## Abstract

**AIM:** To investigate the role of pancreatic stellate cells (PSCs) and galectin-3 (GAL-3) in the proliferation and infiltration of pancreatic cancer cell line SW1990.

**METHODS:** Human pancreatic cancer cell line SW1990 and PSCs were cultured *in vitro*. Supernatant fluid of cultured PSCs and SW1990 cells was collected. Expression of GAL-3 in SW1990 cells and PSCs was detected by ELISA, RT-PCR and Western blotting. Proliferation of cultured PSCs and SW1990 cells was measured by 3-(4, 5-methylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay and flow cytometry. Infiltration of SW1990 cells was detected by a cell infiltration kit.

**RESULTS:** SW1990 cells expressed GAL-3 and this was up-regulated by the supernatant fluid of cultured PSCs. PSCs did not express GAL-3. SW1990 cells stimulated proliferation of PSCs *via* GAL-3. GAL-3 antibody inhibited SW1990 cell proliferation, while the supernatant fluid of PSCs stimulated proliferation of SW1990 cells through interaction with GAL-3 protein. The supernatant fluid of PSCs enhanced the invasiveness of SW1990 cells through interaction with GAL-3.

**CONCLUSION:** GAL-3 and PSCs were involved in the proliferation and infiltration process of pancreatic cancer cells.

## INTRODUCTION

Tumor desmoplasia, a process in which fibrous tissue (e.g., collagen, fibronectin and laminin) infiltrates and envelops neoplasia, is one of the representative histopathological findings in ductal adenocarcinoma of the pancreas. The desmoplastic reaction may contribute to the rapid progression, early metastasis, and a limited response to chemotherapy and radiotherapy of pancreatic carcinoma<sup>[1-5]</sup>. Some studies have confirmed that pancreatic cancer cells activate pancreatic stellate cells (PSCs) *via* transforming growth factor (TGF)- $\beta$  and other cytokines<sup>[6,7]</sup>. Although pancreatic carcinoma cells are able to produce the fibrotic extracellular matrix (ECM) that surrounds carcinoma, most studies have indicated that the fibrotic ECM is mainly produced and secreted by PSCs<sup>[8]</sup>.

Galectin-3 (GAL-3), is a member of the  $\beta$ -galactoside-binding protein family which recognizes the N-acetylglucosamine structure of various glycoconjugates<sup>[9,10]</sup>. Studies on hepatic stellate cells (HSCs) have shown that GAL-3 stimulates HSC DNA synthesis in a dose-dependent manner, but no report on the effect of GAL-3 on PSCs has been published<sup>[11]</sup>. Some studies have been carried out to evaluate the role of GAL-3 in carcinoma proliferation, infiltration and metastasis<sup>[12-18]</sup>, but few of these were on pancreatic cancer. Some immunohistochemical studies have reported that GAL-3 is expressed in pancreatic cancer<sup>[19,20]</sup>. It has been confirmed that laminin, one important component of the fibrotic ECM that surrounds pancreatic cancer, can be recognized by GAL-3, so GAL-3 may play an important role in the progression of pancreatic cancer.

## MATERIALS AND METHODS

### Cell isolation and culture

SW1990 cells were cultured in 100 mL culture bottles containing Dulbecco's modified Eagle's medium (DMEM,

Gibco) supplemented with 10% fetal bovine serum (FBS, Gibco) 100 U/mL penicillin and 100 U/mL streptomycin at 37°C in a 5% CO<sub>2</sub>/air humidified atmosphere. PSCs were provided by our laboratory and were cultured in DMEM/F-12 supplemented with 10% FBS and antibiotics under the same conditions.

### Collecting supernatants of cultured cells

SW1990 cells and PSCs cultured in 100 mL bottles were washed in PBS and then incubated with serum-free DMEM (5 mL/bottle) for 24 h. Supernatants of cells were collected and filtered under sterilized conditions to remove cell debris, and were stored at -80°C. The concentration of GAL-3 protein in these supernatants was detected by ELISA (Bender Systems).

### RT-PCR

SW1990 cells were washed in PBS and incubated with serum-free DMEM for 24 h. The cells were divided into two groups, one was still incubated with serum-free medium, and the other was exposed to serum-free DMEM supplemented with 40% (v/v) supernatants of PSCs (SPSCs). Cells were harvested and counted 24 h later. Total RNA of 10<sup>6</sup> cells in each group was extracted according to the manufacturer's instructions (TRIzol, Gibco-BRL, Rockville, MD, USA). The concentration and purity of RNA was determined by measuring the absorbance at 260 and 280 nm. After that, 1 µg total RNA in each group was reversed-transcribed to cDNA and amplified by RT-PCR (Gibco) according to the manufacturer's instructions. For detection of GAL-3 mRNA, the following oligonucleotide primers were used: 5'-ATGATGCGTTATCTGGGTCT-3' and 3'-TATTGGACGGAAACGGAC-5'. The amplification reaction involved denaturation at 94°C for 5 min followed by 35 cycles of denaturation at 94°C for 1 min, annealing for 1 min at 58°C, and extension for 1 min 30 s at 97°C. Expression of GAL-3 by PSCs was also detected by RT-PCR.

### Western blotting

Two groups of SW1990 cells were prepared as mentioned for RT-PCR. SW1990 cells were centrifuged at 600 g for 10 min. The cell pellet was washed twice with ice-cold PBS, resuspended in 150 µL lysis buffer (1% Triton X-100 in 5 mmol/L Tris-HCl, pH 8.0, 15 mmol/L NaCl, 2 mmol/L PMSF). The fragmented cells were scraped and removed into a sterilized Eppendorf tube and conserved on ice for 20 min, then centrifuged at 12000 r/min for 20 min, and unresolved debris was discarded. Proteins were transferred onto PVDF membranes using the wet transfer technique, and the membranes were incubated overnight with monoclonal mouse anti-human-GAL-3 antibodies (R&D) diluted 1:200 in TBS. After 1 h incubation with horseradish peroxidase-labeled secondary antibodies (goat anti-mouse IgM diluted 1:10 000 in TBS), GAL-3 was visualized with the ECL Western Blot Detection Kit (Gibco).

### Cell proliferation test

Cell growth experiments were performed using the 3-(4, 5-methylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay and were reconfirmed by cell cycle analysis,

which was performed by flow cytometry. In the MTT assay, cells were seeded with medium that contained 10% FBS at a density of 6000 cells/well in 96-well plates, grown overnight, washed in PBS, and incubated with serum-free medium for 24 h. Cells were exposed to different concentration of SPSC (5%, 10%, 20% or 40%), supernatants of SW1990 cells (SSW; 5%, 10%, 20% or 40%), GAL-3 monoclonal antibody (GAL-3 MA; 10, 50 or 250 ng/mL, or 1.25 µg/mL), or recombinant human GAL-3 protein (5, 25, 125 or 625 ng/mL). Twenty-four hours later, MTT was added (50 µg/well) for 4 h. Formazan products were solubilized with DMSO, and the optical density was measured at 490 nm.

For flow cytometry, cells cultured in 100-mL culture bottles were washed in PBS and incubated with serum-free medium for 24 h. Cells were then exposed to 40% SPSC (for SW1990 cells), 40% SSW (for PSCs), 1 µg/mL GAL-3 MA or 100 ng/mL recombinant GAL-3 protein for 24 h. Cells were harvested and resuspended in fixation fluid at a density of 10<sup>6</sup>/mL, then 1800 µL trypsin solution was added to the fixation fluid, followed by 1500 µL RNase solution. Several minutes later, 1500 µL propidium iodide solution was added, and 15 min later, cells were filtered, and the cell cycle was detected by FACSCaliber (Becton Dickinson).

### Cell invasion analysis

Invasion assays were carried out following the manufacturer's instructions of cell invasion assay kit (Chemicon International Inc., catalog: ECM550). For the invasion assay, we used a modified Boyden chamber. The chamber had two compartments divided by a polycarbonate filter (8 µm pore size), coated with a reconstituted basement membrane (ECMatrix solution). 3 × 10<sup>5</sup> SW1990 cells were added to each upper compartment, and chemoattractant fluid was added to the lower compartment (Group A: control group, serum-free medium in the upper compartment and medium containing 2% FBS in the lower compartment; Group B, serum-free medium containing 1 µg/mL GAL-3 MA in the upper compartment and medium containing 2% FBS in the lower compartment; Group C, serum-free medium in the upper compartment and medium containing 2% FBS and 40% SPSC in the lower compartment; Group D, serum-free medium containing 1 µg/mL GAL-3 MA in the upper compartment and medium containing 2% FBS and 40% SPSC in the lower compartment). After 48 h incubation, non-invading cells were removed by cotton-tipped swabs and the filters were stained in the staining solution for 20 min and rinsed several times in water and air dried. Three filters were used per group. The number of invading cells was counted in 10 random high-powered fields per filter under a Zeiss microscope.

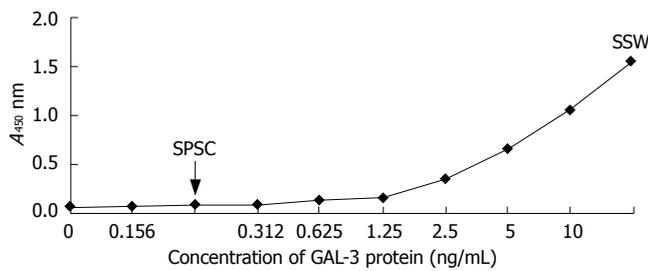

### Statistical analysis

The data were expressed as mean ± SD and compared by ANOVA and the bivariate correlate test. *P* < 0.05 was considered statistically significant.

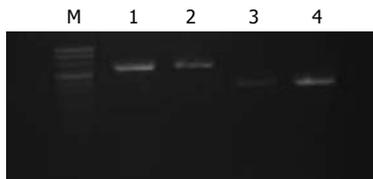

## RESULTS

### GAL-3 in SSWs and SPSCs

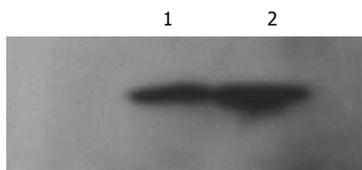

GAL-3 protein in SSWs and SPSCs was measured by

**Figure 1** Concentration of GAL-3 in SPSC and SSW (ELISA).

**Figure 2** GAL-3 mRNA of SW1990 cells detected by RT-PCR. M: Marker; 1: GAPDH of control group; 2: GAPDH after stimulation with 40% SPSC; 3: GAL-3 of control group; 4: GAL-3 after stimulation with 40% SPSC.

**Figure 3** GAL-3 protein of SW1990 cells detected by Western blotting. 1: GAL-3 of control group; 2: GAL-3 after stimulation with 40% SPSC.

ELISA kit (Figure 1). The concentration of GAL-3 in SSWs was above the upper limit of the ELISA kit detection range (10 ng/mL), which meant that SW1990 cells could secrete relatively large amounts of GAL-3 into the extracellular fluid. There was little GAL-3 in SPSCs.

**GAL-3 expression at the mRNA and protein level**

Both RT-PCR (Figure 2) and Western blotting (Figure 3) confirmed that SW1990 cells expressed GAL-3, and the SPSCs up-regulated expression of GAL-3. PSCs showed no expression of GAL-3 according to RT-PCR and Western blotting.

**PSC proliferation**

According to MTT assay (Figure 4), GAL-3 antibody had no effect on the proliferation of PSCs. SSW stimulated PSC proliferation and this was partly inhibited by GAL-3 MA, which suggested that the stimulatory effect of SSW on PSC proliferation was partly mediated *via* GAL-3. This was confirmed by the effect of recombinant GAL-3 protein on PSC proliferation. According to the GAL-3 ELISA kit, the concentration of GAL-3 in SSW was > 10 ng/mL, and in the MTT assay, 5 ng/mL GAL-3 was sufficient to significantly stimulate PSC proliferation, which meant that GAL-3 secreted by pancreatic cells played a role in PSC proliferation in pancreatic cancer.

PSC proliferation detected by flow cytometry is show

**Table 1** PSC cycle detected by flow cytometry (%)

Group	Medium	G0 + G1 fraction	S phase fraction	G2/M fraction	S + G2/M fraction
1 (Control)	Serum-free medium	89.81	1.94	8.25	10.19
2	Serum-free medium containing 40% SSW	89.63	3.23	7.14	10.37
3	Serum-free medium containing 40% SSW and 1 µg/mL GAL-3 antibody	89.42	2.70	7.88	10.58
4	Serum-free medium containing 100 ng/mL GAL-3 protein	87.04	3.68	9.28	12.96

Group 1: PSCs exposed to serum-free medium (control group); Group 2: PSCs exposed to serum-free medium containing 40% SSW; Group 3: PSCs exposed to serum-free medium containing 40% SSW and 1 µg/mL GAL-3 antibody; Group 4: PSCs exposed to serum-free medium containing 100 ng/mL GAL-3 protein.

in Table 1. The S-phase fraction of the control group was the lowest, that of group 4 was the highest, and group 2 had a higher S-phase fraction than group 3. This result was consistent with that of the MTT assay. PSCs are normal cells that grow very slowly, and have high demand on serum during culturing, so the S-phase fraction of all four groups was not very high.

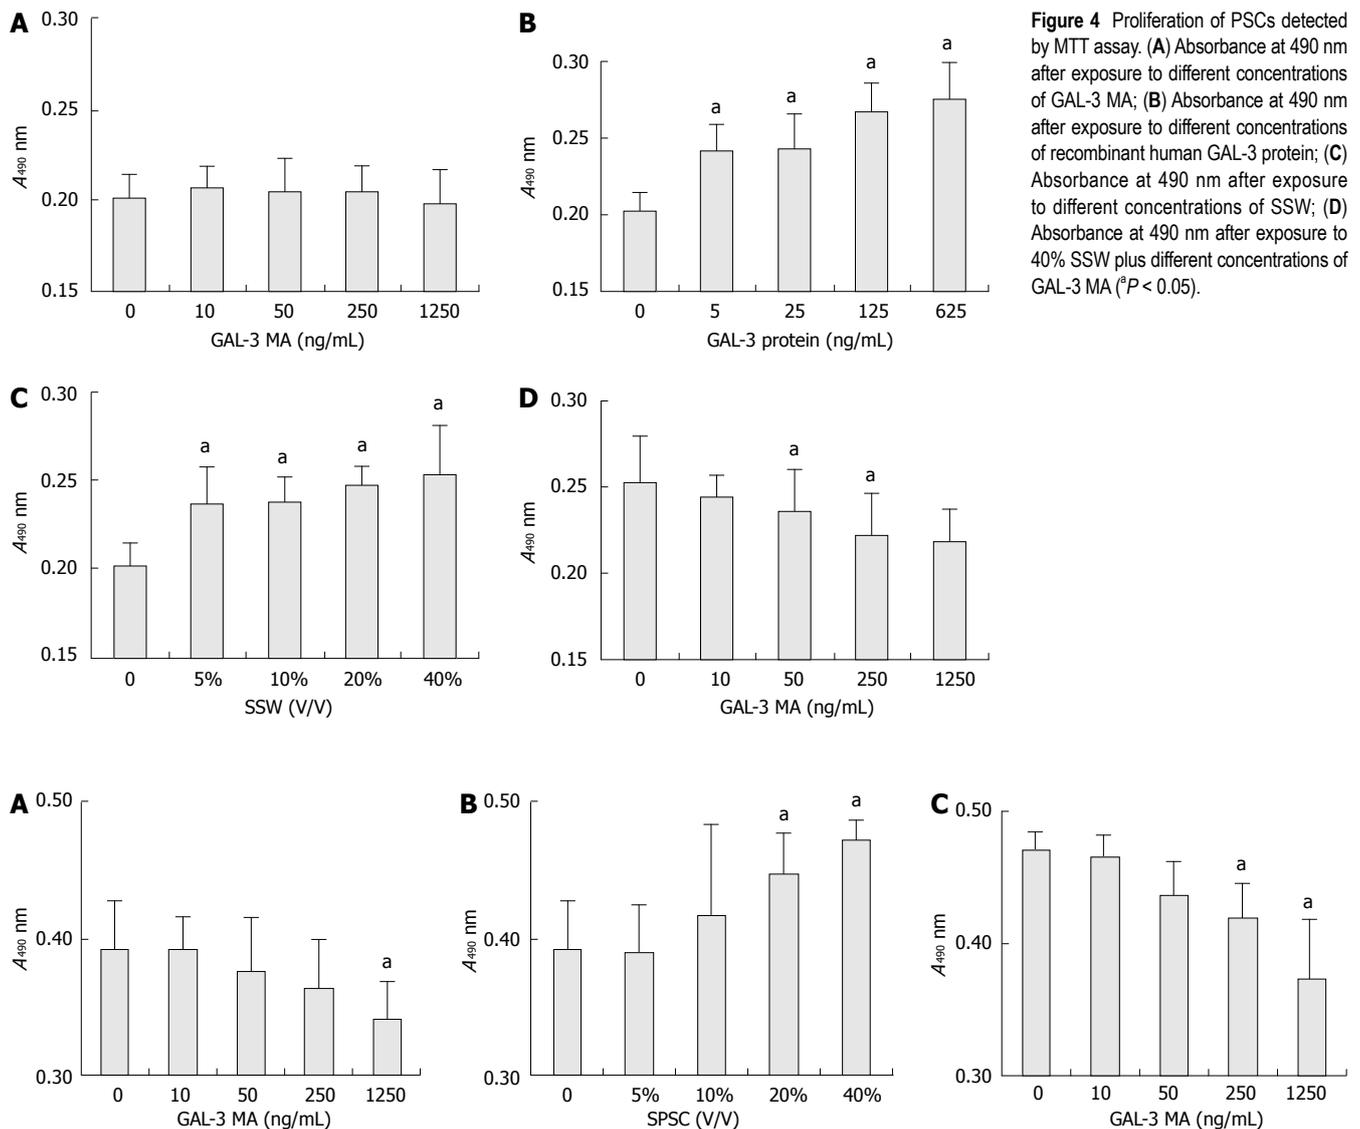

**Proliferation of SW1990 cells**

According to MTT assay (Figure 5), GAL-3 MA inhibited proliferation of SW1990 cells, and this was positively related to antibody concentration, which suggested that GAL-3 protein was involved in the proliferation process of SW1990 cells. SW1990 cells may increase their proliferation by paracrine or autocrine GAL-3 protein. SPSC stimulated proliferation of SW1990 cells. After GAL-3 MA was added to serum-free DMEM containing 40% SPSC, absorbance declined with the increase in antibody concentration, but it was still higher than that in groups that only used GAL-3 MA. There was a significant correlation between the effect of GAL-3 MA and SPSC on absorbance, which suggested that the stimulatory effect of SPSC on proliferation of SW1990 cells was partly related to GAL-3.

SW1990 cell proliferation detected by flow cytometry is show in Table 2. SW1990 cells are quickly proliferating cancer cells, and the S-phase fraction may not properly reflect their proliferation. Therefore, we use the total S phase plus G2/M phase fraction to measure their proliferation. Compared with the control group, GAL-3 MA distinctly inhibited their proliferation, SPSC obviously stimulated proliferation, and GAL-3 MA partly inhibited the SPSC-induced stimulation. This result was consistent with the results of the MTT assay.

**Invasion of SW1990 cells**

The results of cell invasion are shown in Figures 6 and 7. GAL-3 MA had no effect on invasion of SW1990 cells. SPSC stimulated invasion of SW1990 cells and this was partly inhibited by GAL-3 MA, which suggested that the

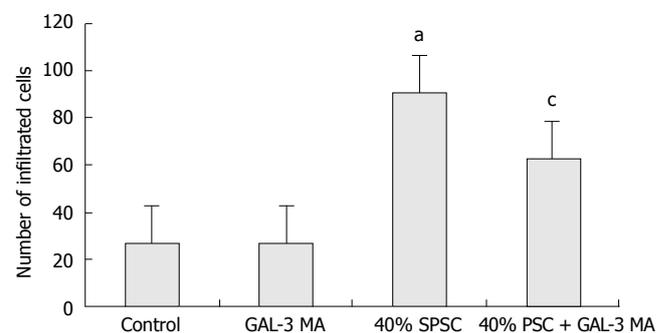

**Figure 4** Proliferation of PSCs detected by MTT assay. (A) Absorbance at 490 nm after exposure to different concentrations of GAL-3 MA; (B) Absorbance at 490 nm after exposure to different concentrations of recombinant human GAL-3 protein; (C) Absorbance at 490 nm after exposure to different concentrations of SSW; (D) Absorbance at 490 nm after exposure to 40% SSW plus different concentrations of GAL-3 MA ( $^aP < 0.05$ ).

**Figure 5** Proliferation of SW1990 cells detected by MTT assay. (A) Absorbance at 490 nm after exposure to different concentrations of GAL-3 MA; (B) Absorbance at 490 nm after exposure to different concentrations of SPSC; (C) Absorbance at 490 nm after exposure to 40% SPSC plus different concentrations of GAL-3 MA ( $^aP < 0.05$ ).

Group	Medium	G0 + G1 fraction	S phase fraction	G2/M fraction	S + G2/M fraction
1 (control)	Serum-free DMEM	71.80%	16.76%	11.45%	28.20%
2	Serum-free DMEM containing 1 $\mu$ g/mL GAL-3 MA	79.28%	13.87%	6.85%	20.72%
3	Serum-free DMEM containing 40% SPSC	62.51%	20.34%	17.15%	37.49%
4	Serum-free DMEM containing 40% SPSC and 1 $\mu$ g/mL GAL-3 MA	67.91%	20.56%	11.53%	32.09%

Group 1: Sw1990 cells exposed to serum-free DMEM (control group); Group 2: SW1990 cells exposed to serum-free DMEM containing 1  $\mu$ g/mL GAL-3 MA; Group 3: PSCs exposed to serum-free DMEM containing 40% SPSC; Group 4: PSCs exposed to serum-free DMEM containing 40% SPSC and 1  $\mu$ g/mL GAL-3 MA.

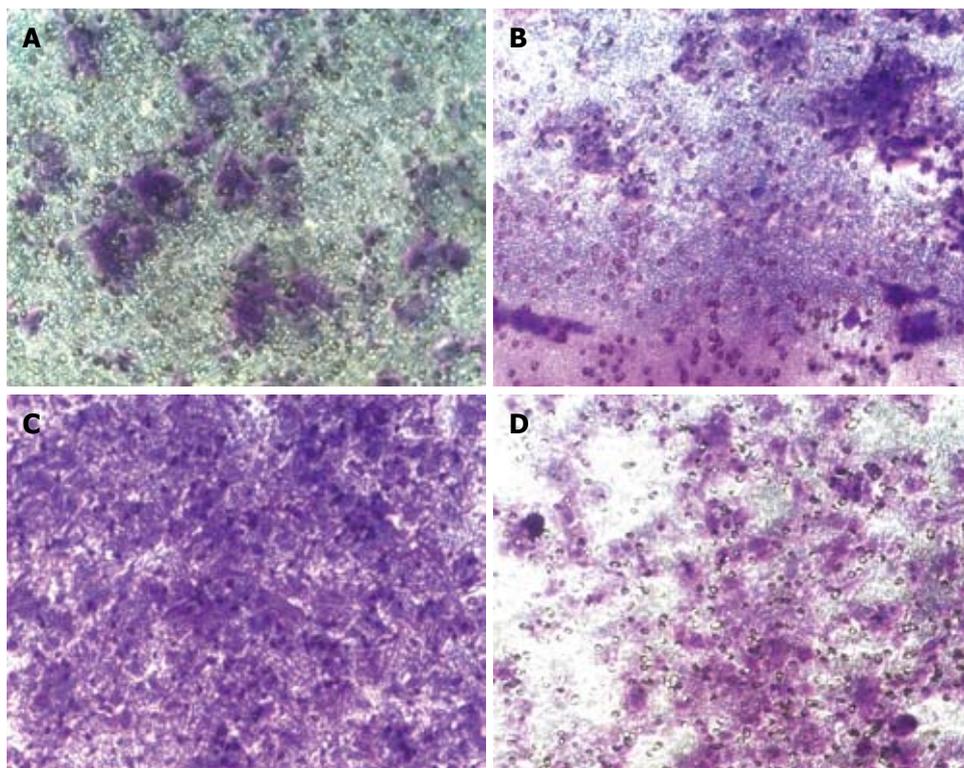

stimulatory effect of SPSC on SW1990 cell invasion was partly mediated *via* GAL-3 expressed on the cells.

**Figure 6** Number of infiltrating cells in each group.  $^aP < 0.05$  vs control;  $^cP < 0.05$  vs 40% SPSC.

## DISCUSSION

Our study confirmed that human pancreatic cancer cell line SW1990 expressed and secreted GAL-3 protein, and that GAL-3 MA inhibited proliferation of SW1990 cells, which suggests that cancer cells such as SW1990 can stimulate their proliferation by autocrine or paracrine GAL-3.

**Figure 7** Infiltrating SW1990 cells. (A) Control group. (B) GAL-3 MA group. (C) SPSC group. (D) SPSC plus GAL-3 MA group. Compared with the control group, GAL-3 antibody had no significant effect on invasion of SW1990 cells. SPSC stimulated the invasion process of SW1990 cells, and this stimulation was partly inhibited by GAL-3 antibody.

However, more studies should be done to clarify this and to establish the signaling pathway through which GAL-3 stimulates proliferation of cancer cells.

Ductal adenocarcinoma of the pancreas is composed of infiltrating cancer cells surrounded by a predominant dense fibroblastic stroma. Previous studies have shown that the fibrotic ECM is mainly produced and secreted by PSCs, and pancreatic cancer cells activate PSCs *via* TGF- $\beta$  and other cytokines such as basic fibroblast growth factor to increase production of ECM<sup>[8]</sup>. Our study, including MTT assay and flow cytometry, confirmed that pancreatic cancer cells stimulated proliferation of PSCs *via* GAL-3, but further studies should be performed to elucidate the stimulation mechanism of GAL-3 on the proliferation of PSCs. Our study also confirmed that PSCs, through interaction with GAL-3, stimulated pancreatic cancer cells to proliferate, but the exact mechanism needs to be further investigated. Our study confirmed that pancreatic cancer cells and PSCs stimulated proliferation of each other. This may be one of the important reasons for the rapid progression of pancreatic cancer, and preventing this counter-stimulation may be very important in slowing the progression of the disease. GAL-3 is involved in the counter-stimulation between pancreatic cancer cells and PSCs, and this may help us to establish new methods for treating pancreatic cancer.

It has been shown by many studies that GAL-3 plays an important role in the interaction between cells and ECM, and this interaction is very important for carcinoma infiltration and metastasis. Activated PSCs can produce and secrete a lot of ECM, including collagen, fibronectin and laminin. Our infiltration study confirmed that the SPSC stimulated the infiltration of pancreatic cancer cells through interaction with GAL-3, which suggests that PSCs

play an important role in the early infiltration of pancreatic cancer. Since GAL-3 stimulated the proliferation of pancreatic cancer cells and PSCs, and was involved in neoplastic and ECM interaction, we suggest that it plays an important role in the infiltration and metastasis of pancreatic cancer.

## COMMENTS

### Background

Bachem *et al*<sup>[9]</sup> discovered pancreatic stellate cells (PSCs) in 1998. After that, several studies showed that there are activated PSCs around pancreatic cancer tissues, pancreatic cancer cells can activate PSCs, and activated PSCs can produce a lot of extracellular matrix (ECM), which lead to the desmoplasia reaction in pancreatic cancer. Galectin-3 (GAL-3) is a member of the  $\beta$ -galactoside-binding protein family which recognizes the *N*-acetylglucosamine structure of various glycoconjugates. Many studies have shown that GAL-3 plays a role in carcinoma proliferation, infiltration and metastasis. One study has also shown that pancreatic cancer may express GAL-3, but the role of GAL-3 in pancreatic cancer has not been investigated.

### Research frontiers

Previous studies have shown that pancreatic cancer cells can activate PSCs *via* cytokines such as TGF- $\beta$  and platelet-derived growth factor, which are expressed by cancer cells, but few have discussed the role of activated PSCs in the progression of pancreatic cancer. Bachem *et al*<sup>[9]</sup> have shown that GAL-1 can activate PSCs, and several others have shown that Gal-3 activates HSCs, but up till now, no study on the effect of GAL-3 on PSCs has been published.

### Innovations and breakthroughs

This study showed that pancreatic cancer cells activated PSCs *via* GAL-3 expressed by cancer cells besides TGF- $\beta$  and PDGF. It showed that activated PSCs promoted progress of pancreatic cancer by stimulating the proliferation and invasion of cancer cells. This study showed that there were complicated interactions between pancreatic cancer cells and PSCs. It also suggests that ECM and polysaccharides might play a role in the progress of pancreatic cancer, since GAL-3 is a lectin that recognizes the *N*-acetylglucosamine structure of various glycoconjugates.

## Applications

This study provides a basis for future studies on the mechanisms of how GAL-3 activates PSCs, and how PSCs promote the proliferation and invasion of pancreatic cancer. It also provides a basis for future studies on treating pancreatic cancer through inhibition of GAL-3.

## Terminology

SW1990 is a commonly used human pancreatic cancer cell line in pancreatic cancer research, which was first derived from spleen metastasis of a grade 2 ductal pancreatic cancer in the early 1980s. PSCs are vitamin A-storage cells that resemble HSCs in the healthy pancreas and comprise approximately 4% of all pancreatic cells; they show a periacinar distribution. GAL-3 is an endogenous  $\beta$ -galactoside-binding protein that is expressed widely in normal and neoplastic cells.

## Peer review

This was a well-executed study. It explored the role of GAL-3 in the proliferation and invasion of pancreatic cancer cells *in vitro*, and showed that GAL-3 may play a role in the progression of pancreatic cancer.

*freudenreichii* ssp. *shermanii* JS (PJS) or a placebo drink for 3 wk. Venous blood and saliva samples were taken at baseline and on d 1, 7 and 21. Fecal samples were collected at baseline and at the end of intervention.

**RESULTS:** The serum hsCRP expressed as the median AUC<sub>0-21</sub> (minus baseline) was 0.018 mg/L in the placebo group, -0.240 mg/L in the LGG group, 0.090 mg/L in the Bb12 group and -0.085 mg/L in the PJS group ( $P = 0.014$ ). *In vitro* production of TNF- $\alpha$  from *in vitro* cultured peripheral blood mononuclear cells (PBMC) was significantly lower in subjects receiving LGG vs placebo. IL-2 production from PBMC in the Bb12 group was significantly lower compared with the other groups.

**CONCLUSION:** In conclusion, probiotic bacteria have strain-specific anti-inflammatory effects in healthy adults.

### Abstract

**AIM:** To evaluate the effects of three potentially anti-inflammatory probiotic bacteria from three different genera on immune variables in healthy adults in a clinical setting based on previous *in vitro* characterization of cytokine responses.

**METHODS:** A total of 62 volunteers participated in this randomized, double-blind and placebo-controlled parallel group intervention study. The volunteers were randomized to receive a milk-based drink containing either *Lactobacillus rhamnosus* GG (LGG), *Bifidobacterium animalis* ssp. *lactis* Bb12 (Bb12), or *Propionibacterium*

### INTRODUCTION

Probiotics are defined as living microorganisms that have beneficial effects on human health<sup>[1]</sup>. The immunomodulatory effects of probiotics have mostly been studied in certain disease conditions, such as allergies<sup>[2]</sup> and inflammatory diseases<sup>[3,4]</sup>, though the general, healthy population mostly consumes probiotics. The immunomodulatory effects of probiotics in healthy populations have not been fully established and only a few randomized, double blind, placebo-controlled studies have addressed this question<sup>[5-9]</sup>. Also, there are few studies where the effects of different

probiotic bacteria have been compared within the same clinical setting. Isolauri *et al*<sup>[10]</sup> and Viljanen *et al*<sup>[11]</sup> have compared the effects of two different probiotics or a probiotic mixture with placebo in allergic infants. Schiffrin *et al*<sup>[12]</sup> and Gill *et al*<sup>[13]</sup> evaluated the effects of two different probiotics in healthy adults, but these studies did not have a placebo group. Efforts trying to compare the *in vitro* results of one probiotic to its results in an *in vivo* setting are even more scarce and are at the moment limited to comparisons between *in vitro* and experimental animal studies<sup>[14-16]</sup>.

In our previous studies, we have characterized the capacity of potentially probiotic bacteria to induce cytokine production in human leukocyte cell culture and found that probiotic bacteria direct immune responses to either the Th1 type or the anti-inflammatory direction in a manner specific to the bacterial genera<sup>[17]</sup>. Based on these findings we selected probiotic bacteria from three different genera for the present study and compared their effects on immune variables in healthy adults in a 3-wk intervention trial.

## MATERIALS AND METHODS

### Subjects

The subjects were healthy adults recruited by an advertisement in the Helsinki area. The inclusion criteria were to be healthy (no chronic illnesses), to exercise regularly (at least three times per week), and to not be participating in any other clinical trials. The exclusion criteria was comprised of milk allergies (due to the nature of the study products), use of antibiotics during the two months before the study, acute gastrointestinal disorders during the two months before the study, gastrointestinal diseases and related medications, pregnancy, and lactation. Before entering the study, the subjects gave their written informed consent. The study protocol was approved by the Ethics Committee of the Hospital District of Helsinki and Uusimaa.

A total of 68 subjects were recruited for the study. Six subjects withdrew from the study during the run-in period and were not included in the analysis. The mean age for the subjects was 44 years (range 23-58) and their mean BMI was 24 kg/m<sup>2</sup> (range 18-30). Of these 62 subjects (45 females, 17 males), one subject withdrew from the study due to a back injury after two study visits and one subject due to an antibiotic treatment after four study visits. These two subjects were included in the statistical analysis.

### Study design and intervention

The study was a randomized, double-blind and placebo-controlled parallel group intervention study. Prior to the intervention period, there was a 3-wk run-in period during which no probiotic-containing products were allowed. Thereafter the subjects received either *Lactobacillus rhamnosus* GG (*n* = 13), *Bifidobacterium animalis* ssp. *lactis* Bb12 (*n* = 16), *Propionibacterium freudenreichii* ssp. *shermanii* JS (*n* = 17) or placebo (*n* = 16) drink for 3 wk. After the intervention period, subjects were followed up for 3 wk without any study drink. A list of probiotic-containing products was given to the subjects, and they were asked

not to consume any other probiotic-containing products at any time during the study.

### Study products

The subjects were advised to consume a 250 mL milk-based fruit drink daily for 3 wk containing either: *L. rhamnosus* GG (ATCC 53103) (LGG) bacteria, on average  $6.2 \times 10^7$  cfu/mL (daily dose of  $1.6 \times 10^{10}$  cfu); *B. animalis* ssp. *lactis* Bb12 (Bb12) bacteria,  $1.4 \times 10^8$  cfu/mL (daily dose of  $3.5 \times 10^{10}$  cfu); *P. freudenreichii* ssp. *shermanii* JS (DSM 7067) (PJS) bacteria,  $1.3 \times 10^8$  cfu/mL (daily dose of  $3.3 \times 10^{10}$  cfu); or a placebo drink without any probiotic bacteria. The subjects consumed the study drinks throughout the 3-wk intervention period after the baseline blood sampling. The amount of probiotic bacteria in the study drinks was measured right after packaging and after 3 wk. The appearance and taste of the study drinks were the same.

### Blood samples

Venous blood samples from the antecubital vein were taken at baseline, on 1, 7 and 21 d, and after the 3-wk follow-up period after an overnight fast. The samples were taken into standard serum tubes and EDTA tubes, centrifuged, and the plasma/serum was collected and stored at -20°C for further analyses. Three EDTA tubes were used in the purification of PBMC.

**Blood cells and immunoglobulins:** Blood cells (leukocytes, monocytes, and lymphocytes) from all time points were determined using an electronic counter (Coulter MAXM Hematology Analyzer, Beckman Coulter, Fullerton, CA, USA). Immunoglobulins (IgA, IgG and IgM) from all time points were measured by immunoturbidimetric method with Tina-quant Roche/Hitachi System reagent using a Roche Hitachi 912 analyzer (Roche Diagnostics GmbH, Mannheim, Germany).

**Highly sensitive C-reactive protein:** Serum levels of C-reactive protein (CRP) were measured at all time points by a highly sensitive particle-enhanced immunoturbidimetric CRP (hsCRP) assay using a Tina-quant C-reactive protein (latex) high sensitive reagent and a Roche Hitachi 912 analyzer (Roche Diagnostics GmbH) with a detection limit of 0.04 mg/L.

**Cytokine levels from serum:** Baseline and 21 d cytokine levels (TNF- $\alpha$ , IL-6, IFN- $\gamma$  and IL-10) in serum were determined using Quantikine HS, Human TNF- $\alpha$ /TNFSF1A (Catalog Number HSTA00D), IL-6 (HS600B), IFN- $\gamma$  (DIF50) and IL-10 (HS100B) immunoassays purchased from R&D Systems (Minneapolis MN, USA). These assays were carried out according to the manufacturer's instructions. The detection limit was 0.5 pg/mL for TNF- $\alpha$ , 0.16 pg/mL for IL-6, 15.6 pg/mL for IFN- $\gamma$  and 0.78 pg/mL for IL-10. For TNF- $\alpha$ , 94% of the samples were over the detection limit, and for IL-6, 89%. For statistical analyses, a detection limit divided by two was given as a value for those samples under the detection limit. None of the IFN- $\gamma$  samples and only 39%

of the IL-10 samples was over the detection limit and were therefore not further analyzed.

### **PBMC cell culture**

**Purification:** Human PBMC were purified by density gradient centrifugation over a Ficoll-Paque gradient (Amersham-Pharmacia Biotech, Uppsala, Sweden), as described previously<sup>[18]</sup>, from freshly collected EDTA blood on the study days (baseline, d 1, 7 and 21 wk and 3 wk after intervention). After washing, the cells were resuspended in RPMI 1640 medium (Sigma, USA) containing 10% heat-inactivated fetal calf serum (FCS) (Integro, Zaandam, Holland) and supplemented with 2 mmol/L L-glutamine (Sigma), 100 U/mL penicillin and 100 µg/mL streptomycin (Gibco BRL, Paisley, Scotland). In stimulation experiments, purified leukocytes ( $2 \times 10^6$  cells/mL) were incubated with stimulants in a final volume of one ml in 24-well plates (Nunc, Roskilde, Denmark) for 24 h in 5% CO<sub>2</sub> at 37°C.

**Stimulations:** During the stimulation experiments, the PBMC were maintained in RPMI-1640 medium containing 10% FCS. PBMC were left unstimulated or were stimulated with one of three different stimulants, simulating Gram-positive bacteria, a Gram-negative bacteria or a virus. Live Group A streptococci *S. pyogenes* serotype T1M1 obtained from the National Public Health Institute, Helsinki, Finland, grown as previously described<sup>[19]</sup>, was used as a Gram-positive bacteria at 1:1 host-cell:bacteria ratio; lipopolysaccharide (LPS) from *E. coli* serotype 0111:B4 (L-3024, Sigma) was used as a model for Gram-negative bacteria at a concentration of 100 ng/mL; and Influenza A H3N2 virus (A/Beijing/353/89) was used to infect cells at a multiplicity of infection of 5. Cell culture supernatants were collected individually at the 24 h time point and stored at -20°C before analysis.

**Cytokine levels from cell culture supernatants of stimulated PBMC:** Cytokine levels (TNF-α, IFN-γ, IL-1β, IL-2, IL-4, IL-5, IL-6, IL-8, IL-10 and IL-12p70) in cell culture supernatants from each time point (baseline, 1 d, 7 d, 21 d and 3 wk after intervention) were determined using the FlowCytomix human Th1/Th2 10 plex kit II (BMS716FFCE) from Bender MedSystems (Vienna, Austria) according to manufacturer's instructions. The detection limit was 4.5 pg/mL for IL-1β, 8.9 pg/mL for IL-2, 6.4 pg/mL for IL-4, 5.3 pg/mL for IL-5, 4.7 pg/mL for IL-6, 6.4 pg/mL for IL-8, 6.9 pg/mL for IL-10, 7.9 pg/mL for TNF-α, 9.7 pg/mL for IL-12p70 and 7.0 pg/mL for IFN-γ. Only those cytokines from which over 80% of the samples were above the detection limit were statistically analyzed. Therefore, all unstimulated samples, IL-4 and IL-5 in all stimulated samples, and IFN-γ in LPS stimulated samples were not included in further analyses. For statistical analyses, samples under the detection limit were replaced by the values obtained by dividing the detection limit by two.

### **Saliva samples and secretory IgA**

An unstimulated saliva sample was taken at every visit (at baseline, d 1, 7 and 21 and 3 wk after the intervention)

after the blood sampling. The saliva samples were placed in Eppendorf tubes, chilled, and stored at -20°C until secretory IgA was analyzed. SIgA from saliva was determined with an ELISA assay (catalog number K8870) purchased from Gentaur (Brussels, Belgium) according to the manufacturers' instructions.

### **Fecal samples and microbiological analyses**

The fecal samples were collected at home at baseline and at the end of the 3-wk intervention period. Immediately after the collection the subjects were asked to deep-freeze (-20°C) the samples at home. They were subsequently transported to the study center on the morning of the study day and the samples were immediately put on dry ice and stored at -70°C until analysis. The amounts of the probiotic strains *L. rhamnosus* GG, *B. animalis* ssp. *lactis* Bb12 and *P. freudenreichii* ssp. *shermanii* JS in the fecal samples were analyzed with a previously described real-time quantitative PCR method<sup>[20]</sup>.

### **Study diary**

Subjects were asked to fill in a structured study diary throughout the study. The study diary included questions about the use of the study product, the presence of any symptoms of respiratory infection, gastrointestinal symptoms or any other symptoms, the amount of exercise, and the use of any medication. No respiratory tract infections or major symptoms were recorded by the subjects during the study. The amount of weekly exercise carried out by the study subjects remained the same throughout the study.

### **Outcome measures and statistical analysis**

The intention-to-treat population (all randomized patients who took at least one dose of the study product) was included in the analysis. The last-observation-carried-forward (LOCF) approach was used for missing data and for subjects who withdrew early.

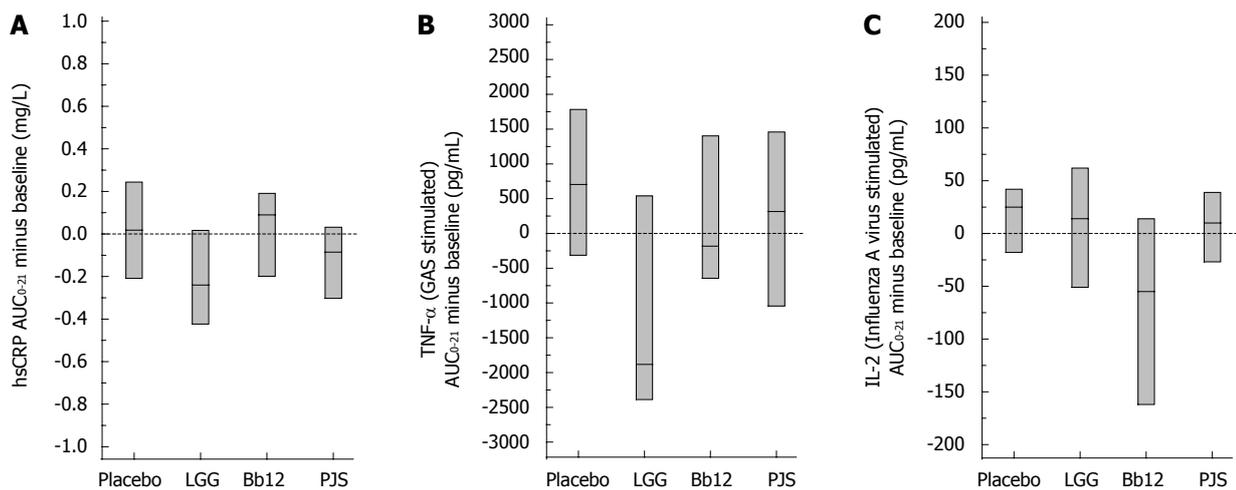

The main outcome measures were the serum hsCRP levels and the cytokines produced by PBMCs. The responses for these outcomes were calculated as the area under the curve from the 0, 1 d, 7 d and 21 d, subtracted by the baseline value (AUC<sub>0-21</sub> minus baseline).

Data is presented as mean with standard deviation (SD) or as median with interquartile range (IQR). The differences between the groups were tested using the Kruskal-Wallis test or median regression analysis with Holm's adjustment for pair wise comparisons. A *P*-value below 0.05 was regarded as statistically significant, but no adjustment was made for multiple testing.

## **RESULTS**

### **Highly sensitive CRP**

In order to study the effect of probiotic bacteria on inflammatory markers, we determined serum CRP levels at different time points during the intervention. The median AUC<sub>0-21</sub> minus baseline (IQR) for hsCRP was 0.018 (-0.209-0.244) mg/L in the placebo group, -0.240 (-0.424-0.017) mg/L in the LGG group, 0.090 (-0.199-0.191) mg/L in the Bb12 group and -0.085 (-0.303-0.032) mg/L

**Figure 1** The median AUC<sub>0-21</sub> (minus baseline) with IQR for serum highly sensitive CRP (hsCRP) levels (A), for *Streptococcus pyogenes* (GAS)-stimulated TNF- $\alpha$  production from peripheral blood mononuclear cells (B) and for Influenza A virus-stimulated IL-2 production from peripheral blood mononuclear cells (C) during the 3-wk intervention period in healthy adults ( $n = 62$ ). LGG: *Lactobacillus rhamnosus* GG; Bb12: *Bifidobacterium animalis* ssp. lactis Bb12; PJS: *Propionibacterium freudenreichii* ssp. *shermanii* JS.

**Table 1** Counts of cells of innate and adaptive immunity ( $10^9/L$ ) and levels of immunoglobulins (g/L) in serum and secretory IgA (g/mL) in saliva in healthy adults ( $n = 62$ ) at baseline presented as median (IQR)

	Placebo ( $n = 16$ )	LGG ( $n = 13$ )	Bb12 ( $n = 16$ )	PJS ( $n = 17$ )	<i>P</i> value <sup>1</sup>

<sup>1</sup>Kruskal-Wallis test with Monte Carlo *P* values. IQR: Interquartile range.

in the PJS group ( $P = 0.014$ ); a statistically significant difference was observed between LGG and Bb12 group by pair wise comparisons. In the LGG and PJS groups, hsCRP appeared to be at a lower level during the 3-wk intervention period compared with the Bb12 and placebo groups (Figure 1A).

### Serum cytokines

The baseline values for pro-inflammatory cytokine TNF- $\alpha$  in serum were 1.2 pg/mL in the placebo group, 1.0 pg/mL in the LGG, 1.0 pg/mL in the Bb12 and 0.8 pg/mL in the PJS. The change (median with IQR) from baseline to the end of 3-wk intervention for TNF- $\alpha$  in these study groups was 0.1 (-0.1-0.3) pg/mL, 0.1 (-0.02-0.2) pg/mL, 0.3 (-0.04-0.4) pg/mL and 0.0 (-0.1-0.3) pg/mL, respectively ( $P = 0.44$ ).

The baseline values for pro-inflammatory cytokine IL-6 were 0.3 pg/mL in the placebo group, 0.6 pg/mL in the LGG, 0.3 pg/mL in the Bb12 and 0.4 pg/mL in the PJS. The change (median with IQR) from baseline to the end of 3-wk intervention for IL-6 in these study groups was -0.5 (-0.6-0.0) pg/mL, -0.2 (-0.3-0.2) pg/mL, 0.1 (-0.3-0.3)

pg/mL and -0.04 (-0.3-0.1) pg/mL, respectively ( $P = 0.26$ ). There were no statistically significant differences between the study groups with respect to serum cytokine levels.

### Blood cells and immunoglobulins

Baseline values for leukocytes, monocytes, neutrophils, basophils, lymphocytes and immunoglobulins are presented in Table 1. There were no differences in these variables between the groups during the intervention.

### Cytokines produced by PBMC

We also determined whether the use of probiotic bacteria has an effect on the overall responsiveness of PBMC to various microbial stimuli in *in vitro* cultured cells. The microbe-induced cytokine production by PBMC is presented in Table 2. *S. pyogenes*-stimulated production of pro-inflammatory cytokine TNF- $\alpha$  was significantly different between the groups ( $P = 0.025$ ); a statistically significant difference was observed between LGG and placebo groups by pair wise comparisons (Figure 1B). Influenza A virus-stimulated production of Th1 cytokine IL-2 was significantly different between the groups ( $P <$

0.001); the statistically significant difference was observed between Bb12 and other groups (Figure 1C). There were no significant differences between the study groups with respect to the other cytokines produced by PBMC.

### Detection of probiotic strains from feces

In order to determine whether the ingested bacteria could also be found in the fecal samples, the bacterial DNA levels were determined at the baseline and after the 3-wk intervention. The baseline levels for all three studied probiotics were low in fecal samples (Table 3). Despite the 3-wk run-in with probiotic restriction, a detectable level of the probiotic strains, especially LGG, was harbored in some of the subjects at baseline before the probiotic ingestion (Table 3). The amount of studied probiotic in feces in a given probiotic intervention group increased significantly from the baseline values during the intervention ( $P < 0.001$ ). In the placebo group, the levels of different probiotics in feces remained low during the whole intervention period.

### Follow-up samples

Three weeks after the intervention period, follow-up samples were taken. The levels for blood cells, immunoglobulins,

hsCRP and cytokines produced by PBMC were at the baseline levels.

## DISCUSSION

In the present study, we studied the *in vivo* effects of three probiotic bacteria from three different genera on immune variables in healthy adults in a randomized, double-blind, placebo-controlled setting. The selection of these probiotics was based on our previous findings showing that, in human leukocyte cell cultures, probiotic bacteria readily induce cytokine production in PBMCs, but different bacteria are able to direct immune responses to either the Th1 type or the anti-inflammatory side in a genera-specific manner<sup>[17]</sup>. Based on the cell culture results, two potentially anti-inflammatory strains (a *Bifidobacterium* and a *Propionibacterium* strain) and a well-studied *L. rhammosus* GG strain<sup>[21]</sup> as a reference probiotic were selected. Our data indicates that *in vivo* probiotics differ in their ability to induce anti-inflammatory and cytokine responses and may have a weak, genera-specific anti-inflammatory effect reflected as a decrease in serum hsCRP levels in healthy adults. In addition, we observed

**Table 3** Detection of individual probiotic genomic DNA from fecal samples by quantitative PCR at baseline and after the 3-wk probiotic intervention in healthy adults ( $n = 62$ )

that, during the intervention, *S. pyogenes*-induced TNF- $\alpha$  responses and influenza A virus-induced IL-2 responses in *in vitro* cultured PBMC were reduced, indicating a clear anti-inflammatory potential of some probiotic bacteria.

To our knowledge, this is the first study to show that probiotics may reduce serum hsCRP levels in healthy adults in a randomized, double-blind, placebo-controlled setting. It appeared that in the *L. rhamnosus* GG and *P. freudenreichii* ssp. *shermanii* JS treated groups, the hsCRP level tended to be lower during the intervention, whereas in *B. animalis* ssp. *lactis* Bb12 and the placebo groups, serum hsCRP levels remained unchanged. CRP is a sensitive marker of inflammation<sup>[22]</sup> and provides an easy way to measure the anti-inflammatory potential of probiotics and other biological or pharmacological substances. This result was somewhat contradictory to our previous findings in leukocyte cell culture<sup>[17]</sup>, where *B. animalis* ssp. *lactis* Bb12 and *P. freudenreichii* ssp. *shermanii* JS were both good inducers of anti-inflammatory cytokines, whereas *L. rhamnosus* GG was a rather poor inducer of any cytokine. Previously, the effect of probiotics on CRP has only been studied in immunocompromised patients<sup>[23-27]</sup>, allergic children<sup>[28]</sup> and patients suffering from rheumatoid arthritis<sup>[29]</sup>. In immunocompromised patients, a combination of *L. casei*, *B. breve* and prebiotic galactooligosaccharides<sup>[26]</sup> and *B. longum*<sup>[30]</sup> have reduced serum CRP levels and also resulted in improvement in the overall clinical appearance of chronic inflammation<sup>[30]</sup>. In contrast to the studies above and to our results in the present study, *Lactobacillus rhamnosus* GG increased serum hsCRP levels compared to placebo in infants with IgE-associated atopic eczema dermatitis syndrome<sup>[28]</sup>. However, *L. rhamnosus* GG had no effect on serum CRP levels in patients with rheumatoid arthritis<sup>[29]</sup>. It is of interest that a combination of four probiotic bacteria (*L. rhamnosus* GG, *L. rhamnosus* Lc705, *B. breve* 99, *P. freudenreichii* ssp. *shermanii* JS) did not have an effect on sensitive CRP<sup>[28]</sup> in the same clinical setting with allergic children. In immunocompromised patients undergoing surgical procedures, *L. plantarum* 299V<sup>[23,25]</sup> or a combination of *L. acidophilus* La5, *B. animalis* ssp. *lactis* Bb12, *S. thermophilus* and *L. bulgaricus*<sup>[24,27]</sup> did not change serum CRP concentrations, either. It appears that the

effect of probiotics on CRP is controversial, and it is very difficult to compare the effects due to the differences in the measurement technique (highly sensitive *vs* normal CRP measurement), the different patient materials (healthy *vs* various diseases) and the different probiotic strains that have been used. It seems that age, the immunological status of the individual and the probiotic strain used in the study has a great impact on the immunomodulatory effects. Probiotics may have a strain-specific ability to lower serum CRP levels, thus having anti-inflammatory effects in apparently healthy adults and in patients suffering from different inflammatory conditions. In allergic patients, however, probiotics seem to induce a low-grade inflammatory response, as evidenced by increased serum CRP levels, and thus the treatment may have a beneficial effect on the host Th1/Th2 balance.

We found that *L. rhamnosus* GG was also able to reduce pro-inflammatory TNF- $\alpha$  production in the Gram-positive bacteria-stimulated PBMC. TNF- $\alpha$  is secreted by the monocytes, and it acts as an inflammatory mediator activating many types of cells. In our previous work with leukocyte cell culture, *L. rhamnosus* GG was found to be a relatively poor inducer of TNF- $\alpha$ , IL-12, IFN- $\gamma$  and IL-10<sup>[17]</sup>. Our present findings are supported by another clinical study carried out in healthy adults showing that *L. rhamnosus* GG treatment leads to decreased TNF- $\alpha$  production in PBMC<sup>[31]</sup>. In addition, when the cytokine expression pattern in the small bowel mucosa was studied, it was found that *L. rhamnosus* GG induced the expression of genes involved in immune response and inflammation (TGF-beta and TNF family members, cytokines, nitric oxide synthase 1, defensin alpha 1)<sup>[32]</sup>. Schultz and coworkers<sup>[31]</sup> observed a decreased IL-6 and IFN- $\gamma$  and an increased IL-10 and IL-4 production in PBMC obtained from *L. rhamnosus* GG treated individuals. We, however, did not find any significant changes in bacteria-induced production of cytokines apart from the TNF- $\alpha$  in the PBMC cultures of our study subjects after *L. rhamnosus* GG treatment. In another study with healthy adults and with patients with Crohn's disease, *L. rhamnosus* GG decreased the production of IL-2, IL-10 and IL-4 from PBMCs sorted as naive and memory T cells<sup>[33]</sup>. It seems that *L. rhamnosus* GG has a role in modulating the cytokine responses and may possess an

anti-inflammatory potential in healthy individuals.

In the present study, we also found that *B. animalis* ssp. *lactis* Bb-12 decreased the T lymphocyte growth factor IL-2 in the influenza-virus-stimulated PBMC, indicating an anti-inflammatory effect, which is consistent with our previous findings in human leukocyte cell culture<sup>[17]</sup>. Our finding is a new one since, in healthy adults, a combination of *B. animalis* ssp. *lactis* Bb-12 and *L. paracasei* ssp. *paracasei* CRL-431 had no effect in *in vitro*-stimulated blood cytokine production<sup>[7]</sup>. IL-2 is a very important cytokine in viral infections and inflammatory responses since it activates NK cells and induces activation and proliferation of T lymphocytes. Therefore, IL-2 production might be an important factor for a probiotic fighting against respiratory tract infections. Based on our present results, the *Bifidobacterium* strain might not be the most optimal strain against respiratory infections. Indeed, it is mainly probiotic strains from *Lactobacillus* genera-*L. rhamnosus* GG<sup>[34]</sup>, *L. casei* DN-114001<sup>[35]</sup>, a combination of *L. gasseri* PA 16/8, *B. longum* SP 07/3 and *B. bifidum* MF 20/5<sup>[5-6]</sup>, and *L. reuteri*<sup>[36]</sup>-that have reduced the incidence or symptoms of common cold or respiratory tract infections. However, the immunomodulatory effects underlying the results observed in these studies have not been fully elucidated.

In conclusion, it appears that probiotics have an anti-inflammatory potential seen as a decrease in serum CRP levels and as a reduction in bacteria-induced production of pro-inflammatory cytokines in PBMC in healthy adults. However, all of the markers were in the normal range, and therefore the real impact of probiotics as anti-inflammatory substances warrants further evaluation in studies during inflammatory processes and with individuals suffering from various types of inflammatory or autoimmune diseases.

## ACKNOWLEDGMENTS

We would like to thank Hanna Valtonen and Mari Aaltonen for their expert technical assistance in the PBMC isolations, Juha Laukonmaa for technical assistance in qPCR analysis and Sirkka Kokkonen for manufacturing the study products.

## COMMENTS

### Background

Probiotics have been mostly studied in the prevention and treatment of different gastrointestinal diseases and allergy. Probiotic products, however, are usually consumed by the general, healthy population but not much is known what kind of effects they have on immune system in healthy adults.

### Research frontiers

It is not fully clarified how probiotics exert their health effects, but one of the most probable action mechanisms is the modulation of immune responses *via* gut mucosal immune system.

### Innovations and breakthroughs

In the present study the immunomodulatory effects of probiotics were studied in healthy adults. Probiotic bacteria had strain-specific anti-inflammatory effects reflected in reduced sensitive C-reactive protein, which is a new finding, and decreased proinflammatory cytokine production in peripheral blood mononuclear cells (PBMC).

### Applications

Understanding of the specific immunomodulatory effects of probiotics may help in

designing future probiotics for targeted purposes. As the effects in the present study were investigated in healthy adults, the real impact of probiotics on inflammatory variables warrants further evaluation during inflammatory processes and with individuals suffering from various types of inflammatory or autoimmune diseases.

### Peer review

The paper by Kekkonen and co-workers investigated the effects of three probiotic bacteria on immune variables in healthy adults. They observed strain-specific anti-inflammatory effects for distinct bacteria. Overall this paper is interesting and it has clearly stated aims, the sample size and the overall designs of the study are fair, the results adequate to provide experimental evidence and to support valid conclusions. As placebo per se could cause effects on immune response, a further control group, formed by healthy subjects, would be advisable in order to analyze the basic fluctuation of all the parameters studied.

### Abstract

**AIM:** To summarize the effects of laparoscopic ethanol injection and radiofrequency ablation (L-EI-RFA), thoracoscopic (T-EI-RFA) and open-surgery assisted EI-RFA (O-EI-RFA) under general anesthesia for the treatment of hepatocellular carcinoma (HCC).

**METHODS:** Time-lag performance of RFA after ethanol injection (Time-lag PEI-RFA) was performed in all cases. The volume of coagulated necrosis and the applied energy for total and per unit volume coagulated necrosis were examined in the groups treated under general (group G) or local anesthesia (group L).

**RESULTS:** The results showed that the total applied energy and the applied energy per unit volume of whole and marginal, coagulated necrosis were significantly larger in group G than those in the group L, resulting in a larger volume of coagulated necrosis in the group G. The rate of local tumor recurrence within one year was extremely low in group G.

**CONCLUSION:** These results suggest that EI-RFA, under general anesthesia, may be effective for the treatment of HCC because a larger quantity of ethanol and

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most serious malignancies worldwide<sup>[1]</sup>, especially in Asian countries due to the high exposure to hepatitis virus. Despite intensive efforts to develop novel treatment modalities for HCC, the prognosis of HCC remains relatively poor<sup>[2-4]</sup>. Although percutaneous ethanol injection (PEI) and percutaneous acetate injection (PAI) are frequently used for the treatment of HCC, these treatment modalities are considered to be effective for patients with relatively small, encapsulated HCC. By contrast, tumor ablation technologies such as microwave, laser, and radiofrequency ablation (RFA), have been shown to be reliable and effective for inducing thermally mediated coagulation necrosis of primary HCC<sup>[5-10]</sup> and metastatic liver cancer<sup>[11,12]</sup>. Among these treatment modalities, it is now possible to obtain larger areas of coagulated necrosis through innovative RFA technologies, while RFA now plays a central role in local treatment due to wider coagulated necrosis in fewer sessions without major complications compared with PEI and PAI. However, in contrast to its efficacy, several disadvantages have been pointed out, such as the limited

coagulated necrosis induced by RFA and frequent local tumor recurrences<sup>[13,14]</sup>. To overcome these weaknesses, we have developed a novel combination therapy of percutaneous ethanol injection and radiofrequency ablation (PEI-RFA) and showed that combined use of ethanol prior to RFA was able to enhance the therapeutic effects with a smaller energy requirement compared with RFA alone<sup>[15-20]</sup>. Although PEI-RFA was shown to enlarge the area of coagulated necrosis, there are HCC cases that are difficult to treat with percutaneous RFA due to the location of the HCC. For example, HCC protruding from the surface of the liver are difficult to treat with RFA percutaneously due to the risk of tumor bleeding. Furthermore, HCC located closely to the diaphragm are difficult to treat with RFA percutaneously due to the poor visualization of the tumor by ultrasonography (US). For these HCC thus other appropriate RFA approaches are desirable. Furthermore, there are some HCC that can not be treated even with both laparoscopic and thoracoscopic approaches due to the location of the tumor, and open surgery-assisted RFA remains the only appropriate treatment. For these kinds of HCC, we applied the combination therapy of ethanol injection and RFA (EI-RFA) to laparoscopic, thoracoscopic, and open-surgery assisted treatments. We summarized and evaluated the effectiveness of laparoscopic-EI-RFA (L-EI-RFA), thoracoscopic-EI-RFA (T-EI-RFA), and open surgery-assisted-EI-RFA (O-EI-RFA) under general anesthesia.

## MATERIALS AND METHODS

### Patients

L-EI-RFA was performed in eight patients (5 male and 3 female; mean age 67 years) with HCC protruding from the surface of the left lobe of the liver (ranging from 1.0-3.0 cm in diameter). T-EI-RFA was performed in nine patients (6 male and 3 female; mean age 69 years) with HCC located closely to the diaphragm (ranging from 1.0-3.5 cm in diameter). O-EI-RFA was performed in five patients (4 male and 1 female; mean age 63 years) with HCC located closely to the diaphragm (ranging from 1.0-2.5 cm in diameter). P-EI-RFA was performed in 40 patients (27 male and 13 female; mean age 65 years). All these studies were conducted with informed consent at the time of enrollment. The characteristics of the enrolled patients are shown in Table 1.

### Treatment of time-lag EI-RFA

We previously reported that time-lag performance RFA after ethanol injection (time-lag P-EI-RFA) was effective for the treatment of HCC<sup>[20]</sup>. Time-lag PEI-RFA was performed under the real-time US guidance with a 3.5-MHz sector probe (TOSHIBA, Xario Prime Ultrasound, SSA-660A). RFA was performed by a Cool-tip RF System (RADIONICS, Burlington, USA)<sup>[21]</sup>, a RTC system (RF3000 Generator, Boston Scientific, USA), and RITA system (Model 90, USA) according to the method described in our manuscripts<sup>[15,16]</sup>. Briefly, a 17-gauge RFA needle with an electrode of 3 cm in length was inserted into the center of tumor, followed by a 21-gauge PEI needle inserted into the liver tumor through the same

attachment hole beside the echo probe. Pure ethanol (99.8%) was then slowly injected into the tumor. The volume of injected ethanol was always kept below double the estimated tumor volume. Five minutes after injection of ethanol into the tumor, the ablation was started with 30 W of power output followed by a stepwise increase of 20 W every 2-3 min. After the end of the ablation (50 W of power output), the circulating cooling water was stopped and the temperature of the RFA electrode was checked. The ablation was performed under impedance control. The ablation was terminated when the temperature of the RFA needle was > 65°C.

### Laparoscopic time-lag EI-RFA (L-EI-RFA)

L-EI-RFA was performed for the HCC protruding from the surface of the liver. First, the laparoscope was inserted into the abdominal cavity beginning in the left-upper portion of the navel. RFA electrode and PEI needle were inserted at a second abdominal site according to the location of the tumor. A sonde was inserted into the abdominal cavity to lift up the liver when the HCC was protruding from the reverse surface of the liver. Under laparoscopic observation, a RFA electrode was directly inserted into the tumor, and then a 21-gauge PEI needle was inserted and ethanol was injected<sup>[18]</sup>.

### Thoracoscopic time-lag EI-RFA (T-EI-RFA)

T-EI-RFA was performed for HCC close to the right diaphragm. Patients were put under general anesthesia with one-lung (left lung) ventilation in a left-decubitus position. Three ports for the thoracoscope, End-fire laparoscopic probe (ALOKA UST-52109), and water-pouring tool were inserted into the pleural cavity through the intercostal space. After putting the collapsed right lung aside by a laparoscope, the End-fire laparoscopic probe was guided to the surface of the exposed diaphragm, and the tumor close to the diaphragm was identified by US (ALOKA ProSound SSD-3500). After visualizing the tumor by US, an RFA electrode was inserted into the tumor through the channel along the End-fire laparoscopic probe. A 21-gauge

Twenty-four HCC were treated with time-lag PEI-RFA with straight type electrode, while 15 HCC were treated with time-lag PEI-RFA with expandable type electrode. After treatment, the longest and the shortest diameters, and the height of the coagulated necrosis were estimated by helical dynamic CT and the approximation volume of total and marginal coagulated necrosis were calculated. Each datum expresses mean ± SD. Each abbreviation in the table is expressing as follows: T-S: Tumor size; EtOH: Amount of ethanol; L: Longest diameter; S: Shortest diameter; H: Height; V: Volume of coagulated necrosis; M: Volume of marginal coagulation; D: Duration of ablation; T-ENE: Total energy requirement; T-ENE/V: Energy requirement per unit volume for whole coagulation; T-ENE/M: Energy requirement per unit volume for inducing marginal coagulation.

PEI needle was inserted and pure ethanol or lipiodol containing ethanol was injected<sup>[19]</sup>.

#### **Open surgery-assisted time-lag EI-RFA (O-EI-RFA)**

O-EI-RFA was performed for HCC which were difficult to treat with other EI-RFA approaches or when splenectomy was simultaneously performed to improve cirrhotic liver dysfunction accompanying severe esophageal varices or a decrease of platelet count. After exposing the liver and confirming the surface location of liver tumors by US, the RFA electrode was directly inserted into the liver tumors and time-lag EI-RFA was performed.

#### **Evaluation of therapeutic efficacy**

Five to seven days after treatment, plain or contrast enhanced CT was performed to evaluate the response to L-EI-RFA, T-EI-RFA, and O-EI-RFA. Tumor necrosis was considered to be complete when no foci of early enhancement were seen around the original regions.

#### **Statistical analysis**

Statistical analysis was performed using Statview II (Version 5.0), statistical significance between the group L and group G was analyzed by a Chi-square test for independence and significant difference was accepted at  $P < 0.05$ .

## **RESULTS**

### **Comparison of the volume of coagulated area and the applied energy requirement for total and unit volume coagulation in patients treated with EI-RFA under local anesthesia (group L) and general anesthesia (group G)**

Group L (40 cases) received time-lag EI-RFA under local anesthesia, while group G (22 cases) received time-lag EI-RFA under general anesthesia. The patients underwent RFA therapy by means of the Cool-tip RF system, RTC system, and RITA system. No major adverse effects were observed in either group. Among treated cases, 40 cases in group L and 15 cases in group G (L-EI-RFA; 6 cases, T-EI-RFA; 8 cases, O-EI-RFA; 1 case) were treated with EI-RFA by means of the Cool-tip RF system. Between these patients treated by the Cool-tip RF system, the effect of EI-RFA was compared using several parameters drawn from the treatments. Comparison of the amount of injected ethanol, the volume of the induced coagulated necrosis, total applied energy for total and per unit volume coagulated necrosis

in both groups are summarized in Table 2. The tumor size was approximately 3 cm in diameter in both groups, and no significant difference was detected between groups. Although the longest and the shortest diameter and the height of the coagulated necrosis did not show a significant difference between the groups, the mean values of all of these parameters in group G were higher than those in group L. Thus, the volume of total coagulated necrosis in group G was significantly larger than that in group L. Furthermore, the volume of marginal coagulated necrosis in group G was also larger than that in group L. According to the analysis of parameters which affect the volume of induced coagulated necrosis in EI-RFA, both the quantity of ethanol and applied energy for ablation in group G were significantly larger than those in group L. Because both, the volume of coagulated necrosis and total applied energy, were increased in group G compared with group L, the applied energy per unit volume for whole and marginal coagulated necrosis were comparable. These results suggest that a higher volume of coagulated necrosis was induced in group G compared with group L because higher amounts of ethanol and energy for ablation could be applied.

### **Rate of local recurrence within a year in group G and L**

Among the 22 patients treated with EI-RFA under general anesthesia (group G), local recurrence was observed in only one case (4.5%) within a year after the treatment. By contrast, local recurrence was detected within a year in four cases (10%) among the 40 cases treated with EI-RFA under local anesthesia (group L). Although the difference of the rate of local recurrence between group G and group L did not reach statistical significance, the rate was extremely low in group G. In one case (patient No. 21) with local recurrence, the volume of marginal coagulated necrosis around the original tumor was lower than in cases without recurrence.

### **Comparison of the effects of L-EI-RFA, T-EI-RFA, and O-EI-RFA**

The results for treatment with L-EI-RFA, T-EI-RFA, and O-EI-RFA are summarized in the Table 3. L-EI-RFA was performed on the HCC located in the left lobe of the liver (segment 2-4) and T-EI-RFA was performed on the HCC of segment 8 of the liver close to the diaphragm (except for one HCC located in the segment 6). O-EI-RFA was performed on the liver HCC of segment 3, 7, and 8. The

Eight HCC were treated with L-EI-RFA, Nine HCC were treated with T-EI-RFA and five HCC were treated with O-EI-RFA. Location of the tumor, tumor size (T-S), instruments for ablation (Ins), amounts of injected ethanol (EtOH), ablated area (A-A), [longest diameter (L) × shortest diameter (S) × height (H)], volume of coagulated necrosis (V) and volume of marginal coagulated necrosis (M) are shown.

approximate estimated volume of the original tumor, volume of whole and the marginal coagulated necrosis were calculated from the CT image after the treatments. In most treated cases, a larger volume of coagulated necrosis and marginal coagulated necrosis was induced compared with the volume of original tumor. In most patients treated with a large amount of ethanol (over 7 mL), larger volume of whole and marginal coagulated necrosis were induced in patients such as No. 2, 4, 5, 9, 11, and 19. The volume of whole and marginal coagulated necrosis was comparable in the patients treated with L-EI-RFA, T-EI-RFA, and O-EI-RFA.

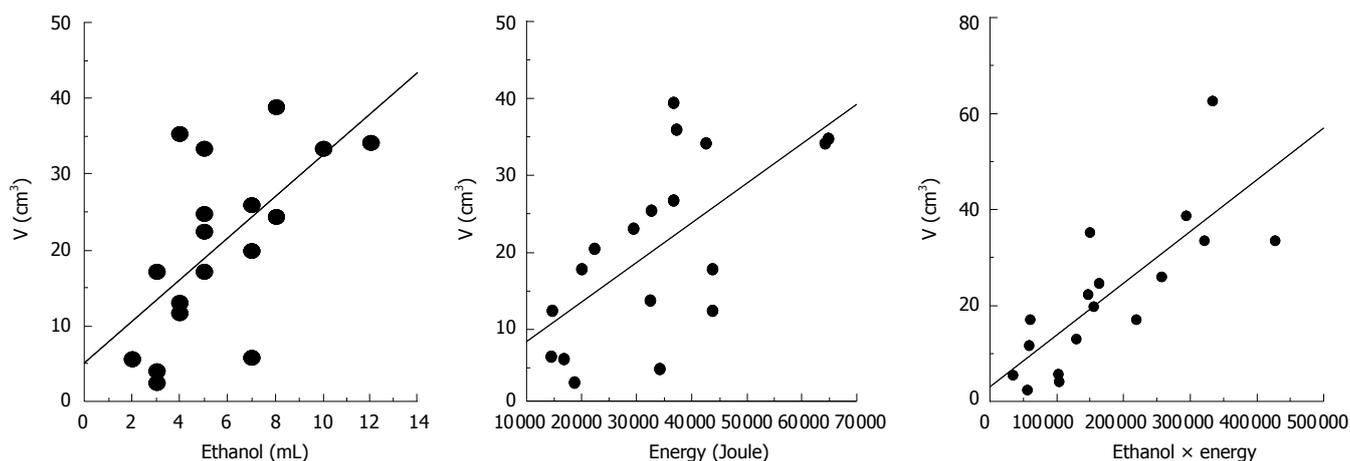

#### Relationship between the amount of ethanol, applied energy, and the volume of coagulated necrosis

In group G, the induced coagulated necrosis increased with the amount of ethanol and applied energy. We previously showed that the amount of ethanol was positively correlated with the volume of coagulated necrosis in patients treated with P-EI-RFA using an RFA instrument equipped with a straight electrode (Cool-tip RF system)<sup>[19]</sup>. In the present study, the relationship between the amount of ethanol or applied energy and the volume of induced coagulated necrosis were evaluated in patients treated with EI-RFA under general anesthesia. Furthermore, the relationship between the product of the amount of ethanol and the applied energy vs the volume of coagulated necrosis was also analyzed. The results showed that both the amounts of injected ethanol and applied energy were significantly and positively correlated with the volume of

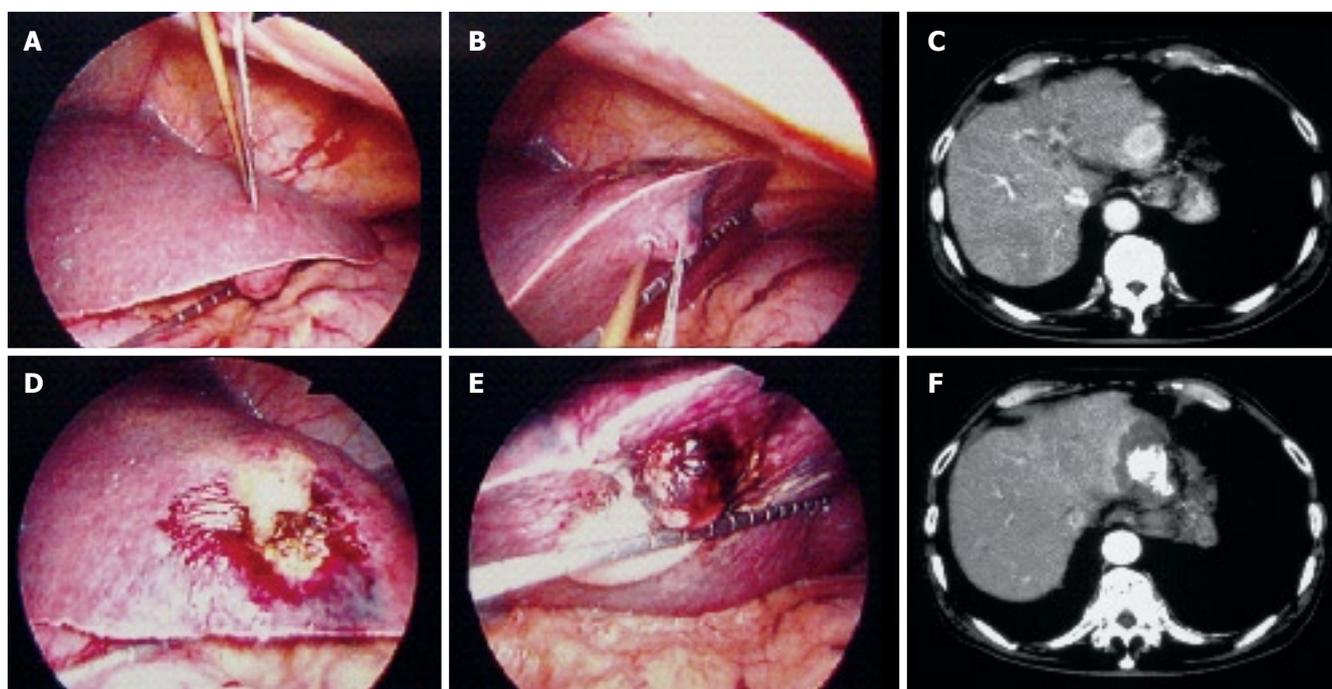

coagulated necrosis (Figure 1A and B). The product of the amount of ethanol and the applied energy was also positively correlated with the volume of coagulated necrosis (Figure 1D). These results clearly indicated that both the amount of ethanol and applied energy were critical factors that regulate the volume of coagulated necrosis in the EI-RFA under general anesthesia.

#### Representative case treated with L-EI-RFA

By analyzing the effects of time-lag EI-RFA under general anesthesia, one point became evident: Total applied energy and the applied energy per unit volume of whole and marginal coagulated necrosis were significantly larger in patients treated under general anesthesia than in those treated under local anesthesia. This led to the induction of a larger volume of coagulated necrosis. A representative case treated with T-EI-RFA was shown in our previous manuscript<sup>[22]</sup>. A case treated with L-EI-RFA is presented. One case with HCC successfully treated with L-EI-RFA is shown in Figure 2. An HCC (2 cm in diameter) was located in the S2 region of the liver protruding from the reverse surface and with an enhanced early vascular phase (Figure 2A) *via* dynamic CT. The laparoscope was inserted from the left-upper portion of the abdomen into the abdominal cavity and the liver was lifted by a sonde. An RFA electrode and PEI needle were percutaneously inserted into the center of the tumor, monitoring the depth of the inserted electrode by the linear type US. The electrode and needle were firstly inserted into the tumor from the upper surface of the liver (Figure 2B), and then inserted into the

**Figure 1** Relationship between the volume of coagulated necrosis induced and the amounts of ethanol injected or total applied energy or the products of the amounts of ethanol and the total applied energy. All the amounts of ethanol, total applied energy, or the products of the amount of ethanol and total applied energy showed a significant positive correlation with the volume of coagulated necrosis. (Ethanol vs volume,  $r = 0.54$ ,  $P = 0.018$ ; energy vs volume,  $r = 0.61$ ,  $P = 0.0057$ ; ethanol  $\times$  energy vs volume,  $r = 0.61$ ,  $P = 0.0078$ ).

**Figure 2** A case of HCC located on the reverse surface of the liver (S2 of the liver) treated with L-EI-RFA. A HCC (2 cm in diameter) showed an enhancement in early vascular phase of helical dynamic CT (A); RFA electrode and PEI needle were firstly inserted from the surface of the liver (B) and secondly inserted from the reverse surface of the liver (C); After injecting the ethanol containing 15% lipiodol, RFA was performed. Dynamic CT after the treatment showed lipiodol deposit associated with the original tumor and low density area was observed around the tumor (D); Laparoscopic observation of the tumor from the surface (E) and from the reverse surface (F) of the liver after the treatment.

tumor from the reverse surface of the liver (Figure 2C). We previously reported the usefulness of injecting the mixture of ethanol and lipiodol to visualize the original tumor by dynamic CT<sup>[23]</sup>. Therefore, a mixture of ethanol and lipiodol (15% lipiodol in ethanol) was injected into the tumor. Five minutes after injection of ethanol containing lipiodol, RFA was started at 30 W, and the power output was stepwise increased to 80 W by a Cool-tip RF system. During ablation, the tumor was constantly lifted by a sonde to prevent the transmission of heat to the mesentery. Abdominal dynamic CT taken after the operation clearly

showed a lipiodol deposit associated with the tumor and the ablated region reached beyond the tumor (Figure 2D). A safety margin was shown to be sufficiently obtained by L-EI-RFA. The laparoscopic findings for the tumor after ablation are shown in Figure 2E and F.

## DISCUSSION

HCC is one of the most serious and common malignancies worldwide<sup>[1,4]</sup>. As a treatment for HCC, RFA now plays a central role for local control of HCC, because RFA

can induce wider coagulated necrosis in a few sessions compared with PEI which is frequently used for relatively small-encapsulated HCC. However, the region of coagulated necrosis induced by RFA is still limited and only considered applicable to tumors within a 3 cm diameter. Furthermore, it is also pointed out that relatively frequent local recurrences of tumor occur after RFA treatment. Therefore, the RFA technique could be further developed to improve the therapeutic effects of this treatment. To enhance the therapeutic effect of RFA, several treatment modalities have been applied in addition to local treatment<sup>[24-29]</sup>. As one of the optional combination therapies, we have developed a novel combination therapy of P-EI-RFA and showed that this combination therapy accurately enlarged the area of induced coagulated necrosis. Total applied energy and the applied energy per unit volume of whole and marginal coagulated necrosis was significantly lower in the P-EI-RFA than RFA alone. Furthermore, we found that the time-lag performance of RFA after ethanol injection (time-lag P-EI-RFA) resulted in a lower energy requirement per total and unit volume of coagulated necrosis than without time-lag performance of RFA after ethanol injection. In this regard, we suggest that time-lag P-EI-RFA can induce wider coagulated necrosis with a smaller energy requirement. Although P-EI-RFA was shown to enlarge the area of coagulated necrosis, there are HCC cases that are difficult to treat with the percutaneous RFA due to the location of the HCC. For these situations, we applied the combined therapy of ethanol injection and RFA (EI-RFA) with laparoscopic, thoracoscopic and open-surgery assisted. Among 22 patients treated with EI-RFA under general, the number of local recurrences was very small [1 case (4.5%)] and its frequency was kept in extremely low level. Analysis of the amount of injected ethanol, applied energy and the volume of coagulated necrosis showed that these parameters in the group treated with EI-RFA under general anesthesia were significantly larger than those in the group treated under local anesthesia. One of the most relevant differences between the EI-RFA under general anesthesia and local anesthesia is presence or absence of pain felt by the treated patients. We have reported in a series of analyses that P-EI-RFA under local anesthesia enabled a comparable coagulated necrosis with smaller energy requirement relative to RFA alone. P-EI-RFA was likely to be less invasive than RFA alone<sup>[16]</sup>. However, in the present study, the rate of local recurrence was reduced in the patients treated under general anesthesia compared with the patients treated under local anesthesia. Taken collectively, these results suggest that higher amounts of ethanol and energy administered under pain-free conditions may result in a decreased rate of local tumor recurrences after RFA treatment. Indeed, although we still believe that PEI-RFA is less invasive for the treatment of HCC, we are sometimes obliged to cease the RFA treatment due to the pain felt by the patient during the percutaneous RFA treatment. Therefore, the results in the present study suggest that it is important to apply enough ethanol and energy for RFA treatment to decrease the local recurrence after percutaneous treatment as well as treatment under general anesthesia. For this purpose, it is beneficial to use anesthesia intravenously to decrease the

pain felt by the patients during the percutaneous treatment as well. Patients under pain-free conditions during treatment may have a decreased rate of local tumor recurrence. Recently, it was reported that there were no differences in tumor control and complications under general anesthesia and analog-sedation in RFA treatment of pulmonary tumors<sup>[30]</sup>. This result is not in accordance with our results obtained during treatment of HCC. In the treatment of HCC located near the surface of the liver, patients often complain about pain originating from the membrane of the liver. In our patients, we usually use pentazocine and non-steroid anti-inflammatory drugs (NSAIDs) (if necessary diazepam is also used on a case by case basis) for the percutaneous RFA treatment. Therefore, it may be better to consider stronger pain relief during the treatment of percutaneous RFA treatment.

In conclusion, we compared the clinical effects, amounts of ethanol, and applied energy in P-EI-RFA between patients under general anesthesia and local anesthesia. The volume of induced coagulated necrosis, amounts of ethanol, and applied energy were significantly larger in the group treated under general anesthesia than that under local anesthesia. The rate of local tumor recurrence in the former group was kept at an extremely low level.

## COMMENTS

### Background

Radiofrequency ablation (RFA) plays a central role for the treatment of hepatocellular carcinoma (HCC) because this newly developed technology appears very effective to induce wider coagulated necrosis. However, several disadvantages have been pointed out for RFA and improvement of RFA technique will be desirable.

### Research frontiers

RFA treatments are performed percutaneously under local anesthesia in many cases. Local tumor recurrence varies according to the location of tumor in the liver, size of tumors, and level of RFA technique. A few reports compared the effects of RFA treatment under local and general anesthesia.

### Innovations and breakthroughs

This report showed that the total applied energy and the applied energy per unit volume of whole and marginal coagulated necrosis were significantly larger in the group treated under general anesthesia (group G) resulting in a larger volume of coagulated necrosis.

### Applications

Patients under pain-free condition during treatment may have a decreased rate of local tumor recurrence. It thus may be better to consider stronger pain relief during the treatment of percutaneous RFA treatment.

### Peer review

Dr. Kurokohchi and colleagues reported the advantage and features of the combination therapy of ethanol injection and radiofrequency ablation (EI-RFA) under general anesthesia for HCC. This manuscript arouses interest for readers and provides an important clue to effectively treat patients with HCC.

Mamori S, Searashi Y, Matsushima M, Hashimoto K, Uetake S, Matsudaira H, Ito S, Nakajima H, Tajiri H. Serum type IV collagen level is predictive for esophageal varices in patients with severe alcoholic disease. *World J Gastroenterol* 2008; 14(13): 2044-2048 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2044.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2044>

### Abstract

**AIM:** To determine factors predictive for esophageal varices in severe alcoholic disease (SAD).

**METHODS:** Abdominal ultrasonography (US) was performed on 444 patients suffering from alcoholism. Forty-four patients found to have splenomegaly and/or withering of the right liver lobe were defined as those with SAD. SAD patients were examined by upper gastrointestinal (UGI) endoscopy for the presence of esophageal varices. The existence of esophageal varices was then related to clinical variables.

**RESULTS:** Twenty-five patients (56.8%) had esophageal varices. A univariate analysis revealed a significant difference in age and type IV collagen levels between patients with and without esophageal varices. A logistic regression analysis identified type IV collagen as the only independent variable predictive for esophageal varices ( $P = 0.017$ ). The area under the curve (AUC) for type IV collagen as determined by the receiver operating characteristic (ROC) for predicting esophageal varices was 0.78.

**CONCLUSION:** This study suggests that the level of type IV collagen has a high diagnostic accuracy for the

### INTRODUCTION

Regular daily drinking is more likely to result in liver damage than intermittent drinking. The longer this pattern is maintained, the more likely it is that alcoholic hepatitis, and subsequently cirrhosis, will develop<sup>[1]</sup>. In patients with cirrhosis, the incidence of esophageal varices increases by nearly 5% per year, and the rate of progression from small to large varices is approximately 5%-10% per year<sup>[2,3]</sup>. Bleeding from esophageal varices is common among patients with cirrhosis. Bleeding from varices may occur in 15%-68% of patients with varices<sup>[4]</sup>. Variceal hemorrhaging is associated with a high mortality and with high hospital costs<sup>[5]</sup>. Both, beta-blockers and endoscopic procedures, have been established as effective preventive modalities for variceal hemorrhage<sup>[5,6]</sup>. Therefore, the early detection of esophageal varices is critical for the effective prevention of variceal hemorrhage<sup>[7]</sup>. Adding an accurate serum marker for hepatic fibrosis to the model may improve the diagnostic accuracy in predicting esophageal varices without performing liver biopsy. Moreover, developing an accurate non-invasive diagnostic model might also decrease the costs for the prevention of hemorrhaging from varices<sup>[7]</sup>.

In daily medical practice, it is common to encounter

patients with liver damage from chronic alcohol consumption. Moreover, when the alcoholic patient is examined, it is often evident that alcoholic liver damage is progressing. Once alcoholic cirrhosis is established, esophageal varices develop in the majority of patients, as found during prolonged follow-up<sup>[8]</sup>. Nevertheless, alcoholic patients tend to be indifferent regarding self health, and are not likely to undergo periodic consultations. We therefore examined predictive factors for esophageal varices in severe alcoholic disease.

## MATERIALS AND METHODS

### Patients

The 444 consecutive patients considered for this study were hospitalized at the Tokyo Medical Center of Alcohol Related Disabilities in Tokyo, Japan, between April and September 2005, July 2006, and June 2007 for alcoholism.

A complete physical examination was performed by a senior physician. The recorded variables included age, gender, height, body weight, mean alcohol consumption, duration of alcohol abuse, jaundice, ascites, and hepatic encephalopathy.

After an overnight fast, serum samples were obtained from all patients for test purposes, including a complete blood cell count, blood platelets, bilirubin, aspartate transaminase (AST), alanine aminotransferase (ALT), gamma glutamyl transpeptidase (GTP), albumin, prothrombin index (ratio between patient and control Quick time expressed in percentage), and type IV collagen (Mitsubishi Chemical Medicine Corporation, Tokyo, Japan).

Ultrasonography (US) was performed by experienced gastroenterologists during the stay in hospital. The spleen was visualized with the patient in the right lateral decubitus position. Measurements were then taken in the sagittal (S) and transverse (T) planes, with the maximum dimension being recorded in each plane<sup>[9]</sup>. Splenomegaly was defined as a spleen index ( $S \times T \times 0.9$ ) > 30. Alcoholic patients with splenomegaly and/or withering of the right liver lobe were defined as severe alcoholic disease patients (SAD) and included into the study. Patients with the following criteria were excluded: (1) the presence of suspected hepatocellular carcinoma on US; (2) the presence of extra-hepatic infectious or inflammatory disease; (3) treatment by any drug known to affect liver fibrosis; (4) seropositivity for the hepatitis B surface antigen, hepatitis C virus, and/or human autoimmune antibodies. Finally, we identified 44 SAD patients (Table 1).

For each patient, upper gastrointestinal (UGI) endoscopy was performed by an endoscopist. The purpose of endoscopy was to evaluate the presence of esophageal varices (Figure 1). The endoscopist evaluated esophageal varices with the Esophagogastric Varices Grading System of the Japan Society for Portal Hypertension<sup>[10]</sup>. The endoscopist performed UGI endoscopy without knowledge of serum data.

### Statistical analysis

The results were expressed as the mean  $\pm$  SD. Differences between the groups were examined for statistical signifi-

Table 1 Characteristics of the study population ( $n = 44$ )

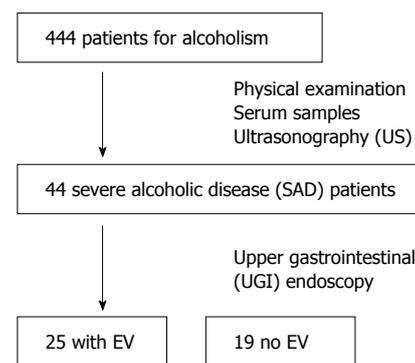

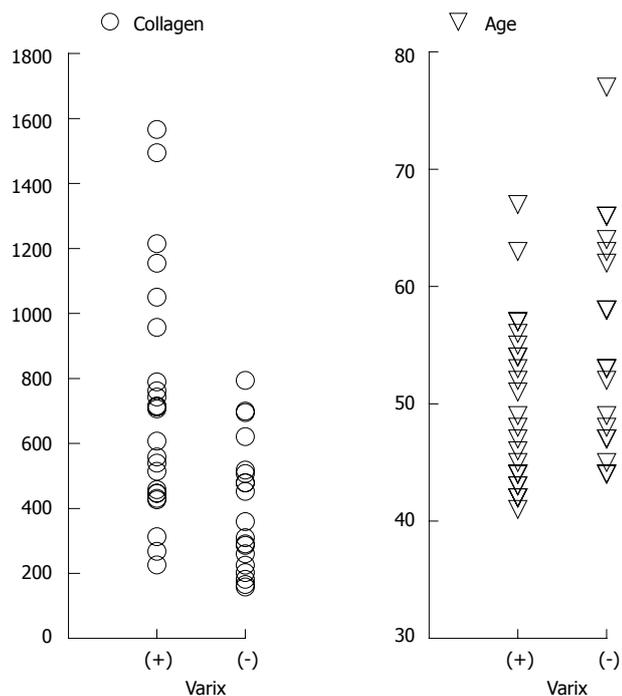

Figure 1 Flow chart of patients in this study. EV: Esophageal varice.

cance using the Mann-Whitney *U* test and a  $\chi^2$  test where appropriate. Independent predictive factors associated with esophageal varices were assessed by a multivariate analysis using a logistic regression model. The sensitivity and specificity of collagen type IV for predicting esophageal varices was determined using receiver operating characteristic (ROC) curves. A *P* value of less than 0.05 was considered to be statistically significant. All analyses were performed using the STATA 10.0 software program (STATA Corporation, College Station, Texas, USA).

## RESULTS

Twenty-five patients (56.8%) had esophageal varices, and 19 (43.2%) had no varice (Figure 1). A univariate analysis revealed a significant difference between patients with and without esophageal varices with regard to age and type IV collagen levels (Table 1 and Figure 2).

These two variables that were significantly linked to the presence of esophageal varices in the univariate analysis, and a factor previously reported<sup>[11]</sup>, age, PT, and type IV collagen, were assessed by multivariate analysis. A logistic regression

**Figure 2** Two independent factors correlated with the appearance of esophageal varices. Collagen: Collagen type IV (ng/mL); (+): Positive patients; (-): Negative patients.

**Table 2** An independent factor for the presence of esophageal varices (odds ratio)

Variable	Odds ratio	95% CI	P value
Collagen type IV	2.02	1.13-3.60	0.017

Data: Collagen type IV per 150 ng/mL.

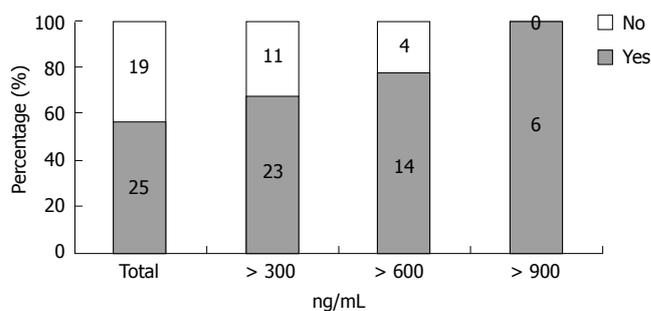

analysis identified type IV collagen as the only independent variable predictive for esophageal varices ( $P = 0.017$ ) (Table 2). Whenever the type IV collagen level raised every 150 ng/mL, the odds ratio of esophageal varices doubled.

Figure 3 shows the positive predictive values at each cut off point of type IV collagen. The positive predictive value of esophageal varices with a type IV collagen value  $> 900$  ng/mL ( $n = 6$ ) was 100%.

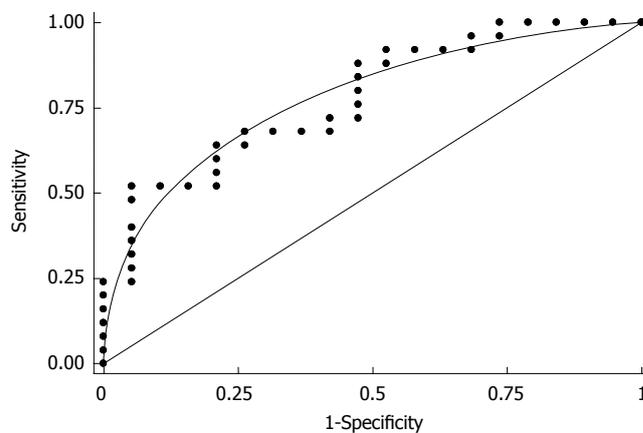

Finally, the area under the curve (AUC) of type IV collagen as determined by ROC for predicting the presence of esophageal varices was 0.78 (Figure 4).

## DISCUSSION

A rupture of esophageal varices is the most frequent complication of portal hypertension, occurring in one third of all cirrhotic patients, and is associated with a high mortality<sup>[12,13]</sup>. The mortality rate from variceal bleeding is about 20% when patients are treated optimally in a hospital<sup>[14]</sup>. However, an appreciable proportion of patients with variceal bleeding die before reaching the hospital<sup>[15]</sup>. Numerous studies have shown that the prevention of UGI bleeding and early detection of esophageal varices reduces mortality, morbidity, and health care costs<sup>[16]</sup>. Nevertheless,

**Figure 3** The positive predictive value for esophageal varices of collagen type IV. Y-axis: Positive percentages of esophageal varices; X-axis: The total predictive value of esophageal varices;  $> 300$  ( $600, 900$ ): The positive predictive value of esophageal varices with a collagen type IV value  $> 300$  ( $600, 900$ ) ng/mL.

**Figure 4** Receiver operating characteristics (ROC) curve of collagen type IV for the diagnosis of esophageal varices [area under curve = 0.7802, se (area) = 0.0704].

Suzuki *et al* demanded further studies to determine which strategies are the most beneficial to patients and society in terms of preventing and treating esophageal varices, in a recent article<sup>[7]</sup>. We thus examined potential esophageal varice prediction factors for SAD on a medical checkup level.

In this study, a non-invasive marker for hepatic fibrosis (type IV collagen) had a high diagnostic accuracy for the detection of esophageal varices. The combination of abdominal ultrasound scan and this marker correctly identified, at a high rate, patients with esophageal varices. These examinations can be conducted on a medical checkup level, so we considered this approach to be of considerable diagnostic value.

A previous report showed the type IV collagen concentration was the most accurate in correctly identifying patients with severe histologic alcoholic hepatitis. At a cut-off of 150 ng/mL, type IV collagen was 89% sensitive and 77% specific<sup>[17]</sup>. First, patient sorting was conducted via the abdominal ultrasound test in this study. The alcoholic patients with splenomegaly and/or withering of the right liver lobe participated in this study. In these 44 patients, the value of type IV collagen was  $> 150$  ng/mL in all specimens. As a result, when suspecting SAD, we thought it very meaningful to add the abdominal

ultrasound test to the characteristics under evaluation.

In a previous report, Geoffroy and colleagues demonstrated that the independent factors of prothrombin index, alkaline phosphatase activity, and hyaluronate level predicted the presence of esophageal varices<sup>[11]</sup>. Nevertheless, their proposed model included two age-dependent serum markers, hyaluronate and alkaline phosphatase, both of which rise in serum with aging<sup>[18]</sup>. We therefore added only the prothrombin index as an examination item. Moreover, another report demonstrated a rise in amino-terminal procollagen III peptide (P<sub>III</sub>NP) following alcohol withdrawal that is likely to be caused by intact P<sub>III</sub>NP<sup>[19]</sup>. We thus decided not to include this fibrosis marker as an examination item at the time of hospitalization. Finally, we elected to add GTP and collagen type IV as examination items.

The serum concentration of laminin and type IV collagen have been reported to be increased in patients with alcoholic hepatitis and to correlate with the degree of inflammation<sup>[20-26]</sup>. In our study, logistic regression identified type IV collagen as the only independent variable predictive for esophageal varices. While based on the findings of these studies, laminin may be predictive for esophageal varices. However, the use of such testing is not covered by the national health insurance program in Japan, so we decided to exclude laminin from this study. We therefore hope that further study of esophageal varices in other countries will help to elucidate and confirm the predictive potential of laminin.

Antler *et al* found that in younger patients, the most common bleeding sites are those associated with alcoholism (esophageal varices, Mallory-Weiss tears, and hemorrhagic gastritis), accounting for 40%-60% of lesions in patients less than 55 years-of-age<sup>[27]</sup>. Another report demonstrated that younger patients had a trend toward more variceal bleeds ( $P = 0.39$ )<sup>[28]</sup>. In our research, there was a positive correlation of esophageal varices with younger age ( $P > 0.05$ ). We think that younger alcoholic patients with high fibrosis markers should be evaluated by GI endoscopy.

In conclusion, this study suggests that the level of type IV collagen has a high diagnostic accuracy for the detection of esophageal varices in SAD. These results show that the non-invasive screening of patients who are at risk for variceal bleeding is possible, and that this approach may assist in the prevention of this most serious complication.

## COMMENTS

### Background

Bleeding from varices may occur in 15%-68% of patients with varices. Variceal hemorrhaging is associated with a high mortality rate, as well as high hospital costs.

### Research frontiers

The early detection of esophageal varices is critical for the effective prevention of variceal hemorrhaging. Adding an accurate non-invasive diagnostic model may improve the diagnostic accuracy in predicting esophageal varices without performing liver biopsy.

### Innovations and breakthroughs

First, patient sorting for alcoholism was conducted via the abdominal ultrasound

test in this study. The existence of esophageal varices with severe alcoholic disease was compared according to a number of clinical background variables. A univariate analysis revealed a significant difference in age and type IV collagen levels between the patients with and without esophageal varices. A logistic regression analysis identified type IV collagen as the only independent variable predictive for esophageal varices ( $P = 0.017$ ). AUC of type IV collagen as determined by ROC for predicting expressed esophageal varices was 0.78.

### Applications

The combination of an abdominal ultrasound scan and type IV collagen correctly identified, at a high rate, alcoholism patients with esophageal varices.

### Terminology

The type IV collagen and laminin are the major components of basement membranes. Early accumulation of type IV collagen and laminin, thus leading to the formation of basement membrane-like material in the space of Disse (capillarization), is considered a typical characteristic of alcoholic liver disease. The amount of collagen in the space of Disse has been shown to correlate significantly with the presence of alcoholic hepatitis and portal blood pressure.

### Peer review

This short paper summarized well the relevance of type IV collagen as a predictive factor for varices in alcoholic liver cirrhosis.

### Abstract

**AIM:** To compare rabeprazole (RPZ; 10 mg) with Lansoprazole orally disintegrating tablets (LPZ; 30 mg OD) in terms of antisecretory activity and blood drug concentration after a single dose.

**METHODS:** Eight *H. pylori*-negative cytochrome P450 (CYP) 2C19 extensive metabolizers were assigned to receive a single oral dose of RPZ 10 mg or LPZ 30 mg OD. Twelve hour intragastric pH monitoring was performed on the day of treatment. Blood samples were also collected after the administration of each drug.

**RESULTS:** LPZ 30 mg OD induced a significantly earlier rise in blood drug concentration than RPZ 10 mg; consequently, LPZ 30 mg OD induced a significantly earlier rise in median pH in the third and fourth hours of the study.

**CONCLUSION:** In *H. pylori*-negative CYP2C19 extensive metabolizers, LPZ 30 mg OD induced a significantly faster inhibition of gastric acid secretion than RPZ 10 mg.

### INTRODUCTION

Gastroesophageal reflux disease (GERD) is a common disease in the West<sup>[1-3]</sup>, with increasing prevalence in Japan<sup>[4-7]</sup>. A recent study in Japan by Ohara *et al* has shown that a total of 42.2% of Japanese experienced heartburn<sup>[6]</sup>, which is a similar proportion to the estimated 42.4% reported in Western studies<sup>[1]</sup>. Moreover, endoscopic studies have shown the overall prevalence of reflux esophagitis (RE) among the adult population of Japanese outpatients is 14%-16%<sup>[4-7]</sup>. The mechanism of GERD is closely associated with gastric acid; thereby, gastric acid suppression is the most common therapeutic approach, and stronger and prompter gastric acid suppression is required<sup>[8]</sup>. At present, drug therapy for reflux esophagitis is common because of its effectiveness; acid suppressing drugs such as H<sub>2</sub> receptor antagonist (H<sub>2</sub>RA) and proton pump inhibitors (PPIs) are commonly used. As PPIs have been shown to be more effective against RE than H<sub>2</sub>RA<sup>[9-11]</sup>, PPIs such as lansoprazole (LPZ) and rabeprazole (RPZ) are now widely used as first-line acid inhibitors. Continuous maintenance with PPIs is considered to be the mainstay of GERD treatment.

However, there are some reports not showing that all GERD patients need continuous acid inhibition. Bour *et al* reported that on-demand therapy with PPI provides an alternative to continuous therapy in patients with mild to moderate gastro-esophageal reflux<sup>[12]</sup>. Several reports have

demonstrated that on-demand therapy with PPI provides an alternative to continuous therapy in patients with mild to moderate gastro-esophageal reflux<sup>[13]</sup>.

In Japan, many studies on RE have been done and although each report differs slightly, an obvious trend is apparent, showing most patients suffered from mild RE<sup>[5-7]</sup>, which is milder than that experienced in Western countries. As a result, some Japanese patients take PPIs when required according to their symptoms in the clinical setting.

It is reported that rapid acid suppression is important for effective pain relief at the onset of treatment in GERD patients<sup>[14]</sup>. Thus, the aim of this study was to examine the correlation between pH value and blood drug concentration in patients treated with RPZ 10 mg or LPZ OD 30 mg at the early post-administration phase (1-12 h).

RPZ and LPZ are generally administered at doses of 10 mg or 30 mg, respectively, in the clinical setting in Japan. Thus, in the present study, the RPZ and LPZ doses were set at 10 mg and 30 mg, respectively.

Furthermore, in Japan many outpatients are administered multiple drugs. Hence, in order to improve drug compliance, RPZ and LPZ are also generally administered after a meal with other drugs. Therefore, we administered both RPZ and LPZ after a meal.

The acid-inhibitory effects of PPIs are significantly dependent on the cytochrome P450 (CYP) 2C19 genotype status, as well as on their intrinsic pharmacokinetic and pharmacodynamic characteristic and dosing schemes<sup>[15-19]</sup>. According to these reports, the metabolism of PPIs is affected by the CYP2C19 polymorphism; the plasma PPI levels and intragastric pH values in extensive metabolizers are significantly lower than those in poor metabolizers<sup>[20-22]</sup>. Therefore, in this study, the subjects were all CYP2C19 extensive metabolizers.

## MATERIALS AND METHODS

### Subjects

The subjects were 8 healthy male volunteers, aged between 24 and 48 years (median, 23 years) and weighing 52-78 kg (median, 54 kg). No patient had a history of gastrointestinal or hepatobiliary disease or of eradication therapy for *H pylori*, and none took regular medications. All volunteers gave written informed consent. The study protocol was approved by the ethical committee of the Tohoku University Graduate School of Medicine.

### Detection of *H pylori* infection

*H pylori* infection was determined by the <sup>13</sup>C-urea breath test<sup>[23]</sup>. A total of 8 *H pylori*-negative subjects were invited and approved to participate in this study.

### CYP2C19 genotyping

After obtaining informed consent, a venous blood sample was collected from all patients. DNA was extracted from the nucleus of venous white blood cells. The genetic mutation was analyzed by either the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method<sup>[24]</sup> or the TaqMan polymerase chain reaction

amplification method (Applied Biosystems Japan, Chiba, Japan)<sup>[25]</sup>. Based on point mutations in exons 4 and 5 of the CYP2C19 gene, individuals can be classified into homo-extensive metabolizers (homo-EMs), hetero-extensive metabolizers (hetero-EMs) and poor metabolizers (PMs)<sup>[20-22]</sup>. Homo-EMs have the wild type alleles (wt/wt) without any mutations in exons 5 and 4; PMs have mutated alleles (m1/m2) with mutations in both exons 5 and 4 (m1/m2, m1/m1 or m2, m2); and hetero-EMs have a mutated allele in either exon 5 or 4 (wt/m1 or wt/m2).

### Study protocol

All subjects (homo EM = 4, hetero EM = 4) participated in an open-label crossover study with RPZ 10 mg tablets or LPZ 30 mg OD. They were randomly assigned to receive a single oral dose of RPZ 10 mg tablet or LPZ 30 mg OD 30 min after eating a standardized meal. There was a washout period of at least 14 d between the two study periods. Twenty-four-hour intragastric pH monitoring was performed on the day of treatment. To monitor gastric pH, a pH electrode was inserted transnasally, and positioned fluoroscopically in the gastric corpus, approximately 5 cm-10 cm below the esophago-gastric junction. Gastric pH was measured at 10 s intervals by means of a portable pH meter attached to a glass pH electrode (Chemical Instrument, Tokyo, Japan). The pH electrode was calibrated before each recording, using standard buffers of pH 1.68, 4.01 and 6.86. The pH data were analyzed with the use of established software (Chemical Instrument). At fixed times (Breakfast 8.30 AM, lunch at noon, snack at 15:00 and dinner at 7:00 PM), standardized meals were consumed (total 1359 kcal; protein, 24 g lipid, 18.5 g glucose 267 g. The individual calorie contents of breakfast, lunch, snacks and supper were 356, 324, 355 and 324 kcal respectively). No additional food was allowed, and 100 mL of tap water was allowed only when the subjects felt thirsty. All subjects were instructed to remain upright until 21:00. Normal daily activities were not restricted.

### Sample collection and assay of LPZ, RPZ concentration in plasma

In order to study the correlation between intragastric pH and blood drug concentration, blood samples were collected in heparinized tubes before and 0.5, 1, 1.5, 2, 3.5, 6, 9 and 12 h after the administration of each drug. After collection, the blood samples were immediately centrifuged at 3000 r/min for 10 min. For the determination of RPZ levels in plasma, 100 µL of 1% diethylamine solution was added to 1 mL of plasma; this was not required for the determination of plasma concentrations of LPZ. All samples were stored at -20°C until assayed. Plasma levels of LPZ and RPZ were measured by high-performance liquid chromatography/tandem mass spectrometry<sup>[26,27]</sup>. This method required only 20 µL of serum and is a simple procedure. Analytes and the internal standard (lansoprazole deuterium derivatives) were separated using a mobile phase of acetonitrile/1 mmol/L ammonium formate (140/60, v/v) on a C18 analytical column and analyzed in the selected reaction-monitoring (SRM) mode. The lower limit of quantification was 500 fg/20 µL.

Table 1 Characteristics of the subjects in this study

Subject	CYP2C19	Age	Height (cm)	Body weight (kg)	BMI
1	Hetero	33	175	70	22.8
2	Hetero	50	175	73	23.8
3	Hetero	31	168	65	23.0
4	Hetero	22	165	60	22.0
5	Homo	31	168	65	23.0
6	Homo	26	173	68	22.7
7	Homo	23	171	70	23.9
8	Homo	25	184	75	22.1

### Statistical analysis

Intragastric pH were expressed as median values (ranges). Differences in these parameters among each regimen were determined by the Wilcoxon signed rank test. *P* values less than 0.05 were considered significant.

## RESULTS

Eight volunteers (all men; mean age 30.3 years, range years) completed the study. There were no adverse events during the study, which was completed according to the protocol by all 8 subjects. Four subjects were homo-EMs, and the other 4 subjects were hetero-EMs (Table 1).

The 12-h trendgram and the profiles of correlation between intragastric pH and blood drug concentration are shown in Figure 1. The lower limit for quantification of blood drug concentration was 500 fg/20 µL in this study. However, the blood drug concentration of RPZ was not detectable until 2 h after drug administration, while LPZ was detectable 0.5 h after drug administration. LPZ 30 mg OD induced a significantly earlier rise in blood drug concentration than RPZ 10 mg tablets.

As a result of this prompt rise in blood LPZ concentration, there was a prompt onset of median pH. The 12-h (median pH per hour) trendgrams of intragastric pH values obtained without medication are shown in Figure 1.

The intragastric pH values increased significantly with both drugs. LPZ 30 mg OD increased the pH value after the second hour of the study, while RPZ 10 mg tablets increased the pH value after the fourth hour of the study, compared with those pH values of individuals without medication.

LPZ 30 mg OD induced a significantly earlier rise in median pH in the third and fourth hours of the study than RPZ 10 mg tablets (Figure 1).

## DISCUSSION

PPIs, such as omeprazole, LPZ and RPZ, are widely used for the treatment of acid-related diseases. The frequency of GERD has increased recently, because of increased average fat intake<sup>[28]</sup>, increased rates of obese patients<sup>[29,30]</sup>, and declining rates of *H pylori* infection<sup>[31,32]</sup>. GERD is a common disease in the West<sup>[1-3]</sup> and appears to be increasing in prevalence in Japan<sup>[4-7]</sup>. Recent endoscopic studies have shown overall prevalence of reflux esophagitis among the adult population in Japan is 14%-16%<sup>[5-7]</sup>. Each report differs slightly, but an obvious trend is that

most patients suffer from mild RE<sup>[5-7]</sup>. Moreover, it is reported that the incidence of atrophic gastritis in the general population is higher in Japan than in Western countries<sup>[33-35]</sup>, and that gastric acid secretion levels in the general population are lower in Japan than in Western countries<sup>[33-36]</sup>. Thereby, some patients in Japan want administration of the drug on demand.

Patients with GERD mainly suffer of intermittent symptoms rather than continuous symptoms<sup>[37]</sup>. On-demand therapy with PPIs is reported to provide an alternative to continuous therapy in patients with mild to moderate gastro-esophageal reflux disease suffering from frequent symptomatic relapse<sup>[12]</sup>.

It is important to use medicines that immediately ameliorate the clinical symptoms. Therefore, it is useful to administer antisecretory drugs which have a faster and stronger onset of pH rise in the stomach among patients with acid-related disorders.

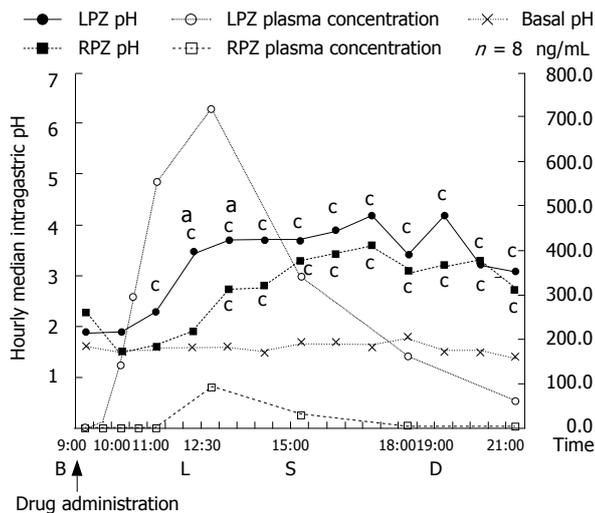

Thus, we studied the effect in the early post-administration phase (1-12 h) of a single dosing of each PPI. In this study, LPZ 30 mg OD induced a significantly earlier rise in blood drug concentration than RPZ 10 mg tablets.

As a result of this prompt rise in blood LPZ concentration, LPZ 30 mg OD induced a significantly earlier rise in intragastric pH values compared with the values in individuals without medication after the second hour of the study, while RPZ 10 mg tablets induced an earlier rise in the fourth hour of the study. Moreover, LPZ 30 mg OD also induced prompt and stronger inhibition of gastric acid secretion than RPZ 10 mg tablets in the early post-administration phase, in the third and fourth hours following a single oral dose of treatment.

These results differ slightly from those of previous reports<sup>[17-19,38,39]</sup> in which RPZ induced an earlier rise in intragastric pH than other PPIs. However, most previous studies examined the effects after administration of RPZ or other PPIs on days 3-7<sup>[17-19,38,39]</sup>, not at the early post-administration phase (1-12 h) of a single dose of treatment, whereas the present study examined the effect in this phase.

There are interindividual variations in the metabolism of PPI, resulting in differences in the acid-suppressing effect of each PPI<sup>[17-19,38,39]</sup>. Each report differs slightly, but CYP2C19 genotype status is shown to influence gastric acid suppression by LPZ and most other PPIs. The metabolism of LPZ, OPZ and other PPIs is affected by the CYP2C19 polymorphism, and the plasma PPI level and intragastric pH values of EMs are significantly lower than those of PMs<sup>[20-22]</sup>. On the other hand, several studies have demonstrated that after a dose of RPZ, intragastric pH is not affected by the CYP2C19 polymorphism on 3 d-7 d of treatment<sup>[17-19,38,39]</sup>. However, Horai *et al.*<sup>[15]</sup> reported the pharmacodynamic effects and pharmacokinetics of RPZ depend on the CYP2C19 genotype status on the first day after a single dose. As the present study is on the effect on the first day after a single dose of PPIs, both RPZ and LPZ are considered to be influenced by CYP2C19 genotype status.

Previous reports have indicated that *H pylori* infection of the gastric mucosa potentiates the effects of proton pump inhibitors<sup>[40,41]</sup>. Therefore, in the present study, the study subjects were all *H pylori*-negative CYP2C19 EMs.

**Figure 1** The 12-h (median pH per hour) trendgrams for all subjects ( $n = 8$ ) and correlations with the blood concentration of each drug. The solid line (●) shows hourly intragastric median pH of individuals administered LPZ 30 mg OD, and the broken line (■) shows that of individuals administered RPZ. The solid line (○) shows the blood drug concentration level in individuals administered LPZ OD 30 mg, and the broken line (□) shows those in individuals administered RPZ 10 mg tablets. The solid line (×) shows the intragastric pH values of all subjects obtained without medication. LPZ 30 mg OD induces an earlier rise in both blood concentration level and median pH than RPZ 10 mg tablets. Arrows: Drug administration. B: Breakfast, L: Lunch, S: Snacks, D: Dinner. Blood sample were collected 1, 1.5, 2, 3.5, 6, 9 and 12 h after the administration of each drug. The significance of differences in these intragastric pHs among each regimen was determined by the Wilcoxon signed rank test.  $^aP < 0.05$  vs RPZ;  $^bP < 0.05$  vs baseline data.

Thus, we clearly state that LPZ 30 mg OD induces a significantly earlier rise in intragastric pH and stronger inhibition of gastric acid secretion than RPZ 10 mg tablets in the early post-administration phase (1-12 h) of a single dose of treatment.

Pipkin *et al* reported that rapid acid suppression is important for effective pain relief at the onset of treatment in GERD patients<sup>[14]</sup>. Thereby, our results perhaps show that administration of LPZ 30 mg OD as an on-demand therapy is useful for mild GERD patients, because of its faster onset of pH rising action.

So why does LPZ 30 mg OD induce a prompt rise in intragastric pH than RPZ 10 mg tablets? This may be partly because of the difference between the dosage forms of RPZ and LPZ. In this study, we compared an enteric-coated tablet formulation of RPZ 10 mg tablets with an enteric-coated microgranule formulation of LPZ OD 30 mg in terms of antisecretory activity and the onset of action of a single dose.

PPIs are degenerated by gastric acid; therefore, for immediate passage through the stomach, some PPIs are formulated as granules or microgranules. This is necessary to ensure their intact passage through the stomach to allow for absorption in the intestine. The discharge speed, namely passage over time through the stomach, depends upon the particle diameter<sup>[42-45]</sup>.

According to physiological reports<sup>[42-46]</sup>, complexes of high amplitude action potentials occur in the stomach and duodenum. The interdigestive complex in the dog is looked upon as a “housekeeper”, which sweeps the

bowel clear of contents at the end of the digestive phase. Using a test food labeled with radionuclide, Davis SS *et al*<sup>[46]</sup> reported that food emptied into the duodenum immediately, consisting of particles smaller than 2 mm without a “housekeeper”. Moreover, particles larger than 2 mm emptied into the duodenum after the “housekeeper,” which occurs after all meals have emptied from the stomach.

As a result, particles smaller than 2 mm empty from the stomach faster than particles larger than 2 mm. LPZ OD particles are smaller than 2 mm; thereby they may passage through the stomach into the duodenum and small intestine faster than RPZ, which is larger than 2 mm. They are absorbed in the small intestine and reach the gastric parietal cells *via* systemic circulation, where they bind to the proton pump, thereby resulting in potent acid inhibition<sup>[16]</sup>. In fact, the plasma concentration level of LPZ 30 mg OD induced a prompt effect than RPZ 10 mg tablets, and consequently, LPZ 30 mg OD induced a prompt rise in intragastric pH than RPZ 10 mg tablets. These findings suggest that LPZ 30 mg OD is suitable for administration as an on-demand PPI, because of the prompt rise in plasma concentration level and the faster rise in intragastric pH.

In conclusion, LPZ 30 mg OD induced a significantly earlier rise in plasma concentration level in the early post-administration phase of a single oral dose than RPZ 10 mg tablets. As a result, LPZ 30 mg OD induced a significantly earlier rise in median pH in the early post-administration phase of a single oral dose than RPZ 10 mg tablets.

## COMMENTS

### Background

The prevalence of gastroesophageal reflux disease (GERD) symptoms is now increasing in Japan. GERD has a high rate of relapse. The rising use of proton pump inhibitor (PPI) therapy on demand has raised issues regarding efficacy.

### Research frontiers

To compare RPZ 10 mg to LPZ 30 mg OD in terms of their antisecretory activity and blood drug concentration in the ultra-early phase after a single dose.

### Innovations and breakthroughs

Most previous studies have examined pH monitoring after administration of PPI on days 3-7, not at the early post-administration phase.

### Applications

We clearly state that LPZ 30 mg OD induced a significantly earlier rise in intragastric pH and stronger inhibition of gastric acid secretion than RPZ 10 mg tablets during the early post-administration phase (1-12 h) of a single dose of treatment. It is reported that rapid acid suppression is important for effective pain relief at the onset of treatment in GERD patients. Thereby, our results show administration of LPZ 30 mg OD as an on-demand therapy might be useful for mild GERD patients because of its faster onset of pH rising action.

### Peer review

In this manuscript, the authors ascertained the effectiveness of LPZ 30 mg OD compared with RPZ 10 mg in the elevation of intragastric pH in the ultra-early state after a single oral administration. The study was well performed and the conclusion was clinically useful.

### **Abstract**

**AIM:** To determine *p16* promoter hypermethylation in gastric tumoral tissue and serum samples, its impact on *p16*-protein expression, and correlation with clinical and histological features.

**METHODS:** Samples were obtained from 52 histologically confirmed cases of gastric adenocarcinoma. Gastric tissue and serum of 50 age- and sex-matched individuals with normal gastroscopy and biopsy were obtained as control samples. Methylation-specific polymerase chain reaction (MSP) was used to evaluate

methylation status of *p16* promoter. *p16*-protein expression was analyzed by immunohistochemical staining on paraffin-embedded sections.

**RESULTS:** Methylation was detected in 44.2% (23/52) of tumoral tissues. 60.9% of them were also methylated in serum, i.e., 26.9% of all patients (14/52). Methylation was not detected in tissue and sera of control samples. *p16*-protein expression was decreased in 61.5% of cases (32/52), and was significantly associated with promoter hypermethylation ( $P < 0.001$ ). Methylation was significantly more frequent in higher pathological grades ( $P < 0.05$ ). Methylation was not associated with other clinicopathological features and environmental factors including *H pylori* infection and smoking.

**CONCLUSION:** *p16* promoter hypermethylation is an important event in gastric carcinogenesis. It is the principle mechanism of *p16* gene silencing. It is related to malignant tumor behavior. Detection of DNA methylation in serum may be a biomarker for early detection of gastric cancer.

### **INTRODUCTION**

Gastric cancer is one of the most widespread cancers and the second leading cause of cancer-related death worldwide<sup>[1]</sup>. It is estimated that gastric cancer is the most common cancer in Iran (Age Standardized Rate = 26.1 per 10<sup>5</sup>), and the incidence rate is higher than the world

average<sup>[2]</sup>. Several genetic and epigenetic alterations have been suggested to play important roles in the carcinogenesis pathway, affecting oncogenes, tumor suppressor genes, apoptosis-regulating or mismatch repair genes<sup>[3]</sup>. Repression of genes by CpG island methylation in the promoter region, which is normally unmethylated, is the most frequent epigenetic alteration, in which the DNA structure is affected while the genetic code remains intact<sup>[4]</sup>. Thus, an increasing number of genes, methylated at the promoter region, are targeted as possible tumor markers for different purposes such as early detection, classification and tumor prognosis, therapeutic strategies and patient follow up<sup>[5-9]</sup>.

Detection of circulating tumoral DNA was first reported about three decades ago<sup>[10]</sup>. Free DNA is thought to originate from apoptotic and necrotic tumoral cells<sup>[11]</sup>. More recently, detection of promoter hypermethylation in serum of patients has been reported in some malignancies such as colorectal or esophageal cancer<sup>[12,13]</sup>. Correlation of clinicopathological features with methylation patterns, which help to predict patient outcome, has been indicated in several studies<sup>[14-18]</sup>.

*p16* is a cell-cycle regulator that induces G1-phase arrest by inhibition of cyclin D-dependent protein kinase 4 (CDK4) and 6 (CDK6), thus interfering with phosphorylation of the retinoblastoma protein (pRb) and further inhibition of transcription of proteins that promote passage of the cell through the restriction point of the G1 stage<sup>[19]</sup>. *p16* inactivation breaks down the regulatory mechanism of the cell cycle. As a tumor suppressor gene, being silenced by any mechanism will promote carcinogenesis. This study was conducted to assess the methylation of *p16* promoter in gastric tumoral tissue and serum samples and its impact on gene expression, and correlation with clinical and histological features for the first time in the Iranian population.

## MATERIALS AND METHODS

### Sample collection and DNA preparation

Tumoral tissue and corresponding serum samples were obtained from 52 consecutive histologically confirmed gastric adenocarcinoma patients. Patients undergoing any therapeutic intervention were excluded. Tumoral tissues were obtained by gastrectomy or endoscopy in unresectable metastatic cases, formalin-fixed and paraffin-embedded. Tumors were histologically verified as gastric adenocarcinoma and subtyped into intestinal, diffuse, or mixed type, as suggested by Lauren<sup>[20]</sup>. Grading was also determined and staging was performed using tumor, node and metastasis (TNM) classification, sixth edition. Fifty age- and sex-matched individuals, with normal gastroscopy and biopsy, were included as a control group. Paraffin-embedded tissue and corresponding serum samples were taken as well. All patients and control individuals gave informed consent according to institutional guidelines, and the study was approved by the research ethics committee of Mashhad University of Medical Sciences. Paraffin-embedded tissues were retrieved by using xylene and alcohol, digested by proteinase K, extracted with phenol/chloroform/isoamyl alcohol, and precipitated in ethanol. Serum samples were isolated by DNA extraction

kit (QIAamp DNA mini kit, QIAGEN, Canada). *H pylori* infection was detected and double checked in serum with an ELISA (Trinity *H pylori* kit, Ireland). None of the patients had a history of *H pylori* eradication.

### DNA modification (bisulfite treatment)

DNA modification with sodium bisulfite causes unmethylated cytosine bases to convert to uracil, while methylated cytosine is resistant and remains unchanged. After treatment, methylated alleles have a different sequence as compared with unmethylated alleles, which can be used to design allele-specific PCR primers, and methylation-specific PCR (MSP) takes advantage of this fact<sup>[21]</sup>. Two micrograms of genomic DNA was first denatured by heating (97°C for 10 min followed by chilling on ice at 0°C for 5 min), and incubated for 20 min at 48°C after adding 3 mol/L NaOH (2 µL). Bisulfite solution (2.5 mol/L sodium metabisulfite and 125 mmol/L hydroquinone) was added and incubated for 12 h at 48°C in the dark, for modification. Modified DNA was purified by using Wizard DNA purification resin (DNA Cleanup Kit; Promega, Madison, WI, USA) according to the manufacturer's instructions. Modified DNA was treated with 3 mol/L NaOH (5 µL) in 37°C for 10 min and precipitated with ammonium acetate 5 mol/L (75 µL), 2.5 volumes 100% ethanol and 2 µL glycogen (20 mg/mL; Fermentase; UAB, Lithuania) and dissolved in 20 µL 5 mmol/L Tris (pH 8.0).

### MSP

Specific primer sets for unmethylated (*p16U*) and methylated (*p16M*) DNAs, described by Herman *et al*<sup>[21]</sup>, were utilized (Table 1). The PCR mixture contained 1 × buffer (Finzymes OY, Finland) with 2 mmol/L MgCl<sub>2</sub>, 500 nmol/L each primer, 0.2 mmol/L dNTPs, 1 U Hot Start Taq polymerase (Finzymes OY, Finland). The PCR amplification of the modified DNA samples consisted of one cycle of 95°C for 10 min, 40 cycles of 94°C for 45 s, 60°C for 45 s, and 72°C for 1 min; then one cycle of 72°C for 10 min. DNA from L132 (embryonic lung cell line) cells was used as a positive control for unmethylated DNA. In order to make a positive control for methylated DNA, normal lymphocyte DNA was treated with M.Sss1 CpG methyltransferase (New England BioLabs, USA) before bisulfite treatment. Six microliters of amplified PCR products were loaded onto 2.5% agarose gels and non-denaturing 8% polyacrylamide gels, stained with ethidium bromide, and directly visualized under UV illumination.

**Figure 1** Analysis of *p16* promoter hypermethylation in tissue and corresponding serum of patients. (A) MSP analysis. IVD served as a positive control for hypermethylated DNA and L132 as a positive control for unmethylated DNA. Patients 4, 24 and 43 were hypermethylated, which revealed 150 bp bands with hypermethylated primers. Patient 10 was not methylated. (B) MSP analysis in corresponding sera of samples depicted in A. Patients 4 and 24 were hypermethylated in serum as well. Patients 43 and 10 were not methylated.

**Table 2** Results of methylation in tumoral tissue and corresponding serum

	Tissue (+)	Tissue (-)
Serum (+)	14	0
Serum (-)	9	29

(+): Methylated; (-): Unmethylated.

**Immunohistochemical staining**

Immunohistochemical staining was performed using the CINtec p16<sup>INK4A</sup> Histology Kit, clone E6H4 (Dako, Carpinteria, CA, USA) and the DakoCytomation Autostainer Instrument, according to the manufacturer’s instructions. Briefly, 4-µm-thick formalin-fixed, paraffin-embedded sections were dewaxed, rehydrated and boiled in Target Retrieval Solution of Dako in a microwave oven for 40 min. After endogenous peroxidase blocking, the slides were incubated with primary p16<sup>INK4A</sup> antibody (clone E6H4) at 1:25 dilutions for 30 min. The antigen-antibody reaction was visualized by 3,3'-diaminobenzidine (DAB) chromogen for 10 min, followed by acidified hematoxyline counterstaining for 1 min. p16-positive cervical squamous cell carcinoma was used as an external positive control, and non-neoplastic stromal cells served as internal positive controls for *p16* in every tumor section.

**Statistical analysis**

Statistical analysis was performed using SPSS software (ver. 11.5). The correlation between two variables was evaluated using Pearson’s  $\chi^2$  and Fisher’s exact test. Statistical significance was defined as  $P < 0.05$ .

**RESULTS**

The studied population consisted of 38 men and 14 women. The median age was 64.5 and the average was 63.7 years (range, 38-81). Hypermethylation of *p16* promoter was detected in 44.2% of tumoral gastric tissue (23/52), while normal gastric samples were all unmethylated. MSP analysis of the *p16* promoter in gastric cancer is shown in Figure 1. Corresponding serum samples were also examined. Among the patients with methylated gastric

tissue, 60.9% were also methylated in their corresponding serum, i.e., 26.9% of all cases (14/52). All normal individuals in the control group were unmethylated in their sera (Table 2).

Clinicopathological features of *p16* promoter hypermethylation are tabulated in Table 3. There was no association between gender and promoter hypermethylation. Methylation had higher frequency in older patients ( $P = 0.051$ ). Methylation was significantly lower in well-differentiated tumors as compared with higher pathological grades ( $P < 0.05$ ). There was no significant difference in methylation status between intestinal and diffuse types. However, it was observed that 4/5 mixed type tumors were methylated, and all five were negative for p16 protein expression. Methylation was more frequent in non-cardiac type of tumor as compared with cardiac type (68.2% vs 31.8%), without statistical significance. *p16* promoter methylation had no correlation with distant metastasis. No association was observed between methylated circulating DNA and lymph node metastasis.

Among environmental factors, we assessed *H. pylori* infection and smoking. Sixty percent of patients (30/50) were infected with *H. pylori* and 17.6% (9/51) were smokers. *p16* promoter methylation had no correlation with smoking and *H. pylori* infection.

**Immunohistochemical staining of p16**

Nuclear p16 immunostaining was positive for protein

**Figure 2** Immunohistochemical staining with monoclonal anti-p16 protein. (A) Nuclear reactivity showed expression of p16 protein (case 48). (B) p16-negative tumor (case 15) failed to stain due to decreased expression of p16 protein.

expression. Positive tumors varied in intensity of nuclear staining, with the proportion of cells ranging from 10% to 95%. In a few positive tumors, we observed marked heterogeneity in different areas with respect to p16 reactivity. Negative staining was observed in 61.5% of patients (32/52). Immunohistochemical staining is depicted in Figure 2. We assessed the correlation between immunohistochemical staining and methylation status (Table 4). Among the p16-negative tumors, 62.5% were methylated, which showed strong correlation between negative immunostaining and promoter region hypermethylation ( $P < 0.001$ ). There was significant correlation with pathological grade and mixed subtype, as well as methylation pattern, but no association was observed with other clinicopathological and demographic features and environmental factors.

## DISCUSSION

Several genetic and epigenetic alterations play an important role in gastric carcinogenesis. Tumor suppressor and other tumor-related genes are the main targets. Aberrant alterations of *p16*, as a tumor suppressor gene, are important events in several tumors, including gastric cancer, and hypermethylation of CpG islands in the promoter region is responsible for a great proportion of tumors<sup>[22-25]</sup>. In this study, we demonstrated that 44.2% of tissues from gastric adenocarcinoma were methylated. The result was consistent with previous studies by Shim *et al*<sup>[26]</sup> and Ding *et al*<sup>[27]</sup> who reported 42% and 45% methylation of *p16* promoter in gastric cancer.

Different mechanisms are suggested for decreased p16 protein expression, including homozygote deletion, point mutation and promoter methylation<sup>[28]</sup>. The first two mechanisms occur in  $< 10\%$  of tumors<sup>[29,30]</sup>. We report that 61.5% of gastric adenocarcinomas were negative for p16 protein expression. Among p16-negative tumors, 62.5% were methylated in their promoter region, which was strongly correlated with decreased protein expression. We conclude that the principle mechanism for decreased p16-protein expression in gastric cancer is hypermethylation of the promoter region. There were three patients with normal protein expression despite promoter hypermethylation. All of these exhibited tumor heterogeneity, although

**Table 4** Results of methylation analysis in p16-positive and negative cases

Immunohistochemistry	Methylated	Unmethylated
p16-positive	3	17
p16-negative	20	12

partial methylation in one or both alleles might have been another possible reason. There were also twelve p16-negative patients with normal methylation status. Alternative mechanisms such as point mutation or homozygote deletion might be responsible for decreased protein expression.

Promoter hypermethylation was detected from sera of 60.9% of patients with tumor methylation, which accounted for 26.9% of all cases. This was similar to the study performed by Koike *et al*<sup>[31]</sup> who reported 27% methylated sera in gastric cancer patients. There are some interesting features that introduce *p16* hypermethylation as a good serum marker for early detection of gastric cancer. As compared with other methods, serum markers are easier to use, less expensive and less invasive. Among serum markers, hypermethylation has some distinct features. It is a frequent event in cancer, while rare or absent in normal tissue, which leads to high specificity for the purpose of tumor diagnosis. Small specific regions of genome are affected, which make it easily detectable, in contrast with mutations. MSP is a sensitive technique that detects free circulating DNA even in small amounts<sup>[32]</sup>. Among many genes altered by methylation in gastric cancer, *p16* promoter methylation is an early event in carcinogenesis<sup>[33]</sup>. We conclude that *p16* is a good serum marker for early detection of gastric cancer.

In this study we showed that hypermethylation is less frequent in well-differentiated tumors. We conclude that *p16* promoter hypermethylation is associated with tumor malignant behavior. There were no significant differences between intestinal and diffuse types in our population, but mixed subtype was strongly associated with silenced expression. However, there were only five cases with mixed type among our patients, and additional studies with a larger number of cases are needed to confirm the finding. In the population studied, 86.5% were at stage 3 and 4, which showed that gastric cancer was diagnosed in advanced stages, which necessitates early detection. We did not statistically compare patients at different stages, because of unbalanced distribution and the consequent bias. Methylation status in cardiac tumors was also compared with that of non-cardiac tumors. We know that cardiac tumors have different behavior from non-cardiac tumors. Methylation tends to occur more in distal tumors (more than two-fold higher), without statistical significance. We did not find any association between *H pylori* and methylation in our population, despite a few previous studies that suggested *H pylori* induces methylation<sup>[34,35]</sup>. Smoking, the other studied environmental factor, had no correlation with promoter hypermethylation. However, our patients consisted of only 17.6% (9/51) smokers, which was not sufficient to draw any strong conclusion. Promoter hypermethylation was not affected by gender, although it tended to occur more often in older patients. Precise

matching and absence of promoter hypermethylation in the control individuals decreased the possibility of methylation induction by aging, unrelated to cancer. No association was observed between circulating methylated DNA and lymph node metastasis. This indicates that the origin of circulating methylated DNA is not from lymph node metastasis. Hypermethylation status in serum was not associated with other clinicopathological features either.

In conclusion, *p16* promoter hypermethylation is an important event in gastric carcinogenesis. It is the principle mechanism of *p16* gene silencing. It is associated with tumor malignant behavior. Detection of *p16* hypermethylation in serum may be a useful biomarker for early detection of gastric cancer. Assessment of other serum markers may increase the sensitivity of screening in future studies. Moreover, promoter hypermethylation will regress after treatment. Further studies will determine whether promoter hypermethylation is a good surveillance marker for patient follow-up after treatment.

## ACKNOWLEDGMENTS

We would like to thank Dr. Velayati, Dr. Gholamin and Mrs. Asadi for their technical assistance and Miss hoseinnezhad for her help in collecting gastric cancer specimens.

## COMMENTS

### Background

Gastric cancer is the second leading cause of cancer-related death worldwide. This is because most cases are diagnosed at an advanced stage, and there is no standard method for early detection. Several genetic and epigenetic alterations play important roles in gastric carcinogenesis. Methylation, the most important epigenetic alteration, influences gene repression without affecting genetic coding. Several recent studies have been conducted to assess the clinical implications of epigenetics in cancer. Free circulating, tumor-derived DNA is a good target for early detection as a serum marker. *p16* is a tumor suppressor gene, which acts as a cell-cycle regulator. It is silenced in early stages of gastric carcinogenesis.

### Research frontiers

*p16* promoter hypermethylation related to clinicopathological features and early detection of gastric cancer.

### Innovations and breakthroughs

A thorough analysis of *p16* promoter hypermethylation, correlations with demographic and clinicopathological features and environmental factors, and implications as an early diagnostic marker were performed for the first time in the Iranian population.

### Applications

Although *p16* promoter hypermethylation is very specific for early detection of gastric cancer, further assessment of other genes will be useful to raise the sensitivity and provide a panel of serum markers for the purpose.

### Peer review

This was a very interesting study. It examined *p16* promoter hypermethylation in gastric adenocarcinoma and free DNA. Methylation was detected in 44% of tumors, and in 26.9% of serum. *p16* promoter hypermethylation in serum was closely correlated with that in gastric tissue. Methylation was significantly associated with pathological grade.

### Abstract

**AIM:** To determine the effect of Prepacol<sup>®</sup>, a combination of sodium phosphate and bisacodyl, on transit and quality of capsule endoscopy (CE).

**METHODS:** Fifty two consecutive patients were included in this prospective study. CE was performed following a 12 h fasting period. Twenty six patients were randomized for additional preparation with Prepacol<sup>®</sup>. The quality of CE was assessed separately for the proximal and the distal small bowel by 3 experienced endoscopists on the basis of a graduation which was initially developed with 20 previous CE.

**RESULTS:** Preparation with Prepacol<sup>®</sup> accelerated small bowel transit time ( $262 \pm 55$  min vs  $287 \pm 97$  min), but had no effect on the quality of CE. Visibility was significantly reduced in the distal compared to the proximal small bowel.

**CONCLUSION:** The significantly reduced visibility of CE in the distal small bowel allocates the need for a good preparation. Since Prepacol<sup>®</sup> has no beneficial effect on CE the modality of preparation and the ideal time of application remains unclear. Further standardized examinations are necessary to identify sufficient preparation procedures and to determine the impact of the volume of the preparation solution.

### INTRODUCTION

Capsule endoscopy (CE) is a well accepted tool for evaluation of small bowel pathologies<sup>[1-4]</sup>. However, it has some limitations due to restricted recording time and reduced visibility by air and residual material especially in the distal small bowel. Therefore, prokinetic drugs, laxatives and defoaming agents have been tested to improve the quality of the examination.

Prokinetic drugs were used to avoid incomplete small bowel examinations due to long gastric retention and slow bowel transit of the capsule. It was shown that domperidone shortened gastric emptying time of the capsule<sup>[5]</sup>. The results on metoclopramide were inconsistent: Keuchel *et al*<sup>[6]</sup> found no effect, whereas Selby<sup>[6]</sup> demonstrated an increased gastric emptying time. Erythromycin accelerated gastric emptying<sup>[7,8]</sup>, however, this treatment had no effect on the visibility in one study<sup>[7]</sup> and led even to an impaired visibility in another study<sup>[8]</sup>.

In order to clean the small bowel from residual material different laxatives were tested. Sodium phosphate improved the view in some studies<sup>[9-11]</sup>. Preparation with polyethylenglycol produced controversial results: In two studies the visibility was improved<sup>[12,13]</sup>, whereas in others it was unchanged<sup>[14-16]</sup>.

Preparation with simethicone, a defoaming agent, resulted in fewer air bubbles and better visibility in one study<sup>[17]</sup>.

However, since the data is scanty and partially inconsistent, to date no standardized protocol has been recommended for bowel preparation for CE.

Prepacol<sup>®</sup> (Guerbet GmbH, Sulzbach, Germany) is a combination of a saline (sodium phosphate) and a stimulant laxative (bisacodyl). It consists of 30 mL of a sodium phosphate solution (containing 6.9 sodium

monohydrogenphosphatedodecahydrate and 16.4 mg sodiumdihydrogenphosphatedihydrate) and 4 tablets (5 mg bisacodyl each). Prepacol® is available in several European countries and mainly applied for preparation before gastrointestinal operations, radiological and endoscopic bowel examinations.

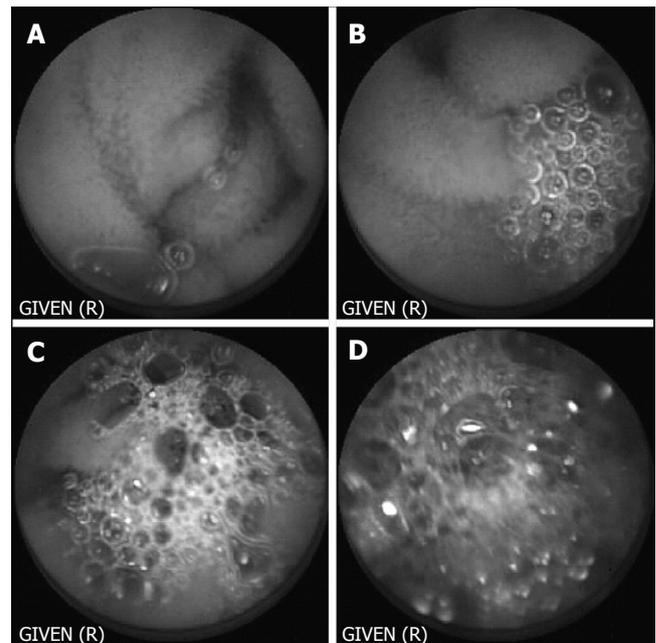

The sodium phosphate solution is poorly absorbable. Water absorption from the gut is therefore impeded by the osmotic gradient. Besides its effects on colonic motor and secretory function, bisacodyl changes the net absorption of sodium and water in the small bowel into a net secretion<sup>[18]</sup> and accelerates small intestinal transit<sup>[18,19]</sup>. It was shown that bisacodyl elicits propulsive contractions of the terminal ileum<sup>[20,21]</sup>. The combination of the osmotic purgative effect of sodium phosphate with the secretory and prokinetic effect of bisacodyl makes Prepacol® at least theoretically an ideal candidate for small bowel preparation for CE. However, its effect on the quality and gastrointestinal transit of CE has not been studied yet.

## MATERIALS AND METHODS

Fifty two consecutive patients receiving capsule endoscopy were included. The patients were prospectively randomized into two groups. Group A fasted at least 8 h before the examination; group B received additionally Prepacol®. A written informed consent was obtained from all patients. The research protocol was approved by the ethics committee of the University of Heidelberg. All patients fasted from 7 p.m. the day before CE, patients in group B received additionally at 7 p.m. 30 mL of the sodium phosphate-solution diluted with 70 mL of tap water. Subsequently, they drank 250 mL of water. At 10 p.m. the patients received 4 tablets Prepacol® (20 mg Bisacodyl totally) again with 250 mL of water. All patients were allowed to drink water until 2 h before the examination. The capsule was swallowed at 10 a.m. with 250 mL of plain water.

Capsule endoscopy films were evaluated by three independent, endoscopically experienced investigators who were blinded concerning the kind of preparation. In a run-in-phase the three investigators corporately generated the appraisal factors and their graduation on the basis of 20 retrospective CE examinations. The following parameters were assessed: total quality of the film, visibility of small bowel mucosa, velocity of the capsule and occurrence of foam, air and residual food. Every parameter was graduated from 1 to 4, accordingly, excellent, good, limited and poor quality. Graduation for occurrence of foam is shown in Figure 1. To evaluate the effect of the preparation with Prepacol® two one-hour-lasting periods were evaluated. The first period started one hour after the capsule left the stomach, the second period ended when the capsule reached the ileocecal valve. Investigators examined the films at a rate of 20 pictures per second.

Quantitative data are expressed as mean  $\pm$  SEM and were analyzed by student's *t*-test for significant differences. Categorical data were evaluated by Chi<sup>2</sup> and Fisher exact test. *P* < 0.05 was chosen as the level of statistical significance.

**Figure 1** Graduation of visibility concerning occurrence of foam. A: Excellent; B: Good; C: Limited; D: Poor visibility.

**Table 1** Patient's data and indications for CE: Group A (fasting) and group B (additionally Prepacol®)

	Group A	Group B	<i>P</i> value
Gender (w/m)	13/13	10/16	NS
Age (yr)	54 $\pm$ 17	56 $\pm$ 20	NS
Weight (kg)	71 $\pm$ 15	79 $\pm$ 17	NS
Length (cm)	170 $\pm$ 10	171 $\pm$ 8	NS
Indication			
GI-bleeding	17 (65%)	19 (73%)	NS
Inflammatory bowel disease	4 (15%)	3 (12%)	NS
Miscellaneous	5 (19%)	4 (15%)	NS

Data are mean  $\pm$  SEM; NS: Not significant.

## RESULTS

Both groups were not different concerning age, weight, length and gender of the patients. Obscure gastrointestinal (GI) bleeding was the main indication for CE in both groups (Table 1). Other indications were suspicion for or follow-up in IBD, celiac disease, small bowel polyps or malignancy and no difference was observed between the groups (Table 1).

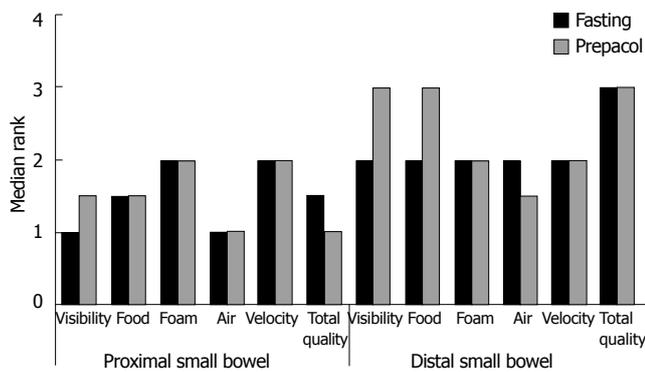

There were no differences in gastric emptying time of the capsule between the two groups (Table 2). Small bowel transit time was slightly but significantly shorter in the Prepacol®-group (262  $\pm$  55 min *vs* 287  $\pm$  97 min, *P* = 0.05) (Table 2). Recording time was not different between both groups.

Figure 2 demonstrates median assessment of investigators concerning visibility of small bowel mucosa, occurrence of foam, air and residual food, as well as velocity of the capsule and total quality of the film separately for the proximal and distal small bowel. Compared to exclusive fasting additional preparation with Prepacol® did not improve any parameter.

**Table 2** GI transit times: Group A (fasting) and group B (additionally Prepacol®)

	Group A	Group B	P value
Gastric retention (min)	38 ± 23	44 ± 47	NS
Small bowel transit (min)	287 ± 97	262 ± 55	0.05
Total recording time (min)	441 ± 36	424 ± 49	NS

Data are mean ± SEM; NS: Not significant.

**Figure 2** Quality of CE as assessed by three independent investigators, separately shown for proximal and distal small bowel, data are median of 52 patients, n = 26 for each group.

The quality was significantly more frequently judged as excellent or good in the proximal compared to the distal small bowel (Figure 3).

Concordance in the assessment between each of the investigators was good (82%, 78% and 87%, respectively).

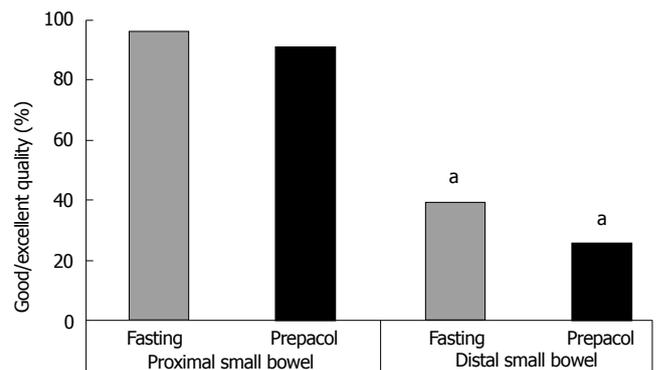

## DISCUSSION

An adequately cleaned bowel is an important precondition for any gastrointestinal endoscopic procedure. Turbid fluid due to intestinal secretion and food residues in the small bowel may limit visibility and therewith the information obtained by capsule endoscopy. Although in some studies preparation with prokinetic agents or laxatives improved quality of CE<sup>[5-16]</sup>, no standard procedure has been reached since the data is scanty and partially inconsistent. The selection of an appropriate preparation is further aggravated by the fact that the evaluation of the quality of capsule endoscopy is subjective. Therefore we chose three independent investigators to estimate the influence of Prepacol® on the quality of CE.

In the present study preparation with Prepacol® had no advantages concerning visibility of the mucosa, occurrence of foam, frequency and extent of air filled segments, food residues, velocity of the capsule and total quality as compared to exclusive overnight fasting.

Quality was significantly inferior in distal small bowel segments compared to proximal segments. This demonstrates that sufficient preparation would be of great help to obtain best possible conditions throughout the whole small bowel.

Prepacol® is not effective as a preparation for capsule endoscopy. This may be due to the pharmacological effect,

**Figure 3** Percentage of good or excellent quality as assessed by three independent investigators, separately shown for proximal and distal small bowel, data are median of 52 patients, n = 26 for each group, <sup>a</sup>P < 0.05 vs proximal small bowel.

the dosage and the time of application in relation to CE. Bisacodyl is mainly activated by bacterial metabolism in the colon. Although both, sodium phosphate and bisacodyl increase luminal fluid in the small bowel, their main effect is documented in colon preparation<sup>[22,23]</sup>. The dose of the sodium phosphates could be too low. Niv and colleagues could show that 90 mL of sodium phosphate in combination with 2 liters of water improved CE quality<sup>[9,10]</sup>. Those studies showing a positive effect of PEG on CE visibility also used volumes of at least 2 liters<sup>[12,15]</sup>. Therefore, not only the pharmacological effect may be responsible, but also the volume itself. Patients in our study were allowed to drink until 2 h before the examination, but no minimum volume was recommended. The volume was not documented, it was therefore not possible to examine if the individual amount of fluid intake had any effect on CE quality.

Double balloon enteroscopy (DBE) is another recent tool for examination of the small bowel<sup>[24-26]</sup>. Requirement for more manpower and a slightly increased complication rate are some disadvantages of DBE compared to CE<sup>[27,28]</sup>. However, DBE has a working channel which enables the examiner for example to take biopsies or intervene in bleedings<sup>[29]</sup>. In contrast to CE no other preparation than fasting is essential when DBE is performed orally, since the small bowel content can be cleaned during the examination by means of the suction channel<sup>[27,28]</sup>.

CE is an expensive and also time consuming examination. An effective preparation is essential to minimize false results at the best possible rate. Therefore, additional studies are necessary to identify sufficient preparation procedures and to determine the impact of the volume of the preparation solution. This has to be performed in consideration of the patient's compliance, which might be reduced by the taste of the preparation solution<sup>[30]</sup>.

## COMMENTS

### Background

Capsule endoscopy (CE), a well accepted tool for evaluation of small bowel pathologies, has some limitations due to reduced visibility by air and residual material especially in the distal small bowel.

### Research frontiers

Several forms of preparation (e.g. prokinetic drugs, laxatives and defoaming agents) have been tried to improve the quality of the examination. However, since the data is scanty and partially inconsistent, to date no standardized protocol has been recommended for bowel preparation for CE.

### Innovations and breakthroughs

The effect of Prepacol<sup>®</sup> (Guerbet GmbH, Sulzbach, Germany), a combination of a saline (sodium phosphate) and a stimulant laxative (bisacodyl), on the quality and transit time of CE was tested. It has been shown that preparation with Prepacol<sup>®</sup> accelerated small bowel transit time, but had no effect on the quality of CE.

### Applications

Since Prepacol<sup>®</sup> has no beneficial effect on CE the modality of preparation and the ideal time of application remains unclear.

### Peer review

Interesting effort to do proper research on SB-preparation.

### Abstract

**AIM:** To evaluate treatment safety and hemodynamic changes during a single 6-h treatment with the Prometheus™ liver assist system in a randomized, controlled study.

**METHODS:** Twenty-four patients were randomized to either the study group or to one of two control groups: Fractionated Plasma Separation Adsorption and Dialysis, Prometheus™ system (Study group;  $n = 8$ ); Molecular Adsorbent Recirculation System (MARS)™ (Control group 1,  $n = 8$ ); or hemodialysis (Control group 2;  $n = 8$ ). All patients included in the study had decompensated cirrhosis at the time of the inclusion into the study. Circulatory changes were monitored with a Swan-Ganz catheter and bilirubin and creatinine were monitored as measures of protein-bound and water-soluble toxins.

**RESULTS:** Systemic hemodynamics did not differ between treatment and control groups apart from an increase in arterial pressure in the MARS group ( $P = 0.008$ ). No adverse effects were observed in any of the groups. Creatinine levels significantly decreased in the MARS group ( $P = 0.03$ ) and hemodialysis group ( $P = 0.04$ ). Platelet count decreased in the Prometheus group ( $P = 0.04$ ).

**CONCLUSION:** Extra-corporal liver support with Prometheus is proven to be safe in patients with end-stage liver disease but does not exert the beneficial effects on arterial pressure as seen in the MARS group.

Effect of Prometheus liver assist system on systemic hemodynamics in patients with cirrhosis: A randomized controlled trial. *World J Gastroenterol* 2008; 14(13): 2065-2071 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2065.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2065>

### INTRODUCTION

The fact that not all patients with end-stage liver disease are suitable for liver transplantation, and the shortage of grafts enhance the need for supportive liver therapy either to secure time to stabilize hepatic functions or to enable bridging to liver transplantation. Indeed, extra-corporal liver support has turned out to be a valuable supplement to standard medical therapy (SMT)<sup>[1]</sup>. Especially, albumin dialysis improves not only the general condition, but also both cardiovascular and renal function<sup>[2-7]</sup> as well as the degree of hepatic encephalopathy<sup>[1,8,9]</sup>. The Fractionated Plasma Separation, Adsorption and Dialysis (Prometheus™) system and the Molecular Adsorbent Recirculation System (MARS™) both represent such treatment modalities.

End-stage liver disease is often accompanied by a hyper-dynamic systemic circulation<sup>[10-13]</sup>. This circulatory

change is caused by a variety of vasoactive factors, such as cytokines, prostacyclins, and nitric oxide<sup>[14-18]</sup>. Infection or bleeding, which are frequent complications in cirrhotic patients, increase the nitric oxide production and result in aggravation of the hyperdynamic circulation<sup>[19]</sup>. Studies comparing the hemodynamic alterations in stable patients with cirrhosis during extra-corporal intervention remain scarce though such knowledge might evidently improve patient safety and perhaps lessen reluctance towards the use of extra-corporal liver support at an early time in the treatment.

This randomized, controlled study was designed to clarify the hemodynamic effects of intervention with Prometheus<sup>TM</sup>, using MARS<sup>TM</sup> and hemodialysis as control groups, in patients with end-stage liver disease.

## MATERIALS AND METHODS

### Subjects

The clinical and paraclinical characteristics of the patients included in the study are listed in Table 1. The study was approved by the Ethics Committee of Copenhagen (jr. nr. KF 01-186/04) and the study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki. Twenty-six patients (10 females and 16 males) were screened and 24 (9 females and 15 males) were enrolled in the study after obtaining written and oral consent from the patient or next-of-kin. All patients included in the study were under evaluation for liver transplantation and had a right-sided heart catheterization by a Swan-Ganz catheter. Former studies from our department have evaluated the effects of a 6-h albumin dialysis on patients with acute-on-chronic liver failure as well as patients with acute liver failure<sup>[20,21]</sup>. Consequently, the present study was designed accordingly with a 6-h treatment to match and complete the former studies. Patients were divided into three groups each receiving a 6-h extra-corporal treatment: Prometheus treatment with MARS and hemodialysis as control groups. The randomization was performed using sealed, opaque envelopes containing a computerized sequence code. Envelopes were drawn by a third person not involved in the study.

Inclusion criteria were pre-existing liver disease with decompensated cirrhosis (verified by histological examination and/or CT/MRI scanning), ascites and a history of hepatic encephalopathy or repeated variceal bleeding.

Exclusion criteria were uncontrolled systemic or intracranial bleeding, uncontrolled systemic infection, extra-hepatic cholestasis, necrotic pancreatitis, cardiovascular failure necessitating > 0.05 µg/kg per minute of norepinephrine, and a history of albumin dialysis within the last 7 d before entering the study.

### Treatment

All patients were treated in our liver ward but they were admitted to our liver intensive care unit for the duration of the extra-corporal treatment. Red blood cells, platelets and fresh frozen plasma were transfused according to the attending physician's orders. Pre-treatment albumin levels were not corrected (Table 1). Measurements of pulmonary

artery core temperature, cardiac output (CO), pulmonary artery mean pressure (PAPM), pulmonary artery wedged pressure (PAWP) and central venous pressure (CVP) were obtained through thermo dilution technique using a four-lumen balloon-tipped catheter (Swan-Ganz; Baxter, Copenhagen, Denmark). Using ultrasound supervision, all patients were equipped with a double-lumen catheter in the femoral vein (24 cm, med. COMP, Harlysville PA, USA) as well as a Swan-Ganz catheter in the right internal jugular vein.

**Extra-corporal treatment:** It was performed using the 4008 hemodialysis machine (Fresenius Medical Care Denmark A/S, Albertslund, Denmark) capable of performing both conventional hemodialysis as well as Prometheus treatments. The 4008 machine was also combined with a MARS monitor to perform MARS treatments. The thermostat of the machine was set to 36.5°C to avoid cooling of the patients. Patients in all three groups were treated with identical blood and dialysate flow rates (225 mL/min and 500 mL/min, respectively).

**Anticoagulation:** Citrate/calcium-anticoagulation was used for all patients using the 4008 hemodialysis machine's built-in citrate/calcium algorithm. Calcium is automatically infused with a rate of 3.33 mmol citrate per litre of perfused blood. The citrate dose is calculated from the ionized calcium content in the patient's venous blood. Venous blood samples were taken every 30 min and immediately analyzed in heparinized syringes (Radiometer, Copenhagen, Denmark). Blood tests before and after the treatment included creatinine, platelet count and bilirubin.

The Prometheus system removes albumin bound toxins in the patient's blood by combining fractionated plasma separation and adsorption (FPSA) with conventional dialysis. The patient's blood first passes through a plasma separator with a pore size of 250 kDa. The filtered plasma fraction then passes over two adsorption columns, a neutral resin and an anion exchange resin adsorber, before it is filtered back to the systemic circulation. The blood then passes through a high-flux dialyzer (F60S, Fresenius, Denmark). The flow rate in the plasma circuit was set to 300 mL/min according to the manufacturer's recommendations.

MARS is an extra-corporal high-flux hemofiltration that removes albumin-bound toxins from the blood over a specialized hybrid (albumin-impermeable) membrane into an albumin-enriched dialysate (500 mL of 200 g/L albumin). MARS combines a standard dialysis machine with a closed-loop albumin circuit, which is re-circulated by the MARS monitor (Gambro, Lyon, France). The albumin dialysate is passed through a conventional dialyzer and afterwards a charcoal and an anion-exchanger column. The flow rate in the closed albumin circuit was set to the maximum rate of 250 mL/min.

Hemodialysis was performed using a high-flux dialyzer (F60S, Fresenius, Denmark).

### Measurements

All measurements determined heart rate (HR), systolic/diastolic and mean arterial blood pressure (MAP), stroke

PBC: Primary biliary cirrhosis; Cholest. stor. dis: Cholesterol ester storage disease.

volume (SV), CO, CVP, PAMP, and PAWP. Baseline measurements were performed 30 min before starting the extra-corporal treatment. Throughout the 6-h treatment, hemodynamic measurements were performed and registered approximately every hour. Blood samples before and after the treatment included platelet count, international normalized ratio (INR), bilirubin, creatinine and alanine transaminase (ALT). During the treatment, we monitored the venous levels of ionized calcium as well as potassium and sodium, hemoglobin, glucose and magnesium. If necessary, substitution by continuous infusion was performed.

Calculations were performed as follows: Cardiac index (CI) ( $\text{L}/\text{min}\cdot\text{m}^2$ ) = CO divided by the body surface area. SV ( $\text{mL}/\text{beat}$ ) = CO/HR; SVRI ( $\text{DS}/\text{m}^2\cdot\text{cm}^5$ ) =  $80 \times (\text{MAP} - \text{CVP})/\text{CI}$ ; PVRI ( $\text{DS}/\text{m}^2\cdot\text{cm}^5$ ) =  $80 \times (\text{PAPM} - \text{PAWP})/\text{CI}$ . Unless stated differently, data were expressed as mean  $\pm$  SEM.

### Statistical analysis

Comparison within a group was performed using the paired *t*-test or Wilcoxon's rank sum test. For comparison between groups, the one-way-ANOVA or Kruskal-Wallis rank sum test were applied. *P* values < 0.05 were considered statistically significant.

## RESULTS

Of the 24 patients included, 22 patients completed the 6-h treatment without complications. Patient number 1 and 7, both randomized to hemodialysis treatment, dropped out of the study due to repeated clotting of the dialysis filters. During the treatment, we recorded no serious adverse

events, i.e. no drop in MAP and no hemolysis or bleeding requiring therapeutic intervention. Patient number 15 from the MARS group experienced bleeding after removal of the dialysis catheter 10 h after termination of the treatment. None of the conscious patients complained of any discomfort that could be related to the extra-corporal treatment. Nine patients were discharged 2 to 19 d after the treatment; 5 patients underwent orthotopic liver transplantation (OLT) and were alive 6 mo after the transplantation, whereas 11 patients died within 4 to 143 d after participating in the study (Table 1). There was no statistical correlation between the study group and the 6-mo outcome (*P* = 0.397).

All hemodynamic measurements are listed in Table 2. A one-way analysis of variance between the three groups comparing baseline values of age, MELD score, INR, bilirubin, albumin, creatinine, hemoglobin, and platelets showed no significant differences. Pre-treatment MAP values were within the normal range (mean 76 mmHg; range 57-98 mmHg), while the other hemodynamic parameters were in accordance with the normal findings in end-stage liver disease: CO was elevated (mean 8.9 L/min; range 4.4-13.9 L/min), CI high (mean 4.6 L/min $\cdot$ m<sup>2</sup>; range 2.3-7.1 L/min $\cdot$ m<sup>2</sup>), and SVRI low (mean 1231 Ds $\cdot$ s/cm<sup>5</sup> $\cdot$ m<sup>2</sup>; range 139-3616).

Only small hemodynamic changes from pre- to post-treatment in all three groups were noted. However, the MARS group showed, during the treatment, a significant increase in the systolic and diastolic blood pressure of 10.5% and 15.2%, respectively. Heart rate, CI and SV remained constant.

Paraclinical values of bilirubin, creatinine, and platelet count measured before and after the treatment were as

Table 2 Hemodynamic variables (mean  $\pm$  SEM)

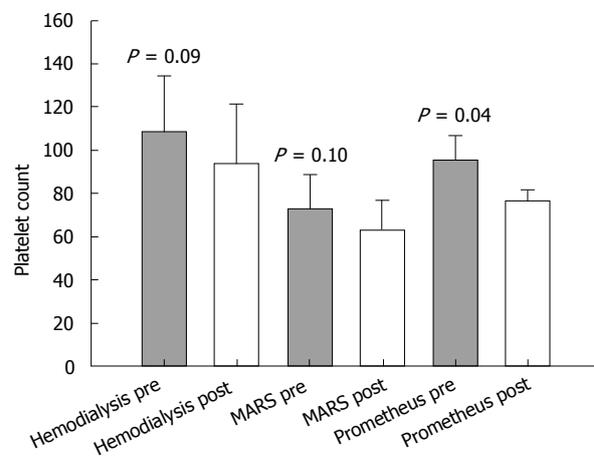

Figure 3 Platelet count pre- and post-treatment using hemodialysis, MARS and Prometheus. All values are given as mean  $\pm$  SEM.

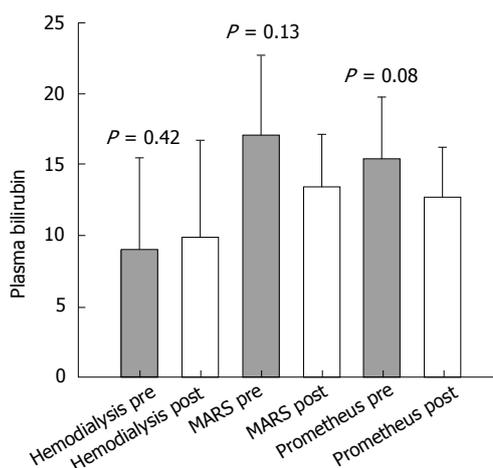

Figure 2 Plasma bilirubin pre- and post-treatment using hemodialysis, MARS and Prometheus. All values are given as mean  $\pm$  SEM.

follows: (1) Prometheus group: pre-treatment values: bilirubin (mean  $15.3 \times 10^{-2}$  g/L; SEM  $4.4 \times 10^{-2}$  g/L), creatinine (mean  $1.44 \times 10^{-2}$  g/L; SEM  $0.35 \times 10^{-2}$  g/L) and platelet count (mean  $96 \times 10^9$ /L; SEM  $11 \times 10^9$ /L);

post-treatment values: bilirubin (mean  $12.6 \times 10^{-2}$  g/L; SEM  $3.6 \times 10^{-2}$  g/L), creatinine (mean  $1.09 \times 10^{-2}$  g/L; SEM  $0.39 \times 10^{-2}$  g/L) and platelet count (mean  $76 \times 10^9$ /L; SEM  $11 \times 10^9$ /L); (2) MARS group: pre-treatment values: bilirubin (mean  $17.0 \times 10^{-2}$  g/L; SEM  $5.6 \times 10^{-2}$  g/L), creatinine (mean  $1.2 \times 10^{-2}$  g/L; SEM  $0.24 \times 10^{-2}$  g/L) and platelet count (mean  $73 \times 10^9$ /L; SEM  $16 \times 10^9$ /L); post-treatment values: bilirubin (mean  $13.4 \times 10^{-2}$  g/L; SEM  $3.8 \times 10^{-2}$  g/L), creatinine (mean  $0.86 \times 10^{-2}$  g/L; SEM  $0.17 \times 10^{-2}$  g/L) ( $P = 0.03$ ), and platelet count (mean  $63 \times 10^9$ /L; SEM  $14 \times 10^9$ /L). (3) Hemodialysis group: pre-treatment values: bilirubin (mean  $9.1 \times 10^{-2}$  g/L; SEM  $6.4 \times 10^{-2}$  g/L), creatinine (mean  $0.64 \times 10^{-2}$  g/L; SEM  $0.16 \times 10^{-2}$  g/L) and platelet count (mean  $109 \times 10^9$ /L; SEM  $25 \times 10^9$ /L); post-treatment values: bilirubin (mean  $9.9 \times 10^{-2}$  g/L; SEM  $6.8 \times 10^{-2}$  g/L), creatinine (mean  $0.49 \times 10^{-2}$  g/L; SEM  $0.06 \times 10^{-2}$  g/L) and platelet count (mean  $94 \times 10^9$ /L; SEM  $28 \times 10^9$ /L).

The results of the paired *t*-test comparing pre- and post-treatment values in each group are shown in Figures 1-3.

Anticoagulation was performed using citrate/calcium infusion. In all patients, we followed the 4008 machine's built-in algorithm, which calculates the citrate infusion rate

from the patient's ionized calcium. Both during and after the treatment, none of the patients required calcium or citrate supplements and no correction of the pH was necessary.

## DISCUSSION

In this study, we compared the systemic circulatory changes during a single treatment of Prometheus with MARS and hemodialysis as control groups in patients with end-stage liver disease. The hemodynamic differences between the three groups showed insignificant differences besides a rise in MAP in the MARS treated group. None of the patients experienced any serious adverse events. Though we have some experience both about the clinical and the hemodynamic effects of the available extra-corporal treatments, i.e. MARS and Prometheus, there is a growing recognition that patients may benefit from the initiation of extra-corporal liver support before treatment for multi-organ failure in the ICU setting is needed<sup>[22]</sup>.

We have been using both MARS and Prometheus for several years in our liver failure unit. Former studies from our unit have determined the hemodynamic changes during a single 6-h MARS treatment both in patients with acute-on-chronic liver failure (AoCLF) as well as hyper acute liver failure<sup>[20,21]</sup>. None of the patients in this study had an acute exacerbation at the time of randomization. Thus our patients represent a group that differs from AoCLF patients but can be characterized as having a chronic liver failure with decompensation. The Child-Pugh score for our patients supports this view with 6 group B and 18 group C patients.

Arterial hypotension is a well-described adverse effect induced by hemodialysis. In the light of this fact, it is interesting that hemodynamic studies have indicated that the MARS system exerts a beneficial influence on CO, SV, SVRI<sup>[20-23]</sup> and MAP<sup>[20-26]</sup>. The present study cannot demonstrate such beneficial changes, neither in the Prometheus nor in the hemodialysis group; however, there was a significant increase in MAP in the MARS group. The overall lack of significant hemodynamic changes (especially on CO, SV, and SVRI as would have been expected in the MARS group) could be attributed to the fact that the patients in the present study were treated early before deterioration of their chronic liver disease: the plasma bilirubin in our patient group was 42% of the value seen in the study by Schmidt *et al.*<sup>[20]</sup> and 48% of the mean value of all three groups in the study by Laleman *et al.*<sup>[2]</sup>.

Both the Prometheus and MARS systems are capable of removing both albumin-bound as well as water-soluble substances. As shown in Figure 2, both albumin dialysis systems, as expected, decreased the plasma bilirubin level but the removal did not reach statistical significance. This was most likely due to heterogeneity regarding pre-treatment bilirubin levels among our group of patients and a low pre-treatment bilirubin level. In addition, the absolute amount of bilirubin eliminated during a treatment depends on blood concentration: higher pre-treatment values will yield higher clearances.

The toxin concentration in the blood is generally thought to cause the hyperdynamic circulation seen in liver failure. If we consider the bilirubin level merely as an

indicator for the general level of albumin-bound toxins in the blood, it could also explain why potential positive hemodynamic effects could not be demonstrated. In our study, the pre-treatment bilirubin level was low and the toxin level would accordingly also be low. Therefore, no significant removal of bilirubin/toxins could be achieved and possible beneficial hemodynamic changes would thus become difficult to demonstrate.

No significant removal of creatinine could be demonstrated in the Prometheus group (Figure 1). This is most likely due to a low pre-treatment concentration and a high standard deviation as mentioned above. As expected, the survival of the patients was not statistically correlated to the randomized study group.

Regarding the safety of the treatment, none of the patients experienced arterial hypotension requiring cessation of the treatment. As a standard routine, the initial blood flow on the 4008 machine was set to 120 mL/min for the first 10 min and was then increased to 225 over the next 5-10 min. As mentioned, one episode of post-treatment bleeding occurred. The event was related to the removal of the dialysis catheter and occurred despite vessel compression for 15 min and a 30-min rest after dialysis-catheter removal, all according to standard guidelines.

Both the study group and the two control groups exhibited a drop in platelet count, yet, it was only statistically significant in the Prometheus group (Figure 3). Low platelet count is well known in cirrhotic patients. In addition, thrombelastography (TEG) often discloses dysfunction of the platelets. Consequently, monitoring the platelet count closely before, during, and after an extra-corporal treatment, especially when using Prometheus treatment, seems advisable as well as substitution, if necessary. Two patients in the hemodialysis group dropped out of the study due to repeated clotting. Patient number 7 showed obvious signs of hyper-coagulation: apart from clotting three hemodialysis filters, the dialysis catheter also clotted during a blood pump stop of 3-5 min. The clotting problems in the hemodialysis group opposed our former clinical experience, which had pointed at patients treated with the Prometheus system in combination with citrate anticoagulation as being most prone to clotting problems. The paraclinical data from patient number 1 and 7 did not account for the repeated clotting. Apart from the reported data, the activated prothrombin time values were within normal range for both patients (data not shown).

In conclusion, the decision to use extra-corporal liver support in the treatment of patients with end-stage liver disease hinges on many factors, with safety considerations as a major concern. The choice of treatment will depend on the risk of adverse events, and possible positive or negative hemodynamic influences between the available treatment modalities. Our study adds to the clarification of these considerations in showing that the Prometheus system does not aggravate the systemic hemodynamics; however, in our study, Prometheus does not exert an equally beneficial influence on MAP as seen during MARS treatment. We conclude that an intervention using extra-corporal liver support with albumin-dialysis should not be withheld merely because of safety considerations.

## COMMENTS

### Background

Patients with end-stage liver disease often need supportive liver therapy either to secure time to stabilize hepatic functions or to enable bridging to liver transplantation. Albumin dialysis improves not only the general condition, but also both cardiovascular and renal function as well as the degree of hepatic encephalopathy. Studies comparing the hemodynamic alterations in stable patients with cirrhosis during extra-corporal intervention remain scarce though such knowledge might evidently improve patient safety and perhaps lessen reluctance towards the use of extra-corporal liver support at an early time in the treatment. This randomized, controlled study was designed to clarify the hemodynamic profile of intervention with Prometheus™, using MARS™ and hemodialysis as control groups, in patients with end-stage liver disease.

### Research frontiers

This paper is related to the scientific efforts to develop clinically valuable artificial liver assist devices to support patients with fulminant liver failure.

### Innovations and breakthroughs

<http://www.ncbi.nlm.nih.gov/sites/entrez>. See under "liver assist devices" or Sen S, Williams R, Jalan R. Emerging indications ofr albumin dialysis. *Am J Gastroenterol* 2005; 100: 468-475.

### Applications

The decision to use extra-corporal liver support in the treatment of patients with end-stage liver disease hinges on many factors, with safety considerations as a major concern. The choice of treatment will depend on the risk of adverse events, and possible positive or negative hemodynamic influences between the available treatment modalities. Our study adds to the clarification of these considerations in showing that the Prometheus system does not aggravate the systemic hemodynamics; however, in our study, Prometheus does not exert an equally beneficial influence on arterial pressure as seen during MARS treatment. We conclude that an intervention using extra-corporal liver support with albumin-dialysis should not be withheld merely because of safety considerations.

### Terminology

Acute-on-chronic liver failure is defined as an acute deterioration in liver function in a patient with cirrhosis that results in dysfunction of other organs, such as the brain or the kidneys.

### Peer review

This is an interesting and well performed study. The abstract gives a clear delineation of the research background, aim, materials and methods, results and conclusion. The design of the study is rational and reliable. The work is of the practical importance.

### Abstract

**AIM:** To assess the value of gray scale (GS) and colour Doppler ultrasonography (CDU) in differentiating the progression of chronic viral hepatitis (CVH) and compensated liver cirrhosis (CIR).

**METHODS:** Seventy-two patients and 32 normal individuals who were used as controls were studied. Forty-four patients suffered from CVH and 28 from CIR. All patients were underwent to liver biopsy. Multiple qualitative and quantitative variables were studied in liver, portal vein (PV), hepatic artery (HA) and spleen with GS and CDU. On the basis of the obtained CDU data, several known indexes were calculated. In addition, alternative indices [PV diameter (D)/time average mean velocity ( $V_{TAM}$ ), HA/PV  $V_{TAM}$  ratio] were calculated and studied.

**RESULTS:** ROC analysis showed that PV congestion index, PV D/ $V_{TAM}$  and HA/PV  $V_{TAM}$  indices had the best sensitivity and specificity in discriminating CVH from CIR. Stepwise discriminant analysis showed that 88.9% of the originally grouped cases could be correctly classified by the three qualitative and four quantitative variables selected as statistically significant predictors. Among the CVH patients who underwent to biopsy, statistically significant changes were found in those at fibrosis stage 5 compared to fibrosis stages 1-4.

**CONCLUSION:** Simple GS and CDU parameters discrimi-

### INTRODUCTION

Chronic viral hepatitis, mainly caused by hepatitis virus B or C, results in liver parenchyma damage and inflammation and may lead to fibrosis, cirrhosis and/or hepatocellular carcinoma<sup>[1-3]</sup>. Cirrhosis often occurs as an indolent disease and a lot of patients remain asymptomatic<sup>[4,5]</sup> until the occurrence of decompensation, and are characterised by portal hypertension, variceal bleeding, ascites and hepatic encephalopathy.

Liver biopsy is the gold standard for diagnosis and determination of the fibrosis and necroinflammatory changes in chronic viral hepatitis and cirrhosis. However, the use of biopsy in clinical practice has some limitations related to sample errors with an estimated false negative percentage of 24% morbidity and mortality in series of blind biopsies<sup>[6]</sup> and complications<sup>[7]</sup>.

The non-invasive assessment of chronic liver disease has been attempted by various research groups using either clinical signs<sup>[8,9]</sup>, gray scale<sup>[10-15]</sup> and colour Doppler ultrasound (CDU) signs and indexes<sup>[16-32]</sup>, or biochemical parameters in the blood<sup>[9]</sup>. The use of CDU in diagnosis and staging of chronic viral liver disease has been based on the hypothesis that alteration in liver haemodynamics due to chronic inflammatory changes may indirectly reflect histological alterations. Therefore, positive correlation studies have usually referred to the velocity ratio of hepatic

artery to portal vein or the resistive index in hepatic artery. However, the role of CDU remains controversial regarding the reproducibility<sup>[33-36]</sup> and the statistical significance<sup>[37,38]</sup> of the measurements in hepatic fibrosis and cirrhosis.

The aim of the present study was to determine the alterations in liver haemodynamics by using the Doppler indexes and measurements of spleen size that may lead to differentiation between chronic viral liver disease and compensated cirrhosis in a group of patients with a well-delineated histological profile. Furthermore, an effort was made to isolate predictive factors for discrimination between patients with chronic viral hepatitis and cirrhosis.

## MATERIALS AND METHODS

### Patient population

Seventy-two patients were enrolled in this controlled prospective study and divided into chronic viral hepatitis (CVH) group and cirrhotic (CIR) group. The CVH group included 44 patients (mean age  $53 \pm 12$  years, 29 males and 18 females) with chronic viral hepatitis. Of them, 20 were positive for hepatitis B surface antigen and 24 were positive for hepatitis C serum markers. All patients underwent needle biopsy at the time of study.

The CIR group consisted of 28 patients suffering from compensated early stage cirrhosis (Child-Pugh A score, mean age  $63 \pm 9$  years, 16 males and 13 females) due to viral hepatitis B or C. All cirrhotic patients had previous needle biopsy that confirmed their disease and endoscopic investigation of the upper GI tract.

All patients included in the study gave their written informed consent and had no known liver tumour or decompensated liver disease. The study was approved by the ethics committee of our institution.

Thirty-two healthy individuals (mean age  $50 \pm 15$  years, 18 males and 14 females) served as controls. They were chosen from healthy volunteers with normal blood profile without evidence of liver disease. Volunteers with complex anatomy related to the hepatic artery were excluded from the study. The alcohol consumption was no more than 28 units a week (one unit = 8 g) for each individual in the control group. None of them had a history of cardiac or liver disease and risk factors for viral hepatitis, or was receiving therapy known to alter liver haemodynamics.

### CDU technique and indexes

All sonographic scans were performed by a single experienced radiologist (first author), who was unaware of the clinical and laboratory data. All asymptomatic patients and healthy adults were fasted overnight before the examination. Patients did not take drugs that could affect their portal or systemic haemodynamics twenty-four hours prior to examination.

All scans were performed with the individuals lying supine using the same sonography system (ATL, HDI 3500) with a curvilinear 2.5-5 MHz transducer. The machine was supported with the proper software for direct and automatic calculation of the haemodynamic parameters based on the spectral Doppler waveform. The examination was started with the observation in gray-

scale scanning of the liver size (normal or enlarged if the midclavicular longitudinal diameter of the organ was greater than  $12.6 \text{ cm}^{[39]}$ , taking the value 1 for enlarged and 0 for normal), contour (nodular yes/no, taking the value 1 for yes and 0 for no) and parenchyma (homogeneity diffuse yes/no, and echogenic yes/no, taking the value 1 for yes and 0 for no). Subsequently, the examination proceeded to study CDU and a transverse section was obtained at the epigastrium to locate the proper hepatic artery in its longitudinal axis. The same method was used at the midlevel of the portal vein trunk to calculate venous indices, since no aberrant anatomy was present in the subjects participating in this study. To decrease the effect of respiration on the portal blood flow, all measurements were obtained during a short time breath-holding to avoid deep respiration. An occasional problem of overlying bowel gas was handled either by extending the scanning time or by setting a new appointment on the following day. For quantitative flow measurements, the position of the scanner was optimised until a Doppler angle of less than  $60^\circ$  was achieved. Haemodynamic parameters were calculated over four cardiac cycles. The sample volume size was always equal to the lumen diameter of blood vessels.

The following portal vein (PV) variables were measured: diameter (D) in cm, cross-sectional area (AR) in  $\text{cm}^2$ , time-averaged maximum velocity ( $V_{\text{MAX}}$ ) in  $\text{cm/s}$ , time-averaged mean velocity ( $V_{\text{TAM}}$ ) in  $\text{cm/s}$ , blood flow volume (BF) in  $\text{mL/min}$  and the congestion index which was calculated as the ratio between cross-sectional area and time-averaged mean velocity ( $\text{CI} = \text{AR}/V_{\text{TAM}}$ ) in  $\text{cm}^2/\text{s}^{[11]}$ . The time-averaged mean portal venous velocity was determined electronically using the software package provided with the ultrasound machine.

Hepatic artery (HA) measurements included: diameter (D) in cm, cross-sectional area (AR) in  $\text{cm}^2$ , time-averaged mean velocity ( $V_{\text{TAM}}$ ) in  $\text{cm/s}$  and blood flow volume (BF) in  $\text{mL/min}$ . Resistance index (RI) of HA (percentage) was the ratio of  $100 \times$  the difference of peak systolic velocity minus end diastolic velocity to peak systolic velocity, automatically given by machine's software. In addition, Doppler perfusion index (DPI)<sup>[22]</sup> was calculated according to the formula:  $\text{DPI} = \text{BF}_{\text{HA}}/(\text{BF}_{\text{HA}} + \text{BF}_{\text{PV}})$ .

We also evaluated two alternative indexes for liver haemodynamics: the ratio of portal vein diameter to  $V_{\text{TAM}}$  ( $\text{PV } r_1 = \text{D}/V_{\text{TAM}}$ ) in  $\text{cm}$  and the artery to portal vein ratio (A/P), which was calculated by the following formula:  $\text{Time-averaged HA mean velocity } (V_{\text{TAM}})/\text{time-averaged PV mean velocity } (V_{\text{TAM}})$ .

Two consecutive measurements of the anatomic and Doppler parameters were made in each blood vessel and the average value was taken for statistical analysis.

The spleen size was estimated by measuring the maximum craniocaudal and transverse diameters<sup>[40,41]</sup>.

### Liver biopsies

Liver biopsies were fixed in formalin and embedded in paraffin. Individual histological sections were prepared and stained using standard procedures. All patients were classified on the basis of the histologic activity index according to Ishak *et al.*<sup>[42]</sup> in six fibrosis stages (F1-F6) with

the sixth (F6) to be cirrhosis stage and necroinflammatory score varying from 0 to 18 in each stage.

### Statistical analysis

The quantitative variables (predictors) were compared by *t*-test and ANOVA between CVH and CIR patients and between controls. Quantitative variables between CVH patients at fibrosis stages lower than 5 and between patients with CVH at the fifth fibrosis stage were compared using Wilcoxon rank sum test since few observations were carried out in the second group and therefore parametric assumption of the *t*-test was violated.  $P < 0.05$  was considered statistically significant.

Analysis of variance between the two consecutive Doppler measurements showed a very high reproducibility.

The predictive value for each of the predictors was evaluated by the area under the receiver operating characteristic (ROC) curves. Accuracy was calculated for the best cut-off value (BCV) of the current data set, defined as the highest sum of sensitivity and specificity. Stepwise discriminant analysis was performed to predict group membership from the set of predictors by the classification functions. All statistical analyses were performed using the SPSS program (version 13).

## RESULTS

According to the histological findings (Table 1), 9 CVH patients were at F1 stage with necroinflammatory score (NI) ranging from 2 to 4, 9 patients at F2 stage with NI ranging from 3 to 6, 9 patients at F3 stage with NI ranging from 3 to 8, 7 patients at F4 stage with NI ranging 5 to 8 and 10 patients at F5 stage with NI ranging 3 to 9. All the 28 cirrhotic patients were at F6 fibrosis stage. No change was observed endoscopically in 8 cirrhotic patients, while first degree varices were found in 16 patients, portal gastropathy in 3 patients, first degree varices and portal gastropathy in 1 patient, respectively.

### Ultrasonography

**CVH group vs control group:** There was a significant decrease in the portal vein mean value related to time average maximum velocity ( $V_{TAM}$ ) and diameter (D) to  $V_{TAM}$  ratio between CVH and control groups ( $P = 0.03$  and  $0.037$ , respectively). In addition, there was a significant increase in the spleen volume between the two groups ( $P = 0.011$ ). The other haemodynamic parameters and indexes did not show any statistical significance (Table 2).

**CIR group vs CVH group:** There was a significant decrease related to the mean value of portal vein blood flow velocities ( $V_{MAX}$  and  $V_{TAM}$ ) and blood flow (BF) between the CIR and CVH groups ( $P < 0.00007$ ,  $P < 0.00002$ ,  $P < 0.005$  respectively, Table 1). In addition, there was a significant increase in BF of the hepatic artery and the spleen volume ( $P < 0.013$ ,  $P > 0.002$ , Table 2). According to the qualitative data, liver in early stage cirrhotic patients had nodular surface, diffuse parenchymal echogenicity and was larger than that in CVH patients (Table 1).

Descriptive statistics and comparative data on qualitative,

Table 1 Liver qualitative parameters in controls, CVH and CIR groups

Variables		Chronic viral hepatitis group (CVH)	Cirrhosis group (CIR)
		<i>n</i>	<i>n</i>
Size	Enlarged	10	12
Contour	Nodular	6	13
Echogenic	Raised	11	1
Homogeneity	Diffuse	11	18

quantitative anatomic and haemodynamic variables as well as the calculated indexes in portal vein, hepatic artery and spleen are presented in Table 2. The  $P$  values for the quantitative variables between the two groups are listed in Table 2.

In comparison with the CVH patients, the mean values of portal vein congestion index, diameter to time average mean velocity ratio, Doppler perfusion index (DPI) as well as hepatic artery RI and HA/PV time average mean velocity ratio were all significantly increased in the early-stage cirrhotic patients ( $P < 0.01$ , Table 2).

**CVH patients at F5 stage vs other fibrosis stages (F1-F4):** Wilcoxon's test between CVH patients at F5 stage to F1-F4 showed a significant increase in portal vein congestion index (CI) ( $P = 0.041$ ). In addition, there was a marginally significant increase in diameter, cross sectional area ( $P = 0.051$ ) and  $D/V_{TAM}$  ratio ( $P = 0.055$ ) in CVH patients (Table 3). Portal Vein  $V_{MAX}$  and  $V_{TAM}$  values were marginally decreased ( $P = 0.056$  and  $0.08$  respectively) while all other variables were not significantly different (Table 3).

**CIR group and F5 CVH group vs other CVH groups (F1-F4):** A significant increase in portal vein's diameter ( $P < 0.05$ ) and cross section area ( $P < 0.05$ ) was observed, while PV  $V_{MAX}$  and PV  $V_{TAM}$  were significantly decreased ( $P < 0.001$ ) in cirrhotic patients and CVH patients (incomplete cirrhosis) at F1-F4. In addition, a significant increase was observed in PV CI and PV  $D/V_{TAM}$  ratio ( $P < 0.01$ ) as well as in DPI ( $P < 0.05$ ) and HA/PV  $V_{TAM}$  ratio between the two groups of patients ( $P < 0.001$ ) (Table 2). Spleen volume was also increased ( $P < 0.05$ , Table 3).

**ROC and stepwise discriminant analysis of CIR group vs CVH group:** Portal vein  $D/V_{TAM}$  ratio, CI and HA/PV  $V_{TAM}$  ratio had the same sensitivity of 85.71% and specificities of 59.09%-68.18% respectively, between CIR and CVH patients. Doppler perfusion index (best cut-off value of 0.29) had a very good specificity (90.91%) but a low sensitivity (42.86%) between the two groups. The area under the curve (AUC), comparing CVH group with CIR group, for each variable as measured by receiver operating characteristic curve (ROC) analysis is presented in Table 4. PV CI,  $D/V_{TAM}$  ratio and HA/PV  $V_{TAM}$  ratio under AUC curves are shown in Figure 1 A-C. The best cut-off value (BCV) for each statistically significant quantitative variable defined as the highest sum of sensitivity and specificity is summarized in Table 5.

The statistically significant variables selected by the stepwise discriminant analysis are ENLARGED, ECHOGENIC, DIFFUSE, PV AR, HA RI, HA/PV V<sub>TAM</sub>, and SPLEEN. The classification scores for the CVH and CIR groups are \* = multiply

$$W_1 = -89.090 - 1.657*ENLARGED + 12.769*ECHOGENIC + 4.202*DIFFUSE - 0.764*PV AR + 235.564*HA RI + 2.961*HA/PV V_{TAM} + 0.007*SPLEEN,$$

$$W_2 = -105.029 + 0.755*ENLARGED + 10.406*ECHOGENIC + 7.683*DIFFUSE - 5.849*PV AR + 251.99*HA RI + 5.473*HA/PV V_{TAM} + 0.010*SPLEEN.$$

Based on these scores, we classified any new patient in the CVH group if  $w_1 > w_2$  and in the CIR group if

$w_2 > w_1$ . According to the classification formula, 41 CVH patients (93.18%) were correctly classified in CVH group while 23 cirrhotic patients (82.14%) were correctly classified in CIR group.

## DISCUSSION

In our study, two major findings are of interest to note regarding haemodynamic parameters and indexes. The first finding is related to a statistically significant increase in PVCI between CVH patients at fibrosis stage 5 and those at fibrosis stages 1-4. At the same time, a marginally significant increase was recorded in PV diameter, cross

section area and D/V<sub>TAM</sub> ratio, while V<sub>MAX</sub> and V<sub>TAM</sub> velocities were marginally reduced. Blood flow volume in the hepatic artery and the portal vein as well as DPI index remained unchanged at all CVH fibrosis stages. Decrease in portal vein blood flow velocities related to fibrotic stage in CVH patients was firstly described by Koda *et al*<sup>[23]</sup>, who also found that portal vein blood flow volume is not significantly affected in the same patients. Tziafalia *et al*<sup>[32]</sup> reported that portal vein blood velocities are decreased in CVH patients. In our study, PV V<sub>MAX</sub> velocity was also decreased in CVH patients.

Gaiani *et al*<sup>[25]</sup> also found that portal vein V<sub>TAM</sub> velocity

**Figure 1** Portal vein congestion index (A), portal vein diameter/time averaged mean velocity (V<sub>TAM</sub>) ratio (B), and hepatic arterial/portal vein time averaged mean velocity (V<sub>TAM</sub>) ratio (C).

is the only haemodynamic variable that is independently associated with the histopathological diagnosis in CVH patients. Bernatik *et al*<sup>[37]</sup> reported that V<sub>MAX</sub> and V<sub>TAM</sub> velocities are reduced at end-stage fibrosis, while DPI does not change significantly and progression of liver fibrosis is associated with a continuous increase in HA resistive index (RI), suggesting that Doppler parameters are not useful in assessing the stage of liver fibrosis. In our study, although the mean HA RI value was significantly increased ( $P = 0.013$ ) in CIR group compared to CVH group, it was not affected in CVH patients at different fibrosis stages.

In our study, the portal vein diameter (D) was significantly enlarged at end-stage fibrosis patients, which is consistent with the reported data<sup>[31]</sup>. Walsh *et al*<sup>[29]</sup> found that hepatic artery blood flow (BF) and DPI are increased in CVH C patients at different fibrosis stages, while portal vein CI values remain unchanged. Our data do not support these findings regarding HA BF volume and DPI. However, we observed a significant change in PV CI.

The second major finding is that there were differences in anatomic, haemodynamic parameters and indexes

between CVH and CIR groups, suggesting that when early cirrhosis and portal hypertension are settled, portal vein blood flow velocity is reduced. This phenomenon is accompanied with enlargement of portal vein D and AR at end-stage fibrosis. On the other hand, hepatic artery blood flow volume increases in an effort to maintain liver blood flow volume. Portosystemic shunts and varices that may subsequently occur decrease portal hypertension. Portal vein D and AR remain for some time unchanged while blood flow velocities are further reduced. These phenomena dramatically increase most haemodynamic indexes such as portal vein CI and DPI as well as the calculated alternative ratios of  $PV D/V_{TAM}$ ,  $HA/PV V_{TAM}$ .

The same observations regarding portal vein CI and DPI have been reported by other investigators<sup>[17,20-26]</sup>, which are consistent with our findings. In the present study, ROC analysis showed that portal vein CI and  $PVD/V_{TAM}$  for the best cut-off values of 0.06 and 0.07 also had a very good sensitivity of 85.71% and a sensitivity of 65.91%-68.18% (Figures 1A and B, AUC = 0.74).

In our study, spleen volume was increased in CVH and cirrhotic patients compared with the controls, which is consistent with the findings in other studies<sup>[19,20,22,24-26,28-31,38]</sup>.

It is well known that a relative interobserver variability may limit the value for gray scale and Doppler ultrasonography<sup>[33-36]</sup>. In this study, we tried to simplify Doppler indexes and haemodynamic parameters such as congestion index<sup>[17]</sup> which is the ratio of area to time average mean blood velocity in portal vein. In the most recent studies, portal vein's area was assumed to be circular and is automatically calculated by the machine's software from the equation  $area = \pi * r^2$ , because  $r^2 = (diameter/2)^2$ . Therefore, we replaced the area with diameter of the vessel. The  $HA/PV V_{TAM}$  ratio at proper hepatic artery has never been described.

Stepwise discriminant analysis showed that the main predictors for discriminating CVH from CIR patients included three liver qualitative variables: ENLARGED, ECHOGENIC, DIFFUSE and four quantitative variables: PV AR, HA RI,  $HA/PV V_{TAM}$  ratio and SPLEEN volume. By calculating the formula, 88.9% of the patients were correctly classified either in CVH group or in CIR group. The interesting finding is that the  $HA/PV V_{TAM}$  alternative ratio was included in the classification function, while other indexes such as PVI and DPI were not included. ROC analysis confirmed the high predictive value of  $HA/PV V_{TAM}$  index for discriminating CVH from CIR patients (best-cut-off value = 1.45, sensitivity = 85.71% and specificity = 61.36%, = 0.80, Figure 1C).

In the past, the "arteriportal index"<sup>[43]</sup> was described as the ratio between  $V_{MAX}$  velocities in HA and PV right and left branches. We consider that the calculation of  $HA/PV V_{TAM}$  ratio would be easier to perform. We also suggest that it can be used in routine practice since these velocities are automatically measured in most studies evaluating liver haemodynamics.

The accuracy of US in assessing diffuse liver disease has been evaluated in previous studies<sup>[25,26]</sup>. The reported sensitivity of gray scale and US is 57%-95% in distinguishing normal from abnormal livers<sup>[44-47]</sup>. However, attempts to identify specific pathological processes, such as fatty

infiltration and fibrosis, have produced conflicting results<sup>[31,45]</sup>, probably related to the different US criteria employed in the studies, such as distribution of the parenchymal echoes and attenuation of the ultrasonic beam. In our study, liver parenchymal changes were simply described and classified by yes or no (1 or 0). For routine practice and simplicity reasons, no further analysis was attempted in echo structure of the liver.

Percutaneous needle biopsy and histological examination of the samples are considered the gold standard for the severity of fibrosis and cirrhosis. However, several studies<sup>[25,28]</sup> have questioned this because liver biopsies lead to false negative diagnoses of cirrhosis due to sampling errors in an estimated average of 24% pooled blind liver biopsy series<sup>[6]</sup>. Schalm<sup>[28]</sup> has reviewed the diagnostic methodology of liver cirrhosis and found that percutaneous liver biopsy has a sensitivity of below 85% in detection of liver cirrhosis.

It was reported that percutaneous liver biopsy sampling errors are significantly decreased when automated spring loaded true-cut needles are used<sup>[47]</sup>. The standard of practice we used in liver biopsies is in agreement with the recently published data<sup>[47]</sup> and unsuccessful biopsies and complications were kept at their minimum. We routinely performed a thorough sonographic investigation of the liver to assess the liver parenchyma and exclude the presence of lesions, such as a cyst. Subsequently, we performed the biopsy after marking the skin with automated cutting needles that according to our experience provide superior liver biopsy specimens in subjects with advanced fibrosis and cirrhosis; more than one samples were always taken.

On the other hand, cirrhosis is a common disease, which is frequently undiagnosed<sup>[4,5]</sup>. The risk of biopsy (morbidity 3%, mortality 0.03%)<sup>[7]</sup> may limit its use in screening for this disease. Finally, cirrhosis is reversible<sup>[48]</sup>, making the use of alternative non-invasive diagnostic tools essential.

Gaiani *et al*<sup>[25]</sup> suggested that ultrasonography may be used to identify cirrhosis with a diagnostic accuracy of 80% for cirrhosis even in the absence of a typical histopathological pattern. In our study, stepwise discriminant analysis showed that its diagnostic accuracy in discriminating cirrhosis from chronic viral hepatitis patients was 82.14%.

In conclusion, gray scale and Doppler ultrasonography can accurately and non-invasively assess liver haemodynamics and discriminate CVH patients at end fibrosis stage from those at other CVH stages as well as CVH patients from early stage cirrhotic patients with compensated function. The method can easily be performed with routine upper abdominal ultrasonography, and is inexpensive and safe.

## COMMENTS

### Background

In recent years, many papers have been published regarding the efforts to correctly classify chronic virus hepatitis (CVH) and distinguish this entity from liver cirrhosis by bloodless means. Blood tests and ultrasonography, or other imaging modalities (CT, MRI) are used to achieve this goal. Doppler ultrasonography of portal vein and hepatic artery has gained its ground in the estimation of portal haemodynamics. Simple recording of portal vein's blood flow velocities is common in daily practice in many institutions. Haemodynamic indexes, although old as a

conception, have not been thoroughly investigated, probably due to the difficulty of producing them from the Doppler measurements in day practice.

### Research frontiers

Our study investigated the value of the most popular liver haemodynamic indexes (congestion index, Doppler perfusion index, arterioportal index). We also simplified these indexes by introducing new alternative to them. Finally our data were compared to those published in literature.

### Innovations and breakthroughs

The major finding of our study is that end CVH at the 5th fibrotic stage can be distinguished from those at other stages. In daily practice, incomplete and complete early stage cirrhosis may be predicted by simple haemodynamic indexes. Stepwise discriminant analysis produced a formula (including qualitative and quantitative variables) that differentiates liver cirrhosis from CVH in 80% of the originally classified cases. ROC analysis could find the best cut off values for discriminating CVH from cirrhosis. The new alternative indexes, particularly "arterioportal index" have been proved to be of great value in discriminating CVH from cirrhotic patients. The "arterioportal index" is first used in porta hepatis (portal vein's trunk and proper hepatic artery). Another major point is that the best cut-off values are similar to those from other investigators contributing to the establishment of internationally accepted values for Doppler haemodynamic indexes.

### Applications

Our data suggest that the "congestion index" and alternative indexes are of value and can be added in daily practice for monitoring CVH and cirrhotic patients. Because the arterioportal index of porta hepatis is first used, more studies are needed to establish more precise best cut off values.

### Terminology

"Arterioportal index": The ratio of time average mean blood velocity in proper hepatic artery to time average blood velocity in portal vein's trunk.

### Peer review

In this study, the authors assessed the value of gray scale (GS) and colour Doppler ultrasonography (CDU) in differentiating the progression of CVH and compensated liver cirrhosis (CIR). Significant differences in haemodynamic parameters and indexes were found between CVH patients at fibrosis stage 5 and those at other fibrosis stages, suggesting that simple GS and CDU parameters can discriminate CVH from CIR.

Endoscopic band ligation and endoscopic hemoclip placement for patients with Mallory-Weiss syndrome and active bleeding. *World J Gastroenterol* 2008; 14(13): 2080-2084 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2080.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2080>

### Abstract

**AIM:** To compare the hemostatic efficacy and safety of two mechanical endoscopic methods: endoscopic band ligation (EBL) and endoscopic hemoclip placement (EHP) in patients with actively bleeding Mallory-Weiss syndrome (MWS).

**METHODS:** A prospective randomized study to compare the efficacy and safety of EHP with EBL was performed from January 2002 to August 2005. Forty-one patients with active bleeding from MWS were treated with EHP ( $n = 21$ ) or EBL ( $n = 20$ ).

**RESULTS:** There were no significant differences between groups with respect to clinical and endoscopic characteristics. The mean number of hemoclips applied was  $3.2 \pm 1.5$  and the mean number of bands applied was  $1.2 \pm 0.4$ . Primary hemostasis was achieved in all patients. Recurrent bleeding was observed in one patient from the EHP group and two from the EBL group. Patients with recurrent bleeding were treated by the same modality as at randomization and secondary hemostasis was achieved in all. There were no significant differences between the two groups in total transfusion amount or duration of hospital stay. No complications or bleeding-related death resulted.

**CONCLUSION:** EHP and EBL are equally effective and

### INTRODUCTION

Mallory-Weiss syndrome (MWS), vomiting-induced mucosal lacerations in the region of the gastroesophageal junction, is one cause of nonvariceal upper gastrointestinal (UGI) bleeding and its incidence is considered to be 5% to 15%<sup>[1]</sup>. In most cases, MWS-related bleeding requires no intervention other than hemodynamic support<sup>[2]</sup>. However, some patients may require intensive care<sup>[3]</sup>, especially those with risk factors such as evidence of active bleeding (for example, fresh blood hematemesis and hemodynamic instability), presence of stigmata of recurrent bleeding (such as visible vessel and adherent clots), and comorbid diseases or bleeding diathesis. Surgery or other therapeutic approaches such as balloon tamponade of the esophagus, transcatheter arterial embolization, and systemic or selective arterial infusion of vasopressin have been used to control active bleeding in patients with MWS<sup>[4-7]</sup>. In recent decades, endoscopic treatment has been the treatment of choice<sup>[8]</sup>. Various endoscopic techniques, mainly consisting of endoscopic coagulation or injection, have been used in the management of patients with MWS at high risk for recurrent bleeding<sup>[9-12]</sup>. However, injection hemostasis may be incomplete for patients with a large and/or long plexuses of vessels and coagulation has the risk of producing transmural injury and perforation due to relatively thin esophageal wall<sup>[13]</sup>. Mechanical

endoscopic methods have recently become one of the therapeutic options for treating patients with actively bleeding MWS<sup>[13-20]</sup>. Among the mechanical methods, endoscopic band ligation (EBL) and endoscopic hemoclip placement (EHP) both has merits and problems related to the hemostatic mechanism and technical procedure itself. However, there have been few studies comparing the hemostatic efficacy of different mechanical endoscopic methods in the treatment of actively bleeding MWS. Therefore, this prospective randomized study was carried out to compare the hemostatic efficacy and safety of EBL with EHP in the treatment of actively bleeding MWS.

## MATERIALS AND METHODS

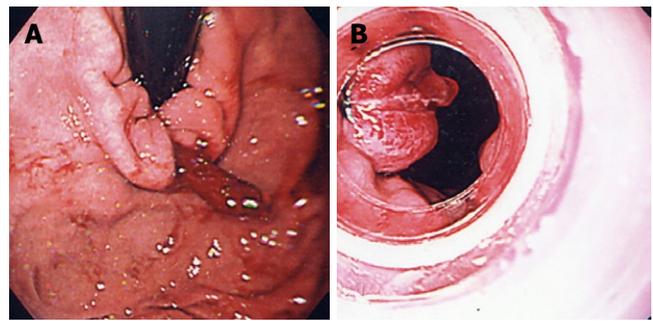

### Subjects

Among patients undergoing upper endoscopy at the gastrointestinal endoscopy center of Uijeongbu St Mary's Hospital from January 2002 to August 2005 because of acute UGI bleeding, all consecutive patients with endoscopically verified MWS (defined as a mucosal tear or laceration near the esophagogastric junction with active bleeding, either spurting or oozing) were considered for inclusion in the study. Written informed consent for endoscopy and participation in the study was obtained from patients or near relatives before the procedure. This research was carried out in accordance with the Helsinki declaration.

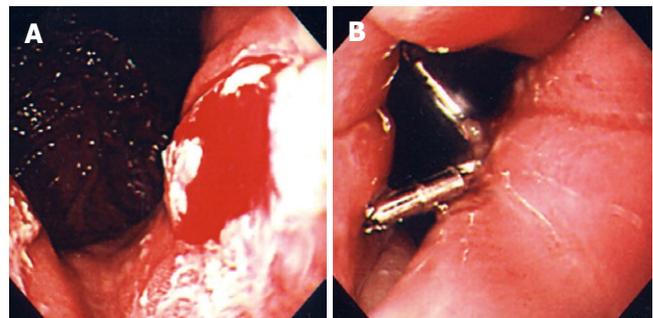

After receiving basic life support, all patients underwent endoscopy within 12 h of the onset of UGI bleeding. Patients were excluded if they were unable or unwilling to give informed consent for endoscopic therapy, if active bleeding was not present at endoscopy, or if more than one source of bleeding was identified. Patients with old adherent clots and clean-based longitudinal mucosal tears near the esophagogastric junction as the only possible origin of bleeding were treated conservatively. All patients' clinical characteristics, including age, gender, presenting symptoms, alcohol use, blood pressure, hemoglobin level, coagulopathy, and comorbid diseases, were recorded. Shock was defined as a systolic blood pressure of less than 90 mmHg and a pulse rate greater than 100 beats/min, accompanied by pallor or cold sweating.

### Therapy

Forty-one patients were randomized to undergo EBL ( $n = 20$ ) or EHP ( $n = 21$ ) by concealed allocation determined according to a table of random numbers. All diagnostic and therapeutic endoscopic procedures were performed by members of the research team of four staff gastroenterologists. They did not participate in the postprocedure care of the patients, which was conducted by other physicians. Endoscopic procedures were performed with videoendoscopes (GIF-Q230, GIF-XQ230, Olympus Optical Co. Ltd, Tokyo, Japan). In the EBL group, an endoscopic ligating device (Pneumoactive EVL device; Sumitomo Bakelite Company, Tokyo, Japan) was used with no overtube. After endoscopic identification of the lesion, the endoscope was withdrawn and was reinserted after attachment of the band ligator. After the hood had been placed over the bleeding site, endoscopic

**Figure 1** Endoscopic view of a Mallory-Weiss tear at the cardia of the stomach. **A:** An actively bleeding vessel; **B:** After band placement.

**Figure 2** Endoscopic view of a Mallory-Weiss tear at the esophagogastric junction. **A:** Oozing vessel; **B:** After hemoclip application to the bleeding vessel.

suction was activated to draw the bleeding site into the banding cylinder. After suction and band release, a polypoid mass of mucosa 1 cm in diameter was formed and active bleeding stopped immediately (Figure 1). In the EHP group, hemoclips (MDS50, Olympus) were placed with a clip application device (HX-3L, HX-5 LR-1; Olympus). In terms of technique, hemoclips were applied directly on spurting or oozing vessels along with surrounding tissues (Figure 2).

Once hemostasis was achieved, the bleeding site was observed for at least 1 min. Primary hemostasis was defined as no endoscopic evidence of bleeding during this time after band ligation or after hemoclip placement, during the first endoscopic session. Patients who continued to bleed, despite receiving EBL or EHP, were given endoscopic injections of epinephrine. If patients continued to bleed despite endoscopic treatment, we planned to undergo transcatheter arterial embolization or emergency surgery, depending on the status of the patient and/or the volume of blood transfused. After endoscopic treatment, all patients were observed closely. During admission, treatment included partial parenteral nutrition and intravenous administration of histamine H<sub>2</sub> receptor antagonists at standard doses. Evidence of recurrent bleeding included the following signs of ongoing bleeding: (1) new hematemesis; (2) fresh blood aspirated *via* a nasogastric tube; (3) continuous melena with instability of vital signs (systolic blood pressure  $\leq 90$  mm Hg, heart rate  $\geq 100$  beats/min, or orthostatic changes in systolic blood pressure of  $\geq 20$  mmHg or heart rate of

**Table 1** Clinical characteristics and outcome of patients in endoscopic band ligation (EBL) and endoscopic hemoclip placement (EHP) groups

	EHP (n = 21)	EBL (n = 20)	P value
Age (yr)	49.5 ± 13.2	47.1 ± 11.9	0.58

Bleeding-related deaths	0	0	1.00
Hospital stay (mean days)	6.7 ± 5.1	7.3 ± 3.3	0.20

≥ 20 beats/min), or a decrease in hemoglobin level of more than 20 g/L within 24 h of obtaining primary hemostasis. When recurrent bleeding was suspected, endoscopy was performed immediately and the same initial therapeutic modality used at randomization was used. After patients were discharged, the clinical outcome was evaluated by physicians who were blinded to the type of endoscopic treatment and who followed the patients for 30 d including initial hospitalization. Permanent hemostasis was defined as the absence of recurrent bleeding during this period.

To evaluate the efficacy of the two hemostatic procedures, data for each patient were collected during hospitalization and included information on demographics, medical history, presenting symptoms, initial hemodynamic status, laboratory values, rate of primary hemostasis, permanent primary hemostasis rate, number of therapeutic endoscopic sessions, need for emergency operation or transcatheter arterial embolization, bleeding-related deaths, transfusion requirements, and duration of hospitalization.

### Statistical analysis

Quantitative data are summarized as the mean ± SD. The Mann-Whitney nonparametric *U* test was used to compare the mean values of continuous variables and Fisher's exact test was used for the comparison of discrete variables. *P* < 0.05 was accepted as indicating statistical significance. The analyses were performed using SPSS version 11.0 for Windows (SPSS Inc., Chicago, IL, USA).

## RESULTS

During the study period, 137 patients with MWS tears underwent emergency endoscopy, but only 41 patients (30%) met the entry criteria and were randomized. Clinical and endoscopic characteristics for the patients at entry are outlined in Table 1. No differences were noted between the two groups with respect to age, gender, presenting symptoms, alcohol use, shock, hemoglobin level, coagulopathy, comorbid diseases, number of bleeding points, length of tear, stigmata of bleeding, or locations of the lacerations. Comorbid diseases in the EBL group included liver cirrhosis, coronary artery disease, stroke, and chronic renal failure; in the EHP group, comorbid diseases included liver cirrhosis, pancreatitis, valvular heart disease, and rheumatoid arthritis. However, no differences were noted between the two groups with respect to frequency of having a spurting vessel or oozing. The most common location of the tear was the esophagogastric junction in all patients (23/41, 56%; Table 1).

Primary hemostasis was obtained in all patients in each group. In the EBL group, treatment was completed in a single session (mean number of bands 1.2 ± 0.4). A single elastic band was applied in 17 patients; two bands were placed in three patients (Table 1). In the EHP group, the mean number of hemoclips applied was 3.2 ± 1.5. Two patients (10%) in the EBL group and one patient (6%) in the EHP group had recurrent bleeding; this was controlled in all three with endoscopic treatment and no patient required surgery. No differences were noted in primary outcomes including rates of primary hemostasis, recurrent bleeding, and permanent primary hemostasis. No differences were noted in the other secondary outcomes, including the number of endoscopic sessions, total procedure time, the need for additional epinephrine injection, the need for emergency operation or transcatheter arterial embolization, bleeding-related deaths, transfusion requirements, or the duration of hospitalization. No significant complications or adverse events attributable to endoscopic treatment were noted in either group, and no recurrent bleeding was noted in either group during outpatient follow-up.

## DISCUSSION

MWS is a relatively common cause of nonvariceal UGI bleeding, in which an abrupt rise in abdominal pressure caused by retching or vomiting induces mucosal tears near the esophagogastric junction<sup>[1,2]</sup>. Because most patients stop bleeding spontaneously, emergency treatment is reserved for those showing active bleeding<sup>[3]</sup>. The rate of recurrent bleeding in patients with MWS is also lower than that for other nonvariceal bleeding<sup>[8]</sup>. However, when bleeding is active and severe, patients require surgical treatment or nonsurgical therapeutic approaches<sup>[4,5]</sup>.

Several endoscopic methods have been used to treat actively bleeding MWS, including injection of different agents, electrocoagulation, application of hemoclips, and band ligation<sup>[8,18]</sup>. Thermal coagulation or injection therapies have been used successfully to control active bleeding from MWS<sup>[10-12,21]</sup>. Laine<sup>[21]</sup> reported that

multipolar electrocoagulation significantly improved hemostasis and reduced surgery in patients with active bleeding from MWS and has been associated with few complications. However, repeated coagulation has the risk of producing transmural injury and perforation because the esophagus lacks serosa and is very thin at the tear site<sup>[22]</sup>. Injection therapy with various agents is an effective, simple, and inexpensive first-line approach<sup>[11,12]</sup>. Llach *et al*<sup>[11]</sup>. Reported that endoscopic injection therapy using epinephrine and polidocanol improved outcomes (rate of recurrent bleeding, hospital stay, and transfusion requirement) compared with supportive measures alone in a prospective, randomized controlled trial. However, injection therapy can produce cardiovascular complications such as ventricular tachycardia and should be avoided in patients with a history of coronary artery disease because of the potential for systemic absorption<sup>[23]</sup>.

EBL, commonly used in variceal bleeding, has also been used to treat nonvariceal bleeding<sup>[8]</sup>. EBL is technically easier to perform than other methods, with the lesions well viewed under direct pressure and suction from the transparent ligation cap<sup>[20]</sup>. The use of EBL for treatment of patients with bleeding MWS has been described in several studies<sup>[13-15,18,20,24]</sup>. Our study also demonstrated high successful rates of primary and permanent hemostasis in such cases.

EHP is acceptable for treating bleeding lesions in nonfibrotic tissues and has advantages over other hemostatic methods because it rarely causes perforation<sup>[25]</sup>. It is effective in the management of bleeding from a Mallory-Weiss tear<sup>[18,19,26]</sup>. Compared with cautery or sclerotherapy, it may be a safer option in the management of bleeding from MWS because of the lack of additional tissue damage with endoclips<sup>[8,19]</sup>. In the event of a deeper extension of the tear with an esophageal perforation, the placement of endoclips can fix both problems simultaneously<sup>[27]</sup>. EHP has been shown to be an effective alternative treatment in critically ill patients with severe gastrointestinal bleeding<sup>[28,29]</sup>. Park *et al*<sup>[30]</sup> reported that EHP and EBL showed similar efficacy and safety in the management of bleeding gastric Dieulafoy's lesions. However, there have been no reports comparing the efficacy and safety of EHP with those of EBL for the treatment of active bleeding from MWS.

In our study, EBL and EHP both achieved low rates of recurrent bleeding and high rates of primary hemostasis. The recurrent bleeding was successfully treated using the same method as at randomization. Shock and comorbid diseases were present in four (20%) and nine (45%) patients in the EBL group, respectively; and three (14%) and nine (43%) patients in the EHP group. Despite these adverse factors, primary hemostasis was achieved in all patients. No patient in either group required additional epinephrine injection or advanced invasive therapy such as transcatheter arterial embolization or emergency surgery, and there was no procedure-related complication in either group. Therefore, the results of our study indicate that both EBL and EHP are effective and safe for treatment of patients with actively bleeding MWS, including those with shock, comorbid diseases, and/or coagulopathy.

In conclusion, EBL and EHP are equally safe and

effective for the control of active bleeding in patients with hemodynamically unstable MWS and/or combined major diseases. Moreover, after treatment, the frequency of recurrent bleeding is low and the rate of permanent hemostasis is high.

## COMMENTS

### Background

Mallory-Weiss syndrome (MWS) is a relatively common cause of nonvariceal upper gastrointestinal bleeding. When bleeding is active and severe, patients require treatment. Several endoscopic methods have been used to treat actively bleeding MWS. We aimed to compare the hemostatic efficacy and safety of endoscopic band ligation (EBL) with endoscopic hemoclip placement (EHP) in the treatment of actively bleeding MWS.

### Research frontiers

Endoscopic injection of epinephrine is effective treatment for MWS but has higher recurrent bleeding rate. Mechanical endoscopic methods is one of treatment options that are effective and safe for actively bleeding MWS.

### Innovations and breakthroughs

EBL and EHP both have merits and problems related to the hemostatic mechanism and technical procedure itself. Although many investigators have reported the usefulness of mechanical endoscopic methods, there have been few studies comparing the hemostatic efficacy of different mechanical endoscopic methods in the treatment of actively bleeding MWS. We showed that both EHP and EBL are effective for MWS. These two methods are also used effectively in patients with hemodynamically unstable MWS or combined diseases.

### Applications

This finding provides evidence that EBL or EHP in the management of actively bleeding MWS can be selected depending on physician's expertise.

### Peer review

This is a report designed to compare the efficacy of two different mechanical endoscopic methods in the management of actively bleeding MWS. It is concluded that EBL and EHP are equally safe and effective. After treatment with both, the frequency of recurrent bleeding is low and the rate of permanent hemostasis is high.

### Abstract

**AIM:** To examine the effects of 10% diluted honey, which has been shown to be scolicedal, on the liver and biliary system and determine whether it could be used as a scolicedal agent in the presence of biliary-cystic communication.

**METHODS:** Thirty Wistar-Albino rats were divided into two groups. Honey with 10% dilution in the study group and 0.9% saline (NaCl) in the control group were injected into the common bile ducts of rats through a 3-mm duodenotomy. The animals were sacrificed 6 mo after the procedure. Histopathological, biochemical, and radiological examinations were performed for evaluation of side effects.

**RESULTS:** At the end of the sixth month, liver function tests were found to be normal in both groups. The tissue samples of liver and ductus choledochus of the honey group showed no histomorphologic difference from the control group. No stricture on the biliary tree was detected on the retrograde cholangiograms.

**CONCLUSION:** According to these results, we concluded

that 10% diluted honey could be used as scolicedal agent safely in the presence of biliary-cystic communication.

Effects of honey as a scolicedal agent on the hepatobiliary system. *World J Gastroenterol* 2008; 14(13): 2085-2088 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2085.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2085>

### INTRODUCTION

Hydatid disease is still an important endemic problem in Turkey and in many other parts of the world. Dissemination of protoscolex-rich fluid during surgery is a major cause of recurrence. Instillation of scolicedal agent into a hepatic hydatid cyst is the most commonly employed measure to prevent this serious complication<sup>[1]</sup>. Biliary system strictures or “caustic sclerosing cholangitis” can develop from the caustic effect of the scolicedal solution diffused from the cyst into the biliary system, during the surgical intervention of hydatid cysts of the liver<sup>[2]</sup>. Surgical treatment has been used around the world for years as the primary choice of treatment. Although percutaneous treatment of hydatid cysts was considered to be contraindicated due to potential risks of anaphylactic shock and dissemination of the hydatid fluid into the abdomen, this method has been used successfully for treatment of hydatid cysts since 1980s<sup>[3]</sup>. Up to date, many scolicedal agents have been used for inactivation of the cyst content, but there is no ideal agent that is both effective and safe<sup>[4]</sup>.

The surgical treatment of hydatid disease of the liver includes evacuation of the cyst with scolicedal irrigation and either excision or drainage of the cyst<sup>[5]</sup>. The objectives of surgical treatment are inactivating scolices, preventing spillage of cyst contents, eliminating all viable elements of the cyst, and managing the residual cavity of the cyst.

Inactivation of scolices with various scolicidal agents has been tried with varying success<sup>[6]</sup>.

Honey is the foodstuff made by honeybees from the nectar of flowers or secretions from other parts of the plants, which they gather, transform together with their own specific materials, and store in honeycomb. Honey is considered as healthy and wholesome food with curative properties. It has antimicrobial effects against many bacteria and this property may be due to its osmolarity, acidity, flavonoids, aromatic acid substances, and hydrogen peroxide<sup>[7]</sup>.

In a previous study, 10% diluted honey has been shown to be highly effective on protoscolices<sup>[8]</sup>.

The aim of the present study was to investigate whether diluted honey would cause caustic sclerosing cholangitis when injected directly into the common bile duct of rats.

## MATERIALS AND METHODS

### Animals

Thirty Wistar-Albino female rats, weighing  $225 \pm 25$  g, were included in this study. Animals were deprived of food 12 h before anesthesia, but had free access to water 2 h before anesthesia. No enteral or parenteral antibiotics were administered at any time. Rats were housed under constant temperature ( $21^\circ\text{C} \pm 2^\circ\text{C}$ ) individually in wire cages with 12 h light-dark cycle. Rats that died during the study were excluded. The procedures in this experimental study were performed in accordance with the National Guidelines for the Use and Care of Laboratory Animals and approved by the Animal Ethics Committee of Ankara Research and Training Hospital.

### Surgical procedure

The rats were randomly divided into two equal groups of 15 rats each. Rats were anesthetized by an intramuscular injection of ketamine HCl (Ketalar, Parke-Davis, Eczacıbasi, Istanbul, Turkey; 40 mg/kg body weight) and xylazine (Rompun, Bayer, Leverkusen, Germany; 5 mg/kg body weight). All animals were allowed to breathe spontaneously during the experiments. After the abdomen was shaved and cleaned with povidone iodine, a midline laparotomy was carried out, and the intestines were covered with sterile gauze pads soaked with isotonic saline at  $36^\circ\text{C}$ - $38^\circ\text{C}$ . A 3-mm duodenotomy was performed. Test solutions, 0.15 mL, either sterile isotonic saline solution (control group) or 10% dilutions of honey (study group) (Anzer honey, Rize, Turkey), were injected without pressure into the common bile duct with 27 gauge syringe. Immediately after the injection, the common bile duct was clamped with an atraumatic vascular clamp (bulldog). The catheter was then withdrawn. The clamp was removed 5 min later, and the duodenotomy was closed with a 6-0 polypropylene (Prolene) suture. There was no operative mortality. The study animals were kept for 6 mo, during which time they were fed with rat chow ad libitum and tap water and kept at room temperature ( $18^\circ\text{C}$ - $20^\circ\text{C}$ ) in separate cages.

Blood samples were obtained 1 wk after the surgical procedure and at the end of the experimental study (6 mo

after the procedure) for liver function tests including bilirubin, aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), and gamma glutamyl transferase (GGT).

Six months after the procedure, retrograde cholangiography was performed under ketamine hydrochloride anesthesia. Midline laparotomy was carried out, and a 3-mm duodenotomy was performed. Radiopaque solution, 0.15 mL, was injected without pressure into the common bile duct using a 27 gauge syringe. Immediately after the injection, the common bile duct was clamped with an atraumatic vascular clamp and antero-posterior cholangiograms were obtained. Following cholangiography, blood samples for determination of liver function tests were obtained. Liver, common bile duct and duodenum were excised en-bloc for histopathological examination.

### Biochemical and histopathological examinations

The biochemical analyses were made by an autoanalyzer (Olympus AU 640, Japan) using commercial kits.

The liver specimens of the right and left lobes and common bile duct were taken and immediately fixed in 10% neutral buffered formalin solution for one week. Tissues were washed in flowing water and dehydrated with rising concentrations of ethanol (50%, 75%, 96% and 100%). After dehydration, specimens were put into xylene to obtain transparency and were then infiltrated with and embedded in paraffin. Histological sections of the specimens in thickness of 6  $\mu\text{m}$  from all the groups were stained with hematoxylin and eosin. The whole tissue blocks were sectioned and histopathological examinations were performed on systematically randomly sampled preparations by a blinded researcher. The specimens were photographed by Nikon eclipse E 600. Liver specimens were evaluated to assess the morphology of the hepatocytes, portal areas, sinusoidal lesions, cellular infiltration in the lobule or portal spaces and parenchymal lesions. Histopathological examination of the common bile duct was performed to assess the histomorphology of the epithelium, connective tissue, inflammation, fibroblastic proliferation and necrosis.

### Statistical analysis

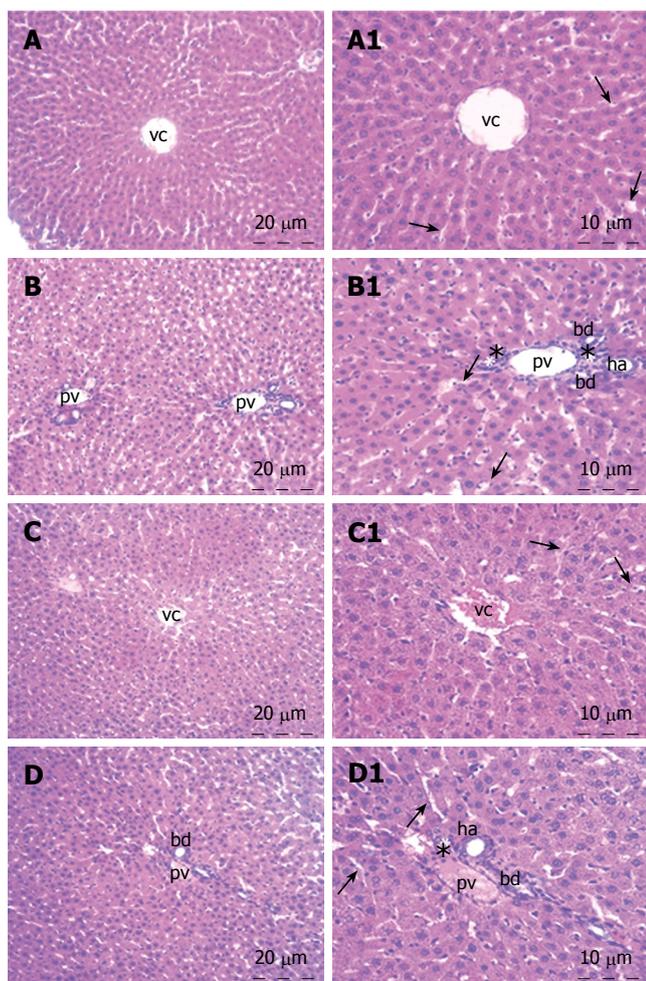

Differences between the groups were analyzed with Mann-Whitney *U* test. Statistical analysis was performed with the Statistical Package for the Social Sciences (SPSS) version 13.0 for Windows (SPSS Inc., Chicago, USA). *P* values less than 0.05 were considered to be significant.

## RESULTS

Five rats from each group died within 5 d after the procedure. Two of ten died in the early postoperative period possibly due to anesthesia, and the others died because of trauma to the common bile duct and leakage into the peritoneum. The remaining 20 rats were alive until the end of the study without any problem.

### Biochemical and radiological results

Liver function tests were slightly elevated 1 wk after the procedure in both groups, and this might be due to the

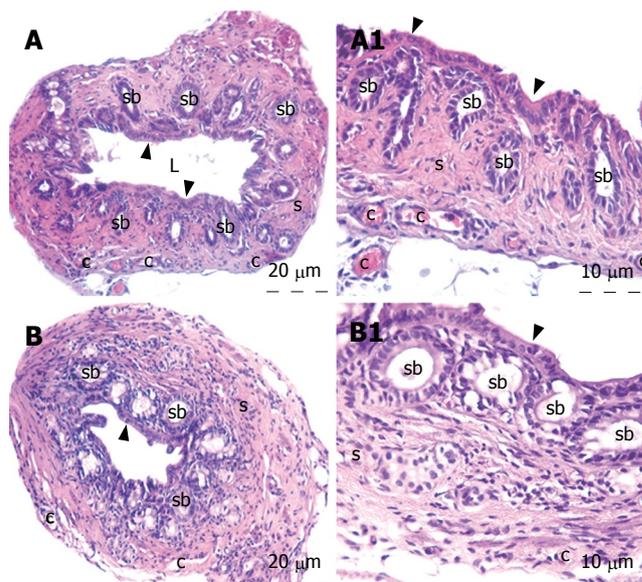

**Figure 1** Liver sections stained with hematoxyline and eosin. **A, B:** Control group showing the regular architecture; **C, D:** Treatment group. vc: Central vein; pv: Portal vein; ha: Hepatic artery; bd: Bile ductules. Arrow, hepatic sinusoids; \*, cell infiltration. The right column of the panel is the larger view of the left column.

cannulation and injection of common bile duct and there was no difference between the groups. At the end of the first and sixth month, liver function tests were found to be normal in both groups.

No stricture in the biliary tree was found on the retrograde cholangiograms.

### Histopathological results

The histopathological evaluation of the liver sections did not reveal any difference between the control and honey groups. Polygonal shaped hepatocytes radiating outward from a central vein in the center and arranging into hepatic cords separated by adjacent sinusoids were demonstrated. Both the hepatic portal vein and hepatic artery branch and also the bile ductules in the corners of hepatic lobules were in normal architecture histologically. There was neither inflammatory cellular infiltration nor bile pigment accumulation in either group (Figure 1). When we examined the tissue samples of the common bile duct, no adverse effect of the honey was demonstrated. The epithelium of the common bile duct was penetrated into the stroma to form pits known as the sacculi of Beale. The dense connective tissue and smooth muscle were

**Figure 2** Common bile duct (ductus choledochus) sections stained with hematoxyline and eosin. **A:** Control group; **B:** Treatment group. L: Lumen; sb: Sacculi of Beale; c: Capillary; s: Stroma; arrow head: Simple columnar epithelium. The right column of the panel is the larger view of the left column.

in regular architecture in both groups. All three layers, mucosa, muscularis and serosa of the common bile duct were viewed normal. There was no inflammation and/or fibroblastic proliferation in the stroma of the control and honey groups. The lining cells of the sacculi of Beale were mucous gland cells that were clearly viewed in the honey group. The tissue samples of liver and common bile duct of the honey group showed no histomorphologic difference from the control group (Figure 2).

### DISCUSSION

The ideal treatment for hepatic hydatid disease should completely eliminate the parasite and prevent recurrence of the disease with minimum morbidity and mortality. There are three available therapeutic modalities for hepatic hydatid disease: systemic chemotherapy, surgery, and percutaneous treatment<sup>[9]</sup>. Meticulous packing of the operative field is necessary irrespective of the surgical technique employed with sponges soaked in scolicedal agents to inactivate the scolices which may leak from the cyst during surgical manipulation. In conventional or minimally invasive hydatid disease surgery, inactivation of the cyst content is essential, justifying the routine use of scolicedal solutions. In the presence of cystobiliary communications, the passage of these solutions may cause hepatic stasis, edema and necrosis in the hepatic tissue as well as histopathological changes in the biliary tree<sup>[2]</sup>. Various experimental studies investigated the effects of 95% alcohol, 10% povidone iodine, 0.9%, 5.0%, 10.0%, 20.0% NaCl, 3% H<sub>2</sub>O<sub>2</sub>, 5% formalin, 0.5% AgNO<sub>3</sub>, cetrimide on the liver and the biliary tree. Severe hepatobiliary complications have been reported for formalin, alcohol and 10%-20% NaCl<sup>[10,11]</sup>.

Sclerosing cholangitis may be due to immunological,

infectious, vascular, or chemical factors. In patients with hydatid disease of the liver, various factors, including injection of scolical agent into the cyst cavity, a communication between the cyst and biliary tree, and a particular sensitivity to the scolical agent seems to be necessary to promote caustic sclerosing cholangitis<sup>[5]</sup>.

Histopathological changes in sclerosing cholangitis is spotty necrosis in the liver parenchyma, widening of sinusoids, regenerative changes in hepatocytes, Kupffer cell hyperplasia, pigment accumulation, periductal fibrosis, inflammation, fibroblastic proliferation, and necrosis in the extrahepatic biliary ducts<sup>[5,12]</sup>. In our study, no histopathological difference was detected in honey group when compared with the control group. None of the above mentioned pathological changes was present in the liver and common bile duct specimens of honey group.

The retrograde cholangiograms were all within normal limits without any evidence for biliary stricture. Liver function tests at the end of the first and sixth month were also within the normal ranges.

In a previous study, we found that honey was a potent scolical agent *in vitro*<sup>[8]</sup>. Honey concentrations of 10% or greater killed all protoscolices. The scolical effects of honey began at the end of the third minute. Intraperitoneal application of honey resulted in adverse effects with this concentration. According to these results, we concluded that honey might be used as a potent scolical agent after the evaluation of side effects on hepatobiliary system and the *in vivo* activity. The ideal scolical agent should have rapid and complete scolical effects with minimal local and systemic side effects<sup>[13]</sup>. No systemic side effects, such as anaphylactic reaction or hyperglycemia, and no local side effects in peritoneal surface developed with intraperitoneal administration<sup>[8]</sup>. Since an important and life-threatening side effect of scolical agents is sclerosing cholangitis, we planned to evaluate the effects of honey on hepatobiliary system with the present study in which we did not find any side effects on hepatobiliary system evaluated by using biochemical, histological, and radiologic parameters.

In conclusion, although sclerosing cholangitis is a major complication that restrict the use of many scolical agents in the presence of a biliary-cystic communication in hydatid liver disease, our experience from the present study shows that honey can be used safely in this situation.

## COMMENTS

### Background

To examine the effects of 10% diluted honey, which has been shown to be scolical, on the liver and biliary system whether it could be used as a scolical agent in the presence of biliary-cystic communication.

### Research frontiers

The present study investigated whether diluted honey would cause caustic sclerosing cholangitis when injected directly into the common bile duct of rats.

### Innovations and breakthroughs

Sclerosing cholangitis is a major complication that restricts the use of many scolical agents in the presence of a biliary-cystic communication in hydatid liver disease, our experience from the present study shows that honey can be used safely in this situation.

### Applications

Evaluates the effects of a 10% honey solution on the liver as a possible scolical agent in the treatment of hydatid cysts.

### Peer review

The rationale behind this study is that the authors have previously shown that a 10% honey solution has scolical properties *in vitro* and that current scolical agents often cause sclerosing cholangitis. It is an interesting paper.

### Abstract

**AIM:** To determine the predictive factors for early aspiration in liver abscess.

**METHODS:** A retrospective analysis of all patients with liver abscess from 1995 to 2004 was performed. Abscess was diagnosed as amebic in 661 (68%) patients, pyogenic in 200 (21%), indeterminate in 73 (8%) and mixed in 32 (3%). Multiple logistic regression analysis was performed to determine predictive factors for aspiration of liver abscess.

**RESULTS:** A total of 966 patients, 738 (76%) male, mean age  $43 \pm 17$  years, were evaluated: 540 patients responded to medical therapy while adjunctive percutaneous aspiration was performed in 426 patients. Predictive factors for aspiration of liver abscess were: age  $\geq 55$  years, size of abscess  $\geq 5$  cm, involvement of both lobes of the liver and duration of symptoms  $\geq 7$  d. Hospital stay in the aspiration group was relatively longer than in the non aspiration group. Twelve patients died in the aspiration group and this mortality was not statistically significant when compared to the non aspiration group.

**CONCLUSION:** Patients with advanced age, abscess size  $> 5$  cm, both lobes of the liver involvement and duration of symptoms  $> 7$  d were likely to undergo aspiration of the liver abscess, regardless of etiology.

**Key words:** Liver abscess; Aspiration and liver abscess; Needle aspiration and liver abscess; Amebic liver abscess; Pyogenic liver abscess; Liver abscess and management

### INTRODUCTION

Liver abscess, particularly due to amebiasis, is an important clinical problem in tropical regions of the world and accounts for a high number of hospital admissions<sup>[1-5]</sup>. It is usually an easily treatable condition with good clinical outcomes. There is however potential for morbidity and even mortality if proper and timely treatment is not provided<sup>[6-9]</sup>. The standard treatment of liver abscess is the use of appropriate antibiotics and supportive care. Needle aspiration can be used as an additional mode of therapy and has been promoted by some authors for routine use in the treatment of uncomplicated liver abscess. It is suggested that needle aspiration can improve response to antibiotic treatment, reduce hospital stay and the total cost of treatment<sup>[10-12]</sup>. Although ultrasound guided needle aspiration is fairly safe, it is nonetheless an invasive procedure requiring the passage of a wide bore needle into a highly vascular organ, and can be associated with the risk of bleeding. Needle aspirations, especially at the time of intervention has therefore remained a debatable issue and it seems important to determine its possible role in the treatment of liver abscess<sup>[13-16]</sup>.

We have used a large database of patients admitted to hospital with liver abscess in order to determine the factors associated with the likelihood of liver abscess aspiration in the treatment of patients with uncomplicated liver abscess.

### MATERIALS AND METHODS

Medical records of all patients admitted to our hospital with liver abscess over a ten-year period (Jan. 1995 to Dec.

2004) were identified using the International classification of diseases 9th revision with clinical modification (ICD-9-CM-USA) and reviewed retrospectively. Patients with complicated liver abscess, generally due to rupture of abscess, were excluded from this analysis, as the indications for needle aspiration in these patients are rather different (Figure 1). Diagnosis of liver abscess was based upon clinical history and abdominal ultrasound or CT scan findings. The following data was collected in all the patients who were diagnosed with uncomplicated liver abscess: demographic information, chief complaint, duration of fever or abdominal pain, associated illnesses, malignancy and history of biliary surgery or other procedures. Results of laboratory investigations and imaging studies done at the time of admission were recorded as were the clinical course of disease, modalities of treatments used and outcome of the patients.

Patients with uncomplicated (non-ruptured) liver abscess were underwent to the following investigations: Complete blood counts, imaging by ultrasound, Indirect Hem-agglutination Assay (IHA) for amebiasis, blood culture and pus culture if the abscess was aspirated. IHA was done with serology reagent "Cellognost Amebiasis" supplied by (Dade Behring Marburg GmbH Germany) and a titer of  $\geq 1:128$  was taken as diagnostic for amebic liver abscess, as per the manufacturer's recommendations. Based upon the results of these investigations, patients with liver abscess were categorized into four groups according to the following criteria: (1) Amebic liver abscess (ALA): IHA titer  $\geq 1:128$  with negative blood or pus culture. (2) Pyogenic liver abscess (PLA): IHA titer  $< 1:32$  with or without positive blood and/or pus culture. (3) Mixed liver abscess (MLA): IHA titer  $\geq 1:128$  with positive blood and/or pus culture and (4) Indeterminate liver abscess (ILA): IHA titer between 1:32 and 1:128 with negative blood or pus culture. According to our usual practice, patients were started on standard treatment of liver abscess and if no clinical response was observed within three days, therapeutic percutaneous needle aspiration was carried out at the discretion of the treating physician. Needle aspiration was done under local anesthesia and ultrasound guidance without catheter drainage and the procedure was repeated in 3-4 d if optimal response was not obtained. Antibiotics were continued for 10-14 d for ALA, 4-6 wk for PLA and mixed infection and 2-6 weeks for indeterminate abscess.

### Statistical analysis

A descriptive analysis was done for demographic, clinical and radiographic features and results were presented as mean  $\pm$  SD for quantitative variables and number (percentage) for qualitative variables. In univariate analyses, differences in proportions for the group of patient underwent to needle aspiration and no aspiration was done by using the Chi-square test or Fisher exact test where appropriate. One-way analysis of variance and independent samples *t*-test were used to assess the difference of means for contrasts of continuous variables. Multiple logistic regression analysis was done and factors associated with likelihood of abscess aspiration were identified.

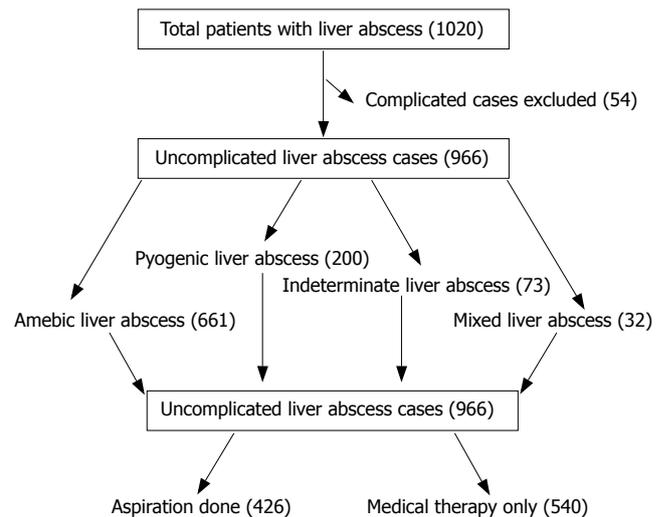

Figure 1 Flow diagram of the patients with liver abscess and treatment received.

## RESULTS

A total of 1020 patients with liver abscess were admitted during the study period. Fifty four patients with complicated liver abscess were excluded from the study and 966 patients with uncomplicated liver abscess were evaluated (Figure 1). The mean age was  $43 \pm 17$  years and 738 (76%) were males. The abscess was diagnosed as amebic (ALA) in 661 (68%), pyogenic (PLA) in 200 (21%), indeterminate (ILA) in 73 (8%) and mixed (MLA) in 32 (3%) patients. Clinical features of the patients in different types of liver abscess are presented in Table 1. Five hundred and forty patients responded to medical therapy alone; adjunctive percutaneous aspiration was performed in 426 patients. Demographic, clinical and laboratory features of the two groups are compared in Tables 2-4. There were significant differences between aspiration and non aspiration groups for many covariates.

In the aspiration group, more patients were older than 55 years (OR = 1.008; 95% CI = 1.0-1.01), duration of symptoms was more than 7 d (OR=1.60; 95% CI = 1.21-2.11), they were more likely to be jaundiced (OR = 1.55; 95% CI = 1.18-2.17), have tender hepatomegaly (OR = 0.68; 95% CI = 0.48-0.97) and hospital stay of more than 5 d (OR = 2.99; 95% CI = 1.75-2.99), as compared to the non-aspiration group (Table 2).

In the laboratory features the meaningful predictors of aspiration were elevated total bilirubin (OR = 1.09; 95% CI = 1.04-1.15), ALT (OR = 1.002; 95% CI = 1.0-1.004), alkaline phosphatase (OR = 1.002; 95% CI = 1.001-1.003), total leukocyte count (OR = 1.01; 95% CI = 1.004-1.03) and platelet count (OR = 1.001; 95% CI = 1.0-1.002), whereas relatively low serum albumin (OR = 0.59; 95% CI = 0.44-0.80) was found in the aspiration group as compared to the non aspiration group (Table 3).

The aspiration group, when compared with the non-aspiration group, was also found to have more patients with abscess sizes larger than 5 cm (OR = 1.59; 95% CI = 1.21-2.09), multiple abscesses (OR = 1.66; 95% CI = 1.23-2.24), involvement of both lobes of the liver (OR =

<sup>1</sup>Raised right hemi diaphragm, pleural effusion, and right lung base atelectasis. Variable compared to reference category (OR = 1), <sup>a</sup>*P* < 0.05.

for aspiration of liver abscess were age > 55 years, (OR = 1.6; 95% CI = 1.2-2.2), size of abscess more than 5 cm (OR = 1.6, 95% CI = 1.2-2.09), both lobes of the liver involvement (OR = 2.2, 95% CI = 1.5-3.4) and duration of symptoms lasting more than seven days (OR = 1.6, 95% CI = 1.2-2.1) (Table 5).

The number of abscesses ranged from 1-6 (median 2). None of the patients with uncomplicated liver abscess required surgery. In 403 (42%) patients, only one aspiration session was done and in 23 (2%) patients, 2-3 aspiration sessions were done before full recovery.

Twelve patients died in the aspiration group, although this mortality was not statistically significant when compared with the non aspiration group (Table 2). No deaths occurred as a direct complication of the needle aspiration.

## DISCUSSION

The use of needle aspiration in the treatment of uncomplicated liver abscess remains a debatable issue. Although

Table 5 Independent predictors for aspiration of liver abscess

Factor	Coefficient	Adjusted odds ratio	95% CI for adjusted odds ratio	Wald P-value

The parameter coefficient, adjusted odds ratio, 95% CI and Wald *P*-value, were estimated using multiple logistic regression. <sup>1</sup>Reference category.

most of these patients respond to antibiotics and supportive care, a significant number eventually require needle aspiration which is generally done at a later stage, while medical therapy alone is considered as inadequate, resulting in an extended hospital stay<sup>[17-21]</sup>.

An early decision regarding aspiration of liver abscess is therefore important as it is likely to reduce the length of hospital stay and hence the cost of treatment. On the basis of patient characteristics at the time of presentation, using a large data set, we have identified some factors that are associated with aspiration of liver abscess irrespective of the underlying etiology but we were unable to evolve a model for aspiration with good power.

Most patients in this series also recovered completely on appropriate antibiotics and supportive care. However in a substantial number of patients, percutaneous needle aspiration was additionally done for complete recovery. Based upon a comparative analysis between the two groups, patients who underwent aspiration were older, had larger or multiple abscesses and longer duration of symptoms than patients who recovered completely on medical therapy alone. Underlying etiology of amebic, pyogenic, mixed or indeterminate infection was not found to be a determinant for aspiration.

This study also reflects the difficulties sometimes faced by clinicians in determining the etiology of liver abscess. In this series, 68% of the 966 patients were diagnosed to have ALA, reflecting the burden of amebic infection in tropical regions of the world<sup>[3]</sup>.

The diagnosis of ALA is usually based on clinical and radiological features along with a positive IHA Entameba titer<sup>[1-3]</sup>. However none of these features are diagnostic and, in clinical practice, confusion can often arise as to the accurate diagnosis of ALA. For example a solitary abscess in the right lobe of the liver is considered to be highly suggestive of ALA<sup>[3,6,22]</sup>, which was true for 79% of ALA patients in this study. However a predominantly single abscess involving the right lobe was also seen in 68% of patients with PLA, suggesting that the presence of a single right lobe abscess should not exclude the diagnosis of PLA even in areas endemic for ALA. Similarly, although multiple abscesses involving both lobes were present more

commonly in patients with PLA<sup>[23-25]</sup>, they were also seen in 21% of patients with ALA.

The IHA Entameba titer is used to confirm the diagnosis of ALA. A high titer of IHA in invasive amebiasis is seen due to prolonged antigenic stimulation of absorbed liver abscess material<sup>[2]</sup>. However some issues should be considered when amoebic IHA is used in clinical practice. There is firstly the problem inherent in any serological assay, and that is the time lag required for the test to become positive so that the first reading may not achieve diagnostic values<sup>[2]</sup>. Secondly, in an endemic area, the appropriate cut off value for a positive test needs to be defined, keeping in mind the background positivity due to repeated (sub clinical) exposures<sup>[1,3]</sup>. Titers of ≥ 1:128 were considered as diagnostic for ALA in this study, based upon the manufacturer's recommendations and current literature<sup>[1,2]</sup>. However the higher the titer, the better is its diagnostic value considered.

Patients with pyogenic liver abscess (PLA) in this study has shown some differences in their clinical profile compared with other reported series; they were younger (mean age of 43 ± 17 years) and the etiology was predominantly cryptogenic<sup>[18,19]</sup>.

Although gallstones were present more frequently in PLA compared to patients with ALA, they were not associated with ascending cholangitis in the present series as reported previously<sup>[15,16]</sup>. The reasons for these differences are not clear. However other reports also show series of patients with PLA where the primary focus of infection was not known<sup>[26-28]</sup>.

Mixed abscess in this series comprised of 32 (3%), similar to the 4%-5%. Prevalence reported in the literature<sup>[20]</sup>. Mixed abscesses are basically ALA with secondary bacterial infection and their outcome was similar to ALA in the current series (Table 5) while in some studies mixed abscess has high mortality<sup>[29,30]</sup>.

Patients with indeterminate liver abscess behaved like ALA as regards response to treatment and outcome of disease. However the IHA titer failed to rise, even on successive testing in some cases. This may be due to a technical failure of the serological tests in these patients for various reasons, including a depressed immune status.

In conclusion, based upon a retrospective analysis of a large series of patients, we have found that if the patient with liver abscess is older in age, the abscess is more than 5 cm in size, both lobes of the liver are involved and the duration of symptoms is more than a week, then these patients are more likely to undergo percutaneous aspiration regardless of the etiology of abscess. A prospective study to validate these observations is underway, and if found accurate, it is likely to have an impact on cost effective approaches and quality of life in the management of such patients.

## COMMENTS

### Background

Liver abscess, especially the amebiasis is more prevalent in the tropical region of the world due to poor hygiene and sanitation. The standard treatment of liver abscess is the use of appropriate antibiotics and supportive care. Needle aspiration can be used as an additional mode of therapy and has been promoted by some authors for routine use in the treatment of liver abscess. It is suggested that needle aspiration can improve responses to antibiotic treatment, reduce hospital stay and the total cost of treatment. Needle aspirations, especially at the time of intervention has therefore remained a debatable issue and it seems important to determine its possible role in the treatment of liver abscess.

### Research frontiers

On the basis of a large dataset, we determine the factors associated with the likelihood of liver abscess aspiration in the treatment of patients with uncomplicated liver abscess.

### Innovations and breakthroughs

Based upon a retrospective analysis of a large series of patients, we have found that if the patient with liver abscess is older in age, abscess is more than 5 cm in size, both lobes of the liver are involved and duration of symptoms is more than a week then these patients are more likely to undergo percutaneous aspiration regardless of the etiology of abscess.

### Applications

A prospective study to validate these observations are underway, and if found accurate, it is likely to have an impact on the cost effectiveness and quality of life in the management of such patients.

### Peer review

This paper by Khan *et al* reports information on predictive factors for aspiration in liver abscess. It is a retrospective study based on a very large series of cases. A number of factors showed predictive values for aspiration in liver abscess. Although retrospective, this study is well-designed and performed and the findings are sound for the clinical arena.

### Abstract

**AIM:** To investigate whether supplementation of male zooid of *Antheraea pernyi* extracts (MZAPE) could enhance immune function of radiated tumor-bearing rats.

**METHODS:** Eighty male Wistar rats were randomly divided into a control group, a simple radiation group, a MZAPE group, and a radiation plus MZAPE group. With the tumor model established by implanting Walker-256 ascites tumor cells, tumor weight and tumor control rate were calculated. The rats in the simple radiation and radiation plus MZAPE groups were underwent to radiation at 10 Gy within 2 d. In the MZAPE and radiation plus MZAPE groups, the MZAPE was gavaged at a dose of 16.53 mg/kg once a day for 7 d. T cell subsets in peripheral blood were determined by flow cytometry and the expression of IL-2, IFN- $\gamma$ , IL-4 and IL-10 in sera were determined by ELISA on the 8th d.

**RESULTS:** The tumor weight of simple radiation group, MZAPE group and radiation plus MZAPE group was lower than that of control group ( $P < 0.01$ ) and tumor

control rates were  $63.08\% \pm 6.43\%$ ,  $69.86\% \pm 7.12\%$  and  $35.30\% \pm 7.67\%$ , respectively. CD4<sup>+</sup> T and CD8<sup>+</sup> T cells in the peripheral blood of the simple radiation group were fewer than in control group. In the MZAPE and radiation plus MZAPE groups, the number of CD4<sup>+</sup> T cells was higher while CD8<sup>+</sup> T cells was lower than in the control and simple radiation groups. Expression of IL-2 and IFN- $\gamma$  in the radiation group was lower than in control group, and significantly enhanced during MZAPE therapy ( $P < 0.05$ ). Expression of IL-4 and IL-10 in the radiation group had no significant changes compared with the control group, and decreased significantly after MZAPE treatment ( $P < 0.01$ ).

**CONCLUSION:** MZAPE administration may help improve the immune function of the radiated tumor-bearing rats and reverse the radiation-induced immune inhibition by promoting the proliferation of T helper cells and inducing the transdifferentiation from Th2 to Th1.

Enhancement of CD4<sup>+</sup> T cell activities and modulation of Th1/Th2 lineage development in radiated tumor-bearing rats treated with male zooid of *Antheraea pernyi* extracts. *World J Gastroenterol* 2008; 14(13): 2094-2099 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2094.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2094>

### INTRODUCTION

Patients and experimental animals with advanced cancer often exhibit a poorly functioning immune system<sup>[1]</sup>, which was manifested by allergy to skin-test antigens<sup>[2]</sup>, decreased T-cell proliferation<sup>[3]</sup>, alterations in signal transducing molecules<sup>[4]</sup>, reduced CD4:CD8 ratios<sup>[5]</sup> and deficient production of Th1 cytokines<sup>[6]</sup>. These alterations correlate with the severity of the disease and poor survival<sup>[7]</sup>. Large doses of radiotherapy in tumor treatment

is associated with normalization of cytokine producing capacity in cancer patients<sup>[6]</sup>. Moreover it will inevitably hurt normal tissues and organs, resulting in a weak body and poor immune functions. Radiotherapy-induced immune suppression could contribute to the spread of the disease and constitute a barrier to immunotherapeutic interventions. Many experimental models have confirmed the correlation between the diversity of clinical or pathological features in immune related diseases in cancer patients. Multiple factors may contribute to radiotherapy-induced immune suppression. These include the number of immunocompetent cells, which are mainly the T lymphocytes that are most sensitive to radiation, and the balance of Th1/Th2 cytokine production<sup>[8]</sup>. The T cell subgroups are general indicators for evaluating the immune state and immune competence of the body. The Th1/Th2 classification scheme is useful in terms of correlation between overall cytokine production patterns and clinical outcomes in a variety of pathological states<sup>[9]</sup>. INF- $\gamma$  secreted from Th1 cells is known to stimulate the differentiation of naive CD4<sup>+</sup> T cells into Th1 cells and to inhibit the proliferation of Th2 cells<sup>[10]</sup>. In addition, IL-4 and IL-10 secreted from Th2 cells are known to induce the differentiation of naive CD4<sup>+</sup> T cells to Th2 cells and to inhibit the function of Th1 cells<sup>[11,12]</sup>. In addition, the regulation of the immune balance of Th1/Th2 cell responses has been shown to be critically important for anti-tumor immune responses, such as inhibition of tumor growth and metastasis, and improvement of survival rate<sup>[13-15]</sup>. As described above, the tumor tissue and radiotherapy-induced immune suppression mainly express Th2 cytokines, resulting in a drift from Th1 to Th2, which further induces immune suppression. Therefore, it is important to improve immune function and to drift Th2 to Th1. Therapeutic interventions aimed at protecting the immune system from damage caused by radiotherapy in cancer patients may, therefore, enhance their immune competence. Seo<sup>[16]</sup> demonstrated that Chinese herbal medicine could change the Th1/Th2 balance by directly weakening the activities of the T cells, and the Th1 cytokines could take the predominant position.

The male zooid of *Antheraea pernyi* (MZAPE) has long been used as a pure preparation of traditional Chinese medicine to treat many illnesses and promote longevity. Our previous study demonstrated that the concentrated liquor of the male zooid could improve immune function, promote recognition and lethal effects toward tumor cells, and it possessed a unique priority for adjunctive therapy against tumors<sup>[17]</sup>. We investigated the mechanism regarding the reversion of radiation-induced immune suppression by the active ingredients of MZAPE extracts in tumor-bearing rats.

## MATERIALS AND METHODS

### Materials

The unmated MZAPE was obtained from the Silkworm Research Institute of Shandong Academy of Agricultural Science. In total, 250 g of zooid was ground into powder and then passed through a mesh screen (#80) and suspended in aqueous ethanol (95%; 20 L) for 24 h. After

filtration, the residue was resuspended in aqueous ethanol (95%; 20 L) for an additional 24 h and refiltered. We then concentrated MZAPE by combined liquid-phase filtration.

### Experimental animals and grouping

Eighty male Wistar rats with an average weight of  $120 \pm 10$  g were purchased from the Animal Center of Shandong University. All animals were housed in groups of 4-6 in 29 cm  $\times$  18 cm  $\times$  13 cm polyethylene cages. The animal room was maintained at 22°C-24°C on a fixed light: dark cycle (12 h: 12 h). Rats were looked after according to the Guide for the Care and Use of Laboratory Animals (National Academy Press, Washington, D.C.). Our hospital Ethical Committee for Animal Welfare approved all the experiments. Hen egg lysozyme (HEL) was purchased from Sigma-Aldrich (St. Louis, MO) and recrystallized three times. Rats were immunized via the hind footpads with 1 nmol/rat of native HEL emulsified in colonization factor antigen (CFA) (Difco, Detroit, MI). The rats were weighed and randomly divided into a control group, a simple radiation group, a MZAPE group, and a radiation plus MZAPE group, and there were 20 rats in each group. The ascites cells of rats bearing with Walker 256 carcinoma were collected, counted and diluted at  $2 \times 10^7$ /mL, and 0.25 mL was applied to the right axilla of each rat *via* hypodermic inoculation. The experiments were carried out when the tumors grew to a diameter of 0.8-1.0 cm.

A Siemens PRIUS medical electronic linear accelerator (Shandong Tumor Hospital) was used. The radiation dose rate was 100 cGy/min, and the source-skin distance was set at 205 cm. The rats in the simple radiotherapy and radiation plus MZAPE groups underwent radiation with 5 Gy/d of routine radiotherapy for two days (10Gy in total). After 24 h, the MZAPE was gavaged at 16.53 mg/kg once a day for seven days in the MZAPE and radiation plus MZAPE groups. The rats in the simple radiation group and control group were gavaged with 2 mL normal saline for seven days. The rats were sacrificed on the first day after MZAPE administration. Tumor tissues were harvested and weighed, and tumor-inhibiting rate was calculated.

### T cell proliferation assay

Spleens were removed on the first day after MZAPE gavage and spleen cell suspensions were prepared. The erythrocytes in the cell suspensions were lysed with Tris-NH<sub>4</sub>Cl. A total of  $5 \times 10^6$  cells/mL in 100  $\mu$ L RPMI 1640 containing 1 mmol/L glutamine, 100 U/mL penicillin, 100  $\mu$ g/mL streptomycin,  $5 \times 10^{-5}$  mol/L 2-mercaptoethanol and 1% heat-inactivated autologous rat serum were added to each well, followed by the addition of 100 mg/L HEL. The cells were cultured for 72 h. Each well was pulsed with 0.5  $\mu$ Ci tritiated thymidine, and the cells were cultured for another 16 h. The cultures were harvested onto fiberglass filters using a multiharvester and counted using standard liquid scintillation techniques.

### Measurement of HEL-specific antibodies

Blood was collected on the first day after MZAPE gavage, and sera were heat-inactivated at 56°C for 30 min.

**Table 1** Effect of MZAPE on tumor weight, tumor-inhibiting rate, suppression of anti-HEL IgG antibody production, and proliferative responses of PBMC to HEL ( $n = 20$ , mean  $\pm$  SE)

Groups	Tumor weight (g)	Tumor-inhibiting rate (%)	Anti-HEL IgG antibody ( $A_{405}$ )	Proliferation ( $\times 1000$ cpm)
Control	4.27 $\pm$ 0.60		0.17 $\pm$ 0.02	6.0 $\pm$ 0.7
Simple irradiation	1.58 $\pm$ 0.40 <sup>b</sup>	63.08 $\pm$ 6.43	0.09 $\pm$ 0.01 <sup>b</sup>	5.31 $\pm$ 0.8 <sup>d</sup>
Radiation plus MZAPE	1.29 $\pm$ 0.33 <sup>b</sup>	69.86 $\pm$ 7.12	0.34 $\pm$ 0.01 <sup>b</sup>	27.4 $\pm$ 2.8 <sup>b</sup>
MZAPE	2.76 $\pm$ 0.37 <sup>b</sup>	35.30 $\pm$ 7.67	0.44 $\pm$ 0.04 <sup>b</sup>	49.6 $\pm$ 3.1 <sup>b</sup>

<sup>b</sup> $P < 0.001$  and <sup>d</sup> $P = 0.006$  vs control group.

IgG, IgG1 and IgG2a antibodies specific for HEL were measured with ELISA (BD Pharmingen, San Diego, CA, USA). In brief, 96-well flat-bottomed microtiter plates were coated with 100  $\mu$ L/well HEL (100 mg/L) at 37°C for 1 h and washed three times with PBS. The wells were then blocked by incubation with 100  $\mu$ L PBS containing 1% ovalbumin at 37°C for 1 h. After washing, the plates were incubated with 100  $\mu$ L of a 1:10000 dilution of each serum sample at 37°C for 30 min. The plates were washed, and 100  $\mu$ L/well of a 1:1000 dilution of rabbit anti-rat IgG, IgG1 or IgG2a labeled with alkaline phosphatase was added and incubated at 37°C for 1 h. After washing, 100  $\mu$ L of 3 mmol/L p-nitrophenylphosphate was added to each well, and the plates were incubated in the dark at room temperature for 15 min. Absorbance was then measured at 405 nm in a Titertec Multiscan spectrophotometer (EFLAB, Helsinki, Finland). The results were expressed as absorbance units at  $A_{405} \pm$  SEM.

### Cytokine assays

Single-cell suspensions from spleens were prepared as described above and  $5 \times 10^6$  cells/mL were cultured in 1 mL aliquots in 24-well tissue culture plates with 100 mg/L HEL. Forty-eight hours later, the supernatants were harvested and stored at -70°C until assayed. The changes in expression of Th1 cytokines (IL-2, INF- $\gamma$ ) and Th2 cytokines (IL-4, IL-10) were detected with ELISA. IL-2, INF- $\gamma$ , IL-10, IL-4 ELISA sets were purchased from BD Pharmingen (San Diego, CA, USA).

### Preparation of lymphocytes

Peripheral blood mononuclear cells (PBMC) were separated from peripheral blood of the rats by Ficoll-Conray method, and the number was counted under microscope.  $1 \times 10^6$  cells diluted in 1 mL PBS were added to each tube and the phenotypic alternations of the peripheral blood lymphocytes were analyzed by flow cytometry.

### FACS analysis

The cells were first stained for surface antigens (30 min at 4°C) with anti-CD3-FITC, anti-CD4-FITC, anti-CD8-FITC, and anti-CD57-FITC (BDIS Biosciences, Stockholm, Sweden). Thereafter, the lymphocytes were permeabilized with FACS-lysing solution and FACS permeabilizing solution (BDIS Biosciences). The staining protocol included isotype controls for both surface and cytoplasmic staining. After staining, the cells were fixed with CellFix (BDIS Biosciences) and acquisition was performed within 2 h. Flow cytometric measurements

**Table 2** Effect of MZAPE on anti-HEL IgG2a and IgG1 antibody production ( $n = 20$ , mean  $\pm$  SE)

Groups	Anti-HEL IgG2a antibody ( $A_{405}$ )	P	Anti-HEL IgG1 antibody ( $A_{405}$ )	P
Control	0.08 $\pm$ 0.01		0.25 $\pm$ 0.02	
Simple irradiation	0.06 $\pm$ 0.01	< 0.001	0.51 $\pm$ 0.03	< 0.001
Radiation plus MZAPE group	0.15 $\pm$ 0.02	< 0.001	0.396 $\pm$ 0.02	< 0.001
MZAPE group	0.32 $\pm$ 0.04	< 0.001	0.24 $\pm$ 0.01	0.053

were performed using a FACS Calibur (Becton Dickinson, Stockholm, Sweden) and at least 10000 cells/sample were collected. Data analysis was done using Cell Quest software (BDIS Biosciences) according to a standardized pattern-protocol. The background fluorescence was determined with markers applied on the isotype control cytograms and was < 1% in all cases.

### Statistical analysis

Statistical analysis was performed using a two-tailed, paired Student's *t* test. Significance was accepted at  $P < 0.05$ .

## RESULTS

### Tumor weight and tumor-inhibiting rate

The weight and volume of tumors in the simple radiation, radiation plus MZAPE and MZAPE groups were significantly lower than those in the control group ( $P < 0.001$ ); moreover the tumor-inhibiting rates in the simple radiation, radiation plus MZAPE and MZAPE groups were 63.08%  $\pm$  6.43%, 69.86%  $\pm$  7.12% and 35.30%  $\pm$  7.67%, respectively, (Table 1).

### Effect of MZAPE on anti-HEL IgG antibody production, proliferative responses to HEL and anti-HEL IgG2a and IgG1 antibody production in rats

The antigen-specific IgG antibodies in sera, the proliferative responses, anti-HEL IgG2a and IgG1 antibody production of rats immunized with HEL and administered MZAPE were measured on the 8th day. The anti-HEL IgG antibody production markedly decreased in simple irradiation group while increased in radiation plus MZAPE group and MZAPE group when compared to control group ( $P < 0.001$ ). The proliferative responses of PBMC to HEL were significantly enhanced in the radiation plus MZAPE group and MZAPE group compared with the control group ( $P < 0.001$ ). The anti-HEL IgG2a antibody production

	IL-2		INF- $\gamma$		IL-4		IL-10	
	Mean $\pm$ SE	<i>P</i>	Mean $\pm$ SE	<i>P</i>	Mean $\pm$ SE	<i>P</i>	Mean $\pm$ SE	<i>P</i>
Control group	181.99 $\pm$ 19.33		89.06 $\pm$ 21.44		97.69 $\pm$ 7.11		180.14 $\pm$ 19.56	
Simple irradiation group	129.14 $\pm$ 16.96	< 0.001 <sup>b</sup>	74.09 $\pm$ 39.29	0.143	100.57 $\pm$ 12.01	0.362	179.26 $\pm$ 18.13	0.883
Radiation plus MZAPE group	138.16 $\pm$ 23.15	< 0.001 <sup>b</sup>	91.25 $\pm$ 27.00	0.778	74.78 $\pm$ 8.28 <sup>d</sup>	< 0.001 <sup>b,d</sup>	180.25 $\pm$ 17.32	0.985
MZAPE group	166.73 $\pm$ 13.34 <sup>d</sup>	0.006 <sup>b</sup>	103.85 $\pm$ 6.55 <sup>d</sup>	0.005 <sup>b</sup>	66.02 $\pm$ 7.14 <sup>d</sup>	< 0.001 <sup>b,d</sup>	136.29 $\pm$ 18.21 <sup>d</sup>	< 0.001 <sup>b,d</sup>
MZAPE group		< 0.001 <sup>d</sup>		0.002 <sup>d</sup>				

<sup>b</sup>*P* < 0.001 vs control group; <sup>d</sup>*P* < 0.001 vs simple irradiation group.

markedly increased in radiation plus MZAPE group and MZAPE group as against the control group ( $P < 0.001$ ). The anti-HEL IgG1 antibody production significantly increased in simple irradiation group and radiation plus MZAPE group ( $P < 0.001$ ). There was no significant change of anti-HEL IgG1 antibody production in MZAPE group (Tables 1 and 2).

#### Effect of MZAPE on peripheral blood lymphocyte changes of rats

The number of CD4<sup>+</sup>, CD8<sup>+</sup> lymphocytes in the peripheral blood of the simple irradiation group and the ratio of CD4<sup>+</sup>/CD8<sup>+</sup> were both decreased. The CD4<sup>+</sup> lymphocytes in the peripheral blood of the radiation plus MZAPE and MZAPE groups were higher than that in the simple radiation and control groups, and the ratio of CD4<sup>+</sup>/CD8<sup>+</sup> increased. The CD8<sup>+</sup> lymphocytes of the radiation plus MZAPE and MZAPE groups showed no significant changes compared to the simple irradiation and control groups (Table 3).

#### Effect of MZAPE on expression of Th1 (IL-2, INF- $\gamma$ ) cytokines and Th2 (IL-4, IL-10) cytokines in rats

The expression of IL-4 and IL-10 in the spleens of the simple radiation group showed no significant changes, while the expression of IL-2 decreased ( $P < 0.001$ ). In radiation plus MZAPE group, the expression of IL-2 and IL-4 significantly increased ( $P < 0.001$ ). In the MZAPE group, the expression of IL-2, INF- $\gamma$ , IL-4 and IL-10 significantly increased when compared with the control group and simple radiation group ( $P < 0.001$ ) (Table 4).

## DISCUSSION

The male zooid, a kind of bombycidae, is an animal derived medicine in China, and disintegrates from the male tussor chrysalis. According to the Dictionary of Traditional

Chinese Medicine, the major components of the male zooid are proteins, with more than 20 kinds of free amino acids and cytochrome c. Actually, the male zooid also contains various active substances, such as brain hormone, prothymosin, hormone of *Antheraea pernyi*, and diuretics, which can regulate metabolism and restore immune functions<sup>[18]</sup>. In addition, such substances may have certain pharmacological activities such as strengthening Yang Qi and astringing essence, promoting host defense mechanisms, and have potentials of anti-aging, anti-tumor and immunity enhancement<sup>[19]</sup>. It can be clinically used to treat impotence, seminal emission and stranguria with hematuria. A number of studies have shown the multiple effects of the male zooid in immune responses. The immune system in the Chinese oak silk moth, *Antheraea pernyi*, originated from a single ancestral gene with that of the *Cecropia* moth, whose antibacterial activity has been tested against nine different bacterial species<sup>[20]</sup>. Zhang *et al.*<sup>[21]</sup> reported that the cecropins from the Chinese oak silkworm *Antheraea pernyi* possess effective anti-tumor activity with no cytotoxicity against normal eukaryotic cells, and impede the neoplastic process in murine large intestines.

It is documented that cytokines such as IL-4 and IL-10 can induce the differentiation of Th1 to Th2 and inhibits the production of Th1 cytokines<sup>[22]</sup>, affecting immune system and the anti-tumor defense functions. In addition, the immune system of malignant tumor patients could be in immune suppression status and manifest Th2 cell superiority<sup>[23]</sup>, and radiotherapy could aggravate immunologic injury of the body while it killed tumor cells, resulting in the progressive deterioration of the body's immune function. When the immune function becomes weak, the tumor would easily relapse or transfer to other sites.

In our study, the number of CD4<sup>+</sup> T cells in the radiated tumor-bearing rats increased after administration of the MZAPE. Such results allow us to hypothesize that

the extracts could strengthen cell immunity by promoting CD4<sup>+</sup> T cells. In contrast, its effect on CD8<sup>+</sup> T cells was not obvious and the exact reason for that needs to be investigated in the future. The MZAPE could inhibit the production of Th2 cytokines and reduce the induction of Th2 cytokines in Th1 cells, thereby increasing Th1 cells. The extracts could stimulate the expression of Th1 cytokines, which might induce the transformation of Th0 cells to Th1 cells. We presume that Th1 cells or large number of cytokines secreted by them would activate or enforce immune cell function. Further experiments are needed to elucidate the above-mentioned process. In conclusion, our results demonstrate that MZAPE selectively alters Th1/Th2 cytokine secretion pattern, strengthens immune function of the body and reverses immune suppression induced by radiotherapy. The extracts have a significant effect on enhancing cell immunity by inducing the transformation of Th2 to Th1. This study provides the pharmacological basis for the clinical application of MZAPE.

## COMMENTS

### Background

Hypoimmunity of tumor patients caused by radiotherapy is one of the major reasons for the failure of treatment and death of patients. Our previous study demonstrated that the concentrated liquor of the male zooid could improve immune function, promote recognition and lethal effects toward tumor cells, and it possessed a unique priority for adjunctive therapy against tumors. In this study the authors evaluated whether supplementation of the male zooid of *Antheraea pernyi* extracts (MZAPE) could enhance the immune function of the radiated tumor-bearing rats.

### Research frontiers

The male zooid contains various active substances, which may have certain pharmacological activities such as strengthening Yang Qi and astringing essence, promoting host defense mechanisms, and has potentials of anti-aging, anti-tumor and immunity enhancement. Some studies have shown the male zooid's immunoregulatory function and anti-tumor activity.

### Related publications

Our previous study entitled "Immunization of mice with concentrated liquor from male zooid of *Antheraea pernyi*", which was published at World Journal of Gastroenterology, demonstrated that the concentrated liquor of the male zooid could improve immune function, promote recognition and lethal effects toward tumor cells, and it possessed a unique priority for adjunctive therapy against tumors. Other studies also reported that the cecropins from the Chinese oak silkworm *Antheraea pernyi* possess effective anti-tumor activity with no cytotoxicity against normal eukaryotic cells, and impede the neoplastic process in murine large intestines.

### Innovations and breakthroughs

The MZAPE administration may improve immune function in radiated tumor-bearing rats and reverse the radiation-induced immune inhibition by promoting the proliferation of T helper cells and inducing the differentiation from Th2 to Th1, and the MZAPE could strengthen the immune function of the body and reverse the immune suppression induced by radiotherapy.

### Applications

The MZAPE selectively alters the Th1/Th2 cytokine secretion pattern, strengthens the immune function of the body and reverses the immune suppression induced by radiotherapy. The study provides the pharmacological basis for the clinical application of the male zooid of *Antheraea pernyi* extracts.

### Terminology

The male zooid of *Antheraea pernyi* extracts (MZAPE): it has long been used as a pure preparation of traditional Chinese medicine, which possesses many health-

care functions. According to The Great Dictionary of Traditional Chinese Medicine, *Antheraea pernyi* is the matured insect of silkworm.

### Peer review

This is an interesting study showing the impact of MZAPE on immune system using a tumor-bearing rat model. The study may benefit from powerful calculation to decide the number of animals needed in each group.

### Abstract

**AIM:** To explore the anti-fibrotic effect of Oxymatrine on CCl<sub>4</sub>-induced liver fibrosis in rats and its modulation on the TGFbeta-Smad signaling pathway.

**METHODS:** One hundred healthy male SD rats were randomly divided into three groups: normal group ( $n = 20$ ), treatment group of Oxymatrine ( $n = 40$ ) and CCl<sub>4</sub>-induced fibrosis group ( $n = 40$ ). Experimental hepatic fibrosis was induced by subcutaneous injection of carbon tetrachloride (CCl<sub>4</sub> soluted in liquid paraffin with the concentration of 300 g/L, the dosage of injection was 3 mL/kg, twice per week for 8 wk). The treated rats received Oxymatrine *via* celiac injection at a dosage of 10 mg/kg twice a week at the same time. The deposition of collagen was observed with H&E and Masson staining. The concentration of serum TGF-β1 was assayed with ELISA. The gene expression of Smads and CBP (CREB binding protein) was detected with *in situ* hybridization (ISH) and immunohistochemistry (IH), respectively. All the experimental figures were scanned and analyzed with special figure-analysis software.

**RESULTS:** A significant reduction of collagen deposition and rearrangement of the parenchyma was noted in the liver tissue of Oxymatrine-treated rats. The semi-quantitative histological scores ( $2.43 \pm 0.47 \mu\text{m}^2$  vs  $3.76 \pm 0.68 \mu\text{m}^2$ ,  $P < 0.05$ ) and average area of collagen in those rats were significantly decreased when compared with hepatic cirrhosis model rats ( $94.41 \pm 37.26 \mu\text{m}^2$  vs  $290.86 \pm 89.37 \mu\text{m}^2$ ,  $P < 0.05$ ). The gene expression of Smad 3 mRNA was considerably decreased in the treated animals. The *A* value of Smad 3 mRNA was lower in the treated rats than the model rats ( $0.034 \pm 0.090$  vs  $0.167 \pm 0.092$ ,  $P < 0.05$ ). Contrarily, the *A* value of Smad 7 mRNA was increased considerably in the treated animals ( $0.175 \pm 0.065$  vs  $0.074 \pm 0.012$ ,  $P < 0.05$ ). There was

an obvious decrease in the expression of CBP mRNA in treated rats as illuminated by a reduction of its *A* value when compared with model rats ( $0.065 \pm 0.049$  vs  $0.235 \pm 0.025$ ,  $P < 0.001$ ).

**CONCLUSION:** Oxymatrine is effective in reducing the production and deposition of collagen in the liver tissue of experimental rats. Oxymatrine could promote the expression of Smad 7 and inhibit the expression of Smad 3 and CBP in CCl<sub>4</sub>-induced hepatic fibrosis in SD rats, could modulate the fibrogenic signal transduction of TGFβ-Smad pathway.

Effect of Oxymatrine on the TGFbeta-Smad signaling pathway in rats with CCl<sub>4</sub>-induced hepatic fibrosis. *World J Gastroenterol* 2008; 14(13): 2100-2105 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2100.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2100>

### INTRODUCTION

Several studies have shown that hepatic fibrosis is a reversible disease, therefore an effective treatment would probably prevent or reverse the fibrotic process in the liver<sup>[1]</sup>. In the long pathological period of hepatic fibrosis to cirrhosis, transforming growth factor beta 1 (TGFβ1) is one of the strongest pro-fibrotic cytokine<sup>[2,3]</sup>, and TGFβ-Smad signaling is the cardinal signal transduction pathway<sup>[4]</sup> which has been verified by several related studies. The down regulation of TGFβ expression and modulation of TGFβ-Smad signaling may be effective in preventing liver fibrosis<sup>[5]</sup>. This study is aimed to explore the anti-fibrotic effect and the probable mechanisms of the extraction of the traditional Chinese medicine, Oxymatrine, in experimental hepatic fibrosis of rats. By examining histopathological changes and deposition of collagen protein in the liver tissue with H&E and Masson

staining, detecting the expression of Smads and CBP with *in situ* hybridization (ISH) and immunohistochemistry (IH), assaying the concentration of serum TGF $\beta$ 1 with ELISA, we present anti-fibrotic effects of Oxymatrine and discuss the molecular mechanism in an experimental model of carbon tetrachloride (CCl<sub>4</sub>)-induced hepatic fibrosis in rats.

## MATERIALS AND METHODS

### Animals

One hundred healthy male SD rats (weight 140-160 g) were obtained from the Experimental Animal Center of Sichuan University (Chengdu, Sichuan Province, China).

### Reagents

Carbon tetrachloride (CCl<sub>4</sub>) was obtained from the Chemical and Industrial Reagent Institute in Chengdu. Oxymatrine was from Green Valley Pharmaceutical Co. Ltd., Shanghai, China. Commercial Rat TGF $\beta$ 1 ELISA Kit and Smad 7 IH Kit were obtained from Boster Biotechnology Co. Ltd., Wuhan, China. The oligonucleotide probe of Smad 3 mRNA (5'→3'): Biotin-GAAGGCCGGCTCACAGTAGGTGACTGGCTG (981-1010 bp, GC% = 63.33), Smad 7 mRNA (5'→3'): Biotin-GAGCTGTCCGAGGCAAAAAGCCAT'CCCCCTG (2310-2339 bp, GC% = 60.00), and CBP mRNA (5'→3'): Dig-TGACAGTTGTTTATGTTTGGACGC (371-394 bp, GC% = 41.67) were obtained from Shanghai Shenergy Biotechnology Co. Ltd.

### Methods

The experimental rats were housed in a room with controlled temperature (15°C-20°C) and lighting (10 h light, 14 h dark). Free access of water and food was allowed during the experimental period. All 100 rats were randomly divided into three groups: Control ( $n = 20$ ), Treatment ( $n = 40$ ) and Model group ( $n = 40$ ). For the model group, 300 g/L CCl<sub>4</sub> soluted in liquid paraffin was injected subcutaneously at a dosage of 3 mL/kg twice per week<sup>[6]</sup>. The treated rats received Oxymatrine celiac injections at 10 mg/kg twice a week besides the injection of CCl<sub>4</sub>. The injection of CCl<sub>4</sub> and Oxymatrine were without anesthesia. There were no bleeding and other complications after injection. The control group was given normal food and water and received the same dosage and duration of liquid paraffin only as the model group. At the end of the 8-wk experimental period, all the rats were anaesthetized by an intra-muscular injection of sodium pentobarbital (30 mg/kg) before being put to death. Blood was collected from the heart and serum was obtained through centrifugation. The liver was removed rapidly and conserved in 40% neutral formalin for further examination.

Serum concentration of TGF $\beta$ 1 was detected with enzyme-linked immunoadsorbent assay (ELISA). Liver samples were embedded in paraffin and stained with hematoxylin-eosin (H&E) and Masson collagen staining<sup>[7]</sup>. A total of five sections for each liver tissue sample were observed under an optical microscope. The semi-quantitative fibrosis staging scores were acquired according

to the HAI<sup>[8]</sup> (histological action index, Table 1): 0: no fibrosis; 1: slight fibrosis, fibrosis located in the central liver lobule; 2: moderate fibrosis, fibrous space formation, but the structure of liver lobule reserved; 3: severe fibrosis, fibrous space enlarged and lobular structure distortion; 4: early cirrhosis or certain cirrhosis, pseudolobule formation.

Each embedded liver sample in paraffin was sliced and fixed onto a poly-L-Lysine covered glass. The gene expression of Smad 3, Smad 7 and CBP mRNA in liver tissues were evaluated with *in situ* hybridization (ISH). The Oligonucleotide probes of Smad 3 and Smad 7 mRNA were marked with biotin at their 5' ends. The Oligonucleotide probe of CBP mRNA was marked with digoxin at its 5' end. The procedure of *in situ* hybridization (ISH) consisted of de-waxing, digesting, pre-hybridizing, hybridizing, coloring, and fixing<sup>[9]</sup>. For the color reaction of Smad 3 and Smad 7 mRNA, the NBT/BCIP method was used, and CBP mRNA was detected using DAB. Positive colors of these two methods were purple and brown, respectively. The expression of Smad 7 protein was detected with immunohistochemistry (IH). The procedure of immunohistochemistry (IH) consisted of de-waxing, exposing antigen, repairing antigen, blocking irrespective antigen, combining antigen and antibody, and coloring, respectively. For the color reaction DAB was used, and the positive result were brown particles in the cytoplasm<sup>[10]</sup>.

### Statistical analysis

The quantified markers were counted with mean  $\pm$  SD. Slices were scanned under the inverted microscope attached to a computer. The figures were collected and quantified with the software of statistics system. (type TE2000-H, Nikon Ltd, Japan). Random analysis of variance was adopted in the comparison among the different groups, and *t*-test was used in the comparison between different groups.

## RESULTS

At the end of experimental period, there were only eighty five rats remained. Five rats in treated group and ten in model group died. Most of the fifteen rats died from injury of biting or being poisoned by Carbon tetrachloride.

### Change of TGF $\beta$ 1 serum concentration

In the control group, the serum concentration of TGF $\beta$ 1 was only at  $1.34 \pm 0.25$   $\mu$ g/L. In the model group, the serum concentration of TGF $\beta$ 1 was significantly elevated to  $3.59 \pm 1.23$   $\mu$ g/L ( $P = 0.004$  *vs* control group). It correlated with the semi-quantitative scores of liver fibrosis (the correlation coefficient *r* was +0.59,  $P < 0.05$ ). With the administration of Oxymatrine, the serum concentration of TGF $\beta$ 1 was decreased significantly to  $1.82 \pm 0.61$   $\mu$ g/L ( $P = 0.023$  *vs* model group), although it was still higher than the serum concentration of the control group ( $P = 0.069$  *vs* control group) (Table 2).

### Histopathological changes in the liver

In the control group, the livers showed normal lobular architecture with central veins and radiating hepatic

Table 1 Semi-quantitative scores of hepatic fibrosis staging

Score	Pathological description	Stage
0	No fibrosis	No fibrosis
1	Slight fibrosis	Periportal fibrosis
2	Medium fibrosis	Enlarged periportal fibrosis
3	Severe fibrosis	Bridging fibrosis
4	Cirrhosis	Cirrhosis

Table 2 Serum TGFβ1 concentration and collagen area in liver tissues (mean ± SD)

Group	TGFβ1 (μg/L)	Collagen area (μm <sup>2</sup> )
Control	1.34 ± 0.25 <sup>b</sup>	56.12 ± 21.45 <sup>a</sup>
Model	3.59 ± 1.23	290.86 ± 89.37
Treat	1.82 ± 0.61 <sup>a</sup>	94.41 ± 37.26 <sup>a</sup>

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs model group.

ords, with 0 staging score. Subcutaneous injection of CCl<sub>4</sub> caused severe hepatic pathological damages such as inflammation, significant hepatic cell necrosis and excessive collagen deposition. The semi-quantitative hepatic fibrosis staging score was raised to 3.76 ± 0.68 in the model group (*P* < 0.01 vs control group). The rats' livers in the Oxymatrine treated group showed less hepatic cells necrosis, less collagen deposition and a significantly decreased staging score of 2.43 ± 0.47 (*P* < 0.05 vs model group) (Table 3, Figure 1 A and B).

### Molecular changes of Smad 3, Smad7 and CBP gene expression

There were less positive signals of Smad 3 and CBP mRNA detected with ISH (*in situ* hybridization) in the normal group. The *A* (optical density) value of CBP was nearly 0 (Table 2). In the model group, the positive expression of Smad 3 and CBP mRNA increased significantly. The *A* value of CBP and Smad 3 were increased to 0.235 ± 0.025 and 0.167 ± 0.092 respectively (*P* < 0.01 vs normal group). The treatment with Oxymatrine significantly reduced the *A* value to 0.065 ± 0.049 and 0.034 ± 0.090 (*P* < 0.05 vs model group). At the same time, the positive rate of Smad 7 protein expression was increased from 1.9% to 4.3% (*P* < 0.05 vs model group) (Table 2). Those results demonstrated that Oxymatrine was effective in inhibiting the expression of TGFβ1, Smad 3 and CBP, promoting expression of Smad 7 in the liver (Figures 2 and 3, Table 4).

## DISCUSSION

Hepatic fibrosis is thought to be a reversible disease, however, there has not been a satisfied method in the clinical practice to reverse the pathological process yet. Several drugs, including antisense TGFβ receptor, cytokines<sup>[11]</sup>, antioxidant, chemical drugs, soluble type II receptor of TGFβ1, antibody of TGFβ1 have been used in research work to block experimental hepatic fibrosis, but their effects were not as prosperous as we had expected.

Table 3 Liver histopathological semi-quantitative scores (According to HAI)

Group	<i>n</i>	Scores					Staging scores
		0	+1	+2	+3	+4	
Control	20	20	0	0	0	0	0 <sup>b</sup>

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs model group.

Besides, some traditional Chinese drugs have been found effective in preventing fibrogenesis and other causes of chronic liver injury<sup>[12,13]</sup>, and this help to develop a more hopeful future in controlling liver fibrosis and cirrhosis. These drugs have the advantages of being cheap, safe and easy to acquire, but most of them are limited in some animal experiments, rough clinical observation and lack of systemic study at molecular level.

The activation of hepatic stellate cells (HSC) "induced by some critical cytokines" is considered to be of great importance during the long period of liver fibrosis<sup>[14]</sup>. This activated HSC then becomes the main source of most cytokines and collagen proteins. Among the cytokines mediating factors, transforming growth factor beta 1 (TGFβ1) has been demonstrated in most research to be an essential pro-fibrogenesis factor<sup>[15-19]</sup>. In addition to that, TGFβ-Smad signaling pathway is the main pathway of TGF-β<sup>[20-23]</sup>, which transfers the stimulating signal from outside into the affected cells. The Smad proteins consists of a large family of transcription factors, which are also found in vertebrates, insects and nematodes. To date, Smads are the only TGF-β receptor substrates with a demonstrated ability to propagate signals. Briefly, two different transmembrane protein serine/threonine kinases, named as TGF-β receptor type I and II respectively, are brought together by the ligand, which acts as a receptor assembly factor<sup>[24]</sup>. Before this occurs, receptor I is inactive because a wedge-shaped GS region is inserted into the kinase domain, dislocating the catalytic center. During the TGF-β signal transduction, receptor II is activated firstly. TGF-β and its receptor then form a activated complex. In the ligand-induced complex, activated receptor II phosphorylates the GS region of receptor type I, resulting in the activation of the receptor I kinase. The type I receptors specifically recognize the Smad subgroup known as receptor-activated Smads (R-Smads), which are Smad 2 and Smad 3<sup>[25]</sup>. Then R-Smads are activated and forms a complex consisting of R-Smads and Smad 4, which belongs to Co-Smad.

**Figure 1** Subcutaneous injection of CCl<sub>4</sub> caused severe hepatic injury such as significant hepatic cell necrosis and excessive collagen deposition. With Masson staining, the collagen fiber was shown blue and hepatic cells were red. (A: Masson,  $\times 200$ ). Oxymatrine treated livers showed less hepatic cell necrosis and less collagen deposition (B: Masson,  $\times 200$ ).

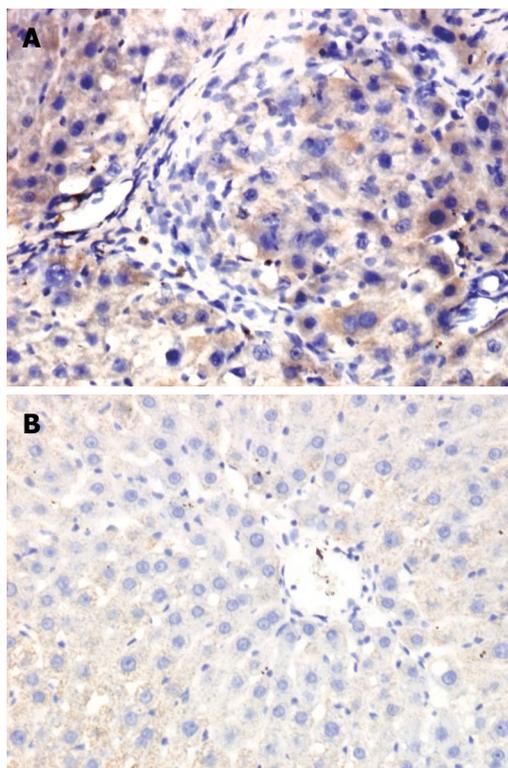

**Figure 2** Expression of Smad 7 protein in liver tissue of model rats was increased when detected with immunohistochemistry (A: IH,  $\times 200$ ) when compared to the control group. However, the expression of Smad 7 protein in the livers of the Oxymatrine-treated group was even more significantly increased (B: IH,  $\times 200$ ). The positive rate of Smad 7 protein expression was 1.9% and 4.3% in the model group and the treated group, respectively (data obtained from statistical software,  $P < 0.05$ ).

The Smads-complex then accumulates in the nucleus. This procedure leads to the formation of the functional transcriptional complexes. Both the R-Smads and the Co-Smads in this complex may participate in DNA-binding and recruitment of transcriptional cofactors<sup>[26,27]</sup>. CBP (Creb binding protein) is the main downstream molecule and the general transcriptional co-activator. After transferring into the nucleus, the transcriptional complex bind to the certain domain of the target gene and cause the gene expression such as collagen production. The excess collagen production would lead to collagen deposition in liver tissue and hepatic fibrosis or cirrhosis at last. In this pathway, there are two inhibitor Smads (I-Smads), named as Smad 6 and Smad 7, which could combine to the Smads-complex in cytoplasm. Smad 6 and Smad 7 could prevent the Smads-complex to transfer into the nucleus, thus prevent the stimulating signal being transferred from outside into cell nucleus. Since the TGF $\beta$ -Smad signaling pathway is very important in the formation of hepatic fibrosis, inhibiting the transduction of it may inhibit hepatic fibrosis. As it was shown in some research, inhibiting the TGF $\beta$ -Smad signaling pathway or modulating the gene expression of certain Smads could interfere with hepatic fibrosis effectively<sup>[28]</sup>.

Oxymatrine, which is the main component of *Sophora flavescens* Ait, has been used clinically in preventing chronic liver disease<sup>[29,30]</sup>. Many studies have shown that it has the effect of protecting hepatocytes, inhibiting the inflammation in liver and reducing the deposition of collagen protein. The present study aimed at exploring the potential mechanisms of Oxymatrine in the prevention of CCl<sub>4</sub>-induced hepatic fibrosis in rats.

In this study, chronic administration of CCl<sub>4</sub> caused liver fibrosis and cirrhosis in experimental rats, which is indicated by the histopathological and molecular biological changes in liver tissues. The serum concentration of TGF $\beta$ 1 in the model group was significantly increased ( $3.59 \pm 1.23 \mu\text{g/L}$  vs  $1.34 \pm 0.25 \mu\text{g/L}$  in the control group,  $P < 0.01$ ), along with the significant collagen deposition. The collagen area was  $290.86 \pm 89.37 \mu\text{m}^2$ , significantly higher than that of the control group ( $56.12 \pm 21.45 \mu\text{m}^2$ ,  $P < 0.05$ ). Under the optical microscope, the liver fibrosis/cirrhosis was verified by the classical liver structure: damage of liver lobular, hepatic cell necrosis and excessive collagen deposition. Some of the samples have even shown pseudo-lobular formation, which was a pathological symbol of liver cirrhosis. However, with the administration of Oxymatrine, the serum concentration of TGF $\beta$ 1 was significantly decreased to  $1.82 \pm 0.61 \mu\text{g/L}$  ( $P < 0.05$  vs model group). The HE and Masson stained histopathological slices showed mild necrosis and less collagen deposition. The semi-quantitative fibrosis staging scores were also decreased obviously ( $P < 0.01$  vs model group). Since the main mechanism of CCl<sub>4</sub>-induced liver fibrosis was toxicosis, there was slight inflammation in the livers of both groups. In the normal control group, the expression of Smad 3, Smad 7 and CBP were very low and could hardly be detected. Along with the formation of liver fibrosis, CCl<sub>4</sub> injection also caused an increase in Smad 7, Smad 3 and CBP gene expression, and the expression of Smad 3 and CBP was increased more significantly than Smad 7. We could show that the expression of Smads in liver fibrosis was unbalanced compared to normal liver. The expression of Smad 7 protein and Smad 7 mRNA

**Figure 3** In the control group, the expression of CBP mRNA was at a very low level, the A (optical density) value of it was nearly 0. After CCl<sub>4</sub> injection, the expression of CBP mRNA in the liver of fibrotic rats was significantly enhanced (A: ISH, × 200). However, in the livers of the Oxymatrine-treated rats, the expression of CBP was also increased compared to the control group (B: ISH, × 200), but it was significantly reduced compared to the model group. The A value of CBP mRNA in model group and treated group were  $0.235 \pm 0.025$  and  $0.065 \pm 0.049$ , respectively ( $P < 0.05$ ).

was increased in the Oxymatrine group compared to the model group. The percentage of Smad 7 protein was  $0.019 \pm 0.002$  in the model group, while in Oxymatrine it was  $0.043 \pm 0.009$  ( $P < 0.05$  vs model group). The A value of Smad 7 mRNA was  $0.074 \pm 0.012$  in the model group and  $0.175 \pm 0.065$  in Oxymatrine group. The gene expression of Smad 3 mRNA and CBP mRNA were significantly increased in the model group and the O.D. value of them were  $0.167 \pm 0.092$  and  $0.235 \pm 0.025$ , respectively. After Oxymatrine treatment, both Smad 3 and CBP mRNA were inhibited significantly ( $0.034 \pm 0.090$  and  $0.065 \pm 0.049$ , both  $P < 0.05$ ) when detected with semi-quantitative evaluation after *in situ* hybridization. However, even with Oxymatrine treatment, Smad 3, Smad 7 and CBP expression remained still significantly increased compared to control group. The detection with *in situ* hybridization and immunohistochemistry could clearly show the change of molecular expression in liver tissue slice. The pathohistological damage of experimental liver could be revealed in the same visual field when the samples were observed under an optical microscope. However, the detection with *in situ* hybridization and immunohistochemistry could not gain an accurate quantity of the molecular expression.

In conclusion, the traditional Chinese medicine Oxymatrine shows significant anti-fibrotic effects in CCl<sub>4</sub>-induced liver fibrosis in rats. It can inhibit the expression of Smad 3 and CBP, and promotes the expression of

Smad7. Further studies are needed to explore the exact molecular mechanisms of Oxymatrine in anti-fibrosis.

### Abstract

**AIM:** To evaluate the long-term effects of gonadotropin-releasing hormone (GnRH)-based vaccine on levels of GnRH antibody and testosterone, and vaccine-induced immunocastration on sexual behavior of male rats.

**METHODS:** The rats were treated with GnRH-PE40 intraperitoneally every other day for 12 wk. GnRH antibody and testosterone level in rat blood were determined by ELISA and radioimmunoassay, respectively. Morphological changes in testes and sexual behavior of rats were evaluated.

**RESULTS:** GnRH-PE40 induced a high production in GnRH antibody, decreased the serum testosterone level, testis atrophy and sexual function in rats.

**CONCLUSION:** Intraperitoneal administration of GnRH-PE40 produces structural and functional castration of male rat reproductive system by inducing anti-GnRH antibody.

### INTRODUCTION

Gonadotropin releasing hormone (GnRH) is secreted by the hypothalamus that stimulates the anterior pituitary gland to release gonadotropins in mammals. GnRH has been widely used as a single medical agent<sup>[1]</sup> or a conjugated compound with other macromolecules<sup>[2]</sup>. Studies indicate that GnRH- based chimerical proteins, consisting of GnRH and toxins, such as *tetanus* toxoid, *diphtheria* toxoid and *pseudomonas aeruginosa* exotoxin A, target specifically at positive tumor cells of GnRH receptor and kill them efficiently<sup>[3-7]</sup>. It was reported that some of the chimeric proteins can effectively control reproductive (prostate, breast, ovary and endometrium) and digestive neoplasms<sup>[8-11]</sup>. However, since its application in this field, high GnRH antibody titer always develops along with the treatment, which often impedes the use of these compounds<sup>[12,13]</sup>. Some authors even reported that the high antibody titer induced by chimeric proteins leads to testis atrophy by depleting immunological hormone<sup>[14]</sup>.

Male livestock are routinely castrated in most countries to prevent their unpleasant odour (known as boar taint), aggressive behavior and unplanned breeding. As we know, intact male animals have superior feed conversion and leaner carcasses than surgically castrated pigs<sup>[15]</sup>. Therefore, the problem is how to concurrently maintain both the intact of animals and the high quality of meat. If the similar strategy of anti-tumor agents mentioned above is applied to contraceptive vaccine, the problem can be possibly solved. Currently, scientists are trying to develop a substitute for the traditional surgical castration. Many preparations based on this theory have been applied to laboratory animals or pets for their immunological castration<sup>[16,17]</sup>. It has been demonstrated that immunocastration can improve the meat quality and increase growth performance<sup>[18-20]</sup>.

GnRH-PE40, one of the recombinant single-chain fusion proteins consisting of GnRH fused to a binding-defective form of *pseudomonas aeruginosa* exotoxin A (PE40), has been developed as a preparation with potential functions of immune castration in male reproductive system. We report here the long term usage of GnRH- based chimeric protein which substantially induces castration in male rat reproductive system.

## MATERIALS AND METHODS

### Reagents

GnRH-PE40 is a genetic engineering product consisting of PE and GnRH from our laboratory.

### Animals

Rats (specific pathogen-free) of Wistar strain, weighing 180–200 g, bought from Animal Center of Military Academy of Medical Sciences (Beijing, PRC), were housed in plexiglass cages (5 per cage) at temperature of 22°C–26°C and humidity of 60% in a 12 h light/dark cycle with free access to food and water. The experimental protocol was approved by the Animal Research Committee of Jinan University.

### Treatment procedure

Twenty male rats were randomly divided into treatment group and control group and received intraperitoneal injection of 150 µg/kg of GnRH-PE40 and saline sodium, respectively, every other day for 12 wk. The sexual behaviors of rats were evaluated 12 h after the last injection. The rats were sacrificed under pentobarbital anesthesia 24 h after the last injection. Blood was collected from the heart of comatose rats for hormone or antibody determination. Testes were taken out, weighed, and fixed for histopathological evaluation.

### Determination of GnRH antibody by ELISA

A 96-well microtiter plate was coated with 50 µL of 10 µg/mL of GnRH in carbonate bicarbonate buffer (CBB, pH 9.6) overnight at 4°C. After blocked with 3% bovine serum albumin (BSA) in PBS for 1 h at 37°C, the plate was incubated with diluted sera (1:100 to 1:12800) from the rats in different groups in 0.05% Tween 20/PBS with 0.3% (w/v) BSA for 1 h at 37°C. After washing, antibody was detected using horseradish peroxidase (HRP) conjugated goat anti-rat-IgG (BD Pharmingen, San Jose, CA, USA) for 1 h at 37°C. Signals were developed using DAB + substrate (Zhongshan Company, Beijing PRC) and optical density was determined at 490 nm using a BIO-RAD model 550 plate reader. Each measurement of a sample was conducted in duplicate. An absorbance equal to or greater than the mean + 3SE of the control group was considered positive.

### Measurement of testosterone

Testosterone level in rat blood was measured by radioimmunoassay using a coat-A-count total testosterone kit (Diagnostic Products Corporation, Los Angeles, USA) according to its manufacturer's instructions. Each measurement of a sample was conducted in duplicate.

### Histopathological examination of testis

Testes were fixed in Bouin's solution overnight at 4°C, followed by embedding, sectioning, staining with haematoxylin and eosin, and finally examined histopathologically under light microscope.

### Mating behavior test

Ovariectomy was performed for female rats under

Table 1 Anti-GnRH antibody titer, testosterone level and testis weight in rats of the control and treatment groups ( $n = 10$ )

	Median Ab titer	Testosterone (µg/mL)	Testis weight (g)
Control	1:100	20.3 ± 4.7	4.5 ± 0.9
Treatment	1:1600 <sup>b</sup>	4.7 ± 0.8 <sup>b</sup>	3.1 ± 1.1 <sup>b</sup>

<sup>b</sup> $P < 0.01$  vs control group.

ethyl ether anesthesia and 15 µg of estradiol benzoate was subcutaneously injected followed by 500 µg of progesterone 48 h later. Only those exhibiting a good sexual receptivity of male rats, that is, lordosis in response to mounting and with no reject behavior, were used.

The mating behavior of male rats was evaluated during the dark cycle in a sound-proof room, under a dim red light, according to the standard procedure<sup>[21]</sup>. After a 10-min adaptation period in a rectangular glass observation cage (60 cm × 50 cm × 40 cm), a stimulus female rat was introduced to a male rat by dropping it gently into the cage. Then following behavioral parameters were recorded or calculated: latency of mount, intromission or ejaculation, and number of mounts, intromissions or ejaculations in a 30-min observation period.

### Statistical analysis

Data were expressed as mean ± SE. Where analysis of variance indicated significant differences between groups with ANOVA, for the preplanned comparison of interest, Student's *t* test was applied utilizing the SPSS11.0 version.  $P < 0.05$  was considered statistically significant.

## RESULTS

### GnRH-PE40 induced production of GnRH antibody

ELISA analysis showed that GnRH-PE40 induced a high production of IgG antibody to GnRH in rats. All the animals treated with GnRH-PE40 showed a positive anti-GnRH response. The antibody titers ranged from 1:800 to 1:3200 with a median of 1:1600 (Table 1).

### GnRH-PE40 reduced testosterone in rats

Intraperitoneal administration of GnRH-PE40 provoked a significant decrease in blood testosterone of rats. The average testosterone level in rats treated with GnRH-PE40 was 5.4 µg/mL compared with 20.3 µg/mL in control group as shown in Table 1 ( $P < 0.01$ ).

### GnRH-PE40 resulted in testis atrophy

Histopathological examination showed that GnRH resulted in remarkable atrophy of testis in rats. The testis weight of rats treated with 150 µg/kg of GnRH-PE40 was decreased by 1.45-fold ( $P < 0.01$ ) (Table 1). The seminiferous epithelium became thinner and the number of spermatogenic cells was decreased compared with that of control group (Figure 1).

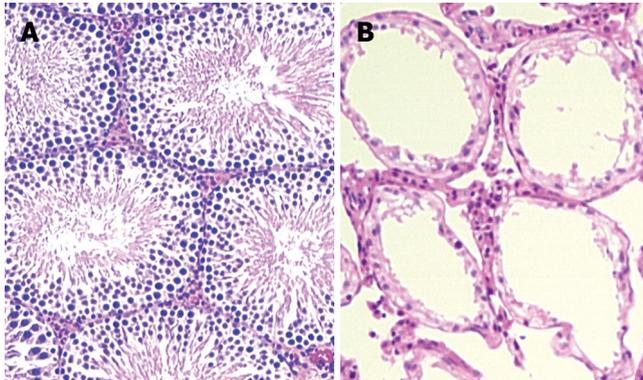

### GnRH-PE40 enhanced mating performance of male rats

Mating behavior test showed that GnRH-PE40 could improve mating performance of male rats. Compared

**Table 2** Influence of GnRH-PE40 intraperitoneal injection on sexual behavior of male rats ( $n = 10$ , mean  $\pm$  SD)

	Latency(s) of			Number		
	Mount	Intromission	Ejaculation	Mount	Intromission	Ejaculation
Control	31 $\pm$ 10	64 $\pm$ 21	605 $\pm$ 107	41 $\pm$ 13	27 $\pm$ 5	2.4 $\pm$ 0.6
Treatment	105 $\pm$ 43 <sup>b</sup>	300 $\pm$ 27 <sup>b</sup>	> 1800	20 $\pm$ 6 <sup>b</sup>	8 $\pm$ 3 <sup>b</sup>	0

<sup>b</sup> $P < 0.01$  vs control group.

**Figure 1** Influence of GnRH-PE40 intraperitoneal injection on spermatogenic cells. **A:** Testes from control rats demonstrating normal seminiferous epithelium (HE,  $\times 400$ ); **B:** Testes from rats treated with 150  $\mu$ g/kg GnRH-PE40 demonstrating a significant decrease in spermatogenic cells (HE,  $\times 400$ ).

with the controls, rats that received 150  $\mu$ g/kg of GnRH-PE40 exhibited an increased mount and an intromission latency, but a reduced mount and an intromission frequency ( $P < 0.01$ ). No successful ejaculation was observed in rats treated with GnRH-PE40, while the mean ejaculation number in controls was 2.4 in a 30-min observation period (Table 2).

## DISCUSSION

GnRH, a short peptide in its natural form, has a poor immunogenicity. When conjugated to a large carrier, it is likely to become an antigen, inducing antibody response. BcePred is a web-based tool for predicting B cell epitope regions in the sequence of an antigen with physicochemical properties. Identified properties of B cell epitope include hydrophilicity, flexibility/mobility, accessibility, polarity, exposed surface and turns. Using this tool, we predicted GnRH motif of GnRH-PE40 with the above properties individually using the default thresholds suggested by software, and found a potential epitope with a higher polarity than the default threshold of 1.8 at GnRH motif<sup>[22]</sup>. We hypothesized that this potential epitope was capable of eliciting antibody reaction, which was verified by antibody assay, suggesting that GnRH-PE40 induces a high titer of anti-GnRH antibodies in sera of rats. Hormone determination and histopathological examination showed that intraperitoneal administration of GnRH-PE40 could decrease testosterone level, testis weight and sexual function, which are all indications of testis atrophy<sup>[23-25]</sup>. Production of GnRH antibody is possibly the cause for testis atrophy<sup>[26]</sup>. It is well-known

that hypothalamus-pituitary-gonadal axis is involved in the control of normal reproductive cycle and maintaining of the structure and function of the reproductive system. Anti-GnRH antibodies reduce the concentration of serum GnRH, which triggers hormone cascades including a lower pituitary LH/FSH and testosterone release, thereby affecting the structure and function of sexual organs<sup>[27]</sup>. A high production of anti-GnRH antibodies in serum blocks primarily the function of GnRH, leading to the impairment of sexual organs<sup>[28,29]</sup>. Studies showed that anti-GnRH antibodies induce testis atrophy in various laboratory animals and pets immunized with GnRH conjugates<sup>[16,17]</sup>.

In another study, we showed that 12-wk intravenous administration of GnRH-PE40 to monkeys produced only a low titer of anti-GnRH antibodies, but no marked testis atrophy was found (results not shown here), providing further evidence that antibodies against GnRH are the reason for testis atrophy.

In conclusion, GnRH-PE40 administration produces immunological castration by inducing anti-GnRH antibodies produced in response to the stimulation of B cell epitope of GnRH motif. GnRH-PE40 can be used in animal sciences as a non-surgical castration substitution for surgical castration<sup>[30,31]</sup>.

## COMMENTS

### Background

Surgical castration has been widely used as a routine way to prevent unpleasant odour and aggressive behavior of animals. Compared with surgical castration, immunocastration has more advantages such as easy operation in large scale, meat quality improvement and good animal welfare. Therefore, it is necessary to develop new drugs for animal immunocastration.

### Research frontiers

Scientists in institutions or pharmaceutical companies are engaged in developing new drugs for animal immunocastration.

### Innovations and breakthroughs

A new compound with potential use as an immunocastration agent was found and its physiological properties and actions were studied.

### Applications

If the compound reported in this article can be used as an animal immunocastration agent, it will contribute greatly to farmers and production of high quality meat.

### Terminology

Castration means surgical removal or artificial destruction of gonads. Immunocastration refers to castration methods based on immunological processes and techniques, such as use of castration vaccines.

### Peer review

In the present study, the authors described the treatment of rats with GnRH-PE40,

which resulted in the production of antibodies against GnRH, lower testosterone levels and sexual behavior. The study was well designed and its results strongly support that GnRH can be used as a potential castration agent.

### Abstract

**AIM:** To examine the expression of connective tissue growth factor (CTGF), also known as CCN2, in gastric carcinoma (GC), and the correlation between the expression of CTGF, clinicopathologic features and clinical outcomes of patients with GC.

**METHODS:** One hundred and twenty-two GC patients were included in the present study. All patients were followed up for at least 5 years. Proteins of CTGF were detected using the Powervision two-step immunostaining method.

**RESULTS:** Of the specimens from 122 GC patients analyzed for CTGF expression, 58 (58/122, 47.5%) had a high CTGF expression in cytoplasm of gastric carcinoma cells and 64 (64/122, 52.5%) had a low CTGF expression. Patients with a high CTGF expression showed a higher incidence of lymph node metastasis than those with a low CTGF expression ( $P = 0.032$ ). Patients with a high CTGF expression had significantly lower 5-year survival rate than those with a low CTGF expression (27.6% vs 46.9%,  $P = 0.0178$ ), especially those staging I + II + III (35.7% vs 65.2%,  $P = 0.0027$ ).

**CONCLUSION:** GC patients with an elevated CTGF expression have more lymph node metastases and a shorter survival time. CTGF seems to be an independent prognostic factor for the successful differentiation of high-risk GC patients staging I + II + III. Over-expression of CTGF in human GC cells results in an increased

### INTRODUCTION

Gastric cancer (GC), one of the most common malignant diseases, is the second leading cause for cancer-related death both in China and in the world (700 000 deaths annually)<sup>[1,2]</sup>.

TNM staging system is used worldwide to predict the prognosis and direct therapeutic decisions of patients with GC<sup>[3]</sup>. The 5-year survival rate of GC patients at stages I and IV is close to 90% and less than 30%, respectively<sup>[4]</sup>. GC exhibits markedly heterogenous in histologic feature and biologic behavior, especially at advanced stages. It was reported that the biological behavior and prognosis of GC can be significantly different among GC patients at the same stage<sup>[5]</sup>. Some studies showed that some biomarkers could provide additional information for predicting the biological behavior and prognosis of GC. More specific and effective markers and therapies should be identified and developed for improving the survival of GC patients.

Connective tissue growth factor (CTGF), also known as CCN2, is a member of the CCN family, including cysteine-rich protein 61 (Cyr61), also known as CCN1, and nephroblastoma-overexpressed gene (Nov), also known as CCN3, as well as Wisp-1/elm1 (CCN4), Wisp-2/rCop1 (CCN5) and Wisp-3 (CCN6)<sup>[6,7]</sup>. The primary translational products of CCN family members are 343-381 residues, which generate proteins of Mr 35 000-40 000 with homologies ranging from 60% to 90%.

All members of the CCN gene family possess a secretory signal peptide at the NH<sub>2</sub> terminus, indicating that they are secreted proteins. CTGF can bind to integrins on cell surface<sup>[6]</sup>, and is a potent stimulator of endothelial cell adhesion, proliferation, migration and angiogenesis *in vivo*<sup>[9-11]</sup>. CTGF is believed to be a multifunctional signaling modulator involved in a wide variety of biologic or pathologic processes, such as angiogenesis, osteogenesis, fibrosis in kidneys and skin, and tumor development<sup>[6-8,12-15]</sup>. It was reported that CTGF plays an important role in the progression of several types of cancer<sup>[16]</sup>. Elevated CTGF levels have been detected in a number of cancers including pancreatic cancer<sup>[16,17]</sup>, breast cancer<sup>[18,19]</sup>, prostate cancer<sup>[20]</sup>, esophageal adenocarcinoma<sup>[21]</sup>, glioma<sup>[22]</sup> and melanoma<sup>[23]</sup>. However, little information on the association between expression of CTGF and GC prognosis is available.

In this study, we examined the expression of CTGF in gastric carcinoma in order to analyze its correlation with histologic type, clinicopathologic feature, and clinical outcome of gastric carcinoma patients.

## MATERIALS AND METHODS

### *Patients and tissue samples*

A consecutive series of 122 patients with gastric carcinoma were studied. All patients were treated at the Department of Surgery, Affiliated Hospital of Binzhou Medical College, between July 1994 and December 2000. All patients gave their written informed consent to participate in this study. There were 88 males and 34 females with a mean age of 56.6 years (range 25-80 years). All patients underwent radical gastrectomy and none of the patients received chemotherapy or radiation therapy prior to operation. Age and sex of the patients, maximum tumor size, histologic grade, status of lymph node metastasis and distant metastasis were obtained from histopathology reports. Stage of GC was defined according to the 1997 tumor-node-metastasis (TNM) classification of malignant tumors by the International Union against Carcinoma<sup>[24]</sup>. All patients were followed-up until May 2007.

### *Immunohistochemistry*

The tissue, fixed in 10% neutral formalin and embedded in paraffin, was cut into 4- $\mu$ m thick sections. CTGF expression was examined by immunostaining using the PowerVision two-step immunostaining method. Briefly, the sections were treated with a 3% hydrogen peroxide solution for 10 min to block the endogenous peroxidase activity after deparaffinized in xylene and rehydrated in a graded ethanol series. Antigen retrieval was performed in 1 mmol/L EDTA (pH 8.0) in an autoclave for 3 min. The monoclonal antibodies used were clone 88430 (1:100, R&D Systems Inc, Minneapolis, MN, USA) which recognizes CTGF. The sections were incubated overnight at 4°C with primary antibody. The primary antibody was detected using the PowerVision two-step histostaining reagent-peroxidase-labeled goat anti-mouse immunoglobulin (PV-6002, DAKO, Glostrup, Denmark) for 1 h at room temperature. After peroxidase activity was developed with 3, 3'-diaminobenzidine tetrachloride (DAB), slides were counterstained with haematoxylin and

observed under a light microscope. Positive and negative immunohistochemistry controls were routinely used.

Three experienced pathologists, unaware of the information on the clinicopathologic data and clinical outcomes of the patients, independently examined the CTGF staining. A scoring system was devised to assign a staining intensity score for CTGF expression from 0 (no expression) to 3 (highest intensity staining). Immunostaining was classified into two groups according to both intensity and extent. Low expression was defined as no staining present (staining intensity score: 0) or positive staining detected in  $\leq 10\%$  of the cells (staining intensity score: 1) and high expression was defined as positive immunostaining present in 10%-50% of the cells (staining intensity score: 2) or  $> 50\%$  of the cells (staining intensity score: 3)<sup>[25]</sup>.

### *Statistical analysis*

All data were analyzed using SPSS 10.0 software. The association of CTGF expression with various clinicopathologic features was analyzed using the Pearson  $\chi^2$  test. Cumulative survival was estimated with the Kaplan-Meier method and the difference in survival curves was analyzed by the log-rank test. The influence of each variable on survival was analyzed with the multivariate analysis of Cox proportional hazard model (backward, stepwise). All statistical tests were two-sided.  $P < 0.05$  was considered statistically significant.

## RESULTS

### *Patients*

The clinicopathologic features of the patients are summarized in Table 1. The follow-up time ranged from 2 mo to 121 mo (median, 27 mo). The 5-year survival rate of patients at stages I, II, III and IV was 88.9%, 66.7%, 28.3% and 2.9%, respectively. The overall 5-year survival rate was 37.7%.

### *CTGF expression in gastric carcinoma*

The CTGF protein was predominantly localized in cytoplasm or membrane of normal or tumor cells. No CTGF expression was detected in normal gastric epithelial cells, but deep glands and fibroblasts were positively stained. Glands in some cases were positively stained in intestinal metaplasia and dysplasia gastric mucosa.

Of the 122 specimens from GC patients analyzed for CTGF expression, 58 (58/122, 47.5%) had a high CTGF expression in cytoplasm of gastric carcinoma cells, 43 (43/122, 35.2%) had a score of 2, and 15 (15/122, 12.3%) a score of 3, while 64 (64/122, 52.5%) had a low CTGF expression, 37 (37/122, 30.3%) had a score of 0 and 27 (27/122, 22.1%) a score of 1 (Figure 1).

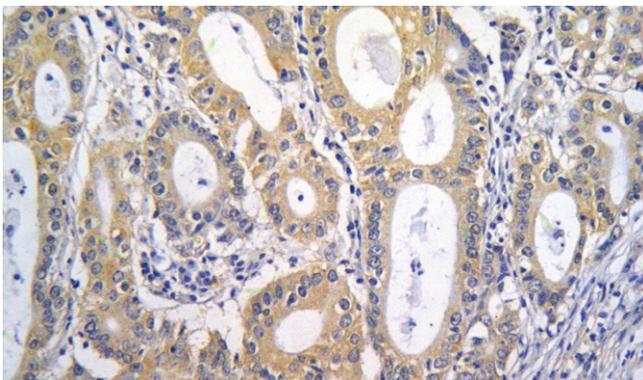

### *CTGF expression in relation to clinicopathologic features of gastric carcinoma*

CTGF was highly expressed more frequently in well-differentiated GC than in moderately- or poorly-differentiated GC ( $P = 0.014$ ) and in intestinal-type carcinoma than in diffuse-type or mixed-type carcinoma ( $P = 0.045$ ). Patients with a high CTGF expression had

**Table 1** Association between CTGF expression and clinico-pathologic factors

Factors	Cases	CTGF expression		P value <sup>1</sup>

a higher incidence of lymph node metastasis than those with a low CTGF expression ( $P = 0.032$ ). No significant relationship was found between the level of CTGF expression and the age and sex, tumor size, TNM stage and distant metastasis of GC patients (Table 1).

#### Univariate analysis of prognostic impact of CTGF expression on gastric carcinoma

Patients with a high CTGF expression had a significantly lower cumulative 5-year survival rate (27.6%) than those with a low CTGF expression (46.9%, two-sided log-rank

**Figure 2** Kaplan-Meier survival curves for patients with a low (—) or a high (----) expression of CTGF (A) and for those at stage I + II + III with a low (—) or a high (----) expression of CTGF (B). The survival of patients with a low CTGF expression was significantly longer than those with a high CTGF expression,  $P = 0.0178$  (A) and  $P = 0.0027$  (B), respectively.

test,  $P = 0.0178$ ; Figure 2A). The prognostic significance of CTGF expression in patients at TNM stage I + II + III was analyzed. Patients at stage I + II + III had a high CTGF expression and a significantly lower 5-year survival rate (35.7%) than those with a low CTGF expression (65.2%, two-sided log-rank test,  $P = 0.0027$ ; Figure 2B).

#### Multivariate analysis of prognostic impact of CTGF expression on gastric carcinoma

Multivariate analysis revealed that CTGF expression, TNM stage, differentiation were independent prognostic indicators for the overall survival of the patients after adjustment for sex, age, tumor size, grade of differentiation, Lauren types, TNM stages, lymph node metastasis and distant metastasis ( $P < 0.05$ , Table 2).

## DISCUSSION

In the present study, we detected CTGF expression in GC patients. High CTGF expression was closely related with lymph node metastasis, grade of differentiation, and Lauren type. Univariate and multivariate analyses revealed that high CTGF expression was a powerful independent predictor for the poor survival of GC patients, especially for those at stage I + II + III. The overall 5-year survival rate of GC patients with a higher CTGF expression and a

lower CTGF expression was 27.6% and 46.9%, respectively ( $P = 0.0178$ ). The 5-year survival rate of GC patients with a higher CTGF expression and a lower CTGF expression at stage I + II + III was 35.7% and 65.2%, respectively ( $P = 0.0027$ ), indicating that over-expression of CTGF could promote the aggressive behavior of GC.

CTGF is a novel, potent angiogenic factor<sup>[9,10]</sup>, which was first identified as a mitogen, detected in conditioned medium from human umbilical vein endothelial cells<sup>[26]</sup>. Integrin is an important receptor for CCN proteins, and receptor activation may produce a variety of effects. CTGF protein can bind directly to integrins  $\alpha v \beta 3$  and  $\alpha II b \beta 3$ <sup>[10,11]</sup>. Shimo *et al*<sup>[9]</sup> and Babic *et al*<sup>[10]</sup> reported that CTGF mediates endothelial cell adhesion and migration through binding to integrin  $\alpha v \beta 3$ , prolong endothelial cell survival, and induce angiogenesis *in vivo*. Yang *et al*<sup>[20]</sup> reported that CTGF is a downstream mediator of TGF- $\beta 1$  action in cancer-associated reactive stroma, and one of the key promoters of angiogenesis in tumor-reactive stromal microenvironment, and plays an important role in prostate carcinogenesis. Breast cancer stage is positively associated with tumor size, lymph node metastasis status and over-expression of CTGF<sup>[19]</sup>. In our study, high CTGF expression was related with lymph node metastasis, depending on the ability of CTGF to induce angiogenesis.

CTGF is believed to be a multifunctional signaling modulator involved in a wide variety of biologic or pathologic processes. CTGF proteins exhibit diverse cellular functions, such as regulation of cell division, proliferation, mitogenesis, differentiation, survival, adhesion and migration, apoptosis, motility, and ion transport. CTGF plays a role in the development and progression of cancer. Recently, Dornhöfer *et al*<sup>[16]</sup> showed that CTGF promotes anchorage-independent pancreatic cancer cell growth. Furthermore, anti-CTGF treatment inhibits anchorage-independent growth *in vitro*, primary tumor growth *in vivo* and macroscopic lymph node metastases<sup>[16]</sup>. In contrast to the above results, CTGF is a new autocrine survival and differentiation factor for human rhabdomyosarcoma cells<sup>[27]</sup>. It was reported that over-expression of CTGF suppresses the growth of oral squamous carcinoma cells transplanted into mice<sup>[28]</sup>. Furthermore, apoptosis of MCF-7 cells induced by TGF- $\beta$  appears to be mediated by CTGF, suggesting that CTGF may play an important role in

human breast cancer cell growth<sup>[29]</sup>. Elevated level of CTGF is significantly correlated with a good prognosis of colorectal cancer<sup>[30]</sup> and lung adenocarcinoma<sup>[25]</sup>, suggesting that the role of CTGF in different types of cancer may vary considerably, depending on the tissue involved. The question of how cell or tissue context determines the action of CTGF protein is interesting and deserves further investigation.

The present study showed that high CTGF expression was a powerful independent predictor for the poor overall survival of GC patients, especially for those at stage I + II + III. Multi-mechanisms are involved in aggressive behaviors of tumors at stage IV. The 5-year survival rate was only about 10% of GC patients at stage IV. Additional biomarkers might be helpful in predicting the prognosis of GC patients and more specific and effective therapies should be developed to improve the survival of GC patients at stage I + II + III. However, the value of additional biomarkers for predicting the prognosis of GC patients at stage IV is poor.

In conclusion, GC patients with an elevated CTGF expression have more lymph node metastases and a shorter survival time. CTGF seems to be an independent prognostic factor that allows successful differentiation of high-risk GC patients at stage I + II + III. Over-expression of CTGF in human GC cells results in an increased aggressive ability of cancer.

The authors thank the staff at Department of Pathology, Affiliated Hospital of Binzhou Medical College for their help with the study.

## COMMENTS

### Background

Connective tissue growth factor (CTGF), also known as CCN2, is a member of the CCN family, which is believed to be a multifunctional signaling modulator involved in a wide variety of biologic or pathologic processes. CTGF plays an important role in the progression of several types of cancer. However, little information on the association between CTGF expression and GC prognosis is available.

### Research frontiers

In this study, we examined the expression of CTGF in gastric carcinoma in order to analyze its correlation with histologic type, clinicopathologic feature, and clinical outcomes of gastric cancer (GC) patients.

### Innovations and breakthroughs

GC, one of the most common malignant diseases, is the second leading cause for cancer-related death both in China and in the world. It has been shown that its biologic behavior and prognosis can be significantly different in GC patients at the same stage. CTGF seems to be an independent prognostic factor that allows differentiation of high-risk patients at stage I + II + III. Over-expression of CTGF in human GC cells results in an increased aggressive ability of GC.

### Applications

CTGF may represent a potential novel target for treatment of GC. Inhibition of CTGF may control primary tumor growth and lymph node metastasis.

### Peer review

In this study, the authors showed that CTGF was a prognostic factor for GC patients. This paper is well-written.

### INTRODUCTION

Castleman's disease (CD) of the pancreas/peripancreas is a very uncommon disease. The differential diagnosis of peripancreatic masses includes pancreatic cancer, tuberculous lymphadenopathy, lymphoma, neurogenic tumors such as paraganglioma, and CD. The initial challenge in CD is to establish its correct diagnosis. Radiology-guided fine needle aspiration (FNA) of deep-seated masses is a standard means of obtaining a tissue diagnosis, but fails to make a definitive distinction from lymphoma<sup>[1]</sup>. Recently, the efficacy of endoscopic ultrasonography (EUS)-guided TCB in diagnosing intra-abdominal/retroperitoneal benign lymph node enlargement or lymphoid malignancies has been reported. Herein, we present the EUS morphologic findings, microscopic examinations, and the advantage of polymerase chain reaction (PCR) for IgH gene rearrangement in a case of peripancreatic CD which was initially sampled by EUS-TCB.

### CASE REPORT

A previously healthy, 50-year-old woman was referred to our institution for further evaluation of a pancreatic mass which was incidentally detected on an abdominal computed tomography (CT) scan performed at another hospital.

Dynamic CT scans of her pancreas disclosed an arterial, enhancing mass measuring 3.9 cm in the upper portion of the pancreas body (Figure 1). EUS (GF-UM2000; Olympus, Japan) demonstrated a homogenous, elongated, and well-delineated hypoechoic mass between the left lobe of liver and the body of the pancreas. The vascularity of the mass was high on Doppler US (Figure 2). A core biopsy specimen of the lesion was obtained using a 19-gauge, trucut needle (EUSN-19-QC, Cook) under the guidance of a linear-array echoendoscope (GF-UCT2000; Olympus, Japan). After the procedure, the patient had no immediate complications, such as bleeding, perforation or peritonitis. The size of the core biopsy specimen was about 1.1 cm in length, but it was fragmented into five

### Abstract

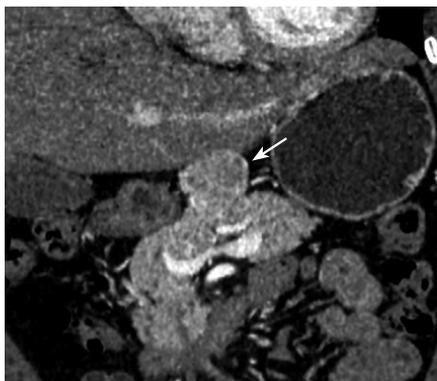

Castleman's disease (CD) of the pancreas/peripancreas is extremely rare. The recently introduced, endoscopic ultrasonography (EUS)-guided trucut biopsy (TCB) is a useful diagnostic modality for obtaining tissue samples from peripancreatic lesions. However, its role in diagnosing CD remains unknown. We report a case of localized, peripancreatic, hyaline-vascular CD biopsied using EUS. The pathology results were initially interpreted as an extranodal, marginal-zone B-cell lymphoma. However, polymerase chain reaction (PCR) study for the IgH gene rearrangement revealed a polyclonal pattern. We also reviewed the relevant literature. To our knowledge, this is the first illustrated report on EUS-TCB findings of CD with its pathology results of EUS-TCB mimicked a B-cell lymphoma.

Rhee KH, Lee SS, Huh JR. Endoscopic ultrasonography-guided trucut biopsy for the preoperative diagnosis of peripancreatic castleman's disease: A case report. *World J Gastroenterol* 2008; 14(13): 2115-2117 Available from: URL: <http://www.wjgnet.com>

**Figure 1** Pancreas dynamic CT scan showing a well-demarcated, arterial, enhancing mass measuring 3.9 cm (arrow) just above the pancreatic body.

**Figure 2** Endoscopic ultrasonography showing a well-delineated, homogenous, elongated mass with a hypervascular appearance on Doppler (small box).

pieces while putting into a tissue container. Microscopic examination showed expanded follicles replaced by dense infiltration of small, mature lymphocytes devoid of follicular center cells which caused an initial suspicion of low-grade, extranodal, marginal-zone B-cell lymphoma. However, according to PCR study for IgH gene rearrangement, the mass was seen to have a polyclonal pattern (Figure 3A and B).

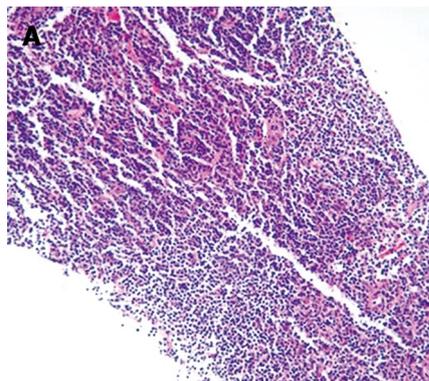

The patient underwent laparoscopic mass excision with curative intent as well as pathologic confirmation. The resected lesion was found to be a well-demarcated, lobulated, rubbery, firm mass (Figure 4A). Microscopically, the lesion was a markedly enlarged lymph node composed of numerous, prominent, lymphoid follicles with atrophic germinal centers devoid of follicle center cells (Figure 4B).

The final diagnosis was CD (angiofollicular lymph node hyperplasia) of a hyaline-vascular (HV) variant. The patient had an uneventful postoperative course and remained disease-free at the time when this report was prepared.

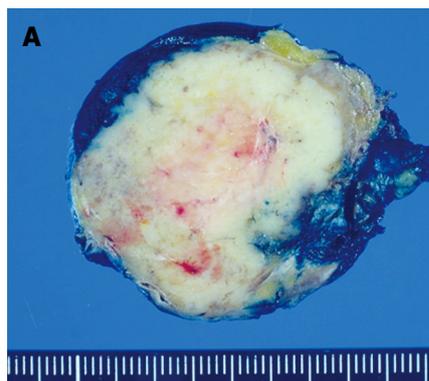

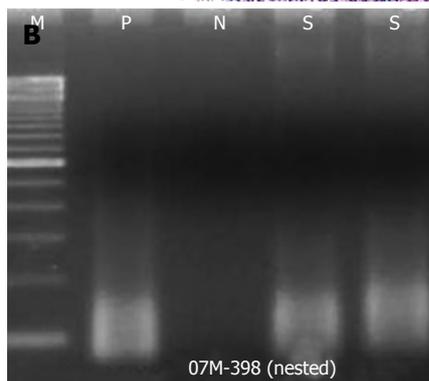

## DISCUSSION

CD has been identified in a series of patients with solitary, hyperplastic, mediastinal lymph nodes with small germinal centers resembling Hassall's corpuscles of the thymus<sup>[2]</sup>. CD can be divided into hyaline vascular type, plasma cell type, and mixed type or into unicentric or localized type and multicentric or generalized type<sup>[3,4]</sup>. The HV type accounts for 90% of all localized disease<sup>[5]</sup> and is often asymptomatic or, as in our patient, has symptoms caused by the mass effect of the lesion.

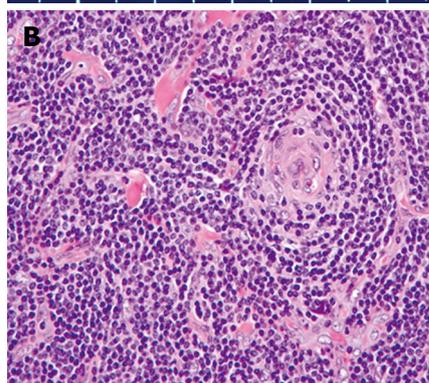

The clinical challenge in CD is to establish its correct

**Figure 3** Microscopic examination of the EUS-TCB specimen showing expanded follicles replaced by a dense infiltration of small, mature, lymphocytes devoid of follicular center cells (A) ( $\times 200$ ) and PCR study for IgH gene rearrangement showing a polyclonal pattern (B).

**Figure 4** Surgical specimen showing creamy white cut surface of the resected tumor with trabeculation and numerous, small blood vessels (A) and lymph node demonstrating burnt-out, atrophic follicles with depletion of follicle center cells and residual, follicular, dendritic cells and surrounding, concentric layers of small lymphocytes (B). Radial penetrating blood vessels are also seen ( $\times 400$ ).

diagnosis. Many imaging modalities, including CT, magnetic resonance (MR), angiography and FDG-PET, have been used to diagnose CD<sup>[6-9]</sup>. Nevertheless, it is the mainstay to obtain and analyze tissue samples for its final diagnosis.

EUS-, US- or CT- guided FNA of deep-seated masses are the standard means of obtaining tissue diagnosis, but cytomorphic, flow cytometric, and

immunohistochemical studies have failed to make a definitive distinction from certain kinds of lymphoma<sup>[1]</sup>. The reason is that FNA specimen is largely restricted in morphologic and immunohistochemical study for the shortage of sample size. On the other hand, EUS-TCB has a higher diagnostic yield and accuracy because it may obtain more adequate core specimens than FNA. It was reported that EUS-TCB has been used in diagnosing gastrointestinal stromal tumor (GIST), leiomyoma, and lymphoma<sup>[10,11]</sup>.

Although the initial microscopic morphology of our case was similar to that of B-cell lymphoma, lymphoma was mostly excluded and CD was strongly suspicious prior to surgery with the help of PCR for IgH gene rearrangement.

In conclusion, peripancreatic CD is rare but should be considered in the differential diagnosis of peripancreatic lesions. The discrimination of CD from lymphoma could be difficult, but we believe that EUS-TCB is more useful in preoperative diagnosis than FNA.

### Abstract

Disseminated signet ring cell carcinomas frequently arise from the stomach. However, primaries in the colon and rectum have also been reported. We present a 68 year old lady who presented with a change in her bowel habit. Colonoscopy showed a stenosing rectal tumour at 7 cm to 8 cm from the anal verge. Multiple scattered ulcers were also noted along the entire length of the colon. Biopsy of the lesions revealed signet ring cell adenocarcinoma. Gastroscopy showed multiple nodules with ulceration over several areas of the stomach which were similar in appearance to the colonic lesions. However, no primary tumour of the stomach was seen. Biopsy of the gastric lesions also showed signet ring cell adenocarcinoma. Computed tomography scan of the abdomen and pelvis revealed circumferential tumour at the rectosigmoid junction with possible invasion into the left ischiorectal fossa. The overall picture was that of a primary rectal signet ring cell carcinoma with peritoneal dissemination. The patient was referred for palliative chemotherapy in view of the disseminated disease. In the present report, we discuss this interesting pathological entity and review the role of various histological techniques in helping to identify the primary tumor.

Sim HL, Tan KY, Poon PL, Cheng A. Primary rectal signet ring cell carcinoma with peritoneal dissemination and gastric secondaries.

### INTRODUCTION

Primary colorectal signet ring cell carcinoma is a rare but distinctive malignancy of the large bowel. More than 96% of the signet ring cell carcinomas arise in the stomach, with the remainder arising from other sites, including colon, rectum, gallbladder, pancreas, urinary bladder and breast<sup>[1]</sup>. Therefore, metastasis to the colon and rectum must be excluded before a definite diagnosis of primary colorectal signet-ring cell carcinoma can be made.

### CASE REPORT

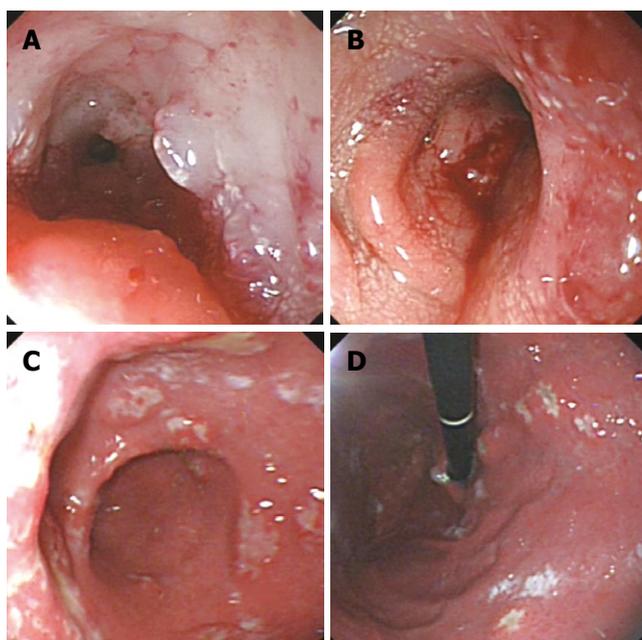

A 68-year-old female patient with history of diabetes mellitus and hypertension presented with one month history of change in bowel habit. The patient complained of increased frequency of stools, with the passage of only small amounts of stools each time. There was no history of rectal bleeding, or loss of appetite or weight. Rectal examination revealed a hard mass about 6 cm from the anal verge.

Colonoscopy showed a hard stenosing rectal tumour at 7 cm to 10 cm from the anal verge (Figure 1A and B). Multiple scattered ulcers were found throughout the colon from the caecum to the sigmoid colon. Biopsy of the rectal tumour and the ulcers were performed. Transrectal ultrasound revealed a UT3N1 tumour of the mid-rectum.

Carcino-embryonic antigen level was 10.7. Computed tomography of the abdomen and pelvis showed a circumferential tumour in the recto-sigmoid junction with no evidence of hepatic metastases or intrabdominal lymphadenopathy or a second primary.

Histopathology of the colonic ulcers and the rectal tumour showed large sheets and aggregates of signet ring cells with foamy cytoplasm and pleomorphic, hyperchromatic eccentric nuclei (Figure 2A). The tumour cells infiltrated between the mucosal glands. Areas of ulceration and focal mucin pools were noted. These appearances were consistent with signet ring cell adenocarcinoma.

In view of the histological finding of signet ring cell adenocarcinoma, gastroscopy was performed to exclude a gastric primary tumor. Gastroscopy revealed multiple nodules with ulceration scattered over body, incisura and

**Figure 1** Colonoscopic pictures (A) and (B) show stenosing primary rectal tumour with multiple ulcerations; Gastroscopy (C) and (D) showed multiple ulcers in the stomach.

antrum of the stomach (Figure 1C and D). No primary gastric tumour was found. Biopsy of the lesions showed signet ring cell adenocarcinoma similar to that found in the rectum and colon.

The clinical picture was that of a primary rectal signet ring cell adenocarcinoma with peritoneal dissemination and gastric metastasis. Immunohistochemical studies were performed to differentiate between a gastric and colonic primary tumor. Both specimens were positive for cytokeratin 7 (CK 7) (Figure 2B) and Cytokeratin 20 (CK 20).

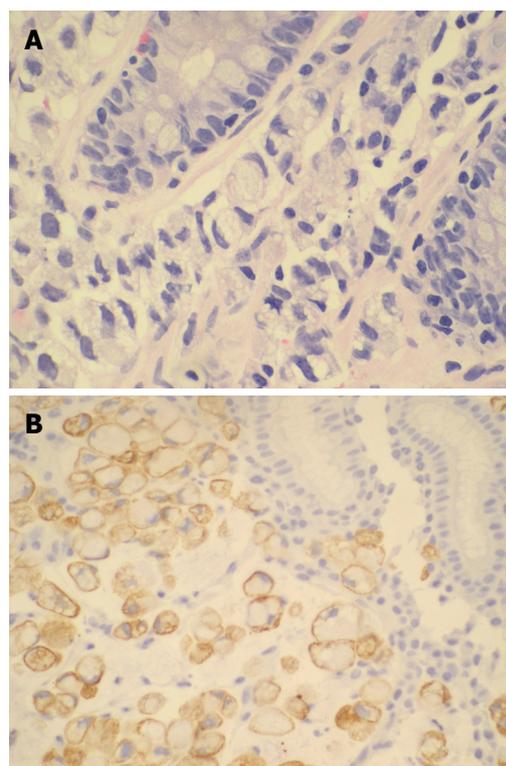

In view of the disseminated peritoneal disease and minimal symptoms, the patient was not offered surgery. She received palliative chemoradiation and was clinically well at 6 mo follow-up.

## DISCUSSION

Primary signet ring cell carcinoma of the colon and rectum is a rare variant of colorectal adenocarcinomas. The incidence of signet ring cell carcinoma is reported to range between 0.1% and 2.4%<sup>[2,3]</sup>. The diagnosis of primary colorectal signet ring cell carcinoma is often based on the histological appearance of the specimen with exclusion of a gastric primary.

Signet ring cell tumours have an aggressive clinical course and a poor prognosis<sup>[4-6]</sup>. There is high incidence of peritoneal metastases and relatively low incidence of hepatic metastases, a characteristic feature distinguishing colorectal signet-ring cell carcinoma from non-signet colorectal carcinoma.

According to Secco *et al*, the 5-year survival rate of primary colorectal signet ring cell carcinoma was 0% (median 15 mo) and disease recurrence was 100%. However, a local study from Singapore reported 5-year survival rate of 12%<sup>[7]</sup>. Generally, the prognosis of signet-ring cell carcinoma

**Figure 2** Photomicrograph A: normal colonic glands with signet ring cells within the lamina propria (HE); B: gastric mucosa with similar signet ring cells which were positive for CK 7.

is worse than that of colorectal adenocarcinoma and most patients present at an advanced stage. It is important to identify disseminated peritoneal disease at the time of the initial diagnosis as these patients are unlikely to benefit from surgery, if the symptoms are minimal. It is important to obtain biopsy of lesions other than the primary tumour (as was done in this case) as it may provide diagnosis of disseminated peritoneal disease.

The histological appearance of the tumour is characterized by cells with abundant intracytoplasmic mucin, which pushes the nucleus to the periphery. The tumour cells may be arranged individually or in loose clusters, and may spread diffusely through the bowel wall. Mucin lakes containing small, primitive and abortive gland structures may be present<sup>[2,8]</sup>.

Given the rarity of colon signet ring cell adenocarcinomas, the question of a primary colon or metastatic gastric adenocarcinoma frequently arises when signet ring cell carcinoma is seen on colonoscopic biopsy.

Immunostaining profiles for CK7 and CK20 have been used to characterize and differentiate signet ring cell carcinomas of breast, stomach and colon<sup>[9,10]</sup>. CK20 is a low molecular weight cytokeratin that is normally expressed in the gastrointestinal epithelium, urothelium and in Merkel's cells<sup>[11]</sup>. CK7 is expressed by tumours of the lung, ovary, endometrium and breast, but not of the lower gastrointestinal tract.

It has been suggested that when a signet ring cell adenocarcinoma is encountered on colon biopsy, the diagnosis of a colon primary is supported by the presence of CK7(-)/CK20(+) staining pattern in the neoplastic

cells, while gastric primary is diagnosed if the cells have a CK7(+)/CK20(-) staining pattern.

However, in the present case, the colonic specimen was positive for both CK7 and CK20, making it difficult to determine whether the primary was gastric or colonic in origin.

To date, a primary rectal signet ring cell carcinoma with peritoneal dissemination and gastric secondaries had not been described. The present case illustrates the aggressive nature of signet ring cell carcinoma and the fact that immunohistochemistry may not be 100% accurate in predicting the primary source of the signet ring cell carcinoma.

### Abstract

Gardner syndrome (GS) is an autosomal dominant disease characterized by the presence of colonic polyposis, osteoma and soft tissue tumors. It is regarded as a clinical subgroup of familial adenomatous polyposis (FAP) and may present at any age from 2 mo to 70 years with a variety of symptoms, either colonic or extracolonic. We present a case of a 23-year-old female patient with GS who presented with gastric polyposis and was successively treated with restorative proctocolectomy in combination with ileal pouch anal anastomosis (RPC/IPAA), ileostomy, ileostomy closure operation, snare polypectomy during 8 mo. After operation, the patient took oral traditional Chinese medicine pills made of *Fructus mume* and *Bombyx batryticatu* for about 6 mo. The innutrition and anaemia of this patient were gradually improved. Gastroscopy showed that the remnant gastric polypi gradually decreased and finally disappeared 19 mo after the first operation. The patient had 2-3 times of solid stool per day at the time we wrote this paper.

Gu GL, Wang SL, Wei XM, Bai L. Diagnosis and treatment of Gardner syndrome with gastric polyposis: A case report and review of the literature. *World J Gastroenterol* 2008;

### INTRODUCTION

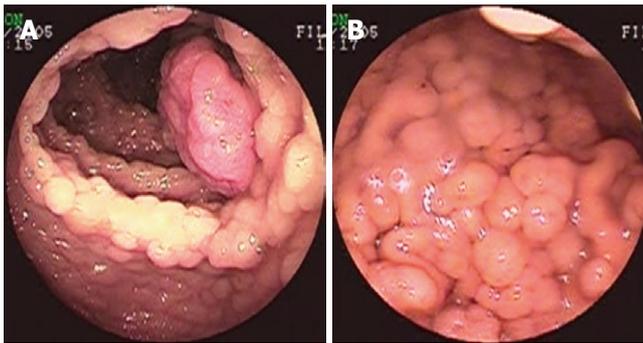

Gardner syndrome (GS) is a rare autosomal dominant inherited disorder with a high degree of penetrance characterized by intestinal polyposis, bone and soft-tissue tumours, including osteoma, epidermal inclusion cyst, lipoma, fibroma, gastric and duodenal polyposis, desmoid fibromatosis. It is regarded as a clinical subgroup of familial adenomatous polyposis (FAP). Since GC was first reported by Gardner and his colleague in early of 1950s, the association of hereditary colonic polyposis and osteomatosis with multiple cutaneous and subcutaneous tumours in GS has been extensively studied<sup>[1-3]</sup>.

Compared with FAP, the extracolonic manifestations of GC may be explained by the variable penetrance of a common mutation. The disorder is linked to the binding of 5q21-q22 (the adenomatous polyposis coli locus, *APC* gene). More than 1400 different mutations of this gene have been identified<sup>[4]</sup>. The mutated specific area of the *APC* gene determines the extracolonic manifestations as well as the number, time frame and malignant potential of adenomatous polyps. It was reported that the mutation of *MYH* gene (1p34.3-p32.1) and environmental factors, such as diet, exercise and smoking, also play an important role in the pathogenesis of GS<sup>[5]</sup>. Although most GS cases show familial clustering, one-third of cases occur due to spontaneous mutations.

The clinical presentation of GS is variable and its diagnosis is often delayed, despite the presence of clues for a significant amount of time. Since GS may involve different organs, it is usually very difficult to treat it, and the therapeutical effect is also uncertain. We present a rare case of a 23-year-old girl with GS who underwent a series of operations and medications which achieved satisfactory therapeutic effects.

### CASE REPORT

A 23-year-old female presented with nausea, vomiting and mucous diarrhoea, occasionally with blood in the stool, for 1 mo. Colonoscopy revealed numerous polyps covering the entire colon and rectum, mostly sigmoid colon and rectum, which were consistent with the diagnosis of FAP

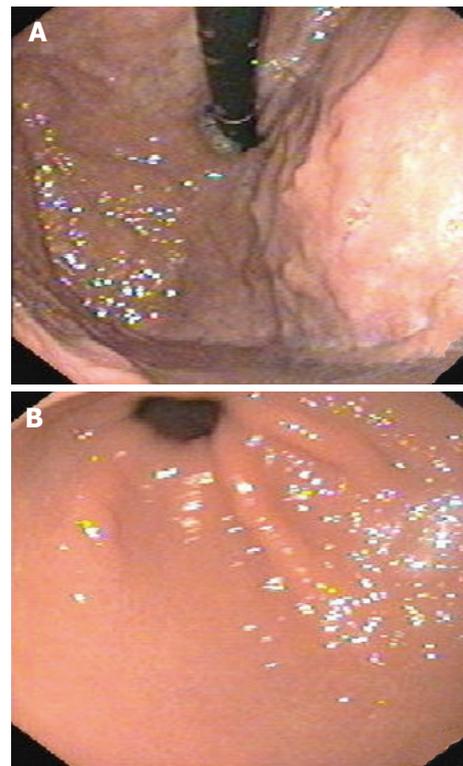

**Figure 1** Preoperative endoscopy examination. **A:** Colonoscopy showing multiple polyps covering the entire colon and rectum; **B:** Gastroscopy showing multiple polyps covering the fundus and corpus ventriculi.

(Figure 1A). Gastroscopy showed numerous polyps covering the fundus and corpus ventriculi, mostly fundus ventriculi (Figure 1B). Biopsy of colon and stomach polyps showed moderate differentiation. Hemoglobin was 72 g/L. The patient was finally diagnosed as GS with innutrition and anemia.

This patient was first treated with restorative proctocolectomy in combination with ileal pouch anal anastomosis (RPC/IPAA) and ileostomy. Pathological examination of the specimen showed that the colorectal polyps were tubular adenomas with moderate differentiation. Then, an ileostomy closure operation and two times of snare polypectomy were performed. After operation, the patient took oral traditional Chinese medicine pills twice per day for about 6 mo. The traditional Chinese medicine pills were made of 3.0 g *Fructus mume* (smoked plum) and 3.0 g *Bombyx batryticatu* (stiff silkworm). Innutrition and anaemia gradually recovered. Gastroscopy showed that the remnant gastric polyps gradually decreased and finally disappeared (Figure 2A and B). The patient had 2-3 times of solid stool per day at the time when we wrote this report.

## DISCUSSION

GS is considered a variant of FAP with certain extracolonic manifestations (such as osteoma, gastric or duodenal polyposis and desmoid fibromatosis). It was reported that GS is caused by truncating mutations of the *APC* gene (codons 1403 and 1578) differing from classic FAP (codons 169-1600), attenuated FAP (amino terminal to codon 157), and congenital hypertrophy of the retinal pigmented epithelium (codons 463-1387)<sup>[4]</sup>. However, there is evidence that patients with identical mutations may have different phenotypic expressions because of unclear reasons. The majority of GS patients may have a family history, but about 25% of GS patients can present with a new dominant mutation and are the first affected member of the family. These patients are generally not under medical surveillance before they have bowel symptoms, and 67% of them may have developed colorectal cancer. In 100% of all untreated patients, cancer develops in the large intestine before the age of 40 years. Hence, prophylactic colectomy is indicated, although desmoid tumors of the

**Figure 2** Post-operative gastroscopy examination shows disappearance of polyps of the fundus and corpus ventriculi (**A**) and smooth mucous membrane of the corpus ventriculi and pars pylorica (**B**).

mesenteric and abdominal wall may develop after surgery. We think that RPC/IPAA is the best operation for FAP (including GS) patients because it not only resects all large intestine mucous membranes to avoid carcinogenesis, but also preserves the intestine function and sex ability and avoids colostomy, thus improving the life quality of patients. In order to insure the concrescence of ileal pouch anal anastomosis, temporary ileostomy is occasionally necessary. After 1 to 3 mo when the anastomosis reaches its concrescence, we can perform an ileostomy closure operation. The distal ileum would play the role of colon in absorbing water from dejecta if the colon is resected, so we should take care to preserve the distal ileum for self-control defecation. The patient were underwent to a series of operations with satisfactory therapeutic effects, showing that such operations can cure similar patients.

It was reported that the carcinogenesis of gastric polyps is obviously lower than that of colorectal polyps and its carcinogenesis time may be about 10 years later than colorectal polyps<sup>[2]</sup>. The gastric polyps in this patient gradually decreased and finally disappeared after two times of snare polypectomy and treatment with traditional Chinese medicine. Although the idiographic reason remains unclear, the prognosis of gastric polyps is well, suggesting that excessive radical operation cannot be performed for gastric polyps. It was reported that non-steroidal anti-inflammatory drugs (NSAID) can maintain the regression of colorectal adenoma in patients with FAP and hereditary nonpolyposis colorectal cancer (HNPCC)<sup>[6-11]</sup>. Use of NSAID may pave a new secure path for the treatment FAP (including GS) and HNPCC. The component of traditional Chinese medicine is complex, the correlation of between traditional Chinese medicine and disappearance of gastric polyps is unclear. However,

reports showed that there are many organic acids and other helpful components in *Fructus mume* and *Bombyx batryticatus*, such as oxalic acid (OA), tartaric acid (TA), malic acid (MA), vitamin C (VC), lactic acid (LA), acetic acid (AA), citric acid (CA), succinic acid (SA),  $\beta$ -sitosterol, uracil, meso-erythritol and palmitic acid, *etc*<sup>[12,13]</sup>. More studies are needed to make sure whether these organic acids and helpful components have the effects of NSAID.

It was reported that about 25% of patients with GS have no family history and the miniaturization of family also makes the hereditary behavior unobvious<sup>[14-16]</sup>. It is very easy to misdiagnose these patients who have no obvious family history or colorectal polypi. We should examine the stomach, thyroid, tooth, skull and eyeground of such patients with colorectal polypi. The examination of *APC* and *MYH* mutation is helpful to differentiate patients with GS and FAP, but *APC* and *MYH* mutation examination is uncertain, thus not widely applied.

Received: November 16, 2007 Revised: December 14, 2007

## Abstract

Functional gastrointestinal disorders (FGIDs) represent a common and important class of disorders within gastroenterology. Rome I, the first edition was published in 1994, with symptom-based diagnostic criteria for FGIDs. These criteria began to change the diagnostic approach to FGIDs, and no longer considered "diagnoses of exclusion" but rather "diagnoses of inclusion". Rome II, the second edition published in 2000, resulted from the continual process of analyzing new scientific and clinical evidence in the study of FGIDs. Rome II, diagnostic criteria for irritable bowel syndrome (IBS), was extended with a focus on the frequency of symptoms occurring twelve weeks (not necessarily consecutive weeks) within twelve months. ROME III, the third edition, conservative one, was published in September 2006, with changes made only where there is good evidence to do so. Some of the differences between Rome II and Rome III criteria are highlighted in this issue.

Mostafa R. Rome III: The functional gastrointestinal disorders, third edition, 2006. *World J Gastroenterol* 2008; 14(13): 2124-2125 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2124.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2124>

## INTRODUCTION

Functional gastrointestinal disorders (FGIDs) represent

a common and important class of disorders within gastroenterology. They are a group of disorders in clinical medicine that have often posed immense problems for patients to experience, for clinicians to diagnose and treat, and for researchers to study.

The "road to Rome" began in Rome, Italy, in 1988 during the 12th International Congress of Gastroenterology, during which a working team was set up to create guidelines for the management and study of irritable bowel syndrome (IBS). After a publication outlining the classification system in 1990, several committees convened in Rome, Italy, throughout 1994 and began a process of review and analysis of the medical literature to improve the methodology for studying, diagnosing and treating 21 FGIDs. The ultimate goal was to improve the lives of patients and their families. The process has matured through three generations, producing a series of publications (Rome I, II and III), with an increased evidence-based approach to the recommendations.

## ROME I AND ROME II

Rome I, the first edition published in 1994, is a compilation of documents previously published in *Gastroenterology International* over a period of 5 years by 30 international investigators who categorized the FGIDs from the esophagus to the anus. The most striking result of this process is the creation of the Rome I symptom-based diagnostic criteria for FGIDs. These criteria began to change the diagnostic approach to FGIDs, and no longer considered "diagnoses of exclusion" but rather "diagnoses of inclusion". The Rome criteria have enabled positive diagnoses without the need for extensive and unnecessary diagnostic studies to "rule out organic diseases".

Rome II, the second edition, published in 2000, resulted from the continual process of analyzing new scientific and clinical evidence in the study of FGIDs. Rome II, diagnostic criteria for irritable bowel syndrome (IBS), is extended with a focus on the frequency of symptoms occurring twelve weeks (not necessarily consecutive weeks) within twelve months.

For the first time, pediatric FGIDs were categorized, and chapters highlighting physiology of motility, sensation, brain-gut interactions, and psychosocial aspects were included.

## ROME III

ROME III, the third edition, published in September

2006, is a 1048-page document written by a collaborative effort of 82 international experts. The book consists of seventeen chapters that contain the most recent information on the epidemiology, pathophysiology, diagnosis, and treatment of FGIDs. Diagnostic criteria for some of the FGIDs have been revised. "Red flag" symptoms and signs that warrant further diagnostic evaluation have been included. Suggestions for when to make a mental health referral have also been given with new chapters on pharmacology and pharmacokinetics, sociocultural perspectives related to gender, age, and cultural impact. One chapter is also devoted to the development and validation of the Rome III: Diagnostic Questionnaire. New appendices contain validated Rome III: adult and pediatric questionnaires and a table comparing Rome II and Rome III diagnostic criteria.

### CHANGES IN ROME III

The Rome III process is a conservative one, with changes made only where there is good evidence to do so. The following is a summary of the changes in criteria and other recommendations along with their justification.

#### **Time frame change for FGIDs**

The time frame for a diagnosis now originates at 6 mo prior to clinical presentation and diagnosis and must be currently active (i.e., meet criteria) for 3 mo. This time frame is less restrictive than that in Rome II (12 wk of symptoms over 12 mo) and is easier to understand in a questionnaire or for research and clinical practice.

#### **Changes in classification categories**

The Rome II: category of Childhood Functional GI Disorders, is now classified as Childhood Functional GI Disorders: Neonate/Toddler (Category G) and Childhood Functional GI Disorders: Child/Adolescent (Category H). This reflects the different clinical conditions existing between the two categories relating to the growth and development of the child, thus removing Functional abdominal pain syndrome (FAPS) from functional bowel disorders (Category C) into its own category (Category D). This is based on the growing evidence that FAPS relates more to CNS amplification of normal regulatory visceral signals rather than functional abnormalities *per se* within the GI tract. The committee members selected for this new category included psychologists, psychiatrists and gastroenterologists involved in brain gut interactions.

#### **Criteria changes**

In Rome III, functional dyspepsia is de-emphasized as an entity for research, due to its symptom heterogeneity. Instead, the gastroduodenal committee has recommended using an umbrella term "dyspepsia symptom complex" which is subclassified into two conditions that may overlap: (1) Postprandial Distress Syndrome, and (2) Epigastric Pain Syndrome. Although similar to the

dysmotility like and ulcer like dyspepsia in Rome II, there now are several items for the criteria derived from factor analytic studies and physiological support instead of being based on the single symptom of epigastric discomfort or pain. Further studies are needed to validate this change. Functional biliary tract disorders have been a challenging group of disorders to diagnose and treat. These disorders are of low prevalence in comparison to other FGIDs, but they tend to be investigated with invasive and risky studies, such as endoscopic retrograde pancreatography (ERCP) or sphincter of Oddi manometry, and treated with unnecessary endoscopic sphincterotomy and surgery. Rome III recommends more restrictive evaluation of these disorders.

Rome III is the single most comprehensive and authoritative resource on the subject of FGIDs. It is readable, well organized, clearly labeled, and extensively referenced. The 82 experts who participated in the Rome III process have created an outstanding work from which clinicians, clinical investigators, basic scientists, mental health providers, the pharmaceutical industry and, most of all, patients with FGIDs will greatly benefit.

### CONCLUSION

The information obtained in Rome III is comprehensive although certainly not complete. It is likely that the next few years will bring considerable advances in our understanding and treatment of these disorders, and when that occurs, revision of such information should be planned before moving to Rome IV.

Brain imaging, using positron emission tomography, functional magnetic resonance imaging, or other modalities<sup>[1-3]</sup> (Drossman 2005, Hobson 2004, and Hobson 2005) provides an opportunity to assess brain function in response to visceral stimulation<sup>[4,5]</sup> (Kern 2002, Yaguez 2005) among healthy subjects and patients with FGIDs. Developing standardization for brain imaging assessment and making recommendations relating to symptom severity for research and clinical care should be emphasized in the next edition.

### Abstract

The pathogenesis of intrahepatic cholestasis of pregnancy (ICP), a disorder that adversely affects maternal wellbeing and fetal outcome, is unclear. However, multiple factors probably interact along with a genetic predisposition. We would like to add some comments on a paper recently published concerning the role of *ABCB11* and *ABCC2* polymorphisms in both ICP and contraceptive-induced cholestasis, especially in the light of our recently published findings about a positive association between ICP and *ABCC2* common variants.

### TO THE EDITOR

We read with great interest the article of Meier *et al.*

about the role of *ABCB11* and *ABCC2* polymorphisms in both intrahepatic cholestasis of pregnancy (ICP) and contraceptive-induced cholestasis<sup>[1]</sup>. The authors observed an association between the *ABCB11* 1331T > C polymorphism and the above mentioned cholestatic disorders. Additionally, the authors claimed of a lack of association with 3 single nucleotide polymorphisms (SNPs) in *ABCC2* gene, concluding that common *ABCC2* polymorphisms are not associated with the development of ICP.

We would like to make several comments on these findings, particularly concerning to the lack of association with *ABCC2* gene variants. First of all, a note of caution should be added to the reported findings, as the markers assumed by the authors as common variants (rs2273697, rs17222723 and rs8187710), except for rs2273697, include one allele at a very low frequency, as the rs17222723-A allele frequency is 0.067 and the rs8187710-A allele frequency is 0.059, at least for data from the HapMap project for Caucasians and from a rough estimation of own author's data<sup>[1]</sup>. Consequently, in the group of patients included by the authors only 5 out 33 patients showed either the rs172227234 or rs8187710 heterozygous AT or AG genotype, respectively, and none of them showed the homozygous AA genotype. The same happened in the pregnant control group. Thus, in this frame, the statistical power of the study even taking into account the additive genetic model is very low (less than 20%) owing to the lower MAF of these variants.

Second, we wish to note that we recently published<sup>[2]</sup> a candidate gene association study showing the contribution of six *ABCC2* gene variants to the risk of ICP. The study involved promoter, coding and non-coding regions of *ABCC2* (4 tag SNPs representing 46 polymorphic sites located in 70 kb of the gene, in addition to the rs17222723 and rs8187710), and showed that, at least, one of the *ABCC2* variants (rs3740066) at the exon 28 was significantly associated with ICP with its estimated risk of disease for homozygous AA subjects being 4-fold higher than that for homozygous GG subjects (OR, 4.44; 95% CI, 1.83-10.78;  $P < 0.001$ ). Although more studies are necessary to establish whether rs3740066 is the causal variant or one linked to it, our results suggest that ICP may be associated with the common variants of *ABCC2*. Interestingly, we also included in the analysis rs172227234 and rs8187710, and we did not observe significant differences in genotype frequencies of the 2 SNPs in ICP and controls.

In conclusion, we consider that the pathogenic involvement of *ABCC2* (*MRP2*) in ICP is still an open issue, particularly in the frame of a small number of studies about the role of the *ABCC2* gene variants in cholestatic disorders, with the exception of the Dubin Johnson phenotype.

Although the major physiological function of *ABCC2* is to transport conjugated metabolites into the bile canaliculus, previous data demonstrated that a major metabolite of human estrogen metabolism, estradiol-17- $\beta$ -D-glucuronide (E<sub>2</sub>17 $\beta$ G), has been shown to be transported by both *MRP2* and *MRP3*<sup>[3]</sup>. These findings support that *ABCC2* represents an alternative candidate protein involved in the pathogenesis of hormonal cholestasis. Additionally, it has been shown that *MRP2* is regulated by three distinct nuclear receptor signaling pathways that converge on a common response element in the 5'-flanking region of this gene<sup>[4]</sup>. Hence, the intimate mechanism, by which gene variants including *ABCC2* may influence ICP susceptibility, is not fully explored and a complex network involving nuclear receptors and other transcription factors may be the cause of liver injury in cholestatic disorders<sup>[5]</sup>.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1215 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

*WJG* publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Patent (list all authors)**

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Inappropriate references**

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/15.doc>

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

**Editorial Office**

**World Journal of Gastroenterology**

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

**Language evaluation**

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

**Copyright assignment form**

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

**Responses to reviewers**

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

**Proof of financial support**

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

**Links to documents related to the manuscript**

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

**Science news releases**

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

**Publication fee**

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## Contents

### EDITORIAL

- 2133 Value of colonoscopy for prediction of prognosis in patients with ulcerative colitis  
*Ando T, Nishio Y, Watanabe O, Takahashi H, Maeda O, Ishiguro K, Ishikawa D, Ohmiya N, Niwa Y, Goto H*
- 2139 MUC1 and colorectal cancer pathophysiology considerations  
*Niv Y*

### REVIEW

- 2142 Necrotizing enterocolitis: A multifactorial disease with no cure  
*Schnabl KL, Van Aerde JE, Thomson ABR, Clandinin MT*

### GASTRIC CANCER

- 2162 Effect of *NHE1* antisense gene transfection on the biological behavior of *SGC-7901* human gastric carcinoma cells  
*Liu HF, Teng XC, Zheng JC, Chen G, Wang XW*

### LIVER CANCER

- 2168 Troglitazone, a peroxisome proliferator-activated receptor  $\gamma$  ligand, induces growth inhibition and apoptosis of HepG2 human liver cancer cells  
*Zhou YM, Wen YH, Kang XY, Qian HH, Yang JM, Yin ZF*

### BASIC RESEARCH

- 2174 Detection of apoptosis induced by new type gosling viral enteritis virus *in vitro* through fluorescein annexin V-FITC/PI double labeling  
*Chen S, Cheng AC, Wang MS, Peng X*
- 2179 Pharmacokinetics and tissue distribution of intraperitoneal 5-fluorouracil with a novel carrier solution in rats  
*Wei ZG, Li GX, Huang XC, Zhen L, Yu J, Deng HJ, Qing SH, Zhang C*

### RAPID COMMUNICATION

- 2187 Prospective cohort comparison of flavonoid treatment in patients with resected colorectal cancer to prevent recurrence  
*Hoensch H, Groh B, Edler L, Kirch W*
- 2194 A red wine polyphenolic extract reduces the activation phenotype of cultured human liver myofibroblasts  
*Neaud V, Rosenbaum J*
- 2200 Effects of estradiol and progesterone on the proinflammatory cytokine production by mononuclear cells from patients with chronic hepatitis C  
*Yuan Y, Shimizu I, Shen M, Aoyagi E, Takenaka H, Itagaki T, Urata M, Sannomiya K, Kohno N, Tamaki K, Shono M, Takayama T*
- 2208 Comparison of CT and MRI for presurgical characterization of paraaortic lymph nodes in patients with pancreatico-biliary carcinoma  
*Kim YC, Park MS, Cha SW, Chung YE, Lim JS, Kim KS, Kim MJ, Kim KW*
- 2213 Thrombospondin-1 expression correlates with angiogenesis in experimental cirrhosis  
*Elpek GÖ, Gökhan GA, Bozova S*

- 2218 Sustained virological response based on rapid virological response in genotype-3 chronic hepatitis C treated with standard interferon in the Pakistani population  
*Zuberi BF, Zuberi FF, Memon SA, Qureshi MH, Ali SZ, Afsar S*
- 2222 Cost saving by reloading the multiband ligator in endoscopic esophageal variceal ligation: A proposal for developing countries  
*Abbas Z, Rizvi L, Ahmed US, Mumtaz K, Jafri W*
- 2226 Effect of thermal cutaneous stimulation on the gastric motor activity: Study of the mechanism of action  
*Shafik A, Shafik AA, Sibai OE, Shafik IA*
- 2230 DNMT3B 579 G>T promoter polymorphism and risk of esophagus carcinoma in Chinese  
*Fan H, Liu DS, Zhang SH, Hu JB, Zhang F, Zhao ZJ*
- 2235 Anti-sense oligonucleotide labeled with technetium-99m using hydrazinonictinamide derivative and N-hydroxysuccinimidyl S-acetylmercaptoacetyltriglycine: A comparison of radiochemical behaviors and biological properties  
*Li YC, Tan TZ, Zheng JG, Zhang C*
- 2241 Effects of simulated carbon dioxide and helium pneumoperitoneum on proliferation and apoptosis of gastric cancer cells  
*Hao YX, Zhong H, Zhang C, Zeng DZ, Shi Y, Tang B, Yu PW*
- 2246 Dynamic changes of IL-2/IL-10, sFas and expression of Fas in intestinal mucosa in rats with acute necrotizing pancreatitis  
*Dang SC, Zhang JX, Qu JG, Mao ZF, Wang XQ, Zhu B*
- 2251 Clinicopathologic characteristics of intrahepatic cholangiocarcinoma in patients with positive serum a-fetoprotein  
*Zhou YM, Yang JM, Li B, Yin ZF, Xu F, Wang B, Liu P, Li ZM*
- 2255 Risk factors for alcohol-related liver injury in the island population of China: A population-based case-control study  
*Shen Z, Li YM, Yu CH, Shen Y, Xu L, Xu CF, Chen JJ, Ye H, Xu GY*
- 2262 Endoscopic diagnosis of gastrointestinal graft-versus-host disease  
*Xu CF, Zhu LX, Xu XM, Chen WC, Wu DP*

**CASE REPORT**

- 2268 Extraintestinal heterotopic gastric tissue simulating acute appendicitis  
*Bender E, Schmidt SP*
- 2270 Steroid responsive eosinophilic gastric outlet obstruction in a child  
*Kellermayer R, Tatevian N, Klish W, Shulman RJ*
- 2272 Ischemic colitis due to obstruction of mesenteric and splenic veins: A case report  
*Hwang SS, Chung WC, Lee KM, Kim HJ, Paik CN, Yang JM*
- 2277 Successful endoscopic treatment of biliary stricture following mesenteric tear caused by blunt abdominal trauma  
*Kang DO, Kim TH, You SS, Min HJ, Kim HJ, Jung WT, Lee OJ*
- 2280 Appendiceal mucocele: Case reports and review of current literature  
*Karakaya K, Barut F, Emre AU, Ucan HB, Cakmak GK, Irkorucu O, Tascilar O, Ustundag Y, Comert M*

### Abstract

Ulcerative colitis (UC) is a chronic inflammatory bowel disorder characterized by exacerbations and remissions. Some UC patients remain refractory to conventional medical treatment while, in others, the effectiveness of drugs is limited by side-effects. Recently, cyclosporine and leukocyte removal therapy have been used for refractory UC patients. To predict the efficacy of these therapies is important for appropriate selection of treatment options and for preparation for colectomy. Endoscopy is the cornerstone for diagnosis and evaluation of UC. Endoscopic parameters in patients with severe or refractory UC may predict a clinical response to therapies, such as cyclosporine or leukocyte removal therapy. As for the patients with quiescent UC, relapse of UC is difficult to predict by routine colonoscopy. Even when routine colonoscopy suggests remission and a normal mucosal appearance, microscopic abnormalities may persist and relapse may occur later. To more accurately identify disease activity and to predict exacerbations in UC patients with clinically inactive disease is important for deciding whether medical treatment should be maintained. Magnifying colonoscopy is useful for the evaluation of disease activity and for predicting relapse in patients with UC.

### INTRODUCTION

Ulcerative colitis (UC) is a chronic inflammatory bowel disorder characterized by diffuse mucosal inflammation of the colorectum with exacerbations and remissions<sup>[1-5]</sup>. Approximately 15% of patients experience a severe exacerbation requiring hospital admission at some time during their illness<sup>[3,6]</sup>. The purpose of treatments for patients with ulcerative colitis is achieving remission and maintaining quiescence of the disease. Patients with UC must rely on multiple medications to control their symptoms, including aminosalicylates, corticosteroids and purine analogs. Although decades of clinical experience in the management of UC have allowed the optimization of approaches to the induction and maintenance of remission, some patients remain refractory to conventional medical treatment and the effectiveness of these drugs may be limited by side-effects<sup>[7-11]</sup>. The use of immunosuppressive agents, including purine analogs, now constitutes a therapeutic modality for the treatment of UC<sup>[12]</sup>. Although highly effective, a disadvantage of these drugs is the significant delay in their onset of clinical benefit, which limits their utility to the treatment of severe disease.

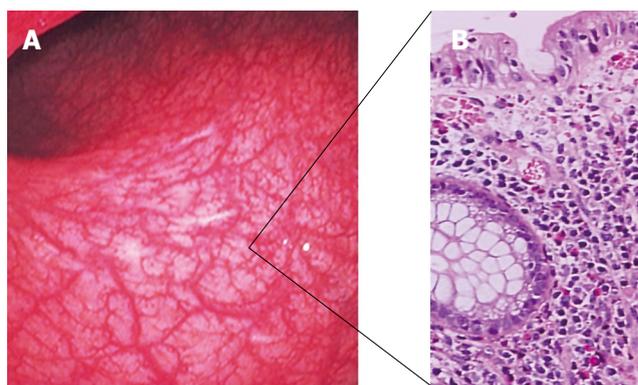

Although the degree of inflammation as assessed by routine colonoscopy is a reliable parameter of disease activity, discrepancies between colonoscopic appearance and histopathologic abnormalities are sometimes seen in patients with clinically inactive UC (Figure 1). Even when routine colonoscopy suggests remission and a normal mucosal appearance, microscopic abnormalities may persist<sup>[13,14]</sup> and relapse may occur later<sup>[15]</sup>. A recently developed high-resolution video-magnifying colonoscope has enabled the observation of pit patterns on the

surface of the colorectal mucosa. This in turn allows an understanding of the morphological relationship between the pit patterns detected colonoscopically and the crypts observed histopathologically<sup>[16-20]</sup>. As far back as 1980, Poulsen *et al*<sup>[21]</sup> examined biopsy specimens from the rectal mucosa of UC patients under a stereomicroscope and found microstructural abnormalities in the mucosal surface in almost every patient, as well as a close correlation between stereomicroscopic features and the clinical disease activity, sigmoidoscopic findings, and histologic activity of the disease.

Here, we discuss endoscopic factors predictive of the efficacy of therapies in patients with intractable UC, and endoscopic factors that may predict the probability of subsequent disease relapse in UC patients in remission. We will reconsider the value of endoscopy when we treat UC patients.

## ENDOSCOPIC PREDICTORS OF RESPONSE TO THERAPIES IN PATIENTS WITH REFRACTORY ULCERATIVE COLITIS

In recent years, steroid-refractory cases of UC have been successfully treated by adding intravenous cyclosporine to the glucocorticosteroids. Cyclosporine is a lipophilic cyclic peptide that interrupts the cellular immune response by blocking interleukin 2 productions by T cells. Uncontrolled studies show that approximately 80% of patients with severe UC refractory to glucocorticosteroid treatment respond to cyclosporine therapy<sup>[22,23]</sup>. The use of cyclosporine is, however, associated with considerable morbidity. Serious complications such as *Pneumocystis carinii* pneumonia and seizures have occurred in as many as 12% of patients in large series, and deaths have been reported<sup>[24-26]</sup>. Less serious, but nevertheless troubling, side-effects including hypertension, liver and renal impairment, tremor, paresthesia and headache, occur in up to 50% of patients<sup>[23,25-27]</sup>. It would be useful to define factors predictive of response to cyclosporine treatment for severe flares of ulcerative colitis, to avoid the side effects as well as reduce the risk of subjecting the patients to increased morbidity and mortality due to needlessly delaying colectomy. However, there has been only limited information as to which factors are associated with a response to cyclosporine that leads to possible avoidance of colectomy in such patients. Rowe *et al* demonstrated that a higher percentage of band neutrophils on admission was predictive of patients who were unlikely to respond to cyclosporine and who would require colectomy<sup>[28]</sup>. On the other hand, McCormack *et al* showed that the *in vitro* cyclosporine sensitivity of proliferating lymphocytes was predictive of the therapeutic response<sup>[29]</sup>. Genetic factors of the host are also considered to play a role in UC outcomes. The TT genotype of exon 21 multidrug resistance gene 1 polymorphisms is associated with a higher risk of cyclosporine failure in patients with steroid resistant UC<sup>[30]</sup>. Our prospective analysis with a logistic regression model, colonoscopic findings predictive of response to intravenous cyclosporine in patients with

**Figure 1** A case of inactive UC. A discrepancy is seen between an endoscopic and a histologic finding. **A:** A routine colonoscopy finding. It shows an almost normal mucosal appearance; **B:** A histologic finding. It shows an intense infiltration of mononuclear cells and neutrophils.

**Table 1** Colonoscopic finding predictive of response to intravenous cyclosporine in ulcerative colitis patients

	Responders (n = 17)	Non-responders (n = 9)	Relative risk <sup>1</sup> (Odds ratio)
Deep and extensive ulcerations (yes:no)	8:9	0:9	14.20 (P < 0.005)
Mucosal bleeding (yes:no)	5:12	7:2	0.12 (P < 0.05)
Poor luminal extensibility (yes:no)	4:13	7:2	0.09 (P < 0.01)

<sup>1</sup>Logistic regression analysis.

steroid-resistant ulcerative colitis included the presence of deep and extensive ulcerations, and the absence of mucosal bleeding or poor luminal extensibility (Table 1).

Findings in active UC include the activation and extravasation of large numbers of granulocytes and monocytes/macrophages into the colonic mucosa<sup>[31,32]</sup>. These infiltrated leukocytes may cause extensive mucosal tissue injury by releasing degradative proteases<sup>[32-34]</sup>, reactive oxygen derivatives<sup>[32,34,35]</sup>, and pro-inflammatory cytokines<sup>[36]</sup>. Leukocyte removal therapy is recognized as a second novel strategy for the treatment of steroid-refractory UC, based on the assumption that this non-drug therapy attenuates intestinal inflammation by reducing excess and activated granulocytes, monocytes and lymphocytes from the circulating blood before they reach the inflamed mucosa<sup>[37]</sup>. Adsorption with beads (granulocytapheresis, GCAP) or filters (leukocytapheresis, LCAP) is most commonly used<sup>[38,39]</sup>. Several studies have reported the beneficial effects of leukocyte removal therapy on both the induction and maintenance of clinical remission in patients with IBD<sup>[40-42]</sup>, suggesting that it may be a useful adjunct to conventional therapy in patients with active severe UC and those refractory to conventional drugs. Further, leukocyte removal therapy might be an effective first line medication<sup>[43]</sup>. First UC episode and short disease duration are good predictors of response to leukocyte removal therapy<sup>[44]</sup>. Steroid-naïve patients respond particularly well to this treatment<sup>[42,45]</sup>. Patients with deep colonic lesions might be less satisfactory<sup>[45]</sup>. However, our prospective analysis in patients

with steroid resistant ulcerative colitis did not find any colonoscopic findings predictive of response to leukocyte removal therapy<sup>[46]</sup>. Further study with a larger population of patients needs to be conducted to define predictors of response to cyclosporine or leukocyte removal therapy, including prolonged outcome, for more appropriate selection of treatment options with these therapies in patients with severe ulcerative colitis.

## PREDICTION OF RELAPSE IN PATIENTS WITH QUIESCENT ULCERATIVE COLITIS

Severity in ulcerative colitis is generally assessed using symptoms, laboratory data<sup>[47]</sup>, colonoscopic findings<sup>[48-55]</sup> and histologic degree of inflammation in the biopsy specimens<sup>[15,56-59]</sup>. Histopathologic assessment is considered the standard for evaluation of disease activity in patients with ulcerative colitis<sup>[60]</sup>. The observation under conventional colonoscopy has been regarded as useful for the evaluation of disease activity, since it offers direct observation of mucosal changes, but it still remains controversial whether colonoscopic grade correlates with histopathologic findings. It has been reported that the degree of histologic inflammation within biopsy specimens did not necessarily correlate with endoscopic abnormalities<sup>[48,49,61,62]</sup>. It is not unusual for routine colonoscopy performed to assess the stage of UC to show quiescent colitis despite the histological persistence of inflammation<sup>[48,61,63]</sup>, which later results in the relapse of colonic inflammation<sup>[15]</sup>. Hurlstone DP *et al* reported high-frequency ultrasound is a valid adjunctive 'tool' for the trans-mural assessment of the colorectal wall in UC<sup>[64]</sup>. This technique may aid in the initial diagnosis, and ongoing chronic management of disease.

Matsumoto *et al* reported usefulness of magnifying chromoscopy for the assessment of severity in UC patients<sup>[65]</sup>. In their study, magnifying colonoscopy was performed in 41 patients with ulcerative colitis, and the findings in the rectum were graded according to network pattern (NWP) and cryptal opening (CO). The clinical, endoscopic and histologic grades of activity were not different between groups divided by the presence or absence of each finding. However, when the two features were coupled, patients with visible NWP and CO had a lower clinical activity index and lower grade of histologic inflammation than those in whom both findings could not be visualized. Furthermore it has been suggested that the presence of branches in surface epithelium may be a factor that predicts future disease relapse<sup>[15]</sup>, and they suggested that altered pattern as defined by magnified colonoscopic views may be predictive of the course of ulcerative colitis<sup>[65]</sup>.

Fujiya *et al* proposed the classification of magnifying colonoscopic findings in patients with ulcerative colitis which is useful for the evaluation of disease activity and for the prediction of periods of remission<sup>[66]</sup>. The classification was devised as follows: regularly arranged crypt opening, villous-like appearance, minute defects of epithelium (MDE), small yellowish spots (YS), and coral reef-like appearance. The colonoscopic findings by classification

were compared with histopathologic findings in 61 patients and the usefulness of the classification for predicting relapse was prospectively analyzed in 18 patients. Under conventional colonoscopic examinations, all areas evaluated as Matts grade 1 had a corresponding histopathologic grade 1. In contrast, most areas assessed as Matts grade 3 or 4 were diagnosed as histopathologic grade 3 or higher. However, grade 2 mucosa had histopathologic findings that varied from quiescent to active disease. These suggest that normal and diseased mucosas are easily recognized by conventional colonoscopy, but it is difficult for conventional colonoscopy to assess the minute mucosal changes that reflect smoldering histopathologic inflammation<sup>[48,49,61]</sup>. In contrast, under magnifying colonoscopic examinations, 37 (82.2%) of the 45 areas in which regularly arranged crypt openings or a villous-like appearance was detected had a corresponding histopathologic grade 1, and all areas in which MDE, SYS, or the coral reef-like appearance was observed had a corresponding histopathologic grade 2 or higher. In this study, the correlation between histopathologic grade and magnifying colonoscopic findings ( $r^2 = 0.807$ ) was better than that for histopathologic grade versus conventional colonoscopy ( $r^2 = 0.665$ ). This study found that patients in whom MDE was observed during clinical remission frequently had a relapse within short periods (6 mo) compared with patients without these findings, and 50% of patients who underwent clinical remission still had active inflamed mucosa with MDE, which correlates with the results of previous studies in which 30% to 60% of patients in remission, as determined by clinical symptoms, were still in the active stage of ulcerative colitis based on histopathologic findings<sup>[49,62]</sup>. In our study we found that magnifying colonoscopy (MCS) grade was associated with the degree of histological inflammation in quiescent patients with ulcerative colitis, and might predict the probability of subsequent disease relapse in patients with ulcerative colitis in remission. Magnifying colonoscopy was performed in 112 patients with ulcerative colitis in remission. The relationship between pit patterns and histological disease activity was evaluated. Pit patterns in the rectal mucosa were classified into three MCS grades on the basis of size, shape, and arrangement (Figure 2). The patients were followed until relapse or a maximum of 12 mo. A positive correlation was identified between MCS grade and histological grade (Figure 3). Multivariate proportional hazard model analysis showed that MCS grade was a significant predictor of relapse. Kaplan-Meier estimate of relapse during 12 mo' follow up was found to increase with increasing MCS grade, with a percentage of 0 for grade 1, 19% for grade 2, and 43% for grade 3 (Figure 4). Although MCS grade positively correlated with histological grade, histological grade was less accurate predictors of disease relapse. One reason may be that they are assessed in biopsy specimens derived from a specific and limited area, whereas magnifying colonoscopy allows the observation of a more extended and representative area of colorectal mucosa, and accordingly greater accuracy by MCS grading.

### Abstract

Several lines of evidence point towards a biological role of mucin and particularly MUC1 in colorectal cancer. A positive correlation was described between mucin secretion, proliferation, invasiveness, metastasis and bad prognosis. But, the role of MUC1 in cancer progression is still controversial and somewhat confusing. While Mukherjee and colleagues developed MUC1-specific immune therapy in a CRC model, Lillehoj and co-investigators showed recently that MUC1 inhibits cell proliferation by a  $\beta$ -catenin-dependent mechanism. In carcinoma cells the polarization of MUC1 is lost and the protein is over expressed at high levels over the entire cell surface. A competitive interaction between MUC1 and E-cadherin, through  $\beta$ -catenin binding, disrupts E-cadherin-mediated cell-cell interactions at sites of MUC1 expression. In addition, the complex of MUC1- $\beta$ -catenin enters the nucleus and activates T-cell factor/leukocyte enhancing factor 1 transcription factors and activates gene expression. This mechanism may be similar to that just described for DCC and UNC5H, which induced apoptosis when not engaged with their ligand netrin, but mediate signals for proliferation, differentiation or migration when ligand bound.

Niv Y. MUC1 and colorectal cancer pathophysiology considerations. *World J Gastroenterol* 2008; 14(14): 2139-2141 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2139.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2139>

MUC1 is a structural membranous bound mucin, expressed on the apical borders of secretory epithelial cells which previously had many names such as DF3, episialin, CA5-3, PAS-O, polymorphic epithelial mucin (PEM), or epithelial membrane antigen<sup>[1]</sup>.

MUC1 gene is located on chromosome 1q21 and has 1201 nucleotides. The N-terminal ectodomain of MUC1 (MUC1-N) consists of variable numbers of 20-amino-acid tandem repeats (VNTRs), with the number of repeats varying from 20 to 120 in different individuals<sup>[2]</sup>. These sites are subject to O-glycosylation that contributes to form a structure that extends beyond the glycocalyx of the cell. The protein has a protective function by binding to pathogens and also functions in a cell signaling capacity<sup>[3]</sup>.

MUC1-N is tethered to the cell membrane as a heterodimer with the MUC1 C-terminal subunit (MUC1-C), which includes a 58-amino acid extracellular domain, a 28-amino acid transmembrane domain, and a 72-amino acid cytoplasmic tail that contains sites for tyrosine and serine phosphorylation<sup>[4]</sup>. Over expression, aberrant intracellular localization, and changes in glycosylation of this protein as found in most human carcinomas, confers anchorage-independent growth and tumorigenicity<sup>[5]</sup>. Other studies have demonstrated that over expression of MUC1 confers resistance to apoptosis induced by oxidative stress and anti-cancer agents<sup>[6]</sup>. Multiple alternatively spliced transcript variants that encode different isoforms of MUC1 have been reported, but the full-length nature of only some of them has been determined<sup>[7]</sup>.

Several lines of evidence point towards a biological role of mucin and particularly MUC1 in colorectal cancer (CRC). A positive correlation was described between mucin secretion, proliferation, invasiveness, metastasis and bad prognosis<sup>[8-10]</sup>. When MUC1 was expressed at the deepest tumor invasive portion, lymphatic and venous invasion was more pronounced as well as lymph nodes and liver metastasis<sup>[11]</sup>. Correlation with bad prognosis was found in mismatch repair (MMR) - proficient colorectal tumors, but not in MLH1 negative tumors or in Lynch syndrome (HNPCC)<sup>[12]</sup>.

But, the role of MUC1 in cancer progression is still controversial and somewhat confusing. While Mukherjee and colleagues, in a very sophisticated way, developed MUC1-specific immune therapy in a CRC model, Lillehoj and co-investigators showed recently that MUC1 inhibits cell proliferation by  $\beta$ -catenin-dependent mechanism<sup>[13,14]</sup>. A similar observation was described by Yuan and co-workers<sup>[15]</sup>.

Interaction of the cytoplasmic tail of MUC1 with  $\beta$ -catenin has a significant effect on cell cycle and

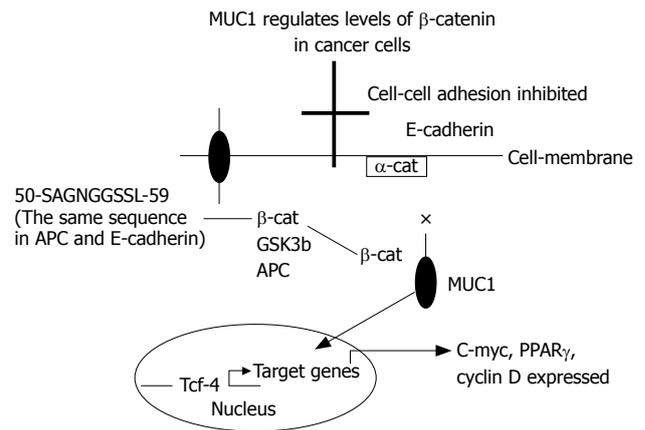

proliferation. This process hardly happens in normal polarized epithelium, because MUC1 resides on the apical surface while  $\beta$ -catenin resides on the lateral surface. Loss of polarity during transformation creates a permissive environment for MUC1 and  $\beta$ -catenin interaction<sup>[7]</sup>.

$\beta$ -catenin can bind directly to the amino acid sequence 50-SAGNGGSSL-59 of the MUC1 cytoplasmic domain (a similar binding site is found on E-cadherin and APC proteins). The binding is promoted by phosphorylation of T41 by Ser/Thr kinase PKC $\zeta$  and of Y46 by Src or EGFR<sup>[16]</sup>. Inhibition of  $\beta$ -catenin binding to MUC1 is the result of phosphorylation of S44 by GSK3 $\beta$  that can also directly degrades  $\beta$ -catenin. Disruption of the  $\beta$ -catenin binding site in MUC1 suppresses its ability to induce anchorage-dependent and independent growth, indicating  $\beta$ -catenin binding to MUC1 is a critical component of its tumorigenic activity. MUC1 also protects  $\beta$ -catenin from degradation by GSK3 $\beta$ , and when co-localized with  $\beta$ -catenin in the nucleus co activates transcription of Wnt target genes<sup>[17-19]</sup>. MUC1 binding to  $\beta$ -catenin suppresses its ability to interact with E-cadherin at adherent junctions, leading to a breakdown in cell-cell interactions. GSK3 $\beta$ -mediated disruption of the complex restores the E-cadherin/ $\beta$ -catenin interaction<sup>[20]</sup>.

In carcinoma cells the polarization of MUC1 is lost, and the protein is over expressed at high levels over the entire cell surface. A competitive interaction between MUC1 and E-cadherin, through  $\beta$ -catenin binding, disrupts E-cadherin-mediated cell-cell interactions at sites of MUC1 expression. In addition, the complex of MUC1- $\beta$ -catenin enters the nucleus and activates T-cell factor/leukocyte enhancing factor 1 (Tcf/LEF-1) transcription factors and activates gene expression<sup>[18]</sup>. This enhances proliferation, and decreases cell-cell adhesion which may both increase carcinogenesis and metastasis. GSK3 $\beta$  interacts with the STDRSPYE motif in MUC1, phosphorylates the serine in this domain, and prevents binding of  $\beta$ -catenin<sup>[16]</sup>.

It is proposed that APC binding prevents the formation of  $\beta$ -catenin-Tcf complex, and that MUC1 binding prevents  $\beta$ -catenin- $\alpha$ -catenin-E-cadherin complex. GSK3 $\beta$  interacts with  $\beta$ -catenin to restore  $\beta$ -catenin-E-cadherin complex, and with APC to bind  $\beta$ -catenin and prevent  $\beta$ -catenin-Tcf complex (Figure 1). The exact mechanism of MUC1 associated cancer cell proliferation and carcinogenesis is not well understood. MUC1 can bind  $\beta$ -catenin, prevents its entering the nucleus or activating Tcf/LEF-1, and inhibits proliferation. On the other hand, MUC1-C complex with  $\beta$ -catenin may enter the nucleus and the opposite action will take place. In both cases,  $\beta$ -catenin binding to MUC1 will prevent its binding to E-cadherin or to APC.

The cytoplasmic tail of MUC1 contains 4 tyrosine residues that are phosphorylated before binding  $\beta$ -catenin. It is speculated that MUC1 is a membranous receptor which maintains cell cycle progression or enhances apoptosis. Activating MUC1 will result in phosphorylation of the tyrosines on the cytoplasmic tail and binding  $\beta$ -catenin. This will prevent  $\beta$ -catenin from binding E-cadherin or activating Tcf/LEF-1 pathway. This mechanism may be similar to that just described for DCC and UNC5H, which

**Figure 1** It is proposed that APC binding prevents the formation of  $\beta$ -catenin-Tcf complex, and that MUC1 binding prevents  $\beta$ -catenin- $\alpha$ -catenin-E-cadherin complex. GSK3 $\beta$  interacts with  $\beta$ -catenin to restore  $\beta$ -catenin-E-cadherin complex, and with APC to bind  $\beta$ -catenin and prevent  $\beta$ -catenin-Tcf complex. X = inhibition; arrow = enhancing.

induced apoptosis when not engaged with their ligand netrin, but mediate signals for proliferation, differentiation or migration when ligand bound<sup>[21]</sup>.

### INTRODUCTION

Necrotizing enterocolitis (NEC) is an inflammatory bowel disease of neonates and remains one of the most common gastrointestinal emergencies in newborn infants<sup>[1]</sup>. Onset of NEC is often within the first three months of life and neonates who are of extremely low birth weight (< 1000 g) and under 28 wk gestation are the most susceptible<sup>[2]</sup>. Full term neonates account for 10% of all NEC cases while premature infants account for 90%<sup>[3]</sup>. With an incidence rate of 1%-5% for all newborns admitted to the NICU<sup>[1]</sup>, a prevalence of 7%-14% of very low birth weight infants (VLBW, 500-1500 g)<sup>[4]</sup> and a mortality rate approaching 20%-50%<sup>[5]</sup>, NEC continues to represent a significant clinical problem. In Canada, the incidence rate is 1.8 per 100 live births with a prevalence of 7% of VLBW infants<sup>[1]</sup>. Advances in obstetric and neonatal care have improved survival rates for smaller, more immature infants, and as more VLBW preterm infants survive the neonatal period, the population at risk for NEC increases<sup>[1]</sup>. No consistent association between sex, race, and rates of NEC has been identified. However, male VLBW infants and black infants are at greater risk of death<sup>[6]</sup>. Due to inadequate treatments and no effective preventative strategy, an estimated 20%-40% of babies with NEC require surgery<sup>[1]</sup> and 10%-30% experience significant morbidity including neurodevelopmental impairment, vision and hearing impairment, failure to thrive, feeding abnormalities, diarrhea, bowel obstruction, and short bowel syndrome<sup>[1,2,7]</sup>. The case fatality rate with surgical intervention is as high as 50%<sup>[1]</sup>. NEC is also a financial burden to the health care system with yearly hospital charges reported to be as high as \$6.5 million in the US<sup>[8]</sup>. Thus, NEC continues to be an important health issue for preterm neonates.

### Abstract

Necrotizing enterocolitis is an inflammatory bowel disease of neonates with significant morbidity and mortality in preterm infants. Due to the multifactorial nature of the disease and limitations in disease models, early diagnosis remains challenging and the pathogenesis elusive. Although preterm birth, hypoxic-ischemic events, formula feeding, and abnormal bacteria colonization are established risk factors, the role of genetics and vasoactive/inflammatory mediators is unclear. Consequently, treatments do not target the specific underlying disease processes and are symptomatic and surgically invasive. Breast-feeding is the most effective preventative measure. Recent advances in the prevention of necrotizing enterocolitis have focused on bioactive nutrients and trophic factors in human milk. Development of new disease models including the aspect of prematurity that consistently predisposes neonates to the disease with multiple risk factors will improve our understanding of the pathogenesis and lead to discovery of innovative therapeutics.

### DIAGNOSIS

#### *Clinical signs and symptoms*

The onset of NEC can occur suddenly within a few

Table 1 Bell's staging criteria for necrotizing enterocolitis

Stage	Systemic signs	Intestinal signs	Radiological signs
I A (Suspected)	Temperature instability, apnea, bradycardia, lethargy	Poor feeding, emesis, ↑ pre-gavage residuals, mild abdominal distension	Normal or intestinal dilation, mild ileus
I B (Suspected)	Same as above	Above and blood from rectum	Same as above
II A (Proven)	Same as above	Above + absent bowel sounds + mild abdominal tenderness	Intestinal dilation, ileus, pneumatosis intestinalis
II B (Proven)	Above + metabolic acidosis + thrombocytopenia	Above + definite abdominal tenderness	Above + portal vein gas + possible ascites
III A (Advanced)	Above + hypotension, respiratory acidosis, neutropenia	Above + peritonitis, marked distension of abdomen	Above + definite ascites
III B (Advanced)	Same as above	Same as above	Above + pneumoperitoneum

hours or may be preceded by several days of feeding intolerance<sup>[7]</sup>. Age at presentation is inversely related to gestational age at birth, with full-term infants often presenting in the first few days of life<sup>[1]</sup>. NEC affects the gastrointestinal tract and, in severe cases, may have profound systemic impact<sup>[9]</sup>. Initial symptoms may be subtle and can include feeding intolerance (gastric residuals, bilious vomiting), bloody diarrhea, temperature instability, lethargy, apnea, bradycardia, decreased peripheral perfusion, delayed gastric emptying, ileus, abdominal distension, or tenderness and respiratory stress<sup>[1,9,10]</sup>. Non-specific laboratory abnormalities can include neutropenia, thrombocytopenia, hyponatremia, hyperglycemia, metabolic acidosis, and bacteria or infectious products isolated from blood, urine, or stool<sup>[9,11]</sup>. Serial C-reactive protein could be useful in the management of the disease. C-reactive protein distinguishes stage I NEC from ileus or benign pneumatosis and high levels predict development of complications such as strictures, abscess, or need for surgery<sup>[12]</sup>. Because early signs of this disease are non-specific, sepsis may be suspected before NEC<sup>[1]</sup>.

### Pathological findings

The ileum and proximal colon are the most commonly affected sites in NEC although any segment of the gastrointestinal tract can be involved including the stomach<sup>[13]</sup>. Severity of bowel wall necrosis ranges from a small localized mucosal necrosis of a bowel segment to transmural necrosis of the entire small intestine and colon in most severe cases<sup>[7]</sup>. In more advanced stages of NEC, pathological findings include gastrointestinal bleeding, inflammation, bacterial overgrowth, intestinal distension with multiple dilated loops of small bowel, pneumatosis intestinalis and portal air, intestinal perforation, coagulative necrosis, hypotension, septic shock, pneumoperitoneum, and intraabdominal fluid<sup>[2,10]</sup>. In 1978, Bell and colleagues<sup>[14]</sup> proposed a system for the uniform clinical staging of infants with NEC. They classified infants as having stage I (suspect), stage II (definite), or stage III (advanced)<sup>[14]</sup>. Bell's staging criteria for NEC are guidelines for the management of NEC (Table 1).

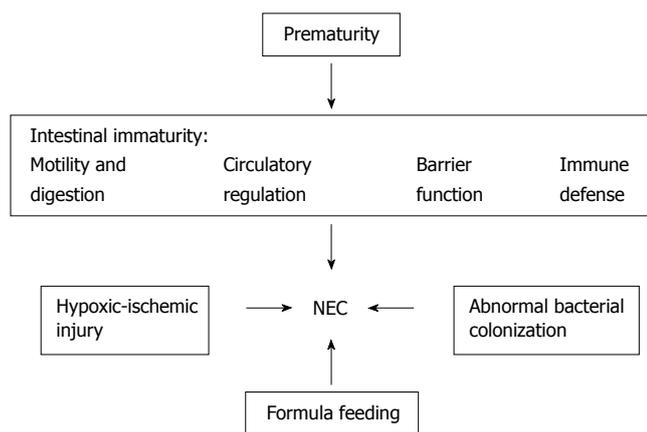

Ideally, nutrition intervention would begin when an infant has one or more risk factors for developing NEC (i.e. preterm birth) or is at an early stage of disease.

### Diagnostic methods

Early diagnosis of gut ischemia and mucosal inflammation/necrosis is crucial in the prevention of NEC or the progression of the illness to late stages requiring surgery and/or bowel resection. An abdominal radiograph and a chest x-ray are used to diagnose gastrointestinal tract abnormalities and changes in the size and shape of the lung and heart, respectively<sup>[10,11]</sup>. The experimental and clinical methods for early detection of gut ischemia or NEC include serum hexosaminidase, plasma amylin, serum cytosolic β-glucosidase activity, plasma pro- and anti-inflammatory cytokines, serum creatinine kinase isoenzymes, cerebro-splanchnic oxygenation ratio, GI tonometry, rectosigmoid pH monitoring, urinary EGF, D-lactate, or thromboxane, breath hydrogen, and MRI<sup>[8]</sup>. Most of these methods do not have high clinical utility either due to accessibility issues, high costs, and need for expert assistance or due to their poor properties as a diagnostic/screening test especially in the early stages of NEC. Some infants present so acutely and severely that morbidity or mortality cannot be avoided despite best treatment. Identification of a biological marker for early disease should allow more timely diagnosis and treatment, but no ideal marker has yet been identified. The serum of symptomatic infants tends to contain high concentrations of certain cytokines such as interleukin-8 (IL-8)<sup>[15]</sup>. Some studies suggest that serum concentrations of fatty acid binding protein in the intestine and liver (I-FABP and L-FABP) could also be used as markers for NEC<sup>[16,17]</sup>. L-FABP concentrations at the onset of clinical signs are highest in infants later diagnosed with stage I NEC and I-FABP concentrations are highest in infants who later develop stage III NEC<sup>[16,17]</sup>. More sensitive and accurate imaging studies, such as ultrasonography, could become helpful adjuncts to abdominal films in the diagnosis of NEC<sup>[18]</sup>. Further research is needed on new approaches for the medical management of NEC that might prevent disease progression and improved surgical outcomes to reduce complications such as short bowel syndrome.

### PATHOGENESIS

Although the exact etiology and pathogenesis of NEC remains elusive, it is well established that NEC is a

**Figure 1** Pathophysiology of necrotizing enterocolitis (NEC).

complex, multi-factorial disease<sup>[2]</sup>. Besides pre-maturity, research suggests that other potential predisposing factors are hypoxic-ischemic injury, feeding with formula milk and colonization by pathological bacteria<sup>[1]</sup> (Figure 1).

Recent studies have shown that carrier state of genetic polymorphisms may be associated with perinatal morbidity, including NEC<sup>[19]</sup>. The hallmarks of NEC are loss of gastrointestinal motility, disruption of intestinal mucosal integrity, and mucosal inflammation, all of which result in the final common pathway, intestinal apoptosis and necrosis<sup>[4,20-23]</sup>. Several inflammatory and vasoactive mediators including platelet activating factor (PAF), cytokines, nitric oxide (NO), endothelin-1 (ET-1), prostaglandins, leukotrienes, and reactive oxygen species (ROS) are considered to play a synergistic and central role in the final inflammatory pathway leading to NEC<sup>[20]</sup>. The consequent breakdown of the mucosal barrier and impaired ability of the mucosa to heal leads to the self-perpetuating vicious cycle resulting in severe NEC, shock, sepsis, and sometimes death<sup>[8,24,25]</sup>.

### **Prematurity**

Prematurity is the only factor consistently found in epidemiological studies to be an independent determinant of NEC<sup>[2]</sup>. Up to 90% of infants with NEC are of low birth weight and the disease is more frequent and severe in those infants with the earliest post-conceptual age<sup>[7]</sup>. The increased susceptibility is attributed to an immature mucosal barrier and barrier response, changing intestinal microflora and increasing enteral volumes<sup>[2,23]</sup>.

### **Immature intestinal motility, digestion, and barrier function**

Intestinal motility is a critical factor in clearing antigens presented to the intestinal mucosal barrier from the gut lumen. The time available for absorption depends on the speed of luminal contents. Migratory motor complexes act as “house keepers” to propel luminal components caudally along the length of the small intestine. Immature intestinal motility and digestion may predispose preterm infants to NEC. Fetal studies in both animals and humans suggest that development of gastrointestinal motility begins in the second trimester, but matures in the third trimester<sup>[26-28]</sup>. Studies of intestinal motility have shown

that premature infants can have immature motility patterns when compared with full-term infants and that maternal-fetal disease states that induce fetal hypoxia can further reduce postnatal intestinal motility<sup>[29-31]</sup>. Immature motility patterns alter normal peristaltic activity and result in overgrowth of anaerobic bacteria in the small intestine with malabsorption of dietary nutrients<sup>[23]</sup>. In addition, to impaired intestinal motility, premature infants have not yet developed the ability to digest and absorb nutrients and incompletely digested molecules could contribute to intestinal injury<sup>[32,33]</sup>. Leberthal and Lee<sup>[34]</sup> showed that the function of the exocrine pancreas is limited in infants and that pancreatic insufficiency may last through the first year of life. Lack of stimulation of gastric acid and pancreaticobiliary secretions and their resulting proteolysis may adversely affect the intestine by allowing a greater bacterial and/or antigenic load. Thus, impaired digestion of nutrients, coupled with delayed transit time and bacterial overgrowth could result in intestinal injury with immature host and barrier defenses.

If structural or biochemical components of the intestinal epithelial barrier are not fully developed, bacteria may gain access to deeper tissues and cause inflammation. Intestinal epithelia are joined by tight junctions that regulate intestinal permeability and form by 10 wk gestation<sup>[35]</sup>. Studies show that intestinal permeability to macromolecules including immunoglobulins, proteins, and carbohydrates is highest in premature infants, particularly in those diagnosed with NEC<sup>[20,23]</sup>. When fully developed, the intestinal epithelial barrier can allow selective permeability to small ions, absorption of nutrients and control of bi-directional fluid flow. Enterocytes use chloride ions and water secretion to flush unwanted pathogens or toxins from the intestinal lumen. Fetal intestinal secretion and absorption are underdeveloped in preterm infants and mature gradually, under the influence of amniotic fluid, from 26 wk gestation to full-term<sup>[32]</sup>. Therefore, pathogens or toxins might not be efficiently washed from the intestinal lumen and could translocate across the leaky intestinal barrier in preterm infants.

Goblet cells are found throughout the small and large intestine. These specialized enterocytes secrete mucins, forming a thick protective layer over the intestinal mucosa. This mucus layer impedes direct microbial-epithelial binding and enhances removal of adherent bacteria<sup>[36]</sup>. Preterm infants have immature goblet cells. Developmental expression of mucin genes changes throughout the intestine and matches adult pattern expression between 23 and 27 wk gestation<sup>[37]</sup>. Microvilli of immature intestine also have altered glycosylation patterns<sup>[38]</sup>. Since carbohydrate sequences are recognition and attachment sites for microbes, changes in glycosylation patterns may influence the bacterial colonization pattern of the gut. An immature mucin layer might lead to increased intestinal permeability and enhanced bacterial adherence, potentially breaching the intestinal epithelial barrier and increasing susceptibility to injury.

Another aspect of the intestinal epithelial barrier that may not be functioning correctly in preterm infants is biochemical defenses. Paneth cells, which are specialized

secretory enterocytes located at the base of small intestinal crypts, secrete lysozyme, phospholipase A<sub>2</sub>, and antimicrobial peptides (also secreted by absorptive enterocytes) that regulate composition and distribution of different bacterial populations<sup>[39,40]</sup>. Defensins ( $\alpha$  and  $\beta$ ) and cathelicidins are the two main families of antimicrobial peptides produced by intestinal cells<sup>[40]</sup>. These antimicrobial peptides have bioactivity against a wide range of microbes including bacteria, viruses, and fungi<sup>[41]</sup>. Some have a pro-inflammatory role and chloride secretory activity<sup>[42,43]</sup>. A better understanding of how biochemical defense molecules modulate host immune defenses *in vivo* should contribute to understanding the pathophysiology of NEC.

It is well established that growth factors, growth factor receptors, or their related signal transduction pathways are aberrant in the immature intestine. Epidermal growth factor (EGF) is a major trophic factor for the development of the intestine and the EGF receptor has been identified on the basolateral surface of enterocytes<sup>[44]</sup>. Exogenous infusion of EGF *in utero* has been shown to accelerate the maturation of intestinal enzyme activity as well as stimulate intestinal growth<sup>[45]</sup>. In the amniotic fluid, there is an increasing concentration of EGF as gestation progresses<sup>[46]</sup>. In fact, the salivary level of EGF is directly proportional to the gestational age of the infant<sup>[46]</sup>. Moreover, expression of EGF receptor involved in intestinal maturation and restitution is decreased in the preterm infant<sup>[7]</sup>. Recently, human data suggests a link between EGF production and NEC. Serum and salivary levels of EGF are significantly reduced in infants with surgical NEC<sup>[47]</sup>. Preliminary studies on the clinical use of EGF report improved epithelial regeneration with no significant toxicities<sup>[48]</sup>.

It is unclear whether the intestinal epithelium of the infant can respond to injury to the same extent as the adult. In animals, infant intestinal epithelium turnover is much slower (4-5 d) than the adult (2 d)<sup>[49]</sup>. If the same finding holds true in humans, regeneration of injured mucosa in the infant will be much slower than the adult. Trefoil factor peptides (TFF1-3) are part of the protective mechanism operating in the intestinal mucosa and play a fundamental role in epithelial protection, repair, and restitution<sup>[50]</sup>. These secreted peptides have been identified in a site-specific pattern in the gastrointestinal mucosa and their expression has been shown to be up-regulated in early stages of mucosal repair<sup>[51,52]</sup>. The role of trefoil peptides in neonatal mucosal protection has not been well investigated. Intestinal trefoil factor is developmentally regulated and deficient in the premature neonate<sup>[20]</sup>. Recent studies demonstrated a lack of trefoil factor expression in response to NEC in the premature gut<sup>[53]</sup> and an insufficient proliferative response to reverse the mucosal insult observed in NEC<sup>[54]</sup>. Thus, impaired restitution of the mucosa may contribute to the cascade of bowel necrosis and generalized sepsis characteristic of NEC.

### **Immature intestinal immunity**

Although the fetus at term may be sensitized to certain antigens, the fetus does lack a fully functional immune

system and has a sterile gastrointestinal tract. Changes occur at, and soon after birth, in order that the immune system of the neonate becomes competent and functional and that the gut becomes colonized with bacteria. Exposure to bacteria during birth and from the mother's skin and the provision of immunological factors in breast milk are amongst the key events that promote maturation of the infant's gut and gut-associated immune system<sup>[55]</sup>. Dendritic cells play an important role in the initiation of the immune response. Microbial and antigenic-priming of dendritic cells develops different signals that drive the differentiation of naïve Th cells into Th1, Th2 or T regulatory cells<sup>[56]</sup>. Developmental changes in glycosylation patterns of immature dendritic cells may play an important role in development, maturation, and immune regulation<sup>[57]</sup>.

Innate and adaptive immune defense systems are abnormal in developing neonates<sup>[20]</sup>. A possible mechanism for the pathophysiology of NEC is that reduced inflammatory signaling could allow bacterial overgrowth. Newborns are Th2 polarized and do not respond efficiently to IFN- $\gamma$ <sup>[58]</sup>. Moreover, newborn macrophages exposed to LPS are defective in producing pro-inflammatory cytokines including tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-1 $\beta$  (IL-1 $\beta$ ), interleukin-6 (IL-6) and interleukin-12 (IL-12)<sup>[58,59]</sup>. Interestingly, inhibitory activity to toll receptors in neonatal but not adult plasma has been detected<sup>[60]</sup>. Neonatal monocyte and T cell production of the anti-inflammatory cytokines interleukin-10 (IL-10) and TGF- $\beta$  are developmentally delayed<sup>[61]</sup>. Preterm infant polymorphonuclear (PMN) counts are lower and premature neonatal macrophages have reduced respiratory burst activation as compared with term newborns<sup>[62]</sup>. Under conditions of stress, PMNs of term and preterm infants do not function with normal phagocytic and microbicidal activities<sup>[63]</sup>. PMNs isolated from the blood of term and preterm neonates consistently display diminished chemotactic and adhesion capacities<sup>[64]</sup>. It is known that intestinal lymphocytes are decreased in neonates (B and T cells) and do not approach adult levels until 3-4 wk of life<sup>[20]</sup>. Newborns also have markedly reduced synthesis of secretory IgA and IgG in response to mitogens, reflecting decreased activity in the intestine<sup>[20]</sup>. Failure to activate inflammatory pathways in premature infants might prevent induction of anti-apoptotic, cytoprotective factors. Thus, developmental immaturity of the inflammatory response could increase susceptibility to apoptosis when cells are challenged by environmental stress.

Long-term survival requires inflammation as a defense mechanism, however, uncontrolled inflammation results in intestinal barrier damage, translocation of pathogens, further inflammation, and tissue damage. Some *in vitro* studies suggest that immature intestinal cells have a propensity for exaggerated inflammatory responses to pathogenic stimuli and researchers postulate that developmentally deficient expression of the NF- $\kappa$ B inhibitor I $\kappa$ B might allow greater NF- $\kappa$ B activity<sup>[65,66]</sup>. NF- $\kappa$ B is a nuclear transcription factor that enhances the production of inflammatory mediators and is essential for innate immunity, adaptive immunity and cell survival<sup>[67]</sup>. In the human newborn, PAF-AH activity is decreased and

**Table 2** Ischemic events associated with necrotizing enterocolitis

Perinatal asphyxia
Polycythaemia
Cyanotic congenital heart disease
Patent ductus arteriosus
Medications that ↓ superior mesenteric blood flow (cocaine)
Maternal pre-eclampsia

PAF synthesis pathways are increased. This imbalance places the newborn at special risk of an increased PAF response before adequate immune stimuli are developed<sup>[7]</sup>.

### Hypoxia-ischemia

Pathological findings of NEC associated with ischemic events (coagulative necrosis, Table 2) and the fact that NEC most commonly occurs in the distal ileum and proximal colon, which make up the watershed area of the superior and inferior mesenteric arteries, suggests that derangement of the circulatory system is involved<sup>[7]</sup>.

Preterm neonates are more susceptible to hypoxia and intestinal ischemia because their system for regulating vascular resistance is poorly developed<sup>[68]</sup>. The most distinguishing feature of the newborn intestinal circulation is its very low vascular resistance due to substantial generation of endothelial derived NO when compared with ET-1<sup>[69]</sup>. Immature intestine handles the increased metabolic demands of growth by increasing blood flow and oxygen consumption<sup>[10]</sup>. However, during episodes of cardiovascular stress, infants are less able to raise intestinal blood flow and metabolic demands overwhelm the infant's ability to increase oxygen consumption<sup>[10]</sup>. Defective pressure flow autoregulation in response to hypotension occurs<sup>[68]</sup>. Consequently, hypoxia in tissues can occur. Hypoxia increases production of vasoconstrictor ET-1 and ischemia/reperfusion compromises production of endothelial derived vasodilator NO<sup>[69]</sup>. Thus, an imbalance between ET-1 and NO production by the newborn intestine following an initial ischemic insult might exacerbate existing intestinal ischemia. Whether the hypoxic/ischemic insult is primary, secondary or both an initiating factor and end result remains controversial. One plausible mechanism that is often cited is the "diving reflex", whereby blood flow is preferentially diverted to the heart and brain in preference to less vital organs<sup>[1]</sup>. Very early descriptions regarding the pathogenesis of NEC suggested a primary or early role for ischemia and hypothesized that a hypoxic/ischemic insult directly damaged the intestinal mucosa disrupting the neonatal gut barrier and promoting bacteria translocation and the inflammatory cascade<sup>[21]</sup>. Animal models suggest that NEC may not occur without significant reperfusion injury resulting from the generation of oxygen-free radicals at the restoration of blood flow and oxygen delivery after ischemia<sup>[9]</sup>. Inflammatory mediators may also cause intestinal ischemia by up-regulating ET-1 production and the expression of its receptor ET<sub>A</sub><sup>[69]</sup>. Current studies show a stronger association with prematurity, rapid feeding, abnormal intestinal colonization and inflammatory

mediators than with ischemia<sup>[23]</sup>. Hypoxia-ischemia might contribute to the pathogenesis of NEC, but it likely plays more of a secondary role.

### Formula feeding

Enteral feeds have a firm association with NEC as 90%-95% of NEC cases occur in infants with initiation/re-initiation of enteral feeds or recent volume advancement<sup>[2,20]</sup>. Infants receiving hyperosmolar formulas or rapid volume advancements are at greatest risk<sup>[20]</sup>. Although the mechanism is not well understood, enteral feeding has been reported to contribute to the development of NEC through disruption of mucosal integrity, blood flow and motility and through provision of a bacterial substrate<sup>[2,10]</sup>. Raising milk intake increases metabolic demands, making it difficult for the infant to expand mesenteric blood flow to meet demands<sup>[10]</sup>. As a result, intestinal hypoxemia may occur. Increased proliferation of potentially pathogenic bacteria may go on to invade the bowel wall<sup>[10]</sup>. Although the newborn gastrointestinal tract is sterile at birth, bacterial colonization occurs within hours<sup>[10]</sup>. Contact with the mother's vaginal flora begins this process, which is further developed by oral feedings and exposure to the environment<sup>[10]</sup>. In fact, breast fed infants are 10X less likely to develop NEC than formula fed infants, suggesting that breast milk contains multiple bioactive factors that influence host immunity, inflammation and mucosal protection. Breast milk notably increases the diversity of gastrointestinal bacterial colonization and contains immunomodulatory factors such as secretory immunoglobulin A, leukocytes, mucin, lysozyme, cytokines, lactoferrin, growth factors, enzymes, oligosaccharides, and polyunsaturated fatty acids not provided in commercially available neonatal formula preparations<sup>[20,55]</sup>. These factors are capable of inducing mucosal protection and neutralizing potent pro-inflammatory cytokines and phospholipids<sup>[55]</sup>. Glutamine and nucleotides may help in gastrointestinal cell metabolism<sup>[10]</sup>. EGF can directly improve gastrointestinal function and promote gut maturity<sup>[25]</sup>.

### Abnormal bacterial colonization and infection

The well-documented epidemics of NEC and the improvement in incidence and severity following the implementation of strict infection control measures validates the role of infection in the pathogenesis of NEC<sup>[2]</sup>. Furthermore, the regions of the intestine that are most often associated with NEC (ileum and proximal colon) have very high bacterial loads. Moreover, no cases of NEC have been described *in utero*, supporting the importance of bacteria colonization in the pathophysiology of NEC<sup>[20]</sup>.

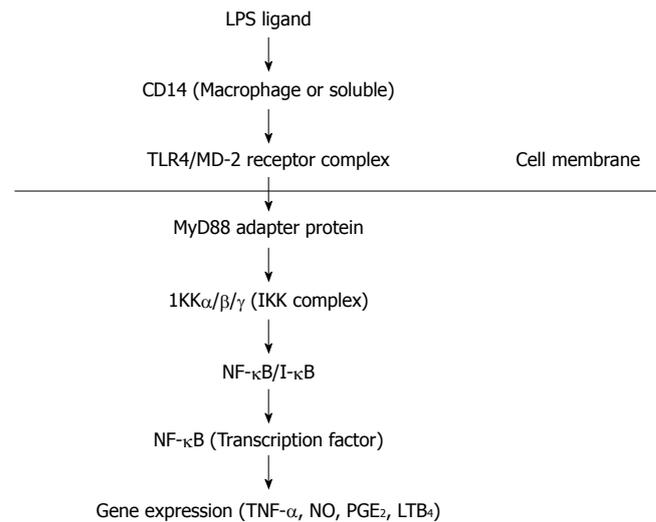

Although several bacterial and viral species have been associated with outbreaks of NEC (*Clostridium* sp, *Klebsiella* sp, *Staphylococcus epidermis*, *Escherichia coli*, *Rotavirus*), no single pathogen has been identified as causative and the ability of the microflora to colonize the epithelium and to ferment unabsorbed nutrients may be more important than the strain itself<sup>[13,70]</sup>. Recently, early abnormal colonization of stools with *Clostridium perfringens* has been correlated with later development of NEC<sup>[71]</sup>. *Clostridium perfringens* has

been isolated from 40% of infants with NEC, compared with 13% of controls<sup>[71]</sup>. Premature infants are especially susceptible to intestinal colonization by pathological bacteria due to their daily exposure to nosocomial flora and the likelihood of exposure to antibiotics and steroids on admission to NICUs<sup>[72]</sup>.

Colonization of the gastrointestinal tract of the premature infant differs greatly from that of the healthy term infant<sup>[9,20]</sup>. Patterns of intestinal colonization also vary according to the type of enteral feeding<sup>[3]</sup>. The colonization of the hospitalized, premature infant gastrointestinal tract has less species diversity and fewer anaerobic species of *Lactobacillus* and *Bifidobacterium*<sup>[9,20]</sup>. Breast-fed infants have large amounts of protective, gram-positive *Bifidobacteria* in their intestine, contrasting with formula-fed neonates who are colonized predominantly by potentially pathogenic gram-negative *Enterobacteria*<sup>[3]</sup>. Gram-positive bacteria yield lactic acid during carbohydrate metabolism, which is readily absorbed from the intestinal lumen, whereas gram negative-bacteria ferment lactose into hydrogen, carbon dioxide and organic acids, producing distension, increased intraluminal pressure, decreased mucosal blood flow and pneumatosis intestinalis<sup>[3]</sup>. Enteral feeds and poor gastrointestinal motility associated with immaturity may promote stasis and bacterial overgrowth<sup>[3]</sup>. This microbial imbalance may represent a fertile environment for the pathologic overgrowth, binding and invasiveness of otherwise non-pathogenic intestinal bacterial species capable of triggering the inflammatory cascade with resultant NEC<sup>[9]</sup>. Recently, inappropriate immunologic responses of premature enterocytes to bacteria colonization have been implicated in the development of NEC<sup>[13]</sup>. Reports indicate that pathogenic stimuli including *Salmonella* and *E. coli*, produce exaggerated pro-inflammatory responses in immature intestinal epithelial cells<sup>[65,66]</sup>.

Abnormal expression of pattern recognition receptors that recognize microbial signatures might also affect the way in which the intestine in premature infants responds to bacterial colonization. One of the first pro-inflammatory molecules to cross the intestinal barrier is lipopolysaccharide (LPS), which is a principal component of the outer cell wall of Gram-negative bacteria that recognizes and binds to toll like receptor 4 (TLR4)<sup>[21]</sup>. Circulating LPS is increased in patients with NEC, which inhibits epithelial restitution and initiates inflammatory signaling cascades within the enterocyte including activation of transcription factor NF- $\kappa$ B and expression of enzymes that produce apoptotic NO and pro-inflammatory eicosanoids and cytokines<sup>[21]</sup> (Figure 2).

In rats, intestinal epithelial cells up-regulate expression of TLR4 in response to stress-induced production of PAF, suggesting that up-regulation of TLR4 might explain how NEC develops in this animal model<sup>[73]</sup>. It remains unclear whether bacterial translocation into submucosa is a prerequisite for disease or whether the activation of the Toll-like receptors from endotoxin and other bacterial cell wall products is adequate to initiate the final common pathway of intestinal injury<sup>[20]</sup>. For premature infants at risk for NEC, there may be increased passage of bacteria

**Figure 2** LPS-Induced signaling pathways leading to NF- $\kappa$ B activation.

from the gut into the systemic circulation and exaggerated pro-inflammatory responses<sup>[10]</sup>. Most of the defenses that would normally prevent passage of bacteria across the mucosal barrier—a well-functioning immune system, intact mechanical defenses and normal intestinal microflora are impaired in patients who are at risk for NEC<sup>[10]</sup>. Gram-negative bacteria translocate to regional lymph nodes and activate resident macrophages to release inflammatory mediators<sup>[2]</sup>. Bacteria endotoxins can leak into the systemic circulation causing release of inflammatory mediators, intestinal damage, shock and death<sup>[2,10]</sup>.

Commensal bacteria interact symbiotically with the mammalian intestine to regulate the expression of genes important for barrier function, digestion, and angiogenesis<sup>[74]</sup>. Commensal bacteria can inhibit inflammatory pathways and perhaps contribute to the maintenance of homeostasis<sup>[75]</sup>. *In vitro* experiments show that a wide range of commensal bacteria can reduce inflammatory signaling in intestinal epithelia by inhibition of the NF- $\kappa$ B signaling pathway<sup>[76,77]</sup>. Preliminary work suggests that early colonization by probiotics (facultative anaerobes such as *Lactobacilli* and *Bifidobacteria*) reduces the risk of NEC in very low birth weight infants<sup>[78,79]</sup>.

### Genetics

Investigation of factors that might cause a genetic predisposition for NEC might eventually allow specific treatments or preventative strategies for the infants most at risk for this disease. Current technology allows for the detection and evaluation of genetic polymorphisms and their influence on disease development. Studies are now emerging which investigate the potential importance of specific polymorphisms for known NEC-associated inflammatory mediators. The presence of genetic variance may contribute to the inter-individual variance of cytokine response to inflammatory stimuli<sup>[19]</sup>. A family of intracytoplasmic pathogen recognition receptors has been shown to sense invading bacteria and activate gene transcription pathways that regulate immune and inflammatory responses. In a recent clinical study, VLBW

infants with mutations in a member of this family, NOD2, demonstrated increased susceptibility to bacterial sepsis<sup>[80]</sup>. Genetic polymorphisms of CD14, TLR4, and NOD2 are not associated with NEC in VLBW infants<sup>[81]</sup>. In preliminary studies, VLBWI with NEC were shown to be less likely to possess the interleukin-4 (IL-4) receptor  $\alpha$ -chain mutant allele compared to infants without NEC<sup>[19]</sup>. The investigated variant of IL-4 receptor  $\alpha$  gene is associated with enhanced transduction of IL-4 signals which shifts the development of lymphocytes to a more pronounced Th2 state<sup>[19]</sup>. It is speculated that the elevated number of Th2 cells in carriers of this genetic polymorphism is a protective factor against the development of NEC<sup>[19]</sup>. The risk of NEC has also associated with the frequency of the IL-18<sup>607</sup> AA genotype. The frequency of the AA genotype is significantly higher in infants with stage 3 NEC compared to stages 1 and 2<sup>[19]</sup>. Thus, the presence of the AA genotype may adversely affect the outcome of NEC through altered IL-18 levels, a cytokine that induces IFN- $\gamma$  and amplifies Th1 cytokine production and IL-8 accumulation<sup>[19]</sup>. Another possible genetic factor is the pro-inflammatory cytokine TNF- $\alpha$ . In animal models, pretreatment with anti-TNF- $\alpha$  reduces the incidence and severity of NEC<sup>[82,83]</sup>. Investigators have not reported a genetic link between TNF- $\alpha$  gene variants and the disease<sup>[84]</sup>.

### **Vasoactive and inflammatory mediators**

Bacterial colonization and enteral feeds coupled with damage to and loss of the integrity of the immature gastrointestinal mucosa trigger the final common pathway leading to the development of NEC<sup>[9]</sup>. Inflammatory mediators are responsible for protecting the body from invading organisms and play a vital role in the pathogenesis of NEC<sup>[3]</sup>. Inflammation can be initiated by a variety of factors including exposure to the bacterial cell wall product, endotoxin, and ischemia reperfusion<sup>[20]</sup>. The release of potent biologically active phospholipids, cytokines, products of arachidonic acid metabolism, vasoactive mediators, neurotransmitters, and reactive oxygen species from the immature and damaged gastrointestinal cells and inflammatory cells amplify the inflammatory response, leading to tissue damage and NEC<sup>[9]</sup>. Studies of animals and human cell lines suggest that the balance between pro-inflammatory and anti-inflammatory modulatory factors in premature infants is pro-inflammatory<sup>[9]</sup>.

### **NO**

NO is a short-lived, labile free radical gas that reacts with a variety of biologically active substances<sup>[85]</sup>. Such reactions result in both local and systemic effects that modulate the inflammatory response in a variety of tissues<sup>[21]</sup>. The synthesis of NO in biological systems is regulated by nitric oxide synthase (NOS), which catalyzes the oxidation of the amino acid L-arginine to release citrulline and nitric oxide<sup>[21]</sup>. Although diverse molecular reactions of NO have been identified in physiological and pathological systems, the fastest and most biologically relevant reaction of NO is with superoxide to produce the potent oxidant peroxynitrite<sup>[21]</sup>. Peroxynitrite is a

key intermediate that is generated at inflammatory sites and is responsible for mediating tissue injury, in part, through lipid peroxidation<sup>[21]</sup>. Three isoforms of NOS exist: Neuronal (nNOS) and endothelial (eNOS), which are calcium/calmodulin dependent and constitutively expressed, releasing physiologically low concentrations of nitric oxide (pM) and the calcium independent inducible isoform (iNOS), which releases toxic concentrations of nitric oxide (nM) in response to infection and inflammatory stimuli<sup>[86]</sup>. All three isoforms are expressed in the gastrointestinal tract<sup>[21,86]</sup>. The constitutive forms are expressed by endothelial cells, enteric neurons, gastric epithelial cells, and enterocytes<sup>[86]</sup>. In the gastrointestinal tract, NO mediates inhibitory nerve-related relaxation of intestinal smooth muscle and plays a role in regulating gut mucosal blood flow, mucosal permeability, intestinal motility and mucosal protection<sup>[85,86]</sup>. Normal smooth muscle sphincteric function as well as coordinated peristalsis is dependent on the integrity of intrinsic nitric oxide neurons of the myenteric and submucosal networks throughout all regions of the gut wall<sup>[85]</sup>. NO also maintains intestinal microvascular integrity by inhibiting platelet aggregation and leukocyte adhesion<sup>[86]</sup>. Ontogenic variation in constitutive NOS activity has been observed in different animal species, in humans and in different organs<sup>[85]</sup>. By contrast, iNOS expression and activity within the intestinal epithelium is normally low, although it may be increased 15-fold after 4 h stimulation with LPS<sup>[21]</sup>. NO and peroxynitrite have anti-microbial properties and play important roles in host defense against pathogens<sup>[86]</sup>. However, sustained high levels of NO production promote bacteria translocation following insults such as endotoxemia and ischemia-reperfusion injury<sup>[86]</sup>. The induction of iNOS mRNA expression by inflammatory mediators has been seen in animal models of NEC and in intestinal resections from patients with NEC where the predominant source of iNOS activity was the enterocytes. Endothelial NOS function is compromised in human intestine resected for NEC<sup>[87]</sup>. Poorly coordinated production of NO by NOS isoforms occur during the early phase of the disease and are involved in altered intestinal blood flow, ischemic damage, disassembly of tight junction proteins, and impaired healing typically seen in NEC<sup>[13]</sup>. Research suggests that NO participates in the pathogenesis of NEC by directly damaging the enterocyte monolayer and by disrupting the ability of the mucosa to repair itself<sup>[21]</sup>. Extensive apoptosis has been shown in the enterocytes of the apical villi of infants with NEC and this correlates with the degree of nitrotyrosine immunostaining, a marker of NO release and tissue reactivity<sup>[88]</sup>. Toxic concentrations of NO have also been shown to decrease enterocyte proliferation and inhibit enterocyte migration<sup>[21]</sup>. It is proposed that peroxynitrite interferes with EGF receptor signaling in enterocytes<sup>[89]</sup>.

### **ET-1**

ET-1, a potent vasoconstrictor agent, is produced at several sites within the intestine including vascular endothelial cells, submucosal stroma, and circularis muscularis layers of the gut wall<sup>[69]</sup>. Although constitutively produced,

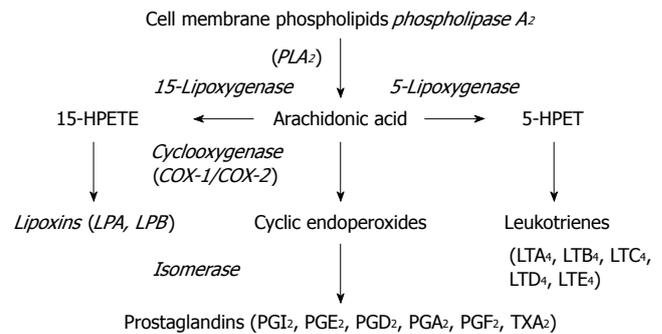

ET-1 production is increased by a wide range of stimuli including reduced flow rate, hypoxia and inflammatory cytokines<sup>[69]</sup>. ET-1 generates a profound degree of ischemia that is sustained for hours because of a unique interaction between ET-1 and its receptor<sup>[69]</sup>. If not balanced by concomitant vasodilatory stimuli, ET-1-induced ischemia can generate hypoxia and tissue death<sup>[69]</sup>. ET-1 induces vasoconstriction by binding to ET<sub>A</sub> receptors present within the newborn intestine and whose activation can generate intestinal tissue damage when excessive amounts of ET-1 are present<sup>[69]</sup>. Recently, ET-1 was demonstrated to be associated with NEC. It has recently been shown that the tissue concentration of ET-1 is greater in human preterm intestine that demonstrates histologic evidence of NEC<sup>[90]</sup>. Moreover, it has been demonstrated that arterioles harvested from intestine exhibiting histologic evidence of NEC exhibits vasoconstriction and that the vasoconstriction can be reversed by blocking ET<sub>A</sub> receptors<sup>[90]</sup>.

### Serotonin

Serotonin is an intermediate product of tryptophan metabolism and is primarily synthesized and released by enterochromaffin cells of the intestine (90%) and enteric/brain neurons (10%) in response to calcium influx, physical mucosal stimulation, nutrients, hypoxia, and elevations in intraluminal pressure<sup>[91]</sup>. Levels of serotonin in the gastrointestinal tract are regulated by a serotonin uptake transporter, SERT, present in the mucosa and enteric nerves<sup>[92]</sup>. The major function of serotonin in the gastrointestinal tract is stimulation of bowel motility, epithelial secretion, and vasoconstriction through serotonin receptor binding<sup>[91]</sup>. Disruption of serotonin homeostasis and signaling is commonly seen in several gastrointestinal motility and inflammatory disorders including bowel obstruction and inflammatory bowel disease<sup>[93]</sup>. In inflammatory bowel disease, serotonin levels and enterochromaffin cell numbers are increased<sup>[93]</sup>. The inflamed intestinal tissue releases more serotonin, has a reduced capacity to remove serotonin and the serotonin receptors are desensitized<sup>[93]</sup>. Some cases of NEC have been associated with maternal use of paroxetine, a long-acting serotonin re-uptake inhibitor<sup>[94]</sup>.

### PAF

PAF, an endogenous phospholipid with powerful pro-inflammatory actions, is synthesized by neutrophils, macrophages, endothelial cells, and enterocytes in response to endotoxin and hypoxia<sup>[10]</sup>. PAF formation begins with the conversion of a phosphatidylcholine precursor to a biologically inactive intermediate, lysoPAF, under the influence of cytosolic phospholipase A<sub>2</sub><sup>[73]</sup>. Subsequent acetylation of lysoPAF at the n-2 position by acetyltransferase completes PAF synthesis<sup>[73]</sup>. PAF has a very short half life as it is rapidly degraded by PAF-acetylhydrolase<sup>[73]</sup>. In the human newborn, PAF synthesis pathways are increased and the activity of the PAF-degrading enzyme PAF-acetylhydrolase is decreased<sup>[7]</sup>. This imbalance places the newborn at special risk of an elevated PAF response before adequate immune stimuli are

**Figure 3** Metabolic pathways of arachidonic acid and eicosanoid production.

developed<sup>[7]</sup>. Formula does not contain PAF-AH like human milk, leaving susceptible neonates at greater risk for NEC. PAF exerts its effects by binding to PAF receptors present on most cells<sup>[73]</sup>. Interestingly, PAF receptors are most highly concentrated in the ileum, the region of the intestine where NEC is very prominent<sup>[24]</sup>. Down-stream signaling includes elevation of cytoplasmic free calcium and stimulation of protein kinase C, mitogen-activated protein kinase (MAPK), and NF- $\kappa$ B with production of inflammatory molecules including iNOS, TNF- $\alpha$ , ET-1, IL-1, IL-6, and IL-8<sup>[73]</sup>. PAF also activates pathways that result in caspase activation and apoptosis<sup>[73]</sup>. PAF is one of the most extensively studied mediators of intestinal injury and has been indicated as an important mediator in several animal models and human analyses of NEC<sup>[4]</sup>. PAF infusion causes intestinal necrosis in animals and PAF receptor antagonists prevent injury following hypoxia, endotoxin challenge and ischemia reperfusion injury<sup>[20]</sup>. Human patients with NEC show high levels of PAF and decreased levels of plasma PAF-AH with levels correlating with NEC severity<sup>[4,24]</sup>. In immature or mildly damaged mucosa, the close proximity of bacteria and intestinal epithelial cells aids transcellular permeation of PAF into the mucosa and local entry of bacteria<sup>[10]</sup>. Injection of LPS and bacterial invasion leads to increased production of platelet activating factor, release of secondary inflammatory mediators and further mesenteric ischemia and damage causing clinical NEC<sup>[10,24]</sup>.

### Eicosanoids

Arachidonic acid is a polyunsaturated fatty acid that is liberated from cell membrane phospholipids and serves as a precursor for many immune active lipids, collectively called eicosanoids (oxygenated C20 fatty acids)<sup>[95,96]</sup>. Classes of eicosanoids that signal in the immune system include prostaglandins, leukotrienes and lipoxins<sup>[95]</sup>. The major producers of eicosanoids are platelets, monocytes, macrophages, neutrophils, and mast cells, although with the exception of leukotrienes, they are also synthesized by a variety of non-immune cell types<sup>[95]</sup>. These lipid mediators are not stored in cells rather they are synthesized from arachidonic acid via three major metabolic pathways, either constitutively or in response to cell-specific trauma, stimuli, or signaling molecules<sup>[96]</sup> (Figure 3).

The 15-lipoxygenase metabolic pathway results in the production of 15-hydroxyperoxy-eicosatetraenoic acid (15-HPETE) that serves as a precursor for the lipoxins

Table 3 Eicosanoid synthesis and actions

Eicosanoid	Cell/tissue origin	Target cell/tissue	Receptor	Action
PGE2	Most cells	Many cells	EP1-EP4	Fever, pain
PGI2	Endothelium	Platelet VSMC	IP	Declumping, vasodilation
PGF2	Uterus	Uterine SMC	FP	Contraction
PGD2	Mast cells	Lung Th2 cells	DP1/DP2	Asthma, chemotaxis
TXA2	Platelets	Platelet VSMC	TP $\alpha$ /TP $\beta$	Aggregation, vasoconstriction
LTB4	Macrophage monocytes	Neutrophils	BLT1/BLT2	Promotes chemotaxis
LTC4/LTD4/LTE4	Macrophage monocytes	Lung SMC	BLT3/BLT4	Bronchoconstriction
LXA4	Leukocytes	Neutrophil	LXA4 R	Inhibits chemotaxis
LXB4	Leukocytes	NK cells	?	Inhibits cytotoxicity

LPA and LPB. Lipoxins exert anti-inflammatory activities through stimulation of macrophage phagocytosis of apoptotic neutrophils and inhibition of natural killer (NK) cell cytotoxicity and pro-inflammatory factor production<sup>[97,98]</sup>.

Prostaglandins are end products of metabolism of arachidonic acid by constitutive and inducible cyclooxygenase isoforms (COX-1 and COX-2, respectively)<sup>[96]</sup>. The COX-1 enzyme accounts for basal prostaglandin synthesis for homeostatic regulation while COX-2 is involved in the synthesis of pro-inflammatory prostaglandins<sup>[96]</sup>. Leukotrienes are generated during the metabolism of arachidonic acid by the 5-lipoxygenase pathway and exert pro-inflammatory effects<sup>[95]</sup>. Prostaglandins and leukotrienes are emitted from their cell of origin and exert their effects in an autocrine or paracrine fashion by signaling through specific G-protein coupled receptors<sup>[95]</sup> (Table 3).

### Cytokines

Pro-inflammatory cytokines are multifunctional proteins produced in response to inflammatory stimuli that communicate to the surrounding tissue the presence of infection or injury. Several pro-inflammatory cytokines that mediate inflammatory cell recruitment through activation and amplification of the immune response in local host defense have been implicated in NEC including TNF- $\alpha$ , IL-1 $\beta$ , IL-6, IL-8, IL-12, and IL-18<sup>[99-101]</sup>. Anti-inflammatory cytokines modulate the host's inflammatory response and if they fail to achieve their goal, pro-inflammatory mediators can continue, resulting in tissue injury<sup>[4]</sup>. The anti-inflammatory cytokines IL-4 and IL-10 have been implicated in NEC<sup>[4]</sup>.

### Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF):

The colony stimulating factors are a group of cytokines central to the hematopoiesis of blood cells, the modulation of their functional responses as well as the maintenance of homeostasis and overall immune competence<sup>[102]</sup>. GM-CSF is produced by a variety of cell types including macrophages, T lymphocytes, fibroblasts, endothelial cells, B lymphocytes, mast cells, eosinophils, and neutrophils<sup>[103]</sup>. In some cases, production of GM-CSF is constitutive as in a number of tumor cells lines; however, in most cases it requires stimulation of the producing cell with other cytokines, antigens, or inflammatory agents<sup>[103]</sup>. All of the biological effects of GM-CSF are mediated via the GM-CSF receptor which signals through

MAPK and JAK/STAT pathways<sup>[103]</sup>. GM-CSF receptor expression is characterized by low number (20-200 per cell) and high affinity<sup>[103]</sup>. GM-CSF has pleiotropic and widespread effects on hematopoietic cells. It functions to promote the proliferation and maturation of neutrophils, eosinophils, and macrophages from bone marrow progenitors<sup>[103]</sup>. It also acts as a growth factor for erythroid and megakaryocyte progenitors in synergy with other cytokines<sup>[103]</sup>. The role of GM-CSF in cell survival results from apoptosis inhibitory mechanisms<sup>[103]</sup>. In addition to its role in the up-regulation of hematopoietic development, GM-CSF has been shown to have a profound influence on the biological functions of neutrophils, eosinophils, basophils, macrophages, lymphocytes, as well as endothelial cells<sup>[103]</sup>. These responses are widespread and point to a central role of GM-CSF in inflammation both through the direct activation of effector cells alone or in combination with other cytokines, as well as indirectly, through the stimulation of additional inflammatory mediator production<sup>[103]</sup>. Some of these biological effects include enhanced antigen presentation, chemotaxis, synthesis of a variety of soluble mediators and enzymes, release of reactive oxygen intermediates and histamines, antibody-dependent cell killing, and phagocytosis which contribute differentially to the immune defenses against bacterial, viral, fungal, and parasitic infections as well as tumor development<sup>[103]</sup>. Over-expression of GM-CSF leads to severe inflammation<sup>[104]</sup>. GM-CSF is used clinically to treat neutropenia in cancer patients undergoing chemotherapy, in AIDS patients during therapy and in patients after bone marrow transplant<sup>[103,105]</sup>.

**TNF- $\alpha$ :** TNF- $\alpha$  release is triggered by a number of inflammatory stimuli including endotoxin (LPS), gram positive bacteria enterotoxin, viruses, fungi, and parasites<sup>[106]</sup>. Important cell sources of TNF- $\alpha$  in the gut are macrophages, lymphocytes, NK cells, neutrophils, endothelial cells, smooth muscle cells, intestinal epithelial cells, and enteric glia<sup>[100,106]</sup>. TNF- $\alpha$  exerts its effects by binding to TNF receptors<sup>[107]</sup>. Binding to the TNF receptor initiates local inflammatory responses through cell activation<sup>[107]</sup>. TNF- $\alpha$  is released early following injury and leads to a cytokine release cascade of IL-1 $\beta$ , IL-6, and IL-8<sup>[100]</sup>. It also inhibits release of glucocorticoids and the regulatory cytokines TGF- $\beta$  and IL-10<sup>[106]</sup>. Some actions mediated by TNF- $\alpha$  include apoptosis induction, neutrophil activation, neutrophil recruitment, expression

of endothelium adhesion molecules, fever, and production and release of acute phase proteins, pro-inflammatory cytokines, NO, PGE<sub>2</sub>, matrix metalloproteases, PAF, and TXA<sub>2</sub><sup>[106]</sup>. The pro-inflammatory effects of TGF- $\alpha$  are mediated in part through NF- $\kappa$ B activation<sup>[106]</sup>. Elevated TNF- $\alpha$  has been detected in full thickness, resected bowel specimens of NEC intestine and in the plasma of babies with NEC<sup>[101]</sup>. In rat models of NEC, TNF- $\alpha$  induces hypotension, septic shock and severe intestinal necrosis synergistically with LPS<sup>[24]</sup>. Recently, a monoclonal anti-TNF- $\alpha$  antibody was demonstrated to reduce hepatic and ileal TNF- $\alpha$  production in a neonatal rat model of NEC<sup>[82]</sup>. Compared with other inflammatory bowel syndromes, TNF- $\alpha$  transcripts are lower in NEC<sup>[108]</sup>. Furthermore, studies indicate that the majority of TNF- $\alpha$  found in the gut lumen comes from Kupffer cells in the liver<sup>[99]</sup>. Taken together, these studies suggest that TNF- $\alpha$  plays a less significant role in the inflammatory cascade associated with NEC as compared with other intestinal inflammatory conditions.

**IL-1 $\beta$ :** IL-1 $\beta$  release is triggered by a variety of stimuli including microbial products, inflammation and TNF- $\alpha$ <sup>[100,109]</sup>. Important cell sources of IL-1 $\beta$  in the gut are macrophages, neutrophils, intestinal epithelial cells, endothelial cells, fibroblasts, dendritic cells, smooth muscle cells, and enteric glia<sup>[100,109]</sup>. IL-1 $\beta$  exerts its effects by binding to the IL-1 receptor and activating the transcription factor NF- $\kappa$ B<sup>[109]</sup>. Some actions mediated by IL-1 $\beta$  include macrophage activation, neutrophil recruitment, expression of endothelium adhesion molecules, fever, and production and release of acute phase proteins, IL-6, IL-8, and PGE<sub>2</sub><sup>[100,109]</sup>. Elevated IL-1 $\beta$  has been detected in full thickness specimens of NEC intestine<sup>[101]</sup>. Studies measuring plasma/serum IL-1 $\beta$  in NEC babies have not consistently reported elevated levels<sup>[13]</sup>. The difference in results may suggest that IL-1 $\beta$  is more predominant in the intestinal tissue in patients with NEC.

**IL-6:** IL-6 release is triggered by a variety of stimuli including microbes, microbial products, TNF- $\alpha$ , and IL-1 $\beta$ <sup>[100,110]</sup>. Important cell sources of IL-6 in the gut are macrophages, endothelial cells, and intestinal epithelial cells<sup>[110]</sup>. IL-6 exerts its effects by binding to the IL-6 receptor that signals through the STAT-4 pathway<sup>[110]</sup>. The IL-6 receptor is only expressed on hepatocytes and some leukocytes<sup>[110]</sup>. Some actions mediated by IL-6 include production of acute phase proteins, B cell growth, antibody production, T cell proliferation, and enhanced activity of hematopoietic growth factors such as GM-CSF<sup>[100,110]</sup>. Anti-inflammatory effects of IL-6 include production of tissue inhibitors of metalloproteinases and inhibition of superoxide production<sup>[111]</sup>. High levels of umbilical cord IL-6 have been associated with neonatal disease processes including NEC and systemic inflammatory response syndrome<sup>[112]</sup>. Elevated IL-6 has been reported in the plasma and stool of babies with NEC<sup>[4]</sup>. A study that looked at IL-6 mRNA expression in surgical intestine specimens from babies with NEC did not

find a difference in comparison to control specimens<sup>[101]</sup>. Since IL-6 plays a dual role in inflammation it may serve as an anti-inflammatory mediator despite being correlated with increased morbidity and mortality in NEC patients.

**IL-8:** IL-8 synthesis and release is triggered in response to various stimuli including LPS, TNF- $\alpha$ , and IL-1 $\beta$ <sup>[113]</sup>. Important cell sources of IL-8 in the gut are macrophages, endothelial cells, intestinal epithelial cells, and fibroblasts<sup>[114]</sup>. IL-8 exerts its effects by binding to chemokine receptors CXCR1 and CXCR2 that signal through phospholipase c and PI3-kinase, respectively<sup>[113]</sup>. Some actions mediated by IL-8 are attraction of neutrophils and basophils to the site of inflammation, neutrophil activation and migration into tissues and production of acute phase proteins<sup>[114]</sup>. In intestinal specimens from patients with NEC, IL-8 mRNA expression was up-regulated, correlated with disease severity and was limited to areas with histological inflammation<sup>[4,115]</sup>. Similarly, plasma IL-8 levels are elevated in infants with NEC and levels correlate with clinical severity<sup>[4]</sup>. The vulnerability of the premature infant to develop NEC may, in part, be explained by the excessive inflammatory response shown by fetal enterocytes compared to more mature enterocytes<sup>[66]</sup>. When exposed to inflammatory stimuli, fetal intestinal cells exhibit a greater IL-8 response compared to mature intestinal cells<sup>[66]</sup>. This exaggerated response may partly be explained by the developmental down regulation of I- $\kappa$ B, an inhibitor of NF- $\kappa$ B<sup>[65]</sup>.

**IL-12:** IL-12 synthesis and release is the early response to bacteria, bacterial products, and viruses<sup>[116]</sup>. Important cell sources of IL-12 in the gut are macrophages, neutrophils, B cells, and dendritic cells<sup>[116]</sup>. IL-12 exerts its effects by binding to IL-12 receptors present on T cells and NK cells<sup>[116]</sup>. Some actions mediated by IL-12 include IFN- $\gamma$  production, Th1 and NK cell proliferation, cytotoxic T lymphocyte and Th1 cell differentiation, macrophage activation, and production of complement-fixing antibodies<sup>[116]</sup>. Several studies have identified putative NF- $\kappa$ B sites in the promoter regions of the IL-12 p40 genes<sup>[117]</sup>. IL-12 is a potentially important cytokine in the development of NEC. Halpern<sup>[99]</sup> localized IL-12 via immunohistochemistry to monocytes in the intestinal mucosa and lamina propria and correlated IL-12 positive cells with tissue damage in a neonatal rat model of NEC.

**Interleukin-18 (IL-18):** IL-18 is a cytokine that shares structural and functional properties with IL-1 and is pro-inflammatory inducing production of TNF- $\alpha$  and IL-1 $\beta$ <sup>[118]</sup>. IL-18 synthesis is triggered by LPS, Fas ligand and gram positive bacteria exotoxins<sup>[119]</sup>. Important cell sources of IL-18 in the gut are macrophages, dendritic cells, and intestinal epithelial cells<sup>[119]</sup>. IL-18 exerts its effect by binding to the IL-18 receptor present on macrophages, neutrophils, NK cells, endothelial cells, smooth muscle cells, and lymphocytes<sup>[119]</sup>. IL-12 upregulates the IL-18 receptor on lymphocytes<sup>[119]</sup>. Binding to the IL-18 receptor results in NF- $\kappa$ B activation. Some actions mediated by IL-18 include IFN- $\gamma$  production,

enhanced NK cell cytotoxic activity, B cell antibody production, macrophage production of IL-8, activation and migration of neutrophils, phagocytosis, and integrin expression<sup>[119]</sup>. IL-18 can promote Th1 or Th2 lineage maturation depending on the underlying genetic influence and cytokine environment. The risk of NEC has been associated with the frequency of the IL-18<sup>607</sup> AA genotype<sup>[19]</sup>. Recent data imply that IL-18, in the absence of IL-12, may facilitate the development of Th2 responses<sup>[118]</sup>. IL-18 is also essential to host defense against a variety of infections<sup>[119]</sup> and is potentially important in the development of NEC. Immunohistochemistry reveals the presence of IL-18 in intestinal epithelial and lamina propria cells which correlates with the degree of tissue damage in a neonatal rat NEC model<sup>[99]</sup>. Depending on the surrounding environment, IL-18 may play a destructive or protective role in NEC.

**IL-4:** IL-4 is a pleiotropic, immunoregulatory cytokine produced by Th2 cells, mast cells, B cells, and stroma cells<sup>[100,120]</sup>. IL-4 displays a wide variety of effects on B cell growth and differentiation, T cell growth and regulation, hematopoietic cells and differentiation of CD4<sup>+</sup> T cells into Th2 cells and is a key regulator in humoral and adaptive immunity<sup>[100,120]</sup>. IL-4 induces B cell class switching to IgE and upregulates MHC class II production<sup>[100,120]</sup>. IL-4 is known to promote Th2 type responses and to exert immunosuppressive effects on macrophages including the suppression of pro-inflammatory cytokine production<sup>[100,120]</sup>. Although data are not available about the importance of IL-4 in NEC, isolated lamina propria mononuclear cells from the inflamed intestinal mucosa of children with chronic inflammatory bowel disease express and secrete IL-4 in lower amounts than control cells<sup>[121]</sup>. In preliminary studies, VLBWI with NEC were shown to be less likely to possess the IL-4 receptor  $\alpha$ -chain mutant allele compared to infants without NEC<sup>[19]</sup>. The investigated variant of IL-4 receptor  $\alpha$  gene is associated with enhanced transduction of IL-4 signals which shifts the development of lymphocytes to a more pronounced Th2 state<sup>[19]</sup>. It is speculated that the elevated number of Th2 cells in carriers of this genetic polymorphism is a protective factor against the development of NEC<sup>[19]</sup>.

**IL-10:** IL-10 is the most important regulatory cytokine in the intestine and is primarily synthesized by Th2 cells, monocytes, and B cells<sup>[120]</sup>. Mononuclear production of anti-inflammatory mediators such as IL-10 is diminished in the newborn when compared to the adult, with preterm infants synthesizing less than term infants<sup>[122,123]</sup>. It is postulated that this phenomenon allows for persistent up-regulation of the inflammatory response and therefore increased susceptibility in the preterm neonate to long-term tissue damage after acute inflammatory conditions<sup>[124]</sup>. Interleukin-10 has been implicated as an inhibitor of pro-inflammatory cytokine production and of several accessory cell functions of the macrophage, T cell and natural killer (NK) cell lines<sup>[120]</sup>. Kuhn<sup>[125]</sup> demonstrated that IL-10 deficient knockout mice were predisposed to developing inflammatory colitis, suggesting that IL-10 works to counterbalance the response

to enteric inflammatory stimuli. In fact, intraperitoneal IL-10 injections in a mouse model of ischemia/reperfusion injury reduced local and systemic inflammatory reactions<sup>[126]</sup>. Edelson<sup>[15]</sup> noticed significantly increased concentrations of IL-10 with severe NEC. IL-10 has also been shown to decrease the production of metalloproteinases<sup>[127]</sup> and suppress iNOS mRNA and NO expression in small bowel, liver and serum<sup>[128]</sup>. These findings indicate that IL-10 is a strong counter regulatory cytokine and that the potential of IL-10 to provide therapy in the setting of NEC is high. Perhaps the high levels of IL-10 in severe NEC are the body's response to dampen the inflammatory response.

## ROS

One of the major endogenous sources of ROS in the intestine is the xanthine dehydrogenase/xanthine oxidase (XD/XO) system<sup>[129]</sup>. Xanthine dehydrogenase (XD), the precursor of XO, is constitutively and abundantly expressed in the intestinal villus epithelium, which catalyzes the conversion of hypoxanthine to xanthine, coupled with the reduction of NAD<sup>+</sup> to NADPH<sup>[130]</sup>. Because XO uses molecular oxygen rather than NAD<sup>+</sup> as an electron acceptor and thereby generates superoxide, XD to XO conversion (during ischemia) has been suggested to play the central role in intestinal reperfusion injury<sup>[129]</sup>. Following PAF challenge, it is the ileum that shows the most dramatic XD to XO conversion<sup>[130]</sup>. The central role of XO and ROS in causing the injury is supported by pre-treatment with allopurinol, a xanthine oxidase inhibitor, which largely prevents PAF-induced bowel necrosis<sup>[131]</sup>. Infusion of superoxide dismutase plus catalase also alleviates the injury<sup>[131]</sup>. In a piglet model of NEC, the level of the tissue antioxidant,  $\alpha$ -tocopherol (vitamin E) was low in formula compared to colostrum fed piglets<sup>[13]</sup>. Thus, infants with NEC are under oxidative stress and may benefit from exogenous sources of antioxidants to replenish limited supplies.

## NEC models

There are a number of accepted models used to study NEC and the cytokine cascade. These models serve to create necrotic bowel in animals to simulate that in the newborn child. LPS, PAF and TNF- $\alpha$  are often used to create intestinal ischemia. LPS is thought to mimic the bacterial overgrowth in the intestinal lumen and PAF and TNF- $\alpha$  cause a hypotensive response and shock<sup>[24]</sup>.

Many animal models can simulate NEC, but often do not contain the aspect of prematurity that is seen in human NEC. The most physiological animal model that most closely resembles human NEC entails removing rat pups from the maternal uterus, exposing them to maternal milk, and stressing them with asphyxia, gram negative bacteria colonization, and artificial formula feedings<sup>[132]</sup>. After a few days of life, the rat pups begin to exhibit signs of NEC including intestinal distension and bloody diarrhea.

Other models have been described that do not physiologically resemble human NEC, but aid in the study of the disease process. These include inducing hypoxia for 5 min followed by 10 min with 100% oxygen<sup>[133]</sup>, hypoxia for 50 s followed by cold exposure<sup>[134]</sup>, superior

mesenteric artery clamping with or without PAF<sup>[135]</sup>, intraarterial injection of TNF- $\alpha$ <sup>[136]</sup>, and placing rats into a 100% nitrogen or 10% oxygen environment<sup>[24]</sup>. Finally, a rat model has been described by Chan<sup>[137]</sup> who created intestinal ischemia by increasing intraluminal pressure and injecting *E. coli* into the lumen.

In addition to *in vivo* animal models, various *in vitro* models have been created. The cell lines are often intestinal-derived and immortal such as CaCo-2, a human colon carcinoma cell line<sup>[138]</sup>. Inflammatory stimulants such as LPS and pro-inflammatory cytokines can be added to cell cultures which can then be analyzed to determine the presence or absence of specific cytokines. In addition, cells can be studied with regards to permeability, viability and expression of inflammatory markers after addition of certain stimulants or creation of hypoxic environments. Paracellular conductance can be assessed by measuring both trans-epithelial resistance (TER) and determining the rate of permeation of radiolabelled, hydrophilic probes between mucosa and serosa compartments of vertical diffusion chambers. It is unfortunate that primary cultures of human enterocytes have a limited life span (hours) in culture and therefore have not been useful as a model.

### Symptomatic treatment and surgery

Due to the limited understanding of the fundamental biological processes that underlie the development of NEC, there is no cure for this devastating pediatric disease<sup>[21]</sup>. Symptomatic treatment of the infant with NEC begins with prompt recognition of the diagnosis and medical stabilization<sup>[2,9]</sup>. The treatment of NEC is based on the severity of the disease and is directed toward reduction of factors that aggravate the disease, treatment of infection and support of respiratory and cardiovascular systems<sup>[139]</sup>. Blood pressure should be closely monitored, all enteral feedings and medications should be discontinued and decompression of the gastrointestinal tract with placement of a gastric tube should proceed to evacuate residual air and fluid<sup>[9]</sup>. Rapid volume expansion with isotonic fluids may be necessary to reverse hypotension as well as frequent monitoring of blood glucose levels<sup>[9]</sup>. An intravenous infusion of total parenteral nutrition should begin during the 10-14 d bowel rest period<sup>[9]</sup>. The reinstatement of feedings generally is done in a slow and cautious manner, using an elemental formulation to allow for optimal absorption of all nutrients and to avoid further potential injury to the intestinal mucosa<sup>[7]</sup>. Broad-spectrum antibiotics including ampicillin and an aminoglycoside should be started as soon as cultures have been obtained<sup>[139]</sup>. With the increasing prevalence of infections from coagulase-negative staphylococcus, vancomycin may be used instead of ampicillin<sup>[2]</sup>. Anti-microbial choices should be guided by local resistance patterns<sup>[2,139]</sup>. Adjunctive therapy includes cardiovascular support (volume expansion with packed red blood cells), pulmonary support (oxygen and ventilation), and hematological support (blood product transfusion) as clinically indicated<sup>[1,139]</sup>. Indications for surgical intervention include peritoneal free air and signs of intestinal perforation<sup>[9]</sup>. Surgical intervention

Table 4 Strategies to prevent necrotizing enterocolitis

Evidence-based support for efficacy	Limited data to support efficacy
Breast feeding	Cautious advancement of feedings
Trophic feeding	Fluid restriction
Antenatal steroids	Oral immunoglobulins
Enteral administration of antibiotics	L-arginine supplementation
	Polyunsaturated fatty acids
	Acidification of milk feeds
	Probiotics, prebiotics and postbiotics
	Growth factors and erythropoietin
	Free radical scavengers

frequently results in resection of areas of necrotic bowel and exteriorization of viable ends (multiple ostomies) to allow for continued bowel decompression<sup>[2,9]</sup>. Recently, primary peritoneal drainage has been proposed as an alternative to surgical treatment. NEC STEPS and NET, prospective multi-centre randomized controlled trials, are currently underway to examine the effectiveness of primary peritoneal drainage versus laparotomy as primary therapy for perforated NEC in VLBW infants<sup>[140,141]</sup>.

## PREVENTION

Strategies to prevent NEC fall into two major categories: Those with probable or proven efficacy and those that are experimental with unproven efficacy<sup>[2]</sup> (Table 4).

The most effective preventative strategies should improve both short-term and long-term outcomes for VLBW preterm infants and address the problems of prematurity.

### Human milk

Human milk has been reported to reduce the incidence of NEC by up to 10 fold compared with infant formula whether using mother's own or donor milk<sup>[142]</sup>. Breast milk also reduces the severity of NEC<sup>[8]</sup>. The protective effect of breast milk has been correlated with its anti-inflammatory components (IL-10), growth factors (EGF), erythropoietin (Epo), lysozyme, immunoglobulins as well as pre- and probiotics that modulate intestinal microflora composition to the advantage of the host<sup>[55,143,144]</sup>. Research looking at a gut-stimulation, or gut-priming protocol has demonstrated potential benefits of promoting maturation of the gut by introducing early feedings with human milk<sup>[3]</sup>. The activity of acetyl hydrolase (PAF-AH), an enzyme that degrades PAF, is lower in neonates under 3 wk of age than at any other time<sup>[145,146]</sup>. The additional presence of PAF-AH activity may also partly explain the protective effect of breast milk, as infant formulas do not contain it<sup>[8]</sup>. Whether preterm human milk reduces the incidence of NEC is not clear at present<sup>[8]</sup>. Despite its advantages, it is important to appreciate that human milk alone will not eliminate NEC as cases are reported in neonates who have been breast-fed exclusively with human breast milk<sup>[8]</sup>.

### Trophic feeds

Initiation of trophic feeds, small volumes of breast milk

or formula, may overcome gut atrophy and inflammatory responses associated with prolonged bowel rest. Trophic feeds improve the activity of digestive enzymes, enhance the release of digestive hormones and increase intestinal blood flow and digestive motility in premature infants<sup>[147]</sup>. In addition, infants given early trophic feeds seem to have better feeding tolerance, improved growth, reduced period of hospitalization and decreased likelihood of sepsis compared with infants who are not<sup>[147]</sup>. Furthermore, early trophic feeds do not increase susceptibility to developing NEC. However, studies have not yet clearly delineated the best feeding strategies for premature infants<sup>[147]</sup>.

### **Antenatal glucocorticoids**

Antenatal glucocorticoid therapy has beneficial effects by suppressing inflammation and promoting gastrointestinal maturation and function including reduced mucosal uptake of macromolecules, decreased colonization with aerobic bacteria, reduced bacterial translocation, and increased activity of enzymes such as lactase, maltase, sucrase, and Na/K-ATPase<sup>[148,149]</sup>. A significant reduction in the incidence and risk of NEC following antenatal glucocorticoid therapy has been reported in several large, randomized control trials<sup>[150,151]</sup>. Mortality rate was also lower and there were fewer indications for surgical intervention<sup>[152]</sup>. Antenatal glucocorticoids have been reported to alter immune system development in very premature infants<sup>[153]</sup>. Mothers with the presence of infection or a condition that may compromise blood flow to the fetus (ex. pre-eclampsia) during pregnancy may be at risk of delivering a premature baby and may potentially benefit from early use of glucocorticoids. Thus, antenatal glucocorticoid therapy is a simple and effective strategy for global prevention of NEC and more research should be done to investigate potential impact on development.

### **Enteral antibiotics**

Enteral antibiotics have been used as prophylaxis against NEC in low birth weight and preterm infants given the role of bacterial colonization in the pathogenesis of the illness. A systemic review and meta-analysis has reported that the administration of prophylactic enteral antibiotics resulted in significant reduction in NEC<sup>[154]</sup>. The trend towards a reduction in deaths was not significant<sup>[154]</sup>. The possible harmful effects of prophylactic antibiotics including the development of bacterial resistance and alteration of the natural microflora make it difficult to recommend this strategy for prevention of NEC.

### **Standardized feeding regimens (cautious advancement of feedings)**

Inter-centre differences in clinical practice involving feeding regimens are significant factors linked to the prevalence of NEC in VLBW neonates<sup>[155]</sup>. A relationship between the rate of feeding advancement and an increased incidence of NEC exists<sup>[156]</sup>. A significant decline of 87% in the incidence of NEC and 29% in the risk of developing NEC was reported following implementation of a standardized feeding regimen in the form of clinical practice guidelines<sup>[157,158]</sup>. Parenteral nutrition coupled

with minimum enteral feeding is the approach commonly advocated for the initial nutritional management of high risk infants and helps protect against NEC<sup>[159]</sup>.

### **Fluid restriction**

Excess fluid has been implicated in the pathogenesis of NEC. A systemic review and meta-analysis indicates that restricted water intake significantly increases postnatal weight loss and significantly reduces the risk of NEC<sup>[160]</sup>. Careful restriction of water intake (meeting the physiological needs without allowing significant dehydration) could be expected to decrease the risk of death from NEC without significantly increasing the risk of adverse consequences.

### **Probiotics**

Since bacterial colonization can affect the course of many intestinal diseases, probiotics are emerging as a promising therapy. Probiotics are living microorganisms, which upon administration in sufficient numbers colonize the gut and exert health benefits beyond basic nutrition on the host<sup>[161]</sup>. As components of infant formula, typically used probiotic microorganisms are members of the genera *Lactobacillus*, *Bifidobacterium*, *Saccharomyces* and to a lesser extent *Streptococcus*. The beneficial effects of probiotics range from changes in intestinal permeability and enhanced mucosal IgA responses to an increased production of anti-inflammatory cytokines and protection of the mucosa against colonization from pathogens<sup>[162]</sup>. *Bifidobacteria* are the most common organisms recovered from the gastrointestinal tract of breast-fed neonates. Given the role of inappropriate gastrointestinal colonization by bacteria in the pathogenesis of NEC, probiotics may be beneficial in the prevention of NEC. Several studies have used different strains of probiotics and different administration regimens (length of treatment and dose) in preterm infants. None of the trials have reported adverse effects and no episodes of pathogenic infection caused by a probiotic organism have been observed<sup>[178,79,163,164]</sup>. Clinical trials show that probiotic supplements (*Lactobacillus acidophilus*, *Bifidobacterium infantis*, *Bifidobacterium bifidus*, and *Streptococcus thermophilus*) reduce the incidence and severity of NEC<sup>[78,79,165]</sup>. Larger clinical trials are necessary to confirm the safety and efficacy of this promising intervention to better define the benefits and risks for premature infants before wider use can be recommended.

### **Prebiotics**

Another potential preventative strategy is to administer prebiotics, non-digestible dietary supplements, such as long chain carbohydrates or mucins, which promote proliferation of beneficial commensal bacteria<sup>[166]</sup>. Preliminary studies show increased *Bifidobacterium* stool colonization and decreased pathogenic bacterial colonization in preterm infants fed with formula containing prebiotics (90% short chain galacto-oligosaccharide, 10% long chain fructo-oligosaccharide) compared with infants fed control formula<sup>[167]</sup>. Furthermore, prebiotic treatment may have a positive effect on host immune function<sup>[168]</sup>. Because prebiotic supplements do not contain live microorganisms, they carry less risk of infection than

probiotic therapies. However, prebiotic administration has been associated with unwanted (but reversible) side effects such as flatulence, bloating and diarrhea<sup>[166]</sup>.

### **Postbiotics**

Another potential therapy involves bacterial metabolites or postbiotics, such as butyric acid, a short-chain fatty acid produced by commensal bacteria in the colon through anaerobic catabolism of complex carbohydrates. Butyrate is a major energy source for colonic enterocytes and has a widely recognized but poorly understood role in intestinal growth and differentiation<sup>[169,170]</sup>, inflammatory suppression<sup>[171]</sup> and apoptosis<sup>[172]</sup>. Butyrate and other small molecule products might generate some of the beneficial effects of the normal flora (and exogenous probiotics and prebiotics), and could be a safe alternative therapeutic strategy. Butyrate has been administered with limited success in human inflammatory bowel disease<sup>[173]</sup>, but there are as yet no studies in neonates.

Other products of commensal bacteria can induce protective responses that promote intestinal health. The beneficial effects of probiotic bacteria can be replicated by treatment with isolated microbe-associated molecular patterns (MAMPs)<sup>[174]</sup>. A MAMP is a molecular sequence or structure in any pathogen-derived molecule that is perceived via direct interaction with a host defense receptor<sup>[175]</sup>. For example, in mice unmethylated probiotic DNA ameliorates colitis<sup>[174]</sup>. Oral administration of inactivated probiotics (heat-killed commensals) or bioavailable toll-like receptor ligands could potentially induce beneficial TLR-mediated protective effects without carrying the infectious risk of probiotic therapies.

### **Arginine supplementation**

Endothelial nitric oxide is an anti-inflammatory agent and vasodilator that is involved in the maintenance of intestinal vascular permeability, mucosal integrity and barrier function<sup>[21,86]</sup>. The plasma levels of the amino acid arginine, a substrate for NOS, have been shown to be low in neonates with NEC<sup>[176,177]</sup>. Arginine supplementation has recently been shown to reduce the incidence of all stages of NEC in a randomized, double blind, placebo controlled trial in preterm neonates<sup>[178]</sup>. Whether the beneficial effects of arginine supplementation in prevention of NEC are related to synthesis of glutamine or to its free radical scavenging action is currently unknown<sup>[179,180]</sup>. Guidelines have not been established for the safety and efficacy of L-arginine at doses above standard dietary practices in NEC<sup>[181]</sup>.

### **Free radical scavengers (anti-oxidants)**

Free radicals have been implicated in several neonatal disease processes including NEC<sup>[182]</sup>. A human recombinant superoxide dismutase is currently available and has been shown to prevent damage and attenuate eicosanoid release in a rabbit model of NEC<sup>[183,184]</sup>. The anti-oxidant vitamin E has been shown to reduce lipid peroxidation and intestinal lesions in a neonatal rat model of NEC induced by hypoxia-ischemia<sup>[183,184]</sup>. More studies on the therapeutic role of anti-oxidants in NEC should be done.

### **Acidification of gastric contents**

Preterm neonates are often hypochlorhydria and enteric, Gram negative bacteria often colonize their stomachs, especially after gavage feeding<sup>[185]</sup>. Carrion and Egan<sup>[186]</sup> have documented that acidifying the feedings of preterm neonates to a pH low enough to inhibit gastric bacterial proliferation significantly lowers the risk and incidence of NEC.

### **Polyunsaturated fatty acids**

Phosphatidylcholine (PC) is a major phospholipid constituent of mucosal membranes and the fatty acid component of PC, arachidonic acid, is a substrate for intestinal vasodilatory and cytoprotective eicosanoids<sup>[8]</sup>. Long chain polyunsaturated fatty acids (PUFA) have been proposed to modulate inflammation and immunity<sup>[187]</sup>. A clinical trial of formula feeds with or without supplementation with PUFA in the form of egg phospholipids in preterm neonates showed that the supplemented formula contained 7-fold more arachidonic acid and docosahexanoic acid and reduced the incidence of stage II and III NEC<sup>[188]</sup>. Recent evidence from an experimental study indicates that the protective effect of long chain PUFA is mediated by modulation of PAF metabolism and endotoxin translocation<sup>[189]</sup>.

### **Oral immunoglobulins**

A number of reports have been published, which suggest that oral immunoglobulins (IgA and IgG) have an immunoprotective effect on the gastrointestinal mucosa<sup>[190,191]</sup>. Premature infants have decreased levels of immunoglobulins, especially secretory IgA<sup>[192]</sup>. A reduction in the incidence of NEC following feeding an oral IgA-IgG preparation was reported as early as 1988<sup>[190]</sup>. A systemic review on oral immunoglobulin for the prevention of NEC did not show a significant reduction on the incidence of definite NEC<sup>[193]</sup>. No randomized controlled trials of oral immunoglobulins for the prevention of NEC have been carried out. Current evidence does not support the administration of oral immunoglobulin for the prevention of NEC.

### **EGF**

EGF is a growth factor that exerts its effects by binding to the EGF receptor. EGF is an important constituent of gastrointestinal secretions and has multiple effects upon gut epithelial cells including cytoprotection, stimulatory effects on cell proliferation and migration, induction of mucosal enzyme and trefoil peptide expression, and inhibitory effects on gastric acid secretion<sup>[48]</sup>. Preterm neonates with NEC have diminished levels of salivary and serum EGF<sup>[194]</sup>. The presence of immunoreactive EGF receptors in gut epithelial cells of preterm neonates with NEC raises the possibility of using EGF for prophylaxis or treatment of NEC<sup>[195]</sup>. In a neonatal rat model of NEC, EGF treatment maintained intestinal integrity at the site of injury by accelerating goblet cell maturation and mucin production and normalizing expression of tight junction proteins<sup>[196]</sup>. Researchers have already warranted that the clinical use of EGF may be associated with a variety of problems and side

effects and that careful selection of patients and evaluation of risk-benefit ratios are necessary<sup>[197]</sup>. Given the potential for adverse effects and the fact that maturity alone is not a protective factor for NEC the use of any growth factors in preterm neonates warrants extreme caution.

### Epo

The presence of Epo in human milk and the expression of Epo receptors on intestinal villous enterocytes of neonates suggest that Epo has a role in growth and development of the gastrointestinal tract<sup>[198-200]</sup>. Ledbetter<sup>[200]</sup> administered recombinant Epo for the prevention and treatment of the anemia of prematurity and demonstrated that the rEpo group had a lower incidence of NEC. Akisu<sup>[133,201]</sup> indicated that rEpo decreased lipid peroxidation but not PAF generation. Although not completely absorbed, Epo acts as a trophic factor in developing rat bowel whether given enterally or parenterally<sup>[199]</sup>. Current evidence indicates that the protective effect of rEpo may be related to inhibition of NO formation<sup>[202]</sup>.

### CONCLUSION

A variety of other experimental agents have been studied in search for an effective agent for the prevention of NEC. These include anti-TNF- $\alpha$ <sup>[82]</sup>, PAF receptor antagonists<sup>[203]</sup>, heparin-binding EGF-like growth factor<sup>[204]</sup>, anti-inflammatory cytokines (IL-10)<sup>[205]</sup>, pentoxifylline<sup>[206]</sup>, intestinal trefoil factor 3<sup>[207]</sup>, and glucagon-like peptide 2. Recent research has identified that complex glycosphingolipids in the form of gangliosides act as bioactive factors down-regulating many acute pro-inflammatory signals in the intestinal mucosa. Perhaps the solution to NEC will involve identification of an intestinal control mechanism that optimizes (or disregulates) the balance between pathways that signal inflammation, hypoxia, and mucosal cell growth or metabolism.

## Abstract

**AIM:** To study the effect of type 1 Na<sup>+</sup>/H<sup>+</sup> exchanger (*NHE1*) antisense human gene transfection on the biological behavior of gastric carcinoma cell line *SGC-7901*.

**METHODS:** Antisense *NHE1* eukaryotic expression on vector pcDNA3.1 was constructed by recombinant DNA technique and transfected into gastric carcinoma cell line *SGC-7901* with DOTAP liposome transfection method. Morphological changes of cells were observed with optic and electron microscopes. Changes in cell proliferative capacity, apoptosis, intracellular pH (pH<sub>i</sub>), cell cycle, clone formation in two-layer soft agar, and tumorigenicity in nude mice were examined.

**RESULTS:** Antisense eukaryotic expressing vectors were successfully constructed and transfected into *SGC-7901*. The transfectant obtained named *7901*-antisense (*7901-AS*) stably produced antisense *NHE1*. There was a significant difference between the pH<sub>i</sub> of *7901-AS* cells (6.77 ± 0.05) and that of *7901-zeo* cells and *SGC-7901* cells (7.24 ± 0.03 and 7.26 ± 0.03, *P* < 0.01). Compared with *SGC-7901* and *7901-zeo* cells, *7901-AS* cells mostly showed cell proliferation inhibition, G<sub>1</sub>/G<sub>0</sub> phase arrest, increased cell apoptotic rate, recovery of contact inhibition, and density contact. The tumorigenicity in nude mice and cloning efficiency in the two-layer soft agar were clearly inhibited.

**CONCLUSION:** *NHE1* antisense gene significantly restrains the malignant behavior of human gastric carcinoma cells, suppresses cell growth and induces cell apoptosis, and partially reverses the malignant phenotypes of *SGC-7901*. These results suggest a

## INTRODUCTION

The type 1 Na<sup>+</sup>/H<sup>+</sup> exchanger (NHE1) is a transmembrane protein found in all eukaryotic cells. One of its functions is to remove excess H<sup>+</sup> in the cytoplasm by Na<sup>+</sup>-H<sup>+</sup> exchange system, resulting in a stable intracellular pH level<sup>[1,2]</sup>. The process of glycolysis induces the tumor cells to produce large quantities of lactic acid and H<sup>+</sup>. There is vigorous Na<sup>+</sup>-H<sup>+</sup> exchange in the tumor cells, dependent upon the enhanced expression of NHE1 membrane protein. Most of the H<sup>+</sup> pumped out of the cells prevents the intracellular acidification of tumor cells, resulting in the protection of tumor cells from apoptosis<sup>[3,4]</sup>. Previous studies have shown that NHE1 protein expression in gastric carcinoma tissues was significantly higher compared to that in normal gastric mucosa and precancerous lesions<sup>[5]</sup>. Therefore, inhibition of up-regulation of *NHE-1* gene expression in human gastric carcinoma cells may induce intracellular acidification, resulting in apoptosis of tumor cells, which is helpful in the treatment of such tumors. In the present study, we constructed the antisense *NHE-1* eukaryotic expression vector and transfected it into gastric carcinoma cell line *SGC-7901* in order to investigate the effects of antisense *NHE1* on malignant biological behavior of the gastric carcinoma cell line *SGC-7901*.

## MATERIALS AND METHODS

### Cell line and cell culture

The human gastric carcinoma cell line *SGC-7901* was

used in this study. The cells were grown in RPMI1640 medium (Sigma, St Louis, MO, USA), supplemented with 10% FBS (fetal bovine serum) and antibiotics (100 µg/mL streptomycin and 100 U/mL penicillin) in an atmosphere consisting of 5% CO<sub>2</sub> in air at 37°C in a humidified incubator.

### Gene transfection

*pEAP* cloning vector of human *NHE1* cDNA was kindly provided by Dr. Josset Noel (Montreal University, Canada). Eukaryotic expression vector *pcDNA3.1 (-)/Zeo* and Zeocin were obtained from Invitrogen Co. The experimental procedures of gene transfection were carried out according to the directions of DOTAP<sup>TM</sup> liposome transfection kit (Roche Diagnostics, Mannheim, Germany). The cells were plated at a density of  $1.5-3 \times 10^5$  cells/35 mm dish and were grown for 24 h. The cells were transfected for 6 h with 2.5 µg plasmid DNA and 15 µL DOTAP in 2 mL of RPMI1640 medium without FBS and antibiotics. The cells were recovered for 48 h in the medium with 10% FBS. The stable transfectant was maintained in 100 µg/mL Zeocin (Invitrogen) in the medium for at least 20 d. The antisense *NHE1* and the control plasmid transfectant were named *7901-AS* and *7901-zeo*, respectively.

### Analysis of exogenous genes integration

In order to identify exogenous integration in the nucleic DNA of *SGC-7901* cells, the Zeomycin-resistant antibiotic-selecting gene (*ZeoR*) was amplified by polymerase chain reaction (PCR) assays with a *ZeoR*-specific primer set (5'-GGCCAAGTTGACCAGTGC-3' as forward and 5'-GTCAGTCCTGCTCCTCGG-3' as backward). DNA was extracted from *SGC-7901* and the transfected cells using standard techniques. The total volume of the PCR reaction system was 25 µL, containing 0.2 mmol/L dNTP, 1 mmol/L of each primer, 2U *Taq* polymerase, 1 × reaction buffer and 100 ng DNA template. After predegeneration at 94°C for 5 min in a PE cycle, 30 PCR cycles were performed at 94°C for 30 s, 53°C for 30 s, and 72°C for 30 s, then extended at 72°C for 5 min in a PCR thermocycler (Pekin-Elmer Cetus, Norwalk, CA, USA). Electrophoresis was performed on 1% agarose gel, and the findings were observed and pictures taken under the Burdick lamp.

### Determination of intracellular pH

High-concentration potassium-buffer containing the following chemicals (in mmol/L): 90-130 KCl, 5 NaCl, 1 MgSO<sub>4</sub>, 1 CaCl<sub>2</sub>, and 10 HEPES was infused into 6 tubes (5 mL in each), with pH values adjusted to 5.5, 6.0, 6.5, 7.0, 7.5, and 8.0, respectively. Nigericin (30 µmol/L) and BCECF (0.25 µmol/L) were added to the 6 tubes. At the logarithm growth phase, the cells were digested with pancreatin to prepare a single-cell suspension. The cells were washed twice with PBS, and an identical number of cells were added to the 6 tubes for inoculation at 37°C for 12 min. The cells were stimulated with argon ion laser at 488 nm. The emitted fluorescence was recorded at 530 nm and 640 nm and the ratio (FIR) was calculated. The ratio curve and the standard curve of pH were drawn.

Cells at the logarithm growth phase were digested with

pancreatin, and centrifugated for 5 min at 1000 r/min. After removal of the supernatant, the cells were washed once using saline. BCECF/AM stock solution (2 mg/mL), prepared with anhydrous DMSO, was added to the serum-free and phenolsulfonphthalein-free medium until the BCECF concentration reached 0.25 µmol/L. Cells in the stock solution were incubated for 12 min for 1 h at room temperature. The cells were stimulated with argon ion laser at 488 nm and the emitted fluorescence at 530 and 640 was recorded, and the ratio (FIR) was calculated. Intracellular pH (pH<sub>i</sub>) was calculated according to the standard curve.

### Cell morphology and growth features observation

The shape, size and growth features (such as contact inhibition, density inhibition and anchorage-dependence) of *7901-AS* cells were observed using invert microscopy and common microscopy after hematoxylin and eosin staining. Cell proliferation speed was assayed by the 3-(4,5-dimethyl-2 thiazoyl)-2,5-diphenyl-2H-tetrazolium bromide method.

### Cell cycle and apoptosis rate analysis

Exponentially growing cells were collected and fixed with 75% cold ethanol for at least 24 h and were analyzed for cell cycle distribution and apoptosis rate by DNA content analysis using propidium staining under flow cytometry (FACS420).

### Double-deck soft agar colony forming efficiency

The cells were planted in 24-hole plastic plates spread with low melting point agar (0.35% in upper layer and 0.6% in low layer). Each type of cell was planted in five holes, with 1000 cells in each hole. The cells were cultivated at 37°C, with 5% CO<sub>2</sub> and under saturation humidity for 2-3 wk. Cells that were larger than 75 µm in diameter or clones with more than 50 cells were counted under an invert microscope. Clone form-rate was calculated according to the clone form number/inoculation cell number × 100%.

### Tumorigenicity assay in nude mice

Nine Balb/c athymic 4-5 wk old female nude mice, bred in specific pathogen free conditions (purchased from the Experimental Animal Center of the Third Military Medical University, Chongqing, China) were randomly divided into three groups. Three different cell lines (*SGC-7901*, *7901-zeo*, *7901-AS*), suspended in 0.1 mL serum-free RPMI 1640, were injected subcutaneously in a dose of  $4-8 \times 10^6$  cells at two different sites of the mice. The tumor diameter was measured every 7 d. The animals were monitored regularly for tumor occurrence and size for at least 2 mo.

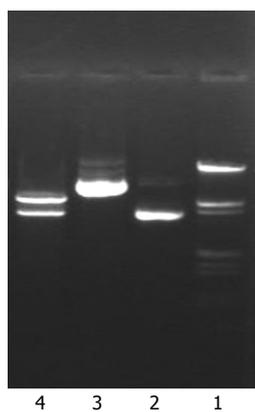

### Statistical analysis

The findings are depicted as mean ± SD. Variance analysis and *t*-test for non-matched data were performed using a professional SPSS statistical program.

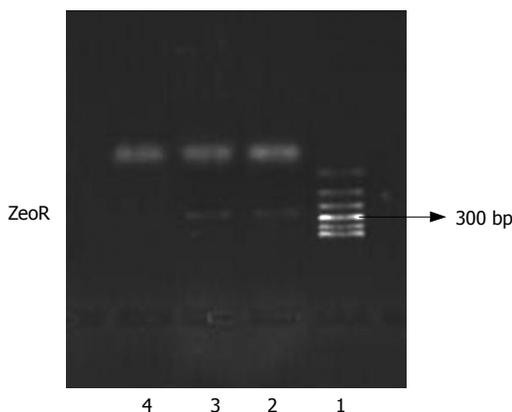

## RESULTS

### Construction and identification of *NHE1* antisense eukaryotic expression vector

Human *NHE1* cDNA (3.6 Kb) digested from plasmid

**Figure 1** Identification of antisense human *NHE1* cDNA vector digested by restriction endonuclease. Lane 1: Marker ( $\lambda$ DNA/*EcoR* I + *Hind*III); Lane 2: *pcDNA3.1* (-)/*Zeo* plasmid; Lane 3: *pcDNA3.1-NHE1* plasmid; Lane 4: *pcDNA3.1-NHE1* plasmid digested by *EcoR* I and *Hind*III (5.0 and 3.6 kb).

**Figure 2** Analysis of exogenous gene integration in nucleic DNA of *SGC-7901*. Lane 1: Polymerase chain reaction marker; Lane 2: *7901-zeo*; Lane 3: *7901-AS*; Lane 4: *SGC-7901*.

*pEAP* with *EcoR* I and *Hind*III restriction endonuclease was inserted into the eukaryotic expression vector in antisense orientation. The recombinant DNA was further shown to be the same as designed by restriction analysis (Figure 1). A fragment of 3.6 Kb was released after digestion of the recombinant plasmid with *EcoR* I and *Hind*III, suggesting that the target fragment was successfully inserted into the expression vector.

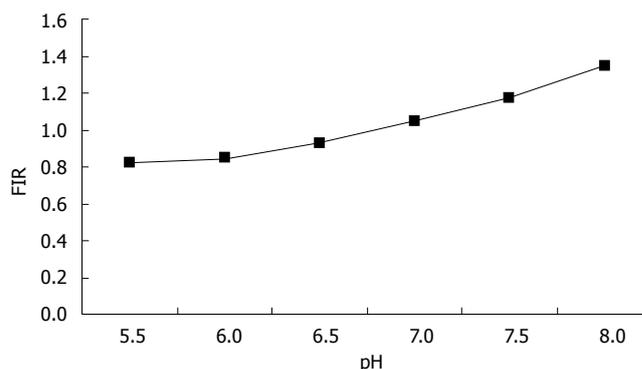

The antisense *NHE1* eukaryotic expression vector was named *pcDNA3.1-NHE1*.

### Identification of transfection

We introduced an antisense *NHE1* cDNA sequence into the *SGC-7901* cell line. Following Zeocin selection, drug-resistant individual clones were randomly collected from cultures infected with *pcDNA3.1-NHE1* (*7901-AS*). For controls, drug-resistant clones were selected from the cultures infected with an empty vector *pcDNA3.1* (-)/*Zeo* (*7901-zeo*). The expression of zeocin resistant gene (*ZeoR*) could be amplified in *7901-AS* or *7901-zeo* cells, but not in untransfected cells. This result suggested that exogenous genes had been integrated into the nucleic DNA of *SGC-7901* cells (Figure 2).

### Determination of intracellular pH

The standard curve drawn according to the buffer is shown in Figure 3. The regression equation was  $y = 0.2144x - 0.4248$  ( $r = 0.96$ ).

**Figure 3** Standard curve of intracellular pH.

**Table 1** Changes in the intracellular pH values of *SGC-7901* gastric carcinoma cells before and after transfection

Cells	Intracellular pH values determined each time			Intracellular pH (mean $\pm$ SD)
	1	2	3	
<i>7901-AS</i>	6.73	6.75	6.83	6.77 $\pm$ 0.05 <sup>b</sup>
<i>7901-zeo</i>	7.20	7.26	7.25	7.24 $\pm$ 0.03
<i>SGC-7901</i>	7.22	7.28	7.28	7.26 $\pm$ 0.03

<sup>b</sup> $P < 0.01$  vs *7901-zeo* and *SGC-7901*.

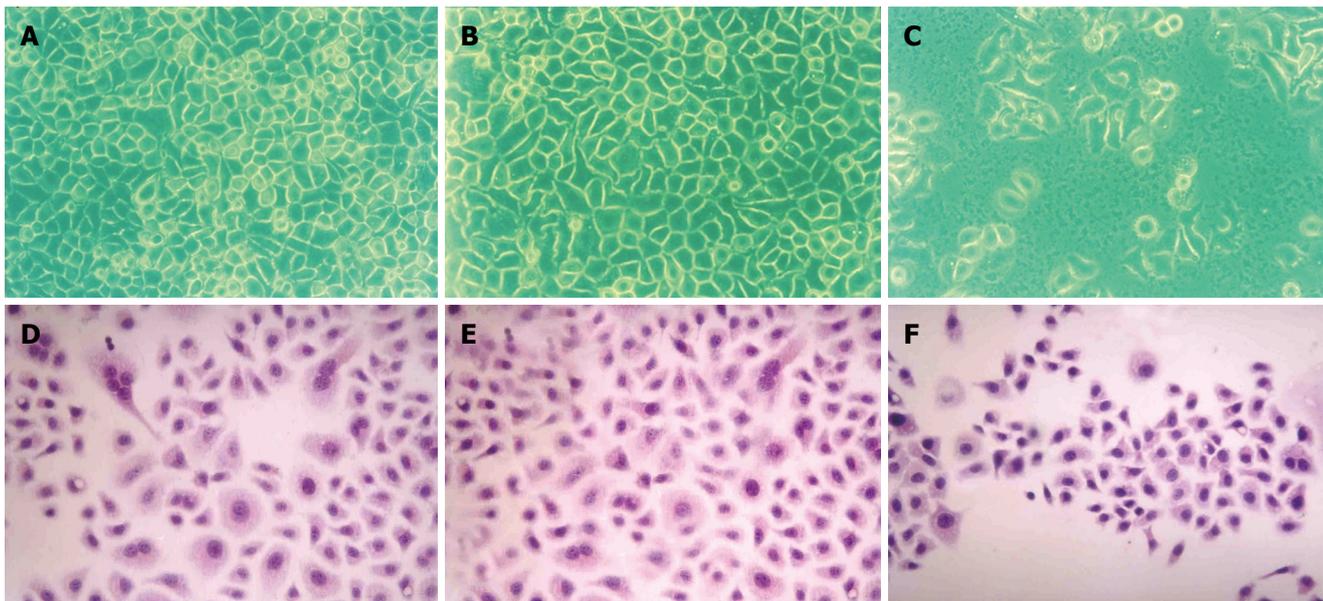

The cells were stimulated with argon ion laser at 488 nm and the emitted fluorescence at 530 nm and 640 nm was recorded and the ratio of 530/640 was calculated. The intracellular pH ( $pH_i$ ) was calculated according to the standard curve. The  $pH_i$  of *7901-AS* cells was 6.77  $\pm$  0.05, whereas the  $pH_i$  of *7901-zeo* and *SGC-7901* cells were 7.24  $\pm$  0.03 and 7.26  $\pm$  0.03, respectively. There was a significant difference between the  $pH_i$  of *7901-AS* cells and that of *7901-zeo* cells and *SGC-7901* cells ( $P < 0.01$ ). The reduced  $pH_i$  of *7901-AS* cells suggested that the transfected antisense *NHE1* gene successfully inhibited the expression of *NHE1* gene and blocked excessive exchange of  $Na^+ - H^+$ , resulting in intracellular acidification. There was no significant difference in the  $pH_i$  of *SGC-7901* and *7901-zeo* cells (Table 1).

### Morphology and growth features of 7901-AS cells

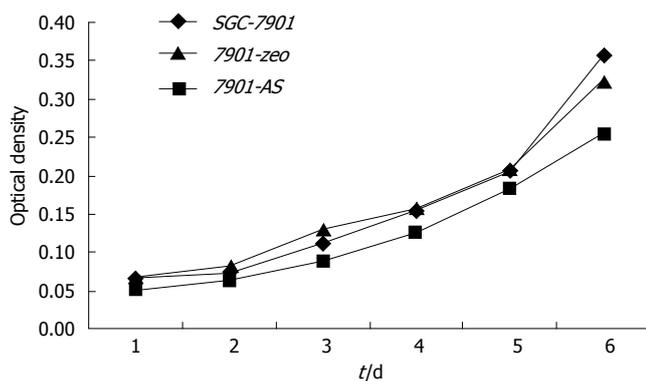

Compared with their parental cells and *7901-zeo* cells, antisense *NHE1*-transfected *7901* cells displayed several morphological changes under light microscopy, such as decreased mitotic figures, multinucleate giant cells, giant nucleate cell numbers, and nucleus:cytoplasm ratio. The *7901-AS* cells only grew in a monolayer and at low cell density. The cell proliferation slowed down on the sixth day when *7901-AS* cells grew into complete confluence (Figures 4 and 5). Further study showed that the parent cells and *7901-zeo* cells grew in clusters with large numbers of big clones. The formation rate was 11% for *SGC-7901* cells and 9.5% for *7901-zeo* cells after 2 wk culture in soft agar. By contrast, the *7901-AS* cells were scattered in soft agar with less number of clones and the formation rate was only 2%.

### Cell-cycle distribution and apoptotic rate of 7901-AS cells

The *7901-AS* cells showed increased apoptotic cells and

**Figure 4** Morphological changes in the transfected cells and parental cells. The first row was observed under inverted microscope. The second row was stained with hematoxylin and eosin, and examined by light microscopy. (A) and (D) SGC-7901; (B) and (E) 7901-zeo; (C) and (F) 7901-AS.

**Figure 5** Comparison of growth curves of transfected cells and parental cells.

G<sub>0</sub>/G<sub>1</sub> cells, and decreased S and G<sub>2</sub>M cells, and reduced proliferative index compared to SGC-7901 and 7901-zeo cells, suggesting that transfection of SGC-7901 cells with antisense *NHE1* gene resulted in leftward shift of the cell cycles and reduced capacity for differentiation and proliferation. Flow cytometry showed apoptotic peak of 7901-AS cells with apoptotic rate of 26.1%, which was significantly higher than that of SGC-7901 cells (4.5%) and 7901-zeo cells (5.1%), suggesting that transfection with antisense *NHE1* induced apoptosis of SGC-7901 cells (Table 2).

#### Tumorigenicity assay in nude mice

After inoculation with  $4 \times 10^6$  SGC-7901 cells or 7901-zeo cells, all mice ( $n = 3$ ) grew palpable tumors on the sixteenth-seventeenth day. Subsequently, the tumors grew progressively. The size and speed of growth of the two different tumors showed no apparent difference at 2 mo. After inoculation with  $4 \times 10^6$  and  $8 \times 10^6$  dose of 7901-AS cells, none of the mice ( $n = 3$ , respectively) grew palpable tumors within 2 mo. This result indicates that

**Table 2** Cell cycle distribution and the apoptotic rate in transfected and untransfected cells

Cell type	Cell cycle distribution (%)				Apoptotic rate
	G <sub>0</sub> /G <sub>1</sub>	S	G <sub>2</sub> /M	PI	
7901-AS	60.0	34.3	6.3	40.3	26.1 <sup>b</sup>
7901-zeo	54.6	39.0	7.6	46.6	5.1
SGC-7901	55.4	37.9	8.0	45.2	4.5

<sup>b</sup> $P < 0.01$  vs SGC-7901 and 7901-zeo.

antisense *NHE1*-transfected SGC-7901 cells completely loose tumorigenicity in nude mice.

## DISCUSSION

Since the successful cloning of human *NHE1*cDNA in 1989 by the Sardet Laboratory<sup>[6]</sup>, the 8 known subtypes of NHE, named as NHE1-8 respectively, have been shown to be identical in structure and are related in function. These form the gene family of membrane exchange protein<sup>[7-10]</sup>. The different subtypes have different number and distribution, different pharmacological properties, and are regulated by different factors. *NHE1*, a house-keeping gene, located at 1p<sup>[1]</sup> with mRNA of 3.8 Kb, is found in nearly all human tissues, and serves to remove excessive H<sup>+</sup> in the cytoplasm by the Na<sup>+</sup>-H<sup>+</sup> exchange system, resulting in the maintenance of a stable pH<sub>i</sub><sup>[11-14]</sup>. Glycolysis of tumor cells may result in the production of large quantities of lactic acid and H<sup>+</sup>. Researchers have long believed that the pH<sub>i</sub> of tumor cells is more acidic than that of normal cells. However, <sup>31</sup>P-NMR spectroscopic studies of tumor cells have shown that the pH<sub>i</sub> measured *in situ* is more alkaline (pH 7.0-7.2) than that of the normal cells (pH 6.5-7.0). This phenomenon of high pH<sub>i</sub> with low extracellular pH (pH<sub>e</sub>) is caused by the activation of NHE1 in the cell membrane with increased mRNA expression,

resulting in strong  $\text{Na}^+\text{-H}^+$  exchange in the tumor cells. Most of the  $\text{H}^+$  pumped out of the cells helps to create an acidic environment in the interstitial fluid of the tumor cells and maintains the  $\text{pH}_i$  in the tumor cells as neutral or more basic<sup>[15-18]</sup>. Our previous studies have shown that the significantly greater expression level of NHE1 protein in gastric carcinoma tissues compared to that in normal gastric tissues is closely associated with the genesis and progression of tumors<sup>[5]</sup>, suggesting that *NHE1* can be used as the target site in the treatment of such tumors. However, further studies are needed to determine whether or not the intervention of antisense *NHE1* gene can decrease type 1  $\text{Na}^+\text{/H}^+$  exchanger of membranous ion exchange protein in gastric carcinoma cells and reverse the malignant phenotypes. Therefore, in the present study, the purpose of transfection of antisense *NHE1* gene into human gastric carcinoma cell line *SGC-7901* was to investigate the effects of antisense therapy targeting *NHE1* gene in the malignant phenotypes of gastric carcinoma cells. It was observed that reduced  $\text{pH}_i$  partially reversed the malignant phenotypes of *SGC-7901* cells transfected with antisense *NHE1*. Compared with *SGC-7901* and *7901- $\Delta$ 0* cells, the *7901-AS* cells showed cell proliferation inhibition,  $\text{G}_1\text{/G}_0$  phase arrest, increased cell apoptotic rate, recovery of contact inhibition and density contact, decreased invasive capacity, and loss of cloning efficiency in soft agar, and tumorigenicity in nude mice. These results indicate that the *NHE1* gene is important in maintaining the phenotypes of the *SGC-7901* cell line. The *NHE1* gene may be closely associated with the malignant biological behavior of the tumor cells, and as a result, the phenotype of the tumor is restrained when the *NHE1* gene is inhibited.

Overexpression of *NHE1* gene plays an important role in the regulation of  $\text{pH}_i$  in tumor cells<sup>[19-26]</sup>. The enhancement of  $\text{Na}^+\text{-H}^+$  exchange by tumor cells, caused by increasing the quantitative distribution of NHE1 on the cell membrane, is the major molecular mechanism in the regulation of  $\text{pH}_i$  in tumor cells. This step is of important biological significance in the maintenance of stable  $\text{pH}_i$  and malignant growth of the tumor cells. The energy consumption process of  $\text{Na}^+\text{-H}^+$  exchange which is dependent on the energy supplied by  $\text{Na}^+\text{-K}^+\text{-ATPase}$ , stimulates glucose absorption and glycolysis by tumor cells and produces more intracellular  $\text{H}^+$ , leading to strong  $\text{Na}^+\text{-H}^+$  exchange in the tumor cells<sup>[27-30]</sup>. Most of the  $\text{H}^+$  pumped out of the cells helps to create the acidic environment in the interstitial fluid of the tumor cells and keeps the  $\text{pH}_i$  neutral or more alkaline in tumor cells, resulting in the protection of the tumor cells from apoptosis<sup>[18,23]</sup>. In the present study, transfection of antisense *NHE1* gene inhibited the expression of *NHE1* gene in *SGC-7901* gastric carcinoma cells, resulting in intracellular acidification and induced apoptosis of *SGC-7901* cells. The inhibited proliferation, increased apoptotic rate, and decreased malignancy in tumor cells resulted in significantly reduced tumorigenicity in nude mice *in vivo*. These results indicate that transfected human *NHE1* antisense gene successfully inhibited  $\text{Na}^+\text{-H}^+$  exchange and destroyed the energy metabolism pattern of gastric carcinoma cells. Our findings point to the feasibility

of treatment of gastric carcinoma by induction of cell apoptosis through the process of intracellular acidification, which may provide a new method for gene therapy of gastric carcinoma.

In conclusion, we transfected *NHE1* antisense into *SGC-7901* cells and observed the morphological and biological changes in the tumor cells. Our results reveal that *NHE1* antisense gene transfection can partly reverse the malignant behavior, resulting in intracellular acidification and induction of apoptosis of *SGC-7901* cells. These finding may provide a potential method for gastric carcinoma gene therapy in the future.

## COMMENTS

### Background

Gastric cancer is one of the most common malignant tumors in China, but the pathogenesis is unclear. Recent investigations have demonstrated that type 1  $\text{Na}^+\text{/H}^+$  exchanger (*NHE1*) mRNA expression is significantly increased in the carcinoma, relative to the occurrence and growth of tumors. Our previous studies have shown that significantly higher expression level of NHE1 protein in gastric carcinoma tissue compared to normal gastric tissue is closely associated with the genesis and progression of tumors. Therefore, the *NHE1* gene may be a good target for antisense gene therapy for gastric cancer. However, further studies are needed to determine whether antisense *NHE1* gene intervention can reduce type 1  $\text{Na}^+\text{/H}^+$  exchanger of the membranous ion exchange protein, and influence the biological behavior of the gastric carcinoma cells.

### Research frontiers

Over expression of *NHE1* gene plays an important role in the regulation of  $\text{pH}_i$  in tumor cells, which is of important biological significance in the malignant growth of tumor cells. However, the role of NHE1 in the regulation of tumorigenic and metastatic properties of tumor cells remains unclear and it is important to determine the precise role of *NHE1*.

### Innovations and breakthroughs

Our results reveal that *NHE1* antisense gene may significantly restrain the malignant behavior of human gastric carcinoma cells, result in intracellular acidification, suppress cell growth, induce cell apoptosis, and partially reverse the malignant phenotypes of *SGC-7901*. These findings suggest a potential role for human tumor gene therapy.

### Applications

The present study may be helpful in determining a potential role for gastric carcinoma gene therapy in the future.

### Terminology

The term  $\text{pH}_i$  means intracellular pH. The  $\text{pH}_i$  of tumor cells measured in situ is more alkaline than that of normal cells. This phenomenon of high  $\text{pH}_i$  with low extracellular pH ( $\text{pH}_e$ ) is caused by the activation of *NHE1* in cell membrane and increased mRNA expression. *NHE1*, a type 1  $\text{Na}^+\text{/H}^+$  exchanger, is a transmembrane protein found in all eukaryotic cells. One of its functions is to reduce excess  $\text{H}^+$  in the cytoplasm by means of  $\text{Na}^+\text{-H}^+$  exchange, resulting in stable intracellular pH levels.

### Peer review

This is an interesting article which examines the effect of inhibiting NHE1 on tumor survival. The manuscript is of interest and the data is good. It would be useful if NHE1 can be explained in more detail in the abstract.

Troglitazone, a peroxisome proliferator-activated receptor  $\gamma$  ligand, induces growth inhibition and apoptosis of HepG2 human liver cancer cells. *World J Gastroenterol* 2008; 14(14): 2168-2173 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2168.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2168>

### Abstract

**AIM:** To examine the effect of troglitazone, a peroxisome proliferator-activated receptor  $\gamma$  (PPAR $\gamma$ ) ligand, on the proliferation and apoptosis of human liver cancer cells.

**METHODS:** Liver cancer cell line HepG2 was cultured and treated with troglitazone. Cell proliferation was detected by 3-(4-,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay; apoptosis was detected by flow cytometry and terminal deoxynucleotidyl transferase-mediated nick end labeling of DNA fragmentation sites (TUNEL) assay; and apoptosis-related protein was detected by immunocytochemistry and Western blotting.

**RESULTS:** Troglitazone inhibited growth and induced apoptosis of HepG2 cells in a dose-dependent manner, and induced activation of caspase-3 expression. Troglitazone not only drove apoptosis-inhibiting factor survivin to translocate incompletely from the nucleus to the cytoplasm, but also inhibited expression of survivin, while it did not affect expression of apoptosis-promoting factor Bax.

**CONCLUSION:** PPAR $\gamma$  ligands inhibit growth and induce apoptosis of liver cancer cells, and may have applications for the prevention and treatment of liver cancer.

### INTRODUCTION

Primary hepatocellular carcinoma (HCC) is the fifth most common malignant tumor worldwide, and causes more than 500 000 deaths annually<sup>[1]</sup>. Dissemination of Hepatitis B virus (HBV) and Hepatitis C virus (HCV) causes the incidence of HCC to increase<sup>[2]</sup>. Surgical resection is the treatment of choice for HCC, but only 10%-20% of HCC patients are resectable at the time of diagnosis<sup>[3]</sup>. Liver transplantation is only indicated for early HCC (Milan criteria 1 tumor, < 5 cm in diameter, or up to three tumors, all < 3 cm in diameter), as far as outcome is concerned<sup>[4]</sup>. In addition, recurrence remains high in patients who receive radical treatment<sup>[5,6]</sup>. It is therefore urgent to seek a new approach for the treatment of HCC.

Peroxisome proliferator-activated receptor (PPAR) belongs to the nuclear hormone receptor superfamily<sup>[7]</sup>. Three subtypes of PPAR (PPAR $\alpha$ , PPAR $\gamma$  and PPAR $\delta$ ) have been identified, among which PPAR $\gamma$  has been studied most extensively. PPAR- $\gamma$  exerts its effects by forming heterodimers with the 9-*cis*-retinoid X receptor (RXR) after ligand activation. The PPAR/RXR heterodimer acts as a regulatory transcription factor with peroxisome proliferator responsive element (PPRE) to regulate the expression of target genes which participate in the physiological and pathological processes of lipid metabolism, glucose metabolism, adipocyte differentiation, energy balance, inflammatory reactions and atherosclerosis<sup>[8,9]</sup>. PPAR $\gamma$  ligands are classified as natural and synthetic. The former include long-chain polyunsaturated fatty acid and eicosanoids, and the latter include thiazolidinediones (TZDs), the most commonly used drugs for diabetes, such as troglitazone, pioglitazone, rosiglitazone and LY171.833. Several recent studies have shown most human tumors

express PPAR $\gamma$ , and there is evidence that PPAR $\gamma$  ligands have anti-tumor activity<sup>[10-20]</sup>. One of the important effects of these drugs is induction of apoptosis, although the exact mechanism remains elusive.

The present study used liver cancer cell line HepG2 that endogenously expresses PPAR $\gamma$  as an experimental model<sup>[15]</sup> to study the effects of PPAR $\gamma$  ligand troglitazone on proliferation and apoptosis of liver cancer cells. It also analyzed the molecular mechanisms of these effects in an attempt to provide experimental clues for the use of PPAR $\gamma$  ligands in the treatment of liver cancer.

## MATERIALS AND METHODS

### Chemicals

Troglitazone (Cayman Chemical Industry, USA) was dissolved in DMSO and then diluted to appropriate concentrations with culture medium. The final concentration of DMSO in the culture medium did not exceed 1 mL/L.

### Cell culture

HepG2 cells were cultured in Dulbecco's modified Eagle's medium (GIBCO Laboratories, Grand Island, NY, USA) containing 10% fetal bovine serum (FBS, GIBCO Laboratories), 100 U/mL penicillin, and 100 g/mL streptomycin. Cells were grown at 37°C in an atmosphere of 95% air and 5% CO<sub>2</sub>.

### MTT assay

Cell proliferation was detected by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) (Sigma, St Louis, MO, USA) assay. When cells were cultured to the log phase, they were seeded on a 96-well plate ( $2 \times 10^4$  cells/100  $\mu$ L/well) for 24 h until confluence. Cells were divided into a control (DMSO) group and a troglitazone group. The concentration of troglitazone was 5, 10, 20, 40, 80 and 100  $\mu$ mol/L. After 120 h, 10  $\mu$ L MTT (5 g/L) was added and incubated at 37°C for 4 h. DMSO (75  $\mu$ L) was added to each well, which was oscillated for 10 min until the crystals were dissolved completely. Absorbance (A) was detected with an enzyme calibrator at 560 nm. Cell viability = (A of study group/A of control group)  $\times$  100%. The experiment was repeated twice. There were six wells for each concentration.

### Flow cytometry

Cells were seeded onto a six-well plate and allowed to grow to 40% confluence. After treatment with or without the drug, both floating and adherent cells were collected. Cells were suspended and then fixed with ice-cold 70% alcohol at -20°C, followed by washing and staining with 50  $\mu$ g/mL propidium iodide in the presence of 100  $\mu$ g/mL ribonuclease A for 30 min at 37°C in the dark. DNA content was analyzed by flow cytometry using Cell Quest software (Becton Dickinson and Beckman-Coulter, San Jose, CA, USA).

### TUNEL assay

HepG2 cells were grown on poly-L-lysine-coated slides in a six-well plate. After treatment with or without the drug, the slides were gently washed three times in 0.1 mol/L PBS

(pH 7.4), fixed with 80% ice-cold ethanol, and immediately transferred to a freezer until use. To study apoptosis of cultured cells, terminal deoxynucleotidyl transferase-mediated nick end labeling of DNA fragmentation sites (TUNEL) assay was performed using Fluorescein FragEL DNA Fragmentation Detection Kit (Oncogene Research Products, San Diego, CA, USA) according to the manufacturer's instructions. Ten high-power areas with even distribution of positive cells were used for calculation of the percentage of apoptotic cells under a fluorescence microscope.

### Immunocytochemistry

HepG2 cells were grown on poly-L-lysine-coated slides in a six-well plate. After treatment with the drug, the slides were washed twice with PBS and fixed in 4% paraformaldehyde for 30 min at room temperature. Immunostaining was performed using the streptavidin-biotin complex method with UltraSensitive S-P Kit (Fuzhou Maxim Biotech, Fuzhou, Fujian, China). The slides were pretreated first with 0.3% hydrogen peroxide in PBS for 10 min to inactivate endogenous peroxidase, and then microwave antigen retrieval was performed with 0.01 mol/L citrate buffer at pH 6.0 for 20 min, followed by incubation with polyclonal rabbit anti-human antibody against the active caspase-3 (1:25; R&D Systems, Wiesbaden, Germany), rabbit anti-human survivin polyclonal antibody (1:50; Santa Cruz Biotechnology, Santa Cruz, CA, USA) at 4°C overnight, biotinylated secondary antibody for 30 min, and peroxidase-labeled streptavidin for 30 min. Color reaction was developed with 3, 3'-diaminobenzidine as a chromogen. Finally, the slides were counterstained with hematoxylin, and dehydrated through graded alcohol. For negative controls, slides were processed as above but treated with PBS instead of the primary antibody.

### Western blotting

Troglitazone-treated HepG2 cells were prepared in a cell-lysis solution. The protein concentration was determined by BCA Protein assay kit (Perbio Science Deutschland, Germany). Protein samples (50  $\mu$ g) were separated by SDS-PAGE and transferred to nitrocellulose membranes, to which rabbit anti-human survivin polyclonal antibody (1:1000), mouse anti-human Bax antibody (1:1000), mouse anti-human  $\beta$ -actin antibody (1:1000), and horseradish-peroxidase-labeled secondary antibody (all from Santa Cruz Biotechnology) were added. The signals were detected by enhanced chemiluminescence according to the protocol supplied with the kit.

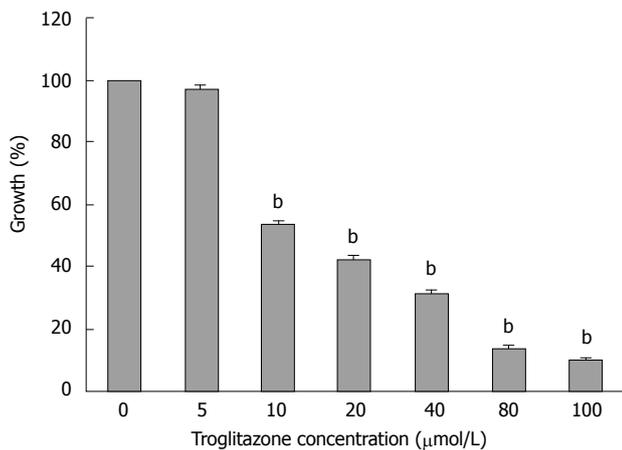

### Statistical analysis

Data were expressed as mean  $\pm$  SD. Statistical correlation of data was checked for significance by ANOVA and Student's *t* test. Differences with *P* < 0.05 were considered significant. These analyses were performed using SPSS 11.0 software (SPSS, Chicago, IL, USA).

## RESULTS

### Troglitazone inhibits cell growth

The MTT assay showed that cell viability was 96.8%  $\pm$  1.22%,

**Figure 1** Effect of troglitazone on growth of HepG2 cells. Cells were incubated with different concentrations of troglitazone for 120 h. Troglitazone inhibited growth of HepG2 cells in a dose-dependent manner, as demonstrated by MTT assay. Data represent the mean  $\pm$  SD from six wells. <sup>b</sup> $P < 0.01$  vs corresponding control group (unpaired Student's *t* test).

53.4%  $\pm$  1.2%, 42.3%  $\pm$  1.2%, 31.4%  $\pm$  1%, 13.6%  $\pm$  0.8% and 9.6%  $\pm$  0.7% at 5, 10, 20, 40, 80 and 100  $\mu$ mol/L troglitazone for 120 h, respectively (Figure 1), which indicated that troglitazone inhibited the growth of liver cells in a dose-dependent manner.

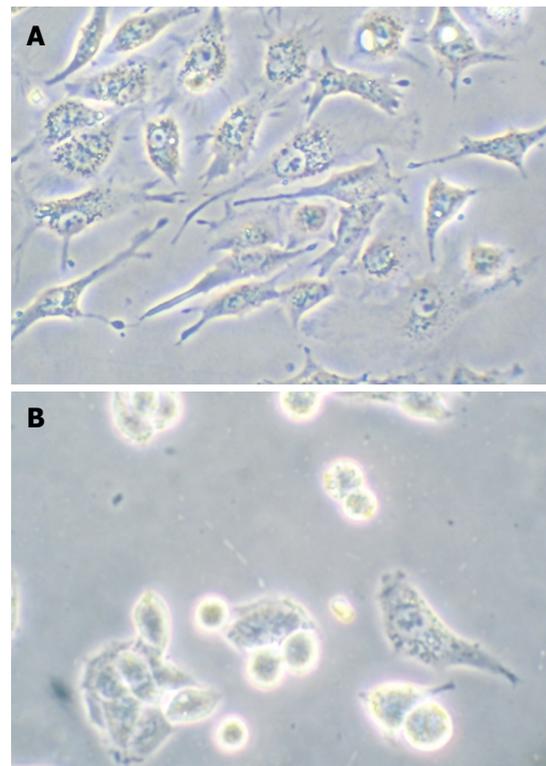

### Troglitazone induces apoptosis

HepG2 cells were treated with troglitazone (20 and 30  $\mu$ mol/L) for 24 h, and phase-contrast microscopy revealed that some cells became round, blunt and smaller in size, accompanied by karyopyknosis; light refraction was increased; and cells became detached and suspended in the medium, especially with 30  $\mu$ mol/L troglitazone. In the control group, cells were regular in morphology and grew fully in patches and confluent, rarely sloughing off (Figure 2).

Flow cytometry showed that after treatment of HepG2 cells with 20 and 30  $\mu$ mol/L troglitazone for 24 h, the percentage of sub-G<sub>0</sub>/G<sub>1</sub> peak apoptotic cells was 25.5%  $\pm$  1.1% and 43.9%  $\pm$  1.7%, respectively. In the untreated controls, none of the cells was found in the sub-G<sub>0</sub>/G<sub>1</sub> peak (Figure 3). TUNEL staining also showed that treatment with troglitazone for 24 h caused apoptosis of HepG2 cells. The apoptotic rate increased with concentration of troglitazone: 22.4%  $\pm$  1.2% for 20  $\mu$ mol/L, and 38.6%  $\pm$  0.8% for 30  $\mu$ mol/L troglitazone. In the control group, there were only background cells, without the presence of TUNEL positive cells (Figure 4,  $P < 0.001$ ).

### Troglitazone induces activation of caspase-3 expression

The caspase family plays a very important role in mediating apoptosis, among which caspase-3 is the key executive molecule, and its activated form has multiple functions in signal transmission of apoptosis<sup>[21,22]</sup>. Troglitazone activated caspase-3 expression. Positive staining was signified by a yellow-brown color, present in smaller cells whose plasma was condensed. After treatment of HepG2 cells with 20 and 30  $\mu$ mol/L troglitazone, the positive cell rate was 21.2%  $\pm$  1.4% and 35.8%  $\pm$  2.4%, respectively (Figure 5). No positive cells were found in the controls.

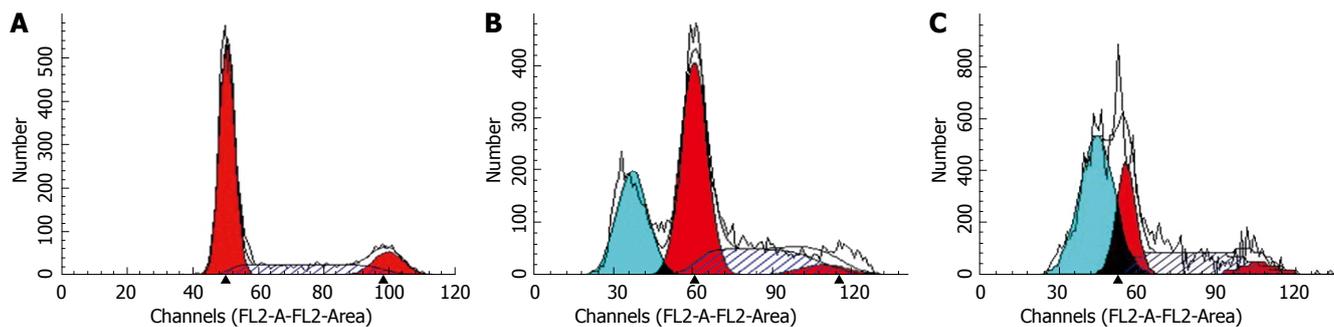

**Figure 2** Morphological changes were examined by phase-contrast microscopy. **A:** Controls; **B:** 30  $\mu$ mol/L troglitazone.

### Troglitazone drives survivin protein to translocate incompletely from the nucleus to the cytoplasm and inhibits its expression

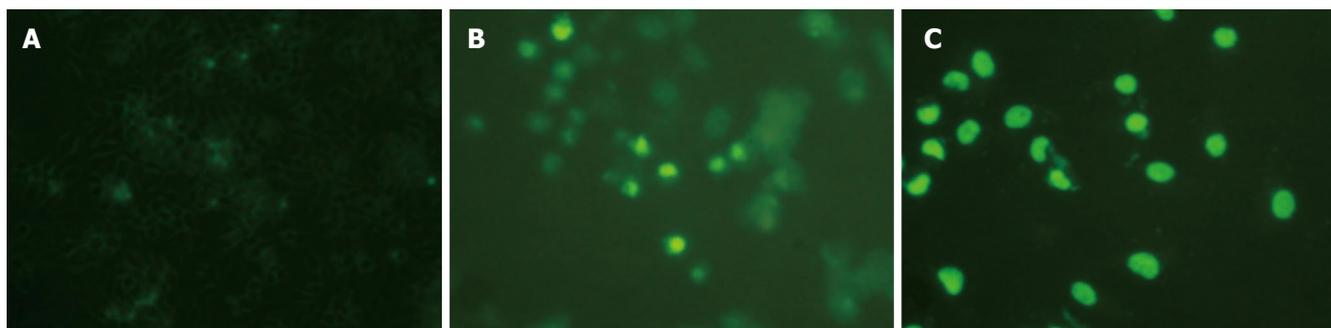

Immunocytochemical staining showed that apoptosis-inhibiting factor survivin was mainly expressed in the nucleus and weakly in the cytoplasm of untreated HepG2 cells. After treatment with 20 and 30  $\mu$ mol/L troglitazone for 24 h, survivin translocated partly from the nucleus to the cytoplasm, and the intensity of its expression decreased markedly. Also, apoptotic cells were seen in the treatment group, and presented with a smaller cell size and condensed cytoplasm (Figure 6). Western blotting revealed that, in HepG2 cells treated with troglitazone for 24 h, expression of HepG2 survivin was inhibited in a dose-dependent manner, but the treatment did not significantly affect expression of apoptosis-promoting factor Bax (Figure 7).

## DISCUSSION

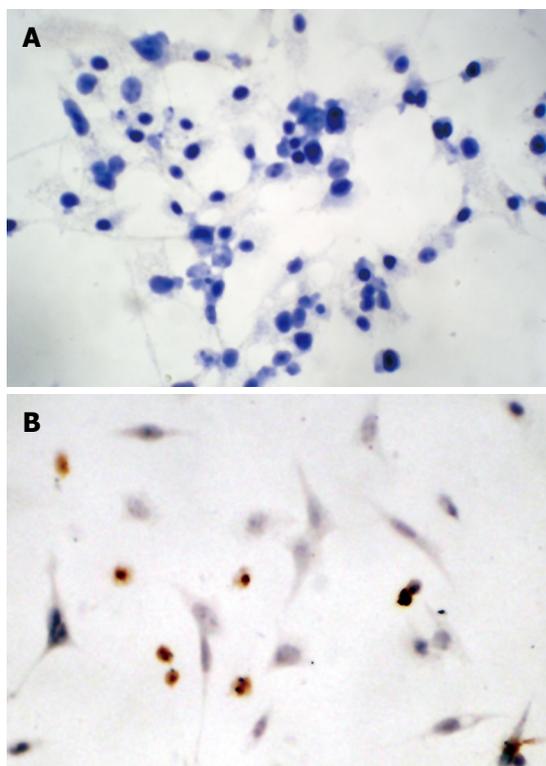

Apoptosis is a normal phenomenon in the process of embryonic growth of all organisms and human development. Disturbance of this process is associated with the development of many severe diseases and disorders including tumors. Selective induction of tumor-cell apoptosis may become the basic strategy in the treatment of malignant tumors. Most of the available chemotherapy drugs work through destroying tumor cells by inducing apoptosis<sup>[23]</sup>. In our study, the MTT assay showed troglitazone inhibited growth of liver cancer cells in a dose-dependent manner. To determine whether the inhibitory effect of troglitazone on the proliferation of liver cancer cells was associated with induction of apoptosis, flow cytometry and TUNEL

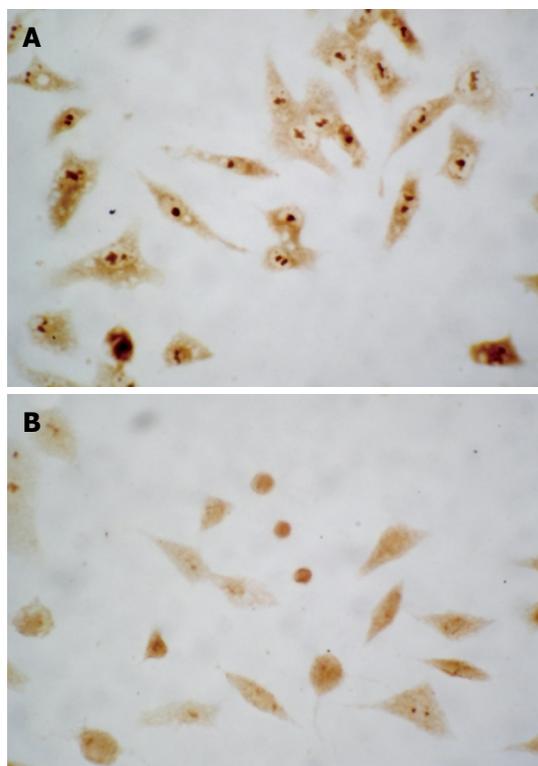

**Figure 3** Cell cycle analysis by flow cytometry. A: Control cells; B: 20  $\mu\text{mol/L}$  troglitazone; C: 30  $\mu\text{mol/L}$  troglitazone.

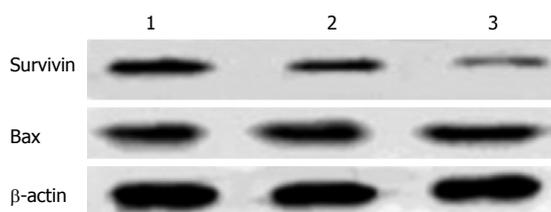

**Figure 4** Troglitazone significantly increased the number of TUNEL-positive cells in a dose-dependent manner. A: Control cells; B: 20  $\mu\text{mol/L}$  troglitazone; C: 30  $\mu\text{mol/L}$  troglitazone.

**Figure 5** Immunocytochemistry showed that caspase-3 was activated. The shrunken cells were positively stained for activated caspase-3. No positive cell was detectable in the control group (A: original magnification,  $\times 200$ ). Whereas large numbers of positive cells labeled for activated caspase-3 were observed in HepG2 cells treated with 30  $\mu\text{mol/L}$  troglitazone for 24 h (B: original magnification,  $\times 400$ ).

**Figure 6** Survivin was present predominantly in the nucleus in untreated cells (A: original magnification,  $\times 400$ ) as demonstrated by immunocytochemistry. After exposure of HepG2 cells to 30  $\mu\text{mol/L}$  troglitazone for 24 h, survivin incompletely translocated from the nucleus to the cytoplasm (B: original magnification,  $\times 400$ ).

**Figure 7** Effect of troglitazone on the expression of Bax and survivin. Lane 1: Control cells; lane 2: 20  $\mu\text{mol/L}$  troglitazone; lane 3: 30  $\mu\text{mol/L}$  troglitazone.

staining were conducted. The results confirmed troglitazone induced apoptosis of HepG2 cells in a dose-dependent manner. Thus, clarifying the apoptosis-related gene protein that is associated with troglitazone-induced apoptosis is of primary importance in explaining the mechanism of action of troglitazone.

Caspase is a group of cysteine hydrolytic proteinases that are able to specifically cleave the peptide chain behind the residue base of the target protein aspartate. It is the key molecule in the regulation of apoptosis. Caspase can trigger a cascade reaction under the control of apoptosis signals. According to their method of entering the apoptotic site, caspases are classified as initiator and effector caspases<sup>[21]</sup>, among which, caspase-3 is the most important terminal effector caspase in apoptosis, and plays an irreplaceable role. After initiation of the apoptotic process, caspase-3 transforms from the zymogen form to the activated form and functions by hydrolyzing proteins essential for survival of many kinds of cells<sup>[22]</sup>.

Survivin is a member of the inhibitor of apoptosis (IAP) family of negative regulators of programmed cell death, and is undetectable in normal adult tissue, but is abundantly expressed in fetal tissue and a variety of human cancers including HCC. High levels of survivin in tumors are frequently correlated with malignant parameters, which suggest a role in tumorigenesis<sup>[24,26]</sup>. Survivin can inhibit terminal effector caspase-3 and caspase-7, and interfere with caspase-9 activity and processing. Therefore, approaches designed to counteract antiapoptotic activity may inhibit tumor growth<sup>[27]</sup>.

There has long been controversy over the subcellular location of survivin. Some researchers have found survivin expression is located in the nucleus in HCC, esophageal squamous cell carcinoma, ovarian carcinoma, mantle cell lymphoma, cholangiocarcinoma, and non-small cell lung cancer, and is associated with poor prognosis. Other researchers have pointed out that survivin expression is located in the nucleus in gastric cancer, bladder mucosa and transitional cell carcinoma, and breast cancer, and is a predictor of good prognosis<sup>[28]</sup>. The results of our immunohistochemical staining confirmed that survivin was expressed mainly in the nucleus of HepG2 cells, and weakly in the cytoplasm. Fortugno *et al*<sup>[29]</sup> have found two survivin pools using immunofluorescence, one in the cytoplasm and the other in the nucleus. Suzuki *et al*<sup>[30]</sup> have found survivin protein can translocate from the cytoplasm to the nucleus. Here, it forms a complex with CDK4, which enables p21 to combine with a precursor released from the CDK4 complex and mitochondrial caspase-3, and inhibits

apoptosis by inhibiting the activity of caspase-3. The results of our study showed troglitazone induced apoptosis in a dose-dependent manner, during which survivin translocated incompletely from the nucleus to the cytoplasm, with a decrease in the intensity of expression; at the same time caspase-3 expression was activated. We presume troglitazone dissociated the survivin/CDK4 complex by inducing survivin expression and driving survivin to translocate incompletely from the nucleus to the cytoplasm. This forced p21 to form a complex with CDK4 by dissociating the combination of p21 and the precursor of mitochondrial caspase-3 and activating caspase-3. This led to cleavage of the corresponding nuclear and cytoplasmic substrates and finally caused apoptosis.

TZD induces massive apoptosis in renal cancer cells, with increased Bax expression and decreased Bcl-2 expression<sup>[18]</sup>. However, troglitazone significantly increases the expression of c-myc mRNA, but has no effect on expression of Bcl-2 and Bax in thyroid carcinoma cells<sup>[13]</sup>. In the current study, we also found Bax may not participate in troglitazone-induced apoptosis, suggesting that the mechanisms by which the PPAR $\gamma$  ligands cause tumor cell apoptosis are different depending on the type of cancer.

In conclusion, PPAR $\gamma$  ligands have the effect of inhibiting growth and inducing the apoptosis of liver cancer cells, and may have applications for the prevention and treatment of liver cancer.

## COMMENTS

### Background

Peroxisome proliferator-activated receptor (PPAR) belongs to the nuclear hormone receptor superfamily. Three subtypes of PPAR (PPAR $\alpha$ , PPAR $\gamma$  and PPAR $\delta$ ) have been identified, among which PPAR $\gamma$  has been studied most extensively. Recent data have shown that ligands for PPAR $\gamma$  exhibit growth-inhibitory effects on many types of human cancer. One of the important effects of these drugs is inducing apoptosis, although the exact mechanism remains elusive.

### Research frontiers

We used liver cancer cell line HepG2 that endogenously expresses PPAR $\gamma$  as an experimental model to study the effects of PPAR $\gamma$  ligand troglitazone on the proliferation and apoptosis of liver cancer cells, and analyzed the molecular mechanisms of these effects.

### Innovations and breakthroughs

Troglitazone inhibited growth and induced apoptosis of HepG2 cells in a dose-dependent manner, and induced activation of caspase-3 expression. Troglitazone not only drove apoptosis-inhibiting factor survivin to translocate incompletely from the nucleus to the cytoplasm, but also inhibited expression of survivin.

### Applications

PPAR $\gamma$  ligand has the effect of inhibiting growth and inducing apoptosis of liver cancer cells, and may have potential as a drug against liver cancer.

### Peer review

This study should arouse interest in readers. It provides important information for the investigation of the anti-cancer mechanism of troglitazone and other PPAR $\gamma$  ligands, and for the development of anti-cancer therapy using PPAR $\gamma$  ligands.

### Abstract

**AIM:** To achieve a better understanding of the pathogenesis of new type gosling viral enteritis virus (NGVEV) and the relationship between NGVEV and host cells.

**METHODS:** The apoptosis of duck embryo fibroblasts (DEF) induced by NGVEV was investigated by fluorescence-activated cell sorter (FACS) and fluorescence microscope after the cells were stained with Annexin V-FITC and propidium iodide (PI).

**RESULTS:** By staining cells with a combination of fluorescein annexin V-FITC and PI, it is possible to distinguish and quantitatively analyze non-apoptotic cells (Annexin V-FITC negative/PI negative), early apoptotic cells (Annexin V-FITC positive/PI negative), late apoptotic/necrotic cells (Annexin V-FITC positive/PI positive) and dead cells (Annexin V-FITC negative/

### INTRODUCTION

In order to eliminate the redundant, damaged, or infected cells, metazoan organisms evolve the cell suicide mechanism termed apoptosis<sup>[1]</sup>. Apoptosis is a physiological process defined by a number of distinct morphological features and biochemical processes<sup>[2,3]</sup>, which distinguish from necrosis<sup>[4,5]</sup>. Apoptosis is recognized as an important process in different biological systems, including embryonic development, cell turnover, and immune response against tumorigenic or virus-infected cells<sup>[6-8]</sup>. An increasing number of viruses or viral gene products were reported to induce apoptosis both *in vitro* and *in vivo*<sup>[9-16]</sup>.

The new type gosling viral enteritis (NGVE) is a new infectious disease and firstly recognized by Cheng *et al*, and it was observed in goslings less than 30 d of age in various areas of Sichuan Province<sup>[17,18]</sup>. The mortality from acute NGVE is high, and it is clinically characterized by respiratory, digestive, and neurological symptoms and

sudden death<sup>[17-19]</sup>. Catarrhal hemorrhagic fibrinonecrotic enteritis of the small intestine and coagulative embolus in the lower middle part of the intestine are the typical pathological changes of the NGVE in infected goslings<sup>[18]</sup>. NGVE virus was recognized as an adenovirus, which was round or oval, and characteristic icosahedral in shape, containing double-stranded DNA genome and fifteen structural proteins<sup>[18-20]</sup>. There are many researches on the histopathology, epizootiology, clinical signs, diagnoses, and immunity of the NGVE<sup>[17-24]</sup>. Interestingly, the apoptosis induced by NGVE virus infection is poorly documented.

In the early stage of apoptosis, which occurs at the cell surface, one of these plasma membrane alterations is the translocation of phosphatidylserine (PS) from the inner side of the plasma membrane to the outer layer, by which PS becomes exposed at the external surface of the cell<sup>[25-27]</sup>. Annexin V-FITC is a phospholipid-binding protein with a high affinity for PS, which can be used as a sensitive probe for PS exposure to the cell membrane<sup>[28-30]</sup>. However, it has also been reported that it binds to the inner face of the plasma membrane that has lost its integrity during the late stage of apoptosis, also known as secondary necrosis<sup>[31]</sup>. During the early apoptosis, the cells become reactive with annexin V-FITC after the onset of chromatin condensation, but prior to the loss of the plasma membrane ability to exclude PI<sup>[32]</sup>. Hence, necrotic cells are both stained by annexin V-FITC and PI, whereas early apoptotic cells are only stained by annexin V-FITC. Double staining of the infected DEF cells with annexin V-FITC and PI in this research could distinguish apoptotic cells from necrotic cells<sup>[33]</sup>. In this way, live, early apoptotic, late apoptotic/necrotic and dead cells can be discriminated on the basis of a double-labeling for annexin V-FITC and PI, and analyzed by either flow cytometry or fluorescence microscopy<sup>[34,35]</sup>.

## MATERIALS AND METHODS

### Primary duck embryo fibroblast (DEF) and viral strain

DEF cells were prepared using 11 to 13-d-old embryonated specific pathogen-free (SPF) eggs and propagated in minimal essential medium (MEM; Gibco) containing 100 mL/L new born calf serum (NBCS; Hyclone), 2.2 g/L NaHCO<sub>3</sub>, 100 U/mL penicillin/streptomycin (Gibco).

The NGVEV-CN strain with a high virulence field was provided by the Avian Diseases Research Centre of the Sichuan Agricultural University. The initial strain (adapted for cell culture growth) was isolated from a natural NGVE virus infection and the SPF gosling was then artificially infected, and the virus was serially passaged in 10-day-old SPF embryo eggs. The allantoic fluid was harvested and adapted to the monolayer DEF cells.

### Experimental NGVE virus infection of DEF

The monolayer DEF cells were washed twice with phosphate buffered saline solution (PBS; 0.15 mol/L, pH 7.2) and subsequently exposed to stock NGVEV-CN on a shaker at 37.5°C for 2 h. Stock virus was harvested from infected DEF when 75% cytopathic effects (CPEs) were observed. After inoculation with NGVEV-CN, cells were

Table 1 Apoptotic rate of DEF cells detected through annexin V-FITC/PI staining and analyzed by FACS

Infection time (h)	Early apoptotic cells (%) (annexin V-FITC <sup>+</sup> /PI <sup>-</sup> )		Advanced apoptotic cells (%) (annexin V-FITC <sup>+</sup> /PI <sup>+</sup> )	
	Mock infected	NGVEV infected	Mock infected	NGVEV infected
24	3.6	4.3	0.3	0.3
48	3.9	8.8	0.8	1.3
72	4.6	21.5	1.7	1.9
96	5.2	30.8	3.4	7.8
120	6.1	35.3	4.5	13.9
144	7.2	33.7	5.1	17.7

cultured at 37°C in a humidified atmosphere of 5% CO<sub>2</sub> in MEM supplemented with penicillin/streptomycin and 20 mL/L NBCS. Mock-infected cells were processed in the same way except that the virus was excluded.

### Annexin V-FITC/PI stained fluorescence-activated cell sorter (FACS)

At 24, 48, 72, 96, 120 and 144 h after infection (p.i.), 3 infected and mock-infected cells were harvested through trypsinization, and washed twice with cold PBS (0.15 mol/L, pH 7.2). The cells were centrifuged at 3000 r/min for 5 min, then the supernatant was discarded and the pellet was resuspended in 1 × binding buffer at a density of 1.0 × 10<sup>5</sup>-1.0 × 10<sup>6</sup> cells per mL. One hundred μL of the sample solution was transferred to a 5 mL culture tube, and incubated with 5 μL of FITC-conjugated annexin V (Pharmingen) and 5 μL of PI (Pharmingen) for 15 min at room temperature in the dark. Four hundred μL of 1 × binding buffer was added to each sample tube, and the samples were analyzed by FACS (Becton Dickinson) using Cell Quest Research Software (Becton Dickinson).

### Annexin V-FITC/PI stained fluorescence microscopy

The annexin V-FITC/PI staining procedure of the sample was adopted as above except that 1.0 × 10<sup>6</sup> cells/mL were centrifuged onto glass slides and studied under fluorescence microscope (Nikon 80i).

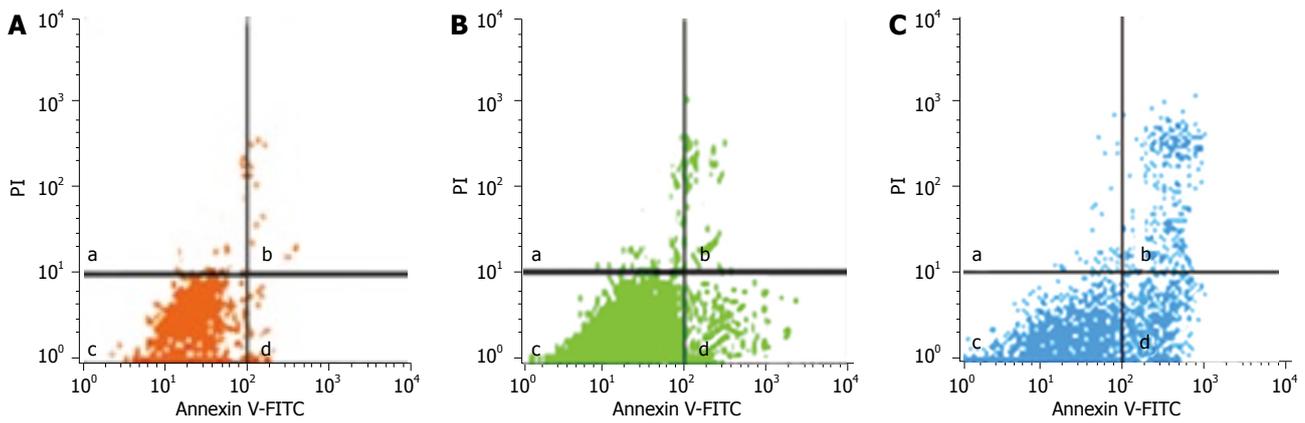

## RESULTS

### Annexin V-FITC/PI stained FACS

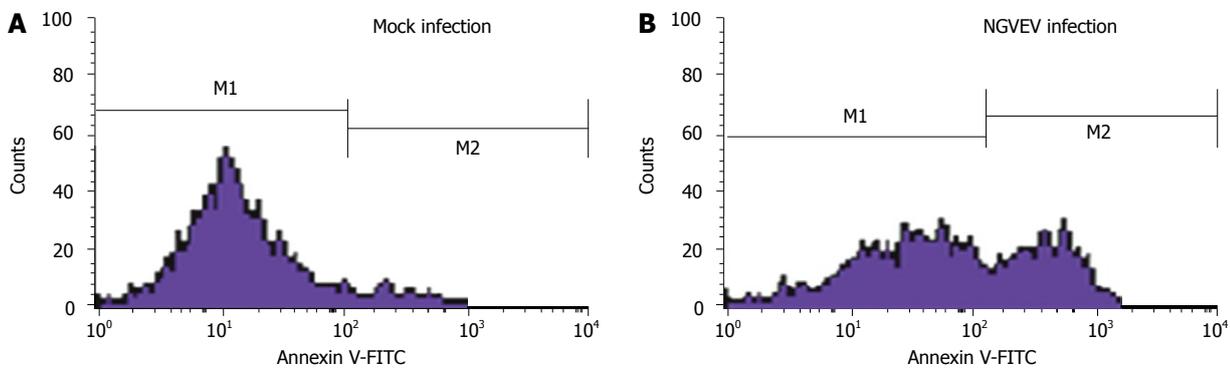

By staining cells with annexin V-FITC and PI, FACS was used to distinguish and quantitatively determine the percentage of dead, viable, apoptotic and necrotic cells after NGVE virus infection (Figure 1 and Table 1). At 72 h p.i., the percentage of apoptotic cells increased from 4.6% in the mock-infected control culture to 21.5% (Figure 2). The percentage of early apoptotic cells increased with incubated time until 120 h p.i. reaching the maximum 35.3%, and the proportion of the late apoptotic/necrotic cells increased from 0.3% to 17.7% (Table 1). A high level of the early apoptosis was detected from 72 h p.i. and high level of the late apoptosis/necrosis was detected after 96 h p.i., while the basal level of apoptosis and necrosis was shown in the mock-infected controls (Table 1).

### Annexin V-FITC/PI stained fluorescence microscopy

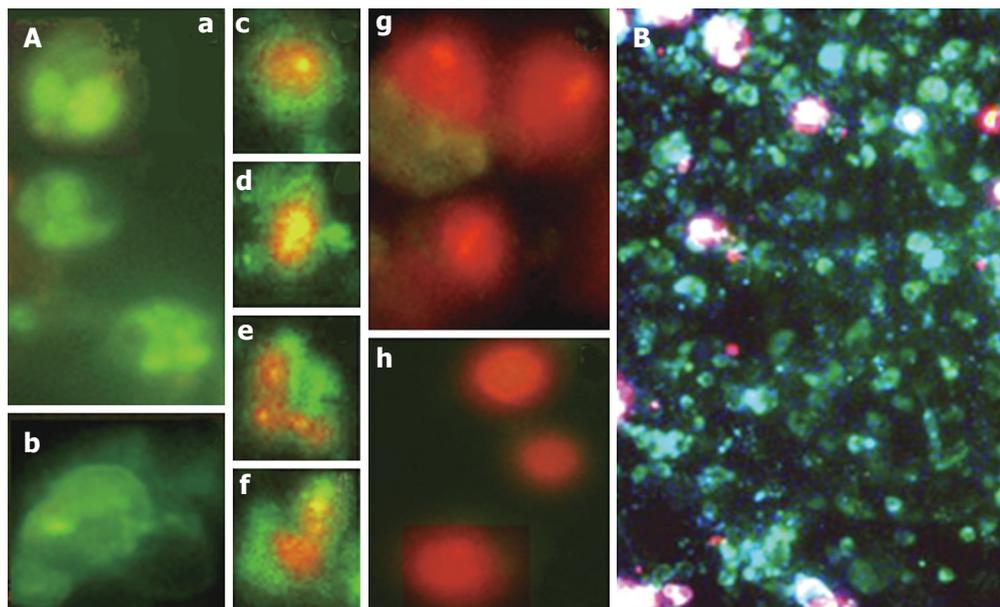

When examined under fluorescence microscopy, different

**Figure 1** NGVE virus infected DEF cells analyzed by FACS, stained with annexin V-FITC/PI. (A-C) display the results of the cells at 48, 96 and 144 h after NGVE virus infection. The proportion of non-apoptotic cells (c: Annexin V-FITC<sup>-</sup>/PI<sup>-</sup>), early apoptotic cells (d: Annexin V-FITC<sup>+</sup>/PI<sup>-</sup>), late apoptotic/necrotic cells (b: Annexin V-FITC<sup>+</sup>/PI<sup>+</sup>) and dead cells (a: Annexin V-FITC<sup>-</sup>/PI<sup>+</sup>).

**Figure 2** Flow cytometry of apoptotic DEF cells as assessed by annexin V-FITC fluorescent intensity. DEF cells are mock infected (A) and infected with NGVE virus (B). Cells harvested at 72 h p.i., and subsequently stained with annexin V-FITC/PI. One million cells are analyzed by flow cytometry, data are presented as fluorescent intensity units of annexin V-FITC (abscissa) and number of counts cells (ordinate). The M1 and M2 gates demarcate annexin V-FITC negative populations (non-apoptotic cells) and positive (apoptotic cells) populations.

**Figure 3** Apoptotic DEF cells induced by NGVE virus infection stained with Annexin V-FITC/PI and observed under fluorescence microscope. The samples are analyzed for green fluorescence (FITC) and red fluorescence (PI). **A:** Different labeling patterns of the NGVE virus infected cells: early apoptotic cells, annexin V-FITC positive and PI negative (a and b); necrotic or late apoptotic cells, both annexin V-FITC and PI positive (c-f); dead cells, annexin V-FITC negative and PI positive (g and h); **B:** 72 h p.i., the early and late apoptotic cells.

labeling patterns in this assay enabled us to identify different cell populations: live cells (Annexin V-FITC negative/PI negative), early apoptotic cells (the intactness

of the cell membrane, affinity for annexin V-FITC and devoid of PI staining) (Figure 3A a, b, 3B), late apoptotic/necrotic cells (the cell membrane loses its integrity,

the cell becomes both annexin V-FITC and PI staining) (Figure 3A c-f, 3B) and dead cells (Annexin V-FITC negative/PI positive) (Figure 3A g, h, 3B).

## DISCUSSION

Modulation of apoptosis is a common feature of infection by animal viruses and it also contributes to the pathogenesis process<sup>[36]</sup>. A variety of animal viruses have been identified to induce apoptosis in cultured cells<sup>[12,14-16]</sup>, which contained adenovirus. Early in 1968, Takemori<sup>[37]</sup> found that *cyt* mutants of human adenovirus could provoke more violent CPEs. Ezoe<sup>[38]</sup> further proved that it could also induce the DNA degradation in infected cells. Rautenschlein<sup>[39,40]</sup> respectively reported that the hemorrhagic enteritis virus (HEV) (fowl adenovirus) could induce B cells and spleen cells undergoing apoptosis. This research indicated that NGVE virus recognized as an adenovirus<sup>[17,19,20]</sup> could induce DEF undergoing apoptosis, which has never been reported before.

FACS is frequently used to monitor early apoptosis<sup>[26-29]</sup>, which should always be confirmed by the inspection of cells under electron or fluorescence microscope. Annexin V-FITC positive cells were first observed in NGVEV-infected DEF cells at 72 h p.i. under fluorescence microscopy, while it can be detected early from 24 h p.i. through FACS. The small number of apoptotic cells presented in mock-infected controls, which may be attributed to physiological cell death *in vitro*. The cells stained by annexin V-FITC alone obviously increased from 72 h p.i., indicating the induction of apoptosis rather than necrosis due to NGVE virus infection. The cells that stained positive for both annexin V-FITC and PI were increased from 96 h p.i. indicated the end stage of apoptosis or necrosis, which also suggested that apoptosis occurs prior to necrosis. This may be due to the fact that apoptosis makes many cell remnants undisturbed *in vitro*, which can be removed by phagocytes *in vivo*. The apoptotic cell debris interfered with the adjacent normal cells, leading to the necrosis. Furthermore, the lysis that eventually occurred at the end of apoptosis, which had essentially the same membrane permeability that occurred in necrosis. Further experiments are needed for a definite the intracellular events that trigger the apoptotic response during NGVE virus infection.

Recent studies demonstrate that the CPEs caused by virus infection *in vitro* is mediated by apoptosis<sup>[41-43]</sup>. Our previous research had revealed that the CPEs became obvious after 72 h p.i.<sup>[24]</sup> and TCID<sub>50</sub> reached a maximum at 120 h p.i., which was consistent to the results of this research: apoptotic cells obviously increased from 72 h p.i. and the apoptotic peak reached at 120 h p.i.. Therefore, it seems likely that apoptosis is related to CPEs during NGVE virus infection.

Virus-induced apoptosis is a complex and important aspect of the pathogenesis of viral infection<sup>[44-46]</sup>. In fact, in the case of virus-infected cells, the induction of cell death can reduce viral spread in the host by early killing of infected cells. In the case of virus itself, apoptosis facilitates persistent viral infection in host cells and is convenient for viral dissemination<sup>[47-49]</sup>. Quantitative assay

of the apoptosis in the present study indicated that the apoptosis was largely induced in the late phase of NGVE virus infection. During late NGVE virus infection, the virus almost completes its replication, therefore, the apoptosis provided a means for releasing the virus particles into the extracellular space without initiating a concomitant host response. It is assumed that NGVE virus induction of apoptosis may be an important mechanism of the efficient dissemination of progeny and the suicide of virally infected cells through apoptosis can limit infection, affording the host organism a certain degree of protection.

Many questions regarding NGVE virus-induced apoptosis remain unanswered, and future studies should be carried out.

## COMMENTS

### Background

New type gosling viral enteritis (NGVE) is a new infectious disease and it is observed in goslings aged less than 30 d. The typical pathological changes of the NGVE in infected goslings are catarrhal hemorrhagic fibrinonecrotic enteritis of the small intestine and coagulative embolus in the lower middle part of the intestine. NGVE virus is recognized as an adenovirus and many reports indicated that adenovirus could induce apoptosis both *in vitro* and *in vivo*. To date, whether the NGVE virus could trigger the host cells to undergo apoptosis has not been reported.

### Research frontiers

A number of viruses or viral gene products have been reported to induce apoptosis both *in vitro* and *in vivo*. Modulation of apoptosis is a common feature of infection by animal viruses and it was proved to contribute to the pathogenesis process. Scant information has been available so far for NGVE, especially in its etiology and pathogenesis. The apoptosis detected in this research during NGVE virus infection may be responsible for its pathogenesis.

### Innovations and breakthroughs

The authors of this paper have indicated that, for the first time, NGVE virus could induce the apoptosis of host cells *in vitro* and the apoptosis occurs prior to necrosis. The combined use of the fluorochrome labeled with fluorescence-activated cell sorter and fluorescence microscope for apoptosis detection can provide a rapid, quantitative and objective assay of cell viability, which may be applied for enumeration of apoptotic or necrotic cells.

### Applications

This work succeeded in a better understanding of pathogenesis process during NGVE virus infection.

### Terminology

Apoptosis: also named as programmed cell death (PCD), is the process whereby individual cells of multicellular organisms undergo systematic self-destruction in response to a wide variety of stimuli. Apoptosis is a genetically controlled preprogrammed event which eliminates cell development when they have become redundant, or functions as an emergency response after radiation damage, viral infection, or aberrant growth induced by the activation of oncogenes.

### Peer review

This is a very interesting study. The authors demonstrated that NGVE virus induces the apoptosis of infected DEF cells and the apoptosis occurs prior to necrosis. The study is well designed, and the analysis is reasonable.

### Abstract

**AIM:** To compare the pharmacokinetics and tissue distribution of 5-fluorouracil administered intraperitoneally with two isotonic carrier solutions: HAES-steri (neotype 6% hydroxyethyl starch), a novel carrier solution with middle molecular weight and physiologic saline (0.9% sodium chloride solution), a traditional carrier solution for intraperitoneal chemotherapy, in rats.

**METHODS:** A total of 60 Sprague Dawley rats were randomized into groups according to the carrier solution administered. Each group was further randomized according to the intraperitoneal dwell period (1, 3, 6, 12, 18 and 24 h). At the end of the procedure the rats were killed, the peritoneal fluid was withdrawn completely and quantitated. Drug concentrations in peritoneal fluid, plasma, and tissues were determined by high-performance liquid chromatography.

**RESULTS:** The mean volumes remaining in the peritoneal cavity were significantly higher with HAES-steri than those with physiologic saline at 1, 6, 12, 18, and 24 h ( $P = 0.047, 0.009, 0.005, 0.005$  and  $0.005$  respectively, the percentages of remaining peritoneal fluid volume were  $89.9 \pm 5.6$  vs  $83.4 \pm 4.9$ ,  $79.9 \pm 2.8$  vs  $56.2 \pm 15.7$ ,  $46.8 \pm 5.5$  vs  $24.7 \pm 9.7$ ,  $23.0 \pm 2.8$  vs  $0.0 \pm 0.0$  and  $4.2 \pm 1.7$  vs  $0.0 \pm 0.0$  respectively). Mean concentrations in peritoneal fluid were significantly higher with HAES-steri than those with physiologic saline at 3, 12 and 18 h ( $P = 0.009, 0.009$  and  $0.005$  respectively, the concentrations were  $139.2768 \pm 28.2317$  mg/L vs

mg/L,  $11.5427 \pm 3.0976$  mg/L vs  $0.0000 \pm 0.0000$  mg/L and  $4.7724 \pm 1.0936$  mg/L vs  $0.0000 \pm 0.0000$  mg/L respectively). Mean plasma 5-fluorouracil concentrations in portal vein were significantly higher with HAES-steri at 3, 12, 18 and 24 h ( $P = 0.009, 0.034, 0.005$  and  $0.019$  respectively, the concentrations were  $3.3572 \pm 0.8128$  mg/L vs  $0.8794 \pm 0.2394$  mg/L,  $0.6203 \pm 0.9935$  mg/L vs  $0.0112 \pm 0.0250$  mg/L,  $0.3725 \pm 0.3871$  mg/L vs  $0.0000 \pm 0.0000$  mg/L, and  $0.2469 \pm 0.1457$  mg/L vs  $0.0000 \pm 0.0000$  mg/L respectively), but significantly lower at 1 h ( $P = 0.009$ , the concentrations were  $4.1957 \pm 0.6952$  mg/L vs  $7.7406 \pm 1.2377$  mg/L). There were no significant differences in the plasma 5-fluorouracil in inferior caval vein at each time-point. 5-fluorouracil concentrations were significantly greater with HAES-steri at 18 h in gastric tissue ( $P = 0.016$ , the concentrations were  $0.9486 \pm 0.8173$  mg/L vs  $0.30392 \pm 0.0316$  mg/L), at 18 h in colon ( $P = 0.009$ , the concentrations were  $0.1730 \pm 0.0446$  mg/L vs  $0.0626 \pm 0.0425$  mg/L), at 3, 6, 12 and 24 h in liver ( $P = 0.009, 0.013, 0.034$  and  $0.013$  respectively, the concentrations were  $0.6472685 \pm 0.5256$  mg/L vs  $0.1554 \pm 0.1043$  mg/L,  $0.8606826 \pm 0.7155$  mg/L vs  $0.0014 \pm 0.0029$  mg/L,  $0.0445 \pm 0.0330$  mg/L vs  $0.0797 \pm 0.1005$  mg/L and  $0.0863 \pm 0.0399$  mg/L vs  $0.0034 \pm 0.0075$  mg/L respectively) and at 18 h in lung ( $P = 0.009$ , the concentrations were  $0.0886 \pm 0.0668$  mg/L vs  $0.0094 \pm 0.0210$  mg/L). There were no differences in 5-fluorouracil concentrations in renal tissue at each time-point.

**CONCLUSION:** The use of intraperitoneal 5-fluorouracil with HAES-Steri carrier solution provides a pharmacokinetic advantage for a local-regional killing of residual tumor cells and improve the accumulated penetrability of 5-fluorouracil with decreased systemic toxicity. Further clinical feasibility studies on the use of HAES-steri as carrier solution for intraperitoneal chemotherapy with 5-fluorouracil are warranted.

## INTRODUCTION

The gastrointestinal cancer tumor is one of the most common clinical malignant tumors<sup>[1]</sup>. Although the surgical interventions have been advancing and radiotherapy, chemotherapy, biotherapy, immunotherapy and Chinese traditional medicine been developing all the time, the prognosis of patients with gastrointestinal cancer has not been improved obviously and the mortality not been decreased greatly so far, for which the main reason is that the regional recurrence and implantation metastasis can not be treated effectively. The recurrence and metastasis of gastrointestinal cancer often occurs in the resection place, peritoneal membrane surface and liver by turns<sup>[2,3]</sup>. Intraperitoneal chemotherapy, which aims at this biological behavior and makes the recurrence and metastasis places of gastrointestinal cancer exposed to anti-cancer drug directly for a long time, provides a new adjunctive therapy for intraperitoneal malignant tumors, especially for gastrointestinal cancer now<sup>[4,5]</sup>. However, two pharmacokinetic problems appear to limit the effectiveness of intraperitoneal therapy: poor tumor penetration and no uniform intraperitoneal distribution by the drug-containing solution<sup>[6]</sup>. Several factors contribute to the drug distribution but intraperitoneal fluid volume is a dominant factor<sup>[7]</sup>. Rosenheim *et al* have demonstrated in monkeys that small volumes of fluid do not flow freely in the peritoneum, even with multiple position changes<sup>[8]</sup>. Volumes large enough to cause moderate abdominal distention result in more uniform intraperitoneal distribution. The ideal carrier solutions for intraperitoneal chemotherapy should expose cancerous surfaces or residual tumor cells within the peritoneal cavity to high levels of cytotoxic agent for as long as possible and make the agents distribute in the abdominal cavity uniformly<sup>[9]</sup>.

Current techniques for intraperitoneal chemotherapy administration most often utilize isotonic micromolecule solutions such as physiological saline, however, the low molecular weight of this solution results in its rapid peritoneal absorption and cannot make the system toxicity from intraperitoneal chemotherapy under satisfactory control<sup>[10]</sup>. A successful attempt has been made to prolong retention of intraperitoneal chemotherapy by using icodextrin<sup>[11-13]</sup>, which is an isomolar glucose polymer-based dialysate solution. Another isomolar glucose polymer solution with a potentially long intraperitoneal dwell time is 6% hydroxyethyl starch<sup>[14,15]</sup>.

Slow clearance would benefit the use of cell cycle-specific drugs whose apoptotic effects enhance penetration in solid tumor. Agents undergoing extensive hepatic metabolism such as 5-fluorouracil and doxorubicin possess the greatest regional advantage with intraperitoneal instillation<sup>[16-18]</sup>.

HAES-steri is a neotype hetastarch with middle molecule, which is commonly used for clinical volume expansion therapy. On the basis of its characteristic that it can stay in the blood vessel for a long time and the research about the solutions of the same kind, HAES-steri is promising to be an ideal carrier solution for intraperitoneal chemotherapy. The purpose of these animal experiments was to determine the pharmacokinetics and tissue concentrations of 5-fluorouracil after intraperitoneal perfusion with two isotonic carrier solutions: physiologic saline, a low molecular weight solution, and HAES-steri, a middle molecular weight solution.

## MATERIALS AND METHODS

### Animals

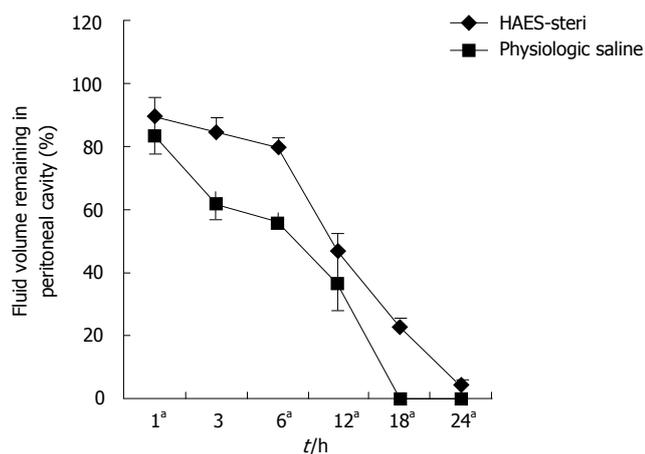

Male and female Sprague Dawley rats weighing between 200 and 300 g were obtained from a single breeding colony (Laboratory Animal center of Southern Medical University). Animals were individually housed and were allowed free access to food and water. These experiments were conducted after approval by Laboratory Animal Center of Southern Medical University. (the license No. is SY × K 2006-0074).

### Surgical procedure

All rats were briefly anesthetized by inhalation of ether (ether, Guanghua Chemistry Co., Ltd. Guangdong, China). Using a 50 mL injection syringe, the cytotoxic agent plus the carrier solution was administered intraperitoneally. The volume of solution administered was 0.1 mL/g body weight. Rats were returned to their cages to recover and were allowed free access to food and water. Rats were anesthetized by inhalation of ether for one minute before the end of the dwell-time. Through a midline thoracotomy the peritoneal fluid was withdrawn completely and quantitated. The blood samples of portal vein and inferior caval vein were taken with a 5 mL injection syringe and 2 mL syringe respectively, and tissue samples were taken from the stomach, colon, liver, kidney and lung.

### Experimental design

A total of 60 rats were randomized into two groups according to the carrier solution administered. 5-fluorouracil (Nantong Jinghua Pharmaceutical Co., Ltd., China) was administered in tamed iodine. The dose of drug used in this study was chosen at 100 mg/kg, which exceeds the intraperitoneal dosage used in humans and was meant to be above the analytic detection limit in fluid samples. Based on this dosage, 5-fluorouracil was administered at a concentration of 1000 µg/mL. Two isotonic carrier solutions (0.1 mL/g body weight) were used: physiologic saline (Shenzhen Pharmaceutical Co., Ltd, Guangzhou, China) and 6% hetastarch (Beijing Fresenius Kabi Pharmaceutical Co., Ltd.). Each group was further randomized according to the length of the dwell period of chemotherapy (1, 3, 6, 12, 18 or 24 h). At the end of the procedure the rats were killed. A midline thoracoabdominal incision was made and all peritoneal fluid removed. The volume of peritoneal fluid was recorded and a 0.5 mL

**Figure 1** Mean peritoneal fluid volume remaining as a percentage of initial chemotherapy solution volume administered (<sup>a</sup> $P < 0.05$  between the two carrier solutions).

sample was retained for analysis. Blood and tissue were also sampled. 5-fluorouracil concentrations in plasma, peritoneal fluid, and tissue samples were analyzed by high-performance liquid chromatography (HPLC).

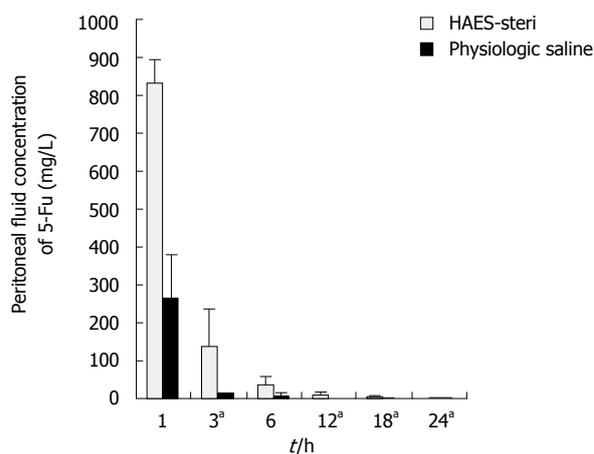

### HPLC analysis C

5-fluorouracil levels were determined in plasma, peritoneal fluid and tissue samples, using the HPLC procedures. The HPLC system consisted of a P200 high pressure constant flow pump, an UV-VIS detector set at 265 nm UV, along with an EC2000 color spectrum workstation, an EC2000 Chromatopac data processor. A reversed-phase Diamonsil C<sub>18</sub> 5 μm silica column 250 mm × 4.6 mm was used, coupled to a guard column of the same chemical consistency (Dikma Technologies, Beijing, China). The mobile phase consisted of an mixture of acetonitrile and ultrapure water (1:19, v/v), run at a flow rate of 1.0 mL/min. Sample injections were 20 μL with 5-bromouracil as internal standard. All solvents used were HPLC grade (Merck, KGaA).

### Sample preparation and analysis

Blood samples were centrifuged and the plasma was separated from the cells. Using a 15-mL polypropylene conical tube, a 500 μL sample of plasma was treated with 100 μL 5-bromouracil as internal standard and 2 mL acetoacetate (Guanghua Chemistry Co., Ltd., Guangdong, China) and mixed thoroughly in a vortex mixer. After centrifugation, the acetoacetate was transferred to another polypropylene tube and evaporated at approximately 40°C by blowing with a gentle stream of nitrogen. The residue was resuspended in 100 μL mobile phase and filtered through a 0.45 μm syringe filter before HPLC injection. Peritoneal fluid samples were treated as blood sample before HPLC injection.

Tissue samples were processed after drying surface moisture with filter paper. A sample of tissue was accurately weighed with electronic balance and homogenized in ultrapure water with the volume as 3 times as the weight of the sample (v:w = 3 mL/g) with a homogenizing machine. The tissue sample site was

**Figure 2** Mean peritoneal fluid concentration of 5-fluorouracil with different carrier solutions (<sup>a</sup> $P < 0.05$  between the two carrier solutions).

consistent for all animals. The homogenate was centrifuged and the supernatant fluid was removed and the following was used as the blood sample.

### Statistical analysis

The main parameters of pharmacokinetics and areas under the concentration-time curve were determined using DAS 2.0 (Drug and Statistics Software, Anhui, China). All pharmacokinetic data were compared between groups at each time-point with Mann-Whitney test (two-tailed) using SPSS 10.0. For all statistical procedures,  $P$  values  $< 0.05$  were considered significant.

## RESULTS

### Intraperitoneal volume

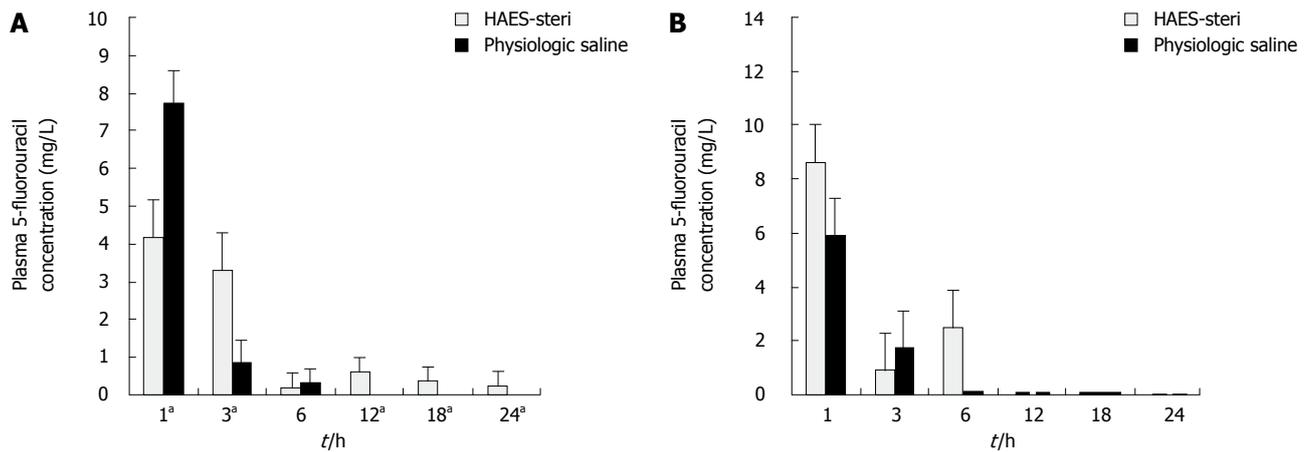

Measurements of peritoneal fluid volume at each time-point showed slower clearance from the peritoneal cavity of HAES-steri when compared to physiologic saline (Figure 1). The mean percentage of fluid volume remaining in the peritoneal cavity was significantly higher with HAES-steri at 1, 6, 12, 18 and 24 h ( $P = 0.047, 0.009, 0.005, 0.005$  and  $0.005$  respectively). No excess peritoneal fluid remained at 18 h with physiologic saline. At 24 h, the percentage of remaining peritoneal fluid volume with HAES-steri was 4.2%.

### Peritoneal fluid drug concentration

At each time-point drug concentrations were determined within the peritoneal cavity (Figure 2). The mean peritoneal fluid 5-fluorouracil concentration was significantly greater at 3, 12, 18 and 24 h ( $P = 0.009, 0.009, 0.005$  and  $0.005$  respectively). There was no significant difference in 5-fluorouracil concentrations of peritoneal fluid between carrier solutions at other time-points.

### Plasma drug concentration in portal vein

Plasma 5-fluorouracil concentrations were significantly lower when the drug was administered with HAES-steri at 1 h ( $P = 0.009$ ) and were significantly higher at 3, 12, 18 and 24 h ( $P = 0.009, 0.034, 0.005$  and  $0.019$  respectively) (Figure 3A).

**Figure 3** A: Mean plasma concentration of 5-fluorouracil in portal vein with different carrier solutions (<sup>a</sup> $P < 0.05$  between the two carrier solutions); B: Mean plasma concentration of 5-fluorouracil in inferior caval vein with different carrier solutions.

### Plasma drug concentration in inferior caval vein

There were no significant differences in plasma 5-fluorouracil concentration in inferior caval vein between different carrier solutions at each time-point (Figure 3B).

### Total quantity of drug in peritoneal fluid

The mean total quantity of 5-fluorouracil in the peritoneal fluid decreased with time for both hetastarch and peritoneal dialysis solution, but was significantly greater with hetastarch at 12 h ( $P = 0.008$ ), 18 h ( $P = 0.009$ ) and 24 h ( $P = 0.009$ ) (Figure 4A). No measurable drug or excess peritoneal fluid was present at 18 h when physiologic saline was used. When HAES-steri was used, the mean volume of peritoneal fluid remaining at 24 h was  $4.2\% \pm 1.7\%$  ( $\pm$  SD) of the initial peritoneal fluid volume. The mean total quantity of 5-fluorouracil in this fluid was extremely low ( $0.7458 \pm 0.1954 \mu\text{g}$ ).

### Area under the curve ratio of peritoneal fluid to plasma 5-fluorouracil concentration

The area under the concentration over time curve (AUC) ratio with HAES-steri was 1551.095 for peritoneal fluid, 17.49 for plasma in portal vein and 19.466 for plasma in inferior caval vein. The AUC ratio for physiologic saline was 824.054 for peritoneal fluid, 14.516 for plasma in portal vein and 20.275 for plasma in inferior caval vein. The AUC ratio of peritoneal fluid to plasma in portal vein was 88.68 for HAES-steri, and 56.76 for physiologic saline. The AUC ratio of peritoneal fluid to plasma in inferior caval vein was 79.68 for HAES-steri, and 40.64 for physiologic saline. There was an increase of 156% in the AUC ratio of peritoneal fluid to plasma in portal vein and 196% in inferior caval vein with HAES-steri ( $88.68$  vs  $56.76$ ;  $79.68$  vs  $40.64$ ).

### Drug concentration in gastric tissue

Mean tissue concentrations of 5-fluorouracil were greater in gastric tissue with HAES-steri. These differences were significant at 18 h ( $P = 0.016$ ). No significant differences were seen in gastric tissue concentrations of 5-fluorouracil at other time-points (Figure 4B).

### Drug concentration in colon tissue

Tissue concentrations of 5-fluorouracil were significantly greater in colon tissue with HAES-steri at 18 h ( $P = 0.009$ ) (Figure 4C). There were no significant differences in colon tissue concentrations of 5-fluorouracil at other time-points.

### Drug concentration in liver tissue

Tissue concentrations of 5-fluorouracil were significantly greater in liver tissue with HAES-steri at 3, 6, 12 and 24 h in liver ( $P = 0.009, 0.013, 0.034$  and  $0.013$  respectively) (Figure 4D). There were no significant differences in liver tissue concentrations of 5-fluorouracil at other time-points.

### Drug concentration in lung tissue

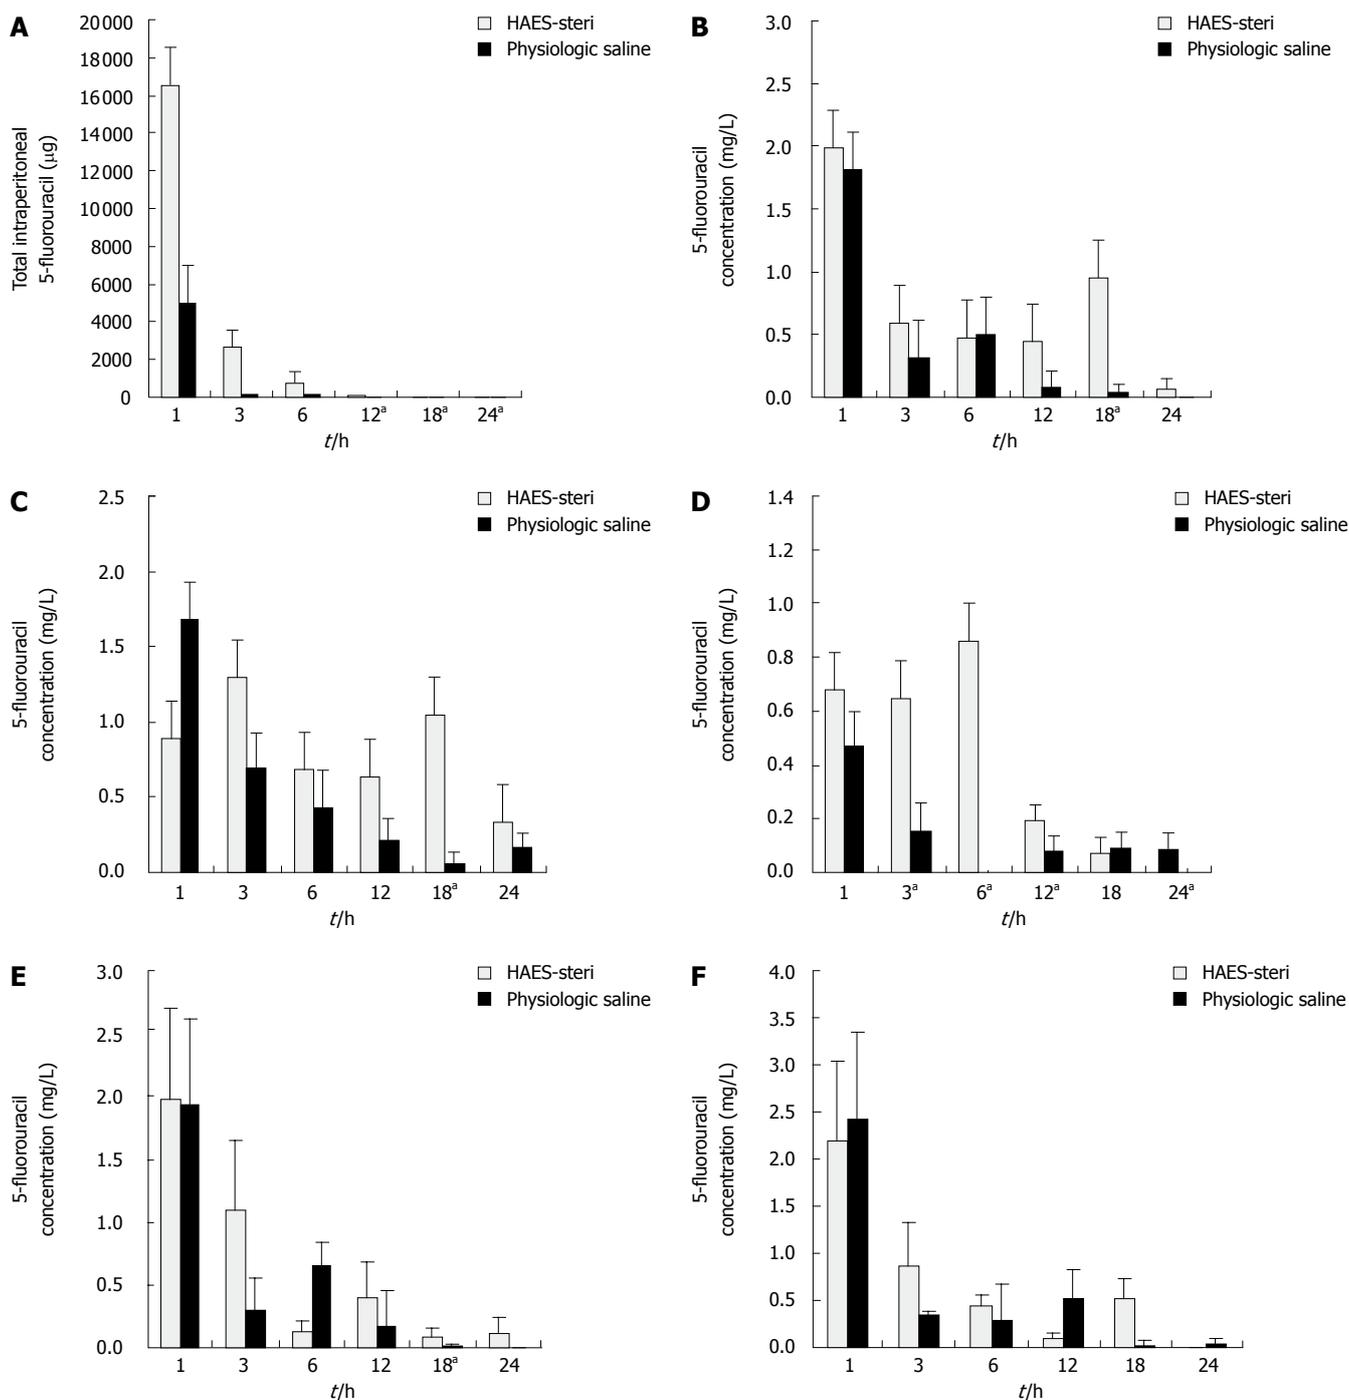

Tissue concentrations of 5-fluorouracil were significantly higher in lung tissue with HAES-steri at 18 h ( $P = 0.009$ ) (Figure 4E). There were no significant differences in lung tissue concentrations of 5-fluorouracil at other time-points.

### Drug concentration in renal tissue

No significant differences were seen in renal tissue concentrations of 5-fluorouracil with the two carrier solutions at each time-point (Figure 4F).

## DISCUSSION

Intraperitoneal chemotherapy has shown certain benefits as a treatment for peritoneal surface malignancies and regional recurrence of gastrointestinal cancer after operation so far<sup>[19-21]</sup>. However, no standard treatment in terms of schedule, dwell-time, drug or carrier solution has been established<sup>[9]</sup>. It remains an unrealized goal that intraperitoneal chemotherapy makes a great stride in improving the survival and prognosis of patients with gastrointestinal cancer. The lack of ideal carrier solutions is one of the main problems which prevent the progress of intraperitoneal chemotherapy. After radical or palliative surgery for gastrointestinal cancer, tumor recurrence within the peritoneal cavity may be due to residual tumor nodules on the peritoneal surface or to implantation of free cancer cells circulating within peritoneal fluid.

**Figure 4** A: Mean total quantity of 5-fluorouracil in peritoneal fluid with different carrier solutions ( $^aP < 0.05$  between the two carrier solutions); B: 5-fluorouracil concentration in gastric tissue with different carrier solutions ( $^aP < 0.05$  between the two carrier solutions); C: 5-fluorouracil concentration in colon tissue with different carrier solutions ( $^aP < 0.05$  between the two carrier solutions); D: 5-fluorouracil concentration in liver tissue with different carrier solutions ( $^aP < 0.05$  between the two carrier solutions); E: 5-fluorouracil concentration in lung tissue with different carrier solutions ( $^aP < 0.05$  between the two carrier solutions); F: 5-fluorouracil concentration in renal tissue with different carrier solutions ( $^aP < 0.05$  between the two carrier solutions).

Preventing recurrence effectively requires that the tumor nodules have prolonged exposure to the cytotoxic drug. It is necessary for chemotherapy solutions to distribute evenly throughout the entire peritoneal cavity for a prolonged period in order to treat peritoneal and visceral surfaces safely and successfully.

However, isotonic salt solutions, the traditional carrier solutions in use for intraperitoneal chemotherapy, tend to be rapidly absorbed due to their low molecular weight. Pesticau and colleagues have proved that isotonic 0.9%

sodium chloride was cleared more rapidly from the peritoneal cavity than high molecular weight solutions and hypertonic sodium chloride, when used as carrier solutions for intraperitoneal chemotherapy with 5-fluorouracil and gemcitabine in an animal model<sup>[9]</sup>. The inability of isotonic salt or dextrose solutions to maintain a prolonged high intraperitoneal fluid volume limits their effectiveness as carrier solutions for intraperitoneal chemotherapy. The osmolality of the solution may play a role in prolonging the dwell time of intraperitoneal chemotherapy. In a

study by Litterst *et al*, it was shown that slightly hypertonic carrier solutions can prolong the peritoneal retention of chemotherapeutic agents within the peritoneal cavity, probably by inducing a fluid shift inward to the peritoneal cavity<sup>[22]</sup>. Although the increased accumulation of drugs in tumor cells and enhanced cytotoxicity of cisplatin in hypotonic solution have been confirmed *in vitro* and *in vivo*<sup>[23,24]</sup>, the clinical success with hypotonic solutions as carrier solutions for intraperitoneal chemotherapy has been limited<sup>[25,26]</sup>. It has been shown that high molecular weight carrier solutions such as Icodextrin and hetastarch have the ability to maintain high intraperitoneal volume for a longer period. Preliminary data receiving intraperitoneal chemotherapy with 7.5% Icodextrin showed that a similar quantity of fluid was drained from the peritoneal cavity as was originally instilled 24 h after administration<sup>[27]</sup>. However, net fluid flow into the peritoneal cavity may occur when 7.5% icodextrin solutions were used, which could decrease the concentration of drug exposed to cancerous surfaces<sup>[6]</sup>. A clinical study on the fluid dynamics of 4% icodextrin as carrier solution for intraperitoneal chemotherapy showed that it maintained its instilled volume for up to 48 h, and half the instilled volume remained after 72 and 96 h<sup>[28]</sup>. Another high molecular weight carrier solution, 6% hetastarch, has also been used in a recent clinical study, which showed reduced clearance of hetastarch from the peritoneal cavity when compared with 1.5% dextrose peritoneal dialysis solution<sup>[29]</sup>.

In the study reported here, the use of HAES-steri, a starch-based carrier solution with middle molecular weight, reduced the clearance of chemotherapy solution from the peritoneal cavity when compared to physiologic saline (0.9% sodium chloride solution). The mean percentage of fluid volume remaining in the peritoneal cavity was significantly higher with HAES-steri at 1, 6, 12, 18 and 24 h. The total quantity of intraperitoneal drug at each time-point was also higher with HAES-steri, especially at 12 h and 18 h. By delaying the clearance of intraperitoneal fluid and thereby maintaining a large distribution, HAES-steri may maximize exposure of cancerous surfaces and optimize intraperitoneal chemotherapy treatments. At the 3, 12 and 18 h time-point, a significantly increased concentration of intraperitoneal 5-fluorouracil was demonstrated. It indicated that HAES-steri could reduce the clearance of 5-fluorouracil from peritoneal cavity and increase the drug concentration exposed to peritoneal surfaces at the same time as this solution maintained high volume in peritoneal cavity for a long time. Accordingly, a larger number of residual tumor cells, minute nodules or free cancer cells in peritoneal cavity can be attacked by high concentrations of anti-cancer drug for over a given time period, which may improve the effectiveness of intraperitoneal chemotherapy for peritoneal regional recurrence of gastrointestinal cancer after surgery.

An important parameter for pharmacokinetic analyses of a drug is the AUC, which represents the total drug exposure integrated over time<sup>[10]</sup>. The AUC is traditionally the relationship between time and plasma concentration, but can also be applied to concentration of drug in peritoneal fluid for intraperitoneal chemotherapy. Cancer chemotherapy pharmacokinetics assumes a definite

relationship of drug response to drug dose. Following intraperitoneal administration of a drug, the AUC reflects the degree of exposure of peritoneal surfaces to chemotherapeutic agent. It is the best estimate of drug delivery and a predictor of response. By comparing the AUC of a drug after intraperitoneal administration in HAES-steri to the AUC after administration in physiologic saline, an estimate of the optimum carrier solution that will prolong contact of peritoneal surfaces and residual tumor cells with chemotherapy solution can be obtained. The ratio of the AUC of 5-fluorouracil in peritoneal fluid to that in plasma of inferior caval vein after intraperitoneal administration reflects exposure of peritoneal surfaces to chemotherapy solution in relation to plasma concentrations of drug, which influences systemic toxicity. The higher AUC ratio of peritoneal fluid to plasma 5-fluorouracil concentration with HAES-steri suggests that better regional exposure of 5-fluorouracil and lower systemic toxicity can be achieved than with physiologic saline. Using intraperitoneal 5-fluorouracil with HAES-steri provides a potential for a favorable antitumor effect on small peritoneal surface tumor deposits or microscopic residual disease.

Another advantage of intraperitoneal chemotherapy is to prevent liver metastasis of gastrointestinal cancer after operation with chemotherapeutics of high concentration in portal vein and liver. In this study, although plasma 5-fluorouracil concentrations were significantly lower when the drug was administered with HAES-steri than with physiologic saline at 1 h, those were significantly higher at 3, 12, 18 and 24 h. Moreover, concentrations of 5-fluorouracil were significantly greater in liver tissue with HAES-steri at 3, 6, 12 and 24 h. This shows that HAES-steri has advantages over physiologic saline as carrier solutions for intraperitoneal chemotherapy to kill free cancer cells in portal vein, consequently, using HAES-steri as carrier solution for intraperitoneal chemotherapy with 5-fluorouracil may improve the effectiveness to prevent liver metastasis of gastrointestinal cancer after surgery.

Tissue concentrations of 5-fluorouracil were significantly higher in gastric and colon tissue at 18-h time-point when HAES-steri was used as carrier solution. This would suggest that HAES-steri increases the accumulated penetrated activity of 5-fluorouracil when used as carrier solution for intraperitoneal chemotherapy, which may benefit the eliminating internal cancer cells in residual tumor nodules. No significant differences were seen in renal tissue concentrations of 5-fluorouracil with the two carrier solutions at each time-point and there were no significant differences in lung tissue concentrations of 5-fluorouracil at time-points except 3-h. These may indicate again that HAES-steri makes the systemic toxicity of intraperitoneal chemotherapy under control when used as carrier solution.

Another advantage of HAES-steri as carrier solution for intraperitoneal chemotherapy is that maintenance of an expanded intraperitoneal space with the use of HAES-steri may additionally ensure separation of loops of bowel to allow direct contact of chemotherapy solution with bowel surfaces prone to adhesion formation and subsequent disease recurrence<sup>[30]</sup>. The reduction in adhesion formation

has been shown with the use of intraperitoneal 4.5% icodextrin lavage and instillation after laparoscopic gynecologic surgery<sup>[18]</sup>. The further pathologic study of the impact on the peritoneum and the healing of the operative incision when HAES-steri is used intraperitoneally is needed.

In brief, this study suggests that HAES-steri, by remaining longer in the peritoneal cavity, provides wider intraperitoneal distribution of 5-fluorouracil, and an increased exposure of peritoneal surfaces to anti-cancer drug with lower systemic toxicity than physiologic saline. HAES-steri is a promising carrier solution for intraperitoneal chemotherapy and further clinical feasibility studies on the use of HAES-steri as carrier solution for intraperitoneal chemotherapy with 5-fluorouracil are warranted.

## COMMENTS

### Background

The principal pharmacokinetic advantage of intraperitoneal chemotherapy over intravenous chemotherapy is the high local drug concentration with low systemic toxicity. The traditional carrier solutions for intraperitoneal chemotherapy fail to optimize this advantage, because these are prone to be cleared from peritoneal cavity rapidly. The ideal carrier solutions should expose cancerous surfaces or residual tumor cells within the peritoneal cavity to high levels of the cytotoxic agent as long as possible.

### Research frontiers

It has been shown in published articles that high molecular weight solutions have the ability to maintain high intraperitoneal volume for a longer period, which may offer a number of advantages over low molecular weight solutions. Further study on the pharmacokinetics of intraperitoneal chemotherapy with middle or high molecular weight solutions may solve the problem that there are no ideal carrier solutions for intraperitoneal chemotherapy.

### Innovations and breakthroughs

In this article, we studied and compared the pharmacokinetics and tissue distribution of intraperitoneal 5-fluorouracil with HEAS-steri, a neotype 6% hydroxyethyl starch as carrier solution, and physiologic saline (0.9% sodium chloride solution), a traditional carrier solution, in rats, which may provide a promising carrier solution for intraperitoneal chemotherapy.

### Applications

This study on the pharmacokinetics and tissue distribution of intraperitoneal 5-fluorouracil with HEAS-steri and physiologic saline offers experimental data for further clinical study and application of HEAS-steri as carrier solution for intraperitoneal chemotherapy.

### Terminology

Intraperitoneal chemotherapy, a treatment in which anticancer drugs are put directly into the abdominal cavity through a thin tube, has obvious pharmacokinetic advantages over intravenous chemotherapy when used in palliative therapy for peritoneal carcinomatosis from gastrointestinal carcinoma and prevention of the postoperative peritoneal recurrences and metastases of gastrointestinal cancer.

### Peer review

In the present study the effect HAES-steri, as a promising carrier solution for intraperitoneal chemotherapy, was investigated. The study showed that HAES-steri delayed the clearance of intraperitoneal fluid and increased the concentration of 5-fluorouracil in the peritoneal fluid, tissue (especially liver) and portal vein. The manuscript deals with an interesting topic and conclusive results.

### Abstract

**AIM:** To investigate biological prevention with flavonoids the recurrence risk of neoplasia was studied in patients with resected colorectal cancer and after adenoma polypectomy.

**METHODS:** Eighty-seven patients, 36 patients with resected colon cancer and 51 patients after polypectomy, were divided into 2 groups: one group was treated with a flavonoid mixture (daily standard dose 20 mg apigenin and 20 mg epigallocatechin-gallat,  $n = 31$ ) and compared with a matched control group ( $n = 56$ ). Both groups were observed for 3-4 years by surveillance colonoscopy and by questionnaire.

**RESULTS:** Of 87 patients enrolled in this study, 36 had resected colon cancer and 29 of these patients had surveillance colonoscopy. Among the flavonoid-treated patients with resected colon cancer ( $n = 14$ ), there was no cancer recurrence and one adenoma developed. In contrast the cancer recurrence rate of the 15 matched untreated controls was 20% (3 of 15) and adenomas evolved in 4 of those patients (27%). The combined recurrence rate for neoplasia was 7% (1 of 14) in the treated patients and 47% (7 of 15) in the controls ( $P = 0.027$ ).

**CONCLUSION:** Sustained long-term treatment with a flavonoid mixture could reduce the recurrence rate of colon neoplasia in patients with resected colon cancer.

### INTRODUCTION

Patients with resected colon cancer are at risk of cancer recurrence which depends mainly on the tumor stage<sup>[1]</sup>. Within 4-5 years after a curative surgical resection about 40%-50% of patients suffer from a tumor recurrence when their initial tumor stage was II or III according to the International Union against Cancer (UICC) classification<sup>[2-4]</sup>. Tumor recurrence can manifest itself as a local recurrence at the site of resection, as metachronous tumor growth somewhere else in the colon or as local or distant metastasis. Recurrence in the colon can take three forms of neoplasia: either as incident carcinoma, as incident adenoma or as a mixture of both.

Patients with colon polyps (adenomas, hyperplastic polyps or serrated polyps) who had a polypectomy are also at risk of recurrence<sup>[5]</sup>. After an index polypectomy these patients can develop incident adenomas in 40% of cases within 3 years depending on the histology of the polyp. The adenoma recurrence is highest for large and multiple adenomas with dysplastic changes of the adenoma structure<sup>[5]</sup>.

There is much controversy about what can be done to reduce the risk or recurrence of neoplasia in tumor and polyp patients. Secondary prevention is urgently needed in these patients; however, it is not yet clear what measures are most effective. Epidemiological studies indicate that dietary interventions with ballast augmented food can be successful for primary prevention of colorectal carcinomas<sup>[6]</sup>. On the other hand diets supplemented with bran<sup>[7]</sup> and fruits and vegetables<sup>[8]</sup> do not suppress the

evolution of colorectal adenomas after polypectomy. Other dietary components such as folic acid, calcium, vitamin D and selenium either have shown only marginal beneficial effects or no effects for prevention<sup>[9-12]</sup>. Antioxidative vitamins could not prevent gastrointestinal cancer<sup>[13]</sup>. Beside dietary factors (bioprevention) chemically defined intervention with aspirin<sup>[14-17]</sup> and nonsteroidal anti-inflammatory drugs (NSAIDs) seem to be effective for primary and secondary prevention of colon neoplasia<sup>[18,19]</sup>. However, their unwanted side effects and complications (ulcerations, bleedings and thromboembolic events) prevent their general use for risk reduction<sup>[20]</sup>.

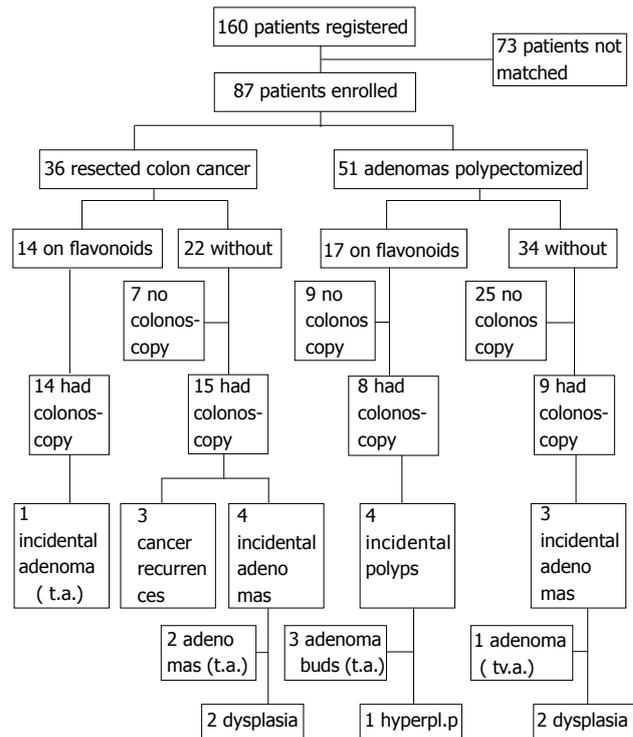

Various modes of bioprevention with dietary components have been tested mostly in epidemiological studies<sup>[21-23]</sup> and in studies with cell culture work and other *in vitro* tests<sup>[24]</sup>. Few clinical intervention studies were reported. Candidates for use in clinical studies include secondary plant products such as flavonoids, indols, isothiocyanates, glucosinolates, allyes, resveratrol, curcumin, saponins and terpenes. Some of these plant products can be applied as nutritional supplements as tablets, thereby facilitating long-term use without side effects or problems of compliance. Tea flavonoids from green tea and camomile contain flavons, flavonols and flavanols. They have been shown to display various anticarcinogenic, antiproliferative, antimutagenic and antioxidative properties *in vivo* and *in vitro*<sup>[24]</sup>. Certain species of dietary flavonoids were able to reduce the risk of colorectal cancer<sup>[25]</sup>, even in a dose dependent manner<sup>[26]</sup>. This is not true for colon neoplasia in general<sup>[27,28]</sup>. Recently, a clinical study<sup>[29]</sup> suggested, that the flavonol quercetin taken together with curcumin suppressed the growth of adenomatous polyps in patients with hereditary colon polyposis syndrome (familial adenomatous polyposis, FAP patients).

We decided to study prospectively the effects of a sustained treatment with a tea-based flavonoid mixture on the evolution of neoplastic alteration in a cohort of high risk patients with resected colon cancer as well as patients after polypectomy. In this proof of principle study we found that a flavonoid intervention can reduce the recurrence rate of neoplasia in patients with sporadic colorectal neoplasia, in comparison with an untreated matched control group.

## MATERIALS AND METHODS

### Study subjects

Between January 2000 and December 2003 a total of 160 patients with colorectal neoplasia (index patients) were recruited and their data were collected from the clinical charts of the Community Hospital Groß-Gerau, Germany (Department of Internal Medicine and General Surgery) and included into the tumor registry for this clinical study. All patients with the diagnosis of colorectal cancer and colon polyps confirmed by pathology reports were eligible for this study if they completed the clinical questionnaire and had surgical tumor resection or polypectomy. By the end of 2003, recruitment was terminated and until December 2005, 87 patients were followed up by surveillance colonoscopy. Patients who were still in the

**Figure 1** Trial profile and outcomes. t.a.: Tubular adenoma; tv.a.: Tubulovillous adenoma; hyperpl.p: Hyperplastic polyp, buds diminutive polyp (< 5 mm).

study at this time were considered to be censored cases for overall survival. All data were extracted from the local tumor registry of the clinic and further pseudonymized for evaluation. In this prospective observational cohort study the investigators had no role in the clinical management; all treatment decisions (except the assignment of the flavonoid nutritional supplementation) and the schedule of surveillance colonoscopies were left at the discretion of the treating physician. Surveillance data were collected prospectively. All 160 patients were treated according to the clinical guidelines for follow-up investigations for colorectal cancer and colon adenomas published by the German Association for Digestive and Metabolic Diseases<sup>[30]</sup>. This study was approved by the Ethics Committee of the Technical University of Dresden, Germany. The patients provided information using a self-administered questionnaire and in this way written informed consent was obtained authorizing use of their data for this study.

### Study protocol

Figure 1 explains the trial profile, the outcome and the patient flow of this controlled study. One hundred and sixty patients were registered and of these 87 patients were enrolled to test the efficacy of flavonoids. During the four years from January 2000 to December 2003 we recruited 31 of the 160 patients to agree to take the flavonoid supplement for tumor prevention. Following assignment to treatment these 31 patients were matched to 56 controls. Matching by gender, age (10 years intervals) and type of neoplasia (resected carcinoma *vs* polypectomized adenomas) was performed by using the data of the 129 untreated patients. The remaining 73 patients of the

total of 160, who did not fulfil the matching criteria, were not followed further in this study. The flavonoid-treated patients took a daily dose of 2 tablets of the flavonoid mixture<sup>[24]</sup> containing 10 mg apigenin and 10 mg epigallocatechin-gallate per tablet. This nutritional supplement (tea bioflavonoids) was produced according to the principles of Good Manufacturing Practice by Köhler-Pharma, Alsbach-Hähnlein, Germany. The content of active ingredients in each batch of the product was tested by chemical analysis (HPLC technique). Flavonoids were taken for 2-5 years; the treatment compliance was evaluated by questionnaire.

Outcomes were evaluated according to the per protocol principle: data of patients using flavonoids (*n* = 31) were analyzed regardless of how long they had been treated. The primary endpoints of this study were the incident neoplasia (cancer and/or adenomas) observed by surveillance colonoscopy.

The self-administered questionnaire provided information on relevant clinical variables which might influence the clinical outcome. These included life style variables, body mass index (BMI), a dietary food frequency questionnaire, information on medical treatment, cancer and adenoma histories of relatives and tea consumption (Table 1). Data on colonoscopy findings were taken from the standardized clinical endoscopy protocols and transferred to the registry. Histological findings of neoplasia provided by the clinical pathologist were rated according to the guidelines as mentioned above<sup>[30]</sup>. Tumor stage was assessed from the surgical protocols and rated according to the UICC classification<sup>[4]</sup>.

### Statistical analysis

The data of the total cohort of 160 patients were subdivided into the two basic sub-cohorts: patients only observed (*n* = 73) and patients surveyed for secondary

prevention (*n* = 87). The latter group was divided into a treatment group (*n* = 31) and a control group (*n* = 56) as described in the Study Protocol. The patient characteristics of the two surveillance groups, the per protocol group of the treated patients (*n* = 31) and their controls (*n* = 56) were compared on baseline as well as for their outcome variables by using descriptive and confirmatory statistical methods. Categorical variables were analyzed using the chi-square test or the 2-sided Fisher Exact Test in the case of small frequencies. Continuous variables (age, BMI) were analyzed using the non-parametric Wilcoxon-Mann-Whitney *U*-Test. They are described by their median and the interquartile range (IQR). The IQR is defined as the range between the 25th and the 75th percentile of the empirical distribution of the data.

Differences of recurrence were expressed in percentages as absolute differences. The relative risk ratio (RRR) and the number needed to treat (NNT) were computed. Because of the observational nature of this study no adjustments for multiplicity were applied and *P* < 0.05 was considered statistically significant.

## RESULTS

The prognostically relevant clinical variables of the treated patients were compared with those of the matched patients (Table 1). During the study period one patient in the treatment group and two patients in the control group died of causes not related to tumor recurrence. The patients in the treated group had significantly higher numbers of follow-up colonoscopies than patients in the control group (Table 1). The time under surveillance both by colonoscopy and by questionnaire was significantly longer for the treatment group (Table 1). The ratio of cancer to polyp patients was not significantly different (45% *vs* 39%) among treatment and control group.

**Table 2** Comparison of clinical variables in patients with resected colon cancer on surveillance colonoscopy treated with flavonoids *vs* controls

	Flavonoid treatment ( <i>n</i> = 14, %)	Controls ( <i>n</i> = 15, %)	<i>P</i> value
Males/females	7/7	7/8	> 0.9
Age (yr) median (IQR)	75.0 (77-82)	81.0 (77-86)	0.12
BMI (kg/m <sup>2</sup> ) median (IQR)	26.2 (24.6-28.0) ( <i>n</i> = 13)	25.9 (24.5-27.5) ( <i>n</i> = 10)	0.57

Surveillance time by colonoscopy			
Years: median (IQR)	4.0 (3.25-5)	3.0 (2-3)	0.022 <sup>1</sup>

IQR: Interquartile range (25%-75%). <sup>1</sup>Significantly different at *P* < 0.05.

**Table 3** Recurrence rates of colon neoplasia in patients with resected colon cancer treated with flavonoids compared to controls

	Treated (% of total, <i>n</i> = 14)	Controls (% of total, <i>n</i> = 15)	Absolute difference (%)	RRR	NNT	<i>P</i> value
Cancer recurrence/no	0/14 (0)	3/12 (20)	20		5	0.125
Adenoma recurrence/no	1/13 (7)	4/11 (27)	20	3.9	5	0.101
Neoplasia recurrence/no	1/13 (7)	7/8 (47)	40	6.7	2.5	0.027 <sup>1</sup>

RRR: Relative risk ratio; NNT: Number needed to treat. <sup>1</sup>Significantly different at *P* < 0.05.

Recurrence rates of cancer were 0 in 20 in the treated group *vs* 3 in 21 in the control group (*P* = 0.23). Polyp recurrence rates were 5 in 20 in the treatment group *vs* 7 in 21 in the control group (*P* = 0.73). The combined rate of recurrence for neoplasia was 5 in 20 in treated *vs* 10 in 21 in the controls (*P* = 0.20). These differences are not statistically significant, but there is a trend for more favourable outcomes in the flavonoid exposed patients. Note that both groups were not adjusted according to surveillance colonoscopy and according to neoplasia type. The sample size of this proof of principle study is small. Also, it can be seen in Figure 1, that the incident polyps in the control group were high grade adenomas (4 adenomas with dysplasia, one tubulovillous adenoma); there were only 2 tubular adenomas. Among the treated patients there were 3 diminutive tubular adenomas (polyp buds), one hyperplastic polyp and one tubular adenoma (with 10 mm diameter). This shows that there were more advanced adenomas present in the control group than in the treatment group.

Fruit consumption of less than 3 d a week was considered as low intake and was found in 29% (8 in 28) of the treatment group as compared to 33% (17 in 52) of the control group (*P* = 0.80). Habitual vegetable intake of less than 3 d a week was reported by 54% (15 in 28) of patients in the treatment group *vs* 57% (29 in 51) in the control group. Habitual drinking of green and black tea was not significantly different among both groups; about 44% drank green tea and 51% black tea. About 10% of the patients in both groups smoked and about 30% of them took aspirin regularly. NSAIDs were taken long

term by 5%-6% of the patients in both groups. Habitual alcohol use was reported by 83% in the treatment group as compared to 62% in the control group (*P* = 0.08). Gender, age and BMI were approximately evenly distributed among the two groups.

Most patients in the flavonoid group (20 in 31) took the nutritional supplement for more than 12 mo, 8 patients took it less than 3 mo, 2 up to 6 mo and one patient up to 12 mo. Three in 27 (11%) reported slight discomfort and discontinued the flavonoid treatment within 3 mo. The majority of 65% (17 in 26) took the flavonoids continuously on a daily basis.

As the data in Table 1 suggested that there is a possible treatment effect of the use of flavonoids we analyzed our data in the well adjusted group of patients with curative colon cancer resection. There were 14 patients with resected colon cancer in the treatment group compared to 15 control patients (Table 2); all had surveillance colonoscopies. None of the treated patients had cancer recurrence *vs* 20% (3 in 15) of the controls. Among the controls two patients had metastatic colorectal cancer and one had local cancer recurrence at the surgical anastomosis. The time to relapse was 2-3 years after surgery in patients with cancer recurrence. Adenomas developed in 7% (1 in 14) of the treated patients and in 27% (4 in 15) of the controls including two adenomas with dysplasia (Table 3). There was a statistically significant difference (*P* = 0.02) between the two groups when the combined endpoint of neoplasia recurrence (incident cancer and incident adenomas) was evaluated. The potentially confounding patient characteristics of both groups did not differ

significantly except for habitual alcohol consumption, which was significantly more prevalent in the treated patients than in controls. For neoplasia recurrence the prognostically most important factor is the previous tumor stage, which was not significantly different between the two groups.

## DISCUSSION

Recurrence risk is the main concern of patients with previous resected colorectal cancer<sup>[1-4]</sup>. On follow-up about 40% of surgically curable colorectal cancers with stage II and stage III (according to the UICC staging system) will suffer recurrent cancers within 3-4 years. The best outcomes were reported for stage I and stage II tumors (around 90% survival without recurrences). The prognosis of stage III cancer (with cancerous regional lymph nodes) is less favourable, but can be improved by adjuvant chemotherapy. Treated cases and controls in our study did not differ regarding the initial tumor stage at surgery; about 40% in both groups were stage III tumors, only 2 of them (controls) had adjuvant chemotherapy because the surgeon felt confident that most of these patients would not be suitable for adjuvant chemotherapy. The tumor recurrence in the controls was not observed in the patients on chemotherapy, but there were too few patients to judge whether this could influence outcomes. We found the expected recurrence rate in the controls (Table 3), but no incident cancers and only one incident adenoma in the flavonoid exposed patients. Eighty-seven of the 160 patients from the registry were enrolled because we detected only 56 controls that could be properly adjusted to the 31 treated patients. The matching ratio of about one to two (31 treated *vs* 56 controls) seems to be appropriate. In this real world study 76% of the treated and 43% of the controls had surveillance colonoscopies; among the resected patients 80% had surveillance by colonoscopy but only 33% of the polypectomized patients. This fact might influence the reliability of the conclusions regarding the adenoma recurrence.

Our controlled clinical trial was a prospective and observational cohort study performed with the aim of finding out whether long-term flavonoid exposure of patients from a tumor registry alters the outcome compared to untreated control patients. This proof of principle study suggests that flavonoids can be used to reduce the recurrence rate in patients with resected colorectal cancers. Flavonoids are good candidates for primary and secondary prevention of colorectal cancer, since numerous *in vitro* studies and animal work report on their beneficial activities in terms of suppression of cancer proliferation, antioxidant and antiangiogenic properties<sup>[24]</sup>. Epidemiological investigations<sup>[22,25,26]</sup>, *in vivo* and *in vitro* experiments<sup>[31-35]</sup> and one clinical intervention study<sup>[29]</sup> support this concept. Other authors could not find protective effects of flavonoids on colorectal cancer incidence<sup>[21,27,36]</sup>. Flavonoids derived from tea plants can be used as a mean of bioprevention and have been manufactured and marketed as nutritional supplements<sup>[24]</sup>. Other methods of prevention are not effective (e.g. vitamins except folic acid), show only marginal efficacy (e.g. calcium, selenium) or cannot be used in general because of their unwanted side effects and complications

(aspirin, NSAIDs)<sup>[20]</sup>.

We tested the efficacy of flavonoid supplementation in a high risk population (resected colorectal cancer) to examine its effect in a relatively small number of patients, which were carefully adjusted for various clinical variables with prognostic relevance. However, there are prognostic clinical factors which were not taken into account such as penetration depth into the colonic wall and histological grading. Clinical studies with a larger sample size and a higher statistical power are necessary to show that flavonoid exposure alters the outcome in terms of tumor recurrence. Flavonoids could prevent recurrences of neoplasia by protecting the genome of colonocytes from genotoxic insults such as oxidative damage, free radical attacks and adduct formation<sup>[37]</sup>. Flavonoids are secondary plant products which could be responsible for some of the healthy effects of fruits and vegetables. It is still unknown which components of vegetables and fruits are effective for tumor prevention; ballast, fibres and secondary plant products play a major role<sup>[6,10,38]</sup>. Flavonoids, indols, isothiocyanates, curcumin, resveratrol, glucosinolates and other plant products affect carcinogenic, mutagenic and neoplastic mechanisms<sup>[24]</sup>, but could also induce protective enzymes of the intestinal mucosa<sup>[39]</sup>. Beside the type of chemical and biological prevention lifestyle factors, type and amount of tea consumption, genetic factors, aspirin and NSAID medication could influence the outcome. These variables have to be considered when evaluating the effects of flavonoid intervention. As shown in Tables 1 and 2 these variables were well balanced among cases and controls. However, alcohol use was more prevalent in the treated patients with resected colorectal cancer than in controls. We do not think that differences of habitual alcohol drinking can explain the difference of recurrence since ethanol is thought of as a carcinogenic risk factor and would rather increase the recurrence risk of the flavonoid exposed patients.

Patient compliance with the flavonoid treatment was evaluated using information derived from a questionnaire given to 31 treated patients in the treatment group. 67% of these treated patients took the nutritional supplement longer than 12 mo, only 10% discontinued the intake within the first 3 mo. No side effects or unwanted symptoms were reported.

The habitual vegetable intake of the patients in both treatment and control groups (Tables 1 and 2) was rather low (< 3 d a week) and only about 40%-50% of the patients consumed vegetables  $\geq$  3 d a week, which still is not sufficient for tumor prevention. About 16%-30% of the patients (cases and controls, Tables 1 and 2) reported low fruit content in their diet (< 3 d a week). Thus, no significant differences of the dietary habits were observed among treated and untreated patients. The self-administered questionnaire which was used to assess dietary habits provided only a crude estimate and was not validated; it is however a simple and practical tool that was well accepted and understood by the patients.

Flavonoids are part of human nutrition and are contained in vegetables and fruits, especially in apples, onions, berries, citrus fruits and teas but also in chocolate. Tea consumption of the patients was moderate and was

reported in most cases only as occasional tea drinking.

More patients with resected colorectal carcinoma of the control group (7 of 14, 50%) took aspirin compared to the cases (4 of 14, 28%) but this difference was not statistically significant (Table 2).

Surveillance by colonoscopy was performed in more cases (65%) than in controls (38%) and the time interval covered by colonoscopy was longer in treated patients than controls (Table 1). Thus the treated patients had a better chance for detection of neoplasia which would be a bias against a treatment effect. If the controls had more surveillance intensity, their recurrence rate would have been even higher.

In patients with prior adenomas that were removed by polypectomy and had surveillance colonoscopies, those treated with flavonoid treatment had a polyp recurrence rate similar to that of controls (about 50%). However, flavonoid treatment was associated with low risk incident adenomas while the control group included polyp recurrence of two adenomas with dysplasia (Figure 1). These differences were not statistically significant but could indicate that flavonoids could also suppress adenoma development and evolution. Cruz-Correa *et al* have recently reported that a combined treatment with quercetin (a flavonol) and curcumin (from curry) inhibited proliferation of adenomas in patients with familiar adenomatous polyposis coli<sup>[29]</sup>. These point to the possibility that flavonoids taken as long-term treatment could suppress neoplasia recurrence in high risk patients.

In conclusion, this pilot study which was controlled, prospective and observational, suggests that long-term flavonoid treatment could reduce the recurrence rate of colon neoplasia in high risk patients particularly in those with resected colorectal cancer. Therefore flavonoid supplementation should be investigated by further clinical studies to prove the efficacy and validity of this concept.

## ACKNOWLEDGMENTS

We are grateful for the cooperation with the department of general surgery of the Community Hospital Groß-Gerau, Germany (Head Michael Kahl, MD) which provided the data from the clinical charts of the patients. We also thank Renate Rausch from the Department of Biostatistics at the German Cancer Research Center for continuing support in the data analysis.

## COMMENTS

### Background

Recurrence of cancer after a curative surgical resection in patients with colorectal cancer is a common problem that occurs in about 20%-40% depending on the previous tumor stage. It is essential for these patients to find ways to prevent this disaster.

### Research frontiers

Prevention of recurrence can be achieved by adherence to a diet containing lots of fruits and vegetables or for higher tumor stages by cytostatic chemotherapy (adjuvant chemotherapy). Chemotherapy is very demanding and prone to unpleasant side effects. Dietary measures are difficult to implement and could give rise to bloating, gas and pain of the abdomen.

### Innovations and breakthroughs

Other authors and articles seem to suggest that flavonoids could prevent colorectal cancers by healthy dietary habits, e.g. intake of foods with a high content of flavonoids. All these studies rely on epidemiological data and these are not always consistent and sometimes controversial. Our study uses an interventional approach with a nutritional supplement (as tablets) and this has not been done previously. Our data suggest that all patients at risk of recurrence of colorectal cancer should be treated with flavonoid supplements.

### Peer review

It is a well-designed paper. The authors showed that sustained long-term treatment with a flavonoid mixture could reduce the recurrence rate of colon neoplasia in patients with resected colon cancer. This is an interesting article.

### Abstract

**AIM:** To test the effect of a standardized red wine polyphenolic extract (RWPE) on the phenotype of human liver myofibroblasts in culture.

**METHODS:** Human myofibroblasts grown from liver explants were used in this study. Cell proliferation was measured with the 3-(4,5-dimethylthiazol-2-yl)-2,5 diphenyltetrazolium bromide (MTT) assay. Signaling events were analyzed by western blot with phospho-specific antibodies. Matrix-metalloproteinase activity was measured with gel zymography.

**RESULTS:** We found that cell proliferation was dose-dependently decreased by up to 90% by RWPE while cell viability was not affected. Exposure to RWPE also greatly decreased the phosphorylation of ERK1/ERK2 and Akt in response to stimulation by the mitogenic factor platelet-derived growth factor BB (PDGF-BB). Finally, RWPE affected extracellular matrix remodeling by decreasing the secretion by myofibroblasts of matrix-metalloproteinase-2 and of tissue inhibitor of matrix-metalloproteinases-1.

**CONCLUSION:** Altogether, RWPE decreases the activation state of liver myofibroblasts. The identification of the active compounds in RWPE could offer new therapeutic strategies against liver fibrosis.

### INTRODUCTION

Liver fibrosis is a serious health problem worldwide. It is a complication of most chronic liver diseases whether due to excessive alcohol consumption, chronic viral hepatitis B or C, non alcoholic steatohepatitis, hemochromatosis or others. The pathophysiology of liver fibrosis has been extensively studied (recently reviewed in<sup>[1,2]</sup>). Whatever the initial insult, the abundant extracellular matrix (ECM) characteristic of liver fibrosis is synthesized by myofibroblastic cells. Myofibroblasts are mostly absent from the normal liver but at least two types of resident liver cells can be differentiated into myofibroblasts during liver disease: hepatic stellate cells, and portal fibroblasts<sup>[3]</sup>. Myofibroblastic differentiation is characterized by a high rate of cell proliferation and of ECM synthesis and by cytoskeletal changes, notably expression of alpha smooth muscle actin (ASMA) that confers contractile properties to the cells<sup>[4]</sup>. In addition, degradation of the normal liver ECM results from an increased secretion of the enzyme matrix metalloproteinase-2 (MMP-2) by myofibroblasts, while the proteolytic degradation of the abnormal ECM is inhibited due to a high level synthesis of a MMP inhibitor, tissue inhibitor of MMP-1 (TIMP-1)<sup>[1,2]</sup>. In the recent years, a series of natural products were shown to be of potential benefit against liver fibrosis<sup>[5,6]</sup>. For instance, we and others found that a polyphenolic component of red wine, trans-resveratrol, was able to strongly deactivate liver fibrogenic cells<sup>[7,8]</sup>, while a related molecule, trans-piceid, was ineffective<sup>[8]</sup>. However, red wine contains many other polyphenolic substances, and red wine polyphenolic extracts (RWPE) showed many interesting biological effects in other settings, notably in the prevention of experimental atherosclerosis<sup>[9]</sup>. One of the mechanisms postulated in this context is related to the inhibitory effect of RWPE on the proliferation of vascular smooth muscle cells<sup>[10]</sup>. Since vascular smooth muscle cells share many characteristics with myofibroblasts, we tested the hypothesis that RWPE would affect the phenotypic characteristics of human liver myofibroblasts, especially those related to their pro-fibrogenic activity.

## MATERIALS AND METHODS

### Materials

Preparation and characterization of the polyphenolic extract (RWPE) from a red French wine (Corbières, A. O. C.) was as described previously<sup>11,12</sup>. One liter of red wine produced 2.9 g of extract, which contained 471 mg/g total phenolic compounds expressed as gallic acid. Phenolic levels in the extract were obtained according to HPLC analysis procedure. In particular, the extract contained 8.6 mg/g catechin, 8.7 mg/g epicatechin, dimers (B1: 6.9 mg/g; B2: 8.0 mg/g; B3: 20.7 mg/g; and B4: 0.7 mg/g), anthocyanins (malvidin-3-glucoside: 11.7 mg/g; peonidin-3-glucoside: 0.66 mg/g; and cyanidin-3-glucoside: 0.06 mg/g), and phenolic acids (gallic acid: 5.0 mg/g; caffeic acid 2.5 mg/g; and caftaric acid: 12.5 mg/g). Stock solutions (1 mg/mL) were prepared in distilled water containing 1% ethanol and further diluted in culture medium. All dilutions were adjusted so as to contain 0.1% ethanol, and medium with 0.1% ethanol was used as a control.

Fetal calf serum (FCS) was from Dutscher (Brumath, France) and human serum from Etablissement Français du Sang (Bordeaux, France). Epidermal growth factor (EGF) was from Peprotech (Tebu, Le Perray en Yvelines, France) and recombinant platelet-derived growth factor BB (PDGF-BB) was from Eurobio (les Ulis, France). Phospho Thr308 AKT-1 and AKT-1 antibodies, phospho-ERK1/ERK2 and total ERK antibodies were from Cell Signaling Technology (Ozyme, Saint Quentin Yvelines, France). ASMA and vimentin antibodies were from Dako (Trappes, France). The TIMP antibody was from Santa Cruz Biotechnologies (Santa Cruz, CA). Beta-actin antibody was from Sigma (Saint Quentin Fallavier, France). IRDye 680 and IRDye 800 conjugated secondary antibodies; Odyssey Blocker and Odyssey infrared imaging system were from LI-COR Biosciences (ScienceTec, Les Ulis, France).

### Cell isolation and culture

Human hepatic myofibroblasts were obtained from explants of non-tumor liver resected during partial hepatectomy and characterized as described previously<sup>13,14</sup>. Specifically, the procedure, based on the selective growth advantage of myofibroblasts in the culture conditions used, allowed for 100% pure myofibroblasts population, as shown by positive staining for ASMA and vimentin, and negative staining for CD68 (a Kupffer cell marker), von Willebrand factor (an endothelial cell marker) or cytokeratin (an epithelial cell marker). This procedure is in accordance with INSERM ethical regulation imposed by French legislation. Myofibroblasts were used between the 3rd and the 6th passage, and were grown in DMEM containing 5% FCS, 5% pooled human serum and 5 ng/mL EGF. EGF was removed from the medium at least 3 d before experiments.

### Cell proliferation assay

Cells were seeded at a density of  $10^4$ /well in 24-well plates. On the following day, the medium was replaced by DMEM with 5% FCS and RWPE dilutions to be tested. After three or seven days, the medium was removed and the cells

incubated with 1 mg/mL MTT [3-(4,5-dimethylthiazol-2-yl)-2,5 diphenyl tetrazolium bromide] for 2 h at 37°C<sup>15</sup>. The crystals were then dissolved with DMSO and the optical density was recorded at 540 nm. Results were expressed as proliferation index = (B-A)/(C-A) where A is the optical density recorded at d 0, B is the optical density with the test compound and C is the optical density obtained in the control wells.

### Measure of cell DNA content

Cells were grown to confluence in 24-well plates, serum-starved for 24 h, then incubated with RWPE. After 24 h, the cells were lysed with NaH<sub>2</sub>PO<sub>4</sub>/Na<sub>2</sub>HPO<sub>4</sub> 50 mmol/L, pH 7.4, NaCl 2 mol/L, EDTA 2 mmol/L, and DNA content was measured as described<sup>16</sup>.

### Western blot

ERK and Akt phosphorylation was measured essentially as described previously<sup>17</sup>. Briefly, cells were grown to confluency and serum-starved for three days. They were then pre-incubated with RWPE in serum-free Waymouth medium for 1 h, and then exposed to 20 ng/mL PDGF-BB for 10 min. At the end of the incubation, cell lysates were prepared in the presence of proteases and phosphatases inhibitors as described<sup>18</sup>. Proteins were measured with a Bio-Rad assay. Equivalent amounts of proteins were separated by SDS-PAGE, transferred to polyvinylidene difluoride membranes, and analyzed by two color Western blotting with antibodies to total-ERK and phospho-ERK, or phospho-Akt-1 and  $\beta$ -actin. Blots were blocked in Odyssey Blocker and incubated simultaneously with both primary antibodies, followed by both IR-labeled secondary antibodies. Signals were detected and quantified using the Odyssey infrared imaging system.

The expression of ASMA and of vimentin was measured in cell extracts from cells exposed for seven days to RWPE using Western blot as described<sup>18</sup>.

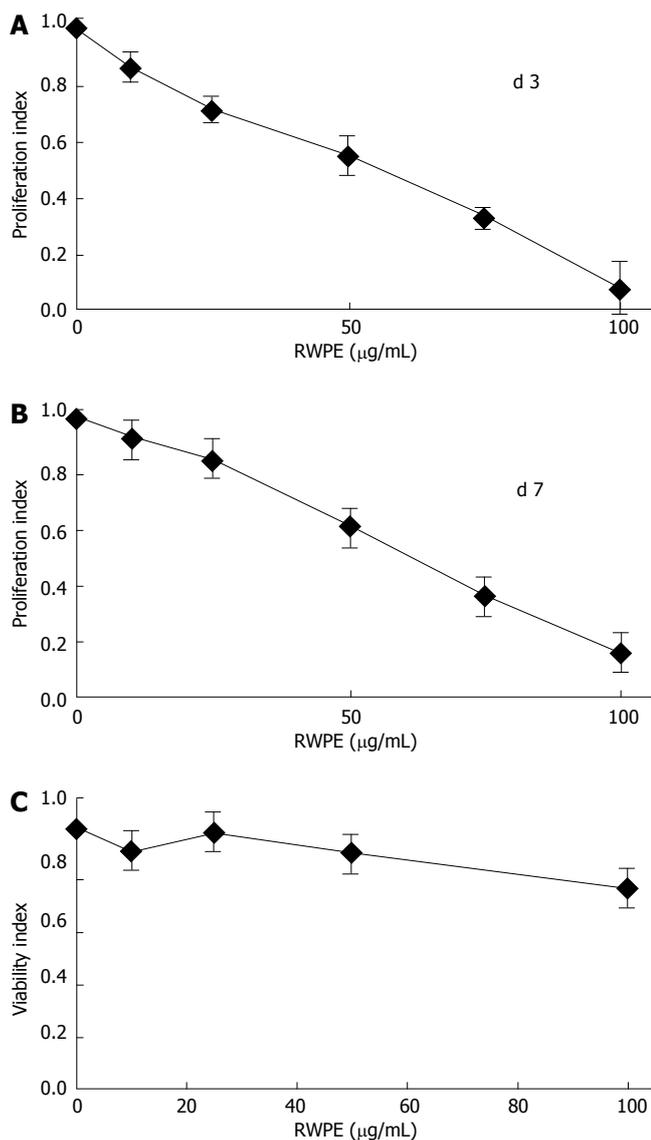

The concentration of TIMP-1 in conditioned medium was also measured by Western blot. Confluent cells were incubated for two days with RWPE, the medium was collected, centrifuged and aliquots, normalized for DNA content of the cell layers, were analyzed by Western blot.

### Zymography for MMP-2 activity

The detection of MMP-2 in conditioned medium was performed by gelatin zymography<sup>19</sup>, essentially as previously described<sup>18,20</sup>. Briefly, cells were grown to confluence in 24-well plates, serum-starved for 24 h, then incubated with RWPE. The medium was collected, centrifuged and aliquots, normalized for DNA content of the cell layers, were analyzed on 8% SDS-PAGE gels containing 1 mg/mL gelatin. Following staining with Coomassie blue, MMP activity is detected as a white zone on a blue background.

### Immunofluorescence detection of alpha-smooth muscle actin

Cells were seeded at a density of  $10^4$ /well on glass coverslips in 24-well plates. On the following day, the medium was replaced by DMEM with 5% FCS and RWPE

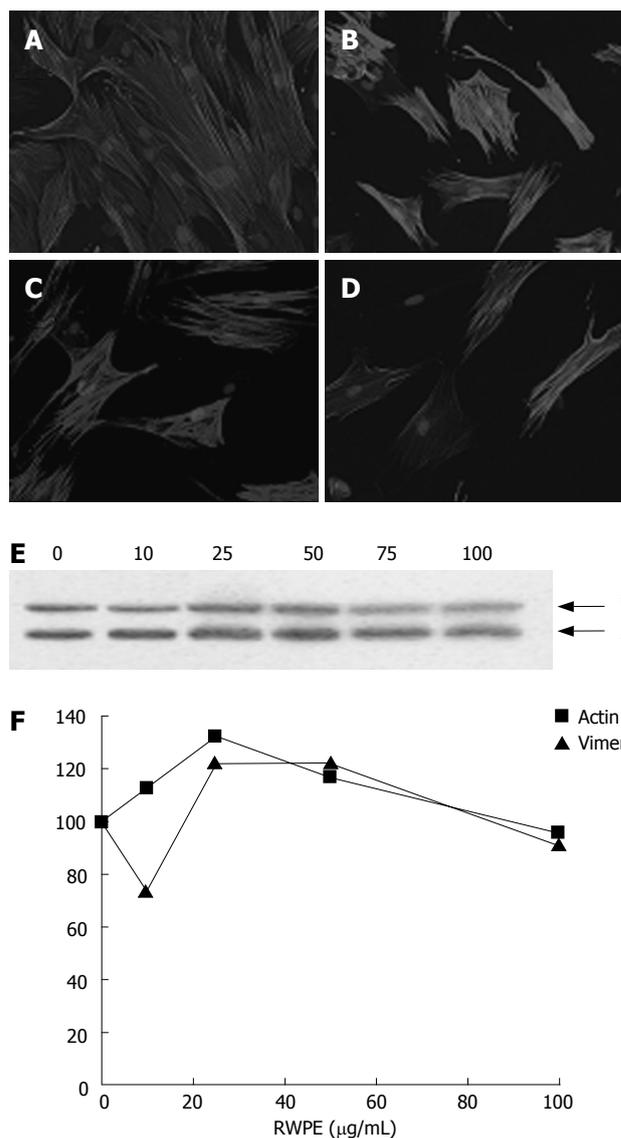

**Figure 1** RWPE decreases myofibroblasts proliferation. Myofibroblasts were grown for either three (A) or seven days (B) in the presence of the indicated concentrations of RWPE. Results are the mean  $\pm$  SD of 4 independent experiments conducted in quadruplicate. The effect of RWPE was highly significant using ANOVA ( $P < 0.0001$ ). In control experiments, myofibroblasts were exposed to RWPE for 24 h and the DNA content of the cell layer was measured (C). Results are expressed as the percentage of the values in treated cells as compared to cells treated with the solvent alone and are the mean  $\pm$  SD of 3 independent experiments conducted in quadruplicate. There were no significant differences between conditions.

dilutions to be tested. After three days, cells were fixed with methanol at  $-20^{\circ}\text{C}$ , then incubated sequentially with an anti-ASMA monoclonal antibody and a Texas Red-conjugated secondary antibody. The slides were examined with a Zeiss Axioplan fluorescence microscope.

## RESULTS

### Effect of the RWPE on cell proliferation

The RWPE dose-dependently inhibited the proliferation of myofibroblasts down to  $7.8\% \pm 4.5\%$  of control at d 3 and  $15.8 \pm 8.0$  at d 7 (Figure 1A and B). The concentration that reduced growth by 50% was  $50 \mu\text{g/mL}$ . A toxic effect of RWPE on cells could be ruled out because no

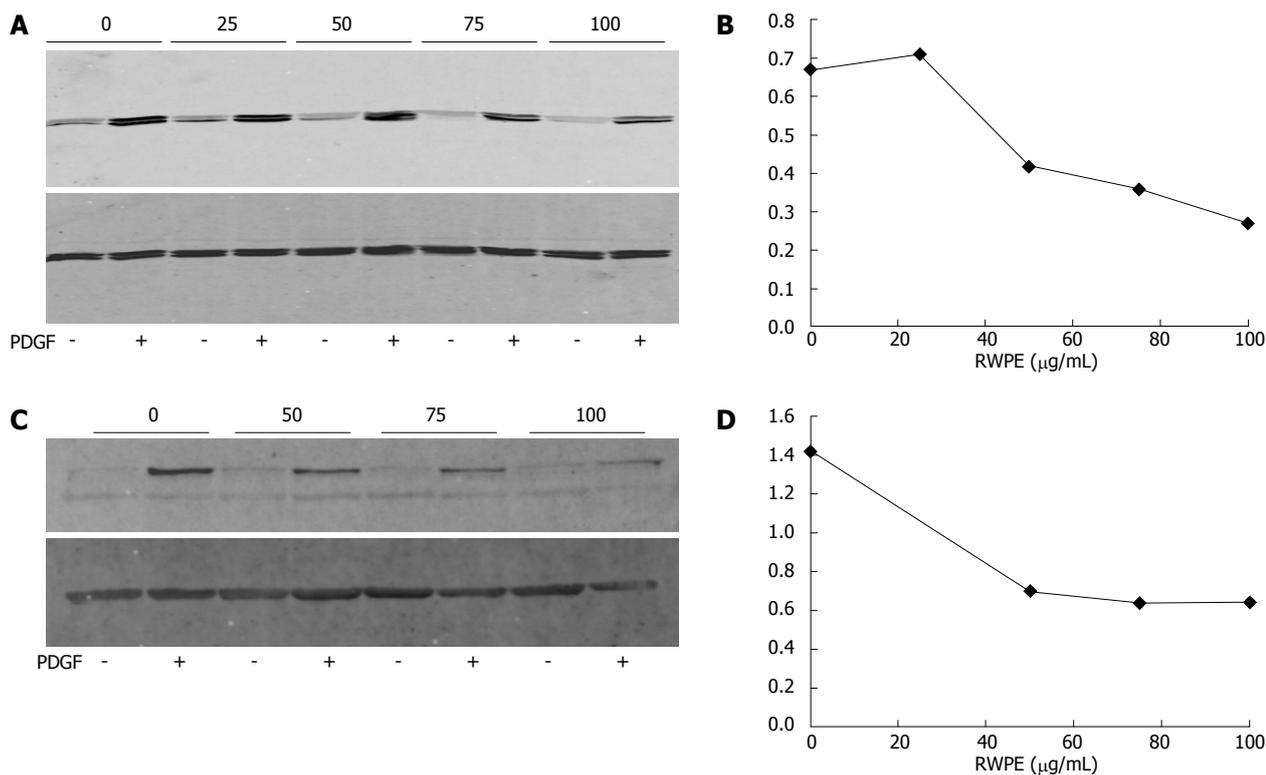

**Figure 2** Effect of the RWPE on expression of alpha-smooth muscle actin. A: Myofibroblasts were incubated for seven days in the absence of RWPE (A) or with  $50$  (B),  $75$  (C), or  $100$  (D)  $\mu\text{g/mL}$  RWPE. Aliquots of cell extracts grown in the same conditions were analyzed by Western blot (E) simultaneously for ASMA (A) and vimentin (V). F: The signals were quantified as described in Materials and Methods. The graph shows the mean of 2 separate experiments.

morphological signs of toxicity nor cell detachment were observed (Figure 2); furthermore, when confluent cells were exposed to a dose range of RWPE, there was no decrease in DNA content of the cell layers even at the highest concentrations (Figure 1C).

### Effect of the RWPE on expression of alpha-smooth muscle actin

Expression of the cytoskeletal protein ASMA is hallmark of activated liver fibrogenic cells. We found that long term (up to seven days) exposure of liver myofibroblasts to RWPE did not affect ASMA expression. This was shown both by immunofluorescence and by Western blot (Figure 2). In addition, the expression of another cytoskeletal protein, vimentin, which expression is independent of fibrogenic cell activation, was also unaffected by RWPE treatment (Figure 2C).

**Figure 3** Effect of the RWPE on the phosphorylation of MAPK and Akt. **A:** Myfibroblasts were pre-incubated for 1 h with the indicated concentrations of RWPE (in μg/mL) or solvent, then exposed for 10 min to 20 ng/mL PDGF-BB or buffer. Identical amounts of cell extracts were analyzed by Western blot with antibodies to phospho-ERK1/ERK2 (top panel) and to total ERKs (bottom panel). The picture is representative of 3 experiments; **B:** Quantitative analysis of the experiment shown in (A). The activation index refers to the ratio between the levels of phospho-ERK to those of total ERK; **C:** Same as in A except that the blot was labelled with an anti-phospho-Akt antibody (top panel) and an antibody to β-actin (bottom panel); **D:** Quantitative analysis of the experiment shown in (C). The activation index refers to the ratio between the levels of phospho-Akt to those of β-actin.

### Effect of the RWPE on the phosphorylation of MAPK and Akt

In order to delineate the mitogenic pathways affected by RWPE, myfibroblasts were briefly exposed to PDGF-BB. PDGF-BB is major mediator of liver fibrogenic cell activation, as it stimulates notably their proliferation<sup>[13,21]</sup> and migration<sup>[22,23]</sup>, and is abundant in serum. We then examined the effect of RWPE on signalization pathways elicited by PDGF-BB. As expected, treatment with PDGF-BB induced a major increase in the phosphorylation of ERK1/ERK2 and of Akt. Exposure to RWPE greatly decreased the effect of PDGF-BB on the phosphorylation of both ERK1/ERK2 and Akt (Figure 3).

### Effect of the RWPE on MMP-2 and TIMP-1 expression

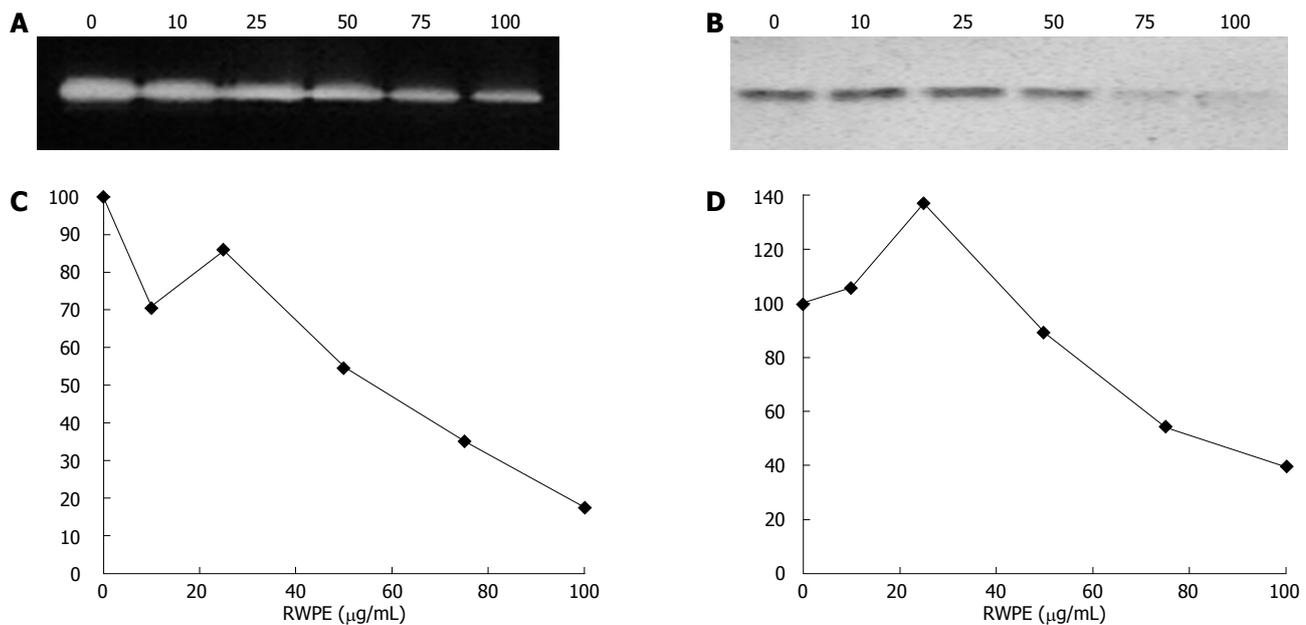

A high level expression of the matrix remodeling enzyme MMP-2<sup>[24]</sup>, and of the inhibitor of extracellular matrix degradation, TIMP-1<sup>[25]</sup>, is characteristic of activated liver fibrogenic cells. Gelatin zymography showed a gelatinolytic band migrating at an apparent molecular weight of 72 kDa characteristic of MMP-2. The RWPE strikingly and dose-dependently decreased the secretion of MMP-2 (Figure 4A). It also greatly decreased TIMP-1 secretion, as assessed by Western blot (Figure 4B).

## DISCUSSION

We show here that a standardized RWPE has striking effects on the phenotype of human liver myfibroblasts.

This is shown by a decreased proliferation rate together with decreased secretion of MMP-2 and of TIMP-1. These effects are not the consequence of a direct toxicity of the extract on cells as shown by morphological examination and DNA content measurement. We investigated further the mechanism of the decreased proliferation rate and found that RWPE treatment largely abolished the phosphorylation of ERK1/ERK2 and of Akt induced by the mitogenic factor PDGF-BB. Previously, Iijima *et al* showed that a RWPE decreased Akt but not ERK activation in vascular smooth muscle cells stimulated with PDGF<sup>[26]</sup>. The differences may be due to the fact that different RWPEs were used, or to a true cell specificity. For instance, despite the fact that myfibroblasts and smooth muscle cells are related cells, we found that they had a differential response to trans-resveratrol<sup>[8]</sup>. Some of the effects of the RWPE are reminiscent of those of trans-resveratrol, raising the possibility that RWPE effects may be due to this compound. However, resveratrol is present only at low concentration in wine (reviewed in<sup>[27]</sup>) and is unlikely to explain the effects of RWPE. In addition, whereas it does indeed decrease myfibroblasts proliferation, MMP-2 secretion<sup>[8]</sup> and Akt activation<sup>[28]</sup>, it does not affect ERK activation in response to PDGF<sup>[28]</sup>. Furthermore, contrary to RWPE, it does decrease ASMA expression<sup>[8]</sup>.

The RWPE effects observed in the present study are potentially of benefit against liver fibrosis, if they held true in the *in vivo* situation. This seems obvious for the reduced cell proliferation that will decrease the number of ECM-

**Figure 4** Effect of the RWPE on MMP-2 and TIMP-1 expression. **A:** Myfibroblasts were incubated for 24 h with the indicated concentrations of RWPE (in  $\mu\text{g/mL}$ ). Aliquots of conditioned medium normalized for the DNA content of the cell monolayers were analyzed on gelatin-containing gels (**A**). The white bands on the dark background indicate gelatinolytic activity. Other aliquots were analyzed by Western blot with an antibody against TIMP-1 (**B**). Another experiment gave similar results; **C:** Quantitative analysis of the experiments. MMP-2: Mean of duplicate samples; TIMP-1: Mean of 2 independent experiments.

producing cells. Notably, the drastic effect on TIMP-1 secretion may have a major implication since TIMP-1 overexpression is considered one of the main determinants of liver fibrosis through the inhibition of ECM-degrading enzymes activity<sup>[29,30]</sup>.

Thus, although excessive wine consumption is one of the major causes of chronic liver diseases, wine itself may unexpectedly contain potent anti-fibrotic compounds. The identification of the active compounds in RWPE could offer new therapeutic strategies against liver fibrosis.

## ACKNOWLEDGMENTS

We thank PL Teissedre for providing the standardized RWPE.

## COMMENTS

### Background

Liver fibrosis is a worldwide problem, as it complicates all chronic liver diseases. There is no established treatment for liver fibrosis.

### Research frontiers

A series of natural products have shown beneficial effects on liver fibrosis in cell culture and animal models. In addition, red wine polyphenols were shown to reduce the proliferation of vascular smooth muscle cells, a cell type closely related to liver fibrogenic cells.

### Innovations and breakthroughs

We found that a standardized red wine polyphenolic extract greatly decreased the proliferation of human liver fibrogenic cells. It also reduced their synthesis of matrix-metalloproteinase-2 and of the tissue inhibitor of matrix metalloproteinase-1, thus suggesting that it could affect the cell ability to remodel the extracellular matrix.

### Applications

The identification of the active compound(s) in the extract could lead to *in vivo* testing of its anti-fibrotic activity in liver disease.

## Terminology

Liver fibrosis: a common complication of most chronic liver diseases, where an excess of extracellular matrix components are deposited in the liver.

## Peer review

This is a very nice communication and provides mechanistic data, is well-written, and ends with a thorough discussion. The results of this study are novel and potentially lay the ground work for the understanding of the effect of wine/wine extracts on human hepatic fibrosis.

### Abstract

**AIM:** To investigate the effects of estradiol (E2) and progesterone on the unstimulated and oxidative stress-stimulated production of tumor necrosis factor (TNF)- $\alpha$ , interleukin (IL)-1 $\beta$ , IL-8, and macrophage chemotactic protein (MCP)-1 by peripheral blood mononuclear cells (PBMCs) from patients with chronic hepatitis C and healthy controls.

**METHODS:** The PBMCs were separated from age-matched 72 males and 71 females with and without chronic hepatitis C, who were divided into two groups based on a mean menopausal age of 50 years. Oxidative stress was induced by hydrogen peroxide in the cells incubated in serum-free media. Cytokines in the culture supernatant were measured by an enzyme-linked immunosorbent assay.

**RESULTS:** The highest levels of the spontaneous production of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 by the unstimulated PBMCs were in the older male patients with chronic hepatitis C and the lowest levels were in the pre-

menopausal female healthy controls. E2 inhibited the cytokine production by the unstimulated PBMCs from the older male and post-menopausal female patients, which was further stimulated by progesterone. The exposure to hydrogen peroxide in the PBMCs from the younger male and pre-menopausal female healthy subjects induced the production of cytokines. The change rates of the hydrogen peroxide-stimulated cytokine production were suppressed by E2 and enhanced by progesterone.

**CONCLUSION:** These findings suggest that E2 may play a favorable role in the course of persistent liver injury by preventing the accumulation of monocytes-macrophages and by inhibiting proinflammatory cytokine production, whereas progesterone may counteract the favorable E2 effects.

### INTRODUCTION

In inflammatory and oxidative liver injury, the accumulation of leukocytes and macrophages including Kupffer cells on the sites of injury and inflammation in the liver is thought to be mediated by such cytokines as chemokines, including interleukin (IL)-8 and macrophage chemotactic protein (MCP)-1. These monocytes and macrophages are in turn

able to release proinflammatory cytokines such as tumor necrosis factor (TNF)- $\alpha$  and IL-1 $\beta$ , thus leading to the occurrence of persistent liver injury. It has been reported that chronic hepatitis C virus (HCV) infection tends to progress more rapidly in men than in women<sup>[1,2]</sup>, and that the decline in estradiol (E2) production with menopause is associated with a spontaneous increase in TNF- $\alpha$  and IL-1 $\beta$ <sup>[3]</sup>. It should be noted that large increases in the amount of reactive oxygen species (ROS) lead to disturbance of prooxidant-antioxidant balance, or oxidative stress. Our previous studies have shown that hepatocytes possessed estrogen receptor (ER), and that in cultured hepatocytes in a state of oxidative stress, E2 inhibited the activation of the nuclear factor  $\kappa$ B (NF- $\kappa$ B), a key transcription factor that induces multiple genes in response to inflammation and oxidative stress<sup>[4]</sup>, through ER<sup>[5,6]</sup>. These findings suggest that E2 could enhance the anti-inflammatory activity in the injured liver by decreasing the proinflammatory cytokine production, and it might, therefore, play a cytoprotective role through ER in the liver<sup>[7,8]</sup>. However, regarding E2 and another female sex steroid, progesterone, there is little information about the direct effects of these sex hormones on the production of chemokines and proinflammatory cytokines by monocytes and macrophages in chronic HCV infection, although *in vitro* experiments in which monocytes were incubated with sex hormones have revealed conflicting results regarding monocyte cytokine production<sup>[9]</sup>. Therefore, this study investigated the effects of E2 and progesterone on the production of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 by the heparinized peripheral blood mononuclear cells (PBMCs), after stimulation with the ROS, hydrogen peroxide<sup>[10]</sup>. These effects were then compared between the blood samples from the age-matched male and female patients with chronic hepatitis C and the healthy controls, which were divided into two groups based on a mean menopausal age of 50 years.

## MATERIALS AND METHODS

### Patients

This study was conducted at Tokushima University Hospital and the subjects consisted of age-matched males ( $n = 72$ ) and females ( $n = 71$ ) including 71 patients with chronic hepatitis C and 72 healthy controls who were divided into younger, or pre-menopausal (< 50 years of age), and older, or post-menopausal ( $\geq 50$  years of age) groups. The chronic hepatitis patients met the following criteria: a persistently elevated serum alanine aminotransferase (ALT, normal serum levels of ALT range between 5 and 40 U/L) level for at least six months; HCV-RNA seropositivity; seronegativity for Hepatitis B virus (HBV) surface antigen; exclusion of all other potential cause of chronic liver disease such as autoimmune hepatitis, primary biliary cirrhosis, drug-induced hepatitis, or metabolic liver disease; and no history of alcohol abuse, defined as an alcohol intake of more than 20 g per day over the previous year. In addition, any individuals taking oral contraceptives or corticosteroids, who had previously undergone an operation on the ovaries were also excluded from the study.

All females in the younger groups with and without

chronic HCV infection had a normal ovarian cycle, and the mean ovarian cycle length was 28 d with a range of 26 to 32 d. Ethical approval was obtained from the Tokushima University Hospital ethics committee, and informed consent was obtained from all patients taking part in the study.

The heparinized peripheral blood samples were obtained in the morning after an overnight fast. In the pre-menopausal females, the blood samples were taken during the luteal phase 5 to 8 d before the onset of menses. The human PBMC fractions were separated using density-gradient centrifugation with a lymphocyte separation medium (Organon Teknika, Durham, NC, USA). After three washes with phosphate-buffered saline and buffered RPMI 1640 supplemented with 100 U/mL penicillin, 100  $\mu$ g/mL streptomycin, and 1% L-glutamine (RPMI culture medium), the mononuclear cells were suspended at a concentration of  $1 \times 10^6$ /mL in RPMI culture medium with 10% heat-inactivated fetal bovine serum. The cells were cultured at 37°C in a 5% CO<sub>2</sub> atmosphere and 100% humidity for 24 h and then treated with and without 17 $\beta$ -E2 (Sigma, St Louis, MO, USA) or progesterone (Wako, Osaka, Japan) for another 6 h in the presence and absence of the estrogen receptor antagonist, ICI-182, 780 (ICI: Tocris Cookson, Ballwin, MO, USA), or the PR antagonist RU486 (RU: Wako). In another experiment, the culture medium was changed with serum-free RPMI, and oxidative stress was induced by hydrogen peroxide ( $10^{-7}$ - $10^{-5}$  mol/L). The cells were then incubated with either E2 or progesterone for up to 6 h in the presence and absence of ICI or RU. The steroid sex hormones and receptor antagonists were initially prepared as an ethanol stock solution ( $10^{-2}$  mol/L) and then were diluted with the culture medium in order to obtain an appropriate working solution concentration.

### Cytokine and female sex hormone assays

The cytokines of TNF- $\alpha$ , IL-1 $\beta$ , IL-8 and MCP-1 and the female sex hormones of E2 and progesterone secreted into the culture supernatant were measured by an enzyme-linked immunosorbent assay (ELISA) using commercial kits (R&D Systems, Minneapolis, MN, USA) and by a radioimmunoassay using commercial kits (CIS Diagnostic, Tokyo, Japan), respectively, according to the manufacturer's instructions.

### Statistical analysis

The data were presented as the mean  $\pm$  SD, unless otherwise indicated. The means were compared between the two groups using the Wilcoxon's signed-rank test and the Mann-Whitney *U* test with Bonferroni correction. A *P* value of less than 0.05 was considered to be statistically significant.

## RESULTS

### Characteristics at the time of isolation of PBMCs from age-matched younger and older males and pre- and post-menopausal females of patients with chronic hepatitis C and healthy controls

As shown in Table 1, the background factors of 4 patient groups with chronic hepatitis C, such as the serum levels of

**Table 1** Characteristics at the time of isolation of PBMCs from age-matched younger and older males and pre- and post-menopausal females of patients with chronic hepatitis C and healthy controls

	Patients with chronic hepatitis C				Healthy controls			
	Males (yr)		Females (yr)		Males (yr)		Females (yr)

The PBMCs were isolated from age-matched males (*n* = 72) and females (*n* = 71) of 71 patients with chronic hepatitis C and 72 healthy controls, who were divided into younger or pre-menopausal (< 50 years of age) and older or post-menopausal (≥ 50 years of age) groups, based on a mean menopausal age of 50 years. The values are the mean ± SD (*n* = 17 or 18). ND: Not detected.

**Table 2** Spontaneous production of TNF-α, IL-1β, IL-8, and MCP-1 by PBMCs from age-matched younger and older males and pre- and post-menopausal females of patients with chronic hepatitis C and healthy controls

Subjects with and without chronic HCV infection			TNF-α	IL-1β	IL-8	MCP-1
			(pg/mL supernatant)			
Males	Younger (< 50 yr)	Patients	354 ± 201 <sup>a</sup>	253 ± 142	918 ± 499	403 ± 216
		Controls	265 ± 161	180 ± 105	780 ± 420	308 ± 161
	Older (≥ 50 yr)	Patients	385 ± 234 <sup>a</sup>	284 ± 160 <sup>a</sup>	1087 ± 576 <sup>a</sup>	461 ± 242 <sup>a</sup>
		Controls	322 ± 200	217 ± 125	899 ± 480	364 ± 187
Females	Pre-menopausal (< 50 yr)	Patients	288 ± 177	198 ± 111	780 ± 410	334 ± 174
		Controls	210 ± 126	167 ± 94	624 ± 335	275 ± 140
	Post-menopausal (≥ 50 yr)	Patients	314 ± 189	264 ± 149 <sup>a</sup>	887 ± 473	387 ± 198
		Controls	241 ± 148	182 ± 100	699 ± 372	362 ± 201

The PBMCs were isolated from age-matched males (*n* = 72) and pre- and post-menopausal females (*n* = 71) of 71 patients with chronic hepatitis C and 72 healthy controls. The levels of TNF-α, IL-1β, IL-8, and MCP-1 in the culture supernatant were detected by means of an ELISA. The values are the mean ± SD (*n* = 17 or 18). <sup>a</sup>*P* < 0.05 vs the pre-menopausal healthy controls.

ALT and HCV-RNA, and platelet counts (normal ranges between 150 and 350 × 10<sup>3</sup>/mm<sup>3</sup>), were not significantly different among the younger (< 50 years of age), or pre-menopausal, and the older (≥ 50 years of age), or post-menopausal groups. There was no significant difference of platelet counts between the patient groups and healthy control groups. Because platelet counts in chronic hepatitis C patients have been reported to be an indicator of the degree of hepatic fibrosis<sup>[11]</sup>, most of the patients in this study seemed to show mild hepatic fibrosis.

**Comparison of the spontaneous production of TNF-α, IL-1β, IL-8, and MCP-1 by PBMCs from age-matched younger and older males and pre- and post-menopausal females of patients with chronic hepatitis C and healthy controls**

PBMCs were isolated from age-matched younger and older males and pre- and post-menopausal females of the patients with chronic hepatitis C and the healthy controls. In the premenopausal females, the blood samples were taken during the luteal phase of the ovarian cycle. The 24-h cultured PBMCs released TNF-α, IL-1β, IL-8, and MCP-1 into the culture medium (Table 2). The levels of E2 and progesterone in the culture supernatant were found to be under 10<sup>-12</sup> mol/L. Although the net cytokine levels were considerably different among the individuals, the spontaneous production levels of cytokines in the unstimulated PBMCs appeared to show different tendencies between the 8 subgroups, the highest levels

were present in the older male patients and the lowest levels were found in the pre-menopausal female controls (*P* = 0.039 for TNF-α, *P* = 0.018 for IL-1β, *P* = 0.013 for IL-8, and *P* = 0.011 for MCP-1). The chronic hepatitis C patients showed higher production levels of TNF-α, IL-1β, IL-8, and MCP-1 as compared with the age-matched healthy controls, and the mean production levels of cytokines in the older groups were higher than those in the younger groups, while the female subjects tended to produce much less cytokines from the unstimulated PBMCs than did the age-matched male subjects (Table 2).

**Effects of E2 and progesterone on spontaneous production of TNF-α, IL-1β, IL-8, and MCP-1 by unstimulated PBMCs from age-matched older male and post-menopausal female patients with chronic hepatitis C**

We next investigated the effects of E2 and progesterone on the augmented production of TNF-α, IL-1β, IL-8, and MCP-1 by the unstimulated PBMCs from the age-matched older male and post-menopausal female patients with chronic hepatitis C. When the unstimulated PBMCs were cultured for another 6 h without female sex hormones or receptor antagonists, the mean percentages of each initial value for the cytokine production reached up to 110%-123% (Table 3). Whereas the treatment with E2 and progesterone in the unstimulated PBMCs for 6 h significantly affected the change rates of the cytokine production in a dose dependent manner, the percentages

+ Progesterone + RU	130 $\pm$ 27	125 $\pm$ 28	132 $\pm$ 30		123 $\pm$ 25

The unstimulated PBMCs from the age-matched older male and post-menopausal female patients with chronic hepatitis C were cultured for another 6 h with and without 10<sup>-8</sup> mol/L E2 (E2) or 10<sup>-7</sup> mol/L progesterone (progesterone) in the presence and absence of 10<sup>-6</sup> mol/L ICI (ICI) or 10<sup>-5</sup> mol/L RU (RU). The levels of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 in the culture supernatant were detected by means of an ELISA. The results were expressed as the percentages of each initial value for the cytokine production in the absence of the female sex hormones and receptor antagonists. The values are the mean  $\pm$  SD ( $n = 18$ ). <sup>a</sup> $P < 0.05$  vs 6-h-cultures in the absence of the female sex hormones and receptor antagonists.

of each initial value decreased significantly in the PBMCs treated with E2 at 10<sup>-8</sup> and 10<sup>-7</sup> mol/L, and they increased significantly in the PBMCs treated with 10<sup>-7</sup> mol/L progesterone (Figure 1). There was no significant difference between the change rates of the cytokine production in the male and female patients with chronic hepatitis C.

The inhibitory effects of 10<sup>-8</sup> mol/L E2 on the unstimulated cytokine production in the male and female patients were blocked by the specific ER antagonist ICI at a dose of 10<sup>-6</sup> mol/L, while the further enhancement effects of 10<sup>-7</sup> mol/L progesterone on the unstimulated cytokine production in both genders were blocked by the PR antagonist RU (Table 3). The treatment with ICI or RU alone had no effect on any of the parameters examined herein (data not shown).

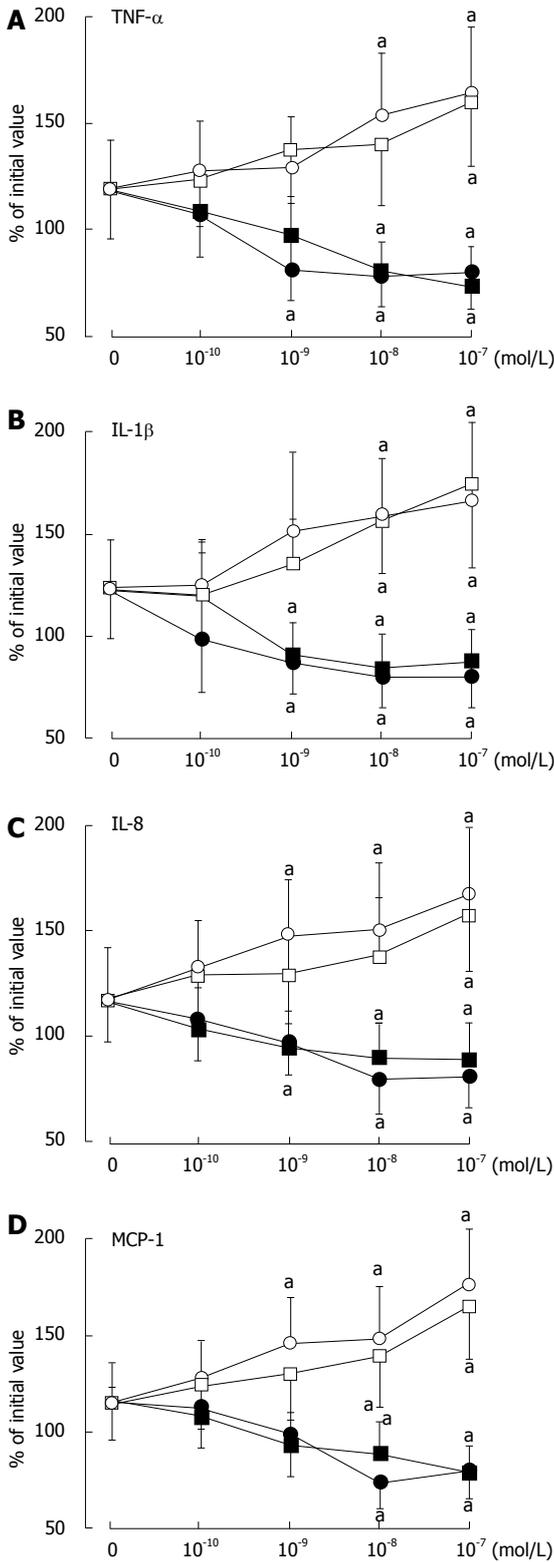

#### **Effects of E2 and progesterone on hydrogen peroxide-stimulated production of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 by PBMCs from age-matched younger male and pre-menopausal female healthy controls**

The exposure to low doses of hydrogen peroxide (10<sup>-7</sup>-10<sup>-5</sup> mol/L) in the PBMCs from the age-matched younger male and pre-menopausal female healthy controls, incubated in serum-free RPMI for 6 h, was observed to stimulate the production of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 in a dose-dependent manner (data not shown). The subsequent studies used a dose of 10<sup>-5</sup> mol/L of hydrogen peroxide for further stimulation of the incubated PBMCs. The exposure to hydrogen peroxide induced a time-dependent and transient cytokine production, peaking at 1-6 h, over a 6 h period (Figure 2). There was no significant difference between the cytokine levels in the male and female healthy controls. The cytokine levels in the culture supernatant (Figure 2) peaked after 6 h. Subsequent studies used an incubation time of 6 h to measure the levels of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 after the hydrogen peroxide exposure.

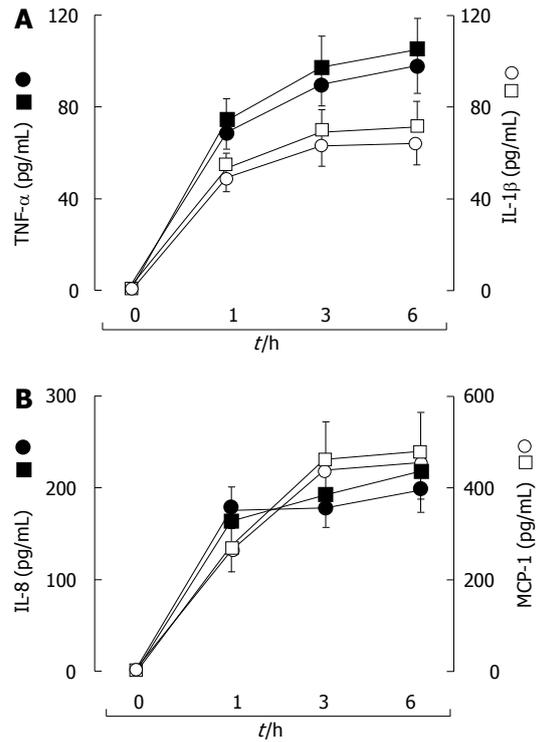

The hydrogen peroxide-stimulated cytokine production was inhibited by 10<sup>-8</sup> mol/L E2 (Table 4). The inhibitory effect of E2 was blocked by 10<sup>-6</sup> mol/L ICI (Table 4). In contrast to E2, progesterone treatment for 6 h resulted in the further cytokine production in the oxidative stress-stimulated PBMCs. The stimulatory effect of progesterone (10<sup>-7</sup> mol/L) was blocked by 10<sup>-6</sup> mol/L RU (Table 4). No parameters examined in the PBMCs were found to be significantly different between the male and female subjects.

## **DISCUSSION**

In the present study, the highest levels of the spontaneous production of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 by the unstimulated PBMCs were found to be in the older male patients with chronic hepatitis C, and the lowest levels were in the pre-menopausal female healthy subjects, although the cytokine levels were considerably different among the individuals. The male subjects tended to produce cytokines from the unstimulated PBMCs to a much greater degree than did the age-matched female subjects. The augmented cytokine production by the PBMCs from the older male and post-menopausal female patients with chronic hepatitis C was inhibited by supplementation with E2, and was further stimulated by supplementation with progesterone through their receptors, when the unstimulated cells were cultured for an additional 6 h. The exposure to low doses of hydrogen peroxide in the PBMCs from younger male and pre-menopausal female healthy subjects incubated in the serum-free media for 6 h was observed to induce cytokine production. The change rates of the hydrogen peroxide-stimulated production of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 in the PBMCs were suppressed by E2, and were enhanced by progesterone through their receptors. The specificity of the E2-mediated anti-inflammatory induction through the ER and the progesterone-mediated proinflammatory induction through the PR was shown

**Figure 1** Effects of E2 and progesterone on spontaneous production of TNF- $\alpha$  (A), IL-1 $\beta$  (B), IL-8 (C), and MCP-1 (D) by unstimulated PBMCs from age-matched older male and post-menopausal female patients with chronic hepatitis C. The unstimulated PBMCs from the age-matched older male (black square) and post-menopausal female (black circle) patients with chronic hepatitis C were cultured for another 6 h with and without E2 ( $10^{-10}$ - $10^{-7}$  mol/L) (solid) or progesterone ( $10^{-10}$ - $10^{-7}$  mol/L) (open). The spontaneous production levels of TNF- $\alpha$  (A), IL-1 $\beta$  (B), IL-8 (C), and MCP-1 (D) in the culture supernatant were detected by means of an ELISA. The results were expressed as the percentages of each initial value for the cytokine production in the absence of the female sex hormones. The values are the mean  $\pm$  SD ( $n = 18$ ). <sup>a</sup> $P < 0.05$  in comparison to the 6-h-cultures in the absence of the female sex hormones.

**Figure 2** Stimulation of TNF- $\alpha$ , IL-1 $\beta$  (A), IL-8, and MCP-1 (B) production after exposure to hydrogen peroxide by unstimulated PBMCs from age-matched younger male and pre-menopausal female healthy controls. The unstimulated PBMCs from the age-matched younger male (black square) and pre-menopausal female (black circle) healthy controls were incubated for up to 6 h in serum-free RPMI in the presence of  $10^{-5}$  mol/L hydrogen peroxide. The levels of TNF- $\alpha$  (A solid), IL-1 $\beta$  (A open), IL-8 (B solid), and MCP-1 (B open) in the culture supernatant were detected by means of an ELISA. The values are the mean  $\pm$  SD ( $n = 10$ ).

by ICI and RU, respectively, in both the unstimulated and oxidative stress-stimulated PBMCs. The inhibitory effect of E2 at a dose of  $10^{-8}$  mol/L on the unstimulated and stimulated cytokine production was blocked by ICI in both gender subjects. Treatment with the progesterone receptor antagonist RU led to a blockage of further cytokine production induced with  $10^{-7}$  mol/L progesterone by the unstimulated and stimulated PBMCs from both genders. No parameters examined in the PBMCs were found to be significantly different between the male and female subjects.

There is a large body of evidence indicating that the decline in the ovarian function with menopause is associated with spontaneous increases in TNF- $\alpha$ , IL-1 $\beta$ , and IL-6<sup>[3]</sup>. E2, at physiological concentrations ( $10^{-11}$ - $10^{-8}$  mol/L), has been reported to inhibit the spontaneous secretion of these proinflammatory cytokines in whole blood cultures<sup>[12]</sup> or PBMCs<sup>[13]</sup>. The unstimulated production of TNF- $\alpha$  and IL-1 $\beta$  in PBMCs has been reported to be higher in patients with chronic hepatitis C than in healthy subjects<sup>[14]</sup>. These findings were consistent with the present data. The *in vivo* treatment with E2 transdermally in postmenopausal women has been reported to decrease the spontaneous IL-6 production by PBMCs after 12 mo of the therapy<sup>[13]</sup>. One preliminary study also showed the hydrogen peroxide-induced TNF- $\alpha$

The unstimulated PBMCs from the age-matched younger male ( $n = 18$ ) and pre-menopausal female ( $n = 18$ ) healthy controls were incubated for up to 6 h in serum-free RPMI after exposure to  $10^5$  mol/L hydrogen peroxide (oxidative stress) with and without  $10^{-8}$  mol/L E2 (E2) or  $10^{-7}$  mol/L progesterone (Progesterone) in the presence and absence of  $10^{-6}$  mol/L ICI (ICI) or  $10^{-6}$  mol/L RU (RU). The levels of TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 in the culture supernatant incubated for 6 h were detected by means of an ELISA. The values are the mean  $\pm$  SD ( $n = 18$ ). <sup>a</sup> $P < 0.05$  vs 1 h cultures for MCP-1 or 6 h cultures for TNF- $\alpha$ , IL-1 $\beta$ , and IL-8 after hydrogen peroxide exposure in the absence of the female sex hormones and receptor antagonists.

and MCP-1 expressions to be attenuated by E2 in the peritoneal macrophages of female mice<sup>[15]</sup>. Furthermore, E2 is able to attenuate IL-1 $\beta$  in ER expressing HepG2 cells<sup>[16]</sup>, and to ameliorate the burn-induced increase in the serum TNF- $\alpha$  levels in rats<sup>[17]</sup>. These findings suggest that E2 may exert a hepatoprotective action against inflammation and oxidative stress, at least in part, by preventing accumulation of monocytes and macrophages and by inhibiting the production of proinflammatory cytokines.

As far as the *in vitro* studies with female sex hormones on the production of TNF- $\alpha$  and IL-1 $\beta$  by monocytes are concerned, however, conflicting data have been published<sup>[9]</sup>, varying from some<sup>[18-20]</sup> to no<sup>[12,21]</sup> effect of E2 or progesterone on cytokine production. E2 has been reported to suppress the TNF- $\alpha$  production in unstimulated PBMCs, but not in endotoxin-stimulated PBMCs, from postmenopausal females with osteoporosis<sup>[22]</sup>. An inhibition of IL-1 $\beta$  production in endotoxin-stimulated monocytes by E2 or progesterone at physiological concentrations has also been reported<sup>[23]</sup>. The results of the reported studies did not correlate with the present data. These conflicting results may possibly be due to the handling of the cells during the *in vitro* research, different experimental methods used, and/or differences in the subjects employed in the studies.

In the premenopausal female subjects with and without chronic hepatitis C enrolled herein, the blood samples were taken during the luteal phase of the menstrual cycle. During the luteal phase, the serum concentration of endogenous progesterone rises up to a maximum of about  $10^{-7}$  mol/L, which can be ten to a hundred times higher than E2. Higher blood levels of TNF- $\alpha$  have been observed during the luteal phase in comparison to the follicular phase<sup>[24]</sup>. In males, a higher percentage of IL-1 $\beta$  producing stimulated monocytes has been demonstrated in comparison to females in the follicular phase<sup>[19]</sup>. The male sex hormone testosterone has some structural and functional similarities to

progesterone<sup>[25]</sup>. Judging from these findings and the present data showing that treatment with E2 ( $10^{-8}$  and  $10^{-7}$  mol/L) and progesterone ( $10^{-7}$  mol/L) significantly affected the change rate of the cytokine production in hydrogen peroxide-stimulated PBMCs, E2 may, therefore, exert an anti-inflammatory action against both inflammation and oxidative stress in the mononuclear cells from the chronic hepatitis C patients, whereas progesterone may counteract the favorable effects of E2.

HCV infections are recognized to be a major causative factor in the development of liver injury leading to cirrhosis<sup>[26,27]</sup>. The HCV core protein has been reported to enhance the signaling pathway of NF- $\kappa$ B activation in human hepatoma HuH-7 and cervical cancer HeLa cells, and the HCV core protein is triggered by TNF- $\alpha$ -related cytokines<sup>[28]</sup>. Damage to the parenchymal cell membranes and liver mitochondria could produce ROS derived from lipid peroxidative processes, which constitute a general feature of a sustained inflammatory response and liver injury<sup>[29]</sup>. In comparison to other types of ROS, hydrogen peroxide is more stable and membrane permeable leading to the hypothesis that it acts as a second messenger in regulating the signaling events, including the mitogen-activated protein kinase (MAPK) activation. We have already reported that E2 inhibited the prooxidant-induced lipid peroxidation in rat liver mitochondria<sup>[5]</sup>, attenuated ROS generation and NF- $\kappa$ B activation in cultured rat hepatocytes in a state of prooxidant-induced oxidative stress<sup>[6]</sup>, while also suppressing the hydrogen peroxide-induced activation of MAPKs and transcription factors including NF- $\kappa$ B in cultured rat hepatic stellate cells<sup>[30]</sup>. In the present study, hydrogen peroxide exposure resulted in an increase in the TNF- $\alpha$ , IL-1 $\beta$ , IL-8, and MCP-1 levels in the cultured mononuclear cells from the male and female healthy subjects. The oxidative stress-stimulated cytokine expression was attenuated by E2 and augmented by progesterone in a dose-dependent manner without any significant difference between the males and females. These effects of E2 and progesterone were blocked by

their receptor antagonists ICI and RU, indicating that ER and PR could mediate female sex hormone action in the oxidative stress-stimulated monocytes and macrophages.

Finally, the current data suggest that E2 may play a favorable role in the course of persistent liver injury, at least in part, by preventing the accumulation of monocytes and macrophages and by also inhibiting the proinflammatory cytokine production through ER, whereas progesterone may counteract these positive E2 effects by enhancing the accumulation of inflammatory cells and their cytokine production through PR.

## COMMENTS

### Background

Parenchymal cell membrane damage could produce reactive oxygen species (ROS) derived from lipid peroxidative processes, which represent the general feature of sustained inflammatory response and liver injury. A chronic hepatitis C virus infection tends to progress more rapidly in men than women. There is little information about the effects of estradiol (E2) and progesterone on the proinflammatory cytokine production by prooxidant-stimulated monocytes in chronic hepatic C patients.

### Research frontiers

We have recently hypothesized that E2 could play a cytoprotective role in the injured liver by inhibiting the ROS generation, antioxidant enzyme loss, and induction of redox sensitive transcription factors.

### Innovations and breakthroughs

This study focused on comparison of the oxidative stress-stimulated proinflammatory cytokine production between younger and older patients, who were divided into two groups based on a mean menopausal age of 50 years, demonstrating that E2 might play a favorable role in the course of persistent liver injury, whereas progesterone might counteract the favorable E2 effects.

### Applications

The favorable activity of E2 may be involved in the persistent liver injury of different liver diseases such as alcoholic and non-alcoholic liver diseases as well as chronic hepatitis C and B.

### Peer review

The study is of particular interest because the role and importance of the sex hormones in the regulation of some cell functions during disturbance in the prooxidant-antioxidant balance is understood. It is very important that study links clinical and experimental part.

### Abstract

**AIM:** To determine the accuracy of computed tomography (CT) and magnetic resonance (MR) for presurgical characterization of paraaortic lymph nodes in patients with pancreatico-biliary carcinoma.

**METHODS:** Two radiologists independently evaluated CT and MR imaging of 31 patients who had undergone lymphadenectomy (9 metastatic and 22 non-metastatic paraaortic nodes). Receiver operating characteristic (ROC) curve analysis was performed using a five point scale to compare CT with MRI. To re-define the morphologic features of metastatic nodes, we evaluated CT scans from 70 patients with 23 metastatic paraaortic nodes and 47 non-metastatic ones. The short axis diameter, ratio of the short to long axis, shape, and presence of necrosis were compared between metastatic and non-metastatic nodes by independent samples *t*-test and Fisher's exact test.  $P < 0.05$  was considered statistically significant.

**RESULTS:** The mean area under the ROC curve for CT (0.732 and 0.646, respectively) was slightly higher than that for MRI (0.725 and 0.598, respectively) without statistical significance ( $P = 0.940$  and  $0.716$ ,

respectively). The short axis diameter of the metastatic lymph nodes (mean = 9.2 mm) was significantly larger than that of non-metastatic ones (mean = 5.17 mm,  $P < 0.05$ ). Metastatic nodes had more irregular margins (44.4%) and central necrosis (22.2%) than non-metastatic ones (9% and 0%, respectively), with statistical significance ( $P < 0.05$ ).

**CONCLUSION:** The accuracy of CT scan for the characterization of paraaortic nodes is not different from that of MRI. A short axis-diameter ( $> 5.3$  mm), irregular margin, and presence of central necrosis are the suggestive morphologic features of metastatic paraaortic nodes.

Comparison of CT and MRI for presurgical characterization of paraaortic lymph nodes in patients with pancreatico-biliary carcinoma. *World J Gastroenterol* 2008; 14(14): 2208-2212 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2208.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2208>

### INTRODUCTION

Paraaortic lymph node metastasis in the patients with pancreatico-biliary carcinoma has been reported as a definite predictor of early recurrence and shorter survival term, despite differences between individual tumors<sup>[1-3]</sup>. It is very difficult to preoperatively predict paraaortic node metastasis with imaging, palpation, or intraoperative sonography. Therefore it is recommended that sampling and pathologic confirmation of paraaortic nodes should be performed before starting radical operation. Many surgeons, including

those in our hospital, do paraaortic node dissection before radical surgery<sup>[4-7]</sup>. Although lymphadenectomy followed by histologic examination of the lymph nodes is still the gold standard for determination of metastasis, this procedure is invasive and could cause many surgical complications<sup>[8-11]</sup>. Therefore preoperative, noninvasive imaging diagnosis of paraaortic node metastasis is very important<sup>[12]</sup>.

Lymph node staging in the various carcinomas has been extensively discussed in the previous literature<sup>[13-19]</sup>. Dorfman *et al.*<sup>[20]</sup> reported that the upper limits of the normal nodes in the upper abdomen are site-specific. Therefore, site-specific nodal evaluation is necessary not only due to different clinical importance but also due to different morphologic criteria for malignancy<sup>[21]</sup>. To our knowledge, however, there have been no radiologic reports on preoperative imaging diagnosis with a focus on the paraaortic node.

The purpose of our study was to compare computed tomography (CT) and magnetic resonance (MR) for preoperative detecting paraaortic lymph node metastasis in the patients with pancreato-biliary carcinoma and to re-define the significant morphologic features of metastatic ones.

## MATERIALS AND METHODS

### Patient population

The protocol for this study was approved by the Institutional Review Board at our institution and informed consent for this retrospective study was not required. From February 2000 to June 2006, 70 patients (37 men, 33 women; mean age, 62.9 years) with pancreatic head cancer ( $n = 22$ ), ampulla of vater cancer ( $n = 16$ ), distal common bile duct cancer ( $n = 24$ ), or gallbladder (GB) cancer ( $n = 8$ ) underwent CT ( $n = 63$ ) and/or MR ( $n = 38$ ) imaging. The mean interval time between lymphadenectomy and imaging evaluation was 16.7 d after CT and 18.3 d after MRI. Paraaortic lymphadenectomy was performed in all of the patients before or during surgical resection operations. Histological examinations revealed metastatic paraaortic nodes in 23 patients and non-metastatic nodes in 47 patients. Both CT and MRI were performed in 31 patients with pancreatic head cancer ( $n = 11$ ), distal common bile duct cancer ( $n = 13$ ), ampulla of vater cancer ( $n = 6$ ) or GB cancer ( $n = 1$ ). Nine patients had metastatic paraaortic nodes and 22 patients had non-metastatic nodes.

### Imaging acquisition

All CT scans were obtained with one of the following commercially available multidetector or single detector CT scanners (Somatom Sensation 64, Somatom Sensation 64, Somatom Plus 4; Siemens Medical Solutions, Erlangen, Germany; Lightspeed Plus or QX/i, GE Medical Systems, Milwaukee, Wisconsin). Each patient received 120-150 mL of iopromide (Ultravist 300 or Ultravist 370; Schering, Berlin, Germany) at a rate of 3 mL/s. CT scans were obtained during the arterial phase (using a 25-35-s delay), portal venous phase (using a 70-75-s delay), and equilibrium phase (using a 3-min delay) after IV administration with 3-5-mm section thickness and 3-5-mm reconstruction interval.

MRI examinations were performed using a 1.5-T

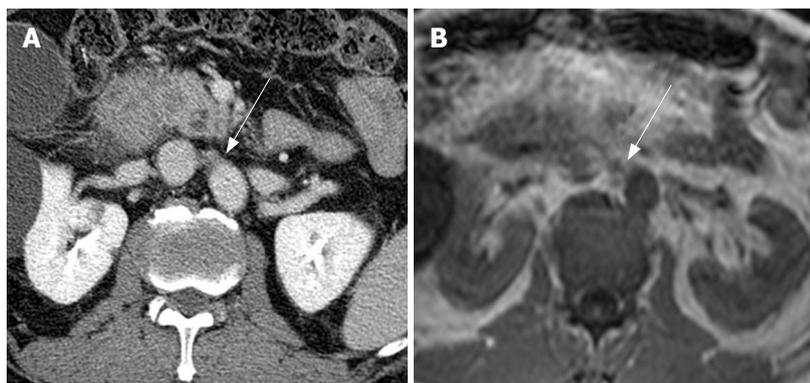

imaging system (Gyrosan Intera, Philips Medical Systems Best, Netherlands), equipped with commercially available phased-array coils (Synergy; Philips Medical Systems, Best, Netherlands). Four-hour fasting was recommended before the examinations. Antiperistaltic agents or oral contrast agents were not used. The MRI protocol consisted of a breath-hold axial T1-weighted dual fast-gradient-recalled-echo sequence [(TR/in-phase TE, 180/4.6 ms; out-of-phase TE = 2.3 ms; flip angle, 90°; field of view, 32-36 cm × 25-29 cm; matrix, 240 × 240; section thickness, 7 mm; slice spacing, 7.7 mm; one signal acquired; number of slices = 24)]; a single shot turbo spin echo (TR/TE, 452/80 and 160; field of view, 32-36 cm × 25-29 cm; matrix, 288 × 230; section thickness, 7 mm; slice spacing, 5 mm; scan slices were overlapped by 2 mm using an interleaved acquisition technique) with spectral fat suppression and respiratory triggering technique; and a breath-hold transverse 3D gradient echo sequence with fat saturation (TR/TE, 3.9/1.1 msec; flip angle, 25°; field of view, 32-36 cm × 25-36 cm; matrix, 320/224; section thickness, 3 mm).

Contrast-enhanced MRI was performed using a breath-hold 3D gradient echo sequence with fat saturation sequence, following an IV bolus of 0.1 mmol gadobenate dimeglumine (MultiHance, Bracco SpA, Milan, Italy) per kilogram of body weight followed by a saline flush of 30 mL. This sequence was repeated four times with data acquisition in the hepatic arterial, portal venous, and equilibrium phases. An automatic infusion system (Spectris MR injection system, Medrad Europe, Maastricht, Netherlands) operating at an injection rate of 2 mL/s was used. The actual pulse sequence was started manually when the fluoroscopic sequence revealed that the contrast material bolus had reached the abdominal aorta.

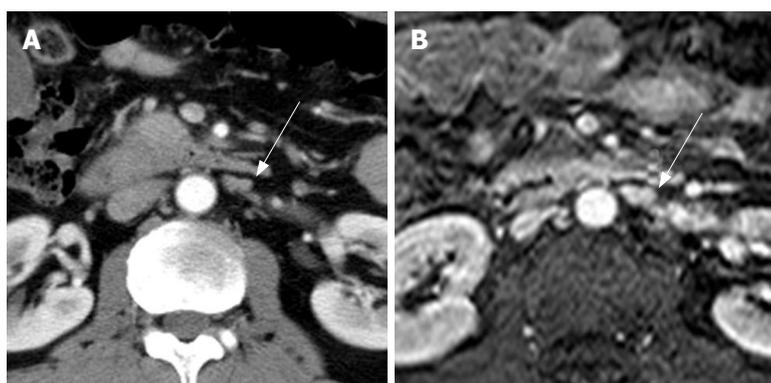

### Image analysis

All of the imaging analysis was performed on a picture archiving and communication system (PACS) workstation (Centricity 1.0; GE Medical Systems). This retrospective study was composed of two parts. To compare the diagnostic accuracy of CT and MRI, two radiologists independently evaluated preoperative CT and MR images within a 3-wk interval in 31 patients, without knowledge of final pathologic diagnosis. They considered the following criteria as the primary findings for metastatic nodes: (1) short diameter > 9 mm; (2) long axis diameter > 13 mm; (3) presence of necrosis; (4) irregular margin. Reviewers graded the paraaortic lymph node on a five-point scale of diagnostic confidence: 1, no node; 2, definitely benign; 3, probably benign; 4, probably metastatic; and 5, definitely metastatic. Diagnostic accuracy was evaluated using receiver operating characteristic (ROC) curve analysis with a calculation of the area ( $A_z$ ) under the ROC curve. Degree of interobserver agreement was expressed by a Kappa value; a kappa value greater than 0.60 indicated excellent agreement, between 0.40 and 0.60 was good, and less than 0.40 was poor<sup>[22]</sup>.

Using the CT and MR images, we redefined the morphologic criteria of metastatic nodes by comparing them with non-metastatic nodes. Two radiologists evaluated the CT scan in consensus for 63 patients (18 metastatic paraaortic nodes and 45 non-metastatic ones)

**Figure 1** Metastatic right paraaortic lymph node in a 63-year-old man with pancreatic head cancer. **A:** Contrast-enhanced CT shows an irregularly shaped lymph node (arrow) with a short axis dimension of 11.5 mm that was interpreted as a definitely metastatic lymph node; **B:** Axial T1-weighted MRI shows an irregularly shaped lymph node (arrow) with a short axis dimension of 8.5 mm that was interpreted as a definitely benign lymph node. Pathologic examination revealed that this lymph node was metastatic.

**Figure 2** Metastatic left paraaortic lymph node in a 51-year-old man with pancreatic head cancer. **A:** Contrast-enhanced CT shows an irregularly shaped lymph node (arrow) with a short axis dimension of 7.2 mm that was interpreted as a probably metastatic lymph node; **B:** Axial contrast-enhanced T1-weighted MRI shows an irregularly shaped lymph node (arrow) with a short axis dimension of 7 mm that was interpreted as a probably metastatic lymph node; this diagnosis was confirmed by lymphadenectomy and pathological examination.

to record the short and long axial diameter and their ratio, margin (smooth or irregular), and the presence of necrosis in the detected paraaortic lymph nodes. The short and long axis diameter and their ratio were compared between metastatic paraaortic and non-metastatic lymph nodes by the independent samples *t*-test. The margin and presence of necrosis of metastatic paraaortic lymph nodes were compared to those of non-metastatic nodes by Fisher's exact test. *P* < 0.05 was considered statistically significant. A ROC curve was used to determine the best cut-off value for the short and long axis diameter for differentiation of metastatic from non-metastatic nodes. When multiple nodes in the paraaortic region were detected, the largest, irregular-shaped, and/or necrotic node was selected and defined as a metastatic node. The imaging findings were compared with histopathologic results on a per-case basis.

## RESULTS

### Accuracy of CT and MRI for detecting metastatic paraaortic lymph nodes

Interobserver agreement between the two readers for CT was excellent (kappa value 0.674; standard error 0.088), but that for MRI was poor (kappa value 0.359; standard error 0.157).

The mean area under the two readers' ROC curve for CT (0.732 and 0.646, respectively) was slightly higher than that for MRI (0.725 and 0.598, respectively) without statistical significance (*P* = 0.940 and 0.716, respectively) (Figures 1 and 2).

### Features of metastatic paraaortic lymph nodes on CT

The comparison between non-metastatic and metastatic

**Table 1** Features of metastatic paraaortic lymph nodes on CT

	Non-metastatic	Metastatic	<i>P</i> value
Mean short diameter	5.17 mm	9.2 mm	< 0.05
Mean long diameter	8.72 mm	13.18 mm	< 0.05
Mean ratio (short/long)	0.58	0.7	0.284
Irregular margin	9%	44%	< 0.05
Necrosis	0%	28%	< 0.05

paraaortic lymph nodes on CT is summarized in Table 1. The short axis diameter of metastatic lymph nodes (mean = 9.2 mm, 3.8-28.1 mm) was significantly larger than that of non-metastatic lymph nodes (mean = 5.17 mm, 2.1-11.8 mm, *P* < 0.05). The long axis diameter of metastatic lymph nodes (mean = 13.18 mm, 5-32.1 mm) was significantly larger than that of non-metastatic lymph nodes (mean = 8.72 mm, 4.6-22.9 mm, *P* < 0.05). However, the ratio of the short to long axis of metastatic lymph nodes (mean = 0.70) was slightly larger than that of non-metastatic lymph nodes (mean = 0.58) without statistical significance (*P* = 0.284). The margins of the paraaortic lymph nodes were irregular in 8 of 18 patients (44.4%) with metastasis (Figures 1 and 2), and 4 of 45 patients (8.9%) without metastasis. The presence of central necrosis was seen in 4 of 18 patients (22.2%) with metastasis, but was not seen in patients without metastasis. Metastatic nodes had more irregular margins (44%) and central necrosis (28%) than non-metastatic nodes (9% and 0%, respectively), with statistical significance (*P* < 0.05).

Based on the ROC curve, we determined that the best cut-off values for differentiating metastatic nodes from non-metastatic nodes were > 5.3 mm for the short axis diameter

**Figure 3** Two metastatic paraaortic lymph nodes in a 49-year-old man with gallbladder cancer. Axial (A) and coronal (B) contrast-enhanced CT shows several paraaortic lymph nodes. Among them, the right largest node (straight arrow) shows 10 mm and 18.8 mm of short and long axis diameters with irregular margin (on coronal image), compatible with metastatic node. The left one (dot arrow) shows 8.2 mm and 12.2 mm of short and long axis diameters, less than the mean value of metastatic ones (9.2 mm and 13.2 mm, respectively). According to the best cut-off value of short diameter more than 5.3 mm and long axis diameter more than 11.6 mm, The left one is also metastatic one rather than non-metastatic one. Pathologic examination revealed that two lymph nodes were metastatic ones among six resected paraaortic lymph nodes.

and > 11.6 mm for the long axis diameter (Figure 3). According to the short axis cutoff of > 5.3 mm, the diagnostic values for metastatic nodes were 77.8% sensitivity (95% confidence interval (CI): 52.4%-93.5%) and 66.4% specificity (95% CI: 48.8%-78.1%). According to the cutoff of > 11.6 mm for the long axis diameter, the diagnostic values for metastatic nodes were 50.0% sensitivity (95% CI: 26.1%-73.9%) and 91.1% specificity (95% CI: 78.8%-97.5%).

## DISCUSSION

Although CT and MR imaging are well established for the staging and follow-up of patients with malignancy, the rates of accuracy for the detection of metastatic lymph nodes vary widely. It has been reported that the accuracy of CT and MRI for the detection of lymph nodes in patients with cervical carcinoma<sup>[23-25]</sup> and the evaluation of regional nodes in the patients with rectal cancer<sup>[26,27]</sup> is comparable. Other studies have suggested that CT is more specific for detecting positive lymph nodes in gynecologic cancers, whereas MR imaging is more sensitive<sup>[23]</sup>. In some reports on the evaluation of cervical cancer, MRI (60%) was reported to be more sensitive than CT (43%), whereas the specificities of the two modalities were comparable<sup>[28]</sup>. Focusing on paraaortic nodes in the patients with pancreatico-biliary cancer, our study showed that the accuracy of CT and MRI were comparable. Our results revealed that the interobserver agreement for CT was excellent, whereas that for MR was poor. This finding suggests that the radiologist's experience is more important for evaluating by MRI than CT, although it is generally accepted that the tissue contrast with MRI is better than that with CT.

Size criteria have been used in the differentiation of metastatic from non-metastatic nodes, despite much dispute<sup>[29]</sup>. In past, the maximum short axis diameter of a normal lymph node was known to vary on abdominal computed tomography, according to the node's location; the upper paraaortic region is 9 mm and the lower paraaortic region is 11 mm<sup>[20]</sup>. A recent study for metastatic paraaortic nodes in pancreatic cancer shows that the size criteria combined with a long axis diameter (12, 10, 8, or 6 mm) and the axial ratio (0.5, 0.7, or 1.0) have a positive predictive value of 13% to 36% and an overall accuracy of 66.7% to 78.9%<sup>[21]</sup>. Therefore it has been concluded that morphologic criteria are not useful in the evaluation of metastatic paraaortic nodes. A previous study of

gallbladder carcinoma, on the other hand, demonstrated a high positive predictive value (86%) in the evaluation of metastatic interaortocaval nodes based on the size and shape criteria; anterior posterior dimensions of 10 mm or larger and ring-like or heterogeneous contrast enhancement<sup>[30]</sup>. In our study, there was a statistically significant difference between two groups: the mean values for the short and long axis diameter of metastatic paraaortic nodes were 9.2 mm and 13.18 mm, respectively, whereas those of nonmetastatic ones were 5.17 mm and 8.27 mm, respectively. In our study, the best cut-off value for differentiating metastatic nodes from non-metastatic nodes was a short axis diameter of more than 5.3 mm (77.8% sensitivity and 66.4% specificity) and a long axis diameter of more than 11.6 mm (50.0% sensitivity and 91.1% specificity).

It is well known that central necrosis has a very high positive predictive value (almost 100%) in the diagnosis of metastasis. Our study also demonstrated that central necrosis was seen only in metastatic nodes. However, central necrosis may be seen with tuberculosis. Moreover, the sensitivity of central necrosis is very low. In our study, irregular margin had a high positive predictive value, although it was not pathognomic.

Our study had some limitations. First, it was a retrospective study and the parameters of the CT and MRI were not uniform. Second, the imaging findings were compared with histopathologic results on a per-case basis not on a per-node basis.

In conclusion, we found that the accuracy of CT and MRI were comparable for the evaluation of paraaortic nodes in the patients with pancreatico-biliary cancer. Central necrosis, irregular margin, and a cut-off value of more than 5.3 mm for the short axis diameter and 11.6 mm for the long axis diameter may be used as the criteria for diagnosing metastatic paraaortic nodes on CT scan. However, functional studies, such as high-resolution MRI with lymphotropic contrast agent, are necessary to overcome the limitation of morphologic evaluation of nodes.

## COMMENTS

### Background

In patients with pancreatico-biliary carcinoma, paraaortic lymph node metastasis has a crucial impact on surgical indication or extent of operation. At present, many surgeons perform paraaortic lymphadenectomy for accurate assessment and

decision for adequate extent of operation. However, because of its invasiveness and complications, paraaortic lymphadenectomy for pancreatico-biliary carcinoma is controversial.

### Research frontiers

Although a comparison between computed tomography (CT) and magnetic resonance (MR) has already been performed in cervical cancer, colorectal cancer and other malignancy, no studies to date have compared CT with MR in terms of detecting paraaortic lymph node metastases from pancreatico-biliary carcinoma. The aim of this study is to determine the accuracy of CT and MR for presurgical characterization of paraaortic lymph nodes in patients with pancreatico-biliary carcinoma.

### Innovations and breakthroughs

The results of this study indicate that the accuracy of CT and MR were comparable for the evaluation of paraaortic nodes in the patients with pancreatico-biliary cancer. The lymph node diameter > 5.3 mm, irregular margin, and central necrosis are the suggestive morphologic features of metastatic paraaortic nodes.

### Applications

CT and MR could be used for the selection of candidates for lymphadenectomy in the patients with pancreatico-biliary carcinoma.

### Terminology

Paraaortic lymph node metastasis in the patients with pancreatico-biliary carcinoma has been reported as a definite predictor of early recurrence and shorter survival term.

### Peer review

This is a very interesting paper, although it is a retrospective study. The idea of paraaortic lymph node in pancreatico-biliary is important for evaluation. This unique study will be a first step to confirm the results of a prospective study in the future.

## Abstract

**AIM:** To investigate the significance of Thrombospondin-1 (TSP-1) expression and its relationship with angiogenesis during experimental fibrosis.

**METHODS:** Cirrhosis was induced in male Wistar rats by intraperitoneal administration of diethyl nitrosamine (DEN). The serial sections from liver tissues were stained with anti-CD34 and anti-TSP-1 antibodies before being quantitated by light microscopy.

**RESULTS:** Our results showed that of TSP-1 expression gradually increases according to the severity of fibrosis (Group I vs group II, Group III and Group IV; Group II vs group III and group IV; group III vs group IV,  $P < 0.05$ ). Moreover, TSP-1 expression was found to be correlated with angiogenesis ( $P < 0.05$ ).

**CONCLUSION:** The correlative evidence of the link between TSP-1 and fibrosis or angiogenesis provided by this study suggests that besides its role as a strong promoter of transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1), TSP-1 might have an additional role in liver fibrogenesis by stimulating angiogenesis and this protein could be a potential target to prevent fibrogenesis in chronic inflammatory diseases of the liver.

correlates with angiogenesis in experimental cirrhosis. *World J Gastroenterol* 2008; 14(14): 2213-2217 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2213.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2213>

## INTRODUCTION

Hepatic angiogenesis is frequently associated with inflammation and fibrogenesis during chronic liver injury<sup>[1-5]</sup>. Currently, it is not clear whether this process plays a beneficial role in the maintenance of homeostasis or contributes to liver damage during chronic inflammation. However, the fact that chronic inflammatory liver diseases respond poorly to immunosuppressive and anti-inflammatory therapy suggests that angiogenesis might be a promising therapeutic target in the prevention of fibrosis<sup>[6-8]</sup>. For this reason, attempts are being directed to evaluate the cellular and molecular mechanisms involved in the development of hepatic angiogenesis during chronic liver injury<sup>[3-5]</sup>.

Thrombospondin 1 (TSP-1), one of the five members of the Thrombospondin gene family, is a matrix protein involved in complex processes including wound healing and angiogenesis<sup>[9,10]</sup>. The exact role of TSP-1 in angiogenesis is still controversial. TSP-1 can function as an inhibitor or as a promoter of angiogenesis, indicating that it might modulate this process in opposite directions<sup>[11-16]</sup>. In malignant and premalignant conditions of the liver, TSP-1 expression and its association with angiogenesis have been demonstrated<sup>[15-18]</sup>. Regarding non-neoplastic liver diseases, although the association of TSP-1 with latent transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) has been demonstrated in a few studies, the relationship between TSP-1 and angiogenesis during liver fibrogenesis has not been documented<sup>[19-21]</sup>.

Therefore, this study was undertaken to investigate the significance of TSP-1 expression during diethyl nitrosamine (DEN) induced experimental liver fibrosis and to evaluate whether any relationship exists between TSP-1 expression and angiogenesis.

## MATERIALS AND METHODS

### Materials

This animal study was approved by the local animal ethics committee of the Akdeniz University. Male adult Wistar rats weighing 250 g were used. They were maintained on

Table 1 Distribution of mean, standard deviation, median and ranges of VD and TSP-1 expression in normal livers (group I) and in DEN treated livers (group II, group III, and group IV)

Group	VD <sup>a</sup>			TSP-1 expression (%) <sup>a</sup>		
	mean ± SD	Median	Ranges	mean ± SD	Median	Ranges
I (n: 8)	3.24 ± 1.41	3	2-6	1.63 ± 1.06	1.5	0-3
II (n: 9)	5.22 ± 1.86	5	2-8	5.89 ± 1.18	4	0-14
III (n: 10)	9 ± 4.57	6	1-16	16.3 ± 7.32	9	2-26
IV (n: 10)	14.5 ± 5.97	11	8-26	68.5 ± 19.73	44	0-95

n: Number of cases; VD: Vascular density; SD: Standard deviation; <sup>a</sup>*P* < 0.05.

a commercial diet and water in a room at 22 ± 2°C under normal laboratory lighting conditions.

### Methods

**Animal model:** The rats received intra-peritoneal injections of DEN (Sigma, Saint Quentin Fallavier, France) at 100 mg/kg of body weight (*n*: 29) or 0.9% sodium chloride (*n*: 8) once a week. The injections were performed for 2 (*n*: 4), 4 (*n*: 5), 5 (*n*: 5), 6 (*n*: 5), 8 (*n*: 5) and 10 (*n*: 5) wk. The animals were sacrificed 2 wk after the last administrations and a hepatectomy was performed. Liver tissue samples were either frozen immediately in liquid nitrogen and stored at -70°C or fixed in 10% buffered formalin and embedded in paraffin.

**Histology and immunohistochemistry:** Four micrometer thick serial sections from the liver tissues originally fixed in formalin and embedded in paraffin were prepared and stained with hematoxylin and eosin for the histopathological assessment. Masson trichrome staining was used in the evaluation of the extent of liver fibrosis.

Immunolabeling was performed using polyclonal antibodies directed anti rat CD34 (sc-7045 goat, dilution: 1:500, Santa Cruz, CA, USA) and thrombospondin-1 (sc-12312 goat, IgG, dilution 1:200, Santa Cruz, CA, USA). An avidin-biotin-peroxidase technique (sc-2023, anti-goat ABC staining Kit; Santa Cruz, CA, USA) was used for labeling. For CD34, sections from paraffin embedded tissue blocks were dried in a hot air oven at 55°C overnight and dewaxed. Microwave antigen retrieval (750 W, 4 × 5 min in citrate buffer 0.01 mol/L, pH 6) was performed. TSP-1 staining was applied to 5 μm thick air dried (30 min) cryostat sections, fixed in acetone (10 min). Endogenous peroxidase was blocked by using 3% hydrogen peroxide in methanol for 30 min. Each step of incubation was followed thorough washing of the slides in phosphate buffered saline (PBS). After incubation with primary antibody against CD34 and TSP-1 (each 30 min), sections were reacted with secondary biotinylated antibody (30 min) and AB enzyme reagent (avidin and biotinylated horseradish peroxidase) for 30 min. Finally, all slides were treated with DAB reagent to develop color and counterstained with Mayer's hematoxylin. Normal goat and rabbit IgG instead of primary antibodies were used as negative control at the same dilution.

The vascular density in portal and periportal areas was assessed by determining the count of CD34 labeled vessel sections at higher magnification (× 400) with the use of

an ocular grid subdivided into 100 areas. For each subject vascular density (VD) was noted.

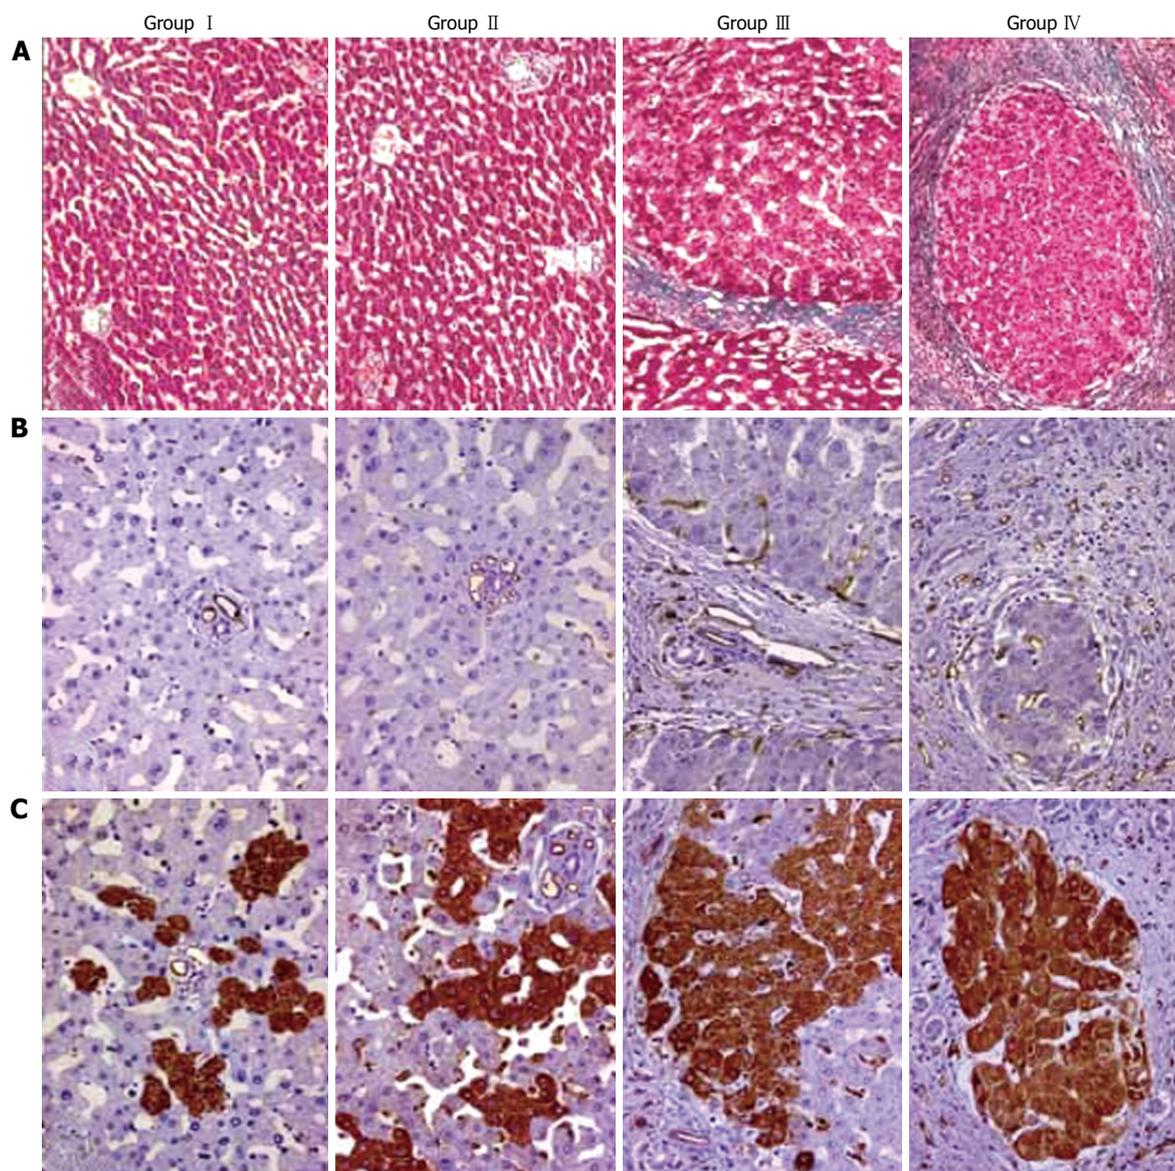

For quantitative evaluation of TSP-1 expression, in each section positive and negative cells were counted in systematically randomly selected 10 to 15 microscopic fields by using an ocular grid at high magnification (× 400). The positive staining was calculated as the percentage of positive cells to total number of counted cells. Positive cells touching the left and lower edge of the grid were not included.

All analysis were performed using Statistical Package for Social Science (SPSS 15.0 for Windows, USA). Mann-Whitney-*U* test was used to establish the difference between groups. Friedman test was used to determine the relationship between quantitative parameters. Data were expressed as mean ± SD and *P* < 0.05 was considered significant.

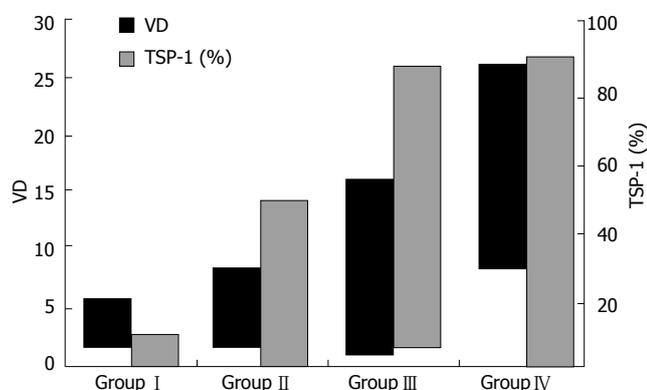

### RESULTS

In this study, fibrogenesis was not observed in the control group. In DEN treated rats, fibrous septa were detected after 5 wk. The liver was cirrhotic in all cases after 8 wk. According to the severity of fibrosis, cases were divided in following groups: Group I: normal livers, group II: non-fibrotic livers (2 and 4 wk), group III: fibrotic livers (5 and 6 wk) and group IV: cirrhotic livers (8 and 10 wk) (Figure 1A). In group I, CD34 staining was restricted to the endothelium of portal vessels. While in non-fibrotic livers CD34 expression was noted in a few vascular structures around portal areas, numerous CD34-labeled vessels were detected in fibrotic livers. In group IV, CD34 staining revealed a dense vascular plexus surrounding the cirrhotic nodules (Figure 1B). Parallel to this finding, VD values were increased together with the progression of fibrosis (Figure 2). DEN-treated cases (group II, III and IV) had higher VD than the control group (*P* < 0.05). The difference between VD values of group II, III and IV was also statistically significant (*P* < 0.05) (Figure 2 and Table 1).

In normal livers (group I), TSP-1 expression was restricted to the endothelium of portal vessels and to a few hepatocytes (Figure 1C). However, in non-fibrotic group TSP-1 expression was higher than normal livers with more positive hepatocytes and perisinusoidal cells (*P* < 0.05). TSP-1 expression continued to increase in fibrotic livers and was more widespread in cirrhotic livers. The expression of TSP-1 in DEN-treated rat groups was significantly different from each other (*P* < 0.05) (Figure 1C, Figure 2 and Table 1).

**Figure 1** Liver fibrosis (A), angiogenesis (B) and TSP-1 expression (C) in the study group. Liver fibrosis was stained by Masson trichrome at different time points of treatment and angiogenesis was evaluated with an anti-CD34 antibody. In normal livers, the number CD34 labeled vessels and TSP-1 positive cells is lower when compared to DEN treated livers. In the latter, their number increases according to the extent of fibrosis.

**Figure 2** Results of the quantitative assessment of angiogenesis and TSP-1 expression in normal and DEN treated rat livers. There is a gradual increase for VD and TSP-1 expressions parallel to the severity of fibrosis.

Friedman test showed that there was a significant correlation between VD and TSP-1 expression ( $P < 0.05$ ).

## DISCUSSION

Results of the recent studies emphasized that hepatic angiogenesis is associated with fibrogenesis in the wound healing response to chronic liver injury<sup>[1-5]</sup>. In our study, parallel to this finding, angiogenesis, assessed as VD, was increased with the progression of fibrosis ( $P < 0.05$ ). Besides, in group II, despite the absence of overt fibrosis, VD was higher than that of normal livers, suggesting that angiogenesis is an early event which might take place before the onset of fibrosis during chronic liver damage.

It is well known that angiogenesis does not involve a single pathway, but is a complex event regulated by many angiogenic and antiangiogenic factors, including TSP-1<sup>[9,10]</sup>. In neoplastic and premalignant conditions of the liver, the relationship between TSP-1 expression and angiogenesis has been studied<sup>[15-17]</sup>. However, in non-neoplastic liver diseases the association of TSP-1 expression with angiogenesis and its role in this complex event has not

been documented. Because TSP-1 is also a known activator of TGF- $\beta$ 1, a key mediator in tissue fibrogenesis, a few studies has been focused to evaluate the effect of TSP-1 in hepatic activation of TGF- $\beta$ 1<sup>[19-21]</sup>. It was concluded that TSP-1 may act in the pathogenesis of liver fibrogenesis as a strong promoter of TGF- $\beta$ 1. Although in the present study TGF- $\beta$ 1 expression was not evaluated, we observed an increase of TSP-1 expression parallel to the severity of fibrosis. TSP-1 expression of normal livers was restricted to the endothelium of portal vessels and to a few hepatocytes. However, this value was 3.61 fold higher in non-fibrotic group. The percentage of TSP-1 expressing cells continued to increase in fibrotic and cirrhotic livers ( $P < 0.05$ ). The present data support the contribution of TSP-1 expression in the wound healing response to chronic liver injury<sup>[19-21]</sup>. Moreover, in this study, a strong correlation between TSP-1 expression and angiogenesis was observed ( $P < 0.05$ ). This finding suggests that TSP-1 is not only involved in fibrogenesis by the hepatic activation of TGF- $\beta$ 1 but also might play another role in the remodeling of the liver architecture by contributing to the development of angiogenesis.

Our results showed TSP-1 might be a stimulator of angiogenesis during liver injury. TSP-1 is generally recognized as an antiangiogenic agent<sup>[11,12,15]</sup>. However results of the some studies have been demonstrated that TSP-1 might be a stimulator of angiogenesis<sup>[13,14,16]</sup>. For this reason the actual role played by TSP-1 in angiogenesis has been investigated in previous studies with several different conclusions. Some studies demonstrated that the effect of TSP-1 may depend on its concentration<sup>[13,22]</sup>, the type of domain being activated<sup>[23]</sup> and the type of receptors present on endothelial cells<sup>[24]</sup>. It has been also speculated that the actual role of TSP-1 might be related to number of its receptors<sup>[25]</sup>. Although it is not possible to conclude, based on our findings, which factor determines the angiogenic effect of TSP-1 during chronic liver injury, our data reinforce its dual role in the modulation of angiogenesis in opposite directions.

In conclusion, the results of this descriptive study reveal that in experimental liver fibrogenesis TSP-1 expression gradually increases according to the severity of fibrosis and strongly correlates with angiogenesis. Our data suggest that TSP-1 might contribute to the wound healing response to liver injury not only as a strong promoter of TGF- $\beta$ 1, but also as an inducer of angiogenesis. In the light of this observation, it would be of interest to evaluate the mechanism triggered by TSP-1 in hepatic angiogenesis with further experimental models, in order to completely clarify if TSP-1 could be a potential target in the manipulation of angiogenesis in chronic inflammatory liver diseases ending with cirrhosis.

## COMMENTS

### Background

Angiogenesis progresses together with fibrogenesis in the wound healing

response to chronic liver injury. Thrombospondin-1 (TSP-1) is a matricellular protein which is involved in complex processes including wound healing and angiogenesis. TSP-1 might modulate angiogenesis in opposite directions. In malignant and premalignant conditions of the liver the relationship between TSP-1 expression and angiogenesis have been demonstrated. Regarding non-neoplastic liver diseases, although the association of TSP-1 with latent transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) has been demonstrated in a few studies, the relationship between TSP-1 and angiogenesis during liver fibrogenesis has not been documented.

### Research frontiers

At present it is not possible to ascertain the exact pathogenic role of angiogenesis in liver fibrogenesis. However, the fact that chronic liver diseases respond poorly to conventional therapies suggests that manipulation of angiogenesis could be a promising approach to treatment. For this reason, the cellular and molecular mechanisms that are involved in the development of angiogenesis during liver fibrogenesis have been a topic of intensive investigations in the recent years.

### Innovations and breakthroughs

This study demonstrated that in experimental liver fibrogenesis TSP-1 expression gradually increases according to the severity of fibrosis and strongly correlates with angiogenesis.

### Applications

Based on the results of this research, TSP-1 might contribute to the wound healing response to liver injury not only as a strong promoter of TGF- $\beta$ 1, but also as an inducer of angiogenesis and could be a potential target in the manipulation of angiogenesis in chronic inflammatory liver diseases ending with cirrhosis.

### Terminology

TSP-1 is a high molecular weight glycoprotein (450 kDa) which is composed of three identical subunits cross-linked by disulfide bonds. Each subunit is composed of several domains interacting with different surface receptors. TSP-1 is involved in various processes such as cell motility, inflammation and wound healing. It also modulates endothelial cell adhesion, motility and growth.

### Peer review

This is quite an interesting investigational paper. This study demonstrated that in experimental liver fibrogenesis, TSP-1 expression gradually increases according to the severity of fibrosis and strongly correlates with angiogenesis. Further study would focus on evaluating the mechanism of TSP-1 in hepatic angiogenesis.

Received: October 3, 2007 Revised: December 11, 2007

### Abstract

**AIM:** To document the sustained virological response (SVR) in rapid virological responders (RVR) of genotype-3 chronic hepatitis C with standard interferon (SdIF).

**METHODS:** Hepatitis C genotype-3 patients during the period July 2006 and June 2007 were included. Complete blood counts, prothrombin time, ALT, albumin, qualitative HCV RNA were done. SdIF and ribavirin were given for 4 wk and qualitative HCV RNA was repeated. Those testing negative were allocated to group-A while the rest were allocated to group-B. Treatment was continued a total of 16 and 24 wk for group A and B respectively. HCV RNA was repeated after 24 wk of treatment. End virological and sustained virological responses were compared by  $\chi^2$  test. ROC of pretreatment age, ALT and albumin were plotted for failure to achieve SVR.

**RESULTS:** Of 74 patients treated, RCV RNA after 16 wk of therapy became undetectable in 34 (45.9%) and was detectable in 40 (54.1%) and were allocated to groups A and B respectively. SVR was achieved in 58.8% and 27.8% in groups A and B respectively. SVR rates were significantly higher in patients who had RVR as compared to those who did not ( $P = 0.0$ ;  $\gamma = 2$ ). Both groups combined ETR and SVR were 70% and 33% respectively. ROC plots of pretreatment age, ALT and albumin for SVR showed only ALT to have a significantly large area under the curve.

**CONCLUSION:** SVR rates were higher in patients who had RVR with SdIF and high pre treatment ALT values correlated to probability of having RVR.

Sustained virological response based on rapid virological response in genotype-3 chronic hepatitis C treated with standard interferon in the Pakistani population. *World J Gastroenterol* 2008; 14(14): 2218-2221 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2218.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2218>

### INTRODUCTION

Hepatitis C virus (HCV) is a big health care problem all over the world with 130 million patients infected with this virus world over<sup>[1,2]</sup>. The problem in developing countries is compounded by the poor economical status of the patients who are unable to afford the expensive therapy. The most prevalent genotype in Pakistan is type-3 (68%-87%) which has a favorable response to standard interferon<sup>[3-6]</sup>. Recently some studies have suggested 16 wk therapy with pegylated interferon (PgIF) in patients who achieve rapid virological response (RVR) at 4 wk. The SVR rates in patients with RVR with pegylated interferon have been reported at 78% and that with standard interferon (SdIF) at 53%<sup>[7]</sup>. The treatment protocols that consider viral load and RVR are proven to be more cost effective than standard protocols<sup>[8]</sup>. For genotype-2 most of the studies are in favour of a 16 wk therapy in patients who achieve RVR but there is no such recommendation for genotype-3 and more data is required to make any such recommendation<sup>[9]</sup>.

In a poor country like Pakistan affordability of even 16 wk of PgIF treatment is financially difficult. There is

no report of 16 wk standard interferon therapy results regarding sustained virological response (SVR) from Pakistan. The current study was conducted to see the end treatment response (ETR) and SVR in patients who achieved the RVR with SdIF.

## MATERIALS AND METHODS

### Subjects

This interventional study was conducted at Civil Hospital and Anklesaria Nursing Home Karachi during the period July 2006 and June 2007. Naïve patients of chronic HCV of Genotype-3 were included. Patients with decompensated disease, depression, allergy to interferon were excluded. Complete blood counts (CBC), prothrombin time (PT), ALT, albumin, qualitative HCV RNA and genotype were done before start of therapy. Therapy was started with SdIF  $\alpha$  2a 3.0 MU thrice weekly (TIW) and ribavirin 800-1200 mg PO according to weight. Qualitative HCV RNA was repeated after 4 wk into therapy. Patients who tested negative at this stage were allocated to Group-A while those in which it was still detectable were allocated to Group-B. Patients in Group-A were continued with the same therapy for 12 more wk for a total of 16 wk and then the therapy was stopped. These patients were retested for HCV RNA after 24 wk of stoppage of therapy for SVR. Patients in Group-B were continued with the same therapy for a total of 24 wk and were retested for HCV RNA for ETR. Patients in which HCV RNA was still detected after 24 wk of therapy were labeled as non-responders. Those who tested negative were followed for a further 24 wk without any treatment and retested for HCV RNA for SVR (Figure 1).

### Methods

CBC was done by a Sysmex Autoanalyzer while biochemical tests were done by Hitachi Autoanalyzer using Merck biomedical reagents. HCV RNA was done by Roche reverse transcriptase method. Sample size was determined for hypothesis testing for two population proportions<sup>[10]</sup>. Keeping the level of significance at 5%, power of study at 90% and reported SVR rates of 78% and 53% the sample size was calculated to be of 74 patients<sup>[7]</sup>. Scale variables of age, ALT, hemoglobin, albumin were compared between the two groups by Students *t*-test. The nominal variables of gender, ETR & SVR were compared by  $\chi^2$  test. Receiver operator curve (ROC) was plotted for age, ALT and albumin at the start of treatment. Failure to achieve RVR was taken as a variable state.

### Statistical analysis

The significant level was set at  $\leq 0.05$ . SPSS version 15.0 was used<sup>[11]</sup>.

## RESULTS

Seventy four eligible patients of genotype-3 HCV satisfying the selection criteria were included. These included 50 (67.6%) males and 24 (32.4%) females. Mean age of males was  $35.9 \pm 8.0$  years and that of females was  $39.1 \pm 8.1$  years. No statistically significant difference was found

Table 1 Demographic details of studied population

	Group A (n = 34)	Group B (n = 40)	$\gamma$	P	95% CI
Age (yr)	35.7 $\pm$ 8.2	38.0 $\pm$ 8.0	72	0.110	-7.198 to 0.751
M:F	22:12	28:12	1	0.804	-
ALT (U/L)	117.5 $\pm$ 38.4	160.4 $\pm$ 38.6	72	0.000	-60.770 to -24.971
Albumin (g/L)	38 $\pm$ 7	38 $\pm$ 4	72	0.789	-0.312 to 0.238

between the ages of the two genders ( $P = 0.11$ ;  $\gamma = 72$ ; 95% CI = -7.7 to 0.8) (Table 1). Patients were started with SdIF 3.0 MU TIW SQ with ribavirin according to body mass. RVR was achieved in 34 (45.9%) of the patients. These patients were allocated to Group-A while the rest of 40 (54.1%) patients who didn't achieve RVR were allocated to Group-B. Patients in Group-A were continued with the same treatment for a further 12 wk making a total of 16 wk of therapy. They were followed off treatment for a period of 24 wk and HCV RNA was repeated for SVR. Among these 20 (58.8%) patients achieved the SVR while 14 (41.2%) had a relapse within 24 wk of the follow-up period. In Group-B after 24 wk of therapy the ETR was achieved in 18 patients while 22 patients did not respond and were excluded from further analysis. After the off treatment follow-up of 24 wk in patients who achieved the ETR in group-B, the SVR was present in 5 (27.8%) and relapse was detected in 13 (72.2%) patients. Comparing the SVR rates between the two groups, SVR rates were statistically higher in Group-A ( $P = 0.044$ ;  $\gamma = 1$ ). SVR rates were significantly higher in patients who had RVR as compared to those who didn't; 20/34 (58.8%) *vs* 5/40 (12.5%) ( $P = 0.0$ ;  $\gamma = 2$ ). The combined outcome results show that RVR was achieved in 34 (45.9%), ETR in 52 (70.3%) & SVR in 25 (33.8%). The total relapse rate was 27 (36.5%) while the total non-responder rate was 22 (29.7%).

ROC plots for age, ALT, and albumin at the time of induction were plotted for failure to achieve RVR at the end of 4 wk (Figure 2). The area under the curve for ALT was significantly high at 0.8 with  $P = 0.000$ . This shows that among the three variables ALT had strong predictive value for RVR failure. At the cutoff of 73.5 IU/dL the sensitivity and specificity of ALT for RVR failure was 1.0 and 0.94 respectively. Thus values of ALT  $\leq 73.5$  U/L at the start of treatment were less likely to have RVR.

## DISCUSSION

Although much research has gone into the treatment of chronic HCV, the optimal treatment is not yet established<sup>[12]</sup>. Many treatment options are in vogue with different success rates<sup>[13-15]</sup>. PgiF based protocols have better responses as compared to the SdIF but cost becomes the major hurdle in developing countries. In Pakistan the most common genotype is 3 which is highly responsive to SdIF<sup>[15,16]</sup>. RVR is now a new landmark in the treatment and retreatment of HCV and it not only determines the duration but also predicts the outcome of the therapy<sup>[17-19]</sup>. For genotype-2 most of the studies are in favour of a 16 wk therapy in patients who achieve RVR but there is no such recommendation for genotype-3<sup>[9]</sup>.

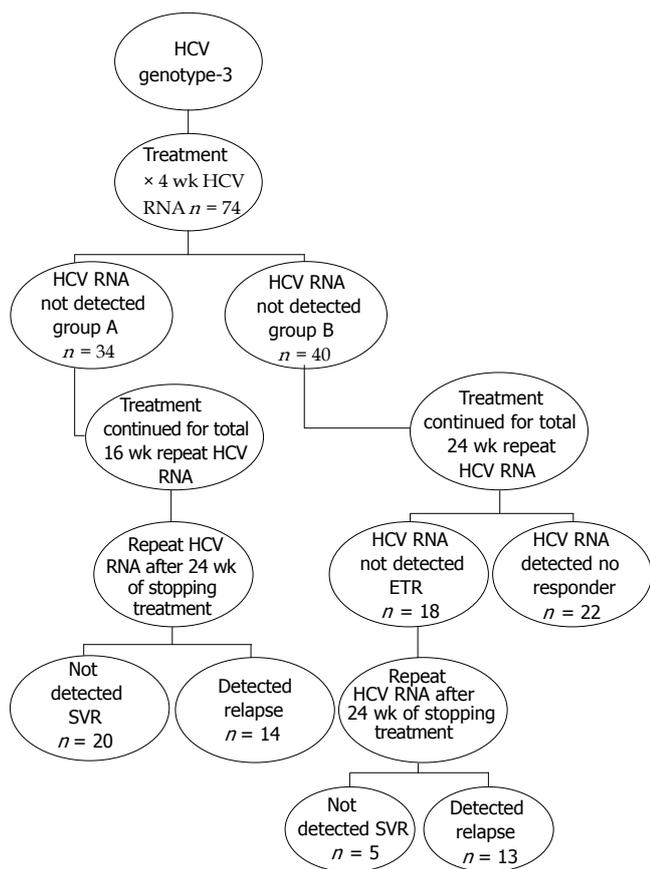

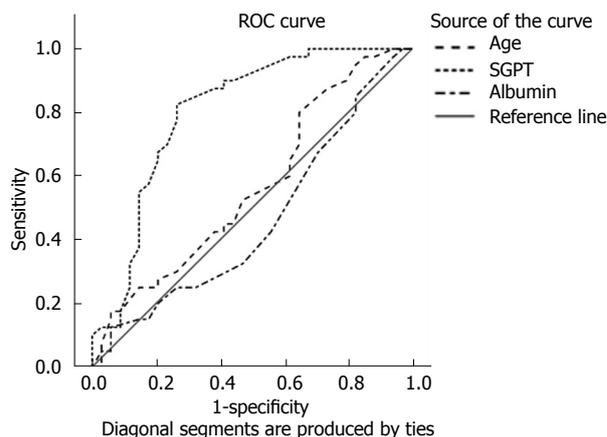

Figure 1 Treatment algorithm flowchart.

Most of the studies with RVR were done in western countries which have a high prevalence of genotype-1. We report our results with SdIF in genotype-3 HCV; with about 46% achieving RVR and about 59% among them achieving SVR. A recent study by Yu *et al*<sup>[20]</sup> with PgIF reported RVR and SVR at 86% and 94% respectively. Another recent study by Yu *et al* reported RVR with PgIF in genotype-3 at 60%<sup>[17]</sup>. Cost effectiveness of the RVR based therapy with PgIF is established by recent reports not only in HCV infection alone but also in combined HCV/HIV infections<sup>[7,8]</sup>. In Pakistan the majority of genotype-3 patients are treated with SdIF due to economic reasons and Pakistan Society of Gastroenterology and GI Endoscopy also favours the use of SdIF in genotype-3<sup>[21]</sup>. Government is also providing only SdIF *via* a special Prime Minister's initiative for a viral hepatitis program, thus PgIF is out of reach for the majority of the patients.

The results of our study with SdIF are not comparable to that with PgIF in genotype-3 HCV on both RVR and SVR. In our study the SVR rates in patients who achieved RVR were about 59% and over all both groups combined SVR was 33% only which are quite low as compared to the recent reports of 86% and 90%<sup>[20]</sup>. Our study did show that SVR rates were higher in patients who attained RVR showing that RVR is an important landmark in management of HCV with SdIF too.

No data is available for prediction of RVR in patients undergoing treatment for HCV, although some data is available for SVR. One such study has been reported

Test result variable (s)	Area	Std. Error (a)	Asymptotic Sig. (b)	Asymptotic 95% CI	
				Upper bound	Lower bound
Age	0.566	0.068	0.332	0.433	0.698
ALT	0.802	0.054	0.000	0.696	0.909
Albumin	0.460	0.068	0.554	0.326	0.594

Figure 2 ROC Curve for age, ALT and Albumin for relapse.

that at the age of 20 years; no cirrhosis/bridging fibrosis; ALT quotient = 7; body mass index 20 kg/m<sup>2</sup>; viral load 40 × 10<sup>6</sup> IU/L was associated with a 97% probability of SVR<sup>[22]</sup>.

In this study we tested the pretreatment levels of ALT, albumin and age as a prediction for RVR by plotting the ROC plots. Only ALT was found a significant marker as patients with high ALT were more likely to achieve RVR.

In conclusion, SVR rates were higher in patients who had RVR with SdIF and high pre treatment ALT values correlated to probability of having RVR.

## COMMENTS

### Background

Treatment of Hepatitis C virus (HCV) has varied response according to the genotype of the infecting virus. Ability to achieve Sustained Virological Response (SVR), which is the HCV polymerase chain reaction (PCR) negativity maintained six months after stopping treatment, is the real objective of the treatment. It is difficult to predict who will achieve Rapid virological response (SVR).

### Research frontiers

Introduction of SVR is the clearance of HCV RNA within one month of treatment. It is being projected as a marker for SVR in patients treated with pegylated interferon. RVR has not been studied for SVR with standard interferon.

### Innovations and breakthroughs

The study documents that in HCV genotype-3 patients treated with standard interferon SVR is related to the RVR. It was also shown that patients with initial high ALT are more likely to have RVR.

### Applications

This will allow for better prediction of treatment results.

### Terminology

SVR: Sustained virological response is defined as HCV RNA negativity six months after stopping the treatment. RVR: Rapid virological response is HCV RNA negativity after one month of treatment.

**Peer review**

Authors have shown that a short course of short acting interferon (16 wk) is efficacious in the patients who experience EVR. Perhaps, this approach would be cost-effective and useful in Pakistan.

### Abstract

**AIM:** To assess the cost savings of reloading the multiband ligator in endoscopic esophageal variceal ligation (EVL) used on the same patient for subsequent sessions.

**METHODS:** This single centre retrospective descriptive study analysed patients undergoing variceal ligation at a tertiary care centre between 1st January, 2003 and 30th June, 2006. The multiband ligator was reloaded with six hemorrhoidal bands using hemorrhoidal ligator for the second and subsequent sessions. Analysis of cost saving was done for the number of follow-up sessions for the variceal eradication.

**RESULTS:** A total of 261 patients underwent at least one session of endoscopic esophageal variceal ligation between January 2003 and June 2006. Out of 261, 108 patients (males 67) agreed to follow the eradication program and underwent repeated sessions. A total of 304 sessions was performed with 2.81 sessions per patient on average. Thirty-two patients could not complete the programme. In 76 patients (70%), variceal obliteration was achieved. The ratio of the costs for the session with reloaded ligator *versus* a session with a new ligator was 1:2.37. Among the patients who completed esophageal varices eradication, cost saving with reloaded ligator was 58%.

**CONCLUSION:** EVL using reloaded multiband ligators for the follow-up sessions on patients undergoing variceal eradication is a cost saving procedure. Reloading the

Cost saving by reloading the multiband ligator in endoscopic esophageal variceal ligation: A proposal for developing countries. *World J Gastroenterol* 2008; 14(14): 2222-2225 Available from: URL: <http://www.wjg-net.com/1007-9327/14/2222.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2222>

### INTRODUCTION

Variceal hemorrhage is a major cause of death among patients with cirrhosis, carrying historically, a mortality rate of up to 50% before the advances in medicine<sup>[1,2]</sup>. Even with the advent of intensive care, vasoactive medications, and endoscopic therapies, the risk of death with variceal hemorrhage is still about 20% per episode<sup>[3,4]</sup>.

Band ligation of esophageal varices is indicated as a primary prophylaxis for large varices and as a secondary prophylaxis for patients who have bled from varices<sup>[5]</sup>. It is the endoscopic procedure of choice to prevent recurrent variceal hemorrhage and eradicate varices which usually requires 3-4 sessions<sup>[6,7]</sup>. Endoscopic variceal ligation (EVL) is an expensive procedure, especially for patients from lower socioeconomic class in developing countries where health insurance and reimbursement systems are not as developed as in other countries. Most of the expenses are due to the high costs of the single polyband ligator use. Thus, reloading this ligator and re-using it for subsequent sessions on the same patient would substantially reduce costs, while also improving compliance to the eradication program as most of the patients are not covered by a health care scheme.

The aim of this study is to review the patients in the eradication program for esophageal varices and estimate the cost saving by using the reloaded band ligator to achieve this purpose.

## MATERIALS AND METHODS

A retrospective analysis on 261 patients who had undergone EVL as primary or secondary prophylaxis between 1st January 2003 and 30th June 2006 was performed.

Saeed's Six Shooter Multi-Band Ligator (Cook Medical Inc, Bloomington, IN ) was used for variceal ligation<sup>[8]</sup>. After each session all the accessories of the ligator were disinfected in glutaraldehyde solution (Cidex, Johnson & Johnson) by standard protocols. The band ligator was then reloaded with six hemorrhoidal bands for the 2nd and subsequent sessions on the same patient. We used hemorrhoidal band ligator for reloading barrel of the variceal ligator<sup>[9]</sup>. The procedure was approved by the Infection Control Committee of the hospital.

The procedures were performed by physicians experienced in the techniques of endoscopic ligation and sclerotherapy. Informed consent was obtained from the patients. Endoscopy was carried out under topical or pharyngeal anesthesia and sedation with intravenous midazolam if needed. Ligation was performed beginning at the most distal discernible extent of a variceal column and proceeding proximally. Subsequent endoscopic therapy sessions with EVL or combination therapy were performed at 14 to 21 d intervals until the varices were eradicated or reduced to grade one. Recurrent bleeding mandated unscheduled intervention.

### Method for reloading

The plaited string or trigger cord of the multiple band ligator becomes separated into two threads near the barrel. Each thread has six beads at regular intervals starting from the tip of the thread. These threads are passed through the barrel of the multiple band ligator from its scope-end side and delivered from the transparent rim side. The banding apparatus is now loaded. The metal cone of the hemorrhoidal ligator is loaded with a band, and then fitted in to the cylinder of the hemorrhoidal ligator and the rubber band rolled from the cone to the cylinder. The cone is removed after charging the cylinder. The first tip (bead) of each thread is brought at the base of the transparent cap and held in position. The transparent rim of the barrel is slid into the cylinder and the handle of the hemorrhoidal ligator is closed to push off the band from the cylinder onto the barrel of the variceal ligator. The band is positioned to the base of the barrel's transparent portion above the first pair of beads. The next pair of beads is now brought above the first band, wrapping the portion of thread between the first and second bead on the barrel by repositioning second beads to 180 degrees. When the two beads are in position above the first band, the second band is applied. In this way all the bands are mounted on the barrel which is now ready for reuse.

## RESULTS

A total of 261 patients underwent at least one session

**Table 1** Cost savings after the first session in 76 patients who completed the eradication of varices. Cost is in US Dollars (1 US Dollar = 61 Pakistani Rupees)

	Reloaded band after first session	New six shooter used each time
Cost of EGD	91.8	91.8
Cost of bands/ligator	6.56	140.82
Cost of single follow up session	98.36	232.62
Cost of bands in 139 follow up session	911.47	19573.93
Total cost of 139 follow-up sessions	13672.13	32334.59
Average cost savings per patient	245.56	
Cost comparison	1	2.37
Overall cost saving	58%	
Cost saving in band ligators	95%	

Cost of EGD includes both the costs of the technical (i.e. equipment and facility costs) and professional fees.

of EVL between January 2003 and June 2006. Patients undergoing sclerotherapy were not included in the study.

Out of 261, 108 patients agreed to follow the eradication program with reloaded band ligator and underwent a total of 304 sessions. Sixty-seven (62%) patients were males. They underwent 2.81 sessions on average. Twenty patients came only for one follow up session, while 12 patients underwent more than one follow-up session but did not complete esophageal varices eradication. Thus, a total of 76 (70%) patients participating in the program achieved eradication. These 76 patients completed esophageal varices eradication in 215 sessions (average 2.83). The reloaded ligator was used in a total of 139 follow-up sessions. The ratio of costs for the session with the reloaded ligator *versus* a first session with a new ligator was 1:2.37. Among the patients who completed the program and achieved eradication of esophageal varices, cost saving with reloading was 58% (Table 1).

The etiologies of esophageal varices among the patients in the eradication program included hepatitis C in 49 (64.5%), hepatitis B in 3 patients (3.9%), hepatitis B & D in 6 (7.9%), non-B non-C in 16 (21.1%), and alcoholic liver disease in 2 patients (2.6%).

## DISCUSSION

Cirrhosis and complications of portal hypertension rank among the top 10 leading causes of death worldwide<sup>[10]</sup>. The prevalence of esophageal varices in patients with cirrhosis ranges from 12% to 90% and the average risk of bleeding from 14% to 78%, depending on the patient population studied<sup>[11]</sup>. Esophageal varices are the most common cause of significant gastrointestinal bleeding secondary to portal hypertension<sup>[12]</sup>. The acute mortality of variceal hemorrhage has been reported to be 15%-50% and the overall mortality within 1-4 years as high as 70%-80% in those with cirrhosis. Furthermore, once varices have bled, the risk of rebleeding is reported to be as high as 70%-80%.

Treatment of patients with esophageal varices includes the prevention of the initial bleeding episode (primary prophylaxis), the control of active hemorrhage, and the prevention of recurrent bleeding after a first episode

(secondary prophylaxis), for which several modalities have been used including endoscopic sclerotherapy and band ligation.

EVL is superior to sclerotherapy, and is considered to be the endoscopic treatment of choice for bleeding varices<sup>[8]</sup>. Placing a rubber band around the variceal vein induces venous obstruction followed by mucosal inflammation, necrosis, and obliteration of the variceal vein. The single-shot mechanism of the ligation device is inherently inefficient, and makes the procedure tedious. It also requires overtube placement, associated with discomfort and complications<sup>[13-15]</sup>. Multiple-band ligation devices make band ligation easier and more efficient, allowing the consecutive application of 5 to 10 bands without removing the endoscope.

Reuse of equipment will always be cheaper than using new equipment. The issue becomes important when patients have to pay for all medical costs themselves and are not covered by a health care plan. The main issue is safety of reusable equipment. There were no band ligator failures or other complications noted in our patients with reloaded equipment. Very occasionally an extra band slipped off while deploying. There were no infection issues in these patients. Reuse of 'disposable' medical equipments may be a source of infection for HBV, HCV, and HIV in less developed countries. We disinfected the disposable items of the ligator with glutaraldehyde according to the standard recommendations and closed in a sealed bag with a label of patient's identification details and stored in an allocated dry place in the endoscopy suite. On arrival of the patient, the bag was opened and the ligator was reloaded with aseptic precautions to be used on the same patient. It is not too difficult to reload the band ligator. The process takes about five minutes

Variceal eradication was achieved in 70% of the patients enrolled in our eradication program. A wide range of success rates in eradication of esophageal varices has been reported in several studies. In the study by Stiegmann *et al*<sup>[6]</sup>, variceal obliteration occurred in 27 patients of 64 (42%) while in the study by Lo *et al*<sup>[7]</sup> varices were eradicated in 74%. Cost savings of the whole procedure using reloaded band ligator were 58%. Cost saving of the ligators, if reloaded equipment was used, was 95%. The band ligator was virtually free as only the costs of the rubber bands was charged. Rest of the expenses was related to the endoscopy and recovery.

In conclusion, EVL using reloaded polyband ligators for the follow-up sessions on patients undergoing variceal eradication is a cost effective procedure and may be recommended for developing countries.

## COMMENTS

### Background

Band ligation of esophageal varices is indicated as a primary prophylaxis for large varices and as a secondary prophylaxis for patients who have bled from varices. It is the endoscopic procedure of choice to prevent recurrent variceal hemorrhage and to eradicate varices. It usually requires 3-4 sessions using multiband ligator and applying up to six bands each time. Endoscopic variceal ligation (EVL) is an expensive procedure, especially for patients from lower socioeconomic class in developing countries.

### Research frontiers

Instead of using new multiband ligator for each session, reloading the ligator and using it for subsequent sessions on the same patient would substantially reduce the costs.

### Related publications

Not much published work related to this aspect is available. We described the method of reloading of the variceal multiple band ligator using hemorrhoidal banding apparatus (letter). *J Pak Med Asso (JPMA)* 2000; 50: 285-286.

### Innovations and breakthroughs

Cost saving of the whole procedure using reloaded band ligator was 58% of the cost had new ligator been used. The band ligator is virtually free as only the cost of the rubber bands is charged. Rest of the expenses is related to the endoscopy and recovery.

### Applications

EVL using reloaded polyband ligators for the follow-up sessions on patients undergoing variceal eradication is a cost effective procedure and may be recommended for developing countries.

### Terminology

Multiband ligator is a device used to ligate esophageal varices, allowing the consecutive application of six rubber bands without removing the endoscope.

### Peer review

This article reports Pakistanis experience about EVL using reloaded multiband ligator. I have a great experience about this procedure in my department. It is indicated for the third world countries. This is a nice, simple, and short paper with a clear point.

Shafik A, Shafik AA, Sibai OE, Shafik IA. Effect of thermal cutaneous stimulation on the gastric motor activity: Study of the mechanism of action. *World J Gastroenterol* 2008; 14(14): 2226-2229 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2226.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2226>

### Abstract

**AIM:** To investigate the mechanism of action of thermal cutaneous stimulation on the gastric motor inhibition.

**METHODS:** The gastric tone of 33 healthy volunteers (20 men, mean age  $36.7 \pm 8.4$  years) was assessed by a barostat system consisting of a balloon-ended tube connected to a strain gauge and air-injection system. The tube was introduced into the stomach and the balloon was inflated with 300 mL of air. The skin temperature was elevated in increments of  $3^{\circ}\text{C}$  up to  $49^{\circ}\text{C}$  and the gastric tone was simultaneously assessed by recording the balloon volume variations expressed as the percentage change from the baseline volume. The test was repeated after separate anesthetization of the skin and stomach with lidocaine and after using normal saline instead of lidocaine.

**RESULTS:** Thermal cutaneous stimulation resulted in a significant decrease of gastric tone  $61.2\% \pm 10.3\%$  of the mean baseline volume. Mean latency was  $25.6 \pm 1.2$  ms. After 20 min of individual anesthetization of the skin and stomach, thermal cutaneous stimulation produced no significant change in gastric tone.

**CONCLUSION:** Decrease in the gastric tone in response to thermal cutaneous stimulation suggests a reflex relationship which was absent on individual anesthetization of the 2 possible arms of the reflex arc: the skin and the stomach. We call this relationship the "cutaneo-gastric inhibitory reflex". This reflex may have the potential to serve as an investigative tool in the diagnosis of gastric motor disorders, provided further studies are performed in this respect.

### INTRODUCTION

External stimuli have been shown to affect gastric motility. Centrally acting stressful stimuli produce gastrointestinal motility changes in rats<sup>[1-6]</sup>, dogs<sup>[7,8]</sup>, and humans<sup>[9-11]</sup>. These actions seem to be mediated through humoral pathways<sup>[12-14]</sup>. Thus  $\alpha$ - and  $\beta$ -adrenergic blockers are claimed to abolish the inhibition of gastric motility induced by cold pain in humans<sup>[15]</sup>. Other investigators suggest that other humoral factors, such as acoustic stress, may be involved in the mediation of the gastrointestinal motor disturbances<sup>[16-19]</sup>. Gastric ulcer and acute pancreatitis may also be related to stress<sup>[11,20]</sup>.

It has been shown that various types of stressors cause a release of the corticotrophin-releasing factor and that intra-cerebroventricular administration of this factor mimics the motor, metabolic, and hemodynamic responses to such stimuli in animals<sup>[21-24]</sup>. However, in anesthetized rodents, an increased gastric motility was observed during restraint stress<sup>[25,26]</sup>, whereas pinching of the skin was accompanied by gastric motor inhibition<sup>[20]</sup>.

Although skin pinching or stressful cutaneous stimuli have been demonstrated to be associated with gastric motor inhibition<sup>[27,28]</sup>, the mechanisms involved in this action have not been elucidated in the literature. Therefore, hypothesizing that skin stimulation induces its effect on the gastric motor activity through a reflex action, we conducted the current study.

### MATERIALS AND METHODS

#### Subjects

Thirty-three subjects [20 men and 13 women; mean age  $36.7 \pm 8.4$  (range 26-45) years] were enrolled in this

study after they had given an informed consent. The results of physical examination including neurological assessment were normal. Laboratory work up including blood count, renal and hepatic function tests, as well as electrocardiography were normal. The study was approved by the Faculty of Medicine Review Board and Ethics Committee of Cairo University.

### Methods

Thermal cutaneous stimulation (TCS) was performed by means of a thermal pad applied to the skin, and the gastric motor activity was recorded with a barostat. A 6F polyvinyl gastric tube, with multiple side holes 4 to 6 cm from its distal end, was used. A thin compliant polyethylene balloon (London Rubber Industries Ltd, London, UK) was fastened to the distal part of the tube that contained the side holes. The tube had a metallic clip applied to its distal end for fluoroscopic control. It was connected to a strain gauge and a computer-controlled air-injection system (G&J Electronics Inc, Toronto, Ontario). This barostat system keeps the pressure within the balloon constant. Thus, when the gastric tone increases, the air in the bag is withdrawn, and when the tone diminishes, the air rushes into the balloon; hence the pressure in the balloon is kept constant at all times. Using this technique, the gastric tone could be assessed by recording the balloon volume variations, expressed as the percentage change from the baseline volume.

The tube was introduced into the stomach through the nose. The tests were performed 20 min later so that the stomach would have adapted to the inserted catheter. The balloon was then inflated with 300 mL of air. Thermal stimulation of the skin was induced by a thermal pad applied to the skin of the upper arm and connected to a thermostat.

The skin temperature was recorded at rest. The pad temperature was then elevated in increments of 3°C above the resting skin temperature up to 49°C or the highest tolerable temperature. Throughout the period of successive skin temperature elevation, the gastric wall tone was simultaneously assessed by measuring the variations in the balloon volume, expressed as the percentage change from the baseline volume. We calculated the latency which is the period between the start of thermal skin stimulation and the beginning of the gastric tone response.

To define whether the effect of thermal cutaneous stimulation (TCS) on the stomach was a direct or a reflex action, the following test was performed.

### Cutaneous and gastric anesthetization

The aforementioned test was repeated after individual anesthetization of the skin and stomach. The skin area, over which the thermal pad was applied, was anesthetized by injection of 3 mL of 2% lidocaine mixed with 3 mL of normal saline; the injection was performed at multiple points in the skin under the pad. The gastric tone response to TCS, as aforementioned, was recorded after 20 min and 3 h later when the anesthetic effect had waned. The stomach was then anesthetized by endoscopic injection of 30 mL of 2% lidocaine in 70 mL of normal saline. The

**Table 1** Change in the gastric tone in response to the different degrees of thermal cutaneous stimulation (mean  $\pm$  SD)

Skin temperature (°C)	Basal tone (% of baseline volume)	
	Mean	Range
37 (basal)	0	0
40	48.2 $\pm$ 6.4	40-56
43	57.3 $\pm$ 5.1	52-63
46	69.7 $\pm$ 3.3	66-74
49	78.6 $\pm$ 4.1	76-83

injection was performed at multiple points in the stomach wall. The gastric tone response to TCS was then registered after 20 min and 3 h later. The aforementioned tests were repeated using normal saline instead of lidocaine.

## RESULTS

The study was completed without any adverse side effects during or after the tests. During TCS, all of the subjects showed a significant decrease in the gastric tone which varied from 40% to 83% (mean 61.2%  $\pm$  10.3%) of the baseline volume according to the degree of TCS (Figure 1, Table 1). There was a progressive decrease in the gastric tone with increasing TCS (Figure 1, Table 1). Gastric tone decline was greater in men than in women but the difference was not significant ( $P > 0.05$ ). Also, there was no significant difference in the gastric tone decrease between the younger and older subjects. The latency varied from 20.6-28.8 ms (mean 25.6  $\pm$  1.29). It decreased with increasing TCS. There was no significant difference in the latency when we compared men to women or younger to older subjects.

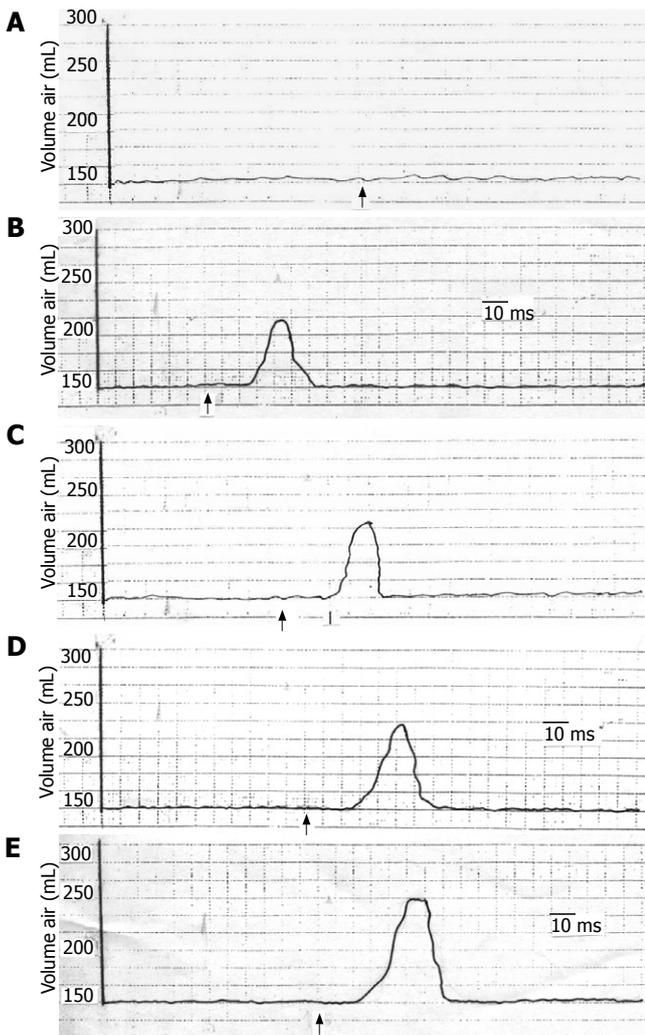

### Effect of TCS on the gastric tone after individual cutaneous and gastric anesthetization

TCS performed 20 min after individual anesthetization of the skin or stomach produced no significant changes in the gastric tone (Figure 2). Three hours later, when the anesthetic effect had waned, the TCS caused a decrease in gastric tone similar to that before anesthetization ( $P > 0.05$ ). When the above tests were repeated using saline instead of lidocaine, the gastric tone response was similar to that before saline application ( $P > 0.05$ ).

Upon repetition of the aforementioned tests in the same subject, similar results were obtained with no significant differences.

## DISCUSSION

It is established that centrally acting stressful stimuli induce changes in the gastrointestinal motility<sup>[1-11]</sup>. These changes are suggested to occur through humoral pathways as supported by the release of  $\beta$ -endorphin and catecholamines into the peripheral circulation during stress<sup>[12-15]</sup>. In agreement with such hypothesis, naloxone or a combination of  $\alpha$ - and  $\beta$ -adrenergic blockers abolish gastric motility inhibition induced by cold pain. Yet, this hypothesis can be ruled out because the aforementioned drugs have no effect on the migrating duodenal activity

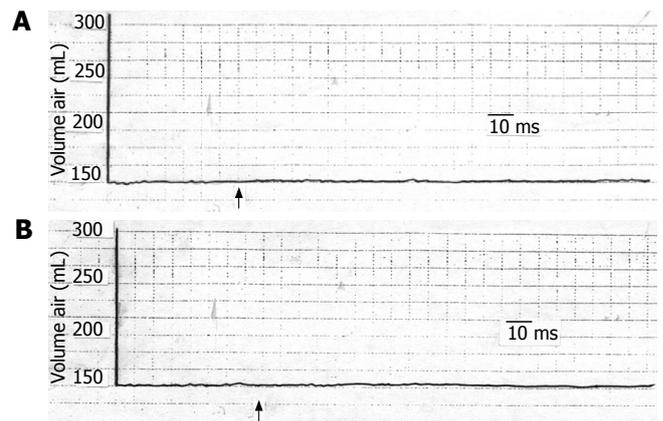

**Figure 1** Decrease in the gastric tone in response to thermal cutaneous stimulation (arrow). (A) 37°C (basal); (B) 40°C; (C) 43°C; (D) 46°C; and (E) 49°C.

induced by labyrinthine stimulation in humans<sup>[24-28]</sup> or on acoustic stress-induced inhibition of gastric motility in dogs<sup>[27]</sup>. This suggests that other factors may be involved in the mediation of gastrointestinal motor disturbances induced by centrally acting stimuli.

The current study demonstrated that TCS affected inhibition of gastric motor activity which progressively increased on incremental enhancement of TCS. This effect was abolished on anesthetization of either the stimulated cutaneous area or the stomach. The inhibited gastric motor activity presumably denotes gastric wall relaxation and gastric dilatation. It seems that the stomach dilates on stress to avoid gastric stimulation that might result in vomiting.

The current findings led to the assumption that the inhibited gastric motor activity in response to cutaneous stressful condition is mediated through a reflex pathway. This hypothesis is evidenced by the findings that, with individual anesthetization of the suggested 2 arms of the reflex arc, i.e. the skin and the stomach, the gastric response was absent. Saline on the other hand did not give rise to such effect. The response returned after the anesthetic condition had worn off. Furthermore, the reproducibility of the effect points to the constancy

**Figure 2** Response of the gastric tone to thermal cutaneous stimulation (arrow) at 46°C 20 min after separate anesthetization of the skin (A) and the stomach (B).

of the results. We call the suggested reflex response of the stomach to cutaneous stimulation, the “cutaneo-gastric inhibitory reflex (CGIR)”. It may be argued that this effect could be humoral as already mentioned by investigators<sup>[10-18]</sup>. However, if the effects of cutaneous stimulation on the stomach were humoral, it would not vanish with either gastric or cutaneous anesthetization as has been shown in the current findings. Meanwhile, the effect of centrally acting stressful stimuli on the stomach<sup>[1-6]</sup> cannot be ignored, albeit that this role alone does not seem to explain the non-response of the stomach to stimulation of the anesthetized skin.

It seems that TCS activates the cutaneous nerve endings which send impulses along the afferent fibers to the spinal cord. Impulses from the spinal cord are in turn transmitted along efferent fibers to the stomach, inhibiting its motor activity.

The point that needs to be discussed is: what could be the possible clinical significance of the CGIR? It is suggested that the CGIR might be of diagnostic significance in gastric motility disorders. Diminished gastric tone response to TCS would indicate a defect in the reflex pathway, such as gastric musculature or nerve damage resulting from a disease of the peripheral nerves, spinal nerve roots or spinal cord or from a central lesion. Significant prolongation of the latency of the CGIR on the other hand may indicate a disorder of the reflex arc. We believe that the CGIR may be incorporated as an investigative tool in the study of patients with gastric disorders after it has been further studied in various pathologic gastric lesions. The reflex assesses the integrity of the gastric motor activity.

In conclusion, TCS results in decrease of the gastric motor activity which apparently leads to gastric wall relaxation. The decrease in gastric tone upon TCS postulates a reflex relationship which was absent on individual anesthetization of the assumed two arms of the reflex arc: the skin and the stomach. We call this relationship the CGIR. This reflex may prove to be of diagnostic significance in gastric motor disorders and have the potential to serve as an investigative tool, provided further studies are performed to validate the current results.

## COMMENTS

### Background

External stimuli have been shown to affect gastric motility. Centrally acting stressful stimuli produce gastrointestinal motility changes in rats, dogs, and humans. These actions seem to be mediated through humoral pathways. Thus  $\alpha$ - and  $\beta$ -adrenergic blockers are claimed to abolish the inhibition of gastric motility induced by cold pain in humans. Other investigators suggest that other humoral factors such as acoustic stress may be involved in the mediation of the gastrointestinal motor disturbances. We hypothesized that skin stimulation induces its effect on the gastric motor activity through a reflex action. This hypothesis was investigated in the current study.

### Research frontiers

It is established that centrally acting stressful stimuli induce changes in the gastrointestinal motility. Other factors may be involved in the mediation of gastrointestinal motor disturbances induced by centrally acting stimuli.

### Innovations and breakthroughs

The point that needs to be discussed is: what could be the possible clinical significance of the cutaneo-gastric inhibitory reflex (CGIR)? It is suggested that the CGIR might be of diagnostic significance in gastric motile disorders. Diminished gastric tone response to thermal cutaneous stimulation (TCS) would indicate a defect in the reflex pathway, such as gastric musculature or nerve damage resulting from a disease of the peripheral nerves, spinal nerve roots or spinal cord or from a central lesion. We believe that the CGIR may be incorporated as an investigative tool in the study of patients with gastric disorders after it has been further studied in various pathologic gastric lesions. The reflex assesses the integrity of the gastric motor activity.

### Peer review

The authors had asked a simple question, namely whether gastric tone responds to cutaneous stimulation with heat. The answer is straight forward: Heat application leads to gastric relaxation and this effect can be abolished by intracutaneous and intragastric injections of lidocaine.

### Abstract

**AIM:** To investigate the relationship between 579 G>T polymorphisms in the DNMT3B gene, which is involved in de novo methylation and associated with the risk of esophagus cancer (EC) in Chinese.

**METHODS:** DNMT3B 579 G>T genotypes were determined by PCR-RFLP in 194 EC patients and 210 healthy controls matched for age and sex, who did not receive radiotherapy or chemotherapy for newly diagnosed and histopathologically confirmed EC.

**RESULTS:** In control subjects, the frequency of T/T and G/T genotypes, and T and G alleles was 80.5%, 19.0%, 90.0% and 10.0%, respectively. The distribution of genotypes and allelotypes in the EC patients was not significantly different from that in the controls. When stratified by sex and age, there was still no significant association between the risks of EC and GT and GG genotypes. This study also showed a distinct difference in the distribution of DNMT3B and single nucleotide polymorphism (SNP) between Chinese and Koreans.

**CONCLUSION:** DNMT3B 579 G>T polymorphism may not be a stratification marker to predict the susceptibility to EC, at least in Chinese. DNMT3B promoter SNP is diverse in ethnic populations.

### INTRODUCTION

Esophagus carcinoma (EC) is one of the most common malignancies and the main cause of cancer-related death in the world. Because symptoms typically remain absent until late in the course of disease, most cancers are detected at an advanced stage when prognosis is poor. Therefore, it is important to investigate the genetic and epigenetic variation in susceptibility to esophagus carcinogenesis and identify the markers that will facilitate identification of individuals at risk of esophagus carcinogenesis.

DNA methylation is a major epigenetic modification involving the addition of a methyl group to the 5' position of a cytosine in a CpG dinucleotide. A number of studies suggested that aberrant DNA cytosine methylation may play an important role in carcinogenesis<sup>[1-5]</sup>. DNMT3A and DNMT3B are required for the establishment and maintenance of genomic methylation patterns and proper murine development<sup>[6-9]</sup>. Both genes are up-regulated to different degrees in some malignancies, including colon cancer and EC<sup>[10-14]</sup>. Recently, several candidate single nucleotide polymorphisms (SNPs) in the DNMT3B gene have been deposited in public databases. Although the functional effects of these polymorphisms have not been elucidated, some studies showed that some of these variants may influence the DNMT3B activity on DNA methylation,

thereby modulating the susceptibility to lung cancer, breast cancer and gastric cardiac adenocarcinoma<sup>[15-17]</sup>. The DNMT3B gene contains a single G>T SNP in the transcription start site of the promoter region (-579 bp from exon 1B), and this probably affects gene function<sup>[18]</sup>. Some studies suggested that DNMT3B -579 G>T may modify susceptibility to tumors. Although conflicting results have been reported in different tumor types, the heterozygous genotypes have a significantly reduced risk of developing lung and colon cancer<sup>[19-21]</sup>. However, no report on the association between this allele and the development of EC is available. This study was to investigate the association between this polymorphism and EC in Chinese.

## MATERIALS AND METHODS

### Study population

This case-control study included 194 EC patients and 210 healthy controls. EC was histopathologically confirmed in the 194 patients during surgery at the Zhongda Hospital of Southeast University and Tumor Hospital, Nanjing, China. The control subjects were selected from cancer-free subjects who visited the same hospital for a regular physical examination and volunteered to participate in the epidemiology survey during the same period. We defined a healthy subject as a person free of disease (including no history of cancer) at health check-up. The controls were matched for age and sex with the patients (Table 1). All patients and controls were ethnically Chinese and resided in Jiangsu Province or in its surrounding regions.

### DNA extraction

Five milliliters of venous blood was drawn from each subject into vacuum tubes containing EDTA and stored at 4°C. Genomic DNA was extracted within one week after sampling by proteinase K digestion and salted out as previously described<sup>[19]</sup>.

### DNMT 3B genotyping

Transition from G to T of the DNMT3B SNP creates a *PvuII* restriction site, which can be exploited for genotyping by PCR and subsequent restriction fragment length polymorphism (RFLP) analysis. PCR was performed in a volume of 25 µL containing 100 ng of DNA template, 10 × PCR master mix (Promega, USA), and 10 pmol/L each of sense primer (5'-GAGGTCTCATATGCGCTAGG-3') and antisense primer (5'-GGGAGCTCACCTTCTAGAAA-3'). For PCR amplification, an initial denaturation at 94°C for 5 min was followed by 30 cycles at 94°C for 30 s, at 57°C for 30 s, at 72°C for 30 s, and a final extension at 72°C for 7 min. The PCR products were digested overnight with 5 units of *PvuII* (New England Biolabs, Beverly, Mass.) at 37°C and separated on 2% agarose gels. RFLP bands were visualized under UV light with ethidium bromide staining. The DNMT3B T/T genotype was expected to show two DNA bands at the positions of 132 bp and 93 bp, whereas the G/G genotype was expected to show a single band (225 bp), and the heterozygote was expected to have three bands (225 bp, 132 bp, 93 bp). For quality control, genotyping analysis was performed blindly with respect to case/control status and repeated twice for all subjects.

**Table 1** Distribution of selected variables in esophagus cancer patients and control subjects *n* (%)

Variables	Patients ( <i>n</i> = 194)	Control ( <i>n</i> = 210)	<i>P</i>
Age (yr)			> 0.05
< 40	1 (0.5)	2 (0.9)	
40-60	117 (60.3)	110 (52.4)	
61-80	76 (39.2)	98 (46.7)	
Sex			> 0.05
Male	150 (77.3)	146 (69.5)	
Female	44 (22.7)	64 (30.5)	

### DNA sequencing analysis

To confirm the genotyping results, selected PCR-amplified DNA samples were examined by DNA sequencing. The PCR fragments were recovered from agarose gel followed by purification with a DNA clean-up kit (Wizard SV Gel and PCR Clean-up System, Promega). DNA sequences of the PCR products were determined using the PCR sense primer with an Applied Biosystems model 377 sequencer (PE Applied Biosystems, Warrington, UK). The results of genotyping were 100% concordant.

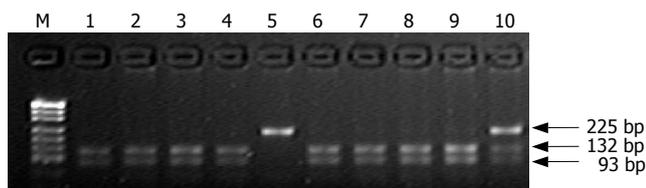

### Statistical analysis

Patients and controls were compared using Student's *t*-test for continuous variables and chi square ( $\chi^2$ ) test for categorical variables. Hardy-Weinberg equilibrium was tested with a goodness-of-fit  $\chi^2$  test with one degree of freedom to compare the observed genotype frequencies with the expected genotype frequencies among the subjects. Comparison of the DNMT3B genotype and allelotype distribution in the study groups was performed by means of two-sided contingency tables using  $\chi^2$  test or Fischer's exact test. The odds ratio (OR) and 95% confidence interval (CI) were calculated using an unconditional logistic regression model and adjusted for age and gender accordingly. *P* < 0.05 was considered statistically significant.

## RESULTS

The demographics of the cases and controls enrolled in this study are shown in Table 1. There were no significant differences in the mean age and sex distribution between cases and controls, suggesting that the matching based on these two variables was adequate. There was no evidence of a deviation from Hardy-Weinberg equilibrium among the cases or controls. The mean age of the patients and controls was 59.6 years ( $\pm$  10.2 years; range, 34-80 years) and 59.6 years ( $\pm$  10.2 years; range, 34-80 years), respectively.

All the patients and controls were successfully genotyped for the DNMT3B polymorphism (Figure 1). The genotyping by PCR-RFLP analysis was completely confirmed by DNA sequencing analysis, and the results of PCR-RFLP genotyping and sequencing analysis were also 100% concordant (Figure 2). The distribution of DNMT3B 579 G>T polymorphism was in Hardy-Weinberg equilibrium. The frequency of G allele in control subjects (0.10) was different from that in the previous

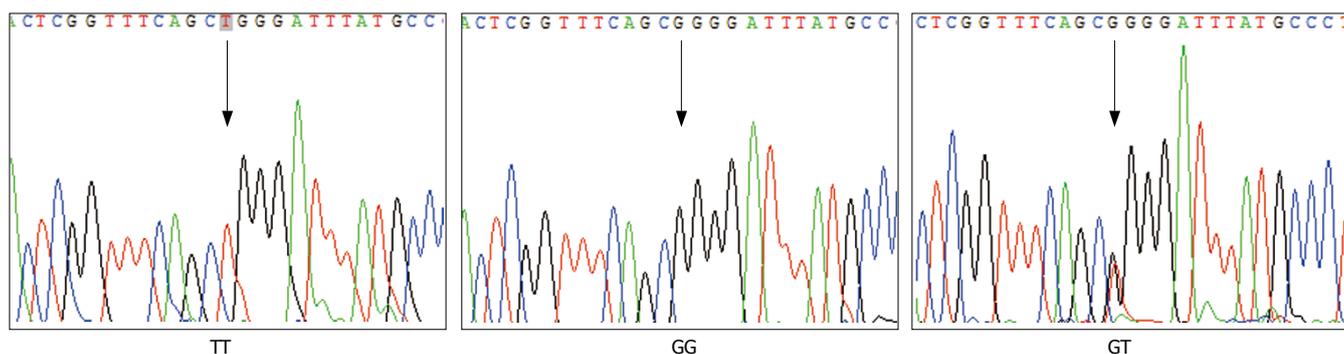

**Figure 1** PCR-based restriction fragment length polymorphism genotyping of DNMT3B 579 G>T. Lanes 1-4, 6-9: TT variants; lane 5: GG wild type; lane 10: GT heterozygote.

study among Koreans (0.20)<sup>[21]</sup>. The distributions of DNMT3B 579 G>T genotypes in Chinese and Koreans are shown in Table 2.

The distributions of DNMT3B 579 G>T genotypes in controls and patients are shown in Table 3. The genotype distributions of both polymorphisms in the controls were in Hardy-Weinberg equilibrium. No significant deviation was observed in the genotype distributions of both polymorphisms between overall esophagus cancer patients and controls. Then we stratified the results by sex and age, patients and controls were found to be slightly different with respect to the genotype distribution (Table 4). Combined GG and GT genotypes were found to have a little higher OR in male esophagus cancer patients and the group under the age of 59 years (males: OR 1.35 ; 95% CI, 0.76-2.39; under 59: OR 1.47 ; 95% CI, 0.74-2.90). However, combined GG and GT genotypes showed no significant association between DNMT3B 579 G>T polymorphism and the risk of esophagus cancer.

## DISCUSSION

Single nucleotide polymorphism (SNP) is the most common form of human genetic variation, and may contribute to an individual's susceptibility to cancer. Studies suggested that some variants in the promoter region of genes may affect either the expression or activity levels of enzymes<sup>[1,18,22]</sup> and therefore may be mechanistically associated with cancer risk. It has been recently shown that SNP of the DNMT3B promoter 579 G>T (from exon 1B transcription start site) decreases the susceptibility of an individual to lung and colon cancer<sup>[20,21]</sup>, suggesting that DNMT3B promoter 579 G>T

**Table 3** DNMT3B genotype and allele frequency in patients and control subjects and their association with esophagus cancer n (%)

	Case patients (n = 194)	Control subjects (n = 210)	OR (95% CI)

Female	35/49	9/15	0.84 (0.33-2.14)

polymorphism can be used as a risk factor for cancer to evaluate the population susceptible to tumors. However, it was also reported that there is no association between polymorphism of 579 G>T and head and neck squamous cell carcinoma<sup>[23]</sup>. However, to the best of our knowledge, the relative significance of SNP in the genetic susceptibility to esophagus cancer has not yet been disclosed. In the

current study, we investigated the influence of DNMT3B polymorphisms on the risk of esophagus cancer in a hospital-based case-control study.

This is the first study of DNMT3B polymorphism in esophagus cancer. We investigated the influence of 579 G>T polymorphism in the DNMT3B gene on the risk of esophagus cancer. Individuals carrying G allele in the DNMT3B gene were found to have a nearly consistent risk of EC compared with those carrying T allele. Then we stratified the results by sex and age, patients and controls. Combined GG and GT genotypes showed no significant association between DNMT3B 579 G>T polymorphism and risk of esophagus cancer, suggesting that 579 G>T polymorphism in the DNMT3B gene cannot be used as a marker of genetic susceptibility to esophagus cancer even in young individuals. Our study showed that DNMT3B polymorphism was not associated with the risk of esophagus carcinoma, at least in the study population, although other studies reported a decreased risk of lung and colon cancer in those harboring G allele. Since the different variants of DNMT3B may alter catalytic activity and are expressed in a tissue specific manner<sup>[24-27]</sup> and the repression of DNMT3B activity does not result in re-expression of all hypermethylated tumor suppressor genes in some cell systems<sup>[28-31]</sup>, it is therefore important to explore the complex interplay of DNMTs in different tumor types.

In this study, a distinct difference was found in the distribution of DNMT3B SNP between Chinese and Koreans. However, few G/G genotypes were found in both populations. Additionally, the frequency of G/T genotype in Chinese was lower than that in Koreans. The great diversity in DNMT3B SNP distribution in different ethnic populations remains unknown.

In conclusion, the DNMT3B gene may not be involved in the development of esophagus cancer. Further studies with a larger sample are required to confirm our findings, to understand the role of DNMT3B polymorphisms in determining the risk of esophagus cancer, and to clarify the association of DNMT3B polymorphism with esophagus cancer in different ethnic populations.

## COMMENTS

### Background

DNA methylation is a major epigenetic modification involving the addition of a methyl group to the 5' position of a cytosine in CpG dinucleotide. DNMT3A and DNMT3B are required for the establishment and maintenance of genomic methylation patterns. Single nucleotide polymorphisms (SNPs) in the DNMT3B gene may influence DNMT3B activity on DNA methylation, thereby modulating the susceptibility to some cancer.

### Research frontiers

Some variants in the promoter region of genes may affect either the expression or activity levels of enzymes and therefore may be mechanistically associated with cancer risk. It has been recently reported that SNP of the DNMT3B promoter 579 G>T (from exon 1B transcription start site) decreases the susceptibility of an individual to lung and colon cancer. However, it was also reported that there is no association between polymorphism of 579 G>T and head and neck squamous cell carcinoma. The relative significance of SNP in genetic susceptibility of an individual to cancer is diverse in different populations.

### Innovations and breakthroughs

It is important to investigate the genetic and epigenetic variation in susceptibility to

esophagus carcinogenesis and identify markers that will facilitate identification of individuals at risk of esophagus carcinogenesis. Although no significant association was found between DNMT3B 579 G>T polymorphism and risk of esophagus cancer, this is the first study of DNMT3B polymorphism in esophagus cancer. This study also showed the significance of great diversity in DNMT3B SNP distribution in different ethnic populations and their susceptibility to cancer.

### Applications

A distinct difference was found in the distribution of DNMT3B SNP between Chinese and Koreans in this study. The significance of great diversity in DNMT3B SNP distribution in different ethnic populations remains unknown. These results suggest that the DNMT3B gene may not be involved in the development of esophagus cancer. Future studies of other DNMT3B sequence variants and their biologic function are needed to understand the role of DNMT3B polymorphisms in determining the risk of esophagus cancer.

### Peer review

The association between DNMT3B 579 G>T polymorphism and the risk of esophagus cancer in Chinese was studied. The results show that the DNMT3B 579 G>T polymorphism was not associated with the risk of esophagus carcinoma, at least in the study population. This study also showed the significance of great diversity in DNMT3B SNP distribution in different ethnic populations and their susceptibility to cancer.

## Abstract

**AIM:** To explore and compare the radiochemical behavior and biological property of anti-sense oligonucleotide (ASON) labeled with technetium-99m using N-hydroxysuccinimidyl S-acetylmercaptoacetyltriglycine (NHS-MAG<sub>3</sub>) and hydrazinonictinamide derivative (HYNIC).

**METHODS:** After HYNIC and NHS-MAG<sub>3</sub> were synthesized, ASON was labeled with technetium-99m using HYNIC and NHS-MAG<sub>3</sub> as a bifunctional chelator. The *in vivo* and *in vitro* stability, binding rates of labeled compounds to serum albumen, biodistribution of  $^{99m}\text{Tc}$ -MAG<sub>3</sub>-ASON and  $^{99m}\text{Tc}$ -HYNIC-ASON in BALB/C mouse and its HT29 tumor cellular uptake were compared.

**RESULTS:** The labeling efficiency and stability of  $^{99m}\text{Tc}$ -MAG<sub>3</sub>-ASON were significantly higher than those of  $^{99m}\text{Tc}$ -HYNIC-ASON ( $P = 0.02$ , and  $P = 0.03$ , respectively).  $^{99m}\text{Tc}$ -MAG<sub>3</sub>-ASON had a significantly lower rate of binding to serum albumen than  $^{99m}\text{Tc}$ -HYNIC-ASON ( $P < 0.05$ ). In contrast to  $^{99m}\text{Tc}$ -HYNIC-ASON, the biodistribution of  $^{99m}\text{Tc}$ -MAG<sub>3</sub>-ASON was significantly lower in blood, heart, liver and stomach ( $P < 0.05$ ), slightly lower in intestines and spleen ( $P > 0.05$ ) and significantly higher in lung and kidney ( $P < 0.05$ ). The HT29 tumor cellular uptake rate of  $^{99m}\text{Tc}$ -MAG<sub>3</sub>-ASON was significantly higher than that of  $^{99m}\text{Tc}$ -HYNIC-ASON ( $P < 0.05$ ).

**CONCLUSION:**  $^{99m}\text{Tc}$ -MAG<sub>3</sub>-ASON shows superior

## INTRODUCTION

Different drugs can be used in anti-sense therapy, among which synthetic anti-sense oligonucleotide (ASON) is used to bind to deoxyribonucleic acid (DNA) translation or transcription in a sequence-specific manner and interfere with the expression of oncogene. However, it is still difficult for ASON to target tumor cells and transport across cell membrane. Besides, because of multi-gene expressions in tumor cells, inhibition of any single target gene is not sufficient to inhibit tumor growth. Radio-labeled ASON targeting specific oncogenes can overcome these problems by direct inhibition of anti-sense and radiation damage. The curative effect of radionuclide anti-sense therapy is closely related to the labeling efficacy of ASON and the characteristics of labeled compounds. In contrast to  $^{188}\text{Re}$ ,  $^{186}\text{Re}$ ,  $^{90}\text{Y}^{[1-3]}$ , hydrazinonictinamide derivative (HYNIC) and N-hydroxysuccinimidyl S-acetylmercaptoacetyltriglycine (NHS-MAG<sub>3</sub>), as a bifunctional chelator, have been known to help label

ASON<sup>[4-6]</sup> with <sup>99m</sup>Tc. However, few reports are available on the comparison of both chelators. This study was to compare the radiochemical behaviors and biological properties of ASON labeled with technetium-99m using NHS-MAG<sub>3</sub> and HYNIC.

## MATERIALS AND METHODS

### Materials

BALB/c nude mice at the age of 6-8 wk, weighing 17-22 g, were obtained from West China Experimental Animal Center. Human colon carcinoma HT29 cell line was obtained from the Laboratory of West China Hospital. HT29 cells were incubated in RPMI 1640 supplemented with 10% fetal calf serum, 100 U/mL penicillin, 100 µg/mL streptomycin. Fifteen-mer phosphorothioate ASON (5'-NH<sub>2</sub>-FACGTTGAGGGGCAT-3', F is adenosine sulfurised), which is complementary to the translation start site of c-myc mRNA, was purchased from GibcoBRL (USA). <sup>99m</sup>TcO<sub>4</sub><sup>-</sup> (37 TBq/L) was obtained from Chengdu Gaotong Isotope Corporation (Chengdu, China). Sephadex G25 was from Pharmacia Fine Chemicals A.B (Uppsala, Sweden). C<sub>18</sub> Sep-Pak reversed-phase column was a product from Waters Company (Milford, USA). CRC-15R dose calibrator was from Capintec Company (Ramsey, New Jersey, USA). FH463A automatic scaler was supplied by Beijing Nuclear Instrument Company (Beijing, China). Unity Inova-400 nuclear magnetic resonator was from Varian Company (USA). UV-2100 spectrophotometer was from Beckman Company (Cotati, California, USA). Frozen desiccator was from Marathon Electric Company (New York, USA). CO<sub>2</sub> incubator was from Sanyo Company (Japan). Centrifuge was from Beckman Company (Cotati, California, USA).

### Synthesis of HYNIC and NHS-MAG<sub>3</sub>

HYNIC was synthesized as previously described<sup>[7]</sup> (Figure 1). The end product was purified by recrystallization in isopropyl alcohol and the yield was 75%. The synthesis process of NHS-MAG<sub>3</sub> has been described elsewhere<sup>[6]</sup> (Figure 2). The melting temperature of the end product was 140°C-155°C, the yield was 80%. The content was 2.38 ppm (S, 3H, SCOCH<sub>3</sub>), 2.80 ppm (S, 4H, succinimidyl), 3.68-3.80 ppm (M, 8H, COCH<sub>2</sub>) and 8.20-8.38 ppm (M, 3H, NHCO), respectively, by nuclear magnetic resonance spectroscopy.

### <sup>99m</sup>Tc labeling ASON via HYNIC

ASON (2 mg/mL) buffer was dissolved in 2 mol/L NaCl, 0.5 mol/L NaHCO<sub>3</sub> and 2 mmol/L ethylenediamine tetraacetic acid (EDTA), and HYNIC (10 mg/mL) was dissolved in dimethylformamide (DMF). In 45°C water bath, 31 µL HYNIC and 2 mmol/L EDTA were gradually dropped into a 25 µL ASON solution at the molar ratio of 25:1. The reaction system was filtered through a Sep-Pak C18 reversed-phase column (10 mm × 5 mm) in 60% methanol to remove HYNIC not binding to ASON. HYNIC-ASON was collected with a UV-2100 spectrophotometer and frosted to dry powder for storage. HYNIC-ASON dry powder was labeled on d 15, 30 or 60, respectively. Ten µg HYNIC-

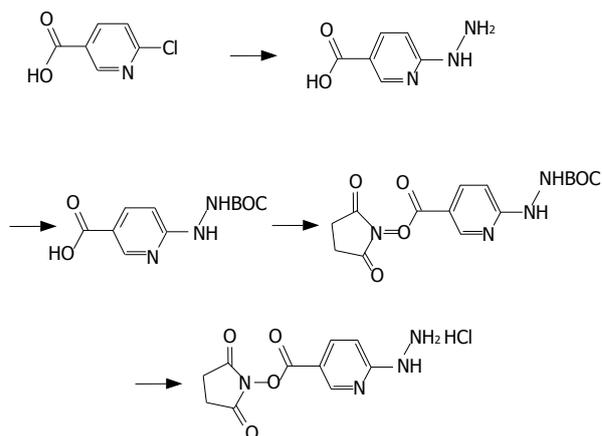

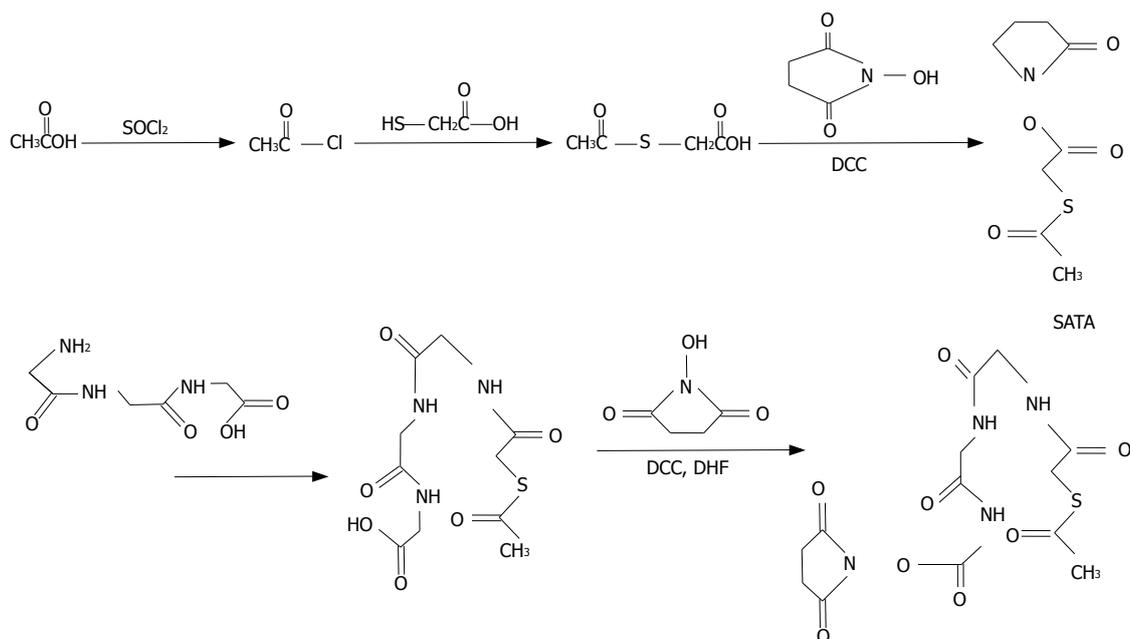

Figure 1 Synthesis of HYNIC.

ASON powder was dissolved in a 0.5 mL tricine solution (70 mg/mL). SnCl<sub>2</sub>·2H<sub>2</sub>O solution (1 mg/mL) was dissolved in 0.1 mol/L HCl at room temperature. HYNIC-ASON solution, 25 µL SnCl<sub>2</sub>·2H<sub>2</sub>O solution and 0.2 mL <sup>99m</sup>TcO<sub>4</sub><sup>-</sup> containing a radioactivity of 370, 740 or 1480 MBq were mixed uniformly. After stored for 30 min at room temperature, the mixture was eluted and purified through a Sep-Pak C18 reversed-phase column (10 mm × 5 mm) in 60% methanol, and <sup>99m</sup>Tc-HYNIC-ASON solution was collected. Chromatographic assay was performed in both solution systems before and after purification to detect the labeling efficacy and radiochemical purity of <sup>99m</sup>Tc-HYNIC-ASON, where Xihua I filter paper as a sustentaculum was developed with 85% methanol as a developer.

### <sup>99m</sup>Tc labeling ASON via NHS-MAG<sub>3</sub>

Twenty-five microliter ASON (2 mg/mL, dissolved in 0.25 mol/L NaHCO<sub>3</sub> and 1 mol/L EDTA, pH = 8.5) was mixed with 42 µL NHS-MAG<sub>3</sub> (10 mg/mL, dissolved in dimethylsulphoxide) at the molar ratio of 1:25. The mixture reacted at room temperature in the dark for 15 min. Any free NHS-MAG<sub>3</sub> was removed through Sep-Pak C18 reversed-phase column (10 mm × 5 mm) in 60% methanol. The bound MAG<sub>3</sub>-ASON was collected with a spectrophotometer and frosted to dry powder for storage. The target-bound complex, dry powder on d 15, 30 or 60 at room temperature, was labeled. Fifty µL MAG<sub>3</sub>-ASON (1 mg/mL) in re-distilled water was mixed with 10 µL NaHCO<sub>3</sub> (0.5 mol/L)-sodium tartrate (50 mg/mL) buffer (pH = 9.2). Ten µL SnCl<sub>2</sub>·2H<sub>2</sub>O fresh solution (1 mg/mL, dissolved in 0.1 mol/L HCl) was dropped into MAG<sub>3</sub>-ASON at room temperature and mixed uniformly. At last, 0.2 mL <sup>99m</sup>TcO<sub>4</sub><sup>-</sup> (containing a radioactivity of 370, 740 or 1480 MBq) was added into the above solutions, respectively. After 15 min, <sup>99m</sup>Tc-ASON-MAG<sub>3</sub> was purified on Sephadex G25 column (250 mm × 5 mm) in an ammonium acetate solution (0.25 mol/L, pH = 5.2) and collected. Chromatographic assay was performed in both specimens before and after purification to evaluate the labeling efficiency and radiochemical purity. A system was demanded to develop Xihua I filter paper in 85% methanol.

**Figure 2** Synthesis of NHS-MAG3. S-acetylthioglycolic acid N-hydroxysuccinimide ester (SATA) was initially synthesized from acetic acid. S-acetyl MAG<sub>3</sub> was obtained by the reaction of SATA and triglycine. NHS-MAG<sub>3</sub> was produced with the coupling of S-acetyl MAG<sub>3</sub> and N-hydroxybutyrylimine.

### Stability of labeled compounds

The stability of labeled compounds was assessed for 1, 2 and 4 h, respectively, at room temperature, by measuring the radiochemical purity on Xihua I filter paper that was developed in 85% methanol.

### Test for plasma protein binding in rabbits

Three hundred and seventy mL MBq <sup>99m</sup>Tc-HYNIC-ASON or <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON was mixed with 2 mL anti-coagulated rabbit fresh plasma for 6 cuvettes. After incubated at 37 °C for 2 h, the mixture was mixed with 5 mL trichloroacetic acid (250 g/L) and centrifuged for 5 min at 1200 × g. The precipitate was washed twice with 2 mL trichloroacetic acid (250 g/L) and the supernatant was collected. The radioactivity of precipitate and supernatant was measured, respectively. The binding rate of <sup>99m</sup>Tc-HYNIC-ASON or <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON to rabbit plasma protein was calculated by the following formula: Binding rate (%) = radioactivity of precipitate/radioactivity of precipitate and supernatant.

### Tissue distribution of labeled compounds in BALB/c mice

<sup>99m</sup>Tc-HYNIC-ASON or <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON (0.2 mL, 148 KBq) was separately injected into the tail veins of 20 BALB/c nude mice (age: 6-8 wk, body weight: 17-22 g) which were randomly divided into four groups (5 in each group). Mice in each group were sacrificed at 0.5, 1, 2 and 4 h, respectively, after injection of <sup>99m</sup>Tc-HYNIC-ASON or <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON. Blood, heart, lungs, liver, kidneys, spleen, stomach, intestine and muscles were removed and weighed. The tissue uptake rate of labeled compounds was calculated according to the following equation: tissue uptake rate (%ID/g) = radioactivity of per gram of wet tissue weight/radioactivity of wet tissue injected into the body. The results were expressed as percentage of radioactivity within per gram of wet tissue.

### Cellular uptake of labeled compounds

Human colon carcinoma HT29 cells were incubated with RPMI 1640 medium containing 10% fetal calf serum, 100 U/mL penicillin and 100 µg/mL streptomycin. Tumor cells were cultured in 80 wells of 96-well plates (1.5 × 10<sup>6</sup> cells/well). It took about 24 h for cells to adhere to wells. The culture medium was pipetted and 2 mL serum-free RPMI 1640 medium containing 74 KBq <sup>99m</sup>Tc-HYNIC-ASON or <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON was added to each of the 80 wells. The cells were incubated in a humidified incubator containing 50 mL/L CO<sub>2</sub> at 37°C for 10, 20, 40, 60 and 120 min, respectively. Each well was rinsed 3 times with RPMI 1640 medium. At last, all the human colon carcinoma HT29 cells and supernatant in each well were collected and the radioactivity was calculated. The following formula was used to calculate the percentage of radioactivity within the cells of each well: cellular uptake rate (%) = radioactivity absorbed in each well/radioactivity added to each well.

### Statistical analysis

The data were expressed as mean ± SD and input into a computer for statistical analysis with SPSS 11 software. Differences among the groups were compared with paired *t*-test. *P* < 0.05 was considered statistically significant.

## RESULTS

### Labeling efficiency and radiochemical purity of labeled compounds

Analysis of labeling efficiency and radiochemical purity of the labeled compounds showed that the flow rate of <sup>99m</sup>Tc-HYNIC-ASON and <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON, <sup>99m</sup>TcO<sub>4</sub><sup>-</sup>, and deoxidized technetium, was 0.9-1.0, 0.6-0.7, and 0-0.1, respectively. The labeling efficiency and radiochemical purity of labeled compounds are

M: <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON; H: <sup>99m</sup>Tc-HYNIC-ASON. Statistical analysis of the same tissue distribution of radioactivity was made after the injection of <sup>99m</sup>Tc-HYNIC-ASON and <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON.

listed in Table 1. The labeling efficiency of <sup>99m</sup>Tc via NHS-MAG<sub>3</sub> was higher than that of <sup>99m</sup>Tc via HYNIC (for interval between binding and labeling: t = 6.715, P = 0.021; for radioactivity of <sup>99m</sup>TcO<sub>4</sub><sup>-</sup>: t = 11.736, P = 0.007). The radioactivity of <sup>99m</sup>TcO<sub>4</sub><sup>-</sup> hardly influenced the labeling efficiency. The radiochemical purity of labeled compounds was higher than 95% and there was no statistical difference between the two methods (for interval between binding and labeling: t = -0.444, P = 0.701; for radioactivity of <sup>99m</sup>TcO<sub>4</sub><sup>-</sup>: t = 2.656, P = 0.117). Either interval between binding and labeling of HYNIC-ASON or that of MAG<sub>3</sub>-ASON had almost no effect on the labeling efficiency and radiochemical purity of labeled compounds.

**Radiochemical purity of labeled compounds**

To assess the radiochemical purity, the labeled compounds were incubated at room temperature or at 37°C after diluted with an equal volume of fresh human serum (Table 2). The radiochemical purity of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON was much higher than that of <sup>99m</sup>Tc-HYNIC-ASON (at room

temperature: t = 5.616, P = 0.030; at 37°C: t = 5.616, P = 0.032), while the radiochemical purity of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON was less affected by incubation time than that of <sup>99m</sup>Tc-HYNIC-ASON.

**Binding rate of rabbit plasma protein**

The binding rate of rabbit serum protein for <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON or <sup>99m</sup>Tc-HYNIC-ASON was 11.17% ± 1.31% and 71.06% ± 3.56%, respectively. The differences between them were statistically significant, and the former was lower than the latter (t = 27.346, P < 0.0001).

**Biodistribution of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON and <sup>99m</sup>Tc-HYNIC-ASON in BALB/c mice**

The biodistributions of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON and <sup>99m</sup>Tc-HYNIC-ASON in BALB/c mice are listed in Table 3. The distributions of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON were significantly lower in blood, heart, liver and stomach than those of <sup>99m</sup>Tc-HYNIC-ASON (P < 0.05). The distributions of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON were significantly higher in lungs and kidneys than those of <sup>99m</sup>Tc-HYNIC-ASON (P < 0.05).

Table 4 Human colon carcinoma HT29 cellular uptake of <sup>99m</sup>Tc-HYNIC-ASON and <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON (mean ± SD)

	10 min	20 min	40 min	60 min	120 min
<sup>99m</sup> Tc-HYNIC-ASON (%)	0.43 ± 0.08	0.56 ± 0.21	0.93 ± 0.54	1.42 ± 0.64	1.67 ± 0.86
<sup>99m</sup> Tc-MAG <sub>3</sub> -ASON (%)	2.78 ± 0.81	5.64 ± 0.51	7.82 ± 2.53	13.63 ± 2.71	15.25 ± 3.13

There was no statistical difference in the distributions of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON and <sup>99m</sup>Tc-HYNIC-ASON in spleen, intestines and muscle.

### Cellular uptake of labeled compounds

Cellular uptake of labeled compounds in human colon carcinoma HT29 cells is listed in Table 4. The cellular uptake of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON was significantly higher than that of <sup>99m</sup>Tc-HYNIC-ASON ( $t = 3.770$ ,  $P = 0.020$ ), which was 6.5, 10.1, 8.4, 9.5 and 9.1-folds higher than those of <sup>99m</sup>Tc-HYNIC-ASON at 10, 20, 40, 60 and 120 min after incubation.

## DISCUSSION

In our studies, because expensive acetylsulfoacetic acid was not available, S-acetylthioglycolic acid N-hydroxysuccinimide ester (SATA) was synthesized as previously described<sup>[5]</sup>. The synergistic coligand of tricine (N-tris-hydroxy-methyl-methylglycine) was applied to the synthesis of HYNIC, to achieve the high radioactivity of labeled compounds. During the synthesis of labeled compounds, isopropylol was used to crystallize the compounds instead of chromatographic column purification. Their synthesis was simple, efficient, economical, with a high yield (75%-80%) and little environmental pollution. Nuclear magnetic resonance of labeled compounds was performed as previously described<sup>[5-7]</sup>. Both Sep-Pak C18 reversed-phase column and Sephadex G25 column could be used to purify the radiolabeled ASON. Both labeling methods can achieve a high radiochemical purity of over 95%.

Stability can be obtained by methylation, amination or sulfonation of the phosphorus atoms in ASON, making it not recognized and degraded by nucleic acid enzyme<sup>[8]</sup>. In the present study, we modified the ASON by replacing the hydroxyl group in the phosphoric acid branch of ASON with a sulphur atom and attaching an amid to the 5' terminal of ASON. Labeled compounds were observed for four hours to detect the stability of ASON labeled with <sup>99m</sup>Tc *via* HYNIC or NHS-MAG<sub>3</sub>. Only 1-2 covalent bonds were formed between a molecule of HYNIC-ASON and a technetium atom. However, it was reported that 4-5 covalent bonds can form between MAG<sub>3</sub>-ASON and technetium<sup>[9,10]</sup>, which may be the reason for a greater stability of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON than that of <sup>99m</sup>Tc-HYNIC-ASON. During labeling, since the mercapto group of ASON-MAG<sub>3</sub> is protected by acetyl group, excessive SnCl<sub>2</sub> is needed to hydrolyze the protection group of ASON-MAG<sub>3</sub><sup>[11]</sup>, which may be the reason for a greater labeling efficiency of <sup>99m</sup>Tc *via* NHS-MAG<sub>3</sub> than *via* HYNIC.

The binding rate of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON to rabbit serum protein was significantly lower than that of <sup>99m</sup>Tc-HYNIC-ASON in our study, suggesting that the distributions of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON are significantly lower in blood, heart and liver of BALB/c mice. The distributions of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON were much lower in stomach than those of <sup>99m</sup>Tc-HYNIC-ASON, suggesting that <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON has a greater *in vivo* ability than <sup>99m</sup>Tc-HYNIC-ASON. The distributions of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON were much higher in kidneys than those of <sup>99m</sup>Tc-HYNIC-ASON, which may be related to the metabolism of MAG<sub>3</sub>-ASON in kidneys.

Cellular targeting uptake of ASON can be improved by receptor-mediated mechanisms<sup>[12-14]</sup>. The conjugation of vasoactive intestinal peptide (VIP)-ASON is very helpful for <sup>125</sup>I-ASON to selectively bind to HT29 tumor cells by VIP receptors. For such tumor cells that highly express VIP receptors, tumor cellular uptake of VIP-<sup>125</sup>I-ASON is significantly higher than that of <sup>125</sup>I-ASON un-conjugated to VIP<sup>[12]</sup>. The c-myc ASON complex entered human melanoma cells (M14) by folacin receptors on tumor cell surface, brings about a greater cellular uptake than that of free-ASON, and inhibits tumor growth by lowering c-myc cancer protein expression<sup>[13]</sup>. As we know, the c-myc oncogene and transferrin receptors are highly expressed in HL-60 and LoVo Dx cells, the addition of transferrin-polylysine-c-myc ASON complex would cause more tumor cell deaths than free c-myc ASON<sup>[14]</sup>. However, receptor mediation was not used in our study. Why HT29 cellular uptake of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON is higher than that of <sup>99m</sup>Tc-HYNIC-ASON is unclear, which is possibly related to the greater stability of <sup>99m</sup>Tc-MAG<sub>3</sub>-ASON, and needs further study.

## COMMENTS

### Background

Anti-sense oligonucleotide (ASON) is used to bind to deoxyribonucleic acid (DNA) translation or transcription and interfere with the expression of oncogene. However, ASON is not sufficient to inhibit tumor growth. In order to enhance anti-tumor effect of ASON, we labeled ASON with technetium-99m *via* N-hydroxysuccinimidyl S-acetylmercaptoacetyltriglycine (NHS-MAG<sub>3</sub>) and hydrazinonictinamide derivative (HYNIC).

### Research frontiers

Many proteins such as monoclonal antibody, polypeptide, ligand, can be labeled with radionuclides, such as <sup>125</sup>I, <sup>131</sup>I, <sup>32</sup>P, <sup>35</sup>S, <sup>99m</sup>Tc, <sup>188</sup>Re, <sup>186</sup>Re, <sup>90</sup>Y. We are trying to label oncolytic virus with radionuclide, in order to achieve a synergistic anticancer effect.

### Innovations and breakthroughs

In this study, we compared the radiochemical behaviors and biological properties of anti-sense oligonucleotide (ASON) labeled with technetium-99m *via* N-hydroxysuccinimidyl S-acetylmercaptoacetyltriglycine (NHS-MAG<sub>3</sub>) and

hydrazinonictinamide derivative (HYNIC) and found that  $^{99m}\text{Tc}$ -MAG<sub>3</sub>-ASON showed superior radiochemical behaviors and biological properties than  $^{99m}\text{Tc}$ -HYNIC-ASON.

### Applications

$^{99m}\text{Tc}$ -MAG<sub>3</sub>-ASON showed superior radiochemical behaviors and biological properties than  $^{99m}\text{Tc}$ -HYNIC-ASON, suggesting that it can be used as a potential radiopharmaceutical agent for *in vivo* application.

### Peer review

In this study, the authors analyzed and compared the radiochemical behaviors and biological properties of anti-sense oligonucleotide (ASON) labeled with technetium-99m via NHS-MAG<sub>3</sub> and HYNIC. The rationale of the study is clearly expressed and the experiments appear to be carefully conducted.

### Abstract

**AIM:** To investigate the effects of carbon dioxide (CO<sub>2</sub>) and helium insufflation administered at different pressures on the growth and apoptosis of cultured human gastric cancer cells.

**METHODS:** The gastric cancer cells MKN-45 were exposed to a CO<sub>2</sub> and helium environment maintained at different pressures (0, 5, 10 and 15 mmHg). The cells were exposed to simulated pneumoperitoneum environment for 4 h, and pH of the culture media was measured after it was moved to normal conditions for 0, 2, 4, 6 and 8 h. Proliferation viability of MKN-45 was examined by 3-[4,5Dimethylthiazol-2-yl],5-diphenyltetrazolium bromide or triazolyl blue (MTT) assay after it was moved to normal conditions. Apoptotic ratio was measured by Annexin V-FITC/PI double labelled staining.

**RESULTS:** The pH of media was acid and recovered to normal after 4 h in the CO<sub>2</sub> group while it was basic in the helium group. There was no difference between CO<sub>2</sub> groups (under 10 mmHg) and control group ( $P > 0.05$ ) in the proliferative viability of the cells. The cultured cells exposed to 15 mmHg CO<sub>2</sub> environment grew more slowly than control group from 4 to 7 d ( $P < 0.01$ ) while there was no difference from 1 to 3 d ( $P > 0.05$ ). The proliferative viability in helium group was not obviously different from the control group ( $P > 0.05$ ). The

apoptotic ratio of the cultured cells was markedly higher than that of the control group ( $P < 0.01$ ) at 10 and 15 mmHg CO<sub>2</sub> insufflation pressure. In helium group, the apoptotic ratio was not obviously different from the control group ( $P > 0.05$ ).

**CONCLUSION:** There is no obvious effect in the proliferation and apoptosis of MKN-45 cells under 10 mmHg CO<sub>2</sub> insufflation pressure and helium in any pressure. Fifteen mmHg CO<sub>2</sub> insufflation pressure can inhibit the proliferation of the cells and improve apoptosis.

### INTRODUCTION

Minimally invasive techniques are increasingly applied in abdominal surgeries<sup>[1,2]</sup>. In recent years, numerous authors reported an acceptable feasibility of minimally invasive techniques for biopsy and resection of various malignant tumors<sup>[3,4]</sup>. However, laparoscopic resection for intra-peritoneal malignancies remains controversial. One of the reasons is the concern whether carbon dioxide (CO<sub>2</sub>) pneumoperitoneum can improve cancer cells' growth<sup>[5,6]</sup>. There is an ongoing debate about the deleterious effects of CO<sub>2</sub> on tumor cell behavior. Some authors showed an increase in cell proliferation and tumor growth<sup>[7]</sup> and others found beneficial effects of CO<sub>2</sub> exposition *in vitro* and in animal studies<sup>[8,9]</sup>.

It is well known that intracellular and extracellular pH in the peritoneum is affected by CO<sub>2</sub> insufflation. And some authors reported that pH in peritoneal cavity may be an important regulator of cell functions, such as adenosine

triphosphate (ATP) production, cell proliferation, and apoptosis<sup>[10]</sup>. Apart from the acid of peritoneal cavity, whether the direct insult of insufflation pressure could affect the growth of tumor cells is unclear.

Therefore, we focused on the different gases and pressures in simulated pneumoperitoneum, and investigated the proliferative viability of gastric cancer cells and apoptotic ratio *in vitro*.

## MATERIALS AND METHODS

### Cell culture

Human gastric cancer cells (MKN-45; personal gift of Professor F Daiming, Fourth Military Medical University) were cultured in RPMI-1640 (HyClone, USA) culture medium supplemented with 100 g/L fetal bovine serum, penicillin G 100 IU/mL and streptomycin sulfate 100 µg/mL.

### Pneumoperitoneum model *in vitro*

To simulate the environment produced during laparoscopic surgery, we designed an *in vitro* pneumoperitoneum according to Ridgway's method<sup>[11]</sup>. We used 100% CO<sub>2</sub> or 100% helium as the insufflation gas-displacement model. Sub-confluent MKN-45 cells which had been plated on 6 cm Petri dishes were placed into modified desiccating chambers. CO<sub>2</sub> or helium insufflation was affected by the connection of a standard surgical insufflator (Stryker, USA) to the chamber. Cells were exposed to a continual pneumoperitoneum for 4 h at 0, 5, 10 and 15 mmHg at 37°C. The pH of the media was examined using an arterial blood gas analyzer (Radiometer ABL 505, Denmark). After the cells were exposed to CO<sub>2</sub> or helium for 4 h, the media was changed and the cells were allowed to grow for 24 h before 3-[4,5Dimethylthiazol-2-yl],5-diphenyltetrazolium bromide or triazolyl blue (MTT) assay or flow cytometry.

### Cell viability

Cell growth was determined with a spectrophotometric assay<sup>[12]</sup>. This water-soluble tetrazolium salt was cleaved by the mitochondrion of living cells to an insoluble purple formazan. Optical density readings were measured at 490 nm.

### Percentage of apoptotic cells

The percentage of apoptotic cells was determined by FITC-labeled Annexin V and PI double staining flow cytometry.

The cell growth and apoptosis for each group were compared with those of the control group using one-way analysis of variance (ANOVA). *P* values less than 0.05 were considered significant.

## RESULTS

### Influence of pneumoperitoneum on pH of media

The pH of media in CO<sub>2</sub> and helium group is shown in Tables 1 and 2. When the pressure of CO<sub>2</sub> pneumoperitoneum was 15 mmHg, the pH of media was 6.18. It became normal after 4 h when moved to normal

cultured environment. In the helium group, the pH of the media was 8.12 when the pressure was 15 mmHg. Six hours later, it dropped to 7.18 when it was moved to normal cultured environment (Tables 1 and 2).

### MTT assay

According to MTT chromometry, the proliferative viability of MKN-45 cells was significantly decreased from d 4 to d 7 after it was exposed to simulated CO<sub>2</sub> pneumoperitoneum at 15 mmHg. When the pressure was under 10 mmHg, the cells' proliferative viability was not obviously different from the control group (*P* > 0.05). In the helium group, there was no difference between various pressures and control group (*P* > 0.05), even at 15 mmHg (Tables 3 and 4).

### Percentage of apoptotic cells

The percentage of apoptotic cells in 10 and 15 mmHg CO<sub>2</sub> groups was significantly higher than control group (*P* < 0.01). In the helium group, there was no significant difference in the percentage of apoptotic cells under different pressures (*P* > 0.05). Even the pressure was 15 mmHg, there was no significant difference from the control group (*P* > 0.05) (Table 5).

## DISCUSSION

Several prospective, randomized studies on laparoscopically assisted surgeries for early gastric cancer have demonstrated that the 5-year survival of patients with laparoscopically assisted radical resection of gastric carcinomas was similar to or even higher than that of open surgery<sup>[13]</sup>. Since March 2004, we have performed 304 cases of laparoscopically

assisted gastrectomy, 236 of the cases were advanced gastric cancer. We found no obvious difference between excising tumor with tumor-free margin and dissecting lymph nodes radically<sup>[14,15]</sup>. However, laparoscopic resection for abdominal malignancy remains controversial, especially for advanced gastric cancer. Among the reasons for this is the concern whether CO<sub>2</sub> pneumoperitoneum can improve port-site metastasis, peritoneal dissemination and recurrence<sup>[5,16,17]</sup>.

The results of experimental studies on the behavior of tumor cells exposed to CO<sub>2</sub> are not conclusive. Numerous authors confirmed a CO<sub>2</sub> associated increase of tumor growth and invasiveness of various cell lines derived from colon carcinoma, adenocarcinoma, and other tumors using animal models<sup>[18-20]</sup>. However, other studies showed that CO<sub>2</sub> pneumoperitoneum could increase cell necrosis and decrease proliferation<sup>[8,21]</sup>. Our data indicated that the exposure to CO<sub>2</sub> decreased the mitochondrial activity of MKN-45 cells, especially in a higher pressure environment (15 mmHg). We noticed this change when it was moved to normal culture environment for 4 h. The percentage of apoptotic cells increased in CO<sub>2</sub> pneumoperitoneum (10 and 15 mmHg group). This phenomenon was also investigated in human ovarian cancer cell lines HO8901, SKVO<sub>3</sub><sup>[22]</sup> and other tumor cells<sup>[23,24]</sup>.

Helium has been suggested for alternative use for

pneumoperitoneum to prevent CO<sub>2</sub> effects such as local acidosis and systemic hypercapnia<sup>[25]</sup>. In addition, a beneficial effect of helium versus CO<sub>2</sub> on the growth of rat mammary adenocarcinoma cells was shown *in vitro*<sup>[26]</sup>. In our experiments, we observed no obvious difference between helium group and control group, even at 15 mmHg pressure. This proved that the increase of cell apoptotic ratio in CO<sub>2</sub> pneumoperitoneum might not only depend on insufflated pressure.

Kos *et al* showed that intracellular and extracellular acidification associated with CO<sub>2</sub> resulted in an attenuation of cytokine release and cell activity in macrophages<sup>[27]</sup>. Takiguchi *et al* believed CO<sub>2</sub> pneumoperitoneum had no effect on cancer cells' proliferative ratio but had a toxic effect on cancer cells<sup>[18]</sup>.

Our current experiments confirmed that the extracellular pH differed significantly between CO<sub>2</sub> and helium exposure and it decreased very sharply at the insufflated pressure. Wildbrett *et al* reported that intracellular and extracellular pH and calcium level were altered with CO<sub>2</sub> pneumoperitoneum<sup>[10]</sup>. pH and calcium are important regulators of cell functions such as ATP production, cell cycle, intracellular signaling and apoptosis<sup>[28,29]</sup>. It is likely that all these changes influence the favorability of tumor-cell implantation at the time of laparoscopic surgery.

West *et al* excluded hypoxia as a cause of alteration of cell functions by exposing cells to 20% and 80% CO<sub>2</sub><sup>[30]</sup>. In our experiments, exposition to both 100% CO<sub>2</sub> and 100% helium may cause hypoxia, but the impact on MKN-45 gastric cancer cells was significantly different. Only CO<sub>2</sub> reduced cell activity, which made no hypoxic effects. The direct effects of CO<sub>2</sub> demonstrated by Takiguchi *et al* on human colon cancer cells *in vitro*<sup>[18]</sup> remain to be confirmed for gastric cancer cells.

CO<sub>2</sub> pneumoperitoneum resulted in severe peritoneal

acidosis, and peritoneal acidosis may play a role in changing tumor cells' implantation during laparoscopic oncologic surgery. The role of peritoneal microenvironment in tumor-cell growth awaits further studies. More studies in the area could enable us to find the safest approach to laparoscopic oncologic surgery.

## ACKNOWLEDGMENTS

We are grateful to Dr. Zhou LX and Dr. Luo J for their helpful support and advice concerning the flow cytometric analysis. We also thank Dr. Sun W for his valuable help in proofreading this article.

## COMMENTS

### Background

Laparoscopic surgery in oncologic patients is increasingly adopted as an alternative to conventional surgical procedures, both for diagnosis and resection. However, some experimental and clinical studies have suggested that the CO<sub>2</sub> pneumoperitoneum influences the development of intra-abdominal tumor dissemination and port site metastases. Numerous authors confirmed a CO<sub>2</sub> associated increase of tumor growth and invasiveness of various cell lines derived from colon carcinoma, adenocarcinoma, and other tumors. However, other studies showed beneficial effects of CO<sub>2</sub>, such as increased cell necrosis and decreased proliferation.

### Research frontiers

The effects of laparoscopic environment on tumor cell biology, including the kind of gas and the pressure of pneumoperitoneum.

### Innovations and breakthroughs

The results of experimental studies on the behavior of tumor cells exposed to CO<sub>2</sub> are not conclusive. In this study, the authors elaborately and clearly demonstrate that it is the CO<sub>2</sub> gas and not the pressure or the hypoxia that inhibits the growth of the cancer cells and increases apoptosis.

### Applications

Laparoscopic resection for intra-abdominal malignancies remains controversial, especially for advanced gastric cancer. One of the reasons is the concern whether CO<sub>2</sub> pneumoperitoneum can improve port-site metastasis, peritoneal dissemination and recurrence. This research on CO<sub>2</sub> pneumoperitoneum could improve the application of CO<sub>2</sub> as the insufflation gas in laparoscopic surgery.

### Terminology

Helium insufflation: The act of blowing helium into any body cavity for experimental, diagnostic, or therapeutic purposes. CO<sub>2</sub> pneumoperitoneum: The presence of CO<sub>2</sub> in the peritoneal cavity. It may occur spontaneously or be deliberately introduced as an aid to operate.

### Peer review

This is a good study. As far as the *in vitro* effects of gases and pressure on cancer cell growth and apoptosis is concerned, one can find studies reporting exactly contradictory findings. The authors elaborately and clearly demonstrate that it is the CO<sub>2</sub> gas and not the pressure or the hypoxia that inhibits the growth of the cancer cells and increases apoptosis.

### Abstract

**AIM:** To investigate dynamic changes of serum IL-2, IL-10, IL-2/IL-10 and sFas in rats with acute necrotizing pancreatitis. To explore the expression of Fas in intestinal mucosa of rats with acute necrotizing pancreatitis (ANP).

**METHODS:** A total of 64 Sprague-Dawley (SD) rats were randomly divided into two groups: normal control group (C group), ANP group (P group). An ANP model was induced by injection of 50 g/L sodium taurocholate under the pancreatic membrane. Normal control group received isovolumetric injection of 9 g/L physiological saline solution using the same method. The blood samples of the rats in each group were obtained via superior mesenteric vein to measure levels of IL-2, IL-10, sFas and calculate the value of IL-2/IL-10. The levels of IL-2, IL-10 and sFas were determined by ELISA. The severity of intestinal mucosal injury was evaluated by pathologic score. The expression of Fas in intestinal mucosal tissue was determined by immunohistochemistry staining.

**RESULTS:** Levels of serum IL-2 were significantly higher in P group than those of C group ( $2.79 \pm 0.51$  vs  $3.53 \pm 0.62$ ,  $2.93 \pm 0.89$  vs  $4.35 \pm 1.11$ ,  $4.81 \pm 1.23$  vs  $6.94 \pm 1.55$  and  $3.41 \pm 0.72$  vs  $4.80 \pm 1.10$ , respectively,  $P < 0.01$ , for all) and its reached peak at 6 h. Levels of serum IL-10 were significantly higher in P group than those of C group at 6 h and 12 h ( $54.61 \pm 15.81$  vs  $47.34 \pm 14.62$ ,  $141.15 \pm 40.21$  vs  $156.12 \pm 43.10$ ,  $89.18 \pm 32.52$  vs  $494.98 \pm 11.23$  and  $77.15 \pm 22.60$  vs  $93.28 \pm 25.81$ , respectively,  $P < 0.01$ , for all). The values of IL-2/IL-10 were higher significantly in P group than those of C group at 0.5 h and 2 h ( $0.05 \pm 0.01$  vs  $0.07 \pm 0.02$  and  $0.02 \pm 0.01$  vs

$0.03 \pm 0.01$ , respectively,  $P < 0.01$ , for all), and it were significantly lower than those of C group at 6 h ( $0.05 \pm 0.02$  vs  $0.01 \pm 0.01$ ,  $P < 0.01$ ) and returned to the control level at 12 h ( $0.04 \pm 0.01$  vs  $0.05 \pm 0.02$ ,  $P > 0.05$ ). In sFas assay, there was no significant difference between P group and C group ( $3.16 \pm 0.75$  vs  $3.31 \pm 0.80$ ,  $4.05 \pm 1.08$  vs  $4.32 \pm 1.11$ ,  $5.93 \pm 1.52$  vs  $5.41 \pm 1.47$  and  $4.62 \pm 1.23$  vs  $4.44 \pm 1.16$ , respectively,  $P > 0.05$ , for all). Comparison of P group and C group, the pathological changes were aggravated significantly in P group. Immunohistochemistry staining show the expression of Fas was absent in normal intestinal tissues, however, it gradually increased after induction of pancreatitis in intestinal tissue, then reached their peaks at 12 h.

**CONCLUSION:** Fas were involved in the pathogenesis of pancreatitis associated intestinal injury. The mechanisms of Fas may be associated to Fas mediated T helper cell apoptosis.

### INTRODUCTION

Acute pancreatitis (AP) is sudden inflammation of the pancreas that may be mild or life threatening but that usually subsides. Although usually self-limiting, 10% to 20% of afflicted patients will progress to acute necrotizing pancreatitis (ANP)<sup>[1,2]</sup>. The mortality rate among patients with ANP may approach 30% when they progress to multiple organ failure (MOF)<sup>[3]</sup>. It is generally accepted that AP is often complicated by intestinal injury. Failure of intestinal barrier function often occurs in this condition, resulting in the increased intestinal permeability. It is clear that increased intestinal permeability and bacteria with

or without endotoxin translocation plays a key role in the development of severe complications such as systemic inflammatory response syndrome (SIRS), sepsis, multiple organ dysfunction syndrome (MODS) and MOF<sup>[4-7]</sup>. However, its pathogenesis remains unclear.

The Fas system was originally characterized as a key mechanism for inducing apoptosis in immune cells, but later it transpired to be very common in various tissues such as liver, ovary, kidney, and testis, especially under I/R conditions. Apoptosis is a teleologically beneficial form of cell death in AP. However, little is known about how the induction of apoptosis reduces the severity of AP<sup>[8]</sup>. Recent research has demonstrated that a Th1 to Th2 immune deviation is beneficial to ANP. The antigen-induced deletion of Th is often accompanied by an imbalance in Th1 and Th2. The two most polarized patterns of cytokine production, Th1 (characterized by production of IL-2, IFN- $\gamma$ , TNF- $\alpha$ , and TNF- $\beta$ ) and Th2 (characterized by production of IL-4, 5, 6, 10, and -13) were reported<sup>[9]</sup>.

In the present study, we performed immunohistochemistry staining of apoptosis-related protein Fas and investigated dynamic changes of serum IL-2, IL-10, IL-2/IL-10 and sFas in rats with ANP.

## MATERIALS AND METHODS

### Animals

Adult Sprague-Dawley rats of both sexes weighing 250-300 g were provided by the Laboratory Animal Center of Jiangsu University. The animals were fed with standard rat chow and water *ad libitum*. The rats were allowed to acclimatize to our laboratory conditions for 1 wk and then subjected to mesh stainless-steel cages at a constant temperature ( $21 \pm 1^\circ$ ) in a 12 h day/night cycle. The animals were fasted for 12 h before the experiments but had free access to water. Animal care and experimental procedure were performed in accordance with the guidelines for Animal Experimentation of Jiangsu University with the approval of the Institutional Animal Care and Use Committee.

### Experimental design

The animals were randomly divided into: control group (C group), ANP group (P group) with 32 rats in each group. Each group was further divided into 0.5, 2, 6 and 12 h subgroups, respectively. The mortality in the present series was not calculated. The rats were anesthetized with an intraperitoneal injection of sodium pentobarbital (50 mg/kg body weight). The rats were infused with sodium taurocholate (4 mL/kg, Na-Tc, Sigma) the pancreatic membrane to induce ANP model as previously described<sup>[10]</sup>. After 30 min, pancreatic edema and dotted bleeding occurred. Normal control group received isovolumetric injection of 9 g/L physiological saline solution using the same method. Animals in each group were sacrificed at 0.5, 2, 6 and 12 h after infusion for further examination. Part of distal ileum and pancreas were removed immediately and fixed in paraformaldehyde solution for 12-24 h and paraffin-embedded for routine histopathologic analysis. The histopathologists were blinded to routine histopathologic analysis.

### Analysis of Th1/Th2 cytokines and sFas

The blood of rats in each group was obtained via superior mesenteric vein for determination of serum IL-2, L-10 and sFas levels at 0.5, 2, 6 and 12 h after infusion. Serum levels of IL-2, L-10 and sFas were measured by double antibody sandwich ELISA according to the manufacturer's protocol (Shanghai Senxiong Technology Enterprise Co., Ltd.). The optical density of each well was determined within 30 min using a microplate reader (492 nm).

### Pathological examination

The whole pancreas and parts of distal ileum were obtained and promptly fixed in 40 g/L phosphate-buffered formaldehyde for further studies. Paraffin-embedded tissue sections (5  $\mu$ m thick) were stained with hematoxylin and eosin. Mucosal damage was assessed according to the standard scale of Chiu *et al.*<sup>[11]</sup>. Grading was performed and classified as 0 = normal mucosa; 1 = development of subepithelial space at the tip of the villus; 2 = extension of the space with epithelial lifting; 3 = massive epithelial lifting; 4 = denuded villi; 5 = disintegration of the lamina propria.

### Immunohistochemistry

After embedding in paraffin, sections 5  $\mu$ m in thickness were immersed twice into xylene for 5 min each, followed by immersion twice for 3 min each in 100% ethanol and then 95% ethanol. Slides were rinsed for 30 sec using deionized water and then immersed twice in deionized water for 5 min. To detect Fas expression, heat-induced Ag retrieval was performed using 0.01 mol/L citrate buffer (pH 6.2) and 10 min slide immersion into 95°C waterbath. Immunoenzyme double staining of intestinal tissue was performed using DAKO EnVision Doublestain System. The sections were then counterstained using hematoxylin before study.

### Statistical analysis

All data were analyzed with the SPSS 11.0 software. The results were expressed in mean  $\pm$  SD except for date on the grading of intestinal mucosal lesions. Differences of grading of intestinal mucosal lesions were determined using the non-parametric Mann-Whitney test. Statistical analysis was performed with post-hoc test.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Serum IL-2 level

At 0.5 h after injection of 50 g/L sodium taurocholate, serum IL-2 level in the samples from mesentery vein in P group were higher than those in C group. From 0.5 h, there was a significant difference between P group and C group ( $P < 0.01$ , Table 1).

### Serum IL-10 level

Upon stimulation, serum IL-10 level was significantly increased in the P group as compared with that of C group at 6 and 12 h ( $P < 0.01$ , Table 1). There was no significant difference between P group and C group at 0.5 and 2 h.

**Table 1 IL-2 and IL-10 level in each group (mean ± SD, n = 8) (pg/mL)**

Group	0.5 h	2 h	6 h	12 h
IL-2 C	2.79 ± 0.51	2.93 ± 0.89	4.81 ± 1.23	3.41 ± 0.72

P	0	2	5	1	0	0 <sup>b</sup>	0	0	2	4	2	0 <sup>b</sup>	0	0	0	1	4	3 <sup>b</sup>	0	0	0	0	3	5 <sup>b</sup>	

<sup>b</sup>P < 0.01 vs C group.

**Serum IL-2/IL-10**

As shown in Table 2, the values of IL-2/IL-10 were higher significantly in P group than those of C group at 0.5 h and 2 h, and it were significantly lower than those of C group at 6 h (P < 0.01) and returned to the control level at 12 h (P > 0.05) (Table 2).

**Serum sFas level**

In serum sFas assay as illustrated Table 2, there was no significant difference between P group and C group. sFas levels were moderate at 0.5 h, peaked at 6 h and decreased at 12 h.

**Pathologic examination of pancreas and intestinal mucosa**

After induction of ANP model, pancreas showed mild edema and congestion. 2 h after introduction of the model, typical pathologic changes were found in P group, such as a large number of inflammatory cells, necrosis of adjacent fat tissues, interstitial edema, parenchyma hemorrhage and necrosis, large amount of ascites. The degree of intestinal pathological injury is shown in Table 3. The grades of P group were significantly higher those of control group (P < 0.01).

**Immunohistochemistry**

We detected the expression of Fas on intestinal tissue with immunocytochemical technique. Immunohistochemistry staining showed Fas expression in intestinal tissue was absent in normal intestinal tissue, Fas expression in intestinal tissue gradually increased 0.5 h after induction of pancreatitis, and then reached a peak at 12 h (Figure 1).

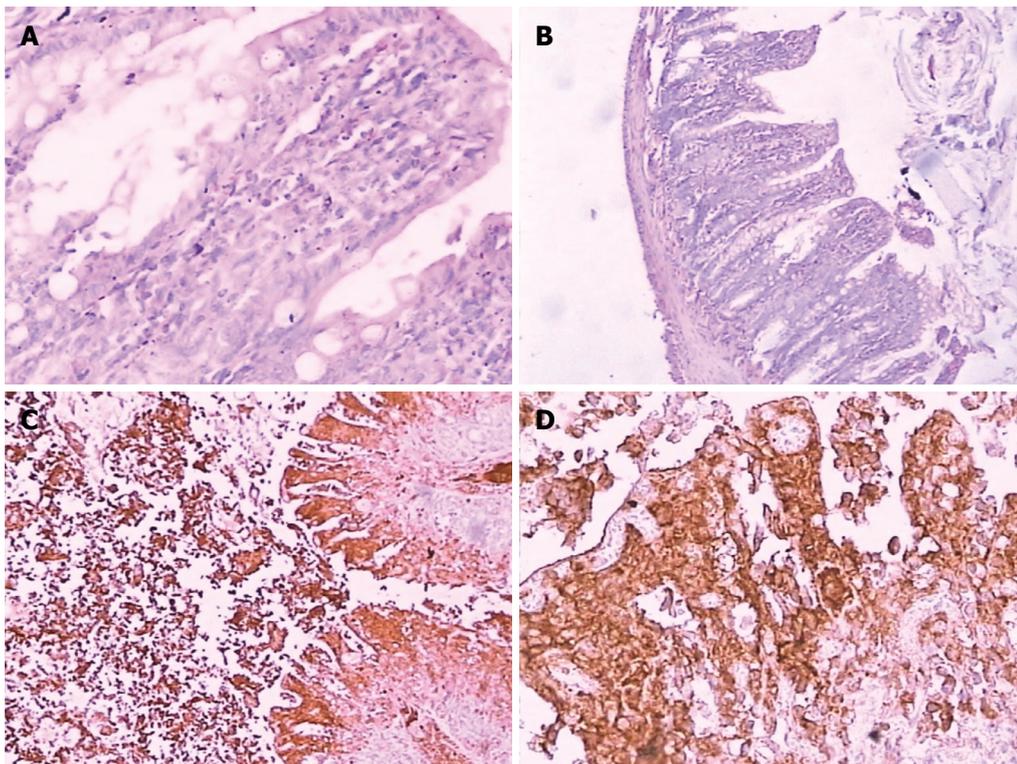

**DISCUSSION**

The Fas system is a widely recognized apoptotic signal transduction pathway in which a ligand-receptor interaction triggers the cell death pathway<sup>[12]</sup>. The Fas system has been implicated in the control of the immune response and inflammation, the response to infection and

death of parenchymal cells in several organs<sup>[13-15]</sup>, which is involved in maintaining homeostasis in various systems, including maintenance of peripheral T cell<sup>[16]</sup>. Recent research has demonstrated that a Th1 to Th2 immune shift is beneficial to mucosal immunity<sup>[17,18]</sup>. A key component of the mucosal immune defense against pathogens is mediated by CD4+ T lymphocytes that can differentiate into functionally distinct subsets<sup>[19]</sup>. Whereas T-helper 1 (Th1) cells secrete the cytokines IL-2, IFN-γ, TNF-α, and TNF-β, Th2 cells secrete IL-4, 5, 6, 10, and 13. In the current study, we used IL-2 levels as a marker of Th1 response and IL-10 as a marker of Th2 response. In this study, the role of the Fas-mediated cell death pathway in intestinal mucosal injury models was assessed and dynamic changes of serum IL-2, IL-10, IL-2/IL-10 and sFas in rats with ANP were also investigated.

According to the result of immunohistochemistry, Fas had a lower expression in intestinal tissue in the P group at 0.5 h and higher expression after 2, 6 and 12 h. In the C groups, Fas was not detected in any part of intestinal tissue. Previous study has shown that IL-10 is a kind of important anti-inflammatory cytokine and plays a role of self-defense mechanism, limiting the intensity of inflammatory process<sup>[20-23]</sup>. However, the effect of IL-10 level in the course of acute pancreatitis is still not clear<sup>[24-26]</sup>. IL-10 is a powerful Th2 cell cytokine produced by lymphoid cells. A marked activation of immune system may be observed in patients with AP, being balanced between pro- and anti-inflammatory cytokines in patients with mild but not severe AP. A reduced functional reserve for the synthesis of IL-10 may be observed in patients with severe AP, which might lead to a worst prognosis<sup>[27-30]</sup>.

From the results of this study, it was found that the release of IL-10 was significantly increased in the P group as compared with that of C group at 6 and 12 h. Serum IL-2 level in the P group were higher than those in C group. From 0.5 h, there was a significant difference between P group and C group. The IL-2/IL-10 ratio was significantly increased in the P group as compared with that of C group

**Figure 1** Morphological changes intestinal mucosa after induction of ANP. **A:** Intestinal section with normal mucosa (ANP 0.5 h); **B:** Disintegration of the lamina propria (ANP 6 h); **C:** Fas positive immunohistochemical staining was present in the intestinal mucosa (ANP 0.5 h); **D:** Fas positive immunohistochemical staining was present in the intestinal mucosa (ANP 12 h).

at 0.5 and 2 h, suggesting that a pro-inflammatory response was predominant in these rats and significantly lower in P group at 6 h suggesting that an anti-inflammatory response was predominant. In the sFas assay, there was no significant difference between P group and C group. Interestingly, IL-2, IL-10 and sFas levels were moderate at 0.5 h, peaked at 6 h and decreased at 12 h. In our model, the intestinal tissue injury which was assessed according to the standard scale of pathological examination was closely paralleled by Fas expression and dynamic changes of IL-2/IL-10.

In conclusion, the abnormal apoptosis of Fas can significantly affect the cytokine. Fas were involved in the pathogenesis of intestinal injury in ANP. The mechanisms of Fas may have been related to Fas mediated T helper cell apoptosis.

## COMMENTS

### Background

Acute pancreatitis (AP) is sudden inflammation of the pancreas that may be mild or life threatening but that usually subsides. It is generally accepted that AP is often complicated by intestinal injury. The Fas system was originally characterized as a key mechanism for inducing apoptosis in immune cells. Apoptosis is a teleologically beneficial form of cell death in AP. However, little is known about how the induction of apoptosis reduces the severity of AP. Recent research has demonstrated that a Th1 to Th2 immune deviation is beneficial to mucosal immunity.

### Research frontiers

Recent research has demonstrated that a Th1 to Th2 immune deviation is beneficial to mucosal immunity. The antigen-induced deletion of Th is often accompanied by an imbalance in Th1 and Th2.

### Innovations and breakthroughs

In the present study, we performed immunohistochemistry staining of apoptosis-related protein Fas and investigated dynamic changes of serum IL-2, IL-10, IL-2/IL-10 and sFas in rats with ANP.

### Applications

To provide the experimental basis by expression of Fas in intestinal mucosa in rats with ANP and provide experimental evidence for the immune treatment of patients with ANP.

### Terminology

Th1 and Th2 response: Th1-type cytokines tend to produce the proinflammatory responses responsible for killing intracellular parasites and for perpetuating autoimmune responses. Interferon gamma is the main Th1 cytokine. Excessive proinflammatory responses can lead to uncontrolled tissue damage, so there needs to be a mechanism to counteract this. The Th2-type cytokines include interleukins 4, 5, 13 and interleukin-10, which has more of an anti-inflammatory response.

### Peer review

This is a potentially interesting study to understand the dynamic changes of several cytokines and sFas in rats with ANP and provide experimental evidence for the immune treatment of ANP patients.

### Abstract

**AIM:** To explore clinicopathologic characteristics of intrahepatic cholangiocarcinoma (ICC) in patients with positive serum a-fetoprotein (AFP).

**METHODS:** One hundred and thirty one patients who underwent surgical dissection for pathologically confirmed ICC were divided into a positive AFP (> 20 ng/mL) group ( $n = 32$ ) and a negative AFP group ( $n = 99$ ), whose clinicopathologic features were analyzed and compared.

**RESULTS:** The positive rate of HBsAg and liver cirrhosis of the positive AFP group was higher than that of the negative AFP group, while the positive rate of CA19-9 (> 37 U/mL) and the lymph node metastasis rate was lower.

**CONCLUSION:** ICC patients with positive AFP share many clinicopathologic similarities with hepatocellular carcinoma.

Clinicopathologic characteristics of intrahepatic cholangiocarcinoma in patients with positive serum a-fetoprotein. *World J Gastroenterol* 2008; 14(14): 2251-2254 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2251.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2251>

### INTRODUCTION

Intrahepatic cholangiocarcinoma (ICC) is a tumor originating from peripheral intrahepatic biliary epithelia, ranking as the second most common primary hepatic malignant tumor next to hepatocellular carcinoma (HCC), accounting for 5% of all primary hepatic malignant tumors<sup>[1]</sup>. The incidence and mortality of ICC is on the rise in recent years<sup>[2]</sup>. Serum a-fetoprotein (AFP), as a tumor marker of HCC<sup>[3-5]</sup>, and carbohydrate antigen 19-9 (CA19-9), as a tumor marker of ICC, have been widely used in clinical practice<sup>[6]</sup>. In about 19% ICC patients, serum AFP is also positive (> 20 ng/mL)<sup>[1]</sup>, but there is little knowledge about the clinicopathologic features of such patients. The purpose of this study was to define clinicopathologic features of ICC patients with positive AFP by comparing them with ICC patients with negative AFP.

### MATERIALS AND METHODS

#### Patients

Included in this study were 131 ICC patients who received surgical dissection at the Eastern Hepatobiliary Surgery Hospital of the Second Military Medical University (Shanghai, China) from March 2002 to June 2003, including 90 males and 41 females ranging in age from 23 to 73 years with a mean of 53 years. Of the 131 ICC patients, serum AFP was positive in 32 patients (24.4%), of whom AFP was > 200 ng/mL in 13 patients (9.9%), and > 1000 ng/mL in 6 patients (4.5%). Their clinical manifestations, pathological findings and surgical outcomes were compared with those of ICC patients whose serum AFP was negative. Positive serum hepatitis B surface antigen (HBsAg) and hepatitis C antibody were biomarkers of chronic viral hepatitis.

The diagnosis of ICC was confirmed by pathology. All the excised specimens were fixed in 4% neutral formaldehyde routinely, paraffin embedded, sliced into 4  $\mu$ m sections, and haematoxylin and eosin (HE) stained.

Table 1 Clinical features of ICC patients with positive AFP

	AFP		P value
	+	-	
Gender (M/F)	24/8	66/33	NS
Age (yr)	48.7 ± 11.7	54.5 ± 9.9	0.007
HBsAg + (%)	25 (78.1)	38 (38.3)	0.000
Anti-HCV + (%)	0	1 (0.01)	NS
CA19-9 (> 37 U/mL) (%)	10 (31.4)	58 (58.6)	0.007
TBIL (> 17.1 μmol/L) (%)	17 (53.1)	39 (39.4)	NS
ALT (> 40 IU/L) (%)	16 (50.0)	26 (26.3)	0.012
AST (> 40 IU/L) (%)	14 (43.8)	23 (23.2)	0.025

NS: Not significant; M: Male; F: Female; HBsAg: Hepatitis B surface antigen; HCV: Hepatitis C virus antibody; TBIL: Total bilirubin; AST: Aspartate transaminase; ALT: Alanine transaminase.

Pathological study included the size, number and location of the tumors, background of cirrhosis, portal or hepatic vein invasion, lymph node metastasis, formation of tumor capsules, and histological grade. Tumors whose diameter was smaller than 3 cm were classified as small ICC.

Immunohistochemistry for HCC marker hepatocyte paraffin 1 (Hep Par 1)<sup>[7]</sup> and ICC marker cytokeratin 19 (CK-19)<sup>[8]</sup> was performed using a polymer-based method with the Envision Kit (Fuzhou Maxim Biotech, China). Formalin-fixed, paraffin-embedded serial tissue sections (4 μm) were deparaffinised and rehydrated in xylene and grade-diluted ethanol. Tissue sections were then incubated in methanol containing 0.3% hydrogen peroxide at room temperature for 20 min to block endogenous peroxidase. Sections were then incubated overnight at 4°C with anti-Hep Par 1 antibody (Dako, Denmark) or anti-CK-19 antibody (NeoMarkers, USA), followed by incubation with Envision reagent at room temperature for 30 min, and color developed with 3, 3'-diaminobenzidine tetrahydrochloride. Finally, the sections were counterstained with haematoxylin, and hyalinized water. For negative controls, the sections were processed the same way, except they were incubated with phosphate-buffered saline instead of the primary antibody.

All patients were followed up after discharge from the hospital, with a median follow-up period of 31 mo (range 5-52 mo).

### Statistical analysis

Data were analyzed with SPSS 11.0 statistical software. Quantitative inter-group comparison was tested by *t* test, and classification inter-group comparison was tested by  $\chi^2$  test. Survival analysis was done by Kaplan-Meier method. Inter-group comparison was done by log-rank method.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Clinical features

The mean age of the positive AFP group was lower than that of the negative AFP group ( $P = 0.007$ ). There was no significant difference in sex distribution between the two groups. The positive rate of HBsAg (78.1%) and

transaminase of the positive AFP group was higher than that of the negative AFP group ( $P = 0.000$  and  $P = 0.036$  respectively), while the positive rate of CA19-9 was lower (> 37 U/mL,  $P = 0.007$ ; Table 1).

### Pathological features

Backgrounds of liver cirrhosis were elicited in 13 ICC patients with positive AFP, which was significantly higher than that of the negative AFP group (40.6% vs 22.2%,  $P = 0.041$ ), but the lymph node metastasis rate was significantly lower (15.6% vs 35.4%,  $P = 0.035$ ). There were no significant differences in the location, size and number of tumors, tumor capsule defect, histological differentiation, portal venous invasion and microvascular invasion (Table 2). Immunohistochemical staining showed that Hep Par 1 expression was negative and CK-19 expression was positive in all 131 cases (Figure 1).

### Outcomes

No hospital death occurred in all the 131 ICC cases. The median postoperative survival of the ICC patients with positive AFP and with negative AFP was 37 mo and 28 mo respectively. The cumulative 1-year and 3-year survival rate of the positive AFP group was 68.7% and 46.8% respectively, both higher than 64.6% and 40.4% of the negative AFP group, though the difference was not statistically significant. Possible risk factors affecting survival included tumor size > 3 cm ( $P = 0.014$ ), lymph node metastasis ( $P < 0.0001$ ), portal venous invasion ( $P = 0.006$ ), and the number of tumors  $\geq 2$  ( $P < 0.0001$ ).

**Figure 1** Representative sections showing immunohistochemical expression of CK-19 in intrahepatic cholangiocarcinoma ( $\times 200$ ).

## DISCUSSION

Human AFP is a fetal glycoprotein with a molecular weight of about 72 kDa. Under physiological conditions, it is synthesized by fetal hepatocytes, yolk sac cells and gastrointestinal cells. AFP level begins to decrease gradually to  $< 10$  ng/mL by 300 d of birth. Since detection of AFP in the serum of HCC patients in 1963, AFP has been widely used for screen examination and clinical diagnosis as an HCC tumor marker. In 60%-70% HCC patients, serum AFP is higher than the normal range<sup>[1,3,4]</sup>. In addition, increased AFP is also found in other pathological conditions such as hepatic cirrhosis, extensive hepatic necrosis, chronic hepatitis, pregnancy, gonadal fetal tumors and digestive tract tumors including gastric carcinoma, pancreatic carcinoma and gallbladder carcinoma. Positive AFP is rarely seen in ICC patients. A series of studies from a Japanese liver cancer research team showed that 19% ICC patients had a serum AFP level  $> 20$  ng/mL, 10.3%  $> 200$  ng/mL, and only 6.3% ICC patients had a serum AFP level  $> 1000$  ng/mL<sup>[1]</sup>. In our series of 131 ICC patients, 32 patients (24.4%) had positive AFP, including 13 patients (9.9%)  $> 200$  ng/mL, and 6 patients (4.5%)  $> 1000$  ng/mL. The exact mechanism of how AFP is synthesized in ICC is not clear.

We found that ICC patients with positive AFP were associated with HBV infection and cirrhosis. This clinical feature is similar to that of HCC. What is consistent with ICC is that transaminase (a biomarker reflecting hepatic impairment) was higher in the positive AFP group than in the negative AFP group. Yamamoto *et al*<sup>[9]</sup> reported that ICC patients who were preoperatively diagnosed as having HCC had a relatively high rate of HCV infection. In ICC patients presenting with a high level of AFP and a low level of CA19-9, surgical treatment similar to HCC should be considered. Okuda *et al*<sup>[10]</sup> found that in ICC patients with positive Lens culinaris agglutinin-A-reactive AFP (AFP-L3), the hepatitis viruses infection rate was as high as 60%.

Lymph node metastasis is a common event in ICC, while it occurs rarely in HCC<sup>[11]</sup>. The data obtained from our study showed that the lymph node metastasis rate was low in ICC patients with positive AFP. What is consistent with previous studies is that lymph node metastasis is an important factor affecting the prognosis

of ICC<sup>[12]</sup>. We found that the 1-year and 3-year survival rate of the positive AFP group was higher than that of the negative AFP group. This may be due to the lower lymph node metastasis rate of ICC patients with positive AFP. However, as the capacity of our cases is small and the follow-up period is not long enough, this statistical difference may not be significant.

The pathogenesis of ICC remains unclear. Recent studies show that HCC, ICC and many other tumors may originate from stem cells<sup>[13]</sup>. It is generally accepted that adult hepatic stem cells are hepatic oval cells. They are a group of intrahepatobiliary multi-potential differentiation cells, capable of differentiating to hepatobiliary cells and to hepatic cells. These cells are mainly located in the fetal liver or the hepatobiliary terminal Hering tube in adults. In normal physiological conditions, the number of oval cells is very small, and they are in a resting state. When the hepatic parenchyma is severely damaged, or regeneration of the hepatic cells is inhibited by virus, drugs, hepatic toxins or carcinogens, oval cells are activated, proliferating in large numbers and differentiating to hepatic and hepatobiliary cells to repair and reconstruct the liver<sup>[13]</sup>. AFP is not only an indicator of cell de-differentiation or immaturity but an important sign of hepatic stem cells<sup>[14]</sup>. Wang *et al*<sup>[15]</sup> reported that the expression rate of hepatic stem cell marker CK7 and CK19 was 100% in 12 ICC patients, while the expression rate of c-kit, Thy-1 and AFP was 41.7%, 33.3% and 33.3%, respectively. Transformation of oval cells to ICC cells was also observed. AFP synthesis in ICC suggests that ICC may originate from hepatic stem cells that underwent malignant transformation<sup>[16]</sup>. However, this presumption awaits verification by more studies.

Liver fluke infection (*Clonorchis sinensis* or *Opisthorchi viverrini*)<sup>[17,18]</sup>, primary sclerosing cholangitis (PSC)<sup>[19,20]</sup>, and hepatolithiasis are thought to be the risk factors for ICC<sup>[21,22]</sup>. Multiple studies in recent years show that viral hepatitis and hepatic cirrhosis are not only closely related to HCC but to ICC<sup>[23-26]</sup>. Our most recent case-control study showed that HBV infection is the possible pathogenic factor causing ICC in Chinese populations<sup>[27]</sup>. Proliferation of large numbers of oval cells was seen in chronic HBV and hepatic cirrhosis<sup>[28-30]</sup>. HBV infection may induce activation of oval cells, and this process may be accompanied with abnormal genetic alteration<sup>[31]</sup>, which in turn triggers malignant transformation of oval cells.

In summary, ICC patients with positive AFP share many clinicopathologic similarities with HCC.

## COMMENTS

### Background

Intrahepatic cholangiocarcinoma (ICC) is the second most common primary hepatic malignant tumor next to hepatocellular carcinoma (HCC). Serum  $\alpha$ -fetoprotein (AFP), as a tumor marker of HCC, has been widely used in clinical practice. In about 19% ICC patients, serum AFP is also positive ( $> 20$  ng/mL), but there is little knowledge about the clinicopathologic features of such patients.

### Research frontiers

One hundred and thirty one patients who underwent surgical dissection for pathologically confirmed ICC were divided into a positive AFP ( $> 20$  ng/mL) group ( $n = 32$ ) and a negative AFP group ( $n = 99$ ), whose clinicopathologic features were analyzed and compared.

### Innovations and breakthroughs

The positive rate of HBsAg and liver cirrhosis of the positive AFP group was higher than that of the negative AFP group, while the positive rate of CA19-9 (> 37 U/mL) and the lymph node metastasis rate was lower.

### Applications

AFP synthesis in ICC suggests that ICC may originate from hepatic stem cells that underwent malignant transformation<sup>[16]</sup>. However, this presumption awaits verification by more studies.

### Peer review

This paper by Yan-Ming Zhou is an interesting study that describes the clinicopathologic characteristics of patients affected by intrahepatic cholangiocarcinoma with positive and negative serum AFP. This study includes 131 patients who underwent surgical dissection for pathologically confirmed ICC. The authors, concluding that ICC patients with positive AFP share many clinicopathologic similarities with HCC, suggest new perspectives in the management of intrahepatic cholangiocarcinoma.

### Abstract

**AIM:** To investigate the association of alcohol dose, duration of drinking and obesity with abnormal alcohol-related liver injury indicators, the prevalence of alcohol-related liver injury in the island population of China.

**METHODS:** Randomized multistage stratified cluster sampling from the island population of China was used in the population-based case-control study. Then interview, physical examination, laboratory assessments and ultrasonography were done.

**RESULTS:** Daily alcohol intake  $\geq 20$  g, duration of drinking  $\geq 5$  years and obesity were closely related to alcohol-related liver injury ( $P < 0.05$ ). The odds-ratio (OR) (95% CI) was 1.965 (1.122-3.442), 3.412 (1.789-6.507) and 1.887 (1.261-2.824), respectively. The prevalence rate of alcohol-related liver injury in  $\geq 20$  g daily alcohol intake group and  $< 20$  g daily alcohol intake group was 37.14% and 12.06%, respectively. The prevalence rate of alcohol-related liver injury in  $\geq 5$  years drinking group and  $< 5$  years drinking group was 34.44% and 8.53%, respectively. No significant dose-response relation was found between daily alcohol intake and abnormal alcohol-related liver injury indicators as well as between duration of drinking and abnormal alcohol-related liver injury indicators. There was no significant difference in the prevalence of alcohol-related liver injury between

beer drinking group and yellow rice wine drinking group, hard liquor drinking group, multiple drinking group.

**CONCLUSION:** The risk threshold of daily alcohol intake is 20 g and duration of drinking inducing alcohol-related liver injury 5 years in the island population of China. Liver injury induced by obesity should be concerned.

### INTRODUCTION

Alcohol-induced liver disease remains one of the most common causes of chronic liver diseases<sup>[1]</sup>. Studies on alcoholic liver disease (ALD) have drawn wide attention in the Western world<sup>[2-5]</sup>. It was reported that ALD should be defined as an alcohol-associated lifestyle disease<sup>[6]</sup>. The predisposition to ALD is largely governed by gene-environment interactions. In recent years, along with the improved living standard and increased alcohol consumption, several epidemiological surveys showed that it has become a serious public health problem in China<sup>[7-10]</sup>. The island population in East China is a specific cluster of population. They feed themselves mainly on fishing, spend most of their time on sea-going ships, and consume a large amount of alcohol compared to the inland population. However, few population-based ALD studies are available from islands in China. Therefore, it is currently difficult to evaluate alcohol-related liver injury in the island population. Certainly, it is extremely important to select a sensitive and specific indicator in epidemiological survey. ALD is characterized by elevated serum gamma-glutamyltranspeptidase (GGT), aspartate aminotransferase

(AST) and alanine aminotransferase (ALT)<sup>[11-13]</sup>. According to the Practical Guidelines for Alcoholic Liver Disease published by the American College of Gastroenterology in 1998<sup>[14]</sup>, GGT, AST and ALT were used as indicators of alcohol-related liver injury in this survey. We conducted a population-based case-control study to investigate the association of alcohol dose, duration of drinking and obesity with alcohol-related liver injury in East China.

## MATERIALS AND METHODS

### Study design and sample selection

We assigned a number to each of the counties is located along the coast of Zhejiang Province, and randomly selected one county (Xiangshan County). We randomly selected two islands (Hepu and Dongmen) of the 5 islands in the Xiangshan County and 9 villages of the 12 villages in the Hepu and Dongmen islands from August 2006 to September 2006. All individuals investigated in this study were at the age of over 18 years. All procedures were approved by the Ethics Committee of Zhejiang University School of Medicine. Each method and potential risks were explained in detail to the participants who gave their written informed consent before the survey.

Through a stratified multistage probability cluster sampling method, we acquired a representative sample from the island population in Zhejiang Province. We investigated 814 individuals aged 18 years or more in this survey, and obtained the complete data on 782 individuals. However, 129 individuals reporting clinical diagnosis of chronic viral hepatitis, schistosomiasis japonica (according to their epidemiological history, enzyme-linked immunosorbent assay results), cirrhosis (according to their medical history and ultrasonography results), or other severe diseases (mainly including drug-induced liver disease, cancer, pancreatitis, kidney disease, *etc*, based on their medical history) were excluded. Therefore, complete data were collected from 653 individuals. Their HBsAg and anti-HCV were negative. All individuals had no history of drug-induced liver disease and other severe diseases. There was no significant difference in the mean age between males and females. The mean age of males and females was  $50.11 \pm 13.48$  years and  $50.56 \pm 11.72$  years, respectively. There was also no significant difference in the mean BMI between males and females. The mean BMI of males and female was  $24.60 \pm 3.83$  kg/m<sup>2</sup> and  $24.54 \pm 3.58$  kg/m<sup>2</sup>, respectively.

### Interview

A face-to-face interview was conducted by trained physicians using a standardized questionnaire at the local community hospital. Data on demographic variables, alcohol drinking status, medical history and health behavior were collected from the questionnaire. Educational attainment of the followed up individuals was categorized into 5 groups according to the years of education (0, 1-6, 7-9, 10-12,  $\geq 12$  years). Based on smoking habit grading<sup>[15]</sup>, the followed up individuals were categorized into non-smoker group (never and cessation of smoking for more than 6 mo), smoking addict group (daily smoking for more than 6 mo),

and smoking non-addict group (cessation of smoking or daily smoking for less than 6 mo). A series of questions of alcohol use included quantity of alcohol intake each time, times of alcohol intake each day, months of alcohol intake each year, years of alcohol intake, types and alcoholicity of alcoholic beverage, drinking and dietary habits. From the above data, we calculated the average daily alcohol intake (g), total alcohol intake (kg), and duration of drinking (years) by alcohol dose convert formula<sup>[16]</sup>.

### Physical examination

All followed up individuals were invited to have a physical examination at the local community hospital after the face-to-face interview. The followed up individuals were required to fast overnight. Body measurements were performed by a trained medical professional using a standardized protocol. Body weight and standing height were measured in light indoor clothing without shoes. Body mass index (BMI) was then calculated as mass (kg)/height (m)<sup>2</sup>. The followed up individuals were divided into non-obese (BMI < 25 kg/m<sup>2</sup>) group or obese (BMI  $\geq 25$  kg/m<sup>2</sup>) group as previously described<sup>[17]</sup>. Blood pressure was measured with an electronic blood pressure monitor (Omron HEM-746C, Omron Healthcare Inc., Bannockburn, Illinois, USA) on the right arm of the followed up individuals at a comfortable sitting position after a 5-min rest. Three measurements were taken. The second and third pressure readings were averaged and used for analysis. Diagnosis of hypertension was based on The JNC 7 Report<sup>[18]</sup> or on the current use of anti-hypertensive medications.

### Laboratory assessments

Peripheral venous blood samples were collected after physical examination and centrifuged at 3000 r/min for 15 min at 4°C. After being frozen, the samples were shipped on dry ice to Department of Clinical Laboratory, First Affiliated Hospital, School of Medicine, Zhejiang University, and stored at -80°C. Blood samples were taken to check alcohol-related liver injury indicators which reflect the changes in the alcohol-related liver injury<sup>[14,16]</sup>, including ALT, AST, GGT. Also, HBsAg, anti-HCV and enzyme-linked immunosorbent assay (ELISA) for schistosomiasis japonica were detected. All serum biochemistries were measured with a Hitachi 7600-110 automatic analyzer (Hitachi co., Tokyo, Japan). Reference value ranges of all indexes were based on the biochemistry criteria of Department of Clinical Laboratory, First Affiliated Hospital, School of Medicine, Zhejiang University. According to the Practical Guidelines for Alcoholic Liver Disease published by the American College of Gastroenterology in 1998<sup>[14]</sup>, abnormal alcohol-related liver injury indicators were defined based upon AST > ALT (ALT or AST exceeding the upper normal level) or GGT exceeding the upper normal level.

### Ultrasonographic examination

Hepatic ultrasonography for all individuals was performed by the same experienced ultrasonographer using a GE Logic Book XP portable ultrasound with a 3.5 MHz probe. Ultrasonographic diagnosis of cirrhosis followed the ultrasonographic criteria<sup>[19]</sup>.

Table 1 Relationship between variables and alcohol-related liver injury detected by using univariate logistic-regression

Variable	$\beta$	S.E.	Wald $\chi^2$	P	OR	95% CI
Male gender	1.152	0.228	25.448	0.000	3.163	2.022-4.948

ALI: Alcohol-related liver injury.

### Statistical analysis

We established a database using Epi Data 3.0 software (The EpiData Association, Odense, Denmark). Two typists recorded the data respectively and checked each other, corrected errors until two pieces of data were consistent. Statistical analysis was performed with SPSS 13.0 statistical package (SPSS Inc., Chicago, Illinois, USA). The mean value for different groups was compared using Student *t*-test. Chi-square ( $\chi^2$ ) test was used for comparing group ratios. We carried out univariate and multivariate stepwise logistic regression analyses.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Risk factors for abnormal alcohol-related liver injury indicators

Of the 653 individuals, 149 were diagnosed having abnormal alcohol-related liver injury indicators in this study. Univariate logistic-regression analysis showed that male gender, smoking,  $\geq 20$  g daily alcohol intake,  $\geq 5$  years drinking,  $\geq 36.5$  kg total alcohol intake, hypertension, obesity were closely related to abnormal alcohol-related liver injury indicators, while age, education level, unmarried state were not significantly related to abnormal alcohol-related liver injury indicators (Table 1).

Multivariate stepwise logistic-regression analysis showed that  $\geq 20$  g daily alcohol intake,  $\geq 5$  years drinking and obesity were closely related to abnormal alcohol-related liver injury indicators (Table 2). Compared to the  $< 20$  g daily alcohol intake group, the odds-ratio (OR, 95% CI) of abnormal alcohol-related liver injury indicators in the  $\geq 20$  g daily alcohol intake group was 1.965 (1.122-3.442). Compared to the  $< 5$  years drinking group, the OR (95% CI) of abnormal alcohol-related liver injury indicators in the  $\geq 5$  years drinking group was 3.412 (1.789-6.507).

### Prevalence of alcohol-related liver injury

Based on the daily alcohol intake and BMI, 216 subjects were assigned to control group (daily alcohol intake  $< 20$  g and BMI  $< 25$  kg/m<sup>2</sup>), 161 to excessive drinking group (daily alcohol intake  $\geq 20$  g and BMI  $< 25$  kg/m<sup>2</sup>), 157 to obese group (daily alcohol intake  $< 20$  g and BMI  $\geq 25$  kg/m<sup>2</sup>), 119 to excessive drinking and obese group (daily alcohol intake  $\geq 20$  g and BMI  $\geq 25$  kg/m<sup>2</sup>). The prevalence rate of abnormal alcohol-related liver injury indicators in the four groups was 10.7%, 27.3%, 14.0% and 50.4%, respectively (Table 3). Compared to the control group, the OR (95% CI) of abnormal alcohol-related liver injury indicators in the other groups was 3.156 (1.813-5.492,  $P = 0.000$ ), 1.367 (0.732-2.553,  $P = 0.325$ ), 8.534 (4.864-14.972,  $P = 0.000$ ), respectively (Table 4).

**Table 5 Dose-response to daily alcohol intake, drinking time and alcohol-related liver injury**

Characteristics	Total	ALI	$\chi^2$	P	OR (95%CI)	PR (%)	PR
Daily alcohol intake (g)							
< 20	373	45	-	-	-	12.06	1.00
20-40	76	25	20.817	0.000	3.573 (2.019-6.324)	32.89	2.73

ALI: Alcohol-related liver injury; PR (%): Prevalence rate; PR: Prevalence ratio.

Based on the duration of drinking and BMI, 175 subjects were assigned to control group (duration of drinking < 5 years and BMI < 25 kg/m<sup>2</sup>), 202 subjects to long-term drinking group (duration of drinking ≥ 5 years and BMI < 25 kg/m<sup>2</sup>), 118 to obese group (duration of drinking < 5 years and BMI ≥ 25 kg/m<sup>2</sup>), 158 to long-term drinking and obese group (duration of drinking ≥ 5 years and BMI ≥ 25 kg/m<sup>2</sup>). The prevalence rate of abnormal alcohol-related liver injury indicators in the four groups was 7.4%, 26.7%, 10.2% and 44.3%, respectively (Table 3). Compared to the control group, the OR (95% CI) of abnormal alcohol-related liver injury indicators in the other groups was 4.547 (2.385-8.668, P = 0.000), 1.411 (0.620-3.209, P = 0.410), 9.913(5.194-18.918, P = 0.000), respectively (Table 4).

**Dose-response relation of alcohol intake with alcohol-related liver injury**

Compared to the < 20 g daily alcohol intake group, the OR of abnormal alcohol-related liver injury indicators in the other groups ( daily alcohol intake was 20-40 g, 40-80 g, 80-160 g, ≥ 160 g, respectively) was 3.573 (P = 0.000), 4.278 (P = 0.000), 4.267 (P = 0.000), 5.371 (P = 0.000), respectively (Table 5). The prevalence rate of abnormal alcohol-related liver injury indicators in the other groups was 12.1%, 32.9%, 37.0%, 36.9%, 42.4%, respectively. Compared to the < 20 g daily alcohol intake group, the prevalence rate in the other groups was 2.73, 3.07, 3.06 and 3.52, respectively. Compared to the < 5 years drinking group, the OR of abnormal alcohol-related liver injury indicators in the other groups (drinking duration was 5-10 years, 10-20 years, 20-40 years, ≥ 40 years ) was 2.382 (P = 0.131), 6.551 (P = 0.000), 6.267 (P = 0.000), 4.535 (P = 0.000), respectively (Table 5). The prevalence rate of abnormal alcohol-related liver injury indicators in the other groups was 8.5%, 18.2%, 37.9%, 36.9%, 29.7%, respectively. Compared to the < 5 years drinking group, the prevalence ratio in the other groups was 2.13, 4.45, 4.32 and 3.49, respectively.

**Different types of alcoholic beverage and alcohol-related liver injury**

Of the 313 drinkers, 126 were beer drinkers, 36 yellow rice

**Table 6 Different types of alcoholic beverage and alcohol-related liver injury**

Type of beverage	Total	ALI (n, %)	Daily intake (g)	$\chi^2$	P
Beer	126	38 (30.16)	40.26 ± 31.35	-	-
Yellow rice wine	36	14 (38.89)	78.15 ± 57.88	0.979	0.322
Hard liquor	41	16 (39.02)	107.09 ± 84.38	1.111	0.292
Multiple	110	44 (40.00)	167.26 ± 109.60	2.509	0.113
Total	313	112 (35.78)			

ALI: Alcohol-related liver injury.

wine drinkers, 41 hard liquor drinkers and 110 multiple drinkers. The prevalence rate of abnormal alcohol-related liver injury indicators in these four kinds of drinkers was 30.2%, 38.9%, 39.0% and 40.0%, respectively. Compared to the beer drinkers, no significant difference was found in the prevalence rate of abnormal alcohol-related liver injury indicators among the other groups (Table 6).

**Analysis of obesity**

Obesity (BMI ≥ 25 kg/m<sup>2</sup>) was also found to be an important risk factor for liver injury (Tables 1 and 2). Multivariate stepwise logistic-regression analysis showed that the OR (95% CI) of abnormal alcohol-related liver injury indicators was 1.887 (1.261-2.824) in the BMI ≥ 25 kg/m<sup>2</sup> group compared to the BMI < 25 kg/m<sup>2</sup> group (Table2).

**DISCUSSION**

Liver is the major alcohol processing organ. Chronic heavy drinking induces liver injury and results in alcoholic liver disease, even irreversible alcoholic liver cirrhosis<sup>[20]</sup>. Since ALD has no specific clinical features<sup>[21]</sup> and no specific laboratory tests<sup>[14]</sup> are available for it, its diagnosis is currently based on drinking history, related laboratory assessments and imaging<sup>[16,22,23]</sup>. Certainly, liver biopsy is the gold standard for diagnosis of ALD<sup>[24]</sup>, but it is hard to use this invasive examination in population-based epidemiological surveys. Irie *et al*<sup>[11]</sup> found that GGT synthesis and protein expression are increased in ALD, leading to elevated serum levels of GGT

that are commonly noted in patients with the disease. Elevated GGT is somewhat more sensitive at 69%-73% with a specificity of 65%-80% for excessive alcohol consumption<sup>[25,26]</sup>. An elevated serum AST in relation to serum ALT has been proposed as an indicator of alcohol-induced organ damage<sup>[27]</sup>. It was reported that most patients with high alcohol consumption but without severe liver disease do not have an AST/ALT ratio above one. A high AST/ALT ratio suggests advanced alcoholic liver disease<sup>[13]</sup>. Therefore, we chose the GGT and AST/ALT ratio as the indicators of alcohol-related liver injury in this epidemiological survey.

In the present study, logistic-regression analysis demonstrated that daily alcohol intake  $\geq 20$  g, drinking time  $\geq 5$  years and obesity were important risks for abnormal alcohol-related liver injury indicators. The risk for abnormal alcohol-related liver injury indicators was 1.965-fold higher in the  $\geq 20$  g daily alcohol intake group than in the  $< 20$  g daily alcohol intake group, while the risk for abnormal alcohol-related liver injury indicators was 3.412-fold higher in the  $\geq 5$  years drinking group than in the  $< 5$  years drinking group. However, the risk thresholds of alcohol intake-induced alcoholic liver injury were different in different areas. No uniformed conclusion has been achieved in alcohol intake-induced alcoholic liver injury<sup>[28-32]</sup>. It was reported that even low alcohol level is a significant risk of developing liver disease<sup>[33]</sup>. Therefore, significant differences exist among different racial and ethnic groups and even in different individuals<sup>[34,35]</sup>. It has been shown that genotype of ethanol metabolizing enzyme genes in the Chinese population is different from Western population<sup>[36]</sup>. Therefore, genetic factors in the island population from East China need to be further studied.

As to the dose-response relation of alcohol intake and abnormal alcohol-related liver injury indicators, our results demonstrate that there was no significant dose-response relation between daily alcohol intake, drinking time and abnormal alcohol-related liver injury indicators. Kamper-Jorgensen *et al.*<sup>[37]</sup> showed that alcoholic threshold has a greater effect on the mortality of alcoholic cirrhosis.

Obesity is also an important risk factor for liver injury. In this study, logistic-regression analysis showed that the risk of obesity for abnormal alcohol-related liver injury indicators was 1.887. Some studies found that obesity is an independent risk factor for liver injury in alcohol drinkers<sup>[38-40]</sup>. In our study, the prevalence rate of alcohol-related liver injury in the non-obese group, non-excessive drinking or no long-term drinking group was lower than that in the obese group, excessive drinking group or long-term drinking group. The highest prevalence rate of alcohol-related liver injury was found in the obese and excessive drinking/long-term drinking group. There was a difference in the odds-ratio of abnormal alcohol-related liver injury indicators between the non-obese and excessive drinking/long-term drinking group, the obese and excessive drinking/long-term drinking group and control group ( $P < 0.05$ ), while was no difference in the odds-ratio of abnormal alcohol-related liver injury indicators between the obese and non-excessive drinking group and no long-

term drinking group, suggesting that the specificity of GGT and AST/ALT ratio can be used as the indicators of alcohol-related liver injury.

However, hepatotoxic consequences of obesity and ethanol ingestion have important prognostic implications and might be useful to formulate body mass index-based guidelines for "safe" alcohol consumption<sup>[41]</sup>.

No significant difference was found in the morbidity of abnormal alcohol-related liver injury indicators between the beer and other groups, suggesting that the types of alcoholic beverage are not closely related with abnormal alcohol-related liver injury indicators. Therefore, we believe that alcohol intake plays a more significant role in liver injury than the type of alcoholic beverage.

The island population from East China is a specific cluster of population. They feed themselves mainly on fishing and spend most of their time on sea-going ships. Although they consume a large amount of alcohol every day, their alcohol-related liver injury is not very severe. Most individuals in this area are alcohol drinkers. It was reported that treatment modalities aiming at reducing alcohol intake in alcohol-dependent patients include psychological, pharmacological and psychological therapies, but many patients benefit more from pharmacological therapy<sup>[42]</sup>. We believe that epidemiology study of the island population from East China is more important than that of the inland population. Certainly, it is more useful to analyze the differences in island and inland populations, including drinking habit, diet habit, living and working pressure, genotype, *etc.* ALD is governed by gene, environmental and psychological factors. We will continue to pay close attention to the island population from East China.

## ACKNOWLEDGMENTS

The authors thank Drs. Guo-Liang Ye and Hong-Tan Chen for their excellent assistance in this survey.

## COMMENTS

### Background

The island population from East China is a specific cluster of population. They consume a large amount of alcohol compared to the inland population. However, few population-based studies on alcoholic liver disease (ALD) are available from islands in China. We conducted a population-based case-control study to investigate the association of alcohol consumption, drinking time and obesity with liver injury in the island population from East China.

### Research frontiers

The association of alcohol consumption and drinking time with alcohol-related liver injury in the island population from East China was studied.

### Innovations and breakthroughs

The risk threshold of daily alcohol intake is 20 g and the drinking time that induces alcohol-related liver injury is 5 years in the island population from East China. Obesity-induced liver injury should also be concerned. Whether hepatotoxic consequences of obesity and alcohol ingestion are additive or synergistic is worthy to be further studied.

### Applications

The results are useful to analyze the differences in the island and inland

population, including drinking habit, diet habit, living and working pressure, genotype.

### Terminology

Gamma-glutamyltranspeptidase (GGT) and aspartate aminotransferase/alanine aminotransferase (AST/ALT) ratio are the characteristics of alcoholic liver disease (ALD). Abnormal alcohol-related liver injury indicators are defined based upon the condition that aspartate aminotransferase/alanine aminotransferase (AST>ALT) (ALT or AST exceeding the upper normal level) or GGT exceeding the upper normal level.

### Peer review

The paper describes the association of alcohol consumption and drinking time with alcohol-related liver injury in the island population from East China. The topic is highly interesting. The island population should be concerned in the follow-up research in future.

### Abstract

**AIM:** To evaluate the diagnostic value of endoscopy in patients with gastrointestinal graft-versus-host disease (GI GVHD).

**METHODS:** We identified 8 patients with GI GVHD following allogeneic hematopoietic stem cell transplantation (HSCT). GVHD was defined histologically as the presence of gland apoptosis, not explained by other inflammatory or infectious etiologies.

**RESULTS:** The symptoms of GI GVHD included anorexia, nausea, vomiting, watery diarrhea, abdominal pain, GI bleeding, *etc.* Upper endoscopic appearance varied from subtle mucosal edema, hyperemia, erythema to obvious erosion. Colonoscopic examination showed diffuse edema, hyperemia, patchy erosion, scattered ulcer, sloughing and active bleeding. Histological changes in GI GVHD included apoptosis of crypt epithelial cells, dropout of crypts, and lymphocytic infiltration in epithelium and lamina propria. The involvement of stomach and rectocolon varied from diffuse to focal.

**CONCLUSION:** Endoscopy may play a significant role in early diagnosis of GI GVHD patients following allogeneic HSCT, and histologic examination of gastrointestinal biopsies is needed to confirm the final diagnosis.

Xu CF, Zhu LX, Xu XM, Chen WC, Wu DP. Endoscopic diagnosis of gastrointestinal graft-versus-host disease. *World J Gastroenterol* 2008; 14(14): 2262-2267 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2262.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2262>

### INTRODUCTION

Allogeneic hematopoietic stem cell transplantation (HSCT) is increasingly performed for a variety of disorders, including acute and chronic leukemia, hematologic malignancies, and marrow failure states<sup>[1]</sup>. Graft-versus-host disease (GVHD) is the leading cause of morbidity and mortality after allogeneic HSCT<sup>[2,3]</sup>. Gastrointestinal (GI) complaints are relatively common within the first 100 d following allogeneic HSCT<sup>[4,5]</sup>. Although nausea, vomiting, anorexia and high-volume diarrhea are the common manifestations of GI GVHD, they may also be attributable to chemoradiation toxicity, medication side effects, or a variety of bacterial, fungal, viral infections. Thus, it is very difficult to establish the diagnosis of GI GVHD based on the clinical grounds alone<sup>[6]</sup>.

Endoscopy with biopsy has been shown to be accurate in the identification of GVHD. Although previous reports have documented a high yield for rectal biopsy<sup>[7,8]</sup>, upper GI biopsies are superior to rectal or rectosigmoid biopsies in the diagnosis of GVHD<sup>[9,10]</sup>. Thus further evaluation may be needed to establish the best diagnostic approach to GI GVHD.

Our aim in the present study was to demonstrate the endoscopic and histological features of GI GVHD. Eight patients with proven GI GVHD were included in the study, and we intended to evaluate the significance of endoscopy and biopsy in the diagnosis of GI-GVHD.

### MATERIALS AND METHODS

#### Patients

From January 2002 to December 2006, eight patients with suspected GI GVHD 20 d following allogeneic HSCT at the First Affiliated Hospital of Soochow University were enrolled in this study. All patients were interviewed and the following data were recorded: age, gender, underlying disease and transplantation type, stool per day, stool volume, nausea, vomiting, diarrhea, anorexia, gastrointestinal bleeding and skin rash. Laboratory studies including liver chemistry tests were also recorded. Routine

Table 1 Characteristics of patients with GVHD

Case No./Sex/Age	Diagnosis	Conditioning regimens	Donor HLA match	GVHD prophylaxis	Stage grading

HLA: Human leucocyte antigen.

stool examination and bacterial culture were performed for all patients. Cytomegalovirus (CMV) antigenemia was monitored twice weekly after conditioning regimens.

### Histocompatibility and stem cell source

One patient with acute myeloid leukemia (AML) underwent 2-locus mismatched unrelated donor transplant. Four patients with chronic myeloid leukemia (CML) were recipients of a matched related donor (MRD) transplant. Three patients with acute lymphoblastic leukemia (ALL) received haploid related donor transplant. Peripheral blood hematopoietic stem cells were collected from donors in all but one case. One case with AML had hematopoietic stem cells harvested from bone marrow through Taiwan Marrow Donor Registry.

### Conditioning regimen and GVHD prophylaxis

Following conditioning regimens were used: BuCy (busulfan 4 mg/kg per day for 4 d and cyclophosphamide 60 mg/kg per day for 2 d) for standard transplantation in patients 1, 3 and 4; Bu-Fludara-ATG (antihuman thymocyte globulin) (busulfan 4 mg/kg per day for 2 d, fludarabine 30 mg/m<sup>2</sup> per day for 6 d, and antithymocyte globulin 2.5 mg/kg per day for 4 d) for non-myeloablative transplantation in patients 2, 5; Me-CCNU (semustine)-TBI (total body radiation)-Cy (Me-CCNU 250 mg/m<sup>2</sup>, -d<sub>8</sub>; TBI 8Gy, -d; Ara-C (arabinosylcytosin) 4 g/m<sup>2</sup>, -d<sub>6</sub>, -d<sub>5</sub>; Cy 1.8 g/m<sup>2</sup>, -d<sub>4</sub>, -d<sub>3</sub>) for all ALL patients.

All patients received cyclosporine A (CSA) with short-course MTX (methotrexate) for the prophylaxis of GVHD. For patient 1 who underwent 2-locus mismatched unrelated transplantation, ATG and MMF (mycophenolic mofetil) were added. Treatment for patients with ALL was intensified and prolonged by using the combination of cyclosporine A, MMF, ATG and anti-CD25 antibody for GVHD prophylaxis.

### Diagnostic criteria and GVHD grading system

GI GVHD could be diagnosed according to its clinical manifestations, endoscopic appearance and histopathological evaluation. Medication-induced side effects, chemoradiation toxicity or GI infections must be excluded. Specific histological criteria could establish the diagnosis of GI GVHD. Focal dropout and apoptosis of GI crypt epithelial cells are usually regarded as golden standard to diagnose GVHD. Acute GVHD

(aGVHD) is defined as occurring within 20 to 100 d after transplantation and chronic GVHD (cGVHD) occurring 100 d after transplantation<sup>[5]</sup>. A clinical grading system based upon the degree of involvement for each of the organ systems was originally developed by investigators in Seattle<sup>[2]</sup>: (1) grade I: 500-1000 cc stool/d, accompanied with anorexia and vomiting; (2) grade II: 1000-1500 cc stool/d, histologically proven GVHD by endoscopic biopsies; (3) grade III: 1500-2000 cc stool/d; (4) grade IV: over 2000 cc stool/d, accompanied with ileus and severe abdominal pain.

### Gastrointestinal endoscopy and biopsy

If patients had persistent unexplained GI symptoms (diarrhea, nausea, vomiting, anorexia, abdominal pain or gastrointestinal bleeding) after transplantation, then upper endoscopy and/or colonoscopy were performed. Upper endoscopy with gastric biopsies of both antrum and body were performed in one patient, colonoscopy was performed with multiple biopsies of the ileum, right colon and rectosigmoid colon in 6 patients. A combination of upper endoscopy with colonoscopy and multiple biopsies was performed in another patient. For each patient, biopsies were systematically performed in the GI tract, two of which were transmitted to the microbiology department and studied further for bacterial, viral, or fungal pathogens. Another two biopsy specimens were immediately snap-frozen in liquid nitrogen and used for CMV immunohistochemical study. The remaining two biopsy specimens were fixed in formaldehyde, and further processed for paraffin embedding. Paraffin blocks were sectioned at 4 µm and stained with hematoxylin and eosin for routine histopathological examination.

## RESULTS

### Clinical presentation of GVHD

Of the eight patients, two developed grade III acute GI GVHD, and four grade IV acute GI GVHD, the remaining suffered from limited chronic GI GVHD. Detailed data are listed in Table 1. The clinical manifestations of upper GI GVHD included nausea, vomiting, anorexia, and abdominal pain. Lower GI symptoms manifested as voluminous secretory diarrhea accompanied with abdominal bloating or pain. Three patients had intestinal bleeding, and only one patient had gastric bleeding (Table 2).

Table 2 Gastrointestinal symptoms of patients with GI GVHD

Case No. /Sex/Age	Nausea	Vomiting	Anorexia	Abdominal pain	Diarrhea	Gastrointestinal bleeding
1/F/29	+	+	+	+	+	+
2/M/47	+	+	+	-	-	-
3/M/39	-	-	-	-	+	+
4/M/23	+	+	-	+	+	+
5/M/63	-	-	-	+	+	-
6/F/35	+	-	-	+	+	+
7/M/42	+	-	+	+	+	-
8/F/23	+	+	-	-	+	-

### Endoscopic findings

The endoscopic findings varied greatly. The first endoscopy for patient 1 with grade IV acute GVHD showed diffuse erythema with mucosal oozing in the antrum and body of the stomach (Figure 1A). Because nausea, vomiting, melena and hematemesis persisted despite empiric treatment, emergency upper endoscopy and biopsy were repeated 1 wk later. The endoscopic appearance revealed a pale mucosal surface with reticulated submucosal small vessels accompanied with erosion and erythema in the antrum (Figure 1B). For the same patient, colonoscopy was performed after gastric bleeding was controlled, and disclosed extensive mucosal hyperemia and edema in the colon. In patient 2 with chronic GI GVHD, the upper endoscopic examination showed subtle mucosal edema with erythema in the antrum, but the appearance of the esophagus and duodenum was grossly normal. In patient 3 with chronic GVHD five months after transplantation, colonoscopic examination disclosed hemorrhagic spots, patchy erosions, and active bleeding. Patients 4, 5 and 6 showed similar diffuse damages, namely widespread erythema, multiple erosions and small ulcer. Two of the three patients had active bleeding in the colon (Figure 2A). Hemorrhagic spots and multiple shallow ulcers could be detected on the surface of rectocolon (Figure 2B). Patients 7 and 8 demonstrated widespread edema, erythema with multiple erosions without active bleeding in the total rectocolon.

### Pathologic findings

In patient 1, histologic examination of gastric biopsy specimens showed focal dropout of crypt epithelial cells, variable lymphocytic infiltration of the epithelium and lamina propria, and colonic biopsies showed nonspecific inflammation. Gastric biopsies disclosed a crypt with multiple apoptotic cells in patient 2. Extensive mucosal erosions, shallow ulcer, sloughing and apoptosis of epithelial cells were found in patient 3. Extensive colonic mucosal erosion and necrosis were observed in patients 4 and 5, and biopsies of the colon in these patients showed clear histological evidence of acute GVHD. Biopsy specimens from patients 6, 7 and 8 illustrated numerous apoptotic bodies in crypts, and small lymphocytic infiltration of the adjacent lamina propria. CMV infection was not confirmed on biopsy specimens from seven patients by immunohistochemical study except for one patient with HLA 2-locus mismatched, in which colonic mucosa was weakly positive, but late antigen was negative

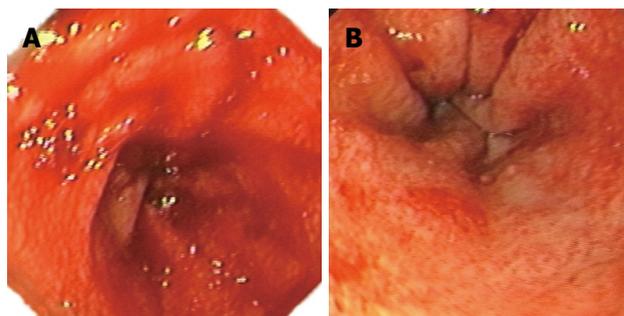

Figure 1 Upper endoscopy showing diffuse and active bleeding in the antrum and body of stomach 160 d after allo-BMT (A) and reticulated submucosal small vessels accompanied with erosion and erythema in the antrum 175 d after allo-BMT (B) in patient 1 with AML.

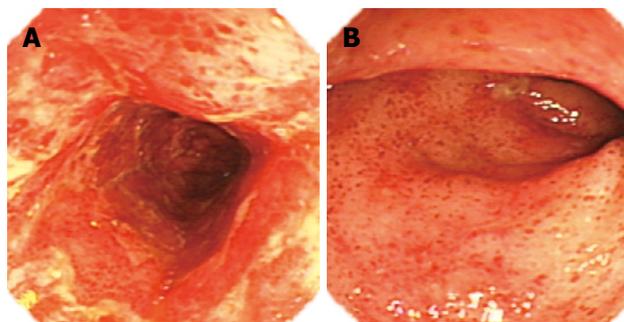

Figure 2 Colonoscopy disclosing mucosal erythema, severe erosions, multiple oozing and sloughing in ascending colon (A) and extensive hemorrhagic spots, patchy erosions, and focal shallow ulcers in the rectum (B) in patient 4 with CML 90 d after allo-HSCT.

205 d after transplantation. Because this patient had concomitantly severe GI GVHD and skin involvement 24 d after allogeneic bone marrow transplantation (BMT), GI GVHD coexisted with CMV infection.

## DISCUSSION

GVHD is the leading cause of morbidity and mortality after allogeneic HSCT, occurring in up to 75% of patients<sup>[11]</sup>. According to the degree of involvement in each of the organ systems, acute GVHD can be clinically classified as grades I-IV. High risk factors include HLA disparity, unrelated-donor transplantation, donor-recipient gender difference, old age, and infection<sup>[12]</sup>. In the present study, one young female patient who underwent two-locus HLA-mismatched unrelated BMT suffered from grade IV acute GI GVHD 24 d after transplantation.

The principal organs with involvement of acute GI GVHD include stomach, small intestine, and rectocolon<sup>[13]</sup>, but esophageal acute GVHD is uncommon<sup>[14,15]</sup>. Roy *et al*<sup>[10]</sup> found that GVHD limited to the upper GI tract accounts for 18% of patients, GVHD involving the lower and upper GI tract accounts for 10%, and 26% of patients. The most prominent symptoms of GVHD involving the upper GI tract are anorexia, dyspepsia, nausea, vomiting, and, occasionally, abdominal pain<sup>[16]</sup>. Lower GI GVHD manifests as voluminous watery diarrhea (typically secretory in nature) accompanied with abdominal bloating,

ileus, and occasionally overt intestinal bleeding<sup>[17,18]</sup>. In contrast to acute GI GVHD, chronic GI GVHD differs markedly in distribution and histopathology. Esophageal involvement of chronic GI GVHD is not uncommon, but the stomach and intestine are rarely involved<sup>[19]</sup>.

In the present study, colonoscopy disclosed scattered hemorrhagic spots and mucosal erosion in one patient with chronic GVHD.

Obviously, clinical manifestations of GI GVHD are nonspecific. There is a wide overlap of symptoms with many GI diseases. Toxicity from the regimen of cytoreductive therapy given before transplantation can cause symptoms of anorexia, nausea, vomiting, all of which are also characteristic of GVHD<sup>[2,20]</sup>. For most conditioning regimens, this variable is less important 20 d after transplantation, when toxicity to intestinal mucosa has largely resolved. A variety of bacterial, fungal and viral infections may affect the diagnosis of GI GVHD. Clinical manifestations of intestinal bacterial infection are mainly bloody stool and pathogenic bacteria can be confirmed from excreta. Endoscopy can also disclose mucosal erosion and pus moss. Fungal infections of the GI tract have become unusual since the routine use of prophylactic fluconazole, and fungus can be identified by examining stool specimens. In addition, since clinical symptoms of enteric CMV infection can resemble GVHD, all patients must undergo viral surveillance. Histologic identification of CMV infection is less sensitive than viral culture. Therefore, viral immunohistology and culture should be done if the patient is at a high risk for CMV infection. For more sensitive detection of CMV reactivation, polymerase chain reaction is also recommended<sup>[21,22]</sup>.

As stated previously, patients with and without GI GVHD cannot be distinguished based entirely upon clinical findings. Accurate and timely diagnosis is essential, as early recognition and intervention may significantly improve the outcome<sup>[23,24]</sup>. Endoscopy combined with tissue biopsy is usually required to establish the diagnosis of acute GI GVHD. In a retrospective study, Terdiman and colleague<sup>[25]</sup> confirmed that acute upper GI GVHD is sensitive to many drugs if early diagnosis could be properly made. While treatment fails, upper GI GVHD may progress to lower GI. Therefore, upper GI GVHD is an early event. Our study revealed that upper endoscopic appearance of GVHD ranged from normal mucosa to erythema, erosion, ulceration and active bleeding. Normal endoscopic examinations have been reported in up to 21% of patients with histologically confirmed acute GVHD<sup>[20]</sup>. Sloughing of the mucosa is uncommon but high specific<sup>[26]</sup>. It is noted that discordance may be seen in different regions of the gut. In the present study, mucosal lesions in the antrum and body were more severe than those in the fundus and duodenum, whereas the esophagus was less involved.

Enteric acute GVHD exhibits diffuse hyperemia, edema, erosion, and slough of mucosa, which can resemble severe ulcerative colitis<sup>[27]</sup>. In the present study, the grossly visible mucosal damage was uneven in distribution, sometimes appearing severely abnormal in one area while being unremarkable at other locations.

Since endoscopic appearance of GVHD is also

nonspecific, endoscopic diagnosis cannot replace histopathological examinations. At present, endoscopy with biopsies remains the gold standard for the diagnosis of acute GI GVHD<sup>[2]</sup>. Histological criteria for GVHD are the presence of epithelial single-cell apoptosis and crypt cell dropout<sup>[28]</sup>. However, the reported mucosal site with the highest diagnostic yield (upper and/or lower) varies in studies. In a prospective study of HSCT patients with diarrhea and upper GI symptoms, Cox and his companies<sup>[29]</sup> discovered that the positive rate of gastric mucosal biopsies was 85% in 29 GVHD patients who were confirmed by histopathology and 58% in biopsies from duodenum and rectum-sigmoid colon. In another prospective study of 24 patients undergoing both upper and lower endoscopy<sup>[23]</sup>, biopsies were obtained from the stomach, duodenum, ileum, right and rectosigmoid colon, while the biopsy site with the highest yield was the distal colon (82%), and a combination of upper endoscopy with sigmoidoscopy and colonoscopy with ileal biopsies was equivalent (94%), suggesting that multiple biopsies should be obtained from stomach, duodenum, and rectum-sigmoid colon, in order to improve the accuracy and sensitivity of diagnosis. Many factors (chemoradiation toxicity, medication side effects, particularly CMV infection), can interfere with the histologic interpretation. Proton pump inhibitor (PPI) therapy is associated with increased apoptosis in antral biopsies. Biopsy from gastric fundus rather than from antrum may be preferable for the diagnosis of upper GI GVHD<sup>[3]</sup>. It is, therefore, important to rule out these factors in making a histologic diagnosis of GVHD after transplantation.

There is a discrepancy between endoscopic and histologic assessments of the severity of the disease<sup>[29]</sup>. Mucosal edema and erythema that are endoscopically impressive will be subtle when corresponding biopsies are assessed microscopically. In contrast, normal mucosa may display focal crypt epithelial apoptosis characteristic of GVHD. Thus, the correlation between endoscopic and histologic findings requires further investigation.

A clinical grading system based on the degree of lower GI symptoms (diarrhea volume, *etc*) does not consider the upper GI symptoms and endoscopic findings. Thus, an alternative, revised grading system needs to be proposed that takes into account the upper GI symptoms and endoscopic findings.

Roy *et al*<sup>[7]</sup> showed upper GI involvement is more common than lower GI in patients with GVHD confirmed by skin biopsy. Weisdorf *et al*<sup>[30]</sup> also confirmed that 59.7% of patients with GI GVHD have skin GVHD. Therefore, endoscopy with tissue biopsies may acquire positive results in patients with negative skin biopsies. It is noted that GI GVHD is not correlated with hepatic venous occlusion diseases (VOD).

It was reported that endoscopic examination is usually safe for patients with GVHD or occasional intestinal perforation, and oozing at the biopsy site due to thrombocytopenia<sup>[27]</sup>. Thus, a platelet count of more than  $50 \times 10^9/L$  is needed before endoscopic examination.

Because of the lack of sufficient samples, diagnostic endoscopic findings need further evaluation. In addition, endoscopists should cooperate with specialists in bone

marrow transplantation to standardize the biopsy location and the number of specimens, method and time to undertake gastroscopy and/or colonoscopy<sup>[23]</sup>.

In summary, endoscopic findings are highly variable in diagnosis of GI GVHD. There is a discrepancy between endoscopic and histologic assessments of the severity of GI GVHD. Gastrointestinal biopsies are needed to confirm the diagnosis of GI GVHD.

## COMMENTS

### Background

Allogeneic hematopoietic stem cell transplantation (HSCT) is increasingly performed for a variety of disorders, such as acute and chronic leukemia, but many patients undergoing HSCT develop acute graft-versus-host disease (GVHD). GVHD involving the gastrointestinal (GI) tract is common, but it is difficult to establish the diagnosis of GI GVHD because of the nonspecific GI symptoms. Recognition of GI GVHD is critical for directing its specific therapy.

### Research frontiers

The diagnosis of GI GVHD often depends on an endoscopic evaluation. The endoscopic appearance of GI GVHD can range from normal to mild edema or erythema to dramatic mucosal slough, but the mucosal damage caused by chemoradiation toxicity, side effects of medications, and enteric infections with viruses, bacteria, and fungi may occur. Although endoscopy with biopsy is commonly used in the evaluation of suspected GI GVHD, the best diagnostic approach remains undefined.

### Innovations and breakthroughs

There is no standardized protocol for upper or lower endoscopy, biopsy number and location. This study demonstrated that endoscopic examinations and histologic evaluation of biopsies could be used to diagnose GI GVHD. There is a discrepancy between endoscopic and histologic assessments of the severity of GI GVHD.

### Applications

The present study further demonstrated the endoscopic role in diagnosing GI GVHD in patients following allogeneic HSCT, and histologic examination of GI biopsies is needed to confirm the final diagnosis.

### Terminology

GVHD: a condition that occurs following bone marrow transplantation or peripheral blood stem cell transplantation, in which lymphocytes from the graft attack specific tissues in the host. The skin, gut, and liver are the most severely affected. Drugs that suppress the immune reaction, such as steroids and cyclosporin A, reduce the severity of rejection.

### Peer review

The present study reported eight patients with proven GI GVHD and demonstrated the role of endoscopic examinations and histologic evaluation of biopsies in diagnosing GI GVHD, which is very important in clinical practice.

## Abstract

We describe the case of a 68-year-old otherwise healthy male who presented to our emergency room with signs and symptoms of acute appendicitis. Exploratory surgery revealed a normal appendix. Further examination revealed an enlarged lymph node-like mass of tissue near the appendix, in the ileocecal mesentery. This mass was removed and was found to be inflamed heterotopic gastric tissue. Although reports of heterotopic gastric tissue in the literature are common, we believe that this case represents the first report of inflamed heterotopic gastric tissue simulating appendicitis.

## INTRODUCTION

Reports of the occurrence of heterotopic gastric tissue in the medical literature are common. Von Radhen *et al*<sup>[1]</sup> and Steele *et al*<sup>[2]</sup> have recently published case reports that included extensive reviews of the literature on this topic. Heterotopic gastric mucosa has been described in the esophagus and in the oral cavity, as a polyp in the distal ileum, as a mass in the rectum and anus, in the scrotum,

in the hepatobiliary system, including the gallbladder and common bile duct, in the mediastinum and in the spinal cord. Typically heterotopic gastric tissue is asymptomatic. In contrast, we present a report of gastric heterotopia in a patient who presented at our institution with signs and symptoms of acute appendicitis. To our knowledge, this presentation of heterotopic gastric mucosa is unique to the medical literature.

## CASE REPORT

The patient was a previously healthy 68-year-old male whose past medical history was significant only for benign prostatic hypertrophy treated with Cardura. He presented to the emergency room with approximately 6 h of right lower quadrant pain and nausea. The pain had started in the peri-umbilical area and had localized to the right lower quadrant by the time of his presentation. The patient denied having had this type of pain previously. On examination, the patient was tender in the right lower quadrant with voluntary guarding and a positive obturator sign. His white blood cell count was 10000 with 89% granulocytes. His abdominal films showed a mild ileus pattern with no evidence of obstruction or free air.

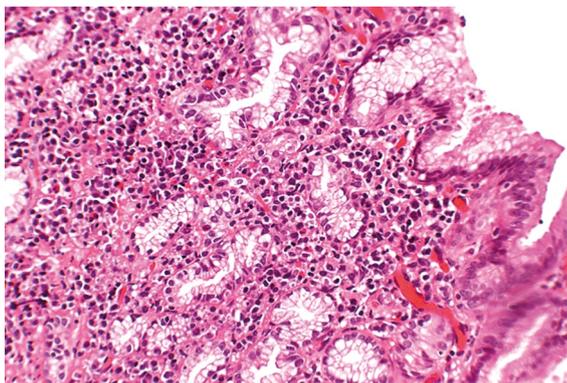

The patient was taken to the operative suite and explored through a McBurney incision. A small amount of straw colored ascites was found upon entrance to the abdomen. The appendix was exceptionally long. However, it did not show any signs of inflammation. However, near the appendix, in the ileocecal mesentery, there was what appeared to be an enlarged, inflamed lymph node. This tissue was removed and sent to pathology for permanent stains. There was no evidence of a Meckel's diverticulum upon examination of the distal two feet of ileum. The right colon was otherwise normal in appearance and by palpation.

The tissue that had been thought to be an enlarged, inflamed lymph node was removed and established by pathology to be gastric heterotopic tissue with evidence of inflammation/gastritis (Figure 1).

Postoperatively, the patient's pain resolved. He was maintained on Prevacid (30 mg once daily) due to the concern that he might have additional areas of gastric heterotopic tissue. However, a technetium-99 scan did not show any areas of uptake postoperatively and he remains asymptomatic three years postoperatively.

## DISCUSSION

We are presenting what we believe to be the first case of

**Figure 1** Gastric heterotopic tissue with evidence of inflammation/gastritis.

extraintestinal heterotopic gastric tissue with inflammation simulating appendicitis. The 2004 literature review by von Rahden *et al*<sup>[1]</sup> noted that heterotopic gastric mucosa has been found in the upper esophagus where it can lead to inflammation and esophageal webbing. A heterotopic gastric mucosa has also been found in Meckel's diverticula. According to Cserni<sup>[3]</sup> the reflux-type gastritis or gastropathy in Meckel's diverticula may account for some symptoms that have prompted removal of appendixes without inflammation.

The authors have searched the literature for similar cases simulating appendicitis using search terms including (ectopic or heterotopic) and (gastric or stomach) and (abdominal pain). Case reports were found that reported patients with abdominal pain due to gastric mucosa in the gall bladder or rectum, but these were not characterized as simulating appendicitis.

Stelle *et al*<sup>[2]</sup> describes the two prominent theories regarding the origin of gastric heterotopic tissue. One suggests that this is congenitally displaced tissue and it therefore represents choristomas. Another leading theory suggests that the tissue originates from irregular differentiation of multipotential cells rather than displaced embryonic cells.

Regardless of the origin of the tissue, the tissue is

known to consist of gastric parietal cells capable of secreting a physiologically effective amount of acid leading to inflammation and occasionally to ulceration. Cserni<sup>[3]</sup> notes that in most cases, the pathology does not yield evidence of *H pylori* organisms. There was no sign of *H pylori* in our specimen.

In conclusion we present what we believe to be the first case of extraintestinal gastric heterotopic tissue simulating appendicitis. We suggest that extraintestinal gastric heterotopia be added to the list of differential diagnoses in patients with acute abdominal pain.

## COMMENTS

### Background

There are no cases reported in the literature wherein heterotopic gastric tissue is described as simulating acute appendicitis.

### Innovations and breakthroughs

This is new information that describes a unique presentation of heterotopic gastric tissue.

### Applications

Although rare, heterotopic gastric tissue could explain pain simulating appendicitis.

### Terminology

Heterotopic means located in an atypical position.

### Peer review

This is a case report of extraintestinal heterotopic gastric tissue simulating appendicitis. It's very interesting and worth reporting.

eosinophilic infiltration of one or more areas of the gastrointestinal tract, without evidence of parasitic or extra-intestinal disease<sup>[1]</sup>. It can be idiopathic, related to food allergies, infections, and rarely infantile inflammatory bowel disease<sup>[2]</sup>. A very rare complication of this entity is distal gastritis leading to gastric outlet obstruction that has been reported to occur in infancy accompanying, mimicking or generating hypertrophic pyloric stenosis<sup>[3,4]</sup> and in adults<sup>[5,6]</sup>, but has not been described in children as an isolated manifestation of EG. Most commonly patients with eosinophilic gastric outlet obstruction have been treated surgically<sup>[3,5,7]</sup> except for a few infantile cases where protein hydrolysate formula<sup>[2]</sup> or steroid therapy<sup>[4,8]</sup> has been used. Resolution of symptoms with steroid treatment has recently been demonstrated in an adult case also<sup>[6]</sup>. We report a 2 and half-year-old Caucasian girl with eosinophilic gastric outlet obstruction treated successfully with steroids.

### Abstract

Gastric outlet obstruction is a rare complication of eosinophilic gastroenteritis, most commonly treated surgically. We report a case of eosinophilic gastric outlet obstruction in a child that responded to conservative medical management. A brief review of this clinical entity is also provided.

### CASE REPORT

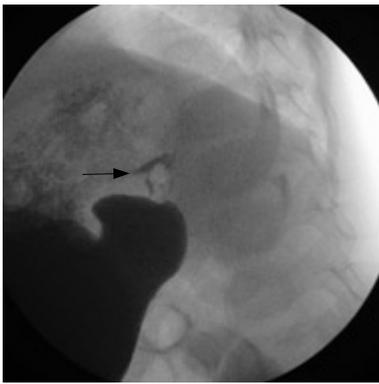

The previously healthy girl presented after a 3-mo history of worsening postprandial emesis leading to an inability to tolerate feedings. She had no history of atopy or diet change. She had 0.08 eosinophils ( $740 \times 10^6/L$ ) on peripheral blood count, but was not anemic nor hypoalbuminemic. IgE level was normal. Upper gastrointestinal imaging showed marked pyloric narrowing (Figure 1). Endoscopy revealed antral edema and severe pyloric stenosis through which a Pentax 2470 endoscope (8.0 mm diameter) could not be passed. Biopsies from this area were consistent with eosinophilic gastritis (Figure 2A). Methylprednisolone (2 mg/kg per day) was started and she began tolerating liquids within two days. Endoscopy five days later revealed decreased pyloric swelling and the endoscope could be passed through the pylorus. No pyloric ulceration was seen and the duodenum appeared normal. Antral and pyloric mucosal biopsies showed resolution of the eosinophilic cellular infiltrate (Figure 2B). She was advanced to a low roughage diet within a few days, switched to oral prednisolone therapy (0.5 mg/kg per day) and discharged home. The steroids were weaned and discontinued after 8 weeks of treatment. She remained symptom free six months following the cessation of steroids.

### INTRODUCTION

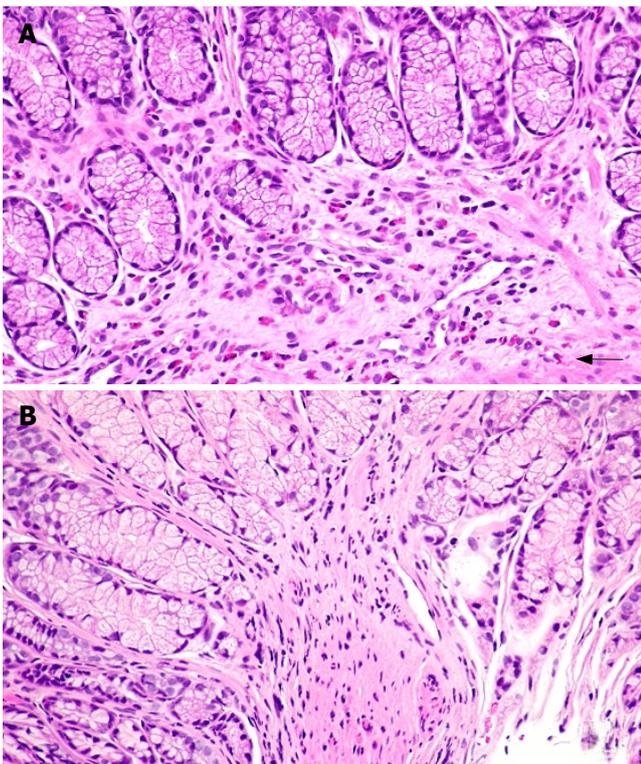

Eosinophilic gastroenteritis or gastroenteropathy (EG) is defined by variable gastrointestinal symptoms and

### DISCUSSION

Reported clinical manifestations of eosinophilic gastroenteritis include obstruction at various levels of the

**Figure 1** Upper gastrointestinal image of the patient. Note the minimal advancement of the contrast material through the pylorus (arrow).

**Figure 2** Histologic images before and 5 d after steroid therapy. **A:** Peripyloric antral sections showed prominent eosinophilic infiltration of the lamina propria (up to 30 eosinophils per single high power field), with occasional degranulation (arrow) of eosinophilic content and infiltration of the muscularis mucosae; **B:** Biopsies 5 d after intravenous steroid therapy demonstrated only a few eosinophils with a peak count of 2 eosinophils per high power field (HE, x 40).

gastrointestinal tract, growth failure, weight loss, anemia, melena, diarrhea, protein losing enteropathy, abdominal pain, pseudo-Crohn's disease, esophagitis, and eosinophilic ascites<sup>[9]</sup>. On rare instances EG can even be complicated

by gastrointestinal perforation<sup>[10]</sup>. While eosinophilic inflammation leading to pyloric stenosis and gastric outlet obstruction has been reported in adults and infants, it has not been described in children (pediatric patients more than 2 years of age) as a localized manifestation of EG to our knowledge. We could only identify one earlier case of antral web related gastric outlet obstruction that was complicated by eosinophilic inflammation in a 3-years-old child<sup>[11]</sup>. Our patient responded briskly to steroid therapy and has remained asymptomatic for more than six months off therapy. Similar clinical response has been recorded earlier in infants with the same condition<sup>[4,8]</sup> and very recently in an adult<sup>[6]</sup>. However, in several instances resolution of the eosinophilic inflammation can be protracted and the course of the disease may wax and wane<sup>[4,10]</sup>. Nevertheless, we conclude that steroid therapy should be considered in cases of eosinophilic gastric outlet obstruction prior to surgical interventions in all age groups.

### Abstract

Ischemic injury to the bowel is a well known disease entity that has a wide spectrum of pathological and clinical findings. A sudden drop in the colonic blood supply is essential to its development. We encountered a 41-year-old male patient, who presented with abdominal pain and bloody diarrhea. A colonoscopy showed markedly edematous mucosa with tortuous dilatation of the veins and a deep ulceration at the rectosigmoid junction. On an abdominal computed tomography (CT) scan and CT angiography, the mesenteric and splenic veins were absent with numerous venous collaterals for drainage. The patient gradually responded to oral aminosalicylate therapy, and was in remission after nine months. In most cases, non-occlusive ischemic injury is caused by idiopathic form and occlusive ischemia is caused by abnormalities of arteries and acute venous thrombosis. However, chronic venous insufficiency due to obstruction of macrovascular mesenteric vein rarely causes ischemia of the bowel. This report describes the first case of ischemic colitis caused by obstruction of the mesenteric and splenic veins.

Ischemic colitis due to obstruction of mesenteric and splenic veins: A case report. *World J Gastroenterol* 2008; 14(14): 2272-2276 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2272.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2272>

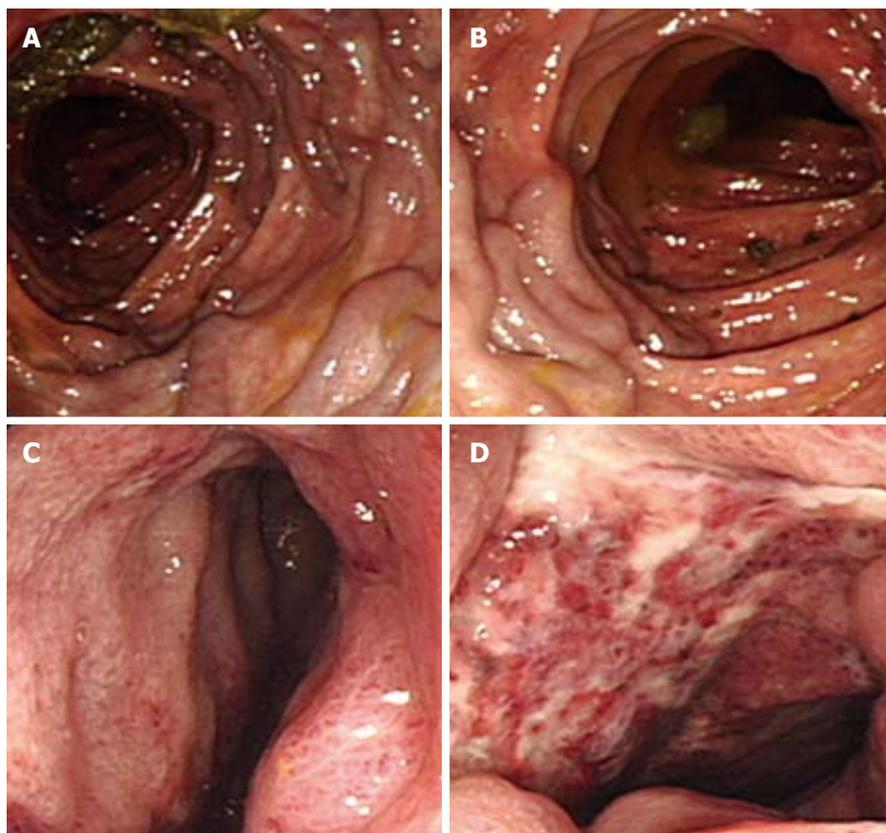

### INTRODUCTION

Ischemic colitis is the most common ischemic injury of the gastrointestinal tract. Although it can occur at any age, approximately 90% of the patients were over 60 years of age<sup>[1]</sup>. It is usually self-limited and is often called transient ischemic colitis.

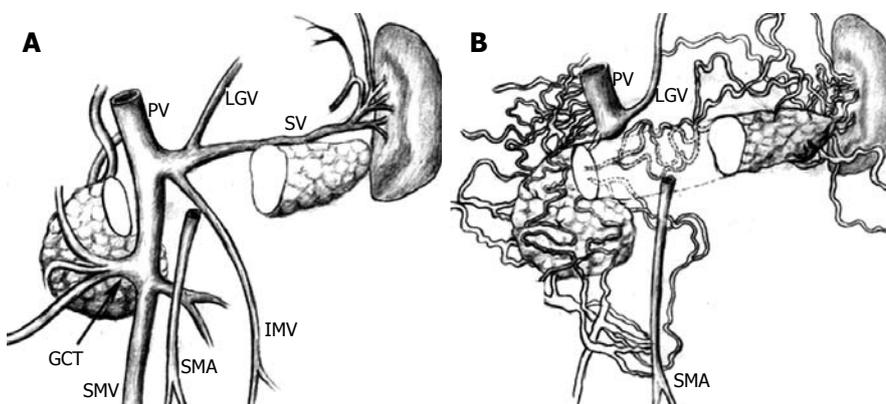

We encountered a 41-year-old male patient, who presented with abdominal pain and bloody diarrhea, and had been diagnosed as having ulcerative colitis. The colonoscopy showed ulcerative colitis, but the rectum was spared from inflammation. Corticosteroids did not relieve the disease, but aggravated the symptoms. On an abdominal computed tomography (CT) scan and CT angiography, the mesenteric and splenic veins were absent with numerous venous collaterals for drainage. The final diagnosis was ischemic colitis with obstruction of the mesenteric and splenic veins. In this report, we describe this unusual case of ischemic colitis caused by chronic venous insufficiency.

### CASE REPORT

A 41-year-old man, a Bangladeshi migrant worker in Korea, was admitted to our hospital with a three-year history of lower abdominal pain and bloody diarrhea. He was diagnosed with ulcerative colitis, treated with oral corticosteroids in an outside clinic, and referred to our facility for further evaluation. The physical examination was remarkable for lower abdominal tenderness without rebound. A routine blood analysis revealed a slightly decreased level of hemoglobin (109 g/L), hematocrit (33.8%), white cell count ( $14.12 \times 10^9/L$ ) and platelets ( $106 \times 10^9/L$ ). Urea and electrolytes, glucose, amylase and liver function were normal but the patient had a slightly raised level of C-reactive protein (6.7 mg/L). The patient was presumed to have ulcerative colitis with moderate to severe activity and was treated with corticosteroids. After 48 hours, he underwent a flexible sigmoidoscopy, which showed a 3-cm sized deep ulceration at the rectosigmoid junction, and friable mucosa in a diffuse circumferential distribution. Severe colitis with superimposed infection was

**Figure 1** Colonoscopic findings. **A, B:** Tortuous and dilated submucosal veins in the colonic mucosa; **C:** Diffuse and edematous mucosa with fine granularity resembling ulcerative colitis; **D:** A deep ulceration at rectosigmoid junction.

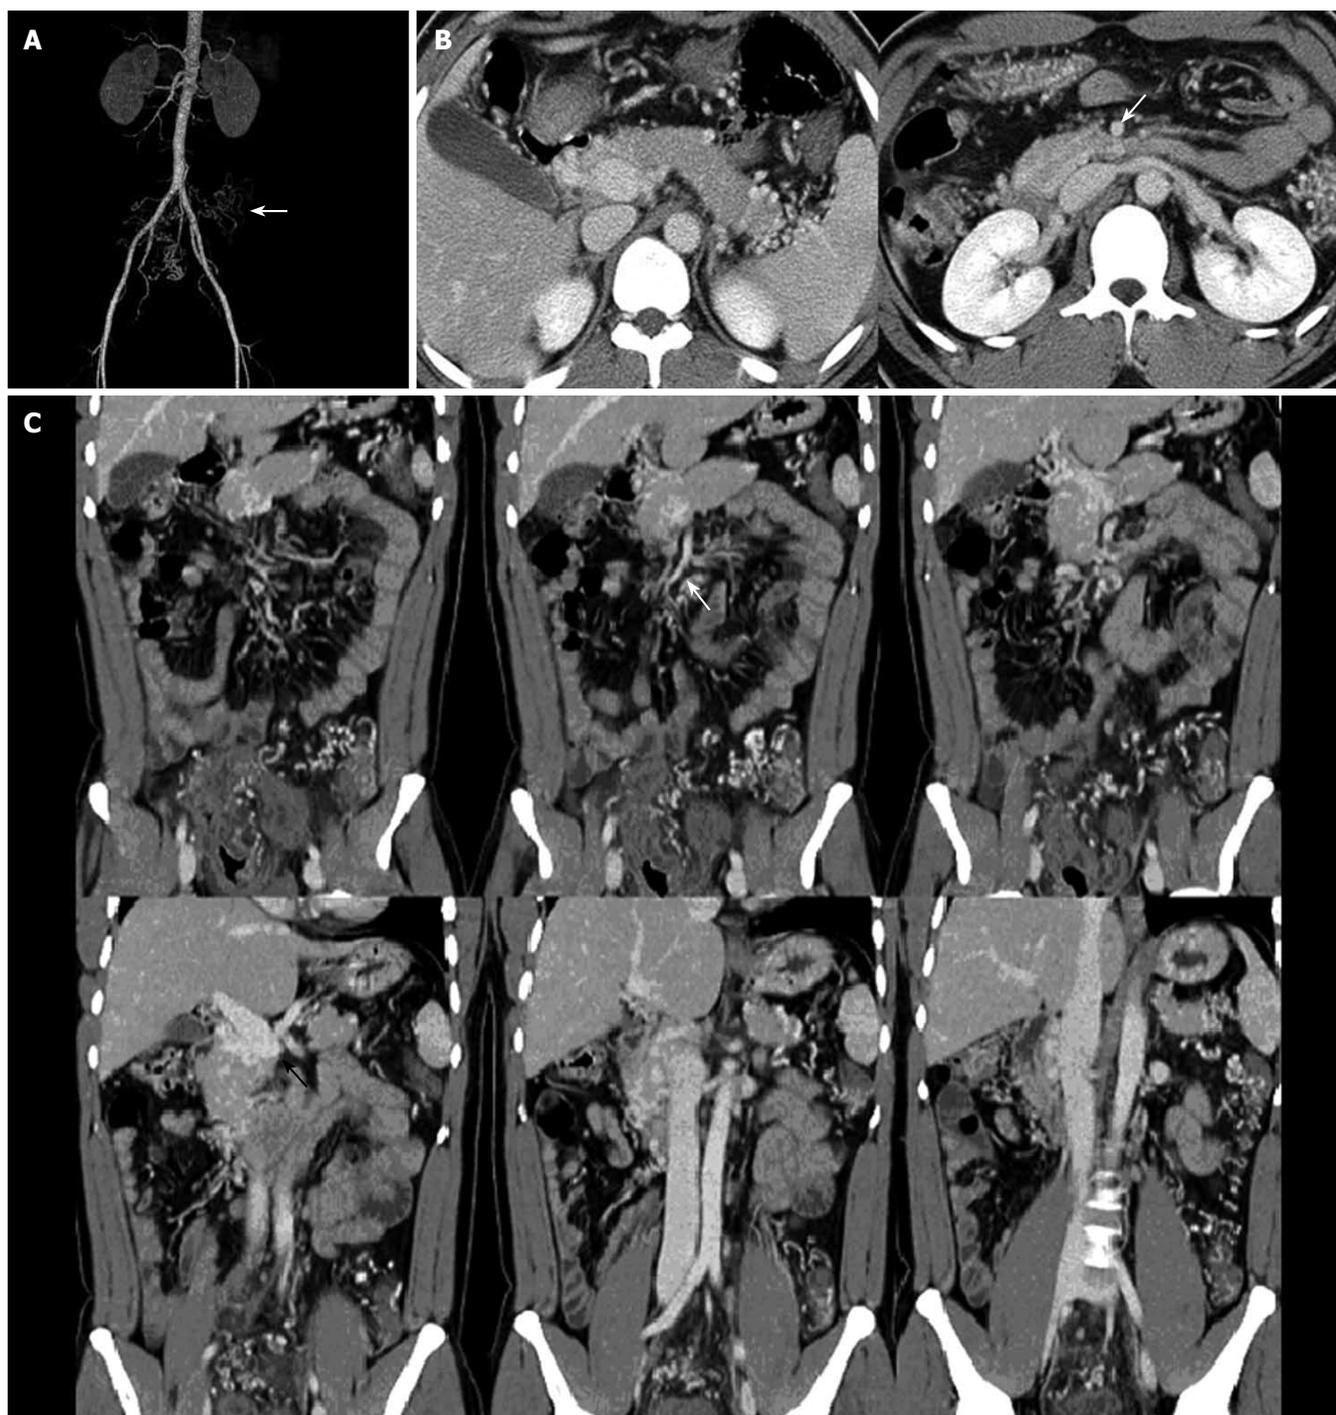

**Figure 2** Dynamic abdominal CT. **A:** The normal anatomy of the main portal vein and its tributaries including the portal vein (PV), left gastric vein (LGV), gastrocolic trunk (GCT), splenic vein (SV), SMA, SMV, and IMV are schematically illustrated; **B:** The normal mesenteric vein (SMV and IMV) and splenic vein are absent. Numerous collateral venous channels developed to drain venous blood from gastrointestinal tract to portal vein.

suspected because of mild fever, and antibiotic treatment was added. Blood and stool cultures were negative. There was a minimal improvement in the clinical course, but his symptoms were not totally alleviated. Two weeks after admission, a colonoscopy was performed to evaluate the extent and other causes of the disease. It demonstrated colitis with markedly edematous mucosa and tortuous and dilated veins throughout the colon, but the rectal mucosa was spared from inflammation. The fine granularity of the mucosa was associated with friability, and contact bleeding with mucus was observed (Figure 1A-D). The biopsy specimens obtained from the edematous colonic mucosa and the ulcer of the rectosigmoid junction showed nonspecific chronic inflammation.

A dynamic abdominal CT was performed. On arterial phase CT, diffuse edematous thickening of the colon with dilated and tortuous peripheral branches of colic arteries

was seen. The rectosigmoid colon appeared markedly thickened. Major abdominal arteries including the celiac axis, splenic artery, superior mesenteric artery (SMA) and inferior mesenteric artery (IMA) were all normal in size and shape. However, on venous phase CT, the splenic vein, superior mesenteric vein (SMV) and inferior mesenteric vein (IMV) were absent. Dilated and tortuous peripheral colic veins drained into the portal vein via tortuously dilated intraperitoneal collaterals (Figures 2A and B, and 3A-C). Venous blood of gastrointestinal tract and spleen drained into the portal vein via various routes of the collateral venous pathway that are similar to the intra-abdominal venous collaterals in patients with portal hypertension. The main collateral venous routes in our patient were pericolic and mesenteric collaterals, splenic hilar and perigastric collateral-pancreaticoduodenal collaterals-the portal vein. Some venous drainage of the lower portion of the left

**Figure 3** Abdominal CT arteriography. **A:** Normal shape and course of SMA, IMA, and splenic artery, tortuous and dilated distal branches of SMA and IMA around rectosigmoid colon; **B:** An axial and **C:** Coronal reformatted abdominal CT reveal the absent splenic vein, SMV, and IMV with numerous intra- and peripancreatic collaterals. colon drained into the left renal vein via the left gonadal vein. In addition, the venous collaterals of the rectosigmoid colon drained into the bilateral internal iliac veins. The patient refused angiographic evaluation for the anomalous abdominal venous system.

The final diagnosis was ischemic colitis with obstruction of the mesenteric and splenic veins. Corticosteroids did not relieve the disease, but aggravated the symptoms. The patient discontinued steroid therapy and gradually

responded to oral aminosalicylates. After nine months, he was in remission and re-evaluated by sigmoidoscopy. It showed some improvement of the colonic inflammation and a complete resolution of the ulcer in the rectosigmoid area.

## DISCUSSION

Ischemic colitis is a well-recognized clinical phenomenon,

although its precise etiology remains unclear. It may manifest a spectrum of severity from mild, transient mucosal erosion to fibrous scarring with stricture formation and even transmural infarction. Some cases are caused by acute macrovascular mesenteric occlusion due to surgical trauma<sup>[2]</sup>, thromboembolism<sup>[3-5]</sup>, or atherosclerosis<sup>[6]</sup>. However, chronic venous insufficiency is rarely associated with ischemic colitis. Ischemic colitis typically develops spontaneously without signs of major vascular occlusion, and viable intestine is present elsewhere in the tract. Isolated case reports have described development of ischemic colitis in conjunction with mild allergy, hypertension, rectal prolapse, acute pancreatitis, sickle cell crisis, colon cancer, systemic lupus erythematosus, amyloidosis, anticardiolipin antibody syndrome, Buerger's disease, and Kawasaki syndrome<sup>[7-9]</sup>. Other case reports described the association between development of ischemic colitis and use of some agents (progesterone, ergotamine derivatives, nonsteroidal anti-inflammatory drugs, and danazol)<sup>[10]</sup>, intravenous vasopressin therapy<sup>[11]</sup>, renal transplantation<sup>[12]</sup>, chronic intermittent peritoneal dialysis<sup>[13]</sup>, cocaine abuse, snake bite and marathon running<sup>[7]</sup>.

Clinical presentation is usually acute, with cramping abdominal pain of abrupt onset, abdominal distention, and bloody diarrhea. There may be local signs of peritoneal irritation over the affected segment, and if mucosal ulceration is present, bacterial invasion may also occur. However, manifestations vary widely, from severe pain with transmural infarction and early perforation to mild abdominal pain and only slight tenderness<sup>[14]</sup>.

It is extremely difficult to differentiate ischemic from ulcerative colitis. Moreover, ischemic and idiopathic ulcerative colitis may coexist<sup>[15]</sup>. An endoscopic finding of ulcerative colitis is characterized by a uniform inflammatory reaction in the colonic mucosa, without intervening areas of normal mucosa. The majority of cases arise in the rectum, and some authorities believe that the rectum is always involved in an untreated patient<sup>[16]</sup>. With inflammation, the mucosa becomes erythematous and granular, and the vascular pattern becomes obscured by edema. In this patient, a similar pattern of mucosal lesions was observed as mentioned above. However, while making the diagnosis as ulcerative colitis, we found that (1) the rectal mucosa was free from inflammatory reaction; (2) although the patient did not have a fulminant clinical course, a deep ulceration was observed; and (3) the disease was resistant to corticosteroid therapy and instead aggravated his clinical course. Color Doppler scans were used to differentiate the bowel-wall thickening in ischemic colitis from that seen in inflammatory bowel disease<sup>[7]</sup>.

Generally, major arterial or venous branches are easily detected on arterial or venous phase CT. The SMV is located anteriorly and to the right of the SMA and posteriorly medial to the head of the pancreas. The SMV tributaries are the ileocolonic, pancreatoduodenal, and gastroepiploic veins. The IMV originates anterior to the sacrum as the superior rectal (hemorrhoidal) vein and receives branches from the sigmoid and descending colon as it ascends to the left of midline, adjacent to the inferior mesenteric ar-

tery and left gonadal vein. In the upper abdomen, the IMV passes from posterior to the distal duodenum, anterior to the left renal vein, and then anterior to the SMA before anastomosing with the portal venous system. The splenic vein is easily detected beneath the pancreas and drains to the portal vein<sup>[17]</sup>. In this patient, the proximal SMV, IMV and most of splenic vein were absent despite the presence of a normal SMA and IMA and splenic artery. The tortuous and dilated distal branches of SMA and IMA around the entire colon were seen on arterial phase CT and no remarkable SMV and IMV were noted on venous phase CT except for the prominent collateral veins. Instead of a normal splenic vein beneath the pancreas, tortuous splenic hilar venous collaterals developed and drained into the portal vein via the peripancreatic venous collaterals. Although we have no direct angiographic evidence, the anomaly described in this report appears unique. We presume the congenital absence of the SMV, IMV, and splenic vein results from excessive involution of proximal vitelline veins.

In this case, the arterial blood supply and venous drainage might have been balanced for a long time because of numerous abdominal venous collaterals. In addition, a possible breakage of this balance may cause venous stasis and ischemia of the gastrointestinal tract. Impaired colonic venous drainage may be a possible cause or vulnerable to the development of ischemic colitis. The relationship between the absence of mesenteric veins with possible venous stasis and ischemic colitis is not clearly established. Although the patient is currently doing well after medical and conservative treatment, a long-term follow-up is needed as there is little information in the literature regarding the outcome of the absence of the proximal mesenteric veins and its influence upon venous drainage.

### Abstract

Biliary duct injuries are frequently iatrogenic, being associated with surgery for gallbladder stones. However, blunt abdominal trauma such as a motor vehicle crash is a rare cause of extrahepatic biliary stricture. A few reports have been published on biliary strictures treated with endoscopic therapy. In the present study, we describe a suprapancreatic biliary stricture associated with mesenteric tear following road traffic accident. We performed endoscopic stent placement, which was successful in relieving the biliary stricture.

### INTRODUCTION

Benign bile duct strictures are uncommon and usually

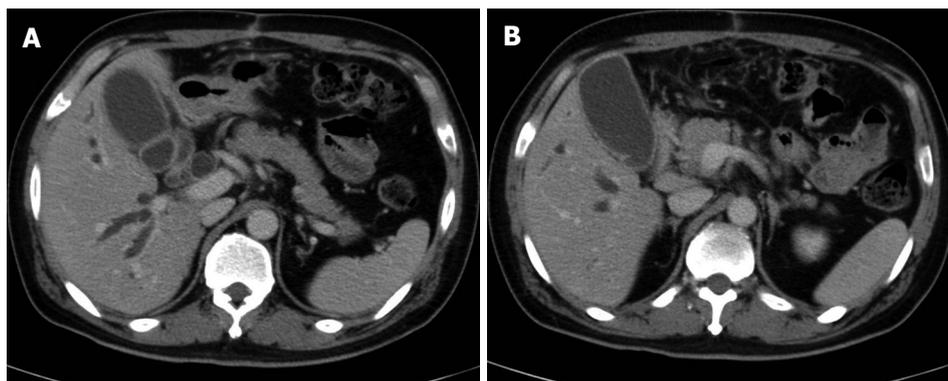

follow surgery for gallbladder stones, both open surgery and laparoscopic surgery<sup>[1]</sup>. However, development of biliary stricture after blunt abdominal trauma is an extremely rare condition<sup>[2-4]</sup>. No definitive treatment has been proposed for biliary strictures caused by blunt abdominal trauma. Recently, nonsurgical intervention using endoscopic approach has been used, with promising results<sup>[4,5]</sup>. We present a patient with a suprapancreatic biliary stricture that developed following a mesenteric tear caused by blunt abdominal trauma due to a traffic accident. The patient was treated successfully with endoscopic plastic stent placement.

### CASE REPORT

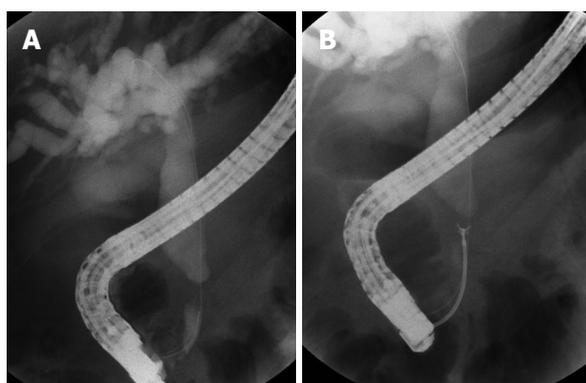

A 36-year-old man had blunt abdominal trauma due to a traffic accident. The patient was the driver and suffered full impact with the steering wheel. The patient was hospitalized for the treatment of hemoperitoneum caused by a mesenteric tear. Surgery was performed and the mesenteric tear was repaired. Two weeks after the accident, the patient developed jaundice and was transferred to our hospital for further evaluation and management.

At admission, the patient had overt jaundice with itching over the entire body. The vital signs were stable. Physical examination showed no abdominal pain, or tenderness to palpation. The bowel sounds were normal. The initial liver function tests were as follows: aspartate aminotransferase 60 U/L (normal range, 0-37 U/L), alanine aminotransferase 92 U/L (normal range, 0-41 U/L), alkaline phosphatase 317 U/L (normal range, 35-130 U/L), gamma-glutamyl transferase 107 U/L (normal range, 8-61 U/L), total bilirubin 16.9 mg/dL (normal range, 0-1.2 mg/dL), and direct bilirubin 11.3 mg/dL (normal range, 0-0.3 mg/dL). The amylase and lipase levels were within the normal range. Computer tomography (CT) scan of the abdomen revealed dilatation of both intrahepatic (IHD) and extrahepatic biliary ducts (EHD) with abrupt cut-off of the suprapancreatic portion of the common bile duct (CBD) (Figure 1). There was no evidence of pancreatitis.

An endoscopic retrograde cholangiopancreatography (ERCP) was performed to determine the cause of the jaundice. The cholangiogram revealed a 1 cm long stenosis of the distal CBD just above the pancreas, with ductal dilatation above the narrowed portion. Endoscopic biliary sphincterotomy using a pull-type papillotome and brushing and biopsy of the narrowed part were performed (Figure 2). At the end of the procedure, an endoscopic nasobiliary drain (ENBD) was placed. After the procedure, the serum

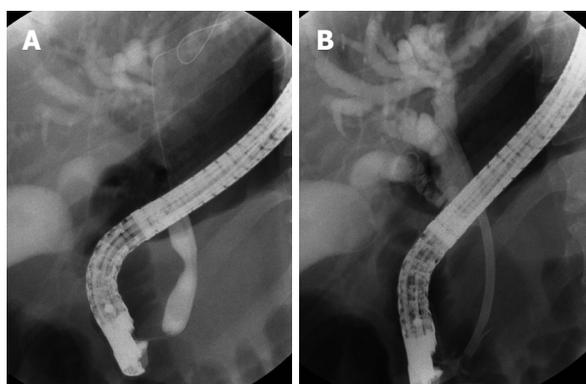

**Figure 1** Abdominal CT scan findings. **A:** Dilated intra- and extrahepatic bile ducts; **B:** Abrupt cut-off of the distal common bile duct.

**Figure 2** ERCP findings. **A:** Stenosis of the distal CBD, approximately 1 cm in length, located just above the pancreas, with ductal dilatation above the narrowed portion; **B:** Biopsy of the stricture was obtained.

**Figure 4** Follow-up ERCP findings. **A:** Improvement of the CBD stricture; **B:** There is normal passage of radiocontrast material into the bile duct through the papilla.

**Figure 3** ERCP findings. **A:** The CBD was dilated with TTS balloons, but the dilatation was not effective; **B:** An Amsterdam-type plastic stent (12Fr, 7 cm) was placed across the stricture.

bilirubin levels decreased gradually. The cytology and biopsy results were negative for malignancy.

A repeat ERCP was performed 5 d after the first procedure and the CBD was dilated with TTS balloons. However, the stricture could not be dilated effectively. Therefore, a 12 Fr. plastic stent, 7 cm in length, was inserted and placed at the site of the lesion (Figure 3). Three months later, the patient was readmitted for a follow-up ERCP. The liver function tests were within the normal range and the patient did not have jaundice. The cholangiogram showed improvement of the CBD stricture. The plastic stent was

removed after observing normal passage of radiocontrast material (Figure 4). During a follow-up period of 26 mo, there has been no recurrence of the biliary stricture as judged by laboratory tests and radiological imaging studies.

## DISCUSSION

The bile ducts are located deep within the abdomen and are protected by the ribs, liver and mesentery. Therefore, non iatrogenic bile duct injuries secondary to blunt abdominal trauma are extremely rare. It is most commonly seen following motor vehicle accidents when an unrestrained driver has an impact with the steering wheel<sup>[2-4]</sup>.

The proposed mechanisms of extrahepatic biliary strictures after blunt trauma differ based on their location. The possible mechanisms underlying the development of a suprapancreatic biliary stricture are: (1) local inflammation followed by fibrosis and stricture formation secondary to ductal tear; (2) disruption of the blood supply to the bile duct, and (3) compression of the biliary duct by an intramural or extrabiliary hematoma<sup>[3-5]</sup>. The possible mechanisms for the development of an intrapancreatic biliary stricture include the following: posttraumatic pancreatitis with swelling of the pancreatic head, and compression of the intrapancreatic portion of the CBD; this usually resolves as the swelling of the pancreas subsides<sup>[6]</sup>. We believe that the suprapancreatic biliary stricture in our patient was caused by disruption of the blood supply and extrinsic compression by a hematoma. The hepatobiliary area was not entered during the surgery, thus reducing the

possibility of an iatrogenic trauma.

Most patients with a biliary stricture secondary to blunt abdominal trauma develop jaundice as the initial symptom. The onset of symptoms is insidious<sup>[3,5]</sup>. The condition may be mistaken for cholangiocarcinoma, if history of abdominal trauma is not available<sup>[7]</sup>, and may result in unnecessary surgery.

The correct diagnosis may be difficult to determine based on imaging studies such as abdominal CT and ERCP, in the absence of a complete history<sup>[5,7,8]</sup>. Therefore, a high index of suspicion is required to ensure a proper diagnosis. To prevent irreversible fibrosis, an early diagnosis of biliary stricture is essential in order to allow timely treatment with percutaneous or endoscopic intervention<sup>[3,5,9]</sup>. Several workers have suggested that endoscopic stent placement is an effective treatment for suprapancreatic biliary strictures caused by blunt abdominal trauma<sup>[5,10,11]</sup>. Park *et al*<sup>[5]</sup> reported eight patients with suprapancreatic biliary stricture due to blunt abdominal trauma. The median length of the stricture was 1 cm. Balloon dilatation was performed in only 1 patient. The median duration of plastic stent placement was 2.9 mo. The patients were all successfully treated with the endoscopic stent placement and there was no recurrence during the follow-up period (median 33 mo). Our case was similar in terms of clinical features and outcome compared to previously reported cases. Endoscopic stenting for biliary stricture after blunt abdominal trauma is associated with low morbidity and excellent long-term outcome<sup>[5,10,11]</sup>. Therefore, endoscopic stenting is the treatment of choice for biliary strictures that develop after blunt abdominal trauma. Surgery should only be undertaken if endoscopic intervention fails<sup>[12,13]</sup>.

In summary, we report a patient with a suprapancreatic biliary stricture secondary to blunt abdominal trauma, which was treated successfully with endoscopic stent placement. The excellent results obtained in our patient suggest that endoscopic stent placement should be considered as the primary treatment for patients who develop an extrahepatic biliary stricture after blunt abdominal trauma. Endoscopic treatment is safe and has a favorable long-term outcome.

## Abstract

The mucocele of the appendix is an uncommon disorder which is often asymptomatic but sometimes causes acute appendicitis-like symptoms. Sometimes, patients with mucocele can present with confusing symptoms. Preoperative suspicion and diagnosis of appendiceal mucocele are important. Ultrasonography and computed tomography are useful tools for the diagnosis of appendiceal mucocele. It may be also recognised by colonoscopy as a smooth submucosal lesion of the cecum. Optimal management of the mucocele could be achieved through accurate preoperative diagnosis. Preoperative diagnosis is a major component for minimizing intra-operative and post-operative complications. We herein report five cases and discuss the diagnostic methods and surgical treatment.

## INTRODUCTION

Appendiceal mucocele (AM) is a rare entity that can present with a variety of clinical symptoms or occur as an incidental surgical finding. The incidence is 0.2%-0.4% of all appendectomized specimens<sup>[1-3]</sup>. AM is a progressive dilatation of the appendix from the intraluminal accumulation of the mucoid substance<sup>[3,4]</sup>. It may be a benign or malignant process. There are four histological types, which lead to individualized surgical treatment and course in each case<sup>[3]</sup>.

Preoperative diagnosis that distinguishes AM from acute appendicitis (AA) is essential for the best choice of surgical approach (open *vs* laparoscopic) to prevent peritoneal dissemination and perform the appropriate surgery<sup>[3,5]</sup>. Herein, we report 5 cases, discuss the diagnostic procedures and management algorithm of these patients, and review briefly the relevant literature. We also aimed to define the incidence of the AM in a tertiary referral centre in Northern Black Sea region of Turkey.

## CASE REPORTS

### Case 1

An 82-year-old man was admitted to the hospital because of pain in the right lower quadrant of the abdomen for 3 d. Standard laboratory tests, serum levels of CA 19-9 and carcino-embryonic antigen (CEA) were within normal ranges. Ultrasonography (USG) and computerized tomography (CT) demonstrated a well demarcated, elliptical 7 cm × 5 cm cystic mass with parietal calcifications in the right lower quadrant of the abdomen. There was an indentation in the cecum by colonoscopy. Surgical exploration revealed the mass to be an AM. Simple appendectomy was performed. Pathological examination revealed a mucinous cystadenoma with dimensions of 8 cm × 6 cm × 5.5 cm. AM restricted to the appendix and cecum was free of the disease. The patient's postoperative course was unremarkable, and he was discharged home on the 4th postoperative day.

### Case 2

A 65-year-old woman was referred to the emergency de-

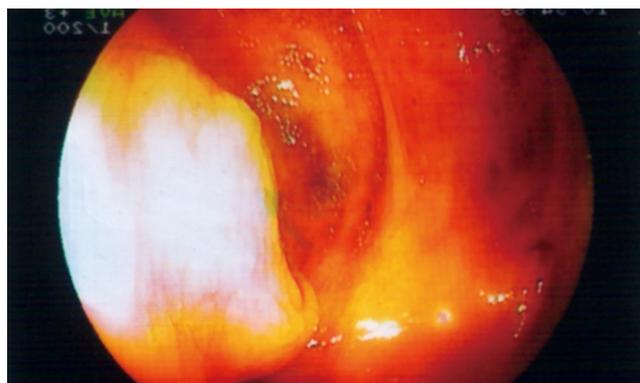

**Figure 1** CT imaging of a soft tissue mass indicated by black arrows in the region of the cecum.

partment with a diagnosis of AA. She complained of an abdominal pain which started 3 d before referral to our hospital. She had a history of coronary by-pass surgery 3 years ago. Physical examination showed diffuse peritoneal irritation. Plain radiography showed gas-fluid levels in the right lower quadrant. She also had mild leukocytosis. USG and CT scans of the abdomen showed presence of free fluid in the intra-abdominal spaces.

An emergency operation revealed ileal and cecal mesenteric ischemia. Partial ileum and cecum resection was performed. Histopathological diagnosis was ischemia of the intestine and simple mucocele of the appendix with a diameter of 5 mm, incidentally. Postoperative recovery was uneventful and she was discharged home on the 7th postoperative day.

### Case 3

A 66-year-old woman was referred to the endoscopy unit for evaluation of a mass in the right lower quadrant of the abdomen with the suspicion of malignant tumor. She had visited another health care unit where the mass was revealed by ultrasound examination. She had been suffering from decreased appetite, nausea, and weakness lasting for a week. She had a history of upper GI hemorrhage managed medically 16 years ago and her surgical history was significant for cholecystectomy 14 years ago. Routine laboratory tests, including complete blood count and serum chemistry were unremarkable. Serum levels of CA19-9 and CEA were also within the normal ranges. USG of the abdomen showed a heterogenic mass (95 mm × 40 mm × 32 mm in dimensions) involving ileocecal part of the intestines. CT imaging revealed a soft tissue mass measuring 8 cm × 4 cm with peripheral enhancement in the region of the cecum (Figure 1). The patient underwent colonoscopy, which revealed a sub-mucosal protrusion to the lumen of the cecum, in the region of the appendiceal orifice. Orifice of the appendix was uncertain (Figure 2). Remaining of the colon was unremarkable. The patient was treated surgically. Surgical exploration revealed a mass in the appendix whitish-grey in color (Figure 3). Resection of cecum was followed by an ileocolic anastomosis. Frozen section examination revealed benign mucoid lesion. Formal pathologic report was hyperplastic type mucocele with evidence of secondary changes and chronic inflammatory mucosa of the intestine. The mucocele was 9.5 cm × 4 cm × 2 cm in dimensions with a wall thickness of 2

**Figure 2** Colonoscopic view of the sub-mucosal mass.

**Figure 3** Intra-operative view of the AM. Arrows indicate the mucine filled appendix.

mm. There was no evidence of malignancy. Postoperative course was unremarkable and she was discharged home on the 5th postoperative day.

### Case 4

A 58-year-old man was referred to the general surgery department for surgical treatment of toxic multi-nodular goitre. He had multiple previous admittances to internal medicine department and emergency department because of pain in the right lower quadrant of the abdomen and anemia. Physical examination was negative for abdominal mass or perianal or rectal lesions. The patient underwent endoscopy to investigate the etiology of anemia. Colonoscopy revealed a submucosal cecal mass. Abdominal CT revealed a polipoid a soft tissue mass measuring 4 cm × 3 cm with peripheral enhancement in the region of the cecum. The patient underwent total thyroidectomy and appendectomy. Histopathological diagnosis was benign cystadenoma without cecal involvement. Postoperative course was unremarkable and he was discharged home on the 6th postoperative day.

### Case 5

A 72-year-old man underwent an open inguinal herniorrhaphy due to recurrent right inguinal hernia. He had complained of bulging and right groin pain which were exacerbated with activity. An appendiceal mass was defined during laparoscopic herniorrhaphy. Open access to the

abdominal cavity was chosen. Simple appendectomy was performed with a clinical suspicion of appendiceal mucocele. Frozen section examination revealed appendiceal mucocele. Pathological examination reported a mucinous cystadenoma measuring 12.5 cm and 5.5 cm without cecal involvement. Postoperative course was unremarkable and he was discharged home on the 7th postoperative day in good conditions.

## DISCUSSION

Mucocele of the appendix is an uncommon tumor, with an incidence of 0.29%-0.4% of all appendectomized specimens<sup>[1-3,6]</sup>. There has been no exact reported incidence of AM in Turkey. Histopathological examinations revealed 5 patients with AM among 240 patients who underwent appendectomies from January 2001 to October 2007 at our institution. The incidence of AM is revealed as 2.01%, which is higher than that reported in literature<sup>[7,8]</sup>. This may be related to the fact that our centre is a tertiary referral centre.

Although a small portion of AM is asymptomatic, clinical manifestations include right lower abdominal pain, palpable abdominal mass, or gastrointestinal bleeding in majority of the AM<sup>[1,3,7,9-12]</sup>. Among the five cases reported above, three had abdominal pain secondary to mucocele while one had symptoms related to groin hernia and the last patient had abdominal pain due to intestinal infarction. AM was an incidental finding for those two patients.

USG, CT and colonoscopic examinations can facilitate preoperative diagnosis of AM<sup>[1,13-15]</sup>. Ultrasound is the first-line diagnostic modality for patients with acute abdominal pain or mass. Different sonographic findings of AM and AA have been described<sup>[3,16,17]</sup>. Appendix diameter 15 mm or more in USG examination has been determined as the threshold for AM diagnosis with a sensitivity of 83% and a specificity of 92%<sup>[3]</sup>. Outer diameter threshold for AA diagnosis has been established as 6 mm<sup>[18]</sup>. USG examination revealed a cystic mass in the right lower quadrant in two of our patients. These findings revealed suspicion of AM.

CT is also an effective diagnostic tool for AM. CT can determine the relation between lesion and the neighbouring organs, and help confirm the diagnosis<sup>[15,16,19,20]</sup>. CT reveals a cystic mass with enhancing wall nodularly in the expected area of the appendix, especially in older patients, in whom AM should be considered<sup>[9,15,16,21]</sup>. AM could be visualized by CT in three of our patients. CT examination was normal in respect of AM for the third patient. AM was an incidental finding for this lady. Radiological investigation was not performed for the patient who had herniorrhaphy for recurrent groin hernia.

USG and CT findings are non-specific and the differential diagnosis should be established with benign appendiceal neoplasms and other pathologies such as carcinoid, lymphoma, mesenteric cysts, ovarian masses, and malign neoplasms of the appendix<sup>[7,22]</sup>. We did not perform fine needle aspiration as dictated in the literature in order to avoid dissemination of the mucus leading to pseudomyxoma peritonei<sup>[16]</sup>.

Colonoscopy in patients with abdominal pain is a use-

ful tool for determination of mucocele<sup>[2,23]</sup>. Generally, an elevation of the orifice of the appendix is seen. A yellowish mucous discharge would be visible from appendiceal orifice during colonoscopy. It is also important for the diagnosis of synchronous or metachronous colon tumor which would be as high as 29%<sup>[1,2,7,13-15,24,25]</sup>. Colonoscopic examinations on three of our patients revealed indentation in the cecum due to AM. The remaining colon was unremarkable in all of them. The 4th patient in emergency conditions was treated surgically based on the diagnosis of mesenteric ischemia and the 5th patient underwent surgery with the diagnosis of groin hernia without colonoscopic examination.

The spontaneous and surgery induced complications of AM include intestinal obstruction, intussusceptions<sup>[20,22]</sup>, intestinal bleeding<sup>[11,13,25]</sup>, fistula formation<sup>[15,26]</sup>, and volvulus<sup>[27,28]</sup>. The worst complication is pseudomyxoma peritonei, characterized by peritoneal dissemination caused by iatrogenic or spontaneous rupture of the mucocele<sup>[5]</sup>. The tissues should be handled carefully during surgery in order to avoid rupture of the mucocele. Thus, conventional surgery is preferred rather than laparoscopic approaches for the treatment in our cases<sup>[2,5,8,22]</sup>. Laparoscopic approach has an increased risk of rupture and subsequent pseudomyxoma peritonei formation<sup>[2,5,8]</sup>. Moreno *et al*<sup>[5]</sup> suggest conversion to an open appendectomy in case of mucocele when laparoscopic appendectomy is intended. Few authors still recommend a minimally invasive approach in selected patients for this rare entity<sup>[9,27,29]</sup>. However, in these reports, laparoscopic approach has been adopted for a small number of patients. Thus, we need a large series to substantiate recommendations of laparoscopic approach.

A simple and thorough evaluation of these patients with a new algorithm has been suggested by Dhage-Ivatury and Sugarbaker<sup>[30]</sup>. Simple appendectomy is the choice of surgical treatment for patients with benign mucocele that has negative margins of resection without perforation. No long term follow-up is needed for these patients<sup>[2,8,27,30]</sup>. Appendectomy was performed for three of our patients with a mucocele limited to the appendix. For patients with perforated mucocele, with positive margins of resection, positive cytology and positive appendiceal lymph nodes, right colectomy/cytoreductive surgery (CRS)/heated intraperitoneal chemotherapy (HIIC) and early postoperative intraperitoneal chemotherapy (EPIC) should be performed. Long term follow-up is obligatory for these patients<sup>[5,24,30,31]</sup>.

Perforated mucocele with positive margins of resection, positive cytology, and negative appendiceal lymph nodes necessitate cecectomy/CRS/HIIC and EPIC. Long term follow-up is also obligatory for these patients<sup>[2,30,32]</sup>. Cecectomy had been performed for one of the patients to obtain negative surgical margins, since the appendiceal wall was contiguous with the cecum and the intraoperative pathology indicated benign mucocele. Long term follow-up in this case has been carried out in the outpatient clinics. Perforated mucocele with positive cytology but negative margins of resection and negative appendiceal lymph nodes should be treated with appendectomy/CRS/HIIC and EPIC<sup>[26,30]</sup>. We did not apply these treatment modal-

ties as none of our patients had had positive lymph nodes or perforated mucocele.

## CONCLUSION

Although a rare disease, surgical treatment of the AM is mandatory because of the potential for malignant transformation and prevention of pseudomyxoma peritonei due to rupture of the mucocele itself. Therefore, preoperative diagnosis or suspicion is required for carefully planned resection to excise the tumor. The incidence of AM in a tertiary referral centre in Northern Black Sea region of Turkey is revealed as 2.01%, which is higher than the incidence reported in the literature.

### Abstract

Two patients with tuberculous abscess in the hepatoduodenal ligament were studied. Both patients underwent contrast-enhanced computed tomography (CT) scan. The abscess showed a low density with an irregular thick wall in the hepatoduodenal ligament on CT images, the margin was poorly defined. Contrast-enhanced CT images showed the contrast-enhanced thick wall, homogeneous and peripheral-enhanced lymph nodes. Although features of the tuberculous abscess in the hepatoduodenal ligament could be conspicuously shown with contrast-enhanced CT, further experience is needed to evaluate the potential value of CT in detecting early tuberculous abscess in relation to other entities in the hepatoduodenal ligament.

### INTRODUCTION

The incidence of tuberculosis is increasing<sup>[1-4]</sup>. Abdominal

tuberculosis can affect the gastrointestinal tract, peritoneum and lymph nodes. Lymphadenopathy is the most common manifestation of abdominal tuberculosis<sup>[5,6]</sup>. To our knowledge, there are no reports on the computed tomography (CT) appearance of tuberculous abscess in the hepatoduodenal ligament in the English radiologic literature. We describe in the paper the CT findings in a series of tuberculous abscesses in the hepatoduodenal ligament.

### CASE REPORTS

#### Case 1

A 24-year-old man had weight loss, easy fatigability, night sweats, and obscure abdominal pains for three months, but no clinically palpable abdominal mass.

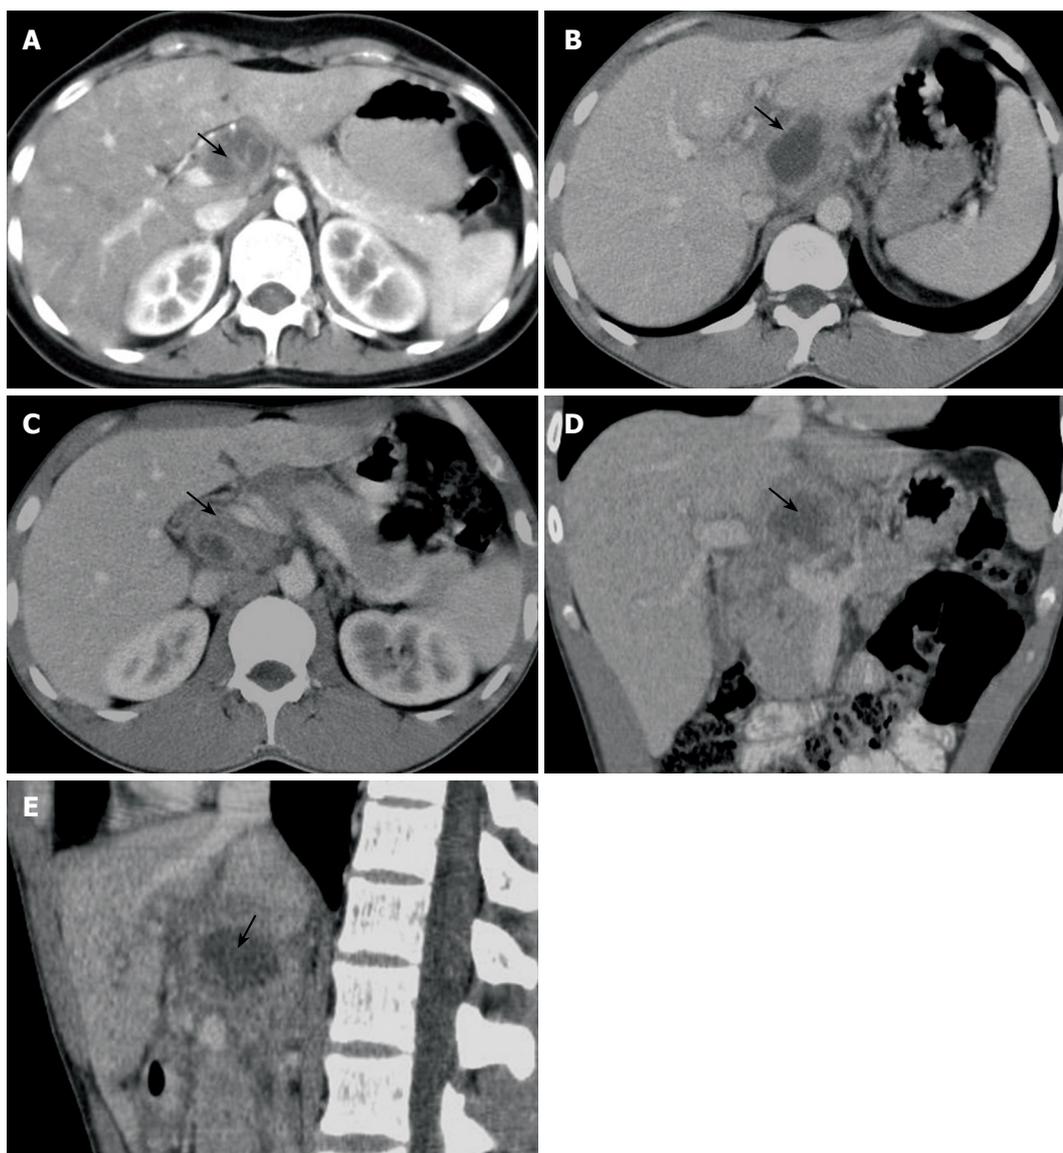

Contrast-enhanced CT was performed on a 16-detector spiral CT scanner (Siemens Sensation). The image protocol consisted of dual-phase CT scan. Medrad-100 power injector was used. Contrast material was Ultravist (Schering Germany, 300 mgI/mL). The range of CT scan covered the upper and middle abdomen. CT parameters were 120 KV, 165 eff mAs, 0.5 s/360°, 16 mm × 0.75 mm, 1 mm multi-planar reconstruction (MPR) slice width. CT scan was performed with intravenous contrast material administered as a bolus. Oral contrast material (1.2% angiografin) was administered. Images were viewed at a window width setting of 400 HU and a window level setting of 50 HU.

Contrast-enhanced CT showed a less dense mass with thick enhanced irregular walls in the hepatoduodenal ligament. The mass measured 3.9 cm × 2.8 cm with its margin poorly defined. The interface between the mass and around organs was not clear. Gas collection was not shown. Enlarged lymph nodes were detected in the portacaval space, gastrohepatic ligament, peripancreatic and upper paraaortic region. Some of them had peripheral enhancement and necrosis in the center (Figure 1A-E).

Operation on abdominal region was performed. Macroscopic pathological examination showed that the mass was tightly adherent to the hepatoduodenal ligament. Enlarged lymph nodes were found. Thirty mL of pus was aspirated from the mass. Microscopic examination revealed that the mass was inflammatory, and bacterial culture showed tuberculosis.

#### Case 2

A 30-year-old man had fever and obscure abdominal pain for two months with no clinically palpable abdominal mass.

**Figure 1** A 24-year-old man with tuberculous abscess in the hepatoduodenal ligament. **A:** Axial CT image (arterial phase) showing a low dense abscess measuring approximately 3.9 cm × 2.8 cm with a slightly contrast-enhanced wall in hepatoduodenal ligament (arrow); **B:** Axial CT image (venous phase) showing a low dense abscess with a contrast-enhanced wall in hepatoduodenal ligament (arrow); **C:** Axial CT image showing enlarged lymph nodes with peripheral and homogeneous enhancement in the portacaval space (arrow); **D:** Coronal CT image showing a low dense abscess with a contrast-enhanced wall in hepatoduodenal ligament (arrow); **E:** Sagittal CT image showing a low dense abscess with a contrast-enhanced wall in hepatoduodenal ligament (arrow).

Contrast-enhanced CT was performed on a spiral CT scanner (Elscent HeliCAT Flash). The image protocol consisted of venous phase. Power injector (MCT Plus, Meddred, Pittsburg) was used. Contrast material was Ultravist (Schering Germany, 300 mgI/mL). The range of CT scan covered the upper and middle abdomen. CT parameters were 120 KV, 250 mA, pitch 1. CT scan was performed with intravenous contrast material administered as a bolus. Oral contrast material (1.2% angiografin) was administered. Images were viewed at a window width setting of 400 HU and a window level setting of 50 HU.

Contrast-enhanced CT showed a less dense mass with thick enhanced irregular walls in the hepatoduodenal ligament. The mass measured 4.1 cm × 2.7 cm with its margin poorly defined. The interface between the mass and surrounding organs was not clear. Gas collection was not shown. Enlarged lymph nodes were detected in the portacaval space, gastrohepatic ligament, which had peripheral enhancement (Figure 2A and B).

Operation on abdominal region was performed. Macroscopic pathological examination showed that the mass was tightly adhered to the hepatoduodenal ligament.

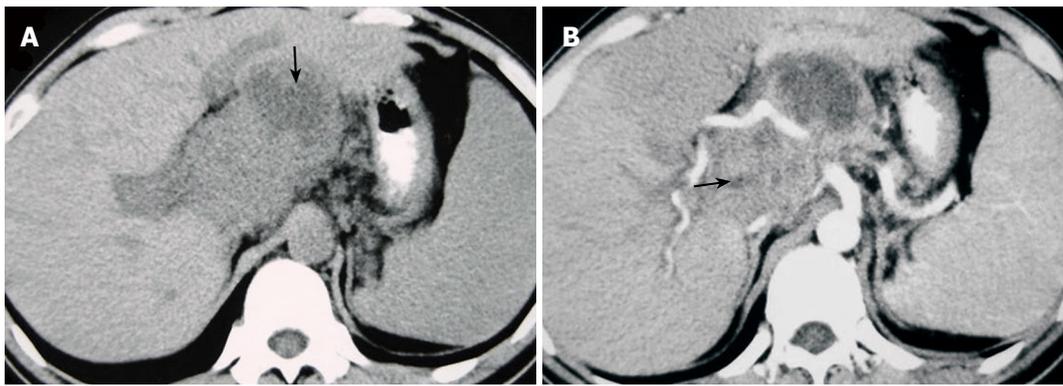

Enlarged lymph nodes were found. Twenty mL of pus was aspirated from the mass. Microscopic examination revealed that the mass was tuberculosis.

Both patients gave their written informed consent.

## DISCUSSION

Tuberculosis demonstrates a variety of clinical and radiologic features depending on the involved organ and has a known propensity for dissemination from its primary site. Thus, tuberculosis can mimic a number of other disease entities, and it is important to be familiar with the various radiologic features of tuberculosis to establish its diagnosis early and accurately<sup>[7]</sup>.

Lymphadenopathy is the most common manifestation of abdominal tuberculosis<sup>[5,6]</sup>. Mesenteric, omental and peripancreatic lymph nodes are most commonly involved<sup>[5]</sup>. Abdominal tuberculosis may be transmitted by three major routes. The first is ingestion of material infected with tubercle bacilli which are carried from a lesion in the intestinal submucosal layer to the lymph nodes draining that segment of the bowel. Drainage is usually from lymphatics

**Figure 2** A 30-year-old man with a tuberculous abscess in the hepatoduodenal ligament. **A:** Axial plain CT image showing a low dense abscess measuring approximately 4.1 cm × 2.7 cm in hepatoduodenal ligament (arrow); **B:** Axial contrast-enhanced CT image showing a low dense abscess with a contrast-enhanced wall and enlarged lymph nodes in hepatoduodenal ligament (arrow).

of the ileocecum, jejunum, ileum, and right side of colon to the peripancreatic and superior mesenteric lymph nodes. The second route of transmission is hematogenous spread. Bacteria are disseminated from a distant site of infection, usually the lungs, to the abdominal lymphatic system. Because this process is systemic, it may cause infection of mesenteric lymph nodes. In the third route of transmission, infection can spread directly to the abdominal lymph nodes from the serosa of adjacent infected structures<sup>[5]</sup>. In this study, two patients had non-disseminated tuberculosis and CT showed enlarged lymph nodes in the portacaval space, gastrohepatic ligament, peripancreatic and upper paraaortic region. So, the anatomic distribution of this disease closely parallels to the route of tuberculous infection.

The nodes are usually large and multiple, and most commonly demonstrate peripheral enhancement with central areas of low attenuation on contrast-enhanced CT images<sup>[5]</sup>. Pathologic findings from surgically obtained specimens of tuberculous lymphadenopathy indicate that caseation or liquefactive substances at the center of enlarged lymph nodes have a low attenuation that presumably results from insufficient blood supply, whereas peripheral inflammatory lymphatic tissue has a higher attenuation on enhanced CT that results from the preserved blood supply<sup>[8]</sup>. In this study, both cases were accompanied with enlarged lymph nodes, suggesting that the tuberculous abscess may be due to the coalescence of the involved lymph nodes.

Cystic lesions, including pseudocysts, necrotic tumors, and cysts of the pancreas and/or adjacent organs, must be differentiated from tuberculous abscess in the hepatoduodenal ligament. Pseudocyst is a unilocular, round mass with a uniform wall, and can be found in patients with clinical and laboratory evidence of pancreatitis. A well-defined rind suggests a pseudocyst or abscess, and gas bubbles suggest an abscess. CT demonstrates small calcification and fat in the teratomas located in the hepatoduodenal ligament area, and its border is round and sharp<sup>[9-11]</sup>. CT of extension of gastrointestinal stromal tumors displays extraluminal growth, inhomogeneous enhancement, absence of calcifications and lymph node metastases<sup>[12]</sup>. Congenital cysts (duplication, mesenteric, omental, or choledochal) may be localized to the hepatoduodenal ligament area. However, the history, clinical findings and the absence of enlarged lymph nodes do not suggest tuberculosis<sup>[11]</sup>. Serous and mucinous cystadenomas are encapsulated and lobulated masses,

showing marked contrast-enhancement of the solid portion. Cystadenocarcinoma is seen as a multilobular, septate, thick-walled cyst or cystic neoplasm with multiple low-density areas. Dilatation of the main pancreatic duct may be seen<sup>[10]</sup>. The radiologic pattern of tuberculous lymphadenitis can also be seen with lymphoma<sup>[7]</sup>. The enhancement patterns of untreated lymphomas are homogeneous. In patients with lymphoma who have undergone therapy, central low attenuation may be found within nodes, simulating tuberculous lymphadenopathy. So, it is important to know the history<sup>[13-16]</sup>.

It was reported that tuberculous lymphadenopathy has the following clinical characteristics<sup>[17]</sup>: (1) some patients have a history of TB and most of them come from areas with a high prevalence of active tuberculosis; (2) patients often suffer from epigastric pain, fever and weight loss; (3) ultrasound and CT scan show enlarged nodules, sometimes with focal calcification. In this study, a patient had weight loss, fatigability, night sweats, and obscure abdominal pains, while the other patient had fever and obscure abdominal pains. Both patients had no clinically palpable abdominal mass.

In summary, tuberculous abscess in the hepatoduodenal ligament is a less dense mass with thick enhanced irregular walls, its margin is poorly-defined, and the interface between the mass and around organs is not clear. It is important to show the peripheral enhanced lymph nodes for its early and accurate diagnosis.

### Abstract

Patients of end stage renal disease on maintenance hemodialysis were enrolled to study the prevalence of occult and dual hepatitis B virus (HBV) and hepatitis C virus (HCV) infection and non-occult hepatitis B and C virus infection. One hundred and two patients were enrolled. Thirty patients had HCV infection, three of them were positive in anti-HCV. So, 27 (90%) of HCV-positive patients had occult HCV infection. Eleven (11%) patients had HBV infection. Five patients were positive in anti-HBc or HBV-DNA, but negative in HBsAg (occult HBV infection). Three (3%) patients had dual HBV and HCV infection. None of the patients showed changes in viral markers during the follow-up of 8 mo on average (1-12 mo).

Jain P, Nijhawan S. Occult hepatitis C virus infection is more common than hepatitis B infection in maintenance hemodialysis patients. *World J Gastroenterol* 2008; 14(14): 2288-2289 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2288.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2288>

### TO THE EDITOR

We read with interest the article "Hepatitis B viral infection in maintenance hemodialysis patients: A three-year

follow-up" by Cao *et al* in 13(45): 6037-6040, 2007, *World Journal of Gastroenterology*<sup>[1]</sup>. We agree that the hepatitis B vaccination and regular surveillance for hepatitis B virus (HBV) infection has reduced the spread of HBV in the dialysis population. The prevalence of hepatitis C virus (HCV) infection in hemodialysis (HD) patients is high and ranges from 2% to 60% between countries and among dialysis units<sup>[2]</sup>. The prevalence of HBV and HCV occult and dual infection<sup>[3,4]</sup> in hemodialysis patients has been variably reported.

We prospectively studied consecutive patients of end stage renal disease (ESRD) on maintenance of HD from June 2006 to June 2007 for prevalence of occult and dual hepatitis B and C virus infection and non-occult hepatitis B and C virus infection. Occult hepatitis C infection was defined as anti-HCV negative and HCV-RNA positive by polymerase chain reaction<sup>[3,5]</sup>. All patients underwent tests of hemoglobin, urea, creatinine, bilirubin, alanine aminotransferase (ALT) and aspartate aminotransferase (AST). The viral markers done were hepatitis B surface antigen (HBsAg), antibody to hepatitis B surface antigen (anti-HBs), antibody to hepatitis B core antigen (anti-HBc), hepatitis B envelope antigen (HBeAg), antibody to hepatitis Be antigen (anti-HBe), antibody to hepatitis C virus (anti-HCV) by enzyme linked immunoassay (ELISA) and qualitatively hepatitis B virus DNA (HBV DNA) and hepatitis C virus RNA (HCV RNA) by polymerase chain reaction.

The demographic, clinical features, biochemical parameters, etiology, history of blood transfusion and time on hemodialysis are described in Table 1. One hundred and two patients were enrolled. The mean age was 41.4 years (range 17-70 years) with a male: female ratio of 68:34. The clinical presentations were generalized swelling 36 (36%), decreased urine output 34 (34%), breathlessness 30 (30%), hypertension 24 (24%) and altered sensorium in 8 patients. The mean hemoglobin, urea, creatinine, bilirubin, AST and ALT were 76.5 mg/L (33-122 mg/L) 184.3 mg/L (84-322 mg/L), 10.8 mg/L (4-23 mg/L), 0.6 mg/L (0.4-0.8 mg/L), 53.5 unit/L (26-188 unit/L) and 38.6 unit/L (16-209 unit/L). Thirty-four patients had histories of blood transfusion.

Among HD patients with HCV infection, serum ALT was elevated in 10 HCV-RNA positive patients, but normal in all the anti-HCV positive patients. Thirty (30%) patients had HCV infection, three them had anti-HCV positivity. So, twenty-seven (90%) of HCV-positive patients had occult HCV infection.

Eleven (11%) patients had HBV infection. Five patients

**Table 1** Demographics, clinical and biochemical parameters of patients on maintenance hemodialysis

Male:Female	68:34
Age (yr) <sup>1</sup>	41.4 (17-70)
Clinical features, cases (%)	
Generalised swelling	36 (36)
Oliguria	34 (34)
Breathlessness	30 (30)
Hypertension	24 (24)
Altered sensorium	8 (8)
Laboratory parameters <sup>1</sup>	
Hemoglobin (mg/L)	76.5 (33-122)
Urea (mg/L)	184.3 (84-322)
Creatinine (mg/L)	10.8 (4-23)
Bilirubin (mg/L)	0.6 (0.4-0.8)
Aspartate aminotransferase (unit/L)	53.5 (26-188)
Alanine aminotransferase (unit/L)	38.6 (16-209)
History of blood transfusion, cases (%)	34 (34)
Past history of jaundice, cases (%)	4 (4)
Etiology, cases (%)	
Chronic glomerulonephritis	44 (44)
Chronic interstitial nephritis	20 (20)
Diabetes mellitus	20 (20)
Polycystic kidney disease	5 (5)
Glomerulopathy, unknown	13 (13)
Time on hemodialysis (mo) <sup>1</sup>	34 (12-60)

<sup>1</sup>Mean (range).

were positive in anti-HBc or HBV-DNA but negative in HBs Ag (occult HBV infection). Rai *et al* reported 12.2% occult HBV infection and 10.3% occult HCV infection in human immunodeficiency virus patients<sup>[5]</sup>. Goral *et al* reported that occult HBV infection was not high in chronic HCV infected patients on HD<sup>[6]</sup>.

Three (3%) patients had dual HBV and HCV infection. Reddy *et al* found dual infection in 3.7% of patients on HD<sup>[4]</sup>. None of the viral markers were positive in 20 patients. Four patients had past histories of jaundice, three of them had HBV infection and one was positive in HCV-RNA.

Thirty patients with positive viral markers had histories of blood transfusion ranging from 1-6 units. Agarwal *et al*<sup>[7]</sup> showed in their studies in 208 ESRD patients with past histories of jaundice and the number of blood transfusion was significantly higher in HCV positive patients than in HCV negative patients. In our study, blood transfusion history was present in most of the patients ( $n = 26$ ) with HCV infection. Two patients had past histories of jaundice.

On follow-up of mean 8 mo (1-12 mo), none of the patients showed change in viral markers. Twelve patients died of cardiac arrhythmias due to hyperkalemia, fluid overload due to inadequate dialysis and sepsis. In our study, the development of cirrhosis, hepatocellular carcinoma

and decompensation of liver function were not observed in HCV and HBV infected patients.

Yakaryilmaz *et al* in their group of 188 ESRD patients on maintenance of HD showed 28.7% had both occult and non-occult forms of HCV infection which was more common than HBV (19.7%) infection<sup>[3]</sup>.

HBV infection was present in 11% of patients on maintenance HD possibly due to a higher percentage (44%) of patients having protective anti-HBs titres. In the previous studies, HBV DNA positive hemodialysis patients had a significantly lower prevalence of past HBV vaccination and lower anti-HBs titres in serum than HBV DNA-negative patients of the same group<sup>[8]</sup>. Nijhawan *et al* did the screening of 69330 subjects for HBsAg and found that prevalence of HBsAg in replacement donors was 3.1% and 2.1% in healthy voluntary donors<sup>[9]</sup>. So, HBV infection is relatively higher in patients on HD.

So, HCV-RNA is recommended in patients on HD and now has been included in our screening program prior to renal transplantation. HBV vaccination of HD patients is an effective way of limiting the risk of transmission of HBV infection to patients on hemodialysis.

## ACKNOWLEDGMENTS

# Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

## Meetings

### Events Calendar 2008-2009

#### FALK SYMPOSIA 2008

January 24-25, Frankfurt, Germany  
Falk Workshop: Perspectives in Liver Transplantation

#### International Gastroenterological Congresses 2008

February 14-16, Paris, France  
EASL-AASLD-APASL-ALEH-IASL Conference Hepatitis B and C virus resistance to antiviral therapies  
[www.easl.ch/hepatitis-conference](http://www.easl.ch/hepatitis-conference)

February 14-17, Berlin, Germany  
8<sup>th</sup> International Conference on New Trends in Immunosuppression and Immunotherapy  
[www.kenes.com/immuno](http://www.kenes.com/immuno)

February 28, Lyon, France  
3<sup>rd</sup> Congress of ECCO - the European Crohn's and Colitis Organisation Inflammatory Bowel Diseases 2008  
[www.ecco-ibd.eu](http://www.ecco-ibd.eu)

March 10-13, Birmingham, UK  
British Society of Gastroenterology Annual Meeting  
E-mail: [BSG@mailbox.ulcc.ac.uk](mailto:BSG@mailbox.ulcc.ac.uk)

March 14-15, HangZhou, China  
Falk Symposium 163: Chronic Inflammation of Liver and Gut

March 23-26, Seoul, Korea  
Asian Pacific Association for the Study of the Liver  
18<sup>th</sup> Conference of APASL: New Horizons in Hepatology

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1224 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

#### Electronic journal (list all authors)

Morse SS. Factors in the emergence of infectious diseases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

#### Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

### Abstract

Opisthorchiasis caused by *Opisthorchis viverrini* (*O. viverrini*) remains a major public health problem in many parts of Southeast Asia including Thailand, Lao PDR, Vietnam and Cambodia. The infection is associated with a number of hepatobiliary diseases, including cholangitis, obstructive jaundice, hepatomegaly, cholecystitis, cholelithiasis and cholangiocarcinoma. The liver fluke infection was induced by eating raw or uncooked fish products that is the tradition and popular in the northeastern and northern region, particularly in rural areas of Thailand. Health education programs to prevent and control opisthorchiasis are still required in high-risk areas.

### INTRODUCTION

Liver flukes are platyhelminth parasites of the class

trematoda, and *Opisthorchis viverrini* is a member of the family *Opisthorchiidae*. *Opisthorchis spp.* is a prevalent human parasite particularly in the Far East and South East Asia. *O. viverrini* is highly prevalent in Thailand and Laos while *C. sinensis* is endemic in south China, Japan, Korea and Taiwan, *O. felineus* is the prominent fluke in Eastern Europe<sup>[1]</sup>. In Thailand *O. viverrini* is the only parasite of opisthorchiasis, the first case of opisthorchiasis was reported in 1911 by Leiper from the autopsy of a corpse in Chiang Mai. Later on Sadun in 1953, Harinasuta and Vajjarasthira in 1961, and Wykoff in 1965 had demonstrated a complete life cycle of *O. viverrini*<sup>[2-4]</sup>. *O. viverrini* has a complicated life cycle with 2 intermediate hosts, a freshwater snail (*Bithynia goniompharus*, *B. funiculata* and *B. siamensis*) is the first intermediate host<sup>[4,5]</sup>, and a freshwater fish (*Cyclocheilichthys spp.*, *Puntius spp.*, *Hampala dispa*) is the second intermediate host where the metacercariae habitat in the muscles or under the scales. Cats, dogs, and various fish-eating mammals including humans are the definitive host<sup>[6]</sup>. More than 7 million were infected by *O. viverrini* that were recorded by various investigators. Humans have become infected by ingesting undercooked fish containing infective metacercariae, this figure shows the tradition of eating raw or uncooked fish products as the main reason that liver flukes are a problem in Thailand. This is very popular in the northeastern and northern region particularly in rural areas. This infection is associated with a number of benign hepatobiliary diseases, including cholangitis, obstructive jaundice, hepatomegaly, cholecystitis and biliary lithiasis<sup>[7]</sup>. Both experimental and epidemiological evidence implicate liver fluke infestation in the etiology of bile duct cancer, i.e. cholangiocarcinoma<sup>[1,8]</sup>. In Thailand, opisthorchiasis is still a serious problem, especially in the northeast and north region. Therefore, this article investigates the distribution of the disease of the people with an emphasis on the north, north-east, central and south regions of Thailand.

### HISTORY OF OPISTHORCHIASIS IN THAILAND

Fish-borne trematode in Thailand, *O. viverrini* was first described in the post-mortem examination of two prisoners from a jail in Chiangmai, northern Thailand, in 1911 by Leiper who obtained specimens from Kerr. Kerr reported that 17% of 230 adult male prisoners examined in a prison in Chiangmai were infected with *O. felineus*<sup>[9]</sup>. In 1927, Prommas identified the worms found at an autopsy of a 17-year-old Thai male residing in Roi-et, northeast Thailand, as *O. felineus*<sup>[10]</sup>. The liver fluke infection in

Thailand was caused by *O. viverrini*, not by *O. felineus*<sup>[2]</sup>, and Wykoff *et al* confirmed this later in 1965<sup>[4]</sup>. Since then, cases of opisthorchiasis were reported each year. *O. viverrini* is still prevalent and a serious health problem in some parts of Thailand, therefore, the health education promotion is still required.

## SOURCE OF THAI HUMAN INFECTION

Three types of preparations contain uncooked, small and medium-sized, fish: (1) *Koi pla*, eaten soon after preparation; (2) Moderately fermented *pla som*, stored for a few days to weeks; and, (3) *Pla ra* extensively fermented, highly salted fish, stored for at least 2-3 mo<sup>[2,11]</sup>. The consumption frequencies of *koi pla* in some communities every week was approximately 80%<sup>[12]</sup>. In the northeasterners who have eaten *koi pla*, studies found the highest prevalence of liver fluke infection<sup>[13,14]</sup>. The frequencies of *koi pla* consumption have declined and are generally confined to special social occasions, while other under-cooked fish preparations like *pla som* and other moderately preserved fish are generally eaten several times a week<sup>[11]</sup>. *Pla ra* and *jaenbong*, fully preserved fish, is an important staple and consumed daily by 60%-98% of northeasterners and lowland Laotians<sup>[12,15]</sup>. At present, the patients still show that *Koi pla* is probably the most infective, followed by fish preserved for < 7 d, then *pla ra* and *jaenbong*, in which viable metacercaria are rare<sup>[11]</sup>.

## EPIDEMIOLOGY OF OPISTHORCHIASIS IN THAILAND

The Helminthiasis control program started in 1950 included opisthorchiasis control in some high risk areas<sup>[16]</sup>. The main liver fluke control strategies comprise of three interrelated approaches, namely stool examinations and treatment of positive cases with praziquantel for eliminating human host reservoir; health education for a promotion of cooked fish consumption to prevent infection, and the improvement of hygienic defecation for the interruption of disease transmission<sup>[16]</sup>. In Thailand, more than 7 million people were infected with *O. viverrini*, estimated by various investigators<sup>[2,4,17,18]</sup>. Prevalence rates of *O. viverrini* in the northeast and the north were, 29.8% and 10.3% respectively<sup>[19]</sup>. A health survey was carried out among residents of 33 villages under the Phitsanulok Irrigation Project Area, Nan River Basin, and northern Thailand. The prevalence of *O. viverrini* was 20%, the significant endemic diseases as potential health problems in this water resources development<sup>[20]</sup>. A study of the prevalence and intensity of *O. viverrini* in relation to morbidity as determined by standard medical examination was carried out in Nong Ranya, a small village containing 309 people in northeastern Thailand. *O. viverrini* infection was determined with an overall prevalence of 94%, and reaching 100% prevalence in most age groups above the age of 10 years. Peak intensity in both males and females occurred at age 40 and above<sup>[21]</sup>.

In 1980-1981 the prevalence in the north, northeast, centre and south of Thailand was 5.59, 34.60, 6.34, and 0.01%, respectively, with an overall prevalence of 14% or

7 million people<sup>[22]</sup>. Incidence, measured as the proportion of persons whose stools become positive within one year, was studied in endemic *O. viverrini*, in a northeastern Thai village over a two-year period. Incidence was higher in males than in females, especially in children under five years of age. It was at least 47% overall in the first year of the study, but declined to below 20% per year in the second<sup>[23]</sup>. The prevalence and intensity of *O. viverrini* infection were investigated among 559 patients who were born in, and had lived all their lives in, either the rural or urban northeastern Thailand. 344 (79.4%) of 433 rural dwellers were infected compared with only 69 (54.8%) of 126 urban dwellers. Infection due to *O. viverrini* appears to be mainly a rural problem strongly associated with the habit and frequency of eating *koi-pla*<sup>[24]</sup>. Tesana *et al* reported the prevalence of *O. viverrini* infection in the villages on the banks of rivers and those far from the rivers in Loei and Nong Khai Provinces, northeast Thailand. Most of the people examined in the present study were agriculturalists. The overall prevalence of *O. viverrini* infection was 41.3%. The prevalence of infection in males and in females in the villages far from the rivers were 52.6% and 51.7%, respectively, while the percent of people in the villages on the banks with infection were 27.9% and 21.7%, respectively. Prevalence of infection among the people residing far from the rivers was higher than those residing on the banks. This was observed despite the higher recording of raw fish consumption in villages on the banks. Infection level increased sharply in the age-group 6-10 years among people residing far from the rivers. High prevalence of infection was observed in age groups from 11 to 50 years<sup>[25]</sup>.

The patterns of infection with *O. viverrini* within a human community assessed by egg count were observed. A striking 81.5% of the total *Opisthorchis* population and 74% of the total egg output were expelled by the most heavily infected 10% of the humans sampled<sup>[26]</sup>. Meanwhile, Sithithaworn *et al*<sup>[27]</sup> investigated *O. viverrini* infection in 181 accident subjects in northeast Thailand. The prevalence increased rapidly with age and reached a plateau at 70%-80% in adults. The overall prevalence estimated by faecal examination was 69.2%, while that measured by worm recovery was 79.2%. In 1991, the survey of *O. viverrini* in 14 villages in Nakhon-Phanom province, Northeast, Thailand was conducted. Overall prevalence of *O. viverrini* infection was 66.4% in a total population of 2412 individuals. The prevalence was 18.5% in children under 5 years, 38.9% in those aged 5-9 years, and ranged from 64.9% to 82.2% in the age group above 10 years. The intensity of *O. viverrini* infection increased with age. The mean faecal egg output was highest in the 30-34 years age group and remained relatively constant in the older aged group. In all age groups the prevalence and intensity of infection in both men and women were similar. The population was divided according to the presence and intensity of infection as follows, 33% were uninfected, 59% had light infections (less than 1000 eggs per g of faeces; EPG), 7% had moderate infections (1000-10000 EPG), and 1% had heavy (greater than 10000 EPG)<sup>[28]</sup>. Thereafter, Peng *et al*<sup>[29]</sup> have been reported that all 1364 Thai labourers in Taiwan were examined for stool samples

and 18.0% were found to be infected, with *O. viverrini* at 7.0%. The prevalence was highest among the 21-25 age group (24.8%). The finding that parasitic infections are prevalent among Thai labourers demonstrates the need for control measures in foreign labourers in Taiwan. Meanwhile, stool samples from 93 Thais working in Israel were examined for the presence of parasites. The overall prevalence of infection by 1 or more species was 74%. *O. viverrini* and hookworm were the most prevalent parasites (51.6% and 44.1%, respectively)<sup>[30]</sup>. In 1994, Radomyos *et al*<sup>[31]</sup> examined *O. viverrini* infection in 681 residents from 16 provinces in northeast Thailand. The prevalence of *O. viverrini* in this group was 92.4%. In the same period, region wide assessments in 1994 were conducted. The prevalence of opisthorchiasis was 18.5% with a large variation in infection rate<sup>[32]</sup>.

In 1998, 431 residents from 16 provinces in northern Thailand who had previously been found positive for *O. viverrini* or *O. viverrini*-like eggs were given praziquantel 40 mg/kg. The stool was collected for 4 to 6 times and examined for adult worms. The prevalence of *O. viverrini* in this group was 11.6%<sup>[33]</sup>. Waree *et al*<sup>[34]</sup> survey the parasitic infection from 584 stool specimens in Noen Maprang, Phitsanulok Province during October 1999 to March 2000. It was found that the prevalence of *O. viverrini* infection was 10.78%. During October to November 2000, faecal samples were collected from study participants from 332 rural northeast Thais, *O. viverrini* was 14.2% and ranging from 8.6-19.4<sup>[11]</sup>. While Wiwanikit *et al*<sup>[35]</sup> reported the prevalence of *O. viverrini* was 8.7% (16 from 183 cases) in Sawasdee Village in the Nam Som District, Udonthani Province in northeastern Thailand in 2001. A cross-sectional study of the prevalence of intestinal parasitic infections at 8 schools in Bo Klau district and 4 schools in Chalerm Prakiet district, Nan Province, in January and February, 2001. A total of 1010 fecal samples were examined and found *O. viverrini* was 1.7%<sup>[36]</sup>. Of 2213 Thai workers who visited the Out-patients Department of the King Chulalongkorn Memorial Hospital between September 2000 and January 2001 the prevalence of *O. viverrini* was 28.9%<sup>[37]</sup>. Rhongbutsri *et al* reported the liver fluke infections, *O. viverrini* (11.1% from 395 samples), the most common in the old age group (51 years and up) in Ban Khok Yai Village, Khon Kaen Province, northeast Thailand<sup>[38]</sup>. The nationwide survey was reported in 2001 by Jongsuksantigul and Imsomboon, the prevalence of opisthorchiasis in the north, northeast, central and south, 19.3%, 15.7%, 3.8% and 0% respectively<sup>[16]</sup>. A small scale survey in Aranyaprathet District, Sa Kaeo Province, eastern Thailand, was conducted in January 2004. Of the 545 stool samples collected and examined, 261 (47.9%) contained small-sized eggs resembling *O. viverrini* eggs<sup>[39]</sup>. Of 24723 participants in Khon Kaen Province of northeast Thailand, 18393 aged 35-69 years were tested for *O. viverrini* infection, by examining stools for the presence of eggs. The average crude prevalence of *O. viverrini* infection in the sample subjects was 24.5%, ranging from 2.1% to 70.8%<sup>[40]</sup>. Recently, a total of 479 stool specimens were collected from rural communities of Ubon Ratchathani Province, Thailand. The prevalence of *O. viverrini* was 14.8%, while the same research group reported an epidemiological survey was conducted in Khon Kaen

Province involving 1124 stool samples using the modified Kato technique. The greatest frequency was *O. viverrini* at 32.0% while the second highest was *Sarocystis spp* at 8.0%<sup>[41]</sup>.

### **Report cases of opisthorchiasis per 100 000 populations by year, Thailand**

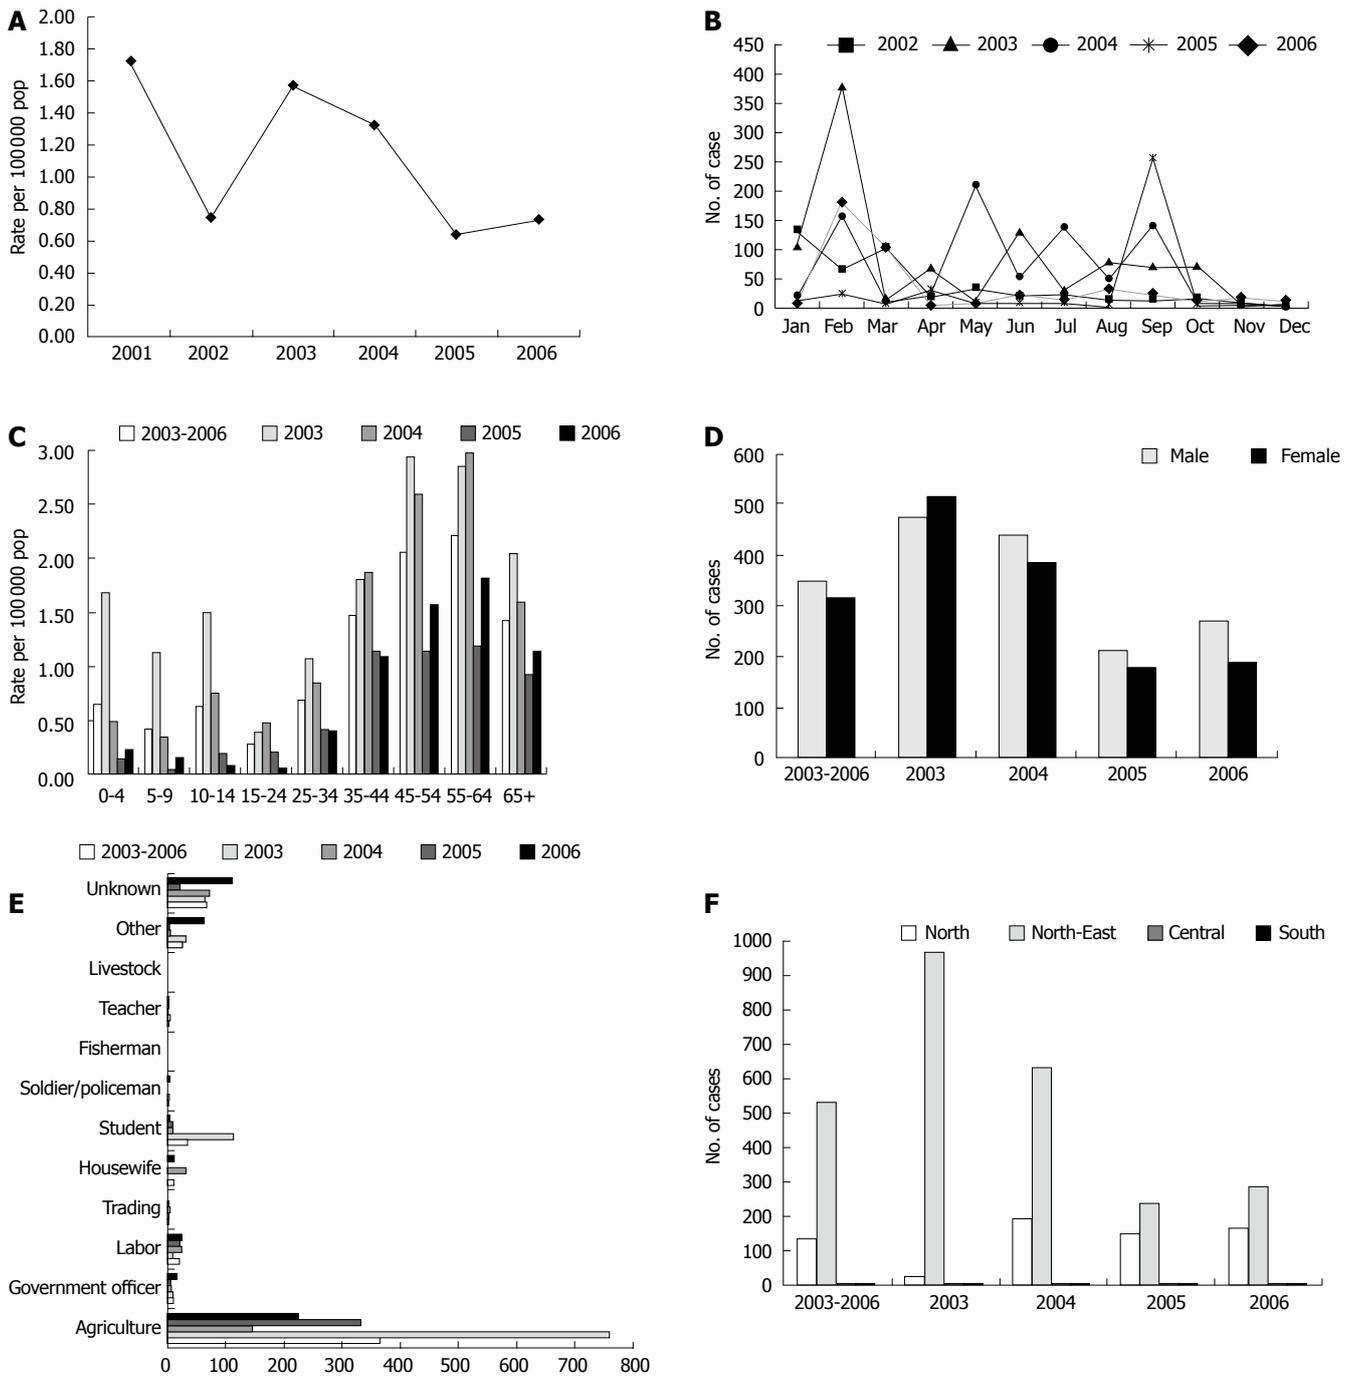

The mortality rate was reported by the Bureau of Epidemiology, Department of Disease Control, Ministry of Public Health, Thailand during 2001-2006. Morbidity rate of opisthorchiasis cases decreased from 1.74 in 2001 to 0.79 in 2002. In 2003, the morbidity rate increased to 1.58, but then, the ratio slightly decreased from 1.33 in 2004 to 0.64 in 2005. In 2006, the morbidity rate slightly increased to 0.73 per 100 000 populations (Figure 1A).

### **Report cases of opisthorchiasis by month**

During 2002-2006, the reported cases of opisthorchiasis by month were presented by the Bureau of Epidemiology, Department of Disease Control, Ministry of Public Health, Thailand. In 2002, the highest number of cases was in January, and the second was in March. Other months were a few cases of opisthorchiasis during the year. In 2003, the highest number of cases was reported, more than the other years from 2002 to 2006. The pattern of reported cases at each month, February was the highest and second was September. February in 2004 was the highest of reported cases followed by September and July. Meanwhile, in 2005 was found the highest opisthorchiasis cases in September, however, the second was February. Recently, in the reported cases February was higher than other months in 2006 (Figure 1B).

### **Report cases of opisthorchiasis by age-group, sex and occupation**

Infection with *O. viverrini* begins at a very early age (0-4 age group, 0.64 per 100 000 population); the prevalence of infection rises rapidly with age up to adult hood and remains relatively high, thereafter, the relationship of prevalence to age being a function of "*Koi pla*" consumption. The intensity of infection (faecal egg output) in both males and females rises steadily in early life, reaches highest in the 55-64 years age group (2.21 per populations), the reported cases were found common in 35-44, 45-54, 55-64 and 65+, 1.48, 2.06, 2.21 and 1.43 per population, respectively (Figure 1C). This figure showed similarity with a previous study, however, Upatham *et al* reported the highest in the 35-44 years age<sup>[14,21]</sup>. Loaharanu and Sornmani estimated the total direct cost of the infected work force (between the age of 15 and 60-year-old) in northeast Thailand to be Baht 2115 million per annum (wage loss = Baht 1620 million; direct cost of medical care = Baht 495 million)<sup>[42]</sup>. Meanwhile, the more frequently reported cases were in males more than females, in a ratio of 1:1.11 (Figure 1D). The opisthorchiasis cases reported by occupation found that agriculture was the most highest of cases than other. It is very surprising that the student group was the third of reported cases during 2003-2006 (Figure 1E). This is a very serious public health problem, health education should be conducted through communication and education.

**Figure 1** Reported cases of opisthorchiasis in Thailand<sup>[43]</sup>. **A:** Reported cases of opisthorchiasis per 100 000 populations, 2001-2006; **B:** Reported cases of opisthorchiasis by month, 2002-2006; **C:** Reported cases of opisthorchiasis per 100 000 populations by age group, 2003-2006; **D:** Reported cases of opisthorchiasis by sex, 2003-2006; **E:** Reported cases of opisthorchiasis by occupation, 2003-2006; **F:** Reported cases of opisthorchiasis by region, 2003-2006.

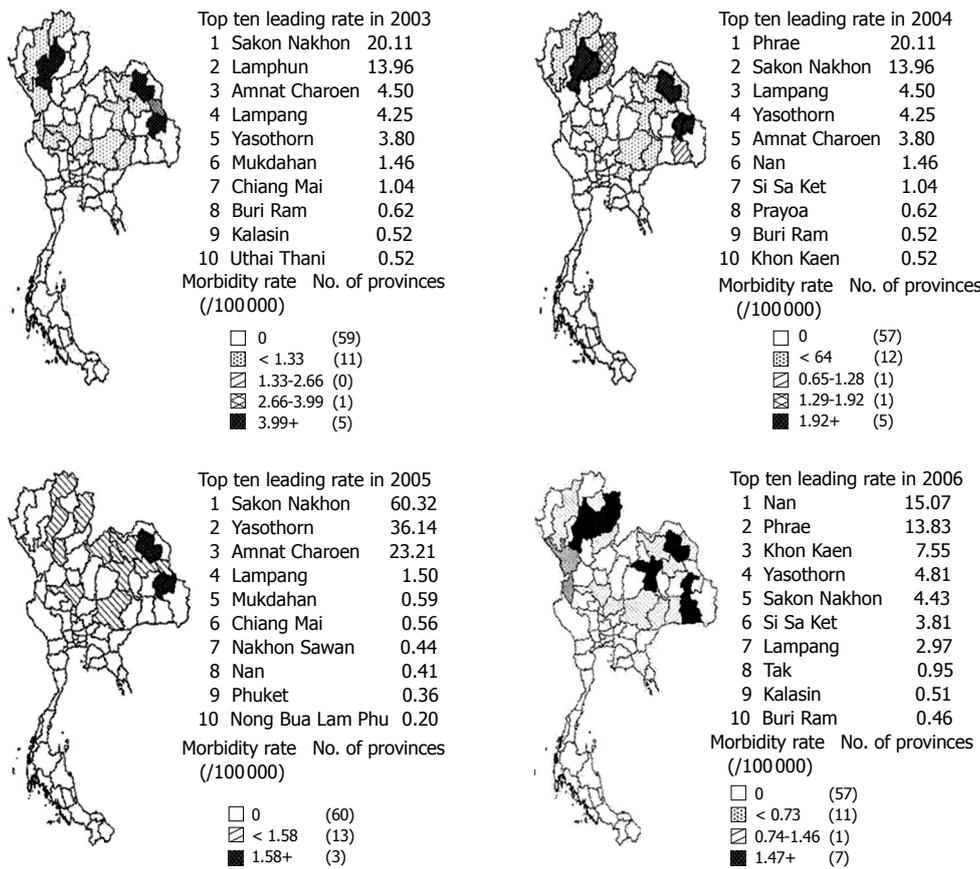

**Report cases of opisthorchiasis by region**

Nationwide survey was reported by<sup>[16]</sup>. The prevalence of *O. viverrini* infection in the north (19.3%), the northeast (15.7%), central (3.8%) and the south (0%) was recently reported. However, from 2003-2006, the reported cases of opisthorchiasis by region were presented by the Bureau of Epidemiology, Department of Disease Control, Ministry of Public Health, Thailand found that the northeast region was the highest of frequency than other regions. The second was the north, while the central region has shown a few opisthorchiasis cases. In the southern region, no cases were reported during 2003 to 2006 (Figure 1F). Although,

the reported cases of opisthorchiasis in the northern region were less than the northeast region in 2005-2006, the morbidity rate was higher than other regions. In 2006, the morbidity rate of opisthorchiasis cases in Thailand was 0.73 per population and in the north, northeast, central and south region was 1.45, 1.34, 0.00 and 0.00 respectively.

**Report of cases of opisthorchiasis by province**

It has also been shown that the prevalence and intensity of infection are greater among rural dwellers than their urban counterparts, an observation strongly associated with the habit and frequency of eating “*Koi pla*”<sup>[24]</sup>. This tradition

**Figure 2** Reported cases of opisthorchiasis per 100 000 populations by province in Thailand, 2003-2006<sup>[43]</sup>.

is commonly found in the northeast and north region of Thailand, therefore, provinces located in 2 regions are also frequently reported with opisthorchiasis cases. The morbidity rate was identified into top ten leading rates during 2003-2006, Sakon Nakhon, Yasothorn, Lamphun, Amnat Charoen, Lampang, Mukdahan, Chiang Mai, Buri Ram, Kalasin, Uthai Thani, Phrae, Nan, Si Sa Ket, Phayao, Khon Kaen, Chiang Rai, Nakhon Sawan, Phuket, Nong Bua Lam Phu, Phrae and Tak. From 2003-2006, Sakon Nakhon and Yasothorn were the provinces that found the opisthorchiasis cases every year (Figure 2).

**CONCLUSION**

*O. viverrini* is a medically important food borne trematode in Thailand including some parts of Southeast Asia countries. The opisthorchiasis have been studied for more than 50 years; the infection is associated with cholangiocarcinoma and other hepatobiliary diseases. This review article emphasizes the passive surveillance data that was reviewed by the Bureau of Epidemiology, Department of Disease Control, Ministry of Public Health, Thailand. The epidemiology is found in some rural areas that the tradition of eating raw or uncooked fish products was the main reason for infection. The northeastern and northern regions of Thailand are still a major public problem in the high-risk areas.

**ACKNOWLEDGMENTS**

The authors thank Dr. Lisa Vandemark for assistance with English-language presentation of the manuscript.

Special thanks Professor Reinhard Buettner for a valuable suggestion and comments on the manuscript.

## Abstract

Gene therapy is a new and promising approach which opens a new door to the treatment of human diseases. By direct transfer of genetic materials to the target cells, it could exert functions on the level of genes and molecules. It is hoped to be widely used in the treatment of liver disease, especially hepatic tumors by using different vectors encoding the aim gene for anti-tumor activity by activating primary and adaptive immunity, inhibiting oncogene and angiogenesis. Despite the huge curative potential shown in animal models and some pilot clinical trials, gene therapy has been under fierce discussion since its birth in academia and the public domain because of its unexpected side effects and ethical problems. There are other challenges arising from the technique itself like vector design, administration route test and standard protocol exploration. How well we respond will decide the fate of gene therapy clinical medical practice.

## INTRODUCTION

Gene therapy is a newly developed approach which emerged at the end of the 20th century and aims to treat human diseases based on transfer of genetic materials to cells<sup>[1]</sup>. It involves sets of recently developed technologies such as gene separation and purification, vector choice (viral and non-viral nature), transfer technique, *etc*<sup>[2]</sup>. This approach develops quickly and has the potential to bring a new era to the treatment of human diseases, though the fierce debate and discussion on its ethics and practicalities in human beings have never stopped since its birth.

Like conventional therapy, gene therapy is under the regulation of the Nuremberg Code (1947) and the Declaration of Helsinki (1964) which established the principal research ethics concerning the vulnerability and interest of the patient as well as the benefit of independent review. However, gene therapy also raises specific ethical issues and public concerns about the three main fronts. Firstly, there exists the risk of deliberate alteration in the human germ line, which may change the inherited nature of human beings. Secondly, various new technologies continue to propel such debates. Taking utero gene therapy for example, it is necessary and feasible in technique, to intervene in some genetic disorders during fetal development, but concerns about the issues of safety, transgenerational risks to the germ line and questions about the fetal awareness, have hampered its development. Thirdly, the impact of adverse effects has kept ethical debate going on. In September 1999, a teenager volunteer, Jesse Gelsinger, died after receiving the adenoviral gene therapy vector for the treatment of the inherited condition "Ornithine Transcarbamylase Deficiency" at the Penn State University. Three years later, in October and December 2002, the Necker Hospital in Paris announced two boys under gene therapy for X-SCID developed a form of leukemia<sup>[3]</sup>. Further evidence appeared in the same year, when Li Z *et al* reported that retroviral vectors can cause oncogenic transformation<sup>[4]</sup>. Though we still do not know to what extent the risks described by these cases can be translated to other trials, it has up-regulated the public concern and led to the stringency of safety assessments and patient monitoring in clinical gene therapy trials.

Nevertheless, the increasing problems and difficulties never put off public focus and scientists' enthusiasm on gene therapy for it has incredible huge potential in the treatment of human diseases and what we have found is only the tip of the iceberg. In the following part, we will review the existing policy and regulations on gene therapy,

especially introduce the point of view from Chinese researchers, and then outline the general information on its application in liver disease and vector choice. Finally, we will focus on gene therapy for hepatic tumors.

## POLICY, ETHICS AND REGULATION ON GENE THERAPY

In 1988, the European Medical Research Council first declared a formal stance against germline gene therapy, which was followed by the Council of Europe in 1991, for its violation of the basic human right to inherit a natural and unchanged genetic pattern from parents<sup>[5]</sup>. Against this background, many individual countries have their own policies. Holland (1989) and the USA (1982) both postponed germline gene therapy due to ethical and technical barriers while Germany (1987) made it a criminal offence in a more rigorous policy<sup>[5]</sup>. However, with the developments in biomedicine, ethical and policy analysis, the notion and practicalities of gene therapy have been under reevaluation. Some scientists have pointed out that “gene therapy” may inadequately describe the process and goals of germline alteration and should be replaced by the phrase “human germline genome modification” (HGLGM)<sup>[6]</sup>.

Unlike the ethical problem of germline gene therapy, somatic gene therapy attracts public controversy on its serious and unexpected side effects, which, in its utmost extent, have taken people's life away. Nevertheless, somatic gene therapy has been shown to be of great value in the treatment of different human diseases<sup>[7]</sup>, which makes a big challenge for scientists to control its advantages over disadvantages. Another related issue is the moral and risk evaluation of conducting gene therapy research in healthy volunteer subjects for there can be only long term potential risk and side effects with no exact benefits for patients. Anyway, most countries support the moral legitimacy of somatic-cell gene therapy for the cure of disease<sup>[8]</sup>.

Although gene therapy has the above mentioned risks when applied to human beings, its potential benefits could be released by our efforts. We have already done something to minimize the risks and maximize its treatment value in human diseases. Except for the legislation of general medicines, many nations have developed centralized but non-statutory device on gene therapy especially referring to the ethics. Under this condition, some specific national ethics committees and advisory boards like the USA Recombinant DNA Advisory Committee (RAC), the UK Gene Therapy Advisory committee (GTAC) and the Australian Gene Therapies Research Advisory Panel (GTRAP) were established. The aim of these regulation committees is to steer gene therapy towards the right direction.

It is interesting to note that a PubMed search of the term “ethics gene therapy” provides 1097 citations, and when narrowed to different Western countries there are always still many papers. However, when narrowed to “ethics gene therapy in China”, only two papers appear—one from UK, the other from Germany but none from China. In terms of language restriction and the large population, it is meaningful to introduce the general

regulations and ethics' consideration of gene therapy in China. After search through the Chinese biomedicine web database and Chinese scientific journals database, a total of 42 reviews were retrieved focusing on ethics of gene therapy. To sum up, currently there are no specific national ethics committees and advisory boards in China at different levels and comparing with Western countries, the legislation of gene therapy is still lagging behind, though three regulations including “the management of the safety of genetic engineering”, “the clinical and research control of human somatic gene therapy”, and “the management of human genetic resource” were established and all gene therapy-related activities are under their supervision. In academic arena, gene therapy also seems to be a grey area, where germline gene therapy is forbidden but somatic gene therapy and other therapies involving genetic engineering techniques are under intensive research. To our knowledge, the researches on gene therapy of hemophilia and mediterranean anemia are supported by Chinese government and some breakthroughs have been achieved. It seems that the awareness of and discussion on gene therapy at public level are less fierce than those in Western countries and actually, people are more interested in the beneficial and potential risks of transgenic food, which is closely related to their daily lives.

## GENE THERAPY FOR LIVER DISEASE AND VECTOR CHOICE

The liver has vital functions in metabolism of lipids, carbohydrates and proteins while liver disease damages the synthesis of plasma proteins and coagulation factors, the clearance of lipids and toxins from serum, the secretion of bile to intestine, *etc*<sup>[9]</sup>. Successful gene therapy needs relevant therapeutic gene, appropriate promoter and regulatory elements, effective vector to deliver the transgene into target cells. End-stage liver failure irrespective of its cause has a high morbidity and mortality while conventional medicine has little ability to promote recovery. However, successful gene therapy for liver disease has been achieved in animal models<sup>[10]</sup>. Introducing the therapeutic gene through adenoviral vector has corrected hyperbilirubinemia in a Gunn rat model of Crigler-Najjar syndrome type I<sup>[11,12]</sup>. Conlon TG *et al*<sup>[13]</sup> found that intramuscular administration of recombinant adeno-associated virus (rAAV) vectors expressing short-chain acyl-CoA dehydrogenase (SCAD) could systemically correct the fatty acid oxidation disorder in SCAD-deficient mice. There are many kinds of liver disease which would benefit from gene therapy, though it still has a long way to go.

The successful gene therapy for liver disease largely depends on the development of gene delivery vector which could mainly be divided into viral and non-viral vectors. In the following, we will outline both sub-divisions.

Adenovirus is a double-stranded DNA virus which possesses a combination of features that make them highly suitable as vectors for expression of a heterologous gene<sup>[14]</sup>. Adenoviral vectors are widely used in experimental gene therapy for cancers and also have a natural tropism

for the liver and a high efficiency for transferring non-dividing cells<sup>[15]</sup>. The non-integrating feature makes it a two-edge sword, which, on the one hand, will decrease the risk of oncogenic side effects caused by gene integration and mutation, on the other hand, leads to transient expression in host cells. Recently, the so called high-capacity adenoviral (HC-Ad) vectors, lacking all the viral sequences except for the packaging signals, provides a prolonged transgene expression by escaping the host immune response<sup>[16]</sup>. Goncalves MA *et al.*<sup>[17]</sup> have generated a hybrid gene transfer vehicle consisting of recombinant adeno-associated virus (AAV) replicative intermediates packaged in adenovirus (Ad) capsids for stable transduction of large DNA.

Retrovirus is a single stranded DNA virus which has the ability to integrate into the host cells. This characteristic increases the long term expression of the transferred gene in host cells but also results in potential side effects like leukemia caused by insertional mutagenesis. In order to decrease such risks, scientists have been exploring the molecular detail of genome packaging, retrovirus assembly and target site selection<sup>[18,19]</sup>. Retroviral vectors have another shortcoming in not easily transferring cells like hepatocytes that do not proliferate actively under physiological conditions. However, the new development of human lentiviral vectors, allowing for the transduction of non-dividing cells and stable gene expression, has shed light on the way forward<sup>[20]</sup>.

Adeno-associated virus (AAV) is a non-pathogenic human parvovirus with the deletion of all viral genes except for ITR. This vector exhibits a number of properties, making it an excellent choice of CNS gene therapy<sup>[21]</sup>, for hemophilia<sup>[22]</sup>, lung disease<sup>[23]</sup>, retinal disease<sup>[24]</sup>, *etc.* Despite its low immunogenicity, toxicity, long-term transgene expression and ability to transduce dividing and non-dividing cells, it has also shown a limited capacity of accommodating foreign genes and to some extent, the oncogenic trait, due to gene integrating<sup>[25,26]</sup>. There is still a lot of work to do on this specific vector.

There are also other viruses used as vectors like herpesvirus, baculovirus and the list is still expanding<sup>[27]</sup>. However, the non-viral vector has its own advantages, which could avoid the problems caused by the viral vector such as endogenous viral recombination, oncogenic effects and unexpected immune response<sup>[28]</sup>. Due to these traits, the non-viral vector has been rapidly developed and categorized into two groups: naked DNA delivery with a physical method like gene gun and electroporation or with chemical carriers such as polymer, peptide and lipid. Though various kinds of non-viral vector have appeared and new transfer techniques are emerging, it still has a long way to overcome its low transfection efficiency caused by extracellular and intracellular barriers and organ specificity<sup>[29,30]</sup>.

## GENE THERAPY FOR HEPATIC TUMORS

Hepatic tumor ranks fifth in frequency worldwide among all malignancies and causes one million deaths annually<sup>[31]</sup>. It is hard to cure when its progression precludes surgical resection and other conventional

techniques, like transarterial chemoembolization and systemic chemotherapy, are of less help because of their low efficacy and high complication rate. Transfer of therapeutic genes to the tumor or peritumor tissues has opened a new door to the treatment, and great efforts have been made to promote this approach at both preclinical and clinical levels. A large number of methods can be chosen for gene therapy, including activation of tumor suppressor genes, inhibition of oncogene and tumor angiogenesis, promoting specific gene sensitivity to drugs, transfer of oncolytic virus and stimulation of anti-tumor immunity<sup>[32]</sup>.

Interleukin (IL)-12 with a potent anti-tumor activity has been extensively studied during the past decades. IL-12 exerts its function as a bridge between innate and adaptive immune responses by inducing TH1 lymphocytes, inhibiting tumor angiogenesis, activating NK cells and cytotoxic T lymphocytes, and facilitating lymphocytes immigrating into the tumor tissues by up-regulating the expression of adhesion molecules on endothelial cells<sup>[33,34]</sup>. However, this cytokine is toxic when administrated systematically either as a recombinant protein or as a naked DNA (encoding IL-12)<sup>[35]</sup>. So what the scientist should do is to find the right way to express IL-12 constrained in local tumor tissue while minimize its systemic toxicity by decreasing the sera concentration.

As a reward for continuous effort, some breakthroughs have been made. Firstly, intra-tumor administration of recombinant adenovirus encoding IL-12 could eradicate neoplastic liver nodules in most of the animal models and increase long term survival. More surprisingly, treating one hepatic lesion also could lead to tumor elimination in a second non-treated hepatic lesion<sup>[36]</sup>. This phenomenon may be explained by the strong hepatic tropism of adenovirus as it escapes from the injected nodule to the general circulation and then infects the whole liver. Secondly, based on the adenoviral vectors, some changes in vector design have been made to increase the transfection efficiency and decrease the systemic toxicity. Wang *et al.*<sup>[37]</sup> have generated a gutless adenoviral vector containing a mifepristone (RU486)-inducible system for liver-specific expression of human interleukin-12 (hIL-12) (GL-Ad/RUhIL-12), which allows a prolonged, regulateable, and tissue-specific transgene expression compared with normal adenoviral vectors. Waehler *et al.*<sup>[38]</sup> demonstrated that intra-tumor adenoviral IL-12 immunotherapy can substantially improve its anti-tumor efficacy and safety profile when a fusion protein of two subunits of IL-12 (scIL-12) is expressed in an adenoviral vector. Dickerson *et al.*<sup>[39]</sup> have engineered a fusion protein of IL-12 linking the vascular homing peptide CDCRGDCFC to directly target the tumor neovasculature. Significant enhancement of antiangiogenic effect, augmentation of anti-tumor activity, and decreased IL-12 toxicity were observed. Thirdly, different administration ways have been developed and tested. Except for the above mentioned intra-tumor and peri-tumor injection, adenovirus encoding IL-12 given by intra-hepatic arterial route<sup>[36]</sup> and portal vein route<sup>[40]</sup> has been also shown to significantly reduce tumor burden and prolong survival. Fourthly, though IL-12-based gene therapy has pivotal anti-tumor effects, the

toxicity caused by inducing interferon gamma production has more or less hampered its application. To solve this problem, scientists are trying to combine IL-12 with other chemokines such as IP-10, to attract immune effector cells to tumors through IP-10 production and to activate attracted lymphocytes with IL-12<sup>[41]</sup>. We can also generate IL-12 secreting dendritic cells (DCs) by infecting them with adenovirus encoding IL-12 *in vitro* and then injecting these engineered DCs into the tumor<sup>[42]</sup>. This approach has proved extremely effective on liver tumor metastases from colorectal carcinoma<sup>[43]</sup>. Finally, adenovirus encoding IL-12 also has the ability to induce anti-tumor effects on liver neoplasms metastasized from other organ tumors<sup>[44,45]</sup>. This effect may be mediated by nonlymphocyte effector cells including macrophages and neutrophils and involve anti-angiogenic chemokines<sup>[46]</sup>.

Besides IL-12 gene therapy for hepatic tumor, there are other methods of gene therapy under exploration. Since p53 is mutated in approximately 50% of human tumors and has an important role in the genesis or progression of hepatocellular cancers, we could use gene replacement therapy of p53 for tumors<sup>[47]</sup>. It was reported that adenovirus encoding CD40 ligand could induce protective and curative anti-tumor immunity<sup>[48]</sup>. There is evidence that combination of adenovirus encoding CD40 ligand and naïve dendritic cells can decrease the amount of CD40 ligand while maintaining normal anti-tumor effect levels<sup>[49]</sup>. Silencing of oncogene or other genes by RNA interference (RNAi) offers a promising approach to the treatment of hepatic tumors<sup>[50]</sup>. We can also use isolated hepatic perfusion (IHP) to increase the adenoviral vector transfection efficiency and decrease the systemic toxicity<sup>[51]</sup>. Transfer of suicide gene into tumor tissue is another way of gene therapy. Terazaki *et al*<sup>[52]</sup> demonstrated that optimal therapeutic expression level of a suicide gene is a novel concept and a promising method.

Although gene therapy for hepatic tumor has been proved effective in most animals, there is still a lack of information about the efficacy and safety of those treatments in humans. Therapeutic gene, dosage and route of administration, type of vector and tumor itself are all complex ingredients and need careful consideration. Gene therapy is mainly used at the moment as a supplement to conventional treatment, and many trials are carried out in patients with advanced tumors. Thus, shortage of data about early cancer may underestimate the real effect of gene therapy on tumors. However, with the booming of phase I and II clinical trials, we will get enough information for analysis and estimation of gene therapy and this treatment method has a bright future.

## CONCLUSION

Gene therapy is a new and powerful tool to correct inherited disorders and treat human diseases. To some extent, this approach can be considered a revolution in the history of medicine for it deepens our vision on the nature of diseases and broadens our methods of treatment focusing on the level of genes and molecules. It can be used not only in the treatment of hepatic tumor which we have described in detail but also in other diseases once

there are any changes at gene level. Though animal models and some pilot clinical trials have shown a convincing future, gene therapy is still at its beginning and there is a lot of work to be done. Referring to the techniques, we should improve the transduction efficiency of vectors, increase the duration of therapeutic gene expression, decrease the unexpected toxicity and side effects, test and polish the routes of drug administration, *etc.* There is also likely a challenge of ethical issues. We should remember that technique itself is innocent, whether it is an evil or a virtue depends on the users. So it is our obligation to establish consummate regulations and policies of gene therapy making it serve human beings. Another problem is how to make gene therapy affordable to ordinary patients. As a new approach, gene therapy is much more expensive than conventional therapy, which is a hurdle for its wider use. How to balance the relationship between gene therapy and conventional therapy is very important. Gene therapy has been used to complement conventional therapy for end-stage diseases that cannot be cured with the latter. With the progress in gene therapy, more and more diseases can be cured at their early stage when conventional therapy is still useful.

In conclusion, despite the difficulties and obstacles, gene therapy has the potential to become a cornerstone of modern medicine.

### Abstract

**AIM:** To investigate the effect and mechanism of blockade of the CXC chemokine receptor-4 (CXCR4) signaling pathway by AMD3100, a small non-peptide CXCR4 inhibitor, on invasion and metastasis of colorectal cancer cells *in vitro*.

**METHODS:** Human colorectal cancer cell line SW480 was treated with AMD3100 at different final concentrations. 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT) assay was used to detect the effect of AMD3100 on cell proliferation. The invasion ability of SW480 cells was determined by cell invasion assay kit. In the presence of AMD3100, the CXCL12-mediated migratory response of SW480 cells was tested by classical chemotaxis assays. RT-PCR analysis and Western blotting were used to detect the expression of vascular endothelial growth factor (VEGF), matrix metalloproteinase-2 (MMP-2) and -9 (MMP-9) in SW480 cells.

**RESULTS:** Cell viability was significantly suppressed by AMD3100 in a dose-dependent manner. AMD3100 (100 and 1000 ng/mL) significantly inhibited the invasion ability of SW480 cells. Treatment with AMD3100 markedly reduced the expression of VEGF and MMP-9 but not MMP-2 in SW480 cells.

**CONCLUSION:** The CXCL12/CXCR4 system is an important mediator of proliferation and invasion of CXCR4-expressing colorectal cancer cells. AMD3100 inhibited invasion and metastasis activity of the colorectal

### INTRODUCTION

Stromal cell-derived factor-1 (SDF-1 or CXCL12) and its unique receptor CXC chemokine receptor-4 (CXCR4) have prominent roles in invasion and metastasis of a diverse number of cancers. The interaction between SDF-1 and CXCR4 has been shown to direct tumor cells to organ sites with high levels of SDF-1 expression, which suggests this molecular pair plays a key role in chemotaxis and homing of metastatic cells. Convincing evidence indicates elevated CXCR4 expression in primary tumors is associated with lymph node metastasis in breasts<sup>[1-4]</sup>, head and neck<sup>[5]</sup>, and colon<sup>[6]</sup>. Furthermore, CXCR4 expression is associated with intraperitoneal carcinomatosis of ovarian<sup>[7]</sup> and gastric<sup>[8]</sup> cancer. High or persistent expression of CXCR4 has been associated with poor prognosis in osteosarcoma<sup>[9]</sup>, epithelial ovarian cancer<sup>[10]</sup>, colon cancer<sup>[6,11,12]</sup>, esophageal carcinoma<sup>[13]</sup>, and melanoma<sup>[14]</sup>. Recently, intensive research has shown that binding of CXCL12 to CXCR4 plays a role in tumor angiogenesis by influencing the secretion of vascular endothelial growth factor (VEGF)<sup>[15]</sup> and increasing invasion associated with matrix metalloproteinase (MMP)-9 activation<sup>[16]</sup>. Therefore, interruption of the interaction between CXCR4 and SDF-1 has received considerable attention since it may provide a means of inhibiting the metastatic process.

AMD3100, a bicyclam molecule, has been identified as a specific inhibitor of CXCR4. It had originally been developed as an inhibitor of T-tropic human

immunodeficiency virus (HIV) infectivity and has been used to block HIV infection of T-tropic, X4-using, virus and induce X4 transformation to R5, which validate CXCR4 as a target for HIV therapy in clinical trials. Furthermore, AMD3100 has also been demonstrated to be an effective mobilizer of hematopoietic stem cells in both healthy volunteers and multiple myeloma and non-Hodgkin's lymphoma patients<sup>[17,18]</sup>. In recent studies, anti-CXCR4 treatment has suppressed primary tumor growth by inhibiting tumor angiogenesis, and has prevented lung metastasis of squamous cell carcinoma of the head and neck (SCCHN) in animal models<sup>[19]</sup>. Treatment of animals with AMD3100 resulted in decreased activation of the mitogen-activated protein kinase and AKT pathways in xenograft brain tumors, which are pathways downstream of CXCR4 that promote survival, proliferation and migration<sup>[20]</sup>.

However, the influence of various concentrations of AMD3100 on invasion and proliferation in human colorectal cancer cell lines has not been reported. The present study showed that inhibition of CXCR4, through using non-peptide small molecule AMD3100, had significant antitumor activity, which represents a novel strategy for targeting highly metastatic colorectal cancer cells.

## MATERIALS AND METHODS

### Cells

Human colorectal cancer (CRC) cell lines were obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA). Tumor cells were maintained in RPMI 1640, supplemented with 10% fetal calf serum, 100 U/mL penicillin, and 100 µg/mL streptomycin in a humidified incubator with an atmosphere of 5% CO<sub>2</sub>, 95% air at 37°C. The specific chemokine receptor CXCR4 antagonist, AMD3100 (Sigma-Aldrich, St. Louis, MO, USA) was dissolved in sterile PBS (GIBCO, Carlsbad, CA, USA) as a × 1000 stock solution, and then diluted with the culture medium for experiments.

### 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT) assay

Cell viability was determined by MTT assay. Briefly, exponentially growing CRC cells were seeded in 96-well culture plates in serum-free medium at an optimal density. After 24 h incubation, either PBS or the indicated dose of AMD3100 was added for 2 h incubation in eight parallel holes. Then, CXCL12 (Peprotech, Rocky Hill, NJ, USA) was added daily at 20 ng/mL. MTT assays (Beyotime, Haimen, China) were performed after 24, 48 and 72 h of AMD3100 treatment. Absorbance was measured at 590 nm. The results were calculated as mean values of eight wells per treatment group.

### Chemotaxis and invasion assays

Cell lines were assessed for migration utilizing a Boyden chamber chemotaxis assay. Chambers with 8 mm pore filters (HTS Transwell-24 System; Corning, Acton, MA, USA) were used. CXCL12 was added to the lower wells with 0.5% fetal bovine serum medium. Selected cells were

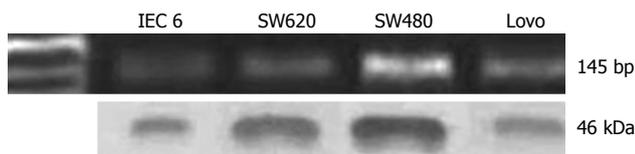

treated with PBS or AMD3100 15 min prior to assay performance. After 3 h incubation at 37°C, cells within the inserts were removed from the upper surface of the membrane using a moist cotton-tipped swab. Migratory cells on the lower surface of the membrane, which had migrated through the polycarbonate membrane, were fixed in 100% ethanol, washed with phosphate buffer solution, air dried and stained with crystal violet for 30 min, then rinsed several times with distilled water. Migration was quantitated by dissolving stained cells in 10% acetic acid, and an equal amount of the dye/solution mixture was transferred onto a 96-well plate for colorimetric reading of A<sub>590</sub>. Invasion assay was performed using Cell Invasion Kit (Chemicon, Temecula, CA, USA). The inserts had an 8-µm pore size polycarbonate membrane with a pre-coated thin layer of basement membrane matrix (ECMatrix, Temecula, CA, USA). After 24 h incubation, invasive cells on the lower surface of the membrane were stained and calculated as previous described. Assays were performed in triplicate.

### Western blotting

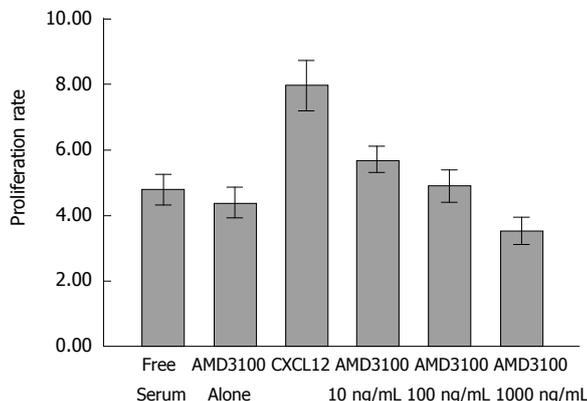

Whole-cell protein and nuclear protein extracts from SW480 CRC cells were prepared with Cell lysis buffer for Western and IP (Beyotime, Haimen, China) and Nuclear Extract Kit (Active Motif, Carlsbad, CA, USA), respectively, according to the manufacturers' instructions. Protein concentrations were determined using an assay kit (Bio-Rad, Hercules, CA, USA). Lysates containing 100 µg protein were mixed with loading buffer with 5% β-mercaptoethanol, and heated for 5 min at 100°C. Samples were separated by SDS-PAGE and transferred onto nitrocellulose membranes by semidry blotting. Membranes were incubated in TBS buffer for 1 h at room temperature, followed by hybridization with anti-CXCR4 antibody (Chemicon, Temecula, CA, USA); 1:1000 dilution), anti-MMP-9, anti-MMP-2 antibody, anti-VEGF antibody (Boster, Wuhan, China; 1:500 dilution) at 4°C overnight. After three washes in TBS/0.1% Tween 20, the membranes underwent hybridization with a horseradish peroxidase-conjugated secondary antibody, rabbit IgG (Santa Cruz Biotechnology, Santa Cruz, CA, USA; 1:5000 dilution) for 1 h at room temperature. After three washes in TBS/0.1% Tween 20, signals were detected by chemiluminescence using the Western blotting luminol reagent (Santa Cruz Biotechnology).

### RT-PCR

Total RNA extraction from CRC cells was performed with Trizol Reagent (Invitrogen, Carlsbad, CA, USA). Then, 2 µg total RNA was reverse transcribed with the First Strand cDNA Synthesis Kit (Takara, Japan). Subsequently, 2 µL cDNA product was subjected to PCR amplification with Taq DNA polymerase (Takara, Japan) on a thermal cycler using the following primers. The Random 9 mers primers for CXCR4, MMP-2, MMP-9, VEGF and β-actin were constructed on the basis of published sequences. The PCR primers used to detect each factor were as follows: CXCR4, sense strand 5'-GGAGGGGATCAGTATATAC A-3'; antisense strand 5'-GAAGATGATGGAGTAGAT

**Figure 1** Expression of CXCR4 in intestinal epithelial cells. Expression of CXCR4 in highly metastatic CRC cell line SW480, using RT-PCR analysis of mRNA, and Western blotting of CXCR4 protein levels.

**Figure 2** Effect of AMD3100 on viability of CRC SW480 cells. After 24 h incubation, cells growing in 96-well plates were treated with AMD3100 for 2 h. CXCL12 was added at 20 ng/mL per day, and the MTT assay revealed that in serum-free medium or the absence of CXCL12, AMD3100-induced inhibition was relatively weak. CXCL12-induced cell proliferation was significantly suppressed by 100 and 1000 ng/mL AMD3100 in SW480 cells. Cell viability was not significantly affected by 10 ng/mL AMD3100 (compared to the unstimulated group). Data are mean ± SD of eight wells after 3 d incubation. Bars indicate mean ± SD of triplicate experiments.

GG-3' (145 bp)<sup>[12]</sup>; *MMP-2*, sense strand 5'-GTGCTGAA GGACACACTAAAGA-AGA-3'; antisense strand 5'-TTGCCATCCTTCTCAAAGTTGTAGG-3', (605 bp)<sup>[21]</sup>; *VEGF*, sense strand 5'-CCTGGTGGACATCTTCCAGG AGTACC-3'; antisense strand 5'-GAAGCTCATCTCTC CTATGTGCTGGC-3', (196 bp)<sup>[22]</sup>; *MMP-9*, sense strand 5'-TCCCT-GGAGACCTGAGAACC-3'; antisense strand 5'-GTCGTCGGTGTTCGTAGT-TGG-3' (704 bp)<sup>[23]</sup> and  $\beta$ -actin, sense strand 5'-ATCTGGCACCA CACCTTCTACAA-TGAGCTGCG-3'; antisense strand 5'-CGTCATACTCCTGCTTGCTGATCCACATCTG-C-3' (838 bp)<sup>[24]</sup>. The PCR conditions were as follows: One cycle of denaturing at 94°C for 2 min, followed by 30-35 cycles amplification, 56°C for 45 s and 72°C for 2 min. The PCR products were loaded onto 2% agarose gels and visualized with ethidium bromide under UV light. The ratio value of each group and the GAPDH group was taken as the relative value.

**Statistical analysis**

Numeric data are presented as mean ± SD of three experiments. The paired student's *t* test or one-way ANOVA was used for comparing the differences between groups. Statistical significance was assigned if *P* < 0.05. Analyses were performed using SPSS 13.0 (SPSS, Chicago, IL, USA).

**Table 1** Effect of AMD3100 on invasion of CRC cells (mean ± SD)

Group	A590 value	Inhibition rate (%)
Control	0.703 ± 0.016	
AMD3100		
10 ng/mL	0.656 ± 0.062	7.57 ± 7.21
100 ng/mL	0.505 ± 0.091 <sup>a</sup>	28.43 ± 12.86 <sup>a</sup>
1000 ng/mL	0.158 ± 0.0325 <sup>b</sup>	77.23 ± 4.26 <sup>b</sup>

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01, vs the control group (*n* = 3).

**RESULTS**

**Expression of CXCR4 in intestinal epithelial cells**

In our previous study, we analyzed CXCR4 expression in several cell lines (SW480, SW620, Lovo and IEC-6). In particular, our data showed lymph-node-metastasis-derived cell line SW480 expressed CXCR4 at a high level, by using RT-PCR and Western blotting (Figure 1). We also examined mRNA expression of *CXCL12*, the ligand of *CXCR4*, by RT-PCR. We found no expression of *CXCL12* mRNA in any of the colorectal cancer cell lines (data not shown).

**Effect of AMD3100 on viability of CRC cells SW480**

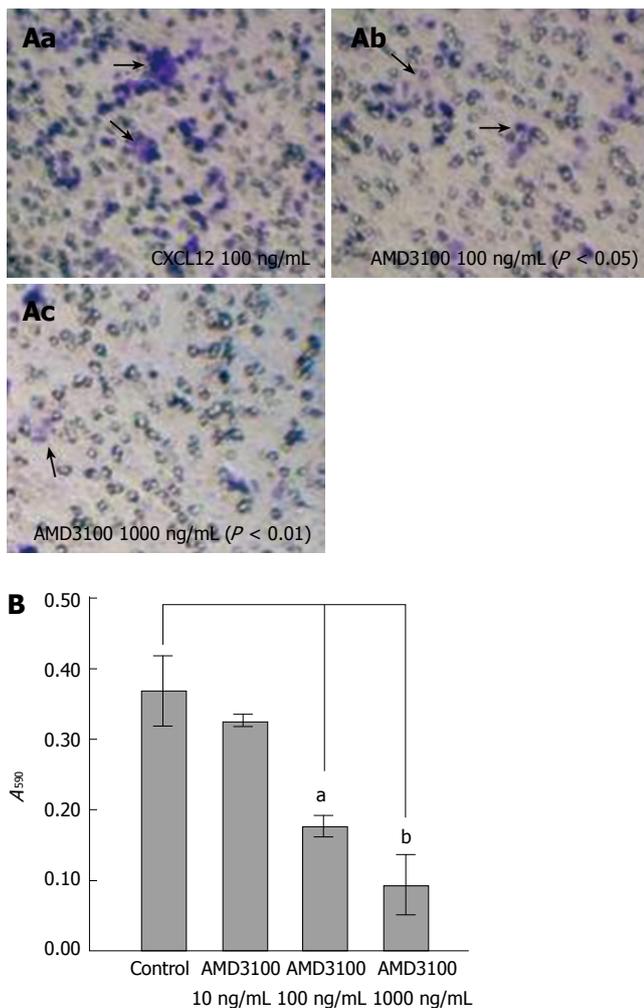

In our previous studies, we found no expression of *CXCL12* mRNA in any of the CRC cancer cell lines. After 3 d incubation, *CXCL12* greatly enhanced SW480 cells viability in the absence of serum (Figure 2). The enhancing effect of *CXCL12* on cell proliferation was strongly inhibited by treatment with different doses of AMD3100. In a dose-dependent fashion, the proliferation rate was reduced to 6.10 ± 0.13, 4.49 ± 0.22, 3.58 ± 0.13 respectively (*P* < 0.05). The effect of 100 and 1000 ng/mL AMD3100 was statistically significant (*P* < 0.01, *n* = 8) compared to that of the CXCL12 group (7.97 ± 0.811). Although a decrease in proliferation was also observed in the AMD3100 alone group compared to the serum-free cells (vehicle-treated cells), the inhibition rate was not significantly different, probably due to a specific effect of blocking CXCL12-CXCR4 interaction. The assay also revealed that, in 24 h, there was no significant difference in viability in any of the groups. Therefore, the cell invasion assay was performed at 24 h to remove its influence on cell viability.

**Effect of AMD3100 on invasion of CRC cells**

To evaluate the effects of inhibition of CXCL12-CXCR4 interaction on CRC invasion, we performed an *in vitro* invasion assay using AMD3100. After 24 h incubation, AMD3100 markedly reduced invasion of SW480 cells at concentrations of 100 and 1000 ng/mL (Table 1), by 28.43% (*P* < 0.05) and 77.23% (*P* < 0.01), respectively.

**Effect of AMD3100 on chemotactic migration of CRC cells**

The effect of AMD3100 on inhibiting CXCL12-induced migration of CRC cells was estimated by a classical chemotaxis assay. The selected CXCR4-positive cell line, SW480, did migrate in response to CXCL12 in a classical

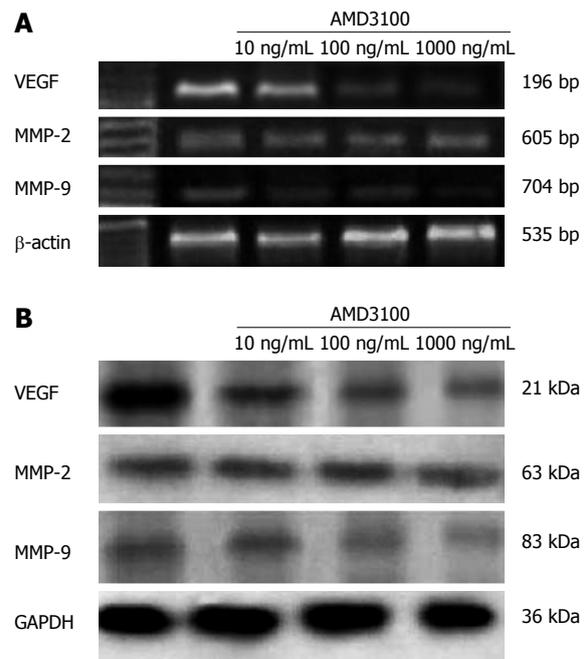

**Figure 3 A:** Effect of AMD3100 on chemotactic migration of CRC cells. The chemotaxis assay indicated that AMD3100 significantly inhibited the CXCL12-mediated migration of SW480 cells at final concentrations of 100 and 1000 ng/mL. The blue-stained cells are those that migrated through the polycarbonate membrane to the lower surface of the membrane (a-c); **B:** CXCL12 inhibited migration of SW480 cells in a dose-dependent manner. Bars indicate mean  $\pm$  SD of triplicate experiments. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ .

chemotaxis assay, with an optimal response at 100 ng/mL. After AMD3100 treatment, chemotactic activity of SW480 cells was reduced in a dose-dependent manner (Figure 3B). The inhibition rate with AMD3100 at 10, 100 and 1000 ng/mL was 5.24%, 47.27% and 62.37%, respectively. The latter two achieved a significant difference compare to the control group (a, b and c in Figure 3A).

#### Effect of AMD3100 on expression of MMP-2, MMP-9 and VEGF in SW480 cells

The CXCL12-CXCR4 axis contributes to invasion and specific organ metastasis through regulation of its target genes, which have recently been shown to be *VEGF* and *MMPs*<sup>[7,16,25,26]</sup>. Therefore, we detected the effect of AMD3100 on expression of *VEGF*, *MMP-2* and *MMP-9*. As shown in Figure 4, 24 h incubation with AMD3100 reduced *MMP-9* and *VEGF* protein expression in a dose-dependent manner in SW480 cells. RT-PCR demonstrated that the expression of *MMP-9* but not *MMP-2* and *VEGF* mRNAs in SW480 cells was significantly downregulated by

**Figure 4 A:** Effect of AMD3100 on expression of *MMP-2*, *MMP-9* and *VEGF* in SW480 cells. Protein samples extracted from SW480 cells treated for 26 h with AMD3100 were subjected to Western blotting for *MMP-2*, *MMP-9*, *VEGF* and *GAPDH* proteins. AMD3100 significantly decreased *MMP-9* and *VEGF* protein expression in SW480 cells in a dose-dependent manner. The level of *GAPDH* expression was determined as a control for equivalent protein loading; **B:** RNA samples extracted from SW480 cells treated for 26 h with AMD3100 were subjected to RT-PCR for *MMP-2*, *MMP-9*, *VEGF* and  *$\beta$ -actin*. AMD3100 also significantly decreased expression of *MMP-9* and *VEGF* mRNAs in SW480 cells, and the inhibitory effect was dose-dependent. RT-PCR for  *$\beta$ -actin* was performed in parallel to show an equal amount of total RNA in the sample.

100 and 1000 ng/mL AMD3100. Densitometric analysis revealed the relative expression decreased to  $17.58\% \pm 3.79\%$  for *MMP-9*, and  $39.44\% \pm 3.07\%$  for *VEGF*, as compared to the controls ( $P < 0.05$ ).

## DISCUSSION

A growing body of literature has indicated CXCR4 is important in a variety of cancers, and more specifically, that this receptor can be a propitious target in treating cancer. In experimental systems, convincing evidence has shown that selective inhibition of CXCR4 suppresses CXCL12-induced migration of cancer cells, invasion, neoangiogenesis and metastases. Neutralizing the interactions of CXCL12 and CXCR4 by monoclonal antibody significantly impairs metastasis of breast cancer cells to regional lymph nodes and lungs<sup>[27]</sup>. Human breast tumor growth can be delayed by inhibiting CXCR4 with siRNA<sup>[28]</sup>. Similarly, CXCR4 antagonists, T140 analogs, inhibit SDF-1-induced migration of human breast cancer, leukemia and endothelial cells *in vitro*, in a manner relevant to tumor spread and angiogenesis<sup>[29]</sup>. The CXCR4 inhibitor RCP168 partially abrogates the protective effect of stromal co-culture system and greatly enhances chemotherapy-induced apoptosis in chronic lymphocytic leukemia cells<sup>[30]</sup>. Redjal *et al* have demonstrated the ability of AMD3100 to reduce the activation of extracellular signal-regulated

kinases 1 and 2 and Akt, all of which are pathways downstream of CXCR4 that promote cell survival, proliferation and migration. Moreover, *in vivo*, combining sub-therapeutic doses of AMD3100 with a conventional cytotoxic agent in an order-dependent manner produces synergistic effects, which result from both a decrease in proliferation and an increase in apoptosis of tumor cells<sup>[31]</sup>.

Our previous studies have shown a significant association between CXCR4 expression and lymph nodal status and increased risk for metastasis in colorectal carcinoma. These initial observations prompted us to further question whether modulation of CXCR4 affects the invasive ability of CRC cells. In the present study, we demonstrated that AMD3100, a CXCR4-specific inhibitor, strongly suppressed CXCL12-induced activity and invasion of the SW480 cell line, which expressed CXCR4 at a high level. Recently, researchers have found that CXCL12-CXCR4 signaling directly regulates MMP-9 expression in CRC cell lines<sup>[16]</sup>. In our present study, the use of AMD3100 markedly reduced the mRNA and protein expression of MMP-9 but not MMP-2 in SW480 cells, through blocking the CXCL12-CXCR4 signaling pathway. This suggests that inhibiting SDF-1/CXCR4 interaction may have a variety of therapeutic benefits in CRC patients. Meanwhile, we also observed a directional migration of CRC cells depending on the presence of extracellular matrix (ECM) proteins. AMD3100 significantly inhibited CXCL12-induced migratory activity and ECM-dependent direct invasive ability.

Recent studies have also shown VEGF expression is associated with poor survival and prognosis in CRC, and that increased VEGF expression is correlated with increased microvessel density, local invasion, liver metastasis, and early recurrence after curative resection<sup>[20,32]</sup>. In the present study, we also found that AMD3100 significantly decreased mRNA and protein expression of VEGF in SW480 cells, which suggests that drug treatment may not only block CXCL12-induced angiogenesis, but also impair formation of microvasculature in metastasis stimulated by VEGF.

In serum-free medium, adding CXCL12 may significantly increase proliferation activity of tumor cells. This kind of protective microenvironment generally exists in various solid tumors, such as CXCR4-positive renal cancer and intracranial glioblastoma, which functionally improves cancer-cell viability, anti-apoptotic survival and chemoresistance<sup>[29]</sup>. Production of CXCL12 in tumor stroma may keep cancer cells tolerant to hypoxic or poor nutritional conditions. On the other hand, hypoxia-induced CXCR4 expression may activate downstream signal transduction, and subsequently regulate cancer cell biological behavior to adapt to hypoxia. In our study, we tested in the presence of CXCL12, the effect of various concentrations of AMD3100 on cell viability. Interestingly, although the treatment failed to decrease the number of cancer cells in serum-free medium, AMD3100 abrogated CXCL12 stimulation during cell proliferation in a dose-dependent manner. Additionally, AMD3100 alone did not significantly affect cell proliferation compared with the unstimulated group, which suggests no autocrine growth stimulatory loops exist in this cell line.

In conclusion, CXCL12-CXCR4 signals are responsible for the invasion and metastasis of human CRC *via*

regulation of cell viability and the expression of genes related to proteolysis and angiogenesis. Blocking the CXCL12-CXCR4 pathway may provide a novel means of preventing the invasion and metastasis of CRC.

## COMMENTS

### Background

CXC chemokine receptor-4 (CXCR4) is by far the most common chemokine receptor overexpressed in human cancer cells. High-level expression of CXCR4 in various primary cancers is significantly associated with poor prognosis and extent of metastasis. Targeting CXCR4, therefore, is now regarded as a novel and efficient strategy for treating human cancer metastases. There are two categories of therapeutic strategy for targeting CXCR4, anti-CXCR4 monoclonal antibody and specific small molecular CXCR4 antagonists such as AMD3100, T140, ALX40-4C and CTCE-9908. Each of these inhibits CXCR4 via different mechanisms.

### Research frontiers

Specific small-molecule CXCR4 antagonists such as AMD3100 may play an important role in the treatment of HIV infections, and many other pathological processes that are dependent on CXCL12-CXCR4 interactions (e.g. rheumatoid arthritis, asthma and cancer metastasis). Treatment of animals with AMD3100 results in decreased activation of the mitogen-activated protein kinase and AKT pathways in xenograft brain tumors. Administration of AMD3100 and 1, 3-bis (2-chloroethyl)-1-nitrosourea (BCNU) in an order-dependent manner produces synergistic cytotoxicity, which results from both a decrease in proliferation and an increase in apoptosis of glioblastoma cells.

### Innovations and breakthroughs

We have demonstrated that CXCL12-induced activity and invasion of CRC cells were markedly suppressed by blocking the CXCL12-CXCR4 signaling pathway with AMD3100, a small non-peptide inhibitors of CXCR4. These findings strongly suggest CXCR4 plays an important role in CRC progression and may provide a novel and effective molecular target for treatment of CRC.

### Applications

Our study showed that blockade of the CXCL12-CXCR4 axis affects the viability, invasion and migration of CRC cells by using various doses of AMD3100. The data also demonstrated the inhibitory effect was dose-dependent. It may be a good start to move from elucidation of the mechanism of action of chemokine receptors in cancer metastasis to development of novel therapeutic targets based on the CXCL12-CXCR4 axis.

### Terminology

Chemokines are small secreted peptides that control adhesion and transendothelial migration of leukocytes, especially during immune and inflammatory reactions. They are divided into four subfamilies: CC, CXC, C and CX3C based on the position of their NH<sub>2</sub>-terminal cysteine residues, and bind to seven transmembrane domain G protein-coupled receptors. CXCL12, also known as SDF-1, belongs to the CXC chemokine family and CXCR4 is the only known physiological receptor for SDF-1.

### Peer review

This is a very interesting study. The authors showed inhibition of CRC cell viability and metastasis by blocking CXCL12-CXCR4 interaction. Although this does not necessarily predict a positive result in human trials, the accumulation of these data may provide additional clues regarding some unanswered questions.

### Abstract

**AIM:** To examine the molecular mechanism of exocytosis in the Brunner's gland acinar cell.

**METHODS:** We used a submucosal preparation of guinea pig duodenal Brunner's gland acini to visualize the dilation of the ductal lumen in response to cholinergic stimulus. We correlated this to electron microscopy to determine the extent of exocytosis of the mucin-filled vesicles. We then examined the behavior of SNARE and interacting Munc18 proteins by confocal microscopy.

**RESULTS:** One and 6  $\mu\text{mol/L}$  carbachol evoked a dose-dependent dilation of Brunner's gland acini lumen, which correlated to the massive exocytosis of mucin. Munc18c and its cognate SNARE proteins Syntaxin-4 and SNAP-23 were localized to the apical plasma membrane, and upon cholinergic stimulation, Munc18c was displaced into the cytosol leaving Syntaxin-4 and SNAP-23 intact.

**CONCLUSION:** Physiologic cholinergic stimulation induces Munc18c displacement from the Brunner's gland acinar apical plasma membrane, which enables apical membrane Syntaxin-4 and SNAP-23 to form a SNARE complex with mucin-filled vesicle SNARE proteins to affect exocytosis.

**Key words:** Apical exocytosis; Brunner's gland acini; Munc18c; Syntaxin-4; Carbachol

### INTRODUCTION

The Brunner's glands in the duodenum contribute to the discharge of mucin<sup>[1,2]</sup> and also the secretion of a number of other products, including immunoglobulin, lysozyme, epidermal growth factor, and trefoil peptides, which collectively contribute to mucosal protection<sup>[2-5]</sup>. Brunner's glands also secrete bicarbonate that contributes to the neutralization of the massive amount of acid coming from the stomach<sup>[2]</sup>, and duodenal alkalization is critical for pancreatic enzyme survival. The Brunner's gland is, therefore, a most versatile exocrine microorgan, but despite its importance in gastrointestinal health, relatively little is known about its secretory biology and regulation, in part because they exist as very small micro-organs buried within the duodenal mucosal epithelium.

To better understand Brunner's physiology, we previously reported the development of an *in vitro* model that permitted the examination of Brunner's gland secretion by video microscopy, which recorded real time changes in diameter of the dilating lumen of Brunner's gland acini that corresponded to the extent of mucin exocytotic emptying<sup>[6,7]</sup>. Using this model, we demonstrated cholinergic stimulation of compound exocytosis of mucin into the ductal lumen, which was confirmed by electron microscopy and histology<sup>[6]</sup>. We then went on to examine vagal neural cholinergic innervation<sup>[6]</sup>, and its coupling to potassium channel current, which regulated the acinar cell membrane excitability leading to secretion<sup>[7]</sup>.

Almost nothing is known about the molecular mechanisms regulating exocytosis *per se* in Brunner's gland acini. In contrast, there has been much insight into

molecular mechanism of exocytosis in the pancreatic acinar cell<sup>[8,9]</sup>. It is very likely that similar exocytotic molecules in the pancreatic acinar cell would be conserved in Brunner's gland acini to mediate exocytosis of mucin. This led us to begin to explore for such exocytotic molecules, including SNARE (soluble NSF attachment protein receptor) proteins and associated Munc18 proteins, which regulate SNARE complex assembly<sup>[10]</sup>. Munc18c binds Syntaxin-4 on the basolateral plasma membrane of the pancreatic acinar cell<sup>[11]</sup>. Upon supramaximal cholinergic (or CCK) stimulation, Munc18c becomes phosphorylated causing its displacement from Syntaxin-4 into the cytosol, which activates Syntaxin-4 to bind SNAP-23, rendering the basolateral plasma membrane receptive to exocytosis by zymogen granules<sup>[11]</sup>. We recently demonstrated this to be a contributing mechanism to supramaximal secretagogue-induced pancreatitis as well as alcoholic pancreatitis<sup>[11-15]</sup>.

In this work, we also found Munc18c, Syntaxin-4 and SNAP-23 to be present in Brunner's gland acini. Unlike pancreatic acini<sup>[11-15]</sup>, these exocytotic molecules are concentrated on the apical plasma membrane. Upon physiologic cholinergic stimulation, Munc18c behavior mimicked that of pancreatic acini<sup>[11-15]</sup>, becoming displaced from the apical membrane into the cytosol, which correlated to massive exocytosis of mucin into the dilating Brunner's gland acinar lumen.

## MATERIALS AND METHODS

### **Antibodies and reagents**

Antibodies used include those generated against Munc18c (a gift from Y Tamori, Kobe University, Japan), Syntaxin-4 (a gift from J Pessin, Stony Brook University, NY, USA), SNAP-23 (generated by us), and Mucin 5AC-clone 45M1 from Lab Vision (Fremont, CA, USA). Fluorochrome-conjugated secondary antibodies were from Jackson ImmunoResearch Laboratories (West Grove, PA, USA). All reagents were from Sigma Chemical Co. (St. Louis, MO, USA).

### **Brunner's gland preparation and stimulation by carbachol**

*In vitro* submucosal preparations containing Brunner's glands were dissected from the duodenum of guinea pigs (150-200 g) of either sex, as previously described<sup>[1,6,7]</sup>. Briefly, animals were anesthetized with isoflurane and killed by decapitation. The duodenum was opened along the mesenteric border and pinned flat with the mucosa side up in Sylgaard-lined petri dishes. The mucosa was dissected off and the underlying submucosa containing sheets of Brunner's glands dissected free from the circular muscle. Submucosal preparations were cut about 1 cm<sup>2</sup> and stored at room temperature (maximum time of 2 h) in physiological Krebs solution containing (in mmol/L): 126 NaCl, 2.5 NaH<sub>2</sub>PO<sub>4</sub>, 1.2 MgCl<sub>2</sub>, 2.5 CaCl<sub>2</sub>, 5 KCl, 25 NaHCO<sub>3</sub> and 11 glucose, equilibrated with 95% O<sub>2</sub>-5% CO<sub>2</sub>. Experiments were approved by the Queen's University and University of Toronto Animal Care Committees and met the guidelines of the Canadian Council of Animal Care.

In all studies, preparations were initially pinned in small

organ baths (1 mL), and superfused with Krebs's solution at 37°C for a 10 min equilibration period. They were then superfused for 3 min with Krebs's solution (control) or carbachol (1 µmol/L or 6 µmol/L). Tissues were then fixed by one of two means (see below) and coded to enable measurements to be performed in a blinded fashion.

### **Examination of exocytosis by transmission electron microscopy**

Following superfusion with carbachol or control solution (Krebs's), preparations were fixed in 2% glutaraldehyde (pH 7.0) for 2 h and washed in sodium phosphate buffer. The fixed tissue was sectioned into segments about 2 mm<sup>2</sup> and immersed in 1% osmium tetroxide for 1 h. Tissue blocks were embedded in Eponar aldite. Brunner's glands were identified in semi-thin sections (0.5-1.5 µmol/L), which were cut perpendicular to the surface of the submucosal preparation and stained with toluidine blue. Plastic blocks were then trimmed to areas of about 0.5 mm<sup>2</sup> and ultrathin sections were cut and mounted on copper grids. These were stained with uranyl acetate and lead citrate and sections were viewed using a Zeiss EM 10 CR transmission electron microscope.

### **Confocal immunofluorescence microscopy**

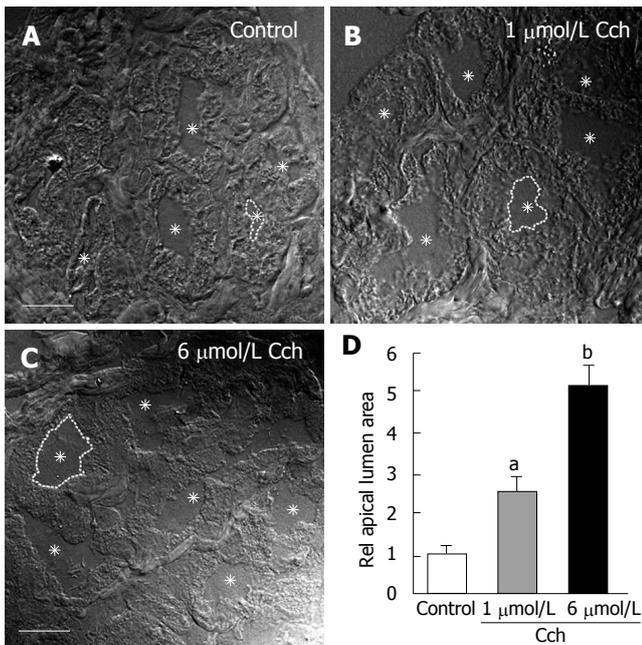

This was performed as similarly described in our previous reports<sup>[11-15]</sup>. Frozen tissues were treated with Tissue-Tek OCT mounting compound from Tedpella (Redding, CA, USA), and then cut at 5 µm-thin sections. Frozen tissue sections were thaw-mounted onto VistaVision HistoBond adhesive slides from VWR (Mississauga, ON, Canada), fixed with 4% paraformaldehyde (1 h), rinsed in PBS and then treated with 100 mmol/L glycine (10 min). The tissues were then permeabilized with 0.1% Triton-X (in PBS), blocked with 5% albumin (overnight, 4°C) and then incubated with the primary antibody (1:50, 5 h). After extensive washing, fluorescently labeled secondary antibodies (1:1000) were added for 1 h, followed by washing, and treatment with Fluorescence Mounting Medium (DAKO Diagnostics, Mississauga, ON). The tissue samples were examined by a laser scanning confocal imaging system (Zeiss LSM510), equipped with LSM software version 5.00 (Carl Zeiss, Oberkochen, Germany).

### **Measurement of Brunner's gland dilation**

Concurrent to obtaining the immunofluorescence images, DIC (differential interference contrast) images from frozen tissue sections were taken using the DIC optics of the confocal microscope. The apical lumens of the acini were measured using Image J software (NIH) by two independent observers in a blinded fashion. Significant differences between the two independent observers were not found and, therefore, the data were averaged for each measurement.

### **Statistical analysis**

Slides were coded to avoid observer bias and measurements were performed in a blinded manner by two independent observers and their results averaged. All data are presented as mean ± SE. Statistical analysis was done

**Figure 1** Carbachol-evoked dilatation of Brunner's gland acinar lumens. **A-C:** Representative differential interference contrast (DIC) images of control (**A**), 1  $\mu\text{mol/L}$  Carbachol (**B**), and 6  $\mu\text{mol/L}$  Carbachol (**C**) showing a dose-dependent dilatation of the acinar lumen. In each panel, the lumens are indicated by asterisks and one of the lumens is highlighted with a broken line. **D:** Statistical analysis of apical lumen area relative to control. For each condition 50 glands from 3 different sets of animals were measured ( $n = 150$ ). Only those glands where the complete acinus was contained in the section were studied. Scale bar = 10  $\mu\text{m}$ . <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ .

by Student's *t* test. Significance was assumed at a *P* value of less than 0.05.

## RESULTS

### **Carbachol evokes a dose-dependent dilatation of Brunner's gland acinar lumens**

Brunner's gland acinar cells contain mucin granules in the apical cytoplasm and previous studies have shown that stimulation-evoked dilation of Brunner's gland apical lumen is associated with the deposition of mucin in this space<sup>[1]</sup>. In the current study, carbachol (1  $\mu\text{mol/L}$  and 6  $\mu\text{mol/L}$ ) evoked a dose-dependent dilatation of the lumen (Figure 1 A-C). Compared to controls ( $1.0 \pm 0.2$ ), carbachol 1  $\mu\text{mol/L}$  caused 2.5-fold increase in luminal surface area ( $2.5 \pm 0.5$ ,  $P < 0.05$ ) and 6  $\mu\text{mol/L}$  caused a 5-fold increase ( $5.1 \pm 0.7$ ,  $P < 0.001$ ; Figure 1D).

### **Carbachol evokes a dose-dependent mucin granule exocytosis into Brunner's gland acinar lumens**

Transmission E.M. was employed to observe the effects of carbachol stimulation on the location and size of the mucin granules (Figure 2). In unstimulated preparations (Figure 2A), membrane-bound, electron-lucent vesicles were packed into the apical cytoplasm. Carbachol stimulation (1  $\mu\text{mol/L}$  and 6  $\mu\text{mol/L}$  in Figure 2B and 2C, respectively) caused fusion of the mucin vesicles deeper in the cytoplasm (indicated by asterisks, shown clearly in image blowups in Biii and Ciii), and migration and fusion of the vesicles with the apical membrane. Apical exocytosis included compound

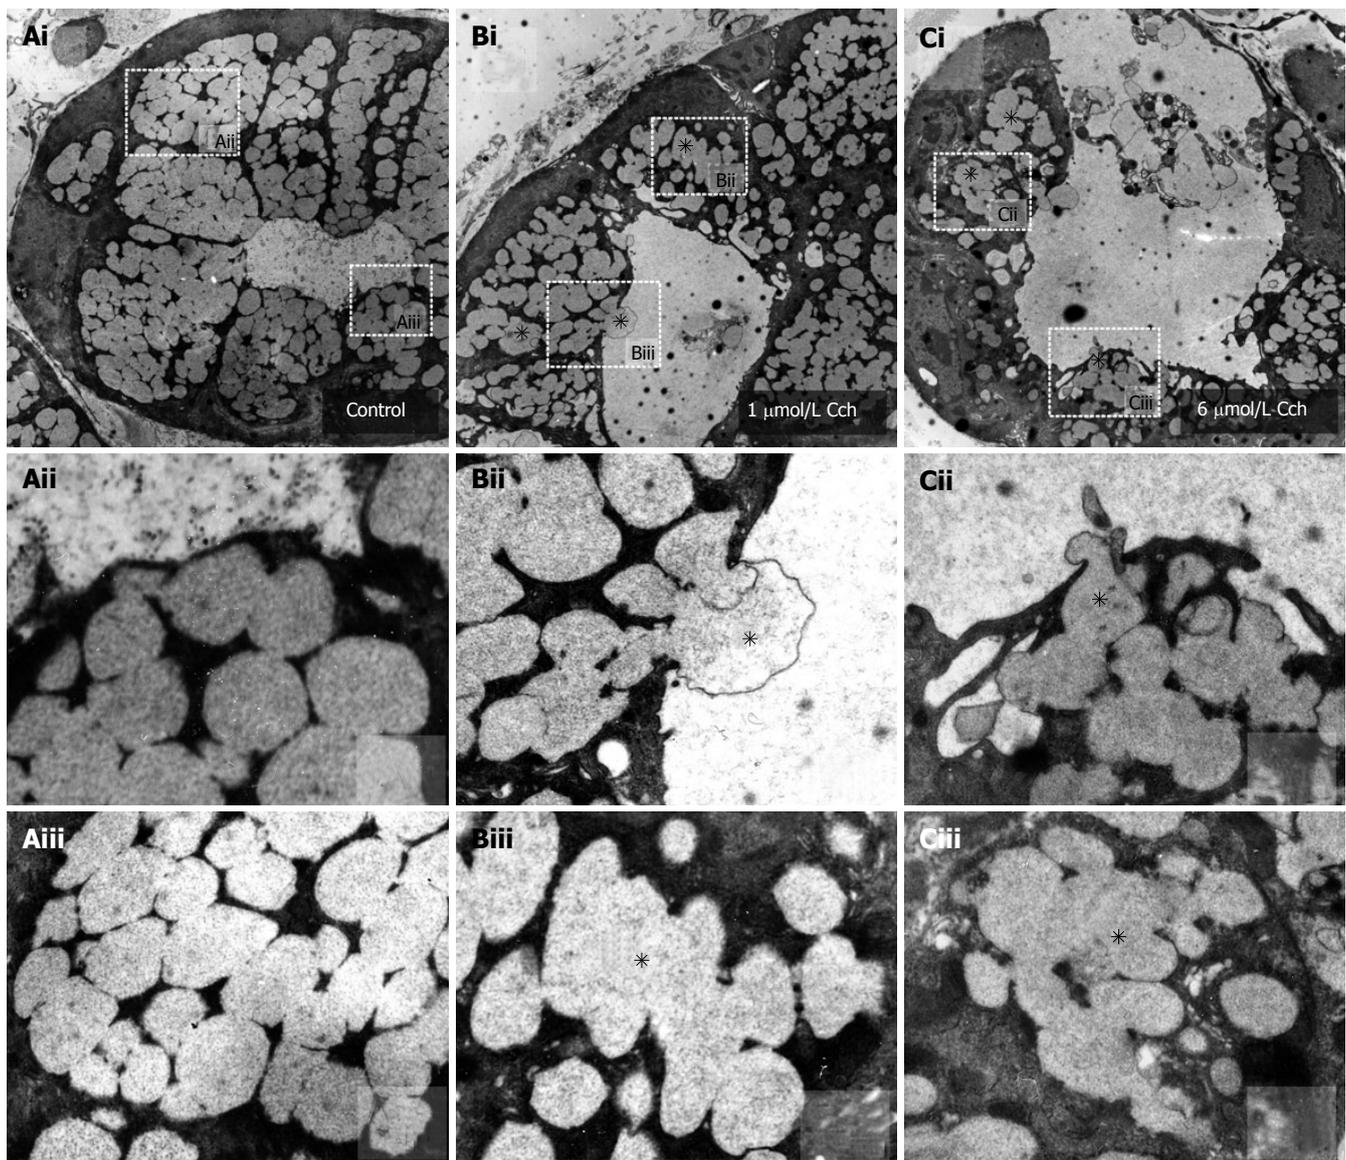

exocytosis (indicated by asterisks, shown clearly in image blowups in Bii and Cii) which enabled very efficient extrusion of the mucin cargo into the lumen resulting in complete collapse of the vesicles and progressive luminal dilatation, which was massive with the 6  $\mu\text{mol/L}$  carbachol stimulation. These findings, together with the measurements of acinar lumen, directly corroborate that carbachol activated compound exocytosis in these tissues.

### **Carbachol displaces Munc18c from the apical plasma membrane of Brunner's gland acinar cells**

The distinct exocytotic events of Brunner's gland acini observed in Figures 1 and 2 are reminiscent of those in pancreatic acini<sup>[8,9]</sup>, and which we and others had reported to involve distinct SNARE and Munc18 proteins<sup>[11-24]</sup>. We, therefore, probed the Brunner's gland acini with antibodies against Syntaxin (-2, -3 and -4), SNAP-23, VAMP (-2 and -8) and Munc18 (b and c), with the expectation that these exocytotic proteins would be differentially distributed in a manner reported in the rat pancreatic acinar cells<sup>[8,9,11-24]</sup>. We also probed for mucin to verify its retention when unstimulated and its absence indicating exocytosis after stimulation. Importantly, these studies were conducted on the same tissues where carbachol-evoked dilation of the acinar lumen was demonstrated (see above), providing parallel functional evidence of exocytosis.

Of all these exocytotic protein antibodies, only Syntaxin-4, SNAP-23 and Munc18c antibodies showed consistent positive signals in the confocal immunofluorescence studies (Figures 3-5). Of note, all of these antibodies were raised against rat sequences and, therefore, the lack of detectable signals suggest that the antibodies may not recognize the guinea pig sequences or that those protein levels in guinea pig acini were not sufficiently abundant. In unstimulated acini, Syntaxin-4, SNAP-23 and Munc18c were abundant on the apical plasma membrane (Figure 3). This is surprisingly different from what had been demonstrated in pancreatic acini wherein these proteins were most abundant along the basolateral plasma membrane, and in fact, undetectable in the apical plasma membrane<sup>[11-17]</sup>. Mucin lodged just beneath these exocytotic proteins, indicating their location in vesicles docked onto the apical pole of the acini. SNAP-23 signal seems to be also present in intracellular structures and the basal plasma membrane.

Upon 1  $\mu\text{mol/L}$  (Figure 4) and 6  $\mu\text{mol/L}$  carbachol (Figure 5) stimulation, Munc18c staining of the apical plasma membrane was progressively reduced. With 1  $\mu\text{mol/L}$  carbachol stimulation (Figure 4), there was much cytosolic staining of Munc18c, but which was no longer present with 6  $\mu\text{mol/L}$  carbachol (Figure 5). The latter is likely due to greater cytosolic proteolysis of Munc18c, which we had previously observed in rat pancreatic acini with supramaximal cholinergic stimulation<sup>[11-14]</sup>. Our acini preparation would not permit us to obtain a large pure population of Brunner's gland acini required to perform biochemical analysis (Western blots) to detect Munc18c proteolytic products, or for the presence of the other exocytotic SNARE and Munc18b proteins. In contrast to Munc18c, Syntaxin-4 and SNAP-23 signals on the

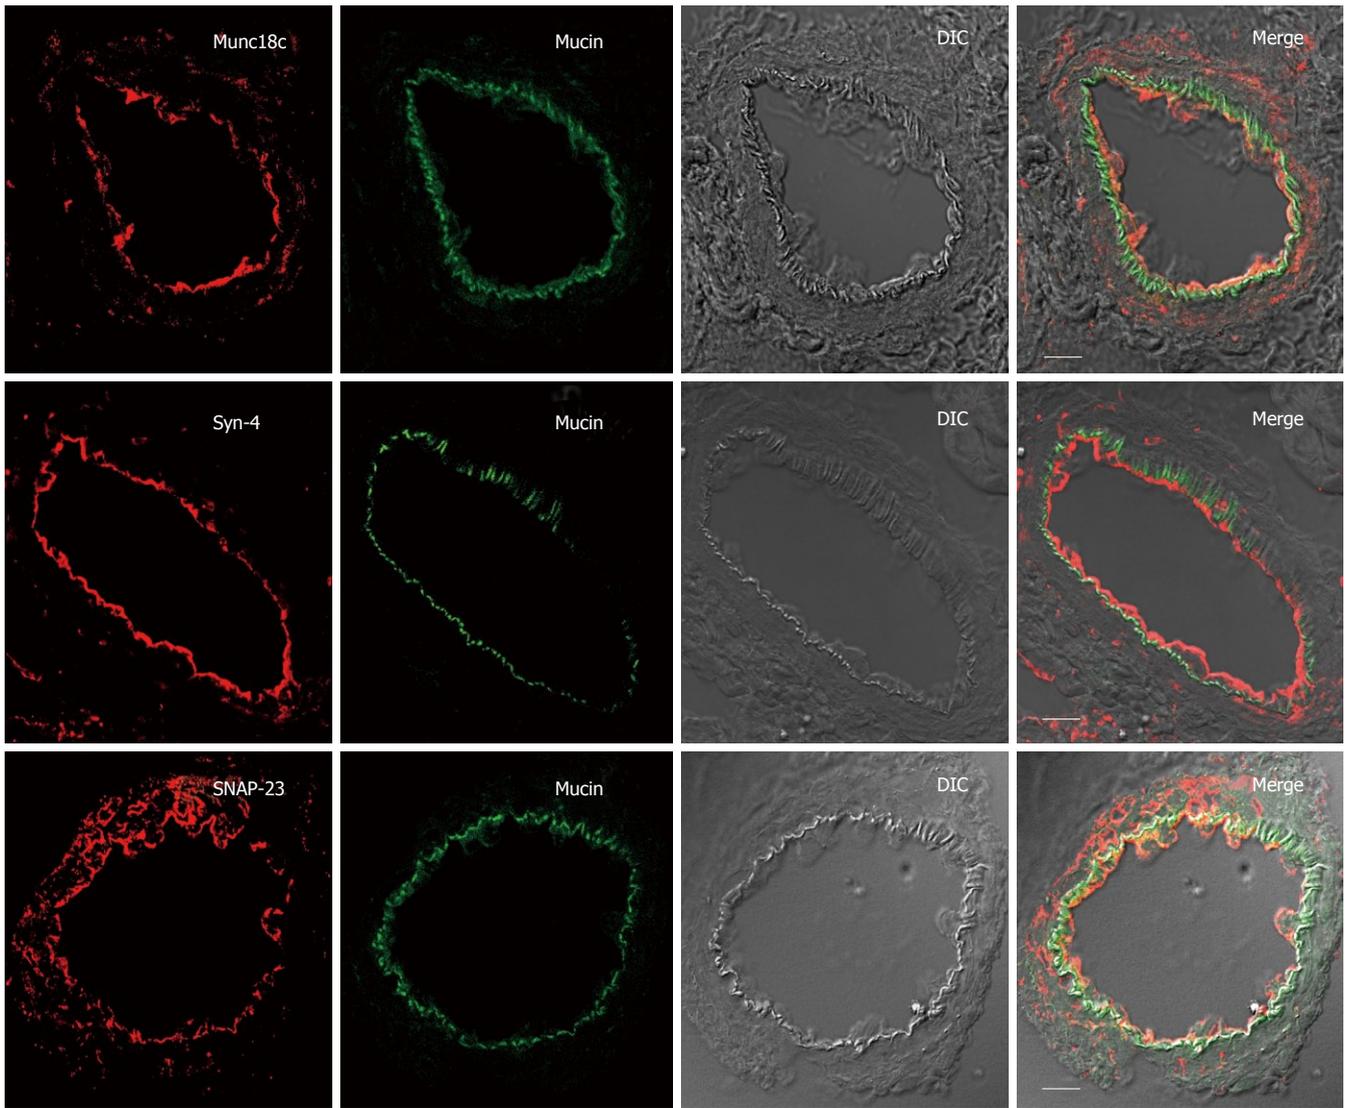

**Figure 2** Carbachol-evoked mucin granule exocytosis into Brunner's gland acinar lumens. Representative transmission electron micrographs of Brunner's glands in unstimulated control (A), 1  $\mu\text{mol/L}$  (B) and 6  $\mu\text{mol/L}$  carbachol (C) stimulated tissue. **A:** Unstimulated Brunner's acinus ( $\times 6250$ ). Aii and Aiii are blowups of indicated regions in Ai, showing small separate vesicles; **B:** One  $\mu\text{mol/L}$  carbachol-stimulated Brunner's acinus showing a larger apical lumen with reduced number of electron-lucent mucin vesicles within the apical poles, with some vesicles undergoing vesicle-vesicle fusions (indicated by asterisk,  $\times 6250$ ). Bii and Biii are blowups of indicated regions in Bi, showing compound exocytosis and vesicle-vesicle fusion (indicated by asterisks), respectively; **C:** Six  $\mu\text{mol/L}$  carbachol stimulated Brunner's acinus. There is much less remaining vesicles some of which are undergoing vesicle-vesicle fusion (indicated by asterisk,  $\times 5000$ ). Cii and Ciii are blowups of indicated regions in Ci, showing compound exocytosis and vesicle-vesicle fusion (indicated by asterisks), respectively.

apical plasma membrane after carbachol stimulation were as strong as unstimulated acini. As we had previously suggested in pancreatic acini, Munc18c displacement from the plasma membrane would enable Syntaxin-4 binding to SNAP-23 rendering the membrane receptive to exocytosis<sup>[11-15]</sup>. Indeed, the mucin staining of the apical poles of the acini was very much reduced after 1  $\mu\text{mol/L}$  carbachol stimulation (Figure 4) and completely absent after 6  $\mu\text{mol/L}$  carbachol stimulation (Figure 5). This reduction or disappearance of acini mucin would correlate to the E.M. results (Figure 3) of the loss of electron-lucent mucin vesicles. The absence of mucin staining in the lumen, which would have been an indication of exocytosed mucin, is likely due to dilution of mucin within the lumen as to render the mucin signal below detection.

## DISCUSSION

Using frozen sections of carbachol-stimulated submucosal preparation of Brunner's gland from guinea pig duodenum, we demonstrated the dilatation of acini lumen as an index of activation of secretion. These results are very similar to our previous reports using video-microscopy real-time recording of the real time changes of dilatation of acini lumen to track secretion<sup>[1,6,7]</sup>. In those reports, we showed the range of cholinergic stimulation was between 0.1  $\mu\text{mol/L}$  to 10  $\mu\text{mol/L}$ , with EC<sub>50</sub> of 2  $\mu\text{mol/L}$ . Here, we used carbachol concentrations on the upstroke of the dose-response curve, that is 1 and 6  $\mu\text{mol/L}$ , to demonstrate mild and near maximal dilatation of the ductal lumen. At 1  $\mu\text{mol/L}$  carbachol stimulation, E.M. performed on the same preparation

Control

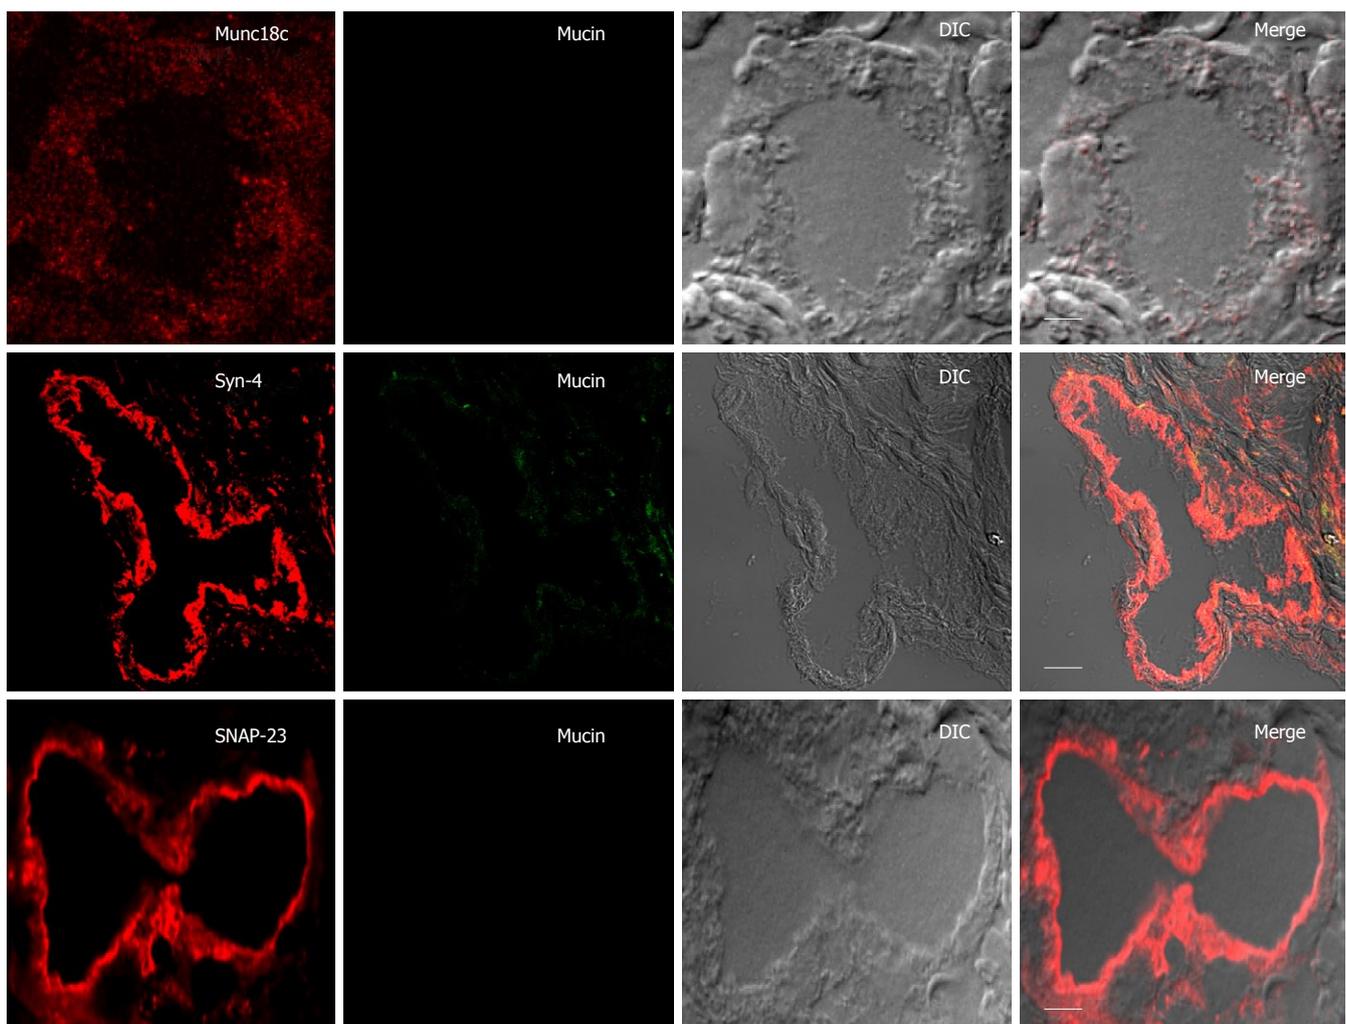

**Figure 3** Apical SNARE localization in unstimulated Brunner's gland acini. Confocal images of unstimulated Brunner's gland acini labeled with anti-mucin antibody (in green) and double labeled with anti-Munc18c, Syntaxin-4 or SNAP-23 antibodies (in red), and an overlay (merge) of the two with the DIC, which is also separately shown. Note the apical plasma membrane staining of Munc18c (and SNAP-23 and Syntaxin-4) and mucin accumulation beneath it. Scale bars correspond to 10  $\mu$ m.

demonstrated some reduction of electron-lucent mucin containing vesicles and a mildly dilated ductal lumen. Here, many of the vesicles have undergone homotypic fusion and these prefused vesicles would surface to the apical plasma membrane to undergo compound exocytosis. These events were even more efficient at 6  $\mu$ mol/L carbachol stimulation, where we noted near total collapse and emptying of these mucin vesicles, leaving fewer apical vesicles. Here, the ductal lumen was massively dilated by the exocytosed mucin, the latter confirmed on our earlier report by PAS staining where upon stimulation the PAS positive material is found between acinar cells rather than within the apical cytoplasm as observed in unstimulated preparations<sup>[1]</sup>. Due to anatomical reasons the best species to isolate Brunner's gland acini is the guinea pig as both the quantity and quality of the acini obtained are superior to that rendered by rat or mouse. This is also an excellent model to examine both hormonal regulation and neural innervation (which is intact in the preparation)<sup>[1,6,7]</sup>; however, this preparation has some

disadvantages. We were not able to perform biochemical studies that require large homogeneous populations of acini, which was not possible to obtain with this preparation. This limitation was a problem in this study as all of antibodies used were against rat and mouse proteins, most of which were not appropriate for immunofluorescence studies of guinea pig acini, but would have been at least slightly positive on western blotting of purified membrane fractions of acini of rat and mouse.

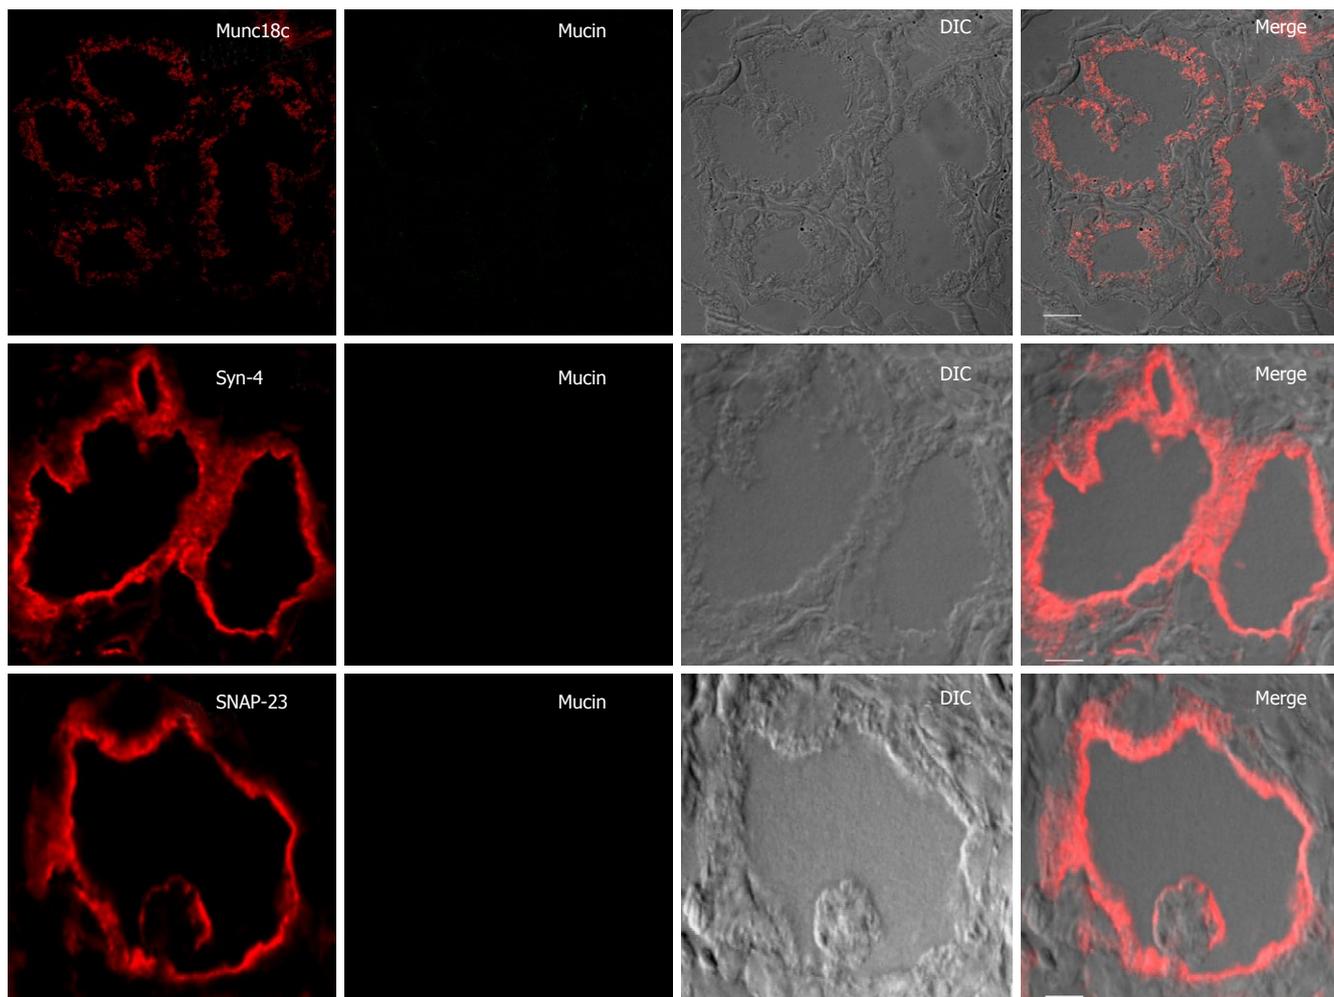

It appears that the molecular machinery for exocytosis is conserved in Brunner's gland acini to mediate exocytosis. This machinery includes distinct combinations of syntaxins, SNAP-25 and VAMP proteins on cognate membrane compartments that would assemble into SNARE complex inducing fusion of the membranes<sup>[11-14]</sup>. Munc18 proteins bind Syntaxins to prevent their interactions with the other SNARE proteins<sup>[10]</sup>. Agonist stimulation of cells induces PKC mediated phosphorylation of Munc18 proteins, which activates the

Cch (1  $\mu\text{mol/L}$ )

**Figure 4** SNARE localization after low carbachol (1  $\mu\text{mol/L}$ ) stimulation of Brunner's gland acini. Confocal images of 1  $\mu\text{mol/L}$  carbachol-stimulated Brunner's gland acini labeled with anti-mucin antibody (in green) and double labeled with anti-Munc18c, Syntaxin-4 or SNAP-23 antibodies (in red), and an overlay (merge) of the two with the DIC, which is also separately shown. Note the loss of apical plasma membrane staining of Munc18c with some staining in the cytosol, and much reduced mucin staining. Scale bars correspond to 10  $\mu\text{m}$ .

Syntaxins into open conformations capable of binding SNAP-25 and VAMPs<sup>[10]</sup>. We and others have previously demonstrated the distinct localization of homologs of these Munc18 (b and c) and SNARE proteins in rat pancreatic acini<sup>[11-24]</sup>. Specifically, Syntaxin-2 is on the pancreatic acinar apical plasma membrane, Syntaxin-3 on the zymogen granules and Syntaxin-4 on the basolateral membrane. Munc18b was on the apical membrane and Munc18c on the basolateral membrane. We had shown that supramaximal cholinergic (or cholecystokinin) stimulation redirected apical exocytosis to the basolateral plasma membrane, a process requiring Munc18c displacement from Syntaxin-4<sup>[11-15]</sup>. We postulated that Munc18c displacement activates Syntaxin-4 to form the exocytotic Syntaxin-4/SNAP-23/VAMP SNARE complex<sup>[11-15]</sup>. In this work, we find that this molecular exocytotic machinery is also operational in Brunner's gland acini. However, it was surprising to see that this exocytotic machinery (Munc18c, Syntaxin-4 and SNAP-23) was localized to the apical plasma membrane of Brunner's

gland acini to mediate apical exocytosis. Of note, this exocytotic machinery also mediated apical exocytosis in rat parotid acinar cells<sup>[25-27]</sup>. In contrast, rabbit lacrimal acini seem to follow a similar distribution for these exocytotic proteins as those described in rat pancreatic acini<sup>[28]</sup>. In fact, like pancreatic acini<sup>[11-14]</sup>, apical exocytosis in rabbit lacrimal acini could also be redirected to the basolateral membrane surface by prolactin<sup>[29]</sup>. The distinct localization of these exocytotic proteins within the family of exocrine tissues is of fundamental importance. Conventional thinking indicates that the localization of these proteins is conferred by signal sequences within these proteins<sup>[30,31]</sup>, which does not seem to be the case for the family of exocrine tissues. Additional cues likely from the membrane compartments themselves or from cytosolic chaperoning proteins that may be different between exocrine glands also seem to be required in determining the compartmental specific targeting of these exocytotic proteins. This notion is supported by our very recent report of a novel protein called Cab45b that is required to chaperone Munc18b to

Cch (6  $\mu\text{mol/L}$ )

**Figure 5** SNARE localization after high carbachol (6  $\mu\text{mol/L}$ ) stimulation of Brunner's gland acini. Confocal images of 6  $\mu\text{mol/L}$  carbachol-stimulated Brunner's gland acini labeled with anti-mucin antibody (in green) and double labeled with anti-Munc18c, Syntaxin-4 or SNAP-23 antibodies (in red), and an overlay (Merge) of the two with the DIC, which is also separately shown. Note the further reduced apical plasma membrane staining of Munc18c (vs Figure 4) and the absence of mucin staining in the cells. DIC images exhibit dilated lumens. Scale bars correspond to 10  $\mu\text{m}$ .

its targeted compartments in pancreatic acinar cells<sup>[19]</sup>.

The behavior of activated Munc18c seems to be cell-context specific. In exocrine tissues (Brunner's gland, pancreatic and parotid acini), agonist stimulation resulted in Munc18c displacement from the plasma membrane into the cytosol as a prerequisite for Syntaxin-4 activation<sup>[11-15,26]</sup>. This is, however, not the case for GLUT4 exocytosis in adipose tissues and skeletal muscles, which also use this set of exocytotic proteins<sup>[32]</sup>. More recent reports suggest that Munc18c facilitates and actually stabilizes SNARE complex assembly<sup>[33,34]</sup>, a process that induces Syntaxin-4 into its open conformation<sup>[35]</sup>. Although this process is associated with reduced Munc18c affinity to Syntaxin-4, the actual displacement of Munc18c from Syntaxin-4 is not required<sup>[33,34]</sup>. Perhaps in acinar tissues, changes in Munc18c conformation after phosphorylation may render the 65 kDa Munc18c protein susceptible to proteolytic degradation<sup>[11,14]</sup>, and such cytosolic proteases may not be present or activated in adipose tissues and muscles. This possibility is supported by our reports in rat pancreatic acini demonstrating cytosolic Munc18c to be mostly a degraded 35 kDa product<sup>[11-14]</sup>.

While apical exocytosis in Brunner's gland acini is mediated by Munc18c/Syntaxin-4/SNAP-23, vesicle-vesicle fusions should be mediated by another exocytotic machinery, likely involving Syntaxin-2 or -3 (and Munc18b) as is the case in pancreatic acini<sup>[8,9,16,21]</sup>. As for vesicle VAMPs, this likely includes VAMP-2 and/or VAMP-8<sup>[18,22,24,36]</sup>. Unfortunately, immunofluorescence studies we had carried out with a battery of antibodies directed against rat sequences (Munc18b, Syntaxin-2 and -3, VAMP-2 and -8) could not detect these proteins in the guinea pig Brunner's gland acini. Whether other secretory products (immunoglobulin, lysozyme, growth factors, trefoil peptides) of Brunner's gland acini<sup>[3-5]</sup> are contained in the same mucin vesicles or distinct vesicle populations involving distinct sets of exocytotic proteins is particularly intriguing and would require further investigation.

## ACKNOWLEDGMENTS

The authors thank Ms. Margaret O'Reilly for her excellent technical assistance.

## COMMENTS

### Background

Brunner's glands are small group of exocrine cells clustered together in small islands located in the duodenum where most peptic ulcers occur. These glands secrete bicarbonate and mucus (packaged in small vesicles) to protect the surrounding mucosa from injury that could be caused by the massive acid coming from the stomach.

### Research frontiers

Exocytosis requires of membranes fusion. The SNARE Hypothesis implies minimal machinery for membrane fusion, including a cognate set of vesicle and target SNAREs on opposing membranes. Additionally, this hypothesis proposes that these SNARE proteins are prevented from spontaneous assembly by clamping proteins, here represented by Munc18c.

### Innovations and breakthroughs

Brunner's glands have been extremely difficult to study until recently when we developed a duodenal submucosal preparation from guinea pigs. Using this preparation, we have now started to examine the molecules responsible for stimulated fusion of the mucus-containing vesicles with the plasma membrane, called exocytosis.

### Applications

Here, we have determined the involvement of a group of intimately-interacting molecules (Munc18c, Syntaxin 4, SNAP-23) in the exocytosis of mucus. This set of molecules is very similar to that which mediates similar exocytotic processes in other exocrine glands in the body, including pancreatic (secreting digestive enzymes) and salivary glands (secreting digestive enzymes and mucus), which are important for food digestion and lubrication. This would indicate that these molecules are conserved in all exocrine glands to regulate secretions important for intestinal protection and food digestion, and which could be targeted for novel drugs to improve these important functions in the treatment of related disorders (peptic ulcer disease, pancreatic insufficiency, salivary gland disorders).

### Peer review

The authors evaluated mechanisms to mediate exocytosis of Brunner's gland acini. Although many previous studies about exocytosis of pancreatic acinar cell were reported, as the authors mentioned, few were known about Brunner's gland acini. They demonstrated with sophisticated technique that Munc18c and SNARE proteins including Syntaxin-4 and SNAP-23 act like they do in the pancreatic acini, and speculated that the mechanisms are similar to those of pancreatic acini. Since a model of Brunner's gland in guinea pig duodenum is previously reported, the novelty of this report is to define the localization of Munc18c and SNARE proteins before and after cholinergic stimulus.

### Abstract

**AIM:** To evaluate the efficacy of Myelophil, an extract containing Astragali Radix and Salviae Radix, for reducing complications induced by 5-fluorouracil (5-FU) in a gastrointestinal cancer model.

**METHODS:** We injected 5-FU into mice and then administered Myelophil to examine the ability of the drug to treat the side effects of 5-FU in mice. Peripheral blood counts, histological examinations, and colony-forming assays of bone marrow were conducted, followed by swimming tests and assessment of survival times.

**RESULTS:** Myelophil restored red and white blood cells and platelets in blood, and recovered cell density in bone marrow to levels comparable to those observed within the control group. In addition, Myelophil significantly increased colony-forming unit granulocyte-macrophage (CFU-GM) and CFU-erythroid (CFU-E) compared to the control group. We confirmed that interleukin-3 gene expression was upregulated by Myelophil in spleen cells. Myelophil administration also doubled the survival rate of mice that were severely myelosuppressed as a result of 5-FU injection at a lethal dose of 70%. Finally, the swimming performance of mice significantly improved as a result of Myelophil treatment.

**CONCLUSION:** These results provide experimental

### INTRODUCTION

The occurrence of undesired effects that result from conventional chemotherapy or irradiation for cancer is inevitable. Nevertheless, reducing adverse effects is a critical issue for patients and doctors, given the importance of quality of life, as well as survival gains<sup>[1-3]</sup>. Accordingly, mitigation of chemotherapy-induced side effects and the development of novel chemotherapeutic agents with fewer toxic effects have been major focuses of recent medical investigations<sup>[4,5]</sup>. In particular, cancer-therapy-related fatigue, diarrhea or myelosuppression-related symptoms are closely associated with failure of the therapy itself. Therefore, many therapeutic developments, including herb-derived remedies, have focused on treating these side effects<sup>[6-9]</sup>.

Fluorouracil is one of the most commonly used drugs to treat gastrointestinal cancers, including those in the stomach, colon and liver, and it commonly causes fatigue, diarrhea and sometimes myelosuppression<sup>[10,11]</sup>. Myelophil is a mixture of Astragali Radix and Salviae Radix extract representing Qi and blood, respectively, which support the liver and gastrointestinal system according to theories of Oriental medicine. Astragali Radix displays immunomodulating, hematopoietic, and anti-fibrotic properties<sup>[12-14]</sup>. Salviae Radix exhibits antioxidant, antiatherosclerosis, and antiplatelet aggregation pharmaceutical effects<sup>[15-17]</sup>. We have used this

drug to treat mainly gastrointestinal cancer patients with post-therapeutic complications such as leukopenia, anemia or severe fatigue since 2002.

Here, we evaluated the therapeutic efficacy of an extract mixture that contained Astragali Radix and Salviae Radix for reducing complications from cancer chemotherapy, using a 5-fluorouracil (5-FU)-induced myelosuppression mouse model.

## MATERIALS AND METHODS

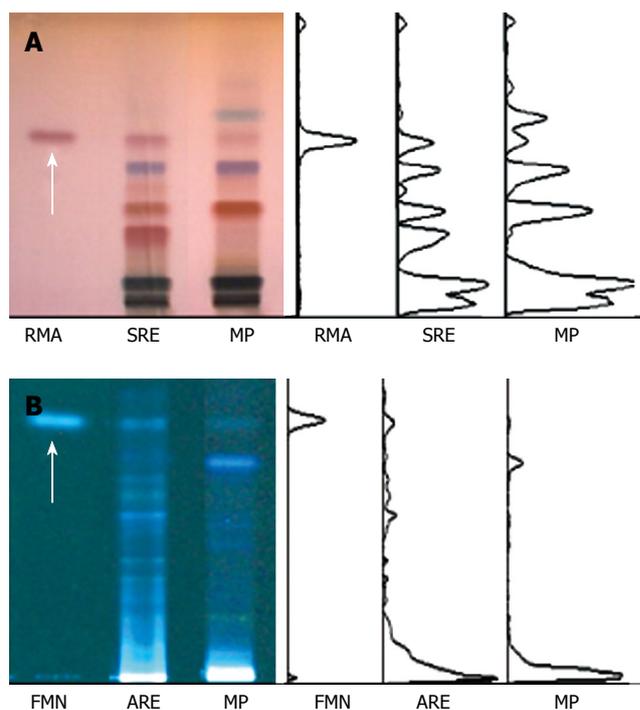

### Manufacturing and fingerprinting of Myelophil

*Astragalus membranaceus* (Leguminosae, VS No: AM-2006-02-Ra) and *Salvia miltiorrhiza* (Labiatae, VS No: SM-2006-01-Ra) were provided by Daejeon Oriental Medical College, Dunsan Oriental Hospital, of Daejeon University, identified by Professor SI Yim of Daejeon University and stored at our laboratory for future use. Samik Pharmaceutical Company (Seoul, Korea) manufactured a lyophilized aqueous extract of Myelophil (mixture of Astragali Radix and Salviae Radix; 1:1) according to over-the-counter Korean monographs. A final product with 20.52% (w/w) yield was stored for future use (VS No: MP-2006-01-WE). 5-FU was purchased from Choongwae Pharma Corporation (Seoul, Korea). Other chemicals were obtained from Sigma (St. Louis, MO, USA).

For the fingerprinting of Myelophil, the water extract of Astragali radix and Salviae radix, and their standard components, formononetin (Sigma) and rosmarinic acid (Carl Roth, Karlsruhe, Germany) were prepared for the high performance thin layer chromatography (HPTLC) system (CAMAG, Muttenz, Switzerland). They were dissolved in HPLC-grade methanol and applied to pre-washed HPTLC plate silica gel 60 F<sub>254</sub> (Merck, Darmstadt, Germany) with an automated applicator (Linomat IV; CAMAG). The samples were then separated and the migrated components were visualized prior to or after derivatization under UV radiation at 366 nm or white light using Reprostar 3 with a digital camera (CAMAG, Figure 1).

### Induction of myelosuppression: Hematological and histopathological analysis

To examine the therapeutic effects of Myelophil on 5-FU-induced myelosuppression, 60 6-wk-old male ICR mice (Koatech, Gyeonggi-do, Korea) were divided into three groups (20 control, and 20 with low- and 20 with high-concentration Myelophil treatment). Another five mice were sacrificed to record physiological standards for hematological parameters at time 0. All three groups were injected intraperitoneally with 0.3 g/kg 5-FU on d 0. Beginning on d 2, Myelophil (0.05 g/kg or 0.1 g/kg) or distilled water (control group) was administered orally once daily for 10 consecutive days. Five mice per group were serially sacrificed on d 0, 4, 7, 10 and 13, and complete blood counts were analyzed using a blood cell counter (HEMAVET; CDC Technologies, CT, USA). In addition, all left-side femoral bones from the mice on d 7 were prepared for general histopathological evaluation, including fixation, decalcification, sectioning (4  $\mu$ m thickness), as well as hematoxylin and eosin (HE) staining.

**Figure 1** Fingerprinting of Myelophil. **A:** Rosmarinic acid (RMA, 2  $\mu$ g), Salviae Radix water extract (SRE, 200  $\mu$ g) and Myelophil (MP, 400  $\mu$ g) were separated using chloroform/ethyl acetate/benzene/formic acid/methanol (15:10:10:1), and then visualized by white light after derivatization with p-anisaldehyde sulfuric acid; **B:** Formononetin (FMN, 0.1  $\mu$ g), Astragali Radix water extract (ARE, 0.8 mg) and Myelophil (MP, 1.6 mg) were separated using dichloromethane/methanol/water (45:10:1), and then visualized under UV at 366 nm.

### Isolation of bone marrow cells and colony-forming assay

To directly examine the effects of Myelophil on bone marrow stem cells, C57BL/6 mice (three for each of the control, and low- and high-concentration Myelophil groups) were injected intraperitoneally with 5-FU (0.2 g/kg). Mice were given Myelophil (0.05 g/kg or 0.1 g/kg) or distilled water (for naive and control groups) for 5 consecutive days beginning 2 d after 5-FU injection. Bone marrow cells were isolated from femurs, and nucleated cells were counted using a blood cell counter (HEMAVET; CDC Technologies). After thoroughly mixing the nucleated cells (400  $\mu$ L  $2 \times 10^5$ ) with 4 mL MethoCult methylcellulose-based medium (Stem Cell Technologies, Seattle, WA, USA), media (1 mL per dish in triplicate) were cultured in a 5% CO<sub>2</sub> incubator for 7 d. According to the morphological characteristics, the number of colonies assessed by CFU-GM or CFU-E was counted under an inverted microscope.

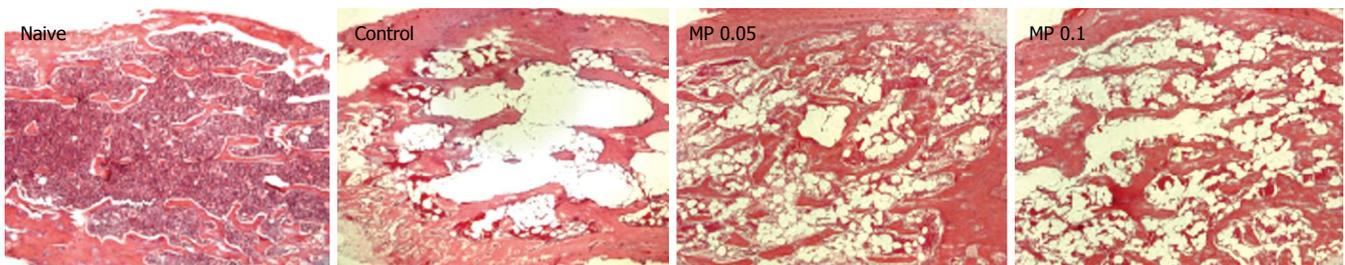

### Interleukin-3 (IL-3) gene expression analysis using real-time PCR

Splenocytes isolated from BALB/c male mice were seeded in a six-well culture plate ( $2.8 \times 10^7$  cells per well), and treated with or without Myelophil (0.001, 0.01 or 0.1 g/L) for 18 h. After purification of total RNA using an RNA mini kit (Qiagen, Valencia, CA, USA) and cDNA synthesis, quantitative real-time PCR was performed using SYBR Green Supermix reagent (Bio-Rad, CA, USA) according to the manufacturer's protocol. The primer sequences (forward and reverse, respectively) were

From 2 d after 5-FU injection, Myelophil (0.05 g/kg or 0.1 g/kg) or distilled water (for the control group) was given to mice for 10 d. On day 0, 4, 7, 10 and 13, complete blood counts were analyzed using a blood cell counter. Data are expressed as mean  $\pm$  SD ( $n = 5$ ). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group. MP: Myelophil.

**Figure 2** Histopathological analysis of bone marrow. After 7 d 5-FU injection (0.3 g/kg, intraperitoneally) and Myelophil treatment for 5 d, the femoral bone was dissected and fixed in 10% neutral-buffered formalin, followed by decalcification, embedding, and micro-sectioning (4  $\mu$ m). Histopathological examination was performed under a microscope ( $\times 200$ ) after HE staining.

as follows:  $\beta$ -actin, GTGGGGCGCCCCAGGCACCA and CTCCTTAATGTCACGCACGATTTC; IL-3, TACATCTGCGAATGACTCTGC and GGCTGAGGTGGTCTAGAGGT.

### Monitoring survival rates with or without swimming-forced stress

To examine whether Myelophil affected the survival time of mice with severe or moderate myelosuppression induced by 5-FU, we conducted two tests. First, severe myelosuppression was induced in 30 male ICR mice (10 in each of the control, and low- and high-concentration Myelophil groups) by 5-FU treatment (0.5 g/kg, intraperitoneally). Two days later, Myelophil (0.05 or 0.1 g/kg) or distilled water (induced group) was administered orally once daily for 10 consecutive days. The number of surviving mice was monitored for the next 20 d.

For the second test, moderate myelosuppression was induced in 30 male ICR mice (10 in each of the control, and low- and high-concentration Myelophil groups) by 5-FU treatment (0.3 g/kg, intraperitoneally). Beginning 2 d following 5-FU injection, Myelophil (0.05 or 0.1 g/kg) or distilled water (for the naïve and control groups) was given orally once daily for five consecutive days. On the final day, all mice were forced to swim in a pool with 22°C water for 30 min. Mice were monitored for survival time and swimming performance.

### Statistical analysis

The results were expressed as mean  $\pm$  SD. Statistical

analysis of the data was conducted using Student's *t* test with significance levels of  $P < 0.05$ .

## RESULTS

### Hematological parameters

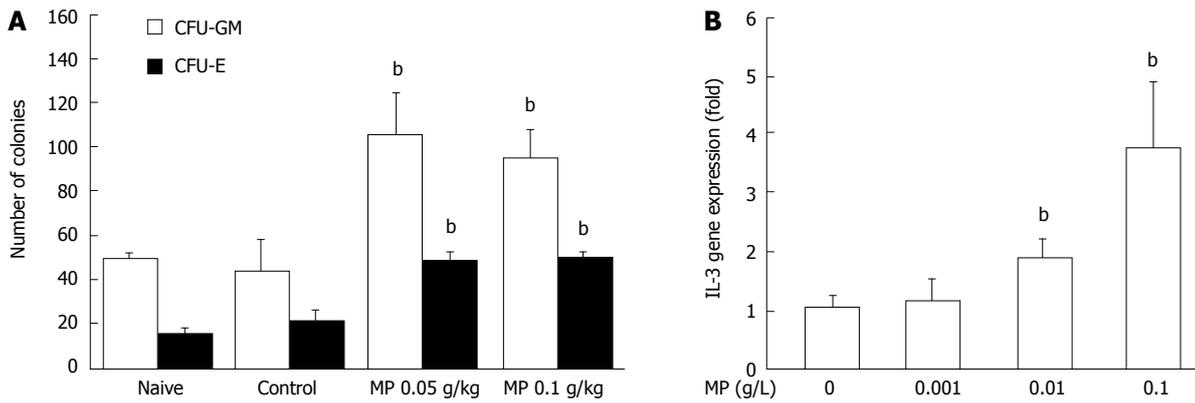

First, we examined changes in hematological parameters (leukocyte, erythrocyte and platelet counts) in 5-FU-induced (0.3 g/kg) myelosuppressed mice every 3 d. As shown in Table 1, peripheral blood white blood cell, platelet, and red blood cell levels drastically decreased, with the lowest numbers recorded on d 7. However, the observed pancytopenia was ameliorated by Myelophil administration, and the number of leukocytes rapidly recovered compared to that in untreated control mice (0.05 g/kg Myeolophil,  $P = 0.0387$ ; 0.1 g/kg Myelophil,  $P = 0.0014$ ).

### Histological examination of bone marrow

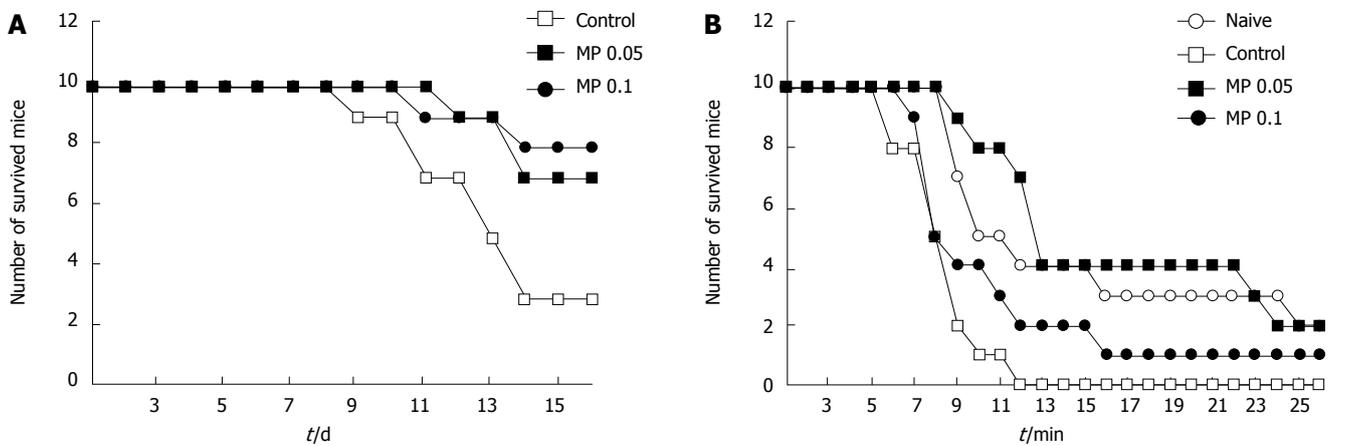

We examined the cellular density of femoral bone marrow from d 7 mice. Similar to the peripheral blood counts, 5-FU injection radically reduced the cellular component in bone marrow by vacuolation, and this was moderately improved by Myelophil treatment (Figure 2).

### CFUs in bone marrow

To investigate how Myelophil affected the hematopoietic stem cells, leukocyte or erythrocyte-lineage colonies were determined using colony forming assay. Myelophil treatment significantly increased the colony numbers of both leukocyte (0.05 g/kg Myeolophil,  $P = 0.0087$ ; 0.1 g/kg Myelophil,  $P = 0.0029$ ) and erythrocyte lineages (0.05 g/kg Myeolophil,

**Figure 3** Colony-forming assay and IL-3 gene expression. **A:** After 7 d 5-FU injection (0.2 g/kg, intraperitoneally) and Myelophil treatment for 5 d, purified bone marrow cells were cultured for 7 d for colony counts of CFU-GM and CFU-E; **B:** Spleen cells were treated with Myelophil for 18 h, and then IL-3 gene expression was analyzed using real-time-PCR. Data are expressed as mean  $\pm$  SD ( $n = 3$ ). <sup>b</sup> $P < 0.01$  vs control group.

**Figure 4** Survival of myelosuppressed mice. **A:** Beginning 2 d after 5-FU injection (0.5 g/kg, intraperitoneally), Myelophil (0.05 or 0.1 g/kg) or distilled water (control) was administered for 10 d. The number of surviving mice was monitored for 20 experimental days; **B:** Beginning 2 d after 5-FU injection (0.3 g/kg, intraperitoneally), Myelophil (0.05 or 0.1 g/kg) or distilled water (for naïve and control groups) was administered orally for 5 d. All mice were then forced to swim in a pool to monitor their survival time for 30 min.

$P = 0.0018$ ; 0.1 g/kg Myelophil,  $P = 0.0021$ ), as shown in Figure 3A.

**IL-3 gene expression in vitro**

We examined changes in IL-3 gene expression in splenocytes following co-culturing with Myelophil using RT-PCR. IL-3 expression was increased in a dose-dependent manner. At a concentration of 0.1 g/L Myelophil, this gene was up-regulated four-fold (Figure 3B).

**Survival rate of myelosuppressed mice**

Following injection with 0.5 g/kg 5-FU (LD70, determined in our experiments), the survival rate of the control group was 30% by 14 d, whereas in the Myelophil-treated groups it was 70%-80% (Figure 4A). Myelophil treatment significantly protected mice from loss of body weight after 5-FU injection (data not shown). In addition, Myelophil treatment extended the survival time of mice that were forced to swim in a pool after injection with 0.3 g/kg of 5-FU (Figure 4B).

**DISCUSSION**

We used a 5-FU-induced myelosuppression mouse model

to evaluate the experimental efficacy of Myelophil, with relevance to the clinical application of reducing chemotherapy-induced side effects. 5-FU is one of the most commonly used anti-metabolic chemotherapeutic drugs for colon, stomach, liver, and head and neck cancer. It has also been applied in anti-myelosuppressive studies due to its observed toxicity toward bone marrow<sup>[18-20]</sup>. We observed that a single injection of 0.5 g/kg 5-FU caused > 70% mortality within 20 d, whereas 0.3 g/kg 5-FU induced mild myelosuppression with no incidence of death.

Peripheral white blood cell, platelet and red blood cell levels drastically decreased in 5-FU-induced (0.3 g/kg) myelosuppressed mice. On d 7, these levels were the lowest and were in accordance with those of severe leukopenia, moderate thrombocytopenia and mild anemia. However, the observed pancytopenia was ameliorated by Myelophil administration, and the number of leukocytes rapidly recovered compared to that in untreated control mice. Next, we examined the cellular density of femoral bone marrow from d 7 mice. Similar to the peripheral blood results, 5-FU injection radically reduced the cellular component in bone marrow induced large vacuole formation, and this was moderately improved

by Myelophil treatment (Figure 2). These results suggest that Myelophil might be beneficial for the alleviation of chemotherapy-associated high susceptibility to pathogenic microorganisms, which is a major problem post-treatment<sup>[21,22]</sup>.

Consequently, we investigated how Myelophil affected the hematopoietic stem cells *via* differential examination of leukocyte- or erythrocyte-lineage colonies. The number and lineage of a colony was decided mainly by quantity and quality of stem cells in different groups. Our results showed Myelophil treatment significantly increased the colony numbers of both leukocyte and erythrocyte lineages (Figure 3A). Processes of hematopoiesis are under the control of various hematopoietic growth factors, such as IL-3, erythropoietin (EPO), thrombopoietin (TPO), granulocyte colony-stimulating factor (G-CSF), or granulocyte/macrophage CSF (GM-CSF)<sup>[23]</sup>. These growth factors have lineage-specific hematopoietic functions and different cellular excretion sources<sup>[24]</sup>. Specifically, IL-3 supports proliferation and differentiation of hematopoietic stem cells, as well as various cell lineages in hematopoiesis<sup>[25]</sup>, and is secreted mainly from natural killer T cells<sup>[26]</sup>. Therefore, we examined changes in IL-3 gene expression in splenocytes following co-culturing with Myelophil. The result showed that IL-3 expression was increased four-fold (Figure 3B).

Given the above results, we observed how Myelophil could restore myelosuppression via IL-3 up-regulation. Generally, myelosuppression is linked strongly to other common side effects caused by conventional cancer therapy, such as fatigue or low energy, as well as low immunity.

Myelophil-treatment significantly protected mice from loss of body weight after 5-FU (0.5 g/kg) injection (data not shown). In addition, Myelophil treatment extended the survival times of mice that were forced to swim in a pool after injection of 0.3 g/kg 5-FU (Figure 4B).

5-FU-induced myelosuppression is the dose-limiting toxicity associated with substantial life-threatening risk and life span of cancer patients<sup>[27,28]</sup>. Many herbal medicines are currently being investigated as good candidates for improving quality of life and reducing toxic side effects such as myelosuppression<sup>[29-32]</sup>. One group has reported the efficacy of one of the two medicinal plant extracts in Myelophil on hematopoiesis induction in mice<sup>[14]</sup>. We found that a mixture of Astragali Radix and Salviae Radix was more effective than a single herb administered alone in our model system (data not shown). We have prescribed Myelophil to treat post-therapeutic complications such as anemia, leukopenia or severe fatigue, mainly for gastrointestinal cancer patients, according to its oriental pharmaceutical theory since 2002.

Herein, we have provided experimental evidence relevant to clinical applications of Myelophil for minimizing cancer chemotherapy-induced side-effects, using a fluorouracil-induced myelosuppression mouse model.

## COMMENTS

### Background

Anticancer-therapy-induced side effects are closely associated with life span and quality of life in cancer patients, so reducing or preventing these has been a major

issue in cancer treatment. Astragali Radix and Salviae Radix extract, Myelophil, has been used to treat mainly gastrointestinal cancer patients with post-therapeutic complications such as leukopenia, anemia or severe fatigue since 2002. This study demonstrated the efficacy of Myelophil for moderating the toxic side effects of 5-FU.

### Research frontiers

Fluorouracil is one of the most commonly used drugs to treat gastrointestinal cancers, including stomach, colon and liver, but it commonly causes fatigue, diarrhea and sometimes myelosuppression. Myelophil significantly ameliorated the toxic side effects of 5-FU, such as leukopenia, anemia and thrombocytopenia and improved survival rate in myelosuppressed mice.

### Innovations and breakthroughs

Myelophil showed dramatic activity against the side effects of 5-FU, a very widely used drug. This study showed evidence that a herbal remedy can be a good candidate for improving quality of life in cancer patients.

### Applications

Myelophil may be of benefit to cancer patients suffering from chemotherapy-induced side effects.

### Peer review

This manuscript examines two herbal extract mixtures that reduce complications induced by the chemotherapeutic agent, 5-FU in a gastrointestinal cancer model. The bone marrow data, colony-forming assay, and interleukin gene expression all support the moderating effects of Myelophil on toxic side effects of 5-FU, and show the possibilities for clinical applications.

### Abstract

**AIM:** To investigate whether human hepatocytes could proliferate after transplantation to normal immunocompetent rats treated with 2-acetaminofluorene or Retrorsine and partial hepatectomy.

**METHODS:** L02 hepatocyte-tolerant Sprague-Dawley rats were injected with Retrorsine, 2-acetaminofluorene or normal saline. L02 hepatocytes were then transplanted *via* the spleen. Human albumin and its mRNA, specific proliferating cell nuclear antigen (PCNA), L02 hepatocyte dynamic distribution, number density and area density of PCNA-positive cells in the liver were determined.

**RESULTS:** All the examined indicators were not significantly different between the rats treated with 2-acetaminofluorene and normal saline, which was not the case with rats treated with Retrorsine. A dynamic distribution of L02 hepatocytes in the rat liver was detected from wk 1 to mo 6 after transplantation in the Retrorsine group and from wk 1 to 10 in the 2-acetaminofluorene group. Human albumin and its mRNA were detected from wk 2 to mo 6 in the Retrorsine group and from wk 1 to 8 in the 2-acetaminofluorene group. Specific human PCNA was detected in the rat liver from wk 2 to mo 6 in the Retrorsine group and from wk 2 to 6 in the 2-acetaminofluorene group. Human albumin and its mRNA contents as well as the number of PCNA positive cells reached a peak at wk 4.

**CONCLUSION:** L02 human hepatocytes could not proliferate significantly after transplantation to the normal, immunocompetent rats treated with 2-acetaminofluorene.

L02 human hepatocytes can survive for 10 wk after transplantation and express human albumin for 8 wk. L02 human hepatocytes can proliferate and express human albumin for 6 mo after transplantation to the rats treated with Retrorsine. The chimeric L02 human hepatocytes, which then underwent transplantation into tolerant rats, were normal in morphogenesis, biochemistry and function.

### INTRODUCTION

An animal model of rats with chimeric human livers has been created with human hepatocytes being transplanted into rat livers. These rats can be used to identify hepatitis virus with the problem of species-specificity being resolved<sup>[1]</sup>. With immunodeficiency<sup>[2]</sup> or induced immunotolerance rats<sup>[3]</sup>, an animal model of rats with chimeric human liver infected with Hepatitis B virus can be established. An animal model of tolerant rats with chimeric human liver can be applied in pathogenesis, antiviral therapy and the development of vaccines<sup>[4]</sup>. However, human hepatocytes transplanted into rats can survive only a limited time. The lifetime of transplanted hepatocytes must be prolonged to establish a persistent animal model. With an exogenous growth stimulus, such as partial hepatectomy, the recipient hepatocytes can not only regenerate but the transplanted hepatocytes can also proliferate<sup>[5]</sup>. If restraining the regeneration of recipient hepatocytes with 2-acetaminofluorene (2-AAF), Retrorsine(Rts), dipin, furan, or 3'-5'-diethoxycarbonyl-1,4-dihydrocollidine (DDC)<sup>[6-8]</sup>, followed by an exogenous growth stimulus such as carbon tetrachloride(CCl<sub>4</sub>) or partial hepatectomy (PH)<sup>[9-11]</sup>, the proliferation of transplanted hepatocytes can be improved significantly. We investigate whether human hepatocytes could repopulate

after transplantation to rats with a normal immune system treated with 2-acetaminofluorene (2-AAF) or Retrorsine (Rts) and partial hepatectomy (PH).

L02 Human hepatocytes were injected into the peritoneal cavities of fetal Sprague-Dawley rats to induce immune tolerance to L02 human hepatocytes. The 2- or 3-wk rats were injected with 2-AAF or Rts. The L02 human hepatocytes stained with 1,1'-Diiodo-3,3',3'-tetramethylindocarbocyanine perchlorate (DiI) were transplanted into the spleen via intrasplenic injection. The survival and proliferation of human L02 hepatocytes in the rat liver were analyzed by an immunofluorescence method, reverse transcription-polymerase chain reaction (RT-PCR), immunohistochemical study, DiI fluorescence tracing and computer-aided image analysis.

## MATERIALS AND METHODS

### Materials

Nine Sprague-Dawley rats at reproductive age were purchased from the Third Military Medical University. Rats at gestational age 15-17 d and weighing 250-300 g were used. They were maintained on an alternating 12-h light/dark cycle with food and water available *ad libitum*. All studies were conducted under protocols approved by the Laboratory Animal Resource Center of the Third Military Medical University, China.

L02 hepatocytes, the isolated normal human hepatocytes, which have not been immortalized, were purchased from Shanghai Institute of Cell Biology of Chinese Academy of Science. L02 hepatocytes were digested with pancreatin, centrifuged twice at 1100 r/min for 3 min, and then resuspended. Hepatocytes were counted using a blood cell counting chamber and cell viability was assessed by trypan blue exclusion assay. Cells with viability above 80% were used in the study.

### Methods

**Induction of immunotolerance of fetal rats:** Sprague-Dawley rats at gestational age 15-17 d were etherized, their abdomens were cut open along the linea alba abdominis, and their uterus was exposed. 50  $\mu$ L of human L02 hepatocytes suspension ( $1 \times 10^8$  cells) were slowly injected into the abdominal cavities of the 8-12 fetal rats in utero using a 1 mL-syringe, and then the abdominal walls of the pregnant rats were sutured layer by layer. Pregnant rats were fed till spontaneous delivery.

**Drug solution preparation:** The drug solution was prepared as described elsewhere<sup>[12]</sup>. Retrorsine (Sigma Company) was added to distilled water at 10 mg/mL and titrated to pH 2.5 with 1 mol/L HCl. The solution was neutralized with 1 mol/L NaOH, and NaCl was added for a final concentration of 6 mg/mL retrorsine and 0.15 mol/L NaCl (pH 7). The working solution was used immediately after preparation. 2-acetaminofluorene was dissolved in M400 polyethylene glycol.

**Animal grouping and drug injection:** Pregnant rats were randomized to three groups, namely, the experimental (2AAF and Rts) group and the control group, and 30

fetal rats were assigned to each group. For the Rts group, immunotolerant rats were intraperitoneally injected with retrorsine (30 mg/kg/rat) 3 and 5 wk post birth. For the 2AAF group, immunotolerant rats were intraperitoneally injected with 2-acetaminofluorene (30 mg/kg/rat) 2 wk post birth, once every other day, total 4 injection. For the control group, immunotolerant rats were intraperitoneally injected with physiologic saline and the other procedures were the same as the experimental group. 7 wk post birth, rats of the Rts group and 3 wk post birth, rats of the 2AAF group and the control group were etherized and underwent 2/3 hepatectomy and transplantation of 100  $\mu$ L of DiI-labeled human L02 hepatocyte suspension ( $> 10^{12}$  cells/L) through the spleen.

**DiI fluorescence staining:** The method was described previously<sup>[13]</sup>. Five  $\mu$ L of 1 mmol/L Vybrant DiI (Sigma Company) cell-labeling solution dissolved in 100% ethanol was added to 1 mL of culture medium. Cells were stained for 40 min at 37°C in a CO<sub>2</sub> incubator. Labeled cells were centrifuged three times by 1100 revolutions per minute (r/min)  $\times$  3 min and washed with phosphate-buffered saline (PBS). They were then counted by trypan blue exclusion assay and suspended at  $1.0 \times 10^{12}$ /L with PBS. Cells were observed and photographed under the fluorescence microscope (Olympus Company) with a rhodamine filter.

**L02 hepatocytes transplantation:** 3 or 7-wk-old fetal rats of the experimental group were etherized. The abdomen was cut open along the linea alba abdominis and the spleen was exposed. 100  $\mu$ L of DiI-stained L02 hepatocyte suspension was slowly injected along the mesenteric edge into the splenic body and tail. The injection site was pressed gently to prevent hemorrhage or effusion.

**Specimen collection:** Specimens were collected one week after transplantation, and then at wk 2, 4, 6, 8 and mo 4 and 6. Specimens were collected from four rats at each collection point. Under anesthetization, rats underwent partial hepatectomy, and fresh liver tissue was subjected to frozen sectioning. Sections were observed under the fluorescence microscope with a rhodamine filter. Some tissue was fixated in 40 g/L neutral formalin, embedded in paraffin and sectioned. After surgery, rats were fed as usual.

**DiI fluorescence tracing:** L02 hepatocytes were stained with DiI and observed under the fluorescence microscope with a rhodamine filter before transplantation. Following L02 hepatocytes transplantation, fresh rat liver tissue was subjected to frozen sectioning and was also observed under the fluorescence microscope.

**Detection of human albumin in liver tissue by immunofluorescence method:** Fresh liver tissue was subjected to frozen sectioning with a thickness of 4-8  $\mu$ m. The sections were placed at room temperature for 30 min and fixated at 4°C in acetone for 10 min. Unspecific staining was blocked at  $< 37^\circ\text{C}$  with 100 mL/L blocking serum for 20 min. The sections were then added to rat anti-

human albumin monoclonal antibody (Sigma Company, 1:400) and kept at 4°C overnight. They were subsequently added to fluorescence labeled a secondary antibody, i.e., Fluorescein isothiocyanate (FITC)-labeled goat anti-rat IgG (Beijing Zhongshan Company, 1:100), and incubated at 37°C in darkness for 45 min. The sections were mounted with 900 mL/L buffering glycerol and observed under a laser confocal microscope (Swiss Zeiss Company). For negative control, the primary antibody was replaced by PBS.

**Immunohistochemical detection of human PCNA in the liver tissue:** Streptavidin peroxidase conjunction (S-P) method was used. In brief, fresh liver tissue was fixated in 40 g/L neutral formalin, embedded in paraffin and sectioned, baked at 60°C for 1 to 2 h, and underwent deparaffinage. The sections were added with PBS containing 0.5 g/L Triton × 100 and incubated at room temperature for 5 min. Then the sections were incubated with 3% hydrogen peroxide at 37°C for 20 min to block endogenous peroxidase. The sections were incubated with specific monoclonal antibody against human proliferating cell nuclear antigen (PCNA) (Chemicon Company, 1:200) or non-specific monoclonal antibody against PCNA (Beijing Dingguo Company, 1:200, against vertebrate PCNA) was added and incubated at 4°C overnight, then polymer boost and horseradish peroxidase-labeled goat anti-rat IgG multimer (Beijing Zhongshan Company) was added. The next steps included 3,3'-Diaminobenzidine (DAB) coloration, after-stain with hematoxylin, mounting with neutral resin, and observation under a light microscope. For negative control, the primary antibody was replaced by PBS.

**Cell image analysis:** The LeicaQWin image analysis system (Germany Leica Company) was used. Five areas were randomly selected in each section at the magnitude of 100 and the number density (cell/ $\mu\text{m}^2$ ) and area density ( $\mu\text{m}^2/\mu\text{m}^3$ ) of PCNA-positive cells were calculated.

**RT-PCR detection of human albumin mRNA in the rat liver tissue:** This step was carried out according to the instructions for use of the Trizol RNA extraction kit. The two-step method using RT-PCR kit (BioDev Company) was adopted for reverse transcription and amplification. Primers were signed and synthesized by Takara Company (Dalian, China). Human albumin mRNA primers: forward primer Hs: 5'-TCGACAACGGCTCCGGCAT-3', reverse primer Ha: 5'-AAGGTGTGGTGCCAGATTTTC-3', length of the amplified fragment: 241 bp; normal rat albumin mRNA primers: forward primer Rs: 5'-CGGT TTAGGGACTTAGGAGAACAGC-3', reverse primer Ra: 5'-ATAGTGTCCAGAAAGCTGGTAGGG-3', length of the amplified fragment: 388 bp. Amplification was carried out by using the following cycle: initial denaturation at 94°C for 5 min, denaturation at 94°C for 50 s, reassociation at 55°C for 50 s, extension at 72°C for 1 min (32 cycles), and a final extension step at 72°C for 8 min. To exclude false positive results, negative control was set by amplification without AMV reverse transcriptase. The products were subjected to 1.5%

agarose gel electrophoresis, ethidium bromide staining and image acquisition using a gel scanner (America Bio-Rad Company).

### Statistical analysis

Data were expressed as mean  $\pm$  SD. Paired *t*-tests were adopted to compare group differences using SPSS 10.0.

## RESULTS

Anesthetic overdose caused one death in the experimental (2AAF) group and two deaths in the control group. The remaining rats survived.

### DiI fluorescence tracing

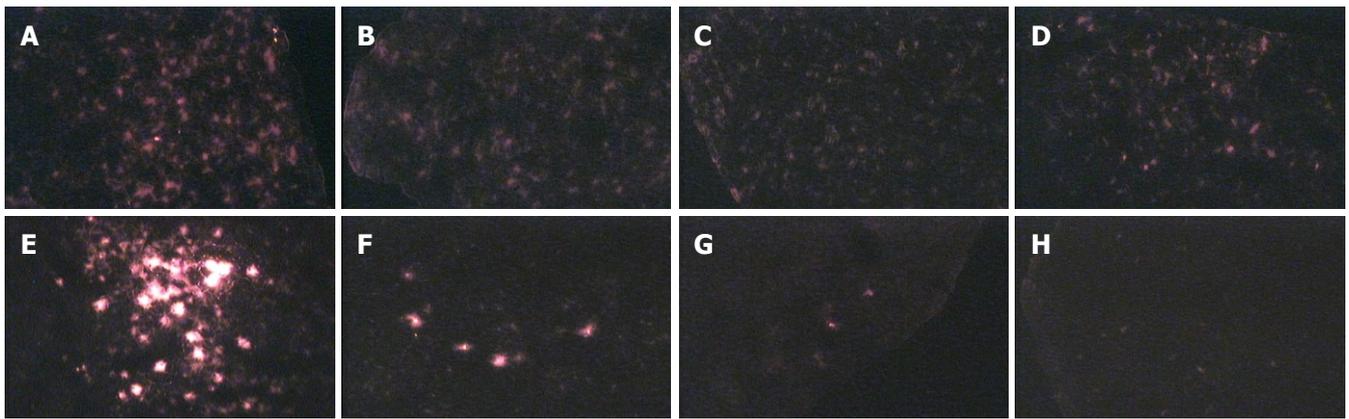

DiI-stained cells gave off red fluorescence seen through a green filter. They were round or elliptical, and evenly stained, and their nuclei could not be differentiated from cytoplasm. At wk 1, 2, 4, 6 and 8 and mo 4 and 6, the distribution of L02 hepatocytes in the rat liver was dynamically observed under the fluorescence microscope in the Rts group. Transplanted L02 hepatocytes distributed in the rat liver parenchyma and weak fluorescence dispersed evenly from wk 1 to mo 4. At mo 6, the number of cells with fluorescence and fluorescence intensity began to decrease, and fluorescence distributed evenly in patches. There was no significant difference between the 2AAF and the control group. Transplanted L02 hepatocytes first distributed in mass in the portal area of the host rat, and then scattered to liver parenchyma. Compared to the Rts group, at the same time point, the number of cells with fluorescence was significantly reduced in the 2AAF or the control group. The number of cells with fluorescence decreased over time and the fluorescence intensity was also weakened over time. Cell fluorescence persisted till week 10 (Figure 1).

### Detection of human albumin in the rat liver tissue by immunofluorescence method

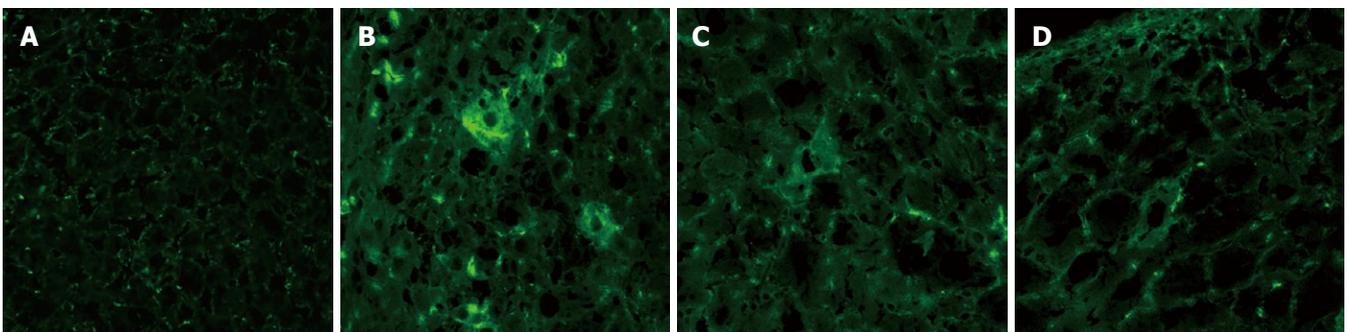

FITC was used to label the secondary antibody, and the positive cell cytoplasm gave off green fluorescence under the laser confocal microscope through the blue filter, and there was a distinct boundary between positive cells and adjacent ones. In the Rts group, at wk 2, 4, 6 and 8 and mo 4 and 6, human albumin was detected, with most cells giving off green fluorescence at week 4. In the 2AAF and the control group, human albumin was detected at wk 2, 4, 6 and 8, but not in 4 rats throughout 10 wk. With time, there was more human albumin at the same time point in the Rts group than in the 2AAF and the control group. In the Rts group liver parenchyma exhibited mild to moderate destruction of hepatic cord, inflammatory cell filtration of the portal area and dispersed enlarged hepatocytes with enlarged nuclei. However, in the 2AAF and the control group these phenomena were not significant. Hepatic fibrosis or liver necrosis was present in neither group (Figure 2).

### Immunohistochemical detection of human PCNA

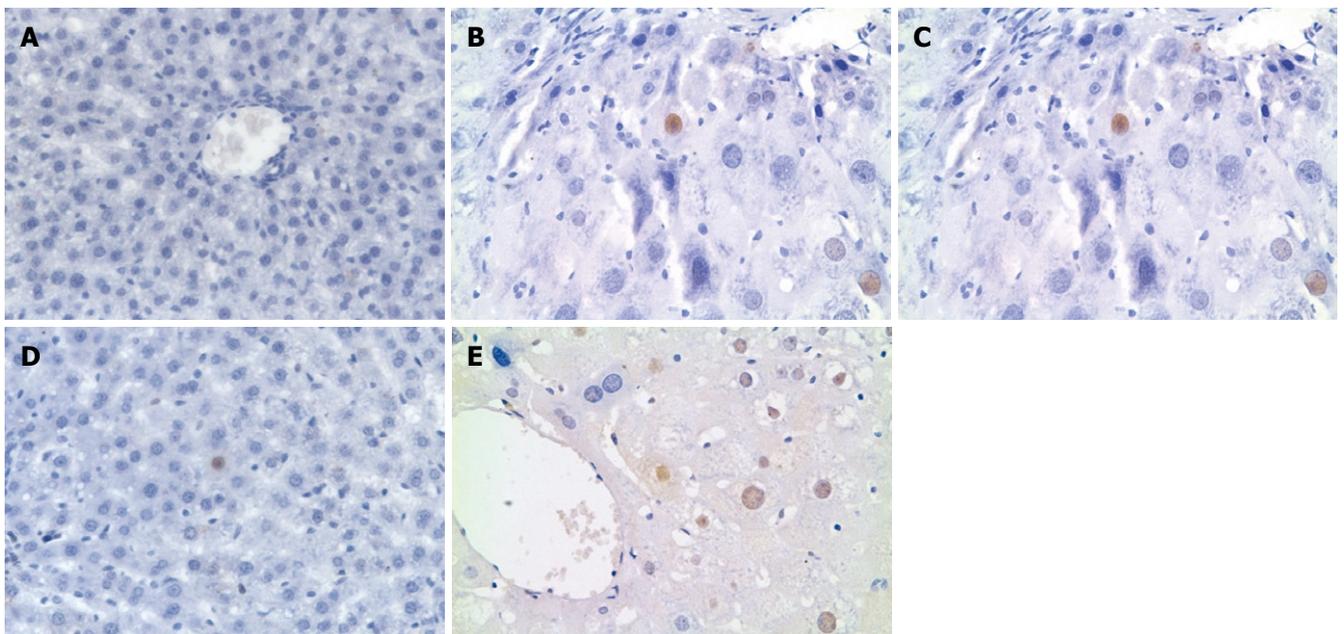

Human PCNA-positive nuclei appeared brown after DAB coloration (Figure 3). The primary antibody was specifically

**Figure 1** Fluorescence image of DiI-stained L02 hepatocytes ( $\times 200$ ). **A-D**: The Rts group at wk 1, 4, 8 and mo 6 after transplantation; **E-H**: The 2AAF group at wk 1, 4, 8 and mo 6 after transplantation.

against human PCNA, and there was no human PCNA detected in the rat liver tissue 1 wk after transplantation. Human PCNA was detected in the Rts group at wk 2, 4, 6 and

8, and mo 4 and 6, with the most detected at wk 4. Human PCNA then gradually decreased, however, still appeared at mo 6. In the 2AAF and the control group, human

<sup>a</sup>*P* < 0.05 vs Control.

PCNA was detected at wk 2, 4 and 6, with the most detected at wk 4. With a primary antibody not specifically against human PCNA, human PCNA was detected in the rat liver tissue 1 wk after transplantation. In the Rts group, a great amount of non-specific human PCNA was detected at wk 1, 2, 4, 6 and 8, and mo 4 and 6, with no decrease in the number of PCNA-positive nuclei. In the 2AAF and the control group, a great amount of non-specific human PCNA was detected at wk 1, 2, 4, 6 and 8, with no changes in the number of PCNA-positive nuclei.

#### Analysis of PCNA-positive cell images

Number density of PCNA-positive cells at various time points were calculated by computer-aided image analysis and were then subjected to statistical analysis. Using the primary antibody specifically against human PCNA, there were significant differences in the number or area density between the Rts and the control group. There were no significant differences between the 2AAF and the control group. While using the primary antibody not specifically against human PCNA, there were no significant differences between either groups (Table 1). The curve chart of number density of PCNA-positive cells is presented in Figure 4.

#### RT-PCR detection of human albumin mRNA

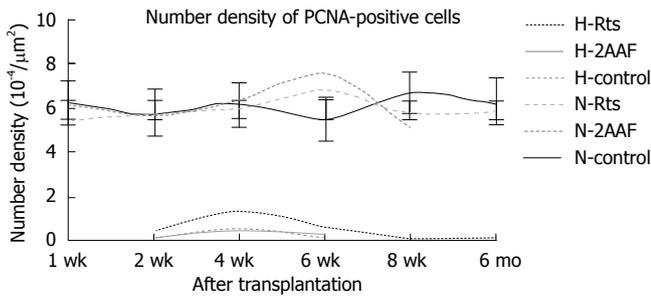

Human *albumin* mRNA was detected at wk 2, 4, 6 and 8, and mo 4 and 6 in the Rts group and at wk 2, 4, 6 and 8 in the 2AAF and the control group. Human *albumin* mRNA band (241 bp) and rat *albumin* mRNA band (388 bp) were detected by RT-PCR in the rat liver tissue using relevant human and rat *albumin* mRNA primers (Figure 5).

## DISCUSSION

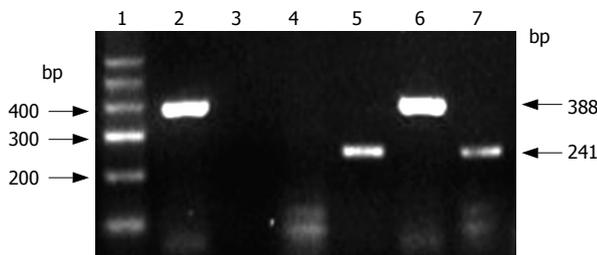

Rodent animal models especially play an important role in the development of hepatology. The hepatitis virus has species-specificity and, susceptible hosts are confined to higher grade primates, such as humans, macaques and chimpanzees<sup>[14]</sup> for various reasons. With immunodeficient or induced immunotolerant rats, rat animal models with chimeric human liver infected with hepatitis virus can be established. During embryonic development, the immune system is not mature, and tolerance of exogenous antigens can occur due to "T lymphocyte clonal deletion"<sup>[15]</sup>.

Hence, animal models for graft tolerance may be established by induction of fetal rat immunotolerance against human hepatocytes by using human fetal hepatocytes and then transplantation of human hepatocytes into normal rat liver<sup>[16]</sup>. An animal model of tolerant rats with chimeric human hepatocytes was established based on the normal immune system, and the chimeric cells in the rat liver were normal human hepatocytes, which are susceptible to many hepatitis-causing agents. Therefore, this rat liver model may be used for studying known hepatitis-causing agents such as HBV, HCV, and HEV virus as well as unknown hepatitis-causing agents.

With the use of labeling technique, transplanted hepatocytes can be easily differentiated from host hepatocytes under the fluorescence microscope or by flow cytometry, and the function, turnover, distribution and survival of transplanted hepatocytes can be monitored directly. We used the lipophilic fluorescent dye DiI to label the whole cell. DiI fluorescence attenuated slowly. It was reported that DiI-labeled neurons can give off fluorescence for more than 4 wk *in vitro* and maintain activity for more than 9 mo *in vivo*. Fluorescence did not attenuate significantly or diffuse to adjacent neurons<sup>[17]</sup>. In this study, DiI fluorescence tracing and immunohistochemical study demonstrated that transplanted L02 hepatocytes first migrated to the distal portal area and liver sinuses in mass in host rat liver, then to liver parenchyma and were then scattered. Under the action of retrorsine, scattered L02 hepatocytes began to proliferate in clusters. In the Rts group, L02 hepatocytes scattered evenly with weak fluorescence during wk 1 after transplantation, suggesting that these cells migrated to the portal area and underwent cell division immediately after migrating to liver parenchyma, leading to weakened fluorescence. In the 2AAF and control groups, the fluorescence intensity was relatively high at the same time point, but the number of cells with fluorescence was significantly small compared to the experimental group, and both were gradually decreased, suggesting less cell divisions. The results demonstrated that retrorsine can significantly promote transplanted L02 hepatocytes to proliferate, but 2AAF cannot. After integrated into the parenchymal plates, transplanted hepatocytes exhibited albumin and enzyme expression and metabolism of biliary. It was observed that there was full reconstitution of gap junction

**Figure 4** Curve chart of number density of PCNA-positive cells number density of PCNA-positive cells. Using the primary antibody specifically against human PCNA, there were significant differences in the number density between the Rts and the control group, there were no significant differences between the 2AAF and the control group, while using the primary antibody not specifically against human PCNA, there were no significant differences between either groups.

**Figure 5** RT-PCR detection of human and rat albumin mRNA in liver tissue. 1: Standard molecular weight DNA marker; 2, 3: Normal rat liver tissue; 4, 5: Human liver tissue; 6, 7: Rats liver tissue with chimeric human hepatocytes at wk 2, 4, 6, 8, and mo 4, 6 in the Rts group and at wk 2, 4, 6, 8 in the 2AAF and the control group; 2, 4, 6: Rat *albumin* mRNA primers used in the RT-PCR reaction system, amplified 388 bp fragment of rat *albumin* mRNA presented in the rat liver tissue of 2 (normal rat liver tissue) and 6 (rats liver tissue with chimeric human hepatocytes), but not in 4 (human liver tissue); 3, 5, 7: Human *albumin* mRNA primers used in the RT-PCR reaction system, the amplified products did not present in 3 (normal rat liver tissue), but in 5 (human liver tissue) and 7 (rats liver tissue with chimeric human hepatocytes), amplified 241 bp human albumin mRNA presented in the rat liver tissue.

and biliar struction between the transplanted and host hepatocytes 5 d after transplantation. This means that successful integration needs at least 5 d<sup>[18]</sup>. In our study, the cells with fluorescence were detected 1 wk after transplantation but human albumin and mRNA were not detected, suggesting that transplanted L02 hepatocytes did not have the ability of human albumin exhibition and proliferation yet, though had been transferred and intergrated into the parenchymal plates. Cell fluorescence lasted for more than 6 mo in the Rts group and 8 wk in the 2AAF and control groups, confirming that DiI attenuates very slowly. In the 2AAF and control groups, disappearance of fluorescence was not due to attenuation but to limited proliferating capability of transplanted cells and decreases in cell viability.

In this study, by using immunofluorescence and RT-PCR, we detected human *albumin* and human *albumin* mRNA at wk 2, 4, 6 and 8, and mo 4 and 6 in the rat liver tissue with chimeric human hepatocytes in the Rts group and at wk 2, 4, 6 and 8 in the 2AAF and control groups. This further confirms the presence and biological function of human L02 cells in the chimeric rat liver. Immunological rejection normally happened 3 wk after transplanta-

tion<sup>[19]</sup>. So we could conclude that the dissolution of transplanted cells was not due to immunological rejection with the host, but to limited proliferating ability of transplanted hepatocytes<sup>[20]</sup>. The presence of human L02 hepatocytes persisted significantly longer in the Rts group than in the 2AAF and control groups. Hepatic fibrosis or necrosis was observed in neither group, suggesting that retrorsine promotes L02 hepatocyte proliferation in the rat liver tissue, and that hepatotoxicity of retrorsine does not affect the biochemical function of transplanted cells. In the Rts group, destruction of liver cord, remarkable inflammatory cell filtration and hepatocytes with enlarged nuclei in liver parenchyma were observed; however, these phenomena were not obvious in the 2AAF and control groups. These findings reflected the integration of transplanted hepatocytes and host cells as well as gradual proliferation and replacement of transplanted cells. The enlarged hepatocytes in rats exposed to retrorsine are interpreted to result from endoreduplication of host cells, which are able to duplicate DNA but cannot proceed through mitosis. Consistent with this interpretation, formation of enlarged cells is dependent on the presence of a stimulus for cell division. The hepatocytes of normal size and appearance could originate either from transplanted or host hepatocytes that were able to withstand the inhibitory effect of retrorsine or from progenitor cells that are unaffected by retrorsine and can differentiate into seemingly normal hepatocytes<sup>[21]</sup>. Laconi *et al* found that since total weight of liver and DNA content did not exceed the normal range during the proliferation of transplanted cells, the transplanted cells not only simply coexist with host cells but replace them<sup>[22]</sup>. Besides retrorsine, transplanted cells per se may also accelerate the replacement of host cells.

Retrorsine and 2/3 hepatectomy (Rts/PH) in combination are frequently used to stimulate proliferation of the transplanted hepatocytes. A two-thirds hepatectomy stimulates chimeric liver regeneration and increases the rate of host cell renewal. Retrorsine potently and persistently blocks the cell cycle of host hepatocytes, but does not affect the cell cycle of transplanted hepatocytes, resulting in stronger growth vigor of transplanted hepatocytes. However, the precise mechanism involved remains unclear. It was shown that compared to injection of retrorsine, injection of a great number of hepatocytes (> 1 × 10<sup>8</sup> cells) into the spleen, repeated transplantation of hepatocytes or induction of liver toxicity before cell transplantation influenced hepatocyte proliferation mildly<sup>[23]</sup>. Although the toxicity of retrorsine may lead to hepatocyte necrosis, it did not affect hepatocyte proliferation, thus shedding light on efficient proliferation of transplanted hepatocytes and the clinical application of retrorsine.

Retrorsine is a pyrrolidine alkaloid derived from Senecio plants, which may potently and persistently block the cell cycle of proliferating host hepatocytes, while not affecting the cell cycle of proliferating transplanted hepatocytes, thus enhancing the selective growth of transplanted hepatocytes. Despite a short half life period, retrorsine may suppress hepatocyte proliferation for weeks and even months<sup>[24]</sup>. Retrorsine mainly blocks phases S and G2 of the liver cell cycle; that is, it blocks cell mitosis. Moreover, it may prevent hepatocytes from entering phase S, binding

to DNA, and blocking DNA synthesis<sup>[25]</sup>. Other DNA-binding agents such as diethylnitrosamine cannot maintain the proliferation of transplanted hepatocytes, indicating the peculiarity of alkaloid<sup>[22]</sup>. Laconi *et al* found that in the absence of exogenous growth stimuli, such as partial hepatectomy, retrorsine treatment may give rise to results similar to those of a combination of retrorsine treatment and partial hepatectomy, suggesting that besides maintenance of selective growth vigor of transplanted hepatocytes, there may be another mechanism of retrorsine action<sup>[26]</sup>. Gordon *et al* investigated the mechanism by which retrorsine causes elimination of irreversibly damaged giant hepatocytes, finding that retrorsine can block liver cell mitosis and results in the accumulation of cells at late phase S and phase G2, and induces apoptosis and cell injury depending on the relative levels of the proapoptotic protein Bax and the anti-apoptotic protein Bcl-xl<sup>[27]</sup>.

2AAF is a hepatotoxic drug that blocks DNA synthesis and suppresses proliferation of host hepatocytes, finally activating the proliferation of oval cells<sup>[28,29]</sup>. In our study, we investigated whether 2AAF can promote the proliferation of transplanting human hepatocytes in the tolerant rat liver.

The computer-aided image analysis system has been widely used to analyze immunohistochemical images and calculate the number, number density, area, and area density of transplanted hepatocytes, maximum cell diameter and other morphological parameters. In our study, the number density and area density of PCNA positive cells at various time points were calculated by computer-aided image analysis and were then subjected to statistical analysis. It was found that, using the primary antibody specifically against human PCNA, human PCNA was observed at wk 2, 4 and 6 both in the 2AAF and control group, showing that human L02 cells in proliferative phase survived in the rat livers.

Image analysis revealed that there were not significant differences in the number density and area density between both groups, suggested that 2AAF could not promote the proliferation of transplanted cells. In both groups, the highest number of proliferating L02 hepatocytes was observed at wk 4, showing the strongest proliferating capability at wk 4. The proliferating L02 hepatocytes disappeared at wk 8, but fluorescence tracing and immunohistochemical results showed that transplanted hepatocytes still survived and owned some functions at wk 8. Image analysis revealed that there were significant differences in the number density and area density between both groups, suggesting that retrorsine significantly promoted the proliferation of transplanted cells. Human PCNA was observed at wk 2, 4, 6 and 8, and mo 4 and 6 in the Rts group and at wk 2, 4 and 6 in the control group, and human PCNA persisted significantly longer in the Rts group than in the control group, suggesting that retrorsine can inhibit the proliferation of host hepatocytes and promote the activation of oval cells and the proliferation of transplanted hepatocytes. Zheng *et al* postulated that regeneration of severely injured liver following retrorsine treatment may first involve the proliferation and differentiation of transplanted adult hepatocytes, and then the proliferation and differentiation of mono- or bi-potent precursor cells<sup>[30]</sup>.

In the Rts group, the highest number of proliferating

L02 hepatocytes was observed at wk 4, with significantly more cells in the Rts group than in the control group, and following this the number gradually dropped. At mo 4 after transplantation, there was a small number of positive cells. This number was similar to that at mo 6, suggesting that the high-level differentiation and proliferation of L02 hepatocytes in the rat liver persisted till mo 4, and L02 hepatocytes still replicated at low levels during late stages. Zheng *et al* transplanted DPPIV + hepatocytes into DPPIV-rats subjected to retrorsine treatment and partial hepatectomy, and they found that DNA replication and cell division were the most frequent at mo 1 and then subsided, and that a platform of cell proliferation was reached at mo 3, but with DNA replication remaining at a low level<sup>[30]</sup>. Our findings are largely in agreement with their results.

Using a primary antibody not specifically against human PCNA, there were no significant differences in the persisting time and number of proliferating L02 hepatocytes between the experimental (Rts or 2AAF) groups and the control group. Non-specific PCNA presented in large amounts after wk 1, demonstrated that the proliferation of rat hepatocytes was remarkable and persistent following partial hepatectomy. Seventy percent hepatectomy is frequently used to reproduce the liver regeneration models in rats. Transplanted hepatocytes accounted for a minority of the cell population in the chimeric liver and partial hepatectomy caused the proliferation of just a few L02 cells. Moreover, even if retrorsine enhanced the proliferation of transplanted cells, specific human PCNA-positive cells were substantially fewer than non-specific PCNA-positive cells at the same time point. Non-specific PCNA was observed at wk 1, while specific human PCNA was not. Retrorsine permitted DNA synthesis in the host hepatocytes and mainly blocked hepatocytes at late phase S and phase G2; that is, it blocked cell mitosis and inhibited the proliferation of host hepatocytes. Through this mechanism<sup>[25]</sup>, hepatocytes with enlarged nuclei emerged following retrorsine treatment, partially because of replication and synthesis of DNA in host hepatocytes and failure of these cells to undergo mitosis, which indicates that selective proliferation of transplanted hepatocytes in retrorsine treated animals is dependent, at least in part, on the persistent cell cycle block imposed by retrorsine on host cells. 2AAF blocked DNA synthesis and suppressed proliferation of host hepatocytes, and mainly promoted the proliferation of oval cells. But in our study, 2AAF did not promote the proliferation of transplanted L02 hepatocytes.

Retrorsine promoted the proliferation of L02 hepatocytes in rat liver with chimeric human hepatocytes and prolonged cell survival, and thus a stable, persistent animal model was achieved. The study sheds light on the usefulness of rat liver models with chimeric human hepatocytes; the animal model based on the normal immune system may open up a new avenue of study on the immune response and pathogenetic mechanism of viral infection, and antiviral therapy as well as the development of potent vaccines.

## COMMENTS

### Background

An animal model of rats with chimeric human liver is that human hepatocytes are transplanted into rat liver. But human hepatocytes transplanted into rats just can survive a limited time. The live time of transplanted hepatocytes must be prolonged to establish a persistent animal model.

### Research frontiers

Retrorsine, or other hepatotoxicity drugs and 2/3 hepatectomy in combination are frequently used to stimulate proliferation of the transplanted hepatocytes. 2/3 hepatectomy stimulates chimeric liver regeneration and increases the rate of host cell renewal. Retrorsine potently and persistently blocks the cell cycle of host hepatocytes, but does not affect the cell cycle of transplanted hepatocytes, resulting in stronger growth vigor of transplanted hepatocytes. 2AAF is a hepatotoxicity drug to block DNA synthesis and suppress proliferation of host hepatocytes, finally activated the proliferation of oval cells.

### Innovations and breakthroughs

The animal model of tolerant rats with chimeric human hepatocytes we established was based on the normal immune system, and the chimeric cells in the rat liver were normal human hepatocytes. With the use of Dil labeling technique, transplanted hepatocytes can be easily differentiated from host hepatocytes under the fluorescence microscope, and the function, turnover, distribution and survival of transplanted hepatocytes can be monitored directly. The survival and proliferation of human L02 hepatocytes in the rat liver were analyzed by immunofluorescence method, reverse transcription-polymerase chain reaction (RT-PCR), immunohistochemical study, and computer-aided image analysis.

### Applications

The chimeric cells in the rat liver were normal human hepatocytes, which are susceptible to many hepatitis-causing agents. Therefore, this rat liver model may be used for studying known hepatitis-causing agents such as HBV, HCV, and HEV virus and unknown hepatitis-causing agents. The animal model of tolerant rats with chimeric human liver can be applied in pathogenesis, antiviral therapy and development of vaccine.

### Terminology

An animal model of rats with chimeric human liver is that human hepatocytes are transplanted into rat liver. With induced immunotolerance rats, it can establish animal model of rats with chimeric human liver infected with Hepatitis B virus, which can be applied in pathogenetic mechanism of viral infection, antiviral therapy and so on.

### Peer review

There is interest in humanized rats and mice for studies of human metabolism and transplantation. In this paper rat livers are repopulated with human hepatocytes after chemical treatment with retrorsine and partial hepatectomy.

### Abstract

**AIM:** To compare the preservation of non-heart-beating donor (NHBD) livers in cold histidine-tryptophan-ketoglutarate (HTK) solution and extracorporeal liver perfusion (ECLP).

**METHODS:** Livers harvested from health pigs were stored for 10 h in cold HTK solution (group A,  $n = 4$ ) or perfused with oxygenated autologous blood at body temperature (group B,  $n = 4$ ). Both groups were then tested on the circuit for 4 h. Bile production, hemodynamic parameters, hepatocyte markers and reperfusion injury of extracorporeal livers were tested in each group. Liver tissues from each group were examined at the end of reperfusion.

**RESULTS:** At 1, 2, 3 and 4 h after reperfusion, bile production, hemodynamic parameters, hepatocyte markers and reperfusion injury of livers in group A were statistically different from those in group B ( $P < 0.05$  or  $P < 0.01$ ).

**CONCLUSION:** ECLP is better than HTK solution to preserve NHBD livers. ECLP can assess the graft viability

### INTRODUCTION

Standard liver preservation involves flushing the liver *in situ* with an organ preservation solution [University of Wisconsin (UW) solution or histidine-tryptophan-ketoglutarate (HTK) solution] and its storage at 4°C for up to 15-18 h before transplantation<sup>[1]</sup>. During the process, pre-preservation injury, cold-preservation injury, re-warming injury, and reperfusion injury may occur. The occurrence rate of primary non-function (PNF) ranges 2%-23%, which is a major cause of death in transplantation<sup>[2]</sup>. Additionally, there is evidence that severe preservation injury is associated with increased liver graft rejection<sup>[3]</sup>.

The system of extracorporeal liver perfusion (ECLP), which was established by our research team, can perfuse the liver with an oxygenated perfusate supplemented with nutritional support at body temperature during the preservation period<sup>[4]</sup>. Studies demonstrated that oxygenated perfusion is able to prevent adenosine tri-phosphate (ATP) loss during ischemia, and reset ATP levels after it<sup>[5,6]</sup>.

In this preclinical study, we compared standard cold storage of livers in HTK solution to normothermic, sanguineous perfusion over a 10 h preservation period in the pig liver model.

## MATERIALS AND METHODS

### Animals

Large white pigs weighing 20–25 kg were obtained from the Experimental Animal Center of Academy of Military Medical Sciences. All animals used in this study received humane care according to the National Guidelines for the Care of Animals in China. The pigs were housed at 23°C–25°C and fed with a standard food with free access to drinking water.

### Equipments

Blood pump (JHBP-2000B) was purchased from Guangzhou Jihua Medical Instruments Company. Hollow fiber oxygenator 3381 and heat exchanger were produced by Medtronic, Inc. USA. Digital measuring and controlling heating water box (GKX21Cr) was a product of Shanghai Jinping Instrument and Meter Company, Shanghai, China. Premature infant incubator (KXK-5G) was made by the 7th Shanghai Medical Instrument Factory, Shanghai, China. Gathering blood container 2000 was purchased from Dongguan Kewei Medical Instrument Company, Guangzhou, China. Euro-Collins solution and HTK solution were from Koehler Chemie GmbH, Germany.

### Experimental design

Livers were harvested from healthy pigs and preserved for 10 h in cold HTK solution (group A,  $n = 4$ ) or perfused with oxygenated autologous blood at body temperature (group B,  $n = 4$ ).

### Reperfusion

The function of all harvested livers was tested after preservation. The ECLP system was used to perfuse the livers with whole blood at body temperature as a substitute for transplantation. The blood used to perfuse livers in group B was changed between the preservation and reperfusion phases and their physiological parameters were compared.

### Operation

Animals were anesthetized with 4 mg/kg propofol (intravenous injection, i.v.) and their ear veins were cannulated. The animals were intubated with an extended endotracheal tube. Anesthesia was maintained with i.v. propofol (1 mg/kg per hour) and halothane inhalation *via* an extended endotracheal tube throughout the procedure. The artery and vein of cervix were inserted into two catheters for transfusion and collecting blood. A midline incision was made to enter the peritoneal cavity. The bile duct was divided and catheterized for bile juice drainage. Hepatic vessels were identified and isolated in a standard fashion. After the collection of autoblood, the portal vein and hepatic artery were catheterized and the inferior vena cava (IVC) was divided with a suite of catheters, then the whole liver was removed. Approximately 1000 mL of autoblood was collected into a reservoir bottle.

### Perfusion

During the preparation of liver, the perfusion apparatus was assembled and primed with 1000 mL of pig blood (Figure 1). The perfusion circuit consisting of blood pump, oxygenator, gathering blood container, perfusion

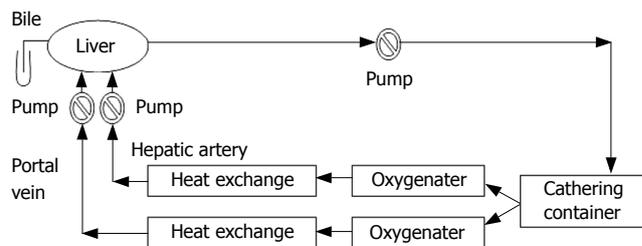

Figure 1 Hepatic circuit for extracorporeal liver perfusion.

Table 1 Bile production in liver of each group at different time points ( $n = 4$ , mean  $\pm$  SD)

Group	Bile production in liver (mL)			
	1 h	2 h	3 h	4 h
A	1.75 $\pm$ 0.29	2.25 $\pm$ 0.29	3.88 $\pm$ 0.25	5.25 $\pm$ 0.29
B	2.62 $\pm$ 0.25 <sup>b</sup>	4.63 $\pm$ 0.48 <sup>b</sup>	6.00 $\pm$ 0.41 <sup>b</sup>	6.63 $\pm$ 0.25 <sup>b</sup>

<sup>b</sup> $P < 0.01$  vs group A.

tubing, gate clamp and heat exchanger was used to maintain the blood temperature at 39°C (normal temperature for a pig). Bottled oxygen was used and ratios were adjusted to maintain the physiological partial pressures. During priming of the circuit, pH, PaCO<sub>2</sub>, and Ca<sup>2+</sup> were adjusted to the normal physiologic range. In general, the perfusion circuit was supplemented with 20 mL 50% glucose and 20 U/heparin.

### Assessment of liver function

The general conditions of liver were observed during perfusion. Bile production, hemodynamic parameters, hepatocyte markers and reperfusion injury of extracorporeal livers in each group were documented every hour during the reperfusion phase. At the end of each perfusion, the liver was sectioned and multiple random samples were assessed for histologic evaluation of reperfusion injury.

### Statistical analysis

The data were analyzed using SPSS 11.0 statistical package. All values were presented as mean  $\pm$  SD. For a single comparison, the significance of differences between means was determined by Student's *t*-test.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Synthetic function

At 1, 2, 3 and 4 h after perfusion, bile production of livers in group A was statistically different from that in group B ( $P = 0.0084, 0.0072, 0.0046, 0.0057$ , respectively; Table 1).

### Hemodynamic parameter

At 1, 2 and 3 h after perfusion, the pressure of hepatic artery in group A was statistically different from that in group B ( $P < 0.05$ ), but at 4 h after perfusion, the pressure of hepatic artery in group A was not statistically different from that in group B. At 1 h after perfusion, the pressure

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs group A.

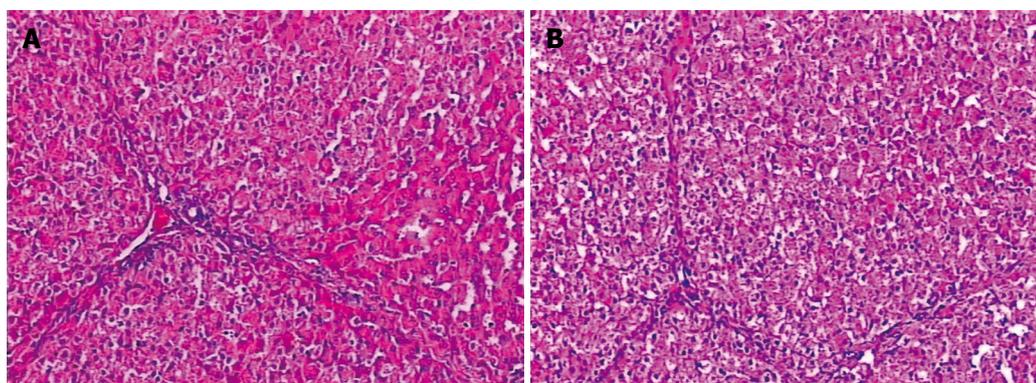

Figure 2 Microstructure changes in hepatic cells (HE,  $\times 200$ ) of group A (A) and group B (B).

of portal vein in group A was statistically different from that in group B ( $P < 0.05$ ), but at 4 h after perfusion, the pressure of portal vein in group A was not statistically different from that in group B (Table 2).

#### Hepatocellular damage

A significant difference ( $P < 0.01$ ) was found in alanine aminotransferase (ALT) between the two groups, which was increased to 115 IU/L in the cold-preserved livers. The corresponding value in the warm-preserved group never exceeded 55 IU/L. A similar change was seen in lactate dehydrogenase (LDH) release ( $P < 0.01$ ), which was higher in cold-preserved livers (Table 3).

#### Metabolic function

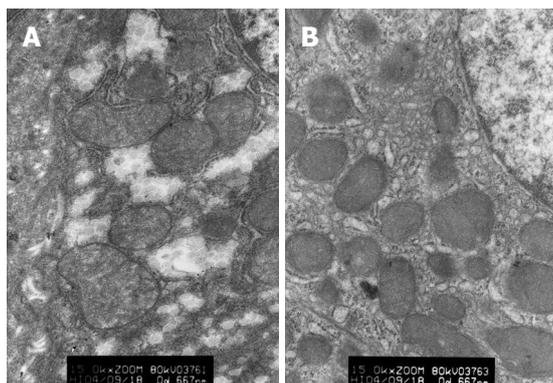

A significant difference ( $P < 0.01$ ) was found in glucose concentrations of the perfusate between the two groups. At 2, 3 and 4 h after perfusion, the rate of oxygen con-

sumption of livers in group A was statistically lower than that in group B ( $P < 0.01$ ), but at 1 h after perfusion the rate of oxygen consumption of livers in group A was higher than that in group B ( $P < 0.05$ , Table 4).

#### Histological findings

**Changes in microstructure of hepatic cells:** The livers in group A revealed edema of hepatic cells, sporadic acidophilic degeneration, mild vacuolization and sinusoidal dilatation. The livers in group B showed slight edema and necrosis of a few hepatic cells (Figure 2).

**Changes in ultrastructure of hepatic cells:** In group A, the karyotheca of hepatic cells was not clear, mitochondria swelled mildly, a few of crista vanished and endoplasmic reticulum expanded slightly. In group B, the karyotheca of hepatic cells was clear and regular, double nuclei were visible and endoplasmic reticulum was normal (Figure 3).

**Figure 3** Ultrastructure changes in hepatic cells ( $\times 15000$ ) of group A (A) and group B (B).

## DISCUSSION

The progressively increases of patients with end stage liver disease is extending the waiting-list for liver transplantation, which, unfortunately, is not followed by a suitable increase in the number of donors<sup>[7]</sup>. The shortage of donor organs has given rise to the interest in liver harvesting from NHBD, which can significantly reduce the large discrepancy between supply and demand for liver transplantation. However, NHBD livers suffer not only from warm ischemic injury but also from cold preservation and reperfusion injury<sup>[8]</sup>. In this pathophysiological process, a number of cytokines, such as TNF- $\alpha$ , release with the activation of Kupffer cells and the obstruction of microcirculation. When blood perfusion is terminated during ischemic preservation, the supply of oxygen and nutrients is eliminated along with the vehicle for disposal of waste and metabolic by-products. During anoxia, ineffective anaerobic metabolism leads to depletion in energy stores, with a concomitant build-up of acidic by-products, which finally results in loss of transcellular electrolyte gradients, cell swelling, influx of free calcium, and subsequent activation of phospholipases. The breakdown of ATP during ischemia creates a setting for the production of reactive oxygen intermediates during reperfusion and a cascade of ischemic injury<sup>[9-12]</sup>.

During the first half of the twentieth century, Carrel<sup>[13]</sup> perfused organs with normothermic, oxygenated serum at supraphysiological volumes and demonstrated gross viability for several days. ECLP has too many external constraints and has thus been largely abandoned. Research of ECLP has largely centered on the treatment of acute liver failure as a bridge to transplantation<sup>[14-16]</sup>. The present study used the system of ECLP to perfuse NHBD livers using dual vessel normothermic sanguineous perfusion with oxygenated blood as the perfusate. The perfusate to the liver artery and portal vein can be oxygenated separately<sup>[4]</sup>. Compared to the storage in cold HTK solution, the ECLP circuit acts not only as a method to store NHBD livers but as a substitute for transplantation, thus, the effect of two preservation methods can be evaluated. The outcome of studies can be influenced by many factors in a large animal transplantation model. If these factors are not considered, any conclusions drawn from this study can be attributed

directly to the preservation process.

The change in hemodynamic parameters reflects the condition of liver microcirculation<sup>[17]</sup>. After 1 h reperfusion with the total hepatic blood flow maintained, the difference in the pressure of liver artery and observed in two groups, showing the different grade obstruction of liver microcirculation. When the reperfusion was continued, the pressure of liver artery and portal vein decreased gradually, while the pressure of portal vein remained unchanged in two groups, indicating that the liver microcirculation is improved. However, the condition of liver microcirculation in group B was better than that in group A. The glucose level in the perfusate represents the balance between supply and uptake of hepatocytes<sup>[18]</sup>, suggesting that the glucose level is an indirect measure of liver metabolism. It was reported that the functional state of an isolated liver can be measured from its ability to induce gluconeogenesis<sup>[19]</sup>. The estimated elimination capacity of glucose concentration seems to reflect the metabolic capabilities during reperfusion. In the study, the glucose level of perfusate in group A was higher than that in group B, suggesting that the ability of liver to take up glucose is different in two groups. Although oxygen consumption might be reasonably assumed to be a measure of hepatocyte function, it fell consistently during perfusion. This was in contrast to other markers of liver function, particularly synthetic activity. Greater oxygen consumption was seen in livers of group A after 1 h reperfusion, which may be explained by the respiratory burst and subsequent oxygen debt that follows prolonged periods of cold ischemia and subsequent reperfusion. This was in contrast to the livers of group B, in which a stable level of oxygen consumption was observed. Bile production increased with time, which may reflect the consumption of substrate and its synthesizing function<sup>[20,21]</sup>.

How to use NHBD livers reasonably and effectively is the key question, which can make the transplanted liver function well and give the recipient a realistic chance of survival. At present, the criteria to decide whether the organ should be utilized or discarded almost depend on an overall judgment made on macroscopic appearance, perhaps with a biopsy. The ECLP system offers an opportunity to assess the viability of a liver to be used<sup>[22,23]</sup>, which may lead not only to a more rational use of the current donor pool but also to an accurate assessment of marginal organs<sup>[24]</sup>.

Although the technique of cold storage is effective and simple, it may have certain limitations in terms of ability to maintain a viable organ avoid of ischemic injury and preservation time. In addition, this technique does not allow for viability assessment, and therefore the use of marginal donor organs remains difficult. By simulating the natural physiological environment of the liver and providing oxygen and other substrates necessary for normal metabolism, ECLP may serve as an ideal organ preservation technique in the future<sup>[25-27]</sup>.

In conclusion, it is better to preserve NHBD livers in ECLP than in cold HTK solution in terms of synthetic and metabolic serum markers, hemodynamic parameters, and histological appearances.

## COMMENTS

### Background

To minimize the ischemia-reperfusion injury in non-heart-beating donor (NHBD) livers, we compared the preservation of NHBD livers in cold histidine-tryptophan-ketoglutarate (HTK) solution and extracorporeal liver perfusion (ECLP).

### Research frontiers

Extracorporeal liver perfusion of NHBD livers can promote cellular recovery from warm ischaemic injury. The present study describes a method of normothermic extracorporeal perfusion by which the viability of livers can be maintained for at least 72 h.

### Innovations and breakthroughs

This is probably the first study using the ECLP system with oxygenating blood. The ECLP circuit can be used not only as a method to store NHBD livers but as a substitute for transplantation, and therefore the effect of two preservation methods can be evaluated.

### Applications

The findings in this study support that normothermic, sanguineous and oxygenated ECLP is better than HTK solution to preserve NHBD liver.

### Peer review

The design of this study was rational and reliable. The statistical methods used were appropriate. The results were sufficient to draw the conclusions. The discussion was well organized and rational.

### Abstract

**AIM:** To investigate the effect of Chaiqinchengqi decoction (CQCQD) on sarco/endoplasmic reticulum  $\text{Ca}^{2+}$ -ATPase (*SERCA*) mRNA expression of pancreatic tissues in acute pancreatitis (AP) rats.

**METHODS:** Thirty Sprague-Dawley (SD) rats were randomized into control group, AP group and CQCQD group ( $n = 3 \times 10$ ). The rats in the CQCQD group were intragastrically administered with CQCQD (10 mL/kg every 2 h) after induction of AP by intraperitoneal injection of caerulein (50  $\mu\text{g}/\text{kg}\cdot\text{h} \times 5$ ) within 4 h. At 6 h after the induction of AP model, pancreatic tissues were collected for the pathological observation, mRNA extraction for determination of *SERCA1* and *SERCA2* mRNA expression or pancreatic acinar cell isolation for measurement of fluorescence intensity (FI) of intracellular calcium ion concentration [ $\text{Ca}^{2+}$ ]<sub>i</sub>.

**RESULTS:** There was no expression of pancreatic *SERCA1* mRNA in the control group and the AP group. The expression of pancreatic *SERCA2* mRNA in the AP group was down-regulated (expression ratio = 0.536;  $P = 0.001$ ) compared with the control group, while that in the CQCQD group was up-regulated (expression ratio

= 2.00;  $P = 0.012$ ) compared with AP group. The FI of intracellular [ $\text{Ca}^{2+}$ ] of pancreatic acinar cells in the AP group (138.2  $\pm$  23.1) was higher than the C group (111.0  $\pm$  18.4) and the CQCQD group (118.7  $\pm$  15.2) ( $P < 0.05$ ) and the pancreatic pathological score in the CQCQD group was lower than that in the AP group (5.7  $\pm$  1.9 vs 9.2  $\pm$  2.7,  $P < 0.05$ ).

**CONCLUSION:** CQCQD can up-regulate the expression of *SERCA2* mRNA of pancreatic tissues, reduce intracellular calcium overload and relieve pancreatic tissue lesions.

### INTRODUCTION

Acute pancreatitis (AP) is a potentially lethal disorder with no specific therapeutic options<sup>[1-5]</sup>. The major obstacle to the development of therapies is our limited understanding of the pathogenesis of AP. Despite a number of theories have been proposed to explain the pathogenesis from various aspects, but there are still controversies about the mechanism of the disorder. Since Ward<sup>[6]</sup> firstly proposed that calcium overload in pancreatic acinar cells should be a "trigger point" of AP, intracellular calcium overload has been generally accepted to play a crucial role in the occurrence and deterioration of AP<sup>[7]</sup>.

The increased intracellular free calcium ion concentration ( $[\text{Ca}^{2+}]_i$ ) is believed to originate from the influx of extracellular  $\text{Ca}^{2+}$  and the release of  $\text{Ca}^{2+}$  of intracellular  $\text{Ca}^{2+}$  stores<sup>[8]</sup>. In AP, the quantity and/or activity of plasma membrane  $\text{Ca}^{2+}$ -ATPase (PMCA) and/or sarco/endoplasmic reticulum  $\text{Ca}^{2+}$ -ATPase (SERCA)

were decreased, the intracellular  $\text{Ca}^{2+}$  was not pumped out of cell or back into  $\text{Ca}^{2+}$  stores in time<sup>[9]</sup>. But the exact mechanism of intracellular calcium overload in AP remains unclear. Therefore, a better elucidation would improve the therapeutic strategies of this disease.

Chaiqinchengqi decoction (CQCQD) has been proved to be effective in the treatment of AP<sup>[10]</sup>. Our previous experiments found that CQCQD inhibited the elevation of  $[\text{Ca}^{2+}]_i$  and had a protective effect on pancreatic acinar cells in AP rats<sup>[11]</sup>. In the present study, we aim to explore the mechanism of intracellular calcium overload by determining the *SERCA* mRNA expression changes of pancreatic tissues in AP rats and further to find out the therapeutic mechanisms of CQCQD in AP rats.

## MATERIALS AND METHODS

### Animal

Thirty male Sprague-Dawley (SD) rats weighing 250-300 g were purchased from the Experimental Animal Center of West China Center of Medical Sciences of Sichuan University. All animals were kept at constant room temperature in a 12-h light/dark cycle with free access to standard chow and water. All animals were adjusted to laboratory conditions for 1 wk and a 12-h fast with free access to drinking water before the experiments. This study was approved by and conducted under the guidelines of Animal Use and the Committee of Scientific Research of West China Hospital of Sichuan University.

### Reagents

Caerulein was purchased from Sigma Co. (USA), trizol and diethyl pyrocarbonate (DEPC) were from Invitrogen Company (USA), hexanucleotide random primer and Superscript II RNase H-reverse transcriptase (RNase H-RT) was from Life Technologies, dNTPs and the RNAase inhibitor were from Takara Co. (Japan), and Taq DNA polymerase was from Promega (USA). Primers for *SERCA1* and *SERCA2* gene were designed according to the method reported previously. Primers for *SERCA1*, *SERCA2* and *GAPDH* genes were synthesized by Shanghai Biotechnology Co. Ltd. (Table 1). Dulbecco's modified Eagle's medium (DMEM) is a product of GIBCO BRL and preoxygenated for 30 min before use. Collagenase P was purchased from Roche Applied Science. Fluo-3/AM was a product of Molecular Probes Co, USA. All other reagents were of the highest purity available and were purchased from Sigma unless indicated otherwise.

### Preparation of CQCQD

The Chinese medicinal herbs in CQCQD provided by Chinese Herbs Pharmacy of West Chinese Hospital of Sichuan University included Chaihu (*Radix Bupleuri*) 15 g, Huangqin (*Radix Scutellariae*) 15 g, Houpo (*Cortex Magnoliae Officinalis*) 15 g, Zhishi (*Fructus Aurantii Immaturus*) 15 g, Yinchen (*Herba Artemisiae Scopariae*) 15 g, Zhizi (*Fructus Gardeniae*) 20 g, Dahuang (*Radix et Rhizoma Rhei*) 15 g and Mangxiao (*Natrii Sulfas*) 10 g. The decoction was made into 200 mL juice and then into lyophilized powder. Before experiment, the lyophilized powder of CQCQD was prepared to a concentration of 2 g/mL of crude herbs.

### Animal grouping and procedure

SD rats were randomized into control group (C group,  $n = 10$ ), AP group ( $n = 10$ ) and CQCQD group ( $n = 10$ ). AP model was induced by intraperitoneal injection of caerulein ( $50 \mu\text{g}/\text{kg}\cdot\text{h} \times 5$ ) within 4 h<sup>[12]</sup>. Rats in the C group were administered with the same volume of physiological saline. After the induction of AP, the rats in the CQCQD group were injected orally into the stomach with CQCQD ( $10 \text{ mL}/\text{kg}\cdot 2 \text{ h}$ ), and other two groups were intragastrically administered with the same volume of physiological saline as CQCQD group. At 6 h after the induction of AP, the rats were anesthetized with intraperitoneal sodium pentobarbital ( $40 \text{ mg}/\text{kg}$ ), the abdomen was opened and the pancreatic tissues were rapidly collected for pathological examination, mRNA extraction or cell isolation for measurement of  $[\text{Ca}^{2+}]_i$ . The rats were sacrificed by exsanguinations after experiments.

### Pathological examination and scoring of pancreatic tissues

After removal of the pancreatic tissues, the sections of samples were fixed in 4% neutral buffer formaldehyde, embedded with paraffin wax, cut into slices, and stained with Hematoxylin-Eosin (HE) and observed under light microscopy. Pathological grading and scoring criteria are shown in Table 2<sup>[13-15]</sup>. For each pathological section, 10 visual fields under a high-power microscope (HE,  $\times 400$ ) were randomly selected and scored by one pathologist. The mean score of the 10 visual fields of one pathological section was calculated as the pathological score.

### Pancreatic acinar cell isolation and $[\text{Ca}^{2+}]_i$ measurement

Pancreatic tissue was quickly removed and immediately transferred to iced DMEM. Collagenase P ( $0.3 \text{ g}/\text{L}$ ) in  $2.5 \text{ mL}$  DMEM containing  $2 \text{ g}/\text{L}$  bovine serum albumin (BSA) and  $0.1 \text{ g}/\text{L}$  soybean trypsin inhibitor (SBTI) was infiltrated into the tissue with a  $5 \text{ mL}$  syringe. The tissue was minced into small fragments and digested in Collagenase P solution at  $37^\circ\text{C}$  in a shaking water bath for  $3 \times 15 \text{ min}$  ( $120 \text{ cycles}/\text{min}$ ), dispersed with a plastic pipette, filtered through a nylon mesh ( $150 \text{ meshes}$ ), and layered into DMEM containing 4% BSA. The acinar cells were centrifuged at  $400 \text{ r}/\text{min}$  for 3 min for three times in fresh DMEM medium containing  $2 \text{ g}/\text{L}$  BSA and  $0.1 \text{ g}/\text{L}$  SBTI and resuspended before use.

According to the previously reported methods<sup>[16]</sup>, the pancreatic acinar cells were loaded with  $5 \mu\text{mol}/\text{L}$  Fluo-3/AM and 0.01% Pluronic F-127 in darkness for 30 min at  $37^\circ\text{C}$  and observed under Leica TCS-sp2 laser scanning confocal microscopy (LSCM). Twenty different cells in each visual field were randomly selected. The cells loaded with Fluo-3/AM were excited at a wavelength of 488 nm and the emitted fluorescence was detected at 488 nm and 560 nm. The relative fluorescence was analyzed using fluorescence quantitative analysis software and the intracellular calcium fluorescence intensity (FI) was presented as intracellular  $[\text{Ca}^{2+}]_i$ .

### Reverse transcription and polymerase-chain-reaction (RT-PCR)

Pancreatic tissues in each group was quickly removed and

Table 1 Probe, primer and product (bp) in RT-PCR

immediately transferred into liquid nitrogen. Total RNA of pancreatic tissue was extracted using Trizol reagent. The integrity of the total RNA was confirmed by agarose gel electrophoresis. Quantity and purity of the total RNA were determined by an ultraviolet spectrophotometer, and RNA concentration of the sample was calculated.

The total RNA was reverse-transcribed using hexanucleotide random primers with RNase H-RT. The cDNA was amplified as a template for subsequent PCR using *Taq* DNA polymerase in a Perkin Elmer Cetus DNA thermocycler. PCR reaction system included 5  $\mu$ L cDNA-RT product, 3  $\mu$ L 10  $\times$  PCR buffer, 3  $\mu$ L MgCl<sub>2</sub> of 25 mmol/L, 0.36  $\mu$ L dNTP of 25 mmol/L, 1  $\mu$ L upstream primer of 10  $\mu$ mol/L, 1  $\mu$ L downstream primer of 10  $\mu$ mol/L, 0.6  $\mu$ L probe of 10  $\mu$ mol/L, 0.3  $\mu$ L *Taq* polymerase of 5 U/ $\mu$ L, and 15.74  $\mu$ L deionized double-distilled water. PCR cycling conditions were as follows: initial denaturation at 94°C for 2 min, followed by 45 cycles of 94°C for 20 s, 56°C for 30 s and 60°C for 40 s.

In this study, a negative control with the same volume of deionized double-distilled water instead of cDNA was used and amplified to control DNA contamination, and a positive control with the same volume of the cDNA of skeletal muscle of rat instead of cDNA of pancreatic tissues. Glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*)

**Figure 1** Scores of pancreatic tissues in three groups ( $n = 10$ , mean  $\pm$  SD). The pathological score of pancreatic tissues was the highest in the AP group ( $9.2 \pm 2.7$ ) and followed by CQCQD group ( $5.7 \pm 1.9$ ) and C group ( $0.8 \pm 1.0$ ), ( $P < 0.05$ ).

gene was used as internal housekeeping gene. The amplified DNAs were resolved by agarose gel electrophoresis and stained with ethidium bromide. The bands were visualized and photographed under ultraviolet light.

### Statistical analysis

Data were expressed as mean  $\pm$  SD. Data in normal distribution were analyzed using analysis of variance; data in abnormal distribution was analyzed using Wilcoxon rank sum test. The Relative Expression Software Tool was employed for statistical analysis of gene expression<sup>[17,18]</sup>.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Pathological scoring of pancreatic tissues

The pathological score of pancreatic tissue in the AP group was the highest ( $9.2 \pm 2.7$ ) and followed by the CQCQD group ( $5.7 \pm 1.9$ ) and the C group ( $0.8 \pm 1.0$ ) ( $P < 0.05$ ), (Figure 1).

### Intracellular $[Ca^{2+}]_i$ of pancreatic acinar cells

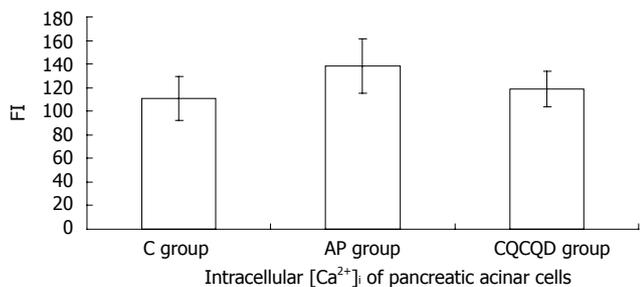

The FI of  $[Ca^{2+}]_i$  pancreatic acinar cells in the AP group was higher than that in the C group ( $138.2 \pm 23.1$  vs  $111.0 \pm 18.4$ ) or CQCQD group ( $138.2 \pm 23.1$  vs  $118.7 \pm 15.2$ ), ( $P < 0.05$ ), but there was no statistical difference between the C group and CQCQD group in  $[Ca^{2+}]_i$  ( $P > 0.05$ ), (Figure 2).

### *SERCA1* mRNA expression

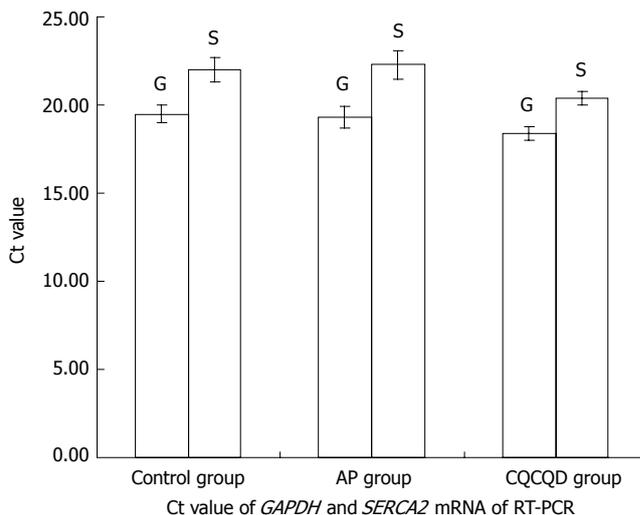

Neither the pancreatic tissues of normal rats nor that of AP rats expressed *SERCA1* mRNA. Skeletal muscle, however, expressed *SERCA1* mRNA as the positive control, shown by the electrophoresis of PCR products in Figure 3.

### *SERCA2* mRNA expression

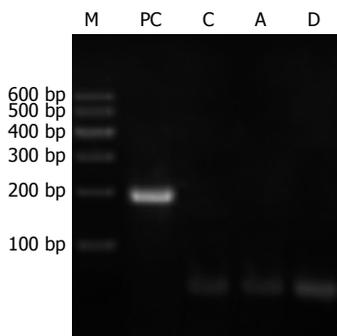

Cycle threshold (Ct) value of *GAPDH* and *SERCA2*

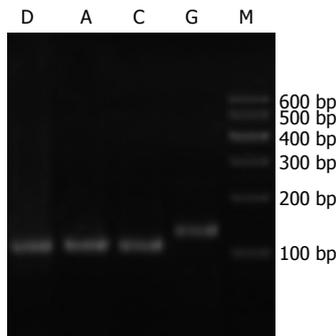

**Figure 2** Intracellular [Ca<sup>2+</sup>] of pancreatic acini (n = 10, mean ± SD). The fluorescence intensity (FI) of intracellular [Ca<sup>2+</sup>] of pancreatic acinar in AP group (138.2 ± 23.1) was higher than C group (111.0 ± 18.4) and CQCQD group (118.7 ± 15.2, P < 0.05), but there was no statistical difference between the C group and the CQCQD group (P > 0.05).

**Figure 4** Ct value of GAPDH and SERCA2 mRNA of RT-PCR. Ct: Cycle threshold; G: Glyceraldehyde-3-phosphate dehydrogenase (GAPDH), the internal housekeeping; S: Sarco/endoplasmic reticulum Ca<sup>2+</sup>-ATPase 2 (SERCA2).

**Figure 3** Agar gel electrophoresis photograph of PCR products of SERCA1 mRNA. The PCR products of sarcoplasmic reticulum Ca<sup>2+</sup>-ATPase (SERCA1) mRNA was 199 bp. M: Marker; PC: Positive control with skeletal muscle; C: Control group; A: Acute pancreatitis group; D: Acute pancreatitis group treated with Chaiqinchengqi decoction.

**Figure 5** Agar gel electrophoresis photograph of PCR products of SERCA2 mRNA. D: Acute pancreatitis group treated with Chaiqinchengqi decoction; A: Acute pancreatitis group; C: Control group; G: Internal housekeeping gene (GAPDH gene); M: Marker.

mRNA in the three groups is shown in Figure 4 and the agar gel electrophoresis photograph of PCR products of SERCA2 mRNA is shown in Figure 5. The expression of SERCA2 mRNA was highest in the C group, and lowest in the AP group, and moderate in the CQCQD group. Compared with the C group, the expression of SERCA2 mRNA in the AP group was decreased with an expression ratio of 0.536 (P = 0.001). Compared with the AP group, the expression of SERCA2 mRNA in the CQCQD group was increased with an expression ratio of 2.000 (P = 0.012).

**DISCUSSION**

Intracellular calcium overload of pancreatic acinar cells has been confirmed in experimental acute pancreatitis<sup>[19-23]</sup> and extensively accepted to be an important triggering and exacerbating mechanism of AP<sup>[6,7,24,25]</sup>. Ca<sup>2+</sup>-ATPase plays a key role in the mechanism of intracellular calcium overload of pancreatic acinar cells. Qiu Y *et al*<sup>[9]</sup> found that the activity of intracellular Ca<sup>2+</sup>-Mg<sup>2+</sup>-ATPase was decreased in AP rats.

As it is known, Ca<sup>2+</sup> in cytoplasm of pancreatic acinar cells during calcium overload mainly originates from the release of intracellular calcium stores<sup>[26,27]</sup>. In pancreatic acinar cells, Ca<sup>2+</sup> released from the store is mainly resealed into the stores by SERCA and only partly expelled into the extracellular space by PMCA<sup>[28]</sup>. There are three isoforms of SERCA, including SERCA1, SERCA2 and SERCA3 in rats, in which the expressions of SERCA1 and SERCA2 mRNA were found in pancreatic tissues. Therefore, intracellular Ca<sup>2+</sup>-ATPase activity was also affected by the change of mRNA expression of the isoforms.

With the consideration that SERCA is the major contributor to maintenance of Ca<sup>2+</sup> homeostasis and it may be affected by the isoforms of SERCA, a decreased quantity or activity of SERCA isoform would be expected to induce intracellular calcium overload and subsequently cause AP<sup>[29-31]</sup> and the rising [Ca<sup>2+</sup>] of pancreatic acinar cells positively correlated to the severity of pancreatic pathology<sup>[32,33]</sup>. To explore the mechanism of intracellular calcium overload in AP rats, we studied the change of SERCA1 and SERCA2 mRNA expressions by real-time RT-PCR. We found that the SERCA1 mRNA did not express in pancreatic tissues of normal rats as well as AP rats with the positive control of rat skeletal muscle; the SERCA2 mRNA expression of pancreatic tissues was down-regulated with remarkable elevation of intracellular [Ca<sup>2+</sup>] and pathological score of pancreatic tissues in AP rats. The results suggested that down-regulated SERCA2 mRNA expression might take part in the pathogenesis of AP by decreasing the activity of SERCA and increasing [Ca<sup>2+</sup>] of pancreatic acinar cells in AP rats.

Chinese medicine CQCQD, modified from Dachengqi decoction, is an effective compound for the treatment of AP<sup>[10]</sup>. It has been proved to improve systemic inflammatory response syndrome in acute necrotizing pancreatitis through the cholinergic anti-inflammatory pathway<sup>[34]</sup>. We have also found that the protective effect

of CQCQD on pancreatic acinar cells was related to the inhibited exocrine of digestive enzymes and reduced elevation of  $[Ca^{2+}]_i^{[11]}$ . Chinese herbs in CQCQD including Herba *Artemisiae Scopariae*, Gardenia and rhubarb may have the activity of calcium channel blockers. Gardenia was found to inhibit the decline of activity of  $Na^+-K^+-ATPase$  and PCMA in AP<sup>[9]</sup>. Our study showed that in AP rats after treatment with CQCQD, *SERCA2* mRNA expression in pancreatic tissues was up-regulated, and intracellular  $[Ca^{2+}]_i$  of pancreatic acinar cells and pathological score of the pancreatic tissues were decreased. The result indicates that CQCQD might protect pancreatic tissues from injuries by increasing *SERCA* activity, reducing calcium overload in pancreatic acinar cells and relieving the pathological severity.

In conclusion, the down-regulated expression of pancreatic *SERCA2* mRNA may be involved in the pathogenesis of intracellular calcium overload in AP. CQCQD has a protective effect on pancreatic tissues by increasing the expression of *SERCA2* mRNA and relieving intracellular calcium overload.

## COMMENTS

### Background

The pathogenesis of acute pancreatitis (AP) has not been fully elucidated up to date, whereas intracellular calcium overload of pancreatic acinar cells has been accepted as the pivot in triggering and deterioration of AP. The increased intracellular free calcium ion concentration ( $[Ca^{2+}]_i$ ) is believed to originate from the influx of extracellular  $Ca^{2+}$  and the release of  $Ca^{2+}$  of intracellular  $Ca^{2+}$  stores. Despite of those theories proposed, the exact mechanism of intracellular calcium overload still remains obscure.

### Research frontiers

This pilot animal experiment has found Chaiqinchengqi decoction (CQCQD), which is an effective herbal prescription in the treatment of AP, has a protective effect on pancreatic acinar cells in AP rats by inhibiting the elevation of  $[Ca^{2+}]_i$ . Advanced researches are needed to explore its mechanism.

### Innovations and breakthroughs

Sarco/endoplasmic reticulum  $Ca^{2+}$ -ATPase (*SERCA*) has been proved to play a key role in the mechanism of intracellular calcium overload of pancreatic acinar cells, but the effect of CQCQD is not available in published studies. The authors innovatively studied the effect of CQCQD on *SERCA* mRNA expression of pancreatic tissue in AP rats. The result reveals for the first time that CQCQD up-regulated *SERCA* mRNA expression and relieved intracellular calcium overload to protect pancreatic tissues. Thus, this study elucidated the mechanism of CQCQD in the treatment of AP from genetic point of view.

### Applications

As the efficacy of CQCQD has been proved in clinical trails, the present study intensively ratified the protective effect on pancreatic tissues in animal experiment. Moreover, the study in genetic mechanism of CQCQD in inhibiting intracellular calcium overload may light up advanced studies on calcium overload in the treatment of AP.

### Terminology

Acute pancreatitis (AP) is a common acute abdominal disorder, caused by the unregulated activation of enzyme within pancreatic acinar cells and the autodigestion of the gland leading to inflammation of pancreas. Calcium overload is intracellular  $[Ca^{2+}]_i$  abnormally increases which may subsequently lead to cell and tissue damages. Chaiqinchengqi decoction (CQCQD) is a herbal prescription comprising 8 Chinese herbals of Chaihu, Huangqin, Houpo, Zhishi, Zhizi and Mangxiao with the main therapeutic effect of clearing heat to detoxification and purging the bowel to restore the motility, which is a basic compound formula commonly used in the treatment of AP. Sarco/endoplasmic reticulum  $Ca^{2+}$ -ATPase

(*SERCA*) is an enzyme in arco/endoplasmic reticulum which in physiological conditions utilizes ATP as the energy to pump  $Ca^{2+}$  back to intracellular calcium stores to maintain intracellular calcium concentration in a normal range.

### Peer review

This is a pilot research that focuses on the value of herbal medicine in reducing the severity of AP and exploring the mechanism on relieving intracellular calcium overload. The results of the study extend our understanding in the treatment mechanism of Chinese herbal prescription for AP and have an edifying value to the studies in this field. Further researches such as protein expression are needed to explain its mechanism.

### Abstract

**AIM:** To investigate the effect of vascular endothelial growth factor (VEGF) transfection on hepatic sinusoidal capillarization.

**METHODS:** Enhanced green fluorescent protein (EGFP)/VEGF transfection was confirmed by immunofluorescence microscopy and immunohistochemistry both in primary hepatocytes and in normal liver. Cirrhotic rats were generated by thioacetamide (TAA) administration and then divided into a treatment group, which received injections of 400  $\mu$ g of plasmid DNA encoding an EGFP-VEGF fusion protein, and a blank group, which received an equal amount of normal saline through the portal vein. The portal vein pressure was measured in the normal and cirrhotic state, in treated and blank groups. The average number of fenestrae per hepatic sinusoid was determined using transmission electron microscopy (TEM), while the relative abundance of VEGF transcripts was examined by Gene array.

**RESULTS:** Green fluorescent protein was observed in the cytoplasm of liver cells under immunofluorescence microscopy 24 h after transfection with EGFP/VEGF plasmid *in vitro*. Staining with polyclonal antibodies against VEGF illustrated that hepatocytes expressed

immunodetectable VEGF both *in vitro* and *in vivo*. There were significant differences in the number of fenestrae and portal vein pressures between normal and cirrhotic rats ( $7.40 \pm 1.71$  vs  $2.30 \pm 1.16$  and  $9.32 \pm 0.85$  cmH<sub>2</sub>O vs  $17.92 \pm 0.90$  cmH<sub>2</sub>O,  $P < 0.01$ ), between cirrhotic and treated rats ( $2.30 \pm 1.16$  cmH<sub>2</sub>O vs  $4.60 \pm 1.65$  and  $17.92 \pm 0.90$  cmH<sub>2</sub>O vs  $15.52 \pm 0.93$  cmH<sub>2</sub>O,  $P < 0.05$ ) and between the treatment group and the blank group ( $4.60 \pm 1.65$  cmH<sub>2</sub>O vs  $2.10 \pm 1.10$  cmH<sub>2</sub>O and  $15.52 \pm 0.93$  cmH<sub>2</sub>O vs  $17.26 \pm 1.80$  cmH<sub>2</sub>O,  $P < 0.05$ ). Gene-array analysis revealed that the relative abundance of transcripts of VEGF family members decreased in the cirrhotic state and increased after transfection.

**CONCLUSION:** Injection of a plasmid encoding VEGF through the portal vein is an effective method to induce the formation of fenestrae and decrease portal vein pressure in cirrhotic rats. Therefore, it may be a good choice for treating hepatic cirrhosis and portal hypertension.

### INTRODUCTION

Fenestrae are described as membrane-bound cytoplasmic holes with an average diameter of about 110 nm in transmission electrical microscopy (TEM) by Wisse in 1970<sup>[1,2]</sup>. Liver sinusoidal endothelial cells (LSECs) possess open fenestrae that perforate the hepatic endothelial lining, but lack a basal lamina. Fenestrae, vesicles and channels together control the bulk of trans-endothelial transport between blood and tissues<sup>[3]</sup>. Structural integrity of the

fenestrated sinusoidal liver endothelium is believed to be essential for the maintenance of the normal exchange of fluids, solutes, particles and metabolites between the sinusoidal blood and hepatocytes<sup>[4,5]</sup>. Although there are various causes and morphologies of hepatic cirrhosis, all forms of cirrhosis are characterized by a defenestrated sinusoidal endothelium and the presence of a subendothelial basement membrane<sup>[6-9]</sup>. It has been demonstrated that the disappearance of the normal filtration barrier in cirrhotic livers results in an impaired bidirectional exchange between the sinusoidal blood and parenchymal cells<sup>[10]</sup>. As a result, capillarization of the sinusoidal endothelium may be a major contributor to hepatic failure in patients with cirrhosis.

Vascular endothelial growth factor (VEGF), which plays a role in regulating vasculogenesis, induces angiogenesis and endothelial cell proliferation. In recent years, it has been proven that VEGF is relevant to the increased number of fenestrae and endothelial permeability in endothelial cells<sup>[10-13]</sup> and renal glomerulus<sup>[14]</sup>. Injection of VEGF-D plasmid into both normal and ischemic rat liver resulted in an increased number of new capillaries around hepatic sinuses<sup>[15]</sup>. Many studies have shown that, in the state of hepatic fibrosis and cirrhosis, both in patients and experimental models, VEGF is increased with harmful effects<sup>[16,17]</sup>. By contrast, other studies have shown decreased expression of VEGF in cirrhotic patients, and suggested that VEGF makes a helpful contribution<sup>[18,19]</sup>. After hepatectomy in cirrhotic rats, VEGF was found to effectively promote liver regeneration<sup>[20,21]</sup>. Moreover, human urokinase-type plasminogen activator gene administration via an adenoviral (Ad)-vector induced cirrhosis regression and ameliorated hepatic dysfunction with up-regulation of VEGF in a model of experimental liver cirrhosis<sup>[22,23]</sup>.

Because defenestration and basement membrane formation result in a disordered exchange between the sinusoidal blood and hepatocytes, it is necessary to restore the function of liver sinusoidal endothelial cells in order to reverse cirrhosis. VEGF provides the perfect means to achieve this, because of it promotes fenestration and permeability. On account of these ideas, we studied the effects of VEGF transfection in cirrhotic rat livers.

## MATERIALS AND METHODS

### *EGFP/VEGF transfection of hepatocytes*

EGFP/VEGF was obtained from the Medical School of Shandong University (Jinan, China). Human VEGF-D cDNA was inserted into pEGFP-N1 plasmid between the constitutive cytomegalovirus promoter (pCMV) and enhanced green fluorescent protein (EGFP) to produce a plasmid encoding an EGFP-VEGF fusion protein (EGFP/VEGF plasmid), which was used as a tool to express VEGF consistently. EGFP was used to detect expression of the plasmid, and the expression of VEGF was detected by immunohistochemistry.

Primary hepatocytes were isolated from the livers of male Wistar rats (150-200 g) by collagenase perfusion as previously described<sup>[24]</sup>. Cells were plated on collagen-

coated 6-well plates at a density of  $3 \times 10^5$  cells/well in Williams' medium E supplemented with 10% fetal bovine serum, 2 mmol/L L-glutamine, 1% penicillin/streptomycin, and 100 nmol/L dexamethasone. The cells were incubated in 5% CO<sub>2</sub> at 37°C to facilitate attachment, and the medium was exchanged after 4 h with serum-free Williams' medium E supplemented with 2 mmol/L L-glutamine, 1% penicillin/streptomycin, and 100 nmol/L dexamethasone. After overnight incubation in 5% CO<sub>2</sub> at 37°C, the medium was exchanged with serum-free Williams' medium E supplemented with 2 mmol/L L-glutamine and 1% penicillin/streptomycin. The EGFP/VEGF plasmid (50 µg) was added to the culture medium and the cells were incubated for 24 h. We investigated 5 dishes for each treatment in the present study.

### *Immunofluorescence microscopy and immunohistochemistry*

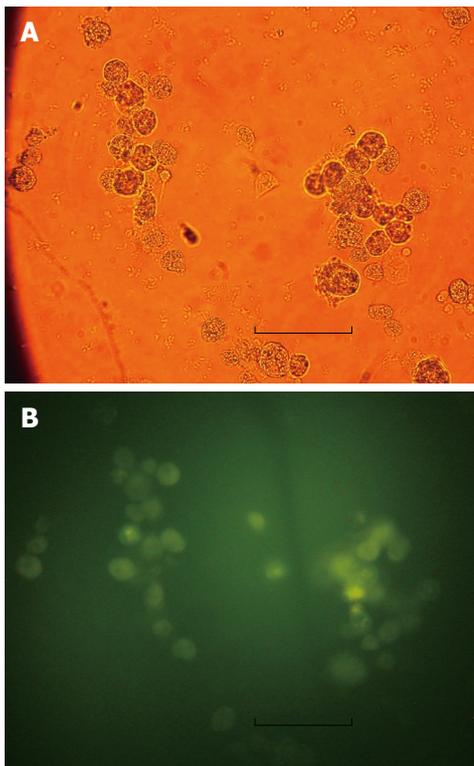

Immunofluorescence microscopy was used to visualize the distribution of EGFP in hepatocytes. At the same time, immunocytochemical staining of VEGF was performed. Cultured hepatocytes were washed with phosphate buffered saline (PBS) 3 times, and fixed with acetone at room temperature for 10 min. Then, they were blocked with goat serum and permeabilized for 30 min with 0.1% Triton X-100 in PBS containing 1% bovine serum albumin (BSA). The cells were incubated overnight with rabbit anti-human VEGF polyclonal antibody (Santa Cruz) at a 1:50 dilution at 4°C. Subsequently, they were incubated with tetramethylrhodamine isomer R1-conjugated swine anti-rabbit IgG (Santa Cruz) at room temperature for 1 h. The distribution of VEGF was visualized by light microscopy.

### *Transfection of normal liver*

Twenty healthy male Wistar rats, weighing 200-220 g, bought from the experimental animal center of Shandong Agricultural Research Center (Jinan, China) were divided equally into two groups. In the study group, each rat received an injection of 400 µg of the EGFP/VEGF plasmid through the portal vein. In the control group, each rat received an equal amount of normal saline in the same manner. All rats were sacrificed eight days after the operation. Liver samples were collected and fixed in 10% neutral-buffered formalin, embedded in paraffin and cut into 4-6 µm sections.

### *Immunohistochemistry*

Immunohistochemistry was performed according to Hong-Lei Weng<sup>[25]</sup>. The integral score method was used to evaluate the positive cell distribution and intensity<sup>[26]</sup>. First, a proportion score was assigned, which represented the estimated proportion of positive-staining cells (0, none; 1, 0 to 1/100; 2, 1/100 to 1/10; 3, 1/10 to 1/3; 4, 1/3 to 2/3; and 5, 2/3). Next, an intensity score was assigned, which represented the average intensity of positive cells (0, none; 1, weak, 2, intermediate; and 3, strong). The proportion and intensity scores were then added to obtain a total score, which ranged from 0 to 8. Then the score was compared between the study and control groups.

**Figure 1** Hepatocytes incubated with EGFP/VEGF plasmid for 24 h. **A:** Light microscopy: no green fluorescent protein was found. Bar denotes 30  $\mu\text{m}$ ; **B:** Immunofluorescence microscopy: green fluorescent protein expression. Bar denotes 30  $\mu\text{m}$ .

### Transfection of cirrhotic liver

The portal vein pressures of 40 normal Wistar rats were measured and hepatic specimens were taken. Then, the rats received an oral administration of 0.03% thioacetamide (TAA) solution instead of feed water. After 5 wk, the concentration of TAA was increased to 0.04%. Ten wk later, 26 cirrhotic rats were identified and randomly divided into a treatment group and a blank group. The portal vein pressures of these rats were measured and cirrhotic liver specimens were obtained. Then, 400  $\mu\text{g}$  of the VEGF/EGFP plasmid was infused through the portal veins of rats in the treatment group, while an equal amount of normal saline was given through the portal vein to rats in the blank group. After 2 wk, portal vein pressures were measured again; then, all rats were sacrificed and liver samples were collected. Comparisons of portal vein pressure were made between the normal and cirrhotic, treated and untreated rats. A randomized controlled trial was carried out to compare the treatment group and the blank group.

### Transmission electron microscopy

Fresh specimens were first fixed in 3% glutaral, and then fixed in 1% glutaral after being washed with PBS 3 times for 60 min in total. The samples were dehydrated with an alcohol gradient, embedded in EPON812 epoxy resin, and then cut into 50-nm sections with an Ultrathin microtome. After being dyed with uranyl acetate and lead citrate for 30 min, the sections were observed under transmission electronic microscope (JEM-1200EX, Japan). Ten hepatic sinusoids with a diameter of 2–3  $\mu\text{m}$  were randomly

selected, and the average number of fenestrae per hepatic sinusoid in each state and group was determined. Valid fenestrae ran through LSECs.

### Gene array

Angiogenesis microarrays were obtained from SuperArray Bio.Co. (Catalog No. ORN-024). Fresh specimens were put into 4°C of RNA later and incubated for one night. The experiment was performed according to the Oligo GEArray assay protocol. Briefly, total RNA was extracted from tissue using TRIzol reagent (Invitrogen Life Technologies, USA). The quantity and purity of RNA were estimated by measuring  $A_{260}$  and  $A_{280}$ . A total of 3  $\mu\text{g}$  of RNA was used to synthesize cDNA. The cRNA was then labeled by Biotin-16-dUTP (Roche Cat. No. 1-093-070) and amplified using a TrueLabeling-AMPTM linear RNA amplification kit. The membranes were hybridized with denatured cDNA probe and processed for chemiluminescent detection on X-ray film, and images were acquired using a flatbed desktop scanner. Subsequently, images of spots were converted into numerical data using the free ScanAlyze software and the raw data was saved as a Microsoft Excel file. All raw signal intensities were corrected for background signal by subtracting the minimum value to avoid the appearance of negative numbers, and were also normalized to the level of a housekeeping gene. These corrected, normalized signals were used to estimate the relative abundance of particular transcripts.

### Statistical analysis

Results are expressed as mean  $\pm$  SD, and statistical analysis was carried out using the Student's *t*-test and Spearman's rank correlation coefficient for paired data. A *P* value of less than 0.05 was considered to be significant.

## RESULTS

### VEGF expression *in vitro* and *in vivo*

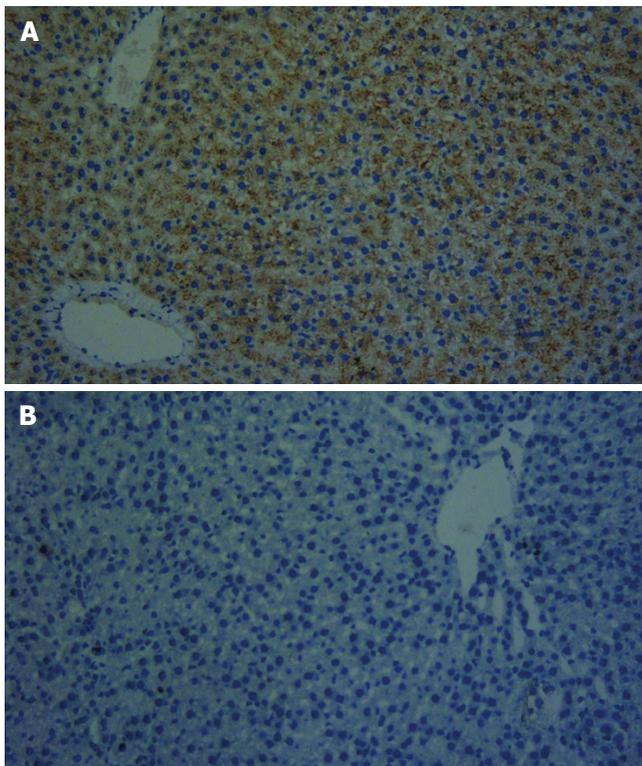

Twenty-four hours after transfection of cultured hepatocytes with the EGFP/VEGF plasmid, green fluorescent protein was observed in the cytoplasm of liver cells under immunofluorescence microscopy, revealing expression of the plasmid (Figure 1). At the same time, staining of hepatocytes with polyclonal antibodies against VEGF illustrated that these cells expressed immunodetectable VEGF (Figure 2). Moreover, the transfection of liver cells following injection of the EGFP/VEGF plasmid into the portal veins of normal rats *in vivo* was also successful, because a considerable amount of VEGF was identified in the study group, but little was seen in the control group (Figure 3). VEGF was mainly observed in the cytoplasm of hepatocytes and some endothelial cells. The stain integral scores of the study group and control group were  $6.0 \pm 1.63$  and  $3.7 \pm 2.31$  respectively, allowing these groups to be differentiated from each other distinctively (Student's *t* test,  $t = 2.74 > 2.62$ ,  $P < 0.05$ ) (Figure 3).

### Fenestrae and portal vein pressures

A comparison was carried out between normal, cirrhotic

**Figure 2** Immunohistochemistry: Positively stained hepatocytes for EGFP/VEGF. Bar denotes 30  $\mu$ m.

**Figure 3** Immunohistochemistry  $\times 200$ . **A:** Study group injected with EGFP/VEGF plasmid, VEGF-positive hepatocytes  $\times 200$ ; **B:** Control group injected with NS, VEGF-negative hepatocytes.

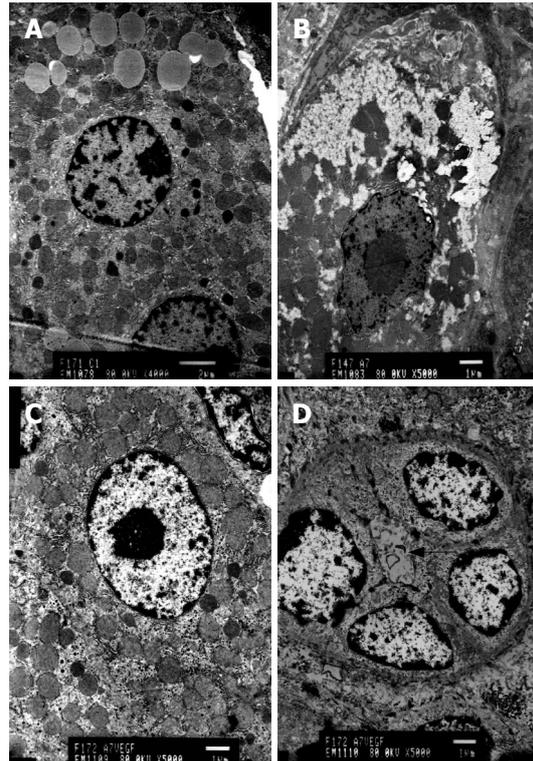

and treated rats. The number of fenestrae per LSEC in cirrhotic and normal rats was  $2.30 \pm 1.16$  and  $7.40 \pm 1.71$ , respectively (Table 1). The decrease in cirrhotic rats was significant (Student's *t*-test,  $t = -7.965 < -6.548$ ,  $P < 0.01$ ). The portal vein pressures were  $17.92 \pm 0.90$  in cirrhotic rats and  $9.32 \pm 0.85$  in normal rats (Table 1), revealing an obvious difference (Student's *t*-test,  $t = 27.32 > 9.30$ ,  $P < 0.01$ ).

After transfection with the EGFP/VEGF plasmid, the number of fenestrae in the treated group was  $4.60 \pm 1.65$  (Table 1), representing a significant increase compared with cirrhotic rats (Student's *t*-test,  $t = -4.14 < -3.56$ ,  $P < 0.05$ ). The portal vein pressure in the treated group was  $15.52 \pm 0.93$  (Table 1), representing a significant

**Table 1** The number of fenestrae and portal vein pressures in different groups ( $n = 11$ )

Group	The number of fenestrae	Portal vein pressures (mean $\pm$ SD) (cmH <sub>2</sub> O)
Normal state	$7.40 \pm 1.71^d$	$9.32 \pm 0.85^d$
Cirrhotic state	$2.30 \pm 1.16$	$17.92 \pm 0.90$
Treated group	$4.60 \pm 1.65^a$	$15.52 \pm 0.93^a$
Blank group	$2.10 \pm 1.10$	$17.26 \pm 1.80$

Paired samples *t* test. Significant differences are shown both in fenestrae and pressure. <sup>a</sup> $P < 0.05$  vs Cirrhotic state; <sup>d</sup> $P < 0.01$  vs Blank group.

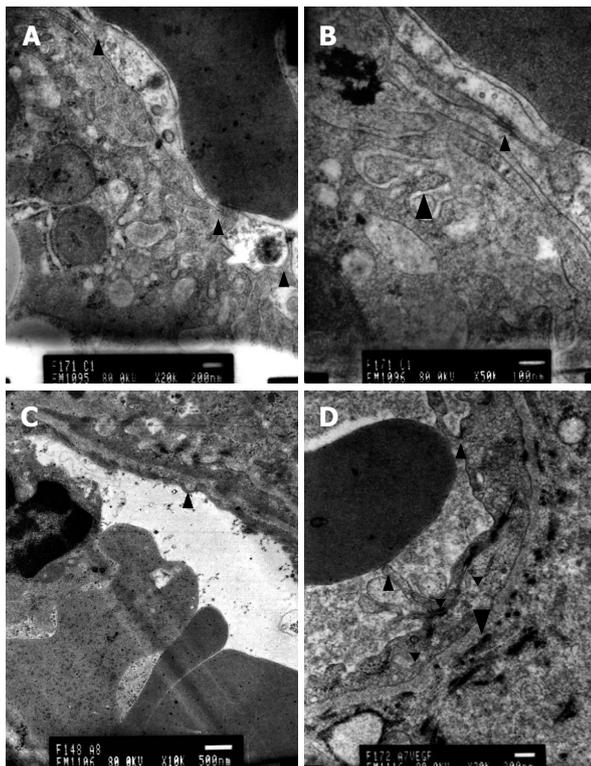

**Figure 4** TEM. **A:** Normal hepatocytes, Bar denotes 2  $\mu$ m; **B:** Cirrhotic state, hepatocyte apoptosis, Bar denotes 1  $\mu$ m; **C:** Cirrhotic rats injected with the EGFP/VEGF plasmid, hepatocyte apoptosis decreased, Bar denotes 1  $\mu$ m; **D:** Cirrhotic rats injected with EGFP/VEGF plasmid, Regenerated hepatocytes and cholangioliol arrowhead, Bar denotes 1  $\mu$ m.

decrease compared with cirrhotic rats (Student's *t*-test,  $t = 6.04 > 3.29$ ,  $P < 0.05$ ).

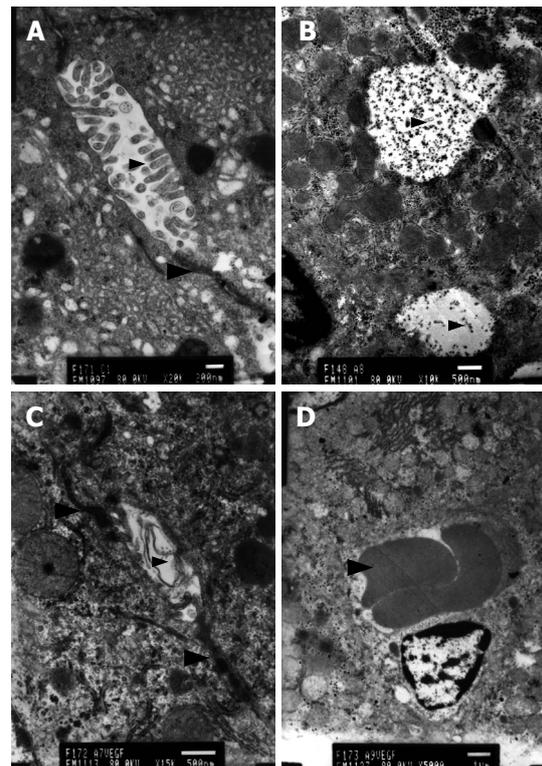

A randomized controlled trial was performed to compare the treated group and the blank group. There was an obvious difference in the number of fenestrae ( $4.60 \pm 1.65$  vs  $2.10 \pm 1.10$ , Student's *t*-test,  $t = 4.04 > 3.90$ ,  $P < 0.05$ ) and in portal vein pressure ( $15.52 \pm 0.93$  vs  $17.26 \pm 1.80$ , Student's *t*-test,  $t = -3.97 < -3.46$ ,  $P < 0.05$ ), but there was no significant difference between the cirrhotic group and the blank group in these measures.

**Ultrastructural changes in cirrhotic rats after EGFP/VEGF plasmid transfection**

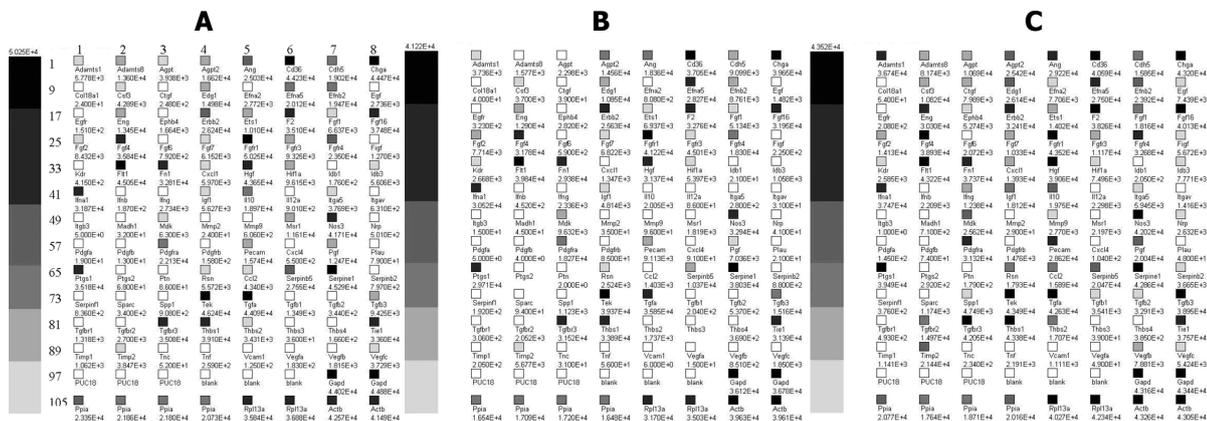

Transmission electron microscopy revealed hepatocellular apoptosis in rats with TAA-induced cirrhosis (Figure 4B); moreover, the fenestrae of endothelial cells disappeared

**Figure 5** TEM. **A:** Normal state, LSECs and fenestrae (arrowhead). Bar denotes 200 nm; **B:** Normal state. **Figure 7** Representative expression profile of angiogenesis-related genes in the liver. The gene microarray included angiogenesis-related genes (1-96), negative control genes (97-99), blank controls (100-102), positive control genes (glyceraldehyde-3-phosphate dehydrogenase (103, 104), cyclophilin A (105-108), ribosomal protein L13a (109, 110) and b-actin (111,112). **A:** Normal state; **B:** Cirrhotic state; **C:** VEGF treated group.

and a basement membrane appeared (Figure 5C). Cell conjunction between hepatocytes was destroyed and particles of bilirubin overflowed into the cytoplasm of hepatocytes and LECs, even into the hepatic sinusoid (Figure 6B). The microvilli of hepatocytes in the space of Disse and the cholangiole were ablated in cirrhotic rats (Figure 5C and Figure 6B). However, this morphology changed after transfection with the EGFP/VEGF plasmid. The fenestrae, cell conjunctions, and microvilli

of hepatocytes were restored, the basement membrane disappeared and cell apoptosis decreased. Newborn capillaries formed by a single liver endothelial cell emerged (Figure 6D).

**Gene array**

A total of 96 genes involved in angiogenesis were identified on the microarray (Figure 7 and Table 2). The levels of 32 genes were decreased by more than 50% in

Table 2 Angiogenesis-related genes on the angiogenesis microarray

Position	Description	Gene Name
1	A disintegrin-like and metalloprotease (reprolysin type) with thrombospondin type 1 motif, 1	Adamts1
2	Mus musculus a disintegrin-like and metalloprotease (reprolysin type) with thrombospondin type 1 motif	Adamts8

cirrhotic rats, and only 8 genes were enhanced by two-fold or greater compared with normal rats. After EGFP/VEGF transfection, 56 genes were increased by two-fold or greater in treated rats; and only one gene was decreased by more than 50% in comparison with cirrhotic rats. In cirrhotic rats, the expression levels of members of the VEGF family were decreased, and the expression levels of members of the VEGF receptor family were increased compared with the levels in normal liver. However, after administration of VEGF, expression of VEGF family members increased and that of receptor family members decreased. Furthermore, the level of VEGF-D was increased by 22-fold, while levels of VEGF, VEGF-B and VEGF-C were increased by more than 2-fold after EGFP/VEGF transfection (Table 3).

## DISCUSSION

VEGF-D was first cloned by Yamada in 1997 from a human lung cDNA library<sup>[27]</sup>. VEGF-D binds VEGF receptor 2 (VEGF R2/Flk-1/KDR) and VEGF R3 (Flt-4)<sup>[28]</sup>. VEGF R2 and VEGF R3 are localized to

vascular and lymphatic endothelial cells and are involved in signaling mediating angiogenesis and lymphangiogenesis<sup>[29]</sup>. There are numerous techniques and approaches that have been investigated for gene transfer to the liver. For gene therapy of hepatic diseases in animal experiments, exogenous genes were usually delivered to the liver through the portal vein and bile duct<sup>[30-33]</sup>. In our studies, EGFP/VEGF plasmid injection through portal vein was found to be an effective method.

The EGFP/VEGF plasmid was specifically designed for mammalian expression, and was constructed using a human VEGF-D cDNA and pEGFP-N1 plasmid. In the first stage of our studies, we tried to ascertain its expression efficiency, both *in vitro* and *in vivo*. *In vitro*, enhanced green fluorescent protein was observed in the cytoplasm of liver cells under immunofluorescence microscopy. At the same time the staining of hepatocytes with polyclonal antibodies against VEGF illustrated that the cells expressed immunodetectable VEGF. *In vivo*, transfection resulted in a comparatively high expression of VEGF protein. These findings demonstrate the efficient transfection of liver cells with the EGFP/VEGF plasmid *in vitro* and *in vivo*.

VEGF is an important regulator of angiogenesis and vascular permeability, whose expression in the adult is correlated with low permeability of the blood-brain barrier endothelium and high permeability of the fenestrated glomerular endothelium<sup>[14,34]</sup>. Fenestrae are critical for the maintenance of the high hydraulic conductivity of the glomerular capillary wall, and their loss results in a reduction in the glomerular filtration rate<sup>[35]</sup>. Defenestration is an early event in the pathogenesis of cirrhosis, and precedes the initiation of fibrosis. Sinusoidal capillarization is believed to be important in the initiation of perisinusoidal fibrosis by altering retinol metabolism<sup>[7]</sup>. In rats with TAA-induced cirrhosis, the fenestrae of endothelial cell disappeared and a basement membrane appeared. As a result, the microvilli of hepatocytes in the space of Disse were ablated, indicating that material exchange between hepatocytes and hepatic sinusoidal blood failed. Hepatocytes could not obtain the necessary nutrition and eliminate metabolites, which resulted in cell apoptosis. Cell conjunction between hepatocytes was damaged and particles of bilirubin overflowed into the cytoplasm of hepatocytes and endothelial cells, and even into the hepatic sinusoid, resulting in jaundice.

VEGF can promote fenestration and permeability of liver sinusoidal endothelial cells; therefore, it can improve the exchange between hepatic sinusoidal blood and hepatocytes, which argues for the development of VEGF gene therapy for cirrhosis. Roberts and Palade<sup>[36,37]</sup> showed that topical administration of VEGF-165 induced fenestrations in continuous microvascular endothelia of muscle and skin, and that tumor neovasculature induced by VEGF is fenestrated. Epithelial cells stably transfected with VEGF cDNA secreted a high level of VEGF and induced a seven- or eight-fold increase in the number of fenestrae and fused clustered vesicles in co-cultured endothelial cells, thus providing direct evidence of a role for VEGF in fenestrae induction. Endothelial cells pretreated with VEGF developed fenestrae and showed increased endothelial permeability<sup>[10]</sup>. However, to date, there have been few reports on using VEGF to heal cirrhosis *in vivo*. In our study, after injection of EGFP/VEGF plasmid into cirrhotic rats through the portal vein, the number of fenestrae increased obviously, accompanied with a decrease in portal vein pressure. Hepatocytes and microvillus regeneration demonstrated that the material exchange between hepatocytes and hepatic sinusoidal blood recovered. Furthermore, cell conjunction of hepatocytes was restored and overflow of particles of bilirubin lessened. Meanwhile, the basement membrane disappeared and cell apoptosis decreased. We suspect that the fenestrae and proliferation of LECs played important roles in this change.

At present, there are three points of view on the use of VEGF in cirrhotic disease. The first is that there is decreased VEGF in cirrhosis, and that administration of exogenous VEGF would have a helpful effect<sup>[18,19]</sup>. The second is that there is increased VEGF in cirrhosis, and that this VEGF has a harmful effect<sup>[16,17]</sup>. The last point of view is that the increased VEGF in cirrhosis is compensative, having a helpful effect<sup>[38]</sup>. Our angiogenic

gene array supports the first point of view. We can see clearly that in rats with TAA-induced cirrhosis, the levels of VEGF family members decreased and the levels of VEGF receptors increased, as a reflective compensation. After VEGF/EGFP transfection, the abundance of VEGF family members increased, and that of VEGF receptors decreased, explaining the newborn capillaries we observed by transmission electron microscopy. In our previous study, the density of capillaries was also increased after VEGF-D plasmid hepatic situ injection<sup>[15]</sup>.

Thus, the levels of transcripts of VEGF family members decreased in TAA-induced cirrhotic livers. Administration of a plasmid encoding an EGFP-VEGF fusion protein attenuated sinusoidal capillarization through increasing the number of fenestrae and the permeability of LECs, which improved the exchange between hepatocytes and sinusoidal blood. Consequently, hepatocytes had more nutrition and oxygen and thus preserved liver function to some extent. Therefore, VEGF gene transfer by injection through the portal vein might be an ideal method for the treatment of cirrhosis.

## COMMENTS

### Background

Hepatic sinusoidal capillarization has been thought to be a major contributor to hepatic failure in cirrhosis. It includes a defenestrated sinusoidal endothelium and the presence of a subendothelial basement membrane. However vascular endothelial growth factor (VEGF) has been proven to increase the number of fenestrae and permeability of liver sinusoidal endothelial cells (LECs).

### Research frontiers

This study was designed to investigate the effect of VEGF transfection on hepatic sinusoidal capillarization by observing the ultrastructural change of cirrhotic endothelium as well as the relationship between the number of fenestrae and portal vein pressure.

### Innovations and breakthroughs

Our study shows effective endothelial growth factor (EGFP)/VEGF transfection *via* injection of plasmid DNA into the portal vein decreases portal pressure in experimental cirrhosis induced by thioacetamide. This effect is mediated by an increase in the formation of fenestrae of liver sinusoids. Previous studies on the role of VEGF in portal hypertension were performed in models of non-cirrhotic pre-hepatic portal hypertension obtained through part portal vein ligation, and showed remarkable angiogenesis effect. The ultra-microstructure in the liver of those rats has not been specifically investigated. This study is more related to what happens in cirrhotic patients.

### Applications

Portal hypertension is an almost unavoidable complication of cirrhosis, and it is responsible for the more lethal complications of this syndrome. Previous research has shown the role of hepatic sinusoidal capillarization in cirrhosis. To understand the mechanisms underlying hepatic sinusoidal capillarization and reverse them will be of benefit to developing a new therapeutic method.

### Peer review

This paper describes the effect of VEGF transfection on hepatic sinusoidal capillarization in cirrhotic animals as compared to normal rats. The authors have shown histological evidence of partial reversal of cirrhosis.

### Abstract

**AIM:** To discuss the expression of  $\alpha$ -adrenoreceptors in pancreatic cancer cell lines PC-2 and PC-3 and the effects of  $\alpha_1$ - and  $\alpha_2$ -adrenoreceptor antagonists, yohimbine and urapidil hydrochloride, on the cell lines *in vitro*.

**METHODS:** We cultured the human ductal pancreatic adenocarcinoma cell lines PC-2 and PC-3 and analyzed the mRNA expression of  $\alpha_1$ - and  $\alpha_2$ -adrenergic receptors by reverse transcription polymerase chain reaction (RT-PCR). The effects of yohimbine and urapidil hydrochloride on cell proliferation were assessed by 3-(4,5-dimethylthiazol-2-yl)-2,4-diphenyltetrazolium bromide (MTT) assay. Apoptosis was detected using the terminal deoxyribonucleotidyl transferase (TdT)-mediated biotin-16-dUTP nick-end labeling (TUNEL) assay and flow cytometry (FCM).

**RESULTS:** PC-2 expressed mRNA in  $\alpha_1$ - and  $\alpha_2$ -adrenoreceptors. MTT assays showed that urapidil hydrochloride had no effect on PC-3 cell lines. However, exposure to urapidil hydrochloride increased DNA synthesis in PC-2 cell lines as compared to the control group. PC-2 cell lines were sensitive to both drugs. The proliferation of the 2 cell lines was inhibited by yohimbine. Cell proliferation was inhibited by yohimbine *via* apoptosis induction.

**CONCLUSION:** The expression of  $\alpha_1$ - and  $\alpha_2$ -adrenoreceptors is different in PC-2 and PC-3 cell lines, which might be indicative of their different functions. The  $\alpha_2$ -adrenoceptor antagonist, yohimbine, can inhibit the

proliferation of both cell lines and induce their apoptosis, suggesting that yohimbine can be used as an anticancer drug for apoptosis of PC-2 and PC-3 cells.

### INTRODUCTION

Pancreatic cancer is the fourth most common malignancy in the United States. The annual incidence rate is almost identical to the mortality rate, and the 5-year survival rate remains less than 5%<sup>[1]</sup>. Approximately 10%-20% of patients have a resectable pancreatic cancer at the time of its diagnosis, and the curative resection rate is only 14% with a median survival of 15-19 mo<sup>[2]</sup>. Because of the inability of early diagnosis, early vascular dissemination, and regional lymph node metastasis, pancreatic cancer has a poor prognosis<sup>[3,4]</sup>.

Recent studies have demonstrated that age, cigarette smoking, alcohol, and chronic pancreatitis are the factors for pancreatic cancer<sup>[5,6]</sup>. However, the mechanism of pancreatic cancer is not entirely clear. It was reported that  $\beta$ -adrenoreceptor expressed in cancer of the pancreas, breast, colon, lung, and prostate cell lines is the key factor that induces tumor formation due to long-term smoking and chronic stress<sup>[7-11]</sup>. Chronic stress could elevate the level of norepinephrine and epinephrine, leading to  $\beta$ -adrenoreceptor activation. Adrenoceptors modulate diverse intracellular processes, such as DNA synthesis through activation of mitogen-activating protein kinases (MAPKs)<sup>[12]</sup>.

The  $\alpha$ -adrenoreceptor subtypes have been classified as  $\alpha_{1A}$ -,  $\alpha_{1B}$ -,  $\alpha_{1D}$ -,  $\alpha_{2A}$ -,  $\alpha_{2B}$ -, and  $\alpha_{2C}$ -adrenoreceptors and  $\beta$ -adrenoreceptors as  $\beta_1$ -,  $\beta_2$ -, and  $\beta_3$ -adrenoreceptors<sup>[13-16]</sup>. Various cancer cell lines could express different adrenoreceptor subtypes impacting tumor cell biological behavior and heteromorphism. It was recently reported that  $\alpha_2$ -adrenoreceptor subtype is expressed in breast cancer cell lines at RNA and protein level. Moreover, these functional receptors are associated with an increase in cell proliferation<sup>[17,18]</sup>.

In this paper, we discuss the expression of  $\alpha$ -adrenoreceptors in pancreatic cancer cell lines PC-2 and PC-3, and the effects of the  $\alpha_1$ - and  $\alpha_2$ -adrenoreceptor antagonists, yohimbine and urapidil hydrochloride *in vitro*. We hypothesize that the  $\alpha$ -adrenoreceptor antagonists could suppress the proliferation of pancreatic cancer cells *via* induction of apoptosis. The aim of this study was to describe and characterize the presence of  $\alpha_1$ - and  $\alpha_2$ -adrenoreceptors in pancreatic cancer cell lines PC-2 and PC-3 at RNA level using reverse transcription polymerase chain reaction (RT-PCR). Moreover, apoptosis was detected by terminal deoxynucleotidyl transferase (TdT)-mediated biotin-16-dUTP nick-end labeling (TUNEL) assay and flow cytometry (FCM), when pancreatic cancer cells were stimulated with  $\alpha$ -adrenoreceptor antagonists.

## MATERIALS AND METHODS

### Materials

Dulbecco's modified Eagle's medium (DMEM) and fetal bovine serum (FBS) were purchased from Gibco (Grand Island, NY, USA). Trizol was purchased from Invitrogen (Carlsbad, CA, USA). Urapidil hydrochloride, yohimbine, streptomycin, penicillin, and 3,3-dimethyl-2-thionotetrahydro-1,3,5-thiadiazine (MTT) were purchased from Sigma Chemicals (St. Louis, MO, USA).

### Cell culture

PC-2 and PC-3 were obtained from the Pathology Department of China Beijing Union Medical University (PC-3 cell line established from human primary exocrine pancreatic head-cancer, PC-2 cell line from human exocrine pancreatic cancer metastasis). Cells were cultured in a high glucose-DMEM medium supplemented with 10% heat-inactivated fetal calf serum, penicillin (100 U/mL), and streptomycin (100 mg/mL) at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub> and 950 mL/L with a relative humidity.

### RT-PCR

RNA was isolated from PC-2 and PC-3 cells lysed with Trizol. Dense RNA was quantified by UV spectrophotometry (at 260/280 nm) and stored at -70°C. For reverse transcriptase reaction, 0.5  $\mu$ g of 18 oligo (dT) primers in diethyl pyrocarbonate (DEPC) water was heated to 70°C for 5 min to allow annealing of the primer to RNA followed by chilling on ice. A total of 10 mmol/L dNTPs, 20 units of RiboLock ribonuclease inhibitor, 5  $\times$  reaction buffer [250 mmol/L Tris-HCl (pH 8.3), 250 mmol/L KCl, 20 mmol/L MgCl<sub>2</sub>, and 50 mmol/L dithiothreitol (DTT)]

were added and the reaction mixture was incubated at 37°C for 5 min. Then, 200 units of M-MuLV reverse transcriptase was added and the mixture was incubated at 42°C for 1 h, followed by heat inactivation for 10 min at 70°C.

PCR was performed with 5  $\mu$ L RT reaction mixture containing 1  $\mu$ L of 10 mmol/L dNTPs, 5  $\mu$ L of 10  $\times$  PCR buffer [100 mmol/L Tris-HCl (pH 8.3), 500 mmol/L KCl, and 15 mmol/L MgCl<sub>2</sub>, 1.5  $\mu$ L of Taq polymerase (Perkin Elmer, Branchburg, NJ, USA), 1  $\mu$ L primers for human  $\alpha_{1A}$ -,  $\alpha_{1B}$ -,  $\alpha_{1D}$ -,  $\alpha_{2A}$ -,  $\alpha_{2C}$ -,  $\alpha_{2B}$ -,  $\beta_1$ -, and  $\beta_2$ -adrenoreceptors, and DEPC water in a final volume of 50  $\mu$ L. Adrenoreceptor primers were designed according to Genbank, NCBI. The  $\alpha_{1A}$  adrenoreceptor primers (sense: 5'-CTCTGCGTCTGGGCACTCT-3' and antisense: 5'-GAAGCAGCCGACCACGAT-3') were used to amplify a 402-bp fragment. The  $\alpha_{1B}$  primers (sense: 5'-AAGAAGTTTCACGAGGACACCC-3' and antisense: 5'-CAGAACACCACCTTGAACACG-3') were used to amplify a 233-bp fragment. The  $\alpha_{1D}$  primers (sense: 5'-TCACTCAAGTACCCAGCCATCA-3' and antisense: 5'-GGAACCAGCAGAGCACGAAG-3') were used to amplify a 487-bp fragment. The  $\alpha_{2A}$  primers (sense: 5'-ATCGGAGTGTTCGTGG-3' and antisense: 5'-AGGAAGCAATAGTGATTAGGG-3') were used to amplify a 489-bp fragment. The  $\alpha_{2C}$  primers (sense: 5'-TGTTTCGTGCTCTGCTGGTTC-3' and antisense: 5'-GGGGAAGGCAAAGGGGTC-3') were used to amplify a 427-bp fragment. The  $\alpha_{2B}$  primers (sense: 5'-AAATCGGGGCGACAATAG-3' and antisense: 5'-GAGACCCAAGCCACTAAAA-3') were used to amplify a 367-bp fragment. The  $\beta_1$  primers (sense: 5'-GGGAGAAGCATTAGGG-3' and antisense: 5'-CAAGGAAAGCAAGGTGGG-3') were used to amplify a 270-bp fragment. The  $\beta_2$  primers (sense: 5'-CAGCAAAGGACGAGGTG-3' and antisense: 5'-AAGTAATGGCAAAGTAGCG-3') were used to amplify a 334 bp fragment. The PCR conditions for the receptors of the above-mentioned primers were as follows: 1 cycle at 94°C for 2 min; 35 cycles at 94°C for 30 s, at 62°C for 60 s, and at 70°C for 2 min; and a final extension at 70°C for 7 min. Reactions were run on a MJ Research PTC-200 thermal cycler. The PCR products and a 100-bp DNA ladder were run on a 1.5% agarose gel for 2 h at 90 V. The gel was imaged using ethidium bromide staining with a UVP GDS 7500 or an Ultra Lum TUI-5000 gel documentation system.

### MTT assay

The effects of yohimbine and urapidil hydrochloride on cell proliferation were detected by colorimetric MTT assay based on the NADH-dependent enzymatic reduction of the tetrazolium salt MTT in metabolically active cells but not in dead cells. Cells were seeded in a basal medium at the concentration of 1  $\times$  10<sup>4</sup> cells/well in 96-well plates, and allowed to grow and adhere in complete media at 37°C with 50 mL/L CO<sub>2</sub> for 20-24 h. The cells were then transferred to basal media with 0.05% FBS and incubated for 24 h with control (no treatment), yohimbine (25-200  $\mu$ mol/L), and urapidil hydrochloride (25-200  $\mu$ mol/L). Following incubation, 20  $\mu$ L MTT (5 mg/mL) was added to each well, and the cells grew in complete media at 37°C with 50 mL/L CO<sub>2</sub> for 4 h. The supernatant was removed,

then 150  $\mu$ L DMSO was added to each well of the 96-well plate and swung for 10 min. The optical density at 490 nm was determined with an enzyme linked immunosorbent assay (ELISA) reader.

**TUNEL assay**

TUNEL assay was performed with the *in situ* cell apoptosis detection kit following its manufacturer's instructions. Briefly, the cells were replaced on cover slips after exposure to urapidil and yohimbine for 24 h and fixed with 4% paraformaldehyde for 30 min and adhered to slides with balsam. Nonspecific chromogen reaction, induced by endogenous peroxidase, was inhibited with 3% H<sub>2</sub>O<sub>2</sub> for 10 min at room temperature. Terminal deoxynucleotidyl transferase (TdT) and biotin-11-dUTP reactions were performed for 1 h at 37°C in a humidified box, and blocking reagent was applied for 30 min at room temperature, followed by Avidin-HRP for 1 h at 37°C in a humidified box. For biochemical controls, positive control slides were treated with DNase and negative control slides were treated with PBS instead of TdT. DNA fragments were stained using DAB as a substrate for peroxidase, and hematoxylin was used as a counter stain. Apoptotic index was calculated as a ratio of the number of apoptotic cells to the total number of tumor cells in each slide.

**Analysis of the apoptosis rate by annexin V and FITC/PI FCM**

The apoptosis rate was measured by FCM according to the instructions supplied with the annexin V-FITC kit. In brief, after treatment with urapidil and yohimbine, PC-2 and PC-3 cells were harvested by centrifugation, washed once with ice-cold PBS and resuspended in binding buffer at a concentration of 1  $\times$  10<sup>6</sup> cells/mL, in which 100 mL of cell suspension was added in a 5 mL FCM tube. A total of 5 mL of annexin V-FITC and 10 mL of 20 mg/mL PI were added and incubated for 15 min in the dark prior to a further addition of 400 mL PBS. Quantitative analysis of apoptotic level was performed using a flow cytometer (BD Biosystems, CA, USA). The apoptotic percentage of 10000 cells was determined and all the experiments reported in this study were performed in triplicate.

**Statistical analysis**

*In vitro* data were analyzed by one-way ANOVA and nonparametric Kruskal-Wallis test by using SPSS version 13.0. Values were expressed as mean  $\pm$  SD, and *P* < 0.05 was considered statistically significant.

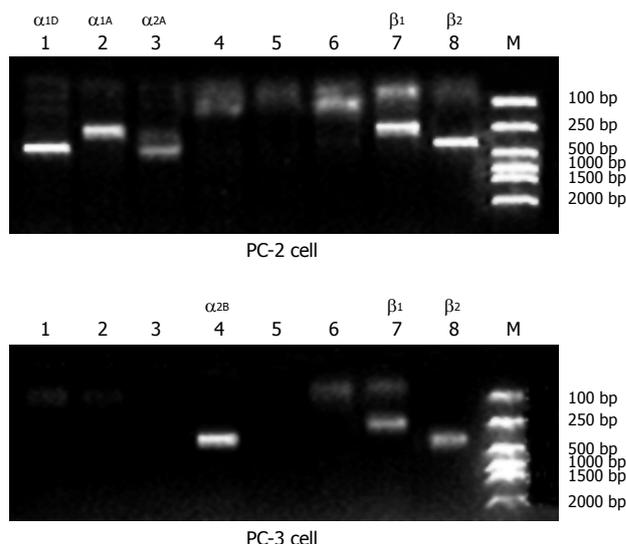

**RESULTS**

**RT-PCR**

RT-PCR results demonstrated that PC-2 expressed mRNA in  $\alpha$ <sub>1D</sub>,  $\alpha$ <sub>1A</sub>,  $\alpha$ <sub>2A</sub>,  $\beta$ <sub>1</sub> and  $\beta$ <sub>2</sub>-adrenoceptors and PC-3 expressed mRNA in  $\alpha$ <sub>2B</sub>,  $\beta$ <sub>1</sub>, and  $\beta$ <sub>2</sub>-adrenoceptors (Figure 1).

**MTT assay**

MTT assays showed that urapidil hydrochloride had no effect on PC-3 cell lines, whereas exposure to urapidil hydrochloride increased DNA synthesis in the PC-2 cell line as compared to the control group. PC-2 was sensitive to

**Figure 1** Expression of mRNA in adrenoceptors of human ductal pancreatic adenocarcinoma cell lines PC-2 and PC-3 by RT-PCR. Lanes 1-8 represent the  $\alpha$ <sub>1D</sub>-,  $\alpha$ <sub>1A</sub>-,  $\alpha$ <sub>2A</sub>-,  $\alpha$ <sub>2B</sub>-,  $\alpha$ <sub>2C</sub>-,  $\alpha$ <sub>1B</sub>-,  $\beta$ <sub>1</sub>-, and  $\beta$ <sub>2</sub>-adrenoceptor subtypes, respectively. Lane maker = 100 bp DNA ladder. PC-2 expressed mRNA in  $\alpha$ <sub>1D</sub>-,  $\alpha$ <sub>1A</sub>-,  $\alpha$ <sub>2A</sub>-,  $\beta$ <sub>1</sub>-, and  $\beta$ <sub>2</sub>-adrenoceptors and PC-3 expressed mRNA in  $\alpha$ <sub>2B</sub>-,  $\beta$ <sub>1</sub>-, and  $\beta$ <sub>2</sub>-adrenoceptors.

**Table 1**  $\alpha$ -adrenoceptor antagonists-induced apoptosis in human pancreatic cancer cells (mean  $\pm$  SD)

Treatment	TUNEL-positive cells (apoptotic index) (%)			
	PC-2 100 $\mu$ mol/L	PC-2 200 $\mu$ mol/L	PC-3 100 $\mu$ mol/L	PC-3 200 $\mu$ mol/L
Yohimbine	20.91 $\pm$ 2.43 <sup>a</sup>	39.41 $\pm$ 3.21 <sup>a</sup>	15.47 $\pm$ 2.19 <sup>a</sup>	21.22 $\pm$ 2.57 <sup>a</sup>
Urapidil	1.57 $\pm$ 0.94	2.47 $\pm$ 1.03	1.98 $\pm$ 0.69	2.33 $\pm$ 0.92
Control	2.56 $\pm$ 0.78		2.14 $\pm$ 0.62	

<sup>a</sup>*P* < 0.05 vs control.

both drugs. The proliferation of 2 cell lines was inhibited by yohimbine. However, the rate of suppression by yohimbine was weaker than that by 5-FU used as a positive control (Figure 2).

**TUNEL assay**

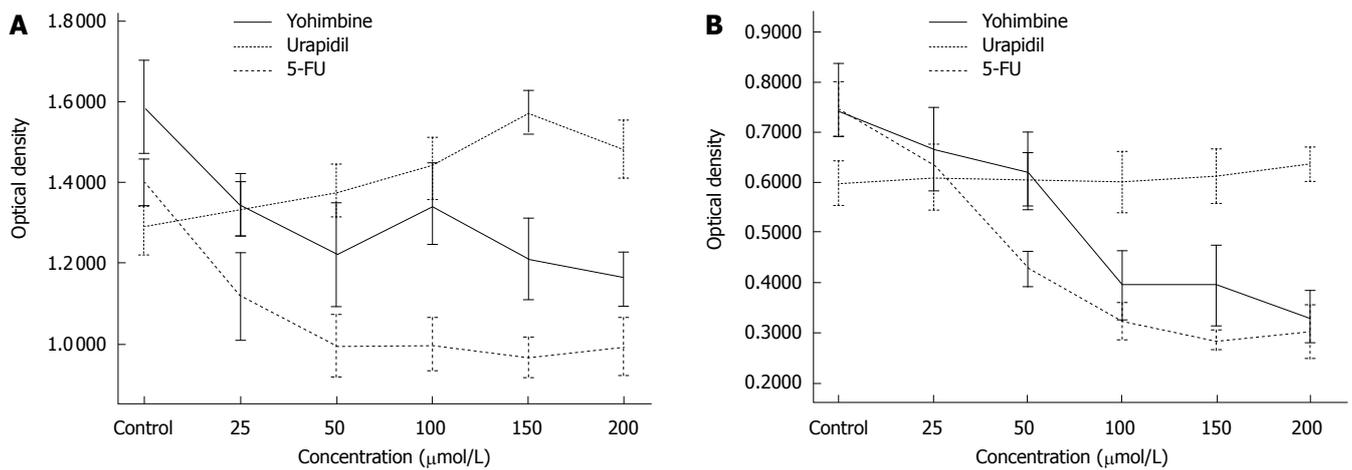

Nuclei of apoptotic cells were condense and stained brown whereas the negative cells were stained blue in the TUNEL assay. The results were in accordance with the MTT assay and revealed that yohimbine could induce apoptosis of both cell lines whereas urapidil hydrochloride had no effect on the 2 cell lines (Figure 3 and Table 1).

**FCM**

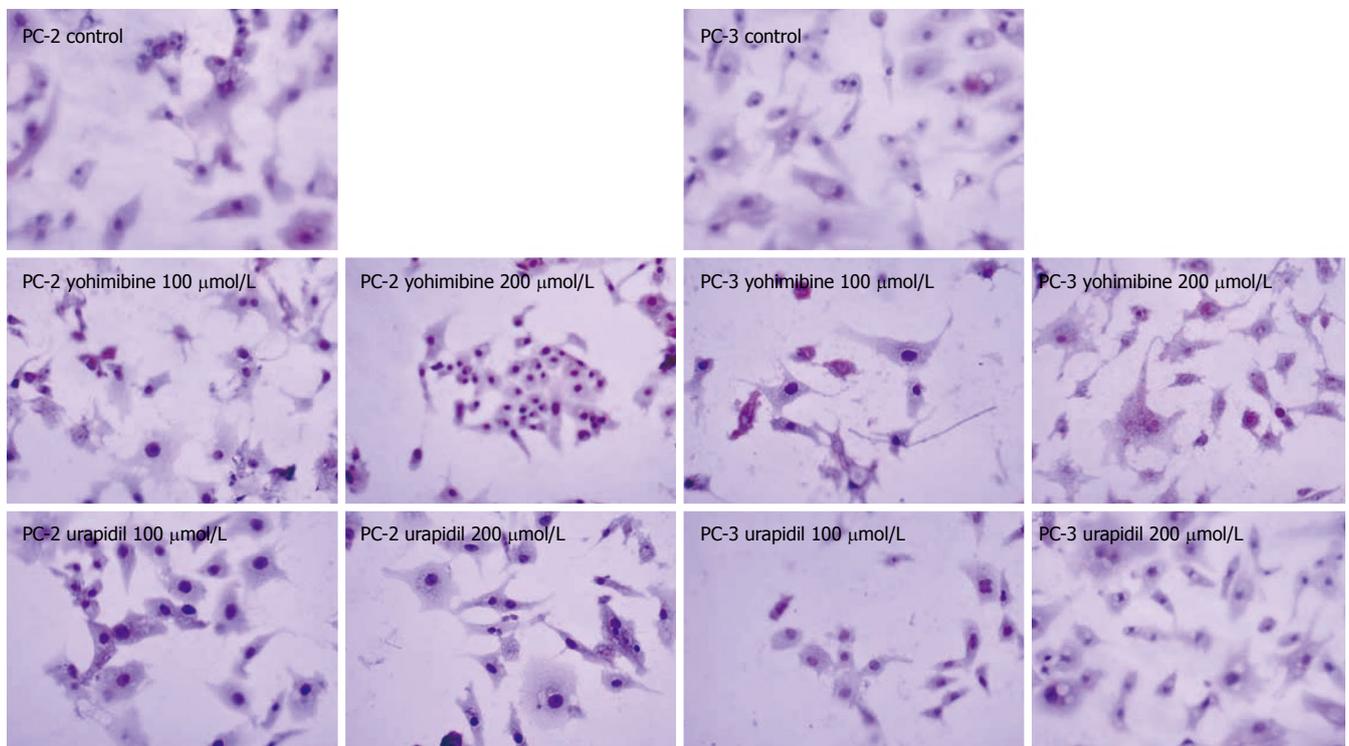

PC-2 and PC-3 cells were treated with the  $\alpha$ -adrenoceptor antagonists, urapidil hydrochloride (200  $\mu$ mol/L) and yohimbine (200  $\mu$ mol/L) for 24 h. The cells treated with urapidil hydrochloride and yohimbine were double stained with annexin V and PI and analyzed by FCM (Figure 4).

**DISCUSSION**

In this study,  $\alpha$ <sub>1</sub>-adrenoceptors were only expressed in

**Figure 2** MTT assay shows that PC-2 cells treated with urapidil hydrochloride for 24 h could increase cellular proliferation in a concentration-dependent manner. Yohimbine inhibited the proliferation of PC-2 cells (A) and urapidil hydrochloride had no effect on PC-3 cell lines while the proliferation of PC-3 cell lines was inhibited by yohimbine (B).

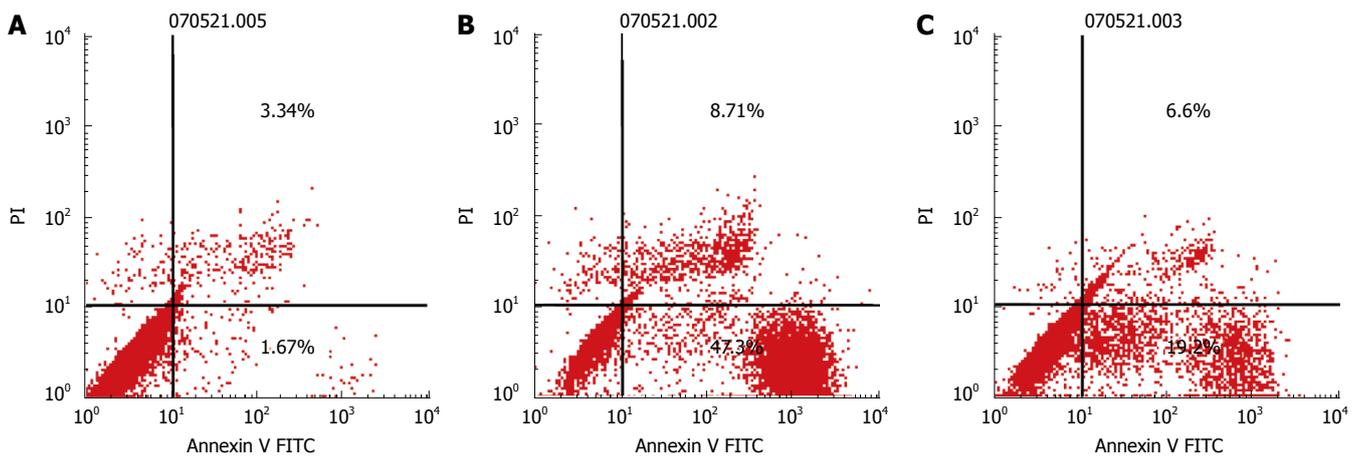

**Figure 3** TUNEL assay showing apoptotic PC-2 and PC-3 cells after treatment with 100  $\mu\text{mol/L}$  urapidil hydrochloride and yohimbine for PC-2 cells and 100  $\mu\text{mol/L}$  yohimbine and 100  $\mu\text{mol/L}$  urapidil for PC-3 cells compared with control group.

PC-2 cells, while  $\alpha_2$ -adrenoceptors were expressed in both PC-2 and PC-3 cells. MTT assay demonstrated that urapidil hydrochloride had no effect on PC-3 cell line, but increased DNA synthesis in PC-2 cell line as compared to the control group. The proliferation of the 2 cell lines was inhibited by yohimbine. The rate of suppression by yohimbine was weaker than by 5-FU used as a positive control.

$\alpha$ -adrenoceptor is a member of the superfamily of G protein-coupled adrenoceptors, which mediate reactions of endogenous catecholamines in a variety of target cells<sup>[12]</sup>. Currently, the following 6 native  $\alpha$ -adrenoceptor subtypes have been identified:  $\alpha_{1A}$ ,  $\alpha_{1B}$ ,  $\alpha_{1D}$ ,  $\alpha_{2A}$ ,  $\alpha_{2C}$ , and

$\alpha_{2B}$ , which have been studied more extensively in diseases of the cardiovascular system, such as vascular constriction and hypertension mechanism<sup>[17,20,21]</sup>. However, there are few reports on the relationship between  $\alpha$ -adrenoceptor subtypes and malignant tumors. Our study identified the mRNA expression of  $\alpha$ -adrenoceptor subtypes in PC-2 and PC-3 cell lines, and showed that the PC-2 cell line expressed  $\alpha_{1D}$ -,  $\alpha_{1A}$ -, and  $\alpha_{2A}$ -adrenoceptor subtype mRNA, and the PC-3 cell line expressed the  $\alpha_{2B}$ -adrenoceptor subtype mRNA.

In the present study, prostatic cells expressed  $\alpha_1$ -adrenoceptors. Catecholamine could promote prostatic cell proliferation<sup>[22]</sup>. Growth of human prostate cancer

**Figure 4** Apoptotic PC-2 and PC-3 cells after treatment with 200  $\mu\text{mol/L}$  urapidil hydrochloride (A) and 200  $\mu\text{mol/L}$  yohimbine (B) for PC-2 cells and 200  $\mu\text{mol/L}$  yohimbine for PC-3 cells (C) detected by FCM. Significant apoptosis was induced by yohimbine on both PC-2 and PC-3 cells, whereas urapidil hydrochloride had no apoptotic effect on PC-2 cell.

cells could be suppressed by  $\alpha_1$ -adrenoceptor antagonists, doxazosin and terazosin, by inducing apoptosis<sup>[23,24]</sup>. On the other hand, the  $\alpha_1$ -adrenoceptor antagonist, urapidil hydrochloride, in our study, had effects on the proliferation of PC-2 cells but not on that of PC-3 cells, which might be related to the  $\alpha$ -adrenoceptor subtype, but the mechanism of action is not clear.

$\alpha_2$ -adrenoceptor is classically linked to the inhibition of adenylyl cyclase leading to a reduction in intracellular cAMP. Recent studies revealed that yohimbine inhibits both intracellular and extracellular cAMP levels in human mammary tumor MCF-7 cells and also suppresses the proliferation of MCF-7 cells, indicating that  $\alpha$ -adrenergic receptors may mediate this kind of action<sup>[16,19]</sup>. Our study demonstrated that the  $\alpha_2$ -adrenoceptor antagonist, yohimbine, could inhibit PC-2 and PC-3 cell proliferation by inducing apoptosis.

The molecular mechanism underlying apoptosis of PC-2 and PC-3 cells induced by yohimbine is unknown. It was reported that expression of a cloned  $\alpha_2$ -adrenergic receptor allows the coupling of this receptor to the p21<sup>ras</sup>-mitogen-activated protein (MAP) kinase cascade in hamster lung fibroblasts via a Gi-mediated pathway that is independent of adenylyl cyclase inhibition or phospholipase stimulation<sup>[24,25]</sup>. MAPK pathway plays a pivotal role in pancreatic cancer progression by stimulating distinct mitotic, antiapoptotic, and angiogenic cascades, and by controlling different intracellular signaling elements activated by other growth factors in pancreatic cancer cells<sup>[26]</sup>. Based on our hypothesis that yohimbine induces apoptosis of PC-2 and PC-3 cells by inhibiting the MAPK or other pathways, our group will document the molecular mechanism underlying the apoptosis induced by yohimbine in future studies.

In conclusion,  $\alpha_2$ -adrenoceptor antagonist, yohimbine but not urapidil hydrochloride, exerts a negative effect on pancreatic cancer cell growth by inducing apoptosis. Although the potential underlying mechanism is presently unknown, yohimbine may suppress pancreatic cell growth by deregulating signal transduction pathways, potentially

involving the MAPK or other pathways. The mechanistic aspects of the antitumor effect of yohimbine against pancreatic tumors are under investigation.

## COMMENTS

### Background

It is supposed that neurobiology would play a key role in development of malignant tumors, by its direct effect on malignant tumors or on tumor micro-environment. Autonomic nerves are closely related with various activities of the body. A few reports are available on the beta-adrenergic receptors in cancer of colon, breast, and prostate, etc. However, little is known about alpha-adrenergic receptors in malignant tumor, we, therefore, studied the distribution and function of alpha-adrenergic receptors of malignant tumour cells.

### Research frontiers

Pancreas is a complex organ, including blood, nerve and lymph. Pancreatic cancer is generally characterized by less blood supply, innervation complex, and lymphatic irregularity, which have been brought difficulty to diagnosis and treatment of pancreatic cancer.

### Innovations and breakthroughs

In recent years, basic researches of malignant tumor concentrated on their biological characteristics, such as invasion and metastasis. This study explored the development, metastasis and infiltration of pancreatic cancer by neurobiology.

### Applications

The study is only a part of our research. The study would screen the drugs suppressing malignant tumor, from cardiovascular drugs.

### Peer review

The study investigated the effects of  $\alpha$ -adrenoceptor antagonists on proliferation and apoptosis of pancreatic cancer cells. The subject is important because very little is known about the role of adrenergic stimulation in the regulation of proliferation and death of pancreatic cancer cells. The study was well designed.

### Abstract

**AIM:** To examine the efficacy and complications of colonoscopic resection of colorectal polypoid lesions.

**METHODS:** We retrospectively reviewed 1354 polypectomies performed on 1038 patients over a ten-year period. One hundred and sixty of these were performed for large polyps, those measuring  $\geq 20$  mm. Size, shape, location, histology, the technique of polypectomy used, complications, drugs assumption and associated intestinal or extra intestinal diseases were analyzed. For statistical analysis, the Pearson  $\chi^2$  test, NPC test and a Binary Logistic Regression were used.

**RESULTS:** The mean patient age was  $65.9 \pm 12.4$  years, with 671 men and 367 women. The mean size of polyps removed was  $9.45 \pm 9.56$  mm while the size of large polyps was  $31.5 \pm 10.8$  mm. There were 388 pedunculated and 966 sessile polyps and the most common location was the sigmoid colon (41.3%). The most frequent histology was tubular adenoma (55.9%) while for the large polyps was villous (92/160 -57.5%). Coexistent malignancy was observed in 28 polyps (2.1%) and of these, 20 were large polyps. There were 17 procedural bleeding (1.3%) and one perforation. The statistical analysis showed that cancer is correlated to polyp size ( $P < 0.0001$ ); sessile shape ( $P < 0.0001$ ) and bleeding are correlated to cardiac disease ( $P = 0.034$ ), tubular adenoma ( $P = 0.016$ ) and polyp size.

**CONCLUSION:** The endoscopic resection is a simple and safe procedure for removing colon rectal neoplastic lesions and should be considered the treatment of choice for large colorectal polyps. The polyp size is an important risk factor for malignancy and for bleeding.

### INTRODUCTION

The colonoscopic polypectomy was introduced by Wolf and Shinya in the early 1970s and has become the most common therapeutic procedure performed within endoscopic units<sup>[1]</sup>. Colonoscopic polypectomy is the first approach and the standard treatment for colon rectal polyps and, therefore, a prevention of colorectal cancer. It is a safe technique when performed by expert hands using a cautious technique and equipment that works properly; so that, in these conditions, complications should be an uncommon event.

Some factors can increase the rate of complications such as the type (pedunculated or sessile) and size of the polyp, its location and other factors regarding the comorbidity of the patient (coagulation disorders or drug assumption) and the technique used. The most common complications after polypectomy are bleeding (from 0.3% to 6.1%) and pain due either to excessive gas accumulation or to parietal damage and perforation after current

application<sup>[2]</sup>. Frequently, these complications follow large polyps polypectomies. Several authors have reported complications during the endoscopic removal of large polyps and in the majority of these studies, "large" was defined as equal to or greater than 20 mm.

Large polyps represent a particular challenge for the endoscopist because they are often related to important risks of haemorrhage (0%-22.1%), perforation (0%-1.3%) and inadequate polypectomy<sup>[3-19]</sup>. The alternative to endoscopic therapy of large polyps is the surgical resection which involves hospitalization and anaesthesia. In addition, the risks of surgery are significant, especially in elderly patients with comorbid diseases. Moreover, the higher mortality (2%-4%) and morbidity (10%) rates reported for surgery with respect to endoscopic polypectomy cannot be overlooked<sup>[3]</sup>.

This study aims to show a retrospective series of endoscopic resections of colon rectal polyps and in particular of large polyps, focusing on the efficacy, complications and risk factors.

## MATERIALS AND METHODS

From January, 1996 to May, 2006, 1038 patients underwent colonoscopy for the removal of 1354 polypoid lesions. Of these polypectomies, 160 (11.8%) were performed on large polyps, those measuring 20 mm or more. The patients were prepared for colonoscopy following standard protocol, following a fiber and residue free diet within 72 h before the investigation and the assumption of 4000 mL of a polyethylene glycol electrolytic lavage solution 18 h before colonoscopy. The colonoscopy was performed according to standard procedure using two Olympus CF-100 HI and one Pentax EC3830FK videocolonoscopes. An electrocautery Erbe ICC 200 and argon plasma coagulation Erbe APC 300 were also used. The sclerosis needle and endoscopic snare used during the polypectomy procedure were the standard models. All procedures were performed by two expert endoscopists.

For the statistical analysis the polyps were split in four groups: the first group represented polyps measuring between 1-10 mm, the second 11-19 mm, the third 20-39 mm and the fourth group of polyps measuring 40 mm or more. For shape, polyps were grouped in pedunculated (pedunculated and semi-pedunculated) and sessile (sessile and flat-elevated). The method of resection was selected according to the size and morphologic features of each lesion and three groups were created: direct snare (hot or cold biopsy and hot or cold snare in smaller lesions and larger protruding lesions), mucosectomy (en bloc, piecemeal, the inject and cut and the inject, lift, and cut for broad-based lesions) and endoloop.

Pedunculated polyps were transected at the stalk just below the polyp head. In all pedunculated polyps injection into the base of the stalk was not performed, before polypectomy, as a prophylactic measure to prevent the bleeding, except for the cases of pedunculated polyps with a very big stalk where bleeding prophylaxis was performed with the application of endoloop. Sessile polyps were resected using two techniques, en bloc and piecemeal.

All resected material was retrieved for histological examination.

Post-polypectomy bleeding was defined as procedural if it occurred during polypectomy, immediate if it occurred within 24 h of polypectomy, and delayed if it occurred more than 24 h after the procedure. Bleeding was treated by injection therapy, with dilute adrenalin at a concentration of 1:10000 with or without 1% polidocanol, hemoclips and thermal coagulation using argon plasma. The variables evaluated in the study were: polyp size, polyp shape, their location along the colon, complications (bleeding and perforation), histology, technique of polypectomy applied, drugs assumption and associated intestinal or extra intestinal diseases.

Continuous data are described by mean and standard deviation or median and range, according to distribution. Categorical data are presented as numbers and percentages. The Pearson  $\chi^2$  test with Brandt-Snedecor and Kimball's formula<sup>[20]</sup> was used to assess the association between categorical variables while to individualize the correlation between categorical variables and some numerical variables a biserial correlation coefficient was used<sup>[21]</sup>. Differences between the groups were evaluated using the non parametric combination NPC Test, based on permutation tests<sup>[22]</sup>. A *P*-value < 0.05 was considered statistically significant. The estimation of a Binary Logistic Regression model allowed for the individualization of the variables which were tied on the bleeding<sup>[23]</sup>. In this context, the estimation of Log-Likelihood test and G test allows for the obtainment of the measure of goodness-of-fit.

Software used included SPSS, Windows 11.0 (2001) for Pearson  $\chi^2$  test and biserial correlation, Microsoft Excel (2002) for the Brandt-Snedecor method and Kimball's formula, Methodologica S.R.L. (2001) for nonparametric analysis NPC test and Minitab Release 13.31, Copyright © 2000 Minitab Inc. for Binary Logistic Regression.

## RESULTS

The demographic and clinical data of the patients studied and the characteristics of polyps according to size are illustrated in Table 1 and Table 2. Among 1354 endoscopic polypectomies, 907 were lesions less than 10 mm of diameter, 287 between 11 and 19 mm, and 160 more than 20 mm; the size of total polyps was  $9.45 \pm 9.56$  (range 1-100) while the size of large polyps was  $31.5 \pm 10.8$ . Macroscopically sessile shapes were prevalent (966/1354 -71.3%) and the pedunculated ones were 388 (28.7%).

The most frequent location of the polyps was the sigmoid colon (559/1354 -41.3%). The most frequent location of large polyps was the sigmoid colon (65/160 -40.7%).

The most commonly used technique was direct endoscopic snare resection in 1294 polypectomies (95.6%) as well as in the group of large polyps 132/160 (82.5%).

The most frequent histological type among all the polyps resected was tubular adenoma, 756/1354 -55.9%, while, for the large polyps, it was the villous type (92/160 -57.5%). Of the removed polyps, 1078 were adenomas with low grade dysplasia (79.6%), 123 with high grade dysplasia (9.1%) and 28 (2.1%) were adenomas containing

Colon rectal cancer	0.130	0.384	0.922	0.036

between cancer and age ( $P = 0.464$ ). To evaluate the association between malignancy and sex, histology, location and shape, we applied a  $\chi^2$  test, where it showed significant results for the association with shape ( $P < 0.0001$ ), in particular sessile and sex ( $P < 0.0001$ ), and the association between cancer and location ( $P = 0.719$ ). Cancer with histology ( $P = 0.819$ ) was not statistically significant.

The endoloop was used as a prophylactic measure to prevent postpolypectomy bleeding in four cases (0.3%) for pedunculated polyps. The “endoloop” prevented bleeding from the stalk in all cases. Procedural bleeding occurred in 1.3 % (17/1354) of all polyps (11 sessile and 6 pedunculated). In large polyps the bleeding occurred in 10/160 (6.3%). Bleeding was always managed by endoscopic means with the application of hemoclips in 3 cases, adrenalin injection in 13 cases and APC in 1 case. There was no acute or late bleeding. There was no need for blood transfusion.

With the application of the Pearson  $\chi^2$  test, the association between the studied variables was shown to be statistically significant: bleeding and extra intestinal diseases ( $P < 0.0001$ ) and the histology ( $P = 0.016$ ). In particular, between bleeding and cardiac diseases ( $P = 0.034$ ) and tubular adenoma ( $P = 0.016$ ). The Pearson  $\chi^2$  test was also applied in the sub-groups for evaluation of the association between the bleeding and the studied variables and the P-values are illustrated in Table 3.

Statistical analysis performed by NPC test showed a highly significant difference between the four groups examined in relation to bleeding; the P-values of the analysis are shown in Table 4.

The results of the Binary Logistic Regression (Table 5) allowed confirmation that the associated extra intestinal diseases, histology and the size of the polyps are statistically significant and are linked to the occurrence of bleeding. For the aforesaid model the Log-Likelihood test assumes a value of -62.662, the G test is equal to 57.276 with 9 degrees of freedom and the P-value is 0.000; for this reason we can affirm that the chosen model is adequate to examine the data.

Perforation occurred in one patient (0.07%) after polypectomy of a malignant sessile polyp in the sigmoid colon, but in this lesion of 15 mm there was no suspicion of malignancy. This patient died after surgery repair of perforation from respiratory failure.

## DISCUSSION

In the past two decades the technique of endoscopic polypectomy or mucosal resection has been significantly improved and is the most common therapeutic procedure performed in the endoscopic unit. A particular challenge is the endoscopic treatment of large polyp because the procedure is difficult and reserved for experts since complications rates are very high. In this study, we described a series of 1354 endoscopic resections of colon rectal polyps performed in our endoscopic units between January, 1996 and May, 2006. The gender and age distribution of patients is similar to that described above in other studies regarding the treatment of colorectal polyps<sup>[3-19]</sup>.

From the literature, it emerges that over 80% of polyps resected during colonoscopy are small polyps less than 10 mm in diameter<sup>[24]</sup> while in our study 67% were 10 mm in diameter. In fact, during a ten-year period we found 11.8% of excised polyps to be 20 mm or more in size out of 1354 total polypectomies. These data illustrate an average of 16 large polyps removed annually. Other authors reported averages of between 8 and 21 large polyps removed annually<sup>[3-19]</sup>. In the present study, all patients with large colorectal polyps were treated endoscopically and in all cases the complete removal of all pedunculated and sessile polyps was possible.

Several previous publications reported a correlation between malignancy and age of patients, polyp shape, histology, location and higher rates in large polyps up to 50%<sup>[6,25-31]</sup>. In the present study, 28 polyps were found to be adenomas containing an area of carcinoma (2.1%) and of these, 20 (12.5%) were in the group of large polyps; however, none of these polyps showed neither vascular or lymphatic invasion.

Statistical analysis, performed by biserial correlation coefficient and the  $\chi^2$  test, showed a correlation between cancer, polyp size ( $P < 0.0001$ ), sex ( $P < 0.0001$ ) and sessile shape ( $P < 0.0001$ ). In accordance with previous publications, we documented a correlation with size, sessile shape and sex. Moreover, our data suggest that invasive carcinoma can appear with an equal probability, both in a

tubular or tubulovillous or villous adenoma. Finally, there was no correlation with the site of the polyp along the colon.

Although the complications of polypectomy widely vary as presented in literature, the most frequent remain haemorrhage and perforation, which are often related to the size of the polyp, its morphology (sessile or pedunculated) and location<sup>[14,32]</sup>. The incidence of bleeding during and after the polypectomies has been reported to range from 0.3% to 6.1%, with higher rates in large polyps up to 22.1% (Table 6)<sup>[3-19]</sup>.

In our series, the Pearson  $\chi^2$  test applied in the subgroups found a correlation between the bleeding and liver diseases ( $P = 0.003$ ), which usually impairs the coagulation function of the patients and location of polyps in transverse colon ( $P < 0.0001$ ), in group 2 with histology and in particular with the hyperplastic polyps ( $P = 0.023$ ) and the malignancy ( $P < 0.0001$ ). In addition, in group 3 bleeding was correlated with liver diseases ( $P = 0.001$ ) and in group 4 the correlation was between the bleeding and associated colon rectal cancer ( $P = 0.036$ ) (before or after surgical resection).

Moreover, the statistical analysis performed by NPC showed that bleeding was related to polyp size because the large polyps bled more than small polyps. These results were confirmed by Binary Logistic Regression. However, the 17 procedural bleeding that we recorded were endoscopically resolved without surgery or blood transfusion, so we can, therefore, consider these cases "non important complications". In large polyps, the rate of bleeding observed, 6.2%, is similar to that reported in the greater number of the studies (Table 6). Nevertheless, this data cannot be considered as a real complication, due to the immediate resolution during the same procedure, by endoscopic means.

The incidence of perforation during therapeutic colonoscopies has been reported to range from 0.08%-2.2%<sup>[33]</sup>. The reported incidence of perforation during polypectomy of "normal-sized" polyps ranges from 0.3%-0.5%<sup>[34]</sup>, while the incidence of injury to the colon wall

(transmural burn, microperforation, or free perforation) in large polypectomies is 0 to 1.3% (Table 6)<sup>[3-19]</sup>.

In our study, no perforation was reported in the group of large polyps while the only late perforation (0.07%) occurred, after polypectomy, in a small (15 mm) malignant sessile polyp located in the sigmoid colon and without endoscopic sign of suspected malignancy. During the removal of this polyp, a procedural bleeding occurred, which was immediately managed by application of two hemoclips and the patients' hospitalization. Twenty four hours after the polypectomy, the patient developed lower left quadrant pain, tenderness and radiographic evidence of free air in the peritoneal cavity. The patient underwent surgery for a small (1-2 mm) perforation of the sigma. Unexpectedly, this patient died four days after surgery from respiratory failure secondary to a pleural mesothelioma, unacknowledged and diagnosed the during post mortem examination.

Summarizing, we can conclude that this study, confirming the findings of several others, demonstrates that the endoscopic polypectomy, performed by an expert hand, is safe and effective and should be considered the treatment of choice also for large colorectal polyps.

Polyp size has been identified as an important risk factor for both malignancy and bleeding. Haemorrhage was the most frequent complication even if it remains questionable whether the bleeding should be considered a complication when it occurs during the procedure and is effectively and immediately controlled by endoscopic means. Similarly, in fact, if during a surgical procedure an artery is sectioned and bleeding, this event is not considered a procedural complication because it is treated successfully. It seems likely there will be, in the upcoming future, a growing need for redefinition of the concept of endoscopic operative complications.

## COMMENTS

### Background

The endoscopic polypectomy is a procedure of choice for non-surgical treatment

of polyps and pre-neoplastic lesions in human colon. The most common complications of polypectomy are early or late bleeding and perforation, frequently correlated to the size of polyps and their eventual coexisting early malignancy.

**Research frontiers**

To investigate whether there are new possible risk factors which can be related to or influence the incidence of post-polypectomy complications type and rate.

**Innovations and breakthroughs**

As others, even the present study emphasizes that the endoscopic remotion of large polyps represents a challenging procedure because of its difficulty, thus should be limited to experienced endoscopists due to very high complication rate. Nevertheless, the endoscopic polypectomy in expert hands is safe and effective, and should be considered the treatment of choice both for small and for large colorectal polyps. The modality of post-procedural complications and their better definition are warranted.

**Applications**

Clinical application: the correlation between the incidence of bleeding and the presence of cardiovascular or liver disease stressed the importance of pre-defining and treating comorbidities in patience undergoing endoscopic resection of colonic polyps, no matter their size or supposed histology.

**Peer review**

This is an interesting article that reports the efficacy and complications of colonoscopic resection of colorectal polypoid lesions. This study indicated that the endoscopic resection is a simple and safe procedure for removing colon rectal neoplastic lesions.

### Abstract

**AIM:** To analyze the efficacy of routine intraoperative ultrasound (IOUS) as a guide for understanding biliary tract anatomy, to avoid bile duct injury (BDI) after laparoscopic cholecystectomy (LC), as well as any burden during the learning period.

**METHODS:** A retrospective analysis was performed using 644 consecutive patients who underwent LC from 1991 to 2006. An educational program with the use of IOUS as an operative guide has been used in 276 cases since 1998.

**RESULTS:** IOUS was highly feasible even in patients with high-grade cholecystitis. No BDI was observed after the introduction of the educational program, despite 72% of operations being performed by inexperienced surgeons. Incidences of other morbidity, mortality, and late complications were comparable before and after the introduction of routine IOUS. However, the operation time was significantly extended after the educational program began ( $P < 0.001$ ), and the grade of laparoscopic cholecystitis ( $P = 0.002$ ), use of IOUS ( $P = 0.01$ ), and the experience of the surgeons ( $P = 0.05$ ) were significant factors for extending the length of operation.

**CONCLUSION:** IOUS during LC was found to be a highly feasible modality, which provided accurate, real-time information about the biliary structures. The

### INTRODUCTION

Laparoscopic cholecystectomy (LC) is widely accepted as a standard treatment for symptomatic cholecystolithiasis. However, the incidence of complications in the form of bile duct injury (BDI) is high, and it has been reported to be as high as twice the normal rate<sup>[1,2]</sup>. Once such BDI occurs, it increases postoperative morbidity<sup>[3]</sup> and mortality<sup>[4,5]</sup>, and decreases long-term quality of life<sup>[6]</sup>, which consequently results in a high number of lawsuits<sup>[7]</sup>; therefore, it should be prevented if at all possible<sup>[1,8]</sup>. It is necessary to have a sufficient understanding of the biliary anatomy to prevent BDI<sup>[1]</sup>, yet the damage is often caused by misidentification of the bile duct and other normal structures<sup>[9-11]</sup>. Therefore, the inappropriateness of a procedure is often not discovered until the bile duct has already been injured.

To prevent BDI, intraoperative guidance by intraoperative cholangiography and intraoperative ultrasonography (IOUS) has been suggested. Although cholangiography is effective in diagnosing biliary tract injury, it remains controversial as to whether the routine implementation of cholangiography will prevent BDI<sup>[2,12-15]</sup>. Moreover, intraoperative cholangiography requires a significant amount of hospital treatment to prevent BDI<sup>[6]</sup>. On the other hand, IOUS requires a shorter examination time<sup>[17-19]</sup>, is safe without incurring radiation exposure,

and is minimally invasive<sup>[18,20]</sup>. It has been reported that IOUS allows for visualization equal to or better than that of cholangiography<sup>[17,20-23]</sup> in the case of biliary anatomy and diagnosis of bile duct stones. However, there have been few studies that have investigated whether the routine implementation of IOUS decreases BDI during LC<sup>[24]</sup>. Moreover, a sufficient learning period is considered necessary for IOUS<sup>[25,26]</sup>. However, there have been very few studies on visualization of biliary anatomy, diagnostic performance, or changes in decision-making during the learning period in less-skilled surgeons, or on the extension of operation time caused by the introduction of IOUS.

Therefore, in this study, IOUS was routinely introduced to an educational program for laparoscopic biliary surgery, to analyze its efficacy in helping surgeons avoid biliary tract injury and other complications, and to analyze the extension of operation time during the learning curve.

## MATERIALS AND METHODS

### Patients

Among 664 patients who underwent laparoscopic biliary surgery at the Hirosaki University Hospital from March 1991 to December 2006, 644 were targeted after excluding 20 in whom surgery other than biliary tract surgery was performed. Senior surgeons with experience in laparoscopic surgery in at least 100 cases were in charge from 1991 to 1997 as a rule, but the educational program for laparoscopic biliary surgery began in 1998 to teach young surgeons with experience of less than 30 LCs. Furthermore, IOUS using a linear probe was introduced in October 1992 for the purpose of making an intraoperative diagnosis and as a guide for surgical procedures at the start of a cholecystectomy. IOUS was used on a sporadic basis at first, but it became routine at the start of the educational program in 1998.

Endoscopic retrograde cholangiopancreatography was performed preoperatively on selective cases with icterus or a high level of serum transaminases. Moreover, intraoperative cholangiography was selectively adopted in the earlier period when bile duct stones were suspected by preoperative examination, and was selectively performed in the later period when bile duct stones or variations in biliary distribution were suspected *via* IOUS.

We included 368 cases before the introduction of the educational program and 276 cases after its introduction (Table 1). There was no gender difference. Although the age was significantly higher in the latter term, all cases underwent elective surgery after sufficient assessment of their general health status. There was no significant difference in the indicated disorders for surgery, and cholelithiasis accounted for at least 80% of the cases. The rate of coexisting biliary infection and the diameter of the bile duct measured in the preoperative examination were comparable between the two periods.

These cases were retrospectively assessed for postoperative morbidity and mortality, operation time, and length of hospital stay, as well as late outcomes before and after the introduction of the educational program that adopted IOUS as a routine operative guide.

Table 1 Patient demographic data

	Before routine IOUS (1991-1997)	Routine IOUS (1998-2006)	<i>P</i>
Patient number ( <i>n</i> )	368	276	
Male/Female	140/228	107/169	0.85
Age (yr)	53.3 ± 13.9	57.1 ± 13.6	0.004
Operative indications, <i>n</i> (%)			0.73
Cholelithiasis	296 (80.4)	228 (82.6)	
Cholecystocholedocholithiasis	39 (10.6)	23 (10.5)	
Choledocholithiasis	7 (1.9)	4 (1.4)	
Gallbladder polyp	22 (6.0)	11 (4.0)	
Others <sup>1</sup>	4 (1.1)	4 (1.4)	
Symptomatic gallstones, <i>n</i> (%)	284 (77.2)	220 (79.7)	0.44
Acute cholecystitis/choolangitis, <i>n</i> (%)	42 (11.4)	32 (11.6)	0.94
Bile duct diameter <sup>2</sup> (mm)	8.9 ± 4.2	8.4 ± 3.6	0.12

<sup>1</sup>Other benign processes including chronic cholecystitis and adenomyomatosis, which need whole biopsy of the gallbladder for suspected malignancy.

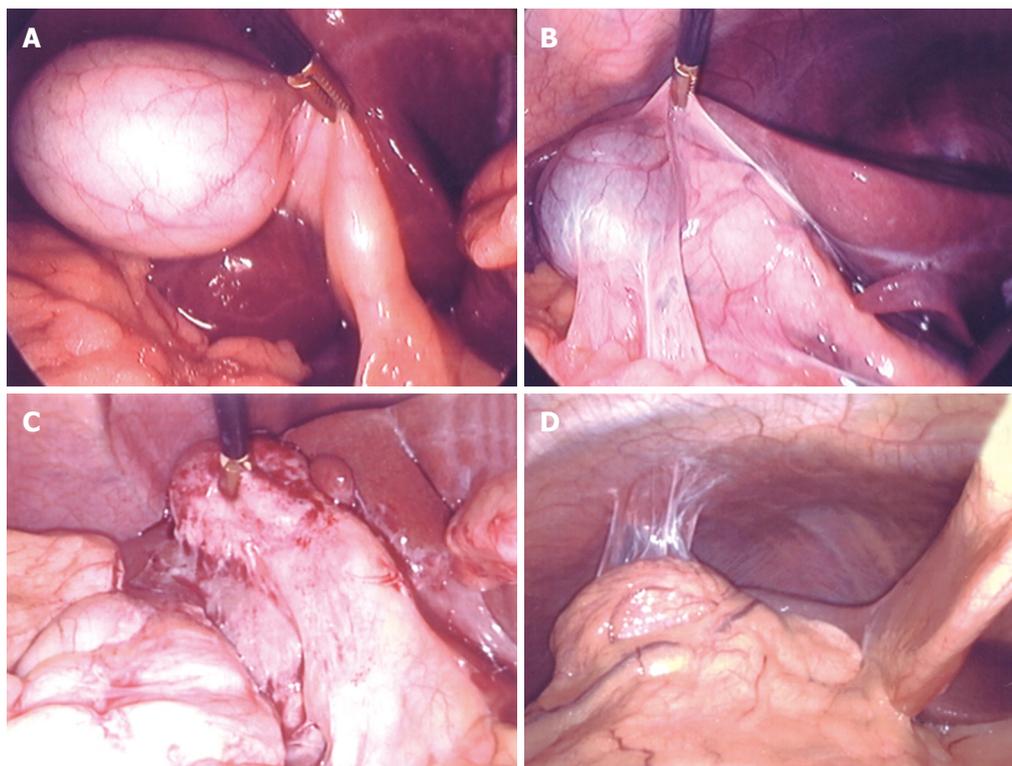

<sup>2</sup>Maximal dimension of the extrahepatic bile duct was measured by drip infusion cholangiography (51%), endoscopic retrograde cholangiography (35%), percutaneous transhepatic cholangiography (4%), magnetic resonance cholangiography (2%), and/or extracorporeal ultrasonography (8%).

For statistical analysis, Student's *t* test,  $\chi^2$  test, and analysis of covariance were used appropriately, and the SPSS 11.0 for Windows was used for the analysis. Statistically, it was determined that *P* < 0.1 indicated a tendency and *P* < 0.05 indicated a significant difference.

### Procedure of IOUS

A deflectable sonographic probe with a linear head of 7-7.5 MHz LAP-703LA (Toshiba-Mochida, Tokyo, Japan), PEF-704LA (Toshiba, Tokyo, Japan) and MH-300 (Olympus, Tokyo, Japan) were used. After pneumoperitoneum, a probe was inserted from a port on the left upper abdomen, and the entire extrahepatic biliary tract from the hepatic hilum to the biliary terminal was scanned, before initiating an exfoliating procedure around the gallbladder. The presence or absence of visualization of the right and left hepatic duct, the common hepatic duct, the common bile duct, the intrapancreatic bile duct, the gallbladder, the cystic duct, and the right hepatic artery were recorded as video recordings and photographs. Next, an intraoperative diagnosis for surgery was made by creating both transverse and longitudinal ultrasonographic images of the gallbladder and the bile duct. When the anatomy at the confluence of the extrahepatic bile duct and the cystic duct could not be sufficiently confirmed due to either acute cholecystitis or adhesion, IOUS was performed during and after the exfoliating procedure and before clipping to avoid duct injury.

In the earlier period, senior surgeons performed IOUS. In the later period, when a senior surgeon performed the operation, a demonstration of the IOUS procedure was given to a junior surgeon. On the other hand, when a junior surgeon performed the operation, they were required to perform IOUS on their own, to understand the biliary anatomy and to make a correct diagnosis. The senior surgeon gave appropriate suggestions or aids, if necessary, according to the junior surgeon's skill.

**Figure 1** Laparoscopic cholecystitis grading. **A:** Normal (G0); **B:** No inflammation with light adhesion (G1); **C:** Marked wall thickening with light adhesion (G2); **D:** Marked inflammation with dense adhesion (G3). Classification of severity of cholecystitis was based on laparoscopic findings to assess the effect of the presence of cholecystitis on intraoperative diagnostic performance and operative performance.

### Laparoscopic cholecystitis grading

Inflammation around the gallbladder affects the visual field in laparoscopic surgery, as well as the level of difficulty of a surgical procedure. Moreover, it may affect diagnostic ability of IOUS. Therefore, laparoscopic cholecystitis grading (LCG) was suggested, based on macroscopic findings at the start of the laparoscopic surgery. The severity of cholecystitis was classified into four grades: G0, normal; G1, no acute inflammation with old fibrous adhesion; G2, marked inflammatory wall thickening with light adhesion; and G3, unidentifiable gallbladder due to dense inflammatory adhesion of the surrounding tissues (Figure 1).

## RESULTS

In the earlier period, senior surgeons performed surgery in 93% of cases, while junior surgeons performed 72%. The average number of operations per surgeon was 5.1 in the later period. IOUS was performed in 19% of cases in the earlier period, but after introduction of the educational program, it was performed in 84% of cases. There was no significant difference in the frequency of anatomical variations of the biliary tree between the two groups (2.7 *vs* 4.3%,  $P = 0.26$ ). According to the cholecystitis grade as determined under laparoscopic view, the degree of cholecystitis was different between the two periods ( $P = 0.03$ ); the percentage with G2 disease was higher in the earlier period, while G3 was higher in the later period. The number of conversions to open surgery due to cholecystitis or adhesion significantly increased in the later period ( $P = 0.007$ ). In the earlier period, there were two cases of BDI treated with hepaticojejunostomy, while in the later period, no patients underwent laparotomy for BDI.

After the educational program began, the operation time increased by an average of 23 min in patients that were treated laparoscopically. There was no difference in surgery for bile duct stones, but in the later period, there was a significant extension of operation time in patients who underwent cholecystectomy ( $P < 0.0001$ ). On the other hand, there was no significant difference in the amount of blood loss between the two groups (Table 2).

An analysis of covariance conducted on the prescribed factors of operative time showed that the degree of LCG ( $P = 0.002$ ), presence or absence of implementation of IOUS ( $P = 0.01$ ), and experience of the surgeon ( $P = 0.05$ ) were significant factors for an extension of operation time after introduction of the educational program. No confounding effect was observed for these three factors (Table 3). The relationship between these three factors and the operation time is shown diagrammatically in Figure 2. The operation time was extended as LCG became more severe, and junior surgeons required more time for IOUS for all LCG compared with senior surgeons. The extension of operation time caused by implementation of IOUS for senior surgeons in the earlier period was 12.7 min ( $78.2 \pm 37.8$  min with IOUS *vs*  $90.9 \pm 32.4$  min without IOUS,  $P = 0.02$ ), while the average extension due to the use of IOUS for junior surgeons was 20.9 min ( $94.3 \pm 43.6$  min *vs*  $115.2 \pm 40.2$  min,  $P = 0.003$ ).

Regarding the frequency of early intraoperative and postoperative complications, the number that required re-operation, and mortality, there was no significant difference between the two periods, despite the fact junior surgeons performed many operations in the later period. Moreover, there were no cases of BDI after introduction of IOUS, and a decreasing tendency was observed ( $P = 0.08$ ). The length of hospital stay was shortened in the later period,

**Table 2** Various operations before and after routine IOUS

	Before routine IOUS (n = 368)	Routine IOUS (n = 276)	P

Surgeon × LCG	0.424	0.736

but it was assumed that a major reason for this included changes in the clinical pathway applied. There was no late bile duct stenosis in the later period (Table 4).

The BDI that occurred in the earlier period included three cases of complete disjunction of the bile duct. All cases were identified for the first time after the bile duct was damaged. In Case 1, the bile duct was severed due to

**Figure 2** Operative time for LC. In an analysis of covariance, LCG, as well as presence and absence of implementation of IOUS, were significant factors that affected operation time. Operation time when IOUS was implemented significantly increased for junior surgeons (all, *P* < 0.01), regardless of LCG, thus requiring approximately double the time in comparison to that of senior surgeons.

**Table 4** Early and late results

Outcome	Before routine use (n = 368)	Routine use (n = 276)	P
Early complication, n (%)			
BDI	4 (1.1)	0	0.08
Arterial bleeding requiring clips	9 (2.4)	5 (1.8)	0.59

Bile duct recurrence	1 (0.3%)	0	0.39
Bile duct stricture	0	0	-

<sup>1</sup>Open hemostasis of postoperative bleeding from the liver bed; <sup>2</sup>Laparoscopic hemostasis of a small arterial bleeding at the port site; <sup>3</sup>Brain stem infarct on POD 4; <sup>4</sup>All treated with percutaneous cholangiofiberscopic lithotripsy through preoperatively-established sinus tracts; <sup>5</sup>Both treated with endoscopic sphincterotomy.

misidentification of the cystic duct, but it was caused by a variant distribution of the cystic duct and the extrahepatic bile duct. In Case 2, because tenting occurred in the common bile duct due to pulling of the gallbladder, the bile duct was misidentified as the cystic duct. Case 3 was caused by variation in the distribution of the biliary tract where the cystic duct joined the accessory hepatic duct. In the remaining case, a small fissure occurred in the hepatic duct during an exfoliating procedure of the severely inflamed gallbladder, and was treated with simple suturing. Furthermore, hepatocholangiojejunostomy was performed during laparotomy in two cases (Table 5).

Regarding the 299 cases in which IOUS was performed, anatomical visualization of IOUS was 100% for the gallbladder, 97.3% for the extrahepatic bile duct, 96.3% for the pancreatic bile duct, 98.5% for the gallbladder duct, and 98.4% for the right hepatic artery.

Table 5 BDI during LC

	Age (yr)/gender	Indication	Anatomical variation	LCG	Type of injury	Repair
1	58/female	Cholecystolithiasis	+ <sup>1</sup>	2	Cutting of the common hepatic duct	Hepaticojejunostomy (Roux-en-Y)
2	43/female	Cholecystolithiasis	-	0	Cutting of the common hepatic duct	Hepaticojejunostomy (Roux-en-Y)
3	86/female	Chronic cholecystitis (cancer suspected)	+ <sup>2</sup>	0	Cutting of the posterior branch of the right hepatic duct	Duct-to-duct anastomosis using an internal stent
4	63/female	cholecystocholedocholithiasis	-	3	A small tear of the common hepatic duct at the dense adhesion to the neck of the gallbladder	Simple suture

<sup>1</sup>The cystic duct ran behind the common hepatic duct and connected with it at the left lateral wall near the pancreas; <sup>2</sup>The cystic duct joined the posterior branch of the right hepatic duct.

Table 6 Diagnostic accuracy of IOUS (%)

	Sensitivity		Specificity		PPV		NPV		Overall accuracy	
	Pre-op	IOUS	Pre-op	IOUS	Pre-op	IOUS	Pre-op	IOUS	Pre-op	IOUS
Anatomical variation	25	100	100	100	100	100	96	100	96	100
Cholecystolithiasis	99	100	100	100	100	100	87	100	99	100
Bile duct stone	76	76	100	99	100	93	95	95	96	95
Polyps	77	82	98	98	77	75	98	99	97	97
Others	50	81	93	95	70	82	86	94	83	92

PPV: Positive predictive value; NPV: Negative predictive value; Pre-op: Preoperative image studies; Anatomical variation: Anatomical variation of the extrahepatic bile duct. Preoperative image studies included extracorporeal ultrasonography (100%), computed tomography (73%), endoscopic retrograde cholangiopancreatography (51%), drip infusion cholangiography (42%), magnetic resonance cholangiopancreatography (20%), and/or percutaneous transhepatic cholangiography (5%).

The diagnostic performance of IOUS regarding the indicated disorders was equal to preoperative diagnostic imaging, but 10 cases determined to have no bile duct stones *via* preoperative diagnostic imaging were diagnosed to have complications of choledocholithiasis *via* IOUS, which turned out to be useful for making changes in the operation policy (Table 6). Biliary tract anatomy was visualized in almost all patients with G0-G2 laparoscopic cholecystitis, whereas visualization remained at 88% for G3 disease (Table 7).

Table 7 Ultrasonographic visualization of the biliary and arterial structures according to the laparoscopic cholecystitis grading (%)

	G0	G1	G2	G3	P value
Gallbladder	100	100	100	100	-
Cystic duct	100	95.6	100	91.4	0.001

Right hepatic artery	100	97.5	100	89.3	0.0004

## DISCUSSION

In the educational program for laparoscopic biliary surgery with IOUS as a guide, no cases of BDI were observed, despite the fact that less-skilled surgeons performed the operation in 72% of patients.

BDI is mostly caused by anatomical misidentification of the bile duct<sup>[9-11]</sup>. In addition, it is frequently caused by less-skilled surgeons<sup>[27,28]</sup>. The reasons for this misidentification are that laparoscopic surgery is performed in a two-dimensional world without any touch sensation, and that young surgeons have fewer opportunities to understand the anatomy of the biliary tract in abdominal surgery. Therefore, auxiliary means to improve understanding of the biliary tract anatomy is necessary to avoid BDI.

Cholangiography is an effective method for understanding biliary tract pathology<sup>[2,5,14]</sup>. However, its preventive effect against BDI is controversial<sup>[12,13,15]</sup>, because a randomized control trial has not yet been conducted. Moreover, cholangiography has an unavoidable risk that examination can cause ductal injury during cannulation. Furthermore, there is the problem that BDI

cannot be prevented in patients in whom the cystic duct merges into the accessory bile duct, as in our Case 3.

IOUS, on the other hand, is a less-invasive procedure than cholangiography. It can be performed in most cases more quickly and repeatedly, without any damage to the biliary tree<sup>[17-20]</sup>. Moreover, it does not require new X-ray apparatus, radiologists, or laboratory technicians. Many studies, including two randomized control trials, have reported that visualization of the biliary tract anatomy and diagnostic performance of IOUS for bile duct stones are as high, or better, than those for cholangiography<sup>[17,21-23]</sup>. It has also been reported that IOUS decreases the necessity to perform cholangiography<sup>[29,30]</sup>.

However, it is necessary to learn properly and fully the technique of implementing IOUS<sup>[25]</sup>. Falcone *et al*<sup>[26]</sup> have reported it is necessary to learn the procedure from at least 10 cases. While there are many reports on the efficacy of IOUS, there has been no analysis on the clinical outcome and the time burden in these learning curve periods needed for IOUS.

Therefore, we introduced routine IOUS to laparoscopic

surgery for the purpose of educating less-skilled surgeons regarding the anatomy of the biliary tract and avoidance of BDI. IOUS was able to be implemented in all cases, and the visualization ability for the extrahepatic bile duct was almost 100%. The diagnostic sensitivity for abnormal distribution of the biliary tract also significantly improved to 100% through the concomitant use of IOUS, from 25% by preoperative examinations only. Consequently, an abnormal distribution or tenting of the biliary tract was identified in all of our patients before the exfoliating procedure and other invasive procedures such as clipping of the cystic duct, so BDI was avoided. Moreover, the incidence rate of postoperative morbidity and mortality in the latter stages did not increase, despite operations being performed by less-skilled surgeons.

While IOUS has high feasibility, there is a concern that inflammatory processes around the gallbladder may reduce visualization of the biliary anatomy. Therefore, an LCG system was suggested to study the visualization rate of the biliary structures according to the degree of cholecystitis. In G0-G2, the confluence of the cystic and bile ducts was confirmed within the hepatoduodenal ligament in almost all cases. Biliary tract injury due to misidentification occurs frequently in cases without or with mild-to-moderate cholecystitis, therefore, IOUS is expected to have an effect in preventing biliary tract injury. On the other hand, for severe cholecystitis (G3), the gallbladder was identified in all cases, but the visualization rate of the extrahepatic bile duct and cystic duct decreased to 88%. In patients in whom the bile duct was visualized *via* IOUS, laparoscopic surgery was performed safely, but in cases in which the bile duct could not be identified, insufficient identification of the bile duct was determined to be the reason for conversion to laparotomy. Therefore, the number of cases converting to a laparotomy increased in the later period, which had a higher percentage of G3 disease.

After the introduction of the educational program for laparoscopic biliary surgery, the operative time became significantly extended. Higher LCG, implementation of IOUS, and performance by an inexperienced surgeon were independent factors that significantly extended the operation time. The operation time with a junior surgeon was extended by an average 20.9 min, after implementation of IOUS, which was approximately double the time in a previous study of 10 min<sup>[17]</sup>. In addition to the technical demonstration of IOUS by senior surgeons, junior surgeons were required to perform IOUS again and record all the biliary structures on a check list. Moreover, the extended time required for IOUS implementation was calculated by measuring the total operation time, which included the time required for preparation and recording of IOUS, unlike in previous studies in which only the time of implementing IOUS was recorded<sup>[17,19,22]</sup>. Consequently, a longer period of time was recorded in this study, especially when junior surgeons operated.

In any educational programs, the burden on the patient must be within acceptable limits. The extended time required for IOUS is believed acceptable compared with the time required for cholangiography<sup>[17-20]</sup>, along with the advantage of increasing the possibility of avoiding

biliary tract injury. Of course, it is necessary to analyze the economic efficiency of the introduction of IOUS. The system of paying medical expenses in Japan has largely changed during the past 10 years, therefore, it is difficult to directly compare expenses. However, after the introduction of this educational program, the frequency of complications did not increase, and the frequency of BDI tended to decrease. Therefore, an extension of operation time was the only economic disadvantage, and the increase in expenses was moderate. Furthermore, the amount invested in probes for IOUS is small, and cost effectiveness is higher than that of cholangiography.

This study had prospective data collection but it did not constitute a randomized control trial. Moreover, because the decrease in frequency of BDI remained at  $P = 0.08$ , the benefit of the education program for using IOUS cannot be concluded. Furthermore, to confirm the educational outcomes, it is necessary to conduct a follow-up review on the performance of subsequent laparoscopic biliary tract surgery performed by a physician who has completed the educational program. It will therefore be necessary to assess the benefits of this educational program for laparoscopic biliary surgery using IOUS after more extensive randomized control trials.

## ACKNOWLEDGMENTS

The authors thank Dr. Masaaki Endoh, previous chair of the hepatobiliary-pancreatic surgery division, for his contribution to the introduction of an IOUS-guided educational program for laparoscopic biliary surgery at our institute.

## COMMENTS

### Background

Bile duct injury (BDI) following laparoscopic cholecystectomy (LC) occurs at a rate twice that observed after open surgery, and misidentification of the biliary tract structures is the major cause of BDI. Intraoperative ultrasound (IOUS) is less invasive and reportedly has an equal or higher visualization ability of the biliary tract anatomy in comparison to cholangiography.

### Research frontiers

In this study, the authors developed a new educational program for laparoscopic biliary surgery by introducing IOUS routinely as a guide for anatomical understanding, and analyzed its efficacy in enabling surgeons to avoid BDI and other complications, as well as any burden during the learning period.

### Innovations and breakthroughs

Under the IOUS-guided educational program, no case of BDI was observed, despite the fact that less-skilled surgeons performed the operation in 72% of patients. Excess operation time was minimal. IOUS was feasible even in the presence of severe cholecystitis.

### Applications

The educational program using IOUS is expected to minimize the incidence of BDI following LC, especially when performed by less-skilled surgeons, by giving them accurate, real-time information about the biliary tract structures.

### Peer review

This study is very interesting, as it appeared to explore a good alternative to intraoperative cholangiography. In general, this clinical research was well performed and the results were convincing.

### Abstract

**AIM:** To investigate changes in numbers and proliferative function of splenic lymphocytes in patients with hypersplenism due to portal hypertension (PH), to provide evidence for further study of immune status of the spleen during PH.

**METHODS:** Twelve spleens from patients with hypersplenism due to PH served as the PH group, and four spleens from cases of traumatic spleen rupture were regarded as the control group. After weighing the spleen, lymphocytes were separated and counted using a cell counting plate to calculate the lymphocyte count per gram of spleen tissue (relative quantity) and total lymphocyte count in whole spleen (absolute quantity). The immunohistochemical SP method was used to observe the density and distribution of lymphocytes in the spleen. The MTT method was used to observe changes in lymphocyte proliferative function.

**RESULTS:** As compared to the control group, the splenic lymphocytes in the PH group showed that: (1) There was no difference in distribution but a significant decrease

in density; (2) the number of lymphocytes per gram of spleen (relative quantity) decreased significantly [ $(0.822 \pm 0.157) \times 10^8$  vs  $(1.174 \pm 0.254) \times 10^8$ ,  $P < 0.01$ ]; (3) with the significant increase in the weight of the PH spleen ( $832.6 \pm 278.2$  g vs  $211.7 \pm 85.6$  g,  $P < 0.01$ ), the total quantity of lymphocytes (absolute quantity) increased significantly [ $(0.685 \pm 0.072) \times 10^{11}$  vs  $(0.366 \pm 0.057) \times 10^{11}$ ,  $P < 0.01$ ]; and (4) the proliferative function of lymphocytes was enhanced: T lymphocytes, ( $0.022 \pm 0.005$  vs  $0.015 \pm 0.003$ ,  $P < 0.05$ ), and B lymphocytes ( $0.034 \pm 0.006$  vs  $0.023 \pm 0.001$ ,  $P < 0.01$ ).

**CONCLUSION:** Although lymphocyte density in the spleen decreased in patients with PH, the total quantity of lymphocytes increased because spleen weight increased greatly, along with the proliferating function. With respect to changes in lymphocytes, PH spleens may still have immune function, although it may be disordered. However, complete evaluation of the immune function of the spleen in PH requires more research.

Changes in count and function of splenic lymphocytes from patients with portal hypertension. *World J Gastroenterol* 2008; 14(15): 2377-2382 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2377.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2377>

### INTRODUCTION

Lymphocytes reside in different organs in the human body. They circulate through the primary lymphoid organs (thymus and bone marrow), secondary lymphoid organs (spleen, lymph nodes, tonsils and Peyer's patches), as well as non-lymphoid organs such as blood, lung and liver. Especially in lymphoid organs, lymphocyte subsets migrate and home to different compartments. About 15%-20% of the blood volume circulates through the spleen at any one time and about 15% of the lymphocytes reside in this organ<sup>[1,2]</sup>.

Therefore, lymphocytes are the immunocytes that have the highest count in the spleen. Their functional status directly influences the immune function of the spleen<sup>[3-5]</sup>.

Currently, there is still some dispute on the immune status of the spleen in patients with portal hypertension (PH)<sup>[6,7]</sup>. We have isolated splenic macrophages and demonstrated that their phagocytosis is enhanced in PH spleens<sup>[8-10]</sup>, but there is little compelling experimental evidence on the distribution, count and function of lymphocytes in the PH spleen. In this study, we isolated and cultured splenic lymphocytes from PH spleen, and observed changes in their density, distribution, count, and proliferative function using the immunohistochemical SP method and 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT).

## MATERIALS AND METHODS

### Patients

Two groups of patients were studied. Twelve patients (median age 46.8 years, range 27-62 years; eight male and four female), with hypersplenism due to PH, in our hospital from September 2005 to March 2006, were included as the PH group. All patients underwent pericardial devascularization with splenectomy. Supporting evidence for hypersplenism due to PH and cirrhosis included clinical features, abnormal laboratory tests, and postoperative pathological examination. Four patients (median age 33.5 years, range 18-38 years; three male and one female) with traumatic rupture of the spleen were enrolled into the control group. Hepatitis, cirrhosis, history of hypersplenism, and abnormalities in postoperative laboratory findings and pathological examinations were absent in the controls. All patients provided written informed consent, and the protocol was approved by the ethics committee of our hospital.

### Lymphocyte count in the spleen

Spleens were weighed after removal from patients. The splenic tissue samples were cut from the upper pole, lower pole, and hilum, and were transferred to the cell culture room, and kept in sealed aseptic bottles filled with 4°C precooled PBS. Further preparations were made: Weighing 5 g tissue with an electronic balance, using a 200-mesh screen to grind the tissue sample into cell suspension, and purifying the lymphocytes with lymphocyte separating medium by gradient centrifugation. After preparation, lymphocytes were counted using a cell counting plate. The lymphocyte count per gram of spleen tissue (relative quantity) was then calculated and multiplied by the weight of the spleen to derive the total lymphocyte count in the spleen (absolute quantity).

### Density and distribution of lymphocytes

The splenic tissue samples were cut from the upper pole, lower pole, and hilum, fixed in phosphate buffer (pH 7.2) containing 4% paraformaldehyde, embedded in paraffin wax, and sectioned at 5 μm. CD3 and CD20 SP method staining was adopted to show T and B lymphocytes, respectively. Periarterial lymphatic sheath (PALS), splenic corpuscle (F), red pulp (RP), and marginal zone (MZ) of spleen tissue were

observed. Five fields of vision were also randomly observed in each part. Positive cells were counted respectively. For the negative control, the primary antibody was replaced by PBS.

### Proliferative function of lymphocytes

Lymphocytes with RPMI1640 culture solution containing 10% fetal calf serum were placed in 96-well flat-bottomed microplates in triplicate at  $2 \times 10^5$  cells/well, then concanavalin A (Con A) or lipopolysaccharide (LPS; both from Sigma, St. Louis, MO, USA) was added to the wells at a final concentration of 10 μg/L and 20 μg/L, respectively. The cells were then incubated in a total volume of 200 μL/well. Serum-free RPMI-1640 medium was used as a control. Cell proliferation was measured by MTT assay 44 h after culture. MTT (Sigma) solution of 20 μL (5 g/L) was added to each well. After 4 h incubation, the cells were lysed and the purple formazan crystals were solubilized. We then measured  $A_{570}$  of each well on an enzyme labeling instrument, and the proliferation level was calculated. Proliferation level = experimental group  $A$  (ConA or LPS) - negative control group  $A$ .

### Statistical analysis

$P$  values were calculated using the independent sample  $t$  test and considered significant at  $P < 0.05$ . All the results were represented by mean  $\pm$  SD.

## RESULTS

### Change in density and distribution of lymphocytes

The distribution of T and B lymphocytes was almost the same in PH spleen as in normal spleen (Figures 1 and 2). Cell counts in single fields of view were significantly less in PH spleen than in normal spleen (Table 1, Figures 3 and 4).

### Change in lymphocyte count

Lymphocyte count was significantly less in PH spleen (relative quantity) than in normal spleen. However, with the increase in spleen weight, lymphocyte count of whole spleen (absolute quantity) was significantly greater in PH spleen than in normal spleen (Table 2).

### Change in lymphocyte proliferative function

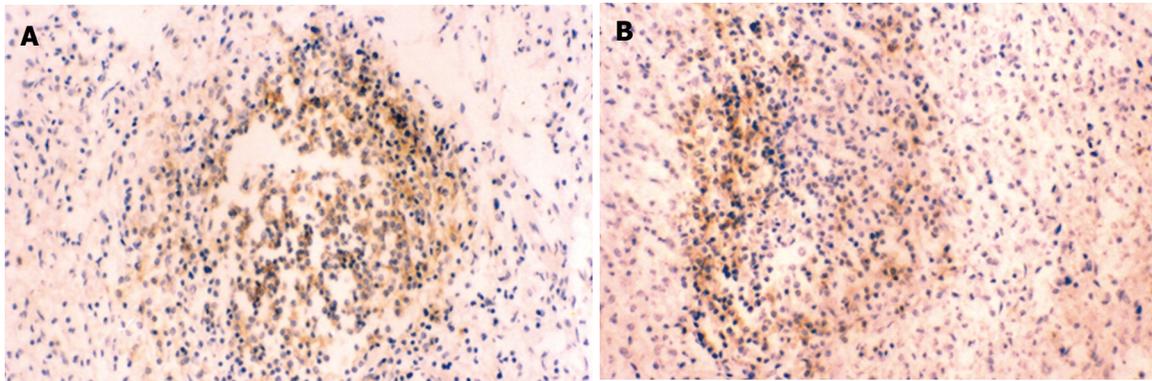

The proliferative function of T and B lymphocytes was significantly higher in PH spleen than in normal spleen (Table 3).

## DISCUSSION

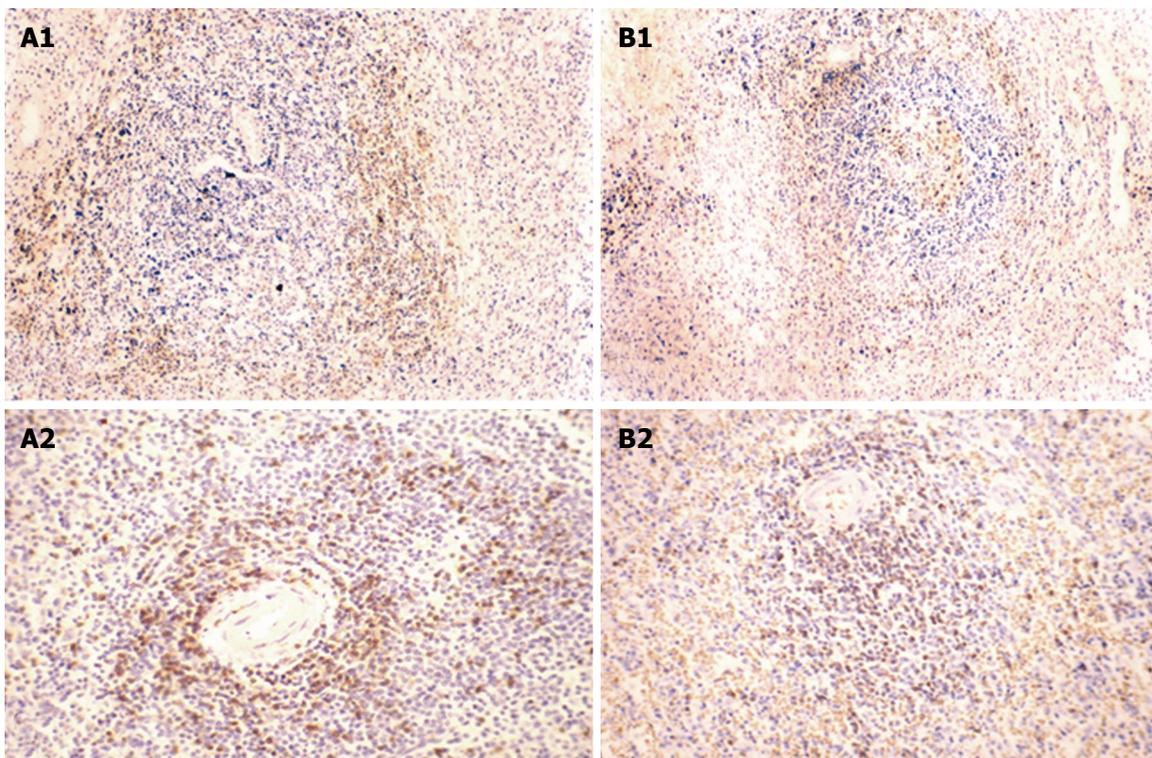

At present, the immune function of the PH spleen is still the subject of some dispute<sup>[7,11,12]</sup>. It is unclear if the preservation of splenic tissue with splenomegaly is beneficial to patients with PH and cirrhosis<sup>[13-15]</sup>. The lymphocytes are important immunocytes in the spleen. The spleen can participate in specific immunity through T-cell-mediated cellular immunity and B-cell-mediated humoral immunity<sup>[16-18]</sup>. Therefore, the evaluation of changes in lymphocyte count and functions in PH spleen is extremely important to an in-depth study of the immune status of the spleen in PH.

Table 1 Changes in density of lymphocyte in PH spleen

Group	T lymphocytes				B lymphocytes			
	F	MZ	PALS	RP	F	MZ	PALS	RP
PH	89.5 ± 14.7	120.0 ± 14.1	122.9 ± 12.1	12.2 ± 2.9	356.5 ± 31.2	138.0 ± 19.5	113.8 ± 21.6	7.4 ± 1.7
Control	126.5 ± 19.3	140.5 ± 11.6	137.0 ± 6.2	20.45 ± 4.5	418.3 ± 22.4	196.0 ± 22.0	153.8 ± 25.8	12.8 ± 4.6

**Figure 1** CD20 immunostaining for distribution of B lymphocytes. There was no significant difference in distribution of B lymphocytes between PH and control groups; they were all mainly located in the splenic corpuscle. **A:** Control group; **B:** PH group ( $\times 100$ ).

**Figure 2** CD3 immunostaining for distribution of T lymphocytes. There was no significant difference in distribution of T lymphocytes between PH and control groups; they were all mainly located in the marginal zone and PALS. **A1:** Control group, marginal zone; **A2:** Control group, PALS; **B1:** PH group, marginal zone; **B2:** PH group, PALS ( $\times 100$ ).

Lymphocytes include T and B lymphocytes. CD3 and CD20 are important differentiation antigens on T- and B-cell membranes. CD3 and CD20 immunohistochemical staining is ideal for analyzing the distribution and count of T and B lymphocytes in tissue<sup>[19]</sup>. Wang *et al* have used the

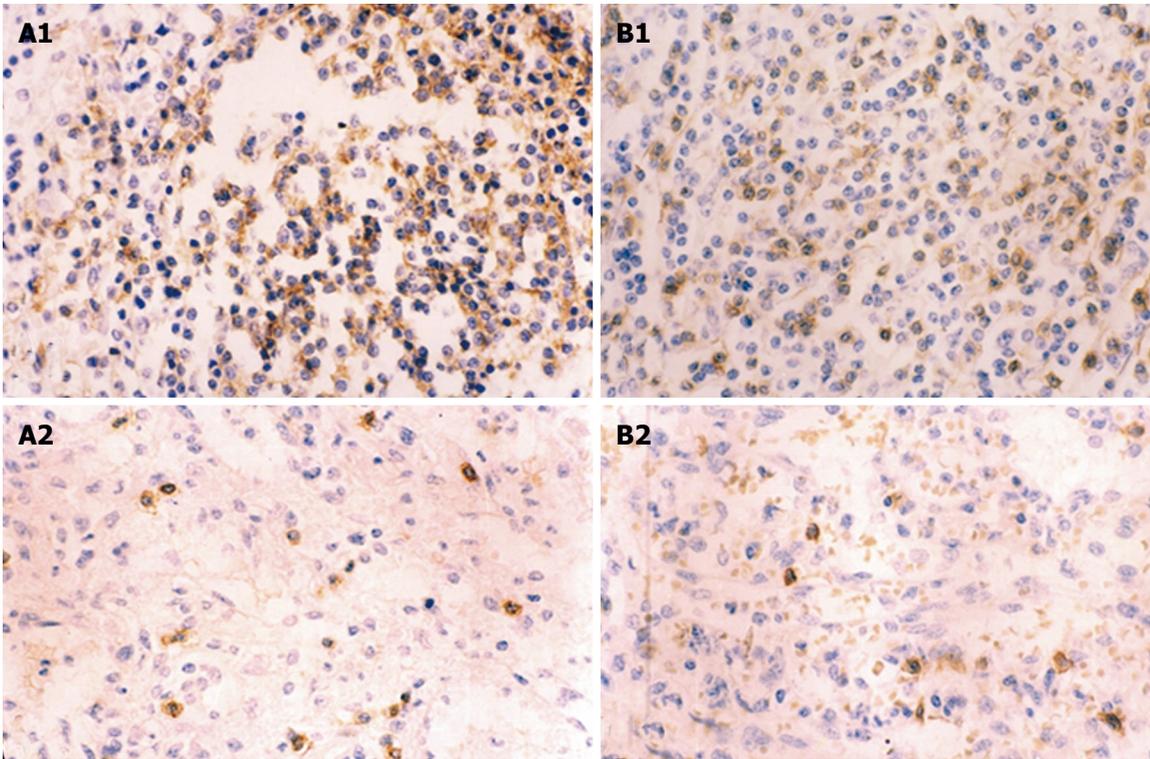

method to observe lymphocytes in pathological sections of PH spleen. They believe that in PH splenomegaly, lymphocyte density in the spleen decreases, which results in a decrease in lymphocyte count<sup>[20]</sup>. We also found in our experiment that the distribution area of lymphocytes had

almost no differences between PH and normal spleens, while the lymphocyte density was significantly lower in the PH spleen. However, the lymphocyte density seen in a single microscopic field of view cannot represent the total lymphocyte count in the spleen. Therefore, in this

study, we purified and counted lymphocytes in the spleen, and then calculated lymphocyte count per gram of spleen tissue (relative quantity) and lymphocyte count in whole spleen (absolute quantity). This made the result more scientific and accurate. The results showed that although

the relative lymphocyte count per gram of spleen tissue was less in the PH spleen than that in normal spleen, as spleen weight increased greatly, the total lymphocyte count in whole spleen was significantly higher in the PH spleen than that in the normal spleen.

In addition, the proliferation of T and B lymphocytes is known as a response to stimulation induced by antigen or mitogens. The proliferative function is one of the important indices of lymphocyte immune function. Shi *et al* have reported that the expression of proliferating cell nuclear antigen (PCNA) in PH spleen is strongly positive in the lymphocyte aggregation area, which indirectly reflects the high proliferation status of lymphocytes<sup>[21]</sup>. PCNA is isolated as a protein with elevated levels during S-phase of the cell cycle. Its expression level may be a marker of the S-phase and represent the proliferative function of cells<sup>[22]</sup>. However, PCNA immunohistochemical staining cannot precisely distinguish S-phase and non-S-phase PCNA-positive cells under a light microscope<sup>[23]</sup>. The result has limited reliability in reflecting lymphocyte proliferation. Furthermore, sample fixation, immunostaining, and other laboratory procedures have certain influences on the demonstration of PCNA. While cellular multiplication induced by Con A is commonly used to detect T lymphocyte immunity *in vitro*, LPS-induced activation of B cells and subsequent immunoglobulin synthesis reflect B-lymphocyte immunity<sup>[24]</sup>. Therefore, the proliferative function of T and B lymphocytes was evaluated by MTT assay after being stimulated with LPS and Con A, respectively. The proliferative function of lymphocytes was also significantly higher in PH spleen than in the normal control group.

The total count and proliferative function of splenic lymphocytes increased in PH spleen. A possible reason is that long-term contact between noxious substances, such as endotoxin and hepatitis virus, and spleen tissue has promoted activation and hyperplasia of lymphocytes in the spleen<sup>[16,25]</sup>. Also, this contact has enhanced its function to maximize the elimination of toxins in the body and maintain body balance<sup>[26-29]</sup>. From this perspective, PH spleen has not completely lost immune function but does have some disorder. However, the immunological mechanism of the spleen is quite complicated. Hence, to confirm whether PH spleen has normal immune function<sup>[30]</sup> and to achieve precise evaluation of the immune function of the PH spleen, further research should be conducted.

## COMMENTS

### Background

A better understanding of the function of the spleen has been gained recently, owing to in-depth studies on its structure, cellular function, secretion and innervation. It is generally accepted the spleen is an important part of the regulatory network between the immune, nervous and endocrine systems. The spleen has many more functions besides blood filtering and storage, hematogenesis, and immunization, and its immune function has characteristics of both "two-way" and "phase". Present knowledge about the immune function of the spleen in patients with PH is still incomplete; it is unclear whether preservation of splenic tissue with splenomegaly is beneficial to patients with PH and cirrhosis. Lymphocytes play a key role in the immune function of the spleen. Studies on splenic lymphocytes will be helpful for precise evaluation of spleen function, especially in a pathological state.

### Research frontiers

It has previously been reported that phagocytosis of macrophages is enhanced

in the PH spleen, but there is little compelling experimental evidence on the distribution, count, and function of lymphocytes in the PH spleen.

### Innovations and breakthroughs

This study proved the total quantity and the proliferating function of lymphocytes were increased. It suggests that the PH spleen may still have immune function, although perhaps with some disorder.

### Applications

Although this was an initial study on the changes in lymphocytes in the spleen in PH, it may offer new evidence for complete evaluation of the immune function of the PH spleen.

### Peer review

The authors investigated changes in the number and proliferative function of splenic lymphocytes in patients with PH. This was a very interesting study.

### Abstract

**AIM:** To analyze the metallochaperone antioxidant-1 (Atox1) gene sequence in Wilson disease patients.

**METHODS:** Mutation analysis of the four exons of the Atox1 gene including the intron- exon boundaries was performed in 63 Wilson disease patients by direct sequencing.

**RESULTS:** From 63 selected patients no mutations were identified after the entire coding region including the intron- exon boundaries of Atox1 were sequenced. One known polymorphism within the Atox1 gene (5'UTR -99 T>C) in 31 (49%) of the Wilson patients as well as one previously undescribed variation (5'UTR -68 C>T) in 2 of the Wilson patients could be detected. Statistical analyses revealed that the existence of a variation within the Atox1- gene showed a tendency towards an earlier onset of the disease.

**CONCLUSION:** Based on the data of this study, no major role can be attributed to Atox1 in the pathophysiology or clinical variation of Wilson disease.

### INTRODUCTION

Copper is an essential trace element for prokaryotes and eukaryotes. It acts as a cofactor for a number of proteins such as cytochrome c oxidase, dopamine  $\beta$ -hydroxylase (production of catecholamines), superoxide dismutase (free radical detoxification), lysyl oxidase (cross-linking collagen and elastin) and ceruloplasmin<sup>[1]</sup>. At the same time, excess or free copper is toxic to the cell.

The inherited disorders of copper metabolism Menkes and Wilson disease (WD) result from a disturbance of copper balance, resulting in either a deficiency (Menkes) or an accumulation of copper (WD) in the body<sup>[2]</sup>. WD occurs in about one of 30 000 people<sup>[3-5]</sup> and is characterized by the accumulation of copper primarily in the liver but also in the brain, kidney, cornea (Kayser-Fleischer-Rings), and spleen. WD is caused by a genetic defect in the ATP7B gene, located on chromosome 13q14.3<sup>[6]</sup>. This gene encodes a polytopic membrane protein containing several motifs characteristic of P-type ATPases, highly expressed in the liver<sup>[7]</sup>. Under steady-state conditions the gene product of ATP7B WNDP (Wilson's disease protein) resides in the trans-Golgi network (TGN)<sup>[8]</sup> where it delivers copper to such secreted copper-dependent enzymes as ceruloplasmin. As the copper content of the hepatocytes increases, this ATPase moves from the TGN to a cytoplasmic vesicular compartment near the canalicular membrane. As copper is transported into this compartment, the intracellular copper concentration falls and the WNDP is recycled back to the TGN while copper is exported from the cell<sup>[9]</sup>.

There are more than 230 mutations in ATP7B<sup>[10]</sup> accounting for Wilson Disease, and no mutation is predominant<sup>[11]</sup>. Patients present, typically between the ages of 5 and 40 years, with quite various hepatic (40%), neurological (40%), psychiatric (14%-18%) or other symptoms<sup>[12,13]</sup>. Although the specific type of mutation might have in part influence on disease severity, even patients with identical mutations show high clinical variability regarding the age of onset, signs and syndromes, ceruloplasmin levels, hepatic copper levels and presence of Kayser-Fleischer-rings<sup>[14,15]</sup>. The following factors are

known to influence the disease: There are certain sex-specific differences: female patients for example show a higher prevalence of acute liver failure than male patients. Schiefermeier *et al* reported that an APO E ε3/3 genotype delays the onset of signs and symptoms<sup>[16]</sup>. Merle *et al* described influence on onset of symptoms of Wilson disease depending on prion protein status<sup>[17]</sup>. It has been proposed that genes influencing human copper metabolism might modify the clinical picture caused by a mutated Wilson disease gene.

As noted above copper is not free within the cell<sup>[18]</sup>. The trafficking of copper from donor and acceptor proteins is mediated by a unique class of proteins termed copper chaperones<sup>[19,20]</sup> that were first identified in the yeast *Saccharomyces cerevisiae*. The yeast ATX1p encodes a small cytosolic copper-binding protein that binds copper via the copper-binding MxCxxC motif and delivers this metal to CCC2<sup>[21]</sup> - the yeast homologue of WNDP - for subsequent transport into the secretory pathway and incorporation into the ceruloplasmin homologue FET3<sup>[22]</sup>. The human homologue Antioxidant-1 (Atox1) is an 8 kDa cytosolic protein that contains a single copy of the highly conserved MxCxxC motif<sup>[23]</sup> in the amino terminus that is repeated 6-fold in WNDP. This metallochaperone interacts directly with the Wilson ATPase<sup>[2]</sup> and can regulate its copper occupancy<sup>[24]</sup>. By modulating the amount of copper bound to the protein Atox1 can regulate the intracellular localization<sup>[25]</sup>, the posttranslational modification<sup>[26,27]</sup> and the enzymatic activity of WNDP<sup>[24]</sup>.

## MATERIALS AND METHODS

### Patients

The Genomic DNA of 63 WD patients was sequenced, which include 42 female and 21 male patients. The average age was 34 years (19-56). Twenty eight (44%) patients presented primarily with hepatic symptoms (including elevated liver enzyme test, ascites, liver cirrhosis, and acute liver failure), 20 (32%) patients primarily with neurological symptoms, 7 (11%) patient with both, 8 (13%) patients were diagnosed preclinically by family screening.

In all patients the definitive diagnosis of WD was established either by DNA analysis or by typical clinical and laboratory constellations [reduced copper levels (< 10 μmol/L) and ceruloplasmin levels (< 0.2 g/L) in the serum, raised free plasma copper levels, increased urinary copper excretion (≥ 2 μmol/24 h), detection of Kayser-Fleischer-rings, elevated hepatic copper concentrations (> 250 μg/g dry tissue)] or both. The ATP7B gene has been sequenced in most patients in part so far in cooperation with Professor Ferenci, Department of Gastroenterology and Hepatology, Vienna, including the analysis of the H1096Q mutation status in all patients and sequencing of exons 8, 13, 14, 15 and 18 in most patients not homozygous for H1096Q. In 36 patients two mutations could be detected within the Wilson disease gene. In 16 patients one mutation and in 11 patients no mutations could be detected within the Wilson gene so far.

### Methods

Genomic DNA was isolated from peripheral EDTA-

Table 1 Oligonucleotide primers used to amplify Atox1

Exon	Sequence	Fragment size
Exon 1-Forward primer	5'-GGAGTGGGAGGGGC CTCCGGGACC-3'	273 bp
Exon 1-Reverse primer	5'-GTAAGCTAGGGGAC AACAGCGCTC-3'	
Exon 2 - Forward primer	5'-GCACITGTGGGGG TCACTCTACAG-3'	320 bp
Exon 2-Reverse primer	5'-GTGAGGATTAATG ATGTGATTCAC-3'	
Exon 3-Forward primer	5'-GAACTCTTCTTGCT GTAACGGGAG-3'	344 bp
Exon 3-Reverse primer	5'-GAGGGCTCTCCCGC TCCAACAAG-3'

Exon 4-Reverse primer	5'-GATCACACAGCAA AGAATCAGAATC-3'	

blood using the QIAamp® DNA Blood mini Kit (Quiagen, Hilden/Germany) according to the manufacturer's instructions.

The four exons of the gene including the intron-exon boundaries were amplified by PCR, using the Oligonucleotide primers shown in Table 1, designed from the published cDNA sequence of the human homologue of Atox1 gene<sup>[23]</sup>.

The 50 μL volume of each PCR reaction contained 100 ng of template DNA, 500 μmol/L of each oligonucleotide primer, 200 μmol/L each dNTP, 2.5 units of Stratagene Pfu-DNA Polymerase (Qiagen, Hilden, Germany) in 10 × QIAGEN PCR Buffer (Qiagen, Hilden).

PCR reactions were performed in a Progene FPROG050 cycler (Techne, Cambridge/ UK) starting with the initial denaturation of the DNA at 95°C for 10 min; followed by 45 cycles (exon 1, 3, 4)/40 cycles (exon 2) of: 45 s denaturation at 95°C, 45 s annealing at 60°C (Exon 1)/56.5°C (Exon 2)/50°C (Exon 3 + Exon 4) and 1 min extension at 72°C, then with a final extension of 72°C for 10 min.

PCR products were purified with the MinElute™ Purification Kit (Quiagen, Hilden/Germany). The sequencing reaction was performed by SEQLAB (Sequence Laboratories Göttingen, Göttingen/Germany).

Sequences obtained by sample sequencing were compared with <http://www.ncbi.nlm.nih.gov/BLAST>.

### Statistical analyses

Statistical analyses were performed with the SPSS, version 13.0 (Statistical Package for the Social Science, SPSS Inc., Chicago, IL, USA.). *P* < 0.05 was taken as significant.

## RESULTS

We analysed Atox1 in 63 WD patients, diagnosed either by DNA analysis or by typical clinical constellations.

There could be no alterations in the Atox1 coding exon sequence or splice junction sequence be detected in any of these individuals.

Direct sequencing of the Atox1 gene within the 5'-UTR region located before exon 1 of the 63 Wilson disease

m.n.d.: Mutation not detected.

patients examined revealed one known polymorphism within the Atox1 gene in 31 (49%) of the Wilson patients (Table 2). Thirty one of 63 (49%) Wilson patients had detectable Atox1 gene changes, with the heterozygous T/C at 5'UTR -99 being the most common with 22 (35%) patients.

In 2 Wilson patients the previously undescribed 5'UTR -68 C>T (heterozygote) genetic variation could be detected.

Seven of the 11 patients where no Wilson disease gene mutation could be found so far and 8 of the 16 patients with a single identified Wilson disease gene mutation showed one of the variations in Atox1.

### 5'UTR -99 T>C

This polymorphism 5'UTR -99 T>C (Figure 1A) is already described in the database (NCBI Sequence Viewer: NM\_004045: "dbSNP: 1549921"). 35% (22 patients) showed this substitution of the base T by C heterozygous, the other nine patients (14%) were homozygous for this variation.

Among these 22 patients with the heterozygous variation 7 persons presented with primarily hepatic symptoms, 7 patients with primarily neurological symptoms, and 3 patients with hepatic and neurological symptoms. Five were presymptomatic at diagnosis.

The nine patients with homozygous variation are composed of 3 patients with primarily hepatic symptoms, 3 persons with primarily neurological symptoms, 1 patient with hepatic and neurological symptoms, and 2 patients diagnosed preclinically by family screening (Figure 1B).

The heterozygote variation could also be found in one healthy control person, homozygote variation could be found in two persons without WD. The healthy control person, [ALT 24 U/L, AST 31 U/L (-35), copper

21 µmol/L (12-35), ceruloplasmin 0.27 g/L (0.2-0.6)] and two persons had no signs of Wilson disease (based on clinical and basic laboratory testing). They had normal levels of serum ceruloplasmin, copper and liver function tests.

### 5'UTR -68 C>T (heterozygot)

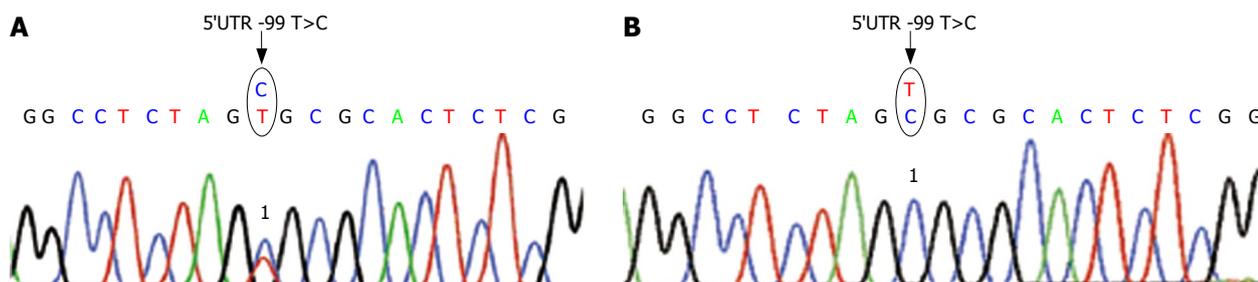

This additional variation of the 5'UTR could be found in two patients. One of them presented with the hepatic presentation, the other one had a mixed presentation (Figure 2).

The detected nucleotide changes in the 5'UTR region of the Atox1 gene did not have significant association with or influence on the average age of initial manifestation of Wilson disease (Table 3). Statistical analyses revealed that the existence of a variation within the Atox1- gene showed no significance towards an earlier onset of the disease (Table 4).

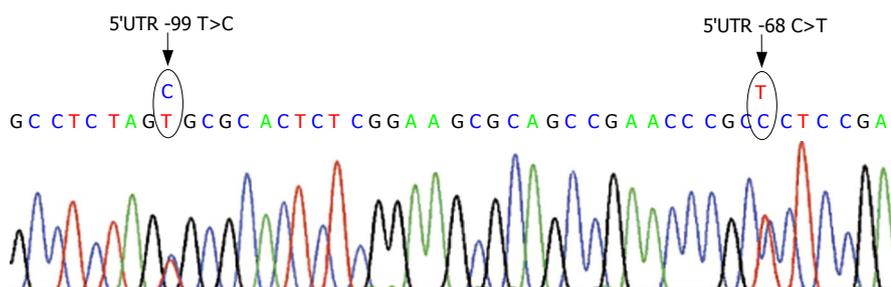

## DISCUSSION

When sequencing the exons of the Wilson disease gene in clinically proven Wilson disease patients, only a single or even no mutation can be detected in 5%-10% of all patients depending on the population examined and the analyzing laboratory. In our study, a single Wilson disease gene mutation could only be identified in 16 patients and no Wilson disease gene mutation could be found in 11 patients so far. However complete sequencing is still under way in most of these patients.

Sixty three patients were analyzed as potential candidates of an Atox1 caused Wilson disease like disease. 31 out of these 63 patients had variations within the Atox1 gene. In terms of clinical presentation (age of onset, hepatic/

**Figure 1** Sequence analysis of genomic DNA of the *Atox1*- gene 5'UTR -99T>C site. **A:** Heterozygote in this site. <sup>1</sup>Heterozygote substitution of the base T by C on position -99 in front of the beginning of the start codon located in exon 1; **B:** Homozygote in this site. <sup>1</sup>Homozygote substitution of the base T by C on position -99 in front of the beginning of the start codon located in exon 1.

**Figure 2** Localization of the 5'UTR -68 C>T gene variation in relation to the 5'UTR -99 T>C variation.

**Table 3** Analysis of average ages of initial manifestation with regard to the variations detected in the *Atox1* gene

<i>Atox1</i> -variation	Average age of initial manifestation	n of patients	Standard deviation
No variation within the sequence	23.68	31	12.993
Variation within the sequence detected	18.88	25	9.909
Total	21.54	56	11.863

neurologic onset), laboratory tests (serum ceruloplasmin, serum copper, 24 h urinary copper excretion) and clinical course (improvements, drug reactions, side effects, initial neurological worsening) there were no significant differences between the 31 WD patients with *Atox1* changes compared to the remaining 32 patients without *Atox1* changes. As these sequence changes were in the 5'UTL region leaving the translated regions as well as the splicing sites and the classical translation initiation complex site of the gene intact, it seemed unlikely, that these detected changes could cause a Wilson disease like disease by themselves or be able to significantly influence the clinical course of Wilson disease. On the other hand, the highly conserved region of the translated *Atox1* gene in humans can be evidence for a vital role of *Atox1* protein in human metabolism or embryonic development. This also might explain the still unknown phenotype of *Atox1*-mutation associated diseases<sup>[2]</sup>, even though different roles and regulatory factors for *Atox1* in human metabolism are emerging out of recent studies<sup>[28-31]</sup>. One might speculate about a Menkes disease like phenotype resulting from a complete disruption of both functional alleles of *Atox1* as suggested by *Atox1* knockout mice data<sup>[32]</sup>.

The association between the *Atox1* variations and the

**Table 4** Statistical data for Analysis of age of initial manifestation

Model	Not standardized coefficients		Standardized coefficients		
	B	Standard error	Beta	T	Significance
ATP7B	4.042	1.970	0.272	2.052	0.045
<i>Atox1</i>	-5.312	3.079	-0.225	-1.725	0.091

changes in the age of onset was weak in this study similar to data published before<sup>[2]</sup>.

Taken together, *Atox1* associated modification of Wilson disease or Menkes disease are still not seen so far and the absence of mutations in the coding regions of the *Atox1* gene speak for an essential role of wild type *Atox1* in human metabolism.

## ACKNOWLEDGMENTS

We sincerely thank the patients for their help and willingness to participate in this study. We thank Professor. Ferenci, Department of Gastroenterology and Hepatology, Vienna for Wilson disease gene analysis and Cathrin Thunert and Uta Merle for collecting clinical data and patient specimens. There is no conflict of interest for all authors of this study.

## COMMENTS

### Background

Cytoplasmic copper has to be transferred into the cellular excretory pathway by copper transport pumps. In patients with the copper storage disease "Wilson disease" the copper transporter ATP7B is defective. This transmembranous ATPase receives cytoplasmic copper from the copper chaperone antioxidant-1 (*Atox1*).

### Research frontiers

Patients with Wilson disease show a wide variation in their clinical presentation.

Proteins interacting with the ATP7B copper transporter, such as Atox1, COMMD1 or chemical such as Platinum-complexes are one important area in explaining this phenomenon.

### Related publications

Atx-1 like chaperones and their cognate P-type ATPases: copper-binding and transfer. *Biometals* 2007; 20: 275-289 [PMID: 17225061]; Merle U, Schaefer M, Ferenci P, Stremmel W. Clinical presentation, diagnosis and long-term outcome of Wilson's disease: a cohort study. *Gut* 2007; 56: 115-120, 314 [PMID: 16709660].

### Innovations and breakthroughs

Proper ATP7B function is regulated by cytoplasmic factors (e.g. COMMD1, Atox1), cytoskeletal factors (e.g. dynactin subunit p62) and by hormones (e.g. prolactin, oestrogens). ATP7B and its sister protein ATP7A (Menkes protein) are regulated by tissue specific factors and by hormones and can be present simultaneously within one cell.

### Applications

Research on modification factors of Wilson disease are aimed to identify protective factors within the clinical course of Wilson disease and providing them to affected patients.

### Terminology

Atox1: antioxidant-1, small cytoplasmic protein with copper binding sites; ATP7B: copper transporting ATPase encoded by the Wilson disease gene; Wilson disease: autosomal recessive copper storage disease due to malfunction of ATP7B.

### Peer review

This paper was well designed and analysed in large-scale patients. Although the results are in part negative, they are important to the scientific community.
