manufacturers of azathioprine and 6-MP, but clinical experience of mothers shows no adverse side effects<sup>[15]</sup>.

**Cyclosporine (CsA) (FDA Class C):** CsA is used to delay surgery in severe UC. It is a selective immunosuppressant with the ability to inhibit activation of T cells, preventing formation of IL-2. Although it is not teratogenic, it crosses the placenta and is secreted in breast milk at high concentrations. CsA is contraindicated with breastfeeding to avoid neonatal immunosuppression. It is most likely safe with no adverse fetal effects during pregnancy. Most of the data regarding the use of cyclosporine comes from transplant patients<sup>[48,56]</sup>. CsA is a highly toxic drug for the mother with risk of hypertension, nephrotoxicity and hepatotoxicity. CsA should not be used during pregnancy, except to prevent urgent colectomy in patients with fulminant UC<sup>[57]</sup>.

**Tacrolimus (FK506) (FDA Class C):** Tacrolimus is a fungus-derived immunosuppressant with a mechanism of action similar to CsA. It has been associated with increased incidence of perinatal hyperkalemia and prematurity<sup>[58]</sup>. A single case report with favourable outcome for a pregnant patient with UC was published in 2005<sup>[59]</sup>. It is contraindicated in breastfeeding due to high concentrations in breast milk.

**Thalidomide (FDA Class X):** Thalidomide is used in treatment of refractory CD. It has extensive teratogenic sequelae including limb defects, central nervous system effects and abnormalities of the respiratory, cardiovascular, gastrointestinal and genitourinary systems. Thalidomide is contraindicated during pregnancy and breastfeeding. Women of childbearing age taking thalidomide should use two methods of contraception 1 mo prior to starting therapy, during therapy and for 1 mo after stopping therapy.

### Biological therapy

**Infliximab (FDA Class B):** Infliximab is a chimeric monoclonal antibody that inhibits TNF- $\alpha$ , a pro-inflammatory cytokine. It is used in treatment of patients with severe active CD. One study and a patient series have provided data for safety of infliximab in pregnancy. The Infliximab Safety Database maintained by Centocor (Malvern, Pennsylvania, USA) presented outcome data on 96 women with direct exposure to infliximab. The outcomes for these women were not different from those of the general population<sup>[60]</sup>. A patient series of ten women on maintenance infliximab throughout pregnancy ended in live births with no congenital malformations for all women<sup>[61]</sup>. Still, long-term implications of in-utero exposure to infliximab remain unknown. Infliximab crosses the placenta but is not detectable in breast milk and case reports of women who breastfed while on infliximab do not suggest toxicity<sup>[62]</sup>. However, long-term effects on the developing infant's immune system while breastfeeding on infliximab are unknown.

**Adalimumab (FDA Class B):** Adalimumab has been recently demonstrated as a safe and efficacious therapy in induction of remission and maintenance therapy in CD<sup>[63]</sup>. There is one case report of a successful pregnancy in a woman with longstanding CD who began adalimumab

1 mo prior to conception<sup>[64]</sup>. There is no data on long-term effects of adalimumab on the developing fetus, or on its safety in breastfeeding.

**Fish oil supplements (FDA Class-not applicable):** Fish oil supplements are used by some patients with IBD as an adjunct to medical therapy. A randomized controlled trial of fish oil supplementation demonstrated prolongation of pregnancy without detrimental effects on growth of the fetus or course of labour<sup>[65]</sup>. Fish oil supplements are not rated by the FDA since they are not classified as a drug.

## CONCLUSION

Mothers with IBD have an increased risk of preterm delivery (< 37 wk) and low birth weight (< 2.5 kg) babies. Active IBD has also been associated with miscarriage and stillbirth. Maintenance therapy for IBD, if possible, should be continued throughout pregnancy and flare-ups of disease should be investigated and treated appropriately as in the non-pregnant patient. If conception occurs with active IBD, inducing remission with medical therapy carries less risk than continuing pregnancy without treatment. Early on, the physician should address fertility, IBD impact on pregnancy outcomes, medication effects and importance of disease remission in minimizing fetal risk with female patients of child-bearing age. It is important to provide patients with careful counseling regarding potential teratogenicity or adverse outcomes of medication use during pregnancy and breastfeeding. Individual patient preference, disease severity and potential for drug toxicity should determine the best therapy choice for each patient.

## Abstract

**AIM:** To isolate and analyze the DNA sequences which are methylated differentially between gastric cancer and normal gastric mucosa.

**METHODS:** The differentially methylated DNA sequences between gastric cancer and normal gastric mucosa were isolated by methylation-sensitive representational difference analysis (MS-RDA). Similarities between the separated fragments and the human genomic DNA were analyzed with Basic Local Alignment Search Tool (BLAST).

**RESULTS:** Three differentially methylated DNA sequences were obtained, two of which have been accepted by GenBank. The accession numbers are AY887106 and AY887107. AY887107 was highly similar to the 11th exon of LOC440683 (98%), 3' end of LOC440887 (99%), and promoter and exon regions of DRD5 (94%). AY887106 was consistent (98%) with a CpG island in ribosomal RNA isolated from colorectal cancer by Minoru Toyota in 1999.

**CONCLUSION:** The methylation degree is different between gastric cancer and normal gastric mucosa. The differentially methylated DNA sequences can be isolated effectively by MS-RDA.

**Key words:** Gastric cancer; DNA methylation; Differential sequences; Methylation-sensitive representational difference analysis

## INTRODUCTION

Epigenetic inactivation of tumor suppressor genes (TSG) is frequently associated with tumor pathogenesis<sup>[1,2]</sup>. The major mechanism of this epigenetic inactivation is through hypermethylation of promoter CpG islands (CGIs). In general, DNA hypermethylation of gene-associated CpG islands results in either down-regulation or complete abrogation of gene expression, indicating that aberrant DNA methylation could execute a similar function to genetic abnormalities, such as inactivating mutations or deletions in the disease state<sup>[1,3,4]</sup>. Numerous studies have indicated that several gene classes such as adhesion molecules, inhibitors of angiogenesis, DNA repair, cell cycle regulators, metastasis suppressors, *etc* are frequently hypermethylated in human primary tumors<sup>[5-9]</sup>. Gastric cancer is the second most common cause of cancer death in the world<sup>[10]</sup>. Compared with other malignant tumors, the incidence and mortality rate of gastric cancer rank first in China<sup>[11,12]</sup>. In the present study, DNA methylation is characterized as an important mode of epigenetic modification in the development and progression of gastric cancer by affecting gene transcription, increasing the frequency of gene mutation, and enhancing genomic instability<sup>[13]</sup>. However, the entire picture of methylation-silenced genes in gastric cancers is still unclear, and further searching for methylation-silenced genes is necessary.

Because analysis of methylation of known genes has limitations, genome-wide screening for CGIs methylated in gastric cancer is needed. In this study, methylation-sensitive representational difference analysis (MS-RDA)<sup>[14-16]</sup>, an advanced biotechnique, was used to detect the methylation

status of two genomes and elucidate the role of methylation in carcinogenesis. Moreover, with this strategy, novel genes related to gastric cancer can be obtained and new targets can be offered for gastric cancer research.

## MATERIALS AND METHODS

### Materials

Tissues from three gastric adenocarcinomas and adjacent normal tissue samples (> 5 cm away from the center of cancer) were collected from gastric cancer patients at a hospital affiliated with Nanhua University. Tumor and adjacent normal tissues were isolated and stored in liquid nitrogen. The histological types were confirmed by histological examination. The study protocol was approved by the Ethics Committee of Nanhua University.

### DNA extraction and HpaII digestion

Genomic DNAs of three gastric adenocarcinomas and adjacent normal mucosa samples were prepared by serial extraction with phenol and chloroform, followed by ethanol precipitation. A 10 µg sample of genomic DNA was digested with 10 µL methylation-sensitive four-base recognition restriction enzymes Hpa II (Fermentas Co., 10 U/µL), and was incubated for 20 h at 37°C.

### Amplicon preparation

Adaptors RHpa24 and RHpa11 (Table 1) were ligated to the mixture of digestion products of three gastric adenocarcinomas and adjacent normal mucosa samples, annealed by gradual cooling from 50°C to 10°C for 40 min, and then ligated to DNA fragments by overnight incubation with T4 DNA ligase at 16°C<sup>[17]</sup>. The ligation product was amplified for 26 cycles (each cycle including 1 min incubation at 95°C and 3 min at 72°C, with the last cycle followed by an extension at 72°C for 10 min) with RHpa24 oligonucleotides as a primer as reported. Three gastric adenocarcinoma samples served as the testers, and three adjacent normal mucosa samples served as the drivers. The DNA fragments with RHpa adaptor were amplified effectively and testers and driver amplicons were obtained<sup>[14]</sup>. Amplicons were detected by 1.0% agarose gel electrophoresis.

### Subtractive hybridizations

The RHpa adaptor in the tester and driver amplicons were removed by digestion with the isoschizomerase MspI (Fermentas Co. 10 U/µg) and separated with a DNA fragment purification and filtration kit (Takara Co., Japan). The JHpa II<sub>24/11</sub> adaptor was then ligated to the tester amplicon with T4 DNA ligase. The subtractive hybridizations with gastric cancer amplicons serving as the tester and normal gastric mucosa amplicons serving as the driver were presumed to be the positive hybridizations, and the converse was presumed to be the reverse hybridizations. The tester DNA with J adaptor at its ends was mixed with the driver DNA at a ratio of 1:40. The DNA mixture was purified by phenol extraction and ethanol precipitation, dissolved in 4 µL of 3 × EE buffer (3 mmol/L EDTA/3 mmol/L N-[2-hydroxyethyl] piperazine-N'-[3-propansulfonic acid], pH 8.0), denatured at 96°C for 10 min, and reannealed

Table 1 Adaptors and sequences in MS-RDA

SHpa II <sub>11</sub>	5'-CGG TGT CGG AAT-3'

MS-RDA: Methylation-sensitive representational difference analysis.

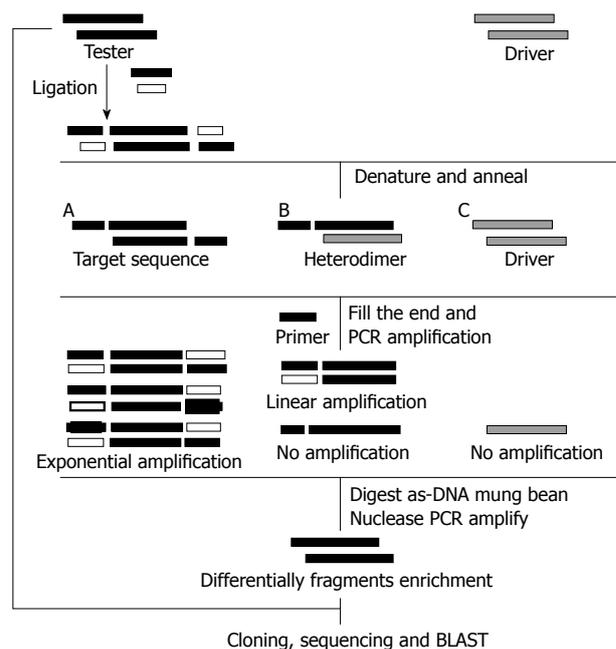

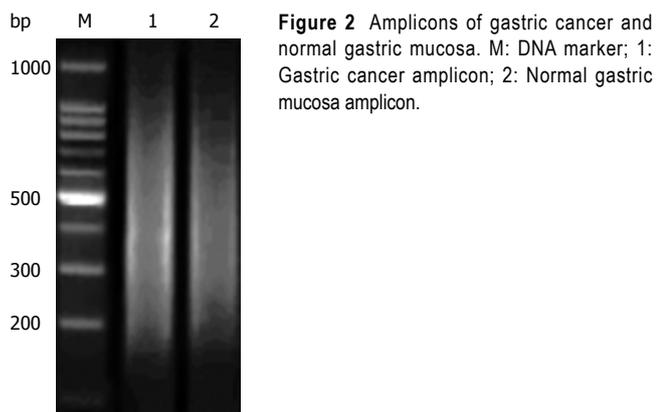

Figure 1 Schematic diagram of MS-RDA experimental strategy.

at 67°C for 24 h. One-tenth of the reannealed product was amplified by PCR with JHpa<sub>24</sub> oligonucleotide as the primer for 13 cycles. Tester/tester and tester/driver double-stranded DNA fragments had J adaptors on either both ends or only one end, respectively, and could be amplified exponentially or linearly. DNA fragments linearly amplified, existing as single-stranded DNA, were digested with mung-bean nuclease (Takara Co., Japan), and the remaining double-stranded DNA was again amplified by PCR for 26 cycles with JHpa<sub>24</sub><sup>[14]</sup>.

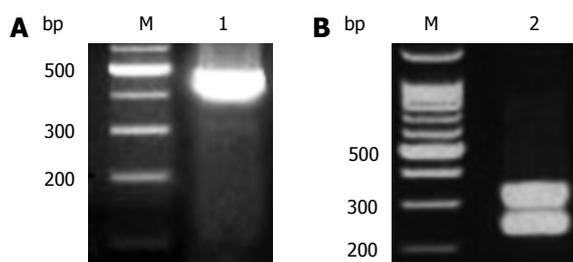

For the second and third cycles of subtractive hybridization to a new adaptor (N/S adaptor for the second cycle; J for the third cycle) (Table 1), the ratio of the tester DNA to the driver DNA was 1:400 and 1:4000, respectively<sup>[18]</sup>, and the differentially methylated sequence between gastric cancer and normal gastric mucosa could be obtained. The experiment fluidogram is displayed in Figure 1.

### Cloning, sequencing and BLAST

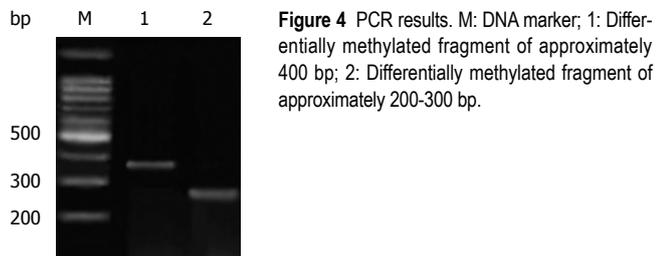

After the final subtractive hybridization, products were electrophoresed through 1.0% agarose gel, and the target bands were recovered with an agarose gel recovery kit

**Figure 2** Amplicons of gastric cancer and normal gastric mucosa. M: DNA marker; 1: Gastric cancer amplicon; 2: Normal gastric mucosa amplicon.

**Figure 3** **A:** Results after the third cycle of competitive hybridization. **B:** After a second cycle of competitive hybridization. M: DNA marker; 1: differentially methylated fragment of approximately 400 bp; 2: Two differentially methylated fragments, one is approximately 400 bp and the other lies between 200-300 bp.

**Figure 4** PCR results. M: DNA marker; 1: Differentially methylated fragment of approximately 400 bp; 2: Differentially methylated fragment of approximately 200-300 bp.

(Takara Co., Japan). The target fragments were subsequently cloned into a pGEM-T vector (Promega Co., USA). Plasmid DNA was transformed into *E. coli* strain JM109. Bacteria were incubated in LB medium for 1 h at 37°C, then plated onto agar plates containing ampicillin (100 µg/mL), X-gal (20 µg/cm<sup>2</sup>) and IPTG (12.1 µg/cm<sup>2</sup>) and incubated for 14 h at 37°C. Positive (white) colonies were picked out and identified by PCR. The primer was the JHpa24 oligonucleotide. After the positive colonies were sequenced, nucleic acid sequence homology searches were performed using the BLAST server at the National Center for Biotechnology Information.

## RESULTS

### **Amplicons of gastric cancer and normal gastric mucosa**

The digestion products of gastric cancer and normal gastric mucosa genomic DNAs were ligated with the RHPa II adaptor using PCR, and the amplicons were enriched (Figure 2). As shown in the figure, amplicons appeared as bright smears between 200-1000 bp.

### **Differentially methylated DNA fragments**

After three cycles of the positive hybridizations, a differentially methylated fragment of about 400 bp could be seen (Figure 3A). After two cycles of the reverse hybridizations, two differentially methylated fragments could be obtained (Figure 3B), one at approximately 400 bp and the other located between 200-300 bp.

### **Cloning, sequencing and BLAST**

Three differentially methylated DNA fragments were cloned into pGEM-T, and the positive colonies were identified by PCR (Figure 4) and sequenced (Figure 5). The differentially methylated DNA fragment from the positive hybridizations was problematic because of its complex secondary structure. Two differentially methylated DNA fragments from the reverse hybridizations were accepted by GenBank. The accession numbers were AY887106 and AY887107, respectively. The two differentially methylated DNA fragments were: AY887106: CCGGCGCCTAGCAGCCGACTTANAACGTG-TGCGGACCAGGGGAATCCGACTGTTAAT-TAAAACAAAGCATCGCGAAGGCCCGCGGC-GGGTGTGACGCGATGTGATTTCTGCCAGT-GCTCTGGATGTCAAAGTGAAGAAATTCAAT-GAAGCGCGGGTAAACGGCGGGAGTAACCAT-GACTCTCTTAAGGTAGCCAAATGCCTCGTCATC-TAATTAGTGACGCGCATGAATGGATGAACGAGATTCCCCTGTCCCTACCTACTATCCAGCGAAAC-CACAGCCAAGGGAACGGGCTTGCGGGAAT-CAGCGGGGAAAGAAGACCCTGTTGAGCTT-GACTCTAGTCTGGCACGGTGAAGAGACAT-GAGAGGTGTAGAATAAGTGGGAGGCTCCCGG; AY887107: ATACCAGCAGCTGGCGCAGGGGAAT-GCCGTGGGGGGCTCGGGCGGGGGCACCGC-CACTGGGGGCCGTGCAGGTGGTCACCGCCT-GCCTGCTGACCCTACTCGTCATCTGGACCTT-GCTGGGCAACGTGCTGGTGTCCGCAGCCATC-GTGTGGAGCCGCCACCTGC CGCCAAAGAT-GACCAACGTCTTCATCGTGTCTTACCTGTGT-CAGACCTCTTCGTGGCGCTGCTGGTCATGTCTT-GGAAGGCAGTCGCCGAGGTGGCCGG.

BLAST indicated that AY887107 was highly similar to the 11th exon of gene LOC440683 located on chromosome 1q21.1, while the 3' end of gene LOC440887 located on chromosome 2p11.1 included the promoter and 1st exon region of gene DRD5 located on chromosome 4p16.1, respectively. Their similarity rates were 98%, 99% and 94% respectively. AY887106 located on ribosomal RNA was linked with a CpG island isolated from colorectal cancer by Toyota *et al*<sup>191</sup>. The characteristics of differentially methylated DNA fragments are shown in Table 2.

## DISCUSSION

Given the role of aberrant DNA methylation in cancer initiation and progression, a distinct effort has been put towards the development of strategies that could facilitate early cancer detection. It is clear that aberrant DNA methylation is an early event in tumor development, as indicated by reports where aberrantly hypermethylated sites could be detected in seemingly normal epithelia from

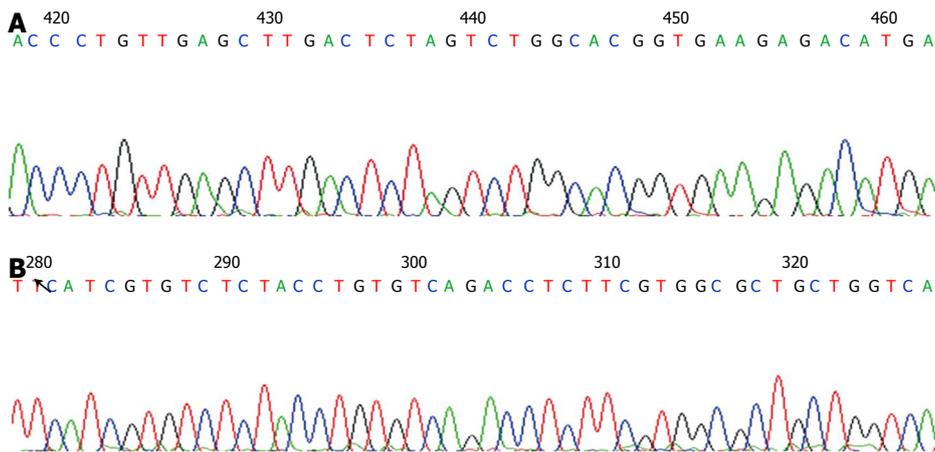

Figure 5 AY887106 (A) and AY887107 (B) sequencing.

Table 2 Characteristics of differentially methylated DNA fragments by MS-RDA

Accession number	Screening time	Size (bp)	GC (%)	CG/ GC	Similarity			
					Location	S	E	Similarity rate (%)
AY887106	2	395	50.6	0.9286	8q13.3	745	0	98
AY887107	2	264	66.3	0.7000	2p11.1	521	e-145	99
					1q21.1	498	e-138	98
					4p16.1	435	e-119	94

patients, years before the overt development of cancer<sup>[20]</sup>. Thus, utilizing DNA methylation as a biomarker might prove to be a useful tool not only for early diagnosis but also for the detection and assessment of high-risk individuals<sup>[21-23]</sup>. This strategy is reported to be successful in various bodily fluids, biopsy materials, lymph nodes obtained at surgery, and serum.

Although Southern Blotting and Restriction Landmark Genomic Scanning have been used for detection of abnormal DNA methylation, it is limited to the detection of known genes and is a complicated and difficult procedure<sup>[24]</sup>. Lisitsyn *et al*<sup>[17]</sup> established a representational difference analysis (RDA) based upon subtractive hybridization in 1993. For this, two genomic DNAs were digested with sensitive restriction enzyme in order to reduce the structural complexity of genomic DNA. After several cycles of subtractive hybridizations and PCR, the target fragments differentially isolated from two genome specimens were obtained. Subsequently, Ushijima *et al*<sup>[14]</sup> developed MS-RDA technology and successfully isolated the differentially methylated genomic fragments in mouse liver tumor. MS-RDA uses the methylation-sensitive four-base recognition restriction enzyme HpaII to digest two genomic DNAs in order to reduce the methylation site complexity of the DNA. The digestion product was ligated to the RHPa II<sup>24/11</sup> adaptor, and PCR was used to effectively amplify the shorter fragments, while longer fragment amplification was difficult by PCR. Accordingly, the difference between “driver” and “tester” can be transformed to the distinction of different digestion sites<sup>[17]</sup>. After several cycles of subtractive hybridizations and PCR, the differentially methylated fragments form homopolymers and are amplified exponentially, while the

identical sequences between “driver” and “tester” form heterodimers and are amplified linearly. Thus, the identical sequences will be eliminated, while the target fragments, existing in the “tester” but lacking in the “driver”, have been amplified effectively. As for the specificity of MS-RDA, it was shown that the contrast between “tester” and “driver” is not a difference in digestion fragment size but rather a difference in the methylation status of two genomes. MS-RDA is an effective method for identifying the silenced genes in various cancers and marker genes linked with diseases.

In this study, MS-RDA was performed using a mixture of DNAs from mucosa of three gastric adenocarcinomas serving as the tester and adjacent normal mucosa serving as the driver. This strategy might have neglected infrequent methylations that occurred in only one gastric adenocarcinoma or that were induced by individual differences. Our data indicate that gene LOC440887 and LOC440683 were highly homologous to the sequences AY887107. Using GenBank, we found that gene LOC440887 and gene LOC440683 are novel genes that are seldom studied. LOC440887 is probably linked to the etiology of myeloid/lymphoid or mixed-lineage leukemia and closely related to the MLL3 gene, which is located on chromosome region 7q36 and encodes a protein homologous to ALR (acute lymphoblastic leukemia-1 related). A previous study by Tan *et al*<sup>[25]</sup> demonstrated that MLL3 does map to 7q36, a chromosome region that is frequently deleted in myeloid leukemia and may be involved in leukemogenesis. Ruault *et al*<sup>[26]</sup> found partial duplications of the MLL3 gene in the juxtacentromeric region of chromosomes 1, 2, 13, and 21. The LOC440887 gene may be a duplicated region containing a fragment of the MLL3 gene on chromosome 2. Digital Northern analysis was applied to the MLL3 gene using the NCBI Web Station. The outcome indicated that the human stomach tissue could express the MLL3 gene and that there were expression differences between the gastric cancer and the normal stomach tissue. We are currently investigating the relative differences in expression level between the tissue samples. Moreover, BLAST indicated that AY887107 was highly similar to the promoter and 1st exon region of gene DRD5 located on chromosome 4p16.1, with a similarity rate of 94%. The DRD5 gene encodes the D5

subtype of the dopamine receptor. The D5 subtype is a G-protein coupled receptor which stimulates adenylyl cyclase. In both gastric and duodenal mucosa, Mezey *et al.*<sup>[27]</sup> demonstrated the presence of significant amounts of the D5 receptor that could serve as a target for locally produced dopamine. Dopamine is a protective agent in the gastrointestinal (GI) tract in both rats and humans. The relationship between DRD5 gene methylation and gastric cancer still needs further studies. The sequence AY887106, which maps to ribosome RNA, has 98% homology to a differentially methylated CpG island genomic sequence obtained from human colon carcinomas by Toyota *et al.*<sup>[19]</sup>. Our research also suggested that this location is likely to be methylated in gastrointestinal carcinomas. In view of the above-mentioned analysis, we will carry out a relative study of three differentially methylated DNA fragments so that novel genes related to gastric cancer can be obtained and new targets can be offered for gastric cancer research.

Various methylation-based strategies, including MS-RDA, restriction landmark genome scanning<sup>[24,28]</sup>, arbitrarily primed PCR<sup>[29]</sup>, and CpG island microarray<sup>[30]</sup>, have been developed and proven to be useful for identifying hypermethylated sequences. MS-RDA was previously established to detect differences in the methylation status of two genomes. As for the specificity of MS-RDA, it was shown that DNA fragments, that are unmethylated in the tester and almost completely methylated in the driver, are efficiently isolated. This indicated that genes that are in a biallelic methylation state or in monoallelic methylation with loss of the other allele are efficiently isolated<sup>[31]</sup>. Takai *et al.*<sup>[32]</sup> first reported the silencing of HTR1B and reduced expression of EDN1 in human lung cancers using MS-RDA. Subsequently, Miyamoto *et al.*<sup>[33]</sup> found methylation-associated silencing of heparan sulfate D-glucosaminyl 3-O-sulfotransferase-2 (3-OST-2) in human breast, colon, lung, and pancreatic cancers. Then in 2004, Hagihara *et al.*<sup>[34]</sup> documented that MS-RDA was used for isolation of 111 DNA fragments derived from CpG islands (CGIs), and 35 of them were from CGIs in the 5' regions of known genes in human pancreatic cancers. MS-RDA is effective in identifying silenced genes in various cancers<sup>[35]</sup>. MS-RDA also has some disadvantages such as complexity of the procedure, requiring high homology between the "tester and driver", inefficiency with amplicons less than 1 kb. In a word, MS-RDA is a promising method for the study of DNA methylation in gastric cancer. It may also be used for isolating novel tumor suppression genes.

## COMMENTS

### Background

Epigenetic inactivation of tumor suppressor genes (TSG) is frequently associated with tumor pathogenesis. The purpose of this study was to isolate the differentially methylated DNA sequences between gastric cancer and normal gastric mucosa.

### Research frontiers

Genome-wide screening for CGIs differentially methylated between gastric cancer and normal gastric mucosa.

### Innovations and breakthroughs

Because analysis of methylation of known genes has limitations, genome-wide screening for CGIs methylated in gastric cancer is needed. In this study,

methylation-sensitive representational difference analysis (MS-RDA), an advanced biotechnique, was used to detect the methylation status of gastric cancer and normal gastric mucosa.

### Applications

This study found that methylation status is different between gastric cancers and normal gastric mucosa. It elucidated the role of methylation in carcinogenesis, and moreover, new targets were offered for gastric cancer research.

### Terminology

Methylation is a term used in chemical sciences to denote the attachment or substitution of a methyl group on various substrates. DNA methylation profiling is gaining momentum as an epigenetic approach to understanding the effects of aberrant methylation (either hyper- or hypomethylation) both in basic research and in clinical applications.

### Peer review

The manuscript by Liao *et al* describes a method to screen differences in methylation status of DNA between gastric cancer samples and normal gastric mucosa. The authors found 3 DNA regions that have changed methylation status between the normal and neoplastic tissue. The data presented is novel and interesting.

### Abstract

**AIM:** To investigate whether the iron stores regulator hepcidin is implicated in colon cancer-associated anaemia and whether it might have a role in colorectal carcinogenesis.

**METHODS:** Mass spectrometry (MALDI-TOF MS and SELDI-TOF MS) was employed to measure hepcidin in urine collected from 56 patients with colorectal cancer. Quantitative Real Time RT-PCR was utilized to determine hepcidin mRNA expression in colorectal cancer tissue. Hepcidin cellular localization was determined using immunohistochemistry.

**RESULTS:** We demonstrate that whilst urinary hepcidin expression was not correlated with anaemia it was positively associated with increasing T-stage of colorectal cancer ( $P < 0.05$ ). Furthermore, we report that hepcidin mRNA is expressed in 34% of colorectal cancer tissue specimens and was correlated with ferroportin repression. This was supported by hepcidin immunoreactivity in colorectal cancer tissue.

**CONCLUSION:** We demonstrate that systemic hepcidin expression is unlikely to be the cause of the systemic anaemia associated with colorectal cancer. However, we demonstrate for the first time that hepcidin is expressed by colorectal cancer tissue and that this may represent a novel oncogenic signalling mechanism.

Increased hepcidin expression in colorectal carcinogenesis. *World J Gastroenterol* 2008; 14(9): 1339-1345 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1339.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1339>

### INTRODUCTION

Anaemia is a common presenting symptom of colorectal cancer, a recent study showing that up to 6% of patients presenting with iron deficiency anaemia (IDA) had colorectal cancer<sup>[1]</sup>. IDA is commoner in patients with right sided than left sided colorectal cancers<sup>[2]</sup>. The reason for this is assumed to be because of the chronic occult blood loss associated with cancers in the right colon compared to overt bleeding of left sided colonic disease which is detected sooner.

What remains unclear is whether a component of the anaemia might be a consequence of the inflammation associated with the neoplastic process. The major pro-inflammatory cytokine implicated in the pathogenesis of anaemia of chronic inflammation is interleukin 6 (IL-6). Recent work has shown that the induction of hepcidin release stimulated by IL-6 is crucial to this process<sup>[3-5]</sup>. Precisely how hepcidin mediates anaemia of chronic disease has been comprehensively investigated by several groups and it is now well established that hepcidin acts to cause a block on cellular iron export by internalization and degradation of ferroportin<sup>[6,7]</sup>. At the level of the macrophage, the major cell type responsible for iron recycling, this results in iron sequestration and interrupts iron delivery to erythroid precursor cells thus causing anaemia<sup>[8]</sup>. Increased hepcidin levels are likely to also cause an accumulation of iron in other ferroportin expressing cell lineages such as colonocytes. Our recent studies have shown that raising colonocyte iron levels can result in increased Wnt signalling which has been shown to be crucial in colorectal carcinogenesis<sup>[9,10]</sup>.

However, to date there are no studies addressing whether hepcidin expression contributes to the anaemia in colorectal cancer and whether hepcidin itself may be considered a pro-oncogenic factor.

There are several strands of evidence to suggest that this hypothesis may be relevant: firstly, the major inducer of hepcidin, IL-6, shows increased expression in both colorectal cancer tissue and in the serum of colorectal cancer patients and is indicative of a more advanced phenotype<sup>[11-13]</sup>. Secondly, consistent with a hepcidin-colonocyte axis, we have reported that ferroportin is cytoplasmic in cellular localization and expression levels are repressed with increasing stage of colorectal cancer<sup>[14]</sup>.

This raises the possibility that hepcidin may have a dual effect in colorectal cancer patients; contributing to the systemic anaemia by acting at the level of the macrophage whilst acting locally at the colonocyte level promoting iron accumulation and Wnt signalling.

Thus the aims of this study were: (1) To measure urinary hepcidin levels by Matrix-assisted laser desorption/ionization time of flight mass spectroscopy (MALDI-TOF MS) and Surface-enhanced laser desorption ionization time of flight (SELDI-TOF MS) in colorectal cancer patients and determine if hepcidin expression was associated either with anaemia or with disease state including T-stage, and nodal involvement; (2) To examine if hepcidin mRNA expression could also be detected in colorectal cancer tissue and, if so, determine cellular localization.

## MATERIALS AND METHODS

### Sample collection

Urine was collected from 56 patients with colorectal cancer prior to surgery, centrifuged at 3000 r/min for 20 min and stored at -80°C. In a separate set of colorectal cancer patients ( $n = 34$ ) surgical resection specimens of colorectal carcinoma matched with normal colonic mucosa from the same resection specimen were collected and processed for RNA extraction.

### Ethics

This work has been carried out in accordance with the declaration of Helsinki (2000) of the World Medical Association. Ethical approval for this study was approved by South Birmingham LREC No. 05/Q2702/17. All patients provided informed written consent.

### Urine hepcidin measurements

SELDI-TOF-MS was performed as previously described<sup>[15]</sup>. Briefly, urine samples were diluted to 10 µg protein/mL in 0.5 mol/L NaCl, 100 mmol/L sodium phosphate (pH 7.0) and applied to Cu<sup>2+</sup> loaded IMAC30 ProteinChip arrays. MALDI spectra were obtained either by applying diluted urine (20 µg protein/mL) or urine desalted using ClinProt C8 magnetic beads (BrukerDaltronic) to GoldChips. Spectra were acquired on a PBS II c ProteinChip Reader (CIPHERGEN) using sinapinic acid as the matrix. Spectra were normalized to total ion current (as previously described for urinary biomarker profiling<sup>[16,17]</sup>), baselines subtracted and peaks picked using CIPHERGEN ProteinChip software. Synthetic hepcidin-25 (Peptides International) was employed for peak/assay validation. Immunocapture was performed as previously described<sup>[15,19]</sup>. Briefly Protein G sepharose beads loaded with or without rabbit polyclonal anti-hepcidin-25

(Abcam 31877) were incubated with human urine containing hepcidin 20, 22 and 25. The beads were washed extensively with 20 mmol/L ammonium bicarbonate and the captured proteins eluted with 50% acetonitrile/0.1% trifluoroacetic acid and analysed by MALDI.

### Real time RT-PCR

Real Time RT-PCR was performed on colorectal cancer tissue specimens (C) and matched uninvolved normal colonic mucosa (N) with all reactions containing 18S ribosomal RNA as an internal standard (PE Biosystems, Roche, USA), and human specific hepcidin probe and primers (Probe 5'-FAM 3' TAMRA AGCTGCAACCCCAGG, Forward primer CCCACAACAGACGGGACAA and Reverse primer TCTGGAACATGGGCATCC) as previously described<sup>[18]</sup>.

### Immunohistochemistry

Immunohistochemistry was performed using paraffin sections of human normal colon ( $n = 10$ ) and colorectal cancer ( $n = 15$ ). All sections were incubated at 95-100°C in WCAP reagent (Surgipath) for 30 min, washed and then incubated in 10:1 Methanol: H<sub>2</sub>O<sub>2</sub> for 10 min. Sections were then incubated in rabbit polyclonal hepcidin antibody (Abcam 31877; 1:20) for 1hr after which immunoreactivity detected with an Envision assay kit and DAB reagent (DakoCytomation). All sections were counterstained in haematoxylin and mounted prior to visualisation. Normal liver sections were utilized as a positive control. Negative control included omission of primary antibody and liver sections incubated with antibody which had prior incubation with the immunizing peptide (Abcam 31875).

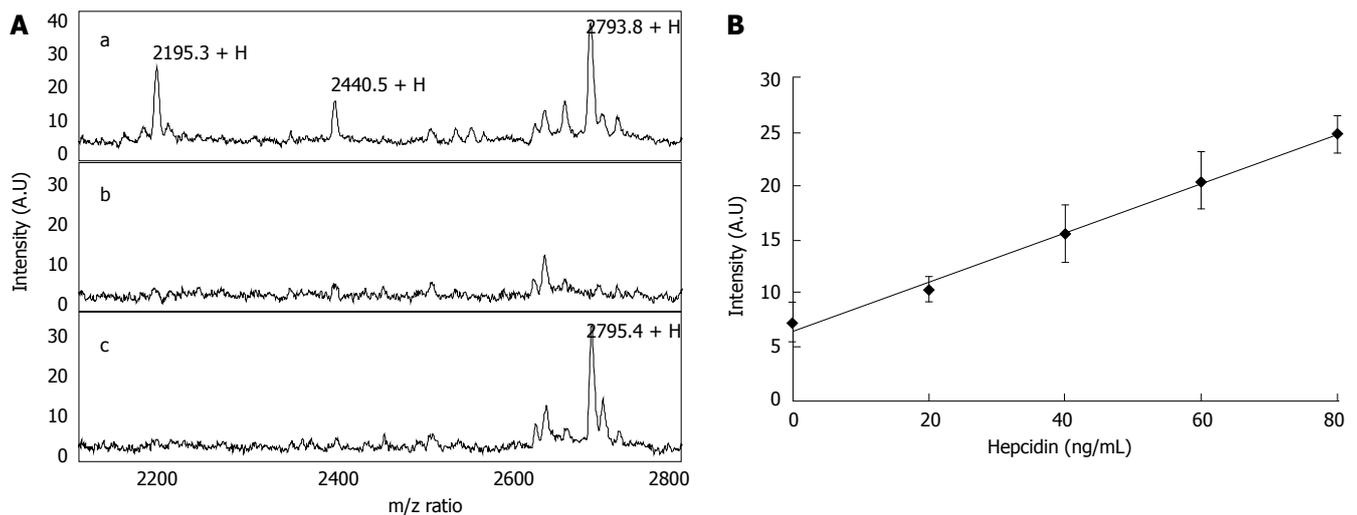

### Statistical analysis

Statistical significance was calculated using the Mann-Whitney test to compare continuous data and the Spearman rank test to assess correlations between data sets. Significance was accepted at  $P \leq 0.05$ . All analyses were performed using SPSS version 14.0 (SPSS Inc, USA). Data are presented with 2 standard errors of the mean.

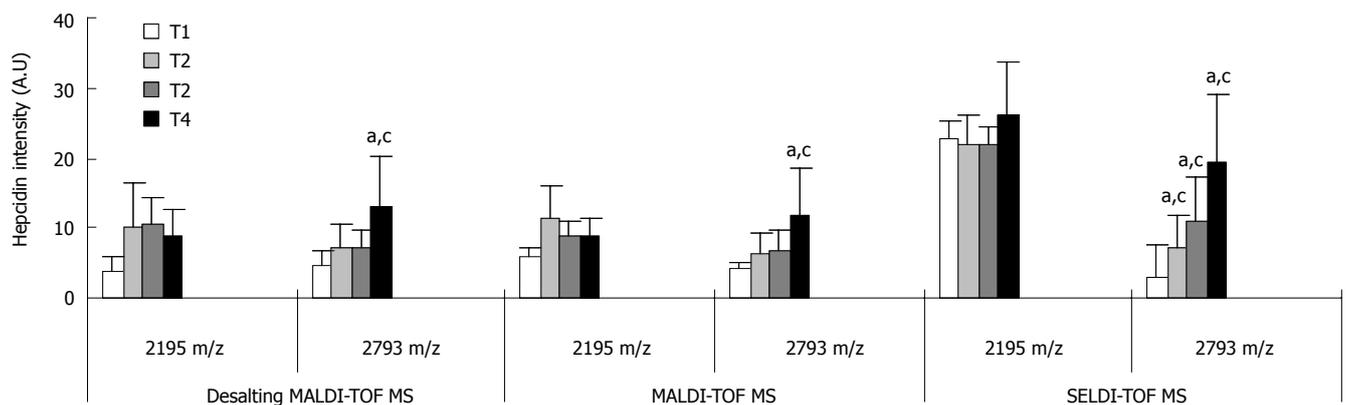

## RESULTS

### Validation of MALDI-TOF MS for the detection of urinary hepcidin

Using a pre determined hepcidin positive urine sample we performed MALDI-TOF MS and were able to detect the two major forms of hepcidin; the mature hepcidin 25 ( $m/z$  2793.8), and the N-terminally truncated hepcidin 20 ( $m/z$  2195.3). In addition we were also able to detect hepcidin 22 ( $m/z$  2440.5) which corresponds to a urinary degradation product of hepcidin 25 (Figure 1Aa). Using a human urine sample devoid of hepcidin (Figure 1Ab) we were able to demonstrate the appearance of a hepcidin 25 peak on spiking with a synthetic human hepcidin peptide (Figure 1Ac). To determine if MALDI-TOF MS could be used in a semi-quantitative manner as has previously been reported for SELDI-TOF MS we spiked a urine sample with low endogenous hepcidin and demonstrated a linear relationship between hepcidin concentration and intensity of the hepcidin 25 peak (Figure 1B).

**Figure 1** Validation of hepcidin expression in urine by MALDI-TOF MS. **A:** (a) A human urine specimen showing the two dominant forms of hepcidin; hepcidin 20 (m/z 2195.3) and hepcidin 25 (m/z 2793.8). In addition the degradation product of hepcidin 25 hepcidin 22 could also be detected by MALDI-TOF MS (m/z 2440.5); (b) A human urine specimen completely devoid of hepcidin which when spiked with synthetic hepcidin 25 clearly shows a detectable peak at 2795.4 (c); **B:** Synthetic hepcidin was spiked into a low hepcidin containing urine sample at concentrations between 0-80 ng/mL and analysed by MALDI-TOF MS followed by analysis of the hepcidin 25 peak intensity.

**Figure 2** Hepcidin expression is associated with T-stage of colorectal cancer. Expression of hepcidin 20 (m/z 2195) and 25 (m/z 2793) was determined in urine samples of 56 colorectal cancer patients by MALDI-TOF MS, before and after desalting with desalting beads (Desalting MALDI-TOF MS), and SELDI-TOF MS and analysed with respect to T-stage. Expression of hepcidin 20 was not altered with T-stage by any of the three techniques. However, all three techniques demonstrated a significant increase in hepcidin 25 expression in T4 cancers compared to T1. Statistical significance compared to T1 ( $^*P < 0.05$ ); Statistical significance compared to preceding T-stage ( $^{\#}P < 0.05$ ). Error bars denote 2 SEM.

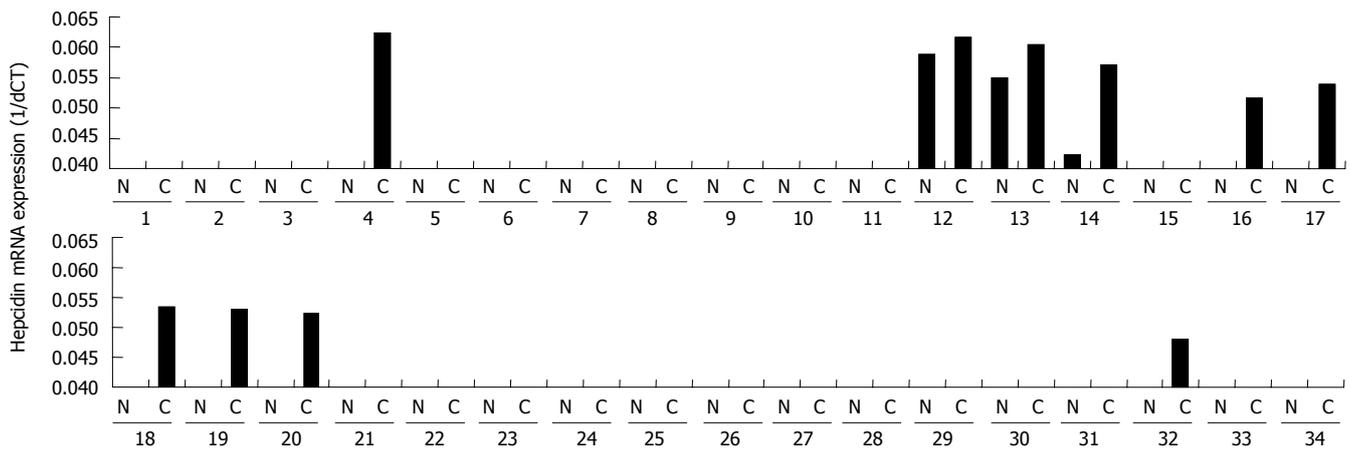

### Analysis of urinary hepcidin levels in colorectal cancer patients

To determine hepcidin levels in urine samples from colorectal cancer patients ( $n = 56$ ) we performed SELDI-TOF MS and MALDI-TOF MS (Figure 2). In addition, as the presence of salt can interfere with mass spectrometry, we desalted the urine samples and once more performed MALDI-TOF MS. Since hepcidin 22 is a urine specific degradation product of hepcidin<sup>[19]</sup> we chose to analyse only the expression level of hepcidin 20 and 25. Using a Spearman Rank test we were able to demonstrate a correlation between all three data sets (MALDI-TOF MS *vs* SELDI-TOF MS, correlation coefficient = 0.59  $P < 0.0001$ , Desalting MALDI-TOF MS *vs* MALDI-TOF MS, correlation coefficient = 0.56  $P < 0.0001$ , Desalting MALDI-TOF MS *vs* SELDI-TOF MS, correlation coefficient = 0.71  $P < 0.0001$ ).

Data was analysed with respect to the site of cancer

(left or right sided), TNM classification, and the presence or absence of anaemia where anaemia was classified as haemoglobin level of less than 13 g/dL for men and 12 g/dL for women. Of the 56 cancers examined, 63% were left sided cancers of which 40% were anaemic, whereas of the right sided cancers 77% were anaemic<sup>[22]</sup>. Our data analyses using all data sets individually (Desalting MALDI-TOF MS, MALDI-TOF MS, and SELDI-TOF MS) for both hepcidin 20 and 25 showed that neither forms of hepcidin were significantly altered in expression in respect to the site of cancer, local nodal involvement, metastasis or haemoglobin level.

However, when examining the relationship between hepcidin and T-stage of disease, whilst hepcidin 20 was not correlated with T-stage, hepcidin 25 significantly increased with increasing stage. All three mass spectrometry techniques demonstrated a significant increase in hepcidin 25 in T4 cancers compared to T1. Moreover, SELDI-TOF

**Figure 3** Hepcidin mRNA expression in colorectal cancer tissue. Using Real Time RT-PCR on 34 cancer specimens (C) each with adjacent normal uninvolved mucosa (N) we demonstrate that hepcidin mRNA expression could be detected in 34% of colorectal cancer tissue specimens (10 out of 34). mRNA expression is presented as 1/dCT. Positive control included human liver. Negative control included omission of cDNA.

MS data delineated a significant stepwise increase between T2 and T1 (7.28 vs 2.77  $P < 0.05$ ), T3 and T2 (11.07 vs 7.28  $P < 0.05$ ), and T4 and T3 (19.17 vs 11.07  $P < 0.05$ ).

#### **Determination of hepcidin expression and localization in colorectal cancer tissue**

The observation that hepcidin is associated with advanced disease led us to speculate that it may have an effect at the level of the colonocyte and that hepcidin may even be expressed by colorectal cancer tissue. Thus we examined hepcidin mRNA expression in 34 cancer specimens (C) each with adjacent normal uninvolved mucosa (N) (Figure 3). Our data shows that hepcidin mRNA was detected in 34% of colorectal cancer tissue specimens (10 out of 34) and, whilst there was no hepcidin mRNA detectable in the majority of matched adjacent uninvolved mucosa, where there was hepcidin mRNA, it was found at a lower level than in the associated cancer. Furthermore we find that hepcidin mRNA expression is inversely correlated with ferroportin mRNA expression (data not shown).

To further verify expression and determine the cellular localization of hepcidin we performed immunohistochemistry. As a positive control for hepcidin expression we utilized human liver. As anticipated we were able to show strong immunoreactivity in all hepatocytes (Figure 4Aa), and this immunoreactivity could be blocked by co-incubation with hepcidin peptide (Figure 4Ab). In normal colon, both on the luminal surface and in the crypts, we were unable to detect any hepcidin immunoreactivity (Figure 4Ac-Ad). However, in approximately 46% (7 out of 15) of colorectal cancer specimens examined there was an abundance of both membranous (Figure 4Ae-Af) and cytoplasmic immunoreactivity (Figure 4Ag-Ah).

To determine what form of hepcidin was being detected by our antibody and thus expressed in colorectal cancer tissue, we performed an immuno-capture experiment on human urine followed by MALDI-TOF MS (Figure 4B). We initially chose a urine sample which had clear and abundant hepcidin 20, 22 and 25 peaks (Figure 4Ba), and incubated with either protein G sepharose or with protein G-sepharose and the polyclonal anti

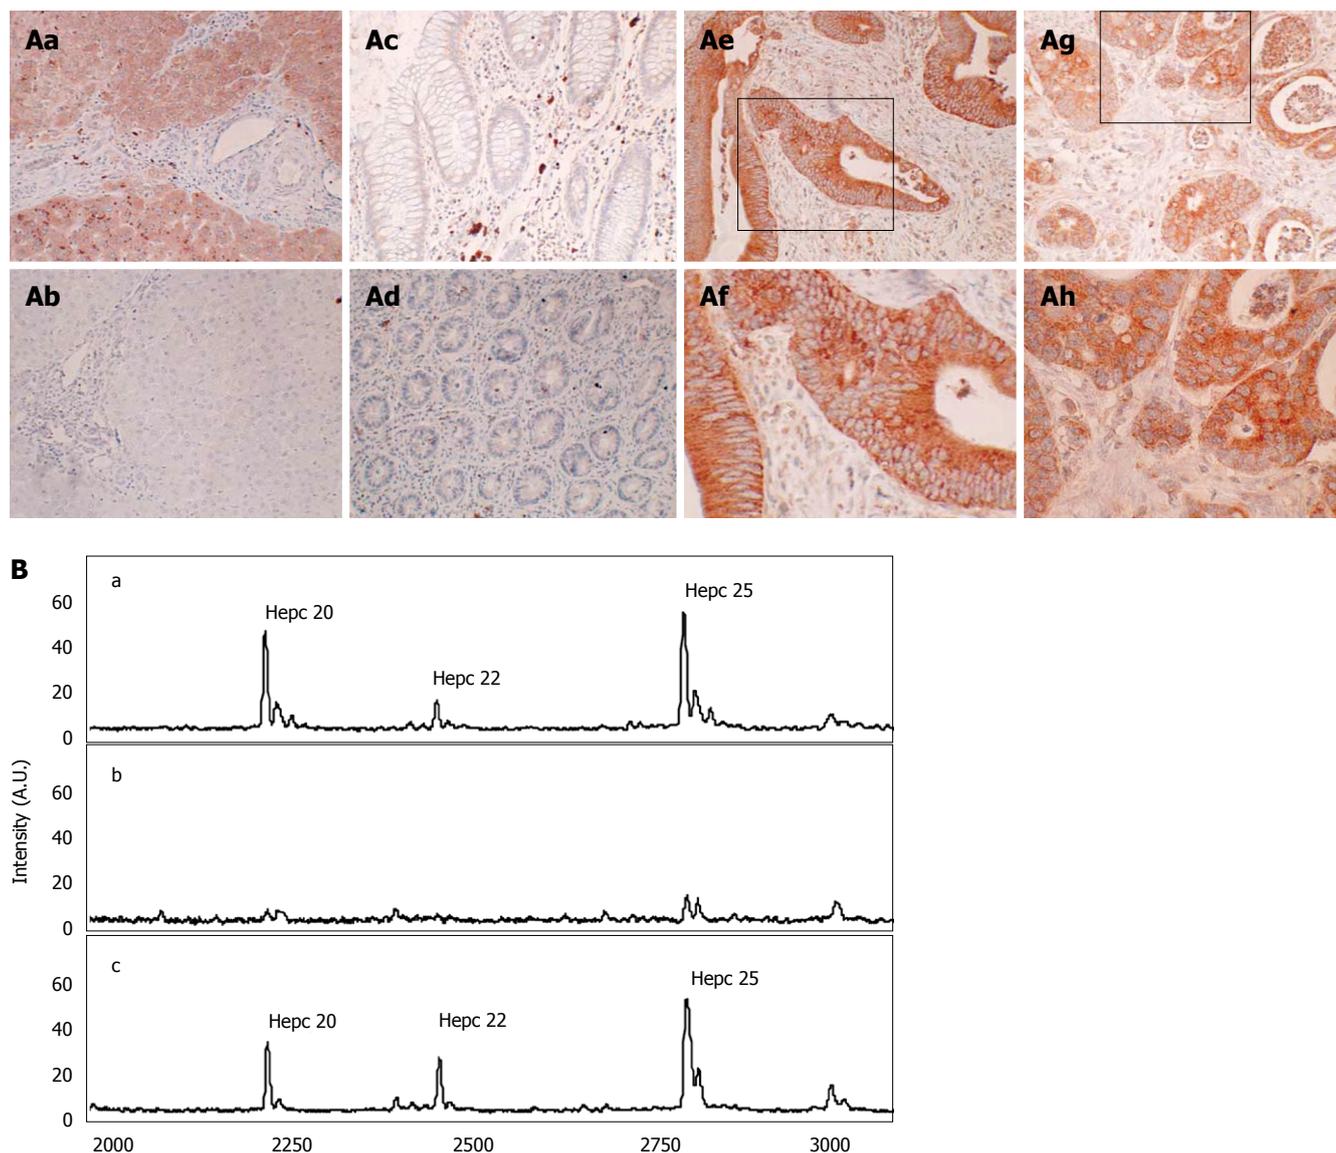

hepcidin antibody. Immunocaptured proteins were then eluted from the protein G sepharose and analysed by MALDI-TOF MS. We clearly demonstrated that incubation with the rabbit hepcidin antibody results in binding of all three forms of hepcidin (Figure 4Bc), whilst incubation with protein G sepharose alone did not bind any form of hepcidin (Figure 4Bb). Thus from this data we infer that the immunoreactivity in colorectal cancer tissue could be due to any of these hepcidin moieties.

## **DISCUSSION**

Anaemia is a common presenting symptom of colorectal cancer, and it is widely assumed to be a consequence of blood loss<sup>[1,2]</sup>. However, it is possible that a component of this anaemia may be a result of inflammatory processes. In particular the anti-microbial peptide hepcidin a downstream target of cytokines such as IL-6 has been widely accepted as a mediator of anaemia of inflammation<sup>[3-5]</sup>. Thus in this study we aimed to address whether hepcidin was involved in the anaemia associated with colorectal carcinogenesis.

We demonstrated using SELDI-TOF MS; a previously validated method for the detection of urinary hepcidin<sup>[19-21]</sup>, and MALDI-TOF MS; a more common proteomic technique, that urinary hepcidin 25 expression was not associated with the presence of anaemia in a small cohort of 56 colorectal cancer patients. However, it is important to point out that the only parameter which was utilized to assess anaemia was a haemoglobin level of less than 13 g/dL for men and 12 g/dL for women. Thus it is quite possible that some of these anaemic individuals may actually have anaemia of chronic disease rather than pure iron deficiency anaemia. To unequivocally discriminate between these two types of anaemia it would be essential to assess both the level serum ferritin and soluble transferrin receptor levels.

However, our result is consistent with previous reports which suggest that the phenotype of the systemic anaemia associated with colorectal cancer is more likely to be an iron deficiency rather than anaemia of chronic disease and

**Figure 4** Cellular localization of hepcidin in colorectal cancer tissue. **A:** To determine hepcidin cellular localization in colorectal tissue immunohistochemistry was performed with a hepcidin specific antibody (Abcam 31877). (Ba) A human urine sample containing hepcidin 20 (m/z 2193.6), 22 (m/z 2438.2) and 25 (m/z 2792.0) was subject to immunocapture with either (Bb) protein G sepharose or with (Bc) protein G-sepharose and a polyclonal anti hepcidin antibody. Immunocaptured proteins were then eluted from the protein G sepharose and analysed by MALDI-TOF MS.

that early detection of blood loss due to colon cancer is life saving<sup>[23]</sup>.

Interestingly using both MALDI-TOF MS and SELDI-TOF MS we showed that urinary hepcidin 25 expression was associated with stage of disease. This association was not observed for the N-terminally truncated hepcidin 20 moiety. This observation led us to speculate that it may have an effect at the level of the colonocyte and that hepcidin may even be expressed by colorectal cancer tissue. Such a hypothesis is strengthened by evidence that the major inducer of hepcidin, IL-6, is over expressed in colorectal cancer tissue and its expression is positively associated with stage of disease<sup>[11-13]</sup>. Moreover, we have recently reported both ferroportin internalization and iron loading in colorectal cancer tissue: both predicted effects of hepcidin<sup>[14]</sup>. Thus consistent with such a hypothesis we were

able to demonstrate for the first time that approximately a third of all colorectal cancer tissues examined expressed hepcidin mRNA.

What the signal for hepcidin induction is in these colorectal cancers is unclear. The two original reports describing murine hepcidin suggested that there was either very low or no hepcidin expressed in the colon consistent with our findings<sup>[24,25]</sup>. However, more recently it has been suggested that as a consequence of an acute phase response the colon does have the potential to induce hepcidin expression<sup>[26]</sup> and furthermore several of the upstream regulators of hepcidin including IL-6, STAT3, Tfr2 and BMP4 have been shown to be over expressed in colorectal cancer tissue<sup>[11-13,27-29]</sup>. In addition a recent report suggests that hepcidin expression is dependent on p53 status, a tumour suppressor which is commonly mutated in colorectal cancers<sup>[30]</sup>.

Irrespective of the mechanism of hepcidin expression the downstream consequences are likely to be internalization and degradation of the cellular iron export protein ferroportin. In the background of an elevation in the cellular iron import proteins such as transferrin receptor 1 and Divalent metal transporter 1, this culminates in cellular iron accumulation; a phenotype which we have previously reported in colorectal cancer<sup>[14]</sup>. Furthermore, we have recently demonstrated that elevating intracellular iron in the presence of mutations in either adenomatous polyposis coli (APC) or  $\beta$ -catenin results in increased Wnt signalling; the major oncogenic signalling pathway in the colon<sup>[9,10]</sup>. Thus hepcidin expression at the level of the tumour may be a mechanism of ultimately accentuating carcinogenesis and that abrogating hepcidin expression either directly or indirectly through IL-6 may provide a strategy for therapeutic intervention.

## COMMENTS

### Background

Anaemia is a common presenting symptom of colorectal cancer, though whether the anaemia is a consequence of blood loss is not known. Recent studies have suggested that anaemia in the context of chronic disease is mediated by the antimicrobial peptide hepcidin.

### Research frontiers

To date there have been no studies addressing whether hepcidin could be the cause of the anaemia associated with colorectal cancer. Similarly, whether colorectal cancer tissue itself can express hepcidin is unknown.

### Innovations and breakthroughs

This is the first study to show that systemic hepcidin levels were positively associated with stage of colorectal cancer. Furthermore, this study suggests that colonic epithelial cancer cells have acquired the ability to express hepcidin; a protein which was previously thought to be largely expressed by the liver.

### Applications

What still remains unclear is whether the circulating level of hepcidin is derived from the liver or whether it has come from the colorectal tumour tissue itself. Irrespective of this, this study suggests that circulating hepcidin levels may provide a useful tool for aiding in the diagnosis of colorectal cancer.

### Terminology

Hepcidin is an antimicrobial peptide which regulates iron metabolism. In instances of high hepcidin it depresses duodenal iron absorption and sequesters iron in the reticulo-endothelial system culminating in anaemia. This type of anaemia is classified as the anaemia of chronic disease and not iron deficiency anaemia which can result from extensive blood loss, compromised duodenal iron absorption and/or low dietary iron intake.

### Peer review

This is the first study to associate hepcidin expression with carcinogenesis.

### Abstract

**AIM:** To investigate the hepatitis B virus (HBV) x gene (HBx) state in the tissues of HBV-related hepatocellular carcinoma (HCC) in Chinese patients and whether there were particular HBx mutations.

**METHODS:** HBx gene was amplified and direct sequencing was used in genomic DNA samples from 20 HCC and corresponding non-cancerous liver tissues from HBsAg-positive patients. HBV DNA integration and HBx deleted mutation were validated in 45 HCC patients at different stages by Southern blot analysis and polymerase chain reaction methods.

**RESULTS:** The frequencies of HBx point mutations were significantly lower in HCC than their corresponding non-cancerous liver tissues (11/19 vs 18/19,  $P = 0.019$ ). In contrast, deletions in HBx gene were significantly higher in HCC than their non-cancerous liver tissues (16/19 vs 4/19,  $P < 0.001$ ). The deletion of HBx COOH-terminal was detected in 14 HCC tissues. A specific integration of HBx at 17p13 locus was also found in 8 of 16 HCC, and all of them also exhibited full-length HBx deletions. Integrated or integrated coexistence with replicated pattern was obtained in 45.5% (20/45) - 56.8% (25/45) tumors and 40.9% (18/45) - 52.3% (23/45) non-tumor tissues.

**CONCLUSION:** HBx deletion, especially the COOH-terminal deletion of HBx is a frequent event in HBV-

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common cancers worldwide and a leading cause of death in many countries, mainly in Asia and Africa. The most prominent factors associated with HCC include chronic hepatitis B and C viral infection, chronic alcohol consumption, aflatoxin-B1-contaminated food and virtually all cirrhosis-inducing conditions<sup>[1,2]</sup>. The hepatitis B virus (HBV) genomic DNA contains four partially overlapping open reading frames: preC/C, P, preS/S and X gene<sup>[3-5]</sup>. The X gene product, HBV X protein (HBxAg) is a trans-activating protein, and a multifunctional regulator that modulates transcription, signal transduction, cell cycle progress, protein degradation pathways, apoptosis, and genetic stability by directly or indirectly interacting with host factors<sup>[6,7]</sup>. Transgenic mice created with the X gene have been reported to develop HCC<sup>[8-10]</sup>. Although the transactivation properties of the X gene and HBxAg overexpressed selectively in human HCC<sup>[11,12]</sup>, its precise role in human hepatocarcinogenesis is still unclear<sup>[1,2]</sup>. In some studies, X gene containing substantial but different deletions in the COOH-terminal region was found in many HBV-infected HCC patients<sup>[13-16]</sup>. To further explore the relationship between nucleotide changes in HBx and the development of HCC, we examined the mutants and

nucleotide sequence of the HBx gene obtained from the tissues of HBV-related HCC in Chinese patients.

## MATERIALS AND METHODS

### *Tissue samples*

Twenty HCCs and corresponding noncancerous liver tissues were obtained from surgically resected samples at Changhai Hospital between August 2003 to October 2004. Patients had not received any treatment before. This study included 18 men and 2 women. Their ages ranged from 31 to 69 years (median 50 years). All patients were positive for serum hepatitis B surface antigen (HBsAg). The median tumor size was 5.5 cm (2.0-12.5 cm). Histopathological diagnosis was made according to the World Health Organization histological classification of tumors of the liver and intrahepatic bile ducts<sup>[17]</sup>. Three HCC were well differentiated, 14 were moderately differentiated, and 3 were poorly differentiated. Of the 20 patients, 6 had evidence of intrahepatic metastasis (portal vein invasion and/or intrahepatic dissemination). Sixteen HCC cases were accompanied with liver cirrhosis and the remaining 4 cases were with chronic hepatitis.

### *Polymerase chain reaction and sequence analysis of HBX*

Genomic DNA was extracted from 20 frozen HCC tissues and corresponding non-cancerous liver tissues using the standard phenol/chloroform extraction and ethanol precipitation method. To amplify the integrated HBx sequences from tissues, we used an HBx-Alu PCR-based approach<sup>[18]</sup>. The sequences of the primers were as follows: 5'-TGCCAAGTGTGTTGCTGACGC-3' (HBV 1176-1195, AY220699), 5'-AAGGAAAGAAGTCAG AAGG-3' (HBV 1960-1978)<sup>[7]</sup>. The fragment size is 803 bp. After denaturation at 94°C for 2 min, 36 cycles of DNA amplification were performed at 94°C for 30 s, at 53°C for 60 s, and at 72°C for 60 s; with a final extension at 72°C for 10 min and stored at 4°C. PCR results were identified by electrophoresis on a 1% agarose gel stained with ethidium bromide.

HBx gene sequence was directly determined by automated DNA sequencing (ABI PRISM<sup>TM</sup> 3730 DNA Sequencer) after purified on silica columns (QIAquick PCR purification kit, Qiagen, Courtaboeuf, France). At least two independent DNA extractions and PCR reactions were performed for each sample, and four sequencing reactions (two for each strand) were carried out to confirm that the reported sequence reflected the most prevalent HBx in a specific sample. The plasmid pHBXB1 containing the full length of the HBV X gene cloned in the pcDNA3 vector, was used as a positive control.

### *Detection of HBV DNA integration and HBx deleted mutation*

To evaluate HBV DNA integration and HBx deleted mutation in HCC tissues, genomic Southern blot analysis and PCR were performed on carcinoma tissues and the corresponding non-cancerous liver tissues from a set of independent samples in 45 HCC patients at different stages from Northwest of China, a relative low-aflatoxins

exposure area. No patient had received treatment before. Serum hepatitis B surface antigen (HBsAg) was positive in all patients. The non-tumor tissues exhibited cirrhosis in 43 patients.

### *HBV DNA integration by genomic Southern blot analysis*

Genomic DNA was extracted from frozen HCC tissues and corresponding non-cancerous liver tissues using the standard phenol/chloroform extraction and ethanol precipitation method. Each sample of extracted genomic DNA (8 µg) was subjected to restriction by EcoRI and Hind III, separated on agarose gel and blotted onto nylon membrane (Zetabind, Life Sci., Ltd.). Southern blot analysis was carried out using 32P dCTP DNA Labeling and Detection Kit (Amersham Life Sci., Ltd., England) with the 32P dCTP-labeled HBV, HBc, HBx coding region and Pre-S as probes (Dupont).

### *Polymerase chain reaction*

HBc, HBc and HBx genes were amplified from HCC genomic DNA by polymerase chain reaction (PCR). The sequences of those primers were HBc: P1 (1903-1929), 5'-ATGGACATCGACCCTTATAAAGAATTTG-3', P2 (2434-2411): 5'-CTAAGATTGAGATCTTCTGAGAC GCGG-3'; HBc and HBx: P2 (2434-2411): 5'-CTAAGA TTGAGATCTTCTGAGACGCGG-3'; P3 (1227-1243): 5'-AGCGCATGCGTGGAAACC-3'. The fragment sizes are 531 bp and 1207 bp, respectively. All PCRs were performed using a Thermal Cycler 9600 (Perkin Elmer, CA) under the following conditions: after denaturation at 94°C for 2 min, 38 cycles of DNA amplification was performed at 94°C for 60 s, at 55°C for 60 s, and at 72°C for 120 s; with a final extension at 72°C for 10 min and stored at 4°C. PCR results were analyzed by electrophoresis on a 1% agarose gel stained with ethidium bromide. To assess the specificity of our results, Southern blot analysis was carried out as described above.

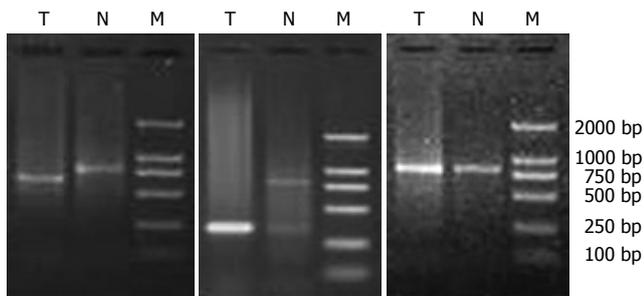

### *Statistical analysis*

All statistical analyses were carried out using the SPSS.11 software. Comparisons between two characteristics were made using Chi-square test or Fisher's exact test.  $P < 0.05$  was considered statistically significant in a two-tail analysis.

## RESULTS

### *HBx gene sequencing in HBsAg-positive HCC tissues*

To confirm the HBx deletion mutation, HBx gene was amplified and direct sequencing was made in 20 HBsAg-positive HCC genomic DNA. The fragment sizes of PCR products ranged from 150 bp to 800 bp (Figure 1). The results of sequencing were compared with the known sequences in the GenBank database using the BLAST programs (Figure 2). The frequencies of HBx point mutations were significantly lower in HCC than in the corresponding non-cancerous liver tissues (11/19 vs 18/19,  $P = 0.019$ ). In 19 available non-tumorous livers, sequencing results revealed 47 different point mutation patterns, including 30 mis-sense mutations, 15 sense mutations and 2 non-sense mutations. The loci with the highest frequency

**Figure 1** PCR amplified products of HBx-DNA. The fragment sizes of PCR products range from 150 bp to 800 bp. M: Marker; T: Tumor; N: Non-tumor.

of mutation were 67aa (8/19, all were gga→ggt sense mutations, Figure 3A) and 127aa (6/19, four were att→act missense mutations, Figure 3B, 1 was atc→att sense mutations, and 1 was direct linked-point HBV -nt1899 leading to deletions of amino acid at the HBx COOH-terminal end).

In contrast, the frequencies of HBx deletion mutation in HCC were significantly higher than the corresponding non-cancerous liver tissues (16/19 *vs* 4/19,  $P < 0.001$ ). Among them, eight exhibited full-length HBx deletions, the other 8 were deletions with size ranging from 4aa to 150aa. The deletion of HBx COOH-terminal end was also detected in 6 of the latter (Figure 4). The COOH-terminal deletion of HBx was exhibited in 14 HCC samples, which is a major feature of HBx identified in tumor tissues.

In addition, a specific integration of HBx at GA-rich region of 17p13 locus (repeat region 56047..56210/rpt\_family = "GA-rich") was also found in 8 of 16 HCC (Figure 5, Table 1). All of these also exhibited full-length HBx deletions. And the specific integration of HBx was more frequent in HCC than in the corresponding non-cancerous liver tissues (8/16 *vs* 1/16,  $P = 0.015$ ). Finally, the translocation occurring between chromosomes 17 and 14 was obtained from HCC tissues from the no. 2 patient. We considered that a mispriming of the HBV primer may have occurred, so we rechecked the primer sequences and found no significant similarities in chromosome 17 using BLAST. The HBx gene was amplified and direct sequencing was duplicated in all samples, and identical results were obtained. A mispriming of HBV primer in the chromosome 17 was eliminated.

### Genomic integrated HBV DNA in HCC tissues

To investigate whether the detected HBV DNA was integrated into the genome of the HCC tissues, genomic DNA was extracted and restricted by EcoRI or Hind III prior to Southern blot analysis. Results revealed that the bands of variable sizes were hybridized with the 32P-labeled HBV, HBc, HBx and Pre-S probe. These include the three band patterns: approximately more than 3.2 kb of integrated pattern, replicated pattern of less than 3.2 kb and mixed pattern (integrated coexistence with replicated) (Figure 6A). In 44 of 45 pair samples, the hybridized bands of HBV full gene and fragments were obtained in 45.5%-56.8% tumors and 40.9%-52.3% non-

cancerous tissues, respectively (Table 2). Hybridized bands of HBx and HBc revealed deletion at least in some cases compared to HBV full-length gene probe. None of HBV full gene and fragments showed single replicated pattern in HCC, indicating that HBx integration had taken place in partial HCC tissues.

### Deleted mutation of HBc and HBx in HCC

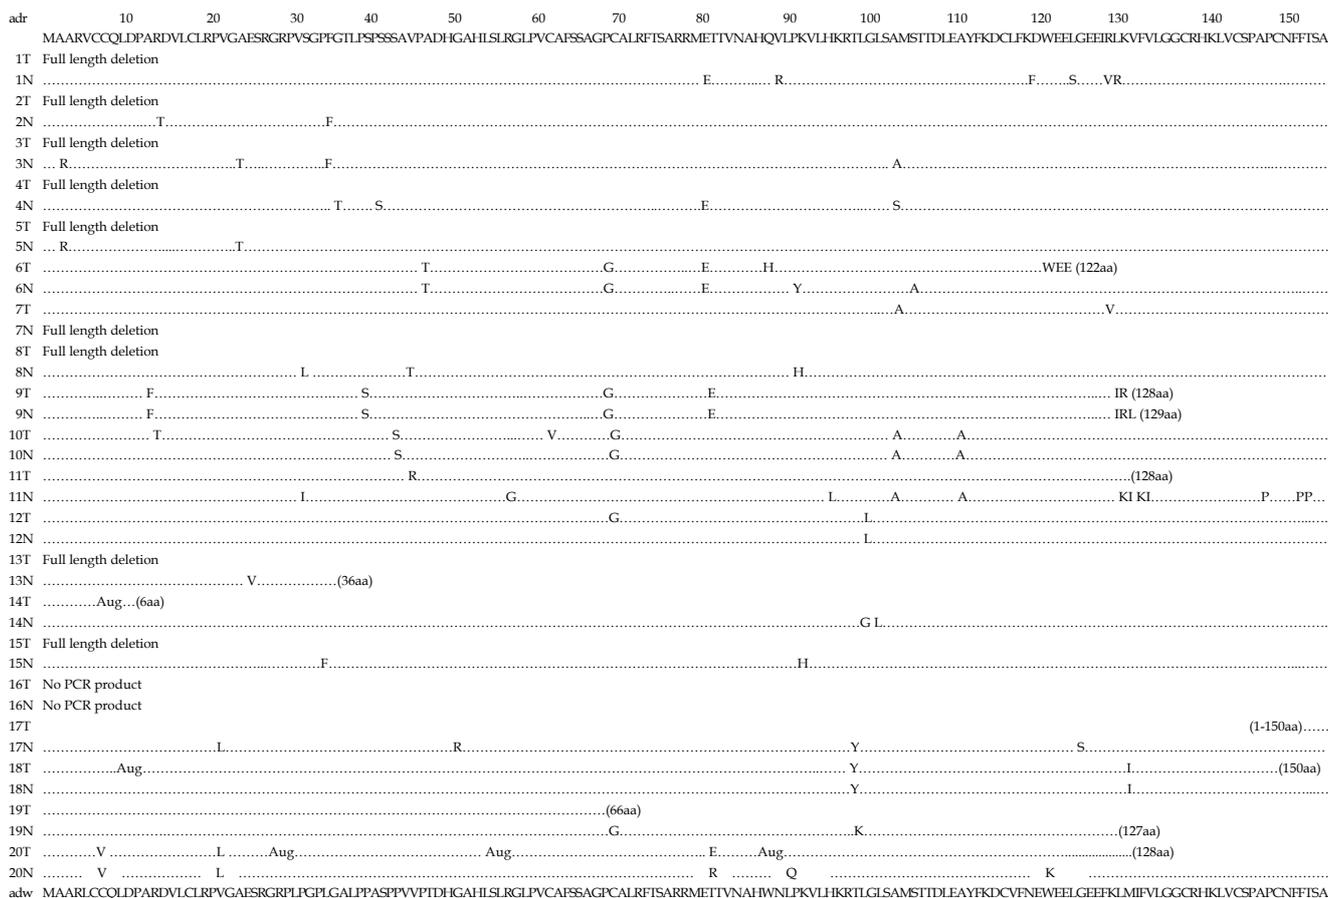

To further confirm that the hybridized bands contained deleted mutation HBx, PCR amplification was carried out using specific primers on DNA extracted from genomic DNA in 45 HCC and their corresponding non-cancerous liver tissues. The fragment sizes include two patterns: approximately 531bp of wild type and less than 531 bp of mutant type in HBc, and approximately 1207 bp of wild type and less than 1207 bp of mutant type in HBc + HBx, respectively (Figure 6B). As shown in Table 3, deleted mutation of HBx was more frequent in HCC than that of HBc. The amplified products were consistent with the genomic Southern blot analysis.

## DISCUSSION

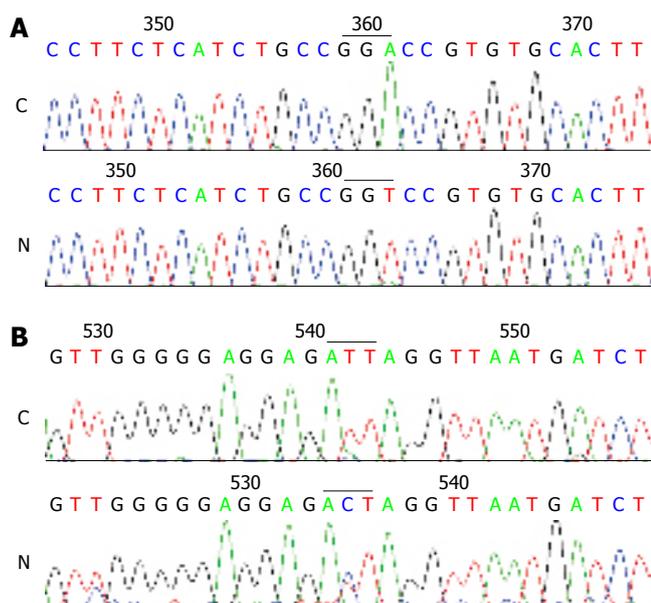

HBV infection is a major factor contributing to the development of HCC in China and the mutation in HBx plays an important role in this process<sup>[2,19-22]</sup>. However, analysis of HBx sequence in tumor tissues of HCC patients from mainland China has not been done<sup>[14,16,22,23]</sup>. A previous study of sera from 67 HCC patients from Taiwan indicates that 52% of samples contain HBx mutations<sup>[23]</sup>. Our present study showed that the frequency of the HBx gene mutation in either tumor tissues or the corresponding non-cancerous liver tissue samples of HCC is very high, 57.9% and 94.7%, respectively. The most frequent spots of mutation identified are 67aa (8/20) and 127aa (6/20). The hot spots reported by other groups are nt. 382-389 (codons 128-130) in HCC samples collected from Qidong, China<sup>[14]</sup>, nt. 204 and 260-264 (codons 68 and 87-88) in HCC samples from Hong Kong<sup>[16]</sup> and nt. 93 (codon 31) in HCC samples from Taiwan<sup>[23]</sup>. These suggested that the HBx may have its own distinguished patterns of mutation in different geographic regions. As was reported by Chen GG *et al*, the biological consequence may be the same in all these regions<sup>[16]</sup>.

The most important finding of this study was the identification of HBx deletion mutation in our samples. HBx deletion was detected in 16 HCC samples, and 14 exhibited the COOH-terminal deletion of HBx in HCC tissues. A COOH-terminal deletion in the HBx gene was found in 5 of 9<sup>[24]</sup> and 5/6 HCCs<sup>[15]</sup>. There may be three regions of the X gene essential for the transactivation function of the X protein (at codons 46-52, 61-69 and 132-139)<sup>[14,25]</sup>. All of these results suggest that HBx mutants with a COOH-terminal deletion were significantly correlated with the development and progression of HCC.

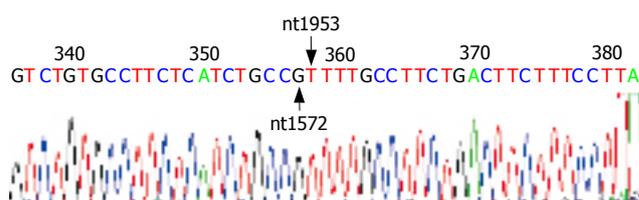

Although the mechanism involved in pathogenesis of HBx mutants with a COOH-terminal deletion remains largely unknown, some studies showed that HBx deleted mutants isolated from tumor tissues abrogated both

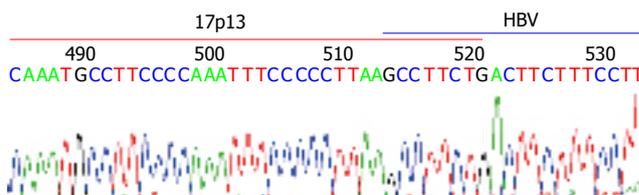

**Figure 2** HBx sequencing in cancer and non-cancerous tissues from 20 HBV-associated HCC patients. The amino acid sequences of HBV adr and adw subtypes are shown at the top or the bottom. Identical amino acid residues are represented by dots. The underlined amino acids were deduced from cellular flanking sequences. The frequencies of HBx point mutations were significantly lower in HCC than in the corresponding non-cancerous liver tissues (11/19 vs 18/19,  $P = 0.019$ ). T: Tumor; N: Non-tumor. the transactivation and antiproliferative effects of wild type HBx<sup>[24]</sup>. When HBx deleted mutant plasmids were transfected to murine and human cell lines, a strongly increased colony formation, accelerated cell cycle progression, and synergetically promoted ras and myc transforming capacity were confirmed<sup>[7,24,26]</sup>. Therefore, a COOH-terminal deletion may alter the balance of HBx functional domains in regulating cell proliferation and apoptosis, viability, and transformation. In addition, as previously reported<sup>[15,27]</sup>, we also noted the coexistence within the same tumor cells of full-length and COOH-terminally deleted HBx sequences, encoded by free or integrated HBV genome sequences. Although we do not exclude the coexistence within the same tumor cells of full-length and COOH-terminally deleted HBx sequences encoded by free or integrated HBV genome, we are investigating the biological implication of the COOH-terminally truncated HBx sequences.

Integration of HBV DNA was found in HCC at

**Figure 6 A:** Detection of integrated HBx fragments in HCC tissues by Southern blot analysis; **B:** HBc and HBx fragment amplified by PCR. M: Marker; T: Tumor; N: Non-tumor.

GA-rich region of 17p13 locus in our study. We have eliminated the mispriming of HBV primer, and identified a specific integration of HBV DNA. This region includes the p53 gene, which is bound to and inactivated by HBxAg prior to tumor formation and then lost during tumor progression<sup>[19]</sup>. This region also encodes microRNAs-22, -132, -195, -212<sup>[19]</sup>; ubiquitin-conjugating enzyme E2G 1 and ubiquitin specific protease<sup>[28]</sup>. We have also noted that most of the samples contained COOH-terminally deleted mutants of the HBx, and the specific integration of HBx was more frequent in HCC than in the corresponding non-cancerous liver tissues, and HBV integration including HBx, occurred in partial HCC tissues by Southern blot. These changes, to the best of our knowledge, have not been described elsewhere. Almost all of the HBV-associated HCCs harbor chromosomally integrated HBV DNA sequences, including chromosome 17p12-13<sup>[4,19,29,30]</sup>. HBV integration can induce deletions in the host chromosome at the integration site<sup>[19]</sup>. It was also recently confirmed that HBV insertion into cellular genes is a frequent event and that integration can occur in genes regulating cellular signal transduction cascades, proliferation control and cell viability<sup>[7,19]</sup>. Thus, the putative HBV-specific integration sites, the biological impacts and the process with functional genomics of HBV associated HCCs need further studies.

In conclusion, HBx deletion, especially the COOH-terminal deletion of HBx, is a frequent event in HBV-associated HCC tissues. HBV integration including HBx, occurred in partial HCC tissues. This supports the hypothesis that the deletion and probably integrated forms of the HBx gene may be implicated in liver carcinogenesis.

## COMMENTS

### Background

The hepatitis B virus (HBV) x protein (HBx) plays a critical role in the molecular pathogenesis of hepatocellular carcinoma (HCC). However, the mechanism remains largely unknown.

### Research frontiers

HBx gene containing substantial but different deletions in the COOH-terminal region was found in many HBV-infected HCC patients from Qidong, Hong Kong and Taiwan, China.

### Innovations and breakthroughs

The frequencies of HBx point mutations were significantly lower in HCC than their corresponding non-cancerous liver tissues. HBx deletion, especially the COOH-terminal deletion of HBx is a frequent event in HBV-associated HCC tissues in China. Integrated or integrated coexistence with replicated pattern were obtained in HCC and non-cancerous tissues.

### Applications

Deletion and probably integrated forms of the HBx gene may be implicated in liver carcinogenesis.

### Peer review

This study showed that HBx deletion, especially the COOH-terminal deletion of HBx is a frequent event in HBV-associated HCC tissues in China. This study confirmed their existence of HBx COOH-terminal deletion in human HCC, and provided some new information to clarify the mechanism in hepatocarcinogenesis.

Received: July 5, 2007 Revised: December 3, 2007

### Abstract

**AIM:** To study the expression of tumor necrosis factor-alpha converting enzyme (TACE) and evaluate its significance in liver regeneration after partial hepatectomy *in vivo*.

**METHODS:** Male SD rats underwent 70% partial hepatectomy. The remaining liver and spleen tissue samples were collected at indicated time points after hepatectomy. TACE expression was investigated by Western blotting, immunohistochemistry, and serial section immunostaining.

**RESULTS:** Expression of TACE in liver and spleen tissues after partial hepatectomy was a time-dependent alteration, reaching a maximal level between 24 and 48 h and remaining elevated for more than 168 h. TACE protein was localized to mononuclear cells (MNC), which infiltrated the liver from the spleen after hepatectomy. The kinetics of TACE expression was in accordance with the number of TACE-staining MNCs and synchronized with those of transforming growth factor- $\alpha$  (TGF $\alpha$ ). In addition, TACE-staining MNC partially overlapped with CD3<sup>+</sup> T lymphocytes.

**CONCLUSION:** TACE may be involved in liver regeneration by pathway mediated with TGF $\alpha$ -EGFR in the cell-cycle progressive phase *in vivo*. TACE production and effect by paracrine may be a pathway of involvement in liver regeneration for the activated CD3<sup>+</sup> T lymphocytes.

Expression of tumor necrosis factor-alpha converting enzyme in liver regeneration after partial hepatectomy. *World J Gastroenterol* 2008; 14(9): 1353-1357 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1353.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1353>

### INTRODUCTION

Tumor necrosis factor-alpha converting enzyme (TACE) is a kind of metalloprotease disintegrins, also known as ADAM17, which is a modular transmembrane protein with a zinc-dependent catalytic domain<sup>[1]</sup>. TACE was originally cloned and named for its ability to cleave and convert tumor necrosis factor- $\alpha$  (TNF $\alpha$ ) into a soluble form. Since then, TACE has been demonstrated to solubilize a variety of substrates including transforming growth factor- $\alpha$  (TGF $\alpha$ ), members of the membrane-bound epidermal growth factor (EGF) family ligands, both TNFR- I and TNFR- II, and macrophage/colony-stimulating factor receptor<sup>[2]</sup>. Liver regeneration after partial hepatectomy is very intricate. The process requires the activation of more than 100 genes and involves multiple cytokines and growth factors such as interleukin- I, hepatocyte growth factor (HGF), TNF $\alpha$ , TGF $\alpha$ , heparin-binding epidermal growth factor-like growth factor (HB-EGF) *etc*<sup>[3,4]</sup>. It has been well documented that TACE mRNA and TACE protein are enhanced in several human malignant diseases such as breast cancer, lung cancer, and liver cancer<sup>[5,6]</sup>. In a study of hepatocyte replication, Gretchen *et al* employed the AML-12 hepatocyte cell line and implicated the participation of TACE in hepatocyte replication by activating the TGF $\alpha$ -EGFR pathway<sup>[7]</sup>. Hence, it is speculated that TACE is involved in cell proliferation and carcinogenesis in addition to inflammation<sup>[8-10]</sup>. It was also reported that the activity of several metalloproteinases increased during liver regeneration<sup>[11]</sup>. However, to date, there has been few studies on the correlation of TACE with liver regeneration after partial hepatectomy *in vivo*. To gain further insight into the involvement of TACE in liver regeneration, we investigated the expression of TACE in both liver and spleen tissues with a rodent partial hepatectomy model.

### MATERIALS AND METHODS

#### Animals and study protocol

All animal experiments were performed following the

institution's criteria for the care and use of laboratory animals in Zhejiang University, China. Male SD rats (200–250 g) were fed standard rodent chow and water *ad libitum* in a temperature-controlled room. Rats were anesthetized with ether and underwent 70% partial hepatectomy according to the method of Higgins and Anderson. At indicated time points after hepatectomy, laparotomy was performed on the rats, and liver and spleen tissue samples were collected. A tissue sample was flash-frozen in liquid nitrogen for Western-blotting analysis, and the remainder was fixed in 4% formaldehyde and embedded in paraffin for immunohistochemical analysis. This study protocol was approved by the Ethics Committee of Zhejiang University, China.

### Immunohistochemical analysis

Four  $\mu\text{m}$ -thick paraffin sections of liver and spleen tissue samples were cut. After deparaffinization, the endogenous peroxidase activity was blocked by placing the slides in methanol containing 3% (w/v)  $\text{H}_2\text{O}_2$  for 30 min at room temperature. Normal goat serum was added and kept at room temperature for 15 min. The primary antibodies, rabbit anti-TACE polyclonal antibodies (1:100 dilution; CHEMICON) and mouse monoclonal anti-CD3 antibodies (1:200 dilution; Acris) were applied overnight at 4°C. After the slides were washed in phosphate buffered saline, the Envision + R system labelled polymer-HRP (Dako; Cytomation) was added and visualized using the DAB chromogen (Merck; Germany). Counterstaining of cell nuclei was accomplished with Mayer's hematoxylin (Sigma). Finally, sections were counterstained with hematoxylin, dehydrated, coverslipped, and evaluated microscopically. Positive-staining cells were counted for each visual field at 400  $\times$  magnification.

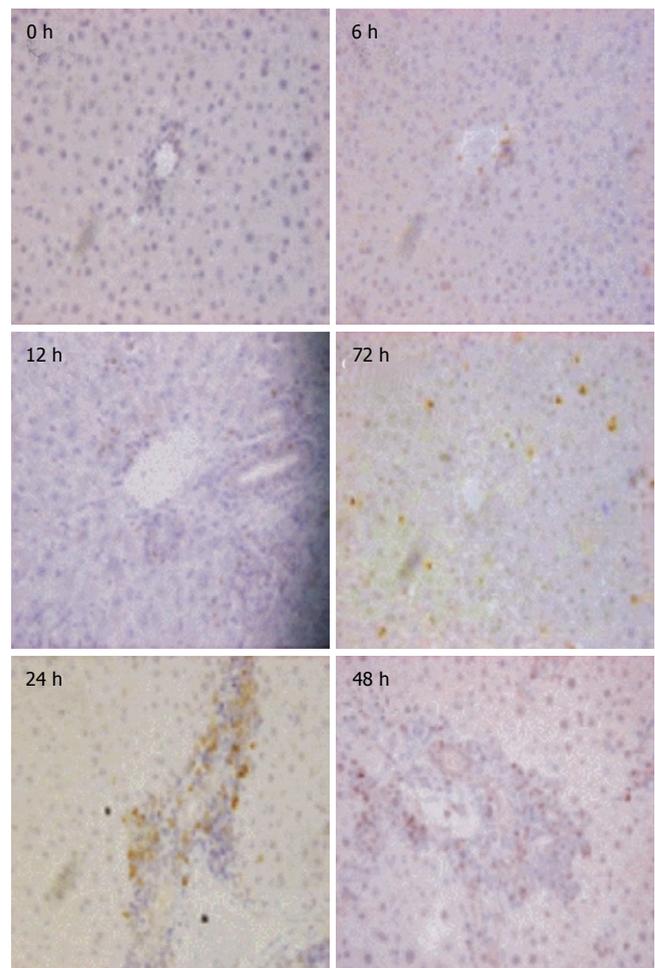

### Western blot analysis

For total protein extraction, samples of rat liver and spleen tissues were homogenized in NETN buffer supplemented with protease inhibitors and centrifuged at 15000 r/min for 60 min at 4°C. Homogenates containing 50  $\mu\text{g}$  of protein were loaded. The proteins were size-separated by electrophoresis on 7.5% polyacrylamide gels (Bio-Rad), and then transferred onto PVDF membranes (Bio-Rad). After blocking, membranes were incubated with a rabbit polyclonal antibody against rat TACE (1:1000 dilution; CHEMICON), and then with an alkaline phosphatase-conjugated anti-rabbit antibody (1:5000 dilution; Amersham). Immunoreactive proteins were detected with a fluorescence scanner (Storm, Pharmacia) using ECF substrate according to the manufacturer's instructions (Amersham). In control experiments, the membrane was incubated with a mouse monoclonal anti- $\beta$ -actin antibody (1:1000 dilution; Sigma) and with an alkaline phosphatase-conjugated anti-mouse antibody (1:5000 dilution; Amersham).

## RESULTS

### TACE expression localization and pattern in liver and spleen following partial hepatectomy

To investigate TACE protein localization and pattern, we examined liver tissue paraffin sections by immunohisto-

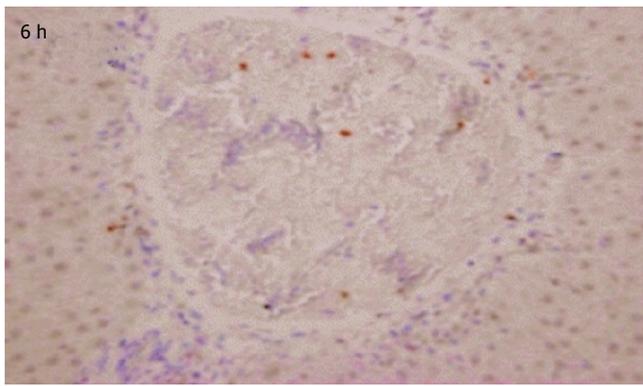

**Figure 1** Rat liver stained using anti-TACE antibodies at various time points after hepatectomy. None of the parenchymal cells was stained at any of the time points. MNC accumulated markedly at periportal sites from 24 to 48 h after hepatectomy while intense TACE staining was seen. MNC declined and distributed to the intermediate regions after 72 h ( $\times 400$ ).

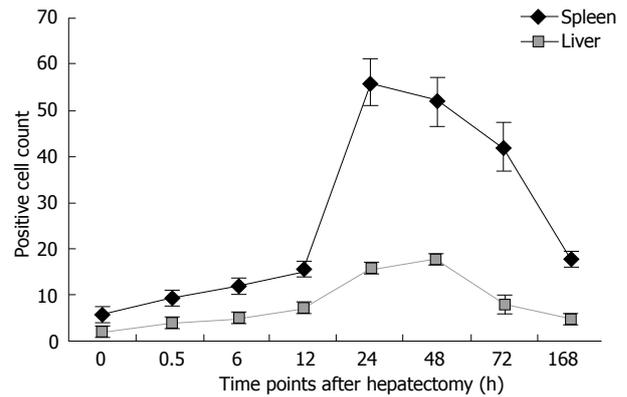

chemistry. Mononuclear cells (MNC) stained positively, but hepatocytes, biliary epithelia cells, and endothelial cells did not. There were few MNC in portal triads, and TACE staining could be hardly detected prior to hepatectomy; however, after hepatectomy, the TACE-staining MNC was observed to infiltrate to periportal sites. Marked accumulation of MNC was found at periportal sites from 24 to 48 h, while intense TACE-staining MNC was visible. The TACE-staining MNC became less abundant and distributed to the intermediate regions after 72 h (Figure 1). Because many TACE-staining MNCs were detected in the portal vein and it was speculated that the MNC mainly came from the spleen through portal vein current (Figure 2), we performed further immunohistochemical studies on spleen tissues. The kinetic feature of TACE-staining in spleen is analogous to that in liver, while the TACE-staining MNC reached the marginal zone and splenic sinus (Figure 3). The quantities of TACE-staining MNC at various time points in liver and spleen of 7 rats in each group were counted randomly under microscopy (Figure 4).

### TACE expression level in liver and spleen following partial hepatectomy

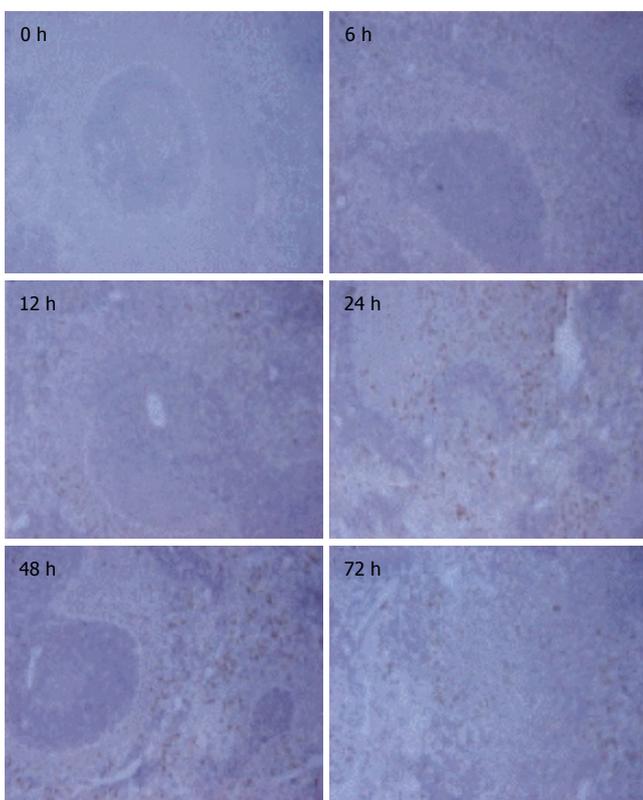

The TACE expression levels in liver and spleen tissues at

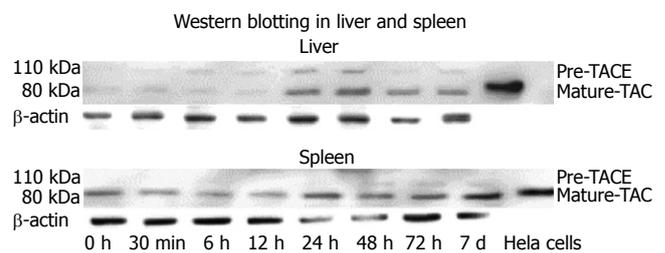

**Figure 2** The TACE stained MNC in portal vein current 6 h after hepatectomy. The MNC infiltrated to periportal sites through portal triad vein endothelial cells ( $\times 400$ ).

**Figure 4** TACE-positive MNC in liver and spleen at various time points after hepatectomy. Data are mean  $\pm$  SD,  $n = 7$  animals in each group.

**Figure 3** Immunostaining of TACE in rat spleen tissue at various time points. The TACE-stained MNC increased, reaching a peak at similar time points with liver. The positively stained MNC distributed at the marginal zone and splenic sinus. Numbers indicate the time points after hepatectomy ( $\times 400$ ).

**Figure 5** TACE protein level in rat liver and spleen following partial hepatectomy. Rat liver and spleen tissue samples taken at various time points were processed and subjected to Western blot analysis using anti-TACE antibodies. The HeLa cells were lysed and the proteins were loaded as a positive control. Expression of TACE in liver and spleen after hepatectomy is a time-dependent alteration, reaching a maximal level between 24 and 48 h.

various time points were evaluated by Western blotting. Because the antibody was directed against the cytoplasmic domain of the protein, both the precursor (pro-TACE) and the mature forms were detected. As shown in Figure 5, TACE expression in the liver and spleen after hepatectomy is a time-dependent alteration, reaching a maximal level between 24 h and 48 h. The TACE level declined from 72 h, but remained elevated for more than 168 h as compared with the pre-hepatectomy level in liver tissues.

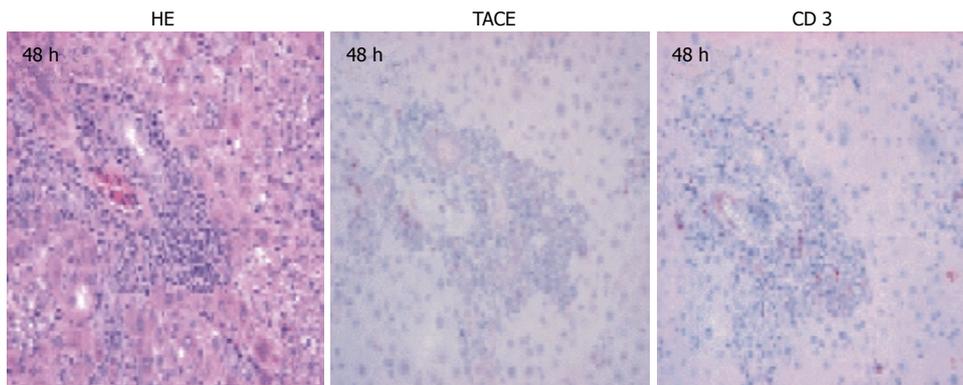

**Correlation of TACE-staining MNC with T lymphocytes**

To identify the stained MNC, we immunostained serial paraffin sections of liver tissues at 48 h after hepatectomy

using an anti-CD3 antibody. This experiment was done in light of the report that during liver regeneration, extrathymic CD3<sup>+</sup> T cells in liver are significantly activated in terms of increases in both proportion and absolute number. The feature demonstrated that the CD3<sup>+</sup> T lymphocytes partially overlapped TACE staining MNC (Figure 6).

**DISCUSSION**

Hepatocyte replication comprises two phases: priming and cell-cycle progression<sup>[12]</sup>. TNF $\alpha$  and interleukin-6 are the main cytokines triggering hepatocyte progression from G0 to G1. HB-EGF and TGF $\alpha$  play an important role in cell-cycle progression. Both TGF $\alpha$  and HB-EGF are ligands of the EGF family and are primary mitogens for hepatocyte proliferation in culture<sup>[13,14]</sup>. It is believed that the functions of TGF $\alpha$  and HB-EGF at least partially overlap during liver regeneration<sup>[15,16]</sup>. Enhanced expression of TGF $\alpha$  mRNA in hepatocytes peaks in 24 h and remains elevated for at least 48 h after hepatectomy<sup>[17]</sup>. TGF $\alpha$  anchored to the cell membrane in precursor form is cleaved by TACE and then binds to EGFR, which activates a phosphorylation cascade leading to DNA replication. The mitogenic cascade involves ERK1/2 and PKB. TNF $\alpha$  enlarges TACE activation by shedding the precursor of TGF $\alpha$ <sup>[18]</sup>. TGF $\alpha$  is produced by hepatocytes and functions through an autocrine mechanism. TGF $\alpha$  and EGF play a

**Figure 6** The serial paraffin sections of liver tissue at 48 h after hepatectomy were stained with HE and immunostained with anti-TACE antibodies and anti-CD3 antibodies. TACE-positive MNC partially overlapped with CD3<sup>+</sup> T lymphocytes ( $\times 400$ ).

major role in the progressive phases of liver regeneration after hepatectomy<sup>[19-21]</sup>.

TACE is mediated by furin and related proprotein convertases. TACE was originally cloned and named for its ability to cleave and convert TNF $\alpha$  into a soluble form. Cells such as macrophages, lymphocytes, and monocytes, which all produce abundant TNF $\alpha$ , are believed to express TACE enzyme<sup>[22]</sup>. TACE is found to be involved in carcinogenesis by TGF $\alpha$ , and the HB-EGF-EGFR pathway. Distinct ADAM metalloproteinases regulate G protein-coupled receptor-induced cell proliferation and survival<sup>[23,24]</sup>. The TACE inhibitor TAPI-1 interferes with TGF $\alpha$  release into the culture medium and subsequent EGFR signalling through ERK1/2 and PKB, thereby blocking DNA replication<sup>[25]</sup>. These data substantiate the idea that TACE plays a significant role and forms a link between cytokine and growth factor pathways in cell proliferation.

In the present study, we examined the kinetic level of TACE expression and localization following partial hepatectomy *in vivo*. It demonstrated that the kinetics of TACE were relatively well synchronized with those of TGF $\alpha$  and hepatocyte proliferation<sup>[5,15,26]</sup>. After hepatectomy in rats, the first peak of DNA synthesis in hepatocytes occurs at about 24 h, with a smaller peak between 36 h and 48 h. The other cells of the liver enter into DNA synthesis at 48 h or later<sup>[12]</sup>. Although TACE is essential for cleaving TNF $\alpha$  and over-expression of TACE promotes inflammation by producing excessive soluble TNF $\alpha$ , our study shows that the kinetics of TACE expression are not compatible with those of TNF $\alpha$  in liver regeneration. TNF $\alpha$  increases abruptly and reaches a peak in the priming phase<sup>[12,27]</sup>, but TACE rises to a peak from 24 h to 48 h post-hepatectomy. Such scenarios may suggest that TACE is involved in liver regeneration by pathways including TGF $\alpha$ -EGFR in the cell-cycle progressive phase, but not by the TNF $\alpha$  pathway. It was also reported that during liver regeneration, extrathymic CD3<sup>+</sup> T cells in the liver are significantly activated in terms of both increases in proportion and absolute number. This activation was observed at an early phase (d 2) of liver regeneration<sup>[28,29]</sup>. IL-1 and TNF $\alpha$ , which are produced by activated kupffer cells and sinusoidal endothelial cells, can induce the activation of T-cell differentiation. The mechanism of T-cell activation of hepatocyte proliferation is unequivocal<sup>[30]</sup>. In this research, immunohistochemical study using serial sections showed TACE-staining

MNC partially overlaps with CD3<sup>+</sup> T lymphocytes. It is conceivable that TACE production and effect by paracrine may be a pathway of involvement in liver regeneration for activated CD3<sup>+</sup> T lymphocytes.

## COMMENTS

### Background

Tumor necrosis factor- $\alpha$  converting enzyme (TACE) is a kind of metalloprotease disintegrins that acts to solubilize a variety of substrates including tumor necrosis factor- $\alpha$  (TNF $\alpha$ ), transforming growth factor- $\alpha$  (TGF $\alpha$ ), epidermal growth factor (EGF) family and has been considered to involve in carcinogenesis by TGF $\alpha$ , heparin-binding epidermal growth factor-like growth factor (HB-EGF) pathway. It was also reported that the activity of several metalloproteinases increase during liver regeneration.

### Research frontiers

Liver regeneration after partial hepatectomy is very intricate. It involves expression of multiple cytokines and growth factors such as HGF, TNF $\alpha$ , TGF $\alpha$  and HB-EGF.

### Innovations and breakthroughs

To date, there has been few studies on the correlation of TACE with liver regeneration after partial hepatectomy *in vivo*. To study the expression of TACE during liver regeneration, we investigated the liver and spleen tissues by a rodent model with partial hepatectomy. It demonstrated that TACE was produced by the activated CD3<sup>+</sup> T lymphocytes and the kinetic expression of TACE was well synchronized with that of TGF $\alpha$  and hepatocyte proliferation.

### Applications

TACE is implicated in liver regeneration by the TGF $\alpha$  pathway that overlaps partially with carcinogenesis.

### Peer review

The authors investigated the expression of TACE during liver regeneration in rats after 70% partial hepatectomy. They observed a time dependant expression with a peak between 24 h and 48 h. They located TACE to mononuclear cells. The authors conclude that TACE expression is synchronized with TNF- $\alpha$  and that TACE is expressed on mononuclear cells.

### Abstract

**AIM:** To examine the prevalence of gastroesophageal reflux disease (GERD) symptoms in a large unselected general population in Japan.

**METHODS:** In Japan, mature adults are offered regular check-ups for the prevention of gastric cancer. A notice was sent by mail to all inhabitants aged > 40 years. A total of 160983 Japanese (60774 male, 100209 female; mean age 61.9 years) who underwent a stomach check up were enrolled in this study. In addition, from these 160983 subjects, we randomly selected a total of 82894 (34275 male, 48619 female; mean age 62.4 years) to evaluate the prevalence of abdominal pain. The respective subjects were prospectively asked to complete questionnaires concerning the symptoms of heartburn, dysphagia, and abdominal pain for a 1 mo period.

**RESULTS:** The respective prevalences of the symptoms in males and females were: heartburn, 15.8% vs 20.7%; dysphagia, 5.4% vs 7.8%; and abdominal pain, 6.6% vs 9.6%. Among these symptoms, heartburn was significantly high compared with the other symptoms, and the prevalence of heartburn was significantly more frequent in females than in males in the 60-89-year age

group. Dysphagia was also significantly more frequent in female patients.

**CONCLUSION:** The prevalence of typical GERD symptoms (heartburn) was high, at about 20% of the Japan population, and the frequency was especially high in females in the 60-89 year age group.

### INTRODUCTION

Heartburn and acid regurgitation, typical symptoms of gastroesophageal reflux disease (GERD), are considered to be reasonably specific for diagnosis<sup>[1,2]</sup>. The dominant mechanism of GERD is contact of the esophageal mucosa with acid, and GERD can also produce symptoms or signs of tissue injury within the oropharynx, larynx and respiratory tract. Recent studies have suggested GERD causes a wide spectrum of non-esophageal conditions including asthma, non-obstructive dysphagia, and non-cardiac chest pain<sup>[3,4]</sup>. Moreover, it has been reported that acid-suppressive therapy resolves heartburn and epigastric pain in GERD patients<sup>[5,6]</sup>. Therefore, epigastric pain may be a clinical symptom of GERD.

GERD is a common condition and its prevalence

varies in different parts of the world. Several population-based studies have reported its prevalence is more frequent in Western<sup>[7-10]</sup> than in Eastern countries<sup>[11,12]</sup>. According to the reports from the Ministry of Health and Welfare in 1994, the incidence of heartburn in Japan was only about 2% of the population who complained of symptoms. A recent study from Japan has reported patients complaining of heartburn account for 24.7%-42.2%<sup>[13-17]</sup>. All of these previous studies were performed on subjects who visited the hospital as outpatients or for routine physical examination<sup>[13-17]</sup>. However, we have to consider the possibility that outpatients are symptomatic, rather than a true random sample of the population. Furthermore, subjects undergoing their annual medical check-up make a periodic visit to each of the medical institutions for routine physical examination. These subjects may have caused some bias, and subjects who visited the hospital as outpatients or for routine physical examination may not be similar to the general population. Therefore, we decided to collect data from subjects attending a primary health care institution that was conducting an annual medical check-up, rather than using data from hospital-based subjects.

In Japan, mature adults are offered regular check-ups for the prevention of gastric cancer. A notice was sent by mail to all inhabitants aged > 40 years. Thus, the majority of subjects in this study were selected according to their age, and we considered this study sample might be more similar to the general population than those of previous studies, and in this respect, this study is considered to be the first to highlight the prevalence of GERD symptoms in a large unselected Japanese population. This is believed to be the first study to target > 100000 unselected subjects in Japan, with the aim of: (1) examining the prevalence of heartburn as a typical symptom of GERD and dysphagia as an atypical symptom of GERD; and (2) identifying an association between GERD symptoms and abdominal pain.

## MATERIALS AND METHODS

### *Health check up in Miyagi prefecture, Japan*

The population of Miyagi prefecture comprises 1889683 adults (909795 male, 979888 female), and there are 1236724 adults aged > 40 years old (579822 male, 656902 female). In Japan, mature adults are offered regular check-ups for the prevention of gastric cancer. Especially in Miyagi prefecture, those over the age of 40 years are recommended to undergo regular health check-ups. A notice was sent by mail in either the first or second half of the year to all inhabitants aged > 40 years who lived in the prefecture. A list of medical institutions was also included so that the subjects could choose where to have the general check-up. Even those subjects under 40 years old could take the check-up if they so desired.

### *Study subjects*

The center chosen for this study was the Institute of the Miyagi Cancer Society. A total of 160983 subjects (60774 male, 100209 female, mean age 61.9 ± 11.1 years) who underwent a regular check-ups for the prevention of gastric cancer at the above center between January and December

**Table 1** Questionnaire used in this study

**Please circle the appropriate responses for each of the following symptoms during a 1-mo period**

- |   |   |       |
|---|---|-------|
| (1) Do you suffer from the symptom of dysphagia?      | 1: yes  | 2: no |
|   | (a: usually; b: sometimes)                          |       |
|   | (c: throat; d: chest; e: stomach)                   |       |
| (2) Do you suffer from the symptom of heartburn?      | 1: yes  | 2: no |
|   | (a: usually; b: sometimes)                          |       |
| (3) Do you suffer from the symptom of abdominal pain? | 1: yes  | 2: no |
|   | (a: usually; b: sometimes)                          |       |
|   | (f: before eating; g: after eating; h: no relation) |       |

2003 were enrolled in this study in a prospective fashion. The 160983 subjects were divided into seven geographical areas, according to the place of residence of the inhabitants, namely Sendai, Tome, Sennan, Kesennuma, Isinomaki, Osaki, and Kurihara. Among these seven geographical areas and 160193 subjects, we additionally randomly selected a total of 82894 subjects (34275 male, 48619 female, mean age 62.4 ± 11.0 years) to evaluate the prevalence of abdominal pain. Subjects were assigned to the following age groups: 30-39, 40-49, 50-59, 60-69, 70-79, and 80-89 years.

### *Methods questionnaire*

Table 1 shows the questionnaire used in this study. The respective subjects were prospectively asked to complete the questionnaires concerning the symptoms of heartburn, dysphagia, and abdominal pain within a 1 mo period. The subjects were requested to simply answer “yes” or “no” to the symptoms, and if they answered “yes”, they were further questioned on the frequency of symptoms (“usually” or “sometimes”). In addition, concerning the symptom of dysphagia, subjects were asked where it occurred (throat, chest or stomach). The relationship of abdominal pain with meals, if any, was elicited. This questionnaire was designed as a self-reporting instrument to measure symptoms experienced over the month previous to returning the completed questionnaire.

### *X-ray examination*

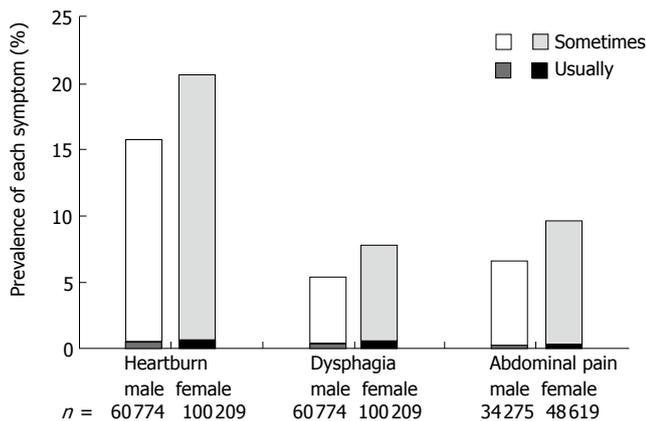

In order to check for gastric cancer, X-ray examinations were also performed on all the enrolled subjects. In addition, we evaluated disease classification based on X-ray examination independently by two experienced gastrointestinal doctors. This was graded in the present study as: normal, gastric ulcer scar, duodenal ulcer scar, gastric and duodenal ulcer scar, hiatus hernia, and patients in whom further endoscopic testing was necessary, because they were suspected of having gastric cancer (cancer suspected). Hiatus hernia in this study was defined as a circular extension of the gastric mucosa of 3 cm or more above the diaphragmatic hernia<sup>[18]</sup>.

### *Statistical analysis*

The 160983 eligible individuals interviewed were considered as a representative sample of the Japanese population. The

Table 2 Disease classification by X ray examinations

Disease classification by X-rays	n (%)	Male/female
Normal	139167 (86.4)	(49338/89829)
Gastric ulcer scar (GU)	2222 (1.4)	(1648/574)
Duodenal ulcer scar (DU)	2346 (1.5)	(1192/1154)
Gastric & Duodenal scar (GDU)	434 (0.3)	(341/93)
Hiatus hernia (HH)	1198 (0.7)	(404/794)
Cancer suspected	15616 (9.7)	(8080/7536)
Total	160983 (100.0)	(60774/100209)

**Figure 1** Prevalence of each symptom. Overall gender-specific prevalence rate for heartburn, dysphagia, and abdominal pain. Among these symptoms, heartburn was significantly high compared with the other symptoms. All symptoms were significantly more common in females than in males ( $\chi^2$  test,  $P < 0.0001$  vs the symptom group).

results are given with a confidence interval of 95%. The values are expressed as frequency, and categorical variables were compared using the  $\chi^2$  test.  $P < 0.05$  was considered significant.

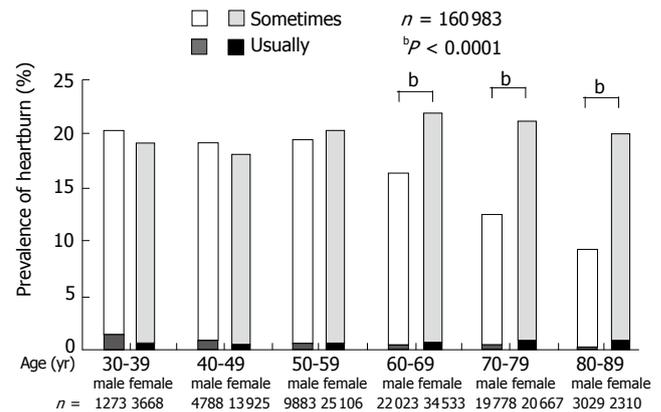

## RESULTS

The mean age of the sample population was  $61.9 \pm 11.1$  years. About 62% of the interviewed subjects (100209) were women. A total of 160848 of the 160983 eligible subjects (99%) responded to the questionnaire on heartburn and dysphagia. Of the total of 82894 eligible subjects additionally randomly selected to evaluate the prevalence of abdominal pain, 82484 (99%) responded to this question.

The disease classification by X-ray examination used in this study and the numbers of subjects are shown in Table 2. Normal classification accounted for 86.4%, and the others in who further endoscopic testing was required because they were suspected of having gastric cancer accounted for 9.7%.

### Frequency of respective symptoms

The overall and gender-specific prevalence rates for heartburn, dysphagia and abdominal pain are shown in Figure 1. The prevalence of the symptoms respectively in males and females were: heartburn, 15.8% (sometimes 15.3%, usually 0.5%) vs 20.7% (sometimes 20.1%, usually 0.6%); dysphagia, 5.4% (sometimes 5.0%, usually 0.4%) vs 7.8% (sometimes 7.3%, usually 0.5%); and abdominal pain,

**Figure 2** Age- and gender-specific prevalence rate for heartburn over a 1 mo period. Heartburn was significantly high in females in the 60-89-year age group ( $\chi^2$  test,  $^bP < 0.0001$  vs each generation group).

6.6% (sometimes 6.5%, usually 0.1%) vs 9.6% (sometimes 9.4%, usually 0.2%). Among these symptoms, heartburn was significantly high compared with the other symptoms, and all symptoms were significantly more common in females than in males.

### Age- and gender-specific prevalence of respective symptoms

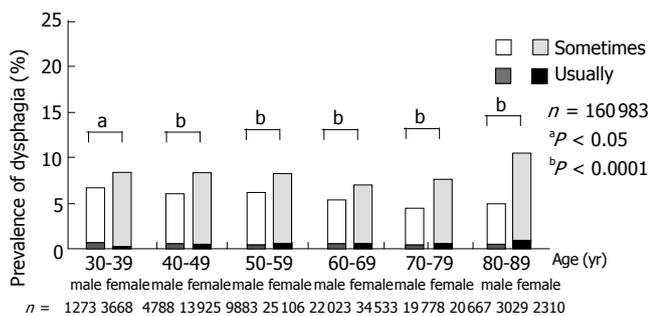

The age- and gender-specific prevalence of heartburn experienced in the month prior to completion of the questionnaires is shown in Figure 2. The prevalence of heartburn remained high with age among women, whereas among men it peaked around the 30-39 years age group, and thereafter declined. The prevalence of heartburn showed a significant age- and gender-related difference in patients in the 60-89 years age group, and the prevalence of heartburn was significantly more frequent in females than in males. The smaller subset of patients reporting "usually" for this symptom is also shown in Figure 2, which was also significantly more frequent in females than in males in the 60-89 years age group.

The age- and gender-specific prevalence of dysphagia experienced in the month prior to completion of the questionnaires is shown in Figure 3. Dysphagia was significantly more frequent in females than in males in all age groups.

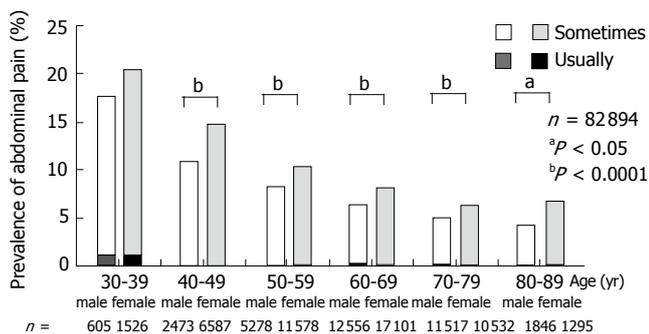

The age- and gender-specific prevalence of abdominal pain experienced in the month prior to completion of the questionnaires is shown in Figure 4. Women were more symptomatic than males in all age groups. Abdominal pain was more prevalent in the younger 30-49 years age group than in the older age groups.

### Association between typical (heartburn) and atypical (dysphagia) symptoms of GERD

Table 3 shows the prevalence of heartburn among subjects in the dysphagia "usually", "sometimes" and no dysphagia groups. The subjects with dysphagia had a significantly higher frequency of heartburn than those without it. Table 4 shows the prevalence of dysphagia among subjects with heartburn "usually", heartburn "sometimes", and no

**Figure 3** Age- and gender-specific prevalence rate for dysphagia over a 1 mo period. Dysphagia was significantly more frequent in females than in males in all age groups ( $\chi^2$  test,  $^bP < 0.0001$  and  $^aP < 0.05$  vs each generation group).

**Figure 4** Age- and gender-specific prevalence rate for abdominal pain over a 1 mo period. Women were significantly more symptomatic than men in all age groups, except 30-39 years ( $\chi^2$  test,  $^bP < 0.0001$  and  $^aP < 0.05$  vs each generation group).

heartburn. The subjects with heartburn had a significantly higher frequency of dysphagia than those without.

**Prevalence of heartburn and dysphagia in relation to the frequency of abdominal pain**

Table 5 shows the prevalence of heartburn and dysphagia among subjects in the abdominal pain “usually”, “sometimes” and no abdominal pain groups. The subjects with abdominal pain had a significantly higher frequency of heartburn and dysphagia than those without.

**Correlation with disease classification**

The prevalence of heartburn and dysphagia was significantly higher in both males and females with hiatus hernia than those without. The prevalence of abdominal pain was significantly higher in both males and females with gastric ulcer, duodenal ulcer, and gastric and duodenal ulcer scarring than in those who were scar-free.

**DISCUSSION**

This is believed to be the first study that has highlighted the prevalence of GERD symptoms in > 100 000 unselected subjects in a prospective fashion in Japan.

Heartburn has been reported to be specific for the diagnosis of GERD<sup>[1,2]</sup>; therefore, we examined heartburn as a typical symptom of GERD. The most important finding was that the monthly prevalence of heartburn was significantly higher (20%) than that for dysphagia and

**Table 3** The prevalence of heartburn in relation to the frequency of dysphagia

	Dysphagia (usually)	Dysphagia (sometimes)	No dysphagia
<i>n</i> = (male/female)	(247/563)	(2806/6875)	(57 476/92 298)
Heartburn (%)

abdominal pain in our Japanese general population.

GERD symptoms are common and its prevalence varies in different parts of the world. The study by El-Serag *et al*<sup>[10]</sup> in 2004 used a questionnaire to survey 496 medical center staff for GERD symptoms. They reported that monthly prevalence of heartburn was 34.2%-40.6% in the United States. On the other hand, in Asia the prevalence has varied, but is generally lower than that in Western studies. Wong *et al*<sup>[11]</sup> have reported that the prevalence of heartburn among 902 randomly selected people occurring at least monthly was 8.9%, while Cho *et al*<sup>[12]</sup> have found a lower prevalence of 4.7% among 2209 randomly selected individuals.

In Japan, Mishima *et al*<sup>[13]</sup> have designed a study to clarify the characteristics of GERD, based on 2760 subjects undergoing their annual medical check-up for gastric cancer. They reported that GERD was present in 17.9% of the Japanese people who presented for annual medical health checks. Fujiwara *et al*<sup>[14]</sup> have reported the prevalence of heartburn among 6035 routine physical examinations was 24.7%. Watanabe *et al*<sup>[16]</sup> have reported the prevalence of GERD among 4139 hospital outpatients was 37.6%. Another study in Japan by Ohara *et al*<sup>[17]</sup> has

shown a total of 42.2% of Japanese individuals who visited hospital for routine physical examination and outpatients experienced heartburn. All of these previously mentioned studies were performed on subjects who visited a hospital as outpatients or for routine physical examination<sup>[13-17]</sup>. However, we consider the possibility that outpatients are symptomatic, rather than a true random sample of the population. Furthermore, subjects who undergo their annual medical check-up make a periodic visit to each of the medical institutions for routine physical examinations. These subjects may have caused some bias, and subjects who visited the hospital as outpatients or for routine physical examinations may not be similar to the general population. On the other hand, in this study, the majority of the sample survey was selected according to age. As stated before, those over the age of 40 years are recommended to undergo regular health check-ups, and a notice was sent by mail to all inhabitants who live in Miyagi prefecture, according to their age. We considered this study sample might be more similar to the general population than that in previous studies<sup>[13-17]</sup>, and in this respect, this study is considered to be the first to highlight the prevalence of GERD symptoms in a large unselected Japanese population.

It is difficult to compare previous reports in terms of difference in the prevalence of GERD symptoms in Japan because of the diverse methodologies used. However, several studies have shown the prevalence of GERD symptoms has recently been gradually increasing<sup>[15-17,19]</sup>. The prevalence of heartburn in this study was about 20%, which is considered to be higher than that of previous studies<sup>[19]</sup>.

There are various factors that might be responsible for the recent upward trend in the prevalence of GERD symptoms in Japan. Risk factors for GERD have been shown to include dietary intake<sup>[20,21]</sup>, smoking<sup>[22]</sup>, alcohol consumption<sup>[23]</sup>, high body mass index<sup>[24]</sup>, family history of reflux symptom<sup>[25]</sup>, aging population, and the presence of a hiatus hernia<sup>[15,17]</sup>. For the first point, the average fat intake in Japan has increased over the past 20 years<sup>[26]</sup>. Dietary fat has been shown to increase the frequency of transient lower esophageal sphincter relaxation<sup>[21]</sup>. Secondly, the population has become increasingly overweight<sup>[27]</sup>, and obesity may lead to an increase in intragastric pressure<sup>[15]</sup>. Thirdly, it has been reported Japanese patients have a high incidence of *H pylori* infection and this leads to an atrophic pattern of gastritis with low acid secretion<sup>[28,29]</sup>. The declining prevalence of *H pylori* infection<sup>[30]</sup>, due to improved hygiene conditions and widespread use of eradication therapy in Japan could also have paradoxically contributed to the increased frequency of GERD. These may be reasons why the prevalence of GERD has recently increased in Japan.

GERD is also associated with a range of other atypical symptom originating in the esophagus, chest and respiratory tract. Several studies have reported approximately one-third of GERD patients suffer from these symptoms, such as dysphagia and chest pain<sup>[3,4]</sup>. We also found considerable overlap among heartburn and dysphagia in this survey, and this suggests an association between GERD and dysphagia.

The age and gender relationships with GERD symptoms

are still controversial. A study in Japan by Ohara *et al*<sup>[17]</sup> has shown GERD symptoms are more common among women, and are unrelated to age. In this study, typical and atypical symptoms were found to be common especially in women. Also, there was a strong relationship between age and gender and the prevalence of symptoms. Our results showed the prevalence of GERD symptoms remained high with age among women, whereas among men, it peaked around the 30-39 years age group, and declined thereafter. One possible reason for high prevalence of GERD in elderly women in Japan may be osteoporosis and kyphosis. Elderly Japanese women tend to have a higher incidence of both osteoporosis and kyphosis than in men the same age<sup>[31]</sup>. Lumbar kyphosis is the major cause of stooped posture, and this may exacerbate the development of hiatus hernia, which is reported as a risk factor for GERD.

Some studies have reported acid suppressive therapy resolves epigastric pain in patients with GERD<sup>[5,6]</sup>. According to these studies, epigastric pain might be one of the clinical symptoms of GERD. In this study, the symptoms of heartburn, dysphagia and abdominal pain also overlapped with each other, similar to previous studies.

The present study has several limitations. First, the main limitation is the fact that the questionnaire was not validated. We estimated the symptom frequency as "usually" or "sometimes". This may be considered vague terminology for precise evaluation of symptom prevalence. Individual subjects might differently interpret the terms of "usually" or "sometimes". However, in order to evaluate some digestive symptoms in a large number of subjects, it was necessary to make the questionnaire simple. As a result, we obtained a very high response rate (99%). As a second limitation, the subjects in this study were not a true random sample of the population. Approximately 40% of the population in Miyagi prefecture is aged < 40 years, and the majority of the study sample was aged > 40 years. Thus, the age structure of the study subjects was different from that of the true unselected population in Miyagi prefecture. However, previous Japanese population-based studies were performed on subjects who visited the hospital for routine physical examinations and as outpatients<sup>[13-17]</sup>, and we have to consider the possibility that they are symptomatic, rather than a true random sample of the population. On the other hand, the majority of people in this study were selected according to their age, and they were considered to be less symptomatic than hospital outpatients. Furthermore, we evaluated the clinical symptoms according to each generation. In this regard, this study is considered to be the first to highlight the prevalence of GERD symptoms in a large unselected population of Japanese subjects who are over > 40 years old. This method may have avoided several sources of bias that have tended to occur in previous studies in Japan.

In summary, we clearly described that reflux symptoms are commonly found in the Japanese general population, especially in older women. We conclude that the prevalence of typical GERD symptoms (heartburn) is high, at about 20%, in the Japanese general population, and the frequency is especially high in women in the 60-89 years age group. We found the symptoms of heartburn, dysphagia and

abdominal pain overlapped with each other with high frequency.

## COMMENTS

### Background

The prevalence of gastroesophageal reflux disease (GERD) symptoms is now increasing in Japan.

### Research frontiers

To examine the prevalence of GERD symptoms in a large unselected general population in Japan.

### Innovations and breakthroughs

Although there have been many studies on the prevalence of GERD in Japan, all of these have been performed on subjects who visited the hospital as outpatients or for routine physical examination. However, we have to consider the possibility that outpatients are symptomatic, rather than a true random sample of the population. Furthermore, subjects undergoing their annual medical check-up make a periodic visit to the each of the medical institutions for routine physical examination. These subjects may have caused some bias, and subjects who visited the hospital as outpatients or for routine physical examination may not be similar to the general population. We decided to collect data from subjects attending a primary health care institution for an annual medical check-up rather than using data from hospital-based subjects. The majority of people in this study were selected according to their age (> 40 years), and they were considered to be less symptomatic than hospital outpatients.

### Applications

This study is considered to be the first to highlight the prevalence of GERD symptoms in a large population of unselected Japanese subjects aged > 40 years old. The prevalence of GERD symptoms among true unselected subjects must continue to be studied in the future.

### Terminology

GERD: Gastroesophageal reflux disease.

### Peer review

In this study, the authors ascertained the prevalence of gastroesophageal reflux symptoms in an extremely large population in Japan. The study was well performed and the conclusions are clear and compatible with those of previous studies.

### Abstract

**AIM:** To evaluate the presence of Na<sup>+</sup>-dependent, active, sugar transport in Barrett's epithelia as an intestinal biomarker, based on the well-documented, morphological intestinal phenotype of Barrett's esophagus (BE).

**METHODS:** We examined uptake of the nonmetabolizable glucose analogue, alpha-methyl-D-glucoside (AMG), a substrate for the entire sodium glucose cotransporter (SGLT) family of transport proteins. During upper endoscopy, patients with BE or with uncomplicated gastroesophageal reflux disease (GERD) allowed for duodenal, gastric fundic, and esophageal mucosal biopsies to be taken. Biopsies were incubated in bicarbonate-buffered saline (KRB) containing 0.1 mmol/L <sup>14</sup>C-AMG for 60 min at 20°C. Characterized by abundant SGLT, duodenum served as a positive control while gastric fundus and normal esophagus, known to lack SGLT, served as negative controls.

**RESULTS:** Duodenal biopsies accumulated 249.84 ± 35.49 (SEM) picomoles AMG/μg DNA (*n* = 12), gastric fundus biopsies 36.20 ± 6.62 (*n* = 12), normal esophagus 12.10 ± 0.59 (*n* = 3) and Barrett's metaplasia 29.79 ± 5.77 (*n* = 8). There was a statistical difference (*P* < 0.01) between biopsies from duodenum and each other biopsy site but there was no statistically significant difference between normal esophagus and BE biopsies. 0.5 mmol/L phlorizin (PZ) inhibited AMG uptake into duodenal mucosa by over 89%, but had no

significant effect on AMG uptake into gastric fundus, normal esophagus, or Barrett's tissue. In the absence of Na<sup>+</sup> (all Na<sup>+</sup> salts replaced by Li<sup>+</sup> salts), AMG uptake in duodenum was decreased by over 90%, while uptake into gastric, esophageal or Barrett's tissue was statistically unaffected.

**CONCLUSION:** Despite the intestinal enterocyte phenotype of BE, Na<sup>+</sup>-dependent, sugar transport activity is not present in these cells.

Absence of Na<sup>+</sup>/sugar cotransport activity in Barrett's metaplasia. *World J Gastroenterol* 2008; 14(9): 1365-1369 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1365.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1365>

### INTRODUCTION

Esophageal adenocarcinoma, which has increased 4-fold between 1973 and 2002, is escalating at an incidence rate which exceeds that of any other malignancy<sup>[1-3]</sup>. Generally detected at a late stage, esophageal adenocarcinoma is extremely lethal, with a 5-year survival rate of just 10%-20%<sup>[4]</sup>. Barrett's esophagus (BE), a condition characterized by a columnar, intestinal-like metaplasia of the normally stratified squamous distal esophagus, confers a dramatically increased risk of progression to esophageal adenocarcinoma and serves currently as the most important clinical risk factor for development of such malignancy<sup>[2]</sup>. In fact, the risk of esophageal adenocarcinoma in BE patients is 30-120 times that of the general population<sup>[2,5]</sup>.

BE may be present in 3% of the western hemisphere population and in at least 10% of gastroesophageal reflux disease (GERD) patients<sup>[1]</sup>. It is impractical to attempt to identify the BE population by means of endoscopic

surveillance of all GERD patients, considering that there are 30 million Americans with GERD<sup>[6]</sup>. Only 5% of patients presenting with esophageal adenocarcinoma are preceded by a BE diagnosis made by upper endoscopy, further illustrating the logistical difficulties in screening a large population by this means<sup>[4]</sup>. Thus, it will be valuable to find and establish biomarkers which may be used to identify BE, simply, safely, and inexpensively, in order to appropriately avert esophageal adenocarcinoma.

Current cellular biomarkers of BE include sucrase-isomaltase (SI) and dipeptidyl peptidase IV (DPP), enzymes which are present in about 60% of BE patients<sup>[7]</sup>. Cdx2, which encodes an intestine-specific transcription factor, is another possible BE biomarker presently under investigation<sup>[8]</sup>. Villin, a cytoskeletal protein related to microvilli, and Ep-CAM, a glandular epithelial glycoprotein are also possible BE biomarkers<sup>[9]</sup>. Other potential markers of BE are the deletion of p53 tumor suppressor gene, deletion or hypermethylation of p16, changes in COX-2 expression, and increases in cell proliferation and cell cycling markers like cyclin D1<sup>[2,4]</sup>. Two inherent disadvantages of these markers are: (1) each individually will not be found in every Barrett's biopsy and (2) all will require tissue biopsies to be taken (upper endoscopies to be performed).

The heterogeneity of BE is evidenced by the presence of columnar non-goblet cells intermixed with the intestinal-like goblet cells in the metastatic Barrett's population<sup>[7]</sup>. The specialized epithelial columnar cells are known to express the small intestinal enzymes, SI and dipeptidyl peptidase, and perhaps represent an "incomplete" stage of intestinal metaplasia<sup>[7]</sup>. Additionally, heterogeneity exists with regard to villin and Ep-CAM expression in Barrett's cells, indicating variations in differentiation state within the Barrett's epithelium<sup>[9]</sup>.

BE, which has a patchy, irregular appearance, typically consists of three distinct cell morphologies: an atrophic gastric fundus type, a junctional gastric cardia type, and an intestinal-like population containing goblet cells and also non-goblet columnar cells (both mucus-containing and pseudo-absorptive in nature)<sup>[5,6,9,10]</sup>. Of these three, only the goblet cell population exhibiting an intestinal phenotype is currently definitively associated with increased risk of malignancy and is thus exclusively required for clinical BE diagnosis<sup>[6,8]</sup>. The histological detection of mucin, which can be achieved in dramatic fashion by Alcian blue staining defines the 'goblet cell metaplasia' character of true BE<sup>[11]</sup>.

Of course, histology requires mucosal biopsies, which can be obtained only through upper endoscopy. A major emphasis of current research in BE is to define new biomarkers which may lead to screening techniques not dependent upon endoscopy and biopsies, due to the expense of anesthesia and risk of the procedure.

The intestinal-like phenotype of BE prompted our group to test for the presence of Na<sup>+</sup>-dependent, active, sugar transport activity (the SGLT family of proteins) in BE as a potential biomarker. Glucose is absorbed in the intestine by SGLT through an energy-, concentration- and Na<sup>+</sup>-dependent fashion<sup>[12-14]</sup>. SGLT is specific to the differentiated, absorptive epithelial cells in the small intestine, kidney proximal tubule, and a few other epithelial cell types and is absent in the stomach, normal esophagus,

and most other somatic cells<sup>[15-18]</sup>. The nonmetabolizable glucose analogue, alpha-methyl-D-glucoside (AMG), is a substrate specific for the sodium-dependent (active) glucose cotransporter (SGLT) family of transport proteins, since a free hydroxyl on carbon 1 is not required for uptake by SGLT<sup>[19]</sup>. AMG is, however, a very poor substrate for the more ubiquitous facilitated diffusion transporters of the GLUT family<sup>[20]</sup>. Phlorizin (PZ) is a competitive inhibitor of intestinal active glucose transport but is not transported itself by the Na<sup>+</sup>/glucose cotransporter<sup>[21]</sup>.

## MATERIALS AND METHODS

### *Biopsy acquisition*

Under an IRB-approved protocol, patients with and without BE, presenting to the Lankenau Hospital Gastroenterology group for upper endoscopy for screening or diagnostic purposes relating to reflux, gastritis, or dysphagia, provided written informed consent for additional biopsies to be taken during upper endoscopy. The patient population of 23 people included 9 females and 14 males, ranging in age from 47 to 81 years. Ten of the study patients were known to have BE, as confirmed by prior positive Alcian blue staining of endoscopic biopsies.

For simple AMG uptake studies, a total of nine biopsies were taken, three each from duodenum, gastric fundus, and Barrett's metaplasia or normal esophagus. For PZ inhibition and Li<sup>+</sup> saline/Na<sup>+</sup> saline studies, a total of eight biopsies were taken from each patient, four each from two of the above listed sites. Duodenum, known to have abundant SGLT, served as a positive control. Gastric fundus and normal esophagus served as negative controls. These tissues are known not to exhibit Na<sup>+</sup>/glucose cotransport activity. By evaluating each BE biopsy individually for uptake of <sup>14</sup>C-AMG, we address the possibility of AMG uptake being expressed in only certain regions of Barrett's epithelium in any individual Barrett's patient.

### *<sup>14</sup>C-AMG uptake studies*

For AMG uptake studies, endoscopic biopsies were placed immediately in ice cold, freshly oxygenated bicarbonate-buffered saline (KRB) and transported from the endoscopy procedure room to the laboratory. Because glucose would interfere with AMG uptake, 5 mmol/L sodium acetate was used to replace glucose as a metabolic substrate in the saline. KRB contained 112 mmol/L NaCl, 5 mmol/L KCl, 1.25 mmol/L CaCl<sub>2</sub>·2H<sub>2</sub>O, 1.1 mmol/L MgCl<sub>2</sub>·6H<sub>2</sub>O, 2.4 mmol/L Na<sub>2</sub>HPO<sub>4</sub>, 0.6 mmol/L NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O, 25 mmol/L NaHCO<sub>3</sub>, 5 mmol/L sodium acetate.

Biopsies were incubated in KRB containing 0.1 mmol/L <sup>14</sup>C-AMG at 20°C for 60 min while being shaken and aerated with 5% CO<sub>2</sub>/95% O<sub>2</sub>. Methyl-alpha-D [U-<sup>14</sup>C] glucopyranoside (AMG) was purchased from Amersham Biosciences (UK). Biopsies were copiously rinsed with 4°C saline (0.154 mol/L NaCl) at the end of the incubation to remove extracellular <sup>14</sup>C-AMG, then a wet weight was recorded followed by addition of biopsy to 0.4 mmol/L perchloric acid for release of intracellular radioactivity, and precipitation (and later measurement) of total DNA by the diphenylamine reaction<sup>[22]</sup>. Intracellular <sup>14</sup>C-AMG released from the samples

**Table 1** Uptake of AMG by duodenal, gastric fundic, and esophageal mucosal biopsies (mean  $\pm$  SE)

	pmoles AMG mg wet wt	pmoles AMG/ $\mu$ g DNA
Duodenum	711.53 $\pm$ 121.63 (11)	249.84 $\pm$ 35.49 (12)
Fundus	41.04 $\pm$ 2.35 (12) <sup>b</sup>	36.20 $\pm$ 6.62 (12) <sup>b</sup>
Esophagus	45.52 $\pm$ 3.76 (3) <sup>a</sup>	12.10 $\pm$ 0.59 (3) <sup>d</sup>
Barrett's	50.27 $\pm$ 4.32 (9) <sup>b</sup>	29.79 $\pm$ 5.77 (8) <sup>b</sup>

The number in parenthesis represents the biopsies tested. Three biopsies were taken from each tissue site of each patient. <sup>b</sup> $P < 0.001$  vs duodenum; <sup>a</sup> $P < 0.02$  vs duodenum; <sup>d</sup> $P < 0.01$  vs duodenum (Student's *t*-test). There was no significant difference ( $P > 0.05$ ) between Barrett's esophagus biopsies and biopsies of fundus or normal esophagus.

**Table 2** Inhibition of AMG uptake by 0.5 mmol/L phlorizin in duodenal, gastric fundic, and esophageal mucosal biopsies (mean  $\pm$  SE)

	Control	Phlorizin
Duodenum	593.34 $\pm$ 120.23 (7)	65.05 $\pm$ 14.41 (7) <sup>b</sup>
Fundus	35.00 $\pm$ 1.82 (8)	30.27 $\pm$ 4.23 (8) <sup>a</sup>
Esophagus	36.73 $\pm$ 4.85 (8)	27.20 $\pm$ 2.63 (8) <sup>a</sup>
Barrett's	53.09 $\pm$ 5.57 (6)	42.66 $\pm$ 4.37 (7) <sup>a</sup>

The number in parenthesis represents the biopsies tested. <sup>b</sup> $P < 0.001$  vs matched control (Student's *t*-test); <sup>a</sup> $P > 0.05$  vs control.

was quantified by scintillation counting and then normalized per wet weight and per total amount of DNA.

### PZ inhibition studies

To confirm the absence of AMG uptake by SGLT, a series of experiments were performed using PZ, a specific, competitive inhibitor of SGLT. PZ dihydrate was purchased from Sigma-Aldrich (St. Louis, MO). For PZ inhibition studies, biopsies were collected in a similar fashion but were pre-incubated in KRB with or without 0.5 mmol/L PZ (and without AMG) for 15 min, while being shaken and aerated with 5% CO<sub>2</sub>/95% O<sub>2</sub>. After 15 min, 0.1 mmol/L <sup>14</sup>C-AMG  $\pm$  0.5 mmol/L PZ was added to the saline and samples were incubated for an additional 60 min. After the incubation period, samples were similarly rinsed, weighed, and digested for determination of <sup>14</sup>C-AMG uptake per sample wet weight.

### Sodium dependence studies

To further confirm a lack of Na<sup>+</sup>/sugar cotransport activity, a series of experiments were performed in which lithium salts replaced sodium salts in the incubation medium. In addition, KRB contained 5 mmol/L lithium acetate in place of sodium acetate. Biopsies were similarly incubated with <sup>14</sup>C-AMG (in KRB with either sodium or lithium salts), rinsed, and weighed for determination of <sup>14</sup>C-AMG uptake per sample wet weight.

## RESULTS

Na<sup>+</sup>/sugar cotransport was assayed by measuring uptake of the nonmetabolizable glucose analogue, AMG, a substrate for all three known SGLTs, with K<sub>m</sub> values of 0.4 mmol/L

**Table 3** Sodium dependence or independence of AMG uptake by duodenal, gastric fundic, and esophageal mucosal biopsies (mean  $\pm$  SE)

	Lithium	Sodium
Duodenum	49.31 $\pm$ 5.86 (10) <sup>b</sup>	544.85 $\pm$ 110.20 (10) <sup>d</sup>
Fundus	35.20 $\pm$ 2.73 (8)	41.15 $\pm$ 1.91 (7)
Esophagus	44.83 $\pm$ 4.03 (9)	41.56 $\pm$ 5.07 (9)
Barrett's	40.47 $\pm$ 1.47 (5)	48.03 $\pm$ 11.72 (5)

The number in parentheses represents the biopsies tested. <sup>b</sup> $P < 0.001$ , <sup>d</sup> $P < 0.001$  vs all other samples. There was no significant difference between lithium and sodium samples.

for SGLT1 and 2 mmol/L for SGLT2 and SGLT3<sup>[23]</sup>. AMG is not a substrate for facilitated diffusional transporters (GLUT1, *etc*) and thus cannot easily efflux from the cell<sup>[20]</sup>, meaning that AMG will accumulate to high intracellular concentrations in cells expressing SGLT. AMG uptake by duodenal biopsy samples was 17-fold greater than gastric biopsies, indicative of the known presence of SGLT in duodenal tissue (Table 1). Dramatically lower AMG uptake in gastric and normal esophageal biopsies correlated with the known absence of SGLT in these tissues. Barrett's biopsies were unable to concentrate AMG to the levels exhibited by duodenal biopsies, suggesting lack of Na<sup>+</sup>-dependent sugar uptake in Barrett's tissue.

To confirm this absence of AMG uptake in Barrett's epithelium, an additional series of experiments was performed using PZ, a competitive inhibitor of sugar uptake specifically by SGLT<sup>[24-27]</sup>. AMG uptake by duodenal biopsies was inhibited over 85% by 0.5 mmol/L PZ, consistent with the known presence of Na<sup>+</sup>/sugar cotransport in duodenum (Table 2). AMG uptake in gastric and normal esophageal biopsies was not significantly inhibited by PZ. This same lack of PZ inhibition of AMG uptake into biopsies of Barrett's metaplasia is a further indication of the lack of active sugar transport activity in Barrett's epithelium.

As final verification of the lack of Na<sup>+</sup>/sugar cotransport in Barrett's epithelium, additional experiments were performed in which lithium salts replaced sodium salts in the incubation saline. Intracellular uptake of AMG into duodenal biopsies in Na<sup>+</sup>-free (Li<sup>+</sup>) saline was only 10% of the levels in Na<sup>+</sup> saline (Table 3). However, the presence of Na<sup>+</sup> did not significantly affect AMG uptake into gastric, esophageal, or Barrett's tissue biopsies. This lack of Na<sup>+</sup>-dependence of sugar transport further confirms the lack of active sugar transport in Barrett's epithelium.

## DISCUSSION

The inability of Barrett's tissue to concentrate AMG, the lack of inhibition by PZ, and the absence of Na<sup>+</sup>-dependence all indicate the absence of an active sugar transport system in BE. Despite the intestinal phenotype ascribed to Barrett's metaplasia, with classic intestinal markers like SI activity and mucin secretion, Barrett's biopsies appear to lack activity associated with SGLT, the active sugar transporter that typifies normal small intestine. The absence of SGLT activity in Barrett's tissue highlights the fact that Barrett's cells are not simply an intestinal cell

type in the distal esophagus, even though Barrett's tissue has other intestinal-like characteristics.

Our results, however, do leave open the possibility, though unlikely, that SGLT is present in the plasma membrane or cells of Barrett's epithelium though it is not functional. Thus, the assays described in this paper were strictly limited to determination of the functional presence of SGLT. Using duodenal biopsies, our group obtained only inconclusive and disappointing results with two commercial SGLT antibodies, therefore not allowing a parallel immunological approach to this question.

Barrett's epithelium develops as a result of damage to the stratified squamous tissue of the distal esophagus by acid and bile from reflux<sup>[5]</sup>. Because of the unique, columnar, intestinal-like phenotype of Barrett's epithelium, it is widely accepted that Barrett's epithelium arises from clonal growth of pluripotent stem cells rather than growth from adjacent inflamed esophageal squamous epithelia, as the "de novo" metaplasia theory suggests<sup>[6,9]</sup>. The duct cell metaplasia theory posits that Barrett's cells derive from stem cells in esophageal glands that colonize the esophagus when the mucosa is damaged<sup>[4,6]</sup>. Finally, the transitional zone metaplasia theory states that, when exposed to bile and acid, the cells of the distal esophagus are replaced by stem cells from the gastroesophageal junction<sup>[5,6]</sup>. Whatever the origin, BE is a "successful adaptation" for protection of the esophagus from further reflux damage, saving the individual with reflux from a future of ulceration and strictures, but carrying with it an increased cancer risk<sup>[5]</sup>.

SGLT is expressed on the apical plasma membrane of absorptive epithelial cells in the small intestine but is not expressed by goblet cells<sup>[17,18,28]</sup>. Also, different rates of Na<sup>+</sup>-dependent glucose transport have been observed in mature cells from the villi of intestine and in immature crypt cells, suggesting that differentiation and enterocyte development state may contribute to SGLT expression and affinity levels<sup>[29-31]</sup>. One must therefore consider that not all small intestinal cell types possess Na<sup>+</sup>/glucose cotransport and that BE may be reflective of these cell types.

Although SGLT may not serve as a biomarker for BE, our group and others have collected evidence that the transporter may be present in intestinalized gastric mucosa and may potentially indicate metaplastic changes related to gastric adenocarcinoma<sup>[32]</sup>. As aforementioned, SGLT is normally not present in the stomach. However, biopsies from a patient with a large, grossly-visible, hyperplastic gastric polyp, exhibited <sup>14</sup>C-AMG uptake that was inhibited by PZ and approximately five times greater than uptake by the patient's normal esophageal biopsies (Data not shown).

In summary, despite the intestinal phenotype ascribed to Barrett's metaplasia with classic intestinal markers like SI activity and mucin secretion, Barrett's biopsies appear to lack activity associated with SGLT, the active sugar transporter present in normal small intestine, and thus cannot serve as a BE biomarker. The absence of SGLT activity in Barrett's biopsies highlights the fact that, although it has other intestinal-like characteristics, Barrett's cells are not simply an intestinal cell type in the distal esophagus, but should rather be treated as a unique entity in future considerations.

## COMMENTS

### Background

In order to effectively avert esophageal adenocarcinoma, it is necessary to find and establish biomarkers to identify Barrett's esophagus (BE). The purpose of this study was to evaluate the presence of Na<sup>+</sup>-dependent, active, sugar transport in Barrett's epithelia as an intestinal biomarker, based on the well-documented, morphological intestinal phenotype of BE.

### Research frontiers

To our knowledge, this is the first paper to investigate Na<sup>+</sup>-dependent, active, sugar transport in Barrett's epithelia as an intestinal biomarker.

### Innovations and breakthroughs

Despite the intestinal phenotype ascribed to Barrett's metaplasia with classic intestinal markers like sucrase-isomaltase (SI) activity and mucin secretion, Barrett's biopsies appear to lack activity associated with SGLT, the active sugar transporter present in normal small intestine, and thus cannot serve as a BE biomarker. The absence of SGLT activity in Barrett's biopsies highlights the fact that, although it has other intestinal-like characteristics, Barrett's cells are not simply an intestinal cell type in the distal esophagus, but should rather be treated as a unique entity in future considerations.

### Applications

While our studies show a lack of functional SGLT1 protein in BE, it may also be valuable to determine the expression of SGLT1 mRNA in Barrett's tissue by RT-PCR.

### Peer review

This nice study set out to assess by functional criteria whether SGLT1 is expressed in Barrett's metaplasia. It well evaluated the presence of Na<sup>+</sup>-dependent, active, sugar transport in Barrett's epithelia as an intestinal biomarker.

Des-gamma-carboxy prothrombin as an important prognostic indicator in patients with small hepatocellular carcinoma. *World J Gastroenterol* 2008; 14(9): 1370-1377 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1370.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1370>

### Abstract

**AIM:** To clarify the effect of a high des-gamma-carboxy prothrombin (DCP) level on the invasiveness and prognosis of small hepatocellular carcinoma.

**METHODS:** Among 142 consecutive patients with known DCP levels, who underwent hepatectomy because of hepatocellular carcinoma, 85 patients met the criteria for small hepatocellular carcinoma, i.e. one  $\leq$  5 cm sized single tumor or no more than three  $\leq$  3 cm sized tumors.

**RESULTS:** The overall survival rate of the 142 patients was 92.1% for 1 year, 69.6% for 3 years, and 56.9% for 5 years. Multivariate analysis showed that microscopic vascular invasion ( $P = 0.03$ ) and serum DCP  $\geq$  400 mAU/mL ( $P = 0.02$ ) were independent prognostic factors. In the group of patients who met the criteria for small hepatocellular carcinoma, DCP  $\geq$  400 mAU/mL was found to be an independent prognostic factor for recurrence-free ( $P = 0.02$ ) and overall survival ( $P = 0.0005$ ). In patients who did not meet the criteria, the presence of vascular invasion was an independent factor for recurrence-free ( $P = 0.02$ ) and overall survivals ( $P = 0.01$ ). In 75% of patients with small hepatocellular carcinoma and high DCP levels, recurrence occurred extrahepatically.

**CONCLUSION:** For small hepatocellular carcinoma, a high preoperative DCP level appears indicative for

### INTRODUCTION

Des-gamma-carboxy prothrombin (DCP) is a tumor marker specific for hepatocellular carcinoma<sup>[1]</sup>. It is believed that the elevation of the serum DCP level correlates with the presence of vascular invasion or intrahepatic metastases<sup>[2-8]</sup>. Furthermore, DCP has been reported to be an independent prognostic factor for recurrence and survival after hepatic resection<sup>[4,9-13]</sup>, liver transplantation<sup>[6,14]</sup>, ablation treatment<sup>[15-17]</sup>, and transarterial chemoembolization (TAE) treatment<sup>[18]</sup>. However, the rate of detectable serum DCP levels in patients with small hepatocellular carcinoma is low<sup>[19-24]</sup>. Although methods have been improved<sup>[25,26]</sup>, sensitivity is still at about 50% for most small cell carcinoma<sup>[27-30]</sup>. Thus, almost all reports on the biological nature of DCP and its prognostic value are based on analyses of patients with larger or more advanced tumors with various degrees of hepatic functional reserve. Reports on the relevance of preoperative DCP level as a prognostic marker in small hepatocellular carcinoma patients are rare.

This study thus aimed analysing the predictive value of preoperative serum DCP level on tumor recurrence and prognosis, particularly in hepatocellular carcinoma patients who had undergone liver resection and who met the criteria for small hepatocellular carcinoma<sup>[31]</sup>, i.e. a single

tumor with all dimensions being 5 cm or less, or no more than three tumors with dimensions of 3 cm or less.

## MATERIALS AND METHODS

From a total of 172 consecutive patients who had undergone a first curative hepatic resection for hepatocellular carcinoma at the Hirosaki University Hospital from 1990 to 2004, 142 patients whose preoperative DCP level was measured by a highly-sensitive assay were enrolled. Patients who met the criteria of small hepatocellular carcinoma, i.e. a single tumor with the largest dimension being 5 cm or less, or no more than three tumors with the largest dimension being 3 cm or less, were compared to the others. Sixteen clinical parameters were recorded [age, gender, Child-Pugh score, serum total bilirubin level, serum albumin level, prothrombin activity, 15-min retention rate of indocyanine green (ICG R15), status of hepatitis virus infection, the number of tumors, the largest dimension of the tumor, the degree of tumor differentiation, the presence or absence of macroscopic and microscopic vascular invasion, the extent of tumor (stage), DCP, and alpha-fetoprotein (AFP)] and the predictivity for probability of recurrence and prognosis of survival were evaluated.

DCP was measured by the chemiluminescent immunoassay using a sensitive anti-DCP antibody (Eisai Co., Ltd., Tokyo, Japan), and threshold values were set to 40, 100, 200, and 400 mAU/mL for determining the presence or absence of a positive reaction. Moreover, the extent of tumor was classified according to the stage classification by the Liver Cancer Study Group of Japan<sup>[32]</sup>.

### Statistical analysis

Comparisons between the two groups were carried out by the Chi-square test for categorical data and Student's *t*-test for continuous data. The continuous variables were reported as the mean  $\pm$  SD. A Cox proportional hazards model was used to test the significance of 16 parameters as predictors of recurrence-free and overall survivals. Kaplan-Meier method and long rank test were also adapted to compare the effect of these factors on survival. These statistical analyses were performed using the SPSS 11.0 statistical software program. *P* values  $< 0.05$  were considered to be statistically significant.

## RESULTS

In this series, 85 of 142 patients met the criteria of small hepatocellular carcinoma, accounting for 60% of the total. Patients' characteristics are given in Table 1. The mean age was  $63.0 \pm 10.6$  years; that of the patients with small hepatocellular carcinoma was significantly higher than that of the patients with greater tumors. No difference was observed between males and females. Concerning Child-Pugh score, Class B was observed more commonly in patients who did not meet the criteria.

Other liver function tests as serum total bilirubin level, albumin level, platelet counts, or ICG R15 were also found to be lower in patients with small hepatocellular carcinoma. A positive status for hepatitis virus, either hepatitis B or C

virus, was more frequent in small hepatocellular carcinoma patients. The largest dimension of the tumor was  $2.9 \pm 1.2$  cm in patients who met the criteria for small hepatocellular carcinoma; it was  $7.6 \pm 4.6$  cm in patients who did not meet the criteria, and lesions  $> 5$  cm in size accounted for more than 70% of the cases in the latter group. Ninety percent of the patients who met the criteria for small hepatocellular carcinoma had a solitary lesion, whereas a significantly larger number of patients outside the criteria had multiple lesions. Pathological evaluation of tumor specimens revealed a significantly higher rate of poorly differentiated tumor cells and a more frequent presence of microscopic vascular invasion in patients who did not meet the criteria for small hepatocellular carcinoma compared to those who did. According to the TNM-Staging by the Liver Cancer Study Group of Japan, approximately 90% of the patients who met the criteria were classified as being in Stage I or II, whereas two-thirds of the patients outside the criteria were classified as being in Stage III or higher. Serum AFP level were not found to be different between the two groups, when threshold was set to 40 ng/mL. However, when a threshold of  $\geq 200$  ng/mL was chosen, the positive rate among patients outside the criteria was high. On the other hand, the serum DCP showed a lower positive rate among patients who met the criteria for small hepatocellular carcinoma compared to those who did not independently on the threshold value.

The recurrence-free survival and the overall survival of the whole group of patients was 60.3% for 1 year, 29.5% for 3 years, and 13.9% for 5 years, and 92.1% for 1 year, 69.6% for 3 years, and 56.9% for 5 years, respectively. The recurrence-free survival of the patients who met the criteria was 66.2% for 1 year, 34.1% for 3 years, and 16.6% for 5 years, with the overall survival of 97.5% for 1 year, 82.5% for 3 years, and 67.9% for 5 years, which compared particularly well to the recurrence-free survival of patients who did not meet the criteria as 49.9% for 1 year, 20.1% for 3 years, and 7.5% for 5 years ( $P = 0.0195$ ), and the overall survival being 82.8% for 1 year, 46.8% for 3 years, and 36.5% for 5 years ( $P < 0.0001$ ).

An univariate analysis, including all patients revealed the number of tumors, the degree of tissue differentiation, vascular invasion, tumor stage, any of the DCP thresholds, and AFP  $\geq 20$  ng/mL, as significant prognostic factors for recurrence. Concerning overall survival, the tumor diameter was also a significant prognostic factor (Table 2). Consequently, a multivariate analysis indicated that microscopic vascular invasions ( $P = 0.03$ ) and DCP  $\geq 400$  mAU/mL ( $P = 0.02$ ) were independent prognostic factors for survival prognosis (Table 3). There was no independent factor reflecting the recurrence-free survival.

The univariate analysis of the 85 patients with small hepatocellular carcinoma showed that DCP of various cut-off values was the most significant prognostic factor (Table 4), and a multivariate analysis showed that DCP  $\geq 400$  mAU/mL was the only independent prognostic factor for recurrence-free survival (Hazard ratio (HR): 3.32; 95% confidence interval (CI): 1.20-9.17,  $P = 0.02$ ) and overall survival (HR: 1.20; 95% CI: 2.98-50.00,  $P = 0.0005$ ) (Table 5).

On the other hand, a multivariate analysis of the 57 patients outside the criteria showed that microscopic

<sup>1</sup>Liver Cancer Study Group of Japan.

vascular invasion was the only independent prognostic factor for recurrence-free survival (HR: 2.97; 95% CI: 1.17-7.58,  $P = 0.02$ ) and overall survival (HR: 3.92; 95% CI: 1.38-11.24,  $P = 0.01$ ) (Table 6).

By performing a Kaplan-Meier analysis of small hepatocellular carcinoma patients, the period of recurrence-free survival was found to be significantly shorter in the group of patients with DCP levels  $\geq 400$  mAU/mL ( $P = 0.02$ ), and more than 70% of the patients experienced some recurrence within 1 year (Figure 1A). Tumor recurrence after surgery occurred within the liver in 95% of patients with DCP levels  $< 400$  mAU/mL, but extrahepatically in 75% of patients with DCP levels  $\geq 400$  mAU/mL ( $P < 0.0001$ ). At the time of tumor recurrence, an elevation of DCP levels was observed among all patients. Most of the patients with tumor recurrence received TAE, local ablation

therapy, or a second hepatectomy, but the overall survival also significantly decreased for the group of DCP  $\geq 400$  mAU/mL ( $P < 0.0001$ ) (Figure 1B).

## DISCUSSION

In this series, a high preoperative level of DCP was the only prognostic indicator for recurrence and poor prognosis in patients who underwent hepatectomy for a small hepatocellular carcinoma. Presence of microscopic vascular invasion, on the other hand, was the independent predictor of poor prognosis of both recurrence-free and overall survivals in more advanced hepatic carcinomas. Thus, different results were obtained for the prognostic factors, depending on disease progression.

There are reports that a high DCP level correlates

with invasiveness and the metastasizing property of carcinoma<sup>[2-8]</sup>. Shirabe *et al*<sup>[8]</sup> reported that the preoperative DCP level, tumor diameter, and histologic differentiation correlated with the presence or absence of microscopic vascular invasion in a study on 218 patients who had undergone hepatic resection. Sakon *et al*<sup>[2]</sup>, Suehiro *et al*<sup>[4]</sup>, Grazi *et al*<sup>[3]</sup>, Sugimoto *et al*<sup>[5]</sup>, and Nanashima *et al*<sup>[13]</sup> also reported that a high preoperative DCP level correlated with the presence of microscopic vascular invasion in patients undergoing hepatectomy. Shimada *et al*<sup>[6]</sup> reported in a study on 40 patients who had undergone a living donor liver transplantation DCP levels ≥ 300 mAU/mL to be correlated with the presence of microscopic vascular invasion and DCP thus to be a poor prognostic factor.

However, the above reports regarding the invasive character of carcinoma among patients with a high level of DCP were based on the analyses of those with various

cancer stages, including more advanced tumors and those with various degrees of liver cirrhosis. There are only a few reports on patients who had undergone a resection for small hepatocellular carcinoma, because vascular invasion or intrahepatic metastases are seldom seen in this group with earlier stage.

It has been reported that the rate of detectable levels of DCP is higher in patients with larger tumors<sup>[19]</sup>. On the other hand, the positive rate of DCP detectability is low for small hepatocellular carcinoma<sup>[19-24]</sup>. Okuda *et al*<sup>[24]</sup> reported that it was 81.3% with a tumor diameter of ≥ 3 cm, while it was 30.4% for ≤ 2 cm. Sassa *et al*<sup>[27]</sup> reported that it was 44.3% for ≤ 2 cm. An assay that employs higher DCP diagnostic sensitivity has been introduced<sup>[25,26]</sup>, but the diagnostic sensitivity for small hepatocellular carcinoma still remains at about 50%<sup>[27-30]</sup>. Thus, most reports on biological properties of DCP positive hepatic

carcinoma are based on more advanced diseases<sup>[7]</sup>.

Many reports state high DCP levels to be of poor prognostic value. It has been shown that patients with high DCP and high AFP levels show poor prognostic factors<sup>[4,6,10-12,14-18]</sup>. Thus, a prognostic staging system in

which DCP has been incorporated is being suggested. From an analysis of 141 patients Kawakita *et al*<sup>[15]</sup> concluded DCP ≥ 100 mAU/mL to be a prognostic factor, and the authors suggested a stage classification in which DCP ≥ 100 mAU/mL should be incorporated into

**Figure 1** Postoperative recurrence-free (A) and overall (B) survival of patients with small hepatocellular carcinoma. In 85 patients who met the criteria for small hepatocellular carcinoma, the period of recurrence-free survival was significantly shorter in patients with DCP  $\geq$  400 mAU/mL than in those with DCP < 400 mAU/mL ( $P = 0.02$ ). More than 70% of recurrences occurred within a year (A). Overall survival was also significantly shorter in patients with DCP  $\geq$  400 mAU/mL (B).

the CLIP score. Nanashima *et al.*<sup>[13]</sup> concluded that DCP  $\geq$  400 mAU/mL was a poor prognostic factor and suggested modified CLIP scoring. Moreover, Omagari *et al.*<sup>[16]</sup> suggested the SLiDe score combined with stages and liver damage, and Toyoda *et al.*<sup>[17]</sup> suggested the BALAD score that can predict the prognosis only by measuring bilirubin, albumin, AFP-L3, AFP, and DCP using preoperative serum samples, according to an analysis of 2600 patients.

In this study, we used the criteria of small hepatocellular carcinoma “a 5-cm single tumor or no more than three 3-cm tumors” as suggested by Mazzaferro *et al.*<sup>[31]</sup>. These criteria are internationally accepted as inclusion criteria for liver transplantation for unresectable small hepatocellular carcinoma, because they reflect a restriction of the tumor to the liver<sup>[33]</sup>.

The univariate analyses of 16 clinical parameters in all patients indicated that the number of tumors, the tumor diameter, the degree of histologic differentiation, vascular invasion, the tumor staging, serum AFP level, and DCP level to be significant prognostic factors. These results are in accordance with previous reports<sup>[3,8,10,12,15-19,34-36]</sup>. However, limiting this to small hepatocellular carcinoma, DCP alone is the independent prognostic factor for both tumor recurrence and patients’ survival, while presence of microscopic vascular invasion is a prognostic factor in patients outside the criteria. Regarding the mechanism of these different results, we assume the following. “Specifically, a high DCP level constitutes a risk factor of microscopic vascular invasion and in small hepatocellular carcinoma, DCP shows positive before the development

of microscopic vascular invasion and becomes an independent prognostic factor. As a tumor becomes larger, the frequency of the detection of microscopic vascular invasion increases and the independence of DCP disappears, thus showing a stronger correlation with the prognosis than does DCP.”

DCP is an abnormal prothrombin that is produced by under-carboxylation of normal prothrombin<sup>[37]</sup>. Suzuki *et al.*<sup>[38]</sup> reported that DCP exerts a mitogenic effect on hepatocellular carcinoma cells *via* a Met-Janus kinase 1-STAT3 signaling pathway. On the other hand, it has been demonstrated that the antiproliferative effect of vitamin K on hepatic carcinoma is not due to a depressed production of DCP, but rather caused by protein kinase A<sup>[39]</sup>. Regarding the above, the mechanism of the antiproliferative effect of DCP on hepatic carcinoma is still unknown. However, in this study, it was clarified that a high DCP level is an important prognostic factor for recurrence, even in a condition in which small hepatocellular carcinoma before the histological invasion of carcinoma such as vascular invasion becomes obvious. This result corresponds to reports by Koike *et al.*<sup>[40]</sup> and Hagiwara *et al.*<sup>[34]</sup> showing that patients who have a high DCP level can expect the expression of future vascular invasion. Moreover, in many of our patients tumor recurred extrahepatically early after resection. Regarding the precise mechanism of DCP on hepatic carcinoma development, it would be necessary to study its effect on the initiation of vascular invasion and on proliferative activity.

## COMMENTS

### Background

Des-gamma-carboxy prothrombin (DCP) is a marker specific for hepatocellular carcinoma, which has been reported to correlate with the presence of vascular invasion. These reports, however, are based mostly on analyses on advanced carcinoma.

### Research frontiers

In this study, the authors retrospectively reviewed the prognostic factors in patients undergoing a first hepatectomy for hepatocellular carcinoma, with special reference to the effect of a high DCP level on the prognosis of small hepatocellular carcinoma.

### Innovations and breakthroughs

Preoperative DCP was found to have a different prognostic impact in small hepatocellular carcinoma compared to more advanced tumors. DCP  $\geq$  400 mAU/mL was an independent prognostic factor for recurrence-free and overall survivals in patients with small hepatocellular carcinoma.

### Applications

Preoperative DCP could be integrated into the prognostic scoring, staging and inclusion criteria for hepatectomy, and liver transplantation in patients with small hepatocellular carcinoma.

### Peer review

The paper with its scientific and innovative contents as well as readability reflects the advanced level of the clinical research in gastroenterology both at home and abroad.

Available from: URL: <http://www.wjgnet.com/1007-9327/14/1378.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1378>

### Abstract

**AIM:** To investigate the anti-neoplastic effect of MK615, an anti-neoplastic compound isolated from Japanese apricot, against human pancreatic cancer cells *in vitro*.

**METHODS:** Three human pancreatic cancer cell lines PANC-1, PK-1, and PK45H were cultured with MK615 at concentrations of 600, 300, 150, and 0 µg/mL. Growth inhibition was evaluated by cell proliferation assay, and killing activity was determined by lactate dehydrogenase (LDH) assay. Expression of Aurora A and B kinases was detected by real-time polymerase chain reaction (PCR) and Western blotting. Cell cycle stages were evaluated by flow cytometry.

**RESULTS:** The growth inhibitory rates of MK615 at 150, 300, and 600 µg/mL were 2.3% ± 0.9%, 8.9% ± 3.2% and 67.1% ± 8.1% on PANC1 cells, 1.3% ± 0.3%, 8.7% ± 4.1% and 45.7 ± 7.6% on PK1 cells, and 1.2 ± 0.8%, 9.1% ± 2.1% and 52.1% ± 5.5% on PK45H cells, respectively ( $P < 0.05$ ). The percentage cytotoxicities of MK615 at 0, 150, 300, and 600 µg/mL were 19.6% ± 1.3%, 26.7% ± 1.8%, 25.5% ± 0.9% and 26.4% ± 0.9% in PANC1 cells, 19.7% ± 1.3%, 24.7% ± 0.8%, 25.9% ± 0.9% and 29.9% ± 1.1% in PK1 cells, and 28.0% ± 0.9%, 31.2% ± 0.9%, 30.4% ± 1.1% and 35.3 ± 1.0% in PK45H cells, respectively ( $P < 0.05$ ). Real-time PCR and Western blotting showed that MK615 dually inhibited the expression of Aurora A and B kinases. Cell cycle analysis revealed that MK615 increased the population of cells in G2/M phase.

**CONCLUSION:** MK615 exerts an anti-neoplastic effect on human pancreatic cancer cells *in vitro* by dual inhibition of Aurora A and B kinases.

### INTRODUCTION

MK615, an extract from the Japanese apricot, *Prunus mume* Siebold et Zuccarini (*ume* in Japanese), contains several triterpenoids and has been shown to exert an anti-neoplastic effect against human cancers. Previous studies have revealed that MK615 has anti-neoplastic effects against gastric cancer<sup>[1]</sup>, breast cancer<sup>[2]</sup>, hepatocellular carcinoma<sup>[3]</sup>, and colon cancer<sup>[4]</sup>. The mechanisms responsible for the anti-neoplastic effect of MK615 include induction of apoptosis<sup>[1,2]</sup> and autophagy<sup>[4]</sup>, and suppression of Aurora A kinase<sup>[3]</sup> in cancer cells. However, the entire mechanisms of the anti-neoplastic effects of MK615 have not been elucidated.

In the present study, we cultured human pancreatic cancer cell lines in the absence and presence of MK615 for the first time, and found that MK615 had an anti-neoplastic effect that was exerted by dual inhibition of Aurora A and B kinases.

### MATERIALS AND METHODS

#### Reagents

MK615 was provided by Japan Apricot Co., Ltd. (Gunma, Japan). MK615 is derived from Japanese apricot fruit<sup>[1]</sup>.

#### Cell culture

Three human pancreatic cancer cell lines PANC-1 (PANC1), PK-1 (PK1) and PK-45H (PK45H) were obtained from the Cell Resource Center for Biomedical Research, Institute of Development, Aging and Cancer, Tohoku University (Miyagi, Japan). The cells were cultured in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 100 mL/L

heat-inactivated fetal calf serum (FCS) and incubated at 37°C in a humidified atmosphere consisting of 50 mL/L CO<sub>2</sub> in air.

### Cell proliferation assay

Cells were plated at  $5 \times 10^3$ /well in 96-well plates in DMEM containing 100 mL/L FCS and cultured with or without MK615 at concentrations of 600, 300, or 150 µg/mL. For the negative control wells, cells were cultured with 10 mL/L DMSO alone. After 48 h, 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium, inner salt (MTT; 5 g/L) was added to each well and the cells were incubated for 4 h. Then according to the manufacturer's recommendation, 100 µL of solubilization solution/stop mix was added and the plates were left to stand for 60 min. The absorbances at 570 nm ( $A_{570}$ ) and 630 nm ( $A_{630}$ ) were then measured with an enzyme-linked immunoassay (ELISA) reader. The actual counts were calculated by subtracting  $A_{570}$  from  $A_{630}$ . Each assay was performed in triplicate and the average absorbance was calculated. The growth inhibition rate was calculated using the ratio of absorbance at each drug concentration relative to the absorbance without drug.

### LDH assay

Lactate dehydrogenase (LDH) assay was performed using the CytoTox 96<sup>®</sup> Non-Radioactive Cytotoxicity Assay (Promega, Madison, WI). Briefly, cells were plated at  $5 \times 10^3$ /well in 96-well plates in DMEM containing 100 mL/L FCS. Cells were cultured with or without MK615 at concentrations of 600, 300, or 150 µg/mL. For the negative control wells, cells were cultured with 10 mL/L DMSO alone. The medium was removed and 100 µL of CytoTox-ONE<sup>™</sup> Reagent was added. The cells were then incubated at 22°C for 10 min and 50 µL of stop solution was added. The plates were shaken for 10 s and the absorbances at 560 nm ( $A_{560}$ ) and 590 nm ( $A_{590}$ ) were measured with an ELISA reader. To obtain the maximum LDH release, 10 µL of lysis solution (10 ×) was added to the positive control wells 45 min prior to harvest. After 48 h, 50 µL of supernatant was transferred into a fresh 96-well plate and incubated with 50 µL of substrate mix for 30 min at room temperature. Fifty microliters of stop solution was added, and the absorbance at 490 nm ( $A_{490}$ ) was measured with an ELISA reader. Each assay was performed in triplicate and the average absorbance was calculated. The percentage cytotoxicity was calculated using the formula: Percentage cytotoxicity =  $100 \times (\text{Experimental} - \text{Culture medium background}) / (\text{Maximum LDH release} - \text{Culture medium and lysis solution background})$ .

### Real-time PCR

The total RNA of each cell line was isolated using a Total RNA Isolation kit (MACHEREY-NAGEL, Düren, Germany). Reverse transcription reactions were performed using a Rever Tra Ace  $\alpha$ -First Strand cDNA Synthesis kit (TOYOBO, Osaka, Japan). Briefly, 1 µg of total RNA, oligo dT-primer, and dNTPs were incubated at 65°C for

5 min, followed by addition of 10 µL of cDNA synthesis mixture and further incubation at 50°C for 50 min. The reaction was terminated by adding 1 µL of RNaseH and incubating the mixture at 37°C for 20 min.

Real-time PCR was performed with an ABI Prism 7700 Sequence Detector (Applied Biosystems, Warrington, UK). The PCR reaction was carried out in a final volume of 2 µL of cDNA, 12.5 µL of 2 × SYBR Green (Applied Biosystems), 0.5 µL of 25 nmol/L sense and antisense primers, and H<sub>2</sub>O up to 25 µL. The PCR conditions consisted of 40 amplification cycles at 95°C for 30 s and 60°C for 30 s. The sequences of the primers were as follows: GAPDH, 5'-CCACCCAGAAGACTGTGGAT-3' (sense) and 5'-TTCAGCTCAGGGATGACCTT-3' (anti-sense); Aurora A, 5'-TTGGAATATGCACCACTTGGA-3' (sense) and 5'-ACTGACCACCCAAATCTGC-3' (anti-sense); and Aurora B, 5'-GGGAGAGCTGAAGATTGCTG-3' (sense) and 5'-GGCGATAGGTCTCGTTGTGT-3' (anti-sense). The level of expression was calculated using the formula: Relative expression (t) = (Copy number of target molecule / Copy number of GAPDH) × 1000. Samples were assayed in triplicate. Means and standard deviations were calculated from the data obtained. The *t* value was calculated from the mean of three different assays.

### Western blotting

Anti-Aurora A and Aurora B, nuclear factor- $\kappa$ B (NF- $\kappa$ B), and phosphorylated NF $\kappa$ B at serine residue 536 [pNF- $\kappa$ B (ser536)] antibodies were purchased from Cell Signaling Technology (Beverly, MA). Cells ( $5-10 \times 10^6$ ) were cultured with MK615 (300 µg/mL) for 48 h, washed twice with cold PBS, lysed with 200 µL of 5 g/L SDS, and centrifuged at  $10000 \times g$ . The supernatants were adjusted to contain equal amounts of protein by dilution, using a BCA Protein Assay kit (PIERCE, Rockford, IL). Samples (20 µg protein) were run on 125 g/L SDS-PAGE with 10% gel and electroblotted onto PVDF membranes. The blots were blocked for 1 h with 50 g/L nonfat milk powder and 1 mL/L Tween 20 in Tris-NaCl, followed by overnight incubation with primary antibody (dilution 1:1000) at 4°C. After extensive washing, the blots were incubated with the secondary horseradish-peroxidase-conjugated antibody (dilution 1:2000) for 2 h at room temperature. Immunoreactive bands were visualized by using an enhanced chemiluminescence detection system (Amersham Life Sciences, Arlington Heights, IL).

### Cell cycle analysis

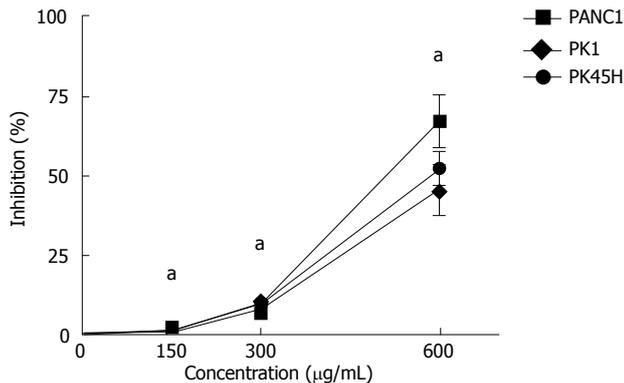

Cells were cultured with 300 µg/mL MK615 for 48 h, then collected by trypsinization. According to the manufacturer's instructions, cell cycle analysis was performed with a Cycle TEST PLUS DNA Reagent kit (Becton-Dickinson, Mountain View, CA) on a FACScaliber (Becton-Dickinson). Results were analyzed with CellFIT software.

### Statistical analysis

For the MTT assay, LDH assay, and real-time PCR, Student's *t* test (two-sided) was used to compare the data obtained from MK615-treated and MK615-untreated groups. A *P* value less than 0.05 was considered statistically significant.

**Table 1** Cell cycle analysis showing MK615 treatment increased the cell population in G2-M phase in all three pancreatic cancer cell lines.

	MK615	G0-G1	S	G2-M
PANC1	(-)	68.1	24.2	7.8
	(+)	71.6	15.4	13.0
PK1	(-)	55.9	42.2	1.8
	(+)	68.8	26.0	5.2
PK45H	(-)	56.0	21.1	22.9
	(+)	59.0	11.7	29.3

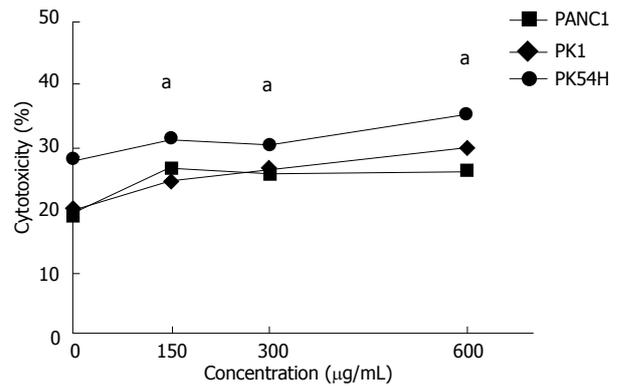

**Figure 1** Growth inhibition of pancreatic cancer cells by MK615. MK615 significantly inhibited the growth of PANC1, PK1, and PK45H cells in a dose-dependent manner ( $^*P < 0.05$ ). Cells were cultured for 48 h. The assay was carried out in triplicate.

## RESULTS

MK615 inhibited growth of the three pancreatic cancer cell lines (Figure 1). The growth inhibitory rates of MK615 at 150, 300 and 600  $\mu\text{g}/\text{mL}$  were  $2.3\% \pm 0.9\%$ ,  $8.9\% \pm 3.2\%$  and  $67.1\% \pm 8.1\%$  on PANC1 cells,  $1.3\% \pm 0.3\%$ ,  $8.7\% \pm 4.1\%$  and  $45.7\% \pm 7.6\%$  on PK1 cells, and  $1.2\% \pm 0.8\%$ ,  $9.1\% \pm 2.1\%$  and  $52.1\% \pm 5.5\%$  on PK45H cells, respectively. The growth inhibition induced by MK615 at all concentrations was significantly higher than that at 0  $\mu\text{g}/\text{mL}$  ( $P < 0.05$ ).

Cytotoxicity of MK615 against pancreatic cancer cell lines was evaluated by LDH assay (Figure 2). The percent specific lysis by MK615 at 0, 150, 300, and 600  $\mu\text{g}/\text{mL}$  was  $19.6\% \pm 1.3\%$ ,  $26.7\% \pm 1.8\%$ ,  $25.5\% \pm 0.9\%$  and  $26.4\% \pm 0.9\%$  in PANC1 cells,  $19.7\% \pm 1.3\%$ ,  $24.7\% \pm 0.8\%$ ,  $25.9\% \pm 0.9\%$  and  $29.9\% \pm 1.1\%$  in PK1 cells, and  $28.0\% \pm 0.9\%$ ,  $31.2\% \pm 0.9\%$ ,  $30.4\% \pm 1.1\%$  and  $35.3\% \pm 1.0\%$  in PK45H cells, respectively. The percent specific lysis induced by MK615 at all concentrations was significantly higher than that at 0  $\mu\text{g}/\text{mL}$  ( $P < 0.05$ ).

Moreover, we examined whether MK615 was able to inhibit Aurora kinases in the pancreatic cancer cell lines. Aurora kinases mRNA expression is shown in Figure 3. The inhibition rate of Aurora A and Aurora B mRNA was  $38.4\% \pm 2.9\%$  ( $P = 0.02$ ) and  $40.8\% \pm 3.2\%$  ( $P = 0.03$ ) in PANC1 cells,  $7.6\% \pm 1.1\%$  ( $P = 0.05$ ) and  $43.4\% \pm 4.5\%$  ( $P = 0.03$ ) in PK1 cells, and  $8.7\% \pm 2.5\%$  ( $P = 0.05$ ) and  $10.5\% \pm 2.1\%$  ( $P = 0.05$ ) in PK45H cells, respectively, indicating a significant inhibition of mRNA expression of both Aurora kinases by MK615.

**Figure 2** Lysis of pancreatic cells by MK615. MK615 lysed PANC1, PK1, and PK45H cells at concentrations of 150, 300, and 600  $\mu\text{g}/\text{mL}$ . The percentage cytotoxicities at 150, 300, and 600  $\mu\text{g}/\text{mL}$  MK615 were significantly higher than those at 0  $\mu\text{g}/\text{mL}$  MK615 ( $^*P < 0.05$ ). Cells were cultured for 48 h. The assay was carried out in triplicate.

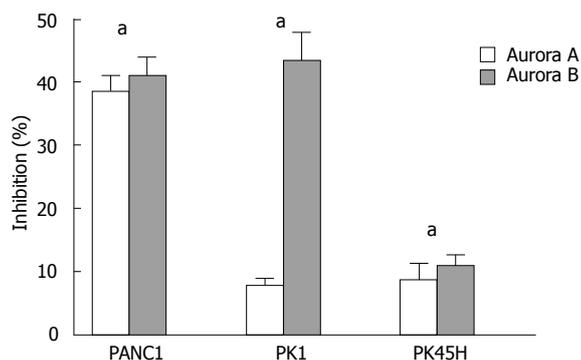

Figure 4 shows the protein expression of Aurora kinases. After 48 h of incubation with 300  $\mu\text{g}/\text{mL}$  MK615, expressions of both Aurora A and B proteins were decreased in PANC1 and PK45H cells. Because endogenous Aurora A expression was low in PK1 cells, no significant decrease in its expression was observed. Consequently, MK615 decreased NF- $\kappa$ B expression in PANC1 and PK45H cells, but no evident decrease in NF- $\kappa$ B expression in PK1 cells was observed. The decrease in NF- $\kappa$ B expression was more evident with the use of anti-phosphorylated NF- $\kappa$ B antibody [pNF- $\kappa$ B (ser536)].

In addition, we analyzed the effect of MK615 on the cell cycle. MK615 increased the proportion of cells in G2-M phase (Table 1) from 7.8% to 13.0% in PANC1 cells, from 1.8% to 5.2% in PK1 cells, and from 22.9% to 29.3% in PK45H cells.

## DISCUSSION

MK615 is isolated from Japanese apricot and contains many defined and undefined substances, including several triterpenoids<sup>[1]</sup>, some of which exert an anti-neoplastic effect. In the present study, MK615 inhibited the proliferation of all three pancreatic cancer cell lines (Figure 1), and LDH assay showed that the anti-proliferative effect of MK615 on these cells was due not only to cell anti-proliferative effect, but also to direct cell killing effect (Figure 2).

In a previous study from our laboratory, MK615 was shown to be capable of inhibiting Aurora kinase A in human hepatocellular carcinoma<sup>[3]</sup>. This prompted us to investigate the effects of MK615 on Aurora B kinases. Aurora kinases are key mediators of cell division by controlling chromatid segregation<sup>[6-8]</sup>. There are three isoforms of Aurora kinases in mammals, Aurora A, Aurora B, and Aurora C. Structurally, all three share a similar domain organization, consisting of the N- and C-terminal domains, and a central region containing the catalytic domain, whose sequence is conserved among all three Aurora kinases<sup>[9]</sup>. Despite their sequence similarities, however, the functions and cellular localization of Aurora kinases differ. Aurora A is localized at the centrosome and forms the mitotic spindle apparatus

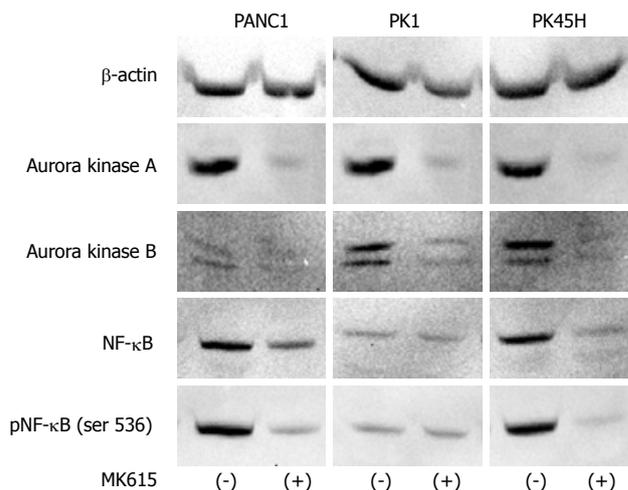

**Figure 3** Dual inhibition of mRNA expression of Aurora A and Aurora B kinases by MK615. MK615 significantly inhibited the transcription of Aurora A and Aurora B mRNA. The percentage inhibition in PANC1, PK1, and PK45H cells was statistically significant ( $P < 0.05$ ). RNA was extracted from the cells cultured with MK615 at a concentration of 300  $\mu\text{g}/\text{mL}$  for 48 h.

that plays a crucial role in segregating chromosomes into daughter cells. Aurora B is localized in inner-centromeric chromatin during metaphase-anaphase transition, and relocalizes to microtubules in the spindle midzone during telophase, being required for accurate cytokinesis<sup>[10,11]</sup>. Unlike Aurora A and Aurora B kinases, the function of Aurora C still remains unclear. Over-expression of Aurora A and Aurora B is frequently observed in various human cancers<sup>[12-15]</sup>.

Our results demonstrated that MK615 inhibited the growth of, and showed cytotoxicity against, all three pancreatic cancer cell lines. The former effect was dose-dependent, while the latter was not. Although the mechanism responsible for the anti-neoplastic effect of MK615 has not been fully elucidated, the results of real-time PCR (Figure 3) and Western blotting (Figure 4) indicated that MK615 inhibited the expression of Aurora A and B kinases. There are several inhibitors of Aurora kinases, including the anti-Aurora B inhibitor, hesperadin<sup>[16]</sup>, anti-Aurora A and B, ZM447439<sup>[17]</sup>, and anti-Aurora A, B, and C, VX-680<sup>[18]</sup>. As shown in the present study, MK615 dually inhibited both Aurora A and B kinases. Inhibition of Aurora kinases mRNA expression varied in three pancreatic cancer cell lines. In PANC1 and PK45H cells, Aurora A and Aurora B mRNA expression was inhibited to the same degree, whereas Aurora B mRNA was inhibited more efficiently by MK615 than Aurora A mRNA in PK1 cells. Consequently, MK615 efficiently inhibited Aurora A and Aurora B in PANC1 and PK45H cells at the protein level (Figure 4), whereas such inhibition was not evident in PK1 cells. Because the protein expression of Aurora A in PK1 cells was weak, the deficient inhibition of Aurora kinases may be due to the low expression of endogenous Aurora A in these cells. Although MK615 suppresses unknown molecules located upstream from Aurora A and B kinases, administration of MK615 at least down-regulates the expression of Aurora A and B kinases in a dual manner.

NF- $\kappa\text{B}$  plays a central role in cell proliferation<sup>[19-21]</sup> and is consistently activated in some human cancers<sup>[22-24]</sup>. Aurora A binds the E2 ubiquitin ligase UBE2N, and UBE2N phosphorylates I $\kappa\text{B}\alpha$ . Activated I $\kappa\text{B}$  translocates NF- $\kappa\text{B}$  from the cytoplasm to the nucleus, resulting in

**Figure 4** Inhibition of protein expression of Aurora A and Aurora B kinases, and NF- $\kappa\text{B}$  by MK615. MK615 dually inhibited the expression of Aurora A and Aurora B kinases in PANC1 and PK45H cells. However, no inhibition was evident in PK1 cells. NF- $\kappa\text{B}$  inhibition was more evident when anti-phosphorylated NF- $\kappa\text{B}$  antibody was used. Protein was extracted from the cells cultured with MK615 at a concentration of 300  $\mu\text{g}/\text{mL}$  for 48 h.

activation of the NF- $\kappa\text{B}$  complex<sup>[25]</sup>. MK615 inhibits the expression of Aurora A, resulting in inhibition of NF- $\kappa\text{B}$  activation<sup>[26-28]</sup>.

A previous study from our laboratory showed that MK615 induced cell-cycle arrest at the end of G2 phase in hepatocellular carcinoma<sup>[3]</sup>. In the present study, MK615 treatment increased the cell population in G2-M phase in all three pancreatic cancer cell lines. MK615 inhibits Aurora A and Aurora B kinases and may induce cancer cell death at the G2-arrest check point<sup>[29,30]</sup>.

In conclusion, MK615 exerts an anti-neoplastic effect on human pancreatic cancer cells *in vitro* via dual inhibition of Aurora A and B kinases. Although further investigation is needed, MK615 seems to have the property anti-Aurora kinase compound.

## COMMENTS

### Background

MK615 is an extract from the Japanese apricot. Previous studies have revealed that MK615 has anti-neoplastic effects against human cancers. The mechanisms of anti-neoplastic effect of MK615 include apoptosis, autophagy, and suppression of Aurora A kinase. However, the entire mechanisms of the anti-neoplastic effects of MK615 have not been elucidated.

### Research frontiers

Pancreatic cancer is one of the leading causes of death worldwide, and the 5-year survival rate is 2%-20%. There has been a need for chemotherapeutic drugs that are less toxic and can inhibit or suppress pancreatic cancer, and MK615 is a promising candidate.

### Innovations and breakthroughs

There are not many inhibitors of Aurora kinases. MK615 is a natural compound which strongly inhibits Aurora A and B kinases.

### Applications

MK615 shows an anti-neoplastic effect on human pancreatic cancer cells *in vitro* via dual inhibition of Aurora A and B kinases. MK615 may prove to be a therapeutic approach in pancreatic cancer therapy.

## Terminology

MK615 is an extract from the Japanese apricot, *Prunus mume* Siebold et Zuccarini (ume in Japanese). Aurora kinases are key mediators of cell division by controlling chromatid segregation. There are three isoforms of Aurora kinases in mammals: Aurora A, Aurora B, and Aurora C.

## Peer review

This is an *in vitro* study of an anti-neoplastic drug MK615 made from Japanese apricot. Its mechanism of action was studied and revealed to have inhibitory effects on Aurora A and B kinases. This is a good basic research on anti-neoplastic agent MK615 for pancreatic carcinoma.

### Abstract

**AIM:** To evaluate the management of Italian children with cholelithiasis observed at Pediatric and Surgical Departments linked to Italian Society of Pediatric Gastroenterology Hepatology and Nutrition.

**METHODS:** One-hundred-eighty children (90 males, median age at diagnosis 7.3 years; range, 0-18 years) with echographic evidence of cholelithiasis were enrolled in the study; the data were collected by an anonymous questionnaire sent to participating centers.

**RESULTS:** One hundred seventeen patients were treated with ursodeoxycholic acid; in 8 children dissolution of gallstones was observed, but the cholelithiasis recurred in 3 of them. Sixty-five percent of symptomatic children treated became asymptomatic. Sixty-four patients were treated with cholecystectomy and in only 2 cases a postoperative complication was reported. Thirty-four children received no treatment and were followed with clinical and echographic controls; in no case the

### INTRODUCTION

In the last years following the extensive use of ultrasound scanning an increasing number of children with cholelithiasis has been identified. In a population based study, prevalence of gallstones and biliary sludge in children was of 1.9% and 1.46%, respectively<sup>[1]</sup>. In an analogue study, performed in Italian adults, the overall prevalence of gallstones diseases was of 9.5% in men and 18.9% in women<sup>[2]</sup>.

Gallstones disease is the most common and costly of all digestive disease in the United States, resulting in 700 000 cholecystectomies and as many as 1 000 000 hospitalizations annually<sup>[3]</sup>. The frequency of hospital admission and operation for gallstones increased in Western countries since the 1950s<sup>[4]</sup>. In England the age-standardized hospital admission rate for cholelithiasis enhanced from 68.7 to 104.9 per 100 000 population between 1989/1990 and 1999/2000 and it increased progressively with age from 1.1 per 100 000 in the 0-14 year age group to 277.1 per 100 000 in the  $\geq 85$ -year age group in 1999/2000<sup>[5]</sup>.

Guidelines for management of cholelithiasis are available for adults. Cholecystectomy is recommended for

symptomatic patients and for those asymptomatic with a predisposition for malignancy (calcified gallbladder wall or family history of gallbladder cancer). For asymptomatic patients an expectant management with periodical clinical and echographic controls is recommended<sup>[6,7]</sup>. On the contrary, little is known about natural history and management of cholelithiasis in childhood. So far, guidelines for management of children with gallstones are lacking. Surgical options for pediatric cholelithiasis include open or laparoscopic cholecystectomy<sup>[8]</sup>. At the present, laparoscopic technique is considered the gold standard for cholecystectomy in children for reduced pain, absence of an upper abdominal incision and scar formation and a shorter period of hospitalization<sup>[9-12]</sup>. The non-surgical approach is based on the use of ursodeoxycholic acid (UDCA); UDCA can reduce cholesterol saturation in bile and progressively dissolve cholesterol gallstones<sup>[13,14]</sup>. Treatment of radiolucent gallstones with UDCA has been well documented in adults<sup>[15-17]</sup>; on the contrary, little information is available for children<sup>[18,19]</sup>. Another approach to pediatric cholelithiasis is represented by expectant management, in which the patients are not treated with medical or surgical therapies but are followed up with periodical clinical and ultrasound controls.

The aim of our multicenter retrospective study was to evaluate the management of Italian children with cholelithiasis observed at Pediatric and Surgical Departments linked to Italian Society of Pediatric Gastroenterology Hepatology and Nutrition (SIGENP).

## MATERIALS AND METHODS

### Subjects

A retrospective study aimed to evaluate the management of the Italian children with cholelithiasis observed at Medical and Surgical Pediatric Departments linked to SIGENP during the period 1995-2005 was performed. An anonymous questionnaire that investigates age, sex, clinical presentation of cholelithiasis, risk factors for cholelithiasis, basal liver function tests and ultrasonographic findings was proposed to SIGENP members. Seven departments (six medical and one surgical) agreed to participate to the study, three in Northern Italy, one in central regions and three in southern Italy. Each department sent data to the Coordinating Centre in Naples for statistical analysis. The SIGENP approved the project. All patients with echographic evidence of cholelithiasis with age range 0-18 years were enrolled in the present study. The diagnosis of cholelithiasis was based on the presence of echogenic foci that produced acoustic shadowing in the gallbladder or in the region of gallbladder fossa. Sludge was defined as non-shadowing, echogenic, intraluminal sediment. When the sludge was seen at the same time of gallstones, the children were considered to have cholelithiasis. The children with diagnosis of biliary sludge were excluded from the present study. Gallstones were distinguished in radio-lucent and radio-opaque on the basis of radiographic aspect. In all patients risk factors for cholelithiasis such as hemolytic disorders, familiarity for gallstones, obesity, total parenteral nutrition (NPT), hepatobiliary chronic disease, cystic fibrosis, therapy with ceftriaxone, abdominal surgery,

IgA deficiency and Gilbert's disease were investigated. The gallstones in patients without risk factors for cholelithiasis were considered idiopathic. With regard to clinical presentation the patients were distinguished in two groups: asymptomatic and symptomatic. Asymptomatic children had no abdominal discomfort or gastrointestinal complaints; their gallstones were diagnosed incidentally on ultrasound examinations for causes unrelated to cholelithiasis. As previously reported, symptomatic children were divided into those with colicky pain, those with typical biliary tract symptoms (right upper quadrant or epigastric pain, nausea, vomiting and food intolerance) and with atypical symptoms<sup>[1]</sup>.

### Management

For each patient, type of treatment and outcome were evaluated. For patients treated with UDCA, therapy was considered effective in case of complete gallstone dissolution at ultrasound scanning and disappearance of clinical symptoms. For surgically treated patients, efficacy of treatment was evaluated on the basis of disappearance of clinical symptoms without the development of "post-cholecystectomy syndrome". Gallstone recurrence was defined as detection of echogenic foci in the gallbladder that produced acoustic shadowing, after that at least in an occasion disappearance of gallstones was documented at ultrasound scanning. We recorded clinical, laboratory and echographic features of all patients, type of treatment and outcome.

### Statistical analysis

Data were analyzed with the  $\chi^2$  test and with Fisher's exact test and Student's *t*-test as appropriate.  $P < 0.05$  was considered significant.

## RESULTS

During the period 1995-2005, 196 children with gallstones or biliary sludge (98 males; median age at diagnosis 7.3 years; range, 0-18 years) were observed at Pediatric Medical Departments of Naples (56 cases), Milan (22 cases), Rome (19 cases), Bari (16 cases), S. Giovanni Rotondo (7 cases), Ferrara (6 cases) and at Pediatric Surgical Department of Brescia (70 cases). 181 patients (92.3%) had gallstones and 15 (7.7%) had biliary sludge and so were excluded from the study. In the patients with gallstones, the sex ratio was equal, but in the adolescent group (12-18 years) there was a female predilection for gallstones. Eighty-six (47.5%) children showed one or more risk factors for gallstones at personal and familial anamnesis (Table 1). Ninety-five (52.5%) patients had no risk factors and their cholelithiasis was defined as idiopathic. Presence of one or more relatives with cholelithiasis represented the most common risk factor at any age, with a sensitive increase of frequency with age (Figure 1). Positive family history for cholelithiasis was described in maternal branch in 27 patients (52.9%), in the paternal in 12 cases (23.6%) and in both branches in 10 patients (19.6%), while in 2 (3.9%) children cholelithiasis was found in the brother and in the sister, respectively. Presence of relatives with cholelithiasis, obesity and hemolytic disorders were the predominant risk

**Table 1 Risk factors for cholelithiasis in 181 children observed at Pediatric Medical and Surgical Department**

Risk factor	Pediatric medical departments	Pediatric surgical department	Total
Hemolytic disorders	9	7	16

Typical biliary tract symptoms	9	14	0
Atypical symptoms	3	3	0
Pancreatitis/Cholecystitis	2	1	0
Resolution of lithiasis	2	50	0
Recurrence of lithiasis	0	0	0
Resolution of symptoms	9	50	0
Recurrence of symptoms	0	0	0

factors in children with gallstones. According to presence of symptoms at diagnosis, the patients were divided in asymptomatic (64 patients, 35.3%) and symptomatic (117 patients, 64.7%).

In the context of the symptomatic children with regard to clinical presentation, four groups of patients could be distinguished: 51 (43.6%) patients (28 males, median age 10 years; range, 3 mo-18 years) with colicky pain with or without jaundice; 50 (42.7%) patients (25 males, median age 7 years; range, 2 mo-16 years) with typical chronic

**Figure 1 Risk factors for cholelithiasis and age at diagnosis.**

biliary tract symptoms; 12 patients (10.3%) (3 males, median age 6.5 years; range, 3 mo-14 years) with atypical symptoms; 4 (3.4%) children (2 males, median age 5.6 years; range, 2-13 years) with pancreatitis/cholecystitis.

The distribution of clinical presentations in the different age groups showed that the rate of colicky pain was higher in older children; instead as for the other clinical presentations, there was no correlation with age at diagnosis. According to therapy, patients could be divided in 3 groups: 117 (64.6%) children treated with UDCA, 64 (35.3%) children treated with laparoscopic or laparotomic cholecystectomy and 34 (18.8%) observed with expectant management. It is to note that 34 children were treated with UDCA in a first phase and thereafter, for persistence of gallstones, with cholecystectomy.

The clinical characteristics, type of therapy and outcome of studied patients are reported in Tables 2 and 3.

### Patients observed at medical departments

**Medical treatment:** Eighty-three (69.7%) of 119 patients with gallstones observed at Medical Departments were treated with UDCA (25 mg/kg per day; range 18-30 mg/kg per day) for median period of 13 (range, 3-96) mo. Thirty-three (39.8%) patients had radiolucent gallstones, 17 (20.4%) radio-opaque gallstones, while 33 patients (39.8%) did not undergo radiographic examination. The median of diameter maximum of gallstones was 8 (range, 2-45) mm. All children completed the therapy without any adverse effects. During UDCA therapy they underwent an ultrasound scanning every 3-6 mo. The gallstones completely disappeared in only 6 (7.2%) children (4 radio-lucent and 2 with unknown radiographic-aspect), but the cholelithiasis recurred in 3 (50%) of them; in one child, gallstones reappeared after 6 years and in the other two biliary sludge were observed after 6 and 10 mo, respectively. Four of 6 patients with gallstones dissolution were symptomatic at diagnosis; all 4 children were relieved of their symptoms during UDCA therapy. The other 2 children remained asymptomatic during the observation period. In other 4 patients disappearance of gallstones was observed, but three of them had a pseudolithiasis (following antibiotic-therapy with ceftriaxone) and one had fetal gallstones. Since these conditions are described as auto-resolving diseases<sup>[20-23]</sup>, the disappearance was not

considered induced by UDCA. In 73 (87.9%) patients treated with UDCA there was persistence of gallstones. Forty-three patients were symptomatic at diagnosis. In 36 (83.7%) of these patients resolution of clinical discomfort was observed, while in 7 (16.3%) of them symptoms persisted unchanged during the therapy. The other 30 (41.1%) children remained asymptomatic during the treatment. Eleven (13.2%) patients underwent cholecystectomy at the suspension of medical therapy for either recurrence or persistence of symptoms. Significant differences in terms of sex, age, characteristics of gallstones (diameters, Rx-aspect) and risk factors for cholelithiasis were not found among the patient's responders and non-responders to UDCA.

**Surgical treatment:** Fourteen (11.8%) patients with gallstones observed at Pediatric Medical Departments were surgically treated. At x-ray examination, 4 (28.6%) of them had radiolucent gallstones, 6 (42.8%) radio-opaque stones; in the remaining 4 (28.6%) cases the radiographic aspect of gallstones was unknown. Eleven (78.6%) patients were symptomatic and 3 (21.4%) asymptomatic. The median of diameter maximum of gallstones was 7 (range, 3-33) mm. In 10 (71.4%) cases cholecystectomy was performed by laparoscopic techniques and in 4 (28.6%) by laparotomy. There were no post-operative complication and in no case residual cholelithiasis or recurrence of gallstones during the follow-up were observed. In three patients recurrence of clinical symptoms after treatment (post-cholecystectomy syndrome) was described.

**Expectant management:** Thirty-three (27.7%) patients were not treated, but they were observed with clinical, laboratory and ultrasonographic controls every 3-6 mo. Two patients (6%) had radiolucent stones, 16 (48.5%) radio-opaque cholelithiasis and the other 15 (45.5%) had not been submitted to x-ray examination. The median of diameter maximum of gallstones was 9 (range, 2-23) mm. In no case development of complication was observed and none of the 17 (51.5%) asymptomatic patients became symptomatic during the follow up (median duration of follow-up, 9 mo, range 1-45).

#### **Patients observed at surgical department**

Seventy patients enrolled in the present study come from the Pediatric Surgical Department of Brescia. To avoid selection bias in the evaluation of the treatment and the outcome we have decided to separately analyze the children of this center.

Sixty-two patients had gallstones and 8 had biliary sludge and so were excluded from the study (median age 7 years; range, 0-18 years). Forty-eight (77.4%) patients were symptomatic at diagnosis, while 14 (22.6%) were asymptomatic. Thirty-four children (54.8%) with gallstones (21 radio-lucent, 9 radio-opaque, and 4 unknown radiographic aspect) were treated with UDCA (median dose 18 mg/kg per day; range, 5-30 mg/kg per day; median duration 5 mo; range, 2-36 mo). Twenty-six patients were symptomatic and eight were asymptomatic. Following UDCA therapy, nine (34.6%) of 26 symptomatic patients became symptom free, while in 17 (65.4%) cases

the symptoms persisted unchanged during the therapy. Gallstones completely disappearance in 2 (5.9%) radiolucent cases. In other 2 patients spontaneous resolution of lithiasis was observed (pseudo-lithiasis induced by ceftriaxone). In the remaining thirty (88.2%) patients (17 radiolucent gallstones, 9 radio-opaque and 4 with unidentified radiographic-aspect) UDCA was inefficacy with persistence of gallstones despite therapy. Twenty-three of these children underwent cholecystectomy, while 7 were followed with periodical controls. The other 27 patients were directly treated with surgical approach. In forty patients (80%) cholecystectomy was performed by laparoscopic technique and in 10 (20%) cases by laparotomic approach. Histological analysis of the removed gallbladders was available for 39 patients: thirty-three (84.6%) had chronic cholecystitis, 2 (5.1%) papillomatosis, 1 (2.6%) adenoma of gallbladder and only 3 (7.7%) patients had normal gallbladder wall. Postoperative complications were not reported except in a child who developed a laparocoele and in another who had dilatation of choledochus duct. In no case the post-cholecystectomy syndrome was observed.

Only one (1.6%) patient was not treated and followed with periodical clinical and echographic controls.

## **DISCUSSION**

Although cholelithiasis is considered as an uncommon condition in children, recent series document an increasing detection of this disorder<sup>[1]</sup>. This increase may be explained by the increased use of abdominal ultrasound scanning in childhood. The frequency of pediatric gallstones, documented in studies in which patients were selected according to initial symptoms, resulted in prevalence's between 0.13% and 0.22%<sup>[1,24]</sup>. In Wesdorp's study, in which patients with cholelithiasis were obtained by screening 4200 abdominal ultrasound scans performed for different reasons such as typical biliary symptoms, general abdominal symptoms or routinely check-ups, a higher prevalence of gallstones and biliary sludge (1.9% and 1.46%, respectively) was observed. For its typology the present study cannot give information on the epidemiology of pediatric cholelithiasis, but it has however confirmed some aspects previously reported, as major frequency in the female only after puberty, increase of the cases with age, association with some risk factors such as familiarity for cholelithiasis, obesity and hemolytic disorders<sup>[1,25,26]</sup>. It was previously reported that approximately 80% of adults with gallstones are asymptomatic<sup>[2,27]</sup>. Instead we have found that only one third of children with cholelithiasis were asymptomatic. This could be explained by the tertiary nature of involved centers or may indicate that asymptomatic cholelithiasis is less frequently in children, as described in other studies<sup>[1]</sup>.

Although the prevalence of cholelithiasis in children is increasing, little information is available about the management of this disorder in childhood. There are only few data on pediatric cholelithiasis and in the majority of cases the studies were performed on a limited number of patients. In our study, in which the management of cholelithiasis was evaluated in a large cohort of children observed at Medical and Surgical Department linked

to SIGENP, both diagnostic approach and therapeutic strategies were extremely heterogeneous. As for diagnostic approach, abdominal X-ray was not performed in all cases; in fact, radiographic aspect of gallstones in a third of patients was not evaluated. As for treatment, although in adults UDCA therapy is recommended only for a specific subset of patients<sup>[15]</sup>, in the present study this drug was used in about two third of cases and only in half of cases the gallstones were radiolucent. Our study confirmed that UDCA was ineffective in dissolution of gallstones in the vast majority of the cases. In addition, there was an important rate of recurrence of cholelithiasis after primary dissolution. Instead UDCA had a positive effect on the symptoms determining the disappearance of abdominal discomfort in the vast majority of the symptomatic patients treated.

In our study laparoscopic cholecystectomy was confirmed to be an efficacy and safe procedure in the treatment of pediatric gallstones for the low rate of post-operative complications (3%) and post-cholecystectomy syndrome (4.7%). In contrast to Wesdorp's study, in which 45% of children with biliary symptoms or colicky pain had recurrence of their symptoms after treatment (Endoscopic Retrograde Cholangiopancreatography (ERCP) or cholecystectomy), in our study the post-cholecystectomy syndrome was observed only in a small percentage of cases. This difference may be explained by the greater recurrence of symptoms associated with ERCP than with cholecystectomy.

The histological analysis of the removed gallbladders showed structural alterations such as chronic cholecystitis, papillomatosis and adenoma in the majority of cases; in only few cases the gallbladder wall was normal. Therefore, for long life expectancy of children, expectant management may not be safe in pediatric patients. In fact, in contrast to adults in whom the natural history of gallstones is well documented, in children it is not known. In adults only 1%-4% per year will develop symptoms or complications of gallstones disease; only 10% will develop symptoms in the first five years after diagnosis and approximately 20% by 20 years<sup>[28-30]</sup>.

A fifth of patients with gallstones enrolled in our study were not treated and followed with periodical clinical and echographic controls; in none of them any complication occurred during the follow-up (median 9 mo; range, 3-45). It is to note, however, that in our study the observation period of untreated was too short to evaluate the effective rate of complications.

Considering the typology of the present study and the heterogeneous management observed in our patients, we are unable to provide clear indications for management of cholelithiasis in children. However on the basis of the available studies and our results, the following approach might be suggested. Firstly, the children with gallstones should be divided in two groups on the basis of clinical presentation: symptomatic and asymptomatic. As for asymptomatic gallstones, considering the low rate of complications observed and the favorable natural history described in adults, we recommend an expectant management with periodical clinical and ultrasonographic

controls. On the other hand, as for symptomatic gallstones, considering the low rate of post-operative complications and post-cholecystectomy syndrome, we suggest surgical approach with laparoscopic cholecystectomy. For its inefficacy on dissolution of gallstones and for high recurrence rate of gallstones, UDCA should not be used in pediatric gallstones, except in symptomatic children with contraindication to surgery for reduce the clinical symptoms.

It is necessary that this approach is validated in further studies including a larger number of children; furthermore, it would be desirable to know in larger series the natural history of cholelithiasis in childhood.

## COMMENTS

### Background

Although recent extensive use of abdominal ultrasound scanning has identified an increased number of cholelithiasis, little is known about the natural history and management of this disorder in childhood.

### Innovations and breakthroughs

Only few data on pediatric cholelithiasis are available and in the majority of cases the studies were performed on limited number of patients. In our study, the management of cholelithiasis was retrospectively evaluated in a large cohort of children observed at Medical and Surgical Department linked to Italian Society of Pediatric Gastroenterology Hepatology and Nutrition (SIGENP).

### Applications

The present study suggests a possible approach to pediatric cholelithiasis. It is desirable, however, that this approach is validated in further prospective studies including a larger number of children.

### Peer review

This retrospective study is well done and nicely written and focused on a relevant topic (cholelithiasis in children).

### Abstract

**AIM:** To determine end-stage pathologic changes in the liver of septic patients dying in the intensive care unit.

**METHODS:** Needle liver biopsies obtained immediately after death from 15 consecutive patients with sepsis and no underlying liver disease were subjected to routine histological examination. Liver function tests and clinical monitoring measurements were also recorded.

**RESULTS:** Liver biochemistries were increased in the majority of patients before death. Histology of liver biopsy specimens showed portal inflammation in 73.3%, centrilobular necrosis in 80%, lobular inflammation in 66.7%, hepatocellular apoptosis in 66.6% and cholangitis/cholangiolitis in 20% of patients. Mixed hepatitic/cholestatic type of liver injury was observed in 6/15 (40%) patients and hepatitic in 9/15 (60%). Steatosis was observed in 11/15 (73.3%) patients affecting 5%-80% of liver parenchyma. Among the histological features, the presence of portal inflammation in liver biopsy was associated with increased hospitalization in the ICU prior death ( $P = 0.026$ ).

**CONCLUSION:** Features of hepatitis and steatosis are

the main histological findings in the liver in the majority of patients dying from sepsis.

Liver histology in ICU patients dying from sepsis: A clinico-pathological study. *World J Gastroenterol* 2008; 14(9): 1389-1393 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1389.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1389>

### INTRODUCTION

Sepsis is the leading cause of death in patients admitted in intensive care units (ICUs)<sup>[1]</sup>. Hepatic dysfunction represents a common manifestation during the sepsis process, ranging from a mild elevation of serum bilirubin and/or liver enzymes to severe hepatic failure<sup>[2]</sup>. The pathophysiology of liver injury in sepsis is multifactorial and involves infection, drugs, metabolic disturbances and a broad spectrum of inflammatory mediators<sup>[3,4]</sup>. The detailed histopathological findings in the liver of patients at the late stages of sepsis remain relatively unknown as scarce data are available in humans.

In the present study, we aimed to assess the pathologic changes in liver core-needle biopsies obtained immediately after death from ICU septic patients and to correlate these with clinical and laboratory data.

### MATERIALS AND METHODS

#### Subjects

We evaluated liver core-needle biopsies, obtained immediately (within 5 min) after death, from 15 patients who were admitted because of sepsis in the ICU of the Hippocraton General Hospital of Athens. The modified sepsis criteria described by Bone *et al*<sup>[5]</sup> were applied, including clinical suspicion of sepsis, hyper- or hypothermia

Table 1 Clinical data of patients admitted to ICU with sepsis

No	Age	Sex	Diagnosis	Cause of hospitalization	APACHE II	Cultured sample	Infective agent
1	58	Male	Respiratory infection	ARD	17	Blood	Klebsiella
2	70	Male	Respiratory infection	ARD	15	Blood	Klebsiella
3	84	Male	Respiratory infection	Heart failure	17	Respiratory (BAL)	Enterobacter
4	57	Male	Respiratory infection	AMI	23	Venous catheter	Klebsiella
5	50	Male	Soft tissue infection	Soft tissue infection	20	Skin	Staphylococcus epidermidis
6	74	Male	Intra-abdominal sepsis	Peritonitis	29	Blood	Enterobacter
7	45	Female	Intra-abdominal sepsis	Peritonitis	21	Venous catheter	Klebsiella
8	74	Female	Peritonitis	Peritonitis	30	Midstream urine sample	Candida albicans
9	86	Male	Sepsis	Sepsis	37	Venous catheter	Pseudomonas
10	75	Male	Respiratory infection	ARD	27	Blood	Pseudomonas
11	33	Male	Soft tissue infection	Burn injury	7	Blood	Acinetobacter
12	69	Male	Peritonitis	Peritonitis	17	Blood	Klebsiella
13	72	Female	Respiratory infection	ARD	15	Blood	Klebsiella
14	70	Male	Respiratory infection	AMI	26	Venous catheter	Klebsiella
15	77	Male	Respiratory infection	Aneurysm	20	Respiratory (BAL)	Candida

ARD: Acute respiratory distress; AMI: Acute myocardial infarction; BAL: Bronchoalveolar lavage.

(rectal temperature > 38.5°C or < 35°C), tachycardia, and at least one of the following indications of altered organ perfusion and function: altered mental status, hypoxemia, elevated serum lactate level and oliguria. Exclusion criteria included pre-existing hepatobiliary disease, HIV infection and malignancies. In all patients, the standard treatment for the managing of sepsis was used according to the Surviving Sepsis Campaign guidelines<sup>[6]</sup>. Death was attributed to multiple organ failure due to sepsis and was defined as the loss of cardiac rhythm which could not be recovered after initial resuscitation. Support was withdrawn from patients with spontaneous cardiopulmonary arrest.

### Methods

Informed consent was obtained from the patients' relatives in all cases. All liver biopsies were performed by the same ICU consultant physician within first 5 min from resuscitation refractory cardiac arrest as defined by three cycles of defibrillator shock. Biopsy specimens were fixed in 10% neutral buffered formalin and embedded in paraffin.

Causative infective agents, sites of infection, causes of admission in the ICU and/or transfer from another department, initial APACHE II Score as well as patients' demographics are shown in Table 1. Initial laboratory values were measured upon admission to ICU, while the most recent values obtained before the reported time of death, were considered as terminal laboratory values.

### Histopathology

Liver biopsies measured 17-46 (mean 25) mm in length and contained 6-28 (mean 12) portal tracts. Serial sections of liver biopsies were cut at 4-μm intervals and mounted on slides coated with poly-L-lysine. Sections were stained with hematoxylin and eosin and with special histochemical stains (reticulin, Masson Trichrome, PAS, PAS-diastase, Prussian blue and Gram) for detailed morphological evaluation by two independent pathologists. Type, zonal location and amount of steatosis were recorded for each case. The latter was graded as 0 (< 5% of parenchymal

involvement), 1 (5%-33%), 2 (> 33%-66%) and 3 (> 66%), according to previously published criteria<sup>[7]</sup>. Apoptotic (acidophilic) bodies were evaluated as the total count in the liver specimen and as the number per mm<sup>2</sup> of examined liver tissue.

### Statistical analysis

Data were analyzed using SPSS 13.0 software. All continuous variables are reported as the median and range. Relationships between categorical variables were tested with  $\chi^2$  analysis, with Fisher's exact test were applicable. Quantitative variables were analysed using non-parametric statistics (Mann-Whitney *U* test for two independent samples). *P* < 0.05 were considered statistically significant.

## RESULTS

### Clinical and laboratory data

Patients' clinical parameters and laboratory data at entry and before death are shown in Table 2. At entry, 2 patients (13.3%) presented with elevated bilirubin levels, while increased AST was present in 7/15 (46.7%), abnormal ALT in 8/15 (53.3%),  $\gamma$ GT in 6/15 (40%) and ALP in 2/15 (13.3%) patients. Before death, elevated serum levels of bilirubin, AST, ALT,  $\gamma$ GT and ALP were observed in 8/15 (53.3%), 8/15 (53.3%), 7/15 (46.7%), 14/15 (93.3%) and 11/15 (73.3%) patients, respectively. In summary, an overall deterioration of liver-related biochemical parameters was observed in all our patients. With respect to the type of liver injury, 3/15 (20%) patients showed a clearly cholestatic biochemical profile, with substantial elevation of  $\gamma$ GT and ALP and normal or nearly normal AST and ALT levels (< 1.5 the upper normal limit), while 12/15 (80%) patients exhibited a mixed hepatic and cholestatic profile.

### Histology

The observed histological findings in liver biopsy specimens were portal inflammation in 11/15 (73.3%, mixed in 8 patients and lymphohistiocytic in 3), centrilobular necrosis in 12/15 (80%), lobular inflammation in 10/15 (66.7%),

**Table 2** Clinical and laboratory parameters in patients who died from sepsis at entry and before death (Data are presented as median, range)

Variable	Initial	Final	P-value
Heart rate (/min)	88 (50-150)	86 (76-140)	NS
Systolic blood pressure (mmHg)	130 (70-180)	110 (60-150)	0.017
Diastolic blood pressure (mmHg)	70 (45-80)	50 (40-80)	0.018
PO <sub>2</sub> (mmHg)	154 (50-579)	81 (45-120.8)	0.008
PCO <sub>2</sub> (mmHg)	42 (23-138)	38 (28.1-81)	NS

hepatocellular apoptosis in 10/15 (66.6%), cholangitis in 1/15 (6.6%), cholangiolitis in 2/15 (13.3%) patients, canalicular cholestasis in 1/15 (6.6%) and ductular cholestasis in 2/15 (13.3%) patients (Figure 1A-C). Damage to bile duct epithelium was not observed.

The type of liver injury was defined as mixed or hepatitic according to overall histological features; 9/15 (60%) patients had the "hepatitic" type when only portal/lobular inflammation and/or centrilobular, frequently hemorrhagic, necrosis were present (Figure 1A), while 6/15 patients (40%) had "mixed" histological liver injury characterized by different combinations of biliary lesions (bile duct and/or ductular hyperplasia, cholangitis, cholangiolitis), cholestasis (canalicular and/or ductular) (Figure 1B and C), portal/lobular inflammation and centrilobular necrosis. Gram stains for bacteria and PAS for fungi were negative in all cases.

Steatosis was observed in 11/15 (73.3%) patients, of whom 5 had grade 1 (parenchymal involvement range: 5%-20%), 3 grade 2 (40%-50%) and 3 grade 3 (70%-80%).

**Figure 1** Histological findings in liver biopsy specimens. **A:** Zone 3 (centrilobular) necrosis (HE, x 100); **B:** Canalicular cholestasis. Bile plugs in dilated canaliculi (black arrows). An apoptotic (acidophilic) body is present (white arrow) (HE, x 200); **C:** Ductular cholestasis and inflammation. Dilated bile ductules at the margin of an inflamed portal tract are filled with bile (black arrows) (HE, x 100).

Four out of 11 patients had macrovesicular, 5/11 microvesicular and 2/11 mixed type of steatosis. Seven of 8 patients (87.5%) who developed hyperbilirubinemia before death had a mixed type of liver injury and one (12.5%) had a hepatitis-like liver injury, whereas those who did not have jaundice ( $n = 7$ ) had no histological features of cholangitis/cholangiolitis. Apoptotic bodies, observed in 10/15 (66.6%) patients, were mainly seen in those who had lobular inflammation. The association of apoptosis with clinical and biochemical analysis at the closed time of death is seen in Table 3.

In order to examine whether the histological findings were associated to the duration of ICU hospitalization we performed univariate regression analysis. Patients with portal inflammation in biopsy specimens had a significant long term ICU hospitalization compared to patients without evidence of portal inflammation [no portal

inflammation vs portal inflammation: 3 (3-49) vs 25 (4-92) days Mann-Whitney *U* test,  $P = 0.026$ ]. None of the other histological findings on liver found to be significantly associated with the length of ICU hospitalization.

## DISCUSSION

In our study, we have observed that liver involvement in sepsis is common and characterized by either a hepatitic-like injury, observed in 60% of our patients, or a mixed, hepatitic and cholestatic, pattern of injury. Furthermore, steatosis was a common finding observed in 74% of our patients. Bacteremia and sepsis have been associated with abnormal liver biochemistry<sup>[2-4,8-10]</sup>. In the current study, elevated serum ALP and  $\gamma$ GT levels were observed in 70% and 93% of our cases before death compared to 13% and 40% at admission, respectively. Similarly, increased bilirubin levels were seen in 53% of our cases before death compared to 13% at admission. In this respect, serum bilirubin,  $\gamma$ GT and ALP may serve as indicators of clinical deterioration in septic critically ill patients. Other studies, however, have showed conflicting data regarding the prevalence of abnormal liver tests in patients with bacteremia<sup>[2,8-10]</sup>. These discrepancies can be attributed to differences in patients' selection criteria as well as in the severity of the underlying disease.

Liver histology in sepsis has been evaluated mainly in animal studies and in postmortem human liver tissue where a significant time period had elapsed between autopsy and time of death<sup>[4,9,11-13]</sup>. In jaundiced septic patients, three histological patterns have been described in a limited number of studies<sup>[4,9,11]</sup>: canalicular cholestasis, usually most severe in zone 3, ductular cholestasis with inflammation and non-bacterial cholangitis associated with the toxic shock syndrome<sup>[12]</sup>. Intrahepatic cholestasis in septicemia could be attributed to many factors such as circulating endotoxin causing functional disorders in bile secretion, disturbances in bile canalicular contraction and ischemia<sup>[14-17]</sup>.

The lack of detailed histological data has led clinicians to evaluate sepsis-related liver damage from the serum biochemical markers while no studies have addressed the correlation between laboratory values and pathologic findings. In the current study, we have obtained liver tissue from our septic patients immediately after death leading to the most accurate identification of sepsis-related liver pathology. Our findings showed that sepsis is characterized by a "hepatitic" like liver injury in 60% of our patients and a "mixed", cholestatic and hepatitic type in 40% of them. Cholangitis and/or cholangiolitis were observed in a few patients. Additionally, ductular cholestasis, a sepsis-specific hepatic lesion<sup>[11,12]</sup>, suggesting increased risk of mortality<sup>[16]</sup> was identified only in two of our patients dying of sepsis, while canalicular cholestasis was present in one. Damage to bile duct epithelium has been previously observed in the liver of a female patient with *E. coli* septicemia<sup>[13]</sup>; however, it was not detected in any of our patients. The contrast between our histological findings and that of previous morphological studies where canalicular or ductular cholestasis predominated in the liver of jaundiced patients who died of sepsis, maybe attributed to the small

number of cases examined. The presence of mixed, cholestatic and hepatitic, features in the majority of our patients with hyperbilirubinemia may alternatively be the result of the direct effect of endotoxin or a drug-induced injury. Centrilobular hemorrhagic necrosis, which was common in our cases, is a frequent finding in livers from patients with peripheral circulatory failure<sup>[19]</sup>. Among the above histopathological findings, the presence of portal inflammation, a common finding in chronic hepatitis, was associated with prolonged hospitalization that may reflect the effect of prolonged exposure to treatment medication.

Steatosis was evident in the liver of most of our septic patients. In previous studies, although steatosis was a common finding in the post-mortem liver of septic patients, its extent and type has not been examined in detail or commented on<sup>[4,9,11]</sup>. The majority of our patients had moderate to severe fatty liver change comprising 40-80% of the liver parenchyma. It is known that sepsis and bacterial toxins may cause macrovesicular<sup>[20]</sup> or microvesicular steatosis<sup>[21]</sup> and hypoxia may play a role in these cases. Also, a wide variety of drugs and total parenteral nutrition may be responsible for the development of fatty liver change<sup>[20]</sup>.

Liver apoptosis can be ascribed to a wide variety of individually or simultaneously acting underlying mechanisms. Tissue hypoxia, inflammatory mediators, free radicals, bacterial toxins and drug toxicity are all implicated in the above mechanisms<sup>[3,20,22-23]</sup>. The presence of apoptosis was much more common in patients with more severe liver histology, as defined by the intensity of portal and lobular inflammation as well as the presence of lobular necrosis and the ductular cholestatic lesions. Prognostic determinants cannot be inferred from the current study, since all our patients succumbed due to multiple organ failure. However, the absence of pre-existing liver disease, as well as the fact that all biopsies were optimally performed immediately after death, suggests that the subsequent pathologic evaluation demonstrates terminal sepsis-related histologic changes in the liver parenchyma.

Summarizing our results, the liver of end stage patients mainly shows histopathological features of hepatitis injury, with additionally cholestatic findings along with steatosis. Biopsies were performed almost immediately after each patients death giving the most precise evaluation of sepsis-induced liver injury. Further studies are needed to clarify the role of apoptosis and application of innovative drugs in sepsis-induced liver injury.

## COMMENTS

### Background

Liver histology in sepsis has only been evaluated in animal studies and postmortem autopsies where a significant time period had elapsed between autopsy and time of death. The lack of histological data has led clinicians to evaluate sepsis-related liver damage from the serum biochemical markers while no studies have addressed the correlation between laboratory values and pathologic findings.

### Research frontiers

In jaundiced septic patients, three histological patterns have been described in a limited number of studies: canalicular cholestasis, usually most severe in zone 3, ductular cholestasis with inflammation and non-bacterial cholangitis associated

with the toxic shock syndrome. Intrahepatic cholestasis in septicemia could be attributed to many factors such as circulating endotoxin causing functional disorders in bile secretion, disturbances in bile canalicular contraction and ischemia.

### Innovations and breakthroughs

In order to perform a more accurate identification of sepsis related liver pathology, investigators performed liver biopsies immediately after death in fifteen septic patients. In the present study portal/lobular inflammation and/or centrilobular necrosis along with steatosis were the main findings in septic patients. Steatosis, a common finding in the post-mortem liver of septic patients was moderate to severe comprising 40%-80% of the liver parenchyma. Previous studies have shown cholestatic damage in liver parenchyma in post mortem septic specimens in contrast to the present study where cholestatic injury was present but not as frequent. The main advantage of the present study is the identification of the exact nature of sepsis related tissue abnormalities dissociated from the postmortem cellular events.

### Applications

The results of the present study further add to the understanding of the pathologic changes occurring in the liver of late stage septic patients. Further studies are needed in order to examine the exact role of cellular events in septic liver.

### Terminology

Portal inflammation: infiltration by inflammatory cells in portal tracts; Lobular inflammation: infiltration by inflammatory cells in hepatic lobules; Centrilobular necrosis: features of hepatocyte death in the center of lobules around terminal hepatic veins; Steatosis: accumulation of fat droplets in the cytoplasm of hepatocytes; Ductular cholestasis: accumulation of bile in bile ducts; Canicular cholestasis: accumulation of bile into bile canaliculi; cholestatic injury: damage in bile ducts due to cholestasis.

### Peer review

The exact nature of liver's histological changes in septic patients described in this study thought to be the hotspot of the article.

### Abstract

**AIM:** To investigate the relationship between loss of heterozygosity (LOH) for mannose 6-phosphate/insulin-like growth factor 2 receptor (M6P/IGF2R) and the outcomes for primary HCC patients treated with partial hepatectomy.

**METHODS:** The LOH for M6P/IGF2R in primary HCC patients was assessed using six different gene-specific nucleotide polymorphisms. The patients studied were enrolled to undergo partial hepatectomy.

**RESULTS:** M6P/IGF2R was found to be polymorphic in 73.3% (22/30) of the patients, and of these patients, 50.0% (11/22) had tumors showing LOH in M6P/IGF2R. Loss of heterozygosity in M6P/IGF2R was associated with significant reductions in the two year overall survival rate (24.9% vs 65.5%;  $P = 0.04$ ) and the disease-free survival rate (17.8% vs 59.3%;  $P = 0.03$ ).

**CONCLUSION:** These results show M6P/IGF2R LOH predicts poor clinical outcomes in surgically resected primary HCC patients.

Clinical significance of loss of heterozygosity for M6P/IGF2R in patients with primary hepatocellular carcinoma. *World J Gastroenterol* 2008; 14(9): 1394-1398 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1394.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1394>

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common type of malignancy, being especially prevalent in the Southeast Asian and sub-Saharan African populations<sup>[1]</sup>. Etiological risk factors for HCC formation include hepatitis virus infection, alcohol consumption and dietary exposure to aflatoxin B1<sup>[1,2]</sup>. In Korea and Taiwan, approximately 90% of all patients with HCC are Hepatitis B surface antigen (HbsAg)-positive, and prospective studies have found Hepatitis B virus carriers have a 200-fold increase in relative risk for HCC. The mannose 6-phosphate/insulin-like growth factor 2 receptor (M6P/IGF2R) is mapped at the chromosome location 6q25-27<sup>[3]</sup>, which is predicted to contain a liver tumor suppressor gene<sup>[4]</sup>. This gene encodes a receptor which functions in intracellular lysosomal enzyme trafficking, transforming growth factor beta (TGF- $\beta$ ) activation, and IGF2 degradation<sup>[5]</sup>. Granzyme B internalization by the M6P/IGF2R is also required for cytotoxic T cells to induce apoptosis in cells targeted for death, resulting in this receptor being referred to as a "death receptor"<sup>[6]</sup>. Elevated IGF2 levels during murine development arising from M6P/IGF2R deficiency result in cardiac abnormalities, cleft palate, fetal overgrowth and prenatal lethality<sup>[7]</sup>. Furthermore, the large-offspring syndrome found in cloned animals is frequently associated with epigenetic changes in M6P/IGF2R imprinting regulation which result in decreased gene expression<sup>[8]</sup>. Thus, M6P/IGF2R plays a crucial role in regulating mammalian fetal growth and development. M6P/IGF2R is also mechanistically involved in the genesis of human cancer<sup>[9-12]</sup>. M6P/IGF2R loss of heterozygosity (LOH), coupled with intragenic loss-of-function mutations in the remaining allele, is a common event in human cancers<sup>[6,10]</sup>. Tumor cell growth is inhibited when M6P/IGF2R expression is restored to normal, whereas it is increased when gene expression is reduced<sup>[13-16]</sup>. The results of

these mutational and functional studies clearly show M6P/IGF2R possesses the characteristics necessary to be classified as a tumor suppressor gene<sup>[17]</sup>. Our results show M6P/IGF2R LOH in primary HCC patients predicts poor therapeutic outcomes.

## MATERIALS AND METHODS

### Patients

Paraffin-embedded tissue sections from 30 patients, who were confirmed histopathologically to have HCC, were obtained from the Gyeongsang National University and the Catholic University of Korea. All patients had a history of hepatitis virus infection and/or cirrhosis, and had undergone partial hepatectomy for the treatment of their disease.

### Tissue microdissection and loss of heterozygosity analysis for M6P/IGF2R

Microdissection of 10- $\mu$ m histology sections from tumor tissue and the surrounding normal liver tissue was performed as described in previous studies<sup>[18,19]</sup>. Briefly, paraffin-embedded sections were deparaffinized in xylene (2  $\times$  5 min), exposed for 2 min to graded ethanol washes (namely, 100%, 95%, 70% and 50% ethanol) and rehydrated in H<sub>2</sub>O before staining. The tissue sections were then stained for 30 s with 2% methylene blue and rinsed in H<sub>2</sub>O before allowing them to air dry. Tumor tissue and the surrounding normal tissue (50-cells) were carefully microdissected using a serial section stained with hematoxylin-eosin for comparison. The normal tissue used for genotyping was connective tissue. The dissected tissues were then placed in 75  $\mu$ L of Tris-ethylenediamine-tetraacetic acid buffer (10 mmol/L Tris-HCl, pH 8.0 at 25°C and 0.5 mmol/L ethylenediamine tetraacetic acid, pH 8.0 at 25°C containing 5  $\mu$ L of 20 g/L proteinase K (Boehringer Mannheim, Indianapolis, IN). This mixture was incubated at 52°C for 3 h and then at 85°C for 10 min. Polymerase chain reaction (PCR) analysis was conducted using 5  $\mu$ L of this mixture, as described below. Six single nucleotide polymorphisms (Table 1), identified as c. 901C > G (exon 6), c. 1197A > G (exon 9), c. 1737G > A (exon 12), c. 2286A > G (exon 16), c. 6206A > G (exon 40) and c. X47-5t > a (exon 47), were also analyzed following 2 rounds of nested PCR. The exon-specific forward and reverse primers have been previously described<sup>[19,20]</sup>. The exons containing these polymorphisms were amplified by PCR from genomic DNA under conditions identical to those described above. The single nucleotide polymorphisms used to determine the loss of heterozygosity in M6P/IGF2R were assessed by directly sequencing the PCR products according to the manufacturer's protocol (Thermo Sequenase, USB Corporation, Cleveland, OH). Taq DNA polymerases may introduce sequence errors during PCR amplification, and unequal amplification of the two alleles can result in the false positive detection of a loss of heterozygosity. Thus, both normal and tumor DNA templates were amplified in three independent PCR reactions, and assessed for LOH in M6P/IGF2R.

Due to the potential for contaminating the tumor tissue sample with normal stroma, allele loss in informative patients was defined as a > 50% decrease in the ratio of

the two alleles in tumor tissue *versus* that in the surrounding normal stromal tissue. This was quantified using a densitometer.

### Statistical analysis

Overall survival and disease-free survival rate represented the clinical end-point. All curves were computed using the Kaplan-Meier method starting from the time of study entry. Curves for different sub-groups were compared by the Cox-Mantel test. A chi-squared test was used to compare the clinical characteristics between M6P/IGF2R-informative and M6P/IGF2R-excluded patients, and between informative patients with and without LOH in M6P/IGF2R. A  $P < 0.05$  was considered to be statistically significant.

## RESULTS

### Analysis of LOH in M6P/IGF2R

The study population consisted of a total of 30 patients who were enrolled in a retrospective clinical trial for primary HCC from March 1999 to June 2003 (Table 2). Among the 30 patients, 22 (73.3%) were informative (that is, polymorphic), and the tumors in 50% (11/22) of these patients exhibited LOH in M6P/IGF2R (Figure 1). There was no significant difference between M6P/IGF2R-informative patients and those not used in this study in terms of the clinical characteristics of sex, age, liver cirrhosis, tumor of differentiation, size of tumor, or type of hepatitis.

### Clinical outcome

The median follow-up for surviving patients enrolled in this trial was 33 mo (range: 2 to 62 mo). The median survival times were 34 mo and 23 mo for overall survival and disease free survival, respectively. There was no relationship between LOH in M6P/IGF2R and clinical factors, such as sex, age, liver cirrhosis, tumor differentiation, tumor size, or the type of hepatitis. The median overall survival times in patients with and without LOH in M6P/IGF2R were 18 mo and 44 mo, respectively, and the two year overall survival rates were 24.9% and 65.5%, respectively (log-rank,  $P = 0.04$ ) (Figure 2A). Likewise, the median disease-free survival rates in patients with and without LOH in M6P/IGF2R were 12 mo and 36 mo, respectively, and the 3 year disease-free survival rates were 17.8% and 59.3%, respectively (log-rank,  $P = 0.03$ ) (Figure 2B). The clinical relevance of LOH in M6P/IGF2R to both overall survival and disease-free survival rates was confirmed in the analysis ( $P < 0.05$  for both comparisons). These results indicate that LOH in M6P/IGF2R results in poor patient outcome when surgical resection is employed, since all other measured clinical characteristics of the primary HCC patients were comparable to those in patients with a non-mutated M6P/IGF2R tumor suppressor gene.

## DISCUSSION

M6P/IGF2R LOH occurs frequently in human breast, liver and lung cancer<sup>[9,10,20]</sup>. Mutation in M6P/IGF2R is

also commonly found in gastrointestinal and gynecological cancers, because the coding sequence of M6P/IGF2R contains a poly-G region, which is a mutational target in tumors with mismatch repair deficiencies and microsatellite instability<sup>[12,21]</sup>. Functional studies show the introduction of an exogenous wild-type M6P/IGF2R with a single inactivated allele into human colorectal cancer cells significantly decreases cell growth rate and enhances apoptosis<sup>[13]</sup>. Conversely, the loss of M6P/IGF2R expression promotes cancer cell growth by increasing intracellular signaling from both the receptors, the insulin-like growth factor 1 receptor and the insulin receptors<sup>[22]</sup>. Kong *et al*<sup>[10]</sup> demonstrated mutations in both alleles of the M6P/IGF2R are found in more than 50% of squamous cell carcinomas of the lung. In the present study, we demonstrated M6P/IGF2R LOH in primary HCC is also associated with poor patient prognosis. Loss of heterozygosity in malignancy can also occur due to chromosomal deletion or somatic recombination resulting in uniparental disomy<sup>[23]</sup>. Because chromosomal deletion can affect more than one gene, M6P/

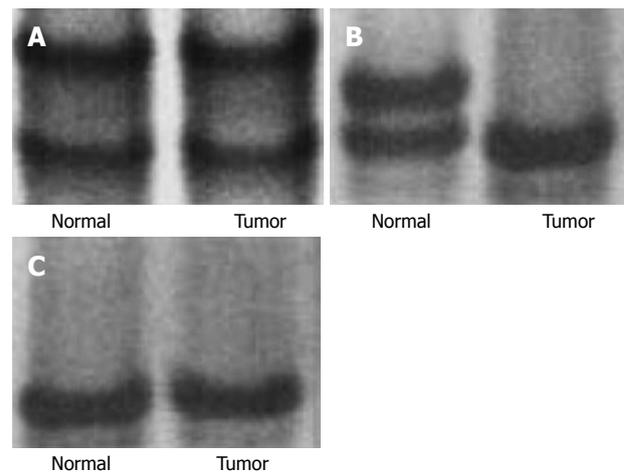

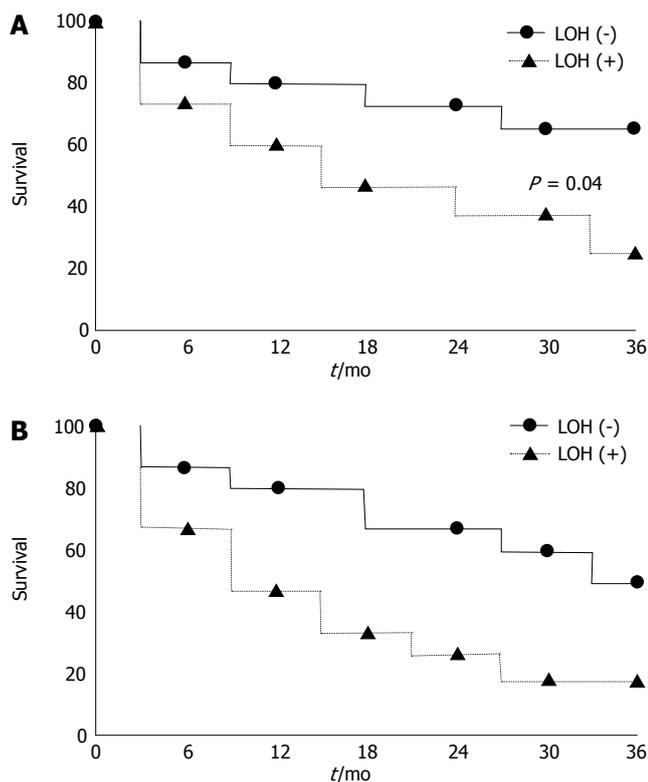

Figure 1 There are three results in the LOH analysis for M6P/IGF2R in primary hepatocellular carcinoma (HCC). A: Informative HCC without LOH in M6P/IGF2R; B: Informative HCC with LOH in M6P/IGF2R; C: Non-informative HCC.

IGF2R LOH does not rule out the possibility of a loss of adjacent genes with tumor suppressor functions in HCC. This study also showed improvements in overall survival and disease-free survival in those patients undertaking surgical resection for primary HCC with M6P/IGF2R LOH. It was found patients with mutations in M6P/IGF2R had a significantly worse prognosis than those who had a non-mutated M6P/IGF2R allele.

M6P/IGF2R is normally imprinted in mice, with only the maternal copy of the gene being expressed<sup>[24]</sup>. By contrast, both copies of M6P/IGF2R are expressed in humans, because genomic imprinting at this locus was lost in the primate lineage approximately 70 million years ago<sup>[25]</sup>. Importantly, the restoration of biallelic M6P/IGF2R expression in mice results in a marked reduction in offspring weight late in embryonic development that persists into adulthood<sup>[26]</sup>. This demonstrates that M6P/IGF2R allelic loss or haploid insufficiency markedly enhances cell proliferation and/or survival during fetal development. Therefore, the mutation of even a single allele of M6P/IGF2R in human somatic cells is predicted to promote cell growth. Haploid insufficiency of tumor suppressor genes, such as Nf2, p27<sup>Kip1</sup>, p53 and TGF- $\beta$ , is known to promote tumor formation<sup>[27-29]</sup>. Yamada *et al*<sup>[9]</sup> demonstrated that, in patients chronically infected with Hepatitis B and/or Hepatitis C viruses, mutations

**Figure 2** **A:** The overall survival according to loss of heterozygosity in M6P/IGF2R; **B:** The disease free survival according to loss of heterozygosity in M6P/IGF2R.

in M6P/IGF2R take place not only in HCC, but also in the phenotypically normal hepatocytes adjacent to these tumors. Interestingly, only one M6P/IGF2R allele is inactivated in the adjacent cirrhotic tissue, even when both alleles are mutated in the HCC. These findings are consistent with the normal appearing, preneoplastic hepatocytes forming clonal masses in the liver, because M6P/IGF2R haploid insufficiency affords them with a selective growth and/or survival advantage relative to normal hepatocytes<sup>[30]</sup>.

In conclusion, this study shows the analysis of M6P/IGF2R LOH provides clinical significance in surgically resected primary HCC patients.

## ACKNOWLEDGMENTS

This paper was presented in part at the 97th Annual Meeting of the American Association for Cancer Research, April 1-5, 2006, Washington, DC.

## COMMENTS

### Background

The associated nature of hepatocellular carcinoma (HCC) and mannose 6-phosphate/insulin-like growth factor 2 receptor (M6P/GF2R) is well reported. However, there is scant research on the clinical significance of loss of heterozygosity (LOH) in M6P/GF2R in patients with primary HCC. In the present study, we aimed to investigate the relationship between LOH for M6P/IGF2R and various factors, including survival rate, in primary HCC patients treated with partial hepatectomy.

### Research frontiers

Several studies have investigated various types of cancer, including HCC, in which

LOH for M6P/IGF2R might appear. We studied the relationship between LOH for M6P/IGF2R and HCC, and confirmed the survival rate is directly related to the LOH for M6P/IGF2R.

### Innovations and breakthroughs

The present research studied cases with primary HCC, but research on the usefulness of LOH for M6P/IGF2R should be continued by comparing cases with metastatic HCC, cholangiocarcinoma and other tumors.

### Applications

The results of this study suggest the presence of LOH for M6P/IGF2 may represent some poor prognostic factors in primary HCC patients treated with hepatectomy.

### Peer review

The paper represents a real advance in the loss of heterozygosity for M6P/IGF2R in patients with primary HCC. The conclusions are valuable. The methodology is correct and the results are well presented.

### Abstract

**AIM:** To assess the intestinal permeability (IP) in patients with Crohn's disease (CD) and study the association of IP with the patient and disease characteristics.

**METHODS:** One hundred and twenty five consecutive patients of CD (Males: 66) were diagnosed on the basis of a combination of standard clinical, endoscopic, imaging and histological features. CD activity index (CAI) was used to calculate the activity of the disease while the behavior of the disease was assessed by the modified Montreal classification. IP was measured by the ratio of the percentage excretion of ingested doses of lactulose and mannitol in urine (LMR). The upper limit of normality of LMR (0.037) was derived from 22 healthy controls.

**RESULTS:** Thirty six percent of patients with CD had increased IP. There was no significant difference in mannitol excretion (patients *vs* controls = 12.5% *vs* 14.2%,  $P = 0.4652$ ), but lactulose excretion was significantly higher in patients compared to healthy controls (patients *vs* controls = 0.326% *vs* 0.293%,  $P = 0.0391$ ). The mean LMR was also significantly higher in the patients as compared to healthy controls [0.027 (0.0029-0.278) *vs* 0.0164 (0.0018-0.0548),  $P = 0.0044$ ]. Male patients had a higher LMR compared to females [0.036 (95% CI 0.029, 0.046) *vs* 0.022 (95% CI 0.0178, 0.028) ( $P = 0.0024$ ), though there was no difference in the number of patients with abnormal IP in both

the sexes. Patients with an ileo-colonic disease had a higher LMR than those with only colonic disease [0.045 (95% CI 0.033, 0.06) *vs* 0.021 (95% CI 0.017, 0.025) ( $P < 0.001$ )]. Of patients with ileo-colonic disease, 57.8% had an abnormal IP, compared to 26.7% with colonic and 15.6% with small intestinal disease. Patients with a stricturing disease had significantly higher LMR compared to non-fistulising non-stricturing disease [0.043 (95% CI 0.032, 0.058) *vs* 0.024 (95% CI 0.019, 0.029) ( $P = 0.0062$ )]. There was no correlation of IP with age, disease activity, duration of illness, D-xylose absorption, upper GI involvement, perianal disease, and extra-intestinal manifestations. On multiple regression analysis, male gender and ileo-colonic disease were independent factors associated with increased IP. Gender, location, behavior of the disease and upper GI involvement could explain up to 23% of variability in IP ( $R^2 = 0.23$ ).

**CONCLUSION:** IP was increased in 36% of patients with CD. Male gender and an ileo-colonic disease were the independent factors associated with increased IP.

### INTRODUCTION

Intestinal permeability (IP) is the property of the intestinal epithelium which refers to the facility with which it allows molecules to pass through by non-mediated diffusion<sup>[1]</sup>. IP has been implicated in the pathogenesis and frequent relapses of Crohn's disease (CD)<sup>[2-6]</sup>. Seven to 18% higher relapse rate has been reported in patients with increased IP compared to those with normal IP<sup>[7-11]</sup>. Moreover,

10%-20% of healthy first-degree relatives have been also shown to have increase IP<sup>[4,12,13]</sup>. IP is measured as a ratio of two non-metabolizable probe molecules that pass across the mucosal barrier and are excreted in the urine. Quantitation of these probes in a timed urine collection provides a measure of the fraction of the ingested dose that penetrated the mucosal barrier<sup>[14]</sup>. The individual variations due to non-mucosal factors (gastric emptying, intestinal transit, dilution by secretions, renal clearance and incomplete urine recovery) are circumvented when the urinary recovery is expressed as a ratio, since both the sugars are equally affected by these factors except the route of permeation<sup>[15]</sup>. A few studies have reported the association of IP with activity and location of Crohn's disease; however, there is a lack of literature on the association of IP with the disease characteristics (duration, extent, behavior, extra-intestinal manifestations) and patient characteristics (age and gender). There are no reports on IP in Asian patients with CD. Hence, this study was planned to assess IP in patients with CD and also to explore the relationship of IP with the patient and disease characteristics.

## MATERIALS AND METHODS

### Patients

One hundred and twenty five consecutive patients with CD from the outpatient and inpatient of Gastroenterology Department, All India Institute of Medical Sciences, New Delhi, were studied between May 2005 and September 2006. The diagnosis of CD was made on the basis of clinical manifestations (chronic diarrhea, hematochezia, abdominal pain and intestinal obstructive symptoms), endoscopic features (skip lesions, asymmetrical involvement, deep ulcers, aphthous ulcers, ileocecal valve and terminal ileal involvement) and histological evidence (acute on chronic colitis, inflammation extending beyond muscularis mucosa, lymphoid follicles and non caseating granuloma). The involvement of small intestine was assessed by barium meal follow through, small bowel enema, magnetic resonance enteroclysis and/or retrograde ileoscopy. Disease activity was assessed using the Crohn's disease activity index (CDAI)<sup>[16]</sup>. The location and behavior of the disease were classified using the modified Montreal classification<sup>[17]</sup>. Patients were treated with maintenance doses of mesalamines and azathioprine, along with hematinics, multivitamins and calcium supplements. Those in the active phase of the disease were treated with steroids. None of the patients in active phase of the disease had any evidence of bacterial or parasitic infection at the time of inclusion into the study.

### Healthy controls

Twenty-two healthy controls comprising of hospital staff and family members of patients with a diagnosis other than inflammatory bowel disease were included to decide the upper limit of normality (cut-off) for lactulose mannitol ratio (LMR). None of the controls had signs and symptoms of gastrointestinal disorders; renal diseases, diabetes and none of them had taken NSAIDs for at least

four weeks prior to the test. None had a history of alcohol intake and smoking.

**Ethical Consideration:** The Ethics Committee of our institution approved the study. An informed consent was taken from all the participants.

### Assessment of intestinal permeability

IP was measured using the lactulose and mannitol (L:M) excretion test in all the patients and healthy controls. The results were expressed as the ratio of percentage excretion of the ingested dose of lactulose and mannitol in urine [lactulose mannitol ratio (LMR) = % lactulose/% mannitol].

### Test procedure

After an overnight fast, the patients evacuated the urinary bladder, collected a pre-test sample and then drank the test solution containing 5 g of lactulose, 2 g of mannitol and 5 g of D-xylose in 100 mL water. No food or drink other than water was allowed until the completion of the test. Water was permitted after one hour of the ingestion of the test solution. All the urine passed in the subsequent five hours was collected into a plastic can containing 20% chlorhexidine as a preservative. Aliquots of the collected urine were stored at -20°C until analysis. Patients were instructed to abstain from NSAIDs for four weeks prior to the test. All the patients and controls tolerated the test solution well.

### Estimation of mannitol in urine

This test was based on the principle of oxidation of mannitol to formaldehyde by periodic acid. The formaldehyde so produced was measured by the method of MacFadyen as described by Corcoran and Page<sup>[18]</sup>.

Periodic acid (0.03 mol/L in 0.25 mol/L sulfuric acid; 500 µL) was added to 2 mL of urine specimen in a test tube and kept at room temperature for 10 min. Stannous chloride (0.125 mol/L; 500 µL) was added to the sample and mixed well. Oxidation of stannous chloride to stannic acid produced a milky precipitate, which was dissolved by adding 5 mL of chromotropic acid reagent. The tubes were then placed in a boiling water bath for 30 min. After cooling the tubes the volume of the solution was made up to 25 mL by adding distilled water and the temperature was stabilized at 25°C in a water bath. A reagent blank was prepared containing 2 mL of distilled water instead of sample and was treated in the same manner along with the sample tubes. The optical density was measured at 570 nm using a spectrophotometer<sup>[18]</sup>.

### Estimation of lactulose in urine

The estimation of lactulose was based on the enzymatic assay of fructose which was produced after the hydrolysis of lactulose to fructose and galactose. In a series of enzymatic reactions, fructose was converted to NADPH. The amount of NADPH produced was directly proportional to lactulose concentration, which was measured by the change in absorbance at 340 nm on a spectrophotometer<sup>[19]</sup>. D-xylose was estimated in urine using the standard method of Roe and Rice<sup>[20]</sup>.

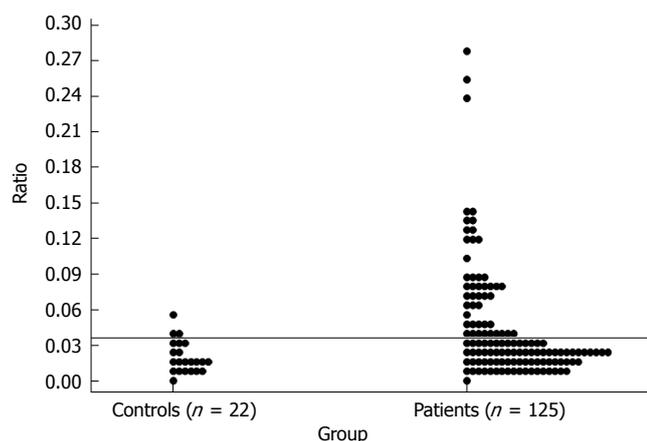

Figure 1 Upper limit of normality for lactulose mannitol ratio (LMR).

### Estimation of the cut-off for the LMR

The results of the LMR in the healthy controls were used to fix the upper limit of IP at one tailed 90% tolerance interval. Since the distribution of LMR in controls was non-normal, a square root-transformation was carried out to determine the mean and standard deviation (SD) and subsequently the cut-off value was established as mean + 1.28 SD of the square root of LMR, assuming that in normal population 10% subjects will have abnormal IP. Thus obtained cut off value would correspond to the 90th percentile. A LMR of > 0.0373 was considered abnormal (Figure 1).

### Statistical analysis

STATA 9.0 (College station, TX, USA) statistical software was used for data analysis. The data were expressed as number (percentage), median (range) and mean (95% CI). The difference in proportions of abnormal IP between different categories of disease area, behavior, activity and gender were compared using  $\chi^2$  test. Non-normal continuous variables were compared between the patients and controls using non-parametric test (Wilcoxon rank-sum test). Bivariate analysis was done using *t*-test, ANOVA or Spearman's correlation as appropriate followed by multiple regression analysis to find the factors related with increased IP. The *P*-value < 0.05 was considered statistically significant.

## RESULTS

The median (range) age of 125 patients was 36 (14-66) years. The median (range) duration of the disease was 50 (3-432) mo. The duration of the disease was less than 36 mo in 52 (41.6%) and more than that in 73 (58.4%) patients. The distribution of the patients according to activity, duration, location, and behavior of the disease is shown in Table 1.

Twenty three (18.4%) patients had involvement of the UGI tract, of which 6 (26.08%) had ileal, 6 (26.08%) had colonic and 11 (47.8%) had ileo-colonic involvement.

Table 2 Comparison of intestinal permeability and D-xylose absorption between patients and healthy controls

Parameter	Patients ( <i>n</i> = 125)	Controls ( <i>n</i> = 22)	<i>P</i> value
Lactulose excretion (%)	0.326 (0.0204-2.76)	0.293 (0.0089-0.665)	0.0391 <sup>a</sup>
Mannitol excretion (%)	12.5 (1.43-43.75)	14.2 (4.95-30.8)	0.4652
Lactulose mannitol ratio (LMR)	0.027 (0.0029-0.278)	0.0164 (0.0018-0.0548)	0.0044 <sup>a</sup>
D-xylose (g/5 g per 5 h)	1.45 (0.32-4.5)	1.89 (0.80-4.73)	0.0277 <sup>a</sup>

All values expressed as median (range); <sup>a</sup>*P* < 0.05.

of LMR and D-xylose excretion are shown in Table 2. Using the upper limit of normality for LMR at 0.0373, 45 of 125 (36%) patients had an abnormal IP, while 80 (64%) had a normal IP.

### Lactulose, mannitol and D-xylose excretion in healthy controls and patients with CD

As shown in Table 2 there was no significant difference in percentage excretion of mannitol in patients and healthy controls (*P* = 0.4652). The percentage excretion of lactulose was significantly higher in patients compared to healthy controls (*P* = 0.0391). Similarly, the LMR was higher in the patients compared to healthy controls (*P* = 0.0044). D-xylose excretion was also significantly low in patients compared to healthy controls (*P* = 0.0277).

D-xylose (g/5 g per 5 h)	-0.1210

#### Relationship of LMR with patient and disease characteristics

As shown in Table 3, male patients had a significantly higher LMR in comparison to that in females ( $P = 0.0024$ ). There was no difference in the number of patients with abnormal IP in both the sexes ( $P = 0.05$ ). There was no significant correlation between IP and age of the patients (Table 4).

**LMR and location of the disease:** On comparison of LMR in patients with different location of the disease (L1, L2, L3), a significant ( $P = 0.0001$ ) difference was found. Patients with ileo-colonic involvement had a higher LMR in comparison to those with only colonic involvement ( $P = 0.0001$ ). Higher percentage (57.8%) of patients with ileo-colonic disease had abnormal IP compared to the colonic (26.7%) and small intestine (15.6%) disease, which was statistically significant ( $P < 0.001$ ).

**LMR and behavior of the disease:** There was a significant difference ( $P = 0.0062$ ) in the LMR of patients with different behavior of the disease (B1, B2, B3). Patients with stricturing disease (B2) had significantly higher LMR in comparison to those with a non-fistulizing and non-

**Table 5** Assessment of the effect of disease and patients characteristics on log LMR using multiple regression analysis

Variable	Regression co-efficient $\beta$ (95% CI)	
	Unadjusted	Adjusted

Area		
Small intestine only <sup>1</sup>		
Large intestine only	-0.284 (-0.764, 0.196)	0.002 (-0.539, 0.543)
Ileo-colonic	0.475 (-0.020, 0.971)	0.579 (0.065, 1.09) <sup>a</sup>
Behaviour		
Non-fistulizing non-stricturing <sup>1</sup>		
Stricturing disease	0.587 (0.230, 0.945)	-0.237 (-0.763, 0.288)
Fistulizing disease	0.152 (-0.366, 0.670)	0.085 (-0.457, 0.628)
Upper GI involvement		
Absent <sup>1</sup>		
Present	0.437 (0.019, 0.856)	0.233 (-0.163, 0.630)

$R^2 = 23\%$ , <sup>a</sup> $P < 0.05$ , significant sqrt-square-root transformation. <sup>1</sup>Reference category;  $\beta$ : Regression coefficient; CI: Confidence interval.

stricturing disease ( $P = 0.004$ ). Higher percentage (46.7%) of patients with a stricturing disease had abnormal IP compared to the non-stricturing non-fistulizing (42.2%) and fistulizing (11.1%) disease ( $P = 0.006$ ).

**LMR and UGI involvement, perianal disease and extra-intestinal manifestations:** There was no significant difference in the LMR of the patients with and without extra-intestinal manifestations and perianal disease ( $P > 0.05$ ). However, patients with an UGI involvement had a significantly higher LMR as compared to those without an UGI involvement ( $P = 0.046$ ).

**LMR and activity and duration of the disease:** Twenty eight of 83 (33.7%) patients in the remission phase and 17 of 42 (40.47%) in the active phase of the disease had increased IP, however, it was not statistically significant. Spearman's correlation did not show any association of LMR with activity and duration of the disease (Table 4).

#### Factors associated with increased IP

Sex, area, behavior and UGI involvement were the significant factors on a bivariate analysis. A multiple regression analysis revealed that all these factors could explain up-to 23% of variability in IP ( $R^2 = 0.23$ ) (Table 5). Out of all these factors gender of the patients and ileo-colonic disease were independent factors associated with increased IP.

On an average, log LMR value among males was 0.429 (95% CI 0.130, 0.727) more as compared to log LMR value in females. Patients with ileo-colonic disease on an average had a 0.58 (95% CI 0.065, 1.09) log units increase in the LMR compared to those with a small intestine disease (Table 5). Thus, male sex and ileo-colonic disease were found to be a risk factor for increased IP in patients with CD.

## DISCUSSION

In our study, 36% of patients with CD had increased

intestinal permeability. Males, patients with ileo-colonic disease, stricturing disease and those with UGI tract involvement had a significantly higher IP than females, patients with colonic disease, those with non-stricturing non-fistulizing disease and those without the UGI tract involvement, respectively. All these factors together could explain up to 23% of variability in IP. Male sex and ileo-colonic location of the disease were the independent factors associated with increased IP. However, there was no correlation of IP with age, duration, activity of the disease and D-xylose absorption.

Thirty three to 68% patients with CD have been reported to have increased IP using a variety of marker probes such as polyethylene glycol (PEG) 400, PEG 1000,  $^{51}\text{CrEDTA}$ ,  $^{99\text{m}}\text{TcDTPA}$ ,  $^{51}\text{CrEDTA}/^{14}\text{C}$ -mannitol, lactulose, mannitol, rhamnose and cellobiose<sup>[21-24]</sup>. In this study, we used lactulose and mannitol (L/M) excretion to quantify IP. L/M test is a simple, non-invasive, reliable and a frequently used test for estimation of IP in clinical practice<sup>[25,26]</sup>. Our study showed that IP, as assessed by LMR, was significantly higher in patients compared to the healthy controls. There was no difference in the mannitol excretion amongst patients and controls, but the excretion of lactulose, was significantly higher in patients as compared to controls. Therefore, an abnormal LMR was due to higher excretion of lactulose in the urine than a reduced excretion of mannitol. Pearson *et al*<sup>[15]</sup>, Murphy *et al*<sup>[3]</sup>, Wyatt *et al*<sup>[7]</sup>, and Katz *et al*<sup>[27]</sup> have also reported similar findings. The probes used to measure IP are water soluble, which cannot penetrate the lipid cell membrane of enterocytes and thus use the paracellular route through the tight junctions (TJs) for permeation. There is a difference between the TJs of the villous tips and villous crypts. The smaller probes can easily pass through the small, more numerous and more accessible TJs of the villous tips, whereas the larger probes make use of the larger, less accessible, and less numerous pores at the crypt of the villous<sup>[28,29]</sup>. While mannitol uses predominantly smaller and more numerous TJs at the villous tips, lactulose being a bigger molecule passes through larger pores in the crypts of the villous. As patients with CD do not generally have diffuse villous atrophy, the mannitol excretion remains unaffected in them and this could explain a normal mannitol excretion values observed in this study. Contrary to this, villous atrophy is the hallmark of celiac disease, which results in loss of smaller TJs at the villous tips, thus affecting excretion of mannitol<sup>[15,30]</sup>. Therefore, an increased IP observed in patients with CD, is predominantly because of increased permeation of lactulose, possibly due to defective TJs at the crypt. Nonetheless, one study has shown a decreased mannitol excretion in patients with CD as compared to the healthy controls<sup>[31]</sup>, where reduced mannitol absorption reflects a reduction in the absorptive area of mucosa rather than change in mucosal leakiness.

We did not find any correlation between IP and age of the patients. Similar findings have been shown by Soderholm *et al*<sup>[23]</sup>. While Munkholm<sup>[32]</sup> and Jogerson *et al*<sup>[21]</sup> found a negative correlation of age with the absorption of mannitol and excretion of  $^{51}\text{CrEDTA}$ , respectively.

Male sex was found to be a risk factor for increased IP on a multiple regression analysis in this study. Jorgensen *et al* reported an association between the male gender and increased permeation of  $^{14}\text{C}$ -mannitol<sup>[21]</sup>. On the contrary, Soderholm *et al*<sup>[23]</sup> did not find any correlation between IP and gender of the patients with CD. The reason of higher IP in male patients is not clear. We presume that it may be attributed to some other environmental factors, like consumption of tobacco and alcohol which was only prevalent among males in our study.

We also observed a significantly higher IP in patients with ileo-colonic disease as compared with those with only a colonic disease. Ukabam *et al*<sup>[31]</sup> and Ainsworth *et al*<sup>[33]</sup> have also reported a significantly increased IP in patients with ileal CD than those with colonic CD using L/M ratio and  $^{51}\text{CrEDTA}$ , respectively. Peters *et al*<sup>[22]</sup> reported a significantly higher median permeability of  $^{51}\text{Cr}$  EDTA in patients with ileal CD compared to normal controls; no significant difference was seen in patients with colonic CD and normal controls. The possible reason that could be given in support of our findings is the choice of marker probes. Different marker probes with regional selectivity are used to study IP in different locations of GI tract. Sucrose is used for gastric and proximal duodenal permeability; lactulose and mannitol for small intestine permeability; sucralose, poly sucralose and EDTA for both large and small intestine permeability<sup>[28]</sup>. Nevertheless, most of the probes are much better in detecting the permeability abnormalities of the small intestine than that of the colon<sup>[34]</sup>. Moreover, mannitol permeability does not differentiate between CD of the small intestine and large intestine. Abnormal IP in patients with ileo-colonic involvement in this study may be a reflection of selection of a marker probe, which assessed the small intestinal permeability only. In a few studies on the other hand, no relation was observed between IP and location of the disease<sup>[23,27,35]</sup>. No association was found between IP and perianal disease.

It was also seen that patients with a stricturing disease had a significantly higher LMR than a non-fistulizing non-stricturing disease. Similar observations have not been reported in the English literature to the best of our knowledge. We also hypothesize that an abnormal IP might lead to frequent and prolonged relapses, which in turn may have lead to the development of intestinal strictures.

Increased IP, molecular mimicry, translocation of antigens and circulating cytokines are the proposed pathogenic mechanisms of extra-intestinal manifestations in patients with CD<sup>[36]</sup>. We, however, did not observe an association between increased IP and extra-intestinal manifestations in this study.

A number of studies have reported a relationship between abnormal IP and the activity of the disease<sup>[3,5,37,38]</sup>. In some reports it has been observed that the magnitude of alterations in L/M ratio increases with the increase in disease activity index. In fact, assessment of IP has been recommended as a more objective way of assessing the activity and severity of the disease<sup>[39]</sup>. But, we did not find any correlation between L/M ratio and activity of the disease. Though there were a greater number of patients

with abnormal IP in the active phase of the disease than in the remission phase, this did not, however, reach a value of statistical significance. Ukabam *et al*<sup>[31]</sup> and Soderholm *et al*<sup>[23]</sup> also did not observe a relationship between IP and activity of the disease. Similarly, Turck *et al*<sup>[35]</sup> reported that the highest excretion values of <sup>51</sup>Cr EDTA were not always observed in children with the most active CD.

In conclusion, we observed increased intestinal permeability in 36% of patients with CD and this was mainly because of the increase in the excretion of lactulose. Male gender and ileo-colonic involvement were independent risk factors for increased intestinal permeability in our patients.

## ACKNOWLEDGMENTS

The authors are grateful to Dr. A Srinivasan, Associate Professor, Department of Biophysics, All India Institute of Medical Sciences, New Delhi for his continuous intellectual inputs in conducting this study. We are also thankful to all the patients and healthy volunteers who willingly participated in this study.

## COMMENTS

### Background

Intestinal permeability (IP) is an important aspect of the gut barrier function of the intestinal mucosa. Its role has been emphasized recently in a number of conditions including Crohn's disease (CD). In case of CD it has been implicated in its etiopathogenesis, assessment of the disease activity, and a predictor of relapse. The incidence of CD has been recently reported to be on a rise in the Asian countries including India. Hence, we decided to study IP and its correlation with the patient and disease characteristics in Crohn's disease in India

### Research frontiers

There are a number of studies from the western world on the study of IP. It has been reported that IP may be abnormal even in those with a macroscopically normal gut. It is believed that IP is maintained by the tight junctions (TJs). It will be interesting to further study that apart from atrophy of the mucosal surface what else makes the TJs ineffective. Probability of some defect or abnormality in TJs proteins has been suggested for the abnormal IP. It will be further interesting to know the characterization of these proteins and then improve upon them by some intervention

### Innovation and breakthroughs

There are several studies reporting abnormal IP not only in CD, but also in blood relations of the patients. There is also a case report where a patient with abnormal IP ultimately developed CD. There have been no reports on IP in Asian patients with CD. Hence this study is an initial attempt in this direction to study IP and identify those patients & disease characteristics which might influence IP in patients with CD.

### Application

Our study reveals that up to 36% of patients have abnormal IP. This shows that IP in Indian patients is the same as that of the western population. We thought that India, being a tropical country, might have greater prevalence of abnormal IP than the western world. The gender difference shown in IP in our patients signifies that there may be a variation in the presentation and clinical course of the disease in both the sexes, as has been reported in pediatric patients with CD.

### Terminology

Intestinal permeability (IP): IP can be defined as the property of the intestinal epithelium or of a membrane which refers to the facility with which it allows molecules to pass through by non-mediated diffusion. Tight Junctions (TJs): The tight junctions encircle epithelial cells at the apical pole, being a narrow belt that

both connects adjacent cells and maintains cell polarity. TJs represent the gating mechanism in the paracellular pathway.

## Peer review

This research adds to the growing body of literature regarding intestinal permeability in a variety of pathogenic states including inflammatory bowel disease. It suggests that the underlying mucosal defect is at the crypt and not at the villous level and thus it yields a new level of understanding to the underlying mechanism.

Scintigraphic evaluation of gallbladder motor functions in *H pylori* positive and negative patients in the stomach with dyspepsia. *World J Gastroenterol* 2008; 14(9): 1406-1410 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1406.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1406>

### Abstract

**AIM:** To evaluate the relationship between gallbladder (GB) motor function and *H pylori* infection in the stomach.

**METHODS:** All cases (86) underwent the  $^{14}\text{C}$  urea breath test (UBT).  $^{14}\text{C}$ -UBT was found as positive in 58 and negative in 28 dyspeptic patients.  $^{14}\text{C}$ -UBT was accepted as a gold standard test. Clo test and histopathologic examination were compared with the results of  $^{14}\text{C}$ -UBT in cases who tolerated upper gastrointestinal endoscopy procedure. Cholescintigraphy with  $^{99\text{m}}\text{Tc}$ -mebrofenin was used to determine the parameters of GB motor function (GB filling and emptying time, half of the emptying time, ejection fraction at 30th and 60th min) in all patients.

**RESULTS:** We found the sensitivity and specificity as 88% and 86% for Clo test and as 89% and 80% for histologic evaluation, respectively. The parameters of GB function were not significantly different in *H pylori* positive and negative patients. The GB emptying was normal in both groups. Minimum GB filling time was 30 min in 34 of 86 cases (39.5%), filling was not observed in 2 cases. The GB ultrasonography (USG) results were normal for all cases and bile composition abnormality was not determined.

### INTRODUCTION

The *H pylori* infection is one of the most common chronic infections in humans<sup>[1,2]</sup>. The *H pylori* colonizing on the surface of the upper gastrointestinal mucosa is an interesting cause of active chronic gastritis and duodenitis or even gastric cancer worldwide<sup>[2-7]</sup>. The presence of *H pylori* infection could predispose to various disorders<sup>[8-14]</sup>. Dental disease might be associated with a higher recurrence of *H pylori* infection<sup>[9]</sup>. Some investigators have recently demonstrated the evidences that *H pylori* infection induced atherosclerosis and that *H pylori*-anti-heat-shock protein antibodies have been related to the prevalence of diseases such as coronary artery disease or cerebral infarction, resulted from atherosclerosis<sup>[10,11]</sup>. The *H pylori* may play a role in the pathogenesis of slow coronary flow *via* the elevation of homocysteine, and/or a possible disturbance in its metabolism<sup>[12]</sup>.

The *H pylori* is present in about 67%-100% of duodenal ulcer patients and 13%-61% of normal population<sup>[13]</sup>. The *H pylori* infection can be diagnosed by invasive techniques requiring endoscopy and biopsy (eg, histological examination and culture) and by noninvasive techniques such as serology, urea breath test or detection of *H pylori*

antigen in stool specimen<sup>[1,16]</sup>. Urea breath tests (UBT) are based on the principle that urease activity is present in the stomachs of individuals infected with *H pylori*. The UBT is considered as the gold standard in the diagnosis of *H pylori* among the noninvasive tests<sup>[16-19]</sup>.

Gallbladder (GB) diseases are related more to an emptying abnormality than to resting volume changes<sup>[20]</sup>. Cholescintigraphy using <sup>99m</sup>Tc-hepatobiliary iminodiacetic acid (HIDA) is a scintigraphic technique for measuring GB emptying. Cholescintigraphy is used to show both morphological and physiological changes in GB. Since physiological changes usually precede morphological alterations by several weeks or months, there is a great potential for early diagnosis by scintigraphy, before irreversible functional changes take place. The main advantage of cholescintigraphy is that the technique is noninvasive, quantitative, reproducible and has a low interobserver error<sup>[20-24]</sup>. Dynamic biliary scintigraphy can measure biliary motor functions noninvasively and quantitatively in *H pylori* positive and negative patients with dyspepsia<sup>[22]</sup>. Few reports have been published on the relationship between gallbladder emptying in patients with *H pylori* positive and negative idiopathic dyspepsia<sup>[22,26]</sup>. Studies performed on this topic have not shown that dyspepsia could be related to gallbladder function.

The association between GB emptying and gastric emptying in dyspeptic patients has been investigated with several techniques such as real time ultrasonography, scintigraphy for gastric emptying, hepatobiliary scintigraphy and the emptying time was found similar for both of them<sup>[25,26]</sup>. There is no literature available to confirm the effects of *H pylori* on the GB and gastrointestinal motor functions and regarding the relationship between these functional disorders and dyspeptic symptoms.

The objective in our study was scintigraphic evaluation of GB motor functions in *H pylori* positive and negative patients affected by dyspepsia.

## MATERIALS AND METHODS

### Patients and data collection

The study included 86 patients (44 male, 42 female) with symptoms of dyspepsia. These patients had no other complaints or systemic diseases and were not on any medications. The permission of the study was given by local ethic committee.

The *H pylori* was determined in each patient with <sup>14</sup>C-UBT (Isotopes Co. Ltd. institute, Noster Sys. AB, HELIPROBE) as a gold standard as it is noninvasive, easy to perform and cheap diagnostic method for *H pylori*. Before the <sup>14</sup>C-UBT, the subject fasted for at least 6 hours. *H pylori* positive 58 patients (23 female, 35 male; mean age 41 years) as study group and *H pylori* negative 28 subject (19 female, 9 male; mean age 45 years) as control group were studied. Written informed consent was obtained for each patient. The subjects were given <sup>14</sup>C-urea capsule orally with 20 mL water. After 15-30 min, the subject exhaled into the BreathCard. The average breathing time was approximately 1-2 min. The Heliprobe BreathCard was put into slot of the Heliprobe Analyzer and after pressing start button, the

analyzer was measured within 4 min. The analysis is based on the number of emitted  $\beta$ -particles and is presented as decay per min (DPM) together with the test result < 50 DPM (0, negative), 50-199 DPM (1, equivocal), and  $\geq$  200 DPM (2, positive). Within one week, the urease test (Clo test) and histopathologic examination were compared with the results of <sup>14</sup>C-UBT in cases who tolerated upper gastrointestinal endoscopy procedure. Upper gastrointestinal endoscopy (Olympus GIF 1T 30) with biopsies from antrum and corpus was performed in total of 74 cases (52 patients and 22 control subjects) after history and physical examination were obtained. Twelve cases (6 patients and 6 control subjects) could not tolerate endoscopic examination.

After <sup>14</sup>C-UBT, every patient was defined by using cholescintigraphy with <sup>99m</sup>Tc-mebrofenin to determine the parameters of GB motor function.

### Dynamic Cholescintigraphy

After 6-8 h of fasting, all patients were injected intravenously 5 mCi of <sup>99m</sup>Tc Mebrofenin (NYCOMED AMERSHAM SORIN S.r.l., BRIDATEC) while lying supine underneath a gamma camera fitted with a 140-keV low energy, all purpose, parallel-hole (LEAP) collimator. The gamma camera (GE- Milenium Acq, entegra) was connected to a computer, which enabled simultaneous data acquisition in a 128  $\times$  128 matrix. Dynamic acquisition was started at time 0 min with simultaneous administration of a bolus injection of <sup>99m</sup>Tc Mebrofenin and was obtained (15 s/frame) for 5 min. After this acquisition, gallbladder filling was observed for approximately 30-60 min and at max. filling time, orally a standard fatty meal (100 g milky chocolate) instead of CCK (sincalide, kinevac) was ingested in the sitting position to stimulate gallbladder emptying. This has provided a physiological stimulation of GB contraction and prevented the false positive results. During the following 15 min, dynamic acquisition was started while lying supine with 30 s/frame and acquisition continued for 60-90 min thorough GB emptying (Figures 1 and 2).

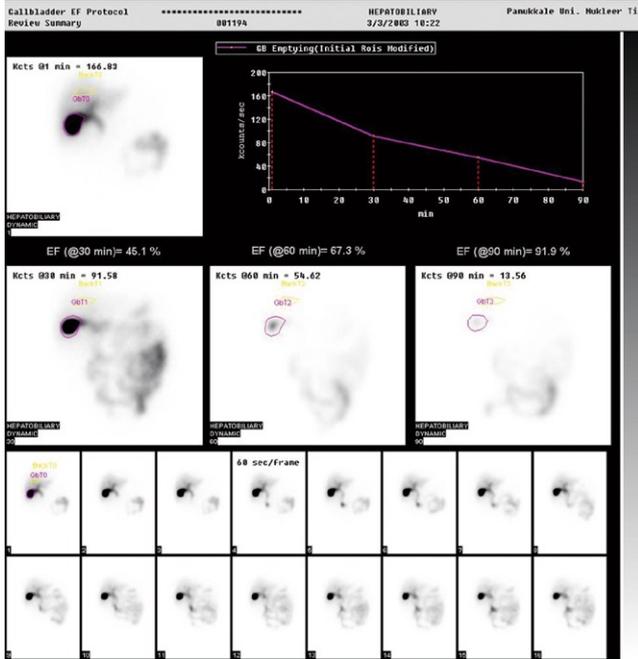

All of the summed dynamic images (before and after oral stimulation of GB emptying) were evaluated with the raw data and cine projections from the computer.

We calculated the following parameters to describe GB emptying: (1) The filling time of gallbladder (GBFT): Time (min) for maximum counts per min during the interval between the filling period of gallbladder and meal ingestion; (2) Gallbladder Ejection Fraction (GBEF) at 30 min and 60 min; (3) Gallbladder half emptying time (GB  $t_{1/2}$ ): This parameter was calculated automatically from the time-activity curve on the computer (GE Entegra).

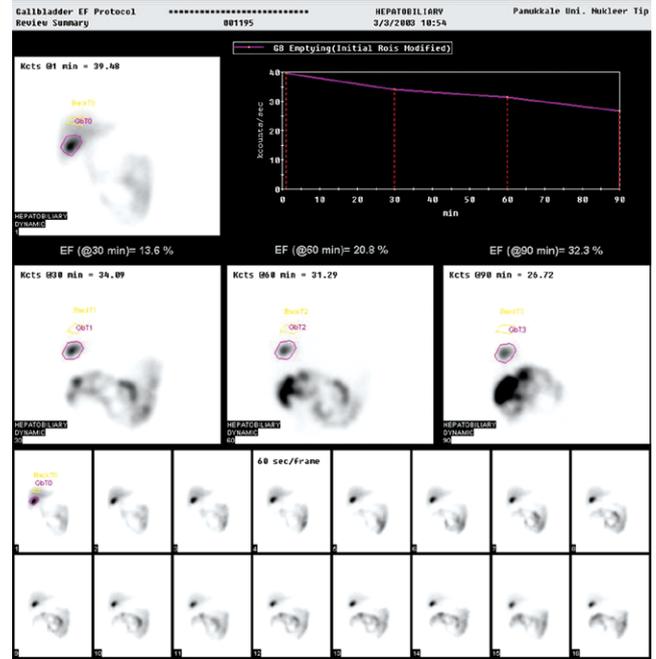

To determine interobserver variation, GBEF (for 30 min and 60 min) was calculated independently by two separate observers (experienced and inexperienced nuclear medicine physicians) at separate times.

### Statistical analysis

Data were analyzed with the SPSS 10.0 program. Statistical analysis was performed by using student's *t* test and *P* < 0.05 was considered as statistically significant. The data was presented as mean  $\pm$  SE or as mean  $\pm$  SD.

**Figure 1** The image of a normal <sup>99m</sup>Tc-mebrofenin cholescintigraphy. Emptying of the whole gallbladder content takes almost 90 min.

**Figure 2** Emptying of the gallbladder content was slower and did not complete during the study in case with impaired GB functions.

**Table 1** Gallbladder motor function parameters in *H pylori* positive and negative patients (mean ± SE)

<sup>14</sup> C-UBT	GBFT (min)	GB t1/2 (min)	GBEF <sub>30</sub> (A) %	GBEF <sub>60</sub> (A) %	GBEF <sub>30</sub> (B) %	GBEF <sub>60</sub> (B) %
Positive (n = 58)	53.71 ± 3.49	44.15 ± 4.38 (n = 27)	36.58 ± 5.82 (n = 36)	52.88 ± 5.38 (n = 33)	35.55 ± 4.07 (n = 40)	53.86 ± 5.06 (n = 36)
Negative (n = 8)	61.21 ± 4.50	51.08 ± 4.43 (n = 12)	24.35 ± 3.80 (n = 20)	47.11 ± 5.88 (n = 19)	26.38 ± 3.53 (n = 21)	47.55 ± 4.57 (n = 20)

GBFT: Gallbladder filling time; GB t1/2: Gallbladder half emptying time; GBEF<sub>30</sub>: Gallbladder ejection fraction at 30 min; GBEF<sub>60</sub>: Gallbladder ejection fraction at 60 min; A: Experienced observer; B: Inexperienced observer.

**RESULTS**

<sup>14</sup>C-UBT was found as positive in 58 dyspeptic patients (35 male, 23 female, mean age of 41 years) and negative in 28 patients (9 male, 19 female, mean age of 45 years). In 74 cases, the sensitivity and specificity were determined as 88%-86% for Clo test and as 89%-80% for histologic evaluation respectively.

The parameters of GB function were not significantly different in *H pylori* positive and negative patients (*P* > 0.05) (Table 1). The GBFT of <sup>14</sup>C-UBT positive patients (53.71 ± 3.49 min) did not differ significantly from that of <sup>14</sup>C-UBT negative patients (61.21 ± 4.50 min) (*P* > 0.05). Minimum value of GBFT was 30 min and gallbladder filled at 30 min in 34 (39.5%) of the 86 cases. Two subjects who are one subject from *H pylori* positive group and the other one from negative group did not show gallbladder filling until the end of the acquisition. In 27 of 58 <sup>14</sup>C-UBT positive patients (46.55%) and in 12 of 28 <sup>14</sup>C-UBT negative patients (42.85%), GB emptying was observed (Figure 1). The GB t1/2 was 44.15 ± 4.38 min and 51.08 ± 4.43 min for <sup>14</sup>C-UBT positive and negative patients, respectively and no significant difference was found between the two groups (*P* > 0.05). Mean GBEF values at 30 min (GBEF<sub>30</sub>) and at 60 min (GBEF<sub>60</sub>) obtained by the experienced observer (A) in <sup>14</sup>C-UBT positive patients

**Table 2** Correlation values of GBEF<sub>30</sub> and GBEF<sub>60</sub> between two observers in <sup>14</sup>C-UBT positive and negative patients

	A	B	r value
<sup>14</sup> C-UBT Positive			
GBEF <sub>30</sub>	36.58 ± 5.82	35.55 ± 4.07	0.78
GBEF <sub>60</sub>	52.88 ± 5.38	53.86 ± 5.06	0.94
<sup>14</sup> C-UBT Negative			
GBEF <sub>30</sub>	24.35 ± 3.80	26.38 ± 3.53	0.88
GBEF <sub>60</sub>	47.11 ± 5.88	47.55 ± 4.57	0.88

GBEF<sub>30</sub>: Gallbladder ejection fraction at 30 min; GBEF<sub>60</sub>: Gallbladder ejection fraction at 60 min; A: Experienced observer; B: Inexperienced observer; r value: Correlation coefficient.

were 36.58% ± 5.82% and 52.88% ± 5.38%, respectively. In <sup>14</sup>C-UBT negative patients GBEF<sub>30</sub> was 24.35% ± 3.80% and GBEF<sub>60</sub> was 47.11% ± 5.88%. Mean GBEF values at 30 min and at 60 min obtained by the inexperienced observer (B) in <sup>14</sup>C-UBT positive patients were 35.55% ± 4.07% and 53.86% ± 5.06%, and in <sup>14</sup>C-UBT negative patients were GBEF<sub>30</sub> 26.38% ± 3.53% and GBEF<sub>60</sub> 47.55% ± 4.57%, respectively. GBEF values did not differ significantly (*P* > 0.05). A highly significant positive correlation of corresponding values was found between the two observers (Table 2).

## DISCUSSION

There is no previously published study regarding the direct relationship between the gallbladder motor functions and *H pylori* infection in dyspeptic patients. In the previous studies, the relationship between gastric and gallbladder emptying functions were reported. But, no definitive physiological data of the gallbladder kinetic parameters has been published yet<sup>[20,25-29]</sup>. Marzio *et al.*<sup>[25,26]</sup> showed that gastric emptying is strictly correlated with gallbladder emptying and refilling. It has been reported that impairment of gallbladder dynamic functions might be due to inflammation resulting from *H pylori* infection. In our dyspeptic patients, high incidence of *H pylori* infection (67%) and delayed GBFT support the hypothesis that this bacteria can cause dyspepsia<sup>[27,15,16]</sup>. On the other hand, since *H pylori* was found as negative in 33% of our dyspepsia patients, it seemed unlikely that *H pylori* was the unique factor for dyspepsia. Abnormal bile composition may be responsible even if GB USG is normal. Further studies in patients with dyspepsia would be helpful in clarifying this issue.

In our study, each subject was studied with a standardized fatty meal releasing endogenous CCK as a stimulant for GB emptying. Krishnamurthy *et al.*<sup>[30,31]</sup> reported that the GBFT and the GB latent period before the beginning of emptying were much longer, and GBEF values at 60 min were significantly lower obtained with fatty meal ingestion than with CCK injection. It probably resulted from the time taken for release of endogenous CCK. They suggested that acquisition has to last for at least 60 min. Dependent on these results, we acquired GB kinetic images up to 90 min and our results supported the reports of Krishnamurthy *et al.*<sup>[30,31]</sup>. In all of our cases, GBFT and GB t1/2 time were increased while the mean GBEF value at 60 min was decreased. Interestingly, that GB functions impaired more prominently in *H pylori* negative patients was observed, however no statistically significant difference was detected between the two groups for each observer (Tables 1 and 2).

In conclusion, cholescintigraphy using <sup>99m</sup>Tc-Mebrofenin and a fatty meal ingestion is a well established and reliable noninvasive method for estimating gallbladder motor functions. Since we did not find any significant difference in gallbladder kinetic parameters between *H pylori* positive and negative patients with dyspepsia, *H pylori* did not seem to cause the abnormal gallbladder function (filling or emptying). Up to date, direct relationship between *H pylori* infection and gallbladder motor functions has not been reported. For that reason, we are not able to compare our results directly with any other published data, and further studies on this topic may help to clarify our findings.

## COMMENTS

### Background

The *H pylori* is an interesting cause of active chronic gastritis and duodenitis or even cancer worldwide. The presence of *H pylori* could also predispose to various disorders such as dental disease, atherosclerosis, coronary artery disease, slow coronary flow and cerebral infarction. Few reports have been published on the relationship between gallbladder emptying in patients with *H pylori* positive and negative idiopathic dyspepsia. Our aim was scintigraphic evaluation of gallbladder motor functions in *H pylori* positive and negative patients affected by dyspepsia.

### Research frontiers

Higher incidence of *H pylori* infection in dyspeptic patients supports the idea that it can cause to the development of dyspepsia. In the previous studies on dyspeptic patients showed that a group of dyspeptic patients had a reduced gallbladder response to a liquid meal. However, no definitive data of the gallbladder kinetic parameters has been published in the previous studies.

### Innovations and breakthroughs

<sup>14</sup>C-UBT is reliable noninvasive method for the diagnosis of *H pylori* infection. Up to date, direct relationship between *H pylori* infection and gallbladder motor functions has not been studied. We showed for the first time that the gallbladder motor functions such as filling time, ejection fraction and emptying time values were not affected from *H pylori* infection.

### Applications

Our study was designed to analyse the scintigraphic gallbladder motor function parameters in *H pylori* positive and negative patients based on dyspeptic symptoms, <sup>14</sup>C-UBT and upper gastrointestinal endoscopy procedure. The *H pylori* did not appear to cause the impairment in gallbladder function.

### Terminology

<sup>14</sup>C-UBT: Urea breath test using <sup>14</sup>C capsule is based on the principle that urease activity is present in the stomachs of individuals affected with *H pylori*; GBEF: Gallbladder ejection fraction parameter describes gallbladder emptying function; <sup>99m</sup>Tc-Mebrofenin: It is a radiopharmaceutical agent for hepatobiliary scintigraphy.

### Peer review

This is a report designed to analyse the gallbladder motor function parameters in *H pylori* positive and negative patients with dyspepsia. This clinical study was well designed.

Costa NR, Mendes N, Marcos NT, Reis CA, Caffrey T, Hollingsworth MA, Santos-Silva F. Relevance of MUC1 mucin variable number of tandem repeats polymorphism in *H pylori* adhesion to gastric epithelial cells. *World J Gastroenterol* 2008; 14(9): 1411-1414 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1411.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1411>

### Abstract

**AIM:** To evaluate the influence of MUC1 mucin variable number of tandem repeats (VNTR) variability on *H pylori* adhesion to gastric cells.

**METHODS:** Enzyme linked immunosorbent assay (ELISA)-based adhesion assays were performed to measure the adhesion of different *H pylori* strains (HP26695 and HPTx30a) to gastric carcinoma cell lines (GP202 and MKN45) and GP202 clones expressing recombinant MUC1 with different VNTR lengths.

**RESULTS:** Evaluation of adhesion results shows that *H pylori* pathogenic strain HP26695 has a significantly higher ( $P < 0.05$ ) adhesion to all the cell lines and clones tested, when compared to the non-pathogenic strain HPTx30a. Bacteria showed a significantly higher ( $P < 0.05$ ) adhesion to the GP202 cell line, when compared to the MKN45 cell line. Furthermore, both strains showed a significantly higher ( $P < 0.05$ ) adhesion to GP202 clones with larger MUC1 VNTR domains.

**CONCLUSION:** This work shows that MUC1 mucin variability conditions *H pylori* binding to gastric cells. The extent of bacterial adhesion depends on the size of the

### INTRODUCTION

The Gram negative bacterium *H pylori* is involved in the pathogenesis of several gastrointestinal diseases, ultimately leading to gastric carcinoma<sup>[1,2]</sup>. In the gastric mucosa, the majority of the bacteria is found within the mucus layer, but can be also attached to gastric epithelial cells<sup>[3]</sup>, a crucial step for the maintenance, spreading and severity of the infection. This attachment is mediated by the interaction of bacterial molecules, such as adhesins and LPS<sup>[4]</sup>, with gastric cell surface ligands such as glycolipids and glycoproteins. MUC1 is a membrane glycoprotein that protects epithelial surfaces and has been recently identified as an *H pylori* binding target<sup>[5,6]</sup>. Extracellular MUC1 variable number of tandem repeats (VNTR) domain is highly glycosylated<sup>[7]</sup>, presenting carbohydrate structures (e.g. Lewis b carbohydrate antigen) involved in the binding of *H pylori* through its adhesins BabA and SabA<sup>[8,9]</sup>. Furthermore this repetitive region shows extensive allelic variation ranging from 25-125 repeat units<sup>[12]</sup>. The relevance of MUC1 VNTR variability for *H pylori* adhesion to gastric cells remains to be clarified.

In this work we tested the hypothesis that MUC1 VNTR polymorphism affects the *H pylori* adhesion to gastric cells and thus plays an important role in the colonization

of gastric mucosa. We used *H pylori* strains with different pathogenicity (strain HP26695 and strain HPTx30a) co-cultured with gastric cell lines GP202 and MKN45, and GP202 clones expressing recombinant MUC1 with different VNTR lengths. Adhesion was evaluated by an enzyme linked immunosorbent assay (ELISA)-based adhesion assay.

The results showed that MUC1 VNTR polymorphism influences the binding of *H pylori* to gastric cells. Furthermore, higher adhesion was observed in co-cultures with the pathogenic strain (HP26695) when compared to the non-pathogenic strain (HPTx30a) and GP202 cell line when compared to the MKN45 cell line. This work contributes to the understanding of the interplay between host and bacterial factors in *H pylori* infection pathogenesis.

## MATERIALS AND METHODS

### Cell lines

We used two gastric carcinoma cell lines: GP202, previously established in our laboratory<sup>[13]</sup> from a signet ring cell gastric carcinoma that constitutively expresses MUC1 and MKN45 (Japan Health Sciences Foundation).

GP202 clones expressing recombinant MUC1 with different VNTR lengths<sup>[14]</sup> were previously established by stable transfection with an eukaryotic expression vector pHb-APr1-neo containing subcloned epitope-tagged MUC1 (FLAG-MUC1) cDNAs with different number of TR units (0, 3, 9 and 42 repeats, respectively GP202-dTR, GP202-3TR, GP202-9TR and GP202-42TR)<sup>[15]</sup>. GP202-Neo was obtained by transfection with empty vector.

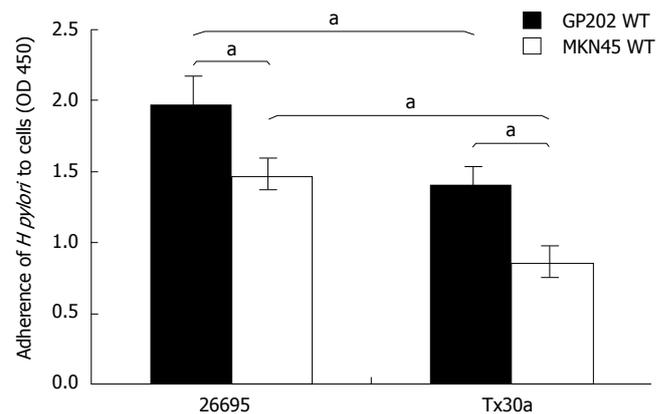

The parental cell lines and transfectants were cultured in 150 cm<sup>2</sup> flasks at 37°C in a humidified 5% CO<sub>2</sub> incubator and maintained in RPMI 1640 medium (with Glutamax and 25 mmol/L HEPES) supplemented with 10% fetal bovine serum and 50 µg/mL gentamicin. Media was changed every 3 d to 4 d, and the cells were passaged when they reached 80% to 90% confluence using 0.05% trypsin-0.53 mmol/L ethylenediamine tetra-acetic acid in Hank's balanced salt solution. Cell culture reagents were obtained from Invitrogen (Carlsbad, CA, USA).

### *H pylori* strains

Two *H pylori* strains were used in this study: the pathogenic strain HP26695 (*vacA* s1/m1, *cag* PAI+, ATCC 700392) and the non-pathogenic strain HPTx30a (*vacA* s2/m2, *cag* PAI-, ATCC 51932). Bacteria were grown on Trypticase soy agar with 5% sheep blood (BioMérieux) at 37°C in microaerobic conditions.

### ELISA assay

Quantitative evaluation of *H pylori* adhesion to gastric cells was performed by ELISA, as previously described<sup>[16]</sup>, with some modifications. Briefly, cells were cultured in 96 well plates and allowed to form confluent monolayers. Cells were washed and *H pylori* suspension was added in a 200:1 bacteria to cell ratio (MOI) and incubated for 60 min. Cells were washed and fixed at 4°C with 8% paraformaldehyde for 60 min. Endogenous peroxidase was inactivated by addition of 1% H<sub>2</sub>O<sub>2</sub> in methanol. After washing with PBS, anti-*H pylori* monoclonal antibody MAB922 (Chemicon, USA) was added overnight, 4°C, followed

**Figure 1** Adhesion of HP26695 and HPTx30a *H pylori* strains to GP202 and MKN45 gastric cell lines. <sup>a</sup>*P* < 0.05.

by addition of peroxidase-conjugated goat anti-mouse immunoglobulins (Santa Cruz Biotechnology) 30 min, RT. Tetramethylbenzidine (TMB) (Sigma, USA) was added and reaction stopped with 1 mol/L HCl. Plates were read in a 680 ELISA microplate reader (Bio-Rad, USA) at 450 nm. OD values were used as the index of the number of *H pylori* adhering to cells<sup>[16]</sup>. Two sets of triplicates were made for each assay.

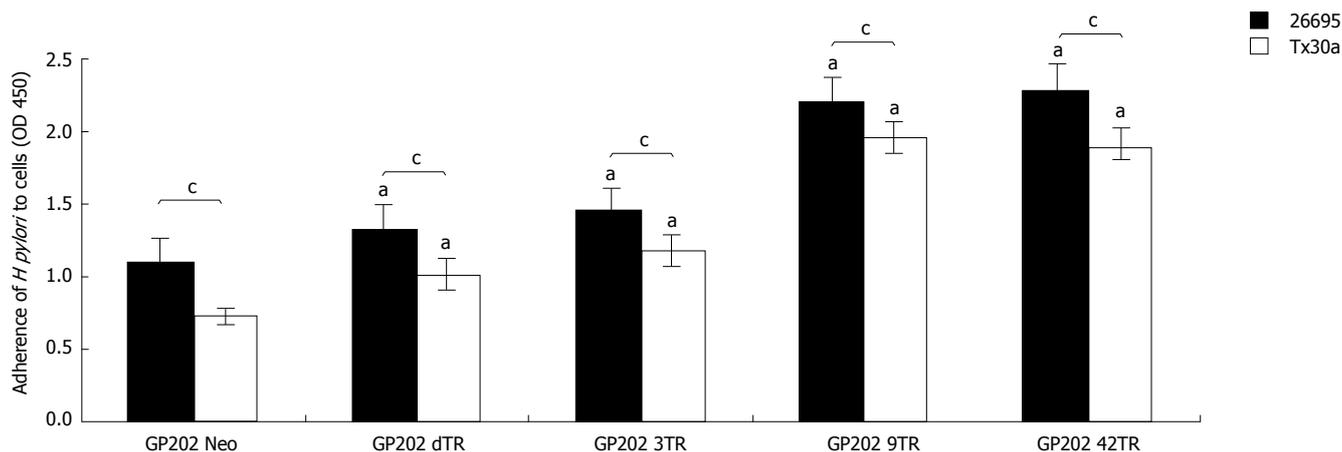

### Statistical analysis

Statistical analysis was performed using the Mann-Whitney test, StatView Software version 5.0 (SAS Institute). A *P* value of less than 0.05 was accepted as statistically significant.

## RESULTS

Evaluation of *H pylori* adhesion shows that pathogenic strain HP26695 has significantly (*P* < 0.05) higher adhesion values for both GP202 and MKN45 cell lines ( $1.97 \pm 0.10$  and  $1.47 \pm 0.06$ ) when compared with the non-pathogenic strain HPTx30a ( $1.40 \pm 0.15$  and  $0.85 \pm 0.15$ ; Figure 1). This statistically significant association between pathogenicity and higher adhesion (strain HP26695 *vs* HPTx30a) is also observed for the GP202 MUC1 recombinant clones (GP202-Neo  $1.1 \pm 0.10$  *vs*  $0.72 \pm 0.06$ ; GP202-dTR  $1.32 \pm 0.09$  *vs*  $1.0 \pm 0.10$ ; GP202-3TR  $1.45 \pm 0.08$  *vs*  $1.18 \pm 0.05$ ; GP202-9TR  $2.2 \pm 0.12$  *vs*  $1.96 \pm 0.12$ ; and GP202-42TR  $2.3 \pm 0.07$  *vs*  $1.89 \pm 0.11$ ; Figure 2). Furthermore, GP202 cell line shows higher adhesion levels than MKN45 cell line for both bacteria strains (HP26695 strain  $1.97 \pm 0.10$  *vs*  $1.47 \pm 0.06$ ; HPTx30a strain  $1.40 \pm 0.15$  and  $0.85 \pm 0.15$ ; Figure 1).

Adhesion of both *H pylori* strains (HP26695 and HPTx30a) is significantly higher in all the GP202-MUC1 transfectants over-expressing MUC1 (GP202-dTR  $1.32 \pm 0.09$  and  $1.0 \pm 0.10$ ; GP202-3TR  $1.45 \pm 0.08$  and  $1.18 \pm 0.05$ ; GP202-9TR  $2.2 \pm 0.12$  and  $1.96 \pm 0.12$ ; GP202-42TR  $2.3 \pm 0.07$  and  $1.89 \pm 0.11$ ) when compared with the control, GP202 Neo ( $1.1 \pm 0.10$  and  $0.72 \pm 0.06$ , Figure 2). There is also an association between the increased number of Tandem Repeats (GP202-9TR and GP202-42TR) and the increased adhesion, for both strains (Figure 2).

**Figure 2** Adhesion of HP26695 and HPTx30a *H pylori* strains to GP202 transfectants GP202-Neo, GP202-dTR, GP202-3TR, GP202-9TR and GP202-42TR. <sup>a</sup>*P* < 0.05, compared to the control (GP202 Neo) and <sup>c</sup>*P* < 0.05.

## DISCUSSION

Epidemiological studies and animal models have shown that *H pylori* chronic infection is associated with several gastric pathologies, ranging from asymptomatic gastritis to gastric adenocarcinoma and MALT lymphoma<sup>[1,2]</sup>. The different consequences of the infection suggest that several factors from the host and the bacteria are involved in the bacteria-host interactions, being the pathogenic potential dependent upon the molecular context of the colonization of gastric mucosa. To date several factors involved in the *H pylori* infection have already been identified (e.g. bacterial adhesins, host mucins and pro-inflammatory cytokines) however the complete mechanism remains to be clarified<sup>[17-19]</sup>.

Adhesion of *H pylori* to gastric mucosa is a fundamental step for epithelium colonization. Different adhesion mechanisms, commonly targeting carbohydrate structures present on gastric cells surface, have been identified<sup>[4]</sup> with *H pylori* ligands including, among others, blood group antigens on mucins and glycolipids<sup>[8-11,20-26]</sup>.

The best-characterized *H pylori* adhesin is BabA, that mediates a strong adhesion between the bacteria and Le<sup>b</sup> blood group antigen expressed on the surface of epithelial cells<sup>[8,27]</sup>. This work showed that adhesion is a relevant feature of *H pylori* pathogenicity potential, with significantly higher adhesion levels observed for the HP26695 (pathogenic strain) when compared to the HPTx30a (non-pathogenic strain) in both cell lines. Considering that both strains don't express BabA adhesin<sup>[28]</sup>, the observed differences can not be explained through the BabA binding model, what suggests that other bacterial molecules are involved in the adhesion process.

Another important observation is that there is a higher adhesion of HP26695 and HPTx30a strains to GP202 cell line when compared with MKN45 cell line. This reflects different expression levels and availability of ligands at the cells surface. Previous characterization of mucins and carbohydrate expression on GP202 and MKN45 cell lines showed that Le<sup>b</sup> has a significantly higher expression in GP202 cell line<sup>[29]</sup>. Still, this difference might not be relevant since BabA is not present in both bacterial strains<sup>[28]</sup>. In addition, the MUC1 expression is

identical for both cell lines<sup>[29]</sup> and therefore can not be held responsible for the observed differences. GP202 has a higher expression of other carbohydrate antigens (Le<sup>a</sup> and Le<sup>y</sup>)<sup>[29,30]</sup> compared to MKN45, that might be involved in *H pylori* binding interactions. Moreover, additional ligands/interactions that are not yet explored may also exist that can explain this difference in adhesion levels between cell lines.

In order to study the influence of MUC1 VNTR variability in *H pylori* binding, we used GP202, the cell line that showed higher bacteria adhesion and we analyzed GP202 transfectant clones expressing recombinant MUC1 with a different number of repeats. These clones overexpress similar levels of recombinant MUC1<sup>[14]</sup>. We observed that MUC1 VNTR polymorphism has influence in the extent of *H pylori* binding to gastric cells, with the higher adhesion levels observed in clones with larger VNTR regions. This may be due to the fact that MUC1 with larger Tandem Repeat regions contains more potential glycan receptors, thus potentially providing more bacterial binding sites. Moreover, we have previously shown that differences in VNTR length lead to glycosylation changes in the MUC1 Tandem Repeat<sup>[14]</sup>, which may also contribute to the altered adhesion observed. Detailed evaluation of the results showed a small increase between the adhesion of GP202-NEO (control) and GP202-dTR that may be explained by the overexpression of MUC1 in recombinant clone GP202-dTR<sup>[14]</sup> and by the potential presence of O-glycosylated binding sites outside the VNTR region. No significant difference was observed between the adhesion of the bacteria to GP202-9TR and to GP202-42TR clones. We have previously observed the overexpression of MUC1 underglycosylated forms in GP202-42TR<sup>[14]</sup>, which might explain why the adhesion levels are not proportional to VNTR size.

All these observations are important for understanding the bacterial and host molecular context of the colonization of gastric mucosa. Identification of a pathogenesis background, based upon host susceptibility traits like MUC1 VNTR polymorphism, will help to identify candidates more prone to bacterial colonization and patients more resilient to eradication strategies.

## COMMENTS

### Background

More than half of the world population is persistently infected by *H pylori*. Adhesion of the bacteria to the gastric mucosa is essential for attachment and infection. Therefore it is important to know host and bacterial factors that condition the adhesion.

### Innovations and breakthroughs

The study of host factors that influence the binding of *H pylori* to gastric cells may help to identify candidates more prone to bacterial colonization and patients more resilient to eradication strategies.

### Applications

These findings may help to develop screening methods to identify candidates more prone to bacterial colonization and to develop more efficient eradication strategies, as well as to develop strategies to prevent or minimize *H pylori* binding to the gastric mucosa.

### Peer review

This is a good study designed to elucidate that MUC1 VNTR polymorphism affects *H pylori* adhesion to gastric cells. The results are informative and potentially helpful for prevention of *H pylori* binding to the gastric mucosa.

### Abstract

**AIM:** To evaluate the sensitivity and specificity of abdominal ultrasound (US) for the diagnosis of hepatic steatosis in severe obese subjects and its relation to histological grade of steatosis.

**METHODS:** A consecutive series of obese patients, who underwent bariatric surgery from October 2004 to May 2005, was selected. Ultrasonography was performed in all patients as part of routine preoperative time and an intraoperative wedge biopsy was obtained at the beginning of the bariatric surgery. The US and histological findings of steatosis were compared, considering histology as the gold standard.

**RESULTS:** The study included 105 patients. The mean age was  $37.2 \pm 10.6$  years and 75.2% were female. The histological prevalence of steatosis was 89.5%. The sensitivity and specificity of US in the diagnosis of hepatic steatosis were, respectively, 64.9% (95% CI: 54.9-74.3) and 90.9% (95% CI: 57.1-99.5). The positive predictive value and negative predictive value were, respectively, 98.4% (95% CI: 90.2-99.9) and 23.3% (95% CI: 12.3-39.0). The presence of steatosis on

US was associated to advanced grades of steatosis on histology ( $P = 0.016$ ).

**CONCLUSION:** Preoperative abdominal US in our series has not shown to be an accurate method for the diagnosis of hepatic steatosis in severe obese patients. Until another non-invasive method demonstrates better sensitivity and specificity values, histological evaluation may be recommended to these patients undergoing bariatric surgery.

### INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) has been recognized as an important and common clinical entity, affecting approximately 20% of the general population<sup>[1]</sup>. The prevalence of NAFLD in obese people has been estimated in 60%-95% and, currently, NAFLD has been suggested to be the liver component of the metabolic syndrome<sup>[2,3]</sup>. It has a large spectrum, ranging from simple hepatic steatosis to steatohepatitis (NASH) and cirrhosis.

Liver biopsy and histological evaluation have been considered the better methods for the diagnosis of steatosis and to establish the prognosis of NAFLD. However, there are controversies about the indication of biopsy in clinical practice, due the lack of an effective medical therapy for NAFLD and the risks associated with this procedure<sup>[4]</sup>.

Nevertheless, various imaging modalities have been used to diagnose the presence of fat in the liver, as ultrasonography, computerized tomography scan and magnetic resonance imaging. Abdominal ultrasound (US), the

cheapest method, has been the most common modality used in clinical practice. Some parameters allow the diagnosis of fatty liver disease with a sensibility of 83% and a specificity of 100%: a diffuse hyperechoic echotexture; deep attenuation; increased liver echotexture compared with the kidney; and vascular blurring<sup>[5]</sup>. However, lower sensitivity values of US have been demonstrated among severe obese people<sup>[6]</sup>. The present study aimed to evaluate the reliability of abdominal US when it is compared to histology to diagnose hepatic steatosis in these patients and its relation to histological grades of steatosis.

## MATERIALS AND METHODS

### Study group selection

A consecutive series of obese patients who underwent bariatric surgery from October 2004 to May 2005 was selected. The eligible criteria for inclusion were: age above 18 years, preoperative abdominal US, and liver biopsy during the surgery and signer agreement to participate the study. All patients had body mass index above 40 kg/m<sup>2</sup>, or 35 kg/m<sup>2</sup> associated to others conditions (hypertension, diabetes, dyslipidemia or sleep apnea)<sup>[7]</sup>. Patients with alcohol intake above 20 g/d or those who had other chronic liver diseases (HBV or HCV infection, hemochromatosis, autoimmune hepatitis, Wilson's disease, primary biliary cirrhosis,  $\alpha$ -1 antitrypsin-deficiency) were excluded. The same surgeon team made all surgeries. Abdominal US was performed in all patients as part of routine preoperative time and different radiologists carried them out.

This study was performed in accordance with a protocol approved by Ethics Committee for Medical Research of Gonçalo Muniz Research Center. All included patients have consented to their participation in this study.

### Clinical evaluation

The parameters studied included: age, gender, height, weight, waist circumference, history of hypertension, dyslipidemia, diabetes and drugs use. Laboratory evaluation included: hemoglobin, hematocrite, leucocytes, prothrombin time, ASL, ALT, total bilirubin, albumin, total cholesterol, HDL-cholesterol, triglycerides, fasting plasma glucose and insulin. Abdominal US exam was performed in all patients. Insulin resistance was calculated using Homeostasis Model Assessment Index (HOMA-IR). Patients were categorized as insulin resistant if the HOMA-IR value was equal or greater than 3.0, as previously described<sup>[8]</sup>. Ultrasonographic definition of steatosis was based on diagnosis criteria usually used in clinical practice, as mentioned above<sup>[5]</sup>.

### Liver biopsy and histological analysis

An intraoperative wedge biopsy was obtained at the beginning of the surgery and all samples were processed and examined by a single pathologist, using hematoxylin-eosin stain. Hepatic steatosis in the biopsy specimens, if present, was graded according the number of involved hepatocytes: Grade I (steatosis in 5%-25% of hepatocytes); Grade II (steatosis in 25%-50% of hepatocytes); Grade III (steatosis in 50%-75% of hepatocytes); Grade IV (steatosis in more than 75% of hepatocytes).

### Statistical analysis

Data were processed and analyzed using the Statistical Package for Social Science program, version 9.0 (SPSS Inc. Chicago, Illinois, USA). Descriptive statistics of the included variables has been carried out. The US and histological findings of steatosis were compared, considering histology as the gold standard. Subsequently, the sensibility, specificity, positive predictive value and negative predictive value for the US in the diagnosis of hepatic steatosis and theirs 95% confidence intervals were calculated using EPI INFO v6.0 (CDC, USA). A Chi-square test was used to compare categorical variables. All statistical methods were two-tailed and the statistical significance was obtained when  $P < 0.05$ .

## RESULTS

Among the 123 severe obese patients with histological and abdominal US evaluation, 105 were finally included. Seventeen patients were excluded because they had a history of alcohol intake above 20 g/d, and one by hepatitis B infection (HBsAg positive).

Demographic and clinical profiles of these 105 individuals are shown in Table 1. The US examination was normal in 38 (36.2%) cases. Steatosis on US was described in 62 (59.0%) cases. Others imaging findings were: hepatomegaly in 8 (7.6%); colelithiasis in 14 (13.3%); and renal cyst in 3 (2.9%) cases.

The histological prevalence of steatosis was 89.5%. The sensitivity and specificity of abdominal US for the diagnosis of hepatic steatosis were, respectively, 64.9% (95% CI: 54.9-74.3) and 90.9% (95% CI: 57.1-99.5). The positive and negative predictive values were, respectively, 98.4% (95% CI: 90.2-99.9) and 23.3% (95% CI: 12.3-39.0). A false positive rate was found in 9.1% (95% CI: 0.5-37.3) and a false negative rate in 35.1% (95% CI: 26.0-45.2).

Table 2 shows the influence of body mass index on accuracy of abdominal US in the diagnosis of hepatic steatosis. The prevalence of steatosis in patients with body mass index between 35.0 kg/m<sup>2</sup> and 39.9 kg/m<sup>2</sup> and in patients with body mass index above 40 kg/m<sup>2</sup> was 83.3% and 91.3%, respectively.

All individuals were separated into two groups, according to the median of waist circumference (below and above the median value) and the sensibility, specificity, positive predictive value and negative value were analyzed in each group. These results are demonstrated in Table 3. The prevalence of steatosis in patients below and above the median value for waist circumference was 81.1% and 94.6%, respectively.

The presence of steatosis on US was associated with advanced grades of steatosis in the biopsy specimens ( $P = 0.016$ ), as shown in Table 4.

## DISCUSSION

Abdominal US has been largely used in clinical practice and in protocols of investigation of patients with NAFLD because it is a cheap and a safe method. As a screening test, its major requirement is a high degree of sensitivity and specificity. In non-obese patients the values of sensitivity

PPV: Positive predictive value; NPV: Negative predictive value; 95% CI: Confidence interval of 95%.

and specificity of US range from 83% to 94%, and 84% to 100% respectively<sup>[5,9]</sup>.

The present study with severely obese patients evaluated the sensitivity and specificity of abdominal US for the diagnosis of hepatic steatosis and its relation to histology. The results showed a low performance of US to diagnosis steatosis, however similar results have been demonstrated in patients with body mass index ranging from 35.0 kg/m<sup>2</sup> to 82.2 kg/m<sup>2</sup>, where the frequency of steatosis was 91.4%<sup>[6]</sup>. In this case, sensitivity and specificity of US in the diagnosis of steatosis was 49.1% and 75%, respectively<sup>[6]</sup>. These values are also demonstrated (sensitivity: 43%; specificity: 79%) for the diagnosis hepatic steatosis in patients infected with hepatitis C virus<sup>[10]</sup>.

Several hypotheses may explain this low performance of US in severe obese people. The diagnosis made by different radiologists may introduce variability in interpretation of images. This could be related to the experience of each radiologist and to the lack of clear standards for the diagnosis of hepatic steatosis<sup>[11]</sup>. The second hypothesis is related to the adipose tissue thickness that may cause technical difficulties for the performance of this exam. The thick layers of subcutaneous fat in obese people may mislead the examiner's judgment of liver echogenicity, as cited in visualizing of the abdominal aorta<sup>[12]</sup> and renal carcinoma<sup>[13]</sup>. The image quality rate also has been discussed and different results have as been found. The analysis of 140 patients, who underwent

**Table 3** Levels of sensibility, specificity, PPV and NPV for the ultrasound in the diagnosis of hepatic steatosis by waist circumference (WC) in severe obese patients

Variables	WC $\leq$ 116.9 kg/m <sup>2</sup>		WC $\geq$ 117.0 kg/m <sup>2</sup>	
	Value (%)	95% CI	Value (%)	95% CI
Sensibility	56.7	37.7-74.0	80	62.5-90.9
Specificity	85.7	42.0-99.2	100	19.8-100

Imaging profile	Grade of steatosis on histological evaluation	
	Grade I / II	Grade III/IV
Ultrasound without steatosis	97.00	3.00
Ultrasound with steatosis	77.00	23.00

*P* = 0.016.

abdominal US, showed that obesity was also associated with a poor sonographic image<sup>[14]</sup>. However, another study did not find the same results<sup>[15]</sup>. Finally, the majority of screening values described in literature were calculated in patients with suspected liver disease. It is more appropriate to use groups of patients resembling those that have been investigated in clinical practice.

This investigation found a higher accuracy of US for the diagnosis of hepatic steatosis in patients with central obesity or more elevated waist circumference. This could be explained by the association between steatosis on ultrasonographic evaluation and histological evidence of steatosis in those patients, as previously showed<sup>[9,16]</sup>. In a multivariate model involving patients with hepatitis C, Hepburn found that the only statistically significant factor associated with steatosis on US was histological grade, with an odds-ratio of 3.6<sup>[10]</sup>. In addition, a better performance of ultrasound associated to a more elevated prevalence of NAFLD was also described in obese people undergoing bariatric surgery<sup>[6]</sup>, obtaining results as high as those found in non-obese people<sup>[5,9]</sup>.

The prevalence of steatosis among the patients in this study was elevated (89.5%) and the central obesity was frequent, as previously described studies<sup>[6,17,18]</sup>. Moreover, the prevalence of NAFLD also has been correlated to body mass index. These results are relevant when we considered that obesity is associated to increased visceral adiposity, free fatty acids and hyperinsulinemia, which are involved in the pathogenesis of NAFLD<sup>[19,20]</sup>.

In conclusion, the results suggest that abdominal US may not be considered an accurate method for the diagnosis of hepatic steatosis in severe obese patients. The liver biopsy and histological evaluation should be recommended to these patients undergoing bariatric surgery, until other non-invasive method demonstrates better sensitivity and specificity values.

## COMMENTS

### Background

Non-alcoholic fatty liver disease (NAFLD) is a common entity among severe obese patients. Although liver biopsy was the best method for its diagnosis, various imaging modalities have been used to diagnose the presence of fat in the liver, and abdominal ultrasound (US) is the most used in clinical practice. Thus, it is important to elucidate if the abdominal US is a good method to diagnose hepatic steatosis in these patients.

### Research frontiers

This study reported the findings of 105 patients with a histological prevalence of steatosis of 89.5%. Low sensitivity and negative predictive rates of US in the diagnosis of hepatic steatosis were described and a better performance of US was associated to advanced grades of steatosis on histology. More accurate methods may change this data.

### Innovations and breakthroughs

Although the reliability of abdominal US for diagnose hepatic steatosis was previously reported, the current study showed different values of specificity and sensibility on severe obese patients by body mass index and waist circumference status and the relationship between grade of steatosis on histology and its presence on US evaluation.

### Applications

Abdominal US results should be carefully analysed in obese patients. Because of the high prevalence of non-alcoholic fatty liver disease, a more accurate method for its diagnosis, as liver biopsy, is recommended in patients undergoing bariatric surgery.

### Terminology

NAFLD means non-alcoholic fatty liver disease; NASH is named as non-alcoholic steatohepatitis; HOMA-IR is homeostasis model assessment index - insulin resistance.

### Peer review

The authors evaluate the use of US in severely obese patients in order to diagnose hepatic steatosis. They compare histological findings, which they consider to be the golden standard, with US data of the same patients. They observe 123 cases and conclude that US may not be considered an accurate method for the diagnosis of steatosis in these patients. The goals of the study, the materials and methods, results and other parts of the manuscript are well formulated and explain the study in well chosen terms. As a histologist, it is nice to hear that histology is the method of choice for this diagnosis, in spite of the fact that US based diagnosis would have been a very direct, non-invasive and cheap method to use.

### Abstract

**AIM:** To investigate the potential therapeutic significance of ghrelin and growth hormone releasing peptide 6 (GHRP-6) in diabetic mice with gastric motility disorders.

**METHODS:** A diabetic mouse model was established by intraperitoneal (*ip*) injection of alloxan. Diabetic mice were injected *ip* with ghrelin or GHRP-6 (20-200  $\mu$ g/kg), and the effects on gastric emptying were measured after intragastric application of phenol red. The effect of atropine, N<sup>G</sup>-nitro-L-arginine methyl ester hydrochloride (L-NAME) or D-Lys<sup>3</sup>-GHRP-6 (a growth hormone secretagogue receptor (GHS-R) antagonist) on the gastroprokinetic effect of ghrelin or GHRP-6 (100  $\mu$ g/kg) was also investigated. The effects of ghrelin or GHRP-6 (0.01-10  $\mu$ mol/L) on spontaneous or carbachol-induced contractile amplitude were also investigated *in vitro*, in gastric fundic circular strips taken from diabetic mice. The presence of growth hormone secretagogue receptor 1a transcripts in the fundic strips of diabetic mice was detected by reverse transcriptase polymerase chain reaction (RT-PCR).

**RESULTS:** We established a diabetic mouse model with delayed gastric emptying. Ghrelin and GHRP-6 accelerated gastric emptying in diabetic mice with gastroparesis. In the presence of atropine or L-NAME, which delayed gastric emptying, ghrelin and GHRP-6 (100  $\mu$ g/kg) failed to accelerate gastric emptying. D-Lys<sup>3</sup>-GHRP-6 also delayed gastric emptying induced by the GHS-R agonist. Ghrelin and GHRP-6 increased the carbachol-induced contractile amplitude in gastric fundic

strips taken from diabetic mice. RT-PCR confirmed the presence of *GHS-R* mRNA in the strip preparations.

**CONCLUSION:** Ghrelin and GHRP-6 increase gastric emptying in diabetic mice with gastroparesis, perhaps by activating peripheral cholinergic pathways in the enteric nervous system.

Gastric motor effects of ghrelin and growth hormone releasing peptide 6 in diabetic mice with gastroparesis. *World J Gastroenterol* 2008; 14(9): 1419-1424 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1419.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1419>

### INTRODUCTION

Delayed gastric emptying occurs in more than 50% of patients with chronic diabetes mellitus (DM) and is always associated with impaired quality of life and diabetic control. While this delay is not always clinically apparent, the range of gastrointestinal symptoms may include nausea, vomiting, regurgitation, fullness, and bloating<sup>[1]</sup>. Diabetic patients with poor gastric emptying have a number of possible metabolic consequences, including poor glycemic control, increased risk of postprandial hypoglycemia and variable drug absorption. At its worst, gastroparesis can lead to intractable vomiting and an inability to feed, and carries a poor prognosis<sup>[2]</sup>.

Present management of diabetic gastroparesis involves empirical use of prokinetic drugs such as domperidone, metoclopramide, cisapride<sup>[2,3]</sup> and erythromycin<sup>[4]</sup>. The effects of these drugs, however, are unpredictable. One possible explanation for this lack of sustained response to treatment is that gastroparesis may be originally associated with progressive autonomic neuropathy<sup>[5,6]</sup>.

Ghrelin, a 28-amino acid peptide with an octanoyl moiety at Ser<sup>3</sup>, was discovered in 1999 as the endogenous

ligand for the growth hormone secretagogue receptor (GHS-R), now often referred to as the ghrelin receptor<sup>[7]</sup>. The ghrelin receptor, originally called GHS-R1a, has also been called GRLN receptor since the discovery of ghrelin<sup>[8]</sup>. This receptor was first characterized, cloned and identified as the receptor for a family of synthetic ligands known as growth hormone secretagogues, which stimulate the release of growth hormone (GH)<sup>[9]</sup>. Ghrelin and its receptor have been localized to the gastrointestinal tracts of many mammalian species, including the mouse, rat and humans<sup>[7,10-13]</sup>. In rats<sup>[14]</sup>, mice<sup>[15,16]</sup> and dogs<sup>[17]</sup>, ghrelin has been found to increase gastric emptying, and the site of action may involve the enteric nervous system. In rats and mice, a gastroprokinetic-like activity of ghrelin may be observed *in vitro* as an increase in neuronally mediated contractions evoked by electrical field stimulation (EFS)<sup>[11,14]</sup>. Growth hormone-releasing peptide-6 (GHRP-6) is a synthetic peptide that causes release of GH, similar to the effect of ghrelin, but through an as yet unknown mechanism. Diabetic gastroparesis is a disabling condition with no consistently effective treatment; however, the effect of ghrelin and its synthetic peptide GHRP-6 on diabetic mice with gastroparesis has not been reported. Therefore, we investigated the potential therapeutic significance of ghrelin and GHRP-6 in diabetic mice with gastric motility disorders.

## MATERIALS AND METHODS

### Chemicals

Rat ghrelin, GHRP-6 and D-Lys<sup>3</sup>-GHRP-6 were obtained from Tocris Cookson (Bristol, UK). N<sup>G</sup>-nitro-L-arginine methyl ester hydrochloride (L-NAME) was purchased from Bachem (Bubendorf, Switzerland). Atropine sulfate, phenol red and alloxan were obtained from Sigma (St Louis, Missouri, USA).

### Preparation of experimental animals

C57 mice weighing 18-22 g were obtained from the experimental Animal Center of the Shanghai Academia Sinica. All procedures were approved by the Medical Ethics Committee of Shanghai Jiaotong University. Mice were housed in stainless steel cages at a controlled temperature (22 ± 2°C) and 60%-65% relative humidity with a normal 12 h light/dark cycle. Six mice were randomly selected as normal controls, and the rest were fed a high-fat diet. After exposure to the high-fat diet for 3 wk, the mice were fasted overnight with free access to water, and injected intraperitoneally (*ip*) with alloxan (0.2 g/kg body weight) dissolved in sterile normal saline solution. Seventy-two h later, the fasting blood glucose levels of the mice were determined using the glucose oxidase method with a Glucose Analyzer. Mice with a blood glucose level greater than 11.1 mmol/L were defined as diabetic (DM) mice. DM mice continued to feed without control of blood glucose for 4 wk; then, the mice that were defined to be DM mice with gastroparesis, as confirmed by subsequent tests, were used for further investigations.

### Studies of gastric emptying *in vivo*

Mice were allowed free access to water 12 h before the

experiment. DM mice were injected with either ghrelin (0, 20, 50, 100, or 200 µg/kg; *ip*) or GHRP-6 (0, 20, 50, 100, or 200 µg/kg; *ip*) in a random order. Modulation of the effects of the growth hormone secretagogue receptor (GHS-R) agonists by pharmacological blockers was tested by *ip* administration of atropine (1 mg/kg), L-NAME (50 mg/kg) or D-Lys<sup>3</sup>-GHRP-6 (5 µmol/kg) 15 min before administration of the GHS-R agonist (ghrelin 100 µg/kg or GHRP-6 100 µg/kg). Each drug treatment group consisted of at least six DM mice. An additional group consisting of at least 6 DM mice were injected with saline as normal controls.

Immediately after the injection of the drug, 5 mg/kg body weight phenol red test meal (0.5 g/L in 0.9% NaCl with 1.5% methylcellulose) was administered intragastrically with an orogastric canula. The mice were sacrificed 20 min later. The stomach was clamped with a string above the lower esophageal sphincter and a string beneath the pylorus to prevent leakage of phenol red. The stomach was cut just beneath the strings and was frozen at -70°C until measurement of gastric emptying. Gastric emptying was determined spectrophotometrically using a previously described method<sup>[18,19]</sup>. The stomach of each mouse was cut just above the lower esophageal sphincter and the pyloric sphincter. Phenol red remained largely in the lumen of the stomach, although some was trapped in the mucus layer of the stomach, and a very small amount of phenol red was reabsorbed in the mucosa after 20 min. The stomach and its contents were submerged in 5 mL of 0.1 mol/L NaOH. The stomach was minced, and these samples contained the total amount of phenol red present in the stomach. The samples were further diluted in 10 mL 0.1 mol/L NaOH and left at room temperature for 1 h. Five mL of the supernatant was then centrifuged at 800 × *g* for 20 min. The absorbance was read at a wavelength of 546 nm with a spectrophotometer (Shanghai Yixian Company, China), and the phenol red content present in the stomach was calculated. The percentage of gastric emptying of the mice was calculated as (infusion-remained/infusion) × 100%.

### Contractility measurements *in vitro*

DM mice were sacrificed by cervical dislocation, and the stomach was removed and rinsed with ice cold saline. Circular muscle strips, freed from mucosa (length 8-10 mm, width 0.2 mm) were cut from the fundus and suspended vertically in an organ bath filled with Krebs solution (120.9 mmol/L NaCl, 2.0 mmol/L NaH<sub>2</sub>PO<sub>4</sub>, 15.5 mmol/L NaHCO<sub>3</sub>, 5.9 mmol/L KCl, 1.25 mmol/L CaCl<sub>2</sub>, 1.2 mmol/L MgCl<sub>2</sub>, and 11.5 mmol/L glucose) warmed at 37°C and gassed with 95% O<sub>2</sub>/5% CO<sub>2</sub>. One end of the strip was fixed to a hook on the bottom of the chamber while the other end was connected by a thread to an external isometric force transducer (BK Company, USA) at the top. After 1 h of equilibration at optimal stretch (0.75 g), the reproducibility of the contractile response to carbachol (0.1 µmol/L) was assessed. Mechanical responses in the smooth muscle strips were measured using an isometric force transducer and stored on a computer for analysis using the SMUP-E biological signal processing system (Chengdu Equipment Factory, China). To investigate the modification

of neuro-effector transmission by GHS-R agonists, the response was studied in the presence and absence of carbachol (0.1  $\mu\text{mol/L}$ ), which, when used, was added to the tissue bath 0.5 min before application of the GHS-R agonists. The effect of GHS-R agonists on spontaneous or carbachol (0.1  $\mu\text{mol/L}$ )-induced contractile activity in DM mouse fundic muscle strips was studied by measuring the mean contractile amplitude of the muscle strips.

### Measurement of the growth hormone secretagogue receptor by RT-PCR

Total RNA was prepared from DM mouse fundic muscle strips using Trizol reagent (Invitrogen, Carlsbad, CA). Single-stranded cDNA was synthesized using an oligo (dT) anchor primer and Superscript<sup>TM</sup> II RNase H<sup>-</sup> reverse transcriptase (Gibco BRL, NY, USA). The obtained cDNA served as a template for polymerase chain reaction, consisting of 35 cycles of amplification (95°C for 10 min, 94°C for 50 s, 60°C for 30 s, 72°C for 30 s) with a final elongation of 10 min at 72°C using 0.5 U of Taq DNA polymerase (Promega, Sweden) and 0.5  $\mu\text{mol/L}$  primers (forward: 5'-CGACCTGCTCT GCAAATC-3' and reverse: 5'-CACGCCACCAGCACGAAGA-3'). PCR using intron-spanning mouse  $\beta$ -actin primers (forward: 5'-CCTGTATGCCTCTGGTTCGTA-3' and reverse: 5'-CCATCTCCTGCTCGAAGTCT-3'), demonstrated that cDNA was present and devoid of genomic DNA contamination. The expected sizes of GHS-R and  $\beta$ -actin fragments were 217 bp and 260 bp, respectively. All primers were selected from conserved regions identified by the alignment of published sequences for GHS-R mRNA in Genbank. PCR products were separated by electrophoresis on 1.4% agarose gels and photos of the separated products were taken.

### Statistical analysis

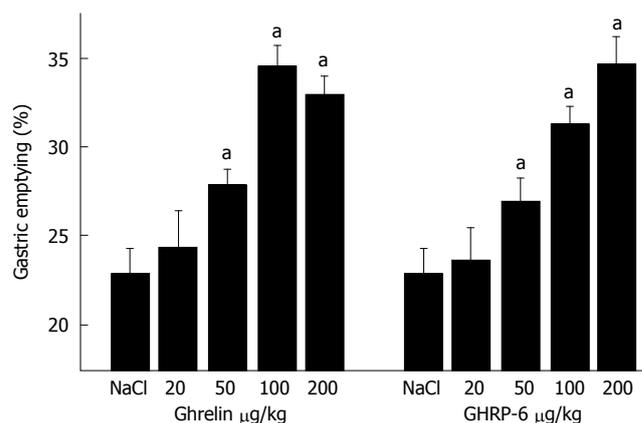

Data are expressed as mean  $\pm$  SE. One-way ANOVA was used for statistical analyses of multiple comparisons, and a *P* value of less than 0.05 was considered to be statistically significant.

## RESULTS

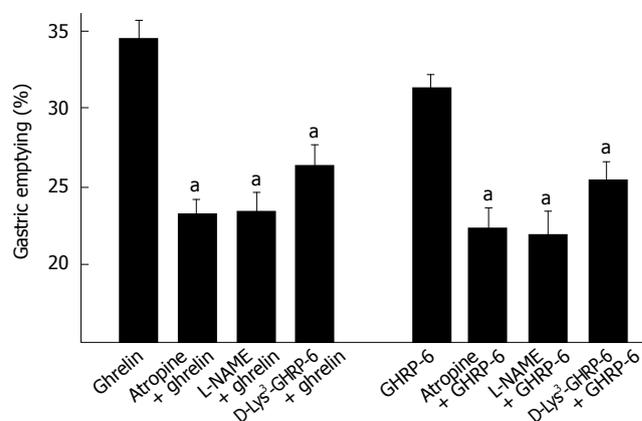

### Contractility in vivo

Compared with the gastric emptying rate of the normal mice (28.10%  $\pm$  1.28%), the gastric emptying rate of the DM mice was significantly reduced (22.90%  $\pm$  1.42%, *P* < 0.05). In DM mice, ghrelin accelerated gastric emptying of the semi-liquid meal at doses of 50, 100 and 200  $\mu\text{g/kg}$ ; the emptying rate was significantly accelerated from 22.90%  $\pm$  1.42% to 27.80%  $\pm$  0.97%, 34.50%  $\pm$  1.20% and 32.90%  $\pm$  1.10% at doses of 50, 100 and 200  $\mu\text{g/kg}$ , respectively (*P* < 0.05, compared to injection of saline) (Figure 1). Similarly, GHRP-6 increased gastric emptying dose-dependently with significant effects at 50, 100 and 200  $\mu\text{g/kg}$  (*P* < 0.05) (Figure 1).

The effect of ghrelin or GHRP-6 on DM mouse gastric emptying was characterized pharmacologically. Ghrelin (100  $\mu\text{g/kg}$ ) or GHRP-6 (100  $\mu\text{g/kg}$ ) was unable to reverse the inhibition of gastric emptying due to pretreatment

**Figure 1** Effect of increasing doses of ghrelin (0–200  $\mu\text{g/kg}$ , *ip*) or GHRP-6 on gastric emptying in DM mice. Bars and error bars represent the mean  $\pm$  SE of at least six animals. <sup>a</sup>*P* < 0.05 vs normal saline (NaCl).

**Figure 2** Effects of atropine, L-NAME and D-Lys<sup>3</sup>-GHRP-6 on the gastroprokinetics of ghrelin or GHRP-6 in the DM mice. Mice were pretreated with atropine (1 mg/kg), L-NAME (50 mg/kg) or D-Lys<sup>3</sup>-GHRP-6 (5  $\mu\text{mol/kg}$ ) before administration of ghrelin (100  $\mu\text{g/kg}$ ) or GHRP-6 (100  $\mu\text{g/kg}$ ), and the effects were compared with those of treatment with ghrelin or GHRP-6 (100  $\mu\text{g/kg}$ ) alone. Bar graph and error bars represent the means  $\pm$  SE of at least six animals. <sup>a</sup>*P* < 0.05 vs treatment with ghrelin or GHRP-6 (100  $\mu\text{g/kg}$ ) alone.

with atropine (1 mg/kg) or L-NAME (50 mg/kg) (*P* < 0.05). Pretreatment of DM mice with D-Lys<sup>3</sup>-GHRP-6 (5  $\mu\text{mol/kg}$ ) also delayed the accelerated gastric emptying induced by ghrelin or GHRP-6 (*P* < 0.05) (Figure 2).

### Contractility in vitro

Fundic strips from the DM mice showed spontaneous contractile activity after 1 h of equilibration. Ghrelin (0.01–10  $\mu\text{mol/L}$ ) or GHRP-6 (0.01–10  $\mu\text{mol/L}$ ) did not significantly change spontaneous contractile responses in the strips (Table 1). However, in the presence of carbachol (0.1  $\mu\text{mol/L}$ ), ghrelin increased the carbachol-induced contractile amplitude at 0.1, 1 and 10  $\mu\text{mol/L}$ . GHRP-6 also increased the carbachol-induced contractile amplitude at 0.1, 1 and 10  $\mu\text{mol/L}$  (Table 2).

### Expression of the ghrelin receptor in mouse fundic strips

The presence of *GHS-R* mRNA in the mouse fundic smooth muscle strips was verified by RT-PCR with

**Table 1** Effects of GHS-R agonists on the spontaneous contractile amplitudes of DM mouse fundic strips

Group	Spontaneous contractile amplitude of DM mouse fundic strips (mg)				
	0	0.01 $\mu\text{mol/L}$	0.1 $\mu\text{mol/L}$	1 $\mu\text{mol/L}$	10 $\mu\text{mol/L}$
Ghrelin	20.4 $\pm$ 1.15	21.3 $\pm$ 0.98	19.8 $\pm$ 1.16	22.1 $\pm$ 1.58	21.5 $\pm$ 1.36
GHRP-6	20.4 $\pm$ 1.15	20.8 $\pm$ 1.12	21.3 $\pm$ 1.74	20.6 $\pm$ 1.27	21.3 $\pm$ 1.35

**Table 2** Effect of GHS-R agonists on the carbachol (0.1  $\mu\text{mol/L}$ )-induced contractile amplitudes of DM mouse fundic strips

Group	Spontaneous contractile amplitude of DM mouse fundic strips (mg)				
	0	0.01 $\mu\text{mol/L}$	0.1 $\mu\text{mol/L}$	1 $\mu\text{mol/L}$	10 $\mu\text{mol/L}$
Ghrelin + carbachol (0.1 $\mu\text{mol/L}$ )	60.4 $\pm$ 1.21	61.3 $\pm$ 1.52	65.7 $\pm$ 1.16 <sup>a</sup>	70.0 $\pm$ 1.58 <sup>a</sup>	78.0 $\pm$ 1.56 <sup>a</sup>
GHRP-6 + carbachol (0.1 $\mu\text{mol/L}$ )	60.4 $\pm$ 1.21	62.3 $\pm$ 2.14	65.4 $\pm$ 1.24 <sup>a</sup>	72.0 $\pm$ 1.42 <sup>a</sup>	82.0 $\pm$ 1.75 <sup>a</sup>

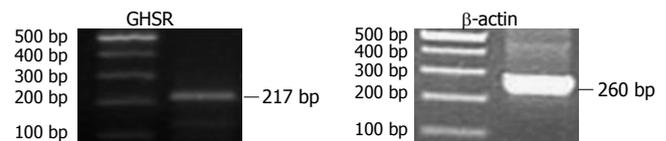

<sup>a</sup> $P < 0.05$ , vs carbachol (0.1  $\mu\text{mol/L}$ )-induced contraction amplitude of the DM mouse fundic strips.

gene-specific primers. Analysis of the PCR products by electrophoresis revealed a band with the expected length of 217 bp (Figure 3).

## DISCUSSION

We have demonstrated, for the first time, that ghrelin and the synthetic peptide GHRP-6 improve gastric emptying in diabetic mice with gastroparesis. This effect may be mediated through potentiation of peripheral cholinergic pathways in the enteric nervous system.

Ghrelin, a recently discovered peptide hormone, is primarily produced by endocrine cells in the oxyntic mucosa of the stomach in rats and humans<sup>[7,12]</sup>. Ghrelin has also been found in the small intestine, testis, pituitary gland, ovary, liver, pancreas, kidney, placenta and hypothalamus, in both humans and rodents<sup>[7,11]</sup>. Ghrelin is a natural ligand for GHS-R, and its receptor is found all over the body, including in the bowel, pancreas, stomach, heart, lungs and brain<sup>[7,12,20]</sup>. In addition to its effect on growth hormone secretion by activating GHS-R in the pituitary gland, ghrelin enhances appetite, increases food intake<sup>[21,22]</sup>, mediates energy balance, regulates glucose metabolism and insulin release<sup>[23]</sup>, stimulates gastric acid secretion<sup>[24]</sup> and promotes anxiety<sup>[25]</sup>. It is well known that many gastrointestinal peptides participate in the regulation of gastrointestinal functions. Ghrelin is one of these candidate gastrointestinal peptides, because it is predominantly present in gastric endocrine cells and is secreted into the bloodstream. In fact, the potential of ghrelin and its synthetic peptide GHRP-6 as a prokinetic agent has been shown previously in *in vitro* and *in vivo* studies. Previous studies on the effect of ghrelin on gastric motility have demonstrated the involvement of vagal and central ghrelin receptors. Thus, the effect of ghrelin on gastric emptying is blocked by atropine and vagotomy in rats and mice<sup>[18,20]</sup>. Peripheral ghrelin may stimulate fasted small intestinal motor activity through receptors on vagal afferents, which activate neuropeptide Y-containing

**Figure 3** Expression of GHS-R mRNA in gastric fundic strips from DM mice. The band at 217 bp corresponds to the amplified GHS-R cDNA product with the expected length. The band at 260 bp corresponds to the amplified  $\beta$ -actin cDNA product with the expected length.

neurons in the brain, as suggested by experiments in rats<sup>[26]</sup>. In addition, expression of the ghrelin receptor in the rat nodose ganglion has been confirmed using RT-PCR<sup>[27]</sup>. In addition to the known vagal pathways, ghrelin and GHRP-6 accelerate gastric emptying and small intestinal transit by activating cholinergic excitatory pathways in the enteric neuron system<sup>[14,15,17]</sup>. Moreover, ghrelin has been shown to increase gastric emptying in patients with gastroparesis, and it has been proposed that ghrelin or its analogues may represent a new class of prokinetic agents for the treatment of gastroparesis<sup>[28,29]</sup>. In our study, we investigated the effects of ghrelin and GHRP-6 on gastric motility in diabetic mice with gastroparesis. Our findings indicate the potential of ghrelin as a therapeutic approach for gastrointestinal motility disorders.

In our study, the gastric emptying rate in the DM mice was significantly reduced relative to the normal mice. Ghrelin and GHRP-6 accelerated gastric emptying of the diabetic mice with gastroparesis. In the presence of atropine or L-NAME, which delayed gastric emptying, ghrelin and GHRP-6 (100  $\mu\text{g/kg}$ ) failed to accelerate gastric emptying. D-Lys<sup>3</sup>-GHRP-6 also delayed gastric emptying induced by GHS-R agonists. Gastric emptying is a complex process involving excitatory and inhibitory nerves, which may contribute to both acceleration and retardation of the emptying process. L-NAME, which blocks inhibitory nitrenergic nerves, delayed gastric emptying, probably by interfering with gastric accommodation and pyloric relaxation. Therefore, the effect of ghrelin may involve both excitatory and inhibitory pathways, as suggested by the inability of ghrelin to overcome the delay induced by L-NAME and atropine. Ghrelin has been shown to induce release of nitric oxide in the rat stomach, and in our study, a nitrenergic pathway could be involved in the acceleration of gastric emptying because the prokinetic effect *in vivo* was lost in the presence of L-NAME. The GHS-R antagonist D-Lys<sup>3</sup>-GHRP-6, also blocked the effect of the GHS-R agonists, and this result indicates that the effect of GHS-R agonists on gastric motility

occurs through GHS-R and likely does not involve cross interactions with other receptors. Ghrelin and GHRP-6 increased the carbachol-induced contractile amplitudes in fundic strips taken from DM mice, and this finding also indicates that GHS-R agonists accelerate gastric emptying of semi-liquid through the activation of GHS-R receptors, possibly located on local cholinergic enteric nerves. Moreover, the presence of *GHS-R* mRNA in the strip preparations was confirmed by RT-PCR.

It remains controversial whether ghrelin can exert a protective effect on gastric mucosa, although previous studies have suggested ghrelin might induce gastric mucosal lesion in rats by increasing acid secretion. It is unlikely the improvement in gastric emptying in DM mice induced by ghrelin or GHRP-6 could be explained by a protective effect of ghrelin and GHRP-6 on gastric mucosa. Acid may inhibit gastric emptying, but the effect of ghrelin on acid secretion remains a controversial issue itself<sup>[24,30,31]</sup>.

In conclusion, ghrelin and its synthetic peptide, GHRP-6, increase gastric emptying in diabetic mice with gastroparesis, perhaps by activating peripheral cholinergic pathways in the enteric nervous system. Although further studies are needed to determine the underlying mechanisms, we propose that ghrelin or its analogues may represent a new class of prokinetic agents for the treatment of diabetic gastroparesis. Therefore, ghrelin and ghrelin agonists have the potential to become useful therapeutic agents for the treatment of diabetic gastroparesis. However, long term animal experiments and clinical trials are needed.

## COMMENTS

### Background

Delayed gastric emptying is common in patients with chronic diabetes and is always associated with impairments in both quality of life and diabetic control. Ghrelin is a potent prokinetic peptide. Our aim was to test the effect of ghrelin and its synthetic peptide, GHRP-6, on delayed gastric emptying in diabetic mice.

### Research frontiers

This study represents the first investigation into the effects of ghrelin and GHRP-6 on diabetic mice with gastroparesis, using both *in vivo* and *in vitro* approaches.

### Related publications

Ghrelin has been under intensive study for its effects on gastrointestinal motor activity and its roles in motility regulation. In addition to influencing food intake and energy balance, ghrelin also possesses prokinetic characteristics mediated by the activation of cholinergic pathways.

### Innovations and breakthroughs

Ghrelin has been shown to accelerate gastric emptying in postoperative and septic ileus animal models. However, it has not been studied in a diabetic animal model.

### Applications

According to our effective therapy in animal experiments, ghrelin and ghrelin agonists may have the potential to become useful therapeutic agents for the treatment of diabetic gastroparesis.

### Terminology

Gastroparesis: A condition of delayed stomach emptying, often seen as a complication of diabetes mellitus.

### Peer review

This paper investigated for the first time *in vivo* and *in vitro* that ghrelin and its

synthetic peptide, GHRP-6, improves gastric emptying in diabetic mice with gastroparesis, and this effect may be mediated through peripheral cholinergic pathways in the enteric nervous system. These results are potentially significant for the clinical treatment of diabetic gastroparesis.

## Abstract

**AIM:** To study the effect of aprotinin used in orthotopic liver transplantation (OLT) on the intraoperative requirement for blood products and on the incidence of laparotomy for bleeding, thrombotic events and mortality.

**METHODS:** A systematic review of the literature in the electronic database Medline and the Clinic Trials Registry Database was performed. Literature that did not fit our study were excluded. Patients in the reviewed studies were divided into two groups; one group used aprotinin (aprotinin group) while the other did not (control group). The data in the literature that fit our requirements were recorded. Weighted mean differences (WMD) in the requirements for blood products between the aprotinin group and the control group were tested using a fixed effect model. A Z test was performed to examine their reliability; the Fleiss method of fixed effect model was used to analyze data on postoperative events, and odds ratios (ORs) were tested and merged.

**RESULTS:** Seven citations were examined in our study. Among them, a requirement for blood products was reported in 4 studies including 321 patients, while postoperative events were reported in 5 studies including 477 patients. The requirement for red blood cells and fresh frozen plasma in the aprotinin group was statistically lower than that in the control group (WMD = -1.80 units, 95% CI, -3.38 to -0.22; WMD = -3.99 units, 95% CI, -6.47 to -1.50, respectively). However, no significant difference was indicated in the incidence of laparotomy for bleeding, thrombotic events and mortality between the two groups. Analysis on blood loss, anaphylactic reactions and renal function was not performed in this study due to a lack of sufficient information.

**CONCLUSION:** Aprotinin can reduce the intraoperative requirement for blood products in OLT, and has no significant effect on the incidence of laparotomy for bleeding, thrombotic events and mortality.

Requirements for transfusion and postoperative outcomes in orthotopic liver transplantation: A meta-analysis on aprotinin. *World J Gastroenterol* 2008; 14(9): 1425-1429 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1425.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1425>

## INTRODUCTION

Orthotopic liver transplantation (OLT) has become the first choice approach for the treatment of patients with end-stage liver diseases<sup>[1]</sup>. However, despite great improvements in graft preservation, surgical skills, anesthetic techniques and perioperative management<sup>[2,3]</sup>, OLT is still associated with severe bleeding and considerable transfusion requirements, which in turn greatly contribute to the peri-operative morbidity and mortality<sup>[4]</sup>. Severe bleeding in OLT occurs for several reasons, among which hemostatic abnormalities remain a major cause<sup>[5,6]</sup>.

Aprotinin, a serine protease inhibitor, is more and more commonly being used in surgeries, such as cardiac surgeries and liver transplantations, to reduce bleeding and the need for transfusions. A meta-analysis of 12 trials ( $n = 626$ ) of children undergoing cardiac surgery demonstrated aprotinin reduced the proportion of children receiving blood transfusions during cardiac surgery with cardiopulmonary bypass, but had no significant effect on the volume of blood transfused or on the amount of chest tube drainage<sup>[7]</sup>. Similarly, a meta analysis of 13 trials ( $n = 506$ ) of patients undergoing major orthopedic surgery demonstrated the pooled blood loss and the amounts of red blood cell (RBC) units (U) transfused intraoperatively and peri-operatively were significantly lower among aprotinin-treated patients than control patients. Moreover, aprotinin was not associated with an increased incidence

of deep vein thrombosis<sup>[8]</sup>. However, there are still some conflicting results on whether aprotinin can reduce blood loss or the requirement for transfusion in OLT<sup>[9,10]</sup>, and whether it can be beneficial to postoperative outcomes<sup>[11,12]</sup>. The objective of this systemic review was to study the effect of aprotinin used in OLT on the intraoperative requirement of blood products, and on the incidence of laparotomy for bleeding, thrombotic events and mortality.

## MATERIALS AND METHODS

### Data source

We searched the electronic database of Medline and the Clinic Trials Registry Database using aprotinin and liver transplantation as keywords. References cited by other retrospective articles and related articles or summaries from foreign journals were searched manually as well. After initial screening, we examined the titles and abstracts of potentially eligible trials, and selected those which met the following predefined inclusion criteria: published clinical controlled trials on the use of aprotinin in liver transplantation, English language, adult study population, with data on (1) the transfusion requirement for blood products, (2) perioperative mortality and morbidity, (3) incidence of postoperative thrombotic events and (4) incidence of laparotomy for bleeding. Citations that did not fit our study or contained insufficient information were excluded.

### Statistical analysis

We recorded the data that fit our requirements, examined their heterogeneity, and calculated the weighted mean difference (WMD) or odds ratio (OR) between the two groups. All calculations were performed using the software Review Manager 4.2 (The Nordic Cochrane Centre, The Cochrane Collaboration 2003, Copenhagen, Denmark).

We used the difference of means ( $y_i$ ) as the effect scale of the data on requirements of blood products and examined their heterogeneity ( $Q < \chi^2_{(0.05, k-1)}$ ,  $P > 0.05$ ), if  $P > 0.05$ , fixed effect model was used to calculate WMD and 95% confidence interval (95% CI); otherwise, a random effect model was used. If the 95% CI included 0, then there was no significant difference between the two groups. However, if the 95% CI was greater than 0, then the control group was supported; otherwise, the aprotinin group was supported.

We calculated the ORs of the incidence of mortality, laparotomy for bleeding and thrombotic events, and tested their heterogeneity ( $Q < \chi^2_{(0.05, k-1)}$ ,  $P > 0.05$ ). If  $P > 0.05$ , the homogeneity was considered good, and a fixed effect model was used to calculate the total OR and 95% CI; otherwise a random effect model was chosen. If 1 was included in the 95% CI, then there was no statistically significant difference between the groups. If the 95% CI was more than 1, the control group was supported; otherwise, the aprotinin group was supported.

## RESULTS

### Recording of data

We identified 87 citations in a primary literature search.

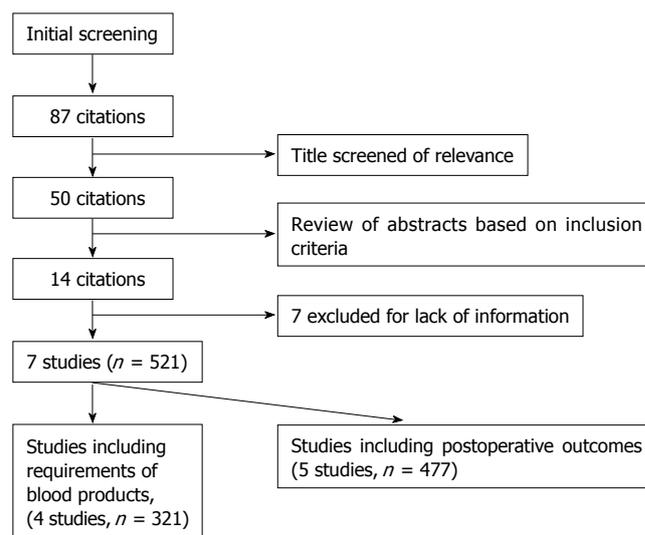

Figure 1 Results of article search and selection.

Titles were screened for relevance, eliminating 37 citations, and then abstracts and contents were read carefully, leading to the exclusion of a further 36 citations; 7 more were excluded because of a lack of information. Finally 7 citations<sup>[9,10,13-17]</sup>, including 521 patients, were included in our study (Figure 1). Of these 7 studies, one used tranexamic acid in the control group<sup>[16]</sup>; two studies contained two aprotinin groups, a high dose group and a routine dose group<sup>[10,15]</sup>; one study contained two control groups<sup>[17]</sup>; and two studies used the same sample<sup>[10,15]</sup>, the size of which was calculated only once.

### Effect of aprotinin on RBC requirement

Four citations, including 321 procedures, contained results on the requirement for blood products including RBCs and fresh frozen plasma (FFP)<sup>[10,14,16,17]</sup>.

One of these studies contained two control groups<sup>[17]</sup> (C1 and C2); Neither aprotinin nor any other antifibrinolytic agent was used in either group, so we just took C2 as the control group. Heterogeneity was tested:  $Q = 8.87$ ,  $\gamma = 3$ ,  $\chi^2_{(0.05, 3)} = 7.81$ ,  $P < 0.05$ . As the homogeneity was low, a random effect model was used: WMD = -1.23 units, 95% CI, -3.17 to 0.71; no statistical significance was indicated. Considering one study used tranexamic acid in control group<sup>[17]</sup>, it perhaps influenced the veracity, so we excluded that study and tested again,  $Q = 3.85$ ,  $\gamma = 2$ ,  $\chi^2_{(0.05, 2)} = 5.99$ ,  $P > 0.05$ , calculated with fixed effect model. It was indicated the intraoperative requirement for RBCs was significantly lower in the aprotinin group than the control group (WMD = -1.80 units, 95% CI -3.38 to -0.22; Table 1A and B).

### Effect of aprotinin on FFP requirement

The heterogeneity of the 4 citations was low ( $Q = 13.77$ ,  $\gamma = 3$ ,  $\chi^2_{(0.05, 3)} = 7.81$ ,  $P < 0.05$ ), so a random effect model was used. No significant difference was indicated (WMD = -3.13 units, 95% CI -6.79 to 0.53). If the study using individuals treated with tranexamic acid as a control group was excluded, the heterogeneity was better ( $Q = 5.25$ ,  $\chi^2_{(0.05, 2)} = 5.99$ ,  $P > 0.05$ ), and a fixed effect model was chosen. It was indicated the intraoperative requirement for

	B	0.02	0.88	0.38	1.75	> 0.05	0.09-1.64

A: Total results; B: Results with study No. 4 excluded.

FFP was significantly lower in the aprotinin group than in the control group (WMD = -3.99 units, 95% CI -6.47 to -1.50; Table 2A and B).

**Effect of aprotinin on postoperative outcomes**

As can be seen from Table 3A and B, no significant difference was indicated in the incidence of laparotomy for bleeding, thromboembolic events and mortality between the two groups.

**DISCUSSION**

Unlike traditional reviews, a meta analysis is a set of statistical procedures designed to accumulate experimental and correlational results across independent studies which address related sets of research questions. The aim of the meta-analysis is to determine a predefined inclusion criteria based on the systematic retrieval of literature on a given topic, and estimate the initial literatures carefully to ensure minimal bias in terms of the objectivity, validity and dependability of the results. The efficiency of the results depends on the choice of statistical method, as well as the rigidity of each study. In this meta analysis, we performed a wide search of the literature, identified as many studies as we could, and tested their heterogeneity ( $Q < \chi^2_{(0.05, k-1)}, P > 0.05$ ). If homogeneity was good ( $P > 0.05$ ), we calculated data with a fixed effect model; otherwise we used a random effect model. Thus, we consider the statistical methods we used were correct and rigorous.

Several factors contribute to excessive bleeding during OLT, including pre-existing coagulopathy in patients<sup>[18-20]</sup>, the procedure of liver transplantation itself, and the experience of the surgeon. However, hemostatic

abnormalities due to hyperfibrinolysis remain a major cause. Hyperfibrinolysis always occurs late in the anhepatic phase and immediately after the reperfusion of the graft<sup>[21]</sup>. This enhanced fibrinolytic activation is due to an excess of tissue-type plasminogen activator (t-PA) on account of the lack of hepatic clearance and its increased release from the ischemically damaged endothelium, associated with the consumption of  $\alpha_2$ -antiplasmin ( $\alpha_2$ -AP) and plasminogen activator inhibitor type 1 (PAI 1)<sup>[22-24]</sup>. Using a suitable method to protect blood and control the coagulopathy of patients can not only reduce the need for transfusions, reduce the transmission of diseases and immunological reactions due to the transfusion of banked blood, but also have great benefit to peri-operative hemodynamic stability. Several methods can be used to protect blood during liver transplantation, including transfusion of autologous blood, appropriate body temperature and perioperative use of blood protective drugs. Aprotinin, a basic polypeptide and non-specific proteinase inhibitor, can inhibit several proteases with serine active groups. Recently, aprotinin became no longer restricted to the treatment of patients with acute pancreatitis; it is being used more and more in cardiac surgeries, orthopedic surgeries and liver transplantations<sup>[25,26]</sup>, and is considered the ideal blood protecting drug.

Aprotinin inhibits kallikrein, reduces the release of callidin and results in a decrease in the level of t-PA. In a larger, randomized, double-blind, placebo-controlled study, Molenaar *et al*<sup>[27]</sup> compared coagulation [fibrinogen level, activated partial thromboplastin time (aPTT), prothrombin time and platelet count] and fibrinolytic variables (tPA antigen and activity, plasminogen activator inhibitor activity and D-dimer), as well as thromboelastography results [reaction time (R), clot formation time, and maximum amplitude] between an aprotinin group and a placebo group. They found fibrinolytic activity (plasma D-dimer and tPA antigen levels) was significantly lower in aprotinin-treated patients compared with the placebo group, but coagulation times (aPTT and R) were significantly more prolonged. It was indicated aprotinin has an anticoagulant rather than a procoagulant effect. Its blood-sparing (prohemostatic) effect appears to be the overall result of a strong antifibrinolytic and a weaker anticoagulant effect. In our study, it was found that, when normal saline or a placebo was used in the control group, the requirement for red blood cells was significantly lower in the aprotinin group than in the control group (WMD = -1.80 units, 95% CI, -3.38 to -0.22 units; moreover, the requirement for fresh frozen plasma was also significantly lower in the aprotinin group than in the control group (WMD = -3.99 units, 95% CI, -6.47 to -1.50). However, no significant difference was indicated in the incidence of laparotomy for bleeding, thromboembolic events, and mortality between the two groups. It was demonstrated aprotinin can reduce the intraoperative requirement for blood products in OLT. The effect of aprotinin on blood loss during OLT was not reviewed in this study because of a lack of information; more clinic trials are needed for advanced investigation.

As an extraneous protein, aprotinin causes allergies, which can induce typical allergic reactions in patients<sup>[28,29]</sup>, especially those who use it again. Aprotinin is mainly

metabolized by the kidney, and it has nephrotoxicity if used at high doses. The serum creatinine levels in patients using aprotinin during an operation increased at 3-5 d postoperatively, indicating an influence on renal function<sup>[14]</sup>. However, it was also reported the number of patients whose serum creatinine levels increased by more than 5 mg/L was lower in the aprotinin group than in the control group. No significant difference was found in peri-operative creatinine clearance rates<sup>[30]</sup>.

There are three causes of thromboembolic events: Injury of blood vessels, changes in the blood stream, and coagulation state. It was reported aprotinin can lead to intravascular thrombosis and thromboembolism during liver transplantation<sup>[31]</sup>. In our study, the OR of thrombosis was 0.42, the 95% CI was 0.14 to 1.30, and there was no significant deviation; While the study using TA as control group was excluded, the OR was 0.38, the 95% CI was 0.09 to 1.64, and there was also no statistically significant deviation. It appears aprotinin has no significant influence upon the incidence of thrombosis in patients undergoing liver transplantation, possibly due to its strong antifibrinolytic and a weaker anticoagulant effect.

As a statistical method for investigation, meta analysis has been used widely, but this method can not eliminate confounding factors and biases in each study, so the result could, unavoidably, include a certain bias. In our study, the dosages of aprotinin were different, and the drugs used in the control groups were not the same, all of which could contribute to bias. In addition, there still exists the "publish bias"; that is, articles that are published often have a tendency to have positive results, which could be decreased by collecting data that is as all-encompassing as possible.

Thus, aprotinin can reduce the intraoperative requirement for blood products in OLT and has no significant effect on the incidence of laparotomy for bleeding, thromboembolic events and mortality. Of course, further clinical randomized controlled trials (RCTs) are needed to confirm this.

## COMMENTS

### Background

Orthotopic liver transplantation (OLT) is associated with severe bleeding and considerable transfusion requirements, while severe bleeding in OLT occurs for several reasons, among which hemostatic abnormalities remain a major cause.

### Research frontiers

We performed a meta analysis to study the effect of aprotinin used in OLT on the intraoperative requirement for blood products and the postoperative outcomes.

### Innovations and breakthroughs

This study clearly shows aprotinin can reduce the intraoperative requirement for blood products and has no significant effect on the incidence of laparotomy for bleeding, thromboembolic events and mortality.

### Applications

Although additional clinical randomized controlled trials (RCTs) are required to clarify the role of aprotinin in OLT, this study strongly confirms the blood transfusion reducing effect of aprotinin, which has no significant effect on the incidence of laparotomy for bleeding, thromboembolic events and mortality.

### Peer review

The authors investigated the effect of aprotinin used in OLT on the intraoperative

requirement of blood products and on the incidence of laparotomy for bleeding, thrombotic events and mortality, using a systematic review of the literature. They concluded aprotinin can reduce the intraoperative requirement of blood product in OLT, and has no significant effect on the incidence of laparotomy for bleeding, thrombotic events and mortality.

Received: July 11, 2007 Revised: October 30, 2007

### Abstract

**AIM:** To determine the safety and efficacy of efficacy of percutaneous cryosurgery for treatment of patients with hepatic colorectal metastases.

**METHODS:** Three hundred and twenty-six patients with non-resectable hepatic colorectal metastases underwent percutaneous cryosurgery under the guidance of ultrasound or CT. Follow-up was 1 mo after cryosurgery and then every 4 mo thereafter by assessment of tumor markers, liver ultrasonography, and abdominal CT. For lesions suspicious of recurrence, a liver biopsy was performed and subsequent repeat cryosurgery was given if histology was positive for cancer.

**RESULTS:** All patients underwent a total of 526 procedures of cryosurgery. There were 151 patients who underwent repeat procedures of cryosurgery for recurrent tumors in the liver and extrahepatic places. At 3 mo after cryosurgery, carcinoembryonic antigen (CEA) levels in 197 (77.5%) patients who had elevated markers before cryosurgery decreased to normal range. Among 280 patients who received CT following-up, cryotreated lesions showed complete response (CR) in 41 patients (14.6%), partial response (PR) in 115 patients (41.1%), stable disease (SD) in 68 patients (24.3%) and progressive disease (PD) in 56 patients (20%). The recurrence rate was 47.2% during a median follow-up of 32 mo (range, 7-61). Sixty one percent of the recurrences were seen in liver only and 13.9% in liver and extrahepatic areas. The recurrence rate at cryotreated site was only 6.4% for all cases. During a median follow-up of 36 mo (7-62 mo), the median survival of all patient was 29 mo (range 3-62 mo). Overall survival was 78%, 62%, 41%, 34% and 23% at 1, 2, 3, 4 and 5 years, respectively, after the treatment. Patients with tumor size less than 3 cm, tumor in right lobe of liver, lower CEA levels (< 100 ng/dL) and post-cryosurgery TACE had higher survival rate. There was

no significant difference in terms of survival based on the number of tumors, pre-cryosurgery chemotherapy and the timing of the development of metastases (synchronous vs metachronous). Patients who underwent 2-3 procedures of cryosurgery had increased survival compared to patients who received cryosurgery once only. There was no intra-cryosurgery mortality. Main adverse effects, such as hepatic bleeding, cryoshock, biliary fistula, liver failure, renal insufficiency and liver abscess were only observed in 0.3%-1.5% of patients.

**CONCLUSION:** Percutaneous cryosurgery was a safe modality for hepatic colorectal metastases. Rather than an alternative to resection, this technique should be regarded as a complement to hepatectomy and as an additional means of achieving tumor eradication when total excision is not possible.

### INTRODUCTION

Hepatic metastasis is the main cause of death in patients with colorectal carcinoma. Hepatic resection is the treatment of choice for liver cancer if metastases are confined to the liver, and may achieve a 5 years survival of 25%-39%<sup>[1-4]</sup>. Resectability is usually determined by the absence of extrahepatic metastases, a maximum of four lesions in the liver and the ability to obtain cancer-free resection margins<sup>[5]</sup>. Therefore, only 10%-20% of patients with hepatic colorectal metastases are suitable

for resection<sup>[6]</sup>. For non-resectable liver metastases, chemotherapy or chemoembolization are often used, but the outcome is poor. Median survival is around 12 mo for non-resectable hepatic colorectal metastases<sup>[7]</sup>.

Cryosurgery has recently been applied to non-resectable liver tumors, and has shown encouraging results<sup>[8-11]</sup>. Between March 2001 and February 2007, 1090 patients with malignant liver tumors were treated by cryosurgery in our hospital. There were 680 patients with hepatocellular carcinoma (HCC), 326 with liver metastases originating from colorectal carcinoma, and 84 with liver metastases from cancer of non-colorectal origin. This study describes the results of percutaneous cryosurgery for the treatment of non-resectable hepatic colorectal metastases, with the purpose of determining the efficacy and safety of this modality.

## MATERIALS AND METHODS

### Patients

Three hundred and twenty six patients with hepatic colorectal metastases were enrolled in this study. There were 243 men and 83 women with a mean age of 54.8 years (range, 32-84). Patient and tumor characteristics are listed in Table 1.

Diagnosis of hepatic colorectal metastases was made by intraoperative findings during colectomy, and in postoperative follow-up, by the combination of increased levels of tumor markers [carcinoembryonic antigen (CEA)] and imaging of lesions by ultrasonography, CT or MRI of the liver. There were 234 patients whose diagnosis was proven by liver biopsy. Liver metastases were synchronous in 65 cases (19.9%) and metachronous in 261 cases (80.1%). The tumors of all cases received a thorough investigation with regard to the presence of multiple nodules or to the presence of a large and/or ill-located tumor, comorbidity, and were considered as non-resectable. Patients with extrahepatic metastases or liver failure were excluded from this study.

All patients were given cryosurgery guidelines, and the study received ethical approval.

### Cryosurgery technique

Cryosurgery was performed with Cryocare Operative System (Endocare, CA, USA) which used the Joule-Thomson effect to cool the end of a cryoprobe in closed systems. In accordance with the gas coefficient and the dimension of the nozzle, different gaseous elements generate different thermal exchange events at the area close to the nozzle. Argon gas is used for cooling (-187°C), and helium is used for heating (67°C). The probe was inserted percutaneously under ultrasound or CT guidance, and two freezing-thawing cycles were performed. We used mainly 2- or 5-mm probes and rarely a 10-mm probe, according to the size of the tumor. Two or more probes were used simultaneously for large lesions. Individual tumors may be frozen sequentially on a tumor-by-tumor basis or simultaneously. The time of freezing was dependent on the achievement of an "ice-ball", visible as a hypoechogenic area on ultrasonography, > 1 cm the diameter of the lesion. Thawing was achieved by input

of helium during a period equivalent to the freezing time before the second freezing process was begun. Hemostasis of the insertion hole of the cryoprobe was obtained by Spongel application to the tract of the cryoprobe and by suture of the insertion site.

### Transarterial chemoembolization (TACE)

After cryosurgery, 280 patients underwent one or two sessions of TACE within 1-2 mo. The reasons for using TACE were larger tumors prior to cryosurgery, multiple tumors, or higher CEA level after cryosurgery. The chemotherapeutic agents for intra-arterial infusion were a mixture of Lipiodol and doxorubicin, cisplatin, 5-fluorouracil, and mitomycin C. Occasionally gelfoam was used as an embolization material.

### Follow-up

Postoperative follow-up was at the first month and then every 4 mo after cryosurgery, by assessment of liver function tests, tumor markers, liver ultrasonography, and abdominal CT. Some of patients received follow-up with positron emission tomography (PET). Efficacy of cryosurgery for tumors was evaluated according to the evolution of tumor size and tumor markers. Changes in tumor mass were measured according to the Response Evaluation Criteria in Solid Tumors (RECIST) protocol<sup>[12]</sup>, which is based on objective measurement of lesion size before and after treatment. Complete response (CR) means cryotreated lesion disappearance (scar) or < 25% of original size. Partial response (PR) means a > 30% decrease in the sum of the largest diameter of all targeted lesions. Stable disease (SD) means < 30% decrease in the sum of the largest diameter of all targeted lesions. Progressive disease (PD) means an increase of > 20% in the sum of the largest diameter of all targeted lesions.

All radiologic studies were reviewed by the same radiologist with expertise in hepatic imaging. For lesions suspicious of recurrence, an ultrasound-guided liver biopsy was performed for histological study. Subsequent repeat

cryosurgery was performed if histology was positive for cancer. A persistent nodule on radiological imaging, without tumor activity shown on PET, or with reduced or normal tumor markers (CEA), or no changes of the nodule size within at least 6 mo since cryosurgery, was considered as a remnant. Tumor recurrence was estimated either by histological examination of the liver, or by combination of size increase of the cryotreated lesion on ultrasound, CT or PET imaging and increased tumor markers.

### Statistical analysis

Survival was determined according to the Kaplan-Meier method. Comparison of survival rates was obtained with the log-rank test.  $P < 0.05$  was considered statistically significant.

## RESULTS

All patients underwent a total of 526 procedures of cryosurgery. There were 175 patients who received a single procedure of cryosurgery, and 151 patients who underwent repeat procedures of cryosurgery for recurrent tumors in the liver and extrahepatic places (Table 2).

### Changes in tumor marker

Increased CEA level was observed in 254 patients (77.9%) at the time of the initial diagnosis. Among these patients, CEA level decreased to within the normal range in 197 (77.5%) patients, and increased in 41 patients (16.1%), with no significant change in 16 cases (6.3%), at 3 mo after cryosurgery.

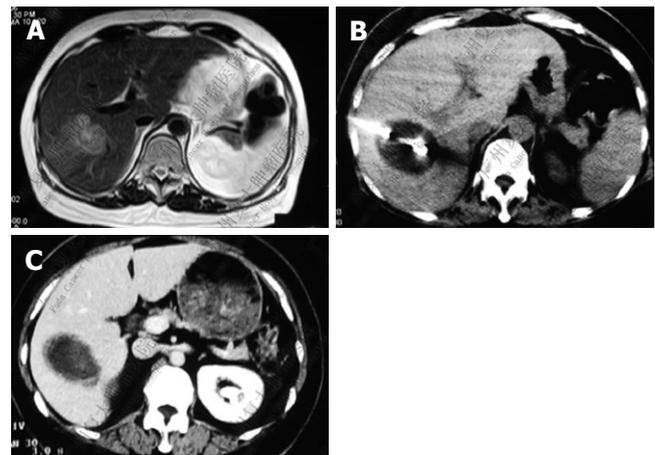

Figure 1 Liver imaging in patients with hepatic colorectal metastases. Complete ablation of histology-proven tumor achieved after percutaneous cryosurgery. A: MRI before cryosurgery; B: During percutaneous cryosurgery under CT guidance; C: Twelve mo after cryosurgery.

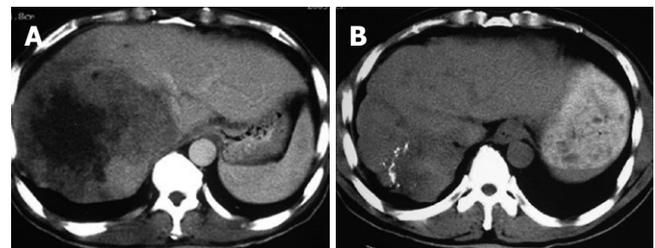

Figure 2 CT of a patient with hepatic colorectal metastases treated by percutaneous cryosurgery. The massive lesion showed a CR to cryosurgery and TACE. A: Before cryosurgery; B: Eight months after cryosurgery and TACE.

### Evolution of tumor size

After cryosurgery, an early increase in the size of lesions in relation to the freezing margin  $> 1$  cm beyond the limit of the tumor was a constant feature. Cryotreated lesions appeared as hypoechogenic or hypodense areas. Among 280 patients who received CT follow-up, CR was observed in 41 patients (14.6%), PR in 115 (41.1%), SD in 68 (24.3%), and PD in 56 patients (20%). Two patients with CR proven by histology and CT are presented in Figures 1 and 2.

### Tumor recurrence

The recurrence rate was 47.2% during a median follow-up of 32 mo (range, 7-61). Recurrence patterns are presented in Table 3. Sixty-one percent of recurrence was in the liver only and 13.9% in the liver and extrahepatic areas. Extrahepatic recurrence was mainly seen in the lungs and lymph nodes. The recurrence at cryotreated site, including at cryotreated site only as well as cryotreated site and the remaining area of liver, accounted 15.3% of cases who had recurrence and 6.4% of all cases.

### Overall survival

During a median follow-up of 36 mo (7-62 mo), the median survival of all patient was 29 mo (range 3-62 mo). One hundred and ninety six patients (60.1%) died during follow-up, and 130 patients (39.9%) are still alive, with a median survival of 26 and 36 mo, respectively. Overall

Acute myocardial infarction and severe arrhythmias	2	0.6

underwent two or three procedures had an increased survival, compared to those who received cryosurgery only once. However, patients who received cryosurgery on more than three occasions had lower survival (Table 4, Figure 3).

**Mortality and morbidity**

The minor and major adverse effects of cryosurgery are shown in Table 5. A temporary pain in the abdominal right-upper quadrant and fever (about 38°C) were observed in about half the patients. An elevation of serum transaminase levels occurred in 124 patients and normalization was observed within 14 d. Differing degrees of thrombocytopenia were seen in 58 patients, only four of whom received infusion of fresh frozen plasma or platelet concentrate, none had poor consequence. Twenty patients, of whom, 18 had sub-diaphragmatic liver tumor, had right pleural effusion, probably due to the irritative process beneath the diaphragm.

There was no cryosurgical mortality. A total of 19 patients developed major adverse effects. Hemorrhage from a cryotreated lesion was seen in five patients, three of whom died of the complication. One patient, who underwent cryosurgery for > 50% of liver volume, died of hepatic failure. One patient, who received cryosurgery for eight large metastases, died of a cryoshock syndrome. Three patients suffered from biliary fistula which resolved with transhepatic drainage. Five patients had temporary renal insufficiency, which presented as increased blood urea nitrogen and creatinine levels for 3-7 d. Two patients developed bacterial hepatic abscess within cryotreated sites and recovered with antibacterial agents and drainage. Two patients, aged 72 and 76 years respectively, died of acute myocardial infarction and severe arrhythmias apparently unrelated to cryosurgery. There were a total of seven patients who died from the main adverse effects after cryosurgery.

**DISCUSSION**

Cryosurgery is a treatment in which tumors are frozen and then left *in situ* to be reabsorbed. Several studies have reported the results of hepatic cryosurgery for treatment of hepatic colorectal metastases<sup>[13-16]</sup>. Survival after

<sup>1</sup>Thirty mo survival; <sup>2</sup>Including 56 cases of hepatic colorectal metastases. Cryo: Cryosurgery; OC: Operative cryosurgery; PC: Percutaneous cryosurgery.

cryosurgery is probably inferior to that achieved by liver resection, but it should be noted that most of the patients undergoing cryosurgery have non-resectable tumors or later stages of the disease. Current long-term follow-up has shown that cryosurgery is an important option for a wide range of non-resectable hepatic colorectal metastases and provides the potential for long-term survival<sup>[17]</sup>.

Until now, cryosurgery for most patients with hepatic colorectal metastases was performed during laparotomy, either as a single modality or in association with liver resection. Operative cryosurgery is still more invasive for the patient. As an advancement of imaging guidance and improvement of cryosurgical apparatus, the percutaneous mode of cryosurgery, a less invasive procedure, has been used for treatment of tumors, and apparently, may be suitable for non-resectable hepatic colorectal metastases.

### Efficacy of percutaneous cryosurgery

This study, in which 326 patients with non-resectable hepatic colorectal metastases who underwent percutaneous cryosurgery were followed-up for a median of 36 mo, showed: (1) after cryosurgery, serum CEA in 77.5% of patients with elevated markers returned to normal. (2) After cryosurgery, CR was achieved in 14.6% of patients, PR in 41.1%, and SD in 24.3%. (3) During a median follow-up of 36 mo (7-62 mo), the median survival of all patients was 29 mo (range 3-62 mo). Overall survival was 78%, 62%, 41%, 34% and 23% at 1, 2, 3, 4 and 5 years, respectively.

Comparing the published results of operative cryosurgery (Table 6), in which the median survival was 21-45 mo, and the 1-, 2-, 3- and 5-years survival was 52%-86%, 36%-62%, 10%-70% and 5%-44%, our results are encouraging, especially in terms of non-resectable tumors.

Similar to operative cryosurgery, the main problem in the face of percutaneous cryosurgery is recurrence. In our patients, 47.2% had recurrence during a median follow-up of 32 mo (range, 7-61). The liver was the main site of recurrence, 61% of which occurred in the liver only, and 13.9% in the liver and some extrahepatic locations. Extrahepatic recurrence was mainly seen in the lungs and lymph nodes. The overall recurrence rate was lower than the 44% in a mean follow-up of 16 mo, reported by Adam<sup>[13]</sup>, and much lower than the 78%

reported by Weaver<sup>[16]</sup>. It is important to point out that in our patients, the recurrence rate at cryotreated site, including at cryotreated site only as well as both of cryotreated site and the remaining areas of liver, was only 15.3% for patients with recurrence and 6.4% for all cases, which is significantly lower than the 58.8% reported by Jungrai Thmayr<sup>[24]</sup>. Obviously, the decreased tumor recurrence is related to better survival.

### Factors influencing survival of patient

This study showed patients with lesions  $\leq 3$  cm had an increased survival rate compared with those with lesions  $> 3$  cm, with a median survival of 39 and 21 mo, respectively. This may have been due to the larger tumor in the vicinity of large vessels and exposure to the heat sink effect. The warming effect of blood flow can cause insufficient cryodestruction of the tumor. Pearson *et al*<sup>[25]</sup> have reported that 66.7% of local recurrence occurs directly in the vicinity of the vena cava or a large vessel. No significant correlation has been found between the number of metastases and survival. Patients with tumor in the right hepatic lobe have higher survival compared with those with left lobe or bilateral tumors, which may be because the latter location is closer to large vessels.

This study also appeared to show a correlation between poor survival and CEA level  $> 100$  ng/dL, with a median survival of 18 mo, which is much less than the 38 mo median survival for patients with lower CEA ( $P < 0.01$ ). The result is consistent with that reported by Weaver *et al*<sup>[15,16]</sup> who showed that patients with CEA  $> 100$  ng/dL prior to cryosurgery had only 10 mo median survival, while the median survival of patients with CEA lower than that level was 17-19 mo. The poor outcome of patients with higher CEA may be related to the biological behavior of CEA-secreting tumors.

According to the results of this study, the possibility of repeat percutaneous cryosurgery may be a factor which brings about better survival and low recurrence. Patients who received two or three cryosurgery procedures had longer survival. In contrast to operative cryosurgery, percutaneous cryosurgery may be performed many times because of its convenience and low intervention. As a result, the recurrence in liver and extrahepatic metastases may be conveniently treated. In this series, there were 12 and 6 patients, respectively, with lung and pancreas

metastases, who were treated by percutaneous cryosurgery.

As shown in this study, patients who received post-cryosurgery TACE had the higher survival compared to patients who did not receive TACE (5-year survival of 47% *vs* 15%). Post-resection TACE has been shown to decrease the recurrence rate for patients with HCC<sup>[26]</sup>. The effect, therefore, may be an additional factor for the longer survival in our patients. We have used combination of percutaneous cryosurgery and absolute ethanol injection for treatment of HCC with good results<sup>[27]</sup>. The strategy may be suitable for hepatic colorectal metastases.

### Safety of percutaneous cryosurgery

In this study, a total of 526 procedures of cryosurgery in all patients were safely performed percutaneously. There were 151 patients who underwent repeat cryosurgery, as many as two to four procedures, for recurrent tumors in the liver and extrahepatic loci. There was no treatment-related mortality. Although about one third of patients had adverse effects, such as pain, fever, increased liver enzymes, thrombocytopenia and pleural effusion, they were generally self-limited without poor outcome. Cryoshock, as the most serious complication of hepatic cryosurgery, was observed in one of our patients, with an incidence of 0.3%, which is lower than the 1% in patients who underwent operative hepatic cryosurgery, based on a worldwide survey<sup>[28]</sup>. Other major adverse effects, such as hepatic bleeding, biliary fistula, liver failure, renal insufficiency and liver abscess, were observed in 0.3%-1.5% of our patients; however, the incidence is no higher than that in patients undergoing operative hepatic cryosurgery<sup>[29,30]</sup>. Therefore, percutaneous cryosurgery is a safe technique for liver surgery.

In conclusion, the results of this study clearly show that percutaneous cryosurgery is a safe modality for hepatic colorectal metastases. Rather than an alternative to resection, the technique should be regarded as a complement to hepatectomy and as an additional means to achieve tumor eradication when total excision can not be accomplished.

## COMMENTS

### Background

Nearly 50% of patients who have colorectal carcinoma will develop liver metastases, which are a frequent cause of death. Without treatment, the average survival of patients with multiple lesions is 5-10 mo, and the 5 years survival rate is 1%. Liver resection is the only established, potentially curative treatment for patients with hepatic colorectal metastases confined to the liver, however, most patients have non-resectable tumors, even when they have no extrahepatic disease. If patients have more than three lesions or have anatomical constraints at presentation, only 5%-10% are suitable for liver resection. Palliative resection is of no significant benefit. Chemotherapy, including intra-arterial continuous infusion, is the most commonly used therapeutic modality but prolongation of survival has not been proven. Irradiation of liver metastases has been shown to relieve pain, but median survival does not appear to be prolonged. Therefore, the search for new treatment modalities for patients with non-resectable hepatic colorectal metastases is very urgent.

### Research frontiers

Cryosurgery has increasingly been recognized as a safe and effective alternative treatment modality that is used alone or in conjunction with hepatic resection for a selected group of patients with non-resectable disease confined to the liver. It has shown some promising results, with a median survival > 2 years in most published studies and the prospect of long-term disease-free survival or cure for some patients.

### Innovation and breakthroughs

Cryosurgery in most patients with hepatic colorectal metastases has been performed with open laparotomy. With improved imaging techniques and cryosurgical equipment, percutaneous cryosurgery, as a minimally invasive alternative for open procedure, is increasingly used for treatment of liver tumors. This study of 326 patients with hepatic colorectal metastases who underwent percutaneous cryosurgery demonstrates encouraging efficacy, with overall survival of 78%, 62%, 41%, 34% and 23% at 1, 2, 3, 4 and 5 years, respectively. These survival rates are much greater than those achieved using other treatments in patients with non-resectable liver metastases from colorectal carcinoma. Moreover, the incidence of complications is no higher than that in patients who underwent operative hepatic cryosurgery.

### Applications

Percutaneous cryosurgery is a safe and feasible approach for treatment of patients with non-resectable hepatic colorectal metastases. Rather than an alternative to resection, it is to be regarded as a complement to hepatectomy and as an additional means to achieve tumor eradication when total excision can not be accomplished.

### Terminology

Ablation destroys tumors locally without requiring resection, with effectiveness comparable to resection. Cryosurgery is one of the ablation techniques. Cryosurgery is referred to as cryotherapy or cryoablation, and is the *in situ* destruction of undesirable tissue by localized freezing. It has become an effective technique for treating tumors of solid organs such as liver, prostate, kidneys, lungs, and has advantages over other surgical techniques. Percutaneous cryosurgery is a minimally invasive technique, which is usually performed by the insertion of one or more cryosurgical probes into the tumor under guidance of ultrasound, CT or MRI.

### Peer review

This is a valuable paper, which describes the efficacy and safety profile of percutaneous cryosurgery. A prospective trial that compares surgical cryoablation and other forms of ablation in terms of patient survival is necessary to confirm the effects of ablation for non-resectable liver cancer.

### Abstract

**AIM:** To investigate the role of Ras association domain family protein 1 isoform A (RASSF1A) in gastric tumorigenesis.

**METHODS:** Through over-expression of RASSF1A gene in the SGC7901 cell line which was induced by a lipofectamine-mediated gene transfer approach. Activator protein-1 (AP-1) DNA binding activity was measured by electrophoretic mobility shift assay (EMSA).

**RESULTS:** Compared with the control clones, cells over-expressing RASSF1A exhibited significant inhibition of cell growth with G<sub>1</sub> cell cycle arrest *in vitro* and *in vivo*. The over-expression of RASSF1A significantly inhibited AP-1 activity in SGC7901 cells ( $0.981 \pm 0.011$  vs  $0.354 \pm 0.053$ ,  $P < 0.001$ ). In addition, both Western blot analysis and immunocytochemistry demonstrated that RASSF1A down-regulated the expression of c-Fos ( $0.975 \pm 0.02$  vs  $0.095 \pm 0.024$ ,  $P < 0.001$ ) but not c-Jun.

**CONCLUSION:** Over-expression of RASSF1A inhibits the growth of SGC7901 cells by negatively regulating the AP-1 activity, the latter in turn negatively signals cell proliferation.

### INTRODUCTION

Gastric carcinoma is one of the most frequent tumors that seriously threaten people's health in China<sup>[1]</sup>. Molecular genetics studies indicate that loss of 3p was observed in different types of solid tumors<sup>[2]</sup>. Frequent loss on 3p21-23 was detected in gastric cancer<sup>[3,4]</sup>.

Ras association domain family protein 1 isoform A (RASSF1A), one transcript of RASSF1 gene, is a recently identified 3p21.3 tumor suppressor gene<sup>[5]</sup>. Loss of expression of RASSF1A was a frequent event in primary gastric carcinoma<sup>[6,7]</sup>. However, the exact role of RASSF1A in gastric tumorigenicity is largely unknown.

Activator protein-1 (AP-1) plays an important role in various human diseases and regulates the expression of multiple genes essential for cell proliferation, differentiation and apoptosis<sup>[8]</sup>. AP-1 is thought to serve as a nuclear target of Ras<sup>[9]</sup>. It is not known whether RASSF1A, as effectors of Ras signaling<sup>[10]</sup>, could or could not inhibit the activity of AP-1.

In this study, we established gastric cancer cell lines stably over expressing RASSF1A. Characterization of these cells with regard to proliferation rate and tumorigenicity *in vitro* and *in vivo* was performed. AP-1 activity was measured by electrophoretic mobility shift assay (EMSA). Our results suggest that over-expression of RASSF1A exerts inhibitory effects on the transformed phenotype of gastric cancer cells and RASSF1A inhibits AP-1 activity.

### MATERIALS AND METHODS

#### Cell culture

The human gastric cancer cells, SGC7901 (Shanghai Cell Bank, Chinese Academy of Sciences), were maintained in RPMI 1640 medium (Life Technologies, Inc, Grand Island,

NY) supplemented with 100 mL/L fetal bovine serum plus penicillin (50 IU/mL) and streptomycin (50 µg/mL) with passage every three days. Cultures were incubated in an incubator containing 5 mL/L CO<sub>2</sub> at 37°C.

#### **Gene transfection and establishment of stable cell lines**

Plasmid pcDNA3.0-RASSF1A and pcDNA3.0 were gifts from Professor Michael White (Department of Cell Biology, UT Southwestern Medical Center, Dallas, TX 75390, USA). Cells were seeded in six-well plates to 70%-80% confluence. The cells were transfected with 4 µg/well plasmids using Lipofectamine 2000 (Invitrogen). After transfection for 6 h, the cells were transferred to normal medium and allowed to recover overnight. The cells were trypsinized and split 1:10, and then seeded into new six-well plates. 48 h after transfection, transfected cells were grown in RPMI containing G418 (Alexis Biochemicals) at 0.8 g/L until all of the nontransfected cells were dead (2 wk). Resistant clones were selected separately using cloning cylinders and maintained in RPMI containing 0.2 g/L G418 for further study. Meanwhile, SGC-7901 cells were transfected with the empty pcDNA3.0 vector as the control.

#### **Preparation of cytoplasmic and nuclear extract**

Nuclear and cytoplasm extracts were prepared as described by Dignam *et al*<sup>[11]</sup>. Confluent cells in 10 cm dishes were treated for various times with the indicated effectors. Cells were resuspended in 400 µL of buffer A [10 mmol/L HEPES (pH 7.9), 1.5 mmol/L MgCl<sub>2</sub>, 10 mmol/L KCl, 0.5 mmol/L DTT, 0.5 mmol/L phenylmethylsulfonyl fluoride, 1 µg/mL leupeptin, 1 µg/mL aprotinin, and 1 µg/mL pepstatin A], kept on ice for 15 min, lysed gently with 12.5 µL of 10% NP40, and centrifuged at 2000 r/min for 10 min at 4°C. The supernatant was collected and used as the cytoplasm extracts. The nuclei pellet was resuspended in 40 µL of buffer C [20 mmol/L HEPES (pH 7.9)], containing 1.5 mmol/L MgCl<sub>2</sub>, 450 mmol/L NaCl, 25% glycerol, 0.2 mmol/L EDTA, 0.5 mmol DTT, 0.5 mmol/L phenylmethylsulfonyl fluoride, 1 µg/mL leupeptin, 1 µg/mL aprotinin, and 1 µg/mL pepstatin A] and agitated for 30 min at 4°C, and the nuclear debris was spun down at 20 000 r/min for 15 min. The supernatant (nuclear extract) was collected and stored at -80°C until ready for analysis. Proteins were measured using the BCA kit (Pierce) according to the manufacturer's protocol.

#### **Western blot analysis**

Eighty µg of cytoplasm proteins or 40 µg nuclear proteins were separated by 10% SDS-PAGE under reducing conditions, and transferred to a nitrocellulose membrane. The nitrocellulose membrane was then incubated with blocking buffer (TBST containing 5% non-fat milk) for 2 h at room temperature and with mouse monoclonal antibody against RASSF1A (Abcam, USA), c-Jun, c-Fos, CyclinD<sub>1</sub> (Santa Cruz Biotechnology, USA) overnight at 4°C with gentle shaking. The membrane was washed with TBST twice for 5 min, and then incubated with rabbit anti-mouse IgG conjugated horseradish peroxidase diluted at 1:2000 (Santa Cruz Biotechnology, USA) for 2 h at room temperature. After washing, RASSF1A was detected using

DAB reagents. The level of β-actin or tubulin was used as a control for equal loading of protein.

#### **Reverse transcription-PCR analysis**

Total RNA from SGC7901 cells was obtained using a RNA Mini Kit (Qiagen, Inc). Two µg of total RNA extracted from each cell line were reverse-transcribed using a RevertAid First Strand cDNA Synthesis Kit (MBI). Five ng of reverse-transcribed cDNA per sample were used to perform PCR in triplicate samples for RASSF1A and β-actin as an internal control. Reactions were carried out under the following conditions: 95°C for 5 min, followed by 35 cycles at 94°C for 30 s, and 52°C for 40 s and 72°C for 60 s. The following primers were used: RASSF1A forward, 5'-TCTGGGGCGTCGTGAGTAAA-3' reverse, 5'-CCACCACCAAGAACAGTCG-3', β-actin forward, 5'-CCTTCCCTGGGCATGGAGTCCT-3', β-actin reverse 5'-GGAGCAATGATCTTGATCTT-3'. Three independent measurements were averaged and relative gene expression levels were calculated as a ratio to β-actin expression of each.

#### **MTT assay**

Cells were cultured in 96-well microtiter plates at a density of  $1 \times 10^4$  cells per well. The surviving cells were measured by MTT assay at 1 d, 2 d, 3 d, 4 d, 5 d, 6 d, 7 d after seeding. 20 µL of 5 g/L MTT [3-(4,5-dimethyl-thiazolyl-2)-2,5-diphenyltetrazolium bromide, Fluka, Buchs, Switzerland] in PBS was added to each well and the cells were incubated for another 4 h at 37°C. The supernatant was removed, and 150 µL of DMSO was added to each well. The absorbency at a wavelength of 595 nm was measured with a micro ELISA reader (BioRad, CA, USA).

#### **Flow cytometry analysis**

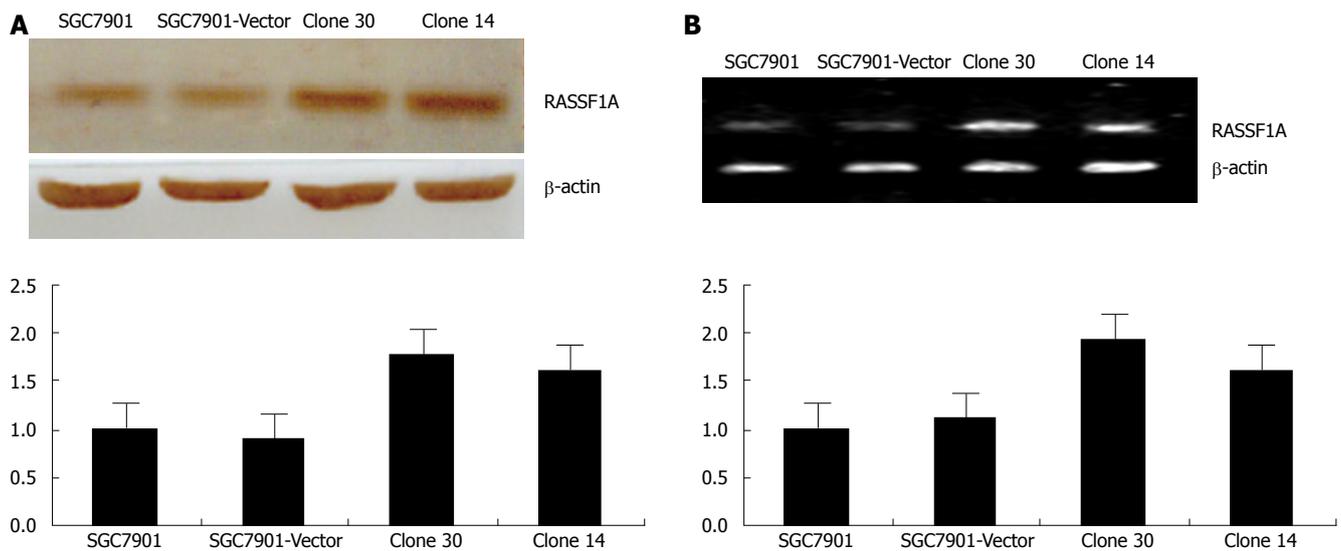

Cells were collected and fixed in 70% of ice-cold ethanol in phosphate buffer saline (PBS) and stored at -20°C. After resuspension, 100 µL RNAase I (1 g/L) and 100 µL propidium iodide (PI, 400 g/L, Sigma, USA) were added and incubated at 37°C for 30 min. Analysis of samples was performed by flow cytometry (Coulter Epics, XL, UK). The cell cycle phase distribution was calculated from the resultant DNA histogram using Multicycle AV software (Phoenix Flow System, San Diego, CA, USA).

#### **Plating efficiency**

Plating Efficiency was prepared as described by Hu *et al*<sup>[12]</sup>. Cells ( $1 \times 10^2$ ) were plated in 6-well plates. Colonies were scored at 14 d, fixed with 70% ethanol, stained with 5% Giemsa (Sigma), and counted under a microscope. Only those colonies containing at least 50 cells were considered to be viable survivors. The plating efficiency (PE) was calculated as follows: PE = (colonies formed/cells seeded) × 100%.

#### **Tumorigenicity in nude mice**

Single cell suspensions were trypsinized and collected. The cell viability was > 95% as determined by trypan blue staining. Cells ( $5 \times 10^6$ ) in a 0.1 mL volume of RPMI were inoculated s.c. into the right flank of 4-6 wk-old female BALB/c-nu/nu mice (Laboratory Animal Unit, Central

**Figure 1** The over-expression of RASSF1A in gastric cancer cell line SGC7901. Cells were stably transfected using Lipofectamine 2000 with RASSF1A or empty vector and were grown in RPMI containing G418 at 0.8 g/L. Resistant clones were selected separately and were measured by Western blotting and RT-PCR,  $\beta$ -actin was used as an internal loading control, and clone30 was used for further study. **A:** RASSF1A expression was analyzed by Western blotting; **B:** RASSF1A expression was analyzed by RT-PCR.

South University). The mice were maintained under sterile conditions for 30 d. At the end of the experiment, the tumors were excised and the tumor weight was measured.

#### Electrophoretic mobility shift assay

EMSA was prepared as described by Li *et al.*<sup>[3]</sup>. Fifteen  $\mu$ g of nuclear proteins were incubated with 1  $\mu$ g each of poly (dI-dC) in the presence of 30 fmol of digoxin (DIG)-labeled double-stranded AP-1 probe (5'-CGCTTGATG ACTCAGCCGGAA-3', BoYa Biotechnology, China) for 15 min at room temperature in a total volume of 20  $\mu$ L using DIG gel shift kit (Roche Diagnostics GmbH, Mannheim, Germany). Oligonucleotide competition experiments were performed in 50-fold excess of unlabeled oligonucleotides. DNA complexes were resolved from free probe with 4% nondenaturing polyacrylamide gels in 0.5  $\times$  Tris-borate-EDTA (pH 8.3) and visualized by fluorography.

#### Immunocytochemistry

Cells were grown to 70% confluency on 22 mm  $\times$  22 mm microscope coverslips, washed with PBS, then incubated for 1 h at room temperature with c-Jun, c-Fos monoclonal antibody (Santa Cruz Biotechnology, USA) at a final dilution of 1:200. Primary antibody was removed by repetitive washes with PBS and secondary antibody was added for 1 h at room temperature. Cells were washed in PBS and stained with DAB.

#### Statistical analysis

The data shown were mean values of at least three different experiments and expressed as mean  $\pm$  SD. Student's *t* test was used for comparison.  $P < 0.05$  is considered statistically significant.

## RESULTS

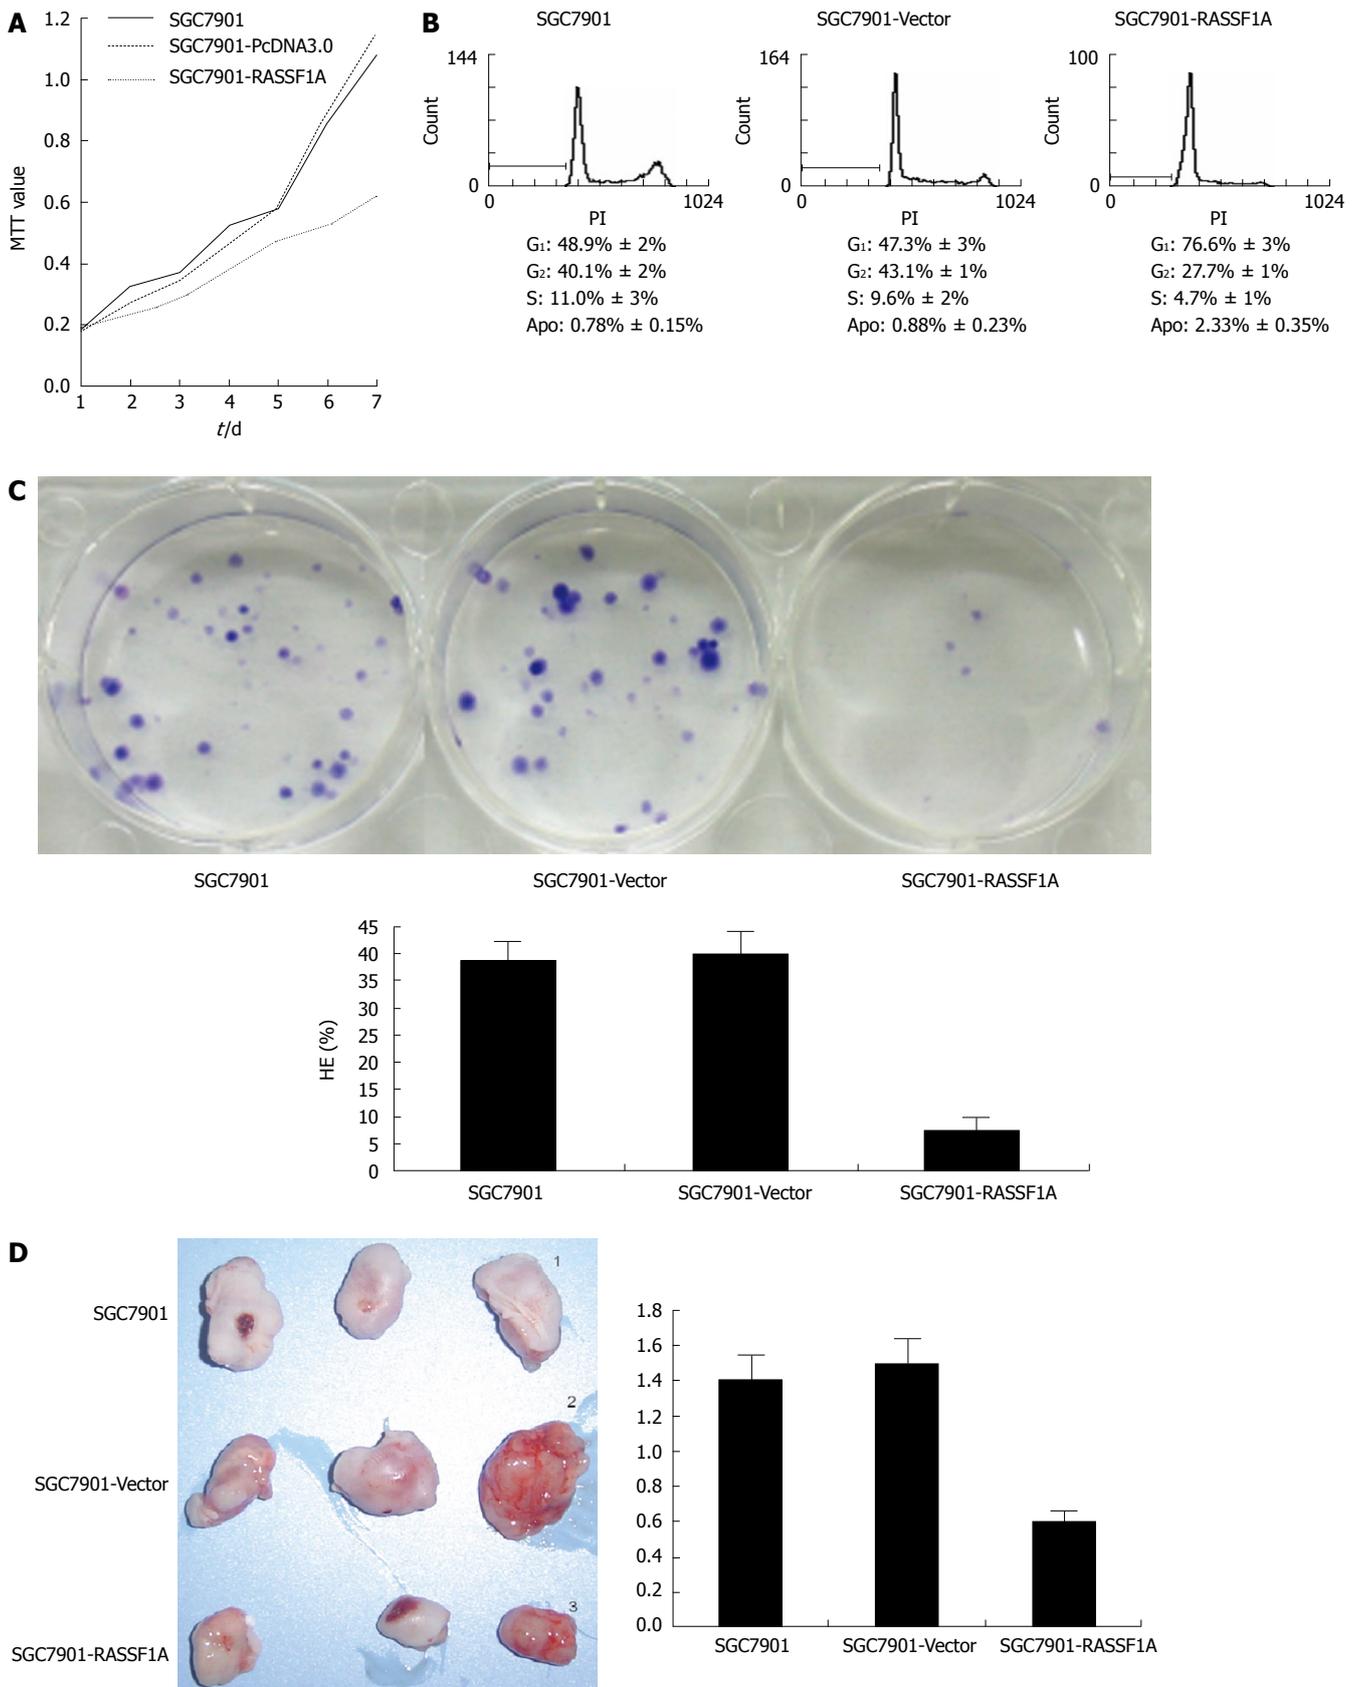

### Generation of gastric cancer cells stably over-expressing RASSF1A

SGC-7901 human gastric cancer cells were transfected

with the control pcDNA3.0, pcDNA3.0-RASSF1A plasmids, respectively. Empty vector pcDNA3.0-transfected cell clones were named vector control and, together with the parental SGC-7901 cells, served as controls in this study. After G418 selection, 4 clones of pcDNA3.0-RASSF1A cells were picked, spread, and collected, including clone14, clone 19, clone 30 and clone 33. The expression of RASSF1A in clone 30 and clone 14 were further detected by Western blot analysis and RT-PCR analysis. As shown in Figure 1A, cells transfected with the control vector did not alter RASSF1A expression when compared with the SGC-7901 cells, whereas introduction of pcDNA3.0-RASSF1A resulted in marked over-expression. The protein expression of RASSF1A was increased about 77.5%, 61.2%, when compared with the parental cells. As shown in Figure 1B, RASSF1A mRNA was increased by 80.2%, 74.7%, respectively, in the corresponding cells. Clone 30, which showed the highest degree of over-expressing RASSF1A, consequently was selected for further study. Thus, the over-expression of RASSF1A was obviously increased in our established transfected cells.

### Cell growth of SGC7901 cell inhibited by RASSF1A

To characterize the gastric cancer cells stably over-expressing RASSF1A protein, we first examined the possible effects on the rate of cell proliferation. Growth curves indicated that the vector control and parental cells displayed rapid growth rates, whereas the growth rate of the SGC7901-RASSF1A cells was significantly reduced (Figure 2A). The suppress rate was 28.13% at 48 h. The cell cycle distribution and apoptosis were determined by flow cytometry. As shown in Figure 2B, RASSF1A induced the cell cycle into G<sub>1</sub> phase. Compared with parental and vector control cells, the percentage of G<sub>1</sub> phase in RASSF1A transfected cells obviously increased ( $P < 0.05$ ). And the apoptosis rate of cells expressing RASSF1A had a slight increase.

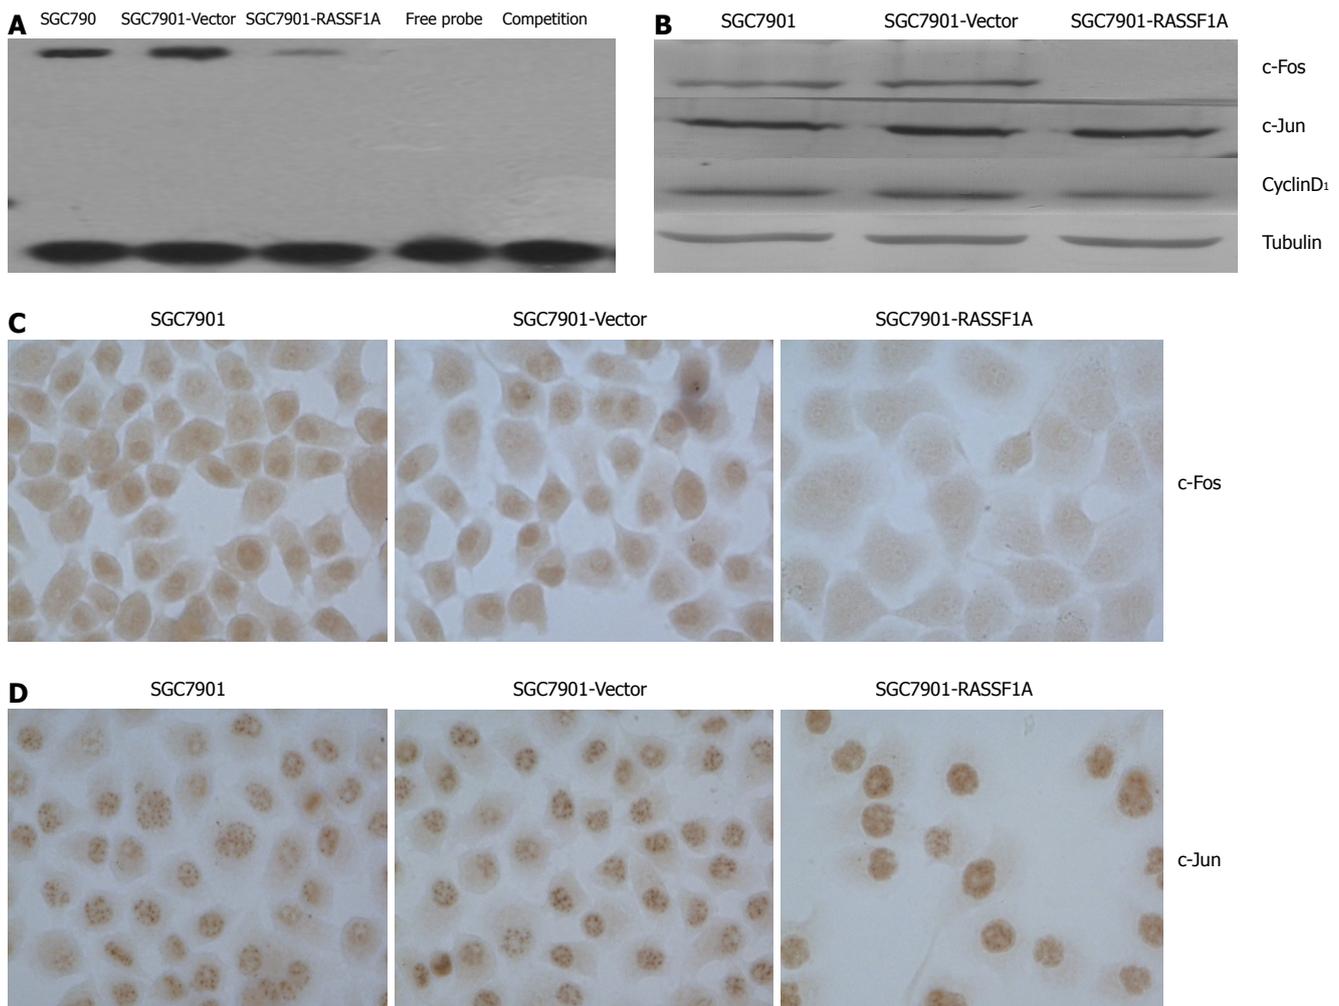

**Figure 2** RASSF1A blocked gastric cancer cell line SGC7901 growth *in vivo* and *in vitro*. **A:** Cell growth curve of gastric cancer cell line SGC7901 measured by MTT assay; **B:** RASSF1A induced gastric cancer cell line SGC7901 G<sub>1</sub> arrest; **C:** RASSF1A inhibited the colony formation of SGC7901 cells measured by planting efficiency; **D:** RASSF1A inhibited the tumorigenicity of SGC7901 cells.

**Colony formation and tumorigenicity inhibited by RASSF1A**

We analyzed the colony forming ability of the RASSF1A

transfectants in planting because anchorage-independent growth often correlates with tumorigenicity. Plating efficiency in parent, vector control and RASSF1A

**Figure 3** The over-expression of RASSF1A inhibited the AP-1 activity in gastric cancer cell line SGC7901. **A:** The over-expression of RASSF1A inhibited the AP-1 DNA binding activity measured by EMSA; **B:** The over-expression of RASSF1A inhibited the c-Fos but not c-Jun expression in nuclear extract of SGC7901 cells. (Western blotting, DAB staining); **C:** The over-expression of RASSF1A inhibited the c-Fos expression in nuclear of SGC7901 cells (immunocytochemistry, DAB staining,  $\times 400$ ); **D:** The over-expression of RASSF1A had no influence on the c-Jun expression in nuclear of SGC7901 cells (immunocytochemistry, DAB staining,  $\times 400$ ).

transfected cells were  $38.6\% \pm 1.5\%$ ,  $39.75\% \pm 2.1\%$  and  $7.3\% \pm 0.6\%$ , respectively (Figure 2C). SGC7901-RASSF1A cells displayed almost complete loss of colony-forming efficiency, and had a  $> 80\%$  decrease when compared with the vector control and parental cells. In view of these results, we examined whether the RASSF1A over-expression in gastric cancer cells might affect their tumorigenicity in nude mice.

$5 \times 10^6$  cells were injected s.c. into athymic nude mice and monitored for 30 d. The tumors appeared in three groups almost at the same time. At the end of the study, all of the tumors were removed and dissociated, and the weights of the tumors were measured. RASSF1A transfection revealed an obvious difference in tumor growth compared with vector control and parental cells during the observation period. The mean tumor weights in mice of parental, vector control cells and RASSF1A transfected cells were  $1.4 \text{ g} \pm 0.26 \text{ g}$ ,  $1.5 \pm 0.32 \text{ g}$  and  $0.6 \pm 0.1 \text{ g}$ , respectively (Figure 2D).

#### AP-1 activity inhibited by RASSF1A

We determined the DNA binding activity of AP-1 in SGC7901 cells by electrophoresis mobility shift assay.

The results showed that AP-1 DNA binding activity was significantly lower in SGC7901-RASSF1A cells than in vector control and parental cells (Figure 3A). Western blotting and immunocytochemistry data showed that c-Fos expression in the nuclear extract of SGC7901-RASSF1A cells was significantly inhibited, while, c-Jun expression in SGC7901-RASSF1A cells had no significant change. Furthermore, cyclinD<sub>1</sub> expression in nuclear extract was significantly lower in SGC7901-RASSF1A cells than in vector control and parental cells (Figure 3 B-D).

## DISCUSSION

In this report, we have demonstrated that RASSF1A inhibited proliferation of SGC7901 cells. The cell growth was reduced by 28.13% at 48 h as determined by the MTT assay. The alteration of cell malignant phenotype was obvious as a result of loss of anchorage-independent growth ability as measured by a plating efficiency test. The tumorigenicity in nude mice was reduced significantly ( $P < 0.01$ ). RASSF1A over-expression induced cell arrest from 48.9% to 76.6% ( $P < 0.01$ ) in the G<sub>1</sub> population, and increased cell apoptosis rate from 0.78% to 2.33%

( $P < 0.01$ ). These results are similar to the findings previously reported in other cancers, such as NSCLC<sup>[5,10]</sup>, kidney<sup>[14]</sup>, prostate<sup>[15]</sup>, nasopharyngeal carcinoma<sup>[16]</sup>, and glioma cell lines<sup>[17]</sup>. RASSF1A differentially regulated many genes identified as having relevance to tumorigenesis including involvement in transcription, cytoskeleton, signaling, cell cycle, cell adhesion, and apoptosis<sup>[18]</sup>.

RASSF1A is predicted to encode a 39 kDa peptide that contains an N-terminal diacylglycerol (DAG)-binding domain, a Ras-association domain, a sequence PxxP and PEST sequences. The Ras-association domain is more than 50% identical and more than 70% similar to the carboxyl terminal 225 residues of mouse Nore1<sup>[10]</sup>. RASSF1 binds Ras in a GTP-dependent manner, both *in vivo* and directly *in vitro*<sup>[19]</sup>. It has also been shown to heterodimerize with Nore1<sup>[20]</sup>. The presence of a Ras-association domain in both RASSF1 isoforms suggests that these proteins may function as effectors of Ras signaling (or signaling of a Ras-like molecule) in normal cells. The fact that RASSF1A can function as a tumor suppressor gene implies that RASSF1 acts in opposition to Ras-effector pathways stimulating proliferation<sup>[10]</sup>.

AP-1 is a transcription factor that consists of either a Jun-Jun homodimer or a Jun-Fos heterodimer. AP-1 regulates the expression of multiple genes essential for cell proliferation, differentiation and apoptosis<sup>[8]</sup>. Our results showed that RASSF1A dramatically decreased basal AP-1 activity. We further detected the expression of c-Jun/c-Fos in SGC7901. Surprisingly we failed to observe any significant change of expression of c-Jun in the present study. However, expression of c-Fos had significant change. This indicated that RASSF1A could inhibit the expression of c-Fos but not c-Jun. However, in lung cancer cells, RASSF1A reduced c-Jun phosphorylation, suppresses the c-Jun-NH2-kinase pathway and inhibits cell cycle progression<sup>[21]</sup>. We thought this difference may be due to the different histology and the role of c-Jun in RASSF1A-mediate growth inhibition in gastric carcinoma needs further investigation.

Shivakumar found that the exogenous expression of RASSF1A induced cell cycle arrest at the G<sub>1</sub> phase by down-regulating CyclinD<sub>1</sub><sup>[22]</sup>. In agreement with this report, we also observed that the ectopic expression of RASSF1A down-regulated CyclinD<sub>1</sub>. As a target of AP-1, CyclinD<sub>1</sub> plays an important role in cell proliferation<sup>[23]</sup>. According to our results, we presumed that RASSF1A induced SGC7901 cell cycle arrest at the G<sub>1</sub> phase by down-regulating CyclinD<sub>1</sub> through inhibition of the activity of AP-1, but needs further investigation. Our current results indicate that inhibition of AP-1 activity contributes to RASSF1A mediated regulation of gastric carcinogenesis.

Thus, our data presented here clearly demonstrated that exogenous RASSF1A inhibits the growth of gastric carcinoma cells SGC7901 and RASSF1A gene may be a suppressor in gastric carcinogenesis. AP-1 may be involved in growth inhibition by the RASSF1A gene in the human gastric carcinoma cell line SGC7901.

of RASSF1 gene, is a recently identified 3p21.3 tumor suppressor gene and it is described as an effector of Ras signaling. Expression loss of RASSF1A was a frequent event in primary gastric carcinoma. However, the exact role of RASSF1A in gastric tumorigenicity is largely unknown.

### Research frontiers

Gastric carcinoma is one of the most frequent tumors that seriously threaten people's health in China. Molecular genetics studies indicate that loss of 3p was observed in different types of solid tumors. Frequent loss on 3p21-23 was detected in gastric cancer. RASSF1A is predicted to encode a 39-kd peptide that contains an N-terminal diacylglycerol (DAG)-binding domain, a Ras-association domain, a sequence PxxP and PEST sequences. The presence of a Ras-association domain in both RASSF1 isoforms suggests that these proteins may function as effectors of Ras signaling (or signaling of a Ras-like molecule) in normal cells. The fact that RASSF1A can function as a tumor suppressor gene implies that RASSF1 acts in opposition to Ras-effector pathways stimulating proliferation.

### Innovations and breakthroughs

Our study is believed to be the first to observe the role of RASSF1A in gastric cancer and the possible mechanisms involved.

### Applications

Our research observed that RASSF1A suppressed the growth of the human gastric cancer cell line SGC7901 and RASSF1A inhibited AP-1 activity through down-regulated c-fos expression. This may have a significant clinical impact in the future.

### Terminology

Electrophoretic mobility shift assay (EMSA): The EMSA technique is based on the observation that protein: DNA complexes migrate more slowly than free DNA molecules when subjected to non-denaturing polyacrylamide or agarose gel electrophoresis. Because the rate of DNA migration is shifted or retarded upon protein binding, the assay is also referred to as a gel shift or gel retardation assay.

### Peer review

This is a well-written paper that suggests the role of RASSF1A in human gastric cancer. But the mechanism remains to be studied further.

### Abstract

**AIM:** To evaluate the association between genetic polymorphisms in *CYP2E1*, *ALDH2* and *ADH1B* and the risk of esophageal squamous cell carcinoma (ESCC) in a high risk area of Gansu Province, in Chinese males.

**METHODS:** A case-control study was conducted to investigate the genetic polymorphisms of these enzymes (*CYP2E1*\*c1/\*c2, *ALDH2*\*1/\*2 and *ADH1B* \*1/\*1 genotypes). A total of 80 esophageal cancer cases and 480 controls were recruited.

**RESULTS:** Compared with controls, cases had a greater prevalence of heavier alcohol consumption (53.8% vs 16.2%) and a higher proportion of alcohol drinkers with > 30 drink-years (28.8% vs 13.5%). Heavier alcohol consumption and alcohol drinking with > 30 drink-years increased the risk of ESCC, with ORs (95% CI) of 3.20 (1.32-9.65) and 1.68 (0.96-3.21). *CYP2E1* (\*c1/\*c1), *ALDH2* (\*1/\*2) and *ADH1B* (\*1/\*1) genotype frequencies were higher among patients with squamous cell carcinomas, at a level close to statistical significance ( $P = 0.014$ ;  $P = 0.094$ ;  $P = 0.0001$  respectively). There were synergistic interactions among alcohol drinking and *ALDH2*, *ADH1B* and *CYP2E1* genotypes. The risk of the ESCC in moderate-to-heavy drinkers with an inactive *ALDH2* encoded by *ALDH2*\*1/\*2 as well as *ADH1B* encoded by *ADH1B* \*1/\*1 and *CYP2E1* encoded by *CYP2E1* \*c1/\*c1 was higher than that in the never/rare-

to-light drinkers with an active *ALDH2* (\*1/\*1 genotype) as well as *ADH1B* (\*1/\*2 + \*2/\*2) and *CYP2E1* (\*c1/\*c2 + \*c2/\*c2) genotypes, with a statistically significant difference; ORs (95% CI) of 8.58 (3.28-22.68), 27.12 (8.52-70.19) and 7.64 (2.82-11.31) respectively. The risk of the ESCC in moderate-to-heavy drinkers with *ALDH2* (\*1/\*2) combined the *ADH1B* (\*1/\*1) genotype or *ALDH2* (\*1/\*2) combined the *CYP2E1* (\*c1/\*c1) genotype leads to synergistic interactions, higher than drinkers with *ALDH2* (\*1/\*1) + *ADH1B* (\*1/\*2 + \*2/\*2), *ALDH2* (\*1/\*1) + *CYP2E1* (\*c1/\*c2 + \*c2/\*c2) respectively, ORs (95% CI) of 7.46 (3.28-18.32) and 6.82 (1.44-9.76) respectively. Individuals with the *ADH1B* combined the *CYP2E1* genotype showed no synergistic interaction.

**CONCLUSION:** In our study, we found that alcohol consumption and polymorphisms in the *CYP2E1*, *ADH1B* and *ALDH2* genes are important risk factors for ESCC, and that there was a synergistic interaction among polymorphisms in the *CYP2E1*, *ALDH2* and *ADH1B* genes and heavy alcohol drinking, in Chinese males living in Gansu Province, China.

### INTRODUCTION

Esophageal carcinoma is the seventh leading cause of cancer deaths worldwide<sup>[1]</sup>. It is a devastating disease with very few patients cured once diagnosed. Esophageal squamous cell carcinoma (ESCC) is one of the most

common malignancies in Gansu province, China. There is great geographic variation in the occurrence of this tumor type in China, including exceptionally high-risk areas such as Gansu Province in the Northwest of China. Within high-risk regions in China, there is a strong tendency toward alcohol drinking, suggesting that genetic susceptibility, in conjunction with alcohol consumption, plays a role in the etiology of ESCC.

Epidemiologic studies have demonstrated that drinking alcoholic beverages is causally related to the development of ESCC<sup>[2,3]</sup>. Genetic polymorphisms in the genes encoding cytochrome P4502E1 (*CYP2E1*)<sup>[4-7]</sup>, aldehyde dehydrogenase-2 (*ALDH2*) and alcohol dehydrogenase-1B (*ADH1B*; previously called ADH2) affect the metabolism of alcohol<sup>[8-12]</sup>. There have been some studies on the roles of alcohol and polymorphisms in the *CYP2E1*, *ALDH2* and *ADH2* genes in ESCC<sup>[13-15]</sup>. However, their results were conflicting.

To provide further data on this issue, we evaluated the susceptibility to ESCC conferred by *CYP2E1*, *ALDH2* and *ADH1B* genetic polymorphisms, and defined the individual and combined roles of these genes and alcohol consumption in a high risk area for ESCC in Chinese males.

## MATERIALS AND METHODS

The case participants in this study were 80 Gansu males with ESCC treated at the Department of Gastroenterology, First Hospital of Lanzhou University and the Department of Gastroenterology, Affiliated Hospital of Gansu College of Traditional Chinese Medicine. All were registered between September 2004 and March 2007.

The 480 age-and-gender matching controls consisted of cancer-free men who received annual health checkups at two Lanzhou clinics between September 2004 and March 2007. Gansu was the ancestral home for all.

Each participant independently completed a structured questionnaire concerning his alcohol drinking habits, and those with cancer were instructed to report their habits before they were diagnosed with cancer. Each participant was asked to classify himself as a drinker or non-drinker, and to report alcohol intake as the frequency of consumption and usual amount(s) and type(s) of alcoholic beverage(s) consumed. The subjects were classified as never drinks alcohol, or drinkers who consumed 200 g/wk (light drinkers), 200-400 g/wk (moderate drinkers) or 400+ g/wk (heavy drinkers).

Polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) methods or a PCR method were performed on lymphocyte DNA samples from all participants, without any knowledge of their cancer status, to determine their P4502E1, *ALDH2* and *ADH1B* genotypes (Tables 1 and 2).

The Rsa I and Pst I linkage disequilibrium polymorphisms of the P4502E1 gene were determined according to the method of Hayashi *et al.*<sup>[16]</sup> with some modification. The final mixture (50  $\mu$ L) was prepared containing 0.3  $\mu$ g of DNA, 0.2  $\mu$ mol/L of dNTP, 0.3  $\mu$ mol/L of each of the primers, 1.5  $\mu$ mol/L of MgCl<sub>2</sub>, 5  $\mu$ L of 10  $\times$  buffer, and 2 U of Taq polymerase. Briefly,

**Table 1** Polymorphisms in the *CYP2E1*, *ALDH2* and *ADH1B* genes

Locus /protein	Gene	Subunit	Nucleotide change	Effect	RFLP
<i>ADH1B</i>	<i>ADH2*1</i>	$\beta$ 1		Wild-type	
	<i>ADH2*2</i>	$\beta$ 2	48G>A	His48; (earlier as His47)	
<i>ALDH2</i>	<i>ALDH2*1</i>			Wild-type	
	<i>ALDH2*2</i>		1510G>A	Lys487	
<i>CYP2E1</i>	<i>CYP2E1*1A</i>		None	Wild type	Pst I-/Rsa I + (c1allele)
		<i>CYP2E1*5B</i>	-1293G>C;		Pst I+/Rsa I - (c2 allele)
		-1053C>T			

*CYP2E1* allele nomenclature, <http://www.imm.ki.se>; NIAAA publications, <http://pubs.niaaa.nih.gov>.

**Table 2** Primer sequences and lengths of PCR products

Gene	Primer	Size of PCR product (bp)	Chromosomal location
<i>CYP2E1</i>	5'-CCAGTCGAGTCTACATTGTC-3'	410	10q24.3-qter
	5'-TTCATTCTGCTCTTCTAACTGG-3'		
<i>ALDH2</i>	5'-CCCTTTGGTGGCTAGAAGATG-3'	91	12q24.2
	5'-CCACACTCACAGTTTTCTCTT-3'		
<i>ADH1B</i>	5'-ATTCGTAGATGGTGGCTGT-3'	76	4q22
	5'-GAAGGGGGTACCAGGTTG-3'		

the samples were denatured at 94°C for 2 min and submitted to 40 cycles of 1 min at 94°C (denaturation), 50 s at 50°C (annealing) and 50 s at 72°C (extension), with a final extension at 72°C for 10 min. PCR products (15  $\mu$ L) were digested by Pst I or Rsa I restriction enzymes (1  $\mu$ L of a 10 U/ $\mu$ L preparation) for 18 h at 37°C. Fragments were separated on 40 g/L low melting point agarose gels, and stained with ethidium bromide.

*ALDH2* and *ADH1B*<sup>[17]</sup> polymorphisms were determined by PCR-RFLP as previously described. Each PCR analysis was performed twice, double blindly.

The allele frequency was determined by direct counting. Deviation of the genotype distribution from Hardy-Weinberg equilibrium was analyzed by the exact test. Fisher's exact test was used for comparing group statistics. The Spearman rank-correlation analysis was used as a nonparametric test for trend. All *P*-values were obtained from 2-sided tests. Associations between genotypes or other potential risk factors and ESCC are expressed as odds ratios (ORs) with 95% confidence intervals (CIs) adjusted for the effects of several possible confounders using a multiple logistic regression model and the STEPWISE method.

## RESULTS

Five hundred and sixty males were enrolled in this study. The cancer cases were age-and-gender matched with cancer-free control subjects. The mean age of the patients was 60.2  $\pm$  8.9, ranging from 49 to 75 years of age. The mean age of the controls was 59.7  $\pm$  9.7, ranging from 49 to 73 years of age.

Table 3 Alcohol drinking in esophageal cancer cases and control subjects

c1/c2	16 (20.0)	180 (37.5)	0.918		
c1/c1	57 (71.3)	225 (46.9)	0.014	2.82	1.23-6.55

Table 3 shows alcohol drinking in esophageal cancer cases and control subjects. We observed that, compared with controls, cases had a greater prevalence of heavier alcohol consumption (53.8% vs 16.2%) and a higher proportion of alcohol drinkers with > 30 drink-years (28.8% vs 13.5%). Heavier alcohol consumption and alcohol drinking with > 30 drink-years increased the risk of ESCC, with ORs (95% CI) of 3.20 (1.32-9.65) and 1.68 (0.96-3.21).

Table 4 shows the distributions of *ALDH2*, *ADH1B* and *CYP2E1* genotypes. Cases and controls differed significantly in the distributions of these genotypes. These genotypes significantly deviated from the Hardy-Weinberg equilibrium (HWE) in ESCC cases, but among controls, all genotypes were in HWE.

There are two *ALDH2* alleles (\*1 and \*2) and three genotypes: \*1/\*1 (GG, typical homozygote), \*1/\*2 (GA, heterozygote) and \*2/\*2 (AA, atypical homozygote), and the distributions of these genotypes were significantly different between the esophageal cancer group and the control group ( $\chi^2 = 2.89$ ,  $P < 0.1$ ). The prevalence of the inactive *ALDH2* encoded by *ALDH2*\*1/\*2 was correlated with susceptibility to esophageal cancer, with an OR (95% CI) of 2.89 (1.11-5.64).

There are three *ADH1B* genotypes: The wild-type genotype (\*1/\*1), heterozygote (\*1/\*2) and homozygote (\*2/\*2) genotypes. The prevalence of the less-active

Table 6 Probability ratios for the combinations of *ADH1B*, *CYP2E1* and *ALDH2* genotypes among moderate-to-heavy drinkers, n (%)

Combined genotypes	Genotype	Cases (n = 80)	Controls (n = 480)	OR	95% CI
<i>ALDH2</i> + <i>ADH1B</i>	<i>ALDH2</i> *1/1 + <i>ADH1B</i> *1/2 + 2/2	28 (35.0)	144 (30.0)	1	
	<i>ALDH2</i> *1/2 + <i>ADH1B</i> *1/1	15 (18.8)	27 (1.9)	7.46	3.28-18.32
<i>ALDH2</i> + <i>CYP2E1</i>	<i>ALDH2</i> *1/1 + <i>CYP2E1</i> *c1/c2 + c2/c2	10 (12.5)	60 (12.5)	1	
	<i>ALDH2</i> *1/2 + <i>CYP2E1</i> *c1/c1	32 (40.0)	15 (3.1)	6.82	1.44-9.76
<i>ADH1B</i> + <i>CYP2E1</i>	<i>ADH1B</i> *1/2 + 2/2 + <i>CYP2E1</i> *c1/c2 + c2/c2	12 (15.0)	36 (2.5)	1	
	<i>ADH1B</i> *1/1 + <i>CYP2E1</i> *c1/c1	14 (17.5)	66 (13.8)	6	

*ADH1B* encoded by *ADH1B* \*1/\*1 increase the risk of esophageal cancer. ( $\chi^2 = 18.664$ ,  $P < 0.0001$ ), OR (95% CI) of 3.67 (1.26-8.73).

There are three *CYP2E1* genotypes: wild homozygote (\*c1/\*c1), heterozygote (\*c1/\*c2) and mutated homozygote (\*c2/\*c2) genotypes. A significant difference in the distributions of the three Pst I/Rsa I genotypes of *CYP2E1* was found between the esophageal cancer group and the control group ( $\chi^2 = 5.977$ ,  $P < 0.05$ ). The c1/c1 genotype was correlated with susceptibility to esophageal cancer, with an OR (95% CI) of 2.82 (1.23-6.55).

Tables 5 and 6 show the frequency distributions and ORs for each combination of alcohol drinking habits and *ALDH2*, *ADH1B* and *CYP2E1* genotypes.

The risk of ESCC was 8.58-fold higher in moderate-to-heavy drinkers with inactive *ALDH2* (encoded by

*ALDH2*\*1/\*2) than in the never/rare-to-light drinkers with an active *ALDH2* (encoded by *ALDH2*\*1/\*1).

When the ORs were compared within each alcohol drinking category, the risk of the ESCC associated with *ALDH2* (\*1/\*2) versus *ALDH2* (\*1/\*1) was 3.12-fold greater among moderate-to-heavy drinkers, whereas no significant increase in risk was observed with *ALDH2* \*1/\*2 versus *ALDH2* \*1/\*1 among never/rare-to-light drinkers.

The results for the *ADH1B* genotype showed that only among moderate-to-heavy drinkers did the less-active *ADH1B* \*1/\*1 genotype significantly increase the risk of cancer, with an OR (95% CI) 5.48 (1.98-14.55). Thus, the risk of the cancer in moderate-to-heavy drinkers with the *ADH1B* (1/1) genotype was markedly higher (by 27.12-fold) than that in never/rare-to-light drinkers with a super-active *ADH1B* encoded by *ADH1B* \*1/\*2 and *ADH1B* \*2/\*2.

The results for the *CYP2E1* genotype showed that, among moderate-to-heavy drinkers, the *CYP2E1* (\*c1/\*c1) genotype significantly increased the risk of cancer, with an OR (95% CI) of 5.32 (1.98-14.55). Thus, the risk of the cancer in moderate-to-heavy drinkers with *CYP2E1* (\*c1/\*c1) was markedly higher (by 7.64-fold) than that in never/rare-to-light drinkers with a super-active *CYP2E1* (genotypes \*c1/\*c2 + \*c2/\*c2).

The results of our analysis of *ALDH2* and *ADH1B* genotypes showed that among moderate-to-heavy drinkers, the combination of *ALDH2* (\*1/\*2) and *ADH1B* (\*1/\*1) genes synergistically increased the risk of cancer, to 7.46-fold higher than that in drinkers with an *ALDH2* (\*1/\*1) + *ADH1B* (\*1/\*2 + \*2/\*2) genotype.

The results of an analysis of the effects of combinations of *ALDH2* and *CYP2E1* genotypes showed that among moderate-to-heavy drinkers, the combination of *ALDH2* (\*1/\*2) and *CYP2E1* (\*c1/\*c1) genes synergistically increased the risk of cancer, to 6.82-fold higher than that in drinkers with an *ALDH2* (\*1/\*1) + *CYP2E1* (\*c1/\*c2 + \*c2/\*c2) genotype.

There was no combinatorial effect of *ADH1B* and *CYP2E1* genotypes.

## DISCUSSION

In the present study, we examined the associations of ESCC with *ALDH2*, *ADH2* and *CYP2E1* genetic polymorphisms in conjunction with alcohol drinking habits among a population at high risk of esophageal cancer. The study was conducted in Gansu province, an area of China with a relatively high alcohol consumption rate.

We found that alcohol intake was associated with ESCC, and that polymorphisms in *CYP2E1*, as well as in the genes encoding alcohol and aldehyde dehydrogenases (*ADH1B* and *ALDH2*) are important risk factors for ESCC in Chinese men living in this high risk area.

We found that heavier alcohol consumption and alcohol drinking for > 30 drink-years could increase the risk of ESCC, with ORs (95% CI) of 3.20 (1.32-9.65) and 1.68 (0.96-3.21), respectively. There is substantial evidence that drinking alcohol increases the risk of ESCC. Alcohol can be considered to induce DNA damage and result in

the modification of nucleotides. Our risk estimates were consistent with those of previous studies<sup>[18]</sup>. This study confirms that alcohol consumption contributes to the etiology of ESCC.

It has been reported that individual differences in cytochrome P450 (CYP) gene expression may contribute to a person's individual susceptibility to pro-carcinogens and, subsequently, to the development of malignancies. CYP plays a central role in the metabolism of carcinogens by activating oxidation reactions, and may be expressed in esophageal mucosa.

*CYP2E1* metabolizes ethanol to acetaldehyde and is primarily responsible for the metabolic activation of many low molecular weight carcinogens, including certain nitrosamines, which may be involved in carcinogenesis of the esophagus. This enzyme is also believed to participate in the oxidation of other compounds, such as ethanol, to produce reactive free radicals that may initiate lipid peroxidation and consequently influence carcinogenesis. In addition, it effectively reduces dioxygen to give rise to radical species, thus contributing to lipid peroxidation and oxidative inhibition. Individuals with the variant Pst I/Rsa I allele (\*c1/\*c2 or \*c2/\*c2) have a lower basal *CYP2E1* activity. Two studies found an association between the *CYP2E1* Pst I/Rsa I variant allele and a decreased risk of ESCC<sup>[19]</sup>. The results of our study indicated that the *CYP2E1* \*c1/\*c1 or c1 allele increased the susceptibility to ESCC in a Gansu population ( $P = 0.014$ ), and that there are synergistic interactions between *CYP2E1* (\*c1/\*c1) and alcohol drinking; the risk of ESCC in moderate-to-heavy drinkers with the *CYP2E1* (\*c1/\*c1) genotype was markedly higher, by 7.64-fold, than in never/rare-to-light drinkers with a super-active *CYP2E1* (genotypes \*c1/\*c2 + \*c2/\*c2).

The genetic polymorphisms of alcohol and aldehyde dehydrogenases affect the metabolism of alcohol. Aldehyde dehydrogenase-2 (*ALDH2*) is the key enzyme for elimination of acetaldehyde. Acetaldehyde, a recognized animal carcinogen derived from alcohol, may play an important role in the pathogenesis of alcohol-related cancers, such as esophageal cancer. In persons with inactive *ALDH2* encoded by *ALDH2*\*1/\*2, the body fails to metabolize acetaldehyde rapidly, leading to excessive accumulation of acetaldehyde.

Polymorphisms in the *ADH1B* and *ALDH2* genes associated with the risk of esophageal cancer have been described in several studies<sup>[20-24]</sup>. *ADH1B* (\*1/\*1) has also been demonstrated to enhance the risk of esophageal cancer, and the combination of *ALDH2* (\*1/\*2) and *ADH1B* (\*1/\*1) increased the risk of esophageal cancer<sup>[8]</sup>.

In our study, we found that polymorphisms in the genes encoding alcohol and aldehyde dehydrogenases (*ADH1B* and *ALDH2*) are important risk factors for ESCC in a Gansu population, and individuals with the *ADH1B* (\*1/\*1) genotype had a 5.32-fold risk (1.98-14.55) of developing esophageal cancer compared with those with the *ADH1B* (\*2/\*2) genotype.

Individuals with the *ALDH2* (\*1/\*2) genotype had a 3.12-fold higher risk (1.86-6.58) of developing esophageal cancer than those with the *ALDH2* (\*1/\*1) genotype, among male Chinese moderate-to-heavy drinkers. We also

found that individuals with a combined *ALDH2* (\*1/\*2) and *ADH1B* (\*1/\*1) genotype showed a dramatically increased risk of ESCC, with an OR (95% CI) 7.46 (3.28-18.32), which is higher than those due to the respective genotypes. These findings indicate the *ALDH2* (\*1/\*2) genotype has synergistic interactions with the *ADH1B* (\*1/\*1) genotype, contributing to the development of ESCC. Our study confirmed the findings of Tetsuji<sup>[8]</sup>.

The significant finding in this study was the interaction between the *CYP2E1* and *ALDH2* genotypes and heavy alcohol drinking, using a case-control study design. Previous studies have not examined this issue in detail and, to our knowledge, this is the first study to show a significant interaction between the *CYP2E1* and *ALDH2* genotypes and alcohol drinking. In our study, we found synergistic interactions among polymorphisms in the *CYP2E1* and *ALDH2* genotypes and heavy alcohol drinking; individuals with a combined *ALDH2* (\*1/\*2) and *CYP2E1* (\*c1/\*c1) genotype showed a dramatically increased risk of ESCC, with an OR (95% CI) of 6.82 (1.44-9.76), which is higher than those due to the respective genotypes.

Conflicting results from studies<sup>[25-28]</sup> in different countries and areas show the complexity of the biological mechanisms underlying ESCC. The susceptibility to ESCC may be correlated with genes, environment, area, race or other factors. The results of this study demonstrate that *CYP2E1* (\*c1/\*c1), *ALDH2* (\*1/\*2) and *ADH1B* (\*1/\*1) genotypes are associated with esophageal cancer risk among moderate-to-heavy drinking Chinese males in Gansu province. In addition, this study also showed *ALDH2* (\*1/\*2) and *CYP2E1* (\*c1/\*c1) carriers, and *ALDH2* (\*1/\*2) and *ADH1B* (\*1/\*1) carriers have a much higher risk of developing esophageal cancer, especially among alcohol drinkers. Future studies are needed to examine the biological mechanisms involved, and to evaluate the contribution of gene and environment interactions to the risk of ESCC.

## COMMENTS

### Background

Worldwide, cancer of the esophagus ranks among the 10 most common cancers. Epidemiological studies have demonstrated that drinking alcoholic beverages is causally related to the development of esophageal squamous cell carcinoma (ESCC). Genetic polymorphisms in the P4502E1 (*CYP2E1*), *ALDH2* and *ADH1B* genes affect the metabolism of alcohol. There have been some studies on the roles of alcohol and the *CYP2E1*, *ALDH2* and *ADH2* genes in ESCC. However, their results were conflicting. Therefore, the aim of the present study was to evaluate the susceptibility to ESCC conferred by *CYP2E1*, *ALDH2* and *ADH1B* genetic polymorphisms, and to define the individual and combined roles of these genes and alcohol consumption in a high risk area for ESCC, among Chinese males.

### Research frontiers

Accumulating evidence from prior epidemiologic studies suggests an association between esophageal cancer and the use of alcohol. The genetic polymorphisms of alcohol and aldehyde dehydrogenases affect the metabolism of alcohol. *ALDH2* is the key enzyme involved in the elimination of acetaldehyde. Polymorphisms in the *ADH1B* and *ALDH2* genes are associated with the risk of esophageal cancer.

### Innovations and breakthroughs

To our knowledge, this is the first study to show significant interactions among the *CYP2E1* and *ALDH2* genotypes and alcohol drinking. We found synergistic interactions among polymorphisms in the *CYP2E1* and *ALDH2* genes and heavy

alcohol drinking: Individuals with a combined *ALDH2* (\*1/\*2) and *CYP2E1* (\*c1/\*c1) genotype showed a dramatically increased risk of ESCC, which is higher than the risk of ESCC due to the respective genotypes.

### Applications

The detection of *ALDH2*, *ADH1B* and *CYP2E1* genotypes may become a useful index for esophageal cancer, and also help clinicians to diagnose esophageal cancer earlier.

### Terminology

Esophageal squamous cell carcinoma: The most common types of esophageal cancer are squamous cell carcinoma and adenocarcinoma. Squamous cell carcinoma develops in flat cells that line the esophagus. Approximately 60% of squamous cell carcinomas develop in the middle third of the organ, 30% occur in the lower third, and 10% occur in the upper third. Adenocarcinoma develops in the lining of the esophagus and is associated with a condition called Barrett's esophagus. This type usually occurs in the lower third of the esophagus. Genetic polymorphisms: The occurrence together in the same population of more than one allele or genetic marker at the same locus, with the least frequent allele or marker occurring more frequently than can be accounted for by mutation alone. Genetic polymorphisms provide us with the ability to predict inter-individual differences in susceptibility to clinical disease. Biomarkers of susceptibility include polymorphisms in carcinogen metabolism, DNA repair capacity and genes that control cell growth.

### Peer review

This is an interesting study on the etiology of esophageal squamous cell cancer in China. They confirm a synergy between alcohol consumption and the phenotype of inactive enzymes.

### Abstract

Chicken bone is one of the most frequent foreign bodies (FB) associated with upper esophageal perforation. Upper digestive tract penetrating FB may lead to life threatening complications and requires prompt management. We present the case of a 52-year-old man who sustained an upper esophageal perforation associated with cervical cellulitis and mediastinitis. Following CT-scan evidence of FB penetrating the esophagus, the impacted FB was successfully extracted under rigid esophagoscopy. Direct suture was required to close the esophageal perforation. Cervical and mediastinal drainage were made immediately. Nasogastric tube decompression, broad-spectrum intravenous antibiotics, and parenteral hyperalimentation were administered for 10 d postoperatively. An esophagogram at d 10 revealed no leak at the repair site, and oral alimentation was successfully reinstated. Conclusion: Rigid endoscope management of FB esophageal penetration is a simple, safe and effective procedure. Primary esophageal repair with drainage of all affected compartments are necessary to avoid life-threatening complications.

### INTRODUCTION

Management of ingested foreign bodies (FB) is a common clinical encounter. Complications of this pathology are dependent on patient age, nature and localization of the FB, presence of a perforation, and initial management procedures<sup>[1]</sup>. Beside the lingual tonsils, the base of tongue and the upper esophagus are the most common sites of FB impaction<sup>[2]</sup>. The most frequent ingested FBs in the upper digestive tract are chicken and fish bones, and they are the most commonly associated with pharyngo-esophageal perforation<sup>[1]</sup>, cervical abscess and potentially life threatening complications<sup>[3]</sup>.

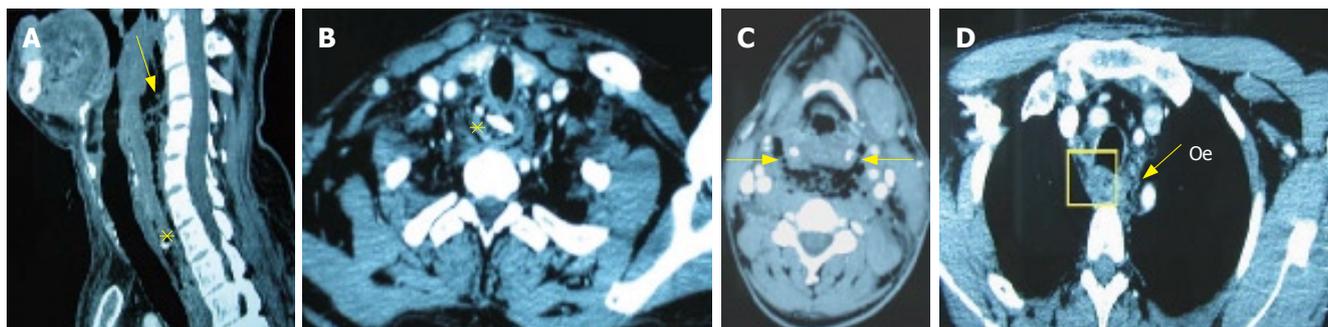

### CASE REPORT

A 52-year-old man, with no relevant past medical history, presented to the ENT clinic complaining of severe dysphagia, substernal pain, and fever for 3 d. Five days prior to presentation, the patients started having symptoms of mild dysphagia after chewing on a piece of chicken. One day later on, exacerbation of dysphagia prompted the patient to seek otolaryngology consultation in town. Following seemingly normal head and neck examination, the patient was reassured and discharged. On admission at the University Medical center of Grenoble, the patient had a fever of 40°C and mild shortness of breath. No abnormalities were noted on examination of the oropharynx, but the hypopharynx and larynx were swollen and there was abundant saliva in hypopharynx. The neck exam revealed bilateral anterior and lateral tenderness, inflammation and edema of the skin, and crepitation. On pulmonary auscultation, sparse rales were heard over the lower part of each hemi-thorax. Cardiac auscultation revealed a regular rhythm and normal heart sounds.

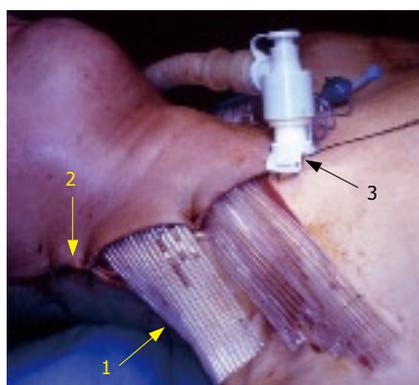

The patient had a white blood cell count of  $20 \times 10^9/L$  with 80% neutrophils and a C reactive protein level to 120 mg/L.

A cervical and thoracic CT-scan revealed a fragment of bone in the upper part of esophagus, air in the retropharyngeal space and the upper part of the posterior mediastinum, and deep subcutaneous collection suggestive of cervical posterior mediastinal collection (Figure 1).

The patient was taken immediately to the operating room for surgical treatment under general anesthesia. Endoscopic examination was performed using a rigid endoscope (Storz  $\phi$  16 mm - L 50 cm, Tuttlingen, Germany) which revealed meat fragments and a piece of chicken bone impacted in the upper esophageal wall, 19 cm

**Figure 1** CT scan on admission. **A:** Mid-sagittal view: Air in posterior retropharyngeal space, Bone fragment (\*); **B:** Axial view at the level of C7. Bone fragment and esophageal perforation (\*); **C:** Axial view at the level of C4 (hyoid bone): Air in posterior retropharyngeal space; **D:** Axial view at the level of T3: Pleural effusion and air bubbles in postero-superior mediastinum → Oe: esophagus.

**Figure 2** Surgical site at the end of the procedure. 1: Multitubular silicone drain; 2: Neck incision; 3: Tracheotomy tube.

from incisors. Meat fragments were aspirated using a 4 mm rigid aspiration; forceful pulling of the FB using forceps caused the edges of the FB to bend, enabling extraction through the rigid esophagoscope. After bone removal, a 4 mm perforation was visible at the site of impaction with pus draining through it. Gastric decompression *via* a nasogastric tube was performed.

A large neck incision was required to drain the pus from cervical spaces (Figure 2), and the collection in the upper posterior mediastinum was evacuated through the same incision following retropharyngeal space dissection. The drainage of the neck abscess revealed a small bone fragment within the purulent discharge, and cultures were taken. The edges of the perforation were carefully debrided and the entire surgical field was well irrigated. The defect was then closed in two layers using fine interrupted absorbable monofilament suture. Drainage of the neck and the upper mediastinum was done by placement of multi-tubular silicone drains through cervical incision. A temporary tracheotomy was performed to bypass the edematous larynx. Broad-spectrum intravenous antibiotics (imipenem 2 g/d+ amikacine 1 g/d+ metronidazole 1 g/d), and parenteral hyperalimentation were started. The patient was admitted to the intensive care unit for 5 d. The patient medical status improved rapidly, and biological laboratory exams were normalized during the first post operative week. Tracheotomy and drains were removed at postoperative d 6 and d 8 respectively. An esophagogram

performed at d 10 revealed no leak at the repair site, and oral alimentation was successfully reinstated. *Streptococcus β C* hemolytic was isolated from the cultured pus, allowing for switching to amoxicillin and clavulanic acid 4 g/d at postoperative d 3, and continued for 7 d. The patient was discharged from the hospital in good condition on postoperative d 15.

## DISCUSSION

The majority of ingested FBs pass through the gastrointestinal tract uneventfully<sup>[1]</sup>. Severe complications are rare, but upper digestive tract perforation is the most frequent. Among the esophageal perforation etiologies, FB represent the second most common etiology after iatrogenic manipulation (esophagoscopy, esophageal dilatation, para-esophageal surgery, external trauma)<sup>[4]</sup>. The diagnosis of esophageal perforation is usually suspected on clinical basis, and suggestive history of sharp bodies ingestion (chicken and fish bones)<sup>[5]</sup>. Symptoms include pain, dysphagia, and rarely hematemesis; pain is the most frequent symptom (> 90%)<sup>[5]</sup>. In case of upper esophagus perforation, tenderness and subcutaneous emphysema of the neck are the two main signs. Substernal pain and polypnea are signs associated with mediastinal extension<sup>[5]</sup>. In these cases, mediastinal crunch (Hamman sign) and crepitations are heard on chest auscultation<sup>[6]</sup>. Fever and leukocytosis with increase in the number of immature polymorphonuclear cells are present in more than 90% of patients<sup>[5]</sup>.

Standard neck and chest radiograms are ordered if an esophageal perforation is suspected. But these exams reveal esophageal perforation in only a small proportion of cases<sup>[7]</sup>. Moreover, even if FB is radiopaque, it can be unrecognized because a lot of bone structures are superposed. The perforation diagnosis is confirmed in almost all cases by contrast esophagograms, which can delineate both the level of perforation and the communication of the injury into cervical and mediastinal spaces<sup>[6,7]</sup>. CT-scan allows the visualization of FB and the identification of findings suggestive of esophageal perforation (esophageal wall thickening and laceration, peri-esophageal air and fluid). Intravenous administration of contrast material helps CT-scan localization of the exact extension of peri-esophageal infection in the

neck, mediastinal, and pleuro-parenchymal spaces<sup>[8]</sup>. Its sensitivity can be increased with gastrografen ingestion. Thus, an appropriate CT examination enables an accurate and timely diagnosis which significantly affects prognosis and provides valuable indications for treatment.

Extraction of FBs located in the first few centimeters under the upper esophageal sphincter, is difficult with a flexible esophagoscope, especially if they have sharp edges, such as bone fragments<sup>[9]</sup>. Rigid endoscopy may be a more appropriate procedure in these instances. The rigid endoscope is placed just above the proximal tip of the FB; it dilates the esophageal lumen to the extent that the impacted FB is movable. The use of a rigid endoscope during removal of an impacted FB has several advantages: it causes expansion of the upper esophagus, which can release totally or in part the impacted FB, and prevents aspiration and esophageal or pharyngeal injury. It must be practiced under general anesthesia by a trained operator.

Non-operative management is excluded in case of cervical and/or mediastinal abscesses<sup>[4]</sup>. Different surgical approaches are available for esophageal perforation, including primary repair with drainage, generally chosen for patients without evidence of a severe esophageal injury and without other esophageal disease<sup>[10]</sup>. A simple suture is recommended in case of small perforation in the cervical esophagus<sup>[5]</sup>. It is not necessary to use mucosal flaps to reinforce the esophageal sutures, contrarily to the recommendations for injuries of the middle and lower parts of esophagus<sup>[11]</sup>. In case of cervical abscess and/or mediastinitis, drainage of the different affected spaces must be done<sup>[12]</sup>. The choice of surgical approach for mediastinal drainage is dependent on abscess localization. In case of posterior and superior mediastinitis, drainage from cervical incision with retropharyngeal space dissection is adopted. Prognosis in case of upper esophageal perforation is relatively good with mortality inferior to 10%<sup>[5]</sup>.

In conclusion, perforation of the upper esophagus caused by a FB is rare, but can cause potentially life threatening mediastinal complications. CT-scan enables accurate and timely diagnosis and provides valuable indications for treatment. Extraction of esophageal FB

with a rigid endoscope is a good and safe treatment alternative. Non-operative management of esophageal perforation is not an option in the presence of neck and mediastinum abscesses and necessitates a surgical suture and drainage.

### Abstract

Hepatic splenosis refers to heterotopic auto-transplantation and implantation of splenic tissue resulting from the spillage of cells from the spleen after splenic trauma or splenectomy. The true incidence of splenosis is unknown, because this entity is usually an incidental finding at surgery. Splenic implants are usually multiple, and can be localized anywhere in the peritoneal cavity. Splenic implants in the peritoneal cavity may be confused with renal tumors, abdominal lymphomas and endometriosis. We describe computed tomography (CT) and magnetic resonance imaging (MRI) findings in a rare case of multiple intra-abdominal splenosis located along the hepatic surface and adjacent to the upper pole of the right kidney, mimicking a renal neoplasm.

A case of multiple intra-abdominal splenosis with computed tomography and magnetic resonance imaging correlative findings. *World J Gastroenterol* 2008; 14(9): 1453-1455 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1453.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1453>

### INTRODUCTION

Hepatic splenosis refers to heterotopic auto-transplantation

and implantation of splenic tissue resulting from the spillage of cells from the spleen after splenic trauma or splenectomy, occurring in up to 67% of patients who have a splenic rupture<sup>[1,2]</sup>. Splenic implants are usually multiple and can be localized anywhere in the peritoneal cavity, but they usually occur on the serosal surfaces of the small and large bowel, the peritoneum, the mesentery and the diaphragm<sup>[3]</sup>.

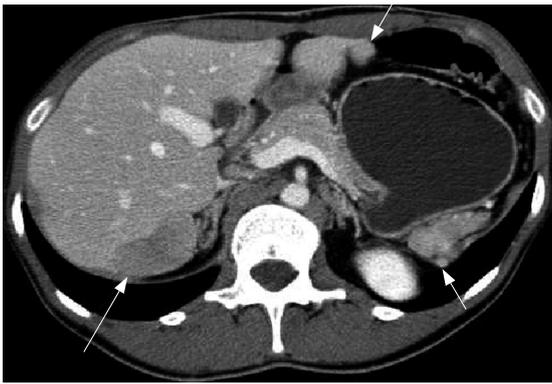

We describe computed tomography (CT) and magnetic resonance imaging (MRI) findings in a rare case of intra-abdominal multiple splenosis located along the hepatic surface and in close proximity to the upper pole of the right kidney, mimicking a renal neoplasm.

### CASE REPORT

A 39-year-old man with a history of Crohn's disease was admitted to our institution because of persistent abdominal pain. Physical examination and past medical history were unremarkable except for the previous history of chronic inflammatory bowel disease and an emergency splenectomy performed at the age of 15 after a car accident. An abdominal ultrasound was performed, revealing small bowel wall thickening at the level of the terminal ileum and minimal ascites in the peritoneal cavity. Ultrasound also revealed the presence of a 4 cm solid echogenic mass in the upper pole of the right kidney.

An helical CT examination showed a well-demarcated 3 cm mass in the sub-capsular posterior portion of the seventh segment of the right hepatic lobe adjacent to the upper pole of the right kidney. The mass was hypodense compared with the surrounding liver parenchyma on unenhanced helical CT examination, and showed heterogeneous enhancement in the arterial phase after the administration of contrast material, becoming hypodense compared with the surrounding parenchyma, during the portal (Figure 1) and equilibrium phases. The CT scan also identified two similar nodular lesions medially to the left lobe of the liver, and adjacent to the upper pole of the left kidney and the pancreatic tail (Figure 1).

A contrast-enhanced helical MRI scan was subsequently obtained, which confirmed the presence of a 3 cm hepatic lesion along the posterior surface of the seventh segment and in close proximity to the upper pole of the right kidney. Furthermore, MRI identified two additional lesions along the lateral surface of the right hepatic lobe and more clearly identified the other intra-abdominal nodular implants medially to the left hepatic

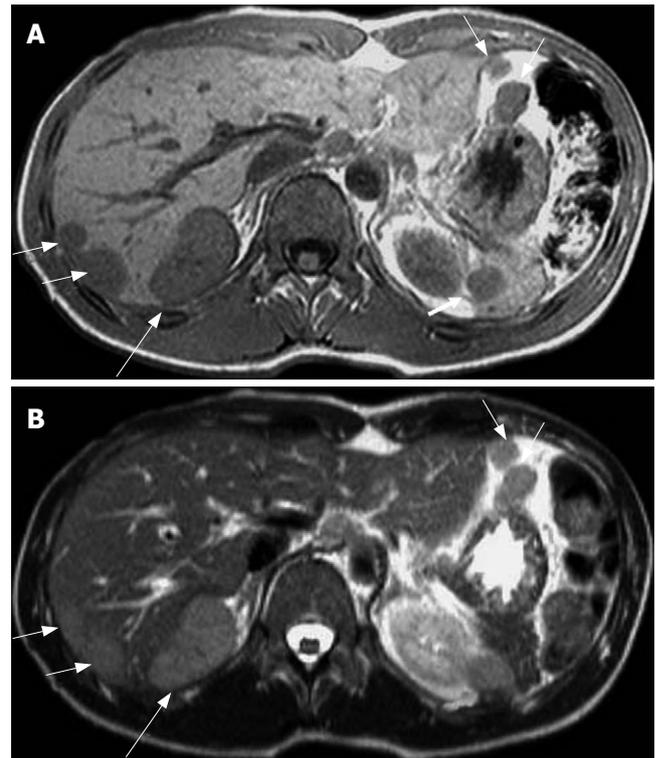

**Figure 1** Contrast-enhanced helical CT obtained during the portal phase of acquisition, showing a hypodense 3 cm lesion along the posterior surface of the seventh segment of the right lobe of the liver (long white arrow), and two similar nodular lesions medially to the left lobe of the liver and adjacent to the upper pole of the left kidney and the pancreatic tail (small white arrows).

lobe and adjacent to the upper pole of the left kidney and the pancreatic tail. These lesions appeared hypointense on T1-weighted unenhanced MRI scans (Figure 2A) and slightly hyperintense on T2-weighted images (Figure 2B), showing nonhomogeneous enhancement during the arterial phase, and hypointensity during the portal and equilibrium phases. The patient subsequently underwent surgical resection of the mass described along the surface of the seventh segment of the liver and adjacent to the upper pole of the right kidney, to exclude the presence of a renal neoplasm. Histopathologic examination indeed demonstrated the benign nature of the lesion, which consisted of splenic tissue. In addition, surgical exploration confirmed the presence of additional foci of splenic tissue in the abdominal cavity.

## DISCUSSION

Hepatic splenosis or the heterotopic implantation of splenic tissue after splenic trauma or splenectomy is a common but under diagnosed entity, occurring in up to 67% of patients who have suffered from a splenic rupture<sup>[1-4]</sup>. The true incidence of this rare condition is unknown, because splenosis is usually an incidental finding at surgery. The implants can be solitary or multiple, and can occur throughout the peritoneal cavity or chest<sup>[3]</sup> if splenic rupture is associated with a diaphragmatic tear. The nodules of splenosis do not generally grow to a large size, because they do not have their own blood supply. Although splenic implants are generally asymptomatic, they can lead to recurrent episodes of abdominal pain or small bowel obstruction secondary to adhesive bands of splenic implants. Most patients who undergo surgery for splenosis present to the surgeon with a diagnosis of intestinal obstruction or appendicitis. Although several cases of splenosis have been described in the past<sup>[1,5]</sup>, this case is the first to describe multiple intra-abdominal heterotopic splenic implants, particularly involving the sub-capsular portion of the liver and the right retroperitoneal space, adjacent to the upper pole of the right kidney, with correlative CT and MRI findings. Differential

**Figure 2** Different image showing a hypointense 3 cm lesion along the posterior surface of the seventh segment of the right lobe of the liver (long white arrow) and 5 additional lesions in the sub-capsular portion of the seventh segment of the liver, medially to the left lobe of the liver and adjacent to the upper pole of the left kidney and the pancreatic tail (small white arrows). A: Unenhanced T1-weighted (TR: 218, TE: 4.6 ms) axial MRI scan; B: T2-weighted (TR: 417, TE: 80 ms) axial image.

diagnoses of splenosis include endometriosis, peritoneal mesothelioma, renal neoplasms<sup>[6]</sup>, abdominal lymphomas<sup>[7]</sup> hepatic adenomas<sup>[8]</sup> and peritoneal metastatic implants. Both <sup>99m</sup>Tc-red blood cell SPECT scans and <sup>99m</sup>Tc-sulphur colloid scans can also be used to differentiate splenosis from malignancies and several reports have described the usefulness of these nuclear medicine techniques to avoid unnecessary surgical intervention<sup>[9,10]</sup>. MRI contrast agents composed of super-paramagnetic iron oxide particles that show a tissue-specific bio-distribution to phagocytic reticuloendothelial cells of liver and spleen after intravenous injection, have also been used in the past in patients with splenosis<sup>[3]</sup>. These agents produce local inhomogeneities in the magnetic field causing rapid dephasing of transverse magnetization, resulting in a loss of signal intensities on MRI of both ectopic splenic tissue and normal spleen. MRI offers the advantages over nuclear medicine techniques of combining higher spatial resolution with a physiological test of reticuloendothelial cell uptake<sup>[11]</sup>. Due to MRI's superior contrast resolution compared with CT, MRI better enabled the identification of multiple intra-abdominal splenic lesions, in particular along the posterior hepatic surface, allowing the presence of a renal neoplasm in the right retroperitoneal space to be excluded. MRI findings coupled with the patient's history of previous splenectomy allowed the correct diagnosis of multiple intra-abdominal splenosis to be made.

### Abstract

Fetal midgut volvulus is quite rare, and most cases are associated with abnormalities of intestinal rotation or fixation. We report a case of midgut volvulus without malrotation, associated with a meconium pellet, during the gestation period. This 2.79 kg, 33-wk infant was born *via* a spontaneous vaginal delivery caused by preterm labor. Prenatal ultrasound showed dilated bowel loops with the appearance of a 'coffee bean sign'. This patient had an unusual presentation with a distended abdomen showing skin discoloration. An emergency laparotomy revealed a midgut volvulus and a twisted small bowel, caused by complicated meconium ileus. Such nonspecific prenatal radiological signs and a low index of suspicion of a volvulus during gestation might delay appropriate surgical management and result in ischemic necrosis of the bowel. Preterm labor, specific prenatal sonographic findings (for example, the coffee bean sign) and bluish discoloration of the abdominal wall could suggest intrauterine midgut volvulus requiring prompt surgical intervention.

### INTRODUCTION

Midgut volvulus is a condition in which the small bowel or proximal colon twists around the superior mesenteric artery. This condition most commonly presents during the first year of life and has high rates of morbidity and mortality<sup>[1,2]</sup>. Midgut volvulus without malrotation is an extremely rare surgical condition, which may also occur during gestation<sup>[3-6]</sup>. We recently encountered an unusual case in which intrauterine volvulus occurred with prenatal meconium pellets. Emergent prenatal ultrasonography revealed the presence of the 'coffee bean sign' in this fetus. The patient required resection of a significant amount of necrotic small bowel and treatment with intra-operative saline irrigation. The patient also needed postoperative gastrografin enema due to persistent meconium ileus. Fortunately, the patient survived and has continued to thrive without parenteral nutrition. We discuss the pathogenesis of intrauterine midgut volvulus associated with complicated meconium ileus and the issues surrounding their emergent diagnosis and management.

### CASE REPORT

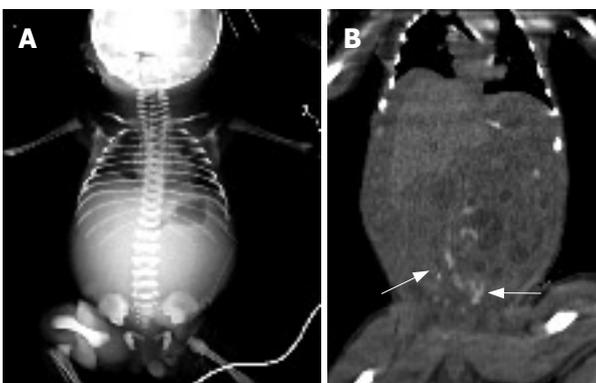

A 27-year-old pregnant woman was referred to our clinic at 33 wk of gestation because of fetal intestinal dilatation found on sonography, and the onset of preterm labor. Routine examinations at a local clinic had revealed a dilated intestine in the fetus, but this had improved spontaneously four weeks earlier. Transabdominal ultrasound on referral showed a segment of markedly dilated fetal intestine, which suggested a closed loop obstruction (Figure 1). Fetal ultrasound measurements were appropriate for the gestational age, and the Doppler indices were normal. No ascites was seen in the fetal abdomen. As it was possible the bowel obstruction would be complicated by intestinal necrosis, preterm delivery was considered beneficial. At 33 wk and two days, a male infant was delivered transvaginally. The patient weighed 2690 g and had Apgar scores of 8 and 9 at 1 and 5 min, respectively.

**Figure 1** A fetal sonogram showing dilated bowel loops with the appearance of a 'coffee bean sign'. No ascites was seen in the fetal abdomen.

**Figure 3** On laparotomy, the infant was found to have a midgut volvulus with necrosis and perforation of the small bowel. The small bowel was found to be twisted at the level of the narrow meconium-filled distal ileum (arrow).

**Figure 2** **A:** Pre-operative infantogram showing a gas shadow only in the stomach, with an absence of any distal gas shadow; **B:** Unenhanced abdominal CT showed meconium (arrow) in the distal small bowel, with mild fluid distension of the proximal small bowel.

The abdomen was distended markedly and there was a bluish skin discoloration on the periumbilical abdominal skin. Nasogastric aspiration recovered 10 mL of bilious material. A rectal examination was normal. Initial laboratory values included a white blood cell count of 26 000/mm<sup>3</sup>, a platelet count of 416 000/mm<sup>3</sup> and prothrombin time of 11 s. Blood gas values from the umbilical artery were pH 7.14, PO<sub>2</sub> 51.3 mmHg and PCO<sub>2</sub> 60.44 mmHg. A plain supine abdominal radiograph did not demonstrate bowel gas, except in the stomach. An emergency computer tomography (CT) scan performed without contrast media revealed marked intestinal dilatation mainly in the left abdomen, and a large amount of hemorrhagic ascites (Figure 2).

Exploration revealed a volvulus of the small bowel with extensive necrosis extending from 40 cm distal to the ligament of Treitz to 15 cm proximal to the ileocecal valve. The distended segment of intestine was twisted at the level of the narrow meconium filled distal ileum (Figure 3). There was no intestinal malrotation, mesenteric defect or atresia. After detorsion of the midgut volvulus, the thick meconium of distal ileum was irrigated by instilling saline with an 8-Fr rubber catheter. The involved loop was then resected and an end-to-oblique anastomosis was constructed between the dilated proximal and smaller

distal bowels by manual anastomosis. On the fourth day after surgery, the patient required treatment with a gastrografin enema to loosen the persisting meconium ileus. A presumptive diagnosis of cystic fibrosis was made postoperatively, based on meconium ileus. There was no family history. To date, the baby has been screened, but all results have been negative. The infant made a remarkable recovery and was able to tolerate enteral feeding with a steady weight gain by four months after surgery.

## DISCUSSION

Midgut volvulus is a surgical emergency frequently encountered in neonates. Most cases of volvulus in infants and fetus are associated with intestinal malrotation or congenital anomalies, such as omphalocele, gastroschisis, intestinal atresia or an annular pancreas<sup>[7]</sup>. On the other hand, the etiology of volvulus without malrotation is unknown, and associated anomalies are rare<sup>[5]</sup>. Several studies have shown that the absence of a segment of small bowel muscle or a mesenteric defect might be associated with this condition<sup>[8-11]</sup>. There is no clear explanation for the cause of this event in our patient, because laparotomy did not reveal any intestinal malrotation or congenital mesenteric anomalies. However, we suggest the fetal midgut volvulus and preterm labor was caused by the complicated meconium ileus. Intestinal volvulus might occur when the distended segment of the small bowel becomes twisted at the level of the narrow pellet-filled distal ileum. Gestational volvulus can result in ischemic necrosis, leading to fetal stress, which might activate the release of both adrenal and hypothalamic stress hormones. These might enhance placental, decidual and amniochorionic corticotrophin-releasing hormone release, while premature rupture of fetal membranes and preterm labor can be mediated by placental and membrane prostanoid release<sup>[12,13]</sup>.

Previous reports have described cases with midgut volvulus in which the fetal sonograms showed intestinal dilatation, a discrete cystic or solid abdominal mass, ascites, peritoneal calcification, polyhydramnios and, typically, the whirlpool or snail sign<sup>[14,15]</sup>. Unfortunately, our patient did not show any definitive sonographic sign of midgut

volvulus. Instead, retrospective analysis of the patient's prenatal sonographic imaging revealed a coffee bean sign, which is a specific indicator of sigmoid volvulus in adult patients. Attention should always be paid to the risk of a midgut volvulus with such prenatal sonographic findings.

The nonenhanced CT scan performed after spontaneous vaginal delivery showed excessive hemorrhagic ascites, which was invisible during prenatal sonography. This suggests the bowel necrosis and meconium peritonitis may have developed rapidly during the spontaneous vaginal delivery. Rapid emergency Cesarean section or accelerated delivery should be considered for such expectant mothers who have a history of recurrent closed loop obstruction in the fetus, and who present with acute preterm labor, because the symptoms might occur perinatally with rapid progression to gangrene.

Delays in diagnosis are likely in such cases, as physicians tend to doubt or not suspect the possibility of intrauterine volvulus because it is so rare. Therefore, close prenatal monitoring is necessary if there is any suspicion of typical sonographic signs in the fetus. The adoption of more prompt delivery methods with exploration, avoidance of unnecessary special studies and appropriate postnatal intervention are all essential to reduce the likely morbidity and mortality of intrauterine volvulus associated with complicated meconium ileus.

### Abstract

Malignant fibrous histiocytoma, which is composed of spindle-shaped cells arranged in a pleomorphic and storiform pattern, is rarely found in the colorectum. Although complete surgical excision remains the main stem of therapy, an optimal treatment strategy according to the stage has not been elucidated. We report a case of a 63-year-old woman with an ulcerative lesion in the anorectal junction and a final diagnosis of malignant fibrous histiocytoma. We introduced an access for transanal local excision and adjuvant radiotherapy because the patient refused abdominoperineal resection. No local recurrences or distant metastases were observed 15 mo after the operation. To our knowledge, this is the first case reported in the English literature of a malignant fibrous histiocytoma treated with the transanal local excision and adjuvant radiotherapy. This report showed that this approach is selectively reserved for early-stage malignant fibrous histiocytoma and for those patients who refuse radical surgery because of the risk in a permanent colostomy.

### INTRODUCTION

Malignant fibrous histiocytoma (MFH) is a soft-tissue sarcoma composed of anaplastic-appearing fibroblasts and histiocytes arranged in a storiform collagenous matrix. MFH is the most common type of soft-tissue sarcoma in adults and it usually localizes in the lower extremities, especially the thigh<sup>[1,2]</sup>. Colorectal MFH, however, remains extremely rare and only a few cases have been reported worldwide<sup>[3-23]</sup>. Surgical resection is thought to be the most effective treatment. Adjuvant chemotherapy or radiotherapy may be advisable, but the optimal histology-specific treatment protocol of this disease has not been clarified.

We report a case of a 63-year-old patient with MFH of the anorectal junction who was treated by transanal local excision and adjuvant radiotherapy. We also briefly discuss the diagnosis, surgical treatment, and adjuvant therapy of this rare case.

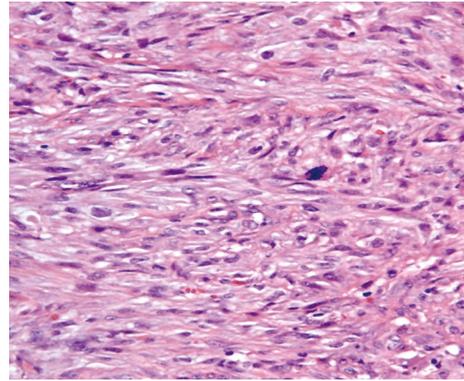

### CASE REPORT

A 63-year-old woman was referred to our institution because of blood tinged stool and anal mass that was discovered during screening colonoscopy. She had no history of anal surgery or radiation therapy. A well defined mass on the right anterior aspect of the anal canal was palpated *via* digital rectal examination and was located 3 cm from the anal verge. Routine laboratory data and levels of tumor marker, carcinoembryonic antigen, alpha-fetoprotein, and carbohydrate antigen 19-9 revealed no marked abnormalities.

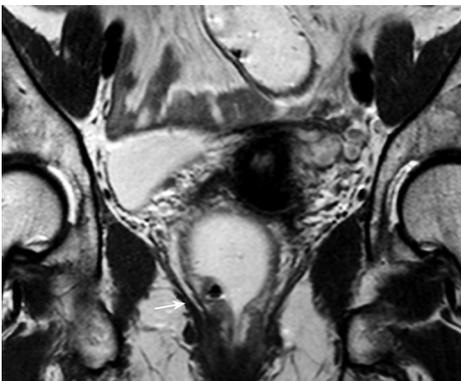

On colonoscopy examination, an ulcerative fungating mass, beginning proximal to the dentate line and extending cranially for about 1 cm, was found (Figure 1). Computed tomography of the abdomen and pelvis did not show the presence of the mass. However, anal magnetic resonance imaging confirmed a tumor of at least 1.5 cm diameter growing into the distal rectal lumen (Figure 2). The surrounding structures appeared to be free from invasion,

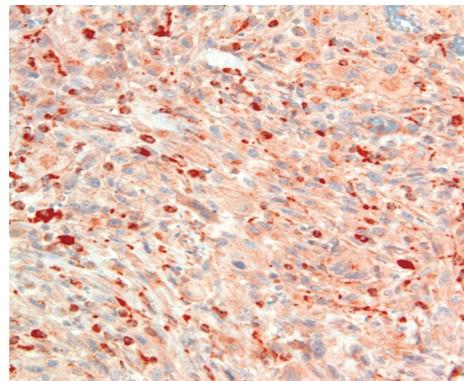

**Figure 1** On colonoscopy, an ulcerated fungating mass was detected 3 cm from the anal verge.

**Figure 3** Histological section shows a typical malignant fibrous histiocytoma featuring spindle cells arranged in a storiform pattern (HE,  $\times 400$ ).

**Figure 2** Magnetic resonance imaging shows a T1-weighted of low signal area (arrow) growing in the anterior portion of the anorectal junction.

**Figure 4** Tumor cells show positive immunostaining for CD68 ( $\times 400$ ).

and we excluded extension into the muscularis propria of the bowel wall. These results were consistent with anal or rectal cancer. However, a colonoscopic biopsy specimen revealed a few giant malignant cells arranged in a sheet like pattern among necrotic granulation tissues. We made a preoperative diagnosis of a malignant spindle-shaped tumor or nonepithelial malignant tumor.

Our first plan, an abdominoperineal resection with end colostomy, was refused by the patient. The alternative, a sphincter-sparing transabdominal approach with colonal anastomosis, seemed to be technically difficult because of the tumor's its low location and possible focal involvement of the dentate line. We decided to use the initial transanal approach to define the tumor character and the risk of aggressive behavior, and to consider a more aggressive treatment if the tumor belonged to a high-risk group. Under general anesthesia, the patient was placed in the jack-knife position, and a transanal local excision was made. The tumor was located in the submucosal layer and was excised completely with just a small amount of adherent fiber of the anal sphincter and a resection-free margin of 1 cm. After excision, we obtained a further resection margin through multiple punch biopsies, which included the proximal and distal margin, right and left lateral margin, and deep margin around the surgical bed. The muscular layer of the surgical bed was closed with Dexon sutures.

Gross pathological examination showed a 1.7 cm  $\times$

1.3 cm  $\times$  0.3 cm fibrous-elastic mass. On the cut section, the tumor was firm in consistency, solid, and yellowish in color. Histological examination showed that the tumor was pleomorphic and composed of atypical spindle cells. These cells were arranged in a storiform pattern (Figure 3). The resection margins of the specimen and all the punch-biopsied tissue were free of tumor. Immunohistochemical stains were positive for CD68, vimentin and negative for cytokeratins, CD117, CD34, alpha smooth muscle actin, desmin, S-100 protein, and HMB-45 (Figure 4). The final histopathological diagnosis was MFH of the anal canal.

The patient had an uneventful postoperative course. No implication in anal continence was observed, and she was discharged on the fifth postoperative day. She received postoperative radiation (60 gray/30 fractions) to the surgical bed. Follow-up studies after 15 mo, including colonoscopy, computed tomography, anal magnetic resonance imaging, and  $^{18}\text{F}$ -fluorodeoxyglucose positron emission tomography scan showed no evidence of local recurrence or distant metastasis.

## DISCUSSION

MFH was first described in 1963 by Ozello *et al* and was established by O'Brien and Stout in 1964, which refers to a group of soft tissue sarcoma composed of both histiocytic and fibrous elements, often has some common features,

Table 1 Clinical features of malignant fibrous histiocytoma of anorectum reported in literature

such as pleomorphism and storiform pattern of growth and is accompanied by inflammatory cells<sup>[24,25]</sup>. The most frequent site of MFH is the deep tissue of the extremities and trunk. In a retrospective series of 167 patients, 50% of MFH arose in the lower limb, 24% in the upper limbs, 16% in the trunk and 9% retroperitoneum<sup>[26]</sup>.

The large bowel is an exceedingly rare site of primary MFH. We found only 21 reported cases of primary MFH originating from the colorectum<sup>[3-23]</sup>. The median age of these patients, including our patient, is 62 years, with a range of 12-85 years and two pediatric cases have been described<sup>[5,16]</sup>. A female predominance has been suggested for extremity MFH, otherwise a review of the literature revealed 19 male and six female patients with colorectal MFH<sup>[20]</sup>. Most tumors are large, ranging from 2 cm to 19 cm in diameter (median diameter, 7 cm), and the tumor in our patient is probably one of the smallest tumor observed. The distribution differs from more common types of colorectal cancer<sup>[22]</sup>. The tumor locations include nine in the right-sided colon, seven in the transverse and descending colon, three in the sigmoid colon, and four in the anorectum. From the literature, we identified four cases with colorectal MFH which were located in the anorectum (Table 1). All reported lesions were located within 6 cm above the dentate line and were removed by abdominoperineal resection. Two patients treated with radiation as adjuvant treatment survived and were disease free 16 and 46 mo after the initial surgery.

The diagnosis of MFH depends on an accurate differential diagnosis from other sarcomas. The differential diagnosis includes gastrointestinal stromal tumor, fibrosarcoma, leiomyosarcoma, and myxoid sarcoma. Gastrointestinal stromal tumor can be easily identified on the immunohistochemical stains which are positive for CD117 and CD34. The uniform population of spindle cells and the absence of histiocytoid cells and storiform pattern areas may aid the diagnosis of fibrosarcoma. The presence of cells with perinuclear vacuoles, intracytoplasmic glycogen, and desmin positivity is suggestive of leiomyosarcoma; and finally, a diffuse, prominent myxoid background with interspersed atypical pleomorphic spindle cells is reminiscent of myxoid sarcoma. It was reported that MFH frequently expresses vimentin, actin, alpha 1-antitrypsin and CD68<sup>[27]</sup>. Therefore, MFH in the current patient was diagnosed based on the histological findings of the characteristic storiform pattern and the positive immunohistochemical staining for vimentin and CD68.

The efficacy of radiation therapy is well established in

the treatment of soft tissue sarcoma of extremities<sup>[28]</sup>. After postoperative radiation therapy, the local recurrence rate is lower (27%) than in patients with similar tumor-related characteristics who were not treated with radiation (58%). The effect of adjuvant radiotherapy to gastrointestinal MFH is unclear. In the current case, there were concerns that a microscopic residual tumor infiltrating through the circumference tissue might remain because we could not perform the radical resection. Moreover, as local recurrence is found in the most common pattern of colorectal MFH, we decided to perform adjuvant radiation therapy in our patient.

Previous studies reported that radical excision, like amputation, decreases the local recurrence rates in soft tissue sarcoma of the extremities. However, limb salvage with more conservative surgery or function sparing-surgery is performed increasingly. As for anorectal gastrointestinal stromal tumors, some authors suggested that most tumors with a diameter less than 5 cm treated with local excision and radical surgery including abdominoperineal resection are associated with high mortality and morbidity<sup>[29]</sup>. It is thought that the natural history of these patients partly excludes the benefit of radical surgery. In our patient, because the primary lesion was detected at an early stage by a screening colonoscopy, we could excise the tumor completely using the transanal approach. Fortunately, no clinical signs of local recurrence or metastasis were detected at the follow-up examination after 15 mo. Based on our experience, we think this approach enables an alternative for early stage patients who cannot tolerate radical surgery or refuse the abdominal-perineal resection.

Due to the rarity of anorectal MFH, there is an absence of histology-specific treatment protocol at present. More data are needed about the oncologic outcomes of sphincter preserving operations with multimodality therapy, as well as the feasibility and safety of salvage operations in case of local recurrence.

### Abstract

Eosinophilic esophagitis (EE) and gastroesophageal reflux disease (GERD) have overlapping clinical, manometric, endoscopic and histopathologic features. The diagnosis of EE is nowadays based upon the presence of 15 or more eosinophils per high power field (eo/HPF) in esophageal biopsies. We report the cases of two young males suffering from dysphagia and recurrent food impaction with reflux esophagitis and more than 20 eo/HPF in upper-mid esophagus biopsies, both of which became asymptomatic on proton pump inhibitor (PPI) therapy. The first patient also achieved a histologic response, while EE remained in the other patient after effective PPI treatment, as shown by 24-h esophageal pH monitoring. Topical steroid therapy combined with PPI led to complete remission in this latter patient. GERD and EE may be undistinguishable, even by histology, so diagnosis of EE should only be established after a careful correlation of clinical, endoscopic and pathologic data obtained under vigorous acid suppression. These diagnostic difficulties are maximal when both diseases overlap. Limited data are available about this topic, and the interaction between EE and GERD is a matter of debate. In this setting, upper-mid esophagus step biopsies and esophageal pH monitoring of patients on PPI therapy are pivotal to evaluate the role of each disease. A PPI trial is mandatory in patients with a histopathologic diagnosis of EE; in those unresponsive to PPI treatment, EE should be suggested. However, a clinical response to PPI may not rule out quiescent EE, as shown in this report.

**Key words:** Eosinophils; Eosinophilic esophagitis;

### INTRODUCTION

Eosinophilic esophagitis (EE) is an emerging under-diagnosed disease in adults, associated with allergic or asthmatic disorders, which typically affect males in the second to fourth decades of life. The main symptoms are dysphagia, heartburn and chest pain, and it may be present in half of all adults with bolus food obstruction of the esophagus<sup>[1,2]</sup>. The classical endoscopic appearance of the esophagus is polymorphic and includes papular elevations, whitish exudates, corrugation, longitudinal furrows, undulated mucosa, reddening, multiple contraction rings and strictures, but may also be normal in 25% of cases<sup>[1,3]</sup>. Esophageal manometry may show non-specific motor disturbances, such as hypoperistaltic and hyperperistaltic disorders, or nontransmitted or simultaneous contraction waves<sup>[3]</sup>.

Thus, EE and gastroesophageal reflux disease (GERD) can not be distinguished based on clinical, manometric or endoscopic features. Mild eosinophilic infiltration of the distal esophagus, usually less than 7-10 eosinophils per high power field (eo/HPF), is a hallmark of GERD, so on histological confirmation, which is required for the diagnosis of EE, dense eosinophil infiltrates (> 15-20 eo/HPF) must be observed along the length of the esophagus, in the absence of eosinophilic gastroenteritis, parasites or fungal infections, vasculitis or granulomatous diseases. The interaction between EE and GERD seems complex, and recently the importance of GERD in EE has been suggested due to its higher than expected prevalence, and the report of the resolution of EE with proton pump inhibitor (PPI) therapy<sup>[4,5]</sup>.

## CASE REPORT

A 21-year-old man (case 1) and a 35-year-old man (case 2) with no prior medical history both presented with acute-onset dysphagia and a complete inability to swallow saliva after food impaction in the mid and proximal esophagus, respectively. Both patients related a 2-year history of non-progressive intermittent dysphagia to solids and recurrent food impaction, which improved after drinking water. They had no previous asthma, allergic disorders or seasonal variations in their symptoms. Neither complained of heartburn, chest pain, or regurgitation. No peripheral eosinophilia or elevation in IgE level was detected in blood samples, while gastric and duodenal biopsies were normal.

### Case 1

A meat bolus impacted at 32 cm from the incisors was removed in the emergency room with a polypectomy snare by endoscopy, which revealed no esophageal mucosa abnormalities (Figure 1A), but no biopsies were taken. A previous upper endoscopy due to meat impaction and a barium swallow revealed the esophagus to be normal. Esophageal manometry demonstrated severe dysmotility in the distal esophagus, with two thirds of all esophageal contractions waves measured being simultaneous and interrupted (Figure 1B) and a normal lower esophageal sphincter pressure. The patient refused 24 h esophageal pH monitoring because of severe intolerance. On this basis, a third esophagoscopy was performed to rule out EE. Upper endoscopy showed three mucosal breaks in the distal esophagus, more than 5 mm long, but not continuous between the tops of adjacent folds, compatible with grade B (Los Angeles classification) reflux esophagitis, while the rest of the mucosa was normal. Upper-mid esophagus step biopsies showed prominent eosinophil micro-abscesses (Figure 1C) and a high density eosinophilic infiltrate (31 eo/HPF, magnification  $\times 400$ ), with a predominantly superficial distribution (Figure 1C, box), mid basal zone hyperplasia and intercellular edema, which also contributed to the suspected diagnosis of EE. A 2-mo course on PPIs (omeprazole 40 mg/d) without steroids led to clinical, manometric and pathologic remission (Figure 1D).

### Case 2

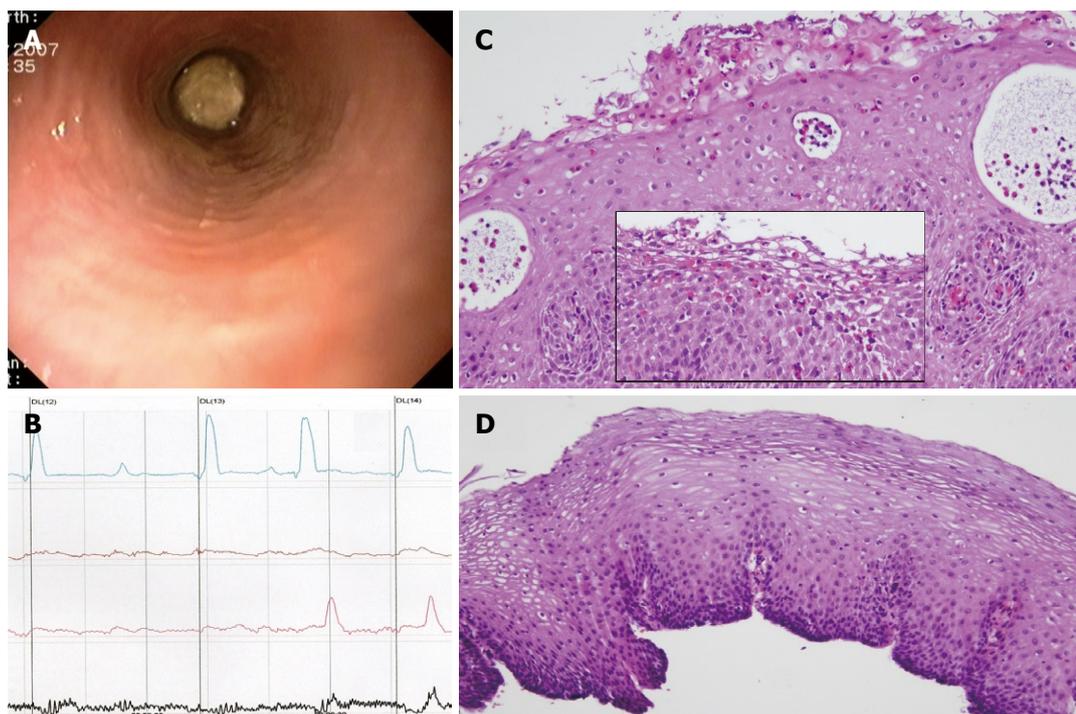

Emergency endoscopy showed a mixed vegetable bolus impacted at 23 cm from the dental margin, which was removed with a polypectomy snare and a Roth retrieval net. A normal caliber upper-mid esophagus with undulated mucosa was detected (Figure 2A), as well as a peptic fibrotic stricture at the cardias (Figure 2B), which was dilated using gentle pressure of the endoscope, with a medium size sliding hiatal hernia below. Esophageal step biopsies from the upper-mid esophagus showed severe lamina propria fibrosis (Figure 2C) and a dense intraepithelial eosinophilic infiltration (37 eo/HPF, magnification  $\times 400$ ) predominantly in the luminal surface of epithelium, with intercellular edema, basal cell hyperplasia and papillae elongation (Figure 2C, box). After a 2 mo course of PPIs (omeprazole 40 mg per day) the patient became asymptomatic, but endoscopic and all pathologic features remained at follow-up endoscopy (Figure 2D), despite PPI therapy, including 32 eo/HPF

with degranulating superficial eosinophils. 24-h esophageal pH monitoring of the patient on PPIs ruled out persistent acid reflux (total time pH  $< 4.0$ , 4%, DeMeester score 3) (Figure 2D, box). Due to these findings, a 3 mo course of fluticasone propionate, at a dosage of 500  $\mu\text{g}$  per 12 h, on top of PPIs, was started. The patient finally achieved histopathologic remission with this combined therapy.

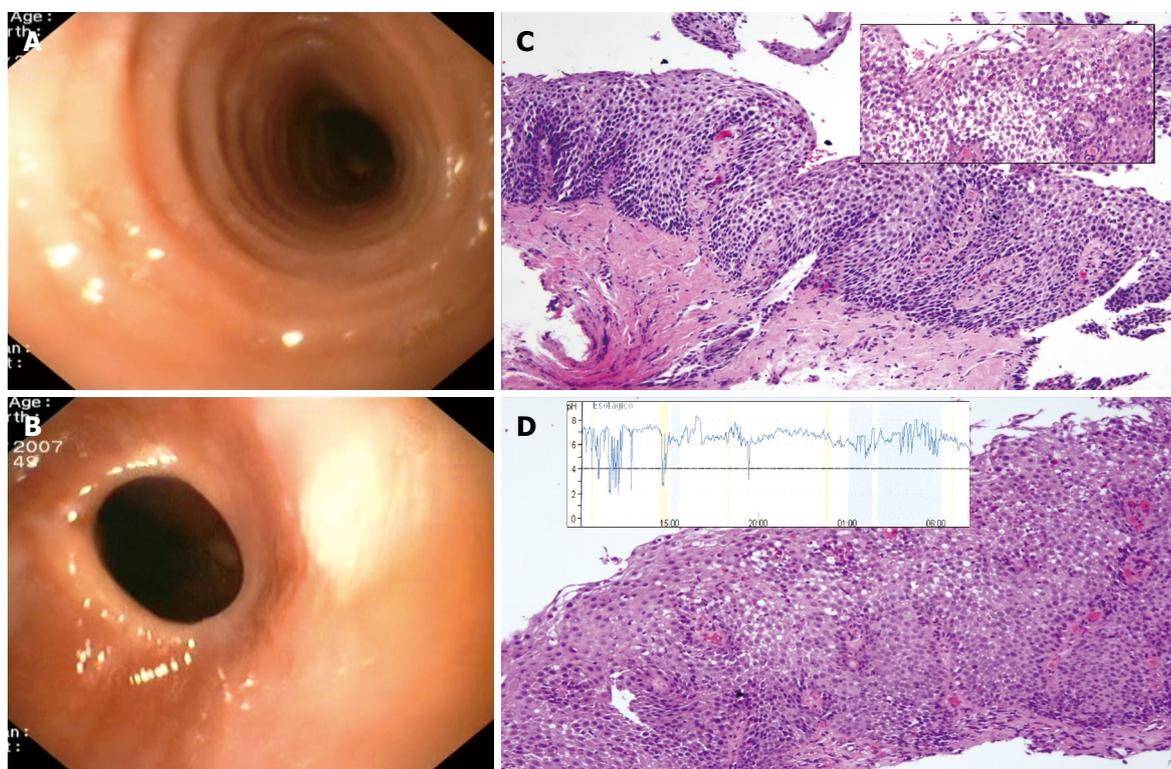

## DISCUSSION

Until recently, diagnosis of EE has been based upon the presence of more than 15-20 eo/HPF in esophageal biopsies. Due to the patchy distribution of EE, multiple-step biopsies of the mid and proximal esophagus are advisable to maximize diagnosis yield, since GERD may also induce esophageal eosinophilia, normally less than 7-10 eo/HPF, although this has been reported to be typically confined to the distal esophagus<sup>[1,3]</sup>. The diagnosis criteria of EE ( $> 15$ -20 eo/HPF) are based on the unlikelihood to observe an eosinophil count above this cut-off value in individuals with GERD and other secondary causes of eosinophilia. This cut-off value is arbitrary, and strict consensus on histopathologic diagnostic criteria of EE is lacking as a recent systematic review has shown a wide variety of eosinophil count cut-off points, methods for counting eosinophils and esophageal biopsy protocols in the literature on EE<sup>[6,7]</sup>. In this setting, eosinophil counts may lose diagnostic power, so the prominence of eosinophils towards the luminal surface, eosinophil micro-abscesses (defined as a cluster of 4 or more eosinophils), degranulating eosinophils and lamina propria fibrosis have been reported as secondary pathologic markers of EE<sup>[7,8]</sup>. Moreover, and to complicate the scenario, there has been a recent report of three cases fulfilling all clinical, endoscopic and histopathologic diagnosis criteria of EE, who achieved complete response to PPI therapy<sup>[5]</sup>. To avoid these diagnostic difficulties, consensus recommendations have recently been made by the First International Gastrointestinal Eosinophil Research Symposium (FIGERS) subcommittees<sup>[9]</sup>, which define EE with three statements: (1) Symptoms including, but not restricted to food impaction and dysphagia in adults, and feeding intolerance and GERD symptoms in children; (2) 15 or more eosinophils/HPF; (3) exclusion of other disorders associated with similar clinical, histological or endoscopic features, especially GERD, with PPI treatment or esophageal pH monitoring.

The report by Ngo<sup>[5]</sup> and case 1 of this manuscript highlight that, in contrast to previously reported data<sup>[1,3]</sup>, it is possible that GERD may cause identical high-density esophageal eosinophilia and histopathologic changes suggestive of EE in both the proximal and distal esophagus. According to initial endoscopic and pathologic data, case 1 would have been unequivocally diagnosed of EE. However, concomitant esophageal reflux lesions at the third endoscopy and complete remission on PPI treatment suggest the main diagnosis was GERD, which may have been triggering EE, or simply GERD mimicking EE histologically. Conversely, case 2 also had histological features of EE and esophageal acid reflux lesions, and became asymptomatic on PPI therapy, which made

**Figure 1** Case 1. **A:** Emergency endoscopy showing a meat bolus impacted at mid-distal esophagus with normal mucosa; **B:** Esophageal manometry demonstrated that two thirds of all contractions in the distal esophagus were simultaneous or interrupted contraction waves; **C:** Prominent eosinophil microabscesses in upper-mid esophagus biopsies (HE,  $\times 100$ ). In the box and on top of the image, a dense eosinophilic infiltrate (31eo/HPF  $\times 400$ ) predominantly spread over the superficial layers can be observed (HE,  $\times 200$ ); **D:** Normal upper-mid squamous epithelium after PPI therapy (HE,  $\times 100$ ).

**Figure 2** Case 2. **A:** Endoscopic view of the upper esophagus showing multiple concentric rings resembling mucosal undulations; **B:** Endoscopic picture of a peptic stricture at cardias 2 mo after dilation, with gentle pressure of the endoscope; **C:** Biopsies of a multiringed esophagus demonstrating severe lamina propria fibrosis at the bottom of the image, as well as marked papillae elongation and basal zone hyperplasia (HE,  $\times 100$ ). In the upper right box, intense intercellular edema, basal zone hyperplasia and dense eosinophilic infiltrate (37eo/HPF,  $\times 400$ ) towards the surface strata (HE,  $\times 200$ ); **D:** Persistent histopathologic features (32 eo/HPF,  $\times 400$ ) in spite of effective PPI therapy, as shown by 24 h pH esophageal monitoring (box).

GERD the most probable diagnosis. However, persistent histopathologic features on effective PPI therapy and resolution on topical steroids showed the simultaneous existence EE and GERD.

These cases emphasize the importance of thoughtful consideration of clinical and histopathologic responses to acid blockade on the whole, and not only eosinophils count, to establish an accurate diagnosis of EE<sup>[10,11]</sup>. The relationship between EE and GERD in adults is a controversial topic nowadays. Some authors defend their unrelated co-existence while others try to search for a plausible casual association. Contradictory data reported on the frequency of acid reflux observed by 24 h esophageal pH monitoring described in adults with EE (38%<sup>[4]</sup> against 11%<sup>[8]</sup>) does not clarify the situation. It has been suggested motor esophageal changes related to EE may contribute to GERD by decreasing lower esophageal sphincter pressure and delaying esophageal clearance, which would expose longer esophageal mucosa to the acid noxa<sup>[10,11]</sup>; this theory may explain the symptomatic response in case 2 under PPI therapy, although endoscopic and pathologic features remained. On the other hand, the previously mentioned report by Ngo<sup>[5]</sup> and case 1 of the present manuscript, with documented complete responses of EE to PPI therapy, support the hypothesis that, at least in a small subset of patients with EE, GERD may cause EE, probably by means of an acid-mediated increase in epithelial permeability, allowing immune cell recruitment or access to allergenic peptides<sup>[10,11]</sup>; in this setting, PPI could represent an effective therapy for both diseases. In patients with confirmed EE, alimentary allergic study is warranted since an elimination diet, mainly based on skin-prick tests, has demonstrated its effectiveness in terms of clinical and pathologic remission<sup>[12]</sup>. In case 2, there were no food allergens detected in a subcutaneous allergic test.

The real interplay between these two diseases is still to be elucidated. Nevertheless, when EE and GERD overlap, the clinical, endoscopic and histologic findings are non-specific in distinguishing both entities. Despite the growing recognition of EE in recent years, the more alert we are to EE, maybe the more we are likely to miss GERD. Indeed, the estimated prevalence of probable EE is 1% in the general population<sup>[13]</sup>, while GERD is a much more frequent condition which may affect 10%-20% of adults in Western countries<sup>[14]</sup>; on this basis, the likelihood to find unrelated GERD in patients with EE is high, especially if we consider that they both commonly affect young males. Then, irrespective of diagnosis criteria of EE and the validation of the relationship between GERD and EE, it is mandatory an initial trial of PPI therapy<sup>[9-11]</sup> for patients with histopathologic diagnosis of EE. In those unresponsive to acid suppression, EE should be suggested. However, a clinical response to PPI may not either preclude underlying EE, as demonstrated in case 2.

In conclusion, we report two cases in which reflux esophagitis and EE overlap, which were similar in terms of symptoms, endoscopic reflux lesions, motor esophageal alterations, high-density eosinophilia in upper-mid esophagus biopsies and good clinical response to PPI, but with different endoscopic and histopathologic outcomes after PPI therapy. This fact may reflect that

the interaction between these diseases may be more complex than originally thought and may depend more on individual patient characteristics. An initial trial of PPI therapy in patients with clinical, endoscopic and pathologic findings of EE is warranted. Lack of a response to PPI may reinforce a diagnosis of EE, but a clinical response to PPI may not rule out quiescent EE, as shown in this report. Esophageal pH measurements and histopathologic data on patients on PPI treatment are pivotal in cases with overlapping GERD and EE in order to evaluate the role of each disease. Due to the fact that EE is an uncommon disease, multicentric studies are needed to establish the real incidence and prevalence of EE and GERD in EE, and to clarify the effects of GERD, food allergy and EE on esophageal eosinophilia.

### Abstract

Echinococcal cysts are usually found in liver and lungs, but any other organ can potentially be involved. Extrahepatic disease due to hydatid cyst may develop in the abdominal and pelvic cavity, aside from in other less common locations, which may make both diagnosis and treatment more complex. We present a rare case of extrahepatic echinococcosis in a 70-year old patient with a 4-d history of dull abdominal pain, anemia within the transfusion range and fever. She underwent surgery for left renal hydatid cysts 30 years ago. After non operative treatment, imaging studies showed a calcified hydatid cyst in a retrogastric location communicating with a proximal jejunal loop. En-block resection of the mass together with the adrenal gland was performed including closure of the enteric fistula. Anatomic pathology confirmed the diagnosis of a calcified hydatid cyst of left adrenal origin. Surgery is the treatment of choice and most authors recommend removal of cyst and adrenal gland.

### INTRODUCTION

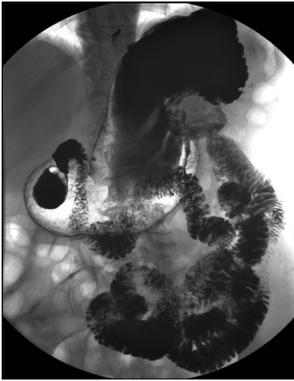

Although hydatid cysts can occur in any location, echinococcosis is usually found in the liver and lung. Extrahepatic hydatidosis has been described in the peritoneal cavity, retroperitoneum, spleen, kidney, adrenal glands and even in the spine, myocardium and abdominal wall<sup>[1,2]</sup>. Most abdominal extrahepatic hydatidosis patients usually present with a clinical picture of abdominal pain or discomfort, or with more specific symptoms, such as an anaphylactic reaction or fever. Diagnostic difficulties are evident in these cases, especially when the disease evolution is unknown and neither clinical nor analytical examinations indicate a hepatobiliary source of the symptoms<sup>[3]</sup>. Complications resulting from this disease are uncommon. Patients with intestinal obstruction have been described as being exceptional cases of extrahepatic hydatidosis. Surgery is considered the treatment of choice by most authors<sup>[4]</sup>.

We present here a case of fistulization of an adrenal hydatid cyst into an intestinal loop and review the presentation, diagnosis and surgical treatment of extrahepatic echinococcosis in such a location.

### CASE REPORT

A 70-year old patient with a history of heart failure and chronic atrial fibrillation visited our hospital for treatment. She underwent surgery for left renal hydatid cysts 30 years ago. Physical examination revealed that she had an incised hernia and history of surgery for gastric ulcer, appendectomy and left hip fracture.

The patient arrived at the Emergency Department with a 4-d history of dull abdominal pain, more intense in the left hypochondrium, and a temperature of 38°C. On examination, a mass and pain in the left epigastrium-hypochondrium were observed on palpation. Blood tests revealed leukocytosis (15 000) with discrete neutrophilia and eosinophils within normal values as well as anemia within the transfusion range (Hb: 7.3; HT: 22). The urinalysis was normal. A simple abdominal X-ray showed a calcified mass in the left epigastric region without signs of intestinal perforation or obstruction. While she was on observation in the hospital, the patient was hemodynamically stable at all times after the transfusion of two units of packed red blood cells. Given the medical history and clinical picture of the patient, an abdominal CT scan was performed, revealing a 9-cm mass with peripheral calcification, wall thickening and central partial fluid image, which seemed to be related to the left kidney's

**Figure 1** Gastrointestinal transit study showing a calcified mass in a retrogastric location communicating with a proximal jejunal loop.

**Figure 2** Surgical specimen showing en-block resection of the hydatid cyst together with the adrenal gland.

upper pole, in contact with the stomach which was impressed on its posterior wall. An inflamed-looking loop was observed in the left hypochondrium, with calcification inside and adjacent fluid, which showed no cleavage plane and was highly suspected of being a fistula. Serum IgE (ELISA) was tested for echinococcus and later read as being within the normal range. The patient's evolution during hospitalization was satisfactory. Her fever subsided after antibiotic treatment and strict diet. Subsequent blood tests were normal and no further transfusion was required. In an outpatient setting, a gastroduodenal transit study was performed, showing a calcified hydatid cyst in a retrogastric location communicating with a proximal jejunal loop. No intraluminal repletion defects were observed in the remaining loops (Figure 1). Following diagnosis of a left adrenal primary cyst with a possible hydatid origin, complicated by a fistula of jejunal loop, the patient was surgically intervened *via* a medium laparotomy with an abdominal approach, which allowed for the confirmation of a 12 cm × 9 cm calcified cyst in the left kidney's upper pole, with fistulization into a proximal jejunal loop through the inflamed supramesocolic tract. En-block resection of the mass together with the adrenal gland was performed, avoiding opening of the said mass at all times, including closure of the enteric fistula (Figure 2). No perioperative anti-helminth treatment was needed because there was no surgical dissemination, and no peritoneal involvement of the rest abdominal cavity was observed during surgery. The patient was discharged 12 d after surgery, with a favorable outcome. Anatomic pathology confirmed the diagnosis of a calcified hydatid cyst of left adrenal origin.

## DISCUSSION

Sixty to seventy percent of hydatid cysts involve the liver, 5%-15% involve the lung and only 0.5% involve the adrenal glands, an uncommon location for a primary cyst not related to a generalized hydatidosis<sup>[5]</sup>.

Diagnostic difficulties arise when the evolution of the disease appearing outside the abdominal cavity (myocardium, spine, thyroid gland) is unknown. Abdominal cysts usually have a non-specific clinical presentation and their most common symptom is abdominal pain<sup>[6]</sup>. However, other symptoms may be experienced, such as pain in the renal fossa, relatively non-specific gastrointestinal symptoms (dyspepsia, nausea, vomiting, constipation) or even a mass palpable on physical examination<sup>[7]</sup>. Sudden

abdominal pain in such patients may be an indicator of intracystic hemorrhage, rupture or infection, and intracystic hemorrhage is the potentially most dangerous complication<sup>[8,9]</sup>. The diagnosis of hydatid cyst in our patient was easy due to her history of hydatidosis and a palpable mass felt in the epigastrium on physical examination. Simple X-ray, necessary in any urgent admission due to fever and abdominal pain, revealed a calcified cyst in the said location which, together with the fever and leukocytosis, indicated a super-infection of the same location. As in the case in question, Akcay<sup>[10]</sup>, described 9 patients with adrenal hydatid cysts. All plain abdominal X-rays revealed calcifications between the 12th thoracic and the 1st lumbar vertebrae, which is probably related to the silent growth and long evolution of this type of cyst over time. Abdominal CT scan and ultrasound usually confirm the diagnosis with 93%-98% sensitivity for ultrasound and 97% for CT<sup>[11]</sup>. It was reported that the presence of calcifications in the adrenal mass greatly supports a diagnosis of hydatid cyst in this location<sup>[11,12]</sup>. In our case, the study with barium contrast was important, since the patient presented with recurrent fever episodes and elimination *via* the feces of echinococcus hydatids. We found this study very useful both to confirm the enteric fistula and to indicate surgery. Even though this is an uncommon complication, it might be interesting to bear these diagnostic tests in mind, particularly in patients with a history of extrahepatic hydatidosis surgery with suspected disease recurrence and a clinical picture of abdominal cyst complicated by abdominal obstruction and super-infection. New laboratory tests for echinococcus such as HAI, ELISA or IgE assist in diagnosis, but their negative results, described in these cases by some authors<sup>[5,11]</sup> do not rule out the presence of disease. It is mandatory to systematically use imaging studies (CT, ultrasound). It must be borne in mind that aside from imaging and laboratory methods, diagnosis is confirmed by macroscopic and microscopic examination of the surgical specimens, which will show the germinal membrane with the daughter hydatids and scolices of cysticercus in intracystic fluid.

Just as in hepatic and pulmonary hydatidosis, surgery is the treatment of choice<sup>[13]</sup>. Most authors recommend removal of cyst and adrenal gland as the safest and most reliable option<sup>[5,14]</sup>. This is normally the case because cysts

are usually large, and there is total or partial destruction of the gland on which it lies, and even, as in our case, destruction of surrounding structures and organs. Different incisions have been employed as approaches to the adrenal gland. Most authors do not recommend a laparoscopic approach in case of complex cysts<sup>[15]</sup>. In order to prevent surgical dissemination, the procedure should be carefully carried out, providing adequate protection of the surgical field and instilling hypertonic saline solution prior to cyst removal. Albendazole (10 mg/kg) or mebendazole (50 mg/kg) should be administered for a month following surgery in case of suspected peritoneal dissemination or when a peritoneal cyst is removed during surgery<sup>[16,17]</sup>.

### ANALYSIS OF DUPLICATED MANUSCRIPT

Both manuscripts are reviews on the molecular basis for E6-induced cell proliferation and apoptosis, and most parts of the article published by *WJG* are exact copies of the manuscript published by *CREGE*, without acknowledgment, and including the same sentences, words and even punctuation marks. The yellow highlighted parts in Figure 1 show the highly similar parts in the article published by *WJG*.

Based on this analysis, *WJG* considers this a typical case of duplicate publication, and is prepared to take strict, appropriate action against such behavior.

### LETTER FROM THE AUTHOR

Dear Editor,

Here I appreciate you can give me an opportunity to explain this.

I once worked in Jason Chen's lab. This review was invited by *Critical Reviews in Eukaryotic Gene Expression (CREGE)*. At that time, he asked me to write the apoptosis part, and promised me a first author. Therefore I compiled this review and the manuscript was submitted. After that I didn't get any information on whether or not it has been accepted or not. After I came back from US, there is some unhappy personal issues happened between Jason Chen and me. He threatened to remove my name in the manuscript, but because considering this review is a personal intellectual product, not experiment related, I told him that I had the right to publish it myself. After that the revised paper was submitted to *WJG* and published.

Please refer to the following emails from Editor of *CREGE* for details about the manuscript. There are two points which can be concluded from the following information: The first, I was enlisted as the first author even at TOC of the print copy; the second, Jason Chen asked the editor to remove my name without my permission.

I consider the fact is that Jason Chen neglected my

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1224 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to the readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The major goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381901-600. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

<sup>[1]</sup>Passed away on October 20, 2007

<sup>[2]</sup>Passed away on June 11, 2007

Total of 1050 editorial members from 60 countries world wide have been active in peer review and editing

National Journal Award  
2005

# World Journal of Gastroenterology®

Weekly Established in October 1995

Volume 14 Number 10  
March 14, 2008

## Contents

<b>EDITORIAL</b>	1477	<i>H pylori</i> recurrence after successful eradication <i>Niv Y</i>
<b>ESOPHAGEAL CANCER</b>	1479	Staging accuracy of esophageal cancer by endoscopic ultrasound: A meta-analysis and systematic review <i>Puli SR, Reddy JBK, Bechtold ML, Antillon D, Ibdah JA, Antillon MR</i>
<b>LIVER CANCER</b>	1491	Synergistic growth inhibitory effects of <i>Phyllanthus emblica</i> and <i>Terminalia bellerica</i> extracts with conventional cytotoxic agents: Doxorubicin and cisplatin against human hepatocellular carcinoma and lung cancer cells <i>Pinmai K, Chunlaratthanabhorn S, Ngamkitidechakul C, Soonthornchareon N, Hahnvajanawong C</i>
<b><i>H pylori</i></b>	1498	Polymorphism of -765G > C <i>COX-2</i> is a risk factor for gastric adenocarcinoma and peptic ulcer disease in addition to <i>H pylori</i> infection: A study from northern India <i>Saxena A, Prasad KN, Ghoshal UC, Bhagat MR, Krishnani N, Husain N</i>
<b>BASIC RESEARCH</b>	1504	Apoptosis of human pancreatic cancer cells induced by Triptolide <i>Zhou GX, Ding XL, Huang JF, Zhang H, Wu SB, Cheng JP, Wei Q</i>
<b>CLINICAL RESEARCH</b>	1510	Hepatitis B virus genotypes in southwest Iran: Molecular, serological and clinical outcomes <i>Mojiri A, Behzad-Behbahani A, Saberifirozi M, Ardabili M, Beheshti M, Rahsaz M, Banihashemi M, Azarpira N, Geramizadeh B, Khadang B, Moaddeb A, Ghaedi M, Heidari T, Torab A, Salah A, Amirzadeh S, Jowkar Z, Mehrabani D, Amini-Bavil-Olyae S, Dehyadegari MA</i>
	1514	Transnasal endoscopic retrograde cholangiopancreatography using an ultrathin endoscope: A prospective comparison with a routine oral procedure <i>Mori A, Ohashi N, Maruyama T, Tatebe H, Sakai K, Shibuya T, Inoue H, Takegoshi S, Okuno M</i>
	1521	Regulatory T cells in patients with inflammatory bowel diseases treated with adacolumn granulocytapheresis <i>Cuadrado E, Alonso M, de Juan MD, Echaniz P, Arenas JI</i>
<b>RAPID COMMUNICATION</b>	1528	Increased basolateral sorting of carcinoembryonic antigen in a polarized colon carcinoma cell line after cholesterol depletion-Implications for treatment of inflammatory bowel disease <i>Ehehali R, Krautter M, Zorn M, Sparla R, Füllekrug J, Kulaksiz H, Stremmel W</i>
	1534	Clinical predictors of colorectal polyps and carcinoma in a low prevalence region: Results of a colonoscopy based study <i>Bafandeh Y, Khoshbaten M, Eftekhari Sadat AT, Farhang S</i>
	1539	Gastric juice for the diagnosis of <i>H pylori</i> infection in patients on proton pump inhibitors <i>Yakoob J, Rasool S, Abbas Z, Jafri W, Abid S, Islam M, Ahmad Z</i>
	1544	High rate of complicated idiopathic gallstone disease in pediatric patients of a North American tertiary care center <i>Herzog D, Bouchard G</i>

- 1549** High circulating D-dimers are associated with ascites and hepatocellular carcinoma in liver cirrhosis  
*Spadaro A, Tortorella V, Morace C, Fortiguerra A, Composto P, Bonfiglio C, Alibrandi A, Luigiano C, De Caro G, Ajello A, Ferraiù O, Freni MA*
- 1553** Impact of obesity on the surgical outcome following repeat hepatic resection in Japanese patients with recurrent hepatocellular carcinoma  
*Utsunomiya T, Okamoto M, Kameyama T, Matsuyama A, Yamamoto M, Fujiwara M, Mori M, Aimitsu S, Ishida T*
- 1559** Prevalence of anti-HAV antibodies in multitransfused patients with beta-thalassemia  
*Siagris D, Kouraklis-Symeonidis A, Konstantinidou I, Christofidou M, Starakis I, Lekkou A, Papadimitriou C, Blikas A, Zoumbos N, Labropoulou-Karatzas C*
- 1564** Prevalence and determinants of delayed gastric emptying in hospitalised Type 2 diabetic patients  
*Kojecky V, Bernatek J, Horowitz M, Zemek S, Bakala J, Hep A*
- 1570** Mutations in components of the Wnt signaling pathway in gastric cancer  
*Pan KF, Liu WG, Zhang L, You WC, Lu YY*
- 1575** Angiopoietin-1 targeted RNA interference suppresses angiogenesis and tumor growth of esophageal cancer  
*Liu XH, Bai CG, Yuan Y, Gong DJ, Huang SD*
- 1582** Refined mapping of loss of heterozygosity on 1q31.1-32.1 in sporadic colorectal carcinoma  
*Zhou CZ, Qiu GQ, Fan JW, Wang XL, Tang HM, Huang L, Sun YH, Peng ZH*
- 1588** Colorectal carcinoma-associated antigen Ca-Hb3 detected by one-dimensional SDS-polyacrylamide gel electrophoresis and liquid chromatography-tandem mass spectrometry  
*Sun S, Guo FJ, Tong YQ, Zhu JG, Li GC*
- 1592** Inhibition of hepatitis B virus replication by pokeweed antiviral protein *in vitro*  
*He YW, Guo CX, Pan YF, Peng C, Weng ZH*
- 1598** Effect of lifestyle intervention on non-alcoholic fatty liver disease in Chinese obese children  
*Wang CL, Liang L, Fu JF, Zou CC, Hong F, Xue JZ, Lu JR, Wu XM*
- 1603** A pilot study on combination of cryosurgery and <sup>125</sup>Iodine seed implantation for treatment of locally advanced pancreatic cancer  
*Xu KC, Niu LZ, Hu YZ, He WB, He YS, Li YF, Zuo JS*
- 1612** Changes of histology and expression of MMP-2 and nm23-H1 in primary and metastatic gastric cancer  
*Wang LB, Jiang ZN, Fan MY, Xu CY, Chen WJ, Shen JG*
- 1617** Entecavir up-regulates dendritic cell function in patients with chronic hepatitis B  
*Lu GF, Tang FA, Zheng PY, Yang PC, Qi YM*

**CASE REPORT**

- 1622** Pseudocirrhosis in a pancreatic cancer patient with liver metastases: A case report of complete resolution of pseudocirrhosis with an early recognition and management  
*Kang SP, Taddei T, McLennan B, Lacy J*

## Contents

- 1625** A case of asymptomatic intraductal papillary neoplasm of the bile duct without hepatolithiasis  
*Hayashi J, Matsuoka S, Inami M, Ohshiro S, Ishigami A, Fujikawa H, Miyagawa M, Mimatsu K, Kuboi Y, Kanou H, Oida T, Moriyama M*
- 1630** Protein-losing enteropathy associated with rotavirus infection in an infant  
*Iwasa T, Matsubayashi N*
- 1633** Melanoma of the rectum: A rare entity  
*van Schaik PM, Ernst MF, Meijer HA, Bosscha K*

### Abstract

Recurrence of *H. pylori* after eradication is rare in developed countries and more frequent in developing countries. Recrudescence (recolonization of the same strain within 12 mo after eradication) rather than reinfection (colonization with a new strain, more than 12 mo after eradication) is considered to be responsible for most of the cases. This observation was confirmed only in developed countries, while in developing countries a recent meta-analysis demonstrated a high rate of reinfection. The proportion of *H. pylori* annual recurrence was 2.67% and 13.00% in developed and developing countries, respectively. Nested meta-analysis (only cases with a longer follow-up and a negative <sup>13</sup>CUBT a year after eradication) revealed annual recurrence rate of 1.45% [relative risk (RR), 0.54] and 12.00% (RR, 0.92) in developed and developing countries, respectively. These findings support the notion that in developed countries many cases of recurrence are due to recrudescence within the first year after eradication, with a 46% drop in the recurrence rate after the first year post eradication, while in developing countries reinfection is more pronounced, and continue at the same rate since eradication. A different approach for follow-up after *H. pylori* eradication is probably needed in patients of developing countries, since reinfection is highly prevalent.

Niv Y. *H. pylori* recurrence after successful eradication. *World J Gastroenterol* 2008; 14(10): 1477-1478 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1477.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1477>

A definite cure of peptic disease and prevention of ulcer complications, as well as cure of mucosa-associated lymphoid tissue (MALT) lymphoma, is dependent on successful eradication of *H. pylori*. Thus, recurrence of infection should be taken seriously into consideration.

More than 120 studies were published in the medical literature about recurrence of *H. pylori* till today, and found a wide range of recurrence rates<sup>[1-5]</sup>. The 12-mo recurrence rate varies in different studies, from 0% to 41.5% or more<sup>[5]</sup>. In a recent 7-year follow up study the annual recurrence rate of *H. pylori* infection after a successful eradication in Israel was only 0.55%<sup>[6]</sup>. This may be explained by the fact that studies are extremely different in design, diagnostic methods, and population base.

Recurrence of *H. pylori* after a successful eradication is rare in developed countries and more frequent in developing countries<sup>[1]</sup>. Recrudescence (recolonization of the same strain) rather than reinfection (colonization with a new strain) is considered more likely to be responsible for most of the cases<sup>[5]</sup>. But this belief is based on heterogeneous methods, using different approaches. Recrudescence is a clinical problem, a result of treatment failure. Reinfection is considered a problem of preventive medicine, and should be dealt in a different way. An accurate diagnosis is difficult, and mostly relies on molecular fingerprinting techniques, confirming that the identified bacteria, before and after therapy, are genetically identical<sup>[1]</sup>. Using this strategy it was found that recurrence was due to recrudescence in up to 80% of the cases<sup>[7]</sup>. Nevertheless, the possibility that reinfection with a strain common to family members or another close contact, cannot be ruled out. The case may be even more complicated since different strains may be sometimes isolated from the same host<sup>[8]</sup>, and microevolution can be observed at a high frequency. Recrudescence is most likely to occur during the first year after eradication, while reinfection may account for recurrence after a year from the eradication therapy. Heavy contamination of the environment and sources such as in drinking water, institutionalized patients, medical personnel or family members, may be the source of reinfection, especially in developing countries<sup>[7]</sup>.

*H. pylori* infection and recurrence examined with many laboratory methods, such as <sup>13</sup>C-urea breath test (<sup>13</sup>CUBT), <sup>14</sup>C-urea breath test, stool antigen test, urease test, histology or culture. In addition, successful eradication measured by a negative test in different periods after the treatment. While most authorities believe that 4 wk time span is enough to confirm eradication<sup>[9]</sup>, some investigators believe that this time should oscillate between 10 wk and 14 wk<sup>[11]</sup>. A recent meta-analysis<sup>[10]</sup> overcame the bias of changing approaches and different strategies, including 17 papers that used <sup>13</sup>CUBT in adults, with a minimum follow up of 12 mo<sup>[2-4,11-24]</sup>. In addition, studies that examined *H. pylori* recurrence after a negative <sup>13</sup>CUBT, at least a year post eradication treatment, were looked at separately. The proportion of *H. pylori* annual recurrence was 2.67% and 13.00% in developed and developing countries, respectively. Nested meta-analysis (only cases with a longer follow-up and a negative <sup>13</sup>CUBT a year after eradication) revealed annual recurrence rate of 1.45% [relative risk (RR), 0.54] and 12.00% (RR, 0.92) in developed and developing countries, respectively. These findings support the notion that in developed countries many cases of recurrence are due to recrudescence within the first year after eradication, with a 46% drop in the recurrence rate after the first year post eradication, while in developing countries reinfection is more pronounced, and continue at the same rate since eradication.

A different approach for follow-up after *H. pylori* eradication is probably needed in patients of developing countries, since reinfection is highly prevalent.

Staging accuracy of esophageal cancer by endoscopic ultrasound: A meta-analysis and systematic review. *World J Gastroenterol* 2008; 14(10): 1479-1490 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1479.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1479>

### Abstract

**AIM:** To evaluate the accuracy of endoscopic ultrasound (EUS) in the staging of esophageal cancer.

**METHODS:** Only EUS studies confirmed by surgery were selected. Articles were searched in Medline and Pubmed. Two reviewers independently searched and extracted data. Meta-analysis of the accuracy of EUS was analyzed by calculating pooled estimates of sensitivity, specificity, likelihood ratios, and diagnostic odds ratio. Pooling was conducted by both the Mantel-Haenszel method (fixed effects model) and DerSimonian Laird method (random effects model). The heterogeneity of studies was tested using Cochran's  $Q$  test based upon inverse variance weights.

**RESULTS:** Forty-nine studies ( $n = 2558$ ) which met the inclusion criteria were included in this analysis. Pooled sensitivity and specificity of EUS to diagnose T1 was 81.6% (95% CI: 77.8-84.9) and 99.4% (95% CI: 99.0-99.7), respectively. To diagnose T4, EUS had a pooled sensitivity of 92.4% (95% CI: 89.2-95.0) and specificity of 97.4% (95% CI: 96.6-98.0). With Fine Needle Aspiration (FNA), sensitivity of EUS to diagnose N stage improved from 84.7% (95% CI: 82.9-86.4) to 96.7% (95% CI: 92.4-98.9). The  $P$  value for the  $\chi^2$  test of heterogeneity for all pooled estimates was  $> 0.10$ .

**CONCLUSION:** EUS has excellent sensitivity and specificity in accurately diagnosing the TN stage of esophageal cancer. EUS performs better with advanced (T4) than early (T1) disease. FNA substantially improves the sensitivity and specificity of EUS in evaluating N stage disease. EUS should be strongly considered for staging esophageal cancer.

**Key words:** Esophageal cancer; Cancer staging; Endo-

### INTRODUCTION

Esophageal cancer is a devastating disease with a significant impact on patients' lives and health-care systems world-wide. Esophageal cancer affects 1%-2% of people in the United States and up to 15% of people undergoing endoscopy for gastroesophageal reflux disease (GERD)<sup>[1]</sup>. The incidence of esophageal cancer is increasing in the USA, approximately 20.6% on average annually, despite a decrease in esophageal squamous cell cancer<sup>[2,3]</sup>. This increase is mostly due to a dramatic rise in esophageal adenocarcinoma, from 1.8 cases per 100 000 during 1987-1992 to 2.5 cases per 100 000 during 1992-1996<sup>[4]</sup>. From 1973 to 2002, esophageal adenocarcinoma has increased fourfold<sup>[5]</sup>. The impact of this disease is significant throughout the world due to its increasing incidence and significant mortality (5-year mortality rate  $> 80\%$ )<sup>[6]</sup>.

Based upon the increasing incidence and devastating consequences of esophageal adenocarcinoma, an increasing amount of resources has been evaluated and implemented in an effort to stage and treat this disease. Based upon the 1996 US national cancer database, the 5-year survival rate for esophageal cancer is as follows: stage 0 (TisN0M0) is 52%, stage I (T1N0M0) is 42%, stage II (T2N0M0 or T3N0M0) or (T1N1M0 or T2N1M0) is 29%, stage III (T3N1M0 or T4NxM0) is 15%, and stage IV (TxNxM1) is 3%<sup>[7]</sup>.

Staging of esophageal cancer is extremely important since it helps differentiate treatment options. To improve survival, many treatment modalities have been utilized for esophageal cancer, including surgery, radiotherapy, chemotherapy, and combinations of the aforementioned options<sup>[7]</sup>. For early disease, recent studies that have investigated endoscopic mucosal resection have shown a 5-year survival of 98%<sup>[8]</sup> and a low recurrence rate<sup>[9]</sup>. Although multiple treatment regimens exist and they overlap

for each stage, the stage of disease is very important in guiding treatment and predicting outcomes.

Many staging modalities have been utilized for esophageal cancer, including chest CT, MRI, positron emission tomography (PET), and endoscopic ultrasound (EUS). CT and MRI lack the ability to differentiate layers of the esophageal mucosa. Thus, these modalities cannot accurately discern T stage of esophageal cancer. Chest CT provides important information regarding tumor size, lymph node involvement, and potential metastatic lesions. However, chest CT alone has a sensitivity of only 48% for mediastinal lymph node involvement<sup>[10]</sup>. MRI has been shown to be useful in preoperative evaluation and equally as accurate as CT in staging esophageal cancer; however, studies do vary<sup>[11]</sup>. MRI staging has been shown to have an accuracy of 40% with very low sensitivity and specificity<sup>[12,13]</sup>. For mediastinal lymph node involvement, thoracoscopic procedures for tissue biopsy carry a risk of complications in 25%-35% of cases<sup>[14,15]</sup>. An alternative to CT or MRI is PET. PET is a non-invasive test which has been shown to be beneficial in detection of metastatic disease (stage IV); however, detection of locoregional metastases is limited<sup>[13]</sup>. Due to limitations of CT, MRI, and PET, other modalities, such as EUS, have been initiated and reviewed.

EUS utilizes an echoendoscope that is passed directly into the esophagus, with the ability to visualize the individual histological layers of the esophagus<sup>[16]</sup>. This approach is particularly useful in evaluating invasion of local disease, especially esophageal cancer. EUS has been shown to detect more locoregional node involvement than CT or PET, with a higher sensitivity<sup>[17,18]</sup>. The accuracy of EUS to determine tumor depth has also been estimated to be quite accurate<sup>[18-20]</sup>. However, studies vary as to the accuracy of EUS in both the depth of local disease, nodal involvement, and the detection of distant metastases<sup>[21-24]</sup>.

With EUS emerging as a very useful staging tool, its role in staging esophageal cancer continues to be addressed. Several studies have identified the potential benefits of EUS with esophageal cancer staging; however, results regarding the extent of its benefits have been inconsistent<sup>[52,72,82]</sup>. We conducted a meta-analysis to examine the role of EUS in the staging of esophageal cancer for loco-regional spread.

This meta-analysis and systematic review was written in accordance with the proposal for reporting by the QUOROM (Quality of Reporting of Meta-analyses) statement<sup>[25]</sup>. Since this study investigated diagnostic accuracy of a test, the study design for this meta-analysis and systematic review conformed to the guidelines of the Standards for Reporting of Diagnostic Accuracy (STARD) initiative<sup>[26]</sup>.

## MATERIALS AND METHODS

### Study selection criteria

Only EUS studies confirmed by surgery or appropriate follow-up were selected. EUS criteria used for T staging were: T1, tumor invades the lamina propria or submucosa but not the muscularis propria; T2, tumor invades but does not extend beyond the muscularis propria; T3, tumor invades the peri-esophageal tissues but not adjacent organs;

and T4, tumor invades adjacent structures. Nodal invasion was defined as invasion of mediastinal lymph nodes. From this pool, only studies from which a 2 × 2 table could be constructed for true-positive, false-negative, false-positive and true-negative values were included.

### Data collection and extraction

Articles were searched in Medline, Pubmed, Ovid journals, CINAHL, ACP Journal Club, DARE, International Pharmaceutical Abstracts, Old Medline, Medline Non-indexed Citations, OVID Healthstar, and Cochrane Controlled Trials Registry. The search terms used were endoscopic ultrasound, EUS, ultrasound, endosonography, esophageal cancer, esophageal cancer, tumor staging, nodal invasion, staging, surgery, sensitivity, specificity, positive predictive value, and negative predictive value. 2 × 2 tables were constructed with the data extracted from each study. Two authors (SP and JR) independently searched and extracted the data. Any differences were resolved by mutual agreement.

### Quality of studies

Clinical trial with a control arm can be assessed for the quality of the study. A number of criteria have been used to assess this quality of a study (e.g. randomization, selection bias of the arms in the study, concealment of allocation, and blinding of outcome)<sup>[27,28]</sup>. There is no consensus on how to assess studies without a control arm. Hence, these criteria do not apply to studies without a control arm<sup>[28]</sup>. Therefore, for this meta-analysis and systematic review, studies were selected based on completeness of data and inclusion criteria.

### Statistical analysis

Meta-analysis for the accuracy of EUS in diagnosing the etiology of mediastinal lymphadenopathy was performed by calculating pooled estimates of sensitivity, specificity, likelihood ratios, and diagnostic odds ratios. EUS studies were grouped into periods of time to standardize the change in EUS technology and EUS criteria for lymph node involvement<sup>[29]</sup>. These periods of time were 1986-1994, 1995-1999 and 2000-2006. Pooling was conducted using the Mantel-Haenszel method (fixed effects model) and DerSimonian Laird method (random effects model). The confidence intervals (CIs) were calculated using the F distribution method<sup>[30]</sup>. Forrest plots were drawn to show the point estimates in each study, in relation to the summary pooled estimate. The width of the point estimates in the Forrest plots indicated the assigned weight for that study. For 0 values, 0.5 was added, as described by Cox<sup>[31]</sup>. The heterogeneity of the sensitivities and specificities was tested by applying the likelihood ratio test<sup>[32]</sup>. The heterogeneity of likelihood ratios and diagnostic odds ratios were tested using Cochran's  $Q$  test, based upon inverse variance weights<sup>[33]</sup>. Heterogeneity among studies was also tested by using summary receiver operating characteristic (SROC) curves. SROC curves were used to calculate the area under the curve (AUC). The effect of publication and selection bias on the summary estimates was tested by the Egger<sup>[34]</sup> and

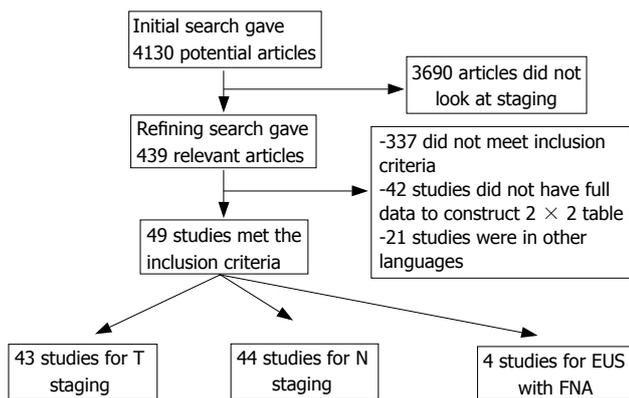

Figure 1 Search results.

Begg-Mazumdar<sup>[35]</sup> bias indicators. Also, funnel plots were constructed to evaluate potential publication bias using the standard error and diagnostic odds ratio<sup>[36,37]</sup>.

## RESULTS

An initial search identified 4130 reference articles, of these, 439 relevant articles were selected and reviewed. Forty-nine studies ( $n = 2558$ ) which met the inclusion criteria were included in this analysis<sup>[10,18,20-24,38-40]</sup>. For T staging, there were 43 studies<sup>[10,18,20-24,39-72]</sup>. There were 44 studies for nodal staging<sup>[10,18,20-24,38-46,48-50,53,54,56-63,66-80]</sup>, and of these, 4 used FNA for nodal staging<sup>[23,38,76,77]</sup>. Figure 1 shows the search results and Table 1 the characteristics for EUS studies included in this meta-analysis. All of the 49 studies included were published as full-text articles in peer-review journals. Not all studies had data for all the stages; we only used data for the available stage of esophageal cancer in a given paper. All the studies included used dedicated EUS machines. The calculated pooled estimates given are estimates calculated by the fixed effect model.

### Accuracy of EUS for T staging

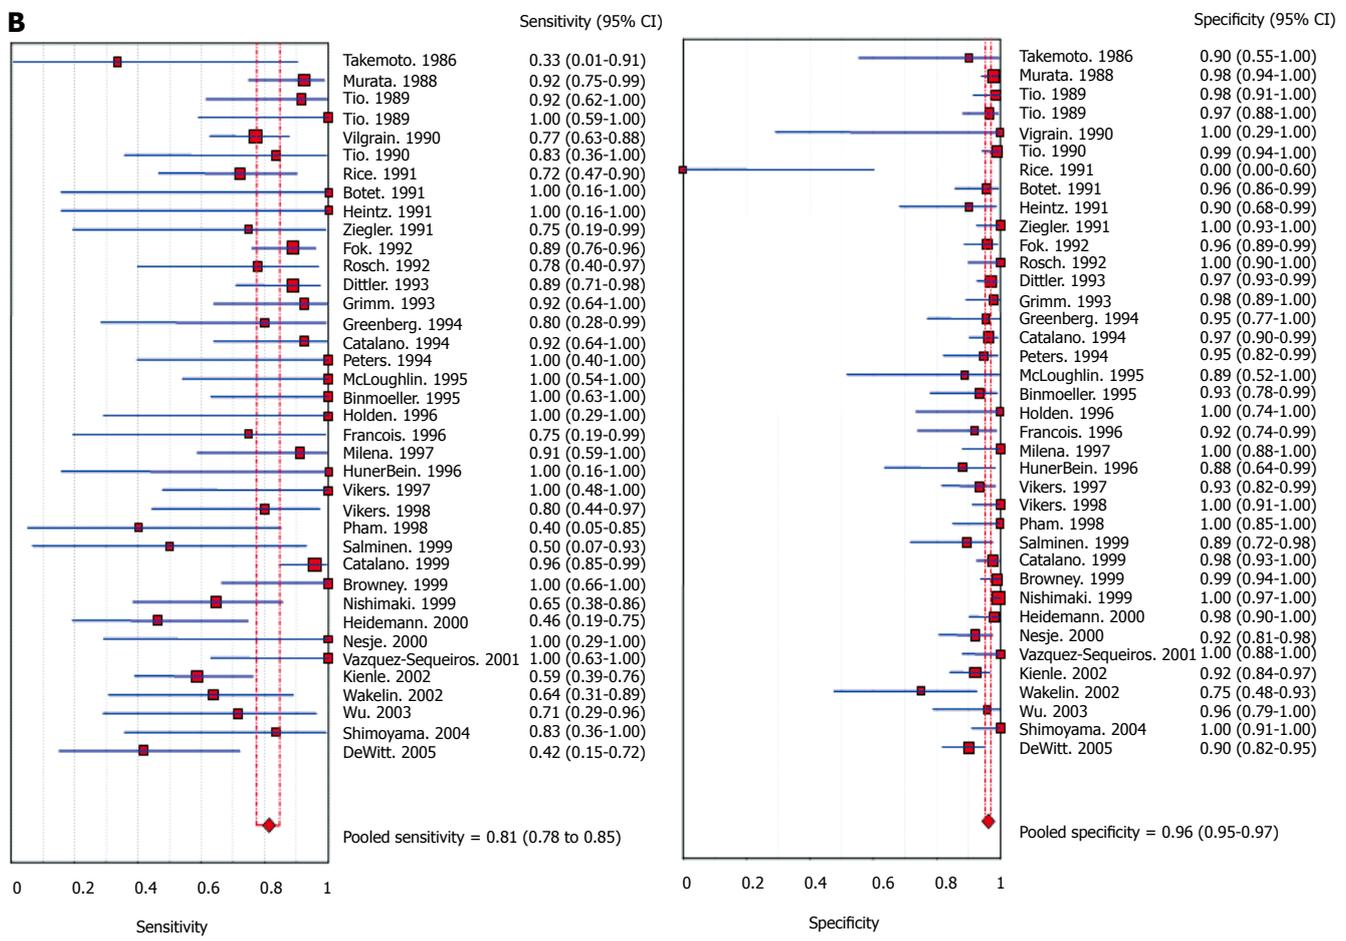

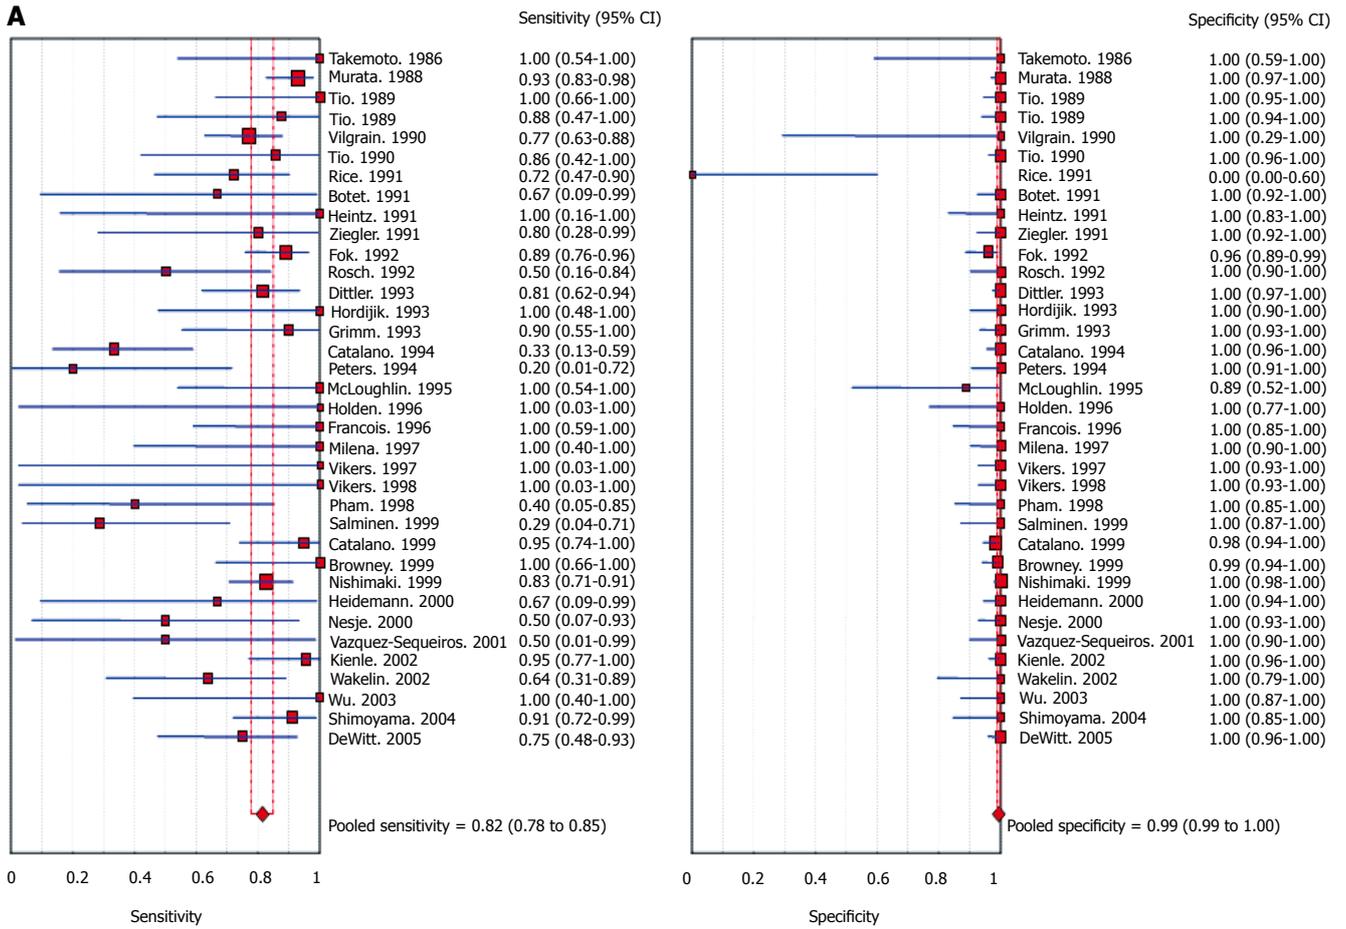

The pooled sensitivity and specificity of EUS to diagnose T1 stage cancer was 81.6% (95% CI: 77.8-84.9) and 99.4% (95% CI: 99.0-99.7), respectively. Figure 2A shows the sensitivity and specificity to diagnose T1 stage cancer in a Forrest plot. For T2 stage, EUS had a pooled sensitivity and specificity of 81.4% (95% CI: 77.5-84.8) and 96.3% (95% CI: 95.4-97.1), respectively. The Forrest plot in Figure 2B shows the sensitivity and specificity of EUS to diagnose T2 stage cancer. For T3 stage, EUS had a pooled sensitivity and specificity of 91.4% (95% CI: 89.5-93.0) and 94.4% (95% CI: 93.1-95.5), respectively. Figure 2C shows the ability of EUS to diagnose stage T3. To diagnose T4 stage cancer, EUS had a pooled sensitivity of 92.4% (95% CI: 89.2-95.0) and specificity of 97.4% (95% CI: 96.6-98.0). The sensitivity and specificity of EUS to diagnose T4 stage cancer from individual studies are shown as a Forrest plot in Figure 2D. A test of heterogeneity for all the pooled estimates for T stages had a  $P$  value  $> 0.10$ . All the pooled estimates calculated by fixed and random effect models were similar. Table 2 shows the pooled accuracy estimates of EUS for T stage esophageal cancer.

### Accuracy of EUS for N staging

With FNA, the sensitivity of EUS to diagnose N stage cancer improved from 84.7% (95% CI: 82.9-86.4) to 96.7% (95% CI: 92.4-98.9). Figure 2E depicts the sensitivity of EUS alone and EUS with FNA in diagnosing N stage cancer. The specificity of EUS improved from 84.6% (95% CI: 83.2-85.9) to 95.5% (95% CI: 91.0-98.2) with FNA. The Forrest plot in Figure 2F shows the specificity of EUS alone and EUS with FNA in diagnosing nodal invasion by esophageal cancer. The accuracy estimates of EUS alone and EUS with FNA are shown in Table 3. All the pooled estimates calculated by fixed and random effect models were similar. The  $P$  values for  $\chi^2$  heterogeneity for all the pooled accuracy estimates were  $> 0.10$ .

Table 5 Bias indicators and AUC with the corresponding Q values for various cancer stages

	Begg-Mazumdar bias (Kendall's tau value, P)	Egger bias (95% CI, P)	AUC (SE)	Q (SE)
T1	-0.51, P = 0.01	-0.48 (95% CI = -2.84 to 1.88, P = 0.68)	0.97 (0.02)	0.91 (0.02)
T2	-0.14, P = 0.24	-0.32 (95% CI = -1.74 to 1.10, P = 0.65)	0.95 (0.02)	0.89 (0.02)
T3	-0.11, P = 0.32	0.33 (95% CI = -1.43 to 2.09, P = 0.70)	0.97 (0.01)	0.92 (0.01)
T4	-0.07, P = 0.56	-2.89 (95% CI = -5.35 to -0.44, P = 0.02)	0.98 (0.01)	0.93 (0.01)
N	-0.26, P = 0.01	0.29 (95% CI = -1.58 to 1.00, P = 0.69)	0.91 (0.02)	0.99 (0.02)

to standardize the change in EUS technology and the change in EUS criteria for tumor staging. These periods were 1986-1994, 1995-1999 and 2000-2006. The pooled estimates of studies during these periods of time are shown in Table 4. The *P* value for  $\chi^2$  heterogeneity for all the pooled accuracy estimates was  $> 0.10$ .

### Bias estimates

The publication bias calculated by the Begg-Mazumdar and Egger bias indicators for each stage of esophageal cancer invasion is shown in Table 5. The funnel plots to investigate the effect of publication bias on T stage is shown in Figure 3A. The effect of publication bias on N stage is shown in Figure 3B.

SROC curves were drawn for AUC and *Q* values. The AUC and *Q* values of EUS to diagnose various stages of esophageal cancer are shown in Table 5. SROC curves for T and N staging are shown in Figure 4A and B, respectively.

A subgroup analysis was performed by removing the studies in which the last or the first author was the same (e.g. Tio *et al.*). This was done to make sure that the same data were not used by the studies, i.e. to avoid duplication. In the subgroup analysis, there was no significant change in the pooled estimates. Separate accuracy estimated for radial *versus* linear EUS technology could not be performed

as the majority of the studies did not make a distinction or give separate accuracy values for radial or linear EUS technology.

## DISCUSSION

This meta-analysis and systematic review shows that the pooled sensitivity of EUS for tumor invasion (T stage) is high (about 81%-90%), with it being higher for advanced disease than early disease. For all the T stages, the pooled specificity of EUS to diagnose depth of tumor invasion is very high (about 99%). Diagnostic odds ratio is defined as the odds of having a positive test in patients with a true anatomic stage of the disease when compared to patients who do not have the disease. EUS as a diagnostic test has a very high diagnostic odds ratio for T staging (about 250 times). For example, if EUS demonstrates that a patient has T1 stage disease, the odds of having the correct anatomic stage of T1 disease is 221 to 1. This helps physicians offer endoscopic treatment with confidence to patients with early disease<sup>[81-87]</sup>. Another way of looking at this is: if a small lesion is found to be esophageal cancer, then EUS is an excellent diagnostic test to examine the depth of tumor invasion, because of its very high sensitivity and specificity. The depth of tumor invasion can help decide if curative surgical or curative endoscopic mucosal resection or submucosal dissection can be offered to resect the lesion en bloc<sup>[81-87]</sup>.

The positive likelihood ratio of a test is a gauge of how well it identifies a disease state. The higher the positive likelihood ratio, the better the test performs in identifying the true disease status. On the other hand, a negative likelihood ratio is a gauge of how well the test performs in excluding a disease state. The lower the negative likelihood ratio, the better the test performs in excluding a disease. For T staging, EUS has a high positive likelihood ratio for all T stages and a low negative likelihood ratio for T4 disease when compared to T1 disease. This indicates that EUS performs better in excluding T4 than T1 disease. Clinically, another viewpoint is: if EUS diagnoses T2 disease then the patient might still have anatomic T1 disease, but if EUS diagnoses T1 disease then the patient probably truly has

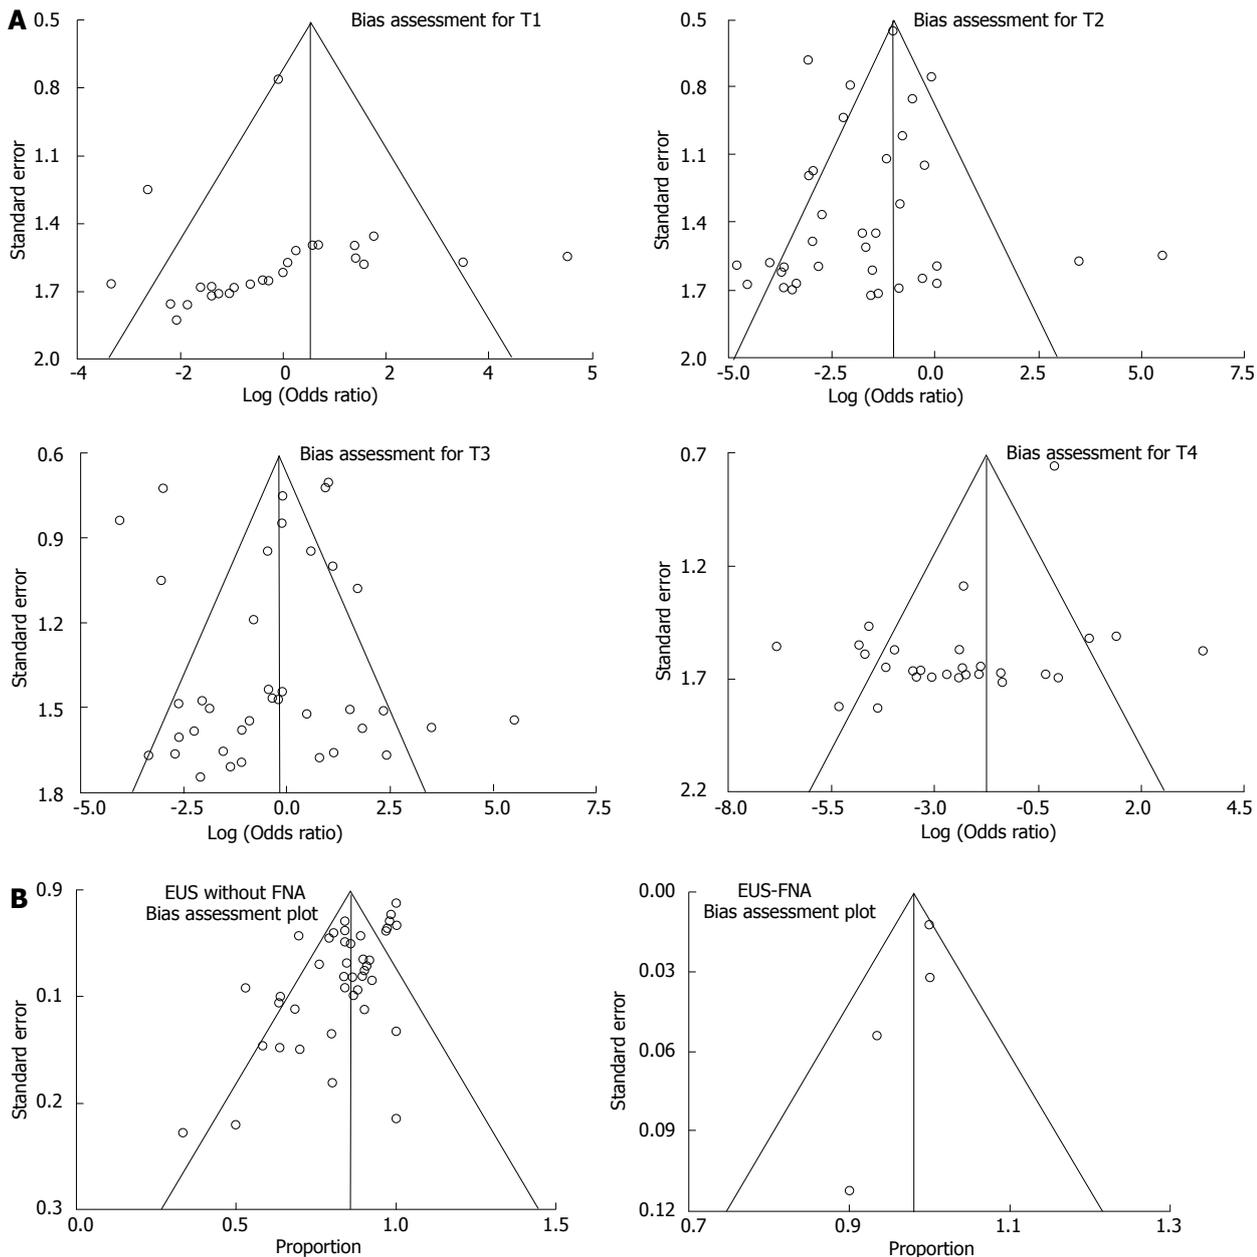

Figure 3 A: Funnel plots assessing bias for T staging; B: Funnel plots assessing bias for N staging.

anatomic T1 disease. This helps physicians offer surgical or endoscopic treatments with confidence if EUS diagnoses a patient with T1 esophageal cancer<sup>[81-87]</sup>.

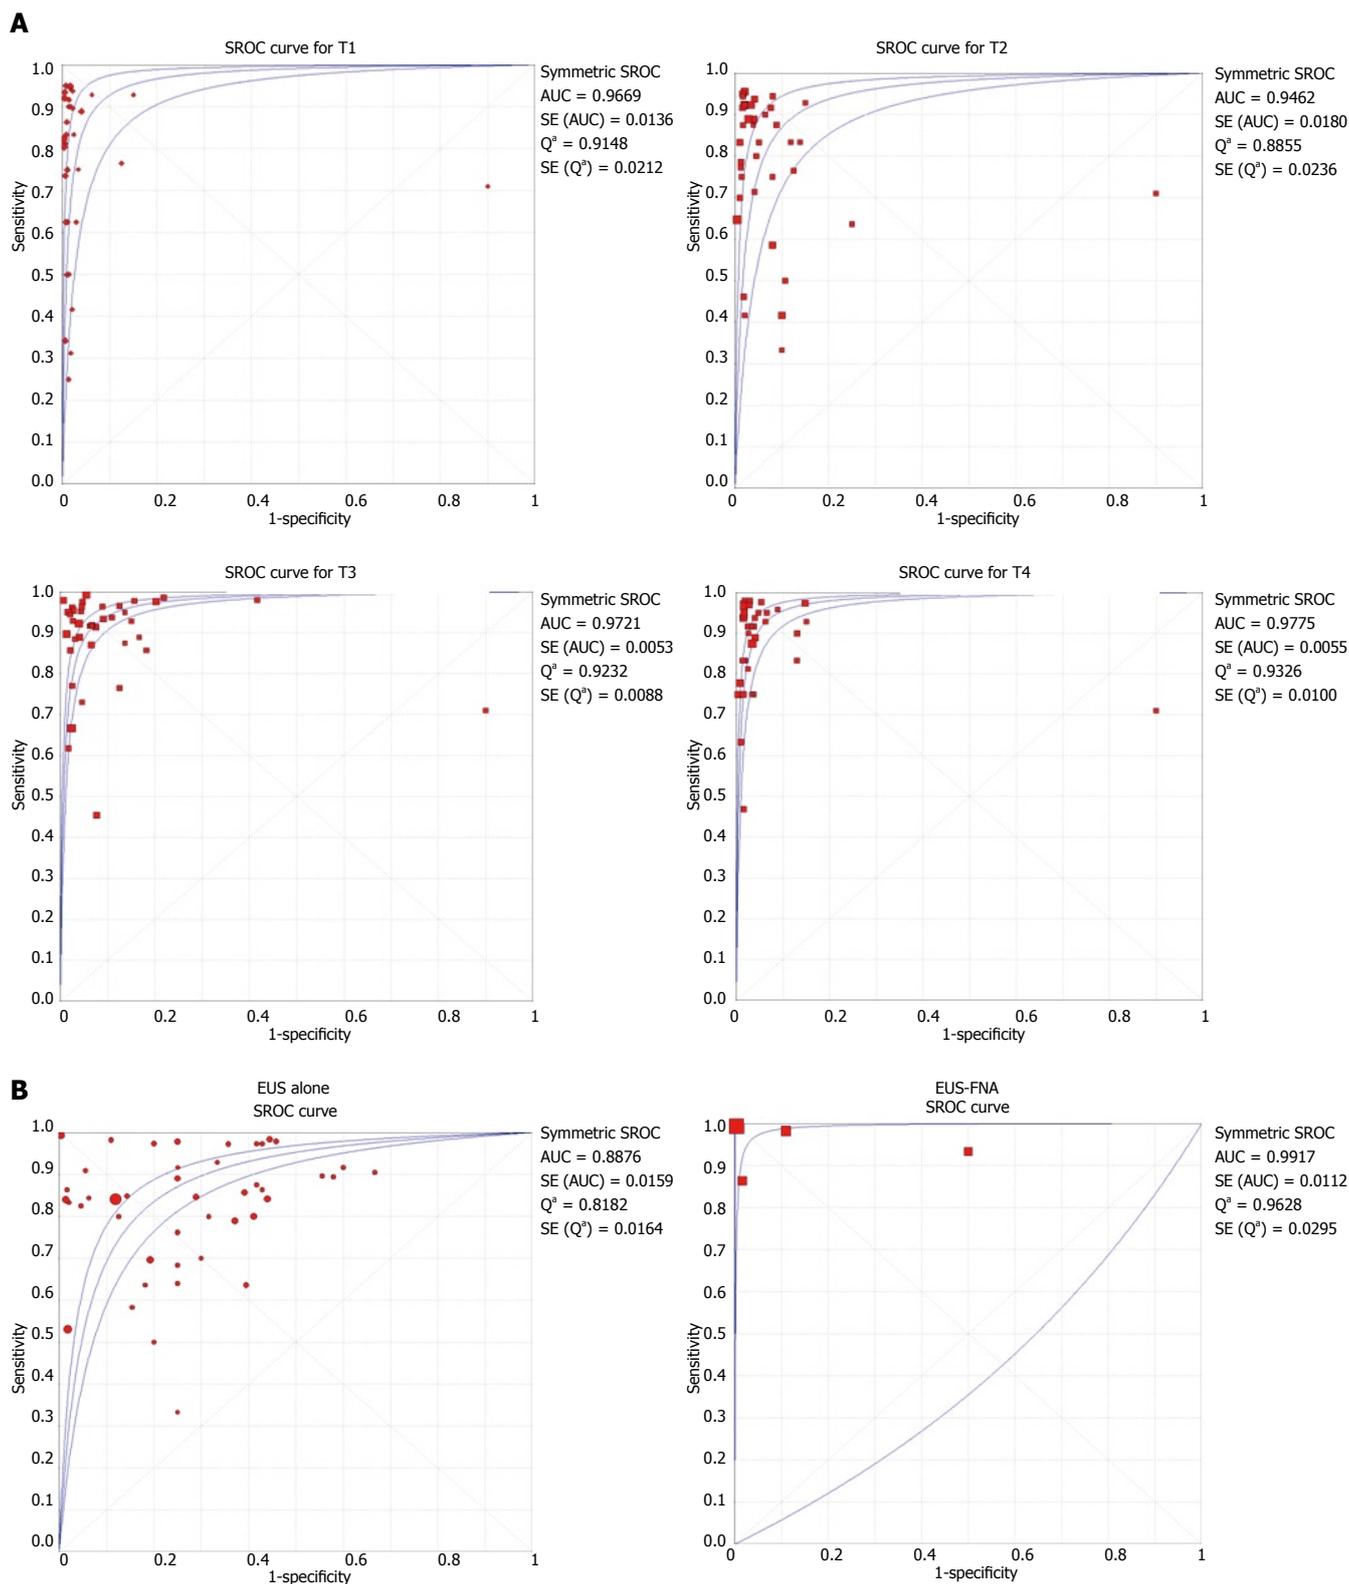

The major advantage of EUS is the ability to perform FNA during the procedure for tissue diagnosis. The procedure is, in comparison with other alternative options, safe, less invasive, and does not require general anesthesia or hospitalization<sup>[88]</sup>. The complication rate is extremely low (0.5%-2.3%), with several studies reporting no complications<sup>[75,76,88,89]</sup>. Other modalities using FNA, such as transbronchial CT or thorascopic procedures, cannot be used for the entire mediastinum<sup>[14,15,92-101]</sup>. EUS has the ability to image the aortopulmonary window, the subcarinal nodes, inferior mediastinum, and the entire posterior part of the mediastinum.

EUS as an imaging modality has high sensitivity and specificity to diagnose N stage esophageal cancer. This

meta-analysis shows that FNA substantially improves the sensitivity (85% to 97%) and specificity (85% to 96%) of EUS in evaluating N stage esophageal cancer, therefore, EUS with FNA should be the diagnostic test of choice.

Over the last two decades, the specificity of EUS to diagnose T stage cancer has remained high. In addition, the sensitivity of EUS for T staging has improved, especially for early disease (T1), over the past two decades, which may represent improvement in imaging technology or training. For nodal staging, all the studies in which FNA was performed were from the most recent periods. The sensitivity and specificity of EUS alone to diagnose N stage cancer has not improved in the past two decades. Our meta-analysis demonstrates that the sensitivity and specificity of EUS markedly improved with FNA.

EUS as a diagnostic tool is not designed to detect distant metastasis, so this was not evaluated in this analysis.

**Figure 4** A: SROC curves for various T stages of esophageal cancer; B: SROC curves for various N stages of esophageal cancer.

Heterogeneity among different studies was determined by drawing SROC curves and finding the AUC, since different studies might use slightly different criteria for staging. An AUC of 1 for any test indicates that the test is excellent. SROC curves for EUS showed that AUC was very close to 1, which indicates that EUS is an excellent diagnostic test for staging esophageal cancer.

Studies with statistically significant results tend to be published and cited. Smaller studies may show larger treatment effects due to fewer case-mix differences (e.g. patients with only early or late disease) than larger trials. This can be estimated by bias indicators and construction of funnel plots. This publication and selection bias may affect the summary estimates. Also, bias among studies can

affect the shape of the funnel plot. In this meta-analysis and systematic review, bias calculations using the Egger<sup>[35]</sup> and Begg-Mazumdar<sup>[36]</sup> bias indicators showed no statistically significant bias. Furthermore, funnel plot analyses showed no significant bias for EUS studies.

In conclusion, EUS has excellent sensitivity and specificity in accurately diagnosing T stage esophageal cancer. EUS performs better with advanced (T4) than early (T1) disease. FNA substantially improves the sensitivity and specificity of EUS in evaluating N stage esophageal cancers. EUS should be the test of choice for TN staging of esophageal cancer.

## COMMENTS

### Background

Prognosis and modality of treatment in patients with esophageal cancer depends on the staging of the tumor. The published data on the accuracy of endoscopic ultrasound (EUS) for staging esophageal cancer is varied. The aim of this meta-analysis and systematic review was to evaluate the accuracy of EUS in staging esophageal cancer.

### Research frontiers

To date, there have been many studies on EUS in staging esophageal cancer, but no meta-analyses.

### Innovations and breakthroughs

With EUS emerging as a very useful staging tool, its role in esophageal cancer continues to be addressed. Several studies have identified the potential benefits of EUS for esophageal cancer staging; however, results regarding the extent of its benefits have been inconsistent.

### Applications

EUS has excellent sensitivity and specificity in accurately diagnosing TN stage of esophageal cancer. EUS performs better with advanced disease (T4) than early disease (T1). FNA substantially improves the sensitivity and specificity of EUS in evaluating N stage cancer. EUS should be strongly considered for staging esophageal cancer.

### Terminology

EUS utilizes an echoendoscope which is passed directly into the esophagus, with the ability to visualize the individual histological layers of the esophagus. This approach is particularly useful in evaluating invasion of local disease, especially in esophageal cancer.

### Peer review

This manuscript is well designed and prepared study finding an important conclusions. The most important point is that the real time PCR is significantly cheaper than the other commercial test.

### Abstract

**AIM:** To examine the growth inhibitory effects of *Phyllanthus emblica* (*P. emblica*) and *Terminalia bellerica* (*T. bellerica*) extracts on human hepatocellular carcinoma (HepG2), and lung carcinoma (A549) cells and their synergistic effect with doxorubicin or cisplatin.

**METHODS:** HepG2 and A549 cells were treated with *P. emblica* and *T. bellerica* extracts either alone or in combination with doxorubicin or cisplatin and effects on cell growth were determined using the sulforhodamine B (SRB) assay. The isobologram and combination index (CI) method of Chou-Talalay were used to evaluate interactions between plant extracts and drugs.

**RESULTS:** *P. emblica* and *T. bellerica* extracts demonstrated growth inhibitory activity, with a certain degree of selectivity against the two cancer cell lines tested. Synergistic effects (CI < 1) for *P. emblica*/

doxorubicin or cisplatin at different dose levels were demonstrated in A549 and HepG2 cells. The *T. bellerica*/cisplatin or doxorubicin also showed synergistic effects in A549 and HepG2 cells. In some instances, the combinations resulted in antagonistic effects. The dose reduction level was different and specific to each combination and cell line.

**CONCLUSION:** The growth inhibitory activity of doxorubicin or cisplatin, as a single agent, may be modified by combinations of *P. emblica* or *T. bellerica* extracts and be synergistically enhanced in some cases. Depending on the combination ratio, the doses for each drug for a given degree of effect in the combination may be reduced. The mechanisms involved in this interaction between chemotherapeutic drugs and plant extracts remain unclear and should be further evaluated.

### INTRODUCTION

Cancer is the third leading cause of death worldwide,

preceded by cardiovascular and infectious diseases. Doxorubicin and cisplatin represent the current standard chemotherapeutic drugs for treatment of cancers. Although there are many therapeutic strategies including chemotherapy to treat cancer, high systemic toxicity and drug resistance limit the successful outcomes in most cases. Accordingly, several new strategies are being developed to control and treat cancer. One such approach could be a combination of an effective phytochemicals with chemotherapeutic agents, which when combined, would enhance efficacy while reducing toxicity to normal tissues.

The notion has evolved that natural products frequently exert a valuable role in broadening the scope of disease intervention strategies used by drug designers. Several herbs and plants with diversified pharmacological properties are known to be rich sources of chemical constituents that may have potential for the prevention and/or treatment of several human cancers<sup>[1-4]</sup>.

*P. emblica* L. (Euphorbiaceae) known as emblic myrobalan, a shrub or tree, is widely used in folk medicine in Southeast Asia. This plant exhibits a variety of pharmacological effects including anti-inflammatory, anti-pyretic, anti-oxidant, anti-carcinogenic, and anti-mutagenic effects<sup>[5-7]</sup>. The active principles or extracts of *P. emblica* have demonstrated anti-proliferative effects in several cancer cell lines both *in vitro* and *in vivo*<sup>[7,8]</sup>. The anti-tumor activity of *P. emblica* extract was attributed to its ability to interfere with cell cycle regulation *via* the inhibition of cdc 25 phosphatase and partial inhibition of cdc 2 kinase activity<sup>[8]</sup>.

*T. bellerica* (Combretaceae), known as belleric myrobalan, is a large deciduous tree, common to the plains and lower hills of Southeast Asia. This plant exhibits several pharmacological effects including anti-bacterial, anti-malarial, anti-fungal, anti-HIV, anti-oxidant, and anti-mutagenic effects<sup>[9-12]</sup>. *T. bellerica* extract exhibited anti-proliferative effects in several cancer cell lines including Shiongi 115, breast cancer MCF-7, prostate cancer PC-3 and DU-145 cells<sup>[13]</sup>. Phytochemical studies have shown that *T. bellerica* contains a variety of chemical components, including gallic acid<sup>[14,15]</sup>. Furthermore, recent studies have demonstrated the cytotoxic activity of gallic acid in human leukemia HK-63, HOS-1 cell, HSC-2, and HL-60 cell lines<sup>[16-19]</sup>. Gallic acid has also been shown to induce apoptotic cell death in HSC-2 and HL-60 cells<sup>[16,18]</sup>.

These findings prompted us to test the anti-proliferative activity of *P. emblica* and *T. bellerica* extracts on human lung carcinoma A549, and human hepatocellular carcinoma HepG2 cell lines, and to investigate whether it can synergize the inhibitory action of doxorubicin and cisplatin, the standard chemotherapeutic drugs.

## MATERIALS AND METHODS

### Plant extracts and chemotherapeutic drugs

The dried fruits of *T. bellerica* and *P. emblica* were collected from Sraokeaw and Nan Provinces in northeastern and northern Thailand, respectively. The voucher specimens were identified and kept by Associate Professor Dr. Noppamas Soonthornchareon, Department of Pharmacognosy, Faculty of Pharmacy, Mahidol University.

The dried fruits of medicinal plant were obtained and extracted with boiling water. Then, the aqueous solution was separated from the plant residues by filtration. After that, the aqueous solution was spray-dried. For testing, the extracts were dissolved in media and diluted to the desired concentrations.

Doxorubicin and Cisplatin (Platinol) were purchased from Ebewe (Austria) and Bristol-Myers Squibb (USA), respectively. The drugs were dissolved in water for injection at a concentration of 2 mg/mL. Both drugs were kept in aliquots at 4°C. Serial dilutions of these drugs were performed in culture media, immediately before each experiment, in order to obtain the required final concentrations.

### Cell culture

The human lung carcinoma (A549) cell was kindly provided by the Chulabhorn Research Institute. The human hepatocellular carcinoma (HepG2) cell (ATCC HB-8065) was obtained from the National Cancer Institute, Bangkok, Thailand. The HepG2, and A549 cells were cultured in RPMI 1640 medium (Hyclone, Logan, UT, USA). Both cell lines were supplemented with 10% heat inactivated fetal bovine serum (Hyclone), 100 U/mL penicillin and 100 µg/mL streptomycin (Gibco BRL, Grand Island, NY). All cell lines were maintained at 37°C in a 5% CO<sub>2</sub> incubator and the media were changed twice weekly.

### In vitro cytotoxicity assay

The sulforhodamine B (SRB) assay was performed to assess growth inhibition using a colorimetric assay, which estimates cell number indirectly by staining total cellular protein with the dye SRB<sup>[20]</sup>.

Briefly, 100 µL/well of cell suspensions (0.5-2.0 × 10<sup>5</sup> cells/mL) were seeded in 96-well microtiter plates and incubated at 37°C to allow for cell attachment. After 24 h, the cells were treated with the extract by adding 100 µL/well of each concentration in triplicate to obtain a final concentration of 0.8, 4, 12.5, 25, 50, 100, 200, 400, and 1000 µg/well for the extracts; 0.029, 0.058, 0.116, 0.174, and 0.348 µg/mL for the doxorubicin; and, 0.1, 0.2, 0.5, 1.0, 2.5, and 5.0 µg/mL for the cisplatin.

The plates were incubated for 1 h (d 0) and 72 h (d 3) at 37°C. At the end of each exposure time, the medium was removed. The cells were fixed with 20% (w/v) trichloroacetic acid (TCA, Fluka, Buchs, Switzerland) at 4°C for 1 h, stained for 30 min with 0.4% (w/v) SRB (Sigma, St. Louis, MO, USA) dissolved in 1% acetic acid (Sigma) for 30 min, and washed four times with 1% acetic acid. The protein-bound dye was solubilized with 10 mmol/L Tris base, pH 10 (Sigma).

The absorbance (OD) of each well was read on an ELISA plate reader (Amersham, Buckinghamshire, UK) at 492 nm. Percentage of cell survival was calculated using the formula: Percentage cell survival = [(OD test sample at d 3 - OD d 0)/(OD control at d 3 - OD d 0)] × 100.

Dose-response curves were plotted, and 50% growth inhibitory concentrations of extracts or drugs (IC<sub>50</sub>) were calculated through computation with the CalcuSyn software program (Biosoft, Cambridge, UK). By comparing the growth inhibitory effect with normal cells,

the selectivity of the extract was expressed as the extract shown to be toxic to specific types of cancer cell lines.

### Evaluation of drug interaction

Combination assays were performed using appropriate concentrations of *P. emblica* and *T. bellerica* extracts (4, 8, 16, 24, and 48  $\mu\text{g}/\text{mL}$  for A549 cells, and 25, 50, 75, 100, and 200  $\mu\text{g}/\text{mL}$  for HepG2 cells) with appropriate concentrations of doxorubicin (0.029, 0.058, 0.116, 0.174, and 0.348  $\mu\text{g}/\text{mL}$ ) or cisplatin (0.1, 0.2, 0.3, 0.4, and 0.8  $\mu\text{g}/\text{mL}$ ). Cells treated with the same final concentrations of the extracts or chemotherapeutic drugs alone were also examined. Cell growth inhibition was determined using the SRB assay, as previously described. In the assessment of synergism, the combination index (CI) method (i.e., additivity or antagonism) according to Chou and Talalay was used<sup>[21]</sup>.

The CIs were calculated by the Chou-Talalay equation<sup>[21]</sup>, which takes into account both the potency ( $D_m$  or  $IC_{50}$ ) and shape of the dose-effect curve. The general equation for the classic isobologram ( $CI = 1$ ) is given by:  $CI = (D_1)/(D_x)_1 + (D_2)/(D_x)_2$  (A) where  $(D_x)_1$  and  $(D_x)_2$  in the denominators are the doses (or concentrations) of  $D_1$  (drug #1, for example, the extract) and  $D_2$  (drug #2, for example, the doxorubicin) alone that gives  $x\%$  inhibition, whereas  $(D_1)$  and  $(D_2)$  in the numerators are the doses of  $D_1$  and  $D_2$  in combination that also inhibits  $x\%$  (i.e., isoeffective). The  $(D_x)_1$  and  $(D_x)_2$  can be readily calculated from the Median-effect equation of Chou *et al.*<sup>[22]</sup>:  $D_x = D_m [f_a/(1 - f_a)]^{1/m}$  (B) where  $D_x$  is the median-effect dose obtained from the anti-log of the X-intercept of the median-effect plot, X-log ( $D$ ) versus,  $Y = \log [f_a/(1 - f_a)]$ , or  $D_m = 10^{-(Y\text{-intercept})/m}$ ,  $f_a$  is the fraction affected by dose  $D$  (e.g., 0.5 if cell growth is inhibited by 50%) and  $m$  is the slope of the median-effect plot. From  $(D_m)_1$ , and  $(D_x)_2$  and  $D_1 + D_2$ , an isobologram can be constructed based on Eq. A: as  $CI < 1$  indicates synergism;  $CI = 1$  indicates an additive effect; and  $CI > 1$  indicates antagonism.

For conservative, mutually nonexclusive isobolograms of two agents, a third term,  $(D_1)(D_2)/(D_x)_1(D_x)_2$ , is added to Eq. A. For simplicity, the third term is usually omitted, and thus the mutually exclusive assumption or classic isobologram is indicated. In this study, the CI values obtained from classic (mutually exclusive) calculations are given.

The dose-reduction index (DRI) defines the extent (folds) of dose reduction possible in a combination, for a given degree of effect, compared with the dose of each drug alone:  $(DRI)_1 = (D_x)_1/(D_1)$  and  $(DRI)_2 = (D_x)_2/(D_2)$ . The relationship between DRI and CI is, therefore, expressed as:  $CI = (D_x)_1/(D_1) + (D_x)_2/(D_2) = 1/(DRI)_1 + 1/(DRI)_2$

### Statistical analysis

The data were analyzed using the SPSS software version 11.0. The  $IC_{50}$  of plants against cancer cells were compared with  $IC_{50}$  of normal cells and calculated by the Student's *t*-test. Differences were considered significant at  $P < 0.01$ .

## RESULTS

### Effect of herbal extracts on cell growth

The effects of *P. emblica* and *T. bellerica* extracts on the

Table 1  $IC_{50}$  values of individual herbal extracts in human cancer cells and normal cells

Extract	$IC_{50}$ value ( $\mu\text{g}/\text{mL}$ )		
	A549 <sup>b</sup>	HepG2 <sup>b</sup>	Vero (Normal)
<i>P. emblica</i>	12.18 $\pm$ 5.83	30.47 $\pm$ 6.67	157.86 $\pm$ 14.90
<i>T. bellerica</i>	27.07 $\pm$ 2.19	82.39 $\pm$ 27.09	238.70 $\pm$ 8.45

Data are shown as mean  $\pm$  SD from three separate experiments. <sup>b</sup> $P < 0.01$  represents the statistical significance between normal cell (Vero) and each cancer cell (A549 and HepG2).

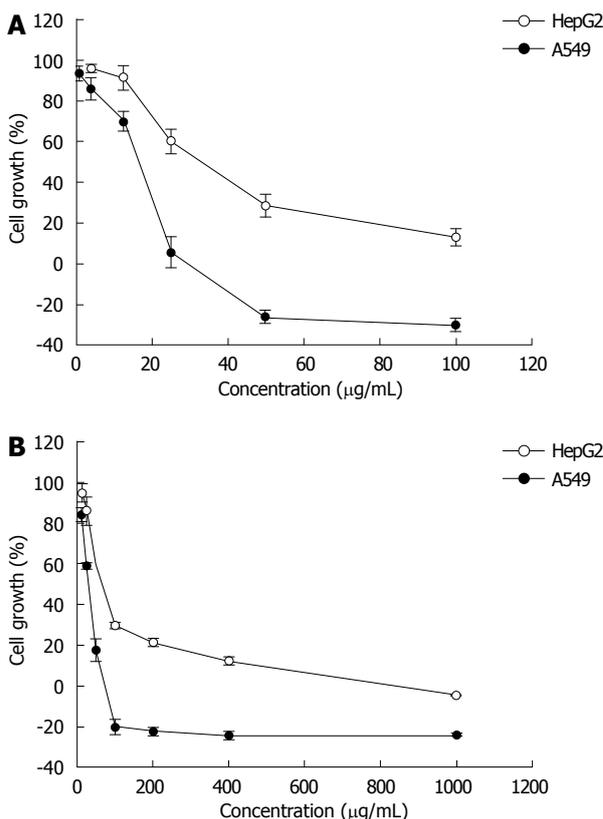

Figure 1 Cytotoxic effects of different concentrations of *P. emblica* (A) and *T. bellerica* (B) extracts on cancer cell lines. The percentage of cell growth was measured using the SRB staining assay. Each value represents the mean  $\pm$  SE of three independent experiments.

proliferation of two cancer cell lines and Vero cells were determined using the SRB assay. All cell lines were growth-inhibited in a dose-dependent manner after exposure to the plant extracts (Figure 1). The  $IC_{50}$  values for *P. emblica* extract ranged from 12.18  $\pm$  5.83 to 157.86  $\pm$  14.90  $\mu\text{g}/\text{mL}$  and for *T. bellerica* extract ranged from 27.07  $\pm$  2.19 to 238.70  $\pm$  8.45  $\mu\text{g}/\text{mL}$  (Table 1).

When the activities of *P. emblica* and *T. bellerica* extracts against the cancer cell lines were compared with that against Vero cells and expressed as the ratio of  $IC_{50}$  values, the *P. emblica* extract had significantly different ratios of 13.0 and 5.2 against the A549 and HepG2 cells ( $P < 0.01$ ), respectively. The *T. bellerica* extract also showed significantly different ratios of 8.8 and 2.9 against the A549 and HepG2 cells ( $P < 0.01$ ), respectively (Table 1). It appears these two plant extracts were selectively toxic against the two cancer cell lines tested, motivating further work to determine

the combination effect of these plant extracts with chemotherapeutic drugs.

**Effect of chemotherapeutic drugs on cell growth**

Using the SRB assay, the effects of doxorubicin and cisplatin on the proliferation of two cancer cell lines were determined. All cell lines were growth-inhibited in a dose-dependent manner (Figure 2). The IC<sub>50</sub> values for doxorubicin *vs* cisplatin ranged from 0.170 ± 0.006 to 0.511 ± 0.025 µg/mL *vs* 1.04 ± 0.21 to 1.05 ± 0.18 µg/mL, respectively (Table 2).

**Combination effects of herbal extracts with chemotherapeutic drugs on cell growth**

The combination effects of *P. emblica* and *T. bellerica* extracts with doxorubicin and cisplatin in the A549 and HepG2 cell lines, as represented by the DRI, the CI and the dose-effect levels of cell growth inhibition (IC<sub>50</sub>-IC<sub>90</sub>), are summarized in Table 3.

The data were also examined using median effect analysis to determine the type of interactions which occurred, i.e. antagonism (CI > 1), additivity (CI = 1) or synergism (CI < 1) (Figures 3 and 4). With A549 cells, the combinations were synergistic at medium and high dose levels (IC<sub>75</sub> and IC<sub>90</sub>) for the *P. emblica*/doxorubicin and *P. emblica*/cisplatin combinations (Table 3, Figures 3 and 4). By contrast, the synergistic and additive effects were recorded at low and medium dose levels (IC<sub>50</sub> and IC<sub>75</sub>) for the *T. bellerica*/cisplatin combination (Table 3, Figure 4). In HepG2 cells, combinations were synergistic at low and medium dose levels (IC<sub>50</sub> and IC<sub>75</sub>) for the *P. emblica*/doxorubicin combination or at a low level (IC<sub>50</sub>) for the *T. bellerica*/doxorubicin combination (Table 3, Figure 3). All other combinations had antagonistic effects.

The DRI showed a considerable dose reduction for herbal extracts and drugs used as a result of their synergism (Table 3). When using synergistic drug combinations at corresponding dose levels, the DRI indicated that the concentration of doxorubicin necessary to inhibit the growth of 50% of cancer cells (IC<sub>50</sub>) could be decreased 1.64-fold (A549, *P. emblica*/doxorubicin) to 4.69-fold (HepG2, *P. emblica*/doxorubicin), and the IC<sub>90</sub> could be reduced 2.59-fold (A549, *P. emblica*/cisplatin) to 2.60-fold (A549, *P. emblica*/doxorubicin; Table 3). The dose reduction level was different and specific to each combination and cell line.

**DISCUSSION**

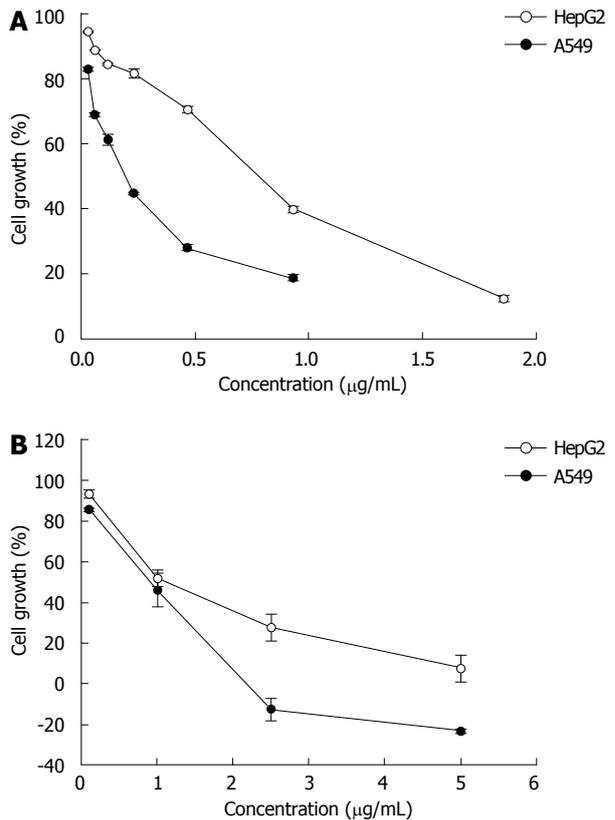

In this study, the growth inhibitory activity of the *P. emblica* and *T. bellerica* extracts and the chemotherapeutic drugs doxorubicin and cisplatin were investigated in A549, and HepG2 cells. Our results indicate that both plant extracts and chemotherapeutic drugs mediated significant growth inhibitory effects on both cell lines tested in a dose-dependent manner (Tables 1 and 2, Figure 1 and 2).

*P. emblica* extract combined with doxorubicin or cisplatin resulted in synergistically enhanced growth inhibitory activity at different dose levels in A549 and HepG2 cell lines. The synergistic effects were also demonstrated when *T. bellerica* extract was combined with doxorubicin or cisplatin in HepG2 and A549 cells. The significance of this

**Table 2** IC<sub>50</sub> values of chemotherapeutic drugs in human cancer cells

Drug	IC <sub>50</sub> value (µg/mL ± SD)	
	A549	HepG2
Doxorubicin	0.170 ± 0.006	0.511 ± 0.025
Cisplatin	1.04 ± 0.21	1.05 ± 0.18

Data are shown as mean ± SD from three separate experiments.

**Figure 2** Cytotoxic effects of different concentrations of doxorubicin (A) and cisplatin (B) on cancer cell lines. The percentage of cell growth was measured using SRB staining assay. Each value represents the mean ± SE of three independent experiments.

finding lies in the fact that doxorubicin and cisplatin are well-known cancer therapeutic agents, but cause high toxicity to normal tissues during cancer therapy<sup>[23,24]</sup>.

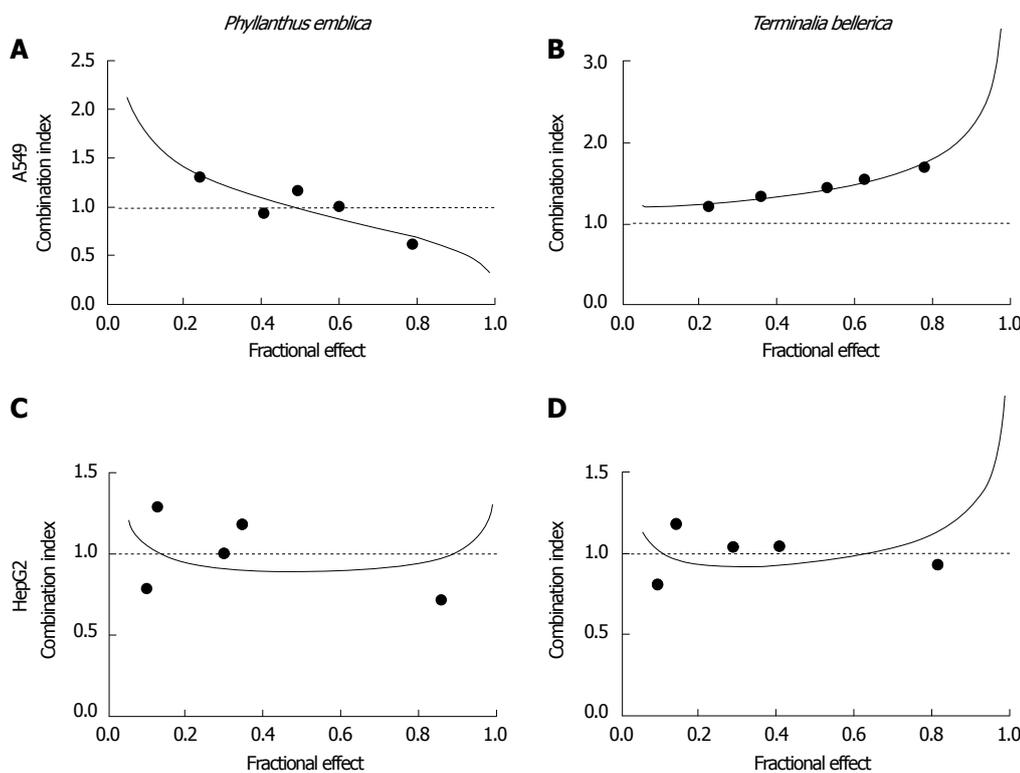

Several studies have shown that doxorubicin has harmful effects on health (i.e., immunosuppression and secondary cardiomyopathy) and can lead to the development of primary and secondary drug resistance in tumor cells thereby limiting the clinical success of cancer chemotherapy<sup>[25,26]</sup>. Recent reports show that combination (rather than single-agent) chemotherapy is a superior modality and that naturally occurring dietary supplements with known anti-cancer activity could be used in combination chemotherapy to reduce the systemic toxicity of chemotherapeutic agents<sup>[27,28]</sup>.

Our study provides corroborative evidence as it showed that *P. emblica* and *T. bellerica* extracts were selectively toxic against two cancer cell lines and that, in combination with doxorubicin and cisplatin, produced an increased growth inhibitory effect in both A549 and HepG2 cells. Calcula-

**Table 3** Dose-effect relationships of extracts and drug combinations in human cancer cell lines

Dose-effect relationships were calculated by the median-effect equation.  $D_m$  median-effect dose (concentration in  $\mu\text{g/mL}$  that inhibits cell growth by 50%),  $m$  shape of the dose-effect curve (where  $m = 1$ ,  $m > 1$ , and  $m < 1$  indicate hyperbolic, sigmoidal, and negative sigmoidal curves, respectively),  $r$  linear correlation coefficient of the median effect plot (indicates conformity of data). CI was calculated by Chou and Talalay's CI equation.  $CI < 1$ ,  $CI = 1$ , and  $CI > 1$  indicate synergism, additive effect, and antagonism, respectively.  $D_m$  and  $m$  values for single drugs, extracts and their combinations were used in the equations  $Dx = Dm [f_a / (1 - f_a)]^{1/m}$  and  $CI = (D)_1 / (Dx)_1 + (D)_2 / (Dx)_2$ .  $f_a$  fraction affected by D (e.g. 0.9 if cell growth is inhibited by 90%),  $(D)_1$  and  $(D)_2$  combined doses of extract 1 and drug 2 for  $x\%$  inhibition,  $(Dx)_1$  and  $(Dx)_2$  doses of the single extract 1 and drug 2 for  $x\%$  inhibition. DRI dose reduction index was measured by comparing the doses required to reach a given degree of inhibition when using the drug as a single agent and in combination.

**Figure 3** Combination index (CI) vs fraction affected ( $f_a$ ) plots obtained from the median-effect analysis program (CalcuSyn, Biosoft, Cambridge, UK). (A) and (B) A549; (C) and (D) HepG2. Curves with solid lines are computer simulated  $f_a$ -CI plots, based on the parameters ( $m$  and  $D_m$  values) for doxorubicin and herbal extract combinations. Circles are actual combination data points.  $CI < 1$ ,  $= 1$  and  $> 1$  indicates synergism, additive effect and antagonism, respectively.

tion of the DRI at the  $IC_{50}$  demonstrated possible reductions in doxorubicin concentrations for the drug combina-

tions ranging from 1.64-fold (*P. emblica* + doxorubicin in A549) to 4.69-fold (*P. emblica* + doxorubicin in HepG2).

**Figure 4** Combination index (CI) vs fraction affected ( $f_a$ ) plots obtained from the median-effect analysis program (CalcuSyn, Biosoft, Cambridge, UK). (A) and (B) A549; (C) and (D) HepG2. Curves with solid lines are computer simulated  $f_a$ -CI plots, based on parameters ( $m$  and  $D_m$  values) for cisplatin and herbal extract combinations. Circles are actual combination data points. CI < 1, = 1 and > 1 indicates synergism, additive effect and antagonism, respectively.

This finding supports our hypothesis that combinations of plant extracts and chemotherapeutic agents allow a reduction in the dosage of the latter (i.e., doxorubicin and cisplatin), yet retaining the benefits but minimizing the cytotoxic effects, thus enhancing therapeutic efficacy.

The mechanism of action is unclear and, possibly, multiple compounds in the herbal extracts are involved<sup>[29]</sup>. Plant derived polyphenols, including tannins and gallic acid, were reported to be the main constituents in *P. emblica* and *T. bellerica*<sup>[13,30]</sup>. Marienfeld *et al*<sup>[31]</sup> reported that tannic acid (TA) could inhibit the malignant cholangiocyte growth both *in vitro* and *in vivo* and also enhance sensitivity of Mz-ChA-1 cholangiocarcinoma cells to camptothecin cytotoxicity which might involve an effect on xenobiotic metabolism. In addition, TA also acts as an inhibitor of the glutathione conjugate export pump. As a result, the sensitivity of tumor cells to anticancer drugs was increased<sup>[32,33]</sup>. This study agreed with the study of Sandhya and Mishra<sup>[34]</sup> which showed the cytotoxic response of human breast cancer cell lines to Triphala, which contained *T. bellerica*, *P. emblica* and *T. chebulu* extracts. It might be possible that *T. bellerica* and *P. emblica* extracts could induce ROS in the induction of apoptosis. Apart from the effect of tannic acid, the cytotoxic effect and apoptosis induction of gallic acid in several cancer cell lines have been reported<sup>[13,34,35]</sup>. It was demonstrated that the effect of gallic acid on cancer cell line particularly lung cancer cells involved caspase activation and oxidative processes<sup>[35]</sup>. In addition, gallic acid, a major component of *T. bellerica*<sup>[14,15]</sup> has the capacity to induce apoptosis<sup>[35]</sup> and increase the efficacy of cisplatin in combined treatment of mice transplanted with LL-2 lung cancer cells<sup>[36]</sup>. These findings suggest that in the synergistic activity of *P. emblica* or *T. bellerica* extracts and doxorubicin it seem to be possible that the extracts could induce cytotoxic to tumor cells by a ROS mediated mechanism in cancer cells but less in normal cell<sup>[37]</sup> as well as inhibit glutathione conjugate export pump as a result, the extracts would increase the sensitivity of A549 and HepG2 cells to doxorubicin and cisplatin.

In summary, our results demonstrate that combinations of *P. emblica* or *T. bellerica* extracts with doxorubicin or cisplatin in A549 and HepG2 cell lines have a better effect than either agent alone. Further studies are needed to assess the underlying mechanism(s), signal transduction pathways, leading to growth inhibition induced by single agents and combinations both *in vitro* and *in vivo*. A positive outcome of such studies would be increased efficacy of existing chemotherapies with reduced toxicity to the normal tissues in treatment of human lung carcinoma and hepatocellular carcinoma.

## ACKNOWLEDGMENTS

We thank Dr. Noppamas Soonthornchareon, Department of Pharmacognosy, Faculty of Pharmacy, Mahidol University, for providing the herbal extracts, Dr. Chariya Hahnvajanawong guidance during the preparation of the manuscript, and Mr. Bryan Roderick Hamman for assistance with the English-language presentation.

## COMMENTS

### Background

Belleric myrobalan (*Terminalia bellerica*) and emblic myrobalan (*Phyllanthus emblica*), are constituents of herbal formulation (Triphala) and is widely used in folk medicine in Southeast Asia. Both extracts have been shown to inhibit cancer cell growth.

### Research frontiers

Currently, a variety of effective phytochemicals have been tested in cancer treatment, which are used alone, or in combination with chemotherapeutic agents of treatment. The combinations of *P. emblica* or *T. bellerica* extracts with doxorubicin or cisplatin have a synergistic growth effect against some cancer cell lines. Depending on the combination ratio, the doses for each drug for a given degree of effect in the combination may be reduced. The mechanism of this synergistic effect is unclear and, possibly, multiple compounds in the herbal extracts are involved.

### Innovations and breakthroughs

In this report, we demonstrate that combinations of *P. emblica* or *T. bellerica*

extracts with doxorubicin or cisplatin in A549 and HepG2 cell lines have a better effect than either agent alone.

### Applications

*P. emblica* and *T. bellerica* extracts appear to be an effective against hepatocellular carcinoma and lung cancer cells and less toxic against normal cells. A combination of an effective *P. emblica* and *T. bellerica* extracts with chemotherapeutic agents which combined may be enhancing efficacy while reducing toxicity to normal tissues.

### Peer review

This is a very nice experimental study about the interaction between drugs and plant extracts performed *in vitro*. In this study, the authors investigated the combination effects of *P. emblica* and *T. bellerica* extracts with conventional cytotoxic agents against human cancer cells. The paper shown a synergistic effect of *P. emblica* and *T. bellerica* extracts with doxorubicin and cisplatin against human hepatocellular carcinoma and lung cancer cells.

### Abstract

**AIM:** To investigate -765G > C *COX-2* polymorphism and *H pylori* infection in patients with gastric adenocarcinoma, peptic ulcer disease (PUD) and non-ulcer dyspepsia (NUD).

**METHODS:** We enrolled 348 adult patients (62 gastric adenocarcinoma, 45 PUD and 241 NUD) undergoing upper gastrointestinal endoscopy at two referral centers between September, 2002 and May, 2007. *H pylori* infection was diagnosed when any of the four tests (RUT, culture, histopathology and PCR) were positive. Genotyping for -765G > C polymorphism of *COX-2* was performed by PCR-RFLP analysis.

**RESULTS:** Frequency of C carrier had significant

association with gastric adenocarcinoma as compared to NUD [77.4% vs 29%,  $P < 0.001$ , odds ratio (OR) 8.20; 95% confidence interval (95% CI), 4.08-16.47] and PUD (77.4% vs 31.1%,  $P < 0.001$ ; OR 8.04; 95% CI, 3.25-19.90). Risk of gastric adenocarcinoma was significantly higher in patients having C carrier with (OR 7.83; 95% CI 3.09-19.85) and without *H pylori* infection (OR 7.06; 95% CI, 2.61-19.09). Patients with C carrier and *H pylori* infection had significant risk for the development of PUD ( $P < 0.001$ ; OR 5.65; 95% CI, 2.07-15.34).

**CONCLUSION:** -765G > C *COX-2* polymorphism with or without *H pylori* could be a marker for genetic susceptibility to gastric adenocarcinoma. *COX-2* polymorphism in presence of *H pylori* infection might be useful in predicting the risk of PUD.

### INTRODUCTION

*H pylori* has been classified as a major cause of chronic gastritis and peptic ulcer disease (PUD), as well as a risk factor for gastric adenocarcinoma and mucosa-associated lymphoid tissue (MALT) lymphoma<sup>[1-3]</sup>. Although there is a considerable high rate of *H pylori* infection in Asian countries such as Japan, China, Thailand, Indonesia and India, there is a remarkable difference in incidence of gastric cancer within these countries (Asian enigma)<sup>[4,5]</sup>. The annual incidence of gastric cancer is disproportionately high in Japan and China in spite of a lower *H pylori* seropositivity<sup>[5]</sup>. In contrast, in India

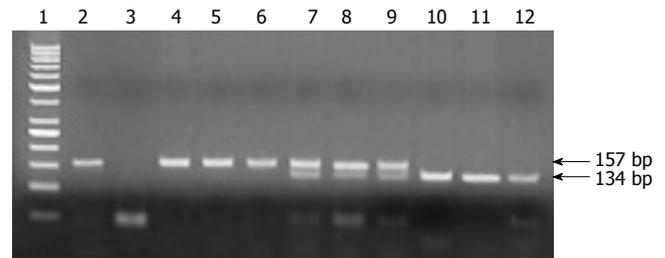

seropositivity of *H pylori* is very high, but the annual incidence of gastric cancer is low (Indian enigma)<sup>[5]</sup>. Even studies based on differences in *H pylori* virulence factors couldn't explain such contradictory findings<sup>[6]</sup>. This shows that *H pylori* may not be the sole factor, but may play a synergistic role with factors like diet and host genetic make up in gastric carcinogenesis<sup>[5]</sup>.

The role of host-related factors in the pathogenesis of diseases caused by *H pylori* infection has largely been ignored<sup>[7,8]</sup>. Overexpression of cyclooxygenase-2 (*COX-2*) has been observed in several forms of cancer<sup>[9-16]</sup>, including gastric cancer and precancerous lesions<sup>[17-19]</sup>. *COX*, (also known as prostaglandin endoperoxide synthase) is a rate-limiting enzyme for the synthesis of prostaglandins (PGs) from free arachidonic acid. Two isoforms of *COX* have been identified; *COX-1* is constitutively expressed in most normal tissues and considered to be a housekeeping enzyme responsible for the maintenance of vascular homeostasis and gastroprotection. In contrast, *COX-2* is the inducible isoform of the enzyme and is rarely expressed in normal tissues, but it is rapidly induced by bacterial lipopolysaccharide (LPS), cytokines, growth factors, mitogens and tumor promoters<sup>[9,10]</sup>. Up-regulation of *COX-2* plays an important role in the inhibition of apoptosis, tumor growth, angiogenesis, invasion and metastasis, which are considered to be important steps in cancer development<sup>[9,17,20,21]</sup>. Several polymorphisms in *COX-2* have been identified so far. However, only a few seemed to have a functional effect on the transcription. Recently, Papafili *et al*<sup>[22]</sup> described a new polymorphism in the promoter region of *COX-2*, characterized by a guanine (G) to cytosine (C) transition at position -765 (-765G > C). This polymorphism appears to disrupt a stimulatory protein 1 (Sp1) binding site, which is considered to be a positive activator of transcription and leads to a 30% reduction of the *COX-2* promoter activity *in vitro*<sup>[22]</sup>. Only a few studies have been published on *COX-2* polymorphisms either in cancer or related diseases<sup>[23-29]</sup> or non-malignant diseases<sup>[30-32]</sup>. The aim of the present study was to evaluate the role of -765G > C *COX-2* polymorphism and *H pylori* infection in patients with gastric adenocarcinoma and PUD.

## MATERIALS AND METHODS

### Patients

We studied 348 adult patients, including 62 with gastric adenocarcinoma, 45 PUD and 241 non ulcer dyspepsia (NUD), undergoing upper gastrointestinal endoscopy at two referral centers in northern India between September, 2002 and May, 2007. The diagnosis of gastroduodenal diseases was based on clinical, endoscopic and histopathological parameters. Patients with NUD were considered as disease control in our study. The Ethics Committee of the institute granted approval for the study and consents were obtained from all the patients. Subjects who had received anti-microbial therapy, H<sub>2</sub> receptor blockers, proton pump inhibitors and non-steroidal anti-inflammatory drugs in the last 4 weeks before endoscopy or anti-*H pylori* treatment in the past were excluded from the study.

**Figure 1** PCR-RFLP analysis of -765 G > C *COX-2* polymorphism. Lane 1: 50 bp DNA ladder; lane 2: PCR product (undigested); lane 3: Negative control; lanes 4 to 6: Homozygous -765 CC genotype; lanes 7 to 9: Heterozygous-765 GC genotype; lanes 10 to 12: Homozygous -765 GG genotype.

### DNA extraction

Genomic DNA was isolated from gastric tissues using the QIAamp DNA mini kit (QIAGEN, Hilden, Germany) as per the manufacturer's instruction.

### Diagnosis of *H pylori* infection

During each endoscopy, antral biopsies were obtained and subjected to the following tests: rapid urease test (RUT), culture, histopathology and *H pylori* specific *ureA* PCR following the standard protocol as described earlier<sup>[33]</sup>. *H pylori* infection was diagnosed if any of the above tests was positive.

### -765G > C *COX-2* polymorphism

Analysis of -765G > C *COX-2* polymorphism was performed by PCR-based restriction fragment length polymorphism (PCR-RFLP) as previously described<sup>[30]</sup>. The sequences of PCR primers were: forward 5'-ATTCTGGCCATCGCCGCTTC-3' and reverse 5'-CTCCTTGTTTCTTGAAAGAGACG-3' (Metabion, Martinsried, Deutschland). PCR conditions were as follows: an initial denaturation at 94°C for 10 min, followed by 35 cycles of denaturing at 94°C for 1 min, annealing at 59°C for 1 min, and extension at 72°C for 1 min. The final extension was continued at 72°C for 10 min and cooling to 4°C. Template free water was used as negative control. After PCR amplification, PCR products were subjected to restriction digestion by *Bsh* 1236I restriction endonuclease (Fermentas, Vilnius, Lithuania) for 8 h at 37°C. The DNA fragments were then separated on 3% agarose gel electrophoresis. Fragments size of 134 and 23 bp indicated the presence of a wild type homozygous -765GG genotype, a single 157 bp fragment indicated the presence of homozygous -765CC genotype and three fragments of 157, 134 and 23 bp indicated the presence of heterozygous -765GC genotype (Figure 1). The 23 bp fragment cannot be distinguished from the primer-dimer band in the agarose gel. All the experiments were repeated twice for the confirmation of RFLP results.

### Statistical analysis

The data analysis was performed by SPSS software (Version 12.0, SPSS, Chicago, IL, USA). *H pylori* status in relation to gastroduodenal diseases was analyzed using Chi-square test. Multivariate logistic regression analyses were

**Table 1** Demography of the study populations and *H pylori* infection

Parameter	Gastric adenocarcinoma (n = 62)	Peptic ulcer disease (n = 45)	Non-ulcer dyspepsia (n = 241)	Overall (348)
Age (yr)	56.60 ± 15.42	49.47 ± 17.22	43.75 ± 14.76	46.78 ± 15.96

<i>H pylori</i> infection <sup>1</sup> (%)	35 (56.5)	36 (80)	133 (55.2)	204 (58.6)

<sup>1</sup>Peptic ulcer disease vs non-ulcer dyspepsia: 80% vs 55.2%,  $P = 0.002$ ; Gastric adenocarcinoma vs non-ulcer dyspepsia: 56.5% vs 55.2%,  $P = 0.858$ ; Peptic ulcer disease vs gastric adenocarcinoma: 80% vs 56.5%,  $P = 0.01$ .

**Table 2** Allelic distribution of *COX-2* polymorphism in gastric adenocarcinoma, peptic ulcer disease and non-ulcer dyspepsia

<i>COX-2</i> genotype	Gastric adenocarcinoma (n = 62)	Peptic ulcer disease (n = 45)	Non-ulcer dyspepsia (n = 241)
GG (%)	14 (22.6)	31 (68.9)	171 (71)
GC (%)	29 (46.8)	12 (26.7)	62 (25.7)
CC (%)	19 (30.6)	2 (4.4)	8 (3.3)
C carrier (%) <sup>1</sup>	48 (77.4)	14 (31.1)	70 (29)

<sup>1</sup>Gastric adenocarcinoma vs non-ulcer dyspepsia:  $P < 0.001$ ; Gastric adenocarcinoma vs peptic ulcer disease:  $P < 0.001$ ; Peptic ulcer disease vs non-ulcer dyspepsia:  $P = 0.74$ .

used to identify the independent risk factors for gastric adenocarcinoma and PUD. Gender and age were included in regression analysis, and assessment for interaction was considered in the model. A two-sided  $P$  value of less than 0.05 was considered significant.

## RESULTS

### Patient characteristics

A total of 348 patients (mean age: 46.78 ± 15.96; 216 male) were enrolled in the study and their distributions were gastric adenocarcinoma 62 (mean age: 56.60 ± 15.42; 47 male), PUD 45 (mean age: 49.47 ± 17.22; 31 male) and NUD 241 (mean age: 43.75 ± 14.76; 138 male, Table 1).

### Diagnosis of *H pylori* infection

Prevalence of *H pylori* infection in our study population was 58.6%. *H pylori* infection was significantly higher in patients with PUD than with gastric adenocarcinoma (80% vs 56.5%,  $P = 0.01$ ) and NUD (80% vs 55.2%,  $P = 0.002$ , Table 1).

### -765G > C *COX-2* polymorphism

All genotypic distributions were in Hardy-Weinberg equilibrium. The potential association of -765G > C *COX-2* polymorphism in patients with gastroduodenal diseases is shown in Table 2. The frequency of the -765 GG, GC and CC genotypes were 71%, 25.7% and 3.3%, in patients with NUD, 68.9%, 26.7% and 4.4% in patients with PUD and 22.6%, 46.8% and 30.6% in patients with gastric adenocarcinoma, respectively. The frequency

**Table 3** *H pylori* infection and *COX-2* polymorphism as risk for gastric adenocarcinoma

<i>H pylori</i> status	<i>COX-2</i> genotype	Gastric adenocarcinoma (n = 62)	Non-ulcer dyspepsia (Controls, n = 241)	OR (95% CI)	$P$ -value
HP-	GG	8	79	Referent	
HP-	C carriers	19	29	7.06 (2.61-19.09)	< 0.001
HP+	GG	6	92	0.83 (0.26-2.59)	0.747
HP+	C carriers	29	41	7.83 (3.09-19.85)	< 0.001

HP-: *H pylori* negative; HP+: *H pylori* positive.

**Table 4** *H pylori* infection and *COX-2* polymorphism as risk for peptic ulcer disease

<i>H pylori</i> status	<i>COX-2</i> genotype	Peptic ulcer disease (n = 45)	Non-ulcer dyspepsia (Controls, n = 241)	OR (95% CI)	$P$ -value
HP-	GG	8	79	Referent	
HP-	C carriers	1	29	0.86 (0.09-7.48)	0.89
HP+	GG	23	92	2.83 (1.18-6.73)	0.019
HP+	C carriers	13	41	5.65 (2.07-15.34)	< 0.001

HP-: *H pylori* negative; HP+: *H pylori* positive.

of C carrier was more common in patients with gastric adenocarcinoma as compared with NUD [77.4% vs 29%,  $P < 0.001$ , odds ratio (OR) 8.20; 95% confidence interval (95% CI), 4.08-16.47] and PUD (77.4% vs 31.1%,  $P < 0.001$ , OR 8.04; 95% CI, 3.25-19.90). However, the frequency of C carrier in patients with PUD and NUD was similar (PUD vs NUD 31.1% vs 29%,  $P = 0.74$ ; OR 1.13; 95% CI, 0.56-2.27).

### Interaction between *H pylori* infection and -765G > C *COX-2* polymorphism

We also examined the potential interaction between *H pylori* infection and -765G > C *COX-2* polymorphism in the development of gastric adenocarcinoma and PUD in our population. Presence of C carrier with ( $P < 0.001$ , OR 7.83, 95% CI, 3.09-19.85) and without *H pylori* infection ( $P < 0.001$ , OR 7.06, 95% CI, 2.61-19.09) was significantly associated with gastric adenocarcinoma (Table 3). We also found that patients with C carrier and *H pylori* infection had significant risk for the development of PUD ( $P < 0.001$ , OR 5.65, 95% CI, 2.07-15.34; Table 4).

## DISCUSSION

We investigated the potential association of -765G > C *COX-2* polymorphism and *H pylori* infection with gastric adenocarcinoma and PUD. We report for the first time that -765G > C *COX-2* polymorphism with or without *H pylori* infection could be a marker for genetic susceptibility to gastric adenocarcinoma. To the best of our knowledge, this is the first study to show that patients with C carriers of *COX-2* gene are susceptible to develop PUD in the presence of *H pylori* infection.

China	1270	2	4	19

Genetic polymorphism is considered an important determinant for the development of cancer. An association between increased COX-2 gene expression and cancer including gastric adenocarcinoma has been reported<sup>[17-19]</sup>. A new polymorphism in the promoter region of COX-2, characterized by a guanine (G) to cytosine (C) transition at position -765 (-765G > C) appears to disrupt Sp1 binding site, which reduces the COX-2 promoter activity to the extent of 30% *in vitro*<sup>[22]</sup>. An altered susceptibility to develop cancer due to the disruption in Sp1 binding site is attributed to this polymorphism (-765G > C) of COX-2 gene<sup>[22,23]</sup>. The frequency of this polymorphism seems to vary, especially among different ethnic populations (Table 5). C allele and C carriers have been frequently reported in the western populations than the Asians. Both C allele (16.2%) and C carriers (29%) in our control populations are more close to the West, but much higher than the other Asian countries<sup>[19,22-24,27,30-32]</sup>.

In our study, -765 C carriers were frequently present in gastric adenocarcinoma as compared to disease controls (Table 3). Patients with C carriers had 8.2-fold increased risk of progression to gastric adenocarcinoma. Pereira *et al* reported nearly 3-fold increased risk of progression to gastric adenocarcinoma in patients with atrophy or intestinal metaplasia carrying C allele<sup>[34]</sup>. Zhang *et al* also reported that patients with C carriers had 2.66-fold increased risk of gastric adenocarcinoma<sup>[35]</sup>. Recently, Guo *et al* described a 2-fold increased risk of esophageal squamous cell carcinoma due to the polymorphism in COX-2 gene<sup>[36]</sup>. It appears that the risk for the development of gastric adenocarcinoma related to COX-2 polymorphism in our population is much higher than other published studies. Although the exact molecular mechanism by which COX-2 polymorphism may increase the risk of gastric adenocarcinoma development is still unclear, studies in the COX-2 promoter revealed that COX-2 transcription is activated by E2 promoter binding factor 1 (E2F1)<sup>[37,38]</sup>. Hence, the ability of this polymorphism to create an E2F binding site, essential for the expression of several genes may be the reason for the increased risk<sup>[30]</sup>. The

contribution of genetic polymorphism to the risk of gastric adenocarcinoma may depend on the study population as well as on several environmental and dietary factors. Therefore, each population has to be evaluated for its own genetic profile for cancer risk that may help to understand the geographic and racial differences for development of gastric adenocarcinoma<sup>[39]</sup>. When we analyzed the combination of C carrier and *H pylori* infection, the risk was nearly 8-fold (OR 7.83; 95% CI, 3.09-19.85) in *H pylori* positive individuals and 7-fold (OR 7.06, 95% CI, 2.61-19.09) in *H pylori* negative individuals. So far, association between *H pylori* infection and COX-2 gene polymorphism in the development of gastric adenocarcinoma has not been studied. The present study clearly shows that C carriers either in presence or absence of *H pylori* infection are susceptible to develop gastric adenocarcinoma. The frequency of C carriers was almost equal in our patients with PUD (31.1%) and disease controls (29%). But the combination of C carrier and *H pylori* infection had nearly 6-fold increased risk to develop PUD (OR 5.65, 95% CI 2.07-15.34). Interestingly, the risk was not increased in *H pylori* negative individuals, implicating a potential interplay between *H pylori* infection and COX-2 polymorphism in the development of PUD (Table 4). There are no data available in literature to compare our observations.

In conclusion, this study suggests that -765G > C COX-2 polymorphism could be a marker for genetic susceptibility to gastric adenocarcinoma. This polymorphism in gastric adenocarcinoma was independent to *H pylori* infection. However, patients with *H pylori* infection and COX-2 polymorphism had higher risk to develop PUD. Thus, COX-2 polymorphism might be useful in predicting the risk of PUD in presence of *H pylori* infection. Further studies on different ethnic groups are warranted to confirm the association of this polymorphism with the risk of gastric adenocarcinoma and PUD.

## COMMENTS

### Background

It remains unclear why only a subpopulation of *H pylori* infected individuals develop peptic ulcer disease (PUD) and gastric adenocarcinoma. This raises the possibility that host genetic factors play an important role in the pathogenesis of *H pylori* infection. Differential expression of COX-2 enzyme might confer inter-individual susceptibility to gastric cancer and PUD. Hence we investigated -765G > C COX-2 polymorphism and *H pylori* infection in patients with gastric adenocarcinoma, PUD and non ulcer dyspepsia (NUD).

### Research frontiers

The role of host-related factors in the pathogenesis of diseases caused by *H pylori* infection has largely been ignored. Role of COX-2 polymorphism in patients with gastric adenocarcinoma and PUD in presence or absence of *H pylori* infection has not been studied. The study showed that COX-2 polymorphism was associated with gastric adenocarcinoma independent of *H pylori* infection. However, patients with combined *H pylori* infection and COX-2 polymorphism had higher risk to develop PUD. Further studies on different ethnic groups are warranted to confirm the association of this polymorphism with the risk of gastric adenocarcinoma and PUD.

### Innovations and breakthroughs

We report for the first time that -765G > C COX-2 polymorphism with or without *H pylori* infection could be a potential marker for genetic susceptibility to gastric adenocarcinoma. To the best of our knowledge, this is the first study to show that patients with C carriers of COX-2 gene are susceptible to develop PUD in the presence of *H pylori* infection.

## Applications

Detection of COX-2 polymorphism might help to identify the subgroup of patients having greater susceptibility to develop gastric adenocarcinoma, and peptic ulcer disease in presence of *H pylori* infection.

## Peer review

COX-2 polymorphism and its role in carcinogenesis is an extremely exciting field. Most of the work in this area has been done in the investigation of colorectal cancer, more because of the relatively higher incidence of colorectal cancer and its ease of detection. This is probably the first study to document the role of COX-2 polymorphism in gastric cancer and PUD in addition to *H pylori* infection.

## Abstract

**AIM:** To investigate apoptosis in human pancreatic cancer cells induced by Triptolide (TL), and the relationship between this apoptosis and expression of caspase-3, bcl-2 and bax.

**METHODS:** Human pancreatic cancer cell line SW1990 was cultured in DMEM media for this study. MTT assay was used to determine the cell growth inhibitory rate *in vitro*. Flow cytometry and TUNEL assay were used to detect the apoptosis of human pancreatic cancer cells before and after TL treatment. RT-PCR was used to detect the expression of apoptosis-associated gene caspase-3, bcl-2 and bax.

**RESULTS:** TL inhibited the growth of human pancreatic cancer cells in a dose- and time-dependent manner. TL induced human pancreatic cancer cells to undergo apoptosis with typically apoptotic characteristics. TUNEL assay showed that after the treatment of human pancreatic cancer cells with 40 ng/mL TL for 12 h and 24 h, the apoptotic rates of human pancreatic cancer cells increased significantly. RT-PCR demonstrated that caspase-3 and bax were significantly up-regulated in SW1990 cells treated with TL while bcl-2 mRNA was not.

**CONCLUSION:** TL is able to induce the apoptosis in human pancreatic cancer cells. This apoptosis may be mediated by up-regulating the expression of apoptosis-associated caspase-3 and bax gene.

## INTRODUCTION

Pancreatic adenocarcinoma is characterized by a poor prognosis and lack of response to conventional therapy. The incidence has shown that no significant sign of decline throughout the past 20 years and almost equals its mortality<sup>[1-3]</sup>. The 5-year survival rate for this disease is less than 4% and the median survival time after diagnosis is less than 6 mo<sup>[2,3]</sup>. Surgical resection of the tumor is still the only effective treatment option, although only 20% of carcinomas of the head of the pancreas are resectable<sup>[4]</sup>. Furthermore, the median survival even after apparent curative resection is only 20 mo, because of early tumor recurrence or rapid metastatic spread<sup>[2,4]</sup>. Other treatment options, such as chemotherapy or radiation therapy, provide limited palliation without significant improvement of survival in patients with unresectable pancreatic cancer<sup>[2]</sup>. Therefore, new targets for chemo-preventive and therapeutic agents need to be identified.

Triptolide (TL), extracts of the Chinese herb *Tripterygium Wilfordii* hook have potent anti-inflammatory and immunosuppressive properties and have been used successfully in traditional Chinese medicine for the treatment of rheumatoid arthritis and lupus erythematosus<sup>[5,6]</sup>. It has been recently reported that TL possesses anti-tumor and proapoptotic activities in many different tumor cell lines, including breast, prostate, lung, and leukemia cells lines<sup>[7-13]</sup>. TL was also shown to

sensitize cells to death induced by a variety of agents, such as Apo2/Trail, TNF- $\alpha$ , and different chemotherapeutic agents<sup>[14-16]</sup>. In this study, we provide evidence that TL potently inhibits human pancreatic cancer cell lines growth *in vitro*, suggesting that TL could be used to prevent or treat pancreatic cancer in the future. Considerable studies indicated that TL functioned through a p53-dependent or independent way<sup>[11,14,17,18]</sup>. Recently, Bing *et al* suggested that TL induced caspase-dependent cell death via the mitochondrial pathway in leukemia cells<sup>[19]</sup>. However, the cellular and molecular mechanisms underlying TL-induced apoptosis in tumor cells are not fully understood.

The purpose of this study is to investigate the inhibitory effects of TL on apoptosis and angiogenesis of pancreatic cancer *in vitro* and further to explore whether TL exerts clinical therapeutic value for patients with pancreatic cancer.

## MATERIALS AND METHODS

### Cell culture

The human pancreatic cancer cell line SW1990 was obtained from Professor Wang Xing Peng, Shanghai JiaoTong University (Shanghai, China). SW1990 was cultured in DMEM media. Media was supplemented with 10% FBS and cells grown as monolayers in a humidified atmosphere at 37°C. Crystalline TL (PG490, purity 99%) was obtained from the Institute of Dermatology, Chinese Academy of Medical Sciences (Nanjing, PR China), and prepared as previously described<sup>[18]</sup>.

### MTT assay

Cells were inoculated onto 96-well plates at the density of  $4 \times 10^3$  cells/well for 24 h, then treated with various concentrations of TL (100  $\mu$ L/well), and incubated for 6, 12, 24 and 48 h, respectively. Then, 5 g/L MTT solution (20  $\mu$ L/well) was added to each well, and cells were incubated for an additional 4 h at 37°C. The supernatant was aspirated, and 100  $\mu$ L of DMSO was added to the wells to dissolve any precipitate present. The suspension was placed on micro-vibrator for 5 min and the absorbance (A) was then measured at 570 nm by an enzyme immunoassay instrument. Cell inhibitory ratio was calculated by the following formula: Inhibitory ratio (%) =  $(1 - A_{570} \text{ of treated group}) / (A_{570} \text{ of control group}) \times 100\%$ . IC<sub>50</sub> was calculated by SAS statistical software.

### Flow cytometry

An early indicator of apoptosis is the rapid translocation and accumulation of the membrane phospholipid phosphatidylserine from the cytoplasmic interface to the extracellular surface. This loss of membrane asymmetry can be detected using the binding properties of Annexin V. To detect apoptosis, Annexin V binding assay was used. After treatment TL 40 ng/mL for 24 h, cells were collected. Cell suspension was added with 10  $\mu$ L of fluorescein-conjugated Annexin V (10  $\mu$ g/mL) and 10  $\mu$ L of PI reagent (50  $\mu$ g/mL) and detected by flow cytometry.

### TUNEL assay

Cells were seeded and set up in chamber slides (Becton Dickinson, Franklin Lakes, NJ), then analyzed for in site apoptosis using the terminal deoxynucleotidyl transferase (TdT)-mediated d-UTP nick end labeling (TUNEL) method. The DNA fragments in apoptotic cells were labeled at free 3'-OH DNA ends and DNA strand breaks. Incorporated fluorescein was detected by anti-fluorescein antibody conjugated with alkaline phosphatase. After substrate reaction stained cells were analyzed with light microscopy.

### Real-time PCR

The human pancreatic cancer cells were treated in the presence or absence of 40 ng/mL, 80 ng/mL, 160 ng/mL TL for 48 h and total RNA was extracted with TRIzol reagent (Invitrogen Life Technologies). Real-time quantitative PCR was performed by using a cyclor (Rocha) and SYBR Green Dye. The primer sequences for genes bcl-2: sense 5'-TCCATGTCTTTGGACAACCA-3', antisense 5'-CTCCACCAGTGTTCATCT-3'; bax: sense 5'-TCCATGTCTTTGGACAACCA-3', antisense 5'-CTCCACCAGTGTTCATCT-3'; caspase-3: sense 5'-AACTGGACTGTGGCATTG-3', antisense 5'-ACCAGGTGCTGTGGAGTA-3';  $\beta$ -actin: sense 5'-AAGTACTCCGTGTGGATCGG-3', antisense 5'-ATGCATTCACCTCCCCTGTG-3'. The experimental procedure was carried out according to the QIAGEN one step RT-PCR Kit. The reaction parameters of bcl-2, bax and caspase-3 were as follows: 94°C 5 min, 94°C 40 s, 56°C 55 s, 72°C 1 min for 36 cycles, 72°C extension 7 min; 94°C 5 min, 94°C 40 s, 58°C 55 s, 72°C 1 min for 36 cycles, 72°C extension 7 min; 94°C 5 min, 94°C 40 s, 50°C 55 s, 72°C 1 min for 36 cycles, 72°C extension 7 min. Ten  $\mu$ L PCR product was placed onto 1.5% agarose gel and observed by EB staining using Gel-Pro analyzer.

### Statistical analyses

All data were expressed as mean  $\pm$  SD. Intergroup comparisons were made using one-way analysis of variance (ANOVA). A *P* value less than 0.05 was considered statistically significant.

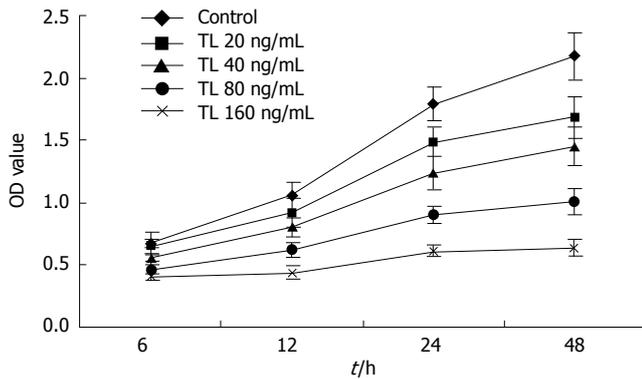

## RESULTS

### Effect of TL on the proliferation of SW1990 cells

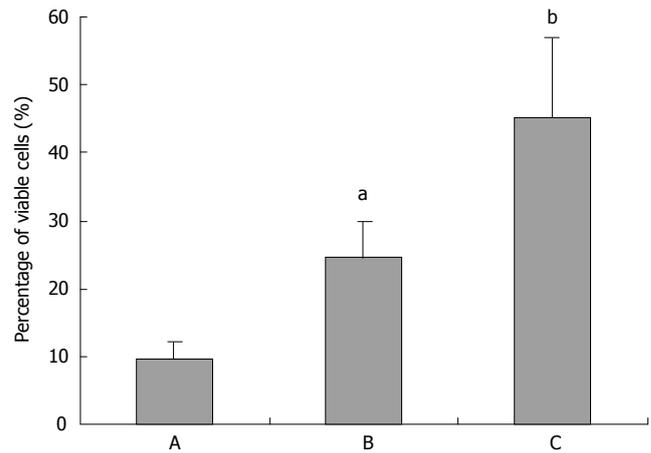

The human pancreatic cancer cells were exposed to increasing concentrations (20 ng/mL to 160 ng/mL) of TL for 6 h to 48 h, respectively. The human pancreatic cancer cells showed death in a dose- and time-dependent manner. The data are summarized in Figure 1.

### TL induced apoptosis in SW1990 cells

Although previous studies reported that TL treatment showed anti-proliferation and induction of apoptosis in some cancer cells, there is heretofore no data on the usage of TL in pancreatic cancer. In the present study, we tested the effects of TL on the viability of the human pancreatic cancer cell line SW1990. Our results showed that treatment with TL resulted in a dose-dependent decrease in viable

**Figure 1** The effect of TL on the growth of SW1990 cells. SW1990 cells were treated with various concentrations of TL for 6 h, 12 h, 24 h or 48 h and viability was determined by MTT assay.

**Figure 2** Triptolide induces significant cell death in pancreatic cancer cell line SW1990. A: TL 0 ng/mL; B: TL 40 ng/mL; C: TL 160 ng/mL. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.001$ .

cells in SW1990 cells (Figure 2). After treatment with 160 ng/mL TL for 24 h, the percentage of dead cells was 45.1% in TL cells, while that was only 9.6% in the control group.

We examined whether the reduced cell viability by TL in pancreatic cancer cell lines was due to induction of apoptosis, because SW1990 cell line seemed to be more sensitive to TL treatment, we chose that cell line and analyzed apoptosis using Annexin V/propidium iodine staining. FCS analysis revealed typical apoptotic phenotype in cells treated with 40 ng/mL TL for 24 h (Figure 3), in contrast, control cells without TL treatment displayed a small quantity of apoptosis. Moreover, we performed TUNEL assay and demonstrated that 40 ng/mL TL treatment could significantly induce apoptosis (Figure 4). These data provided first evidence that TL can be used to inhibit human pancreatic cell line growth *in vitro* and its effect is associated with induction apoptosis.

### Regulation of caspase-3, bax and bcl-2 mRNA expression by TL

After exposure to 40 ng/mL, 80 ng/mL, 160 ng/mL TL for 48 h, caspase-3 and bax mRNA expression were up-regulated remarkably in TL-treated cells. In contrast, the expression of bcl-2 mRNA was not affected by TL (Figure 5).

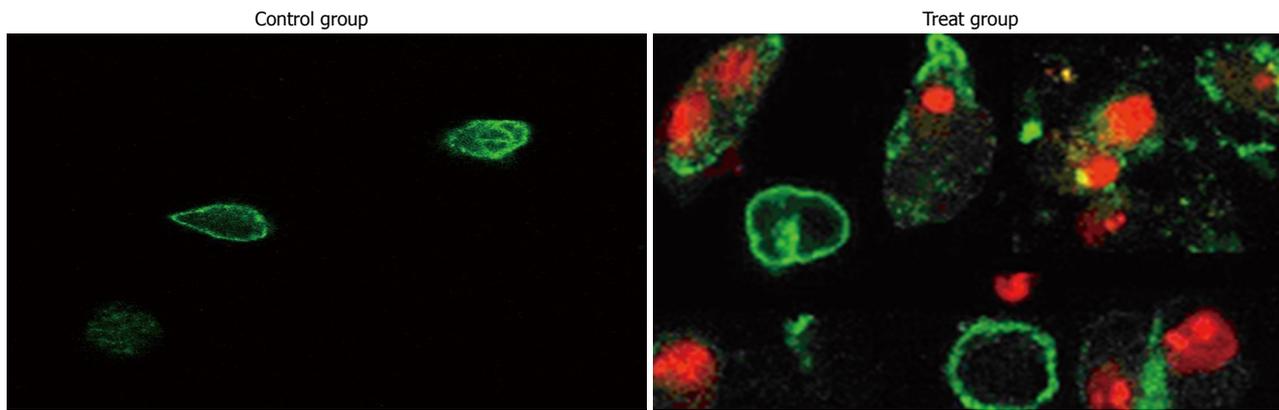

## DISCUSSION

Recent studies revealed many properties of TL relevant to anticancer activity, and anti-inflammatory activity besides. The proliferative and proapoptotic activity of TL has been shown with many different types of cancer cells *in vitro* and *in vivo* [8,21-27]. We therefore decided to test the effects of Triptolide on primary cultures of pancreatic cancer cells to see if this compound would show antitumor activity. In this study, we found that human pancreatic cancer cells treated with TL showed death in a dose- and time-dependent manner in the MTT assay. This suggested TL was able to restrain the growth of human pancreatic cancer cells. It was found that TL has the potential to induce the apoptosis of human pancreatic cancer cells.

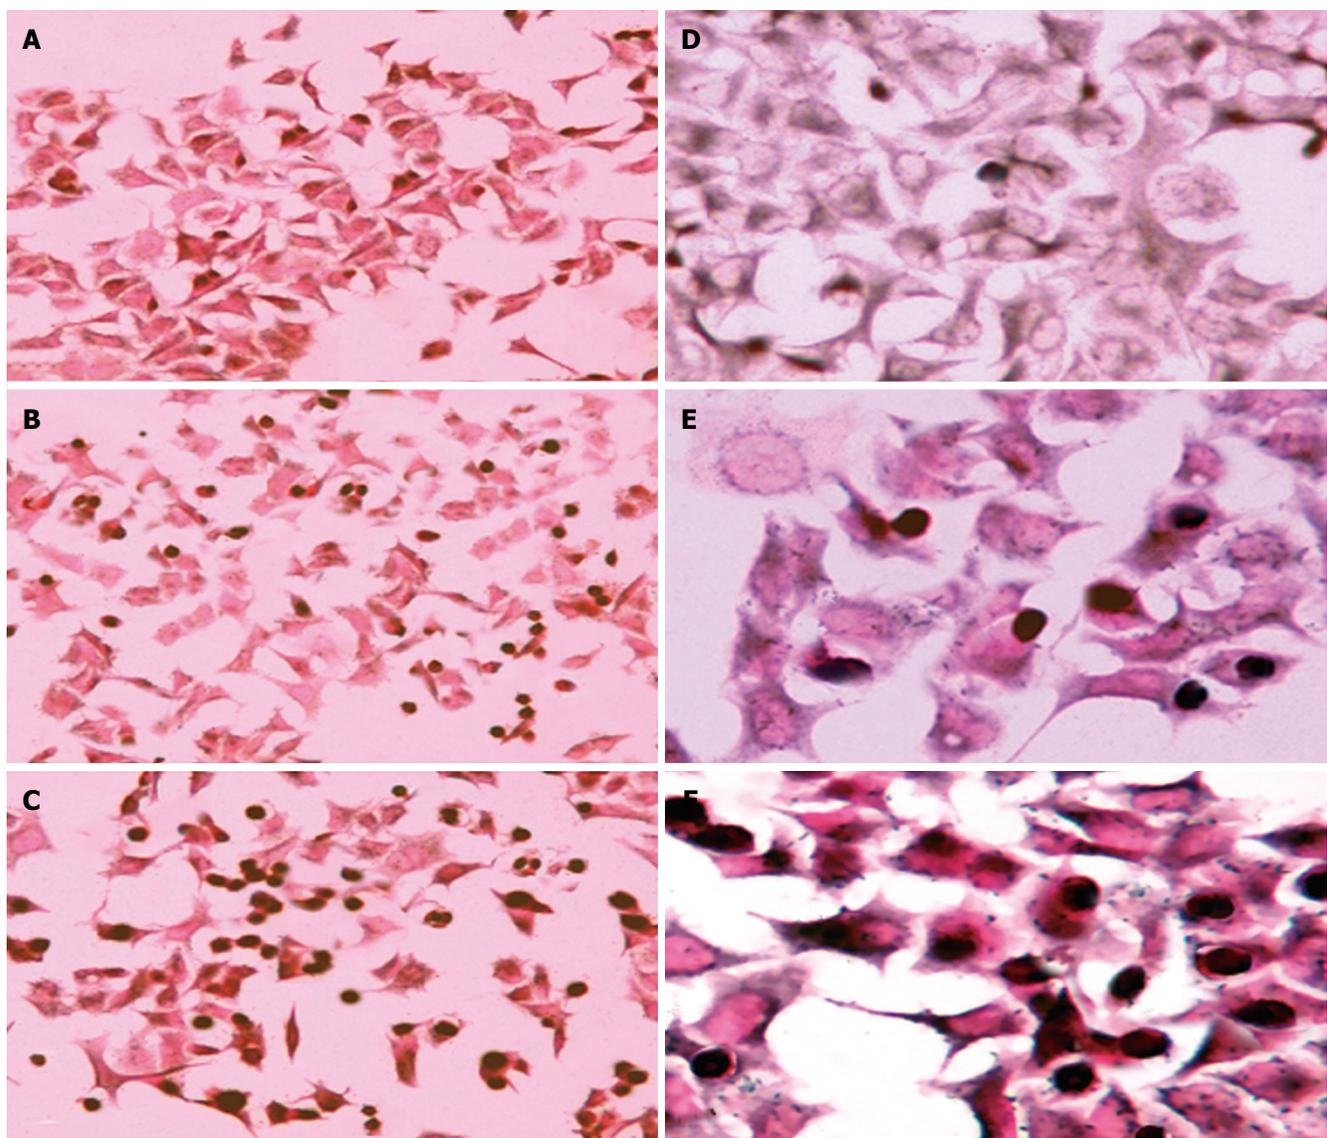

TL has potent anticancer activity. However, the mechanism by which TL exerts its anticancer activities

remains unclear. To explore the molecular mechanisms involved in the anticancer activity of TL, we have examined the effect of TL on the growth of pancreatic carcinoma SW1990 cells. After exposure to 40 ng/mL, 80 ng/mL, 160 ng/mL TL for 48 h, treatment of SW1990 cells with TL caused a marked up-regulation of caspase-3 and bax mRNA expression. In contrast, the expression of bcl-2 mRNA was not affected by TL. Thus it is likely that TL-induced apoptosis of pancreatic carcinoma SW1990 cells has no relation with bcl-2. The study by Wang *et al* [28] has shown that treatment of pancreatic cancer cells with gypenosides extracted from TL does not affect the Bcl-2 expression. This is the reason for our focusing on Bax proteins in exploring the effects of TL on mitochondria-dependent cell death pathway. It is shown that the expression of the Bax in SW1990 cells can be up-regulated by TL in our study. Meanwhile the expression of Bcl-2 was not affected by TL treatment.

Our previous study clearly indicated that TL was able to inhibit 5-LOX gene expression in pancreatic cell lines, which contributes to TL proapoptotic activity [29]. Wang *et al* [28] examined the effect of TL on the growth of pancreatic carcinoma PANC-1 and cervical adenocarcinoma HeLa cells. They found that TL potently suppressed cell growth and induced apoptosis in HeLa and PANC-1 cells, which was indicated by nuclear fragmentation and blebbing. In both HeLa and PANC-1 cells, apoptosis induced by TL was associated with activation of caspase-3 and caspase-8, and with cleavage of poly (ADP-ribose) polymerase and Bid. Moreover, in HeLa cells, caspase-9 is also significantly activated in response to TL. Interestingly, substitution of the 14-OH of TL with an acetyl group abrogated both its anticancer and its antiinflammatory activities. Wang *et al* [26] studies suggest that TL may exert its anticancer effects by initiating apoptosis through both death-receptor- and mitochondria-mediated pathways. Their results indicate that both the apoptosis-promoting and the antiinflammatory activities of TL depend on the 14-OH group. Liu *et al* have shown that caspase 3 is responsible for TL-induced Dendritic cell apoptosis, supported by observations that TL can

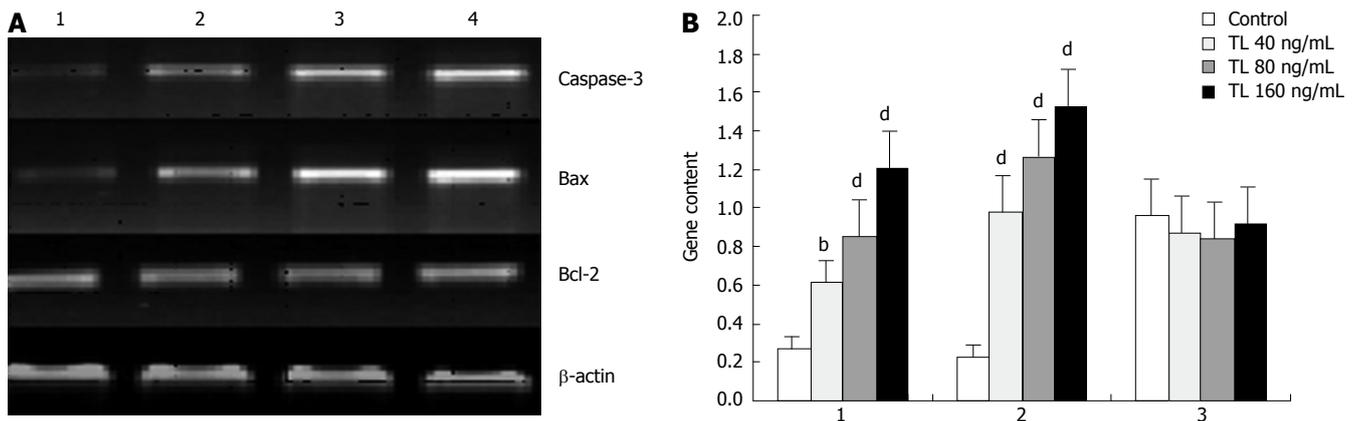

**Figure 3** TL induced apoptosis in SW1990 cell lines. SW1990 cells were suspended in 100  $\mu$ L binding buffer and Annexin V/PI double staining was performed, results showed that 40 ng/mL TL induced increased number of apoptotic cells (Annexin V<sup>+</sup>/PI<sup>+</sup>).

**Figure 4** Apoptotic cell death was revealed by TUNEL staining after 24 h (A, B, C magnification,  $\times 200$ ; D, E, F magnification,  $\times 400$ ) of treatment TL. A, D (TL 0 ng/mL); B, E (TL 40 ng/mL); C, F (TL 160 ng/mL); Apoptotic cells appeared dark after staining.

activate caspase 3 and that specific inhibition of caspase 3 can abrogate the apoptotic effects of TL on Dendritic cell<sup>[28]</sup>.

The present study demonstrated that TL was able to induce the apoptosis in Human pancreatic cancer. This apoptosis may be mediated by up-regulating the

**Figure 5** Detection of Bcl-2, Bax and caspase-3 gene in TL-treated SW1990 cells. Cells were treated with various concentrations of TL and Bcl-2. Bax and caspase-3 genes were analyzed by RT-PCR. **A:** 1: TL 0 ng/mL; 2: TL 40 ng/mL; 3: TL 80 ng/mL; 4: TL 160 ng/mL; **B:** 1: Caspase-3; 2: Bax; 3: Bcl-2. <sup>b</sup>*P* < 0.01, <sup>d</sup>*P* < 0.001.

expression of apoptosis-associated gene caspase-3 and bax. TL may be used as a potential anti-pancreatic carcinoma chemotherapeutic drug.

## COMMENTS

### Background

Pancreatic adenocarcinoma is of a poor prognosis and lack of response to conventional therapy. Among the treatment options, surgical resection of the tumor is still the most effective. The 5-year survival rate for this disease is very low even after curative resection. Therefore; new targets for chemopreventive and therapeutic agents need to be identified. Triptolide (TL) is an extract of the Chinese herb *Tripterygium Wilfordii* hook. It has been reported that TL possesses anti-tumor and proapoptotic activities in many different tumor cell lines, which functions through p53-dependent or independently<sup>[10,12,15,16]</sup>. Recently, Bing suggested that TL induced caspase-dependent apoptosis *via* the mitochondrial pathway in leukemia cells. However, the cellular and molecular mechanisms underlying TL-induced apoptosis in tumor cells have not been fully understood.

### Research frontiers

Pancreatic adenocarcinoma remains one of the most lethal of malignancies. The incidence of pancreatic cancer has steadily increased over the past four decades. Satisfactory treatment is available only for the minority of patients who present with very early-stage disease. There are several articles that TL possesses anti-tumor and proapoptotic activities in many different tumor cell lines, including breast, prostate, lung, and leukemia cells line. TL was also shown to sensitize cells to death induced by a variety of agents, such as Apo2/Trail, TNF- $\alpha$ , and different chemotherapeutic agents

### Innovation and breakthroughs

This study gives us new knowledge of TL and proof that TL was able to induce apoptosis in human pancreatic cancer. This apoptosis may be mediated by up-regulating the expression of apoptosis-associated gene caspase-3 and bax. TL may be used as a potential anti-pancreatic carcinoma chemotherapeutic drug and as a clinical application in the future.

### Application

The results from this study confirm that TL potently induces the apoptosis of human pancreatic cancer cells, which may be mediated by up-regulating the expression of apoptosis-associated gene caspase-3 and bax. It can be seen from this article that TL may be used to prevent or treat pancreatic cancer in the future.

### Terminology

TL extracts of the Chinese herb *Tripterygium Wilfordii* hook have potent anti-inflammatory and immunosuppressive properties and have been used successfully in traditional Chinese medicine for the treatment of rheumatoid arthritis and lupus erythematosus.

### Peer review

This article is of considerable interest and potential importance in demonstrating *in vitro* activity of the herbal extract TL against a human pancreatic cell line by inducing apoptosis. This work should stimulate additional *in vitro* studies in human cell lines, experiments involving animal models of pancreatic cancer, and, possibly, clinical testing of TL.

### Abstract

**AIM:** To investigate the associations of hepatitis B virus (HBV) genotype with HBeAg and anti-HBe status, alanine aminotransferase (ALT) levels and HBV-DNA detection in different groups of HBV-infected patients in southwest Iran.

**METHODS:** A total of 89 HBsAg-positive serum samples were collected from the same number of patients. All sera were then investigated to determine HBV DNA and serological markers. For all the polymerase chain reaction (PCR)-positive samples, biochemical, histopathological assays and genotyping were also performed.

**RESULTS:** Genotype D was the only type of HBV found

in different clinical forms of acute and chronic infections. There was a high prevalence of HBeAg-negative HBV-infected patients with chronic hepatitis (52.7%). Out of 55 patients with chronic hepatitis, seven (12.7%) were diagnosed with cirrhosis. A significant association between the presence of anti-HBe antibody and an increase in ALT level, among either HBeAg-negative ( $P = 0.01$ ) or HBeAg-positive ( $P = 0.026$ ) patients, was demonstrated. No significant differences were observed between the clinical outcomes of HBeAg-positive and -negative individuals ( $P = 0.24$ ).

**CONCLUSION:** Genotype D has been recognized as the only type of HBV found in different clinical forms of HBV infections, including cirrhosis, among the residents of southwest Iran. Anti-HBe possibly plays a role in disease progression in some patients with chronic hepatitis, at least for a period of disease.

### INTRODUCTION

Infection with hepatitis B virus (HBV) is associated with a broad range of clinical infections, including acute hepatitis, asymptomatic carrier, chronic hepatitis, cirrhosis and hepatocellular carcinoma. The course of HBV infection depends on many factors, such as host immune status, age at infection, level of viral replication and probably the

genetic variability of the virus influencing the expression of viral antigens<sup>[1]</sup>. Heterogeneity in the global distribution of HBV genotypes may account for differences in the clinical outcomes of patients infected with HBV, and their different responses to antiviral treatment<sup>[2,3]</sup>.

DNA sequencing of HBV isolates has revealed the existence of 8 viral genotypes A-H, which vary in geographic distribution<sup>[4]</sup>. Genotypes B and C are dominant in the Far East and south-east Asia where HBV infection is highly endemic<sup>[5,6]</sup>. Some studies have found more severe liver disease to be associated with genotype C, as compared with genotype B<sup>[7]</sup>. Genotype C and reactivation of Hepatitis B is associated with increased risk of cirrhosis. By contrast, genotypes A and D are more common in Western Europe and North America<sup>[8,9]</sup>. A large cross-sectional study in Sweden showed that genotype D is associated with more active disease than genotype A<sup>[10]</sup>. Genotype D is also predominant in the Mediterranean area as well as in the Middle East, including India. It has been associated with anti-HBe-positive chronic Hepatitis B infection in the Mediterranean region<sup>[10,11]</sup>. However, the clinical relevance of HBV genotypes isolated from different geographical regions is poorly understood.

Based on HBsAg detection, Iran is located in an intermediate endemic region for chronic HBV infection in the Middle East, and patients with chronic HBV infection are presented with different clinical pictures. The first report of HBV genotyping of 26 HBV isolates from Iranian chronically HBV-infected individuals revealed that HBV genotype D is dominant in Iran<sup>[12]</sup>. Nevertheless, the clinical and serological statuses of patients infected with HBV-D in this geographic region need to be further investigated.

Our aim in this study was to investigate: (1) The prevalence of different HBV genotypes in HBsAg-positive individuals living in southwest Iran, and (2) the association of HBV genotype with HBeAg and anti-HBe status, ALT levels and HBV-DNA detection in different groups of HBV-infected patients.

## MATERIALS AND METHODS

### Subjects

A total of 89 HBsAg-positive serum samples were collected from the same number of Iranian patients (68 males and 21 females, aged between 15 and 77 years) attending the Gastroenterology and Hepatology Clinic at the Department of Internal Medicine, Shiraz University of Medical Sciences, Shiraz, southwest Iran. Patients were registered irrespective of HBeAg status, ALT level, HBV DNA level or antiviral treatment status. Patients were excluded for hepatitis C virus (HCV), hepatitis D virus (HDV) or HIV co-infection. All patients were then tested for the following: HBeAg, antibodies to HBeAg (anti-HBe), anti-HBc, HBV DNA by polymerase chain reaction (PCR) assay, liver panel [aspartate aminotransferase (AST), ALT upper limit of normal (ULN), 667 nkat/L], alkaline phosphatase (ALP), albumin and total bilirubin], complete blood count, international normalized ratio (INR), and  $\alpha$ -fetoprotein (AFP). An abdominal ultrasound was

also performed to determine if there were features of cirrhosis. Liver biopsy was performed based on clinical indications. Liver damage was graded (0-8) according to the inflammatory components and staging (fibrosis; 0-6) was investigated using the modified histological activity indexing<sup>[13]</sup>. The definitions and diagnostic criteria for clinical terms were adopted from American Association for the Study of Liver Disease (AASLD) practice guidelines<sup>[14]</sup>.

### Serological markers

All serological tests were performed as instructed by the manufacturers. HBsAg, anti-HBc-IgG and IgM antibodies, anti-HDV antibody, HBeAg and anti-HBe antibody were measured using commercially available standard one-step enzyme immunoassay kits (MonoLISA, Bio-Rad, France). Anti-HCV (third generation assay) was measured by enzyme immunoassay (EIA) according to the manufacturer's instructions (Innogenetics, Belgium).

### PCR assay

**Preparation of DNA samples from the sera:** Strict measures were adopted to prevent any contamination. Purification of DNA samples was performed using a previously described method<sup>[15]</sup>.

### PCR amplification and detection of HBV genotypes:

DNA amplification and detection of HBV genotypes were performed based on a nested PCR assay, using the type-specific primers previously described<sup>[16]</sup>. Six genotypes (A-F) of HBV were identified by the assay system. To test the validity of the results, detection of HBV genotypes was also performed by quantitative real time PCR using a previously described method<sup>[12]</sup>. Quantitative real time PCR assay was carried out using SYBER-Green signal detection. A standard curve was constructed using ten-fold serial dilutions ( $10^6$ - $10^{11}$  copies/L) of plasmid DNA including the complete clinically isolated HBV-genome.

**Detection of PCR product:** Ten milliliters of reaction product was electrophoresed in a 1.5% agarose gel made in Tris-acetated-EDTA (TAE) buffer, pH = 8-8.5, and visualized by UV illumination after ethidium bromide (10 mg/L) staining.

### Statistical analysis

Fisher's exact test, chi-square test with Yate's correction and the Student's *t* test were used where appropriate.  $P < 0.05$  was considered statistically significant.

## RESULTS

All 89 patients were found to be infected with HBV of genotype D. Genotype D was the only detected type found in different clinical forms of acute and chronic infections, in all HBeAg-positive and -negative patients, in all patients who had elevated or normal ALT levels and at all ages. Thirty-two (36%) out of the 89 patients were categorized as inactive HBsAg carriers. Two patients (2.2%) were diagnosed to have acute hepatitis. The remaining 55 (61.8%) were classified as having chronic hepatitis. Based on histological, clinical and laboratory findings, seven

(12.7%) patients out of 55 were diagnosed as having cirrhosis. The cirrhotic patients consisted of 6 males (85.7%), aged 23 to 77 (average; 49.6 years) and one female (14.3%) aged 52 years. All cirrhotic patients had ALT levels that were at the upper limit for the normal level, but the ALT level was lower than the AST level in all patients. Four (57.1%) of the 7 cirrhotic patients were HBeAg negative. Based on HBeAg serology results, the 55 patients with chronic hepatitis were subdivided into two groups: (1) 26 patients (47.3%) positive for HBeAg, and (2) 29 patients (52.7%) negative for HBeAg. In the latter group, 24 (82.8%) patients had an ALT level that was higher than the normal value. Twenty-three of these were positive for anti-HBe antibody, indicating a possible genetic mutation in the precore/core region of the HBV-DNA genome. However, no significant correlation between the presence or absence of HBeAg and an increase in the level of ALT was observed in patients with chronic hepatitis ( $P = 0.13$ ).

Thirty-two patients with chronic hepatitis (58.2%) were positive for anti-HBe. Significant associations between the presence of anti-HBe antibody and an increased ALT level among both HBeAg negative ( $P = 0.01$ ) and HBeAg positive ( $P = 0.026$ ) individuals were observed. The number of individuals who had HBV DNA levels  $> 10^9/L$  was higher among HBeAg-positive patients (11/26) than among HBeAg-negative subjects (4/29) ( $P = 0.01$ ).

None of the 32 inactive HBsAg carriers demonstrated ALT levels higher than the normal value. They all were negative for HBeAg, but positive for anti-HBe antibody.

Based on histopathological status, more damage to hepatocytes was demonstrated in patients with chronic active hepatitis who were positive for anti-HBe compared with patients who were anti-HBe negative ( $P = 0.001$ ). The laboratory results for the patients are presented in Table 1.

## DISCUSSION

HBV has eight genotypes, which have distinct geographical distributions. There is some evidence the long-term prognosis and the initial clinical picture and response to treatment may differ depending on the genotype of the HBV having infected the patient<sup>[17]</sup>. The viral genome controls antigen expression, leading to different genotypes and a disease spectrum after infection. Genotype D is dominant in the Mediterranean region<sup>[18]</sup>, the Middle East<sup>[19]</sup> and Central Asia<sup>[20]</sup>. However, the clinical outcomes of the individuals infected with HBV of genotype D are still controversial. HBV genotype D is reported to be related to acute self-limited hepatitis<sup>[9]</sup>. Furthermore, HBV genotype D has been found in the majority of asymptomatic carriers (84.2%) and it is not found in patients with liver cirrhosis and hepatocellular carcinoma<sup>[20]</sup>. These findings are in contrast with other studies<sup>[22,23]</sup>. No association between HBV of genotype D and distinct clinical phenotypes has been found in the Turkish population infected with HBV<sup>[18]</sup>.

In our study, HBV-D was the only detectable genotype in different clinical forms of HBV infections, in patients with acute (2.2%), inactive HBsAg (36%) or chronic hepatitis (61.8%). Seven (12.7%) out of 55 patients with chronic hepatitis were diagnosed with cirrhosis. Genotype

**Table 1** Laboratory results for patients infected with hepatitis B, virus genotype D  $n$  (%)

Test	CH HBeAg <sup>+</sup>	CH HBeAg <sup>-</sup>	Inactive HBsAg carriers	Cirrhosis
	( $n = 26$ )	( $n = 29$ )	( $n = 32$ )	( $n = 7$ )

CH: Chronic hepatitis.

D was also found in three patients with a definite diagnosis of hepatocellular carcinoma. Nevertheless, these patients were excluded from the study, because their complete clinical and serological data were not available.

The appearance of anti-HBe usually marks non-replicative viral infection and inactive disease or response to treatment. However, 58.2% of the samples collected from patients with chronic hepatitis containing genotype D were anti-HBe positive. It should be noted that, in Iran, about 58% of HBV-infected individuals are infected with precore mutants, and may have anti-HBe antibodies in spite of actively replicating the virus<sup>[24]</sup>. The findings of this study confirm the presence of a significant association between the presence of anti-HBe antibodies and increased ALT levels among both HBeAg-negative ( $P = 0.01$ ) and HBeAg-positive ( $P = 0.026$ ) individuals. These results suggest that anti-HBe may play a role in the progression of the disease.

Apart from HBeAg status, 65.5% of our patients with chronic hepatitis showed ALT levels that were higher than the normal value. In contrast to a study by Yalcin *et al*<sup>[18]</sup>, diagnosis of cirrhosis, as well as hepatocellular carcinoma, among our patients with chronic hepatitis indicated that this may be associated with ethnic background. Ethnic background might also be an influencing factor on disease progression in patients infected with HBV-D.

Although the number of HBeAg-positive patients with HBV DNA levels higher than  $10^8$  molecules/L was less than that of HBe-negative individuals (23% *vs* 31%), no statistically significant differences were demonstrated between the clinical outcomes of the two groups ( $P = 0.24$ ).

In conclusion, this study suggests the unique characteristic of HBV-D infection is related to geographical location as well as ethnicity. Based on ALT levels and histopathological outcomes, we assume that anti-HBe plays a role in disease progression in some patients with chronic hepatitis, which consequently might lead to cirrhosis and hepatocellular carcinoma. The obtained evidence suggests HBV genotype D is associated with reactivation of chronic disease.

## COMMENTS

### Background

Heterogeneity in the global distribution of hepatitis B virus (HBV) genotypes may account for differences in the clinical outcomes of HBV infected patients and their

responses to antiviral treatment. The clinical and serological statuses of patients infected with HBV of a specific genotype in this geographic region (Iran) need to be further investigated.

### Research frontiers

Genotype D was the only type found in different clinical forms of acute and chronic infections. A significant association between the presence of anti-HBe antibody and increased alanine aminotransferase (ALT) levels among HBeAg-negative and HBeAg-positive individuals was demonstrated.

### Innovations and breakthroughs

This study suggests the unique characteristics of HBV-D infection are related to geographical location as well as ethnicity. The obtained evidence suggests that HBV genotype D is associated with reactivation of chronic disease.

### Applications

Further research should explain the mechanism of pathogenesis of different HBV genotypes and its relation to special geographical region.

### Peer review

This is an interesting and well-written clinical epidemiology study on Hepatitis B genotypes in Iran with disease correlation. The paper contributes to the viral hepatitis literature as there is very little from the Middle East in the area of Hepatitis B.

### Abstract

**AIM:** To investigate if transnasal endoscopic retrograde cholangiopancreatography (n-ERCP) using an ultrathin forward-viewing scope may overcome the disadvantages of conventional oral ERCP (o-ERCP) related to the large-caliber side-viewing duodenoscope.

**METHODS:** The study involved 50 patients in whom 25 cases each were assigned to the o-ERCP and n-ERCP groups. We compared the requirements of esophagogastroduodenoscopy (EGD) prior to ERCP, rates and times required for successful cannulation into the pancreaticobiliary ducts, incidence of post-procedure hyperamylasemia, cardiovascular parameters during the procedure, the dose of a sedative drug, and successful rates of endoscopic naso-biliary drainage (ENBD).

**RESULTS:** Screening gastrointestinal observations were easily performed by the forward-viewing scope and thus no prior EGD was required in the n-ERCP group. There was no significant difference in the rates or times for cannulation, or incidence of hyperamylasemia between the groups. However, the cannulation was relatively difficult in n-ERCP when the scope appeared U-shape under fluoroscopy. Increments of blood pressure and the amount of a sedative drug were significantly lower in the n-ERCP group. ENBD was successfully performed succeeding to the n-ERCP in which mouth-to-nose transfer of the drainage tube was not required.

**CONCLUSION:** n-ERCP is likely a well-tolerable method

with less cardiovascular stress and no need of prior EGD or mouth-to-nose transfer of the ENBD tube. However, a deliberate application is needed since its performance is difficult in some cases and is not feasible for some endoscopic treatments such as stenting.

Transnasal endoscopic retrograde cholangiopancreatography using an ultrathin endoscope: A prospective comparison with a routine oral procedure. *World J Gastroenterol* 2008; 14(10): 1514-1520 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1514.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1514>

### INTRODUCTION

Ultrathin endoscopy has been developed to perform unsedated transnasal esophagogastroduodenoscopy (EGD) as an alternative procedure to conventional oral endoscopy<sup>[1-6]</sup>. Although the evaluation of the ultrathin endoscope has not been established yet<sup>[7-10]</sup>, it has been suggested that transnasal EGD with an ultrathin scope diminishes the cardiopulmonary complications, lowers the cost because of dispensability of post-procedure monitoring related to consciousness sedation, and improves the patient's acceptability<sup>[11,12]</sup>. We have also demonstrated that nasal EGD is better accepted by unsedated patients with less cardiovascular stress compared to conventional oral EGD<sup>[13-15]</sup>.

Very recently, our preliminary studies have shown further application of an ultrathin upper endoscope to endoscopic retrograde cholangiopancreatography (ERCP) through the nasal<sup>[16]</sup> and gastric stomal routes<sup>[17]</sup>. Some complications of ERCP including cardiovascular stress may be related to a large-caliber endoscope<sup>[18]</sup> and furthermore

a side-viewing scope usually used in ERCP is not feasible for the screening of esophagogastroduodenal tract. Thus, the use of an ultrathin forward-viewing scope for ERCP might be beneficial to lessen those disadvantages. In fact, we have shown that transnasal ERCP with an ultrathin scope decreased cardiovascular stress as compared to the conventional oral method<sup>[16]</sup>. Another advantage to use an ultrathin scope is no need of mouth-to-nose transfer of a drainage tube in performing endoscopic naso-biliary drainage (ENBD) because the scope is inserted *via* the transnasal approach<sup>[16]</sup>. Moreover, we as well as others have recently reported the direct cholangioscopy by utilizing an ultraslim endoscope for the diagnosis and treatment of choledocholithiasis<sup>[19-21]</sup>.

Therefore, the application of an ultrathin endoscope to ERCP would be worthy of evaluation. However, limited information is available so far regarding transnasal ERCP with an ultrathin scope. Here, we report a prospective study to estimate the usefulness of an ultrathin scope in performing ERCP comparing to a conventional endoscope. We have used a transnasal method with an ultrathin scope, which may be advantageous in performing ENBD.

## MATERIALS AND METHODS

### Patients

Fifty consecutive patients, who underwent ERCP for the diagnosis and treatment of the pancreatobiliary disorders in Inuyama Chuo Hospital between March 2006 and March 2007 (Table 1), were enrolled in the present study. The patients were assigned alternately to two groups: 25 patients each underwent either transnasal ERCP with an ultrathin endoscope (n-ERCP group) or transoral ERCP with a conventional scope (o-ERCP group). We excluded the patients with a history of esophagogastrointestinal surgery and cardiovascular diseases and those who were expected to undergo sphincterotomy, papillary balloon dilatation. All patients gave written informed consent before participating into the study. The study was performed in compliance with the Declaration of Helsinki and was approved by the review board for human research of our hospital.

### Endoscopy procedure

ERCP was performed by three senior endoscopists with more than 10 years' experience. Two types of endoscopes were used; an ultrathin endoscope (EG530N, Fujinon-Toshiba, Tokyo, Japan with an outer diameter of 5.9 mm, biopsy channel diameter of 2 mm and working length of 1100 mm; forward viewing 120 degree; tip deflection 210 degree up, 90 degree down, and 100 degree right and left) for the transnasal approach and a conventional duodenal endoscope (ED450XT8, Fujinon-Toshiba, Tokyo, Japan with an outer diameter of 13.5 mm) for the oral approach. The nasal cavity was prepared before transnasal ERCP by spraying three doses of 0.111% tramazoline hydrochloride (Alfresa Pharma, Osaka, Japan), followed by the insertion of an 18 Fr catheter covered with 8% lidocaine liquid (Astra Zeneca, Tokyo, Japan) for 3 min. Pharyngeal anesthesia was performed by lidocaine jelly (approximately 5 mL of 2% gel) before the oral endoscopy. Atropine sulfate (0.5 mg) and glucagon (1 USP) were given intramuscularly just before

**Table 1 Patient characteristics and baseline cardiovascular parameters in each group (mean  $\pm$  SD)**

Groups	o-ERCP	n-ERCP	P-value
Number of patients	25	25	
Male/Female	17/8	17/8	0.76
Median age (range)	69 (32-89)	74 (35-85)	0.07
Systolic blood pressure (mmHg)	129 $\pm$ 20	133 $\pm$ 19	0.50
Pulse rate (/min)	71 $\pm$ 12	65 $\pm$ 11	0.08

Indication for ERCP (n)			
Cholecyst lithiasis	6	2	
Choledochus lithiasis	11	10	
Cancer	6	10	0.50
Pancreatitis	1	2	
Others	1	1	

O-ERCP: Oral ERCP; n-ERCP: Nasal ERCP.

both procedures. Conscious sedation was carried out by an intravenous injection of midazolam (Astellas, Tokyo, Japan) during both ERCP procedures.

In performing n-ERCP, an ultrathin endoscope was inserted through the nasal cavity and reached the second or third portion of the duodenum after screening observations of the upper gastrointestinal tract. There was no difficulty in observing the papilla of Vater and the cannulation for cholangiopancreatography was performed using a conventional ERCP tube through the biopsy channel of the ultrathin scope as reported previously<sup>[16]</sup>. In case of need, an ERCP tube was easily replaced by an ENBD tube (ENBD-5-NAG, Cook, Bloomington, USA) using a guide-wire (Jagwire 0.025/450 Boston Scientific, Natick, USA). Thereafter, the scope was withdrawn carefully through the nasal cavity, leaving the ENBD catheter in the bile duct.

### Procedure-related measurements

We have compared between the two procedures the rates of successful cannulation into the common bile duct and/or pancreatic duct, the times required for the first cannulation into either of the ducts, the doses of the sedative drug, the incidence of post-procedural hyperamylasemia and the successful rates of ENBD. The patients with increased serum amylase levels more than twice of normal range after two hours of ERCP were diagnosed hyperamylasemia.

### Measurement of cardiovascular responses

Pulse (P), systolic blood pressure (BP) and peripheral blood oxygen saturation (SpO<sub>2</sub>) were measured using a monitor unit (DS-7100 Dynascope, Fukuda Denshi, Nagoya, Japan) at the right upper arm. The parameters were determined at rest before the examination, just before the cannulation of the papilla of Vater and at the completion of the procedure. Patients lay quietly in the prone position during the procedure. The rate-pressure product was calculated by a multiplication of BP and P. Changes of the parameters ( $\Delta$ P,  $\Delta$ BP,  $\Delta$ SpO<sub>2</sub> and  $\Delta$ rate-pressure product) were calculated by the following equation: (values during the endoscopy) - (values before the endoscopy).

### Sample size

According to our preliminary study<sup>[16]</sup>, the required sample

**Table 2** Esophagogastroduodenoscopy prior to ERCP and its diagnosis

Groups	o-ERCP	n-ERCP
Number of patients	25	25
EGD prior to ERCP	25	0
Diagnosis		
Normal finding	8	10
Pathological findings	17	15
Reflux esophagitis	1	2
Sliding hernia	4	2
Esophageal diverticulum	1	0
Atrophic gastritis	10	11
Duodenal ulcer scar	1	4
Gastric adenoma	1	1
Gastric SMT	0	1

EGD: Esophagogastroduodenoscopy; SMT; Submucosal tumor.

size was estimated for  $\alpha = 5\%$  (two-sided) and  $\beta = 10\%$  as well as concerning a risk of cannulation failure in n-ERCP (approximately 30%). With the aim of detecting a standardized difference of 30 mmHg and a standard deviation of 25 mmHg in  $\Delta$ BP, a sample size of 25 patients per group was needed.

### Statistical analysis

Results were expressed by a median value and interquartile as well as 10%-90% quantity range for nonparametric data, and by a mean  $\pm$  SD and mean  $\pm$  SE for parametric data. Statistical analysis was carried out using Welch-*t* test or paired *t*-test as a parametric test for P, BP, SpO<sub>2</sub> and changes of the parameters. Mann-Whitney-*U* test and chi-squared test were used for as a nonparametric data and categorical data. All analyses were performed with the SPSS for Windows (SPSS Japan, Tokyo, Japan). A *P* value less than 0.05 was considered significant.

## RESULTS

### Patients' characteristics and procedure-related measurements

No significant difference was found in the gender, age or types of diseases between the two groups (Table 1). Requirement of EGD prior to ERCP is shown in Table 2. It is notable that no prior EGD was needed in the n-ERCP group, whereas EGD was routinely performed before ERCP in all the cases in the o-ERCP group in order to avoid the gastrointestinal injury possibly caused by the side-viewing scope. The diagnoses with the screening EGD involved not a few numbers (approximately 20%) of the esophageal disorders that would be difficult to find by a side-viewing scope (Table 2).

Procedure-related measurements are presented in Table 3. We have successfully performed n-ERCP in 23 of 25 cases (92%) except two cases with gallbladder cancer and choledocholithiasis due to the insertion failure of the endoscope into the second portion of the duodenum. In the n-ERCP group we have completed the cannulation into the common bile duct in 18 of 25 cases (72%) and into the pancreatic duct in 21 of 23 attempted cases (91%).

**Table 3** Successful rates of cannulation and endoscopic naso-biliary drainage and rates of post-ERCP hyperamylasemia in each group

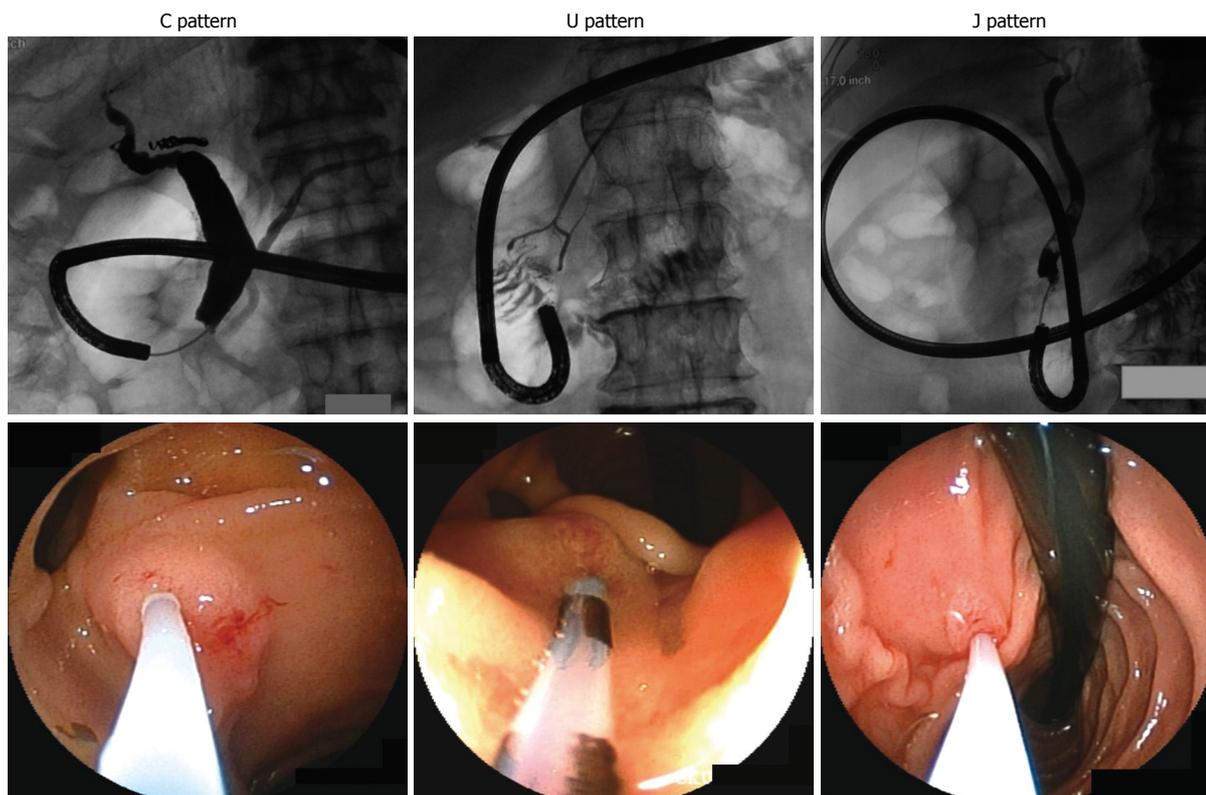

Groups	o-ERCP	n-ERCP	<i>P</i> -value
Successful cannulation (%)			
Either of the ducts	25/25 (100)	23/25 (92)	0.510
Common bile duct	24/25 (96)	18/25 (72)	0.053
Pancreatic duct	24/25 (96)	21/23 (91)	0.940
Median time for cannulation, min (%)	8 (2-24)	7 (4-20)	0.590
Post-procedural hyperamylasemia (%)	7/25 (28)	5/23 (22)	0.870
Successful ENBD (%)	20/21 (95)	13/15 (87)	0.340

O-ERCP: Oral ERCP; n-ERCP: Nasal ERCP; ENBD: Endoscopic naso-biliary drainage.

There was no difference in the procedure time required for the cannulation between the groups (Table 3).

Although no significant difference was found in the rate of successful cannulation between the two groups, there was a tendency to a lower success rate of cannulation into the common bile duct in the n-ERCP group (Table 3). Therefore, we have further analyzed the relationship between the successful insertion rate and the patterns of endoscopic shapes during the approaches to the papilla of Vater. We have classified the manners of approaches into three categories: C, U and J patterns according to the endoscopic shape observed under fluoroscopy (Figure 1). In the C and U patterns the scope was inserted along the duodenal loop in the second and third portions. In the C pattern a front view of the papilla of Vater was observed easily, whereas in the U pattern its observation was more difficult, where the papilla could only be looked up from the third portion of the duodenum (Figure 1). The J pattern was the reverse shape of the U loop. The papilla of Vater was also looked up from the downward in the J pattern, however, its view was obtained more easily than in the U pattern. Favorable results were obtained in the C and J patterns regarding both the cannulation rates and its required times (Table 4). However, because in the U pattern the angle to observe the papilla of Vater was sharpest, we had difficulty in the cannulation, resulting in the lowest cannulation rate into the common bile duct as well as the longest time for cholangiography among the patterns (Table 4).

Post-procedural hyperamylasemia was found in 22% and 28% in the n-ERCP and o-ERCP groups, respectively, which was not significantly different (Table 3). Pancreatitis was not encountered in either procedure, suggesting no disadvantage of n-ERCP regarding procedure-associated complications. Interestingly, the dose of a sedative drug (midazolam) required during the procedure was significantly smaller in the n-ERCP group than in the o-ERCP group ( $P = 0.003$ , Figure 2). Insertion of an ENBD tube was attempted in 15 cases in the n-ERCP group and was successfully performed in 13 cases (87%), except two cases with the incomplete deep cannulation into the common

**Figure 1** Patterns of the endoscopic shape under fluoroscopy in performing transnasal ERCP. Upper panels, fluoroscopic views of the C, U and J shapes of an ultrathin scope; Lower panels, endoscopic views of the papilla of Vater observed in the respective patterns.

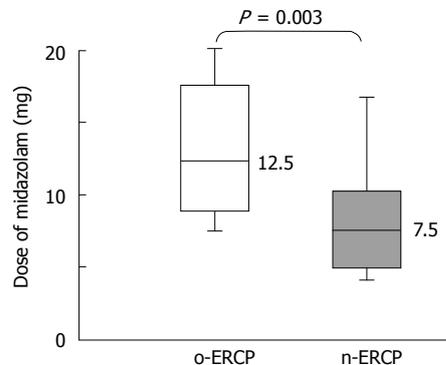

**Table 4** Rates and times required for successful cannulation in each pattern of the endoscopic shape

Patterns	C	U	J	Total
Successful cannulation (%)				
Either of the ducts	6	14	3	23
Common bile duct	6/6 (100)	9/14 (64)	3/3 (100)	18/23 (78)
Pancreatic duct	5/5 (100)	14/14 (100)	2/2 (100)	21/21 (100)
Median time for cannulation, min (%)				
Either of the ducts	6.5	7.3	7	7
Common bile duct	10.5	20	16	17
Pancreatic duct	6	13	6	9
Termination	31	34	24	33
	(14-38)	(11-61)	(12-34)	(11-61)

bile duct (Table 3). No significant difference was found in the successful rate of ENBD between the groups.

#### Measurement of cardiovascular responses

There was no significant difference in the baseline cardiovascular parameters measured before ERCP between the n-ERCP and o-ERCP groups (Table 1). Both  $\Delta$ BP and  $\Delta$ rate-pressure product measurements just before the cannulation of the papilla of Vater and at the end of ERCP procedure were significantly smaller ( $P < 0.001$ , respectively) in the n-ERCP group than in the o-ERCP group (Figure 3A and C). There was no significant difference in  $\Delta$ P (Figure 3B)

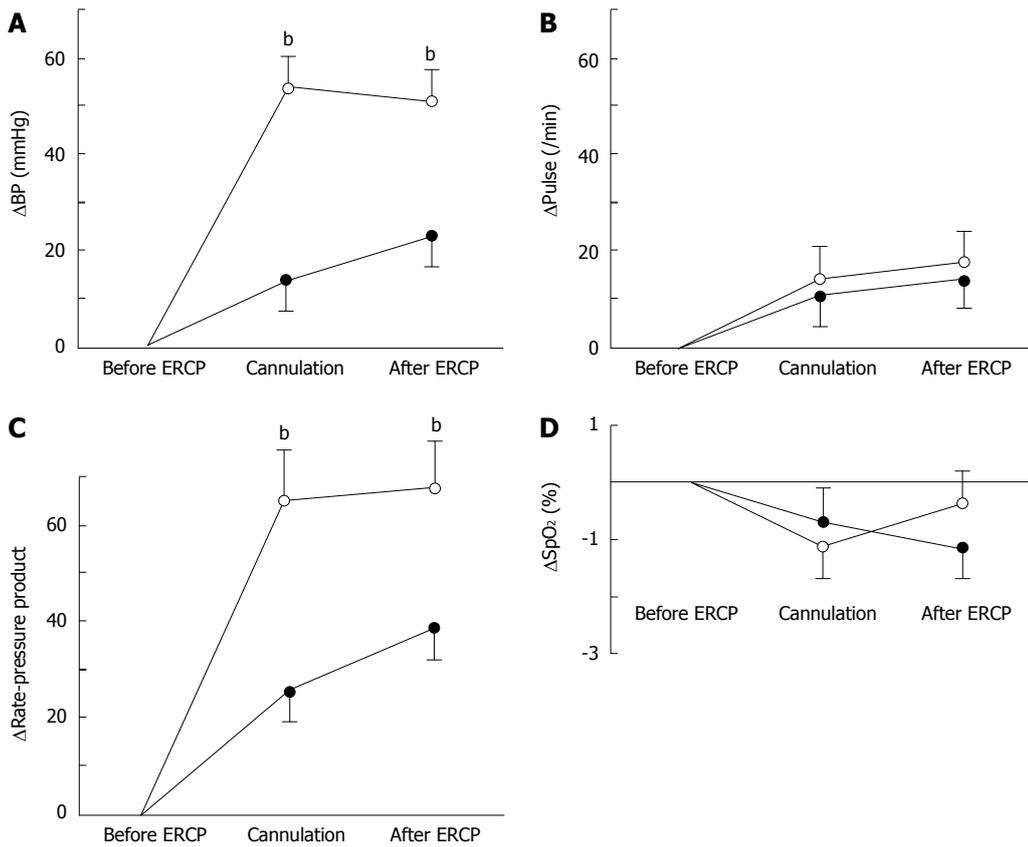

**Figure 2** Dose of midazolam, a sedative drug used in ERCP. Values represent the mean, interquartile and 10%-90% quantities. O-ERCP: Oral ERCP with a conventional scope; N-ERCP: Transnasal ERCP with an ultrathin scope.

and  $\Delta$ SpO<sub>2</sub> (Figure 3D) between the two groups both just before the cannulation and at the end of ERCP.

## DISCUSSION

ERCP is a widespread technique essential for the diagnosis and treatment of the pancreatobiliary disorders. Although ERCP is an established method, there are still several disadvantages in its performance including the procedure-related morbidity<sup>[11]</sup>. Here, we have focused upon the following unfavorable aspects of the conventional ERCP: (1) a side-viewing duodenoscope is not suitable for the screening observation of the esophagogastroduodenal tract prior to performing ERCP, (2) a large caliber scope may exacerbate the cardiovascular stress, and (3) transfer

**Figure 3** Cardiovascular parameters during the ERCP procedure. **A-D** show the changes in systolic blood pressure (**A**), pulse rate (**B**), rate-pressure product (**C**) and peripheral blood oxygen saturation (**D**). The changes of the parameters were calculated as described in the text. Open and closed circles show the oral and transnasal ERCP, respectively. Each parameter was measured before performing ERCP, just before the cannulation and at the completion of the ERCP procedure. Values represent the mean  $\pm$  SE. <sup>b</sup>*P* < 0.001.

of a drainage tube from the oral to nasal cavity is necessary in performing ENBD. We have investigated in the present study if those disadvantages could be overcome by the transnasal approach employing an ultrathin forward-viewing endoscope.

Most of the patients with acute pancreatobiliary disorders have the symptoms indistinguishable from those of the esophagogastrointestinal diseases and in fact the gastrointestinal complications are often encountered in such patients. Therefore, the observation with EGD prior to ERCP is preferable, as we have routinely performed in the present study. However, since a forward-viewing scope employed for n-ERCP is usually used to examine the upper gastrointestinal tract, additional EGD was not necessarily performed prior to n-ERCP. Simultaneous screening of the gastrointestinal tract may not only shorten the time required for the diagnosis but also assist performing safer ERCP by reducing a risk of the esophagogastrroduodenal injuries that might occur during the conventional ERCP procedure with a side-viewing scope. Moreover, a forward-viewing scope has an advantage in examining the esophageal diseases that would be hardly diagnosed by a side-viewing scope. In fact, not a few numbers of esophageal diseases were found in the present study.

A large-caliber endoscope has been suggested to exacerbate cardiovascular stress<sup>[18]</sup>. Here, we have also shown that n-ERCP with an ultrathin scope reduced the cardiovascular stress as we have reported previously<sup>[16]</sup>. A significantly lower increment of the rate-pressure product in n-ERCP may strongly support the reduction of the risk of cardiovascular complications as compared to conventional o-ERCP<sup>[22]</sup>. Furthermore, we have

found that n-ERCP required a significantly lower dose of the sedative drug than o-ERCP. These observations suggest the reduced physical as well as presumably less mental stress in performing n-ERCP. Previous studies have suggested that the sedative used during EGD is an important factor in the genesis of cardiopulmonary complications and thus milder sedation could diminish its incidence<sup>[11,23]</sup>. Therefore, a lower requirement of a sedative drug in n-ERCP might also be advantageous to lessen the cardiovascular complications. In fact, n-ERCP with an ultrathin endoscope has been anticipated being advantageous to reduce myocardial ischemia because of its less mechanical irritation<sup>[24-27]</sup>.

A guideline for the diagnosis and treatment of acute cholangitis and cholecystitis has recently been proposed in which an early biliary drainage is strongly recommended<sup>[28]</sup>. ENBD is a valuable and safe technique for the urgent biliary drainage. We have successfully performed ENBD in succession to n-ERCP without any complications. Because there is no need of EGD prior to ERCP, n-ERCP may be valuable in performing urgent ENBD. Another advantage of transnasal approach is no need to transfer the ENBD tube from oral to nasal cavity.

Those observations in our study suggest that n-ERCP is a well-tolerable technique that may overcome some disadvantages of conventional o-ERCP. However, it should be noted that there are significant limitations in performing n-ERCP due to a narrow channel of the scope. For instance, the technique is not feasible for sphincterotomy, papillary balloon dilatation, and stenting using a large-size stent with a diameter of 5 Fr or more. Therefore, we do understand the necessity and widespread

utility of o-ERCP, and thus we do not intend to emphasize excessively the usefulness of n-ERCP. Moreover, in some cases n-ERCP is difficult to perform and thus would be better replaced with o-ERCP. Particularly, in cases with the U pattern of the endoscopic shape the successful cannulation rate was relatively low and requires a longer time, which might lead to an increased risk of the procedure-related complications such as acute pancreatitis<sup>[29]</sup> and ischemic heart injury<sup>[26]</sup>. Therefore, we propose the following strategy to perform n-ERCP in the clinical practice. In cases who are not expected to undergo sphincterotomy or papillary balloon dilatation, transnasal EGD is routinely performed prior to ERCP using an ultrathin scope that usually reaches the papilla of Vater. Then, when the approach pattern is C or J under fluoroscopy the cannulation for cholangiopancreatography seems to be easily and safely performed and thus n-ERCP may be attempted. However, in cases with the U pattern the scope may better be replaced with a conventional side-viewing duodenoscope when an endoscopist had difficulty in the cannulation. In addition, we have experienced successful n-ERCP in several cases in whom the papilla of Vater was hard to observe using a side-view scope and thus we failed to perform o-ERCP. N-ERCP may also be a good indication in such cases.

Future advancement of ERCP techniques using an ultrathin scope might allow the minimally invasive interventions that otherwise can hardly be carried out by conventional ERCP. For example, endoscopic diagnosis and therapy for the pancreatobiliary disorders may extend to the elderly as well as to the patients with difficulties in oral insertion, including those with esophagogastrintestinal stenosis and gastric stoma as we have reported previously<sup>[17]</sup>. Very recently, we have successfully performed lithotomy under direct cholangioscopy utilizing the same ultrathin scope used in the present study<sup>[19,20]</sup>. Thus, it is possible to remove a biliary stone in succession to n-ERCP in cases who had undergone sphincterotomy. Future development of an ultrathin duodenoscope designed especially for ERCP would bring the wide spread of the transnasal ERCP.

## COMMENTS

### Background

Conventional oral endoscopic retrograde cholangiopancreatography (ERCP) has several disadvantages related to a large caliber side-viewing duodenoscope, including the cardiovascular stress caused by a large-caliber scope, difficulty in observing the esophagogastroduodenal tract prior to performing ERCP, and necessity of mouth-to-nose transfer in performing endoscopic naso-biliary drainage (ENBD). Transnasal upper endoscopy using an ultraslim scope has been shown to be better tolerated with less cardiovascular stress.

### Research frontiers

Very recently, our preliminary studies have shown the better cardiovascular tolerance of transnasal ERCP using an ultraslim forward-viewing scope as well as an application of the scope to direct cholangioscopy. The highlight of the present study is to demonstrate the feasibility of the ultrathin scope in performing ERCP, comparing with conventional oral ERCP.

### Innovations and breakthroughs

Little information has been available regarding the application of an ultrathin upper endoscope to ERCP. The present study is the first report showing the utility and safety of transnasal ERCP with an ultraslim scope. We have demonstrated that

nasal ERCP can be performed safely with similar successful rates of cannulation into the pancreatobiliary ducts as compared with those of the conventional method, and that nasal ERCP is less stressful to the cardiovascular system and is advantageous in performing ENBD due to no necessity of mouth-to-nose transfer of a drainage tube.

### Applications

ERCP using an ultrathin scope may allow endoscopic diagnosis and therapy for the pancreatobiliary disorders in patients with difficulties in insertion, including those with esophagogastroduodenal stenosis and gastric stoma. Future development of the ultrathin duodenoscope might bring the widespread of transnasal ERCP.

### Peer review

The present study is the first demonstration of the feasibility and safety of transnasal ERCP utilizing an ultraslim upper endoscope. The findings are novel and the study design is well organized.

### Abstract

**AIM:** To investigate if the clinical efficacy of granulocytes and monocytes by adsorption (GMA) is associated with an increased frequency of peripheral regulatory T cells (Tregs), as these cells have proven to be successful in suppressing inflammatory bowel disease (IBD) in animal models.

**METHODS:** We report four cases of corticosteroid-dependent ulcerative colitis (UC) and two Crohn's disease (CD) cases with severe cutaneous lesions who received GMA therapy. The frequency of CD4<sup>+</sup> CD25<sup>high</sup> (Tregs) in peripheral blood was analyzed by flow cytometry and the expression of FoxP3 and TGF beta in purified CD4<sup>+</sup> T cells was determined by real time PCR prior to and one month after the last apheresis session, and at the time of endoscopic and clinical assessing.

**RESULTS:** Increased expression of Fox P3 mRNA was found in all five patients who responded to cytappheresis with remission of clinical symptoms, mucosal inflammation and cutaneous lesions, and an increased frequency of circulating Tregs was found in four patients. These changes were not observed in the patient with UC who did not respond to GMA. Variations in TGF- $\beta$  (mRNA) did not parallel that of FoxP3 mRNA.

**CONCLUSION:** The clinical efficacy of GMA on IBD and related extra intestinal manifestations was associated with an expansion of circulating CD4<sup>+</sup> CD25<sup>+</sup> Tregs and higher expression of FoxP3 in CD4<sup>+</sup> T cells. Accordingly, an elevated CD4<sup>+</sup> CD25<sup>+</sup> FoxP3 may be a valuable index of remission in patients with IBD and other chronic relapsing-remitting inflammatory conditions during treatment with GMA.

### INTRODUCTION

Granulocyte-monocyte adsorption apheresis (GMA) with the Adacolumn has shown efficacy in the treatment of inflammatory colitis in a series of studies, mainly performed by Japanese and European investigators<sup>[1,2]</sup>. Adacolumn<sup>R</sup> is a therapeutic extracorporeal device, which selectively adsorbs granulocytes and monocytes from peripheral blood. The selective adsorption is thought to be mediated by interactions of complement and Fc receptors on the granulocytes and monocytes, whereas complement factor and immunoglobulins adhere onto the surface of G-1 beads by ligand-receptor interactions<sup>[3]</sup>. Granulocytes and monocytes are believed to play a significant role in these and other autoimmune inflammatory diseases because of their capability to release a variety of mediators including active oxygen species and inflammatory cytokines, such as tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and interleukin  $\beta$  (IL1- $\beta$ )<sup>[4,5]</sup>. This contention supports the use of GMA-apheresis and other therapeutic attempts to prevent damages caused by granulocytes and monocytes<sup>[6,7]</sup>. However, the clinical efficacy of cytappheresis cannot be fully explained by a simple transient removal of these cells.

CD4<sup>+</sup> CD25<sup>high</sup>, FoxP3<sup>+</sup> regulatory T cells (Tregs) play a major role in controlling the immune response by producing suppressive effects on activated immune cells. It is established that FoxP3, a forkhead/winged-helix transcription factor, is specifically expressed in Treg cells and is a master control protein for the generation of these cells<sup>[8]</sup>. Depletion of Tregs leads to autoimmunity in mice<sup>[9]</sup> and dysfunction of Tregs has been linked to human autoimmune diseases<sup>[10-13]</sup>. Immunosuppressive cytokines like IL-10 and

TGF- $\beta$  are required for the control of autoimmunity in many *in vivo* models, but suppression *in vitro* appears to be solely mediated by a cell-cell contact-dependent, cytokine independent mechanism<sup>[14]</sup>. Further, an inverse correlation has been reported between disease activity and frequency of peripheral Tregs in patients with inflammatory bowel disease (IBD)<sup>[15]</sup>. However, active IBD is not associated with a functional defect but with a contraction of the peripheral blood Treg pool and a moderate expansion in intestinal lesions<sup>[16]</sup>. Further, cultured gut-derived Tregs from patients with Crohn's disease (CD) and healthy individuals suppress T cell proliferation and cytokine secretion<sup>[17]</sup>. Animal studies suggest that adoptive transfer of Tregs can reverse experimental colitis<sup>[18]</sup> and the long-term effects of *ex vivo* activated and transferred Treg cells are likely due to their ability to generate new cytokine-producing CD4+ Treg *in vivo*<sup>[19]</sup>.

The involvement of TGF- $\beta$  in Treg function remains controversial but it has been reported that TGF- $\beta$  produced by CD4+ CD25+ T cells is involved in the suppressor activity of these cells, particularly in their ability to regulate intestinal inflammation<sup>[20]</sup>. There is evidence that TGF- $\beta$  deficiency leads to development of autoimmune disease: TGF- $\beta$  deficient mice and transgenic mice expressing the dominant negative form of TGF- $\beta$  receptor are useful animal models for diabetes and IBD<sup>[21,22]</sup>. Suppressive activity of Tregs may be inhibited in TGF- $\beta$  deficiency by acting on FoxP3. TGF- $\beta$  is able to induce FoxP3 expression and subsequently a Treg phenotype in CD4+CD25- murine and human T cells, as well as a positive auto regulatory loop of TGF- $\beta$  signaling by down-regulation of smad-7, an inhibitory protein for TGF- $\beta$  signaling<sup>[23]</sup>. In addition, over expression of smad 7 that results in insensitivity to TGF- $\beta$  has been associated with human IBD<sup>[24]</sup>.

With the assumption of a role of Tregs in the prevention and potential cure of autoimmune inflammatory diseases, we aimed to ascertain whether the beneficial effects of GMA-apheresis correlate with an increase in CD4+ CD25<sup>high</sup> cell numbers and a higher expression of FoxP3 and TGF- $\beta$  in peripheral blood CD4+ T cells in a small group of patients with ulcerative colitis or Crohn's disease.

## MATERIALS AND METHODS

### Subjects

Four patients with ulcerative colitis (UC) and two patients with CD that were treated by selective GMA were included in this study. Main UC patient's data are presented in Table 1. Steroid dependency was defined as the need for > 10 mg prednisolone daily for at least 4 wk to control clinical symptoms. Both of the two patients with CD had associated severe cutaneous conditions; patient 5, a 26 aged female was diagnosed with CD 7 years ago. This patient had ileocolonic lesions without fistulas and had previously been treated with steroids, 5-ASA, and azathioprine cycles without improvement. On August 2005, she had an ulcerative lesion in the left leg; diagnosis of pyoderma gangrenosum (PG) was made on clinical grounds and confirmed by a dermatologist. A skin biopsy was not required as there was no clinical doubt in the diagnosis.

Patient 6 was a 45-year old female who was diagnosed to have CD with ileocolonic inflammation and has had several flares of uveitis and nodosum erythematosis. She was unsuccessfully treated with steroids and anti-TNF antibodies.

Each patient received five cycles GMA-apheresis at weekly intervals (see below) and a clinical protocol including ileocolonoscopy was applied one month after the end of the therapy. Clinical outcome was assessed using the follow-up criteria: absence/near absence of clinical symptoms as remission; improvement of symptoms, (without increase in steroid dose) as response, and no change or worsening as failure. Disease activity was categorized as mild, moderate or severe, and relapse was defined as an increase in clinical symptoms, as judged by the treating physician. Blood samples were taken at entry and when efficacy was assessed to determine the frequency of peripheral regulatory CD4+ CD25<sup>high</sup> T cells and to quantify mRNAs for FoxP3 and TGF- $\beta$  expressed in purified CD4+ T cells. Results from each individual patient were compared regarding to its clinical response to the therapy (Table 2).

### GMA procedures

Patient's blood was passed through a column that is filled with specially designed cellulose acetate beads of 2 mm in diameter that absorb about 65% of granulocytes, 55% of monocytes and a very small fraction of lymphocytes<sup>[25]</sup>. The apheresis procedures were performed by a specially trained nurse at the outpatient gastrointestinal department. Adacolumn device (JIMRO, Takasaki, Japan) was used in all cases. The GMA sessions were performed at a flow rate of 20-30 mL/min for 60-90 min and the frequency and total number of apheresis sessions were typically 5 weekly sessions per patient. Non-adverse events or toxicity were observed.

### Flow cytometry

Whole blood samples were stained with FITC (fluorescein) labeled anti-CD4 and APC conjugated anti-CD25 Abs; respective mouse isotype controls were employed; optimal dilution of antibodies were used and cells were washed and analyzed by flow cytometry in a FACScalibur cytometer and the CellQuest software (Becton Dickinson). A live gate set around viable lymphocytes was used based on their forward scatter/side scatter (FCS/SCC) characteristics. For analysis of CD25<sup>high</sup> T cells, large activated cells as determined by FCS/SCC properties were excluded. Three cell populations were distinguished in CD4+ T cells, according to the surface expression of CD25: CD4+ CD25- "naive"; CD4+ CD25<sup>low-int</sup> "activated", and CD4+ CD25<sup>high</sup> "regulatory" cells.

### Cell isolation

Peripheral blood mononuclear cells (PBMC) were isolated from 20 mL freshly drawn blood by Ficoll density gradient centrifugation. CD4 positive cells were isolated from PBMC by positive selection using anti-CD4 human micro beads magnetic adhesion cell separator (MACS) antibody (Miltenyi Biotech, Bergisch, Gladbach, Germany).

### Quantitative PCR

CD4+ cell pellets were lysed in RLT buffer (Qiamp RNA blood mini kit (Qiagen, Germany) and total RNA was extracted. One microgram of total RNA was reverse transcribed using MMLV and random hexamers (Promega, USA) at 42°C one hour, and at 65°C 10 min. The cDNA obtained was stored at -20°C until PCR analysis.

FoxP3 and glucuronidase (GUS) as a housekeeping gene were analyzed by quantitative real time PCR performed with the Light Cycler Fast Start DNA Sybr green kit (Roche). FoxP3 and GUS primers and PCR conditions are described in<sup>[26]</sup> and<sup>[27]</sup> respectively. Reverse 3'primer are designed to span contiguous exons in order not to anneal to contaminating genomic DNA. To control for specificity of the amplification products, a melting curve analysis was performed and no unspecific products were observed. A standard curve of cDNA from CD4 cells from a donor with a high expression of FoxP3 was used. Arbitrary units were assigned to each dilution of cDNA. Relative FoxP3 expression values were calculated dividing the arbitrary units of Fox P3 by the GUS results in order to normalized RNA input. The result is expressed in % ratio.

TGF-β1 and human-glucuronyl-6-phosphatase dehydrogenase (h-G6PDH) as a housekeeping gene were analyzed by quantitative real time PCR performed with Light Cycler Fast Start DNA hybridization probes kit (Roche). Primers and probes specific to TGF-β1 isoform were: Forward: exon 6: 5'-ggCTggAAgTggATCCACgA-3' Reverse: 5'-gCaggAgCgCACGATCATgTT-3'; Probes: 5'-CTgCCCCTACATTTggAgCCTggAC-F-3' 5'-LCRed640-gCagTACAgCCA gCagTACAgCAAaggTCCTggCCCT-P-3'. Reverse 3'primer is designed to span contiguous exons in order not to anneal to contaminating genomic DNA. PCR conditions for both gene amplification were: 45 cycles of 3 segments: 95°C 10 s; 58°C 15 s and 72°C 15 s. A melting curve analysis was performed and no unspecific products were observed The copy number of TGF-β1 gene was calculated from a standard curve of a plasmid with the TGF-β1 PCR fragment cloned in the laboratory and h-G6PDH copies were determined with

## RESULTS

### Increase in peripheral Treg in patients with IBD who showed a favorable response to GMA

Regulatory T cells are usually identified by flow cytometry as CD4+ T cells expressing high level of the IL2-R α chain (CD25) at their surface (Figure 1). By using this criterion we found higher frequencies in samples obtained at the end of the GMA-apheresis sessions in three of five patients with IBD that responded favorably to the therapy, but a lower frequency in the one who failed to respond to this treatment. To exclude that changes in the frequency of Tregs reflect nonspecific effects of the therapy on other CD4+ T cell subsets, we also calculated the ratio CD4+ CD25<sup>high</sup> to CD4+ CD25<sup>low-int</sup> and compared the data in each individual case; higher ratio was found in one case, lower ratio in another, and no variation in the remaining four cases. Thus, a selective expansion of true Treg cells in the peripheral blood of treated patients could not be demonstrated. Human CD4+ CD25<sup>high</sup> Treg population is

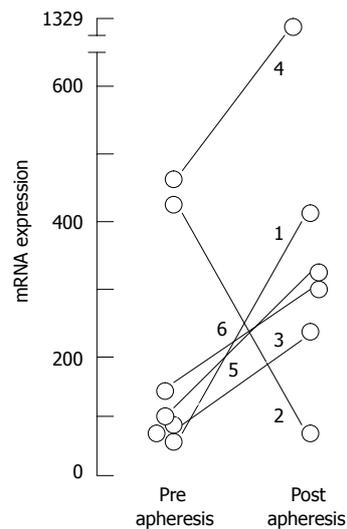

**Figure 1** Variation of peripheral blood CD4+ CD25+ cells in patients treated by GMA-apheresis. **A:** Representative cytogram; **B:** Variation of T regs on each individual patient; **C:** Variation in the ratio CD4+ CD25<sup>high</sup>/CD4+ CD25<sup>low-int</sup>.

relatively indiscreet; the border line between CD25<sup>high</sup> and CD25<sup>low</sup> is often obscure, making it difficult determining the cellular subsets. Even carefully selected CD4+ CD25+ T cell clones do not represent a homogenous population of functional suppressor cells<sup>[28]</sup>. This fact may explain the differences in normal ranges described in the literature but it seems unlikely that its concerns the variations observed in this study.

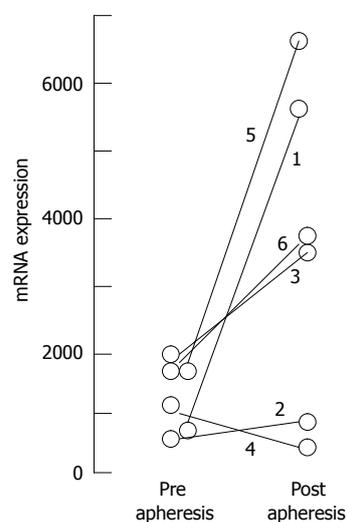

Clearer results were found by quantification of mRNA for FoxP3 expressed in purified CD4+ T cells by real time PCR. In contrast to most phenotypic markers of Tregs, the expression of FoxP3 seems to be crucial for their functional characteristics<sup>[29]</sup>. All five patients which showed successful response to Adacolumn therapy displayed increased levels of FoxP3 mRNA in blood CD4+ T cells after the GMA treatment, whereas diminished levels of FoxP3 transcripts were found in the one that did not respond to this therapy (Figure 2).

**TGF-β expression in CD4+ T cells does not change after GMA**

Next, we analyzed the expression of TGF-β in CD4+ T cells from GMA- treated patients and observed increased

**Figure 2** Variation of mRNA expression for FoxP3 in CD4+ T cells in matched samples from 6 patients treated by GMA-apheresis: Quantitative PCR was performed as described in methods; Results are expressed as FoxP3 expression relative to GUS expression per cent.

**Figure 3** Variation of mRNA expression for TGF-beta in CD4+ T cells in matched samples from 6 patients treated by GMA-apheresis: Quantitative PCR was performed as described in methods; Results are expressed as TGF-beta 1 expression relative to GAPDH expression per cent.

expression of TGF-β in post apheresis samples in four cases but this variation was not parallel to that observed for FoxP3 expression. The remaining two cases did not show variations in TGF-β and have had a different clinical response to GMA-apheresis (Figure 3).

**Adacolumn therapy was successfully applied to healing cutaneous lesions related to inflammatory bowel disease**

Both two patients with Crohn’s disease had severe cutaneous lesions that improved with the Adacolumn’s therapy; Figure 4 shows the complete healing of pyoderma gangrenosum, unsuccessfully treated with steroids, after 13 sessions with GMA-apheresis. A successful response to GMA-apheresis was also observed in the case of erythematous nodosum associated with CD that was unsuccessfully treated with steroids and infliximab anti-TNF-α therapy. The effect of apheresis was transient as the cutaneous lesions recurred four months after the interruption of therapy and remitted with a new cycle of GMA-apheresis sessions.

**DISCUSSION**

A current view is that a disregulated immunity in

**Figure 4** Improvement of pyoderma gangrenosum in a patient with Crohn's disease treated by GMA-apheresis: pictures A-D, were taken at 1, 5, 8, and 13 apheresis sessions.

intestinal mucosa plays a pivotal role in the pathogenesis of IBD and that intestinal inflammation is perpetuated by inflammatory cytokines like IL-1 $\beta$ , TNF- $\alpha$ , IL6 and others<sup>[30]</sup>. Based on this perception, anti cytokine antibodies, notably anti TNF (infliximab) have been added to the conventional anti inflammatory drugs. Steroids, 5-aminosalicylic or sulphasalazine in combination with azathioprine and nutritional support for some patients are used as first-line medication for IBD. However, treatment failure has often been an indication for colostomy in steroid-refractory patients<sup>[31]</sup> and biologicals are dampened by serious concerns about their long-term efficacy and safety profiles<sup>[32,33]</sup>. The underlying rationale for GMA-apheresis is the fact that granulocytes and monocytes/macrophages (GMs) are a major source of inflammatory cytokines<sup>[34]</sup> and that selective removal of these cells, otherwise destined for migration to the intestine, reduce the intestinal inflammation. GMs removal is made by their adhesion to carrier beads through Fc $\gamma$ R and complement receptors, but it is reported that Adacolumn increases peripheral blood lymphocytes, sparing prevailing cells and inducing an increase in *de novo* lymphocytes<sup>[35]</sup>, largely attributable to an increase in CD4+ T cells. These changes on blood lymphocytes were also observed in our patients (data not shown). It is noteworthy that a low lymphocyte count has been associated with relapse of CD<sup>[36]</sup>.

A selective increase of peripheral CD4+ Treg cells in patients treated with GMA has been suggested<sup>[37]</sup> and our results strongly support this opinion. We have observed higher frequency of Tregs and increased expression for FoxP3 mRNA in the blood of IBD patients treated with Adacolumn except in the one that did not respond to the

therapy. Quantitative data showed expression differences in matched samples of purified CD4 T cells, obtained before and after a series of GMA. We think that these results contribute to enlighten the picture hence there is no published data at this time.

The position of GMA-apheresis in the medical therapy of ulcerative colitis has been recently reviewed<sup>[38]</sup>. According to the expressed opinion patients at any stage of their disease might benefit from this therapy and can avoid steroids and other drug based medications. In patients with steroid dependent UC up to 85% show efficacy with an excellent safety profile. Five from our six patients with active and severe IBD responded to GMA-apheresis therapy and the one that did not respond showed a further favorable response to the infliximab. Pyoderma gangrenosum (PG) is a chronic ulcerating skin condition that appears to be immune mediated, and approximately 30% of cases occur in association with IBD<sup>[39]</sup>. The mainstay treatment remains immunosuppression with corticosteroids and cyclosporine, and there is a number of reports of PG responding to anti TNF- $\alpha$  therapy<sup>[39]</sup>. We report the beneficial effect of GMA-apheresis therapy in a case of PG and a case of erythema nodosum, both associated with CD that did not respond to other therapies.

Thus, many patients with IBD likely benefit from GMA-apheresis therapy, potentially by an increase in frequency and function of CD4 Tregs that takes place in the action mechanism(s) of this procedure. The small number of patients in our study precludes to take out any statistical conclusion about this point but, independently of defining the actual mechanism of GMA-apheresis in IBD therapy, our results suggest that quantification of

FoxP3 mRNA expressed in CD4 T cells of treated patients may be used as a valuable index of remission in IBD and perhaps in other chronic relapsing-remitting inflammatory conditions susceptible of this kind of therapy. If that were proved on a large series of GMA-treated patients, it could be helpful to predict the response to GMA and to support the rational use of this high-cost therapy. We also point out the fact that the patient that did not respond to GMA did respond to infliximab, and conversely, those which responded to GMA did not respond to other therapies. Thus, a tailor's patient therapy could be considered in a future and good analytical criteria of response will be welcome.

## COMMENTS

### Background

Granulocyte/monocyte apheresis with Adacolumn seems to offer a safe and efficacious adjuvant treatment option in inflammatory bowel disease (IBD), rheumatoid arthritis and maybe in other inflammatory conditions, but the clinical efficacy cannot be explained by selective removal of these cells. Regulatory T cells play a major role in control of autoimmune diseases, and the FoxP3 transcription factor is specifically expressed in these cells and is crucial for their functional characteristics. Dysfunction of T regs it is suggested in patients with IBD and demonstrated in animal models of these pathologies

### Innovations and breakthroughs

We report that the clinical efficacy of adsorptive cytopheresis in the treatment of inflammatory colitis is associated to an expansion of circulating T reg and increased expression of FoxP3. If that were proved in a large series of treated patients it could be helpful to make a valuable index of remission and to predict the response to this therapy.

### Applications

All the findings of our study will provide a useful way for the treatment of inflammatory colitis.

### Peer review

This is an interesting study. Authors showed that GMA induces increase of Treg and exerts anti-inflammatory response in IBD patients.

### Abstract

**AIM:** To investigate a possible increase of basolateral expression of carcinoembryonic antigen (CEA) by interfering with the apical transport machinery, we studied the effect of cholesterol depletion on CEA sorting and secretion.

**METHODS:** Cholesterol depletion was performed in polarized Caco-2 cells using lovastatin and methyl- $\beta$ -cyclodextrin.

**RESULTS:** We show that CEA is predominantly expressed and secreted at the apical surface. Reduction of the cholesterol level of the cell by 40%-50% with lovastatin and methyl- $\beta$ -cyclodextrin led to a significant change of the apical-to-basolateral transport ratio towards the basolateral membrane.

**CONCLUSION:** As basolateral expression of CEA has been suggested to have anti-inflammatory properties, Cholesterol depletion of enterocytes might be a potential approach to influence the course of inflammatory bowel disease.

**Key words:** Inflammatory bowel disease; Cholesterol; Polarized secretion; Carcinoembryonic antigen; Caco-2

### INTRODUCTION

Carcinoembryonic antigen (CEA, also named CEACAM5, gp180 or CD66e) is a 180 kDa glycoprotein that belongs to a subfamily of the immunoglobulin superfamily. In the intestine, CEA is mainly localized at the apical membrane of the goblet cells and colonic enterocytes<sup>[1]</sup>. Although CEA has been used extensively as a tumor marker for colon carcinoma, its physiological function remains unclear. The induction of CEA by cytokines<sup>[2,3]</sup>, its *in vitro* cell-cell adhesion properties<sup>[4]</sup> and its inhibitory effect on natural killer cells<sup>[5]</sup> have suggested a significant role on immune function. It has been shown that apically expressed CEA can bind to several microorganisms like *E.coli*, *Salmonella*, *Neisseria* or *Haemophilus*, and possibly function as a sensor to trigger or prevent bacterial infection<sup>[6-10]</sup>. On the other hand, basolateral expression of CEA has been shown to act as a CD8 ligand that is involved in the activation of suppressor T cells<sup>[11]</sup>. Interestingly, patients with inflammatory bowel disease (IBD) show a significantly reduced expression of CEA regardless of the activity of the disease<sup>[12,13]</sup>. Therefore, it has been suggested, that reduced expression of CEA may be an inherited defect in IBD<sup>[13]</sup>. Immunohistochemical staining of CEA in intestinal tissues has shown that in normal mucosa, CEA is located predominately at the apical, but possibly also at the basolateral membrane of the enterocytes. These findings are different in IBD patients. There is loss of staining in the basolateral membrane in ulcerative colitis and reduction of both api-

cal and basolateral staining in patients with Crohn's disease<sup>[13]</sup>. CEA is attached to the outer leaflet of the plasma membrane by a glycosylphosphatidylinositol (GPI) anchor. GPI anchored proteins have been shown to use the GPI anchors as a sorting determinant for apical delivery<sup>[14]</sup>. They are sorted by a lipid raft dependent mechanism. Depletion of cholesterol from Madin-Darby canine kidney cells (MDCK cells) results in misrouting of the proteins to the basolateral compartment<sup>[15,16]</sup>.

The putative activity of CEA at the apical and basolateral membranes prompted us to examine the impact of sorting of CEA in a polarized colonic cell line. This maneuver would shift its function from a molecule that binds and possibly promotes bacterial infection and inflammation to a molecule that may activate suppressor T cells and reduce the inflammatory response. In the present study, we were able to show that sorting of CEA to the apical and basolateral membranes can be altered by modifying the cholesterol content of the cell.

## MATERIALS AND METHODS

### Cells

Caco-2 cells were gifted by Professor Fricker, Institute for Molecular Biotechnology, University of Heidelberg. Caco-2 cells were cultured at 37°C in DMEM, supplemented with 10% FCS, 1% non essential amino acid solution, 1% sodium pyruvate, 100 U/mL penicillin, 100 µg/mL streptomycin and 2 mmol/L L-glutamine (Invitrogen, USA) and grown to achieve polarization for 14 d on 2.5 cm, 0.4 µm pore size Transwell polycarbonate filters (Costar, Cambridge, USA). The formation of an intact, confluent monolayer was monitored by measuring the transepithelial electrical resistance (TEER) and in representative experiments by detecting the unidirectional flux of inulin. Cell monolayers in Transwells were incubated in the presence of 3.6 mmol/L [3H]-inulin (NEN) in the basal well and 10 mmol/L methyl-β-cyclodextrin (MβCD, Sigma, USA) for 30-60 min. Two hours after MβCD treatment, radioactivity of the apical medium and of the basal medium were measured as described below using a Beckman LS6000 Scintillation Counter (Beckman, USA). The flux into the apical well was calculated as the percent of total inulin administered into the basal well. The same quantity of cells were used for the corresponding experiments.

### Cholesterol depletion, pulse/chase experiments

For the cholesterol depletion study, the cells were grown for 1 d in either DMEM supplemented with 2 mmol/L L-glutamine, 10% FCS, 2 µmol/L lovastatin (Calbiochem, USA), and 0.25 mmol/L mevalonate or in complete medium. The following day, the cells were treated for 30-60 min with 10 mmol/L MβCD in methionine-free medium (labeling medium), and subsequently metabolically labeled with 100 µCi/dish of [35S]-methionine (NEN). The cells were chased for 2 h in labeling medium containing an excess of 150 µg/mL methionine and 20 µg/mL cycloheximide in order to inhibit protein synthesis. Cholesterol determinations were performed using the Amplex Red Cholesterol Assay kit (Molecular Probes). Proteins from the apical and basolateral medium were precipitated with

trichloroacetic acid and radioactivity from the precipitate was quantified in 5 mL of Ultima Gold<sup>TM</sup> liquid scintillation fluid (Packard Bioscience) using a Beckman LS6000 Scintillation Counter (Beckman Instruments).

### Western blot analysis, CEA quantification

Media from the apical and basolateral chamber were separated on 10% polyacrylamide gel<sup>[17]</sup>, and proteins were transferred to a nitrocellulose membrane. The blot was probed with polyclonal CEA antibody (1:300, A0115, Dako, USA), and protein visualized using an HRP-conjugated secondary antibody and an enhanced chemiluminescence detection kit (Amersham, USA). CEA was quantified using an electrochemoluminescence immunoassay (ECLIA) from Roche Diagnostics that specifically recognizes CEA and not other CEA-like proteins.

### Immunofluorescence

Filter grown Caco-2 cells were treated with lovastatin/mevalonate and MβCD as described above. The cells were fixed for 10 min with 4% PFA at 8°C followed by incubation with 0.1% Triton X-100. The fixed cells were incubated for 1 h at room temperature with the polyclonal antibody against CEA (1:200, Dako) or the monoclonal antibody against Na<sup>+</sup>/K<sup>+</sup>-ATPase (1:100, Affinity BioReagents, Golden, USA) in PBS containing 0.2% gelatine. After three washes with PBS containing 0.2% gelatine, the cells were incubated with the respective Cy3- or Cy2-labeled secondary antibodies (1:600 and 1:100, respectively) in PBS containing 0.2% gelatine for 1 h at room temperature. Confocal image acquisition were done on a Leica TCS SP2 system and pictures arranged with Adobe Photoshop.

### Preparation of detergent resistant membranes (DRMs)

Detergent extraction with Triton X-100 was performed as described<sup>[18,19]</sup>. The cells were grown on filters, washed once with PBS and scraped on ice into 300 µL 25 mmol/L Tris-HCl, pH 7.4, 150 mmol/L NaCl, 3 mmol/L EDTA (TNE) buffer containing 25 g/mL each of chymostatin, leupeptin, antipain and pepstatin A. The cells were homogenized through a 25 G needle and centrifuged for 5 min at 3000 r/min. The postnuclear supernatant was subjected to extraction for 30 min at 4°C in 2% Triton X-100/TNE. The extracts were adjusted to 40% OptiPrep (Nycomed, Oslo) and overlaid in a TLS 55 centrifugation tube with 30% OptiPrep/TNE, and TNE. After centrifugation for 2 h at 55000 r/min, six fractions were collected from the top, and Western blots were performed.

### Statistical analysis

All values are reported as mean and standard error of the mean (mean ± SE). The Kruskal-Wallis test was used to test for statistical significance. Probability values of  $P < 0.05$  were set as threshold for statistical significance.

## RESULTS

### Depletion of cholesterol from polarized Caco-2 cells

Cholesterol depletion was achieved by a combination of lovastatin/mevalonate treatment and MβCD extraction<sup>[19]</sup>. Lovastatin decreases the de-novo synthesis of cholesterol

in the ER by inhibiting HMG-CoA reductase. Mevalonate is used to allow the synthesis of nonsterol products from mevalonate. This is necessary to reduce the toxicity of lovastatin treatment given alone<sup>[16,20]</sup>. M $\beta$ CD has been shown to selectively extract cholesterol from the plasma membrane, in preference to other lipids<sup>[21]</sup>. Caco-2 cells were grown for 24 h in the presence of lovastatin/mevalonate, and immediately prior to metabolic labeling were treated with 10 mmol/L M $\beta$ CD for a maximum 60 min. The extent of cholesterol extraction was monitored using the fluorimetric test. Lovastatin treatment alone resulted in about 10% reduction. The addition of M $\beta$ CD reduced the total cellular cholesterol levels to about 43% of the levels in the control cells (Figure 1A). Increasing the time of exposure or the concentration of M $\beta$ CD, and prolonged treatment with lovastatin had a deleterious affect on cell viability.

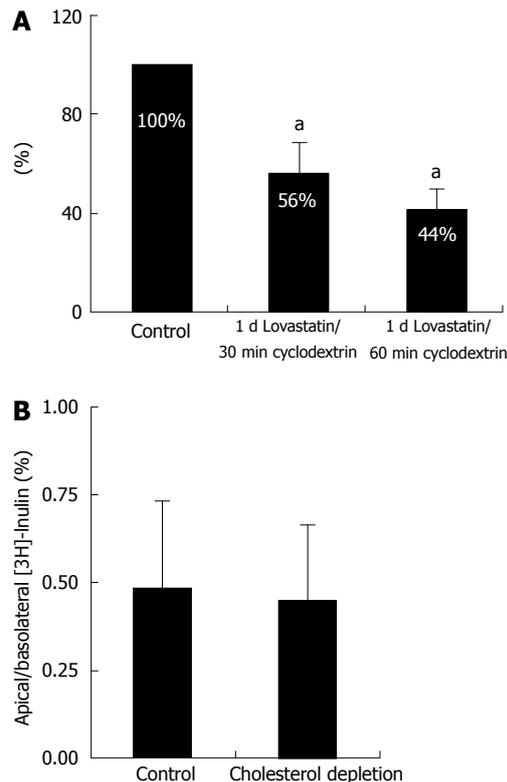

The following experiments were performed 30 min after treatment with 10 mmol/L M $\beta$ CD. In order to determine that the cholesterol depleted Caco-2 cells were still fully polarized, the permeability of the commonly used paracellular marker [3H]-inulin was analyzed<sup>[22]</sup>. Only small amounts of [3H]-inulin are able to move across polarized monolayers unless the tight junctions are altered or cell injury occurs<sup>[23]</sup>. In representative experiments, no increased translocation from basal to apical location was observed after cholesterol depletion (Figure 1B). TEER was measured before and after cholesterol removal. In representative experiments again, there was no significant difference between cholesterol depleted and non-depleted cells ( $99.0 \pm 8.1 \Omega/\text{cm}^2$  vs  $106.9 \pm 9.8 \Omega/\text{cm}^2$ ; mean and SEM of 3 representative experiments). In addition, polarization was controlled by immunofluorescence of filter grown Caco-2 cells, analyzing the basolateral distribution of Na<sup>+</sup>/K<sup>+</sup>-ATPase. The distribution of this protein did not change after cholesterol extraction.

#### **Effect of cholesterol on the overall transport capacity of newly synthesized proteins in the direction of the apical plasma membrane**

To obtain a quantitative assessment of the effect of cholesterol depletion on apical and basolateral protein secretion and to analyze the role of cholesterol in the sorting of newly synthesized proteins in general, pulse/chase experiments were performed. Caco-2 cells were metabolically labeled for 1 h and the total counts of labeled proteins secreted within 2 h into the apical and basolateral medium were analyzed. The chase period was performed in the presence of cycloheximide to inhibit further protein synthesis. In non-depleted cells, the total secreted radioactivity in the apical chamber was  $11.1\% \pm 3.4\%$ . After cholesterol depletion, apical secretion was reduced to  $4.7\% \pm 1.1\%$ . This change was not due to a decrease in protein secretion in general. Whereas cholesterol depletion reduced apical secretion by 35%, at the same time, the basolateral secretion increased by 39% (Figure 2).

#### **Effect of cholesterol depletion on polarized CEA secretion.**

Under normal cell culture conditions, CEA family proteins are sorted predominately to the apical membrane. In polarized Caco-2 cells, there was no significant staining of

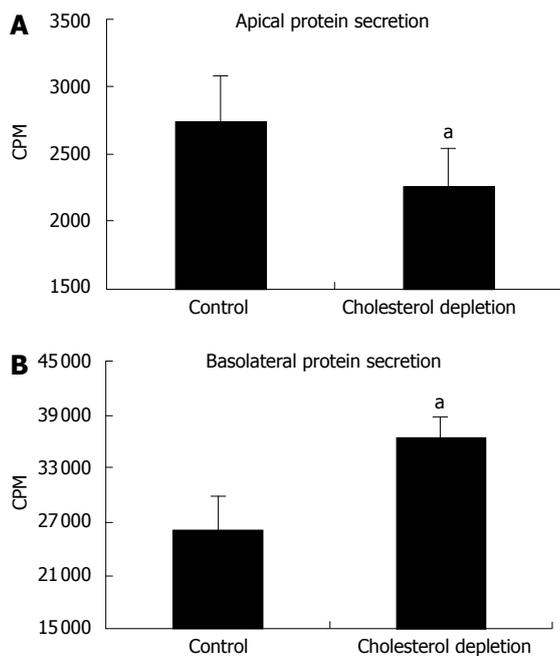

**Figure 1** Cholesterol can be depleted from Caco-2 cells by a combination of lovastatin and M $\beta$ CD. Cells were grown for 1d in the presence of lovastatin/mevalonate and then treated for 30-60 min with 10 mmol/L M $\beta$ CD. **A:** Depending on the time of M $\beta$ CD extraction, the total cellular cholesterol levels could be reduced by about 60%. Exposure for 30min with 10 mmol/L M $\beta$ CD (2nd bar) was used for the following experiments. The cholesterol level was arbitrarily set to 100% in control cells. An asterisk indicates significant differences ( $56.3\% \pm 17.1\%$  vs 100% and  $46.3\% \pm 17.1\%$  vs 100%, both  $^*P < 0.05$ ); **B:** [3H]-inulin permeability did not change after cholesterol depletion ( $P > 0.05$ ).

CEA at the basolateral membrane (Figure 3A). In addition, no significant basolateral secretion of CEA could be measured by Western blot analyses. However, in cholesterol depleted cells, there was significant secretion of CEA from the basolateral membrane (Figure 3B). Immunofluorescent analyses of CEA in cholesterol depleted cells revealed still an apical staining of CEA, however the fluorescent band was much weaker than in the control cells, and no basolateral staining was detected. We believe that cleavage of CEA at the basolateral side may explain the difference between the staining and the amount of CEA present in the basolateral medium. Quantification of secreted CEA within 2 h after cholesterol depletion using a CEA specific electrochemoluminescence immunoassay revealed that apical secretion was reduced by  $39\% \pm 15\%$  (Figure 3C). In non-depleted cells, no significant secretion of CEA was detected in the basolateral medium after 2 h (i.e., still below the detection level), whereas in depleted cells a concentration of  $0.26 \pm 0.06 \mu\text{g/L}$  was obtained.

#### **Effect of cholesterol depletion on association of CEA to DRMs**

One way to analyze if a protein is found is to isolate DRMs. Association of a protein with DRMs is shown by its insolubility in detergents such as Triton X-100<sup>[24]</sup>, which leads to floatation to low densities in sucrose or OptiPrep

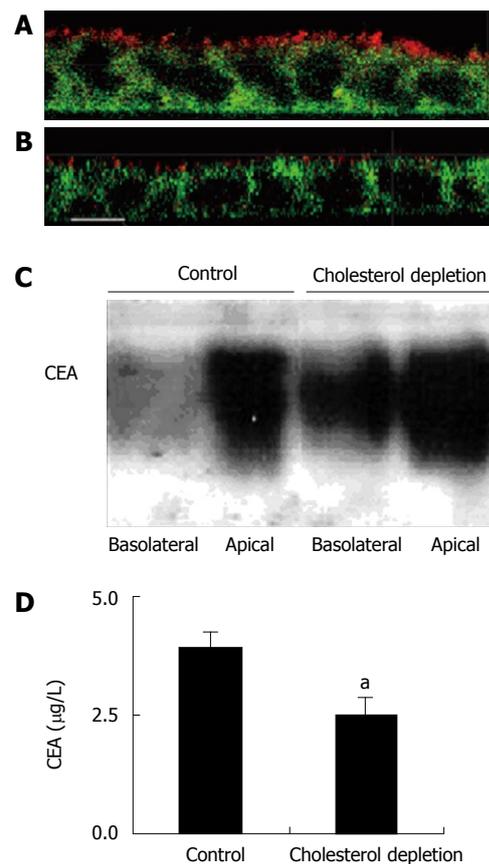

**Figure 2** Effect of cholesterol depletion on polarized protein secretion. Filter-grown Caco-2 cells were pulsed for 1 h with [<sup>35</sup>S]-methionine and the secretion of labeled proteins within 2 h was quantified using a scintillation counter. The total radioactivity of protein precipitates was (A) reduced in the apical medium of cholesterol depleted cells and (B) increased in the basolateral medium. An asterisk indicates significant differences ( $2736.6 \pm 352.7$  vs  $2257.6 \pm 282.4$  and  $28893.2 \pm 3523.1$  vs  $38256.0 \pm 2555.3$ ,  $^*P < 0.05$ ).

gradients. After isolation of cellular membranes our experiments revealed that CEA is found in two membrane compartments within DRMs as well as in detergent soluble parts. Cholesterol depletion reduced significantly the association of CEA with DRMs (Figure 4).

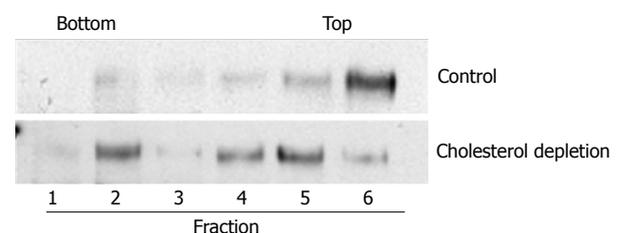

## DISCUSSION

The present data shows that the transport and secretion of CEA to either the apical or the basolateral membrane of polarized Caco-2 cells can be influenced by changing the cholesterol level of the cells. Under normal cell culture conditions, CEA is predominantly sorted and partially released at the apical membrane. Cholesterol depletion results in a significant shift to basolateral secretion.

These findings are in line with previous reports by Keller *et al* and Prydz *et al* who used the model of polarized MDCK<sup>[15,16]</sup>. These workers showed that the overall transport capacity in the direction of the apical membrane is reduced and that the sorting of proteins with a high affinity for lipid rafts is influenced by cholesterol depletion. Therefore, these workers suggested the presence of two constitutive exit routes from the TGN towards the plasma membrane in polarized cells: An apical route, which is lipid raft-dependent, and a raft-independent basolateral route<sup>[15,16]</sup>. Lipid rafts are small platforms, composed of sphingolipids and cholesterol in the outer exoplasmic leaflet, connected to phospholipids and cholesterol in the inner cytoplasmic leaflet of the cellular membranes. In mammalian cells, these are first assembled at the Golgi complex. From there, they move to the plasma membrane and spread into the endocytic pathway. Cholesterol is

**Figure 3** The effect of cholesterol depletion on apical and basolateral secretion of CEA. **A, B:** X-Z confocal views of cells labeled with antibodies directed against CEA (red) and Na<sup>+</sup>/K<sup>+</sup>-ATPase (green). In non-depleted cells under steady state conditions, CEA family proteins are expressed at the apical surface (A). Caco-2 cells were grown to confluency on polycarbonate filters for 14 d and cholesterol-depleted with a combination of lovastatin/MβCD. After cholesterol depletion, CEA was still apical but with a lower expression level (B) but no basolateral staining of CEA was detected (Bar 10 µm). **C:** Media from apical and basolateral chamber were collected for 2 h and Western blots performed. In non-depleted cells, most of the CEA is secreted into the apical medium. In cholesterol depleted cells, a significant amount was also found in the basolateral medium. **D:** Quantification of apical CEA secretion using an ECLISA from Roche. Six similar experiments were performed. An asterisk indicates significant differences ( $3.12 \pm 0.62$  vs  $1.91 \pm 0.81$ ,  $^*P < 0.05$ ).

**Figure 4** Cholesterol depletion reduces association of CEA with DRMs. Filter grown Caco-2 cells with or without treatment with a combination of lovastatin/MβCD were extracted on ice with 2% Triton X-100. After flotation in an OptiPrep step-gradient, fractions were collected and Western blots performed. Cholesterol depletion shifted CEA from the top (raft fractions) to the bottom fractions (non raft fractions).

believed to serve as a spacer between the hydrocarbon chains of the sphingolipids and to function as a dynamic glue that keeps the raft assembly together. Removal of raft cholesterol, leads to the disassociation of lipid rafts and affects its putative functions<sup>[24]</sup>. Under normal cell culture

conditions, the majority of raft proteins are found at the apical membrane where in the presence of cholesterol depletion, these proteins are missorted to the basolateral membrane<sup>[16]</sup>. Typical raft proteins are doubly acylated such as tyrosine kinases of the Src family, cholesterol-linked and palmitate-anchored proteins like hedgehog and GPI-anchored proteins to which CEA belongs<sup>[24]</sup>. Therefore, under normal cell culture conditions, most of the CEA is sorted to the apical membrane and secreted into the apical medium (Figure 3). This picture changes following cholesterol depletion. CEA is sorted and secreted in the basolateral membrane, suggesting that it is no longer associated with lipid rafts. Our results on DRM association support this hypothesis (Figure 4). However, lowering the cholesterol levels is not only a specific treatment to influence lipid raft function, but it also has an impact on several other cellular processes such as lipid metabolism, endocytosis and enzyme activity<sup>[25,26]</sup>. CEA release from the membrane is dependent upon the action of phospholipase D. It has been shown recently that its activity is increased after removal of cholesterol<sup>[27]</sup>. How this phenomenon impacts the polarized secretion of CEA under low cholesterol conditions needs further evaluation.

Influencing the sorting of CEA may be relevant, since the compartmentation of the protein may have distinct functions. Whereas its apical expression may serve to bind mucus and microorganisms<sup>[6-9]</sup>, its basolateral expression influences the activation of anti-inflammatory suppressor T-cells that is important in controlling the inflammatory response of the gut<sup>[28]</sup>. Therefore, an increased basolateral expression of CEA may be beneficial in the clinical course of IBD. IBD is thought to be the result of an uncontrolled intestinal inflammatory response. While the exact pathogenesis of the disease is not understood, it is likely that both the immune system as well as luminal agents (e.g. ingested nutrients or microbial agents) are important. Therefore, factors that are critical in permitting signals from the lumen to the mucosal immune systems may be important targets for therapy. It has been shown that intestinal epithelial cells from patients with IBD have reduced ability to activate suppressor T-cells and this correlates with the level of expression of CEA<sup>[13]</sup>. It is interesting to note that whereas in normal intestinal tissue faint basolateral staining of CEA is detected, in patients with ulcerative colitis the basolateral staining is lost<sup>[13]</sup>. Therefore, it is intriguing to speculate that cholesterol depletion of enterocytes in these patients may enhance the basolateral expression and therefore increase the reduced ability to activate CD8+ T-cells.

One therapeutic approach that has already been used in clinical studies in IBD is to alter the lipid composition of the cellular membranes. Lipid-based therapies such as the use of fish oil and phospholipids have been found to be successful<sup>[29,30]</sup>. In addition, animal experiments employing ganglioside enriched diets and short chain fatty acids have shown reduction in intestinal inflammation<sup>[31,32]</sup>. Interestingly, reducing cholesterol by systemic inhibition of HMG-CoA with pravastatin has also been found to reduce inflammation of DDS-induced colitis in rats<sup>[33]</sup>. The authors noted that the effect of pravastatin was due to a decrease in the activity and expression of endothelial nitric-

oxide synthase (eNOS). Emerging data suggests, that even small changes in cellular cholesterol levels is successful in influencing lipid raft processes<sup>[24,34]</sup>. However, whether different compartmentation of apical and basolateral expressed proteins may, in part, have contributed to the positive effect of statins, remains speculative. Therefore, whether the lipid based therapeutic approach in IBD should include reduction in the cholesterol content of enterocytes, remains an open question. Further studies are needed to determine the clinical significance of our findings.

## ACKNOWLEDGMENTS

We thank Sabine Tuma for help with the cell culture.

## COMMENTS

### Background

Carcinoembryonic antigen (CEA) is a GPI-anchored glycoprotein that is believed to have distinct functions depending upon its expression at the apical or basolateral plasma membrane. Whereas it is possible to interact with bacteria with the apical location, basolateral expression may be involved in the activation of suppressor T-cells and thus have an anti-inflammatory effect. A reduced expression at the basolateral compartment has been implicated in the pathogenesis of inflammatory bowel disease (IBD). Thus influencing the apical to basolateral transport ratio may be a potential tool in the treatment of IBD.

### Research frontiers

Sorting of proteins to the apical or basolateral membrane is a precisely regulated mechanism. One part of this sorting is regulated by the dynamic interaction of protein with lipid rafts. Influencing lipid raft dependent mechanisms by changing the lipid content of cells may provide a new therapeutic approach to human diseases.

### Innovations and breakthroughs

Apical sorting of CEA is cholesterol and presumably lipid raft dependent. After cholesterol depletion, basolateral sorting is increased, thus increasing the presumed basolateral anti-inflammatory properties. These results are in line with previous reports on apical sorting of lipid raft associated proteins.

### Applications

Local depletion of cholesterol from the luminal side of the gut may be a therapeutic approach for inflammatory intestinal disorders. This can possibly be integrated in a lipid based approach in the treatment of IBD, as previously shown with the use of phospholipids and omega-3 fatty acids.

### Peer review

The manuscript is very innovative. Changing the intracellular transport of a protein towards an anti-inflammatory route is interesting. However, the clinical relevance remains unclear.

### Abstract

**AIM:** To estimate the prevalence of colorectal cancer (CRC) in patients with long lasting colonic symptoms undergoing total colonoscopy; and to establish clinical features predicting its occurrence.

**METHODS:** This prospective study was carried out in Imam Hospital, Tabriz University of medical sciences, Iran. Continuous patients with long lasting lower gastrointestinal tract symptoms who had the criteria of a colonoscopy were included. The endoscopist visualized the caecum documented by a photo and/or a specimen from terminal ileum.

**RESULTS:** Four hundred and eighty consecutive symptomatic patients [mean age (SD): 42.73 (16.21)] were included. The prevalence of colorectal neoplasia was 15.3% (34 subjects) and 37.7% (181 subjects) had a completely normal colon. Adenomatous polyps were detected in 56 (11.7%) patients, in 12.3% of men and 10.9% of women. The mean age of the patients with a polyp was significantly higher than the others ( $49.53 \pm 14.16$  vs  $41.85 \pm 16.26$ ,  $P = 0.001$ ). Most of the adenomatous polyps were left sided and tubular; only 22.5% of polyps were more than 10 mm. Cancer was detected in 16 (3.6%) of our study population, which was mostly right sided (57.2%). The mean age of patients with cancer was significantly higher than the others ( $60.25 \pm 8.26$  vs  $42.13 \pm 16.08$ ,  $P < 0.005$ ) and higher than patients with polyps [ $60.25$  (8.26) vs  $49.53$  (1.91) ( $P < 0.0005$ )]. None of the symptoms (diarrhea, abdominal pain, rectal bleeding, constipation, altering diarrhea and constipation, history of cancer, known irritable bowel disease, history of polyp and fissure or family history of cancer) were predictors for cancer or polyps, but the age of the patient and unexplained

anemia independently predicted cancer.

**CONCLUSION:** Less advanced patterns and smaller sizes of adenomas in Iran is compatible with other data from Asia and the Middle East, but in contrast to western countries. Prevalence of colonic neoplasia in our community seems to be lower than that in western population. Colonic symptoms are not predictors for polyps or cancer but unexplained anemia and elder age can predict CRC.

### INTRODUCTION

Colorectal cancer (CRC) is a common cancer especially in industrial countries<sup>[1]</sup>. The disease is related to a high mortality, morbidity and cost. It usually arises over several years from adenomas that undergo a series of specific genetic perturbations<sup>[1]</sup> and therefore is a preventable disease when diagnosed early<sup>[2]</sup> and treated.

Epidemiological studies of different nations and migrated populations strongly support the role of environmental factors as a reason for colorectal cancer such as dietary regimen<sup>[3]</sup>. Its incidence is reported to be 35%-60% in US<sup>[4]</sup> which is very close to European countries<sup>[5]</sup>.

It has been considered to be less common among Asians and Caucasians<sup>[6,7]</sup>. However, recent studies have shown an increasing trend in these populations<sup>[8-10]</sup>.

Variation in the incidence of colorectal neoplasia has been observed in populations and even in cities of one country. In 1997 autopsy studies from Iran have reported the incidence of colorectal polyps to be 1.6%<sup>[11]</sup>. Recent

increases in the incidence of CRC have been reported from cancer registry centers in our country as well<sup>[12]</sup>, but there is a lack of published prospective studies about endoscopic evaluation of CRC epidemiology in Iran. Therefore, we felt a genuine need to understand and to define better the characteristics of the in our local population; while our clinical evidence supports lower incidence of CRC compared to western countries.

Screening asymptomatic patients is the most common manner of detecting colorectal polyps in western countries, while most CRC cases are still detected once evaluating clinical symptoms<sup>[13]</sup>. However most asymptomatic people do not accept a colonoscopy yet.

To find out epidemiological variations between Iranians compared with western populations, we carried out a study in symptomatic patients undergoing colonoscopy; investigating whether their symptoms were related to the chance of having a polyp or cancer.

## MATERIALS AND METHODS

This prospective study was carried out in Imam Hospital, Tabriz University of medical sciences, Iran. Four hundred and eighty consecutive participants who visited the same gastroenterologist (17 years experience) because of unexplained lower gastrointestinal tract symptoms for more than 3 mo and underwent total colonoscopy between May 2005 and April 2007 were studied.

The endoscopist visualized the caecum in all subjects, documented by a photo of caecum and/or specimen of terminal ileum. Withdrawal time was 10-20 min. There was no significant morbidity associated with colonoscopy. A few patients were excluded as a result of failure to reach the caecum (because of poor preparation or technical problems) or because they were referred for polypectomy. A biopsy was performed in patients with an infiltrative lesion and/or polyp smaller than 5 mm, while polypectomy was done in polyps more than 1 mm. Polypectomy in 6-9 mm pedunculated polyps and multiple biopsies in sessile ones was achieved. Specimens were then histopathologically evaluated by a pathologist expert in GI disorders.

Data analysis was performed using SPSS version 13 software. The  $\chi^2$  test and student's *t* were used to determine the significance of associations between different symptoms and colonoscopic findings. Predictive factors for CRC including gender, age groups and symptoms were calculated using multiple logistic regression analysis. A two-tailed test was used for all and a *P*-value of < 0.05 was considered significant.

## RESULTS

The 480 participants included 269 men (56%) and 211 women (44%). Mean age  $\pm$  SD of them was  $42.73 \pm 16.21$ . The indications for colonoscopy are summarized in Table 1.

Taking adenoma and carcinoma together, 72 subjects (15.3%) were found to have colorectal neoplasia confirmed by histopathological examination of biopsy samples and

**Table 1** Long lasting symptoms indicating a total colonoscopy and results regarding each symptom *n* (%)

Indicating symptom	Polyp	Cancer
Rectal bleeding ( <i>n</i> = 142)	20 (14.1)	4 (2.8)
Diarrhea ( <i>n</i> = 164)	7 (4.3)	1 (0.6)
Constipation ( <i>n</i> = 48)	3 (6.3)	2 (4.2)
Altering bowel habit ( <i>n</i> = 27)	1 (3.7)	1 (3.7)
Abdominal pain ( <i>n</i> = 147)	16 (10.9)	7 (4.8)
Irritable bowel disease ( <i>n</i> = 7)	1 (14.3)	0
History of polyp ( <i>n</i> = 4)	0	0
Unexplained anemia ( <i>n</i> = 35)	7 (20.0)	5 (14.3)
Cancer in other organs ( <i>n</i> = 25)	4 (16.0)	2 (8.0)
Family history of cancer ( <i>n</i> = 10)	2 (20.0)	0
Abnormal barium enema ( <i>n</i> = 15)	3 (20.0)	0
Others ( <i>n</i> = 8)	1 (12.5)	1 (12.5)

181 (37.7%) had a completely normal colon. Inflammatory bowel disease was diagnosed in 56 (11.7%), hemorrhoid in 120 (25%), fissure in 14 (2.8%), lipoma in 3 (0.6%), erosion or inflammation in 27 (5.6%). Other findings included fistula, angiodysplasia and diverticle.

During the study we found eight (1.6%) hyperplastic polyps. Four (25%) patients with CRC had synchronous polyps. Adenomatous polyps were detected in 56 patients (11.7%) including 12.3% of men and 10.9% of women (*P* = 0.643); 8 patients (14.3%) had multiple polyps. The mean age of patients with a polyp was significantly higher than that of the others ( $49.53 \pm 14.16$  vs  $41.85 \pm 16.26$  *P* = 0.001). The distribution of adenomatous polyp and cancer according to age trend is described in Table 2. The mean time of symptoms in patients with a polyp (26.58 mo) was not significantly different compared with those without a polyp (27.38 mo).

The mean age of patients and polyp sizes in relation to polyp location are shown in Table 3. The location of the polyps was caecum (4.0%), ascending colon (10.0%), transverse colon (14.0%), descending colon (26.0%), sigmoid (26.0%) and rectum (20.0%). Most of the polyps were tubular (65.0%) followed by tubulo-villous (25.0 %) and villous adenomas (10.0%).

Cancer was detected in 16 (3.6%) which included 3.3% of men and 3.3% of women (*P* = 0.986). The mean age  $\pm$  SD of patients with cancer was significantly higher than that of patients without cancer ( $60.25 \pm 8.26$  vs  $42.13 \pm 16.08$  *P* < 0.005) and that of patients with polyps ( $49.53 \pm 1.91$ , *P* < 0.0005). The mean duration of symptoms was significantly shorter compared with patients without cancer (6.88 mo in patients with cancer vs 27.81 in patients without, *P* < 0.005). The location of the cancer was caecum (14.3%), ascending colon (42.9%), transverse colon (7.1%), sigmoid (14.3%) and rectum (21.4%).

Associations between any of these symptoms and the findings on colonoscopy was assessed by a logistic regression model. Unexplained anemia was an independent predictor for cancer (*P* = 0.004). Unexplained anemia kept its predictive value even after adding age, gender and the duration of the symptoms in the analysis (*P* = 0.006), while age was found as an independent predictor of cancer as well (*P* = 0.037).

Table 2 Age distribution of colorectal neoplasm detected by total colonoscopy in Iranian symptomatic patients *n* (%)

	< 30 ( <i>n</i> = 108)	30-39 ( <i>n</i> = 110)	40-49 ( <i>n</i> = 90)	50-59 ( <i>n</i> = 88)	60-69 ( <i>n</i> = 48)	70-79 ( <i>n</i> = 31)	80 < ( <i>n</i> = 3)	All ( <i>n</i> = 480)
Colorectal cancer	0	0	2 (2.2)	6 (6.8)	4 (8.3)	4 (12.9)	0	16 (3.6)
Colorectal adenomatous polyp	5 (4.6)	10 (9.1)	11 (12.2)	18 (20.5)	7 (14.6)	5 (16.1)	0	56 (11.7)

Values in parentheses are percentages.

Table 3 Age and size of the polyp in the patients according to polyp location (mean  $\pm$  SD)

	Size (mm)	Age (yr)
Rectum	8.83 $\pm$ 13.22	41.80 $\pm$ 13.83
Sigmoid	13.00 $\pm$ 8.48	57.33 $\pm$ 8.43
Descending colon	10.18 $\pm$ 9.08	49.69 $\pm$ 12.10
Transverse colon	5.16 $\pm$ 3.18	41.29 $\pm$ 20.05
Ascending colon	6.60 $\pm$ 1.51	59.20 $\pm$ 8.28
Caecum	8	51.50 $\pm$ 7.77

Patients with diarrhea and constipation had lower chances of having a polyp ( $P < 0.0005$  and  $P = 0.025$  receptively). Diarrhea kept the negative predictive value even after adding age, gender and duration of the symptoms in analysis ( $P = 0.022$ ) while age was found as an independent predictor of polyps ( $P = 0.006$ ).

There was no significant relation between age and location of the polyp or cancer ( $P = 0.606$  and  $P = 0.283$ ). The location of the cancer or the polyp was not related to the gender of the patients either ( $P = 0.336$  and  $P = 0.256$ ).

## DISCUSSION

This report represents the first study to characterize the profile of CRC in symptomatic patients of Iran. Although this is not a population based study, important data about this cancer in a sample of our local population are presented.

The only published report from our province shows age-adjusted rates of CRC (as the 3rd most common GI cancer) to be 6.7 in males and 5.2/100 000 in females in our region<sup>[14]</sup>, which may be influenced by the pathology based manner of the study in part. A report of a recent population based registry from five provinces of Iran showed age-adjusted rates of CRC in Iranian males and females to be 8.2 and 7.0/100 000, respectively while 17% of the cases were younger than 40 years of age at the time of diagnosis<sup>[15]</sup>. This rate decreased to 2%-8% in western countries<sup>[16]</sup>. In contrast to the low risk of CRC in our country, research supports an increase in occurrence of the disease<sup>[17]</sup>. This increase in incidence of CRC in the Asia-Pacific region has been related to the dramatic socio-economic developments<sup>[18]</sup> which can in part explain the higher rate in the younger aged population. The use of fat and thereby prevalence of obesity have increased during the past decade<sup>[19,20]</sup>. Appropriate screening strategies should be considered to decrease the burden of CRC in the young population of Iran. The first step is gathering

satisfactory data on characteristics of the disease to map out an effective plan.

Colorectal adenoma and CRC were detected in 11.7% and 3.6% of our study population with long lasting colonic symptoms. This low rate is compatible with other published data from Asia and Middle East<sup>[15]</sup>. Colonoscopic examination from western countries has shown neoplastic lesions in 37.5% of asymptomatic patients<sup>[21]</sup> which is even higher than our symptomatic (including evidence of bleeding) sample. Genetic factors and the high fibre diets of our community may explain this low incidence but this can be influenced by recent changes like westernization of diet and reduction in physical activity of our population.

No gender differences were noted in our patients. The mean age of diagnosis in our cancer patients and patients with adenomatous polyps (in the 5th decade of life) is consistent with previously established data. Our cancer patients were more than 10 years older than patients with adenomatous polyps which is compatible with transformation of a polyp to cancer in a 10-year period. The incidence of colorectal cancer increases with age. Risk of colorectal cancer increases slightly after the age of 40 and more sharply after 50 years<sup>[22]</sup>. This pattern was also observed in our study. Older age is an independent predictor for polyp and cancer in our population. Lower gastrointestinal symptoms are not predictive of colorectal neoplasia in our study as supported by reports from western countries<sup>[23]</sup>. This may be explained simply by the frequency of lower gastrointestinal symptoms in the general population. However, the rate of rectal bleeding in this study is considerably higher than that in the general population, while a possible explanation is that there is a high prevalence of benign disease likely to cause rectal bleeding. Unexplained anemia is the only sign which can predict CRC.

The characteristics of both patients and adenomas can influence the risk of carcinoma developing in colorectal adenomas. These are the age of the patient, size of the adenoma, its villous component and the severity of dysplasia<sup>[24]</sup>. Villous adenomas seem to be less common in our community compared with western countries, which may become malignant in 29% to 70% of the time<sup>[25-27]</sup>. The majority of polyps detected in our study population were tubular (65%) and villous adenomas comprised 10%.

The size of polyps has been reported as an independent predictor of malignancy in colorectal polyps<sup>[28,29]</sup>. The risk of developing adenocarcinoma is 1% in adenomas of up to 1 cm in size, 10% in adenomas from 1 cm to 2 cm in diameter and 50% in those greater than 2 cm in diameter<sup>[30]</sup>. Only 4% of adenomas less than 6 mm diameter, and 16% of those between 6 mm and 10 mm are reported to have

unfavorable histology<sup>[31]</sup>. According to our results, 40.0% of polyps were less than 6 mm, 37.5% were between 6-10 mm and 22.5% were more than 10 mm which shows smaller groups at higher risk of malignancy.

There has been much discussion about the anatomical distribution of colorectal tumours. A “left” to “right” sided or proximal shift of tumours has been reported in studies mostly from western countries<sup>[32-35]</sup>. Nevertheless, several other studies especially from Asia have shown no such shift<sup>[36-42]</sup>. In the authors’ experience in our region about anatomic sites of adenomatous polyps and CRC (1992 to 2005), there is a predominant location of left side<sup>[43]</sup>. The study was based on evaluation by colonoscopy and barium enema in patients with colorectal adenoma or CRC. In the current study which is based on findings of total colonoscopy, more than 40% of polyps were located in the recto-sigmoid region while a shift to the right side was prominent in the sites of CRC. The former retrospective study focused on patients with adenomatous polyp or CRC among patients evaluated by colonoscopy. Based on this study with a large number of cases, an anatomical distribution pattern and left shift of colorectal adenomas and cancer is compatible with data from most Asian countries. However, the current study was designed on patients with different lower GI symptoms evaluated for colorectal neoplasms. The right side dominance of CRC in this study is more likely not due to a true increase in right-sided tumors but may be a result of a small number of recorded cancer patients as well as younger ages in our study population.

Some previous published studies showed older ages of patients with right-sided tumours. No difference in the age of diagnosis of right-sided and left-sided tumours was observed in our patients which has been noted in other studies as well<sup>[7]</sup>.

Although most cases of rectal bleeding were due to self limiting diseases in our study, the probability of colorectal cancer increases significantly both in people older than 60 years and in association with unexplained anemia indicating the need for a more thorough investigation in such cases.

Smaller size of adenomas, dominance of tubular type and fewer cases with severe dysplasia among colorectal adenoma and lower incidence of cancer in our region compared with western populations is comparable with Asian populations and may suggest that it is not a serious health problem of our community at present. Although suspicious symptoms clearly call for urgent investigation, it is important to recognize lower gastrointestinal symptoms are not predictive of cancer except for unexplained anemia in elderly patients.

## COMMENTS

### Background

Colorectal cancer (CRC) is a common cancer especially in industrial countries and is a preventable disease when diagnosed and treated early.

### Research frontiers

Screening asymptomatic patients is the most common way of detecting colorectal polyps while most cancer cases are still detected once evaluating clinical

symptoms. However most asymptomatic people do not accept endoscopy yet. We carried out a study in symptomatic patients undergoing colonoscopy; investigating whether their symptoms were related to chance of having a polyp or cancer.

### Related publications

Colonoscopic examination from western countries has shown neoplastic lesions in 37.5% of asymptomatic patients which is even higher than our symptomatic. An increase in the incidence of CRC in the Asia-Pacific region is noted and has been related to the dramatic socio-economic developments.

### Innovations and breakthroughs

This report represents the first study to characterize the profile of CRC in symptomatic patients of Iran. Although this is not a population based study, important data about this cancer in a sample of our local population are presented.

### Applications

Colonic symptoms are not a predictor for polyp or cancer but unexplained anemia and older age can predict CRC. Less advanced patterns and smaller sizes of adenomas in Iran is compatible with other data from Asia and Middle East, in contrast to western countries. The prevalence of colonic neoplasia in our community seems to be lower than that in western populations.

### Terminology

Colorectal polyps arise from normal epithelium of the colon after some abnormal changes in genes and may develop to colorectal cancer over time.

### Peer review

This is a potentially interesting manuscript, which describes a prospective colonoscopy based study investigating the prevalence of colorectal polyps and cancer in patients with persistent (> 3 mo) colonic symptoms with the aim of determining whether or not the indications were predictive for the presence of either polyp or CRC. The study group was large (480 patients), indications for colonoscopy diverse and the average age profile relatively young (about 43 years). The results section was rather disjointed and could have been better presented and aided by additional tables and figures.

Gastric juice for the diagnosis of *H pylori* infection in patients on proton pump inhibitors. *World J Gastroenterol* 2008; 14(10): 1539-1543 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1539.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1539>

### Abstract

**AIM:** To determine the efficacy of gastric juice polymerase chain reaction (PCR) for the detection of *H pylori* infection in comparison with histology and gastric antral biopsy PCR in patients on a proton pump inhibitor (PPI).

**METHODS:** Eighty-five consecutive patients with dyspeptic symptoms were enrolled. Gastric biopsies for histology, PCR and gastric juice were collected at endoscopy for PCR of the *H pylori* urease C gene (ure C). Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy, positive and negative likelihood ratio for PCR of gastric juice for the *H pylori* ure C gene was compared to histology and gastric antral biopsy *H pylori* ure C PCR in patients with and without PPI.

**RESULTS:** Gastric juice PCR was positive in 66 (78%) patients. Histology showed *H pylori* associated gastritis in 57 (67%). Gastric biopsy PCR was positive in 72 (85%). In patients not taking PPI, the sensitivity, specificity, PPV, NPV, accuracy and positive and negative likelihood ratio for gastric juice PCR were 89%, 72%, 91%, 67%, 90%, 85%, 3.1 and 0.1 respectively. In patients on PPI these values were 86%, 100%, 100%, 29%, 86%, 9.5 and 1.4, respectively.

**CONCLUSION:** Gastric juice PCR for the diagnosis of *H pylori* infection has increased sensitivity compared to histology with PPI. The use of gastric juice PCR is recommended to confirm *H pylori* status in patients taking PPIs.

### INTRODUCTION

*H pylori* is a spiral gram negative microaerophilic bacterium that infects the human gastric mucosa and is associated with gastritis, gastroduodenal ulcer disease, gastric carcinoma and mucosal associated lymphoid tissue lymphoma<sup>[1,2]</sup>. The prevalence of *H pylori* is high in developing countries. A recent study revealed an early colonization/infection of infants with *H pylori* and a prevalence of 67% at 9 mo of age in a peri-urban community in Karachi, Pakistan<sup>[3]</sup>. *H pylori* serology was positive in 58% of our general population in a previous study but is likely to actually be higher<sup>[4]</sup>. Currently, several diagnostic tests of varying sensitivity and specificity are available for determining the presence of *H pylori*, which include rapid urease test (RUT), histology, culture, urea breath test (UBT), and serology. Isolation of *H pylori* from gastric biopsy specimens constitutes the most specific way to establish the diagnosis of infection and to study the genotype of the infecting strains, however, it is a time consuming process. RUT and histology are still commonly used for the diagnosis of *H pylori* infection in our country as other modalities of *H pylori* testing, such as UBT and facilities for *H pylori* stool antigen tests, are not widely available.

In Pakistan, self-prescription is common and medications are available over the counter without prescriptions<sup>[5]</sup>. It is known that acid reducing drugs; e.g. proton pump inhibitor (PPI), histamine-2 receptor blocker (H2RB), antibiotics and bismuth compounds reduce the sensitivity and specificity of the diagnostic tests for *H pylori*<sup>[6,7]</sup>. In our previous studies, we demonstrated that histology is comparatively less affected by PPI than RUT<sup>[8,9]</sup>. Polymerase chain reaction (PCR) is a highly

sensitive technique that can detect very small amounts of DNA. The DNA molecule is chemically stable and can survive in the environment for long periods<sup>[10]</sup>. PCR may be useful, therefore, in detecting the presence of *H pylori*, even when the organism is in a nonculturable state. In previous studies, gastric juice PCR has been evaluated as a highly specific and rapid method for the detection of *H pylori*<sup>[11,12]</sup>. An efficient and accurate diagnosis of *H pylori* infection is important when seeking to cure patients with persistent gastric symptoms in which *H pylori* infection is suspected. The aim of this study was to determine the efficiency of gastric juice PCR for the detection of *H pylori* infection in patients on PPI and compare it with histology and gastric biopsy PCR.

## MATERIALS AND METHODS

### Patients

Eighty-five consecutive patients with dyspeptic symptoms attending the gastroenterology outpatient clinic from February–November 2006 were enrolled. There were 58 (68%) males and 27 (32%) females. The age range was 17–70 years with a mean age of  $36.8 \pm 11$ . Patients were divided into two groups: (1) those who received PPI (mainly omeprazole 20 mg once a day) for at least 4 wk before undergoing esophagogastroduodenoscopy (EGD); (2) patients with no previous treatment with antibiotics, PPI, H2RB and bismuth compounds. Patients in each respective group also did not use other drugs. Compliance with treatment was ascertained during an outpatient visit before the endoscopy. The study was approved by the Ethics Review Committee of Aga Khan University Hospital. Informed consent was obtained from all patients for EGD with biopsies from the antrum and corpus of the stomach and aspiration of gastric juice. EGDs were performed after an 8 h fast. A sample of gastric juice (5 mL) was aspirated at endoscopy by means of a sterile cannula used for endoscopic retrograde cholangiopancreatography (ERCP), passed through the suction channel and collected in a disposable sterile syringe. After each examination the endoscopes were washed with 2% glutaraldehyde and disinfected with 70% ethanol followed by rinsing with sterile water after each examination. Biopsy forceps were sterilized by autoclaving to ensure lack of cross contamination using the endoscopic equipment. All patients received conscious sedation with intravenous midazolam and topical pharyngeal anesthetic spray. Sterilized biopsy forceps were used to obtain gastric biopsy specimens from the antrum and mid of the corpus. Two biopsy specimens were removed from each site for histology and dispatched in a formalin containing container. Biopsy for PCR was dispatched in normal saline. Sensitivity, specificity, PPV, NPV, accuracy, positive and negative likelihood ratio for gastric juice *H pylori* ure C gene PCR were compared against histology and gastric biopsy PCR in patients with and without PPI to establish the efficiency of this diagnostic approach.

### Histology

Gastric biopsy specimens from each site for histopathology

were stained with hematoxylin and eosin and Giemsa stain for the detection of *H pylori*; the degree of gastritis as determined by hematoxylin and eosin (HE) stain was scored in accordance with the Sydney system<sup>[13]</sup>.

### Extraction of genomic DNA from gastric juice

Extraction of genomic DNA from gastric juice was carried out as previously described<sup>[11]</sup>. A 5 mL of gastric juice aspirate was buffered to a neutral pH with 5 mL of Tris (0.67 mol/L, pH 7.4). Each sample was then concentrated by centrifugation at  $10000 \times g$  for 20 min. The supernatants were removed and the pellets were resuspended in 100  $\mu$ L of sterile distilled water. One hundred  $\mu$ L of lysis buffer [100 mmol/L NaCl, 10 mmol/L Tris-HCl (pH 8.0), 25 mmol/L EDTA, 0.5% sodium dodecyl sulfate], and 5  $\mu$ L of proteinase K (10 g/L) were added. Incubation was carried out at 50°C for 20 h; this was followed by phenol-chloroform extraction and ethanol precipitation. The resulting pellet was allowed to dissolve in 35  $\mu$ L of TE buffer 10 mmol/L Tris-HCl (pH 7.4) and 0.1 mmol/L EDTA (pH 8.0) for 20 h at 37°C. Samples were stored at -20°C before PCR amplification was performed. DNA content and purity was determined by measuring the absorbance at 260 nm and 280 nm using a spectrophotometer (Beckman DU-600, USA).

### Extraction of DNA from gastric biopsy

Briefly, gastric tissue was homogenized to uniformity in 500 mL of sterile water and centrifuged at  $12000 \times g$  for 3 min. Five hundred  $\mu$ L of lysis buffer [100 mmol/L NaCl, 10 mmol/L Tris-HCl (pH 8.0), 25 mmol/L EDTA, 0.5% sodium dodecyl sulfate], and 10  $\mu$ L of proteinase K (10 g/L) were added. Incubation was carried out at 56°C for 20 h; this was followed by phenol-chloroform extraction and ethanol precipitation. The resulting pellet was allowed to dissolve in 40  $\mu$ L of TE buffer [10 mmol/L Tris-HCl (pH 7.4) and 0.1 mmol/L EDTA (pH 8.0)] for 20 h at 37°C. Samples were stored at -20°C before PCR amplification was performed. DNA content and purity was determined by measuring the absorbance at 260 nm and 280 nm using a spectrophotometer (Beckman DU-600, USA).

### PCR for ure C

PCR was performed using extracted DNA as the template and urease gene C for primers. Forward primer (5'-TG GGACTGATGGCGTGAGGG-3') and reverse primer (5'-AAGGGCGTTTTT TAGATTTTT-3') were prepared from the urease gene sequence according to the report of Labigne *et al*<sup>[14]</sup>. PCR amplification was carried out in a total volume of 50  $\mu$ L containing 2  $\mu$ L of 2 mmol/L dNTPs, 1  $\mu$ L containing 50  $\mu$ mol of primer 1, 1  $\mu$ L containing 50  $\mu$ mol of primer 2 (synthesized by ABI Automatic synthesizer), 1 unit of Taq DNA polymerase (Promega), 5  $\mu$ L of  $10 \times$  PCR reaction buffer, 3 mmol/L of MgCl<sub>2</sub>, 2  $\mu$ L of DNA template containing 0.5 ng of extracted DNA and total volume rounded to 50  $\mu$ L by double distilled water. The reaction was carried out in a Perkin Elmer 9700 thermal cycler. The amplification cycle consisted of an initial denaturation of target DNA at 95°C for 5 min and then denaturation at 94°C for 1 min, primer

Table 1 Comparison of histology, gastric biopsy and juice PCR for the diagnosis of *H pylori* infection with and without PPI *n* (%)

	Medication		<i>P</i> value
	On PPI <i>n</i> = 37	Without PPI <i>n</i> = 48	
Histology			
<i>H pylori</i> positive gastritis	23 (62)	34 (71)	0.24
<i>H pylori</i> negative gastritis	14 (38)	14 (29)	
Gastric juice PCR			
Positive	30 (81)	36 (75)	0.50
Negative	7 (19)	12 (25)	
Gastric biopsy PCR			
Positive	35 (95)	37 (77)	0.02
Negative	2 (5)	11 (23)	

annealing at 56°C for 1 min and extension at 72°C for 1 min. The final cycle included an extension step for 5 min at 72°C to ensure full extension of the product. Samples were amplified through 35 consecutive cycles. Negative reagent control reactions were performed with each batch of amplifications, consisting of tubes containing distilled water in place of the DNA samples. Five µL of PCR product was electrophoresed on a 1.5% agarose gel to ensure homogeneity and yield. PCR amplification resulted in a homogeneous DNA fragment of the expected size of 820 bp for ure C gene.

### Statistical analysis

The statistical package for social science SPSS (Release 11.5, standard version, copyright © SPSS; 1989-99) was used for data analysis. The descriptive analysis was done for demographic and clinical features. Results were presented as mean ± SD for quantitative variables and number (percentage) for qualitative variables. Odd ratio (OR) and 95% confidence interval (95% CI) were estimated to check the strength of association. Sensitivity, specificity, PPV, NPV, accuracy and negative and positive likelihood ratio were determined for PCR and histology.

## RESULTS

Thirty seven (43.5%) patients were on PPI while 48 (56.5%) were not taking any medications. Abdominal pain was present in 60 (71%) and dyspepsia 25 (29%). Symptoms were equally common in two groups. The endoscopic diagnosis was pangastric erythema in 56 (66%), antral erythema in 25 (29.4%), gastric ulcer 1 (1.2%), gastric carcinoma 2 (4.2%), and duodenal ulcer 1 (1.2%). The age range of these patients was 25-70 years with mean age 43.5 ± 13.2.

### Comparison of histology, gastric biopsy and juice PCR with and without PPI

Histology showed *H pylori* associated gastritis in 57 (67%) and *H pylori* negative gastritis in 28 (33%). On PPI, 23 (62%) had *H pylori* positive gastritis *P* = 0.24 (Table 1). Gastric juice ure C PCR was positive in 66 (78%) and negative in 19 (22%). On PPI, gastric juice PCR was positive in 30 (81%) *P* = 0.50 (Table 1). Gastric biopsy ure C PCR

Table 2 Comparison of gastric juice PCR and histology using gastric biopsy PCR as the gold standard *n* (%)

	PCR of gastric biopsy		<i>P</i> value
	Positive	Negative	
Over all ( <i>n</i> = 85)			
Histology			
Positive	56 (78)	1 (8)	< 0.001
Negative	16 (22)	12 (92)	
Gastric juice PCR			
Positive	63 (87)	3 (23)	< 0.001

was positive in 72 (85%) and negative in 13 (15%). On PPI, gastric biopsy PCR was positive in 35 (95%) with *P* = 0.02 (Table 1).

### Comparison of histology and gastric juice PCR with gastric biopsy PCR

Seventy two (85%) were positive by ure C PCR of gastric biopsy compared to 57 (67%) by histology and 66 (78%) by gastric juice ure C PCR with *P* < 0.001 and *P* < 0.001, respectively (Table 2). For patients taking PPI, 23 (62%) were positive by histology while 30 (81%) were positive by gastric juice PCR with *P* = 0.17 and *P* = 0.003, respectively (Table 2). For patients not taking PPI, histology was positive in 34 (71%) while 36 (75%) were positive by gastric juice PCR with *P* < 0.001 and *P* < 0.001, respectively (Table 2). For patients taking PPI, the sensitivity, specificity, PPV, NPV, accuracy and positive and negative likelihood ratio for gastric juice PCR and histology were 86%, 100%, 100%, 29%, 86%, 9.5 and 1.4 and 73%, 100%, 100%, 14%, 0.6 and 2.7, respectively (Table 3).

## DISCUSSION

Gastric juice represents a pooled source of events in the entire gastric microenvironment, and it may be valuable for studying *H pylori* whose mucosal distribution is patchy and variable. This is even more relevant in the setting of developing countries, where *H pylori* possibly exists as a dynamic mix of quasi-species. A single biopsy sample may not be able to detect the presence of *H pylori*, whereas gastric juice, being a more global sample, may overcome this limitation because the gastric juice reflects the actual microenvironment and the global level of infection in the stomach. *H pylori* has a very potent urease activity, and because of this highly specific activity of the urease enzyme *H pylori* are able to hydrolyze the urea present in

the stomach. This serves to protect the organism from the harmful effects of gastric acid and the ammonia generated protects the organism by buffering gastric acid<sup>[15,16]</sup>. The proton pump inhibitor reduces gastric acid secretion and inhibits urease activity<sup>[17,18]</sup>. When the secretion of acid is suppressed, *H pylori* in the presence of urea increases the pH of its local environment to alkaline values and are unlikely to survive in a culturable form<sup>[19]</sup>.

This study has demonstrated that for patients taking PPI gastric juice *H pylori* PCR with a specific primer for ure C was more sensitive than histology to detect *H pylori* infection 86% vs 73% (Table 3). Gastric juice PCR was able to detect positively 7 (19%) patients who were negative on histology. This could be due to a patchy distribution of the *H pylori*, obtaining biopsies from an uninfected sites resulting in false negatives on histology and PPI activity against *H pylori*<sup>[20]</sup>. The histology-negative, PCR-positive subjects were older, with a mean age of  $43.5 \pm 13.2$  years. This is in keeping with a previous study<sup>[21]</sup>. *H pylori* infection associated atrophy and intestinal metaplasia progresses with age<sup>[22,23]</sup>. Thus, older patients may be more liable to have false-negative results from the commonly biopsied sites in our practice. Although, the overall sensitivity of the gastric juice PCR as seen in the present study is low. This might be attributed either to the lack of *H pylori* in the gastric juice or the presence of some inhibitor of PCR decreasing sensitivity of the technique. In this study, we did not choose to compare RUT with gastric juice PCR as it is already known that PPI reduces the sensitivity of RUT<sup>[7-9]</sup>. In patients on PPI, the biopsy specimen may contain low bacterial density of viable cells giving a negative urease test. This will also lead to the lack of *H pylori* identification on histology. Similarly, culture of *H pylori* from gastric mucosal biopsies is likely to be negative with PPI as they are not only known to effect the distribution of *H pylori* within the stomach but are also detrimental to *H pylori* in both the antrum and the corpus<sup>[7,24]</sup>.

Proton pump inhibitors have been reported to modify the level of *H pylori* gastritis<sup>[20,25,26]</sup>. The sensitivity, NPV, accuracy and positive likelihood ratio of gastric juice PCR was greater and the negative likelihood ratio was less for *H pylori* in patients on PPI, while specificity and PPV was similar to histology (Table 3). A previous study by Dickey *et al* showed histological examination sensitivity, specificity, PPV, NPV and diagnostic accuracy were reduced on acid reducing drugs<sup>[7]</sup>. In their study, five (83%) of the histology-negative, seropositive patients taking PPI had

histological changes consistent with *H pylori* gastritis even though no *H pylori* were detected<sup>[7]</sup>. In our study, the detection rate of *H pylori* was greater by gastric juice PCR on PPI (Tables 1-3). Of the various tests that are available for *H pylori* detection, histological examination of gastric biopsy is considered the most accurate method of diagnosis<sup>[27]</sup>. If more than one gastric biopsy tissue is used it might improve the test sensitivity without compromising its specificity. Obtaining a serological test in these cases in our population, will not help in deciding whether to treat or not, as a positive result with serology does not tell whether the patient has a current infection or had a past infection that is now cured. The drawbacks of treating these patients who are not actively infected include among many others contribution to antibiotic resistance.

This is the first study to investigate influence of PPI on the results of PCR of gastric juice and histological examinations while using gastric biopsy PCR as the gold standard. In the presence of PPI, gastric juice PCR was more sensitive than histology. Seven (19%) subjects who were negative for *H pylori* by histology and positive by the gastric juice PCR assay should be regarded as having ongoing infections. These patients would have benefited from antimicrobial therapy. However, the results of this study needs to be confirmed in a larger group of patients. In conclusion, the use of the gastric juice PCR can be recommended to exclude *H pylori* infection in patients taking PPI. However, it can also be used as an additive test to confirm the *H pylori* status in patients having histological changes consistent with *H pylori* gastritis though negative for *H pylori*.

## ACKNOWLEDGMENTS

I am grateful to staff members at the Juma Research Laboratory, Aga Khan University for their assistance during this work.

## COMMENTS

### Background

An efficient and accurate diagnosis of *H pylori* infection is important when seeking to cure patients with persistent gastric symptoms in which *H pylori* infection is suspected. In patients on acid reducing drugs such as proton pump inhibitors (PPI), H-2 receptor blockers (H-2RB) *etc*, the accuracy of the rapid urease test, urea breath test and histology are known to be less accurate for the diagnosis of *H pylori* infection.

### Research frontiers

The development of new types of test or targets to test for the *H pylori* infection in patients with prior use of PPI etc is important considering the morbidity and mortality associated with this infection.

### Innovations and breakthroughs

This study determined the efficiency of gastric juice polymerase chain reaction (PCR) for the detection of *H pylori* infection in patients on PPI and compared it with histology and gastric biopsy PCR.

### Applications

It showed gastric juice PCR for the diagnosis of *H pylori* infection had an increased sensitivity compared to histology in patients on PPI. The use of the gastric juice PCR can be recommended to confirm the *H pylori* status in patients taking PPIs.

### Terminology

PPI: proton pump inhibitors are a group of drugs whose main action is pronounced and long-lasting reduction of gastric acid production. They are the most potent inhibitors of acid secretion available today.

### Peer review

The paper means a real advance in the methodology of diagnosis in this field. The conclusions are valuable. The design is original. The methodology is correct and the results are well presented. Statistical analysis is adequate.

Received: July 24, 2007 Revised: January 10, 2008

### Abstract

**AIM:** To assess spectrum and etiology of gallstones and biliary sludge in the pediatric population of a North American tertiary care centre.

**METHODS:** Retrospective review of abdominal ultrasounds recorded at Saint Justine Hospital over a period of 24 mo (8/2003 to 8/2005) in patients < 19 years of age. Patients < 2 years of age were analyzed separately.

**RESULTS:** The presence of gallstones was noted in 127 patients. In 107 it was a new diagnosis, in 48/105 (45.7%) patients > 2 years of age idiopathic gallstone disease was found. These 48 patients represent 2.1% of the population who required ultrasound for abdominal pain. Complicated gallstone disease occurred in 28/48 with idiopathic disease, mainly adolescent girls. Patients with hemolytic disorders, cystic fibrosis, oncologic diseases or kidney transplantation and gallstones were asymptomatic and stones were detected during routine abdominal ultrasound. Twenty two patients < 2 years of age not consulting for abdominal pain had gallstone disease of diverse etiology. Biliary sludge was seen in 84 patients, 78.5% on total parenteral nutrition. In 4 patients, sludge progressed to gallstones.

**CONCLUSION:** Idiopathic gallstone disease and its rate of complication are more frequent in our cohort than expected from previous studies. Adolescent girls with abdominal pain and idiopathic gallstones require special attention for complicated disease course.

### INTRODUCTION

The rising prevalence of gallstone disease in the adult populations of industrialized countries is a cause of concern. Over 10% of European and American population carry gallstones<sup>[1]</sup>. European studies in pediatric patients estimate an overall prevalence of 0.13% to 1.9% for gallstone disease in children up to 19 years of age<sup>[2,3]</sup>. However, no details on the etiology or the occurrence of symptoms and complications, as have been published for adult patients with gallstone disease<sup>[4]</sup>, are known from the pediatric cohorts. Furthermore, only scarce prevalence data for the North American pediatric population is available. In the light of this situation we decided to assess the types, predisposing diseases, modes of presentation and therapies of gallstone disease and biliary sludge in a North American pediatric tertiary care centre.

### MATERIALS AND METHODS

We reviewed the records of all complete abdominal ultrasounds, where the result of the inspection of the upper abdominal site was mentioned in the written report, and which were carried out for abdominal pain, for clinically indicated follow-up of diverse abdominal pathologies, malformation screening or urinary tract infection, in patients < 19 years of age, at Saint Justine Hospital over a period of 24 mo (8/2003 to 8/2005). Repeated ultrasounds in the same patient and for the same pathology were classified as follow-up exams. Charts of patients found to carry gallstones, or biliary sludge were reviewed, and the patients divided in 2 groups: 2 years and > 2 to < 19 years of age. This division appeared to

be logical because patients < 2 years of age were followed for diseases present from the perinatal period onwards. We also reviewed the charts of all patients undergoing cholecystectomy during the study period. Complicated biliary pain was considered an indication for laparoscopic cholecystectomy, which was usually carried out after normalization of liver and pancreatic serum parameters. A first episode of uncomplicated biliary pain was an indication for elective cholecystectomy only after exclusion of other etiologies for right upper quadrant pain with similar duration and nausea. Underlying diseases, weight and height, family history of cholelithiasis, serum lipids repeatedly recorded as elevated and done in the fasting state, alanine aminotransferase, aspartate aminotransferase, gamma-glutamyl transferase, total and direct bilirubin, amylase, lipase as well as the pathology results of cholecystectomy specimens and outcome as far as available were analyzed.

### Definitions

Patients with gallstones and no associated disease were defined as having idiopathic gallstone disease. Cholelithiasis was defined as an echogenic focus producing acoustic shadowing in the gallbladder or in the region of the gallbladder. Biliary sludge was defined as a non-shadowing, echogenic, intraluminal sediment. Biliary pain was defined as paroxysmal abdominal pain with right upper quadrant tenderness increasing over 15 min and lasting maximal 6 h<sup>[5]</sup>. Pancreatitis was defined as elevation of serum amylase > 3 times the normal value and abdominal pain. Cholangitis included cholestasis, fever, and upper abdominal tenderness<sup>[6]</sup>. Elevation of direct and total bilirubin beyond the upper limit of normal for age was considered a sign of biliary obstruction, with or without additional elevation of gamma glutamyl transpeptidase, alanine aminotransferase and aspartate aminotransferase. Overweight was defined as body mass index (BMI) > 95th, tendency for overweight as BMI > 85th percentile<sup>[7]</sup>.

### Statistical analysis

All testing was based on determining statistical significance at a 2-sided  $\alpha$  level of 0.05. The *Kolmogorov-Smirnov* test was used to flag normal distribution. The 2-sample *t*-test served to compare frequency distributions between subgroups, with the *Mann-Whitney U* test for comparison of groups without normal distribution. The study was approved by the Research Ethics Committee of Saint Justine Hospital.

## RESULTS

A total of 13259 complete abdominal ultrasounds in 9203 patients were included and reviewed. Of these, 2218 were done for abdominal pain with or without further clinical specification. Routine follow-up ultrasounds were carried out in patients with hemolytic disorders, cystic fibrosis, chronic liver and intestinal diseases, oncologic diseases or transplanted patients. Age distribution of patients with gallstones detected and the indication of the ultrasound are shown in Table 1. While reviewing all these ultrasounds we also found biliary sludge in 84 patients (0.91%). Table 2

**Table 1** Indications for abdominal ultrasounds in < 2 or 2-19 years old patients with gallstone disease

Ultrasound	For abdominal pain (n = 55)		For follow-up (n = 72)		Total (n = 127)	
	No	Yes	No	Yes	No	Yes

< 2 yr	0	0	0	22	0	22

shows the associated diseases and age distribution of patients with gallstone disease and sludge. A minority of patients with gallstones or sludge required radiological examination for indications other than biliary tract disorders and data on radiopacity of the gallstones are not available.

### Associated disorders in patients older than 2 years of age

**Idiopathic gallstones:** Idiopathic gallstone disease was found in 48/105 (45.7%) patients > 2 years of age (33 girls with a median age of 15 years, and 15 boys with a median age of 12 years, 35.4% of non French or English origins: immigrants from the South American continent (8), Eastern and Southern Europe, Russia, Arabic or Far East countries), 2.1% of all patients requiring ultrasound for abdominal pain. Biliary pain was the reason for an abdominal ultrasound in 19/48 patients, and unspecified abdominal pain in 29/48. The male to female ratio was 1:2. Body mass index > 85th percentile was noted in 14/48 (29.2%, all girls); family history of gallstone disease and cholecystectomy was positive in 25, negative in 3, and not recorded in 20/48 patients. Gallstones evolved with complications such as elevated serum bilirubin and serum amino-transferases without visible choledocholithiasis (13), with pancreatitis (13) and/or choledocholithiasis (8) in 28/48 patients. All had cholecystectomy, 27 within 4 wk after the end of the acute episode, and one pregnant patient after delivery (Table 3). Endoscopic retrograde cholangio-pancreatography and papillotomy for symptomatic and obstructive common bile duct stones were carried out before cholecystectomy in 4/28 patients and intra-operative cholangiography in one. The pathological analysis of cholecystectomy specimens was limited to the description of stone colour and gallbladder wall histology. Stones were described as yellow, pale or yellowish green in 24/28 patients, and as black or predominantly black in 4/28 (4 boys). Gallbladder histology was normal in 3, with signs of chronic cholecystitis in 25/28, and of cholesterolosis in 8 of these 25. In patients with cholesterolosis (2 boys, 6 girls, 12-18 years old at cholecystectomy), serum cholesterol was normal in 3 and not tested in 5. BMI was > 85th percentile in 2/28 patients.

Of the 20/48 patients with abdominal pain and no complications or cholecystectomy (Table 3), 9/20 were lost for follow-up, 11 had regular follow-up for other conditions (asthma in 6, epilepsy in 2, orthopedic problems in 3), and no recurrence of abdominal pain was recorded. Only 2/11 patients were on ursodeoxycholic acid. Positive family history of gallstone disease and cholecystectomy was found in 3, negative in 2, not recorded in 15. BMI was > the 90th and > 95th percentile in 2 patients each.

Table 2 Numbers of patients with gallstones or sludge and associated diseases

Age (median, range)	Hemolytic	CF	Oncologic/transplantation	Infectious	Surgery + TPN	Idiopathic	Total	Male patients (% total patient number)

CF: Cystic fibrosis; TPN: Total parenteral nutrition; <sup>1</sup>Plus TPN.

Table 3 Age, gender and associated diseases in 2-19 years old patients with and without cholecystectomy

Associated disorders and gender (female/male)	Cholecystectomy, <i>n</i> = 37 (median age, yr)			No cholecystectomy, <i>n</i> = 68 (median age, yr)		
	Female	Male	%	Female	Male	%
Idiopathic	23 (14.5 <sup>1</sup> )	5 (13 <sup>1</sup> )	58	10 (16 <sup>1</sup> )	10 (10.5 <sup>1</sup> )	42
Hemolytic	4 (13 <sup>1</sup> )	5 (9.5 <sup>1</sup> )	47	4 (16 <sup>1</sup> )	6 (11 <sup>1</sup> )	53
Cystic fibrosis	0	0	0	7 (15.5 <sup>1</sup> )	3 (15 <sup>1</sup> )	100
Oncologic	0	0	0	8 (9 <sup>1</sup> )	2 (9 <sup>1</sup> )	100
Infectious/TPN/surgery	0	0	0	13 (12 <sup>1</sup> )	5 (11 <sup>1</sup> )	100

<sup>1</sup>Age differences between male and female patients not significant.

**Hemolytic disorders:** Hemolytic disorder was present in 19 (18%) patients > 2 years of age with gallstones (sickle cell disease in 11, hereditary spherocytosis in 6, hemolytic uremic syndrome and autoimmune hemolytic anemia in 1 each), and 3/19 had abdominal pain requiring ultrasound (Table 1 and Table 3). No genetic testing for Gilbert disease had been performed in these patients<sup>[8]</sup>. Preventive cholecystectomy was performed in 9/19 and for gallstone disease with choledocholithiasis in 1 patient only.

**Cystic fibrosis (CF):** None of the 10 patients with CF and gallstone disease had complicated disease, and there was no cholecystectomy (Table 3).

**Oncologic diseases or post-transplantation status:** Ten patients with oncologic diseases or post-transplantation status (Table 3) were found to carry gallstones and no complication occurred and no cholecystectomy was required.

**Diverse diseases:** Multifactorial and chronic disorders were present in 18 patients > 2 years of age and the gallstones were associated with total parenteral nutrition (TPN) or intestinal disorders (Crohn's disease, lymphangiectasia) in 7, hepatic disease in 4, and recurrent, severe infections in 7 patients.

#### Associated disorders in patients younger than 2 years of age

In total, 22 (17.3%) patients < 2 years of age had gallstones. The underlying diseases were infections (12), diseases requiring TPN (7), or congenital hepatic disease [progressive familial intrahepatic cholestasis (1), malformation of the common bile duct (2)] (Table 1). All patients had clinical

follow-up visits, but only 2 required follow-up ultrasound for pain. Eventual stone disappearance was not documented.

**Biliary sludge:** Biliary sludge was found in 84 patients, and 66/84 (78.5%) had TPN at the time of, or until 2 wk before the diagnosis of biliary sludge. 28/84 patients were < 2 years of age (21 TPN, 5 cardiopathies, 2 CF). 56/84 patients were > 2 years of age (8 hemolytic disorders, 31 TPN, 13 severe infections, 4 CF). Biliary sludge evolved with complications, such as bile duct dilatation (2), pancreatitis (12) or thickened gallbladder wall (7) in 21/84 patients (25%, 6 < 2 and 15 > 2 years of age). Cholecystectomy was carried out in 2 patients, in 1 with recurrent pancreatitis, and 1 with sickle cell disease and suspicion of acalculous cholecystitis. Progression from biliary sludge to gallstone disease was documented in 4/84 patients (4.7%), 1 each with sickle cell disease, CF, hemolytic uremic syndrome and sepsis.

## DISCUSSION

Our study revealed 127 patients with gallstone disease: 105 were older than 2 years of age, and about 50% of these had idiopathic gallstone disease. Idiopathic gallstone disease was therefore found in 2.1% of all patients having an abdominal ultrasound for abdominal pain. Half of the patients with idiopathic gallstone disease presented with complications such as cholestasis, choledocholithiasis and/or pancreatitis. Most patients with idiopathic gallstone disease, and most of those with complications were adolescent girls. Furthermore, over 50% of patients > 2 years of age were symptomatic at the time of stone detection, and the majority had idiopathic gallstone disease. In contrast, patients with gallstones of defined etiologies often were not symptomatic.

Comparability of our results with those of recently published studies was limited by discrepancies in the study duration and patient selection. The work with the most comparable design, an European study recently published by Wesdorp *et al.*<sup>[2]</sup>, had to go through 11 years' data (1988-1999) to review a similar number of abdominal ultrasounds as we had the opportunity to accumulate in a 2 years interval (2003-2005). They found idiopathic disease in 23% of their gallstone carriers. No comparison was possible with the Italian survey carried out by Palasciano *et al.*<sup>[3]</sup>, because this study included only healthy children. We therefore reverted to older data<sup>[9-11]</sup>, where temporary conditions such as sepsis, TPN, trauma, antibiotics or immobilization were found in 22% of children with gallstone disease, and other specific conditions, such as short bowel disease, inflammatory bowel disease, and cystic fibrosis in 38%. In those cases, up to another third of children suffered from hemolytic diseases<sup>[1]</sup>. The gallstone rate in our patients with hemolytic disorders was similar to that of the North American surveys<sup>[9,10]</sup>, whereas a much lower rate was found in Europe<sup>[2]</sup>. Differing prevalence of Gilbert syndrome may explain this discrepancy<sup>[8,9]</sup>. The gallstone rate in patients with cystic fibrosis or Crohn's disease was lower in our cohort than in previous pediatric studies<sup>[9]</sup>, but similar to that of the adult North American patient population<sup>[12,13]</sup>, and the European studies. The lower prevalence of these presumed pigment stones and the lack of complications may reflect generally improved treatments for both diseases.

The most noticeable finding, however, was the larger proportion of idiopathic gallstone disease in patients > 2 years of age when compared to the results of the Wesdorp's study (45.7% *vs* 23%), and also in comparison to older North American pediatric surveys<sup>[9-11]</sup>. Furthermore, more than half of the patients with idiopathic disease presented with complications, such as pancreatitis or elevated liver enzymes and/or elevated serum bilirubin, and they all required cholecystectomy. The majority were adolescent girls, and nearly all had yellowish, presumably mixed cholesterol stones. In contrast, the majority of the few male patients in the idiopathic gallstone group with cholecystectomy had black or dark colour stones, and the patients without cholecystectomy classed as idiopathic gallstone disease had an equal gender distribution. We therefore conclude that adolescent female patients with complicated gallstone disease and yellowish gallstones are a patient group with adult type of idiopathic gallstone disease<sup>[13,14]</sup>, as opposed to the remaining patients who may have diverse etiologies, as previously described<sup>[15,16]</sup>.

Patients < 2 years of age (17.3%) were examined as a separate group, because in most cases their conditions had been requiring medical care since birth. Their lithiasis evolved asymptotically, with no cholecystectomy or long-term sonographic follow-up required, and their stones were assumed to be of infectious origin. No gender difference was found in this age group and the rates found were comparable with those published by others<sup>[1,17]</sup>.

Biliary sludge occurred without gender difference, was equally distributed in all age groups and was associated with a lack of enteral feeding due to surgery, intestinal

disease requiring parenteral nutrition, hemolysis or systemic infections. The rate found in our study was similar to that of adult patients<sup>[18-20]</sup>. Complications such as pancreatitis and dilatation of the common bile duct occurred in 25%, which is more than expected<sup>[21,22]</sup>. The high prevalence of complications can be attributed to the high proportion of chronically- and severely-ill patients hospitalized at Saint Justine Hospital. However, cholecystectomy was only exceptionally indicated. The rate of progression of sludge to gallstone disease was comparable with that of other studies<sup>[20]</sup>.

In summary, a higher than expected rate of idiopathic gallstone disease was detected in our patient cohort. Complications such as pancreatitis, elevated liver enzymes and/or elevated serum bilirubin or choledocholithiasis requiring cholecystectomy occurred more frequently than expected. The patients afflicted were mainly adolescent girls, a third of them of non-French Canadian origin. Pediatricians should be aware of the increasingly frequent adult type gallstone disease occurring in adolescent girls presenting with abdominal pain. Further research is necessary to predict children at risk for complicated idiopathic gallstone disease and prevent complications before cholecystectomy.

## COMMENTS

### Background

The prevalence of gallstones in adults of industrialized countries approximates 10% and shows a tendency to rise. Prevalence data in pediatric patients are scarce.

### Research frontiers

Current doctrine teaches that adult gallstone disease is predominantly idiopathic and most stones are composed of cholesterol, whereas the same disease in pediatric patients is due to specific causes like infectious diseases, and intestinal, hepatic or haemolytic disorders, and stones are predominantly composed of bilirubin polymers and calcium salts.

### Innovations and breakthroughs

We found 2.1% patients ( $n = 48$ ) with idiopathic gallstone disease as new diagnosis, mainly adolescent girls, 35% of other than French Canadian origin among patients requiring abdominal ultrasound for abdominal pain. Of these 48 patients, 58% presented with complications such as pancreatitis, cholestasis or choledocholithiasis. Idiopathic gallstone disease and complicated disease presentation were much more frequent than expected from previous studies.

### Applications

Pediatricians should become more aware of a disease until now attributed to adult patients only. In the light of the recent detection of a human lith gene ABCG5/G8 and its association with the risk for cholesterol gallstone formation, the value of genetic evaluations of such families in order to prevent complicated disease presentation should be discussed.

### Terminology

Gallstones of unknown etiology are referred to as idiopathic gallstone disease, in contrast to gallstones of known etiology, such as for instance hemolytic disorders.

### Peer review

This is a well written and informative paper. The study estimated the prevalence of gallstones in the pediatric population (9203 patients < 19 years of age) of Canadian tertiary care centre by reviewing abdominal ultrasounds recorded over two years. Gallstones were found in 127 patients, 50% of these were considered idiopathic which was more than expected from previous studies.

### Abstract

**AIM:** To measure plasma D-dimer levels in cirrhotic patients with and without ascites, assessing the effect of ascites resolution in D-dimer concentration.

**METHODS:** Seventy consecutive cirrhotic patients (M = 44, F = 26, mean age 65 years, SD  $\pm$  13), observed from October 2005 to March 2006 were enrolled. Circulating D-dimer levels were measured using a latex-enhanced, immunoturbidimetric test. In patients with ascites ( $n$  = 42) the test was repeated after ascites resolution.

**RESULTS:** Ascites was present in 42 patients (group A) and absent in 28 (group B). Group A patients had more advanced liver disease. Hepatocellular carcinoma (HCC) was diagnosed in 14 patients and was more frequent in group B. Above normal range D-dimers were found in 45/70 patients. High D-dimers were more frequent in group A than in group B ( $P$  = 0.001). High D-dimers were associated with presence of HCC ( $P$  = 0.048) only in group B. After ascites resolution, obtained in all patients, mean D-dimer values decreased in those 34 patients with high basal levels ( $P$  = 0.007), returning to normal in 17.

**CONCLUSION:** In patients with liver cirrhosis, ascites and HCC are the main factors associated with increased fibrinolytic activity.

### INTRODUCTION

Hemostasis is a dynamic process resulting from the balance between procoagulant and anticoagulant factors. The liver is the site of production of most proteins which favour and inhibit the process of coagulation and fibrinolysis. Patients with liver cirrhosis may develop a serious coagulopathy whose origin is commonly ascribed to a defective hepatic synthesis of clotting factors often in association with thrombocytopenia secondary to portal hypertension. In addition, patients with advanced liver disease have a hyperfibrinolytic state which contributes to the bleeding tendency causing a premature removal of the hemostatic plug. Plasma levels of fragment D-dimer represent an accurate marker of fibrinolytic activity. The finding of high D-dimer plasma concentration in patients with liver cirrhosis, decompensated by ascites, led Agarwal *et al*<sup>[1]</sup> to suggest a major role of ascites in the pathogenesis of hyperfibrinolytic state associated with liver failure. The aims of this study were: (1) to evaluate the relationship between the presence of ascites and hyperfibrinolytic state in liver cirrhosis measuring the circulating levels of D-dimer in patients with and without ascites and (2) to assess the effect of ascites resolution in the plasma concentration of D-dimers.

### MATERIALS AND METHODS

#### Subjects

The study was designed to measure plasma D-dimer levels in all consecutive patients with cirrhosis of the liver referring to the Unit of Clinica Medica, Messina University,

**Table 1** Clinical and demographic features of the patients with liver cirrhosis

	Ascites <i>n</i> = 42	No ascites <i>n</i> = 28	<i>P</i> value
Gender M/F	24/18	20/8	0.735
Mean age ± SD (yr)	67 ± 14	64 ± 14	0.068
Child-Pugh class (%)			0.004
A	8 (19.0)	18 (64.3)	
B	18 (42.9)	8 (28.6)	
C	16 (38.0)	2 (7.1)	
Patients with HCC (%)	2 (4.8)	12 (42.8)	0.000

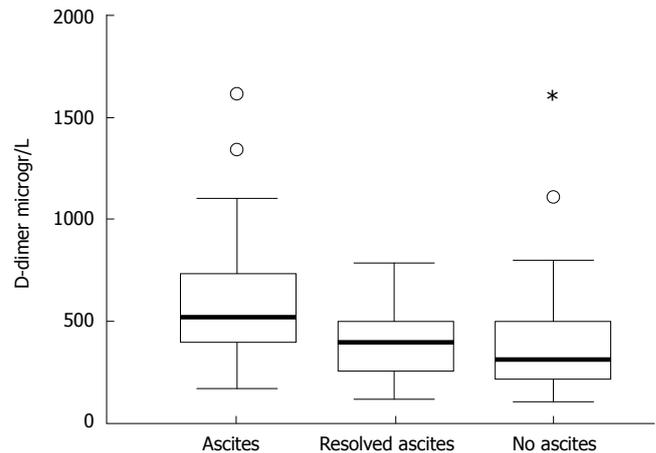

Italy, during a 6 mo period (October 2005-March 2006), with the exclusion of patients with deep venous or portal vein thrombosis. We included 70 patients and excluded 1 patient with portal vein thrombosis. Informed consents were obtained from all patients. The diagnosis of cirrhosis was either histological or made by clinical and/or imaging signs of portal hypertension. The etiology of liver disease was HCV infection in 31 patients, HBV infection in 4, past alcohol abuse in 15, autoimmune in 2, HBV + HCV coinfection in 1, primary biliary cirrhosis in 1, HCV + alcohol abuse in 2 and cryptogenic in 14. Hepatocellular carcinoma (HCC) was diagnosed in 14 patients. All patients underwent color-Doppler ultrasonographic study of the abdomen and the legs. Severity of liver disease was classified by Child-Pugh score. Patients were divided into 2 groups according to the presence of ascites. Patients with ascites were treated with fluid and salt restriction, diuretics and/or paracentesis. The resolution of ascites was confirmed by ultrasonography. D-dimer levels were measured also after disappearance of abdominal fluid. The demographic and clinical features of the patients studied are shown in Table 1.

### Blood collection and testing

Peripheral blood was collected into tubes containing sodium citrate solution. After centrifugation (10 min, 1500 × *g*), the supernatant plasma was removed. Plasma D-dimer was measured by a latex-enhanced, immunoturbidimetric test using a commercially available kit (D-dimer PLUS, Dade Behring, Marburg, Germany). The D-dimer concentration was expressed in µg/L with a normal range of 125-350 µg/L.

### Statistical analysis

Differences between groups were evaluated by non parametric permutation Test (NPC test) for numerical variables and by Anderson Darling Test for categorical variables<sup>[2]</sup>. Association between D-dimer values and gender of patients, Child-Pugh class and HCC presence was analyzed by Log-Likelihood ratio test<sup>[3]</sup>. Correlation between D-dimer values and age of patients was evaluated using biserial correlation coefficient<sup>[4]</sup>. Influence of the variables, gender, age, Child-Pugh class and HCC presence on D-dimer values was estimated by a logistic regression model<sup>[5]</sup>. Softwares SPSS, Windows 11.0 (2001) for Binary Logistic Regression, Microsoft Excel (2002) for *G* test, Methodologica S.R.L. (2001) for nonparametric analysis NPC test and Anderson Darling test were used.

**Figure 1** Distribution of plasma D-dimer in patients with liver cirrhosis. °Indicates outlier between 1.5- IQR (Interquartile Range) and 3-IQR below Q1 (first quartile); \*Indicates outlier more than 3-IQR below Q1.

## RESULTS

Ascites was present in 42 patients (group A) and absent in 28 (group B). No significant differences in age and gender were found between the two groups. Patients of group A had more advanced liver disease. HCC was more frequent in patients of group B (Table 1). Plasma D-dimer levels above the normal range were found in 45/70 patients (64.3%). D-dimer above normal values were more frequent ( $P = 0.001$ ) in group A (34/42) than in group B (11/28). D-dimer mean values were higher ( $P = 0.001$ ) in group A ( $649 \pm 420$  g/L) than in group B ( $359 \pm 219$  g/L, Figure 1). In all patients of group A resolution of ascites was obtained either by fluid and salt restriction and conventional diuretic treatment (in 36) or by paracentesis (in 6). After disappearance of ascitic fluid, confirmed by ultrasonography, mean D-dimer values decreased in all 34 patients with high basal levels ( $P = 0.007$ ), returning to normal range in 17. In these patients, D-dimer values after resolution of ascites ( $438 \pm 279$  g/L) were not significantly different from those found in patients without ascites, group B, (Figure 1).

In the whole population of patients or the separate groups A and B, high D-dimer levels were not associated with gender neither with Child-Pugh class (Anderson-Darling test) and did not correlate with anagraphic age. Only in patients without ascites, group B, high D-dimer levels were associated with presence of HCC ( $P = 0.048$ ). When we inserted the variables age, gender, Child-Pugh class and presence of HCC in a logistic regression model (where the response variable was represented by normal or high D-dimer class), we found that high levels of D-dimer were significantly dependent on the presence of HCC ( $P = 0.030$ ) in patients without ascites (group B) and negatively dependent on age ( $P = 0.019$ ) in patients with ascites (Group A).

## DISCUSSION

Patients with liver cirrhosis have a bleeding tendency that is often not evident from routine clotting studies. In such patients, the incidence of hyperfibrinolysis varies from 19% to 95%<sup>[6-8]</sup> and may contribute to serious bleeding

complications. The pathogenesis of hyperfibrinolysis in liver cirrhosis is not yet clearly known. Having found high D-dimer levels in the blood and in the ascitic fluid, Agarwal *et al* suggested ascites among the possible causes of increased fibrinolysis in patients with liver cirrhosis<sup>[1]</sup>.

The aim of our study was (1) to evaluate the relationship between the presence of ascites and hyperfibrinolytic state in cirrhotic patients measuring the circulating levels of D-dimer in those with and without ascites and (2) to assess the effect of ascites resolution in the concentration of D-dimers. High D-dimer levels in 64% of patients with liver cirrhosis were observed. This finding is in agreement with that of Agarwal *et al* who reported increased plasma D-dimers in 63% of patients with liver cirrhosis<sup>[1]</sup>. This percentage is higher than that reported in another study where abnormal D-dimers were found only in 17% of patients with chronic liver disease. However, 11 out of 86 patients included were not cirrhotic and the number of ascitic patients was not specified<sup>[9]</sup>. When we divided our patients into two groups, according to the presence of ascites, we found high D-dimers in 81% of patients with ascites and in 39% of patients without. This finding is also consistent with that of Agarwal *et al* who showed increased plasma D-dimer values in 93% and 33% of patients with and without ascites, respectively<sup>[1]</sup>. Furthermore, our patients with ascites had mean D-dimer values significantly higher than those without. After resolution of ascites, circulating D-dimers decreased significantly in all patients, returning to normal in half of them. Also, mean D-dimer levels in cirrhotic patients with resolved ascites were not significantly different from those in patients who entered the study without ascites. Therefore, our data confirm the association between circulating high D-dimer levels and the presence of ascites found in cirrhotic patients.

Another interesting finding of our study is the close association between presence of HCC and high D-dimer values in patients without ascites. HCC is often associated with thrombotic invasion of portal or hepatic vein. Although we excluded from the study all patients with clinical and imaging features of thrombosis, we cannot rule out the presence of microvascular invasion in patients with HCC. In fact, Kim *et al*<sup>[10]</sup> also found increased circulating D-dimers in patients with HCC, even in absence of tumor thrombosis in a major branch of the portal or the hepatic vein.

The underlying mechanism for high D-dimer plasmatic levels in cirrhotic patients with ascites remains to be clarified. Some authors suggest the exchange of some coagulation and fibrinolytic proteins between plasma and ascitic fluid<sup>[11,11]</sup>. Violi *et al* propose that hyperfibrinolysis in cirrhotic patients might represent a state of low grade disseminated intravascular coagulation secondary to the passage of gut absorbed bacterial material into the systemic circulation<sup>[12]</sup>. On the basis of this finding, Piscaglia *et al* argue that the association between high plasma D-dimers and ascites might be due only to more advanced liver disease with portal hypertension favouring bacterial translocation. In our study, however, we were not able to demonstrate any correlation between circulating D-dimers and severity of disease<sup>[13]</sup>.

Although some of our patients with high D-dimers had no ascites, it must be underlined that 64% of them had HCC. In conclusion, our study shows that high D-dimers are associated either with presence of ascites or with HCC. In patients with liver cirrhosis, high D-dimer levels in absence of ascites require more careful monitoring for HCC. Depletion of ascitic fluid might prevent bleeding complications, especially if invasive procedures become necessary.

## ACKNOWLEDGMENTS

Dr. Maria Concettina Tripoli for important contribution in the revision of the English language.

## COMMENTS

### Background

Patients with advanced liver disease have a hyperfibrinolytic state which contributes to the bleeding tendency causing a premature removal of the hemostatic plug. Plasma levels of fragment D-dimer represent an accurate marker of fibrinolytic activity.

### Research frontiers

The finding of high D-dimer plasma concentration in patients with liver cirrhosis, decompensated by ascites, led Agarwal *et al* to suggest a major role of ascites in the pathogenesis of hyperfibrinolytic state associated with liver failure.

### Innovations and breakthroughs

High D-dimer plasma levels in patients with liver cirrhosis are associated with presence of ascites and decline after its resolution. In absence of ascites, high D-dimer values are associated with presence of hepatocellular carcinoma (HCC).

### Applications

In patients with liver cirrhosis depletion of ascitic fluid might prevent bleeding complications, especially if invasive procedures become necessary. In absence of ascites, high D-dimer levels rise suspect of HCC and require more careful monitoring.

### Terminology

Fragment D-dimer is a degradation product from a specific region of cross-linked fibrin. High plasma D-dimer levels represent a sensitive but not specific marker of fibrinolysis and thrombosis.

### Peer review

This was a modest but interesting paper with some potential clinic significance.

### Abstract

**AIM:** To evaluate the impact of obesity on the postoperative outcome after hepatic resection in patients with hepatocellular carcinoma (HCC).

**METHODS:** Data from 328 consecutive patients with primary HCC and 60 patients with recurrent HCC were studied. We compared the surgical outcomes between the non-obese group (body mass index: BMI < 25 kg/m<sup>2</sup>) and the obese group (BMI ≥ 25 kg/m<sup>2</sup>).

**RESULTS:** Following curative hepatectomy in patients with primary HCC, the incidence of postoperative complications and the long-term prognosis in the non-obese group (*n* = 240) were comparable to those in the obese group (*n* = 88). Among patients with recurrent HCC, the incidence of postoperative complications after repeat hepatectomy was not significantly different between the non-obese group (*n* = 44) and the obese group (*n* = 16). However, patients in the obese group showed a significantly poorer long-term prognosis than those in the non-obese group (*P* < 0.05, five-year

survival rate; 51.9% and 92.0%, respectively).

**CONCLUSION:** Obesity alone may not have an adverse effect on the surgical outcomes of patients with primary HCC. However, greater caution seems to be required when planning a repeat hepatectomy for obese patients with recurrent HCC.

Impact of obesity on the surgical outcome following repeat hepatic resection in Japanese patients with recurrent hepatocellular carcinoma. *World J Gastroenterol* 2008; 14(10): 1553-1558 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1553.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1553>

### INTRODUCTION

Obesity, the incidence of which has recently been growing at an epidemic rate in Japan<sup>[1]</sup>, as well as in the other Western countries, has been implicated as a risk factor for postoperative complications in general surgery<sup>[2-4]</sup>. Indeed, several studies have shown that obesity increases the risk of wound complications in various types of surgical procedure<sup>[5]</sup>. However, the effects of obesity on surgical outcomes remain controversial<sup>[6-8]</sup>.

The World Health Organization (WHO)<sup>[9]</sup> defines obesity as a body mass index (BMI) above 30 kg/m<sup>2</sup>, but in Japan, the prevalence of the population with such a BMI is no more than 2%-3%, in contrast to the 20%-30% prevalence in Western countries<sup>[10]</sup>. In Japan, the definition

of obesity is proposed to be a BMI above 25 kg/m<sup>2</sup>, since the incidence of obesity-related disorders increases with a BMI ≥ 25 kg/m<sup>2</sup><sup>[11]</sup>. On the other hand, recent epidemiological studies have demonstrated that obesity is a risk factor for hepatocellular carcinoma (HCC)<sup>[12-14]</sup>. To our knowledge, however, there are no data regarding the postoperative outcomes in obese patients with HCC. Therefore, in the present study, we specifically evaluated the influence of obesity (BMI ≥ 25 kg/m<sup>2</sup>) on the early and late surgical results following curative hepatic resection in Japanese patients with HCC.

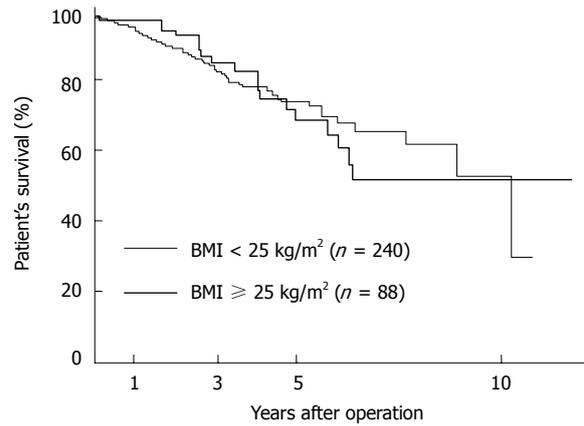

**MATERIALS AND METHODS**

From January 1995 to August 2006, 328 consecutive patients with HCC received a curative primary hepatic resection at Hiroshima Red Cross Hospital and Atomic Bomb Survivors Hospital. Sixty patients with intrahepatic recurrence, who underwent a curative repeat hepatectomy, were also examined. A curative hepatectomy indicates that no tumor remained in the remaining liver based on the findings of an intraoperative ultrasound examination or a computed tomographic (CT) study performed within 3 mo after surgery. Repeat hepatectomy for recurrent HCC was considered to be the treatment of choice for resectable recurrent tumors. Our selection criteria for repeat hepatectomy were the same as those for primary resection for HCC. The selection of type of hepatectomy was made on the basis of tumor location and liver function<sup>[15]</sup>. Patients with uncontrollable ascites are considered to be contraindicated for a hepatic resection. Therefore, no patients with ascites were included in this study. Height and weight were measured preoperatively, and the BMI (kg/m<sup>2</sup>) was calculated as weight (kg) divided by squared height (m). Although the WHO<sup>[9]</sup> defines obesity as a BMI above 30 kg/m<sup>2</sup>, only 7 (2.1%) of the 328 patients with primary HCC and 1 (1.7%) of the 60 patients with recurrent HCC met this definition. Therefore, in the present study, we defined obesity as a BMI ≥ 25 kg/m<sup>2</sup>.

The records of 328 patients with primary HCC were reviewed retrospectively. These patients were classified into two groups based on BMI: an obese (BMI ≥ 25 kg/m<sup>2</sup>) group and a non-obese (BMI < 25 kg/m<sup>2</sup>) group. Similarly, the 60 patients with recurrent HCC were classified into two groups based on BMI. We compared clinicopathological parameters, such as liver function data, operative data, postoperative complications and tumor factors, between the obese group and the non-obese group. Postoperative complications were defined as any event that required specific medical or surgical treatment. We also compared the survival rates and disease-free survival rates between the two groups. All patients were closely followed after operation. Monthly measurements of alpha-fetoprotein and protein induced by vitamin K absence-II (PIVKA-II) were performed. Every 3 to 4 mo, ultrasonographic examination and dynamic CT were performed by radiologists. An angiographic examination was performed after admission when recurrence was strongly suspected.

**Statistical analysis**

To compare the clinicopathological variables between the

**Figure 1** Comparison of the survival curves after a primary hepatectomy in the nonobese group (BMI < 25 kg/m<sup>2</sup>, n = 240) versus the obese group (BMI ≥ 25 kg/m<sup>2</sup>, n = 88). The patient's survival rate in the nonobese group did not differ significantly from that in the obese group.

two patient groups, either the unpaired Student's *t* test or the chi-square test was used. Survival was estimated by the Kaplan and Meier method and the differences in survival between the groups were then compared using the log-rank test. Only a few significant variables were analyzed in the multivariate analysis using Cox's proportional hazard model. A *P* value < 0.05 was considered to be significant.

**RESULTS**

**Impact of obesity (BMI ≥ 25) on hepatectomy for primary HCC**

Table 1 summarizes the clinicopathological variables of the patients in the non-obese (BMI < 25 kg/m<sup>2</sup>, n = 240: 73%) and obese groups (BMI ≥ 25 kg/m<sup>2</sup>, n = 88: 27%). The percentage of female patients in the obese group was significantly higher than that in the non-obese group (*P* < 0.05). However, the percentage of patients with diabetes mellitus was not significantly different between the two groups. No differences were noted between the groups in terms of liver function data, operative data (such as operation time, blood loss and postoperative complications) or tumor factors. The incidence of postoperative infectious complications in the obese patients (7/88, 8.0%) tended to be higher (*P* = 0.092) than that in the non-obese patients (8/240, 3.3%). However, the incidence of other complications, such as intractable ascites and bile leakage, did not differ significantly between the two groups. In total, the incidence of postoperative complications in the obese group was comparable to that in the non-obese group (Table 1).

The survival of patients in the obese group was almost identical to that in the non-obese group (Figure 1). Moreover, no significant difference was found in the disease-free survival rates between the two groups (Figure 2).

**Impact of obesity (BMI ≥ 25) on repeat hepatectomy for recurrent HCC**

Table 2 compares the clinicopathological features between the non-obese (BMI < 25 kg/m<sup>2</sup>, n = 44: 73%) and obese groups (BMI ≥ 25 kg/m<sup>2</sup>, n = 16: 27%). Similar

**Table 1** The clinicopathological data of nonobese (BMI < 25 kg/m<sup>2</sup>) and obese (BMI ≥ 25 kg/m<sup>2</sup>) patients with hepatocellular carcinoma who underwent a primary curative hepatectomy

Variables	BMI < 25 kg/m <sup>2</sup> (n = 240)	BMI ≥ 25 kg/m <sup>2</sup> (n = 88)	P value
Age	65.6 ± 9.9	66.0 ± 8.8	0.725
Gender (male:female)	172:68	50:38	< 0.05

to the patients with primary HCC (Table 1), there was a significantly higher proportion of female patients in the obese group than in the non-obese group (*P* < 0.05). No significant differences were observed in the liver function data and tumor factors. However, the operation time was significantly longer (*P* < 0.05) and the blood loss was significantly greater (*P* < 0.01) in the obese group compared with the non-obese group. Although no statistically significant difference was noted, the patients in the obese group tended to receive blood transfusions more frequently than those in the non-obese group (*P* = 0.068). Four patients (25%) in the obese group had postoperative complications, which included intractable ascites in 2 cases, wound infection in 1 case and angina pectoris in 1 case. The incidence of postoperative complications did not differ significantly between the two groups, and no postoperative hospital death occurred after a repeat hepatectomy.

We also compared the cumulative survival rates, as shown in Figure 3. Patients in the obese group had a significantly poorer prognosis (*P* < 0.05) than those in the non-obese group. The disease-free survival rate in the obese group was also significantly lower than that in the non-obese group (*P* < 0.05; Figure 4). Nineteen of the 44 patients in the non-obese group and 11 of the 16 patients in the obese group had recurrent disease after

BMI: Body mass index; HCV: Hepatitis C virus; AST: Aspartate transaminase; Hr0: Resection less than subsegmentectomy; Hr5: Subsegmentectomy; Hr1: Segmentectomy; Hr2: Bisegmentectomy; fc: Capsular formation; vp: Invasion to portal vein; im, intrahepatic metastasis; AFP: Alpha-fetoprotein. <sup>1</sup>Histologic differentiation of the tumor.

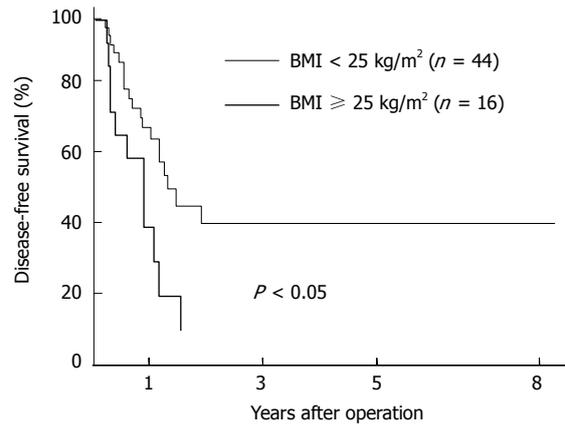

**Figure 2** Comparison of the survival curves after primary hepatectomy in the nonobese group (BMI < 25 kg/m<sup>2</sup>, n = 240) versus the obese group (BMI ≥ 25 kg/m<sup>2</sup>, n = 88). No significant difference in the disease-free survival rate between the two groups was observed.

repeat hepatectomy. Regarding the patterns of recurrence, 11 (58%) of the 19 patients in the non-obese group and 2 (18%) of the 11 patients in the obese group had a solitary intrahepatic recurrence. The remaining patients had a widespread recurrence, including multinodular recurrence in the remnant liver and/or extrahepatic recurrence. Therefore, patients in the obese group (9/11, 82%) showed widespread

**Figure 3** Comparison of the survival curves after repeat hepatectomy in the nonobese group (BMI < 25 kg/m<sup>2</sup>, n = 44) versus the obese group (BMI ≥ 25 kg/m<sup>2</sup>, n = 16). The patient's survival rate in the obese group was significantly lower than that in the nonobese group (P < 0.05).

**Figure 4** Comparison of the survival curves after a repeat hepatectomy in the nonobese group (BMI < 25 kg/m<sup>2</sup>, n = 44) versus the obese group (BMI ≥ 25 kg/m<sup>2</sup>, n = 16). A significantly shorter disease-free survival was found in the obese group than in the nonobese group (P < 0.05).

**Table 3** The results of a multivariate analysis using Cox's proportional hazard model in the patients with recurrent hepatocellular carcinoma who underwent a repeat hepatectomy

Variables	Coefficient	SE	Relative risk	P value
Obesity (BMI ≥ 25 kg/m <sup>2</sup> )	0.770	0.372	2.160	< 0.05
Tumor size (≥ 2 cm)	0.389	0.438	1.477	0.351
Positive vp	0.466	0.433	1.595	0.254

SE: Standard error; vp: Invasion to portal vein.

recurrences more frequently than those in the non-obese group (8/19, 42%) after a repeat hepatectomy.

In a univariate analysis, 3 variables were identified to be significant prognostic factors: obesity (BMI ≥ 25 kg/m<sup>2</sup>), tumor size (≥ 2 cm) and microscopic presence of portal vein invasion. Furthermore, a multivariate analysis using Cox's proportional hazard model demonstrated obesity (BMI ≥ 25 kg/m<sup>2</sup>) to be an independent prognostic indicator in patients with recurrent HCC (Table 3).

## DISCUSSION

Obese patients are at an increased risk of numerous medical problems, such as diabetes mellitus, hypertension and immune dysfunction, which can adversely affect the surgical outcomes. However, several studies have investigated this issue and the results are still controversial, possibly due to the use of different definitions and classifications of obesity, and the lack of a uniform way of reporting surgical complications<sup>[16,17]</sup>. Dindo *et al*<sup>[6]</sup> studied the impact of obesity (BMI ≥ 30 kg/m<sup>2</sup>) on the outcomes of 6336 patients undergoing general elective surgery. They found that obesity alone was not a risk factor for postoperative complications. Since the association between BMI and health risks to Asian populations is different from that in European populations<sup>[11,18]</sup>, we defined obesity as BMI ≥ 25 kg/m<sup>2</sup> in this study. Consistent with the findings of a previous report<sup>[6]</sup>, there was no significant difference in the incidence of postoperative complications

and postoperative hospital death between the non-obese group (BMI < 25 kg/m<sup>2</sup>) and the obese group (BMI ≥ 25 kg/m<sup>2</sup>), following curative hepatectomy in patients with primary HCC. On the other hand, among patients with recurrent HCC, the operation time and blood loss were significantly greater in the obese group than in the non-obese group. Since the operative procedures (extent of hepatic resection) were comparable between the two groups (Table 2), these data reflect the apparent greater technical difficulty of a repeat hepatectomy in obese patients. The wider area of peritoneal adhesion owing to the previous operation and the limited visualization of the surgical field in obese patients might adversely affect the operation time and blood loss. However, the difference in the incidence of postoperative complications after a repeat hepatectomy between the two groups did not reach statistical significance. Therefore, these results indicate that there exists no marked influence of obesity (BMI ≥ 25 kg/m<sup>2</sup>) on the early surgical outcome after a curative hepatic resection, in both patients with primary HCC and those with recurrent HCC.

Only a few investigators have studied the impact of obesity on long-term outcomes following surgery, and the results are conflicting<sup>[3,19]</sup>. Dhar *et al*<sup>[3]</sup> suggested that being overweight was an independent predictor of disease recurrence in T2/T3 gastric cancers, whereas Kodera *et al*<sup>[19]</sup> reported that obesity did not affect long-term survival after a distal gastrectomy in gastric cancer patients. In the current study, we found no remarkable impact of obesity on the long-term prognosis after a curative hepatectomy in patients with primary HCC. On the other hand, among patients with recurrent HCC, the long-term prognosis following repeat hepatectomy in the obese patients was significantly worse than that in the non-obese patients. Furthermore, obesity (BMI ≥ 25 kg/m<sup>2</sup>) was an independent poor prognostic indicator in patients with recurrent HCC. The reason why obesity adversely affects the long-term outcome in these patients is not clear. However, several reports have suggested that obesity is significantly associated with a higher rate of death due to many cancers, including liver cancer<sup>[12,13,20,21]</sup>. In particular, recent studies have implicated that non-alcoholic

steatohepatitis (NASH), which is characterized by obesity, can progress to liver cirrhosis and HCC<sup>[22-24]</sup>. However, pathological examinations in the resected non-cancerous liver specimens revealed only 4 of the 328 patients with primary HCC and one of the 60 patients with recurrent HCC to have NASH in this study. It therefore appears that the poorer prognosis after repeat hepatectomy in obese patients was not attributable to the progression of NASH. The mechanism generally proposed to explain the association between obesity and a worse prognosis include elevated concentrations of insulin-like growth factors<sup>[25]</sup>, leptin<sup>[26]</sup>, hormones<sup>[27]</sup> and cytokines<sup>[28]</sup>. Additional proposed mechanisms include reduced immune functioning and differences in diet and physical activity between obese and non-obese patients<sup>[20,21]</sup>. However, these mechanisms fail to explain the poorer prognosis after a repeat hepatectomy in the obese patients, because such a worse prognosis was not observed in obese patients with primary HCC. Among patients with recurrent HCC, those in the obese group showed a significantly greater amount of blood loss and tended to receive blood transfusions more frequently than those in the nonobese group. Many investigators have demonstrated that the increased blood loss and the need for blood transfusions are risk factors for recurrent HCC<sup>[29,30]</sup>, which is attributed to the induction of immunosuppression. Therefore, the worsened prognosis in obese patients might be associated with the synergistic impacts of the obesity itself and perioperative blood transfusions due to increased blood loss on immune function.

In conclusion, our present findings suggest that the obesity, as defined by a BMI  $\geq 25$  kg/m<sup>2</sup>, does not have an adverse impact on postoperative outcomes, including postoperative complications and long-term prognosis, after a curative hepatectomy in patients with primary HCC. However, more caution seems to be required when planning a repeat hepatectomy for recurrent HCC in patients who are either overweight or obese.

## COMMENTS

### Background

Several studies have shown that obesity increases the risk for postoperative complications. However, the influence of obesity on the postoperative outcome after hepatectomy in patients with hepatocellular carcinoma (HCC) has never been evaluated.

### Research frontiers

Recent epidemiological studies have demonstrated that obesity is a risk factor for HCC. Therefore, it is important to investigate not only the short-term outcome, but also the long-term outcome after hepatectomy in patients with HCC.

### Innovations and breakthroughs

The long-term prognosis after curative resection for HCC remains unsatisfactory, because of a high rate of recurrence. Repeat hepatectomy has been established as the treatment of choice for recurrent HCC. However, our present findings suggest that more caution may be required when planning such a procedure for obese patients with recurrent HCC.

### Applications

The authors would like to emphasize that the incidence of obesity-related disorders increases with a BMI  $\geq 25$  kg/m<sup>2</sup> in Japan. The prevalence of the population with such a BMI in Japan is almost identical to that of the population with a BMI  $\geq$

30 kg/m<sup>2</sup> in Western countries. This is the reason why we considered the definition of obesity used in this study to be reasonable. Therefore, it will be valuable to evaluate the impact of obesity on surgical outcomes following repeat hepatectomy in Western countries.

### Terminology

The WHO defines obesity as a BMI above 30 kg/m<sup>2</sup>. However, in this study, we defined obesity as a BMI  $\geq 25$  kg/m<sup>2</sup>, because of the reasons described above.

### Peer review

I think it is an important paper that adds a great deal to the literature. There is not much on the topic. Your sample was large; the paper was nicely written; tables were well done and figures were very good. It was a pleasure to read.

### Abstract

**AIM:** To detect the prevalence of anti-HAV IgG antibodies in adult multitransfused beta-thalassemic patients.

**METHODS:** We studied 182 adult beta-thalassemic patients and 209 controls matched for age and sex from the same geographic area, at the same time. Anti-HAV IgG antibodies, viral markers of hepatitis B virus (HBV) and hepatitis C virus (HCV) infection were evaluated.

**RESULTS:** Anti-HAV IgG antibodies were detected more frequently in thalassemic patients (133/182; 73.1%) than in healthy controls (38/209; 18.2%,  $P < 0.0005$ ). When we retrospectively evaluated the prevalence of anti-HAV IgG antibodies in 176/182 (96.7%) thalassemic patients, whose medical history was available for the previous ten years, it was found that 83 (47.2%) of them were continuously anti-HAV IgG positive, 16 (9.1%) acquired anti-HAV IgG antibody during the previous ten years, 49 (27.8%) presented anti-HAV positivity intermittently and 28 (15.9%) were anti-HAV negative continuously.

**CONCLUSION:** Multitransfused adult beta-thalassemic patients present higher frequency of anti-HAV IgG antibodies than normal population of the same geographic area. This difference is difficult to explain, but it can be attributed to the higher vulnerability of thalassemics to HAV infection and to passive transfer of anti-HAV antibodies by blood transfusions.

### INTRODUCTION

Hepatitis A virus (HAV) hepatitis is usually spread by the fecal-oral route. Seroprevalence rates in the USA, Western Europe and in several Mediterranean countries have been falling during the past few decades. In some countries no more than 10% of the adult population has evidence of previous infection<sup>[1]</sup>. In Greece, the lack of epidemics of HAV since early 1980s and the improvement of socioeconomic and hygienic conditions over the last decade seems to have contributed to the decline of the prevalence of anti-HAV antibodies<sup>[2,3]</sup>. Dalekos et al tested 1984 healthy individuals of Greek nationality for anti-HAV antibodies and found a prevalence of 39.8% in males and 33.2% in females<sup>[4]</sup>. According to the National Centre for Surveillance and Intervention of Greece, the median annual prevalence of acute hepatitis A in Greece for the time 1998-2003 was 1.88 cases/100 000 of population, which is comparable to the hepatitis A prevalence of the Western Europe<sup>[5]</sup>. Parenteral transmission is extremely rare, but can follow transfusion of blood from a donor who is in the incubation period of the disease<sup>[6,7]</sup>. The relatively short duration of viremia in acute hepatitis A, together with the moderate titer of HAV viral load in the blood<sup>[8]</sup>, diminishes the likelihood of transfusing a unit of blood infectious for HAV. The potential cotransfusion of HAV-specific antibodies to the recipient of multiple

blood units and the rising seroprevalence to HAV with age further diminish the risk of post-transfusion hepatitis A<sup>[9]</sup>.

The aim of this study was to detect the prevalence of anti-HAV IgG antibodies in adult multitransfused beta-thalassemic patients and to compare this with the prevalence in healthy subjects of the same age and geographic area.

## MATERIALS AND METHODS

### Patients

We studied 182 adult multi-transfused patients from West Peloponnese (88 males, 94 females, mean age  $31.6 \pm 9.4$  years, range 17-66 years) suffering from beta-thalassemia major ( $n = 136$ ) or intermedia ( $n = 46$ ). These patients were in follow up at the Thalassemia Center of the University Hospital of Patras. They were receiving regular transfusions of two units of packed red cells at about 3 wk intervals in order to maintain the haemoglobin level above 10 g/dL. The mean age at first blood transfusion was  $2 \pm 1.9$  years, the mean duration of transfusion therapy was  $26.6 \pm 8.5$  years and the mean number of transfusions received up until the time of the present study was  $931 \pm 482$ . Seventy-two patients (39.6%) had undergone splenectomy in the past. None of the patients had a history of intravenous drug use or chronic alcohol abuse. There were no reported cases of HAV hepatitis among the studied patients. In addition, none of the patients had received hepatitis A vaccination in the past. Serum used in the study was obtained just before a scheduled transfusion of packed red blood cells.

The control group was made up of 209 normal subjects from West Peloponnese, matched for age and sex (103 males, 106 females, mean age  $31.2 \pm 8.5$  years, range 17-58 years) from the volunteer blood donor program of our Hospital. Each individual had indicated the absence of significant illness. Physical examination, normal liver function test results and absence of hepatitis B surface antigen (HBsAg) and anti-HCV antibodies in their serum, excluded liver diseases in the control group. None of the healthy subjects had a history of blood transfusion or hepatitis A vaccination in the past.

### Viral markers

Anti-HAV antibodies, IgG and IgM, were tested using standard commercially available enzyme immunoassays (HAVAB-M 2.0 and HAVAB 2.0, AxSYM, Abbott Laboratories, Wiesbaden, Germany) in 182 thalassemic patients and in 209 controls from 10 February 2005 to 10 June 2005. We also retrospectively evaluated the prevalence of anti-HAV IgM and anti-HAV IgG antibodies in 176/182 (96.7%) thalassemic patients whose medical history was available for the previous ten years (about 6-8 tests for each patient). Anti-HCV antibodies were tested by third generation ELISA (AxSYM-Abbott, Wiesbaden, Germany). HCV RNA was detected in anti-HCV positive sera by reverse transcriptase polymerase chain reaction (RT-PCR) (Hepatitis C virus test-version 3.0, Cobas Amplicor, Roche Diagnostics, Branchburg, NJ, USA). Hepatitis B surface antigen (HBsAg) and hepatitis B core antibody (anti-HBc) were determined using standard 3rd

**Table 1** General characteristics and prevalence of anti-HAV antibodies in beta-thalassemic patients and controls

Characteristics	Thalassemic patients ( <i>n</i> = 182)	Healthy donors ( <i>n</i> = 209)	<i>P</i> value
Age (yr)	31.6 ± 9.4	31.2 ± 8.5	0.662
Sex (M/F)	88/94	103/106	0.854
AST (IU/L) <sup>1</sup>	43.9 ± 29.1	23.9 ± 6.9	< 0.0005
ALT (IU/L)	52.6 ± 37.8	23.5 ± 10.6	< 0.0005
GGT (IU/L)	31.8 ± 26.6	22.5 ± 14	< 0.0005
Anti-HAV IgM (+) <sup>2</sup>	0	0	
Anti-HAV IgG (+)	133 (73.1%)	38 (18.2%)	< 0.0005

<sup>1</sup>Normal levels: Aspartate aminotransferase (AST) < 40 IU/L, alanine aminotransferase (ALT) < 40 IU/L, gamma-glutamyltranspeptidase (GGT) < 50 IU/L; <sup>2</sup>Anti-HAV: Hepatitis A virus antibody.

generation commercially available enzyme immunoassays [AxSYM HbsAg (V2), AxSYM CORE].

### Statistical analysis

Values were expressed as prevalence rates or as the mean  $\pm$  SD. Conventional chi-square and Fisher's exact test were used to analyse qualitative differences. The differences between parametric data were evaluated with Student's *t*-test. For non-parametric test values a Mann-Whitney test was used.  $P < 0.05$  was considered significant. Statistical analysis was performed with SPSS 8.0 statistical software. The study was approved by the Ethical Committee of Patras University Hospital and informed consent to participate in the study was obtained from all patients and controls.

## RESULTS

### Prevalence of anti-HAV antibodies in the two groups

Table 1 shows the prevalence of anti-HAV antibodies in beta-thalassemic patients and controls. Anti-HAV IgM antibodies were not found in any patient of the two groups. Anti-HAV IgG antibodies were detected significantly more frequently in thalassemic patients (133/182; 73.1%) than in healthy controls (38/209; 18.2%,  $P < 0.0005$ ). When we retrospectively evaluated anti-HAV IgM and anti-HAV IgG positivity over the past ten years in 176/182 (96.7%) thalassemic patients, we found that 83 (47.2%) of them presented anti-HAV IgG positivity continuously, 16 (9.1%) were initially anti-HAV IgG negative, but then they became persistently anti-HAV IgG positive, 49 (27.8%) presented anti-HAV IgG positivity intermittently (about two or three tests for anti-HAV were negative, while the rest of them were found positive) and 28 (15.9%) were anti-HAV IgG negative continuously. Anti-HAV IgM antibodies were consistently negative in these previous tests. It must be emphasized that the mean numbers of anti-HAV IgG tests were not significantly different between the persistently positive and the intermittent group. When we considered the intermittently anti-HAV IgG positive thalassemics as anti-HAV IgG negative we found that the difference in anti-HAV IgG positivity between thalassemics and healthy subjects was still significant (99/176; 56.3% vs 38/209; 18.2%,  $P < 0.0005$ ).

**Table 2** Clinical characteristics of anti-HAV positive and anti-HAV negative beta-thalassemic patients

	Anti-HAV (+) <sup>2</sup> (n = 133)	Anti-HAV (-) (n = 49)	P value
Age (yr)	31.5 ± 9.6	31.8 ± 8.7	0.844
Sex (M/F)	62/71	26/23	0.440
Duration of transfusion therapy (y)	26.5 ± 8.1	27.1 ± 9.6	0.683
Number of transfusions	989 ± 441	772 ± 556	0.020
Splenectomy	47 (35.3%)	25 (51%)	0.055
AST (IU/L) <sup>1</sup>	38.6 ± 24.2	58.3 ± 36.1	0.001
ALT (IU/L)	49.2 ± 36.2	62.5 ± 40.8	0.039
GGT (IU/L)	29.6 ± 26.0	39.1 ± 27.3	0.057
Albumin (g/dL)	4.7 ± 0.45	4.47 ± 0.57	0.025
Globulins (g/dL)	3.03 ± 0.85	3.26 ± 0.79	0.122
Ferritin (median, ng/mL)	1515	1815	0.590
Anti-HCV (+)	61 (45.9%)	15 (30.6%)	0.064
HCV RNA (+)	36 (27.1%)	8 (16.3%)	0.133

<sup>1</sup>Normal levels: Aspartate aminotransferase (AST) < 40 IU/L, alanine aminotransferase (ALT) < 40 IU/L, gamma-glutamyltranspeptidase (GGT) < 50 IU/L; <sup>2</sup>Anti-HAV: Hepatitis A virus antibody; anti-HCV: Hepatitis C virus antibody.

### Liver disease in thalassemic patients

Seventy-six thalassemic patients (41.2%) were anti-hepatitis C virus (anti-HCV) positive, while 44 (24.2%) of them were also HCV RNA positive. None of them was HBsAg positive. Anti-HBc antibody was found in 56/182 (30.8%) of them.

### Comparison of anti-HAV positive and anti-HAV negative thalassemic patients

When anti-HAV positive ( $n = 133$ ) were compared to anti-HAV negative ( $n = 49$ ) thalassemic patients (Table 2) there was no difference in age, sex or duration of transfusion therapy. Anti-HAV positive patients had received more transfusions than anti-HAV negative thalassemics ( $P = 0.02$ ). We also found that anti-HAV (+) thalassemics had lower frequency of previous splenectomy, although this difference did not achieve statistical significance (35.3% *vs* 51%,  $P = 0.055$ ). An unexpected finding was that anti-HAV (+) thalassemics presented lower mean serum levels of aminotransferases (AST,  $P < 0.001$ ; ALT,  $P = 0.039$ ) and albumin ( $P = 0.025$ ) than anti-HAV (-) patients. No statistical difference was found in ferritin values between these two groups. Patients with antibodies to HAV were also more frequently positive for HCV markers although this difference was not statistically significant.

## DISCUSSION

Liver disease is a leading cause of death in patients with transfusion-dependent thalassemia<sup>[10]</sup>. Transfusion-associated hepatotropic infections, especially HCV infection, and hepatic siderosis can act either synergistically or independently in promoting chronic liver disease, and they may induce cellular damage through similar oxidative pathways<sup>[11]</sup>. There are no recent data on HAV epidemiology of that group of patients<sup>[12-14]</sup>, and blood

transfusion is not considered a significant predisposing factor for HAV infection.

In this study, adult beta-thalassemic patients were found to have significantly higher frequency of anti-HAV IgG antibodies than healthy subjects matched for age and sex in the same geographic area. IgG anti-HAV alone indicates past infection; it persists for decades after acute HAV infection and reflects recovery and immunity to reinfection<sup>[1]</sup>.

It was found that 47.2% of thalassemic patients were continuously anti-HAV (+) over the past ten years. The possibility that multitransfused patients with beta-thalassemia acquire anti-HAV antibodies with higher frequency than normal people of the same geographic area because of socioeconomic reasons is difficult to be supported. There are also no data demonstrating a higher susceptibility of patients with thalassemia for hepatitis A. Unfortunately, we did not study the prevalence of anti-HAV antibodies in family members of these thalassemia patients. Immune deficiency attributed to multiple transfusions and to iron overload<sup>[15]</sup> could be a factor that could predispose thalassemics to HAV infection, but no data exist that immune deficiency per se predispose to HAV infection. However, 41.2% of thalassemics were anti-HCV positive and 24.2% of them were HCV-RNA positive. In addition, thalassemics with anti-HAV positivity presented higher percentage of anti-HCV and HCV-RNA positivity, although these differences were not statistical significant. Two studies from Italy have shown that patients with chronic liver disease present high seropositivity for anti-HAV<sup>[16,17]</sup>.

Another interesting finding was that 9.1% of thalassemic patients acquired anti-HAV IgG antibody during the previous ten years. However, anti-HAV IgM antibodies were not found in these patients during this time, so it is difficult to prove acute infections. IgM anti-HAV in serum is positive from the onset of symptoms and usually remains positive for approximately 4 mo<sup>[18]</sup>. These tests were performed every 1-2 years and it is possible not to detect IgM anti-HAV antibodies in these patients. This is a high rate of HAV seroconversion even for countries of high endemicity. Greece is considered, according to studies of previous decade as a country of low endemicity for HAV infection, with some regions of intermediate endemicity<sup>[2-5]</sup>. Transfusion-associated hepatitis A virus is possible, but it is a very rare event (one per million transfusions)<sup>[19-22]</sup>, so there is no evidence to consider polytransfused patients as a risk group for parenteral hepatitis A infection. Due to the frequent stay of thalassemics in ambulant and hospital premises of the health care system, hospital borne hepatitis A infection should also be taken into consideration. However, the transmission from the medical care stuff to the patients is even more rare<sup>[23]</sup>. In general, hospital-borne hepatitis A disease does not seem a possible explanation of HAV infection in thalassemics.

Finally, 27.8% thalassemics presented anti-HAV positivity intermittently. In this case anti-HAV IgG is apparently not the expression of an actively acquired immunity, but might have been transferred passively

by means of transfusions. It is well known that packed red cells contain leukocytes, microaggregates, plasma containing proteins and immunoglobulins<sup>[24]</sup>. The level of protection that might be conferred by these antibodies is unknown. This finding is similar to that in substituted haemophiliacs where the detection of anti-HAV antibodies is also a frequent finding<sup>[25,26]</sup>. In hemophiliacs, the high concentration of antibodies in plasma preparations of multiple donors and the frequency of their administration facilitate the passive transmission of antibodies. It can be supported that some of the continuously anti-HAV (+) sera in the other thalassemic patients could be also attributed to the passive transfer of anti-HAV antibodies. We think that it is not very possible, as many tests (6-8) for anti-HAV antibodies just before a transfusion and for the previous ten years were found persistently positive.

Previous studies have shown lower prevalence of anti-HAV antibodies in multiply transfused thalassemic patients<sup>[12-14]</sup>. However, in these studies the mean age of thalassemic patients was much lower than that of our population and it is known that seroprevalence rates of HAV are increasing with age.

The lower mean levels of AST in anti-HAV IgG positive thalassemics, is difficult to explain. Ferritin values were found comparable between the two groups. Body mass index (BMI) and alcohol consumption were not different between these two groups. Moreover, no statistical difference was found in anti-HCV or HCV RNA positivity between anti-HAV positive and anti-HAV negative thalassemics that could explain this difference between the two groups.

There are some important limitations in this study. Volunteer blood donors are selected subjects, not comparable with general population. In cases where passive transfer of anti-HAV antibodies was suspected, the frozen aliquots of the donor's plasma were not tested for the presence of anti-HAV antibodies. Additional studies may be needed to confirm our findings.

In accordance to the findings of this study, we suggest that thalassemic patients present higher prevalence of anti-HAV IgG antibodies than matched healthy subjects of the same geographic area. This difference is difficult to explain, but it can be attributed to the higher vulnerability of thalassemics to HAV infection and to passive transfer of anti-HAV antibodies by blood transfusions.

## COMMENTS

### Background

In Greece, the lack of epidemics of hepatitis A virus (HAV) since early 1980s and the improvement of socioeconomic and hygienic conditions over the last decade seems to have contributed to the decline of prevalence of anti-HAV antibodies. However, we observed that the majority of our beta-thalassemia patients were anti-HAV positive.

### Innovations and breakthroughs

Previous studies have shown lower prevalence of anti-HAV antibodies in multiply transfused thalassemic patients. However, in these studies the mean age of thalassemic patients was much lower than that of our population and it is known that seroprevalence rates of HAV are increasing with age.

### Applications

In order to reduce further the incidence of liver infections in polytransfused thalassemic patients, we recommend an active immunization for HAV.

### Terminology

Beta-thalassemia, also known as Cooley's anemia, is a chronic recessively inherited hemoglobinopathy, characterized by severe hemolysis.

### Peer review

The authors reported that multitransfused adult beta-thalassemic patients present higher frequency of anti-HAV IgG antibodies than normal population of the same geographic area. This result is interesting. The strength of this study is surely the dimension of the population and the long history of the patients (10 years).

### Abstract

**AIM:** To determine the prevalence of delayed gastric emptying (GE) in older patients with Type 2 diabetes mellitus.

**METHODS:** One hundred and forty seven patients with Type 2 diabetes, of whom 140 had been hospitalised, mean age  $62.3 \pm 8.0$  years, HbA1c  $9.1\% \pm 1.9\%$ , treated with either oral hypoglycemic drugs or insulin were studied. GE of a solid meal (scintigraphy), autonomic nerve function, upper gastrointestinal symptoms, acute and chronic glycemic control were evaluated. Gastric emptying results were compared to a control range of hospitalised patients who did not have diabetes.

**RESULTS:** Gastric emptying was delayed ( $T_{50} > 85$  min) in 17.7% patients. Mean gastric emptying was slower in females ( $T_{50} 72.1 \pm 72.1$  min vs  $56.9 \pm 68.1$  min,  $P = 0.02$ ) and in those reporting nausea ( $112.3 \pm 67.3$  vs  $62.7 \pm 70.0$  min,  $P < 0.01$ ) and early satiety ( $114.0 \pm 135.2$  vs  $61.1 \pm 62.6$  min,  $P = 0.02$ ). There was no correlation between GE with age, body weight, duration of diabetes, neuropathy, current glycemia or the total score for upper gastrointestinal symptoms.

**CONCLUSION:** Prolonged GE occurs in about 20% of hospitalised elderly patients with Type 2 diabetes when compared to hospitalised patients who do not have diabetes. Female gender, nausea and early satiety are

### INTRODUCTION

It is now recognised, albeit relatively recently, that disturbances in upper gastrointestinal motility represent a major cause of morbidity in diabetic patients<sup>[1]</sup> and affect quality of life adversely<sup>[2]</sup>. Delayed gastric emptying is arguably the most important gastrointestinal complication and has been reported to affect 30%-60% of patients with long-standing Type 1 diabetes<sup>[3]</sup>. In Type 1 patients gastric emptying (GE) is occasionally faster than in normal during euglycemia<sup>[4]</sup>. There is less information about the prevalence of gastroparesis in Type 2 diabetes<sup>[5,6]</sup> and the majority of the cohorts studied have been small<sup>[2,7]</sup>. There is no information about the prevalence of delayed gastric emptying in older patients with diabetes Type 2 who are in many respects different from Type 1 patients. In Type 1 patients it is recognised that the rate of gastric emptying is modulated by acute changes in blood glucose concentration (gastric emptying is slower during hyperglycemia<sup>[8,9]</sup> and accelerated during hypoglycemia<sup>[10]</sup>) and autonomic nerve function. The relationship between gastroparesis and autonomic dysfunction is, however, relatively weak<sup>[11,12]</sup>. The prevalence of gastroparesis is also dependent on the duration of diabetes and may be higher in females than males<sup>[13]</sup>. The relationship of upper gastrointestinal symptoms with the rate of gastric emptying in Type 1 patients is poor<sup>[11]</sup>.

The aims of the study were to evaluate the prevalence,

and determinants, of disordered gastric emptying in a large cohort of predominantly hospitalised, Type 2 patients and the relationship of upper gastrointestinal symptoms with gastric emptying. The latter was quantified using a scintigraphic technique, which is considered as the “gold standard”<sup>[5,14-16]</sup>.

## MATERIALS AND METHODS

The study was performed in 147 patients with Type 2 diabetes (76 women, 71 men), mean age  $62.3 \pm 8.0$  years, duration of known diabetes  $11.4 \pm 7.2$  years, BMI  $31.2 \pm 5.5$  kg/m<sup>2</sup>. One hundred and twenty four patients (84%) had BMI > 25. 72 of the patients (49%) were managed on oral hypoglycemic therapy alone (sulphonylurea and/or metformin, thiazolidindione) and the remaining 75 patients were on insulin. None was on combination of insulin and oral drugs. All but 7 of the 147 patients were hospitalised in patients who were randomly selected from those admitted to the Internal Medicine Department. The primary reasons for hospitalisation are summarised in Table 1.

Subjects were randomly selected from among all patients with Type 2 diabetes treated with hypoglycemic drugs or insulin and without exclusion criteria. Only one patient was enrolled each day because of limitations in the availability of scintigraphy. Exclusion criteria included previous gastrointestinal disease apart from uncomplicated appendectomy, symptomatic cardiac, hepatic, renal or pancreatic disease, the use of medication known to affect gastrointestinal motility<sup>[17-19]</sup> and acute derangement of diabetes during the preceding week. Studies were performed on the day after hospital admission.

### Protocol

In one day patient underwent assessments of upper gastrointestinal symptoms, gastric emptying, glycemic control and autonomic nerve function. An assessment of diabetic retinopathy was performed within one week. The subjects were studied after an overnight fast and were asked to take their usual dose of insulin or oral hypoglycemic medication about 30 min prior to ingestion of the test meal.

Capillary blood samples for the measurement of blood glucose (enzymatic-amperometric measurement EBIO Plus) were obtained immediately before the meal and at 30, 60, 90 and 120 min. Glycated hemoglobin was measured on one of the blood samples. Each patient also completed a questionnaire relating to upper gastrointestinal symptoms<sup>[11]</sup>. Ophthalmological examination was performed to assess diabetic retinopathy, unless this diagnosis had already been established.

Autonomic nerve function was assessed after the completion of gastric emptying measurement using power spectral analysis of heart rate variability. The electrocardiogram was recorded under standardised conditions<sup>[20]</sup> for 5 min (minimum 300 valid R-R intervals) in supine, standing and repeated supine positions using computer-based system VarCor PF6<sup>[21]</sup>. Spectral analysis using fast Fourier transformation was performed in very low (0.02-0.05 Hz), low (0.05-0.15 Hz) and high (0.15-0.5 Hz) frequency spectral bands. The sum of the overall spectral power in the high and low fre-

quency part of the spectra with patients in all relevant positions and the sum of the spectral power in the low frequency part of the spectra were calculated<sup>[22,23]</sup>. Values obtained in healthy subjects were used as a standard<sup>[22]</sup>. Spectral power values less than normal (after adjustment for age) were considered as evidence of cardiovascular autonomic neuropathy (CAN). For the purpose of statistical assessment both borderline and abnormal results were combined.

Upper gastrointestinal symptoms during the previous 3 mo were assessed using a questionnaire adopted from Horowitz *et al.*<sup>[11]</sup>. Anorexia, nausea, early satiety, vomiting, abdominal pain, bloating and heartburn were recorded and graded as 0 = none, 1 = mild, 2 = moderate, 3 = severe. The global symptom score was calculated as the sum of the number and severity of symptoms.

Written informed consent was obtained from all subjects. Data were evaluated using the Mann-Whitney test, Kruskal-Wallis ANOVA and Spearman correlation, *P* values < 0.05 were considered as significant.

### Measurement of gastric emptying

The test meal consisted of 100 g of boiled rice (560 kJ) flavoured with cinnamon and labelled with 185 mBq <sup>99m</sup>Tc sulphur colloid<sup>[24,25]</sup>. The study was performed in the decubitus position and data were acquired for at least 60 min, in 1 min frames using a Picker Int. one-head camera. Time zero was defined as the time of a meal completion. Data were corrected for radionuclide decay and analysed using the Picker Int. Odyssey computer system. The gastric half-emptying time (T<sub>50</sub>) was defined as the time for the activity to fall by 50%. In those subjects in whom total gastric activity at the end of investigation was greater than 50% this parameter was computed using software extrapolation. The lag phase was defined as the period from meal ingestion to the peak of the activity within the gastric region of interest.

Control values were determined from a group of 34 nondiabetic volunteers. Nineteen women, 15 men, mean age  $60.8 \pm 8.9$  years, mean BMI  $30.7 \pm 4.7$  kg/m<sup>2</sup>, 27 subjects

(79%) had BMI > 25. This control group was randomly selected from among hospitalised patients without diabetes and without dyspeptic symptoms using identical exclusion criteria. Reasons for their admission are listed in Table 1. In this group mean T50 was  $49.5 \pm 23.1$  min and lag phase  $7.1 \pm 5.9$  min. The normal range for gastric emptying was defined as mean  $\pm 1.5$  SD of the T50. Values outside of this were considered as abnormal.

## RESULTS

All of the studies were well tolerated. Mean glycated hemoglobin was  $9.1\% \pm 1.9\%$ . Abnormal autonomic nerve function was evident in 103 of 144 (71.5%) patients (in 3 subjects the assessment was not feasible due to their high age or technical artefacts). Diabetic retinopathy (nonproliferative and proliferative) was evident in 21 (14.3%) cases. 52 patients had upper gastrointestinal symptoms and symptoms were reported more frequently by women (46.0% vs 23.9%,  $P < 0.01$ ). The most frequent symptom was bloating (29 subjects), followed by early satiety (10 subjects), pain (8 subjects), nausea and anorexia (6 subjects), heartburn (5 subjects), and vomiting (4 subjects). The median symptom score was 0 (0-9) in the whole group, 2.0 (1-9) in subjects with normal emptying and 3.0 (1-5) in the subgroup with delayed gastric emptying.

The mean T50 was  $64.7 \pm 70.4$  min, and lag phase  $9.6 \pm 7.9$  min, these were related ( $P < 0.01$ ). Gastric emptying was delayed, as assessed by the T50, in 26 subjects (17.7%) and in the whole group was significantly prolonged comparing to the control group ( $64.7 \pm 70.3$  min,  $49.5 \pm 23.4$  min,  $P = 0.03$ ). Mean basal (time 0) glucose was  $9.9 \pm 2.8$  mmol/L, at 30 min  $10.5 \pm 2.8$  mmol/L, at 60 min  $11.5 \pm 2.9$  mmol/L, at 90 min  $11.7 \pm 3.1$  mmol/L, and at 120 min  $11.6 \pm 3.2$  mmol/L. The mean rise in blood glucose was significant ( $P < 0.01$ ). The association of gastric emptying with demographic and biochemical variables and gastrointestinal symptoms is summarised in Table 2.

Gastric emptying did not differ between insulin and oral drug treated subjects ( $68.4 \pm 83.7$  min,  $60.4 \pm 50.9$  min,  $P = 0.47$ ). Gastric emptying (T50) was slower in females than males ( $P = 0.02$ ). Gastric emptying (T50) was not significantly related to either autonomic nerve function ( $P = 0.32$ ), retinopathy ( $P = 0.88$ ) or upper gastrointestinal symptoms ( $P = 0.22$ ). Gastric emptying was however, slower in those patients who had early satiety ( $P = 0.02$ ) and nausea ( $P < 0.01$ ).

Simple regression analysis showed a weak, but significant, relationship between gastric emptying and glycated hemoglobin ( $r = 0.23$ ;  $P = 0.01$ ), but not between the T50 ( $P > 0.35$ ) or lag phase ( $P > 0.07$ ) and blood glucose levels during the gastric emptying measurement ( $P > 0.35$ ). Significant correlation between gastric emptying rate and glycated hemoglobin was noted in the subgroup treated with hypoglycemic drugs ( $r = 0.32$ ;  $P < 0.01$ ). There was no significant relationship between gastric emptying and either age ( $r = -0.05$ ,  $P = 0.55$ ), duration of diabetes ( $r = 0.08$ ,  $P = 0.31$ ) or body mass index ( $r = -0.03$ ,  $P = 0.70$ ). GE did not differ between obese and non-obese subjects both in the diabetes ( $66.9 \pm 74.6$  min,  $50.6 \pm 28.4$  min,  $P = 0.16$ ) and in the control

group ( $48.6 \pm 23.4$  min,  $56.0 \pm 24.8$  min,  $P = 0.25$ ).

In the insulin treated group (75 subjects) the rise of glycemia between 30-60 min. (16.2% vs 5.8%) was greater ( $P = 0.048$ ) in subjects with faster emptying compared to those with delayed GE. In the group treated with oral hypoglycemic drugs the changes were not significantly different.

## DISCUSSION

This is the first study to evaluate the prevalence of delayed gastric emptying in a large cohort of elderly predominantly hospitalised patients with Type 2 diabetes. We have established that (1) when compared to a control range obtained in hospitalised patients without diabetes prolonged GE does not occur frequently and (2) female gender and the presence of nausea and early satiety are associated with higher probability of delayed GE.

Delayed GE is said to occur in 30%-70% patients with longstanding Type 2 diabetes<sup>[5,7]</sup>. Some of the cohorts studied were small, e.g. Tung studied 20 subjects with diabetes<sup>[7]</sup>, and Annese *et al* investigated 35 subjects<sup>[2]</sup>, included otherwise healthy patients with diabetes<sup>[5]</sup>, or patients with upper gastrointestinal symptoms<sup>[7]</sup>, which may not well reflect the situation in general population. We intentionally studied a large cohort of relatively older patients with more severe Type 2 diabetes treated with oral drugs or insulin, of whom the majority had complicated diabetes, and compared them with their age-matched non-diabetic counterparts. In our opinion, this subset of patients corresponds with the status of the older general population. The prevalence of delayed gastric emptying was relatively low and less than we anticipated. Any correlation of our results with other studies is rather difficult due to substantial differences in patient groups and methods used<sup>[5]</sup>. Alteration of the results due to test food used, however, appears unlikely, given that the mean rate of gastric emptying in the diabetic cohort (8.7 kJ/min) was within the expected "physiological" range (i.e. 8.4 to 12.6 kJ/min)<sup>[1,26]</sup>. This confirms that test food used by us is sufficient for activation of feedback regulation, which physiologically slows the emptying down. In a previous study, we found that GE was delayed in 42.8% of Type 1 diabetic outpatients<sup>[27]</sup> us-

ing the same method, and identical control group, a result that is concordant with previous reports<sup>[4,14,25]</sup>. Also, it is against any possible bias caused by technical errors.

Our group involved a selected set of hospitalised subjects where a selection bias may play a role. Any effect of comorbidities on GE has not been so far sufficiently studied. There are some indices that there may exist a certain link between gastric emptying rate and heart, lung, liver diseases or Parkinson's disease<sup>[28]</sup>, occurring frequently in older age. More than 80% of patients screened in this study were treated with other than oral hypoglycemic drugs. Information on the effect of commonly used drugs like beta-blockers, calcium channel blockers, etc. on GE is lacking. Only verapamil and nitrates have been studied so far<sup>[29]</sup>. The accelerated GE was described in obese patients, e.g. by Bertin<sup>[30]</sup> and was also documented in obese non-diabetic persons<sup>[31]</sup>. In spite of the fact that weight in our group was similar to that in Bertin's group, we were not able to confirm any correlation with GE.

There was no significant relationship between the rate of GE and the duration of known diabetes, consistently with previous reports in Type 1 and groups of Type 1 and 2 diabetic patients<sup>[6,32]</sup>. While, the number of complications increases with the duration of diabetes, their development is highly dependent on glycemic control. This is likely to confound a potential association with the duration of diabetes. In the past autonomic neuropathy was considered to be the main factor causing gastroparesis, but it is clear that any relationship between gastric emptying and cardiovascular autonomic function is weak<sup>[5,12,33]</sup>. The prevalence of autonomic nerve dysfunction observed in this study is higher than that reported in groups with a similar duration of diabetes (about 65% after 10 years)<sup>[34]</sup> what is likely to reflect the methodology used. Furthermore, heart rate variability and spectral power is known to decline not only in individuals with diabetic CAN but also in those with ischemic heart disease, poor physical status and/or ageing<sup>[23]</sup>. It is well known that the presence of diabetic retinopathy correlates with that of CAN<sup>[35]</sup>. Both retinopathy and CAN are associated with higher mortality while gastroparesis may not be<sup>[7,36,37]</sup>. Female gender has been reported previously<sup>[13]</sup> to be associated with an increased rate of diabetic gastroparesis; this is also the case for delayed gastric emptying in functional dyspepsia<sup>[38]</sup>. The underlying cause(s) remain uncertain.

Acute glycemia has been suggested as an important determinant of gastric emptying<sup>[14,39]</sup>. However, there are studies<sup>[25,30]</sup>, including the present one, which have failed to confirm this relationship. A possible explanation is, that in spite of relatively large variations in glycemia during the studies (3.1–22.3 mmol/L), average values were about 11 mmol/L, and only 10 individuals had blood glucose levels above 15 mmol/L. The present study is also cross-sectional in design, which is not optimal for evaluation of this issue; furthermore, there was a weak relationship between the rate of gastric emptying with HbA1c.

It is clear that the GE rate of carbohydrate influences postprandial glycemia in both Type 1 and Type 2 diabetes<sup>[40]</sup> in Type 2 patients the postprandial initial glycemic and insulinemic responses to oral carbohydrate are less when gastric emptying is slower<sup>[41]</sup>. Hence it is not surprising that the rise in blood glucose after the meal

was greater in those with faster gastric emptying in those patients treated with insulin. In contrast there is no difference apparent in the patients treated with oral hypoglycemic agents for which we have no clear explanation.

Previously it was thought that dyspeptic symptoms associated with diabetes were a direct consequence of impaired GE, but the correlation between upper gastrointestinal symptoms and the rate of GE rate is weak<sup>[5,11,25]</sup> and patients with gastroparesis may not have symptoms at all<sup>[3]</sup>. Our study confirms that poor correlation between gastrointestinal symptoms and gastric emptying described in Type 1 diabetic patients<sup>[4,27]</sup> also exists in Type 2 diabetes. Recent studies have found an association between abdominal bloating and fullness, particularly postprandially<sup>[6,36,42]</sup> and slow GE, especially when the relationship is assessed according to the severity of symptoms. This study confirms that correlations observed between distinct gastrointestinal symptoms (early satiety/fullness) and GE in Type 1 diabetes<sup>[4]</sup> may also exist in Type 2 diabetes<sup>[6]</sup>. These relationships should be, however, interpreted with caution and in the context of other variables. For example, postprandial dyspeptic complaints may potentially result from deranged intragastric distribution of ingested food, which however, may not be associated with any in the total GE rate<sup>[43]</sup>. It is also well established that blood glucose concentrations may modulate sensations arising from the gastrointestinal tract<sup>[44]</sup>. The authors were not able to confirm any such dependence; nevertheless mean blood glucose levels were not as high as those reported by Jones *et al* (> 15 mmol/L) in their study<sup>[45]</sup>, where the relationship was described.

In conclusion, the present study demonstrates, that delayed GE rate does not occur frequently in elderly hospitalised Type 2 diabetics. Female gender and the presence of nausea and early satiety may predict delayed gastric emptying. Autonomic nerve dysfunction, assessed by means of heart rate variability, however does not correlate with GE rate.

## COMMENTS

### Background

Delayed gastric emptying is the most important gastrointestinal complication in diabetes. The problem of finding a simple way of identifying persons with gastroparesis is gaining ground in view of the rising proportion of Type 2 diabetic patients. An attractive approach appears to identify groups at risk appropriate for further detailed investigation by using simple criteria. This issue has been studied extensively in Type 1 diabetic patients. In contrast, data have been lacking and study groups are small in patients with diabetes Type 2, who are in many respects different from Type 1 patients.

### Research frontiers

To evaluate the prevalence, and determinants (gender, age, BMI, duration of diabetes, control of diabetes, autonomic neuropathy, retinopathy and dyspeptic symptoms) of delayed gastric emptying in older patients with Type 2 diabetes mellitus.

### Innovations and breakthroughs

This is the first study evaluating elderly Type 2 diabetic patients with comorbidities. Delayed GE rate does not occur frequently in these subjects. They do not differ in predictors of delayed GE from Type 1 diabetes.

### Applications

Delayed gastric emptying in old Type 2 diabetic patients may be assumed in

female gender and when nausea and early satiety are present. Presence of diabetic complication (retinopathy, autonomic neuropathy) does not predict disordered gastric emptying.

### Peer review

This study explores the presence of dyspeptic symptoms and the timing of gastric emptying in hospitalised elderly patients with Type 2 diabetes treated with oral hypoglycaemic therapy or insulin, compared to hospitalised patients without diabetes. The study is well designed and conducted.

### Abstract

**AIM:** To explore the contribution of AXIN1, AXIN2 and beta-catenin, components of Wnt signaling pathway, to the carcinogenesis of gastric cancer (GC), we examined AXIN1, AXIN2 exon7 and CTNNB1 (encoding beta-catenin) exon3 mutations in 70 GCs.

**METHODS:** The presence of mutations was identified by polymerase chain reaction (PCR)-based denaturing high-performance liquid chromatography and direct DNA sequencing. Beta-catenin expression was detected by immunohistochemical analysis.

**RESULTS:** Among the 70 GCs, 5 (7.1%) had mutations in one or two of these three components. A frameshift mutation (1 bp deletion) in exon7 of AXIN2 was found in one case. Four cases, including the case with a mutation in AXIN2, had frameshift mutations and missense mutations in AXIN1. Five single nucleotide polymorphisms (SNPs), 334 C>T, 874 C>T, 1396 G>A, 1690 C>T and 1942 T>G, were identified in AXIN1. A frameshift mutation (27 bp deletion) spanning exon3 of CTNNB1 was observed in one case. All four cases with mutations in AXIN1 and AXIN2 showed nuclear beta-catenin expression.

**CONCLUSION:** These data indicate that the mutations

in AXIN1 and AXIN2 may contribute to gastric carcinogenesis.

### INTRODUCTION

The Wnt signaling pathway plays an essential role in human cancer development<sup>[1-3]</sup>. Wnt stabilizes cytoplasmic  $\beta$ -catenin, which stimulates the expression of genes including c-myc, c-jun, fra-1 and cyclin D1<sup>[4,5]</sup>. AXIN1 and its homologue AXIN2, newly recognized as components of the Wnt signaling pathway, negatively regulate this pathway<sup>[6,7]</sup>. Other components of the Wnt signaling pathway, including  $\beta$ -catenin and adenomatous polyposis coli (APC), interact with AXIN, and the phosphorylation and stability of  $\beta$ -catenin are regulated in the AXIN complex<sup>[5]</sup>.

AXIN1 is thought to be critical for degrading cytoplasmic  $\beta$ -catenin. Different domains of AXIN1 were shown to interact with APC, GSK-3 $\beta$ ,  $\beta$ -catenin, PP2Ac and AXIN itself<sup>[8,9]</sup>. The function of AXIN1 in promoting  $\beta$ -catenin degradation suggests that it serves as a tumor suppressor. AXIN1 mutations have been reported in a variety of human carcinomas including sporadic medulloblastomas, hepatocellular carcinomas and colorectal cancers<sup>[10-13]</sup>, suggesting that AXIN1 may be involved in the development of these tumors.

AXIN2, which functions as a scaffold protein in the Wnt signaling pathway<sup>[14]</sup>, has been shown to develop frameshift mutations in mononucleotide repeat sequences located in exon7, in colorectal cancer, with defective DNA mismatch repair (MMR)<sup>[7]</sup>. A recent study has shown that AXIN2 is a transcriptional target of the TCF/LEE transcription factor complex downstream of activated  $\beta$ -catenin<sup>[15]</sup>.

Mutations in CTNNB1 (encoding  $\beta$ -catenin) or APC have been reported in human neoplasms, including colon cancer and gastric cancer (GC)<sup>[16-19]</sup>. However, AXIN1 and AXIN2, the key players in this pathway, have not been investigated in GC. In this study, we identified mutations of the entire coding region of AXIN1, exon7 of AXIN2 (a hot spot of mutation), and exon3 of CTNNB1 in GC cases, and evaluated if such mutations activate the Wnt signaling pathway during GC development.

## MATERIALS AND METHODS

### *Tissue specimens and DNA isolation*

GC samples and their matched normal gastric tissues were obtained from 41 males and 29 females during surgical resections. The study was approved by Institutional Review Board of Peking University School of Oncology, and all subjects gave written informed consent. Fresh samples were collected at the time of surgery, frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$ . Sections from each specimen were determined by a pathologist, and classified according to Lauren's classification<sup>[20]</sup>. Among the GC cases, 32 (46%) were intestinal-type, 27 (39%) were diffuse-type and 11 (16%) were mixed-type. High molecular weight genomic DNA was extracted by standard proteinase K digestion and phenol/chloroform extraction.

### *Primers and PCR*

We screened the entire coding sequence of the AXIN1 gene, exon7 of AXIN2 and exon3 of CTNNB1 with PCR-based denaturing high-performance liquid chromatography (DHPLC). The primer sequences are listed in Table 1. PCR was accomplished with a 25  $\mu\text{L}$  reaction mixture containing 50 ng of genomic DNA, 0.4  $\mu\text{mol/L}$  sense and antisense primers for each exon, 200  $\mu\text{mol/L}$  dNTPs (Perkin-Elmer, CA, USA), 0.2  $\mu\text{L}$  of Ampli Taq Gold polymerase (Perkin-Elmer, USA), and 2.0 mmol/L of  $\text{MgCl}_2$ . After initial activation of the enzyme by denaturation at  $95^{\circ}\text{C}$  for 9 min, PCR amplification was performed for 35 cycles:  $94^{\circ}\text{C}$  for 30 s, the optimized annealing temperature for 45 s, and  $72^{\circ}\text{C}$  for 45 s. Final extension was performed at  $72^{\circ}\text{C}$  for 10 min. The annealing temperatures for various primer sets were:  $58^{\circ}\text{C}$  for AXIN1 exons 1A, 1B, 1C, 2, 3, 4 and 9;  $63^{\circ}\text{C}$  for exons 5A, 6, 7, 8 and 10;  $62^{\circ}\text{C}$  for exon 5B;  $60^{\circ}\text{C}$  for P3-4; and  $59^{\circ}\text{C}$  for AXIN2 exon 7.

### *DHPLC analysis*

PCR products were heated to  $95^{\circ}\text{C}$  for 3 min, then cooled to  $25^{\circ}\text{C}$  over 45 min. Homozygous mutant DNA was combined with wild-type in an approximately 1:1 ratio prior to hybridization; then, this mixture was examined for heteroduplex content by subjecting 50-100 ng of PCR products to DHPLC (WAVE<sup>TM</sup> system, Transgenomic, USA) under partial denaturation conditions<sup>[21,22]</sup>. The mobile phase consisted of a mixture of 0.1 mol/L triethylamine acetate (TEAA, pH 7.0) with or without 25% acetonitrile. The flow rate used in this study was 0.9 mL/min. The column temperatures for various PCR products were:  $59^{\circ}\text{C}$  for P3-4;  $62^{\circ}\text{C}$  for AXIN1 exons 1A, 1B, 1C and 3;  $63^{\circ}\text{C}$  for exons 2 and 10;  $64^{\circ}\text{C}$  for exons 7 and 9;  $65^{\circ}\text{C}$  for exons 5A

and 6;  $66^{\circ}\text{C}$  for exons 5B and 8;  $68^{\circ}\text{C}$  for exon 4; and  $66^{\circ}\text{C}$  for AXIN2 exon 7.

### *Sequencing analysis*

PCR products were treated with exonuclease and shrimp alkaline phosphatase based on the protocol provided by United States Biochemical Corporation and sequenced by the Mayo Clinic DNA sequencing facility. Sequencing reactions were performed in a GeneAmp PCR System 9600 with fluorescent terminations, and products were analyzed on an ABI 377 sequencer (Perkin-Elmer). All sequence alterations were confirmed by bidirectional sequencing of PCR products generated by at least two independent reactions.

### *Immunohistochemical staining*

Tissue specimens were fixed in 10% neutral-buffered formalin and were paraffin embedded according to standard procedures. Four-micrometer-thick sections of representative blocks from each case were deparaffinized in xylene, rehydrated, and treated with 3%  $\text{H}_2\text{O}_2$  for 10 min to block endogenous peroxidase activity. All sections were subjected to heat-induced epitope retrieval in a microwave oven. Sections were incubated with anti- $\beta$ -catenin mouse monoclonal antibody (1:50, Santa Cruz, USA) at  $4^{\circ}\text{C}$  overnight. The sections were treated with polyperoxidase anti-mouse/rabbit immunoglobulin (GBI) for 30 min at  $37^{\circ}\text{C}$  and antibody-binding sites were visualized by DAB kit (Zhongshan Golden Bridge Co., Beijing, China). Negative controls were performed by omitting the primary antibody.

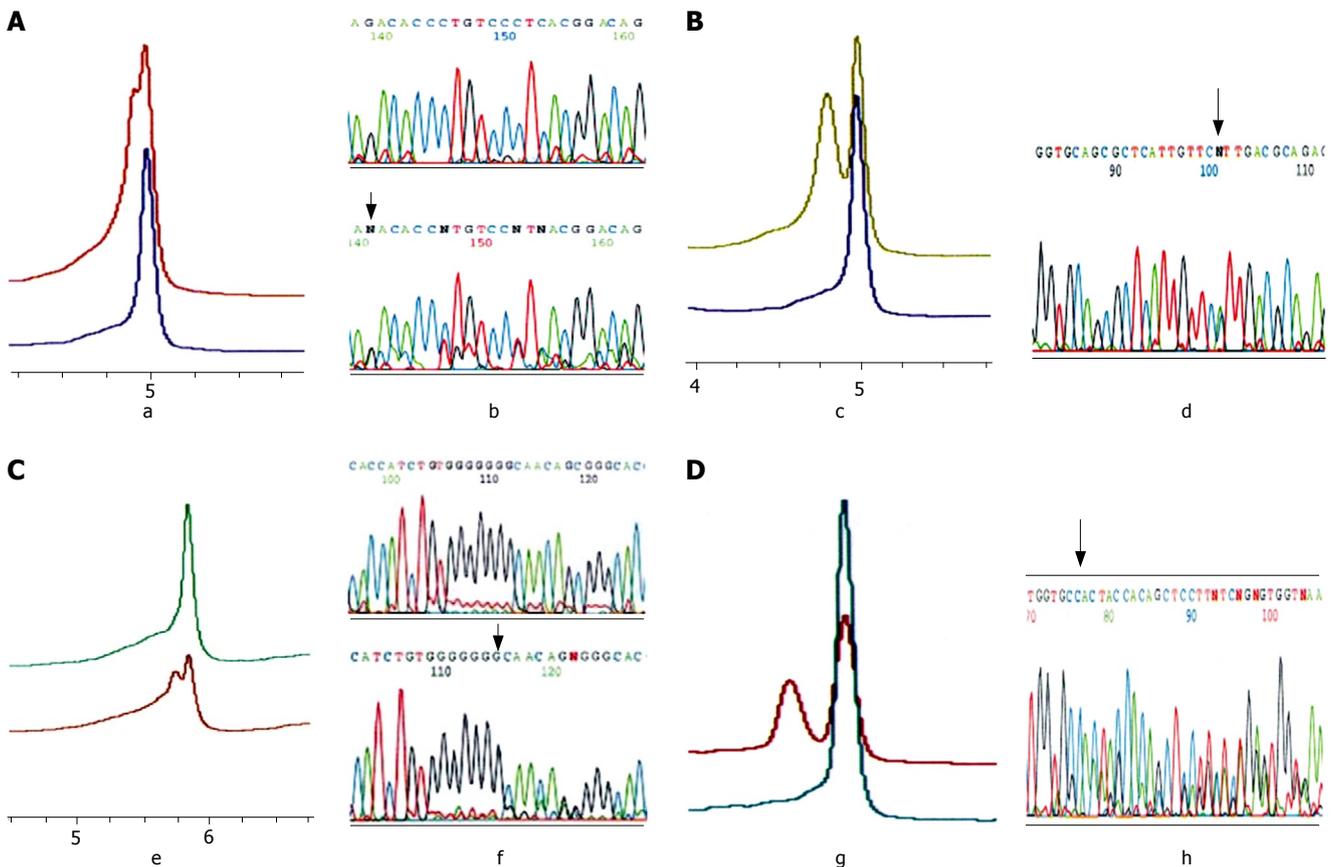

## RESULTS

We evaluated the entire coding region of the AXIN1 gene for mutations by DHPLC followed by sequencing. Two types of mutation were identified in 4 (5.7%) of 70 GC cases, but not in the matched normal tissues. Three cases, including one intestinal-type and two diffuse-type, contained a 1-bp deletion at nucleotide 1076 (Figure 1A). This mutation interrupts the GSK3 $\beta$  and  $\beta$ -catenin binding domains. A point mutation of G to T transition at nucleotide 1578 was observed in one intestinal-type, resulting in a substitution of the amino acid at 489 from glycine to valine (Figure 2). This missense mutation occurs in the  $\beta$ -catenin binding domain. Five single-nucleotide polymorphisms, 334 C>T, 874 C>T, 1396 G>A, 1690 C>T and 1942 T>G, were identified within the coding region. The frequencies of these variant alleles were 0.04, 0.43, 0.10, 0.03 and 0.13, respectively (Table 2). All of them were silent polymorphisms, and the functions of these polymorphisms are unknown. Representative examples of heteroduplexes detected by DHPLC are shown in Figure 1B.

We screened exon7 of the AXIN2 gene for mutations and one intestinal-type revealed a frameshift mutation (1 bp deletion), occurring in the mononucleotide repeat sequences (2083 del G) located in exon7 (Figure 1C). This mutation leads to the elimination of the DIX domain. This case had AXIN2 and AXIN1 (1 bp deletion at nucleotide 1076) mutations.

**Figure 1** Typical elution profiles of DHPLC analysis and sequencing. **A:** AXIN1 (exon2) mutation. a, DHPLC elution profiles. b, Sequence traces. The upper panel is a normal control; the lower panel is a frameshift mutation (del 1 bp). The arrow points to the mutant nucleotide; **B:** AXIN1 polymorphism. c, Representative DHPLC profiles of heteroduplex for AXIN1. The lower panel is a normal control; the upper panel is a heteroduplex. d, Sequence traces. The arrow points to the mutant nucleotide; **C:** AXIN2 (exon7) mutation. e, DHPLC elution profiles. f, Sequence traces. The upper panel is a normal control; the lower panel is a frameshift mutation (del 1 bp). The arrow points to the mutant nucleotide; **D:** CTNNB1 (exon3) mutation. g, DHPLC elution profiles. The lower panel is a normal control; the upper panel is a frameshift mutation (del 27 bp spanning exon3). h, Sequence traces for the frameshift mutation. The arrow points to the mutant nucleotide.

Somatic mutations in exon3 of the CTNNB1 gene were detected in the same samples. A 27-bp deletion spanning exon3 of CTNNB1 was observed in one of the diffuse-type cases (Figure 1D), which did not contain AXIN1 or

AXIN2 mutations. No mutations were detected in any of the normal tissues. This result indicated that AXIN1 and AXIN2 mutations may be solely responsible for the disruption of the Wnt signaling pathway in GC cases.

**Figure 2** Mutations and polymorphisms found in AXIN1. Bold lines indicate the coding regions corresponding to each protein-binding site. GSK3 $\beta$ : Glycogen synthase kinase 3 $\beta$ ; PP2Ac: Protein phosphatase 2Ac; P: Polymorphism.

The functional importance of AXIN1, AXIN2 and CTNNB1 mutations in GC development was further analyzed by immunohistochemical analysis of  $\beta$ -catenin in 50 available GC tissue samples. Ten (20%) of the GCs showed increased nuclear immunoreactivity for  $\beta$ -catenin compared with non-cancerous tissues. All four GCs with AXIN1 and AXIN2 mutations showed nuclear  $\beta$ -catenin expression.

## DISCUSSION

Activation of Wnt signaling is an important step in the development of human tumors<sup>[23,24]</sup>. APC is part of a multiprotein complex in the Wnt pathway which induces  $\beta$ -catenin degradation<sup>[25]</sup>. AXIN1, AXIN2, GSK-3 $\beta$ ,  $\beta$ -catenin, PP2A and PP2C are additional components of this complex<sup>[26]</sup>. In this complex, AXIN1 and AXIN2 play major roles as scaffold proteins. Mutations in CTNNB1 or APC have been reported in GC<sup>[17,18]</sup>. To explore if AXIN1 and AXIN2 are also involved in the pathogenesis of GC, we examined mutations in the entire coding region of AXIN1, exon7 of AXIN2 and exon3 of CTNNB1 in 70 GCs. Four (5.7%) of the 70 GCs had mutations in AXIN1, one had frameshift mutations in AXIN2 and one had a mutation in CTNNB1. Our results showed that AXIN1 and AXIN2 are likely to be tumor suppressor genes involved in the carcinogenesis of GC. This is the first study, to our knowledge, to demonstrate AXIN1 and AXIN2 mutations in GC.

AXIN1 mutations have been reported in hepatocellular carcinomas, hepatoblastomas and sporadic medulloblastomas<sup>[10,11]</sup>. We have now identified genetic alterations of AXIN1 in GCs. We found a 1-bp deletion at nucleotide 1076, which has previously been reported in hepatocellular carcinomas, in three samples<sup>[11]</sup>. This mutation interrupts the GSK3 $\beta$  and  $\beta$ -catenin binding domain. Additionally, we discovered a somatic point mutation in GCs, resulting in a substitution of the amino acid at 489 from glycine to valine, a site located within the  $\beta$ -catenin binding domain. It is possible that such alterations may alter protein secondary structure and thereby the interaction of  $\beta$ -catenin with APC/GSK-3 $\beta$  complex. Since AXIN1 is a negative regulator of  $\beta$ -catenin, failure to form a complex with any one of these key players of Wnt signaling is likely to stabilize  $\beta$ -catenin and lead to its accumulation.

AXIN2 mutations were found in one of the 70 GCs. Such mutations resulted in the elimination of the DIX

**Table 2** The profile of AXIN1 polymorphisms

Exon	Nucleotide changes	Amino acid <sup>1</sup>	Frequency (%)
1	334 C→T	Gly74Gly	4.3
	874 C→T	Asp254Asp	42.8
5	1396 G→A	Ser428Ser	10.0
	1690 C→T	Asp526Asp	2.9
6	1942 T→G	Ala610Ala	12.9

<sup>1</sup>Amino acid number begins from Met at position 113 of GenBank accession, No. AF009674.

domain, which is necessary for AXIN oligomerization<sup>[27-29]</sup>. This case had both AXIN1 and AXIN2 mutations, and showed increased nuclear immunoreactivity for  $\beta$ -catenin. AXIN2 mutations have been previously reported in colorectal cancers (in 10 of 11 cases) and were also accompanied by increased nuclear  $\beta$ -catenin staining<sup>[7]</sup>, similar to our results in GC. This study also showed that frameshift mutations in AXIN2 appear to be specifically associated with defective DNA mismatch repair (MMR) in colorectal cancer<sup>[7]</sup>. To determine the MSI status, we identified two mononucleotide markers, BAT26 and BAT25, by DHPLC<sup>[30]</sup>. This case was detected as MSI-H. Our results indicate that GCs with MMR deficiency often harbor somatic frameshift mutations in cancer-related genes.

CTNNB1 mutations were identified in 70 GCs. A 27-bp deletion spanning exon3 of CTNNB1 was observed in one of the cases, which showed increased membrane and cytoplasmic immunoreactivity for  $\beta$ -catenin. We did not detect any missense mutations of this gene in our GC cases. CTNNB1 mutations occur even more frequently in colon cancer and hepatoblastoma<sup>[11,12]</sup>. A number of studies have identified CTNNB1 mutations in GCs, but the frequencies of these mutations were significantly different in those studies<sup>[17,31]</sup>. The different frequencies of CTNNB1 mutations identified could be due to differences in the populations examined or the method of microdissection of tumor cells used. Analysis of  $\beta$ -catenin in a large sample set using a precise method of microdissection is needed to delineate the functional importance of this gene in GC development.

In conclusion, our results indicate that AXIN1 and AXIN2 mutations may contribute to the pathogenesis of GC *via* activation of the Wnt signaling pathway. Further studies will be required to investigate the function of mutated AXIN1 and AXIN2 variants reported in this study.

## COMMENTS

### Background

The Wnt signaling pathway is known to be involved in tumorigenesis. Recently, AXIN1 and AXIN2, components of Wnt signaling pathway, were characterized as new candidate tumor suppressor genes that may be targeted for deletion or mutation during tumorigenesis.

### Research frontiers

Mutations in AXIN1, AXIN2 and CTNNB1 were identified by PCR-based denaturing high-performance liquid chromatography (DHPLC) and direct DNA sequencing. Beta-catenin expression was detected by immunohistochemical staining.

### Innovations and breakthroughs

A total of 5 (7.1%) GCs had mutations in one or two of these three components. A frameshift mutation in exon7 of AXIN2 was found in one case. Four cases had frameshift mutations and missense mutations in AXIN1, and 5 single nucleotide polymorphisms (SNPs) were identified in AXIN1. All four cases with mutations in AXIN1 and AXIN2 showed nuclear beta-catenin expression.

### Applications

AXIN1 and AXIN2, key players in the Wnt signaling pathway, are involved in gastric carcinogenesis, but the functions of mutated AXIN1 and AXIN2 variants need to be further investigated.

### Peer review

This is an interesting report of mutations in components of the Wnt signaling pathway in 70 patients with gastric cancer. They examined AXIN1, AXIN2 and CTNNB1 and found mutations in only 5 (7.1%) of the patients. This is an important and well-written paper.

### Abstract

**AIM:** To determine the inhibitory effect of the adenovirus-based angiopoietin-1 (Ang-1) targeted small interfering RNA expression system (Ad/Ang-1si) on the expression of the Ang-1 gene, cell growth and apoptosis in human esophageal cancer cell line Eca109.

**METHODS:** siRNA-expressing adenovirus targeting Ang-1 gene was constructed using the Ad Easy System. Cultured Eca109 cells were transfected with Ad/Ang-1si (Eca109/Ang-1si), and Ad/si was used to infect Eca109 cells as control (Eca109/si). Ang-1 gene expression and concentration was determined with RT-PCR and ELISA, respectively. Human umbilical vein endothelial cell (HUVEC) migration and proliferation were analyzed. After s.c. injection into athymic nu/nu mice, the tumor growth, vessel density and apoptosis of each group was also determined.

**RESULTS:** HUVEC migration induced by conditioned medium from Ang-1si-transfected Eca109 cells was significantly less than that induced by conditioned medium from Eca109 cells and control adenovirus-transfected Eca109 cells. Furthermore, after s.c. injection into athymic nu/nu mice, the tumor growth and cell apoptosis of Ad/Ang-1si-expressing Eca109 cells was significantly lower than that of parental or control adenovirus-transfected cells. Vessel density assessed by CD31 immunohistochemical analysis and Ang-1 expression by RT-PCR were also decreased.

**CONCLUSION:** The targeting Ang-1 may provide a therapeutic option for esophageal cancer.

### INTRODUCTION

Human esophageal cancer is the eighth most frequently diagnosed cancer and the sixth most frequent cause of cancer death in the world<sup>[1]</sup>. Esophageal cancer is one of the most lethal cancers of the digestive tract with a very low survival of 16% in the United States and 10% in Europe<sup>[2]</sup>. Most esophageal cancers arise from the middle and lower third of the esophagus. Despite the use of multimodal therapy (chemotherapy, radiation therapy, and surgery), the long-term disease-free survival rate of patients with esophageal cancer is still disappointingly low, particularly in the high-risk groups<sup>[3]</sup>. The identification of new therapeutic targets is therefore needed.

Angiogenesis has been specifically linked to increased growth and metastatic potential in human tumors<sup>[4-9]</sup>. Although numerous growth factors are involved, angiopoietin-1 (Ang-1) play a pivotal role in tumor angiogenesis<sup>[10-17]</sup>. Binding of Ang-1 to its ligand of the Tie-2 receptor reduces endothelial permeability and enhances vascular stabilization and maturation. All these events which contribute to angiogenesis and remodeling of blood vessels. However, Ang-1 contribution to tumor growth has received little attention.

Esophageal cancer is vascular in nature, with a high proliferation rate<sup>[18]</sup>. Several lines of evidence indicate a role of Ang-1 in the pathogenesis of esophageal cancer. Loges *et al* recently reported 94% of tumor specimens expressed Ang-1, implying a close association between Ang-1 expression and microvessel density (MVD)<sup>[19]</sup>. High levels of Ang-1 expression were also detected by immunohistochemical analysis in 42 of 45 esophageal cancer samples, and positive staining for Ang-1 at the time of diagnosis

was correlated with VEGF121 and VEGF165 gene expression<sup>[20]</sup>. Taken together, these data indicate that Ang-1 is associated with neovascularization in the cancer stroma through VEGF networks in esophageal cancer, and inhibition of the expression or function of Ang-1 may improve in the disease outcome.

Our data in this study showed that adenoviruses-based siRNA expression system can be used to down-regulate Ang-1 expression, resulting in suppression of cell growth and induction of apoptosis through inhibiting angiogenesis in a nude mouse model of esophageal cancer. It can be concluded that Ang-1 is an alternative target in developing new therapeutic strategies for the treatment of esophageal cancers.

## MATERIALS AND METHODS

### siRNA-expressing adenovirus targeting angiopoietin-1

siRNA-expressing adenovirus targeting human Ang-1 was constructed according to the manufacturer's instructions. Briefly, one pairs of oligonucleotides targeting human Ang-1 mRNA was synthesized by Sagon DNA technologies (Sagon Biotechnology). The targeted Ang-1 sequences were 5'-GATCCCGAGGCTG-GAAGGAATATAATTCAAGAGATTATATTCCTTC-CAGCCTCTTTT-3', 5'-AGCTAAAAAAGAGGCTG-GAAGGAATATAATCTCTTGAATTATATTCCTTC-CAGCCTCGG-3'. The dsDNA was ligated between the BamHI and HindIII sites on the pShuttle containing H1 promoter and GFP sequences. Adenoviruses were then constructed using the Ad Easy System (Stratagene Biotechnology). The control vector was constructed by inserting a sequence that expresses a siRNA with limited homology to sequences in the human and mouse genomes. Adenoviral DNA was prepared on a large scale in *Escherichia coli* DH5 $\alpha$ , generating Ad/Ang-1si and Ad/si, respectively. All adenoviruses were propagated in HEK293 cells and purified using BD Adeno-X<sup>TM</sup> purification kit (BD Biosciences Clontech). Viral titers were determined using BD Adeno X<sup>TM</sup> rapid titer kit (BD Biosciences Clontech).

### Cell culture and transfection

Eca109 human esophageal cancer cell line was obtained from Shanghai Institute of Cell Biology, Chinese Academy of Sciences. Eca109 cells were cultured in DMEM with 10% fetal bovine serum. Eca109 cells were infected with the Ad/Ang-1si at 50 PFU/cell (Eca109/Ang-1si), Ad/si was used to infect Eca109 cells as control (Eca109/si). Adenovirus generation was confirmed by the expression of GFP. The ECV2304 endothelial cell line, derived from immortalized human umbilical vein endothelial cells (HUVEC) was purchased from Shanghai Institute of Cell Biology and grown in DMEM containing 10% FCS, 2 mmol/L glutamine, HAT (hypoxanthine 0.1 mmol/L, aminopterin 0.4 mmol/L, thymidine 16 mmol/L), and antibiotics. HUVECs (passage 3 or 4) with ~80% confluent were used for most experiments.

### Cell growth assay

Eca109, Eca109/si and Eca109/Ang-1si cells were har-

vested and reseeded at  $1 \times 10^4$  cells/well in 12-well plates. The total cell number was determined every two days with a hemacytometer and under an inverted microscope (Olympus). Cell viability was detected by trypan blue staining. Each value represents the average of triplicate wells.

### RT-PCR for angiopoietin-1

Total RNA was isolated from Eca109, Eca109/si and Eca109/Ang-1si cells using the Trizol protocol (Invitrogen Biotechnology). Reverse transcription reactions were carried out for 1 h at 42°C with 1  $\mu$ g of total RNA, 250 ng of oligo(dT), 1  $\times$  deoxynucleotide triphosphate mix, RNase inhibitor (Promega), 1  $\times$  RT buffer, and 200 units of SuperScript II RT (Invitrogen) in a total volume of 20  $\mu$ L. Amplification of Ang-1 was performed in 50  $\mu$ L of reaction mixture consisting of sense and antisense primers for Ang-1: 2  $\mu$ g of cDNA, 1  $\times$  deoxynucleotide triphosphate mix, 1  $\times$  PCR buffer, 1.5 mmol/L MgCl<sub>2</sub>, and 2.5 units of AmpliTaq Gold DNA Polymerase (Perkin-Elmer, Wellesley, MA). The following primers were used: 5'-ATGACAG TTTTCTTTCC-3', 5'-TCAAAAATCTAAAGGTCG-3' (Sagon Biotechnology).

### Quantification of secreted angiopoietin-1 protein

Eca109, Eca109/si and Eca109/Ang-1si cells ( $2.5 \times 10^5$ ) were seeded into 24-well plates. Fresh medium was added after overnight culture. The cultured supernatants were collected 24 h later and centrifuged to eliminate cellular fragments. Ang-1 protein accumulated in the culture medium was analyzed using sandwich ELISA, wherein the supernatant of the culture was incubated with Ang-1 antibody (goat polyclonal anti-human Ang-1, Santa Cruz Biotechnology) and streptavidin alkaline phosphatase (Santa Cruz Biotechnology). The antigen-antibody complex was then incubated with p-nitrophenyl phosphate (Sigma Biotechnology) dissolved in pNPP buffer (Chemicon Biotechnology). Ang-1 concentrations in the samples were determined from the absorbance at 570 nm spectrophotometrically.

### Cell migration assay

Cultured supernatants from Eca109, Eca109/si, and Eca109/Ang-1si cells were collected. Transwells (Costar, Cambridge, MA) were pretreated with serum-free medium at 37°C for 1 h before seeding with HUVECs at  $1 \times 10^5$  per well in 100  $\mu$ L endothelial basal medium with 0.1% fetal bovine serum. The transwells were then inserted into 24-well plates containing 600  $\mu$ L conditioned medium and incubated at 37°C for 6 h to allow HUVEC cells to migrate. Cells on the upper side of the filter were removed with cotton swabs. Migrated cells on the lower side of the filter were fixed and stained with HE. The number of migrated cells was counted under a binocular microscope.

### Cell proliferative assay

HUVEC cells ( $2.5 \times 10^5$ ) were seeded into 96-well plates, and allowed to adhere for 5 h. The metabolic activity of HUVEC cells was determined every two days by methyl thiazoleterazolium (MTT) assay. Briefly, after light rinsing with PBS, 40  $\mu$ L 5 g/L MTT (Sigma Biotechnology) was

added. After 4 h of incubation at 37°C, HUVEC cells were washed with PBS, and then dissolved in 150  $\mu$ L dimethyl sulfoxide (DMSO). The absorbance of each group was determined spectrophotometrically ( $\lambda = 570$  nm).

### Tumorigenicity assays

Four- to 5-wk-old specific pathogen-free athymic (T-cell deficient) nude mice were purchased from Shanghai Experimental Animal Supply, China. The animal protocol was approved by the Institutional Animal Care and Utilization Committee of the Second Military Medical University. Eca109, Eca109/si, and Eca109/Ang-1si cells in mid-log-growth phase were harvested by trypsinization. Single-cell suspensions ( $2 \times 10^6$  cells in 0.1 mL HBSS) were injected s.c. into the nude mice. The tumors were measured every 4 d with a caliper, and the diameters were recorded. Tumor volume was calculated by the formula:  $a^2b/2$ , where a and b are the two maximum diameters. When tumors reached 2 cm  $\times$  2 cm, the mouse was euthanized, and the tumor tissue was collected, fixed in formalin, embedded in paraffin, cut into 3  $\mu$ m sections, and stained with HE.

### Microvessel counting

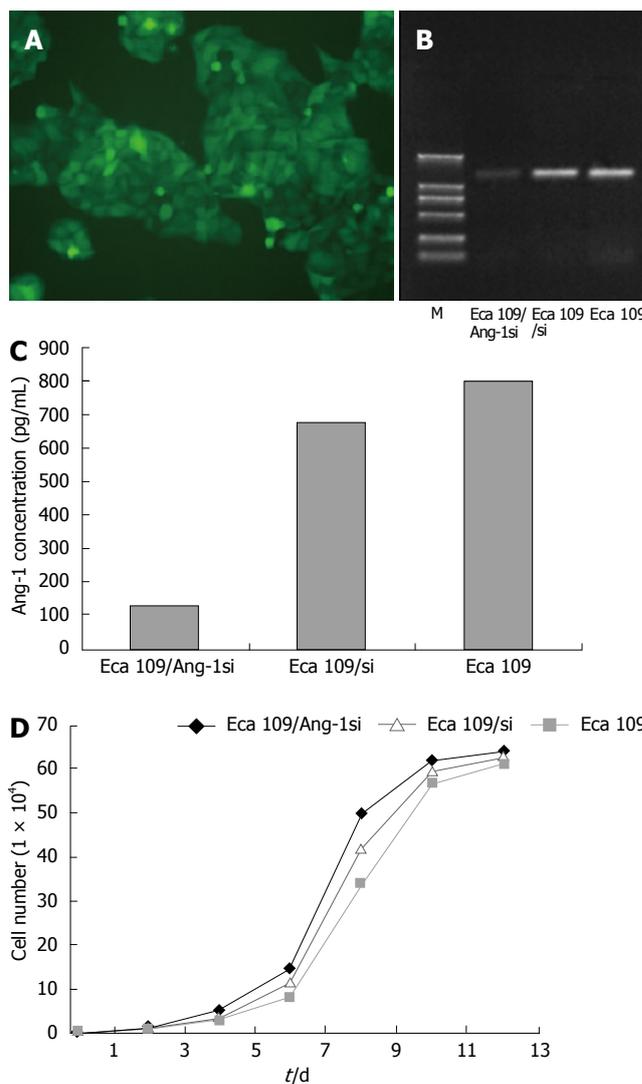

Tissue sections stained with CD31 was used for evaluating MVD. Immunohistochemical staining was performed using the two step immunohistochemical technique with the DAKO EnVision system (EnVision<sup>TM</sup> + Kits, HRP, DAKO Biotechnology). For antigen retrieval, the slides were treated with boiling 0.01 mol/L citrate buffer (pH 6.0) for 15 min. Tissue sections were incubated at room temperature for 1 h with CD31 antibody (goat polyclonal anti-human CD31, Santa Cruz Biotechnology), followed by incubation with horseradish peroxidase-labeled goat anti-mouse immunoglobulin for 30 min and developed with 3, 3'-diaminobenzidine. Then the slides were examined under  $\times 100$  magnification for the hot spots rich in vessels and MVDs were counted under  $\times 200$  magnification (0.708 mm<sup>2</sup>/field), so that every single brown-stained cell and cell cluster was calculated as a blood vessel, no matter whether a vessel lumen structure was seen. For vessels with large lumens, every 40  $\mu$ m length of lumen was calculated as one vessel. Five different fields were chosen on each of the slides, and the stained vessels were counted simultaneously by 2 researchers under a multiocular microscope. The average of the 5 areas was recorded as the MVD score.

### In situ apoptosis detection by TUNEL assay

The TUNEL assay was performed for detection of *in situ* apoptotic cell death according to the manufacturer's instructions (*in situ* cell death detection kit, HRP; Roche Biotechnology). Briefly, the sections were treated with proteinase K (20 mg/L) for 30 min and incubated at room temperature for 1 h with TUNEL reaction mixture, 50  $\mu$ L peroxidase conjugate was added to each slide and the slides incubated for 30 min. For color reaction, 3, 3'-diaminobenzidine was used. The apoptotic index was expressed as the number of TUNEL-positive nuclei per 1000 cells counted for each sample.

### Statistical analysis

The data were expressed as mean  $\pm$  SE. Statistical compar-

**Figure 1** Effect of Ang-1si on Ang-1 expression in Eca109 esophageal cancer cells. **A:** Eca109 cells were infected with Ad/Ang-1si at a multiplicity of infection (MOI) of 50, nearly 100% of cultured Eca109/Ang-1si cells were GFP-positive under the fluorescent microscope; **B:** Ang-1 mRNA was quantified by RT-PCR. Compared with Eca109, the Ang-1 mRNA level of Eca109/Ang-1si cells was reduced by 80%, but no significant alteration in Eca109/si cells; **C:** Secreted Ang-1 protein was quantified by ELISA. Compared with Eca109, the Ang-1 concentration in the media was decreased by Ad/Ang-1si, but no significant change in the cell line transfected with Ad/si; **D:** Cell number was measured at various time points, there was no difference of cell growth curve among Eca109, Eca109/si, and Eca109/Ang-1si cells.

ison was made using SPSS10.0 statistical software package. The criterion for statistical significance was  $P < 0.05$ .

## RESULTS

### Effect of angiotensin-1 small interfering RNA on angiotensin-1 expression

Adenovirus expressing siRNA to Ang-1 was constructed using the Ad Easy System to target human Ang-1 mRNA. Eca109 cells were stably transfected with this adenovirus, the transfection efficiency being approximately 100% (Figure 1A). The Ang-1 mRNA level was measured using RT-PCR, as shown in Figure 1B, Ang-1 expression was significantly inhibited by Ang-1si in Eca109/Ang-1si cells and Ang-1 level was reduced by 80% compared with Eca109

and Eca109/si cells. ELISA was performed using human Ang-1-specific antibody to quantify the amount of Ang-1 protein in the culture media. When cells were transfected with adenovirus expressing siRNA to Ang-1, the Ang-1 concentration in the media was decreased significantly (Figure 1C) compared with Eca109 and Eca109/si cells ( $P < 0.05$ ). These results were in agreement with the amount of Ang-1 mRNA analyzed by RT-PCR experiments.

In addition, cell number was measured at various time points and no difference of cell growth curve was found among Eca109, Eca109/si, and Eca109/Ang-1si cells (Figure 1D).

#### Effect of angiopoietin-1 small interfering RNA on angiopoietin-1 induced endothelial cell proliferation and migration

We collected cultured supernatants from Eca109, Eca109/si, and Eca109/Ang-1si cells. As shown in Figure 2A, the culture supernatants from Eca109 and Eca109/si cells induced robust endothelial cells migration. By contrast, few endothelial cells migrated when conditioned medium from Eca109/Ang-1si cells was used as the chemotactic stimulus.

To determine whether Ang-1 inhibition by siRNA influenced endothelial cells proliferation, the proliferative activity of each cell line was quantified by MTT. However, endothelial cells proliferation was not significantly lower when cells were cultured for 48 h in conditioned medium from Eca109/Ang-1si cells rather than from untransfected or control adenovirus-transfected cells (Figure 2B).

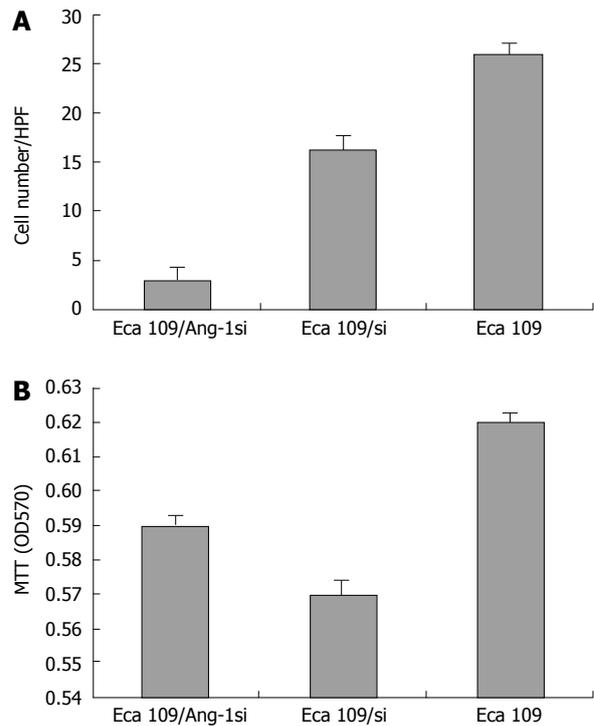

#### Effect of angiopoietin-1 small interfering RNA on esophageal cancer growth in vivo

To determine whether inhibition of Ang-1 by siRNA had an effect on tumor growth, Eca109, Eca109/si, or Eca109/Ang-1si cells was inoculated s.c. into *nu/nu* mice. Eca109 and Eca109/si cells grew rapidly, resulting in palpable tumors 3-4 d following injection. By contrast, tumor formation was significantly slow after inoculation of Eca109/Ang-1si. The Eca109/Ang-1si tumors were significantly smaller than those in both control groups (Figure 3A).

H&E staining showed that Eca109/Ang-1si tumors were pale, with a massively necrotic center and a thin layer of tumor cells in the periphery (Figure 3B). On the contrary, control tumors appeared very vascularized.

As shown in Figure 3C, CD31-positive vessels were abundant in Eca109 and Eca109/si tumors. MVD was significantly decreased in tumors formed by Eca109/Ang-1si, although numerous vessels were seen in the normal tissues surrounding the tumor (Figure 3D). The MVD in tumors treated with Eca109/si was similar to that observed in the Eca109 tumors.

Terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling assay revealed the presence of massive apoptotic and necrotic cells in mice inoculated with Eca109/Ang-1si tumors. Eca109 and Eca109/si tumors showed only small areas of necrosis and apoptosis. Figure 3D shows that the apoptotic cells significantly increased in Eca109/Ang-1si tumors compared to Eca109 and Eca109/si tumors (Figure 3,  $P < 0.05$ ).

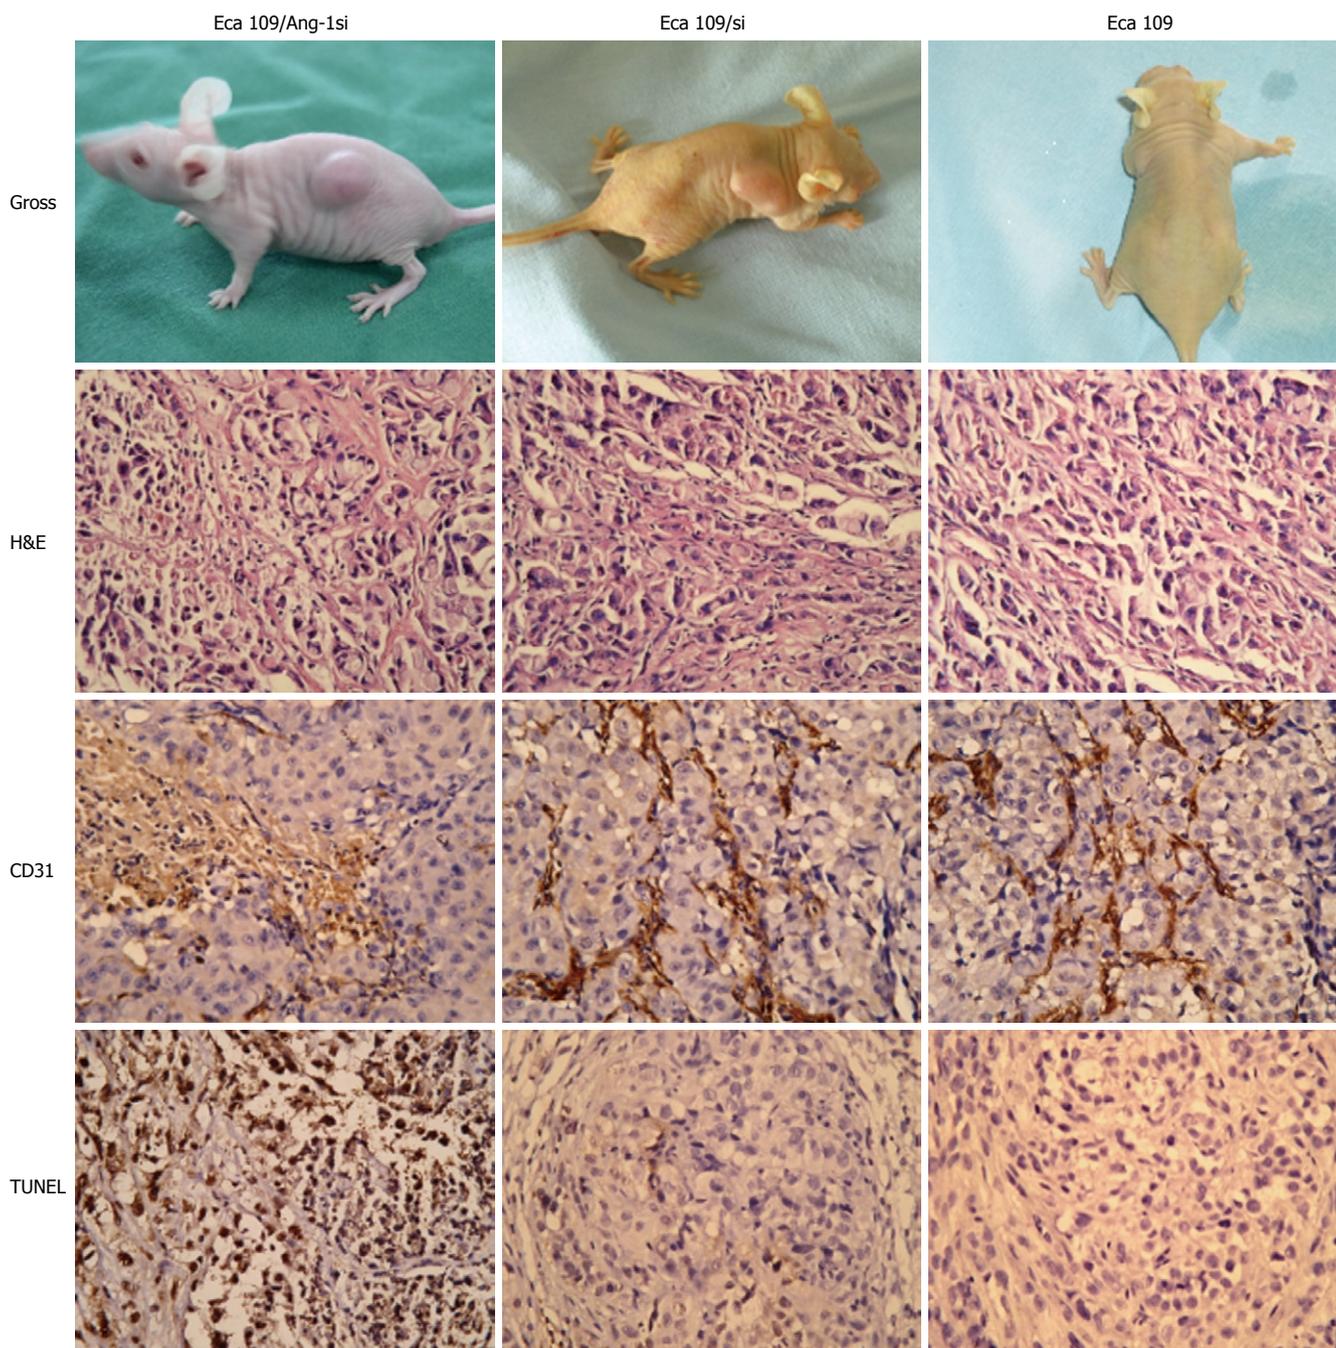

**Figure 2** Effect of Ang-1si on HUVEC cell proliferation and chemotaxis. **A:** HUVEC cell migration was quantified after 6 h, few HUVEC cells migrated as the chemotactic stimulus from Eca109/Ang-1si cells supernatants compared with Eca109 and Eca109/si cells supernatants.  $^bP < 0.01$ ; **B:** HUVEC cells were incubated with the indicated supernatant for 48 h, no difference of proliferative activity of Eca109/Ang-1si cells from Eca109 and Eca109/si cells.  $^bP < 0.01$ .

## DISCUSSION

Several studies have shown that Ang-1 is abundantly expressed in the primary tumors of esophageal cancer patients. In the present study, we showed that Ang-1 played a critical role in the growth of esophageal cancer. This was done by selectively inhibiting Ang-1 expression and protein production using RNA-mediated interference by siRNA.

RNA interference is a phenomenon that can be used to block specific gene expression, and has advantages over other strategies because of its high selectivity and potency. Delivery of small interfering RNA (siRNA) can be achieved through exogenous application of synthetic siRNA or through endogenous expression using plasmid or vector delivery to the target cells<sup>[21,22]</sup>. Chemically or enzymatically synthesized siRNA is costly and has been shown to have a relatively short half-life with only transient inhibition of the target gene because of its low transfection rate and short duration of interference. Moreover, DNA vector-based siRNA technology has some advantages over chemically or enzymatically synthesized siRNA, as it induces more efficient and stable RNA interference<sup>[23,24]</sup>. However, DNA plasmid vector induced siRNA still has limitations with respect to the clinical application of siRNA technology due to its low transfection efficiency.

To overcome these shortcomings, we constructed an adenovirus-based expression system in which sense and antisense strands of short Ang-1 sequence was transcribed into hairpin structures under the control of a H1 promoter and then processed into functional siRNAs by double

**Figure 3** Effect of Ang-1si on esophageal cancer growth *in vivo*. Grossly, the Eca109/Ang-1si tumors were significantly smaller than those in both control groups; Under microscopy, massive necrotic tissue was found in Eca109/Ang-1si tumors, while Eca109 and Eca109/si tumors showed fine necrosis; the Eca109/Ang-1si tumors were avascular with lower MVD, while Eca109 and Eca109/si tumors appeared very vascularized with higher MVD; Eca109/Ang-1si tumors underwent massive apoptosis with more TUNEL-positive cells compared with Eca109 and Eca109/si tumors, which showed a finely granular cytoplasm with evenly dispersed chromatin and lower TUNEL-positive cells.

strand-specific RNase. In this study, we used the highly selective siRNA approach to adenoviral constructs for genetic blockade of Ang-1 with a transfection efficiency of approximately 100%. Ang-1si specifically blocked Ang-1 expression in Eca109 human esophageal cancer cell line. Reduction in Ang-1 protein production was also documented by the finding that HUVEC cell migration induced by Eca109 conditioned medium was almost completely abolished following transfection with Ad/Ang-1si but it was not affected by the Ad/si control adenovirus. By contrast, HUVEC cell proliferation was unchanged in both

Eca109/Ang-1si and Eca109/si cells. These results were in agreement with the reports of Koblizek *et al* that Ang-1 was not an endothelial cell mitogen<sup>[25,26]</sup>; however, it stimulated endothelial cell migration<sup>[27-30]</sup>.

Transfection of Ad/Ang-1si into Eca109 cells did not alter the cell growth *in vitro*. However, when these cells were injected either s.c. or into the bone of nude mice, tumor growth was slower than in parental and Ad/si control-transfected cells. Eca109/Ang-1si cells produced small tumors that were avascular in appearance with decreased vessel density and increased apoptotic and necrotic cells.

Together, these data confirmed once again the specificity of our Ang-1si and indicated that Ang-1 played a pivotal role in esophageal cancer angiogenesis and tumor growth through promoting tumor neovascularization independently from promotion of tumor cell proliferation.

In summary, we have applied the highly selective siRNA approach to adenoviral constructs for genetic blockage of Ang-1 with a high transfection rate and long duration of interference. We found that siRNA technology can be used to specifically inhibit Ang-1 expression. *In vitro* promotion of angiogenesis in Ang-1 protein was documented by the finding that HUVEC cell migration induced by Eca109 conditioned medium was almost completely abolished following transfection with Ad/Ang-1si. *In vivo* cell transfection of Ad/Ang-1si resulted in selective inhibition of Ang-1 expression, leading to decreased tumor vascularity and growth *in vivo*. These data indicated that Ang-1 played a central role in esophageal cancer angiogenesis. Therefore, targeting Ang-1 with specific small-molecule inhibitors may have therapeutic benefit.

## COMMENTS

### Background

Angiopoietin-1 (Ang-1) has been shown to play a pivotal role in tumor angiogenesis. Several lines of evidence indicate that Ang-1 is associated with neovascularization in esophageal cancer, and inhibition of the expression or function of Ang-1 may improve the disease outcome. This study showed that adenovirus-based small interfering RNA (siRNA) expression system can be used to down-regulate Ang-1 expression, resulting in suppression of cell growth and induction of apoptosis through inhibiting angiogenesis in a nude mouse model of esophageal cancer.

### Research frontiers

Angiogenesis has been found to be specifically linked to increased growth and metastatic potential in human tumors. Study in this field has become one of the hot spots at present. Previous studies demonstrated that growth factors, especially Ang-1, are responsible for the growth of esophageal cancer. Based on these findings, treatment targeting this gene has been designed and studied in *in vivo* and *in vitro* models. Preliminary results of these studies have shown beneficial and promising effects. Further experimental and clinical studies are needed before certain conclusions can be reached.

### Innovations and breakthroughs

The association between angiopoietin-1 and angiogenesis and human cancer has been studied previously. However, the inhibitory effect of the adenovirus-based Ang-1 targeted small interfering RNA expression system (Ad/Ang-1si) on the expression of the Ang-1 gene, cell growth and apoptosis in Eca109 has not been explored. This study has bridged this gap and may provide additional targets for therapeutic development.

### Applications

Since some basic evidence provided for angiopoietin-1, angiogenesis and their relationships in the development of human cancer, therapeutic approaches targeting angiopoietin-1 can be implemented in future studies and development of new methods for human cancers.

### Terminology

Angiopoietin-1 (Ang-1): Angiopoietin, a group of proteins including four molecules with similar structure, belongs to a growth factor family. Ang-1 is an endothelium-specific growth factor that can promote angiogenesis. As a 70 kDa glycoprotein, it is mainly produced by juxtavascular cells including pericytes, vascular smooth muscle cells and tumor cells, affecting the surrounding vascular endothelial cells through paracrine action. It can promote migration of endothelial cells, anti-apoptosis, and formation of luminal structure. Thus, it plays an important role in angiogenesis of human cancer.

### Peer review

This is an informative study demonstrating that Ang-1 played a central role in esophageal cancer angiogenesis. Therefore, targeting Ang-1 with specific small-molecule inhibitors may have therapeutic benefit. The preliminary conclusion is justified and substantiated by the results obtained.

### Abstract

**AIM:** To explore precise deleted regions and screen the candidate tumor suppressor genes related to sporadic colorectal carcinoma.

**METHODS:** Six markers on 1q31.1-32.1 were chosen. These polymorphic microsatellite markers in 83 colorectal cancer patients tumor and normal DNA were analyzed *via* PCR. PCR products were electrophoresed on an ABI 377 DNA sequencer. Genescan 3.1 and Genotype 2.1 software were used for Loss of heterozygosity (LOH) scanning and analysis. Comparison between LOH frequency and clinicopathological factors was performed by  $\chi^2$  test.

**RESULTS:** 1q31.1-32.1 exhibited higher LOH frequency in colorectal carcinoma. The average LOH frequency of 1q31.1-32.1 was 23.0%, with the highest frequency of 36.7% (18/49) at D1S2622, and the lowest of 16.4% (11/67) at D1S412, respectively. A minimal region of frequent deletion was located within a 2 cM genomic segment at D1S413-D1S2622 (1q31.3-32.1). There was no significant association between LOH of each marker on 1q31.1-32.1 and the clinicopathological data (patient sex, age, tumor size, growth pattern or Dukes stage), which indicated that on 1q31.1-32.1, LOH was a common phenomenon in all kinds of sporadic colorectal carcinoma.

**CONCLUSION:** Through our refined deletion mapping,

### INTRODUCTION

The progression of the colorectal carcinoma is thought to result from an accumulation of genetic alteration at numerous loci controlling growth and proliferation<sup>[1-3]</sup>. As a model for both multistep and multipathway carcinogenesis, colorectal neoplastic progression provides paradigms of both oncogenes and tumor suppressor genes<sup>[1,2]</sup>. The loss of heterozygosity (LOH), the loss of one paternal or maternal allele at specific locus, on tumor suppressor genes is believed to be one of the key steps to colorectal carcinogenesis<sup>[3,4]</sup>. When this occurs at a tumor suppressor gene locus where one of the alleles is already abnormal, it can result in neoplastic transformation<sup>[5]</sup>. According to the previous study, in colorectal carcinomas, frequent allelic loss was identified in chromosome 5q (30%)<sup>[3,6]</sup>, 8p (40%)<sup>[3,7]</sup>, 17p (75%-80%)<sup>[3,8]</sup>, 18q (80%)<sup>[3,9]</sup>, and 22q (20%-30%)<sup>[3,10,11]</sup>. Moreover tumor suppressor genes APC, p53, and DCC were found, which were located on chromosome 5q, 17p, and 18q, respectively<sup>[12-14]</sup>. The LOH analysis on sporadic carcinoma by means of microsatellite markers has become an effective way to find allelic deletion regions and then to find candidate

tumor suppressor genes<sup>[3,15,16]</sup>. In a previous study we used microsatellite markers to analyze the LOH at 21 loci on chromosome 1 in sporadic colorectal carcinoma. We found that D1S468 (1p36.33-36.31, 9.4 cM) and D1S413 (1q31.1-32.1, 9.8 cM) exhibited higher LOH frequencies, which indicated that the two regions might harbor putative tumor suppressor gene(s)<sup>[17,18]</sup>. However, the allelic deletion region found in our previous studies contained about 50 genes, which was inconvenient for further gene screening and functional studies. Therefore, further LOH scanning with high-density microsatellite markers in the two regions was necessary to narrow the research scope and select fewer candidate genes in the finite regions to functional research. In this study, other six markers from 1q31.1-32.1, at a density of approximately one marker every 1.67 cM, were chosen to analyze refined LOH mapping of the region.

## MATERIALS AND METHODS

### Subjects

This study was based on 83 cases of sporadic colorectal carcinoma, comprising 40 males and 43 females, treated at the surgical department in Shanghai Jiaotong University Affiliated First People's Hospital, China, between 1998 and 1999. Ages ranged from 31 to 84 years with a median of 66 years. All patients were confirmed by pathology and were staged by Dukes criterion. Their distribution according to their clinical stages was as follows: Dukes stage A, 8 cases; stage B, 21 cases; stage C, 40 cases; stage D, 14 cases. Their distribution, according to cancer location, was as follows: proximal colon cancer, thirty-three cases; distal colon, 21 cases; and rectal, 29 cases. The carcinomas were confirmed, *via* pathological examination, as being well differentiated adenocarcinoma in 23 patient cases, moderate differentiated adenocarcinoma in 39 cases, poorly differentiated adenocarcinoma in 6 cases, mucinous adenocarcinoma in 15 cases. HNPCC patients were ruled out by the Amsterdam criteria<sup>[19,20]</sup>. Each patient gave his or her informed consent for the use of his or her tissue in this study.

### DNA extraction

The cancerous and adjacent normal tissues were frozen within 30 min after removal. The tissues were then cut into cubes of approximately 2 mm<sup>3</sup> and immediately frozen in liquid nitrogen. DNA was extracted by standard methods with proteinase K digestion and phenol/chloroform purification<sup>[21]</sup>.

### Microsatellite markers and PCR

By searching in Genothon, NCBI and GDB databases, 6 polymorphic microsatellite markers were chosen, at a density of approximately one marker every 1.67 cM, covering the chromosomal region 1q31.1-32.1 and spanned the D1S413 locus. Based on the databases described previously, the order of these markers was centromere-D1S2877-D1S412-D1S2757-D1S413-D1S2622-D1S2683-D1S2668-qter. The primer sequences are shown in Table 1. Polymorphic microsatellite markers were analyzed in each patients' tumor and normal DNAs by PCR

Table 1 The primer sequences of seven microsatellite markers

Primer	3'-5'	5'-3'
D1S2877	AGACATTNCATTGAAGTCTAT TTAT	CAAGCCACTAGCGTA AGAGC

D1S2757	TTTTTAATGACTGACCAGTG	TGCCTTCGCTATGTTG
D1S413	GCCAAGCCTGAGATCAAAAT	ACTTGAACAGATTGGGATTG
D1S2622	CTGCAACATAAGAACCTAG TGTAAC	AAACTGGTAGGCCATT GATAGA
D1S2683	TGCCITGTCTCAAGAGC	GCAGTGACAGGAATCTGG
D1S2668	AATCACTGAACCTGGGAG	ACTGACTGGCTGTTCTGAG

(GeneAmp PCR System 9700, PE Applied Biosystems Foster city CA, USA). PCR conditions were as follows: 5  $\mu$ L total volume with 1  $\mu$ L (1.4 ng) DNA as a template with 10  $\times$  standard buffer, 0.3  $\mu$ L MgCl<sub>2</sub>, 0.8  $\mu$ L deoxynucleotide triphosphates, 0.3 unit of Hot-start Taq polymerase and 0.06  $\mu$ L of each primer, with the forward primer fluorescence labeled with FAM (Shanghai Shengggong Biological Engineering & Technology and Service Co. Ltd, China), and fill ddH<sub>2</sub>O up to 5  $\mu$ L. Cycling conditions consisted of 3 stages: an initial denaturation at 96°C for 12 min in Stage I; 14 cycles each at 94°C for 20 s, 63-56°C for 1 min (0.5°C decreased per cycle), 72°C for 1 min, in Stage II; 35 cycles each at 94°C for 20 s, 56°C for 1 min, 72°C for 1 min in stage III<sup>[17,18,22-24]</sup>.

### LOH analysis

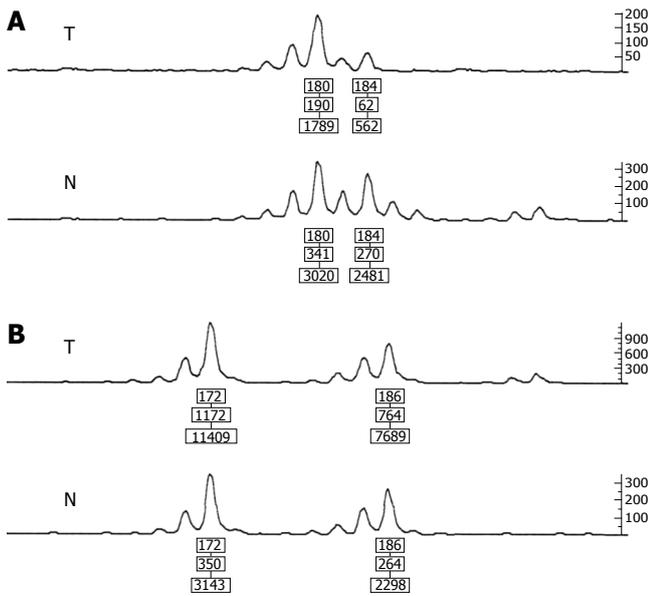

A portion of each PCR product (0.5  $\mu$ L) was combined with 0.1  $\mu$ L of Genescan 500 size standard (PE Applied Biosystems Foster city CA, USA) and 0.9  $\mu$ L of formamide loading buffer. After denaturation at 96°C for 5 min, products were electrophoresed on a 5% polyacrylamide gels on an ABI 377 DNA sequencer (PE Applied Biosystems Foster city CA, USA) for 3 h. Genotype 2.1 software displayed individual gel lanes as electrophoretograms with a given size, height, and area for each detected fluorescent peak. Stringent criteria were used to score the samples. Alleles were defined as the two highest peaks within the expected size range. A ratio of T1:T2/N1:N2 of less than 0.67 or greater than 1.50 was scored as a LOH (Figure 1). Most amplification of normal DNA produced two PCR products indicating heterozygosity. A single fragment amplified from normal DNA (homozygote) and PCR reactions in which fragments were not clearly amplified were scored as not informative. The LOH frequency of a locus was equal to the ratio of the number between allelic loss and informative cases. The average LOH frequency was the average value of each locus LOH frequency<sup>[17,18,22-24]</sup>.

### Statistical analysis

Comparison between LOH and clinicopathological data was performed by  $\chi^2$  test.  $P < 0.05$  was considered statistically significant.

## RESULTS

### LOH analysis on 1q31.1-32.1

**Figure 1** The LOH and normal peak. **A:** The typical peak of LOH: Allele ratio = (T1/T2)/(N1/N2) = (190/62)/(341/270) = 2.43 > 1.5; **B:** The peak of normal (no LOH): Allele ratio = (T1/T2)/(N1/N2) = (1172/764)/(350/264) = 1.15; T: Tumor; N: Normal.

The average LOH frequency of 1q31.1-32.1 was 23.0%, with the highest frequency of 36.7% (18/49) at D1S2622, and the lowest of 16.4% (11/67) at D1S412, respectively. According to this study, a minimal region of frequent deletion was located within a 2 cM genomic segment at D1S413-D1S2622 on 1q31.3-32.1 (Table 2).

**Relationship between clinicopathological features and LOH frequency**

There was no significant association between LOH of each marker on 1q31.1-32.1 and the clinicopathological data (patient sex, age, tumor size, growth pattern or Dukes stage). It indicated that on 1q31.1-32.1, LOH was a common phenomenon in all kinds of sporadic colorectal carcinoma (Table 3).

**DISCUSSION**

During tumorigenesis, loss of the wild-type allele is frequently observed at the appropriate locus. It has been admitted that LOH on tumor suppressor genes plays a key role in colorectal carcinoma transformation. LOH is common to all human solid tumors and allows expressivity of recessive loss of function mutations of tumor suppressor genes. Therefore, detection of recurrent LOH in a chromosome region is now considered critical evidence of localization of tumor suppressor genes<sup>[3,25-28]</sup>. In the previous study, initial LOH scanning was carried out in 83 sporadic colorectal carcinoma samples with 21 highly polymorphic markers on chromosome 1. We found that D1S468 (1p36.33-36.31) and D1S413 (1q31.1-32.1) exhibited higher LOH frequencies<sup>[17,18]</sup>. However, the average genetic distance of the loci in our previous study was 9.6 cM, which contained so many genes that was inconvenient for further gene screening. Further LOH scanning with high-density microsatellite markers in the

**Table 2** LOH frequencies of microsatellite loci on 1q31.1-32.1 in colorectal cancer

Locus	Location	LOH case	Normal case	LOH rate (%)	Informative rate (%)
D1S2877	1q31.1	7	29	19.44	43.37
D1S412	1q31.3	11	56	16.42	80.72
D1S2757	1q31.3	18	43	29.51	73.49
D1S413	1q31.3	13	27	32.50	48.19
D1S2622	1q32.1	18	31	36.73	59.04
D1S2683	1q32.1	10	41	19.61	61.45
D1S2668	1q32.1	4	20	16.67	28.92

two regions was necessary to narrow the research scope and select fewer candidate genes in the finite regions to functional research. In another study of ours, we carried out the refined LOH mapping on 1p36.33-36.31 and found two critical and precise deleted regions, D1S243 (1 cM) and D1S468-D1S2660 (3 cM)<sup>[29]</sup>. In this study, six high-density polymorphic microsatellite markers were chosen for refined LOH mapping of LOH on 1q31.1-32.1 in order to get much more genetic information and to screen the potential tumor suppressor genes.

The results showed that the average LOH frequency of 1q31.1-32.1 was 23.0%, with the highest frequency of 36.7% (18/49) at D1S2622, and the lowest of 16.4% (11/67) at D1S412, respectively. According to this study, a minimal region of frequent deletion was located within a 2 cM genomic segment at D1S413-D1S2622 on 1q31.3-32.1. There are few reports in past years about the relationship between the long arm of chromosome 1 and colorectal carcinoma. Moreover, some previous studies showed that 1q frequently presents allelic loss in other tumors, such as breast cancer, medulloblastoma, thyroid cancer, sporadic insulinoma and esophageal carcinoma. Benitez's<sup>[30]</sup> study showed more than 60% of the breast tumors exhibited allelic loss in the 1q31-32 region. Pietsch *et al*<sup>[31]</sup> found that 36% of the medulloblastomas showed LOH on 1q31-32.1. Moreover accordingly to the study of Kitamura<sup>[32]</sup>, frequent allelic loss was identified on 1q31-42 (40%) in anaplastic thyroid carcinomas. Yang *et al*<sup>[33]</sup> found that thirty-five out of forty (88%) insulinomas had 1q LOH of the 35 insulinomas with 1q LOH, 14 (40%) had 1q21.3-23.2 LOH over a 7.5 cM region, whereas in 21 tumors (60%) LOH occurred at 1q31.3 over an 11.4 cM area. Li *et al*<sup>[34]</sup> analyzed LOH in 61 esophageal squamous cell carcinomas using 18 microsatellite markers on chromosome 1q. Forty-six of 61 tumors (75.4%) presented LOH at one or more loci. These results suggested that putative tumor suppressor genes might locate on the 1q. Our study firstly demonstrated that 1q31-32 exhibited higher LOH frequency in colorectal carcinoma, which suggesting the presence of a tumor suppressor gene in this region. This gene might be involved in the tumorigenesis of colorectal carcinoma and other tumors. Based on our study, allelic deletion was located within 2 cM chromosomal segment encompassing 2 loci (D1S413, D1S2622). Searching the databases, no known tumor suppressor genes have been found in this region. However, we presumed CSRP1 might

be the candidate colorectal carcinoma related gene in this region. At the mRNA level, the highest concentrations of CSRP1 were found in the prostate and the colon followed by the brain and the testis<sup>[55]</sup>. CSRP1 was a member of the CSRP family of genes encoding a group of LIM domain proteins, which might be involved in regulatory processes important for development and cellular differentiation<sup>[36]</sup>. We supposed that the inactivation of this genes could lead to the abnormality of cell differentiation and then result in neoplastic transformation. Recently, Hirasawa *et al.*<sup>[37]</sup> found that CSRP1 were inactivated in HCC by aberrant methylation and they may serve as important biomarkers of malignancy, indicating that CSRP1 was a the tumor related gene. Further functional research will provide additional proof. In order to find the colorectal carcinoma related gene in 1q31.1-32.1, we are performing a microarray-based high-throughput gene screening approach in this region to identify unknown candidate related genes, and this may provide much more genetic information and find the potential tumor suppressor gene(s). In our study, there was no significant association between LOH of all loci on 1q31.1-32.1 and the clinicopathological data, indicating that in this region, LOH was a common phenomenon in all kinds of sporadic colorectal cancer.

In summary, through our detailed deletion mapping studies, the critical and precise deleted region was located within 2 cM chromosomal segment encompassing 2 loci (D1S413, D1S2622). No significant association was found between LOH and clinicopathologic features. The region identified in the present study might harbor one or more tumor suppressor genes, which might be involved in several types of human cancer. Our study provided the significant data to reveal the mechanism of

colorectal carcinogenesis. And further microarray-based high-throughput gene screening and functional research may provide much more genetic information and find the potential tumor suppressor genes.

## COMMENTS

### Background

The loss of heterozygosity (LOH) analysis on sporadic carcinoma by means of microsatellite markers has become an effective way to find allelic deletion regions and then to find candidate tumor suppressor genes. In a previous study Zhou *et al.* found that D1S413 (1q31.1-32.1, 9.8 cM) exhibited higher LOH frequencies and this indicated that this region might harbor the putative tumor-suppressor-gene(s). However, the allelic deletion region the previous studies found contained so many genes that it was inconvenient to further gene screening and functional study. Therefore, in this study, another six markers with high-density microsatellite markers in 1q31.1-32.1 were chosen to analyze refined LOH mapping to narrow the research scope and select fewer candidate genes in the finite regions to functional research.

### Research frontiers

LOH on tumor suppressor genes is believed to be one of the key steps to colorectal carcinogenesis. According to the previous study, in colorectal carcinomas, frequent allelic loss was identified in chromosome 5q (30%), 8p (40%), 17p (75%-80%), 18q (80%), and 22q (20%-30%). Subsequently, tumor suppressor genes APC, p53, and DCC were found, which were located on chromosome 5q, 17p, and 18q, respectively. The LOH analysis on sporadic carcinoma by means of microsatellite markers has become an effective way to find allelic deletion regions and then to find candidate tumor suppressor genes.

### Innovations and breakthroughs

This study found that the precise deleted region was located within 2 cM chromosomal segment encompassing 2 loci (D1S413, D1S2622), in which might harbor one or more tumor suppressor genes related to the colorectal carcinogenesis.

### Terminology

LOH: The loss of one allele at a specific locus, caused by a deletion mutation; or loss of a chromosome from a chromosome pair, resulting in abnormal hemizygosity. It is detected when heterozygous markers for a locus appear monomorphic because one of the alleles was deleted. When this occurs at a tumor suppressor gene locus where one of the alleles is already abnormal, it can result in neoplastic transformation.

### Peer review

It is possible that 1q will be an informative site in colorectal carcinogenesis. But, it may also simply reflect the chromosomal instability (CIN) pathway of genomic instability that was selected for in the selection of predominantly distal, non-mucinous cancers. CIN causes wide spread aneuploidy, and thus LOH in the 1q31.1-32.1 region may be an epiphenomenon, rather than a sentinel event in carcinogenesis. Nevertheless, this study provides some important information about this region. It would be interesting to know whether they have looked at gene expression of CSR1 in any of their samples, or in any CRC cell lines, to support their assertion that this is a likely candidate in this region.

### Abstract

**AIM:** To comprehensively identify the proteins of tumor relative antigen Ca-Hb3 recognized by colorectal carcinoma monoclonal antibody Hb3.

**METHODS:** Ca-Hb3 was isolated by SDS-polyacrylamide gel electrophoresis (PAGE) followed by digestion with trypsin. Trypsin peptides were analyzed by liquid chromatography-tandem mass spectrometry (LC-MS/MS). The proteins identified by mass spectrometry were analyzed using bioinformatics.

**RESULTS:** Ca-Hb3 was identified as a CKAP4-like protein by Nano HPLC tandem mass spectrometry analysis. The molecular weight of CKAP4-like protein was 62.02 kDa, including one hydrophobic region, one transmembrane domain, five coiled coils, four glycosylation sites and forty-nine phosphorylation sites. CKAP4-like protein had a high homogeneity with DeltaNp63 $\alpha$ . The characteristic expression of DeltaNp63 $\alpha$  that is considered a potential oncogene in the isoforms of p63 was similar to that of Ca-Hb3.

**CONCLUSION:** Ca-Hb3 is probably a CKAP4-like protein, belonging to DeltaNp63 $\alpha$  isoform of p63 family.

Colorectal carcinoma-associated antigen Ca-Hb3 detected by one-dimensional SDS-polyacrylamide gel electrophoresis and liquid chromatography-tandem mass spectrometry. *World J Gastroenterol* 2008; 14(10): 1588-1591 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1588.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1588>

### INTRODUCTION

Colorectal cancer can be considered a complex disease with predisposing genetic variants and environmental factors that contribute to the illness as a whole. In recent years, many studies reported that the incidence of colorectal cancer is increased by 4% per year in China<sup>[1-3]</sup>. Hb3 is an anti-colorectal cancer monoclonal antibody produced in our laboratory. Its sensitivity and specificity are superior to those of anti-CEA. Monoclonal antibody Hb3 (mAb Hb3) targets the Hb3 antigen which is expressed in 85% of colorectal cancers, showing that CA-Hb3 may be useful in the diagnosis of colorectal cancer. In this study, using SDS-polyacrylamide gel electrophoresis (PAGE) and microcapillary reversed-phase liquid chromatography-tandem mass spectrometry, we have identified 5 proteins, including one membrane protein which was initially determined to be Ca-Hb3 by bioinformatics analysis.

### MATERIALS AND METHODS

#### Preparation of mAb Hb3

mAb Hb3, a murine IgM-type mAb, was prepared using  $5 \times 10^8$  Hb3 hybridoma cells (our laboratory) to immunize Balb/c mice. Mice were sacrificed and ascites was extracted to obtain supernatant by centrifugation.

#### Instrumentation

NanoLC-MS was performed online with a Waters capillary LC system interfaced with a Waters (Micromass) electrospray ionization quadrupole time-of-flight (ESI-Q-TOF) mass spectrometer.

#### Cells and cell culture

Human colon carcinoma HRT-18 cells were cultured

in RPMI 1640 medium (Promega Inc.) supplemented with 100 mL/L heat-inactivated fetal bovine serum (FBS, Hangzhou Sijiqing BRL Inc.), 30 g/L *L*-glutamine, 100 kg/L streptomycin and 100 U/L penicillin at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub>.

### **SDS-PAGE and Western blot analysis**

Total cell extraction from human colon carcinoma HRT-18 cells was performed by Western blot assay. Samples in the cold lysate buffer (50 mmol/L Tris-Cl pH 8.0, 150 mmol/L NaCl, 10 mmol/L Triton X-100, 10 mmol/L PMSF) were electrophoresed on 10% gradient SDS-polyacrylamide gels in the presence of  $\beta$ -mercaptoethanol. Half of the proteins were transblotted onto a NC membrane, which was blocked with 50 mg/mL fat-free milk and 100 mL/TBS for 2 h and incubated with primary antibody (mAb Hb3) overnight at 4°C. The membrane was washed and incubated with HRP-conjugated goat anti-mouse IgG/IgM (SIGMA Inc.) at room temperature for 1 h. The membrane was washed and the antigen-antibody reaction was visualized using an ECL detection system (KPL Inc.). The other half of proteins were stained with Coomassie blue.

### **Trypsin digestion**

Bands of interest were excised and minced into 1 mm<sup>3</sup> pieces with sterile razor blade. The pieces were washed 3 times with ddH<sub>2</sub>O and then with 50% acetonitrile in 100 mmol/L NH<sub>4</sub>HCO<sub>3</sub>, incubated in water bath for 60 min if necessary. The liquid was discarded, 100  $\mu$ L 1% acetonitrile was added and the dried acetonitrile was removed after 10 min. For SDS-PAGE gel bands, gel pieces were rehydrated and proteins were reduced with 200  $\mu$ L of 100 mmol/L DTT in 100 mmol/L ammonium bicarbonate for 30 min at 56°C. The reduction solution was discarded and 100  $\mu$ L of 50 mmol/L iodoacetamide in 100 mmol/L ammonium bicarbonate was added. Incubation lasted for 30 min at room temperature in the dark. Gel bits were washed with 500  $\mu$ L of 25 mmol/L ammonium bicarbonate in 500 mL/L acetonitrile for 15 min, then 100  $\mu$ L 100% acetonitrile was added and the dried acetonitrile was removed after 10 min. The gel pieces were rehydrated by adding 5  $\mu$ L of trypsin in 40 mmol/L ammonium bicarbonate and incubated overnight at 37°C. The supernatant was removed and placed into a new tube. Peptides were extracted from the gel pieces with 50  $\mu$ L of 20 mmol/L ammonium bicarbonate for 20 min and then with 50  $\mu$ L of 5% formic acid in 50% acetonitrile for 2  $\times$  20 min. The extracts were added to the supernatant. The mixed solution was dried using a Speed-Vas.

### **Nano-HPLC tandem mass spectrometric analysis**

RP-HPLC separation of the peptide samples was performed using a bioinert ultimate nano-HPLC system (Dionex, Sunnyvale, CA, USA). Six microliters of each sample was injected and peptides were purified and concentrated on a C18-PepMap precolumn (0.3 mm ID  $\times$  65 mm, 100Å pore size, 3 mm particle size, Dionex) at a flow rate of 0.02 mL/min. Subsequently, peptides were separated on an analytical 75 mm ID  $\times$  150 mm C18-PepMap column (Dionex, 100Å pore size, 3 mm particle

size) at a column flow rate of 300 mL/min. The ACN gradient (solution A: 1 mL/L formic acid, 20 mL/L ACN; solution B: 1 mL/L formic acid, 800 mL/L ACN) started at 50 mL/L B and ended at 70 mL/L B in 45 min. MS and MS/MS data were collected using a Micromass Q-TOF micro mass spectrometer (Waters, Milford, MA, USA). Doubly and triply charged peptide ions were automatically chosen by the MassLynx software (Waters) and fragmented for a maximum of 7 s for each component. MS data were automatically processed and peak lists for database search were generated by the MassLynx software. Database search was carried out with an in-house MASCOT server using an IPI protein database (Mouse, version 3.07), for a mass tolerance of 5 nkat and allowance for up to 16.67 nKat trypsin miscleavage and variable amino acid modifications consisting of methionine oxidation and cysteine carbamidomethylation.

### **Data analysis and bioinformatics**

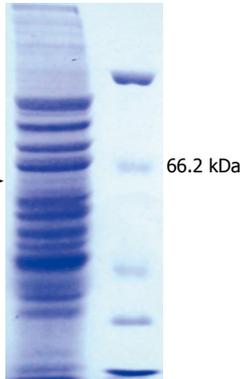

Tandem mass spectrometry (MS/MS) data were collected by the Mass-Lynx 4.0 software (Waters), deisotoped and converted by Waters ProteinLynx Global server 1.0 software to "peak list" (pkl) files, which include the mass values, the intensity (at least 5 counts/s) and the charge of precursor ions. The parameters used in the creation of pkl files were the following background subtraction below curve 10%, which was smoothed three times with "smooth window" (channels) 2.0 in the Savitzky Golay mode, centroid at 80% top and minimum peak width at half height at 4. The pkl files were analyzed using a licensed copy of the Mascot2.0 Program (MatrixScience Ltd., London) on a 2.6 GHz Pentium-4 personal computer with 2 GB of RAM, which compared the files against a human protein non-redundant database containing 146724 protein sequences downloaded as FASTA formatted sequences from NCBI. Search parameters were set as follows: enzyme, trypsin, allowance of up to one missed cleavage peptide, mass tolerance, 0.3u MS/MS mass tolerance, fixed modification parameter, carbamoylmethylation (C), variable modification parameter, oxidation (at Met), auto hits allowed (only significant hit report), result format as peptide summary report. Predictions for putative transmembrane domains (TMDs) in all identified proteins were carried out using the transmembrane hidden Markov model (TMHMM) algorithm, available at <http://www.cbs.dtu.dk/services/TMHMM>.

## **RESULTS**

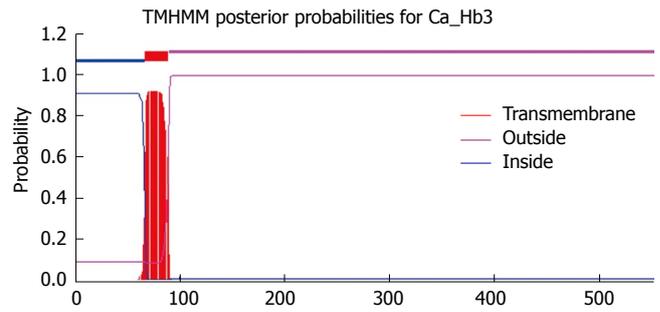

Ca-Hb3 was characterized by Western blot analysis (Figure 1) and one specific electrophoretic band of about 65 kDa in the cell lysates was shown, supporting the previous experiment results<sup>[3]</sup>. Ca-Hb3 crude antigen was separated by one-dimensional SDS-PAGE (Figure 2). Proteins present in the interest band were digested by trypsin. The tryptic peptide was extracted from the purpose band and further separated by reversed-phase nanoLC, detected and sequenced with a Waters Q-TOF micro mass spectrometer. Raw data were analyzed by Mascot ms/ms ion search against the human nonredundant database.

**Figure 1** Western blot analysis of Ca-Hb3 crude antigen.

**Figure 2** One-dimensional SDS-PAGE image of Ca-Hb3 crude antigen.

**Figure 3** Relationship between cellular membrane and CKAP4-like protein.

Using the stringent criteria mentioned above, we identified 5 non-redundant proteins: one inqurate hybrid protein, three nuclear proteins and one CKAP4-like protein. The molecular weight of the second protein (Chain A, crystal structure of the Tpr2a domain of Hop in complex with the Hsp90 peptide Meevd) showed 15484u by MS, and was thus judged to be the inqurate hybrid protein. We found that only CKAP4-like protein (similar to cytoskeleton-associated protein 4) belonged to an integral membrane protein (<http://www.expasy.org>), consistent with the previous experiment results (Figure 3).

**DISCUSSION**

Hb3 is an IgM monoclonal antibody against CA-Hb3<sup>[1-3]</sup>. The results of immunohistochemistry showed that the positive rate of Hb3 reacting with colorectal carcinoma was high.

To characterize the proteins of complex proteomes, the proteins were analyzed by 2D-PAGE followed by MS or MS/MS, or by 2D-LC-MS/MS. Because Ca-Hb3 is located in membrane, it is difficult to resolve membrane proteins by 2D-PAGE. We replaced the 2D-PAGE and 2D-LC with a one-dimensional SDS-PAGE. By applying the method mentioned above, we identified 5 non-redundant proteins. Except for an inqurate hybrid protein and three nuclear proteins, the remaining CKAP4-like protein had a transmembrane domain at the corresponding Ca-Hb3 location.

The p63 gene, independently cloned by multiple laboratories, is a member of the p53 family of transcription factors<sup>[4-6]</sup>. p53 is a tumor suppressor that is inactivated in a majority of human cancers. In response to cellular stresses, such as DNA damage and oncogene activation, p53 is stabilized and acts as a sequence-specific transcription factor, trans-activating target genes are involved in the processes of cell cycle arrest, DNA repair, and apoptosis<sup>[7-10]</sup>. These proteins exhibit a high sequence and structural

similarity to p53, while revealing a considerable functional divergence<sup>[11-15]</sup>.

The human p63 gene consisting of 15 exons, resides on chromosome 3q27-29 and can be expressed in two different promoters<sup>[16,17]</sup>. Transcription from the first and second promoters gives rise to TA or ΔN amino terminus of p63. Both TA and ΔN transcripts can be alternatively split at the carboxy-terminus, leading to formation of α, β and γ isoforms of TA and ΔN p63α. A number of studies have highlighted the oncogenic potential of ΔN p63α which is over-expressed in several epithelial cancers, often as a result of gene amplification<sup>[18-23]</sup>. Over-expression of ΔN p63α isoform in rat-1A cells increases colony growth in soft agar and xenograft tumor formation in nude mice, supporting that p63 acts as an oncogene<sup>[19]</sup>. Furthermore, ΔNp63α can prevent p53-mediated trans-activation, growth arrest, and apoptosis<sup>[24]</sup>. The expression of ΔNp63α is associated with epithelial homeostasis, poor survival of ovarian cancer patients, and promotes keratinocyte adhesion, inhibits apoptosis, and maintains the integrity of epidermal tissue<sup>[25,26]</sup>. ΔNp63α regulates CD44 and keratins 4, 6, 14 and 19 in squamous cell carcinoma of the head and neck, and down-regulation of DeltaNp63α acquires invasive phenotype of human squamous cell carcinoma<sup>[27,28]</sup>. It is hypothesized that ΔNp63α prolongs survival and maintains the proliferating capacity of epithelial stem and cancer cells.

In conclusion, colon cancer monoclonal antibody Hb3 is probably a CKAP4-like protein, belonging to DeltaNp63α isoform of p63 family, which can be considered a marker for colon cancer progression or as a therapeutic target.

**COMMENTS**

**Background**

Hb3 is an anti-colorectal cancer monoclonal antibody produced in our laboratory. Its sensitivity and specificity are superior to those of anti-carcinoembryonic antigen (anti-CEA), showing that CA-Hb3 might be useful in the diagnosis of colorectal cancer.

**Research frontiers**

There are a number of researchers who are searching for a useful marker of tumor. Antigen, as an effect target, is applied in clinical therapy for colon cancer.

**Innovations and breakthroughs**

ΔNp63α obtained by one-dimensional polyacrylamide gel electrophoresis (PAGE) and liquid chromatography-tandem mass spectrometry could be considered a marker for colon cancer progression or as a therapeutic target.

**Applications**

$\Delta$ Np63 $\alpha$  could be applied in treatment of cancer patients as an effect target.

### Terminology

DeltaNp63 $\alpha$  is an isoform of P63 family.  $\Delta$ Np63 $\alpha$  is over-expressed in several epithelial cancers, often as a result of gene amplification. Over-expression of a  $\Delta$ Np63 $\alpha$  isoform in rat-1A cells increases colony growth in soft agar and xenograft tumor formation in nude mice.

### Peer review

This paper is well organized with valuable conclusions.

### Abstract

**AIM:** To explore the inhibitory effects of pokeweed antiviral protein seed (PAP-S) and PAP encoded by a eukaryotic expression plasmid on hepatitis B virus (HBV) replication *in vitro*.

**METHODS:** HepG2 2.2.15 cells in cultured medium were treated with different concentrations of PAP-S. HBsAg, HBeAg and HBV DNA in supernatants were determined by ELISA and fluorescent quantitative PCR respectively. MTT method was used to assay for cytotoxicity. HepG2 were cotransfected with various amounts of PAP encoded by a eukaryotic expression plasmid and replication competent wild-type HBV 1.3 fold over-length plasmid. On d 3 after transfection, HBsAg and HBeAg were determined by using ELISA. Levels of HBV core-associated DNA and RNA were detected by using Southern and Northern blot, respectively.

**RESULTS:** The inhibitory effects of PAP-S on HBsAg, HBeAg and HBV DNA were gradually enhanced with the increase of PAP concentration. When the concentration of PAP-S was 10 µg/mL, the inhibition rates of HBsAg, HBeAg and HBV DNA were 20.9%, 30.2% and 50%, respectively. After transfection of 1.0 µg and 2.0 µg plasmid pXF3H-PAP, the levels of HBV nucleocapside-associated DNA were reduced by 38.0% and 74.0% respectively, the levels of HBsAg in the media by 76.8% and 99.7% respectively, and the levels of HBeAg by 72.7% and 99.3% respectively as compared with controls. Transfection with 2 µg plasmid pXF3H-PAP reduced the levels of HBV nucleocapside-associated RNA by 69.0%.

**CONCLUSION:** Both PAP-S and PAP encoded by a eukaryotic expression plasmid could effectively inhibit HBV replication and antigen expression *in vitro*, and the inhibitory effects were dose-dependent.

### INTRODUCTION

Pokeweed antiviral protein (PAP), a 29-kDa protein isolated from leaves or seeds of *Phytolacca americana*, inhibits translation by catalytically removing a specific adenine residue from the large rRNA of the 60S subunit of eukaryotic ribosomes<sup>[1,2]</sup>. The anti-viral activity of PAP has been described against a wide range of viruses, including HIV, herpes simplex virus, cytomegalovirus, influenza virus and polio virus<sup>[3,4]</sup>. Dose response studies indicate that the anti-HIV activity of PAP from PAP-S was comparable to Zidovudine (AZT)<sup>[5]</sup>.

The purpose of the present study was to evaluate “*in vitro*” the potential usefulness of PAP in therapies against chronic hepatitis B. Hepatitis B virus (HBV) is a major cause of liver disease worldwide, ranging from acute and chronic hepatitis to cirrhosis and hepatocellular carcinoma<sup>[6]</sup>. Despite the availability of an effective and safe vaccine against HBV, infection by this virus is an important worldwide health problem<sup>[7]</sup>. Although several pharmacological strategies are currently being implemented to treat affected patients, no effective antiviral therapy

against HBV infection has yet been fully developed<sup>[8]</sup>. Thus, new drugs to be used alone or in combination with existing treatments are needed. In this respect, “*in vitro*” screening of potentially active compounds is a useful step in the development of novel drugs.

In this study, we assessed anti-HBV activities of PAP from PAP-S by detecting HBsAg, HBeAg, and HBV DNA in the supernatant of HepG2 2.2.15 cell lines. We also constructed the eukaryotic expression plasmid encoding PAP, cotransfected it and the replication competent wild-type HBV 1.3 fold over-length plasmid into the HepG2 cells to investigate the inhibitory effect of the eukaryotic expression plasmid of PAP. PAP was found to be a remarkably potent and fast-acting antiviral agent against HBV replication *in vitro* in the absence of any obvious signs of toxicity. This is the first report of the anti-HBV effects of PAP. Our observations suggest that PAP deserves further investigation as a potential alternative or complementary anti-HBV agent.

## MATERIALS AND METHODS

### Plasmid constructs and reagents

The plasmid pGEM-PAP containing the PAP gene was kindly supplied by Prof. YAN Bo (Institute of Biotechnology, Yunnan Academy of Agricultural Sciences, China). The replication competent wild-type HBV 1.3 fold over-length plasmid (genotype, ayw) and the plasmid pXF3H derived from the cytomegalovirus-driven vector pRK5 were both kindly supplied by Dr. Lei Yanchang. The coding gene of PAP (Gene Bank GI: 218010) was amplified from the plasmid pGEM-PAP by PCR using forward primer 5'-CGGGATCCAATAAATACAATCACCTTCGTAA-3' and reverse primer 5'-CC AAGCTTAGGGAA CATGGCACTTTGGTAA-3'. The PCR product was cloned into *Bam*H I / *Hind*III restriction sites of the CMV-driven expression vector fused with a hemagglutinin fusion epitope tag at its N-terminus (pXF3H).

PAP-S, purified from pokeweed (*Phytolacca americana*) seeds, was kindly supplied by Professor HU Zhong (Kunming Institute of Botany, The Chinese Academy of Sciences, China).

### Cell culture and treatment

HepG2 and HepG2 2.2.15 cells were grown at 37°C with 50 mL/L CO<sub>2</sub> in Dulbecco's modified Eagle medium (DMEM) supplemented with 10% fetal calf serum (FCS) (Invitrogen, CA, USA).

HepG2 cells were seeded on plastic dishes (3.5 cm in diameter) at a density of  $4.5 \times 10^5$  cells per well in 6-well plates 18 h prior to transfection. Transfection of HepG2 cells was performed with lipofectamine 2000 (Invitrogen, CA, USA) following the manufacturer's instructions. The replication competent wild-type HBV 1.3 fold over-length plasmid pHBV1.3 and various amounts of a CMV-driven expression vector pXF3H-PAP were cotransfected into the HepG2 cells.

HepG2 2.2.15 cells were treated with PAP-S at various concentrations for 2 or 4 d in DMEM supplemented with 10% FCS in a 24-well plate at a density of  $2 \times 10^4$  cells

per well. The corresponding suspension was collected for analysis of the levels of HBsAg, HBeAg, and HBV DNA, in duplicate every 2 d for 4 d. The HepG2 2.2.15 cells as controls were washed twice with phosphate-buffered saline (PBS) and refed with culture medium every 2 d for 4 d.

### HBsAg and HBeAg assays and Western blot analysis

The concentration of HBsAg or HBeAg in culture supernatants of HepG2 2.2.15 or the transfected HepG2 cells was detected by an enzyme-linked immunosorbent assay (ELISA) kit (Shanghai Kehua Company, China) and quantified relative to a standard curve of serial dilutions of recombinant HBsAg or HBeAg. Inhibition rate (%) = (P/N values of the control wells - P/N values of the test wells) / (P/N values of the control wells - 2.1) × 100%, and the median inhibition dose (ID<sub>50</sub>) represented the concentration of PAP-S when the inhibition rate was 50%. The median cytotoxic dose (CD<sub>50</sub>) represented the concentration of PAP-S when the number of the survival cells was 50%.

In order to determine the efficiency of transfection, Western blot with polyclonal anti-HA antibody was used to detect the expression of PAP in cotransfected HepG2 cells. For Western blot analysis, cytoplasmic lysates were incubated with 1 volume of 2 × loading buffer containing 10% beta-mercaptoethanol for 10 min at 95°C before loading onto a 12.5% SDS-PAGE. Proteins were transferred onto a nitrocellulose membrane via electroblot. The membranes were incubated with anti-hemagglutinin fusion epitope polyclonal antibody (Santa Cruz, USA) followed by horseradish peroxidase conjugated mouse anti-rabbit antibody. Proteins were visualized via enhanced chemiluminescence (Roche, Germany).

### Supernatant HBV DNA from HepG2 2.2.15 cells analysis by quantitative real-time PCR

For HBV DNA from HepG2 2.2.15 cells, the DNA was detected by real-time PCR kit (DA AN GENE CO., Guangzhou, China) following the instruction manual provided. Amplification and detection were performed with an ICycler (Bio-Rad) Detection system. The program was optimized with denaturation at 94°C for 2 min followed by 40 cycles of amplification (at 94°C for 20 s, 55°C for 20 s, and 72°C for 20 s).

### Detection of HBV core-associated DNA and mRNA by Southern and Northern blot in cotransfected HepG2 cells

On d 3 after transfection, HepG2 cells were lysed with 0.8 mL of 0.01 mol/L Tris-HCl (pH 8.0), 0.05 mol/L NaCl, 5 mL/L NP-40, 1 mmol/L EDTA at room temperature for 10 min as previously described<sup>[9]</sup>. For the Southern hybridizations, 20 µg of total DNA was digested with *Hind*III, electrophoresed on a 1.4% agarose gel, and then transferred onto nylon membrane. The probe containing the full-length HBV genome was labeled with digoxigenin dUTP (DIG) by the DIG-high Prime DNA labeling and Detection Starter kit II according to the manufacturer's protocol (Roche, Germany). The membrane was hybridized with HBV probe at 50°C overnight.

For Northern blot analysis, total RNA was extracted from the transfected cells with TRIZOL reagent (Gibco, USA) according to the manufacturers instructions. A total of 20 µg of RNA was resolved in 1.2% denatured gel and then transferred onto the nylon membrane and the membrane was hybridized with DIG-labeled HBV DNA fragment described above. For hybridization of glyceraldehyde-3-phosphate dehydrogenase (G3PDH), the full-length HBV DNA probe was removed from the membrane by washing twice at 37°C in 0.2 mol/L NaOH containing 1 mL/L sodium dodecyl sulfate (SDS) solution for 15 min and then re-hybridized with DIG-labeled probe for G3PDH.

**Analysis of cytotoxicity**

HepG2 2.2.15 cells were used for determining the cytotoxicity of PAP-S. Cells were plated onto a 96-well plate at a density of 1 × 10<sup>4</sup> cells per 100 µL prior to drug treatment. PAP-S was added at concentrations of 0.1, 1.0, 10, 50 and 100 µg/mL and the cells were refed with drug-containing fresh medium every 2 d for up to 4 d, and then 20 µL of 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyl (MTT) was added to each well and further incubated in a CO<sub>2</sub> incubator at 37°C for 90 min. The absorbance (A) at 490 nm was read. Data were calculated as a percentage of negative control cells that were not treated with PAP-S.

**Statistical analysis**

Data points were obtained from at least three different cell cultures, in which each condition was assayed in triplicate. Values were expressed as mean ± SD. To calculate the statistical significance of differences within or among groups, the paired *t*-test was used. Statistical significance was set at *P* < 0.05.

**RESULTS**

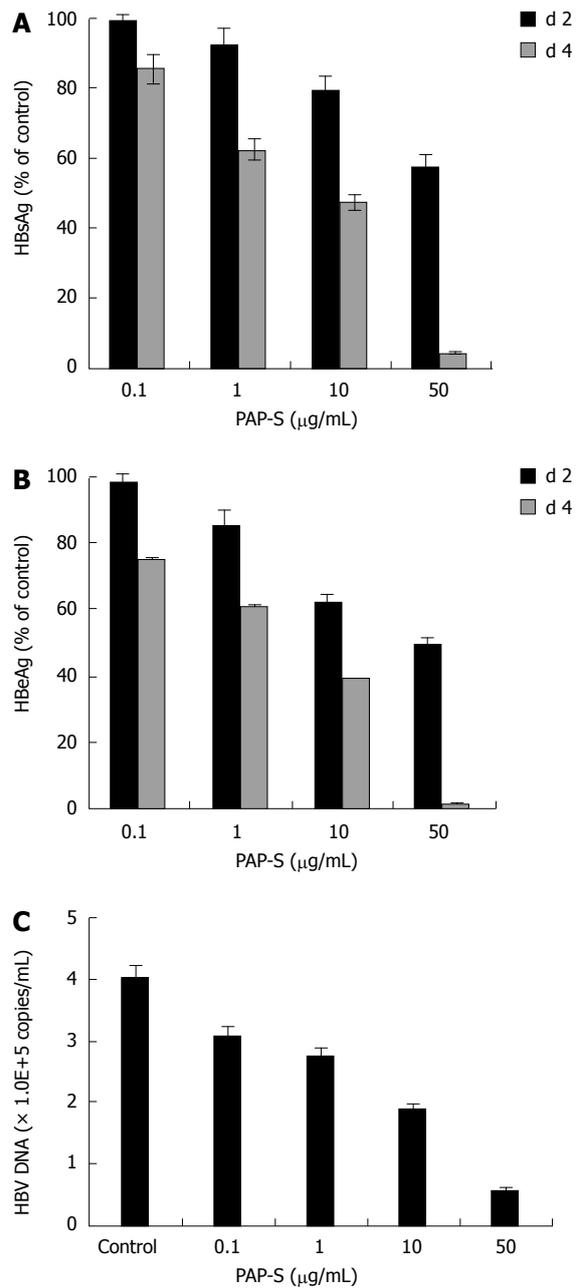

**Anti-HBV activity of PAP-S in HepG2 2.2.15 cells**

In HepG2 2.2.15 cells, MTT assay revealed that PAP-S had no inhibitory effect on cell proliferation up to 50 µg/mL. PAP-S inhibited the growth of HepG2 2.2.15 cells at concentrations above 50 µg/mL. The CD<sub>50</sub> value was 29.3 µg/mL.

As shown in Figure 1A-C, treatment of above 1 µg/mL PAP-S could statistically significantly reduce HBsAg, HBeAg and HBV DNA in a dose dependent manner as compared with vehicle controls (*P* < 0.01). The ID<sub>50</sub> of PAP-S to inhibit HBsAg and HBeAg production was 6.9 and 3.2 µg/mL on d 4, respectively. The therapeutic index (TI) for HBsAg and HBeAg was 4.3 and 9.3 on d 4, respectively. The data in this report clearly showed that the inhibitory activity of PAP-S on HBsAg and HBeAg was promoted time-dependently (*P* < 0.01). The suppression of HBV DNA was dose-dependent and approximately 53.3% inhibition was observed in the 4-d culture treated with PAP-S (10 µg/mL).

**Effect of pXF3H-PAP on HBV DNA replication in cotransfected HepG2**

On d 3 after transfection, levels of HBV core-associated DNA were detected by Southern blot. As shown in

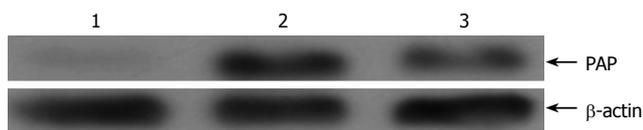

**Figure 1** Effects of PAP-S on secreted HBsAg (A), HBeAg (B) and HBV DNA(C) in HepG2 2.2.15 cell cultures. Data are expressed as mean ± SD of three independent experiments. Except the first group (0.1 µg/mL), *P* < 0.01 vs the corresponding controls (Student's *t*-test).

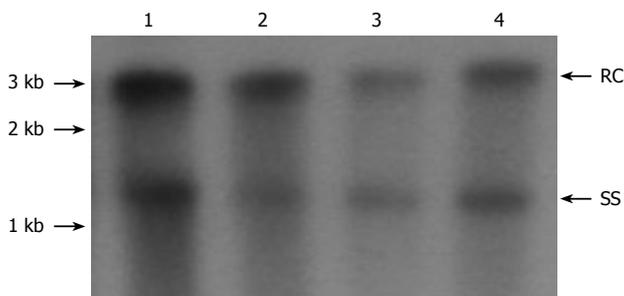

Figure 2, Western blot showed that PAP was expressed in cotransfected HepG2 cells. As compared with controls, the levels of HBV nucleocapside-associated DNA were reduced by 38.0% and 74.0% respectively after transfection of 1.0 and 2.0 µg plasmid pXF3H-PAP into HepG2 cells. The levels of HBV nucleocapside-associated DNA were reduced by 63.0% when the transfected HepG2 cells were exposed to 20.0 µmol/L 3TC (Figure 3). The present results indicated that PAP reduced the HBV nucleocapside-associated DNA in a dose-dependent manner.

**Effects of pXF3H-PAP on secreted HBsAg and HBeAg in cotransfected HepG2**

As compared with controls, the levels of HBsAg in the

**Figure 2** Western blot analysis of the expression of pXF3H-PAP in cotransfected HepG2 cells  $\beta$ -actin as internal reference; 1: pHBV1.3 (1.0  $\mu$ g) + pXF3H (2.0  $\mu$ g); 2: pHBV1.3 (1.0  $\mu$ g) + pXF3H-PAP (2.0  $\mu$ g); 3: pHBV1.3 (1.0  $\mu$ g) + pXF3H-PAP (1.0  $\mu$ g).

**Figure 3** Southern blot analysis of the effect of pXF3H-PAP on intracellular HBV DNA replication in cotransfected HepG2 cells 3 d after transfection. RC: Relaxed circular DNA; SS: Single stranded DNA. 1: pHBV1.3 (1.0  $\mu$ g) + pXF3H (2.0  $\mu$ g) 2: pHBV1.3 (1.0  $\mu$ g) + pXF3H-PAP (1.0  $\mu$ g); 3: pHBV1.3 (1.0  $\mu$ g) + pXF3H-PAP (2.0  $\mu$ g); 4: pHBV1.3 (1.0  $\mu$ g) + 3TC (20.0  $\mu$ mol/L).

media were reduced by 76.8% and 99.7% respectively on d 3 after transfection of 1.0  $\mu$ g and 2.0  $\mu$ g plasmid pXF3H-PAP into HepG2 cells. The levels of HBsAg were reduced by 93.7% when the transfected HepG2 cells were exposed to 20.0  $\mu$ mol/L 3TC. The levels of HBeAg in the media were reduced by 72.7% and 99.3% respectively after transfection of 1.0  $\mu$ g and 2.0  $\mu$ g plasmid pXF3H-PAP into HepG2 cells. The levels of HBeAg were reduced by 82.4% when the transfected HepG2 cells were exposed to 20.0  $\mu$ mol/L 3TC. The present results indicated that PAP reduced the levels of HBsAg and HBeAg in a dose-dependent manner.

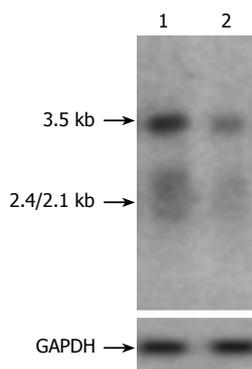

#### Effects of pXF3H-PAP on HBV core-associated RNA in cotransfected HepG2

Northern blot indicated that the HBV core-associated RNA levels of 3.5 kb, 2.4/2.1 kb in cotransfected HepG2 cells were significantly suppressed by PAP (Figure 4). After transfection of 2.0  $\mu$ g plasmid pXF3H-PAP, the levels of HBV core-associated RNA were reduced by 69% as compared with controls.

## DISCUSSION

The anti-viral activity of PAP has been described against numerous pathogenic viruses<sup>[3,4]</sup>, which included poliovirus, HIV, herpes simplex virus, cytomegalovirus, influenza virus and now, the double-strand DNA virus, hepatitis B virus. The ability of PAP to inhibit viral protein synthesis and depurinate viral RNA and DNA<sup>[10,11]</sup> as well as capped rRNA and mRNAs<sup>[12]</sup> and its ability to inhibit ribosomal frame shifting and retransposition, make it an ideal candidate for anti-viral strategies.

In this study, we evaluated the effects of PAP from

**Figure 4** Northern blot analysis of the effect of pXF3H-PAP on intracellular HBV RNA transcription in cotransfected HepG2 cells on d 3 after transfection. GAPDH as internal reference; 1: pHBV1.3 (1.0  $\mu$ g) + pXF3H (2.0  $\mu$ g) 2: pHBV1.3 (1.0  $\mu$ g) + pXF3H-PAP (2.0  $\mu$ g).

PAP-S on hepatitis B virus *in vitro* by the HepG2.2.15 cell line transfected with hepatitis B virus DNA. Furthermore, we constructed the eukaryotic expression plasmid encoding PAP, cotransfected it and the replication competent wild-type plasmid pHBV1.3 into the HepG2 hepatoma cells in order to explore the inhibitory effect of PAP on HBV replication.

Previous studies suggested that the antiviral activity of PAP was attributed to its ability to inhibit protein synthesis by catalytically cleaving a specific adenine base from the highly conserved alpha-sarcin/ricin loop (SRL) of the large ribosomal RNA<sup>[13]</sup>. However, animal studies have suggested that the antiviral action of PAP may not be contributed to its inactivation of ribosomes<sup>[14,15]</sup>. PAP produced only 30% inhibition of total protein synthesis in herpes simplex virus-infected cells, whereas it inhibited virus production by 90%<sup>[16]</sup>. Similarly, it has been reported that PAP inhibits HIV-1 production of p24 in both T cells and macrophages at concentrations that do not adversely affect protein synthesis<sup>[17]</sup>, which suggested that antiviral activity of PAP can be dissociated from its toxicity<sup>[18-21]</sup>.

Further research discovered that not only rRNA but also polynucleotide, single-stranded DNA, double-stranded DNA and mRNA, can be depurinated by PAP<sup>[22,23]</sup>. Rajamohan<sup>[11,24]</sup> treated HIV-1 RNA with various concentrations of PAP. The depurinating activity of test PAP was determined by measuring the amount of adenine and guanine released from the HIV-1 RNA using a quantitative HPLC method, which confirmed that PAP caused a concentration-dependent depurination from HIV-1 RNA. These findings indicate that PAP should be capable of recognizing and depurinating viral RNA.

In this study, it was found that both PAP-S and PAP encoded by a eukaryotic expression plasmid (pXF3H-PAP) could inhibit the levels of HBsAg, HBeAg and HBV DNA in a dose-dependent manner *in vitro*. At the RNA level, PAP might be capable of recognizing and depurinating HBV-mRNA, which included 3.5 kb pregenome mRNA and 2.4/2.1 kb pregenome mRNA, so that the levels of HBV mRNA were reduced. At the DNA level, on one hand, because the 3.5 kb pregenome mRNA was inhibited, the levels of HBcAg/HBeAg and HBV polymerase translated from 3.5 kb pregenome mRNA and the minus strand HBV DNA transcribed from the 3.5 kb pregenome mRNA template were reduced accordingly. On the other hand, PAP might be capable of recognizing and depurinating the new synthesized HBV DNA, so that the

levels of HBV DNA were reduced. At the protein level, on one hand, because HBV-mRNA was inhibited, the HBcAg and HBeAg translated from 3.5 kb mRNA and the HBsAg and pre-S antigen translated from 2.4 kb or 2.1 kb mRNA were inhibited accordingly. On the other hand, PAP might inhibit HBV protein translation by depurinating rRNA.

Further research demonstrated that PAP cleaved supercoiled pBR322 dsDNA, generating relaxed and linear molecules<sup>[25]</sup>. PAP could identify the characteristic spatial conformation of supercoiled DNA and hydrolyze AMP in specific area, turn the supercoiled DNA into nicked circle DNA or linear DNA so that the supercoiled DNA exerted irreversible topological inactivation<sup>[26]</sup>. HBV covalently closed circle (cccDNA) is also supercoiled DNA and has a characteristic spatial conformation, so we speculated that PAP could inhibit HBV by identifying and inactivating the HBV cccDNA template.

Several nucleoside analogs are under clinical development for use against HBV. Lamivudine (3TC), a nucleoside analog, and adefovir dipivoxil (ADV), an acyclonucleotide analog, are clinically approved. However, long-term treatment can induce viral resistance, and following the cessation of therapy, viral rebound is frequently observed<sup>[27,28]</sup>. There continues to be a need for new antiviral agents with novel mechanisms of action. The anti-HBV mechanism of PAP might be different from 3TC that targeted the viral polymerase. A previous study had reported that PAP exhibited potent *in vivo* activities against nucleoside reverse transcriptase inhibitor-resistant HIV-1 in a surrogate human peripheral blood lymphocyte (Hu-PBL) SCID mouse model of human AIDS<sup>[29]</sup>. More work is needed, however, to determine the mechanism of anti-HBV activity of PAP.

Moreover, we have detected the cytotoxicity of PAP on the cell and found that the tested concentration of PAP exerted little growth inhibition. The findings demonstrated that repetitive intravaginal administration of PAP at concentrations as high as 2000 times its *in vitro* anti-HIV IC<sub>50</sub> value was not associated with local or systemic toxicity<sup>[30]</sup>. PAP may be useful as an anti-HBV agent.

In conclusion, the present study demonstrated that the eukaryotic expression plasmid pXF3H-PAP and PAP-S could effectively inhibit HBV antigen secretion and HBV replication in a dose-dependent manner *in vitro*. The present anti-HBV medicine cannot eliminate HBV cccDNA in the hepatocytes so that they cannot clear HBV thoroughly. PAP is therefore worthy to be further investigated as an excellent candidate for potential clinical studies.

## ACKNOWLEDGMENTS

We are grateful to Professor HU Zhong and Professor B Yan for providing PAP-S and the plasmid PGEM-PAP, and also to Dr. YC Lei for providing the 1.3 fold over-length HBV plasmid and pXF3H.

## COMMENTS

### Background

Hepatitis B virus (HBV) is a major cause of liver disease worldwide, ranging from acute and chronic hepatitis to cirrhosis and hepatocellular carcinoma. The anti-

HBV medicines such as interferon and nucleoside analogs are currently being implemented to treat affected patients. However, long-term treatment can induce viral resistance, and following the cessation of therapy, viral rebound is frequently observed. There continues to be a need for new antiviral agents with novel mechanisms of action.

### Research frontiers

The aim of this study is to explore the inhibitory effects of Pokeweed antiviral protein (PAP) on HBV replication *in vitro*.

### Innovations and breakthrough

This study clearly showed that PAP could effectively inhibit HBV replication and antigen expression in a dose-dependent manner *in vitro*. This is the first report of the anti-HBV effects of PAP.

### Applications

PAP might be useful as a potential alternative or complementary anti-HBV agent. The perspective of future application: the further study for the exact mechanisms of anti-HBV activity of PAP.

### Peer review

This is an interesting study. PAP has not been studied against HBV previously, so the manuscript provides new information to confirm that PAP, as expected, has an antiviral effect against HBV. The data and anti-HBV mechanisms are novel.

**CONCLUSION:** Both a short-term lifestyle intervention and vitamin E therapy have an effect on NAFLD in obese children. Compared with vitamin E, lifestyle intervention is more effective. Therefore, lifestyle intervention should represent the first step in the management of children with NAFLD.

Effect of life style intervention on non-alcoholic fatty liver disease in Chinese obese children. *World J Gastroenterol* 2008; 14(10): 1598-1602 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1598.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1598>

### Abstract

**AIM:** To investigate the effect of lifestyle intervention on non-alcoholic fatty liver disease (NAFLD) in Chinese obese children.

**METHODS:** Seventy-six obese children aged from 10 to 17 years with NAFLD were enrolled for a one-month intervention and divided randomly into three groups. Group 1, consisting of 38 obese children, was an untreated control group without any intervention. Group 2, consisting of 19 obese children in summer camp, was strictly controlled only by life style intervention. Group 3, consisting of 19 obese children, received oral vitamin E therapy at a dose of 100 mg/d. The height, weight, fasting blood glucose (FBG), fasting serum insulin (FINS), plasma alanine aminotransferase (ALT), aspartate aminotransferase (AST), triglyceride (TG), total cholesterol (TCHO) and homeostasis model assessment-insulin resistance (HOMA-IR) were measured at baseline and after one month. All patients were underwent to an ultrasonographic study of the liver performed by one operator who was blinded to the groups.

**RESULTS:** The monitor indices of BMI, ALT, AST, TG, TCHO and HOMA-IR were successfully improved except in group 1. BMI and ALT in group 2 were reduced more significantly than in group 3 ( $2.44 \pm 0.82$  vs  $1.45 \pm 0.80$ ,  $P = 0.001$ ;  $88.58 \pm 39.99$  vs  $63.69 \pm 27.05$ ,  $P = 0.040$ , respectively).

### INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) tends to become epidemic in children worldwide in the latest decade. NAFLD is recognized as a cause of potentially progressive liver damage. The entire range of liver involvement in NAFLD can occur in children, such as hepatic macrovesicular steatosis without inflammation, steatosis with inflammation or fibrosis [which defined as non-alcoholic steatohepatitis (NASH)] and cirrhosis. NAFLD may be the hepatic aspect of the metabolic syndrome that comprises central obesity, insulin resistance, hypertension and dyslipidemia in adults and children<sup>[1]</sup>. The natural history of NAFLD is only partly known, the disease slowly progresses to cirrhosis and the initial assessment of NASH as being benign is not supported by the available evidences<sup>[2-8]</sup>. Insulin resistance has been shown to be the basic pathophysiological mechanism responsible for the fatty transformation of liver (first hit) as well as the second hit which leads to hepatocyte injury<sup>[9,10]</sup>. The gold standard of diagnosis is liver biopsy, but it is not frequently performed in the pediatric population. Liver ultrasonography (US), although not sensitive enough to assess liver fibrosis or inflammation, has a sensitivity of 89% and a specificity of 93% for detecting histological steatosis<sup>[11,12]</sup>. In the absence of liver

biopsy, presumed NASH is conventionally diagnosed by classical ultrasonography together with an elevated serum level of alanine aminotransferase (ALT)<sup>[13]</sup>.

Multiple therapeutic agents such as vitamin E,  $\beta$ -carotene, metformin, PPAR- $\gamma$  agonists and the lipase inhibitor orlistat have demonstrated to be useful in NAFLD in a series of small cases<sup>[14-18]</sup>. Lifestyle intervention (dietary restriction and exercise) has also improved the liver function of patients with NAFLD<sup>[19]</sup>. Conflicting data on the therapeutic efficacy of these drugs have been reported in the literature<sup>[14-18]</sup>.

The aim of this study was to investigate the short-term effect of a lifestyle intervention on liver biochemistry and fasting insulin levels and compare with that of the vitamin E therapy in obese children with NAFLD.

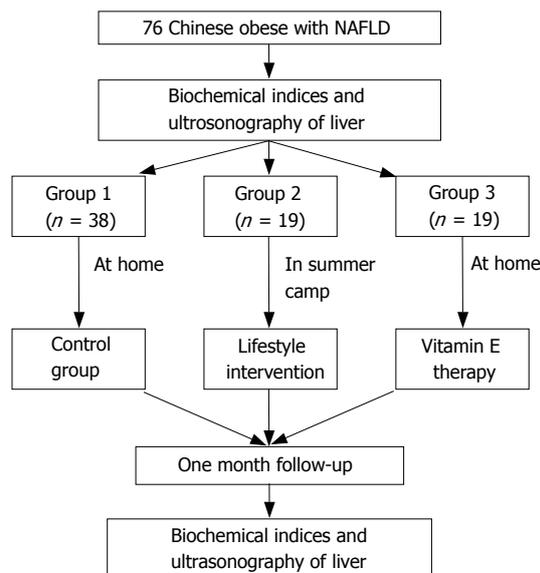

## MATERIALS AND METHODS

Seventy-six obese children, according to the criteria that a child was considered to be obese when the body mass index (BMI) exceeded the 95th BMI percentage for age and sex<sup>[20]</sup>, were enrolled in this study. The age of the subjects ranged from 10 to 17 years (mean  $13.7 \pm 1.9$  years). They were all obese children with liver fatty infiltration in ultrasonic appearance and abnormal liver function with higher alanine aminotransferase (ALT) by at least 1.5 times over the upper normal limit which was diagnosed as NASH<sup>[21]</sup>. They were divided randomly into three groups and the ultrasonography operator was blinded to the groups. Group 1 was an untreated control group, consisting of 38 obese children, who had not taken any medicine and lifestyle intervention. Group 2 had 19 obese children, taking no drug and treated only with strict lifestyle intervention at summer camp. Group 3, consisting of 19 obese children, was treated with vitamin E, while improving their behaviors and enjoying their lives freely by themselves at home. Patients who had positive markers for other liver diseases (hepatitis virus, TORCH, metabolic, genetic) or who had a history of alcohol intake were all excluded. Studies of the three groups were carried out at the same time, that of group 2 at the summer camp, and the others were done separately at home. They were all observed for one month, because the camp lasted only a month (Figure 1). The characteristics of the three groups are shown in Table 1.

Written informed consent was obtained from all participants and in case of minors, it was obtained from their parents. The study was conducted in accordance with the guidelines proposed in the Declaration of Helsinki and was approved by the Ethics Committee of the Children's Hospital of Zhejiang University School of Medicine.

### Lifestyle intervention

Nineteen patients in group 2 were strictly controlled by lifestyle intervention without any drug therapy. They took part in the summer camp without their parents. The Nuote Nutrient Center which was in charge of the camp, consisted of nutrient experts, physical experts and pediatricians. Physical exercises, including swimming, playing basketball and table tennis, were taken freely for three hours of aerobic exercise each

**Figure 1** The dispositions of subjects. (76 obese children and adolescents with NAFLD aged between 10 and 17 years were enrolled in this study).

BMI: Body mass index; ALT: Plasma alanine aminotransferase; AST: aspartate aminotransferase; TG: Triglyceride; TCHO: Total cholesterol; FBG: Fasting blood glucose; FINS: Fasting serum insulin; HOMA-IR: Homeostasis model assessment-insulin resistance.

intensity aerobic exercise to reach a 50%-60% maximum of their heart beat and maintained for 30 min, 2-3 times a week). Thirty-eight patients in group 1 did not receive any lifestyle intervention.

#### Drug therapeutic protocol

Patients in group 3 received vitamin E capsule at a dose of 100 mg/d for one month. Groups 1 and 2 received no drug treatment.

#### Monitoring indices

Indices of all patients, including the height, weight, fasting blood glucose (FBG), fasting serum insulin (FINS), plasma alanine aminotransferase (ALT), aspartate aminotransferase (AST), triglyceride (TG) and total cholesterol (TCHO), were measured in the morning after an overnight fast and repeated after a month. Fasting blood glucose was measured by the glucose oxidase method (Beijing North Biotechnology Invest, China) with intra-assay and inter-assay CV of 2.1% and 4.4%, respectively. Fasting serum insulin levels were determined by radioimmunity assay (Beijing North Biotechnology Invest, China). The intra-assay and inter-assay CV were 6.4% and 9.7%, respectively. ALT, AST, TG and TCHO were measured by routine laboratory test (BECKMAN Synchron Clinical System CX4, American) at the central laboratory of our unit. In this study, hypertransaminasemia (or elevation of serum ALT) was defined as serum ALT levels being raised by

at least 1.5 times over the upper normal limit (normal range: < 50 IU/L). BMI = weight (kg)/height (m<sup>2</sup>). To compare BMI among different ages in both boys and girls, BMI Z-score was considered. The Z-score represents the number of s.d. above or below the mean value based on standardized tables for children<sup>[22]</sup>. Insulin resistance was assessed by homeostasis model assessment (HOMA-IR) based on serum fasting insulin and glucose concentrations. HOMA-IR = (FINS in mIU/L × FBG in mmol/L)/22.5. Our previous study proved that HOMA-IR was a valid insulin sensitivity index from OGTT parameters in obese children and adolescents<sup>[23]</sup>.

All patients underwent an ultrasonographic study of the liver performed by one operator who was blinded to the groups. The apparatus used (LOGIC 500, GE corporation) was equipped with a convex 3.0-5.0 MHz probe. Longitudinal, subcostal, ascending, and oblique scans were performed. The ultrasonographic criteria of liver-kidney echo discrepancy, echo penetration into the deep portion of the liver, and clarity of liver blood vessel structures were used to diagnose fatty liver according to Graif M, *et al*<sup>[24]</sup>.

#### Statistical analysis

Statistical analyses were conducted using SPSS software (Version 13.0). Pearson Chi-square was used to measure the enumeration data between subgroups. Quantitative data were presented as mean ± SD or median (range) and estimated by one-way ANOVA or paired-samples *t* test. Mann-Whitney test was used to evaluate the significance of skewed distributed data. A two-tailed *P* < 0.05 was considered statistically significant.

## RESULTS

A total of 76 NASH patients were analyzed and observed for a month. The baseline characteristics of the three groups were not significantly different (*P* > 0.05) (Table 1). After one month, these characteristics in group 1 were not improved (*P* > 0.05) (Table 2).

In groups 2 and 3, all patients had declined BMI, Z<sub>BMI</sub>, ALT, AST, TG, TCHO, FINS and HOMA-IR after a month. There was more significant reduction in BMI and ALT levels after intervention in group 2 than in group 3 (*U* = 73.000, *P* = 0.001; *U* = 117.000, *P* = 0.040, respectively). No difference was found in the other indices between groups 2 and 3 (*P* > 0.05). Ten patients (52.63%) in group 2 had normal liver functions after the camping was completed.

Nine patients (47.37%) in group 3 became normal in liver functions in the end. The liver ultrasonography did not demonstrate any predominant changes after a one-month lifestyle intervention.

## DISCUSSION

Non-alcoholic fatty liver disease affects a large proportion of the population. In our previous study, the prevalence of NAFLD was 22.41% among all obese subjects and the male is apt to obesity with NAFLD<sup>[1,25]</sup>. The pathogenesis of NAFLD has remained poorly understood since the earliest

description of this disease. However, insulin resistance and oxidative stress play critical roles in the pathogenesis of non-alcoholic fatty liver disease. As yet no accepted drug treatment of NAFLD/NASH has been reported.

In this study, we found that the body weights of all the patients except control group were successfully reduced. Lifestyle intervention was associated with ALT improvement after a month. And it seemed that vitamin E therapy also improved the liver function. At the same time, lifestyle intervention proved to be more efficient than vitamin E therapy on BMI and ALT. The liver ultrasonography did not demonstrate any predominant change after a month intervention. It is likely that ultrasonography is not sensitive enough to detect an initial and short improvement in steatosis. Weight reduction will improve not only the liver condition but also the metabolic (insulin resistance) syndrome. Exercise is known to improve the sensitivity of muscle mass to insulin<sup>[26-28]</sup>. Furthermore, a recent clinical trial showed that exercise has modest therapeutic effect in reducing visceral fat and improving glucose intolerance<sup>[29]</sup>. These may partially explain the beneficial effect of lifestyle intervention in improving the hypertransaminasemia. Frequency and intensity of ideal exercise for treatment of NAFLD remains unknown. Suzuki A *et al* reported that patients with NAFLD should be encouraged to keep regular exercise and at least twice a week<sup>[30]</sup>.

Vitamin E is frequently used among patients with NAFLD. The useful effect of vitamin E on inflammation and fibrosis among patients with NASH has been attributed to its potent antioxidant action. Oxidant stress has been cited as an important second hit in the pathogenesis of NASH, and obese children have been demonstrated to have significantly decreased serum levels of  $\alpha$ -tocopherol<sup>[31-34]</sup>. In these studies, the dose of vitamin E was 300-1200 mg/d. In one study, vitamin E 300 mg/d was associated with fibrosis reversal<sup>[35]</sup>. However, Nobili *et al* reported that in 90 patients in biopsy-proven NAFLD children, a balanced calorie diet, physical exercise, and placebo or alpha-tocopherol 600 IU/d plus ascorbic acid 500 mg/d and a 12-mo double-blind placebo study found that vitamin E therapy had no effect on ALT or insulin resistance<sup>[36]</sup>. Kugelmans *et al* found that vitamin E improved insulin sensitivity and several of its associated parameters, including ALT levels in overweight otherwise healthy subjects but the effect of treatment was not sustained<sup>[37]</sup>. In our study, vitamin E was also found to improve insulin sensitivity and ALT level in a month therapy. So, we conclude that a short-time therapy with 100 mg vitamin E and lifestyle intervention may have an effect on ALT levels and insulin resistance in children with NAFLD.

Lifestyle intervention has been recommended for the treatment of NAFLD in obese children. Early intervention should attempt to increase physical activity while implementing dietary and other antiobesity measures. The emphasis should be laid on slow and modest reduction of body mass, not exceeding 2 pounds (1 kg)/wk, coupled with increased physical activity<sup>[20]</sup>. It is very encouraging that lifestyle intervention had short-term effect, but the long-term effect on NAFLD remains to be clarified. After the camping, the children and their monitors were assembled

and taught how to do exercise and how to arrange daily diet. They were encouraged to have a low-intensity aerobic exercise such as playing basketball and table-tennis, quick walking, slow running or string jumping, etc to reach a 50%-60% maximum of their heart beat and maintain for at least 30 min 2-3 times a week. Diet was tailored based on individual preferences and balanced as hypocaloric diet (25-30 cal/kg per day, carbohydrate 50%-60%, fat 23%-30%, protein 15%-20%, fatty acid: two-thirds saturated, one-third unsaturated,  $\omega 6/\omega 3$  ratio = 4:1).

In summary, our results suggest that simple lifestyle intervention with physical exercise and diet in children with NAFLD can lead to a significant improvement of liver function and insulin resistance. A short-term vitamin E therapy also has a effect on NAFLD in obese children. Compared with vitamin E therapy, lifestyle intervention is more effective. Therefore, lifestyle intervention should represent the first step in the management of children with NAFLD.

## ACKNOWLEDGMENTS

We thank all children and their parents for participating in this project.

## COMMENTS

### Background

Non-alcoholic fatty liver disease (NAFLD) is likely to become epidemic in children worldwide in the latest decade. NAFLD is recognized as a cause of potentially progressive liver damage. The gold standard of diagnosis is liver biopsy but it is not frequently performed in the pediatric population. In the absence of liver biopsy, presumed NASH is conventionally diagnosed by classical ultrasonography together with an elevated serum level of alanine aminotransferase (ALT).

### Research frontiers

Multiple therapeutic agents such as vitamin E, metformin, and lifestyle intervention have demonstrated to be useful in NAFLD. However, no accepted drug treatment of NAFLD/NASH has been reported.

### Innovations and breakthroughs

Although the relation between diet and fat liver is known, it is the first report about lifestyle intervention on NAFLD in Chinese obese children. In this study, both a short-term lifestyle intervention and a short-term vitamin E therapy have an effect while lifestyle intervention is more effective than vitamin E.

### Applications

Lifestyle intervention should represent the first step in the management of children with NAFLD.

### Terminology

NAFLD encompasses a spectrum of disease ranging from simple hepatic steatosis to non-alcoholic steatohepatitis. The entire range of liver involvement characterizing NAFLD can occur in children, such as hepatic macrovesicular steatosis without inflammation, steatosis with inflammation or fibrosis (which defined as non-alcoholic steatohepatitis, NASH), and cirrhosis. NAFLD may be the hepatic aspect of the metabolic syndrome that comprises the central obesity, insulin resistance, hypertension and dyslipidemia in adults and children.

### Peer review

This manuscript is of some interest because therapeutic intervention is limited to one month and the adherence to the program is really rigorous. This experiment may provide insights on the short-term modification of some indexes of NAFLD that probably anticipate the improvement of fatty liver.

### Abstract

**AIM:** To study the therapeutic value of combination of cryosurgery and <sup>125</sup>Iodine seed implantation for locally advanced pancreatic cancer.

**METHODS:** Forty-nine patients with locally advanced pancreatic cancer (males 36, females 13), with a median age of 59 years, were enrolled in the study. Twelve patients had liver metastases. In all cases the tumors were considered unresectable after a comprehensive evaluation. Patients were treated with cryosurgery, which was performed intraoperatively or percutaneously under guidance of ultrasound and/or computed tomography (CT), and <sup>125</sup>Iodine seed implantation, which was performed during cryosurgery or post-cryosurgery under guidance of ultrasound and/or CT. A few patients received regional celiac artery chemotherapy.

**RESULTS:** Thirteen patients received intraoperative cryosurgery and 36 received percutaneous cryosurgery. Some patients underwent repeat cryosurgery. <sup>125</sup>Iodine seed implantation was performed during freezing procedure in 35 patients and 3-9 d after cryosurgery in 14 cases. Twenty patients, 10 of whom had hepatic

metastases received regional chemotherapy. At 3 mo after therapy, CT was repeated to estimate tumor response to therapy. Most patients showed varying degrees of tumor necrosis. Complete response (CR) of tumor was seen in 20.4% patients, partial response (PR), in 38.8%, stable disease (SD), in 30.6%, and progressive disease (PD), in 10.2%. Adverse effects associated with cryosurgery included upper abdomen pain and increased serum amylase. Acute pancreatitis was seen in 6 patients one of whom developed severe pancreatitis. All adverse effects were controlled by medical management with no poor outcome. There was no therapy-related mortality. During a median follow-up of 18 mo (range of 5-40), the median survival was 16.2 mo, with 26 patients (53.1%) surviving for 12 mo or more. Overall, the 6-, 12-, 24- and 36-mo survival rates were 94.9%, 63.1%, 22.8% and 9.5%, respectively. Eight patients had survival of 24 mo or more. The patient with the longest survival (40 mo) is still living without evidence of tumor recurrence.

**CONCLUSION:** Cryosurgery, which is far less invasive than conventional pancreatic resection, and is associated with a low rate of adverse effects, should be the treatment of choice for patients with locally advanced pancreatic cancer. <sup>125</sup>Iodine seed implantation can destroy the residual surviving cancer cells after cryosurgery. Hence, a combination of both modalities has a complementary effect.

## INTRODUCTION

Pancreatic cancer is a rapidly growing tumor that is nearly always fatal. The majority of pancreatic cancers are detected at a late stage of illness, and only a minority of patients are candidates for curative surgical resection. Overall, the 1- and 5-year survival rates are only 20% and 5%, respectively<sup>[1-3]</sup>. Paclitaxel and gemcitabine are considered to be effective agents in pancreatic cancer, but their response rates are no more than 20%, and the effectiveness is less than 6 mo<sup>[4,5]</sup>. Therefore, it is necessary to seek novel treatment modalities<sup>[6,7]</sup>. This report examines the role of combined cryosurgery and <sup>125</sup>iodine seed implantation in the treatment of locally advanced pancreatic cancer.

## MATERIALS AND METHODS

### Patients

From March 2001 to November 2007, forty-nine patients with locally advanced pancreatic cancer underwent cryosurgery combined with <sup>125</sup>iodine seed implantation. There were 36 males and 13 females, aged 28-89 years, with a median age of 59 years. Tumor size ranged from 2.2-7.1 cm in the largest diameter. Twelve patients had hepatic metastasis. In all patients, the diagnosis was based on ultrasound, computed tomography (CT) and MRI imaging, and 38 patients had a positive histology. Before hospitalization, 14 cases had received 4-6 cycles of chemotherapy (gemcitabine, cisplatin, 5-FU). All patients received a comprehensive evaluation and were considered to be unresectable. The patients were provided information on cryosurgery guidelines, and the study received ethical approval.

### Cryosurgery

Cryosurgery was performed with intraoperative or percutaneous approaches. Intraoperative cryosurgery: Patients were administered general anesthesia and were positioned for an upper abdominal incision. The involved pancreas was exposed by trans-peritoneal mobilization of the bowel and stomach. Once the pancreatic mass was identified, an 18-gauge Tru-Cut biopsy needle was used to obtain one or two cores of tissue from the solid mass. If it was determined that the tumor was unresectable, after a thorough investigation, cryosurgery was performed under direct vision and under ultrasound guidance. A variable number (one to three) of 2 or 3 mm cryoprobes were placed directly into the pancreatic mass and positioned under ultrasound guidance. In general, lesions smaller than 3 cm could be frozen reliably with a single centrally placed 3-mm probe, whereas larger lesions required multiple probes. A double cycle of freeze/thaw procedure was used with an argon gas-based cryosurgical unit (EndoCare, Inc., CA, USA). Each cryoprobe was cooled to -160°C and the resulting iceball was monitored with ultrasound until the frozen region encompassed the entire mass of the tumor with at least a "0.5-cm safe border". The tissue was then allowed to slowly thaw to 0°C. A second cycle of freezing/thawing was performed after repositioning of the cryoprobes. The cryoprobes were then removed and the

still-frozen tract made by the cryoprobe was packed with thrombin-coated Gelfoam to control bleeding. Metastases of the liver were treated with cryosurgery at the same time<sup>[8,9]</sup>.

**Percutaneous cryosurgery:** The procedure was performed under local anesthesia and under guidance of ultrasound or CT. Based on the location of the tumor, cryoprobe insertion was often carried out via the retroperitoneal approach. Generally, 2 or 3 mm cryoprobes were used. For tumors greater than 3 cm in size, 2 to 3 probes were used. For liver metastases, simultaneous cryosurgery was performed using additional cryoprobes which were inserted through the right intercostal space. The cryosurgery procedure was similar to that performed intraoperatively<sup>[9]</sup>.

**Seed implantation:** The procedure was performed either at the time of cryosurgery or after cryosurgery through the percutaneous approach under ultrasound or CT guidance. The <sup>125</sup>iodine seeds were implanted at the tumor border. The number of seeds employed depended on the tumor size, with each seed implanted at a distance of 0.5 cm.

**Postoperative management:** The patients were instructed to stop eating for at least 3 d after the procedure. An analogue of somatostatin was given by intravenous infusion, usually for 3-4 d, or extended further until the abdominal pain subsided and the elevated serum amylase levels normalized. Aprotinin (Trasylol), an inhibitor of pancreatic enzymes, and a proton pump inhibitor were given by intravenous infusion to patients with abdominal pain and elevated serum amylase levels.

**Adjuvant regional chemotherapy:** Infusion of chemotherapeutic drugs was initiated one wk after cryosurgery, via a catheter in the celiac artery or hepatic artery. The treatment consisted of cycles of 5-FU 500 mg/m<sup>2</sup>, mitomycin C 8.5 mg/m<sup>2</sup> and gemcitabine 500 mg/m<sup>2</sup>, every 2 wk.

### Follow-up

Postoperative follow-up was performed at one mo after treatment and every 3 mo thereafter. On each visit, the patients were assessed by tumor marker assay, abdominal ultrasonography, and CT. Some patients were examined by positron emission tomography-CT PET-CT. The efficacy of cryosurgery was evaluated based on tumor size and survival of the patients. Changes in tumor mass were measured according to The Response Evaluation Criteria in Solid Tumors (RECIST) protocol<sup>[10]</sup>, which is based on objective measurements of the tumor size before and after treatment. Complete response (CR) means that all targeted lesion had disappearance (scar) or reduced to less than 25% of the original size. Partial response (PR) means a greater than 30% decrease in the sum of the largest diameter of all targeted lesions. Stable disease (SD) means less than 30% decrease in the sum of the largest diameter of all targeted lesions. Progressive disease (PD) means an increase of greater than 20% in the sum of the largest diameter of all targeted lesions.

All radiologic studies were reviewed by the same radiologist with an expertise in pancreatic imaging. Ultrasound-guided biopsy was performed for lesions that were suspicious for recurrence. Cryosurgery was repeated if histology showed a positive result. The presence of a persistent nodule on imaging studies without tumor activity on PET-CT, with decreasing or normal tumor markers (CA19-9), or no changes in the absence of any other treatment for an interval of at least 6 mo after cryosurgery, was considered as remnant tumor. Tumor recurrence was determined by a positive histology, or by the combination of an increase in the cryotreated lesion on ultrasound, CT or PET-CT imaging, an increase in the tumor markers or by the discovery of metastases.

### Statistical analysis

Survival was calculated using the Kaplan-Meier test<sup>[11]</sup>. Prognostic factors influencing survival were tested using the Log-rank, Tarone-Ware or Breslow test for univariate analysis and Cox regression<sup>[12]</sup>; Cox's proportional hazard model with the forward-stepwise method (likelihood ratio) was used for multivariate analysis with various covariates. A significant difference was indicated by  $P < 0.05$ . Statistical analysis was performed using SPSS version 11.5 (SPSS, Chicago, USA).

## RESULTS

Thirteen patients received intraoperative cryosurgery, and 36 underwent percutaneous cryosurgery. Among the patients who received percutaneous cryosurgery, 17 received a second course of cryosurgery and 3 received three courses of cryosurgery. <sup>125</sup>Iodine seed implantation was performed during cryosurgery in 35 patients, and 3-9 d after cryosurgery in 14 cases. The median number of <sup>125</sup>Iodine seeds implanted was 34, with a range of 18-54 seeds. Twenty patients received adjuvant regional chemotherapy, 10 of whom had hepatic metastases. Five patients received 1 cycle of chemotherapy, ten received 2 cycles, three 3 cycles and two 4 cycles.

**Response to treatment:** Based on CT findings, at 3 mo after treatment, most patients showed varying degrees of tumor necrosis. The results of CR, PR, SD and PD were 20.4% (10/49), 38.8% (19/49), 30.6% (15/49) and 10.2% (5/49), respectively.

**Adverse reactions:** As shown in Table 1, 69.4% of patients had abdominal pain, which usually subsided in 2-3 d. About one-half of the patients (51.0%) had elevated serum amylase levels, which generally ranged 1-2 times of the normal reference values and lasted for 5-7 d. Acute pancreatitis with acute abdominal pain, and elevated serum amylase levels to four times or more was seen in 6 patients (12.2%), one of whom developed severe pancreatitis with intra-abdominal fluid effusion, and serum amylase levels 12 times of the normal reference values. All patients with pancreatitis recovered with conservative management. Three patients (6.1%) had intra-abdominal bleeding, however, abdominal fluid obtained by paracentesis did

Table 1 Adverse effects of pancreatic cryosurgery

Adverse effects	No. of patients (n)	%
Abdominal pain	34	69.4
Fever	26	53.1
Acute pancreatitis <sup>1</sup>	6	12.2
Increased amylase levels <sup>2</sup>	25	51.0
Abdominal bleeding <sup>3</sup>	3	6.1
Pulmonary infection	3	6.1
Myocardial infarction	1	2.0
Cerebral infarction	1	2.0

<sup>1</sup>With abdominal pain and fever; <sup>2</sup>Including 6 patients with acute pancreatitis; <sup>3</sup>With abdominal pain.

not have increased amylase levels. The intra-abdominal bleeding disappeared within four days. Nearly one-half of the patients (53.1%) had fever of 38-39.5°C, accompanied with chills. Fever persisted for 3-4 d, generally less than 7 d. Two patients had pulmonary infection, which recovered within 7-10 d with antibiotic therapy. Two patients aged 78 and 91 years, developed cerebral infarction and myocardial infarction respectively. There was no treatment-related mortality.

### Overall survival

During a median follow-up of 18 mo (range of 5-40 mo), the median duration of survival was 16.2 mo. Twenty-six patients (53.1%) survived 12 mo or more, 8 of whom lived for 24 mo or more. The patient with the longest survival (40 mo) is still living without any evidence of tumor recurrence. A total of 36 patients died, in whom 17 died of cancer spread, 11 with hepatic metastases died of liver failure, 5 of cardio-cerebral vascular diseases and 3 of unknown causes. The 6-, 12-, 24- and 36-mo survival rates were 94.9%, 63.1%, 22.8% and 9.5% respectively (Figure 1A).

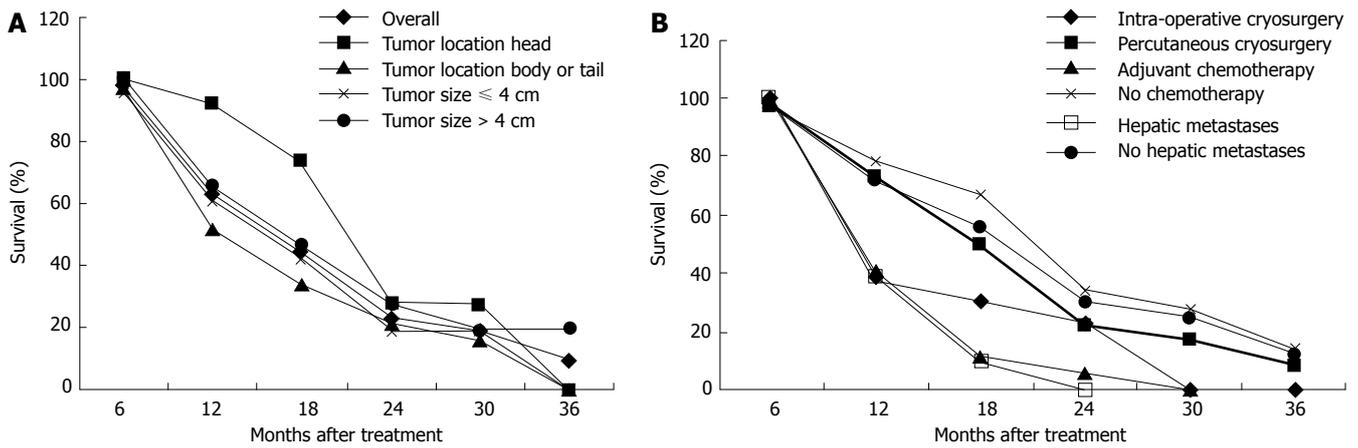

Univariate analysis was performed for factors influencing survival. Of the 5 variables tested, adjuvant chemotherapy and hepatic metastases were associated with a poor prognosis. The mode of cryosurgery (intraoperative *vs* percutaneous), tumor size ( $\leq 4$  cm *vs*  $> 4$  cm), and location (head *vs* body or tail) did not show independent significance for prognosis (Figure 1A and B).

The univariate analysis (Breslow test) of median survival in the different subgroups of patients with pancreatic cancer is shown in Table 2. The following factors were associated with longer median survival: cancer of pancreatic head, absence of hepatic metastases and absence of adjuvant chemotherapy.

A Cox model for multivariate regression analysis showed that apart from adjuvant chemotherapy, of the six factors tested, including patient's age, gender, tumor size, location, mode of cryosurgery, number of <sup>125</sup>Iodine seeds implanted and hepatic metastases, only hepatic metastases was an independent prognostic factor ( $P = 0.007$ ).

### Six case studies

Case 1. Male, 80 years old. Ultrasound showed a 3 cm × 3 cm lesion in the pancreatic neck. Biopsy revealed cystadenocarcinoma. The patient underwent percutaneous cryosurgery with <sup>125</sup>Iodine seed implantation under CT

**Figure 1** Survival rates of patients with pancreatic cancer. **A:** Overall results and those in patients with different location and size of the tumor; **B:** Pancreatic cancer with different modes of therapies, and with or without hepatic metastases.

guidance. Three mo after treatment, CT scan showed tumor necrosis, containing <sup>125</sup>I iodine particles. Current ultrasound and CT scan show that the original tumor has decreased to 1.5 cm × 1.1 cm in size (Figure 2). The patient has had recurrence-free survival of 40 mo.

Case 2. Male, 61 years old. CT scan showed low-density areas, 4 cm × 5.5 cm in size in the body of pancreas and 3 intrahepatic lesions ranging from 2 cm to 5 cm in size. Biopsy showed adenocarcinoma. The serum CA19-9 was 512 IU. The patient underwent percutaneous cryosurgery and <sup>125</sup>I iodine seed implantation under CT/ultrasound guidance for the pancreatic lesion and hepatic metastases. Repeat CT scan showed tumor shrinkage and stability of lesions in both the pancreas and liver (Figure 3). Ultrasound-guided biopsy showed no evidence of cancer. CA19-9 levels decreased to < 40 IU. The patient is now alive for 27 mo.

Case 3. Male, 36 years old. Ultrasound and CT revealed a mass in the pancreatic head with dilated common bile duct. Serum CA19-9 was 210 IU. The patient underwent laparotomy which revealed a mass, 5 cm × 5 cm in size in the pancreatic head. Biopsy showed moderately differentiated adenocarcinoma. A palliative cholecystojejunostomy was carried out to relieve the obstructive jaundice, and cryosurgery was performed under direct vision and ultrasound guidance. A repeat CT at three mo after treatment showed shrinkage and necrosis of the pancreatic mass with “honeycomb”-like change (Figure 4). CA19-9 had decreased to 48 IU. The patient survived for 19 mo.

Case 4. Male, 67 years old, with obstructive jaundice was found to have a mass, 5 cm × 3 cm in size in the pancreatic head with dilated common bile duct and gallbladder. Biopsy of the mass showed moderately differentiated mucinous adenocarcinoma. He was treated with percutaneous cryosurgery and <sup>125</sup>I iodine seed implantation. CT at 8 mo after treatment showed shrinkage and necrosis of the pancreatic mass (Figure 5).

Case 5. Female, 59 years old. CT scan showed a mass, 4 cm × 3 cm in size, in the pancreatic tail. Biopsy revealed adenocarcinoma. Percutaneous cryosurgery with <sup>125</sup>I iodine seed implantation was performed (Figure 6). Follow-up

**Table 2** Median survival in different subgroups of patients with pancreatic cancer (breslow test)

after 14 mo of treatment showed stable pancreatic tumor. The patient is currently alive 28 mo after diagnosis.

Case 6. Female, 59 years old. Ultrasound and CT showed a mass of the pancreatic head, 4 cm × 4 cm in size. Biopsy showed poor-differentiated adenocarcinoma. She underwent percutaneous cryosurgery and <sup>125</sup>I iodine seed implantation. Twelve mo later, the tumor in the pancreatic head was stable, however a new lesion has appeared in the pancreatic body. The patient underwent a second course of percutaneous cryosurgery for the lesion in the pancreatic body. Follow-up PET-CT at 3 mo after the treatment, showed a significant decrease in the metabolic activity of the original lesion (Figure 7).

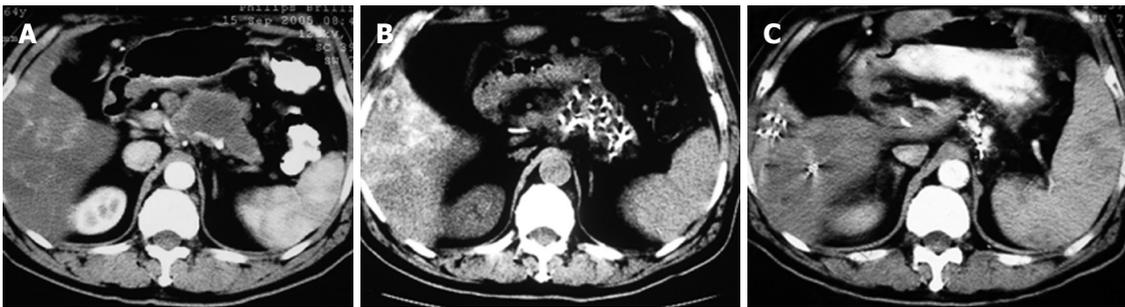

## DISCUSSION

Cryosurgery has provided a novel therapeutic approach to the treatment of benign and malignant tumors, especially unresectable tumors<sup>[13]</sup>. A number of clinical trials have been published using this modality for the treatment of liver cancer, prostate cancer, kidney tumors, and breast cancer, with encouraging results<sup>[14,15]</sup>.

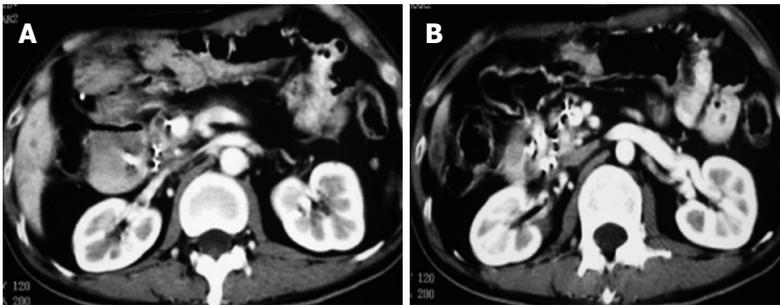

There are few reports on the use of cryosurgery for the treatment of pancreatic cancer. Kovach<sup>[16]</sup> reported 9

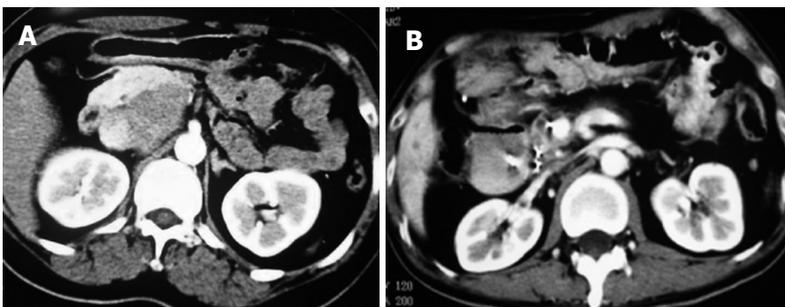

**Figure 2** Pancreatic CT scan in case 1. **A:** Before treatment; **B:** Three months after treatment; **C:** Twelve months after treatment.

**Figure 3** CT scan of case 2. **A:** Before treatment, a mass was seen in pancreatic body and tail; **B:** One month after treatment; **C:** Six months after treatment.

**Figure 4** CT scan in case 3. **A:** One month after treatment; **B:** Three months after treatment.

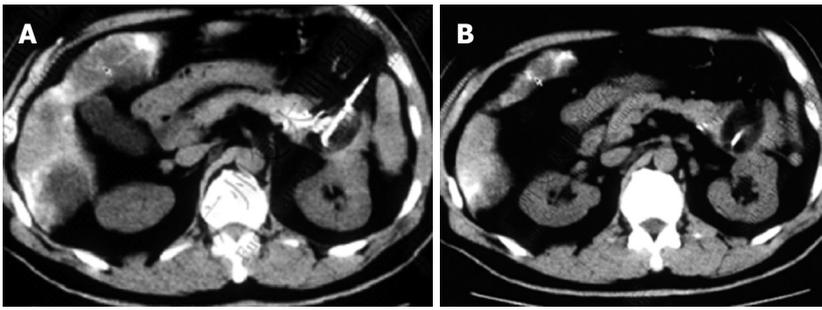

**Figure 5** CT scan in case 4. **A:** Before treatment; **B:** Eight months after treatment.

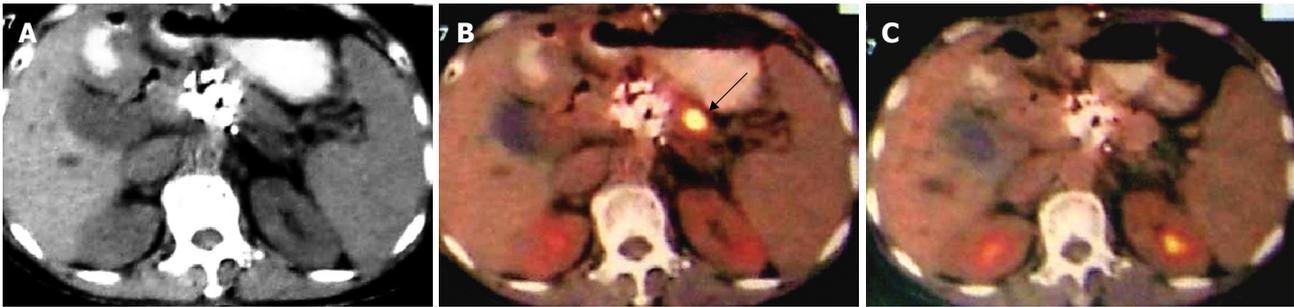

patients with unresectable pancreatic cancer who received a total of 10 sessions of intraoperative cryosurgery under ultrasound guidance. There was no cryosurgery-related mortality and no post-cryosurgery pancreatic fistulae or pancreatitis. Following treatment, patients experienced alleviation of pain and reduction in the use of analgesic agents. All patients were able to take normal diet at the time of discharge from the hospital. Patiutko<sup>[17]</sup> treated

30 patients with locally advanced pancreatic cancer with a combination of cryosurgery and radiation. All patients had effective control of pain, reduction in CA19-9, improvement of performance, and increase in the survival rate. Korpan<sup>[18]</sup> summarized the experience of cryosurgery for pancreatic cancer, and concluded that most patients obtained good results with this therapeutic modality.

The effectiveness of cryosurgery is dependent upon

**Figure 6** CT scan in case 5. **A** and **B** showing cryoprobe and  $^{125}\text{I}$ iodine seeds in different layers during treatment.

**Figure 7** CT and PET-CT in case 6. **A**: CT at 10 mo after the first treatment, showing  $^{125}\text{I}$ iodine seeds; **B**: PET-CT at 12 mo after the first treatment showing new lesion in pancreatic body; **C**: PET-CT at 3 mo after second treatment.

complete cryoablation to all the targeted tissue. Tumor persistence or recurrence at the site of cryoablation is often the result of incomplete destruction. Temperatures lower than  $-40^{\circ}\text{C}$  are believed to be necessary for tumor ablation. Ice-balls targeted lesions are thus necessary for complete destruction of the tumor, because the outer several millimeters of the iceball circumference are at nonlethal temperatures. The 1-cm ice-ball extension beyond the tumor borders is required for adequate ablation<sup>[19,20]</sup>. However, because the pancreatic volume is relatively small, cancer often involves most of the gland, and over-freezing increases the risk of complications, it is often difficult to ensure the “1 cm safe border”. Therefore, we decided to use the combination of cryosurgery with  $^{125}\text{I}$ iodine seed implantation for the treatment of the pancreatic cancer.  $^{125}\text{I}$ iodine with a half-life of 59 d provides  $\gamma$  radiation for a short distance, resulting in the death of the targeted cells. Brachytherapy using  $^{125}\text{I}$ iodine seed implantation has been successfully used for the treatment of prostate cancer and metastatic or recurrent cancer<sup>[21-24]</sup>. As a result, the use of  $^{125}\text{I}$ iodine seed implantation is likely to be complementary to cryosurgery.

In the present study, 49 patients with locally advanced pancreatic cancer were treated with a combination of cryosurgery and  $^{125}\text{I}$ iodine seed implantation. Thirteen patients underwent intraoperative cryosurgery and 36 patients percutaneous cryosurgery under ultrasound and CT guidance. The tumors showed different degrees of necrosis, and the CR, PR and SD were 20.4%, 38.8% and 30.6%, respectively, and only 10.2% demonstrated PD. During the median follow-up of 18 mo (5-40 mo), the median survival was 16.2 mo, of whom 26 patients (53.1%) survived 12 mo or more. The 6-, 12-, 24- and 36-mo survival rates were 94.9%, 63.1%, 22.8% and 9.5%, respectively.

Currently, the conventional therapies for locally

advanced pancreatic cancer are chemotherapy and radiotherapy. Previous reports showed a median survival of 6-10 mo in patients with locally advanced disease treated with 5-FU-based chemoradiation. Patients with metastatic disease had a shorter survival (3-6 mo)<sup>[1]</sup>. A recently described combination regimen that is under investigation consists of gemcitabine, 5-FU, cisplatin, capecitabine and/or radiation<sup>[25-34]</sup>. These combination therapies produced a median progression-free survival ranging from 3-10 mo, and median survival of 7-16 mo, the objective response rate of the tumors was 22%-40%, and 1-year survival was 20%-78% (less than 60% in most reports) (Table 3). The results in our series were similar to those reported previously. However, it is important to note that in this series there were 8 cases who survived for 24 mo or more. The patient with the longest survival is living for 40 mo, with no evidence of recurrence. The findings indicate that combination of cryosurgery and  $^{125}\text{I}$ iodine seed implantation offers the possibility of complete remission.

Using univariate and multivariate analysis, presence of hepatic metastasis was an independent prognostic factor and was associated with poor outcome. It was surprising to note that patients who were underwent to adjuvant regional chemotherapy had a lower survival. This finding could in part be related to patient selection; patients receiving chemotherapy had more severe illness, and one-half had hepatic metastases.

By univariate analysis, it was observed that patients with cancer of pancreatic head had longer median survival compared with patients with cancer of pancreatic body or tail. The reasons may be that cancer of pancreatic head is detected relatively earlier because of the development of obstructive jaundice.

It is believed that tumor size is of critical importance in cryotherapy<sup>[35]</sup>. However, tumor size could not be

Table 3 Recent chemoradiation trials in patients with locally advanced pancreatic cancer

Reporter	No. of patients (n)	Therapy	Median progression-free survival (mo)	Median survival (mo)	Objective response (%)	Survival at 12 mo after treatment (%)
El-Rayer <sup>[25]</sup>	47	Gemcitabine, cisplatin, and infusional fluorouracil				34
Tokuuye <sup>[26]</sup>	53	Small-field radiotherapy in combination with concomitant chemotherapy		10.2		35.2

confirmed as an independent prognostic factor in our analysis. This finding may be related to the possibility that the combination of cryosurgery and <sup>125</sup>Iodine seed implantation may effectively destroy the entire tumor or a greater part of the targeted tissue, even in the presence of a large mass.

A great deal of attention has been paid to the safety of cryosurgery in the treatment of pancreatic cancer. Korpan<sup>[8]</sup> performed an experimental study on dogs who received pancreatic cryosurgery using the disc cryoprobe. None of the animals developed complications and there was no cryosurgery-related mortality. Moreover, there was no post-cryosurgery bleeding, pancreatic fistulae or secondary infection. In our series, no cryosurgery-related mortality was observed. The main adverse effects were abdominal pain, fever and increased serum amylase levels. Some patients developed acute pancreatitis, but none had a poor outcome. In addition, <sup>125</sup>Iodine seed implantation can be performed at the same time, and is not accompanied with the adverse effects observed with chemo-radiotherapy. As a whole, combination therapy of cryosurgery and <sup>125</sup>Iodine seed implantation is a less invasive procedure.

Korpan<sup>[8,18]</sup> pointed out that there were almost no known contraindications to the use of cryosurgery for pancreatic cancer. For most patients with pancreatic cancer, cryosurgery can substitute conventional surgery. These observations need to be confirmed by more studies. According to our experience, cryosurgery has several advantages in the treatment of unresectable pancreatic cancer: (1) The conventional management of unresectable pancreatic cancer involves a bypass operation without removal of the tumor. Cryosurgery can make up this shortcoming of conventional therapy, by converting the surgery from “palliative” to “radical”. (2) Cryosurgery is less invasive, and has lower rate of complications compared with conventional resection. (3) Unresectable tumors can be treated with percutaneous cryosurgery under ultrasound or CT guidance, with similar efficacy as intraoperative cryosurgery and is much less invasive to the patient. (4) During percutaneous cryosurgery, other modalities, such as <sup>125</sup>Iodine seed implantation, can be used simultaneously. (5) Metastatic tumors can be treated simultaneously, using the combination technique. (6)

Immune enhancement or activation after cryosurgery may occur probably due to quantitative and qualitative changes in the surface antigen (component) of tumor cells<sup>[36]</sup>. That is called “cryoimmunity”<sup>[37]</sup>. (7) The cryoablated cancerous tissue has increased sensitivity to chemo/radiotherapy<sup>[38,39]</sup>.

In conclusion, although the present data is preliminary, it indicates that combination of cryosurgery and <sup>125</sup>Iodine seed implantation may play an important role in the treatment of locally advanced pancreatic cancer. These findings warrant further refinement of the technique as well as initiation of controlled clinical studies to better define the true value of combination treatment in pancreatic cancer.

## COMMENTS

### Background

Pancreatic cancer is the fifth leading cause of cancer-related death for both men and women. Patient survival depends on the extent of the disease and patient's performance status at diagnosis. Patients who undergo surgical resection for localized non-metastatic pancreatic cancer have an approximately 20% longer survival rate, with a median survival of 12-20 mo. However, patients with locally advanced disease have a median survival of only 6-10 mo. The current approach of using chemoradiation, including gemcitabine, has failed to improve the outcome of this disease. Therefore, it is important to develop newer treatment modalities which are able to improve tumor control without the increasing toxicity in patients with locally advanced pancreatic cancer.

### Research frontiers

Recently, cryosurgery has provided encouraging results in the treatment of prostate cancer and liver cancer. However, there is limited clinical experience using cryosurgery for the treatment of pancreatic cancer. Moreover, the use of <sup>125</sup>Iodine seed implantation has not been reported in the treatment of pancreatic cancer.

### Innovations and breakthroughs

To our knowledge, this is the first report on the use of combined cryosurgery and <sup>125</sup>Iodine seed implantation in the treatment of locally advanced pancreatic cancer. Both cryosurgery and <sup>125</sup>Iodine seed implantation are local ablative techniques, with different mechanisms of action, and it is proposed that their combined use may have a complementary effect.

### Applications

Cryosurgery and <sup>125</sup>Iodine seed implantation can be performed during surgery or percutaneously. Both techniques are mini-invasive modalities and can be adapted to treat unresectable tumor. In more than 80% of patients with pancreatic cancer,

surgical resection is not feasible at the time of diagnosis. Of the patients who undergo an operation with curative intent, only 30%-50% have successful removal of the tumor. Therefore, cryosurgery and <sup>125</sup>Iodine seed implantation are of special significance in the management of unresectable pancreatic cancer.

### Terminology

Pancreatic cancer is derived mainly from ductal tissue with adenocarcinoma being the most common malignancy. There are very few pancreatic cancers which are classified as adenosquamous, giant cell cancers, and mucinous cystadenocarcinomas. Microscopically, these tumors may vary from well-differentiated to undifferentiated tumors. Seventy to 80 percent of respectable pancreatic cancers have already spread into lymph nodes at diagnosis. Ultrasonography and CT are the principal means of diagnosis of pancreatic cancer.

### Peer review

This is an interesting and well written paper of much practical value. The presentation is adequate and easy to understand. The results of this paper, despite the limited case number and the short follow-up, suggest that benefit exists in the treatment of locally advanced pancreatic cancer with combined cryosurgery and <sup>125</sup>Iodine seed implantation.

### Abstract

**AIM:** To investigate the changes of histology and expression of MMP-2 and nm23-H1 in primary and metastatic gastric cancer.

**METHODS:** One hundred and seventy-seven gastric cancer patients with lymph node and/or distal metastasis between 1997 and 2001 were reviewed. Differences in histology of the primary and metastatic gastric cancer were assessed. MMP-2 and nm23-H1 immunoreactivity was compared in 44 patients with tumor infiltration to the serosa layer.

**RESULTS:** Poorly and moderately differentiated metastatic gastric cancer was found in 88.7% (157/177) and primary gastric cancer in 75.7% (134/177) of the patients. The histological type of metastatic gastric cancer that was not completely in accordance with the preponderant histology of primary gastric cancer was observed in 25 patients (14.1%). MMP-2 immunoreactivity in metastatic gastric cancer was significantly stronger than that in primary gastric cancer, while nm23-H1 immunoreactivity showed no difference in primary and metastatic gastric cancer.

**CONCLUSION:** Metastatic gastric cancer presents more aggressive histological morphology and higher MMP-2 immunoreactivity than primary gastric cancer. This heterogeneity may elicit a possible mechanism of gastric cancer metastasis.

**Key words:** Heterogeneity; Gastric cancer; Nm23-H1; MMP-2; Histological change

**Peer reviewer:** Shingo Tsuji, Professor, Department of Internal Medicine and Therapeutics, Osaka University Graduate School of Medicine (A8), 2-2 Yamadaoka, Suita, Osaka 565-0871, Japan

### INTRODUCTION

Gastric cancer, one of the most common malignant diseases in the world, has been shown to frequently metastasize. Certain studies have reported the possible mechanisms underlying its metastasis<sup>[1-3]</sup>. However, whether there is a histological difference between primary and metastatic gastric cancer is unclear and has been rarely reported.

Matrix metalloproteinases (MMPs) are defined as a family of enzymes which degrade extracellular membrane proteins, thus playing a significant role in tumor invasion and metastasis<sup>[4]</sup>. MMP-2 is one of the most extensively studied MMPs in the process of cancer. It was reported that elevated MMP-2 level is related to increased tumor metastasis and stage in the lung, breast, stomach and colon<sup>[5-8]</sup>. However, differences in MMP-2 expression between primary and metastatic gastric cancer have been rarely assessed.

The nm23 gene is a putative metastasis suppressor gene originally identified in metastatic murine melanoma cells<sup>[9]</sup>. Reduction in nm23 expression is related with a high incidence of lymph node metastasis or poor prognosis of gastric cancer<sup>[10,11]</sup>. However, there is no inverse relationship between nm23 expression and metastatic potential of gastric cancer<sup>[12]</sup>. Their relationship in gastric cancer remains controversial.

Our study was to investigate the differences in histology and expression of MMP-2 and nm23-H1 between primary and metastatic gastric cancer, and to elucidate the possible mechanism of tumor heterogeneity underlying gastric cancer metastasis.

### MATERIALS AND METHODS

#### Patients and tissue specimens

Complete data and tissue specimens were obtained from

230 gastric cancer patients, who underwent resection of gastric cancer at Sir Run Run Shaw Hospital, Zhejiang University College of Medicine between June 1997 and January 2001. Among them, 177 patients including 124 males and 53 females, ranging in age from 20 years to 79 years with a mean age of 55.5 years, had pathologically confirmed lymph node and/or distal metastasis and were enrolled to assess the differences in histology between primary and metastatic gastric cancer. Their clinicopathological features are shown in Table 1. Disease stage was classified based on the 5th edition of the International Union against Cancer and the American Joint Committee for Cancer Staging.

Forty-four patients, who had pathologically confirmed tumor infiltration to the serosal layer (24 pts, T<sub>3</sub>N<sub>1-3</sub>M<sub>0</sub>, 20 pts, T<sub>3</sub>N<sub>x</sub>M<sub>1</sub>), were recruited to evaluate the difference in MMP-2 and nm23-H1 immunoreactivity between primary and metastatic gastric cancer by immunohistochemistry.

Slides of tissue from primary and metastatic gastric cancer were observed by two pathologists. Following the criteria of World Health Organization (WHO), papillary adenocarcinoma was classified as well differentiated type, signet cell carcinoma and mucous adenocarcinoma as poorly differentiated type, tubular adenocarcinoma as well or moderately or poorly differentiated type.

We set the largest proportion of histological type of primary gastric cancer as the preponderant histological type. Thereby, percentage of the preponderant histological type of metastatic gastric cancer was as follows: -: lower than 5%; +: 5%-25%; ++: 25%-50%; +++: 50%-75%; ++++: higher than 75%. Comparison of changes in histology between primary and metastatic gastric cancer was made based on the percentages of their preponderant histological type.

### Immunohistochemistry

Immunohistochemical study was performed using the following antibodies: anti-nm23-H1 protein (GE-213, monoclonal, 1:100; Manxin, Fuzhou, China) and anti-MMP-2 (CA-4001, monoclonal, 1:50; Manxin, Fuzhou, China). Four- $\mu$ m thick sections of 10% formalin-fixed, paraffin-embedded gastric cancer tissue were cut, mounted on glass slides coated with 3-aminopropyltriethoxysilane, and air-dried overnight at 60°C. The sections were deparaffinized in xylene and rehydrated in ethanol. Endogenous peroxidase was blocked with methanol containing 3% hydrogen peroxidase for 25 min. For staining with anti-MMP-2, sections were pretreated with citrate buffer (0.01 mol/L, pH 6.0) and heated at 100°C in a microwave oven for 20 min. For staining with anti-nm23-H1, sections were pretreated with trypsin (0.5%, pH 7.4) for 20 min at room temperature. The sections were incubated with primary antibodies at 4°C overnight, stained with a streptavidin-biotin-peroxidase kit (Manxin, Fuzhou, China), and reacted in a solution containing 3, 3'-diaminobenzidine and peroxytrichloride substrate, and counterstained with hematoxylin. The provided sections known to react positively with nm23-H1 or MMP-2 (Manxin, Fuzhou, China) were used as a positive control. As a negative control, the primary antibody was deleted.

**Table 1** Clinicopathologic data obtained from 177 gastric cancer patients

	Patients	
	n	%
Tumor size (cm) (mean $\pm$ SD)	6.0 $\pm$ 2.9	
Location		
Upper or whole body	40	22.6
Lower or middle body	137	77.4
Gross type		
Localized	39	22.0
Infiltrative	138	78.0
Depth of invasion		
T1	25	14.1
T2	86	48.6
T3	44	24.9
T4	22	12.4
Retrieved lymph nodes (mean $\pm$ SD)	22.4 $\pm$ 3.5	
Stage		
I	6	3.4
II	29	16.4
III	88	49.7
IV	54	30.5

### Evaluation

The immunoreactivity of each antibody was evaluated. MMP-2 and nm23-H1 immunoreactivity was graded as -: without or with immunoreactivity in less than 5% tumor cells; +: immunoreactivity in 5%-25% tumor cells; ++: immunoreactivity in 25%-50% tumor cells; +++: immunoreactivity in over 50% of tumor cells.

### Statistical analysis

All statistical analyses were conducted using the statistical program SPSS 10.0 for windows (SPSS, Chicago, IL, USA). Differences in histological morphology and expression of MMP-2 and nm23-H1 between each group were analyzed by chi-square test or by Fisher's exact test.  $P < 0.05$  was considered statistically significant.

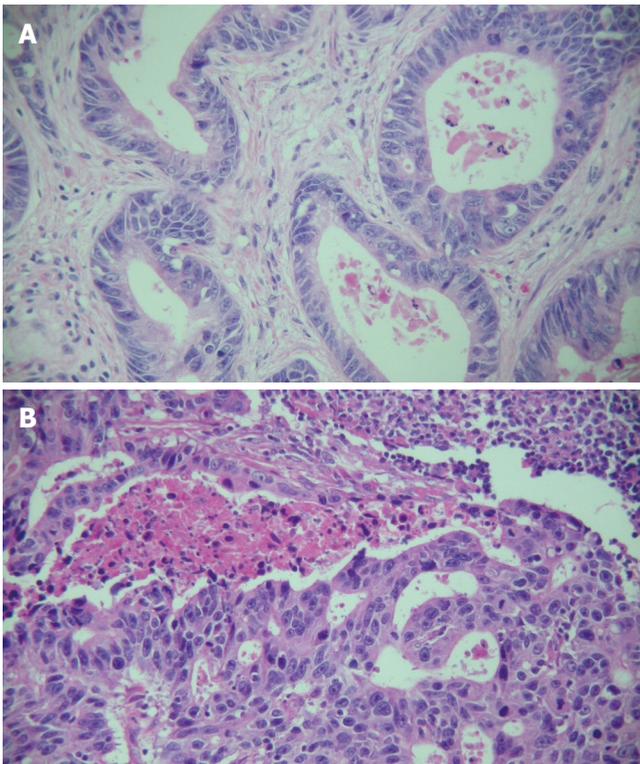

## RESULTS

### Histological changes

We observed different histological changes in primary and metastatic gastric cancer patients (Figure 1). Poorly and moderately differentiated metastatic gastric cancer was found in 88.7% (157/177) of the patients while primary gastric cancer in 75.7% (134/177) of the patients. The preponderant histological types of primary gastric cancer, graded as +++ and ++++, were more than those of metastatic lymph nodes (170 *vs* 138,  $P < 0.01$ ). Moreover, the preponderant histological type of the metastatic lymph nodes in 14.1% patients (25/177) was not completely in accordance with that of primary gastric cancer (Table 2).

### MMP-2 immunoreactivity

MMP-2 immunoreactivity was significantly stronger in metastatic gastric cancer than in primary gastric cancer. For the 20 patients with distal metastasis, a different MMP-2 immunoreactivity was observed in primary and metastatic gastric cancer (Table 3). MMP-2 immunoreactivity was stronger in metastatic gastric cancer than in primary gastric

**Figure 1** Histological changes in primary and metastatic gastric cancer (case 15) ( $\times 200$ ). **A:** Histological change in primary gastric cancer showing a well differentiated adenocarcinoma of the stomach with a glandular pattern; **B:** Histological changes in metastatic gastric cancer showing a moderately differentiated adenocarcinoma with a cribriform pattern.

cancer. However, the immunoreactivity was similar in metastatic lymph nodes and distal metastasis (Figure 2).

**nm23-H1 immunoreactivity**

There was no significant difference in nm23-H1 immunoreactivity between primary and metastatic gastric cancer. The immunoreactivity was quite similar in primary and metastatic lymph nodes and distal metastasis (Table 4).

**DISCUSSION**

Studies on intratumoral and intertumoral heterogeneity have provided valuable insights into the pathogenesis and progression of different tumors<sup>[13-15]</sup>. Although the concept of intratumoral heterogeneity of tumors has been generally accepted, studies on it in gastric cancer are scant. Previous reports focused mainly on comparison of molecular genetic alterations in each individual. However, this study investigated the tumor heterogeneity including histological morphology changes in primary and metastatic gastric cancer.

We observed different histological changes in primary and metastatic gastric cancer. Metastatic gastric cancer showed poorer differentiation. Meanwhile, the preponderant histological type of primary and metastatic gastric cancer was not completely identical. In the present study, the preponderant histological type of primary and metastatic gastric cancer site was different in 14.1% patients. These findings may imply that not all the histological types

of primary gastric cancer have potential to metastasize, poorly differentiated cancer cells may play a significant role in lymph node metastasis, which may possibly explain why a small proportion of poorly differentiated cancer cells in primary gastric cancer may be preponderant in metastatic gastric cancer.

It is widely accepted that tumor may synchronously contain multiple histological types, reflecting different tumor differentiation and biological behavior. Most tumors may contain multiple cell clones with a diverse metastatic potential. Cell clones with a high metastatic potential are apt to metastasize to lymph nodes or distal organs<sup>[16,17]</sup>. This dynamic heterogeneity may give a possible explanation for the different changes in histology between primary and metastatic gastric cancer. Although the preponderant histological change in primary gastric cancer is generally considered a prognostic predictor, the other histological changes in primary gastric cancer, especially in poorly differentiated subclones, may be as important as the preponderant histological change for the prognosis of primary gastric cancer. However, few studies have been addressed this issue, further investigations are warranted.

Because of its ability to degrade the basement membrane, MMP-2 has been postulated as a potential marker of tumor progression and prognosis in different malignancies such as ovarian cancer, gastric cancer and lung carcinoma<sup>[8,18]</sup>. Schwartz *et al*<sup>[19]</sup> reported that MMP-2 is expressed in SK-GT1, SK-GT5 and SK-GT6 but not in

**Figure 2** Immunohistochemistry of MMP-2 in gastric cancer (case 9) ( $\times 200$ ). **A:** Primary gastric cancer showing grade (-) immunoreactivity in MMP-2; **B:** Metastatic gastric cancer showing grade (+++) immunoreactivity; **C:** Distal metastatic gastric cancer showing grade (+++) immunoreactivity.

SK-GT2 and SK-GT4 gastric cancer cell lines. Ji *et al.*<sup>[20]</sup> reported that MMP-2 expression is significantly higher in advanced than in early gastric cancer patients<sup>[20]</sup>. These findings indicate that gastric cancer cells with a greater malignant and metastatic potential may secrete much more MMP-2 protein. Moreover, it has been shown that down-regulation of MMP or MMP-2 may inhibit tumor growth and metastasis, indicating that MMP-2 is correlated with gastric cancer invasion and metastasis<sup>[21,22]</sup>. In this study, MMP-2 immunoreactivity was significantly higher in metastatic than in primary gastric cancer. This is in agreement with previous reports and suggests that when cancer tends to become invasive, elevated MMP-2 may play a pivotal role in its metastasis.

It was reported that Nm23 is a metastasis suppressor gene<sup>[23]</sup>. However, its role in gastric cancer metastasis is controversial<sup>[24,25]</sup>. Nakayama *et al.*<sup>[26]</sup> demonstrated that reduced expression of nm23 is associated with gastric can-

cer metastasis. Similar results have been reported by Hsu *et al.*<sup>[27]</sup>. However, Wang *et al.*<sup>[28]</sup> found that patients with a high nm23 expression are easy to develop distal metastasis and have a lower nm23 expression, displaying that nm23 may play a trivial role in inhibiting tumor metastasis. Yeung *et al.*<sup>[29]</sup> reported that there is no difference in nm23 expression between primary and metastatic gastric cancer. Similar results were observed in the present study, suggesting that nm23 expression is not associated with gastric cancer metastasis. Further study is needed to find the definitive role of nm23 in cancer metastasis.

In conclusion, metastatic gastric cancer is more aggressive and has a higher expression in tumor genes than primary gastric cancer. This heterogeneity may elicit one of the possible mechanisms underlying gastric cancer metastasis.

## COMMENTS

### Background

Gastric cancer metastasis occurs frequently and its possible mechanism has not been well addressed. Intratumoral and intertumoral heterogeneity plays a significant role in tumor progression. However, studies on gastric cancer are rarely reported.

### Research frontiers

The aim of this study was to evaluate the morphology and tumor metastatic gene heterogeneity in gastric cancer.

### Innovations and breakthroughs

This study showed the changes in morphology and expression of MMP-2 of primary and metastatic gastric cancer.

### Applications

The heterogeneity in gastric cancer may provide a clue to the possible mechanism of cancer invasion and metastasis.

### Peer review

This is a nice study comparing primary and metastatic gastric cancer. The expression of MMP2, one of the known metalloproteases relating to tumor invasion and metastases, was stronger in metastatic than in primary gastric cancer. However, NM23-H1 expression did not change in primary and metastatic gastric cancer. Primary and metastatic gastric cancer were found to have different histological types.

### Abstract

**AIM:** To investigate the *in vitro* effect of entecavir (ETV) on the function of dendritic cells (DCs) derived from chronic hepatitis B (CHB) patients.

**METHODS:** Mononuclear cells were isolated from peripheral blood of patients with CHB. DCs were incubated with RPMI-1640 medium supplemented with fetal bovine serum, IL-4, granulocyte-macrophage colony-stimulating factor (GM-CSF). DCs were treated with or without ETV on the fourth day. Cell surface molecules, including CD1a, CD80, CD83 and HLA-DR, were assessed by flow cytometry. Concentrations of IL-6 and IL-12 in the supernatant were assayed by enzyme-linked immunosorbent assay (ELISA). The ability of the generated DCs to stimulate lymphocyte proliferation was observed.

**RESULTS:** Compared with CHB control group, the expression levels of CD1a ( $29.07 \pm 3.20$  vs  $26.85 \pm 2.80$ ), CD83 ( $25.66 \pm 3.19$  vs  $23.21 \pm 3.10$ ), CD80 ( $28.00 \pm 2.76$  vs  $25.75 \pm 2.51$ ) and HLA-DR ( $41.96 \pm 3.81$  vs  $32.20 \pm 3.04$ ) in ETV-treated group were higher ( $P < 0.05$ ). ETV-treated group secreted significantly more IL-12 ( $157.60 \pm 26.85$  pg/mL vs  $132.60 \pm 22.00$  pg/mL ( $P < 0.05$ ) and had a lower level of IL-6 in the culture supernatant ( $83.05 \pm 13.88$  pg/mL vs  $93.60 \pm 13.61$  pg/mL,  $P < 0.05$ ) than CHB control group. The ability of DCs to stimulate the proliferation of allogeneic lymphocytes was increased in ETV-treated group compared with CHB control group ( $1.53 \pm 0.09$  vs  $1.42 \pm 0.08$ ,  $P < 0.05$ ).

### INTRODUCTION

Hepatitis B virus (HBV) infection is a global public health problem, and over 400 million people suffer from HBV infection worldwide currently<sup>[1,2]</sup>. Chronic HBV infection results from impaired antiviral immune response of the host that cannot produce sufficient competent specific cytotoxic T lymphocytes (CTL) to eliminate the invading virus<sup>[3,4]</sup>. However, its mechanism remains unclear. Dysfunction of dendritic cells (DCs) is regarded as one of the factors for chronic hepatitis B (CHB) infection<sup>[5]</sup>. DCs are crucial antigen-presenting cells responsible for initiating antiviral immune responses<sup>[6,7]</sup>. Thus, one of the methods to treat CHB infection is to enhance the antigen presentation function of DCs in CHB patients, yet the precise mechanism needs to be further understood.

Entecavir (ETV), a nucleoside analogue, has been used in the clinical treatment of CHB infection because it can specifically inhibit the hepadnaviral DNA polymerase by competing with the corresponding dNTP for incorporation in ascent DNA and by acting on it as a chain terminator after incorporation<sup>[8]</sup>. It appears to be transported into the cells *via* pyrimidine nucleoside transporters and is activated by several sets of cellular enzymes<sup>[9]</sup>. Recent reports showed that lamivudine, a nucleoside analogue, can up-regulate the expression of major histocompatibility complex (MHC) class II<sup>[10]</sup>. We hypothesize that ETV up-regulates DC function by increasing MHC and costimulatory molecules to enhance T lymphocyte immune response, thus strengthening the antiviral immune response. Therefore, we isolated DCs

from peripheral blood mononuclear cells of CHB patients, pulsed them with designated concentrations of ETV *in vitro* and observed its effects on DC phenotype and function. The results of this study provide new evidence to support the application of medicine and DC-based immunotherapy for CHB patients.

## MATERIALS AND METHODS

### Patients and materials

Twenty-five CHB patients with positivity HBsAg, HBeAg, HBcAb and serum HBV-DNA were enrolled in this study. All of them were negative for HCV and HIV and had no histories of other liver diseases. Ten healthy volunteers from postgraduates of Zhengzhou University were recruited into this study as controls (Table 1).

rhGM-CSF, rhIL-4, mouse anti-human HLA-DR-PE, CD80-FITC, CD1 $\alpha$ -FITC, CD83-PE were purchased from BioLegend, RPMI-1640 from GIBCO (USA), fetal calf serum (FCS) from Hangzhou Sijiqing Biological Engineering. Ficoll-Hypaque density gradient separate solution was purchased from Tianjin Jinmai Gene Biotechnology Company. rhIL-6 and IL-12 enzyme-linked immunosorbent assay (ELISA) kits (Peprotech) were purchased from Shanghai Shenxiong Technology Company. ETV was purchased from Bristol-Myers Squibb Company in Shanghai.

### Preparation of DCs

Peripheral blood was collected from CHB patients and healthy volunteers and heparinized. Peripheral blood mononuclear cells (PBMC) were isolated by centrifuging on a column of Ficoll-Conray *in vitro* as previously described<sup>[11-13]</sup>. Briefly, PBMC were suspended in RPMI 1640 medium supplemented 10% fetal bovine serum (FBS) and seeded in 24-well plastic plates for 2 h. The non-adherent cells were gently removed and the adherent cells were cultured in RPMI-1640 medium supplemented with 10% FBS, 10 ng/mL rhGM-CSF, 5 ng/mL rhIL-4 in a humidified atmosphere containing 50 mL/L CO<sub>2</sub> at 37°C. On the fifth day DCs from CHB patients were treated with or without ETV (0.05  $\mu$ g/mL) and designated as ETV treatment group and CHB control group, respectively. DCs from healthy volunteers were designated as healthy control group not treated with ETV. Half of the medium was replaced with a fresh medium every other day. DCs were harvested on the eighth day.

### Morphological analysis and flow cytometry

DCs were observed under an inverted microscope. Surface makers of DCs, such as CD1a, CD80, CD83, HLA-DR, were analyzed by flow cytometry (FCM) on the eighth day using conjugated monoclonal mouse-anti-human antibodies (FITC-anti-CD1a, FITC-anti-CD80, PE-anti-CD83, PE-anti-HLA DR) as previously described<sup>[14]</sup>.

### Allogeneic mixed leukocyte reaction (All MLR)

Mononuclear cells were isolated from peripheral blood of healthy subjects. After incubated for 2 h, the non-adherent cells were collected as lymphocytes. Mitomycin C (50  $\mu$ g/mL)

was added to the culture. DCs were harvested from each group after 30 min and then seeded onto 96-well culture plates ( $1 \times 10^4$ /well) as stimulator cells together with lymphocytes ( $1 \times 10^5$ /well) as responder cells. Triple wells were set for each group. After cultured for 72 h, OD570 was assayed by MTT and stimulator index (SI) was calculated following the formula of SI = OD experiment/(OD responder cells + OD stimulator cells).

### Measurement of IL-12 and IL-6 levels in culture supernatant of DCs

Concentrations of IL-12, IL-6 in the supernatant of DCs on the eighth day were detected with ELISA kits according to the manufacturer's instructions. Triple wells were set for each sample.

### Statistical analysis

Data were analyzed with SPSS10.0 statistical software. The significant difference between groups was determined by one-way ANOVA.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Morphology analysis

After cultured for 24 h, swarming of cells was observed under a microscope. Two days later the size of DCs became larger and five days later much ecphyma was found on the surface of DCs, many nebulous substances floating on the culture liquid were demonstrated on the seventh day. However, the ETV-treated group had a distinct modal difference compared with the CHB control group (Figure 1).

### Phenotype of DCs

Markers of DCs were examined by flow cytometry on the eighth day. Compared with healthy control group, The expression levels of CD1a, CD80, CD83 and HLA-DR on DCs were lower in the CHB control group than in the healthy control group ( $26.85 \pm 2.80$  vs  $39.41 \pm 3.12$ ,  $P < 0.001$ ;  $25.75 \pm 2.51$  vs  $38.52 \pm 3.18$ ,  $P < 0.001$ ;  $23.21 \pm 3.10$  vs  $40.76 \pm 3.15$ ,  $P < 0.001$ ; and  $32.20 \pm 3.04$  vs  $59.62 \pm 4.73$ ,  $P < 0.001$ ), and were higher in the ETV-treated group than in the CHB control group ( $29.07 \pm 3.20$  vs  $26.85 \pm 2.80$ ,  $P = 0.043$ ;  $28.00 \pm 2.76$  vs  $25.75 \pm 2.51$ ,  $P = 0.046$ ;  $25.66 \pm 3.19$  vs  $23.21 \pm 3.10$ ,  $P = 0.027$ ; and  $41.96 \pm 3.81$  vs  $32.20 \pm 3.04$ ,  $P < 0.001$ ) (Table 2).

### Concentration of IL-12 and IL-6 in supernatant of DCs

The concentration of IL-12 was reduced more significantly in the CHB control group than in the healthy control group ( $132.60 \pm 22.00$  pg/mL vs  $301.90 \pm 39.54$  pg/mL,  $P < 0.001$ ), while the concentration of IL-6 was increased more significantly in the CHB control group than in the healthy control group ( $93.60 \pm 13.61$  pg/mL vs  $44.10 \pm 9.69$  pg/mL,  $P < 0.001$ ). DCs treated with ETV secreted more IL-12 than DCs in the CHB control group ( $157.60 \pm 26.85$  pg/mL vs  $132.60 \pm 22.00$  pg/mL,  $P = 0.041$ ) and had a lower level of IL-6 in the culture supernatant ( $83.05 \pm 13.88$  pg/mL vs  $93.60 \pm 13.61$  pg/mL,  $P = 0.042$ , Figure 2).

Table 1 Clinical and serological data from patients studied (mean  $\pm$  SD)

Group	n	Age (yr)	HBsAg	HBeAg	Anti-HBc	HBV-DNA (IU/mL)	ALT <sup>1</sup> (nkat/L)
Patients	25	25.7 (18-42)	+	+	+	> 2.0E + 04	2645.09 $\pm$ 1799.87
Volunteers	10	26.2 (24-32)	-	-	-	NT	311.28 $\pm$ 83.40

NT: not tested; <sup>1</sup>Normal range < 666.8 nkat/L.

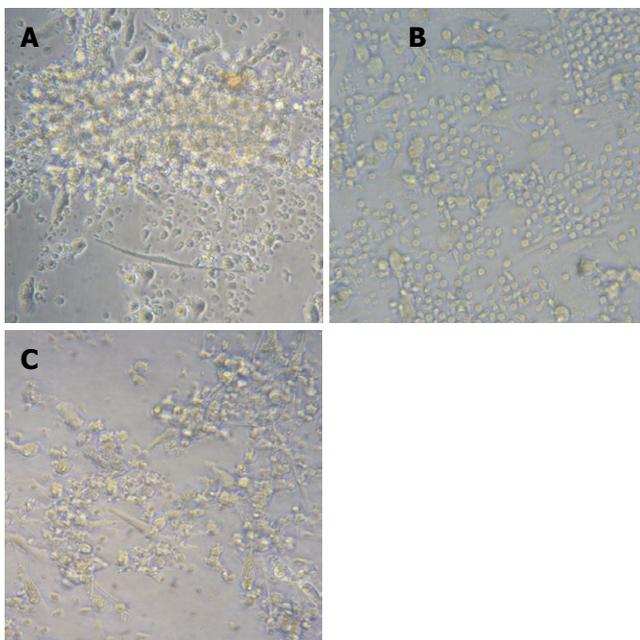

Figure 1 Morphology of DCs on d 8 ( $\times$  400) in healthy control group (A), CHB control group (B), and ETV treatment group (C).

### Priming lymphocytes *in vitro* pulsed with ETV-treated DCs

The stimulator index of DCs in the ETV-treatment group was markedly higher than that in the CHB control group ( $1.53 \pm 0.09$  vs  $1.42 \pm 0.08$ ,  $P = 0.032$ ), and lower than that in the healthy control group ( $1.53 \pm 0.09$  vs  $1.78 \pm 0.09$ ,  $P = 0.040$ ).

## DISCUSSION

Weak and oligospecific antiviral B and T cell responses are responsible for the insufficient control of chronic HBV infection<sup>[15]</sup>. However, the mechanism underlying this immunological hyporesponsiveness remains unknown<sup>[16,17]</sup>. Immune tolerance may play an important role<sup>[18,19]</sup>. It was reported that the immune system and cytokine play a key role in HBV clearance<sup>[11]</sup>. Patients infected with HBV

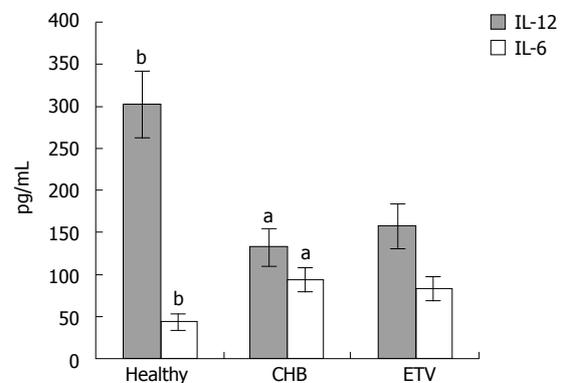

Figure 2 Secretion of IL-12 and IL-6 from different groups of patients (<sup>a</sup> $P < 0.05$  vs ETV; <sup>b</sup> $P < 0.01$  vs CHB control).

start up a series of non-specific immunology responses including activation of natural killer cells and interferon. However, the complete clearance of HBV must rely on the activation of HBV-specific T lymphocytes<sup>[20]</sup>. If HBV cannot be completely eliminated, the number of HBV-antigen specific CD8+ T lymphocytes would decrease, resulting in immune tolerance to the invading virus and CHB<sup>[21]</sup>.

DCs are antigen-presenting cells that link innate immunity with adaptive immunity and are essentially involved both in the initiation of primary immune responses and in the establishment of peripheral tolerance<sup>[22]</sup>. The mechanism of CHB is related to the impairment of immune capacity resulting from functional deficiency of DCs in quality and quantity<sup>[23]</sup>. HBV might cause phenotypic and functional alterations by directly affecting the DC precursors in blood or bone marrow<sup>[14]</sup>. So one of the important pathways is to selectively modify DCs and activate HBV specific immune response during CHB treatment<sup>[24]</sup>. Beckebaum *et al.*<sup>[10]</sup> argued that lamivudine can increase the expression of HLA-DR on DCs while processing HBV. Based on this fact, we cultured DCs for four days and pulsed them *in vitro* with entecavir, a new nucleoside analogue, at certain concentrations, and then observed the effect of ETV on DC phenotype and function.

The key mechanism underlying DC-mediated T cell stimulation after antigen uptake and process by APC includes engagement of the antigen-specific T cell receptor by peptide-loaded MHC molecules, interaction of costimulatory molecules with their receptors on T cells and secretion of cytokines<sup>[25]</sup>. CD1a is a specific marker of human DCs, CD83 is the mature sign of human DC, and HLA-DR, one of the MHC II molecules, mostly takes part in the antigen presentation, while CD80, one of the co-stimulating molecules, promotes T cell activation by combining with the correspondent T cell receptor<sup>[26,27]</sup>. A significantly reduced expression of CD1a, CD80, CD83 and HLA-DR on DCs from CHB patients was detected in the present study. Flow cytometry showed that the expression of cellular surface markers such as CD1a, CD80, CD83 and HLA-DR on DCs increased more significantly in the ETV treatment group than in the CHB control group. The enhanced stimulatory capacity of ETV-treated DCs in MLR indicates that other mechanisms may be involved in the activation and proliferation of T cells apart from the mechanism underlying the traditional double-signs.

DCs dictate Th0 cells to differentiate towards Th1 and Th2 cells accompanying secretion of IL-6, IL-12 and IFN- $\gamma$ <sup>[28]</sup>. IL-12 secreted by mature DCs drives Th0 cells to develop into Th1 cells, promotes secretion of IL-2, IFN- $\gamma$  and participates in the cellular immune response. IL-6 secreted by immature DCs is related to Th2 cell development, restrains the cellular immune response and induces immune tolerance<sup>[29]</sup>. Since IL-12 plays a critical role in the Th1 cell differentiation, decreased IL-12 levels in CHB patients can be the factor that directly attributes to the weak T-cell stimulatory capacity of DCs from CHB patients in MLR<sup>[30]</sup>. During our experiments, secretion of IL-12 increased more significantly in the ETV treatment group than in the CHB control group. The level of IL-6 was lower in the ETV treatment group than in the control group. Thus, we may conclude that DCs pulsed by ETV at designated concentrations can promote Th1 cell proliferation and enhance cellular immune response.

In conclusion, ETV could increase the expression of CD1a, CD80, CD83 and HLA-DR and the secretion of IL-12, reduce the secretion of L-6 and enhance the proliferation of T cells in the present study, indicating that ETV can change the biological activities of DCs derived from CHB patients, which can be utilized as a DC-based immunotherapy for CHB infection. Finally, our data, similar to those of previous reports<sup>[31]</sup>, have a limitation in interpretation for immune pathology of chronic hepatitis B virus infection since the *in vitro* generated DCs can be found at different developing stages with variable functional aspects, although this study model has been employed in similar studies<sup>[31]</sup>.

## COMMENTS

### Background

Hepatitis B virus (HBV) infection is a global public health problem. Immune response of the host plays an important role in the pathogenesis of chronic HBV infection.

### Research frontiers

One of the important factors responsive for the immune tolerance in chronic

hepatitis B (CHB) is the impaired function of dendritic cells (DCs) which cannot efficiently present HBV antigens to the host immune system.

### Innovations and breakthroughs

DC-based therapeutic vaccine has recently been considered a potential approach to the treatment of CHB. Entecavir, a nucleoside analogue, specifically inhibits the hepadnaviral DNA polymerase and up-regulates the host immune system.

### Applications

Results of the present study support the application of entecavir and DC-based immunotherapy for CHB.

### Peer review

This is a good paper, describing that entecavir combined with DCs may be an effective therapeutic approach to eradication of chronic HBV infection.

Pseudocirrhosis in a pancreatic cancer patient with liver metastases: A case report of complete resolution of pseudocirrhosis with an early recognition and management. *World J Gastroenterol* 2008; 14(10): 1622-1624 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1622.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1622>

### Abstract

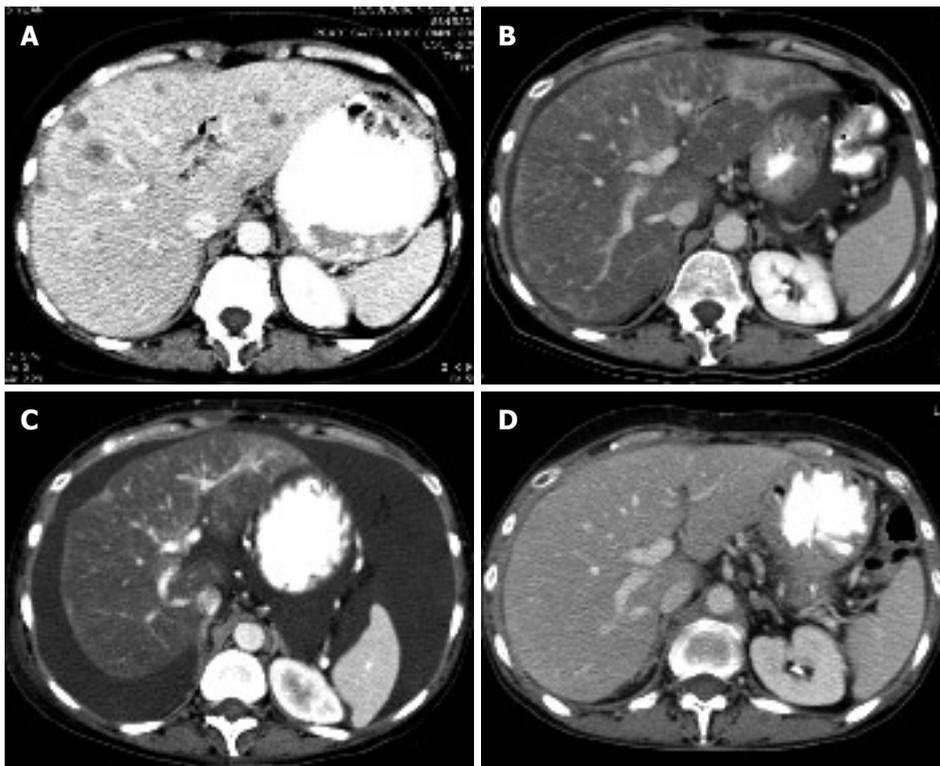

We report a case of pseudocirrhosis arising in the setting of regression of liver metastases from pancreatic cancer. A 55-year-old asymptomatic woman presented to our clinic with newly diagnosed metastatic pancreatic cancer with extensive liver metastases. She underwent systemic chemotherapy with gemcitabine and oxaliplatin (GEMOX). After 8 cycles of therapy, she had a remarkable response to the therapy evidenced by decline of carcinoembryonic antigen (CEA) and CA19 by > 50% and nearly complete resolution of hepatic metastases in computed tomography (CT) scan. Shortly after, she developed increasing bilateral ankle edema and ascites, associated with dyspnea, progressive weight gain, and declining performance status. Gemcitabine and oxaliplatin were discontinued as other causes of her symptoms such as congestive heart disease or venous thrombosis were ruled out. CT scan 6 mo after the initiation of GEMOX revealed worsening ascites with a stable pancreatic mass. However, it also revealed a lobular hepatic contour, segmental atrophy, and capsular retraction mimicking the appearance of cirrhosis. She was managed with aggressive diuresis and albumin infusions which eventually resulted in a resolution of the above-mentioned symptoms as well as complete resolution of pseudocirrhotic appearance of the liver and ascites in CT scan. This case demonstrates that pancreatic cancer patients can develop pseudocirrhosis. Clinicians and radiologist should be well aware of this entity as

### INTRODUCTION

In patients with metastatic cancer involving the liver, treatment with chemotherapy can result in areas of retracted tumor tissue and scarring. This entity is referred to as pseudocirrhosis because it resembles macronodular cirrhosis radiographically and has been associated with hepatic decompensation. Pseudocirrhosis has been reported almost exclusively in patients undergoing treatment for metastatic breast cancer. We report a patient with pancreatic cancer and liver metastasis who developed pseudocirrhosis after achieving a clinical and radiographic response to gemcitabine and oxaliplatin.

### CASE REPORT

A 55-year-old woman presented to our institution in November 2006 with newly diagnosed, untreated metastatic pancreatic cancer, as well as biopsy-proven liver metastases and peritoneal deposits. She was asymptomatic with an ECOG performance status of 0, had no risk factors for hepatitis or cirrhosis, and her physical examination was unremarkable. Her hemoglobin was 102 (120-160 g/L), albumin was 33 (35-50 g/L), alkaline phosphatase was 300 (30-130 U/L), and total bilirubin

**Figure 1** Computed tomography (CT) of the liver. CT scan is the initial imaging study. **A:** CT of the liver after contrast enhancement showing numerous liver metastases; **B:** CT scan 4 mo after initial study showing marked diminution of the metastases and marked fatty infiltration of the liver; **C:** The liver 2 mo after B showing no evidence of metastasis but findings which simulate cirrhosis with ascites, and irregular contours with retraction. This constellation of CT findings is consistent with a diagnosis of pseudocirrhosis; **D:** CT scan 2 mo after C showing a nearly normal liver and only a trace of ascites present in the pelvis (image not shown).

was 1.54 g/L (less than 1.20 g/L). CA19-9 and CEA were elevated at presentation to 464 (0-37.0 U/mL) and 12.5 (0-3.0 ng/mL), respectively. A CT scan of the chest, abdomen and pelvis in December 2006 revealed multiple bilateral lung nodules which measured 5 mm or less, a 4.7 cm × 3.2 cm neoplasm at the head of the pancreas, and innumerable liver metastases (Figure 1A).

The patient began systemic chemotherapy with gemcitabine (1000 mg/m<sup>2</sup>) and oxaliplatin (100 mg/m<sup>2</sup>) every other week in December 2006. On a restaging CAT scan obtained after 3 cycles of treatment, innumerable hepatic metastases appeared less conspicuous. After 8 cycles of the therapy, she remained clinically well, CEA and CA19 were declined by > 50%, and CT scan on 4/10/2007 revealed nearly complete resolution of pulmonary nodules and hepatic metastases while the pancreatic mass remained stable. Fatty infiltration of the liver and new ascites were noted (Figure 1B).

In May 2007, she developed increasing bilateral ankle edema and ascites, associated with dyspnea, progressive weight gain, and declining performance status. Gemcitabine and oxaliplatin were discontinued. The ascites and fluid retention continued to worsen despite escalation of diuretics, and serum albumin decreased to 24 g/L, cardiac echocardiogram and duplex Doppler ultrasound of the lower extremities revealed no evidence of congestive heart disease or venous thrombosis. CT scan on June 7, 2007 revealed worsening ascites with a stable pancreatic mass. However, it also revealed a lobular hepatic contour, segmental atrophy, and capsular retraction mimicking the appearance of cirrhosis (Figure 1C). Hepatic Doppler ultrasound on June 21, 2007 revealed patent splenic, portal confluence, and hepatic veins with normal direction of flow. Her albumin declined to a nadir of 17 g/L. Bilirubin

and ALT (SGPT) were normal, and AST (SGOT) was < 2X upper limit of normal. The patient underwent a large volume paracentesis and the serum-to-ascites albumin gradient was greater than 11 g/L, indicating portal hypertension as the cause of her ascites. She was managed with aggressive diuresis and weekly albumin infusions. Over the next three months, she had marked improvement in her overall status with resolution of peripheral edema, diminished ascites, and normalization of albumin to 37 g/L. The patient's follow-up CT scan 14 wk after discontinuation of chemotherapy revealed a near resolution of pseudocirrhotic appearance of the liver and ascites along with a decrease in the size of the pancreatic head mass (Figure 1D). CA19-9 was decreased further to 64.

## DISCUSSION

In patients with metastatic cancer involving the liver, treatment with chemotherapy can result in areas of retracted tumor tissue and scarring. This entity is referred to as pseudocirrhosis because it resembles macronodular cirrhosis radiographically and can be associated with hepatic decompensation, while lacking of the classic pathologic attributes of cirrhosis<sup>[1]</sup>. Pseudocirrhosis has been reported almost exclusively in patients undergoing treatment for metastatic breast cancer. We report herein the first case of pseudocirrhosis arising in a patient with metastatic pancreatic cancer.

A wide range of chemotherapeutic agents are associated with pseudocirrhosis in patients with breast cancer, including adriamycin, cyclophosphamide, 5-fluorouracil, methotrexate, cisplatin, carmustine, tamoxifen, paclitaxel, megestrol acetate, vinblastine, etoposide, thiotepa, ifosfamide, navelbine,

and vincristine<sup>[1-3]</sup>. Patients exhibit radiographic findings of cirrhosis, such as capsular retraction with volume loss and lobulation of the liver contour adjacent to the treated metastatic disease<sup>[1,3-5]</sup>. The degree of change tends to correlate with the extent of metastatic burden in the liver<sup>[4]</sup>. In the series by Young *et al*, 52% and 27% of cases resulted in ascites and splenomegaly, respectively<sup>[1]</sup>. While it is rare, there are case reports on severe manifestations of portal hypertension, such as hepatic encephalopathy or variceal bleeding, associated with pseudocirrhosis, suggesting that the life threatening clinical consequences can be equivalent to those seen in classic cirrhosis despite the differences in respective pathophysiology<sup>[1,3,6]</sup>.

The mechanism of pseudocirrhosis arising in the setting of chemotherapy-induced regression of liver metastases is unclear. It has been proposed that tumor shrinkage and subsequent scar formation around the treated liver lesions are a possible mechanism, since volume loss and capsular retraction typically occur adjacent to the treated metastases. Alternatively, nodular regenerative hyperplasia (NRH) in response to chemotherapy-induced hepatic injury has been proposed as the causal mechanism of pseudocirrhosis<sup>[1,7,8]</sup>. The formation of regenerative hepatic nodules with subsequent compression and atrophy of intervening parenchyma without hepatic fibrosis is the hallmark of NRH<sup>[1]</sup>. NRH has been associated with various chemotherapeutic agents including oxaliplatin, 5-FU, and agents used in acute leukemia<sup>[7,9-11]</sup>. Oxaliplatin has been linked to the development of hepatic sinusoidal lesions, with areas of hepatic regeneration which can occasionally reach a pattern of NRH. However, clinically significant hepatic decompensation in association with these histopathologic findings has not been reported with oxaliplatin. Gemcitabine-associated liver toxicities have been very rarely reported<sup>[12-15]</sup>.

To our knowledge, this represents the first reported case of pseudocirrhosis arising in the setting of regression of liver metastases from pancreatic cancer. The absence of a liver biopsy is the major limitation in fully understanding the etiology of this patient's pseudocirrhosis. Since this patient had dramatic resolution of liver metastases and declining tumor markers prior to developing pseudocirrhosis, we cannot distinguish between tumor regression with scar formation or hepatotoxic effects of chemotherapy as potential mechanisms. However, the complete resolution of the radiographic and clinical hallmarks of pseudocirrhosis with cessation of chemotherapy suggests that, in this case, pseudocirrhosis was due, in part, to chemotherapy-associated hepatic injury.

In conclusion, this case illustrates that pseudocirrhosis can occur in pancreatic cancer as well as in breast cancer. Clinicians should be aware of this entity when treating patients with extensive liver metastases from pancreatic cancer. Early recognition and appropriate management, including discontinuation of implicated chemotherapeutic agents, cannot only prevent further liver damage and life-

threatening consequences of portal hypertension, but can also lead to a full recovery of liver function.

### Abstract

A 65-year-old woman was found to have dilatation of the intrahepatic bile duct in the right anterior segment during a general health. Laboratory data were within normal ranges and no solid mass was detected in her abdominal computer tomography (CT) or nuclear magnetic resonance imaging (MRI). However, endoscopic retrograde cholangiopancreatography (ERCP) demonstrated an obstruction of the right bile duct. Intraoperative cholangiography showed stenosis of the intrahepatic bile duct in the anterior inferior segment (B5) and narrowness of the intrahepatic bile duct in the anterior superior segment (B8), so that we strongly suspected intrahepatic cholangiocarcinoma (ICC). Histologically, surgically resected liver specimens, without tumor mass by macroscopic observation, showed intraductal papillary proliferation with fibrovascular cores and intraductal spreading of carcinoma *in situ* throughout a considerable area, especially in bile ductules around the peripheral small portal area. Furthermore, the immunohistochemical profile of the tumor (MUC5AC+/CK7+) was compatible with an intraductal papillary neoplasm of the bile duct (IPN-B). Consequently, this case was diagnosed as IPN-B with spreading CIS, stage I (pT1, pN0, P0, H1, M0). We report a case of IPN-B with interesting histopathological

### INTRODUCTION

Intraductal papillary neoplasm of the bile duct (IPN-B) is a neoplastic lesion preceding invasive intrahepatic cholangiocarcinoma (ICC) and is a new definition of a tumor with papillary growth in the intra- or extra-hepatic bile duct<sup>[1,2]</sup>. Histologically, IPN-B is characterized by a prominent papillary growth of atypical biliary epithelium with distinct fibrovascular cores and, frequently, mucin-secretion. It has previously been described as biliary papillomatosis<sup>[3]</sup>, bile duct cystadenocarcinoma<sup>[4]</sup>, intrahepatic cholangiocarcinoma (ICC)<sup>[5]</sup> or a mucin hypersecreting bile duct tumor<sup>[6]</sup>.

On the other hand, biliary intraepithelial neoplasia (BilIN) showing, microscopically, growth of atypical biliary epithelium, has been identified as another type of neoplastic lesion preceding ICC<sup>[7]</sup>. BilIN is known often to progress to tubular adenocarcinoma, while IPN-B is associated with mucinous carcinoma and tubular adenocarcinoma<sup>[1,2,8]</sup>. Biliary papillary tumors, including IPN-B, resemble, histologically, intraductal papillary mucinous neoplasms of the pancreas (IPMN-P)<sup>[9,10]</sup>. In both organs, these neoplasms arise within the duct system and show a predominantly intraductal growth pattern, commonly an overproduction of mucin and an association with invasive adenocarcinoma<sup>[11]</sup>.

Based on gross morphology, ICC can be divided into three types: mass-forming, periductal-infiltrating and intraductal growth types<sup>[12]</sup>. Of these, the intraductal growth type, which corresponds to IPN-B, is associated with the most favorable outcome<sup>[13]</sup>. One feature of IPN-B is its relatively good prognosis after complete hepatic resection<sup>[14,15]</sup>. Therefore, it is important to make a precise diagnosis at an early stage and to perform early surgical resection.

We report the clinical and histological findings of a patient who was diagnosed as IPN-B without hepatolithiasis and underwent a hemihepatectomy.

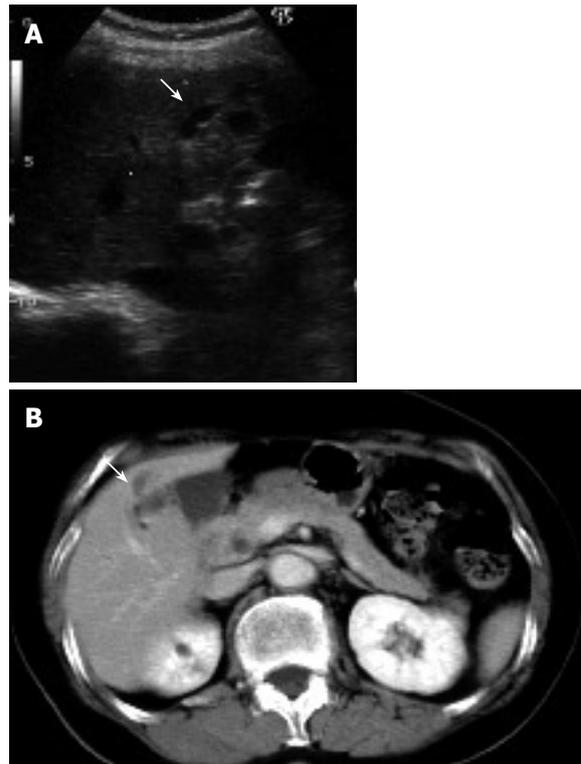

## CASE REPORT

A 65-year-old woman was found to have dilatation of the intrahepatic bile duct in the right anterior segment during a general health examination in our hospital (Figure 1A). She had no history of liver disease, including hepatolithiasis. She was admitted to our hospital for detailed examination. Physical examination on admission revealed a height of 152.3 cm, a weight of 45 kg, a temperature of 37.1°C, a blood pressure of 117/61 mmHg, a pulse rate of 78/min, and a respiration rate of 22/min. Pertinent laboratory values included a white blood cell count (WBC) of 3180/ $\mu$ L, aspartate aminotransferase (AST) level of 30 IU/L, alanine aminotransferase (ALT) level of 30 IU/L, alkaline phosphatase (ALP) level of 400 IU/L,  $\gamma$ -glutamyl transferase ( $\gamma$ -GTP) level of 15 IU/L, CEA of 1.4 ng/mL, CA19-9 of 3 U/mL, and AFP of 5.6 ng/mL. Abdominal computed tomography (CT, Figure 1B) and magnetic resonance imaging (MRI) showed dilatation of the intrahepatic bile duct in the right anterior segment, but no solid mass around it. No metastases were found inside or outside the liver. Celiac angiography did not reveal any hypervascular tumors. Endoscopic retrograde cholangiopancreatography (ERCP) demonstrated an obstruction of the right bile duct at the root of the right hepatic duct but the common and left intrahepatic bile ducts were not dilated (Figure 2). These findings suggested that the dilatation of bile duct was due to the invasion of ICC and prompted us to plan a curative excision.

Neither ascites nor a palpable tumor of the liver was detected during laparotomy. Intraoperative US showed only dilatation of the bile duct (B5), as had been detected preoperatively. Subsequently, cholangiography demonstrated stenosis of the B5 bile duct and narrowness of the B8 bile duct (Figure 3). This feature was strikingly suspicious of cholangiocarcinoma, so we elected to perform a right-lobule hepatectomy. An intraoperative frozen section was negative for malignancy in the margin of the right bile duct.

Macroscopic examination of the resected liver revealed bile duct dilatation in the right hepatic lobe (Figure 4). However, we could not identify any mass lesions and mucin was not observed macroscopically.

Microscopically, intrahepatic bile ducts were dilated with slight peri-ductal fibrosis. Within the dilated bile ducts, atypical biliary epithelium proliferated in a papillary fashion, associated with fine fibro-vascular cores (Figure 5A). Atypical cells showed nuclear enlargement, irregular nuclear

**Figure 1** A: Abdominal ultrasonography (US) of the liver showing slight dilatation of bile ducts in the right liver (S5); B: Contrast-enhanced CT scan of the abdomen showing markedly dilatation of bile ducts in the liver (S5). Solid masses were not observed.

**Figure 2** Endoscopic retrograde cholangiopancreatography (ERCP) showing a biliary obstruction at the root of the hepatic duct, suggesting cholangiocarcinoma.

membranes and distorted cellular polarity (Figure 5B). These atypical features corresponded to carcinoma *in situ*. Carcinoma cells proliferated continuously from the intrahepatic large bile ducts to small bile ducts (Figure 5C). Interestingly, carcinoma cells also were observed in proliferating bile ductules, which showed an irregular arrangement and slight dilatation (Figure 5D). Portal tracts showing irregular bile duct dilatation resembled Caroli's disease; however, we could not identify any features of Caroli's disease in the non-neoplastic area. No invasive growth could be detected.

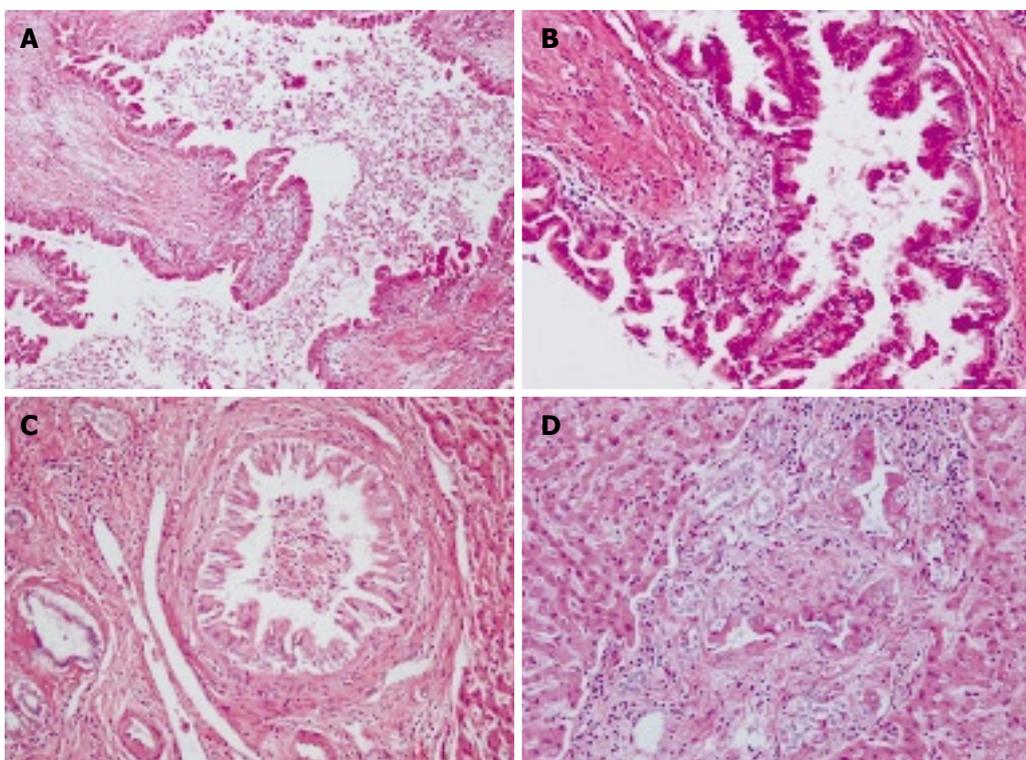

Immunohistochemical examination revealed that tumor cells were positive for CK7, CK20 and MUC5AC, and negative for MUC1, MUC2, and p53 (Figure 6). Finally, we diagnosed this lesion as IPN-B (carcinoma *in situ*), showing

**Figure 4** Macroscopic appearance of the resected right liver showing dilatation in the stump of the right intrahepatic duct, without a solid tumor component, which is surrounded by a fibrotic area.

**Figure 5** Histopathological findings showing. **A:** A view of the intrahepatic bile ducts dilated with peri-ductal fibrosis (x 100); **B:** Carcinoma cells continuously proliferating from the intrahepatic large bile ducts to small bile ducts (x 400); **C:** Carcinoma cells continuously proliferating from the intrahepatic large bile ducts to small bile ducts (x 200); **D:** Carcinoma cells in bile ductules around the small portal area (x 200).

extensive intraductal spreading. The histopathological stage of the tumor according to the General Rules for Surgical and Pathological Studies on Cancer of Biliary Tract was the final stage I (pT1, pN0, P0, H1, M0) and final curability was evaluated as A. No event has been observed during the medical follow-up (an 18-mo period).

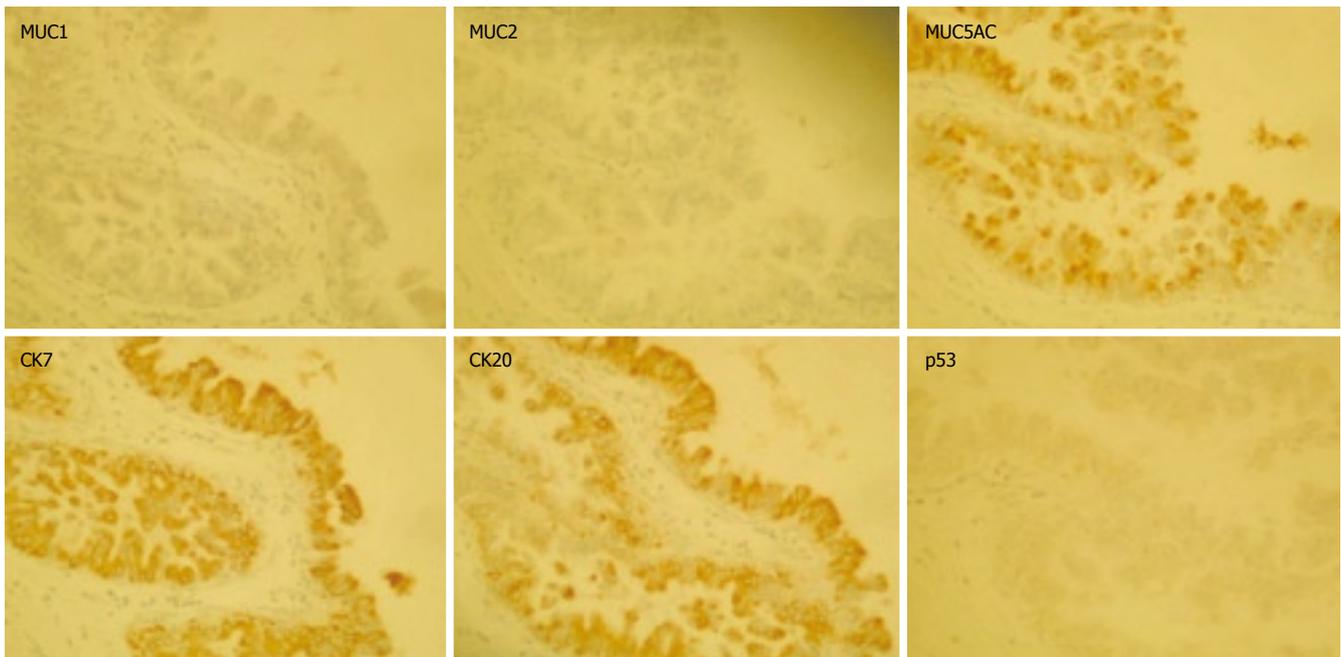

## DISCUSSION

IPN-B is characterized by intrabiliary papillary growth, overproduction of mucin, multifocal occurrence, jaundice and cholangitis, and also has been reported to be accompanied by hepatolithiasis<sup>[1,2]</sup>, which is recognized as being a risk factor for ICC. Recently, it has been reported that the number of cases of IPN-B without hepatolithiasis is much higher than those with it, and that it is hard to diagnose ICC with hepatolithiasis before laparotomy<sup>[16,17]</sup>.

In our case, when dilatation of the intrahepatic bile duct in the right anterior segment was detected by abdominal ultrasonography, neither a solid mass component nor hepatolithiasis was observed on imaging studies, and all laboratory data, including liver function and tumor markers (AFP, CEA, CA19-9), were within normal ranges. Therefore, we had difficulty in determining whether this case was malignant.

Several types of primary liver tumor with apparent cystic changes were considered in the differential diagnosis of our case<sup>[18]</sup>. For instance, biliary mucinous cystadenocarcinoma, intraductal neoplasm of liver (IPNL) and cholangiocarcinoma arising in a congenital cystic liver fibrosis are known examples.

We performed ERCP to evaluate the cause of intrahepatic cholangiectasis. This showed an obstruction of the right bile duct at the root of the right hepatic duct,

**Figure 6** Immunohistological staining: MUC5AC, CK7 and CK20 are expressed in the tumor cells, whereas MUC1, MUC2 and p53 are not.

which might have been due to a mucinous plug. ERCP is recommended to determine the presence and location of suspected intraductal tumors before laparotomy<sup>[19]</sup>.

Furthermore, we believe that cholangiography is a reliable procedure for investigating the cause of bile duct dilatation and the image showed abnormalities of the bile ducts that were strikingly suspicious of the infiltration of carcinoma cells along the intrahepatic biliary epithelium. These results demonstrated that cholangiographic images are helpful in diagnosing IPN-B and determining the extent of dissection in case of surgical treatment. Generally, the prognosis of ICC (especially the non-papillary type) at an advanced stage is poor, whereas surgical excision of IPN-B has a good prognosis<sup>[13,20]</sup>. Early detection of cancer in IPN-B improves survival, although it is hard to make an accurate assessment of the tumor invasion at an early stage, when a curative excision can be performed. As mentioned above, ERCP and cholangiography are useful for the diagnosis *in situ* carcinoma such as our case besides CT and MRI. Otherwise, bile cytology or biopsy of the bile duct as complementary diagnostic tools may be helpful to diagnose malignancy. It is necessary to cumulate the number of IPN-B cases and to observe their clinical manifestations and long term survival in advanced stage, compared to ICC.

We observed some remarkable findings in terms of histopathology. First, we needed to distinguish IPN-B from BiliN. In general, the former is characterized by flat or low papillary growth of atypical biliary epithelium, whereas the latter is characterized by papillary growth of that tissue. In our case, prominent papillary growth of atypical biliary epithelium was predominant, and this was appropriate for the diagnosis of IPN-B. As mentioned above, it is said that IPN-B could be the counterpart of pancreatic IPMN, and it is divided into various clinical stages: adenoma, carcinoma *in situ* (CIS) and periductal

infiltrating type<sup>[9,10]</sup>. There are a lot of similarities in terms of the clinicopathological findings. This case corresponds to CIS, because dysplasia of biliary epithelium was mild in the small portal vein area and severe in the large bile duct. Secondly, regarding the dilatation of the bile duct, we had to distinguish the dilatation with tumor from focal Caroli's disease or congenital hepatic fibrosis, etc. However, we considered that the dilatation was associated with a tumor because we were not able to find evidence of disease in other areas. Most IPN-Bs are characterized by mucin overproduction and dilatation of bile duct with a remarkable papillary mass, but these are not detected in some cases comparable to ours. Finally, low papillary carcinoma cells extended superficially along the intrahepatic bile ducts, which was a very interesting feature.

Zen *et al* reported various expression patterns of MUCs and cytokeratins in neoplastic biliary epithelia of BiliN and IPN-B with progression to ICC in hepatolithiasis<sup>[21]</sup>. IPN-B with hepatolithiasis was characterized predominantly by the intestinal phenotype (MUC2+/CK20+). However, in the present case, the immunophenotype was of the MUC2-/CK20+/MUC1-/MUC5AC+/CK7+ pattern, which corresponds to that of the pancreaticobiliary type<sup>[22]</sup>. This type consists of carcinoma cells, including CIS but not adenoma, and is likely predominant in such a case without hepatolithiasis. According to recent analyses, biliary papillary tumors are characterized by the common expression of MUC2, CDX2 and CK20, and CK7 is expressed in neoplastic lesion of biliary papillary tumors<sup>[23-25]</sup>. Identification of immunophenotypes of MUCs and CKs may aid following up patients in terms of progression.

Although there are some reports of carcinogenesis of ICC arising from IPN-B or IPNL, the carcinogenic pathways in IPN-B are still unclear. However, it has been reported recently that the state of field cancerization may

affect the carcinogenesis<sup>[26]</sup>. It is proposed to investigate the phenotypic and genetic changes in IPN-B for improving diagnosis and therapy.

Recently, it has been reported that highly invasive IPN-B may be involved in cases of ICC at an advanced stage, although IPN-B is generally characterized by lower malignancy and well differentiated histology. Further analyses of cases are necessary to establish its clinical features, therapy and prognosis.

### Abstract

Rotavirus is an acute enteric pathogen in infants and children. We reported a rare case of a 6-mo-old infant with protein-losing enteropathy (PLE) caused by rotavirus gastroenteritis, and evaluated the immunological profile in peripheral blood lymphocytes. Laboratory examinations showed lymphopenia, hypoproteinemia, hypoalbuminemia, hypogammaglobulinemia, and elevation of alpha-1-antitrypsin ( $\alpha$ 1-AT) clearance. Lymphocytes subpopulation study revealed the reversal of CD4+/CD8+ ratio with the selective decrease of CD4-positive lymphocytes. Moreover, the excessive increase of T cells producing IFN-gamma (IFN- $\gamma$ ) was found, which plays an important role in the protection against viral infection. The primary or secondary activation of immune system by rotavirus may influence structural integrity and vascular permeability, which may play a triggering role in protein-losing enteropathy.

### INTRODUCTION

Rotavirus is the most important acute enteric pathogen in children. Rotavirus infection sometimes causes severe dehydration that is characterized by vomiting and diarrhea. Unusual complications by rotavirus infection are pneumonia, aseptic meningitis, acute myositis, encephalopathy and pancreatitis<sup>[1-3]</sup>. There are several causes of protein-losing enteropathy (PLE) in children, involving allergic enteropathy, congenital heart disease<sup>[4-6]</sup>, and gastroenteritis, lymphangiectasia. We reported a case of an infant with PLE following rotavirus gastroenteritis and investigated the phenotypic profile in this patient.

### CASE REPORT

A 6-mo-old boy presented with vomiting and diarrhea for 2 d prior to admission. Subsequently, he was hospitalized because of dehydration. The physical examinations revealed normal body weight (6755 g), pretibial pitting edema, abdominal distention and hypoactive bowel sounds. Laboratory examinations showed white blood count 9500/ $\mu$ L with 12% lymphocytes, decreased protein (27 g/L)/albumin (14 g/L) with low IgG levels (< 1.9 g/L) and hypocalcemia (0.068 g/L). C-reactive protein (CRP) was normal. A stool examination on the day of admission demonstrated positive rotavirus antigen (rapid immunochromatographic test) and no eosinophils, but rotavirus antigen was not detected on d 5 of disease. No bacteria was detected in the stool culture. Alpha-1-antitrypsin (A-1-AT) clearance was elevated to 638 mL/d (normal value < 30 mL/d). A urinalysis demonstrated neither proteinuria nor hematuria. Abdominal ultrasound and computed tomography showed bowel expansion and intestinal wall thickening with a small amount of ascites. Therefore, the diagnosis of PLE associated with rotavirus gastroenteritis was made. However, Tc-99m-labeled albumin scintigraphy and intestinal biopsy could not be performed due to poor state of the patient. Although we started treatment with intravenous hyperalimentation for caloric intake and extensive replacement of albumin and gamma globulin, it was difficult to keep the normal serum level of these proteins. Although vomiting stopped, white-watery diarrhea developed more than ten times per day. Periorbital edema and abdominal distention were increased, and body weight increased to 7215 g (460 g/wk). The patient was treated with intravenous dexamethasone. After the improvement of diarrhea, we initiated the

medium-chain triglycerides (MCT) milk and the symptom did not recur. About one month later, A-1-AT clearance was decreased to 43.9 mL/d, yet abdominal CT partially showed persistent intestinal wall thickening. Lymphocytes, serum protein and albumin were normalized. In the acute phase, immunophenotyping of peripheral blood lymphocytes revealed selectively decreased percentage of CD4+ cells (15.71%) with normal percentage of CD8+ cells (38.76%) and reversal of CD4/CD8 ratio (0.41). IFN- $\gamma$  producing CD4+ and CD8+ lymphocytes were markedly elevated to 14.85% and 77.58%. CD19+, CD16+ and CD56+ were within normal range. One month later, immunophenotyping still revealed selectively decreased percentage of CD4+ cells (14.55%) and reversal of CD4+/CD8+ ratio (0.42), but IFN- $\gamma$  producing CD4+ and CD8+ lymphocytes were decreased to 3.46% and 0.19%. Three months later, in the convalescent phase, the proportion of CD4+ lymphocytes was normalized with CD4/CD8 ratio almost 1.0. The rotavirus antibody titer determined using complement-fixation (CF) antibody was negative (1:4) at the time of admission. Five weeks later, the antibody titer increased to 1:128. Both IgM and IgG antibodies for cytomegalovirus were negative in serological test. In clinical course, no elevation of CRP occurred.

## DISCUSSION

PLE is a disease characterized by a leakage of protein loss from the gastrointestinal tract, which results in hypoproteinemia. PLE is associated with many disorders. Although PLE is etiologically diverse, the mechanism of protein loss was classified into two groups: (a) an abnormality of the lymph system; (b) enhancement of vascular permeability and/or an abnormality of intestinal mucosal membrane. In this patient, we believed that rotavirus gastroenteritis was involved in the pathogenesis of PLE. Because rotavirus antigen was detected on the day of admission, this is not nosocomial infection. We speculated that the mechanism of protein and lymphocyte leakage resulted from enhancement of vascular permeability, which was triggered by rotavirus infection damaging intestinal mucosa. Immunological studies showed markedly increased percentage of IFN- $\gamma$  producing CD4+ and CD8+ lymphocytes. IFN- $\gamma$  plays a major role in the host defense against rotavirus and the development of Th1 response. Gao *et al.*<sup>[7]</sup> reported that serum and stool levels of IL-18 and IFN- $\gamma$  were increased in children with rotavirus enteritis. These cytokines might have protective effects against acute rotavirus infection at the early stage. Xu *et al.*<sup>[8]</sup> suggested that multiple toll-like receptors might modulate the immune response in the acute phase with rotavirus infection and play a role in the activation of IFN- $\gamma$ . In other reports, determination of serum cytokines (interleukin-6, interleukin-8, tumor necrosis factor- $\alpha$  and CRP) might be a useful in differentiating viral from bacterial gastroenteritis<sup>[9-11]</sup>. These cytokines in patients with bacterial gastroenteritis were significantly higher than those in patients with viral gastroenteritis, especially in combination with interleukin-6 and CRP. Although we tested only CRP, it has never been elevated in clinical course. Therefore, we diagnosed our case as

viral infection and gave no treatment of antibiotics, but more studies for other cytokines will be needed. Recently, it has been reported that a high frequency of rotavirus infections may increase the risk of celiac disease autoimmunity<sup>[12-14]</sup>. Unfortunately, we could not exclude the possibility of this disease because of no examinations for autoantibodies, including antigliadin antibodies (AGA), antitransglutaminase antibodies (TGA) and antiendomysium antibodies (EMA). Wang *et al.*<sup>[15]</sup> described rotavirus infection induced strong inflammation and immune responses. Although treatment with steroid in PLE patients is controversial, we treated this patient with dexamethasone to control inflammation, achieving some improvement.

Previous phenotypic studies have demonstrated that the percentages of CD4+ and CD8+ cells was reduced in acute phase of rotavirus infection with diarrhea, and subsequently this proportion of T lymphocytes recovered to almost normal levels in convalescent phase<sup>[15]</sup>. In PLE associated with cytomegalovirus, lymphocytes subpopulation showed normal percentage of T cells, B cells and NK cells. Furthermore, the CD4/CD8 ratio was normal<sup>[16]</sup>. It is not clear why the CD4+ lymphocytes were selectively reduced in the peripheral blood in this case. In patients with PLE, Garty *et al.* described two hypotheses for selective CD4+ cells loss after Fontan procedure<sup>[5]</sup>. The first is that CD4+ cells may have a longer half-life, leading to faster depletion from the circulation. A slower replenishment of the cells may result in fewer availability. Another hypothesis may be the selective transport of CD4+ cells. Our immunological studies of rotavirus induced PLE revealed the selective CD4+ lymphocyte reduction and the excessive inflammation. Some immune-mediated process induced by rotavirus gastroenteritis may play a triggering role in the pathogenesis of PLE, but further investigations are needed.

In summary, we reported a rare case of severe transient rotavirus gastroenteritis accompanied with PLE. Interestingly, although the reason is not clear, the immunophenotyping of peripheral blood lymphocytes in acute phase showed a markedly decreased percentage of CD4+ cells. Rotavirus infection should be considered in patients with acute and symptomatic protein loss of gastrointestinal origin.

### Abstract

A 41-year-old man presented with a 6-mo history of changed defecation and rectal bleeding. A 3-cm polypoid tumor of the lower rectum was found at rectosigmoidoscopy, which proved to be a leiomyosarcoma upon biopsy. Dissemination studies did not show any metastases. He was underwent to an abdomino-perineal resection (APR). Histopathology of the specimen showed a melanoma (S-100 stain positive). Two years after the resection, metastases in the abdomen and right lung were found. He died one and half years later. Primary anorectal melanoma is a rare and very aggressive disorder. According to current data, one should always perform a S-100 stain when anorectal sarcoma is suspected. A positive S-100 stain suggests the tumour to be most likely a melanoma. Subsequently, thorough dissemination studies need to be performed. Depending on the outcome of the dissemination studies, a surgical resection has to be performed. Nowadays, a sphincter-saving local excision combined with adjuvant loco-regional radiotherapy should be preferred in case of small tumors. The same loco-regional control is achieved with less "loss of function" compared to non-sphincter saving surgery. Only in the case of large and obstructing tumors an abdomino-perineal resection is the treatment of choice.

### INTRODUCTION

The majority of colorectal and anal malignancies are adenocarcinomas and squamous cell cancers. Despite the predominance of these neoplasms at these locations, rare histotypes of the colon, rectum, and anus occur. These histotypes include lymphoma, melanoma, diffuse cavernous hemangioma, and sarcomas, such as leiomyosarcoma or Kaposi's sarcoma.

Primary anorectal melanoma is a rare disorder. About 1% of all anorectal carcinomas are melanomas<sup>[1,2]</sup>, typically presenting in the fifth or sixth decade of life and predominantly in woman. Patients present themselves with local symptoms like rectal bleeding and a changed defecation pattern<sup>[1-6]</sup>. Prognosis is very poor with a median survival of 24 mo and a 5-year survival of 10%<sup>[3]</sup>. Almost all patients die because of metastases<sup>[4]</sup>. At this moment there is no consensus on which surgical approach is favourable. The surgical procedure of choice ranges from an abdomino-perineal resection to local excision with or without adjuvant radiotherapy.

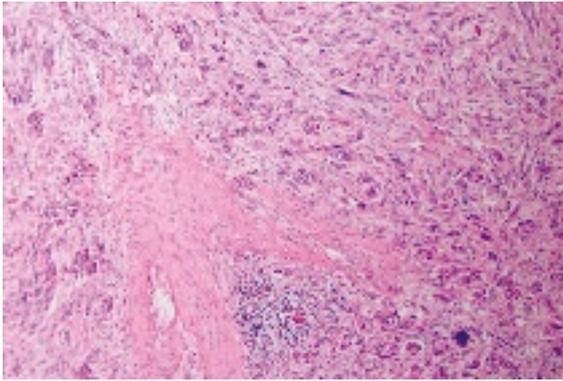

### CASE REPORT

A 41-year-old man was admitted with a 6-mo history of modified defecation and rectal bleeding. His past history was unremarkable, and his family history was negative for colon and/or rectal carcinoma. He had lost some weight, despite maintaining a good appetite. By physical examination, a 4 cm nodular mass was palpated just behind the anal verge.

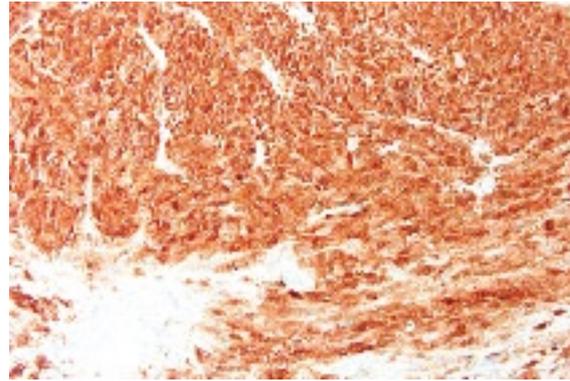

Rectosigmoidoscopy demonstrated a polypoid tumor with a diameter of 3 cm, involving half the circumference. Histopathological examination delineated the tumor as a leiomyosarcoma (Figure 1). MRI showed a tumor just behind the anal verge, without evidence of invasion in the sphincter, growth outside the rectum or enlarged lymph nodes (Figure 2). Abdominal ultrasonography showed no evidence for metastases, especially not in the liver. X-ray of the thorax and CT-thorax were free from any signs of metastases.

An abdomino-perineal resection was performed. The postoperative period was uneventful. Histopathology of the resected specimen showed a melanoma (S-100 stain positive) (Figure 3).

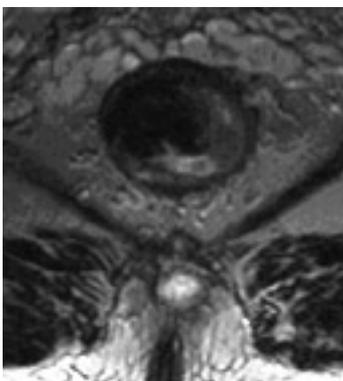

Two years after the initial diagnosis, metastases in the abdomen were found with growth into the second lumbar vertebra and in the right lung. The patient was treated with radio-chemotherapy with good locoregional response. He underwent a metastasectomy of the right lung following

**Figure 1** Histopathological examination of a biopsy taken at rectosigmoidoscopy showed the tumour to be a leiomyosarcoma (HE, x 100).

**Figure 3** Histopathological examination of the abdomino-perineal resection (S-100 Positive, x 200). S-100 staining performed with an automatic system (Benchmark XT, Ventana Systems). Diffuse expression of S-100 staining typical for melanoma. In leiomyosarcoma, S-100 is never expressed.

**Figure 2** MRI-rectum showing a tumour just behind the anal verge.

radiochemotherapy. The postoperative period was uneventful and the disease seemed to be in remission. Three and a half year after the initial diagnosis, however, he died because of intra-abdominal metastases.

## DISCUSSION

A malignant melanoma of the rectum is a rare and very aggressive rectal disorder<sup>[1-6]</sup>. This disease presents itself usually starting from the fourth decade, predominantly in women, with an increase of incidence in the fifth or sixth decade of life<sup>[5]</sup>. Almost 60% of patients have already metastases at initial diagnosis<sup>[2]</sup>. Patients often present with rectal bleeding and tenesmus<sup>[1-6]</sup>.

If a biopsy shows a specimen suspicious for sarcoma (e.g. leiomyosarcoma), one should be alert. Preferably, S-100 staining should be performed in addition to routine stainings. A positive S-100 stain suggests the tumour most likely to be a melanoma. Subsequently dissemination studies, including chest X-ray and CT-scan of chest/abdomen/pelvis are performed. Curative surgical resection has to be performed in the absence of metastases proven by dissemination studies.

There is no consensus at this moment on which surgical approach is preferred.

A number of studies claim that an abdomino-perineal resection (APR) is the treatment of choice<sup>[7,8]</sup>. This is based on the hypothesis that the disease spreads proximally via the submucosa to the mesenteric lymph nodes. Retrospec-

tive studies have revealed a statistically significant improvement in local-regional control when patients are managed with APR compared with local excision alone (without radiotherapy) (74% vs 34%)<sup>[5]</sup>.

Other studies, however, have recommended only a sphincter-saving excision for two reasons. Firstly, treatment is often palliative and wide radical surgery unnecessary mutilating. Secondly, tumor stadium and biological behaviour of the tumor determines survival instead of the choice of surgical operation<sup>[9,10]</sup>.

Recent studies show that sphincter-saving local excision combined with adjuvant loco-regional radiotherapy at the primary site of the tumor and the regional pericolic and inguinal lymphatics (5 X 6 GY) results in the same loco-regional control with less loss of function compared to APR (70% vs 74%)<sup>[5]</sup>.

Local excision seems to be the treatment of choice in case of small tumors, because of lower morbidity compared to APR. Only in the case of large and obstructing tumors, an APR is the surgical treatment of choice.

In conclusion, a malignant melanoma of the rectum is a rare disorder. The prognosis is poor and patients often have already metastases at the time of diagnosis. If a biopsy shows a sarcoma, the S-100 stain should be performed in addition to routine stainings. A positive staining strongly suggests a melanoma. The first choice, among surgical treatments, seems to be local excision with adjuvant radiotherapy. Only in the case of large and obstructing tumors one should perform an abdomino-perineal resection.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1224 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to the readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The major goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381901-600. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

### SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

- |                        |             |   |
|------------------------|-------------|---|
| <b>EDITORIAL</b>       | <b>1641</b> | Novel therapeutic approaches for hepatocellular carcinoma: Fact and fiction<br><i>Zhang YY, Xia HHX</i>   |
| <b>OBSERVER</b>        | <b>1643</b> | Complications of collagenous colitis<br><i>Freeman HJ</i>   |
| <b>REVIEW</b>          | <b>1646</b> | Gastric cancer: Animal studies on the risk of hypoacidity and hypergastrinemia<br><i>Fossmark R, Qvigstad G, Waldum HL</i>  |
| <b>TOPIC HIGHLIGHT</b> | <b>1652</b> | Natural history of hepatitis-related hepatocellular carcinoma<br><i>But DYK, Lai CL, Yuen MF</i>  |
|                        | <b>1657</b> | Hepatocellular carcinoma, human immunodeficiency virus and viral hepatitis in the HAART era<br><i>Macdonald DC, Nelson M, Bower M, Powles T</i>   |
|                        | <b>1664</b> | Radioembolization for the treatment of unresectable hepatocellular carcinoma: A clinical review<br><i>Ibrahim SM, Lewandowski RJ, Sato KT, Gates VL, Kulik L, Mulcahy MF, Ryu RK, Omary RA, Salem R</i> |
|                        | <b>1670</b> | Harnessing the RNA interference pathway to advance treatment and prevention of hepatocellular carcinoma<br><i>Arbuthnot P, Thompson LJ</i>  |
|                        | <b>1682</b> | Is human hepatocellular carcinoma a hormone-responsive tumor?<br><i>Di Maio M, Daniele B, Pignata S, Gallo C, De Maio E, Morabito A, Piccirillo MC, Perrone F</i>                                       |
|                        | <b>1690</b> | Reactivation of the insulin-like growth factor- II signaling pathway in human hepatocellular carcinoma<br><i>Breuhahn K, Schirmacher P</i>  |
|                        | <b>1699</b> | Activins and activin antagonists in hepatocellular carcinoma<br><i>Deli A, Kreidl E, Santifaller S, Trotter B, Seir K, Berger W, Schulte-Hermann R, Rodgarkia-Dara C, Grusch M</i>                      |

## Contents

	<b>1710</b>	Current role of ultrasound for the management of hepatocellular carcinoma <i>Maruyama H, Yoshikawa M, Yokosuka O</i>
	<b>1720</b>	Tumor suppressor and hepatocellular carcinoma <i>Martin J, Dufour JF</i>
	<b>1734</b>	Molecular mechanism underlying the functional loss of cyclindependent kinase inhibitors p16 and p27 in hepatocellular carcinoma <i>Matsuda Y</i>
	<b>1741</b>	DNA methylation in hepatocellular carcinoma <i>Tischoff I, Tannapfel A</i>
<b>LIVER CANCER</b>	<b>1749</b>	Genome-wide differences in hepatitis C- vs alcoholism-associated hepatocellular carcinoma <i>Derambure C, Coulouarn C, Caillot F, Daveau R, Hiron M, Scotte M, François A, Duclos C, Gorla O, Gueudin M, Cavard C, Terris B, Daveau M, Salier JP</i>
<b>BASIC RESEARCH</b>	<b>1759</b>	Aberrant activation of nuclear factor of activated T cell 2 in lamina propria mononuclear cells in ulcerative colitis <i>Shih TC, Hsieh SY, Hsieh YY, Chen TC, Yeh CY, Lin CJ, Lin DY, Chiu CT</i>
<b>CLINICAL RESEARCH</b>	<b>1768</b>	Endoscopic and histopathological study on the duodenum of <i>Strongyloides stercoralis</i> hyperinfection <i>Kishimoto K, Hokama A, Hirata T, Ihama Y, Nakamoto M, Kinjo N, Kinjo F, Fujita J</i>
<b>RAPID COMMUNICATION</b>	<b>1774</b>	Model for end-stage liver disease score <i>versus</i> Child score in predicting the outcome of surgical procedures in patients with cirrhosis <i>Hoteit MA, Ghazale AH, Bain AJ, Rosenberg ES, Easley KA, Anania FA, Rutherford RE</i>
	<b>1781</b>	Short-term overlap lamivudine treatment with adefovir dipivoxil in patients with lamivudine-resistant chronic hepatitis B <i>Nam SW, Bae SH, Lee SW, Kim YS, Kang SB, Choi JY, Cho SH, Yoon SK, Han JY, Yang JM, Lee YS</i>
	<b>1785</b>	<i>Cyclooxygenase 2</i> polymorphism and colorectal cancer: -765G>C variant modifies risk associated with smoking and body mass index <i>Xing LL, Wang ZN, Jiang L, Zhang Y, Xu YY, Li J, Luo Y, Zhang X</i>
	<b>1790</b>	Herbal compound 861 regulates the mRNA expression of collagen synthesis- and degradation-related genes in human hepatic stellate cells <i>Wang L, Wang BE, Wang J, Xiao PG, Tan XH</i>

### Abstract

Hepatocellular carcinoma (HCC) is the most common primary liver cancer and accounts for 80%-90% of this class of malignancy. So far, understanding of its pathogenesis and effective therapeutic methods are rather limited. In this issue, 11 invited review articles are published to address current advance of underlying molecular mechanisms for the development of HCC, and novel therapeutic approaches for HCC. This series of review articles provide an in-depth understanding of HCC that has led to or may lead to the development of novel therapies for HCC.

Zhang YY, Xia HHX. Novel therapeutic approaches for hepatocellular carcinoma: Fact and fiction. *World J Gastroenterol* 2008; 14(11): 1641-1642 Available from: URL: <http://www.wjgnet.com/1007-9327/14/1641.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.1641>

Liver cancer is the fifth most common cancer worldwide and the third most common cause of cancer mortality<sup>[1]</sup>. Hepatocellular carcinoma (HCC), which accounts for 80%-90% of primary liver, is characterized by a very poor prognosis and is associated with high mortality<sup>[1-3]</sup>. It has been well known that chronic viral hepatitis B and C infections are the most important risk factors, responsible for 80% of HCC worldwide<sup>[1-3]</sup>. However, current available therapeutic modalities for HCC are largely inadequate. Surgical approaches such as resection and transplantation

are the treatment of choice for HCC; however, because of underlying liver disease, only a minority of patients are suitable for resection, and access to transplantation is limited by organ availability. Local tumor ablation is effective for early HCC, and chemoembolization is of benefit in intermediate-stage disease. So far, no first-line therapy has emerged for advanced HCC. Cytotoxic chemotherapy has proven ineffective<sup>[3]</sup>. Therefore, research efforts are focused on novel targeted therapies.

In this issue of the *World Journal of Gastroenterology*, 11 invited review articles are published to reflect the current advance in understanding the etiology of HCC and underlying molecular mechanisms for the development of HCC, and, particularly, to provide expert opinions and new insights on the potential novel therapeutic approaches for HCC.

But *et al* update the incidence and describe different patterns and risk factors for HCC, speculate on carcinogenesis in hepatitis B virus (HBV), and hepatitis C virus (HCV), point out the clinical difference between HBV- and HCV-related HCC, and describe the natural history of HCC, prediction factors for survival, and HBV vaccination<sup>[4]</sup>. Macdonald *et al* emphasize that the incidence of HCC in patients with immunodeficiency virus (HIV) is increasing, and HCC in HIV almost invariably occurs in the context of HBV or HCV co-infection. Moreover, human HIV co-infection seems to accelerate disease progression and reduces the efficacy of anti-HBV and anti-HCV therapy<sup>[5]</sup>. Further, Macdonald *et al* point out updated information on the screening, prevention and treatment of HCC in patients with HIV in the HAART (highly active antiretroviral therapy) era<sup>[5]</sup>. The knowledge on HCC etiology and epidemiology is of significant value in guiding the clinical practice including diagnosis, prevention and treatment.

Various treatments options have been under investigation in order to achieve the greatest survival benefit with the least toxicity. Salem *et al* highlight the use of segmental infusion of intra-arterial radiotherapy with Yttrium-90 (Y90) or Phosphorus-32 (Ph-32) for the treatment of inoperable HCC and update the recent clinical and research advancements in radiotherapy<sup>[6]</sup>. Maruyama *et al* discuss the increasingly important roles of ultrasound (US) in the diagnosis (e.g. US-guided needle puncture, color Doppler US, and real-time 3-dimensional US images), and in the treatment of HCC (e.g. high intensity focused ultrasound)<sup>[7]</sup>.

Many studies have been carried out with the aim of developing a systematic treatment and/or achieving targeted therapy at the molecular level. Silencing HCC-related cellular oncogenes or the HBV and HCV viruses has been attempted for HCC treatment. Many studies have

demonstrated promising results, and an early clinical trial assessing RNAi-based HBV therapy is currently in progress. However, there are several significant hurdles that need to be overcome before the goal of RNAi-based therapy for HCC is realized. This aspect has been well covered by Arbuthnot *et al*<sup>[8]</sup>. Di Maio *et al* review the association between sex hormones and HCC tumorigenesis and the efficacy of anti-hormone therapy. Although epidemiological and pre-clinical studies support a strong association, several clinical trials have virtually produced negative results. Thus, there is no robust evidence that HCC is a hormone-responsive tumor, and hormonal therapy should not be a part of current management for HCC<sup>[9]</sup>. Breuhahn and Schirmacher focus on the alterations in the insulin-like growth factor (IGF)-II signaling pathway and *in vivo* models that support the central role IGF-II signaling during HCC development and progression<sup>[10]</sup>. This pathway has become the center of interest as a target for potential anti-cancer therapy in many types of malignancies. Therefore, inhibitors targeting IGF-IR and other RTKs or combinations of different specific substances targeting distinct pathways might be attractive therapeutic approaches for HCC in the future. The contribution by Deli *et al* reviews the alterations in components of the activin signaling pathway that have been observed in HCC and discuss their potential significance for liver tumorigenesis<sup>[11]</sup>. Activin A, and possibly activin E, may have a similar tumor suppressive function in the liver as TGF- $\beta$  although whether activins may also shift to a pro-tumorigenic function during tumor progression is little explored. Activin antagonists may serve to block the growth inhibitory and pro-apoptotic activity of activin A on hepatocytes. Therefore, a targeted inhibition of activin antagonists might restore sensitivity to activin-induced growth inhibition and apoptosis, and may thus represent a feasible strategy to inhibit tumor growth. Future studies will clarify whether such approaches may offer new therapeutic opportunities for combating liver cancer<sup>[11]</sup>.

The review of Martin and Dufour address the various tumor suppressors which have been implicated in HCC<sup>[12]</sup>. Specifically, they discuss the function of these tumor suppressors and the related signaling pathways such as p53, Wnt, Ras/Jak/Stat and other pathways and the involvement of inactivation of these tumor suppressors in the initiation or progression of HCC as well as the underlying mechanisms of their inactivation<sup>[12]</sup>. Matsuda provides evidence that p16 and p27, two potent tumor suppressors that inhibit cyclin-dependent kinase, are functionally related, i.e. loss of p16 expression is associated with over-expression but functional inactivation of p27 in HCC. In addition, loss of p16 expression is an independent prognostic factor for a poor outcome in HCC cases expressing high levels of p27. Thus, p16 and p27 may become more accurate biomarkers predicting the prognosis of HCC<sup>[13]</sup>. Moreover, comprehensive understanding of the functions of and interactions among these tumor suppressors and the underlying mechanisms of their inactivation is a prerequisite to design innovative treatments of HCC.

It has been well known that development of HCC

is a multistep process with accumulation of genetic and epigenetic alterations in regulatory genes, leading to activation of oncogenes and inactivation or loss of tumor suppressor genes (ref. above). Tischoff *et al* further discuss the epigenetic alterations in HCC focusing on DNA methylation<sup>[14]</sup>. In HCC, aberrant methylation of promoter sequences occurs not only in advanced HCC, but also in premalignant conditions such as chronic viral hepatitis B or C and hepatic cirrhosis. Therefore, epigenetic changes in preneoplastic or early neoplastic stages may serve as an indicator or "biomarker" for screening of patients with an increased risk for HCC. Moreover, it has been demonstrated that reexpression of TSGs that are epigenetically silenced is possible by using demethylating and histone modifying agents, indicating a potential therapeutic approach by specifically modulating DNA hypermethylation<sup>[14]</sup>.

It is our hope that this series of review articles will give our readers an in-depth understanding of all aspects of HCC that have led to or may lead to the development of novel therapeutic approaches for HCC.

### Abstract

Microscopic forms of colitis have been described, including collagenous colitis. This disorder generally has an apparently benign clinical course. However, a number of gastric and intestinal complications, possibly coincidental, may develop with collagenous colitis. Distinctive inflammatory disorders of the gastric mucosa have been described, including lymphocytic gastritis and collagenous gastritis. Celiac disease and collagenous sprue (or collagenous enteritis) may occur. Colonic ulceration has been associated with use of nonsteroidal anti-inflammatory drugs, while other forms of inflammatory bowel disease, including ulcerative colitis and Crohn's disease, may evolve from collagenous colitis. Submucosal "dissection", colonic fractures or mucosal tears and perforation from air insufflation during colonoscopy may occur and has been hypothesized to be due to compromise of the colonic wall from submucosal collagen deposition. Similar changes may result from increased intraluminal pressure during barium enema contrast studies. Finally, malignant disorders have also been reported, including carcinoma and lymphoproliferative disease.

### COLLAGENOUS COLITIS

Collagenous colitis was first described just over 3 decades ago and usually presents as a watery diarrhea syndrome<sup>[1]</sup>. Distinct histopathologic changes consisting of a colonic mucosal inflammatory process with a characteristic subepithelial hyaline deposit in the lamina propria region (Figures 1 and 2) have been described<sup>[1]</sup>. These pathological features are analogous to those reported earlier in collagenous sprue<sup>[2]</sup>. Ultrastructural studies have confirmed that the deposits consist of collagen fibers<sup>[3]</sup>.

Most often, middle-aged to elderly females are affected, although even children have been reported with collagenous colitis<sup>[1,4]</sup>. The cause has not been defined, but the disorder is very heterogeneous and may have multiple causes. It has frequently been associated with celiac disease<sup>[5]</sup> and use of a broad range of medications, including nonsteroidal anti-inflammatory drugs and proton pump inhibitors, i.e., lansoprazole<sup>[1]</sup>. Moreover, there are familial cases suggesting that genetic or heritable factors play a critical role<sup>[6]</sup>. There are also reports suggesting that collagenous colitis may be precipitated by enteric infections, such as *Yersinia* species or, possibly, bacterial toxins<sup>[7-9]</sup>. In addition, collagenous colitis has appeared as a reversible paraneoplastic phenomenon<sup>[10]</sup>. Finally, collagenous colitis has also been recorded in non-human species, such as the baboon<sup>[11]</sup>. Collagenous colitis may also be readily distinguished from other forms of inflammatory bowel disease (Table 1).

Spontaneous resolution may occur so that evaluation of the response to different therapies may be made more difficult. Even histological endpoints are difficult to evaluate because the sub-epithelial collagen deposits tend to be patchy, rather than diffuse and continuous in mucosal distribution<sup>[1]</sup>. Treatment has most often focused on symptom resolution using added dietary fiber, non-specific anti-diarrhea agents and anti-inflammatory medications. Steroids, specifically budesonide, were shown to be useful in clinical trials<sup>[12]</sup>. In some, other immunosuppressants have been used and even surgical treatment has been described<sup>[13]</sup>. Of note, ileostomy and sigmoidostomy were reported to lead to both clinical and histologic remission. Later ostomy closures, however, led to recurrent symptoms and re-development of collagen deposits. Possibly, a diverted noxious luminal factor was important<sup>[14]</sup>. Finally, collagenous pouchitis has also been described after restorative proctocolectomy<sup>[15]</sup>.

Long-term studies of collagenous colitis have suggested that it generally runs a very benign clinical course, at least

Table 1 Comparative features of collagenous colitis (CC) with ulcerative colitis (UC) and Crohn's disease (CD)

	CC	UC	CD
Usual age at diagnosis	Mid to older age, most over 40	Youth to middle age	As for UC, most under 40
Sex predominance	Usually female	Similar	Similar
Diarrhea	Watery	Usually bloody	Watery, sometimes with blood
Distribution in colon	Patchy, rare rectal sparing	Continuous with rectal involvement	Patchy or focal; some with rectal sparing
Mucosal involvement	Yes, with	Yes	Yes, with granulomas
Small bowel disease	Occurs; also celiac disease	"So-called 'reflux' ileitis with severe pancolitis"	Common, especially ileum
Complicating cancer	To date, no increased frequency	"Increased rates with extensive disease"	"Increased rates with extensive disease; small bowel cancer"
Autoimmune disorders	Yes	Yes	Yes

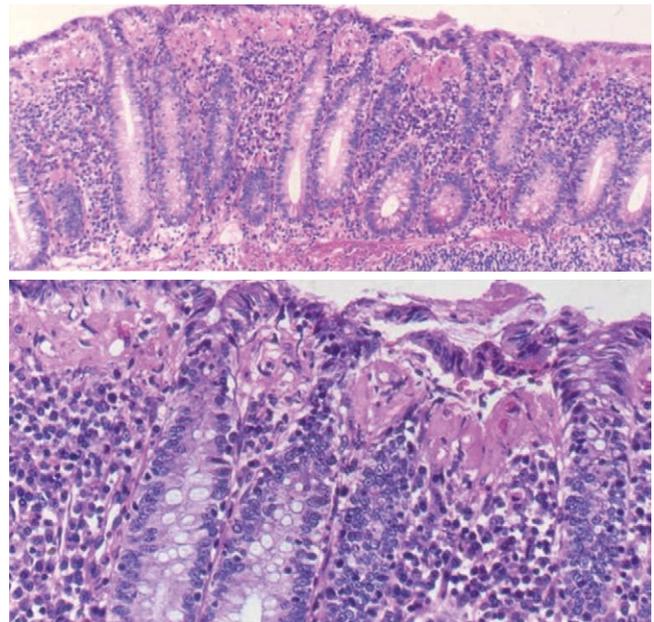

**Figure 1** Gross macroscopic appearance of colonic mucosa in collagenous colitis. During colonoscopy, the mucosa may appear virtually normal with minimal alteration in the clarity of the vascular pattern. Diagnosis depends on microscopic evaluation of a colonic biopsy, not the macroscopic appearance of the colonic mucosa.

during evaluation over a period of about 10 years<sup>[16]</sup>. In most, symptoms spontaneously resolved or remission occurred in association with anti-inflammatory drug therapy alone. Some experienced persistent diarrhea or intermittent periods of recurrent diarrhea that required ongoing chronically-administered medication. Occasionally, however, collagenous colitis may be complicated by other disorders of the stomach, small or large intestine and these may dominate its clinical course.

## COMPLICATIONS

In a prospective evaluation of established collagenous colitis, celiac disease was subsequently detected in over 20%<sup>[5]</sup>. This could have implications for patients with celiac disease not appearing to respond to a gluten-free diet; in these, the colonic disease, rather than celiac disease, might be causing symptoms. Collagenous involvement of the gastric and/or small intestinal mucosa also has been detected with collagenous colitis suggesting that, in some, histological changes may not be simply localized in the colon, but may be a far more extensive process<sup>[10,17,18]</sup>. Even with extensive collagenous involvement of the intestinal tract, however, complete histological remission is possible<sup>[10,18]</sup>.

While most patients with collagenous colitis have a benign or sometimes relapsing and remitting course, recent reports have increased appreciation for some of its possibly more unusual clinical features involving the colon. A severe and protracted course with a fatal outcome

**Figure 2** Lower and higher power photomicrographs of the colonic mucosa in collagenous colitis. A mucosal inflammatory process is present with well preserved crypt architecture. Note the subepithelial mucosal band of collagen material.

attributed to the colitis has been recorded<sup>[19]</sup>. Surface epithelial cell sloughing may be appreciated in colonic biopsies leaving a naked subepithelial deposit; in many of these patients, mucosal permeability may be altered and protein-losing enteropathy has been noted in the absence of small intestinal disease<sup>[20]</sup>. Colonic ulceration may occur, possibly related to concomitant use of medications, such as nonsteroidal anti-inflammatory drugs<sup>[21]</sup>. Occasionally, evolution of collagenous colitis into severe ulcerative colitis or Crohn's disease has been recorded<sup>[22-24]</sup>. With the onset of ulcerative colitis, complete disappearance of the collagen deposition occurred<sup>[22]</sup>. Rarely, submucosal "dissection" may occur<sup>[25]</sup>. Colonic fracturing after endoscopic instrumentation, possibly related to air insufflation and barotrauma, or insertion of barium contrast agents, has been recorded<sup>[26]</sup>. Recently, a report entitled "cat scratch colon" emphasized the macroscopic changes involving the proximal colon that are most often observed during colonoscopy in collagenous colitis<sup>[27]</sup>. Spontaneous peritonitis with colonic perforation has also been recorded<sup>[28]</sup>. In all of these, it has been hypothesized that the integrity of the colonic wall may be compromised owing to submucosal collagen deposition.

A particularly striking finding, to date, is the rarity of reported malignant disease complicating the clinical course of collagenous colitis. Colorectal cancer has been noted<sup>[10,29]</sup>, including cecal cancer<sup>[30]</sup>, but these may have been only coincidental. In an extensive survey study, the overall risk of colorectal cancer was similar to the general control population; only 2 patients with collagenous colitis were seen with colorectal cancer, but these occurred before development of colitis<sup>[31]</sup>. Interestingly, collagenous involvement of the small and large intestine resolved completely following resection of a colon cancer suggesting an unusual paraneoplastic phenomenon<sup>[10]</sup>. Other neoplasms that have been rarely recorded include lymphoproliferative disorders<sup>[32,33]</sup> and carcinoids<sup>[34]</sup>. Because this is a relatively "new" disease, sufficient time may not yet have passed to observe sufficient superimposed disease complications. Alternatively, factors linked to pathogenesis, such as the use of nonsteroidal anti-inflammatory drugs, may induce a chemopreventive effect on development of colonic neoplasia.

### Abstract

Gastric hypoacidity and hypergastrinaemia are seen in several conditions associated with an increased risk of gastric malignancy. Hypoacidity and hypergastrinaemia are closely related and their long-term effects are difficult to study separately in patients. Studies using animal models can provide valuable information about risk factors and mechanisms in gastric cancer development as the models allow a high degree of intervention when introducing or eliminating factors possibly affecting carcinogenesis. In this report, we briefly review findings from relevant animal studies on this topic. Animal models of gastric hypoacidity and hypergastrinaemia provide evidence hypergastrinaemia is a common causative factor in many otherwise diverse settings. In all species where sufficient hypoacidity and hypergastrinaemia have been induced, a proportion of the animals develop malignant lesions in the gastric oxyntic mucosa.

### INTRODUCTION

Gastric hypoacidity and subsequent hypergastrinaemia

occur in patients with parietal cell loss due to atrophic gastritis as well as in patients using drugs inhibiting gastric acid secretion. The increased risk of developing gastric carcinoids as well as adenocarcinomas is well documented in patients with pernicious anemia<sup>[1-4]</sup>, whereas there is no direct evidence that hypoacidity and hypergastrinaemia caused by proton pump inhibitors promote gastric carcinogenesis in humans. Proton pump inhibition for up to five years has led to enterochromaffin-like (ECL) hyperplasia related to hypergastrinaemia<sup>[5]</sup>. Patients with gastrinomas often develop ECL cell carcinoids secondary to hypergastrinaemia, as well as signet ring cell carcinoma<sup>[6]</sup>. ECL cell carcinoids develop more often in patients with multiple endocrine neoplasia type 1 (MEN1)<sup>[7]</sup>, but are also found in patients without MEN1<sup>[8,9]</sup>. The common factor in the above mentioned conditions is prolonged hypergastrinaemia, and it has been presumed that hypergastrinemia in itself increases the risk of gastric neoplasia in humans<sup>[10,11]</sup>.

However, gastric carcinogenesis in humans is a process that progresses over years to decades and may be influenced by numerous factors. Dissecting the mechanisms of gastric carcinogenesis in humans is therefore difficult and several animal models have been used to reduce the number of variables affecting this process. Various animal models have demonstrated that regulation of acid secretion and oxyntic mucosal growth are interwoven and animal models have provided detailed knowledge regarding the role of hypoacidity as well as hormones and signal substances in gastric carcinogenesis. In this report, we briefly review findings from animal studies on the role of gastric hypoacidity and hypergastrinaemia in gastric carcinogenesis.

### GASTRIN AND THE GASTRIN RECEPTOR

Gastrin, which stimulates gastric acid secretion, was the second hormone to be postulated to exist<sup>[12]</sup>. The release of gastrin from G cells is inhibited by hydrochloric acid. Gastrin exerts its effect on the CCK-B receptor, which was first localised in the brain<sup>[13]</sup>, but later found to be identical to the gastric gastrin receptor<sup>[14]</sup>. Gastrin regulates gastric acid secretion through a cellular sequence in which gastrin stimulates ECL cells to secrete histamine, which in turn stimulates secretion of hydrochloric acid from parietal cells<sup>[15,16]</sup>. However, parietal cells have also been reported to express gastrin receptors<sup>[17,18]</sup> and whether or not these are functional has been debated. Very high concentrations of gastrin potentiates histamine-stimulated acid secretion from isolated parietal cells<sup>[19]</sup>, suggesting the existence of a functional gastrin receptor on parietal cells. However,

fluorescein-labeled CCK-8 binds to rat ECL cells, but not to parietal cells<sup>[20]</sup>, and gastrin does not stimulate acid secretion in either histidine decarboxylase (HDC)-deficient<sup>[21]</sup> or H2 receptor-deficient<sup>[22]</sup> mice. Altogether, this implies the physiological effect of gastrin is fully mediated by histamine secreted by the ECL cell and that only the gastrin receptors on ECL cells are of physiological importance. These observations are also relevant to understanding the trophic and carcinogenic effects of gastrin on the oxyntic mucosa.

## GASTRIC HYPOACIDITY, HYPERGASTRINEMIA AND GASTRIC NEOPLASIA

Gastrin was shown early to have a general trophic effect on the oxyntic mucosa<sup>[23]</sup>. In 1985 it was first published that rats develop ECL cell carcinoids after lifelong inhibition of gastric acid secretion by administration of the long-acting insurmountable histamine 2 receptor antagonist loxidine<sup>[24]</sup>. At the time, it was speculated whether this effect was specific for one drug, but the following year it was found that life-long administration of the proton pump inhibitor omeprazole also caused hyperplasia of the oxyntic mucosa and carcinoids in rats<sup>[25]</sup>. Even the short-acting histamine 2 receptor antagonist ranitidine was later shown to cause ECL cell carcinoids in 19 of 100 rats after 2-year of administration, and these animals showed a 3-fold increase in plasma gastrin<sup>[26]</sup>.

Short-term administration of omeprazole (400  $\mu\text{mol/kg}$ ) to rats caused a 15-fold increase in plasma gastrin as well as hyperplasia of the oxyntic mucosa<sup>[27-29]</sup>. The ECL cell density was tripled after 10 wk, whereas the total oxyntic mucosal thickness increased 20%<sup>[28]</sup>.

Hypoacidity and hypergastrinaemia are closely related in the normal state, but the effects of each factor can be studied separately in several animal models. Infusion of gastrin has been mentioned and is feasible for short-term proliferation studies in which the specific proliferative effect on ECL cells has been documented<sup>[30-32]</sup>.

Low pH in the antrum inhibits gastrin release, and, by removal of a large proportion of the oxyntic mucosa by partial corpectomy, the antral pH is raised and gastrin release is stimulated. Rats develop carcinoids in the remaining 25% of the oxyntic mucosa<sup>[33]</sup> demonstrating that acid-inhibiting drugs per se do not cause neoplasia, but antral hypoacidity and subsequent hypergastrinaemia. Furthermore, oral administration of ciprofibrate, which is a peroxisome proliferator and a hypolipidemic compound, induces hypergastrinemia and carcinoid formation after 2 years in rats<sup>[34]</sup>. Ciprofibrate does not cause gastric hypoacidity<sup>[35]</sup>, but induces hypergastrinemia through a direct effect on the antral G cell<sup>[36]</sup>. Altogether, there is evidence that hypergastrinaemia induced by either method, whether accompanied by gastric hypoacidity or not, causes ECL cell carcinoids in rats.

After carcinoid development due to hypergastrinemia was demonstrated in the rat, similar experiments were performed in mice to examine possible species differences. Administration of loxidine to mice at various doses for

2 year induced carcinoid tumors of the gastric corpus<sup>[37]</sup>, whereas long-term studies with proton pump inhibitors in mice have been inconclusive, as mice require much higher doses of proton pump inhibitors than rats to maintain a high gastric pH<sup>[38]</sup>.

Transgenic (INS-GAS) mice over-express gastrin and have a 4-fold increase in plasma gastrin at age 6 mo, which leads to an increased gastric acid secretion<sup>[39]</sup>. In this animal model it is possible to study the effects of hypergastrinemia without gastric hypoacidity, mimicking human gastrinomas. Young INS-GAS mice have an increased ECL cell number and a proportion of these mice develop adenocarcinomas in the gastric corpus at the end of their lifespan<sup>[39]</sup>. Inoculation with *Helicobacter felis* increases gastrin levels 7-fold and accelerates carcinogenesis considerably<sup>[39]</sup>, but mice without *Helicobacter* infections also develop carcinomas, demonstrating that carcinogenesis does not depend on infection and inflammation. The reason why INS-GAS mice develop malignancy in the oxyntic mucosa with an adenocarcinoma phenotype, whereas mice and rats develop ECL cell carcinoids after long-term acid inhibition or ciprofibrate administration, is not known. A synergistic inhibitory effect of gastrin and histamine receptor antagonists on hypergastrinemia-driven carcinogenesis has been found in INS-GAS mice<sup>[40]</sup>, suggesting a role for both gastrin and histamine, but leaves questions regarding the cellular location of the histamine 2 receptor, and thus, the cellular origin of the adenocarcinomas. It has been found *H. pylori* lipopolysaccharides stimulate ECL cell proliferation and secretion in the rat<sup>[41]</sup>, supporting a concept of synergism of gastrin and *H. pylori* infection on ECL cell growth.

INS-GAS mice have been inoculated with a *H. pylori* strain and only inoculated males developed gastric cancer, whereas serum gastrin concentrations did not differ between the sexes<sup>[42]</sup>.

HDC-deficient mice show gastric hypoacidity and a threefold increase in plasma gastrin levels<sup>[21]</sup>. This model has been mainly used for studying acid secretion, and long-term studies examining the possible carcinogenic effects of hypergastrinemia in the absence of histamine have not been published to date. However, in animals aged 8 to 12 wk there was no difference in mucosal thickness<sup>[21]</sup>.

Another genetically modified mouse model is H<sup>+</sup>K<sup>+</sup>ATPase beta subunit-deficient mice. These mice are anacidic, show a 7-fold increase in serum gastrin levels and hyperplasia in the oxyntic mucosa<sup>[43,44]</sup>. H<sup>+</sup>K<sup>+</sup>ATPase-deficient mice have been followed for up to 14 wk only, and changes in the gastric mucosa in old mice have not been published. Gastrin and H<sup>+</sup>K<sup>+</sup>ATPase double knock-out mice are anacidic without gastrin and do not develop hypertrophic changes in the oxyntic mucosa, demonstrating that gastrin is responsible for these changes<sup>[43]</sup>.

Gastrin-deficient mice show no basal acid secretion<sup>[45]</sup> and provide a model for studying the effect of gastric hypoacidity without hypergastrinemia. Gastrin-deficient mice develop antral adenocarcinomas<sup>[46]</sup> through a mechanism that must be different from carcinogenesis in the oxyntic mucosa in hypoacidic and hypergastrinemic mice. The development of carcinomas in the absence of gastrin is attributed to bacterial overgrowth and subsequent formation

of carcinogenic substances<sup>[47,48]</sup>. However, gastric hypoacidity is also found in H<sup>+</sup>K<sup>+</sup>ATPase-deficient mice which do not develop antral carcinomas (Fossmark R *et al* unpublished observations) and it is possible the lack of gastrin itself induces the carcinomas.

## GROWTH PROMOTION MEDIATED BY ECL CELLS

In the oxyntic mucosa, only ECL cells have gastrin receptors shown to have a functional role in mucosal growth regulation. Several studies mentioned have described the trophic effects of gastrin on the oxyntic mucosa, and the trophic effect on the ECL cell in particular, but less is known about the further mediation of the gastrin effect. It has been shown administration of gastrin has a proliferative effect in the neck region of the oxyntic glands<sup>[49]</sup>, where stem cells are located. However, it has not been possible to settle whether this proliferative effect is a direct effect or mediated by growth factors released by ECL cells<sup>[50]</sup>. Several ECL cell products have been suggested to stimulate growth of the oxyntic mucosa, either on parietal cells, stem cells or ECL cells themselves.

Histamine was the first ECL cell product to be identified and has been suggested to have a trophic effect<sup>[50]</sup>, but the effects of histamine are not fully understood. Histamine has been shown to stimulate proliferation of gastric cancer cell lines<sup>[51]</sup>, but the histamine 1 receptor antagonist astemizole has an additional trophic effect when administered to rats with omeprazole-induced hypergastrinemia<sup>[52]</sup>. Histamine 2 receptor-deficient mice are hypergastrinemic and develop hypertrophy of the oxyntic mucosa<sup>[22]</sup>, supporting previous studies suggesting the mediation of histamine's trophic effect does not involve the H2 receptor<sup>[53]</sup>. However, in histamine decarboxylase-deficient mice there was no difference in parietal and ECL cell numbers compared with controls, in animals aged 8 to 12 wk, and no increase in oxyntic mucosal thickness<sup>[21]</sup>, indicating an important role for histamine as a mediator of hypergastrinemia-driven mucosal growth.

The regenerating gene (Reg) cDNA was first isolated from regenerating pancreatic islets in rats and its human homologue was named RegI alpha<sup>[54]</sup>, but Reg protein is also expressed in ECL cells<sup>[55]</sup>. Gastrin stimulates Reg protein expression in ECL cells, and Reg protein is mitogenic to gastric mucosal cells<sup>[56]</sup>, suggesting Reg protein is involved in gastrin-induced gastric mucosal cell growth. Reg expression is also increased in healing gastric mucosa<sup>[57]</sup>. Reg protein receptors are found on parietal cells and chief cells in the lower part of the corpus glands<sup>[58]</sup>. A recent study using INS-GAS mice has found expression of Reg1 is controlled through separate promoter elements by gastrin and *Helicobacter*<sup>[59]</sup>, implying that these factors affect carcinogenesis through Reg protein. RegI alpha protein is also found in 35% of human gastric adenocarcinomas, particularly in those that are less well differentiated<sup>[60]</sup>, and Reg protein expression is associated with higher proliferation rates in early gastric cancers<sup>[61]</sup>. Altogether, this makes Reg protein a strong candidate for mediating the general trophic effects of gastrin on the oxyntic mucosa.

## OTHER ANIMAL MODELS OF HYPOACIDITY AND HYPERGASTRINEMIA IN GASTRIC CARCINOGENESIS

A strain of Japanese cotton rats develops spontaneous carcinomas in the oxyntic mucosa with a marked female predominance<sup>[62]</sup>. Animals developing carcinomas have gastric hypoacidity of an unknown cause and secondary hypergastrinemia<sup>[63]</sup>. The tumors develop from an oxyntic mucosa with marked hyperplasia of chromogranin A, synaptophysin and HDC-immunoreactive cells, and a proportion of the tumor cells are chromogranin A-, pancreastatin-, HDC- and Sevier-Munger-positive<sup>[63-66]</sup>. Carcinomas develop after 4 mo of hypergastrinemia, but are prevented by the gastrin receptor antagonist YF486<sup>[64]</sup>, demonstrating gastrin is essential in carcinoma development in cotton rats. Carcinomas can also be induced in male cotton rats by administration of the histamine 2 receptor antagonist loxidine<sup>[67]</sup>, as well as by partial corpectomy<sup>[68]</sup>, two different methods of inducing pronounced hypergastrinemia. It has also been found ECL cells in hypergastrinemic animals gradually lose ultrastructural characteristics as well as chromogranin A and pancreastatin immunoreactivity<sup>[66]</sup> suggesting ECL cells dedifferentiate during long-term stimulation by gastrin. The cotton rat model is important as it demonstrates tumors with an adenocarcinoma phenotype, but with neuroendocrine differentiation, are induced by gastric hypoacidity and hypergastrinemia and develop through dedifferentiation of ECL cells.

In the African rodent *Mastomys*, multicentric gastric carcinoids frequently develop in the oxyntic mucosa of a proportion of aging animals. Serum gastrin levels in *Mastomys* developing tumors is normal<sup>[69]</sup> and the development of spontaneous ECL cell tumors is most likely related to a gastrin receptor mutant which shows ligand-independent activity; that is, the receptor is constitutively activated<sup>[70]</sup>. However, endogenous gastrin is involved in the growth of ECL cell carcinoids in *Mastomys* as the development of these tumors is significantly enhanced by loxidine-induced hypoacidity and hypergastrinemia<sup>[71,72]</sup> and carcinoid development is inhibited by a gastrin receptor antagonist<sup>[73]</sup>. There is no sex-difference in the occurrence of such tumors. The development of carcinoids in *Mastomys* is prevented by a somatostatin analogue<sup>[74]</sup>.

Mongolian gerbils inoculated with *H. pylori* are used extensively in research on *H. pylori*-related gastric carcinogenesis. In the context of this paper, Mongolian gerbils are interesting as they become hypergastrinemic in response to *H. pylori* infection and develop mainly ECL cell carcinoids, but also gastric adenocarcinomas<sup>[75,76]</sup>. Inoculated animals show a five to ten-fold rise in serum gastrin, increasing with time after inoculation<sup>[77]</sup>. An increasing proportion of the gerbils develop ECL cell hyperplasia and carcinoids from 12 to 24 mo after inoculation<sup>[76]</sup>. Atrophic gastritis and focal intestinal metaplasia and dysplasia also appear 6 mo after inoculation, and premalignant changes can be reversed after *H. pylori* eradication<sup>[78]</sup>. Hypergastrinemia in *H. pylori*-infected animals is associated with increased Reg gene expression, and both plasma gastrin and Reg mRNA levels are normalized after *H. pylori* eradication<sup>[79]</sup>.

Finally, the possibility of species differences in relation to carcinoid development after long-term administration of acid inhibitors has also been studied in dogs. Beagle dogs were given omeprazole daily for 7 years, but there were no changes in the gastric mucosa at termination and there were specifically no increases in ECL cell numbers<sup>[80]</sup>. However, dogs receiving omeprazole had fasting and meal-stimulated plasma gastrin levels at the same level as controls, and changes in the oxyntic mucosa should therefore not be expected.

## CONCLUSION

Animal models can provide valuable information about risk factors for gastric cancer as the models allow a high degree of intervention when introducing or eliminating factors possibly affecting carcinogenesis. The various animal models of gastric hypoacidity and hypergastrinemia provide evidence hypergastrinemia is a common causative factor in many otherwise diverse settings. In all species where sufficient hypoacidity and hypergastrinemia has been induced, a proportion of the animals develop neoplastic lesions. Bearing in mind that gastrin acts on gastrin receptors located on ECL cells, which are stimulated to secretion and proliferation, we find it obvious ECL cells have a pivotal role in the gastric carcinogenesis associated with hypergastrinemia. Findings in Japanese cotton rats and Mongolian gerbils in particular suggest carcinoids and adenocarcinomas develop through a similar mechanism, and derive from ECL cells. Hypergastrinemia induces gastric neoplasia whether accompanied by gastric hypoacidity or not, and experiments using the above-mentioned models could explain why carcinoids develop in some situations, whereas tumors with an adenocarcinoma phenotype develop in other models.

## Abstract

Hepatocellular carcinoma (HCC) is an important cause of cancer death in the world. It has great regional differences in the pathology and epidemiology. The variation is greatly influenced by the aetiologies of the disease. Hepatitis B and C infection are the most important risk factors. HCC incidence rates are higher but in decreasing trend in developing countries. However, the figures in the developed countries are contrary. Successful hepatitis B virus (HBV) vaccination programs, better food hygiene, increased global hepatitis C virus (HCV) prevalence and population migration are the possible explanations. A number of clinical and pathogenic differences exist between HBV- and HCV-related HCC. HBV infection leads to the development of HCC through direct and indirect pathways as it has the ability to integrate into the host genome affecting cellular signaling and growth control. HCV causes HCC mainly through indirect pathways: chronic inflammation, cell deaths and proliferation. As a result, HCC is almost exclusively found in cirrhotic HCV patients while HCC is sometimes found in HBV patients without significant liver cirrhosis. Due to the different severities of liver cirrhosis and HCC extent, therapeutic strategies from resection, liver transplantation to symptoms palliation are available. Poorly differentiated histology, lack of fibrous capsule, large tumour size, early vascular invasion and elevated serum levels of alpha fetoprotein (AFP) are the features for more aggressive disease. Combined with markers of liver reserve and performance status, accurate scoring systems and models have been developed to predict patients' survival and match best treatment option.

**Key words:** Natural history; Hepatitis; Hepatocellular carcinoma

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the third most common cause of cancer death in the world. It results in 598 000 deaths per year worldwide. Because of its poor prognosis, this number of deaths is almost the same as the number of cases being diagnosed each year (626 000)<sup>[1]</sup>. From a global perspective, the two most important risk factors for HCC are chronic hepatitis B and C infection. The geographic distribution patterns of HCC and hepatitis B virus (HBV) almost coincide with each other. The characteristics of patients with HCC are influenced by the etiology and the status of the underlying liver disease. The understanding of its natural history may influence the prognosis and choice of treatment.

## HISTORY OF HCC

HCC was believed to be a rare disease in the early 1900s. In Germany, Eggel found only 163 cases of HCC autopsies when he surveyed the world literature for HCC. He proposed an anatomical classification that HCC was classified as nodular, massive and diffuse<sup>[2]</sup>. However, it was found that the disease was more prevalent outside Europe. In 1911, Yamagiwa suggested a classification based on the origin of the cancer cell, hepatocellular and cholangiocellular, with the terminology of "hepatoma" and "cholangioma" respectively. After Berman's report of the extremely high HCC incidence among young Mozambican males in 1951, the interest in the studies of HCC increased. It has been shown that there is great regional difference in the pathology and epidemiology of the condition.

## DIFFERENT HCC PATTERNS

HCCs in South Africa are mostly large sized and poorly

differentiated with relatively healthy surrounding liver tissues. On the contrary, HCCs in non-African countries are relatively smaller in size and more differentiated with a background of cirrhotic liver. This can be the result of the difference in aetiologies. Aflatoxin B1, a mycotoxin produced by *Aspergillus* species, is believed to be a major carcinogenic factor in the South African population. Chronic hepatitis and the resultant cirrhosis are believed to be important risk factors in non-Africans. The distinct fibrolamellar type of HCC almost exclusively found in young Caucasian patients may be due to ethnic factor.

## HCC INCIDENCE

Liver cancer incidence rate varies widely from 52.1 per 100 000 in China to 5.1 per 100 000 in Northern Europe. Developing countries contribute more than 80% of cases with China alone accounting for 55%<sup>[1]</sup>. Other areas with high incidences are sub-Saharan Africa, eastern and southeastern Asia, and Melanesia. In the past decades, liver cancer incidence has decreased in some areas with high incidence in the past such as Shanghai, Singapore and Hong Kong. However, the opposite was reported in some of the countries in Europe, North America and Oceania. It is believed that effective HBV vaccination programmes and the better control of aflatoxin exposure in the high HCC incidence areas are contributing to the decreased HCC incidence while the increasing HCC incidence in some of the western countries is attributed to the increasing prevalence of hepatitis C virus (HCV) infection and immigration of people from countries with high endemicity for HBV infection.

## RISK FACTORS FOR HCC

The main established risk factors for HCC development are chronic viral hepatitis B and C infection and aflatoxin B1. Liver cirrhosis *per se* may also lead to HCC development. Hepatitis C infection probably causes HCC through the pathway of cirrhosis. Alcoholic liver disease, autoimmune liver diseases, primary hemochromatosis and Wilson's disease are also associated with the development of HCC. Overall, hepatitis B and C infections are causally associated with over 80% of HCC in the world<sup>[3]</sup>.

Worldwide, there are 400 million people infected with chronic hepatitis B, seventy five percent of whom are Asians. The natural history of chronic hepatitis B infection in Asian and African countries is different from that in the western world. In Asia and Africa, the majority of the people acquire the infection during the perinatal period or during very early childhood. There is a characteristically prolonged immune tolerance phase in the first few decades of life. The HBV viral loads are high and the liver transaminases are nearly normal. The lifetime risk of HCC in infected men is estimated to be 10% to 25% while the risk in women is somewhat lower<sup>[3]</sup>. Case-control studies have shown that chronic HBV carriers have more than 100-fold increased risk of HCC compared with non-infected individuals. Furthermore, the risk of HCC development is related to

the disease status of chronic hepatitis B infection. For example, the estimated annual risk of HCC in chronic carriers is 0.26% to 0.6%. The risk increases to 1% in patients with active hepatitis<sup>[4]</sup>. It further increases to 2% to 3% in cirrhotic patients. Certain viral status also poses a higher risk of HCC. Studies in Taiwan showed that genotype C chronic hepatitis B infection has a more aggressive progression than genotype B in HBeAg-positive patients<sup>[5]</sup>. Core promoter mutations (T1762/A1764) are also found to be related to a more progressive disease<sup>[6]</sup>. In the majority of HCC cases (70% to 90%) there is underlying liver cirrhosis. However, HBV, being an oncogenic virus, can cause HCC in the absence of cirrhosis through the pathway of integration into the human genome.

## HBV CARCINOGENESIS

As with many malignancies, the carcinogenesis of HCC is a multi-step process involving a number of different genetic alterations that ultimately lead to malignant transformation of the hepatocyte. It is postulated that HBV infection causes HCC *via* direct and indirect pathways. Continuous hepatocyte injury and regeneration in cirrhosis of the liver leads to increased liver cell turnover and hence accumulation of critical mutations in the host genome. This may result in genetic alterations, such as chromosomal rearrangements as well as activation of cellular oncogenes or inactivation of tumour suppressor genes. However a higher rate of chromosomal abnormalities is found in HBV-related HCC than those linked to other risk factors<sup>[7,8]</sup>. Alternative mechanisms in HBV carcinogenesis must also be involved. HBV belongs to the group of oncogenic viruses known as hepadna virus. It is able to integrate its DNA into the genome of the infected cell. Integrated HBV sequences have been observed in established hepatoma cell lines and in about 80% of human HBV related HCCs<sup>[9]</sup>. It is postulated that the HBV DNA integration may confer a selective growth advantage on target cells and leads to the onset of tumor progression. The integration sites are frequently detected in cellular genes involving cell signaling or growth control. Host chromosomal instability is also enhanced by HBV DNA integration. Large inverted duplications, deletions, amplification, chromosomal translocation have all been observed to be associated with HBV integration. In addition, the regulatory proteins HBx and the PreS2 activators can exert a tumor promoter-like function, resulting in positive selection of cells producing a functional regulatory protein.

## HCV CARCINOGENESIS

HCV infection is a more important factor than HBV in the development of HCC in western countries. Markers of HCV infection are found in a higher proportion of HCC patients than that in most of the Asian countries; ranging from 44% to 66% in Italy, 27% to 58% in France, 60% to 75% in Spain<sup>[10]</sup>. Japan, unlike other Asian countries, also has a high proportion of HCC caused by HCV infection accounting for 80% to 90% of all the cases<sup>[10]</sup>.

HCC risk increases to 17-fold in HCV-infected patients compared with HCV-negative subjects<sup>[11]</sup>. The risk of HCC occurrence is different among all HCV patients. It is a function of the degree of liver fibrosis and the time of acquisition of the infection. The risk for cirrhotic HCV patients (F4) was the highest with 5.8% per year, compared to those who had less fibrosis (F1-3, 0.5% to 2.6%)<sup>[12]</sup>.

Because of the absence of reverse transcription activity of the HCV RNA virus, its viral genome unlike HBV is not able to integrate into the genome of the infected cell. Therefore, HCV causes HCC *via* an indirect pathway by causing chronic inflammation, cell death, proliferation and cirrhosis. Accordingly, HCV-related HCCs are almost exclusively found in patients with cirrhosis. However, there are studies raising the possibility that HCV may also operate through other pathways in promoting malignant transformation of hepatocytes. HCCs without cirrhosis in HCV-infected patients, though rare, have been reported. The transforming potential of NS3 protein and core protein has been described.

## CLINICAL DIFFERENCES BETWEEN HBV- AND HCV-RELATED HCC

Apart from the difference in the carcinogenic mechanisms, there are a number of clinical differences between HBV- and HCV-related HCC. For reasons yet to be known there is a larger proportion of male HBV infected patients with HCC than the HCV counterpart. The male-to-female ratio is higher in HBV-related HCC than in HCV-related HCC (6.7:1 and 3.3:1 respectively in one study)<sup>[13]</sup>. Studies consistently show that HCC develops 10 years earlier in HBV carriers than in HCV carriers, a difference possibly due to the earlier age at exposure to the causative agent<sup>[13,14]</sup>.

Due to the different mechanisms involved in carcinogenesis, their rate of HCC development is also different. In a Japanese study, 795 patients with viral or alcoholic cirrhosis were observed from 1974 to 1989. Two hundred and twenty five patients (27.8%) developed HCC. The cumulative rates of HCC development in the 180 HBV cirrhotic subgroup at 3, 5, 10 and 15 years after follow up were 7.2%, 14.2%, 27.2% and 27.2% respectively. At 9 years after the follow up, the rate of HCC development began to decrease, and the cumulative rate remained the same thereafter. The corresponding rates in HCV-related cirrhosis were 10.4%, 21.5%, 53.2% and 75.2% respectively in the 349 HCV patients. The authors conclude that the cumulative rate of HCC occurrence has a linear relationship with time in HCV patients whereas it seems to plateau after 10 years for HBV patients<sup>[15,16]</sup>. However, according to an Italian study, the cumulative rates of HCC at 5, 10 and 15 years continue to increase with 6.5%, 23.4% and 31.9% for patients with HBV-related cirrhosis, and 4.6%, 24% and 56.2% for patients with HCV-related cirrhosis, respectively<sup>[17]</sup>. At the time of HCC diagnosis, a higher proportion of HCV infected patients than HBV infected patients has advanced liver histology and has a higher Child Pugh's score<sup>[13]</sup>.

The HCC tumor size and the growth pattern also tend

to be different between HBV- and HCV-related HCCs. In most patients with HCV-related HCC, the tumors are more likely to be solitary, smaller sized and encapsulated whereas HBV-related HCC are more commonly infiltrative and multinodular<sup>[18]</sup>. Extensive hepatic involvement and portal vein invasion by the tumor were found in 44% and 52% respectively in 95 HBsAg-positive HCC patients compared to 25% and 28% respectively in 370 HBsAg-seronegative HCC patients<sup>[19]</sup>.

## NATURAL HISTORY OF HCC

The natural history of HCC depends on tumour growth characteristics as well as the underlying liver cirrhosis. The majority of hepatitis-related HCC develops in cirrhotic livers with a relatively poor liver reserve. Given a wide range of tumor doubling time, some patients may die from liver failure before the tumor grows to an advanced stage. Features of HCC shown to indicate more aggressive behaviour include poorly differentiated histology, lack of fibrous capsule, large tumour size, early vascular invasion and elevated serum levels of alpha fetoprotein (AFP). Tumor growth rates have a wide range of variability even among patients of the same region and regardless of disease stage. Doubling time ranges from 1 mo to 19 mo with a median of 4 to 6 mo<sup>[20]</sup>.

Vascular supply of HCC is derived from the hepatic arterial network and the efferent vessels of portal origin have been described to create arterioportal or arteriovenous shunts which serve as a low resistance path for tumour thrombi fragments to survive and spread within the portal efferent network. In a large autopsy study from Sweden, 56% of HCC had evidence of vascular invasion but biliary tract involvement was observed in only 4%<sup>[25]</sup>. In another autopsy study in Japan, vascular involvement was noted up to 82% and the likelihood of vascular involvement was related not only to tumor size but also the macroscopic types<sup>[26]</sup>. The frequency of portal vein invasion is higher than hepatic vein invasion<sup>[27]</sup>.

A retrospective analysis was performed in the United States of America on 347 HCC patients who received a metastatic workup including bone scans and computed tomography scans of the chest, abdomen, and pelvis. Clinical and tumor characteristics were evaluated as risk factors for metastasis by univariate and multivariate methods. One hundred forty-five patients had metastases: 72 had thoracic, 57 had abdominal, and 34 had bone metastases. Poor tumour differentiation, multilobular spread, and tumour size of 5 cm or more were the strongest predictors of metastatic disease by logistic regression analysis<sup>[28]</sup>. In a Japanese study, the relationship between HCC specimen staining for AFP, serum AFP levels and pathological findings were examined. The disease prognosis was studied with respect to the staining for AFP in excised tumors. The mean serum AFP level in patients with positive AFP staining was significantly higher than in those with negative AFP staining. No significant relationship was found between AFP positivity and tumor size, tumor encapsulation, degree of vascular invasion, or the histological differentiation grade of the tumor. However, patients with AFP-positive

carcinomas had a poorer prognosis than those with AFP-negative carcinomas (5-year survival rate of AFP-positive and negative groups were 26.7% and 56.5%, respectively)<sup>[29]</sup>.

## PREDICTION OF SURVIVAL

The prognosis of HCC has been dismal because patients with HCC usually present late and have already developed advanced liver cirrhosis. Curative resection was seldomly possible. Therefore, the life expectancies of patients with newly diagnosed HCC were classically measured in terms of weeks to months with mortality to incidence ratio close to 1. Due to the increased awareness of the disease and HCC surveillance programmes in some parts of the world, HCC can be diagnosed at its earlier phase permitting timely curative interventions. In a Hong Kong study<sup>[30]</sup>, the clinical features and disease outcome of 306 HCC patients were analysed. The characteristics of those present with symptoms and those with the disease diagnosed by screening were compared. One hundred and forty two patients with HCC diagnosed by regular screening have a significantly lower serum AFP level, smaller tumour size, less bilobar disease, less portal vein infiltration and less distant metastasis compared with the 164 symptomatic subjects. As a result a higher proportion of patients could undergo curative resection (26.8% *vs* 7.9%).

Scores and models for predicting survival probability are invaluable to tailor suitable treatment options. The traditional TNM cancer staging system has limited applicability as it does not take into account the possible poor liver function in HCC patients. Eighty percent of HCC patients cannot be treated with surgery, so the tumour pathologic information needed in TMN cancer staging is not available. This further limits its prognostic use. Child-Pugh score on the other hand was designed to predict survival in liver cirrhosis without any component of HCC tumour morphology and consideration of disease extension. The first widely accepted staging system to predict survival for HCC which incorporates tumour biology and hepatic function was proposed by Okuda *et al* in 1985<sup>[31]</sup>. Tumour size, serum bilirubin, albumin and the presence of ascites are included in the calculation of Okuda staging. In a Hong Kong study of 106 untreated unresectable HCC patients performed in 2001, the median survival was 5.1 mo in stage I, 2.7 mo in stage II and 1.0 mo in stage III. These figures were remarkably similar to the original report by Okuda, in which the median survival of stages I, II and III disease was 8.3, 2, and 0.7 mo respectively. Among other staging systems, only Okuda staging was independently correlated with prognosis in the final multivariate model. As more treatment options become available, newer prognostic models are introduced. The Cancer of the Liver Italian Group Programme (CLIP) proposed a staging system which has been shown to be superior to that of the Okuda stage with a higher number of categories and greater discriminant ability. It reveals a subgroup of patients with an impressively more favourable prognosis who could be candidates for more aggressive therapeutic strategies. On the other hand, it also sorts out a subset of patients with a median survival long enough to be considered for clinical trials of palliative

antineoplastic treatment. It includes Child-Pugh score, tumour size, presence of portal vein thrombosis, and serum AFP. Another survival model is the Barcelona Clinic Liver Group (BCLC) staging system which also effectively selects patients for aggressive treatments. It is constructed from several cohort studies and randomized controlled trials (RCTs) by the Barcelona group. This classification uses variables related to tumour stage, liver functional status, physical status, and cancer-related symptoms, and links the five stages described (0, A-D) with a treatment algorithm. The therapeutic approach configured into the BCLC staging system for patients with non-surgical HCC is based on the study by Llovet *et al* in which asymptomatic patients without evidence of disease extension (vascular invasion or metastasis) had significantly better survival compared to those with more advanced disease<sup>[28]</sup>. Such patients are classified as having intermediate HCC and may be better candidates for tumour ablative interventions or chemoembolization.

## HBV VACCINATION

HBV vaccination has been shown to be effective to protect against HBV infection. The vaccination is recommended to high risk population groups such as health care workers, patients with immunocompromised states or with chronic liver diseases or with the need for regular blood product transfusion or hemodialysis, and neonates of HBV carrier mothers. Vertical and early horizontal transmission is the major route of HBV transmission in high prevalent areas. The transmission rate was estimated to be as high as 90% in HBeAg positive mothers. The use of HBV vaccine and hepatitis B immunoglobulin (HBIG) can greatly reduce the infection rate of the neonates to 10% to 15%<sup>[33]</sup>. The use of vaccination in all newborns can reduce the chance of infection acquired *via* other routes during early childhood and thus preventing the prolonged immunotolerant phase of this unique infection. By eliminating HBV seroprevalence in the population, HCC incidence should be greatly reduced in high prevalence areas. In Taiwan, a universal HBV vaccination programme was carried out in 1984. A study had shown that the HCC incidence in children was decreased since the introduction of the vaccination programme<sup>[34]</sup>. In that study, the author showed that the annual incidence of childhood liver cancer was reduced from 0.70 per 100 000 to 0.36 per 100 000 in the children born between 1981 to 1986 and 1990 to 1994 respectively. Therefore a similar decrease in the adult HCC incidence is expected in the future. Likewise, vaccination programmes in high endemic areas like Gambia, intermediate endemic areas like Italy had shown impressive reduction of the HBV seroprevalence. This may transform to a reduction in HCC incidence similar to the Taiwan study. However, the development of an effective vaccine has been hampered by the high genetic variability of HCV.

## CONCLUSION

HCC is a complex neoplasm often occurring in a preneoplastic cirrhotic liver, and thus, survival and treatment options depend on variables of both HCC and cirrhosis.

Among chronic viral hepatitis-related HCC, differences in carcinogenesis and clinical presentation exist between HBV and HCV patients. Survival models using tumour size, invasiveness, liver function, patient physical performance status can predict prognosis and guide treatments.

### Abstract

The incidence of hepatocellular carcinoma (HCC) in patients with human immunodeficiency virus (HIV) is rising. HCC in HIV almost invariably occurs in the context of hepatitis C virus (HCV) or hepatitis B virus (HBV) co-infection and, on account of shared modes of transmission, this occurs in more than 33% and 10% of patients with HIV worldwide respectively. It has yet to be clearly established whether HIV directly accelerates HCC pathogenesis or whether the rising incidence is an epiphenomenon of the highly active antiretroviral therapy (HAART) era, wherein the increased longevity of patients with HIV allows long-term complications of viral hepatitis and cirrhosis to develop. Answering this question will have implications for HCC surveillance and the timing of HCV/HBV therapy, which in HIV co-infection presents unique challenges. Once HCC develops, there is growing evidence that HIV co-infection should not preclude conventional therapeutic strategies, including liver transplantation.

### INTRODUCTION

With the increased survival of human immunodeficiency virus (HIV) patients with access to highly active antiretroviral therapy (HAART), it is unsurprising that conditions with a typically long latency are now being observed more frequently. Hepatocellular carcinoma (HCC) is such a disease, usually occurring several decades after the initial infection with hepatitis C virus (HCV) or hepatitis B virus (HBV). While few suspect that HIV infection alone is a risk-factor for HCC (indeed, this has been excluded in large retrospective cohort studies<sup>[1]</sup>), associated infection with HCV or HBV is common and the significantly increased risk of HCC with viral hepatitis is well-documented. More is now known of the interaction between HIV and HBV and/or HCV over the long-term. Broadly speaking, HIV co-infection seems to accelerate disease progression and reduces the efficacy of anti-HCV and anti-HBV therapy. However, it is unclear whether HIV infection directly increases the likelihood of HCC in viral hepatitis.

Some other key questions are as follows:

What is the true prevalence of HIV and HBV and/or HCV co-infection worldwide?

How should HIV status affect screening and treatment for HCC?

How should HIV infection influence therapy for viral hepatitis?

Answering these questions is essential to planning effective strategies for the prevention, screening and treatment of HCC in HIV-positive patients in the future. Here we review recent attempts to address these challenges.

### THE WORLDWIDE AT-RISK POPULATION- WHAT IS THE TRUE PREVALENCE OF HIV AND VIRAL HEPATITIS CO-INFECTION?

HBV and HCV infection have distinct epidemiological and geographical profiles due to different modes of transmission. In broad terms, HCV transmission is predominantly due to intravenous drug use in Western societies and a mix of IV drug use and iatrogenic transmission in developing countries. These modes of transmission also apply to HBV but in endemic areas the primary route is through sexual contact and vertical transmission. HIV shares modes of transfection

Table 1 Examples of internationally diverse prevalences of HBV and HCV co-infection in HIV populations.

Country	Germany, Ockenga <i>et al</i> 1997 <sup>[45]</sup>	Greece, Dimitrakopoulos <i>et al</i> 2000 <sup>[45]</sup>	Thailand, Sungkanuparph <i>et al</i> 2004 <sup>[45]</sup>	TREAT Asia HIV Observational Database (TAHOD) <sup>[45]</sup>	Spain, Gonzalez-Garcia <i>et al</i> 2002 <sup>[45]</sup>	Australia, Lincoln <i>et al</i> <sup>[45]</sup>	Ivory coast, Rouet <i>et al</i> 2004 <sup>[45]</sup>
<i>n</i>	232	181	529	1498	2820	3309	501
HCV + ve	23%	13.80%	7.80%	10%	-88%	10.70%	1%
HBV + ve	9%	67.40%	8.70%	10%	-5%	4.80%	26%

with both diseases and therefore its geographical and demographic distribution encompasses that of both HBV and HCV. There are many exceptions to this broad rule, however. In the Far East, for example, the HCV burden is predominantly found in the elderly population and probably represents iatrogenic exposure from poorly sterilized medical equipment in the 1920s<sup>[1]</sup>. Rates of HIV co-infection are predictably low in this cohort.

Between HIV positive populations in different countries, relative proportions of HCV and HBV co-infection vary widely according to the prevalence of different high-risk behaviours in the populations tested. Examples of these diverse prevalences are given in Table 1.

Most of these studies are disadvantaged by a small sample size (especially in developing countries) or are limited to one particular at-risk group (e.g. haemophiliacs or IV drug users). Thus wide variation is often seen between studies in the same geographical region. For example, in Greece a recent study of 737 HIV infected individuals found a prevalence of 48.1% and 12.1% of HCV and HBV co-infection respectively<sup>[3]</sup>, a marked contrast to a study only 6 years earlier in the same country (13.8% and 67.4% respectively<sup>[4]</sup>).

The recorded prevalence is likely to be inaccurate for other reasons. Around 30% of HCV antibody-positive patients will have undetectable HCV RNA (i.e. have cleared the virus) and yet most studies of prevalence use the antibody test alone. Hepatitis B surface antigen (HBsAg) is almost universally used as a surrogate of HBV co-infection, yet there is growing recognition for a significant subset of patients who are HBsAg-negative but have detectable HBV DNA on quantitative PCR and/or positive anti-HB core antibodies. So-called "occult" hepatitis B infection is frequently detected in patients with HCV infection, HIV and HCC of non-HCV aetiology. The prevalence of occult HBV co-infection in HCV may be as high as 80% in HCV endemic areas such as Japan<sup>[4]</sup>. Occult HBV infection is also more common in HIV-positive than HIV negative patients in HBV endemic areas (22.1% vs 2.4%)<sup>[5]</sup>. This is especially relevant to studies of HCC in HIV infection, since occult HBV infection seems to maintain its oncogenic potential despite lower viral titres. In a recent Italian study, HBV DNA was detected in 68 of 107 cases of HBsAg-negative HCC (63.5%)<sup>[6]</sup> and occult HBV infection has been demonstrated in up to 70% of patients with HBsAg-negative HCC in Japan<sup>[7]</sup>.

It thus seems that larger prevalence studies using RNA and DNA titres are needed to achieve a more accurate estimate of the true burden of viral hepatitis in HIV, particularly in developing countries where the largest reservoirs of infection exist.

## HIV CO-INFECTION AND PROGRESSION TO HCC IN VIRAL HEPATITIS

### *The pathogenesis of HCC in viral hepatitis*

Up to 75% of cases of HCC worldwide are thought to be associated with hepatitis B or C<sup>[8]</sup>. While the continual inflammation and repair of cirrhosis is an important pathogenic factor in both diseases, the degree of viral replication is more closely related to HCC risk in HBV than in HCV infection. The risk of HCC in active chronic hepatitis B is some 90-fold greater than age-matched healthy controls but only 9-fold greater in inactive carriers of HBV where viral load is low. Also, viral titres seem to correlate directly with the risk of HCC in hepatitis B<sup>[9]</sup>.

In hepatitis C, the presence of cirrhosis is a prerequisite to the development of HCC, which occurs in between 1%-4% of patients per annum once cirrhosis is established. Indeed, the increased risk of HCC in cirrhotic patients persists in the absence of the virus after successful eradication with IFN therapy<sup>[10]</sup>.

These differences probably represent the different underlying pathogeneses of HCC in HBV *versus* HCV<sup>[11]</sup>. In the former, the random integration of viral DNA into the host chromosomes (an incidental process not necessary for viral replication) leads to secondary chromosomal rearrangement and genomic instability. The HBV DNA product protein HBx (crucial to replication) transactivates genes involved in cell-cycle control (c-jun and c-myc for example). *In vitro* HBx has been shown to disrupt cell-cycle control and inhibit DNA repair and apoptosis all of which have oncogenic potential in their own right<sup>[12]</sup>.

By contrast, the HCV does not integrate into host cell DNA. Some HCV core proteins do enter the nucleus and modify a variety of signal transduction pathways. Additionally, oxidative cellular injury occurs as a direct result of HCV core protein expression both *in vitro* and *in vivo*<sup>[13]</sup>. Although this may participate in the carcinogenic process to a small degree, the principal oncogenic effect of HCV is mediated indirectly through activation of the immune-mediated inflammation and its downstream effects on cell proliferation and apoptosis.

### *The incidence of HCC in the HIV positive cohort*

The 2001 French Mortavic study<sup>[14]</sup> was a prospective 1-year cohort study of 25 178 HIV positive patients across 65 national centres comparing the incidence and causes of death to similar cohorts in 1995 and 1997. Deaths from end-stage liver disease (ESLD) rose significantly from 1995 to 2001 (1.5% to 14.3%) and the proportion of those deaths due to HCC also rose 5-fold (4.7% to 25%). Nearly all deaths from HCC were in patients

with HCV co-infection. Deaths from AIDS during this period fell from 91.6% to 48.7% and overall mortality from 8.15% to 1.05%. The authors thus concluded that increased longevity in the HAART era is the principle reason for increased ESLD and HCC in the 2001 cohort. A large retrospective cohort study of US veterans (following 14018 male veterans from 1997 to 2004) has also confirmed a much higher risk of HCC in the HIV population, nearly exclusively in association with HCV (and to a lesser extent HBV) co-infection<sup>[15]</sup>. A third retrospective cohort-spanning the pre-HAART and HAART eras-revealed a much higher incidence of HCC in patients with HIV/HCV co-infection than average and the difference was much more marked in the HAART era (only 5 diagnosis of HCC were made in the entire cohort of 11678 patients in the pre-HAART era, *versus* 22 in the HAART era)<sup>[11]</sup>. Smaller, retrospective cohort studies in Europe have yielded similar results. One study of 2383 HIV positive patients found a higher-than-expected incidence of HCC (6 cases in total, four of which had HCV co-infection) compared with the population average<sup>[16]</sup>.

It is noteworthy that studies examining cohorts in the pre-HAART era or in countries where HAART is not readily available, have frequently found the incidence of HCC to be lower or equal to average population rates<sup>[17,18]</sup>. The more recent studies, however, proffer convincing evidence that HCC incidence is higher than the population average and rising amongst the HIV-positive population receiving HAART-nearly exclusively in association with HCV or HBV infection- and cite increased longevity as the principal cause of this phenomenon.

However, none of the above studies indicates that there is a higher incidence of HCC in HIV and viral hepatitis co-infection compared to isolated HCV or HBV infection- as one might expect if HIV accelerates the disease progression of viral hepatitis towards HCC.

### **HCC oncogenesis in viral hepatitis-is HIV a true additional risk factor?**

While the HIV virus itself is not considered to be particularly oncogenic in its own right, a number of cancers are well known to occur with increased frequency in people with HIV infection. For the most part this is a consequence of impaired immunity and failure to clear several common oncogenic viruses such as HHV8 in Kaposi sarcoma (KS), EBV in non-Hodgkin's (NHL) and HPV in anal and cervical cancer.

*In vivo* studies in murine models have revealed a potential role for the HIV Tat gene in liver tumorigenesis. Transgenic mice expressing this gene have a greater incidence of hepatocellular carcinoma. This is thought to be mediated by extra-hepatic growth signals rather than by direct disruption of the hepatocyte cell cycle by the Tat product and the effect is not specific for hepatocarcinoma; these animals suffer a higher incidence of other extra-hepatic tumours (leiomyosarcomas, squamous cell papillomas and carcinomas, adenocarcinomas of skin adnexa and B-cell lymphomas). In humans, however, large retrospective cohort studies in the HAART era have shown no increased incidence of HCC in HIV monoinfection<sup>[1]</sup>.

There is clearer evidence that HIV can accelerate disease progression of both HBV and HCV and thus indirectly increase the chance of subsequent HCC. HIV affects the natural history of HCV infection in two important ways: firstly, it increases the likelihood of chronic infection following the acute episode<sup>[19]</sup> and secondly, it hastens the development of cirrhosis once chronic infection is established<sup>[20,21]</sup>. This has important implications for the subsequent development of HCC and any screening strategy. HIV co-infection has also been shown to accelerate the progression of HBV infection<sup>[22]</sup>, with patients suffering from more severe disease at an earlier stage. Increased liver injury in viral hepatitis may also be mediated indirectly in HIV by antiretroviral therapy-related hepatotoxicity and by immune reconstitution syndrome. Indeed, HCV infection seems to increase the risk of HAART-related hepatotoxicity<sup>[23]</sup>. It must also be considered that once HCC has developed, a putatively weaker anti-tumour response due to chronically low CD4+ and CD8+ lymphocyte counts may result in more rapid growth and spread of disease.

Despite evidence for acceleration of cirrhosis in viral hepatitis with HIV co-infection, attempts to demonstrate a specific increase in HCC in this context-over and above that observed in HCV or HBV monoinfection- have so far yielded variable results.

In the US veterans studies mentioned above, direct comparisons were made between HCV mono-infected subjects and groups with HIV/HCV co-infection.

Mcguinnis *et al* (2001)<sup>[15]</sup> compared the incidence of HCC between 14018 HIV positive and 28036 age-, sex- and location-matched HIV-negative controls in a large retrospective cohort study from 1997 to 2004. A higher age-matched incidence of HCC was clearly demonstrated in the HIV positive group (incidence rate ratio 1.68) but when adjusted for HCV infection and/or alcohol consumption the incidence rate ratios were similar, suggesting HIV co-infection confers no additional risk of HCC compared to HCV infection alone.

A precursor of this study (another retrospective cohort of US veterans) compared the incidence of cirrhosis and HCC in 26641 HCV-only with 4761 HCV/HIV co-infected subjects between 1991 and 2000<sup>[24]</sup>. The incidence of HCC in both groups was found to be the same in the HAART era and lower in the HIV/HCV co-infection group in the pre-HAART era. This would corroborate the premise that HIV patients did not survive sufficiently long in the pre-HAART era to develop HCC, but also suggests that in the HAART era HIV status does not seem to alter the likelihood of progression to HCC in HCV infection.

These studies, however, are subject to several sources of error. In one retrospective cohort the authors concede that up to 50% of the apparent HCV-only group were never tested for HIV (which would bias the study towards the null) and it was also subject to changes in disease reporting and coding during the study period which may have lead to significant acquisition bias. More importantly, a recurring confounding factor is the rising incidence of cirrhosis (and therefore HCC) throughout the study period in patients with isolated HCV infection. This may reflect earlier acquisition of HCV in this group (often in

the 1970s in the US) compared to their HIV co-infected counterparts and highlights a recurring deficiency in such retrospective cohort studies: they rarely include data on when infection was acquired. Although HCC rates may be similar in HIV/HCV and HCV-only groups in the immediate post-HAART era, the HIV/HCV co-infected cohort may well have acquired HCV more recently and thus the equal incidence may actually belie accelerated disease progression in this group.

The 2004 Italian cooperative group on AIDS and Tumours (GICAT) study examined 41 cases of HCC in HIV positive individuals (from a joint Italian and Spanish database) and compared them with 384 HIV-negative controls diagnosed over the same period (1995-1998)<sup>[25]</sup>. This is the largest study purporting to show an acceleration of liver disease towards HCC in HIV and viral hepatitis co-infection. The HIV group with HCC were much younger at presentation (age 40-46 *vs* 60-70) and had more advanced infiltrating disease. There was also a trend to more advanced cirrhosis at presentation in the HIV positive population. Accordingly, few of the HIV patients were offered active treatment and survival rates were poor. Again, HCV co-infection was clearly the main risk factor in both the HIV positive group and negative controls. In this study, the younger age at diagnosis and the limited data available on the timing of HCV infection in both HIV co-infected and HCV-only groups suggested HIV-HCV co-infected patients develop HCC some 10 years earlier than expected (compared with a previous series examining HCC in HIV-negative patients with post-transfusion HCV).

Three further studies have also described earlier development of HCC (and poorer outcome) in HIV co-infected subjects compared with HBV or HCV mono-infection, including one cohort of British haemophilic men and boys<sup>[26]</sup>, one of homosexual men in the United States<sup>[27]</sup> and a Spanish retrospective cohort of 2383 HIV positive subjects<sup>[28]</sup>. The total numbers of cases of HCC in each study were very low, however.

Convincing evidence for an HIV-induced acceleration of disease progression in viral hepatitis towards HCC thus remains lacking. Of note is a glaring lack of studies specifically addressing HBV and HIV co-infection—presumably because this is far less prevalent than HCV/HIV co-infection in the developed countries which have the advanced information infrastructure needed to carry out retrospective trawls of large databases.

If one postulates the ideal study to address whether HIV is a true additional risk factor for HCC in viral hepatitis, it would consist of a prospective cohort of HIV/HCV/HBV co-infected and HCV- and/or HBV-only subjects with all subjects cross-tested for co-infection before allocation to groups (and at regular intervals thereafter). It would also instigate screening for HCC on a regular basis. It might be reasonable to expect that even if HIV has an accelerative effect on HCC pathogenesis this might be countered viral suppression by HAART, therefore such a study would undertake regular monitoring of HIV viral load in the HIV co-infected group. Crucially, if the duration of HIV and HBV/HCV infection is known for each patient, fewer patients and years of follow-up would be necessary to detect an accelerative affect of HIV

on progression to HCC.

It is telling that almost none of the studies mentioned above include any such parameters. On the basis of existing evidence, we can only conclude that if an additional risk of progression to HCC in viral hepatitis is conferred by HIV it is not large enough to be detected by relatively crude retrospective examination within the short space of time (relative to normal HCC pathogenesis) that has passed since the introduction of HAART.

## SCREENING, PREVENTION AND TREATMENT OF HCC IN HIV

### *Treatment and outcome of HIV patients with HCC*

In the HIV negative population, solitary or a small number of HCC lesions are resectable, and associated with a 5-year survival of 60%-70%<sup>[27]</sup>. In the presence of cirrhosis patients with operable lesions are offered transplantation resulting in equivalent survival data. Operability is determined by the Milan criteria (no evidence of extrahepatic tumour and unifocal tumour mass < 5 cm in diameter or multifocal tumours < 4 in number, each < 3 cm in diameter<sup>[29]</sup>), although some large-volume centres now adopt the more aggressive University of California, San Francisco (UCSF) criteria which have extended tumour burden limits with similar outcomes<sup>[30]</sup>. Ethanol injection is another treatment option for patients with local disease who are not candidates for surgery and is associated with 5-year survival rates of approximately 50%<sup>[31]</sup>. Patients with more advanced disease are limited to palliative embolization. No chemotherapy or targeted therapy has been shown to offer a survival benefit for these patients.

Data from other HIV positive non-AIDS defining cancers, such as lung cancer, suggest these patients are offered curative therapy less frequently than their HIV negative counterparts due to the advanced nature of their disease at presentation<sup>[32]</sup>. In the series described in the GICAT study<sup>[32]</sup> 15 of the 41 patients with HIV and HCC had disease within the Milan criteria that would be deemed curable with liver transplantation. However, none underwent liver transplantation and only two underwent surgical resection. Overall, HIV positive patients have a much worse outcome compared to their HIV negative counterparts with only a 28% 1 year survival.

Although HIV-positive status was previously an absolute contraindication to liver transplantation, this is now becoming more commonplace following several transplant series which have demonstrated similar survival outcomes in MELD-score matched HIV- positive and negative recipients<sup>[33-38]</sup>. There is no evidence, as previously feared, that the subsequent immunosuppressive therapy results in progression of HIV disease<sup>[39]</sup>.

There is now data specifically addressing liver transplants in HIV positive patients with HCC. Di Benedetto *et al* recently reported a series of 7 patients with HIV and HCC who fulfilled Milan criteria and underwent liver transplantation<sup>[40]</sup>. After a mean follow-up of 232 d, the overall patient and graft survival was 85.7%. One patient died of a myocardial infarction with a functioning graft and no evidence of HCC recurrence.

Liver transplant patients with HIV, for any indication, clearly face specific problems post-transplant compared with HIV negative counterparts. These include more aggressive HCV re-infection, more common lamivudine resistance in HBV and a higher incidence of tacrolimus toxicity<sup>[41]</sup>. However, where an increased mortality has been observed it is frequently cited that late referral plays a role<sup>[42]</sup>. A greater proportion of HIV-positive patients seem to die on the waiting list for liver transplantation from liver-related causes. Two conclusions can therefore be drawn: firstly, patients with HIV and HCC should not be denied the opportunity for liver transplantation and secondly, detecting these cancers early is of paramount importance.

### **Preventative therapy in HIV and HBV/HCV co-infected patients**

Patients with HIV-HCV co-infection benefit from HCV eradication for the same reasons as those with HCV alone. Sustained virological response rates (SVR) of between 27%-40% have been achieved with IFN and ribavirin therapy in HIV co-infected patients<sup>[43]</sup>. Not only is the risk of HCC reduced with HCV eradication but the resulting enhanced liver function increases tolerance to antiretroviral agents. Treatment of the HIV-HCV patient presents several challenges however, such as (1) more severe and frequent IFN related myelosuppression, (2) more frequent haemolytic anaemias caused by ribavirin interaction with zidovudine, (3) antagonism of zidovudine phosphorylation (4) increased risk of lactic acidosis. Most significantly, patients with low CD4+ counts respond very poorly to HCV eradication therapy<sup>[44]</sup>.

In HIV-HBV infection, there is every reason to suspect the risk of progression to HCC can be reduced by viral suppression just as it is in mono-infected HBV cases. Given that HAART and HBV suppression regimens share many common agents (lamivudine, for example) the principal problem encountered in this group is cross-resistance. Dual therapy for effective HBV suppression is frequently required (e.g. lamivudine plus tenofovir) but, as in HCV coinfection, response rates are poor in patients with low CD4+ counts.

Although anti-viral therapy in HIV and HBV and/or HCV is more complex and generates more potential adverse events, if early hepatological expertise is sought then the vast majority of patients should have the option of potentially curative therapy in HCV and effective long-term viral suppression in HBV.

### **Screening for HCC in patients with hepatitis and HIV co-infection**

The European association for study of the liver (EASL) has released guidelines for screening HIV and HCV/HBV co-infected individuals. These are similar to HCV and HBV mono-infected patients with established cirrhosis and recommend screening every 6 mo with ultrasonography and alpha-fetoprotein levels. In the United States suggested screening of co-infected individuals incorporates the use of ultrasound as the primary screening modality. They suggest AFP should not be used alone unless

ultrasonography is unavailable; screening should occur at 6-12 mo intervals and should include all those at elevated risk for HCC<sup>[32,38]</sup>.

In our unit we currently do screen co-infected individuals with both  $\alpha$ -fetoprotein (AFP) and ultrasound scans if the AFP is raised. This has not been validated and early unpublished results suggest these may be problems with sensitivity and specificity of AFP in this setting, especially as HAART can cause an increase in AFP levels<sup>[41]</sup>. Anecdotally our programme has revealed a low sensitivity and specificity. This may in part be due to patient selection and the potentially rapid development of the disease. More frequent imaging surveillance in very high-risk groups (such as those with persistently high HBV titres, for example) may prove to be the way forward. Data in this setting is urgently required.

## **CONCLUSION**

Retrospective cohort studies warn us that an increase in HCC in the HIV population is already underway in regions where HAART therapy is available. Increased access to HAART can be expected to have similar consequences in developing countries but the timing of this increase will be difficult to predict. Insufficient epidemiological data on HIV and HBV/HCV co-infection (especially in the developing countries which are most affected) makes the at-risk population very difficult to locate and quantify. Because the latency of HCC in HIV co-infection may be shorter than in isolated viral hepatitis, there may be less time than we might expect to prepare adequate screening, prevention and treatment services.

Such services are currently far from optimal. A recent US study of HIV clinic management of HBV co-infection found that HBV viral load was inadequately monitored in HIV co-infected patients despite regular measurements of HIV titres<sup>[45]</sup>. Other guidelines for HBV management were loosely adhered to. The applicability of current HCC screening techniques in viral hepatitis mono-infection remains untested in the context of HIV co-infection, and once HCC is diagnosed, patients are referred for potentially effective treatment less frequently and much later than their HIV-negative counterparts.

Although guidelines now exist on the management of viral hepatitis and HIV co-infection, there will always be unique scenarios not covered by these that present both opportunities (e.g. anti-viral cross-efficacy) and pitfalls (e.g. cross-resistance). As the HAART era takes us into uncharted waters, holding to the optimum course through prevention, screening and therapy for HCC will require both HIV physician and hepatologist at the helm.

### Abstract

Hepatocellular carcinoma (HCC) is the sixth most common cancer in the world. The majority of patients with HCC present with unresectable disease. These patients have historically had limited treatment options secondary to HCC demonstrating chemoresistance to the currently available systemic therapies. Additionally, normal liver parenchyma has shown intolerance to tumoricidal radiation doses, limiting the use of external beam radiation. Because of these limitations, novel percutaneous liver-directed therapies have emerged. The targeted infusion of radioactive microspheres (radioembolization) represents one such therapy. Radioembolization is a minimally invasive transcatheter therapy through which radioactive microspheres are infused into the hepatic arteries that supply tumor. Once infused, these microspheres traverse the hepatic vascular plexus and selectively implant within the tumor arterioles. Embedded within the arterioles, the  $^{90}\text{Y}$  impregnated microspheres emit high energy and low penetrating radiation doses selectively to the tumor. Radioembolization has recently shown promise for the treatment of patients with unresectable HCC. The objective of this review article is to highlight two

currently available radioembolic devices ( $^{90}\text{Y}$ ,  $^{188}\text{Re}$ ) and provide the reader with a recent review of the literature.

### INTRODUCTION

Hepatocellular carcinoma (HCC) claims half a million lives across the globe each year<sup>[1]</sup>. It is the sixth most common cancer in the world and is the third most common cause of cancer-related mortality<sup>[2]</sup>. Various etiologic factors have been implicated in the transformation of benign hepatic parenchyma to malignancy, however, no one factor has been shown to cause cancer in all cases. Although several postulates for tumorigenesis have been proposed, the exact underlying mechanism for neoplastic change remains unknown<sup>[1,3]</sup>.

The incidence of HCC varies considerably across geographic regions with some areas reporting cases as high as 20/100 000 per annum<sup>[3]</sup>. Various studies have shown that advanced age and male sex portends a higher likelihood of developing HCC. Several important risk factors have been identified which substantially increase the possibility of developing disease. Among these, the most common risk factor recognized worldwide is the hepatitis B carrier state. Others inciting factors include chronic hepatitis C infection, cirrhosis, environmental toxins such as aflatoxin and contaminated drinking water, alcohol abuse, diabetes mellitus, and hereditary hemochromatosis.

In patients diagnosed with this lethal malignancy, less than 15% are candidates for surgical procedures. A survival

benefit has been observed in patients that meet the rigorous criteria for curative resection or transplantation<sup>[4]</sup>. For the remaining majority, various treatments options have become available without universal agreement on which treatment option offers the greatest survival benefit with the least toxicity.

The use of external beam irradiation has historically played a limited role in the treatment of HCC due to the radiosensitive nature of normal hepatic tissue<sup>[5]</sup>. Investigators have shown that liver exposure to radiation doses greater than 40 Gy may result in a clinical syndrome characterized by ascites, anicteric hepatomegaly, and elevated liver enzymes weeks to months following therapy<sup>[5,6]</sup>. Additionally, a condition recognized as veno-occlusive disease, marked by central venous congestion and atrophy of adjacent hepatocytes, may develop. Together, the clinical and pathologic spectrum described above has been referred to as radiation induced liver disease (RILD) or radiation hepatitis. This is the most prominent treatment related complication in patients undergoing hepatic irradiation from external sources<sup>[7]</sup>.

Given this limitation and the need for higher doses to inflict lethal injury to malignant tissue<sup>[8-10]</sup>, minimally invasive intra-arterial devices have emerged. These devices, loaded with radioactive Yttrium-90 microspheres or Rhenium-188, can deliver very high tumoricidal doses without the development of RILD<sup>[11]</sup>. Using segmental infusion techniques, doses as high as 4993 Gy to liver tissue have been reported<sup>[12]</sup>. Although the use of these devices dates back to the early 1960's, only recently has the therapeutic safety and efficacy associated with its use been realized<sup>[13,14]</sup>. For the purpose of this review, we aim to highlight the use of intra-arterial radiotherapy for the treatment of inoperable HCC and update the reader on recent clinical and research advancements.

## DEVICE AND DOSIMETRY CONSIDERATIONS

Yttrium-90 intra-arterial radiotherapy, also known as radioembolization, is a minimally invasive catheter-based therapy that delivers internal radiation via the arterial vessels that feed tumors. "Radio" refers to the radiation that is imparted to tissue; "embolization" refers to the microembolic effect<sup>[15]</sup>. This technology takes advantage of the dual blood supply to the liver. Normal hepatic tissue derives greater than 70% of its blood supply by way of the portal system whereas malignant tissue is preferentially supplied by the arterial system. There are currently two commercially available Yttrium-90 microsphere devices. TheraSphere<sup>®</sup> (MDS Nordion, Ottawa, Ontario, Canada) is made of glass and SIR-Spheres<sup>®</sup> (Sirtex Medical, Sydney, Australia) is made of resin. These two devices are different in a number of important respects<sup>[16]</sup>. TheraSphere<sup>®</sup> is a minimally embolic device consisting of 20-30 micron particles with higher specific activity (2500 Bq) and lower number of spheres (1.2 million microspheres/3 GBq). Conversely, SIR-Spheres<sup>®</sup> are moderately embolic, consisting of 20-60 micron particles, with lower specific activity (50 Bq), and greater

number of spheres (approximately 40-80 million spheres/3 GBq). A third agent, available in certain countries, uses a Rhenium-188 based radioconjugate delivered in a trans-arterial manner analogous to the Yttrium-90 based devices<sup>[14]</sup>.

### <sup>90</sup>Y Glass microspheres

<sup>90</sup>Y microspheres (TheraSphere<sup>®</sup>, MDS Nordion, Ottawa, Canada) are composed of nonbiodegradable glass microspheres ranging from 20 to 30  $\mu\text{m}$  in diameter, in which <sup>90</sup>Y is an integral constituent of the glass. <sup>90</sup>Y is a pure  $\beta$ -emitter with a physical half-life of 64.2 h, after which <sup>90</sup>Y decays into stable zirconium. The average energy of  $\beta$ -emission is 0.9367 MeV, mean tissue penetration of 2.5 mm and a maximum penetration of 10 mm. One gigabecquerel (27 mCi) of <sup>90</sup>Y per kilogram of tissue provides a dose of 50 Gy. The microspheres are supplied in 0.5 mL of sterile, pyrogen-free water contained in a 0.3-mL V-bottom vial secured within a 12-mm clear acrylic shield. The specific activity is 2500 Bq at the time of calibration.

The typical method of calculating the required activity level (in GBq) to be injected and the actual dose delivered to the liver and lung has been previously published. CT or MR imaging is used to determine the targeted liver volume to be treated with <sup>90</sup>Y microspheres<sup>[17-19]</sup>. The targeted liver volume is that portion of liver tissue that will be perfused once the catheter is in the desired location. A conversion factor of 1.03 g/cm<sup>3</sup> is used to calculate the corresponding targeted liver mass from the targeted liver volume. The required activity is calculated from the following formula:

$$\text{Activity (GBq)} = [\text{target dose (Gy)} \times \text{target liver mass (kg)}] / 50$$

When lung shunt fraction (LSF) and percentage of residual activity (R) in the vial after treatment are taken into account, the actual dose delivered to the target mass is calculated by rearranging the previous equation as follows:

$$\text{Dose (Gy)} = [\text{Infused activity (GBq)} \times 50 \times (1 - \text{LSF}) \times (1 - R)] / \text{liver mass (kg)}$$

Cumulative liver dose is defined as the accumulated dose to that specific volume that was treated multiple times. By targeting delivery to a hepatic segment or lobe, <sup>90</sup>Y therapy results in high radiation doses to the tumor while sparing liver parenchyma. These tumoricidal doses have proven effective in the ability of <sup>90</sup>Y microspheres to reduce tumor viability, demonstrating an increasing therapeutic effect with radiation dose<sup>[11]</sup>.

### <sup>90</sup>Y Resin microspheres

SIR-Spheres<sup>®</sup> consist of biodegradable resin-based microspheres containing <sup>90</sup>Y. The average size of a sphere is 35 microns in diameter. Upon *in vivo* administration, the spheres are permanently implanted. Each vial contains 3 GBq of <sup>90</sup>Y in a 5 mL vial. Each vial contains 40-80 million spheres. The activity per microsphere is 50 Bq at the time of calibration.

The radioactivity to the liver can be calculated by one of two methods:

(1) The first method allows the calculation be based on body surface area to determine an approximate tumor burden:

$$\text{Activity (GBq)} = \text{body surface area (m}^2\text{)} - 0.2 + (\% \text{ tumor burden} / 100)$$

(2) Based on a broad estimate of tumor burden which then requires the user to increase the recommended activity by 0.5 GBq per 25% increase in tumor burden.

Activity for tumor involvement < 25%, 25%-50% and > 50% are 2.0 GBq, 2.5 GBq and 3.0 GBq, respectively.

Using either dosimetry model, activity administered is decreased depending on the extent of identified lung shunt. Also, recent clinical practices have shown that an additional 25%-30% activity reduction is usually necessary for SIR-Spheres<sup>®</sup>[20]. The dosimetry model for SIR-Spheres<sup>®</sup> is based on whole liver infusion. If a lobar administration is intended, the activity to be administered should be calculated using whole liver volume and then corrected for the target volume anticipated for treatment. As an example, if a right lobe infusion is anticipated, the calculated GBq should be multiplied by the percentage of right lobe as a proportion to the entire liver. Dosimetric issues and technical considerations have been described in detail previously<sup>[16,20,21]</sup>.

### Rhenium-188 radioconjugate

This is available through the use of a Rhenium-188 generator. The half-life of Rhenium-188 is 16.9 h. The isotope delivers high-energy beta (2.1 MeV max) and a low energy gamma (155 keV) emissions, permitting imaging. Usually, this radioconjugate is in the form of Rhenium-188 4-hexadecyl 1, 2, 9, 9-tetramethyl-4, 7-diaza-1, 10-decaethanol labeled with iodized oil. Dosimetry is based on the safe and tolerable dose to organs at risk including the liver, lungs and bone. A small scout dose of the radioconjugate (3.7 MBq) is administered on the day prior to treatment. Subsequently, transmission scans with a Rhenium-188 flood source are performed to determine the attenuation correction factors for lung and liver to be used in the dosimetric calculations the following day. Anterior and posterior images are obtained to calculate geometric mean counts. After correcting for scatter, regions of interest are placed around the whole liver, tumor and lungs. Using medical internal radiation dosimetry and by adjusting for the difference in total body and organ masses between the patient and the anthropomorphic model, the proper activity required is calculated using the following dose limitations: 12 Gy to the lungs, 30 Gy to the normal liver, 1.5 Gy to the bone marrow.

### Absolute and relative contraindications

Two absolute contraindications exist for the use of <sup>90</sup>Y microsphere treatment in any patient. The first includes a pretreatment <sup>99m</sup>Tc macro-aggregated albumin (MAA) scan demonstrating significant hepatopulmonary shunting that would result in > 30 Gy being delivered to the lungs with a single infusion or as much as 50 Gy for multiple infusions. The second includes the inability to prevent deposition of microspheres to the gastrointestinal tract with modern catheter techniques. A number of relative contraindications exist including non-compromised pulmonary function, adequate liver reserve, serum creatinine < 2.0 mg/dL, and a platelet count > 75 × 10<sup>9</sup>/L. For relative contraindications, clinical judgment should be exercised when determining whether a patient is appropriate to undergo this procedure.

### Observed toxicities

The most common clinical toxicity observed with the use of <sup>90</sup>Y is a mild post-embolic syndrome. This syndrome, unlike that observed with other embolic treatments such as transarterial chemoembolization (TACE), includes fatigue, vague abdominal discomfort, pain, and fever<sup>[11,22,23]</sup>. Other avoidable toxicities that occur as a result of non-target radiation include: cholecystitis, gastric ulceration, gastroduodenitis, pancreatitis, radiation pneumonitis, and RILD<sup>[16,24-27]</sup>. With meticulous planning, careful selection, and proper technique, the majority of these toxicities can be mitigated. Finally, hematologic toxicities seen in the immediate post-procedural period include lymphopenia. This is not an unexpected finding given the sensitivity of lymphocytes to radiation. Despite this, no infectious complications have been documented<sup>[16,21,28]</sup>.

### LITERATURE REVIEW

A comprehensive literature review was completed in 2006 describing the entire clinical and scientific evidence for <sup>90</sup>Y in detail<sup>[13]</sup>. Since then, additional evidence has been generated<sup>[16]</sup>. A consensus panel report from the radioembolization brachytherapy oncology consortium concluded that there is sufficient evidence to support the safe and effective use of this loco-regional therapy in HCC patients<sup>[20]</sup>. The authors further suggested the need to investigate the benefits of <sup>90</sup>Y in combination with other traditional therapies. The results from phase I and II studies in combining <sup>90</sup>Y with targeted therapies (Raf-kinase, EGFR) for HCC are underway and should provide valuable insight into the toxicity and efficacy of such regimens.

Sangro *et al* reported on 24 HCC patients with Child-Pugh A disease who underwent radioembolization with resin microspheres<sup>[29]</sup>. The median activity delivered was 2.2 GBq. The investigators reported a reduction in size of target lesions in 19 patients. Using RECIST criteria, 88% of the cohort had either partial response or stable disease. The authors did not observe any post-embolization syndrome and all patients were discharged within 24 h of treatment. Two patients became jaundiced at 1 mo and 3 mo after the procedure from uncertain causes. Two treatment-related deaths were recorded. At median follow-up of 12.5 mo none of the treated patients progressed. Given the tumor response and minimal toxicity profile, the investigators concluded that radioembolization is a viable therapy for patients with portal vein thrombosis and preserved liver function and that this therapy needs to be considered in patients who are awaiting transplant in order to prevent extension of disease beyond the Milan criteria.

Rivera *et al* presented a case report of a 42 years old hepatitis C cirrhotic male with tumor recurrence 22 mo post-transplantation<sup>[30]</sup>. The investigators in the study then treated the patient with <sup>90</sup>Y resin microspheres. The author noted no change in liver function post-procedurally and follow-up MRI demonstrated the absence of arterial enhancement and tumor necrosis. The authors concluded the use of <sup>90</sup>Y for post-transplant recurrence may help prolong patient and graft survival in patients that develop recurrence.

Gulec *et al* retrospectively analyzed the data from a heterogeneous cohort of 40 patients with primary and

metastatic liver malignancies who underwent single whole liver treatments using <sup>90</sup>Y resin microspheres<sup>[31]</sup>. The average administered activity was 1.2 GBq and tumor absorbed doses ranged from 40.1 to 494.8 Gy. Sixty-seven percent of the treated cohort responded to therapy with favorable responses reported in those with higher tumor flow ratios. The authors concluded that doses up to 100 Gy to the uninvolved liver were tolerated by this procedure without the development of veno-occlusive disease or liver failure. The authors further noted that lowest tumor dose necessary to generate a detectable response was 40 Gy.

Kamel *et al* reported on 13 patients prospectively treated with <sup>90</sup>Y glass microspheres. MR imaging was compared 24 h pre-treatment to an average follow-up of 55 d post-therapy<sup>[32]</sup>. Targeted tumors demonstrated a mean decrease in arterial enhancement of 22%, a mean decrease in venous enhancement of 25% and unchanged tumor size in both targeted and non-targeted tumors. The authors reported a median survival of 12 mo from time of diagnosis and emphasized the need for surrogate imaging measures such as diffusion-weighted MR in order to assess response.

Keppke *et al* reported on the imaging findings and median survival of 42 patients using <sup>90</sup>Y glass microspheres<sup>[33]</sup>. The response rates according to WHO, RECIST, necrosis and combined criteria (RECIST and necrosis) were 26%, 23%, 57% and 59%, respectively. The median survival for Okuda I patients was 660 d. The authors concluded that the imaging findings, using a combined criteria (size and necrosis), resulted in a more accurate assessment of tumor response after <sup>90</sup>Y radiotherapy when compared to size criteria alone.

In an attempt to address the question of retreatment using this therapy, Young *et al* recently reported on the relationship between cumulative radiation dose and the development of liver toxicities in 41 patients stratified to Okuda I and II<sup>[34]</sup>. The authors observed a statistically significant mean cumulative radiation dose of 390 Gy and 196 Gy tolerated by Okuda I and Okuda II patients, respectively, before the occurrences of toxicity. This suggests that some patients can tolerate multiple treatments prior to the development of liver toxicities. Median survival from date of first treatment for Okuda I and Okuda II were 660 d and 431 d, respectively ( $P = 0.44$ ).

More recently, Kulik *et al* reported on 21 patients from a large database of 251 patients who had undergone <sup>90</sup>Y glass microsphere therapy and subsequently bridged to transplantation<sup>[35]</sup>. Target tumor dose administered was 120 Gy with toxicities including fatigue in the majority of patients (42%). The authors reported a mean reduction in alpha fetoprotein (AFP) of 33% from pre-treatment levels. The investigators noted complete necrosis by pathologic exam in 14 of 21 patients (66%). Four of 21 patients had disease recurrence with a mean time to recurrence of 250 d, a finding not uncommon following transplantation<sup>[36-38]</sup>. The authors concluded that treatment with <sup>90</sup>Y achieves complete necrosis in the majority of targeted lesions in patients bridged to transplantation, but that recurrence was a possibility despite the radiographic findings of complete necrosis.

Additionally, Kulik *et al* reported on the safety of <sup>90</sup>Y in a 108 patient cohort treated with glass microspheres, with

subset analysis comparing patients with and without portal vein thrombosis<sup>[39]</sup>. Thirty-seven of 108 patients presented with imaging proven portal vein thrombosis (PVT). Patients were stratified by Okuda, Child Pugh, baseline bilirubin, ECOG, presence of cirrhosis and location of PVT (none, branch, and main). The cumulative dose administered to those with and without PVT were 139.7 Gy and 131.9 Gy, respectively. Liver related adverse events reported included elevation of bilirubin in 40%, ascites in 18%, and hepatic encephalopathy in 4% of the patients with cirrhosis and main PVT. In the patients without cirrhosis, elevated bilirubin occurred in 4%, ascites in 4% and no cases of encephalopathy. Tumor response using WHO criteria and EASL recommendations were 42.2 and 70%, respectively<sup>[40]</sup>. Median survival from the date of first treatment for patients without PVT and cirrhosis was 813 d. In patients with branch PVT, survival was 304 d from time of treatment (cirrhotics: 261 d, non-cirrhotics: 427 d). The authors concluded that the microembolic effect of <sup>90</sup>Y microspheres did not increase the risk of liver adverse events in patients with proven PVT. Glass microspheres did not result in a microembolic effect that is seen with other loco-regional therapies using larger diameter particles.

Investigators also studied the use of Rhenium-188 for patients with inoperable HCC<sup>[41]</sup>. A multicenter clinical trial was completed looking at Rhenium-188 (Rh-188) lipiodol delivered in a transarterial manner. After complete clinical evaluation (including serum alpha-fetoprotein (AFP), tumor burden, patency of portal vein, Child-Pugh and Okuda classification), radiation absorbed dose (rad) to various organs, including tumor, was calculated after injecting 185 MBq of Rh-188 iodized oil *via* the hepatic artery. From this value, the maximum tolerable activity, defined as the amount of radioactivity delivering no more than 12 Gy of rad to lungs, 30 Gy to normal liver, or 1.5 Gy to bone marrow, was calculated and injected. Ninety-three patients were successfully treated with a mean age of 53 years (80 men and 13 women). Mean cumulative dose was 7.8 GBq. Sixty-eight percent of patients had serologic evidence of hepatitis B and/or C; 40% had clinical/radiologic evidence of cirrhosis. Mean tumor diameter was  $10.3 \pm 4.4$  cm, with 40% of patients having more than three lesions; in 50% of patients, tumor was either unilateral, occupying 50% or more of the liver, or bilateral. AFP was elevated in 68% of patients and serum levels exceeding 300 ng/mL was observed in 44% of these patients. There was portal vein thrombosis in 38% of patients, Child-Pugh B disease in 37% of patients, and Okuda stage II or III disease in 50% of patients. Mean first administered activity was  $5.3 \text{ GBq} \pm 1.6$ , which delivered 88 Gy to the tumor. Treatment was tolerated well. Five patients had complete tumor response, while 17 had a partial response ( $> 50\%$  tumor reduction) for an overall objective response rate of 33%. Thirty-five percent of patients had stable disease. Only dose to the tumor was found to be significantly ( $P = 0.001$ ) associated with tumor and/or AFP response. Median survival for the entire cohort was 356 d and varied accordingly with baseline characteristics. Responders by imaging survived longer than those that did not exhibit a response and interestingly was correlated with dose administered to tumor. The

authors concluded that this was a safe, effective, and promising therapy in patients with HCC with favorable cost-benefit profile.

## CONCLUSION

Clinical investigations into the use of  $^{90}\text{Y}$  radioembolization for the palliative treatment of unresectable hepatocellular carcinoma appear promising. This therapy potentially offers survival benefit with a low toxicity profile, making it an attractive tool in the battle against a uniformly fatal disease. Unlike external beam therapy, radioembolization can deliver high cumulative radiation doses to targeted hepatic segments without the clinical manifestation of RILD. Additionally, investigators have shown favorable survival outcomes in patients with limited hepatic reserve and portal vein thrombosis. These patients were previously excluded from most therapeutic options. Furthermore, this therapy has successfully been used to bridge and downstage patients to resection, ablation or transplantation<sup>[29,41-44]</sup>. Although phase II paradigms have provided useful data, there is a need to carry out randomized controlled trials comparing  $^{90}\text{Y}$  therapy to those accepted as standard of care for this patient population. These studies will then establish the role of radioembolization within the framework of other universally accepted first line therapies for inoperable disease. Finally, the development of targeted therapies at the molecular level represents the beginning of a new era in the treatment of HCC<sup>[45]</sup>. Clinical investigations into combining the cytotoxic effect of  $^{90}\text{Y}$  with the cytostatic mechanism of targeted therapies are currently in progress and will provide valuable safety and toxicity data that may translate into improved clinical outcome and overall survival.

## Abstract

Primary liver cancer is the fifth most common malignancy in the world and is a leading cause of cancer-related mortality. Available treatment for hepatocellular carcinoma (HCC), the commonest primary liver cancer, is rarely curative and there is a need to develop therapy that is more effective. Specific and powerful gene silencing that can be achieved by activating RNA interference (RNAi) has generated enthusiasm for exploiting this pathway for HCC therapy. Many studies have been carried out with the aim of silencing HCC-related cellular oncogenes or the hepatocarcinogenic hepatitis B virus (HBV) and hepatitis C virus (HCV). Proof of principle studies have demonstrated promising results, and an early clinical trial assessing RNAi-based HBV therapy is currently in progress. Although the data augur well, there are several significant hurdles that need to be overcome before the goal of RNAi-based therapy for HCC is realized. Particularly important are the efficient and safe delivery of RNAi effectors to target malignant tissue and the limitation of unintended harmful non-specific effects.
