**CONCLUSION:** Using univariate analysis, predictive factors for overall survival were international prognostic index (IPI) score, hemoglobin level, erythrocyte sedimentation rate (ESR), and platelet numbers ( $P < 0.005$ ). In addition to this, Cox proportion hazard model differentiate IPI score, ESR, and platelets as predictors of survival.

Primary gastric mucosa associated lymphoid tissue lymphoma: Clinical data predicted treatment outcome. *World J Gastroenterol* 2008; 14(15): 2388-2393 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2388.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2388>

### Abstract

**AIM:** To determine clinical characteristics and treatment outcome of gastric lymphoma after chemotherapy and immuno-chemotherapy.

**METHODS:** Thirty four patients with primary gastric mucosa associated lymphoid tissue (MALT) lymphoma (Ann Arbor stages I to IV) were enrolled. All had upper gastric endoscopy, abdominal ultrasonography, CT and *H pylori* status assessment (histology and serology). After anti-*H pylori* treatment and initial chemotherapy, patients were re-examined every 4 mo.

**RESULTS:** Histological regression of the lymphoma was complete in 22/34 (64.7%) and partial in 9 (26.5%) patients. Median follow up time for these 31 responders was 60 mo (range 48-120). No regression was noted in 3 patients. Among the 25 (73.5%) *H pylori* positive patients, the eradication rate was 100%.

### INTRODUCTION

Gastric low grade B cell lymphomas arising from mucosa associated lymphoid tissue (MALT) are the most frequent lymphomas among those located in the primary digestive tract. Approximately 40% of all non-Hodgkin's lymphomas occur in extranodal locations. The majority is of the diffuse large B cell type, but extranodal marginal zone B cell lymphoma of MALT is the commonest extranodal small B cell non-Hodgkin's lymphoma. Approximately 37% of extranodal lymphomas occur in the gastrointestinal tract and esophagus. The most common site is the stomach (23% of extranodal lymphomas) followed by the small intestine (7.5%) and the colorectum (5.5%). The initiating step in the pathogenesis of MALT lymphoma at all sites is the acquisition of organized lymphoid tissue. This will have the characteristic features of MALT with a germinal centre, mantle and marginal zone, plasma cell differentiation, and an associated T cell component. B cells may infiltrate epithelial structures, if present, to mimic a lymphoepithelium similar to that

seen in native MALT in Peyer's patches<sup>[1]</sup>. The B cells of MALT lymphoma share the immunophenotype of reactive marginal zone B cells (CD20+, CD21+, CD35+, IgM+, and IgD-)<sup>[2]</sup>. The analysis of the rearranged variable region of the immunoglobulin heavy chain gene by means of polymerase chain reaction (PCR) shows a monoclonal proliferation of neoplastic B cells<sup>[3]</sup>.

Gastric MALT lymphoma seems to develop along 2 major molecular pathways that emerge from the oncogenic inflammatory milieu of the stomach, one dependent on the presence of t (11; 18) and the other associated with a methylator-prone phenotype (CIMP). Four disparate chromosomal translocations are associated with extranodal MALT lymphoma, including t (11; 18) (q21; q21), t (1; 14) (p22; q32), t (14; 18) (q32; q21), and t (3; 14) (p14; q32)<sup>[4]</sup>. They most frequently affect the *MALT1* gene, including both the t (11; 18) (q21; q21) and t (14; 18) (q32; q21), and interestingly, are mutually exclusive cytogenetic events. However, 3 of the translocations appear to involve a common pathogenic mechanism, leading to constitutive activation of NF- $\kappa$ B signaling. It has been reported that lymphomas responding to *H pylori* therapy are t (11; 18) negative<sup>[5]</sup>, thus this translocation may be associated with more advanced disease. In the majority of cases in the stomach (but not all) the stimulus for acquisition of MALT is *H pylori* infection. Indeed, *H pylori* provides the antigenic stimulus which is mediated by mucosal T cells for sustaining growth of gastric MALT lymphoma. *H pylori* tumor cells show somatic hypermutation in the immunoglobulin genes that are characteristic of antigen selection<sup>[6]</sup>. MALT lymphoma cells resemble memory B cells still responsive to differentiation signals, such as CD40 costimulation and cytokines produced by antigen-stimulated helper T cells, and dependent for their growth on stimulation by *H pylori*-specific T cells. Thus, *H pylori* stimulation of lymphoma B cells is not direct, but occurs through tumor-infiltrating T cells, involving both CD40 and CD40L costimulatory molecules. The surface immunoglobulin on gastric MALT lymphoma B cells does not recognize *H pylori*, but instead recognizes various autoantigens, suggesting that malignant cells are transformed from autoreactive B cells. Initially, MALT lymphoma is sustained by *H pylori*-induced T cell help, remains localized, and subsequently regresses<sup>[7]</sup>. Since the first cases of gastric lymphoma (GL) regression after such eradication were reported in 1993, various remission rates of 41%-100% have been published for several low grade GL series<sup>[8]</sup>.

In contrast to primary gastric NHL, secondary involvement of the GI tract by nodal NHL, which occurs in 20% to 60% of newly diagnosed cases, reflects disseminated disease that necessitates systemic treatment strategies<sup>[9,10]</sup>. Studies analyzing the incidence of secondary gastric NHL revealed a great discrepancy between the frequencies of GI involvement diagnosed before treatment as opposed to postmortem findings. The aim of this study was, therefore, to determine, in consecutive patients with gastric MALT lymphoma, the predictive factors of lymphoma regression in concordance with the course of the disease.

## MATERIALS AND METHODS

### **Patients and diagnostic criteria**

From July, 1997 to September, 2003, thirty four patients with primary gastric MALT lymphomas were enrolled in the study. Informed consent was obtained from all patients and the study was approved by the local Ethics Scientific Committee.

All patients underwent baseline endoscopy and gastric mucosal biopsies of the stomach. Lymphomas were staged clinically by the Ann Arbor system modified by Musshoff and Schmidt-Vollmer and by Rohatiner<sup>[11,12]</sup>. Staging procedures included recording of the patients' physical examination, ileocolonoscopy, together with upper gastrointestinal tract endoscopy, small bowel and chest radiography, abdominal computed tomography (CT) scan, Waldeyer's ring examination with endoscopy and biopsies or CT scan, and bone marrow biopsy.

The histopathological diagnosis was based on the REAL classification. Histological specimens were stained with hematoxylin eosin (HE) and Giemsa (Figure 1). Immunohistochemical analyses (Dako, Glostrup, Denmark) were performed on all paraffin embedded biopsies, and MALT lymphoma cells, like marginal zone B lymphocytes, had phenotypic profile: CD20+, CD21+, CD35+, IgM+, CD5-, CD10-, IgD-, BCL-10+ (Figure 2).

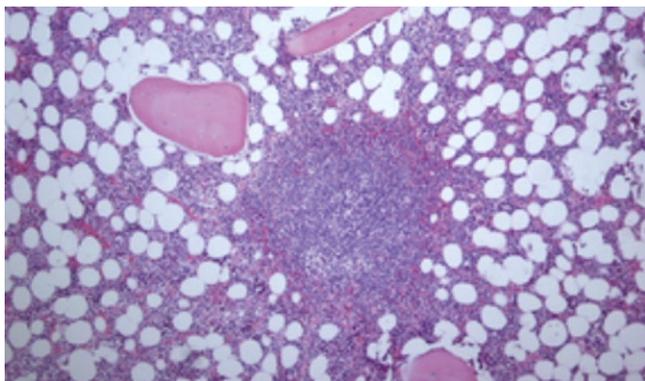

All patients had HIV negative status (detected by ELISA testing-Axym, Abbott, USA, and Vitros, Ortho USA). *H pylori* was systematically looked for using the Giemsa stain method. Also, for culture, tissue biopsies were grounded, plated on three media (two selective and one non-selective), and incubated in a microaerobic atmosphere at 37°C for 7-10 d. *H pylori* was identified on the basis of positive oxidase, catalase, and urease tests.

### **Treatment**

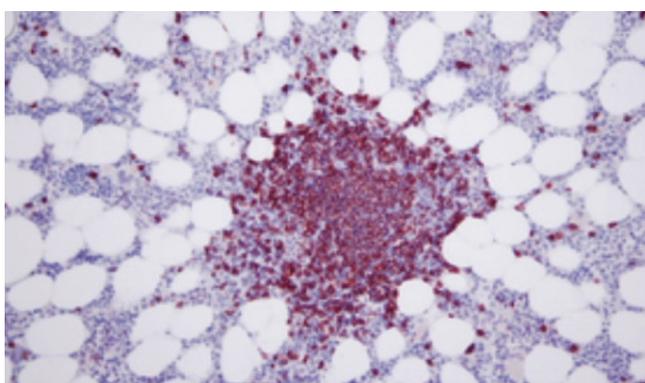

All patients with gastric MALT lymphoma received poly- or monochemotherapy (Cyclophosphamide, Doxorubicine, Vincristine, Prednisolone-CHOP; Chlorambucil, Vincristine, Procarbazine, Prednisolone-LOPP; or Chlorambucil) or combined immuno-chemotherapy (Rituximab-CHOP) as the first line treatment. Four patients were operated (subtotal gastrectomy). Patients who were *H pylori* positive, received triple anti-*H pylori* treatment combined with chemotherapy or immuno-chemotherapy as first line management.

### **Statistical analysis**

Overall survival was calculated from the date of diagnosis until death or last follow-up. The actuarial survival curves were estimated using the Kaplan-Meier method. Student *t*-test was used to evaluate the difference in the values of clinical parameters. The log-rank test evaluated association between overall survival (OS) and clinical characteristics. The use of the Cox proportional hazards model determined independent prognostic factors which influenced OS, while logistic regression detected prognostic factors overall survival significant for outcome.

**Figure 2** Immunohistochemistry of CD20 antigen expression in bone marrow biopsy (× 200). Nodal lymphoid BM infiltration with CD20+ in lymphoma cells.

## RESULTS

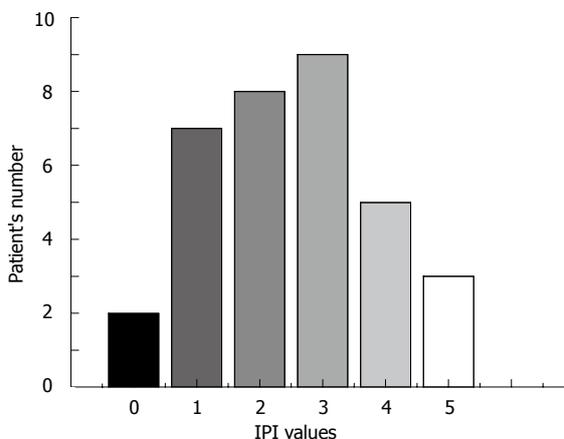

A total of 34 (18 male, 16 female, median age 62 years, range 34-82 years) patients with gastric MALT lymphoma were included in the study. Median follow up was 72 mo (range 48-120). Accordingly to clinical stage (Table 1), all patients were treated with chemotherapy (23/34 i.e. 67.6%), monochemotherapy only in patients with IE2 clinical stage, or immunochemotherapy (11/34 i.e. 34.4%). The reason for giving chemotherapy or immunochemotherapy to all patients as first line treatment was the BCL-10 positivity of all patients with clinical stage I + II. There were no differences in outcome of patients between the groups with mono and polychemotherapy. Also, all patients who were *H pylori* positive (25/34 i.e. 73.5%) received on d 0, the same anti-*H pylori* treatment for 14 d: 40 mg Omeprazole twice daily, 1 g amoxicillin twice daily, and 500 mg Clarithromycin twice daily. The first endoscopy follow up examination was performed 30 d after the end of treatment to check both the effectiveness of *H pylori* eradication, as assessed by histology, tissue culture, and PCR, and the absence of macroscopic tumor progression. Those patients with persistent *H pylori* were tested for susceptibility to Metronidazole and given a second line treatment. Patients with stable and progressive disease, and one patient with partial remission were operated (subtotal gastrectomy)

**Table 1** Modified Ann-Arbor clinical staging system

Clinical stage		Number of patients (n)
I E1	Mucosa + submucosa	0
I E2	Muscularis propria + subserosa	8
II E1	Perigastric lymph nodes	2
II E2	Regional lymph nodes	8
III E	Lymph nodes on both sides of the diaphragm	4
IV E	Visceral metastases or second extranodal site	12

**Table 2** Clinical data and response to treatment

Clinical characteristics	n (%)
Dominant site of gastric lesion	
Fundus	10 (29.4)
Corpus	18 (53.0)
Antrum	4 (17.6)
Anemia (Hb < 110 g/L)	21 (61.7)
Thrombocytopenia (PLT < 100 × 10 <sup>9</sup> /L)	9 (26.5)
Elevated ESR (> 10/1 h)	16 (47.1)
Bone marrow infiltration	8 (23.5)
Constitutional "B" symptoms	28 (82.4)
Answer to therapy	
Complete remission	22 (64.7)
Partial remission	9 (26.5)
Stable disease	1 (2.9)
Progressive disease	2 (5.9)

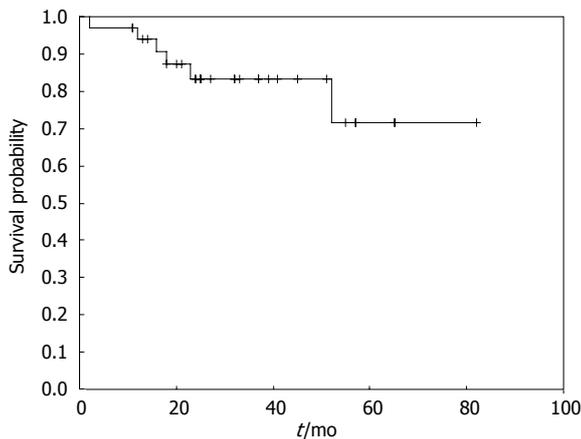

**Figure 3** Distribution of IPI values in gastric MALT lymphoma patients. IPI score was a highly significant ( $P < 0.01$ ) prognostic factor for overall survival of patients.

after restaging 4 mo after the starting initial systemic therapy.

Various clinical characteristics of patients with MALT lymphoma, and data relating to therapy response are summarized in Table 2. Distribution of IPI value showed that the most number of patients, nine, had an IPI score of 3 (Figure 3).

Patients had high remission rate to first-line chemotherapy or immunochemotherapy combined with anti-*H pylori* treatment. Remission was obtained in 91.2%, CR in 64.7% and PR in 26.5% of patients. After the end of the follow up period 28 (82.4%) patients were still alive. The cause of death in all patients was disease progression.

The actuarial survival curve estimated high survival rate

**Figure 4** Kaplan-Meier curve of cumulative survival probability in gastric MALT lymphoma patients. Cumulative survival probability was high in the following period with low rate of death.

(83%) in the first 12 mo of the following period (Figure 4).

The use of the Cox proportional hazard model determined negative independent prognostic predictive factors for overall survival (OS): high IPI score, elevated ESR (erythrocyte sedimentation rate) and low platelets ( $\chi^2 = 13.397$ ,  $df = 3$ ,  $P = 0.0039$ ).

Multivariate logistic regression showed the significance of elevated CS and low value of hemoglobin as independent prognostic factors that had negative influence for the outcome (dead or alive) of the disease ( $df = 1$ ,  $P = 0.0049$ ), whilst the elevated ESR had negative impact for achieving CR ( $df = 1$ ,  $P = 0.0107$ ).

## DISCUSSION

We have described the clinical characteristics of primary gastric MALT lymphoma in 34 patients. Gastric MALT lymphoma offers a paradigm of infection-associated malignant disease. Most of them are multifocal and involve the antrum or distal body, but may occur in any part of the stomach<sup>[13]</sup>.

Classically, MALT lymphomas reveal a histological triad composed of reactive lymphoid follicles, diffuse infiltration of small irregular lymphocytes (centrocytes), and lymphoepithelial lesions (LELs). The histological features closely simulate those of Peyer's patches<sup>[14]</sup>.

The lymphoma infiltrates, around reactive follicles in the region corresponding to the marginal zone, were found to be spreading diffusely into the surrounding mucosa. The tumor cells typically resemble reactive marginal zone B cells, having moderate amounts of pale clear cytoplasm. However, the cytological appearance in individual cases was varied. A characteristic feature of MALT lymphomas is the presence of LELs formed by the invasion of glands by neoplastic cells.

We have focused on the patients treated with chemotherapy (67.6%) or immuno-chemotherapy (34.4%) as first line treatment, combined with triple way therapy against *H pylori* in *Helicobacter* positive patients. The reason for this approach was the fact that all patients in I and II CS expressed BCL-10, and also had constitutional "B"

symptoms, so we identified them as high risk patients. In about 25% of cases, resistance of gastric MALT lymphoma to *H pylori* eradication seems to be caused by chromosomal translocation involving the BCL-10 locus, such as t (1; 14) (p22; q32) and t (1;2) (p22; p12)<sup>[15]</sup>. They are typically found at advanced stages and are unlikely to respond to *H pylori* eradication. GL bearing these translocations can be detected immunohistochemically by strong BCL-10 nuclear expression<sup>[16]</sup>.

In concordance with this is fact that patients who have t (11; 18) do not respond to anti-*H pylori* treatment. This translocation was described in 1989, and occurs specifically in MALT lymphoma, but not in other non-Hodgkin's lymphomas, including its absence in cases of nodal and splenic marginal zone lymphoma.

The translocation is absent from *H pylori* gastritis and other premalignant diseases<sup>[17]</sup>. The t (1; 14) (p22; q32) and t (1; 2) (p22; p12) were described in MALT lymphoma in 1990 and 2000, respectively<sup>[18,19]</sup>. They have been reported exclusively in MALT lymphoma and represent approximately 3% of gastric MALT lymphomas<sup>[20]</sup>.

The translocation t (11; 18) seems to favorably influence the response to *H pylori* eradication whereas its expression and the presence of BCL-10 mutations appear to be associated with failure to respond to antibiotics and with a more aggressive disease behavior<sup>[21,22]</sup>.

Under normal circumstances, signaling through the antigen receptor facilitates the interaction of BCL-10 and MALT1, which synergize to activate NF- $\kappa$ B. BCL-10 forms a complex with MALT1 and the 2 molecules synergize in the activation of NF- $\kappa$ B. In cases with t (11; 18) (q32; q21), the API2-MALT1 fusion protein activates the NF- $\kappa$ B pathway through self-oligomerization. MALT lymphomas with these translocations show strong to moderate nuclear BCL-10 expression, and give anti-apoptotic signal to neoplastic lymphoid cells<sup>[20-22]</sup>.

There is some evidence that a few factors may influence a better chance of response. One factor may be limited extension of the disease, affecting only superficial layers of the stomach, low grade histopathology with low proportion of blast cells and clusters of blast cells<sup>[23]</sup>.

Other factors may be the specific gastric localization (with improved chances for gastric distal localization). The favorable response to *H pylori* eradication is rather exceptional and does not mean that all patients with localized (stage I) high grade gastric MALT lymphoma should be treated exclusively with eradication treatment. Rather it suggests that after eradication therapy as the initial treatment in patients with limited superficial disease, no infiltration of deeper layers of the gastric wall, and limited areas of high grade lymphoma, and most of all, when these patients can be closely monitored, chemotherapy may be postponed until follow up indicates whether or not further treatment is necessary. A prospective study of larger numbers of such patients may help to detect the factors that may predict a good response to *H pylori* eradication to avoid the use of an unnecessary and toxic treatment such as chemotherapy in patients that may already have been cured<sup>[24,25]</sup>.

In our group of patients, we have a large proportion

with advanced CS, III and IV (16 i.e. 47%), but the diagnosis was clear that it was primary gastric lymphoma. Obvious differences between primary and secondary gastric lymphoma became evident with regard to tumor localization and growth pattern. Secondary gastric NHL was seen more frequently as multifocal disease involving the gastric fundus and duodenum; both sites are rarely affected in primary gastric NHL like in our patients. In contrast to secondary gastric NHL, unifocal growth pattern is the most important endoscopic finding in primary gastric NHL. A unifocal growth pattern facilitates local radical treatment strategies, such as surgery, which may be associated with prolonged remission and a more favorable prognosis<sup>[10,26]</sup>.

As the part of diagnostic procedures, we used abdominal CT in concordance to modified Ann Arbor staging system. According to CS and findings that none of the patients had CS IE1 and these with CS IE2, CS IIE1 and more advanced staged were BCL-10+ with "B" symptoms, we made decision to aggressively treat them with or without anti-*H pylori* treatment (in dependence of *H pylori* status). The most recent studies presented the role of endoscopic ultrasound (EUS) as procedure that should be included as part of staging for the diagnosis and treatment of gastric MALT lymphoma. The presence or absence of deep submucosal invasion as assessed by EUS was the most critical factor for pretreatment assessment. Therefore, EUS has a much higher sensitivity in distinguishing stage IE from stage IIE1 lymphoma, compared with CT scan. Furthermore, with analysis of the response data according to depth of infiltration, the overall response rate was highest for mucosa stage IE1 and then decreased with the depth of gastric wall infiltration<sup>[23,27-29]</sup>.

Among all examined prognostic factors, the IPI score was the most powerful prognostic factor for OS, together with ESR and platelet number in the Cox hazard regression model ( $P = 0.0039$ ). The distribution of IPI score showed that only two patients had IPI = 0, and the highest number of patients (9) had IPI of intermediate-high risk (IPI = 3). About one quarter of patients had thrombocytopenia, due to BM infiltration, which correlated with shorter survival. The standard biochemistry parameter ESR was elevated in one half of patients, and the acute phase reactant had prognostic influence on survival. In addition, elevated ESR had a negative influence on achieving CR by using multivariate logistic regression. Anemia, as a result of erythropoiesis suppression in malignant disease and due to BM infiltration, had a negative influence on disease outcome as well as high Ann Arbor modified clinical stage. Our findings are in agreement with prognostic factor analysis in described literature data<sup>[29,30]</sup>.

In contrary to persistence of disease, the basic goal would be prevention of MALT lymphoma appearance. Even though, *H pylori* is a tumor-inducing pathogen, it does not induce malignant diseases in the vast majority of infected hosts. Therefore, vaccination strategies must acknowledge this co-evolution of *H pylori* with its human host in which many of the host-pathogen interactions that occur could prove potentially beneficial<sup>[31]</sup>.

In conclusion, these data show that adequate patient selection for treatment option offers them a good chance

for long-term survival. Using novel diagnostic procedures, such as EUS, differentiate low risk patient candidates for only antibiotic approach and avoids an aggressive treatment option. As a final point, murine models using infection with several gastric *Helicobacter* species provided a distinctive experimental method to examine the progression of the MALT lymphoma from early immune responses to fully developed malignant disease. These systems offer the model of gastric lymphoma development through a series of molecularly events. Analysis of these steps using gene expression profiling gave some insights into the mechanisms involved in the lymphogenesis and can be prove in large prospective studies<sup>[32]</sup>.

## COMMENTS

### Background

Gastric low grade B cell lymphomas arising from mucosa associated lymphoid tissue (MALT) are the most frequent lymphomas among those located in the primary digestive tract. The translocation t (11; 18) seems to favorably influence the response to *H pylori* eradication whereas its expression and the presence of BCL-10 mutations appear to be associated with failure to respond to antibiotics and with a more aggressive disease behavior. In about 25% of cases, resistance of gastric MALT lymphoma to *Helicobacter pylori* eradication seems to be caused by chromosomal translocation involving the BCL-10 locus, such as t (1; 14) (p22; q32) and t (1; 2) (p22; p12). They are typically found at advanced stages and are unlikely to respond to *H pylori* eradication. Besides, few factors may influence a better chance of response. One factor may be limited extension of the disease, distal gastric localization, affecting only superficial layers of the stomach, low grade histopathology with low proportion of blast cells and clusters of blast cells.

### Research frontiers

The favorable response to *H pylori* eradication is rather exceptional and does not mean that all patients with localized (stage I) high grade gastric MALT lymphoma should be treated exclusively with eradication treatment. Rather it suggests that after eradication therapy as the initial treatment in patients with limited superficial disease, no infiltration of deeper layers of the gastric wall, and limited areas of high grade lymphoma, and most of all, when these patients can be closely monitored, chemotherapy may be postponed until follow up indicates whether or not further treatment is necessary.

### Innovations and breakthroughs

We have focused on the patients treated with chemotherapy (67.6%) or immuno-chemotherapy (34.4%) as first line treatment, combined with triple way therapy against *H pylori* in *Helicobacter* positive patients. The reason for this approach was the fact that all patients in I and II CS expressed BCL-10, and also they had constitutional "B" symptoms, so we identified them as high risk patients. Patients had high remission rate (91.2%) to first-line chemotherapy or immuno-chemotherapy combined with anti-*H pylori* treatment. Among all examined prognostic factors, the IPI score was a powerful prognostic factor for OS, together with ESR and platelet number in the Cox hazard regression model ( $P = 0.0039$ ).

### Applications

These data show that adequate patient selection for treatment option offers them good chance for long-term survival.

### Peer review

The manuscript is an interesting, generally well written series of gastric MALTOMA patients, reflecting on the impact of clinical factors upon outcome with current treatment.

Radiotherapy for 65 patients with advanced unresectable hepatocellular carcinoma. *World J Gastroenterol* 2008; 14(15): 2394-2400 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2394.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2394>

### Abstract

**AIM:** To evaluate the efficacy of radiotherapy (RT) in patients with advanced unresectable hepatocellular carcinoma (HCC).

**METHODS:** A total of 65 patients were treated with RT in the Korea University Medical Center. The median age of the patients was 60 years, and 86.2% were men. 18.5% and 81.5% of the patients were diagnosed as TNM stage III and IV-A, respectively. Treatment response was assessed 4 mo after initiation of RT. Tumor regression rate 1 mo after initiation of RT (TRR<sub>1m</sub>) was also assessed. Duration of survival was calculated from the initiation of RT.

**RESULTS:** The objective treatment response was 56.9%. The 12 mo survival rate was 34.7%. Predictive factors for survival were Child-Pugh grade,  $\alpha$ -fetoprotein level and treatment response. An objective response was achieved more frequently in patients with TRR<sub>1m</sub>  $\geq$  20% than in those with TRR<sub>1m</sub> < 20% ( $P < 0.001$ ).

**CONCLUSION:** RT is effective in treating advanced HCC with a tumor response rate of 56.9%.

### INTRODUCTION

In Korea, hepatocellular carcinoma (HCC) accounts for 83% of primary liver cancer, which is the third most common cancer and the third leading cause of cancer-related death<sup>[1,2]</sup>. Although surgical resection is considered to be the treatment of choice for long-term control of HCC, this treatment is considered at diagnosis in less than 20% of HCC patients due to disease extent or a hepatic function that is inadequate for resection<sup>[3-5]</sup>.

Although percutaneous ablation therapy, such as percutaneous ethanol injection or radiofrequency ablation, could be the best treatment in patients who are not suitable for resection, this treatment is limited to early-stage HCC<sup>[6]</sup>. Transarterial chemoembolization (TACE) is used for patients with unresectable HCC who are also ineligible for percutaneous ablation<sup>[6]</sup>. However, because complete tumor necrosis is rare with TACE, repeated treatments are often needed. Additionally, TACE-induced vascular injury can limit further TACE<sup>[7-10]</sup>. Finally, patients with portal vein thrombosis or extensive tumor burden are poor candidates for TACE, because their tumors are frequently associated with arterio-portal shunts and TACE-related liver damage. For these advanced HCCs, hepatic arterial infusion of chemotherapy (HAI) has yielded promising results in several recent studies<sup>[11-13]</sup>, but the benefit of HAI is still controversial.

Radiotherapy (RT) for the treatment of HCC has been attempted over the last four decades, but the results have been unsatisfactory because the doses were too low to be adequately tumoricidal<sup>[14-16]</sup>. Recently, however, several studies have suggested local, high-dose RT is well tolerated and leads to a favorable treatment response in patients

with unresectable HCC<sup>[17-20]</sup>. Therefore, this study was performed to evaluate the treatment responses of RT and survival in patients who underwent RT for unresectable HCC.

## MATERIALS AND METHODS

### Patients

This study was performed with patients who underwent RT for unresectable advanced HCC without distant metastases. Between July 2003 and June 2006, 80 patients with unresectable HCC underwent local RT to the liver at the Korea University Medical Center. Fifteen of these patients were excluded due to the presence of distant metastases prior to RT.

Diagnosis of HCC was based on either the identification of hypervascular masses by two imaging studies or by one imaging study combined with a serum alpha-fetoprotein (AFP) level > 400 ng/mL. If the vascular profile by dynamic imaging was not characteristic of HCC and the AFP was less than 400 ng/mL a biopsy was performed<sup>[21]</sup>. Unresectability was determined using accepted surgical criteria<sup>[3]</sup>.

The baseline characteristics of the 65 patients are presented in Table 1. Fifty-six patients (86.2%) were male and 9 were female. The median age was 60 years (range, 42-83) years. Underlying liver diseases included chronic Hepatitis B virus (HBV) infection in 49 patients (75.4%), alcoholic liver cirrhosis in 13 patients (20%) and chronic Hepatitis C virus (HCV) infection in two patients (3.1%). In one patient (1.5%), co-infection with HBV and HCV was noted. Liver cirrhosis was present in 50 patients (76.9%). According to the Child-Pugh classification, 43 patients (66.2%) were classified as grade A and 22 patients (33.8%) were classified as grade B. Patients in class C were not included. Baseline tumor size was  $10.8 \pm 4.7$  cm (median, 9.9 cm). In 31 patients (47.7%), the tumor size was larger than 10 cm. Based on the types of HCC described by Egge<sup>[22]</sup>, the most frequent tumor type was massive (58.5%), followed by multinodular (36.9%) and single nodular (4.6%). Prior to RT, portal vein thrombosis was observed in 45 patients (69.2%); this was confirmed by CT and/or angiogram. Among these 45 patients, thrombosis was observed in the main portal vein in 20 patients (30.8%), at the first branch level in 23 (35.4%), and at the second branch level in 2 (3.1%). The hepatic vein and bile duct were involved in 8 and 6 patients, respectively. No patients showed evidence of extrahepatic metastasis prior to RT. According to the TNM staging system of the Liver Cancer Study Group of Japan<sup>[23]</sup>, 53 patients (81.5%) fell into stage IV-A, and 12 (18.5%) fell into stage III.

### Treatment

RT was performed as a primary treatment in 40 of the 65 patients (61.5%) due to an overly large tumor size in 20 patients (30.8%), portal vein thrombosis in 12 patients (18.5%), IVC thrombosis in 3 patients (4.6%), bile duct invasion in 3 patients (4.6%), and a massive portosystemic shunt around the tumor in 2 patients (3.1%). In the remaining 25 patients (38.5%), RT was performed as

**Table 1** Baseline characteristics of the 65 patients who underwent radiotherapy for unresectable hepatocellular carcinoma

Characteristics	Number of patients (%)
Age (yr)	60 (42-83) <sup>1</sup>
< 60/≥ 60	35 (53.8)/30 (46.2)
Gender (Male/Female)	56 (86.2)/9 (13.8)
Underlying liver disease (viral/alcohol)	52 (80.0)/13 (20.0)
Liver cirrhosis	50 (76.9)
Ascites	24 (36.9)
Child-Pugh class (A/B)	43 (66.2)/22 (33.8)
Albumin (g/dL) <sup>2</sup>	3.4 ± 0.5
Bilirubin (mg/dL) <sup>2</sup>	1.2 ± 0.9
Alkaline phosphatase (IU/L) <sup>2</sup>	151.8 ± 79.3
Platelet (10 <sup>3</sup> /mL) <sup>2</sup>	156.3 ± 66.2
Prothrombin time (INR) <sup>2</sup>	1.2 ± 0.2
Sodium (mEq/L) <sup>2</sup>	137.7 ± 3.7
Creatinine (mg/dL) <sup>2</sup>	1.0 ± 0.9

a salvage treatment after ineffective TACE (21 patients, 32.3%) or vascular inaccessibility to the feeding vessel of the HCC (4 patients, 6.2%). External beam RT at a target dose of 61 Gy/34 fractions was planned, using 10 MV of X-rays. The RT strategy was devised using a CT-based 2-D planning system (CT Port, Toshiba, Tokyo, Japan). To account for respiratory-based liver motion, a 1-1.5 cm margin was added in the craniocaudal direction. The full 61-Gy irradiation dose was feasible in 55 of the 65 patients (84.6%).

During and after RT, TACE was also employed in 57 patients (87.7%;  $2.9 \pm 1.8$  sessions; median, three sessions; range, 1-8 sessions). TACE was performed with an emulsion of doxorubicin at a dose of 10-30 mg and 4-12 mL of mixed solution of lipiodol and contrast agent. TACE was usually combined with embolization using gelfoam particles, except in cases with significant portal vein thrombosis. In 16 patients with portal vein invasion (24.6%), HAI with cisplatin and 5-FU was combined with or without TACE ( $3.3 \pm 2.4$  cycles; median, 2.5 cycles; range, 1-8 cycles).

### Evaluation of treatment response

Tumor size was measured by computed tomography (CT) and was calculated as the longest diameter multiplied by the longest perpendicular diameter. CT scans were obtained before RT, 1 and 4 mo after the initiation of RT, and then every 2-3 mo. If a patient had multiple nodules, the extent of the tumor was determined by the sum of the extent of all tumors > 2 cm in diameter.

Treatment response was assessed at four months after initiation of RT. A complete response was defined as the complete disappearance of all clinical and radiographic tu-

mor evidence. A partial response was defined as more than a 50% decrease in tumor size from baseline. Stable disease was defined as less than a 50% decrease or a 25% increase in tumor size. The objective treatment response was calculated based on the complete and partial responses. Progressive disease was defined as a greater than 25% increase in extent of the tumor from the nadir extent of the tumor.

To evaluate the efficacy of using the early tumor response to predict the treatment response, the tumor regression rate at one month after initiation of RT ( $TRR_{1m}$ ) was assessed using the following equation:  $TRR_{1m} = [(baseline\ tumor\ extent - tumor\ extent\ at\ one\ month\ after\ RT) / baseline\ tumor\ extent] \times 100$ .

Adverse events were evaluated weekly during RT and one month following the treatment. Adverse hematologic events were evaluated by measuring hemoglobin, white blood cell (WBC) and platelet counts, while hepatic adverse events were evaluated by measuring serum bilirubin, albumin, aspartate aminotransferase (AST), alanine aminotransferase (ALT) and alkaline phosphatase (ALP) levels. Gastrointestinal (GI) bleeding included any bleeding from the esophagus, stomach, duodenum, or liver. All adverse events were graded according to Common Terminology Criteria for Adverse Events V3.0.

### Statistical analysis

All calculations were performed using SPSS 10.0 software for Windows (SPSS, Chicago, IL). Quantitative variables were expressed as mean  $\pm$  SD or medians. Differences in quantitative and qualitative variables were assessed using the Student's *t*-test and chi-square test, respectively. Logistic regression analysis was performed to evaluate predictive factors for tumor response. Survival and progression-free survival were assessed from the initiation of RT according to the Kaplan-Meier method. Differences between variables were assessed using the log-rank test. The Cox regression model was used to detect associations between survival and AFP status, tumor type, the location of tumor thrombi, stage and therapeutic models. For multivariate analysis, variables with  $P < 0.2$  at univariate analysis were entered. Differences with  $P < 0.05$  were considered to be statistically significant.

## RESULTS

### Tumor response

Fifty-five of 65 patients (84.6%) completed the RT schedule. Ten patients (15.4%) could not complete RT due to HCC aggravation or deterioration of liver function after RT. Interruption of RT was more frequent in Child-Pugh class B patients (7 of 20 patients, 35%) than in class A patients (3 of 45, 6.7%;  $P = 0.003$ ). Among the 55 patients who completed RT, treatment response was evaluated 4 mo after the initiation of RT. None of our patients had completely responded at this point in the response evaluation, but 37 patients (67.3%) had partially responded. Seventeen patients (30.9%) had stable disease, and 1 (1.8%) had progressive disease. Therefore, the objective treatment response at four months was 67.3%.

Table 2 Baseline characteristics of the 65 patients, according to treatment response

	Pts without OTR (n = 28)	Pts with OTR (n = 37)	P value
Age (yr)	61 $\pm$ 10	58 $\pm$ 8	0.271
Gender (M:F)	22:6	34:3	0.124
Hepatitis B	21 (75%)	28 (75.7%)	0.950
Hepatitis C	2 (7.1%)	1 (2.7%)	0.573
Alcohol abuse	5 (17.9%)	8 (21.6%)	0.707
WBC (/mm <sup>3</sup> )	5450 $\pm$ 1671	6079 $\pm$ 2229	0.216
Hemoglobin (g/dL)	11.4 $\pm$ 2.2	12.0 $\pm$ 1.8	0.207
Platelet ( $\times 10^3$ /mm <sup>3</sup> )	160 $\pm$ 738	154 $\pm$ 608	0.733
AST (IU/L)	111 $\pm$ 93	71 $\pm$ 53	0.032
ALT (IU/L)	62 $\pm$ 51	69 $\pm$ 90	0.686
ALP (IU/L)	175 $\pm$ 89	134 $\pm$ 67	0.038

Albumin (g/dL)	3.3 $\pm$ 0.4	3.5 $\pm$ 0.5	0.103
Prothrombin time, INR	1.16 $\pm$ 0.22	1.15 $\pm$ 0.14	0.796
Creatinine (mg/dL)	1.17 $\pm$ 1.31	0.92 $\pm$ 0.25	0.329
Liver cirrhosis	21 (75%)	29 (78.4%)	0.749
Child-Pugh grade A	14 (50%)	31 (83.8%)	0.003
Alpha-fetoprotein (ng/dL)	31474 $\pm$ 98160	6844 $\pm$ 15814	0.199
$\geq 400$ ng/dL	15 (53.6%)	22 (59.5%)	0.635
Tumor size (mm)	118 $\pm$ 37	99 $\pm$ 52	0.112
$\geq 10$ cm	18 (64.3%)	14 (37.8%)	0.035
Multiple tumor	24 (85.7%)	30 (81.1%)	0.622
Massive type	18 (64.3%)	20 (54.1%)	0.407
Main portal vein thrombosis	10 (35.7%)	10 (27%)	0.452
Tumor stage IV	23 (82.1%)	30 (81.1%)	0.913

OTR: Objective treatment response; WBC: White blood cell; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; ALP: Alkaline phosphatase; INR: International normalized ratio; Tumor stage: According to the TNM staging system of Liver Cancer Study Group of Japan.

However, if we label the 10 patients who did not complete RT as non-responders, then the partial response and stable disease rates decreased to 56.9% (37 of 65 patients) and 26.2% (17 of 65 patients), respectively.

Table 2 presents baseline characteristics according to treatment response. Logistic regression analysis was performed to evaluate predictive factors for an objective treatment response. Child-Pugh grade was the only independent predictive factor for an objective treatment response (Child-Pugh grade A *vs* B; OR, 5.167; 95% CI, 1.643-16.250;  $P = 0.005$ ). Among the 45 patients with Child-Pugh grade A, 31 patients (68.9%) showed a partial response, as did 6 of the 20 grade B patients (30%,  $P = 0.003$ ).

### Time to progressive disease

During follow-up, 4 of the 37 patients showing a partial response (10.8%) and 3 of the 25 patients showing stable disease (12%) had progressive disease after a median of 6 (range, 3-9) mo. Among the 65 patients, time to progressive disease was 5  $\pm$  3 mo after initiation of RT (median, 4 mo). Duration without progressive disease was longer in patients who met the objective treatment response (14.8  $\pm$  1.4 mo) than in patients who did not (4.6  $\pm$  0.4 mo,  $P < 0.001$ ; Figure 1).

### Survival

All enrolled patients were followed for 8  $\pm$  6 (median,

6; range, 1-30) mo. During this period, 37 patients died. Fourteen patients died of hepatic failure, 13 died of HCC aggravation, 5 died of gastrointestinal bleeding, 2 died of tumor rupture, and 2 died of sepsis. The cumulative survival rates at 6, 12 and 18 mo were 61.5%, 34.7% and 27.0%, respectively. Patients who showed an objective treatment response (median survival, 346 d) survived longer than those who did not (median survival, 212 d;  $P = 0.032$ ; Figure 2).

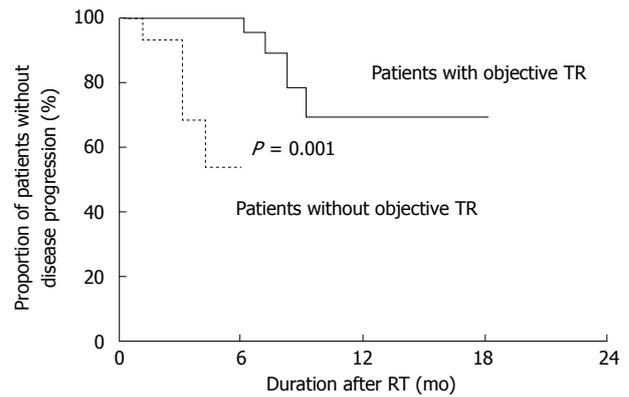

When multivariate Cox-regression analysis was performed with baseline characteristics, large tumor size ( $\geq 10$  cm *vs*  $< 10$  cm; OR, 2.416; 95% CI, 1.213-4.811;  $P = 0.012$ ), Child-Pugh grade B *vs* A (OR, 4.094; 95% CI, 1.977-8.480;  $P < 0.001$ ) and the presence of tumor thrombi in the main portal vein (OR, 2.315; 95% CI, 1.156-4.634;  $P = 0.018$ ) were independent predictive factors for mortality. However, when multivariate analysis was performed after inclusion of the objective treatment response, Child-Pugh grade B *vs* A (OR, 3.706; 95% CI, 1.718-7.996;  $P = 0.001$ ), high serum AFP level (OR, 2.459; 95% CI, 1.187-5.094;  $P = 0.015$ ) and a failure to meet the objective treatment response (OR, 5.619; 95% CI, 2.475-12.760;  $P < 0.001$ ) were independent prognostic factors for mortality (Table 3).

#### Tumor regression rate at 1 mo after RT initiation

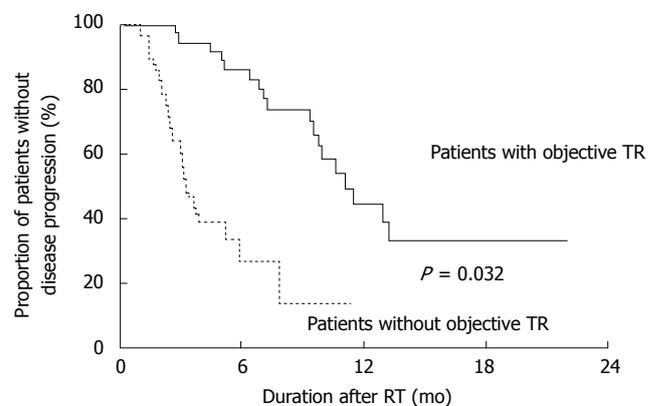

TRR<sub>1m</sub> was assessed in all 65 patients. TRR<sub>1m</sub> was more than 20% in 41 patients (63.1%). Of the 41 patients with a TRR<sub>1m</sub>  $\geq 20\%$ , 35 patients (85.4%) showed a partial response, while only 2 (8.3%) of the 24 patients with TRR<sub>1m</sub>  $< 20\%$  showed a partial response ( $P < 0.001$ ; Figure 3). When logistic regression analysis was performed after inclusion of TRR<sub>1m</sub> among the variables used to predict objective treatment response, Child-Pugh grade A (OR, 0.121; 95% CI, 0.019-0.784;  $P = 0.027$ ) and TRR<sub>1m</sub>  $\geq 20\%$  (OR, 158.302; 95% CI, 14.032-1785.827;  $P < 0.001$ ) were independent predictive factors.

#### Adverse events

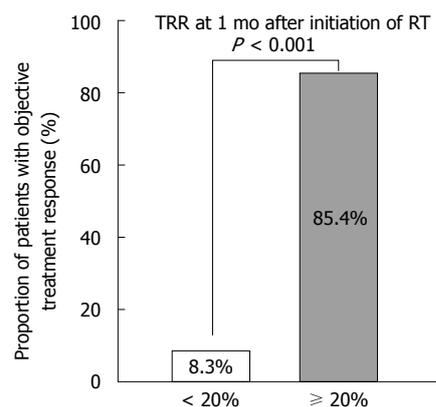

Adverse events during and one month after RT are summarized in Table 4. Adverse hematologic events were identified in 78.5% of patients. Although most of them were mild and transient, grade 3 or 4 adverse events were noted in six patients (9.2%). Grade 3 or 4 hematologic adverse events were more frequent in patients who underwent RT combined with HAI (4 of 16 patients, 25%) than in patients with RT alone (2 of 49, 4.1%;  $P = 0.012$ ). Adverse hepatic events were identified in 51.8% of the patients; the most common were hypoalbuminemia (33.8%) and hyperbilirubinemia (24.6%). Grade 3/4 adverse hepatic events developed in four patients (6.2%), with hyperbilirubinemia or elevation of AST in 1 (1.5%). Grade 3/4 adverse hepatic events were more frequent in patients with TRR<sub>1m</sub>  $< 20\%$  (4 of 24 patients, 16.7%) than in those with TRR<sub>1m</sub>  $\geq 20\%$  (1 of 41, 2.4%;  $P = 0.038$ ). GI bleeding developed in five patients. The status of two patients with peptic ulcer disease and one patient with variceal bleeding was improved with medical or endoscopic treatment. However, two patients with hemobilia or HCC rupture expired after these events.

**Figure 1** Duration without disease progression, according to treatment response. TR: Treatment response; RT: Radiotherapy.

**Figure 2** Overall survival of the 65 patients who underwent radiotherapy for advanced hepatocellular carcinoma according to treatment response. Patients with objective treatment responses (median survival, 346 d) survived longer than those without objective treatment responses (median survival, 212 d;  $P = 0.032$ ). RT: Radiotherapy; TR: Treatment response.

## DISCUSSION

Recently, a number of reports have documented the effect of local RT on HCC<sup>[17-20]</sup>. Although fractionation schemes were not identical to each other, local, high-dose RT alone or in combination with another modality such as

**Table 3 Multivariate analysis of the mortality of patients who underwent radiotherapy for advanced hepatocellular carcinoma**

		P value	β	Odds ratio	95% CI
Tumor size	0 ≤ 10 cm; 1 ≥ 10 cm	0.012	0.954	2.597	1.232-5.473
Child-Pugh grade	0 = Grade A; 1 = Grade B	0.001	1.336	3.802	1.687-8.568
Combined with TACE	0 = Yes; 1 = No	0.001	1.671	5.315	2.015-14.018
Objective treatment response	0 = Yes; 1 = No	0.006	1.194	3.300	1.414-7.699

**Table 4 Adverse events in the 65 patients who underwent radiotherapy for unresectable hepatocellular carcinoma n (%)**

	Grade					
	0	1	2	3	4	5
Hematologic	14 (21.5)	33 (50.8)	12 (18.5)	5 (7.7)	1 (1.5)	-
Hepatic	32 (49.2)	20 (30.8)	8 (12.3)	4 (6.2)	1 (1.5)	-
GI hemorrhage			1 (1.5)	2 (3.1)		2 (3.1)

TACE<sup>[19,24]</sup>, systemic chemotherapy<sup>[25]</sup> or intra-arterial chemotherapy<sup>[26,27]</sup> has achieved a substantial objective response. In this study, RT was performed with or without other treatment modalities and the objective response rate was 56.9%, which was somewhat lower than previous reported<sup>[24,28-30]</sup>. However, when 10 patients (15.4%) who did not complete the whole RT schedule were excluded, the objective treatment response rate increased to 67.3%. We have no idea how the patients who could not complete RT were treated during these previous studies, because this was not reported. It is possible that all patients completed RT in the previous studies. However, a significant proportion of patients could not complete the RT schedule in the present study. Therefore, selection of appropriate patients for RT may be very important before RT initiation.

Child-Pugh grade was the only significant predictive factor for treatment response. This seems to be associated with the higher proportion of Child-Pugh grade B patients (35%) who could not complete the RT schedule compared with those with grade A (6.7%; *P* = 0.003). This speculation is supported by the fact that no variable was significantly associated with treatment response when the logistic analysis was performed on the 55 patients who completed RT (data was not shown). These results suggest that a circumspective decision was required in considering RT for patients with Child-Pugh grade B. Previously, tumor size was the one significant factor affecting treatment response<sup>[29]</sup>. Similarly, a treatment response was more frequently seen in patients with a smaller HCC (23 of 32 patients, 69.7%) than in patients with a larger HCC (14 of 32 patients, 43.8%; *P* = 0.035). However, when multivariate analysis was performed, the significance disappeared.

Our results suggest RT may improve prognosis in patients who achieved an objective treatment response. RT appears to be associated with prolonged survival as well as prolonged suppression of HCC progression in patients who show an objective treatment response.

After the effects of other prognostic factors were corrected for, patients who achieved objective treatment responses survived longer than those who did not, as determined by multivariate analysis. In addition, time to progression was significantly longer in patients who met the objective treatment response than in patients who did not. However, several limitations should be discussed. First, 10 patients who could not complete the RT schedule were included in this analysis. However, even though these 10 patients were later excluded, patient survival still differed according to treatment response (*P* = 0.002; data not shown). Second, most patients were treated with not only radiotherapy, but also with TACE or HAI, and these combined treatments may affect patients' survival. To ideally assess the effect of RT on patient prognosis, RT should be the only treatment modality. However, considering the limitations of dose and field of RT, it seems unwise to use RT as the only treatment modality for advanced HCC.

In this study, the one-year survival rate was 34.7%, which was lower than in previous studies<sup>[24,28-31]</sup>. It may be the patients enrolled in this study had more advanced disease than those in previous studies<sup>[24,28-31]</sup>. In the present study, tumors were larger than 10 cm in 47.7% of patients, 69.2% of the cases had thrombi in portal vein, and 81.5% of the patients had stage IV-A disease. In addition, 10 patients (15.4%) who could not complete RT schedule were included in this study; none of these patients survived more than four months after initiation of RT. By contrast, most of the previous studies included patients who completed the RT schedule<sup>[24,28-31]</sup>, which may have led to the observed discrepancies with the present study.

In recent studies, PVT was the one prognostic factor for survival<sup>[30,32]</sup>. Similarly, in this study, the presence of tumor thrombi in main portal vein as well as Child-Pugh grade and tumor size were independent prognostic factors for survival when multivariate analysis was performed with variables of baseline characteristics. However, when treatment response was included in the analysis, Child-Pugh grade, AFP level and treatment response were associated with survival. This result suggests that even if tumor thrombi are present in main portal vein before RT, RT may still improve survival when an objective treatment response is achieved.

In all of our patients, CT was performed at one month after initiation of RT. Tumor response at one month after initiation of RT was a useful predictor for RT response. In addition, grade 3 or 4 adverse hepatic events were more frequent in patients with TRR<sub>1m</sub> < 20%. These results suggest if the mass does not decrease to 20% from baseline after one month of RT, interruption of RT can be considered due to the likelihood of a low objective treatment response rate and a high rate of severe adverse hepatic events.

In conclusion, RT was effective for the treatment of HCC with an objective tumor response rate of 56.9%; moreover, patients who met the objective treatment response survived longer than those who did not. Tumor regression at one month after the initiation of RT may be a useful predictor for RT response as well as severe adverse hepatic events.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is one of the most common causes of cancer-related death in the world, especially in Asia. In a large proportion of patients, HCC is diagnosed at an advanced stage and, in this stage, widely performed treatment modalities including surgical resection, local ablation therapy and transarterial chemoembolization are not indicated. Recently, several reports have suggested high-dose radiotherapy (RT) could be an effective treatment option for advanced HCC.

### Research frontiers

Most previous studies have included only patients who completed the RT schedule. However, according to our experience, some proportion of patients could not complete the whole RT schedule and their prognosis was usually very poor. Therefore, this might lead to a selection bias when analyzing the treatment response and survival of patients. In this study, all patients with HCC who were treated with RT for more than 1 mo during the study period were included. In addition, we evaluated the prognostic significance of early tumor response by follow-up CT at 1 month after the initiation of RT.

### Innovations and breakthroughs

RT was effective in patients with advanced HCC with an objective tumor response rate of 56.9%. Early tumor response rate at 1 month after the initiation of RT was shown to be a good prognostic indicator for RT response. In addition, severe adverse events were more frequent in patients with poor early tumor response rates.

### Applications

RT could be considered as a treatment option for patients with advanced HCC. If the tumor does not decrease to 20% from baseline after one month of RT, interruption of RT can be considered due to the likelihood of a low objective treatment response rate and a high rate of severe adverse hepatic events.

### Peer review

This is an interesting article, which may offer new insights in the treatment of advanced unresectable HCC. The paper is well organized and the results are clearly described and commented.

### Abstract

**AIM:** To investigate the correlation between the changes of pancreatic enzyme, the biochemical markers and the clinical results according to the Balthazar computer tomography (CT) grade.

**METHODS:** Between July 2004 and July 2005, we reviewed the charts of 119 patients who were admitted to our hospital with acute pancreatitis.

**RESULTS:** Eighty-three patients (69.7%) were male, and the mean age of the patients was  $57 \pm 15.7$  years. The biliary pancreatitis patients had an older mean age. Forty-nine patients (41.1%) had biliary pancreatitis and forty-six (38.6%) had alcoholic pancreatitis. Group 3 patients had a longer duration of pain ( $2.51 \pm 1.16$  vs  $3.17 \pm 1.30$  vs  $6.56 \pm 6.13$ ,  $P < 0.001$ ), a longer period of fasting ( $7.49 \pm 4.65$  vs  $10.65 \pm 5.54$  vs  $21.88 \pm 13.81$ ,  $P < 0.001$ ) and a longer hospital stay ( $9.17 \pm 5.34$  vs  $14.63 \pm 8.65$  vs  $24.47 \pm 15.52$ ,  $P < 0.001$ ) than the other groups. On the univariate analysis, the factors that affected the radiological grade were the leukocyte count at admission ( $P = 0.048$ ), the hemoglobin ( $P = 0.016$ ) and total bilirubin concentrations ( $P = 0.023$ ), serum lipase ( $P = 0.009$ ), the APACH II scores at admission ( $P = 0.017$ ), the APACH II scores after 24 h ( $P = 0.031$ ), the C-reactive protein (CRP) titer ( $P = 0.0001$ ) and the follow up CRP titer ( $P = 0.003$ ). But the CRP level ( $P = 0.001$ ) and follow up CRP titer ( $P = 0.004$ ) were only correlated with the radiological grade on multivariate analysis. According to the ROC curve, when we set the CRP cut off value at 83 mg/L, the likelihood

ratio for a positive test was 3.84 and the likelihood ratio for a negative test was 0.26 in group 3.

**CONCLUSION:** In conclusion, our study suggests that the CRP with the radiological severity may be used to estimate the severity of acute pancreatitis.

Is there correlation between pancreatic enzyme and radiological severity in acute pancreatitis? *World J Gastroenterol* 2008; 14(15): 2401-2405 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2401.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2401>

### INTRODUCTION

Acute pancreatitis is major cause of acute abdominal pain, and it is caused by alcohol ingestion, biliary stone, idiopathic causes and therapeutic endoscopy<sup>[1,2]</sup>. The clinical presentation of the acute pancreatitis is variable. Most of these patients recover without specific complications, but some patients display severe complication such as pancreatic ascites and pancreatic necrosis; these patients show high mortality<sup>[3,4]</sup>.

The diagnostic markers (pancreatic enzymes such as amylase and lipase) and the risk factors that affect the clinical outcome are not well established by the previous clinical studies<sup>[5-7]</sup>. However, we have reservations about any correlation of various diagnostic markers, including pancreatic enzymes and the clinical features, to the outcome of acute pancreatitis. Further, the recent development of radiological diagnostic instruments allows for a more accurate diagnosis and easier follow up<sup>[8-10]</sup>. So in this study, we determined the correlation between the levels of pancreatic enzyme and the radiological severity of acute pancreatitis.

### MATERIALS AND METHODS

Between July 2004 and July 2005, we reviewed the re-

Table 1 Characteristics of each group (%)

	Total	G-1	G-2	G-3
Sex				
Male	83 (69.7)	8 (23.5)	30 (25.2)	25 (21.0)
Female	36 (30.3)	13 (10.9)	16 (13.4)	7 (6.0)
Mean age (yr)	55.7 ± 15.7	51.2 ± 15.3	62.4 ± 14.6	51.9 ± 14.8
Etiology

cords of 119 patients who were admitted to Chung Nam National University Hospital with acute pancreatitis. The diagnosis of acute pancreatitis was based on typical symptoms, including acute abdominal pain and a serum amylase level that was three times higher than the normal limit. After diagnosis is established, computed tomography (CT) scanning was performed to determine the findings and grade of disease. We excluded cases which the CT scan was not performed. We reclassified the CT grade into three groups. Group 1 was CT grade A + B, group 2 was CT grade C and group 3 was CT grade D + E. Serum amylase and lipase levels, the equivalent series resistance (ESR), and C-reactive protein (CRP) were tested and measured at admission, and again at 24, 48 and 72 h after admission. Also, the Ranson score and APACHE II score were calculated at the same time. The above markers were also measured when the patients started their oral diet. Abdominal CT was performed weekly to evaluate the change of severity of pancreatitis before starting an oral diet. We evaluated the correlation of these various factors and the clinical severity of acute pancreatitis.

### Statistical analysis

Each result was calculated as a mean value and standard error. We analyzed the data using the SPSS 13.0 for windows. Chi-square tests, Student *t*-test, One-Way ANOVA test and MANOVA tests were used. For the different scoring systems, the sensitivity, specificity and overall correctness of prediction, the positive and negative predictive values and the likelihood ratios of the positive and negative tests were determined. Each score value obtained from the different scoring systems was used to calculate the different true positive (sensitivity) and false positive (1-specificity) rates to create the ROC curves. A *P* value less than 0.05 was considered a statically significant result.

## RESULTS

A total of 119 acute pancreatitis patients were included in this study. The characteristics of the patients are shown in Table 1. Eighty-three patients (69.7%) were male, and the mean age of the patients was 57 ± 15.7 years. The biliary pancreatitis patients mean age was older than that of the alcoholic pancreatitis. Forty-nine patients (41.1%) showed biliary pancreatitis and there were forty-six (38.6%)

Table 2 Serum pancreatic enzyme (at initial) according to etiology

	Amylase	Lipase	L/A ratio
Alcohol	614 ± 466.9	2227.2 ± 1988.8	4.3 ± 2.4
Biliary	1107.6 ± 1185.9	3561.6 ± 3023.8	3.9 ± 2.0
Drug	427 ± 273.5	1320.3 ± 811.7	3.1 ± 0.1
Idiopathic	893 ± 1026.9	2481.9 ± 2983.9	3.6 ± 2.5

Reference values: Total amylase 13-65 IU/L, lipase 0-200 IU/L.

alcoholic pancreatitis patients. Forty-six patients suffered with drug-associated pancreatitis and 21 patients suffered with idiopathic pancreatitis. Various autoantibodies were checked for rule out autoimmune pancreatitis for the idiopathic pancreatitis patients. According to radiological severity, there were 41 (34.5%) patients in-group 1, 46 (38.6%) patients were in-group 2 and 32 (26.8%) patients were in-group 3. The CT grade was severe in the alcoholic pancreatitis patients. The serum pancreatic enzyme level at admission was higher in the biliary pancreatitis patients than in the alcoholic pancreatitis patients, but statistical significance was not present (Table 2).

Early elevation of serum pancreatic enzyme showed a statically significant result for the severe pancreatitis group. In this group, 3 of the patients' initial serum lipase concentrations were higher than that of the other groups and this decreased more rapidly during 24 h (*P* = 0.008) after admission. The serum albumin level, BMI and Ranson score are known to be predictive risk factors for acute pancreatitis, but in our study, they did not correlate with the CT grade.

What factors were associated with radiological severity grade in our study? On univariate analysis, old age, the initial leukocyte count, the initial hemoglobin level, the initial APACH II score and the APACH II score after 24 h, the initial serum lipase concentration and initial CRP titer were all correlated with the CT grade (Table 3). But, the initial CRP level and follow up CRP titer were only correlated with the radiological grade on multivariate analysis (Table 4). Between the CRP, APACH II score and the Ranson score (Table 5), the CRP titer is more predictive and this diagnostic test result will raise the pre-test probability for prediction of the radiological severity. Group 3 patients had a longer duration of pain (2.51 ± 1.16 *vs* 3.17 ± 1.30 *vs* 6.56 ± 6.13, *P* < 0.001), a longer fasting period without an oral diet (7.49 ± 4.65 *vs* 10.65 ± 5.54 *vs* 21.88 ± 13.81, *P* < 0.001) and a longer hospital stay (9.17 ± 5.34 *vs* 14.63 ± 8.65 *vs* 24.47 ± 15.52, *P* < 0.001) than other groups. Also, the complication rate of pancreatitis was higher in-group 3 than in the other two groups (*P* < 0.005).

According to the ROC curve (Figure 1), when we set the CRP cut off value at 83 mg/L, the likelihood ratio for a positive CPR test was 3.84 and the likelihood ratio for a negative CPR test was 0.26 in group 3. This result showed good correlation with the radiological grade in the course of acute pancreatitis (Table 6).

## DISCUSSION

Acute pancreatitis arises from a variety of causes. The

<sup>a</sup>P < 0.05.

process of this disease varies from mild to severe necrotic pancreatitis. Most of these patients recover through the conservative management<sup>[11,12]</sup>. But, a few patients progress to pancreatic necrosis and multi-organ dysfunction. In this study, the mortality was very high and near 30%<sup>[13]</sup>.

There was no gold standard therapy for acute pancreatitis except for conservative management such as fasting and injection of analgesics. Therefore, prediction of severity has not yet been important for the treatment of acute pancreatitis. However, this will be an important task in the future for the preventive and treatment of complications because various drugs and therapy strategies are now being tried<sup>[6]</sup>.

We know that various methods have been used to predict the progress of acute pancreatitis, such as clinical evaluation (include multivariate analysis of the prognostic factors), radiological evaluation *via* abdominal

**Table 5** Likelihood ratio for prognostic markers at two time intervals

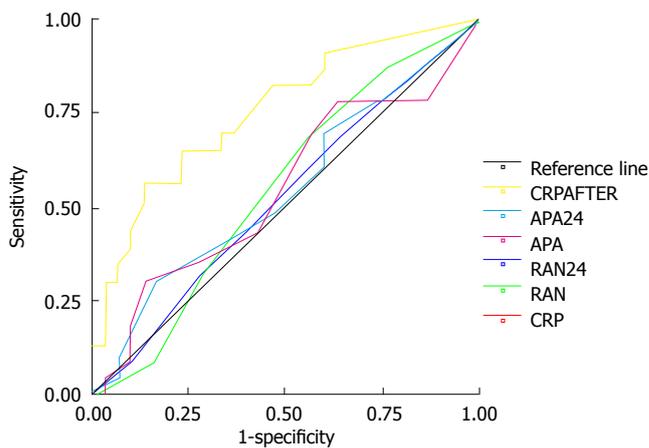

Marker	Initial	24 h after
CRP	2.22/0.39	2.09/0.46
Ranson	1.22/0.71	1.09/0.87
APACH- II	1.23/0.70	1.01/1.00

**Figure 1** ROC curve predictive severe radiologic severity.

CT, and testing of various serological markers<sup>[14-18]</sup>. The development of abdominal CT allows precise estimation of the severity of pancreas and retroperitoneal lesion. Furthermore, changes of parenchymal necrosis are now being evaluated using a dye that shows the changes of the microcirculation in the pancreas. Abdominal CT was recently used for determining the presence and diagnosis of complications in acute pancreatitis<sup>[8,9,19]</sup>. The CT grade has shown good correlations with the clinical course and the prediction of mortality, so this is good method as compared to multivariate estimation of different factors<sup>[17,20]</sup>. In our study, the CT grade was a more predictive method for the clinical course, that is, the higher the radiological grade, the longer the pain duration, the fasting duration and the hospital stay. But, those factors that represent the progress of acute pancreatitis have limitations.

We investigated the correlation between the changes of the pancreatic enzyme, the biochemical markers and the clinical results according to the Balthazar CT grade. We knew that acute pancreatitis was more frequent in six-

decade old males. The biliary pancreatitis patients were older than the alcoholic pancreatitis patients, but any radiological differences were not present. Most patients were of an alcoholic and biliary origin. We reported the difference of the pancreatic enzyme concentrations according to the etiology of pancreatitis. Our study showed that the serum amylase and lipase concentrations are higher in the biliary pancreatitis patients than the pancreatitis patients of an alcoholic origin. In another study, patients with severe biliary pancreatitis tended to have higher serum amylase levels at admission than the other groups<sup>[21]</sup>.

On the univariate analysis, the factors that affected the radiological grade were the leukocyte count at admission, the hemoglobin level, the total bilirubin concentration, serum lipase, CRP and the follow up CRP. The serum lipase concentration was used to diagnose acute pancreatitis due to its high specificity and sensitivity, but it cannot predict disease prognosis and severity. Also, in our study, the serum lipase concentration at admission was elevated in proportion to radiological severity, but it is not correctly correlated with the radiological severity on multivariate analysis. There were significant differences in each group for the APACH-II score at admission and also at 24 h. The estimation of severity through the Ranson criteria is not precise and is not an appropriate method because this method needs 48 h to complete and it has low specificity and sensitivity (77% and 75%, respectively). There was no significant correlation between the Ranson criteria and the radiological grade in our study.

The APACH-II score is the sum of the various physiologic parameters. This score has been used for evaluation of severe patients<sup>[22-24]</sup>. It has high specificity and sensitivity for acute pancreatitis. In our study, groups 2 and 3 showed high sensitivity and specificity compared to group 1. But, the APACHE II score allows monitoring both the disease progression and the response to therapy, but the system is complex, difficult to perform and less accurate for identification of local complications<sup>[25]</sup>. On our multivariate analysis, the complex APACHE II system was not correlated with the radiological grade when compared to the easily detectable CRP concentration, and the APACHE II system had a lower positive likelihood ratio and accuracy rate.

CRP is an acute stage protein that's synthesized in the liver. This parameter is usually used because it is simple and cheap<sup>[26,27]</sup>. CRP is known to be a significant factor in the differential prognosis of acute pancreatitis<sup>[5,28-30]</sup>. In this study, the CRP titer was only a predicative factor with good correlation to the radiological grade on multivariate analysis. Our results show statically significant differences at admission for prediction of severity. Also, changes of the CRP level during treatment reflect the prognosis of disease. When the cut-off value of CRP was 8.3 g/L, the positive predictive value was 38.4 mg/L in-group 3, and the negative predictive value was 0.26 in group 3. This single factor was the most precise and accurate for determining the radiological severity.

In conclusion, our study suggests that the CRP with the radiological severity may be used to estimate the severity of acute pancreatitis.

## COMMENTS

### Background

The diagnostic markers (pancreatic enzymes such as amylase and lipase) and the risk factors that affect the clinical outcome are not well established in acute pancreatitis. Abdominal computer tomography (CT) has recently been used for determining the presence and diagnosis of complications in acute pancreatitis patients.

### Research frontiers

Previous studies haven't showed that clinical evaluation and biochemical marker predict severity in acute pancreatitis. The CT grade has shown good correlations with clinical course and the prediction of mortality.

### Innovations and breakthroughs

C-reactive protein (CRP) and radiological severity have good correlation and may be used to estimate the severity of acute pancreatitis. CRP is easily measurable and is a simple method. CT is a good method which allows the prediction of clinical course and mortality, but it is expensive. Therefore, CRP is alternative method and clinically useful for prediction severity.

### Peer review

This interesting study suggests that the CRP with the radiological severity may be used to estimate the severity of acute pancreatitis. The contents of the manuscript are reasonable, and this may be a useful method for prediction of clinical course and mortality, as the author's state.

### Abstract

**AIM:** To compare the antisecretory activity and plasma drug concentrations of a single oral dose of 10 mg lafutidine, a novel H<sub>2</sub> receptor antagonist, with those of the proton pump inhibitor lansoprazole (LPZ) 30 mg.

**METHODS:** Ten volunteers without *H. pylori* infection participated in this crossover study comparing lafutidine 10 mg with LPZ 30 mg. Intra-gastric pH was monitored for 6 h in all participants, and blood samples were collected from four randomly selected individuals after single-dose administration of each drug.

**RESULTS:** The median intra-gastric pH was significantly higher in individuals who received lafutidine 10 mg than in those who received LPZ 30 mg 2, 3, 4, 5, and 6 h after administration. Maximal plasma drug concentration was reached more promptly with lafutidine 10 mg than with LPZ 30 mg.

**CONCLUSION:** In *H. pylori*-negative individuals, gastric acid secretion is more markedly inhibited by lafutidine

than by LPZ.

### INTRODUCTION

Gastroesophageal reflux disease (GERD) commonly occurs in the western countries<sup>[1,2]</sup>, and its prevalence is now increasing in Japan<sup>[3,4]</sup>. Recently, Ohara *et al*<sup>[5]</sup> have shown that 42.2% of Japanese adults experience heartburn, similar to the rate of 42.4% reported in western studies<sup>[1]</sup>. Gastric acid has an important role in the pathogenesis of GERD. Suppression of gastric acid secretion is the most common therapeutic approach, and more effective and promptly acting treatments are required.

Two types of potent gastric acid-suppressing agents, proton pump inhibitors (PPIs) and histamine H<sub>2</sub> receptor antagonists (H<sub>2</sub>RAs), are widely used to treat GERD. PPIs such as lansoprazole (LPZ), rabeprazole, and omeprazole, the most potent acid inhibitors available, are often used for first-line treatment. Controlled studies have demonstrated that PPIs are far more effective than H<sub>2</sub>RAs in patients with GERD<sup>[5-9]</sup>. In the treatment of reflux esophagitis, H<sub>2</sub>RAs have a number of disadvantages compared to PPIs, including shorter lasting efficacy and the development of tachyphylaxis, both limiting routine use<sup>[10]</sup>. In contrast, PPIs are highly effective, and produce profound and sustained inhibition of gastric acid secretion, making these agents the mainstay of treatment for GERD.

GERD has a high rate of relapse. The rising use of PPI therapy on demand has raised issues regarding efficacy. Several studies have demonstrated that on demand therapy with PPIs provides an alternative to continuous treatment in patients with non-severe GERD<sup>[11,12]</sup>. However, pH monitoring studies<sup>[13-15]</sup> have shown that PPIs require 2 d to 3 d to inhibit acid secretion efficiently. In contrast, H<sub>2</sub>RAs potentially and promptly suppress gastric acid secretion<sup>[16,17]</sup>. In this respect, H<sub>2</sub>RAs might have advantage over PPIs, especially on the first day of treatment, i.e., when used on demand, for GERD. Furthermore, concerning the characteristics of GERD in Japan, it is important to distinguish the significant difference of acid secretion in Japanese patients when compared with that of western countries<sup>[18,19]</sup>. Acid secretion among Japanese patients is lower compared to that of western population irrespectively of the status of *H. pylori* infection. Moreover, endoscopic studies<sup>[3,4]</sup> have shown that GERD is mild in most Japanese patients. H<sub>2</sub>RAs are thus sometimes used for the treatment of mild-to-moderate GERD in Japan.

Lafutidine is a newly synthesized H<sub>2</sub>RA. Previous studies have shown that lafutidine promptly inhibits gastric acid secretion not only at night but also during the day<sup>[16]</sup>, in contrast to other conventional H<sub>2</sub>RAs. Since patients with GERD often have symptoms during the day, we evaluated lafutidine in this study.

Few studies<sup>[17]</sup> have examined the correlation between intragastric pH and blood drug concentrations in the early phase (1-6 h) after a single dose of H<sub>2</sub>RAs or PPIs. The acid inhibitory activity of PPIs depends significantly on cytochrome P450 (CYP) 2C19 genotype, as well as on intrinsic pharmacokinetic and pharmacodynamic characteristics and dosing schemes<sup>[20,21]</sup>. CYP2C19 genotypes were therefore determined for all participants in this study.

The major aim of this study was to compare the antisecretory activity of a single oral dose of 10 mg lafutidine (H<sub>2</sub>RA) with that of a single dose of 30 mg LPZ (PPI). We also examined the correlation between intragastric pH and plasma drug concentrations during the early phase (1-6 h) after single-dose administration.

## MATERIALS AND METHODS

### Participants

Ten healthy male volunteers aged between 24 years and 48 years (mean, 28.7 years) and weighing 55 kg to 86 kg (mean, 68.6 kg) were included. Nobody of them had a history of gastrointestinal or hepatobiliary disease or of *H. pylori* eradication therapy. None were receiving regular medication. All volunteers gave written informed consent. The study protocol was approved by the ethical committee of Tohoku University Graduate School of Medicine.

### Detection of *H. pylori* infection

*H. pylori* infection was diagnosed by the <sup>13</sup>C-urea breath test<sup>[22]</sup>. A total of 10 *H. pylori*-negative volunteers were invited and agreed to participate in this study.

### Cytochrome P450 (CYP) 2C19 genotyping

After obtaining informed consent, a venous blood sample

was collected from all participants. DNA was extracted from the nuclei of venous white blood cells. Genetic mutations were analyzed by either the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method<sup>[23]</sup> or by the TaqMan PCR amplification method (Applied Biosystems Japan, Chiba, Japan<sup>[24]</sup>). On the basis of point mutations in exons 4 and 5, CYP2C19 gene status can be classified as homo-extensive metabolizer (homo-EM), hetero-extensive metabolizer (hetero-EM), or poor metabolizer (PM)<sup>[25-27]</sup>. Homo-EM has wild type alleles (wt/wt) without any mutation in exons 5 or 4; PM has mutated alleles (m1/m2) with mutations in both exons 5 and 4 (m1/m2, m1/m1, or m2/m2); and hetero-EM has a mutated allele in either exon 5 or 4 (wt/m1 or wt/m2).

### Study protocol

All subjects (homo-EM = 3, hetero-EM = 6, PM = 3) participated in an open-label crossover study with lafutidine 10 mg or LPZ 30 mg. They were randomly assigned to receive a single oral dose of lafutidine 10 mg tablets or LPZ 30 mg capsule at a fixed time. A washout period of at least 14 d intervened between the two study periods. Intragastric pH was monitored for 6 h after drug administration. To monitor intragastric pH, a pH electrode was inserted transnasally and positioned fluoroscopically in the gastric corpus, approximately 10 cm below the esophagogastric junction. Intragastric pH was measured at 10-second intervals by means of a portable pH meter attached to a glass pH electrode (Chemical Instrument, Tokyo, Japan). The pH electrode was calibrated before each recording, using standard buffers of pH 1.68, 4.01, and 6.86. The pH data were analyzed using a commercially available software (Chemical Instrument). No food was allowed, and 100 mL of tap water was allowed only when participants felt thirsty. All subjects were instructed to remain upright; normal daily activities were not restricted.

### Sample collection and assay for lafutidine and LPZ plasma concentration

To study the correlation between intragastric pH and plasma drug concentrations, blood samples were randomly collected from four individuals (No. 3, 5, 6, 7) in heparinized tubes before and 0.25, 0.5, 1, 1.5, 2, 3, 4, and 6 h after drug administration. Blood samples were immediately centrifuged at 3000 r/min for 10 min. All samples were stored at -20°C until assay. Plasma LPZ levels were measured by high performance liquid chromatography/tandem mass spectrometry<sup>[28,29]</sup>. This method requires only 20 µL of serum and is a simple procedure. Analytes and the internal standard (lansoprazole deuterium derivatives) were separated using a mobile phase of acetonitrile/1 mmol/L ammonium formate (140/60, mL/L) on a C18 analytical column and analyzed in the selected reaction-monitoring (SRM) mode. Detection limit was 500 fg/20 µL.

Plasma lafutidine concentrations were determined by high-performance liquid chromatography (HPLC), using 2-phenyl-1H-benzimidazol as an internal standard (IS). A 1 mL plasma sample added to 0.5 mL of 1 N NaOH and 0.05 mL of IS (20 µg/mL) was mixed with 5 mL of

Table 1 Characteristics of study participants

Subject	CYP2C19	Age	Height (cm)	Body weight (kg)	BMI
1	Homo-EM	23	171	70	23.9
2	Homo-EM	26	170	58	20.1
3	Homo-EM	28	169	60	21.0
4	Hetero-EM	22	165	60	22.0
5	Hetero-EM	28	170	80	27.6
6	Hetero-EM	40	172	75	25.3

Homo-EM: Homo-extensive metabolizer; Hetero-EM: Hetero-extensive metabolizer; PM: Poor metabolizer.

n-hexane/dichloromethane (1:1). The mixture was shaken and then centrifuged at 3000 r/min at 5°C for 5 min. The organic phase was dried under a stream of nitrogen. The residue was dissolved in 0.2 mL of 10 mmol/L phosphate buffer (pH 6.1):acetonitrile (77:23), and the solution was injected into an HPLC system (Waters-2690) with a YMC-Pack Pro C18 column (4.6 i.d. × 150 mm, 5 μm), and a flow rate of 1 mL/min. UV absorbance was quantified at 230 nm. Detection limit was 5 ng/mL.

### Statistical analysis

Intragastric pH is expressed as median values (ranges). Differences in between groups were assessed with the Wilcoxon signed-rank test. *P* values < 0.05 were considered to be statistical significant.

## RESULTS

All 10 volunteers (all men; mean age, 28.7 years) completed the study according to the protocol. There were no adverse events. Three subjects were homo-EMs, 4 were hetero-EMs, and 3 were PM (Table 1).

Median intragastric pH values during the first 6 h after the administration of each drug are shown in Figure 1. The median intragastric pH was significantly higher with lafutidine 10 mg than with LPZ 30 mg 2 h, 3 h, 4 h, 5 h, and 6 h after drug administration.

Mean plasma drug concentrations during the first 6 h after treatment are shown in Figure 2. The time to peak plasma concentration ( $T_{max}$ ) was shorter with lafutidine 10 mg (1 h) than with LPZ 30 mg (2 h).

## DISCUSSION

PPIs and H<sub>2</sub>RAs are potent agents widely used for the treatment of GERD. Recently, the frequency of GERD has been increasing in Japan. Endoscopic studies have shown that the overall prevalence of reflux esophagitis among Japanese adults is 14% to 16%<sup>[3,4]</sup>.

The increasing use of on-demand PPI therapy has raised various issues regarding efficacy. On-demand therapy has been reported an alternative to continuous treatment in patients with mild-to-moderate GERD who have frequent symptomatic relapses<sup>[11,12]</sup>. Although many

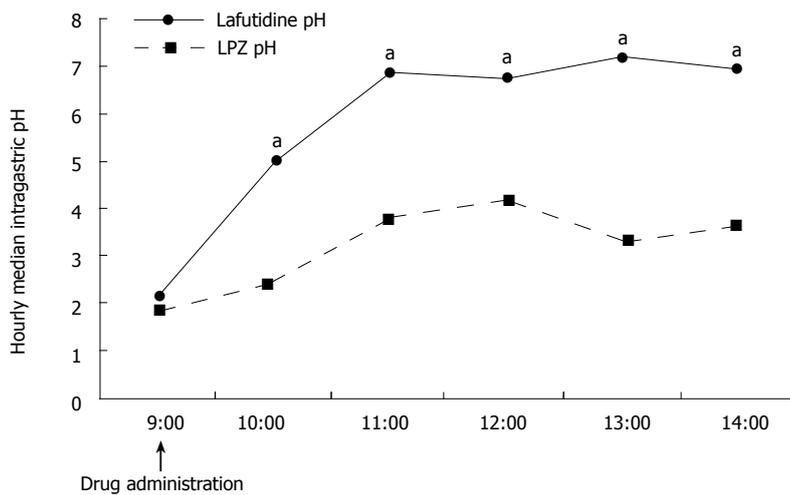

clinicians regard PPIs to be superior to H<sub>2</sub>RA in terms of continuous gastric acid suppression, a systematic review<sup>[13]</sup> of the efficacy of PPIs for heartburn relief during the first 1 d to 2 d of therapy found that symptoms were completely relieved for the entire day in about 30% of patients after their first dose. In contrast, H<sub>2</sub>RAs potently and quickly suppress gastric acid secretion<sup>[17]</sup> and may thus have advantages over PPIs, especially for the on-demand treatment of GERD.

The incidence of atrophic gastritis in the general population is estimated to be higher in Japan than in western countries<sup>[30,31]</sup>, whereas gastric acid levels are generally lower in Japan<sup>[18,19]</sup>. Moreover, endoscopic studies<sup>[3,4]</sup> have reported that most Japanese patients have nonerosive reflux disease or mild forms of GERD. Consequently, some Japanese patients use H<sub>2</sub>RAs rather than PPIs for the management of mild-to-moderate GERD. Against this background, we compared the H<sub>2</sub>RA lafutidine with LPZ, one of the most widely used PPIs for the treatment of GERD in Japan.

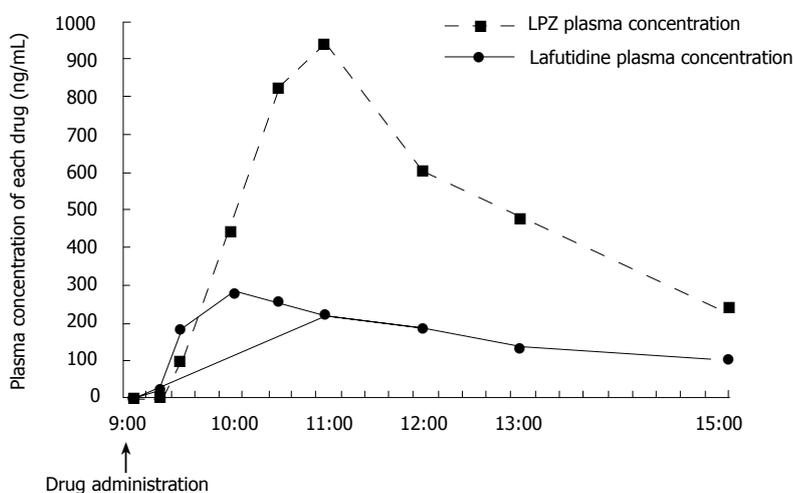

In this study, lafutidine 10 mg was associated with a significantly prompter rise in intragastric pH and stronger inhibition of gastric acid secretion than was LPZ 30 mg during the early period (1-6 h) after administration of a single oral dose of either drug. Moreover, analysis of blood samples collected from randomly selected subjects showed that lafutidine 10 mg produced a significantly faster prompter rise in the plasma drug concentration than did LPZ 30 mg. These findings suggest that lafutidine 10 mg is especially useful for the on-demand treatment of acid-related symptoms in patients with mild GERD because of its prompter onset of action. However, we must consider the fact that H<sub>2</sub>RA have a number of disadvantages as compared with PPI, including a shorter duration of action and the development of tachyphylaxis, limiting routine use<sup>[10]</sup>.

Our results are attributed to the different mechanisms of action of PPIs and H<sub>2</sub>RAs. PPIs are absorbed in the small intestine and transported *via* the systemic circulation to gastric parietal cells, where they bind to the proton pump and potently inhibit gastric acid secretion<sup>[32]</sup>. Some time is required for the PPIs to accumulate in parietal cells and then inhibit acid secretion. H<sub>2</sub>RAs are absorbed in the small intestine, reach gastric cells *via* the systemic circulation, and then directly and rapidly bind to gastric cell histamine receptors, resulting in immediate inhibition of gastric acid secretion.

Inhibition of gastric acid secretion by PPIs is known to significantly depend on CYP2C19 genotype status, as well as on intrinsic pharmacokinetic and pharmacodynamic characteristics and dosing schemes<sup>[20,21]</sup>. PPIs, such as LPZ, omeprazole, and pantoprazole, are mainly metabolized by CYP2C19 in the liver. As stated above, CYP2C19 genotypes are classified into the three groups: homo-EM, hetero-EM, and PM. Plasma PPI levels and intragastric pH values during PPI treatment are lowest in homo-EM, followed by hetero-EM, and highest in PM<sup>[23-25]</sup>. Although the subjects this study included 3 PMs, lafutidine 10 mg was associated with a prompter rise in median intragastric pH during the early period (1-6 h) after administration of a single oral dose, as compared with LPZ 30 mg.

**Figure 1** Median intragastric pH during a 6 h post administration period for all subjects ( $n = 10$ ). The solid line (●) shows the hourly median intragastric pH after administration of 10 mg lafutidine, and the broken line (■) that after administration of 30 mg LPZ. The median intragastric pH values during the post administration period were significantly higher with lafutidine than with LPZ 2, 3, 4, 5, and 6 h after drug administration. Arrow: drug administration. The statistical significance of differences between the drug groups in intragastric pH among was assessed with the Wilcoxon signed-rank test.  $^aP < 0.05$  vs LPZ pH.

**Figure 2** Plasma drug concentrations during a 6 h post administration period in four individuals (No. 1, 4, 5, 6). The solid line (●) indicates the plasma drug concentration after the administration of 10 mg lafutidine, and the broken line (■) that after the administration of 30 mg LPZ. Lafutidine ( $T_{max}$  1 h) reached its peak plasma concentration faster than LPZ ( $T_{max}$  2 h). Arrow: Drug administration.

In conclusion, lafutidine 10 mg has a prompt onset of action than LPZ 30 mg in the early phase (1-6 h) after administration of a single oral dose. Lafutidine may thus offer advantages over LPZ for the on-demand treatment of GERD.

## COMMENTS

### Background

The prevalence of Gastroesophageal reflux disease (GERD) symptoms is now increasing in Japan. Concerning the characteristics of GERD in Japan, it is important to distinguish the significant difference of acid secretion in Japanese patients when compared with that of patients from western countries. Acid secretion among the Japanese individuals lower when compared to that of the western population irrespectively of *H. pylori* infection status. In Japan, histamine  $H_2$  receptor antagonists ( $H_2$ RAs) are thus sometimes used for the treatment of mild-to-moderate GERD.

### Research frontiers

To compare lafutidine 10 mg ( $H_2$ RAs) to LPZ 30 mg (proton pump inhibitors: PPI) in the antisecretory activity and blood drug concentration in the immediate early period after administration of a single dose.

### Innovations and breakthroughs

Few studies have reported the effect at the early post-administration phase (1-6 h) of single dose of  $H_2$ RA and PPI.

### Applications

We clearly state that lafutidine 10 mg has a prompt onset of action than LPZ

30 mg in the early phase (1-6 h) after administration of a single oral dose. It is reported that rapid acid suppression is important for effective pain relief at the onset of treatment in GERD patients. Thereby, our results show that lafutidine offers advantages over LPZ for the on-demand treatment of GERD.

### Peer review

This is a nice clear study. The authors ascertained the effectiveness of lafutidine compared with LPZ in the elevation of intragastric pH in the immediate early period after a single oral administration.

### Abstract

**AIM:** To evaluate the association between colonic polyps and diverticular disease in Japan.

**METHODS:** We retrospectively reviewed the medical records of 672 consecutive patients who underwent total colonoscopy between August 2006 and April 2007 at Nishinjo Hospital, Okinawa, Japan. Patients with a history of any of the following were excluded from the study: previous polypectomy, colonic resection, and inflammatory bowel diseases. The association between colonic polyps and diverticular disease was analyzed by logistic regression analysis, adjusted for age and sex.

**RESULTS:** Prevalence of colonic polyps in all patients with diverticular disease was significantly higher than that in those without diverticular disease (adjusted odds ratio 1.7).

**CONCLUSION:** Our data showed that patients with diverticular disease have a higher risk of colonic polyps compared to those without.

### INTRODUCTION

The prevalence of colonic neoplasia and diverticular disease has increased in recent years<sup>[1-5]</sup>. Both have common risk factors such as age and a lack of dietary fiber<sup>[6-10]</sup>. Despite common epidemiological trends and risk factors, any association between these diseases has not been clarified. Although some data have been reported regarding the association between these diseases in Western countries<sup>[11-14]</sup>, there has been no study in Japan. There are differences between diverticular disease in Western countries and that seen in Asia, including Japan<sup>[15-19]</sup>. Diverticular disease of the right colon is rare in Western countries<sup>[20-22]</sup>, whereas in Asia, diverticular disease of the right colon is common and has been increasing in recent years<sup>[23-27]</sup>.

This study evaluated the association between colonic polyps and diverticular disease in Japanese patients undergoing total colonoscopy.

### MATERIALS AND METHODS

We retrospectively reviewed the medical records of consecutive patients who underwent total colonoscopy between August 2006 and April 2007 at Nishinjo Hospital, Okinawa, Japan. The major indications for total colonoscopy were screening examination after hemorrhoidectomy and rectal bleeding. Patients with a history of any of the following were excluded from this study: Previous polypectomy, colonic resection, and inflammatory bowel diseases. The location of diverticula and polyps was classified into three groups: Distal, proximal and bilateral colon. The borderline between the distal and proximal colon was set at the splenic flexure. Diverticular disease was defined as the presence of one

**Table 1** Number of patients with diverticular disease and colonic polyps by colon segment *n* (%)

Colon segment	Patients with diverticular disease (%)	Patients with polyps (%)
Distal colon	20 (3.0)	89 (13.2)
Proximal colon	98 (14.6)	53 (7.9)
Bilateral colon	47 (7.0)	47 (7.0)
Total	165 (24.5)	189 (28.1)

**Table 2** Comparison of demographic features between patients with or without diverticular disease

	Patients with diverticular disease	Patients without diverticular disease
No. of patients	165	508
Mean age (SD)	58.0 (13.6) <sup>b</sup>	47.3 (14.7)
Sex (female: male)	52:113 <sup>d</sup>	219:289
No. of patients with polyps (%)	71 (43.0) <sup>d</sup>	118 (23.2)

<sup>b</sup>*P* < 0.01 *vs* without diverticular disease using the *t* test; <sup>d</sup>*P* < 0.01 *vs* without diverticular disease using the chi-square analysis.

or more diverticula, and all polyps were diagnosed as adenoma by histological examination.

### Statistical analysis

The chi-square test was used to compare sex and prevalence of colonic polyps, and the *t* test to compare mean age. Logistic regression analysis was used to examine the association between diverticular disease and colonic polyps, adjusting for age and sex. *P* < 0.05 was considered statistically significant. All statistical analyses were performed with SPSS 15.0 for Windows.

## RESULTS

The present study included 672 consecutive patients. Of these, 165 (24.5%) had diverticular disease and 189 (28.1%) had colonic polyps. The most common segment for diverticular disease was the proximal, followed by the bilateral and distal colon. The most common segment for colonic polyps was the distal, followed by the proximal and bilateral colon (Table 1). Among patients with diverticular disease, none had active segmental colitis.

Table 2 summarizes the demographic features of patients with or without diverticular disease. The mean age of patients with diverticular disease was significantly higher than that of patients without diverticular disease (*P* < 0.001). There were significantly more males in those patients with diverticular disease than those without (*P* = 0.008). The prevalence of colonic polyps in patients with or without diverticular disease was significantly different at 43% and 23.2%, respectively.

Using logistic regression analysis adjusted for age and sex, we calculated the adjusted odds ratio (OR) for colonic polyps (Table 3). This confirmed that the prevalence of colonic polyps in all patients with diverticular disease or those with diverticular disease in the proximal colon was significantly higher than that in

**Table 3** Association between colonic polyps and diverticular disease adjusted for age and sex by logistic regression analysis

Segment with diverticular disease	No. of patients with polyps /No. of patients with diverticular disease (%)	OR	95% CI	<i>P</i> values
Distal colon	11/20 (55.0)	2.3	0.9-5.8	0.09
Proximal colon	41/98 (41.8)	1.9	1.2-3.0	0.01
Bilateral colon	19/47 (40.4)	1.2	0.6-2.3	0.60
Total	71/165 (43.0)	1.7	1.1-2.5	0.01

patients without diverticular disease (adjusted OR 1.7 and 1.9, respectively).

## DISCUSSION

Colonic neoplasia and diverticular disease have common epidemiological trends and risk factors such as age and a lack of dietary fiber<sup>[6,7]</sup>. However, little is known about any association between these diseases. Morini and others found an increased risk for sigmoid colon adenoma in Italian patients with diverticular disease, in a prospective study<sup>[28]</sup>. Kieff and others have reported an increased risk for distal neoplasia in women in the USA with extensive distal diverticulosis, in a cross-sectional study<sup>[29]</sup>. Although the sample size and distribution of patients included in the present study might inadequately reflect the general population of Japan, our data showed a 1.7-fold increased risk for colonic polyps in patients with diverticular disease, as compared to those without. In addition, although the prevalence of colonic polyps in patients with diverticular disease in the proximal colon and that in patients without was significantly different, the prevalence of colonic polyps in patients with diverticular disease in the distal or bilateral colon and that in patients without diverticular disease was not significantly different. This observation may be the result of the limited number of patients with diverticular disease in the distal and bilateral colon. However, this result was similar to a previous study in Korea, in which patients with proximal diverticular disease had a higher risk of any proximal neoplasia than did other patients<sup>[30]</sup>. Diverticular disease of the proximal colon is rare in Western countries, whereas in Asia including Japan, diverticular disease of the proximal colon is relatively common<sup>[16,17,23,24]</sup>. These results suggest that, regardless of the segment with diverticular disease or race, patients with diverticular disease have a higher risk of colonic neoplasia.

In conclusion, our data showed patients with diverticular disease have a higher risk of colonic polyps compared to those without (OR 1.7). This finding needs to be taken into account in surveillance for colonic neoplasia. However, further research is needed to clarify the mechanism of the association between these diseases.

## COMMENTS

### Background

Prevalences of colonic neoplasia and diverticular disease have increased in recent years. Both colonic neoplasia and diverticular disease have common risk factors such as age and a lack of dietary fiber. Despite common epidemiological trends and risk factors, any association between these diseases has not been clarified.

**Research frontiers**

There is an increasing body of epidemiological evidence regarding an association between diverticular disease and colonic polyps.

**Innovations and breakthroughs**

This study clarified the strong association between diverticular disease and colonic polyps. Moreover, this study suggested that regardless of the segment with diverticular disease or race, patients with diverticular disease have a higher risk of colonic neoplasia.

**Applications**

These results need to be taken into account in surveillance for colonic neoplasia.

**Peer review**

It is interesting that in the authors' series there were similar associations between left and right sided diverticulosis and polyps.

### Abstract

**AIM:** To determine the immediate surgical outcome and recovery of bowel function following posterior pelvic exenteration (PPE) for primary rectal cancer with suspected local invasion to the female internal reproductive organs, in comparison with a case-control series of standard resection for primary rectal cancer.

**METHODS:** We analyzed 10 consecutive female patients undergoing PPE for the aforementioned indication between December 2003 and May 2006 in a single institution. Data were prospectively collected during hospitalization, including patient demographics, tumor- and operation-related variables and early surgical outcomes. These patients were compared with a group of female patients, matched for age, co-morbidity and location of tumor, who underwent standard resection for primary rectal cancer in the same period (non PPE group).

**RESULTS:** In the PPE group, pathological reports showed direct invasion of the reproductive organs in 4 cases and an involvement of lymph nodes in 7 cases. A sphincter-saving operation was performed in each case. Operative time was longer (274 min *vs* 157 min,  $P < 0.001$ ) and blood loss was greater (769 mL *vs* 203 mL,  $P = 0.008$ ) in the PPE group. Time to first bowel movement, time to first defecation, time to resumption of normal diet, and hospital stay were not significantly different between the two groups. Postoperative complication rates were also similar.

**CONCLUSION:** PPE for rectal cancer was associated

with longer operative time and increased blood loss, but did not compromise immediate surgical outcomes and postoperative bowel function compared to standard rectal resection.

Comparison of immediate surgical outcomes between posterior pelvic exenteration and standard resection for primary rectal cancer: A matched case-control study. *World J Gastroenterol* 2008; 14(15): 2414-2417 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2414.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2414>

### INTRODUCTION

The incidence of rectal cancer invading the female reproductive organs has been reported to be up to 18%<sup>[1-3]</sup>. An en-bloc resection of the rectum, uterus and both ovaries, known as a posterior pelvic exenteration (PPE), is a curative procedure for this condition<sup>[4-6]</sup>. There is also certainty that PPE should be performed in every female rectal cancer patient with suspected local invasion to the reproductive organs because it is difficult to distinguish intraoperatively whether adherence to the adjacent organs is malignant or only due to the peritumoral inflammatory process<sup>[2,7]</sup>. Non en-bloc resection of the tumor invading other structures resulted in higher risk of local recurrence and poorer survival<sup>[7]</sup>.

PPE remains a radical procedure associated with significant morbidity and mortality<sup>[8-10]</sup>. Details of early surgical outcomes related to the procedure are not clearly defined in the available literature. Furthermore, most investigations<sup>[11-16]</sup> included heterogeneous patients with different surgical operations, including cases of primary and recurrent rectal cancer, and focused primarily only on patient survival rate.

The aim of this study was to determine the immediate surgical outcome and recovery of bowel function following PPE for primary rectal cancer with suspected local invasion to the female internal reproductive organs in comparison with a case-control series of standard resection for primary rectal cancer.

## MATERIALS AND METHODS

### Patients

We carried out an analysis of 10 consecutive female patients with rectal adenocarcinoma with suspected local invasion to the female internal reproductive organs who underwent PPE between December 2003 and May 2006 at the Department of Surgery, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand. Data were prospectively collected during hospitalization. The study was approved by the Institutional Ethics Committee and informed consent was obtained from all the patients. These patients were compared with a group of female patients who underwent standard resection for primary rectal cancer in the same period (non PPE group). They were matched for age, co-morbidity and location of tumor, with the ratio of 1 PPE case to 2 non PPE cases.

Rectal cancer was defined as a tumor with the lower edge located within 15 cm from the anal verge measured by rigid sigmoidoscopy. PPE was defined as an extirpation of the rectum in block with the internal genital organs and draining lymph nodes. Patients receiving neoadjuvant therapy, or who had recurrent tumor or laparoscopic resection, were excluded.

### Surgical procedure

All patients were operated on by the same surgical team in the colorectal unit. Gynecologists participated in a few cases with PPE. Each patient underwent preoperative mechanical bowel preparation using 2 liters of polyethylene glycol a day before surgery. In the operating room, all patients received general anesthesia with or without epidural anesthesia. Intravenous prophylactic antibiotics were administered. The abdominal operation was performed *via* midline incision. Standard oncological resection was performed in every patient. Adequate mesorectal excision was performed in tumors of the upper third of the rectum and total mesorectal excision in tumors of the middle and lower third of the rectum. The type of reconstruction, either straight, side-to-end or colorectal anastomosis, was left to the discretion of each surgeon. No protective stoma and pelvic drain was performed. Prophylactic intravenous antibiotics were discontinued within 24 h-48 h.

### Statistical analysis

All data were recorded including patient demographic, operative details (suspected organs involved, operative time and blood loss), pathological staging and postoperative outcomes. The postoperative outcomes, including mortality, morbidity, time to first bowel movement, time to first defecation, time to resumption of normal diet, and hospital stay, were analyzed. Patients were discharged from

Table 1 Correlation between indications, tumor location and pathologic findings in PPE group ( $n = 10$ )

Suspected organs involved	$n$ (lower: middle: upper rectum)	Pathological findings		
		Direct invasion (T4)	Perirectal invasion (T3)	Positive lymph nodes (N-positive)
Vagina	1 (1:0:0)	0	1	1
Uterus	7 (0:5:2)	2	5	4
Ovaries	2 (0:1:1)	2 <sup>1</sup>	0	2
Total	10 (1:6:3)	4	6	7

<sup>1</sup>Including 1 case of Krukenberg tumor.

the hospital when they had no fever, good ambulation, good appetite and satisfactory recovery of bowel function. All patients were scheduled for follow-up at 30 d postoperatively. Patients with T3/4 or N-positive tumors were further scheduled for adjuvant therapy.

All data were prepared and compiled using SPSS computer software (version 10.0 for Windows). Means and standard deviations were assessed. The Kolmogorov-Smirnov test was used to test for the pattern of data distribution. *t*-tests were used to compare data between the two groups when they showed normal distribution. Mann-Whitney *U* tests were used when data were not normally distributed. Pearson chi-square tests or Fisher's exact tests were used for categorical data. A *P* value of less than 0.05 was considered statistically significant.

## RESULTS

During the 2.5-year period mentioned, 64 female patients underwent various curative resection of the rectum for primary rectal cancer. Ten patients (16%), with a mean age of 57 years (range 43-81), underwent PPE. Sphincter-saving operations and R0 resection were achieved in all cases studied.

In the PPE group, pathological reports showed direct invasion of reproductive organs in 4 cases and an involvement of lymph nodes in 7 cases. Correlation between indications, tumor location and pathologic findings in the PPE group are shown in Table 1. Patient- and tumor- related variables were not statistically different between the PPE and non-PPE groups. The average operative time and blood loss were significantly greater in the PPE group (274 min *vs* 157 min,  $P < 0.001$ ; 769 mL *vs* 203 mL,  $P = 0.008$ , respectively; Table 2).

No thirty-day postoperative mortality occurred in this study. Each group had a complication rate of 10%; one intraabdominal abscess requiring a 10-d regimen of intravenous antibiotics occurred in the PPE group, one superficial surgical site infection and one anastomotic leakage requiring percutaneous drainage and bowel rest occurred in the non-PPE group. Time to first bowel movement, time to first defecation, time to resumption of normal diet and postoperative hospitalization were not significantly different between the two groups (Table 3).

## DISCUSSION

In the present series, PPE was employed in 16% of the

**Table 2** Patient- and tumor- related variables between PPE group and non PPE group (mean  $\pm$  SD)

Variables	PPE (n = 10)	Non PPE (n = 20)	P
Patient related			
Age (yr)	57.4 $\pm$ 13.5	57.8 $\pm$ 13.1	0.94
BMI (kg/m <sup>2</sup> )	22.2 $\pm$ 2.9	21.4 $\pm$ 3.7	0.58
ASA status I : II : III	30:50:20	45:50:05	0.39
Hypoalbuminemia <sup>1</sup>	50	25	0.23
Preoperative CEA (ng/mL)	36.9 $\pm$ 44.7	11.5 $\pm$ 21.0	0.12
Tumor related			
Stage I : II : III : IV <sup>2</sup>	0:30:60:10	20:20:60:0	0.30
Tumor size (cm)	6.0 $\pm$ 2.2	4.8 $\pm$ 2.0	0.16
Location of the tumor from the anal verge (cm)	9.1 $\pm$ 3.3	9.0 $\pm$ 3.0	0.93

BMI: Body mass index; ASA: American society of anesthesiologists; CEA: Carcinoembryonic antigen. <sup>1</sup>Serum albumin less than 3.5 mg/dL; <sup>2</sup>Patient with Krukenberg tumor.

female patients with primary rectal cancer, which was comparable to previous reports of 14%-28% in the literature<sup>[1,7,17]</sup>. The mortality rate after PPE is generally less than 10%<sup>[1,13,18,19]</sup>, depending on patient characteristics, comorbidity and hospital setting. The zero 30-d mortality found in the present study may be the result of the fact that all the operations were electively performed by experienced colorectal surgeons and few patients had severe co-morbidity. In order to minimize mortality, PPE should be performed in selective cases in a specialized and well-equipped medical institution.

The PPE group tended to have larger tumors and a higher preoperative carcinoembryonic antigen (CEA) level than the non PPE group. However, this finding did not decrease the rate of sphincter-saving operation because preservation of the anal sphincter mainly depends on the location of the tumor in relation to the anal verge rather than the size of the lesion<sup>[20,21]</sup>. In our experience, PPE increases the operative time and blood loss but does not increase morbidity and hospital stay time. Bannura *et al*<sup>[1]</sup> revealed that PPE was associated with prolonged operative time, increased postoperative complications and delayed hospital discharge when compared with non PPE cases. This report from Chile included 50% morbidity with an average hospital stay of 19 d in the PPE group. The high morbidity in that study may be due to one-third of PPE involving abdominoperineal excision and one-fifth receiving neoadjuvant chemoradiation. Operation for recurrent pelvic malignancy<sup>[13]</sup>, concomitant resection of bony pelvis<sup>[16]</sup>, and preoperative pelvic radiation<sup>[22]</sup> have been identified as risk factors for postoperative morbidity after PPE. The common complications following PPE include intraabdominal hemorrhage, pelvic abscess or fluid collection, anastomotic leakage, urinary tract infection, wound infection, and intraperineal fistula<sup>[23,24]</sup>.

In the present study, we found no difference in clinical recovery of bowel function between the two groups. There have been a number of independent factors influencing recovery of gut function<sup>[25-27]</sup>, including postoperative complications, narcotics administration, electrolyte imbalance, and hypoalbuminemia<sup>[28]</sup>. However,

**Table 3** Operation related variables and surgical outcomes between PPE group and non PPE group (mean  $\pm$  SD)

Variables	PPE (n = 10)	Non PPE (n = 20)	P value
Operation related			
Operative time (min)	274 $\pm$ 73	157 $\pm$ 62 <sup>b</sup>	< 0.001
Blood loss (mL)	769 $\pm$ 549	203 $\pm$ 136 <sup>b</sup>	0.008
Outcomes			
Complications	10	10	1.00
Time to first bowel movement (h)	70 $\pm$ 29	59 $\pm$ 26	0.31
Time to first defecation (d)	5.0 $\pm$ 1.2	4.6 $\pm$ 1.5	0.42
Time to resumption of normal diet (d)	5.8 $\pm$ 3.0	4.6 $\pm$ 0.9	0.09
Hospital stay (d)	11.5 $\pm$ 7.2	9.2 $\pm$ 4.1	0.26

<sup>b</sup>P < 0.01.

no published study has been able to demonstrate any correlation between prolonged operative time or increased blood loss and delayed recovery of postoperative bowel function<sup>[29]</sup>. Length of hospital stay for the PPE group and non-PPE group was not significantly different. This finding may suggest that additional non-gastrointestinal resection does not increase operative risk and hospital stay in rectal cancer surgery<sup>[30]</sup>.

In conclusion, PPE was associated with longer operative time and increased blood loss, but did not compromise immediate surgical outcomes and postoperative bowel function compared to standard rectal resection. PPE can be justified as a liberal and safe operation for primary rectal cancer with suspected local invasion to the female internal reproductive organs.

## COMMENTS

### Background

Posterior pelvic exenteration (PPE) is the gold standard operation for rectal cancer invading the female reproductive organs. There is also no doubt that PPE should be performed in every female rectal cancer patient with suspected local invasion to the reproductive organs because it is difficult to distinguish intraoperatively whether adherence to the adjacent organs is malignant or only peritumoral inflammatory process. However, PPE remains a radical procedure and could be associated with a significant morbidity and mortality.

### Research frontiers

Details of early surgical outcomes following PPE are not clearly defined in available literatures. Furthermore, most investigations included heterogeneous patients with different surgical operations, and both with cases of primary and of recurrent rectal cancer.

### Innovations and breakthroughs

The present study clearly demonstrated that PPE did not compromise immediate surgical outcomes and postoperative bowel function comparing with standard rectal resection for rectal cancer.

### Applications

PPE could be justified as a liberal and safe operation for primary rectal cancer with suspected local invasion to the female internal reproductive organs although it is associated with longer operative time and increased blood loss comparing with standard rectal resection. Further research might focus on the long-term outcomes (such as disease free survival and survival time) between the two procedures in female patients with locally advanced rectal cancer.

**Peer review**

This clinical study compares the short-term surgical outcomes between posterior pelvic exenteration and standard rectal resection. The manuscript is well-written and very informative. It has an impact on surgical management for locally advanced rectal cancer.

### Abstract

**AIM:** To examine the relations of alcohol consumption to the prevalence of metabolic syndrome in Shanghai adults.

**METHODS:** We performed a cross-sectional analysis of data from the randomized multistage stratified cluster sampling of Shanghai adults, who were evaluated for alcohol consumption and each component of metabolic syndrome, using the adapted U.S. National Cholesterol Education Program criteria. Current alcohol consumption was defined as more than once of alcohol drinking per month.

**RESULTS:** The study population consisted of 3953 participants (1524 men) with a mean age of  $54.3 \pm 12.1$  years. Among them, 448 subjects (11.3%) were current alcohol drinkers, including 405 males and 43 females. After adjustment for age and sex, the prevalence of current alcohol drinking and metabolic syndrome in the general population of Shanghai was 13.0% and 15.3%, respectively. Compared with non drinkers, the prevalence of hypertriglyceridemia and hypertension was higher while the prevalence of abdominal obesity, low serum high-density-lipoprotein cholesterol (HDL-C) and diabetes mellitus was lower in subjects who consumed alcohol twice or more per month, with a trend toward reducing the prevalence of metabolic syndrome. Among the current alcohol drinkers, systolic blood pressure, HDL-C, fasting

plasma glucose, and prevalence of hypertriglyceridemia tended to increase with increased alcohol consumption. However, low-density-lipoprotein cholesterol concentration, prevalence of abdominal obesity, low serum HDL-C and metabolic syndrome showed the tendency to decrease. Moreover, these statistically significant differences were independent of gender and age.

**CONCLUSION:** Current alcohol consumption is associated with a lower prevalence of metabolic syndrome irrespective of alcohol intake (g/d), and has a favorable influence on HDL-C, waist circumference, and possible diabetes mellitus. However, alcohol intake increases the likelihood of hypertension, hypertriglyceridemia and hyperglycemia. The clinical significance of these findings needs further investigation.

Fan JG, Cai XB, Li L, Li XJ, Dai F, Zhu J. Alcohol consumption and metabolic syndrome among Shanghai adults: A randomized multistage stratified cluster sampling investigation. *World J Gastroenterol* 2008; 14(15): 2418-2424 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2418.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2418>

### INTRODUCTION

Alcohol consumption is a double-edged sword, and perhaps no other factor in cardiovascular health is capable of cutting so deeply in either direction depending on how it is used. Accumulating scientific evidence indicates that light to moderate alcohol consumption is associated with a lower cardiovascular mortality and a reduced risk of developing type 2 diabetes mellitus<sup>[1-6]</sup>. Some of the biological mechanisms reported to explain this observation include an improvement in lipid profile, especially high-density-lipoprotein-cholesterol (HDL-C) and increased insulin sensitivity<sup>[1-6]</sup>. In contrast, heavy or risky drinking is toxic to both the heart and the overall health and is the third

leading cause of premature death among Americans<sup>[1]</sup>.

Metabolic syndrome is a clustering of low serum HDL-C, elevated serum triglycerides, hyperglycemia, abdominal obesity, and elevated blood pressure, mediated in part by insulin resistance. Metabolic syndrome is associated with an increased risk of developing diabetes mellitus and cardiovascular disease<sup>[7]</sup>. Alcohol consumption has a favorable influence on selective components of metabolic syndrome, contributing to the reduction in risk of developing metabolic syndrome in the U.S. population<sup>[8-10]</sup>. However, the validity of its putative benefits to metabolic disorders has not been well evaluated in Chinese.

The present study was to investigate the prevalence of current alcohol drinking and metabolic syndrome among Shanghai adults, and to explore the relationship between alcohol consumption and components of metabolic syndrome.

## MATERIALS AND METHODS

### Survey design and study sample

We assigned a number to each of the 16 urban districts of Shanghai and selected two districts at random (Yangpu District and Pudong New District). Of the 11 residential districts within Yangpu and Pudong, we randomly selected the Pingliang and Shanggang residential districts, containing 30 and 26 neighborhood communities, respectively. From these, we selected eight neighborhood communities in total. Resident groups were randomly selected from each sample neighborhood community. From October 2002 to April 2003, investigations were conducted in adults aged 20 years or more in the selected resident groups at home. We excluded individuals from the study if they had a history of malignancy and other severe diseases.

This program was approved by the Research Ethics Committee of the Shanghai Health Bureau and all participants provided their written informed consent prior to their inclusion in the study. General physical examinations and laboratory assessments were performed for each study subject at a mobile examination center following an overnight fast of at least 12 h.

### Data collection

**Interview:** Selected individuals were interviewed at their homes using a self-designed questionnaire that gathered information on demographic characteristics, medical history, medications and health-related habits. Consumption of alcohol was ascertained from a series of questions including whether the respondent consumed 12 drinks (one drink is considered to contain 10 g alcohol) in the past 12 mo. If so, respondents were asked to quantify the number of days they consumed alcohol over the past 1 year and the number of drinks per day on drinking days. From these data, we calculated an average daily intake of alcohol. The questionnaire was pre-tested in the population prior to the study.

**Physical examination:** Body weight of the participants was measured in light clothing and without shoes to the nearest half kilogram. Their height was measured to the nearest half centimeter. Body mass index (BMI) was

calculated as weight (kg) divided by height squared (m<sup>2</sup>). Waist circumference (to the nearest half centimeter) was measured at the mid-point between the lower border of the rib cage and the iliac crest, whereas hip circumference was similarly obtained at the widest point between the hip and buttock, enabling calculation of the waist-to-hip ratio. Three blood pressure readings were obtained at intervals of one min. The second and third systolic and diastolic pressure readings were averaged and used in the analyses.

**Laboratory assessments:** Venous blood samples were collected at 0 and 120 min following a 75 g oral glucose challenge for non-diabetics or 100 g steamed bread for diabetics. Samples were centrifuged at 2000 g for 10 min at 25°C immediately, frozen and shipped to a central laboratory of the Shanghai Center for Disease Control and Prevention, where they were stored initially at -20°C and then at -70°C. Subsequently, serum glucose was determined using a modified hexokinase method. Fasting serum total cholesterol (TC) and triglyceride concentrations were measured enzymatically by color absorptiometry based on a peroxidase-catalysed reaction. HDL-C was measured after precipitation of other lipoproteins with a polyanion/divalent cation mixture. Low-density-lipoprotein-cholesterol (LDL-C) was calculated from the measured values of TC, triglycerides and HDL-C using the following formula:  $LDL = (TC) - (HDL) - (triglycerides/5)$ . LDL was not calculated if the triglyceride concentration was > 4.52 mmol/L. All these serum biochemistries were performed using a Bayer model 1650 automated bio-analyzer (Bayer Diagnostic, Basingstoke, UK).

**Quality control:** Field researchers were recruited from Shanghai Center for Disease Control and Prevention, and Shanghai Jiaotong University School of Medicine. Before the investigation, the researchers were given systematic training to ensure standardization of the investigation procedure. For further quality control, 5% of questionnaires and blood samples were re-examined. Kappa analysis of these samples showed a good consistency in the diagnostic test (data not shown).

**Definitions:** Obesity and abdominal obesity were categorized according to the new BMI criteria for Asians by the regional office for Western Pacific Region of the World Health Organization (WHO)<sup>[11]</sup>. Hypertension was defined as given in the Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC7)<sup>[12]</sup>. Diagnoses of impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and type 2 diabetes were based on WHO criteria published in 1999 (WHO/NCD/NCS/99.2)<sup>[13,14]</sup>. Dyslipidemia (including hypertriglyceridemia and low HDL-C) and metabolic syndrome were diagnosed on the basis of the adapted U.S. National Cholesterol Education Program's Adult Treatment Panel III (NCEP ATP III) criteria with the exception of abdominal obesity (waist circumference 90 cm in men and 80 cm in women)<sup>[7,15]</sup>. We regarded participants who reported current use of antihypertensive or anti-diabetic medications or fibrates as participants with a high blood pressure or diabetes or hypertriglyceridemia, respectively.

Current alcohol consumption was defined as more than once of alcohol drink per month. The participants were then divided into current alcohol drinkers and current non drinkers, the former were further classified into light drinkers (1-9.9 g/d), moderate drinkers (10-29.9 g/d) and excessive drinkers ( $\geq 30$  g/d) according to their average daily alcohol intake in the past 12 mo<sup>[1,9,10,16]</sup>.

**Statistical analysis**

All data were analyzed using SPSS 11.0 software (SPSS, Chicago, IL, USA). Unpaired *t*-test,  $\chi^2$  contingency test, Fisher’s exact test and trend analysis were performed whenever appropriate. Non-parametric methods were also used for abnormally distributed values. Some analyses were adjusted for age and sex. Kappa analysis was performed for blood biochemical data as a quality control. All *P* values provided are for two-sided tests. *P* < 0.05 was considered statistically significant.

**RESULTS**

**Sampling status and general data**

We used a stratified, multistage probability cluster sampling method to obtain a representative sample from the Shanghai non-institutionalized population. The neighborhoods investigated contained 3953 residents aged 20 years or more as subjects in the present study, corresponding to approximately 2.99/10 000 of the Shanghai population according to the data collected in the Fifth China National Census in 2002 (<http://www.china-un.ch/eng/ljzg/shjjtj/t85845.htm>).

The study population included 1524 males and 2379 females (excluding pregnant women), giving a male to female ratio of 1:1.56. Their age ranged 20-88 years and no significant difference was noted between the ages of male and female subjects. In comparison with the sex and age obtained from the Fifth National Census of Shanghai, the study population contained a higher percentage of elderly subjects and women (*P* < 0.01). Therefore, some of the results were adjusted for age and sex in order to better represent the real situation in Shanghai.

**Prevalence of current drinking and metabolic syndrome**

Of the 3953 enrolled subjects, 448 (11.3%) had a history of current alcohol consumption, men accounted for 26.6% and women 1.8% (*P* < 0.001). As shown in Table 1, the prevalence of current alcohol drinking both in overall subjects and in males increased with age and reached its peak at the age of 40-49 years. However, no significant changes were found in females. After adjusted for age and sex, the prevalence of current alcoholic drinking among Shanghai adults was found to be 13.0%, which was significantly higher in males than in females (24.5% *vs* 1.5%, *P* < 0.001).

Among the 448 participants with a history of current alcohol drinking, over two-thirds (72.1%) of them were light to moderate drinkers, light to moderate female drinkers accounted for 95%. There was no difference in age among different drinking groups (Table 2). Since only 125 (27.9%) subjects were found to be excessive drinkers in the

**Table 1 Sex and age related prevalence of current alcohol drinking in 3953 adults in Shanghai *n* (%)**

Age (yr)	Total	Current drinking	Male	Current drinking	Female	Current drinking
20-29	139	8 (5.8)	61	7 (11.5)	78	1 (1.3)
30-39	157	16 (10.2)	65	15 (23.1)	92	1 (1.1)
40-49	895	118 (13.2)	306	108 (35.3)	589	10 (1.7)
50-59	1305	167 (12.8)	477	153 (32.1)	828	14 (1.7)
60-69	794	77 (9.7)	327	67 (19.1)	467	10 (2.1)
$\geq 70$	663	62 (9.4)	288	55 (19.1)	375	7 (1.9)
Total	3953	448 (11.3)	1524	405 (26.6)	2379	43 (1.8)

Current alcohol drinking is defined as more than once of alcohol drinking per mo in the past one year.

**Table 2 Classification of 448 subjects with current alcohol drinking according to alcohol consumption *n* (%)**

	Light drinking	Moderate drinking	Excessive drinking
Total ( <i>n</i> = 448)	180 (40.2)	143 (31.9)	125 (27.9)
Male ( <i>n</i> = 405)	149 (36.8)	133 (32.8)	123 (30.4)
Female ( <i>n</i> = 43)	31 (72.1)	10 (23.3)	2 (4.7)
Age (yr)	54.47 $\pm$ 10.80	55.35 $\pm$ 11.62	55.05 $\pm$ 9.84
Alcohol intake (g/d)	2.60 $\pm$ 2.84	17.95 $\pm$ 5.07	58.30 $\pm$ 80.13

Light drinking is defined as average alcohol consumption of less than 10 g/d, moderate drinking as average daily alcohol consumption of 10-30 g, and excessive drinking as average alcohol consumption of equal to or more than 30 g/d in the past 12 mo.

study, their average daily alcohol consumption was 58 g, and few of them were heavy or risky drinkers (alcohol consumption > 40 g/d), so we did not further distinguish heavy drinkers from excessive drinkers.

The prevalence of obesity, abdominal obesity, hypertension, hypertriglyceridemia, low serum HDL-C, diabetes mellitus and metabolic syndrome in the 3953 study subjects was 43.3%, 35.4%, 49.3%, 25.7%, 21.3%, 14.8% and 23.9%, respectively. After adjusted for age and sex, the prevalence of metabolic syndrome among adults in Shanghai was 15.3% according to the adapted NCEP-ATP III criteria<sup>[17]</sup>.

**Effects of current alcohol consumption on metabolic syndrome**

The effects of current alcohol drinking on metabolic syndrome features in 3953 Shanghai adults are shown in Table 3. The blood pressure, serum concentration of triglyceride, HDL-C and FPG, prevalence of hypertension and hypertriglyceridemia were higher while the prevalence of abdominal obesity, low serum HDL-C and diabetes mellitus were lower in alcoholic drinkers than in non-alcoholic drinkers. However, the prevalence of metabolic syndrome in alcoholic drinkers only decreased mildly compared with the non-alcoholic drinkers. When adjusted for sex and age, the differences in metabolic syndrome features still existed between the two groups.

Among the 448 subjects with current alcohol consumption, the trend analysis showed that systolic blood pressure (SBP), serum HDL-C and FPG, and prevalence of hypertriglyceridemia increased progressively, while se-

**Table 3** Effects of current alcohol drinking on metabolic syndrome features in 3953 Shanghai adults

	Non-drinking (n = 3505)	Current drinking (n = 448)	P value
Age (yr)	54.2 ± 12.4	54.9 ± 10.8	> 0.05

LDL-C (mmol/L)	2.90 ± 0.82	2.73 ± 0.83	< 0.001
FPG (mmol/L)	5.77 ± 1.60	5.98 ± 1.70	< 0.01
Obesity, n (%)	1512 (43.1)	199 (44.2)	0.67
Abdominal obesity, n (%)	1270 (36.2)	129 (28.8)	< 0.01
Hypertension, n (%)	1525 (43.5)	246 (45.9)	< 0.001
Hypertriglyceridemia, n (%)	874 (24.9)	140 (31.3)	< 0.001
Low HDL-C, n (%)	770 (22.0)	72 (16.1)	< 0.05
IFG/IGT, n (%)	950 (27.1)	118 (26.3)	0.24
Diabetes mellitus, n (%)	540 (15.4)	45 (10.0)	< 0.01
Metabolic syndrome, n (%)	841 (24.0)	103 (23.0)	0.09

BMI: Body mass index; SBP: Systolic blood pressure; DBP: Diastolic blood pressure; HDL-C: High-density-lipoprotein cholesterol; LDL-C: Low-density-lipoprotein cholesterol; FPG: Fasting plasma glucose; IFG: Impaired fasting glucose; IGT: Impaired glucose tolerance.

rum LDL-C, prevalence of abdominal obesity, low serum HDL-C and metabolic syndrome declined progressively with increased alcohol consumption among the three drinker groups (Table 4). When adjusted for sex and age, alcohol consumption still showed its effects on metabolic disorders among alcoholic drinkers.

## DISCUSSION

In the present study, the sex- and age-adjusted prevalence of current alcohol drinking and metabolic syndrome among Shanghai adults was 13.0% and 15.3%, respectively; serum LDL-C concentration, risk of abdominal obesity, low serum HDL-C and metabolic syndrome tended to decrease in parallel to the history of alcohol consumption; arterial blood pressure, FPG and serum triglyceride concentration tended to increase in parallel to the amount of alcohol consumption; the effects of current alcohol drinking on metabolic syndrome features were independent of gender and age.

Metabolic syndrome is highly prevalent in industrialized Shanghai with a high Western life style<sup>[15-17]</sup>. However, the prevalence of current alcohol drinking among Shanghai adults is relative lower (only accounting for 13.0% of the total population and 24.5% of men), than that in other cities of China (accounting for 27.0% in Hangzhou, Zhejiang Province and 35.1% in Xi'an, Shaanxi Province)<sup>[18,19]</sup>. According to the Third National Health and Nutrition Examination Survey conducted in the USA, 57.9% of the participants were current alcohol drinkers with a higher percentage of men (66.0%) than of women (50.0%)<sup>[9]</sup>, and the prevalence of current alcohol drinking in 27030 healthy Korean men was even up to 83.3%<sup>[20]</sup>. The majority of subjects were light to moderate alcohol drinkers, and the average daily alcohol consumption even in the exces-

**Table 4** Effects of alcohol consumption on metabolic syndrome features in 448 subjects with current drinking according to the amount of alcohol consumption

Diabetes mellitus, n (%)	21 (11.7)	1 (0.70)	10 (8.0)	> 0.05
Metabolic syndrome, n (%)	46 (25.6)	32 (22.4)	25 (20.0)	< 0.05

BMI: Body mass index; SBP: Systolic blood pressure; DBP: Diastolic blood pressure; HDL-C: High-density-lipoprotein cholesterol; LDL-C: Low-density-lipoprotein cholesterol; FPG: Fasting plasma glucose; IFG: Impaired fasting glucose; IGT: Impaired glucose tolerance. P value for trend analysis reflects the overall difference among the three groups.

sive drinkers was less than 60 g/d in the present study. This might be related to the different alcohol drinking culture backgrounds worldwide and the universal concern about the overall health among Shanghai adults<sup>[16,18,21]</sup>. The low prevalence of current alcohol drinking is consequently consistent with the uncommon alcoholic fatty liver (0.79%). Alcoholism only accounts for 5% of the etiology of fatty liver among Shanghai adults<sup>[16]</sup>.

Although alcohol consumption has a negative effect on the morbidity and mortality of liver disease, the correlation between alcohol consumption and metabolic syndrome gives rise to much controversy<sup>[1,2,5,6,20,22-27]</sup>. A cross-sectional analysis of data from the Third National Health and Nutrition Examination Survey conducted in the USA showed that mild to moderate alcohol consumption is associated with a lower prevalence of metabolic syndrome, showing a favorable influence on lipids, waist circumference, and fasting insulin<sup>[8,9]</sup>. Yoon *et al*<sup>[24]</sup> reported that 1-15 g of alcohol per day is associated with decreased prevalence of metabolic syndrome. Park *et al*<sup>[25]</sup> reported that the prevalence of metabolic syndrome decreases only in women, and Santos *et al*<sup>[26]</sup> have not found any association between alcohol consumption and metabolic syndrome in both genders. However, Yokoyama *et al*<sup>[22]</sup> reported that alcohol consumption (> 20 g/d) is associated with an increased prevalence of metabolic syndrome in male Japanese. In the present study, alcohol consumption was associated with reduced prevalence of metabolic syndrome and excessive alcohol drinkers had the lowest prevalence of metabolic syndrome. However, no statistically significant difference was found between alcohol and non-alcohol

drinkers. Inconsistent results were also found between alcohol consumption and obesity. Some studies demonstrated that light to moderate alcohol drinking can reduce weight whereas non-alcohol and heavy alcohol drinking cannot reduce weight<sup>[1,2,23,25]</sup>. In the present study, neither positive nor negative association was found between alcohol consumption and BMI and risk of obesity. However, a consistent association was observed between alcohol consumption and decreased prevalence of abdominal obesity. Most excessive alcohol drinkers consumed only a little higher than 30 g/d in our study, and might be moderate alcohol drinkers in some other studies<sup>[1,2,18,20,24,28-30]</sup>. Therefore, it is not entirely clear how different levels of alcohol consumption affect the risk of obesity and metabolic syndrome.

Epidemiologic investigations showed that moderate alcohol consumption is associated with increased blood pressure<sup>[1,29,30]</sup>. It was reported that SBP and diastolic blood pressure (DBP) are increased to 2.7 mmHg and 1.4 mmHg, respectively, after a period of sustained alcohol consumption<sup>[1,29]</sup>. In the present study, SBP and DBP had an average increase of 3.78 mmHg and 4.06 mmHg, respectively, in current alcoholic drinkers. Furthermore, SBP increased gradually in alcohol drinkers. A meta-analysis of data showed that excessive alcohol consumption was associated with a higher blood pressure while a fall in blood pressure of 2-4 mmHg is associated with reduced alcohol consumption<sup>[30]</sup>.

It is well known that increased concentration of triglycerides and HDL-C is associated with increased alcohol consumption<sup>[1,2]</sup>. Interestingly, alcohol consumption was negatively associated with serum LDL-C concentration and was the lowest in excessive alcohol drinkers in this study, which is consistent with the findings in Korean men<sup>[20]</sup>.

The relationship between alcohol consumption and glucose regulation is rather complex<sup>[1,2]</sup>. A meta-analysis based largely on the prospective studies suggested that there is a U-shaped relationship between alcohol consumption and type 2 diabetes, and moderate alcohol drinkers have the lowest risk of developing type 2 diabetes<sup>[31]</sup>. However, several cross-sectional evaluations of healthier population have reported higher fasting glucose concentrations and greater risk of diabetes associated with alcohol consumption<sup>[31-34]</sup>. Paradoxically, alcohol consumption has also been found to be associated with lower insulin concentrations<sup>[8,20]</sup>. In our study, alcohol consumption was positively associated with FPG but negatively with the risk of diabetes. However, no change was observed in IFG and IGT, suggesting that regular alcohol consumption might benefit to insulin sensitivity and improve insulin resistance. However, it is not entirely clear how different levels of alcohol consumption affect glucose homeostasis.

The strengths of our investigation include the use of a large sample from Shanghai adults with good quality control (thereby enhancing our generalization) and the evaluation of both serum lipids and oral glucose tolerance. However, there are several limitations that merit comment. First, given the cross-sectional design, we could not draw any causal inferences regarding the association of alco-

hol consumption with metabolic syndrome. Second, the data on alcohol consumption were based on self-report with the possibility of misclassification of exposure (e.g., under reporting). However, such bias, if non-differential, would be expected only to increase the amount of alcohol consumption associated with reduced prevalence of metabolic syndrome. Third, other factors such as smoking, physical activity, and type of beverages were not excluded by multivariable linear regression analysis, thus limiting our ability to give comment on the relation of alcohol consumption to the prevalence of metabolic syndrome<sup>[1,2,35]</sup>. Prospective studies are therefore needed to confirm these findings and to assess the influence of alcohol drinking patterns and other possible factors on the association between alcohol consumption and metabolic syndrome.

In summary, current alcohol drinking is associated with a lower prevalence of metabolic syndrome and a favorable influence on serum lipids, waist circumference, and possibly type 2 diabetes mellitus. The clinical significance of these findings needs further investigation. It must be noted that alcohol consumption also causes hypertension, hypertriglyceridemia and hyperglyceridemia, constituting alcohol-related metabolic syndrome. The latest American Heart Association guidelines advise that people should not start alcohol drinking if they have not drunk it, because it is not possible to predict who will have a problem due to alcohol abuse<sup>[35]</sup>.

## COMMENTS

### Background

Alcohol consumption is a double-edged sword to health. Light to moderate alcohol consumption is usually associated with a lower cardiovascular mortality and a reduced risk of developing type 2 diabetes mellitus. However, heavy or risky alcohol drinking is toxic to the heart and overall health, and is the third leading cause for premature death among Americans. Metabolic syndrome is associated with an increased risk of developing diabetes and cardiovascular disease, the favorable influence of alcohol consumption on selective components of metabolic syndrome has contributed to the possibility that alcohol consumption reduces the risk of metabolic syndrome in the adults of USA, Japan and South Korean. However, its putative effect on metabolic disorders has not been well evaluated in mainland China or oversea Chinese.

### Research frontiers

It was recently reported that moderate alcohol drinking is associated with a lower prevalence of metabolic syndrome. Although studies showed statistically significant interactions between alcohol consumption and metabolic syndrome, integration of variables and homogeneity in definitions is required. Since alcohol-associated health problem is also influenced by ethnicity, it is thus needed to investigate the interactions in Chinese.

### Innovations and breakthroughs

One of the major findings in the present study is the relative lower prevalence of current alcohol drinking (13%) in Shanghai than in other regions of China and most foreign countries. This might be due to the different alcohol drinking culture backgrounds and the general concern about the dangers of alcohol consumption to the overall health among Shanghai people. However, metabolic syndrome is common in Shanghai as compared to Japan and South Korea, and the prevalence

of metabolic syndrome among Shanghai adults is only slightly lower than that in USA, suggesting that alcohol drinking is not a major risk factor for metabolic syndrome in humans, even though current alcohol consumption is associated with a lower prevalence of metabolic syndrome irrespective of the average daily alcohol consumption in the present study. On the one hand, alcohol drinking reduces serum LDL-C concentration, risk of abdominal obesity and low HDL-C. On the other hand, alcohol consumption might increase the prevalence of hypertension, hypertriglyceridemia and hyperglycemia. These effects of alcohol consumption on metabolic disorders are consistent with the most other related or similar findings from other countries. The results of this study provide the epidemiological data on the correlation between alcohol consumption and metabolic syndrome in Chinese.

### Applications

There is sufficient evidence that light to moderate alcohol consumption is associated with decreased risk of cardiovascular disease. Nevertheless, the effects of alcohol consumption on health are dependent on the consumed amount of alcohol, the pattern of drinking, and the potential for problem drinking, suggesting that alcohol should not be advised for health enhancement of individuals.

### Terminology

Metabolic syndrome refers to a cluster of metabolic derangements that increased the risk of developing type 2 diabetes and cardiovascular diseases associated with insulin resistance. Current alcohol drinker refers to alcohol drinking habituation regardless of the amount of alcohol consumption, and is usually defined as more than once of alcohol drinking per month over the past 12 mo. The classification of current alcohol consumption is far from consensual at present. In the present study, light alcohol drinking is defined as average alcohol consumption of less than 10 g/d, moderate alcohol drinking as average daily alcohol consumption of 10-30 g/d, and excessive alcohol drinking as average alcohol consumption of equal to or more than 30 g per day in the past 12 mo.

### Peer review

The authors conducted a population-based study on 3953 adults in Shanghai to evaluate the association between alcohol consumption and metabolic syndrome, and found that current alcohol consumption was associated with a lower prevalence of metabolic syndrome. Overall, the study was well designed with good quality control, and detailed data were collected from participants with a randomized multistage stratified cluster sampling method. The manuscript provides important data and is relatively well written.

### Abstract

**AIM:** To investigate the role of the duodenum in the regulation of plasma ghrelin levels and body mass index (BMI), and the correlation between them after subtotal gastrectomy.

**METHODS:** Forty-two patients with T<sub>0-1</sub>N<sub>0-1</sub>M<sub>0</sub> gastric cancer were divided into two groups after gastrectomy according to digestive reconstruction pattern, Billroth I group (*n* = 23) and Billroth II group (*n* = 19). Ghrelin levels were determined with radioimmunoassay (RIA) before and on d 1, 7, 30 and 360 after gastrectomy, and BMI was also measured.

**RESULTS:** The two groups had identical postoperative trends in ghrelin alterations during the early stage, both decreasing sharply to a nadir on d 1 (36.7% vs 35.7%), then markedly increasing on d 7 (51.0% vs 51.1%). On d 30, ghrelin levels in the Billroth I group were slightly higher than those in the Billroth II group. However, those of the Billroth I group recovered to 93.6% on d 360, which approached, although lower than, the preoperative levels, and no statistically significant difference was observed. Those of the Billroth II group recovered to only 81.6% and manifested significant discrepancy with preoperative levels (*P* = 0.033). Compared with preoperative levels, ghrelin levels of the two groups decreased by 6.9% and 18.4% and BMI fell

by 3.3% and 6.4%, respectively. The linear regression correlations were revealed in both groups between decrease of ghrelin level and BMI ( $R_1^2 = 0.297$ ,  $P = 0.007$ ;  $R_2^2 = 0.559$ ,  $P < 0.001$ ).

**CONCLUSION:** Anatomically and physiologically, the duodenum compensatively promotes ghrelin recovery and accordingly enhances BMI after gastrectomy. Regarding patients with insufficient ghrelin secretion, ghrelin is positively associated with BMI.

Role of the duodenum in regulation of plasma ghrelin levels and body mass index after subtotal gastrectomy. *World J Gastroenterol* 2008; 14(15): 2425-2429 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2425.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2425>

### INTRODUCTION

Ghrelin, a recognized brain-gut peptide with 28 amino acids, was recently discovered as the intrinsic ligand of the secretagogue receptor<sup>[1]</sup>, which exerts considerable vital physiological activities within the body, beyond stimulating growth hormone release. The duodenum is the major source of ghrelin secretion apart from the stomach, which is responsible for most of ghrelin production in the body<sup>[2]</sup>, while the bowel and some organs secrete less through paracrine or autocrine mechanisms, which accounts for the partially compensatory secretion after gastrectomy<sup>[3-8]</sup>. Known as a unique orexigenic hormone, ghrelin contributes to maintaining the body's energy balance by communicating signals of energy stores to the brain, then inducing appetite, promoting food intake, and reducing energy expenditure<sup>[5-9]</sup>.

Gastrectomy is the predominant therapy for most stomach-associated diseases, including tumors and complex ulcers. However, weight loss is a ubiquitous sequela for which no satisfactory explanations have been

given, although various measures have been employed to treat it, including drugs, diet therapy, and even secondary surgery. Regarding the gastroduodenum as the main source of ghrelin, which has a considerable influence on energy balance, a lot of research has focused on the correlation between ghrelin and energy balance. However, to date, there have been no studies on the role of the duodenum in regulating ghrelin plasma levels and body mass index (BMI) after gastrectomy. It is thought that the digestive endocrine and exocrine functions will be impaired if the duodenum is devoid of long-term contact with gastric contents<sup>[8,10-12]</sup>. Accordingly, we hypothesize that a similar situation would exert the same influence on ghrelin levels.

## MATERIALS AND METHODS

### Study subjects

Patients with T<sub>0-1</sub>N<sub>0-1</sub>M<sub>0</sub> (AJCC, American joint committee on cancer, 2003) stage gastric cancer were enrolled in our study from September 2004 to July 2006. Their clinical characteristics were collected, comprising gender, age, height, weight and BMI. Patients with coincidental endocrine diseases such as diabetes mellitus, thyroid or pituitary disease were excluded, as were those with BMI beyond the range of 18-26 kg/m<sup>2</sup>. Curative subtotal gastrectomy, defined as resection of no less than two-thirds of the distal stomach, with standard D<sub>2</sub> lymph node resection, was performed on each patient by the same team. Those who contracted severe complications, such as anastomosis leakage, intra-abdominal infection, or ileus, and those who displayed tumor recurrence or metastasis by endoscopy, abdominal computer tomography (CT), sonography, or tumor biomarkers during regular follow-up, were also excluded. The subjects were divided into two groups according to their reconstruction patterns of digestive continuity, gastroduodenal anastomosis, i.e., Billroth I anastomosis (*n* = 23); and gastrojejunal anastomosis, with an end-to-side anastomosis of the jejunum, i.e., Billroth II anastomosis (*n* = 19).

As concerns the impact of the operation itself on ghrelin levels, during the same period, we chose 20 colorectal cancer patients who underwent surgery in our department as a control group, with the same screening conditions as the study group. All patients gave their informed consent before the study. Blood samples (10 mL each) were collected at 8:00 a.m. preprandially before and on d 1, 7, 30 (1 mo) and 360 (1 year) after operation. All patients fasted from midnight before blood collection. Plasma ghrelin and leptin levels of each sample were analyzed. In addition, with regard to the impact of cancer on both hormones, subjects were contrasted with 20 healthy individuals whose blood samples were drawn during regular physical examinations.

### Hormone measurements

All blood samples were drawn into tubes containing EDTA and aprotinin. Plasma was obtained and stored at -70°C until assayed. Blood samples were centrifuged at 4°C for 15 min. Total plasma ghrelin was measured with a commercially available RIA kit (Phoenix Pharmaceuticals,

Belmont, CA, USA) using <sup>125</sup>I-labelled ghrelin tracer and a rabbit polyclonal antibody against full-length octanoylated human ghrelin that measures total circulating ghrelin. Plasma leptin was measured with a human RIA kit (Linco Research, Inc., St. Charles, MO, USA) using <sup>125</sup>I-labelled leptin tracer. Both hormones were measured in duplicate and the mean was determined.

### Statistical analysis

All results were expressed as mean ± SD. ANOVA with Student-Neuman-Keul post hoc test was used to determine the statistical significance of differences in ghrelin, leptin levels and BMI between the two groups before operation, and ghrelin or leptin levels of the same group between different time points after operation. Differences of ghrelin levels between the two study groups at the same time after operation were analyzed with the unpaired *t* test. Both decrease and increase of ghrelin, leptin levels and BMI were expressed as a percentage of the preoperative levels. The relationship between them was displayed with linear regression. The coefficient of correlation *R*<sup>2</sup> was used as the gauge of their relationship. A one-tailed test was adopted in each analysis. *P* < 0.05 was considered statistically significant.

## RESULTS

### Influence of duodenum on plasma ghrelin level and BMI after gastrectomy

There was no significant difference in preoperative characteristics, including ghrelin, leptin levels and BMI between the groups (Table 1). As for the control group, ghrelin levels increased slightly at first, then gradually decreased to preoperative levels during 360 d after operation (Figure 1). Leptin levels of all groups were less affected and no difference existed between the groups at the same time. The two groups had identical trends in ghrelin levels during the early stage after the operation, decreasing sharply to a nadir on d 1 (36.7% vs 35.7%). The levels then increased markedly on d 7 (51.0% vs 51.1%), and showed no difference between the two groups at the same time (169.35 ± 45.9 pg/mL vs 163.7 ± 49.3 pg/mL; 235.4 ± 61.3 pg/mL vs 232.1 ± 67.0 pg/mL). Nevertheless, the ghrelin levels of the Billroth I group recovered more obviously during the later stage compared with the Billroth II group (Figure 2). On d 30, ghrelin levels in the two groups increased to 70.6% (330.2 ± 77.1 pg/mL) and 67.2% (300.3 ± 80.1 pg/mL) respectively, with those of the Billroth I group higher than those of the Billroth II group, whereas no significant difference existed between the two. On d 360, ghrelin levels of the Billroth I group recovered to 93.1% (435.9 ± 110.2 pg/mL), although they were lower than preoperative levels, but no significant difference was revealed. However, ghrelin levels in the Billroth II group recovered to only 81.6% (369.7 ± 90.1 pg/mL), evidently lower than preoperative levels (*P* = 0.033). On d 360, ghrelin levels in the Billroth I group were distinctly higher than those in the Billroth II group (*P* = 0.035). From d 7 through to d 360, ghrelin levels in the two groups increased by 42.1% and 30.6%, respectively, with a significant difference between the levels (*P* = 0.003).

Table 1 Preoperative characteristics of the study objects

Group	Healthy	Control	Bilroth I	Bilroth II
Object number	20	20	23	19
Gender (male:female)	8:12	13:7	11:12	8:11
Age (yr)	40.4 ± 10.2	42.2 ± 7.4	50.7 ± 5.5	48.0 ± 6.4
BMI	22.2 ± 2.2	22.7 ± 2.2	21.9 ± 2.8	21.7 ± 2.7
Ghrelin (pg/mL)	460 ± 117.8	472 ± 115.9	468.0 ± 126.9	460.5 ± 129.4
Leptin (ng/mol)	2.0 ± 1.2	2.4 ± 1.1	2.2 ± 1.3	2.6 ± 1.7

### Correlation between ghrelin and BMI after gastrectomy

Compared with preoperative levels, ghrelin levels in the Billroth I and Billroth II groups decreased by 6.9% and 18.4%, respectively, on d 360, which showed a significant difference between the two groups ( $P = 0.035$ ), while BMI decreased by 3.3% and 6.4%, respectively, which also showed a significant difference ( $P = 0.035$ ). The linear regression correlations were manifested between decrease of ghrelin level and BMI in both groups ( $R_1^2 = 0.297$ ,  $P = 0.007$ ;  $R_2^2 = 0.559$ ,  $P < 0.001$ ). Neither the correlation nor the regression coefficient of the Billroth II group was higher than that of the Billroth I group (Figure 3).

## DISCUSSION

Ghrelin has recently been implicated in the development of malignant tumors<sup>[13]</sup>, whereas these tumors did not show any effect on plasma ghrelin levels in our study. Postoperative ghrelin levels in colorectal cancer patients increased and then recovered gradually to normal, while those in gastric cancer patients decreased abruptly in the early stage, then rose gradually, although remaining lower, one year later compared with the preoperative level. We can generalize from the above that a postoperative decrease in ghrelin was induced by gastrectomy, but not the surgery itself or by trauma, or anesthesia or any factors involved in anesthesia.

As far as gastrectomy was concerned, a major portion of the stomach was removed, including part of the fundus, a major source of ghrelin production. This accounted for a sharp postoperative decrease in ghrelin levels, whereas due to compensatory secretion of the remaining part of the stomach, the duodenum, and other organs involved, ghrelin levels increased gradually.

Intriguingly, in the early phase after the operation, the two groups manifested identical profiles of ghrelin levels, whereas in the late phase, the ghrelin levels in the Billroth I group increased more distinctly than those in the Billroth II group, although neither approached preoperative levels. We consider that the cause of this was the discrepant restoration patterns of digestive continuity. This reveals that the duodenum is the most crucial ghrelin-producing organ, except for the stomach. The duodenum compensatively secretes ghrelin more effectively in an anatomical-physiological continuity, as in a Billroth I anastomosis, as compared to that in the relatively isolated Billroth II anastomosis.

This implies that long-term absence of contact with gastric contents exerts a predominant effect on the duodenum in postoperative ghrelin secretion. It is

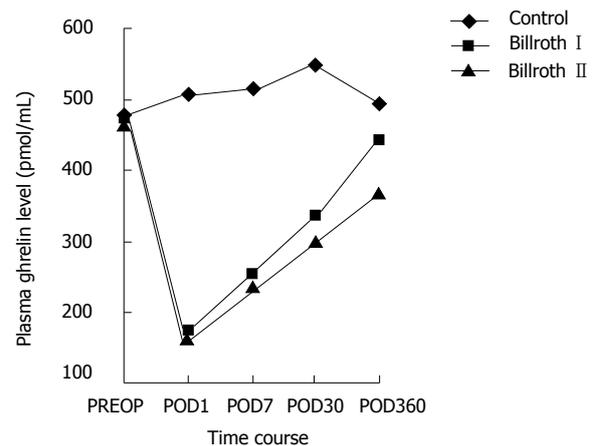

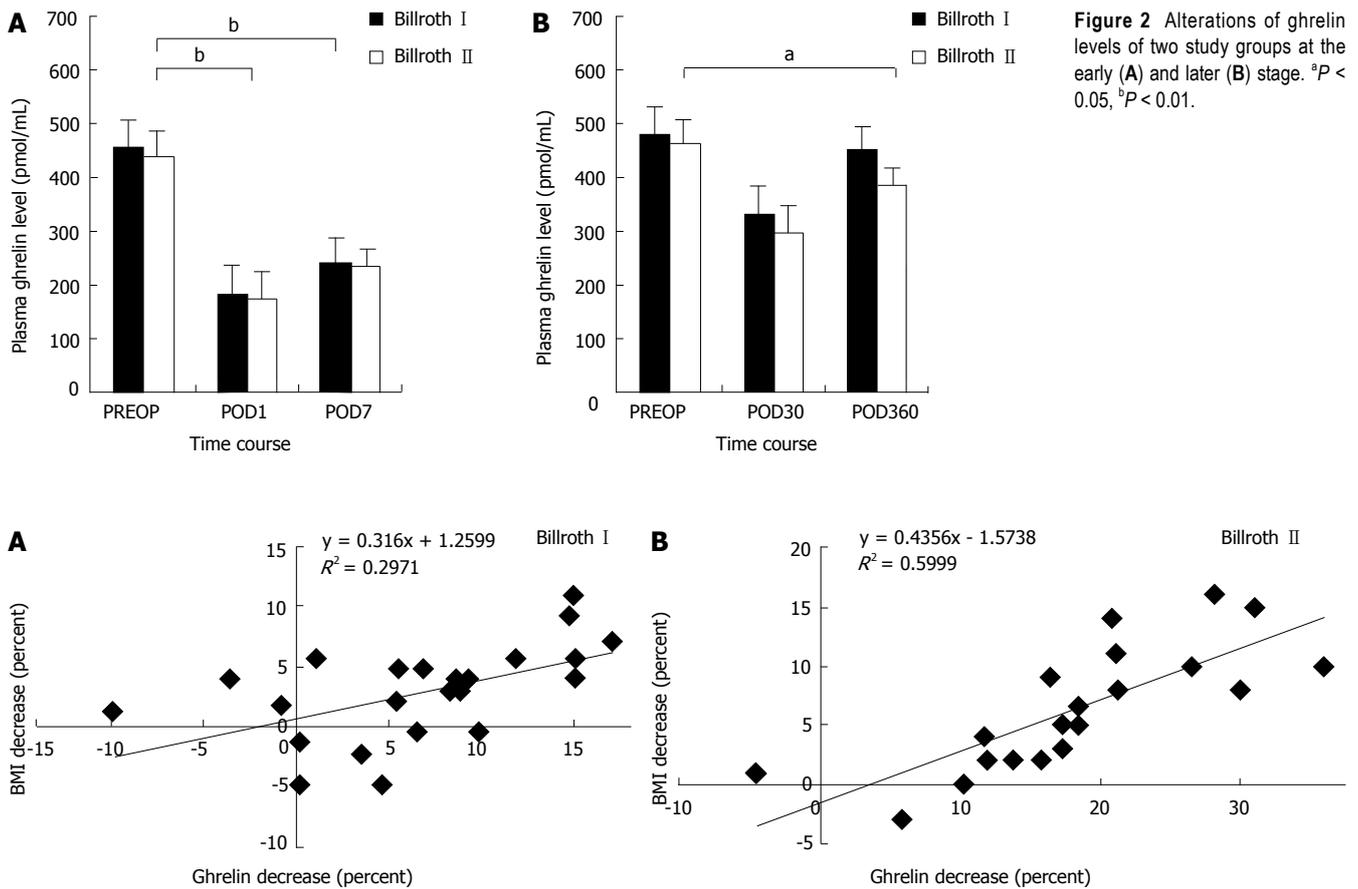

Figure 1 Alterations of ghrelin level during 360 d after operation of the two study groups and the control group. POD: Postoperative day.

considered by some researchers that gastroduodenal exposure to food is not essential to ghrelin secretion, in that most X/A-like cells are closed, which means that they have an impact upon the basolateral membrane adjacent to the bloodstream, but do not open towards the digestive lumen<sup>[2,14]</sup>. However, merely by virtue of this, it cannot be denied that there is probably a trigger for the production of ghrelin related to food contact by some other unknown means. Furthermore, X/A-like cells in the duodenum and intestine gradually open concurrently towards the lumen and the microvascular circulation.

Compatible with our point, Qader *et al* have demonstrated ghrelin concentrations in plasma and gastroduodenal mucosa in rats given short-term total parental nutrition were reduced by 50% simultaneously<sup>[15]</sup>. Long-term lack of food contact would reduce the duodenum to atrophy and hypoplasia, and even disturb endocrine functions, which if severe, would lead to pathophysiological disorders<sup>[16,17]</sup>. Thus, anatomical-physiological normalcy is essential for the duodenum to exert its customary ghrelin-producing activity after gastrectomy.

It has been revealed that ghrelin levels decrease as biliopancreatic limbs lengthen in Roux-en-Y gastric bypass surgery for obesity<sup>[18]</sup>, which is in accordance with our view that the opportunity for interactive contact between the duodenum and gastric contents decreases as biliopancreatic limbs lengthen. Cummings *et al* have demonstrated downregulation or reduction of ghrelin levels may be a result of "overridden inhibition" of gastroduodenal ghrelin-producing cells isolated from contact with enteral nutrients. This resembles the paradoxical suppression of growth hormone by continuous signaling from gonadotropin-releasing hormone or growth hormone-releasing hormone<sup>[19,20]</sup>. However, it lacks convincing proof and further investigation is required to decipher how the duodenum regulates ghrelin production and levels after gastrectomy with different digestive continuity reconstructions.

Considerable evidence supports the view that ghrelin levels correlate inversely with BMI and manifest compensatory changes in response to body weight

**Figure 2** Alterations of ghrelin levels of two study groups at the early (A) and later (B) stage. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01.

**Figure 3** Linear regression correlations. (A) Detected between decrease in ghrelin level and BMI in Billroth I group patients 1 yr after operation. (B) Detected between decrease in ghrelin level and BMI in Billroth II group patients 1 yr after operation.  $R^2 = 0.297$ ,  $P < 0.007$ .  $R^2 = 0.559$ ,  $P < 0.001$ .

alterations<sup>[20-25]</sup>. Several clinical studies have demonstrated long-term administration of ghrelin promotes weight gain in patients with cachexia due to chronic heart failure, chronic obstructive pulmonary disease, or even malignant tumors, by stimulating food intake, decreasing energy expenditure and regulating other aspects of energy homeostasis<sup>[21,25,26]</sup>.

As regards patients with insufficient ghrelin secretion after gastrectomy, we found it interesting that a decrease in ghrelin level was positively correlated with a decrease in BMI. This means that the ghrelin level is positively associated with BMI in individual patients, which implies that postoperative weight loss results from down-regulation of ghrelin levels after gastrectomy, and may be treated with administration of exogenous ghrelin. With regard to linear regression correlation between ghrelin levels and BMI, the Billroth II group presented a higher correlation or regression coefficient compared with the Billroth I group, which implies that the efficacy of ghrelin for the regulation of BMI is associated to some extent with its concentration.

In summary, anatomical-physiological duodenal normalcy promotes ghrelin recovery through compensatory secretion, thereby leading to BMI recovery, while an isolated duodenum displays obviously insufficient ghrelin secretion, which results in a decrease in BMI. Regarding the individual patient with insufficient ghrelin secretion after gastrectomy, ghrelin levels correlate positively with BMI.

## COMMENTS

**Background**  
It has been revealed that ghrelin contributes to weight gain and maintaining energy balance within the body, and weight loss is a ubiquitous sequela after subtotal gastrectomy. It is unclear whether anatomical-physiological duodenal normalcy promotes ghrelin recovery through compensatory secretion and weight gain after gastrectomy.

**Research frontiers**  
The aim of this study was to analyze whether the duodenum plays a role in regulation of plasma ghrelin levels and body mass index (BMI) after subtotal gastrectomy.

**Innovations and breakthroughs**  
This was a prospective clinical study that focused on the duodenum in different digestive reconstruction models, which contributed differently to ghrelin secretion and weight gain.

**Applications**  
This study provides surgeons with evidence to apply digestive reconstruction that has an anatomical-physiological duodenal normalcy during operation, and it also reveals that exogenous ghrelin may be useful in therapy of severe weight loss due to gastrectomy.

**Terminology**  
Ghrelin, a brain-gut peptide, was recently discovered as the intrinsic ligand of the secretagogue receptor. BMI (kg/m<sup>2</sup>) is widely used as a gauge to measure fat storage within the body.

**Peer review**  
This was a study of the long-term effect of exclusion of the duodenum on the

production of ghrelin, and presents original information about the role of the duodenum. It is very interesting.

Zhao H, Gu XM. Study on vasculogenic mimicry in malignant esophageal stromal tumors. *World J Gastroenterol* 2008; 14(15): 2430-2433 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2430.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2430>

### Abstract

**AIM:** To investigate whether malignant esophageal stromal tumors contain PAS-positive patterned matrix-associated vascular channels, which are lined by tumor cells, but not vascular endothelial cells. That is vasculogenic mimicry (VM) independent of tumor angiogenesis.

**METHODS:** Thirty-six tissue samples of malignant esophageal stromal tumors were analyzed. Tissue sections were stained for Vascular endothelial growth factor (VEGF), CD31 and periodic acid Schiff (PAS). The level of VEGF, the microvascular density (MVD) and the vasculogenic mimicry density (VMD) were determined.

**RESULTS:** PAS-positive patterned matrix-associated vascular channels were detected in 33.3% (12/36) of tumor samples. Within these patterned channels, red blood cells were found. The level of VEGF and the MVD in tumors containing patterned channels were significantly higher than those in tumors not containing patterned channels ( $P < 0.05$ ). At the same time, the malignant degree of tumors was higher, the proportions of tumors containing patterned channels were not only more, but also in the each kind of tumors containing patterned channels.

**CONCLUSION:** In malignant esophageal stromal tumors, a VM mechanism causes some tumor cells to deform themselves and secrete extracellular matrix; thus, PAS-positive patterned matrix-associated vascular channels appear and supplying blood to the tumors to sustain their growth and metastasis.

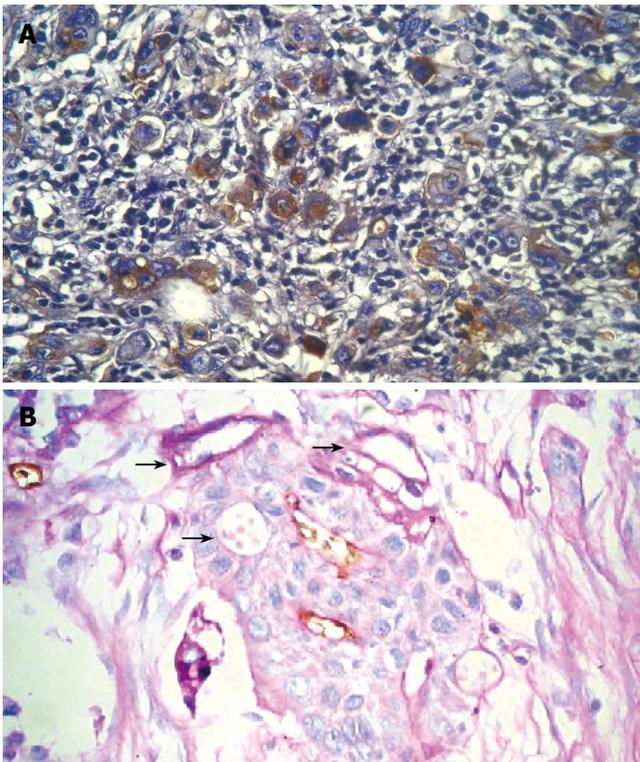

### INTRODUCTION

Vasculogenic mimicry is defined by the phenomenon whereby plastic malignant tumor cells transform and excrete extracellular matrix, thus mimicking the blood transport channel formation of normal vascular tissues<sup>[1]</sup>. Vasculogenic mimicry (VM) is a totally new pattern of tumor angiogenesis, which differs from normal angiogenesis remarkably. Tumors containing VM show such biological behaviors as higher malignancy, non-directional or bi-directional, rapid proliferation, and high incidence of metastasis by a vascular route<sup>[2]</sup>. VM was first discovered in a human uvea malignant melanoma by Maniotis<sup>[1]</sup> in 1999. In recent years, it has been reported that VM mainly exists in bi-directional malignant tumors, such as malignant melanomas in other sites, synovial sarcomas, mesotheliosarcomas, sarcoma epithelioides and acinus rhabdomyosarcomas<sup>[2]</sup>; it was also found in inflammatory breast cancers, inflammatory liver cancers, prostate cancers and ovary cancers<sup>[3]</sup>. Based on the features of VM discussed above, with regard to the fact gastrointestinal stromal tumors are a group of non-directional tumors, commonly vascular stromal tumors arising from the gastrointestinal mesenchymal cells (Cajal cells), we selected esophageal stromal tumors to investigate the existence of VM. To date, similar studies on the relationship between VM and malignant esophageal stromal tumors have not been reported broadly.

### MATERIALS AND METHODS

#### Patients

Among paraffin samples collected from 1997 to 2000

**Figure 1** A: VEGF and PAS double staining; B: CD31 and PAS double staining ( $\times 400$ ).

in Shandong University, Qilu Hospital, 36 samples of malignant esophageal stromal tumors with follow-up documents were selected and observed. Eighteen of these showed low malignancy, while the others were highly malignant. Combined with a review of the history, they were diagnosed once again and stratified into low malignancy and high malignancy groups based on the degree of differentiation and mitosis count, and the existence of necrosis.

### Immunohistochemistry

At least 4 sections were obtained from each sample, and these were stained for VEGF, CD31, and PAS by immunohistochemistry as described previously<sup>[2]</sup>. The glass slides were silicificated, and the cover slides were soaked and washed with 50 mL of 75% ethanol containing one drop of concentrated hydrochloric acid.

The streptavidin peroxidase method was used. Mouse monoclonal anti-human VEGF and CD31 antibodies, caprine-anti-mouse IgG and DAB developer were all purchased from Zhongshan BioTechnologies Company. The periodic acid Schiff (PAS) reagents were prepared in our laboratory. Three samples of gastric mucous adenocarcinomas were stained as a control group. All of the mucous locations were stained cherry red, which proved the reliability of the quality of the PAS reagents.

The level of VEGF was evaluated using a stereological grid counting method. CD31- and PAS-stained sections were observed using a 200 times objective on a light microscope; the positive CD31 and PAS staining images were taken as measurement objects. Ten fields of vision were selected randomly to assess the microvascular density

**Table 1** Relationship between VM and the expression of VEGF and MVD

Existence of VM	Samples	VEGF	MVD
Yes	12	91.49 $\pm$ 29.12	45.84 $\pm$ 13.81
No	24	128.39 $\pm$ 18.45	76.92 $\pm$ 14.62
<i>t</i> value		3.874	5.972
<i>P</i> value		0.002	0

(MVD) and the vasculogenic mimicry density (VMD); the average of the 10 counts was taken as the ultimate expression of MVD and VMD.

### Statistical analysis

Statistical analyses were performed using software from SPSS for Windows 10.0. The data was analyzed with a matched paired rank sum test.  $P < 0.05$  was taken to indicate statistical significance.

## RESULTS

### The distribution of VM in malignant esophageal stromal tumors

Based on CD31 and PAS staining, CD31-negative, PAS-positive vascular-like patterns, which indicated VM, could be seen in 33.3% (12/36) of malignant esophageal stromal tumors. VM could be found in 20.0% (4/20) of low malignancy tumors and 50.0% (8/16) of highly malignant tumors; this difference in the level of VM was statistically significant. Analysis of clinical data revealed that the 5 years survival rate of tumors expressing VM was 8.3% (1/12), which is much less than that of tumors not expressing VM (41.7%; 10/24).

### PAS-positive malignant esophageal stromal tumors

The PAS-positive human uvea melanomas identified by Maniotis showed linear, parallel linear, cruciform, half-moon, annuliform, and lattice forms<sup>[1]</sup>. All of the forms talked about above were also found in malignant esophageal stromal tumors. Besides, red blood cells were also found in the angiogenesis mimicry (Figure 1).

The levels of VEGF as well as MVD in tumors including VM were less than those in tumors that did not include VM ( $P = 0.002$ ,  $P < 0.0001$ , respectively; Table 1). With increased tumor malignancy, the levels of VEGF, as well as MVD and VMD increased gradually, all of which showed statistical significance between high and low malignancy tumors ( $P = 0.047$ ,  $P = 0.002$ ,  $P = 0.037$ , respectively). Moreover, among low malignancy tumors, MVD was greater than VMD. However, the opposite was true of highly malignant tumors (Table 2).

## DISCUSSION

Maniotis *et al* firstly reported the phenomenon of VM in 1999, providing a primary description and explanation. They found in human uvea malignant melanoma new blood transport channels, the walls of which were formed by metamorphoses from the malignant melanoma and its matrix. Because the structure of these channels was

**Table 2 Relationship between the degree of tumors' malignancy and the expression of VEGF, as well as MVD and VMD**

Malignancy	Samples	VEGF	MVD	VMD
Low	4	45 ± 19	15 ± 8	38 ± 25
High	8	128 ± 42	81 ± 17	122 ± 39
F value		4.1262	12.139	5.826
P value		0.047	0.002	0.037

similar to that of the normal vasculature, it was called angiogenesis mimicry. VM channels, co-existing with the normal vasculature, formed the microcirculation system concomitantly in tumors, and provided blood supply for their growth. Light microscopic, electron microscopic and immunohistochemical investigations of endothelial cells confirmed that the walls of VM channels consisted of tumor cells, not vascular endothelial cells. However, neither necrosis nor fibrosis was found in areas containing VM channels. PAS staining showed that a layer of PAS-positive basal membrane was found outside of the VM channels, while confocal laser scanning microscopy revealed that red blood cells could be seen in VM channels. Then they found in tumor cells three dimensional cultures vascular reticulate structure, reproduced the former discovery and confirmed the blood cells in VM channels. Taking advantage of macromolecular contrast agents, dynamic MRI angiography revealed VM channels communicating with the normal vasculature in inflammatory breast cancers<sup>[3]</sup>. The blood flow was also found based on such technique. Genetic array analysis showed that highly invasive melanoma cells showed plasticity and a polyergic embryoid genetic phenotype; thus, they could mimic endothelial cells, forming VM channels that were strikingly different from normal vascular channels. VM channels had the features of embryoid invasion, which were commonly found in invasive tumors and related to the invasion and prognosis of tumors<sup>[5]</sup>.

Our study selected 36 malignant esophageal stromal tumors. Based on CD31 and PAS staining, VM was observed. With increasing malignancy of tumors, the proportion of VM tumors increased gradually; the level of VEGF, as well as MVD and VMD also increased gradually, showing positive correlation tendency with the presence of VM. The possible causes of this are as follows. The higher the malignancy, the more rapidly tumor cells divide and proliferate, the more immature their differentiation, and thus, the plasticity they show. If tumors grow too rapidly, the current vascular would not be able to provide sufficient nutrition and oxygen; thus, hypoxia would induce the expression of VEGF and further tumor angiogenesis, concomitant with the high expression of CD31 or MVD. If the tumor angiogenesis still could not synchronize with the rapid growth of tumors, partial tumor cells may then deform and excrete extracellular matrix, mimicking the normal vascular structure, forming a blood transport system, and communicating with the normal vasculature, all of which ensure the blood supply to new tumor cells<sup>[5]</sup>. At the same time, it could also be appreciated that when angiogenesis did not synchronize with the growth of tumors and VM is not found in some part of malignant

gastrointestinal stromal tumors, necrosis or fibrosis is an inevitable event<sup>[1-5]</sup>. Our study also observed that, on the inner walls of a minority of VM channels, CD31 was expressed; this could be explained by the assumptions that few tumor cells on the inner walls of VM channels have potent plasticity, could mimic the activity of endothelial cells, and have the capacity to excreting CD31 molecules. However, it remains to be determined whether the VM phenomenon is just an emergent mechanism when the tumor cells are in the "condition of hunger", which serves to solve the shortage of blood supply resulting from the rapid growth of tumor cells, temporarily, and is then replaced by normal vasculature formed by endothelial cells with the passage of time.

Analysis of clinical data revealed tumors that formed more VM channels were usually found in patients showing early metastasis, poor prognosis, and shorter life span. The formation of VM channels may be explained as follows. VM channels and normal vasculature form the tumor's microcirculation concomitantly and communicate with the body's circulation system; thus, the tumor becomes rich in vasculature. The inner walls of VM channels consist of metamorphosed tumor cells, which structures are crumbly than normal vascular, all of which serve to the tumor cells' blood route metastasis<sup>[6]</sup>. Recent research<sup>[7]</sup> showed more highly invasive malignant melanomas express more protein tyrosine kinase (PTK), and immunofluorescence showed that protein tyrosine kinase phosphorylation was centered specifically in the area where VM channels formed. Yet the PTK signal transduction path has a close relationship with various intracellular growth factors, overexpression of which could facilitate the growth, differentiation, proliferation, adhesion and metastasis of tumor cells. Thus, it could be concluded PTK overexpression has a close relationship with the formation of VM channels and the blood metastasis of tumor cells. That study also confirmed the capacity of inhibitors of PTK to decrease VM in malignant tumors. Currently, the inhibitor of PTK imatinib has been extensively used in the clinical treatment of gastrointestinal stromal tumors, primarily being targeted toward inhibiting continuous activation of Kit PTK caused by the mutation of oncogene *c-Kit* in GIST, thus further decreasing the division and proliferation of tumor cells<sup>[8]</sup>. However, the capacity of inhibitors of PTK to decrease VM could be one of the reasons why such drugs could be successfully used in the treatment of GIST. It was also reported<sup>[9]</sup> that MMP (matrix metalloproteinase) inhibitor, PI-3K (phosphatidylinositol-3 kinase) inhibitor, PSMA (prostate-specific membrane antigen) inhibitor, tetrocycalamycin (CMT-3) modified chemically, and an antibody against laminin or laminin 5γ2 strand antisense oligonucleotides have a role in the inhibition of VM.

The phenomenon of VM deepens our knowledge about the mechanisms underlying tumors' blood supply and blood metastasis. However, study of VM in tumors is still at the early stage, and further research and discussion on various problems is required. It is reasonable to believe that with increased knowledge of its underlying mechanism, inhibiting VM is sure to provide a new target in the treatment of various neoplasms, including malignant esophageal stromal tumors.

## COMMENTS

### Background

Many studies have declared vasculogenic mimicry as a new pattern of tumor angiogenesis, which differs from the normal angiogenesis remarkably. Studies on the relationship between vasculogenic mimicry (VM) and malignant esophageal stromal tumors have not been reported broadly.

### Research frontiers

This study was designed to investigate whether malignant esophageal stromal tumors contain PAS-positive patterned matrix-associated vascular channels.

### Innovations and breakthroughs

In malignant esophageal stromal tumors, VM enables tumors to establish additional blood supply to sustain their growth and metastasis

### Peer review

The authors investigated the relationship of VM and malignant esophageal stromal tumors. It is a very interesting study.

Received: November 10, 2007 Revised: January 30, 2008

### Abstract

**AIM:** To investigate the effect of omega-3 fatty acid parenteral supplementation postoperatively on clinical outcomes and immunomodulation in colorectal cancer patients.

**METHODS:** Forty-two patients undergoing radical colorectal cancer resection with an indication for total parenteral nutrition postoperatively were enrolled in this prospective, double-blind, randomized, controlled study. Patients received total parenteral nutrition supplemented with either soybean oil (LCT; Intralipid<sup>®</sup>, Fresenius-Kabi, SO group,  $n = 21$ ) or a combination of omega-3 fish oil and soybean oil (LCT:fish oil = 5:1, fish oil; Omegaven<sup>®</sup>, Fresenius-Kabi, FO group,  $n = 21$ ), up to a total of 1.2 g lipid/kg per day for 7 d postoperatively. A same volume calorie and nitrogen was administrated. Routine blood test, biochemistry, systemic levels of IL-6 and TNF- $\alpha$ , percentage of CD3<sup>+</sup>, CD4<sup>+</sup>, and CD8<sup>+</sup> lymphocytes were evaluated preoperatively and on postoperative d 1 and 8. Patient outcome was evaluated considering mortality during the hospital stay, length of postoperative hospital stay, and occurrence of infectious complications.

**RESULTS:** Both lipid regimens were well tolerated. No differences between the two groups were noticed in demographics, baseline blood test, biochemistry, serum levels of IL-6 and TNF- $\alpha$ , percentage of CD4<sup>+</sup>, CD8<sup>+</sup> lymphocytes, and ratios of CD4<sup>+</sup>/CD8<sup>+</sup>. Compared with those on postoperative d 1, serum IL-6 levels on

postoperative d 8 were significantly depressed in the FO group than in the reference group ( $-44.43 \pm 30.53$  vs  $-8.39 \pm 69.08$ ,  $P = 0.039$ ). Simultaneously, the ratios of CD4<sup>+</sup>/CD8<sup>+</sup> were significantly increased in the FO group ( $0.92 \pm 0.62$  vs  $0.25 \pm 1.22$ ,  $P = 0.035$ ). In addition, depression of serum TNF- $\alpha$  levels ( $-0.82 \pm 2.71$  vs  $0.27 \pm 1.67$ ,  $P = 0.125$ ) and elevation of CD3<sup>+</sup> and CD4<sup>+</sup> lymphocyte percentage ( $12.85 \pm 11.61$  vs  $3.84 \pm 19.62$ ,  $P = 0.081$ ,  $17.80 \pm 10.86$  vs  $9.66 \pm 17.55$ ,  $P = 0.084$ , respectively) were higher in the FO group than in the reference group. Patients in the FO group trended to need a shorter postoperative hospital stay ( $17.45 \pm 4.80$  d vs  $19.62 \pm 5.59$  d,  $P = 0.19$ ). No statistically significant difference was found when stratified to mortality and occurrence of infectious complications.

**CONCLUSION:** Postoperative supplementation of omega-3 fatty acids may have a favorable effect on the outcomes in colorectal cancer patients undergoing radical resection by lowering the magnitude of inflammatory responses and modulating the immune response.

Impact of postoperative omega-3 fatty acid-supplemented parenteral nutrition on clinical outcomes and immunomodulations in colorectal cancer patients. *World J Gastroenterol* 2008; 14(15): 2434-2439 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2434.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2434>

### INTRODUCTION

Lipid emulsions are regularly used postoperatively to supply energy and essential fatty acids<sup>[1]</sup>. Recently, the pharmacological role of fatty acid and omega-3

polyunsaturated fatty acid (PUFA) deficiency in colorectal cancer patients has been appreciated<sup>[2]</sup>. Conventional lipid soybean oil emulsions contain a very large amount of linoleic acid (LA; 18: 2n-6) and a relatively low amount of  $\alpha$ -linolenic acid (LNA; 18: 3n-3). Arachidonic acid (AA, C20: 4n-6), derived from linoleic acid, is metabolized by cyclo-oxygenase and lipo-oxygenase pathway to pro-inflammatory mediators, such as prostaglandin, thromboxane, and leukotriene. Omega-3 long-chain polyunsaturated fatty acid, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), which can compete with AA for the production of less inflammatory active eicosanoid, are absent in these vegetable oils<sup>[3,4]</sup>. Therefore, omega-3 fatty acids should be added directly into lipid emulsions to suppress the system inflammatory response and to decrease the risk of postoperative thrombosis. Recently, supplementation with fish oil is supposed to improve standard clinical therapy for chronic hyper-inflammatory diseases such as Crohn's disease<sup>[1,5]</sup>, rheumatoid arthritis<sup>[6]</sup>, cancer cachexia<sup>[7,8]</sup>, and as an adjunct therapeutic measure for trauma, injure, and sepsis<sup>[2,9-12]</sup>. Although several studies have demonstrated the beneficial effects of omega-3 fatty acid supplementation on patient outcome or immune competence, randomized controlled clinical trials focusing on the use of parenteral fish oil are scarce<sup>[13-17]</sup>. The aim of this study was to assess whether parenteral supplementation of omega-3 fatty acid postoperatively improves the inflammatory and immunological function of colorectal cancer patients and their clinical outcomes.

## MATERIALS AND METHODS

### Patients

Forty-two patients with colon or rectal cancer staging TNM I-III undergoing radical resection, who gave their written, informed consent to participate in the study, were prospectively enrolled consecutively from May 2002 to October 2003. After operation, 41 patients were randomly assigned to receive total parenteral nutrition (TPN) supplemented with either soybean oil (SO) or SO + fish oil (FO) emulsion, one patient withdrew because of the unresectable disease. The clinical characteristics of the two groups of patients are summarized in Table 1.

### Exclusion criteria

Exclusion criteria were: (1) age < 18 or > 70 years; (2) body mass index (BMI) < 16 or > 30; (3) diabetes mellitus; (4) hypertriglyceridemia (> 200 mg/dL) or hypercholesterolemia (> 240 mg/dL); (5) abnormal liver function (ALT>60 IU/L or total bilirubin > 1.2 mg/dL); (6) abnormal renal function (serum creatinine > 1.6 mg/dL or BUN > 30 mg/dL); (7) post-splenectomy; (8) endocrine diseases, such as hyperthyroidism, hyperadrenocorticism, or medication with thyroxine, corticoids or other immunomodulators; (9) pregnancy or breast-feeding; (10) early chemotherapy or radiotherapy before postoperative d 8.

### Interventions

Patients were assigned to respective groups by computer-

**Table 1** Demographic characteristics of the patients at entry (mean  $\pm$  SD)

derived block randomization. The pharmacist was the only person who was aware of the randomization list. Both the patients and the investigators were, thus, unaware of the infused drug. Postoperatively, all patients received TPN for consecutive 7 d, as shown in Table 2, through an indwelling central venous catheter or peripheral catheter. Glucose, amino acids, SO emulsion, fat- and water- soluble vitamins as well as trace elements were provided to both groups by infusion pumps for 16-20 h daily in an "All-In-One" manner. In the FO group, the omega-6 lipid content of TPN was partially replaced by omega-3 PUFA (Omegaven, Fresenius-Kabi) up to 0.2 g/kg body weight daily. Thus, in the FO group, the omega-3/omega-6 ratio was 1:3. Calculated on body mass, the nutrition in both groups was isonitrogenous and isocaloric.

### Blood samples and analytical methods

For laboratory measurements, 12 mL of whole blood (8 mL serum, 4 mL EDTA) was withdrawn before breakfast in the morning before operation (POD-1) and on the first and eighth days after the operation (POD+1, POD+8). Routine blood test and biochemistry analysis were immediately performed at the Department of Clinical Chemistry, Peking University People's Hospital according to standard procedures. Serum vials for analysis of cytokines such as IL-6 and TNF- $\alpha$  were separated and kept at 2°C-8°C and measured in 24 h. For quantitative detection of IL-6 and TNF- $\alpha$ , enzyme immunoassays were performed according to the manufacturer's instructions with IL-6 or TNF- $\alpha$  enzyme-linked immunosorbent assay (ELISA) kit commercially available from R&D Systems (Minneapolis, MN, USA). Percentage of CD3<sup>+</sup>, CD4<sup>+</sup>, and CD8<sup>+</sup> lymphocytes was analyzed by flow cytometry (COULTER EPICS ELITE ESP, USA). Fluorescence-labeled antibodies were purchased from BD (Franklin

Lakes, NJ, USA) and flow-check fluorospheres were obtained from Beckman-Coulter (Fullerton, CA, USA). Cytokines and percentage of CD3<sup>+</sup>, CD4<sup>+</sup>, and CD8<sup>+</sup> lymphocytes were analyzed at the Department of Clinical Chemistry, Peking Union Medical College Hospital.

Outcomes of the patients were evaluated considering mortality during the hospital stay, length of postoperative hospital stay, and occurrence of infectious complications.

**Statistical analysis**

Data were expressed as mean  $\pm$  SD and tested for statistical significance using the software SPSS (version 10.0). Analysis of variance or Student’s t-test or chi-square test was used in statistical analyses. *P* < 0.05 was considered statistically significant.

**RESULTS**

**Clinical characteristics of patients**

Only one patient withdrew from the study because of the unresectable disease, whereas 41 patients completed the study, without changes in medication. There were no statistically significant differences between the two groups of patients at entry concerning the clinical characteristics (Table 1). Blood test, biochemistry, serum levels of IL-6 and TNF- $\alpha$ , percentage of CD4<sup>+</sup>, CD8<sup>+</sup> lymphocytes, and ratios of CD4<sup>+</sup>/CD8<sup>+</sup> are shown in Tables 3 and 4. Both lipid regimens were well tolerated with no adverse events in terms of bleeding complication.

**Clinical outcomes**

No death occurred in both groups during the hospital stay, and only one case had incision infection in each group. Therefore, no statistical significant difference was found when stratified to death and occurrence of infectious complications. Although patients in the FO group trended

to need a shorter postoperative hospital stay, no statistically significant difference was found (17.45  $\pm$  4.80 d *vs* 19.62  $\pm$  5.59 d, *P* = 0.19).

**Laboratory parameters**

Seven days after parenteral nutrition, no statistically significant difference was observed with respect to routine blood test and biochemical evaluation. White blood cell count and serum level of  $\gamma$ -GT in the FO group were lower than those in the SO group (Table 3). Compared with POD+1, serum IL-6 levels on POD+8 were significantly lower in group FO than in reference group (Table 4, -44.43  $\pm$  30.53 *vs* -8.39  $\pm$  69.08, *P* = 0.039). Simultaneously, the ratios of CD4<sup>+</sup>/CD8<sup>+</sup> were significantly increased in the FO group (Table 5, 0.92  $\pm$  0.62 *vs* 0.25  $\pm$  1.22, *P* = 0.035) compared with the reference group. In addition, depression of serum TNF- $\alpha$  levels (-0.82  $\pm$  2.71 *vs* 0.27  $\pm$  1.67, *P* = 0.125) and elevation of CD3<sup>+</sup> and CD4<sup>+</sup> lymphocyte percentage (12.85  $\pm$  11.61 *vs* 3.84  $\pm$  19.62, *P* = 0.081, 17.80  $\pm$  10.86 *vs* 9.66  $\pm$  17.55, *P* = 0.084, respectively) were higher in the FO group than in the reference group (Tables 4 and 6).

**DISCUSSION**

To obtain a homogenous population, we selected patients with colorectal cancer staging TNM I -III to undergo radical resection. Patients were enrolled consecutively and randomly assigned to receive TPN supplemented with either SO or SO + FO emulsion. There were no statistically significant differences between the two groups at entry.

It was reported that reduction in platelet aggregation can be modified by increasing omega-3 long-chain fatty acid content of platelet phospholipids in humans<sup>[18]</sup>. In a randomized, controlled double-blind study, Heller AR

and colleagues<sup>[19,20]</sup> demonstrated that no coagulation and platelet abnormalities are evoked by fish oil supplementation as high as 0.2 g/kg per day for five postoperative days. In the present study, the change in platelet counts showed no statistical difference between the two groups. Neither bleeding complication nor other adverse events were observed. This is in line with the notion that a short-term parenteral administration of omega-3 fish oil is safe<sup>[9,21]</sup>. In addition, our results demonstrate that the serum level of  $\gamma$ -GT on POD+8 in the FO group was lower than that in the SO group. Heller AR *et al.*<sup>[20]</sup> found that after a major abdominal tumor surgery, fish oil supplementation could improve liver and pancreas function. Animal experiments have demonstrated improved perfusion and fewer translocations of viable bacteria from the gut into the mesenteric lymph nodes and liver after omega-3 fatty acid infusion in rats<sup>[22,23]</sup>. Therefore, our results suggest that parenteral nutrition supplemented with omega-3 fish oil might protect liver function after a major abdominal operation in colorectal cancer patients.

Omega-3 and -6 PUFAs are essential for humans and must be nutritionally provided. Recently, omega-3 PUFA deficiency has been recognized and appreciated<sup>[2]</sup>. After intravenous administration, EPA and docosahexaenoic acid (DHA) promptly incorporate into the cell membrane, compete with arachidonic acid (AA) in the cyclooxygenase and 5-lipoxygenase pathways, resulting in a reduced generation of diene prostanoids (e.g. PGE<sub>2</sub>, PGI<sub>2</sub>, TXA<sub>2</sub>) and tetraene leukotrienes (e.g. LTB<sub>4</sub>), derived from AA in favor of the corresponding triene prostanoids (e.g. PGE<sub>3</sub>, PGI<sub>3</sub>, TXA<sub>3</sub>) and pentaene leukotriene (LTB<sub>5</sub>) derived from EPA<sup>[13,24]</sup>. In a randomized controlled trial, Köller *et al.*<sup>[17]</sup> demonstrated that release of 5-series leukotrienes from isolated leukocytes stimulated with Ca-ionophore is increased in patients receiving fish oil. Leukotrienes

have numerous effects on inflammatory and immune functions, such as leucocyte-endothelial interaction, lymphocyte proliferation, and induction of cytokine gene expression (e.g. IL-1, IL-6, or TNF- $\alpha$ )<sup>[25,26]</sup>. In a randomized controlled study, Wachtler *et al.*<sup>[25]</sup> showed that the systemic levels of IL-10, IL-6 and TNF- $\alpha$  are significantly decreased in surgical patients 5 d after administration of TPN enriched with omega-3 fatty acids. In another clinical trial, Weiss *et al.*<sup>[27]</sup> also found that IL-6 levels are significantly decreased and TNF- $\alpha$  release from monocytes is also decreased in patients receiving fish oil perioperatively. In addition, HLA-DR expression induced by monocytes, an indicator of compensatory potential required to balance immune response, is significantly decreased<sup>[128,29]</sup>. Mayer *et al.*<sup>[13]</sup> displayed that neutrophil function is significantly improved in patients receiving omega-3 fatty acids, including leukotriene generation and respiratory burst. In our study, serum IL-6 levels were significantly lower in the FO group than t in the reference group. This is in agreement with the previous reports<sup>[25,27,30]</sup>. Simultaneously, the ratios of CD4<sup>+</sup>/CD8<sup>+</sup> were significantly increased in the FO group. In addition, depression of serum TNF- $\alpha$  levels and elevation of CD3<sup>+</sup> and CD4<sup>+</sup> lymphocyte percentage were noted in the FO group. In an experimental animal model, administration of parental fish oil during sepsis could prevent sepsis-induced suppression of lymphocyte proliferation and IL-2 release<sup>[31]</sup>. These findings suggest that supplementation of omega-3 PUFA may restrain inflammatory response, modulate lymphocyte proliferation, and maintain the function of immunocompetent cells under inflammatory conditions such as surgical trauma.

The lower magnitude of postoperative inflammatory response to administration of omega-3 fatty acids may have a favorable impact on clinical outcomes of patients with CRC. A shorter postoperative hospital

stay was noted in our study. No statistically significant difference was found when stratified to death and occurrence of infectious complications. In a cohort of elective postoperative patients, mortality is such a rare event that changes in mortality is underpowered to be detected. Various factors may influence the outcomes of surgical patients. A short single nutritional intervention is unlikely to produce extensive effects on the outcomes of postoperative patients. Recently, in a randomized controlled trial, Weiss *et al*<sup>[27]</sup> have demonstrated a shorter postoperative ICU and hospital stay, and a lower rate of severe infections in patients administering omega-3 fish oil perioperatively beginning on POD-1. These results suggest that supplementation with omega-3 fatty acids may have a more favorable effect on the outcomes of CRC patients after a major surgery.

In conclusion, postoperative supplementation of omega-3 fatty acids may have a favorable effect on the outcome of colorectal cancer patients by lowering the magnitude of inflammatory responses and modulating the immune response. Perioperative administration of omega-3 fish oil may have a more favorable effect on the outcome of CRC patients after a major surgery. Further prospective, randomized controlled trials are required to delineate this effect in a larger number of patients.

## COMMENTS

### Background

Omega-3 and -6 polyunsaturated fatty acids (PUFAs) are essential for humans and must be nutritionally provided. After incorporated into cell membrane, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) promptly compete with arachidonic acid (AA) on the cyclooxygenase and 5-lipoxygenase pathways, resulting in a reduced generation of diene prostanoids (e.g. PGE<sub>2</sub>, PGI<sub>2</sub>, TXA<sub>2</sub>) and tetraene leukotrienes (e.g. LTB<sub>4</sub>), derived from AA and are in favor of triene prostanoids (e.g. PGE<sub>3</sub>, PGI<sub>3</sub>, TXA<sub>3</sub>) and pentaene leukotriene (LTB<sub>5</sub>) derived from EPA. Therefore, the benefit of omega-3 fatty acids is to suppress the system inflammatory response and decrease the risk of postoperative thrombosis, which has been appreciated recently.

### Research frontiers

Recently, clinical nutrition has attempted to combine caloric support with modulation of the immune response. Several new generations of lipid emulsion containing n-3 lipids have been introduced, and immunonutrition has become the hot spot or an important area in this research field.

### Innovations and breakthroughs

Although several studies have demonstrated the beneficial effects of omega-3 fatty acid supplementation on the outcome or immune competence of patients, randomized controlled clinical trials focusing on the use of parenteral fish oil are scarce, especially in colorectal cancer patients. To obtain a homogenous population, patients with colorectal cancer staging TNM I-III were selected to undergo radical resection, and concomitant disorders were restricted according to the exclusion criteria. Depression of inflammatory parameters, such as serum level of IL-6 and TNF- $\alpha$  was observed. Elevation of CD4<sup>+</sup>/CD8<sup>+</sup> ratio, CD3<sup>+</sup> and CD4<sup>+</sup> lymphocyte percentage, was noted after administration of omega-3 fatty acids supplementation. Meanwhile, a near-significant improvement in clinical outcome was demonstrated. Patients accepted omega-3 fatty acid supplementation trended to need a shorter postoperative hospital stay. In view of the authors, postoperative supplementation of omega-3 fatty acids may have a favorable effect on the outcome of colorectal cancer patients undergoing radical resection by lowering the magnitude of inflammatory responses and modulating the immune response.

### Applications

By summing up the available data from surgical patients, we conclude that fish oil

should be included in parenteral nutrition yielding positive impact on the outcome of patients.

### Terminology

Immunonutrition, which combines caloric support and modulation of the immune response, has become the hot spot in this research field.

### Peer review

This article on the effect of omega-3 fatty acid supplementation on colorectal cancer is interesting.

Analysis of risk factors for the interval time, number and pattern of hepatic metastases from gastric cancer after radical gastrectomy. *World J Gastroenterol* 2008; 14(15): 2440-2447 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2440.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2440>

### Abstract

**AIM:** To analyze the risk factors for interval time, number and pattern of hepatic metastases from gastric cancer after radical gastrectomy, and provide evidence for predicting and preventing hepatic metastasis from gastric cancer after radical gastrectomy.

**METHODS:** A retrospective study of 87 patients with hepatic metastasis who underwent radical gastrectomy for gastric cancer from 1996 to 2001. The data was analyzed to evaluate significant risk factors for interval time, number and pattern of hepatic metastases originating from gastric cancer after radical gastrectomy.

**RESULTS:** The size of gastric cancer and lymph node metastases were independently correlated with the interval time of hepatic metastases; the depth of invasion was independently correlated with the number of hepatic metastases; while the depth of invasion and Lauren classification were independently correlated with the pattern of hepatic metastases.

**CONCLUSION:** We evaluated the interval time of hepatic metastases with the size of gastric cancer and lymph node metastases. The depth of invasion could be used to evaluate the number of hepatic metastases, while the depth of invasion and the Lauren classification could be used to evaluate the pattern of hepatic metastases in patients who underwent radical gastrectomy.

### INTRODUCTION

Over 60% patients with gastric cancer are diagnosed at an advanced stage in China, and the overall 5-year survival remains less than 50%. Advances in the operative techniques and perioperative care have reduced the operative mortality and morbidity, but have not improved the stage-specific cancer survival rate. Long-term survival after radical gastrectomy for gastric cancer in China is very poor<sup>[1,2]</sup>. A number of prospective trials have failed to show a survival advantage with more extensive gastric resection<sup>[3-5]</sup> and extensive lymphadenectomy<sup>[6,7]</sup>. Moreover, patients with advanced stage disease continue to have disease recurrence at a high rate, and the recurrence is mainly focused in specific areas (locoregional, peritoneal, or liver). Hepatic metastasis from gastrointestinal carcinoma is a frequent and critical problem. Several studies have shown that hepatic resection for metastatic tumors from colorectal cancer is associated with improved outcome<sup>[8-10]</sup>, and as this procedure has become safer, the indications for its use in such situations have expanded. However, in the case of liver metastases from gastric carcinoma, which is equally common, very few patients are candidates for hepatic resection because of the presence of multiple, widespread, bilobar metastases. As a result, spread of disease to different sites such as peritoneal dissemination, lymph node metastases, and distant metastasis is very common. There are very few reports on surgical resection of hepatic metastases from gastric cancer, and the results are disappointing<sup>[11,12]</sup>. It is important to determine the

risk factors for hepatic metastasis in order to improve the survival rate of gastric cancer after radical gastrectomy. The aims of this study were to identify independent risk factors for interval time, number and pattern of hepatic metastases originating from gastric cancer after radical gastrectomy, and to propose steps for the prevention of hepatic metastases after radical gastrectomy.

## MATERIALS AND METHODS

### Patients

Between 1996 and 2001, 87 patients with gastric carcinoma who underwent radical gastrectomy in the Gastrointestinal Cancer Department, Tianjin Cancer Hospital, Tianjin Medical University, Tianjin were selected. These patients consisted of 32 with the primary tumor located in the proximal stomach, 8 with tumor in middle stomach and 45 with distal stomach tumor. There were 77 men and 10 women, with a mean age of 62 years (range 38-78). All patients had complete resection of the primary gastric cancer. No patient died during the initial hospital stay or for 1 mo after surgery. Follow-up ranged from 3 mo to 60 mo (median 32 mo).

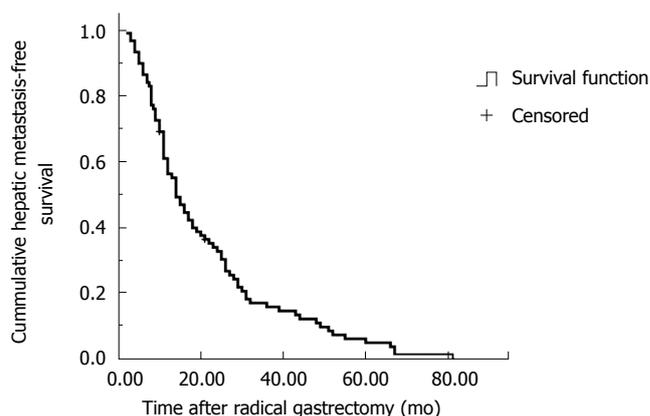

### Methods

The demographic and clinical information comprised of the following parameters: age, gender, interval time between radical gastrectomy and hepatic metastases, surgical procedure and postoperative chemotherapy.

Macroscopically, the size of the primary tumor, primary tumor location, number and pattern of metastasis, and metastatic interval time were recorded. Microscopic features evaluated were histologic differentiation, depth of invasion of the primary tumor, lymph node metastasis, Lauren classification, presence of vascular invasion, presence of neural invasion, and peritoneal metastasis. In patients with multiple hepatic metastases, the pathologic findings of the largest tumor were taken as representative of the other tumors, because all the tumors showed similar pathologic features. The histologic types of the primary gastric cancer and the hepatic metastasis were determined according to the World Health Organization Classification<sup>[6]</sup>. The depth of invasion, extent of lymph node metastasis, Lauren classification, and presence of vascular and neural invasion of the primary gastric cancer were also evaluated. The pathologic diagnosis and classification of the primary cancer were performed by at least two pathologists using the TNM classification of the UICC<sup>[7]</sup>, and results of gastric cancer study in surgery and pathology in Japan<sup>[8]</sup>.

### Statistical analysis

The various clinicopathologic factors were analyzed by the method of Kaplan and Meier, and Log-rank test was used to determine univariate significance. Factors that were deemed of potential importance on univariate analysis ( $P < 0.05$ ) were included in the multivariate analysis. Logistic regression or Cox proportional hazards model were used for multivariate analysis. Significance was defined as  $P < 0.05$ . Surgical procedures were classified as proximal radical gastrectomy, esophago-gastric resection, distal radical

**Figure 1** Kaplan-Meier cumulative hepatic metastasis-free survival plot for the entire cohort of 87 patients who underwent gastrectomy of gastric adenocarcinoma.

gastrectomy or total gastrectomy. Statistical analysis was performed using the statistical analysis program package (SPSS 13.0, Chicago, IL).

## RESULTS

### Clinicopathologic data

Histological analysis revealed that all the primary gastric tumors were adenocarcinomas. There was no evidence of metastases to other organs or peritoneal dissemination determined by imaging studies (such as B ultrasonography, CT or MRI), before curative gastrectomy was performed. Esophago-gastric resection was performed on 23 patients, proximal radical gastrectomy 8 patients, distal radical gastrectomy 45 patients and total gastrectomy 11 patients. The median interval time between gastrectomy and hepatic metastasis in all patients was 14 mo (range 3-31).

### Patient outcome

The time interval for hepatic metastasis free survival for the 87 patients who underwent radical gastrectomy is shown in Figure 1. Factors associated with interval time of hepatic metastases after radical gastrectomy are shown in Table 1. The actuarial interval time for < 6 mo, 6-12 mo, 12-36 mo, and more than 36 mo for hepatic metastases after primary radical gastrectomy were 9 (10.3%), 26 (29.9%), 38 (43.7%) and 14 (16.1%) respectively. The median hepatic metastasis-free survival time was 14.0 mo. With univariate analysis, five factors were found to have statistically significant association with the interval time of hepatic metastases after radical gastrectomy: size of gastric cancer, lymph node metastasis, No. 12 lymph node group metastases, No. 8 lymph node group metastases, and Lauren classification. Only the size of gastric cancer and lymph node metastasis showed significant correlation with the interval time of hepatic metastases using the Cox proportional hazards model analysis.

Factors associated with the number of hepatic metastases after radical gastrectomy are shown in Table 2. The number of patients with solitary metastasis and multiple metastases after primary radical gastrectomy were 11 (12.6%), and 76 (87.4%) respectively. With univariate analysis, three factors were found to have statistically significant association

with the number of hepatic metastases after radical gastrectomy: size of gastric cancer, depth of invasion, and Lauren classification. Only the depth of invasion of primary gastric tumor showed significant correlation with the number of hepatic metastasis, using the Logistic regression multivariate analysis.

Factors associated with the pattern of hepatic metastases after radical gastrectomy are depicted in Table 3. The pattern of hepatic metastases comprised of three subtypes (H1-3, according to the general rules for gastric cancer study in surgery and pathology in Japan). H1 subtype indicates that all the hepatic metastatic lesions are unilobar in

## DISCUSSION

The outcome of gastric cancer has not shown a significant improvement with the current treatment approaches. Although early detection improves the prognosis, most patients with gastric cancer are identified at an advanced

stage and have a poor prognoses despite developments in surgical techniques and the use of anticancer chemotherapy. In addition, patients with advanced cancer have very high rate of tumor recurrence, which is nearly always lethal<sup>[1,13]</sup>. Hepatic metastasis is the most frequent presentation of recurrent gastric cancer after radical

gastrectomy. The prognosis of gastric cancer in patients with hepatic metastasis is poor, and the best method of treatment remains unclear. The benefit of resection of hepatic metastases from gastric carcinoma is not widely accepted, and nonsurgical treatments, including the use of systemic or hepatic artery infusion chemotherapy has not produced satisfactory results. Hepatic resection of metastatic tumors from colorectal cancer is considered the standard of care, however, patients with metastatic liver tumors from gastric cancer are rarely considered good candidates for surgical treatment because most cases have multiple metastases and peritoneal dissemination<sup>[12,14]</sup>. Only 10% to 20% of patients with hepatic metastases from gastric cancer after gastrectomy are suitable for surgical treatment; the procedure has a median survival of 5-8 mo, with 15%-50% survival at 1 year and the 5-year survival rate is close to zero<sup>[15-19]</sup>.

The prolonged disease-free interval after gastrectomy in long-term survivors suggests that these tumors have a more indolent biologic character. Imamura *et al* reported that the prognosis of patients with an interval time > 1 year was better than that of patients whose interval time from gastrectomy to hepatic metastasis was < 1 year<sup>[19]</sup>. This feature may be useful in designing an adjuvant treatment program for such patients after surgical resection. Ambiru *et al* observed that the interval time from gastrectomy to hepatic metastases was an independent factor in determining the prognoses of patients who underwent hepatic resection<sup>[20]</sup>. Our findings show that the size of gastric cancer (OR = 1.989,  $P = 0.019$ ) and lymph node metastases (OR = 1.892,  $P = 0.001$ ) has significant correlation with the interval time of hepatic metastases, based on the results of the Cox proportional hazards model analysis. Lee *et al* proposed that both size and pattern of lymph node metastases provide prognostic information on the survival rate of gastric cancer patients<sup>[21]</sup>. Dong *et al* observed that the regional lymph node metastatic rate of patients with a mean gastric tumor size > 3 cm was greater than that of patients with a mean gastric tumor size less than 2 cm ( $P < 0.01$ )<sup>[22]</sup>. Baba *et al* reported absence of metastasis in lesions less than 1 cm in diameter, and the incidence of positive nodes increased with increasing size of the primary gastric tumor<sup>[23]</sup>. These observations and our own findings indicate that the size of the primary gastric tumor is associated with lymph node metastases, which is the most important factor in determining the recurrence of gastric cancer after radical gastrectomy, and has critical impact on the interval time from gastrectomy to hepatic metastases.

The presence of solitary or metachronous hepatic metastases are significant determinants for a favorable prognosis after radical gastrectomy. In liver metastases from colorectal carcinoma, the number of metastases is no longer considered an important predictor of long-term survival, if complete excision is achieved, survival after resection of up to eight metastases is similar to that after resection of a solitary metastasis<sup>[24]</sup>. The difference in the results between colorectal and gastric metastases is believed to reflect the aggressive biologic behavior of gastric cancer. Indications for resection

of hepatic metastases should be based on the biologic character of the primary tumor. In our study, all patients who underwent radical gastrectomy and resection of the hepatic metastases had metachronous metastases. Solitary hepatic metastasis was seen in only 11 cases, the remaining 76 patients had multiple hepatic metastases. In the present study, we attempted to correlate several clinical and histological factors with the number of hepatic metastases from gastric cancer after radical gastrectomy. By univariate analysis, a number of variables that affected the outcome were identified. However, by multivariate logistic regression analysis, only the depth of invasion of the primary gastric tumor was an independent risk factor for hepatic metastasis (OR = 8.799;  $P = 0.046$ ; 95% CI, 0.789-79.280). The depth of invasion of the primary gastric tumor and the number of metastatic lymph nodes were considered the most reliable prognostic indicators, with the strongest influence on the risk of recurrence after radical gastrectomy<sup>[25-30]</sup>. Michael *et al* reported that the depth of primary gastric tumor was associated with higher rates of metastasis to the peritoneum (locoregional, peritoneal, or distant), and was associated with a significantly shorter median time from recurrence to death<sup>[31]</sup>. Patients who had surgery for early gastric cancer had an excellent chance of long-term survival, whereas patients with serosal involvement had a very poor prognosis<sup>[32-34]</sup>. These studies suggested that greater depth of primary gastric cancer was associated with higher propensity to develop hematogenous metastases.

Usually, patients with hepatic metastasis were initially found to have multiple lesions in the liver. According to the general rules for the study of gastric cancer in surgery and pathology in Japan, hepatic metastases from gastric cancer should be divided into three subtypes (H1-3). H1 subtype refers to unilobar distribution metastasis. H2 subtype indicates metastatic lesions in both lobes. H3 subtype of hepatic metastases indicates the presence of numerous metastatic lesions in both lobes. Irrespective of whether the number of hepatic lesions is single or multiple, H1 subtype of hepatic metastases is an absolute indication for hepatic resection. However, most experts consider H2 and H3 subtypes as contraindications for hepatic resection<sup>[12,17,19,20,35]</sup>. Chen *et al* reported that the median survival time of H1 subtype treated with hepatic resection was longer than that of H2 or H3 subtypes treated without surgery ( $P = 0.0072$ )<sup>[36]</sup>. In the present study, the number of patients with H1, H2, and H3 metastases were 12, 31 and 44 respectively. Only the depth of invasion of the primary gastric cancer and Lauren classification showed significant correlation with the number of hepatic metastases, based on Logistic regression multivariate analysis. The Lauren classification divides tumors into intestinal type, diffuse type, and mixed (unclassifiable) type<sup>[37]</sup>. The Lauren diffuse type is associated with significantly worse prognosis for gastric cancer compared to the other types<sup>[38-40]</sup>. The depth of primary gastric tumor was associated with higher rate of recurrence of gastric cancer after gastrectomy<sup>[31]</sup>. These observations suggest that both the Lauren diffuse type and advanced depth of primary tumor are important

risk factors for hepatic metastasis from gastric cancer after radical gastrectomy.

The following conclusions can be drawn based on the present study. The size of the primary tumor (> 5 cm) and advanced lymph node metastases are important predictors of the interval time for hepatic metastases from gastric cancer after radical surgery. The prognostic value of the depth of the primary gastric cancer is independent of the number of hepatic metastases from gastric cancer after radical surgery. Both advanced depth of the primary gastric cancer and diffuse Lauren type are associated with H2 and H3 subtypes of hepatic metastases from gastric cancer after radical surgery.

## COMMENTS

### Background

Several studies have shown that resection is the ideal treatment for hepatic metastases from gastric cancer after radical gastrectomy. Assessment of the number and the pattern of hepatic metastases are very important for the surgeon to ascertain suitable candidates for surgical treatment. In addition, the interval time of hepatic metastases can determine in part the biologic character of the tumor. However, factors which affect the interval time, and the number and pattern of hepatic metastases from gastric cancer after radical surgery remain unclear.

### Research frontiers

We observed that the size of the gastric cancer and lymph node metastases are independent risk factors in predicting the interval time of hepatic metastases after radical gastrectomy. In the present study, only the depth of invasion was an independent risk factor for the number of hepatic metastases after radical gastrectomy. In addition, both the depth of invasion and the Lauren classification were found to be independently correlated with the pattern of hepatic metastases.

### Innovations and breakthroughs

From the results of this study, we can draw the following conclusions about hepatic metastases from gastric cancer after radical gastrectomy: the size of primary tumor and lymph node metastases are important predictors of the interval time; the depth of the primary gastric cancer is independent of the number of hepatic metastases; both the depth of primary gastric cancer and the Lauren type are associated with the pattern of hepatic metastases.

### Applications

The clinicopathological risk factors for hepatic metastases from gastric cancer after radical gastrectomy have been elucidated in the present study. Based on our findings, we can predict hepatic metastases in patients with gastric cancer after radical gastrectomy.

### Peer review

The author retrospectively analyzed 87 patients with hepatic metastasis who underwent radical gastrectomy for gastric cancer, and elucidated the risk factors for interval time, number, and pattern of hepatic metastases after curative gastrectomy. The results of this study provide important clues to predicting hepatic metastases in gastric cancer patients after radical gastrectomy.

### Abstract

A number of cutaneous changes are known to occur in the course of inflammatory bowel diseases (IBD), including pyoderma gangrenosum, erythema nodosum, perianal disease, erythematous eruptions, urticaria, and purpura. However, occurrence of skin manifestations prior to the development of ulcerative colitis is a rare occasion. Here, we report a case of ulcerative colitis associated with leukocytoclastic vasculitis in which the intestinal symptoms became overt 8 mo after the development of skin lesions.

### INTRODUCTION

Leukocytoclastic vasculitis is characterized by neutrophilic invasion and fibrinoid necrosis along with endothelial

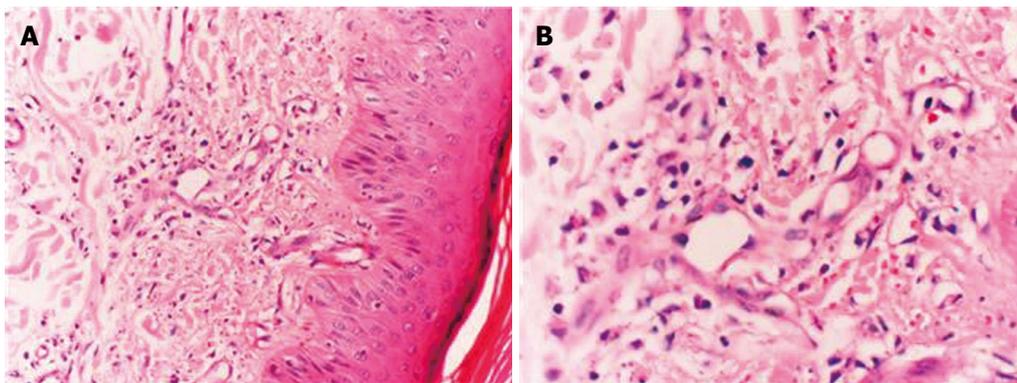

enlargement in postcapillary venules<sup>[1]</sup>. It is a syndrome in which patients most commonly present with palpable purpura on lower extremities and ankles.

Inflammatory bowel disease (IBD) can be associated with skin manifestations<sup>[2]</sup>. Association between leukocytoclastic vasculitis and ulcerative colitis is uncommon and in most cases cutaneous leukocytoclastic vasculitis proceeds the intestinal symptoms<sup>[3]</sup>. Here, we present a case diagnosed with leukocytoclastic vasculitis 8 mo before the development of ulcerative colitis.

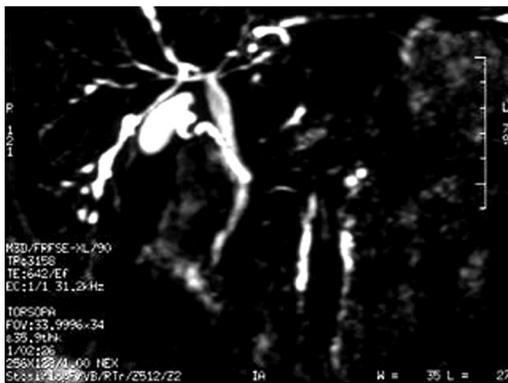

### CASE REPORT

A 20-year-old female had a history of itching in arms and legs which began in February 2005. She had no fever, diarrhea, weight loss, hematuria, vision problems, or headache. Anti-allergic medications did not show any favorable effects on the symptoms. Meanwhile, multiple reddish-brown macular lesions developed on her heels spreading upwards to legs and buttocks. She was treated with oral prednisolone at a dose of 20 mg/d. Although old lesions seemed to subside following treatment, new lesions appeared on the back, neck, and arms. Light brown macular lesions united to form plaque-like non-blanching lesions with erythema at the center. Skin biopsy was consistent with leukocytoclastic vasculitis. Figure 1A and B demonstrate the histologic characteristics of the skin biopsy specimen. Although, the dose of prednisolone was increased to 40 mg/d, she did not respond to it, thus, it was discontinued.

She was admitted to our clinic with the complaint of bloody diarrhea in September 2005, eight months after the first appearance of skin lesions. She reported that she passed bloody stool containing mucus, 8-10 times a day. Apart from the scars of old lesions and new light-brown macular lesions around the ankles, physical examination yielded normal results. Results of the laboratory investigations included the followings: 9.870/mm<sup>3</sup> white blood cells, 10.6 g/dL hemoglobin, 72 fL MCV, 409.800/mm<sup>3</sup> platelets. Peripheral blood smear showed hypochromia, microcytosis and anisocytosis, 29 mm/h of erythrocyte sedimentation rate, 34 C-reactive proteins, 75 U/L ALT (normal: 0-50 U/L), 64 U/L AST (normal: 0-40 U/L), 159 U/L ALP (normal: 40-150 U/L), 272 U/L GGT (normal: 5-64 U/L), and 0.81 mg/dL total bilirubin (normal: 0.2-1.2 mg/dL). Urine analysis was normal. Blood fasting glucose, urea, creatinine, total protein, albumin levels and electrolyte (albumin, sodium, potassium, chloride, and calcium) concentration were within

**Figure 1** Skin biopsy specimen (HE,  $\times 200$ ) showing polymorphonuclear cells and lymphocyte infiltration in and around the vessels of dermis beneath the multilayered keratinized squamous epithelium with some nuclear debris in the interstitium (A) and fibrin deposits in the vessel wall and nuclear debris (B).

**Figure 2** Magnetic resonance cholangiopancreatography demonstrating ductal irregularities and beading appearance in the distal branches of the right and left hepatic canals.

normal limits. HBsAg (-), anti-HCV (-), anti-HIV (-), thyroid function tests, anti-TPO antibody, and anti-TG antibody were normal. Other selected laboratory tests showed serum folic acid of 4.82 ng/mL (normal  $> 3.00$  ng/mL), vitamin B<sub>12</sub> of 226 pg/mL (normal: 160-980 pg/mL), ferritin of 3.3 ng/mL (normal: 5-148 ng/mL), serum iron of 6 g/dL (normal: 40-170 g/dL), and serum iron binding capacity of 470 g/dL (normal: 250-425 g/dL).

Abdominal ultrasonography revealed a mild edematous appearance in intestinal walls with no other abnormalities. Colonoscopic examination of the terminal ileum revealed a normal mucosa and lumen. The ileocecal valve appeared to be normal. However, mucosa of the entire colon was diffusely hyperemic and edematous with disappearance of the submucosal vascular network, and scattered shallow ulcerations. Histopathological examination of colonic specimen showed chronic mucosal inflammation with cryptic abscesses and distortion, suggestive of ulcerative colitis. Treatment with mesalazine (5-ASA) at a dose of 2 g/d was commenced and the patient was asked to visit one month later.

One month later, her bloody diarrhea and skin lesions disappeared and she passed formed stools once a day. However, liver function tests remained elevated (67 U/L AST, 92 U/L ALT, 165 U/L ALP, and 224 U/L GGT). Thus, quantitative serum immunoglobulin tests were as follows: ANA (-), anti-ds DNA (-), AMA (-), ASMA (-), anti LKM-1 (-), SLA/LP M2 (-), p-ANCA (+), 1.33 g/L C<sub>3</sub> (normal: 0.9-1.8 g/L), 0.15 g/L C<sub>4</sub> (normal: 0.1-0.4 g/L),

19.10 g/L IgG (normal: 7-16 g/L), 1.56 g/L IgM (normal: 0.4-2.3 g/L), and 3.01 g/L IgA (normal: 0.7-4 g/L).

Since serum ALP and GGT values were high and p-ANCA was positive, a magnetic resonance cholangiopancreatography (MRCP) was performed with the suspicion of primary sclerosing cholangitis (PSC). MRCP revealed ductal irregularities at distal branches of the right and left hepatic canals (Figure 2). Thus, ursodeoxycholic acid (UDCA) was started at a dose of 20 mg/kg, once a day, with a presumptive diagnosis of PSC. Following the treatment, her liver function tests returned to normal within two months. She was still well with oral 5-ASA and UDCA treatment at the time when we wrote this paper.

## DISCUSSION

Various skin findings can accompany inflammatory bowel disorders<sup>[2]</sup>. Skin manifestations occur in about 15% of patients with inflammatory bowel disorders<sup>[4]</sup>. Most frequently accompanying skin manifestations are pyoderma gangrenosum and erythema nodosum, while necrotizing vasculitis, cutaneous polyarteritis nodosa and granulomatous perivasculitis are less frequently seen<sup>[5-8]</sup>. Although the etiopathogenesis of extra-intestinal manifestations is not clear, a partial defect of immunity common to the skin and intestines has been suggested<sup>[5]</sup>.

Leukocytoclastic vasculitis is a disorder characterized by neutrophilic infiltration and nuclear debris in postcapillary venules<sup>[1,9]</sup>. It is believed to be an immune-complex disorder triggered by various drugs, infections, malignancies, and systemic and autoimmune disorders<sup>[10-13]</sup>. Although it usually involves the skin, systemic manifestations such as fever, arthralgia, myalgia or asthenia may also develop<sup>[2]</sup>. Leukocytoclastic vasculitis is less frequently seen in patients with ulcerative colitis as compared to other skin manifestations<sup>[14-18]</sup>. Clinically, it is generally synchronous with ulcerative colitis. Three previous ulcerative colitis cases who presented leukocytoclastic vasculitis before onset of the intestinal disease have been reported<sup>[3,15]</sup>. As reported by Newton *et al*<sup>[15]</sup>, vasculitic symptoms appear 1 to 6 mo before the onset of intestinal symptoms. Iannone *et al*<sup>[3]</sup> reported another case whose intestinal disease occurred 2 years after appearance of vasculitic skin lesions. In our case, leukocytoclastic vasculitis developed 8 mo before the appearance of intestinal symptoms.

One possible explanation of the association between these two disorders can be that the pathogenesis of

both is based on immune mechanisms and deposition of immune complexes in the vascular wall and intestinal mucosa for leukocytoclastic vasculitis and ulcerative colitis, respectively<sup>[19]</sup>. Another possible explanation might be that IBD is a systemic disorder involving different tissues (skin, joints, intestine) at different episodes<sup>[3]</sup>.

Skin lesions of leukocytoclastic vasculitis can be treated with corticosteroids, dapsone, colchicine, or immunosuppressive agents<sup>[1]</sup>. The treatment can be directed to the underlying cause (i.e., drugs, infections, malignancies, autoimmune diseases), if it is present. As previously mentioned, cases of leukocytoclastic vasculitis accompanying ulcerative colitis can be effectively treated with colchicine and sulfasalazine. In our case, both intestinal symptoms and skin lesions were successfully treated with 5-ASA.

The other diagnosis of our patient was PSC. It was reported that the prevalence of PSC in patients with ulcerative colitis is 5.5%<sup>[20]</sup>. ANCA positivity in patients with PSC is 56%-88%. Patients with PSC can be asymptomatic (25%-45%) at the time of diagnosis<sup>[21]</sup>. In our case, it is possible that PSC developed synchronously with leukocytoclastic vasculitis. Not any case in the literature presented PSC along with leukocytoclastic vasculitis.

In conclusion, IBD should be kept in mind as a cause of leukocytoclastic vasculitis, although it is a rare occasion. A careful follow-up of such cases may improve both vasculitis and IBD.

### Abstract

Although both primary biliary cirrhosis (PBC) and idiopathic thrombocytopenic purpura (ITP) are autoimmune diseases, the association of the 2 diseases is rare. Here, we report a case of ITP that developed during the follow-up of PBC in a 74-year-old man. The patient had been diagnosed with PBC 12 years previously, and had received treatment with ursodeoxycholic acid. The platelet count decreased from approximately  $60 \times 10^9/L$  to  $8 \times 10^9/L$ , and the association of decompensated liver cirrhosis (PBC) with ITP was diagnosed. Steroid and immune gamma globulin therapy were successful in increasing the platelet count. Interestingly, human leukocyte antigen genotyping detected the alleles DQB1\*0601 and DRB1\*0803, which are related to both PBC and ITP in Japanese patients. This case suggests common immunogenetic factors might be involved in the development of PBC and ITP.

### INTRODUCTION

Primary biliary cirrhosis (PBC) is a chronic liver disease characterized by progressive biliary injury as a result of an underlying autoimmune process. PBC is often associated with extrahepatic autoimmune diseases such as Sjögren's syndrome and chronic thyroiditis. Idiopathic thrombocytopenic purpura (ITP) is a well-defined autoimmune disease, but the association of PBC with ITP is rare. However, cases of simultaneous occurrence of PBC and ITP as well as ITP after liver transplantation for PBC have been reported<sup>[1-4]</sup>. We describe a case in which ITP developed during the follow-up of PBC in an elderly man and discuss the possible mechanisms underlying the association of the 2 diseases.

### CASE REPORT

A 74-year-old man was referred to our hospital in November 2000 because of liver dysfunction detected during a medical checkup. The patient had been diagnosed with nephrotic syndrome in 1995. Laboratory examinations showed elevated serum hepatobiliary enzymes and IgM, and the presence of antimitochondrial antibodies. Serologic markers for Hepatitis B and C viruses were negative. Histopathologic examination of a liver biopsy specimen obtained at laparoscopy revealed non-suppurative destructive cholangitis in the portal area (Figure 1). The diagnosis of PBC (Scheuer stage 3) was confirmed and ursodeoxycholic acid, 900 mg daily, was started. In January and June 2002, the patient underwent endoscopic variceal ligation plus endoscopic injection sclerotherapy as well as argon plasma coagulation for worsening esophageal varices.

In September 2007, the patient was admitted for the

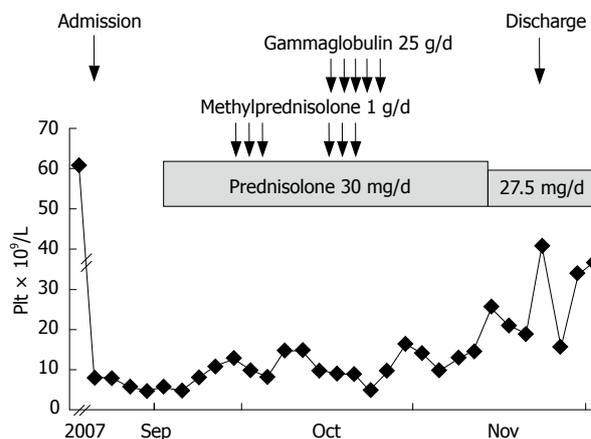

Figure 2 The clinical course of the patient.

treatment of recurrent esophageal varices. The platelet count had ranged between  $52 \times 10^9/L$  and  $69 \times 10^9/L$  for several years, but it was noted to decrease from  $61 \times 10^9/L$  in June 2007 to  $8 \times 10^9/L$  just before admission. Before the deterioration of thrombocytopenia, the patient had no infectious diseases and received no other medication. On admission, the patient had neither purpura nor bleeding episodes. Table 1 shows the laboratory data on admission. The platelet-associated IgG level was markedly high. Bone marrow biopsy revealed normocellular marrow without cellular atypia. Ultrasonography and magnetic resonance imaging revealed a cirrhotic liver with splenomegaly, ascites, and gallstones. The spleen size had remained unchanged from previous imaging examinations. Based on these findings, the association of PBC (decompensated liver cirrhosis) with ITP was diagnosed. Human leukocyte antigen (HLA) genotyping determined by polymerase chain reaction-sequencing-based typing or polymerase chain reaction-sequence specific primers (SRL, Inc., Tokyo, Japan) detected A\*02010101, B\*400201, C\*030401, C\*07020101, DPB1\*0501, DQA1\*0103, DQA1\*030101,

DQB1\*030201, DQB1\*060101, DRB1\*080201, and DRB1\*080302. The 13C urea breath test for *H pylori* infection was negative.

Figure 2 shows the clinical course. Oral prednisolone, 30 mg daily, for ITP was started on day 11, and diuretic therapy combined with albumin infusion for ascites was performed. As the platelet count did not increase notably, pulse therapy with intravenous methylprednisolone, 1 g daily, was added on d 22 to 24. However, the response was weak and temporary. On d 31, mild melena was identified. The patient was given a trial of intravenous immune gamma globulin therapy, 25 g daily, on d 32 to 36, combined with a second round of intravenous methylprednisolone pulse therapy on d 32 to 34. Because a moderate response was observed, prednisolone was continued, and the platelet count increased slowly. The ascites was relatively well controlled with diuretics at discharge. Considering the decompensated liver cirrhosis and the platelet count, we determined the patient required careful follow-up of esophageal varices without prophylactic endoscopic therapy.

## DISCUSSION

Because immunogenetic factors are believed to influence the development of autoimmune diseases, the relationship between HLA alleles and susceptibility to PBC and ITP has been investigated<sup>[5-8]</sup>. In Japanese patients with PBC, the frequency of DPB1\*0501, DQA1\*0103, DQB1\*0601, and DRB1\*0803 is increased<sup>[5,6]</sup>. On the other hand, those with ITP have an increased frequency of DRB1\*0410<sup>[7]</sup>, and strong associations between anti-platelet surface glycoprotein autoantibodies and HLA alleles have been reported, including an association of anti-glycoprotein IIb/IIIa antibody with DQB1\*0401 and DRB1\*0405, and of anti-glycoprotein I b/IX antibody with DQB1\*0601 and DRB1\*0803<sup>[8]</sup>. Of these HLA alleles, DPB1\*0501, DQA1\*0103, DQB1\*0601, and DRB1\*0803 were detected in the present case. It should be noted that DQB1\*0601 and DRB1\*0803 are related to both PBC and ITP. The frequency of a combination of the 2 HLA alleles in patients with PBC and ITP is significantly higher than that in general population<sup>[6,8]</sup>. Furthermore, it is estimated patients with a combination of the 2 HLA alleles are at least several-fold more susceptible to PBC and ITP. The 2 HLA alleles might be common immunogenetic factors for the development of PBC and ITP, and the mechanism underlying ITP development might be anti-glycoprotein I b/IX antibody-mediated platelet destruction. Unfortunately, anti-glycoprotein autoantibodies were not examined. Immunogenetic analyses should shed light on the mechanism of the association of PBC with ITP.

The present patient already had thrombocytopenia related to liver cirrhosis at the onset of ITP. Based on an evaluation of platelet kinetics, a recent study has shown reduced platelet production and enhanced platelet turnover in patients with liver cirrhosis<sup>[9]</sup>. Hypersplenism, as observed in the present case, is well known to enhance platelet turnover; the pathologically enlarged and congested spleen accelerates the sequestration and destruction of platelets. Another mechanism of thrombocytopenia in liver cirrhosis is anti-platelet autoantibody-mediated platelet destruction. Kajihara *et al*<sup>[10]</sup> have revealed a similar profile of the anti-glycoprotein IIb/IIIa autoantibody response between patients with liver cirrhosis and those with ITP, and concluded that immune-mediated platelet destruction may contribute, at least in part, to cirrhotic thrombocytopenia. In the present case, an autoimmune response to platelets might have been induced or enhanced by the underlying liver cirrhosis.

Panzer *et al*<sup>[11]</sup> have reported autoantibodies eluted from a patient with PBC and ITP precipitate glycoprotein IIb/IIIa of autologous and allogeneic platelets and bind to an epitope of the rat 70-kDa mitochondrial protein M2. Furthermore, computer analysis of published peptide sequences of the mitochondrial protein and glycoprotein IIb/IIIa showed partial amino acid sequence homology, suggesting the possibility of a common antibody-binding site. In another study, it was suggested the development of the immune phenomenon in PBC may also involve immune-mediated platelet destruction<sup>[12]</sup>. There might be

a mechanism by which PBC-related autoantibodies cross-reacting with platelet surface autoantigens cause ITP.

In summary, we experienced a rare case of the association of PBC with ITP. HLA genotyping suggests that common immunogenetic factors might be involved in the development of PBC and ITP.

## Abstract

Non-invasive predictors of varices in cirrhosis would reduce the need for screening endoscopies. Platelet count and spleen size have been shown to be useful parameters, in mixed groups of cirrhotics with different aetiologies. We evaluated this in two homogeneous groups with cirrhosis due to hepatitis C and alcohol. Non-invasive predictors appear promising in the former group, but less so in the latter group.

## TO THE EDITOR

We read with interest the study by Alempijevic *et al* on non-invasive prediction of oesophageal varices in cirrhosis<sup>[1]</sup>. We agree this is an important clinical goal, thus reducing the need to screen all individuals with cirrhosis. Importantly, such predictors must have a high sensitivity, even at the cost of a lower specificity, to ensure that patients with varices are not missed. Platelet count and spleen size appear consistently discriminatory in recent

series<sup>[2-6]</sup>. Giannini *et al*<sup>[2,3]</sup> have suggested the platelet:spleen size ratio as informative. Sharma and Aggarwal<sup>[6]</sup> have recently proposed a predictor function derived from these two parameters. Of note, all these studies evaluated mixed groups of cirrhosis with different aetiologies. We routinely measure spleen size by ultrasound and performed a retrospective study of all patients with cirrhosis due to either hepatitis C alone ( $n = 93$ ) or alcohol alone ( $n = 77$ ) who underwent screening gastroscopy in our unit over a four-year period. Patients with tumour, splenectomy or portal vein thrombosis were excluded.

In the hepatitis C group, both platelet count and spleen size had a good predictive ability for the presence of oesophageal varices, while the platelet:spleen size ratio and the reported predictor function were slightly superior (Table 1). The optimum cut-off for the platelet:spleen size ratio was 6.50, compared with 9.09 by Giannini *et al*<sup>[2,3]</sup>, and that for the predictor function was 1.00, compared with the published figure of 1.09 (although the latter was for large varices only). We found, however, that a simple clinical predictor based on the best cut-off values obtained individually for platelet count and spleen size, was the most sensitive predictor of the presence of oesophageal varices. Platelet count  $\leq 90 \times 10^9/L$  and/or spleen size  $\geq 14$  cm achieved a sensitivity of 92% and a specificity of 69% in this cohort.

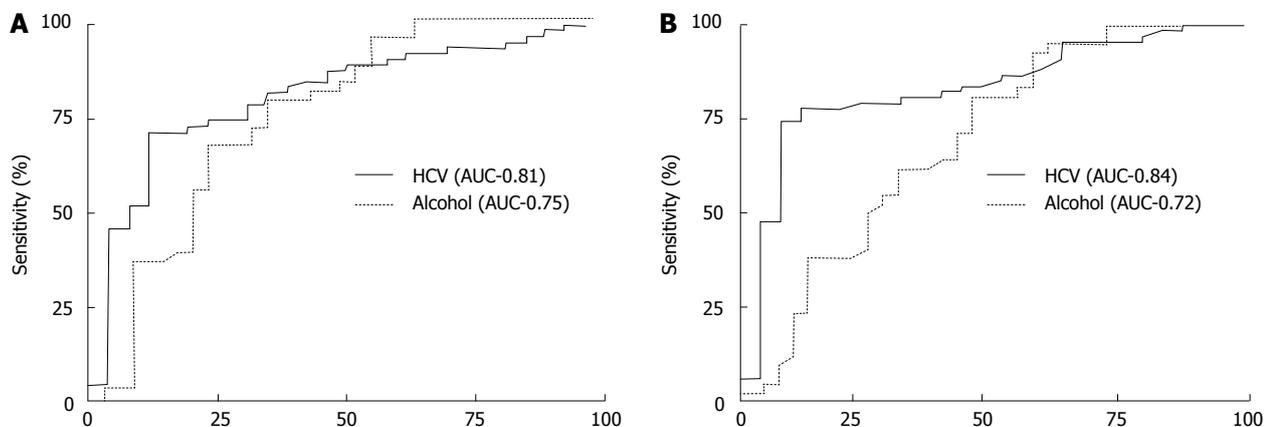

In the alcohol-related cirrhosis group, however, the predictive ability of all these parameters was generally poorer, as evidenced by a lower area under the curve (AUC) as well as a lower sensitivity and specificity compared with hepatitis C (Figure 1 and Table 1). Moreover, for the derived functions, cut-off values, which differed from those noted in the hepatitis C group and from the published values, had to be chosen to get a reasonable balance between sensitivity and specificity. With a platelet count  $\leq 120 \times 10^9/L$  and/or spleen size  $\geq 12$  cm, only a sensitivity of 74% and a specificity of 55% were obtained.

Our data suggest that easily obtainable non-invasive markers are effective for predicting oesophageal varices in hepatitis C cirrhosis but are not as promising for cirrhosis due to other aetiologies such as alcohol. In hepatitis C cirrhosis, portal pressure is presumably relatively stable whereas in alcohol-related liver disease, portal pressure may vary with consumption and abstinence. Furthermore, alcohol can cause thrombocytopenia through folate deficiency and a direct effect on platelet function and survival which may render platelet count a less accurate marker of portal pressure. This may explain why published predictors of varices which incorporate platelet count and

a mix of aetiologies do not demonstrate the high sensitivity we observed in hepatitis C. The right liver lobe/albumin ratio proposed by Alempijevic *et al*<sup>[1]</sup> may, however, prove to be more consistently reliable in generalized cirrhosis. Further prospective studies should help to delineate the optimum approach and we look forward to future consensus guidelines which incorporate these strategies, reducing the burden of endoscopy for patients with cirrhosis.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1224 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/15.doc>

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Total of 1050 editorial members from 60 countries world wide have been active in peer review and editing

National Journal Award  
2005

# World Journal of Gastroenterology®

Weekly Established in October 1995

Volume 14 Number 16  
April 28, 2008

## Contents

- |                            |      |   |
|----------------------------|------|---|
| <b>EDITORIAL</b>           | 2461 | Treatment of gastrointestinal neuroendocrine tumors with inhibitors of growth factor receptors and their signaling pathways: Recent advances and future perspectives<br><i>Höpfner M, Schuppan D, Scherübl H</i>  |
| <b>REVIEW</b>              | 2474 | Nonalcoholic fatty liver disease: An overview of current insights in pathogenesis, diagnosis and treatment<br><i>Schreuder TCMA, Verwer BJ, van Nieuwkerk CMJ, Mulder CJJ</i>   |
| <b>GASTRIC CANCER</b>      | 2487 | Effect and mechanism of the <i>Twist</i> gene on invasion and metastasis of gastric carcinoma cells<br><i>Luo GQ, Li JH, Wen JF, Zhou YH, Hu YB, Zhou JH</i>  |
| <b>BASIC RESEARCH</b>      | 2494 | Effect of 5-LOX/COX-2 common inhibitor DHDMBF30 on pancreatic cancer cell Capan2<br><i>Zhang B, Wang CL, Zhao WH, Lv M, Wang CY, Zhong WX, Zhou WY, Yu WS, Zhang Y, Li S</i>  |
| <b>CLINICAL RESEARCH</b>   | 2501 | Identification of osteopontin as the most consistently over-expressed gene in intrahepatic cholangiocarcinoma: Detection by oligonucleotide microarray and real-time PCR analysis<br><i>Hass HG, Nehls O, Jobst J, Frilling A, Vogel U, Kaiser S</i>  |
|                            | 2511 | Anti-inflammatory activity of probiotic <i>Bifidobacterium</i> : Enhancement of IL-10 production in peripheral blood mononuclear cells from ulcerative colitis patients and inhibition of IL-8 secretion in HT-29 cells<br><i>Imaoka A, Shima T, Kato K, Mizuno S, Uehara T, Matsumoto S, Setoyama H, Hara T, Umesaki Y</i> |
|                            | 2517 | Severe acute pancreatitis in the elderly: Etiology and clinical characteristics<br><i>Xin MJ, Chen H, Luo B, Sun JB</i>   |
| <b>RAPID COMMUNICATION</b> | 2522 | Prognostic factors for progression of liver structural lesions in chronic hepatitis C patients<br><i>Mendes LSC, Nita ME, Ono-Nita SK, Mello ES, da Silva LC, Alves VAF, Carrilho FJ</i>  |
|                            | 2529 | T cell responses to hepatitis B surface antigen are detectable in non-vaccinated individuals<br><i>Wehrauch MR, von Bergwelt-Baildon M, Kandic M, Weskott M, Klamp W, Rösler J, Schultze JL</i>   |
|                            | 2534 | Alteration of sister chromatid exchange frequencies in gastric cancer and chronic atrophic gastritis patients with and without <i>H pylori</i> infection<br><i>Karaman A, Binici DN, Kabalar ME, Dursun H, Kurt A</i>   |
|                            | 2540 | Diagnostic value of plasminogen activity level in acute mesenteric ischemia<br><i>Gunerhan Y, Koksall N, Kayahan M, Eryavuz Y, Sekban H</i>   |

- 2544 Use of infliximab in the prevention and delay of colectomy in severe steroid dependant and refractory ulcerative colitis  
*Willert RP, Lawrance IC*
- 2550 Treatment of gastric remnant cancer post distal gastrectomy by endoscopic submucosal dissection using an insulation-tipped diathermic knife  
*Hirasaki S, Kanzaki H, Matsubara M, Fujita K, Matsumura S, Suzuki S*
- 2556 Effect of biliary obstruction and internal biliary drainage on hepatic cytochrome P450 isozymes in rats  
*Fukushima S, Okuno H, Shibatani N, Nakahashi Y, Seki T, Okazaki K*
- 2561 Effect of erythromycin on image quality and transit time of capsule endoscopy: A two-center study  
*Niv E, Bogner I, Barkay O, Halpern Z, Mahajna E, Depsames R, Kopelman Y, Fireman Z*
- 2566 Hepatoprotective activity of *Sapindus mukorossi* and *Rheum emodi* extracts: *In vitro* and *in vivo* studies  
*Ibrahim M, Khaja MN, Aara A, Khan AA, Habeeb MA, Devi YP, Narasu ML, Habibullah CM*
- 2572 Ghrelin improves delayed gastrointestinal transit in alloxan-induced diabetic mice  
*Qiu WC, Wang ZG, Lv R, Wang WG, Han XD, Yan J, Wang Y, Zheng Q, Ai KX*
- 2578 Effect of histone deacetylase inhibitor on proliferation of biliary tract cancer cell lines  
*Xu LN, Wang X, Zou SQ*
- 2582 Increased N-terminal pro-brain natriuretic peptide level predicts atrial fibrillation after surgery for esophageal carcinoma  
*Hou JL, Gao K, Li M, Ma JY, Shi YK, Wang Y, Zhao YF*

**CASE REPORT**

- 2586 Transrectal EUS-guided FNA biopsy of a presacral chordoma-report of a case and review of the literature  
*Gottlieb K, Lin PH, Liu DM, Anders K*
- 2590 Double aortic arch and nasogastric tubes: A fatal combination  
*Massaad J, Crawford K*
- 2593 An uncommon cause of gastro-duodenal ulceration  
*Mallach S, Ramp U, Erhardt A, Schmitt M, Häussinger D*
- 2596 Concomitant autoimmune and genetic pancreatitis leads to severe inflammatory conditions  
*Frossard JL, Dumonceau JM, Pastor C, Spahr L, Hadengue A*
- 2599 Extreme gastric dilation caused by chronic lead poisoning: A case report  
*Begovic V, Nozic D, Kupresanin S, Tarabar D*
- 2602 Systemic gemcitabine combined with intra-arterial low-dose cisplatin and 5-fluorouracil for advanced hepatocellular carcinoma: Seven cases  
*Uka K, Aikata H, Takaki S, Kawaoka T, Saneto H, Miki D, Takahashi S, Toyota N, Ito K, Chayama K*
- 2609 Endoscopic enucleation of gastrointestinal stromal tumors of the stomach: Report of five cases  
*Kato T, Itoh Y, Mohri T, Suzuki H*

**Contents**

**2612** Acute necrotizing pancreatitis complicated with pancreatic pseudoaneurysm of the superior mesenteric artery: A case report  
*He Q, Liu YQ, Liu Y, Guan YS*

**LETTERS TO THE EDITOR 2615** Lower gastrointestinal bleeding: Association with Sevelamer use  
*Madan P, Bhayana S, Chandra P, Hughes JI*

**2617** Is the required therapeutic effect always achieved by racemic switch of proton-pump inhibitors?  
*Zhou Q, Yan XF, Pan WS, Zeng S*

**ACKNOWLEDGMENTS 2620** Acknowledgments to Reviewers of *World Journal of Gastroenterology*

## Abstract

The limited efficacy of conventional cytotoxic treatment regimes for advanced gastrointestinal neuroendocrine cancers emphasizes the need for novel and more effective medical treatment options. Recent findings on the specific biological features of this family of neoplasms has led to the development of new targeted therapies, which take into account the high vascularization and abundant expression of specific growth factors and cognate tyrosine kinase receptors. This review will briefly summarize the status and future perspectives of antiangiogenic, mTOR- or growth factor receptor-based pharmacological approaches for the innovative treatment of gastrointestinal neuroendocrine tumors. In view of the multitude of novel targeted approaches, the rationale for innovative combination therapies, i.e. combining growth factor (receptor)-targeting agents with chemoradiotherapeutics or with other novel anticancer drugs such as HDAC or proteasome inhibitors will be taken into account.

Treatment of gastrointestinal neuroendocrine tumors with inhibitors of growth factor receptors and their signaling pathways: Recent advances and future perspectives. *World J Gastroenterol* 2008; 14(16): 2461-2473 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2461.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2461>

## INTRODUCTION

Neuroendocrine tumors form a heterogeneous group of malignancies that do not only include gastrointestinal neuroendocrine tumors but also neoplasias such as pheochromocytoma, pituitary tumors, medullary thyroid cancer, and even undifferentiated (small cell) neuroendocrine cancer. Gastroenteropancreatic neuroendocrine tumors (GEP NET) are usually classified according to localization of the primary, grade of differentiation and functionality. The former traditional classification distinguished between pancreatic neuroendocrine tumors and carcinoid tumors<sup>[1]</sup>. Both tumor types often display well-differentiated histologic features, and often preserve the ability to release excessive amounts of biogenic amines and/or neuropeptides thereby causing characteristic hypersecretion syndromes. The resulting, often bizarre clinical symptoms are generally well controlled by somatostatin analogs or interferon- $\alpha$ <sup>[2,3]</sup>. However, tumor growth and spread of GEP NETs are not always well controlled by either biotherapy or chemotherapy. Thus, therapeutic options to inhibit growth and spread of gastrointestinal neuroendocrine tumors are still unsatisfactory.

Significant advances in our knowledge of the particular biology of GEP NETs made over the past decades shows that GEP NETs represent a tumor entity with an extraordinary high vascularization along with an abundant production and secretion of growth factors such as VEGF, EGF, IGF, PDGF, HGF, FGF or TGF- $\alpha$ . Expression and signaling of growth factors and their cognate receptors in GEP NETs has been studied quite extensively<sup>[4-10]</sup>, and paved the way for new and molecular targeted strategies for GEP NET treatment. Among the most promising new therapeutic approaches is the inhibition of synthesis and/or secretion, as well as receptor binding of angiogenic

growth factors such as vascular endothelial growth factor (VEGF). These antiangiogenic approaches are mostly based on the use of specific monoclonal antibodies or tyrosine kinase inhibitors to attenuate tumor microvessel formation and hence the vital supply of the tumor with nutrients and oxygen<sup>[11,12]</sup>. Furthermore, dysregulation and/or overexpression of other oncogenic growth factor receptors in GEP NETs, such as the epidermal growth factor receptor (EGFR), insulin-like growth factor receptor-1 (IGF-1R), or the platelet-derived growth factor receptor (mainly PDGFR- $\beta$ ) offer additional targets for future chemotherapeutic intervention<sup>[13,14]</sup>. These growth factor receptor-based strategies mainly target the receptors' intrinsic tyrosine kinase activity with small molecule inhibitors or ligand-receptor interactions with monoclonal antibodies. The underlying rationale for this treatment strategy is to specifically interrupt the downstream mitogenic and antiapoptotic signaling cascades that are triggered by ligand-activation of a specific growth factor receptor, events that have been shown to play a crucial role in the expansion and spread of the tumors.

Besides therapeutically targeting growth factor receptors, a third promising approach is the direct inhibition of receptor-mediated downstream signaling pathways such as the phosphatidylinositol-3-kinase (PI3K)-AKT-mammalian target of rapamycin (mTOR) pathway or the Ras/Raf-mitogen-activated kinase (MAPK) pathway<sup>[15,16]</sup>. There is increasing evidence that specific inhibition of several key components of these pathways, such as mTOR and Raf, is thought to exert enhanced antineoplastic potency as compared to the single inhibition of just one pathway or pathway-activating receptor. Thus, the abrogation of single growth factor receptor activities are found to be counter-balanced by compensatory signaling and transactivation of other growth factor receptors<sup>[17-20]</sup>.

This review will provide a perspective overview of selected agents, which are currently in development, consideration or testing for such targeted treatment approaches for GEP NET (Table 1). Moreover, promising approaches, which have not yet been evaluated in GEP NET, but warrant future evaluation, will be discussed.

## ANTIANGIOGENIC TREATMENT STRATEGIES

Angiogenesis plays a central role in tumor growth and progression, and its implication has been extensively investigated and described in the literature for various cancers<sup>[21,22]</sup>. In the early 1970s, Folkman was the first to develop the concept of angiogenesis-dependent tumor growth and postulated that the specific blocking of blood flow to the tumor should be a promising strategy for cancer treatment<sup>[23]</sup>.

Among the angiogenic factors/receptors described so far, the vascular endothelial growth factor (VEGF) and VEGF receptor family including the secreted glycoproteins VEGF-A (synonym: VEGF), VEGF-B, VEGF-C, VEGF-D, VEGF-E, the placental growth factors (PlGF-1, -2), and their cognate receptors VEGFR-1 (Flt-1), VEGFR-2 (Flk/KDR) play major

roles (not only in physiological) but also in pathological angiogenesis. VEGF that binds to both VEGFR-1 and -2 is the key regulator of the development of the vascular system and is commonly overexpressed in a variety of solid tumors<sup>[24]</sup>. Hypervascularized GEP NETs, have also been demonstrated to (over-)express VEGF and its cognate receptors (VEGFR-1, -2) in the tumor and its surrounding vasculature<sup>[25-28]</sup>. In addition, elevated levels of circulating VEGF are correlated with the progression of GEP NETs<sup>[29]</sup>. In this line, a recent study confirmed the particular role of VEGF for the prognosis and progression of GEP NET by showing that elevated expression of VEGF correlated with increased angiogenesis and decreased progression-free survival among patients with low-grade neuroendocrine tumors<sup>[30]</sup>.

Based on the particular significance of VEGF and its receptors (VEGFR-1, -2) in GEP NETs and because of VEGF's action on endothelial cell activation for new tumor vessel formation, the VEGF/VEGFR system has been an extensively studied target for the treatment of GEP NET.

## ANTIBODY-BASED ANTIANGIOGENIC THERAPY

### Anti-VEGF treatment

Bevacizumab is a humanized murine monoclonal anti-VEGF antibody, which has entered the clinic for antiangiogenic treatment of cancer. Standard cytostatic treatment plus bevacizumab significantly increased survival in metastatic colorectal cancer as compared to standard treatment alone in a phase III clinical trial<sup>[31]</sup>, a finding that led to the approval of bevacizumab for treatment of colorectal cancer in 2005. Comparable results were obtained in a recent phase III clinical trial with bevacizumab for treatment of non-small cell lung cancer (NSCLC). This study was interrupted before finalization because of the obvious survival advantage of patients in the bevacizumab arm<sup>[32]</sup>.

The first clinical trials with bevacizumab for treatment of GEP NET were reported 3 years ago<sup>[33]</sup>. In a randomized Phase II trial, the effect of monotherapy with bevacizumab (15 mg/kg every 3 wk) was compared to the effects of pegylated IFN- $\alpha_{2b}$  (0.5  $\mu$ g/kg per week) in patients with advanced carcinoid tumors. After 18 wk an almost 30% higher rate of progression free survival rate (PFS) was observed in the bevacizumab arm (98% PFS) as compared to the peg-IFN- $\alpha_{2b}$  arm (68% PSF) (NIH: NCT00055809). In bevacizumab-treated patients, CT scan, monitoring the antiangiogenic effects of bevacizumab at the individual patients' level, showed a dramatic decrease in tumor perfusion. Based on these encouraging findings a phase III trial is currently being proposed to evaluate the benefit of bevacizumab as compared to IFN- $\alpha_{2b}$  for the treatment of patients with advanced carcinoid tumors and a poor-prognosis who are under stable doses of depot octreotide (South West Oncology Group; unpublished study-protocol of study: S0518).

Several other studies using bevacizumab for combination therapy of GEP NET are currently ongoing.

Table 1 Current status of clinical trials with agents that target growth factor receptors and related signaling pathways for treatment of gastrointestinal neuroendocrine tumors

Name	Target	Mechanism	Tumor type	Cotreatment	Status	Reference
Bevacizumab	VEGF	VEGF-neutralizing antibody	Carcinoid	Peg IFN- $\alpha$	Phase II	[35]
			Carcinoid	Depot-octreotide	Phase III	South West Oncology Group: S50518
			Carcinoid	Panzem	Phase II	NCT00227617
			Advanced GEP NET	FOLFOX	Phase I / II	NCT00328497
			Advanced GEP NET	Oxaliplatin, capecitabine	Phase II	NCT00398320
			Pancreatic and other unresectable carcinoid	Temzolomide	Phase II	NCT00137774
Sunitinib	VEGFR, PDGFR, c-KIT, FLT3	Tyrosine kinase inhibitor	Carcinoid		Phase II	[48]
			Carcinoid		Phase II	NCT00428597
			Carcinoid <sup>1</sup>		Phase II	NCT00434109
Pazopanib	Pan-VEGFR, PDGFR, c-KIT	Tyrosine kinase inhibitor	Low-, intermediate grade GEP NET		Phase II	NCT00454363
AMG706	pan-VEGFR, PDGFR, c-KIT	Tyrosine kinase inhibitor	Low-grade GEP NET		Phase II	NCT00427349
Vatalanib	VEGFR, PDGFR, c-KIT	Tyrosine kinase inhibitor	Progressive GEP NET <sup>2</sup>		Phase II	[64]
			Progressive GEP NET		Phase II <sup>3</sup>	NCT00227773
Gefitinib	EGFR	Tyrosine kinase inhibitor	Progressive GEP NET	Cetuximab	Phase II	[79]
			Advanced GEP NET		Phase II	NCT00397384
NVP-AEW541	IGF-1R	Tyrosine kinase inhibitor	NET cells		Pre-clinical	[14]
Everolimus	mTOR	Protein kinase inhibitor	Islet carcinoid		Phase II	[136]
			Carcinoid	Octreotide	Phase II	[127]
Temsirolimus	mTOR	Protein kinase inhibitor	Recurrent, metastatic GEP NET		Phase II	[137]
Sorafenib	c-Raf, B-Raf, VEGFR, PDGFR	Tyrosine kinase inhibitor	Progressive, metastatic GEP NET		Phase II	NCT00131911
Imatinib	PDGFR, c-KIT, ABL	Tyrosine kinase inhibitor	Carcinoid		Phase II	[127]
			Advanced GEP NET		Phase II	[59]
Bortezomib	Proteasome	Proteasome inhibitor	Metastatic GEP NET		Phase II	[153]

<sup>1</sup>Liver predominant metastases after hepatic arterial embolization; <sup>2</sup>Progressive after somatostatin treatment; <sup>3</sup>Withdrawn.

A pending Phase I / II trial is recruiting patients with advanced neuroendocrine tumors to determine the safety and efficacy of bevacizumab in combination with 5-fluorouracil, leucovorin and oxaliplatin (FOLFOX) (NIH: NCT00227617). Additionally, the efficacy of bevacizumab together with oxaliplatin and capecitabine is currently being investigated in metastatic and unresectable GEP NETs in a non-randomized, open label phase II trial (NIH: NCT00398320). Bevacizumab is also being tested in combination with 2-methoxyestradiol (Panzem) in patients with locally advanced or metastatic carcinoid tumors (NIH: NCT00328497). Panzem is a metabolite of estradiol that has recently emerged as a promising anticancer agent because of its potent growth-inhibitory and proapoptotic effects on both endothelial and tumor cells<sup>[34,35]</sup>. Besides other antiangiogenic and cytotoxic properties panzem's mode of action involves the inhibition of the hypoxia-inducible factor (HIF)-1 $\alpha$ , a transcription factor, which drives the expression of several pro-angiogenic genes<sup>[36]</sup>. *In vitro* and *in vivo* (animal) studies of several tumor types, including sarcoma, lung, and breast cancer, have documented potent inhibitory effects on tumor cells and angiogenesis without major clinical signs of toxicity<sup>[37]</sup>. Thus, a dual targeting of GEP NETs at the level of both the tumor cell and tumor microvessel formation

by panzem and bevacizumab appears to be a promising combination.

Another interesting phase II trial currently explores the combination of bevacizumab and the DNA-methylating drug temzolomide (NIH: NCT00137774). The rationale for this particular combination is based on findings of a former phase II trial, in which an enhanced antitumoral efficacy of a combination treatment with temzolomide together with the mildly antiangiogenic VEGFR- and bFGFR- inhibitor, thalidomide, was demonstrated for advanced pancreatic GEP NETs and metastatic carcinoid tumors<sup>[38]</sup>. However, thalidomide is considered a risky drug that has been associated with neurological side effects and severe and frequent teratogenicity in the 1950s and 1960s<sup>[39]</sup>. Thus, in order to replace thalidomide by a safer antiangiogenic drug, bevacizumab is now being studied as a combination partner for temzolomide.

### Anti-PIGF treatment

The use of a neutralizing anti-PIGF monoclonal antibody in VEGF-inhibitor resistant tumors is an attractive new antiangiogenic that has been tested in an animal study<sup>[40]</sup>. The antibody specifically inhibits the binding of PIGF to its receptor VEGFR-1, present on tumor associated endothelial cells and macrophages. The underlying idea of

using this approach derives from gene inactivation studies showing that endogenous PIGF is redundant for vascular development and physiological vessel maintenance, but an important contributor to the “angiogenic switch” in solid tumor growth. This led to the hypothesis that unlike VEGF inhibitors, PIGF inhibition might reduce pathological angiogenesis, without affecting physiological blood vessel homeostasis and thus not causing unwanted side effects. Hence, anti-PIGF treatment could perhaps substitute for anti-VEGF therapy in the future. Moreover, as PIGF levels are known to increase in the circulation of cancer patients receiving anti-VEGF treatment<sup>[41-43]</sup>, anti-PIGF could also counter this potential downside of anti-VEGF therapy. In this line, the data on inhibition of angiogenesis, lymphangiogenesis, tumor growth and motility in the anti-PIGF-treated anti-VEGF-resistant tumor bearing mice are impressive, especially with regard to blocking the so-called rescue-angiogenesis, a major problem in current antiangiogenic approaches, together with an excellent tolerability compatibility of the treatment. In addition, anti-PIGF treatment may permit long-term treatment of cancers in children, pregnant women, or patients at risk for thrombotic, cardiac or other complications for whom the adverse effects of other VEGF/VEGFR-inhibitors may be excessive and prohibitive.

#### **Antiangiogenic therapy with small molecule inhibitors**

In addition, several agents, which inhibit the tyrosine kinase activity of angiogenic growth factor receptors like the VEGFR or PDGFR, have been synthesized by combinatorial chemistry. These tyrosine kinase inhibitors are small molecules that occupy the ATP binding site of the tyrosine kinase domain of the intracellular portion of the receptor. Because of their effects on downstream signaling, these inhibitors interfere with a number of key biologic functions associated with VEGFR activation. Although drugs that are directed to the VEGFR proved their clinical efficacy, the redundancy in the angiogenesis pathways will likely necessitate multiple targeting agents appealing<sup>[44]</sup>.

#### **SUNITINIB**

Recent clinical studies showed remarkable growth suppression of several non-GEP NET tumors by sunitinib, an orally available inhibitor of multiple receptor tyrosine kinases such as VEGFR-, PDGF- $\beta$ R, c-KIT and FLT-3. Sunitinib has been approved for the treatment of renal cell carcinoma<sup>[45]</sup>. With restricted indication sunitinib is also approved for the therapy of gastrointestinal stromal tumors (GIST)<sup>[46]</sup> and is currently tested in phase I and II trials for hepatocellular carcinoma (NIH: NCT00361309; NCT00247676).

In GEP NETs, a phase II trial reported partial responses of 15% in pancreatic islet cell carcinoma and 2% in carcinoid tumors. In both groups, a high rate of disease stabilization, 75% for islet tumors and 93% for carcinoid tumors, was observed<sup>[47,48]</sup>. Based on these encouraging results an international randomized and

double-blind phase III trial has been launched to study the effect of sunitinib given daily as a continuous dose versus placebo in patients with advanced carcinoids and islet cell tumors (NIH: NCT00428597). In a single-center, non-randomized, prospective phase II trial GEP NET patients with liver-predominant metastases are currently recruited to investigate sunitinib efficacy to improve time to liver cancer progression following hepatic arterial embolization (NIH: NCT00434109).

#### **PAZOPANIB AND AMG706**

These two orally available drugs are pan-VEGFR inhibitors, which also block the activity of the PDGFR and c-kit. Antineoplastic activity of AMG706 has been shown in preclinical non-NET models<sup>[49]</sup>. Good tolerability and antitumor efficacy have been observed in first clinical trials with advanced refractory solid tumors<sup>[42]</sup>. Additional studies of AMG706 as monotherapy and in combination with various agents are ongoing<sup>[42,50]</sup>. At present, a clinical study assesses the efficacy of a monotherapy with AMG706 in patients with low-grade NET (NIH: NCT00427349). The primary goal of the trial is to evaluate the tolerability and 4-mo progression free survival under AMG706 treatment.

For pazopanib (GW786034) an excellent antiangiogenic effect on both tumor cells and tumor associated endothelial cells has been shown in pre- and early clinical studies, and good tolerability has been reported in patients with ovarian- and advanced renal cell carcinoma<sup>[51,52]</sup>. Currently a phase II trial is recruiting patients to evaluate the suitability of pazopanib for the treatment of advanced low-grade or intermediate-grade NET (NIH: NCT00454363).

#### **IMATINIB**

The phenylaminopyrimidine derivative Imatinib mesylate (Gleevec) is an orally available small molecule that selectively inhibits the tyrosine kinases ABL, c-Kit and PDGFR. Due to its ABL- and c-Kit-inhibiting potency, imatinib has significantly improved the treatment of cancers that crucially depend on the activation of these growth factor receptors, such as chronic myelogenous leukemia and gastrointestinal stromal tumors<sup>[53,54]</sup>. Moreover, imatinib demonstrated clinical efficacy by inhibition of PDGFR-signaling in dermatofibrosarcoma protuberans, a neoplasm that depends on an abnormal activation of PDGFR $\beta$  through an autocrine loop<sup>[55]</sup>.

Although there have been no reported mutations in ABL, c-Kit, and PDGFR in NET, they are characterized by a simultaneous upregulation of PDGF ligands and their receptors (PDGFR- $\alpha$  and PDGFR- $\beta$ )<sup>[6,56,57]</sup>. Thus, imatinib may also be interesting for GEP NET treatment. Yao and coworkers evaluated this hypothesis in a phase II trial of patients with advanced carcinoids who were treated with 400mg imatinib twice daily. However, only one of the 27 treated patients achieved an objective response, while 17 patients had stable disease, and 9 patients showed disease progression when evaluated with RECIST criteria (Response Evaluation Criteria in Solid Tumors)<sup>[58]</sup>. Another

study that included 15 patients with advanced GEP NET, imatinib (400 mg or 800 mg imatinib/day for up to 12 mo) was not effective, but was associated with remarkable toxicity and increased bleeding tendency<sup>[59]</sup>.

The low response rate to imatinib, as compared to other antiangiogenic agents, may be related to its sole activity towards the PDGFR, while it completely lacks VEGFR-inhibitory activity. Moreover, PDGFR-inhibition by imatinib is relatively low, as compared to other PDGFR-targeting agents. For instance, the small molecule inhibitor sunitinib has a tenfold higher potency to inhibit PDGFR-signaling, and moreover also inhibits VEGFR-signaling.

From the data obtained so far, monotherapy with imatinib does not seem to be beneficial for patients with advanced GEP NET. Future trials will have to focus on imatinib suitability as an additive agent for combination therapy, e.g. in conjunction with VEGFR-inhibitors<sup>[60]</sup>.

## VATALANIB

Vatalanib (PTK787/ZK222584) inhibits the activities of VEGFR-1 and -2 tyrosine kinases and shows antineoplastic effects in several solid tumors<sup>[61-63]</sup>. This oral agent achieved a 25% biochemical partial response rate (defined as > 50% decrease in 5-HIAA) in NET patients with progressive disease following unsuccessful somatostatin-analog therapy<sup>[64]</sup>. Although partial radiographic responses have not been observed, further recruitment for this phase II trial is currently ongoing. By contrast, another phase II trial investigating vatalanib alone and in combination with somatostatin analogs for the treatment of progressive NET has only recently been withdrawn (NIH: NCT00227773). At present, it is unclear if this was due to insufficient antitumoral activity, toxicity or other reasons.

## EGFR-BASED STRATEGIES

The crucial role of epidermal growth factor receptor (EGFR) in tumor proliferation and its overexpression in several solid tumors have provided the rationale for targeting and interrupting this key signaling network. EGFR blockade with monoclonal antibodies and tyrosine kinase inhibitors has translated into clinical benefit in gastrointestinal tumors, particularly colorectal cancer<sup>[65]</sup>.

Over the past few years, three EGFR-specific agents have received regulatory approval: (1) The monoclonal anti-EGFR antibody cetuximab for metastatic colorectal cancer, and squamous cell carcinoma of the head and neck; (2) The tyrosine kinase inhibitor erlotinib for advanced or metastatic pancreatic cancer and NSCLC; and (3) The EGFR tyrosine kinase inhibitor gefitinib for advanced or metastatic NSCLC. However, the general FDA approval for NSCLC treatment with gefitinib was recently withdrawn after it failed to demonstrate a survival benefit either alone or with chemotherapy in three phase III trials<sup>[66,67]</sup>.

Several reports indicate that EGFRs are frequently expressed and upregulated in NET in general<sup>[68,69]</sup>, as well as in gastrointestinal NET<sup>[70-75]</sup>. In addition, EGFR contributes to the growth characteristics of GEP NETs<sup>[76-78]</sup>. Hence, the EGFR is an attractive target for

GEP NET disease, and EGFR-inhibitors have already been shown to inhibit GEP NET cell growth *in vitro*<sup>[13]</sup>.

Despite the encouraging preliminary findings on the general suitability of anti-EGFR-based-approaches for the treatment of GEP NET<sup>[13,78]</sup>, no clinical trials have been conducted so far, while their efficacy has been demonstrated in other tumor entities, especially colorectal cancer, renal cell carcinoma and NSCLC.

Hobday and coworkers now conducted a phase II trial of gefitinib monotherapy in patients with progressive GEP NET. The study showed that gefitinib is well tolerated and prolongs disease stabilization in patients with prior documented objective progression of islet cell carcinoma and carcinoid tumors. The 6-mo progression free survival of gefitinib-treated patients was 30% for carcinoid tumors and 10% for islet cell carcinoma. However, no objective responses have been observed<sup>[79]</sup>.

In another ongoing trial the efficacy of a combination treatment with the EGFR-TK inhibitor, erlotinib<sup>[80]</sup>, together with the EGFR-antibody, cetuximab<sup>[81]</sup>, is currently evaluated in patients with advanced gastrointestinal cancers, including carcinoid tumors (NIH: NCT00397384). The rationale for the combination of two EGFR-targeted agents is that erlotinib may stop the growth of GEP NET cells by blocking essential growth-related signaling pathways, while cetuximab may additionally mark GEP NET cells with IgG for attack by immune effector cells<sup>[82]</sup>. Moreover, erlotinib and cetuximab are thought to stop the growth of GEP NET cells also by antiangiogenic effects on the tumor endothelium.

Anti-EGFR-based therapies have their greatest potential in combination either with conventional cytostatics or with other targeted-agents<sup>[81,83-85]</sup>. Again, the rationale for using combination therapies is the existence of multilevel receptor cross-stimulation or of redundant signaling pathways that lead to neoplasia. Blocking only one of these pathways allows others to act as salvage or escape mechanisms for cancer cells. Preclinical evidence of synergistic antitumor activity achievable by combining targeted agents that block multiple signaling pathways has recently emerged<sup>[17,86]</sup>. The multi-target approach can be accomplished by using either combinations of selective agents or single agents, which interfere with various targets<sup>[18]</sup>.

## IGF/IGFR-BASED STRATEGIES

Both insulin-like growth factors, IGF- I and - II, and their receptor tyrosine kinase, IGF-1R, are involved in the development and progression of cancer<sup>[87-90]</sup>. Activation of the IGF-1R by IGF- I and - II plays a pivotal role in tumor cell proliferation and spread, by promoting cell cycle progression, preventing apoptosis, and by regulating and maintaining the metastatic tumor phenotype. A wide variety of tumors including GEP NET show abnormal or enhanced expression of IGFs and IGF-1R, which leads to auto- and paracrine growth stimulation, and which has been correlated with enhanced proliferation, tumor de-differentiation, disease stage, development of metastases and reduced patient survival. In GEP NET, the dysregulation of the IGF/IGFR system also contributes

to the excessive secretion of biogenic amines<sup>[8,91-95]</sup>. In gastrinoma patients, the increased expression of the IGF/IGFR-system is associated with low curability and the development of metastases<sup>[96,97]</sup>. Thus, the inhibition of the functionally upregulated IGF/IGFR-signaling system is a promising novel approach to treat GEP NET.

Several groups have demonstrated the therapeutic potential of interfering with IGF-1R mediated signaling *in vitro* and *in vivo*, including the use of IGF-1R blocking antibodies, IGF-1R antisense oligonucleotides, or IGF-1R siRNA<sup>[98-101]</sup>. Recently, we and others validated the potent and selective IGF-1R tyrosine kinase inhibitor NVP-AEW541 as a promising novel agent for the therapy of several cancers<sup>[102-104]</sup>, including GEP NET<sup>[14]</sup>. The antineoplastic properties of NVP-AEW541 and related compounds such as NVP-ADW742 have been demonstrated in preclinical studies on Ewing's sarcoma-bearing mice, fibrosarcoma, breast cancer, and musculoskeletal carcinoma<sup>[105-109]</sup>. Specific IGFR-antibodies potently suppressed prostate and breast cancer cell growth *in vitro*<sup>[110]</sup>. The clinically most advanced anti-IGFR antibody is CP-751 871, which is currently being tested in three phase II trials for advanced breast cancer, NSCLC and prostate cancer (www.clinical-trials.gov). Importantly, the preliminary clinical studies indicate that IGFR-inhibition is well tolerated<sup>[110,111,112]</sup>. Safety is important, since IGFR-based inhibition has long been regarded as a high-risk intervention, because of the high homology of the IGF-1R receptor with the related insulin-receptor, and the fear that IGF-1R tyrosine kinase inhibitors may lead to insulin resistance and overt diabetes<sup>[113]</sup>. However, the current *in vivo* data do not support this assumption, resulting in a growing interest in anti-IGFR-based therapies<sup>[114]</sup>.

Due to crosstalk between the signaling of the IGF/IGFR system and other growth factor receptors that can attenuate the antineoplastic effect of monotherapeutic approaches, IGF/IGFR-targeting therapies will likely have to be combined with other therapies to enhance efficacy<sup>[115,116]</sup>. This can be achieved by dual-targeting the EGFR- and the IGF-1R, since the EGFR is activated by the IGF/IGFR-system leading to mito-oncogenic EGFR-tyrosine kinase activity without ligand stimulation of the EGFR<sup>[20]</sup>. In this line IGFR- combined with EGFR-inhibition can over-additively enhance the antineoplastic effect of the respective monotherapies in gastrointestinal cancers<sup>[81,83,104]</sup>.

## DUAL-TARGETING SMALL MOLECULE INHIBITORS

The use of dual-targeting small molecule inhibitors, simultaneously blocking less related kinases such as VEGFR and EGFR tyrosine kinases, may also become promising for future treatment of GEP NET. These agents inhibit both tumor cell proliferation/survival by blocking mito-oncogenic EGFR signaling of the tumor cells and angiogenesis by inhibiting endothelial VEGFRs. In recent *in vivo* studies of non-GEP NET tumor models (colon, cholangiocarcinoma, prostate, NSCLC) the

dual-targeting tyrosine kinase inhibitor NVP-AEE788 displayed significant antineoplastic efficacy<sup>[117-120]</sup>. Also for ZD6474 (zactima), another EGFR/VEGFR tyrosine kinase inhibitor, promising phase II/III results were reported for NSCLC and thyroid cancer showing response rates of 30% in patients with locally advanced medullary thyroid cancer<sup>[121]</sup> as well as significant prolongation in the progressive free survival of NSCLC patients<sup>[122,123]</sup>. Furthermore, dual targeting of the EGFR and the insulin like growth factor receptor are promising new approaches for the treatment of solid tumors, including the GEP NETs<sup>[116]</sup>.

## OTHER STRATEGIES

### Targeting the 'mammalian target of rapamycin' (mTOR) pathway

The activated PI3K/AKT/mTOR pathway has emerged as a novel contributor to (GEP NET-) tumor development. PI3K associates with the intracellular domain of several growth factor receptors. Upon receptor activation, PI3K triggers the generation of phosphatidylinositol 3,4,5-trisphosphate (PIP3), which provokes the subsequent activation of AKT, a serine/threonine kinase that activates multiple cellular target proteins, such as the mammalian target of rapamycin (mTOR) subfamily. mTOR is a serine-threonine kinase that regulates apoptosis, proliferation and cell growth by modulating cell cycle progression. Specifically, mTOR is involved in the modulation of mRNA-translation of proteins, which are necessary for cell cycle progression from G1 to S-phase, including the E4-binding protein (E4-BP1), and p70<sup>S6</sup> kinase<sup>[124]</sup>.

In nontransformed cells the PI3K/AKT/mTOR pathway is controlled by the phosphatase and tensin homolog deleted on chromosome ten (PTEN), a tumor suppressor which inhibits this pathway by reversing PI3K and subsequent AKT activation. Mutation or silencing of the PTEN gene leads to activation of the mTOR pathway and promotes carcinogenesis. Loss of PTEN expression has been shown in GEP NET<sup>[125]</sup>. Accordingly, in sporadic islet cell carcinoma a frequent loss of 10q, the site of the PTEN gene, as well as an altered subcellular localization of PTEN have been reported<sup>[126,127]</sup>. Thus, constitutive activation of the PI3K/AKT/mTOR pathway can be due to enhanced stimulation of growth factor receptors, like EGFR and IGFR, but also to decreased PTEN expression or to its altered cellular compartmentalization<sup>[128]</sup>. Importantly, 76% of all GEP NETs display constitutive AKT phosphorylation<sup>[78,125]</sup>. It is therefore likely that a majority of GEP NET is sensitive to mTOR inhibitors. Indeed, antiproliferative effects of mTOR inhibition in GEP NET cells were recently demonstrated *in vitro*<sup>[129]</sup>.

### mTOR-inhibitors

The natural antibiotic rapamycin (sirolimus) is a potent inhibitor of mTOR<sup>[130]</sup>. Recently, three analogues of rapamycin with superior pharmacokinetic and biological properties have emerged. The cell cycle inhibitor-779 (CCI-779, temsirolimus) is a soluble ester analogue. RAD001 [40-O-(2-hydroxyethyl)-rapamycin, everolimus] is

a derivative of rapamycin with high oral bioavailability, and AP23573 is a non-pro-drug analogue of rapamycin. These agents have been tested successfully for their antineoplastic potency and/or tolerability in various malignancies in early clinical trials (e.g. CCI-779 in renal, breast and lung cancers), or are currently being studied in open clinical trials for the treatment of colorectal, endometrial, and brain tumors (RAD001, everolimus)<sup>[131-133]</sup>. AP23573 has been successfully tested in a phase II trial in sarcomas<sup>[134]</sup> and two phase I studies in patients with refractory or advanced solid tumors showed partial responses and disease stabilization in individual patients<sup>[135]</sup>.

So far, two-phase II trials exploring mTOR-inhibitors for NET treatment have been reported. Studies with everolimus (RAD001)<sup>[136]</sup> and temsirolimus (CCI-779)<sup>[137]</sup> have recently completed the recruitment of low-grade NET patients.

The study by Yao *et al.*, reported on 32 patients (18 carcinoids, 13 islet cell carcinomas) who had received 5 mg everolimus orally per day and depot octreotide 30 mg intramuscularly every 28 d. After 12 wk of treatment, the evaluation by RECIST criteria (response evaluation criteria in solid tumors) showed a 15% response. There were four patients with partial response, 22 with stable disease and 4 patients with progressive disease. Progression occurred in two carcinoids and two islet-cell carcinomas. The rate of progression free survival (PFS) at wk 24 was 64% and the treatment was generally well-tolerated<sup>[136]</sup>. The promising results of this study led to the development of a multicenter phase II study, RADIANT (RAD001 in advanced NET), in which everolimus (RAD001) is investigated as second-line treatment in patients with advanced pancreatic neuroendocrine tumors after failure of cytotoxic chemotherapy. A similar phase II trial has been activated to evaluate RAD001 in patients with carcinoid tumors<sup>[127]</sup>. In both cases, RAD001 will be used as a monotherapy and in combination with octreotide, which inhibits the activated IGF/IGFR pathway of GEP NET. The underlying rationale is that the dual inhibition of mTOR activation by directly targeting mTOR with everolimus, and also its upstream activation *via* IGF/IGFR-signaling with octreotide will completely abrogate this important pathway in NET. This assumption is supported by *in vitro* data that demonstrated the antiproliferative potency of the dual inhibition of endogenous and IGF-stimulated mTOR activity of GEP NET cells by rapamycin<sup>[8]</sup>.

In the other phase II trial<sup>[137]</sup>, the clinical and pharmacodynamic effects of the temsirolimus, were investigated in 37 patients with recurrent or metastatic GEP NET. However, temsirolimus showed only modest activity accompanied by distinct but manageable drug-related adverse effects (mainly fatigue, hyperglycemia, rash). The authors concluded that based on the sobering results of this study no further investigation of temsirolimus as a single agent in patients with advanced GEP NET was justifiable. However, evaluation of temsirolimus in combination with other targeted agents, such as multi-kinase inhibitors or antiangiogenic compounds, was suggested<sup>[124]</sup>.

### Targeting the Ras/Raf/MAPK pathway

The proliferative Ras/Raf/MEK/ERK pathway is one of the key signaling cascades that underlie the development and maintenance of cancers. This pathway transduces extracellular signals from the various growth factor receptor tyrosine kinases (e.g. EGFR, IGFR, VEGFR, PDGFR) to the nucleus with a series of specific phosphorylation events, resulting in the expression of proteins for cell cycle progression, apoptosis resistance, extracellular matrix remodeling, cellular motility, angiogenesis or drug resistance<sup>[138]</sup>. Dysregulation of this crucial pathway occurs due to oncogenic transformation of Ras and Raf isoforms, or to overexpression and/or overactivation (*via* phosphorylation) of the Ras and Raf genes<sup>[139,140]</sup>. Although activating mutations of (B)-Raf are rare in GEP NET<sup>[141]</sup>, wildtype B-RAF and its activating small G-protein Rap-1 are highly prevalent in the majority of GEP NET. Overexpression of Rap-1 was shown to activate MAPK-signaling and the expression of mitogenic transcription factors of GEP NET cells, thus providing an interesting molecular target for GEP NET treatment<sup>[142]</sup>.

### SORAFENIB

The bi-aryl urea derivative sorafenib (nexavar<sup>TM</sup>) is an oral multi-kinase inhibitor, which targets kinases of wild-type B-Raf, mutantV559EB-Raf and C-Raf, and importantly receptor tyrosine kinases involved in angiogenesis, including VEGFR-2, and -3, and PDGFR<sup>[143]</sup>. Sorafenib has been approved by the FDA for the treatment of advanced renal cell carcinoma, and only recently it gained accelerated approval for the treatment of inoperable hepatocellular cancer.

Sorafenib's effect on several molecular targets in addition to the Raf isoforms makes it difficult to determine which of its targets contributes most to the anti-tumor activity of sorafenib in the particular tumor types. For instance, a recent HCC trial suggested that inhibition of the Raf/MEK/ERK pathway was central to sorafenib's mode of anti-tumor action<sup>[144]</sup>, whereas in other cancers, such as renal cell carcinoma or NSCLC the antineoplastic activity was attributed mainly to its antiangiogenic activity<sup>[16,145]</sup>. In 2005, an international multicenter phase II trial has started to evaluate the efficacy of sorafenib in patients with progressive metastatic NET (NIH: NCT00131911). Results from this study, which enrolled 90 patients, are pending.

### Targeting the proteasome

Effective cancer treatment may also be achieved by inhibition of the 26S proteasome, a large protease complex that is present in both the nucleus and the cytoplasm of eukaryotic cells. The proteasome functions as a proof-reader and terminator of proteins branded for destruction by the attachment of ubiquitin. The so-called ubiquitin-proteasome pathway (UPP) is the major non-lysosomal proteolytic system in eukaryotic cells and triggers degradation of a multitude of proteins, including those involved in cell cycle progression, apoptosis, nuclear factor kappaB (NF-κB) activation, and angiogenesis, as well as

mutant, damaged, and misfolded proteins<sup>[146]</sup>. Inhibition of the proteasome has emerged as an attractive target for cancer therapy, since a functional UPP is critical for cell survival and proliferation, especially of cancer cells.

## BORTEZOMIB

Bortezomib (Velcade™) blocks multi-ubiquitinated protein degradation by inhibiting the active site threonine residue of the 26S proteasome in a competitive and reversible manner<sup>[147]</sup>. Antineoplastic activity of bortezomib has been documented in several *in vitro* and *in vivo* studies<sup>[148-150]</sup>, including NET cells<sup>[151]</sup>. Bortezomib is the first proteasome inhibitor that has been approved for treatment of advanced multiple myeloma and mantle cell lymphoma<sup>[146,152]</sup>.

So far, only one clinical study on bortezomib in advanced metastatic GEP NET has been reported. However, in contrast to the encouraging findings in other cancers, no or only marginal responses to bortezomib monotherapy was observed in the investigated 12 carcinoid and 4 islet carcinoma patients. Given the slow growing nature of these tumors, the observed disease stabilization of 69% (11 of 16 patients) could not be attributed unequivocally to an antitumor effect of bortezomib. Although bortezomib was generally well-tolerated, peripheral sensory neuropathy developed in 37% of the patients<sup>[153]</sup>. Specific attention has to be paid to such side effects, when bortezomib (or other targeted agents) are to be combined with other antitumoral drugs, especially conventional chemotherapy, which likely increases gastrointestinal or neurologic toxicity.

Moreover, bortezomib has been combined with multi-kinase inhibitors or histone deacetylase inhibitors (HDAC). Especially, the combination of bortezomib with HDAC inhibitors appears to be a promising approach in GEP NET disease. Baradari and coworkers showed that HDAC inhibition had strong antiproliferative and proapoptotic effects in GEP NET cells<sup>[154]</sup>. Recently, the potency of bortezomib combined with HDAC inhibitors has been demonstrated for other gastrointestinal tumors, too. Thus, HDAC inhibition by the benzamide derivative, MS-275 combined with bortezomib led to an overadditive growth inhibition of cholangiocarcinoma cells<sup>[148]</sup>. Hence, targeting two or more molecular pathways at the same time appears promising for innovative treatment strategies of GEP NET disease.

## CONCLUSION

Targeted-therapies, which specifically inhibit growth factor receptors and their related signaling pathways are promising approaches for the innovative medical treatment of GEP NET disease. Especially antiangiogenic strategies, multi-kinase or mTOR inhibition as well as combination treatments with biotherapeutics or cytostatics emerge to prove particularly efficient, as they leave fewer mechanisms of escape for the tumor cells. Combinations of these targeted drugs are particularly intriguing, and in the future agents like the multi-kinase inhibitors sunitinib or sorafenib

as well as mTOR inhibitors will be combined with other growth factor receptor inhibitors, histone deacetylase inhibitors, proteasome inhibitors, biotherapeutics or cytostatics to effectively control advanced GEP NET. The advantage of such novel combination therapies is their higher tumor cell specificity and higher efficacy, combined with acceptable toxicity and side effects. The novel combination treatments will widen the therapeutic spectrum for GEP NET; the results of (ongoing) clinical studies are eagerly awaited.

### Abstract

Estimates of people suffering from overweight (one billion) and obesity (300 million) are increasing. The accumulation of triglycerides in the liver, in the absence of excess alcohol intake, has been described in the early sixties. It was not until 1980, however, that Ludwig *et al* named this condition nonalcoholic steatohepatitis (NASH). Subsequently, nonalcoholic fatty liver disease (NAFLD) has been used as a general name for conditions ranging from simple steatosis through steatohepatitis to end-stage liver disease (cirrhosis). Many studies have demonstrated the significant correlation with obesity and insulin resistance. Other studies have revealed a significant correlation between hepatic steatosis, cardiovascular disease and increased intima-media thickness. WHO estimated that at least two million patients will develop cirrhosis due to hepatic steatosis in the years to come. Longitudinal cohort studies have demonstrated that those patients with cirrhosis have a similar risk to develop hepatocellular carcinoma as those with other causes of cirrhosis. Taken all together, NAFLD has become the third most important indication for liver transplantation. Therefore, training programmes in internal medicine, gastroenterology and hepatology should stress the importance of diagnosing this entity and treat properly those at risk for developing complications of portal hypertension and concomitant cardiovascular disease. This review will focus on the clinical characteristics, pathophysiology, imaging techniques and the readily available therapeutic options.

### INTRODUCTION

When living creatures have a surplus of food at their disposition, they start to hoard energy for future scarce times. The breakthrough in agriculture and founding of villages around 9500 BC in several independent parts of the world not only laid the pavement for modern society, but also gave people the opportunity to cultivate and store more food than needed for their support and their families. This excess of energy has led to the current situation nowadays where the caloric availability exceeds the caloric needs by far. The human body still possesses the quality to store excess energy in adipocytes, a quality that now works in its disadvantage. The extreme storage of excess energy and a reduction in physical activity have led to a worldwide epidemic of obesity. The World Health Organization (WHO) estimated that the number of overweight (BMI > 25) individuals is over one billion, of whom 300 million are obese (BMI > 30)<sup>[1]</sup>. In future prospects, this number will increase further<sup>[2,3]</sup>. Although the biggest concern of most obese or overweight persons is about their appearance, obesity has been recognised as a pathogenic factor for a vast array of other pathologies, such as Diabetes mellitus, Insulin resistance, Hypertension, Dyslipidemia, Endocrine changes, Kidney stones, Cancer (overall and specific), Coronary disease, Heart failure, Myocardial steatosis, Atrial fibrillation/flutter, Stroke, Venous thrombosis, Hepatobiliary disease, GERD/esophageal cancer, Osteoarthritis, Skin changes, Gout, Dementia, Psychosocial *etc*. A subset of diseases often occurring in the same patient have been clustered, now known as the metabolic syndrome<sup>[4-6]</sup>. Vehement research has unravelled major parts of the pathophysiological mechanisms underlying obesity and metabolic syndrome, although many issues have not been explained yet<sup>[7,8]</sup>. It has been shown that non-alcoholic fatty liver disease (NAFLD) has a strong relation with metabolic syndrome<sup>[9-16]</sup>. NAFLD mainly with accumula-

tion of triglycerides in the liver, in the absence of excess alcohol intake, has been described in the early sixties<sup>[17,18]</sup>. It was not until 1980, however, that Ludwig *et al* named this condition non-alcoholic steatohepatitis (NASH)<sup>[19]</sup>. Subsequently, NAFLD has been used as a general name for conditions ranging from simple steatosis through steatohepatitis to end-stage liver disease (cirrhosis)<sup>[20]</sup>. The first is rather benign<sup>[21,22]</sup>, the second is of significant clinical importance<sup>[23]</sup> and the last one has an increased risk of hepatocellular carcinoma<sup>[24,25]</sup>. An almost universal association with hepatic and adipose tissue insulin resistance (IR) has been established in a number of studies<sup>[26-34]</sup>. Browning *et al*<sup>[35]</sup> used <sup>1</sup>H-NMR-spectroscopy to measure the hepatic triglyceride content in a multi-ethnic urban US population-based study. Hepatic steatosis was found in 31% of their population and increased up to 67% in obese subjects. Other studies<sup>[36-38]</sup> have confirmed this positive correlation between BMI, waist-to-hip-ratio and hepatic steatosis. A few studies focusing on the natural history of NAFLD showed that only 1%-5% of patients with simple steatosis eventually develop actual cirrhosis<sup>[39,40]</sup>. WHO estimated that at least 2 million people will develop cirrhosis due to hepatic steatosis. Taken all together, NAFLD has become the third most important indication for liver transplantation and will become the leading indication in the next decades. In this respect, the finding of NASH in young obese children is very alarming<sup>[41]</sup>. Training in paediatrics, internal medicine, gastroenterology and hepatology should emphasize the awareness of this entity to avoid complications of portal hypertension, minimize the need for liver transplantation and prevent the associated cardiovascular disease.

This review will focus on the clinical characteristics, pathophysiology, imaging techniques and therapeutic opportunities of this disease.

## CLINICAL CHARACTERISTICS

Most patients with NAFLD are asymptomatic and the symptoms are usually non specific when they occur. Frequent complaints are fatigue and vague right upper quadrant abdominal discomfort. Because of the latter, steatosis is often found at ultrasound examinations made for suspicion of biliary disease. Ultrasound abnormalities and elevated alanine transaminase (ALT) levels are often found at routine check-up or when patients present themselves with physical complaints due to other diseases. Given that NAFLD is widely accepted as a part of metabolic syndrome, or at least being related with it, most patients present with other pathologies linked to this syndrome. Once other pathologies (Table 1) are ruled out as a cause of steatosis, NAFLD can be allocated as the most common cause for elevated ALT levels and/or steatosis. Mildly raised levels of ALT have been found in hospitalized NASH patients, but not higher than four times the upper limit of normal (ULN)<sup>[42-46]</sup>. These levels fluctuate but never return to normal values. Abnormal AST levels have also been found, especially in cirrhotic patients. Gamma-glutamyl transpeptidase ( $\gamma$ GT) and alkaline phosphatase levels can increase although in unknown frequency. In

Table 1 Possible causes for steatosis hepatitis

Causes	
Metabolic	Abetalipoproteinemia Glycogen storage diseases Weber-Christian disease Wolmans disease Acute fatty liver of pregnancy Lipodystrophy Iron overload syndromes $\alpha$ -1-antitrypsin deficiency
Nutritional	Malnutrition Total parenteral nutrition Severe weight loss Refeeding syndrome Jejuno-ileal bypass Gastric bypass Jejunal diverticulosis with bacterial overgrowth
Inflammatory	HIV <sup>1</sup> Chronic Hepatitis C infection
Drugs	Methotrexate Diltiazem HAART <sup>2</sup> Amiodarone Glucocorticoids
Toxins	Alcohol Environmental hepatotoxins (e.g. toxic mushroom) Wilson's disease
Autoimmune	Autoimmune hepatitis Celiac disease

<sup>1</sup>HIV: Human immunodeficiency virus; <sup>2</sup>HAART: Highly active anti-retroviral therapy.

conclusion, these mild laboratory abnormalities would not be very helpful in diagnosing this disease due to their low sensitivity and specificity.

At more advanced disease stages, liver stigmata like jaundice, spider naevi and erythema palmare may develop. In these patients, laboratory abnormalities are consistent with progressed liver disease.

## PATHOPHYSIOLOGY

### Healthy subjects

Within the body's system, the liver plays a crucial role in controlling fatty-acid and triglyceride (TG) metabolism by synthesizing, storing, secreting and oxidizing free fatty acids (FFA). The liver responds to and manages fatty acids that originate from ingested foods, adipose stores and its own *de novo* production. Oxidation of FFA is considered the main energy source for gluconeogenesis in a fasting state. TG is incorporated into very low dense lipoprotein (VLDL) particles while being transported out of the liver to peripheral tissues. Fatty acids are mainly stored in adipose tissues of human beings. In healthy individuals, fasting lipolysis causes release of TG into the plasma nonesterified fatty acid (NEFA) pool, while adipocytes will take up fatty acids. Postprandial pancreas-released insulin

increases lipogenesis and decreases lipolysis and fatty acid oxidation in mitochondria. The second source of fatty acids contributing to the total liver supply is hepatic *de novo* lipogenesis (DNL). In healthy individuals, this source is a minor contributor while fasting and insulin levels are low. The third source of fatty acids is the absorption of dietary fats.

In 1998, Day *et al*<sup>[47]</sup> launched the “two-hit-theory”, stating that two succeeding wallops have to be delivered to the liver to cause NASH. The first hit, development of hepatic steatosis, is the accumulation of TG consisting of 3 fatty acids and a glycerol backbone, in the hepatocytes. The development of hepatic steatosis is a form of ectopic lipid accumulation, resulting from a disturbance in the balance between supply, formation, consumption and hepatic oxidation or disposal of TG. Consumption includes mitochondrial  $\beta$ -oxidation, production of ketone bodies, and secretion of TG in VLDL particles. Many animal and human studies have shown that there is an inextricable relation between obesity and insulin resistance (IR)<sup>[48-52]</sup>. IR is a key pathogenic factor for the development of hepatic steatosis<sup>[26-34]</sup>.

### Insulin resistance

Insulin resistance (IR) is the disruption of signalling pathways in cells, leading to a diminished ability to execute normal cellular responses to insulin. For details of the insulin pathway, the reader is referred to excellent reviews by Herman *et al*<sup>[53]</sup> and Taniguchi *et al*<sup>[54]</sup>. In summary, the insulin receptor is tyrosine-phosphorylated upon binding to insulin, which in turn causes tyrosine phosphorylation of the insulin receptor substrate (IRS) proteins. There are two important IRS: IRS-1 and IRS-2. IRS-1 is the initiator in the pathway of glucose metabolism. Upon phosphorylation, IRS-1 induces stimulation of the phosphatidylinositol 3-kinase (PI3K)-AKT/protein kinase B (PKB) pathway, resulting in recruitment of glucose transporters (GLUT). IRS-2 cranks up lipid metabolism in cells and is a main regulator in DNL *via* sterol regulatory element binding protein 1c (SREBP-1c). SREBP-1c is a member of the SREBP family, a group of transcription factors that play a fundamental role in cellular lipid metabolism<sup>[55]</sup>. Three different SREB proteins have been identified. These SREB proteins activate the complete program of cholesterol and fatty acid synthesis in the liver<sup>[56]</sup>. SREBP-1c is the isoform that plays a role in synthesis of fatty acids and TG in the liver, by stimulating the formation of enzymes, most important acetyl CoA carboxylase (ACC) and fatty acid synthase (FAS)<sup>[57]</sup>. Most SREBP-1c-stimulated enzymes are also regulated by carbohydrate response element binding protein (ChREBP)<sup>[58]</sup>. For a long time, it was assumed that a defect in muscle tissue is the first step in the origination of insulin resistant states. In the last decade, however, this doubtful honour shifted towards the adipocyte. Besides the lump storage of fat, in the mid 90's, the exocrine functions of fat were recognised, and it became clear that fat is the choirmaster in the aetiology of IR<sup>[59]</sup>. It has been found that mice lacking GLUT4 in adipocytes develop IR in muscle and liver tissue<sup>[60]</sup>, suggesting that fat cells secrete a substance that can induce IR in other tissues.

Adipocytes excrete a number of bioactive peptides that are collectively called “adipokines”. Leptin (Greek for ‘thin’), discovered by Zhang *et al* in 1994<sup>[61]</sup> is the prototype, but since then other adipokines, such as adiponectin<sup>[62]</sup>, ghrelin<sup>[63]</sup>, resistin<sup>[64]</sup> and recently retinol binding protein 4 (RBP4)<sup>[65]</sup>, have been identified and characterized. RBP4 works partly by blocking the action of insulin in muscle and liver<sup>[65,66]</sup>. Depending on the amount of lipids, a stored adipocyte releases adipokines when its maximum storage is reached (leptin, RBP4) or more capacity available (adiponectin). Each adipocyte secretes a small amount of these peptides into its direct surroundings. In obese states, adipocytes also excrete inflammatory cytokines<sup>[52]</sup>. It has been found that TNF- $\alpha$  is over expressed in obese people<sup>[67]</sup>. Since this discovery, more inflammatory mediators have been recognised and investigated<sup>[68]</sup>. Excretion of inflammatory cytokines attracts macrophages, probably as a natural response to the clearance of the extreme swollen body and malfunctioning of fat cells. Macrophages themselves also release inflammatory substances. In the copious blood flow in adipose tissue, these peptides readily manoeuvre into the blood, which enables them to exert a number of endocrine and autocrine functions. Together, all adipocytes make up the largest endocrine organ resulting in a considerable influence of adipokines on body function<sup>[69-71]</sup>. Especially because adipocytes grow and proliferate in an overfed situation, this will lead to more excreted adipokines navigating lipids to certain specific areas of the body. Muscle and liver tissue are the main sites for ectopic fat accumulation<sup>[72]</sup>. In myocytes and hepatocytes, FFA cause IR in genetically susceptible subjects through defects in the insulin signalling pathway. Although the search for specific defects in the pathogenesis is complicated by the complexity of insulin signalling cascades, one of the major problems is a disturbance in the IRS1/PI3-kinase/Akt/GLUT pathway. IRS-1 tyrosine phosphorylation leads to serine phosphorylation, thereby interrupting the pathway for the transport of glucose via the GLUT transporters to the membrane. A number of inflammatory kinases have been found to induce this inhibitory serine phosphorylation, such as IKK-kinase- $\beta$  (IKK- $\beta$ ), jun-kinase-1 (JNK-1) and suppressor-of-cytokine-signalling-3 (SOCS3). Interestingly, SOCS3 receptors have also been found in the hypothalamus, where it may be involved in leptin signalling. JNK-1 is found to be an important mediator in the development of inflammation in obese tissue<sup>[73]</sup>. Özcan *et al*<sup>[74]</sup> found that the protein is triggered by endoplasmic reticulum (ER) stress. In obese states, the metabolic demand on the ER, is maximal and sometimes even more. As a response to the continuously high workload, the ER initiates a complex response system, referred to as the unfolding protein response (UPR). This UPR leads to the activation of JNK-1, IKK- $\beta$  and TNF- $\alpha$ . More evidence comes available that the ER in this way translates the metabolic stress into an inflammatory signal.

Interestingly, it has been found that in hepatic IR states, the IRS-2 signalling is relatively intact, insulin down-regulates the IRS-2 receptor, resulting in over-expression of SREBP-1c and up-regulation of DNL<sup>[75]</sup>.

### Supply

**Plasma FFA:** The plasma nonesterified fatty acid (NEFA) pool contributes to the majority of fatty acids that flow to the liver in the fasting state, thus providing the bulk of FFA secreted by the liver in VLDL particles<sup>[76]</sup>. The storage of TG and FFA in adipose tissue is mediated by insulin, especially in visceral fat. In healthy individuals, consumption of a meal induces an increase in plasma insulin concentration and subsequent suppression of adipocyte lipolysis, thereby reducing the plasma NEFA pool. Adipose tissues, especially visceral adipocytes, function as a depot for energy that can be released in times of need. IR develops after long-term excess energy intake, thus decreasing the inhibitory effects of insulin on peripheral lipolysis and increasing the availability of FFA. FFA is released into the blood stream by flow of visceral adipocytes to the liver without any circumbendibus. Paradoxically, the contribution of FFA derived from the plasma pool flowing into the liver is relatively smaller in NAFLD patients compared to healthy subjects. This is due to the increased contribution of other mechanisms in these patients.

**Dietary fat intake:** Dietary fats are supplied to the liver by two different routes. Chronic intake of energy-enriched food challenges the processing capacity of adipocytes, with an overflow of NEFA into the plasma as a result<sup>[77]</sup>. Lipid accumulation in non-adipose tissue, mainly muscle and the liver, is a characteristic of obesity, but is also seen in lipodystrophy. Where in obesity the adipocytes overflow, in lipodystrophy there are no or insufficient adipocytes to store lipids, both being a factor for the increased ectopic lipid accumulation. A second route is *via* remnant chylomicrons. FFA and monoglycerides are absorbed separately and packaged into TG in intestinal epithelial cells. They are then secreted in chylomicrons (lipoproteins with a very high lipid content), which release FFA to adipose and muscle cells, mediated by lipoprotein lipase. Chylomicrons depleted of most lipids (known as chylomicron remnants) are absorbed by the liver. Studies have shown that in the remnant delivered to the liver, up to 50% of the FFA can still be present, which then have to be processed by the liver. Dietary fat intake is responsible for approximately 15% of the FFA supply to the liver<sup>[78]</sup>.

**De novo lipogenesis (DNL):** The term lipogenesis refers to the biosynthesis of lipids. DNL indicates that synthesis of fatty acids occurs in various non-fat precursors. Most important precursors are glucose, aminoacids and ethanol which produce acetyl-CoA during their catabolism and are therefore susceptible to conversion to fatty acids in the intermediary metabolism. SREBP-1c plays a key role in the regulation of DNL and is activated by insulin, endocannabinoid receptor CB-1<sup>[79]</sup>, liver X receptor (LXR)- $\alpha$ <sup>[80]</sup>, oxysterol binding protein<sup>[81]</sup> and suppressor of cytokine signalling (SOCS)-3<sup>[82]</sup>. Leptin and glucagon have antagonising effects. The suppressing effect of leptin on SREBP-1c seems paradoxical, as obese persons often exhibit high levels of leptin and high expression of SREBP-1c. This is the consequence of, on the one hand, an increase in leptin production by the expanding mass of fat cells, and on the

other hand, a decrease in leptin sensitivity<sup>[83]</sup>.

LXR- $\alpha$  is an oxysterol-activated nuclear receptor. Activation of LXR- $\alpha$  induces SREBP-1c transcription through the co-activation of retinoid X receptor (RXR)- $\alpha$ . Grefhorst *et al.*<sup>[84]</sup> showed that exogenous administration of LXR- $\alpha$  ligands results in extensive hepatic steatosis.

The observation of an increase in appetite in association with the use of cannabis has led to the hypothesis that the endocannabinoid pathway might play a role in energy intake and fat metabolism. The most prominent receptors are the cannabinoid receptor 1 (CB-1) and cannabinoid receptor 2 (CB-2). CB-2 is mostly expressed in the immune system, while CB-1 is found to be involved in the SREBP-1c pathway in liver and brain. In these pathways, the effect of CB-1 is twofold that of CB-2. Regulation of the hypothalamic-driven feeding behaviour<sup>[85,86]</sup>, has direct effects on energy intake. A second effect is on hepatic fatty acid synthesis, hepatic TG quantity and activation of the released fatty acids from adipose tissue<sup>[79,87]</sup>.

SOCS3 is an adipocyte-excreted cytokine that up-regulates hepatic SREBP-1c. Although the mechanisms have not been fully elucidated, TNF- $\alpha$ , interleukin (IL)-6 and leptin seem to augment excretion of SOCS3, whereas adiponectin is found to have inhibitory effects<sup>[82]</sup>. In healthy individuals, DNL is a minor supplier of fatty acids to hepatocytes in the fasting state, when insulin levels are low. Less than 5% of the total supply of fatty acids originates from DNL. In the postprandial state, insulin stimulates DNL which then accounts for over 26% of the FFA supplies. This more or less diurnal rhythm is not seen in NAFLD patients where the contribution of DNL is continuously 26%<sup>[78]</sup>.

### Oxidation

In normal conditions, mitochondria take up FFA as a substrate for  $\beta$ -oxidation while fasting fatty acid oxidation is the main substrate for the production of energy used in gluconeogenesis. In IR states, the amount of FFA available for oxidation exceeds the mitochondrial capacity. A bulk of acetyl CoA enters the citric acid cycle, resulting in the delivery of electrons to the respiratory chain, where they generate reactive oxygen species (ROS).

### Outflow

In physiological conditions, transport of TG from hepatocytes occurs through formation of VLDL by the ER in two steps. The first step is the lipidation of apolipoprotein B (ApoB), which creates a so-called pre-VLDL. This lipidation of ApoB is catalyzed by the microsomal triglyceride transfer protein (MTTP). The pre-VLDL is transported to the smooth ER and further lipidated before its migration to the cell membrane again. MTTP is the catalysor in this process. The second step is progression of ApoB to pre-VLDL, which is dependent on the amount of TG available. If insufficient lipids are available, the ApoB protein will degrade. Insulin is a strong promotor of ApoB degradation *via* the PI3K pathway and can thus influence the number of VLDL particles synthesized. SREBP-1c inhibits the formation of MTTP, thereby reducing the amount of VLDL particles produced. In IR

states, the PI3K pathway is eliminated to a certain extent but the up-regulated SREBP-1c leads to a decrease in VLDL synthesis. The size of the particle is dependent on the amount of TG stored in cells. It has been shown that VLDL particles in fatty livers are sufficiently larger, most likely as a result of the decreased production<sup>[84]</sup>. It is likely that export of TG is impaired in IR states.

### From hepatic steatosis to NASH

Steatohepatitis is characterized microscopically by hepatic fat accumulation, mixed lobular inflammation, ballooning degeneration of hepatocytes, Mallory bodies, glycogenated hepatocyte nuclei, and pericellular fibrosis. The characteristic “chicken wire” pattern of pericellular fibrosis affects portal areas only at later stages. Accumulation of FFA and TG in hepatocytes by mechanisms described above spreads over the bed for the second hit in Day’s widely accepted theory<sup>[42]</sup>. By far, not all fatty livers progress to steatohepatitis<sup>[39,88]</sup>. Although a considerable amount of evidence is available for environmental influences, there is inevitably a genetic compound that contributes to the origination and progression of the disease. Factors responsible for the progression from simple fatty liver to NASH are extensively researched. TNF- $\alpha$  expression, lipid peroxidation and mitochondrial dysfunction are likely to be involved. The mechanism is triggered and starts a sequence that leads to inflammatory response and release of inflammatory cytokines, eventually resulting in the development of fibrosis and cirrhosis. Since the lipid-laden liver of steatotic patients does not increase in size, the entire lipid content must come in place of existing structures and compress them somewhat. To resolve this disadvantageous condition, hepatocytes need to clear FFA and TG, for which they can use two mechanisms. The first is the above described excretion of TG through formation of VLDL particles. It is postulated that this mechanism is impaired in hepatic steatosis. The other mechanism is the metabolism of FFA by mitochondrial  $\beta$ -oxidation<sup>[89]</sup>. In summary, these metabolic changes in steatotic livers result in the formation of reactive oxygen species (ROS) by mitochondria as a result of increased mitochondrial  $\beta$ -oxidation, hepatic microsomal cytochrome P450 2E1(CYP2E1) up-regulation and formation of Kupffer cell ROS.

The mechanism by which mitochondrial  $\beta$ -oxidation is up-regulated in steatotic livers still remains unclear, but it is thought that especially DNL-derived FFA and peroxisome proliferator-activated receptor (PPAR)- $\alpha$  are important stimulators of carnitine palmitoyltransferase-1 (CPT-1) responsible for the entry of FFA into mitochondria. The massive influx of FFA from peripheral tissue and mostly the increased DNL within hepatocytes exceeds the metabolic capabilities of mitochondria, with the formation of ROS and an inflammatory response as a result.

CYP2E1 is predominantly found in the ER, but significant amounts are present in the cytosol and mitochondria where it stimulates microsomal fatty acid oxidation. Increased CYP2E1 activity and expression are found in NASH patients<sup>[90]</sup>, but the mechanisms behind this remain unclear. Recently Rahman *et al* found that CCAAT/Enhancer binding protein (C/EBPbeta) expression may be

an important factor in the upregulation of CYP2E1<sup>[91]</sup>. Other authors have postulated the influence of IR<sup>[92,93]</sup> and increased ketogenesis<sup>[94]</sup>.

In various models, steatosis endotoxin receptors on Kupffer cells are increased, which may trigger the assemblage of NAD(P)H oxidase on the plasma membrane of hepatocytes and thereby causing ROS formation<sup>[95]</sup>.

The surplus of FFA within the liver causes the formation of excess amounts of ROS. Mitochondria in non-fat-laden hepatocytes also produce rather large amounts of ROS, but enzymatic processes can change ROS into “safe water”. Excessive ROS formation can lead to an overburden of this escape mechanism and ROS can leave the mitochondria. In the cytosol, ROS enhances lipid peroxidation products and mitochondrial DNA (mtDNA). Increased mitochondrial ROS formation could also directly oxidize mitochondrial DNA, proteins and lipids, and trigger hepatic TNF- $\alpha$  formation by activating nuclear factor (NF)- $\kappa$ B and deplete antioxidants, thus further increasing mitochondrial ROS formation. Induction of the inflammatory cascade can also be the result of the reduced availability of anti-inflammatory products as adiponectin<sup>[96]</sup>.

Another worsening and possible triggering factor might be the tumour necrosis factor (TNF)- $\alpha$ <sup>[97,98]</sup>. In obese and IR patients, serum levels of TNF- $\alpha$  are proportionally increased and one of the striking differences between patients with NASH and those with simple steatosis is the serum level of TNF- $\alpha$ <sup>[99]</sup>. Not hepatic, but mainly adipose tissue is the main supplier of TNF- $\alpha$ . In normal conditions, hepatocytes that frequently come into contact with a variety of endo- and exotoxins are not very sensitive to TNF- $\alpha$ , but in NASH patients it might be possible that the increased levels cause leakage of the mitochondrial outer membrane and thereby increasing ROS formation<sup>[89]</sup>. TNF- $\alpha$  also has direct effects on IRS phosphorylation and stimulates SOCS3 formation *via* interleukin 6 (IL-6) and inhibitory  $\kappa$ B-kinase (IKK), thereby worsening IR and steatosis<sup>[100,101]</sup> (Figure 1).

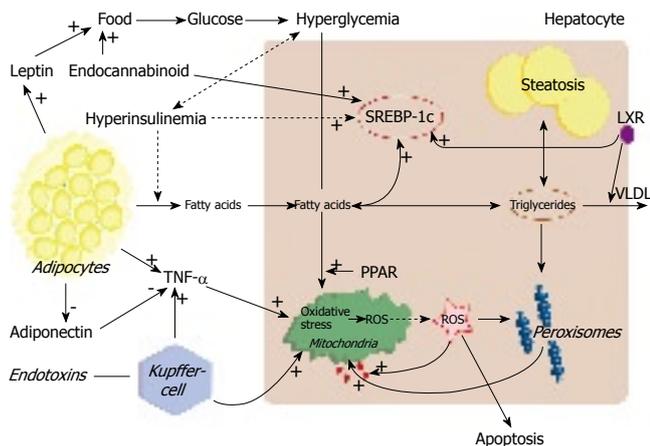

## DIAGNOSIS

### General

As noted before, NAFLD patients are mostly asymptomatic because slightly elevated liver enzymes are accidentally found. There is some debate about the question when further investigations are performed, especially in liver biopsy. Generally, it is reasonable to undertake action when the ALT level is  $> 2 \times$  ULN measured at two different occasions<sup>[102]</sup>. When the diagnosis of NAFLD is considered, it is important to exclude other pathological conditions that are associated with elevated ALT levels and/or steatosis (Table 1). It is especially difficult to find the difference between alcoholic and non-alcoholic liver diseases, as not all patients are honest about their alcohol intake and there is no adequate diagnostic difference between the two diseases. An abdominal ultrasound is performed to exclude hepatobiliary obstructions or tumours.

### Imaging techniques

Ultrasonography, computerized tomography (CT) scan,

**Figure 1** Pathogenesis of nonalcoholic steatohepatitis during insulin resistance. FFA is supplied to the liver through dietary intake, and lipolysis in adipocytes via chylomicron remnants. Transcription of SREBP-1c is chronically up-regulated resulting in DNL. Simultaneous inhibition of VLDL synthesis results in disruption of triglycerides export. The surplus of fatty acids is stored in triglycerides or metabolized via peroxisomal and mitochondrial oxidation. The excessive oxidation will lead to production of ROS and oxidative stress. This will trigger the inflammatory response and apoptosis as well activation of stellate cells.

and magnetic resonance imaging (MRI) can all be used to diagnose hepatic steatosis. Ultrasonography, the most commonly used and least expensive method, can be used to diagnose moderate to severe steatosis. Studies in the 1980's found that its sensitivity and specificity vary from 60% to 94% and 88% to 95%, respectively. Palmentieri *et al.*<sup>[103]</sup> investigated a subgroup of patients with hepatic steatosis > 30%, showing that the sensitivity and specificity of US increase up to 90% and 97%, respectively. Although the diagnostic capacity of ultrasonography increases with higher degrees of steatosis<sup>[103-105]</sup>, accurate quantification of hepatic fat and comparison between simple hepatic steatosis and steatohepatitis are impossible. Un-enhanced CT imaging can accurately detect and quantify the amount of steatosis in patients<sup>[106,107]</sup>. Grey scales (representing the amount of radiation absorbed) of the liver and spleen are measured and expressed in Hounsfield units (HU). For quantification of the amount of fat-infiltrated hepatocytes, the difference in grey scale between the liver and spleen can be measured in HU. This measurement correlates well with the percentage of hepatocytes with fatty infiltration<sup>[107]</sup>, where the hepatic attenuation decreases with the increased fat. For steatosis > 33%, the sensitivity and specificity are 82%-93% and 100%, respectively<sup>[106]</sup>. There is no difference in diagnostic value between a non-contrast CT scan and a contrast-enhanced one, with specifically more attenuation in the blood vessels than in the liver parenchyma. Contrast-enhanced CT scan does not provide more information. In fact, its sensitivity and specificity for steatosis are lower than those of un-enhanced CT imaging. Another drawback of contrast-enhanced CT scan of steatosis is the greater difficulty in its measurement due to the more complicated protocol.

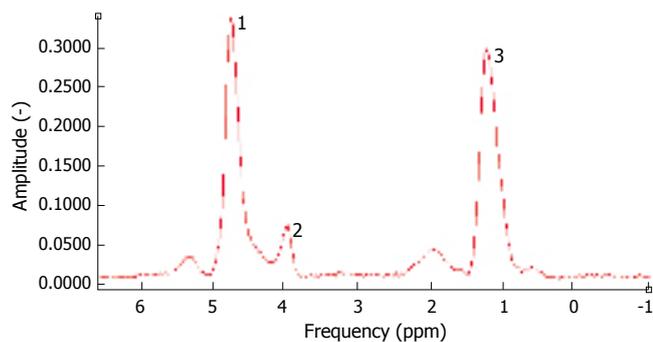

The most accurate available technique for detection and quantification of hepatic steatosis is NMR<sup>[108-110]</sup>. T1-weighted dual-echo chemical shift gradient-echo NMR is commonly used to obtain images. The main advantage of

this technique is the possibility of acquiring in-phase (water) and opposed-phase (fat) images in one breath hold, thereby reducing the influence of breathing movements and contrast absorption. Besides, this technique is useful for follow-up due to the lack of the use of fluoroscopy. Qualitative measurement or detection of steatosis is assessed on opposed-phase images. On T1-weighted images, a shorter relaxation time represents the higher signal intensity (SI). In healthy individuals, the SI of the liver is higher than that of the spleen. Steatosis causes a drop in SI on opposed-phase images. When SI of the liver equals to that of the spleen, a diagnosis of mild steatosis is made. Moderate or severe steatosis is diagnosed when SI of the liver is less than that of the spleen. Quantification of steatosis is possible with MRI by calculating the mean SI of the liver on in-phase and opposed-phase images. A number of regions of interest (ROI) are drawn in sections of the liver, from which the mean can be calculated. Using the same method, the mean SI of the spleen or fat issue surrounding the liver can be calculated as a reference. The difference in SI on opposed-phase and in-phase images can be calculated and expressed as a percentage of fatty infiltration of the liver. MRI shows a good correlation with histological examination, the sensitivity and specificity of MRI are 100% and 92.3%, respectively<sup>[110]</sup>.

Another relatively new NMR technique under development, widely used to quantify hepatic triglyceride content, is magnetic resonance spectroscopy (MRS)<sup>[111,112]</sup>. MRS of *in vivo* biological tissues was first reported in 1973 and used in the field of chemistry before NMR was introduced in hospitals. The principle of MRS is based on the differences in resonance frequencies of protons. The electron cloud surrounding molecules shields protons to varying degrees depending on the specific molecule structure and the specific position of protons in the molecule. This shielding causes protons in different molecules or even in different places of the same molecule to have a slightly different resonance frequency. Instead of using resonance frequencies for creating anatomical images, the differences in spectroscopy frequency are used to identify different chemical compounds. By using these differences, protons in water molecules can be differentiated from protons in lipids. Quantifying the amount of a certain biochemical component is possible by calculating the area under the "fat resonance peak" and comparing it to the "water resonance peak" (Figure 2).

Technically, coronal, axial and sagittal images of the liver are acquired and a volume of interest is defined, avoiding major blood vessels and bile ducts.

Unfortunately, to date, no conventional diagnostic imaging method that can accurately distinguish NASH from simple steatosis is available<sup>[111,113]</sup>. Transient elastography (fibroscan) is a technique under development. Studies in chronic hepatitis C (CHC) patients showed that cirrhosis (severe fibrosis) can adequately be distinguished from mild fibrosis, but this accuracy is much less in distinguishing various degrees of fibrosis<sup>[114]</sup>. Another drawback of the fibroscan method is that it is difficult to use and inaccurate in obese patients. A combination of serologic markers is under investigation to assess the severity of fibrosis<sup>[115]</sup>. Although results seem promising, further study is wanted.

**Figure 2** Spectrum of a fatty liver measured by  $^1\text{H}$ -magnetic resonance spectroscopy. The water peak is at 4.3 ppm. 1: Residual water partially suppressed; 2: Glycerol/phospholipids; 3:  $(-\text{CH}_2)_n$  of saturated fat.

## THERAPEUTIC OPTIONS

### Life style modifications and weight reduction

Since the majority of patients suffer from obesity, insulin resistance and concomitant cardiovascular disease, weight reduction of approximately 10% has been advised by the American Gastroenterological Association<sup>[116]</sup>. An analysis by Wang *et al*<sup>[117]</sup> of all published articles and meeting abstracts have revealed no randomized controlled trials. Besides, the use of variable primary endpoints and control groups worsened the analysis of this comprehensive review. Although on a theoretical basis, reduced caloric intake, exercise and weight loss would eventually improve hepatic steatosis, very scarce evidence is available to support this hypothesis. The limited data are due to the small number and lack of histological evidence. Recently, Huang *et al*<sup>[118]</sup> analyzed the effect of a 12-mo standardized nutritional counseling in 16 of 23 patients and found that the mean weight reduction is 2.9 kg with histological improvement in 9 patients.

No data are available on the long-term effect of weight loss on liver-related diseases such as cirrhosis or its complications.

### Pharmacological interventions

**Drug-induced weight reduction:** The only two registered drugs for pharmacological weight reduction, Orlistat ( $n = 4$ ) and Sibutramine ( $n = 1$ ), have been investigated in a few small non-randomized studies<sup>[119-123]</sup>. Orlistat, a gastric and pancreatic lipase inhibitor resulting in fat malabsorption (approximately 30%), has been studied in one case series<sup>[119]</sup>, three pilot studies<sup>[120,121,123]</sup> and one RCT<sup>[124]</sup>. Overall, patients can achieve impressive weight loss (10-15 kg) with improvements in liver enzymes but variable results in histology.

Sibutramine, a serotonin and norepinephrin reuptake inhibitor, acts on enhancing satiety *via* central mechanisms. There is only one published study on NAFLD in 25 patients demonstrating weight loss, improvement in liver enzymes and hepatic steatosis on ultrasound. Unfortunately, repeated liver biopsy was not performed.

**Antioxidants:** Since the pathogenesis of NAFLD is thought to be in a two-hit fashion, it is believed that oxidative stress

causes a second hit leading to inflammation. *In vitro* and *in vivo* animal and human studies<sup>[125,126]</sup> have been performed on the effects of vitamins E and C as antioxidants. The promising results in one study were counteracted by another. Harisson *et al*<sup>[126]</sup> reported that a between group analysis cannot show any beneficial effect of the combination of vitamins E and C after 6 mo, compared to placebo. Recently, Lirussi *et al*<sup>[127]</sup> identified 6 trials that were analyzed according to the intention-to-treat principle and found that despite the significant improvements in liver enzymes and minor adverse events, radiological and histological data are too limited to support or repudiate the use of antioxidants in patients with NAFLD.

**Ursodeoxycholic acid (UDCA):** UDCA, approved as a drug of choice in treatment of patients with PBC, exerts its effect by reducing the portion of hydrophobic bile acids contributing to oxidative stress. Four clinical trials<sup>[128-131]</sup>, of which only one assessed histology<sup>[129]</sup> and had a low-bias risk, have been conducted. No significant differences in the degree of steatosis, inflammation or fibrosis could be found between the treated and placebo groups. Unfortunately, these studies had no heterogeneity with respect to inclusion criteria, sample size, duration of treatment and methods of outcome assessment. Therefore, the Cochrane analysis by Orlando *et al*<sup>[132]</sup> concludes that the data are insufficient to use UDCA in treatment of patients with NAFLD.

**Metformin:** Metformin, a biguanide, has been shown to be an effective drug for the treatment of patients with type 2 diabetes mellitus<sup>[133]</sup>. Its administration improves hepatic steatosis and hepatomegaly. In addition to this observation, human pilot studies performed with variable results<sup>[134,135]</sup> could not demonstrate a beneficial effect of metformin compared to a calorie-restricted diet. Similar to the previous mentioned therapies, histological data are limited to support an association between improvements in liver enzymes and histological findings.

**Thiazolidinediones (TZD):** This class of agents acts as agonists of the peroxisome proliferator-activated receptor gamma on ameliorating insulin resistance and glucose and lipid metabolism. The first generation of TZD, e.g. troglitazone, appears to be effective on ALT levels, although it has been withdrawn from the market due to its severe hepatotoxicity<sup>[136,137]</sup>. In addition, the second generation of TZD (pioglitazone and rosiglitazone) is safer. A Cochrane analysis by Angelico *et al*<sup>[138]</sup>, (excluding trials treating patients with type 2 diabetes mellitus) extracted only one RCT by Sanyal *et al*<sup>[139]</sup>, showing that combination therapy with vitamin E and pioglitazone is significantly superior to vitamin E alone in terms of the degree of hepatic steatosis, but not other histological variables.

An open label trial of rosiglitazone in 26 biopsy-proven NASH<sup>[140]</sup> and two pilot studies with pioglitazone<sup>[141,142]</sup> ( $n = 73$ ) during 48 wk demonstrated improvements both in liver chemistry and in histological features like steatosis, necroinflammation and fibrosis. Weight gain seems to be the most important adverse event. Recently, the use of rosiglitazone has been associated with the slightly

increased bone loss in postmenopausal women and elderly diabetics<sup>[143-145]</sup> and an increased risk of cardiovascular events, i.e. myocardial infarction<sup>[143,146,147]</sup>. Further research focusing on larger randomized controlled trials with this class of drugs will be valuable.

**Lipid lowering drugs:** Use of statins or fibrates has not been investigated in large randomized trials. Primary endpoints of these studies are liver enzymes but not histology. No definite conclusions can be made from these limited studies<sup>[121,148]</sup>.

**Adipokines:** As mentioned before, adipocytes act as hormonal active tissue producing cytokines, like leptin, resistin, adiponectin and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ). It was reported that levels of TNF- $\alpha$  are increased in patients with NASH<sup>[99]</sup>. TNF- $\alpha$ , as a potential proinflammatory cytokine, promotes insulin resistance and thereby hepatic steatosis<sup>[101]</sup>. Some animal and even fewer human studies focusing on the effect of blocking this adipocytokine showed that patients treated with pentoxifyllin for 6 or 12 mo have a significant improvement in liver enzymes<sup>[149,150]</sup>.

Administration of synthetic adiponectin, exposing opposite effects to TNF- $\alpha$ , in two animal models can ameliorate hepatomegaly, steatosis and elevated ALT-levels<sup>[151]</sup>.

Leptin, a 16-kDa protein hormone, has been shown to play a pivotal role in energy homeostasis by activating and inhibiting certain neurons<sup>[152]</sup>. It has been shown that administration of leptin infusions in patients with generalized lipodystrophy significantly ameliorates insulin resistance, glucose and triglyceride levels as well as hepatic steatosis<sup>[153,154]</sup>. No such studies have been performed yet in NAFLD patients.

Resistin, another adipocytokine, is a subject of controversy regarding to its causal role in obesity and type 2 diabetes mellitus. Due to this controversy, no published data are available about its beneficial effects on inhibition of resistin.

## FUTURE DIRECTIONS

Up until now, the exact treatment strategy for the treatment of patients with NAFLD has not been well established in RCT. Research topics in this field are challenging. In the United States and Europe, some research groups are focusing on comparing different treatment options and identifying those patients most in need for treatment. Evolving new imaging techniques like proton magnetic resonance spectroscopy might differentiate between those patients having type 1 NAFLD (defined as simple steatosis without features of inflammation) and type 2 NAFLD (containing patients with variable grades of inflammation and fibrosis eventually resulting in cirrhosis).

Several registered drugs aiming at improving metabolic syndrome should be further investigated on their exact anti-steatotic effects. The most promising drugs are insulin sensitizers (especially Thiazolidinediones), which should be further investigated in a larger RCT aiming at establishing

the optimal dosage, time of treatment and adverse effects.

Since the discovery of two cannabinoid receptor antagonist receptors (CB1 and CB2) in the late 1980's and the beginning of the 1990's in the brain<sup>[155,156]</sup> and gastrointestinal tract<sup>[157]</sup>, it has gained more and more interests from both researchers and clinicians. CB1 has been extensively found in the central nervous system, affecting many neurological and psychological phenomena, like appetite, mood and spatial coordination of muscle tone<sup>[158]</sup>. In contrast, CB2 detected in peripheral cells of the immune system (lymphocytes, monocytes and neutrophils) exerts additional effects on the gut (inhibition of motility) and vasodilation<sup>[159,160]</sup>. Research in animal models revealed that activation of the endocannabinoid system leads (partially) to the development of portal hypertension and arterial hypotension through macrophages and platelets activated by bacterial lipopolysaccharides<sup>[161,162]</sup>. Secondly, anandamide, an endogenous ligand for CB-receptors, appears to be up-regulated in patients with endotoxic shock<sup>[163]</sup> and subsequently hepatocellular apoptosis has been linked to anandamide and its lipid-lipid plasma membrane interaction, resulting in enhanced susceptibility to oxidative stress<sup>[164]</sup>. Thirdly, another hypothesis is that an activated CB-system may have influence on hepatic encephalopathy<sup>[165]</sup>. In humans, endocannabinoids have been used in the treatment of three patients with cholestatic-related intractable pruritus<sup>[166]</sup>. SR141716A (Rimonabant, Sanofi-Aventis, Paris, France) under investigation may be used in the treatment of patients with obesity and metabolic syndrome<sup>[167]</sup>. In obese Zucker rats, administration of this drug could ameliorate markers of hepatic damage (defined as increased liver enzymes, focal hepatic TNF- $\alpha$  and decreased adiponectin), and decrease hepatomegaly<sup>[167]</sup>. Preliminary results in humans are promising since the used drug is safe, effective in achieving weight reduction and amelioration of the lipid profile and metabolic syndrome<sup>[85,168,169]</sup>.

In conclusion, the development of drugs acting both on the cannabinoid system influencing the central nervous system through inhibition of appetite and on the peripheral tissue ameliorating hepatic hemodynamics, inflammation and weight reduction accompanying improvement in metabolic syndrome, will lead to new research aims in the field of hepatology. In particular, the development and conductance of RCT with synthetic, non-psychotropic cannabinoids might result in optimizing treatment strategies for patients with NASH.

## CONCLUSION

Nonalcoholic fatty liver disease, especially nonalcoholic steatohepatitis, forms a definite threat to human health. With the increase in obesity, an increase in NAFLD patients can be expected, eventually leading to an increased number of liver transplantations. Pathophysiological mechanism is the subject of research all around the world, leading to a continuous current of new evidence and more knowledge about the complex mechanisms behind the disease. At the same time, diagnostic methods for detecting steatosis and steatohepatitis are under development.

<sup>1</sup>H-magnetic resonance spectroscopy is accurate in the detection and quantification of fat in the liver, but the eagerly wanted non-invasive tool for the detection of fibrosis or inflammation in steatotic livers is not available. Therapeutic options do increase. Weight loss by dietary and lifestyle intervention remains the cornerstone of treatment, but motivated patients can be supported by medications. Most promising results are found with thiazolidinediones, but recent upheaval around rosiglitazone means a setback of this drug.

## Abstract

**AIM:** To study the effect of the transfected *Twist* gene on invasion and metastasis of gastric carcinoma cells and the possible mechanisms involved.

**METHODS:** Human gastric carcinoma MKN28 cells were stably transfected with *Twist* sense plasmid, and MKN45 cells were stably transfected with *Twist* antisense plasmid using the lipofectamine transfection technique. RT-PCR, Western blotting, EMSA, gelatin zymography assay, and *in vitro* invasion and migration assays were performed. Nude mice metastasis models were established by the abdominal cavity transfer method.

**RESULTS:** Cell models (*TwistS*-MKN28) that steadily expressed high *Twist* protein were obtained. Compared with MKN28 and pcDNA3-MKN28 cells, adherence, migration and invasion ability of *TwistS*-MKN28 cells were clearly raised. The number of cancer nodules was increased significantly in the abdominal cavity and liver of nude mice inoculated with *TwistS*-MKN28 cells. Overexpression of *Twist* in MKN28 cells increased Tcf-4/Lef DNA binding activity, and promoted expression of Tcf-4's downstream target genes cyclin D1 and MMP-2. However, suppression of *Twist* (*TwistAS*-MKN45) inhibited MKN45 cell invasion and the expression of cyclin D1 was reduced. The activity of MMP-2 was also decreased.

**CONCLUSION:** These results indicate that *Twist* promotes gastric cancer cell migration, invasion and metastasis, and *Twist* may play an important role in Wnt/Tcf-4 signaling.

## INTRODUCTION

Gastric cancer is one of the most common cancers in the world. Several lines of evidence implicate the Wnt signaling pathway as a contributor to gastric carcinogenesis<sup>[1]</sup>. In the presence of certain Wnt proteins, or due to the loss of tumor suppressors such as *APC*, glycogen synthase kinase-3 (GSK-3) activity is inhibited, which results in inhibition of  $\beta$ -catenin phosphorylation and inhibition of degradation. The resulting accumulation of  $\beta$ -catenin leads to the activation of the Tcf-4/Lef transcription factor, which up-regulates the expression of downstream target genes. People with a germ-line mutation of the *APC* tumor suppressor gene have a 10-fold increased risk of developing gastric cancer as compared with normal individuals<sup>[2]</sup>. Mutations in the *APC* gene have been found in sporadic gastric cancer<sup>[3]</sup>.  $\beta$ -catenin mutations have also been detected in intestinal-type gastric carcinoma tissues and gastric cancer cell lines<sup>[4]</sup>. Based on these studies, we conclude that the Wnt/Tcf-4 signaling pathway is very important in gastric cancer cells.

Besides transforming growth factor  $\beta$  and receptor tyrosine kinase/Ras signaling, autocrine factors and Wnt-dependent pathways are reported to contribute to epithelial mesenchymal transition (EMT). EMT is a process whereby epithelial cells lose polarity and cell-to-cell adhesion, and undergo dramatic remodeling of the cytoskeleton. Concurrent with loss of epithelial cell adhesion and cytoskeletal components, cells undergoing EMT acquire

expression of mesenchymal components and a migratory phenotype. EMT was first recognized in embryogenesis in the early 1980s. Today, evidence is growing that carcinoma cells activate the dormant EMT program in promoting cell migration, invasion and metastasis<sup>[5-7]</sup>. However, its pathogenesis in human carcinoma is obscure.

Several key inducers of EMT are transcription factors that repress E-cadherin expression, such as Snail, Slug, SIP1 and *Twist*. Recent studies have shown that *Twist*, a highly conserved basic helix-loop-helix protein that is essential for early embryogenesis, promotes EMT and plays an essential role in metastasis in a breast tumor model<sup>[8]</sup>. *Twist* has also been suggested to have oncogenic properties. Overexpression of *Twist* in rhabdomyosarcoma inhibits myc-induced apoptosis and interferes with p53 tumor suppression<sup>[9]</sup>. Up-regulation of *Twist* is associated with malignant transformation in T-cell lymphoma<sup>[10]</sup>. Forced expression of *Twist* triggers resistance of human cancer cells to drugs that inhibit microtubule formation, such as taxol and vincristine<sup>[11]</sup>. Furthermore, expression of *Twist* has been implicated in promotion of metastasis and invasive pathological subtypes in several types of carcinoma<sup>[12,13]</sup>.

However, the effect and mechanism of *Twist* gene on invasion and metastasis of gastric carcinoma remain enigmatic. Therefore, in the present work, two gastric cancer cell lines with different differentiation were steadily transfected with sense and antisense *Twist* vectors. The effect of *Twist* gene on cell migration, invasion and metastasis was investigated.

## MATERIALS AND METHODS

### Cell culture

Human gastric carcinoma cell line MKN28 was kindly provided by Dr. JI Shuyu (Kunming Medical college, Kunming, China). Gastric carcinoma cell line MKN45 was purchased from Type Culture Collection of the Chinese Academy of Sciences (Shanghai, China). Cells were cultured in RPMI 1640 medium (Gibco Biocult, Paisley, UK) that contained 10% fetal bovine serum at 37°C in a humidified 5% CO<sub>2</sub> atmosphere.

### Plasmids and reagents

The *Twist* sense and antisense expression vectors (pcDNA3/*TwistS*, pcDNA3/*TwistAS*) were kindly provided by Dr. Glackin C<sup>[14]</sup>. The identity of *Twist* was confirmed by gene sequencing and routine agarose gel electrophoresis. Primary antibodies (anti-*Twist*, anti-MMP-2 and anti-β-actin) were from Santa Cruz Biotechnology (Santa Cruz, CA, USA) and secondary antibody (HRP-linked IgG) was from Cell Signaling Technology (Beverly, MA, USA).

### Generation of stable transfectants

Cell transfection was carried out using Lipofectamine 2000 according to the manufacturer's instructions. Briefly, cells were grown to 80%-90% confluence, without antibiotics. Vectors that contained the different constructs (10 μg) were diluted in RPMI 1640 (100 μL) and mixed with the transfection solution for 15 min. After washing, the cells

were incubated with the transfection mixture at 37°C for 10 h, and then allowed to grow in fresh medium. Stable transfectants were isolated by selection with 600 mg/mL G418 (Geneticin; Amresco, Solan, OH, USA) for 2 wk. Pools of geneticin-resistant clones were passaged and expanded for Western blot analysis. Cells transfected with the pcDNA3 vector were used as controls.

### Western blotting

Cell total proteins were prepared in SDS sample buffer and boiled for 3 min. Equal amounts of cell protein, quantified by the BCA Protein Assay kit (Pierce Biotechnology, Rockford, IL, USA), were loaded onto 10% SDS-PAGE. After electrophoresis, the separated proteins were transferred to nitrocellulose membranes. The membranes were stained with ponceau (Amresco) and blocked with 5% non-fat milk for 1.5 h, and then incubated with antibody for 18 h at room temperature. The blots were subsequently incubated with an HRP-conjugated secondary antibody. Proteins were visualized using 3,3'-diaminobenzidine, with β-actin as a control.

### Extraction of nuclear protein

Cells were lysed in 400 μL ice-cold buffer A (10 mmol/L HEPES, pH 7.9, 10 mmol/L KCl, 0.1 mmol/L EDTA, 0.1 mmol/L EGTA, 1 mmol/L DTT, 0.5 mmol/L PMSF) by gentle pipetting. The cells were allowed to swell on ice for 15 min, then 40 μL of a 10% solution of Nonidet P-40 was added, and the tube was vigorously vortexed for 10 s. The homogenate was centrifuged for 30 s in a microfuge. The supernatant was transferred and the nuclear pellet was lysed with 50 μL buffer C (20 mmol/L HEPES, pH 7.9, 0.42 mol/L NaCl, 1 mmol/L EDTA, 1 mmol/L EGTA, 1 mmol/L DTT, 1 mmol/L PMSF), and the tube was vigorously rocked at 4°C for 15 min on a shaking platform. The nuclear extract was centrifuged for 5 min in a microfuge at 4°C. The supernatant containing nuclear protein was quantified by the BCA Protein Assay kit (Pierce Biotechnology) and stored at -70°C.

### Electrophoretic mobility shift assay (EMSA) of TCF-4 DNA binding activity

EMSA was performed with the LightShift Chemiluminescent kit (Pierce Biotechnology). Specific oligonucleotides for binding of TCF-4 (S: 5'-CCCTTTGATCTTACC-3'; A: 3'-GGTAAGATCAAAGGG-5') were prepared by end labeling of the 5' terminus with biotin (synthesized by Bioasia Biotech, Shanghai, China). Briefly, nuclear extract protein (10 μg) was incubated with reaction mixture [10 × binding buffer, 1 μg/L poly (dI.dC), 1% NP-40, labeled probe] for 20 min at room temperature. Each sample was electrophoresed in 6% non-denaturing polyacrylamide gel at 100 V for 1.5 h. The gel was then electrophoretically transferred to a nylon membrane. Finally, the membrane was detected by chemiluminescence. In competitive studies, a 100-fold excess of unlabeled probe was included in the reaction mixture.

### RT-PCR

Cells were lysed in TRIzol reagent (Invitrogen, Carlsbad, CA, USA) and total RNA was prepared according to

the manufacturer's instructions. cDNA was synthesized by the Superscript<sup>TM</sup> First Strand Synthesis System (Life Technologies, Gaithersburg, MD, USA). The cDNA was then amplified by PCR with specific primers, cycline D1 sense: 5'-ACGGCCGAG-AAGCTGTGCAT; antisense: 5'-TTCCAATCCGCCCTCCATGGA. The cDNA of GAPDH was amplified as a control for the amount of cDNA present in each sample (sense: 5'-ACGGATTTGGTTCGTATTGGG antisense: 5'-TGATTTTGGAGGG-ATCTCGC). The relative expression levels were generated by comparing the density to the controls and indicated underneath each gel.

### Evaluation of cell adherence

Fifty milligrams per liter Matrigel solution diluted with sterilized double distilled water (1:8) was prepared, added to 96-well plates (50  $\mu$ L/well), and incubated for 12 h at 4°C. Ten grams per liter BSA were used as a control. After abandoning remnant liquid, no-serum culture solution that contained 10 g/L BSA (50  $\mu$ L/well) was added and incubated at 37°C for 30 min. Tumor cells were digested with 2.5 g/L pancreatic enzyme and modulated to a density of  $1 \times 10^5$  cells/mL. One hundred microliters of cell suspension was seeded in invested Matrigel per well. Every group had four samples at equal pace. The cells were cultivated with RPMI 1640 medium that contained 10 g/L BSA and 10% fetal bovine serum for 1 h at 37°C, then the absorbance (A) was determined by the MTT colorimetric method. Cell adhesion rate of the Matrigel group was calculated by the following formula:

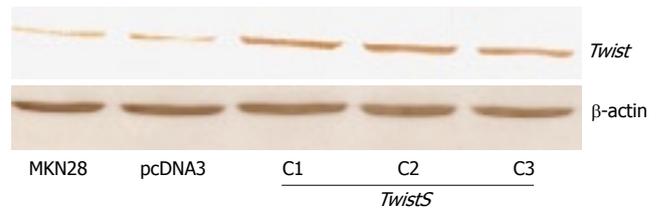

$$\text{Adhesion rate} = (A_{\text{exp}}/A_{\text{BSA}} - 1) \times 100\% \text{ equation 1}$$

### In vitro invasion and migration assay

Invasion assays were done in a Boyden chamber with polyethylene terephthalate filter inserts for 24-well plates containing 8- $\mu$ m pores (Becton Dickinson Labware, NY, USA). Briefly, after coating the filter with 100  $\mu$ L 1:3 diluted Matrigel (Becton Dickinson) overnight at 4°C, cells were seeded in the upper chamber at a final concentration of  $1.0 \times 10^5$ /mL in serum-free medium with 0.1% BSA. Eight hundred microliters medium conditioned with 10  $\mu$ g/mL fibronectin was placed in the lower compartment of the chamber as a chemoattractant. After 24 h incubation, the remaining tumor cells on the upper surface of the filters were removed by wiping with cotton swabs, and the invading cells on the lower surface were stained with hematoxylin-eosin. The invading cells on the underside of the membrane were photographed and counted under a microscope at a magnification of  $\times 200$ . We performed four individual experiments using the invasion assay in triplicate. *In vitro* migration assays were done under the same conditions as the invasion assays, but in non-Matrigel-coated chambers.

### Establishment of an experimental metastasis model in nude mice

Cells were digested with 2.5 g/L pancreatic enzymes, washed with no-serum culture solution, and centrifuged at 1800 r/min. The cell sediment was washed with serum-free culture solution, centrifuged twice and floated in sterile PBS solution. Two hundred microliters of cell suspension

**Figure 1** Western blot analysis of *Twist* expression in MKN28, pcDNA3 control and *TwistS* transfectant clones (C1, C2 and C3).

that contained  $1 \times 10^7$  MKN28, pcDNA3-MKN28 and *TwistS*-MKN28 cells was seeded into the abdominal cavity of nude mice by syringe. The vim, appetite and defecation of nude mice were observed regularly, and their weight was recorded. After 9 wk, nude mice were killed and examined.

### Gelatin zymography assay

MKN45, pcDNA3-MKN45 and *TwistAS*-MKN45 cells were cultured. Three days later, cells were washed by D-Hanks' solution, and then seeded into serum-free culture solution. Twenty-four hours later, the supernatant was collected and concentrated with Amicon filters (Millipore) to a 10% initial volume. Each sample was guaranteed to contain the same amount of total protein. Gelatin zymography was performed in 10% (w/v) polyacrylamide that contained 0.1% (w/v) gelatin. The identification of transparent bands at 62 kDa on the Coomassie blue background of the slab gel was considered positive for the presence of enzymatic activity.

### Statistical analysis

Results were expressed as mean  $\pm$  SD for experiments with triplicate measurements. Differences between groups were tested with Student's *t* test and  $P < 0.05$  was considered significant.

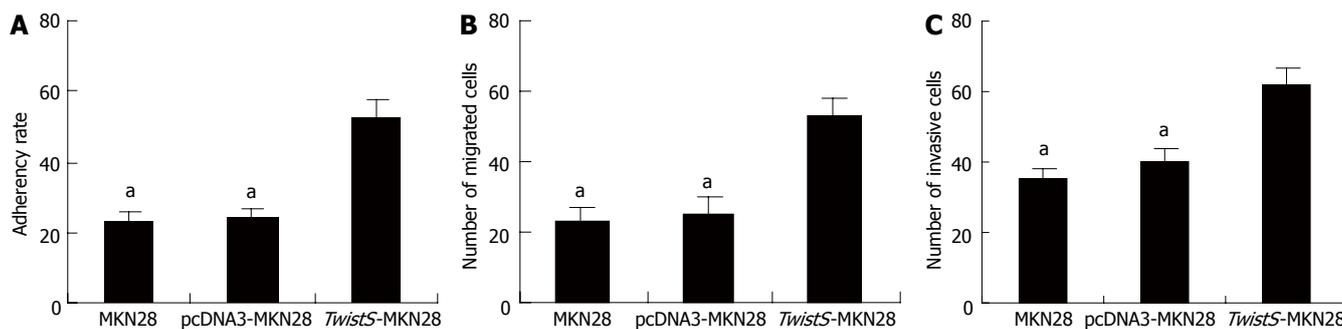

## RESULTS

### Gene transfection

MKN28 cell clones transfected with pcDNA3 or pcDNA3-*TwistS* were obtained after gene transfection. Expression of *Twist* protein was increased in the three positive cell clones that were transfected with pcDNA3-*TwistS* (Figure 1). To avoid the deviation brought about by a single cell clone, three positive cell clones were used simultaneously.

### Overexpression of Twist in MKN28 cells promoted adherence, migration and invasion ability

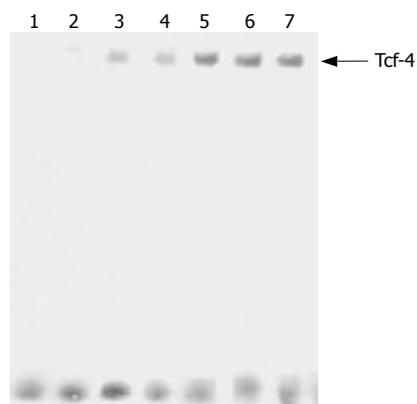

A value was decided by the MTT colorimetric method and cell adhesion rate was calculated by equation 1. Compared with that of MKN28 (23.5%) and pcDNA3-MKN28 cells (24.2%), the adherence rate of *TwistS*-MKN28 cells (52.8%) was obviously increased ( $P < 0.05$ ) (Figure 2A). Compared with that of MKN28 (22) and pcDNA3-MKN28 cells (25), the migration rate of *TwistS*-MKN28 cells (54) clearly increased ( $P < 0.05$ ) (Figure 2B). Compared with that of MKN28 (40) and pcDNA3-MKN28 cells (36), the invasion rate of *TwistS*-MKN28 cells (62) also clearly increased ( $P < 0.05$ ) (Figure 2C). Every sample was

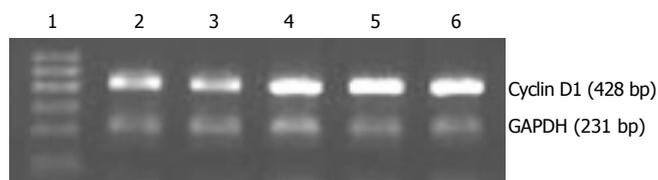

**Figure 2** Cell adherence rate, and cell migration and cell invasion ability. **A:** Adherence rate in three cell lines; **B:** Migration ability in three cell lines; **C:** Invasion ability in three cell lines. <sup>a</sup>*P* < 0.05 vs *TwistS*-MKN28 cells.

counted for five different visual fields.

### Establishment of an experimental metastasis model in nude mice

The metastasis models of gastric carcinoma cells were established in fifteen nude mice. Eight weeks later, the mice were killed and underwent exploratory laparotomy. Number and size of metastatic nodules were calculated and measured. There were lots of bigger cancer nodules in the abdominal cavity and liver of the nude mice inoculated with *TwistS*-MKN28 cells, while fewer nodules were present in the nude mice inoculated with MKN28 and pcDNA3-MKN28 cells (Figure 3).

### Overexpression of *Twist* in MKN28 cells increased Tcf-4/Lef DNA binding activity

Consistent with the increasing expression levels of *Twist*,

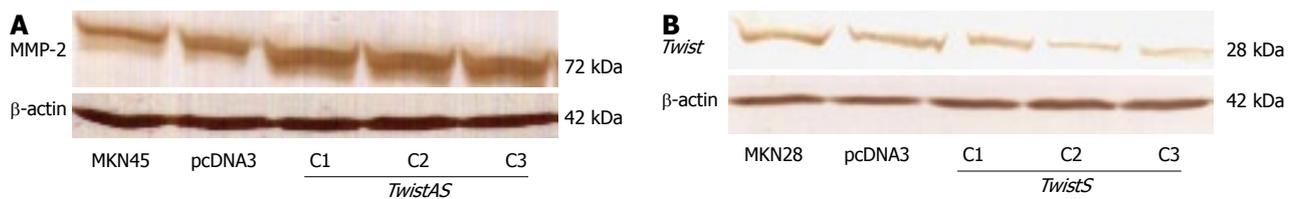

induction of Tcf-4/Lef binding activity was observed in MKN28 and pcDNA3 control cells. Moreover, Tcf-4/Lef DNA binding was significantly increased in *TwistS* transfectants (Figure 4).

### Overexpression of *Twist* promoted expression of cyclin D1 and mmp-2

We explored whether overexpression of *Twist* affected expression of cyclin D1 and mmp-2. By RT-PCR, cyclin D1 RNA levels were markedly higher in *TwistS* cells than in MKN28 and pcDNA3 control cells (Figure 5). Western blot analysis showed that *TwistS* cells exhibited increased expression levels of MMP-2 compared with those in MKN28 cells and pcDNA3 control cells (Figure 6A).

### Suppression of *Twist* inhibited invasion in the human gastric cancer cell line MKN45

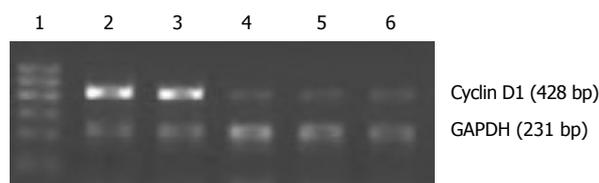

To observe the invasion-promoting effect of *Twist* in gastric cancer cells, a pcDNA3/-*TwistAS* vector was transfected into MKN45 cells to generate stable transfectants. As shown in Figure 6B, *Twist* expression was

**Figure 6** Western blot analysis in each cell line. **A:** Expression of MMP-2 in MKN28 cells, pcDNA3 control cells and *TwistAS* cells by Western blot analysis; **B:** Western blot analysis of *Twist* expression in MKN45, pcDNA3 control and *TwistS* transfectants clone (C1, C2 and C3).

**Figure 7** Down-regulation of *Twist*-inhibited invasion in MKN45 cells. Representative photographs of invasion in three cell lines (hematoxylin-eosin staining, × 200 magnification). **A:** MKN45; **B:** pcDNA3-MKN45; **C:** *TwistAS*-MKN45.

**Figure 8** Suppression of *Twist*-inhibited expression of cyclin D1 mRNA by RT-PCR. Lane 1: Marker; Lane 2: MKN45 cells; Lane 3: pcDNA3 control cells; Lanes 4-6: Three *TwistAS* clones.

inhibited by *TwistAS* transfectants at the protein level. We assessed the effect of down-regulation of *Twist* on cell invasion. Representative photos showed that invasion in *TwistAS* transfectants was markedly reduced compared with that of MKN45 or pcDNA3 –MKN45 cells (Figure 7).

#### Suppression of *Twist* inhibited expression of cyclin D1

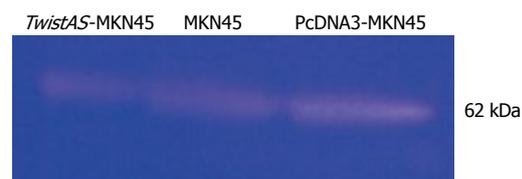

We investigated whether suppression of *Twist* affects the expression of cyclin D1. Cyclin D1 RNA levels were markedly lower in *TwistAS* cells than in MKN45 and pcDNA3 control cells (Figure 8).

#### Suppression of *Twist* inhibited gelatinase activity

Gelatin zymography revealed prominent 62 kDa bands (Figure 9), and there was activity of MMP-2 in MKN45, pcDNA3-MKN45 and *TwistAS*-MKN45 cell supernatants. Compared with that of MKN45 and pcDNA3-MKN45 cells, the activity of MMP-2 in *TwistAS*-MKN45 cells dropped markedly.

## DISCUSSION

It is commonly believed that *Twist* expression is correlated

**Figure 9** Comparison of activity of MMP-2 by gelatin zymography assay.

with potent invasiveness as well as poor prognosis in epithelial cancer<sup>[8,11,13,19]</sup>. In gastric cancer, a recent report has shown overexpression of the *Twist* gene is more frequently found in diffuse-type carcinoma tissues with high N-cadherin gene expression<sup>[15]</sup>. However, no definitive results have indicated *Twist* promotes the invasion and metastasis of gastric cancer. We have previously demonstrated endogenous *Twist* is expressed abundantly in MKN45 cells, but at much lower levels in MKN28 cells. Therefore, we transfected MKN28 cells with the *Twist* sense plasmid. Our findings suggested *Twist* probably promoted adherence, migration, invasion and metastasis of gastric cancer cells, using the MTT and Boyden chamber methods, and metastasis models of gastric carcinoma in nude mice. However, when we transfected MKN45 cells with the *Twist* antisense vector, results indicated suppression of *Twist* inhibited cell invasion. Therefore, we think *Twist* may play an important role in invasion and metastasis of gastric carcinoma.

A large number of genes relevant for tumor formation and progression have been found to be transcriptionally activated by the  $\beta$ -catenin/Tcf complex. Some of these are implicated in growth control and cell cycling (c-myc, cyclin D1), Some are relevant for cell survival (Id2, MDR1), one is the EMT marker vimentin, and others are

implicated in tumor invasion and metastasis (matrilysin, VEGF, cd44)<sup>[16-18]</sup>. Tcf-4/Lef is the transcription factor for Wnt signaling. Our results indicated that overexpression of *Twist* in MKN28 cells increased Tcf-4/Lef DNA binding activity, and promoted expression of Tcf-4' downstream gene cyclin D1. The reason may be that overexpression of *Twist* redistributes  $\beta$ -catenin to the nucleus, in which it forms a functional transacting complex by associating with the Tcf4/Lef-1 transcription factor, and enhances the transactivation of a number of genes including cyclin D1, VEGF and EMT marker vimentin. Cyclin D1 plays an important role in cell proliferation<sup>[20]</sup>. Our results agreed with previous studies that showed that *Twist* promotes growth of breast cancer cells. In breast cancer MCF-7 cells, colocalization of  $\beta$ -catenin and E-cadherin was prominent at the plasma membrane, whereas in MCF-7 cells with overexpression of *Twist*, these proteins were distributed within the cytoplasm and to a lesser extent within the nucleus. In addition, the total amount of epithelial marker protein  $\beta$ -catenin and E-cadherin was lower in MCF-7 cells<sup>[21]</sup>. This can partly explain the phenomenon of EMT by *Twist*.

Metastatic potential requires proteolytic degradation of the extracellular matrix, and MMPs are thought to play an important role in tumor invasion and metastasis. We demonstrated that overexpression of *Twist* in MKN28 cells promoted expression of mmp-2, while suppression of *Twist* in MKN45 cells inhibited the activity of mmp-2. However, to the best of our knowledge, the E-box site, which is the binding site for *Twist*, was not observed in the promoter region of the MMP gene family. One possible explanation is that MT1-MMP expression is induced through  $\beta$ -catenin/Tcf4 expression<sup>[22,23]</sup>, followed by increased activation of MMP-2. Another explanation is that MMP-2 activity is induced through the up-regulation of MT1-MMP expression, by inhibition of zonula occludens 1 tight junction complex expression that is changed by EMT<sup>[24]</sup>.

In conclusion, *Twist* may contribute to the invasion and metastasis of gastric carcinoma cells, mainly through EMT after regulation of Wnt signaling, or through an effect on MMP-2. At the same time, recent evidence suggests *Twist* is a major factor that participates in tumor development and progression<sup>[25-28]</sup>. As a novel player in the invasion and metastatic program, *Twist* is gaining rapid attention<sup>[29,30]</sup>. Our findings of a functional link between *Twist* and Tcf4/Lef-1 suggest targeting *Twist* may provide novel therapeutic cocktails for gastric cancer intervention.

## ACKNOWLEDGMENTS

We thank Dr. Charlotta A Glackin (Division of Molecular Medicine, Beckman Research Institute of the City of Hope, CA, USA) for kindly providing the *Twist* sense and antisense expression vector. And we also thank Dr. Xiao-Ming Xie (Department of Molecular and Cellular Oncology, University of Texas, MD Anderson Cancer Center) for generous assistance in preparing the manuscript.

## COMMENTS

### Background

Invasion and metastasis are the most common cause of death and is a major

obstacle to successful treatment of gastric cancer. It is necessary to develop effective new strategies for the prediction, diagnosis and treatment of gastric cancer invasion and metastasis.

### Research frontiers

Recent investigations have shown *Twist* is elevated in prostate and breast cancer. High expression of *Twist* is positively related to cancer invasion and metastasis, but few studies have investigated *Twist* expression in gastric cancer, and the impact of *Twist* on prognosis.

### Innovations and breakthroughs

*Twist* promotes gastric cancer cells migration, invasion and metastasis, and *Twist* may play an important role in Wnt/Tcf-4 signaling.

### Applications

Our finding of a functional link between *Twist* and Tcf4/Lef-1 suggests that targeting *Twist* may provide novel therapeutic cocktails for gastric cancer intervention.

### Terminology

EMT is a process whereby epithelial cells lose polarity and cell-to-cell adhesion, and undergo dramatic remodeling of the cytoskeleton. Concurrent with loss of epithelial cell adhesion and cytoskeletal components, cells undergoing EMT acquire expression of mesenchymal components and a migratory phenotype.

### Peer review

This study was well designed and may be important for providing additional evidence to support the role of *Twist* expression in promoting tumor metastasis, including in gastric cancer.

Effect of 5-LOX/COX-2 common inhibitor DHDMBF30 on pancreatic cancer cell Capan2. *World J Gastroenterol* 2008; 14(16): 2494-2500 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2494.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2494>

### Abstract

**AIM:** To study the effect of 5-lipoxygenase/cyclooxygenase-2 (5-LOX/COX-2) dual inhibitor 7-tert-butyl-2, 3-dihydro-3, 3-dimethyl substituted dihydrofuran 30 (DHDMBF30) on proliferation and apoptosis of the pancreatic cancer cell line Capan-2 and the effect of DHDMBF30 on human pancreatic cancer in a nude mouse model.

**METHODS:** Investigate the effect of 5-LOX/COX-2 dual inhibitor DHDMBF30 on proliferation and apoptosis of the pancreatic cancer cell line Capan-2 by RT-PCR, MTT assay, FCM and electron microscope. Cell line Capan-2 was inoculated percutaneously on the outer thigh of 12 nude mice. The VEGF mRNA of transplantation tumor was detected by RT-PCR.

**RESULTS:** DHDMBF30 inhibits the proliferation of cell line Capan2, reduces the expression of 5-LOX, COX-2 and VEGF. After Capan2 was treated with DHDMBF30, we found that the apoptosis peak of the experimental group was significantly higher than that of the contrast group ( $3.08 \pm 1.89$  vs  $27.67 \pm 0.52$ ,  $P < 0.001$ ). The tumor weight of the DHDMBF30 group was significantly lower than PBS control groups ( $1.35 \pm 0.47$  vs  $2.92 \pm 0.73$ ,  $P < 0.01$ ). Expression of VEGF in the DHDMBF30 group was significantly decreased.

**CONCLUSION:** DHDMBF30 inhibits the proliferation of

### INTRODUCTION

Through many years of practice and research, the treatment of pancreatic cancer has made some advancement in the areas of surgical operation, radiotherapy and chemotherapy, but the therapeutic effect is not yet satisfied enough, especially in the patients of advanced stages, and the remission rate or survival rate has not been improved significantly. At present, the major treatment method is the combined therapy, such as surgical operation combined with chemotherapy and (/or) radiotherapy *etc.* The prevention and treatment mechanism of non-steroid anti-inflammatory drug (NSAIDs) against tumors are still not clear now, but it is certain that NSAIDs can inhibit cyclooxygenase-2 (COX-2), which is the key enzyme in the synthesis of prostaglandin (PG). Some experiments demonstrated that the selective COX-2 inhibitors could inhibit the tumor cell proliferation, induce apoptosis and inhibit the generation of new vessels for tumors<sup>[1,2]</sup>. In recent years, a number of research studies have demonstrated that NSAIDs could inhibit 5-lipoxygenase (5-LOX), thereby inhibiting proliferation and inducing apoptosis of many malignant tumors<sup>[3,4]</sup>. In our early phase study, it was demonstrated that the expression rates of 5-LOX and COX-2 in the pancreatic cancer tissues were respectively 74.3% and 80%<sup>[5,6]</sup>, and all the pancreatic cancer tissues expressed 5-LOX or COX-2, sometimes expressed both, which supported that

there were crossed and complementary expressions, so the designed 5-LOX/COX-2 dual inhibitor can exert a synergistic effect. So we chose the 5-LOX/COX-2 dual inhibitor DHDMBF30 to act against pancreatic cancer cells, and observed the anticancer effects in order to provide a foundation for its clinical application.

## MATERIALS AND METHODS

### Materials

The human pancreatic cancer cell Capan-2 was obtained from the Pathology Teaching Research Department of Peking Union Medical College Hospital; pancreatic cancer cell medium RPMI1640 (GIBCO company) contained 20 mmol/L NaHCO<sub>3</sub>, 100 U/mL penicillin, 100 U/mL streptomycin, 10% calf serum (Hangzhou Sijiqing Biological Engineering Materials Co, Ltd); 0.25% trypsin (Sigma company). The primers were synthesized by the Shanghai Institute of Biochemistry, Chinese Academy of Sciences, RNA extract reagent Trizol<sup>®</sup> and RT-PCR kits were bought from GIBCO company. DHDMBF30 was bought from Procter & Gamble Pharmaceuticals (Ohio). Experimental animals: BALB/C nu hairless mice were bought from the Institute of Laboratory Animal Science, Chinese Academy of Medical Sciences. The mice were 4-6 wk old, and there were 6 males and 6 females.

### Cell culture

Pancreatic cancer cell strain Capan-2 was cultured in RPMI1640 medium containing 20% calf serum, and the cell strain was generally cultured in 37°C incubator with 5% CO<sub>2</sub>. Digestion of the strains was performed with 0.25% trypsin and serially sub-cultivated after 70%-80% of them coalesced during the adherent growth process. Next, we inoculated Capan-2 cells into the 100 mL culture flask at a dose of 10<sup>6</sup>/flask after the strains were digested, then divided the strains into control group and experimental group, cultured for 3 d, and changed the medium when the cells entered into the exponential division phase, then added 12 μmol/L DHDMBF30 into the culture flask in the experimental group and cultured for another 24 h.

### The experimental animals were randomly divided into two groups

Six mice in each group were put into a rearing cage. Experimental group: on the second day after cell inoculation each mouse was subcutaneously injected with 0.2 mL (12 μmol/L) DHDMBF30 in the inoculation area of tumor cells twice a week for 3 wk; PBS control group: the injection time, site and volume were the same as the treatment group. After the tumor could be touched, we measured the long and short diameters of the tumor every 3 d. Hairless mice were sacrificed 35 d later, the tumor mass measured and tissue fixed with 10% formalin. Immunohistochemistry and pathological examinations were then performed.

### Detect the cell inhibition ratio by MTT method

Cells were cultured in 1640 liquid culture media containing

20% calf serum, and transferred into 1640 liquid without calf serum after 24 h, prepared at a 5 × 10<sup>4</sup>/mL cell suspension and added into a 96 well plate with 0.1 mL suspension in each well. For every dose group, a set of 3 auxiliary wells were prepared and we added DHDMBF30 of different concentrations, set the final concentrations at 5 μmol/L, 10 μmol/L, 15 μmol/L, and 20 μmol/L with the total volume of 100 μL and continued to culture the cells. Added 20 μL 5 mg/mL MTT 4 h before stopping drug at 12, 24, 36 and 48 h, then returned the culture plate into the CO<sub>2</sub> incubator at 37°C for 4 h (the cells would deoxidize the yellow MTT to hyacinthine crystallization under the action of SDH). Next we aspirated and discarded 90% of the culture liquid in the wells, added 100 μL DMSO into each well and thoroughly shook the wells for 10 min to completely dissolve the crystals. We determined the A values of each well at the wavelength of 570 nm, and calculated the GIR of the cells. We repeated the experiment 6 times. Calculated GIR with the formula:

GIR (%) = A value of control pore - A value of experimental pore × 100% A value of the control pore.

### Detect the Capan-2 cell apoptosis with flow cytometry

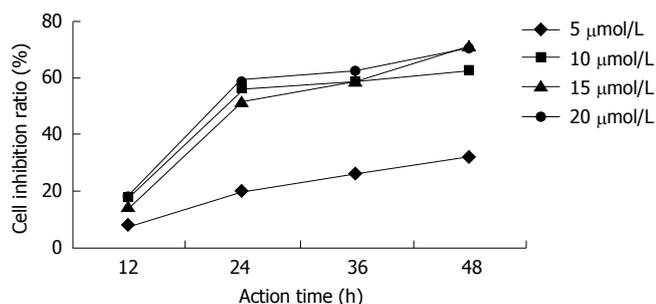

After the cells were cultured in the 1640 liquid culture media containing 20% calf serum for 24 h, the liquid was replaced with the 1640 liquid culture media without calf serum for another 24 h culture, and finally the cells were digested with 0.25% trypsin and 0.02% EDTA to prepare a unicell suspension with the cell concentration at about 5 × 10<sup>5</sup>/mL. The suspension was plated into a 6-well plate with 1 mL suspension in each well. The control group was drug free; 12 μmol/L DHDMBF30 was added to the experimental group and cultured for 24 h again. We repeated this experiment 3 times. Suspensions were also prepared and stained with propidium iodide (PI), then injected the suspension.

### Sample preparation for transmission electron microscopy

Cells from the control and experimental groups were fixed, dehydrated, replaced, soaked and embedded, prepared semi thin sections, stained with electrons and observed for ultra structural structures.

### RT-PCR

**Process:** (1) Collect the cells from the control and experimental groups: take cells cultured for 24 h, digest with 0.25% trypsin to prepare unicell suspension, centrifuge at 500 r/min for 10 min, collect the cell precipitates and rinse with 0.01mmol/L PBS (pH = 7.4) for one time, then store at -70°C; (2) Extraction of total RNA of the cell: extract the total RNA with the Trizol<sup>®</sup> kit, learn about the integrity of the extracted RNA by formaldehyde denaturing gel electrophoresis, determine A<sub>260 nm</sub> and A<sub>280 nm</sub> values by ultraviolet spectrophotometer to analyze its purity, and fix quantity at the same time; (3) The synthesis of cDNA: mix 1 μg RNA sample with 1.2 μL random hexamer primer, put them into an iced bath after annealing at 70°C for 5 min, then add 4 μL reverse transcriptase buffer, 1 μL 20-40 Mu/L Rnasin and 2 μL 10 mmol/L dNTP, mix them completely at 25°C for 5 min; add 2 μL MmuLV reverse transcriptase finally and add water to 20 μL volume, heat at 25°C for

**Figure 1** Effect of DHDMBF30 against the Capan-2 cell proliferation of human pancreatic cancer.

5 min, 37°C for 60 min and 70°C for 10 min, stop the reaction and store the reagents at 4°C; (4) PCR: the primer sequence of 5-LOX was 5'-CCCGGGGCATGGAGAGCA-3', 5'-GCGGTCGGGCAGCGTGTGTC-3'; COX-2: 5'-TTCA AATGAGATTGTGGAAAATTGCT-3', 5'-AGATCATC TCTGCCTGAGTATCTT-3'; VEGF: 5'-TTGCTGCTCTA CCTCCAC-3', 5'-AATGCTTTCTCCGCTCTG-3'; β-actin: 5'-GTGGGGCGCCCCAGGCACCA-3', 5'-CTCCTTAAT GTCACGCACGATTT-3'. The lengths of the amplification fragments were 416, 305, 418, 500 bp respectively; the reaction systems were 0.8 μL cDNA, 2 μL 10 × Taq enzyme buffer, 0.4 μL 10 mol/L dNTP, 0.8 μL 25 mmol/L MgCl<sub>2</sub>, the up and down stream primers were 0.4 μL and 0.5 μL Taq enzymes, and the water was added to 20 μL. PCR conditions: denature at 95°C for 45 s, anneal at 54°C for 90 s, elongate at 72°C for 90 s, and repeat for 30 cycles. At last, elongate at 54°C for 2 min and 72°C for 3 min. After the reaction, take out 10 μL amplification products to 17 g/L agarose gel for electrophoretic analysis. In order to compare the intensities of expression levels, scan the amplification bands by image analyzer for semi-quantitative analysis.

We detected the VEGF mRNA of the transplanted tumor by RT-PCR, and the VEGF protein by the immunohistochemistry SP method. We measured the absorbance of the immunohistochemistry stained slide by microspectrophotometer, chose 100 cells randomly in each slide, scanned the absorbance value of each cell at the wavelength of 460 nm and calculated the expression area, worked out their means to express the relative content of VEGF protein.

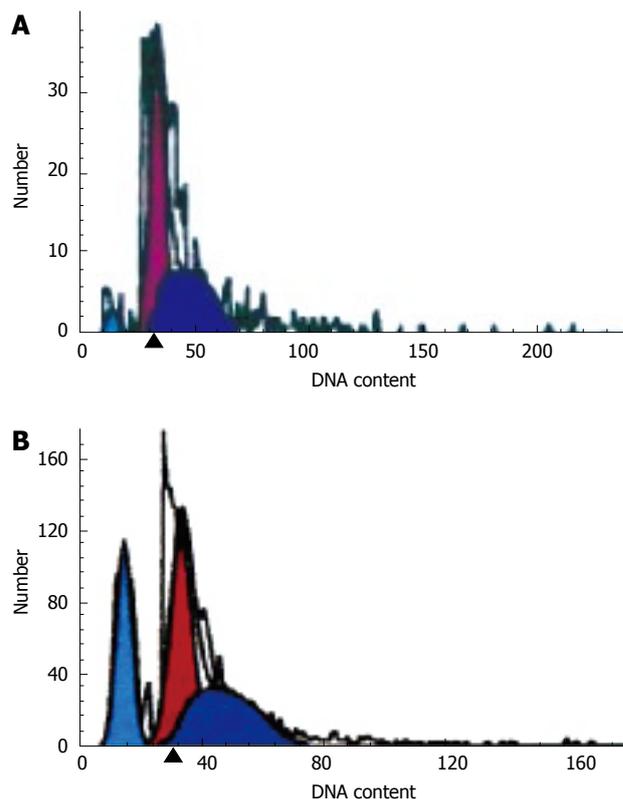

## RESULTS

### The effect of DHDMBF30 against the Capan-2 cell proliferation of human pancreatic cancer

After the actions of DHDMBF30 of different concentrations against Capan-2 cells for 12 h, 24 h, 36 h, 48 h, with the concentration increasing and the duration prolonging, the inhibition was strengthened, but after the concentration and the prolonged duration reached certain values, the inhibition ratio didn't increase anymore, but a plateau appeared, the IC<sub>50</sub> was 12 μmol/L and the inhibition ratio didn't increase after 24 h (Figure 1).

### Detect the Capan-2 cell apoptosis rate with flow cytometry

There was an apoptosis peak of Capan-2 cells (3.08 ± 1.89)

**Figure 2** Apoptosis rate of Capan-2 cells. A: Before the treatment of DHDMBF30; B: After the treatment of DHDMBF30.

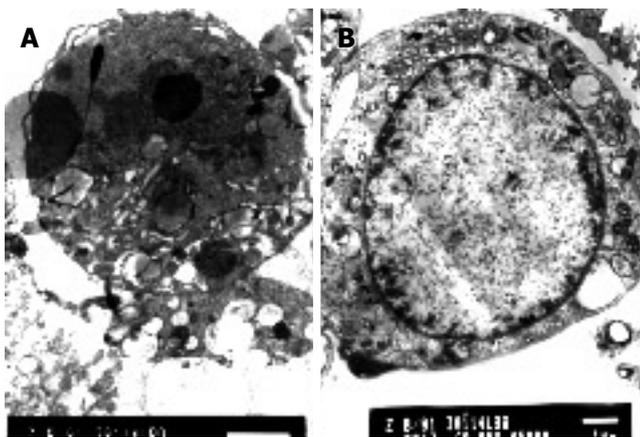

before G<sub>0</sub>/G<sub>1</sub>, and the peak (27.67 ± 0.52) was higher after the treatment by DHDMBF30, which was significantly different compared with the control group (P < 0.001) (Figure 2).

### Observation by transmission electron microscope

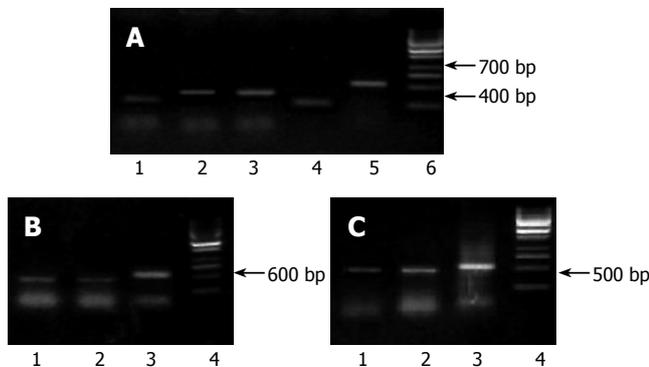

The Golgi's complexes in the Capan-2 cells of the control group were developed, there were a lot of rough endoplasmic reticula, chondrosomes were swelling, the karyoplasmic ratio was high, the karyotheca showed depressed wrinkles, and the chromatins were abundant in the nucleus and nucleoli were large. After a 12 h treatment with DHDMBF30, microvilli of most of the cell surface were reduced, the cell volume was decreased and the cytoplasm concentrated, a large number of vacuolar degenerations appeared in some cells; the cell nucleus was shrunk, the karyotheca existed but the nucleolus disappeared, the dyeing of chromatins was darkened and the latter congregated into masses adjoining the karyotheca; 24 h later, the membrane became smooth and the cytoplasm continued to condense, there were concentrated nuclear fragments, and some cells produced apoptotic bodies through budding. The following figures show the nuclear fragments enclosed by membrane structures and degenerated cell organs (Figure 3).

### The expressions of 5-LOX and COX-2 genes in the pancreatic cancer Capan-2 cells and the inhibition of DHDMBF30 against them

In the electrophoretic analysis on RT-PCR products of pancreatic cancer cell strains in the control group, one

**Figure 4** The effect of DHDMBF30 against different mRNA. **A:** Against 5-LOX mRNA and COX-2-mRNA in Capan2 cells. Lane 1: COX-2 after inhibition; Lane 2: 5-LOX after inhibition; Lane 3: 5-LOX before inhibition; Lane 4: COX-2 before inhibition; Lane 5:  $\beta$ -actin; Lane 6: Marker; **B:** Against VEGF mRNA in Capan2 cells. Lane 1: Control group; Lane 2: Treatment group; Lane 3:  $\beta$ -actin; Lane 4: Marker; **C:** Against the VEGF mRNA of transplant pancreatic tumor cell in the hairless mice. Lane 1: Treatment group; Lane 2: Control group; Lane 3:  $\beta$ -actin; Lane 4: Marker.

416 bp and one 304 bp amplification bands could be observed; the 416 bp and 304 bp amplification bands also existed in the experimental group, but the brightness was lowered (Figure 4A), which demonstrated that there were expressions of 5-LOX and COX-2 genes in the Capan-2 cells of pancreatic cancer, and the inhibitor decreased their expressions.

#### **The effect of DHDMBF30 against VEGF mRNA in Capan2 cells of the human pancreatic cancer**

A 418 bp band was obtained in the electrophoretic analysis of RT-PCR products from the pancreatic cancer cell strains in the control group, and there was also a specific 418 bp amplification band with a lower brightness in the experimental group (Figure 4B).

**The growth conditions of the transplant tumor:** The subcutaneous tumor began to form 2-3 wk after the inoculation, and the volume reached 2-3 cm 4-5 wk later. In the PBS control group, the transplant tumor formed in all the inoculation regions, and all of the tumor volumes

**Table 1** The inhibition of DHDMBF30 against the transplant human pancreatic tumor in the hairless mice

Groups	Tumor formation rate (%)	Tumor weight (g)
DHDMBF30 group	67 (4/6)	1.35 $\pm$ 0.47 <sup>b</sup>
PBS group	100 (6/6)	2.92 $\pm$ 0.73

<sup>b</sup> $P < 0.01$  vs PBS group.

**Table 2** The effect of DHDMBF30 against VEGF proteins of the transplant pancreatic tumor

Groups	Absorbance	Expression area ( $\mu\text{m}^2$ )
Experimental group	36.36 $\pm$ 7.23 <sup>b</sup>	45.82 $\pm$ 9.67 <sup>b</sup>
Control group	66.61 $\pm$ 9.63	73.06 $\pm$ 8.45

<sup>b</sup> $P < 0.01$  vs control group.

were large, the tumor formulation rate was 100% (6/6); while the formulation rate in the experimental group was 67% (4/6) and the volume was small. The subcutaneous tumors grew slowly and the tumor bodies were hard, they were all fixed on the lateral side of the thigh. When the diameter of the tumor body reached 25 mm in the advanced stage, gross nutrition vessels could be observed on the skin upon the tumor body.

The growth of transplant tumor under the skin of the hairless mice and the change of tumor weight: the growth rate of the transplant pancreatic tumor in hairless mice of the experimental group was obviously lower than the PBS control group; the tumors could be touched on the 14th d in the PBS group, while it was the 20th d in the experimental group. The average weight of the hairless mice in the experimental group was (1.50  $\pm$  0.52) g, which was significantly lower than (2.18  $\pm$  0.96) g of the PBS control group ( $P < 0.01$ ) (Table 1).

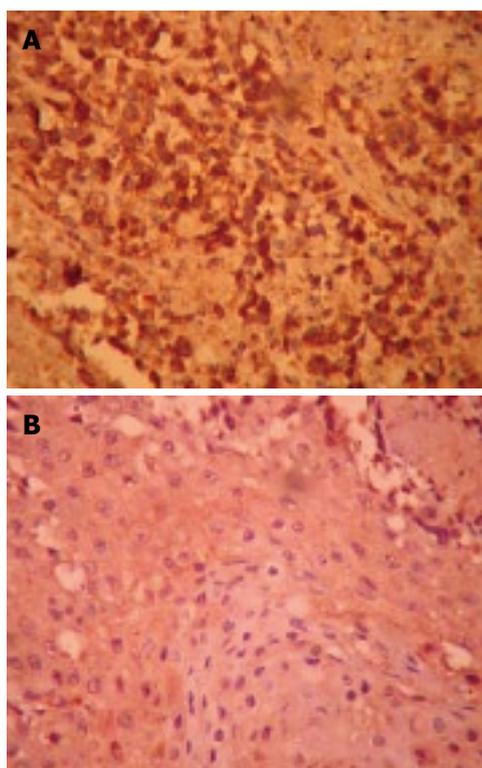

#### **Detection of VEGF mRNA and proteins**

**The detection results of VEGF mRNA:** The 418 bp band amplified in transplant tumor indicated the expression of the VEGF mRNA, and the brightness of VEGF mRNA band in the DHDMBF30 treating group was obviously lowered (Figure 4 C).

**The expression of VEGF protein:** The results of immunohistochemistry showed that the VEGF expression was positive in the transplant human pancreatic tumor in the hairless mice of the control group. Positive buffy granules could be seen in the cytoplasm of the pancreatic cancer cells; the cytoplasm of pancreatic cancer cells of the DHDMBF30 group stained lightly, and the stained cell number was small, so it was weakly positive. Please refer to the table for the comparison of absorbance and expression area (Figure 5; Table 2).

## **DISCUSSION**

NSAIDs mainly act against the mechanism of arachidonic acid (AA) to produce a marked effect. There are two major

**Figure 5** The VEGF expression of different group. **A:** Control group; **B:** DHDMBF30 group.

metabolic enzymes of AA: lipoxygenase (LOXs) and cyclooxygenase (COXs)<sup>[7,8]</sup>. It has been found in a large number of studies in recent years that, 5-LOX and COX-2 of the lipoxygenase and cyclooxygenase can not only act against infections, but also relate to the pathogenesis, development and transfer of the tumors<sup>[9-14]</sup>. Luo *et al*<sup>[15]</sup> reported that 5-LOX in the endothelial cells could promote the generation of cancer, colonitis, psoriasis, *etc.* Ohno, *et al*<sup>[16-19]</sup> determined the expression quantity of COX-1 and COX-2 of the surgical sample obtained from gastric cancer in 33 patients by RT-PCR, stained the COX-2 antibody in the sample with immunohistochemistry staining and did routine histology examination at the same time, and they found that the COX-2 expression index in the gastric cancer was significantly higher than the normal mucosa (3.4-0.7 *vs* 2.2-0.7,  $P < 0.05$ ), and the index of COX-2 increased with the infiltration of gastric cancer advancing.

Tenidap developed by Pfizer was a drug with a double inhibition effect against COX/5-LOX, and it was demonstrated in the clinical trials that its therapeutic effect was superior over other NSAIDs, such as diclofenac sodium, Naproxen, *etc.*, but its hepatotoxicity was high, so it was withdrawn before long it came into the market. There was still a study in which the effect of the combination of COX-2 and 5-LOX inhibitors against the tumor was observed. At present, the researchers dedicated themselves to research and develop the selective 5-LOX/COX-2 double inhibitors, the DHDMBF had a certain double inhibition effect<sup>[20-22]</sup>, through modifying the cycles or sites, researchers obtained more than 30 chemicals, among which the effect of DHDMBF30 was

good both *in vivo* and *in vitro* and its inhibition ratio against COX-1 was extremely low, but there was no study on its effect against tumors. We found in our study that, 24 h after DHDMBF30 of different concentrations acted against Capan-2 cells, the inhibition ratio of the higher concentration group to Capan-2 was obviously increased; after the DHDMBF30 treatment on Capan-2 cells, the cellular morphologies were obviously altered, the granules and vacuoles were increased, some cells contracted and became rounder, the cell membrane shrunk, many cells dropped from the glass wall and were suspended in the culture liquid, and the dropped cells gradually increased with duration in culture and increasing drug concentration. Twenty-four hours later, the cellular membrane became smoother and the cytoplasm continued to condense, concentrated nuclear fragments could be observed and apoptotic bodies were produced in some cells through budding. In the detection of Capan-2 cell apoptosis by flow cytometry, it was found that there was an apoptosis peak of the Capan-2 cells in the control group before G<sub>0</sub>/G<sub>1</sub>, and the peak was heightened after the treatment of DHDMBF30, the results were significantly different compared with the control group<sup>[23,24]</sup>.

In former studies, COX-2 or 5-LOX inhibitors were separately applied to interfere in the tumor cells, and their effects were observed. Recently, some researchers have combined selective COX-2, 5-LOX inhibitors or broad-spectrum inhibitors to act against the tumor cells to maximally kill the tumor cells, but with increasing dose, the side effects were certainly increased. Thereby, we applied one drug to observe its effect in order to obtain the optimal therapeutic effect. As a common clinically applied and symptomatic treating drug for arthritis, the side effects of NSAIDs in the gastrointestinal tract were common, so the pharmaceutical chemists at home and abroad had always tried to find a new anti-inflammatory agent of high efficiency and low toxicity. The inhibiting concentration ratio (IC<sub>50</sub>) of NSAIDs against COX-2/COX-1 could reflect the side effects of the drug for the applied anti-inflammatory dose: if the COX-2/COX-1 IC<sub>50</sub> was less than 1, the drug could selectively inhibit COX-2, the anti-inflammatory effect was strong while the side effects on stomach and kidney were less; if the COX-2/COX-1 IC<sub>50</sub> was more than 1, the drug could strongly inhibit COX-1 with more side effects. Garcia Rodrigues and Jick<sup>[25]</sup> publicized epidemiological statistics data of the side effects of NSAIDs, the results confirmed that the inhibition concentration ratio of COX-2/COX-1 and side effects of gastrointestinal tract had a parallel relationship. The selective COX-2 inhibitor meloxicam, which had been registered in our country and some other countries, was designed to treat rheumatoid arthritis and ostarthritis, it had stronger anti-inflammatory effects and fewer side effects, and its inhibiting concentration ratio to COX-2/COX-1 was 0.07. The DHDMBF30, which we chose, was synthesized in recent years, its inhibiting concentration ratio to COX-2/COX-1 was 0.03, and the effect was good in both *in vivo* and *in vitro* experiments<sup>[26-30]</sup>.

By using RT-PCR, we confirmed Capan2 cell expressed 5-LOX mRNA, COX-2 mRNA and VEGF mRNA,

and the expression of 5-LOX mRNA, COX-2 mRNA, VEGF mRNA was obviously decreased after the treatment of DHDMBF30; morphologic changes of shrinkage and apoptosis were also observed by microscope and electron microscopy; flow cytometry detected that the apoptosis rate of Capan2 cells was significantly increased. DHDMBF30 could inhibit the proliferation of Capan2 cells and induce its apoptosis, down regulate the vascular endothelial growth factors; its effect was better than the single application of COX-2 or 5-LOX inhibitor, and it could make up the ineffective result if the 5-LOX or COX-2 was not expressed.

The tumor formation rate, the weight and volume of the tumor body of the hairless mice in the DHDMBF30 treating group were all significantly less than those of the PBS control group, and no side effects were observed at the same time. The VEGF expression of the transplant pancreatic tumors in hairless mice was decreased, and the division, growth and assorting effects on the vascular endothelial cells in the tissues were lowered. Meanwhile, it inhibited the increase of vasopermeability and decreased the exudation of matrix ingredients such as blood plasma from the tissue, the foundations on which the vascular endothelial cells and tumor cells relied were eliminated, and thereby the goal of tumor growth inhibition was achieved.

The regional injection of DHDMBF30 could inhibit the growth of pancreatic cancer, and the manifestations were the prolonged incubating stages of the tumor and the lighter tumor weight ( $P < 0.01$ ). But DHDMBF30 still could not completely inhibit the tumor growth, which might be related to the dose, and it was demonstrated that the dose-effect relationship and time-effect relationship should be further studied.

## COMMENTS

### Background

The prevention and treatment mechanism of non-steroid anti-inflammatory drug (NSAIDs) against tumors are still not clear now. In our early phase study, it was demonstrated that the expression rates of 5-lipoxygenase (5-LOX) and cyclooxygenase-2 (COX-2) in the pancreatic cancer tissues were respectively 74.3% and 80%<sup>[5,6]</sup>, and all the pancreatic cancer tissues expressed 5-LOX or COX-2, sometimes expressed both, which supported that there were crossed and complementary expressions, so the designed 5-LOX/COX-2 dual inhibitor can exert a synergic effect.

### Research frontiers

It has been found in a large number of studies in the recent years that, 5-LOX and COX-2 of the lipoxygenase and cyclooxygenase can not only act against infections, but also relate with the pathogenesis, development and transfer of the tumors<sup>[9-14]</sup>. At present, the researchers dedicated themselves to research and develop the selective 5-LOX/COX-2 double inhibitors, the 7-tert-butyl-2,3-dihydro-3,3-dimethyl substituted dihydrofuran (DHDMBF) had certain double inhibition effect<sup>[20-22]</sup>, through modifying the cycles or sites, researchers obtained more than 30 chemicals, among which the effect of DHDMBF30 was good both *in vivo* and *in vitro* and its inhibition ratio against COX-1 was extremely low, but there was no study on its effect against tumors.

### Innovations and breakthroughs

DHDMBF30 inhibits the proliferation of Capan2 cells and induces its apoptosis, down regulates the vascular endothelial growth factors; its effect was better than the single application of COX-2 or 5-LOX inhibitor, and it could make up the ineffective result if the 5-LOX or COX-2 was not expressed.

### Applications

The regional injection of DHDMBF30 could inhibit the growth of pancreatic cancer, and the manifestations were the prolonged incubating stages of the tumor and the lighter tumor weight ( $P < 0.01$ ). We chose the 5-LOX/COX-2 dual inhibitor DHDMBF30 to act against pancreatic cancer, and observed its anticancer effects.

### Terminology

NSAIDs: Non-steroid anti-inflammatory drug. DHDMBF: The selective 5-LOX/COX-2 double inhibitors, the 7-tert-butyl-2, 3-dihydro-3, 3-dimethyl substituted dihydrofuran.

### Peer review

This article is interesting which studied the effect of a kind of 5-LOX/COX-2 dual inhibitor on proliferation and apoptosis of pancreatic cancer cell line Capan2 and the effect of it on human pancreatic cancer in nude mice model. It provided a foundation for its clinical application.

## Abstract

**AIM:** To investigate the molecular pathways involved in human cholangiocarcinogenesis by gene expression profiling.

**METHODS:** Oligonucleotide arrays (*Affymetrix* U133A) were used to establish a specific gene expression profile of intrahepatic CCC in comparison to corresponding non-malignant liver tissue. To validate the expression values of the most overexpressed genes, RT-PCR experiments were performed.

**RESULTS:** Five hundred and fifty-two statistically differentially expressed genes/ESTs (221 probes significantly up-regulated, 331 probes down-regulated;  $P < 0.05$ ; fold change  $> 2$ ;  $\geq 70\%$ ) were identified. Using these data and two-dimensional cluster analysis,

a specific gene expression profile was obtained allowing fast and reproducible differentiation of CCC, which was confirmed by supervised neuronal network modelling. The most consistently overexpressed gene (median fold change 33.5, significantly overexpressed in 100%) encoded osteopontin. Furthermore, an association of various genes with the histopathological grading could be demonstrated.

**CONCLUSION:** A highly specific gene expression profile for intrahepatic CCC was identified, allowing for its fast and reproducible discrimination against non-malignant liver tissue and other liver masses. The most overexpressed gene in intrahepatic CCC was the gene encoding osteopontin. These data may lead to a better understanding of human cholangiocarcinogenesis.

## INTRODUCTION

Cholangiocarcinoma (CCC) is the second most common primary hepatic malignancy next to hepatocellular carcinoma (HCC), arising from cholangiocytes of intra- or extrahepatic bile ducts. In contrast to HCC, cholangiocarcinomas are, in most cases, adenocarcinomas and relatively hypovascularised. Two principal forms of these tumors are recognized based on the clinical presentation<sup>[1]</sup>. The most common form is a highly desmoplastic cancer with a growth pattern characterized

by periductal extension and infiltration, leading to an early onset of jaundice as one of the first clinical signs of this disease (perihilar and distal extrahepatic CCC). The other form of CCC grows as a mass lesion within the liver, very often leading to the misdiagnosis of hepatocellular carcinoma or metastatic adenocarcinoma (intrahepatic CCC).

Despite recent progress in various imaging modalities the neoplasm lesion is, in most cases, advanced by the time of diagnosis. Thus, curative treatment options by surgical resection are limited, leading to a poor prognosis with median survival times of only three to six months, especially in patients with intrahepatic CCCs<sup>[2,3]</sup>.

Recent epidemiologic studies have shown an increasing incidence of CCC in western countries<sup>[4,5]</sup>. In most patients with CCC, no risk factors for cholangiocarcinogenesis can be identified. However, established risk factors for ductal cholangiocarcinoma include diseases leading to chronic inflammation of the bile ducts, such as infections with *Clonorchis sinensis*, *Opisthorchis viverrini* (liver flukes) and chronic viral hepatitis, chronic intrahepatic lithiasis, primary sclerosing cholangitis (PSC), congenital diseases (Caroli disease, congenital choledochal cysts) and exposure to the radiopaque medium thorium dioxide (Thorotrast)<sup>[6-8]</sup>. In particular, patients with PSC have an increased risk for cholangiocarcinogenesis and epidemiologic studies have shown a lifetime risk for CCC of approximately 1.5% per year of disease<sup>[9]</sup>.

Despite this knowledge about the major role of chronic inflammation in cholangio-carcinogenesis, little is known about the molecular pathways involved in CCC that lead to uncontrolled cell growth, downregulated apoptosis and, as a result, to tissue invasion.

Therefore, it is important to identify the genes involved in these molecular pathomechanisms, as this may shed light on the specific tumor biology and help to establish prognosis patterns as well as specific markers for screening in patients with a known increased risk for CCC (for example, patients with PSC). At present, the most commonly used markers in CCC include tumor antigens or products, such as CA 19-9, cytokines (for example, interleukin-6), (epi-)genetic lesions (for example, *K-ras* and p53 mutations), and metabolic products as lactate and proteases (for example, trypsinogen-2). However, none of these have been proven to be a useful diagnostic tool with high specificity and sensitivity for CCC<sup>[9]</sup>.

Today, high-throughput techniques using cDNA or oligonucleotide arrays for the simultaneous and fast analysis of thousands of genes are available, potentially leading to the identification of new markers and subclassification of various human carcinomas<sup>[10-12]</sup>. In the present study oligonucleotide arrays (HU 133A, *Affymetrix*) containing more than 20 000 genes and expressed sequence tags (ESTs) were used to analyze gene expression in intrahepatic CCC tissues. The aim was first to detect specific genes (by comparison with genes expressed in non-malignant liver tissue) that may be helpful for discrimination between non-malignant and different malignant liver masses, and to establish a specific diagnostic genetic profile of intrahepatic CCC for clinical

routine, and second, to elucidate the genetic pathways that are typically altered in cholangiocarcinogenesis.

## MATERIALS AND METHODS

### Acquisition of samples

Surgical specimens were obtained from 10 patients who underwent surgical treatment with curative intention for intrahepatic CCC between 2003 and 2004 (Table 1). In 8 cases, the adjacent corresponding non-malignant liver tissue was also acquired for microarray analyses. No patient received preoperative or adjuvant chemo- or radiotherapy.

Samples were resected after appropriate informed consent was obtained and the genetic analysis of the tumor and liver tissue was conducted in accordance with the guidelines of the Declaration of Helsinki (1995) and approved by the local ethic committee. Samples of sufficient weight (> 400 mg) from malignant and corresponding non-malignant liver tissue were excised and snap-frozen in liquid nitrogen within 20 min after excision. Until RNA isolation, samples were stored constantly at -80°C.

### Histopathological evaluation

The various architectural patterns and cytological variants of cholangiocarcinoma and especially hepatocellular may complicate the differentiation of primary liver tumors and even that between primary liver tumors and metastases. Therefore, pathological reports with tumor typing, staging (performed using UICC criteria) and grading as well as clinical data were obtained for each tissue sample. Hematoxylin-eosin staining was performed for detection of features like bile canalicular structure and Mallory hyaline bodies. Additional histochemical and immunohistochemical stainings with a panel of antibodies were used routinely (HEP-PAR-1, CK7, CA19-9, CD10, CEA, AFP; Figure 1A and B) in all resected tissue biopsies to confirm the histogenesis of cholangiocellular carcinoma and to exclude hepatocellular carcinoma or metastases. In particular, CK7 is used as an important marker for CCC, as it is significantly overexpressed in CCC compared with HCC and most cases of other adenocarcinoma<sup>[13]</sup>.

### Oligonucleotide array analysis

**Sample preparation:** Samples were processed with only minor modifications according to the Affymetrix GeneChip® Expression Analysis Manual (Santa Clara, CA/ USA). For the extraction of total RNA frozen samples were homogenized in Trizol (Invitrogen, USA). The total RNA yield for each sample was 200-400 µg. After washing with DEPC-treated water (Ambion, USA), total RNA was cleaned using RNEasy mini kits (Quiagen). The amount of total RNA was measured photometrically using a BIO-Photometer (Eppendorf; OD1 E260 = 40 µg/mL).

**Preparation of labeled cRNA and hybridization to oligonucleotide arrays:** For transcription of total RNA into cDNA, 8 to 10 µg of total RNA was used for cRNA preparation using the SuperScript Choice system (Invitrogen, USA). First-strand cDNA synthesis was primed using a T7-(dT24) oligonucleotide primer

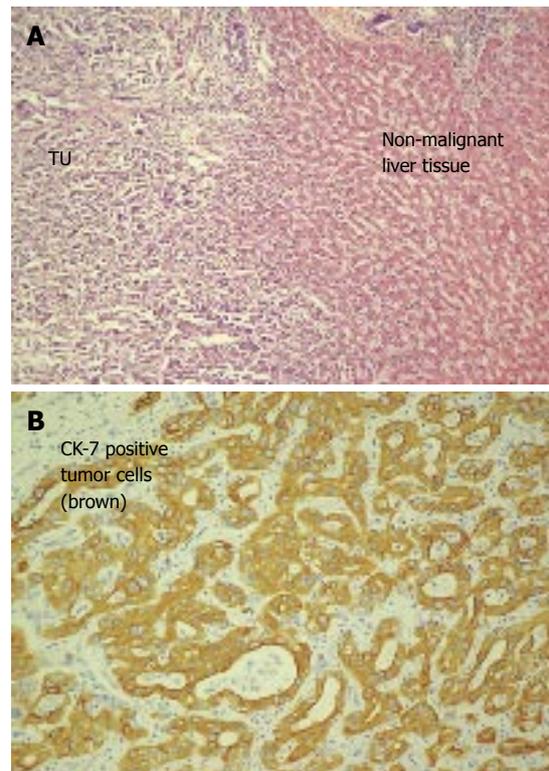

Table 1 Patient demographics and histopathological data

Patient No.	Sex	Age	Histology	Stage	Grading
1	F	57	Adenocarcinoma	pT3pNxpM0	G3
2	F	65	Adenocarcinoma	pT3pN0pM0	G2
3	F	68	Adenocarcinoma	pT2pNxpM0	G2
4	M	74	Adenocarcinoma	pT3pN1pM0	G3
5	F	62	Adenocarcinoma	pT3pN0pM0	G2
6	F	47	Adenocarcinoma	pT3pNxpM0	G2
7	M	73	Adenocarcinoma	pT3pN0pM0	G2
8	F	71	Adenocarcinoma	pT2pNxpM0	G2
9	M	52	Adenocarcinoma	pT3pN2pM0	G2
10	M	65	Adenocarcinoma	pT3pNxpM0	G1

with an RNA polymerase promoter site added to the 3' end. After second-strand synthesis, *in vitro* transcription was performed in the presence of biotin-11-CPT and biotin-16-UTP (Enzo Diagnostics) to produce biotin-labeled cRNA. After fragmentation of the cRNA products (20 µg at 94°C for 35 min) to lengths of 35-200 bp, the samples were added to a hybridization solution to a final cRNA concentration of 0.05 mg/mL. Hybridization was performed by incubation (18-20 h) of 200 µL of the sample to an Affymetrix human GeneChip (Hu 133A) containing 22283 probe sets for known genes/ESTs and stained with streptavidin-phycoerythrin. A Gene Array scanner G2500A (Hewlett Packard, ID) was used to scan the arrays according to procedures described in the Affymetrix manual.

To validate the relative change in gene expression of the most consistently overexpressed gene in all tumor samples (osteopontin, OPN), further analysis with real-time PCR using the LightCycler® system (Roche Diagnostics, Mannheim, Germany) was performed in 8 samples (tumor tissue *vs* corresponding non-malignant liver tissue).

Gene-specific primers corresponding to the coding region were designed using OLIGO software and were obtained from Biomers.net (Ulm, Germany; forward primer OSTEO: 696 U; GGACAGCCGTGGGAAGG, reverse primer OSTEO 810 L; TCAATCACATCGGAATGCTCA). Preliminary experiments were performed to test for the specificity of product formation, determine annealing temperatures, and check for  $T_m(\text{Product-Primer Dimer}) > 3^\circ\text{C}$ . Validation experiments were performed within a fluorescence signal window excluding primer-dimer formation. The correct PCR efficiency for each target was determined by constructing relative standard curves using five-point half-logarithmic RNA dilutions from one sample. Template concentrations were given arbitrary values of 1, 0.316, 0.1, 0.0316 and 0.01. RT-PCR reactions were performed using the LC RNA Amplification Kit containing SYBR Green I, (Roche Diagnostics; Mannheim, Germany). Amplification was followed by melting curve analysis. Relative values for the initial target concentration in each sample were determined using Light Cycler software 3.5. Crossing points ( $C_p$ ) were computed using the "2nd derivative maximum method", part of the software above. The relative change in gene expression was computed by pairwise comparison of tumor samples

**Figure 1** A: HE staining of infiltrative intrahepatic cholangiocarcinoma (Patient No. 6; left tumor tissue with cells of a moderate (G2) differentiated adenocarcinoma, right non-malignant liver tissue); B: Detection of cytokeratin 7 in intrahepatic cholangiocarcinoma (same patient as in A) using immunohistochemistry. Cytokeratin 7 was detected in over 80% of all analyzed CCCs strongly overexpressed (14.6-fold change).

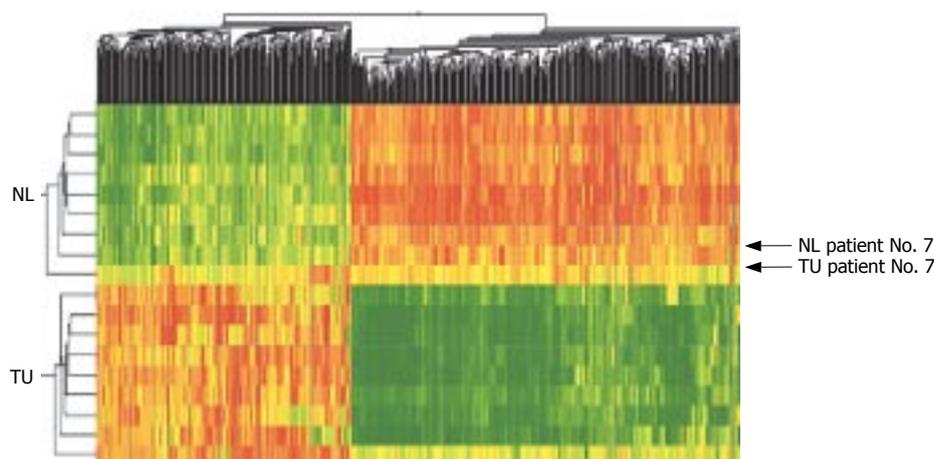

to samples of adjacent normal tissue for each patient.

### Statistical analysis

The statistical analyses and presentation of the obtained data were performed in accordance with the MIAME criteria and will be published on the web page ([www.matri-gene.de/geneprofiles/CCC](http://www.matri-gene.de/geneprofiles/CCC)).

**Preliminary data analysis:** Raw data analysis was conducted using the software of the Affymetrix microarray suite (MAS *vs* 5.0.1). MAS produced an expression value plus an index parameter indicating positive or negative detection (present call index) for each of the 22283 probe sets (known genes/ESTs) on the array. Statistical analysis and post-processing were performed using GeneSpring (*vs* 6.1; Silicon Genetics, Redwood City, CA) and Gene-Explore (*vs* 1.1; AppliedMaths, Saint-Martens-Latem, Belgium) software. Mismatch probes acted as specific controls on each array and allowed the direct subtraction of both background and cross-hybridization signals. Only Chip results with scaling factors of 0.5 to 1.8 were accepted for further analyses. Expression values were log<sub>2</sub> transformed on the basis of the signal log ratio, given by the comparison of two array results between tumor and non-tumorous tissues.

A *P*-value cut off of  $< 0.05$  (*t*-test) and a fold change difference of  $\geq 2$  in 70% or more of all analyzed samples were considered to be significant.

**Figure 2** Two-dimensional cluster analysis of CCC (TU) and corresponding non-malignant liver tissues (NL) using 552 dysregulated genes/ESTs (red: overexpressed genes, green: downregulated genes; Pearson's correlation). Dysregulation was defined as different genetic expression in > 70% of all probes with a fold change > 2.0. Horizontal lines show all dysregulated genes in one singular tissue probe, vertical lines show the expression of one gene in all analyzed tumor and non-malignant tissue probes. Using cluster analysis a fast differentiation between tumor tissue and non-malignant tissue was possible in 90% of cases (tumor tissue of Patient No. 7 showed many genetic similarities to non-malignant liver tissue).

**Second analysis step - Hierarchical clustering and supervised analysis:** To identify differentially expressed genes in CCC, normalized expression data on statistically different genes were used for a paired data analysis by hierarchical clustering with gene trees/experiment trees using either Pearson's correlation or standard correlation algorithms (Genespring *vs* 6.1; GeneExplore *vs* 1.1).

The class predictor program (supplied by GeneSpring 6.1) was used for supervised learning and training (neuronal training) to identify unknown probes as tumor or non-tumorous tissue. A list of the most predictive genes was made for each class and an equal number of genes with the lowest *P*-value using Fischer's exact test were taken from each list. To make a prediction, the class predictor uses the k-nearest-neighbour method.

To detect statistically differentially expressed genes in well and poor differentiated intrahepatic CCC (genetic subclassification), a 1-way ANOVA test was performed. In a second step significantly dysregulated genes ( $P < 0.05$ ) in tumor samples were used for a weighted two-dimensional clustering.

#### Identification of significantly altered metabolic pathways involved in cholangiocarcinogenesis:

To identify specific signaling or metabolic pathways involved in cholangiocarcinogenesis data on significantly differentially expressed genes were transferred to a public domain software program (GenMAPP 2.0 beta<sup>©</sup>Gladstone Institutes, 2000-2004).

## RESULTS

### Gene expression profiling of intrahepatic CCC

Primary chip data were screened for RNA quality by 5' to 3' degradation. Of the 22283 probes (genes/ESTs) present on the chip, on average, 43.3% (SD  $\pm$  4.53) and 39.0% (SD  $\pm$  3.48) of genes were expressed in CCC and corresponding non-malignant tissue samples.

Based on the primary data an algorithm was developed to identify and rank the most consistently up- and downregulated genes in CCC compared with non-malignant tissue. All statistically different genes ( $P < 0.05$ ) with a fold change of at least a 2-fold increase or decrease in 70% or higher percentage of the CCC tumor samples

were used to generate a databank of 552 genes/ESTs. Of these, 221 were upregulated and 331 were downregulated. This set of data was used for two-dimensional clustering. Ninety percent of all tumor samples showed a consistent pattern of up- and downregulated genes; only 1 case (No. 7) showed characteristics of both tumor and non-tumor tissue (Figure 2).

To further test the robustness of this cluster, a supervised learning method (SLM) based on neuronal networking was applied. An optimal prediction with subsequent cross-validation was obtained using all significantly dysregulated genes/ESTs and 8 neighbors; using this, all 10 tumor samples could be correctly identified. This resulted in a positive prediction value of 90% ( $P < 0.001$ ) and a negative predictive value of 100% ( $P < 0.00023$ ) of the Gene cluster with the expression pattern of the 552 probes (Table 2).

Using these data, even a specific and fast discrimination between intrahepatic CCC and other malignant liver tumors (HCC, metastases; data not shown), with a high predictive value ( $P < 0.001$ ), was possible by two-dimensional cluster analysis and SLM.

### Dysregulated genes and specifically involved metabolic pathways in intrahepatic CCC

CCC gene expression profile data were imported into GeneMapp software to identify specific changes in molecular pathways. Of the 552 dysregulated genes, a total of 364 genes could be assigned to specific metabolic or signaling pathways. Most of the consistently and strongly overexpressed genes were related to cell cycle regulation and DNA replication (15 genes, including *ribonucleoside-diphosphate reductase M2*, *calgizarrin*, *calcyclin*, *BUB1B*) or intracellular signaling (15 genes, including *CD24* and *MARCKS*), genes encoding transcription factors (6 genes, such as *SOX9*), or genes involved in nuclear organization and nucleic metabolism (13 genes, such as *thymidylate synthetase*). Most of the other up-regulated genes could be attributed to gene families, such as genes coding for extracellular matrix and cell adhesion molecules (37 genes, for example, *OPN*, *ADAM9*, *thymosin beta-10*, *integrin alpha-6*), cytoskeleton structure (16 genes, such as *tropomyosin2*, *cytokeratin 7* and *19*) or protein biosynthesis (4 genes).

Pat. No. 9, CCC	CCC	Malignant	0.00103
Pat. No. 10, CCC	CCC	Malignant	0.00103

Statistical results of the ability to differentiate between normal and malignant liver tissue (CCC) using a supervised neuronal training method. In all cases, a fast and correct differentiation was possible with a high positive ( $P < 0.001$  in 90%) and negative (100%,  $P < 0.00023$ ) predictive value.

According to an upregulation of genes involved in cell cycle regulation, most of the genes encoding proteins involved in cellular apoptosis (7 genes, such as growth-arrest specific protein 2, *CIDE-B*) were found to be down-regulated in intrahepatic CCC. Furthermore, a significant suppression of genes encoding proteins important for metabolic pathways like amino acid metabolism (39 genes), carbohydrate and fat metabolism (13 and 11 genes) or electron transport (27 genes) was noted. For clarity, only the 41 most consistently dysregulated (increased or decreased) genes ( $P < 0.001$ ; 4-fold change in 100%) are listed in Table 3.

#### Separation of well and poorly differentiated intrahepatic CCC by 2-dimensional cluster analysis

For subclassification of intrahepatic CCC in relation to histopathological differentiation (grading) a weighted two-dimensional clustering of the tumor samples was performed. All expressed genes/ESTs in the tumor samples (43.3%, approx. 9650 genes/ESTs) were grouped according to the histological grading ranging from 1 to 3 and then ranked according to their significantly differential expression values. Differentiation of the gene expression profiles of tumor samples, according to the histopathological grading of 1 and 3, identified a total of 136 dysregulated genes ( $P < 0.05$  and two-fold change upregulation or downregulation in  $\geq 70$ ), which were used for a weighted two-dimensional cluster analysis (Figure 3). Interestingly, upregulation of specific cell surface antigens such as cytokeratins (for example, cytokeratin 6, 7, 13 and 15) and specific membrane proteins (such as EMP1, EVA1 and proteoglycan 2) was detected in well differentiated tumor samples (G1, G2) when compared with more dedifferentiated tumor samples. In contrast, G3-tumor samples showed a relative overexpression of genes

involved in G-protein signaling and genes involved in transcription (Table 4).

#### Results of RT-PCR for detection of dysregulated OPN expression

The most consistently overexpressed gene (median fold change 33.5) in all analyzed intrahepatic CCC samples was that encoding the glycoprotein OPN.

To validate this observation the expression levels of OPN were confirmed by quantitative RT-PCR in 16 tissue samples (malignant and corresponding non-malignant tissue from 8 patients) using the LightCycler<sup>®</sup> system. In general, the changes in OPN expression levels detected by microarray reflected the results obtained by RT-PCR. However, the dynamic range of real-time PCR results was greater than that of the microarray data (Figure 4).

## DISCUSSION

The poor response of cholangiocarcinoma to therapy, along with the concerning worldwide increase in morbidity and mortality<sup>[4,5]</sup>, highlights the need for increased efforts to understand the etiology and pathogenesis of this primary liver cancer.

Previous studies have examined the potential role of known genes involved in human carcinogenesis to elucidate the molecular pathways involved in cholangiocellular carcinoma, for example, members of the type I family of growth factor receptors (EGF-R, c-erbB-2)<sup>[14-16]</sup>, (proto-) oncogenes (c-met, c-Ki-ras, Cyclin D)<sup>[17-19]</sup>, dysregulated tumor-suppressor genes (p53, pRB, p16INK4a, p21*WAF1*)<sup>[20,21]</sup>, and apoptosis-related genes (bcl2, FAS-L, BAX)<sup>[22,23]</sup>. Other studies have shown microsatellite instability and loss of heterogeneity (LOH) as contributing factors in the development of CCC<sup>[24,25]</sup>.

Excepting the actual data there are only two other reports using gene expression analysis to detect dysregulated genes and prognostic markers in cholangiocarcinogenesis<sup>[26,27]</sup>. The present study identified a high number of differentially expressed genes and ESTs in CCC (43.6 vs 39.01%,  $P > 0.05$ ). Based on a relatively conservative arbitrarily chosen algorithm, a gene expression profile of 552 dysregulated genes (221 genes upregulated, 331 genes downregulated) for CCC was generated. This profile was validated based on a neuronal training method by its ability to differentiate the CCC profile from the expression profiles of corresponding and non-corresponding non-malignant liver tissues. This method achieved a fast and reproducible differentiation between CCC and non-malignant liver tissue in all samples, as well as between CCC and other malignant tissues (HCC, liver metastases; data not shown). One tumor sample (No. 7) also showed characteristics of non-malignant liver tissue in that the tissue expressed a number of genes that were more frequently expressed in non-diseased human liver than in CCC samples. The sample was attributed to the non-malignant tissue group in two-dimensional hierarchical clustering. A potential reason for this could be a putative contamination of tumor sample with normal liver tissue, especially owing to the fact that no microdissection of tumor tissue was used. However, using a supervised neuronal training method to

reanalyze all of the obtained array data, correct assignment to malignant and non-malignant tissue groups was possible for all samples (including No. 7).

Previous studies have shown a correlation between differentially expressed genes and tumor progression or tumor dedifferentiation in various human tumors<sup>[28,29]</sup>. In the present study we used two-dimensional cluster

analysis with all expressed genes in the tumor samples (> 9000 genes/ESTs) for the detection of statistically significantly differentially expressed genes in relation to tumor differentiation (grading). This method detected 136 differentially expressed genes when tumor samples with low (G1) and high (G3) grading were compared. Because of the small number of analyzed tumor

**Figure 3** Subclassification of intrahepatic CCC using two-dimensional cluster analysis of 136 different regulated genes/ESTs (dysregulation in more than 70% of all probes, fold change of genetic expression > 2.0; Pearson's correlation) in relation to histopathological findings (well to poor differentiated tumor tissue). Horizontal lines show all dysregulated genes in one singular tumor tissue probe, vertical lines show the expression of one gene in all analyzed G1-, G2- and G3-tumors. Overexpressed genes are coloured red, downregulated genes are shown in green).

No data: No significant (< 2-fold change) or consistent (< 70% of all cases) change in the expression level of the gene in this subgroup of CCC (G1-, G2- or G3-tumors).

samples (one highly differentiated tumor (G1) among 10 samples) it was not possible to create an unambiguous clear correlation between all dysregulated genes and the histopathologic grading. However, an obvious trend towards a higher expression of specific cell surface proteins (EMP1, EVA1, proteoglycan2) and intermediate filaments (cytokeratin 6, 7, 13, 15, 17) in well-differentiated tumors was observed, whereas samples of high-grade intrahepatic CCC had an elevated expression of genes involved in G-protein signaling and nuclear transcription. Pathological alterations to the chemical composition, molecular structure, or spatial arrangement of the liver matrix will ultimately lead to specific changes in the intermediate filament pattern in human cholangiocytes. It can be assumed that the dedifferentiation of tumor cells in CCC results in pathological alterations of cell surface antigens, cell-to-cell and cell-to-matrix attachment, followed by a switch from physiological to pathological cell-activation. More investigations are needed to elucidate the role of dysregulated genes in tumor progression with histomorphological tumor dedifferentiation in cholangiocarcinogenesis.

To further validate the microarray data, real-time PCR

was performed. The gene encoding OPN was identified as the highest and most consistently overexpressed gene (33.5-fold change) in all analyzed tumor samples. The expression profile determined by real-time PCR correlated well with the resulting ratios carried out with the gene expression data of the analyzed CCC. However, as has been shown previously for other similar comparisons<sup>[30,31]</sup>, the dynamic range of real-time PCR was about 1.5-fold to 10-fold higher than that of array analysis.

Using oligonucleotide arrays we were able to identify genes already known to be dysregulated in other human cancers<sup>[32,33]</sup>. However, a significant number of the genes identified to show a significant alteration in their expression values, have not been known to be involved in cholangiocarcinogenesis until now. By incorporating the expression data into GenMAPP software, a specific pattern of signaling and metabolic pathways as well as changes in cell cycle regulators specific for CCC could be generated. For example, changes in apoptosis-regulating genes consistent with the decreased cell death rate typical of tumor cells were identified. Generally, the changes in cell cycle metabolism are well in line with a pattern of increased cell growth. However, the major focus of this

**Figure 4** Comparison between expression values of osteopontin in 8 intrahepatic CCCs estimated by RT-PCR (LightCycler®System; grey) and gene expression data (HU 133A, Affymetrix; white). The detected changes in osteopontin expression levels measured by RT-PCR reflected very well the changes in gene expression between tumor and non-malignant liver tissue obtained by microarray analysis. The results of RT-PCR revealed larger changes than the microarray data in all cases.

study was to establish a specific genetic profile of CCC for differentiation against non-malignant liver tissue and other malignant liver tumors (HCC, metastases) for clinical routine. This approach intentionally did not take into consideration the different origins of the analyzed tissue probes (tumorous epithelium cells *vs* non-malignant transformed hepatocytes). Thus, it remains a possibility that our observations of the downregulation of genes involved in specific metabolic pathways, such as amino acid metabolism, may be a consequence of the different origin of malignant and non-malignant tissue rather than a specific feature of cholangiocarcinogenesis. Nevertheless, our own unpublished data revealed similarities between the genetic profiles of other malignant liver tumors (HCC, metastases of adenocarcinomas) and CCC with a downregulation of hepatocyte-specific metabolic functions and an upregulation of genes well known to be involved in human carcinogenesis.

The gene encoding OPN, a secreted adhesive glycoprotein was identified as the most consistently overexpressed gene in all CCC samples (see above). OPN has been shown to be overexpressed in excessive amounts in a variety of human carcinomas and its expression level has been linked to the recurrence of metastasis or to clinical progression<sup>[34-36]</sup>.

OPN is not a typical oncogene; it is mutationally activated in cancer cells, but it is regulated by a variety of stimuli, such as the Wnt/Tcf signaling pathway, steroid receptors, growth factors, TNF-alpha and transcription factors, such as AP-1 and Ras proto-oncogene<sup>[37]</sup>. OPN is a ligand of CD44, binds to alphaV-containing integrins and has an important role in malignant cell attachment and tumor invasion<sup>[38,39]</sup>. Potential mechanisms of OPN in human carcinogenesis include the regulation of different signaling cascades through activation of various kinases<sup>[40]</sup>. Thus, OPN seems to be a potent anti-apoptotic factor *via* inhibition of caspase 3 activation<sup>[41]</sup>; it also induces increased activation of promatrix metalloproteinase-2 (pro-MMP2, mediated by nuclear factor kappaB) and secretion of urokinase-type plasminogen activator<sup>[42]</sup>.

Using gene expression profiling, OPN has been shown to be one of the highest overexpressed genes in hepatocellular carcinoma (HCC) and it has been shown

the expression of OPN correlates with earlier recurrence, poorer prognosis and metastasis in HCC<sup>[43,44]</sup>. To the best of our knowledge, there is only one report on OPN in human cholangiocarcinogenesis<sup>[45]</sup>. Interestingly, Terashi *et al* observed a correlation between low OPN levels and tumor aggressiveness, whereas another group found high levels of the glycoprotein in CCC in a rat model system<sup>[46]</sup>. Therefore, it remains to be shown whether OPN is a potential prognostic marker and target for anticancer treatment in CCC.

In conclusion, the present study represents one of the first attempts to establish a gene expression pattern of intrahepatic CCC by genetic comprehensive analysis. Based on the analysis of a subgroup of 364 genes, a specific pattern of changes in metabolic and signaling pathways, as well as receptors, cell cycle changes and alterations in apoptosis could be identified. The observed changes are consistent with some of the known characteristics of CCCs in particular and tumors in general. The gene expression profile appears to be useful as a diagnostic tool, especially in terms of differentiation from other liver masses as well as for the subclassification of intrahepatic CCC in comparison to histopathological findings.

Conclusively, besides a number of known overexpressed tumor-related genes in intrahepatic CCC, we describe here for the first time other strongly and consistently dysregulated genes in cholangiocarcinogenesis, which are well known to be involved in other human cancers. Although our data at present do not support a correlation between the expression of these genes and tumor stage for CCC, this gene expression pattern is in line with the usually observed bad clinical prognosis of this cancer. Another evolving application based on the profile described in this report and the observation of OPN as the most consistently overexpressed gene might be the identification of novel therapeutic targets and related genes predicting survival and outcomes of therapeutic modalities.

## COMMENTS

### Background

Cholangiocarcinoma (CCC) is the second most common primary hepatic malignancy with increasing incidence in western countries. Despite recent progress

in various imaging modalities, intrahepatic CCC is in most cases advanced by the time of diagnosis. Aggravating circumstances leading to a poor prognosis with median survival times of only three to six months are the limited curative treatment options by surgical resection and the low effect of palliative chemotherapy in CCC. Therefore a better understanding of human cholangiocarcinogenesis is strongly needed to establish new diagnostic markers and therapeutic approaches.

### Research frontiers

Despite the advances in genomic profiling of many human malignancies in recent years, there have only been a few reports of gene expression analysis in CCC. In this study, oligonucleotide arrays were used to detect differentially expressed genes and to establish a specific genetic profile of intrahepatic CCC. To subclassify between well and poorly differentiated tumors, additional analyses were performed.

### Innovations and breakthroughs

A total of 41 genes that were strongly deregulated (upregulated or downregulated in 100%,  $fc > 4$ ) in CCC were detected by gene expression analysis. For the first time, a subclassification of intrahepatic CCC in relation to malignant differentiation using oligonucleotide arrays was performed. The gene encoding osteopontin (OPN) was the most overexpressed gene with a high fold-change of 33.5, which was confirmed by RT-PCR.

### Applications

Besides a number of known overexpressed tumor-related genes in intrahepatic CCC, other strong and consistently dysregulated genes were described for the first time in human cholangiocarcinogenesis. Another evolving application based on the profile described in this report and the observation of OPN as the most consistently overexpressed gene might be the identification of novel therapeutic targets and related genes predicting survival and outcomes of therapeutic modalities.

### Peer review

The manuscript by Hass *et al* describes a microarray analysis of genetic changes in human cholangiocarcinoma samples compared to non-tumor tissue. The analysis revealed very intriguing data with respect to the overexpression of a number of genes, the most consistent of which is OPN, and further analysis with respect to tumor grade was performed.

### Abstract

**AIM:** To determine the anti-inflammatory activity of probiotic Bifidobacteria in Bifidobacteria-fermented milk (BFM) which is effective against active ulcerative colitis (UC) and exacerbations of UC, and to explore the immunoregulatory mechanisms.

**METHODS:** Peripheral blood mononuclear cells (PBMNC) from UC patients or HT-29 cells were co-cultured with heat-killed probiotic bacteria or culture supernatant of *Bifidobacterium breve* strain Yakult (BbrY) or *Bifidobacterium bifidum* strain Yakult (BbiY) to estimate the amount of IL-10 or IL-8 secreted.

**RESULTS:** Both strains of probiotic Bifidobacteria contained in the BFM induced IL-10 production in PBMNC from UC patients, though BbrY was more effective than BbiY. Conditioned medium (CM) and DNA of both strains inhibited IL-8 secretion in HT-29 cells stimulated with TNF- $\alpha$ , whereas no such effect was observed with heat-killed bacteria. The inhibitory effect of CM derived from BbiY was greater than that of CM derived from BbrY. DNAs of the two strains had a comparable inhibitory activity against the secretion of IL-8. CM of BbiY induced a repression of IL-8 gene expression with a higher expression of I $\kappa$ B- $\zeta$  mRNA 4 h after culture of HT-29 cells compared to that in the absence of CM.

**CONCLUSION:** Probiotic *Bifidobacterium* strains in BFM enhance IL-10 production in PBMNC and inhibit IL-8 secretion in intestinal epithelial cells, suggesting that BFM has anti-inflammatory effects against ulcerative colitis.

### INTRODUCTION

Ulcerative colitis (UC) is assumed to be a result of an impaired intestinal immune response to intestinal environmental antigens such as ubiquitous microflora<sup>[1,2]</sup>. There is evidence that probiotic treatment is effective against UC<sup>[3-6]</sup>. We have previously shown that treatment with bifidobacteria-fermented milk (BFM) containing live bifidobacteria is more effective than the usual treatment in inducing<sup>[7]</sup> and maintaining remission<sup>[8]</sup> of ulcerative colitis. An improvement in the composition of intestinal flora by BFM may prevent the overgrowth of potentially pathogenic bacteria such as *Bacteroides vulgatus*, but we hypothesized that probiotic strains of bifidobacteria in BFM may directly interfere with the host signaling events that drive the intestinal inflammatory response. In inflammatory bowel disease, IL-10 is a cytokine of particular therapeutic interest since it has been shown in animal models that interleukin (IL)-10(-/-) mice spontane-

ously develop intestinal inflammation. IL-10 plays a key role in the control of inflammatory responses to enteric organisms<sup>[9-12]</sup>. More recently, it has been shown in animal models that probiotic strains displaying an *in vitro* potential to induce higher levels of the anti-inflammatory cytokine IL-10 and lower levels of the inflammatory cytokine IL-12, offer the best protection against *in vivo* colitis in the model<sup>[13]</sup>. A genetically engineered *Lactococcus lactis thy12* producing IL-10 ameliorated colitis in two models of experimental colitis, providing proof of principle that topically delivers IL-10, can be therapeutically efficacious<sup>[14]</sup> and a recent proof-of-principle experiment using this transgenic bacterium expressing IL-10 in 10 patients with Crohn's disease showed efficacy<sup>[15]</sup>. In addition, there is an increasing amount of evidence to suggest that the potent neutrophil chemoattractant, IL-8, has an important role in the pathogenesis of inflammatory bowel disease (IBD)<sup>[16-19]</sup>. Recently, a higher concentration of IL-8 was found in more histologically inflamed tissue segments from pediatric IBD patients, suggesting that IL-8-specific therapies may universally modify the inflammatory activity in IBD patients<sup>[20]</sup>. In this study, we focused on the effect of probiotic strains on the secretion of IL-10 by peripheral blood mononuclear cells and also the production of IL-8 by intestinal epithelial cells.

## MATERIALS AND METHODS

### Bacteria and related preparations

*Bifidobacterium bifidum* strain Yakult (BbiY) and *Bifidobacterium breve* strain Yakult (BbrY) were grown in MRS broth (Becton, Dickinson and Company, Sparks, MD). Heat-killed BbiY or BbrY was prepared by heating bacteria resuspended in distilled water at 100°C for 30 min, and then lyophilized<sup>[21]</sup>. For the preparation of conditioned medium (CM), bacteria grown in MRS broth were collected by centrifugation and cultured over 16 h in RPMI-1640 medium (Sigma-Aldrich, St Louis, MO) containing 10% fetal calf serum (FCS) and 2% lactose, then centrifuged<sup>[22]</sup>. The supernatant was filtrated on a 0.22 µm membrane and neutralized with sodium hydroxide. To characterize the active component in CM, it was separated into fractions of more than and less than 3 kDa through Centricon YM-3 (Millipore, Bedford, MA), adjusted to the initial volume, and then to heat treatment at 100°C for 15 min<sup>[23]</sup>. DNA was isolated using the method of Yuki<sup>[24]</sup> with a slight modification. Briefly, bacterial cells were suspended in Tris-EDTA buffer (pH 8.0) containing 0.5 mol/L sucrose and treated with N-acetylmuramidase SG (Seikagaku Corp., Tokyo, Japan) and lysozyme (Sigma-Aldrich) at 37°C for 1 h. The cells were lysed by addition of sodium dodecyl sulfate and proteinase K (Sigma-Aldrich) followed by a 60-min incubation at 65°C. Deproteinization was done by extraction with Tris-saturated phenol and phenol/chloroform/isoamyl alcohol (25:24:1). Finally, DNA was precipitated by ethanol.

### Peripheral blood mononuclear cells

Peripheral blood mononuclear cells (PBMNC) were isolated from peripheral blood of UC patients by Ficoll-Conray (Lymphosepar I; Immuno-Biological Laboratories, Takasaki, Japan) density gradient centrifugation. Table 1

summarizes the patient characteristics. All 9 patients (outpatient) had active UC which was moderate or mild (1 mild, 8 moderate) according to the criteria of Truelove & Witts<sup>[25]</sup>. All patients received a standard therapeutic regimen consisting of oral 5-ASA (mesalazine) and five of the 9 patients with active UC took a low dose of oral predonine. Cells ( $2 \times 10^5$ ) were cultured with heat-killed bacteria (10 µg/mL) in 200 µL of AIM-V medium (Invitrogen Corp., Carlsbad, CA) in a flat-bottomed 96-well culture plate (Nunc, Roskilde, Denmark) for 48 h. Supernatant was collected and frozen until cytokine levels were quantified. In each assay, a positive control with lipopolysaccharide (LPS, 10 µg/mL) added to PBMNC and a negative control with no stimuli were included.

### Quantification of cytokine levels in culture supernatant

IL-10 and IL-8 levels in the culture supernatant were determined by sandwich enzyme-linked immunosorbent assay (ELISA). IL-10 was detected using anti-human IL-10 antibody (51-26171E, BD Biosciences PharMingen, Franklin Lakes, NJ) and biotinylated antibody (51-26172E, BD Biosciences PharMingen). IL-8 was detected using anti-human IL-8 antibody (AHC0932, Invitrogen BioSource) and biotinylated anti-human IL-8 antibody (AHC0789, Invitrogen BioSource).

### HT-29 cell culture

HT-29 cells were cultured at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub> in RPMI-1640 medium containing 10% FCS, 1 mmol/L sodium pyruvate (Invitrogen) and 10 mmol/L 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES). Confluent monolayers were incubated in 96-well or 24-well tissue culture plates with human TNF-α (10 ng/mL, PeproTech, London, UK).

### Quantitative RT-PCR

Total RNA was isolated from HT-29 cells using the TRIzol reagent (Invitrogen) according to the manufacturer's instructions. The RNA was reverse transcribed into cDNA using a SuperScript First-Strand Synthesis System kit (Invitrogen). Real-time quantitative PCR was performed in an ABI prism 7500 Real Time PCR System (Applied Biosystems, Foster City, CA) with the SYBR Premix Ex Taq (Takara Bio, Shiga, Japan). The following primers were used to amplify cDNA fragments: IL-8: forward: 5'-ACACTGCGCCAACACAGAAATTA-3', reverse: 5'-TTTGCTTGAAGTTTCACTGGCAGTC-3'; GAPDH: forward: 5'-GCACCGTCAAGGCTGAGAAC-3', reverse: 5'-ATGGTGGTGAAGACGCCAGT-3'; IκB-ζ: forward: 5'-ACGCGCAAACATGAGTCCAG-3', reverse: 5'-CTCAGCAGCAGCAACAGCATC-3'. All results were finally determined after correction with GAPDH expression.

### Statistical analysis

Results were expressed as mean ± SD. Differences in mean values between groups were analyzed with Student's *t*-test.

## RESULTS

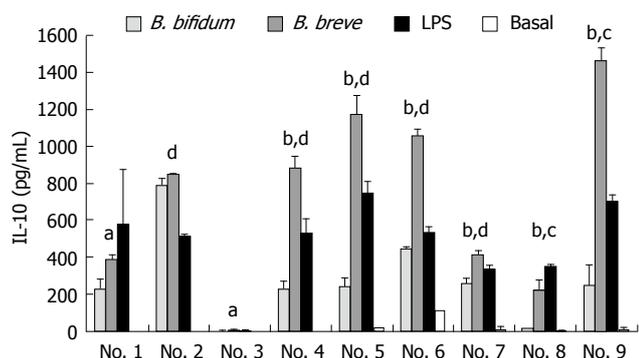

### Effect of probiotic bacteria on IL-10 secretion in PBMNC

The secretion of IL-10 increased in all the cultures of

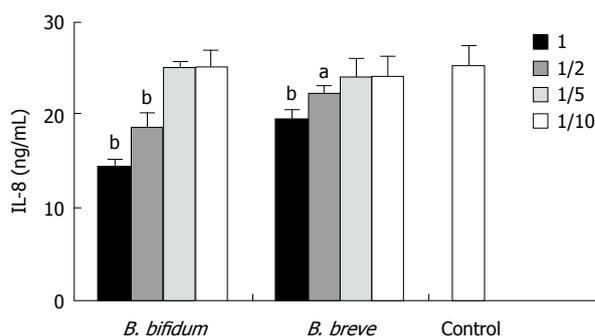

**Figure 1** Effects of probiotic bifidobacteria on IL-10 production in PBMC. PBMC were isolated from 9 ulcerative-colitis patients and incubated with heat-killed probiotic BbiY or BbrY (10 µg/mL), or LPS. At forty-eight hours after incubation, the IL-10 concentration was determined by ELISA (mean ± SD, n = 3). <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01 vs BbiY; <sup>c</sup>P < 0.05, <sup>d</sup>P < 0.01 vs LPS.

**Figure 2** Effects of probiotic bifidobacteria on IL-8 production in HT-29 cells. HT-29 cells were stimulated with TNF-α (10 ng/mL) in the absence or presence of various concentrations of probiotic bacteria. Six hours after incubation, the IL-8 concentration was determined by ELISA (mean ± SD, n = 4).

PBMC isolated from the nine UC patients with a historical record of the treatment as shown in Table 1 in the presence of heat-killed BbrY or BbiY, compared to the basal secretion in the absence of probiotic bacteria (Figure 1). BbrY induced significantly higher levels of IL-10 than BbiY in 8 out of the 9 PBMC preparations. Incubation with BbrY also elicited significantly higher levels of IL-10 than that with LPS (10 µg/mL) in 6 out of the 9 PBMC preparations.

**Figure 3** Effects of probiotic bifidobacteria-derived CMs on IL-8 production in HT-29 cells. HT-29 cells were stimulated with TNF-α in the absence or presence of graded dilutions of CMs. CMs were prepared as described in the Methods. Other experimental conditions are shown in Figure 2. <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01 vs control.

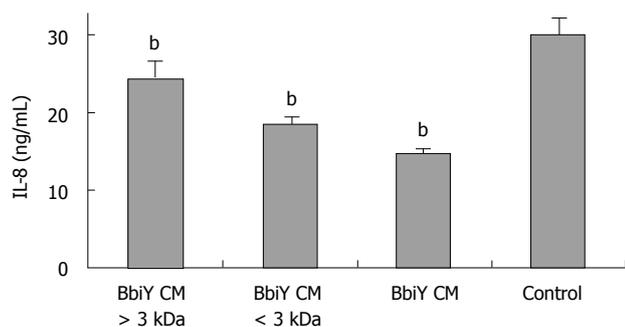

**Effect of probiotic Bifidobacterium on IL-8 secretion in TNF-α-stimulated HT-29 cells**

HT-29 cells were incubated with TNF-α for six hours in the presence or absence of heat-killed BbiY and BbrY. Neither of the heat-killed probiotic bacteria had an effect on the secretion of IL-8 at the concentration ranging from 1 µg/mL-100 µg/mL (Figure 2).

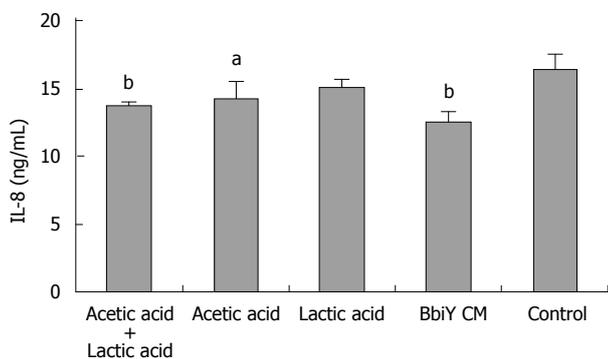

Next, we examined the effect of conditioned medium (CM) on IL-8 secretion by HT-29 cells. Both CMs of BbiY and BbrY inhibited TNF-α-induced secretion of IL-8 in a dose-dependent manner (Figure 3). Concentrations of BbiY and BbrY cultured over 16 h in RPMI-1640 medium were  $3.6 \times 10^8$  CFU/mL and  $2.2 \times 10^8$  CFU/mL, respectively.

**Nature of the inhibitory effect on IL-8 secretion in probiotic-derived CM**

To investigate the nature of this soluble factor, BbiY-derived CM was subjected to molecular sieve and heat treatment. The fractions of less than and more than 3 kDa both retained the inhibitory activity toward the secretion of IL-8 in HT-29 cells, though the former fraction was greater than the latter one (Figure 4). The inhibitory effect of the latter fraction but not the former one was diminished by heat-treatment (data not shown). We checked the effect of acetic and lactic acid with their major constituents in less than 3 kDa fraction. Acetic acid but not lactic acid inhibited the IL-8 secretion in HT-29 cells, when added at the same

**Figure 4** Assessment of the molecular weight of active component in probiotic-derived CMs. CM was separated into fractions of more than and less than 3 kDa, adjusted to the initial volume. The inhibitory effect on the secretion of IL-8 was determined as described in Figure 2. <sup>b</sup>*P* < 0.01 vs control.

**Figure 5** Effects of acetic acid and/or lactic acid on IL-8 secretion in HT-29 cells. HT-29 cells were incubated with approximately the same concentration of acetic acid (11 mmol/L) and/or lactic acid (4 mmol/L) to that of CMs. The inhibitory effect on the secretion of IL-8 was determined as described in Figure 2. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control.

concentration as in the CM, 11 mmol/L and 4 mmol/L, respectively (Figure 5).

**IL-8 and IκB-ζ expression during incubation with probiotic bacteria in HT-29 cells**

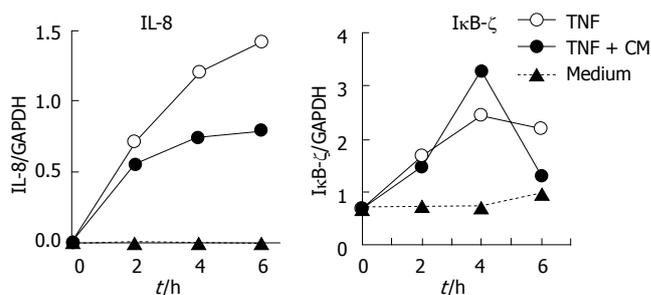

MRNA levels of IL-8 and IκB-ζ were determined in TNF-α-stimulated HT-29 cells in the presence or absence of BbiY-derived CM (Figure 6). A repression of IL-8 expression occurred with an up-regulation of IκB-ζ expression 4 h after incubation of HT-29 cells with probiotic-CM.

**Probiotic DNA inhibited epithelial secretion of IL-8**

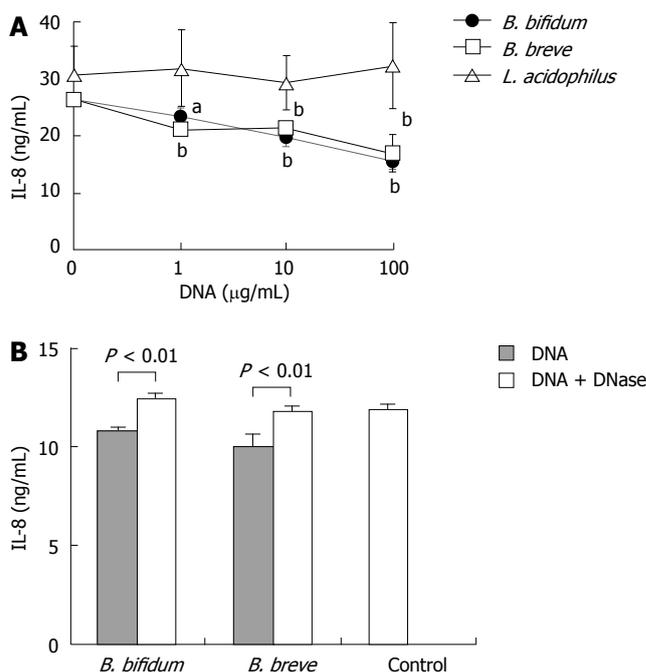

HT-29 cells were stimulated with TNF-α in the presence or absence of bacterial DNA isolated from BbiY or BbrY. DNA from both BbiY and BbrY significantly inhibited the IL-8 secretion in HT-29 cells, at the concentration ranging from 1 μg/mL-100 μg/mL, while DNA from *L. acidophilus* (YIT 0168) had no effect (Figure 7A). Treatment of probiotic DNAs with DNase abolished their inhibitory effects on the secretion of IL-8 (Figure 7B).

**DISCUSSION**

The efficacy of bifidobacteria-fermented milk (BFM) in the treatment of ulcerative colitis has been reported

**Figure 6** IL-8 and IκB-ζ mRNA expression during the culture of HT-29 cells in the presence of probiotic-derived CMs. The mRNA expression was quantified as described in Materials and Methods. Results are representative of three separate experiments.

**Figure 7** Effects of probiotic DNAs on IL-8 production in HT-29 cells. HT-29 cells were stimulated with TNF-α in the absence or presence of various concentrations of probiotic DNA without (A) or with DNase treatment (B). The inhibitory effect on IL-8 secretion was determined as described in Figure 2. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control.

elsewhere<sup>[7,8]</sup>. To determine the anti-inflammatory activity of probiotic *Bifidobacterium* strains in the BFM, we firstly investigated the effects of these strains on the production of anti-inflammatory cytokine IL-10 by PBMNC isolated from UC patients *in vitro*. IL-10 down regulates the TNF-α secretion by macrophages<sup>[26]</sup>. IL-10 knockout mice develop IBD under conventional conditions, indicating the importance of IL-10 in the control of intestinal inflammation<sup>[27]</sup>. It was reported that intragastric administration of IL-10-secreting *Lactococcus lactis* causes a 50% reduction in colitis in mice treated with dextran sulfate sodium<sup>[14]</sup> and BFM containing BbiY and BbrY ameliorates IBD in SAMP1/Yit mice with an up-regulation of IL-10 synthesis and down-regulation of IFN-γ production in mesenteric lymph node cells<sup>[28]</sup>. In this study, the two heat-killed probiotic bacterial strains in BFM induced the secretion of IL-10 in PBMNC isolated from UC patients.

It has been found that the degree of local inflammation and tissue damage in patients with IBD is dependent on the local expression of specific chemokines within affected tissues<sup>[16]</sup>. IL-8 protein<sup>[17]</sup> and mRNA<sup>[18]</sup> expression are associated with inflammation in UC. The fact that conditioned media of BbiY and BbrY reduced the TNF- $\alpha$ -induced secretion of IL-8 by HT-29 cells suggests that both probiotic strains in the BFM could produce soluble anti-inflammatory factors that inhibit IL-8 secretion in intestinal epithelial cells. No single factor produced by the probiotic strain seems to be responsible, because the fractions of less than and more than 3 kDa, differing in heat-sensitivity, were found to have inhibitory effects on IL-8 secretion in this study. Acetic acid but not lactic acid, a major component of CM, was likely to largely contribute to the inhibitory activity of the less than 3 kDa fraction. Components responsible for the inhibition of IL-8 in the more than 3 kDa fraction remain to be investigated.

I $\kappa$ B- $\zeta$  is an inducible nuclear factor- $\kappa$ B (NF- $\kappa$ B) regulator, which is associated with the p65 and p50 subunits of NF- $\kappa$ B and inhibits transcription as well as the DNA-binding of the transcription factor<sup>[29,30]</sup>. Increased expression of I $\kappa$ B- $\zeta$  mRNA in the presence of probiotic-derived CM was observed with repression of IL-8 gene expression in HT-29 cells compared to that in the absence of CM, indicating that NF- $\kappa$ B-mediated IL-8 gene expression in HT-29 cells is inhibited through the induction of I $\kappa$ B- $\zeta$  expression by the CM of the *Bifidobacterium* strain.

The present study has shown that the *Bifidobacterium* strains proved to be beneficial in inducing and maintaining remission of ulcerative colitis exhibit regulatory activities that contribute to the control of intestinal inflammation, thus unraveling the biological basis of the beneficial effects of probiotics in human disease.

## ACKNOWLEDGMENTS

The authors are grateful to Dr. Pena AS (VU University Medical Center Amsterdam) for critical reviewing of the manuscript and to Dr. H Ishikawa H (Kyoto Prefectural University of Medicine) for helpful discussion and advice regarding the manuscript.

## COMMENTS

### Background

We have previously shown that treatment with bifidobacteria-fermented milk (BFM) containing live bifidobacteria is more effective than usual treatment in inducing and maintaining remission of ulcerative colitis (UC). We hypothesized that probiotic strains of Bifidobacteria in BFM may interfere with the intestinal inflammatory response as well as prevention of the overgrowth of potentially pathogenic bacteria such as *Bacteroides vulgatus*. In this study, we focused on the effect of probiotic strains on the secretion of IL-10 by peripheral blood mononuclear cells (PBMNC) and also the production of IL-8 by intestinal epithelial cells.

### Research frontiers

There is evidence that probiotic treatment is effective in patients with UC. The precise mechanisms by which probiotic microorganisms used in clinical trials exert their beneficial effect have not been well defined yet.

### Innovations and breakthroughs

This study has shown that *Bifidobacterium* strains that proved to be beneficial in

inducing and maintaining remission of ulcerative colitis exhibit regulatory activities that contribute to the control of intestinal inflammation, thus unraveling the biological basis of the beneficial effects of probiotics in human disease.

## Applications

Anti-inflammatory activity of probiotic bifidobacteria shown in this study supports the beneficial effects of BFM on in clinical trials. Therapeutic applications of BFM in the treatment of UC are promising.

## Peer review

Probiotic *Bifidobacterium* strains in BFM that proved to be beneficial in inducing and maintaining remission of UC enhanced IL-10 production in PBMNC and inhibited IL-8 secretion in intestinal epithelial cells, suggesting that BFM has anti-inflammatory effects against UC. The mechanism of action regarding the immunosuppressive effect of probiotics has wider therapeutic implications for the treatment of inflammatory bowel disease in general.

### Abstract

**AIM:** To investigate the etiology and clinical characteristics of severe acute pancreatitis (SAP) in elderly patients ( $\geq 60$  years of age).

**METHODS:** We reviewed retrospectively all the SAP cases treated in Xuanwu Hospital in Beijing between 2000 and 2007.

**RESULTS:** In 169 patients with SAP, 94 were elderly and 16 died. Biliary and idiopathic etiologies were the first two causes that accounted for over 90% of SAP in the elderly. Biliary, hyperlipemic and alcoholic etiologies were the first three causes in the young. The proportion of co-morbidity of cholelithiasis, biliary infection, hypertension and coronary heart disease in the aged was significantly higher than that in their young partners. The scores of APACHE II and Ranson were also significantly higher in the elderly except the CT score. Organ failures were more common in the elderly, but the local pancreatic complications were not different between the two groups. Mortality of the aged was correlated with the severity of SAP, multiple co-morbidity and incidence of multiple organ dysfunction syndrome (MODS). MODS was the main cause of death.

**CONCLUSION:** The etiology of SAP in the elderly is quite different from that in the young. Biliary and unknown factors are main causes in the aged. The elderly are subject to major organ failures but there is no difference in the occurrence of local pancreatic complications between the elderly and the young. It is crucial to monitor and improve the functions of major organs so as to prevent MODS in the aged with SAP.

### INTRODUCTION

Severe acute pancreatitis (SAP) refers to the acute pancreatitis (AP) associated with organ failure and/or local complications such as necrosis, pseudocyst or abscess. The overall mortality of SAP has decreased in recent years to around 15%-20%<sup>[1,2]</sup>. Tenner<sup>[3]</sup> has shown in the aged, the presence of complications like infected pancreatic necrosis can increase the mortality to 50%. Fan<sup>[4]</sup> investigated the AP in the elderly ( $> 75$  years old) patients and indicated that the high mortality of this group is probably due to a higher prevalence of cardiopulmonary diseases and biliary stones. However, in China, the elderly refers to people aged 60 or over 60 years clinically. Few studies have compared the clinical characteristics between the elderly ( $\geq 60$  years old) and the young patients with SAP. In this retrospective study, we aimed to investigate whether there is a difference in etiology and clinical characteristics between the aged and its younger partners with SAP, and to analyze the factors that attribute to the high mortality in the elderly.

### MATERIALS AND METHODS

#### Patients

Between January 2000 and January 2007, 169 patients with SAP were treated in the surgery intensive care unit (SICU) and the Department of General Surgery at Xuanwu Hospital of Capital Medical University in Beijing, China. All patients' medical charts were reviewed retrospectively and the relative clinical data were collected. Acute pancreatitis was diagnosed based on the facts of the elevation of serum amylase to more than 3 times the upper normal limit and a typical clinical picture, and the

diagnostic criteria of SAP were the APACHE II score of more than 8 within 72 h after admission<sup>[5]</sup>. Clinical severity evaluations were carried out by APACHE II and Ranson's scoring systems within 48 h after admission<sup>[6,7]</sup>. A serial abdominal contrast-enhanced CT (CECT) was performed in each patient and the findings were graded according to the Balthazar classification<sup>[8]</sup>.

On admission, all patients were treated medically according to generally accepted principles consisting of withholding oral intake, inserting a nasogastric tube for drainage, providing pain relief, restoring fluid and electrolytes intravenously, and administration of prophylactic antibiotics. A proton pump inhibitor and somatostatin were given to prevent stress ulcers and to inhibit pancreatic excretion. The Dachengqi decoction (a Chinese herbal medicine in fluid form) was given through the nasogastric tube twice a day to improve gastrointestinal function.

Patients with gallstones were evaluated by sonography routinely. Endoscopic retrograde cholangiopancreatography (ERCP) was performed in cases of biliary etiology, as proven by ultrasonography, or magnetic resonance cholangiopancreatography and elevated bilirubin, alkaline phosphatase and aspartate aminotransferase. A papillotomy was done if stones and sludge were present in the common bile duct and some were followed by an endoscopic nasobiliary drainage. Surgical intervention (necrosectomy with drainage and continuous postoperative lavage) was performed if infected pancreatic necrosis was clinically suspected or confirmed by positive bacteriologic results of CT-guided fine-needle aspirations.

Patients consuming large amounts of alcohol were considered as having alcoholic pancreatitis. Serum triglyceride level more than 11.3 mmol/L (1000 mg/dL), and exclusion of other etiologies were accepted as the hyperlipidemic etiology<sup>[9]</sup>. Patients were classified as having an idiopathic etiology if the history and laboratory findings ruled out any known etiologic factors, and ultrasonography revealed a normal biliary tract.

Co-morbidity was defined as a pre-existing disease or a condition in addition to the acute pancreatitis. Co-morbidity was diagnosed if the condition was an active problem and/or need routine treatment prior to the onset of acute pancreatitis. The assessment of organ function and diagnosis of multiple organ dysfunction syndrome (MODS) was performed on the basis of the Marshall multiple organ dysfunction score<sup>[10]</sup>.

### Statistical analysis

Statistical evaluation was performed with SPSS 11.0 for Windows. The significant differences of clinical characteristics of the aged and young SAP patients were tested with the  $\chi^2$  test. Clinical severity scoring of SAP, such as Ranson, APACHE II and CT scorings, was described with mean  $\pm$  SD. The differences between the two groups were tested through independent samples *t* test. *P* < 0.05 was considered statistically significant.

## RESULTS

### General clinical characteristics

Patient general characteristics are summarized in Table 1.

**Table 1** General clinical characteristics of patients with severe acute pancreatitis

	Elderly ( $\geq 60$ yr) ( <i>n</i> = 94)	Young (< 60 yr) ( <i>n</i> = 75)	<i>P</i> value
Mean age (yr, range)	70.9 (60-87)	44.2 (17-59)	-
Male	44 (46.8%)	49 (65.3%)	0.0197
Female	50 (53.2%)	26 (34.7%)	0.0197
Medium ICU stay in days (range)	8 (2-56)	8 (2-90)	-
Medium hospital stay in days (range)	21 (13-64)	19 (12-90)	-
Hospital deaths	16 (17.0%)	4 (5.3%)	0.0291

**Table 2** Etiology of severe acute pancreatitis *n* (%)

	Elderly ( $\geq 60$ yr)	Young (< 60 yr)	<i>P</i> value
Biliary	61 (64.9)	28 (37.3)	0.0006
Alcohol	2 (2.1)	15 (20.0)	0.0001
Hyperlipemia	3 (3.2)	22 (29.3)	< 0.0001
Abdominal surgery	2 (2.1)	1 (1.3)	1
Drug-induced	1 (1.1)	0 (0.0)	1
Idiopathic	25 (26.6)	9 (12.0)	0.021
Total	94	75	-

There were 169 patients with SAP in this study, including 94 aged ( $\geq 60$  years old) and 75 young (< 60 years old). The mean age of the aged was 70.9 years (range 60-87) and the young was 44.2 years (range 17-59). Of the 94 elderly patients, 44 (46.8%) were men, and 50 (53.2%) women. In patients younger than 60 years old, 49 (65.3%) were men, and 26 (34.7%) women. Medium stay in SICU was 8 d (2-56 d) in the aged and 8 d (2-90 d) in the young patients. Medium hospital stay was 21 d (13-64 d) in the aged and 19 d (12-90 d) in the young. The mortality rate of SAP was 17.0% (16 cases) in the aged and 5.3% (4 cases) in the young.

### Etiology

The two major etiological factors responsible for acute pancreatitis were biliary and alcohol, although the proportions of pancreatitis attributed to these two factors varied considerably in different countries and regions. In our 169 SAP patients, biliary pancreatitis was the first common etiology in both the aged and the young groups (Table 2), but it was more common in the elderly (64.9% *vs* 37.3%, *P* = 0.0006). Interestingly, the idiopathic pancreatitis was the second most common etiology in the aged patients, significantly more common than in its younger counterparts (26.6% *vs* 12.0%, *P* = 0.0210). In patients younger than 60 years of age, the second and third causes were hyperlipemia (29.3%) and alcohol (20.0%) respectively. However, in the elderly, these two etiologies were less common (3.2% and 2.1% respectively). Two cases of pancreatitis underwent abdominal surgery in the elderly and one in the young. The operations were esophageal cancer resection, cholecystectomy and gastrectomy, respectively. One elderly woman experienced drug-induced SAP while taking Methotrexate.

Table 3 Co-morbidity of severe acute pancreatitis *n* (%)

	Elderly (≥ 60 yr)	Young (< 60 yr)	<i>P</i> value
Cholelithiasis	47 (50.0)	18 (24.0)	0.0008
Biliary infection	20 (21.3)	5 (6.7)	0.0087
Hypertension	20 (21.3)	4 (5.3)	0.0035
Coronary heart diseases	14 (14.9)	4 (5.3)	0.0490
Previous stroke	5 (5.3)	0 (0.0)	0.0667
Previous myocardial infarction	4 (4.3)	1 (1.3)	0.3836
Diabetes mellitus	8 (8.5)	9 (12.0)	0.6079
Liver cirrhosis	3 (3.2)	2 (2.7)	1.0000
Malignant diseases	4 (4.3)	1 (1.3)	0.3836
Autoimmune diseases	0 (0.0)	1 (1.3)	0.4438

Table 4 Clinical scoring of severe acute pancreatitis (mean ± SD)

	Elderly (≥ 60 yr, <i>n</i> = 94)	Young (< 60 yr, <i>n</i> = 75)	<i>P</i> value
Ranson	3.4 (1.7)	2.8 (1.6)	0.0069
APACHE II	14.0 (7.6)	9.9 (6.6)	0.0003
CT score	4.0 (1.9)	4.8 (1.8)	0.0020

### Co-morbidity

Co-morbidity was defined as a pre-existing disease or condition in addition to the current onset of pancreatitis (Table 3). The morbidity of cholelithiasis, biliary infection, hypertension and coronary heart disease in the aged was significantly more common than in the young. Previous stroke was diagnosed in five aged patients but none in the young (5.3% *vs* 0%, *P* = 0.0667). Diabetes mellitus, previous myocardial infarction, liver cirrhosis, malignancies and autoimmune diseases might be seen in both groups.

### Clinical scoring of SAP

In our study, three clinical scores, APACHE II, Ranson's and CT score, were collected (Table 4). The scores of APACHE II and Ranson were significantly higher in the aged than in the young (3.4 ± 1.7 *vs* 2.8 ± 1.6, *P* = 0.0069). Surprisingly, the CT score was higher in the younger patients (4.8 ± 1.8 *vs* 4.0 ± 1.9, *P* = 0.0020).

### Organ failures and complications of SAP

Organ failures and complications were two major characteristics of SAP distinguished from mild pancreatitis. As shown in Table 5, the most frequent complications of SAP in the aged are acute lung injury (ALI) and/or acute respiratory distress syndrome (ARDS) (30.9%), followed by MODS (26.6%), electrolyte disturbances (21.3%), renal failure (18.1%), pancreatic encephalopathy (17.1%) and cardiovascular insufficiency (17.0%). Except for metabolic disorders and cardiovascular insufficiency, the incidences of ALI/ARDS, MODS, renal failure and pancreatic encephalopathy in the elderly were significantly higher than those in the young. The other complications, such as GI bleeding, paralytic ileus, pancreatic pseudocyst, pulmonary infection, fungous infection, abdominal compartment syndrome (ACS) and disseminated intravascular coagulation (DIC), occurred less frequently (< 15%) in both the elderly and the young.

Table 5 Organ failures and complications in severe acute pancreatitis *n* (%)

	Elderly (≥ 60 yr)	Young (< 60 yr)	<i>P</i> value
Total	94 (100)	75 (100)	
ALI/ARDS	29 (30.9)	13 (17.3)	0.0498
Renal insufficiency	17 (18.1)	5 (6.7)	0.0375
Cardiovascular insufficiency	16 (17.0)	11 (14.7)	0.8331
Pancreatic encephalopathy	16 (17.0)	4 (5.3)	0.0291
Hepatic insufficiency	8 (8.5)	5 (6.7)	0.7754
Metabolic disorders	20 (21.3)	12 (16.0)	0.4334
DIC	5 (5.3)	4 (5.3)	1.0000
GI bleeding	5 (5.3)	5 (6.7)	0.7521
With single organ failure	42 (44.7)	16 (21.3)	0.0019
With MODS	25 (26.6)	10 (13.3)	0.0374
Pancreatic abscess	13 (13.9)	13 (17.3)	0.6685
Pancreatic pseudocyst	11 (11.7)	8 (10.7)	1.0000
Ileus	9 (9.6)	6 (8.0)	0.7909
ACS	5 (5.3)	4 (5.3)	1.0000
Fungous infection	4 (4.3)	1 (1.3)	0.3836
Sepsis	8 (8.5)	6 (8.0)	1.0000

ALI/ARDS: Acute lung injury or acute respiratory distress syndrome; MODS: Multiple organ dysfunction syndrome; GI: Gastrointestinal; ACS: Abdominal compartment syndrome; DIC: Disseminated intravascular coagulation.

Table 6 Clinical characteristics of dead and survived cases in the aged with severe acute pancreatitis *n* (%)

		Death ( <i>n</i> = 16)	Survival ( <i>n</i> = 78)	<i>P</i> value
Gender	Male	9 (56.3)	35 (44.9)	0.4255
	Female	7 (43.7)	43 (55.1)	0.4255
Etiology	Biliary	10 (62.5)	51 (65.4)	1.0000
	Idiopathic	5 (31.3)	20 (25.6)	0.7570
Scoring (mean ± SD)	Ranson	5.6 ± 1.8	3.1 ± 1.3	< 0.0001
	APACHE II	26.3 ± 9.3	11.9 ± 4.7	< 0.0001
	CT score	5.6 ± 2.1	3.7 ± 1.7	0.0001
Co-morbidity	Single	4 (25.0)	28 (35.9)	0.5647
	Multiple	12 (75.0)	24 (30.8)	0.0015
Organ dysfunction	Single	1 (6.3)	16 (20.5)	0.2882
	MODS	15 (93.8)	10 (12.8)	< 0.0001

### Mortality of SAP in the elderly

The mortality of SAP in the aged was significantly higher than that of the young in our data (17.0% *vs* 5.3%, *P* = 0.0291, Table 1). We further compared the clinical characteristics of the dead and the surviving patients of the elderly (Table 6). We found no difference in either gender or etiologies between the two subgroups. Only the severe scores, multiple co-morbidities and MODS were significantly higher in the subgroup of the dead patients and almost all of this subgroup died of MODS.

## DISCUSSION

In most studies, the two major etiological factors, biliary disease and alcohol abuse together account for more than 80% of AP patients<sup>[11,12]</sup>. Studies in the United Kingdom reveal that 40%-57% of patients with AP have small gallstones<sup>[13,14]</sup>.

In our study, biliary pancreatitis was the most common

cause for SAP in both aged and young patients. However, biliary etiology in the elderly is as high as 64.9%, we thought it was because very few patients were addicted to alcohol and the incidence of cholelithiasis increased in this subgroup. Meanwhile, unknown etiology, or idiopathic pancreatitis accounted for 26.6% of the elderly and ranked second, quite different from the etiologies in the young patients. This is similar with other reports in which 30%-40% of elderly patients with acute pancreatitis have an unclear etiology<sup>[15]</sup>. Interestingly, the second more common etiology was not alcohol abuse but hyperlipemia in the young patients in our study. Although alcoholism was associated with over 80% of patients in studies from New York and around 70% in Scandinavian countries, in the Beijing area, it seems not a major concern.

Many drugs are associated with the development of acute pancreatitis. These include didanosine, furosemide, corticosteroids, azathioprine and sodium valproate<sup>[16]</sup>. However, there is no clinical feature that can differentiate drug-induced pancreatitis from other factor caused-pancreatitis. Drug-induced pancreatitis is usually diagnosed using the following criteria: pancreatitis developed during treatment, resolved following the discontinuation of the drug, and re-developed following re-challenge of the offending drug<sup>[17]</sup>. Because no causal factor for pancreatitis was found after the initial work-up, acute pancreatitis induced by Methotrexate was suspected in a 63 years old woman who took it for a week and her symptom was relieved after cessation of the drug.

Even though the mortality of SAP is around 22%-30%, few data showed the mortality of SAP in the elderly. A Japanese survey done from 1991 to 1995 showed that the mortality of SAP is greater than 20% in patients over 50 years of age<sup>[18]</sup>. Andersson reported that the hospital mortality of AP in a university hospital in Sweden decreased slightly, from 4.7% (1975-1985) to 3.7% (1986-1996), and that the average age of the dead patients markedly increased from 59.2 to 73.6 years<sup>[19]</sup>. This suggested that the older the patients, the higher mortality they have. Fan<sup>[4]</sup> has concluded that mortality from AP was related to coexisting diseases in the elderly, not to the severity of acute pancreatitis and reported a 21.3% mortality from AP in patients aged above 75 years. Browder<sup>[15]</sup> also believed organ function compromise correlates with mortality and appears more significant than severity of pancreatic disease. In our study, the co-morbidities, including cholelithiasis, biliary infection, hypertension and coronary heart disease were more common in the aged. The mortality of SAP in this group was 17%, but 5.3% in the young.

Recently, Kaya<sup>[20]</sup> demonstrated that the APACHE II score is the best predictor of mortality among Ranson, Imrie and APACHE II scores. We found that both APACHE II and Ranson's criteria were of significance in predicting mortality in the aged. Unexpectedly, the CT score was different from the two above scores, and it was lower than in the aged patients. This seems that the average local pathological conditions in the aged were less serious than that in the young patients. To explain this data with caution and to exclude the heterogeneity of the aged group, we further analyzed the dead and the living cases in the elderly. The CT score was markedly higher

in the deceased cases, suggesting that it is still a sensitive predictor for mortality from SAP. Leung<sup>[21]</sup> reported that the sensitivity of CT severity index (CTSI) is higher than Ranson score and APACHE II score, although they are also the predictors for complications, mortality and the length of AP course. Some researches suggest that MRI seems to be a reliable method of staging AP severity in comparison with CECT scan<sup>[22]</sup>. Otherwise, C-reactive protein (CRP) is a useful indicator for assessing severity and recommended to apply in clinical practice<sup>[23,24]</sup>.

The most frequent complication of SAP in the aged in our study is ALI/ARDS (29 cases, 30.9%), followed by MODS (25, 26.6%), electrolyte disturbances (21.3%), renal failure (17, 18.1%), pancreatic encephalopathy (16, 17.0%) and shock (16, 17.0%). Currently, there are no specific examinations or unified diagnostic standards for pancreatic encephalopathy. It results from the combined actions of multiple factors based on cerebral demyelination due to pancreatin<sup>[25]</sup>. In our study, it was diagnosed according to clinical symptoms and electroencephalogram or MRI.

The local pancreatic complications, such as pancreatic abscess, pancreatic pseudocyst and ACS, are not different between the two groups. It supports the opinion that the local pathological condition is not the critical factor but organ dysfunction, especially cardiovascular, pulmonary, renal and cerebellar function, for the high incidence of death in the elderly. This phenomenon could be related to the progressive decline in physiological function of major organs with aging. The other complications, such as alimentary tract hemorrhage, pulmonary infection, fungous infection and disseminated intravascular coagulation (DIC), do not occur so frequently (< 15%) and there is no difference between the elderly and the young. We suggest that in treatment of SAP in the aged, priority should be given to monitoring and improving the functions of major organs so as to prevent MODS. At the same time, it is necessary to find out the origin of SAP and remove it early by minor-injury method. Additionally, the fluid quantity and speed of transfusion should be decreased in the aged and the dose of medicine should be used properly in order to avoid injury of the organ function.

In our study, the incidence of paralytic ileus was less than 10%. It may be associated with the gastrointestinal functions. SAP patients admitted to our intensive care unit were given purgatives, such as magnesium sulfate, Mannitol, lactulose and Dachengqi decoction (Chinese herbal medicine). These drugs could promote gastrointestinal motility, ameliorate intestinal permeability and decrease bacterial translocation<sup>[26,27]</sup>. They can also improve bile discharge and decrease effusion in the abdominal cavity. Rhubarb is the main constituent of Dachengqi decoction. Rhubarb can exert protective effects on SAP by inhibiting the inflammation of pancreas in rats, improving pancreatic microcirculation and altering exocrine secretion<sup>[28]</sup>. Wu<sup>[29,30]</sup> also reported the benefit from Chinese herbal medicine in treatment of SAP and recommended the regimen for clinical use.

In conclusion, SAP in the aged had obviously different features from the young. Both of biliary and unknown etiological factors result in over 90% of SAP in elderly. The co-morbidities of cholelithiasis, biliary

infection, hypertension and coronary heart disease are more common than in the young. APACHE II scores and Ranson's criteria are markedly higher in the elderly and CT scores much higher in the elderly who died in the hospital. Therefore, the mortality of the aged patients is correlated with the severity of SAP, and co-morbidity and incidence of MODS are not relevant to patients' gender or etiologies. Importance should be attached to monitoring and improving the functions of major organs so as to prevent MODS in the aged with SAP.

## COMMENTS

### Background

The overall mortality of severe acute pancreatitis (SAP) has decreased in recent years to around 15%-20%. Few studies compared the clinical characteristics between the elderly ( $\geq 60$  years old) and the young patients with SAP.

### Research frontiers

Some researches have shown that the presence of complications such as infected pancreatic necrosis, in the aged ( $> 75$  years old) can increase the mortality of AP to 50%, probably due to a high prevalence of cardiopulmonary diseases and biliary stones.

### Innovations and breakthroughs

The authors retrospectively reviewed the SAP cases that were treated in a hospital in Beijing between 2000 and 2007 to investigate the etiology, clinical characteristics and outcomes of SAP in the elderly patients.

### Applications

The authors suggest that importance should be attached to monitoring and improving the functions of major organs so as to prevent MODS in the aged with SAP.

### Peer review

This article reviews the experience with elderly patients in China with SAP. This is an interesting and well-written paper.

Mendes LSC, Nita ME, Ono-Nita SK, Mello ES, da Silva LC, Alves VAF, Carrilho FJ. Prognostic factors for progression of liver structural lesions in chronic hepatitis C patients. *World J Gastroenterol* 2008; 14(16): 2522-2528 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2522.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2522>

### Abstract

**AIM:** To evaluate the epidemiological, clinical, laboratory and histological variables capable of predicting the progression of hepatic structural disturbances in chronic hepatitis C patients during the time interval between two liver biopsies.

**METHODS:** Clinical charts of 112 chronic hepatitis C patients were retrospectively analyzed, whereas liver biopsies were revised. Immunohistochemical detection of interferon receptor was based on the Envision-Peroxidase System.

**RESULTS:** In the multivariate analysis, the variables in the age at first biopsy, ALT levels, presence of lymphoid aggregates and siderosis were the determinants of the best model for predicting the severity of the disease. The direct progression rate of hepatic structural lesions was significantly higher in untreated patients, intermediate in treated non-responders and lower in treated responders to antiviral therapy (non-treated *vs* responders,  $0.22 \pm 0.50$  *vs*  $-0.15 \pm 0.46$ ,  $P = 0.0053$ ). Immuno-expression of interferon receptor is not a relevant factor.

**CONCLUSION:** The best predictors of the progression of fibrosis are age at the first liver biopsy, extent of ALT elevation, inflammation at liver histology and hepatic siderosis. Antiviral treatment is effective in preventing the progression of liver structural lesions in chronic hepatitis C patients.

### INTRODUCTION

Studies on hepatitis C virus (HCV) in Brazil indicate a moderate prevalence in the country as a whole. The prevalence of HCV infection in the city of São Paulo<sup>[1]</sup> was estimated at 1.4%, ranging from 0.7% to 2.12% according to age, geographical region and socioeconomic characteristics. The most prevalent genotype in North America, comprising approximately 60% of all cases of HCV, is genotype 1, followed by genotypes 2 and 3. In Brazil, genotype 1, subtype 1b is also the most prevalent except in the south of the country where there are more cases of infection by genotype 3<sup>[2-4]</sup>.

Hepatic cirrhosis and hepatocellular carcinoma (HCC) are consequences of chronic hepatitis C. It is estimated that HCC will develop in 1%-4% of patients per year in the first five years following the onset of hepatic cirrhosis<sup>[5]</sup>. The mean interval from the time of infection to onset of cirrhosis is approximately 30 years, but cirrhosis may occur within a range of 10-50 years<sup>[6]</sup>. In the majority of the patients, progression of the disease involves fibrosis, its extension in the hepatic tissue being the determinant of more severe clinical events in patients with HCV<sup>[6]</sup>. Once cirrhosis is established, it represents an irreversible condition, and strategies to avoid the progression of fibrosis are essential in order to avoid progressive liver dysfunction<sup>[7]</sup>. During the chronic infection, 30% of the patients will evolve asymptotically with no significant fibrosis or evidence of serious hepatic dysfunction even in the presence of persistently high enzyme levels<sup>[8]</sup>. In another 30% of cases, the persistently elevated aminotransferase levels will result in fibrogenesis and progressive liver dysfunction. In

10% cases, the clinical course is variable.

Previous studies have identified some factors associated with the worst evolution of chronic hepatitis C, such as age > 40 years at the time of infection and alcohol intake > 50 g/d, as independent factors for the worst prognosis<sup>[9]</sup>. Controversial reports on elevated alanine aminotransferase (ALT) levels as a predictive factor for increased histological deterioration have been published in the literature; however, increased histological deterioration has been described as related to apoptosis in patients with chronic hepatitis C and normal ALT<sup>[10]</sup>.

Hepatic fibrogenesis is a result of the action of several aggressive factors on the liver. Various cells are involved in this process, including Kupffer cells (liver macrophages), sinusoidal endothelial cells, hepatocytes and stellate cells (Ito cells or lipocytes). Hepatic stellate cells play a key role in the development of fibrosis and are the major source of extracellular matrix. There is approximately one such cell for every six hepatocytes<sup>[7]</sup>. Chronic hepatitis C is defined as the continuous hepatic aggression associated with the elevation of aminotransferases or positive viral markers for periods longer than 6 months. Various consensus has concluded that treatment modality should usually be based on structural alterations and hepatic necroinflammatory activity status<sup>[11]</sup>. The purpose of a biopsy in the pretreatment phase is different in those patients with moderate inflammation and an advanced level of fibrosis for whom treatment would be indicated, and in those with mild inflammation and an absence or minimal portal fibrosis in whom treatment would be of little use. The French Cooperative Group METAVIR<sup>[12]</sup> proposed a scoring system to distinguish fibrosis of the portal spaces from that associated with the lobular-central vein, and graded the stage of portal fibrosis on a five-point scale, consisting of 2 different grades in the septum and 3 grades in the central lobular veins according to the amount of fibrosis and its association with perisinusoidal fibrosis. According to the METAVIR scoring system, patients with fibrosis stages F2, F3 and F4 should be considered for antiviral therapy. The objective of studying serial biopsies is to evaluate the progression of liver damage in chronic HCV. Several parameters have been used in the staging of hepatic disease at the tissue level. The ideal staging system should evaluate each histological component separately such as piecemeal necrosis, confluent necrosis, lobular activity and portal inflammation. Among the patients treated with IFN in various regimens and with various drug combinations, a significant number failed to respond to treatment, while of those who did respond to treatment, some experienced a relapse. Several virological variables such as HCV genotypes 2 and 3 and low HCV RNA load, as well as other variables related to the host such as young age, short disease duration and absence of cirrhosis, have already been cited as being directly related to a higher chance of responding to IFN. Data in the literature on the ability of IFN receptors to predict response rates are sparse. Yatsunami *et al.*<sup>[13]</sup> studied 55 patients with chronic HCV infection treated with IFN- $\alpha$  for 16 wk at a dose of 6 million units/day in the first two weeks followed by 6 million units three times per week up to the end of treatment. The patients not responding to the treatment

were those with lower hepatic IFN receptor expression.

The aim of this study was to evaluate the epidemiological, clinical, laboratory and histological variables that may be predictive of the progression of fibrosis in chronic hepatitis C patients during the interval between two liver biopsies.

## MATERIALS AND METHODS

### Patients

Epidemiological, clinical, laboratory and histological data were retrospectively analyzed from 112 patients with chronic hepatitis C, receiving care at the Hepatology Clinic of the Department of Gastroenterology, *Hospital das Clinicas*, University of São Paulo School of Medicine (São Paulo, Brazil). The study was approved by the institute's Internal Review Board and was carried out in accordance with the Helsinki Declaration. The patients had been subjected to two liver biopsies at two different periods of time. The first biopsy was performed between March 1992 and January 2002. The patients received or did not receive treatment with interferon alpha-2 and ribavirin for 6-12 mo according to the genotype. Patients with non-genotype 1 HCV were treated for 6 mo following the first biopsy, while those with genotype 1 or when genotype was unknown at the time of the initial biopsy received treatment for a year. The patients who remained HCV RNA negative for 6 mo or longer after the treatment were considered responders.

**Inclusion criteria:** Chronic hepatitis C, defined by the presence for at least 6 mo of serum anti-HCV antibodies, as confirmed by ELISA (Enzyme-Linked Immunosorbent Assay) and HCV RNA, evaluated using qualitative and quantitative methods in a reverse transcription polymerase chain reaction assay; adults over 18 years of age whose medical charts were available at the time of the first liver biopsy; no HCV treatment prior to the first biopsy.

**Exclusion criteria:** History of prior HCV treatment, hepatitis B virus (HBV) infection; HIV infection or AIDS; chronic renal failure; patients with transplants; cancer patients or those in use of any immunosuppressive drugs; alcohol use (> 20 g/d); autoimmune and metabolic diseases of the liver; schistosomiasis mansoni; abnormalities in serum alpha-fetoprotein levels suggesting primary hepatic neoplasia; and use of any hepatotoxic drug.

### Histopathological evaluation

Fragments of liver tissue were obtained by percutaneous needle biopsy before and after therapy in the treated group and on two different occasions according to clinical indication during follow-up in the untreated group. In all biopsies, sections were stained with hematoxylin and eosin (H&E), Masson's trichrome, Perl's Prussian blue and reticulin stain, and re-evaluated blindly by a single pathologist. Image analysis was done with Image Pro-Plus 4.5.1 software (Media Cybernetics, Bethesda, MD, USA). By evaluating the natural history of chronic hepatitis C infection in the interval between the two biopsies, it was possible to predict whether evolution would be mild or

severe. Severe histopathological disease was defined as necroinflammatory activity  $\geq 2$  ( $A \geq 2$ ) and/or fibrosis  $\geq 2$  ( $F \geq 2$ ) in accordance with the classification defined by POYNARD *et al*<sup>[14]</sup>.

To predict the evolution of hepatic structural disturbances in the interval between the two biopsies, the presence or none histological findings of ductal lesion, lymphoid aggregates, steatosis and siderosis were assessed in the first biopsy.

Necroinflammatory activity was graded by integrating the intensity of piecemeal and lobular necrosis as proposed by the METAVIR group<sup>[15]</sup>. A0: No histologic necroinflammatory activity; A1: Minimal histologic necroinflammatory activity; A2: Moderate histologic necroinflammatory activity; and A3: Severe histologic necroinflammatory activity.

The levels of structural changes were defined following the scoring system by the METAVIR group<sup>[15]</sup>. F0: No fibrosis; F1: Portal fibrosis without septa; F2: Portal fibrosis with few septa; F3: Numerous septa without cirrhosis; and F4: Cirrhosis.

The progression of hepatic architectural disturbances was assessed according to the METAVIR scoring system<sup>[14]</sup>. In particular, the estimated (indirect) progression of fibrosis was calculated from the ratio between the stage of fibrosis at the first biopsy and the time after infection, i.e. the estimated duration of the infection in years, expressed in METAVIR units of fibrosis per year (METAVIR FU/year). In this model, it is assumed that at the time of infection the patient had no hepatic fibrosis (F0) and from that day on, the progression of fibrosis was constant. In those patients in whom the time of infection was unknown, it was impossible to calculate the indirect progression of fibrosis. In order to evaluate these cases correctly, we excluded patients with any other possible epidemiological causes of fibrosis (see exclusion criteria). The direct progression of fibrosis over time was defined as the difference in the stages of fibrosis between the first and the second biopsy, i.e. progression during the interval of years between the two biopsies, with the final result expressed in fibrosis units per year.

#### **IFN receptor immunohistochemical detection**

Whenever there was sufficient remaining tissue available from the paraffin block, two histological slides for each patient were submitted to immunohistochemical detection of interferon receptor, using a monoclonal antibody (clone ANOCK 4866; Otsuka Pharmaceutical, Tokushima, Japan) which was kindly provided by Dr. Michitami Yano of the Institute for Clinical Research, Nagasaki Chuo National Hospital, Japan. As previously standardized, antibody dilution was 1:100 followed by the dextran polymer-peroxidase Envision System (Dako, Carpinteria, CA). The results were expressed as positive or negative, and a reaction was considered positive when hepatocytes showed cytoplasmic reactivity.

#### **Serum biochemical analysis**

Laboratory biochemical tests were performed by standard methods using automated techniques (Modular P800;

Roche Diagnostics; Indianapolis, IN, USA).

#### **Statistical analysis**

Descriptive analysis was carried out for both continuous and qualitative variables, obtaining means or medians and frequencies or percentages, respectively. The results were then correlated with the treatment. For analysis of the prognostic factors related to the progression of the mild or severe forms of the disease throughout its natural history at the time of the first biopsy, univariate and multivariate methods were applied. In the univariate analysis, Student's *t* test for independent samples was used in the evaluation of continuous variables, and the Kruskal-Wallis test was applied when the variables were nominal or continuous with non-normal distribution. Pearson's  $\chi^2$  test or Fisher's exact test were also used in the evaluation of proportions between the categorical variables. Multivariate techniques were applied to evaluate whether significant variables in the univariate analysis were able to predict the mild or severe forms of hepatic disease. Logistics regression with *forward selection* using the likelihood ratio test was used to identify significant variables. Significance was established at  $P \leq 0.05$ .

## **RESULTS**

The general features of the patients in this study are described in Table 1. Table 2 shows the results of the univariate analysis in which age at first biopsy, duration of the infection, ALT levels, albumin, prothrombin activity, lymphoid aggregates and siderosis were identified as potential candidates for the multivariate analysis.

The variables were studied in various models and the final model was obtained through progressive comparison using the likelihood ratio test to identify the most adequate and stable model capable of distinguishing between progression to mild or severe liver disease. The variables including age at first biopsy, ALT levels, lymphoid aggregates and siderosis, were determinants of the best model for predicting the severity of the disease (Table 3).

The indirect progression to hepatic fibrosis was evaluated in all patients. Patients with more severe forms of the disease had a significantly higher mean progression rate than those with mild disease ( $P < 0.0001$ ) (Table 4).

Regarding the direct progression of hepatic fibrosis, a total of 112 patients underwent two liver biopsies. Following the first biopsy, 79 of these patients were treated, while 33 received no treatment. The direct progression of hepatic fibrosis was different ( $0.2184 \pm 0.4987$ ) in the groups of untreated patients, treated non-responders and treated responders ( $P = 0.01$ ) as seen in Table 5. Untreated patients had higher progression rates contrasting to lowest rates in those who responded to antiviral treatment ( $-0.1459 \pm 0.4584$ ). It is important to acknowledge that even the non-responders to the anti-viral treatment were benefited, showing herein intermediate rates of progression of liver structural disturbances ( $0.0382 \pm 0.3661$ ). There was a clear reduction in the progression of fibrosis in those treated patients. Compared with the untreated patients, treated non-responders and treated responder groups, the

**Table 1** Clinical and laboratory features of patients at first biopsy

Variables	Values
Number of patients	112
Age in years (mean $\pm$ SD)	46.9 $\pm$ 12.3
Gender (Male/Female)	65/47 (58%/42%)

Treatment	
Non-treated	33/112 (29.5%)
Treatment responders	23/112 (20.5%)
Treatment non-responders	56/112 (50.0%)

UNL: Upper normal limit.

relationship between direct progression of hepatic fibrosis (according to the METAVIR scoring system) and IFN receptor-positivity (by immunohistochemistry) was not predictive of response to treatment. Although necroinflammatory activity at the first biopsy was not a determinant of the direct progression of fibrosis, a good correlation was observed between progression of necroinflammatory activity (defined as the difference in activity between the first and the second biopsy) and direct progression of fibrosis ( $P = 0.03$ ).

## DISCUSSION

According to the model described by Poynard *et al.*<sup>91</sup>, the annual rate of fibrosis progression can only be calculated in those patients with a clear duration of infection prior to the first liver biopsy (natural history). Therefore, the uni- and multivariate analysis could only be performed in

**Table 2** Univariate analysis of factors associated with presence of significant hepatic disease according to liver biopsy in patients with chronic HCV infection

Variables	Odds ratio	95% CI	P
Age at first biopsy (yr)	1.0853	1.0370-1.1357	0.001

93 of the 112 patients. Since none of these patients had been treated previously, excluding other causes of fibrosis, fibrosis was assumed to have been absent at the time of initial infection. Poynard *et al.*<sup>91</sup> analyzed 2235 patients with

chronic hepatitis C and found a mean fibrosis progression rate of 0.133 FU/year, similar to the mean rate found in this study (0.106 FU/year). On the other hand, in 2003, Ghany *et al*<sup>[16]</sup> reported a fibrosis progression rate of 0.44 FU/year. Considering the difficulty in identifying other fibrosis markers, various clinical, epidemiological, laboratory and histological variables have been evaluated to define their relevance in the natural history of chronic hepatitis C<sup>[17]</sup>. Using uni- and multivariate analysis, Poynard *et al*<sup>[18]</sup> reported that age at first liver biopsy was higher in those patients who progressed to severe disease ( $P < 0.001$ ; OR:1.09), mean age at first biopsy being  $53.4 \pm 10.6$  years for patients with severe disease and  $43.8 \pm 10.9$  years for patients with mild disease. Previous studies have described the duration of infection and the occurrence of fibrosis as relevant factors associated with progressive liver dysfunction. Verbaan *et al*<sup>[19]</sup> described fibrosis (rather than histological activity) as a factor related to the duration of infection; however, in the present study, no difference was found in the duration of infection between the groups with severe and mild disease.

On the other hand, the mean age of the patient at infection was significantly different between the two groups ( $P < 0.004$ ). The univariate analysis showed the mean age at infection of  $30.2 \pm 13.4$  years in the group that progressed to severe disease, was almost 10 years higher than those with mild disease. Poynard *et al*<sup>[9]</sup> observed a worse evolution of hepatitis C in patients infected after the age of 40 years. It is possible that in the present study, the age at first biopsy was statistically significant as an independent predictor of a more severe disease because of the older age at infection rather than the duration of the infection. In addition, most of these patients were under 40 years of age. In our series, age at first biopsy was a significant variable in the logistic model. Tassopoulos *et al*<sup>[20]</sup> also found that patients with mild chronic hepatitis were younger than those with moderate to severe diseases, with mean ages of 41 and 45 years, respectively.

Although there was a tendency towards significance, elevated levels of alanino aminotransferase (ALT) and aspartate aminotransferase (AST) were not found to be predictive of the evolution to mild or severe disease. Mathurin *et al*<sup>[21]</sup> evaluated 204 untreated patients prospectively, and found slower fibrosis progression in those with normal ALT. Koda *et al*<sup>[22]</sup> developed the FibroIndex, which is derived from the platelet count, AST and gamma globulin measurements. The authors concluded that this is a simple and reliable index for predicting significant fibrosis in chronic hepatitis C. In our study, elevated GGT failed to identify patients with severe disease at the first biopsy. Mathurin *et al*<sup>[21]</sup> described significantly elevated GGT in patients with abnormal ALT levels, which was in turn correlated with higher fibrosis scores.

Platelet count was not predictive of the severity of liver disease. Our results contradict the data reported by Poynard *et al*<sup>[18]</sup> showing the age of the patient and platelet count as being independent factors for progression to severe liver disease. Moreover, Ghany *et al*<sup>[16]</sup> described platelet count as a factor for differentiating early from

advanced stages of liver disease. The lack of statistical significance for platelet count as a predictor in the present study may be due to the inclusion of cases of fibrosis grade 2 (F2) in the severe group in contrast to the findings of previous studies reporting a correlation between platelet count and advanced liver disease with fibrosis 3 (F3) and 4 (F4). Ohta *et al*<sup>[23]</sup> developed a simple surrogate index consisting of platelet count and albumin level, which reflect the histological fibrosis stage of patients with chronic hepatitis C.

Steatosis was not related to severe disease in 93 patients of this study. Some authors reported a higher frequency of steatosis in patients with genotype 3 HCV<sup>[24,25]</sup>. Westin *et al*<sup>[26]</sup> studied 98 treatment-naïve patients and described a higher fibrosis progression rate in those with steatosis and genotype 3 HCV. Wyatt *et al*<sup>[27]</sup> reported that steatosis is strongly associated with fibrosis and tends to increase over time, but is reduced in patients developing cirrhosis.

Other histological variables such as interferon receptors failed to correlate with the evolution of the disease. Interferon receptor expression is associated with a higher response to interferon treatment<sup>[13]</sup>; however, no analysis has been carried out taking the natural history of the disease into consideration. Lower receptor expression would be expected in the group with worse evolution. The lack of significance may be due to the qualitative method used, and further studies are necessary since patients with liver cirrhosis are known to be less responsive to interferon treatment<sup>[28]</sup>.

The presence of siderosis at the first biopsy was correlated with the evolution of liver disease, with an odds ratio of 9.54 in the univariate and 6.48 in the multivariate analysis. This variable has been reported by some authors to be associated with higher fibrosis progression<sup>[29]</sup>.

The presence of lymphoid aggregates had an odds ratio of 3.97 for evolution of disease in the univariate analysis. After the logistic regression model, this factor persisted as a significant factor, with an odds ratio of 4.83. Similar results have also been observed by Delladetsima *et al*<sup>[30]</sup>.

Univariate analysis showed that the time interval between the two liver biopsies was similar in the three groups: untreated patients, non-responders and responders to treatment. The direct fibrosis progression rate was higher in the untreated group followed by the non-responder and responder groups. However, when the mean fibrosis progression rates of the untreated and non-responder groups were compared, no significant difference was found between the two groups. The direct fibrosis progression rates were 0.0382 and 0.2184 FU/year, respectively ( $P < 0.15$ ). Sobesky *et al*<sup>[31]</sup> previously found a higher direct fibrosis progression rate in untreated patients and a lower progression rate in patients who responded to treatment, while the progression rate was slightly lower in patients who did not respond to treatment. Similarly, Poynard *et al*<sup>[15,32]</sup> reported a lower progression rate of fibrosis in treated patients, which was correlated with virological response and duration of treatment. In addition, an improvement at histology was described in patients who responded to treatment.

Interferon receptor expression is associated with a greater response to interferon treatment<sup>[13]</sup>. The presence

of receptors would increase the probability of response to both endogenous and synthetic interferon, resulting in reduced progression of fibrosis. However, this was not observed in this study. The lack of correlation between interferon receptor expression and response to treatment may be explained by the qualitative method used in this study in contrast to the quantitative methods used in other studies<sup>[1,3]</sup>.

Elevated levels of ALT and progression of liver fibrosis has been previously described<sup>[33,34]</sup>. However, in this study, elevated ALT levels were not predictive of a higher direct progression rate of fibrosis, probably due to the effect of treatment since the patients with higher ALT values were in the treated group.

Histological variables failed to correlate with the direct progression of fibrosis. Even siderosis, an independent factor for indirect fibrosis progression in the multivariate analysis, failed to show any association with direct fibrosis progression.

Although steatosis was not associated with fibrosis progression in this study, Westin *et al.*<sup>[26]</sup> gave a higher direct fibrosis progression rate in patients with genotype 3 HCV and steatosis.

The patients with deteriorated necroinflammatory activity at histology had a mean direct fibrosis progression rate of 0.1883 FU/year, while patients with histological improvement had a rate of 0.0751 FU/year. These results indicate a good correlation between direct fibrosis progression rate and histological activity because fibrosis might be a result of the necroinflammatory activity.

In conclusion, among untreated chronic hepatitis C patients (natural history), the mean fibrosis progression rate was  $0.036 \pm 0.06$  METAVIR units per year in those with mild disease and  $0.17 \pm 0.14$  in those with severe disease. The best predictors of fibrosis progression are: age at first liver biopsy, the extent of ALT elevations, inflammation at liver histology and hepatic siderosis. The other factors, such as interferon receptor expression, are not significantly associated. When the histological progression rate is evaluated between 2 liver biopsies, the progression of fibrosis in METAVIR units per year is higher in non-treated patients and lower in those patients who responded to treatment. The worst histological evolution is correlated with the highest progression rate of fibrosis. No laboratory or histological variable is able to predict the evolution of fibrosis between two liver biopsies.

## COMMENTS

### Background

Chronic hepatitis C virus (HCV) infection may progress to cirrhosis over an average of 30 years. Once cirrhosis is established, it represents an irreversible condition, and strategies to avoid the progression of fibrosis are essential in order to avoid progressive liver dysfunction. The extent of inflammation, neovascular formation and fibrosis are debated as possible determinants of more severe clinical course of HCV.

### Research frontiers

Hepatitis C virus infection is often referred to as "the Silent Epidemic", because the progression to symptomatic liver disease may take decades. The clinical profiles in chronic hepatitis C are highly heterogeneous in terms of severity and progression rates towards end stage complications. Therefore staging and prognostic

assessment in the individual case would be a valuable strategy to identify patients at higher risk of progression.

### Innovations and breakthroughs

This study identified age at first liver biopsy, extent of ALT elevation, inflammation at liver histology and hepatic siderosis as the best predictors of the progression of fibrosis. Antiviral treatment was effective in preventing progression of liver structural lesions in patients with chronic hepatitis C.

### Applications

The mean interval from time of hepatitis C virus infection to onset of cirrhosis is approximately 30 years, but cirrhosis may occur within a range of 10-50 years. The results of our study contribute to a better understanding of the predictors of progression of fibrosis in chronic hepatitis C and will help identify patients at higher risk of rapid progression of the disease.

### Terminology

The progression of hepatic structural disturbances was assessed according to the METAVIR scoring system. The direct progression of fibrosis over time was defined as the difference in the stages of fibrosis between the first and the second biopsy, i.e. progression during the interval of years between the two biopsies, with the final result expressed in fibrosis units per year (Table 5).

### Peer review

The scientific conclusions are reliable and valuable for practical medicine. The references are appropriate, relevant and updated. The study is of particular interest to the practical medicine.

after the third vaccination. Surprisingly, these individuals showed response even before the first vaccination. T cell response to control antigens and mitogens was similar in all groups.

**CONCLUSION:** Our data suggest that there is no general immune deficiency in non-/low-responders. Thus, we hypothesize that the induction of anti-HBsAg responses by vaccination is significantly dependent on the pre-existing T cell repertoire against the specific antigen rather than the presence of a general T cell defect.

T cell responses to hepatitis B surface antigen are detectable in non-vaccinated individuals. *World J Gastroenterol* 2008; 14(16): 2529-2533 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2529.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2529>

### Abstract

**AIM:** To evaluate, whether humoral hepatitis-B-vaccine non-responders also fail to mount a T cell response and to compare these results to normal vaccines.

**METHODS:** Forty-seven health care employees were enrolled in this study including all available non-responders ( $n = 13$ ) with an anti-HBsAg titer  $< 10$  kU/L and all available low-responders ( $n = 12$ ) with an anti-HBsAg titer  $< 100$  kU/L. Also, 12 consecutive anti-HBsAg negative pre-vaccination subjects were enrolled as well as 10 subjects (+7 from the vaccinated group) with titers  $> 1000$  kU/L as controls. PBMC from all subjects were analyzed by IFN- $\gamma$  and IL-4 ELISPOT assays for the presence of hepatitis B surface antigen (HBsAg) reactive T cells.

**RESULTS:** Non-responders and low-responders had no or only very limited T cell responses, respectively. Individuals responding to vaccination with the induction of a high anti-HBsAg titer showed a strong T cell response

### INTRODUCTION

Worldwide, hepatitis B virus (HBV) infections are a growing problem with a high prevalence of over 8% hepatitis B surface antigen (HBsAg) positive individuals in Africa, South America, parts of Eastern Europe, South Asia, and Canada<sup>[1]</sup>. It is estimated that approximately 350 million people are chronic carriers of HBV with 1-1.5 million dying from liver cirrhosis and primary liver cancer<sup>[2]</sup>. Nowadays, protective repeated vaccinations with recombinant HBsAg are not only recommended to all health care workers and travellers, but have recently been included in the childhood and adolescence immunization schedule. Hepatitis B vaccinations prevent HBV infections as well as its complications in most of the vaccines<sup>[3,4]</sup>. However, 5% to 10% fail to produce protective anti-HBsAg titers after three vaccinations irrespective of the source of the antigen, which is a problem not only for health care workers, and represents a major medical as well as economic challenge<sup>[5-7]</sup>. Low- (HBsAg titer 10-99 kU/L) or

non-responsiveness (HBsAg titer < 10 kU/L) to vaccination are associated with certain human leukocyte antigen (HLA)-class II alleles. DRB1\*0301, DRB1\*0701, and DQB1\*0201<sup>[5,8,9]</sup> were shown to have a higher prevalence in non-responders, whereas other antigens (DRB1\*0101, \*1301, \*1501, and DPB1\*0401) seem to mediate strong immune responses<sup>[9-12]</sup>. Higher age, obesity, male gender, smoking, and chronic dialysis are risk factors for a non-/low-responsiveness<sup>[8,9,13-15]</sup>.

Monitoring of vaccination efficacy is currently performed by measurements of humoral immune responses (antibody titers) using ELISA assays, which does only indirectly reflect antigen-specific T cell responses. However, the T cell response plays an important role in the immune defence against viral infections. Patients with defects in T-cell function or repertoire such as human immunodeficiency virus (HIV) or transplant patients often suffer from opportunistic infections with viruses including cytomegalovirus (CMV), Epstein-Barr virus (EBV), herpes simplex viruses (HSV), and varicella zoster virus (VZV). It remains unclear, if vaccines with no or low anti-HBsAg titer similarly have a compromised T cell response to HBsAg<sup>[16-18]</sup>. Thus, it remains an open question, whether a B cell non-responder is also a T cell non-responder. To clarify this issue, we initiated a study to analyze whether HBsAg non- or low-responders are able to mount a significant T cell response against the HBsAg and compared them to "normal" vaccines.

## MATERIALS AND METHODS

### *Healthy individuals included in the study*

Forty-seven healthy employees of the University of Cologne (median age 32 years, range: 19-61 years, 21 male, 35 female) were enrolled in this study. These 47 employees including 12 consecutive health care employees, who received the first hepatitis B vaccine, were included as well as 10 vaccinated subjects with an anti-HBsAg titer > 1000 U/L. Documented non- and low-responders were contacted and asked to participate in the study, of whom 25 agreed. Of these 25, 13 individuals were non-responders as defined by an anti-HBsAg titer of 0-9 IU/L after the third of three vaccinations and 12 were low-responders (titer 10-99 IU/L). In this study, 3 different groups were analyzed. Non-responders ( $n = 13$ , titer 0-9 U/L), low-responders ( $n = 12$ , titer 10-99 U/L), vaccines before the first and after the third vaccination ( $n = 12$ ), and high-responders. The last group comprises 10 selected individuals with an anti-HBs titer > 1000 U/L plus 7 vaccines after the third vaccine with a titer > 1000 U/L (total  $n = 17$ ). Therefore, the patient number ( $n = 47$ ) and the subjects analyzed in the 3 groups ( $n = 54$ ) do not match.

### *Cell separation and ELISPOT analysis*

PBMC were isolated by Ficoll density centrifugation from 15 mL of blood and stored in liquid nitrogen until performance of ELISPOT assays. Membrane-bottomed 96-well plates (MAHA, Millipore) were coated overnight with 50  $\mu$ L of anti-IFN- $\gamma$  or anti-IL-4 antibodies (Hölzel, Cologne, Germany) at a concentration of 10 mg/L car-

bonate coating buffer (0.1 mol/L Na<sub>2</sub>CO<sub>3</sub>, 0.1 mol/L NaHCO<sub>3</sub>, pH 9.6) at 4°C. Plates were washed three times with RPMI 1640 and incubated with CellGenix medium (CellGenix, Freiburg, Germany) supplemented with 100 mL/L fetal calf serum (FCS) for 1 h at 37°C. Triplets of  $2 \times 10^5$  PBMC in 100  $\mu$ L CellGenix medium containing Glutamax I (Gibco BRL, Karlsruhe, Germany) were added per well and incubated with medium only, 5 mg/L yeast-derived HBsAg (subtype adw, Biotrend, Cologne, Germany), 5 LF/mL tetanus toxoid, or 10 mg/L pokeweed mitogen (PWM) at 37°C and 5% CO<sub>2</sub>. After 72 h, plates were extensively washed with PBS/0.05% Tween and incubated with 100  $\mu$ L/well of 10 mg/L biotinylated anti-IFN- $\gamma$  or anti-IL-4 antibodies (Hölzel, Cologne, Germany) for 2 h at 37°C and 5% CO<sub>2</sub>. After washing with PBS, plates were incubated with 100  $\mu$ L/well of 1:2000 diluted streptavidin-ALP for 1 h at 37°C and 5% CO<sub>2</sub>. Development of spots was performed with 50  $\mu$ L/well of chromogenic alkaline phosphatase substrate (BCIP/NBT, Sigma Aldrich, Germany). The reaction was terminated after approximately 5 min by rinsing plates with tap water. Spots were counted after drying of plates with an automated AELVIS Plate Elispot reader (AELVIS GmbH, Hannover, Germany). Specific T cell frequencies were calculated by subtracting mean background + 2 times standard deviation of background from counted spots. Therefore, the absolute numbers of spots are relatively low compared to data from other groups.

### *Statistical analysis*

All statistical calculations were performed with the software package SPSS V12.0 for Windows (Chicago, IL). T cell responses between groups were compared by using a 2-sided Student *t*-test. Probabilities  $P < 0.05$  were considered as statistically significant.

## RESULTS

### *Subjects with high anti-HBsAg titers show a strong T cell response*

All subjects with an anti-HBsAg titer > 1000 IU/L were analyzed for T-cell responses against the HBsAg and tetanus. This group comprised of a total of 17 subjects (6 male, 11 female, including 7 subjects from the vaccinee group) with a median age of 31 years (range: 20-44 years). The average IFN- $\gamma$  spot count for HBsAg was  $5.4 \pm 5.1$ , the average IL-4 spot count was  $1.0 \pm 2.1$ . The average IFN- $\gamma$  spot count for tetanus Ag was  $9.1 \pm 6.2$ , the average IL-4 spot count was  $3.0 \pm 3.7$ .

### *Non-/low responders lack a sufficient T cell response against HBsAg*

Twenty-five subjects had an anti-HBsAg titer < 100 IU/L after at least 3 vaccinations, of whom 13 were non-responders (anti-HBsAg titer of 0 IU/L) and 12 were low-responders (mean anti-HBsAg titer  $36 \pm 16$  IU/L). The median age of non-responders and low-responders was 40 years (range: 20-57 years) and 32 years (range: 19-61 years), respectively. Of the 13 non-responders, 4 were male, 9 female, of the 12 low-responders 4 were male, 8

Table 1 Number of spots in IFN- $\gamma$  and IL-4 ELISPOT assays for all individuals (*n*)

	<i>n</i>	Mean anti-HBsAg titer (IU/L)	IFN-g response (# of spots)		IL-4 response (# of spots)	
			HBsAg	TT Ag	HBsAg	TT Ag
Non-responders	13	0 $\pm$ 0	1.0 $\pm$ 1.3	9.1 $\pm$ 4.3 (6)	0.2 $\pm$ 0.3	3.5 $\pm$ 3.9 (6)
Low-responders	12	36 $\pm$ 16	1.7 $\pm$ 2.6	7.8 $\pm$ 6.5 (7)	0.5 $\pm$ 1.0	6.2 $\pm$ 10.1 (4)
High-responders	17	> 1000	5.4 $\pm$ 5.1	9.1 $\pm$ 6.2	1.0 $\pm$ 2.1	1.7 $\pm$ 3.9 (13)
Vaccines before 1st vx	12	0 $\pm$ 0 (9)	4.5 $\pm$ 5.7	11.2 $\pm$ 7.3 (11)	0.3 $\pm$ 0.5 (9)	4.5 $\pm$ 4.9 (5)
Vaccines after 3rd vx	12	10 $\times$ > 1000, 1 $\times$ 211, 1 $\times$ 394	7.1 $\pm$ 6.2	10.0 $\pm$ 8.4	2.7 $\pm$ 5.6	3.0 $\pm$ 4.4 (8)

were female. PBMCs were stimulated with medium only, HBsAg, tetanus Ag, or pokeweed mitogen (PWM) to evaluate T-cell specific cytokine release of IFN- $\gamma$  and IL-4. When assessing T cell responses against the mitogen PWM, there was no difference between non-responders, low responders, or high responders. A strong cytokine production occurred in all samples after stimulation with PWM (positive control). Similarly, when assessing antigen-specific T cell responses against tetanus Ag, we observed comparable T cell responses in all three groups. Non-responders showed a mean IFN- $\gamma$  response against tetanus Ag of  $9.1 \pm 4.3$  spots (*n* = 6) and a mean IL-4 response of  $3.5 \pm 3.9$  spots (*n* = 6). Low-responders had an average count of  $7.8 \pm 6.5$  IFN- $\gamma$  spots (*n* = 7) and  $6.5 \pm 10.0$  IL-4 spots (*n* = 4). For high-responders, T cell response against tetanus Ag was  $9.1 \pm 6.2$  IFN- $\gamma$  spots (*n* = 11) and  $4.5 \pm 4.9$  IL-4 spots (*n* = 5) before vaccination and  $10.0 \pm 8.4$  IFN- $\gamma$  spots (*n* = 17) and  $1.7 \pm 3.9$  IL-4 spots (*n* = 13, Table 1).

In contrast, when assessing responses to the HBsAg, we observed clear differences between the three groups. Non-responders had a mean anti-HBsAg IFN- $\gamma$  T cell response of  $1.0 \pm 1.3$  spots and a mean IL-4 T cell response of  $0.2 \pm 0.3$  spots. Low-responders showed a slightly higher T cell response with mean IFN- $\gamma$  responses of  $1.7 \pm 2.6$  spots and a mean IL-4 T cell response of  $0.5 \pm 1.0$  spots) compared to high-responders with an average IFN- $\gamma$  spot count for HBsAg of  $5.4 \pm 5.1$ , and an average IL-4 spot count of  $1.0 \pm 2.1$ .

Taken together, although all individuals tested showed strong responses to the mitogen PWM and significant responses to tetanus Ag, there was a clear difference between non-responders and high responders (*P* = 0.006 for IFN- $\gamma$  results, *P* = ns for IL-4) with low-responders showing intermediate values. These data suggest that antibody titers indeed correlate with T cell responses as assessed by ELISPOT analysis.

#### T cell responses against HBsAg are measurable in vaccines before the first immunization

To further corroborate the above findings, we assessed T cell responses and anti-HBsAg titers before the first and after the third vaccination in 12 individuals. The median age was 31 years (range: 23-50 years), 3 subjects were male, 9 were female. All had a negative anti-HBsAg titer before the first and an anti-HBsAg titer > 200 IU/L after the third vaccination suggesting all to be within the intermediate or high-titer group. The average T cell response against HBsAg was  $4.5 \pm 5.7$  IFN- $\gamma$  spots and  $0.3 \pm 0.5$  IL-4 spots

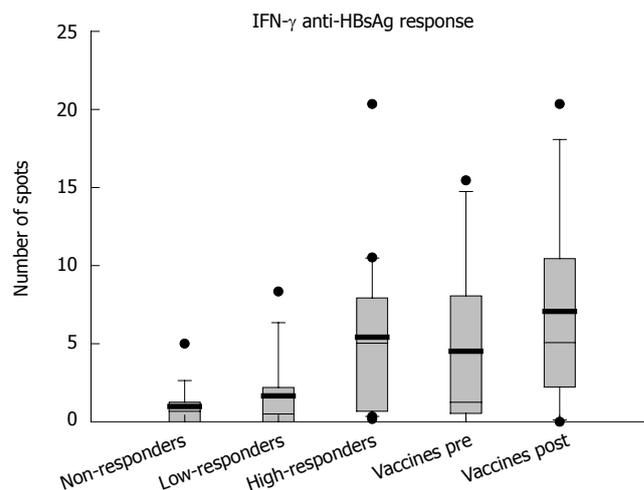

Figure 1 Box and whisker plots of number of IFN- $\gamma$  spots from ELISPOT assays of PBMC stimulated with HBsAg. The black dots show the outliers.

before the first vaccination and  $7.1 \pm 6.2$  IFN- $\gamma$  spots and  $2.7 \pm 5.6$  IL-4 spots after the third vaccination, respectively. The difference between pre- and post-vaccination anti-HBsAg response was not significant in a Student *t*-test (*P* = 0.08 for IFN- $\gamma$ , *P* = 0.10 for IL-4, Table 1 and Figure 1).

## DISCUSSION

Approximately 5% to 10% of the healthy population fails to mount a protective anti-HBsAg antibody titer after three vaccinations. However, it has not been evaluated, whether patients with a low antibody titer are also incapable of producing an HBsAg specific T cell response. Our data clearly show that humoral non- and low-responders have no or only a limited T cell repertoire reacting to HBsAg compared to responders. Only 1 out of 13 non-responders and 2 out of 12 low-responders had (IFN- $\gamma$ ) T-cell responses that were equal to or exceeded the average T cell response of the high-responder group. Two other studies have reported decreased IL-2, IFN- $\gamma$ , and IL-10 cytokine production in ELISA assays of non-responders to HBsAg stimulation and conclude that these subjects may have a defect in either the primary HBsAg-specific T cell repertoire or antigen presentation<sup>[16,17]</sup>. Our ELISPOT data clearly indicate that non- and low-responders do not have a general immune defect as their T cell response to control antigens (e.g tetanus toxoid) is comparable to that of “normal” vaccines. Also, their lymphocytes were capable of strong cytokine secretion after PWM stimulation.

So what prevents a non-responder from developing a protective HBsAg titer? As non-responsiveness to HBsAg is associated with certain HLA-haplotypes, it has been hypothesized that antigen presenting cells of non-responders are unable to adequately present this specific antigen<sup>[19]</sup>, although a recently published trial showed that HLA-DR0301 non-responders are not deficient in their HBsAg-presentation and do not lack B7 co-stimulatory molecules<sup>[20]</sup>. Other studies suggested that non-responsiveness was caused by the presence of suppressor T cells<sup>[21,22]</sup> or the absence of the Th1 cells or cells with TCR specificity for HBsAg<sup>[23]</sup>. Salazar *et al*<sup>[24]</sup> reported that non-responders show a defect in HBsAg reactive CD4<sup>+</sup> helper T cells. Our data extend these hypotheses suggesting that a preexisting T cell repertoire exists in the majority of vaccines that may be critical for strong post vaccination T cell responses. Except for 2 out of 12 individuals, all vaccines had a (IFN- $\gamma$ ) T cell response before vaccination. In contrast, non-/low-responders lacked a significant T cell response. Thus, we hypothesize that a pre-existing immunologic T cell cross-reactivity against the HBsAg is necessary in order to respond to vaccinations.

This cross-reactivity is probably triggered by a common infectious agent, which is processed by antigen presenting cells to peptides similar in structure to parts of the HBsAg. In certain HLA-haplotypes MHC/peptide complexes do or do not induce crossreactive effector or regulatory T cells. This could be the explanation, why non-/low-responsiveness is linked to certain MHC/HLA-types. What we do not know, is whether this cross-reactive T cell response alone yields any protection against a HBV infection. But because HBsAg vaccinations are a very effective measure against a new infection<sup>[25,26]</sup>, it seems that a concurrent B cell response (*i.e.* protective anti-HBsAg titer) is primarily necessary to prevent HBV replication.

In our trial, IFN- $\gamma$  was used to study TH1 response and IL-4 for TH2 response. However, the number of spots were relatively low, which has been reported before<sup>[27]</sup>. It is especially surprising that the TH2 response was very low in our responders although the hepatitis B vaccine is considered to be an immunization primarily based on a strong TH2/B-cell response. However, our data are in good concordance with other studies demonstrating a dominant TH1 cell response after hepatitis B vaccination<sup>[27-30]</sup>. Bauer *et al* recently showed that 15 hepatitis B individuals, who had been successfully vaccinated, but had lost anti-HBs titers were able to mount a significant TH1 response similar to our responders<sup>[27]</sup>. This again shows that non- and low-responders significantly differ from responders, even if the latter lose their anti-HBsAg titers.

In light of the burden of HBV infection several strategies are currently under study to increase the efficacy of HBsAg vaccination, e.g. by applying double vaccination dose<sup>[31]</sup>, using intradermal boosters<sup>[32-34]</sup>, or adding adjuvants such as monophosphoryl lipid A (MPLA) or influenza vaccine<sup>[35,36]</sup>. Although these measures were more effective than the yeast derived hepatitis B vaccine alone, not all non-responders showed seroconversion. Currently, early studies using immunostimulatory CpG oligodeoxynucleotides (CpG ODN) suggest a breakthrough in hepatitis B prevention. Not only do vaccines develop considerably higher titers after

three vaccinations with this new combination vaccine, but most of them already mount protective titers after the first vaccination compared to none of the controls immunized with HBsAg alone<sup>[37]</sup>. It will be interesting to study whether the seroconversion after HBV-CpG ODN vaccination is also accompanied by the induction of T cell responses as shown here and whether previous non-responders will now mount comparable T cell responses as a result of vaccination. As the safety of a CpG-ODN vaccine is still to be evaluated, a possible future strategy could be to identify possible non-/low-responders with an ELISPOT assay and administer CpG-ODN admixed vaccine for these individuals. The majority of people could still be vaccinated with the common hepatitis B vaccine.

## COMMENTS

### Background

Non-responsiveness to hepatitis B vaccine is a problem often experienced by professional health-care workers. It is believed that non-responders lack certain properties in their immune system or are even immunocompromised.

### Innovations and breakthroughs

Here, we find that all subjects responding to the hepatitis B vaccine already had a T-cell response against the hepatitis Bs antigen before their first vaccination. We hypothesize that the induction of anti-HBsAg responses is dependent on the pre-existing T-cell repertoire against the specific antigen, which may be expanded by the cross-reaction to a ubiquitous antigen.

### Applications

By new adjuvants as CpG-ODN, it may be possible in the future to induce a sufficient anti-HBs antigen response in all vaccines.

### Terminology

Hepatitis Bs Ag is the hepatitis B surface antigen (HBsAg). Antibody titers against this antigen are an indicator of a good immune response against the pathogen.

### Peer review

In this well written article authors find that all subjects responding to the hepatitis B vaccine already had a T-cell response against the hepatitis Bs antigen before their first vaccination, so they hypothesize that the induction of anti HBsAg responses by vaccination is significantly dependent on the pre-existing T-cell repertoire against the specific antigen rather than the presence of a general T-cell defect, which timely contribute to us.

### Abstract

**AIM:** To determine, by counting sister chromatid exchange (SCE) frequencies, whether genetic impairment and DNA damage have an effect on the pathogenesis of gastric cancer (GC).

**METHODS:** Analysis of SCE is a cytogenetic technique used to show DNA damage as a result of an exchange of DNA fragments between sister chromatids. We analyzed SCE frequency in 24 patients with GC, 26 patients with chronic atrophic gastritis (CAG), and 15 normal controls. The presence of *H pylori* was confirmed by urease test, toluidine-blue stain and hematoxylin-eosin stain.

**RESULTS:** SCE was significantly increased in *H pylori*-negative GC patients, and in *H pylori*-negative CAG patients compared with controls ( $7.41 \pm 1.36$  and  $6.92 \pm 1.20$ , respectively, vs  $5.54 \pm 0.8$ ,  $P < 0.001$ ). There was no difference in the SCE frequency between *H pylori*-negative GC patients and *H pylori*-negative CAG patients ( $P > 0.05$ ). On other hand, the SCE frequencies in *H pylori*-positive GC patients were higher than those in *H pylori*-positive CAG patients ( $9.20 \pm 0.94$  vs  $7.93 \pm 0.81$ ,  $P < 0.01$ ). Furthermore, *H pylori*-positive GC patients had a higher SCE frequency than *H pylori*-negative GC patients ( $9.20 \pm 0.94$  vs  $7.41 \pm 1.36$ ,  $P < 0.001$ ). Similarly, a significant difference was detected between *H pylori*-positive CAG patients and

*H pylori*-negative CAG patients ( $7.93 \pm 0.81$  vs  $6.92 \pm 1.20$ ,  $P < 0.05$ ).

**CONCLUSION:** We suggest the increased SCE in patients reflects a genomic instability that may be operative in gastric carcinogenesis.

### INTRODUCTION

Gastric cancer is the second leading cause of cancer death and the fourth most common cancer in terms of new cases worldwide<sup>[1]</sup>. The development of gastric cancer in humans has been shown to be a multi-step process, ranging from chronic gastritis to atrophy, intestinal metaplasia, dysplasia and finally, invasive cancer<sup>[2-5]</sup>.

Multiple genetic and epigenetic alterations in oncogenes, tumor suppressor genes, cell-cycle regulators, cell adhesion molecules, DNA repair genes and genetic instability, as well as telomerase activation, are implicated in the multi-step process of gastric carcinogenesis. p53, a tumor suppressor gene is thought to play a critical role in the multistep process of gastric carcinogenesis<sup>[6-9]</sup>. Inactivation of p53 by 17p (p53), loss of heterozygosity (LOH) and mutation seems to be an early event in neoplastic progression in gastric carcinomas, because it develops in diploid cells before aneuploidy and other LOH events involving chromosomes 1, 5, 6, 7, 10, 11 and 12<sup>[10,11]</sup>.

*H pylori* is an important human pathogen, responsible for most cases of chronic gastritis, peptic ulcer, gastric cancer and gastric mucosa-associated lymphoid lymphoma<sup>[12-16]</sup>. Evidence that it acts as a carcinogen has come mainly from epidemiological studies<sup>[17-19]</sup> and animal studies<sup>[20]</sup>. The working group of the Agency for Research on Cancer reported in 1994 that *H pylori* is indeed a group-1 carcinogen<sup>[21]</sup>.

*H pylori* is a carcinogen in humans, although it is not thought to cause gastric cancer directly. It may, however, provide a suitable environment, by causing chronic gastritis and intestinal metaplasia, for neoplastic changes. *H pylori* infection leads to changes in many factors, such as the vitamin C content of gastric juice, the levels of reactive oxygen metabolites in the tissues and epithelial cell proliferation, which are important in the pathogenesis of gastric cancer<sup>[22]</sup>.

The sister chromatid exchange (SCE) phenomenon is widely used as a reliable and sensitive indicator of chromosome (DNA) instability, since the SCE patterns can reveal a general genome instability<sup>[23]</sup>. Variations in DNA repair mechanisms or detoxifying enzymes have been implicated as causing genetic susceptibility associated with cancer<sup>[24]</sup>. SCE in peripheral lymphocytes has been widely used to assess exposure to mutagens and carcinogens<sup>[25-27]</sup>. The SCE frequency was found to be significantly higher in individuals with Werner syndrome, Bloom's syndrome, and myelodysplastic disease than in their control groups. These diseases are known to be associated with genomic instability<sup>[28,29]</sup>.

Several groups of investigators have suggested active oxygen species may be implicated in the production of high basal SCE frequencies in chromosome instability syndrome cells, because oxygen free radicals are thought to be responsible for chromosome damage in these cells<sup>[30]</sup>. Oxidative damage to DNA over time can cause changes to both the structure and function of chromosomes. These changes in the genetic code may lead to cancer and other chronic diseases<sup>[31,32]</sup>. The mutagenic effects of reactive oxygen species (ROS) have been detected in human lymphocytes by using the SCE technique; elevated ROS in cells can cause an increase in mitotic recombination frequency<sup>[33]</sup>. Recently, the genotoxicity of ROS has been well established, and oxidative stress has been shown to cause genomic damage<sup>[34,35]</sup>.

The aim of this study was to determine, by counting SCE frequencies, whether genetic impairment and DNA damage have an effect on the pathogenesis of GC.

## MATERIALS AND METHODS

### Patients

This study was conducted between February 2007 and June 2007 in the Erzurum State Hospital. We performed SCE analysis in 24 non-smoking (8 females and 16 males) patients with GC (age, mean  $\pm$  SE: 62.2  $\pm$  5.94 years), 26 non-smoking (7 females and 19 males) patients with CAG (age, mean  $\pm$  SE: 54.3  $\pm$  12.27 years), and 15 healthy, non-smoking (6 females and 9 males) controls (age, mean  $\pm$  SE: 51.26  $\pm$  6.27 years). Nine of the 24 GC patients were infected with *H pylori*. Nine of the 26 CAG

patients infected with *H pylori*. The presence of *H pylori* was confirmed by the urease test, toluidine-blue stain and hematoxylin-eosin stain. The patients were selected from non-smoking and nonalcoholic subjects. None of the subjects had a history of viral infection, bacterial infection or any metabolic diseases. The patients had not been treated with chemotherapy or radiotherapy during the last 4 mo. The patient and control groups were chosen for their similar habits. The hospital Ethical Committee approved the human study. All patients were analyzed prior to treatment.

### Sister chromatid exchange analysis

For SCE analysis, 2 mL of heparinized blood was drawn from each individual. Cultures were established by adding 0.5 mL of blood to 5 mL karyotyping medium (Biological Industries, Beit Haemek, Israel) with 2% phytohaemagglutinin M (PHA) (Biological Industries, Beit Haemek, Israel), and incubating for 24 h at 37°C. A 5-bromo-2'-deoxyuridine (BrdU) (Sigma, USA) solution at a final concentration of 5  $\mu$ g/mL was added. Lymphocytes were cultured in the dark for 48 h and metaphases were blocked during the last 2 h with colcemid (Biological Industries, Beit Haemek, Israel) at a final concentration of 0.1  $\mu$ g/mL. Further processing included hypotonic treatment, fixation, slide preparation and fluorescein plus Giemsa (FPG) staining for the detection of SCE<sup>[36]</sup>. Fifty second-division metaphases were scored on coded slides by a single observer as the number of SCEs/cell per subject. The SCE data were analyzed statistically by Student's *t*-test.

## RESULTS

The associations of GC and CAG with SCE frequencies in *H pylori*-positive and negative groups are shown in Table 1. According to these results, there was no difference in mean SCE frequency between *H pylori*-negative GC patients and *H pylori*-negative CAG patients (7.41  $\pm$  1.36 *vs* 6.92  $\pm$  1.20 per metaphase, respectively; *P* > 0.05); however, the mean SCE frequencies of both patient groups were significantly higher than that of the control group (5.54  $\pm$  0.8 per metaphase, *P* < 0.001 for both patient groups). On the other hand, the mean SCE frequency of *H pylori*-positive GC patients was significantly higher than that of *H pylori*-positive CAG patients (9.20  $\pm$  0.94 *vs* 7.93  $\pm$  0.81 per metaphase, respectively; *P* < 0.01). Furthermore, the mean SCE frequency in *H pylori*-positive GC patients was higher than that in *H pylori*-negative GC patients (9.20  $\pm$  0.94 *vs* 7.41  $\pm$  1.36 per metaphase, respectively *P* < 0.001). Similarly, *H pylori*-positive CAG patients had a higher mean SCE frequency than *H pylori*-negative CAG patients (7.93  $\pm$  0.81 *vs* 6.92  $\pm$  1.20 per metaphase, respectively *P* < 0.05).

## DISCUSSION

Gastric cancer is still a common cause of cancer-related deaths worldwide, despite improved diagnostic and therapeutic implications. Hence, early diagnosis has critical importance. Cancer results from accumulated genetic or

Table 1 SCE frequency in *H pylori*-positive and -negative groups of patients and healthy controls (mean  $\pm$  SE)

		Sex F/M	n	Age, yr	Age at diagnosis, yr	SCE
GC Patients	<i>H pylori</i> -positive	3/6	9	53.77 $\pm$ 10.27	53.33 $\pm$ 9.26	9.20 $\pm$ 0.94
	<i>H pylori</i> -negative	5/10	15	63.20 $\pm$ 6.98	63.06 $\pm$ 7.06	7.41 $\pm$ 1.36
CAG Patients	<i>H pylori</i> -positive	2/7	9	51.33 $\pm$ 11.21	50.11 $\pm$ 15.16	7.93 $\pm$ 0.81
	<i>H pylori</i> -negative	5/12	17	57.23 $\pm$ 13.58	56.65 $\pm$ 13.65	6.92 $\pm$ 1.2
Controls		6/9	15	51.26 $\pm$ 6.27		5.54 $\pm$ 0.8

GC: Gastric cancer; CAG: Chronic atrophic gastritis.

epigenetic alteration(s) in a variety of genes that directly or indirectly control cell division, cell differentiation, and cell death<sup>[37]</sup>. The development of gastric cancer in humans has been shown to be a multi-step process, ranging from chronic gastritis to atrophy, intestinal metaplasia, dysplasia and finally invasive cancer<sup>[2-5]</sup>.

Exposure of cells to a variety of genotoxic and cytotoxic agents has the potential to elicit prolonged and dynamic changes that compromise the stability of the cellular genome<sup>[38]</sup>. Many of these changes, whether induced directly or indirectly by DNA damage, lead to increases in gene mutation and amplification, reduced cloning efficiency, elevated micronuclei, sister chromatid exchanges, and multiple karyotypic abnormalities<sup>[38]</sup>.

Cytogenetic tests have been widely used in medicine for the assessment of a causal association between disease and cytogenetic damage. In the present study, we investigated whether cytogenetic abnormalities participate in the pathogenesis of GC. SCE, as an indicator of DNA damage, might reflect an instability of DNA or a deficiency of DNA repair. Therefore, it could be used to investigate any causal association between various diseases and any cytogenetic damage<sup>[39-41]</sup>.

SCE is known to be increased by exposure to various genotoxic carcinogens<sup>[42]</sup> and seems to reflect the repair of DNA lesions by homologous recombination<sup>[43]</sup>. Important sources of exposure include diet, general environment, medical exposure to ionizing radiation, and internal generation of genotoxic species. Internal phenomena, such as metabolism, errors of DNA replication, inflammation and oxidative stress, may be of importance. Inflammatory diseases, oxidative stress and radiation exposure have been associated with the generation of clastogenic factors, which may be quite persistent<sup>[44-46]</sup> and might play an important role in carcinogenesis.

Numerous studies have clarified the relationship between *H pylori* infection and gastric cancer<sup>[14-16]</sup>. Epidemiological studies have shown that *H pylori* infection is an important risk factor in gastric cancer<sup>[22,47]</sup>. Several *H pylori* virulence-associated genes have been found in Western populations to be associated with an increased risk of gastric cancer and precancerous lesions<sup>[48]</sup>. Studies from Japan have confirmed IL-1 $\beta$  polymorphisms do contribute to the gastric acid secretory response to *H pylori* infection, and subsequently to clinical sequelae<sup>[49,50]</sup>. A polymorphism in the IL-1 $\beta$  gene cluster, which has both pro-inflammatory and potent acid suppressive effects, is associated with an augmented cytokine response to *H pylori* infection that increases the risk of gastric atrophy, gastric ulcer, and gastric cancer<sup>[3,51]</sup>.

Tsai *et al*<sup>[52]</sup> reported alterations in gene expression associated with cell damage, inflammation, proliferation, apoptosis, and intestinal differentiation in gastric tissues, taking into account *H pylori* status. More changes in gene expression, possibly associated with persistent *H pylori* infection and progression of preneoplasia, were observed in the placebo group. No gene was upregulated over time in tissues from the treatment group. This observation is consistent with current knowledge that *H pylori* infection induces cell hyperproliferation, inflammation, and genomic instability<sup>[53]</sup>.

The frequency of SCE is increased in patients with carcinoma of cervix uteri, nasopharyngeal carcinoma, prostate carcinoma, ovarian carcinoma, acute leukemia, chronic lymphocytic leukemia and breast cancer<sup>[54-59]</sup>. Concerning gastric cancer, in one of the earliest studies SCE was increased to similar levels in patients with GC and those with CAG. However, the mean frequencies of both groups were significantly higher than that of the control group<sup>[60]</sup>. Furthermore, Gulten *et al*<sup>[61]</sup> reported increased SCE frequencies in a group of gastritis patients infected with *H pylori*.

In our study, we found significantly elevated SCE frequencies in both *H pylori*-negative GC patients and *H pylori*-negative CAG patients compared with controls. However, there was no difference in SCE frequency between *H pylori*-negative GC patients and *H pylori*-negative CAG patients. This result is consistent with the study of Zhou L *et al*<sup>[60]</sup>. On the other hand, *H pylori*-positive CAG patients had a higher SCE frequency than *H pylori*-negative CAG patients. This finding is consistent with the study of Gulten *et al*<sup>[61]</sup>. Similarly, *H pylori*-positive GC patients had a higher SCE frequency than *H pylori*-negative GC patients. Furthermore, the SCE frequencies in *H pylori*-positive GC patients were higher than those in *H pylori*-positive CAG patients. These findings clearly indicate the significance of simultaneous application of SCE for the screening of high-risk individuals. In addition, the results suggest the genotoxic effect of *H pylori* infection is a risk factor for gastric cancer. Intense *H pylori* infection may contribute more to DNA damage and promote carcinogenesis in patients with gastric cancer. Furthermore, chronic *H pylori* infection is also associated with increased gastric cell turnover, which is probably of importance in malignant transformation<sup>[62,63]</sup>.

Our study, which showed increased SCE frequencies in the lymphocytes of CAG patients, could support these observations, as the induction of changes in DNA that lead to mutations play a role in carcinogenicity. Establishment of inherited susceptibility factors is

important to recognize individuals at a higher risk of developing gastric cancer, so that they may benefit from early detection and prevention programs.

Recent studies have demonstrated a significantly increased risk for the development of gastric carcinoma in patients with CAG<sup>[3,4,64,65]</sup>. Patients with CAG have a markedly increased risk of GC, but the mechanism underlying this increased risk is not well understood. Chronic inflammation has been associated with the development of chromosomal aberrations in both disorders that progress to neoplasia, such as ulcerative colitis<sup>[66]</sup>, and Barrett's esophagus<sup>[67]</sup>. Our results confirm and extend these findings to patients with CAG. Many investigators have demonstrated genomic instability and abnormalities in patients with CAG and GC<sup>[60,61,64,65]</sup>. Our analysis suggests that chromosomal instability (DNA) is present at very early stages of neoplastic progression in CAG and GC patients. This instability may be permissive for the generation of other genomic aberrations associated with gastric cancer progression.

In conclusion, our results suggest increased chromosomal instability may be associated with the pathogenesis of early gastric cancer. In addition, our findings indicate that the genotoxic potential of *H. pylori* infection is a risk factor for gastric cancer. Thus, SCE is a promising biomarker for assessing the risk of neoplastic progression in gastric carcinoma.

## COMMENTS

### Background

It is known there is an increased sister chromatid exchange (SCE) frequency in neoplastic diseases. Gastric cancer is still a common cause of cancer-related deaths worldwide, despite improved diagnostic and therapeutic implications. Hence, early diagnosis has critical importance.

### Research frontiers

Analysis of SCE is a cytogenetic technique used to show DNA damage as a result of an exchange of DNA fragments between sister chromatids. Therefore, in this study, we aimed to determine, by assessing SCE frequencies, whether genetic impairment and DNA damage have an effect on the pathogenesis of GC.

### Innovations and breakthroughs

Our results suggest increased chromosomal instability may be associated with the pathogenesis of early gastric cancer. The identification of increased SCE frequency in patients with gastric lesions may be helpful in the early diagnosis of gastric cancer.

### Applications

SCE analysis has come into use as a sensitive means of monitoring the DNA damage. SCE analysis may be used as a marker to estimate the risk of gastric cancer.

### Terminology

Sister chromatid exchange (SCE): SCE is known to result from reciprocal DNA interchange in homologous loci of sister chromatids during the replication process.

### Peer review

This study indicated genetic impairment and genetic instability may play an important role in gastric cancer. In addition, these findings show the genotoxic potential of *H. pylori* infection is a risk factor for gastric cancer.

### Abstract

**AIM:** To investigate the changes in plasminogen activity level during mesenteric ischemia.

**METHODS:** We performed laparotomy in 90 female Wistar-Albino rats (average weight 230 g). In sham groups (SL) (Groups I and II) the superior mesenteric artery (SMA) and vein (SMV) were explored, but not tied. In SMA groups (Groups III and IV) the SMA was ligated, and in SMV groups (Groups V and VI) the SMV was ligated. On re-laparotomy 2 mL of blood was drawn at 1 h in groups I, III and V, and at 3 h in groups II, IV and VI. Plasminogen levels were assessed and comparisons were made between groups and within each group.

**RESULTS:** The mean plasminogen activity in the SL group was significantly higher than SMA ( $25.1 \pm 10.8$  vs  $11.8 \pm 4.6$ ,  $P < 0.001$ ) or SMV ( $25.1 \pm 10.8$  vs  $13.7 \pm 4.4$ ,  $P < 0.001$ ) groups both at 1 h and at 3 h ( $29.8 \pm 8.9$  vs  $15.1 \pm 5.7$ ,  $P < 0.0001$ ;  $29.8 \pm 8.9$  vs  $14.2 \pm 2.9$ ,  $P < 0.0001$ ). There were no significant differences between the values of SMA and SMV groups at 1 h ( $P = 0.28$ ) and at 3 h ( $P = 0.71$ ). In each group, plasminogen activity levels did not change significantly between the two measurements performed at 1 h and 3 h.

**CONCLUSION:** We conclude that blood plasminogen activities decrease during early phases of both arterial and venous mesenteric ischemia which may be a useful marker for early diagnosis.

**Key words:** Mesenteric ischemia; Necrosis; Activity level

### INTRODUCTION

Successful treatment of acute mesenteric ischemia depends on restoration of circulation before the development of intestinal necrosis, and hence on early diagnosis<sup>[1-4]</sup>. However, laboratory signs are non-specific even after the development of necrosis and the rate of mortality is still over 50% even in experienced centers<sup>[5-7]</sup>.

Plasminogen is a protease synthesized in the liver. It is a member of the fibrinolytic system and its plasma level are stable. Plasma plasminogen level is known to decrease in several conditions such as disseminated intravascular coagulation, severe hepatic failure, thrombotic disorders, thrombolytic treatment, and primary and secondary fibrinolysis<sup>[8,9]</sup>. Plasminogen is the most important element of the fibrinolytic pathway and our literature search has not revealed any studies examining the change in plasminogen level during acute mesenteric ischemia. Thus, in the present study, the potential use of plasminogen level for the early diagnosis of acute mesenteric ischemia has been investigated.

### MATERIALS AND METHODS

The study protocol was approved by the Ethics Committee of Haydarpasa Training and Research Hospital. A total of 90 female Wistar-Albino rats, with an average weight of 230 g (range: 190-270 g), were fed with standard food and water at room temperature, and were allocated into 6 study groups, each having 15 rats.

#### Surgical procedure

Rats were placed in a bowl containing a cotton pad soaked with diethyl ether for about 3 min and then anesthetized with ketamine 50 mg/kg, IM. After shaving and sterilization of the abdominal wall with povidone

iodine solution, laparotomy was performed through a midline incision. In all groups the superior mesenteric artery (SMA) and vein (SMV) were explored and 3/0 silk suture materials were placed around the vessels. In sham laparotomy groups (Groups I and II) sutures were not tied. In the SMA occlusion groups (Groups III and IV) the SMA was ligated; while in the SMV occlusion groups (Groups V and VI) the SMV was ligated. Abdominal walls were closed with continuous 3/0 silk sutures.

### Blood sampling

Exploration and ligation of the artery and the vein were taken as zero time point. Re-laparotomy was performed at 1 h in groups I, III and V, and at 3 h in groups II, IV and VI, and 2 mL of blood was drawn from the heart with a 21G syringe.

### Tests and assessments

Two-milliliter blood samples, collected at 1 h and at 3 h, were centrifuged in citrated tubes for 15 min at 4500 r/min. They were then stored at -20°C until being assayed. Plasminogen was assessed as chromogenic enzyme activity by the Streptokinase method by using a Dade Behring Coagulometry. SMA occlusion, SMV occlusion and Sham laparotomy (SL) groups were compared with respect to plasminogen activity levels at 2 time points. Also plasminogen activities at 1 h and at 3 h were compared within each group.

### Statistical analysis

The statistical analyses were performed with SPSS (Statistical Package for Social Sciences) for Windows 10.0. Wilcoxon test was used to compare the data obtained at different time points. Kruskal-Wallis H analysis was used to compare three groups and Mann Whitney U Test was used for pair wise comparisons between groups. The results were evaluated at a confidence interval of 95%, and *P* values less than 0.05 were considered statistically significant.

## RESULTS

During the first hour of ischemia, the small intestine and right colon were pale and edematous at laparotomy in SMA- and SMV-ligated rats. These structures turned dark red and/or purple by the end of the third hour. At 1 h, the mean plasminogen activity in the SL group was significantly higher compared to the SMA or SMV occlusion groups ( $25.1 \pm 10.8$  vs  $11.8 \pm 4.6$  or  $13.7 \pm 4.4$ ,  $P < 0.001$ ). Although plasminogen activity levels in the SMA occlusion group were lower than the SMV occlusion group, the difference between the two was not statistically significant. Also, at 3 h, plasminogen activity in the SL group was significantly higher compared to the SMA and SMV occlusion groups ( $29.8 \pm 8.9$  vs  $15.1 \pm 5.7$  or  $14.2 \pm 2.9$ ,  $P < 0.0001$ ). Plasminogen activities in the SMA occlusion group were higher than those in the SMV occlusion group with no significant difference.

In each group, plasminogen activity levels did not change significantly between the two measurements performed at 1 and 3 h. Plasminogen activity levels within and between groups are presented in the Table 1.

**Table 1** Plasminogen activity levels (%) of groups at two time points

Time points	Sham group	SMA occlusion group	SMV occlusion group	<i>P</i> value
1st h	25.1 ± 10.8	11.8 ± 4.6	13.7 ± 4.4	$P < 0.001$
3rd h	29.8 ± 8.9	15.1 ± 5.7	14.2 ± 2.9	$P < 0.0001$
<i>P</i> values	$P = 0.21$	$P = 0.088$	$P = 0.71$	

SMA: Superior mesenteric artery; SMV: Superior mesenteric vein.

## DISCUSSION

Both metabolic and morphologic changes are observed during mesenteric ischemia. As reported by Brown *et al.*, structural changes start to occur within the first 10 min of ischemia<sup>[10]</sup>. It has also been reported that within 30 min of ischemia a remarkable amount of fluid accumulates, both in the basement membrane and between cells resulting in paleness of villi, and also inflammatory cells accumulate<sup>[11,12]</sup>. Thus, laboratory markers with high sensitivity and specificity that can be utilized 1 to 2 h prior to the occurrence of irreversible changes would be beneficial in the early diagnosis of acute mesenteric ischemia.

Most of the previous studies examining intracellular enzymes released from ischemic bowel failed to identify any marker sensitive or specific to disease for early diagnosis<sup>[13-15]</sup>. The most likely explanation for the failure to identify such an early marker is that these enzymes usually appear in the blood only after irreversible ischemia has occurred in the bowel and that they are taken to the liver through the portal system to be metabolized. Murray *et al.*<sup>[16]</sup> demonstrated an increase in the blood levels of D(-)-lactate, a product of bacterial metabolism, 2 h following superior mesenteric artery occlusion. However, D(-)-lactate is also known to be produced in increased amounts in several conditions associated with bacterial proliferation, such as non-ischemic obstruction, intestinal perforation and peritonitis. So, D(-)-lactate does not seem to be specific for this disease.

Inorganic phosphate, which is the most important anion at the intracellular space, has also been investigated in models of mesenteric ischemia<sup>[17-20]</sup>. A significant rise in serum phosphate level occurred after 4 h of ischemia, which was not helpful for an early diagnosis<sup>[19]</sup>. Regional intestinal ischemia is reported to be detected and monitored by means of a microdialysis catheter placed in the peritoneal cavity or the bowel lumen by measuring lactate, pyruvate, glycerol and glucose levels<sup>[21]</sup>.

Plasma markers of coagulation and fibrinolysis such as fibrinogen, soluble fibrin, D-Dimer, tissue plasminogen activator/plasminogen activator inhibitor complex levels, have previously been studied in intestinal ischemia<sup>[22-26]</sup>. However, the change in plasminogen levels, a fibrinolytic marker, has not been studied during acute mesenteric ischemia. In the present study, the role of plasminogen as a novel and specific marker for the early diagnosis of mesenteric ischemia was investigated.

Plasminogen is a single-chain glycoprotein that is produced in the liver and found in plasma under normal conditions; it has a half-life of 2.2 d. Average plasma level

is 21 mg/dL and its enzymatic activity ranges between 75% and 150% in humans. The level of plasminogen activity in rats changes with age and sex of the animal, but it is much lower than those in humans. The parameters we measured in this study are comparable with those in the literature<sup>[26-29]</sup>. Plasminogen binds to fibrin as soon as a fibrin clot forms. That is, the fibrinolytic system is activated as coagulation continues. Plasminogen is converted to active plasmin by tissue plasminogen activator (t-PA), which is present in many tissues as well as in plasma and endothelial cells<sup>[30-31]</sup>. During intestinal ischemia coagulation and fibrinolysis are activated. Fibrin production is coupled with the conversion of plasminogen to plasmin by t-PA released from hypoxic intestinal endothelium<sup>[20]</sup>.

In this rat model of acute mesenteric ischemia produced by arterial and venous occlusion, we measured blood plasminogen activity levels after 1 h and 3 h of ischemia and compared the plasminogen activities within and between groups. After 1 h of ischemia, a significantly lower activity of plasminogen was observed in both arterial and venous occlusion groups compared to the sham group, and the difference was maintained up to 3 h of ischemia. No significant differences between plasminogen activity levels after 1 h and 3 h of ischemia were present within the groups. The decrease in plasminogen levels may be attributed to the increased consumption of plasminogen by conversion to plasmin, due to the increased t-PA activity and fibrinolysis.

These data suggest that blood plasminogen activities are decreased during the early phase of both arterial and venous mesenteric ischemia, and plasminogen activity levels may be a useful marker for the early diagnosis of this disease. However, more research is required to exclude other possible causes of the fall in plasminogen activities.

## COMMENTS

### Background

Acute mesenteric ischemia has no specific marker for early diagnosis and thus, it is mortal in half of the cases. In this study, we investigated significance of changes in plasma plasminogen activity level during mesenteric ischemia.

### Research frontiers

In this study we found a significant reduction in plasminogen activity level during early phases of both venous and arterial mesenteric ischemia. However, we need more research to understand its value in human mesenteric ischemia and also we should find equipment in laboratories for urgent plasminogen level determination so that the test could be helpful before bowel necrosis developed.

### Innovations and breakthroughs

Several parameters have been studied for early diagnosis of mesenteric ischemia but none of them are found to be valuable. As plasminogen is a member of the fibrinolytic pathway we thought its plasma level could change in the condition and this change could be diagnostic.

### Applications

Plasminogen level determination may be helpful in early diagnosis of mesenteric ischemia before bowel necrosis develops and we can manage the patient early preventing mortality.

### Terminology

Mesenteric ischemia is an acute condition resulting from occlusion of either mesenteric artery or vein. It is recommended early management is necessary

because after the development of bowel necrosis there is not much to do for the recovery of the condition. Plasminogen is a protein synthesized in liver which is known as a member of the fibrinolytic pathway.

### Peer review

The research is very interesting since the author's demonstrated that blood plasminogen activities decrease during early phases of both arterial and venous mesenteric ischemia, which may be a useful marker for early diagnosis. It appears that many potential cases could be lost or misrepresented by the range on values in normal and abnormal groups.

### Abstract

**AIM:** To determine if infliximab can prevent or delay surgery in refractory ulcerative colitis (UC).

**METHODS:** UC patients who failed to have their disease controlled with conventional therapies and were to undergo colectomy if infliximab failed to induce a clinical improvement were reviewed. Patients were primarily treated with a single 5 mg/kg infliximab dose. The Colitis Activity Index (CAI) was used to determine response and remission. Data of 8 wk response and colectomy rates at 6 mo and 12 mo were collected.

**RESULTS:** Fifteen patients were included, 7 with UC unresponsive or intolerant to IV hydrocortisone, and 8 with active disease despite oral steroids (all but one with therapeutic dosage and duration of immunomodulation). All the IV hydrocortisone-resistant/intolerant patients had been on azathioprine/6-MP < 8 wk. At 8 wk, infliximab induced a response in 86.7% (13/15) with 40% in remission (6/15). Within 6 mo of treatment 26.7% (4/15) had undergone colectomy and surgery was avoided in 46.6% (7/15) at 12 mo. The colectomy rate at 12 mo in those on immunomodulatory therapy < 8 wk at time of infliximab was 12.5% (1/8) compared with 100% (7/7) in patients who were on long-term maintenance immunomodulators ( $P < 0.02$ ).

**CONCLUSION:** Infliximab prevented colectomy due to active disease in immunomodulatory-naïve, refractory UC patients comparable to the use of Cyclosporine. In patients, however, on effective dosage and duration of immunomodulation at time of infliximab therapy colectomy was not avoided.

Willert RP, Lawrance IC. Use of infliximab in the prevention and delay of colectomy in severe steroid dependant and refractory ulcerative colitis. *World J Gastroenterol* 2008; 14(16): 2544-2549  
Available from: URL: <http://www.wjgnet.com/1007-9327/14/2544.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2544>

### INTRODUCTION

Ulcerative colitis (UC) is characterized by a life-long chronic course with remissions and exacerbations, with 15% of patients having a severe attack requiring hospitalization at some time during their illness. While the management of a severe exacerbation has traditionally been dependent on intravenous steroids, up to 40% of patients fail to respond resulting in colectomy during that admission<sup>[1,2]</sup>, this rate has remained unchanged over 30 years<sup>[3]</sup>. Even in those who respond, 25% become steroid dependent and an additional 20%-30% require colectomy at 12 mo<sup>[4]</sup>. Cyclosporine (CsA) has been shown to be an effective rescue therapy in acute UC in up to 80% of patients<sup>[5]</sup>, but despite this and the use of azathioprine or 6-mercaptopurine (6-MP) as maintenance therapy, over 65% of patients have relapsed and 30% require colectomy within 12 mo<sup>[6-8]</sup>. Concerns over the safety profile of CsA, even with low dose CsA (2 mg/kg per day), has also resulted in reluctance for clinicians to use this due to its well documented side effects<sup>[9]</sup>.

The early inflammatory bowel disease studies investigating infliximab, a chimeric monoclonal antibody to the proinflammatory cytokine tumour necrosis factor alpha (TNF- $\alpha$ ), focused on Crohn's disease where it was known that TNF- $\alpha$  was implicated. Initially the role of TNF- $\alpha$  was considered to be less predominant in UC although more recently TNF- $\alpha$  has been shown to play an important role in

the inflammatory process in UC<sup>[10,11]</sup>. The initial uncontrolled published studies suggested efficacy in the use of infliximab for acute steroid refractory UC<sup>[12-14]</sup>, although only two of three small randomised placebo controlled trials supported its role<sup>[15-17]</sup>. Two large randomised placebo controlled trials (ACT 1 and ACT 2) recently confirmed the efficacy of infliximab in moderate UC<sup>[18]</sup> and a recent meta analysis of randomised studies in UC demonstrated infliximab to be more effective than placebo, with a mean response rate of 68% and a 40% remission rate at 2 wk, giving the patient number needed to treat as 3 to 5<sup>[19]</sup>. In clinical practice, however, patients with acute severe UC requiring IV steroids and chronic steroid refractory UC are clearly distinguished but limited data exists on any differences in efficacy of infliximab in long term outcomes in either group<sup>[20,21]</sup>. Only the ACT 1 and ACT 2 studies provide data beyond 3 mo in a randomised controlled trial. These subjects achieved a 45% response and 35% remission at 54 wk (ACT 1), but patients received infliximab every 8 wk following a three dose induction at 0 wk, 2 wk and 6 wk and 78% remained on steroids at one year. These data do not reflect current practice in the management of most patients with UC in the majority of countries around the world and there is little data on long-term outcome following a single dose of infliximab in patients with UC not responsive to standard medical therapy.

In this paper we present our clinical experience of using infliximab in the context of patients with both acute severe UC and chronic refractory UC where surgery was the planned outcome if infliximab failed to induce a clinical improvement in either group.

## MATERIALS AND METHODS

All subjects were patients at the Fremantle Hospital in the southern metropolitan region of Perth, Australia, which is a 450 bed tertiary institution and is a centre for the management of IBD. All patients receiving infliximab for IBD were considered for treatment only after failure of disease control with conventional therapy including 5-aminosalicylic acids, steroids and immunomodulation and were treated between August 2001 and December 2006. All patients were planned to go to surgery if treatment with infliximab failed. Patients received a single induction dose of 5 mg/kg in all but one case. Prior to the infliximab infusion patients received a 200 mg IV injection of hydrocortisone unless already on IV hydrocortisone. No prophylactic antibiotics were given. Tuberculosis was excluded in all patients both by a normal chest X-ray and a negative Mantoux test or QuantiFERON-TB Gold (QFT-G, Cellectis Limited, Carnegie, Victoria, Australia). Patients' records were reviewed retrospectively and data was collected from the hospital patient IBD database which includes demographic details, disease duration and extent, endoscopy and medication history, dates, doses and indications for therapy, blood results and recorded adverse outcomes and surgery.

Patients were classified as having UC according to the "Montreal Classification" (a modification of the Vienna Classification)<sup>[22]</sup>. The diagnosis of IBD had to be definite, and was made in accordance with previously established

**Table 1 Medications taken by patients at time of infliximab treatment**

Medication	UC patients (n = 15)
5-ASA	
Current	93.3% (14/15)
Intolerant	6.7% (1/15)
Steroids	
IV	40.0% (6/15)
PO	53.3% (8/15)
Intolerant	6.7% (1/15)
Immunomodulators	
AZA/6MP	86.7% (13/15)
< 8 wk	53.3% (8/15)
≥ 8 wk	33.3% (5/15)
Intolerant	13.3% (2/15)
Tacrolimus	6.7% (1/15)
Methotrexate	6.7% (1/15)

international criteria<sup>[23]</sup> based upon clinical, endoscopic, histopathological, and radiological findings. The diagnosis of UC was exclusive of infective enterocolitis (excluded by stool microscopy and culture, bacterial and amoebic serology, acid-fast staining of biopsies and mycobacterial cultures), Behcet's disease and microscopic colitis. Demography, disease status, infusion number, response and remission rates and adverse effects were recorded.

A clinical response was defined as a reduction of 4 or more points in the colitis activity index (CAI)<sup>[24]</sup> and remission was considered to be a sustained CAI of less than or equal to 4. This was determined at 2-4 wk and again at 8 wk after the initial infusion. For remission to be considered to have occurred, steroids needed to be successfully withdrawn within the 8 wk period following the infliximab infusion without recurrence of symptoms. Time till colectomy and current UC status was determined from review of the patients' records and IBD database.

Adverse effects were analysed. Adverse effects identified as unlikely related, possibly related and probably related to infliximab use. Serious adverse effects are defined as any adverse drug experience occurring that results in death, life-threatening adverse event, persistent or significant disability/incapacity, required in-patient hospitalisation, or prolonged hospitalisation or congenital anomaly or birth defect.

## RESULTS

### Patient demographics

Fifteen patients (10 male, 5 female) aged 18 years to 59 years (mean age 39 years) received infliximab at 5 mg/kg. Seven patients had acute severe UC at the time of infliximab, six were not responsive to 5 d of IV hydrocortisone and one was steroid intolerant. All seven of these patients had been on concomitant azathioprine/6-MP for < 8 wk. Eight patients had active disease despite oral steroids and therapeutic dosage and duration of immunomodulatory therapy in all but one patient at the time of infliximab. Fourteen patients were receiving 5-ASAs, with one patient intolerant of this therapy (Table 1).

86.7% (13/15) of patients had extensive UC, one patient left-sided disease and one proctitis as defined by the

**Table 2 Individual patient data of disease extent, CAI scores pre and post infliximab, steroid usage and therapeutic immunomodulation (therapy > 8 wk at ≥ 1.5 mg/kg of 6-MP) at time of infliximab and time to colectomy**

	Sex	Age at diagnosis	Age at infliximab	Disease extent	CAI at infliximab	CAI at 8 wk	On steroids IV or oral	Therapeutic immuno-modulation	Response to infliximab	Time to surgery (mo)

**Table 3 Remission and response rates at 8 wk to infliximab in the UC patients and colectomy rates at 6 mo and 12 mo**

Disease type	Response wk 8	Remission wk 8	Colectomy ≤ 6 mo	Colectomy ≤ 12 mo
E1 - proctitis	0% (0/1)	0% (0/1)	0% (0/1)	100% (1/1)
E2 - left sided	0% (0/1)	0% (0/1)	100% (1/1)	100% (1/1)
E3 - extensive	100% (13/13)	46.20% (6/13)	23.10% (3/13)	46.10% (6/13)
Total	86.70% (13/15)	40.00% (6/15)	26.70% (4/15)	53.30% (8/15)

**Table 4 Colectomy rates at 6 mo and 12 mo compared to clinical response to infliximab**

Response	No surgery at 12 mo	Colectomy ≤ 6 mo	Colectomy ≤ 12 mo
No response	0% (0/3)	50% (1/2)	100% (2/2)
Partial response	28.60% (2/7)	28.60% (2/7)	71.40% (5/7)
Complete response	83.30% (5/6)	16.70% (1/6)	20% (1/5)
Total	46.70% (7/15)	26.70% (3/16)	57.10% (8/14)

Montreal classification<sup>[22]</sup>. The average CAI was 13 (SEM ± 2.8, range 8-20; Table 2) and 84.6% of patients had a raised CRP (Median 42 mg/L, range 8-110 mg/L) pre infliximab.

**Efficacy at 8 wk**

At 8 wk 86.7% (13/15) of patients had responded to infliximab with 40% (6/15) in remission (Tables 2 and 3) as determined by the CAI. All those patients considered to be in remission also had had their steroids withdrawn by the 8 wk assessment. Of the responders, all had extensive colitis, while the two non-responders either had proctitis or left-sided UC (Tables 2 and 3). The median CRP at 8 wk was 21.4 mg/L (range < 1-88 mg/L).

**Efficacy at 6 mo**

At 6 mo 26.7% (4/15) of patients had undergone colectomy, 2 within the first mo of infliximab and 1 at 5 mo and 1 at 6 mo (Tables 3 and 4). Three of these patients were on therapeutic dosages and durations of immunomodulators at the time of the infliximab therapy (defined as > 8 wk duration of 6-Mercaptopurine at ≥ 1.5 mg/kg). One of the two patients who had a colectomy within 1 mo of infliximab was not on a therapeutic duration of immunomodulation, but had no active UC endoscopically post infliximab. She, however, suffered from recurrent massive

acute colonic bleeding that required hospitalization on 2 separate occasions that included blood transfusions. This patient chose to undergo colectomy. Pathology of the surgical specimen identified mild active chronic colitis with no cause of the massive colonic bleeding identified. Despite this, surgery resolved the bleeding issue. The other patient had had no response to the infliximab.

The patient who underwent colectomy at 6 mo also had a complete response to infliximab therapy but was intolerant of azathioprine/6-MP, and had suffered from chronic ankle pain that commenced within minutes of the infliximab infusion and remained for the next 6 mo. The patient also developed pneumonia 2 wk after infliximab therapy and when he developed a significant flare of his UC, he decided to undergo surgery rather than further infliximab treatments.

**Efficacy at 12 mo**

By 12 mo a further 26.7% (4/15) of patients had undergone colectomy giving a 12 mo colectomy rate of 53.3% (8/15). All of these patients were on therapeutic dosages and durations of immunomodulators at the time of the infliximab therapy. Three were on azathioprine/6-MP and one was on oral tacrolimus due to intolerance to azathioprine/6-MP. Of the 4 patients who underwent colectomy within 6 mo to 12 mo 1 was for steroid depen-

dent proctitis. Two patients had colectomy at nine mo and one at 12 mo for pan colitis. These 3 patients had an initial partial response to infliximab (Tables 3 and 4).

There was a significant difference between the 12 mo colectomy rate for those patients who were on therapeutic dosages and durations of immunomodulators compared with those patients on immunomodulatory therapy for < 8 wk at the time of infliximab therapy [100% (7/7) *vs* 12.5% (1/8),  $P < 0.02$ ].

### Long term follow up

Of the seven patients who avoided surgery at 12 mo one patient required colectomy at 26 mo for an acute flare but six remained off steroids and was maintained on azathioprine/6-MP with follow up averaging 25.8 mo (range 12-56 mo).

### Side effects

One patient had an adverse side effect to infliximab with the development of arthralgia in his ankle within minutes of initiation of the infliximab infusion, which persisted for 6 mo. The same patient had a significant adverse event with the development of community acquired pneumonia 2 wk post infusion which was treated with standard antibiotic therapy with no long term sequelae. No post operative complications were recorded.

## DISCUSSION

Infliximab has become an accepted treatment option following recent data on its efficacy in moderate to severe UC with a 35%-40% remission rate at 8 wk<sup>[19]</sup>. Five randomised double blind studies have compared infliximab with placebo for the treatment of UC<sup>[15-18]</sup> with two further randomised studies comparing infliximab with steroids<sup>[25,26]</sup>. Despite significant heterogeneity in the study populations and trial designs used, all but one study demonstrated a significant improvement in the disease treated with infliximab compared to placebo<sup>[16]</sup>. Apart from the ACT 1 and ACT 2 studies, however, all the studies have had limited follow-up of 3 mo or less and have not used maintenance infliximab therapy. The remission rates in ACT 1 using infliximab at 5 mg/kg were 38.8%, 33.9% and 34.7% at wk 8, 30 and 54 respectively; with 78% of patients still requiring steroids at 54 wk despite 8 wk infliximab. Given the financial implications of regular maintenance infliximab therapy and the lack of data comparing induction therapy alone with induction plus maintenance therapy in longer-term outcomes in UC our study retrospectively analysed the outcomes of all UC patients at our institution who were to undergo colectomy if infliximab therapy did not induce a clinical improvement. All patients who received infliximab had confirmed ongoing active disease despite steroids.

The 86% response rate and 40% remission rate at 8 wk in our patients is comparable with previous published studies. At 6 mo only 4 of 15 patients had required colectomy, 1 of whom was a complete responder at 8 wk, but who was intolerant of 6-MP and who declined further infliximab treatment following a flare due to its side effects. Another patient chose to undergo colectomy within 1 mo of infliximab for recurrent massive PR bleeding for which no

cause could be identified but endoscopically her UC was in remission. By 12 mo 53% (8 of 15 patients) had undergone colectomy. Five of the seven patients who avoided surgery were in remission at 8 wk following a single infliximab infusion and the remaining 2 had an initial response but not remission. Six of the seven patients who avoided surgery had acute severe UC unresponsive to IV hydrocortisone and had been on 6-MP for less than 8 wk at the time of infliximab. The seventh patient was on high dose oral steroids and had also been on 6-MP for less than 8 wk. The efficacy of infliximab in these patients with more acute disease in our institution is in keeping with higher response rates to infliximab in studies of steroid refractory UC when compared with steroid dependent cases<sup>[27]</sup>, although the data remains conflicting<sup>[20,28]</sup>. It would be anticipated, however, that a greater role of TNF- $\alpha$  in severe UC would result in a greater clinical efficacy of infliximab in this setting. The fact that colectomy was prevented at 12 mo in 7 of the 8 patients, (with one patient having surgery but without active UC) who were naive to immunomodulators (*ie* less than 8 wk of therapy), suggests that infliximab could be used as bridging therapy. This induces remission whilst giving more time for azathioprine/6-MP to reach therapeutic effect which can then be used to maintain this without the need for regular maintenance infliximab. A similar phenomenon has recently been reported with the use of CsA in acute severe colitis where the colectomy rate was significantly lower in patients who were commenced on azathioprine concurrently with CsA compared with those who were already on azathioprine<sup>[6-8]</sup>. In those patients where immunomodulatory therapy has failed, however, regular maintenance therapy with infliximab may be of greater benefit although further studies are required to assess the risks of regular biological therapy versus colectomy in this group of patients.

Our data suggest that at 12 mo the outcome following a single induction dose of infliximab is similar to that seen in the ACT studies, without the need for regular maintenance infusions, provided immunomodulatory therapy can be commenced and continued. This is supported by a recent paper from Oxford assessing their use of single dose infliximab in UC<sup>[20]</sup>. This has significant cost implications since the direct cost saving of single dose infliximab therapy with maintenance immunomodulators compared to maintenance infliximab therapy over one year would be €15 000 (\$20 000 US) per patient. Whilst the limitations of this study, being a small, uncontrolled retrospective analysis, prevent direct comparisons being made, further controlled studies assessing the long-term outcomes of induction therapy without maintenance infliximab are warranted.

Infliximab was well tolerated in all but one patient who developed acute arthralgia, within minutes of the infusion, which lasted 6 mo. This patient also developed community-acquired pneumonia 2 wk after infliximab, which responded to standard antibiotic therapy. Despite complete remission at 8 wk he subsequently flared at 5 mo (having been intolerant of 6-MP) and went to colectomy after declining further infliximab therapy. The side effect profile of infliximab is highly relevant when considering rescue therapy for severe UC as both CsA and infliximab have

similar response rates, although there is currently no randomised trial comparing their efficacy and safety in acute severe UC. Whilst the retrospective nature of our data analysis may not have detected mild adverse events associated with infliximab our data are consistent with published studies which demonstrate an adverse side effect profile in UC similar to that seen in Crohn's disease<sup>[29]</sup>. This may favour the use of infliximab over cyclosporine as a rescue therapy, as there has been reluctance in some countries to use cyclosporine, even at 2 mg/kg, due to the risks of hypertension, seizures and nephrotoxicity<sup>[30]</sup>.

In conclusion, infliximab induced a rapid response in over 80% of UC patients refractory to standard therapy with a 40% remission rate at 8 wk. There was avoidance of colectomy in 46% of all patients at 12 mo, without the need for regular infliximab maintenance therapy. There was, however, a significant difference in the 12 mo colectomy rate for those patients who were on therapeutic dosages and durations of immunomodulators compared with those patients on immunomodulatory therapy for < 8 wk at the time of infliximab therapy with 87.5% of these patients avoiding colectomy.

## COMMENTS

### Background

Corticosteroids have long been the predominant therapy for the induction of remission in severe ulcerative colitis (UC) with immunomodulators being efficacious in maintaining remission. However, over 30% fail to respond or lose response to therapy and require surgery. Cyclosporine has been used as a salvage therapy but 30% proceed to colectomy within 12 mo. The introduction of new biological agents such as infliximab have been shown to be efficacious in acute severe UC but data on long term follow up is limited.

### Research frontiers

Infliximab has recently become an accepted treatment option in moderate to severe UC but the only prospective randomised long term data is in patients on maintenance infliximab for mild to moderate UC. This study was aimed at assessing the long term efficacy, safety profile and need for colectomy, following induction therapy with infliximab, without maintenance infliximab, in patients with UC who had failed standard medical therapy.

### Innovations and breakthroughs

A single dose of infliximab had greater efficacy in patients with severe acute disease in our institution rather than in those with chronic UC who were flaring despite current treatment. This is in keeping with higher response rates to infliximab in studies of steroid refractory UC when compared with steroid dependent cases and may reflect a greater role of TNF- $\alpha$  in early disease.

### Applications

Infliximab induction therapy is safe and appropriate in acute UC patients failing standard medical therapy but response rates appear poor in those with chronic refractory disease. A head to head randomised controlled trial of cyclosporine versus infliximab for the induction of remission in acute severe UC is urgently needed.

### Terminology

Infliximab is a chimeric monoclonal IgG1 antibody directed against tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ) which is able to almost completely neutralize its biological activity.

### Peer review

A single dose of infliximab had greater efficacy in patients with severe acute disease in this study rather than in those with chronic UC who were flaring despite current treatment. A small but useful retrospective study looking at the treatment

outcomes following a single dose of infliximab as rescue therapy in refractory UC in a clinical practice setting.

Received: December 12, 2007 Revised: March 4, 2008

### Abstract

**AIM:** To evaluate the effectiveness of endoscopic submucosal dissection using an insulation-tipped diathermic knife (IT-ESD) for the treatment of patients with gastric remnant cancer.

**METHODS:** Thirty-two patients with early gastric cancer in the remnant stomach, who underwent distal gastrectomy due to gastric carcinoma, were treated with endoscopic mucosal resection (EMR) or ESD at Sumitomo Besshi Hospital and Shikoku Cancer Center in the 10-year period from January 1998 to December 2007, including 17 patients treated with IT-ESD. Retrospectively, patient backgrounds, the one-piece resection rate, complete resection (CR) rate, operation time, bleeding rate, and perforation rate were compared between patients treated with conventional EMR and those treated with IT-ESD.

**RESULTS:** The CR rate (40% in the EMR group vs 82% in the IT-ESD group) was significantly higher in the IT-ESD group than in the EMR group; however, the operation time was significantly longer for the IT-ESD group ( $57.6 \pm 31.9$  min vs  $21.1 \pm 12.2$  min). No significant differences were found in the rate of underlying cardiopulmonary disease (IT-ESD group, 12% vs EMR group, 13%), one-piece resection rate (100% vs 73%), bleeding rate (18% vs 6.7%), and perforation rate (0% vs 0%) between the two groups.

**CONCLUSION:** IT-ESD appears to be an effective treatment for gastric remnant cancer post distal gastrectomy because of its high CR rate. It is useful for histological confirmation of successful treatment. The

long-term outcome needs to be evaluated in the future.

Treatment of gastric remnant cancer post distal gastrectomy by endoscopic submucosal dissection using an insulation-tipped diathermic knife. *World J Gastroenterol* 2008; 14(16): 2550-2555 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2550.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2550>

### INTRODUCTION

Distal gastrectomy has been widely accepted as a standard operation for early stage gastric cancer. Gastric cancer of the proximal gastric remnant is now increasing in Japan. Nozaki *et al*<sup>[1]</sup> described that the gastric remnants of 457 cases post distal gastrectomy due to gastric cancers were surveyed periodically by endoscopic examination, and 10 patients (2.2%) were diagnosed as having gastric remnant cancer within 12 years. Endoscopic submucosal dissection (ESD) techniques using a variety of knives, such as the insulation-tipped diathermic knife (IT-knife), hook knife, needle knife, or flex knife, have been developed in Japan<sup>[2-10]</sup> and high one-piece resection rates have been reported for the treatment of mucosal malignancies<sup>[3,11-17]</sup>. The remnant stomach post distal gastrectomy has narrow spaces. Thus, in this condition, it is more difficult to completely resect gastric remnant cancer by endoscopic technique than from an unoperated stomach. Few reports have described the results of ESD using an insulation-tipped diathermic knife (IT-ESD) for gastric remnant cancer. The purpose of this study was to evaluate the effectiveness of IT-ESD for patients with gastric remnant cancer post distal gastrectomy.

## MATERIALS AND METHODS

### Patients

We retrospectively reviewed the records of post distal gastrectomy patients with gastric remnant cancer, who underwent distal gastrectomy for the treatment of gastric cancer, admitted to Sumitomo Besshi Hospital and Shikoku Cancer Center between January 1998 and December 2007. Patients admitted during this period were divided into a conventional endoscopic mucosal resection (EMR) group and into a IT-ESD group according to the endoscopic resection method. Since 2000, the IT-knife procedure has been used instead of the conventional EMR for the treatment of gastric remnant cancer. Patient backgrounds, the one-piece resection rate, complete resection (CR) rate, operation times, bleeding rate, and perforation rate were compared between the groups. Patients with severe underlying disease, such as heart disease, respiratory disease, liver disease, or bleeding tendency, were excluded from the indication of ESD in our institute; however, no patients had severe underlying disease in this study. Patients taking drugs to promote bleeding, such as ticlopidine, aspirin, or warfarin, underwent ESD after a fixed term of drug discontinuance. All patients fulfilled the following criteria in this study: diagnosed as having mucosal gastric carcinoma by endoscopic findings or endoscopic ultrasonography, a biopsy specimen obtained from the lesion revealed differentiated adenocarcinoma, without ulceration of the lesion, no residual/local recurrence lesion after endoscopic treatment and the diameter of the lesion was up to 30 mm. The performance status (PS) of each patient was less than 2 on the Eastern Cooperative Oncology Group (ECOG) scale. IT-ESD was performed under informed consent. Two highly skilled endoscopists familiar with EMR and ESD performed endoscopic resection in this study.

### EMR technique

Conventional EMR was performed with a 2-channel endoscope<sup>[16,18]</sup>. The mucosa around the lesion was marked with coagulation current, and saline containing 0.0025% epinephrine was injected until the mucosa around or under the lesion was raised. Grasping forceps was passed through the loop of the conventional polypectomy snare, and an area near the lesion was grasped with the forceps to elevate the lesion. Then the snare was opened and the lesion was strangled. The specimen was completely resected by electric current application.

### IT-ESD technique

IT-knife was developed by Hosokawa and Yoshida in 1994 in Japan<sup>[19]</sup>. IT-knife has a ceramic ball at the top of the incising needle knife<sup>[11,12,19-21]</sup> to prevent perforation of the gastric wall. IT-ESD was performed as previously described using a single-channel endoscope<sup>[3,12,14,17,22]</sup>. Marks were made at several points along the outline of the lesion with a coagulation current, and saline containing 0.0025% epinephrine was injected just outside the marks to prevent perforation until the mucosa around the lesion was raised. A circumferential incision in the mucosa just outside the marks was made using an IT-knife, with a safe lateral margin, and the submucosal tissue under the circumcised

area was abraded with it. The specimen was then either completely resected using the IT-knife, or finally removed using a conventional polypectomy snare if it was attached only to a pedicle (Figure 1).

### Histological assessment

A gastrointestinal pathologist evaluated the ESD specimens with special attention to the depth of tumor invasion, and the lateral and deep margins of the excision. Resected specimens were cut into 2 mm slices according to the Japanese Classification of Gastric Carcinoma<sup>[23]</sup> and evaluated as to whether cancerous glands were present or absent at the margin of each slice.

### Definition of complete and incomplete resection

When one-piece resection could be performed, it was easy to evaluate the completeness of the resection histologically. The efficacy of resection was determined according to the completeness of the resection: when the tumor was resected as a single piece, contained within the mucosal layer, and when the margin was definitely free of tumorous glands, resection was considered to be complete. Multifragment resections were defined as incomplete when tumorous glands were present in 2 or more fragments histologically, even if endoscopically the lesion had been completely removed. If the lateral margin of the lesion could not be evaluated histologically because of the effects of the electrosurgical current or mechanical damage, the resection was defined as being incomplete.

### Complications

Bleeding and perforation were two major complications of ESD. Bleeding (delayed bleeding) was defined as clinical evidence of bleeding as hematemesis or melena at 1 d-10 d after ESD and requiring endoscopic treatment.

### Statistical analysis

Values are expressed as the mean  $\pm$  SD. Statistical analysis was performed using the unpaired Student's *t*-test and the chi-square test. A *P* value of  $< 0.05$  was considered significant.

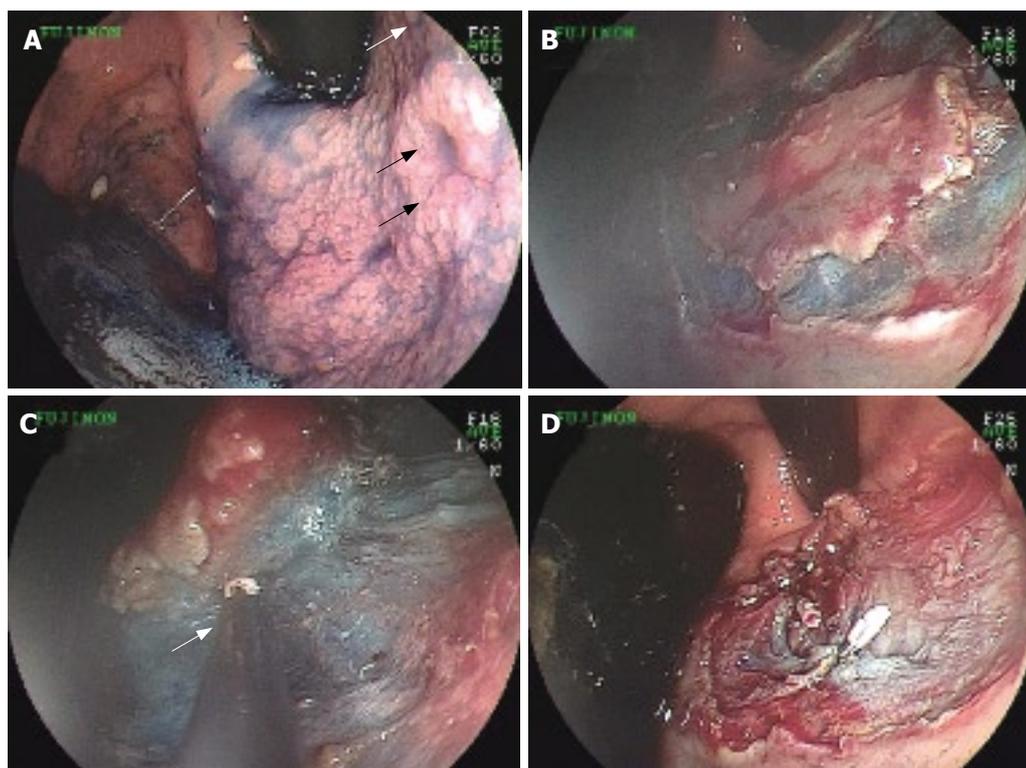

## RESULTS

### Clinicopathological features of the tumors

Concerning tumor location and gross type, no significant differences were found between patients included in the EMR ( $n = 15$ ) and those included in the IT-ESD ( $n = 17$ ) group (Tables 1 and 2, and Figure 2).

### Patient backgrounds

The mean age was  $68.3 \pm 9.2$  years (range, 46-80 years) in the EMR and  $73.1 \pm 5.4$  years (range, 64-84 years) in the IT-ESD group. The mean size of the lesion was  $12.7 \pm 2.9$  mm and  $15.5 \pm 5.6$  mm in the in the EMR and the IT-ESD group, respectively, with no significant difference between the two groups. No significant differences were found in the rate of underlying cardiopulmonary disease between the two groups [2 patients (13%) in the EMR group and 2 patients (12%) in the IT-ESD group] nor in

**Figure 1** The procedure of endoscopic submucosal dissection using an insulation-tipped diathermic knife (IT-ESD). **A:** A IIc lesion (black arrows) is seen near the suture line (white arrow) in the remnant stomach; **B:** Completion of IT-knife cutting around the lesion with a safe lateral margin; **C:** Abrasion of the submucosal tissue under the circumcised area with IT-knife (white arrow); **D:** the tumor is completely resected with IT-knife.

**Table 1** Tumor characteristics of patients in the ESD and EMR groups

	ESD group	EMR group
<i>n</i>	17	15
Location of the tumor (%)		
Posterior wall	4 (23.5)	3 (20)
Anterior wall	4 (23.5)	2 (13)
Lesser curvature	6 (35)	6 (40)
Greater curvature	3 (18)	4 (27)
Gross type of the tumor (%)		
Superficial depressed type	11 (65)	10 (67)
Superficial elevated type	6 (35)	5 (33)

the number of patients receiving anticoagulant therapy [one patient (6.7%) in the EMR group *vs* one patient (5.9%) in the IT-ESD group].

#### Evaluation of resected specimens and clinical outcomes

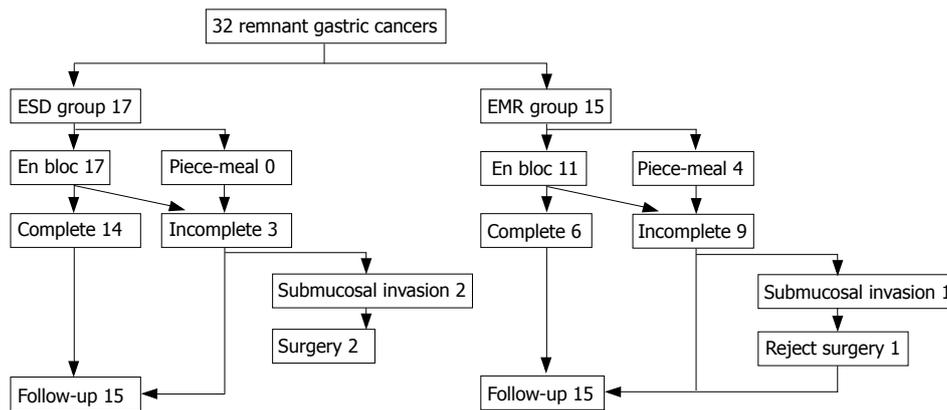

There was no significant difference in the one-piece resection rate among the groups (73% in the EMR group *vs* 100% in the IT-ESD group). The CR rate was significantly higher in the ESD group (40% in the EMR group *vs* 82% in the IT-ESD group). The mean operation time was 21.1 min  $\pm$  12.2 min for the EMR group and 57.6 min  $\pm$  31.9 min for the IT-ESD group. There were 4 cases of bleeding after endoscopic resection: one (6.7%) in the EMR group and 3 (18%) in the IT-ESD group, but no patient needed further surgery. All 3 patients with delayed bleeding developed clinical signs of hematemesis or melena 1 or 2 d after ESD. No patient developed hematemesis or melena later than 3 d after ESD. There was no severe delayed bleeding with a need for transfusion. Perforation

**Table 2** Characteristics and results of clinical data of patients in the ESD and EMR groups

	ESD group (tumor size: 10-26 mm)	EMR group (tumor size: 10-18 mm)	<i>P</i>

NS: Not significant.

occurred in none of the patients. Twelve patients were judged as having incomplete resection in both groups. The margin of the fragment was positive for tumor or the lateral margin of the lesion could not be evaluated because of the effects of the electrosurgical current in 5 patients (four in the EMR group and one in the IT-ESD group). These five patients did not undergo additional laser or surgical therapy, although they have remained under close periodic observation. Three patients (one in the EMR group and two in the IT-ESD group) were judged as having submucosal invasion and two underwent total gastrectomy

**Figure 2** Clinical courses after endoscopic submucosal dissection (ESD) and conventional endoscopic mucosal resection (EMR) for remnant gastric cancers.

of the remnant stomach with regional lymph nodes dissection (additional surgery). The remaining case (in the EMR group) refused surgery and has been under close periodic observation. A total of 30 patients who did not undergo additional surgery were followed by endoscopy in both groups at least every year after treatment. The mean follow-up period was 2135 d (range 180-3285 d). There were no local recurrences after CR in the 20 patients in both groups and one patient resulting in incomplete resection in the IT-ESD group during that period. Only one patient in the EMR group resulted in piece-meal resection had a local recurrence 2 years after EMR and underwent additional EMR therapy.

## DISCUSSION

EMR has become a standard treatment for intramucosal gastric cancer because it is less invasive for patients compared with surgical resection<sup>[24-28]</sup>. To achieve cure by EMR, one-piece resection is optimal for all lesions because it may reduce the local recurrence rate<sup>[10,29]</sup>. IT-ESD is a useful new endoscopic mucosal resection (EMR) method, which has recently become widespread in Japan due to its high one-piece resection rates<sup>[3,11,13,15-17]</sup>. Few reports have described the results of IT-ESD for gastric remnant cancers in comparison with the usual strip biopsy method (conventional EMR).

Although PS for all patients was less than 2, and no patients had severe underlying diseases or severe complications in both groups, the CR rate was higher and operation time was longer in the IT-ESD group. In the present study, the one-piece resection rate and CR rate were high for over 10 mm lesions in the IT-ESD group. In contrast, the CR rate was low in the EMR group. In the unoperated stomach, it is easier to remove a tumor larger than 10 mm in diameter with IT-ESD than with the usual strip biopsy method<sup>[11,22]</sup>. The reason why the one-piece resection rate and CR rate were high in the IT-ESD group in our study might be as follows: we adequately abraded the submucosal tissue under the lesion before snaring, and in more than half of the patients in this study, direct dissection of the submucosal layer was carried out with an IT-knife until complete removal had been achieved<sup>[14,17]</sup>. The reason why the CR rate was low in the EMR group (under the condition of a remnant stomach) may be owing to the

difficulty of handling a polypectomy snare in the narrow space of the remnant stomach. In the IT-ESD method, the narrow space of the remnant stomach also makes IT-ESD procedures difficult; however, if the surgeon cuts around the lesion with a safe lateral margin, frequent CR is expected with the IT-ESD method. We speculated that it was difficult to ensure a safe lateral margin by snaring in the EMR technique because there were more patients with positive lateral margin in the EMR group (4/15) than in the IT-ESD group. Our study proved that the CR rate was significantly higher in the IT-ESD group, and IT-ESD was useful for gastric remnant cancers post distal gastrectomy that were larger than 10 mm in diameter, although it took longer.

The circulatory and respiratory states did not worsen in any patient during IT-ESD even if with underlying diseases or a long operation time. We should pay particular attention to patients with hypertension or anticoagulation therapy before or during ESD because they are related to bleeding during IT-ESD and the operation time<sup>[14]</sup>. The good result in the IT-ESD group in this study might be due to the small number of patients having anticoagulation therapy. The operation time for IT-ESD was significantly longer than that of conventional EMR. The reasons why IT-ESD took longer than conventional EMR in this study might be as follows: complicated operation of the IT-knife for abrasion of the submucosal tissue, a high frequency of bleeding, and narrow space of the remnant stomach.

As for complications, the delayed bleeding frequency was 18% (3/17) in the IT-ESD group, which was higher than in Onozato *et al.*<sup>[30]</sup> who reported it as 7.6%, although the total number of patients enrolled in this study was small. However, there were no problems due to delayed bleeding in this study in the IT-ESD group because we prevented delayed bleeding by follow-up endoscopic examination according to the clinical pathway<sup>[3]</sup>. It is necessary to pay particular attention to perforation with the ESD technique<sup>[13]</sup> because Ohkuwa *et al.*<sup>[11]</sup>, Miyazaki *et al.*<sup>[13]</sup>, Ono *et al.*<sup>[20]</sup>, and Fujishiro *et al.*<sup>[31]</sup> reported that the incidence of perforation with IT-ESD is 5%-11.5%. We think that the risk of perforation with the ESD technique on a remnant stomach is higher than with the usual strip biopsy method on an unoperated stomach.

In conclusion, the CR rate was significantly higher in the IT-ESD group than in the EMR group, although the

operation time was significantly longer in the IT-ESD group. Our study proved that IT-ESD was an effective treatment for gastric remnant cancer post distal gastrectomy, and is useful for histological confirmation of successful treatment, although the long-term outcome should be evaluated in the future.

## COMMENTS

### Background

Endoscopic submucosal dissection (ESD) is a useful new endoscopic mucosal resection (EMR) method, which has recently become widespread in Japan due to its high one-piece resection rates. Gastric cancer of the proximal gastric remnant is now increasing in Japan. The aim of this study was to evaluate the effectiveness of ESD using an insulation-tipped diathermic knife (IT-ESD) for the treatment of patients with gastric remnant cancer post distal gastrectomy.

### Research frontiers

It is still uncertain whether conventional EMR or IT-ESD results in better clinical outcome in the treatment of gastric remnant cancer post distal gastrectomy. Further investigations on a larger scale to compare the efficacy and safety of conventional EMR vs IT-ESD should be conducted.

### Innovations and breakthroughs

In this article we analyze if IT-ESD is superior to conventional EMR in the complete resection rate in 32 patients with gastric remnant cancer post distal gastrectomy.

### Applications

This study serves as a reminder to readers of the management of mucosal remnant gastric cancer post distal gastrectomy with IT-ESD. Because of its high complete resection rate, IT-ESD may be worth trying as the first therapy for treating patients with mucosal remnant gastric cancer post distal gastrectomy.

### Peer review

It is an interesting initial series comparing conventional EMR to IT-ESD in the treatment of gastric remnant cancer post distal gastrectomy. The study presents novel findings.

Effect of biliary obstruction and internal biliary drainage on hepatic cytochrome P450 isozymes in rats. *World J Gastroenterol* 2008; 14(16): 2556-2560 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2556.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2556>

### Abstract

**AIM:** To investigate the total cytochrome P450 (CYP) content, microsomal mixed-function oxidase (MFO) activity, and expression of mRNAs for various CYP isozymes in a simple rat model of reversible obstructive jaundice.

**METHODS:** Obstructive jaundice was created in male rats by causing bile duct obstruction with polyester tape. In another group of rats, bile duct obstruction was followed by internal biliary drainage after releasing the tape. The expression of various CYP isozyme mRNAs was semi-quantitatively assessed by competitive RT-PCR.

**RESULTS:** The total CYP content and microsomal MFO activity showed a significant decrease after biliary obstruction, but returned to respective control levels after biliary drainage. A marked reduction in the expression of CYP1A2, 2B1/2, 2C11, 2E1, 3A1, and 3A2 mRNA was detected during biliary obstruction, while expression increased significantly toward the control level after biliary drainage. Although expression of CYP4A1 mRNA showed no reduction during biliary obstruction, it still increased significantly after biliary drainage.

**CONCLUSION:** These results suggest that not only obstructive jaundice, but also the subsequent internal biliary drainage may affect regulatory medications of the synthesis of individual CYP isozymes differently.

### INTRODUCTION

A large number of drugs are metabolized in the liver. The hepatic cytochrome P450-dependent microsomal mixed-function oxidase (MFO) system plays a major role in the metabolism of both exogenous and endogenous substrates. It is well known that some drug-metabolizing enzymes are inhibited in cholestatic human liver<sup>[1]</sup> while the total cytochrome P450 (CYP) content and MFO activity are reduced after bile duct ligation (BDL) in rats<sup>[2-4]</sup>. A possible explanation for these changes has been suggested to be bile acid-mediated destruction of CYP heme proteins.

CYP has multiple isozymes with different substrate specificities and the broad range of substrates for the hepatic MFO system is based on the existence of these multiple isozymes. These isozymes have been shown to be the heme protein products of the CYP supergene family<sup>[5]</sup>.

Previous studies have verified different susceptibility of BDL among CYP isozymes: male sex-specific CYPs (CYPs 2C11 and 3A2) than sexually undifferentiated CYPs (CYPs 1A, 2A1, 2B, 2C6, and 2E1)<sup>[6,7]</sup>. There are also different alterations of hepatic CYP isozyme expression in patients with cirrhosis depending on the presence or absence of cholestasis<sup>[1]</sup>. In patients with obstructive jaundice, biliary drainage has proved effective for both the treatment of jaundice itself and the subsequent complications. Ameliorating effect of biliary drainage on the total CYP content and MFO activities has been observed in bile duct obstructed rats<sup>[8,9]</sup>; however, effects of biliary drainage on individual CYP isozymes remain unknown. In this study, using a simple model of reversible obstructive jaundice, the total CYP content, MFO activity and levels of mRNAs for various CYP isozymes were compared before and after internal biliary drainage in rats with bile duct obstruction.

## MATERIALS AND METHODS

### **Animals and reversible obstructive jaundice model**

Male Wistar rats, weighing 200-240 g were fed standard laboratory chow and had free access to tap water. All animals were handled according to the local institutional guidelines for the care and use of laboratory animals. Animals were randomly assigned to undergo either bile duct obstruction alone for 4 d or 10 d (d 4-BO and d 10-BO,  $n = 5$  each) or bile duct obstruction for 4 d followed by drainage for 6 d (BOD,  $n = 5$ ). Another 10 rats underwent a sham operation and served as controls for the BO and BOD rats (d 4-sham,  $n = 5$  and d 10-sham,  $n = 5$ ). Each rat was anesthetized with a subcutaneous injection of pentobarbital sodium (50 mg/kg), and placed in the supine position on the operating table. Reversible bile duct obstruction was produced by a modification of the method described by Posner *et al.*<sup>[10]</sup>. Using a sterile technique, a midline abdominal incision was made and the porta hepatis was isolated. In BO and BOD rats, a 2-mm wide polyester tape was placed posterior to the bile duct at the hepatic hilum. The two ends of the tape were brought out through bilateral incisions at sites 1 cm lateral to the xiphoid process. Then the abdomen was closed in two layers with 2-0 surgical silk. Proper tension was applied to the bile duct with the tape, and two ends of the tape were fixed to the skin with 4-0 silk sutures. In BOD rats, the tape was carefully removed on the 4th postoperative day, allowing free internal bile flow. In sham operated rats, the same operation was performed, but the tape was placed loosely in order to avoid pressure on the bile duct. A blood sample was collected from each rat and analyzed with standard laboratory techniques for serum alanine aminotransferase (ALT) and total bilirubin. After blood collection, the rats were sacrificed and their livers were immediately removed. Then the livers were frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$  until use.

### **Preparation of hepatic microsomes**

Livers were homogenized in a 4-fold volume of 0.15 mol/L KCl solution containing 10 mmol/L EDTA. The homogenate was centrifuged at 10000  $g$  for 15 min. The supernatant was centrifuged at 105000  $g$  for 60 min, the pellet was suspended, and centrifugation was done again. These preparations were performed at  $0-4^{\circ}\text{C}$ . The resulting pellet was suspended in 20 mmol/L potassium phosphate buffer (pH 7.4) containing 15% glycerol and used as hepatic microsomes.

### **Determination of the total hepatic microsomal CYP content and MFO activity**

The concentration of hepatic microsomal protein was determined according to the method of Lowry *et al.*<sup>[11]</sup>. The total CYP content was determined according to the method of Omura and Sato<sup>[12]</sup>. Three types of MFO activity (i.e., aniline 4-hydroxylation, aminophylline N-demethylation and 7-ethoxycoumarin O-demethylation) were determined according to the methods described by Imai *et al.*<sup>[13]</sup>, Nash<sup>[14]</sup>, and Ullrich and Weber<sup>[15]</sup>, respectively. Each type of MFO activity was assayed by using NADPH as the sole electron source.

### **Determination of CYP mRNA levels by competitive RT-PCR**

Total RNA was extracted from frozen hepatic tissue according to the method of Chomczynski and Sacchi<sup>[16]</sup>. The resulting RNA was reconstituted in diethylpyrocarbonate-treated water, quantitated by spectrophotometry at 260 nm, and adjusted to 500 ng/ $\mu\text{L}$ . The levels of mRNA for CYP1A2, 2B1/2, 2C11, 2E1, 3A1, 3A2, and 4A1 were determined with the rat cytochrome P450 competitive reverse transcriptase (RT) polymerase chain reaction (PCR) Set (Takara, Kyoto, Japan) and an RNA LA PCR<sup>TM</sup> Kit (Takara, Kyoto, Japan). Reverse transcription was performed in a final volume of 100  $\mu\text{L}$  containing RT-buffer, 500 ng of total liver RNA, 5  $\mu\text{L}$  of various concentrations of RNA competitor ( $1 \times 10^7$ ,  $4 \times 10^7$ ,  $1.6 \times 10^8$  and  $6.4 \times 10^8$  copies/ $\mu\text{L}$ ), 5 mol/L  $\text{MgCl}_2$ , 1 mol/L of each dNTP, 1 U/ $\mu\text{L}$  of RNase inhibitor, 0.125 pmol/ $\mu\text{L}$  of oligo dT-adaptor primer, and 0.25 U/ $\mu\text{L}$  of AMV reverse transcriptase. Samples were incubated at  $30^{\circ}\text{C}$  for 10 min,  $55^{\circ}\text{C}$  for 20 min,  $95^{\circ}\text{C}$  for 5 min, and  $5^{\circ}\text{C}$  for 5 min. PCR amplification was performed in a final volume of 50  $\mu\text{L}$ , containing PCR buffer, 10  $\mu\text{L}$  of RT products, 5 mol/L  $\text{MgCl}_2$ , 0.025 U/ $\mu\text{L}$  of Taq DNA polymerase, and 0.2  $\mu\text{mol/L}$  each of the sense and antisense PCR primers. The primers were designed to specifically amplify the mRNA for CYP1A2, CYP2B1/2, CYP2C11, CYP2E1, CYP3A1, CYP3A2, CYP4A1, and cyclophilin. Cyclophilin is a housekeeping gene to correct for differences in RNA amounts between samples. Samples were incubated at  $94^{\circ}\text{C}$  for 2 min, followed by 24 cycles consisting of denaturation at  $94^{\circ}\text{C}$  for 30 s, annealing at  $56^{\circ}\text{C}$  for 30 s, and an elongation at  $72^{\circ}\text{C}$  for 30 s. Incubation of the samples was performed in a Gene Amp PCR system 9600 (Perkin-Elmer, USA). RT-PCR products were electrophoresed in 2% agarose gel. Then the gels were stained with ethidium bromide, and RT-PCR signals were visualized with UV light. Quantitation was performed by comparing RT-PCR signals generated from each specific CYP mRNA with the RT-PCR signals generated from varying concentrations of each RNA competitor.

### **Statistical analyses**

Statistical analysis was done with the Mann-Whitney  $U$  test, and  $P < 0.05$  was defined as indicating a significant difference between groups.

## RESULTS

### **Characteristics of reversible obstructive jaundice model**

No significant differences of the serum ALT and bilirubin levels were observed between the controls, d 4-sham rats, and d 10-sham rats. BO rats became jaundiced 4 d after bile duct obstruction, and their serum ALT and total bilirubin levels were significantly elevated compared with those of d 4-sham rats. At 6 d after the subsequent internal biliary drainage (BOD rats), these values showed a significant decrease compared with those in d 10-BO rats and were not significantly different from those in d 10-sham rats (Table 1).

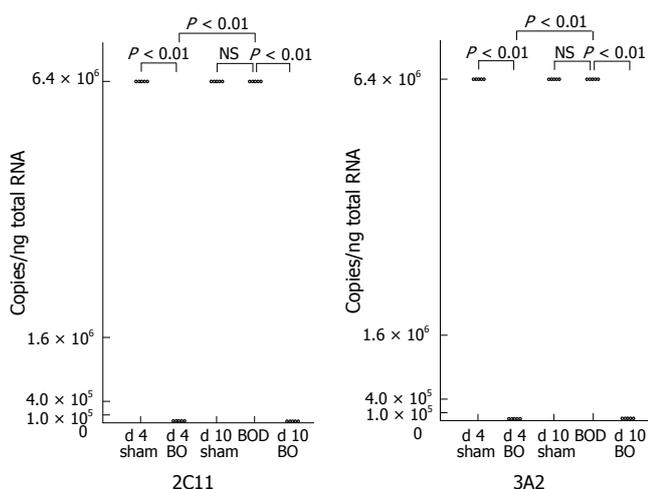

### **Total CYP content and MFO activity**

The total CYP content and MFO activity showed

**Table 1** Serum total bilirubin concentration, serum ALT concentration, the total cytochrome P450 content in hepatic microsomes and enzyme activities in hepatic microsomes from sham, bile duct obstruction alone and bile duct obstruction plus drainage groups (mean  $\pm$  SD,  $n = 5$ )

	d 4-sham	d 4-BO	d 10-sham	BOD	d 10-BO
Serum total bilirubin (mg/dL)	0.12 $\pm$ 0.04	10.54 $\pm$ 3.54 <sup>a</sup>	0.12 $\pm$ 0.04	0.16 $\pm$ 0.05 <sup>e</sup>	11.18 $\pm$ 1.03

<sup>a</sup> $P < 0.05$  vs d 4-sham; <sup>b</sup> $P < 0.05$  vs d 4-BO; <sup>c</sup> $P < 0.05$  vs d 4-BO and d 10-BO; d 10-BO and d 10-sham; BO: Bile duct obstruction alone; BOD: Bile duct obstruction plus drainage; CYP: Cytochrome P450.

**Figure 1** Effect of bile duct ligation and following internal biliary drainage on the mRNA expression of male-specific CYP isozymes. The mRNA expression was measured semi-quantitatively by competitive RT-PCR.

no significant differences between d 4-sham rats and d 10-sham rats. The total CYP content, aniline 4-hydroxylation activity, and 7-ethoxycoumarin O-demethylation activity were significantly decreased at 4 d after bile flow blockade and returned to the respective control levels after 6 d of internal biliary drainage. Aminophylline N-demethylation activity was also significantly decreased at 4 d after bile flow blockade and showed a significant increase after 6 d of internal biliary drainage, but did not return to the control level (Table 1).

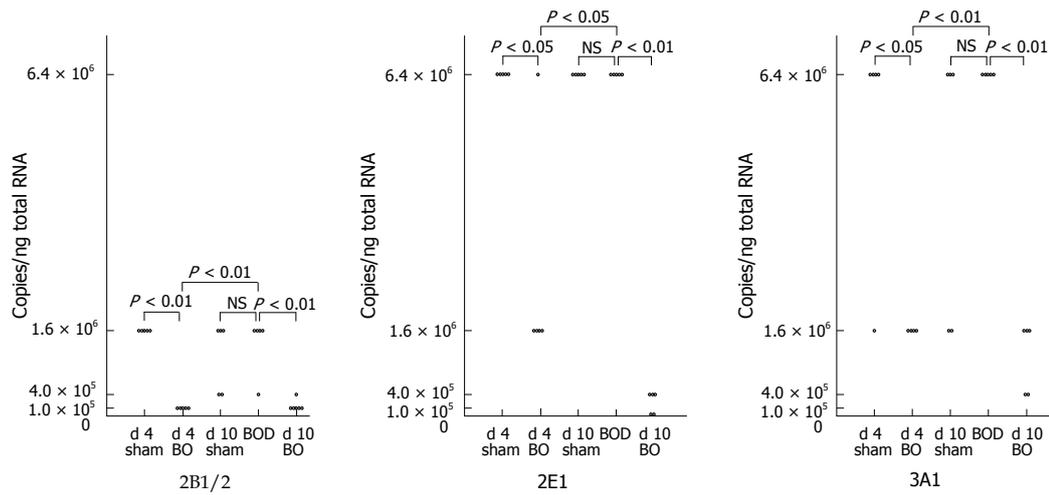

### CYP mRNA levels

CYP mRNA levels demonstrated no significant differences between d 4-sham rats and d 10-sham rats. The levels of CYP2C11, CYP3A2, CYP2B1/2, CYP2E1 and CYP3A1 mRNAs were significantly decreased at 4 d after bile flow blockade, and returned to the respective control levels after 6 d of internal biliary drainage (Figures 1 and 2). CYP1A2 mRNA also showed a significant decrease at 4 d after bile flow blockade and increased significantly after 6 d of internal biliary drainage, but did not return to the control level (Figure 3). CYP4A1 mRNA did not demonstrate significant change after 4 d of bile flow blockade, but showed a significant increase after 6 d of internal biliary drainage (Figure 3).

## DISCUSSION

When patients suffer from obstructive jaundice caused by conditions such as choledocholithiasis or bile duct cancer, various drugs are administered to prevent subsequent complications (e.g. acute obstructive suppurative cholangitis or sepsis). Endoscopic or percutaneous transhepatic biliary drainage has also proved effective for the treatment of obstructive jaundice and its complications<sup>[17-19]</sup>. Several studies have been conducted to ascertain the effects of bile duct obstruction on drug metabolism in the liver using animal<sup>[2-4]</sup> models and human<sup>[20]</sup>, but the changes of hepatic drug metabolism following biliary drainage have not been clarified. Therefore, we investigated the total hepatic cytochrome P450 content, MFO activity, and expression of mRNA for various CYP isozymes prior to and following internal biliary drainage in rats with obstructive jaundice. The experimental model used in the present study was the internal biliary drainage model proposed by Posner *et al*<sup>[10]</sup>. External biliary drainage models are unphysiologic because bile is excreted out of the body after the relief of obstructive jaundice. With other internal biliary drainage models such as choledochojejunostomy, the effects of surgical invasion and anesthesia during internal biliary drainage must be taken into account. These events could affect CYP after following the relief of obstructive jaundice. On the other hand, the internal biliary drainage model used in the present study is more physiologic, and the impact of anesthesia and surgical invasion are relatively small. In rats with bile duct obstruction, irreversible fibrosis of the liver occurs after more than 14 d of bile duct obstruction<sup>[21]</sup>. Therefore, in order to observe the changes of CYP during internal biliary drainage after acute obstructive jaundice, we performed internal biliary drainage after four days of bile duct obstruction.

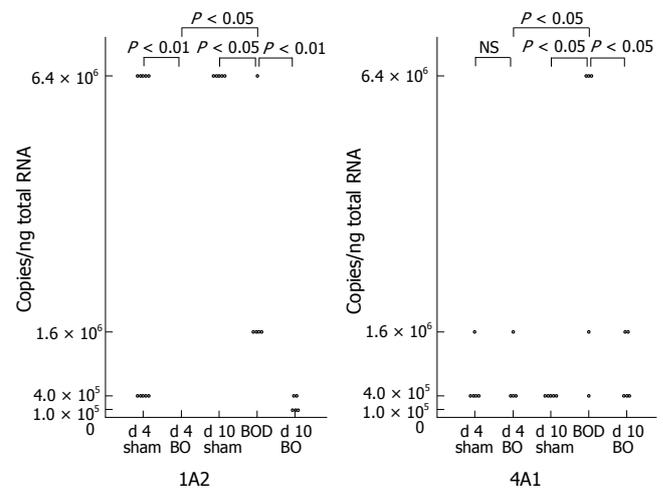

In jaundiced patients, proinflammatory cytokines such as TNF or IL-6 are known to be released<sup>[22]</sup>, and an increase of TNF and IL-6 has been reported in murine obstructive jaundice models<sup>[23]</sup>. On the other hand, it has been reported that both TNF and IL-6 decrease the expression of mRNA for CYP isozymes<sup>[24-26]</sup>. These findings suggest that one of the mechanisms of reduced mRNA expression of CYP isozymes in obstructive jaundice may be an increase in the level of cytokines such as TNF and IL-6.

**Figure 2** Effect of bile duct ligation and following internal biliary drainage on the mRNA expression of sexually undifferentiated CYP isozymes. The mRNA expression was measured semi-quantitatively by competitive RT-PCR.

The changes of the total CYP content and MFO activity following internal biliary drainage were comparable to those reported previously<sup>[8]</sup>. In the present study, although the expression of mRNA for CYP isozymes decreased after bile duct obstruction, it returned to the control level after 6 d of internal biliary drainage, except for CYP1A2. The expression of CYP1A2 mRNA was also increased after 6 d of internal biliary drainage, but not to the control level. However, this does not exclude the possibility that the expression of CYP1A2 mRNA could return to the control level after more than 6 d of internal biliary drainage. The recovery of CYP mRNA expression can be explained as follows: factors that reduced expression of the various CYP isozymes after bile duct obstruction, such as changes of sex steroids and cytokines, were eliminated or reduced by internal biliary drainage. In addition, bile duct obstruction did not alter the expression of CYP4A1 mRNA, while internal biliary drainage increased its expression. Peroxisome proliferators such as clofibrate have been known to induce CYP4A1<sup>[27,28]</sup>. It has been reported that LPS administration increases the expression of CYP4A1 mRNA in Fischer 344 rats<sup>[29]</sup>. On the other hand, it has been reported that bile duct obstruction increases the serum estradiol concentration, and that estradiol suppresses the induction of CYP4A1 by clofibrate<sup>[30]</sup>. The results of the present study showed that bile duct obstruction did not affect CYP4A1 mRNA expression although internal biliary drainage promoted of factors that increased its mRNA expression. However, it is also possible that bile duct obstruction produced multiple factors that both induced and suppressed CYP4A1 mRNA expression, so that there was no apparent change. Internal biliary drainage may then have selectively eliminated the suppressive factors and led to increased expression of CYP4A1 mRNA.

Clinically, patients with obstructive jaundice resulting from biliary disease such as choledocholithiasis or bile duct cancer are generally treated by biliary drainage, and the effectiveness of this treatment has been well documented<sup>[17-19]</sup>. In the present study, bile duct obstruction increased the serum ALT and total bilirubin levels, but both returned to their control levels after 6 d of internal biliary drainage, and obstructive jaundice dissipated. Similarly, the reduced total CYP content returned to the control level. Nonetheless, the bile duct

**Figure 3** Effect of bile duct ligation and following internal biliary drainage on the mRNA expression of sexually undifferentiated CYP isozymes. The mRNA expression was measured semi-quantitatively by competitive RT-PCR.

obstruction and internal biliary drainage did not affect the expression of mRNA for the various CYP isozymes in the same manner. Internal biliary drainage did not result in sufficient recovery of the expression of mRNA for some CYP isozymes, and while bile duct obstruction had no effects, internal biliary drainage increased the expression of mRNA for some CYP isozymes. Therefore, even after the recovery of common indicators of obstructive jaundice, such as serum ATL and total bilirubin, hepatic drug metabolism could remain compromised. Caution should therefore be exercised when administering drugs following apparent recovery from obstructive jaundice.

Changes of CYP isozymes following obstructive jaundice and internal biliary drainage differed among the various isozymes, suggesting the existence of not simply a single mechanism, but multiple mechanisms. Further studies, such as the measurement of various cytokines, are therefore warranted in the future.

## COMMENTS

### Background

The hepatic cytochrome P450-dependent microsomal mixed-function oxidase

(MFO) system plays a major role in the metabolism of exogenous and endogenous substrates. Several authors have observed a decrease of the total hepatic cytochrome P450 (CYP) content and MFO activity in cholestatic bile duct ligation models. Since CYP consists of multiple isozymes with different substrate specificities, liver damage would probably affect various isozymes differently.

### Research frontiers

This study focuses on the effect of biliary drainage on individual CYP isozymes in rats with bile duct obstruction. We used a model of reversible obstructive jaundice due to bile duct obstruction, and mRNA levels of different CYP isozymes were compared before and after internal biliary drainage.

### Innovations and breakthroughs

There have been previous reports about the effects of biliary drainage on the total CYP content and MFO activity in rats with bile duct obstruction, but the effects of biliary drainage on individual CYP isozymes remain unknown. We demonstrated that bile duct obstruction and subsequent internal biliary drainage had various effects on the activity and mRNA expression of different CYP isozymes.

### Applications

The effects of obstructive jaundice and internal biliary drainage differed among the various CYP isozymes. These results suggest the existence of multiple mechanisms that modify CYP activity, so further studies are warranted in the future.

### Peer reviewer

This study used a simple model of reversible obstructive jaundice in rats to demonstrate that biliary obstruction and subsequent biliary drainage had a differential effect on the expression of mRNA for several CYP isozymes. The experiments were well designed and conducted.

### Abstract

**AIM:** To compare the effect of oral erythromycin *vs* no preparation with prokinetics on the transit time and the image quality of capsule endoscopy (CE) in evaluating small bowel (SB) pathology.

**METHODS:** We conducted a retrospective, blinded (to the type of preparation) review of 100 CE studies, 50 with no preparation with prokinetics from one medical center (Group A) and 50 from another center with administration of a single dose of 200 mg oral erythromycin 1 h prior to CE (Group B). Gastric, SB and total transit times were calculated, the presence of bile in the duodenum was scored, as was cleanliness within the proximal, middle and distal intestine.

**RESULTS:** The erythromycin group had a slightly shorter gastric transit time (21 min *vs* 28 min, with no statistical significance). SB transit time was similar for both groups (all  $P > 0.05$ ). Total transit time was almost identical in both groups. The rate of incomplete examination was 16% for Group A and 10% for Group B ( $P = 0.37$ ). Bile and cleanliness scores in different parts of the intestine were similar for the two groups ( $P > 0.05$ ).

**CONCLUSION:** Preparation for capsule endoscopy with erythromycin does not affect SB or total transit time. It tends to reduce gastric transit time, but it does not increase the cecum-reaching rate. Erythromycin does not adversely affect image quality. We consider the routine use of oral erythromycin preparation as being unjustified, although it might be considered in patients with known

### INTRODUCTION

Capsule endoscopy (CE) is a well accepted methodology which provides a direct and noninvasive way to view the entire small bowel (SB) mucosa<sup>[1-6]</sup>. Capsule technology has enriched our knowledge about small bowel pathology and revolutionized the management of SB diseases<sup>[7,8]</sup>. The best way to ensure the most complete and high-quality visualization of the entire small bowel is, however, a subject of controversy in the literature. In addition to improving the technical characteristics of the capsule itself, two ways of achieving these aims are proper preparation and the use of prokinetics<sup>[9]</sup>. Decreasing gastric and SB transit times were expected to allow the capsule to successfully reach the cecum and to overcome the problem of the capsule's too-short battery lifetime ( $7 \pm 1$  h).

Erythromycin is a well-known prokinetic agent. It induces high amplitude gastric propulsive contractions by the initiation of gastric interdigestive migrating motor complexes. As a result, it accelerates gastric emptying, including that of indigestible particles<sup>[10-12]</sup>. The effect of erythromycin on small bowel motility is less known. As such, its use to accelerate capsule transit time in the stomach and probably in the small intestine seemed to be an attractive idea, and several studies were conducted to explore this possibility<sup>[13-15]</sup>. The number of such studies is very small and each includes few patients. Another aspect that has not yet been investigated is whether or not erythromycin stimulates the biliary-pancreatic secretions

to the small intestine, thereby adversely affecting image quality.

Uncertainty about these preparation-related issues of CE led to the uses of different CE preparation protocols among medical centers. Two Israeli medical centers have been routinely following two different protocols: patients undergoing CE at the Tel-Aviv Sourasky Medical Center (TASMC) are instructed to undergo a standard 12-h fast while those is examined at the Hillel-Yaffe Medical Center (HYMC) fast for 12 h and also take oral erythromycin to accelerate gastric emptying. The objective of the current study was to compare the CE data from these two medical centers in order to determine whether the addition of erythromycin leads to a relative acceleration of gastric and small intestinal transit times of the capsule without adversely affecting its image quality.

## MATERIALS AND METHODS

This retrospective study was conducted in two Israeli medical centers, TASMC and HYMC. The protocol of the study was approved by the local Helsinki committees of both centers. The films of 50 capsules were randomly chosen from each center's Department of Gastroenterology's archives between 2000 and 2007. All 50 of the TASMC patients underwent a standard 12-h overnight fast preparation protocol (Group A), while all 50 of the HYMC patients followed a protocol that involved a 12-h overnight fast and a single dose of 200 mg oral erythromycin taken 1 h prior to undergoing the test (Group B). The CE procedure was standard in both centers: all patients ingested a PiliCam™ SB wireless video capsule (Given® Diagnostic Imaging System, Yokneam, Israel) with a small amount of water. An array of 8 sensors was attached to the abdominal wall, and a belt holding a recorder with a battery was fastened around their waists. Patients were allowed to drink 2 h after ingesting the capsule and to eat a light meal 4 h later. Eight h after capsule ingestion, the recorder was disconnected and the sensors were removed. The recorded digital information was downloaded onto the computer and the images were analyzed using RAPID® software. The provenance of the films was concealed from an independent expert who reviewed all 100 films.

The following data were collected from the CE studies and the CE endoscopy reports of all participating patients: demographics, the indications for referral to the procedure, the findings in the small intestine, and the rate of cecal arrival (i.e., the completeness of evaluation). The gastric transit time was calculated from the first view of the gastric mucosa to the first image of the duodenum and it was expressed in minutes. The SB transit time was calculated from the first view of the duodenum up to the first cecal image and it, too, was expressed in minutes. If the capsule did not reach the cecum during the battery's lifetime, the SB transit time was calculated as 480 min (8 h) minus gastric transit time.

The presence of bile in the duodenum lumen was evaluated using a scale of 1 to 4, with 1 representing none and 4 indicating more than 90% of the lumen being full of bile (Figure 1). The quality of visualization of SB mucosa

Figure 1 Grading of bile presence in the duodenum.

(i.e., cleanliness) was also evaluated by a 4-point scale, with 1 representing no residual material in the lumen and 4 indicating more than 90% of the lumen having residual material. The SB section of the CE study was divided into three parts, proximal, middle and distal intestine, and each was given a separate grading of cleanliness. A CE study was defined as having been completed if the capsule reached the cecum.

Comparisons between patients with and without erythromycin preparation with regard to demographic (age, gender) and clinical parameters (transit time, indications, diagnosis, *etc*) were performed using the Chi-square, Fisher's Exact and unpaired t-tests. The non-parametric Mann-Whitney test was applied since the continuous parameters did not follow a normal distribution. The relationships between transit time and other continuous parameters were examined by the Spearman's correlation coefficients. This was done for the entire sample and for each group separately (according to preparation type). The statistical analysis was performed by the SPSS for Windows software (Chicago, USA), version 14.0. The statistical tests were defined as having a confidence interval of 95%. A *P* value < 0.05 was considered significant for all tests performed.

## RESULTS

A total of 100 CE studies were reviewed by an independent expert who was blinded to the center-belonging of the films. Fifty patients were from TASMC who used no preparation (Group A) and 50 patients were from HYMC who used an erythromycin preparation (Group B). In two studies (one from TASMC and one from HYMC), the gastric transit time was extremely prolonged (longer than 3 h) and, therefore, each of those studies was replaced by a randomly chosen one from the each center's archives.

Table 1 summarizes the study cohort's demographic and other relevant clinical data. Both groups were fairly similar, with the exception of the greater number of cases

**Table 1** Demographic and clinical data of the study patients (*n* = 100)

Parameter	No erythromycin ( <i>n</i> = 50)	Erythromycin ( <i>n</i> = 50)	<i>P</i>
Age, yr (mean ± SD)	51.7 ± 21.6	52.1 ± 19.4	0.93 <sup>1</sup>
Male/Female	32/18	36/14	0.39
Indications			0.40
Suspected Crohn's	19	18	0.84
Obscure GI bleeding	23	28	0.32
Others <sup>2</sup>	8	4	0.22
Final diagnosis in SB			0.10
Normal findings	23	19	0.42
Non-specific findings	9	7	0.59
Crohn's disease	1	7	0.06
Angiodysplasia	7	2	0.16
Polyps	1	3	0.62
Others <sup>2</sup>	9	12	0.46

<sup>1</sup>Unpaired *t*-test; <sup>2</sup>Includes Indication (abdominal pain, celiac and polyposis syndrome) and final diagnosis (nodular hyperplasia, edematous fold, *etc*); the rest of *P* values are according to nonparametric Mann-Whitney test. SB: Small bowel; GI: Gastrointestinal.

**Table 2** Transit times, bile and cleanliness scores in the two study groups (mean ± SD)

	No erythromycin ( <i>n</i> = 50)	Erythromycin ( <i>n</i> = 50)	<i>P</i>
Gastric transit time (min)	28.36 ± 23.56	21.08 ± 15.13	0.07 <sup>1</sup> 0.16
SB transit time (min)	270.42 ± 108.13	279.14 ± 103.89	0.83
Total transit time (min)	299.26 ± 108.18	300.22 ± 103.25	0.97
Did not reach the cecum (%)	8 (16%)	5 (10%)	0.37
Bile presence score	1.75 ± 0.61	1.76 ± 0.58	0.99
Cleanliness score			
Proximal SB	1.78 ± 0.76	1.77 ± 0.74	1.00
Middle SB	2.22 ± 0.75	2.16 ± 0.77	0.73
Distal SB	2.79 ± 0.65	2.75 ± 0.74	0.73

<sup>1</sup>Unpaired *t*-test; the rest of *P* values are according to nonparametric Mann-Whitney test. SB: Small bowel.

with a final diagnosis of Crohn's disease belonging to Group B (i.e., 1 case in Group A *vs* 7 cases in Group B, *P* = 0.06).

Table 2 compares the transit times, the rates at which the capsule reached the cecum, and the bile and cleanliness scores between the two groups. There was a trend towards a shorter gastric transit time for the patients in Group B (28 min in Group A *vs* 21 min in Group B, *P* = 0.07, unpaired *t*-test). The Mann-Whitney test (which is more accurate in groups with high variability) did not, however, confirm this finding (*P* = 0.16). Nevertheless, there was a higher variability of gastric transit times among the patients within Group A compared with the variability within Group B, which had more uniformity (*P* = 0.076 according to Levene's test for equality of variances).

There were no group differences in SB transit time (270 min in Group A *vs* 279 min in Group B) or in total transit time (299 min *vs* 300 min, respectively; Table 2). The capsule did not reach the cecum during the battery's lifetime in 8 Group A cases (16%) compared with 5 Group B cases (10%, *P* > 0.05). There was no case of capsule

**Table 3** Gastric transit time with respect to cecum reachability

	No erythromycin ( <i>n</i> = 50)	Erythromycin ( <i>n</i> = 50)	<i>P</i> value
Gastric transit time in cases failing to reach cecum (min)	36.75 ± 33.93 ( <i>n</i> = 8)	22.2 ± 14.45 ( <i>n</i> = 5)	0.52
Gastric transit time in cases where cecum was reached (min)	26.76 ± 21.22 ( <i>n</i> = 42)	20.96 ± 15.36 ( <i>n</i> = 45)	0.24
<i>P</i>	0.52	0.81	

**Table 4** Transit times according to indication for capsule endoscopy in Crohn's disease and obscure gastrointestinal bleeding (OGIB)

Transit time	Indication	No erythromycin ( <i>n</i> = 50)	Erythromycin ( <i>n</i> = 50)	<i>P</i>
Gastric transit time (min)	Crohn's disease	27.16 ± 26.11	16.72 ± 13.21	0.19
	OGIB	29.82 ± 23.53	23.61 ± 16.49	0.43
	<i>P</i>	0.41	0.16	
Small bowel transit time (min)	Crohn's disease	285.53 ± 96.31	324.50 ± 114.57	0.28
	OGIB	230.39 ± 103.00	255.32 ± 90.81	0.44
	<i>P</i>	0.066	0.04	

retention. Even after excluding from the calculations those cases in which the capsule did not reach the cecum, there were still no significant differences between Group A and Group B in SB and total transit times: the respective SB transit times were 237.50 ± 82.69 min and 259.29 ± 89.28 min (*P* = 0.44), and the respective total transit times were 264.83 ± 79.99 min and 280.24 ± 88.27 min (*P* = 0.56).

A comparison of the presence of bile (a score of 1.75 in Group A *vs* 1.76 in Group B, *P* = 0.99) and of the cleanliness scores in different parts of the SB failed to show any differences as well (Table 2). As expected in each group, the presence of residual material was more prominent in the distal than in the proximal intestine, assuring a better visualization of the SB mucosa in the proximal intestine.

We sought to determine whether or not the gastric transit time in cases in which the capsule failed to reach the cecum was longer than in cases with completed tests, assuming that extended transit time may consume valuable battery time for gastric visualization than for the small intestine. It emerged that the gastric transit time was fairly similar for all subgroups, regardless of cecum reachability (Table 3).

An additional analysis was performed to explore the relationships between the patient's clinical picture and capsule transit times (Table 4). The two major indications for undergoing CE that were chosen for this assessment were a clinical picture suspicious for Crohn's disease (abdominal pain, diarrhea, elevated CRP, anemia, *etc*) and for obscure gastrointestinal (GI) bleeding (OGIB). There were no differences in gastric transit times between these two indications for either Group A or Group B or between the two groups. SB transit time was, however, significantly longer in the cases suspected to have Crohn's disease

than OGIB in Group B and almost significantly longer in Group A ( $P = 0.04$  and  $P = 0.063$ , respectively). Neither the preparation with erythromycin nor the indication for CE affected the cecum-reaching rates in both groups ( $P = 0.160$  and  $P = 0.452$ , respectively).

Age below or above 40 years old (decided arbitrarily) did not affect gastric or SB transit time, but there was some tendency for shorter total transit time in patients above age 40 only in Group A ( $P = 0.07$ ). In addition, Group A demonstrated a borderline gender-dependent difference: females in Group A tended to have a shorter gastric transit time and a longer SB transit time ( $P = 0.052$  and  $P = 0.069$ , respectively). No influence of age or gender on transit times was evidenced in Group B.

## DISCUSSION

The results of our comparative two-center study demonstrate that preparation with oral erythromycin before a CE study does not affect SB transit time, total transit time or the rate of the capsule in reaching the cecum. The medication may have had a possible shortening effect on gastric transit time and it tended to reduce the variability of gastric transit times among the patients in the group that used it. The length of gastric time does not, however, predict the likelihood that the capsule will reach the cecum during the battery's lifetime. We demonstrated that the indication for patients undergoing CE affects the SB transit time, but not any of the other examined parameters, and that the influences of age and gender are only marginal. Erythromycin does not affect adversely an image quality as measured by presence of bile and residual material in the intestine.

Our study is the largest thus far to address the issue of erythromycin preparation before a CE study. Leung *et al*<sup>[14]</sup> conducted a small prospective comparative study on 24 patients who received an oral erythromycin preparation *vs* 14 patients who were not given any prokinetics. While no differences were found in SB transit times, in cecum arrival rates or in the quality of images, there was a highly significant difference in gastric transit time between these two groups (16 min *vs* 70 min, respectively,  $P = 0.005$ ). Caddy *et al*<sup>[15]</sup> performed a study of similar design (22 and 23 patients in each group) and demonstrated no significant difference in gastric and SB transit times, cecum arrival rate or image quality between the two groups. The third published study on this issue was conducted by Fireman *et al*<sup>[15]</sup>. Their investigation included one group prepared with polyethylene glycol (26 patients), another with erythromycin (29 patients) and a third with no preparation (40 patients). According to their results, erythromycin had no effect on SB transit time, but it did show some tendency for shortening gastric transit time. The erythromycin group in Fireman *et al* study<sup>[15]</sup> had significantly more residual material in the lumen and poorer image quality.

Altogether, there is general agreement among the available studies that erythromycin does not affect SB transit time but that it may or may not shorten gastric time. There are some minor differences in design between those earlier studies and our current one. We excluded the patients with extremely prolonged gastric emptying time ( $> 3$  h) in order

to prevent skewing of the data during the statistical analysis (1 patient from Group A and 1 patient from Group B). In addition, the dosage of erythromycin used in the other studies was slightly higher than in ours (250 mg *vs* 200 mg, respectively) although the route of administration (oral) and timing (1 h prior to CE study) were identical. Our study was retrospective, but all the CE studies were re-examined by an independent expert who was blind to the hospital in which any given CE study had been performed.

The question about whether or not erythromycin stimulates the secretion of bile and by doing so impairs the image quality in the duodenum had not been previously explored in CE studies. Using a bile score, we could now clearly show that there is no such stimulation of bile secretion. As for the controversial issue of erythromycin's affecting the cleanliness score, we used a separate score for the proximal, middle and distal parts of the intestine and found no negative impact of the medication on the cleanliness of the intestine.

In conclusion, we suggest that the routine use of oral erythromycin 200-250 mg for SB or total transit time in CE is unfounded. It should, however, be considered as part of the preparation for patients with known prolonged gastric emptying time (i.e. either from a previous CE study or other imaging tests) or in patients with symptoms characteristic of gastroparesis (e.g. feeling of upper abdominal fullness, vomiting, *etc*). The optimal dosage (probably higher dosage) and the preferred route of administration of erythromycin (intravenous *vs* oral) in the setting of CE await further study.

## COMMENTS

### Background

Capsule endoscopy (CE) is a well accepted methodology which provides a direct and noninvasive way to view the entire small bowel (SB) mucosa. The best way to ensure the most complete and high-quality visualization of the entire small bowel is, however, a subject of controversy in the literature. The aim of this study is to compare the effect of oral erythromycin *vs* no preparation with prokinetics on the transit time and the image quality of CE in evaluating SB pathology.

### Research frontiers

We conducted a retrospective, blinded (to the type of preparation) review of 100 CE studies, 50 with no preparation with prokinetics from one medical center (Group A) and 50 from another center with administration of a single dose of 200 mg oral erythromycin 1 h prior to CE (Group B). The results of the study demonstrated that preparation for capsule endoscopy with erythromycin does not affect SB or total transit time ( $P > 0.05$ ). It tends to reduce gastric transit time ( $P = 0.07$ ), but it does not increase the cecum-reaching rate ( $P = 0.37$ ). Erythromycin does not adversely affect image quality (both bile score and the score of cleanliness). We consider the routine use of oral erythromycin preparation as being unjustified, although it might be considered in patients with known prolonged gastric emptying time.

### Innovations and breakthroughs

Our study is the largest thus far to address the issue of erythromycin preparation before a CE study. In addition, we used a new bile score and a separate score of cleanliness for different parts of the small intestine. These innovations made the conclusions more precise. Our study was retrospective, but all the CE studies were re-examined by an independent expert who was blind to the hospital in which

any given CE study had been performed. We concluded that the routine use of oral erythromycin 200 mg-250 mg for SB or total transit time in CE is unfounded. It should, however, be considered as part of the preparation for patients with known prolonged gastric emptying time (i.e. either from a previous CE study or other imaging tests) or in patients with symptoms characteristic of gastroparesis (e.g. feeling of upper abdominal fullness, vomiting, *etc*).

### Applications

The conclusions of our study may spare to the patients an unnecessary use of antibiotics before the capsule procedure.

### Peer review

This is a retrospective comparative study comparing two preparation regimens for capsule endoscopy. One group received oral erythromycin and the second did not receive a prokinetic preparation. The study aimed to look for differences in capsule transit time, but was not able to demonstrate an advantage for the erythromycin group. The paper is well written and the study design although retrospective adequate.

Hepatoprotective activity of *Sapindus mukorossi* and *Rheum emodi* extracts: *In vitro* and *in vivo* studies. *World J Gastroenterol* 2008; 14(16): 2566-2571 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2566.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2566>

### Abstract

**AIM:** To study the hepatoprotective capacity of *Sapindus mukorossi* (*S. mukorossi*) and *Rheum emodi* (*R. emodi*) extracts in CCl<sub>4</sub> treated male rats.

**METHODS:** The dried powder of *S. mukorossi* and *R. emodi* was extracted successively with petroleum ether, benzene, chloroform, and ethanol and concentrated in vacuum. Primary rat hepatocyte monolayer cultures were used for *in vitro* studies. *In vivo*, the hepatoprotective capacity of the extract of the fruit pericarp of *S. mukorossi* and the rhizomes of *R. emodi* was analyzed in liver injured CCl<sub>4</sub>-treated male rats.

**RESULTS:** *In vitro*: primary hepatocytes monolayer cultures were treated with CCl<sub>4</sub> and extracts of *S. mukorossi* & *R. emodi*. A protective activity could be demonstrated in the CCl<sub>4</sub> damaged primary monolayer culture. *In vivo*: extracts of the fruit pericarp of *S. mukorossi* (2.5 mg/mL) and rhizomes of *R. emodi* (3.0 mg/mL) were found to have protective properties in rats with CCl<sub>4</sub> induced liver damage as judged from serum marker enzyme activities.

**CONCLUSION:** The extracts of *S. mukorossi* and *R. emodi* do have a protective capacity both *in vitro*

### INTRODUCTION

The liver is an organ of paramount importance. Due to its unique and considerable regenerative capacity, even a moderate cell injury is not reflected by measurable change in its metabolic functions. However, some of its functions are so sensitive that abnormalities start appearing depending upon the nature and the degree of initial damage.

The etiology of the liver disorders depends on various factors as nutritional, biochemical, bacteriological, viral, or environmental aberration. The liver plays a significant role not only in the metabolism and disposition of the chemicals to which it is exposed directly or indirectly, but also in the metabolism of fats, carbohydrates, proteins, and immunomodulation.

The impairment of the liver function is generally caused by xenobiotics, excessive exposure to various pharmacological and chemical agents, and protozoal or viral infections. Depending upon the severity of cellular injury, acute hepatitis can lead to chronic hepatitis, which is finally terminated to cirrhosis or malignant lesions in untreated cases. In case of deranged liver functions, the chemical composition of liver or its subcellular organelles are possibly altered. A slight alteration in hepatic structure and function may result in portal hypertension, ascities, jaundice, and increased bleeding, and causes multiple metabolic changes affecting other organs as well. Medical

survey indicates exceptionally high occurrence of hepatic diseases and has become one of the most serious problem in the area of public health. Acute viral hepatitis is a diffuse inflammatory lesion of the liver usually accompanied by clinical and biochemical abnormalities and often caused by the well-characterized hepatitis virus. Acute hepatitis closely resembles viral hepatitis clinically, biochemically, and histologically. It can also be induced by chemicals or drugs.

Alcoholic liver disease (ALD) is one of the most serious consequences of chronic alcohol abuse. Liver cirrhosis, the culmination of the illness, is one of the leading causes of death in western countries<sup>[1,2]</sup>.

According to Wang<sup>[3]</sup> chronic and excessive ethanol consumption is associated with cellular proliferation, fibrosis, cirrhosis, and cancer of the liver. An important characteristic of alcohol-induced liver injury is an impaired vitamin A nutritional status. Studies in human Hep G2 cells have shown that ethanol is cytotoxic to Hep G2 cells, which are transduced to express P-450 2E1 (CYP 2E1) and this toxicity is apoptotic in nature<sup>[4]</sup> predominantly in the liver. The main pathways for hepatic oxidation of ethanol to acetaldehyde involve alcohol dehydrogenase<sup>[5]</sup> and are associated with the reduction of NAD<sup>+</sup> to NADH<sup>[6]</sup>.

The magnitude of derangement of liver by disease or hepatotoxins is generally measured by the level of glutamate pyruvate transaminase (ALT), glutamate oxaloacetate transaminase (AST), alkaline phosphatase (ALP), bilirubin, albumin, and whole liver homogenate.

Herbal drugs are playing an important role in health care programs worldwide, and there is a resurgence of interest in herbal medicines for treatment of various ailments including hepatopathy. India, the abode of Ayurvedic system of medicine, assigns much importance to the pharmacological aspects of many plants. Hepatoprotective effect of some plants like *Spirulina maxima*<sup>[7]</sup>, *Eclipta alba*<sup>[8]</sup>, *Boehmeria niveda*<sup>[9]</sup>, *Cichorium intybus*<sup>[10]</sup>, and *Picrorhiza kurroa*<sup>[11]</sup> has been well established. Nearly 150 phytoconstituents from 101 plants have been claimed to possess liver protecting activity<sup>[12]</sup>. At the same time, surprisingly, we do not have satisfactory plant drugs/formulations to treat severe liver diseases. Most of the studies on hepatoprotective plants are carried out using chemical induced liver damage in rodents as models. A few excellent reviews have appeared on this subject in the recent past<sup>[13]</sup>.

This study is based on the natural products responsible for repairing and healing of adversely affected liver cells. In the present study, we selected two plants namely *S. mukorossi* and *R. emodi* and investigated the hepatoprotective effect of these plant extracts against CCl<sub>4</sub> induced hepatocyte damage *in vitro* and liver injury *in vivo*.

*S. mukorossi* Gaerten (Sapindaceae), commonly known as Ritha or Aritha is found throughout India. The major constituents of its fruit are saponins (10%-11.5%), sugars (10%) and mucilage<sup>[14]</sup>. The fruit of the plant is reported to have expectorant, emetic, alexipharmic, and abortifacient effects. It is also used in excessive salivation, epilepsy and chlorosis<sup>[15,16]</sup>. Saponins from this plant are known to be spermicidal *in vitro*<sup>[17]</sup>. This spermicidal property has been used in contraceptive cream<sup>[18]</sup>. The alcoholic extract

(*Sapindus trifoliatus* Linn) is reported to possess anti-implantation activity.

*R. emodi* (Polygonaceae) commonly known as Indian or Himalayan Rhubarb is found in India. The major constituents of rhubarb rhizomes are anthraquinones. Rhubarb is used as a laxative, diuretic to treat kidney stones, gout, and liver diseases characterized by jaundice. Externally, it is used to heal skin sores and scabs. Paradoxically, although larger doses are used as laxative, small doses are used to treat dysenteric diarrhea<sup>[19]</sup>. Chinese use rhubarb as an ulcer remedy and consider it a bitter, cold, dry herb used to "clear heat" from the liver, stomach and blood, to expel helminthes and to treat cancer, fever, upper intestinal bleeding (ulcers), and headache<sup>[20,21]</sup>. It is also used to treat toothache<sup>[22]</sup>. In Europe, rhubarb is a component of spring tonics or blood cleansing cures, including Swedish bitter<sup>[23]</sup>. Turkish or medicinal rhubarb is also one of the four major ingredients in the herbal cancer remedy.

We isolated the extracts from both plants, and a study was designed using the products of *S. mukorossi* and *R. emodi* to assess the hepatoprotective effect of these plant extracts against CCl<sub>4</sub> induced hepatocyte damage *in vitro* and liver injury *in vivo*.

## MATERIALS AND METHODS

### Plant materials

Authentic samples of *S. mukorossi* and *R. emodi* were obtained from authorized supplier M/s Munnalal Dawasas and Co. Hyderabad, Andhra Pradesh, India. The plants were previously identified and authenticated by experts in the Post Graduate and Research Department of Botany, Anwar-ul-loom College Hyderabad, Andhra Pradesh, India.

### Animals

Male Wister rats weighing 175-200 g were obtained from the animal house of Deccan College of Medical Sciences, Hyderabad and housed in polycarbonate cages. The rats had free access to standard pellet chow and water *ad libitum* throughout the experiment with the exception of some experiments (see below) in which the animals were deprived of food, but not water, for 18-24 h before the experiments were performed. After procurement, all the animals were divided into different groups and were left for one week for acclimatization to experimentation room and were maintained on standard conditions (23°C, 60%-70% relative humidity and 12 h photo period). There were six animals in each group for observational screening and acute toxicity studies. All experimental protocols described below were approved by the ethical board.

### Extraction, separation, and purification of the compounds

For phytochemical analysis, approximately 100 g of fruit pericarp of *S. mukorossi* and rhizomes of *R. emodi* was collected and materials were chopped, air dried at 35-40°C and pulverized in electric grinder. The powder obtained was successively extracted with the following chemicals, petroleum ether (60-80)°C, benzene, chloroform, and ethanol, respectively.

The extracts were then powdered by using rotary evaporator under reduced pressure. Fruit pericarp of *S. mukorossi* yielded 38 g, 28 g, 34 g, and 35 g and rhizomes of *R. emodi* yielded 19 g, 17 g, 21 g, and 22 g powdered extracts with petroleum ether, benzene, chloroform, and ethanol, respectively.

The extracts were obtained by percolation using 70% of ethanol as solvent at room temperature; according to process A of Farmacopeia dos Estados Unidos do Brasil (1959) (AOAC 1990). The extracts were evaporated at 40°C under vacuum and the residue was freeze-dried. The dry extracts of the fruit pericarp of *S. mukorossi* and rhizomes of *R. emodi* were tested for the presence of saponins and anthraquinones.

Each extract of the fruit pericarp of *S. mukorossi* (SM) and rhizomes of *R. emodi* (RE) were column chromatographed over Silica gel (200 mesh), eluting with CHCl<sub>3</sub>-MeOH (70:30, 60:40, 50:50, 25:75) and compound fractions of (250 mL each) were collected and monitored by TLC. These column chromatographed compound fractions were further filtered to yield saponins from *S. mukorossi* and anthraquinones from *R. emodi*, which were separated by paper chromatography and preparative TLC to yield saponins [(SM-A (petroleum ether), SM-B (benzene), SM-C (chloroform) & SM-D (ethanol)], and anthraquinones [(RE-A (petroleum ether), RE-B (benzene), RE-C (chloroform) & RE-D (ethanol)], respectively. All the filtrates obtained were dried by evaporation (Rotometer, 40°C), the dried extracts were individually dissolved in 10 mL ethanol (95%) and then subjected to complete drying process and weighed according to the AOAC (1990) method<sup>[20]</sup>.

### Hepatotoxins

It is emphasized that hepatotoxins that cause acute hepatitis should have close resemblance with the viral hepatitis, clinically, biochemically, and histologically. Certain drugs are also responsible for chronic hepatic disease such as chronic hepatitis, fatty liver, cirrhosis, and several vascular lesions of the liver. In many instances drug induced hepatitis is indistinguishable from viral hepatitis. Chemically induced hepatic injury for experimental studies should be severe enough to cause cell death or to modify hepatic functions. The mechanism of acute hepatic injury depends upon the chemical compound and the species of animals used. We have studied hepatoprotective activity against carbon tetrachloride (CCl<sub>4</sub>) induced hepatotoxicity.

CCl<sub>4</sub> is one of the most powerful hepatotoxin in terms of severity of injury. It causes toxic necrosis leading to biochemical changes having clinical features similar to those of acute viral hepatitis<sup>[24,25]</sup>. Liver injury was produced by administration of CCl<sub>4</sub> mixed with liquid paraffin. Animals were given single doses of CCl<sub>4</sub> 100 µL/kg *p.o.* per day through out the experimental setup. Control animals received an equal volume of liquid paraffin.

### Methods for the hepatoprotective evaluation of extracts of *S. mukorossi* and *R. emodi*

**In vitro:** Fasting Wistar male adult rats weighing 280-300 g were used. Liver cells were isolated by using a modified procedure of Kiso *et al.*<sup>[27]</sup>. The animal was cleaned

thoroughly using rectified alcohol and anaesthetized with ether. Dissection of the animal was carried out under aseptic conditions using sterilized instruments. A midline incision was made on the abdomen of the anaesthetized animal. The portal vein was cannulated with needle no 25 connected to an infusion set. The needle was tied in place and the inferior vena cava was cut below the renal vein. Perfusion of the liver was started immediately with Ca<sup>2+</sup>-Mg<sup>2+</sup> free Hanks buffer salt solution (pH 7.4 at 37°C) which was prepared according to the procedure of Ohno (1965). When the liver was thoroughly perfused (*i.e.* has turned white), the flow of HBSS was stopped and the needle was removed. The liver was transferred to a sterile Petri dish containing Ca<sup>2+</sup>-Mg<sup>2+</sup> free HBSS and minced into small pieces, which were transferred to a conical flask containing 10 mL of 0.075% collagenase in HBSS. This was placed on a magnetic stirrer at 37°C for 10 min. The cell suspension thus obtained was centrifuged at 50 g for 10 min. The supernatant was aspirated and the cell suspended in the Ca<sup>2+</sup>-Mg<sup>2+</sup> free HBSS. The cells were washed twice and counted in the presence of trypan blue dye. Viability of the cells in each of the experiment performed was found to be 90%. The isolated hepatocytes were cultured in Eagles MEM, supplemented with 10% inactivated serum at density of 0.5 × 10<sup>9</sup> cells/L in sterile disposable culture bottles and incubated in a humidified incubator at 37°C under 5% CO<sub>2</sub>. The viability of hepatocytes was studied after 6, 12, and 24 hrs. The hepatocytes which settled down were observed for their growth. Cytotoxicity of *S. mukorossi* and *R. emodi* extracts was tested in primary hepatocytes monolayer cultures. Neither of the extracts caused significant enzymes release or were cytotoxic (Table 1).

Hepatocytes were prepared from male Wistar rats by the collagenase perfusion technique<sup>[26]</sup>. Cells were purified by several centrifugations and inoculated at density of 0.5 × 10<sup>8</sup> cells/L on collagen coated plates. One day after the isolated rat hepatocytes were plated, cells were exposed to medium containing 7 mmol/L CCl<sub>4</sub> with or without the sample to be tested for the hepatoprotective activity<sup>[27]</sup>. After the exposure to CCl<sub>4</sub> for 1 h the culture medium was collected and used for the determination of different parameters.

Lipid peroxidation was assessed as TBA-reactive substances using malondialdehyde (MDA) as reference.

Silymarin CCl <sub>4</sub> +	50	563.47 $\pm$ 49.22 <sup>b</sup>	421.54 $\pm$ 30.82 <sup>b</sup>	47.96 $\pm$ 2.49 <sup>b</sup>	0.42 $\pm$ 0.02 <sup>b</sup>

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control.

Rat hepatocytes  $1 \times 10^9$  cells/L were incubated in a final volume of 1.0 mL HBSS buffer containing test materials in presence of 200  $\mu\text{mol/L}$  FeSO + 100  $\mu\text{mol/L}$  H<sub>2</sub>O<sub>2</sub>.

The biochemical estimations were carried out by using the usual techniques (Tables 1 and 2).

**In vivo:** Detailed evaluation of extracts of *S. mukorossi* and *R. emodi* for hepatoprotective activity was carried out against CCl<sub>4</sub>. The animals were divided into five groups of six animals each. Group 1 served as vehicle control and was administered with normal saline. Group 2 rats were given CCl<sub>4</sub> 1.0 mL/kg, *p.o.* checking the biochemical parameters periodically for hepatotoxicity. Group 3 rats were given CCl<sub>4</sub> + extracts of *S. mukorossi* 2.5 g/kg, *p.o.* Group 4 rats were given CCl<sub>4</sub> + extracts of *R. emodi* 3.0 g/kg, *p.o.* Group 5 rats were given CCl<sub>4</sub> + Silymarin 50 g/kg, *p.o.* Blood was collected from the orbital sinus in all animals 2 h after last treatment and serum separated for different estimations (Table 3). The rats were anesthetized and sacrificed after the experimental period by cervical decapitation. The liver tissue was examined histopathologically.

### Statistical analysis

The data obtained was subjected to statistical analysis using ANOVA for comparing different groups (Armitage, 1987) and Dunnett's *t* test for control and test groups (Dunnett, 1964). The two tailed unpaired student *t* test for comparing means before and after treatment and one

tailed unpaired student *t* test for comparing control and drug treated group, ED50 value with 95% confidence limits (CL) by regression analysis using log dose response (Swinscow, 1980 & Ghosh, 1984) were used.  $P < 0.05$  or less was taken as the criterion of significance.

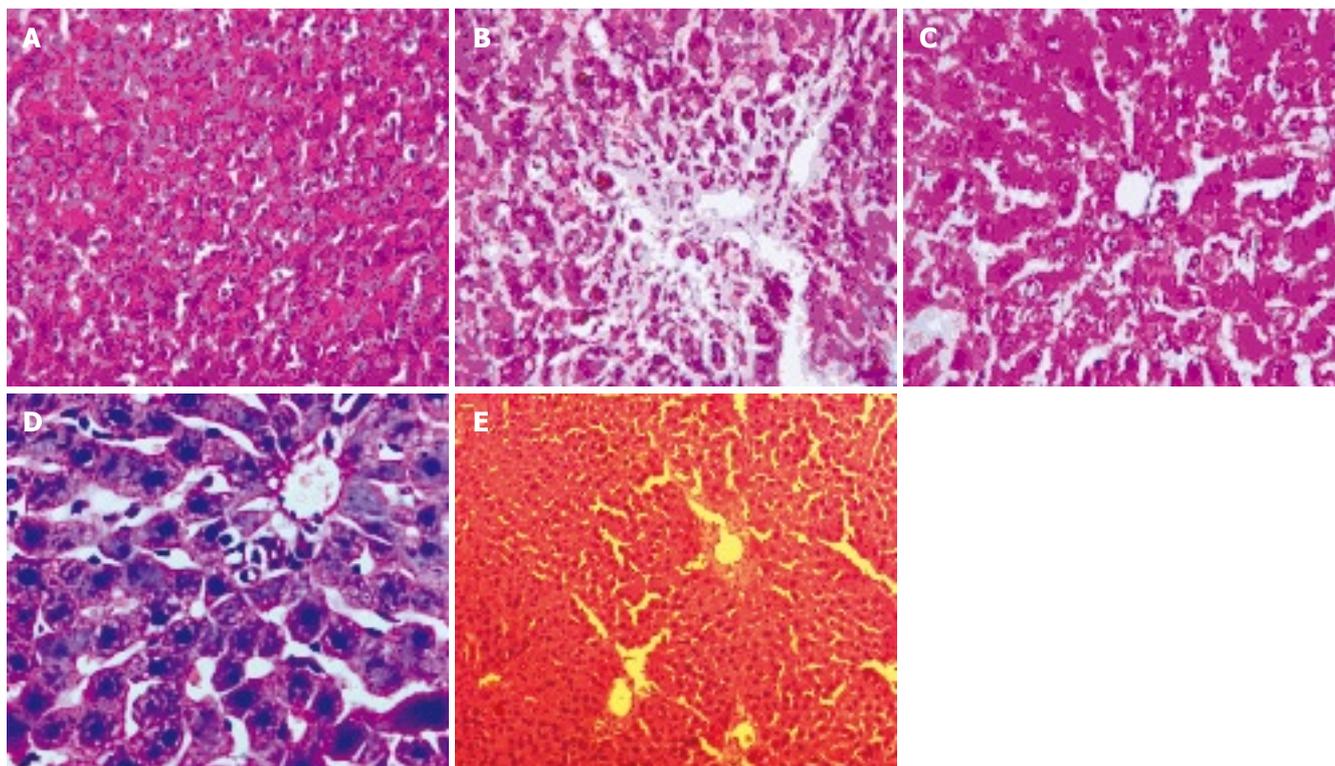

## RESULTS

### In vitro study

*S. mukorossi* and *R. emodi* extracts showed significant hepatoprotective activity against CCl<sub>4</sub> induced liver injury in primary hepatocytes cultures (Table 2). The hepatotoxic effects of CCl<sub>4</sub> are attributed to its metabolism by P450 to yield toxic trichloromethyl radicals that can act as free radical initiators<sup>[28]</sup>. These radicals are believed to induce injury either by interacting with the unsaturated fatty acids of cell membranes, thereby causing lipid peroxidation, or by binding covalently to important macromolecules such as proteins, lipids, or DNA<sup>[29,30]</sup>. The extracts of *S. mukorossi* and *R. emodi* reduced the levels of LDH and GPT released from CCl<sub>4</sub> injured rat hepatocytes into the medium in a concentration dependent manner, thus signifying their hepatoprotective activity.

### In vivo study

In CCl<sub>4</sub> intoxicated rats, serum activities of AST, ALT, ALP, and bilirubin were increased significantly when compared to the control (Table 3). The CCl<sub>4</sub> treated group

**Figure 1** Photograph of rat liver shows (HE,  $\times 100$ ). **A:** Liver of a control rat showing normal hepatocytes and normal architecture; **B:** Liver section from a  $\text{CCl}_4$  treated rat demonstrating the destruction of architectural pattern, nodule formation in the lobular zone, inflamed periportal zone, moderate inflammation of portal area; **C:** Liver section from a Silymarin treated rat showing regeneration of normal hepatocytes; **D:** Liver section from a *R. emodi* treated rat showing normal lobular architecture; **E:** Liver section from a *S. mukorossi* treated rat showing normal lobular architecture no necrosis or fatty changes or any inflammatory reaction can be seen.

showed a marked increase in serum bilirubin (mg %) ( $0.82 \pm 0.08$ ), ALT (IU/L) ( $1142.36 \pm 80.97$ ), AST (IU/L) ( $833.59 \pm 34.85$ ), and ALP (IU/L) ( $64.06 \pm 3.00$ ) activity indicating the injury caused by  $\text{CCl}_4$ . Treatment with the extracts of *S. mukorossi* and *R. emodi* significantly decreased the above elevated parameters and the normal architectural liver pattern was restored as given below.

Liver section of control rat showed normal hepatocytes and normal architecture (Figure 1A). Liver sections from  $\text{CCl}_4$  treated rats demonstrated the destruction of architectural pattern, nodule formation in the lobular zone, inflamed periportal zone, and moderate inflammation of portal area (Figure 1B). Liver sections from Silymarin treated rats showed regeneration of normal hepatocytes (Figure 1C). Liver sections from *R. emodi* treated rats showed normal lobular architecture (Figure 1D). Liver sections from *S. mukorossi* treated rat showed normal lobular architecture, and no necrosis or fatty changes or inflammatory reaction were seen (Figure 1E). These histopathological findings demonstrate a hepatoprotective effect of the extracts against  $\text{CCl}_4$ -mediated liver damage.

## DISCUSSION

The purpose of this study was to explore the hepatoprotective effect of *S. mukorossi* and *R. emodi* extracts in the hepatic damage caused by  $\text{CCl}_4$ . Administration of  $\text{CCl}_4$  to normal rats increased serum levels of AST, ALT, ALP, and bilirubin. The enzymes leaking out from damaged liver cells into circulating blood represent the damage to hepatic cells.

It is well established that the toxic metabolite of  $\text{CCl}_4$ , a free radical  $\text{CCl}_3$  is responsible for damage to liver cells. *S. mukorossi* and *R. emodi* extracts caused statistically significant decrease in all the above parameters at the dose of 2.5 mg/kg and 3.0 mg/kg given orally to  $\text{CCl}_4$  treated rats. Histopathological examination of the liver sections of rats treated with  $\text{CCl}_4$  showed destruction of architectural pattern, nodule formation in the lobular zone, inflamed periportal zone, moderate inflammation of portal area (Figure 1B). The group of rats treated with an extract of *R. emodi* showed normal lobular architecture (Figure 1D).

The group of rats treated with *S. mukorossi* showed normal lobular architecture and no necrosis or fatty changes or inflammatory reaction (Figure 1E). This suggests the reparative quality and maintenance of structural integrity of hepatocytic cell membrane of damaged liver cells by the extracts. The group of rats treated with Silymarin showing regeneration of normal hepatocytes was taken as standard (Figure 1C).

The ability of *S. mukorossi* and *R. emodi* to reduce the injurious effect or to preserve normal hepatic function disturbed by the hepatotoxin  $\text{CCl}_4$  is the index of its hepatoprotective effect.

These findings show the prophylactic and curative efficacy of *S. mukorossi* and *R. emodi* in maintaining the integrity and functional status of hepatocytes.

In conclusion, the data presented here indicate that the extracts of *S. mukorossi* and *R. emodi* are hepatoprotective both in  $\text{CCl}_4$  treated male rats and in  $\text{CCl}_4$  treated cultured primary rat hepatocytes. In addition, the *in vivo* studies

carried out using the extracts also proved to be highly efficient in terms of dosage, tolerability, and restoring the liver. We now intend to look at the mechanism by which these extracts maintain the integrity of the liver.

## ACKNOWLEDGMENTS

We are very grateful to Dr. CM Habibullah and Mr. Mohammed Jafer for patronage, encouragement, guidance, and financial support extended by them during the course of the study.

## COMMENTS

### Background

This article is based on the natural products responsible for repairing and healing of adversely affected liver cells. Our study suggests that the extracts of *S. mukorossi* and *R. emodi* are hepatoprotective both *in vitro* in CCl<sub>4</sub> damaged primary hepatocytes monolayer cultures and *in vivo* with doses of *S. mukorossi* (2.5 g/L) and *R. emodi* (3.0 g/L) in a CCl<sub>4</sub> induced liver injury animal model.

### Research frontiers

Great effort has been and is still being done to minimize costs and side effects of synthetic drugs which are being used in the treatment of liver diseases.

### Innovations and breakthroughs

The products are effective both *in vitro* and *in vivo* studies with minimal side effects and are cost effective. The herbal products were observed to have an excellent reparative effect on the CCl<sub>4</sub> damaged hepatocytes.

### Applications

This article helps to understand and implement the process of treatment with herbal medicines in liver diseases, which is safe and cost effective in comparison with the synthetic drugs.

### Peer review

This article tries to explore the safety and efficacy of the herbal drugs in the treatment of acute liver hepatitis and other liver disorders. The results revealed fewer side effects compared to synthetic drugs. It might be meaningful for the management and treatment of liver diseases in the clinic.

Received: December 24, 2007 Revised: March 18, 2008

**CONCLUSION:** Ghrelin accelerates delayed GE and IT but has no effect on CT in diabetic mice. Ghrelin may exert its prokinetic effects via the cholinergic pathway in the enteric nervous system, and therefore has therapeutic potential for diabetic patients with delayed upper gastrointestinal transit.

Ghrelin improves delayed gastrointestinal transit in alloxan-induced diabetic mice. *World J Gastroenterol* 2008; 14(16): 2572-2577 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2572.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2572>

### Abstract

**AIM:** To investigate the effects of ghrelin on delayed gastrointestinal transit in alloxan-induced diabetic mice.

**METHODS:** A diabetic mouse model was established by intraperitoneal injection with alloxan. Mice were randomized into two main groups: normal mice group and diabetic mice group treated with ghrelin at doses of 0, 20, 50, 100 and 200  $\mu\text{g}/\text{kg}$  ip. Gastric emptying (GE), intestinal transit (IT), and colonic transit (CT) were studied in mice after they had a phenol red meal following injection of ghrelin. Based on the most effective ghrelin dosage, atropine was given at 1 mg/kg 15 min before the ghrelin injection for each measurement. The mice in each group were sacrificed 20 min later and their stomachs, intestines, and colons were harvested immediately. The amount of phenol red was measured. Percentages of GE, IT, and CT were calculated.

**RESULTS:** Percentages of GE, IT, and CT were significantly decreased in diabetic mice as compared to control mice ( $22.9 \pm 1.4$  vs  $28.1 \pm 1.3$ ,  $33.5 \pm 1.2$  vs  $43.2 \pm 1.9$ ,  $29.5 \pm 1.9$  vs  $36.3 \pm 1.6$ ,  $P < 0.05$ ). In the diabetic mice, ghrelin improved both GE and IT, but not CT. The most effective dose of ghrelin was 100  $\mu\text{g}/\text{kg}$  and atropine blocked the prokinetic effects of ghrelin on GE and IT.

### INTRODUCTION

Ghrelin is a 28-amino acid peptide that is synthesized in endocrine cells of the gastric mucosa<sup>[1]</sup>. The major actions of this recently-discovered peptide include stimulation of growth hormone (GH) release<sup>[1-3]</sup>, regulation of appetite and nutrient ingestion<sup>[4-6]</sup>, and improvement of digestive motility<sup>[7-9]</sup>. When injected into mice<sup>[7,10]</sup>, rats<sup>[8,9]</sup>, or dogs<sup>[11]</sup>, ghrelin accelerates gastric emptying after a liquid or solid meal. *In vitro* studies showed that in addition to known vagus nerve-dependent mechanisms, the activity of ghrelin is mediated via the enteric nervous system. Ghrelin increases electrically evoked cholinergic neural responses in strips of rat stomach<sup>[12,13]</sup>. The presence of ghrelin and its receptors has been proven morphologically for myenteric neurons of guinea pig stomach and ileum<sup>[14]</sup>, but ghrelin receptors are difficult to identify on smooth muscles<sup>[15]</sup>.

Delayed gastrointestinal transit is a well-known diabetic complication, and may lead to uncomfortable gastrointestinal symptoms, such as frequent vomiting, emaciation, and unpredictable changes in blood glucose, all of which impair the quality of life of diabetic patients<sup>[16,17]</sup>. Gastrointestinal transit of solid or nutrient liquid meals is abnormally slow in about 50% of diabetic patients<sup>[16]</sup>. Delayed gastrointestinal transit may be associated

with cardiac autonomic neuropathy, blood glucose concentration, and gastrointestinal symptoms<sup>[16]</sup>.

Ghrelin has also been shown to accelerate gastric emptying in animal models of postoperative ileus<sup>[18]</sup>, septic ileus<sup>[10]</sup>, and burn-induced slow gastrointestinal transit<sup>[19]</sup>. Ghrelin injections accelerate gastric emptying after a meal in humans even in the presence of deficient gastric innervation<sup>[20]</sup>. However, ghrelin has never been studied in a diabetic animal model. It is unknown whether ghrelin can exert a similar prokinetic effect on the impaired gastrointestinal motility of diabetic mice, thus potentially having a clinical role in the treatment of impaired gastrointestinal motility in diabetic patients. In the present study, alloxan-induced diabetic mice were selected as an animal model of diabetic gastroparesis, resulting from autonomic neuropathy injury induced by prolonged hyperglycemia. We tested the effect of this newly-discovered gastric peptide on delayed gastrointestinal transit in diabetic mice.

## MATERIALS AND METHODS

### Chemicals

Rat ghrelin was obtained from Tocris Cookson (Bristol, UK). Atropine sulphate, phenol red, and alloxan were purchased from Sigma (St Louis, MO).

### Diabetic mouse model

C57 mice (weighing 18–22 g) were provided by the Experimental Animal Center of Shanghai Academia Sinica. All procedures for the animal experiments were approved by the Medical Ethical Committee of Shanghai Jiaotong University. The mice were housed in stainless steel cages at a controlled temperature ( $22 \pm 2^\circ\text{C}$ ) with a 60%–65% relative humidity in a normal 12-h light and dark cycle. After exposure to a high-fat diet for 3 wk, the mice were fasted overnight with free access to water and injected intraperitoneally with alloxan (0.2 g/kg body weight) dissolved in a sterile normal saline solution. Seventy-two hours later, the fasting blood glucose level in the mice was determined using the glucose oxidase method on a glucose analyzer. Mice with a blood glucose level higher than 11.1 mmol/L were classified as diabetic mice (DM mice). The DM mice were continuously fed without control of blood glucose for 4 wk, and a model of DM mice was established for further investigations.

### Animal grouping for gastrointestinal transit studies

Gastric emptying, intestinal and colonic transit studies were then performed. In each study, mice were divided into two groups: a normal (control) group and a diabetic group. Mice in the diabetic group were treated with different doses of ghrelin (0, 20, 50, 100 and 200  $\mu\text{g}/\text{kg}$ ) given in a random order with a total of six mice in each subgroup. A dose-response curve for ghrelin was obtained for the experiment. Based on the most effective dose of ghrelin, another group of 6 mice was given atropine (1 mg/kg) injections 15 min before ghrelin injection.

### Gastric emptying

After a 12-h fast, the diabetic mice were injected with

different doses of ghrelin (0, 20, 50, 100 and 200  $\mu\text{g}/\text{kg}$ ). After ghrelin injection, the mice received a gavage feeding (5 mg/kg body weight) of a phenol red test meal (0.5 g/L in 0.9% NaCl with 1.5% methylcellulose). Twenty minutes later, the mice were sacrificed. Their stomachs were clamped with a string above the lower oesophageal sphincter and a string beneath the pylorus to prevent leakage of phenol red. Gastric emptying was determined spectrophotometrically, according to the method previously described with certain slight modifications. The stomach of each individual mouse was resected just above the lower oesophageal sphincter and pyloric sphincter. Phenol red remained partly in the lumen of the stomach. The stomach and its contents were put into 5 mL of 0.1 mol/L NaOH. The stomach was minced. The samples containing the total amount of phenol red present in the stomach were further diluted to 10 mL with 0.1 mol/L NaOH and left at room temperature for 1 h. Five milliliters of the supernatant was then centrifuged at 800 g for 20 min. The absorbance was read at a wavelength of 546 nm on a spectrophotometer (Shanghai Yixian Company, China), and the phenol red content in the stomach was calculated. Percentage of gastric emptying of the phenol red was calculated as  $[\text{infusion amount} - \text{remains}] / \text{infusion amount} \times 100\%$ .

### Intestinal and colonic transit

After an overnight fast, mice were given general anesthesia (2%–3% isoflurane inhalation) and underwent abdominal surgery. A small polyethylene tube was placed in the duodenum (or colon) *via* the stomach (or cecum), 0.5 cm distal to the pylorus (or ileocolic junction), fixed with sutures to the gut wall, and then tunneled through the abdominal wall subcutaneously to exit from the skin at the nape of the neck. Midline incisions were sutured, and mice were left to recover in separate cages. Food and water were abundantly provided. Three days later, after a 12 h fast, the mice were given different doses of ghrelin (0, 20, 50, 100 and 200  $\mu\text{g}/\text{kg}$ ) intraperitoneally. After ghrelin injection, a phenol red test meal at 5 mg/kg (0.5 g/L in 0.9% NaCl with 1.5% methylcellulose) was injected into the duodenum (or colon) *via* the implanted polyethylene tube. After 20 min, the mice were sacrificed. The distance of phenol red transit and the full length of the intestine or colon were calculated. Small intestine or colonic transit was assessed using the percentage ratio of phenol red transit over the full intestinal or colonic length.

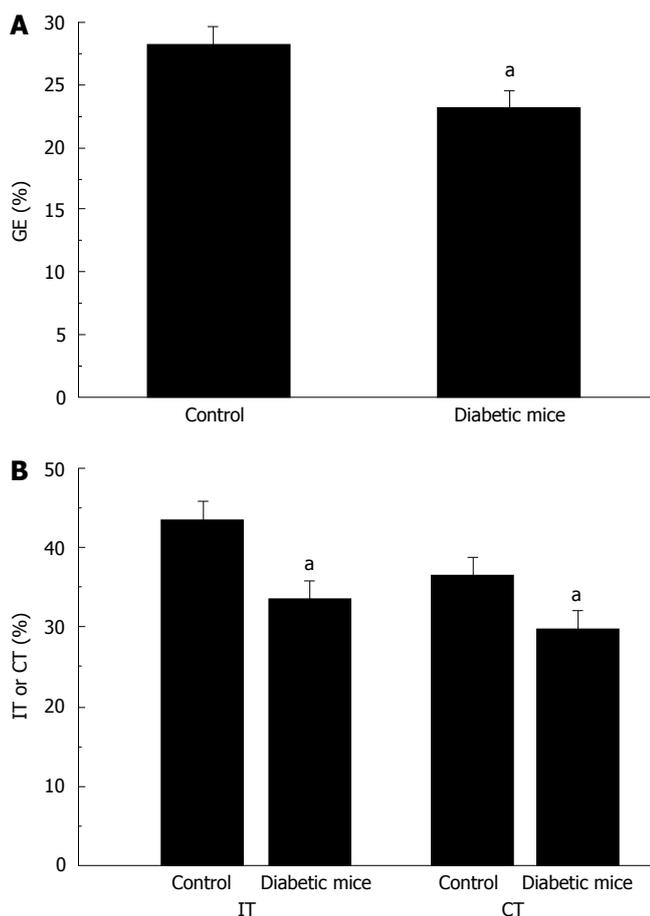

### Statistical analysis

Statistical analysis of the data was conducted using one-way ANOVA for multiple comparisons. Data are expressed as mean  $\pm$  SE.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Gastric emptying and intestinal and colonic transit in diabetic mice

Significantly delayed gastric emptying, intestinal and colonic transits were found in diabetic mice. Gastric emptying was significantly decreased in diabetic mice compared to normal mice ( $22.9\% \pm 1.4\%$  *vs*  $28.1\% \pm$

**Figure 1** Delayed gastric emptying and intestinal and colonic transit in diabetic mice. **A:** Percentage of gastric emptying was significantly decreased in diabetic mice, <sup>a</sup>*P* < 0.05 vs control; **B:** Percentage of intestinal and colonic transits was significantly decreased in diabetic mice, <sup>a</sup>*P* < 0.05 vs control.

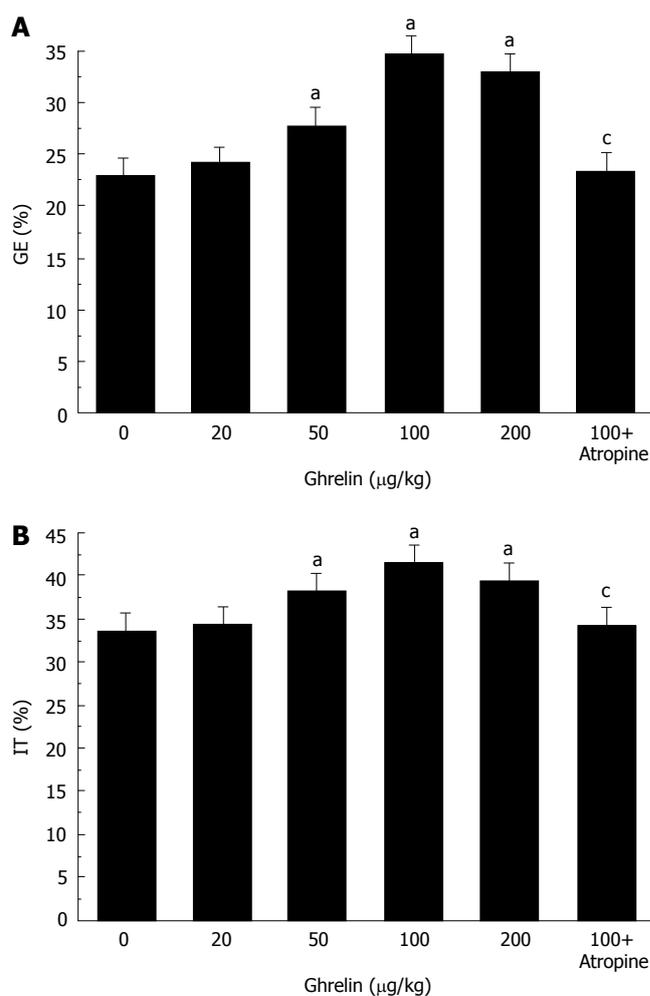

1.3%, *P* < 0.05, Figure 1A). Also, intestinal transit was significantly decreased in diabetic mice compared to normal mice (33.5% ± 1.2% vs 43.2% ± 1.9%, *P* < 0.05, Figure 1B). In addition, colonic transit was also decreased in diabetic mice compared to normal mice (29.5% ± 1.9% vs 36.3% ± 1.6%, *P* < 0.05, Figure 1B).

**Effect of ghrelin on delayed gastric emptying in diabetic mice**

Ghrelin significantly accelerated gastric emptying in diabetic mice. The percentage of gastric emptying was 24.3% ± 2.1%, 27.8% ± 1.0%, 34.5% ± 1.2%, and 32.9% ± 1.1%, respectively, in the mice treated with 20, 50, 100, and 200 µg/kg ghrelin. Except for the lowest dose, all of these doses normalized the rate of gastric emptying in diabetic mice (*P* < 0.05, Figure 2A). We considered that 100 µg/kg ghrelin could most effectively increase the rate of gastric emptying.

**Effect of ghrelin on delayed small intestinal transit in diabetic mice**

Ghrelin significantly accelerated intestinal transit in diabetic mice. The percentage of intestinal transit was 34.6% ± 2.0%, 38.2% ± 1.6%, 41.5% ± 1.9%, and 39.5% ± 1.8%, respectively, in the mice treated with 20, 50, 100, and 200 µg/kg ghrelin. All of these doses except for 20 µg/kg

**Figure 2** Ghrelin significantly increases gastric emptying (A) and intestinal transit (B) in diabetic mice. <sup>a</sup>*P* < 0.05 vs control, <sup>c</sup>*P* < 0.05 vs 100 µg/kg ghrelin.

normalized the delayed intestinal transit (*P* < 0.05, Figure 2B). As above, 100 µg/kg ghrelin was considered most effective in accelerating intestinal transit.

**Effect of ghrelin on delayed colonic transit in diabetic mice**

Ghrelin had no effect on delayed colonic transit. The percentage of colonic transit was 30.6% ± 1.3%, 30.2% ± 1.8%, 29.2% ± 1.5%, and 31.6% ± 2.2%, respectively, in the mice treated with 20, 50, 100, and 200 µg/kg ghrelin. None of these doses was able to accelerate intestinal transit (Figure 3).

**Effect of atropine on delayed gastric emptying and intestinal transit in diabetic mice**

Atropine blocked the positive effect of 100 µg/kg ghrelin on gastric emptying and intestinal transit. The percentage of gastric emptying was significantly decreased from 34.5% ± 1.2% to 23.5% ± 1.7% (*P* < 0.05, Figure 2A). The small intestine transit was significantly decreased from 41.5% ± 1.9% to 34.2% ± 1.6% (*P* < 0.05, Figure 2B).

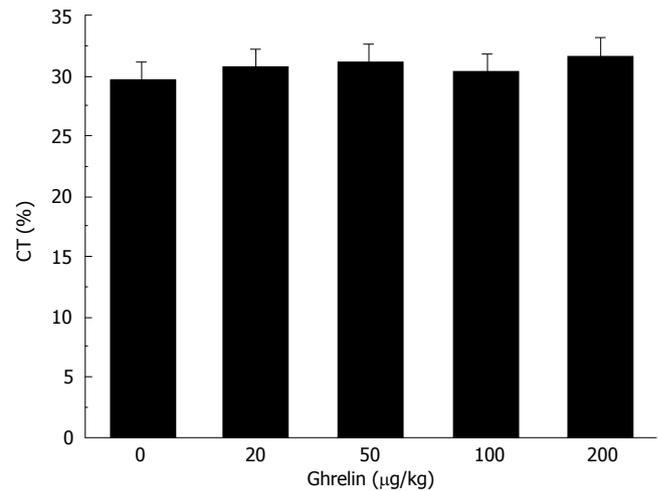

**DISCUSSION**

In the present study, mice with alloxan-induced diabetics

had mild or moderate gastroparesis with slow gastric emptying and intestinal transit due to an autonomic neuropathic injury induced by prolonged hyperglycemia as compared with normal controls. Thus, mice with alloxan-induced diabetics could be used as an animal model of diabetic gastroparesis. Significantly delayed gastric emptying, intestinal and colonic transit were seen in the mice with alloxan-induced diabetics. Different doses of ghrelin were able to accelerate gastric emptying and intestinal transit in the diabetic mice, but had no effect on colonic transit. The most effective dose of ghrelin for accelerating upper gastrointestinal transit was 100  $\mu\text{g}/\text{kg}$  per mouse. Atropine blocked the ghrelin effect on gastric emptying and intestinal transit.

In the present study, gastric emptying and intestinal and colonic transit were significantly delayed in the mice with alloxan-induced diabetics, which is consistent with the previously reported findings<sup>[21,22]</sup>. Gastrointestinal motility disturbances including esophageal motor dysfunction, gastroparesis, constipation and diarrhea, are common in patients with diabetes mellitus. It was reported that gastrointestinal transit is significantly slower in the diabetic animal model of human diabetes<sup>[21-23]</sup>. Inhibition of gastrointestinal motility has also been reported in humans with diabetes mellitus<sup>[24,25]</sup>. The pathogenesis of slow gastrointestinal transit in diabetes mellitus patients is not clear, but several mechanisms have been proposed<sup>[16]</sup>. Among them, autonomic neuropathy, a complication of long-standing diabetes mellitus, has been widely accepted as the culprit. This may lead to the absence of postprandial gastrointestinal response, a reflex that should present in healthy people<sup>[24]</sup>. Recent studies have shown that an acute change in blood glucose concentration also has a major effect on gastrointestinal motor function in healthy subjects<sup>[25]</sup>. In particular, acute hyperglycemia inhibits both the gastrointestinal and ascending components of peristaltic reflex. Poor glycemic control has the potential to cause delayed gastrointestinal transit in diabetic patients<sup>[26]</sup>.

To the best of our knowledge, this is the first report on the effect of ghrelin on gastrointestinal dysmotility in diabetic mice. Ghrelin possessing prokinetic characteristics increases gastric emptying in healthy mice<sup>[27,28]</sup>, gastric emptying<sup>[13,29,30]</sup>, frequency of migrating motor complex, and intestinal transit<sup>[31,32]</sup> in healthy rats. In healthy dogs, ghrelin stimulates antral contractility and antroduodenal coordination, thus increasing gastric emptying<sup>[33]</sup>. In healthy volunteers<sup>[29]</sup>, subjects with normal weight<sup>[34]</sup>, and gastroparetic<sup>[35]</sup> human subjects with gastroparesis, ghrelin also increases gastric emptying. The mechanisms underlying the action of ghrelin seem to be neuron-dependent. *In vitro*, isolated strips of muscle fail to contract significantly when exposed to ghrelin. *In vivo*, the gastrokinetic effect of ghrelin in rats is abolished by atropine and vagotomy. Diabetic gastroparesis is classically attributed to autonomic neuropathy induced by prolonged hyperglycemia, which did not preclude the gastrokinetic effect of ghrelin in our investigation. Our data strongly suggest that ghrelin can exert a prokinetic action on the upper alimentary tract *via* the enteric nervous pathway. In our study, atropine blocked the effect of 100  $\mu\text{g}/\text{kg}$  ghrelin

**Figure 3** No effect of Ghrelin on delayed colonic transit in diabetic mice.

on gastric emptying and intestinal transit, suggesting that the prokinetic effect of ghrelin is mediated *via* the cholinergic pathway in the enteric nervous system. There are other mechanisms involving tachykinergic pathways, as demonstrated in electrical field stimulation studies in isolated rat stomach<sup>[13]</sup>.

Moreover, we found that the dose-response relationships of ghrelin between gastric emptying and colonic transit in diabetic mice were bell-shaped. There are many causes for bell-shaped dose-response curves. Desensitization is one of the possibilities, because ghrelin receptor is susceptible to rapid desensitization<sup>[36]</sup>. Another possibility is the existence of high and low affinity receptor binding sites in different pathways. In our study, however, ghrelin showed no effect on colon transit, which is consistent with the results seen both in animal models of postoperative ileus<sup>[18]</sup> and in burn-induced gastrointestinal delayed transit<sup>[19]</sup>. We believe that this result might be related to the distribution of ghrelin receptors in the gut<sup>[37,38]</sup>.

Based on this study, it is reasonable to assume that ghrelin can be used as a potential drug for the treatment of diabetic patients with delayed gastrointestinal transit. Clinically, improvement in gastrointestinal transit facilitates enteral resuscitation, corrects blood glucose concentrations and reduces gastrointestinal symptoms in diabetic patients.

In conclusion, ghrelin accelerates gastric emptying and intestinal transit in diabetic mice, an action that may be mediated *via* the cholinergic pathway in the enteric nerve system. Ghrelin may have a therapeutic potential for diabetic patients with delayed upper gastrointestinal transit. The physiological role of ghrelin in the gastrointestinal tract remains to be identified, and its pharmacotherapeutic potential deserves to be further explored in diabetic patients suffering from delayed upper gastrointestinal transit.

## COMMENTS

### Background

Delayed gastrointestinal transit is common in patients with chronic diabetes and is always associated with impairments in quality of life and diabetic control. Ghrelin is

a potent prokinetic peptide. The effect of ghrelin on delayed gastrointestinal transit was studied in diabetic mice.

### Research frontiers

The effects of ghrelin on gastrointestinal motor activity and roles in motility regulation have been extensively studied. This study is the first to investigate the effects of ghrelin on diabetic mice with delayed gastrointestinal transit.

### Innovations and breakthroughs

Ghrelin has been shown to accelerate gastric activity in postoperative and septic ileus animal models. However, it has not been studied in a diabetic animal model.

### Applications

According to animal experiments, ghrelin may be used as a potential therapeutic agent for the treatment of delayed gastrointestinal transit in diabetes.

### Peer review

This paper shows for the first time that ghrelin has an effect on gastric emptying and intestinal transit in diabetic mice, which may be mediated through the cholinergic pathways in the enteric nerve system. These results show that ghrelin can be used as a potential therapeutic drug for the treatment of delayed gastrointestinal transit in diabetes.

Xu LN, Wang X, Zou SQ. Effect of histone deacetylase inhibitor on proliferation of biliary tract cancer cell lines. *World J Gastroenterol* 2008; 14(16): 2578-2581 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2578.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2578>

### Abstract

**AIM:** To explore the effect of histone deacetylase inhibitor, trichostatin A (TSA) on the growth of biliary tract cancer cell lines (gallbladder carcinoma cell line and cholangiocarcinoma cell line) *in vivo* and *in vitro*, and to investigate the perspective of histone deacetylase inhibitor in its clinical application.

**METHODS:** The survival rates of gallbladder carcinoma cell line (Mz-ChA-I cell line) and cholangiocarcinoma cell lines (QBC939, KMBC and OZ cell lines) treated with various doses of TSA were detected by methylthiazol tetrazolium (MTT) assay. A nude mouse model of transplanted gallbladder carcinoma (Mz-ChA-I cell line) was successfully established, and changes in the growth of transplanted tumor after treated with TSA were measured.

**RESULTS:** TSA could inhibit the proliferation of gallbladder carcinoma cell line (Mz-ChA-I cell line) and cholangiocarcinoma cell lines (QBC939, KMBC and OZ cell lines) in a dose-dependent manner. After the nude mouse model of transplanted gallbladder carcinoma (Mz-ChA-I cell line) was successfully established, the growth of cancer was inhibited in the model after treated with TSA.

**CONCLUSION:** TSA can inhibit the growth of cholangiocarcinoma and gallbladder carcinoma cell lines *in vitro* and *in vivo*.

### INTRODUCTION

Biliary tract cancer, consisting of gallbladder carcinoma and cholangiocarcinoma, presents many challenges to physicians. It is a relatively rare cancer often causing a diagnostic dilemma, as its presentation may be similar to that of non-malignant conditions<sup>[1,2]</sup>. It was reported that the misdiagnosis rate of biliary duct cancer is 19.1% and the median survival time of biliary tract cancer patients is about 7 mo<sup>[3]</sup>. At present, treatment of biliary tract cancer is also difficult<sup>[4]</sup> and complex due to a morbid patient population and limited data on the optimal therapeutic approach. Surgery remains the mainstay of treatment, although the extent of resection required is still controversial. Despite recent advances in imaging modalities, most of the patients are at the advanced stage of the disease at presentation, thus making radical surgery not feasible, which seriously affects its prognosis. The role of adjuvant therapy is also controversial. Different chemotherapeutic regimens have been investigated in small uncontrolled studies, with generally disappointed results<sup>[5]</sup>. In patients with unresectable biliary duct cancer, combination of chemotherapy and radiotherapy can result in a prolonged survival time of some patients. In a palliative setting, biliary stenting and other supportive measures can alleviate symptoms and improve survival. Ultimately, treatment decisions should be individualized and participation in clinical trials is encouraged. Further progress in the management of biliary tract cancer is anticipated using biological therapies and continued research is essential to discover the optimal treatment for this challenging disease<sup>[2]</sup>. It is, thus, important to research its biological characteristics and biotherapy.

Cancer is a disease resulting from both genetic and epigenetic changes. There are many important epigenetic changes in its early carcinogenesis. Accumulating evidence indicates, however, that disparities in gene expression resulting from variable modifications in DNA methylation and chromatin structure in response to the environ-

ment also play a role in differential susceptibility to the disease<sup>[6,7]</sup>. Histone acetylation/deacetylation constitutes the most relevant chromatin remodelling mechanism underlying the DNA access to nuclear machinery and mutagenic agents<sup>[8]</sup>. It has been recently shown that histone acetylation/deacetylation is closely related with tumorigenesis<sup>[9,10]</sup>. Acetylation of histone plays a very important but incompletely understood role in genetic regulation<sup>[11]</sup>. Histone deacetylase inhibitors could markedly inhibit the growth of tumor cell lines<sup>[12,13]</sup>. It has been shown that expression of p53BP1, a non-histone protein, is associated with HDAC4 and plays a role in histone acetylation of fully-grown oocytes<sup>[14]</sup>. Other data indicate that the known non-histone targets may play a role in the pathogenesis of cholangiocarcinoma<sup>[15]</sup>.

Experiments *in vitro* have shown that TSA can be used in the treatment of ovarian cancer, pancreatic endocrine carcinoma, prostate cancer, *etc*<sup>[16-18]</sup>. The results of this study focusing on the effect of histone deacetylase inhibitor, trichostatin A (TSA) on the proliferation of gallbladder carcinoma cell line (Mz-ChA-1 cell line) and cholangiocarcinoma cell lines (QBC939, KMBC and OZ cell lines) *in vivo* and *in vitro*, have demonstrated the value of biotherapy for biliary tract cancer with TSA.

## MATERIALS AND METHODS

### Cell lines

QBC939 cell line (a human cholangiocarcinoma cell line), KMBC cell line (a human cholangiocarcinoma cell line), OZ cell line (a human cholangiocarcinoma cell line) and Mz-ChA-1 cell line (originally isolated from human gallbladder adenocarcinoma) were used in our study. QBC939 cell line was kindly provided by Professor Shu-Guang Wang, The Third Military Medical University, Chongqing, China. KMBC, OZ and Mz-ChA-1 cell lines were kindly provided by Dr. Ke-Qin Hu, University of California, Irvine Medical Center, California, USA. Cell culture media and supplements were purchased from GIBCO Invitrogen Corporation (Carlsbad, CA, USA).

### Animals

Sixteen male BALB/c nude mice at the age of 4 wk, weighing  $10.0 \pm 2.1$  g, were purchased from the Experimental Animal Center of Tongji Medical College, Huazhong University of Science and Technology (Wuhan, China). The mice were caged individually under specific pathogen-free conditions and fed with standard maintenance diet and water throughout the experimental period. All animals received care treatment in compliance with the Guidelines of Ministry of Public Health of China.

### Cell culture

All biliary tract cancer cell lines (QBC939, KMBC, OZ and Mz-ChA-1 cell lines) were grown as a monolayer in RPMI-1640 medium (Sigma, USA) supplemented with 10% fetal bovine serum, penicillin (100 000 U/L), cultured in T-75 cm<sup>2</sup> culture flasks, maintained at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub>. At the beginning of experiment, cells at the exponential growth phase were removed from the flask with a solution containing

0.25% trypsin and 0.02% EDTA and seeded in 96-well plates containing RPMI-1640 medium supplemented with 10% fetal bovine serum.

### Methylthiazol tetrazolium (MTT) assay

QBC939, KMBC, OZ and Mz-ChA-1 cells at logarithmic growth phase were digested with 0.25% trypsin and then suspended. Cells were calculated under microscope with the cell suspension adjusted to  $2 \times 10^5$ /mL. The wells in the plate were divided into 6 experiment groups and 1 blank control group. Cells were added into the plate (200  $\mu$ L per well,  $0.4 \times 10^5$ ), and medium into the blank control wells. After 18 h, the medium for the experiment groups was replaced with a medium containing 0.10, 0.25, 0.50, 1.0, 1.5, 2.0  $\mu$ mol/L TSA, respectively. The culture was continued, then 20  $\mu$ L of 5 mg/mL MTT was added into each well after 4, 12, 24, 36 and 48 h, respectively. After another 4 h, the medium was discarded and 150  $\mu$ L DMSO was added into each well. The *A* value for each well was measured at the wave length of 490 nm. The survival rate was then calculated and the survival curve was plotted following the formula: survival rate (%) = the *A* value of experiment groups - the *A* value of blank control group / the *A* value of negative group - the *A* value of blank control group  $\times 100\%$ .

### Treatment of Mz-ChA-1 cell lines and establishment of gallbladder carcinoma transplanted tumor model

Mz-ChA-1 cells at the logarithmic phase were divided into two groups: one group was treated with 0.75  $\mu$ mol/L TSA, the other group was cultured in medium. Cells were digested and counted after 24 h. The 16 male BALB/c nude mice at the age of 4 wk were randomly divided into group A (control group) and group B (TSA group) randomly, 8 in each group. The mice in group A were subcutaneously inoculated with untreated Mz-ChA-1 cell suspension *via* the back, while those in group B were subcutaneously inoculated with Mz-ChA-1 cell suspension treated with TSA for 24 h *via* the back. The wound was slightly pressed with a cotton swab for hemostasis and closed. The volume of cell suspension was 0.2 mL, with a concentration of  $1 \times 10^5$ /mL. The volume of tumors was calculated in the sixth week according to the following formula: the volume = the biggest diameter  $\times$  transverse diameter<sup>2</sup>/2.

### Statistical analysis

Statistical analysis was performed using the rank sum test (*H* test) for multi-sample comparison and *t*-test for two-sample comparison. The data were expressed as mean  $\pm$  SE. *P* < 0.05 was considered statistically significant.

## RESULTS

### Effect of TSA on survival of QBC939, KMBC, OZ and Mz-ChA-1 cell lines *in vitro*

QBC939, KMBC, OZ and Mz-ChA-1 cell lines were shrunk and died when TSA was added at various concentrations. MTT assay showed that TSA could shorten the survival time of QBC939, KMBC, OZ and Mz-ChA-1 cell lines in a dose-dependent manner. The inhibition of cell survival increased with the increased dose of TSA (Table 1, Figure 1).

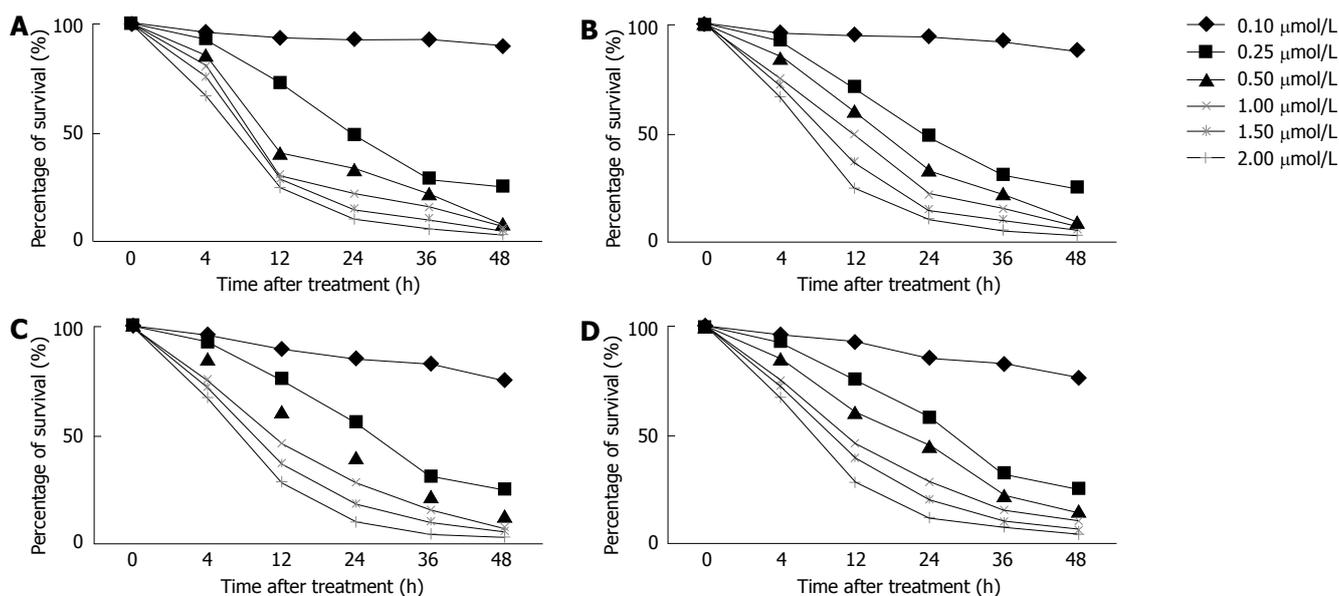

Figure 1 Effect of TSA on the survival of QBC<sub>939</sub> (A), KMBC (B), OZ (C), and Mz-ChA-I (D).

Table 1 Effect of TSA on the survival of biliary tract cancer cell lines

Concentration of TSA	Percentage of survival of cell lines (median and quartile)			
	QBC <sub>939</sub>	KMBC	OZ	Mz-ChA-I
0.10 μmol/L	92.87 (93.09)	93.27 (94.87)	83.07 (87.72)	83.26 (88.75)
0.25 μmol/L	33.38 (60.61)	34.88 (59.60)	36.63 (65.60)	38.58 (66.51)
0.50 μmol/L	24.90 (36.45)	24.86 (46.64)	26.90 (50.64)	27.90 (52.64)
1.00 μmol/L	16.99 (26.30)	17.09 (35.80)	18.46 (37.23)	18.46 (37.23)
1.50 μmol/L	11.29 (21.63)	11.32 (25.36)	12.29 (27.36)	12.79 (29.86)
2.00 μmol/L	6.52 (17.35)	6.28 (16.36)	6.28 (19.25)	9.03 (20.25)
Value of <i>H</i>	15.66	16.11	14.23	14.32
<i>P</i>	0.0082	0.0076	0.046	0.043

The survival percentage of cell lines treated with various doses of TSA was detected after 4, 12, 24, 36 and 48 h, respectively, by MTT assay. The MTT value was expressed as median and quartile.

**Effect of TSA on survival of Mz-ChA-I cell line**

All the male BALB/c nude mice survived. The mice in group A were subcutaneously inoculated with untreated Mz-ChA-I cell suspension *via* the back. The mice in group B were subcutaneously inoculated with Mz-ChA-I cell suspension *via* the back after treated with TSA for 24 h. After the Mz-ChA-I cell line was transplanted into the nude mice for 6 wk, the tumor volume of group A was 930.25 ± 261.64 mm<sup>3</sup>, the transplanted tumor volume of group B was smaller than that of group A, and there was a significant difference between them (*t* = 2.50, *P* = 0.036).

**DISCUSSION**

Regulation of genes is a new topic<sup>[19]</sup>. Genetic information is regulated and expressed precisely. Gene expression can be greatly regulated by histone remodeling. This is a kind of basic post formation theory of gene regulation<sup>[20]</sup>. Histone deacetylase (HDAC) and histone acetyl transferase (HAT) are two counteracting enzymes. Their activities can control the acetylation of protein lysine residues, notably those contained in the N-terminal extensions of the core

histones. Acetylation of histones affects gene expression through its influence on chromatin conformation<sup>[21,22]</sup>. A lot of data have shown that HDAC is one of the promising targets of cancer treatment as many HDAC inhibitors of solid and liquid tumors have entered clinical trials<sup>[23]</sup>. HDAC inhibitor is a kind of chemical compound regulating gene expression at the transcription level by changing chromosome structure through inhibiting HDAC. The HDAC inhibitors-inhibited HDAC enzymes shift the balance between the deacetylation activity of HDAC enzymes and the acetylation activity of histone acetyltransferases, resulting in hyperacetylation of core histones. Exposure of cancer cells to HDAC inhibitors is associated with a multitude of molecular and biological effects, ranging from transcriptional control, chromatin plasticity, protein DNA interaction to cellular differentiation, growth arrest and apoptosis. HDAC inhibitors are an exciting new addition to the arsenal of cancer therapeutics<sup>[24,25]</sup>.

This study focused on the effect of histone deacetylase inhibitor, trichostatin A (TSA) on the survival of QBC939, KMBC, OZ and Mz-ChA-I cell lines and determined if TSA can be used in the treatment of biliary tract cancer. Our results show that TSA could shorten the survival time of QBC939, KMBC, OZ and Mz-ChA-I cell lines *in vitro* in a dose-dependent manner. We have successfully established a nude mouse model of transplanted gallbladder carcinoma. The growth of biliary tract cancer was inhibited in the mice after treatment with TSA. Our results show that TSA could shorten the survival time of gallbladder carcinoma and cholangiocarcinoma cell lines *in vivo* and *in vitro*, indicating that TSA is a potential drug for the treatment of biliary tract cancer. It was reported that HDACIs MS-275, NVP-LBH589 and NVP-LAQ824 can effectively inhibit the growth of human biliary tract cancer cells<sup>[26,27]</sup>. However, early diagnosis and treatment of biliary tract cancer are still difficult<sup>[29-34]</sup>. In order to improve its diagnosis and treatment, further study on its epidemiology, clinicopathology and molecular biology is needed.

## COMMENTS

### Background

Biliary tract cancer, consisting of gallbladder carcinoma and cholangiocarcinoma, presents many challenges to physicians. At present, treatment of biliary tract cancer is difficult. This study focused on the effect of trichostatin A (TSA) on the proliferation of biliary tract cancer cells.

### Research frontiers

Cancer is a disease resulting from both genetic and epigenetic changes. There are many important epigenetic changes in its early carcinogenesis. It has been recently shown that histone acetylation/deacetylation is closely related with tumorigenesis. Acetylation of histone plays a very important but incompletely understood role in genetic regulation. Histone deacetylase inhibitors could markedly inhibit the growth of tumor cells.

### Innovations and breakthroughs

TSA can inhibit the growth of cholangiocarcinoma and gallbladder carcinoma cell lines *in vitro* and *in vivo*.

### Applications

TSA can be used as a potential drug for the treatment of biliary tract cancer.

### Peer review

This manuscript describes the effect of histone deacetylase inhibitor on the proliferation of four biliary tract cancer cell lines. The study was well designed, and had novel findings. The conclusion is of clinical value.

postoperative AF (odds ratio = 4.711, 95% CI = 1.212 to 7.644,  $P = 0.008$ ).

**CONCLUSION:** An elevated perioperative plasma BNP level is a strong and independent predictor of postoperative AF in patients undergoing surgery for esophageal carcinoma. This finding has important implications for identifying patients at higher risk of postoperative AF who should be considered for preventive antiarrhythmic therapy.

Increased N-terminal pro-brain natriuretic peptide level predicts atrial fibrillation after surgery for esophageal carcinoma. *World J Gastroenterol* 2008; 14(16): 2582-2585 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2582.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2582>

### Abstract

**AIM:** To evaluate the value of plasma N-terminal pro-brain natriuretic peptide (NT-proBNP) level for predicting postoperative atrial fibrillation (AF) in patients undergoing surgery for esophageal carcinoma.

**METHODS:** NT-proBNP levels were measured in 142 patients 24 h before and 1 h after surgery for esophageal carcinoma. All patients having a preoperative cardiac diagnosis by electrocardiogram (ECG), remained under continuous monitoring for at least 48 h after surgery, and then underwent clinical cardiac evaluation until discharge.

**RESULTS:** Postoperative AF occurred in 11 patients (7.7%). AF patients were significantly older ( $69.6 \pm 12.2$  years vs  $63.4 \pm 13.3$  years,  $P = 0.031$ ) than non-AF patients. There were no significant differences in history of diabetes mellitus, sex distribution, surgical approach, anastomosis site, intraoperative hypotension and postoperative fever. The preoperative plasma NT-proBNP level was significantly higher in patients who developed postoperative AF ( $121.3 \pm 18.3$  pg/mL vs  $396.1 \pm 42.6$  pg/mL,  $P = 0.016$ ). After adjustment for age, gender, chronic obstructive pulmonary disease (COPD), history of cardiac diseases, hypertension, postoperative hypoxia and thoracic-gastric dilation, NT-proBNP levels were found to be associated with the highest risk factor for

### INTRODUCTION

Postoperative infections and cardiac events are the major complications after surgery for esophageal carcinoma and the dominating causes of death. Atrial fibrillation (AF) is a frequent arrhythmia after esophageal procedures and is associated with an increased morbidity and mortality and a longer, more expensive hospital stay<sup>[1-5]</sup>.

In a previous study, we retrospectively studied 63 patients with AF after surgery for esophageal carcinoma in comparison with 126 patients without AF after esophagectomy during the same time. We identified some risk factors as predictors of AF after surgery for esophageal carcinoma, such as postoperative hypoxia, history of obstructive pulmonary disease (COPD), thoracic-gastric dilatation, age older than 65 years, male gender, and history of cardiac disease<sup>[6]</sup>. However, our ability to accurately identify patients at high risk for AF is still limited. No accurate assessment tool or biomarker has

been identified that could predict the occurrence of AF early after esophageal procedures so far. Since a targeted preventive treatment cannot be performed easily, a sensitive blood biomarker that can predict the occurrence of AF in patients after surgery for esophageal carcinoma with a high specificity is desirable.

Brain natriuretic peptide (BNP) is a neurohormone which is stored mainly in myocytes of the cardiac ventricles and released as a result of volume and pressure overload or myocardial damage<sup>[7-10]</sup>. N-terminal pro BNP (NT-proBNP) has a longer half life than brain natriuretic peptide and is less influenced by acute therapeutic regimens and clinical deteriorations, making it available for predicting cardiac functions<sup>[11-14]</sup>. NT-proBNP has been proved useful for diagnostic and prognostic purposes in patients with congestive heart failure and other cardiac conditions<sup>[15-18]</sup>. It was recently reported that increased NT-proBNP can indicate the underlying subclinical predisposition to AF both in patients undergoing cardiac surgery<sup>[19]</sup> and in patients without a history of cardiac disease<sup>[20]</sup>. To our knowledge, the ability of NT-proBNP to predict AF after esophageal procedures has not been evaluated.

We speculate that an elevated level of NT-proBNP could predict the occurrence of AF early after esophageal procedures. The aim of this study is to determine whether NT-proBNP levels are associated with AF after surgery for esophageal carcinoma.

## MATERIALS AND METHODS

### Patients

One hundred and fifty consecutive patients undergoing elective surgery for esophageal cancer were identified in our hospital from December 2006 to May 2007. Patients with a history of heart failure ( $n = 3$ ), chronic AF ( $n = 2$ ), severe renal dysfunction ( $n = 1$ ), and antiarrhythmic drug use ( $n = 2$ ) were excluded from the study. One hundred and forty-two patients (113 males and 29 females with an average age of 66.5 years, range 49-86 years) accordant with the inclusion criteria were enrolled in the study.

All patients having a preoperative cardiac diagnosis by electrocardiogram (ECG) remained under continuous monitoring for at least 48 h after surgery and then underwent clinical cardiac evaluation until discharge. AF was defined as absent P wave before the QRS complex with irregular ventricular rhythm on the rhythm strips.

Plasma NT-proBNP concentration was measured 24 h before and soon (within 1 h) after surgery. Blood samples were collected into tubes containing potassium EDTA, centrifuged for 5 min at 1500 r/min and kept at 4°C. The separated plasma was kept at -30°C until analysis. NT-proBNP analyses were done with Elecsys Roche Diagnostics commercial kits on a semiautomatic analyzer (Elecsys-2010, Roche Diagnostics, Germany). The test is self-processing and produces a result within 15 min. The precision, analytic sensitivity and stability characteristics of this system have been described elsewhere<sup>[21]</sup>.

### Statistical analysis

Continuous variables are expressed as mean  $\pm$  SD or median (range) and were compared by Student's *t*-test.

Chi square test or Fisher's exact test was used to compare groups of categorical data. The relationship between the occurrence of postoperative AF and baseline predictors was assessed with multivariable logistic regression model adjusted for factors presumably associated with AF risk, including advanced age, male gender, COPD, cardiac diseases, hypertension and diabetes mellitus, site of anastomosis, postoperative hypoxia, thoracic-gastric dilation and plasma NT-proBNP<sup>[1,22-25]</sup>.  $P < 0.05$  was considered statistically significant. Statistical analysis was performed using the SPSS 11.0 statistical software package (SPSS, Inc).

## RESULTS

The baseline characteristics of the 142 patients are listed in Table 1. The patients were divided into 2 groups according to whether they developed postoperative AF. Postoperative AF occurred in 11 patients (7.7%). Postoperative AF patients were significantly older ( $69.6 \pm 12.2$  years *vs*  $63.4 \pm 13.3$  years,  $P = 0.031$ ) than non-postoperative AF patients. Patients in the postoperative AF group had a history of COPD (45.5% *vs* 12.2%,  $P = 0.021$ ) and cardiac disease more frequently (6.9% *vs* 27.3%,  $P = 0.046$ ). Postoperative AF patients had a significantly higher incidence of postoperative hypoxia (36.4% *vs* 8.4%,  $P = 0.018$ ) and thoracic-gastric dilation (45.5% *vs* 12.2%,  $P = 0.021$ ) than non-postoperative AF patients. There were no significant differences in gender, history of hypertension, diabetes mellitus, surgical approach, anastomosis site, intraoperative hypotension and postoperative fever between the two groups. Preoperative plasma NT-proBNP level was significantly higher in patients who developed postoperative AF ( $121.3 \pm 18.3$  pg/mL *vs*  $396.1 \pm 42.6$  pg/mL,  $P = 0.016$ ).

In a multivariable logistic regression model adjusted for age, gender, COPD, history of cardiac disease, hypertension, diabetes mellitus, site of anastomosis, postoperative hypoxia, thoracic-gastric dilatation and plasma NT-proBNP, NT-proBNP levels were associated with the highest risk factor for postoperative AF (odds ratio = 4.711, 95% CI = 1.212 to 7.644,  $P = 0.008$ ) (Table 2).

## DISCUSSION

AF after esophagectomy remains one of the most frequently encountered complications. The incidence of AF in this study was 7.7%, lower than the reported data ranging from 11.3% to 22%<sup>[26,27]</sup>. Although the causes for postoperative AF after esophagectomy have not been completely disclosed, we speculate that AF after esophagectomy is precipitated by the resolution of inflammatory response following blunt or sharp surgical trauma to sympathovagal nerve fibers supplying the heart, which alters the autonomic modulation of atrial myocardial cells to endogenous catecholamines. Although postoperative AF is self-limited in most cases, it can increase the risk of postoperative stroke<sup>[28]</sup>. The treatment of postoperative AF requires a prolonged hospital stay and additional costs. Although previous studies<sup>[6,22,27]</sup> have shown different risk factors for postoperative AF,

Table 1 Characteristics of study subjects, *n* (%)

Characteristic	No postoperative AF ( <i>n</i> = 131)	Postoperative AF ( <i>n</i> = 11)	<i>P</i>
Age (yr)	63.4 ± 13.3	69.6 ± 12.2	0.031
Male	109 (83.2)	9 (81.8)	0.971
COPD	16 (12.2)	5 (45.5)	0.021
History of cardiac diseases	9 (6.9)	3 (27.3)	0.046
History of hypertension	8 (6.1)	1 (9.1)	0.717
Diabetes mellitus	7 (5.3)	1 (9.1)	0.63
Site of anastomosis			
Neck	28 (21.4)	3 (27.3)	0.721
Above the aortic arch	81 (61.8)	6 (54.5)	0.812
Below the aortic arch	22 (16.8)	2 (18.2)	0.921
Right thorax approach	12 (9.2)	1 (9.1)	0.994
Intraoperative hypotension	9 (6.9)	1 (9.1)	0.798
Postoperative fever	29 (22.1)	3 (27.3)	0.76
Postoperative hypoxia	11 (8.4)	4 (36.4)	0.018
Thoracic-gastric dilatation	16 (12.2)	5 (45.5)	0.021
NT-proBNP, pg/mL			
Before surgery	121.3 ± 18.3	396.1 ± 42.6	0.016
After surgery	160.3 ± 17.3	589.5 ± 51.2	0.009

a definite relation between these factors and occurrence of AF has not been well established. A proper preventive treatment of AF is still a challenge. Even if preventive therapies with antiarrhythmic agents can reduce the occurrence of postoperative AF, their use has been limited because of potential side effects<sup>[29]</sup>.

BNP and NT-proBNP are members of the natriuretic peptide family synthesized and secreted by the ventricular myocardium. The natriuretic peptide family plays a role in regulation of the cardiovascular system<sup>[30]</sup>. Moreover, it was reported that an elevated NT-proBNP level can be used as a diagnostic and prognostic marker in patients with congestive heart failure, myocardial infarction, unstable angina and left ventricular hypertrophy<sup>[15-18]</sup>.

The present study evaluated the role of NT-proBNP in predicting postoperative AF in patients undergoing surgery for esophageal carcinoma. The results showed that an elevated level of plasma NT-proBNP obtained before or soon after surgery for esophageal carcinoma was a strong and independent predictor of the occurrence of postoperative AF, suggesting that patients can be stratified according to their risk of postoperative AF. A targeted preventive therapy may be performed only for high risk patients with an elevated NT-proBNP level before or soon after esophageal surgery to prevent the occurrence of operative AF. Low-risk patients with a high negative predictive value of NT-proBNP should not receive any preventive treatment.

Our study provided a new prospective in terms of preventive strategies against postoperative AF. It was reported that NT-proBNP-tailored therapy reduces the occurrence of cardiovascular events in patients with heart failure<sup>[11,12]</sup>. Further studies are needed to demonstrate that reduction in this marker before esophageal surgery is paralleled to a consequent reduction in the risk of AF occurrence. Our study has some limitations, such as a small number of patients, NT-proBNP determined only once after esophagectomy.

In conclusion, an elevated level of perioperative NT-

Table 2 Multivariable analysis for assessing predictors of postoperative atrial fibrillation

Variables	Odds ratio	<i>P</i>	95% CI
NT-proBNP	4.711	0.008	1.212-7.644

History of diabetes mellitus	0.938	0.624	0.378-1.297

proBNP is a strong and independent predictor of AF occurrence in patients undergoing surgery for esophageal carcinoma.

## COMMENTS

### Background

Atrial fibrillation (AF) is a frequent arrhythmia after esophageal procedures and is associated with an increased morbidity and mortality. Although some risk factors for AF can be predicted after surgery for esophageal carcinoma, no accurate assessment tool or biomarker has been identified that can predict the occurrence of AF early after esophageal procedures. Therefore, a sensitive blood biomarker that can predict the occurrence of AF in patients after surgery for esophageal carcinoma with a high specificity is desirable.

### Research frontiers

Previous studies have identified some risk factors as predictors of AF after surgery for esophageal carcinoma, such as postoperative hypoxia, history of obstructive pulmonary disease (COPD), thoracic-gastric dilatation, age over 65 years, male gender, and history of cardiac disease. However, the ability to accurately identify patients at a high risk for AF is still limited.

### Innovations and breakthroughs

This study evaluated the role of NT-proBNP in predicting postoperative AF in patients undergoing surgery for esophageal carcinoma. The results showed that an elevated level of plasma NT-proBNP obtained before or soon after surgery for esophageal carcinoma was a strong and independent predictor of the occurrence of postoperative AF. These results may allow us to stratify patients according to their risk of postoperative AF and have important clinical implications.

### Applications

An elevated level of perioperative NT-proBNP is a strong and independent predictor of AF occurrence in patients undergoing surgery for esophageal carcinoma. This finding may allow us to stratify patients with perioperative risk for AF and to plan preventive strategies for selected high-risk patients.

### Terminology

N-terminal pro-brain natriuretic peptide (NT-proBNP) is a neurohormone which is stored mainly in myocytes of the cardiac ventricles and released as a result of volume and pressure overload or myocardial damage. NT-proBNP has been proved useful for diagnostic and prognostic purposes in patients with congestive heart failure and other cardiac conditions.

### Peer review

In this study, the authors examined whether NT-proBNP level is associated with AF after surgery for esophageal carcinoma, showing that an elevated perioperative plasma NT-proBNP level is an independent predictor of postoperative AF in patients undergoing surgery for esophageal carcinoma. This study has certainly provided important implications for identifying higher risk patients.

### Abstract

Chordomas are rare tumors which originate from the remnants of the notochord. These tumors are locally aggressive and have a predilection for the ends of the axial skeleton. An important prerequisite for optimal management of these tumors is a correct preoperative diagnosis. The present case is the first report of the use of endoscopic ultrasound to obtain transrectal fine needle aspiration biopsy of a presacral chordoma. A review of the prior computer tomography (CT) scans allowed us to calculate the tumor volume doubling time (18.3 mo). Transrectal biopsy of chordomas is controversial, however we believe that such concerns are not justified.

Transrectal EUS-guided FNA biopsy of a presacral chordoma-report of a case and review of the literature. *World J Gastroenterol* 2008; 14(16): 2586-2589 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2586.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2586>

### INTRODUCTION

Presacral chordomas are rare tumors that pose radiographic

and clinical diagnostic challenges. In most instances, a preoperative pathological diagnosis is important in order to plan the optimal management strategy. Tumors located deep in the pelvis pose technical challenges due to the loco-regional anatomy. Although several methods of obtaining tissue [surgical, computer tomography (CT) guided and percutaneous ultrasound guided sampling] have been described, there is much controversy regarding the appropriateness of transrectal biopsy in patients with a suspected chordoma. Transrectal ultrasound-guided biopsy (TRUS) of lesions of the prostate is well established, however, the size and nonflexible nature of the transducers is a limiting factor. A Medline search using search terms chordoma, endoscopic ultrasound (EUS) (or endosonography) produced no results. In this article, we describe the first reported use of EUS with fine needle aspiration (FNA) biopsy for the characterization and diagnosis of a presacral chordoma. We discuss the pathophysiology of chordoma, and the controversies that surround the use of transmural biopsy.

### CASE REPORT

A 60-year-old registered nurse who had undergone a radical prostatectomy for prostate cancer 6 years ago presented with increasing pelvic pain. The PSA was non-detectable. The patient was concerned about recurrence of the prostate cancer. A non-contrast pelvic CT scan demonstrated a presacral tumor measuring 45.9 mm by 35.3 mm (Figure 1). Pelvic CT scans from 6 years ago, that were obtained as part of his prostate cancer work-up, were reviewed. In retrospect, these showed a pubococcygeal tumor measuring 17.6 mm by 14.8 mm. Using an ellipsoid volume formula, the tumor volume doubling time was determined to be 548 d (18.3 mo).

The patient was referred for EUS, which revealed a well circumscribed, echo-rich tumor with a safe window for FNA (Figure 2). FNA biopsies were obtained using the Olympus GF-UC140P curved-linear array echoendoscope (Olympus Co., Tokyo, Japan). Quick stains suggested mesenchymal origin of the tumor. The final cytology and immunohistochemistry was diagnostic of a chordoma (Figure 3).

### DISCUSSION

Chordomas are rare tumors which are locally aggressive but rarely metastasize. In the United States, the age-adjusted incidence is 0.8 per million<sup>[1]</sup>. Chordomas are

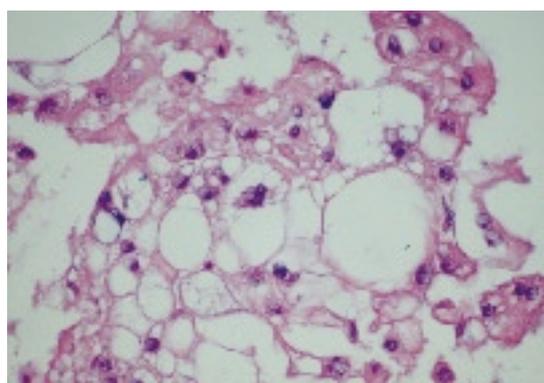

**Figure 1** Post processing sagittal reconstruction of non-contrast pelvic CT demonstrating a hypo attenuating spherical lesion anterior to the coccyx.

**Figure 2** Endoscopic ultrasound with the Olympus GF-UM160 radial echoendoscope demonstrates a well circumscribed hyperechoic lesion, with some focal areas of heterogeneous echotexture, corresponding to the lesion described in Figure 1.

believed to arise from benign notochordal remnants. However, this theory has recently been challenged by Yamaguchi *et al* who proposed that chordomas instead arise from benign notochordal cell tumors<sup>[2]</sup>. The microscopic hallmark of these tumors is the presence of characteristic large cells with numerous cytoplasmic vacuoles known as physaliphorous (Greek: droplet bearing) cells. Chordomas constitute only a small percentage of osseous or neurogenic tumors, and are rarely seen in children or adolescents. Men are affected more frequently than women<sup>[1]</sup>. Although not malignant in the usual sense, chordomas are locally destructive and have a remarkable tendency for local recurrence after cytoreductive surgery. The tumors can also metastasize. Chordomas are rare in humans, but in a series of 533 ferrets with tumors, chordomas constituted 5% of all neoplasms and 86% of bone tumors<sup>[3]</sup>. About one-half of chordomas are located in the sacro-coccygeal region and approximately 30%-35% are present at the base of the skull. However, chordomas can occur anywhere along the vertebral column<sup>[1]</sup>. Macroscopically, the tumors are lobulated gelatinous and brownish-grey in color, and occasionally appear translucent. Histologically, these tumors are characterized by the presence of the above noted physaliphorous cells which are very rich in mucin and glycogen. These cells

**Figure 3** Tissue section of the aspirate sample shows sheets of vacuolated "physaliphorous" cells, classic of chordoma. These cells demonstrate immunoreactivity with pan-cytokeratin and epithelial membrane antigen stains.

are distributed in cords of irregular lobules embedded in a matrix of reticular fibers and an amorphous intercellular substance that contains chondroitin sulfate, hyaluronic acid and keratin sulfate<sup>[4]</sup>. Morphologically, chordomas are similar to chondrosarcomas which, however, lack the physaliphorous cells, and some older studies without the help of immunohistochemical analysis may have inadvertently lumped these distinct entities together.

Surgical resection is the treatment of choice and radiation therapy is often used as supplemental treatment. However, since the extent of tumor resection is difficult to ascertain, and the use of terms such as local failure and disease free survival are difficult to standardize, it is difficult to interpret the results of the small series of treated patients<sup>[5]</sup>. Recently, encouraging results have been obtained with tyrosine kinase inhibitors such as imatinib. However, a detailed discussion of the therapeutic options is beyond the scope of this report, and the interested reader is referred to a recent review published in 2007<sup>[6]</sup>.

The notion that chordomas are slow growing tumors requires qualification. As Crockard *et al* pointed out<sup>[5]</sup>, some chordomas grow fast and there appears to be a good correlation between the rate of tumor growth and prognosis. In their study of skull-base chordomas, 24 patients were followed prospectively by serial MRIs after the initial surgery to evaluate the regrowth rates. The data was correlated with histological features and Ki67 labeling index as a measure of proliferation. Volume doubling times and labeling index showed a close correlation although most of the cases clustered around volumetric doubling-time of around 25 mo. It is not clear whether growth rate of recurrent tumors is the same as the growth rate of untreated tumors, and whether growth rate of the larger sacro-coccygeal tumors is different from that of tumors at the skull-base, which become symptomatic earlier. Our patient had a volumetric doubling time of 18.3 mo which is within the expected range based on the data presented by Crockard *et al*<sup>[5]</sup>.

Controversy exists as to the best approach for biopsy, since several published reviews state that transrectal and

transmural biopsies may incur a risk of tumor tract seeding and poor outcomes. This demands a more in-depth evaluation. Needle tract seeding with tumor is rare but well described for prostate cancer. A Medline search of "chordoma-tract (or track) seeding" produced no results. The same search using the Google internet search engine retrieved as a first hit a review in a family practice journal entitled "What was this retrorectal tumor?" The hyperlink referred to the full article<sup>[7]</sup> where a box with a red "Key Point" label stated: "A preoperative biopsy should not be performed with a retrorectal mass because of the risks of biopsy tract seeding and infection." Two references are cited to support this advice. One of the two (a review by Fourney and Gokaslan<sup>[8]</sup>) refers to another review (Samson *et al*<sup>[9]</sup>) as the sole supporting evidence that transrectal biopsies should not be done. We will revisit the Samson paper shortly. The other cited source<sup>[10]</sup> is a 22 years old review which stated the following: "Of our 30 patients with chordomas, 16 received a curable resection. Nine had preoperative transrectal or trans-sacral biopsies. Recurrent tumors, including four instances of distant metastasis, subsequently developed in six of these patients. Seven patients in whom biopsy was not done received total resection, and only one patient had a recurrent tumor. In addition to recurrence, there were three complications after biopsy: two rectal abscesses and one fecal fistula. A biopsy has no role in diagnosis of retrorectal tumors unless the tumor is unresectable or highly likely to be metastatic." Clearly, rectal biopsies or biopsies of any sort should not be done if they are followed by abscess or fistula formation in 33 percent of the cases. However, this is hardly the current experience. No causality between biopsies and poor outcomes has been established. We should also note that the authors do not discuss about the need to resect the rectum, they just observed the fact that the cases which had undergone the type of transrectal biopsy available at the time were more likely to be associated with recurrent disease in their study. No statistical tests were done. If we apply Fisher's exact test to their data, which is appropriate here, these differences were not significant ( $P = 0.0514$ ).

Interestingly, Fourney and Gokalan<sup>[8]</sup> state in their review that fine needle aspiration cytology should be done in almost all cases but not through the rectum or vagina. The single supporting reference for this statement is a paper summarizing the experience with sacro-cooccygeal chordomas over a 20 years period at the Massachusetts General Hospital from 1972 to 1992 by Samson *et al*<sup>[9]</sup>. The authors of this older series state that "in three patients the rectum and anus were included in the resection after a diverting colostomy had been performed. In two of these patients the procedure was necessary because a transrectal biopsy had been performed, which Mindell has stated to be inappropriate." The only other information we have is that these two cases had been referred to the authors for further management. The conclusion that transrectal biopsies were the culprit was probably the opinion of the attending physician abstracted from the chart or the opinion of the reviewers. Could this be referral bias and attribution bias? Readers will note that

in one of the three cases, colostomy was necessary and no transrectal biopsy had been performed. To conclude from this limited data that transrectal biopsies lead to poor outcome appears unsound. We also do not know whether or not these biopsies were cutting (core) needle biopsies or FNA biopsies, guided by ultrasound. In the 1970's, transrectal biopsies were often carried out with digital guidance<sup>[11]</sup>. Mindell stated more than 25 years ago<sup>[4]</sup>: "For instance, the biopsy should not be done through the rectum, or complete removal may necessitate resection of the rectum" but the author provided no cases or references to illustrate this belief. That the author is discussing about core biopsies rather than FNA cytology can be inferred from the following passage in the same paragraph: "Occasionally needle biopsy through a direct posterior route is satisfactory if both the surgeon and the pathologist are familiar with the techniques of obtaining adequate specimens through a needle and of preparing small plugs of tissue for histological examination".

We believe that we have shown that there is no convincing data that transrectal biopsies of chordomas, especially if performed under real-time ultrasound guidance, are inherently more risky than transrectal biopsies of, for example, prostate cancer. There are several reports of recurrence of prostate carcinoma in the submucosa of the rectum along the needle tract as evidenced by the presence of small nodules or micrometastases observed at surgery for other reasons<sup>[12]</sup>, but the overall risk of this is extremely small. It is hard to conceive that this should be any worse in tumors which grow much more slowly than even prostate cancer. Transrectal FNA biopsies may actually have a theoretical advantage since the needle tract is typically the shortest.

## CONCLUSION

We believe that biopsy of a suspected chordoma is essential. If a chordoma is found the patient should be encouraged to seek treatment at a referral center where relevant experience exists. Of all the biopsy modalities available, transrectal FNA biopsy under ultrasound guidance seems to offer the best risk-benefit ratio.

## Abstract

Double aortic arch is a common form of complete vascular ring that encircles both the trachea and the esophagus, and presents with various respiratory and esophageal symptoms, usually in the pediatric population. We present a case of double aortic arch in an adult patient that manifested as massive upper gastrointestinal bleeding after prolonged nasogastric intubation.

Massaad J, Crawford K. Double aortic arch and nasogastric tubes: A fatal combination. *World J Gastroenterol* 2008; 14(16): 2590-2592 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2590.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2590>

## INTRODUCTION

Aorto-esophageal fistula is a life threatening complication and its diagnosis can often be delayed in the adult patient without any history of thoracic aortic aneurysm or esophageal malignancy. It is important to note that all imaging modalities to diagnose this entity can be unsuccessful and the best chance for patient survival is a clinical diagnosis made with confidence.

We present a case of an aorto-esophageal fistula complicating nasogastric tube placement in a patient with a double aortic arch, to emphasize the importance of

clinical suspicion in diagnosing aorto-esophageal fistulas, as well as the catastrophic events that might result from nasogastric tube insertion in patients with congenital aortic arch abnormalities.

## CASE REPORT

A 38-year-old woman was transferred to our hospital for management of tricuspid valve endocarditis. She had a history of intravenous drug use and had been treated for 2 wk with intravenous antibiotics, but eventually required valvular replacement. On postoperative day 11, she developed massive upper gastrointestinal bleeding. Urgent endoscopy showed a large esophageal ulcer with a probable visible vessel at 22 cm from the gums. Endoscopic therapy with epinephrine injections was performed. Two hours later, she bled again, now more severely, with secondary shock. Given the location of the esophageal ulcer and the degree of bleeding, a clinical diagnosis of aorto-esophageal fistula was made, and the patient was taken to the operating room, in which an aortic endograft was performed, with control of the bleeding. Complete aorto-esophageal fistula repair was planned once the patient's condition stabilized. She was discharged to a subacute rehabilitation facility a few weeks later. On review of her records, it was noted that the patient had a double aortic arch that completely encased her trachea and esophagus, seen on previous chest computed tomography. The patient had a nasogastric tube for more than 5 d postoperatively for feeding and medication administration.

## DISCUSSION

Double aortic arch is a complete vascular ring that encircles both the trachea and the esophagus. The most common presenting symptoms, usually in the pediatric population, are respiratory (stridor) and gastrointestinal (dysphagia)<sup>[1-3]</sup>. The incidence of aorto-esophageal fistula development in adult patients with congenital aortic arch abnormalities and prolonged nasogastric intubation has been previously reported. An extensive literature review showed an abundance of cases of congenital aortic arch abnormalities, including double aortic arch, and aorto-esophageal fistula in the setting of prolonged nasogastric intubation in the pediatric population<sup>[4-11]</sup>, but only a few in the adult patient population<sup>[12-18]</sup> (Tables 1 and 2).

The pathogenesis of this life-threatening complication is probably related to the continuous and pulsatile pressure between the aorta and the esophagus. In this anomaly, the

RESCA: Retroesophageal subclavian artery.

trachea and the esophagus are tightly constricted within a double aortic arch and any inserted tubes (esophageal or endotracheal) can produce pressure necrosis and a resultant fistula<sup>[5]</sup>. Aorto-esophageal fistula is a life-threatening complication and its diagnosis can often be delayed in adults without any history of thoracic aortic aneurysm or esophageal malignancy. It is important to note that all imaging modalities to diagnose this entity can be unsuccessful, and the best chance for patient survival is a clinical diagnosis made with confidence. We present this case to alert clinicians to another potential and life-threatening complication of prolonged nasogastric intubation in this specific patient population.

In conclusion, aorto-esophageal fistula is a highly fatal but potentially avoidable complication in patients with vascular rings. The risks of prolonged nasogastric intubation in this patient population definitely outweigh the benefits. The diagnosis of vascular rings can often be missed in the pediatric population, and it is only when a fatal complication such as aorto-esophageal fistula develops in adults that clinicians are alerted to the significance of this anomaly. The need to screen patients who are expected to have prolonged nasogastric intubation for any congenital aortic arch abnormalities should at least be suggested, if not emphasized, because the development of

an aorto-esophageal fistula is a fatal complication that can be avoided with a more meticulous screening technique.

### Abstract

Gastrointestinal ulcers occur frequently and are mainly caused by *H pylori* infection. In this report, we present a rare case of gastro-duodenal ulcer following selective internal radiation therapy (SIRT). SIRT is a palliative treatment for unresectable liver tumours. During SIRT, <sup>90</sup>Y-microspheres are infused into the hepatic artery. Pre-treatment evaluation for the presence of arterial shunts to neighbouring organs should be determined in order to avoid complications of SIRT.

### INTRODUCTION

Gastric or duodenal ulceration is generally caused by damage to the mucosal barrier of the stomach or duodenum secondary to preponderance of acid valences. In the vast majority of cases, gastric ulceration is an *H pylori*-related disease, especially in the case of duodenal ulceration. Other

causes of gastric or duodenal mucosal damage include excessive use of non-steroidal anti-inflammatory drugs, posttraumatic ischemic mucosal injury, hyperacidity caused by abuse of nicotine or changes in electrolytes, i.e. elevated serum calcium levels<sup>[1,2]</sup>.

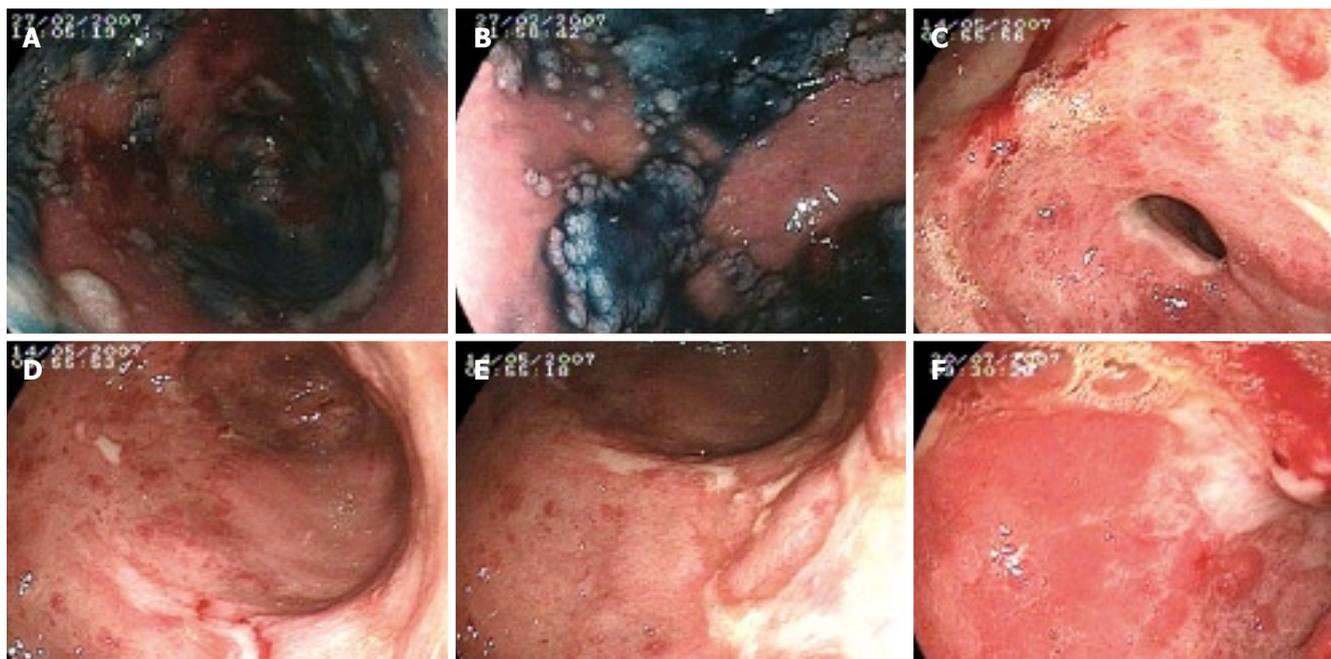

In this report, we present a case of radiation-induced gastro-duodenal ulceration after selective internal radiation therapy (SIRT) for the treatment of hepatic metastases from a sigmoid adenocarcinoma.

Patients with hepatic metastases from a colorectal primary often die from complications associated with the impairment of liver function. Thus, in recent years development of new methods of treatment of non-resectable hepatic tumours has received much attention. External radiation is regarded as ineffective in the treatment of hepatic primary or secondary tumours since the dose of radiation that can be applied to the tumour is limited by the tolerance level of the nontumorous liver tissue<sup>[3-5]</sup>.

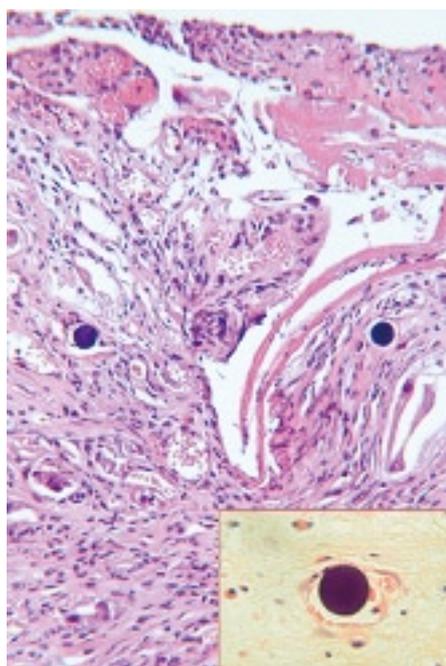

Intra-arterial administration of <sup>90</sup>Yttrium-microspheres, i.e. selective internal radiation therapy, is a palliative treatment for unresectable liver tumours such as hepatocellular carcinoma or liver metastases. This technique allows the application of high radiation dose to hepatic tumours while sparing, for the most part, normal liver parenchyma. During SIRT, <sup>90</sup>Y-microspheres are infused into the hepatic artery either by a surgically placed subcutaneous port or through a percutaneous femoral catheter<sup>[3-6]</sup>. The radiopharmaceutical agent consists of non-biodegradable <sup>90</sup>Y-imprinted microspheres with a glass or a resin matrix with a diameter of 29-35 µm. After injection into the hepatic artery, the microspheres induce microembolization of the hepatic arterioles, mainly in the tumour tissue since its blood supply depends largely on the hepatic artery. <sup>90</sup>Yttrium is a beta-emitter with an average tissue penetration depth of approximately 2.4 mm. Thus, apart from microembolization, a radiation dose from 30 to 60 Gy can be applied to the tumour tissue. Furthermore radiation therapy may be followed by the selective infusion of chemotherapeutic agents into the hepatic artery<sup>[4,7,8]</sup>.

### CASE REPORT

Our patient had sigmoid adenocarcinoma with disseminated hepatic metastases, which responded poorly to systemic chemotherapy with 5-fluorouracil, folinate, irinotecan and bevacizumab. SIRT was applied through a percutaneously placed femoral artery catheter. Several days after the administration of <sup>90</sup>Y-microspheres, the patient developed typical symptoms of upper gastrointestinal ulceration. The patient complained of epigastric pain, nausea and anorexia,

**Figure 1** Chromoendoscopy. **A-B:** Chromoendoscopy with 0.6% Kongored stain showing initial mucosal damage of the gastric antrum; **C-E:** Multiple ulcerations (Forrest III) and severe mucosal inflammation of the gastric antrum, 3 mo after SIRT; **F:** Partially reepithelialized ulcer (Forrest III) in the duodenal bulb, 5 mo after SIRT.

**Figure 2** Gastric biopsy showing ulceration and typical inflammatory eschar at the surface. The mucosa contains granulation tissue with inflammatory cells and several small blood vessels. Two round microspheres can be seen on the right and left side of the figure. Inset: <sup>90</sup>Y-microsphere within a capillary adjacent to an erythrocyte.

followed by increasing weight loss, requiring parenteral nutrition.

Initial gastroscopy showed an extensive pangastritis with mucosal damage and a Forrest type III ulcer in the antrum and proximal duodenum which was confirmed histologically (Figures 1A, B and 2). No *H pylori*-colonization was found in gastric biopsies.

Based on these findings, the patient was treated with high dose proton-pump inhibitor therapy and sucralfate. However, the symptoms persisted and the patient experienced a further weight loss of 7 kg. Two weeks and 3 mo after the initial diagnosis, further gastroscopic examinations were performed and showed progression of the duodenal ulcer with multiple smaller Forrest III ulcers in the gastric antrum (Figure 1C-E). The ulcerations persisted even after 5 mo (Figure 1F).

Because of the close chronological association between the application of SIRT and the development of the patient's symptoms, treatment-related complication was suspected. Pathological examination was expanded to ascertain whether mucosal histological abnormalities may show typical features of radiation damage. Therefore a more detailed histological examination was conducted in order to search for microspheres in the biopsy specimens. Indeed, <sup>90</sup>Y-microspheres embolized into the capillary system were detected and photo-documented as shown in Figure 2.

Clinically, the radiation-induced ulcer persisted despite the continuous use of antacid therapy.

## DISCUSSION

In general, SIRT is a well tolerated technique employed in the treatment of unresectable liver tumours, especially colorectal liver metastases. Nevertheless, complications are seen in about 20% of patients. These include radiation hepatitis and cholecystitis. A Medline literature research using terms as "gastric ulcer", "duodenal ulcer", "internal radiation" and "radiation therapy" revealed that gastroduodenal ulceration occurs in up to 12% patients after treatment with <sup>90</sup>Y-microspheres<sup>[7-12]</sup>. Gastroduodenal ulceration has also been reported after conventional TACE with an incidence of 3% to 5.3%<sup>[13]</sup>. However, the present

report indicates that radiogenic ulceration and radiation-induced side effects persist for a long time and are refractory to pharmaceutical therapy. Radiogenic ulceration led to significant symptoms associated with a sustained decline in the quality of life and an enduring influence on the nutritional status of the patient.

There are several options for pre-treatment planning before the use of SIRT including CT- and PET-scans, visceral angiography and the application of 99m-Technetium macroaggregated albumin to assess tumour vasculature, tumour volume and extrahepatic shunting<sup>[9,14-16]</sup>. With regard to the frequently occurring side-effects of SIRT, the importance of pre-treatment assessment and pre-therapeutic embolization of arterial shunts to neighbouring organs must be established in order to avoid inappropriate loss of quality of life in these patients.

## Abstract

Chronic pancreatitis characterized by an early onset should be extensively investigated including the search for a mutation of the *PRSS1*, *SPINK-1* or *CFTR* genes and potential features of autoimmune pancreatitis. We here describe a case of chronic pancreatitis with an onset at a very young age in which a mutation of the *PRSS1* and several features of autoimmune pancreatitis were identified.

Concomitant autoimmune and genetic pancreatitis leads to severe inflammatory conditions. *World J Gastroenterol* 2008; 14(16): 2596-2598 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2596.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2596>

## INTRODUCTION

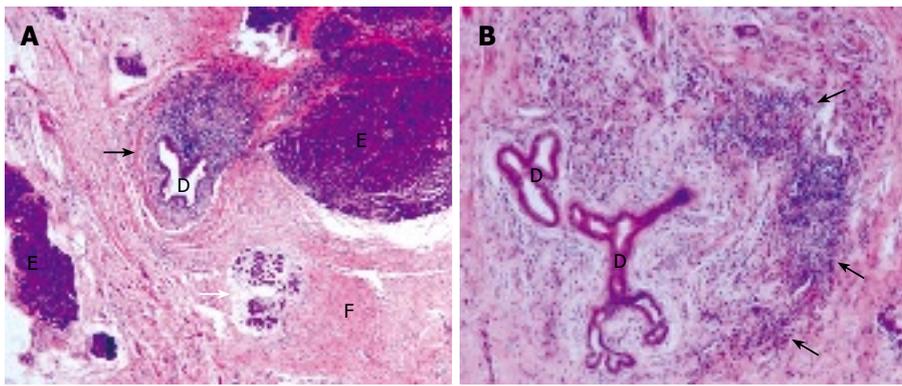

Chronic pancreatitis is a progressive inflammatory disease of the pancreatic gland that will finally result in both exocrine and endocrine insufficiency<sup>[1]</sup>. The insult to the gland is usually caused by recurrent episodes of pancreatic necro-inflammation, leading to pancreatic atrophy and dysfunction. It manifests clinically as maldigestion,

weight loss, constant or intermittent abdominal pain and eventually diabetes. Over the past decade, tremendous advance has been made regarding the etiology of chronic pancreatitis<sup>[2]</sup>. Alcohol abuse remains the most frequent cause of chronic pancreatitis, while other causes have been delineated such as tobacco abuse, genetically determined pancreatitis and autoimmune pancreatitis<sup>[3]</sup>. Additional causes such as pancreas divisum are controversial. Cases of recurrent acute pancreatitis and some forms of chronic pancreatitis have been definitively associated with genetic mutations<sup>[4]</sup>. Indeed, genetic analyses have identified a specific gene for hereditary pancreatitis on the long arm of the chromosome 7 (cationic trypsinogen gene or *PRSS1*). Some *PRSS1* mutations enhance trypsinogen autoactivation, explaining the onset at young age, recurrent acute episodes of pancreatitis and progress into chronic pancreatitis. Other mutations may render some patients more susceptible to pancreatitis in the presence of other insults to the pancreas as shown in AIDS patients receiving potentially harmful drugs for the pancreas<sup>[5]</sup>. Thus, serine protease inhibitor Kazal type 1 (*SPINK1*) and cystic fibrosis transmembrane conductance regulator (*CFTR*) genes have been involved in idiopathic recurrent acute pancreatitis and chronic pancreatitis. Since 1965, several authors have paid attention to particular cases of pancreatitis of an autoimmune pattern and some of the cases were associated with Sjögren's syndrome or primary biliary cirrhosis<sup>[6]</sup>. This entity was recognized as autoimmune pancreatitis, a condition responsible for both acute and chronic pancreatitis.

We herein describe a case of chronic pancreatitis with an onset at a very young age, in which a mutation of the *PRSS1* and several features of autoimmune pancreatitis were identified.

## CASE REPORT

A 33-year-old man approached to our pancreatic outpatient unit for information because he read on internet about recent advance made in the understanding of the causes of pancreatitis. His disease history started 23 years ago at the age of 10 years with the first episode of acute pancreatitis that required a 21-d hospital stay. The first episode was characterized by an acute onset of abdominal pain localized in the epigastric area accompanied by intractable vomiting associated with increased serum amylase concentrations twice the upper normal values. White blood cell counts were  $10\,350/\text{mm}^3$  with 19% of

**Figure 1** A: Pancreatic histological section showing the periductular infiltrate composed of lymphoplasmocytic inflammatory cells (black arrow), and areas of acinar cell necrosis (white arrow); B: High power field magnification section depicting the lymphoplasmocytic infiltrate around pancreatic ducts (black arrows), a typical feature of autoimmune pancreatitis. D: Pancreatic duct; E: Acinar cells and; F: Area of diffuse fibrosis.

band form granulocytes. Calcium, triglyceride levels and liver enzymes were within normal range. Mumps serology confirmed a previous disease. Percutaneous abdominal sonography identified an enlarged gland while the gallbladder was normal without stone. There was no familial history of pancreatic disorders and the patient had no other relevant past medical history. A conservative approach was applied while the extensive search for the etiology of acute pancreatitis remained unsuccessful after exclusion of biliary disease, alcohol abuse, drug-induced acute pancreatitis. Between 1986 and 1990, the patient subsequently developed four recurrent episodes of acute pancreatitis, the cause remains inconclusive. A sweat test was normal excluding cystic fibrosis, while there was a suspicion of pancreas divisum during endoscopic retrograde cholangiopancreatography. In 1990, the patient underwent cholecystectomy and surgical papillotomy. Transcystic cholangiopancreatography showed a normal common bile duct and a normal pancreatic ductular tract, ruling out the previous suspicion of pancreas divisum. The progress between 1990 and 1996 was marked by 5 additional episodes of pancreatitis with calcifications localized in the head and corpus of the pancreas. In 1996, a magnetic resonance imaging (MRI) performed during the 10th episode of pancreatitis identified a ductular stenosis of the caudal part of the main duct associated with distal dilatation of side branch ducts. A caudal pancreatectomy was performed without complications. Histological analysis showed pancreatic atrophy associated with large fibrous strains. Since 1996, the patient has suffered from 9 additional uncomplicated episodes of acute pancreatitis. He never drank alcohol neither was addicted to tobacco use. He was referred to us after the last severe acute pancreatitis in May 2007.

Based on the clinical presentation of the patient, we choose to investigate point mutations in the cationic trypsinogen gene (*PRSS1*) that underlie hereditary pancreatitis, although we had no data suggestive of familial pancreatitis in this patient. For *CFTR* mutations and *SPINK1* polymorphisms, we only analysed the most frequent 33 mutations associated with a more severe clinical importance. Whereas genetic testing revealed normal *CFTR* and *SPINK1* genes, *PRSS1* analysis revealed the mutation p.A16V which represents the third most common mutation in *PRSS1* besides *R122H* and *N29I*. Serum auto-antibodies including antilactoferrin antibodies, anticarbonic anhydrase antibodies type I and II were strongly positive,

whereas serum gammaglobulin levels IgG4 reached 12.8% (normal range: 2.5%-5.9%). A second interpretation of the pancreatic specimen collected in 1996 was performed in our University Hospital and clearly showed a periductular lymphoplasmocytic infiltrate and a diffuse pancreatic fibrosis (Figure 1), and all features characterized autoimmune pancreatitis.

## DISCUSSION

Personal and familial histories, clinical symptoms, laboratory tests, and histological studies when available may help identify some of the etiologies of chronic pancreatitis, but 15%-25% of the cases remain of unknown origin. Recently, autoimmune diseases and genetic mutations have been described in association with pancreatic diseases. Particularly, the *PRSS1*, *R122H* and *N29I* mutations have been found to be responsible for hereditary pancreatitis, a rare cause of pancreatitis characterized by an autosomal dominant inheritance pattern and high penetrance reaching 70%-80%<sup>[7]</sup>. Whereas the *R122H* and *N29I* mutations enhance trypsinogen autoactivation, the *PRSS1* variant p.A16V displays another harmful mechanism by increasing the activation rate of peptide processing regulated by chymotrypsin, which finally accelerates the trypsinogen activation. Moreover, the p.A16V is found most exclusively in patients without a familial history of pancreatitis, a feature shared by our patient. Molecular test represents a very effective tool to investigate the acute and chronic pancreatitis after having ruled out more common causes of pancreatitis such as biliary stones migration, alcohol-abuse and pancreatitis-induced pancreatitis<sup>[8]</sup>. Indeed, genetic test can be used to identify unsuspected cases of genetically transmitted disease, particularly in patients without a strong history in pedigrees. Surprisingly, the patient concomitantly presented with several biological and histological features that confirm the diagnosis of autoimmune pancreatitis. To what extent autoimmune pancreatitis has influenced the course of the disease in the patient remains speculative, but two key points should be stressed. The median age of the onset of hereditary pancreatitis is 12 years<sup>[9]</sup>, while the patient became symptomatic at age 10. The pain usually improves or resolves with time in the majority of patients while the patient still had severe attacks that need a long hospital stay. The steroids would be used to treat next attack and the clinical response will be observed. If positive,

the attributable role of autoimmune pancreatitis will be definitively delineated.

In summary, we present for the first time a patient with a chronic pancreatic disease that may result from a combination of genetic mutations and autoimmune diseases.

### Abstract

Lead is a toxic metal that affects many organ systems and functions in humans. In the majority of adults, chronic lead poisoning comes from exposures to work places and can occur in numerous work settings, such as manufacturing, lead smelting and refinement, or due to use of batteries, pigments, solder, ammunitions, paint, car radiators, cable and wires, certain cosmetics. In some countries, lead is added to petrol. We present a rare case of gastric dilation caused by long-term petrol ingestion. A 16-year-old young man was admitted to our hospital due to a 6-mo history of exhaustion, dizziness, nausea, abdominal cramps and constipation. X-ray examination revealed dilated stomach descending into the pelvis and small bowel distension. After a long clinical observation, we found that the reason for the chronic lead poisoning of the patient was due to a 3-year history of petrol ingestion. The patient spontaneously recovered and stomach returned to its normal position and size. Lead poisoning should be taken into consideration in all unexplained cases of gastric dilation.

### INTRODUCTION

Lead is a toxic metal that affects many organ systems and functions in humans. In the majority of adults, chronic lead poisoning comes from exposures to work places and can occur in numerous work settings, such as manufacturing, lead smelting and refinement or due to use of batteries, pigments, solder, ammunitions, paint, car radiators, cable and wires, certain cosmetics<sup>[1]</sup>. In some countries, lead is added to petrol. Inorganic lead is absorbed from the respiratory or gastrointestinal tract. Approximately 30%-40% of inhaled lead is absorbed into the blood stream<sup>[2]</sup>. Gastrointestinal absorption varies depending on nutritional status and age. Iron is believed to impair lead uptake in the gut, while iron deficiency is associated with increased blood lead concentrations in children. Once absorbed, 99% of circulating lead is bound to erythrocytes for approximately 30-35 d (only 1% of absorbed lead is found in plasma and serum) and is dispersed into the soft tissues of liver, renal cortex, aorta, brain, lungs, spleen, teeth, and bones in the following 4-6 wk. The clinical manifestations can vary from individual to individual. Diagnosis of lead toxicity is mainly based on the elevated blood lead levels (BLL). There is a general correlation between toxic effects of lead and BLL. New data implicate that lower blood lead levels, previously considered normal, can cause cognitive dysfunction, neurobehavioral disorders, different neurological damages, hypertension and renal impairment<sup>[3-6]</sup>.

Toxicity of petrol is usually associated with inhalation of vapor leading to dysfunction of the central nervous system. Ingestion of petrol by adults is rare and happens accidentally during siphoning of petrol tanks. The incidence of petrol ingestion in children is relatively low. An accidental ingestion of petrol causes acute symptoms of gastrointestinal tract including abdominal pain, nausea, vomiting and diarrhea. We report a rare case of extreme gastric dilation caused by long-term petrol ingestion.

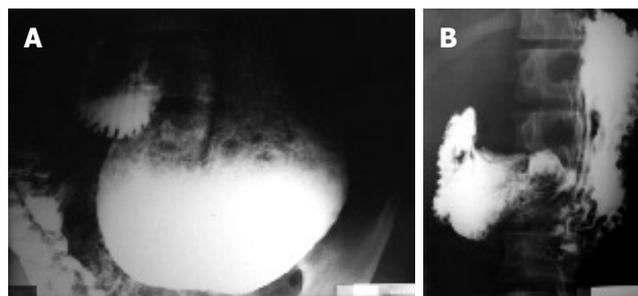

### CASE REPORT

A previously healthy 16-year-old young man was admitted to our hospital due to a 6-mo history of exhaustion, dizziness, nausea, abdominal cramps and constipation.

He was not drug addictive. At admission to our hospital, he was pale, with slightly icteric eyes, normal heart and lungs, generalized abdomen tenderness, but no hepatosplenomegaly. Neurological examination was normal. Laboratory investigation revealed normocytic anemia, 117 g/L hemoglobin, 7  $\mu\text{mol/L}$  iron (normal 11-30  $\mu\text{mol/L}$ ), 26  $\mu\text{mol/L}$  bilirubin (normal 0-20  $\mu\text{mol/L}$ ), 21  $\mu\text{mol/L}$  unconjugated bilirubin, 41 IU/L AST (normal 0-30 IU/L), 56 IU/L ALT (normal 0-41 IU/L). Blood tests showed that white blood cells, platelets, urea, creatinine, acid uric, albumin, HBsAg, anti-HCV, anti-HIV, and urine were normal or negative. Chest radiography and abdominal ultrasound were normal. X-ray examination of the stomach revealed extreme gastric dilation (Figure 1A). The stomach descended into the pelvis. Gastroscopy showed chronic erosive gastritis. Colonoscopy was normal. After supportive therapy, the patient was discharged without explanation for gastric dilation. Control hospitalization in our hospital was four months later. During that time, he was feeling well and had no abdominal pains. Physical examination at admission was normal. Laboratory investigations displayed that hemoglobin was decreased to 111 g/L and iron to 8  $\mu\text{mol/L}$  while bilirubin was increased to 32  $\mu\text{mol/L}$  (unconjugated 30  $\mu\text{mol/L}$ ). Red blood cells, white blood cells, aminotransferases, urea, creatinine, acid uric and urine returned to normal. Coombs test was negative. Stool examination was negative for parasites. X-ray examination of stomach was the same as in previous hospitalization. Then we intended to do more aggressive medical examinations but the patient told that he was selling petrol on the street before he had symptoms three years ago. It was an illegal work and the patient was afraid to admit it before. During the siphoning, he often swallowed a small amount of petrol. We, therefore, determined his lead blood level (BLL) which was 30 mcg/dL (normal < 10.0 mcg/dL). Urinary excretion of aminolevulinic acid was normal. It was obvious that the patient had chronic lead poisoning but we did not treat him because his condition was good due to no longer lead exposure. We saw the patient four years later during his military service. In that period, he sometimes felt nausea and paresthesia in fingers and toes. Physical examination was normal. Laboratory analyses were normal except for an increased bilirubin value of 43  $\mu\text{mol/L}$  (unconjugated 37  $\mu\text{mol/L}$ ). Serum lead concentration was normal (2.66 mcg/dL). X-ray examination revealed that his stomach returned to its normal size and position (Figure 1B). Nerve conduction studies showed mixed sensory-motor polyneuropathy.

## DISCUSSION

Lead is widely dispersed in the environment. In the world, the main sources of lead exposure are gasoline additives, food-can soldering, lead-based paints, ceramic glaze and drinking water systems, cosmetic and folk remedies. In literature, there are single reports on long-term lead exposure and few reports on lead poisoning from retained bullets<sup>[7,8]</sup>. Two-year consumption of homemade wine can cause lead poisoning<sup>[9]</sup>. Chronic lead poisoning has many symptoms and signs, including pains, numbness or tingling of the extremities, muscular weakness, headache, loss mood dis-

**Figure 1** X-ray examination showing dilated stomach descending into the pelvis (A) and the stomach having returned to its normal size and position (B).

orders, reduced sperm count, and abnormal sperm. Our patient had mixed sensory-motor polyneuropathy and anemia. Lead has effects on cell membrane, interfering with various energy and transport systems, which may explain why it can shorten erythrocyte survival time and cause anemia. Peripheral blood smear could show basophilic stippling in several red cells from a patient with lead poisoning. Lead can interfere with the heme synthetic pathway especially enzyme delta-aminolevulinic acid dehydratase causing accumulation of aminolevulinic acid and increasing urinary excretion. Since aminolevulinic acid could be detected in urine only when BLL exceeds 35 mcg/dL, it is not a marker of low lead toxicity<sup>[10]</sup>. Our patient had a lower BLL and normal urinary aminolevulinic acid excretion. Gastrointestinal manifestations of lead poisoning include chronic or recurrent abdominal pain, nausea, vomiting, constipation, bloating, anorexia and weight loss<sup>[11-13]</sup>. These symptoms associated with anemia could lead to toxic etiology especially in the absence of other causes. Our patient had a 6-mo history of unexplained abdominal cramps after stopping petrol ingestion. Generally, all toxic effects of petrol are associated with vapor inhalation. A few minutes after vapor inhalation, symptoms resembling alcohol intoxication (dizziness, excitement, incoordination, *etc*) occur<sup>[14]</sup>. Accidental ingestion of petrol is very rare and may cause symptoms of acute gastrointestinal irritation. The main health effect associated with petrol exposure is pneumonitis, resulting from pulmonary aspiration of vomitus following ingestion<sup>[15,16]</sup>. No report on long-term petrol ingestion is available. In addition to a number of potentially neurotoxic chemicals (benzene, toluene, ethyl benzene, n-hexane, *etc*), lead in petrol is a main additive. Since 2000 in most countries, petrol has only been commercially available in unleaded form, but our patient in Serbia, was selling petrol with lead. When lead is inhaled or absorbed through skin, it is toxic to humans. We could not find any other similar case of extreme gastric dilation caused by lead. Srebocan *et al*<sup>[17]</sup> have described gastric dilation in a dog with lead poisoning. The pathogenesis of such dilation remains uncertain, but it seems that lead has a paralytic action on gastrointestinal system. Normal gastrointestinal motor function is a complex series of events that require coordination of the sympathetic and parasympathetic nervous systems, neurons within the stomach and intestine, and the smooth muscle cells of the gut. Abnormalities of this process can delay gastric emptying (gastric stasis) and gastric tonus (gastric ptosis). It seems that reduction of heme body pool

caused by lead impairs cyto-dynamics impairing nerve conduction and paralysis of stomach. Diagnostic evaluation of adults with potential lead toxicity includes medical and environmental history, searching for potential sources of exposure, signs and symptoms of lead poisoning, and laboratory examination. BLL is essential for the diagnosis of lead poisoning. However, BLL measures current exposure to lead, but lead may also be incorporated into bone due to prior exposures not shown in BLL until this bone-lead becomes "mobilized" through pregnancy or fracture healing. X-ray fluorescence (XRF) equipment can be used to measure lead concentrations in bones<sup>[18]</sup>. The standard elevated BLL is above 25 mcg/dL in adults and above 10 mcg/dL in children. BLL was 30 mcg/dL in our patient ten months after stopping petrol ingestion. The decision to treat it with chelating agents depends on a number of factors, including presence of lead-related symptoms, current BLL, duration of excessive lead exposure and symptoms. Patients with BLL over 80 mcg/dL should be treated<sup>[19]</sup>. Chelation therapy is recommended for individuals with blood lead levels between 40 mcg/dL and 80 mcg/dL if they have lead-related symptoms. The main chemicals used in chelation therapy are ethylenediaminetetraacetic acid (EDTA) administered through injection and oral drug dimercaprol (BAL). Since our patient had a lower BLL, he could recover by avoiding exposure to lead.

In conclusion, this case illustrates that lead poisoning should be taken into consideration in all unexplained cases of gastric dilation.

### Abstract

The combination of intra-arterial low-dose cisplatin and 5-fluorouracil (5-FU) is effective against advanced hepatocellular carcinoma (HCC). Systemic gemcitabine chemotherapy seems effective in many cancers. We report the results of combination therapy with systemic gemcitabine, intra-arterial low-dose cisplatin and 5-FU (GEMFP). Seven patients with non-resectable advanced HCC were treated with GEMFP. One course of chemotherapy consisted of daily intra-arterial cisplatin (20 mg/body weight/hour on d 1, 10 mg/body weight per 0.5 h on d 2-5 and 8-12), followed by 5-FU (250 mg/body weight per 5 h on d 1-5 and 8-12) *via* an injection port. Gemcitabine at 1000 mg/m<sup>2</sup> was administered intravenously at 0.5 h on d 1 and 8. The objective response was 57%. The response to GEMFP was as follows: complete response (no patients), partial response (four patients), stable disease (three patients), and progressive disease (no patients). The median survival period was 8 mo (range, 5-55). With regard to the National Cancer Institute Common Toxicity Criteria (NCI-CTC) grade 3 or 4 adverse reactions, seven (100%), seven, six (86%) and one (14%) patients developed leukopenia, neutropenia, thrombocytopenia and anemia, respectively. GEMFP may potentially be effective for non-resectable advanced HCC, but it has severe hematologic toxicity.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common neoplasms in Africa and Asia, including Japan<sup>[1-3]</sup>. Despite advances in diagnostic techniques and therapeutic procedures [e.g. ultrasonography (US), computed tomography (CT), magnetic resonance imaging (MRI), angiography (AG), surgical resection, radiofrequency ablation (RFA), percutaneous ethanol injection (PEI), and transcatheter arterial chemoembolization (TACE)], morbidity [e.g. portal vein tumor thrombosis (PVTT) and distant metastasis], mortality rates for non-resectable advanced HCC remain poor<sup>[4-8]</sup>.

Advances in implantable drug delivery systems have made it possible to administer repeated arterial infusion of anticancer agents. Initial attempts have included monotherapy with intra-arterial 5-fluorouracil (5-FU) for non-resectable HCC<sup>[9,10]</sup>. However, such treatment results in a low response rate (13% and 22%). Several groups have used low-dose cisplatin and 5-FU for advanced HCC with PVTT, and have reported favorable results<sup>[11-13]</sup>. Several recent studies have reported the survival benefits of combination therapy of intra-arterial 5-FU and subcutaneous interferon alpha (IFN- $\alpha$ ) therapy for advanced HCC with PVTT<sup>[14-18]</sup>.

Gemcitabine is a novel nucleoside analog with a broad spectrum of antitumor activity in preclinical murine leukemia and solid tumor models<sup>[19-23]</sup>. Several studies have reported the efficiency of intravenous gemcitabine alone and in combination with other anticancer agents for advanced HCC<sup>[21-23]</sup>. Such regimens have resulted in response rates ranging from 17.8% to 20.0%. When considered with the results of the above chemotherapy, systemic gemcitabine combined with intra-arterial chemotherapy may potentially be useful for patients with advanced HCC. However, to the best of our knowledge, there is no information about systemic gemcitabine combined with intra-arterial low-dose cisplatin and 5-FU (GEMFP) for advanced HCC. We report here the efficacy and safety of GEMFP in the treatment of seven patients with advanced HCC.

## CASE REPORT

### Eligibility

The treatment eligibility criteria were as follows: (1) Age 20-70 years; (2) Child-Pugh class A; (3) leukocyte count > 3500/ $\mu$ L; (4) neutrophil count > 2000/ $\mu$ L; (5) hemoglobin > 12 g/dL; (6) platelet count > 65000/ $\mu$ L; (7) total bilirubin < 2.0 mg/dL; (8) serum creatinine < 1.0 mg/dL; (9) aminotransferase < 100 IU/L (10) non-resectable HCC or not suitable for local ablation therapy because of multiple tumors or PVTT (in the first branch or trunk); (11) HCC not suitable for TACE or TACE was ineffective; (12) main tumor size > 40 mm; (13) tumor number > 5; (14) bilobular lesions; (15) Eastern Cooperative Oncology Group performance status (PS) of 0<sup>[24]</sup>; (16) HCC without marked arteriovenous shunt; (17) HCC without marked arteriportal shunt; (18) no extra-hepatic metastases; (19) absence of other malignant diseases; (20) no recent history of upper gastrointestinal bleeding; (21) no history of heavy alcohol abuse; and (22) no other serious medical condition that would interfere with participation in this study. Participation also required signing informed consent to the study, which had been pre-approved by the Institutional Review Board of Hiroshima University.

### Patients

From June 2002 to December 2006, 282 consecutive patients with non-resectable HCC were admitted to our hospital. Due to the progression of HCC (e.g. PVTT, extrahepatic metastases), these patients were not suitable candidates for either surgical resection or local ablation therapy, including RFA and PEI. Diagnosis of HCC was established based on typical hypervascular radiological features or histopathological examination of needle biopsy specimens. HCC was also assessed by US, CT and AG. Furthermore, CT was obtained during arterial portography and computerized tomographic hepatic arteriography. Further assessment of HCC was conducted by measuring  $\alpha$ -fetoprotein (AFP) and Des- $\gamma$ -carboxy prothrombin (DCP). PVTT grading based on the location of the tumor thrombus was determined according to the criteria of the Liver Cancer Study Group of Japan<sup>[25]</sup>. Of the 282 patients with advanced HCC, seven agreed to be treated with GEMFP. Table 1 lists the baseline profiles, response,

and treatment outcomes. The seven patients were assessed retrospectively.

### Treatment protocol

One course of chemotherapy lasted for 2 wk. Patients received repeated arterial infusions of anticancer agents (5-FU and cisplatin) *via* an injection port. One course of chemotherapy consisted of daily intra-arterial cisplatin (20 mg/body weight on d 1, 10 mg/body weight on d 2-5 and 8-12), followed by 5-FU (250 mg/body weight on d 1-5 and 8-12). D 6 and 7 were a rest period. Cisplatin and 5-FU were administered by a mechanical infusion pump at 20 mg/h and 250 mg/5 h, respectively. Gemcitabine at 1000 mg/m<sup>2</sup> was administered intravenously at 0.5 h on d 1 and 8. Ondansetron hydrochloride, a serotonin antagonist, was administered intravenously. Intravenous hydration was provided by saline infusion (1000 mL) to prevent nephrotoxicity during chemotherapy. In principle, GEMFP was repeated for several courses until evidence of progressive disease, worsening of PS, worsening of hepatic reserve function, unacceptable toxicity, or patient refusal to continue. A 4-8-wk rest period of no treatment was allowed after each treatment course.

### Evaluation

The maximum response to treatment was assessed in all seven patients. The response was defined according to the criteria of the Response Evaluation Criteria in Solid Tumors (RECIST)<sup>[26]</sup>. Adverse reactions were assessed every week during and after treatment using the National Cancer Institute Common Toxicity Criteria (NCI-CTC) (version 2.0)<sup>[27]</sup>.

### Response and outcomes

The objective response was 57% (Table 1). No patients showed a complete response (CR) to GEMFP and four patients showed a partial response (PR). Three patients achieved stable disease (SD) (Cases 5-7). No patient showed progressive disease (PD). In the four patients with a PR (Cases 1-4), marked regression of tumor and a decrease in tumor markers were observed after the initiation of GEMFP. The median survival period was 8 mo (range, 5-55 mo). One patient was still alive (55 mo) at the end of the observation period (Case 1). Six patients died during the observation period. Three patients died of intrahepatic HCC-related liver failure (Cases 4, 6 and 7), one from respiratory failure associated with lung metastases (Case 2), one from subarachnoid hemorrhage (SAH) (Case 3), and one from aspiration-related pneumonia due to vertebra metastasis (Case 5). Each clinical course is described in detail below.

**Case 1:** This patient is still alive without recurrence of HCC at the end of the observation period. The patient received two courses of GEMFP and achieved PR at 1.5 mo after the initiation of GEMFP. He then underwent surgical resection for remnant HCC, and histopathological examination of the excised tumor showed HCC with massive coagulative necrosis. Six months after surgical resection, a recurrent tumor appeared in subsegment 6, with a diameter of 15 mm. The tumor was treated with RFA. No other recurrence has been detected so far.

Table 1 Baseline profiles, response, and outcome of seven patients with HCC

Case	Age (yr)	Sex	PS	Hepatitis	Child-Pugh class	AFP (ng/mL)	L3 (%)	DCP (mAU/mL)	Main tumor size (mm)	Main tumor morphology	Vascular invasion	Tumor location	Tumor volume	Previous treatment	Treatment cycles	Response	Outcome (mo)	Cause of death
1	40	M	0	HBV	A	934.3	15.9	333	50	Massive	Vp3/Vv0	Bilobular, multiple	< 50%	None	2	PR	55, alive

Vp0: No PVTT; Vp3: PVTT in the first branch; Vp4: PVTT in the trunk; Vv0: No hepatic venous tumor thrombus; Vv3: Hepatic venous tumor thrombus in inferior vena cava; Multiple lesions; massive type HCC; Nodular, nodular type HCC; diffuse type HCC; Bilobular: Lesions; HAI: Hepatic arterial infusion chemotherapy of low-dose cisplatin and 5-FU.

**Case 2:** A 35-year-old man with Hepatitis B virus (HBV)-related chronic hepatitis and massive HCC (130 mm primary tumor in right hepatic lobe) and multiple intrahepatic metastases associated with PVTT in the trunk, and hepatic venous tumor thrombus in the inferior vena cava was admitted to our hospital. He was considered not suitable for surgical resection, local ablation therapy, or TACE because of the far advanced HCC. He was first treated with one course of intra-arterial low-dose cisplatin and 5-FU, which resulted in PD. Next, he received three courses of GEMFP. At 3 mo after the initiation of GEMFP, the levels of AFP and lectin-reactive AFP (AFP-L3) decreased from 593350 to 66450 ng/mL and 21 to < 0.5%, respectively. Repeat CT scans showed regression of the primary tumors, PVTT and hepatic venous tumor thrombus (Figures 1-2). Nevertheless, the patient developed severe leukopenia, neutropenia, thrombocytopenia, and anemia, which required treatment with granulocyte colony-stimulating factor (G-CSF), and platelet and blood transfusion. No bleeding tendency or infectious disease was observed. One month after the end of the three courses of GEMFP (4 mo after the initiation of GEMFP), a CT scan showed multiple lung metastases. PR was persistently seen with respect to the intrahepatic HCC. Eight months after the initiation of GEMFP, brain metastases were identified. Subsequently, the patient received systemic chemotherapy but it was ineffective. Finally, 10 mo after the initiation of GEMFP, he died of respiratory failure due to lung metastases. Regrowth of intrahepatic HCC was not observed during the follow-up period.

**Case 3:** This patient was treated with three courses of

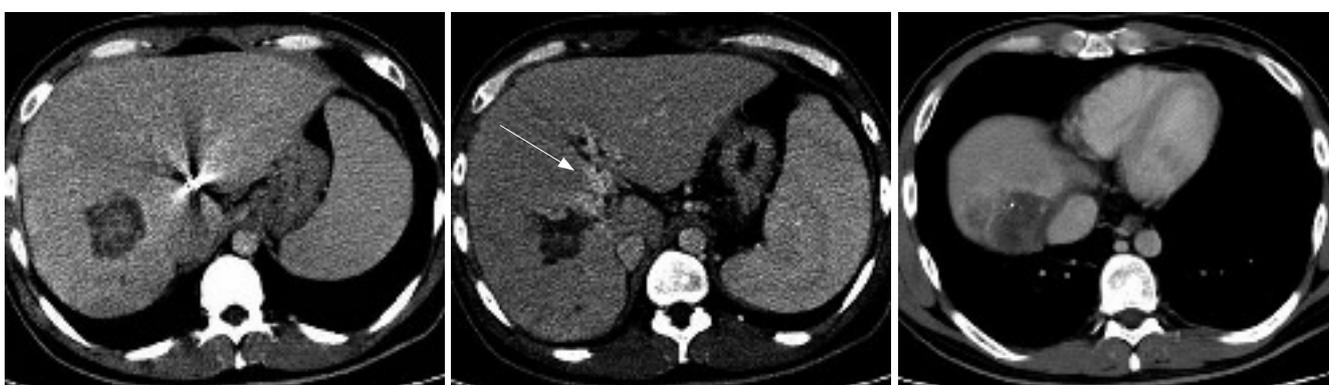

GEMFP. After one course, 1 mo after the initiation of GEMFP, he achieved PR. He continued to be treated with GEMFP and remained in PR. One month after completion of three courses of GEMFP, 8 mo after the initiation of GEMFP, he died of SAH due to rupture of a cerebral aneurysm. Because bleeding tendency and hematologic toxicity were not observed at the onset of SAH, the relationship between cause of death and GEMFP could not be confirmed.

**Case 4:** This patient received one course of GEMFP. One month after the initiation of GEMFP, he achieved PR. He required a long (2 mo) rest period from GEMFP because of severe leukopenia, neutropenia and thrombocytopenia. During that period, regrowth of HCC appeared on CT scan. Hepatic reserve function rapidly deteriorated because of the extent of the tumor. No further chemotherapy could be used because of poor hepatic reserve function. Six months after the initiation of GEMFP, he died of intrahepatic HCC-related liver failure.

**Case 5:** This patient was treated with one course of GEMFP. He subsequently achieved SD, 1 mo after the initiation of GEMFP. The treatment protocol was modified (intra-arterial low-dose cisplatin and 5-FU) after the single course of GEMFP because of severe thrombocytopenia. He continued to be treated for HCC, and 14 mo after initiation of GEMFP, vertebral metastasis was noticed. The patient developed complete spinal cord injury due to vertebral metastasis, with gradual worsening of PS. Finally, PS changed to 4 and he died of aspiration-related pneumonia. He survived for 25 mo after the initiation of GEMFP.

**Figure 1** A CT scan showing massive HCC with PVTT in the trunk and hepatic venous tumor thrombus in the inferior vena cava (arrow). Primary tumor diameter was 130 mm in the right hepatic lobe. No portal blood flow was observed in the right first branch to the trunk.

**Figure 2** After three courses of GEMFP, CT scanning showed marked regression of the primary tumor (55 mm) with demonstrable portal blood flow (arrow) and the disappearance of hepatic venous tumor thrombus in the inferior vena cava.

**Case 6:** This patient received two courses of GEMFP and achieved SD after one course, 1 mo after the initiation of GEMFP. He continued to receive GEMFP. After 2 courses of GEMFP, 5 mo after initiation of GEMFP, CT scan showed progression of HCC and laboratory tests showed associated worsening of hepatic reserve function. Six months after the initiation of GEMFP, spontaneous rupture of HCC occurred suddenly. This resulted in progressive hepatic reserve dysfunction. Finally, he died of intrahepatic HCC-related liver failure 7 mo after the initiation of GEMFP.

**Case 7:** This patient received two courses of GEMFP, and achieved SD after 1 course, 1 mo after the initiation of GEMFP. He continued to be treated with GEMFP. After two courses of GEMFP, 4 mo after initiation of GEMFP, progression of HCC was noted on CT scan, together with associated obstructive jaundice and progressive hepatic reserve dysfunction. Finally, he died of intrahepatic HCC related liver failure 5 mo after initiation of GEMFP.

#### Adverse reactions

Table 2 summarizes the adverse reactions encountered during and after GEMFP treatment. No complications arising from catheter implantation and injection port were noted. Nausea, anorexia and anemia were mostly NCI-CTC grade 1 or 2 adverse reactions. With regard to NCI-

CTC grade 3 or 4 adverse reactions, seven, seven, six and one patients developed leukopenia, neutropenia, thrombocytopenia and anemia, respectively. Four patients (Cases 2, 4, 6 and 7) required administration of G-CSF. Five patients (Cases 1-4 and 7) required platelet transfusion, and one (Case 2) required both blood and platelet transfusion. No patients developed bleeding tendency, gastrointestinal bleeding, deterioration of hepatic function, renal damage or infectious disease.

#### DISCUSSION

The prognosis of patients with advanced HCC complicated with PVTT remains poor, particularly in those with PVTT in the first branches or the trunk. The median survival time of HCC patients with PVTT in the trunk is reported to be about 90 d with supportive care<sup>[28]</sup>. Three recent studies have reported the efficacy and survival benefits of combination therapy of intra-arterial low-dose cisplatin and 5-FU for patients with advanced HCC<sup>[11-13]</sup>. These studies included nine, 48 and 18 patients with advanced HCC and PVTT (in the second branch, first branch, or trunk), who showed objective response rates of 44% (4/9 patients), 48% (23/48 patients) and 33% (6/18 patients), respectively. The cumulative survival rates were 40% at 36 mo, 25% at 36 mo, and 28% at 12 mo, respectively. Furthermore, there has been a study of combination

Table 2 NCI-CTC grade of adverse reactions during and after GEMFP

Case	Leukocyte count (pre/end, / $\mu$ L)	Neutrophil count (pre/end, / $\mu$ L)	Hemoglobin (pre/end, g/dL)	Platelet count (pre/end, $\times 10^4$ )	Nausea	Anorexia
1	3 (5050/1670)	3 (3232/835)	0 (14.6/11.8)	4 (7.5/1.5)	0	1
2	4 (7260/640)	4 (5520/420)	4 (15.7/6.2)	4 (14.8/1.8)	0	0
3	3 (3950/1720)	3 (2489/774)	0 (14.0/12.0)	4 (6.9/1.7)	0	0
4	3 (7950/1430)	4 (5168/352)	0 (16.1/11.7)	4 (20.7/2.0)	0	0
5	3 (3990/1700)	3 (2993/840)	0 (14.6/11.3)	3 (9.6/4.0)	1	0
6	3 (3840/1040)	4 (2380/357)	2 (15.2/8.5)	4 (15.3/0.5)	0	1
7	3 (6790/1950)	4 (3870/468)	2 (12.4/9.6)	2 (13.9/6.4)	0	0

therapy with intra-arterial high-dose 5-FU and cisplatin in 41 patients with advanced HCC<sup>[29]</sup>. Objective response rate was 22% (9/41) and the cumulative survival rate was 47% at 12 mo.

A phase II study of intravenous gemcitabine monotherapy in 28 patients with non-resectable advanced and large HCC (> 10 cm) in 17 patients, extrahepatic metastases in nine, and PVTT in the trunk in 11, and the objective response rate was 18% (5/28 patients)<sup>[21]</sup>. The median survival time of all patients treated with intravenous gemcitabine monotherapy was 19 wk, and 35 wk for those who achieved an objective response. The objective response rate was 18% (six patients) in another phase II study of intravenous gemcitabine plus intravenous oxaliplatin in 34 patients with non-resectable advanced HCC (10 patients with lung metastases, 12 with PVTT, and seven with a PS of 2)<sup>[22]</sup>, and their median survival time was 12 mo (range, 9-14 mo).

In the present study of GEMFP, the objective response rate was 57%. Compared with the objective response rates of the above studies of intra-arterial low-dose cisplatin and 5-FU (33%-48%), intravenous gemcitabine treatment (18%), and intravenous gemcitabine plus intravenous oxaliplatin treatment (18%), the objective response rate of GEMFP for advanced HCC seems better and more satisfactory. The objective response rate for intra-arterial 5-FU and subcutaneous IFN- $\alpha$  therapy for advanced HCC was reported to be 29% in our hospital<sup>[18]</sup>. The objective response rate for GEMFP might be favorable compared to that for intra-arterial 5-FU and subcutaneous IFN- $\alpha$  therapy. The current study had a small sample size. So, a further larger, prospective randomized trial is worth considering for assessing combination therapy in patients with advanced HCC. Each chemotherapeutic agent (gemcitabine, 5-FU and cisplatin) has an antitumor effect. Cisplatin has a synergistic effect as a modulator of 5-FU<sup>[30-32]</sup>. Although the mechanism is not clear, addition of gemcitabine might have a more potent antineoplastic effect compared with intra-arterial low-dose cisplatin and 5-FU alone. Gemcitabine may also have a biomodulator effect that enhances the antineoplastic activity of 5-FU. Gemcitabine and 5-FU might synergize each other's antineoplastic effects. Cases 2-4 had been treated with low-dose cisplatin and 5-FU before the present study, but all three showed PD. Then, the treatment protocol was changed to GEMFP, and all achieved a PR. Thus, addition of gemcitabine seemed to produce beneficial effects in these patients.

With regard to the adverse reactions to intra-arterial low-dose cisplatin and 5-FU, nausea, loss of appetite, pep-

tic ulcer, leukopenia, thrombocytopenia, deterioration of hepatic function, and renal damage have been reported in previous studies<sup>[11-13]</sup>. Most of these adverse reactions were considered to be relatively mild and no patient required administration of G-CSF or blood transfusion. With regard to the adverse reactions associated with intravenous gemcitabine monotherapy, leukopenia, anemia, thrombocytopenia, nausea, vomiting, stomatitis, diarrhea, alopecia, skin rash, and fatigue have been reported<sup>[21]</sup>, although they were mostly mild in nature. With regard to NCI-CTC grade 3 or 4 adverse reactions associated with intravenous gemcitabine monotherapy, leukopenia (11%), anemia (14%), thrombocytopenia (11%) and deterioration of hepatic function (14%) have been reported. As for adverse reactions with intravenous gemcitabine plus intravenous oxaliplatin combination therapy, neutropenia, anemia, thrombocytopenia, neurotoxicity, nausea, vomiting, stomatitis, diarrhea, alopecia, and hand-foot syndrome have been reported<sup>[22]</sup>, which were mostly mild. With regard to NCI-CTC grade 3 or 4 adverse reactions associated with intravenous gemcitabine plus intravenous oxaliplatin combination therapy, neutropenia (24%), anemia (9%), thrombocytopenia (27%), and neurotoxicity (9%) have been reported. In the present study, hematologic toxicity was the most severe. With regard to NCI-CTC grade 3 or 4 adverse reactions, seven, seven, six and one patients developed leukopenia, neutropenia, thrombocytopenia and anemia, respectively. Compared with adverse reactions reported with intra-arterial low-dose cisplatin and 5-FU and systemic gemcitabine, the severe hematologic toxicity noted with GEMFP was considered to be mainly due to gemcitabine. However, hematologic toxicity was more severe than that seen with the above systemic chemotherapy using gemcitabine. The combination of intra-arterial low-dose cisplatin, 5-FU and gemcitabine might cause severe hematologic toxicity. Close monitoring of hematologic toxicity is very important with GEMFP. In our patients, Child-Pugh class was A and PS was 0. These limitations in part account for the good tolerance results. HCC patients with Child-Pugh class B or C, and PS > 1 might discontinue this treatment protocol.

The median survival period was 8 mo (range, 5-55 mo) in this study. The median survival of intra-arterial 5-FU and subcutaneous IFN- $\alpha$  therapy for advanced HCC has been reported to be 9 mo in our hospital<sup>[18]</sup>. Four of the seven patients achieved PR. With regard to three of the four patients with PR, intrahepatic HCC was well controlled during the observation period. However, extrahepatic metastases occurred in one of these patients, and he died of respiratory failure due to lung metastases (Case 2).

Although intrahepatic HCC was well controlled by GEMFP, GEMFP was ineffective for extrahepatic metastases. GEMFP in this study seemed to show a poor effect on extrahepatic metastases. However, this study had a small sample size. So, further, larger studies are needed to assess GEMFP. Effective treatment against extrahepatic metastases is needed. Intrahepatic HCC was not well controlled in another patient with PR (Case 4). He died of intrahepatic HCC-related liver failure, 6 mo after the initiation of GEMFP. This survival period was unsatisfactory. This was probably mainly due to the long rest period from GEMFP therapy because of severe hematologic toxicity, during which regrowth of HCC occurred. Tolerability is as important as survival. Modification of the treatment protocol might be considered to avoid hematologic toxicity.

In conclusion, we reported seven cases in which GEMFP may have been an important component of the basic therapeutic regimen for non-resectable advanced HCC with Child-Pugh class A. Although bleeding tendency or infectious disease did not happen, hematologic toxicity was severe in our study. G-CSF and/or platelet transfusion were frequently required. A modified treatment protocol (e.g. dose reduction of gemcitabine) or inclusion criteria (e.g. leukocyte count > 5000/ $\mu\text{L}$ , neutrophil count > 3000/ $\mu\text{L}$ , hemoglobin > 12 g/dL and platelet count > 100 000/ $\mu\text{L}$ ) or supportive treatment protocol using G-CSF and/or blood transfusion should be examined to avoid hematologic toxicity. Further studies are needed, including long-term follow-up, cost-benefit, and larger sample size to assess GEMFP-based chemotherapy.

## Abstract

Gastrointestinal stromal tumor (GIST) of the stomach was treated by endoscopic enucleation in five patients. They were three men and two woman, aged 36-56 years. Tumors located in the cardia were completely enucleated endoscopically without any serious complication. The largest diameter of removed tumors ranged from 1.2 to 2.5 cm. Histopathological diagnosis was GIST with low risk of malignancy (mitotic index < 5/50 high power field) in all cases. The patients were disease-free for 10.5-42.2 mo after endoscopic enucleation.

DOI: <http://dx.doi.org/10.3748/wjg.14.2609>

## INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal subepithelial tumors of the gastrointestinal tract. Immunohistochemical studies have indicated their relationship to the interstitial cells of Cajal, with which they share differentiation markers such as CD-117 (c-kit) and CD34<sup>[1]</sup>. They are tumors with uncertain malignant potential, the risk of which is predicted by tumor size and mitotic index<sup>[1]</sup>.

Large GISTs of the stomach carry a high risk of

malignancy, and surgical resection is the gold standard for treatment of these tumors. On the other hand, small GISTs (< 3 cm in diameter) are usually benign and there is no consensus about treatment recommendations for such tumors; surgery or observation with regular follow-up<sup>[2]</sup>. In several recent studies, laparoscopic<sup>[3,4]</sup> or endoscopic resection<sup>[2,5,6]</sup> has emerged as minimally invasive treatment for small GISTs of the stomach. However, most of these studies have been in single or a small number of cases, and the safety and efficacy of these novel treatments has not been established.

In this brief communication, we report the results of endoscopic enucleation of GISTs of the stomach in five patients. Endoscopic enucleation appears to be a safe and effective method of treatment of small GISTs of the stomach, if the tumor tissue does not adhere to the muscularis propria.

## CASE REPORT

The patients were three men and two women, aged 36-56 years (median, 50 years). None of them complained of abdominal symptoms. Submucosal tumor of the stomach was found by endoscopy performed as a part of a medical check-up. The tumors were located in the stomach fundus in all cases, and their diameter ranged from 1.1 to 2.5 cm (median, 1.8 cm). They were diagnosed as GIST from the endoscopic appearance shown in Figure 1. Ultrasonography showed the origin of the tumor was in the submucosa, leaving the muscularis propria free from the tumor (Figure 2). Endoscopic enucleation was indicated and written informed consent to the procedure was obtained from all the patients.

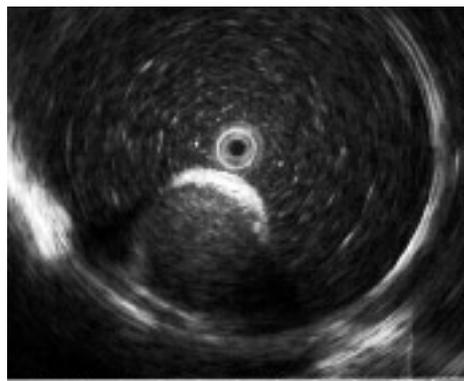

Endoscopic enucleation was carried out as follows: 5-10 ml physiological saline was injected into the submucosa, and the mucosa covering the tumor was removed using a snare or a cutting knife. Then the tumor was dissected from the surrounding tissues (Figure 3A). The tumor was removed completely by snaring its base (Figure 3B). The enucleated lesion was shown in Figure 3C.

Duration of the operation was 18-45 min. (median, 25 min) and no serious complications were encountered. Several days after endoscopic removal of the tumor, oral intake was started without any trouble. Follow-up examinations at 6-8 wk after endoscopic surgery disclosed that the ulcer at the site of the enucleation had healed completely.

Histopathology of the tumor tissue was KIT-positive

**Figure 1** Endoscopic appearance of a subepithelial tumor in the cardia of the stomach.

**Figure 2** Ultrasonography indicated the tumor was confined within the submucosa.

**Figure 3** A: Dissection of submucosal tumor after removing the covering mucosa; B: Snaring of the base of the tumor; C: Specimens of the enucleated tumor and its covering mucosa.

GISTs with low risk for malignancy (mitotic index, < 5 per 50 high power field) in all of the patients. The patients were disease-free at 10.5-42.5 mo (median, 26.6 mo) after the operation.

## DISCUSSION

Reports on endoscopic removal of small GISTs of the stomach have been increasing, but they are mostly documentation of single or a small number of cases<sup>[2,5,6]</sup>. Park *et al*<sup>[7]</sup> have recently reported the experience of endoscopic enucleation of submucosal tumors of the esophagus and the stomach in 15 patients. There were four patients with GISTs of the stomach. Tumor tissue was removed completely in these patients but a small perforation occurred in one patient, in whom the tumor involved the muscularis propria and had grown outward to the serosa. Roesch *et al*<sup>[8]</sup> have treated 14 patients with submucosal tumors of the esophagus and the stomach by endoscopic surgery. In their series, there were five patients with GIST of the stomach. No serious complications were encountered in these patients but complete removal was uncertain in two patients with gastric GISTs that originated in the muscularis propria.

These reports, together with our experiences reported here, indicate endoscopic enucleation is a safe and effective method of treatment for most patients with gastric GISTs.

Endoscopic enucleation, however, is not indicated if the tumor is > 3 cm in diameter or if involvement of the muscularis propria is suspected from preoperative ultrasonography.

If GIST is completely removed by endoscopic resection and histopathological examination discloses that the risk for malignancy is low, then no further treatment is necessary. However, if resection is incomplete and/or the tumor tissue has a high risk of malignancy, additional wide resection is indicated. At present, whether postoperative imatinib can improve disease-free survival in high-risk patients is still uncertain<sup>[9]</sup>.

## Abstract

Acute necrotizing pancreatitis complicated with pancreatic pseudoaneurysm is a rare emergency associated with high mortality that demands immediate treatment to save the patient's life. We treated a 64-year-old man who presented with a bleeding pseudoaneurysm of the superior mesenteric artery caused by acute pancreatitis, using interventional embolizing therapy. In the present report we show that interventional treatment is an effective therapeutic modality for patients with acute necrotizing pancreatitis complicated with intra-abdominal bleeding.

## CASE REPORT

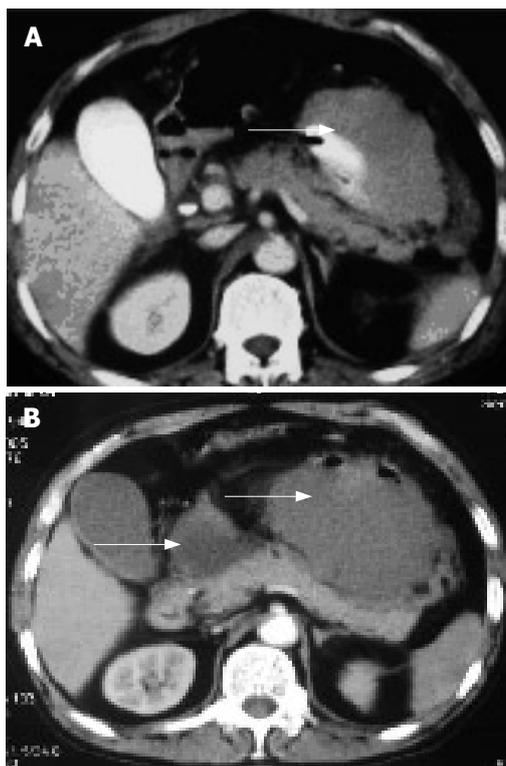

A 64-year-old man was admitted with an abrupt onset of pain in the left midsection of the abdomen. He began to feel sharp pain after dinner, which was accompanied with alcohol. The pain persisted for 8 h and became increasingly

unbearable. Blood tests showed serum amylase (AMY) of 501 IU/L, lipase (LIP) 779 IU/L and hemoglobin (Hb) 171 g/L. He was diagnosed as acute necrotizing pancreatitis based on the blood tests and findings at computer tomography (CT) scan (Figure 1A). The patient was transferred to the Department of Integrated Traditional Chinese Medicine and Western Medicine for treatment of pancreatitis, which is a special expertise of this department. The next day, the patient experienced sudden pain without any precipitating factor, accompanied with dyspnoea. Blood tests revealed that the Hb level had dropped from 171 g/L to 40 g/L. From that point on, the patient began to deteriorate rapidly and developed features of hemorrhagic shock despite continuous transfusion of 2000 mL whole blood. Severe intra-abdominal bleeding was suspected as the principal cause of his symptoms. In view of the high mortality rate of such a complication, one group of surgeons recommended prompt surgical intervention. However, after consultation with the family members we arranged an emergent angiography to identify the bleeding source. During the procedure, a ruptured pseudoaneurysm of the superior mesenteric artery (SMA) was identified, with extravasation of contrast medium from the vessel (Figure 2A and B).

Gelatin sponge pieces were infused in order to embolize the ruptured artery, and the bleeding stopped (Figure 2C). After the interventional treatment and transfusion of 400 mL of fresh blood, the Hb increased to 93 g/L. The patient was transferred to the Intensive Care Unit. Six days later, the patient was in stable condition but experienced continuous dull abdomen pain. Repeat CT scan showed that the size of the postperitoneal hematoma had increased from 6 cm to 8 cm, and a 3 cm parapancreatic cyst was noted (Figure 1A and B). The patient was operated upon to evacuate the cyst, hematoma and the necrotic tissues. A communication was made with the jejunum to create a pancreaticojejunostomy. The patient recovered gradually and was discharged from the hospital 2 wk later.

## DISCUSSION

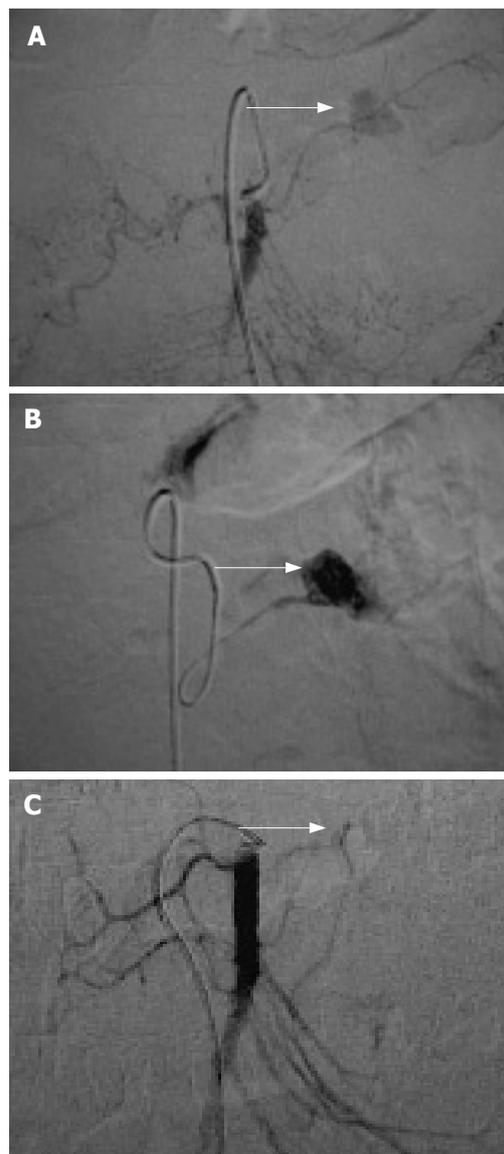

Acute pancreatitis is an inflammatory condition, which leads to acinar cell damage, interstitial edema and hemorrhage. Some patients may develop severe acute pancreatitis accompanied with multiple organ dysfunction syndrome. Acute pancreatitis is initiated by

**Figure 1** CT scan. **A:** Presence of the postperitoneal hematoma (arrow); **B:** Increase in the size of postperitoneal hematoma and presence of a pseudocyst (arrows).

the activation of pancreatic enzymes in the acinar cells. Local inflammation, caused by activation of trypsinogen to trypsin, is followed by the activation of inflammatory mediators. These mediators and the associated damage is not restricted to the pancreatic tissue, but may involve other organs, particularly the lungs, liver, and blood products, which are responsible for the systemic manifestations of this condition<sup>[1]</sup>.

Rupture of a pancreatic pseudoaneurysm is a rare complication of pancreatitis, and is associated with poor prognosis. The mortality correlates with the severity of the pseudoaneurysm (acute pancreatitis), and the overall mortality of this complication (severe acute pancreatitis) is about 7.8%. Angiography is usually required for confirmation of the diagnosis. Non-invasive imaging techniques such as color Doppler ultrasound and contrast-enhanced CT with sagittal or coronal reconstruction are also useful in the diagnosis of pancreatic pseudoaneurysm associated with acute necrotizing pancreatitis. Despite the advent of other imaging modalities, CT is the most effective technique to evaluate the lesion after pancreatic surgery<sup>[2-5]</sup>. In addition, CT may demonstrate early (leakage of anastomosis, pancreatico-jejunal fistula, hemorrhage, acute pancreatitis of the remnant pancreas, peritonitis) and late (chronic fistula, abscess, aneurysms, anastomotic bilio-enteric stenosis, perianastomotic ulcers, biloma, and intra-abdominal bleeding) complications. Magnetic resonance is an alternative imaging modality when renal insufficiency or contrast sensitivity precludes the use of iodinated contrast material or when assessment of the biliary tree is the primary focus of the study. However, these imaging

**Figure 2** Angiography. **A:** SMA angiography shows a pseudoaneurysm in a branch of the SMA with extravasation of the contrast (arrow); **B:** Subselective angiography illustrates extravasation of the contrast more clearly (arrow); **C:** After embolization of the damaged artery, there is cessation of extravasation of the contrast, with disappearance of the nidus (pseudoaneurysm) (arrow).

techniques do not obviate the need for diagnostic and therapeutic angiography<sup>[6]</sup>.

With respect to therapeutic choices, endoscopic papillotomy and endoscopic removal of biliary stones is the gold standard in the treatment of gallstone-related acute pancreatitis<sup>[6,7]</sup>. For other causes of acute pancreatitis, medical treatment should be started as early as possible with intensive care management in patients with severe acute pancreatitis. The optimal treatment is controversial. Surgical and interventional treatments, either alone or as temporizing techniques with subsequent surgery are some of the therapeutic options. However, in patients with necrotizing pancreatitis, angiographic embolization has been found to be very useful<sup>[6,8,9]</sup>, since surgical ligation or repair of the bleeding vessel is complicated by higher rebleeding rates (46%) compared to partial pancreatectomy (17%). In patients with infected pancreatic necrosis,

hemorrhage or peritonitis, surgery is the only therapeutic option, while the role of surgical treatment in the presence of sterile pancreatic necrosis accompanied with multiple organ dysfunction syndrome, which is unresponsive to medical therapy, remains unclear. Complications such as bleeding and bowel perforation are seen mostly in patients who undergo several reoperations<sup>[10-12]</sup>. Surgery in patients with necrotizing pancreatitis carries a high mortality (about 21% for the operation<sup>[13-15]</sup>). Surgical procedures are extremely unsafe when such patients develop acute gastrointestinal bleeding. However, angiography is the gold standard therapeutic approach in such patients. More importantly, angiography does little harm and has the highest chance of stopping bleeding in situations such as that of our patient.

Our patient was already in shock despite rapid blood transfusions when he was brought to the angio-room. As soon as we succeeded in embolizing the feeding artery, the patient's blood pressure began to improve and it was soon restored to the normal level. The subsequent treatment after embolism is as important as stopping the bleeding itself. In the present case, the patient required further surgery and intensive care treatment, resulting in gradual improvement of the patient's condition.

In summary, the present case report demonstrates that interventional treatment is an effective treatment for patients with acute necrotizing pancreatitis complicated with intra-abdominal bleeding, especially in patients who are in poor condition and those who cannot tolerate laparotomy. We wish to emphasize that stopping the bleeding is only the first step in the treatment of such patients and a close cooperation between the physicians and surgeons is required for optimal results.

### Abstract

Stercoral ulceration results from impaction of hard fecal mass on the colonic wall and is a relatively unknown cause of lower gastrointestinal bleeding. In this report, we describe a case of lower gastrointestinal bleeding due to stercoral ulceration resulting from Sevelamer, a drug which is commonly associated with constipation.

### TO THE EDITOR

Stercoral ulceration is defined as an ulcer caused by pressure necrosis from hard fecal mass (fecaloma) pressing on the colonic wall. It is a relatively unknown cause of lower gastrointestinal bleeding<sup>[1]</sup>. A prolonged history of constipation is present in almost 80% of the patients with this condition<sup>[1]</sup>. Sevelamer, a phosphate binder, is often used in treatment of hyperphosphatemia associated with chronic

kidney diseases. It is associated with constipation in 8%-10% of the patients<sup>[2]</sup>. To the best of our knowledge, this is the first case in which stercoral ulceration as a cause of lower gastrointestinal bleed has been ascribed to Sevelamer use.

A 62-year-old woman presented with bleeding per rectum for one day. She reported a history of constipation which occurred 1 mo ago when she started taking Sevelamer. She had not had a bowel movement for several days and when she started straining in the toilet, "something gave way" and she passed two hard stools and started bleeding from rectum. The blood was bright red in color. She felt lightheaded and was brought to the hospital. Her previous medical history was significant for diabetes mellitus, end-stage renal disease, coronary artery disease and cerebrovascular accident with no residual deficit. Besides Sevelamer, she was also taking Clopidogrel but never had similar episodes of bleeding before. Physical examination revealed tachycardia and hypotension. Her hemoglobin dropped from baseline of 12 gm/dL to 9.5 gm/dL. She was stabilized with intravenous fluid, red blood cell transfusions and subjected to colonoscopy which revealed stercoral ulcers in rectum (Figure 1). Histological examination of the ulcer showed denuded mucosa with acute and chronic inflammation. Her bleeding stopped spontaneously and she did not have any further episodes of bleeding and was later discharged on stool softeners after stopping the offending drug.

The exact prevalence of stercoral ulceration in general population is unknown. Autopsy studies have revealed presences of stercoral ulceration in about 1.3%-5.7% of elderly institutionalized patients<sup>[3,4]</sup>. Stercoral ulcers are usually asymptomatic but may cause two dreaded complications: perforation and bleeding. However, these complications are rare in literature. Stercoral ulceration was first described in 1894 and since then less than 100 cases of stercoral ulceration associated perforation have been reported<sup>[1]</sup>. The number of stercoral ulceration presenting as hematochezia is even lower.

Severe constipation is considered to be the main causative factor in formation of stercoral ulceration and is present in 81% of the patients<sup>[1]</sup>. The elderly, debilitated or institutionalized patients on multiple medications are affected most frequently. Stercoral ulceration with consequent perforation has been reported in association with narcotics, amitriptyline, verapamil, immunosuppressive agents, aluminum based antacids and non-steroidal anti-inflammatory drugs (NSAIDs)<sup>[5-8]</sup>. The effect of NSAIDs might be related to its inhibitory effect on formation of

**Figure 1** Stercoral ulcers in the rectum.

mucosa protecting prostaglandins rather than constipation. We could not find any report in which stercoral ulceration had been found as the consequence of Sevelamer use.

Stercoral ulcers are caused by pressure necrosis from the hard fecaloma pressing on the colonic wall. The contours of stercoral ulcers are often well-demarcated corresponding to the shape of fecolith. A fecaloma is most likely to form in the distal colon where the stools are in the most dehydrated form. The fecaloma is frequently impacted at the site of recto-sigmoid junction which is also the narrowest part of the colon. As a result of impaction, the intraluminal pressure often exceeds the capillary perfusion pressure of the bowel wall predisposing the mucosa to necrosis and ulceration<sup>[1]</sup>.

Treatment of stercoral ulceration depends upon the presenting symptoms. Complications arising from stercoral ulceration may lead to a 50% mortality in the population

at risk due to accompanying comorbidities. The stercoral perforation is usually treated surgically and those presenting with massive hemorrhage may require emergent resection or endoscopic therapy<sup>[9]</sup>.

A common clinical problem such as constipation can sometimes cause relatively unknown but potentially fatal complication such as stercoral ulceration. An internist should monitor development of constipation in a patient who is newly started on Sevelamer.

### Abstract

Many of the drugs currently used in medical practice are racemates. The enantiomers of a racemic drug differ in pharmacodynamics and/or pharmacokinetics, thus in some cases it is preferable to develop pure enantiomers by racemic switch. In a recent study by Pai *et al*, dexrabeprazole [R(+)-rabeprazole] (10 mg) was found to be more effective than rabeprazole (20 mg) in the treatment of gastroesophageal reflux disease. We read with great interest in this study and discussed whether such racemic switch would be applicable to other proton-pump inhibitors (PPIs). A literature review indicates that stereoselective pharmacokinetics, rather than stereoselective pharmacological activity, is the main cause of differences in clinical efficacy between pure enantiomer and racemic PPI. Racemic switches of PPI provide the therapeutic advantages such as reducing metabolic load on the body, simplifying pharmacokinetics, providing benefit to the non-responders to standard dose of racemate, more homogenous response to treatment and better efficacy with equal safety. Further studies in quantitative structure-activity relationships (QSARs) are needed to address the fact that the preferred enantiomer of PPI is not always in the same absolute configuration, i.e., S-form is for omeprazole, pantoprazole and

tenatoprazole whereas R-form is for lansoprazole and rabeprazole.

### TO THE EDITOR

We read with great interest in the study by Pai *et al*<sup>[1]</sup>, who compared the therapeutic outcomes of dexrabeprazole (10 mg) with rabeprazole (20 mg) in the treatment of gastroesophageal reflux disease (GERD). The results showed that efficacy of dexrabeprazole (10 mg) is better than rabeprazole (20 mg), with regards to improvement/healing of endoscopic lesions and relief from symptoms of regurgitation. Rabeprazole is a racemic mixture of two enantiomers, R(+)-enantiomer and S(-)-enantiomer in 1:1 proportion. Dexrabeprazole is the chirally pure R(+)-enantiomer which is more effective than the racemate and S(-)-rabeprazole in inhibiting acid-related gastric lesions in rats<sup>[2]</sup>. A superior pharmacokinetic profile, i.e., higher maximal plasma concentrations ( $C_{max}$ ) and area under the curve ( $AUC$ ), was observed with R(+)-rabeprazole compared to its S(-)-enantiomer<sup>[3]</sup>. Dexrabeprazole was launched as Dexpure<sup>®</sup> by Emcure Pharmaceuticals Ltd in September 2007.

Racemic switch stands for the development in single-enantiomer form of a drug that was first approved as a racemate. We have reported that the enantiomers of a racemic drug differ in pharmacodynamics and/or pharmacokinetics as a consequence of stereoselective interaction with optically active biological macromolecules, and the decision to perform racemic switch should be based on enough evidence<sup>[4,5]</sup>. As far as proton-pump inhibitors (PPIs) are concerned, is the required therapeutic

effect achieved by racemic switch? We would discuss and share our perspectives below.

Omeprazole, lansoprazole, pantoprazole and rabeprazole possess asymmetric sulfur in their chemical structure and have been typically used in clinical practice as a racemic mixture. Esomeprazole, S(-)-enantiomer of omeprazole, is the first enantiomerically pure PPI and the compound is now marketed as Nexium<sup>®</sup>. The enantiomers of omeprazole produce similar pharmacological effects<sup>[6]</sup>. The metabolic profile of S(-)-omeprazole is distinct from that of R(+)-omeprazole. Both enantiomers are metabolized by CYP2C19, but the enzyme plays a less role (73% vs 98%) in the metabolism of the S(-)-enantiomer. As a result, the pharmacokinetic profile of the S(-)-enantiomer is less dependent on CYP2C19 genotype, hence leading to a less interpatient variability in clearance than omeprazole.  $AUC_{po(PM)}/AUC_{po(EM)}$ , the ratio of AUC after oral administration ( $AUC_{po}$ ) derived from poor metabolizers (PM) and extensive metabolizers (EM), is 3.0 and 7.4 for esomeprazole and omeprazole<sup>[7]</sup>, respectively. Moreover, S(-)-omeprazole is cleared more slowly and has an improved oral bioavailability (81%-98% vs 35%-65%), leading to the greater inhibition of gastric acid secretion compared to omeprazole.

Lansoprazole is extensively metabolized by CYP2C19 and CYP3A4 in the liver. CYP2C19 genotype influences the disposition of S(-)-lansoprazole to a greater extent than the R(+)-enantiomer, resulting in less interpatient variability in clearance with R(+)-lansoprazole compared to lansoprazole. Both enantiomers of lansoprazole possess equal potency. Therefore, the use of R(+)-lansoprazole alone would be highly desirable for clinical application<sup>[8]</sup>.

Pantoprazole is a racemic mixture of two enantiomers. Animal studies confirmed that S(-)-pantoprazole is more potent than R(+)-enantiomer in inhibiting acid-related lesions<sup>[9]</sup>. Pantoprazole is metabolized mainly by CYP2C19 followed by sulfation and, to a lesser extent, by CYP3A4. The enantiomers of pantoprazole are differentially affected by CYP2C19 genotype. The  $AUC_{po(PM)}/AUC_{po(EM)}$  ratio is 11, 2.5 and 6.0 for the R(+)-enantiomer, S(-)-enantiomer and pantoprazole, respectively<sup>[10]</sup>. The pharmacokinetics of S-pantoprazole depend less on CYP2C19 genotype, resulting in uniform therapeutic plasma levels of the drug, thus providing benefit to the non-responders to standard dose of racemic pantoprazole. A comparative clinical trial of S(-)-pantoprazole versus racemic pantoprazole in the treatment of GERD has been carried out by Pai *et al*<sup>[11]</sup>. S(-)-pantoprazole (20 mg) was found to be more effective than racemic pantoprazole (40 mg) in improving symptoms. S(-)-pantoprazole exhibits both pharmacokinetic and pharmacodynamic advantages and this compound known as PANPURE<sup>®</sup> was developed by Emcure Pharmaceuticals Ltd in 2006.

Tenatoprazole is a new PPI under clinical development by Negma-Gild. It is a racemic mixture of two enantiomers. Significant stereoselective differences in pharmacodynamics were observed in *in vivo* studies in rats and dogs, with S(-)-tenatoprazole being a eutomer<sup>[12]</sup>. The S(-)-enantiomer is metabolized approximately 7 times more slowly than the R(+)-enantiomer, resulting in a much longer mean residence

time in the human body and an improved tissue exposure to S(-)-tenatoprazole in comparison with the R(+)-enantiomer. The S(-)-enantiomer is mainly metabolized *via* CYP3A4, which can compensate for a potential deficiency or blockade of CYP2C19. The R(+)-enantiomer is metabolized via two pathways, i.e., mainly the CYP2C19 and, to a lesser extent, by CYP3A4. Clinical studies showed the linear pharmacokinetic and pharmacodynamic characteristics of S(-)-enantiomer after 7-d treatment of tenatoprazole. In contrast, the plasma concentration of the R(+)-enantiomer is not linear, thus being not predictive of the efficacy and the tolerability of the drug. Furthermore, the pharmacokinetics of S(-)-enantiomer shows a markedly lower inter-subject variability compared to that of the R(+)-enantiomer, hence a better use of the product and a more homogenous response to treatment in all patients. Consequently, S(-)-tenatoprazole is a promising PPI with a safe general pharmacological profile.

In conclusion, stereoselective pharmacokinetics, rather than stereoselective pharmacological activity, is the main cause of differences in clinical efficacies between pure enantiomer and racemic PPI (e.g. omeprazole, lansoprazole, pantoprazole, rabeprazole and tenatoprazole). Racemic switches of PPIs provide therapeutic advantages such as reducing metabolic load on the body, simplifying pharmacokinetics, providing benefit to the non-responders to prior standard dose of racemate, more homogenous response to treatment and better efficacy with equal safety. Further studies on the quantitative structure-activity relationships (QSARs) are needed to address the fact that the preferred PPI enantiomer is not always in the same absolute configuration, i.e., S-form is for omeprazole, pantoprazole and tenatoprazole whereas R-form is for lansoprazole and rabeprazole.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/15.doc>

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
