INTRODUCTION

World Journal of Gastroenterology is an international, open-access, peer-reviewed, and multidisciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

Abstract

Intrahepatic cholestasis of pregnancy (ICP) is a pregnancy-specific liver disorder characterized by maternal pruritus in the third trimester, raised serum bile acids and increased rates of adverse fetal outcomes. The etiology of ICP is complex and not fully understood, but it is likely to result from the cholestatic effects of reproductive hormones and their metabolites in genetically susceptible women. Equally unclear are the mechanisms by which the fetal complications occur. This article reviews the epidemiology, clinical features, diagnosis, etiology and management of ICP.

Key words: Cholestasis; Pregnancy; Pruritus; Bile acid

Peer reviewer: Andreas Geier, MD, Division of Gastroenterology & Hepatology, Zürich University Hospital, Raemistrasse 100, CH-8901 Zürich, Switzerland

INTRODUCTION

Intrahepatic cholestasis of pregnancy (ICP), which is also known as obstetric cholestasis, is a liver disease of pregnancy associated with raised serum bile acids and increased rates of adverse fetal outcomes.

ICP was originally described in 1883 by Ahlfeld as recurrent jaundice in pregnancy that resolved following delivery. Pruritus was not mentioned in this report, but in subsequent case reports published in the 1950s, severe pruritus with or without jaundice was reported in conjunction with the condition, in addition to complete resolution following delivery and high recurrence rates in subsequent pregnancies[1,2].

Over the years, ICP has also been described as jaundice in pregnancy, recurrent jaundice in pregnancy, idiopathic jaundice of pregnancy, obstetric hepatosis, hepatosis gestationalis or obstetric cholestasis.

Most authors now agree that ICP should be defined as pruritus with onset in pregnancy, which is associated with abnormal liver function in the absence of other liver disease and which resolves following delivery.

EPIDEMIOLOGY

The incidence of ICP varies widely with geographical location and ethnicity (Table 1)[3-27]. It is most common in South America, particularly in Chile, where early reports described an overall incidence of 10%, with higher rates seen in women of Araucanian Indian descent[6]. More recently, this has fallen to approximately 1.5%-4%[28]. The reasons for this decline are unclear but do not appear to reflect changing diagnostic criteria which have become more inclusive in recent studies; while early reports commonly used jaundice to diagnose ICP, more recently, any abnormality in liver function has been used. Instead, it has been proposed that the decline is due to changes in environmental factors, which will be discussed in more detail later in this article. The incidence of ICP is lower in Europe (approximately 1%) and has been stable for many years.

ICP is more common in the winter months in Finland, Sweden, Chile and Portugal[23,24]. A higher incidence is seen in twin pregnancies (20%-22%)[10,18] and following *in vitro* fertilization treatment (2.7% *vs* 0.7%)[29]. One study has suggested that it is more common in women over the age of 35 years[11]. There is a higher incidence of gallstones in both affected women and their families[30,31]. Hepatitis C seropositivity has been reported to be a risk factor for ICP, and may be associated with early onset of the condition[15,32]. It has also been suggested that women with ICP have more severe and prolonged emesis, and higher rates of drug sensitivities[33].

Table 1 The reported incidence of ICP in different countries and ethnic groups

P: Pruritus; J: Jaundice; LFT: Raised AST and/or ALT; SBA: Raised serum bile acids [upper limit of normal defined as in the study (μmol/L)]; B: Raised bilirubin; PR: Postnatal resolution; LD: Other liver diseases excluded; R: Recurrence in subsequent pregnancy; NA: Information not available. [1]Absence of parenchymal necrosis on liver biopsy; [2]Absence of fever or malaise, LFT's only performed if jaundiced, dark urine or doubt over diagnosis; [3]Absence of hepatomegaly; [4]Absence of gallstones; [5]Increased cholic acid percentage; [6]Absence of other hepatic disease associated with pregnancy.

CLINICAL FEATURES

Maternal disease

The most common presenting symptom of ICP is pruritus that usually presents in the third trimester. This becomes progressively more severe as the pregnancy advances and typically resolves within 48 h of delivery. Pruritus is defined as an unpleasant sensation that evokes the desire to scratch. It most frequently affects the palms of the hands and soles of the feet but it can be generalized or affect other areas of the body. There are no associated dermatological features other than excoriation marks, which may be severe. Many women report that their pruritus worsens at night and may become so extreme that it causes insomnia.

Approximately 80% of affected women present after 30 wk of gestation[30,34], but ICP has been reported as early as 8 wk[23].

The relationship between onset of pruritus and development of deranged liver function is not clear. It has been reported that itch may be present either prior to or after abnormal liver function is detected[35], and this may reflect the heterogeneous nature of the condition.

Clinical jaundice is rare, affecting approximately 10%-15% of pregnant women with ICP, and if it does occur, it tends to be mild with bilirubin levels rarely exceeding 100 μmol/L. Unlike the pruritus, it does not typically deteriorate with advancing gestation[36].

Constitutional symptoms of cholestasis may also be present, including anorexia, malaise and abdominal pain. Pale stools and dark urine have been reported and steatorrhea may occur[37]. Theoretically steatorrhea is associated with an increased risk of post-partum haemorrhage as a result of malabsorption of vitamin K, although there are only a small number of reports of this complication in the literature[38]. Steatorrhea may respond to treatment with pancreatic enzymes.

There have been some reports of the co-existence of ICP with other pregnancy-related disorders including pre-eclampsia[14,39-41], acute fatty liver of pregnancy[30,42], and gestational diabetes[39]. This reflects the etiological heterogeneity of the condition and thus it is important to exclude other causes of hepatic impairment in women who present with cholestasis in pregnancy.

ICP is not typically associated with ongoing hepatic impairment after pregnancy and the biochemical abnormalities normally resolve within 2-8 wk of delivery. There are a few case reports of a more prolonged course with biochemical abnormalities lasting up to 34, 45 and 82 wk postpartum[43,44]. In women with continued liver dysfunction it is important to exclude alternative underlying diagnoses. In the majority of women, ICP recurs in subsequent pregnancies, but disease severity cannot be predicted by the course in previous pregnancies.

Fetal disease

There is considerable debate in the literature about the extent of the ICP-associated fetal risk. There are consistent reports of adverse fetal outcomes in association with the condition[45,46], although most studies are not sufficiently large to allow accurate quantification of the frequency of the complications. Many studies have tried to correlate maternal serum biochemistry with fetal outcomes and one series reported higher

Table 2 The incidences of adverse fetal outcomes reported in the literature

S: Spontaneous preterm labour; I: Iatrogenic preterm labour; U: Unspecified preterm labour; NS: Not specified; B: Bradycardia; T: Tachycardia; LD: Late decelerations; PPH: Post-partum hemorrhage; -: Not reported. [1]Cases were recruited between 1999 and 2003, but the affected pregnancies had occurred from 1986; [2]Controls in this study had a history of stillbirth in a previous pregnancy; [3]Glantz *et al*[25] report findings of asphyxial events (defined as operative delivery due to abnormal CTG, post-partum umbilical artery pH < 7.05 or Apgar score < 7 at 5 min).

rates of fetal complications in women with jaundice compared to those with pruritus alone[38]. Bile acids have been repeatedly implicated in the etiology of the fetal disease, and the sensitivity of bile acids as a predictive marker of fetal risk has been examined in several studies involving small numbers of cases[18,39,47,48]. A recent, more definitive study from Sweden reported that there was a 1%-2% increase in risk of spontaneous preterm labour, asphyxial events (defined as operative delivery due to asphyxia, Apgar score < 7 at 5 min or arterial cord pH < 7.05) or meconium staining of the amniotic fluid and/or placenta and membranes for every additional μmol/L of maternal serum bile acids[25]. This study also reported no increase in adverse outcomes if the maternal fasting serum bile acids were below 40 μmol/L, leading the authors to suggest there is no increased risk to the fetus with mild ICP according to this definition. This result was generally consistent with the findings of other smaller studies in Finnish and American Latina populations[47-49] (Figure 1), although the magnitude of the effect varied in different studies, possibly relating to variations in management strategy, maternal ethnicity and study design. The reported incidence of each adverse fetal outcome is shown in Table 2.

Meconium staining of the amniotic fluid: The incidence of meconium staining of amniotic fluid (MSAF) in normal term pregnancies is approximately 15% and is considered to be a sign of fetal distress. In ICP, MSAF has been reported in 16%-58%[38,39] of all

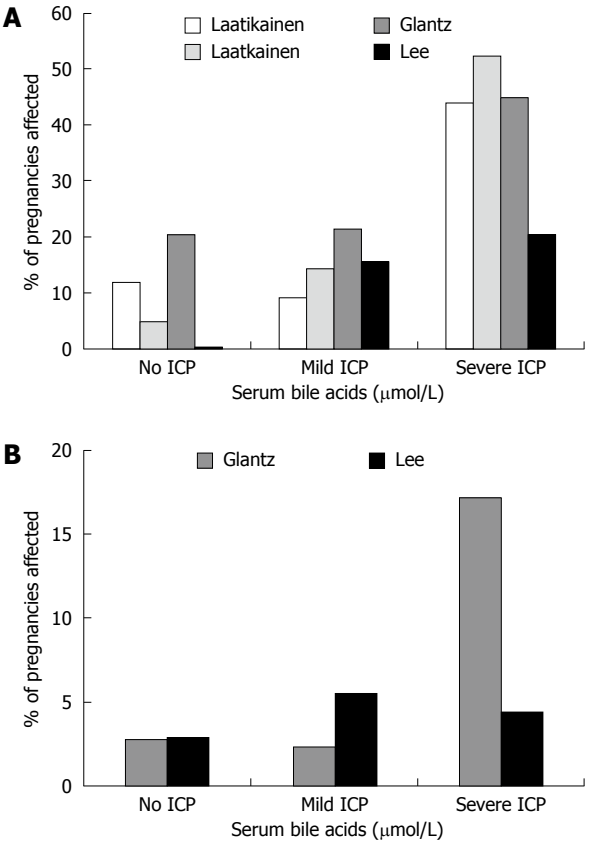

Figure 1 Graphs showing the incidence of meconium staining of the amniotic fluid (A) and preterm labour (B) in studies of the relationship between the maternal serum bile acid level and adverse fetal outcomes[25,47-49]. The total maternal serum bile acid level was used in all studies except Laatikainen *et al*[47] (represented by the white bar), where cholic acid only was used (normal range < 5 μmol/L). Serum bile acid level has been categorized as no ICP (< 10 μmol/L), mild ICP (10-40 μmol/L) or severe ICP (> 40 μmol/L) by the authors. One study[25] used fasting maternal bile acids and compared fetal outcomes with the single highest bile acid reading available. The other studies did not specify whether the mothers were fasted. One study[48] compared fetal outcomes to the serum bile acid level from the week before delivery, and the other studies did not specify which serum bile acid level was used.

cases and up to 100% of cases affected by intrauterine death (IUD)[45]. The group in which the incidence of MSAF is particularly striking is women who had amnioscopy or amniocentesis at approximately 37 wk of gestation, as the rates are significantly higher than in controls at this time[20]. The frequency of MSAF is greater in pregnancies with higher reported levels of maternal serum bile acids[25,47-49] (Figure 1).

Cardiotocography (CTG) abnormalities: Both ante- and intrapartum CTG abnormalities have been reported in association with ICP, including reduced fetal heart rate variability, tachycardia and bradycardia (< 100 bpm)[13,38,48,50]. More recently, a case report has described fetal tachyarrhythmia (220-230 bpm) leading to atrial flutter during labour at 37 wk gestation[51].

Preterm labour: There is an increased risk of spontaneous preterm labour, which has been seen in as many as 60% of deliveries in some studies[4], but most studies report rates of 30%-40% in ICP cases without active management. Reid *et al*[38] found an overall incidence of 36%, but interestingly this rose to 48% in women with raised bilirubin. Two studies have related the maternal serum bile acid level to the rate of spontaneous preterm delivery[25,49]. The rate of this complication was significantly higher in ICP pregnancies with maternal fasting serum bile acids > 40 μmol/L in the larger study of Swedish ICP cases[25]. However it was not higher in pregnancies with mildly raised (< 20 μmol/L) or more markedly raised maternal serum bile acids in a study of American Latina cases[49].

In more recent studies, the majority of preterm deliveries are iatrogenic (Table 2), which reflects the relatively frequent practice of electively delivering ICP cases at around 37 wk, with the aim of reducing the risk of fetal complications. There have been concerns raised over whether this in itself carries an increased risk of neonatal morbidity for the fetus. Studies have shown that there is an increased risk of respiratory distress syndrome (RDS) with either induction of labour or elective cesarean section at this stage of gestation[52]. It should be noted that the risk of neonatal respiratory distress is considerably higher with elective cesarean section, and it should be borne in mind that labour is induced in the majority of women with ICP. Also, there are some data to suggest that neonatal respiratory distress following ICP may be a consequence of the disease process. A recent series reported unexpected respiratory distress in association with maternal cholestasis in three infants delivered between 36 and 37 wk gestation with good indices of lung maturity in the amniotic fluid and negative blood, urine and cerebrospinal fluid cultures[53]. The authors therefore proposed that the development of RDS was as a direct consequence of ICP. In follow-up studies, RDS was found to affect 28.6% of newborns from cholestatic pregnancies and high levels of bile acids were found in the bronchoalveolar fluid of 10 infants with RDS[54,55].

Sudden IUD: Older studies using biochemical abnormalities to diagnose ICP have reported a perinatal mortality rate of 10%-15%[13,38]. This has been reduced to 3.5% or less in more recent studies employing policies of active management[11,13,18,20,25,30,39,46,48,56]. The term active management may encompass many different clinical practices, including increased fetal monitoring, frequent biochemical testing, pharmacotherapy with ursodeoxycholic acid (UDCA) or delivery at 37-38 wk gestation. These management protocols are based on evidence showing that stillbirths in ICP tend to cluster around 37-39 wk (Figure 2)[13,18,23,25,31,38,45-48,56-58]. However, there have been reports of stillbirths at less than 37 wk; in one series a fetus died at 32 wk[45] and in another one, twin fetuses died at 31 wk[31].

The risk of adverse fetal outcomes is thought to relate to the maternal serum bile acid level, and a recent study has shown that there is a 1%-2% increased risk for every μmol/L of bile acid above 40 μmol/L[25]. It is therefore likely that the risk of IUD is higher in

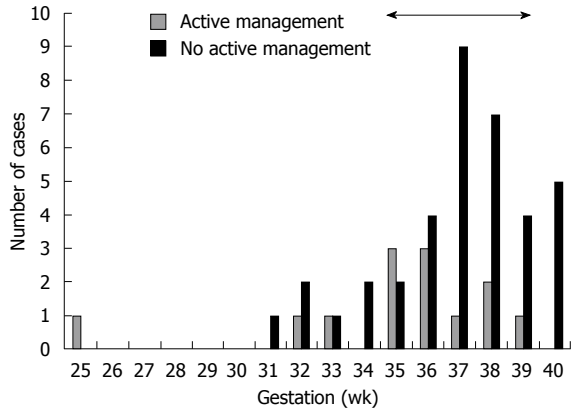

Figure 2 Graph showing the timing of IUD associated with ICP[13,18,23,25,31,38,45,47,48,56-58]. The arrow represents six additional cases of IUD from two series with no active management reported as a range of gestational ages at the time of fetal death[45,46].

ICP pregnancies with more severe hypercholanemia. However, the same study reported a stillbirth with maternal serum bile acid levels of 27 μmol/L and there are additional case reports of stillbirths at 39 wk with bile acids of 15 and 21 μmol/L[48,58]. It is not clear how close to the fetal death these blood specimens were taken, and maternal serum bile acid level is high in the majority of IUDs reported in the literature[25,47], but these observations illustrate the difficulty encountered by clinicians in using biochemical measurements to dictate delivery strategies for ICP cases.

Other findings: Several studies have shown that there is no increase in the number of small for gestational age infants born to women with ICP[18,59]. However, lower mean birth weight has been noted in three studies[4,11,38], although this does not appear to be due to intrauterine growth restriction. One study reported an increased placental/fetal mass, i.e. larger placentas in ICP[11].

INVESTIGATIONS

The diagnosis of ICP is one of exclusion and alternative causes of hepatic impairment or pruritus should be considered before the diagnosis is made.

Liver function tests (LFTs)

Liver function in normal pregnancy: Liver function does not change in normal pregnancy, although it is recommended that adjusted upper limits of normal are used. The upper limit of the normal reference range for serum alanine transaminase (ALT) and aspartate transaminase (AST) should be reduced by 20%[60] and the γ-glutamyl transpeptidase (GGT) level is reduced by a similar amount in later pregnancy[61]. Total and free bilirubin is also lower during all three trimesters, and conjugated bilirubin is lower in the second and third trimesters[61].

LFTs in ICP: The transaminase enzymes are located within hepatocytes and raised serum levels are thus indicative of hepatocellular damage. In ICP, ALT and AST may rise before or after serum bile acids[39,62]. Of the two, ALT is thought to be a more sensitive marker of ICP; there is a 2-10-fold increase in serum levels that is generally more marked than the rise in AST[3,47,62].

Bilirubin is normal in the majority of ICP cases and is of limited value in diagnosis or follow up. If raised, it tends to be a conjugated hyperbilirubinemia[62].

GGT has been shown to be raised in some studies[24,56,63] but is more commonly normal[47]. It has been proposed that elevations in GGT are associated with a greater impairment in other LFTs[63], and that they can provide insights into the genetic etiology of the condition.

Alkaline phosphatase (ALP) levels may rise in ICP but production of large amounts of the placental isoform render this biochemical marker of limited diagnostic value.

Glutathione *S*-transferase alpha (GSTA) is a phase Ⅱ detoxification enzyme that is rapidly released into the circulation following acute hepatic damage. It is reported to be a more sensitive and specific marker of hepatic integrity than standard LFTs[64-66]. A longitudinal study comparing serum levels from ICP, control and pruritus gravidarum cases demonstrated higher GSTA in ICP at all gestations from 24 wk to term[67]. A recent study confirmed that GSTA levels are elevated in ICP cases[68], and the authors of both studies proposed that it may be a useful tool for early diagnosis of the condition.

Bile acids: The primary bile acids cholic acid (CA) and chenodeoxycholic acid (CDCA) are the end products of hepatic cholesterol metabolism and represent the major route for excretion of cholesterol. Following synthesis, CA and CDCA are conjugated with taurine or glycine (in a ratio of approximately 1:3) before export across the canalicular membrane to enter the bile. In the terminal ileum and colon, CA and CDCA undergo bacterial modification, mainly deconjugation and 7α-dehydroxylation, to form the secondary bile acids deoxycholic acid (DCA) and lithocholic acid (LCA), respectively. UDCA is a tertiary bile acid as it results from bacterial modification followed by hepatic metabolism. It is normally detectable in trace amounts in normal serum. Bile acids are reabsorbed in the terminal ileum and enter the portal vein for transport back to the liver. The enterohepatic circulation is highly efficient and 95% of all bile acids are reabsorbed. A more detailed account of bile acid synthesis, canalicular secretion, sinusoidal uptake and homeostasis is given in a number of recent reviews[69,70].

Bile acids in normal pregnancy: In healthy pregnancy, there is a minimal rise in total serum bile acids as gestation advances[71,72]. Studies in which individual bile acid levels have been measured show that there is no change in DCA but CDCA doubles by term[73]. The data concerning CA are not so conclusive, with some studies reporting a significant increase in the third

trimester compared to the first[59,72], and others showing no change[73]. However, in all studies the level stayed well within the normal range (< 1.5 μmol/L). Perhaps a more informative measure is the ratio of the two primary bile acids (CA:CDCA), which is reported to be between 0.68 and 1.9 at term (38-40 wk)[72,73].

The reference range used for total serum bile acids in pregnancy varies, but most authors accept an upper limit of normal of between 10 and 14 μmol/L.

The phenomenon of asymptomatic hypercholanemia of pregnancy (AHP) has recently been reported. AHP is defined as raised serum bile acids in pregnancy in the absence of symptoms and other biochemical markers of ICP[74]. Specifically, they describe a change in the profiles of serum bile acids in women with AHP with increased CA and relatively unchanged CDCA levels. AHP is reported to affect approximately 10% of the pregnant population, and 2%-3% of women with AHP during the second trimester subsequently develop ICP.

More recently, Castaño *et al*[75] reported that AHP affects 40% of pregnant women in Argentina and that the pregnancy outcome is similar to that of normal pregnancies, suggesting that mild hypercholanemia may fall within the biochemical spectrum of normal pregnancy.

Bile acids in ICP: Serum bile acid measurement is now considered to be the most suitable biochemical marker for both the diagnosis and monitoring of ICP[76], with the cholic acid level[59] or the CA:CDCA ratio proposed as being the most sensitive indicator for the early diagnosis of the condition[24,62]. Levels of the secondary bile acid DCA also rise[73], although to a lesser extent, and indicate impairment of the enterohepatic circulation.

There are reports in the literature of elevations in serum bile acids as high as 100 times the upper limit of normal[73,77].

In addition, maternal cholestasis results in elevated levels of bile acids in the fetal circulation and a reversal in the normal feto-maternal transplacental bile acid gradient[39,78,79].

There is as yet no consensus on whether a rise in serum bile acids precedes the onset of symptoms. There are reports of women with elevated serum bile acids prior to the onset of symptoms or the appearance of other biochemical abnormalities[62]. Equally, there is no agreement on whether serum bile acids should be measured in the fasted or post-prandial state. In ICP, consumption of a standard test meal causes a more dramatic and prolonged post-prandial rise in serum bile acids, particularly CA, than in control women, suggesting that the use of a standard test meal may help to distinguish mild forms of the disease from normal[80,81]. However, this approach would be costly and time-consuming if used in routine obstetric practice.

The biliary bile acid profile is also altered in ICP. Although CA remains the predominant bile acid, the proportion is greatly increased, with a consequent reduction in the proportion of CDCA. DCA is markedly diminished, suggesting a significant impairment of the enterohepatic circulation in ICP[82].

Other serum biochemistry

Lipids: Cross-sectional studies have reported deranged lipid profiles in association with ICP[34,83,84], and in a prospective longitudinal study LDL cholesterol, apolipoprotein B-100 and total cholesterol concentrations were found to be elevated[85]. However, it should be noted that this study was performed in a group of patients who were not fasted at the time of sample collection.

Glucose: One study has shown that ICP is associated with impaired glucose tolerance. Although there was no difference in fasting glucose levels between cases and controls, both the 2 h post-prandial glucose and oral glucose tolerance tests were higher in ICP[21].

Clotting: One study reported a prolonged prothrombin time in 20% of patients[12]. However this is not consistent with the author's experience. In 65 ICP cases with raised serum bile acids managed in our hospital from 1996-2003, there were none with an abnormal clotting profile.

Other biochemical markers investigated in ICP are summarized in Table 3[86-100].

Urine

Analysis of the urine from women with ICP shows an increased excretion of total bile acids, with a 10- to 100-fold increase in CA and CDCA, but decreased excretion of DCA and LCA. The reduced excretion of the secondary bile acids supports the hypothesis that a canalicular defect is a primary feature of ICP, and is consistent with an impaired enterohepatic circulation. The bile acid profile shows a shift from glycine to taurine conjugation and an increased proportion of sulfated species[101]. In a longitudinal study of two women, the first detectable change in urinary bile acids was the appearance of tetrahydroxylated species, which are known products of CA metabolism. This change occurred before the rise in total bile acid excretion[102].

Liver/gallbladder ultrasound scan

Gallstones are reported in 13% of women with ICP[31]. While it is likely that affected women have increased susceptibility to cholelithiasis, there have been no robust studies of ICP cases and controls, and pregnancy itself is also associated with an increased incidence of asymptomatic gallstones[103,104]. First-degree relatives of affected women also have higher rates of cholelithiasis (26% of relatives of 227 ICP cases compared to 9% of 234 controls, $P < 0.001$, χ^2) (unpublished data, C. Williamson).

In ICP, the intrahepatic bile ducts appear normal, but the fasting and ejection volumes of the gallbladder are greater, possibly predisposing these women to the

Table 3 Additional biochemical markers that have been investigated in relation to ICP

Number of cases (controls)	Gestation	Parameter investigated	Main findings	References

NR: Not reported; T3: Third trimester; T2: Second trimester; PN: Postnatal.

formation of gallstones[105-107]. However, ICP has been described in women with previous cholecystectomy[108], suggesting that the presence of gallstones is not causative of ICP.

Liver biopsy

Several studies have reported that there is normal liver structure with no evidence of liver cell damage and only mildly dilated bile ducts, bile stasis in canaliculi, bile plugs and mild portal tract inflammation in liver biopsies from women with ICP[5,109]. Electron microscopy findings show generally well-preserved architecture with dilated bile capillaries, distorted microvilli and granular deposits (bile thrombi)[5,109].

ETIOLOGY OF MATERNAL DISEASE

The etiology of ICP is complex and not fully understood. Evidence from ICP pedigrees suggests that there is a genetic component to the disease[110], and the relative risk for parous sisters of affected women is 12[9,111]. Insights into the genetic etiology come from studies of the familial cholestasis syndromes progressive familial cholestasis (PFIC) and benign recurrent cholestasis (BRIC). These autosomal recessive syndromes are caused by homozygous mutations in the genes encoding biliary transport proteins, and case reports have described ICP in the heterozygous mothers of affected children.

Candidate genes

The most extensively studied candidate gene in ICP is *ABCB4*, which encodes the multidrug resistance protein 3, a floppase that transports phosphatidylcholine from the inner to the outer leaflet of the hepatocyte canalicular membrane[112-114]. Homozygous mutations result in a spectrum of phenotypes that include PFIC type 3[115] and cholelithiasis[116]. ICP-associated variants were first described in a case report published in 1999, in which the mother of a child with PFIC type 3 was found to have a heterozygous single nucleotide deletion (1712delT). She and five of her female relatives had a history of ICP[117]. However, a second study screening 57 Finnish cases for this mutation concluded that it does not play a significant role in the etiology of ICP in this population[118]. Subsequent to this, there have been 12 different genetic variants and four splicing mutations in *ABCB4* reported in ICP cases[119-126]. The first *ABCB4* mutations were described in patients with elevated serum GGT levels, a biochemical phenotype that is also found in PFIC type 3, and not in types 1 and 2. However, some recent studies have described *ABCB4* variants in ICP patients with normal GGT[120,126]. A recent study has also described an *ABCB4* haplotype which is associated with the "severe" phenotype of serum bile acids > 40 μmol/L[127].

Homozygous mutations in the familial intrahepatic cholestasis one gene (FIC1, *ATP8B1*) cause PFIC type 1 and BRIC. The function of the FIC1 protein is disputed, but it is hypothesized to be an aminophospholipid translocase which transports phosphatidylserine from the canaliculus into the hepatocyte, thus maintaining membrane asymmetry and the function of the other biliary transporters embedded within the membrane. Variation in *FIC1* occurs in a small number of ICP cases, although the functional consequences are currently not known[128,129].

Genetic variation in the bile salt export pump (BSEP), encoded by *ABCB11* has also been reported in ICP. BSEP is located exclusively in the hepatocyte canalicular membrane and is the primary export pump for bile acids. Homozygous mutations in *ABCB11* are associated with PFIC type 2. Two studies investigated the role of *ABCB11* variation in Finnish ICP cases. One study reported that single nucleotide polymorphisms in exons 28 and 19 were susceptibility loci for ICP[130]. However, a subsequent study in a larger number of cases with a more diverse ethnic background failed to confirm these findings, suggesting that ICP is a genetically heterogeneous disease[131]. Further evidence for genetic heterogeneity was provided by a study of 16 individuals from two affected Finnish families. Segregation of haplotypes and multipoint linkage analysis of microsatellite markers in *ABCB11*, *ABCB4* and *ATP8B1* excluded genetic variation in these genes from playing a role in the etiology of ICP[132]. Other BSEP variants reported to be associated with ICP include N591S and the V444A polymorphism[123,126,133]. The latter of these variants is particularly interesting as it is also reported to be a susceptibility factor for estrogen-induced cholestasis[133]. A recent UK study demonstrated that two common PFIC2-associated mutations (E279G and D482G) and N591S are present as heterozygous variants in a small proportion of ICP cases. This study of 491 Caucasian ICP cases and 261 controls also demonstrated that the V444A allele is a significant risk locus for ICP in this population[134].

Genetic variation has also been reported in another biliary transporter, *ABCC2*, which encodes the multidrug resistance related protein 2 (MRP2). MRP2 exports organic anions including bilirubin into the bile. A study from South America has suggested that a polymorphism in exon 28 is associated with ICP[135].

The farnesoid X receptor encoded by *NR1H4* is the principal bile acid receptor and is responsible for the regulation of bile acid synthesis and transport within the liver. A recent study has described four heterozygous variants within FXR that are associated with ICP, three of which were shown to have functional effects[136].

A variety of other genetic loci have been investigated in ICP cases and the reader is referred to a recent review for full details of all studies to date[111].

Influence of hormones

Several studies provide evidence that reproductive hormones play a role in the etiology of ICP. The disease is more common in multiple than singleton pregnancies (20.9% *vs* 4.7% in one study)[10], and the symptoms may recur in a subgroup of affected women when taking the combined oral contraceptive pill[31]. In addition, most women present with symptoms of ICP in the third trimester when estrogen and progesterone levels are highest.

Most studies have focussed on estrogen rather than progesterone. In clinical studies, administration of ethinylestradiol to both men and women results in a decreased clearance of sulfobromophthalein, and this is further reduced in women with a personal history of ICP and their male relatives[137]. Furthermore, administration of the depot estrogen, ethinylestradiol propanolsulphonate to 20 healthy women significantly increased the total serum bile acid concentration, and in particular, the proportion of taurine conjugates[138]. *In vitro* studies have demonstrated that the cholestatic estrogen metabolite, 17-β-estradiol glucuronide, transinhibits the BSEP following excretion into the bile canaliculus by MRP2[139]. Supporting this hypothesis, administration of 17-β-estradiol glucuronide to rats causes endocytic internalization of BSEP in an MRP2 (Mrp2; Abcc2)-dependent manner[140]. Estrogen also impairs the expression and/or function of, BSEP and MRP2 in rodent studies[141-143].

However, progesterone may play an even greater role in the pathogenesis of ICP. Bacq *et al*[144] observed that administration of natural progestin to women with threatened preterm labour resulted in ICP in 11 of the 12 women treated. This finding was confirmed by two subsequent studies[56,145]. Although total progesterone does not rise in comparison to normal pregnancies, the profile of metabolites is considerably different. An excess of monosulfated and disulfated (in particular 3α and 5α) isomers has been reported in the serum and urine of women with ICP, and this may reflect impaired excretion of these metabolites at the canalicular membrane, or abnormal synthesis[146,147]. Studies of umbilical cord serum have also shown that disulfated progesterone metabolites are increased in the fetal compartment of affected pregnancies compared with normal pregnancies. Moreover, the level of steroid sulfates synthesized by the fetus, e.g. 16α-hydroxydehydroepiandrosterone sulfate are decreased, suggesting that maternal cholestasis is associated with impaired fetal steroid synthesis[148].

There are few *in vitro* studies that have investigated the mechanism of progesterone metabolite induced cholestasis. One study has shown that sulfated progesterone metabolites, but not progesterone itself, cause reduced bile flow in the rat[149]. The same authors demonstrated that these metabolites inhibit BSEP-mediated bile acid efflux in *Xenopus* oocytes.

Environmental factors

Selenium: Serum levels of selenium usually decrease with advancing gestation, but normal serum levels are maintained if dietary intake is adequate[96]. Dietary selenium intake is lower in Finland and Chile, and serum levels have been shown to be reduced in women with ICP compared to pregnant controls in both countries[90,96]. Glutathione peroxidase is a powerful antioxidant that is dependent on selenium. Estrogens and bile acids cause oxidative stress, and it has been proposed that reduced serum selenium levels may contribute to the etiology of ICP and may also provide an explanation for the geographic variation in the prevalence of the condition.

Seasonal variation: The incidence of ICP peaks in the winter months in Scandinavia and Chile, suggesting a possible association with an environmental trigger. Interestingly, serum selenium levels have also been reported to be significantly higher in the summer than winter[96].

Infection: There is an increased incidence of hepatitis C infection in women with ICP, and one study has reported that affected women develop cholestasis at earlier gestations[32]. There have also been reports of an increased incidence of urinary tract infection and pyelonephritis in the early stages of pregnancy than in controls[13].

Drug cholestasis: Johnston *et al*[4] reported higher rates of drug sensitivities among the ICP population, especially to antibiotics. There may be overlapping etiological factors that influence susceptibility to ICP and drug-induced cholestasis. For example, the V444A allele of BSEP that confers increased risk for ICP is also found more commonly in individuals with drug-induced cholestasis[150].

Leaky gut: Increased gut permeability as measured by the urinary lactulose/mannitol ratio (L/M) has been reported in a subgroup of ICP patients (five of the 20 women in the study), and the authors postulate that this may participate in the pathogenesis of the condition by enhancing the absorption of bacterial endotoxins[151]. However, levels of anti-lipopolysaccharide antibodies and pro-inflammatory cytokines [tumor necrosis factor-α, interleukin (IL)-1β, IL-6 and IL-10] were measured and no significant differences were shown, suggesting that this may not be the case. It should also be noted that the abnormal excretion of lactulose and mannitol persisted for up to 2 years in four of the five women identified, and thus it is possible that a leaky gut is a permanent abnormality in these women rather than a result of ICP.

Pruritus: The itch associated with ICP is often the most troubling symptom for affected women. It has been speculated that it is due to accumulation of bile acids in the interstitial fluid of the skin. However, serum bile acid levels do not correlate well with maternal symptoms and, while application of bile acids to blister bases or intradermal injection of bile acids results in pruritus[152,153], absolute concentrations of bile acids in the skin do not correlate well with the sensation of itch[154]. Furthermore, some studies have reported pruritus before the onset of biochemical abnormalities[35]. These findings suggest that an alternative compound acts as a pruritogen in this and possibly other forms of cholestatic liver disease. Candidates include reproductive hormone metabolites, and a recent study has reported that serum sulfated progesterone metabolites were reduced following treatment with UDCA, concurrently with a reduction of pruritus[155]. Interestingly, a 5-hydroxytrytamine 3 receptor agonist has been reported to rapidly reduce pruritus in both ICP and other liver diseases, raising the possibility that serotonin is involved in the etiology of pruritus[156,157].

ETIOLOGY OF FETAL COMPLICATIONS

The etiology of the fetal complications associated with ICP is poorly understood, but is thought to relate to an increased flux of bile acids into the fetal circulation, as indicated by elevated levels in amniotic fluid, cord serum and meconium. *In vitro* studies of isolated placental vesicles have shown that vectorial transfer of bile acids from fetus to mother is impaired in ICP, and that this is specifically the result of decreased efficiency of ATP-independent transport[158,159]. Taken together, these findings suggest that bile acids accumulate in the fetal compartment and thus are likely to exacerbate fetal risk. Furthermore, a recent study of fetal outcomes in ICP has shown that the risk of adverse fetal outcomes increases with increasing levels of maternal serum bile acids[25].

MSAF

Evidence for the involvement of bile acids in the etiology of MSAF comes from studies of fetal sheep infused with CA, in which 100% of the treated lambs were born with MSAF[160]. The mechanism by which bile acids cause this effect is not clear from this study: the lambs did not show any signs of fetal distress. However, bile acids are known to cause an increase in colonic motility[161,162] and this is a possible explanation. Alternatively, the bile acids may cause fetal distress and subsequent meconium passage.

CTG abnormalities

Individual neonatal rat cardiomyocytes treated with taurocholic acid show a decrease in the rate of contraction, which is reversible. Furthermore, cells in a network lose their ability to beat synchronously after the addition of taurocholic acid and have abnormal calcium dynamics, suggesting that elevated levels of bile acids in ICP may be responsible for the CTG abnormalities observed[163].

Spontaneous preterm labour

Rodent studies have shown that the non-pregnant rat myometrium displays a dose-dependent increase in contractility in response to CA[164], and sheep infused with this bile acid have an increased incidence of spontaneous preterm labour[160]. Furthermore, it has been suggested that the myometrium of ICP patients may be more responsive to the effects of oxytocin[165,166].

RDS

Bile acid aspiration or accumulation within the fetal circulation is thought to be responsible for the increased incidence of RDS seen in association with ICP. In animal models, bile acids have been shown to cause severe chemical pneumonitis and pulmonary edema[167,168].

Furthermore, intra-tracheal injection of bile acids in rabbits resulted in atelectasis, eosinophilic infiltration and formation of hyaline membrane, which could be reversed by the administration of surfactant[169]. It has therefore been hypothesized that elevated levels of bile acids in the fetal circulation cause a reversal of the action of phospholipase A2, thereby causing the degradation of phosphatidylcholine and a lack of surfactant[53]. Interestingly, administration of intra-tracheal surfactant to two of the infants reported in a recent series resulted in some improvement in their condition[53].

IUD

The mechanisms causing sudden IUD are poorly understood. At autopsy, the majority of the stillborn babies are of normal weight and have no signs of chronic utero-placental insufficiency, but do have signs of acute anoxia[38]. However, several studies have reported non-specific morphological changes in the placenta, including increased syncytial knot formation and villous edema, which are suggestive of hypoxic insults[47,170,171]. These findings are comparable to the morphological appearance of placentas from a rodent model of ICP, which is also associated with increased placental oxidative stress[172].

As previously discussed, there is MSAF in up to 100% of ICP-associated stillbirths. Studies of meconium from healthy pregnancies has shown that it penetrates deep into placental and umbilical cord tissue in less than 3 h[173], and can cause vasoconstriction of the placental and umbilical vessels. The mechanism is not known, but heat-inactivated meconium did not induce an effect in one study[174], suggesting that a peptide or prostaglandin produces the effect. In ICP, the meconium contains significantly elevated levels of bile acids (13.5 ± 5.1 μmol/g *vs* 2.0 ± 0.5 μmol/g)[175], and as bile acids are known to cause vasoconstriction of the placental chorionic vessels[176], it is possible that placental vasoconstriction is a mechanism that contributes to the risk of IUD in ICP.

MANAGEMENT OPTIONS

The aims of management are to reduce symptoms and biochemical abnormalities in the mother and to reduce the risk of fetal distress, preterm delivery and sudden fetal death.

Fetal monitoring

There are several case reports of normal CTG and/or normal fetal movements in the hours preceding fetal loss[18,48,177,178]. Thus, the general consensus is that these forms of fetal surveillance do not prevent IUD. However, they may be reassuring to women with ICP and the clinicians responsible for their care at the time they are performed. One study reported good fetal and neonatal outcomes with a policy of routine amnioscopy at 36 wk to assess amniotic fluid color in addition to standard monitoring for fetal wellbeing[20]. However, this approach may be considered overly invasive by many obstetricians.

Elective delivery

Some studies have reported good outcomes with a policy of induction of labour at 37 or 38 wk gestation[20,46]. Many clinicians in the UK have adopted this practice as the IUDs appear to cluster at later gestations (Figure 2). However there have been very few reports of the gestational week at which the IUD occurs, nor have there been any large prospective studies of whether drug treatment or early delivery prevents adverse fetal outcomes.

Drugs

UDCA: UDCA is a naturally occurring hydrophilic bile acid that constitutes < 3% of the physiological bile acid pool in humans. It has been used with positive effects in the management of primary biliary cirrhosis and other cholestatic disorders for several years, and is gaining popularity as a treatment for ICP. There is evidence that UDCA stimulates biliary secretion by post-transcriptional regulation of BSEP and the alternative exporters MRP4 and MRP3. In addition, it has antiapoptotic effects and has been shown to reduce the mitochondrial membrane permeability to ions and cytochrome c expression[179,180]. Finally, UDCA lowers serum levels of ethinyl-estradiol 17β-glucuronide, a major cholestatic metabolite of estrogen.

The first reported use of UDCA in ICP was by Palma *et al*[181] in 1992. In an uncontrolled series of eight cases, UDCA was prescribed at a dose of 1 g/d either continuously for 20 d or for two 20-d periods interrupted by a 14-d drug-free period. Both groups had a significant improvement in serum biochemistry and symptoms after 20 d treatment, but relapse was seen after the first week of the drug-free period in the latter group. Subsequently, UDCA was used to treat three patients with recurrent ICP, all of whom had rapid symptomatic and biochemical improvements with no adverse fetal outcomes[45]. This was followed by three small randomized, controlled trials (maximum of eight patients in each arm), the first of which showed that 20 d of UDCA treatment (600 mg/d) resulted in a significant reduction of pruritus and LFTs, including bile acids, compared to baseline[182]. One other study failed to show any reduction in pruritus compared with placebo, and the final one showed a reduction that did not reach statistical significance because of the small numbers of women treated[183,184]. In both studies, UDCA caused a significant reduction in serum transaminases and bilirubin compared to placebo. One study also showed a significant reduction in serum bile acids[183]. There have been several additional case series demonstrating that UDCA treatment results in clinical and biochemical improvement in ICP[26,185-188].

More recently, a randomized placebo-controlled trial comparing the efficacy of UDCA and dexamethasone therapy in ICP reported that UDCA, but not dexa-

methasone, significantly reduced ALT and bilirubin in all women treated. Furthermore, there was a significant reduction of pruritus and bile acids in women with serum bile acid levels exceeding 40 μmol/L at inclusion[189].

Studies examining the bile acid pool composition have shown that, in addition to a reduction in the serum bile acid concentration, treatment with UDCA results in a normalization of the CA:CDCA and glycine:taurine ratios[190], and a reduction in urinary excretion of sulfated progesterone metabolites, which the authors propose is associated with a concurrent reduction in pruritus[155].

There have been no reports of fetal morbidity or mortality resulting from UDCA treatment, although no study has had sufficiently large numbers to allow this to be fully evaluated. However, UDCA treatment has been shown to reduce the bile acid level in cord blood[187], amniotic fluid[187,191,192] and colostrum[193], and it reduced cord blood bilirubin levels in one study[194]. As previously discussed, the level of bile acids in meconium is considerably elevated in ICP, and this is not influenced by treatment with UDCA[175]. However, this may be because bile acids had already accumulated in the meconium prior to UDCA treatment. It is likely that, if UDCA reduces the maternal serum bile acid level, and thus placental transfer of bile acids, then there should be a corresponding reduction in the level in meconium from the time of treatment.

Finally, UDCA has been shown to correct the impaired bile acid transfer kinetics observed in ICP placentas[159] and to reverse the morphological changes seen in the placentas of a rodent model of ICP[195]. In addition, placental MRP2 protein and mRNA expression were significantly increased in patients treated with UDCA compared to controls[194]. UDCA also protects cardiomyocytes from bile acid-induced arrhythmias in an *in vitro* model[196].

There are very few side effects reported with UDCA treatment. At higher doses women may complain of gastrointestinal upset and diarrhea, but this is rare.

Dexamethasone: Dexamethasone inhibits placental estrogen synthesis by reducing secretion of the precursor, dehydroepiandrosterone sulfate, from the fetal adrenal glands[197,198]. An early observational study of 10 affected women from Finland suggested a beneficial effect with reduced serum estriol and estradiol levels and symptomatic improvement in all cases. In addition liver biochemistry, including the serum bile acid level, was improved and symptoms did not recur on cessation of treatment[199]. However, this was not supported by subsequent studies[189,200,201].

In addition to the conflicting reports of efficacy, there are concerns over safety. Dexamethasone has been widely used to promote fetal lung maturity and is reported to be safe in this context. However, it crosses the placenta easily, and animal and human data suggest that repeated high doses are associated with decreased birth weight[202] and abnormal neuronal development[203].

Rifampicin: Although there are no published studies reporting the use of rifampicin in ICP, it has been used with good results in several other liver diseases, including gallstones and primary biliary cirrhosis[204-206]. In these studies treatment with rifampicin resulted in significant decreases in serum levels of transaminases and total bile acids, as well as an improvement in pruritus, suggesting that it might also be useful in the treatment of ICP. A recent study investigating the molecular mechanism by which rifampicin works has shown that it enhances bile acid detoxification, an effect that is complementary to the up-regulation of bile acid export induced by UDCA, suggesting that the two drugs used in combination may be more effective than monotherapy[204]. The authors are aware of several ICP cases that have not responded to monotherapy with UDCA, but have responded to combined treatment with rifampicin and UDCA.

Vitamin K: ICP is associated with a risk of malabsorption of fat soluble vitamins due to reduced enterohepatic circulation of bile acids and subsequent reduction of uptake in the terminal ileum. Therefore many clinicians opt to treat women with oral vitamin K to guard against the theoretical risk of fetal antepartum and maternal intra- or postpartum hemorrhage. However, there have been no studies to support or refute this practice.

Others: S-Adenosyl-L-methionine (SAMe) is the principal methyl group donor involved in the synthesis of phosphatidylcholine, and therefore, it influences the composition and fluidity of hepatic membranes and hence biliary excretion of hormone metabolites[207]. It reverses estrogen-induced impairment of bile flow in rats[208-210]. Furthermore, in a human study of estrogen-induced cholestasis in women with a history of ICP, SAMe was shown to prevent ethinylestradiol-induced elevations in AST/ALT, bile acids and bilirubin[211]. Early studies of SAMe in the treatment of ICP reported that it improved both symptoms and biochemistry[212, 213], and these findings were confirmed by a subsequent placebo controlled study in which 15 women were treated with high dose SAMe (800 mg/d iv)[214]. However, a double-blind, placebo-controlled trial showed no improvement in symptoms or biochemistry following treatment with SAMe[215]. Finally, the efficacy of SAMe has been compared to that of UDCA, combination therapy with UDCA and SAMe, and placebo in one study[183]. Women treated with SAMe had a larger reduction in pruritus score and biochemical parameters than women in the placebo group, but this was not as large in the UDCA group. Furthermore, treatment with a combination of UDCA and SAMe was more effective than SAMe alone in reducing bile acid levels. Some patients have reported problems with peripheral veins following prolonged intravenous administration[215]. No other adverse maternal or fetal effects have been reported and SAMe seems to be well tolerated.

Cholestyramine is an anion exchange resin which acts by binding bile acids in the gut, thereby inhibiting the

enterohepatic circulation and increasing fecal excretion of bile acids. There have been several studies suggesting that cholestyramine is effective at reducing pruritus in ICP[216,217]. However, it has no effect on serum bile acid levels or other biochemical markers of cholestasis[216]. Furthermore, it may reduce the intestinal absorption of fat-soluble vitamins, thus depleting the levels of vitamin K and increasing the risk of hemorrhage for the mother and fetus[218]. Cholestyramine is therefore no longer considered a first-line therapy for ICP.

Guar gum is a dietary fiber that acts in a similar manner to cholestyramine. One small study has reported the use of guar gum in the treatment of ICP and reported no effect on serum bile acids or bilirubin and only a minimal reduction in pruritus score[219]. Subsequently, a randomized controlled trial has shown that guar gum is no more effective than placebo in improving pruritus or reducing serum bile acids[220].

Peroral activated charcoal has been shown to reduce serum bile acids in seven of nine women treated in one study. However, there was no improvement in symptoms[221].

Topical treatment with aqueous cream with 2% menthol is of value in the relief of pruritus, but does not improve biochemical abnormalities.

PROGNOSIS

Most women have no lasting hepatic damage, but ICP recurs in the majority of cases, with variations in intensity in subsequent pregnancies[10,222]. Recurrence is less likely following multiple pregnancy. Women with a history of ICP may also develop symptoms if taking the combined oral contraceptive pill or in the second half of the menstrual cycle[31]. Long-term follow-up studies have shown an increased risk of gallstones, non-alcoholic cirrhosis and pancreatitis, hepatitis C and autoimmune hepatitis[223,224].

CONCLUSION

ICP is a relatively common cause of hepatic impairment in pregnancy. It has a complex etiology with genetic, endocrine and environmental components. ICP causes maternal pruritus with impaired liver function and raised serum bile acids. The maternal cholestasis is transient with postnatal resolution, although affected women have increased rates of hepatobiliary disorders in later life. ICP is associated with adverse fetal outcomes. The risk of meconium-stained liquor, fetal asphyxia and spontaneous preterm delivery is greater in pregnancies with more marked elevations in maternal serum bile acid levels. The condition is also associated with IUD. The most effective pharmacological therapy for improvement of maternal symptoms and biochemical abnormalities is UDCA, and this has also been shown to reduce placental abnormalities and to improve placental bile acid transport in *in vitro* studies. Fetal outcomes are improved with a variety of strategies of active management, although the most effective intervention has not currently been established. A common practice is induction of labour at 37-38 wk of gestation with the aim of reducing the risk of IUD as many deaths occur at later gestations. Large therapeutic trials are required to establish which specific drug treatments or management strategies are effective at reducing the rates of adverse fetal outcomes.

Abstract

Inflammatory bowel disease (IBD), in particular Crohn's disease refractory to conventional therapy, fistulizing Crohn's disease and chronic active ulcerative colitis, generally respond well to anti-tumor necrosis factor (TNF) therapy. However, serious side effects do occur, necessitating careful monitoring of therapy. Potential side effects of anti-TNF therapy include opportunistic infections, which show a higher incidence when concomitant immunosuppression is used. Furthermore, antibody formation against anti-TNF is associated with decreased efficacy and an increased frequency of infusion reactions. The hypothesis of a slightly increased risk of lymphomas in IBD patients treated with anti TNF-therapy is debatable, since most studies lack the specific design to properly address this issue. Alarmingly, the occurrence of hepatosplenic T-cell lymphomas coincides with combined immunosuppressive therapy. Despite the potential serious side effects, anti-TNF therapy is an effective and relatively safe treatment option for refractory IBD. Future research is needed to answer important questions, such as the long-term risk of malignancies, safety during pregnancy, when to discontinue and when to switch anti-TNF therapy, as well as to determine the balance between therapeutic and toxic effects.

Key words: Anti-tumor necrosis factor; Biologics; Inflammatory bowel diseases; Crohn's disease; Infliximab

INTRODUCTION

Inflammatory bowel disease (IBD), including Crohn's disease and ulcerative colitis, is an idiopathic chronic relapsing inflammatory disorder of the intestinal tract[1]. The chronic and relapsing course of disease makes IBD a disabling disease that is complex to treat. Conventional therapy, including corticosteroids and thiopurines, is aimed at control of inflammation but does not appear to change the natural course of disease. Moreover, many patients become refractory to conventional therapies during the course of disease.

Infliximab was introduced in the late 1990s as the first result in the development of biologic therapies, and changed the therapeutic potential in IBD dramatically. Anti-tumor necrosis factor (TNF) therapy is currently used for the treatment of corticosteroid-refractory, active, corticosteroid-dependent, fistulizing Crohn's disease, as well as refractory ulcerative colitis[2,3]. Anti-TNF therapy is remarkably effective in patients who do not respond to conventional treatment. However, the use of biologics is associated with significant, but rarely, fatal complications, leading to serious concerns about safety and long-term consequences (Table 1). This review will discuss the current knowledge and safety issues as well as future directions for the role of anti-TNF therapy in the treatment of IBD.

SIDE EFFECTS OF BIOLOGIC THERAPY

Infections

The immunosuppressive effect of currently used biologics leads to an increased risk of specific infections during therapy. Most commonly, these infections arise from the upper respiratory tract and the urinary tract. Forty-eight patients had an infectious event and

Table 1 Side effects associated with anti-TNF therapy

Side effect	Example
Infections	Tuberculosis, histoplasmosis
Antibody formation	Antibodies to infliximab, antibodies to adalimumab
Infusion reactions	Anaphylaxis, delayed-type hypersensitivity
Autoimmunity	Antinuclear antibodies
Malignancies	Hepatosplenic T-cell lymphoma
Demyelization	Guillain-Barré syndrome
Abnormal liver function tests	Hepatitis, cholestatic disease
Cardiac abnormalities	Heart failure
Skin eruptions	Psoriasiform dermatitis

20 patients had a serious infection (an infection that requires antimicrobial therapy or hospitalization) during anti-TNF therapy, including fatal sepsis in two patients, in 500 Crohn's disease patients receiving infliximab[4]. In contrast, the CHARM study included 854 Crohn's disease patients, 517 of whom received adalimumab[5], and infectious adverse events occurred in 36%-44% of these patients. Serious infectious adverse events occurred in 2.7% of patients, and both types of adverse events were comparable to those in the placebo group. Serious infectious complications occurred in six of 216 patients (3%) treated with certolizumab[6].

Serious infections during anti-TNF therapy include the reactivation of latent tuberculosis. The increased awareness of this complication has led to a decrease in the number of reports of tuberculosis during biologic therapy. The risk of reactivation of latent tuberculosis was increased by seven-fold when the screening recommendations were not completely followed, as demonstrated by the Spanish national registry for anti-TNF therapy in rheumatoid arthritis[7]. After initiation of guidelines for tuberculosis screening prior to anti-TNF therapy, the rate of tuberculosis decreased by 78% in this registry[8]. Latent tuberculosis was identified by positive skin test and/or fibrotic lesions on chest X-ray in 16 patients in a single center cohort study including 734 IBD patients receiving infliximab. After chemoprophylaxis, none of these patients developed tuberculosis during infliximab therapy[9]. These findings suggest that the current treatment guidelines are indeed effective in preventing reactivation of latent tuberculosis. From 2001 to 2006, 130 patients with tuberculosis during anti-TNF therapy were reported in the USA[10]. The most important risk factor for disease reactivation was concomitant immunosuppressive therapy. Ominously, 34 patients in this group demonstrated a negative tuberculin skin test prior to anti-TNF therapy. Currently, every patient undergoing anti-TNF therapy should be screened by a careful medical history revealing any tuberculosis contact, followed by a chest X-ray and tuberculin skin test. As mentioned, this test is controversial due to reader variability and false-negative results. The recent T-cell-based interferon-γ assay seems more reliable with better sensitivity and specificity than the skin test, as shown in a group of 97 rheumatoid arthritis patients before initiation of anti-TNF therapy[11]. Patients with latent tuberculosis should start with chemoprophylaxis, for example isoniazid for 6 mo, during which anti-TNF medication can be introduced. Active tuberculosis should be fully treated before the start of anti-TNF therapy.

Data on the risk of fungal infections during anti-TNF therapy is limited. A database search identified 226 patients with fungal infections during infliximab therapy[12]. The most common pathogens were those causing histoplasmosis (30%), candidiasis (23%), and aspergillosis (23%). The majority of patients in this group were on concomitant immunosuppressive therapy (98%). Pneumonia was the most common manifestation of infection[12].

The reported risk of opportunistic infections in IBD patients treated with infliximab varies between 0.3% and 0.9%[13]. Interestingly, the risk of opportunistic infections dramatically increases when anti-TNF therapy is combined with additional immunosuppressive therapy, such as corticosteroids or thiopurine therapy[14]. The odds ratio for an opportunistic infection during infliximab therapy was 4.4, compared to 14.5 when combined with corticosteroids or thiopurines in 100 IBD patients with opportunistic infections, compared with a matched control group of IBD patients without opportunistic infections. The TREAT registry, which enrolled 6290 patients who received infliximab, showed that the increased risk for infections during anti-TNF therapy was associated with the use of corticosteroids and disease activity but not with the use of infliximab[15].

In summary, concomitant immunosuppression appears to be an important risk factor for infections during anti-TNF therapy. In daily practice, moderate to severe infectious complications prior to or during anti-TNF therapy require appropriate treatment of the infection before biologic therapy can be initiated or resumed safely.

Antibody formation

The monoclonal antibodies used for anti-TNF therapy frequently induce the formation of antibodies [antibodies to infliximab (ATI); antibodies to adalimumab (ATA)]. Sixty one percent of patients developed ATI in a study of 125 Crohn's disease patients who received on average four infusions of infliximab[16]. This development of ATI was associated with a shorter duration of response to therapy (35 d *vs* 71 d) and a higher rate of infusion reactions (relative risk 2.4)[16]. However, this correlation was not linear and did not predict infusion reactions in an individual patient. Importantly, immunosuppression in the latter study did decrease the formation of ATI.

Interestingly, recent data suggest that IBD patients who discontinued thiopurine therapy while continuing anti-TNF therapy did not show statistically significant clinical differences, compared to the group of patients receiving combination therapy[17]. This was demonstrated during a 2-year trial of 80 Crohn's disease patients. However, it should be noted that the infliximab

monotherapy group demonstrated lower infliximab trough levels and higher levels of C-reactive protein at 18-mo follow-up. We speculate that a prolonged follow-up period might have shown significant differences in the latter trends. ATI formation did not influence the pharmacokinetics of infliximab retreatment, although the authors discuss the influence of serum infliximab on the ATI assay in their paper, leading to an inability to draw firm conclusions[17]. Feagan *et al*[18] demonstrated that the efficacy of infliximab monotherapy was comparable to combination therapy with infliximab and methotrexate after 50 wk of treatment in Crohn's disease patients. Thus, although concomitant immunosuppression does reduce the formation of ATI, the clinical impact has recently been questioned. To further investigate the rationale for combination therapy with azathioprine and biologics, the SONIC trial included Crohn's disease patients who were naïve to immunosuppressive agents and biologic therapy with moderate to severe disease[19]. Patients were started on either azathioprine, infliximab, or a combination of both, and each group included 169 patients. At 26 wk, patients treated with infliximab monotherapy or infliximab plus azathioprine were more likely to achieve steroid-free remission and complete mucosal healing than those receiving azathioprine alone, whereas infliximab plus azathioprine was more effective than infliximab monotherapy. Further investigation in this field is warranted in order to guide patients in evidence-based choices to advise mono- or combination therapy.

Dosage and interval play a role in the development of ATI. For example, infliximab appears to be less immunogenic with increasing dose, as shown with different doses (1, 3 and 10 mg/kg) of infliximab in rheumatoid arthritis patients[20]. The immunological phenomenon of high-dose tolerance may explain this inverse dose-response correlation. Episodic treatment with anti-TNF therapy will also lead to an increased chance of developing antibodies to anti-TNF upon rechallenge. Therefore, scheduled maintenance rather than episodic therapy is recommended[21].

Adalimumab is a fully humanized IgG1 antibody to TNF and is considered less immunogenic than infliximab. The CLASSIC-2 trial demonstrated 2.6% antibody development in 269 patients receiving maintenance therapy for 56 wk[22]. All patients who developed antibodies in this study were not on concomitant immunosuppressive therapy. Yet, an ELISA was used for the detection of antibodies in this study. This technique has significant limitations due to the lack of discrimination between antibodies and anti-TNF medication[23]. This phenomenon may lead to underestimation of the true concentration of antibodies. Therefore, it is recommended that serum samples should be tested shortly before the next dose of anti-TNF in order to reduce the interference of anti-TNF medication[23]. A radioimmunoassay (RIA) is another technique to measure antibodies to anti-TNF medication. This technique measures specific high-avidity IgG antibodies against infliximab or adalimumab by an antigen-binding test[24]. The advantages of this assay are that it includes IgG4 antibodies, and it is more sensitive than ELISA due to a higher protein-binding capacity[23]. RIA measurements led to the detection of a higher percentage of patients who developed ATI or ATA when compared to previously reported findings[23]. Indeed, West *et al*[25] looked at 30 Crohn's disease patients who lost response to infliximab and were subsequently started on adalimumab. ATA were detected in five patients using RIA, four of these were non-responders to adalimumab. In this study, 17 patients were not on concomitant immunosuppression, and this subgroup included four patients with ATA. The authors concluded that ATA negatively influenced responses to adalimumab. In patients treated with certolizumab as maintenance therapy, 12% developed antibodies without concomitant immunosuppression, while 2% developed antibodies with immunosuppression[6].

Of interest, Aarden *et al*[23] demonstrated that low levels of anti-TNF, just prior to administration of the next dose, preceded the detection of ATI or ATA. Given the need for prevention of antibody formation during maintenance therapy and the technical challenges in the measurement of antibodies, assessment of trough levels rather than antibody development could be used as a biomarker for therapy adjustment. Therapeutic drug monitoring to guide therapy efficacy has not yet been elaborated.

Infusion reactions

The overall percentage of infusion reactions with infliximab was 6.1% in a group of 165 IBD patients[26]. These reactions included a burning sensation, itching, erythema, and pain. The estimated occurrence of serious adverse reactions (including shortness of breath, hypotension, or stridor) was 1.0%. In the latter study, all reactions were effectively treated[26]. Prophylactic antihistamines or a single-dose of hydrocortisone can be considered. In addition, patients who are off treatment for more than 4 mo are more susceptible to developing ATI and infusion reactions and should preferably receive these precautions. Most patients can be rechallenged after the appropriate precautions. Rarely, a genuine allergic reaction occurs, which is characterized by shortness of breath and urticaria[26]. These reactions are IgE-mediated and due to mast cell or basophil degranulation. In this case, the infusion should be stopped and switching to a different anti-TNF agent, such as adalimumab[27].

Delayed hypersensitivity-like reactions occur 3-14 d after anti-TNF therapy. Arthralgia and muscle ache are the most common symptoms[26]. It is believed that immune complex depositions take place and cause the latter symptoms[27]. Most patients with a large interval after the first administration of anti-TNF therapy develop delayed hypersensitivity upon rechallenge. Symptoms can be treated by acetaminophen and high-dose corticosteroids; symptoms usually resolve after 1-2 wk[27]. This group of patients will benefit from switching to a fully humanized anti-TNF therapy since poor responses to infliximab can be expected due to circulating ATI[16].

As a rule, adalimumab and certolizumab are administered subcutaneously. Injection site reactions, attributed to local irritation, were observed in 4% during adalimumab and 3% during induction therapy with certolizumab[5,28]. However, in our experience, injection site reactions are a frequently reported bothersome side effect of long-term adalimumab use. Injection site reactions regarded as a direct toxic effect do not improve following administration of antihistamines.

Autoimmunity

Anti-TNF therapy leads to cell lysis, in turn inducing circulating DNA and cell fragments, followed by the formation of autoantibodies such as antinuclear antibodies (ANAs). The percentages of autoantibodies differ depending on the therapy administered. Antibodies developed in 8% of certolizumab-treated patients after 6 mo, while infliximab led to > 50% of patients testing positive for autoantibodies[29,30]. Antibodies against double-stranded DNA were observed in 33% of 43 ANA-positive Crohn's disease patients receiving infliximab[30]. The development of antibodies is not limited to IBD patients or the use of infliximab; adalimumab induced ANAs in 45% of patients after 24 wk of treatment, and for infliximab, this number was 63% in a group of 91 rheumatoid arthritis patients[31]. Forty-one of 43 rheumatoid arthritis patients receiving infliximab and methotrexate demonstrated ANAs on at least one occasion, suggesting that concomitant immunosuppression does not reduce the formation of autoantibodies[32]. Furthermore, the formation of autoantibodies did not affect the efficacy of anti-TNF therapy and did not predispose to autoimmune diseases, in particular, systemic lupus erythematosus.

Malignancies

TNF plays a role in apoptosis and tumor suppression; it is believed that interference with these pathways can potentially lead to an increased risk of malignancies. However, the small size of clinical trials relative to the low incidence of lymphomas, the underlying risk of malignancies due to IBD, and the concomitant immunosuppressive therapy make it difficult to estimate the true effect, if any, of anti-TNF therapy on the genesis of malignancies in IBD patients. A large population-based study including 47 000 Crohn's disease and ulcerative colitis patients showed a standardized incidence ratio for lymphomas of 1.0 and 1.3 for ulcerative colitis and Crohn's disease, respectively[33,34]. The odds ratio for all types of cancer was 3.3 in a pooled analysis of both Crohn's disease and rheumatoid arthritis patients receiving infliximab or adalimumab[35]. Ten lymphomas were detected in 3493 patients receiving anti TNF therapy, whereas no lymphomas were reported in the control group. However, rheumatoid arthritis is associated with an increased risk of lymphomas, the latter being a disputed association in Crohn's disease[36,37]. The TREAT registry demonstrated that there was no significant increase in the relative risk for lymphoma (1.3) in 3272 patients treated with infliximab[15].

IBD patients undergoing immunosuppression are at increased risk for infections, including Epstein-Barr virus, which in turn may be associated with an increased risk of developing lymphomas. Seven of 18 lymphomas detected in IBD patients were Epstein-Barr-virus-positive, five patients in this group underwent therapy with azathioprine or 6-mercaptopurine[38]. However, the use of anti-TNF agents was not recorded in this study.

Hepatosplenic T-cell lymphoma is a rare type of non-Hodgkin's lymphoma with an aggressive and mostly fatal outcome. Until recently, 16 patients, mostly Crohn's disease patients who were exposed to infliximab, developed this type of lymphoma[39]. All patients received concomitant immunosuppressive therapy with thiopurines, and most patients also received corticosteroids. Of interest, three patients in this group received adalimumab, including two patients who previously received infliximab. It is alarming that nine cases were reported in the last 2 years, although increased awareness and subsequent reporting might play a role in this recent increase. Currently, it is unclear whether infliximab, thiopurine therapy, concomitant immunosuppressive therapy, the underlying disease, separately or in combination, are risk factors for the development of these lymphomas.

Taken together, the hypothesis of a slightly increased risk of lymphomas in IBD patients treated with anti TNF-therapy is debatable. Most studies lack the specific design to properly address this issue. The relative contribution of many risk factors for the development of lymphomas remains to be determined, such as the duration of anti-TNF therapy, concomitant immunosuppressive therapy, and the activity of the underlying disease.

Pregnancy and biologic therapy

Large-sized antibodies do not pass the placenta in the first trimester of pregnancy, but placental transfer is indeed possible in the second and third trimester of pregnancy. However, infliximab was not detected in breast milk[40,41]. To date, limited data are available to address the safety of anti-TNF medication during pregnancy. Live births occurred in 67%, miscarriages in 15%, and therapeutic terminations in 19% in a series of 96 pregnant patients receiving infliximab for either Crohn's disease or rheumatoid arthritis[42]. These results are comparable to Crohn's disease patients not receiving infliximab. However, it should be noted that most women stopped infliximab after conception. The TREAT registry reported 66 pregnancies including 36 during infliximab infusions[15]. The number of miscarriages and neonatal complications were similar in the infliximab-receiving *versus* infliximab-naïve patients. In another study of 10 pregnant Crohn's disease patients intentionally receiving infliximab during pregnancy, all had live births, of which three infants were premature and one had a low-birth weight[43]. Infliximab was detectable in newborns from 2 to 6 mo after delivery in a group of five mothers who were followed from the sixth month of pregnancy until

after delivery[44]. The decreasing levels of infliximab in newborns despite continuous breastfeeding do suggest placental transfer rather than transfer *via* breast milk. According to the FDA drug safety classification, infliximab is a drug without documented human toxicity, and is therefore considered category B.

Data on the use of adalimumab is limited, although case reports do not show adverse effects after the use of adalimumab during pregnancy[45,46]. No increased risk for adverse pregnancy outcomes was observed in a prospective cohort including 30 pregnant adalimumab-exposed rheumatoid arthritis patients, compared to a control group. A similar outcome was detected for an additional 66 pregnant patients exposed to adalimumab who did not meet the study cohort criteria[47].

Until now, the use of infliximab and possibly adalimumab does not appear to lead to an increased risk for fecundity, pregnancy, or fetal development. The available data on toxicity and long-term effects during pregnancy and in newborns are limited, therefore, a restrictive approach of using anti-TNF therapy prior to and during pregnancy seems appropriate. However, it is also important to realize that active IBD is documented to be detrimental to fecundity and pregnancy, and active disease can potentially do more harm to the embryo, fetus and mother than anti-TNF therapy.

Other safety issues

Neurological disorders following anti-TNF therapy have been described. Nineteen cases of demyelinating events following administration of anti-TNF agents were revealed in a review of the Adverse Events Reporting System of the Food and Drug Administration[48]. The latter observation was associated with a variety of neurological symptoms, including paresthesia, cognitive dysfunction, ocular symptoms, difficulty walking, incontinence, and hemiparesis[48]. Most, but not all, patients demonstrated partial or full recovery. Furthermore, nine patients on infliximab and one patient on adalimumab developed Guillain-Barré syndrome[49]. Also, optic neuritis was described in eight patients receiving infliximab and in two patients receiving adalimumab[50].

Abnormal liver function tests are associated with infliximab therapy. These abnormalities include cholestatic disease[51] as well as hepatitis-like syndromes[52]. Five patients receiving infliximab for Crohn's disease (one), rheumatoid arthritis (three) and psoriatic arthritis (one) developed liver disease, including one with autoimmune hepatitis and one with cholestatic liver disease leading to liver failure[53]. In addition, mildly elevated liver enzymes do occur, and it is recommended that anti-TNF infusions are stopped when these increases exceed three times the upper limit of normal in the case of alanine aminotransferase[54]. Abnormal liver functions tests generally return to normal after discontinuation of anti-TNF therapy. Reactivation of viral hepatitis[55,56] has been described in patients treated with anti-TNF therapy. Therefore, it is advocated that in high-risk groups, patients receiving anti-TNF therapy should be screened for hepatitis B prior to the initiation of therapy, and if positive, nucleoside analogs should be prescribed prior to the start of biologic therapy[56]. Interval monitoring of serum aminotransferases and viral load is recommended[56].

Data on the use of anti-TNF therapy in HIV-positive patients are limited. No clinical adverse effects or changes in CD4 count and viral load were detected in eight patients with rheumatic disease that were followed during their therapy with infliximab or etanercept. In this group, five patients received concomitant methotrexate, and five patients were using highly active antiretroviral therapy[57].

Dermatological symptoms have been reported as a side effect of infliximab therapy. 150 patients developed a wide variety of skin eruptions in a single-center cohort study including 734 infliximab-treated patients[58]. The majority of these patients (61%) were diagnosed with psoriatic dermatitis. Most skin lesions responded well to topical corticosteroids.

Anti-TNF therapy can lead to an increase in the rate of heart failure with an increased risk of death. Worsening of congestive heart failure was reported through the FDA's MedWatch in a number of postmarketing reports. Of 47 reported cases, 38 were new and nine were exacerbations[59]. Therefore, its use is contraindicated in patients with class Ⅲ-Ⅳ New York Heart Association congestive heart failure.

FUTURE DIRECTIONS

The potential risk for malignancies and infections during anti-TNF therapy appears strongly increased with concomitant immunosuppressive therapy, such as thiopurines. Therefore, risk stratification in order to reduce side effects in IBD patients requiring immunosuppressive therapy will become an important part of long-term treatment in these patients. For example, previous and latent infections (Epstein Barr virus, tuberculosis, and hepatitis B), previous malignancies and comorbidity should be taken into account to decide whether to withdraw immunosuppressive agents in order to reduce long-term side effects and maintain remission in IBD patients. Studies that address the reduction of immunosuppressive agents, like the withdrawal of thiopurines and continuation of infliximab in the study by Van Assche *et al*[17], provide valuable data for the potential reduction of concomitant therapies in IBD patients. Future trials to determine the effects of monotherapy *versus* combination therapy, such as anti-TNF, thiopurines, and methotrexate, will be important to guide this strategy. Furthermore, goals of therapy need to be defined. Should physicians aim for more aggressive therapy to ultimately achieve mucosal healing while increasing the risk of side effects, or should clinical remission remain the goal? Future research will help to provide patients with optimal therapy leading to quiescent disease and minimal side effects.

CONCLUSION

Anti-TNF therapy is a robust and effective therapy for

refractory IBD patients. The side effects can be severe, therefore, careful consideration and monitoring can partially prevent damage. Abscesses and opportunistic infections should be treated, and screening for tuberculosis as well as hepatitis B and HIV in high-risk patients is mandatory before the start of treatment. Antibody formation against anti-TNF agents can be prevented with concomitant immunosuppressive therapy, and the majority of infusion reactions due to infliximab can be prevented with antihistamines and corticosteroids. The risk of lymphomas requires careful consideration before the start of biologic therapy. Information on anti-TNF therapy in pregnancy is limited, although no adverse effects have been reported so far.

Abstract

The shortage of organ donors is a problem worldwide, with approximately 15% of adult patients with life-threatening liver diseases dying while on the waiting list. The use of cell transplantation for liver disease is an attempt to correct metabolic defects, or to support liver function as a bridge to liver transplantation and, as such, has raised a number of expectations. Most of the available studies briefly reported here focus on adult hepatocyte transplantation (HT), and the results are neither reproducible nor comparable, because the means of infusion, amount of injected cells and clinical variability differ among the studies. To better understand the specific role of HT in the management of end-stage liver disease, it is important that controlled studies, designed on the principles of evidence-based medicine, be done in order to guarantee the reproducibility of results.

INTRODUCTION

The shortage of organ donors is a problem worldwide, with approximately 15% of adult patients with life-threatening liver diseases dying while on the waiting list. Hepatocyte transplantation (HT) may therefore become a viable alternative treatment to liver transplantation (LTx) for these patients. From 1992 to date, several studies on adult human HT have been conducted in patients with acute or chronic liver failure, in an attempt to correct metabolic defects or support liver function as a bridge to LTx[1]. Hepatocytes are isolated from the patient's liver (autologous) or from discarded transplant organs (homologous). Other potential sources are livers obtained from non-heart-beating donors, marginal grafts (steatotic, liver trauma), and segment Ⅳ (with or without caudate lobe) from split-liver techniques, in which one liver is used for two recipients[2].

ISOLATION AND INFUSION TECHNIQUES

The isolation of hepatocytes must meet the standards of good manufacturing practice. The liver is digested by collagenase and the hepatocytes obtained are generally transplanted fresh or thawed after cryopreservation. Both types of cells seem to be efficient, although there is perhaps an advantage to using fresh cells. Although the liver and the spleen are the most reliable sites used, the peritoneal cavity has also been used for transplantation in patients with fulminant hepatic failure[3]. While the infusion route used for cell transplantation is usually the portal vein, the splenic artery or a direct splenic puncture have also been used. The choice of the organ to infuse should be based on the underlying liver architecture, which, in the case of cirrhosis, may limit the hepatocyte engraftment because: (1) there is diffuse and abundant extracellular matrix, i.e. a potential endothelial barrier for nesting; (2) the portosystemic shunts could favor the translocation of hepatocytes to the pulmonary circulation; and (3) the presence of portal hypertension may expose patients to the risk of portal thrombosis,

with the consequence of further deterioration of the existing liver function. Injection through the portal vein should then be reserved for correcting inborn metabolic errors, while the splenic artery should be considered for patients with a fibrotic liver. The splenic puncture poses too many risks for patients with splenomegaly and portal hypertension. For hepatocyte transplantation into the liver, up to 10^9 cells per treatment can been infused *via* the portal vein, either through an indwelling catheter into a branch of the inferior mesenteric vein or through a catheter placed transhepatically under radiographic control. During the infusion, it is essential to monitor the portal venous pressure to avoid the risk of portal hypertension. The hypothetical aim is to perform repeated cell infusions in order to provide approximately 5%-10% of total liver mass, though it is still not clear what constitutes the maximum number of liver cells that can be infused each time, how many infusions can be performed in total and what the required hepatocyte mass is, depending on the specific metabolic deficit and stage of chronic liver disease.

Transplanted hepatocytes engraft, proliferate and function metabolically, as shown by several animal models. Moreover, in humans, their capacity to engraft in the liver has been demonstrated in a female patient with acute liver failure who received 2.8×10^7 male hepatocytes through the splenic artery. Nested PCR for the Y chromosome was performed in the explanted liver 10 d after the infusion, showing an engraftment ratio of 1:4000[4]. The immunosuppression scheme resembles that used in whole-organ transplant, and is generally based on tacrolimus ± steroids.

CLINICAL STUDIES

Adult HT for metabolic liver diseases

Inborn errors of metabolism affect around 1 in 900 live births, and LTx is an accepted and successful treatment for liver-based metabolic disorders, with more than 90% of children achieving long-term survival[5]. The success of auxiliary LTx in humans[6] supports the observation in animal experiments that a relatively small amount of liver tissue can provide sufficient function to correct the underlying metabolic defects. The number of transplanted cells is between 5% and 10% of the liver mass, with a varying amount of cells depending on the use of fresh *vs* cryopreserved cells. About 27 children have received liver cell transplantation, through portal or umbilical vein, for inborn errors of metabolism. Among children with urea cycle disorders, three of them with ornithine transcarbamylase deficiency (OCT) had NH3 control and evidence of OCT activity on liver biopsy. A 3.5-year-old girl with argininosuccinate lyase (ASL) deficiency and psychomotor retardation received a total of 4.7×10^9 hepatocytes (divided into 11 infusions), with important ammonium level reduction, a 3% ASL activity on liver biopsy at 8 mo (undetectable at baseline), and evidence of engrafted male cells (12.5%) at 1 year[2,7-10]. A 9-year-old Crigler-Najjar type 1 baby achieved a 50% reduction of bilirubin after receiving 5% of the hepatic mass divided into three intrahepatic infusions over 24 h, and returned toward pre-transplant levels 2 years later, despite evidence of functioning, engrafted allogenic hepatocytes[12]. Five patients with homozygous familial hypercholesterolemia were transplanted with autologous (left lateral liver segment resected) genetically modified hepatocytes, with an *ex vivo* transduced low-density lipoprotein (LDL) receptor gene. In three of them, a more than 20% reduction in LDL-cholesterol was observed up to 28 mo after liver-cell transplantation (the longest sustained reduction rate reported in pediatric cases), but with evidence of a < 5% transgene expression at 4 mo[15]. Three children with factor Ⅶ deficiency showed an 80% reduction in exogenous factor Ⅶ replacement up to 6 mo after transplantation[11,16]. Intraportal HT had no benefit for two children with progressive familial intrahepatic cholestasis, but the failure was attributed to significant liver fibrosis found at the time of LTx[11]. Twelve patients, who had received HT as a bridge to transplantation, subsequently underwent elective orthotopic LTx (Table 1).

Table 1 Adult HT in metabolic liver disorders

	Patients (n = 27)	Range of viable[1] cells number	Outcome (died/LT)	References

Others	6[2]	$3.2\text{-}7.5 \times 10^9$	-/3	[11,17,18,20]

[1]In a few cases several cell infusions were performed; in one patient up to 18 infusions; [2]Glycogenosis type 1 (n = 2); refsum disease (n = 1); progressive familial intra-hepatic cholestasis (n = 2); α-1-antitrypsine deficiency (n = 1).

Adult HT for chronic liver disease and fulminant hepatic failure

Twenty patients have received HT for chronic liver disease. The first human hepatocytes were autotransplants performed in 1992 in 10 patients with chronic liver disease, using the left lateral segment as cellular source[19]. Transplanted hepatocytes were detected in the spleen with Tc 99m labeling at 1 and 6 mo. The next 10 patients were treated mostly with intrasplenic artery infusion (in two cases, the infusion was intraportal) and had some improvement in encephalopathy, hepatic protein synthesis and renal function. Four of them died. A liver transplant recipient with acute graft dysfunction, who had received an intraportal infusion, developed portal thrombosis and died the same day (Table 2)[4,20-22].

Patients with fulminant hepatic failure (FHF) have the highest mortality while on the waiting list, with an estimated 10% survival. HT can potentially support liver function until an organ becomes available or the liver regenerates. In a 1994 study[3], fetal hepatocytes

(60×10^6/kg body weight) were injected in 10 patients intraperitoneally through a dialysis catheter. Three of them recovered, showing neurological improvement, and decreased ammonia and bilirubin levels just 48 h after the infusion. No complications were related to the procedure. Among the 22 patients who received adult HT (Table 2), 11 had splenic artery infusion, nine had portal vein infusion and two received both splenic and intraportal infusion. Nine patients had a complete recovery (seven of whom received LTx). Two patients with herpes simplex virus and one with hepatitis B virus-related liver disease died[1,4,13,20,22,23].

FUTURE PERSPECTIVES

Most of the studies done in this field still focus on adult hepatocytes for transplantation, because this type of hepatocyte is considered a potential resource for bridging to LTx. However, this emphasis should perhaps be tempered by two important considerations: (1) adult hepatocytes are scarcely available, since they are obtained principally from discarded organs that cannot be transplanted; and (2) adult hepatocytes have limited proliferative capacity.

Alternative cell sources with vast capacities to consider for clinical application are stem cells and stem-cell-derived hepatocytes. Fetal tissues are in fact already deemed by the scientific community to be a promising source of liver stem cells to be used for clinical purposes. In Europe (Italy included), a multicenter study is underway on the use of fetal neuronal cells for the treatment of degenerative diseases. A study published in 2000 showed a functional improvement of cognitive-motor abilities in patients with Huntington's disease after human fetal neuron transplantation[24]. Fetal liver cells have several advantages compared to adult liver cells: greater availability, proliferative capacity and plasticity, less immunogenicity, good adaptation and integration capacity, and greater resistance to cryopreservation and ischemia. Moreover, there are no reports of oncogenic transformation, at least 2 years after intrasplenic fetal hepatocyte transplantation, in animal models[25].

The use of cell transplantation for liver disease raises a number of expectations, though it is important that controlled studies designed on the principles of evidence-based medicine be done in order to guarantee the reproducibility of results. At the same time, before establishing the safest and most effective number of cells to be infused, an accurate method for quantifying the engraftment rate, associated with specific tests of hepatocyte functionality, should be developed. A strict selection of candidates, and stratification by clinical scores (e.g. Meld score), could finally help clinicians to better understand the specific role of HT in the management of end-stage liver disease.

CONCLUSION

The results available in the literature are neither reproducible nor comparable. The means of infusion, the amount of injected cells and the clinical variability differ among the studies. In addition, a well-defined protocol of clinical and biochemical monitoring has yet to be established. However, the partial correction of the inborn errors, the sustained engraftment of at least 1/8 of the infused hepatocytes, and the prolonged survival in pediatric patients with metabolic liver diseases are encouraging enough to consider adult HT an effective bridging procedure to LTx for this category of patients. As it can be seen from the cases summarized in Table 2, 40.9% of patients with FHF and 60% of patients with chronic liver disease benefited from the hepatocyte infusion because they survived, with or without LTx. Nevertheless, it is possible that patients who recovered could have done so by spontaneous remission of the disease. Otherwise, in the remaining half of the patients, it could be hypothesized that the reason HT was not effective was attributable to the paucity of cells injected (rather than the loss of hepatic function in liver failure), or to the immunosuppressive regimens used (based on those for whole organ transplantation), which were not optimal for guaranteeing the function of the transplanted cells.

Abstract

Whipple's disease was initially described in 1907. Over the next century, the clinical and pathological features of this disorder have been better appreciated. Most often, weight loss, diarrhea, abdominal and joint pain occur. Occasionally, other sites of involvement have been documented, including isolated neurological disease, changes in the eyes and culture-negative endocarditis. In the past decade, the responsible organism *Tropheryma whipplei* has been cultivated, its genome sequenced and its antibiotic susceptibility defined. Although rare, it is a systemic infection that may mimic a wide spectrum of clinical disorders and may have a fatal outcome. If recognized, prolonged antibiotic therapy may be a very successful form of treatment.

Key words: *Tropheryma whipplei*; Small intestinal malabsorption; Abdominal lymphadenopathy; Periodic acid-Schiff staining; Whipple's disease

INTRODUCTION

Whipple's disease was first described in 1907. It required almost 100 years before the responsible organism, *Tropheryma whipplei* (*T. whipplei*) was cultivated, its genome sequenced and its antibiotic susceptibility defined[1-5]. Detailed and authoritative reviews regarding the disease have also recently appeared[6,7]. Whipple's disease is known to mimic a wide spectrum of medical conditions, and yet, only 1500 cases or so have been described to date in the literature. Most expert clinicians, including specialist gastroenterologists, never see a single case over the course of their entire careers, however this disease is a principal bacterial cause of chronic malabsorption. As such, recognition of Whipple's disease should not be minimized since timely treatment might impact on the outcome of this potentially fatal disorder.

ORGANISM AND HOST FACTORS

Whipple's disease often affects middle-aged Caucasian men (but not exclusively), causing weight loss, arthralgia, diarrhea, steatorrhea and abdominal pain. Occasionally, other atypical presentations may occur due to involvement of the heart, lungs or central nervous system. The responsible organism is rod-shaped and can be seen in many different ultrastructural forms present in cells and extracellular spaces[8,9]. Usually, the organism is detected within macrophages of the lamina propria of the small intestine and its lymphatic drainage. The organisms, however, may also occur in epithelial cells as well as cells of the immune system. Because of genetic heterogeneity, some strains are non-pathogenic or may cause atypical clinical presentations such as an isolated infectious form of endocarditis[10]. Using a polymerase chain reaction (PCR) method, researchers found *T. whipplei* occurring in the environment and it has been documented in sewage water, fecal material and in sewage plant workers without Whipple's disease[11,12]. There may be a selective immune defect in host T-cells (or macrophages) that leads to Whipple's disease, or alternatively, these immune defects may be secondary and caused by *T. whipplei* itself[13].

CLINICAL AND LABORATORY FEATURES

Table 1 displays common clinical and laboratory features of *T. whipplei* infection. In some cases, there is a "prodromal phase" with fever and isolated joint manifestations, including arthralgia, preceding any gastrointestinal symptoms[14,15]. These joint symptoms

Table 1 Clinical and laboratory changes in *T. whipplei* infection

may be migratory in type and rheumatoid-factor-negative. Large joints may be involved more often than small joints alone and there may be treatment resistance to antirheumatic drugs. Duodenal biopsies may be negative, but synovial fluid and biopsies examined using PCR, immunohistochemistry or electron microscopy may reveal the diagnosis[16]. Diarrhea, weight loss and malabsorption associated with low serum carotene may occur[14,15]. Anemia with an elevated sedimentation rate may develop. Peripheral edema with hypoalbuminemia and ascites (associated with protein-losing enteropathy) may develop later in the clinical course. Endoscopic changes may be noted in some, but not all, patients and have recently been illustrated by Armelao *et al*[16]. Essentially, duodenal folds appear thickened and erythematous and yellow-white plaques may be seen. Duodenal biopsies are still the basis for diagnosis in the majority of cases and have been illustrated well elsewhere[17]. The histological features can be readily appreciated on standard hemotoxylin-eosin-stained sections of mucosal biopsies as massive infiltration of the lamina propria with foamy macrophages. These macrophages contain the organism. A periodic acid-Schiff (PAS) stain will confirm the suspected diagnosis. Rarely, the infiltrate may be limited to the submucosa. Lamina propria plasma cells and lymphocytes are not increased; indeed, with extensive macrophage infiltration, they may appear to be decreased. Small collections of fat may also be present in the lamina propria (thus, the term intestinal lipodystrophy coined by Whipple) and the overlying villus epithelium may appear vacuolated because of fat accumulation[17]. In part, this may reflect obstruction of lamina propria lacteals and regional lymphatics by lymph node involvement[17]. After treatment, the bacilli may disappear and the macrophage numbers become reduced, but both may persist for years[17].

Approximately a quarter of patients with Whipple's disease develop neurological changes, and some, despite treatment, are irreversible[18,19]. Neurological change may be the initial clinical feature, and rarely may occur in isolation[19-21]. Cognitive manifestations, such as dementia, are common. Altered ocular movements may occur, including a progressive form of supranuclear ophthalmoplegia. Headache, psychiatric changes, focal or generalized seizures and ataxia are frequent. Even without neurological symptoms, cerebrospinal fluid infection may be defined by PCR analysis[22]. Ocular involvement may include uveitis, retinitis and optic neuritis with papilloedema[23]. Historically, the disorder has been recognized as a form of culture-negative endocarditis. Diagnosis by valve explantation has been recorded[10,24].

Laboratory diagnosis of *T. whipplei* infection is still largely based on duodenal biopsy. Foamy macrophages in the lamina propria are seen that are PAS-positive, but diastase-resistant. Possibly, this positive staining reaction is related to the inner membrane of the polysaccharide bacterial cell wall. A Ziehl-Nielsen stain (most typically used for mycobacteria species) is negative. Other sites, e.g. lymph nodes, may also yield a classic PAS-positive staining reaction in the macrophages. PCR has a high sensitivity and specificity but is not recommended for screening because healthy carriers with a positive PCR have been noted. Recent studies using quantitative PCR on saliva and fecal materials make a case for a role of PCR in initial evaluation[25], followed by more invasive biopsy evaluation. Immunostaining with specific *T. whipplei* antibodies may reveal the organism in PAS-negative tissues[26]. Other biomarker methods are being explored[27].

TREATMENT

Before antibiotic treatment, a fatal course was often recorded. Later, tetracycline was often used, but recurrence was common and more recent treatment recommendations have been based on antibiotics that are capable of crossing the blood-brain barrier. Recent recommendations suggest that a 2-wk course of intravenous ceftriazone to achieve high cerebrospinal fluid levels, followed by twice daily cotrimoxazole for 1 year is very effective[7]. Most recover completely, although central nervous system symptoms may not resolve[7]. Others have suggested trimethoprim-sulfamethoxazole twice daily for 1-2 years[6]. Interestingly, treatment may be successful even if the diagnosis is established many decades after the onset of symptoms[28].

If ceftriaxone hypersensitivity is evident, then induction has been recommended with penicillin, cephalosporins, carbapenems, or chloramphenicol[7]. As an alternative to long-term cotrimoxazole, combination doxycycline and hydroxychloroquine have been recommended[7].

Recurrent neurological changes in Whipple's disease have a poor prognosis, and use of interferon gamma therapy has been described[29].

Abstract

Inflammatory bowel disease (IBD) results from the interaction between an individual's immune response and precipitant environmental factors, which generate an anomalous chronic inflammatory response in those who are genetically predisposed. Various feeding practices have been implicated in the origin of IBD based on epidemiological observations in developed countries, but we do not have solid evidence for the etiological role played by specific food types. IBD is associated with frequent nutritional deficiencies, the pattern and severity of which depends on the extent, duration and activity of the inflammation. Nutritional support allows these deficiencies in calories, macro- and micro-nutrients to be rectified. Enteral nutrition is also a primary therapy for IBD, especially for Crohn's disease, as it allows the inflammatory activity to be controlled, kept in remission, and prevents or delays the need for surgery. Nutritional support is especially important in childhood IBD as an alternative to pharmacological treatment. This report discusses the complex relationship between diet and IBD.

Key words: Nutritional support; Inflammatory bowel disease; Enteral diet; Crohn's disease; Ulcerative colitis

INTRODUCTION

Inflammatory bowel disease (IBD) encompasses a heterogeneous group of chronic diseases of unknown etiology, unclear pathogenesis and a systemic nature that cause inflammation of the digestive tract, and includes Crohn's disease (CD) and ulcerative colitis (UC), which are traditionally found at opposite ends of the disease spectrum. While UC is exclusively restricted to the large bowel, CD can virtually affect any segment in the digestive tract, and may even be accompanied by extraintestinal manifestations. All diseases in the group involve alteration of the immunological tolerance system of the digestive tract mucosa[1], triggered by a certain factor which gives rise to an inappropriate, serious and prolonged inflammatory response in genetically predisposed individuals[2,3]. The ultimate causes of IBD have not yet been identified, but epidemiological studies show differences in the rate of IBD in terms of age and onset, race and geographical areas[4,5]. The existence of environmental factors is therefore suggested, which are capable of substantially altering the appearance of CD and UC. Among these, smoking and appendicectomy are the most notably implied, but the possible etiological role in the disease played by oral contraceptives, perinatal and childhood infections, or infections caused by atypical mycobacteria and diet has also been highlighted.

Various dietary and nutritional factors have been suggested as being significant etiological factors both for CD and UC[6], but at the same time, and more importantly, nutrition itself has proven to be a central component in the treatment of the disease, both as a primary therapy and for correcting the various nutritional deficiencies shown by these patients[7]. This report addresses these matters through a literature review, adding certain recommendations for the nutrition management of patients with IBD in the light of the evidence available.

DIET IN IBD

IBD results from the interaction of three essential co-factors: genetic susceptibility, environment and the immune response of the individual[8]. Environmental

factors may include both the local microenvironment (enteric microflora), and the nutritional environment. We do not have definitive data to demonstrate that diet is a cause of CD or UC, but over the past few decades, numerous studies have highlighted the potential etiological role played by certain feeding practices, based on the proportional increase of the incidence of IBD in developed countries and the appearance of new feeding habits in these regions[4]. New lifestyles include new feeding habits in which the consumption of cow's milk by children, the consumption of high quantities of refined sugar and fat and the low consumption of dietary fiber, fruit and vegetables take precedence.

Several studies have shown that breastfeeding reduces the possible development of UC[9-11] and CD[11-13]. Even in the case of infants who were breast fed for a short period of time, the risk of CD was significantly increased compared to the group that was breast fed for a longer time[12]. The consumption of cow's milk has also been implicated in the etiology of IBD[14], and these patients were shown to have higher levels of serum antibodies against cow's milk protein compared to healthy controls[15], with a correlation between the levels of specific antibodies and the index of activity in the case of adults with CD[16]. The relationship between breastfeeding and IBD has not been observed in other studies but various assumptions provide explanations as to the protective mechanisms of breastfeeding against IBD including: protection provided by breast milk against gastrointestinal infections[17-19]; its ability to stimulate the development of the gastrointestinal mucosa and its immunological capacity in children[20-23]; or postponing contact with cow's milk and other allergens and potentially infectious agents. Recently, the possible etiological role of *Mycobacterium avium paratuberculosis* as being an infectious agent which causes CD has been suggested[24,25]; this organism, originating from infected cows, could be transmitted through the milk and resist pasteurization[26]. However, several arguments against the putative role of *M. avium paratuberculosis* in causation of CD have been given, such as the lack of epidemiological support for transmissible infection, the absence of therapeutic benefit of traditional antimycobacterial antibiotics, and the low incidence of IBD in developing countries[27].

New feeding habits involve a high consumption of sugar and refined carbohydrates. Since the 1970s, various studies have indicated the high consumption levels of these products in patients with IBD[28,29], to the extent that they are now considered a risk factor for CD[30-32] and UC[31,33-35]. Conversely, the consumption of citrous fruit, fruit juices and vegetables could lower the risk[36] of the development of both diseases[37-39], and a particular study even showed an inverse relationship between the consumption of bran and the onset of CD[40]. To date, it has been impossible to determine whether the potentially protective effect is due to the action of the fiber or to other micronutrients contained in fruit and vegetables. The utility of low refined carbohydrate diets in the treatment of CD has been suggested by several authors[32,34], although extensive clinical trials have not confirmed the benefits of this measure[41].

In recent years, special attention has been paid to the lipid components of the diet as triggers of IBD. Since the earliest epidemiological relationships were demonstrated between the consumption of partially hydrogenated fats (margarine) and granulomatous ileitis[42] and UC[43], various studies have shown that new consumption patterns, such as fast food, could be linked to an increased risk in the development of CD and UC[36,44]. In addition, the consumption of large amounts of monounsaturated and polyunsaturated fats are both associated with a higher risk of UC[45,46]. The observation that the Eskimos in Greenland, consumers of large quantities of n-3 polyunsaturated fatty acids (PUFAs) deriving from fish oils, had a low prevalence of IBD[47,48] led to the study of the anti-inflammatory properties of n-3 PUFAs[49], in comparison with pro-inflammatory n-6 PUFAs. The latter have been clearly implicated in the origin of IBD, given that they affect the arachidonic acid metabolism by increasing the production of leukotriene B4, with pro-inflammatory action. These discoveries have opened up new channels of knowledge regarding the ability of lipids in the diet to regulate inflammatory processes in different diseases, as they are the fundamental component of cell membranes, including those of lymphocytes, which orchestrate immune system responses[50].

Short-chain fatty acids (SCFAs), of which butyrate is the most representative, are particularly worthy of note and are generated during the colonic fermentation of dietary fiber and other unabsorbable carbohydrates. A quantitative SCFA deficiency or their oxidation by colonocytes have been implicated in the physiopathology of UC[51,52], and SCFA *in vivo* oxidation is also lower in affected patients[53].

With regard to the protein and calorie intake in the diet, some studies have suggested that the intake of proteins[46,54] and calories[54] might be higher in patients with IBD compared to controls, although these data have not been uniformly observed and we do not know whether these factors are a cause or a consequence of the disease.

Despite the data presented at this moment in time, we still lack solid evidence regarding the accountability of certain dietary components in the etiology of IBD, although the aforementioned data oblige us to consider that the changes in the composition and characteristics of the diet which typifies modern life have been accompanied by substantial changes in the epidemiology of IBD in developed counties. However, we must remember that, beyond diet, our current lifestyle also has other characteristics whose possible etiological role in IBD has not been studied in depth.

NUTRITIONAL DEFICIENCY IN IBD

From the earliest descriptions of the disease, IBD,

especially CD, has been traditionally associated with serious nutritional deficiency. The pattern and severity of malnutrition in IBD depends on the duration, activity and extent of the disease, with significant differences having been described between CD and UC, given that the involvement of the small intestine is accompanied by a higher incidence of protein-calorie malnutrition and deficiencies in specific nutrients[55]. Furthermore, CD presents considerable chronic deficiencies, whereas in UC, the nutritional status tends to be more preserved, although during the flares of activity of the disease and in cases of hospitalization, the deficiencies tend to be significant[56]. In accordance with the methods and criteria considered for diagnosis, between 20% and 85% of IBD sufferers have nutritional deficiencies with prominent calorie-protein malnutrition in CD and protein malnutrition in UC[57]. A high proportion of CD patients (between 25% and 80%) and UC patients (between 25% and 50%) present hypoalbuminemia during hospitalization[55,58], which may clinically manifest as weight loss.

The origins of malnutrition in CD are multifactorial, but dietary restrictions (due to intolerance of diet or therapeutic fasting) are the most important. Also included are: the increase in energy requirements[59-61], the malabsorption of nutrients in the case of extensive intestinal involvement, gastrointestinal losses and the interaction between nutrients and drugs. Furthermore, the underlying inflammatory mediators of the physiopathology of IBD[62], such as tumor necrosis factor (TNF)-α, and interleukins-1 and -6 can increase catabolism and lead to anorexia. Table 1 provides a summary of the causes of malnutrition in IBD[63].

Table 1 Causes of malnutrition in IBD (modified from García-Manzanares *et al*[63])

Decrease in oral intake	Restrictive diets, therapeutic fasting
	By the disease itself: diarrhea, abdominal pain, nausea and vomiting, *etc*
	Alteration in taste: due to drugs, vitamin and mineral deficiencies, pro-inflammatory mediators
	Anorexigenous effect of pro-inflammatory cytokines
Gastrointestinal losses	Diarrhea
	Rectorrhagia/hematochezia
	Loss of mucus and electrolytes
	Protein-losing enteropathy
Metabolic disorders	Increase in resting energy expenditure
	Enhanced fat oxidation
Increase in nutritional requirements	Inflammatory states
	Increased basal oxidative metabolism
	Infectious complications
	Post-surgery
Drug interaction	Corticoids and calcium reabsorption
	Corticoids and protein catabolism
	Salazopirine and folates
	Methotrexate and folates
	Cholestyramine and liposoluble vitamins
	Antimicrobials and vitamin K
	Anti-secretors and iron
Poor absorption of nutrients	Reduction of the absorptive surface: intestinal resection, enteric fistulas, hypertrophy of the villi
	Blind loops, bacterial overgrowth
	Poor absorption of bile salts in ileitis or resection

Although micronutrient deficiency in IBD is common, in most cases it does not tend to have any evident clinical manifestation, except with regard to iron, folic acid, and vitamin B12[57]. However, those micronutrients which have an impact on bone mineral density, thrombophilia or carcinogenesis are of significant clinical interest. Little is known about other micronutrient deficiencies in IBD in terms of their consequences, frequency and subclinical development, due to the lack of studies in this area. However, many of them could be involved in regulating immune response at different levels[64].

IBD patients show an increased loss of bone mass[65,66], which could lead to osteopenia and osteoporosis, and which in certain studies, affects up to half the number of patients with CD and UC[67,68] and contributes to an increased risk of fractures up from 40% to 60%[60]. Although multifactorial in origin, the action of certain pro-inflammatory cytokines (especially TNF-α) has recently been highlighted with respect to bone loss[67]. Aside from the chronic or recurring use of corticosteroids[69], age, the female gender, type of IBD, smoking and other hormonal and genetic factors also contribute to osteoporosis in IBD[67].

Folic acid deficiency observed in half the number of patients with IBD might be due to difficulties in swallowing (low-fiber diets), poor absorption or competitive inhibition by certain treatments, such as sulphasalazine or methotrexate[63]. The absence of folic acid has been related to the increased risk of colitis-associated carcinogenesis[55,70], as it has a protective effect against high-grade dysplasia and cancer in patients with long-term UC[71,72]. Folate deficiency is also linked to the increased incidence of arterial and venous thromboembolic events observed in CD and UC[73], due to hyperhomocysteinemia, a well-known inducer of hypercoagulability states. Both folic acid and vitamin B12 are essential co-factors in the metabolic route of homocysteine-methionine[74]. Between 20% and 60% of patients with CD and terminal ileitis are deficient in vitamin B12.

Other relevant nutritional deficiencies in CD are iron, zinc or selenium. Zinc is a vital component for the healing of wounds and its deficiency should be considered in the case of recurrent fistulous disease[75,76]. In addition, zinc is a co-factor of superoxide dismutase, which protects against cell damage caused by free radicals. Selenium is a co-factor of glutathione periodoxase[63]. Oxidative stress is one of the factors which perpetuates the inflammatory response in IBD[77], which is why a sufficient intake of antioxidant agents such as vitamins A, C, E and selenium is of extreme importance and has been inversely correlated with the plasma levels of pro-inflammatory agents[77,78].

Malnutrition has particularly serious direct consequences for patients with IBD. The scope thereof

depends on various factors, noteworthy being the age at which the disease begins and its activity. Delayed growth in children is the most frequent extraintestinal manifestation[79]; it is detected early and affects 75% of patients with CD and 10% of cases of UC[63]. Various pro-inflammatory cytokines, which are frequently high in IBD[80], are involved in the growth retardation and puberty of these children, as well as absorption deficiencies or increased catabolism. The objectives in the treatment of these patients should be aimed at acquiring knowledge of the inflammatory mechanisms and the control of their effects using immunomodulatory and biological treatments and at optimizing nutritional treatment[81], which frequently requires coordination among gastroenterologists, endocrinologists and nutritionists.

Calorie-protein malnutrition causes humoral and cellular immunodeficiency. Its effects on the intestine lower the efficiency of the mucosal barrier, lead to alteration of the functionality of the mucosa-associated lymphoid tissue and to a greater risk of infection by bacterial translocation. Hypoplasia of the intestinal villi perpetuates malabsorption and increases the risk of infections.

Metabolic bone disease develops silently in these patients, the origin of which is probably multifactorial[82]: steroids, lack of physical activity, deficiencies of calcium, vitamins and other micronutrients and alterations of the intestinal villi.

NUTRITION AS AN EFFICIENT PRIMARY TREATMENT IN IBD

Nutrition therapy should play a fundamental role in the clinical management of all patients with IBD. Its objectives are to correct macro and micronutrient deficiencies in frequently malnourished patients subject to increased oxidative catabolism, to reverse the physiopathological consequences of such deficiencies, and also to exert its own anti-inflammatory therapeutic effect.

Enteral feeding using formulas or liquids should always take preference over parenteral feeding, unless it has been completely contraindicated. If oral feeding were not possible, feeding the patient through a nasogastric or nasoenteric tube should be considered. The value and benefits deriving from its use are directly dependent on the geographical location of the disease, its extent and gravity and enteral feeding is therefore especially indicated for CD patients when the small intestine is affected, while there is no evidence which supports the use of enteral nutrition in the treatment of UC. We have very little data regarding the efficiency of enteral nutrition in CD that is exclusively confined to the colon, although its remission rates might not show any differences compared to other locations of CD[83].

Apart from the intake of calories, proteins and micronutrients, enteral nutrition using liquid formulas performs other primary therapeutic functions in CD[84]. In 1973, the therapeutic effect of enteral nutrition exclusively using basic formulas (amino acids with no antigenic capacity) was described for the first time in adults with CD resistant to other therapies[85], as similar remission rates were achieved to corticosteroids[86,87]. This ability to abate CD activity in both adults[83] and children[88], extends to efficiency in maintaining remission[89-91], allowing delay in the need for surgery or reintervention[92]. Furthermore, it is a safe treatment for which no significant adverse effects have been reported.

With regard to enteral nutrition formulas, no differences were identified between the efficiency of elemental diets and non-elemental formulas[87,93], which leads to the rejection of the previously held idea that a diet lacking in antigenic capacity could restore the altered intestinal immune response. In this respect, the therapeutic effect of enteral nutrition in CD seems to be independent from the nitrogen source used[55]. On the other hand, the fat composition of the enteral diet seems to be more important in terms of its therapeutic effect on CD[94], as this fat composition could be the key factor of the diet's therapeutic action on the disease[95]. This has been suggested by various studies, but results are difficult to interpret, which means that we do not know what the ideal fat content in enteral nutrition should be for the treatment of CD. Various studies have assessed the efficiency of supplements using n-3 PUFAs in maintaining patients with CD[96,97] and UC[98] in remission, showing that they might only prove effective for maintaining CD cases in remission, although more extensive studies are required in order to unequivocally establish the utility of these therapies. In any case, these treatments are safe and no side effects have been reported.

The precise mechanism of action through which enteral nutrition operates in CD is not well known, but it has been suggested that it could act by modulating the immune system's mucosa, regulating imbalances in the bacterial flora capable of precipitating inflammation[99,100], or by modifying the luminal content, thereby altering the expression of certain genes in the epithelium with an effect on the immune system of the mucosa, as well as reducing the exposure of the intestine to antigens.

In recent years, we have increased our knowledge of the immunoregulatory function of intestinal microflora and its possible participation in the physiopathology of IBD[101,102]. Alteration of the composition and function of intestinal microbiota could lead to increased stimulation of the intestinal immune system, epithelial dysfunction and greater permeability of the mucosa, and accordingly, the correct characterization of the components of these microflora and the definition of their functions are vital in order to consider probiotic treatment for IBD[103,104]. Probiotics have shown to be as effective as mesalazine in preventing relapses in patients with UC and in the treatment of pouchitis. Efforts have also been made to identify dietary components (prebiotics) which are capable of regulating the bacterial

composition, or which have a trophic effect on the intestinal epithelium. SCFAs (butyrate, propionate and lactate) result from the fermentation of fiber by bacterial species in the colon (*Bifidobacterium*, *Eubacterium* and *Lactobacillus*), and are an important metabolic substrate for colonocytes that promote the good functioning of the mucosa[105]. The anti-inflammatory effect of butyrate has been the most studied at different levels in the physiopathology of the inflammation[51,106], and it has been successfully tested as a treatment for patients with UC[107,108].

Parenteral nutrition is of scant therapeutic interest in IBD since diverse studies have shown that intestinal rest is not beneficial to control the disease[109,110]. Consequently, parenteral nutrition is not useful for the induction or maintenance of remission in CD, nor do we have any evidence to support its use in UC. It is also very expensive and poses an additional risk due to the use of venous catheters[111]. Its utility is therefore restricted to certain cases involving efforts to close enterocutaneous or other complicated fistulas in patients with fistulizing CD[112,113], the treatment of short bowel syndrome following extensive resections for CD, or when enteral feeding is impractical for other reasons.

PRACTICAL CONSIDERATIONS

IBD is an important risk for malnutrition. Nutritional support using liquid formulas should be considered as a primary treatment for all patients with CD and in serious cases of UC, but especially for children and for those who may require prolonged cycles of corticosteroids, such as the youngest patients, those who are corticodependent, or those who present other risk factors for osteoporosis. Enteral nutrition may be considered both as a primary treatment and as a supplement to other medication in order to achieve or maintain CD remission[91].

A rich and varied diet should be recommended for all patients with IBD during remission, which includes fruit and vegetables, meat, olive oil and fish, especially blue fish. There are no reasons to restrict insoluble fiber in the diet except in the case of significant intestinal stenosis or when irritable bowel syndrome might co-exist that does not respond to other therapies. We do not have any studies that support the restriction of fiber in the diet during flares of the disease but the consumption thereof could be temporarily restricted at this time.

Because of their calcium content, dairy products are especially recommended for these patients and milk should only be restricted in the case of lactose intolerance, substituted by other fermented products (yoghurts and cheese) or calcium-enriched soya-based products. Calcium and vitamin D3 supplements are also required during treatments with systemic steroids and with those with a greater local effect, such as budesonide or beclomethasone. Iron and folic acid deficiencies should be routinely monitored in patients with IBD due to their high occurrence. Deficiency in one or both micronutrients is the main cause of anemia in these patients and can be easily remedied. We should warn that ferritin is an acute phase reactant that increases during inflammation, which restricts its value as a marker of ferropenia in IBD. For treating iron deficiency in IBD, iron can be orally or intravenously administered; the latter is recommended in cases of active inflammation in CD, since oral supplementation might be of limited efficacy. The absorption deficiency of vitamin B12 contributes to anemia and hypercoagulability. The resection or involvement of the terminal ileum in CD requires vitamin B12 supplementation *via* the parental route.

Ileum actively participates in enterohepatic circulation, which refers to circulation of bile acids from the liver where they are produced, to the small intestine, where they aid in digestion of fats and other substances, back to the liver. In this way, the distal ileum is necessary for fat and fat-soluble vitamin absorption. CD patients frequently undergo resection of the terminal ileum, and if a large segment of bowel is removed, malabsorption of these lipid diet components may appear.

The prevention of therapeutic non-compliance in IBD also includes nutritional supplements to diet and medication. In complying with nutritional treatment, aspects such as flavor, presentation, tolerability to the food, its potential adverse effects (diarrhea, nausea), the patients' motivation and that of the healthcare professionals who attend them, are influential. Attention should be paid to the distribution of the doses during the day and to the simultaneous administration of other solid food, together with the preferences of the patients themselves[55].

A number of commercial supplements are available that provide nutritional support in IBD, are wide in variety in terms of composition and nutritional content, and have a diversity of flavors allowing personal choice. We must warn that, for palatability reasons, the elemental or semi-elemental formulas are more suitable for administration *via* a nasogastric tube. Feeding using a nasogastric tube may also be considered for patients with specific protein or energy intake requirements, which for different reasons, can not be satisfied by oral means, but they may be fed a nutritional supplement *via* a tube during the night.

As detailed above, guaranteeing a sufficient calorie and protein intake can be a complicated task that may require the involvement of nutritionists and dieticians. Mutual trust between the patients, their families and the health professionals is vital to ensure the sufficient level of motivation for the adequate long-term nutritional compliance required by a chronic disease. Enteral nutrition is considered the number one treatment for CD in children, as an alternative to immunomodulatory drugs, due to its excellent safety record and advantages concerning growth. In these cases, cooperation between the patient's family and the professionals who care for him or her are particularly important to guarantee correct nutritional support.

Abstract

AIM: To analyze the relevance of the microRNA *miR-196a* for colorectal oncogenesis.

METHODS: The impact of *miR-196a* on the restriction targets *HoxA7*, *HoxB8*, *HoxC8* and *HoxD8* was analyzed by reverse transcription polymerase chain reaction (RT-PCR) after transient transfection of SW480 cancer cells. The *miR-196a* transcription profile in colorectal cancer samples, mucosa samples and diverse cancer cell lines was quantified by RT-PCR. Transiently *miR-196a*-transfected colorectal cancer cells were used for diverse functional assays *in vitro* and for a xenograft lung metastasis model *in vivo*.

RESULTS: *HoxA7*, *HoxB8*, *HoxC8* and *HoxD8* were restricted by *miR-196a* in a dose-dependent and gene-specific manner. High levels of *miR-196a* activated the AKT signaling pathway as indicated by increased phosphorylation of AKT. In addition, high levels of *miR-196a* promoted cancer cell detachment, migration, invasion and chemosensitivity towards platin derivatives but did not impact on proliferation or apoptosis. Furthermore, *miR-196a* increased the development of lung metastases in mice after tail vein injection.

CONCLUSION: *miR-196a* exerts a pro-oncogenic influence in colorectal cancer.

Key words: Micro-RNA; Cancer; Colorectal; *miR-196a*; Migration; Homeobox

Schimanski CC, Frerichs K, Rahman F, Berger M, Lang H, Galle PR, Moehler M, Gockel I. High *miR-196a* levels promote the oncogenic phenotype of colorectal cancer cells. *World J Gastroenterol* 2009; 15(17): 2089-2096 Available from: URL: http://www.wjgnet.com/1007-9327/15/2089.asp DOI: http://dx.doi.org/10.3748/wjg.15.2089

INTRODUCTION

Survival in colorectal cancer (CRC), one of the three most prevalent malignancies in western countries, is delineated by local recurrence, lymphatic and distant dissemination[1-3]. Molecular determinants occurring during the adenoma-carcinoma sequence of sporadic CRC include mutations in certain tumor-suppressor genes (*APC*, *DCC*, *Smad-2*, *Smad-4*, *p53*) and oncogenes (*K-ras*) that have been summarized by Fearon and Vogelstein[4-6]. However, as only 8% of CRCs harbor concomitant mutations of *APC*, *K-ras* and *p53*, it seems very likely that additional pathogenic alterations are instrumental in promoting progression and metastasis of colorectal cancer[7].

A recently discovered class of non-protein-coding small RNAs, microRNAs (miRNAs), extend our understanding of oncogenesis. miRNAs are endogenous small RNA molecules of 20-25 nucleotides length, regulating gene expression by inhibiting transcription,

inducing direct cleavage of the targeted mRNAs or blocking translation through their complementarity *versus* targeted mRNAs at 3' untranslated regions[8-13].

More than 50% of all known miRNA genes are located in cancer-associated regions or in fragile sites of the genome, indicating that miRNAs might play an important role in oncogenesis[14]. Supporting evidence is the close location of miRNAs, as *miR-196a*, in homeobox (*Hox*) gene clusters[14]. Hox proteins are major transcription factors that play a crucial role during embryogenesis, organogenesis and oncogenesis[15].

While some miRNAs can function as oncogenes, others act as tumor suppressors. Specific miRNAs, such as *let-7*, are under-expressed in cancer and function as tumor suppressors by regulating oncogenes in normal tissue. New evidence indicates that down-regulation of *let-7* transcription is a relevant step during oncogenesis which is significantly associated with shortened postoperative survival in lung cancer[16-18]. *Let-7* negatively regulates the expression of oncogenes *Ras* and *Myc* by targeting their mRNAs for translational repression in diverse malignancies[19].

In contrast, over-expressed miRNAs, such as *miR-17-92*, function as oncogenes promoting cancer development through inhibition of tumor suppressor genes. The expression of miRNA *miR-17-92* is significantly increased in small-cell lung cancer[20]. Interestingly, the known targets of *miR-17-92* include the two well-known tumor suppressor genes, *PTEN* and *RB2*[21].

The miRNA *miR-196a*, encoded at three locations in the mammalian Hox clusters A, B, and C, depicts evolutionarily conserved complementarity to mRNA of *HoxB8*, *HoxC8*, and *HoxD8*[22]. Interestingly, *miR-196a*-directed cleavage of *HoxB8* was detected in mouse embryos, and additional *in vivo* experiments revealed a down-regulation of *HoxB8*, *HoxC8*, *HoxD8* and *HoxA7* in mammalian cells. These results indicate a miRNA-mediated regulation of *Hox* gene expression during vertebrate embryogenesis[22].

Matching these observations, Hornstein and colleagues describe that *miR-196a* acts upstream of *HoxB8* and *sonic hedgehog* (*Shh*) *in vivo* during limb development[23]. Analyzing the miRNA expression pattern in pancreatic adenocarcinoma by large-scale miRNA chip analyses, Croce and colleagues found that 75% of tumors expressed *miR-196a* at a high level, predicting poor patient survival and linking *miR-196a* to human oncogenesis (14.3 mo *vs* 26.5 mo)[24].

As we had previously investigated the relevance of *Hox* genes for gastrointestinal cancer progression and observed a tumor-suppressive function of high *HoxC8* expression levels, we hypothesized that *miR-196a* might exert a pro-oncogenic influence in human cancer cells.

MATERIALS AND METHODS

Cell culture and human tissue

The human colorectal cancer cell lines SW480, SW620 and HT29 and the human gastric cancer cell line Snu16 were cultured in RPMI-1640 (Invitrogen, Germany) supplemented with 10% FCS, 100 U/mL penicillin, 100 μg/mL streptomycin (Cambrex, Germany) and 1 mmol/L L-glutamine (Invitrogen, Germany).

Colorectal cancer and mucosal tissue has been collected from the resectate of seven patients undergoing elective surgery for colorectal cancer after obtaining patients' written informed consent and approval by the local ethics committee.

miRNA isolation and quantitative reverse transcription polymerase chain reaction (RT-PCR)

miRNA isolation was performed from four cancer cell lines, and from seven colorectal cancer and matching mucosal samples using the MirVana miRNA Isolation Kit according to the manufacturer's recommendations (Ambion, Austin, USA). HSA-*miR-196a* and *U6* primer sets were commercially acquired and applied for quantitative RT-PCR using the MirVana QRT-PCR miRNA Detection Kit with Super *Taq* Polymerase (Ambion). For amplification, an Applied Biosystems 7900 HT Fast Realtime PCR System (Applied Biosystems, Foster City, USA) was used.

miR-196a transfection

3×10^5 SW480 colon cancer cells were plated in a six-well plate and cultured as described before. SW480 cells were used, as they had the lowest *miR-196a* transcription levels (see below). *miR-196a* was commercially synthesized (MWG Biotech, Germany) and applied at different concentrations (0, 20, 40, 80, 160 and 240 nmol/L). Transfection was performed with Lipofectamine siRNAmax (Invitrogen, Carlsbad, CA, USA) according to the recommendations of the manufacturer. Cells were harvested 24-48 h after transfection and either applied in the functional assays, in a xenograft bioassay or collected for RNA/protein extraction, respectively.

Proliferation assays

6×10^3 transiently transfected SW480 cells (mock or 160 nmol/L *miR-196a*) were plated in 96-well plates and cultured as described above. The start of analyses was 24 h after transient transfection. The number of cells per well was determined daily by absorbance (MTT). Absorbance was quantified with an ELISA reader. Each condition was performed in quadruplicate.

Adhesion assay

For adhesion assays, SW480 cells were used. Transient transfection (mock or 160 nmol/L *miR-196a*) was performed 48 h prior to assay start. Ninety-six-well plates had been prepared with laminin (10 μg/mL, 30 min, room temperature, Sigma, Germany), fibronectin (10 μg/mL, 30 min, room temperature, Sigma) or PBS and were blocked with albumin (2%, overnight, 4℃, Serva, Germany), respectively. After trypsinization, 4×10^4 cells were seeded per 96-well and allowed to attach for 45 min. Thereafter, the medium and non-attached cells were removed. Each

well was washed twice with 100 μL pure RPMI-1640 cell culture medium. The number of attached cells per well was determined by luminescence assay (Celltiter-Glo Cell Viability assay; Promega, USA). Emitted luminescence was quantified with a luminometer. Each condition was performed in quadruplicate. For dose-dependent quantification of adhesion (0, 40, 80 or 160 nmol/L *mi*R-*196a*) non-modified 96-well plates were used.

Migration and invasion assays

For migration and invasion assays SW480 cells were used 48 h after transient transfection (mock or 160 nmol/L *mi*R-*196a*). Migration and invasion were assayed with 24-well HTS FluoroBlock Inserts in triplet approaches (8 μmol/L pore size; Becton Dickinson, USA). For invasion assays, membranes were covered with fibronectin in advance (10 μg/mL, 30 min, room temperature, Sigma) and blocked with albumin (2%, overnight, 4℃, Serva).

In brief, 4×10^4 cells were re-suspended in serum-free RPMI-1640 medium and added to the upper chamber. Consecutively, RPMI-1640 medium with 20% FCS and 100 ng/mL CXCL12 was added to the lower chamber. Chambers were incubated for 24 h at 37℃ in a humid atmosphere of 5% CO_2. After incubation, the amount of cell invasion and migration into the lower chamber was determined by luminescence assay (Celltiter-Glo, Cell Viability assay; Promega) according to the recommendations of the manufacturers. Emitted luminescence was quantified with a luminometer. Each condition was performed in triplicate.

Chemosensitivity

3×10^5 SW480 cells (mock or 160 nmol/L *mi*R-*196a*) were seeded per six-well plate. Twenty-four hours after plating, 5-fluorouracil (5-FU) (10 μg/mL), irinotecan (40 μg/mL), oxaliplatin (10 μg/mL), cisplatin (20 μg/mL) or placebo (1 × PBS) were added to the medium. The number of apoptotic cells was determined after 48 h by apoptosis assay. In brief, suspension cells were collected and adherent cells were trypsinized prior to fixation with 100% ethanol, stained with propidium iodide and analyzed by FACS without gating. Each condition was performed in quadruplicate.

Western blotting analysis

SW480 cells were harvested 2 d after transient transfection (mock or 160 nmol/L *mi*R-*196a*), washed twice with PBS (1 ×) and lysed in 2 × RIPA solution. For Western blotting analysis, 100 μg of protein was loaded on a 13% SDS-PAGE gel. After separation, the gel was transferred to a PVDF membrane (Roth, Karlsruhe, Germany). AKT protein was detected with a rabbit-anti-human antibody (1:1000, overnight, 4℃, rabbit-anti-human monoclonal antibody, pan AKT, 4685; Cell Signaling, Danvers, MA, USA). Phosphorylated AKT (pAKT) protein was detected with a rabbit-anti-human antibody (1:1000, overnight, 4℃, rabbit-anti-human monoclonal antibody, Phospho-AKT, 9267, Cell Signaling). MEK1/2 was detected with a monoclonal rabbit-anti-human antibody (1:1000, overnight, 4℃, rabbit-anti-human monoclonal antibody, 9122; Cell Signaling). pMEK1/2 was detected with a monoclonal rabbit-anti-human antibody (1:1000, overnight, 4℃; rabbit-anti-human monoclonal antibody, 9121; Cell Signaling). Alpha-tubulin was analyzed with a monoclonal mouse-anti-human antibody (T5168, 1:2000, overnight, 4℃, Sigma). The secondary antibodies used were goat-anti-rabbit (1:10 000, 1 h, RT, SC-2033, Santa Cruz Biotechnology, Santa Cruz, CA, USA) and goat-anti-mouse (1:10 000, 1 h, RT, SC-2031, Santa Cruz Biotechnology). For visualisation the Roti Lumin systems 1 and 2 were applied (P79 and P80; Roth).

Lung metastases xenograft biosystem

Transient transfection (mock or 160 nmol/L *mi*R-*196a*) of SW480 was performed 48 h prior to assay start. 4×10^4 tumor cells were re-suspended in 0.2 mL pure RPMI-1640 medium and applied for induction of lung metastases in 7-8-wk-old nod-Scid mice. Nod-Scid mice were radiated with 1.8 Gy 1 d prior to intravenous injection (tail vein) of tumor cells. Lung tumors grew for 7 wk before the animals were sacrificed. Thereafter, lungs were resected and tumor nodules quantified manually using surgical magnifying glasses.

RNA isolation and semiquantitative RT-PCR

RNA isolation was performed using the Qiagen RNeasy Kit according to the manufacturers recommendations (Qiagen, Hilden, Germany). Gene transcription of *β-actin*, *HoxA7*, *HoxB8*, *HoxC8*, *HoxD8* was analyzed by a two-step RT-PCR: reverse transcription was performed with 2 μg of RNA (20 μL total volume; Ominscript RT Kit; Qiagen) according to the recommendations of the manufacturer. One microliter of cDNA was used as a template for the specific PCR reactions. Primers applied were *β-actin*-forward: 5'-TGACGGGGTCACCCACACTGTGCCCATCTA-3', *β-actin*-reverse: 5'-CTAGAAGCATTTGCGGTGGACGATGGAGGG-3' (661 bp fragment), *HoxA7*-forward: 5'-CCGCATGAAGTGGAAGAAAG-3', *HoxA7*-reverse: 5'-CAGTCCACAAAAGTTGGGAG-3' (347 bp fragment), *HoxB8*-forward: 5'-GCAATTTCTACGGCTACGAC-3' and *HoxB8*-reverse: 5'-GAAACAGAAGCTGGAGCGG-3' (434 bp fragment), *HoxC8*-forward: 5'-CACGTTCAAGACTTCTTCCACCACG-3' and *HoxC8*-reverse: 5'-GGTTCCAGAACCGAAGGATGAAGTG-3' (449 bp fragment), *HoxD8*-forward: 5'-ACAGCCGATTTTTACGACCC-3' and *HoxD8*-reverse: 5'-GCTTCCTTTTTCGTTTCCCC-3' (399 bp fragment).

For amplification, a DNA Engine PTC200 (MJ Research, Watertown, USA) thermocycler was used. Cycling conditions of the respective PCR were as follows: initial denaturation (4 min at 95℃), followed by the respective number of cycles (*β-actin*: 20; *HoxA7*: 29, *HoxB8*: 29, *HoxC8*: 29, *HoxD8*: 29) of denaturation (1 min at 94℃), annealing (1 min; *β-actin*: 57℃; *HoxA7*:

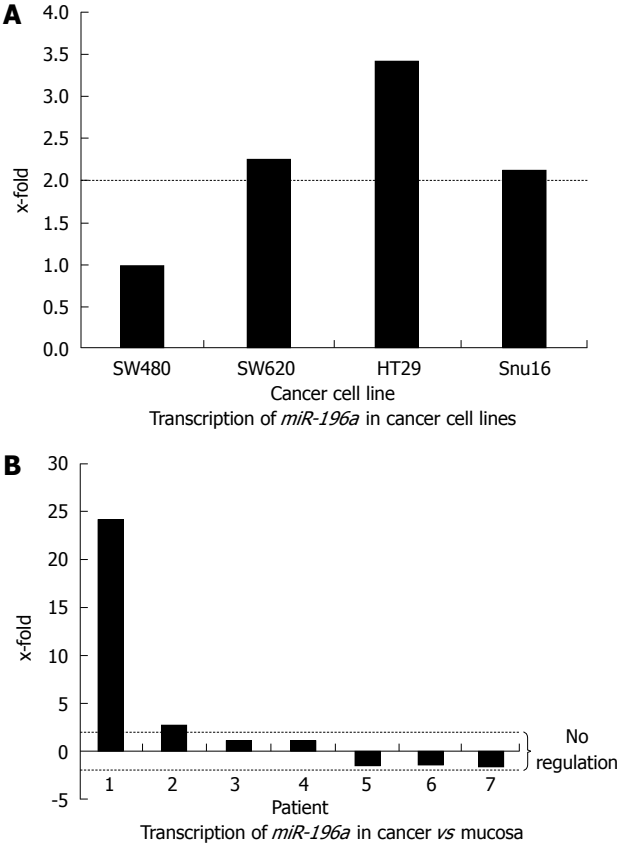

Figure 1 Transcription levels of *miR-196a* in cancer cell lines and human CRC. A: Cancer cell lines SW620, HT29 and Snu16 reveal increased *miR-196a* levels as compared to the primary colon cancer cell line SW480; B: *miR-196a* transcription is up-regulated in two of seven cancer samples in comparison to the matching mucosa sample. In contrast, no down-regulation in the respective tumor samples was observed.

58℃, *HoxB8*: 56℃, *HoxC8*: 62℃, *HoxD8*: 57℃) and elongation (2 min at 72℃). After the last cycle, a final extension (10 min at 72℃) was added and thereafter the samples were kept at 4℃. Seven microliters of the products were run on a 1.8% agarose gel, stained by ethidium bromide and analyzed under UV light.

Statistics analysis

The χ^2 test was used to compare all other patient and tumor characteristics by group. The *t* test was applied to compare results obtained from function assays. For all tests, $P < 0.05$ was considered significant.

RESULTS

miR-196a transcription in cancer cell lines

Real-time analyses of four cancer cell lines revealed U6 adjusted differences in regulation of *miR-196a* (Figure 1A). The SW480 cell line, which was initially isolated from a primary colon cancer, revealed the weakest transcription level. In contrast, SW620 cells, isolated from metastases of the same patient depicted a 2.25-fold up-regulation of *miR-196a*. HT-29, another colorectal cancer cell line revealed a 3.38-fold up-regulation of *miR-196a*. Similarly, SNU16 generated from metastases of a disseminated gastric cancer showed a 2.14-fold up-regulation of *miR-196a*.

miR-196a transcription in colon cancers versus mucosa

Real-time analyses of colon cancer and matching mucosa revealed an U6 adjusted up-regulation of *miR-196a* in two of seven colon cancers samples analyzed (24.3- and 2.5-fold, respectively; Figure 1B). In contrast, five of seven samples did not depict any transcription differences between tumor and mucosa (1.14-, 1.04-, -1.03-, -1.08- and -1.28-fold regulation, respectively).

Functional analysis using miR-196a transiently transfected SW480 cancer cells

Functional analyses did not depict any significant impact of *miR-196a* on proliferation (Figure 2A). Absorbance analyses after 4 d of cell culture revealed the following results: +m*iR-196a*: 1.506 ± 0.079, -m*iR-196a*: 1.533 ± 0.131; $P = 0.66$; (*vs* NS).

Interestingly, transfection with *miR-196a* decreased the adhesion of cancer cells to plastic and fibronectin but not to laminin (Figure 2B). Adhesion analyses revealed following results: for plastic surface: +m*iR-196a*: 10.2% ± 1.15%, -m*iR-196a*: 16.6% ± 1.73%; $P = 0.001$. For laminin coating: +m*iR-196a*: 3.86% ± 1.3%, -m*iR-196a*: 2.84% ± 0.95%; $P = 0.25$; (*vs* NS) and for fibronectin coating: +m*iR-196a*: 10.86% ± 1.64%, -m*iR-196a*: 13.8% ± 1.56%; $P = 0.08$; (NS).

In addition, *miR-196a* transfection resulted in a significant increase of migration and invasion (Figure 2C and D): Migration: +m*iR-196a*: 9.7% ± 3% *vs* -m*iR-196a*: 3.6% ± 2.4%; $P = 0.05$. Invasion: +m*iR-196a*: 12.6% ± 3% *vs* -*miR-196a*: 5.14% ± 3%; $P = 0.039$.

Influence of miR-196a on classical signal cascades

In order to analyze the relevance of *miR-196a* on activation of signal cascades we quantified phosphorylation of AKT and MEK (Figure 3A). Transient transfection with *miR-196a* resulted in an increased phosphorylation of (p)AKT but not of (p)MEK. These results imply that *miR-196a* increases activation of the *PI3K-AKT-mTor* signalling pathway.

Chemosensitivity analyses

Analyses of apoptosis did not reveal any significant impact of *miR-196a* (Figure 3B): +m*iR-196a*: 0.61% ± 0.08% *vs* -m*iR-196a*: 0.62% ± 0.07%, $P = 0.3$; (NS); nor in combination with 5-FU [+m*iR-196a*: 15.67% ± 1.45% *vs* -m*iR-196a*: 14.05% ± 0.74%, $P = 0.18$; (NS)] or irinotecan [+m*iR-196a*: 11.97% ± 0.51% *vs* -m*iR-196a*: 12.06% ± 1.36%, $P = 0.92$; (NS)]. However, *miR-196a* significantly increased chemosensitivity to oxaliplatin (+m*iR-196a*: 13.56% ± 2.08% *vs* -m*iR-196a*: 9.46% ± 1.19%, $P = 0.05$) and cisplatin (+m*iR-196a*: 23.11% ± 1.93% *vs* -m*iR-196a*: 18.42% ± 1.92%; $P = 0.04$). In summary, *miR-196a* increases chemosensitivity to platin derivates.

Lung metastases xenograft

Transient transfection of SW480 cancer cells with *miR-196a* resulted in a significant increase of pulmonary metastases growth after 7 wk of incubation: +m*iR-196a*: 7.5 ± 1.7 *vs* -*miR-196a*: 3.25 ± 0.96, $P = 0.009$ (Figure 3C).

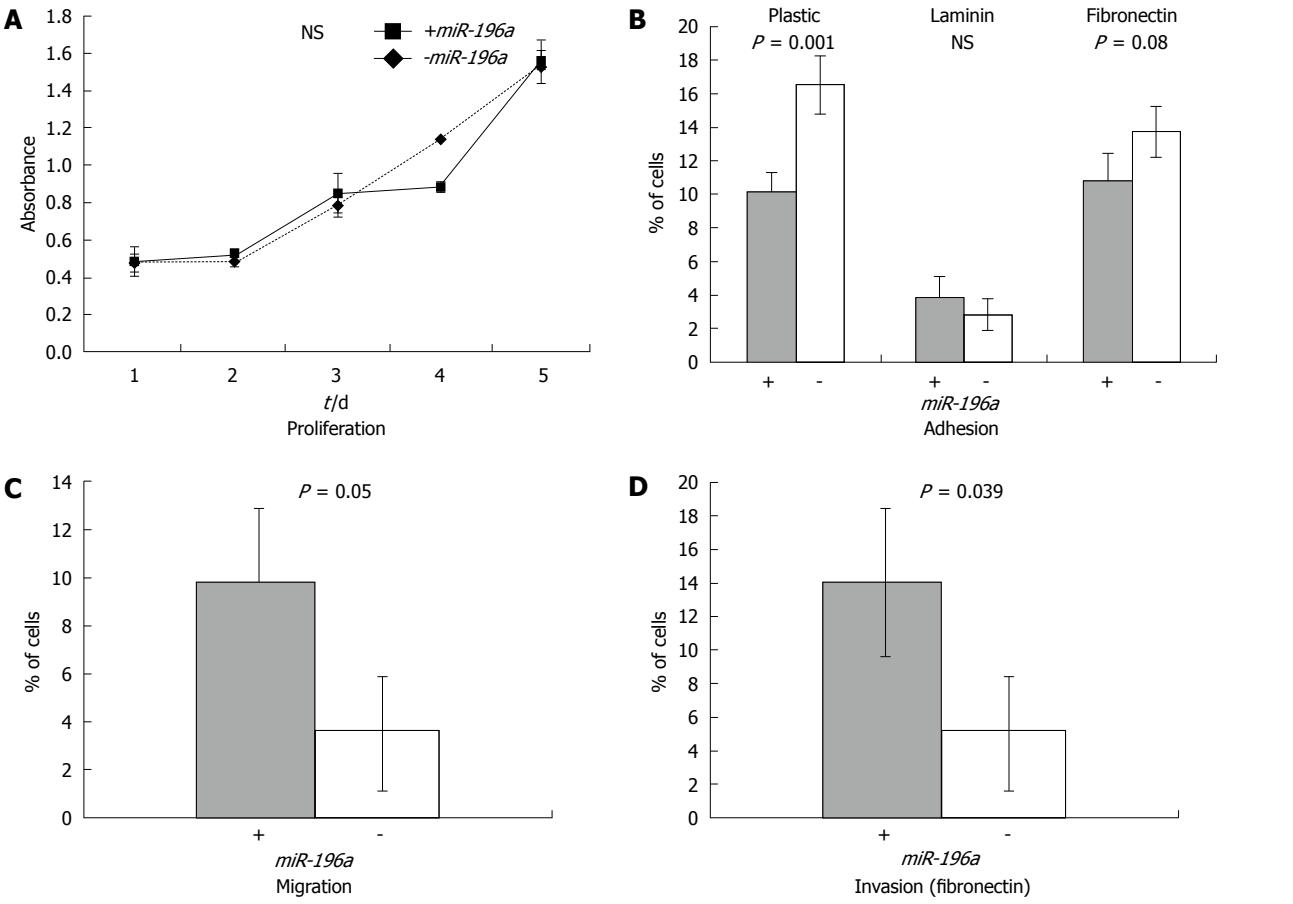

Figure 2 ***In vitro*** **effect of** ***miR-196a*** **in human CRC.** Transient *miR-196a* transfection significantly decreases adhesion, increases migration and invasion but does not impact on proliferation or apoptosis of SW480 colon cancer cells.

Verification of miR-196a target genes

Transient transfection of SW480 cells with *miR-196a* verified *HoxA7*, *HoxB8*, *HoxC8* and *HoxD8* as *miR-196a* targeted genes (Figure 4A). However, significant differences in target restriction were observed. While low *miR-196a* concentrations (20 nmol/L) sufficiently restricted *HoxB8* mRNA, higher concentrations were necessary to completely restrict *HoxC8* mRNA and to restrict a significant amount of *HoxD8* mRNA. However, the impact of *miR-196a* on *HoxD8* was weaker than on *HoxC8*. Only the highest *miR-196a* concentrations (240 nmol/L) decreased mRNA levels of *HoxA7*. These data verify the predicted *Hox* genes *HoxA7*, *HoxB8*, *HoxC8* and *HoxD8* as human targets of *miR-196a* but also reveal dose-dependent differences in restriction of target genes.

Dose-dependent inhibition of cellular adhesion

Transfection with *miR-196a* significantly decreased the adhesion of cancer cells to plastic in a dose-dependent manner. Numbers reflect the percentage of cells that adhered to the bottom of the well: 0 nmol/L *miR-196a*: 15.21% ± 0.47%; 40 nmol/L *miR-196a*: 14.27% ± 0.46%; $P = 0.07$; (NS); 80 nmol/L *miR-196a*: 12.43% ± 0.42%; $P = 0.002$ and 160 nmol/L *miR-196a*: 10.6% ± 0.3%; $P = 0.0003$ (Figure 4B).

DISCUSSION

Expression patterns of miRNAs are systematically altered in colon cancer as recently described by Schetter and colleagues[25]. In particular, Schetter *et al*[25] reported that at least 37 miRNAs are differentially expressed in colon cancer. Of those the expression profiles of *miR-20a*, *miR-21*, *miR-106a*, *miR-181b* and *miR-203* were validated. Interestingly, high *miR-21* expression was associated with poor survival.

We were interested in the relevance of *miR-196a* transcription for human colorectal cancer progression for specific reasons. Yekta and colleagues described *HoxB8* as a restriction target of *miR-196a* and predicted *HoxA7*, *HoxC8* and *HoxD8* as additional restriction targets in humans[22]. *Hox* genes are known to be master regulators of embryogenesis and oncogenesis[15]. We were able to confirm these data presented by Yekta and colleagues, as mRNA levels of those four *Hox* genes were reduced by *miR-196a*. However, dose-dependent differences in target restriction were observed. While low *miR-196a* concentrations resulted in a complete restriction of *HoxB8* mRNA, higher concentrations of *miR-196a* were mandatory to completely restrict *HoxC8* mRNA and to significantly decrease *HoxD8* mRNA levels. In contrast, even the highest *miR-196a* concentrations did not result in a complete restriction

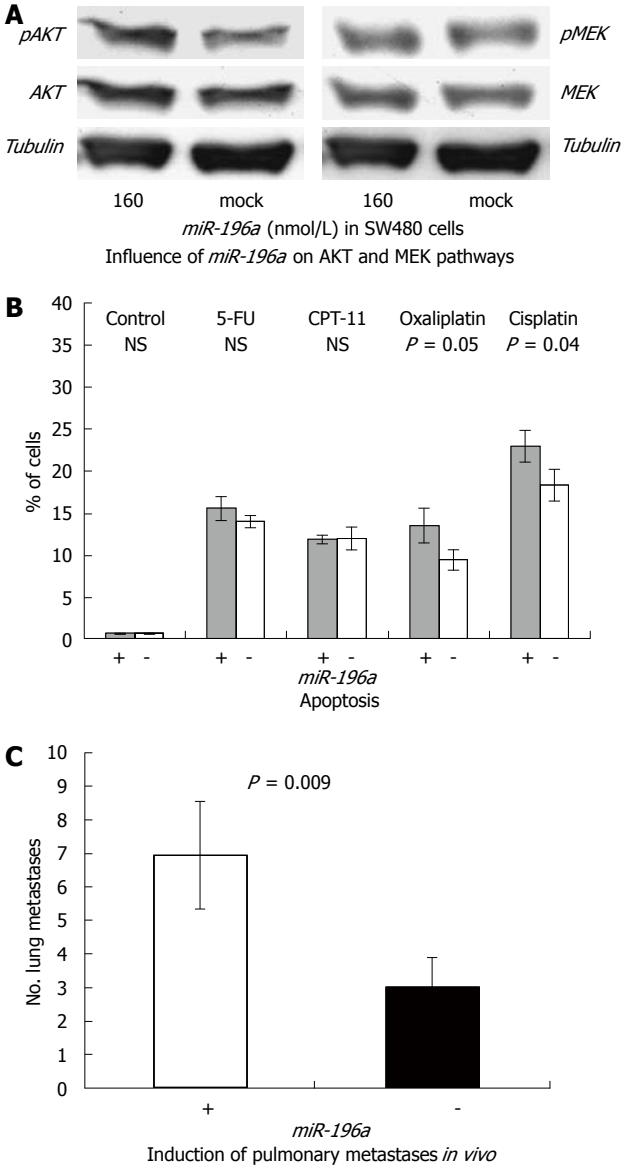

Figure 3 Impact of *miR-196a* on cellular signaling, *in vitro* chemosensitivity and *in vivo* induction of lung metastases. A: *miR-196a* transfection activates the AKT pathway but does not impact on the MEK pathway; B: *miR-196a* transfection significantly increases chemosensitivity towards oxaliplatin and cisplatin but not towards 5-FU or irinotecan; C: *miR-196a* significantly promoted growth of lung metastases in a xenograft biosystem after tail-vein injection and 7 wk of incubation.

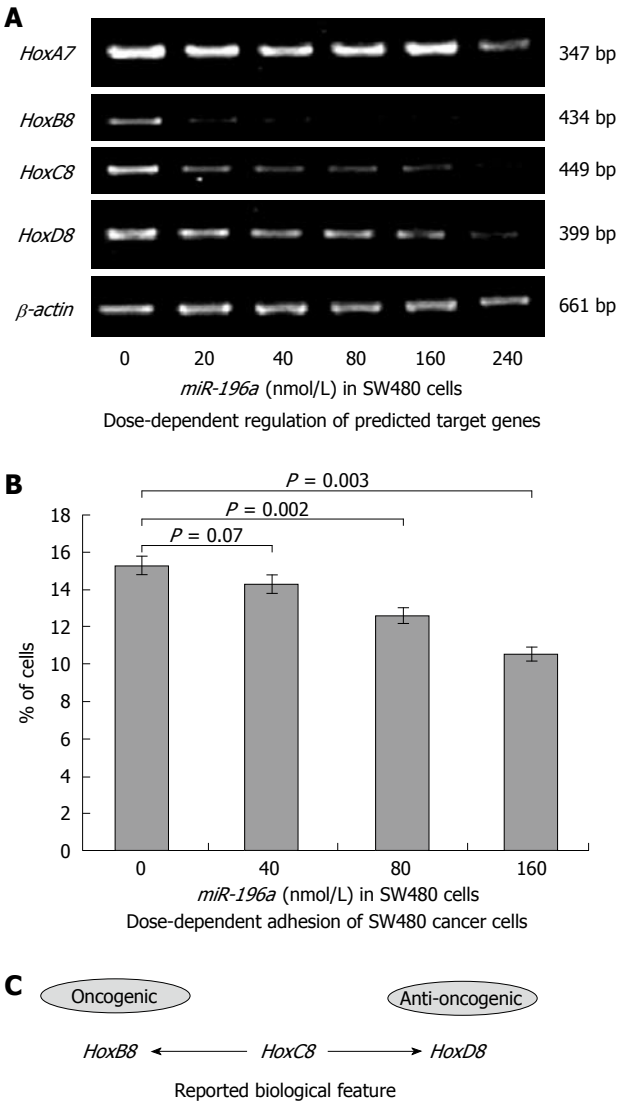

Figure 4 Dose-dependence of *miR-196a* promoted effects. A: *miR-196a* decreases *HoxA7*, *HoxB8*, *HoxC8* and *HoxD8* mRNA levels with a dose-dependent and gene-specific character; B: *miR-196a* inhibits cancer cell adhesion to plastic covers in a dose-dependent manner; C: Biological features of *HoxB8*, *HoxC8* and *HoxD8* as reported in literature. *HoxB8* exerts an oncogenic effect, while *HoxD8* might have tumor-suppressive relevance. For *HoxC8* both, pro-oncogenic and anti-oncogenic features, have been reported.

of *HoxA7*. These data clearly reveal mRNA specific and dose-dependent target restriction. To clarify the dose-dependence of *miR-196a* we performed adhesion assays after transfection with different concentrations of *miR-196a*. These assays revealed a dose-dependent inhibition of tumor cell adhesion.

To further analyze the impact of *miR-196a* on tumor cells, we then performed functional assays and found that high *miR-196a* concentrations increased migration and invasion of cancer cells in trans-well assays and inhibited adhesion to different surfaces and matrix proteins. Chemosensitivity assays with standard chemotherapeutics revealed that *miR-196a* does not sensitise against 5-FU nor irinotecan, but does sensitize against the platin derivatives oxaliplatin and cisplatin. However, *miR-196a* did not impact on proliferation or apoptosis of colon cancer cells.

Analyzing signaling cascades that are often altered in human cancer, we observed that induction of the pro-migratory phenotype is most likely linked to activation of the *PI3K-AKT-mTor* pathway, as *miR-196a* increased the level of pAKT. In contrast, no change in the pMEK/MEK ratio was observed. Our data are consistent with earlier reports showing that overexpressed miRNAs can act as oncogenes. A well known example is *miR-17-92*, which is significantly increased in small-cell lung cancer and correlates with a poor prognosis[20]. Interestingly, the known targets of the *miR-17-92* include the two tumor suppressor genes *PTEN* and *RB2*[21]. As a consequence, restriction of *PTEN* unleashes the *PI3K-AKT-mTor* pathway as also observed for *miR-196a*. However, the exact mode of action of *miR-196a* has still to be analyzed.

Quantitative real-time PCR of *miR-196a* in matching colon cancer and colon mucosa samples showed an up-regulation in 28% of samples. In contrast, all other cancer samples revealed no regulation at all. Most interestingly, the metastatic cancer cell lines SW620 and HT29 showed a significant up-regulation of *miR-196a* in contrast to SW480 cells isolated from a primary colon cancer. Therefore, *miR-196a* is up-regulated in a subset of colorectal cancers and might exert an oncogenic function, when transcribed at a high level. Matching these observations, Croce and colleagues recently found that 75% of pancreatic cancers expressed *miR-196a* at a high level, predicting poor patient survival (14.3 mo *vs* 26.5 mo) when investigating the miRNA transcription pattern in pancreatic adenocarcinoma with large scale miRNA chips[24]. Therefore, similar mechanisms seem possible for pancreatic and colorectal cancer.

To verify the oncogenic potential of high *miR-196a* concentrations, we further analyzed the impact of *miR-196a* in an *in vivo* lung metastases xenograft biosystem. After transient transfection of cells with high concentrations of *miR-196a* prior to tail-vein injection, mice developed significantly more pulmonary metastases within 7 wk as compared to mock-transfected cells.

In summary, we observed an oncogenic effect of high *miR-196a* concentrations. However, several data imply that *miR-196a* might function as a double-edged sword with opposing effects at different concentration for following reasons. (1) *miR-196a* is transcribed in colon mucosa at low levels, implying a role for the epithelial phenotype. (2) A hypothesized suppressive effect of low *miR-196a* transcription levels on tumor dissemination might be exerted through a dose-dependent restriction of *miR-196a* target genes *HoxB8*, *HoxC8* and *HoxD8*. Up-regulation of *HoxC8* and *HoxB8* in colorectal cancer was reported as early as 1997, however the relevance of those genes for carcinogenesis had not been analyzed[26]. A relevant leukemogenic property of *HoxB8* mediated through inhibition of differentiation has been described for acute myeloid leukemia[27,28]. These data are intriguing, as low concentrations of *miR-196a* completely restrict *HoxB8*, thus erasing the pro-oncogenic and leukemogenic effects of *HoxB8*. (3) Only very limited data concerning the relevance of *HoxD8* is available, indicating that *HoxD8* are up-regulated after chemical induced re-differentiation of neuroblastoma cells[29]. However, this observation is of particular interest, as high *miR-196a* concentrations are needed to significantly reduce *HoxD8* mRNA levels, which might result in an inhibition of differentiation, thus promoting oncogenic features as observed in our analyses. (4) The data concerning the relevance of *HoxC8* is unclear. Both pro- and anti-oncogenic influences have been discussed. In particular, *HoxC8* was reported to be a retinoic acid induced gene, rescuing *APC* mutants in zebrafish[30]. In contrast, studies on prostate cancer have reported a correlation with aberrant *HoxC8* expression and a malignant phenotype[31,32]. As *Hox* genes are master transcription factors, they might exert different functions at variable expression levels. However, the observation of Croce and colleagues that *miR-196a* predicts poor survival in pancreatic cancer might rather correlate with inhibition of *HoxD8* than *HoxB8* expression, as *HoxD8* has a suppressive and *HoxB8* a progressive character in the literature[24]. Further studies analyzing the clinical and biological impact of *miR-196a*, as well as additional large scale analyses of restriction targets, are warranted.

COMMENTS

Background

MicroRNAs (miRNAs) are small RNA molecules regulating gene expression in vertebrae and non-vertebrae. In humans, more than 50% of all known miRNA genes are located in cancer-associated regions, indicating that miRNAs might play an important role in oncogenesis. Some miRNAs are known to function as oncogenes, while others act as tumor suppressors inhibiting tumor growth.

Research frontiers

Hox proteins are major transcription factors that play a crucial role during embryogenesis, organogenesis and oncogenesis. The miRNA *miR-196a* depicts complementarity to the mRNA of *HoxB8*, *HoxC8* and *HoxD8*. Therefore, the relevance of *miR-196a* for human tumorigenesis has been discussed.

Innovations and breakthroughs

High levels of *miR-196a* activated oncogenic pathways inside the human tumor cells and induced tumor cell detachment, migration and invasion. In addition, *miR-196a* promoted growth of lung metastases in mice. However, *miR-196a* also increased the chemosensitivity towards platin derivatives such as cisplatin and oxaliplatin.

Applications

High levels of *miR-196a* might predict response of cisplatin- or oxaliplatin-containing chemotherapies. In future, suppression of *miR-196a* by anti-miR technologies might inhibit tumor progression and dissemination.

Terminology

miRNAs are endogenous small RNA molecules of 20-25 nucleotides length, regulating gene expression by inhibiting transcription, inducing direct cleavage of the targeted mRNAs or blocking translation through their complementarity *versus* targeted mRNAs at 3' untranslated regions.

Peer review

This is a very interesting study which contributes to our understanding of colorectal cancer, its development and prognosis. The paper is well written.

Abstract

AIM: To investigate whether the farnesoid X receptor (FXR) regulates expression of liver cystathionase (CSE), a gene involved in hydrogen sulfide (H_2S) generation.

METHODS: The regulation of CSE expression in response to FXR ligands was evaluated in HepG2 cells and in wild-type and FXR null mice treated with 6-ethyl chenodeoxycholic acid (6E-CDCA), a synthetic FXR ligand. The analysis demonstrated an FXR responsive element in the 5'-flanking region of the human *CSE* gene. The function of this site was investigated by luciferase reporter assays, chromatin immunoprecipitation and electrophoretic mobility shift assays. Livers obtained from rats treated with carbon tetrachloride alone, or in combination with 6-ethyl chenodeoxycholic acid, were studied for hydrogen sulphide generation and portal pressure measurement.

RESULTS: Liver expression of CSE is regulated by bile acids by means of an FXR-mediated mechanism. Western blotting, qualitative and quantitative polymerase chain reaction, as well as immunohistochemical analysis, showed that expression of CSE in HepG2 cells and in mice is induced by treatment with an FXR ligand. Administration of 6E-CDCA to carbon tetrachloride treated rats protected against the down-regulation of CSE expression, increased H_2S generation, reduced portal pressure and attenuated the endothelial dysfunction of isolated and perfused cirrhotic rat livers.

CONCLUSION: These results demonstrate that CSE is an FXR-regulated gene and provide a new molecular explanation for the pathophysiology of portal hypertension.

Key words: Nuclear receptor; Farnesoid X receptor; Cystathionase; Hydrogen sulfide; Portal hypertension

INTRODUCTION

In mammals, cysteine is provided through the diet or by the trans-sulfuration pathway, in which L-cysteine is synthesized by sulfur transfer from L-methionine to L-serine. Cystathionine-γ-lyase (CSE) is a pyridoxal 5'-phosphate-dependent enzyme, which catalyze the final essential step of the trans-sulfuration pathway; the conversion of L-cystathionine into L-cysteine, α-ketobutyrate and ammonia[1-3]. Cysteine is further irreversibly metabolized in the liver to yield glutathione[4-6], taurine[7] and hydrogen sulfide (H_2S), a gaseous bioactive molecule[3,8]. CSE is the main enzyme involved in H_2S generation by vascular smooth muscle cells[9,10] and accounts for the vasodilatory effect of H_2S in the systemic circulation[11,12]. In the liver, H_2S generated by hepatocytes and hepatic stellate cells exerts vasodilatory activities and reduces intrahepatic resistance counter-acting the effect of vasomotor mediators on presinusoidal myofibroblasts[13,14].

An alteration of the trans-sulfuration pathway is common in chronic liver diseases, with hyperhomocysteinemia occurring in two-thirds of cirrhotic

patients, regardless the etiology of liver damage[15,16]. An imbalance of the trans-sulfuration pathway linked to reduced expression and activity of CSE is observed in rodent models of liver injury. This alteration leads to a combination of hyper-homocysteinemia and reduced generation of H_2S, translating into an enhanced vasomotor tone and increased intrahepatic resistance[17,18]. Homocysteine is a negative regulator of nitric oxide (NO) bioactivity in endothelial cells. Perfusion of the normal and cirrhotic rat livers with homocysteine results in attenuated NO generation and impaired hepatic vasodilation in response to acetylcholine and shear stress, highlighting the critical role of intermediates of the trans-sulfuration pathway in regulating intrahepatic vasomotor activity[18].

Little is known about the mechanism responsible for the reduced expression of CSE in the injured liver. The fact that CSE expression is modulated during development, being detected at very low levels in embryos while a gradual increase of expression occurs after birth, suggests that genes involved in liver differentiation or proliferation might control the expression of this gene[1].

The farnesoid X receptor (FXR, NR1H4), a member of the ligand-activated nuclear hormone receptor superfamily, is primarily expressed in the liver, kidney, and intestine[19]. It functions as a heterodimer with the retinoid X receptor (RXR)[20] and binds to response elements in the promoters of target genes involved in bile acid homeostasis, and lipid and glucose metabolism[21]. The FXR-RXR heterodimer binds with highest affinity to an inverted repeat sequence in which consensus receptor-binding hexamers are separated by one nucleotide (IR1: AGGTCA*g*TGACCT)[22]. FXR functions as a bile acid sensor, and upon activation, it reduces the conversion of cholesterol into bile acids and increase bile acid excretion from hepatocytes by activating canalicular transporters. In the present study, we investigated whether FXR regulates H_2S generation. Our results demonstrate that the 5'-flanking region of the human *CSE* gene contains an FXR response element (AGTTCA*g*TGTACCT) and that FXR activation *in vitro* and *in vivo* enhances CSE expression and activity, and directly stimulates H_2S generation. These data suggest that FXR directly regulates the generation of a vasodilatory mediator in the liver and provide new pathophysiological insights into the molecular mechanism of portal hypertension.

MATERIALS AND METHODS

Cell culture

HepG2 cells were grown at 37℃ in Minimum Essential Medium with Earl's salts containing 10% fetal bovine serum (FBS), 1% L-glutamine and 1% penicillin/streptomycin. Cells were serum starved for 24 h and then stimulated with 6E-CDCA (6-ethyl-chenodexycholic acid) 10 μmol/L for 18 h. At the end of treatment, total RNA and proteins were extracted to investigate the expression of CSE. Cells were also fixed in acetone and stained with a CSE monoclonal antibody (provided by Dr. N. Nishi, Kagawa Medical School, Japan)[19].

RNA extraction

Total RNA was isolated from liver or HepG2 cells using the TRIzol reagent according to the manufacturer's specifications (Invitrogen, Milan, Italy). One microgram of RNA was purified from genomic DNA by DNase- I treatment (Invitrogen) and reverse-transcribed using random hexamer primers with Superscript Ⅱ (Invitrogen) in a 20-μL reaction volume.

Qualitative and quantitative real-time polymerase chain reaction (RT-PCR)

The amplification of cDNA (50 ng) was achieved in a 50-μL mixture containing 200 nmol/L dNTPs, 1.5 mmol/L $MgCl_2$, 200 nmol/L gene-specific sense and antisense primers and 1 U Platinum *Taq* DNA Polymerase (Invitrogen). All PCR primers were designed using software PRIMER3-OUTPUT using published sequence data from the NCBI database (Table 1). Quantitative RT-PCR conditions were as described previously[13].

Western blotting anti-CSE

Total lysates were prepared by solubilization of cells or liver homogenates in NuPage sample buffer (Invitrogen) containing Sample Reducing Agent (Invitrogen) and separated by PAGE. The proteins were then transferred to nitrocellulose membranes (Bio-Rad) and probed with primary antibodies CSE[17,23] and tubulin (Sigma). The anti-immunoglobulin G horseradish peroxidase conjugate (Bio-Rad) was used as the secondary antibody, and specific protein bands were visualized using Super Signal West Dura (Pierce), following the manufacturer's suggested protocol.

Immunohistochemical analysis of CSE

Immunohistochemical analysis of CSE was performed in HepG2 cells and in liver sections from FXR +/+ and FXR -/- mice not treated and treated with CCl_4. Cells were fixed in 95% acetone for 5 min and endogenous peroxidase was blocked using Dako Peroxide Blocking (DAKO) for 10 min. An anti-CSE monoclonal antibody[23] was used at a dilution of 1:100 for 1 h at room temperature and a biotin-streptavidin-HRP detection/DAB substrate chromogen system was used to visualize the detected proteins. For liver staining, portions of the right and left liver lobes (15 mg/each) from each animal were fixed in 10% formalin, embedded in paraffin, sectioned, blocked with Dako Peroxide Blocking and stained with CSE monoclonal antibody diluted 1:100 for 1 h at room temperature. A biotin-streptavidin-HRP detection system was used using DAB substrate as the chromogen.

Measurement of CSE activity

The CSE activity was assessed accordingly to the method reported by Ogasawara *et al*[24] with minor modifications;

h: Human; m: Mouse; r: Rat; hCSE-IR1: Primers used for real-time PCR of the CSE promoter in chromatin immunoprecipitation assay.

DL-propargylglycine (final 1 mmol/L) instead of 4,4-dithiodipyridine (final 3 mmol/L) was used to inactivate CSE. This method utilizes colorimetry for the determination of pyruvate produced from β-chloro-L-alanine by a CSE-catalyzed elimination reaction, coupling a color-generating enzymatic reaction with pyruvate oxidase and peroxidase. The CSE-specific activity was expressed as the ratio (between sample and sample blank) of absorbance at 727 nm per microgram of protein per seconds of incubation. Sulfide concentrations and production from liver supernatants were measured as previously described[13].

Transactivation assay

For the luciferase assay, 24 h before transfection, 10×10^5 HepG2 cells were plated in six-well plates and cultured in E-MEM supplemented with 1% penicillin/streptomycin, 1% L-glutamine and 10% FBS. Cells were grown at 37℃ in 5% CO_2. All the transfections were made using Fugene HD according to manufacturer's specifications (Roche) and performed using 1 μg pGL3 or pGL3 $(CSE\text{-}IR1)_{4X}$ or $pGL3CSEIR1_{mutated}$ as reporter vectors, 200 ng pCMV-βgalactosidase as an internal control for transfection efficiency, and 100 ng of each expression plasmid pSG5-FXR and pSG5-RXR. The pGEM vector was added to normalize the amounts of DNA transfected in each assay to 2.5 μg/well. Forty-eight hours post-transfection, HepG2 cells were stimulated with a dose response of 6E-CDCA (from 0.01 to 10 μmol/L) or with bile acids (25 μmol/L) for 18 h. Control cultures received vehicle (0.1% DMSO) alone. For the competition assay, an FXR antagonist, such as guggulsterone, was used at 50 μmol/L alone, or in combination with 6E-CDCA 10 μmol/L, for 18 h. Cells were lysed in 100 μL diluted reporter lysis buffer (Promega), and 5 μL of cellular lysate was assayed for luciferase activity using Luciferase Assay System (Promega). Luminescence was measured using an automated luminometer. Luciferase activities were normalized for transfection efficiencies by dividing the relative light units by β-galactosidase activity. All experiments were done in triplicate and were repeated at least once.

Electrophoretic mobility shift assay (EMSA)

Preparation of nuclear extract from HepG2 cells was done using NE-PER (Pierce). The probes used for EMSA (CSERE-IR1, $CSERE\text{-}IR1_{mutated}$ and FXRE-IR1) were labeled with biotin using Biotin 3' end DNA labelling kit (Pierce) according to the manufacturer's instructions. For EMSA, 5 μg of nuclear extract from HepG2 cells not treated or stimulated with 6E-CDCA 10 μmol/L were incubated with 15 fmol of the CSERE-IR1 probe, while 5 μg of nuclear extract from HepG2 stimulated with 6E-CDCA was incubated with $CSERE\text{-}IR1_{mutated}$ and FXRE-IR1 probes in a total volume of 20 μL of binding buffer (50 mmol/L NaCl, 10 mmol/L Tris-HCl, pH 7.9, 0.5 mmol/L EDTA, 10% glycerol, 1 μg of poly dI-dC) for 20 min at room temperature. For competition assays, an excess of CSERE-IR1 unlabeled oligonucleotides were pre-incubated with nuclear extract from 6E-CDCA-treated cells for 15 min prior to the addition of the biotin-labeled CSERE-IR1 probe. For antibody-mediated supershift assay, extracts from stimulated cells were pre-incubated with 1 μg anti-FXR antibody H-130 (Santa Cruz Biotechnology, Santa Cruz, CA, USA) or with 1 μg anti-RXR antibody ΔN 197 (Santa Cruz Biotechnology) at room temperature for 20 min before the addition of the biotin-labeled CSERE-IR1 probe. The reactions were loaded on a 6% polyacrylamide non-denaturing gel in 0.5 × Tris-borate-EDTA buffer and electrophoresed for 1 h at 100 V. The protein/DNA complexes were then transferred to positively charged nylon membrane (Pierce) and the supershift was detected using the Chemiluminescent Nucleic Acid Detection Module (Pierce).

Chromatin immunoprecipitation (ChIP)

A ChIP assay was performed according to the manufacturer's protocols (Abcam Ltd, Cambridge, UK) with minor modifications. In brief, HepG2 cells serum starved for 24 h, not treated or stimulated with 6E-CDCA 10 μmol/L for 18 h, were cross-linked with 1% formaldehyde at room temperature, and then the reaction was terminated by the addition of glycine to a final concentration of 0.125 mol/L. Cells were washed in ice-cold PBS and lysed with SDS lysis buffer (1% SDS, 10 mmol/L EDTA, and 50 mmol/L Tris-HCl, pH 8). Cellular lysates were diluted with ChIP dilution buffer, sonicated, and immunoprecipitated with specific

antibodies: anti-FXR or anti-CD4 as a negative control (Santa Cruz Biotechnology). Immunoprecipitates were collected with protein A beads (Amersham Bioscience) and washed sequentially, first with a low-salt wash buffer and then with high-salt wash buffer using the manufacturer's recommended procedures. DNA was eluted by addition of 1% SDS and 0.1 mol/L $NaHCO_3$, and the cross-linking reactions were reversed by heating the mixture to 65℃ overnight. The DNA was recovered from immunoprecipitated material by proteinase K treatment at 65℃ for 1 h followed by phenol/chloroform (1:1) extraction, ethanol precipitation and dissolved into 50 μL of water. Five microliters was used for quantitative real-time PCR. Five microliters of PCR reactions were extracted after 40 complete cycles for visualization on agarose gels and stained with ethidium bromide.

In vivo experimental studies

All animal procedures were approved by the Animal Study Committees of the University of Perugia. In the first study, the effect of FXR ligands on liver expression of CSE was investigated in FXR +/+ and FXR -/- mice treated by intraperitoneal injection of 6E-CDCA 5 mg/kg body weight for 3 d while control animals were treated with vehicle alone (methyl-cellulose). C57BL/6j mice, obtained from Charles River Breeding Laboratories (Monza, Italy), and homozygous C57BL/6j FXR -/- mice, obtained from Gonzalez *et al*[25] were used with a 12 h light/12 h dark cycle with free access to water and standard laboratory chow diet. At the end of the study, mice were sacrificed and their livers were removed to measure the relative mRNA expression of CSE, the activity of the enzyme and the production of H_2S. In the second study, cirrhosis was induced in FXR +/+ and FXR -/- mice by administering phenobarbital sodium (35 mg/dL) to the mice with drinking water for 3 d, followed by intraperitoneal injection of 100 μL/100 g body weight of CCl_4 in an equal volume of paraffin oil twice 1 wk for 6 wk. CCl_4 administered mice were treated with intraperitoneal injection of 6E-CDCA 5 mg/kg body weight, while control animals were treated with vehicle alone (methyl-cellulose). Mice were sacrificed and their livers were removed for histological, histochemical, and real-time PCR analysis. Blood samples were taken for biochemical analysis. In the third study, cirrhosis was induced in rats obtained from Harlan Nossan (Italy) by administering phenobarbital sodium (35 mg/dL) with drinking water for 3 d, followed by intraperitoneal injection of 100 μL/100 g body weight of CCl_4 in an equal volume of paraffin oil twice 1 wk for 6 wk. After the treatment with CCl_4, animals were administered with an intraperitoneal injection of 6E-CDCA, 10 mg/kg for 5 d while control animals were treated with vehicle alone (methyl-cellulose). At the end of the treatment, analysis of hepatic vascular responses to norepinephrine (from 10 nmol/L to 10 μmol/L) was performed using the isolated perfused rat liver preparation[26]. Briefly, a median laparotomy was performed and an PE-50 catheter was introduced into the inferior mesenteric vein and advanced to the portal vein for the measurement of portal pressure. The liver was perfused in a recirculating mode with Krebs solution equilibrated with CO_2, using a peristaltic pump as previously described[27]. The perfusion pressure was continuously monitored and recorded with a strain-gauge transducer connected to a PowerLab PC (A.D. Instruments, Milford, MA, USA). The preparation was allowed to stabilize for 20 min. The global viability of livers was assessed by standard criteria: gross appearance, stable pH of the perfusate, stable perfusion pressure for 20 min, and bile flow of > 1 μL/min per gram liver. The flow rate during each individual perfusion was maintained at a constant rate of 20 mL/min. Two additional groups of normal and cirrhosis rats were sacrificed and liver specimens were snap frozen in liquid nitrogen and stored at -70℃.

Serum biochemistry analysis

Serum bilirubin, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were measured by routine clinical chemistry testing performed on a Hitachi 717 automatic analyzer.

Liver histology

For histological examination, portions of the right and left liver lobes were fixed in 10% formalin, embedded in paraffin, sectioned, and stained with Sirius red.

Western blotting anti-smooth muscle actin (αSMA)

Total cellular proteins of frozen tissues were extracted using Tissue Protein Extraction reagent (Pierce) and solubilized in NuPage sample buffer (Invitrogen) containing Sample Reducing Agent (Invitrogen). Proteins were resolved by electrophoresis on 10% SDS-polyacrylamide gels and transferred to nitrocellulose membranes (Bio-Rad). After protein transfer, filters were probed with an αSMA primary antibody (Santa Cruz Biotechnology) for 1 h at room temperature. The anti-immunoglobulin G horseradish peroxidase conjugate (Bio-Rad) was used as the secondary antibody, and specific protein bands were visualized using Super Signal West Dura (Pierce), following the manufacturer's suggested protocol.

Statistics analysis

All values are expressed as mean ± SE of *n* observations per group. Comparisons of more than two groups were made with a one-way ANOVA with post-hoc Tukey's test. Comparison of two groups was made using Student's *t* test for unpaired data when appropriate. Differences were considered statistically significant if P was < 0.05.

RESULTS

CSE expression is regulated by FXR activation *in vitro*

We first investigated whether FXR activation modulates *CSE* gene expression. Serum-starved HepG2 cells, wild-type and stimulated with 10 μmol/L 6E-CDCA (a synthetic FXR ligand that activates FXR with an EC_{50} of about 300 nmol/L) were used in these experiments. As illustrated in Figure 1, FXR activation by this agent resulted in a robust induction of CSE expression

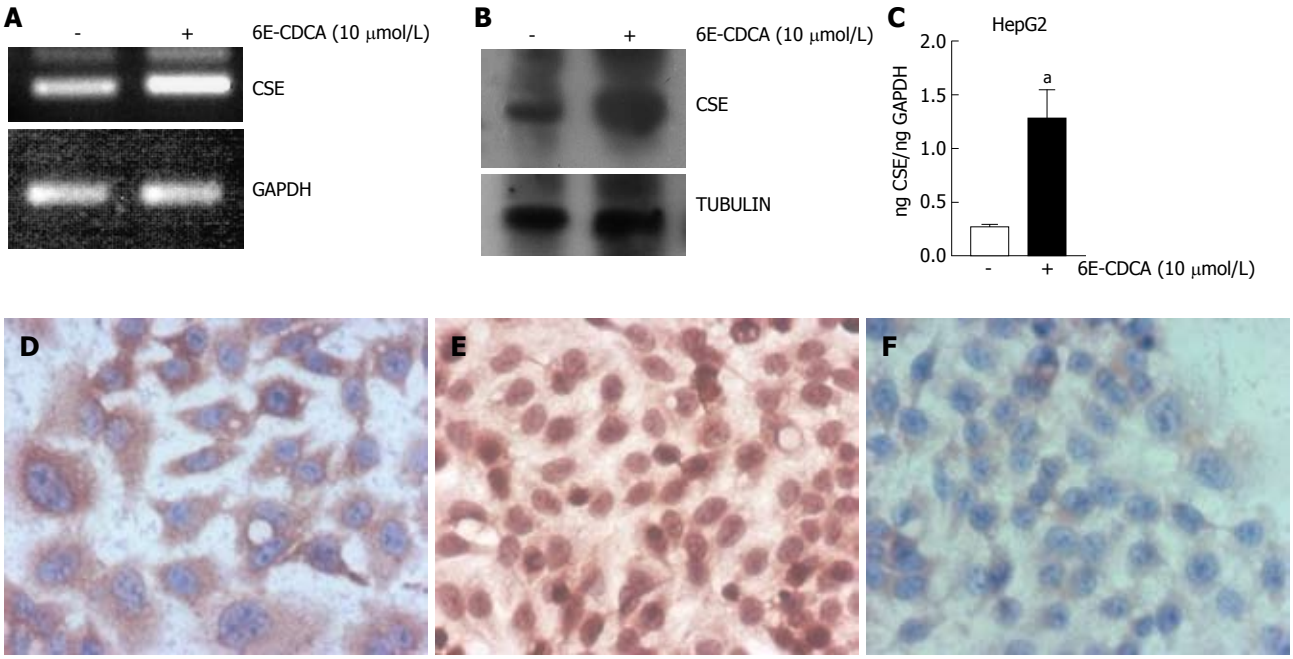

Figure 1 ***CSE*** **gene expression is regulated by bile acids.** A, B: Qualitative and quantitative PCR showing the up-regulation of CSE mRNA in HepG2 cell line stimulated with FXR ligand 6E-CDCA (10 μmol/L) for 18 h. Data are shown as mean ± SD of three experiments. $^{a}P < 0.05$ *versus* not stimulated cells; C: Western blotting analysis showing the up-regulation of CSE protein in HepG2 cell line stimulated by 6E-CDCA 10 μmol/L for 18 h; D, E: Immunohistochemistry analysis of CSE expression in HepG2 cells non-treated (D) and treated (E) with 6E-CDCA (10 μmol/L) for 18 h (Magnification × 40); F: Negative control was obtained by cell staining only with the secondary antibody.

as measured by qualitative and quantitative PCR (Figure 1A and B; $n = 3$, $P < 0.05$ *vs* not stimulated cells) and Western blotting analysis (Figure 1C). Consistent with these findings, the immunohistochemical analysis of CSE expression demonstrated a significant increase in cell expression of this protein in HepG2 cells exposed to 10 μmol/L 6E-CDCA for 18 h (Figure 1E). These data establish that FXR activation in hepatocytes up-regulates CSE mRNA and protein expression.

Identification of an IR-1 sequence in the human CSE promoter

Having showed that the expression of human *CSE* gene is induced in response to FXR activation, we then investigated whether the CSE promoter contains any potential FXR binding sites. FXR binds preferentially to the IR1 element, and a putative IR1 sequence (CSE-IR1: AGTTCA*g*TGTACCT) was identified in the 5'-flanking region of the *CSE* gene (Figure 2A). This sequence is located 699 base pairs upstream of the transcriptional start site. To explore the functional role of this non-canonical IR1 sequence, four copies of the CSE-IR1 were cloned in the pGL3 basic vector [pGL3 $(CSE\text{-}IR1)_{4X}$]. Additionally (Figure 2B), a construct containing a mutated IR1 site ($CSE\text{-}IR1_{mutated}$: ATTTCT*g*TGTACCT) was generated and cloned in the pGL3 vector ($pGL3CSE\text{-}IR1_{mutated}$). Using these reagents we investigated whether the identified FXR response element confers responsiveness to bile acid stimulation on the luciferase reporter gene. For this purpose, HepG2 cells co-transfected with pSG5-FXR and pSG5-RXR expression vectors were transiently transfected with the pGL3 $(CSE\text{-}IR1)_{4X}$ and then treated with natural FXR ligands: deoxycholic acid (DCA), litocholic acid (LCA), cholic acid (CA), chenodeoxycholic acid (CDCA) and the synthetic FXR ligand 6E-CDCA at 25 μmol/L for 18 h. As show in Figure 2C, treating HepG2 cells with natural FXR ligands resulted in an approximately two to three-fold increase in luciferase activity, while the treatment with synthetic ligand resulted in an approximately eight-fold increase in luciferase activity ($n = 3$, $P < 0.05$ *vs* not treated cells). 6E-CDCA-mediated induction of reporter gene expression was concentration-dependent with an EC50 of 300 nmol/L (Figure 2D; $n = 3$, $P < 0.05$ *vs* not treated cells).

To further confirm the role of CSE-IR1 in mediating CSE induction in response to FXR activation, HepG2 cells co-transfected with pSG5-FXR and pSG5-RXR expression vectors were then transfected with pGL3 or pGL3 $(CSE\text{-}IR1)_{4X}$ or $pGL3CSE\text{-}IR1_{mutated}$ and then stimulated with 6E-CDCA 10 μmol/L for 18 h. Cells transfected with the pGL3 basic vector alone were used as an internal control (Figure 2E columns 1 and 2). As expected, co-transfection of pSG5-FXR and pSG5-RXR with pGL3 $(CSE\text{-}IR1)_{4X}$ resulted in a substantial increase in luciferase activity compared to co-transfection with the luciferase reporter vector alone. (Figure 2E, columns 1 and 3; $n = 3$, $P < 0.05$ *vs* not stimulated pGL3 transfected cells). The construct containing the wild-type IR-1 [pGL3 $(CSE\text{-}IR1)_{4X}$] was found to cause about a four-fold increase in luciferase expression in the presence of a synthetic FXR ligand [Figure 2E, columns 3 and 4; $n = 3$, $P < 0.05$ *vs* not stimulated pGL3 $(CSE\text{-}IR1)_{4X}$ transfected cells]. The transactivation was abolished in cells transfected with a reporter gene in which the IR1 sequence was mutated [Figure 2E, column 5; $n = 3$, $P < 0.05$ *vs* not stimulated pGL3 $(CSE\text{-}IR1)_{4X}$ transfected cells] and the luciferase activity of the $pGL3CSE\text{-}IR1_{mutated}$ was similar to pGL3 basic. Similar results were obtained

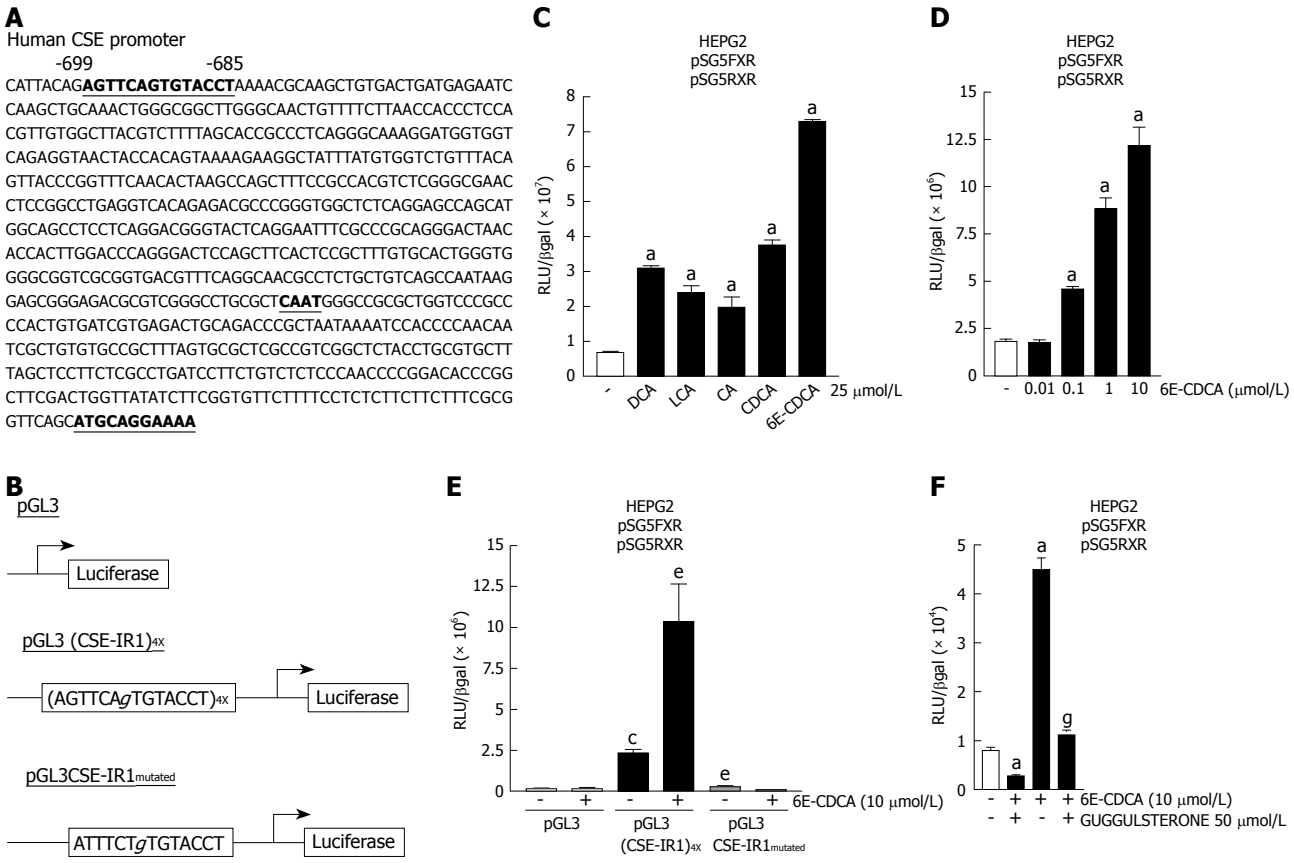

Figure 2 An FXR responsive element is expressed in the CSE promoter. A: Analysis of the promoter of the human *CSE* gene, showing a putative IR-1 site at -699/-685 base pairs upstream of the transcriptional start site ATG; B: Schematic representation of reporter constructs containing four CSE-IR1 elements [pGL3 (CSE-IR1)$_{4x}$] or the mutated CSE-IR1 (pGL3CSE-IR1$_{mutated}$); C: HepG2 cells were transfected with pSG5-FXR and pSG5-RXR expression vectors and with the construct containing four copies of the CSE-IR1 [pGL3 (CSE-IR1)$_{4x}$]. Forty-eight hours after transfection, cells were stimulated with 25 μmol/L of DCA, LCA, CA, CDCA and 6E-CDCA for 18 h. Luciferase activity is shown as the ratio of luciferase to β-galactosidase activities. $^{a}P < 0.05$ *versus* not treated cells; D: Dose-dependent induction of Luciferase activity by 6E-CDCA. $^{a}P < 0.05$ *versus* not treated cells; E: Mutagenesis of CSE-IR1 results in a loss of activation by FXR ligands. HepG2 cells were transfected with pSG5-FXR and pSG5-RXR expression vectors and with pGL3 or pGL3 (CSE-IR1)$_{4x}$ or pGL3CSE-IR1$_{mutated}$. Forty-eight hours after transfection, cells were stimulated with 10 μmol/L of 6E-CDCA for 18 h. Luciferase activity is show as the ratio of luciferase to β-galactosidase activities. $^{c}P < 0.05$ *versus* not stimulated pGL3 transfected cells. $^{e}P < 0.05$ *versus* not stimulated pGL3 (CSE-IR1)$_{4x}$ transfected cells; F: Guggulsterone abolished the transactivation of the CSE-IR1 element. HepG2 cells co-transfected with pSG5-FXR and pSG5-RXR expression vectors and with pGL3 (CSE-IR1)$_{4x}$ were stimulated with 50 μmol/L of guggulsterone alone or in combination with 10 μmol/L of 6E-CDCA. $^{a}P < 0.05$ *versus* not treated cells. $^{g}P < 0.05$ *versus* 6E-CDCA stimulated cells. Data represent the mean ± SD of three experiments.

using the FXR antagonist guggulsterone (Figure 2F). As expected, the stimulation of HepG2 cells co-transfected with pSG5-FXR, pSG5-RXR and pGL3 (CSE-IR1)$_{4x}$ with guggulsterone at 50 μmol/L for 18 h resulted in robust repression of luciferase activity with respect to non-stimulated cells (Figure 2F, columns 1 and 2; $n = 3$, $P < 0.05$ *vs* control cells). Treatment with 6E-CDCA resulted in about a four-fold increase of luciferase activity (Figure 2F, columns 1 and 3; $n = 3$, $P < 0.05$ *vs* not treated cells), while the transactivation was reduced in cells stimulated with both 6E-CDCA and guggulsterone with respect to cells stimulated only with 6E-CDCA (Figure 2F, columns 3 and 4; $n = 3$, $P < 0.05$ *vs* 6E-CDCA stimulated cells). These data establish that the IR1 motif in the proximal human CSE promoter is a functional FXR response element.

CSE-IR1 site binds FXR

To determine whether the IR1 element binds FXR, we performed an EMSA using the following biotin-labeled probes: CSE-IR1, CSE-IR1$_{mutated}$ and FXRE-IR1. CSE-IR1 biotin-labeled probe was incubated with nuclear extracts prepared from HepG2 cells left untreated or treated with 6E-CDCA 10 μmol/L for 18 h. As shown in Figure 3A, CSE-IR1 binding was detected in HEPG2 wild-type cells and exposure to 6E-CDCA enhanced this binding (Figure 3A, lanes 2 and 3). We confirmed the specificity of this interaction by adding 50-fold excess of unlabeled oligo or 1 μg anti FXR primary antibody or 1 μg anti RXR primary antibody (Figure 3A, lanes 4, 5 and 6). These approaches resulted in a reduction of DNA binding of the nuclear extract to CSE-IR1 probe. The specificity of the FXR interaction to CSE-IR1 was also confirmed using the mutated probe, CSE-IR1$_{mutated}$, and the positive control, FXRE-IR1. DNA binding and supershift was completely abrogated using the CSE-IR1$_{mutated}$ probe, while the FXRE-IR1 probe caused same supershift as the CSE-IR1 probe (Figure 3A, lanes 7 and 8). To study the DNA-protein complex interaction within the context of chromatin, ChIP was performed using serum-starved HepG2 cells exposed to 6E-CDCA 10 μmol/L. As show in Figure 3B and C, qualitative and

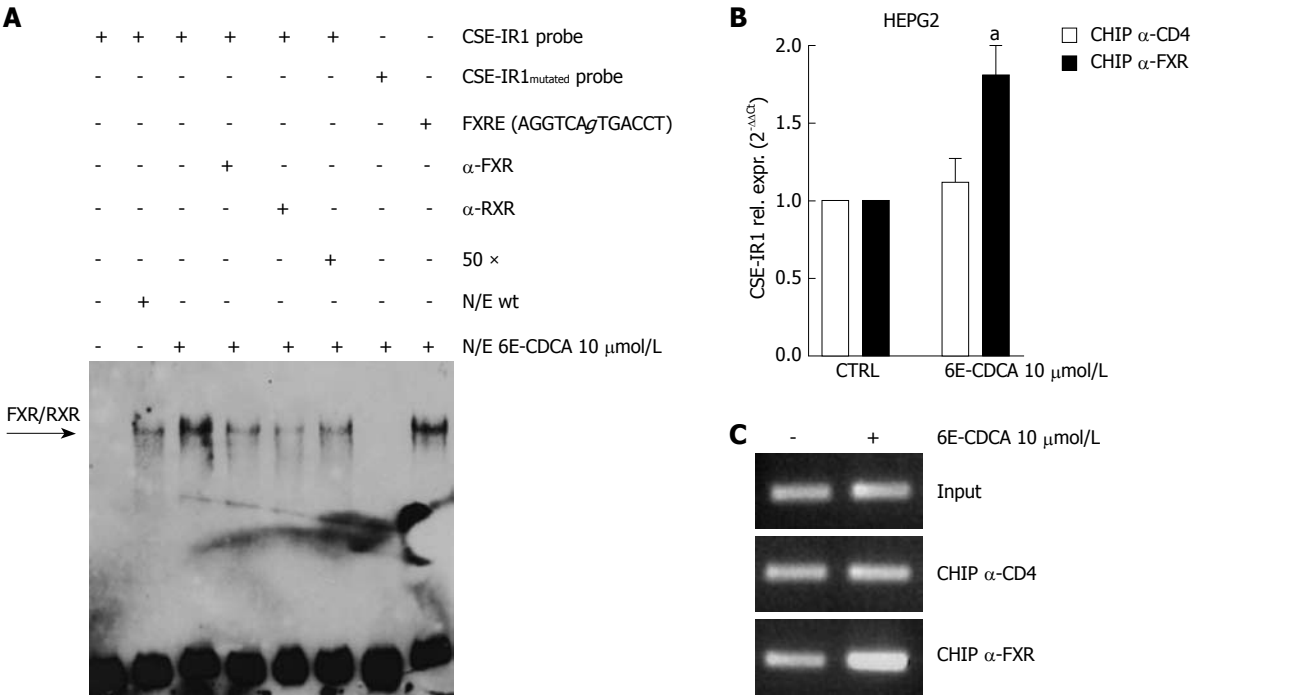

Figure 3 Activation of FXR regulates CSE expression. A: FXR/RXR bind to CSE-IR1 of the *CSE* gene. EMSAs were performed to analyze binding of FXR/RXR to the putative IR1 sequence in the CSE gene. CSE-IR1, CSE-IR1$_{mutated}$ and FXRE-IR1 probes, biotin-labeled, were used in this experiment. CSERE-IR1 probe was incubated with nuclear extracts from HepG2 cells not treated or treated with 6E-CDCA 10 μmol/L for 18 h. Competition experiments were performed using a 50-fold excess of unlabeled oligo or 1 μg of FXR antibody or 1 μg of RXR antibody. CSE-IR1$_{mutated}$ and FXRE-IR1 probes were incubated with nuclear extracts from HepG2 stimulated cells; B: CSE-IR1 site binds FXR in the context of intact chromatin structures. ChIP experiments were performed with HepG2 cells. Chromatin was prepared and immunoprecipitated with antibodies directed against FXR and CD4. CD4 antibody was used as a negative control. Real-time PCR of the immunoprecipitated DNA by using the primer pairs indicated in Table 1. Data represent the mean ± SD of three experiments. $^{a}P < 0.05$ *versus* not treated cells; C: Qualitative PCR of the immunoprecipitated DNA by using the primer pairs indicated in Table 1.

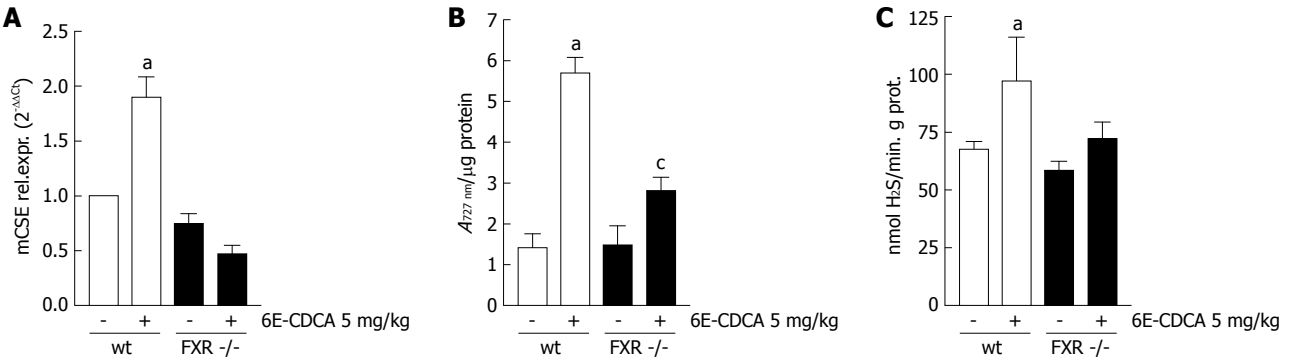

Figure 4 CSE expression/activity is regulated with an FXR ligand *in vivo*. A: FXR +/+ and FXR -/- mice were treated for 3 d with vehicle or with 6E-CDCA 5 mg/kg body weight. quantitative PCR performed with primers flanking the CSE promoter containing the IR1 sequence, confirmed the binding of FXR at the *CSE* gene (Figure 3B; $n = 3$, $P < 0.05$ *vs* not treated cells). Thus, the functionality of this IR1 site was further confirmed in the context of intact chromatin structures.

CSE expression is induced by 6E-CDCA in vivo

To investigate whether FXR regulates *CSE* gene expression *in vivo*, wild-type and FXR -/- mice were administered with 6E-CDCA 10 mg/kg for 3 d and sacrificed to measure liver CSE expression, CSE activity and H_2S production. As show in Figure 4A, while an induction of CSE mRNA expression was seen in wild-type mice treated with 6E-CDCA ($n = 6$, $P < 0.05$ *vs* FXR +/+ control mice), this effect was not observed in FXR -/- mice, confirming that the *CSE* gene is a specific target of FXR. Interestingly, FXR activation by 6E-CDCA increased CSE activity in both wild-type and FXR -/- mice (Figure 4B; $n = 6$, $P < 0.05$ *vs* FXR +/+

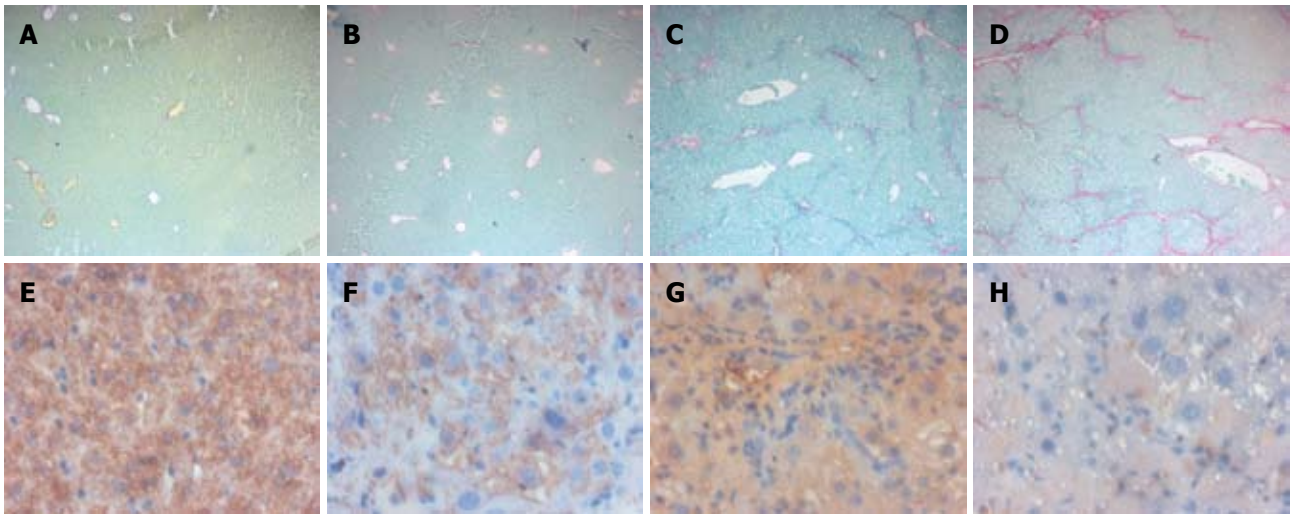

Figure 5 FXR loss of function sensitizes mice to CCl_4-induced liver fibrosis. A: Sirius red staining of liver section obtained from FXR +/+ mice; B: Sirius red staining of liver section obtained from FXR -/- mice; C: Sirius red staining of liver section obtained from FXR +/+ mice treated with CCl_4; D: Sirius red staining of liver section obtained from FXR -/- mice treated with CCl_4; E: Liver section stained with CSE monoclonal antibody obtained from FXR +/+ mice; F: Liver section stained with CSE monoclonal antibody obtained from FXR -/- mice; G: Liver section stained with CSE monoclonal antibody obtained from FXR +/+ mice treated with CCl_4; H: Liver section stained with CSE monoclonal antibody obtained from FXR -/- mice treated with CCl_4.

Table 2 Effect of loss of FXR on liver injury induced by 12 administrations of CCl_4 (6 wk)

	AST (U/L)	ALT (U/L)	Bilirubin (mg/dL)
FXR +/+ naive	127 ± 15	48 ± 8	0.015 ± 0.001
FXR +/+ CCl_4	250 ± 40[a]	369 ± 35[a]	0.118 ± 0.004[a]
FXR -/- naive	143 ± 10	79 ± 25[a]	0.068 ± 0.004[a]
FXR -/- CCl_4	740 ± 230[c,e]	354 ± 137[c]	0.252 ± 0.02[c,e]

Data are mean ± SD of six mice. [a]$P < 0.05$ *vs* FXR +/+ control mice; [c]$P < 0.05$ *vs* FXR -/- control mice; [e]$P < 0.05$ *vs* CCl_4 FXR +/+ mice.

control mice, $P < 0.05$ *vs* FXR -/- control mice). Taken together, these data suggest that while mRNA expression of CSE is regulated by an FXR-dependent mechanism, the induction of CSE activity by bile acids might be regulated by an FXR independent mechanism, possibly by TGR5 activation induced by bile acids. Finally, liver H_2S generation was significantly up-regulated by 6E-CDCA treatment in FXR +/+ mice but not in FXR -/- mice (Figure 4C; $n = 6$, $P < 0.05$ *vs* FXR +/+ control mice).

FXR loss of function sensitizes mice to CCl_4-induced liver fibrosis

We next investigated whether *in vivo* loss of FXR function sensitizes mice to development of liver fibrosis induced by administration of CCl_4. AST, ALT and bilirubin are commonly used biochemical markers of liver damage. As show in Table 2, the levels of ALT and bilirubin, but not of AST, in FXR -/- mice were much higher compared with the wild-type mice. *In vivo* administration of CCl_4 showed a significant increase of AST, ALT and bilirubin in FXR -/- mice with respect to FXR +/+ control mice (Table 2). Morphometric analysis of FXR +/+ and FXR -/- liver sections stained with Sirius red showed a normal distribution of collagen, with a variable amount in the portal tract and a thin rim around the terminal hepatic vein (Figure 5A and B), while histological evaluation of liver specimens obtained from FXR -/- mice treated with CCl_4 for 6 wk showed extensive perilobular fibrosis, resulting in an increase in the surface area of hepatic collagen in comparison with control FXR +/+ mice treated with CCl_4 (Figure 5C and D). Expression of CSE, observed by histochemical staining of liver sections, was reduced in FXR -/- mice compared with the wild-type mice (Figure 5E and F). Furthermore, FXR -/- mice administered with CCl_4 showed a significant reduction in CSE expression compared to FXR +/+ mice treated with CCl_4 (Figure 5G and H). Taken together, these data confirmed that mice lacking FXR are more likely to develop liver fibrosis, and that FXR loss of function correlates with reduction of CSE protein expression in the liver.

FXR activation restores H_2S production and CSE activity in a rodent model of liver cirrhosis

We then investigated whether *in vivo* administration of FXR ligands modulate CSE expression, the activity of the enzyme and H_2S production, in wild-type but not in FXR -/- mice administered with CCl_4. As show in Figure 6A, development of liver injury is associated with a significant reduction in CSE mRNA expression, in both the wild-type and FXR -/- mice treated with CCl_4 for 6 wk. In wild-type mice, administration of an FXR ligand resulted in a robust induction of CSE expression. This effect was not reproduced in FXR -/- mice, confirming the specificity of 6E-CDCA (Figure 6A; $n = 6$, $P < 0.05$ *vs* FXR +/+ control mice. $P < 0.05$ *vs* CCl_4 FXR +/+ mice). Similarly, we found that α1-collagen mRNA expression was down-regulated by 6E-CDCA in wild-type mice but not in FXR -/- mice (Figure 6B; $n = 6$, $P < 0.05$ *vs* FXR +/+ control mice. $P < 0.05$ *vs* CCl_4 FXR +/+ mice. $P < 0.05$ *vs* FXR -/- control mice). In addition, we found that liver CSE activity was down-regulated by CCl_4 administration in both FXR +/+ and FXR -/- mice, but this effect was reversed by treating the mice with 6E-CDCA (Figure 6C; $n = 6$, $P < 0.05$ *vs* FXR +/+ control mice. $P < 0.05$ *vs* CCl_4 FXR +/+ mice.

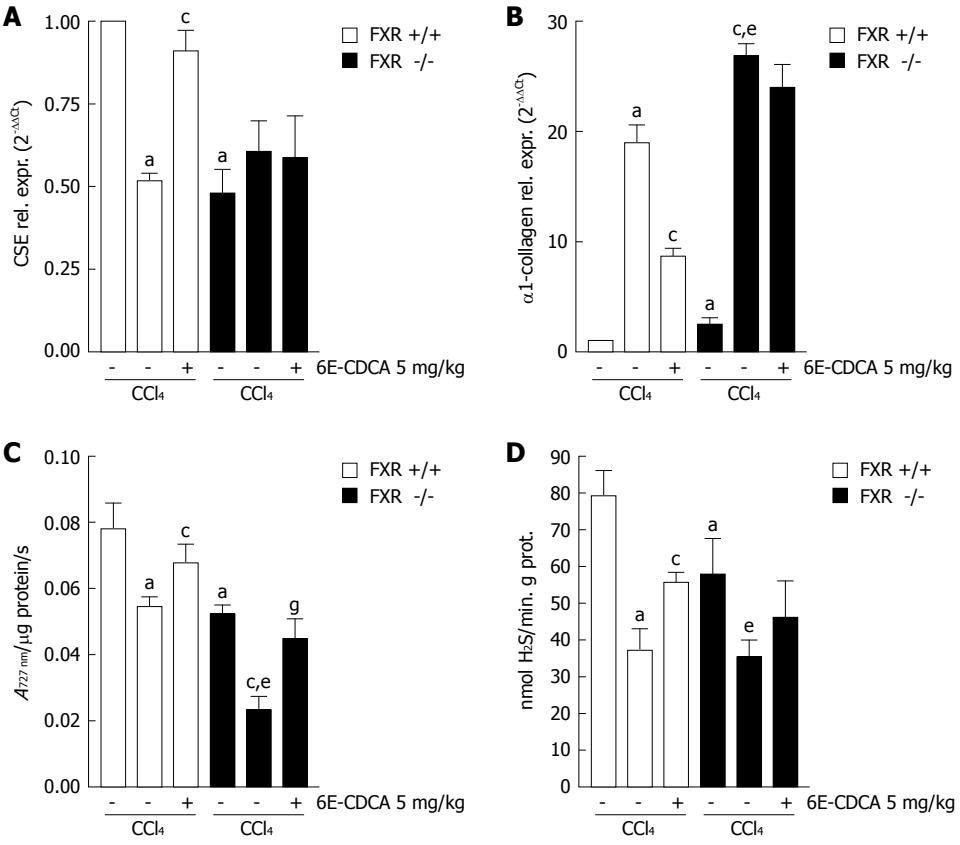

Figure 6 FXR activation induces *CSE* gene expression and regulated CSE activity in the liver with cirrhosis. FXR +/+ and FXR -/- mice were treated with CCl_4 and 6E-CDCA as described in the methods section. A and B: Quantitative real-time PCR of CSE mRNA and α1-collagen mRNA from FXR +/+ and FXR -/- liver homogenates; C: Liver CSE activity; D: Liver H_2S production. Data are mean ± SD of six mice. $^{a}P < 0.05$ *versus* FXR+/+ control mice. $^{c}P < 0.05$ *versus* CCl_4 FXR +/+ mice. $^{e}P < 0.05$ *versus* FXR -/- control mice. $^{g}P < 0.05$ *versus* CCl_4 FXR -/- mice.

$P < 0.05$ *vs* FXR -/- control mice. $P < 0.05$ *vs* CCl_4 FXR -/- mice). CCl_4 administration down-regulated liver H_2S production in both FXR +/+ and FXR -/- mice, while the administration of 6E-CDCA enhanced liver H_2S generation only in FXR +/+ mice (Figure 5D; $n = 6$, $P < 0.05$ *vs* FXR +/+ control mice. $P < 0.05$ *vs* CCl_4 FXR +/+ mice. $P < 0.05$ *vs* FXR -/- control mice).

FXR activation reduces portal perfusion pressure response to norepinephrine in cirrhotic rat liver

The reduction of CSE expression in the cirrhotic liver contributes to the development of increased intrahepatic resistance and portal hypertension. We therefore investigated whether *in vivo* administration of an FXR ligand modulates hepatic resistance in cirrhotic rats. As shown in Figure 7, the development of liver injury in rats reduced the expression of FXR and CSE (Figure 7A and B; $n = 6$, $P < 0.05$ *vs* control rats, $P < 0.05$ *vs* CCl_4 rats) while small heterodimer partner mRNA expression was unaffected (Figure 7C; $n = 6$, $P < 0.05$ *vs* CCl_4 rats). In contrast, CCl_4 administration up-regulated α1-collagen and αSMA mRNA (Figure 7D and E; $n = 6$, $P < 0.05$ *versus* control rats) Thus, treating CCl_4 rats with 6E-CDCA resulted in a robust induction of *FXR*, *SHP* and *CSE* genes (Figure 7A-C; $n = 6$, $P < 0.05$ *vs* CCl_4 rats), as well as suppression of α1-collagen gene expression (Figure 7D; $n = 6$, $P < 0.05$ *vs* CCl_4 rats). The CSE activity was strongly down-regulated by administration of CCl_4 in rats and the treatment with 6E-CDCA led to an increase of this enzyme activity (Figure 7F; $n = 6$, $P < 0.05$ *versus* control rats; $P < 0.05$ *vs* CCl_4 rats). Furthermore, as shown in Figure 8, the expression of CSE and αSMA was also investigated at the protein level by Western blotting analysis. We found that the CSE protein was strongly down-regulated during liver injury and that 6E-CDCA treatment resulted in a robust induction of this enzyme (Figure 8A). In contrast, CCl_4 treatment up-regulated the pro-fibrogenetic marker αSMA and administration of 6E-CDCA resulted in a suppression of this protein (Figure 8B). We then investigated whether FXR activation by a synthetic ligand lowers portal pressure in rodent models of liver injury. Under basal conditions, portal pressure was significantly higher in cirrhotic rats compared with the control rats (Figure 9A; $n = 6$, $P < 0.05$ *vs* control rats). In the cirrhotic rats, treatment with 6E-CDCA significantly decreased the portal pressure (Figure 9A; $n = 6$, $P < 0.05$ *vs* CCl_4 rats). Finally, data shown in Figure 9B demonstrated that in livers with cirrhosis, norepinephrine produced a dose-dependent increase in the portal perfusion pressure compared with control rats (Figure 9B; $n = 6$, $P < 0.05$ *vs* control rats). In contrast, treatment with 6E-CDCA reduced the hyper-responsiveness of livers with cirrhosis to norepinephrine (Figure 9B; $n = 6$, $P < 0.05$ *versus* CCl_4 rats).

DISCUSSION

Portal hypertension is associated with changes in intrahepatic, systemic, and portosystemic collateral circulation[28,29]. Alterations in vasoreactivity (vasodilatation and vasoconstriction) play a central role in the pathogenesis of this condition by contributing to increased intrahepatic resistance, hyperdynamic circulation and expansion of the collateral circulation[28,29]. The molecular basis of the vascular abnormalities that contribute to development of

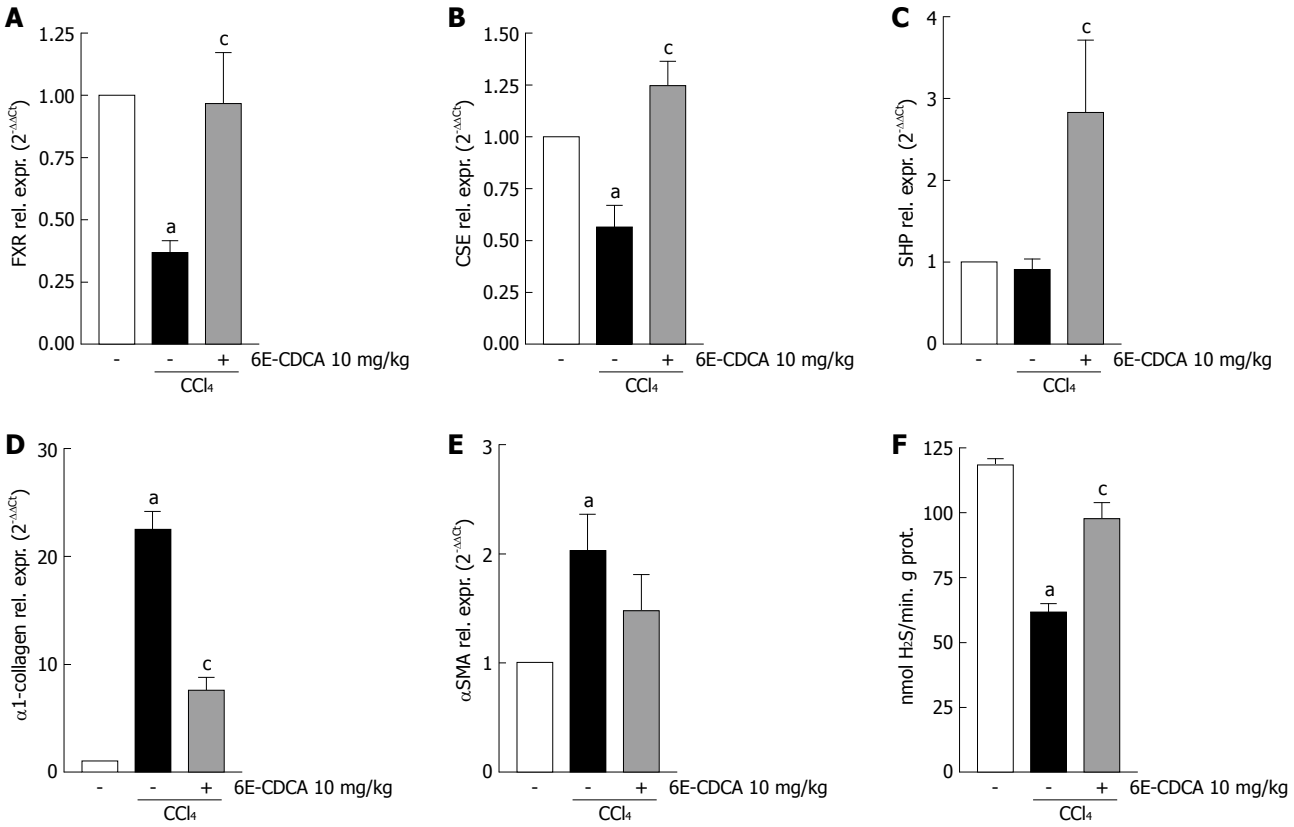

Figure 7 FXR activation induces both CSE mRNA expression and activity in rats with liver cirrhosis. portal hypertension are only partially identified[17,30-32]. A diminution in endothelial-nitric-oxide-synthase-derived NO production by liver sinusoidal cells contributes to this process by impairing the ability of hepatic microcirculation to vasodilate and therefore increases intrahepatic resistance[33]. We have previously described that along with NO, H_2S causes a direct relaxation of intrahepatic microcirculation, suggesting a physiological role for this gaseous mediator in regulating resistance of intrahepatic microcirculation. H_2S exerts a portal-pressure-lowering effect in normal rats as well as in rats rendered cirrhotic by CCl_4 administration, an experimental setting characterized by endothelial dysfunction of intrahepatic circulation and reduced generation of NO[9]. Finally, we have previously provided evidence that a robust reduction of H_2S generation takes place in cirrhotic rats and that this defect is linked to a decrease in the liver expression and activity of CSE, a key enzyme in the pathway that leads to generation of H_2S[17].

Little is known about the molecular mechanism responsible for the regulation of *CSE* gene expression and there is no evidence of the regulation of the *CSE* gene by nuclear receptors. FXR is one of the major nuclear receptors responsible for regulation of liver metabolism, therefore, we decided to study whether CSE expression in the liver was regulated by FXR. In the current study, we have shown, for the first time, that the liver expression of CSE is regulated by bile acids by means of an FXR mediated mechanism. By Western blotting, qualitative and quantitative PCR, as well as immunohistochemical analysis, we have shown that expression of CSE (mRNA and protein) in HepG2 cells is induced by treatment with bile acids and 6E-CDCA, a semi-synthetic FXR ligand. The molecular mechanism of the CSE activation by FXR was revealed by identifying a sequence in the 5' flanking region of the *CSE* gene, containing an element composed of two inverted repeats separated by one nucleotide (a potential IR1 binding site). Four copies of this IR1 binding site were cloned into the pGL3 vector containing the luciferase reporter gene, and in addition, a single copy of the IR1 binding site was mutated and cloned in the pGL3 vector. Co-transfection of HepG2 cells with FXR and RXR resulted in transactivation of the CSE promoter in the presence of an FXR ligand, while the mutation of the IR1 binding site and the treatment with an FXR antagonist, such as guggulsterone, abrogated this response. The FXR/RXR heterodimer bound specifically

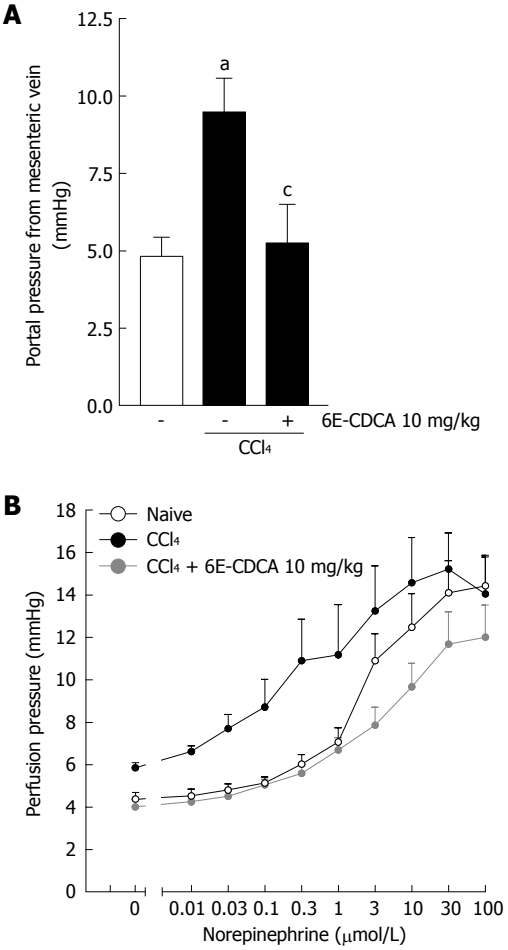

Figure 9 FXR activation reduces portal pressure in rat liver with cirrhosis. Data are mean ± SD of six mice. A: Basal portal pressure from mesenteric vein. $^{a}P < 0.05$ *versus* control rats. $^{c}P < 0.05$ *versus* CCl_4 rats; B: Effects of 6E-CDCA on pre-contracted rat liver with cirrhosis. $^{a}P < 0.05$ *versus* control rats. $^{c}P < 0.05$ *versus* CCl_4 rats.

to the CSE IR1 binding site, but not to the mutant form, as shown by a gel mobility shift assay using nuclear extracts from HepG2 cells not treated or treated with 6E-CDCA. The functionality of this IR1 site was also confirmed in the context of intact chromatin structures by a ChIP assay.

The role of FXR in the regulation of CSE has been further investigated *in vivo*, in mice harboring a targeted disruption of the *FXR* gene. These mice lack functional FXR and are unable to correctly regulate bile acids biosynthesis and excretion. Interestingly, when compared to the wild-type, FXR -/- mice displayed significantly lower levels of CSE and a reduced ability to produce H_2S. Similarly to the *in vitro* results, we found that in the normal liver, CSE expression was significantly increased when mice were fed a chow diet supplemented with 5 mg/kg body weight of 6E-CDCA, while the FXR ligand failed to up-regulate CSE mRNA expression in FXR knock-out mice. In contrast, administration of 6E-CDCA induced CSE activity in both wild-type and FXR knock-out mice. This finding suggested that the activity of the enzyme might be regulated by bile acids at the post-translational level, and a possible mechanism could be linked to the activation of the TGR5 induced phosphorylation cascade through the bile acids. We also confirmed that CSE liver expression was down-regulated in an animal model of liver damage induced by CCl_4 and that the reduction of H_2S generation seen in this model is likely to contribute to portal hypertension. One of the major findings of this study was the demonstration that mice lacking FXR are more likely to develop liver fibrosis and that loss of FXR function correlates with reduction of CSE protein expression in the liver. Treatment with an FXR ligand increased both CSE expression and activity in the cirrhotic liver, restoring the ability of injured livers to generate H_2S. These findings were not observed in cirrhotic FXR -/- mice treated with 6E-CDCA.

In addition to inhibition of NO formation by sinusoidal endothelial cells, homocysteine triggers an H_2S-sensitive contraction of hepatic stellate cells *in vitro*[18]. Contraction of presinusoidal myofibroblasts has relevance in regulating intrahepatic resistance and short-term administration of 6E-CDCA regulates CSE expression in normal mice, therefore, we investigated whether acute administration of an FXR ligand effectively modulates CSE expression in CCl_4 treated rats and whether this treatment was effective in correcting hepatic microcirculation hyper-responsiveness to norepinephrine. Despite the fact that even 3 d of administration of 6E-CDCA attenuated expression of 1-collagen and SMA mRNA, this anti-fibrotic activity did not completely explain the rapid re-induction of CSE expression in the liver that was associates with a restored ability to generate H_2S and a robust attenuation of hyper-responsiveness of cirrhotic livers to norepinephrine. The ability of the FXR ligand to lower portal pressure and to correct the enhanced vasomotor activity is consistent with the finding that perfusion of cirrhotic livers with H_2S attenuates the endothelial dysfunction that takes place in injured livers.

In conclusion, we have shown that CSE, a key enzyme in the trans-sulfuration pathway, is an FXR-regulated gene. Despite the fact that the level of expression/function of FXR in chronic liver disorders is still unknown, FXR is severely down-regulated in several models of liver injury. Reduction of FXR-regulated genes might contribute to the metabolic dysfunction that takes place in advanced cirrhosis. By linking the deficiency of CSE to the FXR activity the present study provides a new molecular explanation of the pathophysiology of portal hypertension. It also proposes the concept that FXR agonists might correct for the altered generation of endogenous hepatic vasodilators that takes place in chronic liver diseases.

COMMENTS

Background

Portal hypertension is primarily caused by the increase in resistance to portal outflow and an increase in splanchnic blood flow. Alterations in systemic and liver vasoreactivity play a central role in the pathogenesis of this condition by contributing to increased intrahepatic resistance, hyperdynamic circulation and expansion of the collateral circulation. Nitric oxide and hydrogen sulfide (H_2S) cause a direct relaxation of intrahepatic microcirculation suggesting a physiological role for these gaseous mediators in regulating resistance of intrahepatic microcirculation.

Research frontiers

Understanding of the pathophysiology of portal hypertension is essential in the development of new pharmacological treatment of this condition.

Innovations and breakthroughs

Farnesoid X receptor (FXR) is a bile acid sensor and upon activation it reduces the conversion of cholesterol into bile acids and increases bile acid excretion from hepatocytes by activating canalicular transporters. The authors demonstrate that cystathionase, a key enzyme for H_2S production, is an FXR regulated gene.

Applications

FXR agonists might correct for the altered generation of endogenous hepatic vasodilators that takes place in chronic liver diseases.

Peer review

The manuscript by Renga *et al* is a comprehensive study demonstrating the effect of FXR activation by bile acids on the expression of cystathione-γ-lyase and subsequent hydrogen disulfide production. Furthermore, mice lacking the FXR are more susceptible to the liver damage induced by CCl_4. This is a thorough and well-written manuscript that highlights important bile acid signaling events.

Abstract

AIM: To investigate the relationship between 90-kuD ribosomal S6 kinase (p90RSK) and collagen type Ⅰ expression during the development of hepatic fibrosis *in vivo* and *in vitro*.

METHODS: Rat hepatic fibrosis was induced by intraperitoneal injection of dimethylnitrosamine. The protein expression and cell location of p90RSK and their relationship with collagen type Ⅰ were determined by co-immunofluoresence and confocal microscopy. Subsequently, RNAi strategy was employed to silence p90RSK mRNA expression in HSC-T6, an activated hepatic stellate cell (HSC) line. The expression of collagen type Ⅰ in HSC-T6 cells was assessed by Western blotting and real-time polymerase chain reaction. Furthermore, HSCs were transfected with expression vectors or RNAi constructs of p90RSK to increase or decrease the p90RSK expression, then collagen type Ⅰ promoter activity in the transfected HSCs was examined by reporter assay. Lastly HSC-T6 cells transfected with p90RSK siRNA was treated with or without platelet-derived growth factor (PDGF)-BB at a final concentration of 20 μg/L and the cell growth was determined by MTS conversion.

RESULTS: In fibrotic liver tissues, p90RSK was over-expressed in activated HSCs and had a significant positive correlation with collagen type Ⅰ levels. In HSC-T6 cells transfected with RNAi targeted to p90RSK, the expression of collagen type Ⅰ was down-regulated (61.8% in mRNA, $P < 0.01$, 89.1% in protein, $P < 0.01$). However, collagen type Ⅰ promoter activity was not increased with over-expression of p90RSK and not decreased with low expression either, compared with controls in the same cell line ($P = 0.076$). Furthermore, p90RSK siRNA exerted the inhibition of HSC proliferation, and also abolished the effect of PDGF on the HSC proliferation.

CONCLUSION: p90RSK is over-expressed in activated HSCs and involved in regulating the abnormal expression of collagen type Ⅰ through initiating the proliferation of HSCs.

INTRODUCTION

Hepatic fibrogenesis is a response to injury in the liver. It is characterized by both a quantitative and qualitative change in the extracellular matrix (ECM), within which

collagen type I predominates[1,2]. The activated hepatic stellate cell (HSC) is primarily responsible for excessive collagen deposition during liver fibrosis[3-6]. Recently, multiple cellular signals, especially extracellular signal-regulated kinase 1 and 2 (ERK1/2), have been reported to be involved in the process of activation of HSCs by increasing protein phosphorylation and up-regulation of gene transcription[7-9]. 90-kuD ribosomal S6 kinase (p90RSK) is an important downstream substrate of ERK1/2. p90RSK itself interacts with numerous substrates in the cytoplasm and nucleus, and is involved in gene expression, protein synthesis, cell survival, cell cycle proliferation and progression[10-13]. p90RSK has been implicated in the pathogenesis of some tumors and some other chronic diseases[14]. However, the role of p90RSK in hepatic fibrosis has not yet to be fully elucidated. It is known that in rat hepatic fibrosis, p90RSK is significantly up-regulated in association with elevated collagen type I levels[15]. However, the relationship between p90RSK and collagen type I , including any regulatory effects of p90RSK on the expression of collagen type I , is elusive.

Hence the present study was undertaken to explore the relationship between p90RSK and collagen type I expression in the fibrotic liver.

MATERIALS AND METHODS

Animal model

Male adult Sprague-Dawley rats weighing 250 ± 12.3 g were purchased from the Centre of Experimental Animals in Jinling Hospital. The rats received intraperitoneal injections of dimethylnitrosamine (DMN) (Sigma, Saint-Quentin Fallavier, France) at 10 mg/kg body weight (n = 30) or 0.9% sodium chloride (n = 10) thrice a week as previously described[16]. The rats were injected for 1 wk (n = 10), 2 wk (n = 10), and 3 wk (n = 10), and were sacrificed 3 d after the last administration. At the time of sacrifice, a hepatectomy was performed and liver tissue samples were fixed in 10% buffered formalin and embedded in paraffin. The experimental protocol was approved by the Institutional Animal Care committee of Jinling Hospital.

Immunofluorescent staining

Liver sections were blocked with 5% normal goat serum after fixing and then simultaneously incubated with both monoclonal anti-p90RSK (1:200 dilution, BD Biosciences, San Jose, CA, USA) and polyclone anti-collagen type I (1:50 dilution, Rockland, Gilbertsville, PA, USA), or polyclonal antibody of α-smooth muscle actin (α-SMA) (1:100 dilution, Rockland, Gilbertsville, PA, USA) prepared in phosphate-buffered saline (PBS). The sections were incubated overnight at 4℃ or 1 h at room temperature and then washed with PBS. Sections were then simultaneously incubated with fluorescein isothiocyanate (FITC)-conjugated secondary antibody (1:100 dilution, Jackson Immunoresearch Laboratories, West Grove, PA, USA) and rhodamine-conjugated secondary antibody (1:200 dilution, Jackson Immunoresearch Laboratories) for 30 min at 37℃ in the dark. After extensive washing with PBS, the slides were mounted in a drop of Vectashield mounting medium (Vector Laboratories, Burlingame, CA, USA) to reduce photobleaching. Control experiments were performed in parallel with the omission of one of the primary antibodies. For double-staining experiments, both primary antibodies were produced in the different species.

Confocal microscopy and image analysis

Antibody labeling was examined under a Zeiss LSM-510 laser scanning confocal microscope. Optical slices (1.8 μm) were taken perpendicular to the liver section. A 488-nm argon laser was used in combination with a 499/505-530-nm excitation/emission filter set for fluorescence examination. For rhodamine, the 543-nm helium neon laser was used with a 543-nm excitation filter and 560-nm emission filter. Simultaneous images of FITC or rhodamine were captured from the same optical section. The captured images were then pseudocolored: red for rhodamine and green for FITC. Regions of co-localization appeared in yellow, reflecting the additive effect of superimposing green and red pixels. Image analysis was performed using the standard system operating software provided with the Zeiss LSM-510 series microscope.

Design of p90RSK siRNA and cell transfection

The RNAi targeting the p90RSK mRNA was designed by the software on the www.ambion.com. Forward oligo: TCGACAAAAGAGATCCCTCCGAAGTTCGCTTC GGAGGGATCTCTTTTTTTT. Reverse oligo: CTAG AAAAAAAAGTAGATCCCTCCGAAGCGAACTT CGGAGGGATCTCTTTTG. The vector of p90RSK siRNA was constructed using standard techniques[17]. p90RSK siRNA fragments and the vector pAVU6+27 were ligated, and the constructed plasmid with p90RSK siRNA was referred as pAVU6-siRSK. The activated cell line HSC-T6, a kind gift from Dr. Friedman (Mount Sinai School of Medicine), was cultured as previously described[18], and transfected with pAVU6-siRSK or empty plasmid pAVU6+27 by lipofectamine reagents (Invitrogen, Carlsbad, CA, USA), according to the manufacturer's instructions.

RNA extraction and real-time polymerase chain reaction (RT-PCR)

Total RNA was isolated from HSC-T6 cells transfected with pAVU6-siRSK or pAVU6+27 respectively, using Trizol in accordance with the manufacturer's instructions (Invitrogen, Carlsbad, CA, USA). One microgram of total RNA was then treated with DNAse for 30 min at 37℃. Reverse transcription was performed using the Omniscript RT kit (Qiagen, Valencia, CA, USA) and random primers (Promega, Madison, WI, USA). RT-PCR for rat p90RSK1 and collagen type I were performed using the ABI Prism 7700 Sequence Detection System, the Taqman universal PCR Master Mix, and assay-on-demand probes and primers (Shanghai Shengong Ltd.,

Table 1 RT- PCR primers

	Forward	Reverse
P90RSK	5′-TCTCTGTCCAGCG GCGGGTGAGGA-3′	5′-GCATTCACAGCG CCCATGCGCAG-3′
Collagen I	5′-CCAGCCGCAAAG AGTCTACATGTC-3′	5′-TCACCTTCTCAT CCCTCCTAA-3′
18S RNA	5′-GTCTGTGATGC CCTTAGATG-3′	5′-AGCTTATGACC CGCACTTAC-3′

Shanghai, China), according to standard protocols. The primers in RT-PCR are presented in Table 1. Parameters for baseline and threshold-cycle (C_t) settings were kept constant for each gene. To calculate ΔC_t, the C_t value for each target gene was standardized against that for the internal rRNA (18S) control probe.

Western blotting

Rat HSCs were lysed in 1 × sample buffer (62.5 mmol/L Tris-HCl, pH 6.8, 10% glycerol, 2% SDS, 5% 2-mercaptoethanol, 1 mmol/L Na_3VO_4). Ten micrograms of each sample were subjected to SDS-PAGE (7.5%-15%) and then transferred onto an Immobilon P membrane (Millipore Corp., Bedford, MA, USA). After blocking non-specific binding sites, the filters were incubated in Tween PBS at 4℃ for 16 h with one of the following antibodies: (1) mouse monoclonal antibodies directed against rat p90RSK (1:200) (BD); or (2) rabbit polyclonal antibody against rat collagen I (1:1000). Revelation was performed by a chemiluminescence-based method (ECL; Amersham Pharmacia Biotech, San Francisco, CA, USA).

Reporter assays

COL1A1 promoter (-378 to -340 bp)-luciferase reporter constructs were kindly provided by Dr. Huang (Nanjing Medical University). HSC-T6 cells (4×10^6), were electroporated (270 V, 950 μF) with 10 μg of the COL1A1-luciferase reporter and 2 μg of a Renilla luciferase expression construct (Promega), alone or in combination with pAVU6-siRSK, pAVU6+27 (empty vector), pMT2·RSK1 or pMT2 (empty vector) expression construct, respectively. HSC-T6 transfection efficiency was monitored by electroporation of a green fluorescent protein expression construct (10 mg). The relative luciferase value (RLV) was defined as the ratio of the luciferase activity divided by the activity of Renilla luciferase in transfected cell lysates. The RLV of unstimulated cultures was given the arbitrary value of 1. Each experiment was repeated a minimum of three times.

Analysis of HSC proliferation

Cell growth curves of HSC-T6 cells transfected with pAVU6-siRSK or control plasmid pAVU6+27 were analyzed by MTS conversion. Furthermore, to examine the effect of p90RSK siRNA on HSC proliferation induced by platelet-derived growth factor (PDGF), rhPDGF-BB (Boehringer Mannheim Co., Mannheim, Germany) was added to the medium at a final concentration of 20 μg/L in HSC-T6 cells transfected with pAVU6-siRSK or control plasmid pAVU6+27; cell growth was determined by MTS conversion as mentioned. The absolute number of HSCs in different groups by counting cells under microscopy after staining was also measured at the same time.

Statistics analysis

Statistical Package for the Social Sciences (version 10.0 for Windows; SPSS, Chicago, IL, USA) was used for statistical analysis. The calculation of Spearman's rank correlation coefficient was used to assess the relationship between quantitative parameters. Student's *t* test and the Mann-Whitney *U* test were used to compare data from different treatment groups. Data are expressed as mean ± SE. Differences were considered significant when *P* was less than 0.05.

RESULTS

Expression and relation of p90RSK with collagen type I in DMN-treated rats

Immunofluorescent double-staining showed abundant expression of collagen type I and p90RSK in the fibrotic liver (Figure 1A and B). However, in normal liver, only a little collagen type I could be observed and no p90RSK was detected (Figure 1D and E). Image analysis showed that both of p90RSK and collagen type I were up-regulated simultaneously, but these two signals did not co-localize (Figure 1C and F).

Cellular localization of p90RSK in DMN-treated rats

α-SMA, a typical marker of activated HSCs, was selected for this study to determine the cellular localization of p90RSK in fibrotic liver. The localization of p90RSK and α-SMA was visualized by immunofluorescent double labeling and laser scanning confocal microscopy. Image analysis showed a diffused distribution of p90RSK throughout the fibrotic liver (Figure 2A), and a similar distribution was observed with α-SMA staining (Figure 2B). When the two images merged, p90RSK showed a very high degree of co-localization with α-SMA throughout the fibrotic liver (Figure 2C).

Identification of p90RSK siRNA

The recombinant pAV-siRSK was identified by enzyme digestion (Figure 3) and sequencing, which showed that digestion product of pAV-siRSK was about 350 bp, compared with 300 bp production of pAVU6+27. The sequencing result showed siRSK was 52 bp.

Regulation of p90RSK siRNA on collagen type I

The RT-PCR experimental conditions were optimized to obtain an efficacy up to 90% of standard curves. When p90RSK mRNA in HSC-T6 cells was silenced using RNAi and the mRNA of p90RSK and collagen type I examined in HSC-T6 cells transfected with pAVU6-siRSK or empty pAVU6+27, there was an obvious reduction of 72.6% in p90RSK mRNA levels within HSC-T6 cells transfected with pAVU6-siRSK.

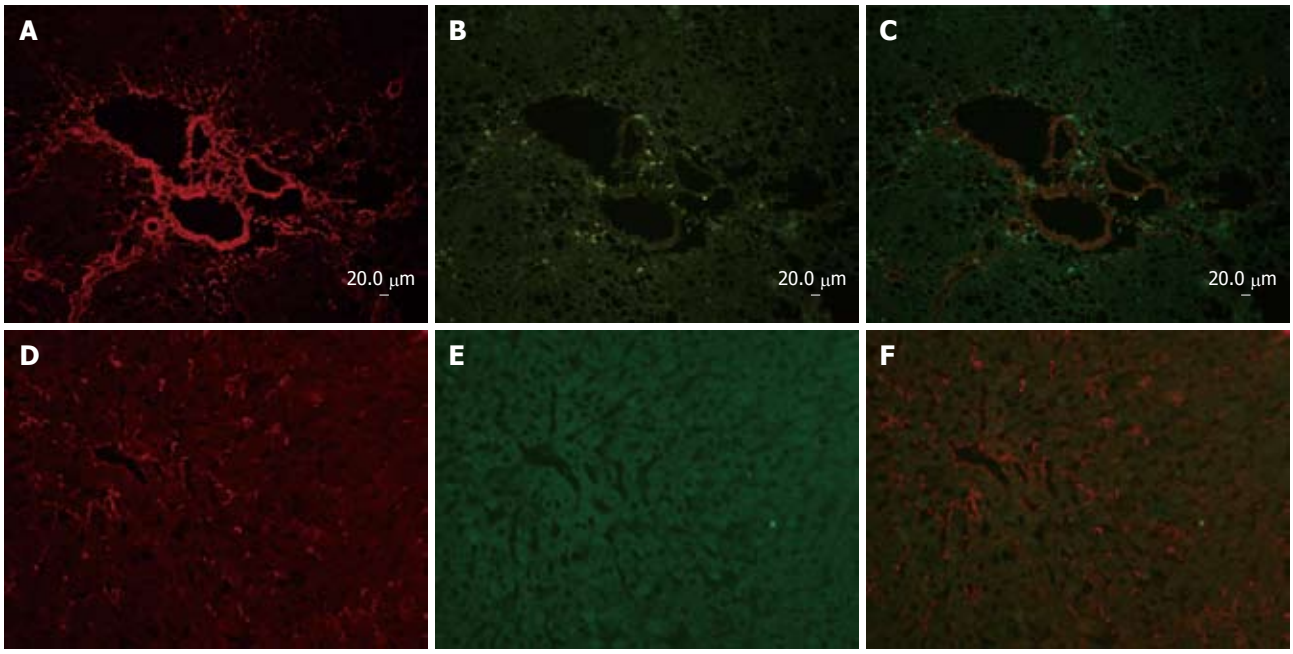

Figure 1 Co-immunofluoresence of p90RSK and collagen type Ⅰ in fibrotic liver and normal liver. Sections (A-C) are from rat liver with intraperitoneal injection of DMN for 3 wk, and sections (D-F) are from normal livers as control. Sections of fibrotic liver mostly demonstrate that collagen type Ⅰ (rhodamine) and p90RSK (FITC) immunoreactivity were both present around central veins as well as in the interstitium, and up-regulated in fibrotic liver. Sections of normal liver mostly demonstrate that collagen type Ⅰ (rhodamine) immunoreactivity was less in normal liver than in fibrotic liver and p90RSK (FITC) was hardly observed in nomal liver simultaneously.

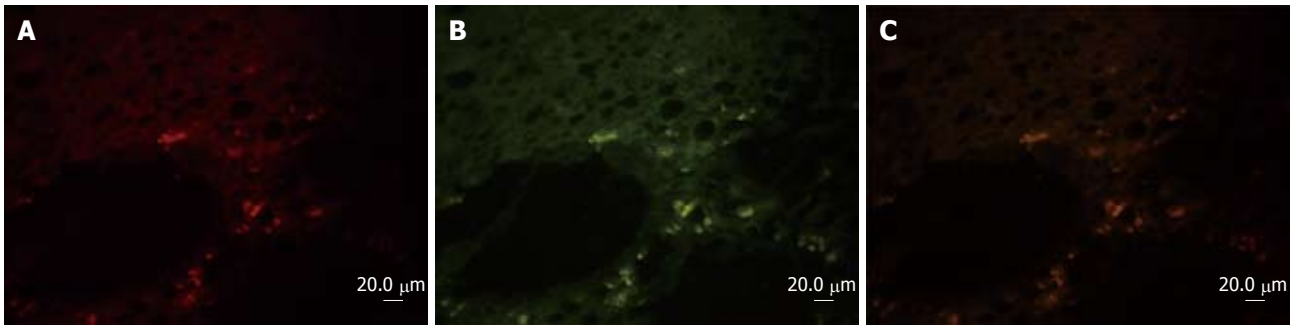

Figure 2 Cellular localization of p90RSK in fibrotic liver and co-immunofluoresence and confocal microscopy of p90RSK and αSMA in fibrotic liver. A: α-SMA (rhodamine)-positive cell represent the activated HSC, which deposited in interstitium; B: P90RSK (FITC)-positive cell were also present in interstitium; C: The yellow areas on the merged image show co-localization of α-SMA and p90RSK.

There was also a reduction of 61.8% in collagen type Ⅰ ($P < 0.01$, Figure 4).

The protein level of p90RSK and collagen type Ⅰ were examined by Western blotting in HSC-T6 cells transfected with pAVU6-siRSK or empty pAVU6+27. The protein level of p90RSK and collagen type Ⅰ was reduced to 75.6% and 89.1%, respectively, after RNAi ($P < 0.01$, Figure 5).

Effect of p90RSK siRNA on collagen type Ⅰ promoter activity

Collagen type Ⅰ is a heterotrimer composed of two coordinately expressed α1 chains and one α2 chain. They are encoded by distinct genes, COL1A1 and COL1A2, respectively[19]. The -378 to -340 region of the COL1A1 promoter exploited in this study is the site of convergence of different stimuli to modulate the gene transcription[20]. In this study, we observed that over-expression of p90RSK had little effect on activity of this region. Similarly, silencing of p90RSK expression did not decrease its activity either (Figure 6). The results showed that p90RSK did not work on COL1A1 promoter. Herein, we identified p90RSK could not alter transcriptional activity of collagen type Ⅰ in HSCs.

Effect of p90RSK siRNA on HSC proliferation

PDGF is a well known ligand able to elicit proliferation as well as to operate through ERK1/2 pathway and the most potent mitogen for HSCs *in vitro*. To further investigate the role of the p90RSK in the mitogenic effects on HSCs, we used the RNAi strategy, to produce the post-transcriptional gene expression silencing of p90RSK in HSCs. In accordance with previous studies, our data showed that p90RSK siRNA significantly inhibited the proliferation of HSC-T6 (Figure 7A) and also abolished the effect of PDGF-BB on HSC proliferation (Figure 7B).

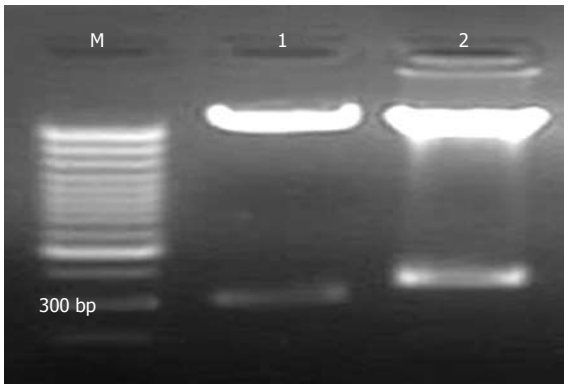

Figure 3 Agarose gel electrophoresis of restriction enzyme digestion of pAV-siRSK. M: 1 kb marker; 1: Restriction enzyme digestion product of pAVU6+27 was about 300 bp; 2: Restriction enzyme digestion product of pAV-siRSK. The siRNA of p90RSK was designed of 52 bp.

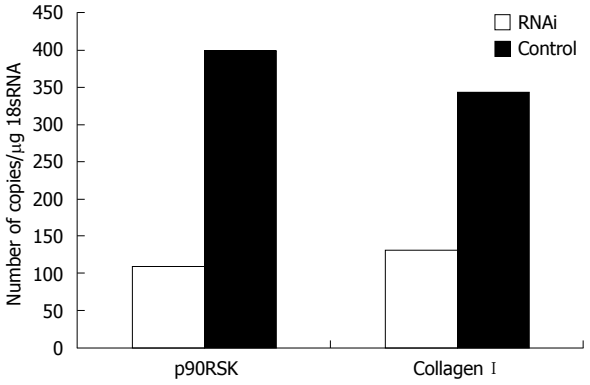

Figure 4 RT-PCR assessment of p90RSK and collagen type I in HSC-T6 transfected with or without pAVU6-siRSK. Quantification of p90RSK and collagen type I normalized to 18S RNA in HSC-T6 cells transfected with pAVU6-siRSK decreased 72.6% and 61.8%, respectively, compared with control ($P < 0.01$). Results are expressed as mean ± SE of three separate experiments.

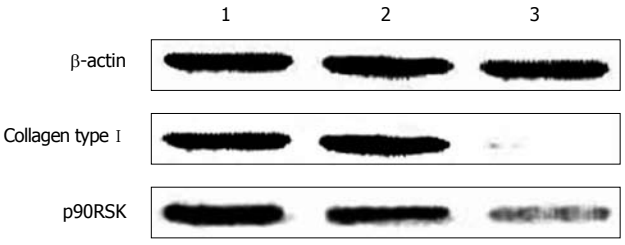

Figure 5 Western blotting analysis of p90RSK, collagen type I in HSC-T6 cells transfected with or without pAVU6-siRSK. β-actin provided as an inner control. 1: Normal HSC-T6 cells; 2: HSC-T6 transfected with empty plasmid; 3: HSC-T6 transfected with pAVU6-siRSK. With p90RSK siRNA, the expression of p90RSK decreased 75.6% compared with controls, and the expression of collagen type I decreased 89.1% accordingly ($P < 0.01$). Results are expressed as mean ± SE of three separate experiments.

DISCUSSION

Northern blot and immunohistochemical analysis has previously demonstrated that the expression of p90RSK has a significant correlation with that of collagen type I during the development of hepatic fibrosis[15]. In that study, the measurements were performed separately, preventing the determination of any spatial relationship between p90RSK and collagen

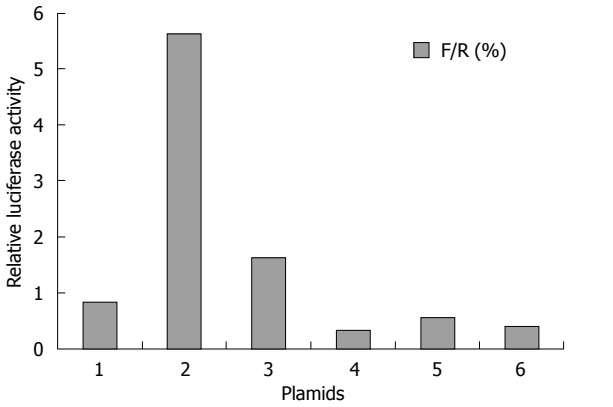

Figure 6 Effect of p90RSK on collagen type I promoter activity. HSCs transfected with the pAVU6-siRSK (bar 3, to decrease p90RSK expression), pMT2·RSK1 (bar 5, to increase p90RSK expression) showed no alteration of collagen type I promoter activity compared to control cells sham-transfected with pAVU6+27 (bar 4), pMT2 (bar 6), respectively. HSCs transfected with collagen type I luciferase reporter construct (bar 1) as normal control and Renilla luciferase expression construct (bar 2) as positive control. After 24 h incubation, the luciferase activity was determined. Data represent luciferase activity relative to the control (bar 1) and are expressed as mean ± SD of three separate experiments.

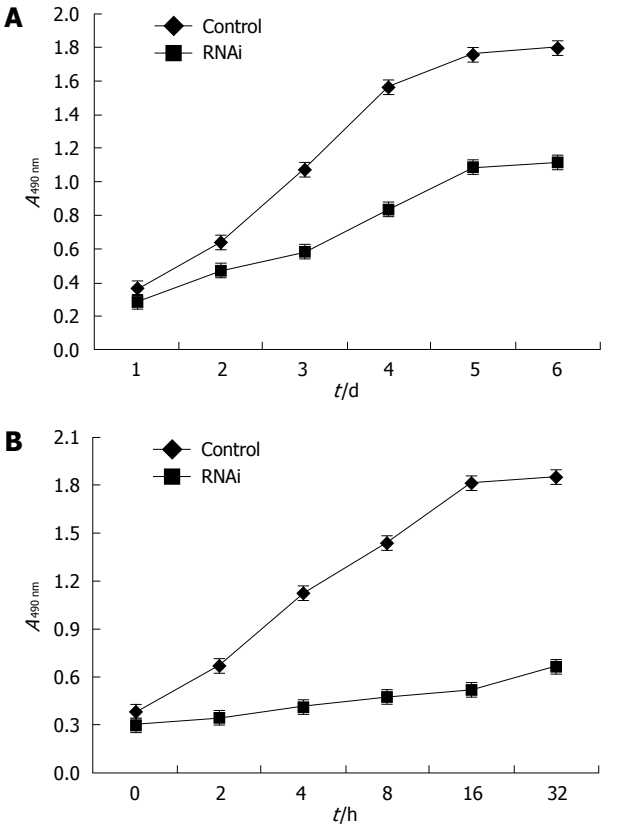

Figure 7 Effect of p90RSK siRNA on the proliferation of HSCs. A: p90RSK siRNA inhibited the proliferation of HSC-T6 cells. Cell growth curves of the recombinant cells with or without p90RSK siRNA were analyzed by MTS conversion; B: p90RSK siRNA abolished the effect of PDGF-BB on the proliferation of HSCs. rhPDGF-BB was added to the medium at a final concentration of 20 μg/L in HSC-T6 cells transfected with pAVU6-siRSK (RNAi), which showed decreased proliferative activity compared to sham transfected control cells (control). Each sample was tested in triplicate and error bars were included.

type I . Therefore, to ascertain whether there was any association between them, the expression of p90RSK and collagen type I was measured simultaneously by immunofluorescent double-staining and confocal microscopy. The results indicate that both p90RSK and collagen type I increase simultaneously in the same section of the fibrotic liver.

The activated HSC is the primary cell type in the liver responsible for the excess synthesis and deposition of ECM, within which collagen type I predominates[5,9]. It resides in the perisinusoidal space of Disse in the liver[21]. In our previous studies, p90RSK was observed in interstitial cells, which include activated HSCs and some other interstitial cells. To determine whether the over-expression of p90RSK was located in activated HSCs, α-SMA was employed as an HSC activation marker[21-23]. The result of confocal microscopy showed that p90RSK and α-SMA are co-localized within the interstitium. Hence, up-regulated p90RSK is located within activated HSC.

HSC-T6 is the immortalized rat HSC line, which retains all features of activated stellate cells, including expression of desmin, α-SMA, and glial acidic fibrillary protein, as well as collagen[24]. Because primary stellate cell cultures and isolation is extremely time-consuming, yields are modest, and there is considerable preparation-to-preparation variability, we used HSC-T6 cells to study the role of p90RSK *in vitro*. We observed that down-regulation of the post-transcriptional gene expression of p90RSK in the HSC-T6 cells, was achieved through the administration of p90RSK siRNA. Subsequently, the expression of collagen type I mRNA was significantly reduced, leading to a reduction of collagen type I in cell culture supernatant. This is in agreement with previous reports[15], and strengthens the evidence for p90RSK production having an influence on collagen type I expression in activated HSCs.

It is known that HSCs are directly involved in mediating the fibrogenic response in hepatic fibrosis. They become fibrogenic by synthesizing ECM proteins and activated HSCs proliferate, thereby amplifying the fibrogenic response[25]. It is becoming clear that both proliferative (i.e. PDGF)[17] and fibrogenic (i.e. transforming growth factor-β)[26] cytokines activate ERK1/2 signaling cascades in the development of hepatic fibrosis. p90RSK could be activated by the above stimuli and has widely distributed substrates[17,27-29]. The diversity of these stimuli and substrates suggests that p90RSK may be involved in the regulation of a wide range of cellular functions[11-13]. ERK1/2 has an important role in the signaling pathway that leads to the proliferation of HSCs. From this, it might be speculated that p90RSK, as a potent downstream substrate of the ERK1/2 signaling pathway, is involved in the fibrogenic activation of HSCs, or proliferation of HSCs, or both. Reporter assays designed to address the ability of p90RSK to regulate the activity of the collagen type I promoter were used to explore the role of p90RSK in the transcriptional induction of collagen type I gene expression in HSCs. The results showed that neither an increase nor decrease of p90RSK has any effect on the collagen type I promoter activity. Otherwise, the analysis of HSC proliferation showed that p90RSK siRNA significantly inhibited the proliferation of activated HSCs and also abolished the effect of PDGF-BB on that of HSCs. This suggests that p90RSK has no effect on the fibrogenic activation of HSCs, rather that p90RSK increases the collagen type I expression *via* the initiation of HSC proliferation. This observation is in line with the recent report that p90RSK phosphorylates C/EBPβ to inhibit activated HSC apoptosis in liver fibrosis[30].

Therefore, we conclude that p90RSK is over-expressed in activated HSCs and involved in the regulation of collagen type I expression through the initiation of HSC proliferation.

ACKNOWLEDGMENTS

We gratefully acknowledge Dr. Scott L Friedman (Professor in Mount Sinai School of Medicine) for kindly providing the cell line HSC-T6. We are grateful to Dr. Joseph Avruch (Professor of the Harvard Medical School) for the plasmid pMT2·RSK1 and Dr. David R Engelke (Professor of biological chemistry in University of Michigan) for the plasmid pAVU6+27.

COMMENTS

Background

Hepatic fibrogenesis is a response to injury in the liver. It is characterized by both a quantitative and qualitative change in the extracellular matrix, within which collagen type I predominates. The activated hepatic stellate cell (HSC) is primarily responsible for excessive collagen deposition during liver fibrosis. Recently, multiple cellular signals, especially extracellular signal-regulated kinase 1 and 2 (ERK1/2), have been reported to be involved in the process of activation of HSCs by increasing protein phosphorylation and up-regulation of gene transcription. However, the molecular mechanism is not fully elucidated.

Research frontiers

90-ku ribosomal S6 kinase (p90RSK) is an important downstream substrate of ERK1/2. p90RSK itself interacts with numerous substrates in the cytoplasm and nucleus, and is involved in gene expression, protein synthesis, cell survival, cell cycle proliferation and progression. p90RSK has been implicated in the pathogenesis of some tumors and some other chronic diseases. The authors' previous research has demonstrated that p90RSK is significantly up-regulated in rat hepatic fibrosis. However, the role of p90RSK in hepatic fibrosis has yet to be fully elucidated. In this study, the authors demonstrate that the overexpression of p90RSK could be a potential mechanism for mediating collagen type I expression.

Innovations and breakthroughs

Recent reports have highlighted the importance of p90RSK in cell proliferation and differentiation. In particular, p90RSK is required for cytostatic factor arrest in *Xenopus laevis* eggs. This is the first study to investigate the regulatory mechanism of p90RSK on collagen type I expression in rat HSCs.

Applications

This study may represent a future strategy for therapeutic intervention in the treatment of hepatic fibrosis.

Terminology

p90RSK is a serine/threonine kinase, which is the key substrate of the ERK1/2 signal pathway and involved in the phosphorylation of transcription factors, including nuclear factor-κB, c-Fos, Nur77, and cAMP response element-binding protein.

Peer review

The study by Yang *et al* investigated the relationship between p90RSK and

collagen type Ⅰ expression during the development of experimental hepatic fibrosis induced by dimethylnitrosamine. By also employing a number of experimental procedures and the T6 rat-model of immortalized HSCs, the authors conclude that p90RSK is over-expressed in activated HSCs and involved in the abnormal expression of collagen type Ⅰ, although collagen type Ⅰ promoter activity is not affected by either p90RSK over-expression or silencing. The study, of appreciable technical quality, is of potential interest for a reader interested in liver fibrosis. Data are mostly straightforward.

Abstract

AIM: To explore the effect of *Echinococcus multilocularis* (*E. multilocularis*) on the activation of mitogen-activated protein kinase (MAPK) signaling pathways and on liver cell proliferation.

METHODS: Changes in the phosphorylation of MAPKs and proliferating cell nuclear antigen (PCNA) expression were measured in the liver of patients with alveolar echinococcosis (AE). MAPKs, MEK1/2 [MAPK/extracellular signal-regulated protein kinase (ERK) kinase] and ribosomal S6 kinase (RSK) phosphorylation were detected in primary cultures of rat hepatocytes in contact *in vitro* with (1) *E. multilocularis* vesicle fluid (EmF), (2) *E. multilocularis*-conditioned medium (EmCM).

RESULTS: In the liver of AE patients, ERK 1/2 and p38 MAPK were activated and PCNA expression was increased, especially in the vicinity of the metacestode. Upon exposure to EmF, p38, c-Jun N-terminal kinase (JNK) and ERK1/2 were also activated in hepatocytes *in vitro*, as well as MEK1/2 and RSK, in the absence of any toxic effect. Upon exposure to EmCM, only JNK was up-regulated.

CONCLUSION: Previous studies have demonstrated an influence of the host on the MAPK cascade in *E. multilocularis*. Our data suggest that the reverse, i.e. parasite-derived signals efficiently acting on MAPK signaling pathways in host liver cells, is actually operating.

Key words: *Echinococcus multilocularis*; Hepatic alveolar echinococcosis; Mitogen-activated protein kinase; Host-parasite interactions; Liver

INTRODUCTION

Changes in the metabolic pathways involved in homeostasis and growth regulation of hepatic cells, and especially in the mitogen-activated protein kinase (MAPK) system, have been extensively studied in infectious/inflammatory conditions; of those, viral infections, and especially HBV and HCV in relation to hepatic carcinogenesis, have received most attention[1-3]. Very little is known about the capacity of helminth parasites and/or their components/secretions to influence liver cell homeostasis metabolic pathways. Actually, a few helminth parasites do affect the liver[4]. Among them, infection with *Echinococcus multilocularis* (*E. multilocularis*) larva (metacestode) affects primarily the liver and causes alveolar echinococcosis (AE) in intermediate hosts. It is an aggressive chronic parasitic infection that is characterized by a multivesicular structure surrounded by an extensive fibro-inflammatory host reaction[5]. In humans, who behave as accidental intermediate hosts, the severity of this life-threatening disease results from both a continuous asexual proliferation of the metacestode and an intense granulomatous infiltration around the parasite; the lesions behave like a slow-growing liver cancer. Invasion of biliary and vascular walls is another hallmark of this severe disease[6,7]. The ensuing fibrosis protects the patients against parasitic growth, but at the same time distorts the liver parenchyma[8-13]. Hepatomegaly is a usual symptom of AE; it has been ascribed to the liver regeneration which accompanies the pseudo-tumoral process[7]. However, unlike other forms of liver injury, e.g. from neoplasms, viral hepatitis or physical injury in which cell cycle regulatory genes have been extensively investigated[14,15], the cellular and molecular consequences of *E. multilocularis* infection on liver cells have never been studied.

It has been shown that the larval development of *E. multilocularis* is triggered by cell signaling originating from the intermediate host[16,17]. The phosphorylation of EmMPK1, a parasitic orthologue of the extracellular signal-regulated kinase (ERK) MAPK, is specifically induced in *in-vitro*-cultured *E. multilocularis* metacestode vesicles, in response to exogenous host serum, hepatic cells and/or human epidermal growth factor (EGF). The *E. multilocularis* metacestode is thus able to "sense" host factors which results in an activation of the parasite MAPK cascade[18]. The fact that tissue-dwelling *E. multilocularis* expresses signaling systems with significant homologies to those of the host raises the interesting question whether cross-communication between cytokines and corresponding receptors of host and parasite can occur during an infection, i.e. whether the parasite may also influence signaling mechanisms of host cells through the secretion of various molecules that might bind to host cell surface receptors. Such interactions could contribute to immunomodulatory activities of *E. multilocularis* or be involved in mechanisms of organotropism and/or in host tissue destruction or regeneration during parasitic development. Only gross changes in carbohydrate metabolism[19] and in protein/albumin secretion by liver cells[20] have been studied in experimental and *in vitro* models of *E. multilocularis* growth. To the best of our knowledge, no study has reported on the activation pattern of liver cell MAPK during *E. multilocularis* host infection. MAPKs are key regulators of cellular signaling systems that mediate responses to a wide variety of extracellular stimuli. MAPK signaling pathways, including c-Jun N-terminal kinase (JNK), p38 MAPK and ERK, play important roles in signal transduction from the cell membrane to the nuclear transcriptional factors; they cross-communicate and regulate the balance between cell survival and cell death in acute and chronic liver injury[21,22]. Generally, the JNK and p38 MAPK families appear to be pro-apoptotic, while the ERK pathway appears to be anti-apoptotic in mediating specifically cell growth and survival signals in many cell types[23]. The dynamic balance of their activities appears critical in acute liver injury such as viral hepatitis, drug- or toxin-induced toxicity or acute rejection after liver transplantation as well as in chronic liver injury[1,24]. For all these reasons we chose them as a first target.

The aim of the present study was thus to explore the influence of *E. multilocularis* metacestode on the activation of MAPK signaling pathways (ERK1/2, JNK and p38) and on liver cell proliferation. To reach this goal, we first studied the changes induced in the liver of patients with chronic AE, and then, the changes in hepatic cell cultures in contact *in vitro* with (1) *E. multilocularis* vesicle fluid (EmF), and (2) *E. multilocularis*-conditioned medium (EmCM).

MATERIALS AND METHODS

Tissue samples

The diagnosis of AE was established on positive serology with ELISA using crude *E. multilocularis* and Em2 antigens[25] and characteristic liver lesions observed at ultrasound and CT-scanning, and confirmed by histological examination of the lesions. To demonstrate the influence of *E. multilocularis* lesions on the surrounding hepatic cells, paired liver specimens (volume: 0.5 cm^3 each) were obtained at surgery by an experienced surgeon from AE patients at the Liver Surgery and Transplantation Units of the University Hospital, Besancon, France (one patient), and of 1st Teaching Hospital, Xinjiang Medical University (TH-XMU), Urumqi, China (four patients). In each patient, one specimen was taken close to the parasitic lesions (i.e. 0.5 cm from the macroscopic changes due to the metacestode/granuloma lesion, thus avoiding liver contamination with infiltrating immune cells and parasitic tissue), and one was taken distant from the lesions (i.e. in the non-diseased lobe of the liver whenever possible, or at least at 10 cm from the lesion), according to a previously described procedure[11]. Absence of contamination by the parasitic lesions was checked on all samples by histological examination. The patients gave their informed consent for the use of tissue samples for research, as part of a research project approved by the "*Comité*

Régional de Protection des Personnes en Recherche Biomédicale" de Franche-Comté, according to the French regulation, and by the Ethical Committee of TH-XMU. The liver samples were homogenized in ice-cold lysis buffer as previously described[26] and homogenates were clarified by centrifugation at 10000 *g* for 10 min at 4℃. Protein concentration was estimated by the BCA Assay kit (Sigma, Steinheim, Germany). Samples were stored at -80℃ until use.

EmCM and EmF

The EmCM without serum was kindly provided by Klaus Brehm (Institute of Hygiene and Microbiology, University of Würzburg, Germany) and was prepared as described previously[27] and stored at -80℃ until used.

EmF was extracted from vesicles in *E. multilocularis*-infected *Cricetulus migratorius* maintained at the Experimental Animal Research Laboratory of TH-XMU, according to the international guidelines for the maintenance of experimental animals for medical research. All procedures were carried out in a class Ⅱ laminar flow cabinet with appropriate protective clothing. The parasite material was removed from the peritoneal cavity under aseptic conditions, and was washed three times in phosphate buffered saline. The membrane was punctured with a 21-gauge needle connected to a 50-mL syringe. Fluid was withdrawn carefully until *E. multilocularis* vesicles had visibly lost turgidity. The apex was dissected and the remaining fluid removed, ensuring that no protoscoleces were aspirated. EmF was centrifuged (10000 *g*, 10 min) to remove debris, filtered through a 0.2-μm filter and stored at -80℃ until use.

Cell isolation, culture of rat hepatocytes and treatment with EmCM or EmF

Rat hepatocytes were prepared as described previously[28] and cultured in William's E culture medium in a humidified incubator at 37℃ and 5% CO_2 for 20 h before the start of the experiment, supplemented with 100 U/mL penicillin and 100 mg/mL streptomycin (Invitrogen, Paisley, UK), without the addition of hormones or growth factors. During the attachment period (4 h), 2 mmol/L glutamine, 4 mg/mL bovine insulin, 1 μmol/L dexamethasone, and 10% fetal calf serum (Life Technologies Ltd) were added to the medium. Hepatocyte viability was always more than 90% and purity more than 95%.

For the experiment, cells were washed and cultured for 20 h in serum-free insulin-free William's E culture medium, then incubated with either EmF for 15 min, 30 min, 1, 2, 8 and 24 h or EmCM for 15 min, 30 min, 1, 2, 3, 8 and 24 h, respectively.

Western blotting analysis

Western blotting analysis of cell lysates was performed by SDS-PAGE using NuPAGE (Invitrogen, Carlsbad, CA, USA) followed by transfer to nitrocellulose membrane (Invitrogen). Ponceau S (Sigma) staining was used to ensure equal protein loading and electrophoretic transfer. Using the appropriate antibodies, ERK1/2, JNK, p38 and their corresponding phosphoproteins, phosphorylated MAPK/ERK kinase 1/2 (MEK1/2), phosphorylated ribosomal S6 kinase (RSK), phosphorylated transcription factor Elk-1 (Elk-1), [Cell Signaling Technology (Beverly, MA, USA) and β-tubulin (Sigma)] were detected with the WesternBreeze Kit (Invitrogen). The expression levels of p-ERK1/2 /total ERK1/2 (signal at 44 kDa), p-p38/total p38 and p-JNK/total JNK (signal at 54 kDa) proteins (in "relative units") in control cultures and cultures treated with EmCM or EmF were quantified using Quantity One software (Bio-Rad, Hercules, CA, USA).

Assay for cytotoxicity of EmCM or EmF

Primary cultures of rat hepatocytes were plated in 96-multiwell plates. After attachment, they were treated with EmF (diluted by half in William's E culture medium) or pure EmCM for 24 h and cell viability was assessed[29]. No toxic effect was found.

Detection of proliferating cell nuclear antigen (PCNA) in liver sections

Formalin-fixed, paraffin-embedded sections of the five AE patients' livers were stained for the presence of PCNA using a biotinylated anti-PCNA antibody (Boshide Inc., Wuhan, China) according to the manufacturer's instructions. PCNA-positive hepatocytes were counted in three random visual fields of 0.95 mm^2 each, at initial magnification × 20, for each sample, and the number expressed as the percentage of PCNA-positive cells to the total number of cells counted.

Statistics analysis

Data were presented as the mean ± SD and analyzed using SPSS version 11.0 software (SPSS, Chicago, IL, USA). Statistical significance was tested using the Student *t* test; a *P* value of less than 0.05 was considered significant.

RESULTS

ERK1/2 and p38 activation in AE patients

ERK1/2 phosphorylation was assessed in liver samples taken close to and distant from the parasitic lesions in five AE patients. As shown in Figure 1A, ERK1/2 phosphorylation was 1.58-fold to 4.26-fold higher in the liver close to the parasitic lesion than in the distant liver. p38 phosphorylation was found in the liver of all AE patients; it was more prominent in the liver close to the parasitic lesion than in liver distant from the lesion (1.70 to 3.40-fold), except in one patient (0.55-fold) (Figure 1B).

Expression of PCNA in AE patients

The expression of PCNA, an important growth marker and DNA replication regulator, was assessed in the liver close to and distant from the parasitic lesions in five AE patients. As shown in Figure 2A, an increased expression of PCNA was observed in the liver close to the parasitic

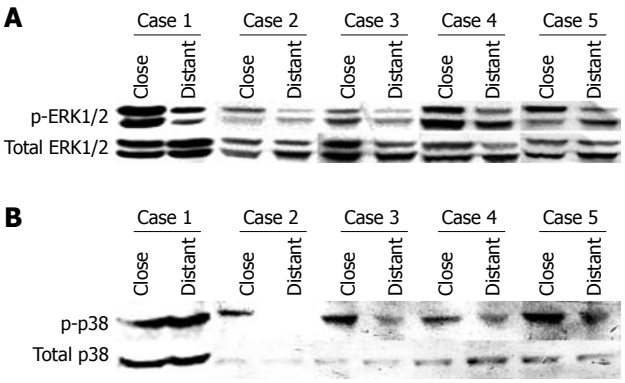

Figure 1 ERK1/2 (A) and p38 (B) activation in liver samples from five AE patients. Western immunoblot analyses were performed on lysates with antibodies that recognize phosphorylated and total ERK1/2 respectively (A), and phosphorylated- and total p38, respectively (B). Close: Liver samples close to the parasitic lesions in AE patients; Distant: Liver samples distant from the parasitic lesions in AE patients.

lesions compared to the liver distant from the parasitic lesion (Figure 2B). Although a faint expression of PCNA could be detected in the distant liver in one case, there was a significant difference between PCNA expression in the hepatocytes close to and distant from the parasitic lesion ($P < 0.05$, Figure 2C).

MAPKs (ERK1/2, JNK and p38) activation by exposure of primary hepatocytes to EmF or EmCM

To investigate whether the MAPKs were also activated in primary cultured hepatocytes in contact with EmF or EmCM, we measured phosphorylated and total ERK1/2, JNK and p38. As shown in Figure 3A, increased ERK1/2 phosphorylation was observed from 15 min to 2 h and peaked at 1 h after incubation with EmF. EmF increased the phosphorylation of ERK1/2 (threonine-202, tyrosine-204) from approximate 2.50-fold at 15 min to 6.50-fold at 1 h (Figure 3B). There was a significant difference between non-treated and EmF-treated liver cell cultures at the 15 min, 30 min and 1 h time-points ($P < 0.05$). In contrast, EmCM only weakly stimulated ERK activity from approximately 1.37-fold at 15 min and approximately 1.84-fold at 8 h to approximately 2.42-fold at 24 h (Figure 3C and D).

EmF slightly activated p38 at 1, 2 and 24 h (Figure 4A). No activation of p38 MAPK could be detected in EmCM-stimulated hepatocytes (Figure 4B).

EmF increased the phosphorylation of JNK (threonine-183, tyrosine-185) from 2.63-fold at 15 min to 2.23-fold at 30 min, respectively (Figure 5A and B). Similar results were found in the EmCM-treated liver cells, as shown in Figure 5C and D: increased JNK phosphorylation was observed from 3.26-fold at 15 min to 1.94-fold at 30 min, respectively, and then there was a decrease to the baseline.

Taken together, these results clearly show that EmF stimulated all 3 classes of MAPKs, but EmCM only induced ERK1/2 and JNK activation in primary hepatocytes.

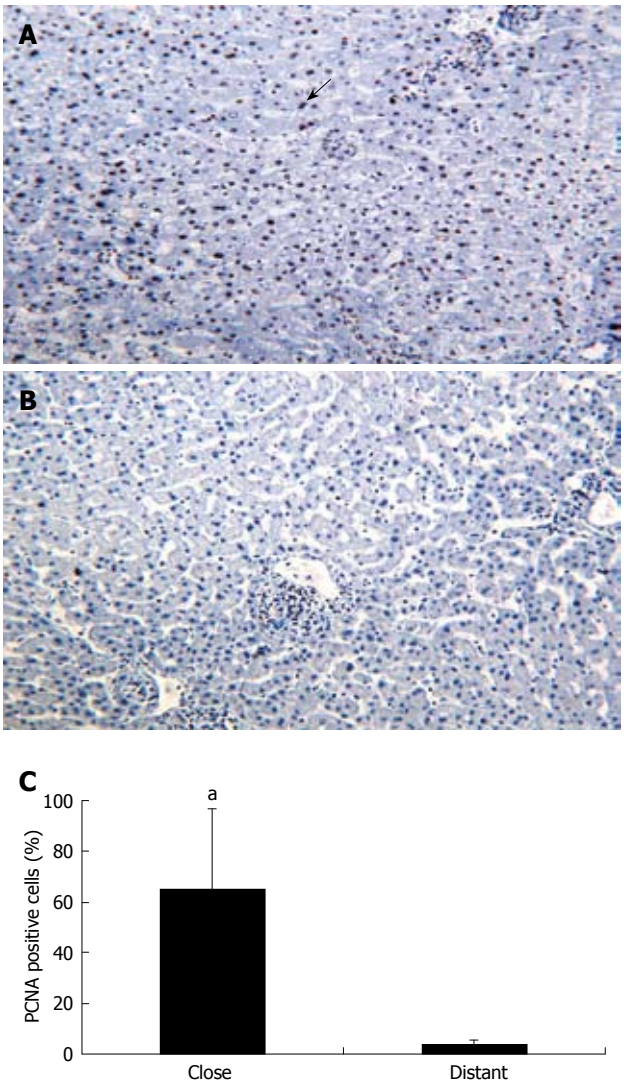

Figure 2 PCNA expression by hepatic cells in the liver from five patients with AE (immunohistochemical analysis). A: Hepatic cells close to the parasitic lesions were strongly labeled by the anti-PCNA antibody; all cells with a dark-brown/black nucleus are positive cells; some of them indicated by an arrow (initial magnification: × 20); B: Hepatic cells distant from the parasitic lesions did not express PCNA (initial magnification: × 20); C: Quantitative expression of PCNA was significantly higher in the liver cells close to the parasitic lesions than in those distant to them ($^aP < 0.05$).

ERK1/2 pathway activation by exposure of primary hepatocytes to EmF or EmCM

To further explore the effect of EmF and EmCM on the ERK activation pathway, we first studied the activation of MEK1/2, the physiological activator of ERK[21,30]. We did indeed observe an activation of MEK1/2 from 15 min to 2 h of EmF exposure (Figure 6A). In contrast, MEK1/2 activation was not detectable at any time points during EmCM exposure (data not shown). Then, we studied the phosphorylation of RSK and Elk-1, cytoplasmic substrates of ERK1/2 and mediators of cell survival[23,31,32]. As shown in Figure 6B, RSK phosphorylation was observed after exposure to EmF and maximal RSK activation was observed at 30 min. No phosphorylation of Elk-1 could be detected neither after EmF nor EmCM incubation (data not shown).

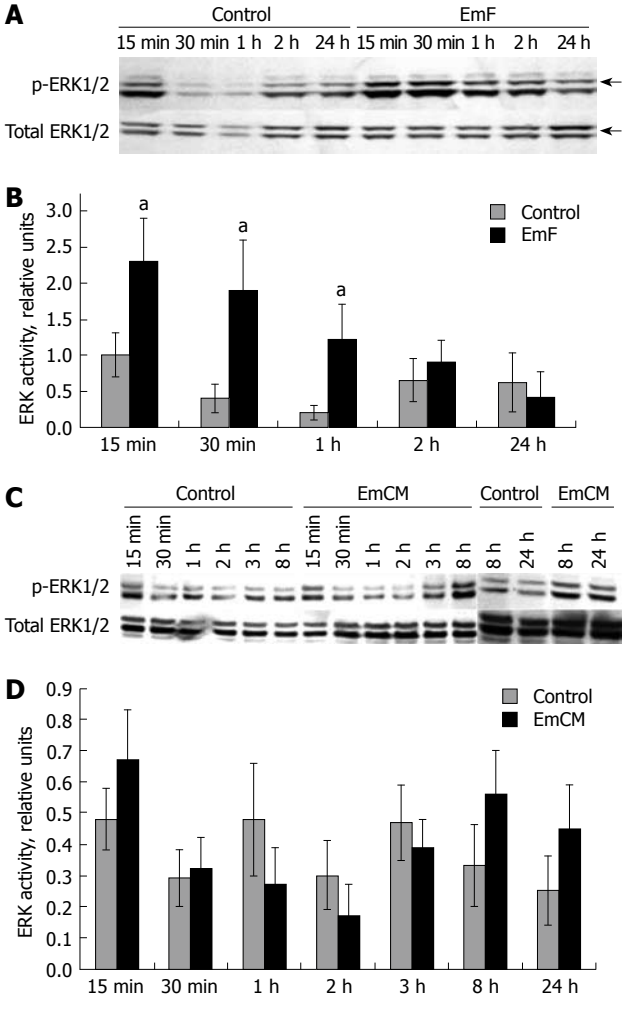

Figure 3 Time course of EmF- or EmCM- induced phosphorylation of ERK1/2 kinase. Primary cultures of rat hepatocytes were stimulated with EmF (A, B) or EmCM (C, D) and harvested at the indicated time points (15 min to 24 h). Western immunoblot analyses were performed on lysates with antibodies that recognize phosphorylated (p-) and total ERK1/2 (A, C), respectively. Relative amount of phosphorylated to total ERK1/2 and ERK1/2 was calculated from semi-quantitative analysis of the Western blotting using densitometry (B, D). $^{a}P < 0.05$, EmF or EmCM-induced *versus* control hepatocytes. All experiments were performed three times independently with similar results.

Thus, EmF exposure, but not EmCM exposure, induced RSK activation in hepatocyte cultures; none of them activated Elk-1.

DISCUSSION

In this study we found a significant influence of *E. multilocularis* metacestode on the activation of MAPK signaling pathways. *In vivo*, in the liver of AE patients, increased proliferation of hepatocytes was observed and ERK1/2 and p38 were phosphorylated, both being higher in the vicinity of the parasitic lesions. *In vitro*, in primary cultures of rat hepatocytes, three MAPKs (p38, JNK and ERK1/2) were activated upon exposure to *E. multilocularis* parasitic fluid, while p38 was undetectable and only JNK was up-regulated after incubation with supernatants of *E. multilocularis* axenic cultures.

The liver has the unique ability to regenerate after injury or loss of tissue. Liver regeneration is controlled

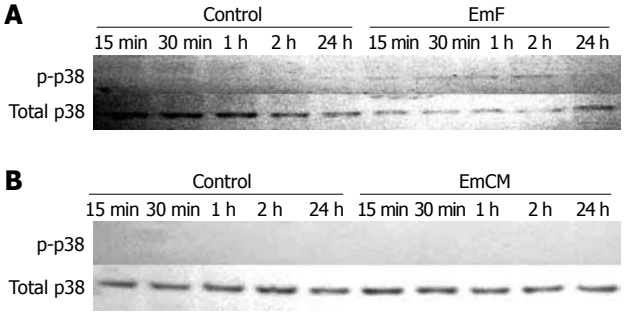

Figure 4 Time course of EmF- or EmCM-induced phosphorylation of p38 kinase. Primary cultures of rat hepatocytes were stimulated with EmF (A) or EmCM (B) and harvested at the indicated time points (15 min to 24 h). Western immunoblot analyses were performed on lysates with antibodies that recognize phosphorylated (p-) and total p38. All experiments were performed three times independently with similar results.

by a wide array of signaling factors and plays a key role in recovery after acute and chronic liver injury[33]. Hepatic cell proliferation represents a central and unique feature of tissue repair after liver injury. ERK1/2 is considered to be an important inducer of the pro-mitogenic pathway and ERK1/2 activation is correlated with hepatocyte DNA replication *in vivo* and hepatocyte proliferation *in vitro*[33,34]. In *E. multilocularis* infection, parasitic influence on liver cell proliferation might be crucial to ensure metacestode survival within the liver. Our data indicate that *E. multilocularis* infection of the liver actually activates ERK1/2 and induces cell proliferation. The major extent of size increase of the normal liver lobes has often been stressed in AE patients[7].

Specific stimulation of hepatocyte proliferation by metacestode-derived substances may add to the regeneration process that normally occurs following liver injury and explain this clinical observation. Such influence may be due either to a direct effect of substances of parasitic origin or to an indirect effect, through a response to host cytokines which are secreted by the macrophages and lymphocytes surrounding the parasitic lesions. A variety of host cytokines are actually present in the periparasitic environment of *E. multilocularis* infection[13]. They include both pro-inflammatory cytokines such as tumor necrosis factor-α, interleukin-6 (IL-6) and IL-1β[13,35] and anti-inflammatory cytokines such as IL-10[36,37] and transforming growth factor-β (TGF-β)[38], and might be responsible for the observed changes in the MAPK system. As *in vivo* studies in infected patients did not allow us to determine precisely the mechanism of activation and the pathways involved, we used *in vitro* cultures of hepatocytes directly in contact with substances of parasitic origin to further analyze the origin of the activation processes.

MAPK activation occurred in rat hepatocyte cultures incubated with fluids of parasitic origin, in the absence of inflammatory cells. We may anticipate that at least part of the activation was related to direct interactions between *E. multilocularis* metacestode-derived components and the liver cells. Cross-functioning between parasite-derived molecules and

Primary cultures of rat hepatocytes were stimulated with EmF and harvested at the indicated time points (15 min to 24 h). Western immunoblot analyses were performed on lysates with antibodies that recognize phosphorylated (p-) MEK1/2 and p-RSK. Protein loading control was performed using β-tubulin. MEK: MAPK/ERK kinase.

host liver was described for parasite-derived enzymes: for instance, *E. multilocularis*-derived transglutaminase was shown to efficiently catalyze human liver-derived osteonectin cross-linking[8]. The significant changes observed using EmCM, which is totally free of host components, demonstrated that parasitic components specifically activated JNK and were actually acting on hepatocyte metabolic pathways. The most consistent data, however, were obtained by the incubation of rat hepatic cells with EmF. Upon exposure of hepatic cells to EmF, the expression of phosphorylated ERK1/2 paralleled that of phosphorylated JNKs. EmF exposure also induced the activation of MEK1/2 and RSK in hepatocytes. The differences between both stimuli might result from differences in the concentration of potential activators, EmF being more concentrated than EmCM. Alternatively, they might be due to the simultaneous presence of activating and inhibiting factors after 40 h of metacestode culture, while EmF collected in intermediate hosts infected with *E. multilocularis* for several weeks could be more concentrated in activating factors. Involvement of host factors stored in EmF could also explain the differences. In fact, in addition to proteins secreted by the germinal layer of *Echinococcus* sp. *metacestodes*, the vesicle fluid (often called hydatid fluid) may contain host proteins that are transported across the laminated layer and the germinal layer of the parasite. Albumin and globulins[39], inhibitors of the complement cascade[40] and, recently, host-derived active matrix metalloproteinase 9[41], were found in *Echinococcus granulosus* hydatid fluid or bound to the cyst wall. Heat shock proteins hsp70 and hsp20, which can interfere with MAPKs, especially p38, were also found in *E. granulosus* hydatid fluid[39]. It is highly likely that hydatid fluid from both species, *E. granulosus* and *E. multilocularis*, may also contain cytokines and growth factors of host origin and serve as storage for continuous release of factors both to the parasite and to the host through the laminated layer which appears critical at the host-parasite interface[42]. Dual interactions could thus ensure growth and survival of the parasite while interfering with host liver cells.

Several lines of evidence suggest that *E. multilocularis* differentiation is dependent on the receipt of appropriate host signals through surface receptors and their transduction through functional MAPK signaling pathways in the parasite[16,18,43,44]. Our data show that the reverse, i.e. parasite-derived signals efficiently acting on MAPK signaling pathways in host liver cells, is actually operating. Although the precise nature of these signals cannot be inferred from the present study, insulin and EGF, which have been identified as candidates for MAPK activation from the host to the parasite[18,44] are possible candidates for MAPK activation from the parasite to the host. This has to be studied by additional experiments *in vitro*. In addition, other candidates cannot be ruled out; among them, TGF-β, which is present in the serum of infected experimental intermediate hosts[45] and in the periparasitic environment of *E. multilocularis* in the human liver[38]. TGF-β does not activate the MAPKs directly but may exert an indirect influence through

the activation of Smads. *E. multilocularis* metacestode is sensitive to TGF-β signaling[46,47] and the metacestode ERK-like kinase, EmMPK1, phosphorylates EmSmadD, a metacestode analogue of the Co-Smads of the TGF-β signaling cascade[46]. TGF-β is involved in immune suppression/tolerance[48], liver cell proliferation[49] and liver fibrosis, where it plays a major role in the activation and progression processes[50], where all three effects are essential to the pathogenesis of AE. This does not preclude, however, the importance of other cytokines or stress molecules.

In summary, three MAPKs, p38, JNK and ERK1/2, and the upstream (MEK1/2) and downstream (RSK) components of the ERK1/2 signaling pathways, are activated in primary cultures of rat hepatocytes by parasite- and/or host-derived substances. JNK activation by host-free supernatant of *E. multilocularis* cultures suggests that liver cell signaling pathways are actually activated by parasitic components. Hepatic proliferation in AE could thus be induced through a direct influence of the parasite and not only linked to the usual reaction of hepatic cells to the occupying process that takes place in the liver. The current investigation is the first which addresses the possible influence of *E. multilocularis*-related molecules on liver cells and demonstrates changes that are consistent with liver cell signaling through these molecules. Attempts to elucidate the nature and origin of the parasite-derived factors which influence intracellular signaling pathways in host cells may especially clarify the mechanism used by *E. multilocularis* to increase cell proliferation but also concomitant events, including parasite survival, immune suppression and induction of liver fibrosis.

ACKNOWLEDGMENTS

We would like to thank Professor Klaus Brehm, Institute of Hygiene and Microbiology, University of Würzburg, Germany, for his generous gift of EmCM and his constructive advice and comments on this study, Professor Bernadette Kantelip, head of the Department of Pathology, Besançon University Hospital, for her valuable help in histopathological aspects of the study, and Catherine Guyon and Alexandre Bonet and Hui Liu for their excellent technical assistance.

COMMENTS

Background

Changes in the metabolic pathways involved in homeostasis and growth regulation of hepatic cells, and especially in the mitogen-activated protein kinase (MAPK) system, have been extensively studied in infectious/inflammatory conditions. Very little is known, however, on the capacity of helminth parasites and/or their components/secretions to influence liver cell homeostasis metabolic pathways and no study has reported on the activation pattern of liver cell MAPK during *Echinococcus multilocularis* (*E. multilocularis*) infection. Helminths developing in the liver may influence hepatic cell proliferation through the activation of MAPKs. The authors thus explored the effect of *E. multilocularis* on the activation of MAPKs signaling pathways and on liver cell proliferation.

Research frontiers

MAPKs play important roles in signal transduction from the cell membrane to the nuclear transcriptional factors; they cross-communicate and regulate the balance between cell survival and cell death in acute and chronic liver injury. The dynamic balance of their activities appears critical in acute liver injury such as viral hepatitis, drug- or toxin-induced toxicity or acute rejection after liver transplantation, as well as in chronic liver injury. Thus, exploring this system is the best way to study the interactions between the parasite and the host, relating to proliferation processes.

Innovations and breakthroughs

It is the first *in vivo* demonstration that a helminth parasite influences the proliferation/regeneration of hepatic cells and the concomitant activation of the MAPK metabolic pathway. Previous studies have demonstrated an influence of the host liver on the MAPK cascade in *E. multilocularis* metacestode; the data suggest that the reverse, i.e. parasite-derived signals efficiently acting on MAPK signaling pathways in host liver cells, is actually operating.

Applications

The observed changes could be involved in the development of the massive hepatomegaly often observed as a presenting symptom in alveolar echinococcosis in humans, and which makes major hepatic resections a therapeutic option for this disease. It could also be involved in other aspects of the host-parasite relationship, including parasite survival, immune suppression and induction of liver fibrosis. This opens new avenues of research to understand parasite-host interactions in the liver.

Terminology

MAPKs are cell signaling pathways that include c-Jun N-terminal kinase (JNK), p38 MAPK and extracellular signal-regulated kinase (ERK). Generally, the JNK and p38 MAPK families appear to be pro-apoptotic, while the ERK pathway appears to be anti-apoptotic in specifically mediating cell growth and survival signals in many cell types. The metacestode of *E. multilocularis* is the larval form of this cestode, which develops in rodent intermediate hosts and is responsible for the hepatic disease alveolar echinococcosis in humans.

Peer review

The manuscript describes an investigation on cell signaling events in the liver induced by infection with *E. multilocularis*. Experiments were performed on samples of infected human liver specimens or using conditioned media or vesicle fluid from infected animals to induce activation of the MAPK pathway in cultured hepatocytes. Whilst the *in vitro* hepatocyte data are supported by evidence of global MAPK activation in whole liver lysates, it would be interesting to complete the study by immunostaining with phospho-specific monoclonal antibodies for ERK and p38 in liver tissue, to identify which cell types are being modulated by the presence of parasite and the precise location of these cells. The study is well conceived and on the whole the experiments have been well thought out.

Abstract

AIM: To study the sensitivity of gastric smooth muscle to C-type natriuretic peptide (CNP) in streptozotocin (STZ)-induced diabetic rats.

METHODS: The spontaneous contraction of a gastric smooth muscle strip was recorded by using physiological methods in rats. The expressions of CNP and natriuretic peptide receptor-B (NPR-B) in gastric tissue were examined by using immunohistochemistry techniques in the diabetic rat.

RESULTS: At 4 wk after injection of STZ and vehicle, the frequency of spontaneous contraction of gastric smooth muscle was significantly reduced in diabetic rats, and the frequency was decreased from 3.10 ± 0.14 cycle/min in controls to 2.23 ± 0.13 cycle/min (n = 8, P < 0.01). However, the amplitude of spontaneous contraction was not significant different from the normal rat. CNP significantly inhibited spontaneous contraction of gastric smooth muscle in normal and diabetic rats, but the inhibitory effect was significantly potentiated in the diabetic rats. The amplitudes of spontaneous contraction were suppressed by 75.15% ± 0.71% and 58.92% ± 1.32% while the frequencies were decreased by 53.33% ± 2.03% and 26.95% ± 2.82% in diabetic and normal rats, respectively (n = 8, P < 0.01). The expression of CNP in gastric tissue was not changed in diabetic rats, however the expression of NPR-B was significantly increased in diabetic rats, and the staining indexes of NPR-B were 30.67 ± 1.59 and 17.63 ± 1.49 in diabetic and normal rat, respectively (n = 8, P < 0.01).

CONCLUSION: The results suggest that CNP induced an inhibitory effect on spontaneous contraction of gastric smooth muscle, potentiated in diabetic rat *via* up-regulation of the natriuretic peptides-NPR-B-particulate guanylyl cyclase-cyclic GMP signal pathway.

INTRODUCTION

Gastroparesis (delayed gastric emptying) is frequent in diabetic patients. It is a well-recognized complication of long-standing diabetes. The symptom complex typically associated with gastroparesis occurs in 25%-55% of patients with long-standing type 1 or type 2 diabetes[1,2]. Symptoms of diabetic gastropathy can range from mild dyspepsia to recurrent vomiting and abdominal pain, and may progress to irreversible end-stage gastric failure known as gastroparesis. Gastroparesis seriously affects the quality of life. There is deterioration in glycemic control and incapacitating symptoms such as malnutrition, water and electrolyte imbalance, and aspiration may occur. However, the pathophysiology of diabetic gastropathy

and gastroparesis, including impaired fundic and pyloric relaxation and impaired electrical pacemaking, is still not delineated[3,4]. It is generally considered that diabetic gastropathy and gastroparesis may be due to visceral autonomic neuropathy, hyperglycemia and degeneration of smooth muscle. Several physiological studies have reported that dysfunction of gastric smooth muscle in diabetes is associated not only with neural factors, but also with intracellular signaling pathways[5,6].

Since atrial natriuretic peptide (ANP) was isolated from atrium by de Bold *et al*[7] in 1981, brain natriuretic peptide (BNP), C-type natriuretic peptide (CNP), dendroaspis natriuretic peptide (DNP), micrurus natriuretic peptide (MNP), and ventricular natriuretic peptide (VNP) were found in succession. Natriuretic peptides (NPs) are distributed all over the body besides the heart and exert natriuretic-diuretic, vasorelaxation, and other functions designed to decrease blood pressure and to control electrolyte homeostasis. Three types of single-transmembrane natriuretic peptide receptors (NPRs) for ANP, BNP and CNP have been identified[8,9]; i.e. NPR type A (NPR-A), type B (NPR-B) and type C (NPR-C). NPR-A and NPR-B receptors have membrane-bound particulate guanylate cyclase (pGC), which catalyzes the formation of cGMP from GTP[10-12]. NPR-A preferentially binds ANP and BNP, but has a low affinity for CNP; NPR-B has a much higher affinity for CNP than either ANP or BNP[13]. NPs are also secreted from gastric mucosa[14-16]. Our previous study indicated that CNP relaxes gastric circular and longitudinal smooth muscles in human, rat and guinea-pig stomach, and that NPRs are distributed in rat gastric smooth muscle layer[17-19]. In smooth muscle, CNP activates its cognate NPR-B, which includes an intracellular pGC domain and catalyzes the synthesis of cGMP within the cytosol[20]. CNP and NPR-B have been detected in the stomach[17,21,22]. CNP mRNA expression was increased in the kidney of streptozotocin (STZ)-induced diabetic rats and NPR-B expression was enhanced in vascular smooth muscle in the diabetic mouse[23,24].

However, it is not clear what the relationship is between diabetic gastroparesis and the natriuretic peptide signal pathway. In the present study, the possibility as to whether the natriuretic peptide-dependent cGMP signal pathway is involved in diabetic gastropathy or gastroparesis was investigated in STZ-induced rats.

MATERIALS AND METHODS

STZ-induced diabetic animal model

Male Sprague-Dawley rats (200-220 g) were purchased from the Experimental Animal Center of Yanbian University College of Medicine. Animals were allowed to have free access to food and water. A total of 30 rats were divided into two groups (15 per group): one was the normal control group and another was the diabetic group. All rats were used for the experiment at 4 wk after the injection of STZ and vehicle. Diabetes was induced by a single intraperitoneal injection of STZ (Sigma-Aldrich, St. Louis, MO, USA) in 0.1 mol/L citrate buffer (pH 4.0) at a dose of 65 mg/kg body weight[6]. Control animals received an equal volume of citrate buffer. The glucose concentration in tail-blood was determined at the end of the experiment with a SureStepPlus apparatus (LifeScan, Milpitas, CA, USA). Diabetes was confirmed by measurement of blood glucose concentrations and defined as blood glucose above 350 mg/dL. Animals were treated in accordance with the Guide for Care and Use of Laboratory Animals published by the National Institutes of Health (China).

Organ bath study

Four weeks after treatment with STZ and vehicle, animals were anesthetized with sodium pentobarbital (50 mg/kg, ip) and then the abdomen was opened. The stomach was removed and placed in pre-oxygenated Kreb's Ringer solution at room temperature. The mucosal layer was removed and the strips (about 2.0 mm × 15.0 mm) of gastric antral circular muscle from control and diabetic rats were prepared, respectively. The longer axis of the stomach was cut parallel to the circular muscle fibers. Muscle strips were placed in a 2-mL organ bath containing modified Kreb's Ringer solution at 37℃, aerated with 95% O_2 and 5% CO_2. One end of the muscle strip was anchored to a stationary support, and the other end was connected to an isometric force transducer (Grass FT03C, Quincy, MA, USA). The tension loaded onto each strip was 1.0 g. Isometric contractions were recorded using a computerized data acquisition system (Power Lab/8SP, AD Instruments, Castle Hill, NSW, Australia). The muscle strip was allowed to incubate for at least 40 min before experiments were started. The composition of the modified Kreb's Ringer solution (mmol/L) was as follows: NaCl 120; KCl 4.7; $CaCl_2$ 2.0; $MgCl_2$ 1.2; $NaHCO_3$ 25; KH_2PO_4 1.2; and glucose 14.

Immunohistochemistry study

Tissues of normal control and STZ-diabetic rats stomach antrum were fixed in 4% buffered formalin for 24 h, dehydrated in ethanol, and embedded in paraffin. Sections were cut at 5 μm, and mounted on poly-L-lysine-coated slides. Sections were deparaffinized in three changes of xylene, hydrated in a graded ethanol series, and washed in tap water. Endogenous peroxidase activity was blocked by immersing slides in 0.3% H_2O_2 for 30 min. After being washed in phosphate buffered saline (PBS), slides were incubated for 45 min at 37℃ in a humidified container with normal goat serum to block non-specific binding of the primary antibody. The blocking serum was removed by gentle tapping, and slides were incubated for 24 h at 4℃ in a humidified container with either rabbit anti-CNP (1:600, Santa Cruz Biotechnology, Santa Cruz, CA, USA) or rabbit anti-NPR-B (1:500, Santa Cruz Biotechnology). After being washed thoroughly in PBS, slides were incubated for 30 min at 37℃ in a humidified container with biotin-labeled goat anti-rabbit serum. After being washed in PBS, the peroxidase-

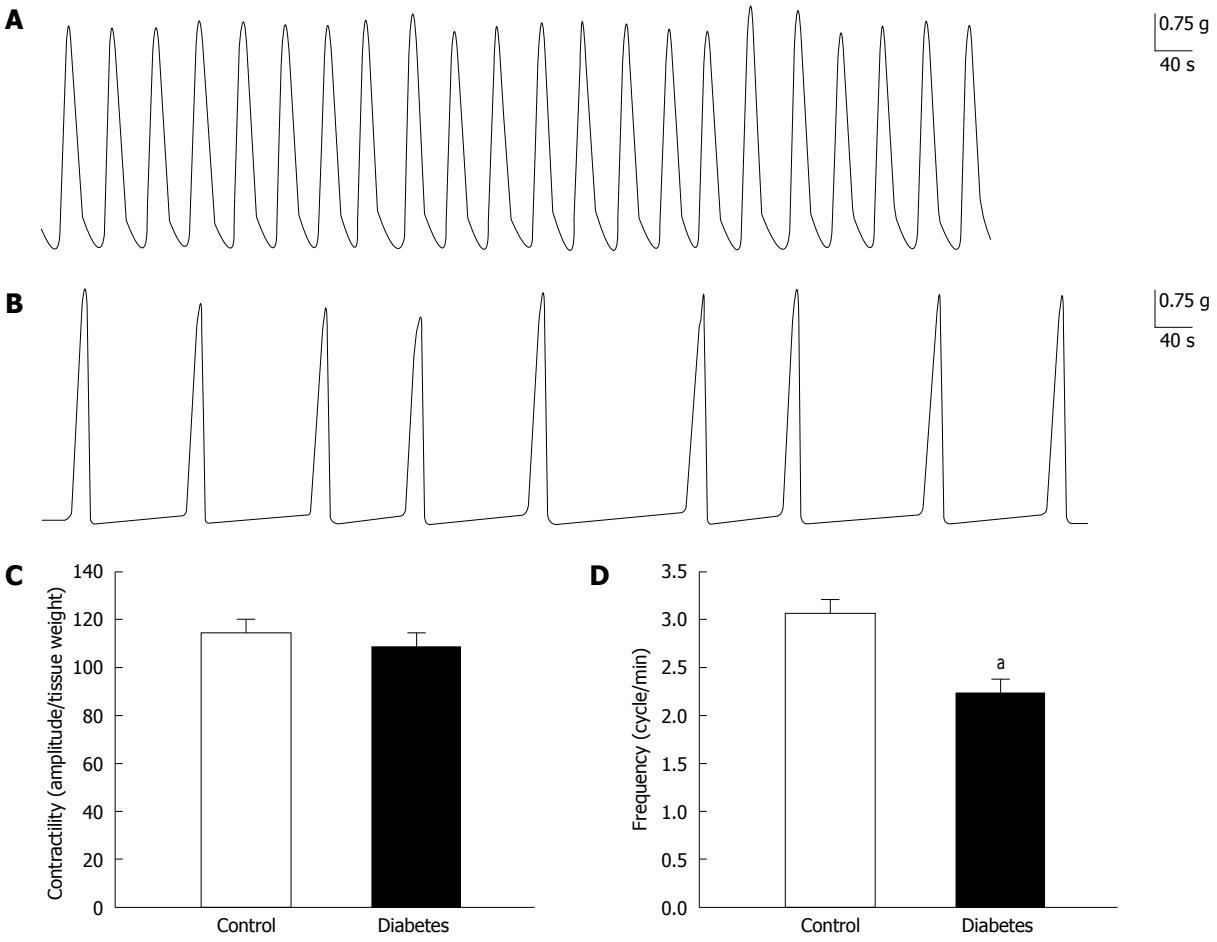

Figure 1 Comparison of gastric smooth muscle contractilities between normal and diabetic rats. A, B: The row traces gastric smooth muscle spontaneous contractions in normal and diabetic rats; C, D: Summary of the contractility in normal and diabetic rats. The contractility per weight of gastric smooth muscle strip was not significantly different between normal and diabetic rats (A-C, $n = 8$, $P > 0.05$). However, the frequency of spontaneous contraction was significantly depressed in diabetic rats (A, B and D, $n = 8$, $^{a}P < 0.01$).

labeled streptavidin complex reagent was added, and the slides were incubated for 30 min at 37℃ in a humidified container. After being washed in PBS, antibody binding was visualized using 3,3'-diaminobenzidine. Slides were washed in running tap water, counterstained lightly with hematoxylin, and mounted in permount. For negative controls, sections were incubated with PBS in place of the primary antibody.

Drugs

CNP (rat CNP-22), STZ, cGMP antibody and chemicals were purchased from Sigma-Aldrich (St. Louis, MO, US). CNP was dissolved in distilled water (1 mmol/L) and further diluted in the superfusion buffer to the concentrations indicated in the text.

Statistics analysis

The staining index was calculated from the staining intensity and area by means of image analysis software, in three areas per section, three sections per group, and weak, medium and strong CNP and NPR-B staining intensities graded as 1, 2 and 3 points according to Feng J Lai's method[25]. The contractility = amplitude of spontaneous contraction (g)/gastric smooth muscle strip weight (g). Inhibitory percentages = amplitude in control - amplitude decreased by CNP/amplitude in control × 100%. Staining index = staining intensity × staining area. Data were expressed as mean ± SE. Statistical significance was evaluated by *t* test. Differences were considered significant when $P < 0.05$.

RESULTS

Change in body weight and plasma glucose

Rats were used for experiments at 4 wk after injection with STZ. At the time of the experiment, all STZ-treated rats exhibited hyperglycemia; their blood glucose concentrations (478.0 ± 27.9 mg/dL) were significantly higher than those of the non-diabetic control rats (108.9 ± 11.4 mg/dL, $n = 8$, $P < 0.001$) and the body weights of the diabetic rats (209.7 ± 8.0 g) were significantly lower than those of the control rats (247.4 ± 13.1 g, $n = 8$, $P < 0.05$).

The spontaneous contraction of gastric smooth muscle

To determine the extent of gastric motility impediment in diabetic rats the spontaneous contractions of gastric smooth muscle strips were observed in control and

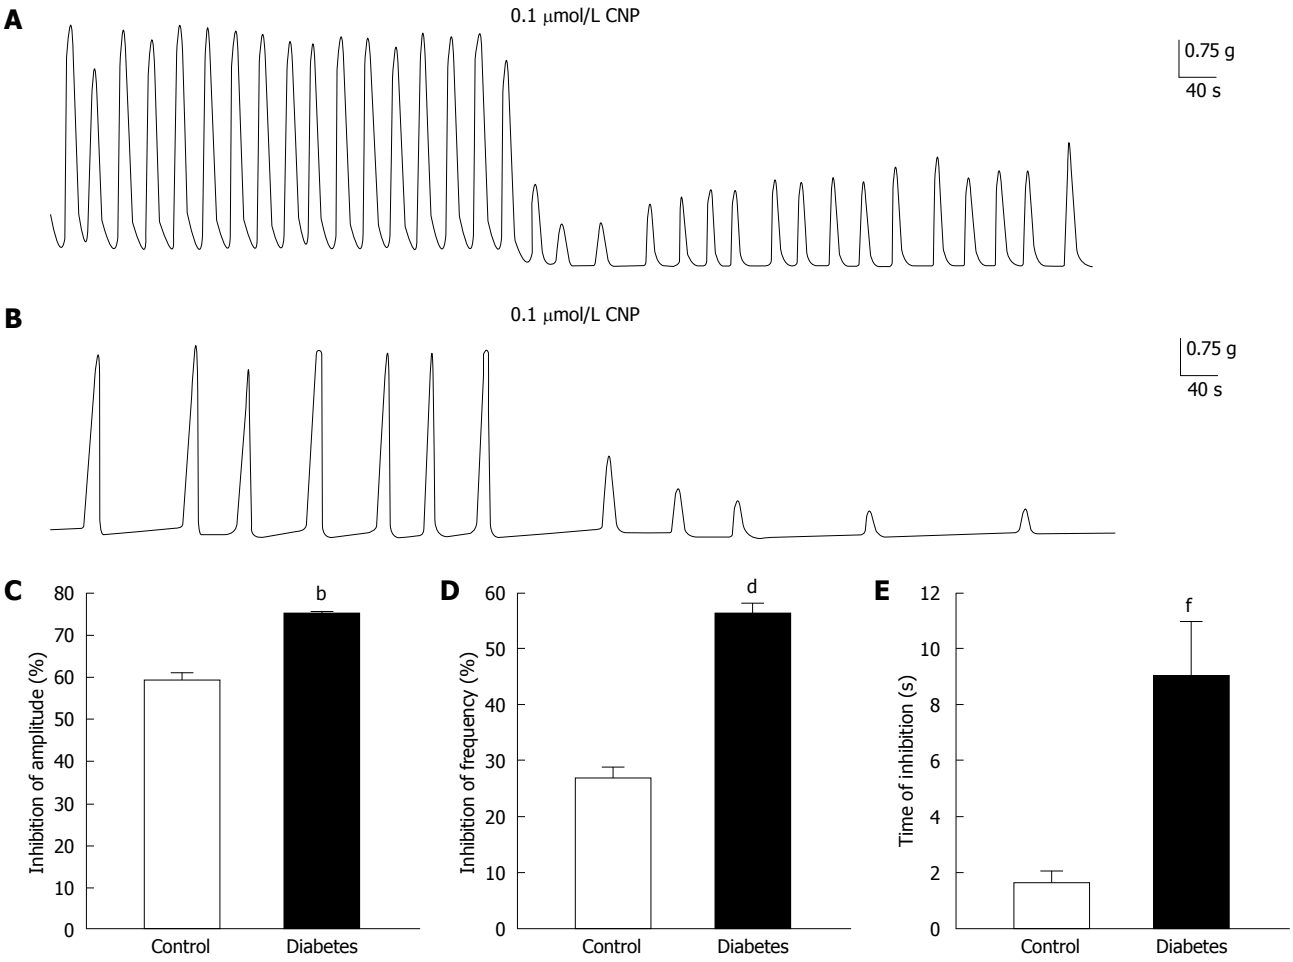

Figure 2 The sensitivity of gastric smooth muscle to CNP. A, B: The row traces gastric smooth muscle spontaneous contractions in response to CNP in normal and diabetic rats; C-E: Summary of the contractility in response to CNP in normal and diabetic rats. CNP induced relaxation of gastric antral smooth muscle in control and diabetic rats (A, B). However, CNP-induced inhibition of spontaneous contraction was potentiated in diabetic rats, and the amplitude (C, $n = 8$, $^{b}P < 0.01$) and frequency (D, $n = 8$, $^{d}P < 0.01$) of spontaneous contraction were more potentially suppressed by CNP in diabetic rats. The inhibition time of CNP of spontaneous contraction was significantly prolonged in diabetic rats (E, $n = 8$, $^{f}P < 0.01$).

diabetic rats. At 4 wk after injection of STZ and vehicle, the spontaneous contraction was recorded in gastric smooth muscle strips of normal and diabetic rats. In order to compare the contractilities of gastric smooth muscle between normal and diabetic rats, the amplitudes of spontaneous contraction of gastric smooth muscle were normalized by every muscle strip weight. The frequency of spontaneous contraction was significantly decreased in diabetic rats, while the amplitude of spontaneous contraction was not significantly affected in diabetic rats (Figure 1A and B). The frequency of spontaneous contraction was decreased from 3.10 ± 0.14 cycle/min of the control to 2.23 ± 0.13 cycle/min (Figure 1D, $n = 8$, $P < 0.01$), however, the contractilities were 115.18 ± 8.69 and 109.34 ± 6.54 in normal and diabetic rats, respectively (Figure 1C, $n = 8$, $P > 0.05$).

The sensitivity of gastric smooth muscle to CNP

To determine the role of the natriuretic peptide signal pathway in diabetic gastroparesis, the effect of CNP on spontaneous contraction was observed in normal and diabetic rats. CNP significantly inhibited the spontaneous contractions in both groups (Figure 2A and B), however, the inhibitory effect was potentiated in diabetic rats. The amplitude of spontaneous contraction was suppressed by 58.92% ± 1.32% and 75.15% ± 0.71% in normal and diabetic rats, respectively (Figure 2C, $n = 8$, $P < 0.01$). The frequency of spontaneous contraction was decreased by 26.95% ± 2.82% and 53.33% ± 2.03% in normal and diabetic rats, respectively (Figure 2D, $n = 8$, $P < 0.01$). The time of CNP-induced inhibition (inhibition time) was measured as the time from starting to reduce the amplitude of spontaneous contraction to starting to recover from peak inhibition. The inhibition time was prolonged from 1.43 ± 0.80 min of control to 8.95 ± 2.07 min in diabetic rats (Figure 2E, $n = 8$, $P < 0.01$).

CNP and NPR-B expression in gastric tissues

Since the CNP-induced inhibition of spontaneous contraction was potentiated in diabetic rats, the expressions of CNP and NPR-B in gastric tissues were further confirmed. There was no CNP immunopositive expression in negative controls of normal and diabetic rats (Figure 3A and B). The CNP immunopositive brown granules were mainly expressed in gastric muscle layers of normal and diabetic rats (Figure 3C and D),

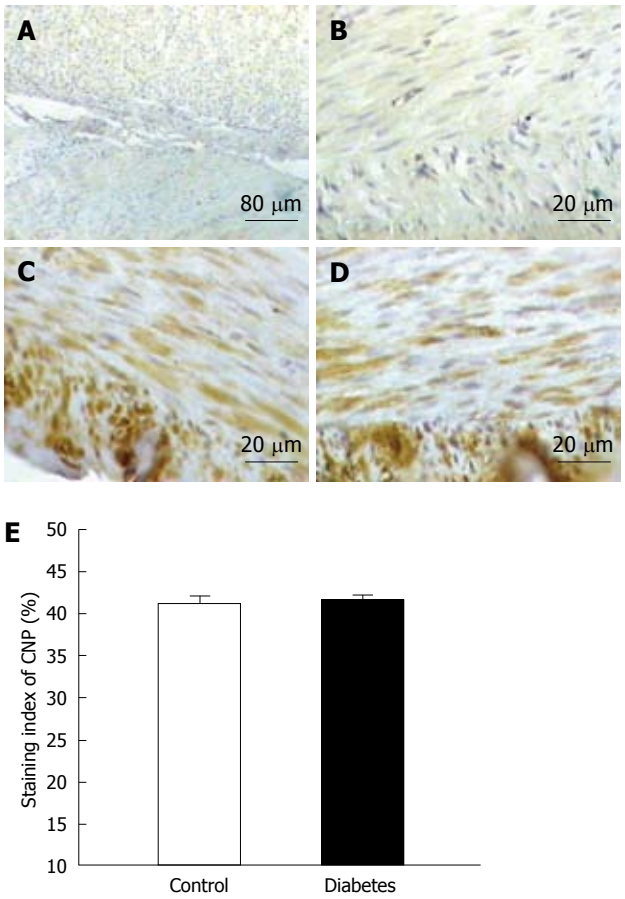

Figure 3 CNP expression in gastric tissues in normal and diabetic rats. A-D: CNP expression in gastric smooth muscle in normal and diabetic rats. In negative controls CNP was not expressed in normal and diabetic rats (A, B) and the CNP immunopositive brown granules were mainly expressed in gastric muscle layers of normal and diabetic rats (C, D); E: Summary of CNP expression in normal and diabetic rats. The staining indexes were not significantly different between normal and diabetic rats (E, n = 8, P > 0.05). Scale bars = 80 μm (A), 20 μm (B-D).

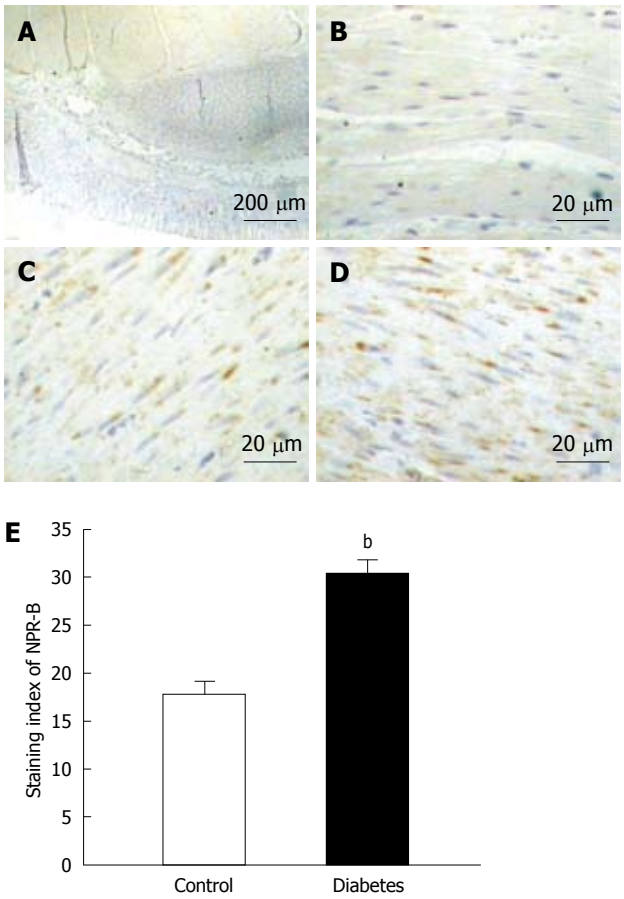

Figure 4 NPR-B expression in gastric tissues in normal and diabetic rats. A-D: NPR-B expression in gastric smooth muscle in normal and diabetic rats. There was no NPR-B immunopositive expression in negative controls of normal and diabetic rats (A, B). The NPR-B immunopositive brown granules were expressed in gastric antral smooth muscle in normal and diabetic rats. The staining was deeper in diabetic rats (C, D); E: Summary of NPR-B expression in normal and diabetic rats. The staining indexes were increased significantly in diabetic rats (E, n = 8, ^bP < 0.01). Scale bars = 200 μm (A), 20 μm (B-D).

and the staining indexes were not significantly different between normal and diabetic rats (Figure 3E, n = 8, P > 0.05). There was no NPR-B immunopositive expression in negative controls of normal and diabetic rats (Figure 4A and B). The NPR-B immunopositive brown granules were expressed in gastric antral smooth muscle in normal and diabetic rats, however the staining was deeper in diabetic rats (Figure 4C and D). The staining indexes were increased from 17.63 ± 1.49 in controls to 30.67 ± 1.59 in diabetic rats, and there were significant differences between normal and diabetic rats (Figure 4E, n = 8, P < 0.01).

DISCUSSION

The effects of CNP on gastrointestinal motility have been described by some reports: relaxant effect on chick rectum muscle strip[26] and guinea pig cecum circular smooth muscle[27], and inhibitory effect on rabbit colon[28]. We previously reported that CNP significantly inhibited spontaneous contraction of gastric smooth muscles in rats, guinea pigs and humans[17]. Although previous studies demonstrated that spontaneous activity of the smooth muscle in the gastrointestinal tract was attenuated in diabetic-model animals[29-31], no studies were made of the relationship with the NPR-pGC-cGMP signal pathway. In our present study, at 4 wk after injection of STZ and vehicle, the frequency of spontaneous contraction was significantly depressed in diabetic rats (Figure 1A and B), while the amplitude of spontaneous contraction was not significantly affected in diabetic rats (Figure 1C). CNP induced relaxation of gastric antral circular smooth muscle in normal and diabetic rats, however the relaxation response induced by CNP was significantly potentiated in diabetic rats (Figure 2). The results indicate that the gastric smooth muscles were more sensitive to CNP in the diabetic rats than in the normal rats, and they suggest that the NPs-NPR-B-pGC-cGMP signal pathway may be upregulated in STZ-induced diabetic rat.

Three types of single-transmembrane NPRs for ANP, BNP and CNP have been identified[8,9], i.e. NPR-A, NPR-B and NPR-C. NPR-A and NPR-B have membrane-bound pGC which catalyzes the formation of cGMP from GTP[10-12]. NPR-A preferentially binds ANP and BNP, but has a low affinity for CNP, NPR-B

has a much higher affinity for CNP than either ANP or BNP[13]. CNP mRNA expression was increased in the kidney of STZ-induced diabetic rats and NPR-B expression was enhanced in vascular smooth muscle in the diabetic mouse[23,24].

In smooth muscle, CNP generally causes relaxation by eliciting membrane-bound pGC-mediated cGMP production[32]. Moreover, many experiments also demonstrated that CNP cognate receptors were distributed in gastrointestinal smooth muscle[23,24,28]. In our present study the NPR-B immunopositive brown granules were increased in the gastric antral smooth muscle of diabetic rats (Figure 4). However, the CNP expression in gastric muscle was not significantly different from normal rats (Figure 3). These results suggest that the NPs-NPR-B-pGC-cGMP signal pathway may be involved in diabetic gastropathy *via* increasing of the NPR-B expression. Furthermore, the data are compatible with the idea that up-regulation of the NPs-NPR-B-pGC-cGMP signal pathway may be an important factor which hastens or induces the disorder of gastric motility, and occurs concomitantly with development of gastrointestinal dysfunction, for example, gastroparesis. Thus, every stage of the NPs-NPR-B-pGC-cGMP signal pathway may be a potential target for investigating the mechanism of diabetic gastropathy or gastroparesis and preventing diabetic gastrointestinal dysfunction.

In summary, this study has demonstrated that diabetes firstly induces frequency depression of gastric motility but not contractility. The CNP-induced relaxation response is potentiated in STZ-induced diabetic rats, and this is related to increased NPR-B expression in the gastric smooth muscle. These results suggest that the NPs-NPR-B-pGC-cGMP signal pathway plays an important role in diabetic gastropathy or gastroparesis.

COMMENTS

Background

A common gastrointestinal complication of diabetes is gastroparesis. However, the pathogenesis is not clear yet. A recent study has indicated that atrial natriuretic peptide (ANP) is secreted from gastric mucosa and plays an inhibitory role in the regulation of gastrointestinal motility, but the effect of the natriuretic peptides (NPs) signal pathway on diabetic gastroparesis has not been reported.

Research frontiers

NPs are distributed all over the body besides the heart, for example, the gastrointestinal tract and enterochromaffin cells in gastrointestinal mucosa secrete NPs. However, the many functions of NPs in the gastrointestinal tract in physiological and pathophysiological conditions need to be explored. In the present study, the possibility as to whether the NPs/cGMP signal pathway is involved in diabetic gastroparesis was investigated in streptozotocin-induced diabetic rats.

Innovations and breakthroughs

Recent reports have highlighted the pathogenesis of diabetic gastroparesis. This is the first study to report that the expression of NP receptor type B in gastric tissue is increased and the sensitivity of gastric smooth muscle to C-type NP (CNP) is significantly enhanced in the diabetic rat. This study suggests that the NPs/cGMP signal pathway may be involved in diabetic gastroparesis.

Applications

By understanding that the NPs/cGMP signal pathway may be involved in diabetic gastroparesis, this study may represent a future strategy for therapeutic or preventive intervention in the treatment of patients with diabetes.

Terminology

Gastroparesis (delayed gastric emptying) is frequent in diabetic patients. Symptoms of diabetic gastropathy can range from mild dyspepsia to recurrent vomiting, abdominal pain and may progress to gastric failure known as gastroparesis. NPRs are natriuretic peptide receptors for ANP, brain natriuretic peptide and CNP.

Peer review

It is an interesting article pointing to a novel mechanism that may explain diabetic changes in gastric function. The results showed are logical, attractive and congruent. In many ways the work is interesting and quite novel and is probably worthy of publication.

Abstract

AIM: To investigate the relationship between ferritin and steatosis in patients with chronically abnormal liver function tests (LFTs) and high ferritin level.

METHODS: One hundred and twenty-four consecutive patients with hyperferritinemia (male > 300 ng/mL, female > 200 ng/mL) were evaluated; clinical, biochemical and serological data, iron status parameters, *HFE* gene mutations and homeostasis model assessment score were obtained. Steatosis was graded by ultrasound as absent or present. Histology was available in 53 patients only.

RESULTS: Mean level of ferritin was 881 ± 77 ng/mL in men and 549 ± 82 ng/mL in women. The diagnosis was chronic hepatitis C in 53 (42.7%), non-alcoholic fatty liver disease/non-alcoholic steatohepatitis in 57 (45.9%), and cryptogenic liver damage in 14 (11.3%). None was diagnosed as hereditary hemochromatosis (HH). Hepatic siderosis on liver biopsy was present in 17 of 54 (32%) patients; grade 1 in eight and grade 2 in nine. Overall, 92 patients (74.2%) had steatosis. By logistic regression, ferritin and γ-glutamyltransferase were independent predictors of steatosis. Ferritin levels were significantly related to low platelet count, steatosis and hepatitis C virus infection.

CONCLUSION: In a non-obese cohort of non-alcoholic patients with chronically abnormal LFTs without HH, high serum ferritin level is a risk factor for steatosis.

Key words: Steatosis; Serum ferritin; Chronic liver disease; Hepatitis C; γ-glutamyltransferase

INTRODUCTION

There may be high serum ferritin levels in systemic inflammatory conditions and in renal, liver and neoplastic diseases[1,2]. Among patients with chronic liver disease, high serum ferritin, besides being a hallmark of hereditary hemochromatosis (HH), is frequently found in chronic hepatitis C, in alcoholic or non-alcoholic steatohepatitis (NASH), and in non-alcoholic fatty liver disease (NAFLD).

A raised ferritin level, with an increased transferrin saturation and liver iron concentration, is a typical presentation of HH, an autosomal recessive disorder linked to *HFE* gene mutations[3], which account for most cases of HH in northern Europe and the USA[4]. Epidemiological studies in Mediterranean populations have shown that C282Y occurs only sporadically, while H63D is found among 13.5% of the general population[5]. In this area, *HFE* polymorphism seems to have a modest diagnostic relevance, since many cases of HH do not display the classic pattern of mutations[5]. It

has been suggested that *HFE* mutations may be involved in cases of liver disease complicated by iron overload and in patients with type 2 diabetes[6].

Patients with chronic hepatitis C virus (HCV) infection often have elevated serum iron indices[7], but these do not reflect accurately hepatic iron content, nor are they able to predict clinically important endpoints, such as progression of fibrosis and responsiveness to interferon-based regimens[8-10]. Studies attempting to link iron and the course of chronic hepatitis C have been inconclusive[11]. In chronic hepatitis C, steatosis is a common histological finding and occurs in 30%-70% of patients[12-13]. The biological mechanism underlying steatosis in HCV infection is not definitively understood and is considered to be multifactorial with metabolic mechanisms, including insulin resistance (IR)[14] and iron overload[8,11,15]. In fact, steatosis in patients infected by HCV genotype 1 is linked to a raised γ-glutamyltransferase (GGT) and to IR as a result of lipid peroxidation in the liver[14]. The high prevalence of diabetes in subjects chronically infected with HCV has been ascribed to an increase in IR mediated by an increase in iron deposits[16,17].

In NAFLD, recent studies[18-20] have reported conflicting data on the role of iron in causing liver damage. George *et al*[21] and Bonkovsky *et al*[22] have shown that patients with NAFLD and iron overload have more severe liver disease, whereas Younossi *et al*[19] and Angulo *et al*[20] did not observe any relationship between iron and clinical or pathological outcomes in patients with NAFLD. Mendler *et al*[23] have reported that patients with NAFLD have no more iron overload than patients with isolated steatosis, and that the *HFE* genotype does not influence liver damage, although unexplained hepatic iron overload is nearly always associated with metabolic abnormalities.

We analyzed in a cross-sectional study a cohort of non-obese, non-alcoholic patients with compensated chronic liver disease characterized by elevated serum ferritin levels, of varying etiology, excluding HH, to reassess the link between hyperferritinemia and other markers of the metabolic syndrome, mainly steatosis.

MATERIALS AND METHODS

Patients

We studied all patients consecutively referred to our Gastroenterology & Hepatology Unit, a tertiary referral center, between January 2001 and January 2004. Patients were included in the study if they had abnormal liver function tests and a high serum ferritin level, and if their clinical workup conclusively excluded a final diagnosis of HH. HH was excluded by measurement of transferrin saturation following an overnight fast, according to American Association for the Study of Liver Diseases practice guidelines[24].

Serum ferritin was considered raised according to the WHO criteria if > 300 ng/mL in men and > 200 ng/mL in women. Patients were excluded if they had a history of alcohol abuse (alcohol consumption > 30 g/d in men and > 20 g/d in women), obesity [body mass index (BMI) $\geqslant$ 30], transferrin saturation > 45%, hepatitis B surface antigen positivity, autoimmune hepatitis, celiac disease, Wilson disease, α-1-antitripsin deficiency, porphyria cutanea tarda, or previous antiviral treatment in patients with chronic HCV infection. Alcohol intake and drug use or abuse was evaluated through the administration of a questionnaire. Concomitant inflammatory diseases potentially capable of causing hyperferritinemia were ruled out on the basis of the absence of clinical signs or abnormal blood test results (erythrocyte sedimentation rate, rheumatoid factor, and C reactive protein).

One hundred and twenty-four consecutive patients fitting the above criteria were selected from about 1800 subjects admitted for evaluation of abnormal LFTs to our unit (2001-2004). Clinical features, biochemical data, HCV and HBV status, histological features and iron status parameters were registered at baseline. All patients were genetically tested for *HFE* gene mutations. IR was determined by the homeostasis model assessment (HOMA) method using the following equation: insulin resistance (HOMA-IR) = fasting insulin (μU/mL) × fasting glucose (mmol/L)/22.5.

All patients had liver ultrasound (US); liver biopsy was performed only when clinically appropriate and in patients who did not refuse. Steatosis on US was assessed as present or absent; when present, it was graded as mild, moderate or severe by two experienced ultrasonographers (always the same throughout the study period), who were unaware of the clinical and laboratory results. The presence of steatosis was determined in a qualitative manner according to standardized criteria[25].

HFE mutation analysis

HFE gene mutations were evaluated by a reverse hybridization assay (Nuclear Laser Diagnostics) that assessed 11 *HFE* gene mutations: V53M, V59M, H63D, H63H, SC65C, C282Y, Q127H, E168Q, E168X, W169X, Q283P on DNA from peripheral blood mononuclear cells. Extracted DNA fragments were amplified by PCR and PCR products were hybridized with allele-specific oligonucleotide probes, and the hybridized probes were read by a colorimetric reaction.

Histological examination

Biopsies were evaluated for grade and stage according to Ishak[26] and, on Perl's Prussian-blue-stained sections, for iron content. Stainable iron was scored as: grade 0, no detectable iron; grade 1, granules of iron visible at 400 × magnification; grade 2, discrete iron granules visible at 100 × magnification; grade 3, iron visible at 25 × magnification, and grade 4, masses of iron visible at 10 × magnification.

Statistics analysis

Continuous variables were summarized as mean ± SD and categorical variables as frequency and percentage. Multiple logistic and linear regression models were used to assess the relationship of steatosis, high ferritin

and chronic liver disease. The dependent variable was steatosis on US, coded as 0 (absent) or 1 (present). As candidate risk factors for steatosis, we selected age, sex, BMI, presence of cirrhosis, baseline alanine aminotransferase (ALT)/aspartate aminotransferase (AST), platelets, GGT, ferritin, serum iron, transferrin, transferrin saturation, glucose, bilirubin, and diabetes. Multiple logistic regression analysis was performed to identify independent predictors of steatosis. Multiple linear regression analysis was performed to identify independent predictors of ferritin levels as a continuous dependent variable. Variables found to be associated with the dependent variables on univariate logistic or linear regression at $P \leq 0.10$ were included in multivariate regression models. Regression analyses were performed using PROC LOGISTIC and PROC REG subroutines (SAS Institute, Inc., Cary, NC, USA)[23].

RESULTS

Features of the patients included in the study are shown in Table 1. The 124 patients (34 women and 90 men) had a mean age of 53.3 ± 1.2 years. The mean value of ferritin was 799 ± 75 ng/mL and that of serum iron was 126 ± 6.3 μg/dL.

Table 2 Univariate analysis of risk factors for absent/present liver steatosis in 124 patients with high serum level ferritin

Variable	Steatosis		*P* value
	Absent (*n* = 32)	Present (*n* = 92)	
Age (yr)	50.9 ± 3.1	54.2 ± 1.3	0.06
Sex	18 (56.2)	72 (78.2)	0.14
BMI (kg/m^2)	24.4 ± 3.2	25.2 ± 3.1	0.30

GGT	93.1 ± 20.7	174.1 ± 19.7	0.03
Anti-HCV positivity	24 (75)	28 (30.4)	0.02
Ferritin (ng/mL)	464 ± 183	1060.8 ± 79	0.0006
Serum Iron (μg/dL)	96.3 ± 7.5	137 ± 7.7	0.8
Platelet count × 10^3/cmm	217.8 ± 16.1	176.9 ± 8.26	0.24
HOMA	3.0 ± 2.25	3.5 ± 2.8	0.23
HFE mutations	14 (43.7)	40 (43.4)	0.63
Diabetes	11 (34.3)	11 (12)	0.2

HCV infection was detected in 53 patients (42.7%), 35 of whom (28.2%) had NAFLD without overt diabetes, 11 (8.8%) had NAFLD associated with diabetes, and 11 had NASH at histology. Finally, 14 patients (11.3%) were classified as having cryptogenic chronic hepatitis.

Overall, 92 patients (74.2%) had steatosis on US: 46 moderate and 46 severe. The etiological pattern of the patients with steatosis was as follows: 35 (38%) subjects were infected with HCV, 35 (38%) had NAFLD, 11 (12%) were diabetic with NAFLD, and 11 (12%) had a diagnosis of NASH at histology.

HCV infection was detected in 53 patients (42.7%). All these were infected by HCV genotype 1b; 36 (68%) had steatosis, nine were detected by US and 27 by liver biopsy.

At liver biopsy, performed in 54 patients out of 124 (43.5%), 27 (50%) had chronic hepatitis C and nine (16.6%) had micronodular cryptogenic cirrhosis. Seven patients (12.9%) had NAFLD (macrovesicular steatosis) and 11 (20.3%), NASH (macrovesicular steatosis and lobular inflammation). Seventeen patients (31.5%) had siderosis: eight, grade 1 and nine, grade 2.

Among the 11 *HFE* gene mutations analyzed, only two (H63D and C282Y) were present in our population, while the remaining nine mutations were not found in any patient. H63D and C282Y mutations were distributed as follows: 53 patients tested (42.7%) carried at least one *HFE* gene mutation. These were distributed as follows: 49 (39.5%) patients were H63D heterozygous, two (1.6%) were C282Y heterozygous, and two (1.6%) were C282Y/H63D, compound heterozygous. None were ultimately diagnosed with HH on clinical and laboratory criteria.

Univariate and multivariate analyses were performed to identify predictors of steatosis. By univariate analysis age ($P = 0.06$), ferritin ($P = 0.0006$), GGT ($P = 0.03$) and anti-HCV positivity ($P = 0.02$) were associated with steatosis ($P < 0.10$) (Table 2). By multivariate analysis, ferritin (OR: 1.002; 95% CI: 1.001-1.004), and GGT (OR: 1.007; 95% CI: 1.001-1.013) were the only independent predictors of steatosis (Table 3). The baseline ferritin

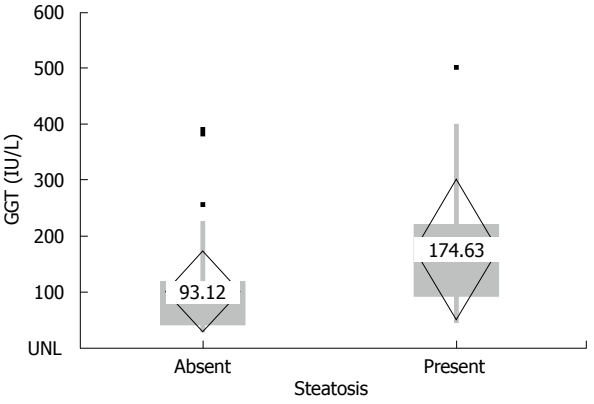

Figure 1 Baseline GGT levels according to steatosis in 124 non-obese, non-alcoholic patients without hereditary haemochromatosis (HH).

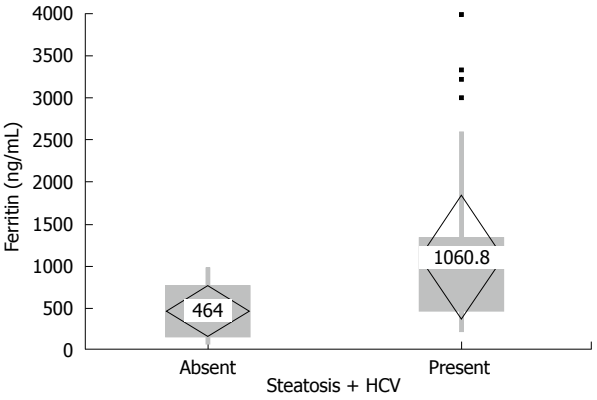

Figure 2 Baseline ferritin levels according to steatosis and HCV infection status in 124 non-obese, non-alcoholic patients without hereditary haemochromatosis (HH).

and GGT levels in patients with or without steatosis are shown in Figures 1 and 2.

To identify predictors of ferritin levels, univariate and multivariate linear regression analyses were performed. Univariate analysis showed that male sex, anti-HCV positivity, platelet count, AST, ALT, GGT level and steatosis were significantly associated with ferritin levels. The model for the independent predictors of ferritin levels as a continuous variable by multiple linear regression analysis (Table 4) included anti-HCV positivity (P = 0.0028), platelet count (P = 0.0161) and steatosis (P < 0.0001). Figure 2 outlines baseline ferritin levels according to HCV infection status.

DISCUSSION

Hyperferritinemia is frequent in patients with chronic liver disease, whatever the etiology of the underlying damage. In this cohort of 124 non-obese, non-alcoholic patients with high serum ferritin levels, without HH, the cause of liver disease was chronic HCV infection in 42.7%, NAFLD/NASH in 45.9%, and untraceable in 11%. Steatosis on US was predicted independently by ferritin and GGT levels. High ferritin levels were associated with HCV infection and with more advanced liver disease, shown by low platelet counts.

In our study, no patients could be finally diagnosed with HH, although at least one of the characterized *HFE* gene mutations (C282Y and/or H63D, mostly the latter) was found in 50% of our patients in an heterozygote state. In fact, none of these carriers of *HFE* mutations had a transferrin saturation > 45%, liver siderosis beyond grade 1, or evidence of any other organ damage attributable to iron overload. It is noteworthy that an excess H63D allele frequency observed in our patients, as compared to the 12%-19% range observed in the normal population in our area[5,28], suggests that heterozygosity for this mutated allele may increase the appearance of high ferritin levels, once predisposing factors such as IR, steatosis and cirrhosis are operating.

Chronic hepatitis C, with or without cirrhosis, often presents with abnormal iron indices[29,30], particularly

with raised levels of ferritin, which does not necessarily represents iron overload. Several mechanisms have been hypothesized to explain the altered iron indices and possible liver siderosis, including an excess of oxygen free radicals, increased fibrogenesis through activation of stellate cells and impairment of the host immune response[31-34]. Among our 29 patients with chronic liver disease caused by HCV genotype 1b, in whom liver biopsy was performed, only 17 had siderosis (eight mild, nine moderate, none severe). Theoretically, serum ferritin could be elevated as an acute phase reaction linked to the necroinflammatory process of chronic hepatitis C, but the moderate increase in ALT and the degree of activity typically observed in these patients negates this interpretation, even if in our analysis chronic HCV infection was independently linked to higher ferritin levels at multivariate analysis. It is however difficult to disentangle the role of HCV from that of steatosis, which is commonly associated with raised levels of ferritin[35,36], and is a common finding in HCV infection[37], even when caused by HCV genotype 1[14]. In our study, HCV-infected patients also showed a moderate degree of steatosis. NAFLD is known to be by itself strongly associated with the metabolic syndrome, which may explain the strong relationship between HCV infection and diabetes. The association between IR and moderate/severe steatosis in chronic hepatitis C is well supported[36-38]. In fact, IR could lead to the development of steatosis of the liver in HCV-infected patients[14], which makes them prone to the onset of diabetes.

In NAFLD, lipid peroxidation promotes transition from steatosis to steatohepatitis, which involves multiple cellular adaptations and evokes biomarkers of the oxidative stress that occurs when fatty acid metabolism is altered. The induction of heme-oxygenase 1 is an adaptive response against oxidative damage elicited by lipid peroxidation, and may be critical in the progression of the disease[39]. The association we found between ferritin and moderate/severe steatosis supports the concept that serum ferritin is a risk factor for fatty liver. Further support for this hypothesis is lent by the data of Zelber-Sagi *et al*[40] who demonstrated that NAFLD is the major determinant of increased serum ferritin levels at a population-based level. Moreover, they have shown that the association between serum ferritin and insulin is much more evident in the NAFLD group. Although recent studies have suggested that serum ferritin is a marker of IR[42-44], we could not provide evidence for a direct correlation between IR and elevated levels of serum ferritin. Consonant with Zelber-Sagi *et al*[40], we believe that the association found in previous studies between ferritin and IR may depend upon undiagnosed NAFLD.

Data from the third National Health and Nutrition Examination Survey (1988-1994) show a significant association between elevated serum ferritin and newly diagnosed diabetes mellitus[16]. We found that 17.7% of our patients had type 2 diabetes. In our study, however, ferritin levels were not significantly associated with IR, as evaluated by HOMA score, as well as by the presence of overt diabetes, probably as a result of the relatively small size of this sample, in which younger patients under evaluation for chronic hepatitis C predominated. Although a recent study has suggested that diabetes is the main factor accounting for the high ferritin level detected in chronic HCV infection[45], we could not provide evidence for a direct correlation between IR and hyperferritinemia.

An important finding of this work is the association we found between raised ferritin and reduction in platelet counts, a known marker of portal hypertension[46]. We confirmed the observation by Bugianesi *et al*[36] who demonstrated that serum ferritin, but not iron stores, was a significant predictor of severe fibrosis in patients with NAFLD. All these data provide further evidence that hyperferritinemia might be another surrogate marker of advanced liver disease of any etiology.

According to recent reports, GGT is an independent predictor of liver steatosis[14]. Our data indicate that patients with elevated GGT levels have the greatest likelihood of having moderate/severe steatosis. The administration of a questionnaire regarding alcohol intake and drug use or abuse makes us confident in excluding any role of these potential confounders on GGT levels. Lack of data on smoking, however, could affect the accuracy of the results[47]. The association between GGT levels and steatosis is likely the result of the association between regional body fat distribution and fatty liver, irrespective of total body fat quantity, which is consistent with the assumption that GGT is a surrogate marker of central fat accumulation. Therefore, the GGT level may be a simple and reliable marker of visceral and hepatic fat and, by inference, of hepatic IR. Thus, patients with elevated serum ferritin and GGT levels are at risk of developing liver steatosis[48]. Modelling the indication for US scanning on these predictors would maximize its cost effectiveness.

The main limitation of the current study, as well as of other cross-sectional studies, is that it is unable to distinguish the temporality of the associations between hyperferritinemia, steatosis and chronic hepatitis C. Lack of histological data in a proportion of subjects, particularly on intra-hepatic iron deposition, could also affect the interpretation of our findings. We are aware that the use of a more sensitive imaging technique such as magnetic resonance imaging could improve the rate of steatosis detection. In addition, we cannot exclude the possibility that denied alcohol abuse may be responsible for the observed prevalence of steatosis. A further methodological issue arises in the potential limitation of the generalizability of our results to new populations and settings. Our study included a Mediterranean cohort of non-obese patients without HH, which limits the broad application of the results.

In conclusion, this study shows that in a non-obese cohort of non alcoholic patients, steatosis and chronic HCV infection are the main causes of hyperferritinemia. In Southern European populations, the finding of high

ferritin levels, after the exclusion of diagnosis of HH, represents a risk factor for steatosis and has clinical relevance, being associated with low platelet count.

COMMENTS

Background

Patients with chronic hepatitis C virus (HCV) infection often have elevated serum iron indices, but these do not accurately reflect hepatic iron content, nor are they able to predict clinically important endpoints, such as progression of fibrosis and responsiveness to interferon-based regimens.

Research frontiers

In this study, the authors showed that, in a non-obese cohort of non-alcoholic patients, steatosis and chronic HCV infection are the main causes of hyperferritinemia. In southern European populations, high ferritin levels, after exclusion of a diagnosis of hereditary hemchromatosis (HH), represent a risk factor for steatosis and have clinical relevance, being associated with low platelet count.

Innovations and breakthroughs

In a non-obese cohort of non-alcoholic patients with chronically abnormal liver function tests, without HH, serum ferritin high level is, therefore, a risk factor for steatosis.

Applications

Hyperferritinemia can be used as markers of steatosis in non-obese and non-alcoholic patients.

Peer review

The authors study the underlying liver disease in a cohort of individuals selected because they had both chronic liver disease as well as elevated serum ferritin levels. They found that most individuals had either chronic HCV or fatty liver disease. Additional analysis of clinicopathological data showed an association between ferritin and steatosis and GGT and steatosis. Overall the paper is well written.

Abstract

AIM: To establish a rabbit rectal VX2 carcinoma model for the study of rectal carcinoma.

METHODS: A suspension of VX2 cells was injected into the rectum wall under the guidance of X-ray fluoroscopy. Computed tomography (CT) and magnetic resonance imaging (MRI) were used to observe tumor growth and metastasis at different phases. Pathological changes and spontaneous survival time of the rabbits were recorded.

RESULTS: Two weeks after VX2 cell implantation, the tumor diameter ranged 4.1-5.8 mm and the success implantation rate was 81.8%. CT scanning showed low-density foci of the tumor in the rectum wall, while enhanced CT scanning demonstrated asymmetrical intensification in tumor foci. MRI scanning showed a low signal of the tumor on T_1-weighted imaging and a high signal of the tumor on T_2-weighted imaging. Both types of signals were intensified with enhanced MRI. Metastases to the liver and lung could be observed 6 wk after VX2 cell implantation, and a large area of necrosis appeared in the primary tumor. The spontaneous survival time of rabbits with cachexia and multiple organ failure was about 7 wk after VX2 cell implantation.

CONCLUSION: The rabbit rectal VX2 carcinoma model we established has a high stability, and can be used in the study of rectal carcinoma.

Key words: Rectal carcinoma; Animal model; Rabbit; VX2; Computed tomography; Magnetic resonance imaging

INTRODUCTION

Rectal carcinoma is a common malignant tumor of the gastrointestinal tract. Imaging examination plays an important role in its identification, diagnosis, preoperative staging, treatment decision, and postoperative assessment[1-3]. Currently, experimental animal models of rectal carcinoma are often induced by chemical carcinogens[4-6]. This kind of methods requires lots of time and individual variations can be very large. In this study, a rabbit rectal carcinoma model was established and evaluated, which can be monitored dynamically by computed tomography (CT) and magnetic resonance imaging (MRI) and used in diagnosing and staging rectal carcinoma.

MATERIALS AND METHODS

Experimental animals

Twenty-two (4-5 mo old) New Zealand white rabbits, weighing 2.4-2.9 kg, were used in this study, and the breeding rabbits were donated by Professor Bin Hu,

Department of Ultrasound, Sixth People's Hospital of Shanghai Jiaotong University, China.

Preparation for surgery

Experimental rabbits were lavaged 24 h prior to surgery. Mannitol (20%) was prepared with warm water at a ratio of 1:1 and the lavage dose was approximately 250 mL per rabbit. Lavaged rabbits were fasted with free access to water prior to surgery. VX2 tumor cells were grown in the hind leg muscle of rabbits and harvested for the preparation of suspended tumor cells at a concentration of 1-2 × 10^7/mL.

Establishment of rectal carcinoma model

Experimental rabbits were anesthetized with 30 mg/kg pentobarbital sodium *via* the ear vein. Rabbits were placed at a dorsal position with their legs fixed. A 7-cm long sterilized plastic hollow pipe, 7 mm in diameter, was inserted into the anus to brace the rectal cavity. A 22G transfixion pin was injected into approximately 4-5 cm of the rectal wall around the anus. A contrast medium (0.2 mL, Ultravist 300) was injected with its distribution monitored by X-ray fluoroscopy. If its border was ill-defined and dispersed, the needle point would be in a gap region between the outside of the organ and the rectal wall. Then, the puncture needle was reinserted into the rectal wall until the border of contrast medium became sharply margined. At this point, 0.2 mL of suspended VX2 cells was injected, then 0.1-0.2 mL of normal sodium was injected to fully rinse all the VX2 cells into the rectal wall. After 5 min, the needle was withdrawn slowly. The rabbits were allowed to have normal food following recovery from anesthesia.

CT and MRI scanning of tissue sections

Rabbits were anesthetized with 30 mg/kg pentobarbital sodium before CT and MRI scanning of tissue sections at 2-, 3-, 4-, 5- and 6-wk intervals after VX2 cell implantation. CT scanning was performed using a GE LIGHT SPEED VCT 64 CT set with the following parameters: 80 kV, 100 mA, 14-16 cm in field of view (FOV), 512*512 matrix, 1.25 mm section thickness, and 1.25 mm section interval. A contrast medium (Ultravist 300) was injected at 0.5 mL/s and 1.5-2.0 mL/kg. Arterial phase scanning was started 15 s after contrast medium injection and after 30 s during the portal venous phase. The image was processed at the ADW4.0 workstation. MRI scanning was performed by a Philips Achieva 3.0 imager, with the rabbit placed at a supine position in a phased-array articular genu coil. MRI sequences included the pre-contrast T_1W-TSE, gadolinium-enhanced T_1W-TSE, and T_2W-TSE sequences in the axial plane (TR-2727 ms, TE-100 ms, 2.0 mm section thickness 2.0 mm, and section interval 0.8 mm), T_2_TSE_SPAIR sequence in the axial plane (TR-4341 ms, TE-62 ms, section thickness 2.0 mm, and section interval 0.2 mm), and PD_SPAIR sequence in the coronal planes (TR-4710 ms, TE-30 ms, section thickness 2.0 mm, and 0.2 mm section interval 0.2 mm). The contrast medium (Magnevist) was injected at 0.5 mL/s and 1.5-2.0 mL/kg. Enhancement scanning was started 20 s after contrast medium injection, and the image was processed at a View Forum R5.1 V1L1 workstation.

Measurement of tumor volume

Gross tumor volume (V) was measured following the equation: $V = 0.5 (a \times b^2)$, where a represents the maximum tumor diameter, and b represents the minimum tumor diameter. Tumor growth rate (TGR) was calculated following the equation: $TGR = (V_2 - V_1)/V_1 \times 100\%$, where V_1 represents the gross tumor volume measured at an earlier time point and V_2 represents the gross tumor volume measured at a later time point.

Histopathological changes in rabbit rectal VX2 carcinoma model

Three rabbits were sacrificed after each CT and MRI scanning at 2-6 wk intervals after VX2 cell implantation for observation of pathological changes in the rectal VX2 carcinoma model. Autopsies were also performed after spontaneous death of the rabbits. Tumor location, size, activity, circumscription, and metastasis were observed grossly. The rectum-implanted tumor and the major organs involved were fixed in formalin and embedded in paraffin. Tumor tissue was cut into sections, which were stained with hematoxylin-eosin (H&E), and evaluated under a light microscope.

Statistical analysis

Data were presented as mean ± SD. Gross tumor volumes at an earlier and later time point were compared by Student's *t* test. Statistical analyses were performed using SPSS 11.0 software. $P < 0.05$ was considered statistically significant.

RESULTS

Twenty-two New Zealand white rabbits were used to establish the model. Eighteen of them developed primary tumors with a success rate of 81.8%.

CT detection

Tumor implanted in the rectal wall of each rabbit could be detected by CT scanning 2 wk after VX2 cell implantation. The appearance of rectal enteric cavity at this time point was still normal without obvious stricture. However, part of the rectal wall exhibited irregularly intensified armillary after enhancement (Figure 1A). The gross tumor volume was increased 3 wk after VX2 cell implantation, and appeared as a small lump with low density or isodensity on CT images. The boundary between the tumor and normal rectal wall could not be clearly distinguished. However, the rectal enteric cavity became elliptical with stricture, allowing the tumor margin to be distinguished from its surrounding tissue (Figure 1B). After 4 wk, the gross tumor volume was increased, the rectal wall was thickened, and the rectal enteric cavity became flatter, with increased stricture.

Table 1 Gross tumor volume and TGR after tumor implantation

Time after implantation	a (mm)	b (mm)	V (mm^3)	TGR (%)
2 wk	5.029 ± 0.544	4.129 ± 0.475	46.180 ± 14.583	-
3 wk	16.783 ± 1.387	9.942 ± 1.326	848.239 ± 270.715	1736.8
4 wk	19.419 ± 1.150	15.800 ± 1.255	2443.569 ± 480.966	185.7
5 wk	24.763 ± 1.762	22.163 ± 1.388	6163.157 ± 1181.274	159.3

Tumor volume (V) = 0.5 ($a \times b^2$), where a and b represent the maximum and minimum tumor diameters, respectively; TGR = (V_2 - V_1)/V_1 × 100%, where V_1 represents the gross tumor volume measured at an earlier time point and V_2 represents the gross tumor volume measured at a later time point.

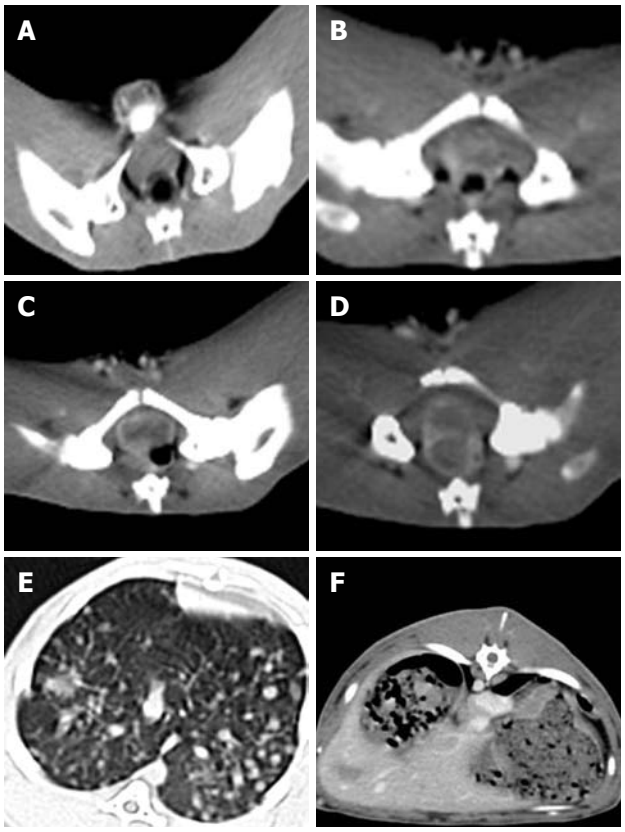

Figure 1 CT enhancement scanning images of rectal wall 2(A), 3(B), 4(C), and 5(D) wk after VX2 cell implantation in the experimental rabbits, and images of metastatic nodes detected in the lung (E) and liver (F), respectively.

Necrosis could be detected in the middle of the tumor, and the surrounding tissue was involved at different degrees. CT scanning showed that the tumor appeared to have an intensified, solid marginal zone and a central region with low density but without intensification. In contrast, the surrounding tissue was intensified as the tumor (Figure 1C). CT scanning revealed significant stricture of the tumor, which was fixed to the pelvic wall and rectal enteric cavity 5 wk after VX2 cell implantation (Figure 1D). After 6 wk, the rectal enteric cavity was almost compressed to the point of closure and metastatic nodes were detected in the lung (Figure 1E) and liver (Figure 1F), as in the seroperitoneum. The metastatic nodes appeared in the lung earlier and much more obviously than in the liver, since the blood supply in the lower part of rectum returns to the inferior vena cava but not to the hepatic portal vein.

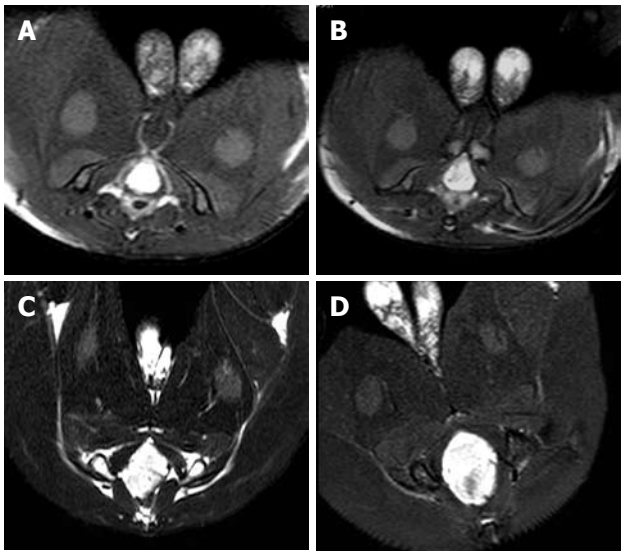

Figure 2 MRI of T2-TSE-SPAIR 2(A), 3(B), 4(C), and 5(D) wk after VX2 cell implantation in the experimental rabbits.

MRI detection

MRI showed that the signal of VX2 tumor was low on T_1-weighted imaging (T_1WI), resulting in the detection of an indistinct boundary, and high on T_2-weighted imaging (T_2WI), allowing clear visualization of the boundary. In addition, the signal of VX2 tumor in PD sequence was higher than that on T_1WI. Tumor boundary could be distinguished from its surrounding tissue after enhancement. Necrosis with low signals, but without intensification after enhancement, could be detected in the middle of the primary tumor 4 wk after VX2 cell implantation. MRI and CT demonstrated similar growth and metastasis of the tumor. However, MRI identified more precisely the tumor boundary, size and infiltration, and infection foci than CT scanning. MRI of the tumor at 2-, 3-, 4-, and 5-wk intervals after VX2 cell implantation are shown in Figure 2. The gross tumor volume (V) and the TGR at these time points were also calculated (Table 1). The TGR at each time point was quite different ($P < 0.0001$), but the fastest growth of tumor was observed 3 wk after VX2 cell implantation.

Histopathological changes

Macroscopic image of the resected tumor appeared as a single node with an obscure boundary and affluent vascellum (Figure 3A and B). Metastasis

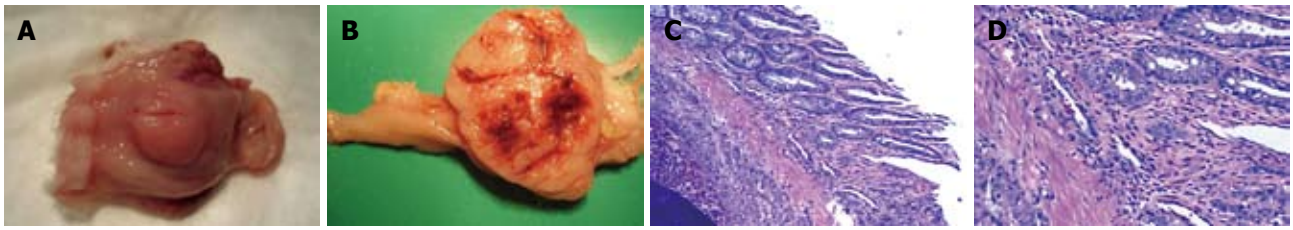

Figure 3 Characteristics of isolated rectal carcinoma specimens (A, B) and light microscope images of HE stained tissue sections (C, × 40; D, × 100).

outside the rectal wall was not detected until 4 wk after VX2 cell implantation. The rectal wall was thickened due to different degrees of enteric cavity stricture. No enterectasis or rectum obstruction was observed. Necrosis appeared in the middle of the tumor 4 wk after VX2 cell implantation, with enteric cavity stricture and enterectasis, as well as metastasis outside the rectal wall in the pelvic cavity. Metastases to the lung and liver, and seroperitoneum and rectum obstruction were detected 6 wk after VX2 cell implantation. However, the metastasis in the liver was not as obvious as that in the lung, and sometimes it was not detectable, because the metastasis in the liver was not sufficiently large to be visualized. The experimental rabbits developed cachexia and multiple organ failure, and died spontaneously about 7 wk after VX2 cell implantation.

Tumor tissue sections were stained with H&E and evaluated under a light microscope. Infiltrating tumor cells were visible and the interstitial tissue boundary was not distinct. Minimal connective tissue was observed, and dispersed tumor cells were found with separation of fibers. Fresh capillaries were abundant (Figure 3C), consistent with the large, irregular tumor volume. Cytoplasm of the tumor cells was abundant, and pale red in color. There was an abnormal number of mitotic nuclei. Hypertrophic nuclei were also found, varying in shape, size, and color (Figure 3D). Two weeks after VX2 cell implantation, the tumor grew in the rectal wall with no involvement of its peripheral tissue. However, by 3 wk after VX2 cell implantation, the tumor grew through the rectal wall with the mesorectal fascia tissue involved 4 wk after VX2 cell implantation.

DISCUSSION

Since lymph in the gastrointestinal tract is very rich, the survival rate of heterogeneic tumor tissue transplanted to the intestine wall of experimental animals is practically zero. Because of this, smaller animal models are often used in the study of rectal carcinoma. Experimental animal models can be established by repeated injection of chemical carcinogens into the abdominal cavity of animals, or repeated lavaging of the intestinal tract. However, these methods are time consuming and their success rate is low. Furthermore, these small animal models cannot contribute to the diagnosis of rectal carcinoma.

VX2 cells can be implanted into rabbits where they can grow. It has been shown that this cell line, implanted into the muscle, kidney, liver, lung, pleura, ossature, and mammary gland of rabbits, can produce an *in situ* tumor model that mimics the human condition[7-12]. The implantation techniques for VX2 cells include implanting a small lump of VX2 tumor tissue and injecting a suspension of VX2 cells directly or under the guidance of B-mode ultrasound or CT. Wang *et al*[13] demonstrated that laparotomy could be used to establish a rabbit model of rectal VX2 carcinoma, with a success rate of 60%. Considering the substantial damage caused by laparotomy, we established the rabbit model of rectal VX2 carcinoma by injecting a suspension of VX2 cells into the rectal wall through the skin of the anorectum under the guidance of X-ray fluoroscopy. CT or MRI showed the implanted tumor in the rectal wall 2 wk after VX2 cell implantation. The involved tissue around the rectum was observed and metastases to the lung and liver were detectable 4 and 6 wk, respectively, after VX2 cell implantation. The success rate of this method was 81.8%.

This rabbit rectal VX2 carcinoma model was evaluated by CT scanning, MRI, and histopathology.

CT has many advantages in monitoring rectal tumor by displaying its location, size, shape, peripheral tissue and lymph node involvement[14,15]. Recently, with the update of CT instruments and CT imaging techniques, the sensitivity and specificity of CT in detection of tumors have been greatly improved. Multi-section CT (MSCT) is more advantageous than ordinary CT, by reducing the shadow of motion and displaying dynamic enhancement effects[16-18]. Furthermore, CT plays an important role in preoperative staging of rectal carcinoma, especially in detecting metastasis in the lung and liver[19]. CT scanning has been recommended to patients with colorectal cancer[20-22]. In this study, MSCT showed the growth of tumor and its surrounding tissue, as well as distant organ metastasis, suggesting that CT scanning is an ideal method for monitoring VX2 rectal carcinoma.

Since the location of the rectum is relatively fixed, tumor tissue can be observed by contrast with the peripheral fat, and is seldom affected by the shadows that result from respiration. MRI is a good imaging technique for detection of rectal tumor and can show the layers of the rectal wall, including the mucosa with a low-intensity signal, submucosa with a high-intensity signal, muscularis propria with a weak-intensity signal, perirectal fat with a high-intensity signal, and mesorectal fascia with a low-intensity signal. T_1WI can be used to evaluate fatty infiltration around the rectum, while T_2WI can display the infiltration depth in the rectal wall

and the relation between inherent muscle layers and mesorectal fascia. The most significant advantage of MRI in rectal carcinoma staging is its ability to describe the correlation between tumor and mesorectal fascia[23-25]. MRI can determine the circumferential resection margin (CRM)[26]. Induction of 3.0T magnetic resonance and improvement in phased-array coils make MRI display the CRM much more precisely[27,28]. Its accuracy for the prediction of CRM is consistent with histopathological assessment of specimens after surgery[29-32]. It has also been reported that MRI can predict the infiltration depth of rectal tumor in the range of 0.5 mm[33], which is consistent with histopathology results. MRI is more sensitive in detecting early stage tumor growth than CT, especially in measuring the tumor size. In addition, MRI can display metastasis of tumor to lymph nodes.

This animal model is easy to establish, reproducible, and induces minimal damage to experimental animals. In addition, the tumor growth time is short. The growth and metastasis of rectal VX2 carcinoma in rabbits are similar to those in humans. Therefore, it can be used in the study of rectal carcinoma.

COMMENTS

Background

Currently, experimental animal models of rectal carcinoma are often induced by chemical carcinogens, which is time consuming. It has been shown that implantation of VX2 cells into the muscle, kidney, liver, lung, pleural, ossature, and mammary gland of rabbits can produce an *in situ* tumor model that mimics the human condition.

Research frontiers

The implantation techniques for VX2 cells include implanting a small lump of VX2 tumor tissue and injecting a suspension of VX2 cells directly, or under the guidance of B-mode ultrasound and computed tomography.

Innovations and breakthroughs

It is feasible to establish a rabbit rectal VX2 carcinoma model by injecting a suspension of VX2 cells into the rectum wall under the guidance of X-ray fluoroscopy. This model is similar to human rectal carcinoma models in terms of tumor pathology, development, and metastasis.

Applications

This rabbit rectal VX2 carcinoma model can be used in examination, staging and diagnosis of rectal carcinoma.

Terminology

VX2 cell strain, a squamous carcinoma strain induced by Shope virus, can be implanted in rabbits.

Peer review

The animal model presents many analogies to human rectal carcinoma in terms of pathological findings and tumor development.

Abstract

AIM: To explore the relation between B-cell-specific Moloney murine leukemia virus insertion site 1 (Bmi-1) expression and the clinicopathological features of gastric carcinoma (GC).

METHODS: Immunohistochemistry was used to detect the expression of Bmi-1 and ki-67. Double-labeling staining was used to display the distribution of Bcl-2$^+$/ki-67$^-$ cells in 162 cases of GC and its matched normal mucosa and precancerous lesion.

RESULTS: The positive rate of Bmi-1 expression in GC (52.5%) was significantly higher than that in normal gastric mucosa (21.6%, χ^2 = 33.088, P < 0.05). The Bmi-1 expression in GC was closely related with the Lauren's and Borrmann's classification and clinical stage (χ^2 = 4.400, 6.122 and 11.190, respectively, P < 0.05). The expression of ki-67 was related to the Borrmann's classification (χ^2 = 13.380, P < 0.05). Bcl-2 expression was correlated with the Lauren's classification (χ^2 = 4.725, P < 0.05), and the Bmi-1 expression both in GC (r_k = 0.157, P < 0.05) and in intestinal metaplasia (r_k = 0.270, P < 0.05).

CONCLUSION: Abnormal Bmi-1 expression in GC may be involved in cell proliferation, apoptosis and cancerization. This marker can objectively indicate the clinicopathological characteristics of GC.

INTRODUCTION

B-cell-specific Moloney murine leukemia virus insertion site 1 (Bmi-1) is a transcriptional repressor belonging to the polycomb group gene family[1], which is a potent negative regulator of the Ink4a/Arf locus. Bmi-1 regulates cell proliferation and apoptosis and is over-expressed in several human tumors[2,3]. Reinisch *et al*[4] reported that Bmi-1 protein is expressed in stem cells, specialized cells and tumors of the gastrointestinal tract. In the present study, the expressions of Bmi-1, ki-67 and Bcl-2 were detected immunohistochemically. The distribution of Bcl-2$^+$/ki-67$^-$ cells was observed in gastric carcinoma (GC) and its matched normal mucosa as well as precancerous lesion. The relation between Bmi-1 expression and clinicopathological features of GC was explored.

MATERIALS AND METHODS

Clinicopathological data

Specimens were collected from 162 cases of GC with its matched normal gastric mucosa, 82 cases of intestinal metaplasia (IM), and 52 cases of dysplasia from the First Affiliated Hospital of China Medical University during August 2006-May 2008. The age of the patients was 30-80 years. According to the WHO's histological classification of gastric cancer, the 162 cases of GC were classified as four of papillary adenocarcinoma, 12 of well-differentiated adenocarcinoma, 50 of moderately differentiated adenocarcinoma, 75 of poorly differentiated adenocarcinoma, 10 of mucinous adenocarcinoma, nine of signet ring cell carcinomas and two of undifferentiated adenocarcinoma. Samples were fixed in 10% formalin, embedded in paraffin, cut into 4-μm thick sections and constructed in four blocks for tissue microarray. All the samples were evaluated by two experienced pathologists for diagnosis.

Immunohistochemistry

Expression of Bmi-1 and ki-67 in the specimens was detected using the PV-9000 kit (Beijing Zhongshan Goldenbridge Biotechnology Company) following its manufacturer's instructions. The working anti-human rabbit Bmi-1 polyclonal antibody (Abcam, USA) was diluted at 1:80. Anti-human mouse monoclonal antibodies ki-67 and Bcl-2 (ready to use) and double-labeling staining kit were purchased from Fuzhou Maixin Company (China). Immunohistochemical double-labeling staining was used to display the distribution of Bcl-2^+/ki-67^- cells. Antigens were retrieved after they were placed in a pressure cooker at a full pressure for 160 s in citrate buffer (pH 6.0). All procedures were implemented according to their manufacturer's instructions, respectively. For negative controls, sections were processed as above but treated with 0.01 mol/L phosphate-buffered saline instead of primary antibodies.

Two hundred cells from two selected representative fields of each section were counted by two independent observers for the determination of their immunostaining intensity. Staining intensity was classified as 0 (negative), 1 (weak), 2 (moderate), and 3 (strong). Half of the positive cells were quantified as a percentage of the total number of the same kind of cells counted in two high-power fields (× 400), and defined as 0: < 5%, 1: 5%-25%, 2: 26%-50%, 3: 51%-75% and 4: > 75%. Immunostaining intensity was divided into 0: negative (-), 1-4: weakly positive (+), 5-8: moderately positive (++), and 9-12: strongly positive (+++). A 5-bromo-4-chloro-3-indolyl-phosphate/nitro-blue tetrazolium (BCIP/NBT) and 3-amino-9-ethylcarbozole (AEC) double staining system was used to display Bcl-2^+/ki-67^- cells. Red fine granules in cytoplasm with unstained nuclei in the same cells were defined as Bcl-2^+/ki-67^- cells. Photoes were taken with a digital camera (Olympus AX70, Japan).

Table 1 Expression of Bmi-1 in normal gastric mucosa, GC and precancerous lesion

Disease features	Cases (*n*)	Positive Bmi-1 expression rate			χ^2	*P*

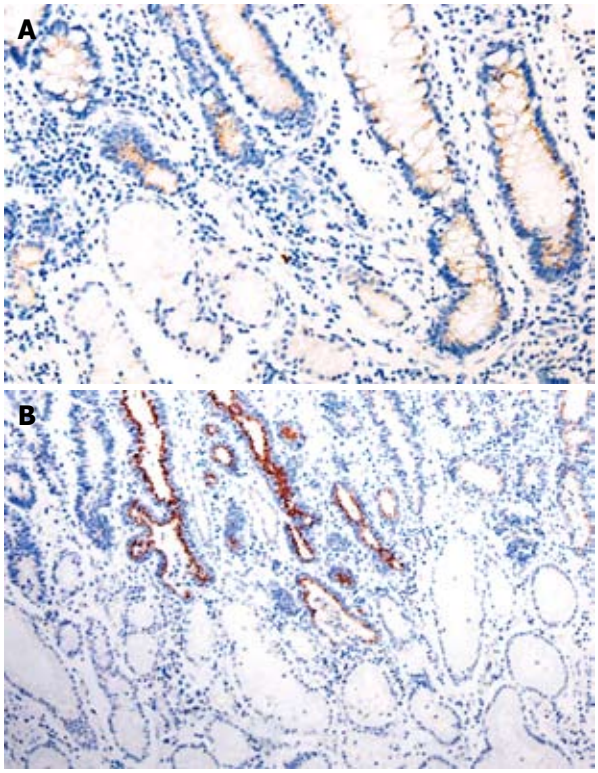

Figure 1 Expression of Bmi-1 in IM (A, × 200) and GC (B, × 100) (PV-9000).

Statistical analysis

Statistical analysis was performed using SPSS 11.5. χ^2 test was used to differentiate the rates of different groups and Kendall's tau-b rank correlation. $P < 0.05$ was considered statistically significant.

RESULTS

Bmi-1 expression in normal gastric mucosa, GC and precancerous lesion, and its relation with GC

The positive rate of Bmi-1 expression was 52.5%, 79.3%, and 80.8%, respectively, in GC, IM, and dysplasia (DYS), which was significantly higher than that (21.6%) in normal gastric mucosa (χ^2 = 33.088, 74.844, 59.819, respectively, $P < 0.05$). The immunoreactivity to Bmi-1 protein was located in the cytoplasm (Table 1, Figure 1).

The expression of Bmi-1 was related to the Lauren's and Borrmann's classification and clinical tumor stage

Expression of ki-67 and distribution of Bcl-2$^+$/ki-67 cells in normal gastric mucosa, GC and precancerous lesion

The immunoreactivity to Bcl-2 and ki-67 was located both in the cytoplasm (red fine granules) and in nuclei (dark blue fine granules), respectively. Most Bcl-2$^+$/ki-67$^-$ cells were distributed in the proliferating zone of gastric mucosa. The expression of ki-67 and Bcl-2 was correlated to the Borrmann's and Lauren's classification (χ^2 = 13.380 and 5.552, $P < 0.05$, Table 3).

Relation between expressions of Bmi-1, ki-67 and Bcl-2 in GC and IM

A positive relation was observed between Bmi-1 and Bcl-2 expressions in GC (r_s = 0.157, P = 0.043) and IM (r_s = 0.270, P = 0.038) (Figures 2 and 3, Table 4).

DISCUSSION

The Bmi-1 proto-oncogene is a transcriptional repressor, which can be discovered by retroviral insertion mutagenesis when transgenic mice are infected with Moloney murine leukemia virus[1]. It has been shown that Bmi-1 plays an important role in sustaining self-renewal of cell activity by repressing the *INK4A* locus that encodes $p16^{INK4A}$ and $p19^{ARF}$ in humans[5]. $P16^{INK4A}$ and $p19^{ARF}$ are capable of inducing growth arrest, cellular senescence and apoptosis. Several studies suggested that the pro-survival and pro-proliferation actions of Bmi-1 may be related to its ability to suppress the expression of proteins that regulate cell cycle progression. For example, in some cell types, when Bmi-1 is absent, the levels of $p16^{INK4A}$ and $p19^{ARF}$ increase[6]. Our study showed that the expression rate of Bmi-1 was 52.5%, 79.3%, and 80.8%, respectively, in GC, IM, and DYS, which was significantly higher than that (21.6%) in normal gastric mucosa ($P < 0.05$), indicating that Bmi-1 expression is involved in the mechanism that determines malignant potential[6], and may play a role in the occurrence and development of GC. In the absence of Bmi-1, $p16^{INK4A}$ may be up-regulated, leading to cell cycle arrest, senescence or apoptosis. In contrast, deregulation of *INK4a* allows cell cycle progression. $p19^{ARF}$ prevents the degradation of p53 by sequestering the p53-inhibitor MDM2, thereby allowing p53-mediated cell cycle arrest and apoptosis[7]. Since *INK4a-ARF* is the critical downstream target of Bmi-1 in the regulation of cell proliferation and apoptosis[7], and the stability of cells is

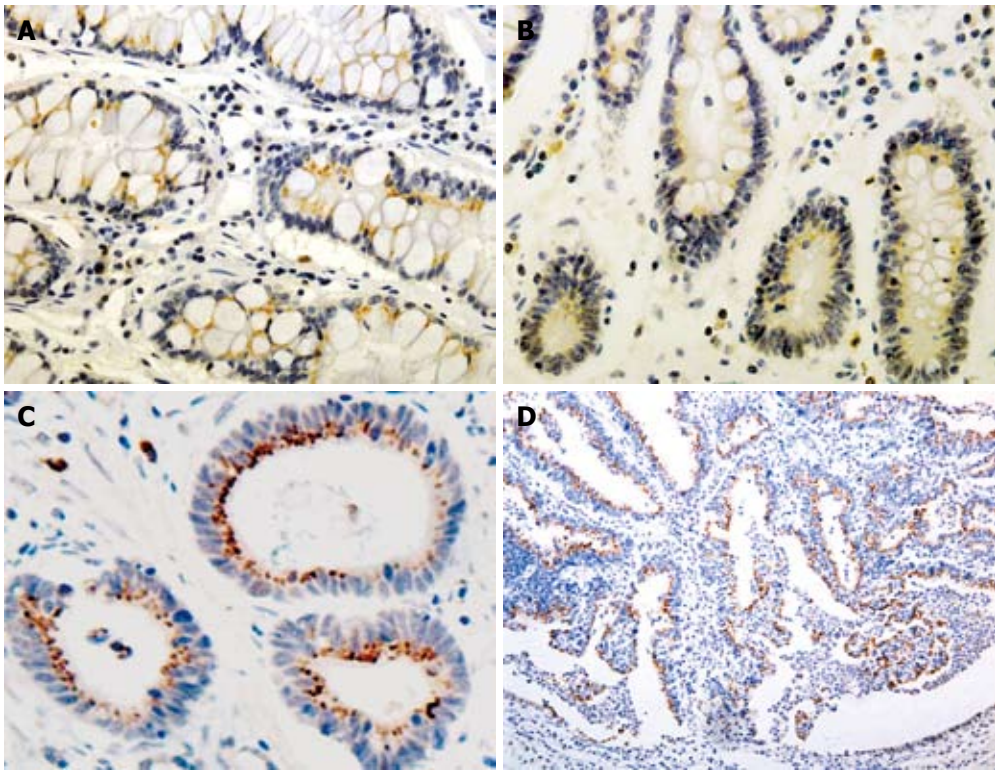

Figure 2 Expression of Bmi-1 in IM (A), mild DYS (B), gastric tubular adenocarcinoma (C) and papillary adenocarcinoma (D) (PV-9000 A-C × 400, D × 200).

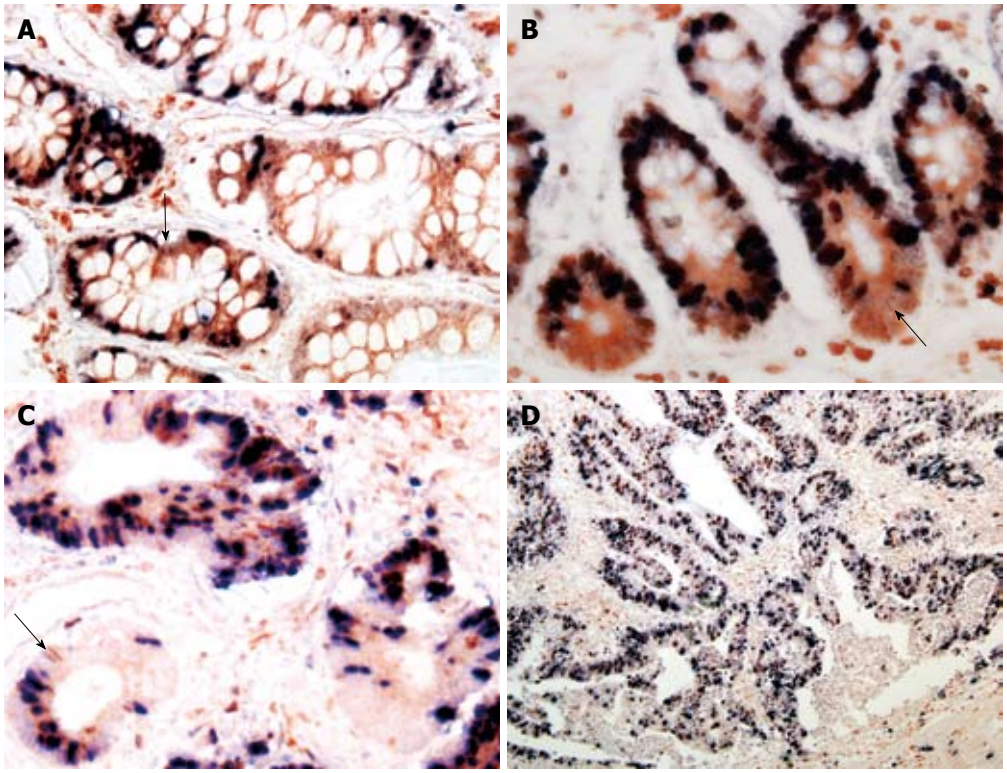

Figure 3 Distribution of Bcl-2$^+$/ki-67$^-$ cells in IM (A), mild DYS (B), gastric tubular adenocarcinoma (C) and papillary adenocarcinoma (D). Red fine granules in cytoplasm and unstained nuclei were defined as Bcl-2$^+$/ki-67$^-$ cells as shown by the arrows (Immunohistochemical double staining, A-C × 400, D × 200).

impaired, cancerization may be increased. In this study, Bmi-1 expression was significantly higher in gastric precancerous lesion than in normal gastric mucosa, indicating that Bmi-1 plays a role in the malignant transformation of gastric mucosa cells[6].

In the present study, over-expression of Bmi-1 occurred in high-grade intraepithelial dysplasia and colon cancerous cells, which is consistent with the reported findings[6]. This study also showed that the expression of Bmi-1 was related to the Lauren's and Borrmann's classification and the clinicopathological tumor stage, suggesting that Bmi-1 may be related to cell differentiation in the progression of gastric mucosa injury to cancerization. Therefore, Bmi-1 may underlie the tumorigenesis and infiltration of GC. Variation of Bmi-1 expression in intestinal and diffuse GC indicates that Bmi-1 may be related to cell differentiation, which is consistent with the over-expression of Bmi-1 in gastric IM. Liu *et al*[8] reported that Bmi-1 is up-regulated at

both transcriptional and translational levels in GC tissues compared with that in its adjacent non-cancerous tissues, as confirmed by reverse transcription polymerase chain reaction and Western blotting, showing that Bmi-1 can serve as a valuable marker for the diagnosis and prognosis of GC.

Ki-67 is a nuclear antigen expressed in proliferating but not in quiescent cells. Consequently, ki-67 is used in tumor pathology to detect proliferating cells in neoplastic diseases. Bcl-2, known as a key regulator of the apoptosis, is a proto-oncogene first discovered in human follicular lymphoma and is involved in the inhibition of apoptosis and the survival of a variety of cell types. The distribution of Bcl-2^+/ki-67^- cells in gastric pyloric glands and intestine crypts might be potential cell compartments involved in cancerization of the gastrointestinal tract. In our study, Bcl-2^+/ki-67^- were used as potential markers for gastric stem cells, immunohistochemical double-labeling staining was used to display the distribution of Bcl-2^+/ki-67^- cells in GC and precancerous lesions, which showed that the distribution of Bmi-1^+ cells was consistent with that of Bcl-2^+/ki-67^- cells, and that Bmi-1 expression in IM was positively correlated with that of Bcl-2, suggesting that the expression of Bmi-1 is closely related with gastric cancer cellular proliferation and apoptotic progression of gastric carcinogenesis.

Lessard *et al*[9] reported that Bmi-1 has an essential role in regulating the proliferative activity of both normal and leukemic stem cells. It has been shown that Bmi-1 is a key regulator of self-renewal in both normal and tumorigenic human solid tumor stem cells, including

several types of brain cancer[10] and breast carcinoma[11]. Dovey *et al*[12] showed that Bmi-1 is over-expressed in numerous epithelial tumors and plays a key role in lung adenocarcinoma, thus providing a clue to lung cancer cell origin and lung tumorigenesis. Thus far, the relation between Bmi-1 and stem cells of gastrointestinal tract still remains unclear. Reinisch *et al*[4] reported that Bmi-1 expression serves as a potential stem cell marker of the gastrointestinal tract, which also shows that Bmi-1 expression is correlated with gastrointestinal stem cells as well as numerous specialized cell types. These results indicate that Bmi-1 protein is involved in cellular differentiation in addition to maintaining stem cells, which is consistent with the research of Molofsky *et al*[13]. Sangiorgi *et al*[14] found that Bmi-1 is expressed in discrete cells located near the bottom of crypts in small intestine. These cells proliferate, expand, self-renew and give rise to differentiated cell lineages of small intestinal epithelium, and ablation of Bmi1 (+) cells using a Rosa26 conditional allele expressing diphtheria toxin leads to crypt loss, suggesting that Bmi-1 is an intestinal stem cell marker *in vivo*.

In summary, Bmi-1 plays an important role in gastric cancer development, indicating that gastric cancer cells require Bmi-1 for their tumorigenic activity, and that interference with Bmi-1 activity may be a therapeutic strategy for GC. Thus, it is essential to elucidate the molecular mechanism of Bmi-1 involved in the cell cycle and to correlate this function with gastric stem cells in future.

COMMENTS

Background

It has been reported that B-cell-specific Moloney murine leukemia virus insertion site 1 (Bmi-1) is a transcriptional repressor that belongs to the polycomb-group family of proteins involved in hematopoiesis, regulation of proliferation and axial patterning. Bmi-1, an important factor for self-renewal and senescence of various stem cells, is highly expressed in various human malignant tumors.

Research frontiers

Bmi-1, identified as a protein that down-regulates $p16^{ink4a}$, is mandatory for the persistent existence of several stem cell classifications, such as hematopoietic and neural stem cells. It has been reported that Bmi-1 is a potential stem cell marker of the gastrointestinal tract. The expression of Bmi-1 is correlated with gastrointestinal stem cells as well as numerous other specialized cell types, and this protein plays a role in cellular differentiation rather than in stem cell maintenance. Bmi-1 is also a marker for carcinoma progression in nasopharyngeal cancer, bronchial carcinogenesis and myelodysplastic syndrome. Furthermore, microarray analyses performed in several other cancer types suggest that Bmi-1 mRNA is a prognostic marker.

Innovations and breakthroughs

In this study, immunohistochemical double-labeling staining was used to investigate the distribution of Bcl-2$^+$/ki-67$^-$ cells, and to explore its correlation with Bmi-1, which provides a valuable clue to the location of normal gastric mucosal and gastric cancer stem cells.

Applications

Investigating the expression of Bmi-1 in gastric carcinoma (GC) and precancerous lesions helps researchers analyze its role and significance in tumorigenesis of GC. Bmi-1 may serve as an adjuvant marker for the diagnosis and prognosis of GC.

Terminology

Bmi-1: an abbreviated form of B-cell-specific Moloney murine leukemia virus insertion site 1, a transcriptional repressor belonging to the polycomb group gene family.

Peer review

The study seems to be very interesting. The results, based on immunohistochemical observation, suggest that Bmi-1 plays a role in the progression of GC and is related to cell differentiation in the progression of gastricl mucosa injury to cancerization. Therefore, Bmi-1 may be used as an adjuvant prognostic marker. If the research incorporated reverse transcription polymerase chain reaction and Western blotting to quantify the RNA/protein expression, the results would be perfect.

Abstract

AIM: To systematically assess the efficacy and safety of β-adrenergic blocker plus 5-isosorbide mononitrate (BB + ISMN) and endoscopic band ligation (EBL) on prophylaxis of esophageal variceal rebleeding.

METHODS: Randomized controlled trials (RCTs) comparing the efficacy and safety of BB + ISMN and EBL on prophylaxis of esophageal variceal rebleeding were gathered from Medline, Embase, Cochrane Controlled Trial Registry and China Biological Medicine database between January 1980 and August 2007. Data from five trials were extracted and pooled. The analyses of the available data using the Revman 4.2 software were based on the intention-to-treat principle.

RESULTS: Four RCTs met the inclusion criteria. In comparison with BB + ISMN with EBL in prophylaxis of esophageal variceal rebleeding, there was no significant difference in the rate of rebleeding [relative risk (RR), 0.79; 95% CI: 0.62-1.00; $P = 0.05$], bleeding-related mortality (RR, 0.76; 95% CI: 0.31-1.42; $P = 0.40$), overall mortality (RR, 0.81; 95% CI: 0.61-1.08; $P = 0.15$) and complications (RR, 1.26; 95% CI: 0.93-1.70; $P = 0.13$).

CONCLUSION: In the prevention of esophageal variceal rebleeding, BB + ISMN are as effective as EBL. There are few complications with the two treatment modalities. Both BB + ISMN and EBL would be considered as the first-line therapy in the prevention of esophageal variceal rebleeding.

INTRODUCTION

Cirrhotic patients with esophageal variceal bleeding have a very high incidence of rebleeding and a significant risk of death. Therefore, it was radical to adopt some interventional measures to prevent esophageal variceal rebleeding. Both endoscopic band ligation (EBL) and β-adrenergic blocker (BB) are the main therapies for secondary prophylaxis of esophageal variceal bleeding. Compared with untreated controls, these treatments can decrease the rate of variceal rebleeding and mortality[1-2]. Despite using adequate BBs, the portal pressure does not decrease in over one-third of patients[3]. Combined β-adrenergic blocker and 5-isosorbide mononitrate (BB + ISMN) was more effective than BBs alone in the prevention of esophageal variceal rebleeding[4-5]. It is still unknown whether drug therapy is superior to EBL for preventing variceal rebleeding. Several randomized controlled trials have shown different results[6-9].

Meta-analyses can statistically combine the results of several studies and resolve discrepancies among single studies. Because of combining the sample of individual studies, a meta-analysis greatly increases the overall sample size, which increases the statistical power of the

analysis, as well as the precision of the estimation of the therapeutic effect. The purpose of this study was to perform a meta-analysis of randomized controlled trials (RCTs) comparing BB + ISMN with EBL for secondary prophylaxis of esophageal variceal bleeding, and draw an overall conclusion about the safety and efficacy of the two treatments.

MATERIALS AND METHODS

Study selection

Any studies that met all of the following inclusion criteria were included: (1) the study was an RCT comparing the efficacy and safety of BB + ISMN and EBL on prophylaxis of esophageal variceal rebleeding; (2) duration of follow-up was at least 6 mo; and (3) outcome evaluation included at least one of the following: rebleeding, all-cause mortality, bleeding-related deaths and complications.

Search strategy

Medline, Embase, Cochrane Controlled Trial Registry and China Biological Medicine database were searched from January 1980 to August 2007 to locate published research in the area of esophageal variceal rebleeding. Key words used for searching included: esophageal variceal bleeding, BB, EBL, 5-ISMN, rebleeding, prevention and RCT. There was no language restriction applied to the search.

Assessment of study quality

Two of us independently assessed the methodological quality of each study in accordance with the criteria of Moher *et al*[10]. The trials were considered of high quality if the methodological quality score was three or more. The Jadad standard included four components: allocation sequence generation (computer-generated random number or similar, 2; not described, 1; and inadequate, 0); allocation concealment (central randomization and sealed envelops, 2; not described, 1; inadequate, 0); double blinding (identical placebo tablets or double dummy, 2; double blind but method not described, 1; no double blinding or inadequate method, 0); and description of protocol deviations, withdrawals and dropouts (numbers and reasons described, 1; not described, 0).

Statistical analysis

The measurement of association used in this meta-analysis was relative risk (RR) with 95% CI. Statistical heterogeneity between trials was evaluated by the Cochran Chi-square test and defined at a P value less than 0.1. In the absence of statistically significant heterogeneity, summary RR with 95% CI was calculated using fixed-effect models whereas potential reasons for heterogeneity was explored by subgroup analysis and sensitivity analysis using random-effect model. P value less than 0.05 was considered significantly different. All analyses and calculations were performed using the Revman 4.2 software.

RESULTS

Description of selected trials

Five RCTs met the inclusion criteria after searching the electronic databases, and one was excluded because it did not provide the same data. Four RCTs included 476 patients. The characteristics and quality of these four RCTs are summarized in Table 1. Two RCTs showed that BB + ISMN were as effective as EBL, one showed that pharmaceutical therapy was better, and the other showed a benefit of EBL. Three studies compared nadolol plus 5-ISMN with EBL, and propranolol plus 5-ISMN were administered in one study. A few patients in the EBL group received one or two sessions of sclerotherapy simultaneously in the Romero 2006 study.

Outcome evaluation

Rebleeding: Data from four randomized trials included 476 patients available for the assessment of rebleeding. Rebleeding was seen in 105 of 240 patients in the BB + ISMN group and in 109 of 236 patients in the EBL group. Summary RR for all four trials showed no significant difference in the rate of rebleeding between the BB + ISMN and EBL groups (RR, 0.94; 95% CI: 0.64-1.38; $P = 0.76$) using a randomized-effect model (Figure 1A). Test of heterogeneity for the rate of rebleeding was significant ($\chi^2 = 10.54$, $P = 0.01$). Clinical parameters were used to explore the cause of statistical heterogeneity. The proportion of patients who had large varices was higher in the BB + ISMN (30/61) than in the EBL group (19/60) in the LO2002 study[7]. Excluding this trial, the heterogeneity of χ^2 value for the remaining three trials was 2.37, $P = 0.31$. Summary RR for all these three trials showed no significant difference in the rate of rebleeding between the BB + ISMN and EBL groups (RR, 0.79; 95% CI: 0.62-1.00; $P = 0.05$) using a fixed-effect model.

All-cause mortality: Fifty-nine patients died in the BB + ISMN group and 72 in the EBL group. There was no significant heterogeneity between the studies ($P = 0.58$). Summary RR for all four trials showed no significant difference in the rate of all-cause mortality between the BB + ISMN and EBL groups (RR, 0.81; 95% CI: 0.61-1.08; $P = 0.15$) using a fixed-effect model (Figure 1B).

Bleeding-related deaths: Three trials evaluated bleeding-related deaths. There was no significant heterogeneity among studies ($P = 0.58$) and no significant difference in the rate of bleeding-related deaths between the BB + ISMN and EBL groups (RR, 0.76; 95% CI: 0.31-1.42; $P = 0.40$) (Figure 1C).

Complications: Adverse events were found in 76 patients in the BB + ISMN group including bradycardia, hypotension and headache, and 55 patients in the EBL group including bleeding ulcers, perforation, stenosis and chest pain. There was no mortality resulting from complications in either group. Summary RR for all four trials showed no significant difference in the occurrence of

complications between the BB + ISMN and EBL groups (RR, 1.26; 95% CI: 0.93-1.70; $P = 0.13$) using a fixed-effect model (Figure 1D). Test of heterogeneity was not significant in the occurrence of complications ($P = 0.16$).

DISCUSSION

EBL has significantly reduced the frequency of variceal rebleeding, mortality and complications, and has replaced endoscopic injection sclerotherapy as the first-line therapy in the prevention of esophageal variceal rebleeding[11]. However, this treatment has a high recurrence, needs advanced technique and incurs a high cost[12]. The association of BB + ISMN enhances the reduction in portal pressure. Some clinical trials have found that combined BB + ISMN is superior to sclerotherapy and BB alone in the prevention of esophageal variceal rebleeding, with few complications, low cost and convenient administration[13]. It is still unknown whether drug therapy is superior to EBL for preventing variceal rebleeding. Our study included four RCTs and systematically assessed the efficacy and safety of BB + ISMN and EBL on prophylaxis of esophageal variceal rebleeding.

The meta-analysis showed that the overall rebleeding rate with BB + ISMN (43.8%) did not differ significantly from that of EBL (46.2%). There was a significant heterogeneity among the individual trials. The proportion of patients who had large varices was higher in the BB + ISMN (30/61) group than in the EBL group (19/60) in the LO2002 study, which may be the cause of the significant difference. Excluding this trial, there was no significant difference among the individual trials. Summary RR for all these three trials showed no significant difference in the rate of rebleeding between the BB + ISMN and EBL groups (RR, 0.79; 95% CI: 0.62-1.00; $P = 0.05$) using a fixed-effect model. The result showed that BB + ISMN was as effective as EBL in the prevention of esophageal variceal rebleeding. Decreasing the portal pressure by EBL did not result in increasing the bleeding at other local sites.

A total of 59 (24.5%) patients died in the BB + ISMN group and 72 (35.1%) in the EBL group. The mortality rate was similar in both groups (RR, 0.81; 95% CI: 0.61-1.08; $P = 0.15$). Three trials further evaluated the bleeding-related deaths, and there was no significant difference between the BB + ISMN and EBL groups (RR, 0.76; 95% CI: 0.31-1.42; $P = 0.40$). The comparative results between the BB + ISMN and EBL groups did not affect the all-cause and bleeding-related mortality.

Complications occurred in 71 (29.5%) patients in the BB + ISMN group and 55 (23.3%) in the EBL group ($P = 0.13$). None of the complications was fatal in either group. The occurrence rate of complications in our study was higher than that in other similar studies[14-15] because minor complications were included. Although Villanueva *et al*[6] showed that the incidence of severe adverse events was higher in the EBL group (12%) than in the BB + ISMN group (3%), this did not affect the overall result of our meta-analysis. However, the occurrence of complications was higher in the BB + ISMN group (29.5%) than in the EBL group (23.3%), and more patients withdrew from the study in the BB + ISMN group because they could not tolerate the complications of BBs.

In summary, combined therapy with BB + ISMN is as effective as EBL in the prevention of variceal rebleeding. The complications and survival are similar in the two interventional treatments. Both BB + ISMN and EBL are considered as the first-line therapy in the prevention of esophageal variceal rebleeding.

This meta-analysis was only based on published data and publication bias has not been evaluated because of the paucity of RCT data. The conclusion of this meta-analysis should be further demonstrated by large-scale and multicenter RCTs.

COMMENTS

Background

Cirrhotic patients who bleed from esophageal varices have a very high incidence of rebleeding and a significant risk of death. Both endoscopic band ligation (EBL) and β-adrenergic blocker plus 5-isosorbide mononitrate (BB + ISMN) are the main therapies for secondary prophylaxis of esophageal variceal bleeding. It is still unknown whether the drug therapy is superior to EBL for preventing variceal rebleeding. Several randomized controlled trials (RCTs)

have displayed different results. The authors performed a meta-analysis of RCTs comparing BB + ISMN with EBL for secondary prophylaxis of esophageal variceal bleeding, to draw an overall conclusion about the safety and efficacy of the two treatments.

Research frontiers

EBL has significantly reduced the frequency of variceal rebleeding, mortality and complications. However, this treatment has a higher recurrence, needs advanced techniques and is expensive. Some clinical trials have found that the combination of BB + ISMN is superior to sclerotherapy and BB alone in the prevention of esophageal variceal rebleeding, with few complications, and is cheap and convenient in administration.

Innovations and breakthroughs

To the best of our knowledge, this is the first published meta-analysis comparing BB + ISMN with EBL for secondary prophylaxis of esophageal variceal bleeding.

Applications

The research showed that combined therapy with BB + ISMN is as effective as EBL in the prevention of variceal rebleeding. BB + ISMN can be considered as the first-line therapy in the prevention of esophageal variceal rebleeding.

Peer review

Although good work has been done by this meta-analysis study, this paper needs some revisions.

Abstract

Eosinophilic gastroenteritis (EG) is an uncommon disease characterized by focal or diffuse eosinophilic infiltration of the gastrointestinal tract, and is usually associated with dyspepsia, diarrhea and peripheral eosinophilia. Diffuse gastrointestinal tract and colonic involvement are uncommon. The endoscopic appearance may vary from normal to mucosal nodularity and ulceration. Gastrointestinal obstruction is unusual and is associated with predominantly muscular disease. We present five unusual cases of EG associated with gastric outlet and duodenal obstruction. Two cases presented with acute pancreatitis and one had a history of pancreatitis. Four cases responded well to medical therapy and one had recurrent gastric outlet obstruction that required surgery. Four out of the five cases had endoscopic and histological evidence of esophagitis and two had colitis. Two patients had ascites. These cases reaffirm that EG is a disorder with protean manifestations and may involve the entire gastrointestinal tract. Gastric outlet and/or small bowel obstruction is an important though uncommon presentation of EG. It may also present as esophagitis, gastritis with polypoid lesions, ulcers or erosions, colitis and pancreatitis and may mimic malignancy.

Key words: Gastroenteritis; Eosinophilic; Gastrointestinal obstruction; Eosinophilic esophagitis; Eosinophilic colitis; Eosinophilic pancreatitis

INTRODUCTION

Eosinophilic gastroenteritis (EG) is an uncommon inflammatory disease characterized by eosinophilic infiltration of the gastrointestinal tract[1-5]. In 1937, Kaijser first described the disease in two patients with syphilis who were allergic to neoarsphenamine[5]. More than 300 cases have been reported in the literature since 1937[1-10]. The disease affects all races and any age group from infancy to old age, although in adults, it usually presents in the third to fifth decade[1-4].

It is reported to be more common in men with a ratio of 3:2[1-4]. Any part of the gastrointestinal tract from the esophagus to rectum may be involved. Eosinophilic proctocolitis is almost exclusively seen in children[1-4]. Although the exact etiology is unknown, a personal or family history of food allergies and atopic disorders can be elicited in 50% to 70% of cases[1-4]. Almost all patients have tissue eosinophilia; many have peripheral eosinophilia and raised IgE levels. The majority of cases have a favorable response to steroids, suggesting a type-1 hypersensitivity reaction. Eosinophils are bilobed granulocytes with secondary granules produced in the bone marrow under the influence of interleukin-3 (IL-3), IL-5 and granulocyte-macrophage colony-stimulating factor (GM-CSF)[1-4]. Eosinophils primarily reside in the

lining of the gastrointestinal tract providing protection against parasitic infections. The basic pathophysiological defect in EG is believed to be an alteration in the mucosal integrity, resulting in localization of various antigens in the gut wall and inducing tissue and blood eosinophilia[1-4,10,11]. Specific food antigens can cause mast cell degranulation in the gastrointestinal wall, releasing eosinophil chemotactic factors, leukotrienes and other platelet activating factors[12-16]. The degranulation of eosinophils causes the release of histamine, cationic proteins like major basic protein, eosinophil peroxidase, eosinophil-derived neurotoxin and cytokines such as tumor necrosis factor-α. Cytokines like GM-CSF, IL-3 and IL-5 induce eosinophil proliferation and differentiation in the bone marrow, and are strong chemotactic agents that attract eosinophils to sites of tissue inflammation[13-16]. These proteins promote inflammation, tissue damage and further mast cell degranulation, resulting in a vicious circle[10-14]. Eotaxin, a novel 73-amino-acid chemokine, plays a central role in the recruitment of eosinophils into tissues[10-16]. Eotaxin is a specific eosinophil chemoattractant produced by epithelial cells at the site of inflammation. It induces aggregation of eosinophils and promotes their adhesion to endothelial cells[2,9,15]. Some cases of EG are associated with unrecognized parasitic infestations and allergic or toxic reactions to drugs. An outbreak of eosinophilic enterocolitis due to the canine hookworm *Ankylostoma canium* was reported in Queensland, Australia[17,18]. Drugs such as gold, azathioprine, carbamazepine, enalapril, clofazimine and co-trimoxazole have been reported to cause eosinophilia with variable involvement of the gastrointestinal tract[19,20]. The clinical presentations of EG are protean[1-5,10] and may vary depending on the location and depth of involvement of the different layers of the digestive tract. On the basis of predominant involvement, Talley *et al*[7] and Klein *et al*[21] have classified eosinophilic gastroenteritis into mucosal, submucosal (muscular) and serosal disease. Mucosal disease is the most common (25%-100%) and presents with nausea, vomiting, abdominal pain, diarrhea and weight loss[1-5]. Muscular disease is the next most common (13%-70%) and presents with intermittent obstructive symptoms and complications such as perforation or aspiration. Serosal disease is less common (12%-40%). Intense peripheral eosinophilia, eosinophilic ascites and prompt response to steroid therapy are the hallmarks of serosal disease[1-7]. Rarely, EG may involve the pleura, pericardium, urinary bladder, pancreas, gall bladder, spleen, liver and the biliary tree[1-5,9,10].

The diagnosis is established by demonstrating eosinophilic infiltration on biopsies obtained on endoscopy, laparoscopy or laparotomy. Multiple biopsies are required because of the patchy nature of the disease[1,5,8,11]. Full-thickness surgical biopsies may be required for accurate diagnosis, if the disease process is confined to the muscle layer. An enzyme-linked immunosorbent assay has been developed in Australia to diagnose *Ankylostoma canium* infestation[17,18]. Barium studies, CT scanning and ultrasonography may all reveal thickening of the mucosal folds with or without nodular filling defects or gastric outlet obstruction. The CT scan may also demonstrate ascites, pleural effusions and lymphadenopathy in some cases[7,8,20]. The endoscopic findings may be patchy and vary from normal mucosa to mild erythema, thickened mucosal folds, nodularity and frank ulceration[1,5,7-9]. Corticosteroids remain the mainstay of treatment for EG. Some patients may have a relapsing course that requires long courses of steroid therapy.

CASE REPORT

Case 1

A 71-year-old woman presented with a history of nausea, abdominal pain, a weight loss of 10 pounds and diarrhea for 2 years. Stools studies were negative for ova, parasites and common pathogens. Clinical examination was unremarkable except for upper abdominal tenderness. A complete blood count revealed a WBC count of 6000/mm^3 with an eosinophil count of 8.2% (normal 0% to 4%). Other laboratory tests were unremarkable. The serum IgE level was 26 U/mL (normal 6-12 U/mL) and RAST testing for a battery of allergens, including common foods, was negative. CT scan of the abdomen was normal. Esophagogastroduodenoscopy (EGD) revealed distal esophagitis. There were multiple polypoid nodules in the gastric antrum, varying from 0.5 to 1 cm in size (Figure 1). Thickened gastric mucosal folds, antral erythema with small ulcers and erythema of the duodenal bulb were also noted. Histological examination of the polypoid nodules and biopsies from the esophagus, gastric antrum and duodenum demonstrated heavy eosinophilic infiltration and numerous degranulated eosinophils (Figure 2). Colonoscopy and random biopsies from the colon were normal. The patient was treated with prednisone 40 mg/d for 6 wk and tapered down to a maintenance dose of 10 mg/d for 6 mo, without much improvement in her symptoms. Repeat EGD revealed healing of the antral ulcers, without any change in the size and endoscopic appearance of the gastric polypoid lesions. Repeat biopsies revealed eosinophilic infiltration as before, with more fibrosis. Sodium cromoglycate 200 mg *tid* was added to her treatment with modest improvement of her symptoms. However, her abdominal pain recurred and she reported worsening nausea, postprandial fullness and bloating over the next 6 mo. Endoscopic examination revealed an increase in the number and size of the polypoid lesions, especially in the antrum, causing partial gastric outlet obstruction. Histological examination of the polypoid lesions demonstrated marked fibrosis but significantly decreased eosinophilic infiltration. Her obstructive symptoms worsened requiring antrectomy and gastrojejunostomy. She did well after surgery on low-dose steroids and sodium cromoglycate.

Case 2

A 57-year-old man presented with a history of generalized aches, nausea and upper abdominal pain for 4 mo. He was treated with H-2 blockers and later switched to proton pump inhibitors. His symptoms worsened and he developed postprandial fullness and bloating. His past medical history was remarkable for an episode of

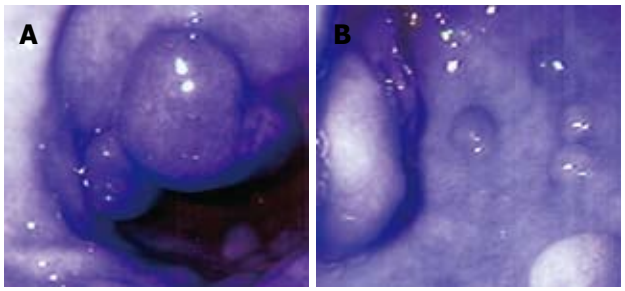

Figure 1 Endoscopic appearance of stomach (A and B) showing multiple gastric antral polyps of 4-10 mm in size and antral mucosal erythema.

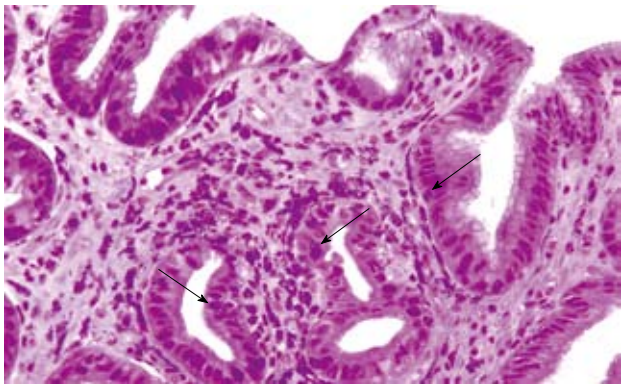

Figure 2 Histological appearance of the gastric polyp showing eosinophilic infiltration of the lamina propria by numerous degranulated eosinophils and some polymorphonuclear cells (arrows). Some intraepithelial eosinophils are also seen. (HE, × 200).

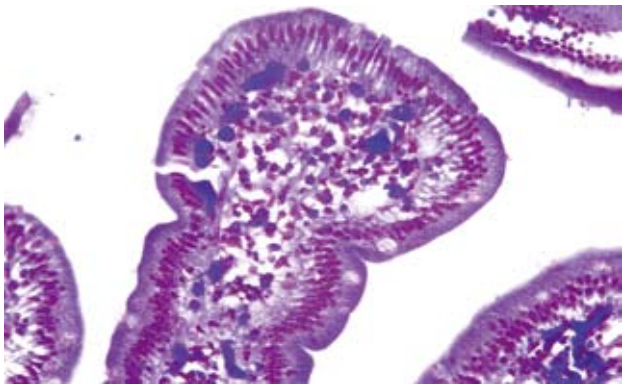

Figure 3 Histological appearance of duodenal mucosal biopsy demonstrating moderately severe infiltration with eosinophils and some intraepithelial eosinophils. (HE, × 200).

Figure 4 Barium upper GI demonstrating stricture and stenosis of the second and third part of duodenum, with reflux of the contrast medium into the biliary tree.

self-limiting pancreatitis of unclear etiology. He had no personal or family history of allergic disorders. Clinical examination demonstrated mild abdominal distension and epigastric tenderness. Laboratory data revealed, a WBC count of 10000/mm^3, and an eosinophil count of 33% (normal 0%-1%). The serum amylase level was 94 U/L (normal 25-115 U/L) and serum lipase was 415 U/L (normal 114-286 U/L). Stool studies for ova and parasites were negative. Barium X-ray series of the upper gastrointestinal tract revealed retained gastric secretions and narrowing of the gastric outlet with features of gastric outlet obstruction. Endoscopic examination demonstrated thickened and erythematous antral and duodenal folds with pyloric channel and duodenal narrowing. The gastric and duodenal biopsies revealed subacute and chronic inflammation with moderately intense eosinophilic infiltration (Figure 3). A CT scan of the abdomen demonstrated thickened pyloric and duodenal folds and unremarkable pancreas. The patient responded well to a course of oral steroids and his symptoms continued to improve on maintenance steroids.

Case 3

A 74-year-old man presented with intermittent bloating and fullness after meals for 3 years. He also complained of intermittent nausea and vomiting, abdominal pain and diarrhea. His symptoms had worsened over the past year and he had lost 10 pounds in weight. His past medical history was remarkable for an attack of pancreatitis of unclear etiology. He had no personal or family history of allergic disorders. Clinical examination was unremarkable except for mildly distended and tender abdomen. Laboratory tests revealed a WBC count of 6000/mm^3, and an eosinophil count of 9.6% (normal 0% to 4%). Serum IgE level was 54 U/mL (normal 6-12 U/mL). Stools studies were negative for ova and parasites. Barium X-rays of the upper gastrointestinal tract showed features of gastric outlet obstruction and irregular narrowing at the level of the second and third portion of the duodenum, with contrast medium refluxing into the common bile duct (Figure 4). A CT scan of the abdomen confirmed the presence of stenosis at the level of the second and third portion of the duodenum. An EGD revealed mild esophagitis and a dilated stomach and retained food. The antrum and proximal duodenal bulb were erythematous. There was mild narrowing at the level of the pylorus but significant narrowing of the duodenal bulb. The endoscope could not be advanced further. Biopsies from the antrum and the bulb showed moderately intense eosinophilic infiltration. Colonoscopy showed diverticular disease and random colonic biopsies revealed moderately intense eosinophilic infiltration. The patient did not accept steroid therapy or endoscopic dilatation initially. He had only partial improvement of symptoms with sodium cromoglycate 200 mg *tid*. His symptoms persisted and he

agreed to steroid therapy. He responded well to a 6-wk course of prednisone 40 mg/d, tapered down to a maintenance dose of 10 mg/d.

Case 4

A 43-year-old African American man was admitted with a history of intermittent abdominal pain, nausea, vomiting and diarrhea for 3 mo. He had experienced postprandial fullness and bloating for the past month and lost 8 pounds in weight. He had used ranitidine and omeprazole without benefit. He had no history of food allergies and his mild asthma was controlled by serevent inhalation. His clinical examination was remarkable for dehydration, abdominal distension and mild upper abdominal tenderness. Laboratory tests on admission revealed a WBC count of 6400/mm^3 with an eosinophil count of 20% (normal 0%-4%). Serum amylase was 471 U/L (normal 25-115 U/L) and serum lipase was 1785 U/L (normal 114-286 U/L). Serum IgE level was 650 U/L (normal < 140 U/L). Other laboratory tests including liver function tests, routine stool studies, serum lipid profile and serum immunoglobulins, were normal. An ultrasound and CT scan of the abdomen revealed a dilated stomach with retained food and mild thickening of the antral and duodenal folds. The pancreas was normal and there were no gallstones. The patient was treated conservatively with rehydration and nasogastric suction. EGD showed mild distal esophagitis, multiple antral erosions and thickened antral folds with antro-pyloric narrowing. Multiple 2-6-mm ulcerated nodules were noted in the duodenal bulb, with thickening of the duodenal folds extending into the second part of the duodenum. Biopsies of the esophagus revealed esophagitis with mild eosinophilic infiltration. Biopsies of the antrum and duodenum showed chronic gastritis and duodenitis with intense eosinophilic infiltration of the lamina propria and submucosa. Colonoscopy showed mild patchy erythema and biopsies showed mild eosinophilic infiltration in the lamina propria. The patient was treated with steroids. His eosinophil count normalized and his symptoms of gastric outlet obstruction resolved. His symptoms recurred on tapering down the steroids. Sodium cromoglycate was added to his therapy and helped in tapering down his steroids. After 6 mo of maintenance steroid therapy, he stopped the treatment and is doing well.

Case 5

A 60-year-old Indian woman was admitted with a history of upper abdominal pain for 3 wk, associated with nausea, vomiting and diarrhea. She had mild asthma controlled by albuterol inhalation. She was a teetotaller. Clinical examination was unremarkable except for mild upper abdominal tenderness. Laboratory data revealed a serum amylase of 375 U/L (normal 25-115 U/L) and serum lipase of 1115 U/L (normal 114-286 U/L). Complete blood count was remarkable for a WBC count of 12 500/mm^3 and an eosinophil count of 17% (normal 0%-4%). Other laboratory data including liver function tests, routine stool studies, serum lipid profile and serum immunoglobulins were normal. A CT scan of the abdomen was unremarkable. The patient was treated conservatively for a clinical diagnosis of acute idiopathic pancreatitis. However, she continued to have abdominal pain and diarrhea and lost about 20 pounds in weight over the next 5 wk. An endoscopic retrograde cholangiopancreatographic examination was normal except for prominent and erythematous ampulla. Brushings from the intra-ampullary pancreatic duct were normal and biopsies of the ampulla revealed dense eosinophilic infiltration with mild reactive glandular proliferation. An EGD showed distal esophagitis, antral gastritis and duodenitis with narrowing of the antrum and duodenal bulb. Biopsies revealed chronic esophagitis and gastritis with moderate eosinophilic infiltration, and severe chronic duodenitis with intense eosinophilic infiltration. The patient was treated with a course of steroids and responded promptly with resolution of symptoms and weight gain. She was maintained on a low dose of maintenance steroids for 3 mo. She was subsequently tapered off the steroids and is doing well.

DISCUSSION

These five patients presented had unusual manifestations of EG, testifying to the varied presentations of this disorder[1-5,7-9]. Two of five patients (40%) had a significant personal history of allergic disorders (asthma) and none had a history of food allergy. In a review of 220 cases, Naylor reported a history of allergy in 52% of cases[8]. Food allergy has been reported to be present in 50% of cases[1-5,21,22]. All five of our cases had abdominal pain and diarrhea, which are the most common symptoms in patients with EG being present in 72% and 50% of cases, respectively[1-5,7-9]. All five of our cases had predominant involvement of the stomach and duodenum, resulting in gastric outlet and duodenal obstruction. In the past, benign diseases such as peptic ulcer disease accounted for most of the cases of gastric outlet obstruction. With the evolution of effective therapy for peptic ulcer disease, malignancy and EG have emerged to be the most important causes of gastro-duodenal obstruction[23-26]. It is therefore imperative to rule out EG and malignancy in these patients. In children, EG may mimic congenital pyloric stenosis[24]. Other uncommon causes of gastric outlet obstruction including Crohn's disease, post-surgical strictures, pancreatic pseudocyst, gallstones and chronic pancreatitis should also be considered in the differential diagnosis. Weight loss, especially in elderly patients, should heighten the suspicion for malignancy. A long history of symptoms, unremarkable CT scan and normal tumor markers may be helpful in ruling out a malignant etiology.

All five of our cases (100%) had endoscopic and histological evidence of eosinophilic gastritis and duodenitis. Endoscopic and histological evidence of eosinophilic esophagitis was present in four of our five (80%) cases and one patient did not have esophageal biopsies performed. Colonoscopy and random colonic biopsies were performed in three cases and revealed eosinophilic colitis in two (66%). Although EG can involve the entire gastrointestinal tract, the esophagus

and colon are uncommonly involved[1-5,26]. However, esophageal involvement is now more frequently reported, especially in children and young adults[1-5].

In a review of 220 cases, Naylor *et al*[8] reported that the stomach was the most frequently involved organ (43% of cases). The duodenum and the rest of the small bowel are less frequently involved. Small bowel involvement may present with abdominal pain, diarrhea or frank malabsorption[27,28], and rarely bowel obstruction[1-5,7-9,29-31]. There have been only a few case reports of jejunal and ileal strictures[25,26]. Colonic involvement presents as abdominal pain and/or diarrhea[9,11,29-31].

Eosinophilic gastroenteritis may present as an acute abdomen due to acute pancreatitis, intestinal or colonic obstruction, intussusception and perforation[25,26,31-33]. Two of our five cases (40%) presented with acute pancreatitis of unknown etiology. Interestingly, the two cases with acute pancreatitis had very high eosinophil counts, and biopsies from a prominent and erythematous ampulla in one patient showed intense eosinophilic infiltration. There was no recurrence of pancreatitis after steroid treatment, supporting eosinophilic infiltration as the etiology. The barium X-rays of one of the patients with a history of pancreatitis revealed an interesting finding of spontaneous barium reflux into the biliary tree (Figure 4). We believe the duodenal stricture from EG facilitated the reflux of barium into the biliary tree. Eosinophilic infiltration can cause edema, fibrosis and distortion in the ampulla and periampullary duodenum and cause pancreatitis[33,34]. Pancreatic involvement may also mimic a pancreatic malignancy[33,34]. Hepatic, splenic, biliary tract, gall bladder and urinary bladder involvement has also been reported[1-5,7-9,34-37].

The peripheral eosinophil count was high in all five (100%) of our cases and very high in two cases. Peripheral eosinophilia has been reported in up to 80% of cases[1-5,7]. Patients with predominantly serosal disease have higher absolute eosinophil counts (average 8000/dL) than patients with mucosal disease (average 2000/dL) and muscle layer disease (average 1000/dL)[33,34]. None of our cases had evidence of significant blood loss or malabsorption, which have been reported in the literature in 20%-30% patients, especially those with mucosal disease[6-8]. Serum IgE level was checked in only three of our patients and was elevated in two (66%). IgE levels are more likely to be high in children with EG than in adults[35,36]. Our patients demonstrated almost the whole spectrum of endoscopic features including, erythema, ulcers, nodularity, thickening of folds and pseudopolypoid lesions.

All five of our patients (100%) responded to steroid therapy. Only one patient required surgery for gastric outlet obstruction. One of our patients had a partial response to sodium cromoglycate and in another patient this drug helped in tapering off his steroids. Steroids are the mainstay of treatment in EG and about 90% patients respond to this therapy[5,7-9]. Patients with serosal disease usually show a dramatic response to steroids[1-5,7-9]. Azathioprine may be helpful as a steroid-sparing agent in patients requiring high doses for maintenance. Sodium cromoglycate is a mast cell stabilizer that prevents release of toxic mediators like histamine, platelet activating factors and leukotrienes from mast cells. There have been several reports of a beneficial response to this drug[38,39]. The usual dose is 200 mg three or four times per day. Ketotifen is similar to sodium cromoglycate in its biological profile and may be useful in some cases[40]. Elimination of presumed dietary articles is unhelpful in most cases[1-5]. Successful treatment of EG with montelukast, a leukotriene modifier, has been reported[12]. Suplatast tosilate is a new IL-4 and IL-5 inhibitor effective in treating asthma, and has been reported to be useful in treating a patient with EG[41]. A humanized anti-IL-5 monoclonal antibody (mepolizumab) has been found to be beneficial in a small series of four patients with hypereosinophilia syndrome[42]. This antibody may have a potential therapeutic role in treating patients with EG.

As demonstrated by our five cases, the clinical course of EG is highly variable. However, the long duration of illness in most cases testifies to the generally good prognosis of EG. Fatalities from EG are rare and are usually due to perforation of the gastrointestinal tract[43,44].

From our experience with these five cases, we conclude that EG is truly protean in its clinical and endoscopic manifestations, sites of involvement in the digestive system, response to therapy and clinical course. Gastroduodenal involvement is common, esophageal involvement is being increasingly reported and colonic involvement is uncommon. EG can present with gastric outlet and duodenal stricturing resulting in gastric outlet obstruction. Malignancy is an important differential diagnosis and should be ruled out by appropriate diagnostic modalities. Patients with EG may present with acute pancreatitis and this should be considered in the differential diagnosis. The course of EG is variable and relapses are common. However, the response to treatment and overall prognosis is good.

Abstract

Endoscopic submucosal dissection (ESD) with a knife is a technically demanding procedure associated with a high complication rate. The shortcomings of this method are the inability to fix the knife to the target lesion, and compression of the lesion. These can lead to major complications such as perforation and bleeding. To reduce the risk of complications related to ESD, we developed a new grasping type scissors forceps (GSF), which can grasp and incise the targeted tissue using electrosurgical current. Colonoscopy on a 55-year-old woman revealed a 10-mm rectal submucosal nodule. The histological diagnosis of the specimen obtained by biopsy was carcinoid tumor. Endoscopic ultrasonography demonstrated a hypoechoic solid tumor limited to the submucosa without lymph node involvement. It was safely and accurately resected without unexpected incision by ESD using a GSF. No delayed hemorrhage or perforation occurred. Histological examination confirmed the carcinoid tumor was completely excised with negative resection margin.

INTRODUCTION

Recently, colonoscopy has facilitated the diagnosis of rectal carcinoid tumors at an early stage. Theoretically, rectal carcinoid tumors less than 1 cm in diameter and a depth of invasion limited to the submucosal layer can be curatively treated by endoscopic resection[1-4]. Conventional snare polypectomy or endoscopic mucosal resection often results in incomplete resection of rectal carcinoid tumors and the need for additional surgery that sometimes requires a stoma[4-6]. Endoscopic submucosal dissection (ESD) has been reported to improve the rate of successful *en bloc* resection in early stage rectal tumors[6]. Furthermore, ESD can accurately control the depth of submucosal exfoliation under endoscopic view. However, ESD, and particularly the process of submucosal dissection, is technically difficult and carries a high risk of perforation and bleeding[6-9]. Conventional devices for submucosal incision such as IT knife and needle knife merely contact the knife to the submucosal tissue and cut using electrosurgical current. These cutting methods without fixing the knife to the target have a potential risk of incomplete resections or major complications due to unexpected incision. To resolve the problems related to ESD using a conventional knife, we have developed a grasping type scissors forceps (GSF), which can accurately grasp and incise the targeted tissue using electrosurgical current[10,11]. In our previous study for early gastric neoplasms, we resected four tumors safely and easily without unintentional incision by ESD

using the GSF[9]. In this report, we first describe a new method of ESD using GSF for rectal carcinoid tumors.

CASE REPORT

Colonoscopy on a 55-year-old woman revealed a 10-mm rectal submucosal nodule (Figure 1A). The histological diagnosis of the specimen obtained by biopsy was carcinoid tumor. Subsequent endoscopic ultrasonography (EUS) demonstrated a hypoechoic solid tumor in the submucosa without lymph node involvement (Figure 1B). It was treated by ESD using a newly developed GSF (XDP2618DT; Fujifilm, Saitama, Japan) (Figure 2)[10], after obtaining written informed consent from the patient. A two-channel multi-bending endoscope (GIF-2T240M; Olympus, Tokyo, Japan) was used in this case. During ESD, the patient was sedated with an intravenous injection of flunitrazepam (0.4 mg) and pethidine (35 mg). The ESD technique using GSF was carried out as follows (Figure 3). Marking dots were placed approximately a few millimeters outside the margin of the lesion with a hook knife (KD-620LR; Olympus, Tokyo, Japan), with a coagulation current of 20 W (Forced coagulation mode) created by an electrosurgical generator (ICC 200; Erbe, Tübingen, Germany). Next, a concentrated glycerin solution mixed with a small volume of epinephrine and indigo carmine dye was injected into the submucosal layer around the target lesion to lift the entire lesion. The lesion was separated from the surrounding normal mucosa (Figure 4A) around the lesion with the GSF using an electrosurgical current (Autocut mode 120 W). A piece of submucosal tissue was grasped and cut with the GSF (Autocut mode 120 W) to achieve submucosal excision. During the dissection, ESD using GSF can accurately control the depth of submucosal excision under endoscopic vision (Figure 4B). Finally, the lesion was completely resected (*en bloc* resection) by GSF (Figure 4C). It took 91 min for the ESD. Macroscopically, the mass was yellowish-white and solid, measuring 11 mm × 10 mm in diameter. Microscopically, the tumor was composed of small uniform cells, arranged in small nests and cords, with an anastomosing ribbon-like pattern in the submucosal layer. Immunohistochemically, the tumor cells were positive for synaptophysin. The vertical and horizontal cut margins were negative. There was no lymphovascular invasion. These findings established curative resection of the rectal carcinoid tumor (Figure 4D). After ESD, the patient stayed in the hospital and was prohibited from eating until the fourth day of ESD. Laboratory findings and chest and abdominal X-ray remained unremarkable after ESD. She was permitted oral soft food and discharged 7 d after the procedure. No hemorrhage, perforation, or other complication occurred.

Newly developed GSF

The GSF (XDP2618DT) (Figure 2) can grasp and cut a piece of tissue, using an electrosurgical current. It has a 0.4-mm wide and 4-mm long serrated cutting edge to facilitate grasping the tissue. The outer side of the forceps is insulated so that electrosurgical current energy is concentrated at the blade to avoid burning the surrounding tissue. Furthermore, the forceps can be rotated to the desired orientation. The diameter of the forceps is 2.7 mm. The GSF is available for standard endoscopy with a working channel width of 2.8 mm or over. This device, which is disposable and not reusable, was used for circumferential marginal incision and submucosal dissection.

Ethical considerations

The advantages and disadvantages of the ESD using GSF, as well as alternative endoscopic options (ESD using conventional device, endoscopic mucosal resection *etc*), were discussed with the patient. The patient was aware of the experimental nature of the planned treatment. She gave her written informed consent to the designated intervention. This study was reviewed and approved by the ethics committee of Aso Iizuka Hospital. It was conducted in accordance with the ethical principles of the Declaration of Helsinki and in compliance with good clinical practice.

DISCUSSION

The rectum is one of the most frequent primary sites of carcinoid tumors. Rectal carcinoids less than 2 cm rarely metastasize, indicating local excision including endoscopic resection[2]. Furthermore, when the tumor is smaller than 1 cm and the depth of invasion is lim-

Figure 2 Distal tip of the GSF. The outer side of the forceps is insulated so that electrosurgical current energy is concentrated at the blade to avoid burning the surrounding tissue.

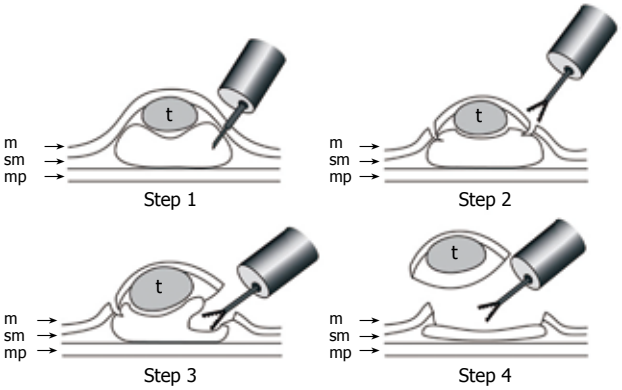

Figure 3 Schematic shows ESD using GSF. Step 1: A concentrated glycerin solution mixed with a small volume of epinephrine and indigo carmine dye is injected into the submucosal layer around the target lesion to lift the entire lesion; Step 2: The lesion is separated from the surrounding normal mucosa by complete incision around the lesion using the GSF; Step 3: A piece of submucosal tissue is grasped and cut with the forceps using an electrosurgical current to effect submucosal exfoliation; Step 4: The lesion is resected in one piece. m: Mucosa; sm: Submucosa; mp: Muscularis propria; t: Tumor.

ited within submucosa, the risk of metastatic disease is extremely low, and endoscopic resection is considered curative[1-5]. Technically, complete resection of carcinoid tumors of the rectum is difficult with conventional endoscopic polypectomy[12], because 76% of these tumors extend into the submucosa[4-6]. However, various modified endoscopic therapies, such as strip biopsy[13], aspiration resection[14], band-snare resection[15] and endosonography probe-guided band ligation[16] result in good outcome for submucosal rectal carcinoid tumors less than 1 cm, so the application of ESD for carcinoids may be limited. When the lesions are larger, around 1-2 cm (1.1 cm in our case), or massively invade the submucosal layer, which may result in tumor-positive margin resection[3], incomplete resection with endoscopic resection sometimes results in the need for additional surgery. In such circumstances, ESD should be applied[3].

ESD was originally developed to obtain one-piece resection for early gastric cancers[7-11]. ESD has the advantage of permitting *en bloc* resection and histologically complete resection. On the other hand, this method has the disadvantages of a long procedure time and a high frequency of complications, as well as demanding a high level of technical skill. However, ESD can control

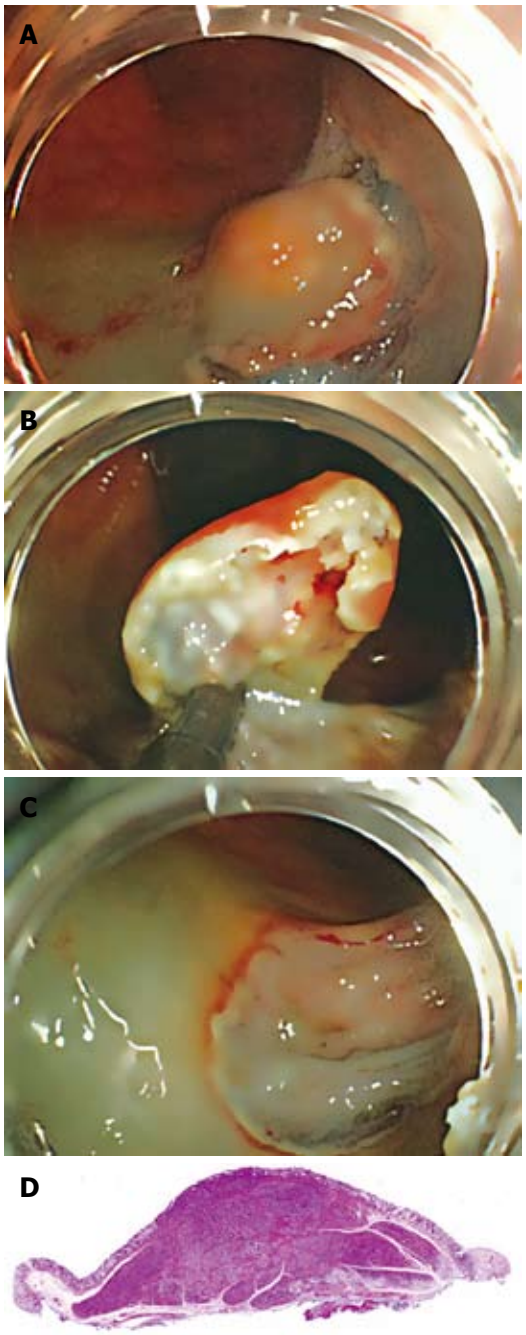

Figure 4 ESD using GSF of rectal carcinoid. A: Endoscopic view of the partial circumferential incision of the tumor using GSF; B: Endoscopic view of the submucosal exfoliation under the tumor using GSF; C: The lesion is cut completely from the muscle layer; D: The resected specimen showing curative *en bloc* resection of the lesion.

the depth of submucosal dissection under endoscopic view[6-11]. Therefore, ESD is a theoretically suitable therapeutic option for rectal carcinoid located within the submucosa[2,3,6]. If the tumor invades the muscularis propria, ESD is contraindicated due to the risk of perforation and metastasis. Pretherapeutic EUS is vital for decision making concerning the indication of ESD for this disease.

Incision using knife devices merely contact the knife to the tissue and cut using electrosurgical current. These cutting processes without fixing the device to the tar-

geted tissue make it difficult to place the knife accurately during electrosurgical incision because of bowel movement. Lack of complete endoscopy control can cause unexpected incision and result in incomplete resection or severe complications such as perforation and bleeding[6-9]. Our approach was to perform endoscopic resection with a GSF that can be passed through the ordinary working channel. This device was developed by us for ESD of early gastric cancer[10,11]. It has a thin serrated cutting edge to facilitate grasping the tissue. The outer side of the forceps is insulated so that electrosurgical current energy is concentrated at the blade to avoid burning the surrounding tissue. Furthermore, the forceps can be rotated to the desired orientation. Theoretically, the main advantage of GSF for ESD is the fixed device, which can accurately control the depth of submucosal exfoliation under good endoscopic vision[11]. GSF can be used to grasp the targeted tissue again if necessary, before electrosurgical cutting. Furthermore, the GSF can reduce post-cut hemorrhage by a compression effect similar to a polypectomy snare[11]. Thus the grasping step before cutting allows accurate targeting and compression of the vessel, and reduces the chance of incomplete resection and major complications (perforation and bleeding). In our method, sufficient separation of the tumor from the underlying muscularis propria, using submucosal injection of the solutions, is effective in preventing perforation due to thermal damage or capture of the muscularis propria by the GSF. Therefore, frequent additional submucosal injection of solution during the procedure is vital to reduce the risk of such complications. Each cut of the GSF goes a length of about 4 mm. As for the perforation, the direction of the device is the most important factor. If the device goes as far as the muscularis propria, perforation will occur, so we should operate the device parallel to the muscularis propria. The maximal advantage of the GSF is having the visual confirmation step for accurate and safe targeting by the device before cutting during the grasping stage. However, the GSF is unsuitable for marking like an IT-knife. For marking, a needle knife, flex knife, argon plasma coagulator probe, *etc* are available. In our method, we used a hook-knife. Furthermore, if the scope is strongly retroflexed, the rotation of the GSF is a little difficult. This is the limitation of this device. In this case, it was safe and accurate to resect the rectal carcinoid with a sufficient negative resection margin using GSF. To the best of our knowledge, this is the first report of ESD using GSF for rectal carcinoid. We believe this technique has the potential to become the method of choice for removal of GI tract carcinoid tumor when the tumor is limited to the submucosa.

Abstract

There have only been a few reports on lansoprazole-associated collagenous colitis. Colonic mucosa of collagenous colitis is known to be endoscopically normal. We present a case of collagenous colitis where the mucosa showed diffuse cloudiness mimicking ulcerative colitis. A 70-year-old woman developed watery diarrhea four to nine times a day. She had interstitial pneumonia at 67 and reflux esophagitis at 70 years. Lansoprazole 30 mg/d had been prescribed for reflux esophagitis for nearly 6 mo. Lansoprazole was withdrawn due to its possible side effect of diarrhea. Colonoscopy disclosed diffuse cloudiness of the mucosa which suggested ulcerative colitis. Consequently sulfasalazine 2 g/d was started. The patient's diarrhea dramatically disappeared on the following day. However, biopsy specimens showed subepithelial collagenous thickening and infiltration of inflammatory cells in the lamina propria, confirming the diagnosis of collagenous colitis. One month after sulfasalazine therapy was initiated, colonoscopic and histological abnormalities resolved completely. Five months later the diarrhea recurred. The findings on colonoscopy and histology were the same as before, confirming a diagnosis of collagenous colitis relapse. We found that the patient had begun to take lansoprazole again 3 mo ahead of the recent diarrhea. Withdrawal of lansoprazole promptly resolved the diarrhea. Endoscopic and histological abnormalities were also completely resolved, similar to the first episode. Retrospectively, the date of commencement of sulfasalazine and discontinuation of lansoprazole in the first episode was found to be the same. We conclude that this patient had lansoprazole-associated collagenous colitis.

INTRODUCTION

Collagenous colitis and lymphocytic colitis, collectively termed microcytic colitis, are considered to be etiologically related and to be a spectrum of the same disease[1]. The disease is well known to have normal mucosa endoscopically. However, endoscopic abnormalities are observed in about 30% of cases: abnormal vascular pattern, loss of vascular pattern, edema, and erythema[2,3]. The treatment of the disease is similar to that in ulcerative colitis[3,4]. The etiology of the disease is unknown but a significant proportion may be drug-induced[5-7]. Immunological disposition is implicated because the disease is often seen in patients with a variety of autoimmune diseases[4,8].

Lansoprazole is widely prescribed for gastroesophageal reflux and benign peptic ulcer disease. We present a case of lansoprazole-associated collagenous colitis where the mucosa showed diffuse cloudiness mimicking ulcerative colitis. We mistook this case initially for an atypical case

of ulcerative colitis, and the patient was then diagnosed with collagenous colitis, which seemed to respond to sulfasalazine. In fact, the response was to the removal of lansoprazole.

CASE REPORT

A 70-year-old woman with watery diarrhea four to nine times a day in an orthopedic ward was referred to a gastroenterologist at the beginning of April 2007. She had a past history of: pulmonary tuberculosis and hypertension at 54 years, cerebral hemorrhage with a sequel of left hemiplegia at 63; diabetes mellitus, constipation, internal hemorrhoid and interstitial pneumonia at 67; neurogenic bladder at 68; gastroduodenal ulcers at 69; and reflux esophagitis at 70. She had a fracture of the femoral head and underwent surgery for insertion of an artificial femoral head on March 16, 2007. The patient had diarrhea four to nine times a day since March 26. Abnormalities on routine blood testing included mild anemia (hemoglobin 105 g/L), hypoproteinemia (49 g/L) and increased C-reactive protein (33 mg/L). Stool culture for pathogens was negative and fecal occult blood tests were negative. The following immunological and hormonal tests were normal: anti-nuclear antibody, rheumatic factor, perinuclear antineutrophil cytoplasmic antibody, anti-Scl 70 antibody, anti-centromere antibody, thyroid test, microsome antibody, free T3, free T4, and thyroid stimulating hormone. The gastroenterologist (MC) decided to check her drugs for diarrhea as a side effect and asked the orthopedist to withdraw lansoprazole 30 mg/d if possible, and to change loxoprofen sodium to etodolac. Lansoprazole had been prescribed for reflux esophagitis for nearly 6 mo and loxoprofen sodium had been prescribed for anal pain of unknown cause after the episode of diarrhea. Neither metronidazole of 1 wk duration for suspected antibiotic-associated diarrhea nor trimebutine maleate of 1 wk duration for suspected irritable bowel syndrome was effective. Therefore, colonoscopy was performed on April 16. This disclosed diffuse cloudiness of the mucosa in the entire colorectum observed from the rectum to the descending colon (Figure 1A). These findings suggested ulcerative colitis. Consequently, sulfasalazine 2 g/d was started that day. The patient's diarrhea dramatically disappeared on the following day. The findings of three biopsy specimens each from the descending colon, the sigmoid colon, and the rectum showed similar results: erosion and moderate infiltration of inflammatory cells in the lamina propria (Figure 2A). Crypt abscess was not found, however, subepithelial collagenous thickening was found (Figures 2A and 3A). Therefore, collagenous colitis was diagnosed. One month later, colonoscopy showed a clear vascular pattern (Figure 1B) and disappearance of subepithelial collagenous thickening (Figures 2B and 3B). Neither lansoprazole nor loxoprofen sodium was prescribed on her discharge (May 25, 2007). The dose of sulfasalazine was later decreased from 2 g/d to 1 g, followed by 0.5 g/d. Since diarrhea recurred around the end of September 2007, the dose of sulfasalazine was increased to 2 g/d. However, diarrhea persisted and she was readmitted on December 10, 2007. Since the findings on colonoscopy and histology were the same as before, a relapse of collagenous colitis was diagnosed. Following admission, we found that the patient had been taking lansoprazole since July 2, 2007 which was prescribed by another hospital. At this time, we were aware of lansoprazole-associated collagenous colitis[9-12]. Lansoprazole was withdrawn on December 16. The diarrhea improved within a few days. Endoscopic and histological normalization was ascertained on January 31, 2008. We retrospectively found that in the first episode, the date of withdrawal of lansoprazole by the orthopedist coincided with the commencement of sulfasalazine. We finally diagnosed this patient as having lansoprazole-associated collagenous colitis.

DISCUSSION

Microscopic colitis was originally described as mucosa that is endoscopically normal. Recently new endoscopic findings have been added: red spots[13], aphthoid ulcer[14], ulcer[6], mucosal tears[15,16], hemorrhagic lacerations[17], and longitudinal ulcers[18]. In our case, distinct diffuse cloudiness of the mucosa was observed on two occasions in this patient with collagenous colitis. In collagenous colitis, in addition to subepithelial collagenous thickening, there are significant numbers of inflammatory cells in the lamina propria. These changes completely disappear on recovery. Therefore, it seems reasonable that diffuse mucosal cloudiness rather than normal mucosa is endoscopically observed in collagenous colitis.

Diffuse cloudiness of the mucosa can be seen in a mild type of ulcerative colitis. Therefore, we at first diagnosed the patient with ulcerative colitis and sulfasalazine was prescribed. The current strategy for collagenous colitis is similar to that of ulcerative colitis[3,4]. In this patient, sulfasalazine seemed dramatically effective against ulcerative colitis before collagenous colitis was diagnosed, and against collagenous colitis after collagenous colitis was diagnosed.

Microscopic colitis is associated with a variety of immunological disorders and immunological phenomena: thyroid disease, rheumatoid arthritis, polyarthritis, CREST syndrome, eosinophilia, and the presence of autoantibodies[4,8]. The present case had interstitial pneumonia, which is frequently associated with autoimmune diseases. Interstitial pneumonia is to be added to a list of immunological disorders associated with microscopic colitis.

Microscopic colitis is known to be associated with various drugs including nonsteroidal anti-inflammatory drugs[5-7]. Recently, lansoprazole has been shown to cause microscopic colitis[9-12,18]. The frequency of lansoprazole-associated microscopic colitis is not known, but at least six of 850 subjects who took lansoprazole (0.7%) were found to develop microscopic colitis[10]. The period from

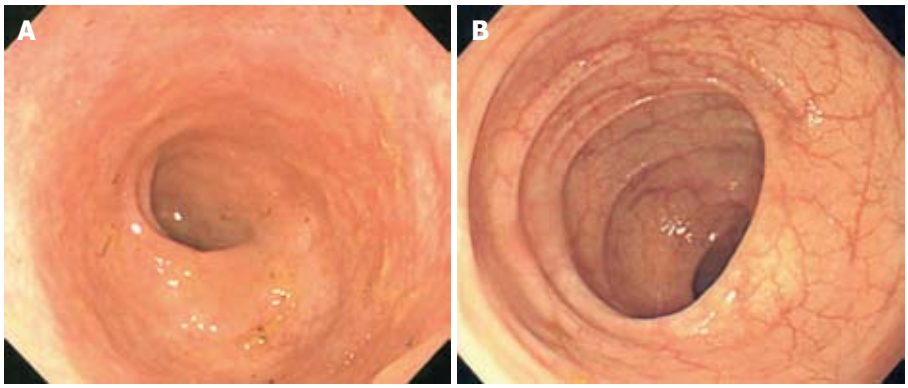

Figure 1 Colonoscopy on April 16 (A) and May 17 (B), 2007 showed diffuse cloudiness of mucosa in the colon and clear normal vascular patterns, respectively.

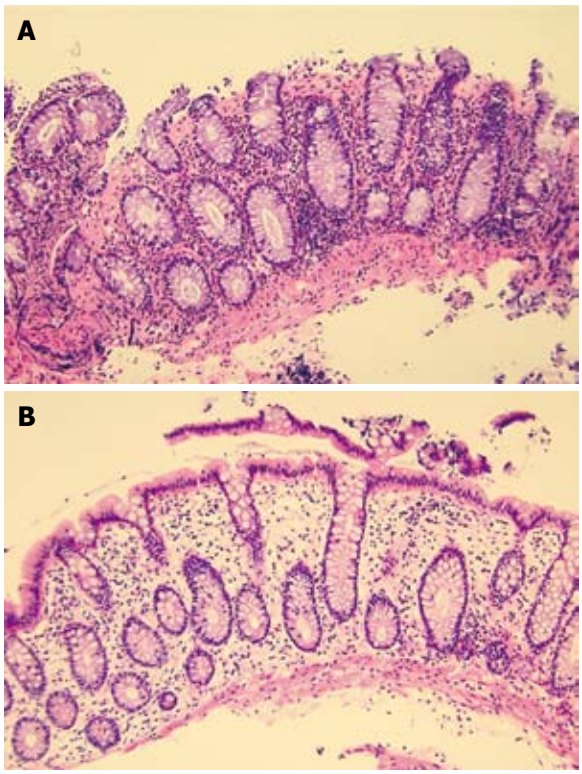

Figure 2 Biopsy specimens taken on April 16 (A) and May 17 (B), 2007 (hematoxylin and eosin staining, × 100). The former showed erosion, moderate infiltration of inflammatory cells in the lamina propria, and subepithelial collagenous thickening. The latter showed disappearance of these abnormalities.

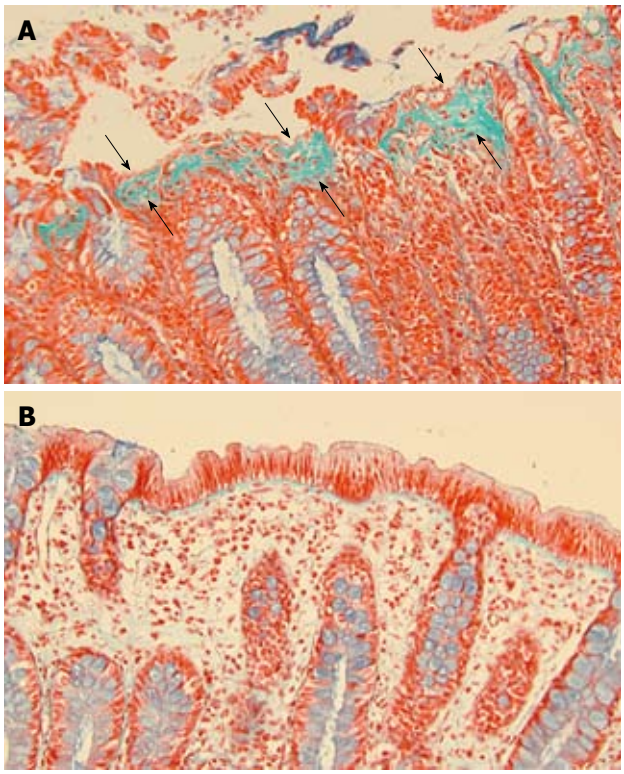

Figure 3 Biopsy specimens taken on April 16 (A) and May 17 (B), 2007 (Masson's trichrome staining, × 200). Subepithelial collagenous thickening (A, arrows) disappeared on May 17 (B).

initiation of lansoprazole to the onset of diarrhea varies extensively from 5 d to 9 mo[9-12]. In our case, it was about 3 and 6 mo in the two episodes, respectively. Treatment of lansoprazole-associated microscopic colitis is withdrawal of lansoprazole. Prompt resolution of diarrhea occurs within 1-10 d[9-12]. In our case, it was 1 d in the first episode and a few days in the second episode. Complete histological normalization subsequently occurred in our case[10,11]. In lansoprazole-associated microscopic colitis, the substitution of omeprazole for lansoprazole was reported to be successful without diarrhea[10].

From the present case it can be concluded that: diffuse cloudiness of colorectal mucosa can be seen endoscopically in collagenous colitis; lansoprazole can cause microscopic colitis; and discontinuation of lansoprazole results in the prompt resolution of diarrhea.

Abstract

Nigella sativa (*N. sativa*) decreases DNA damage and thereby prevents initiation of carcinogenesis in colonic tissue secondary to exposure to toxic agents such as azoxymethane. *N. sativa* is of immense therapeutic benefit in diabetic individuals and those with glucose intolerance as it accentuates glucose-induced secretion of insulin besides having a negative impact on glucose absorption from the intestinal mucosa. *N. sativa* administration protects hepatic tissue from deleterious effects of toxic metals such as lead, and attenuates hepatic lipid peroxidation following exposure to chemicals such as carbon tetrachloride.

Key words: *Nigella sativa*; Thymoquinone; Colon cancer; Glutathione-S transferase; Schistosomiasis

Peer reviewer: Valentin Fuhrmann, MD, Department of Internal Medicine 4, Intensive Care Unit, Medical University Vienna, Waehringer Guertel 18-20, A-1090 Vienna, Austria

TO THE EDITOR

Yildiz *et al*[1] in their recent article, published in the September issue of the "*World Journal of Gastroenterology*", have clearly highlighted the efficacy of *Nigella sativa* (*N. sativa*) in relieving the deleterious effects of ischemia reperfusion injury in the liver. Their findings bring into highlight the increasing clinical and therapeutic applications of *N. sativa* and its derivatives in the field of gastroenterology.

N. sativa decreases DNA damage and thereby prevents initiation of carcinogenesis in colonic tissue secondary to exposure to toxic agents such as azoxymethane[2]. In fact, sustained delivery of thymoquinone (derived from *N. sativa*) is almost as effective in causing apoptosis of colon cancer cells as sustained delivery of 5-fluorouracil[3]. Similarly, hepatic metastasis from tumors such as mastocytomas is markedly decreased following administration of *N. sativa*[4]. *N. sativa*, when used in combination with *Hemidesmus indicus* and *Smilax glabra*, also seems to decrease hepatic carcinogenesis secondary to exposure to agents such as diethylnitrosamine[5]. These anti-carcinogenic effects are mediated in part by thymoquinone secondary to its inhibitory influence on the NF-κB activation pathway[6].

N. sativa is of great therapeutic benefit in diabetic individuals and those with glucose intolerance, as it accentuates glucose-induced secretion of insulin, besides having a negative impact on glucose absorption from the intestinal mucosa[7,8]. In fact, *N. sativa* attenuates the damage to β-cells of the pancreas following exposure to toxic elements such as cadmium[9]. Similarly, *N. sativa* administration attenuates the ulcerative effects of ethanol on gastric mucosa by decreasing the glutathione-S transferase levels in gastric mucosa[10].

Besides these effects, *N. sativa* also demonstrates anti-parasitic effects. For instance, its administration decreases the number of eggs as well as worms in schistosomiasis, which tends to affect hepatic and intestinal tissues[11]. In addition, *N. sativa* attenuates the side effects associated with some common medications used by gastroenterologists. For instance, cyclosporine, used by gastroenterologists for disorders such as recalcitrant Crohn's disease, is often associated with nephrotoxic side effects, which can be limited by *N. sativa* due to its anti-oxidant properties[12]. Similarly, *N. sativa* administration protects hepatic tissue from deleterious effects of toxic metals such as lead and attenuates hepatic lipid peroxidation following exposure to chemicals such as carbon tetrachloride[13,14].

Thymoquinone, derived from *N. sativa*, has also been demonstrated to induce apoptosis of human colon cancer cells[15]. The above examples clearly illustrate the massive clinical and therapeutic potential of *N. sativa*.

Personally, I believe that the anti-carcinogenic effects of *N. sativa* hold the maximum therapeutic potential. Given the significant benefits associated with its administration, broad-spectrum studies are clearly and urgently needed to further assess and elaborate its therapeutic benefits in gastroenterology.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Articles: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; (13) Guidelines: To introduce Consensuses and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice in gastroenterology and hepatology.

The WJG Press and Baishideng

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials. gov sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words). Available from:http://www.wjgnet.com/wjg/help/8.doc

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/14.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc*.
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.
Biology: *H pylori*, *E coli*, *etc*.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office
World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/10.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/9.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

INTRODUCTION

World Journal of Gastroenterology is an international, open-access, peer-reviewed, and multidisciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

Abstract

Gastric carcinoids (GCs), which originate from gastric enterochromaffin-like (ECL) mucosal cells and account for 2.4% of all carcinoids, are found increasingly in the course of upper gastrointestinal tract endoscopy. Current nosography includes those occurring in chronic conditions with hypergastrinemia, as the type 1 associated with chronic atrophic gastritis, and the type 2 associated with Zollinger-Ellison syndrome in multiple endocrine neoplasia type 1, and type 3, which is unrelated to hypergastrinemia and is frequently malignant, with distant metastases. The optimal clinical approach to GCs remains to be elucidated, depending upon type, size and number of carcinoids. While there is agreement concerning the treatment of type 3 carcinoids, for types 1 and 2, current possibilities include simple surveillance, endoscopic polypectomy, surgical excision, associated or not with surgical antrectomy, or total gastrectomy. Moreover, the recent introduction of somatostatin analogues represents a therapeutic option of possibly outstanding relevance.

Key words: Gastric carcinoids; Endocrine tumors; Well-differentiated tumors; Hypergastrinemia; Chronic atrophic gastritis; Zollinger-Ellison syndrome; Multiple endocrine neoplasia tupe 1; Enterochromaffin-like cells

Peer reviewer: D Mark Pritchard, PhD, FRCP, Gastroenterology of University of Liverpool, 5th Floor UCD Building, Daulby St, Liverpool L69 3GA, United Kingdom

INTRODUCTION

The term gastric carcinoid (GC) describes inadequately the pathological continuum of a wide spectrum of distinct neoplasms that arise from gastric enterochromaffin-like (ECL) cells. Carcinoid tumors represent a variety of significantly diverse lesions, which are distinct from adenocarcinomas in their etiology, biological behavior and prognosis. Over the past 5 years, a marked increase in reports addressing GCs has been evident[1]. These tumors are also known by their modern term of gastric neuroendocrine tumors, although the term carcinoid is still commonly used. This review focuses on the biology, diagnosis and treatment of GCs.

EPIDEMIOLOGY

GC tumors that arise from ECL cells have long been considered as rare lesions, and account for less than 2% of all carcinoids tumors and less than 1% of all stomach neoplasms[1-3]. However, recent reviews have indicated that the incidence of GCs may be on the rise[4-6]. In fact, a recent analysis[4] of the National Cancer Institute's (NCI) Surveillance, Epidemiology, and End Results (SEER) database by Modlin *et al* found that, from 1992 to 1999, GCs comprised 8.7% of all gastrointestinal carcinoid tumors. Also, during the period 1950-1999, a total of 562 GCs were recorded in the NCI databases, but from 2000 to 2004, in the SEER database, 1043 new GCs have been reported, which comprises 11.7% of all gastrointestinal carcinoid tumors[7]. On the other hand, a major decline in incidence and mortality of gastric adenocarcinomas has been described over several decades[8]. The male:female ratio for GCs is about 1:2, with 64% of carcinoids found in women, whereas males are almost twice as likely to develop non-carcinoid

Table 1 Characteristics of GC types

	Type 1	Type 2	Type 3
Percentage (%)	70-85	5-10	15-25
Tumor characteristics	Often small, multiple, polypoid, multicentric	Often small, multiple, polypoid, multicentric	Single, > 1-2 cm, polypoid and often ulcerated
Mean age at diagnosis (yr)	63	50	55
Gender	Females > males	Females = males	Males > females
Associated conditions	Chronic atrophic gastritis type A	ZES/MEN1	Sporadic
Serum gastrin levels	Increased	Increased	Normal
pH of gastric juice	Increased	Low	Normal
Ki-67 (%)	Usually < 2	Usually < 2	Usually > 2
Metastases (%)	2-5	< 10	> 50

gastric-cancer (ratio male:female 1.71)[3].

The reasons for the recent marked increase in GCs are unknown, although the wide use of screening upper endoscopy, the routine habit to obtain biopsies in the course of upper gastrointestinal endoscopy, the application of specific immunohistological identification techniques, and a greater clinical focus on the subject may contribute to increased detection of GCs[9]. On the other hand, our knowledge on the biological basis of these tumors, as well as on the complex interplay between genetic and environmental factors that ultimately results in GC development, are still partial. Hypergastrinemia represents a necessary condition for the development of type 1 and type 2 GCs, even if not sufficient[5,10]. The widespread use of proton pump inhibitors can also induce gastric achlorhydria, thus contributing to hypergastrinemia[11,12], even if it is not clear that it has a real association with an increased risk of GCs. On the other hand, the importance of genetic and molecular background remains to be elucidated. Loss of heterozygosity at the multiple endocrine neoplasia type 1 (MEN-1) gene locus 11q13 has been found in all type 2 tumors that are associated with Zollinger-Ellison syndrome/MEN-1, but also in 17%-73% of type 1, and in 25%-50% of type 3 GCs, although these tumors do no develop in MEN-1 patients[13]. A role for the apoptosis-inhibiting protein BCL-2 has also been proposed, with the hypothesis that the anti-apoptotic activity of BCL-2 may contribute to the development of carcinoid tumors by extending the exposure of hyperplastic ECL cells to other so-far-unknown oncogenic factors[14]. Mcl-1 protein expression also increased specifically in human hypergastrinemia-associated type 1 GC tumors. Gastrin-induced mcl-1 expression may therefore be an important mechanism that contributes toward type 1 GC development[15].

CLASSIFICATION

GCs are endocrine tumors of the gastric mucosa that originate from ECL cells[12,13,16-20]. These tumors are classified into three distinct types (Table 1).

Type 1 (GC-1) includes the vast majority (70%-85%) of GCs and is closely linked to chronic atrophic gastritis type A, characterized by decrease acidity, resultant hypergastrinemia and subsequent ECL cell hyperplasia. The spectrum of ECL cell lesions includes hyperplasia (simple, linear and micronodular), dysplasia, and eventually, carcinoids[21]. The lesions are located in the gastric fundus and body and are multicentric, polypoid, small, limited to the mucosa or submucosa, without angioinvasion, well-differentiated, and tend to display benign behavior. It is more frequent in females.

Type 2 (GC-2) accounts for 5%-10% of GCs, is associated with ZES and occurs almost exclusively in the context of MEN-1. MEN-1/ZES patients usually have small duodenal or pancreatic gastrinomas causing hypergastrinemia and subsequent ECL proliferation. The increased incidence of GC-2 in patients with MEN-1 (13%-37%), who display loss of heterozygosity at the MEN-1 gene locus, versus patients with sporadic ZES (0%-2%), supports the genetic role in the pathogenesis of GCs. Type 2 GCs are usually multiple and small, and have low-grade malignancy, although up to 35% of cases are metastatic at presentation. Unlike GC-1, GC-2 is equally frequent in male and female patients[22,23].

Type 1 and type 2 GCs are both associated with hypergastrinemia. In the first case, hypergastrinemia is secondary to hypo/achlorhydria caused by the destruction of gastric parietal cells. In the second case, it is caused by the presence of a primary gastrinoma that, on the contrary, causes hyperchlorhydria. Therefore pH of gastric juice and blood test are useful to discriminate the presence of pernicious anemia by ZES/MEN1. Pernicious anemia is characterized by increased gastric juice pH, low vitamin B12 and presence anti-parietal cells and/or anti intrinsic factor antibodies. The presence of ZES/MEN1 is characterized by low gastric juice pH or better by a basal acid output $\geqslant$ 15 mEq/h. This condition can be investigated by testing a full evaluation of pituitary and parathyroid function, in addition to genetic analysis.

Type 3 (GC-3) represents 15%-25% of GCs, is not related to hypergastrinemia, is characterized by a far more aggressive course, and presents with lymph node and distant metastases in more than 50% of cases. Lesions are typically solitary, larger than 1-2 cm, ulcerated and deeply invasive. They are usually located in the gastric fundus and body, but may occur also in the antrum. This type of GC is more frequent in males[1,3,12,17,18]. Unlike GC-1 and GC-2, GC-3 may be associated with an atypical carcinoid syndrome that

Table 2 Clinicopathological characteristics of endocrine tumors of the stomach according to WHO classification[23]

Well-differentiated tumor-carcinoid
Benign behavior: confined to mucosa-submucosa, non-angioinvasive, ≤ 1 cm in size, non-functioning
ECL cell tumor of corpus-fundus associated with hypergastrinemia and chronic atrophic gastritits (CAG) or MEN1 syndrome
Serotonin-producing tumor
Gastrin-producing tumor
Uncertain behavior: confined to mucosa-submucosa, > 1 cm in size, or angioinvasive
ECL cell tumor with CAG or MEN1 syndrome or sporadic
Serotonin-producing tumor
Gastrin-producing tumor
Well-differentiated endocrine carcinoma-malignant carcinoid
Low-grade malignant, deeply invasive (muscularis propria or beyond), or with metastasis
Nonfunctioning
ECL cell carcinoid, usually sporadic, rarely in CAG or MEN1 syndrome
Serotonin-producing tumor
Gastrin-producing tumor
Functioning
ECL cell carcinoid with atypical carcinoid syndrome
Serotonin-producing carcinoid with syndrome
Gastrin-producing carcinoma-malignant gastrinoma
ACTH-producing carcinoma with Cushing syndrome
Poorly differentiate endocrine carcinoma-small cell carcinoma, high grade malignant, usually non-functioning, occasionally with Cushing syndrome

Table 3 Proposed TNM staging system for GC tumors[7]

	Primary tumor		
	Depth of invasion		Size
T1	Up to and including muscularis propria		≤ 3 cm
T2	Beyond muscularis propria		≤ 3 cm
T3	Up to and including muscularis propria		> 3 cm
	Beyond muscularis propria		> 3 cm
	Lymph node		
N0	No lymph node metastasis		
N1	Regional lymph node metastasis		
	Distant metastasis		
M0	No distant metastasis		
M1	Distant metastasis		
Disease stage	T	N	M
Ⅰ	T1	Any N	M0
Ⅱ	T2	N0	M0
	T3	N0	M0
Ⅲ	T2	N1	M0
Ⅳ	T3	N1	M0
	Any T	Any N	M1

presents with itching, bronchospasm and cutaneous flushing, thought to be mediated by histamine released from ECL cells[1].

Also, type 4 GCs (GC-4) have been described[17]. This type of tumor is not derived from ECL cells, but from other endocrine cells of the stomach, such as those producing serotonin or gastrin. These tumors may have a very aggressive course and may be located in the gastric fundus, body or antrum.

According to the WHO classification[24], type 1 GCs are well-differentiated endocrine tumors with a benign or, more rarely, an uncertain behavior. Type 2 GCs are usually well-differentiated endocrine tumors, but may also be well-differentiated endocrine carcinomas with angioinvasion, invasion of muscularis propria, and metastases at regional lymph nodes, or less frequently at distant sites. Also, occasionally poorly differentiated endocrine carcinomas have been found in patients with ZES/MEN-1. Type 3 CGs may be well-differentiated endocrine tumors or carcinomas, but usually are poorly differentiated endocrine carcinomas with high mitosis rates and Ki-67 values, and regional and distant metastases (Table 2). Moreover, recently, a tumor-node-metastasis (TNM) staging, and a grading system, based on the proliferative status (mitotic count and Ki-67 index) have been suggested for GCs[7] (Table 3), but remain to be validated in clinical practice.

DIAGNOSIS

Diagnosis is currently made during upper gastrointestinal endoscopy performed for a variety of clinical reasons, such as abdominal pain, gastrointestinal bleeding, anemia and dyspepsia. The diagnostic accuracy and the correct characterization of GCs necessitate extensive sampling from both the antrum (two samples) and body-fundus (four samples), in addition to biopsies/removal of the largest polyps. Proliferation rate and degree of dysplasia of gastric endocrine cells may often be difficult to identify with standard histopathological procedures. Histochemistry with chromogranin A (CgA) and synaptophysin assessment is of relevance in identifying hyperplasia, dysplasia and malignant transformation of ECL cells[20,25,26]. Also, immunohistochemical determination of the proliferative index Ki-67 and evaluation of the mitotic index, by counting number of mitosis per 10 high-power fields, are mandatory[27], with a negative prognostic meaning when Ki-67 is > 2% and mitotic index is > 2.

Endoscopy and sampling for histology are currently

considered sufficient when faced with small type 1 and type 2 GCs, reserving endoscopic ultrasound (EUS) for tumors > 1 cm in size[27]. EUS can give information about the location and depth of lesions and local spread, or even highlight the primary gastrinoma in GC-2. EUS can also allow fine-needle aspiration of submucosal lesions.

Computed tomography, magnetic resonance imaging and somatostatin receptor scintigraphy are required for larger tumors, those shown to be invasive by EUS, and type 3 GC, in order to detect distant metastases[27]. The minimal biochemical tests in GC patients include serum gastrin and CgA levels, the most important generic marker for neuroendocrine tumors, with evaluation of gastric juice pH. These tests should be performed at diagnosis. Moreover, determination of CgA could be of relevance in the course of follow-up[5,21,27].

PROGNOSIS

GCs are usually considered as largely benign in prognosis, even if it depends on the type of GC tumor and the extent of the disease. Prognosis ranges from an indolent course for type 1 GCs to the worst one for type 3 GCs.

Rappel and colleagues[28] reported an overall survival rate of 78% in 110 patients with GCs, with the highest rate (100%), when aged-corrected, in the 88 patients with GC-1. Therefore, the authors concluded that patients with GC-1 tumors have a life expectancy comparable to that of the general population. Type 2 GCs have a similar outcome to type 1 GCs, although their overall survival is closely related to the course of the associated gastrinoma, with a 5-year survival of 62%-75%[29]. Type 3 GCs have the worst prognosis and are typically associated with an overall 5-year survival of < 50%[2]. On the other hand, in an update of the SEER database study by Modlin *et al*[4], the 5-year survival rate was 63% for all GCs, 21.2% for metastatic disease, and only 69.1% in the subset of patients with localized lesions. Moreover, a cumulative analysis of GCs in the SEER database from 1992 to 1999 has indicated that distant metastases or regional spread were evident in 10%-30% of cases at the time of diagnosis, thus suggesting that the widespread opinion regarding the benign behavior of GC tumors should be revised.

A further frustrating finding is represented by the lack in the last 30 years of changes in mean overall survival for patients with GCs, as well as for those with other gastroenteropancreatic neuroendocrine tumors[9,30], despite the increased proportion of patients diagnosed at an earlier stage of the disease. However, it should be noted that many variables, other than types of GC, can affect the overall prognosis, such as age, gender, ethnicity, tumor size, depth of invasion, lymph node involvement, distant metastasis, degree of differentiation, and histological subtype.

MANAGEMENT

The clinical approach to GCs is largely dependent upon the type and size of lesions (Figure 1). Management of type 3 GC is fairly clear and comparable to that used for gastric adenocarcinomas, which includes partial or total gastrectomy with extended lymph node resection[1,3,12,16] in the absence of visceral metastases, or systemic chemotherapy if surgery is not feasible, even if, so far, the results are not very encouraging. The questionable efficacy of conventional cytotoxic chemotherapy has prompted investigation of novel therapeutic approaches for patients with advanced carcinoid. These include the use of targeted radiotherapy, as well as regimens incorporating inhibitors of angiogenesis (e.g. bevacizumab) and small molecule tyrosine kinase inhibitors (e.g. sunitinib). The treatment of metastatic liver disease includes hepatic resection, embolization of the hepatic artery, radiofrequency ablation and cryoablation[31].

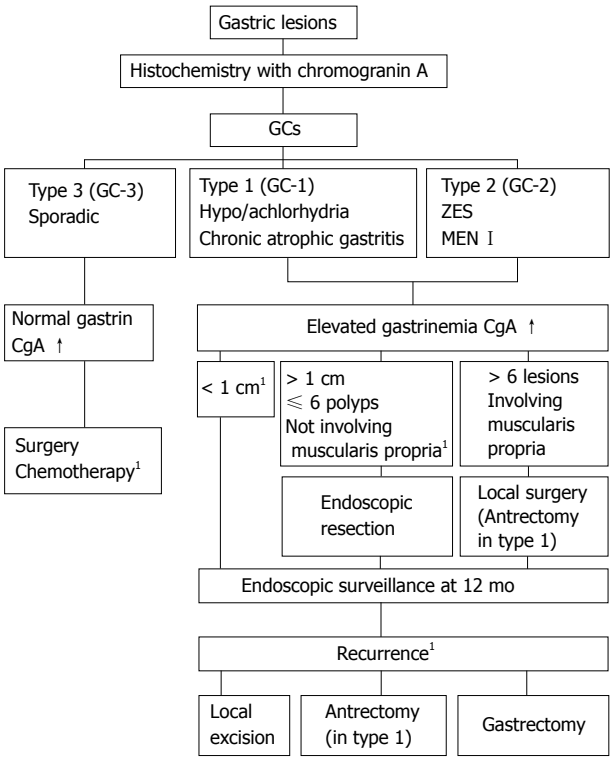

Figure 1 Management flow chart of GCs according to ENETS guidelines[26]. [1]Consider SSAs.

We consider the more controversial management of types 1 and 2 GCs, which are characterized by more benign biological behavior. In GC-1, a conservative approach based on endoscopic resection seems to be the treatment of choice when the size (< 1 cm) and the number (< 3-5) of the tumors render it feasible[1]. However, recently the European Neuroendocrine Tumor Society (ENETS) Consensus Guidelines[27] have suggested that annual surveillance is appropriate when dealing with patients with type 1 GC of less than 10 mm in size. This practical approach is supported by some reports[28,32,33] that suggest that the above careful endoscopic follow-up represents a reasonable and safe option in selected patients. However, further studies including a more consistent number of patients and

with an adequately long follow-up are necessary to support this statement. In fact, despite their usually benign biological and clinical course, type 1 GCs can sometimes exhibit a not entirely negligible mortality rate, as deducible from series with long follow-up[4]. In case of tumors > 10 mm and with up to six polyps not involving the muscularis propria at EUS examination, endoscopic resection remains the reference approach[27]. In the presence of deep gastric parietal wall invasion and positive margins following endoscopic mucosal resection, surgical resection of the tumor should be carried out[27]. Once again, it should be noted that, with these tumors often being multiple and recurrent, antral resection, aimed at avoiding chronic ECL cell stimulation by ongoing hypergastrinemia, is recommended, which is effective in 80% of type 1 tumors[27,34-36]. Moreover, in the case of malignant transformation or recurrence despite local surgical resection, partial or total gastrectomy with lymph node dissection should be performed, as suggested by current guidelines[27].

Overall, despite a generally benign prognosis, the recommended approach in selected subgroups of GC-1 patients appears disproportionately aggressive, and the long-term benefits of antrectomy are still uncertain[34]. Indeed, in some cases, the tumors may become autonomous and no longer gastrin-dependent, and therefore, continue to grow after antrectomy. An octreotide suppression test has been proposed[37] to predict the beneficial outcome from antrectomy, by measuring histidine decarboxylase (HDC) mRNA in the pre- and post-treatment biopsy specimens. In fact, HDC is the enzyme that catalyzes the synthesis of histamine from histidine in ECL cells, a process that is gastrin dependent. A marked decrease in HDC mRNA after octreotide administration indicates that the tumor is still likely to be gastrin dependent.

In extreme situations, i.e., when the biological behavior of the tumor is well defined and definitely benign or malignant, the current guidelines are clear and unambiguous. Conversely, they are less clear for GCs with uncertain behavior, which show atypical characteristics, such as elevated Ki-67, or submucosal invasion, even if they are smaller than 1 cm. Moreover in this situation, according to current guidelines, only endoscopic follow-up is indicated, therefore, information about deep invasion and margin infiltration is not available. At present, relevant controversies and doubts remain in these particular subgroups of patients. It should be stressed that the overall approach is based mainly on the tumor size, but this parameter may not represent the only prognostic factor. Recent studies[38,39] have suggested that proliferation indexes such as Ki-67 are of relevance, but the current best aggregate indicators of prognosis and malignancy seem to be the evidence of invasive growth and the presence of regional or distant metastases (TNM staging system)[38]. At present, however, the criteria to delineate the degree of malignancy remain unclear, and the histological analysis often fails to define precisely the likelihood of aggressive or metastatic potential.

Over the last few years, somatostatin analogues (SSAs) have been used in the treatment of patients with either GC-1 or GC-2[40-45], based on their capability to inhibit gastrin release from the antral G cells, thus reducing ECL cell hyperplasia. However, biotherapy is not currently recommended in patients with type 1 and 2 tumors, except in the rare patients with functioning tumors, and in type 2 patients if indicated for an underlying disease (i.e., other endocrine tumors). Preliminary reports[41] have shown that SSAs have some beneficial effects, for example, by reducing the size and number of carcinoids tumors after 6 mo of treatment. Moreover, the treatment with long-acting SSAs given at monthly intervals for a period of at least 6 mo produces significant suppression in gastrin and CgA levels[40]. Overall, however, the best schedule of treatment remains to be defined.

The management of type 2 GC has to be approached in the context of the MEN-1 syndrome that is present in these patients. As for type 1 GC, endoscopic treatment can be an option, whereas gastric surgery should be performed only in highly selected patients, particularly if the histological examination shows the features of poorly differentiated endocrine tumors. The treatment of type 2 GCs is further complicated by the controversies regarding the treatment of gastrinoma in MEN-1. Currently, no definitive evidence exists that surgery decreases the mortality in MEN-1 or the likelihood that clinically important metastases will develop. Then, the question of whether or not to recommend duodenal-pancreatic surgery in patients with MEN-1 who have pharmacologically controllable ZES and no other clinically evident hormonal excess syndrome is a difficult one. In these cases, the SSA octreotide has been demonstrated to be effective at reducing tumor growth[43].

CONCLUSION

A lot of controversies still exist about the optimal treatment of GC tumors. In fact, endoscopic follow-up could have some risk and is expensive, which leads to further examinations. On the other hand, a more aggressive approach, based on endoscopic or surgical resection may represent over-treatment, with possible unnecessary side effects and high costs. Treatment with long-acting SSAs may therefore represent an alternative option that, even if expensive, seems to be both efficient and safe. Based on the current lack of validated recommendations[40,41,44,45], SSAs should probably be reserved for tumors with atypical characteristics or for multiple small tumors, when surgery is not feasible or judged excessive, and when iterative endoscopic removal is too fastidious or impractical.

Abstract

In liver, the most intensively studied transmembrane and intracellular signal transduction pathways are the Janus kinase signal transduction pathway, the mitogen-activated protein kinases signal transduction pathway, the transforming growth factor β signal transduction pathway, the tumor necrosis factor α signal transduction pathway and the recently discovered sphingolipid signal transduction pathway. All of them are activated by many different cytokines and growth factors. They regulate specific cell mechanisms such as hepatocytes proliferation, growth, differentiation, adhesion, apoptosis, and synthesis and degradation of the extracellular matrix. The replication cycle of hepatitis C virus (HCV) is intracellular and requires signal transduction to the nucleus to regulate transcription of its genes. Moreover, HCV itself, by its structural and non-structural proteins, could influence the activity of the second signal messengers. Thus, the inhibition of the transmembrane and intracellular signal transduction pathways could be a new therapeutic target in chronic hepatitis C treatment.

Key words: Liver; Hepatitis C virus infection; Signal transduction pathway; Proliferation; Apoptosis

INTRODUCTION

Hepatitis C virus (HCV) was discovered by Choo *et al*[1]. in 1989. HCV is included in the Flaviviridae family within the distinct genus of *Hepacivirus*[2]. According World Health Organization (WHO) data, there are currently about 170 million HCV-infected persons worldwide, which is approximately 3% of the human population. In Poland, the number of chronic HCV-infected persons is estimated to be 750 000, which is about 1.4 % of the general population[3]. In the natural history of HCV infection, there is an 80% risk of chronic infection, as well as the high possibility of severe complications such as liver cirrhosis or hepatocellular cancer (HCC).

The main target cell for HCV infection is the hepatocyte, however the virus also infects B lymphocytes and affects other immune system components. The HCV replication cycle is intracellular and requires activation of many transmembrane and intracellular signal transduction pathways, which are mainly activated by cytokines such as tumor necrosis factor α (TNF-α), interleukins (IL-4, IL-6, IL-12 or IL-13), interferons, mitogens hepatocyte growth factor (HGF), epidermal growth factor (EGF) or transforming growth factor α (TGF-α) and growth inhibitors (TGF-β and activine).

TRANSMEMBRANE AND INTRACELLULAR SIGNAL TRANSDUCTION PATHWAYS

Janus kinase (JAK) signal transduction pathway

The JAK signal transduction pathway is activated by more than fifty different cytokines and growth factors. This intracellular pathway operates not only in hepatocytes but also in immune, hematopoietic and neural system cells. After extracellular ligand-receptor interaction, receptor multimerization and the activation

Table 1 STATs activation and function

STAT protein	Activating factor	Activation effect
STAT 1	IFN-α/β (type Ⅰ INF) IFN-γ (type Ⅱ INF)	Antiviral response, inflammation and hepatocyte damage development, apoptosis stimulation
STAT 2	INF-α/β i INF-λ	Antiviral response
STAT 3	IL-6 and its family, IL-10, IL-22, EGF, HCV proteins	Participates in antiviral IFN-α effect, direct cytoprotective and anti-inflammatory influence on hepatocytes
STAT 4	IL-12	Probably plays a critical role in hepatocytes damage during hepatic ischemia/reperfusion injury and in Th1 differentiation
STAT 5	Growth factors	Regulates the genes expression essential for hepatocytes metabolism, growth and differentiation
STAT 6	IL-4, IL-12 and IL-13	Participates in Th2 lymphocytes response during viral hepatitis and decreases hepatocytes damage during hepatic ischemia/reperfusion injury

of JAK1, JAK2, JAK3 and tyrosine kinase 2 (Tyk2) is observed. The receptor-kinase complex phosphorylates cytoplasmic SH-2-containing transcription factors: signal transducers and activators of transcription (STAT) 1, 2, 3, 4, 5, 6. Activated STATs present two main functions: signal and transcriptional by forming homo- and heterodimers, which translocate to the nucleus to influence transcription. STATs are specifically inhibited by protein inhibitors of activated STAT (PIAS)[4] and by suppressor of cytokine signaling (SOCS) through negative feedback control (Figure 1A). SOCS proteins include SOCS 1, 2, 3 and cytokine-induced Src homology 2 protein (CIS), which bind to JAK kinase inhibiting its enzymatic activity[5].

STATs perform different, often opposing functions in the liver. STAT1 is mainly activated by IFN type I (IFN-α/β) and IFN type Ⅱ (IFN-γ). Its essential function in liver is the participation in antiviral immune defense, as well as in the development of inflammation and apoptosis. IFN-α/β and IFN-λ are ligands for STAT2, whose major function is antiviral defense. Membrane the IFN-α/β receptor (IFNAR) is a complex of two subunits: IFNAR1 and IFNAR2. IFNAR2 presents three diverse forms: full-length IFNAR2c is responsible for signal transduction and transcription process, whereas short form IFNAR2b and soluble form IFNAR2a inhibit these processes[6]. The complex IFN-α/β - IFNAR activates JAK1 and Tyk2 kinases. IFN-γ takes effect by IFN-γ receptor (IFNGR): IFNGR1 and IFNGR2. STAT3 function is especially regulated by IL-6 and its family members such as cardiotrophin-1 (CT-1), oncostatin M (OSM), IL-11, leukemia inhibitory factor (LIF) or ciliary neurotrophic factor (CNTF), by IL-10, IL-22, EGF and HCV proteins. STAT3 participates in the acute phase response, stimulates hepatocytes regeneration and regulates lipid and carbohydrate metabolism in the liver[7]. Moreover STAT3 is one of the main anti-HCV-defense elements that acts by increasing the IFN-α antiviral effect and by its direct cytoprotective and anti-inflammatory influence on hepatocytes[8]. IL-6 and its related cytokines bind gp130 receptor protein, which plays a key role in liver regeneration.

Furthermore, Li *et al*[9] confirmed that gp130 activity is independent of the activities of other kinases, such as MAKP. The ligand-gp130 complex activates JAK1, JAK2 and Tyk2. Recently, the influence of HCV infection on STAT1-3 factors was demonstrated. HCV structural proteins C, E2 and non-structural protein NS5A were shown to reduce the number of membrane receptors (IFNAR1 and IFNAR2c) blocking STAT1-3 activation by IFN-α. STAT1-3 are also inactivated by ethanol and increased level of TNF-α, IL-1β and IL-10[7]. As a result, viral replication, as well as inflammation and fibrosis in the liver, is augmented and has a negative effect on IFN-α treatment response among patients with severe liver damage. However, HCV does not affect IFN-γ function, and in consequence, STAT1 activation[10]. Moreover, Sun and Gao showed that IFN-γ produced by NK cells inhibits hepatocytes regeneration during HCV infection[11]. STAT4 is the least known transcription factor. STAT4 has been shown to be activated by IL-12 and to play a critical role in hepatocytes damage during hepatic ischemia/reperfusion injury and in Th1 differentiation[12]. STAT5 is mainly activated by growth factors and regulates the expression of genes encoding cytochrome P450, HGF and insulin growth factor 1 (IGF1), which are essential for hepatocytes metabolism, growth and differentiation. STAT6 is regulated by IL-4, IL-12 and IL-13. These factors participate in Th2 lymphocytes response during viral hepatitis and reduce hepatocytes damage during hepatic ischemia/reperfusion injury. A summary of STATs activation and function are shown in Table 1.

MAPK signal transduction pathway

EGF, HGF and TGF-α bind with membrane receptors having intrinsic tyrosine kinase enzymatic activity. Ligand-receptor complex multimerization and autophosphorylation are then observed. Ras proteins and GTP create a transient complex activating RAF kinases and MAPK kinases (MKK), which can activate MAPK by dual phosphorylation of threonine and tyrosine. Activated MAPK phosphorylates transcription factors such as cAMP response element-binding (CREB) and Ets-related transcription factor 1 (ELK-1). The MAPK signal transduction pathway is evolutionarily one of the oldest signal transduction pathways in eukaryotic cells. It contains three different signal tracts: the extracellular regulated protein kinase (ERK, p42/44 MAPK) tract, the stress activated protein kinase (SAPK, p38 MAPK, p38-RK or p38) tract, and the c-Jun-NH2-terminal kinase (JNK, p64/54 SAPK) tract (Figure 1B). All of

these pathways regulate processes such as cell growth, differentiation, maturation, proliferation and apoptosis. In mammalian cells every single pathway is activated by two MKK: JNK by MKK4 and MKK7, ERK by MKK1 and MKK2, and SAPK by MKK3 and MKK6. This dual role of MKK in the activation of the JNK, ERK and SAPK signal transduction pathways is still unclear[13]. It has been shown that ERK play a key role in the regeneration of the majority of eukaryotic cells. However the role of SAPK, especially in hepatocytes regeneration, is as yet undefined. Physiologically, the activity of JNK in the liver is minimal but increases during liver regeneration, probably associated with high hepatic TNF-α levels[14].

TGF-β signal transduction pathway

TGF-β is cytokine family member that plays a key role in the processes of cell growth, differentiation, adhesion, apoptosis, and synthesis and degradation of the extracellular matrix. In the liver, during HCV infection, TGF-β is responsible for hepatocytes regeneration and fibrosis, and for epithelial cells proliferation and differentiation. TGF-β1 serum concentration in patients with chronic liver diseases, including chronic HCV infection, is higher the more severe the liver failure is, confirming the association between this cytokine and hepatic fibrosis[15]. Concurrently, in patients with chronic hepatitis C, TGF-β1 serum concentration decreases and normalizes after successful antiviral therapy[16].

The TGF-β membrane receptor consists of two subunits having intrinsic serine/threonine kinase enzymatic activity: the type Ⅰ receptor (TβR-Ⅰ) and the type Ⅱ receptor (TβR-Ⅱ). After binding of the ligand to TβR-Ⅱ, TβR-Ⅰ is phosphorylated in the GS domain containing many glycine and serine amino acids. Activated TβR-Ⅰ influences receptor-specific R-Smad proteins (Smads) and common-partner Smad (Co-Smad). SMADs are a class of proteins that modulate the activity of transforming growth factor beta ligands. Newly created complexes translocate to the nucleus and stimulate transcription and apoptosis[17] (Figure 1C). During liver regeneration, elevated TGF-β concentration is observed, though it does not give rise to an increase of hepatocytes apoptosis, which is probably linked with parallel augmentation of the concentrations of Smads: Ski and SnoN, and other antiapoptotic proteins such as Bcl-2 and Bcl-X in hepatocytes[18]. HCV, through the NS5A protein, inhibits TGF-β signal transduction pathway activity. NS5A reacts directly with TβR-Ⅰ using the region between amino acids 148 and 237. As a result, Smads phosphorylation, complex creation and its migration to the nucleus are blocked. In contrast, NS5B protein has no inhibitory effect on TβR-Ⅰ. TGF-β pathway inhibition can be the result not only of HCV infection, but also of other viruses such as hepatitis B virus (HBV), adenoviruses and HPV. This effect can be due to the direct interaction between the X protein and Smad4 (HBV), interaction between the E1 protein and R-Smad (adenoviruses) or through the inhibitory effect of the E7 protein on R-Smad and Co-Smad complex formation in the nucleus (HPV)[19].

TNF-α signal transduction pathway

TNF-α is produced by macrophages, monocytes, mast cells and NK cells. TNF-α is one of the main mediators of the antiviral inflammatory response, which enhances lymphocytes proliferation and differentiation, acute phase proteins production and cell apoptosis. Two essential TNF-α membrane receptors are known: TNF-R1 (CD120a, TNF-55r or p55) and TNF-R2 (CD120b or p75). TNF-R1 plays a key role in the liver due to its presence not only in hepatocytes membrane but also in Kupffer cells and hepatic sinusoidal endothelial cells. TNF-R1 consists of three domains: extracellular, transmembrane and intracellular (known as the death domain (DD). Activated TNF-R1 binds, *via* the DD, to an adaptor protein TNFR-associated protein with death domain (TRADD), which afterwards activates Fas associated death domain (FADD) proteins, TNF-associated factor-2 (TRAF-2) and receptor-interacting protein (RIP). All of these proteins influence different signal transduction pathways. FADD activates caspases 8 and 10 leading to Death-Inducing Signaling Complex (DISC) formation, which regulates apoptosis[20], whereas TRAF-2 and RIP activate two tracts taking part in the anti-apoptotic effect of TNF-α: IκB kinase (IKK) and nuclear factor kappa-light-chain-enhancer of activated B cells (NFκB factor), as well as JNK and ERK from MAPK signal transduction pathway[21] (Figure 1D). NFκB is a transcription factor comprising two subunits: p50 having a molecular weight of 50 kDa and p65 (also known as RelA, v-rel reticuloendotheliosis viral oncogene homolog A or nuclear factor of kappa light polypeptide gene enhancer in B-cells 3) having a molecular weight of 65 kDa. The RelA subunit is mainly responsible for the anti-apoptotic function of NFκB. In the cytoplasm, NFκB, with inhibitor proteins IκBα or IκBβ (IKK), creates the inactive form. TRAF-2/RIP activates IKK, which phosphorylates IκB leading to its subsequent degradation in proteasomes. Activated NFκB translocates to the nucleus where it binds with DNA through a zinc finger motif and stimulates transcription of genes encoding cytokines, acute phase proteins, immunoglobulins and adhesion factors[22]. TNF-α linked with TNF-R1 leads, depending on activated cellular proteins, to cell proliferation or apoptosis. Kato *et al*[23] showed that HCV core protein C and, to a lesser degree, NS4B protein, influence cell proliferation and production of proinflammatory cytokines such as IL-1, IL-2, IL-3, IL-6, IL-8, IL-12, TNF-α and INF-β stimulating three diverse pathways through NFκB, activator protein-1 (AP-1) and serum response element (SRE). AP-1 is a complex of homo- or heterodimers encoded by c-jun and c-fos family genes. Moreover, AP-1 stimulates proliferation dependent on growth factors, oncogenes and inflammatory peptides. SRE regulates the promoters of immediate early (IE) genes such as c-fos and PIP92. MAPK cascade activation phosphorylates Elk-1 factor binding with SRE and serum response factor (SRF)[24]. The thus created complexes affect transcription of genes taking part in cell proliferation.

Sphingolipid signal transduction pathway

Initially sphingolipids were demonstrated to be major components of eukaryotic plasma membranes and mediators of cell-to-cell interactions. Since 1989, many studies have shown that sphingolipids are also the essential second messengers in transmembrane and intracellular signal transduction. This new pathway was called the sphingolipid signal transduction pathway[25]. Generally,

it mediates specific cell reactions such as proliferation, growth arrest, differentiation, apoptosis and calcium homeostasis. It is activated by many proapoptotic and promitotic factors, such as cytokines TNFα and IL-1, Fas (Apo-1, CD95) receptor agonists, CD-40, CD-28, CD-5, DR-5, lymphocyte function-associated antigen-1 (LFA-1), CD-32 (FcγRII), CD-20, hormones (progesterone), vitamin D3, protein kinase C inhibitors, growth factors [platelet-derived growth factor (PDGF), epidermal growth factor (EGF), and nerve growth factor (NGF)], infection (by *P. aeruginosa, S. aureus, N. gonorrhoeae, Sindbis virus* and *Rhinoviru)*, γ radiation, UV and chemotherapeutics (such as doxorubicine and cisplatin)[26]. The final effect of pathway activation (cell survival or death) depends on the inductive factor and the balance between the intracellular levels of its main components: ceramide (Cer) and sphingosine-1-phosphate (S1P). This balance is known as "the Cer/S1P rheostat".

The most intensively studied second messenger of sphingolipid signal transduction pathway is ceramide, which is highly antiproliferative (Figure 1E). Firstly, Cer activates c-Jun kinase (JNK), stress activated protein kinases (SAPK), cathepsin D, methionine adenosyl transferase 1A (MAT1A) and caspase 3, which are responsible for destruction of the cytoskeleton, nuclear and plasma membranes[27]. Secondly, Cer stimulates the mitochondria to release reactive oxygen species (ROS) and cytochrome c, activating the apoptotic proteases[28]. Finally, Cer decreases, by dephosphorylation, the intracellular level of anti-apoptotic proteins of the Bcl-2 family and the activity of anti-apoptotic enzymes like kinases that depend on the intracellular Ca^{2+} levels [protein kinase C, (PKC), PKCα and PKCβa/Akt]. Paradoxically, Cer synthesized from the hydrolysis of sphingomyelin (SM) by neutral sphingomyelinases (NSMases), enhances the activity of the ceramide activated protein kinase (CAPK) and afterwards the serine/threonine kinase Raf and Akt, extracellular signal-regulated protein kinases (ERK 1/2) and the mitogen-activated protein kinase (MAPK). All these kinases stimulate the proliferation process[29]. Cer regulates the cell growth processes through its influence on PKC, kinase suppressor of Ras (KSR), Raf-1, MAPK and ceramide-activated protein phosphatase (CAPP), controlling the protein phosphatases PP1 and PP2. Cer also take a part in plasma membrane reorganization, facilitating transmembrane proapoptotic signal transduction and modulating the autophagocytosis[30]. Autophagocytosis relies on degradation of damaged, dead or used cell structures to prolong cell life. Cer inhibits autophagocytosis by stimulating apoptosis[31].

A further second messenger of sphingolipid signal transduction pathway is sphingosine (SFO). SFO is synthesized from the hydrolysis of Cer by ceramidases (CDases). SFO has a key role in apoptosis by stimulating ROS production in mitochondria and activation of caspase 3, 7 and 8[32]. Additionally, sphingosine inhibits Akt, resulting in the augmentation of the cellular effects of cytochrome c and caspase 3[33]. Moreover, SFO directly blocks DNA synthesis, methylation and replication. SFO also reduces the activity of protein kinases such as PKC, calmodulin-dependent protein kinase and insulin receptor kinase. The PKC inhibition proceeds in two parallel ways: directly and indirectly by decreasing the level of intracellular diacylglycerol (DAG) and Ca^{2+} ions. The PKC inhibition leads to disturbances of nuclear proteins phosphorylation (RNA polymerase, topoisomerase Ⅱ, histones and matrix proteins[34]). Some studies underline the proliferative character of SFO. It seems that low cellular concentrations of SFO stimulate cell proliferation and DNA synthesis, whereas the high concentrations stimulate apoptosis.

Sphingosine-1-phosphate (S1P), synthesized from SFO, has a potent anti-apoptotic character. An increase in the intracellular level of S1P can activate cell proliferation and its passing from G_1 phase to S phase, augment the general number of cells resting in S phase, shorten the time needed for cell division, enhance survival rate of cells subjected to proapoptotic factors, mobilize calcium ions from intracellular compartments, influence cytoskeletal architecture and the processes of cell migration and adhesion. S1P modulates cell functions in two different ways: as an intracellular messenger and as a ligand of G protein-coupled receptors, known as endothelial differentiation genes (Edg) - Edg-1, -3, -5, -6 and -8[35].

Cer may be phosphorylated by ceramide kinase to ceramide-1-phosphate (C1P), which can be dephosphorylated back to ceramide by C1P phosphatase. Similarly to S1P, C1P promotes cell proliferation[36].

Recently, some studies have shown that the inhibition of sphingolipid metabolism can be a new therapeutic target for HCV infection[37].

CONCLUSION

All phases of HCV replication cycle are intracellular and consequently require signal transduction to the host cell nucleus to regulate transcription of viral genes. Although the pathogenesis of transmembrane and intracellular signal transduction during HCV infection is still unclear, it has been shown that HCV could influence activity of the second signal messengers. This mechanism can regulate specific cell mechanisms such as hepatocytes proliferation, growth, differentiation, adhesion, apoptosis, and synthesis and degradation of the extracellular matrix, leading to severe complications of chronic HCV infection such as liver cirrhosis or hepatocellular cancer. For instance HCV, through the NS5A protein, inhibits the TGF-β, signal transduction pathway activity and through the core protein C and, to a lesser degree, the NS4B protein, influences production of proinflammatory cytokines such as TNF-α. Accordingly, it seems that the inhibition of the activity of the intracellular messengers and pathways could be a new therapeutic target for chronic hepatitis C treatment, leading not only to overall HCV elimination from hepatocytes and from other extrahepatic components, but also to decrease the possibility of developing chronic hepatitis C complications. Moreover, the discovery of the role of the JAK signal transduction pathway as the principal signaling pathway for IFN-α opens new research options for a better understanding of IFN-α resistance. HCV structural proteins C and E2 and non-structural protein NS5A have been shown to

reduce the number of membrane receptors IFNAR1 and IFNAR2c blocking STAT1-3 activation by IFN-α. As a result, viral replication, as well as inflammation and fibrosis in the liver, are augmented and has a negative effect on IFN-α treatment response among patients with severe liver damage. Therefore, a better understanding of these signaling defects might lead to new therapeutic strategies, making IFN-α therapy more effective in a larger percentage of patients with chronic hepatitis C infection.

Abstract

Chronic hepatitis B and C together with alcoholic and non-alcoholic fatty liver diseases represent the major causes of progressive liver disease that can eventually evolve into cirrhosis and its end-stage complications, including decompensation, bleeding and liver cancer. Formation and accumulation of fibrosis in the liver is the common pathway that leads to an evolutive liver disease. Precise definition of liver fibrosis stage is essential for management of the patient in clinical practice since the presence of bridging fibrosis represents a strong indication for antiviral therapy for chronic viral hepatitis, while cirrhosis requires a specific follow-up including screening for esophageal varices and hepatocellular carcinoma. Liver biopsy has always represented the standard of reference for assessment of hepatic fibrosis but it has some limitations being invasive, costly and prone to sampling errors. Recently, blood markers and instrumental methods have been proposed for the non-invasive assessment of liver fibrosis. However, there are still some doubts as to their implementation in clinical practice and a real consensus on how and when to use them is not still available. This is due to an unsatisfactory accuracy for some of them, and to an incomplete validation for others. Some studies suggest that performance of non-invasive methods for liver fibrosis assessment may increase when they are combined. Combination algorithms of non-invasive methods for assessing liver fibrosis may represent a rational and reliable approach to implement non-invasive assessment of liver fibrosis in clinical practice and to reduce rather than abolish liver biopsies.

INTRODUCTION

Chronic liver diseases (CLDs) represent a major cause of morbidity and mortality worldwide. The major etiologies are chronic infection with hepatitis B (HBV) and C (HCV) viruses, and alcoholic and non-alcoholic fatty liver disease. Chronic hepatitis B and C are the leading causes of cirrhosis and of hepatocellular carcinoma (HCC) worldwide. Approximately 400 million people are chronically infected with HBV and 25%-40% of them die of cirrhosis and of its end-stage complications[1]. HBV is the most important carcinogen after tobacco and the incidence of HCC is 300 000 cases per year[2]. Chronic hepatitis C is a major health concern with around 200 million individuals affected worldwide, with a greater prevalence in Western countries[3]. Natural history studies indicate that advanced fibrosis and cirrhosis develop in about 20%-40% of patients with chronic viral hepatitis[4,5]. Alcoholic liver disease (ALD) is one of the leading causes of end-stage CLD. It is well established that only a minority of heavy drinkers, estimated at between 10% and 30%, will ever develop advanced ALD and that the risk increases with cumulative alcohol intake[6,7]. Non-

alcoholic fatty liver disease (NAFLD) has become the most common cause of chronic liver disease and impaired liver function in industrialized countries, where 10%-23% of the adult population is estimated to be affected[8,9]. The disease has a spectrum ranging from fatty liver alone to non-alcoholic steatohepatitis (NASH), and progressive steatofibrosis. Many cases of cryptogenic cirrhosis may be end-stage forms of NASH[10]. Hepatic steatosis is currently considered a manifestation of metabolic syndrome[11,12], which is defined as an association of at least 3 of the following disturbances: insulin resistance, central obesity, arterial hypertension, and dyslipidemia, whether hypertriglyceridemia or low HDL-cholesterol levels. Only a percentage of individuals with liver steatosis progress to more advanced stages of the disease[8-10]. The pathogenesis of NAFLD and the reasons why some patients with fatty liver develop NASH and have progressive liver disease are not entirely understood. The most widely supported theory implicates insulin resistance as the key mechanism in NAFLD, leading to hepatic steatosis, and perhaps also to NASH. Obesity, type 2 diabetes, hyperlipidemia and other conditions associated with insulin resistance are generally present in patients with NAFLD[11,12]. A "two-hit" hypothesis has been proposed, involving the accumulation of fat in the liver ("first hit"), together with a "second hit" that produces oxidative stress. Hepatic steatosis has been recognised as the first of two hits in the pathogenesis of NASH, since the presence of oxidizable fat within the liver is enough to trigger lipid peroxidation[13]. However, many patients with fatty liver do not progress to steatohepatitis. Potential second hits for the evolution towards NASH include all mechanisms contributing to the development of inflammation and fibrosis. The presumed factors initiating second hits are oxidative stress and subsequent lipid peroxidation, proinflammatory cytokines (principally tumour necrosis factor alpha), and hormones derived from adipose tissue (adipocytokines)[12]. The progression of liver disease in CLDs presents with a common histopathological pathway which is the formation and accumulation of fibrosis leading to the development of progressive distortion of the hepatic architecture that is the hallmark of evolution to cirrhosis. Liver fibrosis is the result of chronic injury and it appears to play a direct role in the pathogenesis of hepatocellular dysfunction and portal hypertension[14,15]. Development of fibrosis is a progressive process starting from minimal fibrosis limited to the portal tracts, followed by more extensive fibrosis with septa expanding into the liver parenchyma, which can form bridges between two portal tracts or portal tracts and central veins, eventually ending in complete cirrhotic nodules. In patients with CLDs precise definition of the hepatic fibrosis stage is of paramount importance to evaluate the prognosis and the follow-up of the hepatic disease and to decide the need for antiviral therapy in HBV and HCV chronic infections. In CLDs liver biopsy has always been the gold standard for evaluating presence, type and stage of liver fibrosis and to characterize necroinflammation. This procedure, however, presents some limitations since it is invasive, costly and difficult to standardize. Recently, there has been increasing interest in non-invasive assessment of liver fibrosis by using surrogate markers measurable in the peripheral blood or by using instrumental devices, but some concerns about their large-scale clinical use have been raised, based on their performance and validation. This article aims to review the current status of the literature regarding non-invasive assessment of liver fibrosis in CLDs, considering its limitations and advantages. Finally, decisional algorithms to be applied to the most validated and reliable methods in clinical practice are here proposed.

Table 1 METAVIR and Ishak staging systems for liver fibrosis

Description	METAVIR (F)	Ishak (S)
No fibrosis	0	0
Portal fibrosis without septa	1	1-2
Portal fibrosis with few septa	2	3
Septal fibrosis without cirrhosis	3	4
Cirrhosis	4	5-6

Portal fibrosis is a stellate enlargement of portal tracts without any bridging fibrosis on the biopsy sample. Few septa means at least one fibrous septum on the core biopsy. Theoretically, a fibrous septum is a bridge of connective tissue between two portal tracts, a portal tract and a centrolobular vein, or between two centrolobular veins. Septal fibrosis means that the liver biopsy is crossed by several septa; the transition between F2 and F3 by METAVIR or S3 and S4 by Ishak begins when there are more fibrous septa than portal tracts without septa on the biopsy. Cirrhosis means that liver tissue is mutilated by nodular fibrosis that delineates hepatocytes nodules.

HISTOLOGICAL SYSTEMS TO STAGE LIVER FIBROSIS

Several semiquantitative scoring systems have been proposed to stage fibrosis and to grade necroinflammation in the liver. The Ishak's system is a revised version of the older histological activity index[16,17]. It describes grading and staging as two separate items and liver fibrosis is classified as absent (0), mild (1-2), moderate (3-4) and severe/cirrhosis (5-6). This classification system is mainly applied to hepatitis B and C. The METAVIR scoring system for staging has been frequently used in recent times particularly for chronic hepatitis C (Table 1)[18]. Brunt classification of fibrosis assessment is generally used for NASH and it includes five stages: stage 0, no fibrosis; stage 1, zone 3 perisinusoidal or pericellular fibrosis, focally or extensively present; stage 2, zone 3 perisinusoidal or pericellular fibrosis with focal or extensive periportal fibrosis; stage 3, zone 3 perisinusoidal or pericellular fibrosis and portal fibrosis with focal or extensive bridging fibrosis; stage 4, cirrhosis[19]. All these scoring systems have some limits, being semiquantitative, not linear and prone to intra- and inter-observer variation and to sampling variability.

LIVER BIOPSY: IS IT A GOLD OR A SILVER STANDARD?

Liver biopsy has long been the gold standard for staging of

Table 2 Pros and Cons of liver biopsy in staging of hepatic fibrosis

PROS	CONS
Staging of liver fibrosis	Invasiveness (pain, bleeding)
Grade of necroinflammation	Cost (hospitalization)
Steatosis (common in hepatitis C)	Sampling errors
Iron overload (common in hepatitis C)	Possibly refused by patient, concern of physician
Comorbidities (autoimmunity stigmates)	Static data, no information on fibrogenesis

liver fibrosis in CLDs. Liver biopsy has the advantage of obtaining direct information not only about fibrosis, but also about many useful parameters, such as inflammation, necrosis, steatosis, iron or copper deposits. Furthermore, it allows the identification of suspected or unexpected cofactors and comorbidities. However, biopsy is associated with potential morbidity and mortality and has several limitations (Table 2). A single liver biopsy provides static data but with no information on fibrogenesis and fibrolysis that characterise the dynamic processes related to extracellular matrix (ECM) metabolism. Moreover, many recent studies clearly indicate that liver biopsy is prone to sampling errors and may underestimate the amount of liver fibrosis. Cirrhosis could be missed on a single blind percutaneous liver biopsy in 10%-30% of cases[20,21]. When three different liver samples were analyzed, the percentage of correct diagnoses increased from 80% to 100%[22]. In more recent times, Regev *et al*[23] have shown that samples obtained from the right and left lobes of the liver during laparoscopy give different fibrosis staging in one third of cases, with a concordance rate of more than 90% between two experienced pathologists. Other studies have analyzed agreement/disagreement among pathologists. Although the use of more standardized scoring systems, such as those of the Ishak's, METAVIR's and Brunt's classifications, has improved the inter-observer and intra-observer variability, there are still several factors that may significantly influence the reliability of a liver biopsy. The size of the liver sample is very important, especially if we consider that a hepatic sample of 15 mm length represents 1/50000 of the whole parenchyma. Colloredo *et al*[24] have carefully analyzed the impact of the sample size on a correct staging of liver fibrosis in patients with hepatitis C. By reducing progressively the dimensions of the same liver biopsy, they reported that the smaller was the sample analyzed, the milder was the diagnosis made by the pathologist in relation to the stage of fibrosis. Other studies have reported that the type and the size of needle used are also important. The Tru-Cut needle was found to be superior to the Menghini needle, particularly for the diagnosis of more advanced fibrosis[25]. The use of a thicker needle ameliorates the accuracy of the diagnosis but also implies an increased risk of bleeding and perforation for the patient. Interestingly, Rousselet *et al*[26] reported that the degree of experience of the pathologist, as indicated by longer duration of practice or belonging to an academic setting, may have an outstanding impact on the diagnostic interpretation of liver biopsy, even higher than that determined by the one related to sample size. Another shortcoming of liver biopsy is its cost. A cost-benefit analysis showed that in the US the cost of a liver biopsy is 1032 USD and it could rise to 2745 USD when complications occur[27].

Table 3 Features of an adequate liver biopsy sample

LIVER BIOPSY: CONSENSUS AMONG PATHOLOGISTS?

Pathologists have tried to define the features (including length and number of complete portal tracts) of an adequate liver biopsy sample able to reduce the risk of misclassification of liver fibrosis (Table 3). Some authors would suggest that an adequate liver biopsy sample should contain more than 5 portal tracts and be at least 15 mm in length[28,29]. Other studies reported a higher threshold for optimized accuracy. Guido and Rugge have produced a critical review of the literature concerning the use of liver biopsy in chronic viral hepatitis[30]. They suggest that liver biopsy is very often flawed by unacceptable methodological limits and that a biopsy sample of 20 mm or more containing at least 11 complete portal tracts should be considered reliable for adequate grading and staging. Other authors have recommended even bigger samples, up to 25 mm in length[31]. Scheuer has recently concluded that "bigger is better"[32].

LIVER BIOPSY: CONSENSUS AMONG CLINICIANS?

The pathologist's need for obtaining a liver sample of adequate size is in contrast with the patient's need for a procedure causing limited pain and risks. Liver biopsy may in fact be a risky procedure for some patients, particularly for those with more advanced liver fibrosis. Indeed, one third of patients experience pain at the time of the procedure, and the proportion of 0.3%-0.6% of cases presents with serious adverse events like bleeding and even death in decompensated cirrhosis[33]. A French survey which interviewed 1177 general practitioners concluded that liver biopsy may be refused by up to 59% of patients with hepatitis C and that 22% of the physicians share the same concern for the invasiveness of the procedure[34]. On this topic, a survey assessing the consensus among Italian hepatologists on when and how to take a liver biopsy in chronic hepatitis C showed great divergence in the management of the same subgroup of patients[35]. A nationwide survey about assessment of liver fibrosis in hepatitis C among French hepatologist showed

that liver biopsy was still systematically performed by only 4% of respondents. Guidelines for the clinical use of non-invasive methods for assessment of liver fibrosis were required by 95% of the respondents[36].

THE IDEAL NON-INVASIVE METHOD FOR LIVER FIBROSIS

In view of all the shortcomings regarding liver biopsy, in the last decade clinical investigators have been searching for non-invasive methods for accurate information about liver fibrogenesis activity and fibrosis stage in patients with CLDs. Fibrosis is a structural change in the liver that accompanies chronic injury; fibrogenesis refers to the production of ECM. Fibrogenesis increases in response to injury and is essential to tissue repair. The key step in the pathophysiology of liver fibrogenesis is the balance between ECM deposition and removal. An excess of ECM produced after injury stimulates fibrolysis which is mediated by several specific matrix metalloproteinases (MMPs). The hepatic stellate cells (HSCs) are the major source of ECM[14]. Guidelines and Recommendations indicate that staging of liver fibrosis is the most important parameter for the definition of prognosis and for the subsequent management of the patient with CLD[37,38]. Natural history studies indicate that, if only an insignificant rate of patients without fibrosis will develop cirrhosis in the following 5 years, this percentage goes up to 20% for cases with portal fibrosis and to more than 40% for cases with septal fibrosis[39]. Moreover, the decision whether to start an antiviral therapy in cases of chronic viral hepatitis is highly influenced by the staging of liver fibrosis, since treatments are usually long, costly and cause side effects. Identification of patients with cirrhosis is essential to start screening for end-stage liver complications, including esophageal varices (OV) and HCC. International guidelines have defined two stages of liver fibrosis that significantly modify the management of the patients in clinical practice[37,38]: (1) Significant fibrosis, defined as a liver fibrosis stage (F) $\geqslant$ 2 according to METAVIR for hepatitis C or (S) $\geqslant$ 2 according to Ishak for hepatitis B. Significant fibrosis is a definitive indication to start antiviral therapy in chronic hepatitis B and in chronic hepatitis C due to difficult-to-treat genotypes (HCV-1 and HCV-4). For patients infected with HCV genotype 2 or 3 histological definition is not necessary except for those cases with relative contraindications, not motivated or elderly age. The recent Italian Guidelines on the management of chronic hepatitis B have underlined the importance of the stage of liver fibrosis not only in deciding who to treat, but also in deciding the first choice treatment: interferon for mild-moderate fibrosis and nucleoside/nucleotide analogues for cirrhosis, especially if decompensated[38]. (2) Hepatic cirrhosis, defined as liver fibrosis stage of (F) 4 by METAVIR and of (S) 6 by Ishak. Cirrhosis, even when fully compensated and still clinically occult, requires a different and more specific management than simple chronic hepatitis, including screening for OV with annual gastroscopy and for HCC with ultrasound and alpha-fetoprotein every 6 mo.

Table 4 Features of the ideal non-invasive method for liver fibrosis

Reliable (high diagnostic accuracy)
Widely available (simple, least expensive)
Providing information on both fibrosis stage and fibrogenesis activity
Validated by large-scale studies
Validated by independent studies (different authors from the proposing study)
Validated in various etiologies of CLDs (HCV, HBV, ALD, NAFLD)
Identifying clinically important fibrosis stages (significant fibrosis and cirrhosis)

CLDs: Chronic liver diseases; ALD: Alcoholic liver disease; NAFLD: Non-alcoholic fatty liver disease.

The ideal marker test would be able to accurately stage disease and also be sensitive to changes in fibrosis induced by the natural course of disease progression or by therapy (Table 4). Non-invasive methods for detecting liver fibrosis may be divided in two main groups: markers measured in peripheral blood, which could be single parameters or panels combining more parameters, and a technical device that measures the liver stiffness through transient elastography (fibroscan).

SERUM NON-INVASIVE MARKERS OF LIVER FIBROSIS

Among the proposed markers in the literature, some are directly linked to the modifications in ECM turnover occurring during fibrogenesis, the so-called "direct markers", while others reflect alterations in hepatic function but do not directly reflect ECM metabolism, the so-called "indirect markers"[14,15]. The direct markers of liver fibrosis include several glycoproteins (hyaluronan, laminin, human cartilage glycoprotein 39), the collagens family (procollagen Ⅲ, type Ⅳ collagen), the collagenases and their inhibitors and a number of cytokines connected with the fibrogenetic process (TGF-β1, TNF-α). These markers have a pathophysiologic rationale since they may be an expression of either deposition or removal of ECM, thus giving information on its metabolism. They may potentially be used not only to stage liver fibrosis, but also to assess the speed of liver fibrogenesis with the most relevant prognostic value, and also to estimate and monitor the efficacy of and the response to antifibrotic drugs. A limitation to the clinical use of direct markers of liver fibrosis is that they are not routinely available in all hospital settings. The indirect markers of liver fibrosis are biochemical parameters that are measurable in the peripheral blood. They are an indirect expression of liver damage and have a statistical association with liver fibrosis stage. While direct markers of liver fibrosis reflect the process of fibrogenesis, indirect markers satisfy the request for a simple and easy-to-perform marker. Both direct and indirect markers for liver fibrosis may be single or a combination of parameters (Tables 5 and 6). Most of them have been proposed and validated in chronic hepatitis C. Table 7 describes the accuracy of various

Table 5 Single serum non-invasive markers for liver fibrosis

Direct markers	Indirect markers
Hyaluronic acid	Platelet count
Laminin	AST, ALT
Procollagen Ⅲ	γGT
Type Ⅳ Collagen	γ-globulins
Metalloproteinases	Albumin
Inhibitors of metalloproteinases	Prothrombin time

serum non-invasive markers for liver fibrosis as reported in the literature. The performance of non-invasive markers is usually expressed as sensitivity, specificity, positive and negative predictive values (PPV, NPV), accuracy, and compared area under the receiving operating characteristic curve (AUROC).

Hyaluronic acid has been extensively studied in hepatitis C while few studies are available in other etiologies. Overall, a rather good accuracy of this marker in the different CLDs has been reported for detection of significant fibrosis, with an AUROC ranging from a minimum of 0.82 to a very good 0.92[40-46]. In a study conducted in 326 patients, the AUROC was 0.86 and the specificity was 95% for significant fibrosis while the AUROC was 0.92 and the specificity was 89.4% for cirrhosis when a cut off level of 110 μg/L was used[45]. However, another cohort study with more than 400 cases has reported an AUROC of only 0.73 for significant fibrosis[42]. In the same study, cirrhosis could be excluded with excellent NPV and sensitivity (100%) and with excellent AUROC (0.97) using a cut off level of 50 μg/L. Similar results were reported in another study of 486 patients in which hyaluronic acid levels < 60 μg/L excluded cirrhosis with 99% NPV[40]. In ALD the performance of hyaluronic acid for significant fibrosis varied significantly[43,46] while the marker showed very good performance for cirrhosis, with an AUROC of 0.93[46]. The results of a study conducted in 79 patients with NAFLD were also encouraging, since hyaluronic acid had a 0.92 AUROC value for cirrhosis[44]. On the basis of its good accuracy, especially for exclusion of cirrhosis, hyaluronic acid has also been used in panels combining other serum non-invasive markers for liver fibrosis. Recently it has been proposed in combination with AST-to-platelet ratio index (APRI) in hepatitis B. In this study, a combination of APRI > 1.5 and of hyaluronic acid > 300 ng/mL had 98.9% specificity and 93.7% PPV[47]. Laminin is another component of ECM that has been studied as a non-invasive marker. Serum levels of laminin have been used by several authors as a non-invasive parameter to assess liver fibrosis in ALD patients as well as in those presenting with viral hepatitis and hemochromatosis[48]. This determination, however, was progressively discontinued as it did not demonstrate superiority to those of other components of the ECM such as hyaluronic acid. It showed 77% accuracy for detection of significant fibrosis in hepatitis C in a detailed study on 243 patients with CLD[49]. With regard to NAFLD, however, the use of laminin serum levels could be further investigated since a single report, which investigated liver fibrosis in 30 overweight patients, showed a rather good accuracy (87%)[50]. Among the collagens, type Ⅳ collagen has been investigated as surrogate marker of liver fibrosis. Type Ⅳ collagen has been studied in hepatitis C and a good performance for significant fibrosis has been reported (AUC = 0.83)[51]. Murawaki *et al*[52] have compared the diagnostic performance of type Ⅳ collagen with that of hyaluronic acid in hepatitis C and reported the superiority of the latter marker. The role of type Ⅳ collagen has also been investigated in 112 patients with NAFLD and its performance has been compared with hyaluronic acid[53]. The results showed a better diagnostic accuracy for type Ⅳ collagen (0.828 *vs* 0.797 AUROC, respectively). Metalloproteinases (MMPs) and their inhibitors (tissue inhibitors of metalloproteinases, TIMPs) have also been proposed as surrogate markers of liver fibrosis. Those reported to have some clinical impact include MMP-2 and TIMP-1[54]. Boeker *et al*[54] reported a very high performance of MMP-2 in detecting cirrhosis (0.97 AUROC). Unfortunately, it has been difficult to obtain good standardization of the method for routine clinical use. Some authors proposed panels of direct non-invasive markers with the aim of increasing the accuracy of the single parameters. Fibrometer combines age, platelets, prothrombin index, AST, α-2-macroglobulin, hyaluronan and urea. In a few studies, the AUROC for significant fibrosis has been reported as 0.89 in hepatitis C, raising to an excellent 0.943 in patients with NAFLD[55,56]. Patel *et al*[57] proposed fibrospect which combines hyaluronic acid, TIMP-1 and α-2-macroglobulin. It showed an AUC 0.832 for METAVIR stages F2-F4 fibrosis with PPV and NPV of 74.3% and 75.8%, respectively. Another model, named Hepascore, combines bilirubin, γGT, hyaluronan, α-2-macroglobulin, age, and sex, and showed in hepatitis C and ALD a quite good performance for diagnosis of significant fibrosis, ranging from 0.78 to 0.85, and excellent performance for cirrhosis, ranging from 0.89 to 0.92[58,59]. Unfortunately, for both these combination panels large-scale, independent validation studies are lacking. The European Liver Fibrosis (ELF) study group proposed a panel of markers combining age, hyaluronan, type Ⅲ collagen and TIMP-1. In a cohort study of more than one thousand patients with a variety of CLDs the panel detected moderate or advanced fibrosis (Scheuer stages 3, 4) with a 0.77 to 0.94 AUROC in hepatitis C and ALD, respectively[60]. The panel has also been recently validated in 196 patients with NAFLD, with 0.90 AUROC for detection of severe fibrosis, that could increase to 0.98 when the original panel was combined with simple markers[61]. Similar results in terms of accuracy have been recently obtained in 112 consecutive pediatric patients with NAFLD[62].

AST-to-ALT ratio (AAR) was one of the first non-invasive markers proposed. It is easily available and without any cost but it showed a highly variable performance in the studies conducted on HCV patients: sensitivity was between 31.5% and 81.3%, specificity was between 55.3% and 97% and accuracy ranged from 60%-83.6%[63,64]. Another concern about this test may be that it does not identify significant fibrosis but only cirrhosis. In a prospective study, we have also validated AAR in 110 patients with chronic hepatitis B and we obtained 78.9% accuracy for the diagnosis of cirrhosis[65]. AST-to-platelet ratio in-

Table 6 Combinations of serum parameters for non-invasive diagnosis of liver fibrosis

Marker	Description	Settings in which validation exists	Ref.
AST/ALT	AST to ALT ratio	HCV, HBV	[63-65,71,72]

AUROC: Area under the receiving operating characteristic curve; MMP-2: Metalloproteinase 2; TIMP-1: Tissue inhibitor of metalloproteinases 1; ELF: European liver fibrosis study group; AAR: AST-to-ALT ratio; APRI: AST-to-platelet ratio index.

dex (APRI) is a simple and cheap ratio between AST and platelets, easily available in the clinical practice. It classifies both significant fibrosis and cirrhosis but around 50% of the cases result as unclassified. APRI performance is variable among the studies on hepatitis C: sensitivity ranges between 41% and 91%, specificity between 47% and 95% and accuracy between 60% and 82.7% for significant fibrosis; for cirrhosis, sensitivity ranges between 38.4% and 65.8%, specificity between 86.7% and 93% and accuracy between 60% and 88.4%[15,66,67]. We have also validated APRI in hepatitis B, obtaining 76.1% accuracy for the diagnosis of significant fibrosis and 79.2% for the diagnosis of cirrhosis[65]. Most recently, APRI has been modified into Lok index by adding alanine aminotrasferase (ALT) and international normalized ratio (INR), with further improvement of the diagnostic accuracy, particularly for cirrhosis[68].

Forns' index is a simple panel resulting from the combination of age, γGT, cholesterol and platelets. It does not give any information about cirrhosis, but only about significant fibrosis. Around half of the cases cannot be classified. In hepatitis C, the accuracy reported in various studies was variable (between 50% and 85%)[67,69]. We have also validated Forns' index in hepatitis B, obtaining 64.8% accuracy for the diagnosis of significant fibrosis[65]. It has been suggested that Forns' index might be less accurate in patients with HCV genotype 3 which is associated with very low cholesterol levels[70]. However, this has not been confirmed by other data[67]. In a study performed on 3690 patients with chronic hepatitis C, a combination panel derived from platelets, AST, and γ-globulin named Fibroindex showed 0.83 AUROC in predicting significant fibrosis[71]. However, following validation studies it showed a lower performance[72]. Another combination of simple markers named Fib-4 was recently proposed and it uses platelets, ALT, AST and age. It showed good performance for detection of severe fibrosis (0.85 AUROC) and even better for the diagnosis of cirrhosis (0.91 AUROC) in chronic hepatitis C[73]. The performance of the panel was also evaluated in a cohort of patients with chronic hepatitis B, with similar accuracy for diagnosis of significant fibrosis (0.81 AUROC)[74]. The validity of Fib-4 as a non-invasive marker for liver fibrosis has also been investigated in patients with HCV/HIV coinfection and the reported accuracy was 0.79 for significant fibrosis and 0.80 for cirrhosis[75]. Fibrotest is a patented test that combines γGT, total bilirubin, haptoglobin, α-2-macroglobulin, apolipoprotein A1, age and gender[76]. To date, it is the most validated non-invasive method for liver fibrosis in various etiologies: HCV, HBV, ALD, NAFLD and HIV/HCV coinfected. Between 2001 and 2008 more than 60 scientific studies have investigated fibrotest and 20 of them are independent with respect to the group that have commercialized the test. Overall, independent studies have investigated fibrotest in more than 3000 patients with CLD, mostly hepatitis C. The accuracy reported ranges from 70%-85%[15,67,76]. Fibrotest has been applied to hepatitis B patients and the accuracy reported varies between 83.3% and 87.3% for significant fibrosis and between 86.1% and 94.4% for the diagnosis of cirrhosis[65,77]. In HIV/HCV coinfected patients AUROC was 0.85 for significant fibrosis and 0.87 for cirrhosis[78]. Fibrotest was also validated in ALD, with excellent results, especially for cirrhosis (0.84

AUROC for significant fibrosis and 0.95 AUROC for cirrhosis)[79]. Fibrotest was also applied in 170 patients with NAFLD and the AUROC for significant fibrosis was 0.86[80]. These results in HIV/HCV coinfected, ALD and NAFLD cases need, however, further confirmation from independent groups. Some conditions may alter the result of fibrotest, including Gilbert syndrome and hemolysis. In these cases the clinician should be cautious in the interpretation of the result and the test should be repeated. Overall, among the various serum markers proposed in the literature, APRI and fibrotest are the most validated in all etiologies, and also validated in many independent studies.

TRANSIENT ELASTOGRAPHY (FIBROSCAN)

Apart from serum markers, another method for non-invasive assessment of liver fibrosis is the measurement of liver stiffness[81]. Transient elastography is measured through a device that is called fibroscan (Echosens, Paris) which is composed of an ultrasound transducer probe mounted on the axis of a vibrator. Vibrations of mild amplitude and low frequency are transmitted by the transducer, inducing an elastic shear wave that propagates through the underlying tissues. Pulse-echo ultrasound acquisition is used to follow the propagation of the shear wave and to measure its velocity, which is directly related to tissue stiffness: the stiffer the tissue, the faster the shear wave propagates. Transient elastography measures liver stiffness in a volume that is approximately a cylinder 1 cm wide and 4 cm long, between 2.5 cm and 6.5 cm below the skin surface. This volume is at least 100 times bigger than a biopsy sample. Fibroscan examination is painless, rapid (less than 5 min) and easy to perform at the bedside or in the outpatient clinic. The examination is performed on a non-fasting patient lying flat on his/her back, with the right arm tucked behind the head. The probe transducer is placed on the skin, between the rib bones at the level of the right lobe of the liver where biopsy would be performed. The operator performs 10 valid acquisitions and then the software of fibroscan calculates the median value. The software itself determines whether each measurement is successful or not. Results are expressed in kilo-Pascals (kPa). Liver stiffness values range from 2.5-75 kPa. The results are immediately available and are operator-independent[82]. The exam can be done after a short learning curve (about 100 examinations). The validity of a fibroscan result should be based on two important parameters: (1) the interquartile range (IQR), which reflects the variability of the validated measures, and should not exceed 30% of the median value; (2) the success rate, that is the percentage of valid measurement, should be at least 60%. Despite the exam being relatively easy to perform, the clinical interpretation of results should always be in the hands of an expert clinician who should have at his disposal all clinical information regarding the patient. The result of the fibroscan is given according to cut-off values expressed in kPa: according to the various studies, presence of significant fibrosis is defined by a cutoff value of 7.1 to 8.7, and cirrhosis is diagnosed by a cutoff value of 12.5 to 14.5[83,84]. In various studies, the accuracy of fibroscan results were similar to that of serum non-invasive markers for the diagnosis of significant fibrosis, sometimes with inadequate figures (< 80%). On the other hand, fibroscan showed excellent performance for the diagnosis of cirrhosis (Table 8)[85]. Liver stiffness measurements can be difficult in obese patients or in those with narrow intercostal space and impossible in patients with ascites[81]. Failure rates range between 2.4% and 9.4% in the different studies[81-83,86]. Factors associated with inter- and intra-observator variability were BMI > 25, high grade hepatic steatosis and mild fibrosis (F0-F1 by METAVIR)[82]. A single report suggested that transaminase flares during chronic HBV infection may alter the result of fibroscan because of high flogosis and recruitment of inflammatory cells into the liver parenchyma[87]. Interestingly, a report suggested that acute viral hepatitis increases liver stiffness measured by fibroscan, thus the authors recommend that the extent of necroinflammatory activity needs to be carefully considered in future studies, particularly in patients with absent or low-stage liver fibrosis[90]. Non-invasive assessment of liver fibrosis with fibroscan has also been applied to ALD with 0.91 AUROC for significant fibrosis and 0.92 for cirrhosis[91]. Table 9 summarizes the main limitations of fibroscan. A recent meta-analysis concluded that for the diagnosis of significant fibrosis, transient elastography cannot be used sufficiently in clinical practice. Inclusion of transient elastography in an algorithm with a combination of non-invasive serum markers may be considered[92]. Transient elastography can be used in clinical practice as an excellent tool for the confirmation of cirrhosis when other clinical signs and examinations are non-decisive.

Table 8 Accuracy of fibroscan for the diagnosis of significant fibrosis and cirrhosis

COMBINATION ALGORITHMS AND IMPLEMENTATION OF NON-INVASIVE METHODS FOR LIVER FIBROSIS IN CLINICAL PRACTICE

The accuracy of most non-invasive methods for liver fibrosis showed variability among different studies and is still considered inadequate to substitute for liver biopsy and for implementation of non-invasive markers for liver fibrosis in clinical practice[15,29,93]. Some preliminary

Table 9 Limitations of fibroscan in clinical practice

Difficult to perform in obese patients (5% rate failure)
Inter-observer and intra-observer variability influenced by liver steatosis
Influence of ALT flares (HBV reactivation)
Lower performance for diagnosis of significant fibrosis

studies suggested that accuracy of non-invasive methods may improve when they are combined in diagnostic algorithms. We have recently proposed an approach that combines APRI and fibrotest sequentially with the aim of increasing the diagnostic accuracy[67]. This is a rational approach for the use of non-invasive markers for liver fibrosis in clinical practice. Indeed, these markers are used when they present with adequate accuracy, while liver biopsy is used only in those patients in which non-invasive markers showed inadequate accuracy. This approach has been named SAFE (Sequential Algorithms for Fibrosis Evaluation) biopsy and its aim is to reduce the number of liver biopsies that are necessary to correctly stage liver fibrosis and to minimize misclassified cases. Through stepwise modeling, two algorithms were developed with the aim of correctly classifying the two stages of liver fibrosis that are clinically significant: (1) significant fibrosis, (2) cirrhosis. The modeling of the algorithms was aimed at achieving > 90% accuracy and minimizing misclassified cases. In the model APRI has been used as first line test since it is cheap and simple, fibrotest has been used as second line test since it is costly and more complex. Liver biopsy has been used only as third line test in those cases in which the two non-invasive markers did not show adequate accuracy and/or in unclassified cases (only for APRI) (Figures 1 and 2). The modeling of the stepwise algorithms was based on the predictive values of the single markers. In the algorithm for significant fibrosis (Figure 1), 0.5 cut-off of APRI had low NPV to exclude significant fibrosis, while 1.5 cut-off showed high PPV to diagnose significant fibrosis. Similarly, 0.49 cut-off of fibrotest showed high PPV to diagnose significant fibrosis, whereas values less than 0.48 could not accurately exclude significant fibrosis. In the algorithm for cirrhosis (Figure 2), 1 cut-off for APRI showed high NPV to exclude cirrhosis, while 2 cut-off did not show sufficient PPV to diagnose cirrhosis. Similarly, 0.48 and 0.75 cut-offs of fibrotest showed good NPV and PPV, respectively, for cirrhosis, while intermediate values could not give accurate diagnosis.

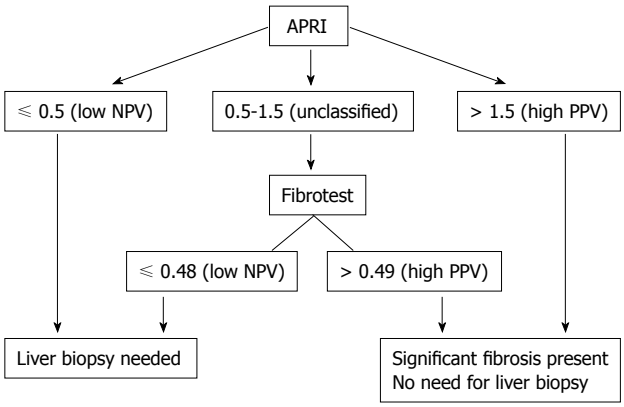

Figure 1 The SAFE-biopsy algorithm for significant fibrosis (≥ F2 by METAVIR). The figure reports the cut-offs used for APRI and Fibrotest in the decisional tree.

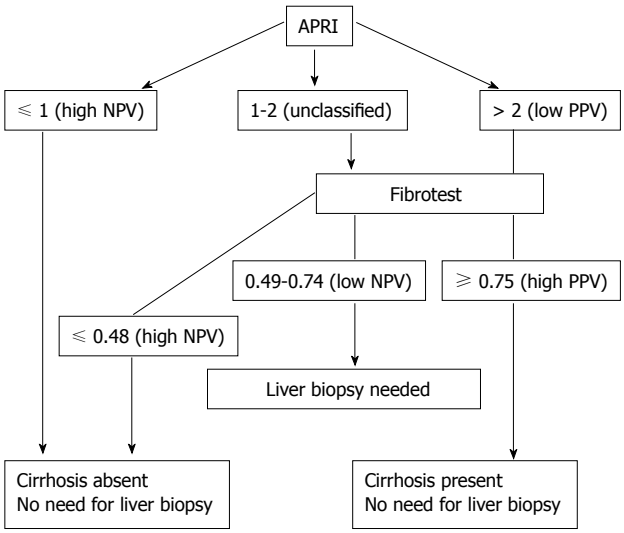

Figure 2 The SAFE-biopsy algorithm for cirrhosis (F4 by METAVIR). The figure reports the cut-offs used for APRI and Fibrotest in the decisional tree.

IMPLEMENTATION OF SAFE BIOPSY IN CLINICAL PRACTICE

In clinical practice, SAFE biopsy can provide the following responses: (1) Presence of significant fibrosis, then indication to administer antiviral therapy; (2) Presence of liver cirrhosis, then indication to specific follow-up with abdominal ultrasound, α-fetoprotein and gastroscopy; (3) absence of cirrhosis; (4) liver biopsy needed to correctly stage hepatic fibrosis.

The main concept of SAFE biopsy is that liver biopsy cannot be completely avoided but can be markedly reduced and limited to those cases in which serum markers for liver fibrosis do not show enough accuracy. Indeed, SAFE biopsy may avoid the diagnostic funnel represented by liver biopsy and it may stimulate general practitioners and patients to perform the initial screening for CLD. With this approach, liver biopsy and non-invasive markers for liver fibrosis are not antagonists, but they are agonists towards the common goal of correctly classifying liver fibrosis. SAFE biopsy has been recently validated in a multicentre, international study on serum non-invasive markers for liver fibrosis. This study, named SAFE protocol protocol, has enrolled more than 2500 cases of patients with CLD in whom APRI and fibrotest were available and liver histology was used as reference standard. The centers involved were from Italy, US, France and Romania. To date, this is the largest independent study on non-invasive methods for liver fibrosis. We have recently presented the results on 2035 cases with hepatitis C and they have confirmed high accuracy and high number of saved liver biopsies[94] (Table 10). The results of an interim analysis conducted on 210 HBV patients also showed high ac-

curacy (> 90%) of SAFE biopsy algorithms for both significant fibrosis and cirrhosis, with a percentage of saved liver biopsies ranging from 45%-82%. We have also compared in 1013 HCV cases the performance of SAFE biopsy with another two algorithms combining non-invasive markers for liver fibrosis that were then proposed: Fibropaca algorithm, based on concordance of Forns' index, APRI and fibrotest; Leroy algorithm, based on concordance of APRI and fibrotest[95-97] (Table 11). Fibropaca algorithm and SAFE biopsy showed a similar accuracy but the latter saved more liver biopsies and allowed us to perform a minor number of non-invasive markers, with a consequent saving in terms of costs. The main advantages of SAFE biopsy include a larger first level screening of liver fibrosis, higher patient compliance and lower screening costs. In some specific settings, SAFE biopsy may show even more efficient results when compared with the diagnostic funnel represented by liver biopsy alone.

ALGORITHMS FOR IMPLEMENTATION IN CLINICAL PRACTICE

Castera *et al*[83] have recently proposed an algorithm which combines fibrotest and fibroscan with the aim of increasing the accuracy of the single non-invasive methods in hepatitis C. This algorithm results in an increased accuracy, especially for the diagnosis of significant fibrosis. A recent collaborative study was aimed at comparing the algorithm combining fibroscan and fibrotest (named Bordeaux algorithm) and SAFE biopsy in 302 patients with hepatitis C[98] (Table 12). The results showed that the Bordeaux algorithm saved more liver biopsies for diagnosis of significant fibrosis, although both algorithms saved a similar number of overall liver biopsies, and Bordeaux algorithm showed a higher overall accuracy for diagnosis of cirrhosis. On the other hand, Bordeaux algorithm uses fibrotest and fibroscan in all patients, while SAFE biopsy uses fibrotest in a subgroup of patients that are not well classified by APRI, which has virtually no cost. The two algorithms could be used for large scale screening of liver fibrosis and the choice of the algorithm may be based on the local availability of the non-invasive methods. Interestingly, the use of either fibroscan or fibrotest has been recently recommended in France by the Haute Autorité de Santé for the first line assessment of liver fibrosis in patients with hepatitis C without comorbidities[85]. Figure 3A and

B show a rational proposal for the use of non-invasive methods for liver fibrosis in clinical practice, based on the local availability of the different methods and on their performances. A combination approach for clinical use has also been proposed by others[99]. Non-invasive methods for liver fibrosis and combination algorithms may be of paramount importance for the monitoring of progression of liver disease. Indeed, if it is acceptable to perform a liver biopsy at time 0, it is inconceivable however to perform a liver biopsy every year to monitor liver fibrosis progression, while this is feasible with non-invasive methods for liver fibrosis. According to local availability of the methods and attainment of non-invasive markers by the clinician, two different approaches may be used: (1) to fix the value with combined use of biopsy and non-invasive markers at time 0 and then monitoring with non-invasive markers; (2) to use non-invasive markers and then perform a liver biopsy when clinically necessary (Figure 4A and B).

MONITORING OF EFFICACY OF ANTIVIRAL THERAPIES

Apart from the diagnosis of liver fibrosis stage, few recent studies have focused on the possible use of non-invasive methods for liver fibrosis in the monitoring of antiviral therapies. Indeed, especially in hepatitis B, antiviral therapies may be long-term, such as treatments with nucleoside/nucleotide analogues, and the clinician may want to know not only the biochemical or virological response, but also and more appropriately the histological

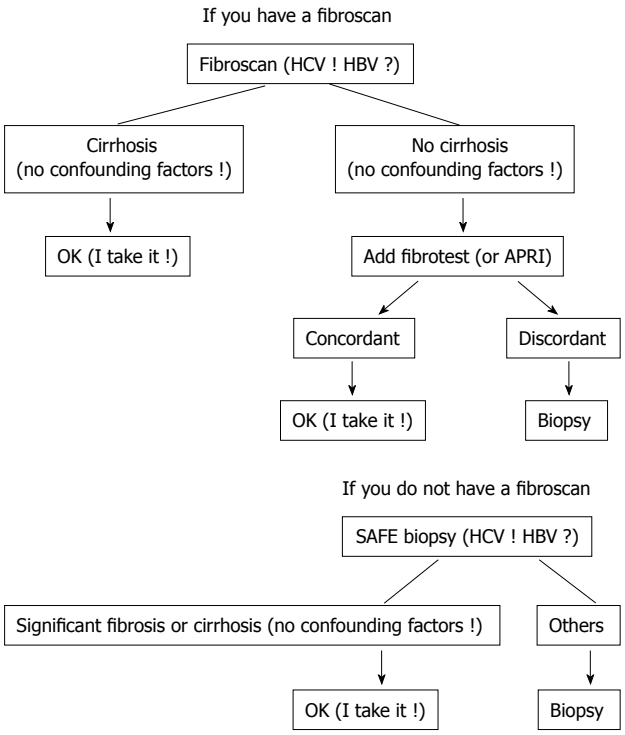

Figure 3 Diagnostic algorithms for implementation of non-invasive methods for liver fibrosis in clinical practice based on the local availability of the most validated methods.

response. Initial reports have shown that both fibrotest and fibroscan values change significantly during and after antiviral therapy in both hepatitis C and B[100-102]. Indeed, a significant improvement in fibrotest and fibroscan value has been reported in patients who achieve sustained virological response (SVR) *vs* those without SVR, and in some cases this was also maintained for 12 mo after therapy[101]. This may mean that there is a regression of liver fibrosis with antiviral treatment but further prospective, large-scale studies are needed.

MONITORING OF LIVER DISEASE COMPLICATIONS

A very attractive application of non-invasive methods for liver fibrosis may be the monitoring of liver disease complications to predict clinical events in compensated cirrhosis. Preliminary results suggest that liver stiffness values in cirrhotic patients may increase as liver disease is more advanced. In a retrospective study of 711 patients with CLD (95 with histologically-proven cirrhosis), liver stiffness values significantly correlated not only with the Child-Pugh score but also with clinical parameters (past history of bleeding varices or ascites, HCC), biochemical parameters (platelets, INR, factor V, albumin and bilirubin) and others (2-3 grade OV, splenomegaly on sonography, nodular surface, heterogeneous parenchyma) of liver disease severity[86]. Cut-off values of 27.5, 37.5, 49.1, 53.7 and 62.7 kPa had > 90% NPV for the presence of grade 2-3 OV, Child-Pugh scores B or C, past history of ascites, HCC and esophageal bleeding,

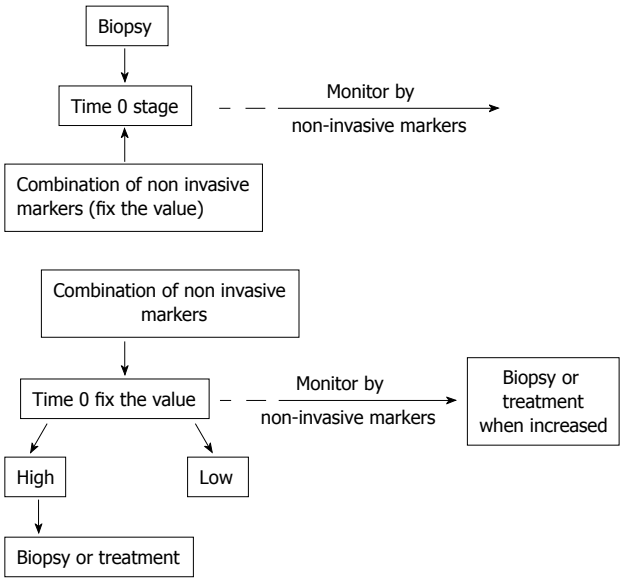

Figure 4 Perspectives for the use of non-invasive markers for long term monitoring of chronic liver diseases.

respectively. More recently, Vizzuti *et al*[103] reported a rather high sensitivity (90%) of fibroscan for prediction of OV with 17.6 kPa cut-off. Other preliminary studies have suggested that some non-invasive markers for liver fibrosis could predict the presence of OV. Sanyal *et al*[104] reported high NPV for excluding grade 2-3 varices when platelets were > 150 000/mm^3. Giannini *et al*[105] reported a good sensitivity (91.5%) with an overall accuracy of 86% for diagnosis of OV with a 909 cut-off of platelet count to spleen diameter ratio. A recent multicenter, international study was aimed at investigating in 510 consecutive cirrhotic patients the role of 7 simple non-invasive markers for liver fibrosis in predicting the presence of OV of any grade and of grade 2-3 OV[106]. The markers analyzed were platelets, AAR, Lok index, APRI, Forns' index, Fib-4, Fibroindex. Presence of grade 2-3 OV could be excluded with > 96% NPV by a specific cut-off of Lok index (1.5). None of the tests were able to predict the presence of grade 2-3 OV due to low PPV. A combination of Lok index (cutoff 0.9) and Forns' index (8.5) could predict the presence of OV of any grade with 88% PPV, 83% accuracy and 0.82 AUC. The conclusion was that, even if simple non-invasive markers for liver fibrosis cannot be a substitute for endoscopy for OV screening, they may be used to stratify cirrhotics by risk. In a recent prospective study of 298 patients with chronic hepatitis C, the performance of fibroscan, fibrotest and simple serum markers for detection of cirrhosis and its complications have been assessed[107]. The authors concluded that fibroscan is the most accurate method for diagnosis of cirrhosis but it cannot replace endoscopy for screening of OV. These preliminary findings are promising but need to be confirmed in long-term prospective follow-up studies.

Several recent studies have reported a correlation between liver stiffness values and portal hypertension,

assessed by measurement of hepatic venous pressure gradient (HVPG) which is considered the gold standard for the diagnosis and staging of portal hypertension[103,108-110]. Carrion *et al*[108] reported a close direct correlation between liver stiffness values and HVPG in 124 HCV-infected liver transplant recipients. More recently, Vizzutti *et al*[103] reported similar results in 61 patients with HCV-related severe CLD (METAVIR F3-F4). Other authors have failed to find similar results[111].

THE FUTURE: GENETICS FOR THE IDENTIFICATION OF PATIENTS WITH CHRONIC LIVER DISEASES AT RISK OF PROGRESSION

The identification of patients at high risk of developing progressive liver disease on the basis of genetic profile may be extremely useful in the future. A recent collaborative study used seven genetic variants to identify patients with hepatitis C at risk for developing cirrhosis, based on the analysis of paired liver biopsies. A cirrhosis risk score (CRS) was calculated on the basis of seven single nucleotide polymorphisms and the patient's gender[112]. In this case, increasing CRS was associated with fibrosis progression in HCV patients presenting with no liver fibrosis. CRS genetic signature could potentially be a useful prognostic indicator of those patients with HCV infection most likely to develop fibrosis progression and/or cirrhosis.

HIGHLIGHTS

Staging of liver fibrosis is essential in clinical practice for the management of patients with CLDs. Nowadays liver biopsy can no longer be considered the exclusive tool for the diagnosis of liver fibrosis since the available data support a rational use of the most validated non-invasive methods for liver fibrosis and especially of their combination algorithms. This is particularly true for chronic hepatitis C, where an adequate validation of some non-invasive methods for liver fibrosis exists. Non-invasive methods for liver fibrosis, when combined, may reduce by 50%-80% the number of liver biopsies needed for correctly classifying hepatic fibrosis. However, liver biopsy cannot be completely avoided but should be used in those cases in which non-invasive methods show poor accuracy. In clinical practice, the choice of the non-invasive method and, especially, of the combination algorithms may depend on their performance and on local availability. Further studies, especially in chronic hepatitis B, ALD and NAFLD, are needed to better assess performance of non-invasive markers in these settings and to develop rational algorithms for implementing non-invasive assessment of liver fibrosis. Future studies should also focus on non-invasive monitoring of antiviral treatment efficacy and cirrhosis complications, and genetic studies for precocious identification of patients who are at high risk of developing end-stage liver diseases.

Abstract

Stomach cancer is still the fourth most common cancer; thus, it remains an important public health burden worldwide, especially in developing countries. The remarkable geographic variations in the rates of stomach cancer indicate that dietary factors, including a range of food groups to which salt and/or nitrates have been added, may affect stomach cancer risk. In this paper, we review the results from ecologic, case-control and cohort studies on the relationship between salt or salted foods and stomach cancer risk. The majority of ecological studies indicated that the average salt intake in each population was closely correlated with gastric cancer mortality. Most case-control studies showed similar results, indicating a moderate to high increase in risk for the highest level of salt or salted food consumption. The overall results from cohort studies are not totally consistent, but are suggestive of a moderate direct association. Since salt intake has been correlated with *Helicobacter pylori* (*H pylori*) infection, it is possible that these two factors may synergize to promote the development of stomach cancer. Additionally, salt may also cause stomach cancer through directly damaging gastric mucus, improving temporary epithelial proliferation and the incidence of endogenous mutations, and inducing hypergastrinemia that leads to eventual parietal cell loss and progression to gastric cancer. Based on the considerable evidence from ecological, case-control and cohort studies worldwide and the mechanistic plausibility, limitation on salt and salted food consumption is a practical strategy for preventing gastric cancer.

Key words: Disease prevention; *Helicobacter pylori* infection; Salt consumption; Stomach cancer

INTRODUCTION

Stomach cancer is the fourth most common cancer and is the third leading cause of cancer death worldwide[1-3]. The estimated number of stomach cancer cases worldwide was 933 900 in 2002, with two-thirds occurring in developing countries[3]. Tremendous variation in both incidence and mortality rates exists across geographic regions, with > 10-fold differences observed between low-risk and high-risk areas[4]. Although stomach cancer incidence rates have been decreasing slowly over recent decades in China, it was estimated that there were 0.4 million new cases diagnosed and 0.3 million deaths from this malignancy in 2005[5]. Therefore, this disease remains an important public health burden throughout the world, especially in developing counties including China.

Several risk factors for stomach cancer have been identified, including *Helicobacter pylori* (*H pylori*) infection, salt-preserved foods, dietary nitrite, smoking, alcohol, obesity, radiation, and family history[6,7]. Researchers also found that the incidence rates of stomach cancer varied across different geographic regions and this variation may be associated with genetic, lifestyle or environmental

factors, including diet[8]. Salt intake was first reported as a possible risk factor for stomach cancer in 1959[9]. In some early studies, using refrigerators for food storage, which may be an indicator of less salted food consumption or decreased salt intake, was found to be correlated with a reduction in stomach cancer rates[10,11], leading researchers to hypothesize that salt intake may play a role in the development of stomach cancer. A Japanese ecological study suggested a nearly linear correlation between the cumulative mortality rate of stomach cancer and the median 24 h urine salt excretion level[12,13]. Experimental studies[14,15], including rodent models, have also suggested that salt may play an important role in the etiology of stomach cancer. Based on the available experimental and epidemiological data, a report from World Health Organization (WHO)/Food and Agriculture Organization (FAO) Expert Consultation in 2003 concluded that "salt-preserved foods and salt probably increase the risk of stomach cancer"[16].

The purpose of this paper was to review the current literature on salt consumption and the risk of stomach cancer. We obtained the relevant papers and identified our literature search through PubMed from SCI papers. All cohort papers were selected with cohort size more than 2000; case-control papers were filtered out with case sample size around or more than 100. At the end, we summarized the evidence from epidemiological perspectives regarding salt intake and stomach cancer risk.

EPIDEMIOLOGICAL STUDIES OF SALT AND STOMACH CANCER RISK

When evaluating epidemiologic studies on the relationship between salt or salted food consumption and stomach cancer risk, it is essential to consider the diversity of salted foods. Some studies analyzed overall dietary salt intake, whereas others evaluated stomach cancer risk associated with salt intake in various categories, such as table salt or salted fish.

Ecologic studies

Several ecologic studies reported positive associations between different indicators of salt consumption and stomach cancer mortality at the population level[17-21]. In an ecologic study of 24 countries, median urinary sodium levels, ascertained on randomly selected samples from each country, were significantly correlated with stomach cancer mortality (r = 0.70 in men; 0.74 in women) (both $P < 0.001$)[17]. Another study evaluated correlations between both salt intake and 24 h urinary sodium excretion and stomach cancer mortality among men in four geographic regions of Japan, and reported a strong correlation between stomach cancer mortality and salt excretion, but not with dietary salt intake[21]. An ecologic study of stomach cancer mortality in 65 Chinese counties observed significant, yet modest, correlations for intake of salt-preserved vegetables (r = 0.26 in men and 0.36 in women)[18]. A Japanese study administered a 38-item food frequency questionnaire to a sample of 634 men and the wives of 373 of these men from five districts in Japan. The rank correlation coefficient between gastric cancer mortality and pickled vegetable consumption was 0.36[19]. In a similar study of 207 Japanese men and the wives of 165 of the men, average daily sodium consumption, estimated using a 3 d weighed food record, was correlated with stomach cancer mortality rates (partial rank r = 0.45)[20].

In summary, the majority of ecological studies indicated that the average salt intake in each population was closely correlated with gastric cancer mortality. However, employing dietary assessment methods in these studies has some limitations, such as variation of the questionnaire validity in different population, and use of the same composition table calculating salt intake in diverse dietary cultures. One validated questionnaire used by one population may not be appropriate or valid for another population; thus in population based studies, dietary estimates may not be highly accurate and the association between dietary factors and disease may be much compromised. Applying the same composition table to calculate the same food in different dietary culture may cause bias, since the same food in different areas may have different salt content. For example, the regional average salt content of miso in 39 regions of 20 prefectures across Japan ranged from 9.1% to 18.2%[22]. Furthermore, as with all ecologic studies, diet and stomach cancer were neither measured nor analyzed on the individual level. Rather, the diets of sampled individuals were used to represent entire populations or geographic regions. Thus, misclassification is an obvious concern. Furthermore, associations observed at the population level cannot be assumed to hold at the individual level, and causality cannot be inferred from this type of study.

Case-control studies

Forty two case-control studies on salt consumption in relation to stomach cancer are presented in Table 1[23-64]. Of these, twenty two studied overall salt, table salt or sodium[23-44], twelve estimated salted/dried fish and/or salted fish gut or cod roe[25,39,45-54], six investigated salted or pickled vegetables[25,32,52-55], three focused on salty snacks[41,56,57], and twelve studied salted foods in general[29,30,32,52,54,58-64].

Among the sixteen studies that estimated overall dietary salt or sodium intake, eight in Puerto Rico, Spain, Korea, Italy, Mexico, China (two) and USA have shown strong statistically significant increases in risk (OR = 1.5-5.0 for the highest intake levels)[28-31,33,34,36,43]. Seven of them reported statistically non-significant OR of 1.1 to 1.5 for consumption in the upper half of overall salt or sodium intake[24-27,32,35,44], and the remaining study reported no association[23]. Six of the studies specifically examined the use of table salt, with three studies (in Belgium, England, and Poland) reporting statistically significant increases in risk with OR = 1.6, 1.8, 6.2, respectively[38,40,42]. Two other studies each reported statistically non-significant odds ratios of 1.5 for consumption of the upper half of the table salt intake distribution[37,39]; the remaining study reported no

Table 1 Summary of 45 case-control studies that evaluated the association between salt consumption and stomach cancer risk

[1]RR: Relative risk.

association[41].

Of the twelve studies that estimated salted fish intake, four found strong statistically significant increases in risk (OR = 1.4-5.5 for the highest intake levels)[39,45,47,48]. One Japanese study reported a statistically significant increase in risk for high consumption of salted fish gut and cod roe in males, but not females, and no significant association for salted/dried fish for both genders[48]. Seven other studies reported statistically non-significant correlations[25,46,49-53]; the remaining study reported a statistically significant inverse association with odds ratios of 0.7 for consumption in the upper half of the salted fish intake distribution[54].

Six studies in Table 1 examined salted vegetables; of these, three reported statistically significant increases in risk with higher intakes of salted vegetables[32,53,55], the remaining three studies in China, Korea and Lithuania showed no relationship to stomach cancer risk[25,52,54]. Additionally, three studies reported on salted snacks. Of them, only one study in Mexico reported a statistically significant relationship to stomach cancer[56], with the other two reporting no substantial associations[41,57].

Twelve studies examined consumption of salted soya paste, salted side dishes and salty foods in general[29,30,32,52,54,58-64]. Nine of them observed a moderate increase in risk with higher consumption (OR = 1.6-4.5)[29,30,32,54,60-64], the remaining three reported no association[52,58,59].

In summary, many case-control studies found similar results, indicating a moderate to high increase in risk for the highest level of salt or salted food consumption. Given the large number of studies that reported data on salt, sodium and salty foods consumption, some inconsistent results were to be expected. The inconsistencies may be due, at least in part, to the retrospective assessment of salt exposure, which might have changed after the diagnosis of stomach cancer. Furthermore, the degree to which each of these measures reflects total salt intake varies, and it is therefore not surprising that results would vary.

Cohort studies

Eleven cohort studies, investigating salt or salted food consumption and stomach cancer risk in the US, Japan, Sweden, and the Netherlands have produced inconsistent results (Table 2)[65-75]. When viewed separately in the Table, the results were inconsistent for both salt intake and intake of salty foods. Four Japanese studies reported

statistically significant associations (range of RR = 2.2-5.4 for the highest intake level)[67,68,73,75], including one study that reported significantly elevated risks in both men and women after 10 years follow up of 20 300 men and 21 812 women[73]. Another study, conducted in rural Japan with 8035 subjects and 76 stomach cancer deaths, reported a significantly elevated relative risk for the most frequent intake of highly salted foods compared with the least frequent intake (RR = 5.4; 1.8-16.3; *P* for trend < 0.01)[75]. In a study that examined 18 684 men and 20 381 women and included 486 histologically confirmed stomach cancer cases (358 men and 128 women), there was a dose-dependent association between salt consumption and stomach cancer risk in men (*P* for trend < 0.001), but not in women (*P* for trend = 0.48)[67]. Shikata *et al*[68] categorized 2476 subjects into four groups according to daily salt intake. After 14 years of follow-up, the age- and sex-adjusted incidence was significantly higher in the second to fourth groups than in the first group (RR = 2.4, 95% CI: 1.2-4.7; RR = 2.1, 95% CI: 1.0-4.3; RR = 3.0, 95% CI: 1.5-5.8, respectively). With the exception of these positive findings, the remaining seven cohort studies showed no substantial associations[65,66,69-72,74]. It is perhaps noteworthy that four studies with statistically significant positive results were conducted in Japan, which may be related to a potentially higher range of salt intake in that country.

In summary, some cohort studies suggest that a higher intake of salt or of salted food, as estimated by validated food frequency questionnaires, may be directly associated (or at least indirectly linked) with subsequent development of stomach cancer. Although the overall results from cohort studies are not totally consistent, they are suggestive of a moderate direct association.

EVIDENCE ON INTERACTIONS BETWEEN SALT OR SALTED FOODS AND HELICOBACTER PYLORI INFECTION

Even though *H pylori* infection is the strongest risk factor for stomach cancer, it cannot completely explain the worldwide distribution of this disease. It is very important to evaluate the potential joint effects of *H pylori* infection and other factors, including salt intake, in stomach cancer carcinogenesis.

Few epidemiological studies have investigated *H pylori* infection in relation to salt consumption. In an international ecologic study[76], statistically significant correlations between national *H pylori* infection rates and national salt excretion levels were found in older (age 50-64) men and women (r = 0.73 and r = 0.83, respectively) and in younger (age 20-34) men (r = 0.73), but not in younger women (r = 0.52). A cross-sectional study of 634 Japanese men[77] reported that daily consumption of miso soup was associated with the prevalence of *H pylori* (OR = 1.60, *P*< 0.05). Similarly, increasing consumption of pickled vegetables was associated with increased *H pylori* infection risk (OR = 1.90 for the highest level, *P* for trend = 0.02). Despite limitations inherent in these types of studies, they can nevertheless provide information on potential associations between salted foods and *H pylori* infection in humans, which may be evaluated more fully in case-control and cohort studies.

Three previous epidemiological studies have examined the potential synergistic relationship between salt consumption and *H pylori* infection in the development of stomach cancer; however, the results are inconsistent[35,68,78]. A case-control study in Japan analyzing the independent and joint effects of diet and *H pylori* infection found that subjects with *H pylori* infection and with high salt intake (OR = 14.2) had a higher odds ratio compared with subjects with *H pylori* infection and low salt intake (OR = 9.7) (reference group was no *H pylori* infection and low salt intake), but there was not a statistically significant interaction between the two risk factors[35]. A Korean case-control study investigating the role of salt and *H pylori* infection in stomach cancer found that subjects with *H pylori* infection and high salt consumption had a 10-fold risk of early stomach cancer compared with subjects without *H pylori* infection and with a low salt consumption (*P* = 0.047)[78]. These two case-control studies have some limitations, including issues of possible recall bias and misclassification. For example, both *H pylori* and salt intake were assessed after the development of stomach cancer. Advancing stomach cancer can combine with the loss of infection characterized by a fall in circulating anti-*H pylori* antibodies and changes in salt exposure (or in recollection of dietary exposures prior to the onset of disease). Only one cohort study, conducted in Japan, evaluated the potential interaction between diet and *H pylori,* and found that the positive association between increased salt intake and gastric cancer was statistically significant among subjects with *H pylori* infection only[68]. The relative risks were similar, however, and the authors note that findings for dietary salt were most pronounced in subjects who had both *H pylori* infection and atrophic gastritis. The three studies discussed above have relatively small sample sizes, ranging from 69 to 122 stomach cancer cases, and thus the estimation of relative risk is imprecise and results should be interpreted cautiously, especially in the analyses of effect modification (interaction). Finally, the tendency of case-control studies to show stronger associations than cohort studies suggests the possibility that some degree of recall bias and/or selection bias may have influenced the results of the former.

Critical issues in interpreting salt consumption with stomach cancer risk

Most epidemiological data suggest an association between salt intake and the development of stomach cancer. When interpreting these data, several issues must be considered.

Assessment of salt intake is difficult and prone to some potential biases. Many commonly used dietary assessment methods, such as food frequency questionnaires and diet records, have reported only

moderate reproducibility in epidemiological studies, and thus some misclassification of dietary intake is inevitable[79,80]. This may be particularly true of total salt intake, given its nearly ubiquitous addition to most processed foods. In addition, use of different salt assessment methods may lead to different conclusions. For example, both 24 h urinary excretion and 3 d dietary record methods for salt intake estimation were used in one Japanese ecologic study. Only urinary salt excretion level showed a strong correlation with stomach cancer mortality, while dietary salt was weakly and non-significantly correlated[21]. Although 24 h urine collection may be an optimal method in estimating routine salt intake, it is impracticable for a large-scale population study, especially a cohort study with long-term follow-up.

Another critical issue in interpreting salt consumption in relation to stomach cancer risk is the variation in the salt consumption levels across the population. To date, there is no standard method for salt intake categorization, and several studies have reasonably compared categories, such as quintiles for the application in the specific study population. Because average salt intake varies across different populations, salt consumption levels considered "high" in one study might be considered "low" in another study. For example, in a study conducted in Japan, subjects reporting once per week consumption of salted food were in the lowest exposure category[48]; in contrast, the subjects in a Turkish study reporting once per week were classified into the highest exposure level (defined as $\geqslant$1-2 times/week)[60]. Finally, in some studies[75], salted food levels were calculated from the sum of the scores of foods belonging to the food items (pickled vegetable + foods deep-boiled in soy sauce), making it impossible to compare effects at similar levels of consumption across studies.

Because of the complexity of diets, the traditional approach with a single nutrient may potentially be confounded by the interactions between food components that are likely to be interactive or synergistic[81]. It is possible that the increased risks in stomach cancer could be due to compounds other than salt in foods that were produced during the preservation process[56]. In East Asia, salted foods and sauces are also high in NO_3, a chemical carcinogen, which may either be added to the foods or synergize from amino acids during fermentation. Nitrite and salt may work at an early stage[82] in a synergistic fashion on stomach cancer carcinogenesis[17] that might cause the strong associations between highly salted foods and gastric cancer[67]. However, nitrite was not clearly related with stomach cancer risk[83] and its function may be influenced by other factors. For example, when lower salt intake was combined with higher NO_3 intake, stomach cancer mortality rates tended to be lower[17]. However, this might be explained by a higher intake of fresh fruits and vegetables, which are the major source of nitrate and also protect against cancer[84,85].

Moreover, it may be difficult to separate the effects of salt from other nutrients that may contribute to stomach cancer risk. The absence of adjustment for confounding factors (such as age, sex, smoking and dietary habit) can hamper the statistical estimation causing over- or underestimation of the real association between salt or salted food and stomach cancer. In Tables 1 and 2, few studies have controlled for dietary factors in their analyses of salt consumption, which makes it difficult to compare the different studies according to the dietary variables adjusted in the analysis. However, the study results that were adjusted by a wide range of potentially confounding variables, such as age, sex, *H pylori* infection, atrophic gastritis, medical history of peptic ulcer, family history of cancer, body mass index, diabetes, total cholesterol, physical activity, alcohol intake, smoking habit and other dietary factors[68], showed no difference from the crude results. Studies with adjustment for some or most of the above potential confounding factors[66,68,72,73] showed no systematically apparent differences from the studies with adjustment for a few or several confounders.

BIOLOGICAL MECHANISMS

Several mechanisms by which salt intake may increase stomach cancer risk have been postulated, although to date there has been no consistent conclusion. High dietary salt intake may potentiate the colonization of *H pylori*[86], a known risk factor for stomach cancer, through the increase of surface mucous cell mucin and decrease of gland mucous cell mucin[87]. At the molecular level, high dietary salt intake may potentiate *CagA* (*H pylori* gene) expression and enhance the ability of *CagA* to translocate into gastric epithelial cells and enhance the ability of *H pylori* to alter gastric epithelial cell function[15]. Another explanation for the potential effect of high salt intake in gastric carcinogenesis is that high dietary salt intake helps to change the mucous viscosity protecting the stomach, potentiate exposure to carcinogens such as N-nitroso compounds, and lead to cell death[88]. In addition, high salt intake can cause damage to, and inflammatory responses of, the gastric epithelium[14], which may increase epithelial cell proliferation as part of the repair process and increase the probability of endogenous mutations[89,90]. One mechanism of high salt action in gastric carcinogenesis has been considered to induce hypergastrinemia in *H pylori*-infected gerbils[87]. Gastrin itself may mediate epithelial cell growth in *H pylori*-colonized mucosa[91] and chronic hypergastrinemia can synergize with *Helicobacter* infection and lead to eventual parietal cell loss and progression to gastric cancer[92].

ANIMAL STUDIES OF SALT AND STOMACH CANCER

Most published animal studies focus on the relationship between gastric cancer and several important suspected carcinogens, salt, *H pylori*, N-methyl-N-nitro-N-nitrosoguanidine (MNNG), and 4-nitroquinoline-1-oxide (NQO). In general, salt alone has no apparent

effect on the development of gastric carcinogenesis, but administration of salt in rats induced a concentration-dependent damage of surface mucous cell layer, and also increased replicative DNA synthesis[89]. Interestingly, a synergistic effect was observed when salt and other risk factors (*H pylori*, MNNG, NQO) were analyzed simultaneously. This conclusion was derived in animal experiments addressing gastric carcinogenesis from both the molecular level and tumor progression. At the molecular level, a high salt diet was associated with an elevation of anti-*H pylori* antibody titers, serum gastrin levels, and inflammatory cell infiltration in a dose dependent model in Mongolian gerbils infected with *H pylori*[87]. Similarly, in *H pylori* infected gerbils, a high-salt diet significantly up-regulated the expression of cyclooxygenase-2 (COX-2), and nitric oxide synthase (iNOS)[93]; the number of colony-forming units was also significantly higher. Dietary sodium chloride also produced a reduction in cell yield, and an increase in S-phase cell numbers that are the most susceptible to mutagenesis, which may possibly increase tumor incidence[90]. Several studies examined gastric tumor progression in mice infected with *H pylori* and administered with a high-salt diet, and all of these studies consistently demonstrate that a high-salt diet enhances the effects of *H pylori* infection, and consequently promotes the development of stomach cancers[88,94,95]. Additionally, a high-salt diet significantly increased gastric tumor incidence in those mice pre-treated with MNNG[14] or MNU[96], suggesting that salt and chemical carcinogens also exert a synergistic effect in the development of gastric carcinogenesis.

CONCLUSION

Most published epidemiological studies provide positive evidence for an association between salt or salted food consumption and stomach cancer risk, which was also supported by experimental studies[14,87,94,97]. The limitations of salt assessment in epidemiological studies may have attenuated the true effect of salt intake on stomach cancer risk, or even biased the results away from the null, in the reviewed ecological, case-control, and cohort studies. Ideally, dietary modification of salt intake, as well as eradication of *H pylori* infection, is a promising strategy for gastric cancer prevention throughout the world, especially in developing counties. However, the former strategy is more practical than the latter according to previous epidemiological studies. Future studies that address the association with salt and other dietary factors and the interactions between these factors in different aspects, e.g. molecular level, may help to shed light on the etiology of stomach cancer.

Abstract

AIM: To evaluate the feasibility and utility of confocal laser endomicroscopy (CLE) in the description of normal gastrointestinal (GI) mucosa and in the diagnosis of GI disorders in children, in comparison to histology.

METHODS: Forty-four patients (19 female) median age 10.9 years (range 0.7-16.6 years) with suspected or known GI pathology underwent esophago-gastro-duodenoscopy (OGD) (n = 36) and/or ileocolonoscopy (IC) (n = 31) with CLE using sodium fluorescein and acriflavine as contrast agents. Histological sections were compared with same site confocal images by two experienced pediatric and GI histopathologists and endoscopists, respectively.

RESULTS: Duodenum and ileum were intubated in all but one patient undergoing OGD and IC. The median procedure time was 16.4 min (range 7-25 min) for OGD and 27.9 min (range 15-45 min) for IC. A total of 4798 confocal images were compared with 153 biopsies from the upper GI tract from 36 procedures, and 4661 confocal images were compared with 188 biopsies from the ileocolon from 31 procedures. Confocal images were comparable to conventional histology both in normal and in pathological conditions such as esophagitis, *Helicobacter pylori* gastritis, celiac disease, inflammatory bowel disease, colonic heterotopia, and graft versus host disease.

CONCLUSION: CLE offers the prospect of targeting biopsies to abnormal mucosa, thereby increasing diagnostic yield, reducing the number of biopsies, decreasing the burden on the histopathological services, and reducing costs.

Key words: Confocal laser endomicroscopy; Histology; Pediatric; Gastrointestinal mucosa; Gastrointestinal disorders

INTRODUCTION

Modern endoscopy has recently seen the development of technological advances with the aim of increasing and optimizing diagnostic yield from the procedure. These have included video and magnification endoscopes[1]. Greater surface definition has been achieved with chromo-endoscopy, and recently, narrow-band imaging has allowed greater definition of vascular architecture[2-4]. However *in vivo* sub-surface pathology remained obscure to the endoscopist until the advent of confocal endomicroscopy, which affords magnification up to

1000 ×, and with sequentially deeper images from the epithelial surface to approximately 250 μm below the surface. This allows histological assessment of the *in vivo* gastrointestinal (GI) mucosal structure at the cellular and subcellular level[5,6]. In addition, this technique avoids crush artefacts from the grasp biopsy forceps and changes from histopathological processing.

The diagnosis of upper GI disorders in children depends to a great extent on endoscopy and subsequent histology of biopsy specimens[7]. Pathology such as gastroesophageal reflux disease (GERD)[8-10], eosinophilic esophagitis (EE)[11,12]; *Helicobacter pylori (H pylori)* gastritis[13,14], and celiac disease (CD)[15,16], in conjunction with various other investigative modalities have, as pivotal to their diagnosis, histological confirmation. Similarly, pediatric ileocolonic conditions such as inflammatory bowel disease (IBD)[17,18], familial adenomatous polyposis (FAP), graft versus host disease (GVHD)[19,20], and allergic colitis[21,22] necessitate a tissue diagnosis.

The aims of this study were to evaluate the feasibility and utility of confocal laser endomicroscopy (CLE) in the description of confocal features of normal GI mucosa and in the diagnosis of GI disorders in children.

MATERIALS AND METHODS

Patients

Forty-four patients with a potential diagnosis of GI pathology that required upper GI endoscopy and/or ileocolonoscopy as part of the clinical management were enrolled in the study. Written informed consent was obtained from parents and, where age and competency were appropriate, from each patient, before the examination. The study protocols were reviewed and approved by South Sheffield Regional Ethics Committee. Patient exclusion criteria were as follows: inability to give signed informed consent; age > 18 years; previous documented adverse reaction/allergy to sodium fluorescein or acriflavine hydrochloride; and non-correctable coagulopathy (PT > 14 s/platelet count < 90 000). The study was conducted between December 2005 and July 2007 at Sheffield Children's Hospital NHS Foundation Trust.

Indications for upper GI endoscopy alone included: children with suspected GERD; Barrett's esophagus; suspected peptic ulcer disease; suspected celiac disease based on raised anti-endomysial and tissue transglutaminase antibodies; and non-specific recurrent upper abdominal pain. Indications for ileocolonoscopy included: chronic diarrhea; presence of fecal blood; recurrent abdominal pain; weight loss; mutation of the APC gene; colonic heterotopia; and suspected GVHD.

Forty-four patients (19 female) with a median age of 10.9 years (range 0.7-16.6 years), and a median weight of 41.5 kg (range 8-97 kg) with suspected or known GI pathology were enrolled.

Patients undergoing ileocolonoscopy were admitted the previous day and had bowel preparation as for standard ileocolonoscopy. Patients undergoing upper GI endoscopy were admitted on the day of the procedure. All procedures occurred under general anesthesia, as is normal practice in our institution for pediatric GI endoscopy.

CLE

CLE involves the use of a highly miniaturized confocal microscope that has been incorporated into the distal tip of a flexible endoscope to allow *in vivo* microscopic examination of the gut mucosa. The confocal microscope uses a single optical fiber to deliver 488 nm laser light to the distal tip of the endoscope, where it is focused to a single diffraction-limited point within the tissue. The laser light excites fluorescent molecules within the tissue. Fluorescent light emanating from the specific point of focus is collected into the same optical fiber of the confocal microscope and delivered to the photodetector. Light emanating from outside the focally illuminated spot is not focused into the optical fiber and therefore, is geometrically rejected from detection. The focused point of laser light is scanned in a raster pattern across the field of view, and the intensity of the fluorescent signal returning to the detector from successive points is measured (12-bit digitization) to produce two-dimensional images that are *en face* to the tissue surface. By moving the microscope optics within the confocal microscope, the operator can dynamically adjust the imaging depth to allow microscopic imaging at and below the surface of the mucosa; hence each image is an optical section representing one focal plane within the specimen[5,23], and collection of multiple optical sections at successive depths results in true volumetric sampling of the tissue. As a three-dimensional volume is thus sampled, this can be thought of as a virtual biopsy.

The Pentax EC3870CILK endoscope has a 5-mm diameter miniaturized confocal microscope integrated into the distal tip of the endoscope. The diameter of the distal tip and insertion tube of the endoscope is 12.8 mm. In addition to the integrated confocal microscope, the distal tip also contains a color CCD camera which enables simultaneous confocal microscopy with standard video-endoscopy, air and water jet nozzles, two light guides, a 2.8-mm working channel, and an auxiliary water jet channel. During CLE, the laser delivers an excitation wavelength of 488 nm at a maximum laser output of 1 mW to the tissue (typically 300-700 μW). Confocal images can then be collected at either 1024 × 1024 pixels (0.8 frames/s) or 1024 × 512 pixels (1.6 frames/s). The optical sections have a 475 μm × 475 μm field of view, with a lateral resolution of 0.7 μm, axial resolution of 7.0 μm, and an imaging depth (z axis) range of 0-250 μm below the tissue surface, in 4-μm steps. The imaging depth below the tissue surface can be dynamically controlled by the operator. CLE magnifies images 1000-fold.

Contrast agents

Fluorescein sodium (FS) 10% and acriflavine hydrochloride (AH) 0.05% were used as contrast agents. FS is highly water-soluble and, on intravenous administration, rapidly diffuses in seconds from the

capillaries into the extra-vascular tissue. FS, when exposed to light of wavelength 465-490 nm (blue), emits light at longer wavelengths (520-650 nm, with the peak emission in the 520-530 nm green-yellow region)[24]. This enables visualization of microvessels, cells and connective tissue. However FS is not enriched in the nuclei of intestinal epithelial cells, and hence, the nuclei are not readily visible in the confocal images. To circumvent this limitation, AH (0.05%) is used topically to enrich the superficial nuclei and to a lesser extent the cytoplasm.

CLE was performed by a single experienced endoscopist (MT), who had completed the Mainz CLE training program prior to patient recruitment, using the confocal laser endomicroscope (EC3870CILK; Pentax, Tokyo, Japan). Ten to twenty milligrams Buscopan (hyoscine-N-butyl-bromide; Boehringer, Ingelheim, Germany) was given intravenously to limit peristaltic artefacts. Following duodenal or ileal intubation, 0.05-0.1 mL/kg of 10% FS was administered intravenously and flushed adequately with normal saline. AH (0.05%) was applied to the mucosa using a spray catheter at all sites undergoing confocal imaging.

CLE image acquisition was performed by placing the tip of the colonoscope in direct contact with the target tissue site. Using gentle suction to stabilize the mucosa, image acquisition and focal plane z-axis scanning depth was then actuated using two discrete hand-piece control buttons. Confocal images were sequentially obtained from a third part of the duodenum, gastric antrum and body, and distal and proximal esophagus in the upper GI tract, and ileum, cecum, ascending, transverse, descending and sigmoid colon, and rectum in the ileocolon region. Confocal images were acquired simultaneously with ongoing video endoscopic imaging. Same site mucosal specimens were obtained using standard biopsy forceps. The biopsy specimens were fixed in buffered formalin solution, embedded in paraffin wax, and serial sections were obtained and stained with hematoxylin and eosin (HE). The histological specimens from each site were compared with same-site confocal images jointly by the endoscopists and two experienced pediatric and GI histopathologists (MC, CE).

RESULTS

Twenty-three patients underwent both upper GI and ileocolonoscopy, while 13 had upper GI endoscopy and eight had ileocolonoscopy alone. The youngest patient 8 mo of age, with suspected GVHD, had proctoscopy alone. The duodenum at upper GI endoscopy and the terminal ileum at ileocolonoscopy were intubated in all patients, except for one who weighed 10 kg, in whom the pylorus and ileocecal valve were both too narrow to accept the confocal endomicroscope. The youngest and smallest patient to have full successful examinations up to a third part of the duodenum and terminal ileum was 18 mo old and weighed 11 kg. The procedure time was 7-25 min (median 16.4 min) for upper GI endoscopy, and 15-45 min (median 27.9 min) for ileocolonoscopy. A total of 153 pinch biopsies were taken from the upper GI tract from 36 procedures and 188 from the ileocolon from 31 procedures.

No complications or adverse effects occurred, except on one occasion when precipitation was observed in the peripheral venous line when fluorescein was injected immediately after neostigmine.

Upper GI tract

Thirty-six patients underwent upper GI endoscopy. The duodenum was intubated in all patients except one. A total of 4798 confocal images were obtained, which included 2010 from the duodenum, 1616 from the stomach and 1172 from the esophagus, and were compared with 153 biopsies.

On confocal imaging, the duodenal villi had a long, slender and finger-like appearance (Figure 1A) similar to that in histological specimens (Figure 1C). The single layer of brush border columnar epithelial cells interspersed with intraepithelial lymphocytes and goblet cells was clearly visible. Crypts were not normally visible except in the presence of villous atrophy.

The gastric pits or foveolae appeared as invaginations on the surface epithelium (Figure 1B and D). Each confocal image showed several evenly spaced such pits lined by columnar epithelium. The center of the pits appeared dark.

The esophagus was lined by non-keratinized squamous epithelium with polygonal epithelial cells. The nuclei of the epithelial cells were highlighted clearly following topical administration of acriflavine (Figure 1C and F). Furthermore, the capillary loops in the papillae were visible in deeper planes following subsurface optical sectioning, and surface to capillary distance could be measured as each level was deeper by 4 μm. This allowed assessment of GERD-like histopathology, given that papillary height was increased and epithelial surface to papillary tip (i.e. where capillary loops appeared on confocal endomicroscopy) distance was thereby shorter.

Lower GI tract

A total of 31 patients underwent ileocolonoscopy. Two patients had only proctoscopy, while total ileocolonoscopy was performed in the rest, with the terminal ileum intubated in all but one patient, who weighed 10 kg. A total of 4661 confocal images, which included 945 from the terminal ileum, 2919 from the colon and 797 from the rectum, were compared with 184 biopsies.

The confocal appearance of the normal ileum and colon in adults has been described previously[25]. The villi in the terminal ileum appeared similar to those in the duodenum. Colonic architecture on confocal imaging showed numerous evenly distributed crypts lined by columnar-shaped enterocytes (Figure 2A and B). The luminal openings of the crypts appeared as black holes in the horizontal axis. The mucin-containing goblet cells were readily identified and appeared dark. At deeper planes, the vessel architecture had a hexagonal, honeycomb pattern, which represented a network of capillaries that outlined the stroma surrounding the

luminal openings of the crypts. Individual red cells were also visible as black dots in the lumen of the capillaries.

Confocal imaging in GI pathology

Upper GI pathology: Two patients had histologically proven esophagitis. At CLE, capillary loops were visible at about 24 and 44 μm below the surface epithelial layer, which indicated the presence of papillae. In comparison, capillary loops were seen at a median of 72 μm (range 48-100 μm) from the surface of the esophageal mucosa in those without histologically proven esophagitis.

One patient with suspected *H pylori* upon endomicroscopy of the gastric antrum showed multiple focal lesions that resembled focal accumulation of *H pylori*, which was subsequently confirmed by Campylobacter-like organism test and histology. These lesions were demonstrated both on the surface of the epithelium and deeper in the crypt lumen.

Four patients had a histological diagnosis of celiac disease (Figure 3A and C). Three patients had Marsh type 3b with marked villous atrophy, increased intra-epithelial lymphocytes and crypt hyperplasia. CLE features (Figure 3B) in these patients were as follows: (1) increased basal width of villi; (2) gross distortion of the cellular architecture of the villous epithelium with loss of the honeycomb pattern; (3) damaged villous border; (4) "sticky" villi with inter-villous bridging; and (5) in-folding of villi. One patient had total villous atrophy. Confocal imaging revealed absence of villi with crypt hyperplasia (Figure 3D).

Lower GI pathology: Seven patients had a histological diagnosis of IBD, including three patients each with ulcerative colitis and Crohn's disease, and one with

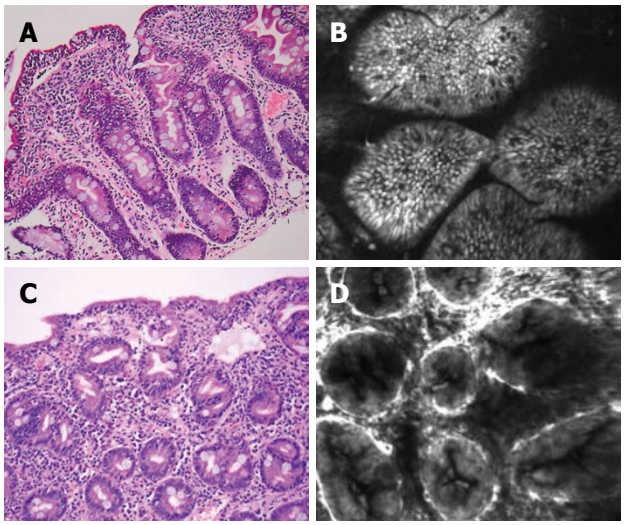

Figure 3 Comparison of confocal with conventional histology in celiac disease. A: Histological image of celiac disease, Marsh type 3b; B: Comparative confocal image; C: Histological image of celiac disease, Marsh type 3c; D: Comparative confocal image.

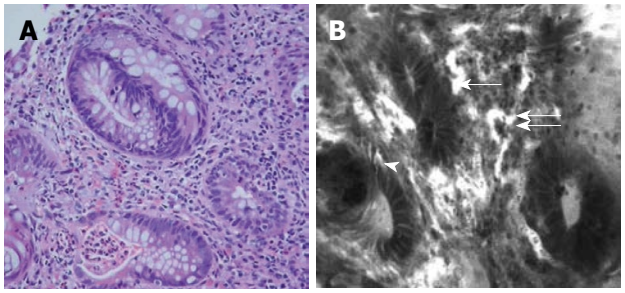

Figure 4 Comparison of confocal with conventional histology in ulcerative colitis. A: Histologic image in Ulcerative colitis; B: Comparative confocal image showing bifid crypt (arrow), crypt destruction (arrow head), tortous vessels (double arrows).

indeterminate colitis. Features of IBD seen on confocal imaging included bifid crypts, crypt distortion and destruction, crypt abscess/cryptitis goblet cell depletion and inflammatory cell infiltration, enlarged tortuous vessel architecture (Figure 4B), and comparable to histology (Figure 4A).

Other lower GI pathologies: Two patients with suspected GVHD following bone marrow transplantation underwent proctoscopy. Apoptotic nuclei were visualized during confocal imaging. This was confirmed on histology of biopsy specimens. A rare case of colonic heterotopia that presented with persistent diarrhea and had large tracts of abnormal looking mucosa on endoscopy, showed squamous, gastric and small-intestinal mucosal features on confocal imaging. Histology confirmed the presence of aberrant mucosa.

DISCUSSION

A definitive diagnosis of GI disorders in children usually requires GI endoscopy and histology of biopsy tissue. Technological innovations have led to the development of chromo-endoscopy, for which dyes such as methylene blue and indigo carmine are used to aid localization of lesions, and magnifying endoscopy has enabled visualization of surface structures at approximately × 100 magnification. In adults, several studies have validated these techniques in differentiating neoplastic from non-neoplastic lesions[26-29], diagnosis of neoplastic lesions in flat and depressed lesions in the colorectum, and in cancer surveillance in patients with long-standing ulcerative colitis[30,31]. Confocal endomicroscopy is a newly developed tool that enables surface and subsurface imaging of living cells in the mucosa during ongoing endoscopy. It offers the combination of video endoscopy and confocal endomicroscopy, which uniquely provides *in vivo* histology and what might be termed a virtual biopsy[6]. The confocal endomicroscopy images obtained are in a single optical plane parallel to the surface of the tissue. Collection of multiple optical sections at successive depths allows detailed visualization of successive tissue layers, and allows sampling of a three-dimensional volume of tissue. This is in contrast to conventional histology in which the tissue is sectioned vertically, making it possible to see all the tissue layers in one view using a bench top light microscope. Hence, it is pertinent that confocal images require comparison with similarly sectioned histological images. The endoscopist also requires training in normal and abnormal microscopic anatomy, which takes time. Also a certain amount of training in using the endomicroscope and interpreting the image data is necessary.

In this study, the feasibility of CLE in the diagnosis of GI disorders was determined in children as young as 8 mo of age and as light as 10 kg, for the first time. Confocal findings of normal GI mucosa are described. In addition, confocal features in conditions such as pediatric manifestations of GERD, *H pylori* gastropathy, celiac disease, IBD, GVHD, and colonic heterotopia were illustrated.

The tantalizing prospect of targeted biopsies or even a biopsy-free endoscopic procedure in the diagnosis of childhood GI disorders arises, with obvious potential benefits in terms of avoidance of biopsy-associated complications, and diminution of the considerable histological burden that this patient cohort places on already over-stretched histopathological services, along with the prospect of considerable associated cost savings.

COMMENTS

Background

Histology of biopsy specimens has a major role in the definitive diagnosis of pediatric gastrointestinal (GI) disorders, but is subject to changes from crush artefacts and processing, in addition to an inherent delay in diagnosis. Confocal laser endomicroscopy (CLE) is a recent development that enables surface and subsurface imaging of living cells *in vivo* at × 1000 magnification.

Research frontiers

The relatively new tool of CLE has been used in the assessment and *in vivo* diagnosis of various GI disorders in adults, such as Barrett's esophagus, esophageal, gastric and colorectal cancers, and inflammatory bowel disease and other forms of colitis.

Innovations and breakthroughs

This is believed to be the first study to assess this innovation in the diagnosis of pediatric GI disorders. This study confirmed the feasibility and diagnostic

reliability of CLE for the *in vivo* diagnosis of a wide range of GI disorders in childhood.

Applications

This study provides a basis for future studies on the use of this advanced diagnostic technique in providing a real-time diagnosis during endoscopy in children.

Peer review

This was a well-conducted study, which shows that it is feasible to use confocal endomicroscopy in the diagnosis of childhood GI disorders.

Abstract

AIM: To find a rapid and efficient analysis method of gastrointestinal microflora in Pi-deficient (spleen-deficient) rats and to evaluate traditional Chinese drugs.

METHODS: Enterobacterial repetitive intergenic consensus-PCR (ERIC-PCR) based assay was performed to examine changes of intestinal microflora in two Pi-deficienct animal models and to evaluate the efficacy of four traditional Chinese drugs as well as a probiotic recipe and another therapy in Pi-deficient rats.

RESULTS: A molecular marker was identified for Pi-deficiency in rats. The pharmacodynamic evaluation system, including identified molecular markers (net integral area and abundance of DNA bands), Shannon's index for diversity of intestinal microflora, and Sorenson's pairwise similarity coefficient, was established. The four major clinical recipes of traditional Chinese drugs for Pi-deficiency in rats, especially at their medium dose (equivalence to the clinical dose), produced more pronounced recovery activities in Pi-deficient rats, while higher doses of these recipes did not show a better therapeutic effect but some toxic effects such as perturbation deterioration of intestinal microflora.

CONCLUSION: Both fingerprint analysis and identified marker can show Pi-deficiency in rats and its difference after treatment. The identified molecular marker may be applied in screening for the active compounds both in relative traditional Chinese drugs and in pharmacodynamic study of Pi-deficiency in rats.

Key words: Pi-deficiency; Enterobacterial repetitive intergenic consensus-PCR; Traditional Chinese medicine

INTRODUCTION

Pi-deficiency (spleen deficiency), a common clinical syndrome in traditional Chinese medicine (TCM), is described as symptoms such as epigastralgia, flatulence after meal, lack of appetite, wilted complexion, loose stool, lassitude, fatigue, *etc.* The "Pi" here is the Chinese spelling of "spleen" in TCM, which relates to the functions of digestion, absorption and nutrition, differs from the "spleen" in Western medicine that belongs to the blood and immune systems. Pi-deficiency in TCM is one of the most common digestive diseases and usually the patients' equilibrium of gastrointestinal microflora is broken, which plays an important role in the growth, development and performance of the host[1]. Therefore, more clinical interests are arising in monitoring changes of intestinal microflora in intestinal disease and its consequent treatment with TCM therapies. It has been found that some traditional Chinese drugs have curative effects on Pi-deficiency by regulating the equilibrium of intestinal microflora and therefore promote the recovery of Pi-deficiency[2-4].

However, methods of monitoring the intestinal flora are quite limited, not only because of the complexity of

its constitution, but also the difficulty in culturing most gastrointestinal bacteria *in vitro*. Recent development in molecular biology techniques provides various possibilities of illustrating microbial biodiversity without *in vitro* culture of bacteria[5-6]. Enterobacterial repetitive intergenic consensus (ERIC) sequences are non-coding sequences of highly conserved 127 bp that are repeated multiple times through the genome of most bacterial species[7]. Variation in the number and location of ERIC sequences between different populations of microbes will result in differences between strains in the number and size of PCR products by ERIC primers. Based on this, ERIC-PCR has been used to investigate the diversity of bacteria[8-11].

In this study, we introduced ERIC-PCR fingerprinting in study of Pi-deficiency syndrome, used molecular markers to detect changes of intestinal microflora in Pi-deficient rats, and evaluated the therapeutic effects of traditional Chinese drugs.

MATERIALS AND METHODS

Animals

Wistar rats (200 ± 20 g) of either sex were obtained from the Experimental Animal Centre of Shenyang Pharmaceutical University (Shenyang, China). The rats were kept under standard environmental conditions with free access to rodent diet and water. All animal experiments were performed in accordance with the Guidelines for Use of Experimental Animals established by Shenyang Pharmaceutical University.

Plant materials

Plant materials including *Radix* and *Rhizoma Rhei*, *Folium Sennae, etc,* used in the study, were purchased from a local TCM apothecary in Shanghai, China (Table 1), and identified by Dr. Meng-Yue Wang, Department of Pharmacognosy, School of Pharmacy, Shanghai Jiao Tong University.

Preparation of traditional Chinese drug decoctions

One hundred milliliters aqueous decoction was prepared with 100 g of each crude *Radix, Rhizoma Rhei* and *Folium Sennae*. For the preparation of decoction of traditional Chinese drug recipes, the crude drugs were mixed first according to the ratio as prescribed, and then decocted 3 times in 10 volumes of distilled water for 30 min, finally the solution was filtered and concentrated. The ratios and concentrations are shown in Table 1.

Induction of Pi-deficiency in rats and treatment with traditional Chinese drugs

Rats were randomly divided into 16 groups (n = 8). Rats in group 1 received distilled water only (10 mL/kg, *po*) during the whole experiment. Rats in groups 2-16 were intragastrically given *Radix* and *Rhizoma Rhei* extract, 10 mL/kg, twice a day for the first 10 d to induce Pi-deficiency[12]. Rats in group 2 (model group) received distilled water only, once a day for 10 d. Rats in group 3 received Entrocoordinatibiogen (16.2 mg/kg, *po*), once a day for 10 d. Rats in group 4 received Banxia Houpu Tang (Decoction of Pinellia and Magnolia Bark, 4.3 g crude drug/kg, *po*), once a day for 10 d. Rats in groups 5-7 were treated with Si Junzi Tang (Decoction of Four Noble Drugs, 1.2, 3.5 and 10.5 g of each crude drug/kg, *po*), once a day for 10 d. Rats in groups 8-10 received Lizhong Tang (Decoction for Regulating the Function Of Middle Jiao, 1.8, 5.4 and 16.2 g of each crude drug/kg, *po*), once a day for 10 d. Rats in groups 11-13 received Buzhong Yiqi Tang (Decoction for Regulating the Function Of Middle Jiao and Supplementing Qi, 1.6, 4.8 and 14.4 g of each crude drug/kg, *po*), once a day for 10 d. Rats in groups 14-16 received Yiwei Tang (Decoction for Nourishing the Stomach, 1.9, 5.8 and 17.4 g of each crude drug/kg, *po*), once a day for 10 d. Banxia Houpu Tang is a recipe for tussis but not for Pi-deficiency. Si Junzi Tang, Lizhong Tang, Buzhong Yiqi Tang and Yiwei Tang are commonly used clinical recipes for Pi-deficiency. Another experiment was performed as described above, except that 10 mL/kg *Folium Sennae* was given instead of *Radix and Rhizoma Rhei* to induce Pi-deficiency[13,14].

Sample collection and total DNA extraction

Three or four pieces of fecal pellets (about 1 g) per rat were directly collected from the anus into sterile plastic tubes and stored at -20℃ immediately. Fecal pellets were collected 5 d before induction of Pi-deficiency and then every two days.

Total DNA was isolated from the fecal samples as previously described[10] with some modifications. Each sample (0.2 g) was suspended in 1 mL sterile 0.05 mol/L PBS (pH 7.4) followed by vortexing for 5 min in a 2 mL tube. The suspension was centrifuged at 200 × g for 6 min and the supernatant was transferred to a new tube. Then 1 mL sterile PBS was added to the pellets and vortexed for 5 min, the suspension was centrifuged and the supernatant was transferred to the new tube as well. Combination of the two sets of supernatant was then centrifuged at 300 × g for 6 min to remove coarse particles. The cells in the supernatant were collected and washed twice with PBS by centrifuging at 10000 r/min for 6 min. The washed cell pellets were resuspended in 300 μL of solution Ⅰ containing 150 mmol/L NaCl, 50 mmol/L Na_2EDTA (pH 8.0). The suspension was gently mixed with 100 μL lysozyme solution (100 mg/mL) and 20 μL RNase (10 mg/mL), pre-warmed in 37℃ water bath for 30 min and then combined with 300 μL of solution Ⅱ containing 100 mmol/L NaCl, 50 mmol/L Tris base (pH 8.0). The cell suspension was gently mixed with 100 μL of 10% SDS and 50 μL of 20% PVP, and incubated on ice for 5 min. DNA was then purified by sequential extraction with Tris-equilibrated phenol and chloroform-isoamyl alcohol (v/v/v, 25:24:1), and chloroform isoamyl alcohol (v/v, 24:1) followed by precipitation with 2 volumes of ethanol and 50 μL of 3 mol/L sodium acetate. DNA was collected by centrifugation and washed once with 70% ethanol,

[a]N: Net area of 380 bp; A: Abundance of 380 bp; C: Sorenson's pairwise similarity coefficient (Cs); H: Shannon's index (H'); ↑: Increase; ↓: Decrease; [1]: Significant ($P < 0.05$).

air dried and dissolved in 50 μL of sterile distilled water. The DNA was checked for integrity first by electrophoresis analysis on 1% agarose gel (compared with size-known Hind Ⅲ digested bacteriophage λ DNA), and then quantified.

ERIC-PCR

ERIC-PCR was performed on a MJ Research PTC-100 thermal cycler (MJ Research, Inc., Waltham, USA) using the ERIC primers (ERIC1R: 5'-ATGTAAGCTCCTGGGGATTCAC-3', ERIC2: 5'-AAGTAAGTGACTGGGGTGAGCG-3')[7]. The reaction system was optimized and determined with orthogonal array design and statistic analysis method as previously described[15]. PCR consisted of 2.5 μL 10 × buffer, 200 μmol/L dNTP, 2.5 mmol/L Mg^{2+}, 0.4 μmol/L primer, 1U HotstarTaq DNA polymerase and 2 μL DNA template (or correspondingly 2 μL sterile distilled water in controls) in a total 25 μL volume. PCR conditions were as follows: an initial denaturation at 94℃ for 5 min, followed by 35 cycles of denaturing at 95℃ for 50 s, annealing at 49℃ for 30 s, at 46℃ for 30 s, extension at 72℃ for 3 min, and a final extension at 72℃ for 9 min. PCR products were separated by electrophoresis on 2% agarose gel (Agarose LE, Mdbio, Inc.) containing 0.5 μg/mL ethidium bromide and observed under UV light by Tannon GIS2010 Image System Ver. 3.73 (Tanon, Inc., Shanghai, China). The size and quantity of the amplified fragments were determined using 1 kb plus DNA makers (Tiangen, Inc., Beijing, China).

Statistical analysis of ERIC-PCR fingerprint

ERIC-PCR profiles were analyzed using the Gel Compare function of Tannon GIS2010 Image System Ver. 3.73 and transformed to data sets by taking into account the relative square root of the area under each PCR peak and abundance of each peak. Similarities between samples and their temporal stability were determined by calculating Sorenson's pairwise similarity coefficient (Cs), which is commonly used to compare the species composition of different ecosystems. Two identical profiles create a value of 100%, whereas two completely different profiles result in a value of 0%.

$$Cs\ (\%) = (2 \times j)/(a+b) \times 100\%$$

where 'a' is the number of total bands in the ERIC-PCR pattern for one sample, 'b' is the number for the other, and 'j' is the number of the common bands shared by both samples[16].

Shannon's index (H'), which originally refers to the community richness, was also employed to measure the distribution of PCR bands in our study. We used it to describe the quantitative difference in intestinal microflora under different conditions, although each ERIC-PCR band does not have to stand for one individual bacterial species.

$$H' = -\sum(Pi)(\ln Pi)$$

where P*i* is the relative abundance of each band, calculated as the proportion of the *i*th band in the fringerprint[16-18].

Results were described as mean ± SE. The statistical significance ($P < 0.05$) of difference between means was determined using paired-samples *t* test or ANOVA with SPSS version 11.5 (SPSS Inc., Chicago, USA), where appropriate.

RESULTS

ERIC-PCR fingerprint of intestinal microflora in naive rats

ERIC-PCR profiles of total fecal DNA were obtained for samples collected from naive rats before induction. Repeats of fingerprints showed that there were 9-12 fragments ranging 120-3000 bp with various intensities. There was a considerable variation of ERIC-PCR profiles between individual rats, in which only approximately 50% similarity was seen (Figure 1A). However, samples collected on different days from the same rat showed much a better consistency, with a similarity (Cs) ranging 63%-88% (data not shown). The occurrence of each fragment was calculated using Tannon GIS2010 Image System. Two fragments (590

bp and 300 bp) showed a higher occurrence of 83% and 74% respectively (occurrence > 70%) among the fingerprints of 128 rats, indicating that these two predominant bands are likely to be populations-associated naive rat gastrointestine.

ERIC-PCR fingerprint of intestinal microflora in Pi-deficient rats

Symptoms of Pi-deficiency[1-4], including humped back, narrow eyes, watery stools, listlessness, lack of appetite and weight loss[14] occurred in the rats that received *Radix* and *Rhizoma Rhei* or *Folium Sennae*. A remarkable difference in ERIC-PCR profile was found between rats with Pi-deficiency induced by *Radix* and *Rhizoma Rhei* or *Folium Sennae* and normal rats (Figures 1 and 2). Shannon's index (H') of the rat Pi-deficiency model (1.77 ± 0.03, n = 200) was significantly lower than that of normal ones (2.02 ± 0.02, $P < 0.05$, n = 200), indicating that altered profiles and lesser diversities of ERIC-PCR fingerprints are in the status of Pi-deficiency. The similarity (Cs) of ERIC-PCR fingerprints of the same rat before and after Pi-deficiency induction decreased to approximately 39% in groups 2-16, whereas 62% in control group that received distilled water only ($P < 0.05$), suggesting that the constitution of intestinal bacterial community in Pi-deficiency rats is significantly different from that in normal rats.

Molecular markers of intestinal microflora in rats with Pi-deficiency induced by Radix and Rhizoma Rhei

Analysis of ERIC-PCR profiles for 100 rats with Pi-deficiency induced by *Radix* and *Rhizoma Rhei* implied that three fragments (590, 380 and 300 bp) showed that *Radix* and *Rhizoma Rhei* administration can induce significant changes in abundance and band net integral area ($P < 0.05$), as well as the occurrence of those fragments (Table 2). The 590 bp and 300 bp fragments, especially the 300 bp fragment, were shown in most normal rats, but in much fewer rats after Pi-deficiency induction (Figure 1B). Different from the 590 bp and

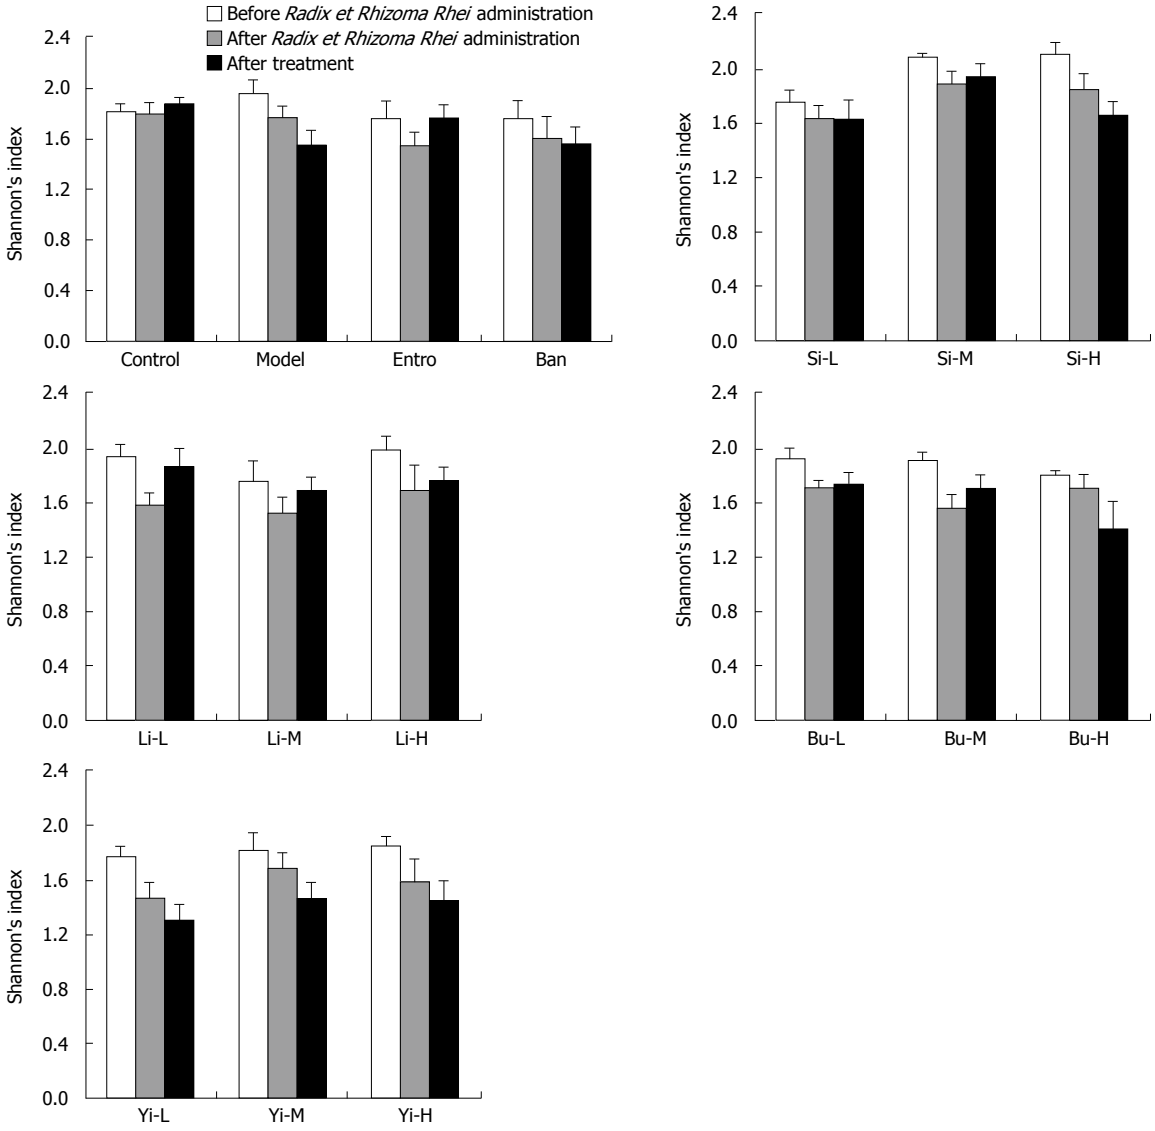

Figure 3 Shannon's index of ERIC-PCR fingerprintings of Pi-deficient rats before and after TCM treatment. Pi-deficiency was induced by *Radix* and *Rhizoma Rhei* first in all groups except for the control group (Group 1) that received distilled water. Control: Group 1 received distilled water in both inducement and treatment phases. Model: Group 2 received *Radix et Rhizoma Rhei* but distilled water during treatment; Entro: Group 3 received Entrocoordinatibiogen during treatment; Ban: Group 4 received decoction of *Ban-xia-hou-pu-tang* during treatment; Si-L, Si-M, Si-H: Groups 5-7 received low, middle and high doses of *Si-jun-zi-tang*, respectively; Li-L, Li-M, Li-H: Groups 8-10 received low, middle and high doses of *Li-zhong-tang*, respectively; Bu-L, Bu-M, Bu-H: Group 11-13 received low, middle and high doses of *Buzhong Yiqi Tang*, respectively; Yi-L, Yi-M, Yi-H: Groups 14-16, received low, middle and high doses of *Yi-wei-tang*, respectively.

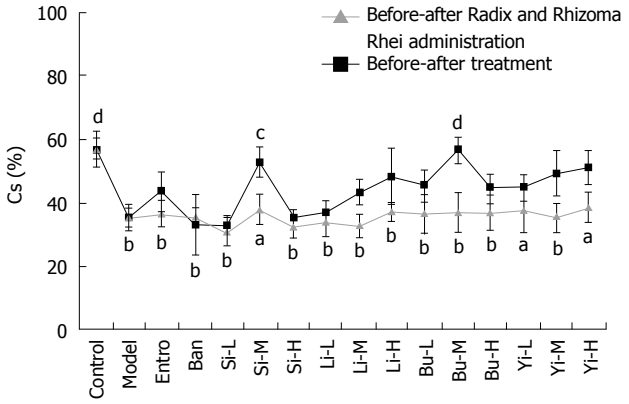

Figure 4 Similarity coefficient (Cs) for ERIC-PCR fingerprintings of Pi-deficient rats before and after treatment. Samples were the same as in Figure 3. Gray: Cs before and after *Radix* and *Rhizoma Rhei* uptake; Black: Cs before and after treatment. Statistical significance of differences was calculated by One-Way ANOVA. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control group; $^{c}P < 0.05$, $^{d}P < 0.01$ *vs* model group.

300 bp fragments, the 380 bp fragment was not seen in normal rats, but in most Pi-deficient rats, indicating that *Radix* and *Rhizoma Rhei* administration can induce great changes in the proportion of individual bacterial species. The rest fragments were randomly detected in either normal or Pi-deficient rats, with no correlation between the presence of fragments and Pi-deficiency. Therefore, these fragments (590, 380 and 300 bp) were selected as preliminary biomarkers for intestinal microflora ERIC-PCR fingerprints of rats with Pi-deficiency induced by *Radix* and *Rhizoma Rhei*.

In order to further identify the optimal biomarker of ERIC-PCR fingerprints for rats with Pi-deficiency, the profile of preliminary biomarkers (590, 380 and 300 bp) in different groups of Pi-deficient rats that received TCM treatment was also investigated. As a result, 4 TCM recipes restored the net integral area and abundance of 380 bp fragment to a certain extent. However, changes

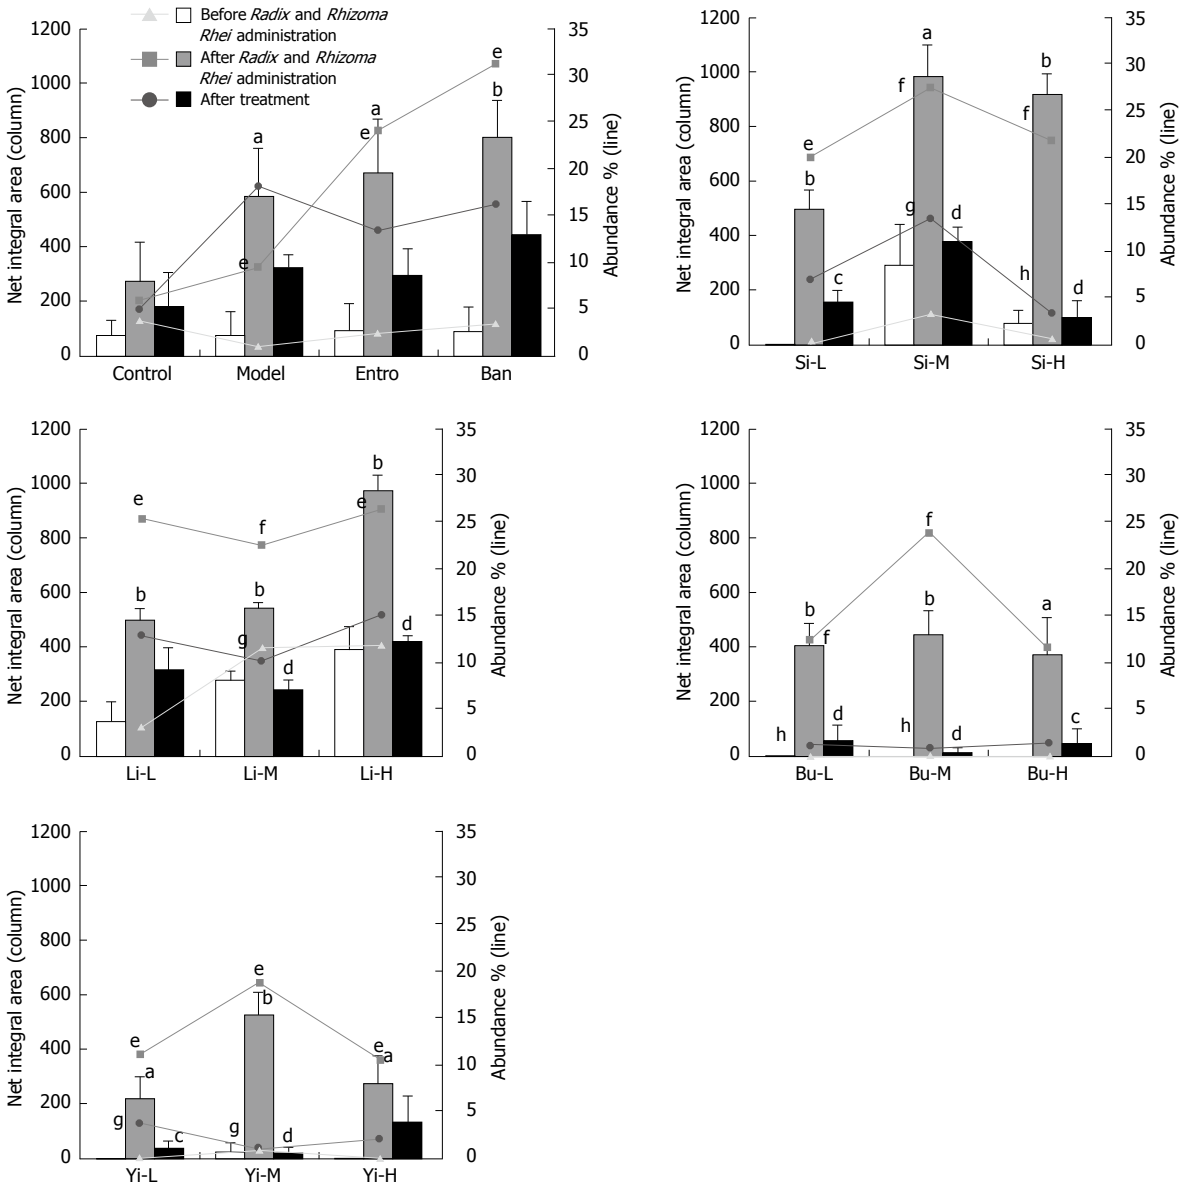

Figure 5 Net integral area and abundance of the 380 bp fragment in rats with Pi-deficiency induced by *Radix* and *Rhizoma Rhei* and after treatment. Columns: Net integral area of the 380 bp fragment; Lines: Abundance of 380 bp fragment. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* healthy condition; $^{c}P < 0.05$, $^{d}P < 0.01$ *vs* Pi-deficiency status; $^{e}P < 0.05$, $^{f}P < 0.01$ *vs* healthy condition; $^{g}P < 0.05$, $^{h}P < 0.01$ *vs* Pi-deficiency status. Samples were the same as in Figure 3.

in 590 bp and 300 bp fragments were not as significant as in 380 bp fragment (data not shown). Given the data above, the 380 bp fragment was identified as the biomarker of ERIC-PCR fingerprints for rats with Pi-deficiency induced by *Radix* and *Rhizoma Rhei*, the net integral area and abundance of the 380 bp fragment could therefore be used as parameters to evaluate the therapeutic effects of TCM on Pi-deficiency.

Additionally, in 7 out of 12 Pi-deficient groups that received TCM recipes, The Shannon's index (H') of ERIC-PCR fingerprints was restored (Figure 3). A similar trend of the similarity (Cs) of ERIC-PCR fingerprints was seen in those groups that received TCM recipes (Figure 4), indicating that Shannon's index (H') and Sorenson's pairwise similarity coefficient (Cs) can also be considered as biomarkers for Pi-deficiency and used to evaluate the therapeutic effects of TCM on Pi-deficiency.

Evaluation of therapeutic effects of TCM recipes on P1-deficiency induced by Radix and *Rhizoma Rhei using the identified biomarkers*

As shown in Figures 3-5 and Table 1, Si Junzi Tang reduced the net integral area and abundance of the 380 bp fragment and increased the Sorenson's pairwise similarity coefficient (Cs) in a dose-dependent manner. The effects were most significant at the dose of 3.5 g crude drug/kg. However, the Shannon's index (H') increased after treatment with Si Junzi Tang at the dose of 3.5 g crude drug/kg, but decreased after treatment with Si Junzi Tang at a higher dose of 10.5 g crude drug/kg.

The net integral area and abundance of the 380 bp were significantly different before and after treatment with Lizhong Tang at the dose of 5.4 g. The Sorenson's pairwise similarity coefficient (Cs) increased in a dose-dependent manner and the Shannon's index (H') also increased at the three doses with no significant

difference.

Moreover, Buzhong Yiqi Tang also significantly decreased the 380 bp fragment and increased the Sorenson's pairwise similarity coefficient (Cs) in a dose-dependent manner, in which the maximal and significant effects were shown at the dose of 4.8 g crude drug/kg. Buzhong Yiqi Tang increased and decreased the Shannon's index (H') at the doses of 1.6 and 4.8 g crude drug/kg, and 14.4 g crude drug/kg, respectively.

The net integral area and abundance of the 380 bp were decreased after treatment with Yiwei Tang, indicating that the effect is statistically significant at the dose of 1.9/5.8 g crude drug/kg. Yiwei Tang increased the Sorenson's pairwise similarity coefficient (Cs) in a dose-dependent manner. However, the Shannon's index (H') was lower than that before treatment.

The H' and Cs values as well as the net integral area and abundance of the 380 bp fragment were decreased in rats that received water, which might be due to the long-term Pi-deficiency. A similar trend was seen in the group that received Banxia Houpu Tang. Entrocoordinatibiogen increased the Shannon's index (H') and Sorenson's pairwise similarity coefficient (Cs) ($P < 0.05$), but had no significant effects on the net integral area and abundance of the 380 bp fragment.

Evaluation of therapeutic effects of TCM on Pi-deficieny induced by Folium Sennae

The four biomarkers (H', Cs, net internal area and abundance of the 380 bp fragment) that were identified in rats with Pi-deficiency induced by *Radix* and *Rhizoma Rhei* were also proved to be valid for *Folium Sennae* induced Pi-deficiency. The four recipes (Si Junzi Tang, Lizhong Tang, Buzhong Yiqi Tang and Yiwei Tang) for Pi-deficiency significantly reduced the net integral area and abundance of the 380 bp fragment at smaller and medium doses, but significantly increased the Shannon's index (H') and Sorenson's pairwise similarity coefficient (Cs) (data not shown).

DISCUSSION

This study reported the changes of intestinal microflora in rats with Pi-deficiency induced by *Radix* and *Rhizoma Rhei* or *Folium Sennae*. ERIC-PCR fingerprinting system is highly reproducible when it is used to examine the status of intestinal microflora in rats. In this study, fingerprints of the Sorenson's pairwise similarity coefficient (Cs) from the same DNA extraction were over 95%, respectively.

The dominating intestinal microbial population may vary in subjects due to changed physiological conditions. The replicates (collected on different days) of PCR fingerprints from the same rat showed a high reproducibility (Cs > 75%). However, this value decreased to 57% after water administration, indicating that water administration can affect the intestinal physiology after intragastric operation. These results indicate that ERIC-PCR is a sensitive tool for examining the structure of fecal bacterial community.

Entrocoordinatibiogen (Shenyang No. 1 Pharmaceutical Factory, Shenyang, China) consisting of bacillus licheniformis, a kind of probiotics and a biotherapeutic agent modulating microdysbiosis of intestine, is used in treatment of acute bacillary dysentery. Based on the analysis of ERIC-PCR intestinal microflora molecular markers, the rats that received Entrocoordinatibiogen had a certain extent of recovery as indicated by the increased Shannon's index (H') and Sorenson's pairwise similarity coefficient (Cs). However, neither the net integral area nor the abundance of 380 bp fragment significantly decreased. The 4 major clinical recipes for Pi-deficiency recovered the activities of Pi-deficient rats, especially Si Junzi Tang and Buzhong Yiqi Tang at their medium dose (equivalent to the clinical dose). These results strongly support the rationale behind the current common use of these two recipes for Pi-deficiency[12,14,19]. However, it should be noted that the higher dose of these recipes did not show a better therapeutic effect on Pi-deficiency in the present study. A possible explanation of this phenomenon might be that the recipes have some anti-microorganism actions on Pi-deficiency. It was reported that Si Junzi Tang and some TCM recipes have certain modulating functions in intestinal flora[20-22].

The pathogenesis of Pi-deficiency induced by *Folium Sennae* or by *Radix* and *Rhizoma Rhei* is similar. *Folium Sennae, Radix* and *Rhizoma Rhei*, classified as "bitter-cold" in terms of taste and properties, can simulate the intestinal motility and secretion to induce diarrhea, which results in Pi-deficiency. However, the diarrhea-inducing action of *Folium Sennae* is weaker than that of *Radix* and *Rhizoma Rhei*. That is why the four recipes showed a better recovery profile for *Folium Sennae*-induced Pi-deficiency than that for *Radix* and *Rhizoma Rhei*-induced Pi-deficiency, in the present study.

In conclusion, Pi-deficiency, one of the most common digestive system diseases, is generally caused by the change in intestinal microflora. Although the underlying mechanism of action of TCM is not completely understood, it has been known that TCM has positive effects on some syndromes including Pi-deficiency. ERIC-PCR fingerprints can be used to screen changes in composition of bacterial communities associated with the development of intestinal disease, and to investigate the pharmacodynamic effect of TCM on intestinal microflora or intestinal diseases such as Pi-deficiency.

COMMENTS

Background

Pi-deficiency, a clinical syndrome in traditional Chinese medicine (TCM), is one of the most common digestive system diseases and generally considered to be associated with abnormalities of gastrointestinal microflora.

Research frontiers

Although the underlying mechanism of action of TCM is not completely understood, it has been known that TCM has positive effects on some syndromes including Pi-deficiency. It was reported that some TCM have certain modulating functions in intestinal flora.

Innovations and breakthroughs

In this study, the authors used the molecular markers in study of Pi-deficiency

syndrome, changes in intestinal microflora, and evaluation of the therapeutic effects of traditional Chinese drugs. This is the first study reporting the changes in intestinal microflora of Pi-deficient rats using the enterobacterial repetitive intergenic consensus-PCR (ERIC-PCR) fingerprint profiles.

Applications

ERIC-PCR fingerprints can be used to screen changes in the composition of bacterial communities associated with the development of intestinal disease, and to investigate the pharmacodynamic effect of TCM on intestinal microflora or intestinal diseases including Pi-deficiency.

Terminology

ERIC-PCR is a PCR-based technique in which DNA is isolated from a mixed sample and amplified using conserved ERIC primers targeting short repetitive sequences which are dispersed throughout various bacterial genomes.

Peer review

The authors identified the molecular markers of intestinal microflora by modified ERIC-PCR in rats with Pi-deficiency induced by administration of *Radix* and *Rhizoma Rhei*. In addition, data on the effect of several decoctions on P-deficiency induced by *Radix* and *Rhizoma Rhei* are interesting and seem reliable. The study is interesting and well-designed.

FAT10 level in human gastric cancer and its relation with mutant p53 level, lymph node metastasis and TNM staging. *World J Gastroenterol* 2009; 15(18): 2228-2233 Available from: URL: http://www.wjgnet.com/1007-9327/15/2228.asp DOI: http://dx.doi.org/10.3748/wjg.15.2228

Abstract

AIM: To investigate the role of FAT10 and mutant p53 in the pathogenesis, severity and prognosis of gastric cancer.

METHODS: FAT10, mutant p53 mRNA and protein levels were measured by reverse transcription (RT)-PCR and immunohistochemistry in gastric cancer tissue (n = 62), tumor-adjacent tissue (n = 62) and normal gastric tissue (n = 62). Relation of FAT10 and mutant p53 expression with clinicopathological features and clinical outcomes of gastric cancer patients were analyzed.

RESULTS: The FAT10, mutant p53 mRNA and protein levels were significantly higher in gastric cancer than in its adjacent and normal tissue. The FAT10 and mutant p53 levels in gastric cancer tissue were significantly correlated with lymph node metastasis and tumor, nodes, metastasis (TNM) staging. Moreover, the high FAT10 level was associated with the overall survival rate of patients. Multivariate Cox-proportional hazards model analysis showed that mRNA and protein levels of FAT10 and mutant p53, lymph node metastasis, distant metastasis and TNM stage were the independent prognostic factors for gastric cancer.

CONCLUSION: FAT10 may be involved in gastric carcinogenesis, and is a potential marker for the prognosis of gastric cancer patients. FAT10 and mutant p53 may play a common role in the carcinogenesis of gastric cancer.

INTRODUCTION

FAT10, also known as diubiquitin, is a ubiquitin-like modifier (UBL) of the ubiquitin protein family, first discovered by Fan *et al*[1] in mapping HLA-F gene in 1996. It has been shown that FAT10 is expressed in mature B cells and dendritic cells[2]. It has been reported that FAT10 regulates cell-cycle and non-covalently binds to the human spindle assembly checkpoint protein (MAD2) that is responsible for the maintenance of spindle integrity during mitosis. Inhibition of MAD2 may lead to chromosomal instability, a common feature of tumorigenesis[3,4]. Lee *et al*[5] found that FAT10 is up-regulated in liver, uterine cervix, ovarian, rectal, pancreatic cancers and small intestinal adenocarcinoma, suggesting that FAT10 plays an important role in tumorigenesis.

P53 gene is located on the short arm of chromosome 17 and classified into wild *p53* and mutant *p53*. P53 protein depletion or gene mutation has been detected in over 50% of all cancers. Under the regulation of upstream signals such as DNA damage, proto-oncogene activity, spindle damage and hypoxia, p53 is activated and functions as a modifier in the processes of cell apoptosis, cell cycle arrest, and DNA repair[6,7]. It was reported that damaged DNA enters into S stage, changes cell hereditary characteristics, and finally induces tumorigenesis when p53 is deleted or mutated[8]. There is evidence that the p53 mutation rate is higher in gastric cancer with atrophic gastritis than in that without atrophic gastritis[9]. Rugge *et al*[10] demonstrated

that the *p53* gene mutation rate is 9.7% in patients (less than 40-year old) with gastric cancer of intestinal type, and lower than in old people (40%-60%) and that the p53 mutation rate is lower in young (6.8%) than in old people (10%-25%) with gastric cancer of diffuse type. Moreover, *Helicobacter pylori* (*H pylori*) infection is an important risk factor for gastric tumorigenesis, whereas patients with gastric cancer and *H pylori*-related cytotoxin-associated gene (CagA) are often accompanied with p53 mutation[11], suggesting that p53 gene mutation also plays an important role in gastric tumorigenesis.

Gastric cancer, one of the most common malignant tumors, is a leading cause of cancer-related death worldwide. The mortality of male and female patients with gastric cancer is on the top of the list in China[12]. Although various genetic and molecular alterations have been found in gastric cancer that underly the malignant transformation of gastric mucosa during the multi-step process of carcinogenesis, the detailed mechanism underlying the development of gastric cancer still remains uncertain. It has recently proposed that FAT10 is a downstream target of p53, and dysregulation of FAT10 expression in p53-defective cells can contribute to carcinogenesis[13]. Therefore, it would be of importance if the function of both FAT10 and p53 and their correlation are investigated in human beings. Furthermore, although many researches are available on the structure and function of FAT10, and its inducing factors, little is known about the role of FAT10 in gastric tumorigenesis and its relation with mutant p53 and other gastric cancer biomarkers. In the present study, we analyzed the expression of FAT10 and mutant p53 in gastric cancer tissue and its adjacent tissue and normal gastric mucosa tissue, in an attempt to discover the potential role of FAT10 in the development of gastric cancer.

MATERIALS AND METHODS

Gastric cancer specimens

In this study, gastric cancer tissue and its adjacent tissue (within 2 cm next to the margin of tumor tissue) and normal gastric tissue (more than 5-10 cm next to the margin of tumor tissue) were obtained from 62 gastric cancer patients who were underwent surgical resection in the First Affiliated Hospital of Medical College, Zhejiang University, from March 2003 to May 2004. None of the patients received any preoperative therapies such as chemotherapy or radiotherapy. The patients consisted of 38 males and 24 females, their age ranged 21- 86 years (mean age: 59.62 years). The tumor, nodes, metastasis (TNM) stage of gastric cancer referring to the p-TNM stage were promulgated by the International Union against Cancer (UICC) in 1997. This study was approved by the Hospital Review Board and written consent was obtained from each involved patient.

Immunohistochemistry

FAT10 and mutant p53 protein levels were routinely measured by immuno-histochemistry. Briefly, gastric cancer tissue and its adjacent tissue and normal gastric tissue were sequentially fixed with 10% formalin, embedded in paraffin and cut into 4-μm thick sections. The sections were deparaffinaged and endogenous peroxidase was blocked with H_2O_2. Antigen retrieval was performed by heating the sections in a 0.01 mol/L citrate buffer in a microwave oven. Nonspecific binding was blocked by incubating the sections with normal rabbit serum for 20 min. The sections were then incubated at 37℃ for 2 h with either polyclonal FAT10 antibody (Shanghai Jintai Biological Science and Technology Ltd, China) or monoclonal mutant P53 antibody (Beijing Zhongshan Biological Science and Technology Ltd, China). Controls without primary antibodies were also included. After washed three times with PBS, the sections were incubated with biotin-conjugated secondary antibody (Shanghai Jintai Biological Science and Technology Ltd, China) for 40 min at room temperature. Immunocomplexes were detected with 3, 3-diaminobenzidine (Fuzhou Maixin Biological Science and Technology Ltd, China) that acts as a chromogen and results in deposition of brown reaction products. Species with 0%, about 10%, about 50% of positively stained cells were scored as -, +, and ++, respectively.

RNA extraction and reverse transcription polymerase chain reaction (RT-PCR)

RNA was extracted using Trizol reagent with one-step extraction method. In brief, 1 mL Trizol reagent was added to cultured cells or to approximately 100 mg tissue specimens, respectively, and total RNA was isolated following the manufacturer's instructions. RNA integrity was assessed by agarose gel electrophoresis when clear 18 S and 28 S strips appeared on the gel, whereas total RNA concentration was measured with a spectrophotometer ($A_{260/280}$ Ratios of 1.8-2.0) following its manufacturer's instructions. Total RNA (5 μL) was reversed into cDNA in a 24 μL reaction system at 42℃ for 60 min and at 70℃ for 10 min, sequentially. The mixture contained 5 μL 5-RT-buffer, 1 μL Oligo (dT), 2 μL 10 mmol/L dNTPs mix, 1 μL ribonuclease inhibitor (20 U/μL), 1 μL M-MMLV reverse transcriptase (200 U/μL), and 9 μL DEPC water. The final RT reaction solution was used in PCR (GeneAmp 2400 PCR System, Perkin Elmer Company, USA). The primers and lengths of PCR amplifications are listed in Table 1. DNA products were run in agarose gel at 80-100 V and then analyzed by BIO-RAD image acquisition with an analysis system, followed by semi-quantitative analysis with Quantity One software. The 295 bp, 478 bp, and 492 bp long fragments were detected under UV light. Gray scale scanning was performed on electrophoresis strips using an image acquisition and analysis system.

Statistical analysis

Immunohistochemical expression was defined as positive when moderate to strong nuclear staining was observed in more than 10% cells. χ^2 test was used to determine

the difference in FAT10 and p53 protein levels between different groups and the correlation between positive FAT10 ratio and clinicopathological parameters of patients. RT-PCR semi-quantitative results were expressed as mean ± SD. Student's *t*-test was employed to analyze differences in mRNA levels. Relation between FAT10 and p53 was statistically analyzed using Spearman's rank correlation. Overall survival rate was calculated by Kaplan-Meier curves. Cox proportional hazards model was used to examine the effect of potential prognostic variables on survival. Statistical analysis was performed with SPSS software version 12.0. $P < 0.05$ was considered statistically significant.

RESULTS

Detection of FAT10 and mutant p53 protein in different gastric tissues by immunohistochemistry

FAT10 protein was mainly detected in nuclei of malignant and benign cells which were stained brown-yellow (Figure 1A). Positive staining of FAT10 cells was found in tumor tissue and its adjacent tissue and normal tissue samples from 32 (51.61%), 8 (12.90%) and 4 (6.45%) of the 62 cases. The FAT10 level was significantly different in gastric cancer tissue, and its adjacent tissue and normal tissue ($\chi^2 = 40.96$, $P < 0.01$). The rate of positive FAT10 cells in gastric cancer tissue was significantly higher than that in its adjacent tissue and normal tissue ($P < 0.01$) but was not significantly different between adjacent tissue and normal tissue (Table 2). Mutant P53 was expressed mainly in nuclei and cytoplasm (Figure 1B). Positive immunostaining of mutant fp53 was noted in 45.16% (28/62) of tumor tissue samples, 14.51% (9/62) of adjacent tissue samples and 9.63% (6/62) of normal tissue samples ($\chi^2 = 25.83$, $P < 0.01$). The positive rate of mutant p53 expression in tumor tissue was significantly higher than that in adjacent tissue and normal tissue ($P < 0.01$, Table 2).

Detection of FAT10 and mutant p53 mRNA in different gastric tissues by RT-PCR

The levels of FAT10 and mutant p53-mRNA in tumor tissue and non-tumor tissue were measured. RT-PCR analysis revealed that the relative FAT10-mRNA expression in gastric cancer tissue was significantly higher than that in its adjacent tissue ($t = 3.12$, $P < 0.01$) and normal tissue ($t = 4.64$, $P < 0.01$), whereas no significant difference was detected between tumor-adjacent and normal tissues ($t = 1.03$, Figure 2). Mutant P53-mRNA expression was significantly higher in gastric cancer tissue than in its adjacent tissue ($t = 6.79$, $P < 0.01$) and normal tissue ($t = 5.51$, $P < 0.01$). The difference in mutant p53-mRNA expression between adjacent and normal tissue was not statistically significant ($t = 1.22$, Figure 2).

Normal gastric tissue	58	4 (6.45)	56	6 (9.68)

Relation between FAT10 protein and mRNA levels and clinicopathological features of gastric cancer

To test the potential value of FAT10 as a gastric cancer biomarker, we performed χ^2 test to evaluate the correlation of FAT10 expression with clinicopathological features of gastric cancer (Table 3). The positive rate of FAT10 expression in gastric cancer with regional lymph node metastasis was significantly higher than that without

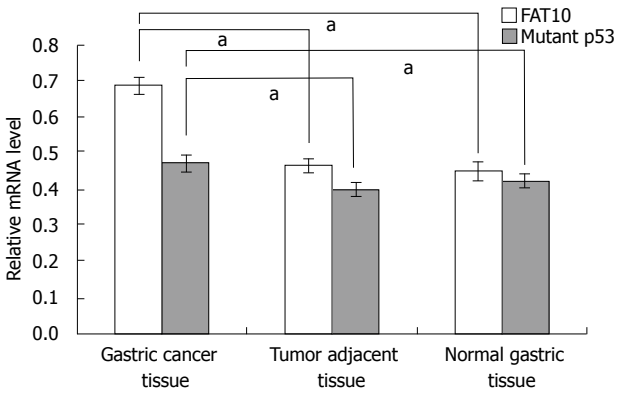

Figure 2 Relative mRNA levels of FAT10 and mutant p53 in different tissues. The column represents the relative gray values of FAT10 and mutant p53 mRNA by normalizing the gray value of β-actin. $^aP < 0.05$ (for FAT10: 0.689 ± 0.023 in gastric cancer tissue, 0.463 ± 0.019 in tumor adjacent tissue, 0.451 ± 0.028 in normal gastric tissue; for mutant p53: 0.471 ± 0.021 in gastric cancer tissue, 0.398 ± 0.017 in tumor adjacent tissue, 0.421 ± 0.019 in normal gastric tissue).

Total	62	32	30

($P < 0.05$), but not with age and sex of patients, tumor size, location, histological grade, and distant metastasis, which was similar to the immunohistochemical results (Table 4).

Correlation between FAT10 and mutant p53 in gastric cancer tissue

The expression rate of FAT10 was 82.14% (23/28) and 26.47% (9/34) in positive and negative mutant p53 tumor tissues, respectively (Table 5). The correlation between FAT10 and mutant p53 was analyzed by Spearman rank correlation. The expression of FAT10 was positively correlated with mutant p53 in gastric cancer ($r = 0.865$, $P < 0.05$). Furthermore, Spearman rank correlation analysis showed that FAT10-mRNA was significantly correlated with mutant p53-mRNA ($r = 0.548$, $P < 0.05$).

Predictive role of FAT10 in gastric cancer

To investigate the impact of FAT10 over-expression

p53 mRNA	0.758	0.346	6.857	1	0.004	1.521

on the clinical outcome of patients, univariate survival probability curves were plotted with respect to the immunohistochemical and RT-PCR results. Except for 4 patients (2 with positive FAT10 protein and FAT10-mRNA, and 2 with negative FAT10 protein and FAT10-mRNA), the other patients were followed up for 48-72 mo. We found that high FAT10 protein and mRNA levels in gastric cancer showed a tendency towards unfavorable prognosis regarding the overall survival rate as shown by Kaplan-Meier analysis ($P < 0.05$, Figure 3). In the Cox regression model, multivariate survival analyses showed that FAT10 protein and mRNA, as well as lymph node metastasis, distant metastasis, TNM stage, and mutant p53 mRNA protein, were the independent adverse prognostic factors for the overall survival rate (Table 6).

DISCUSSION

FAT10 is a member of the ubiquitin-like modifier family of proteins. Over-expression of the FAT10 gene has been observed in several epithelial cancers and high FAT10 expression can increase chromosome instability by reducing kinetochore localization of MAD2 during the prometaphase stage of cell-cycle[14]. In the present study, we measured the FAT10 protein and mRNA levels in gastric cancer tissue, its adjacent tissue and normal tissue from 62 patients. The immunohistochemical analysis suggested that FAT10 protein was mainly expressed in cell nuclei, indicating that FAT10 may participate in cell cycle regulation. The positive expression rate of FAT10 protein and mRNA in gastric cancer tissue was significantly higher than that in its adjacent tissue and normal tissue, suggesting that FAT10 may play an important role in the process of gastric carcinogenesis

Recent researches have shown that the expression of mutant p53 and FAT10 mRNAs is increased in cancer cell line[15,16]. However, the correlation between mutant p53 and FAT10 has not been analyzed in human gastric cancer. In this study, FAT10 and mutant p53 protein/mRNA were over-expressed in gastric cancer tissue whereas high FAT10 and mutant p53 expression levels in tumor tissue were positively correlated. It was reported that p53 negatively regulates the expression of FAT10 and p53 depletion, thus contributing to tumorigenesis by uncontrolled up-regulation of FAT10[13], suggesting that mutant p53 may also activate the FAT10 gene and promote gastric tumorigenesis due to the loss of its anti-carcinoma effect. Moreover, proinflammatory cytokines up-regulate FAT10 in liver and colon cancer, indicating that they play a potential role in activating FAT10 in gastric tumor and merit further investigation[16]. Although p53 binds to the 5' half consensus sequence of p53-binding site at the FAT10 promoter[13], the exact p53-binding site is still unclear, thus further study is needed.

No report is available at present on the correlation between FAT10 protein expression and clinicopathological characteristics of gastric cancer patients. In the present study, FAT10 protein and mRNA levels were closely correlated with lymph node metastasis and TNM stage (Ⅲ + Ⅳ/ Ⅰ + Ⅱ) ($P < 0.05$), indicating that FAT10 can promote tumor invasion and metastasis, and may be a candidate prognostic factor for lymph node metastasis and tumor progression. Large scale studies are needed to further confirm our findings.

Tumor metastasis has become one of the most challenging problems in tumor therapy. Many efforts have been made to predict gastric cancer behaviors, but specific predictive markers for metastasis and recurrence are still lacking[17]. In our study, the patients with a high FAT10 expression level showed a tendency towards unfavorable prognosis. Since FAT10 and mutant p53 protein and mRNA, lymph node

metastasis, distant metastasis, and TNM stage are the independent prognostic factors for poor patient survival, determination of FAT10 status may be an important step in formulating right therapeutic strategies. Moreover, FAT10 may be related with other predictive biomarkers of tumor metastasis, such as CD44v6, nm23, MTA1 and MMPs.

In conclusion, FAT10 is over-expressed in gastric cancer tissue, and positively correlated with mutant p53 expression, lymph node metastasis and tumor progression, and can promote tumor invasion. FAT10 is of prognostic value for human gastric cancer and is a potential target for cancer biotherapy.

COMMENTS

Background

FAT10 belongs to the ubiquitin-like modifiers of ubiquitin protein family, first discovered in mapping HLA-F gene in 1996, and is expressed in mature B cells and dendritic cells. It has been reported that FAT10 can regulate cell-cycle and may play an important role in tumorigenesis. *P53* gene, located on the short arm of chromosome 17, can be divided into wild *p53* and mutant *p53*. P53 protein depletion or gene mutation has been detected in over 50% of all cancers, suggesting that P53 may play an important role in gastric tumorigenesis. Gastric cancer, one of the most common malignant tumors, is a leading cause of cancer-related death worldwide, and is on the top of the list in China. The detailed mechanism underlying the development of gastric cancer still remains uncertain.

Research frontiers

It has been recently found that FAT10 can non-covalently bind to the human spindle assembly checkpoint protein (MAD2) that is responsible for the maintenance of spindle integrity during mitosis. Inhibition of MAD2 may lead to chromosomal instability, a common feature of tumorigenesis. It has been shown that damaged DNA enters into S stage, changes cell hereditary characteristics, and finally induces tumorigenesis when p53 is deleted or mutated. Moreover, there is evidence that the p53 mutation rate is higher in gastric cancer with atrophic gastritis than in gastric cancer without atrophic gastritis. FAT10 is a downstream target of p53, and down-regulation of FAT10 expression in p53-defective cells contributes to carcinogenesis.

Innovations and breakthroughs

In this study, the FAT10 and mutant p53 mRNA and protein levels were significantly higher in gastric cancer tissue than in its adjacent tissue and normal tissue. The FAT10 and mutant p53 levels in gastric cancer tissue were significantly correlated with lymph node metastasis and TNM staging. Moreover, mRNA and protein levels of FAT10 and mutant p53, lymph node metastasis, distant metastasis, and TNM stage were found to be independent prognostic factors for patients with gastric cancer.

Applications

FAT10 may be a potential marker of gastric cancer prognosis, which needs to be further verified. FAT10 is positively correlated with mutant p53, indicating that it may play a role in carcinogenesis and becomes a novel therapeutic target of gastric cancer.

Terminology

FAT10: a protein belonging to ubiquitin-like modifier (UBL) of ubiquitin protein family, is mainly expressed in mature B cells and dendritic cells and regulates cell-cycle and chromosomal instability, thus playing an important role in tumorigenesis.

Peer review

This study describes the increased FAT10 and mutant p53 mRNA and protein levels in gastric cancer and the correlation between FAT10 and mutant p53. Furthermore, the authors also found that mRNA and protein levels of FAT10 were independent prognostic factors for patients with gastric cancer. These results are innovative, showing that FAT10 may be involved in gastric carcinogenesis and in gastric cancer prognosis. However, further study is needed to further verify their findings.

Abstract

AIM: To investigate the effect of 5-allyl-7-gen-difluoromethylenechrysin (ADFMChR) on apoptosis of human liver carcinoma HepG2 cell line and the molecular mechanisms involved.

METHODS: HepG2 cells and L-02 cells were cultured *in vitro* and the inhibitory effect of ADFMChR on their proliferation was measured by MTT assay. The apoptosis of HepG2 cells was determined by flow cytometry (FCM) using propidium iodide (PI) fluorescence staining. DNA ladder bands were observed by DNA agarose gel electrophoresis. The influence of ADFMChR on the proxisome proliferator-activated receptor γ (PPARγ), NF-κB, Bcl-2 and Bax protein expression of HepG2 cells were analyzed by Western blotting.

RESULTS: MTT assay showed that ADFMChR significantly inhibited proliferation of HepG2 cells in a dose-dependent manner, with little effect on growth of L-02 cells, and when IC_{50} was measured as 8.45 μmol/L and 191.55 μmol/L respectively, the potency of ADFMChR to HepG2 cells, was found to be similar to 5-fluorouracil (5-FU, IC_{50} was 9.27 μmol/L). The selective index of ADFMChR cytotoxicity to HepG2 cells was 22.67 (191.55/8.45), higher than 5-FU (SI was 7.05 (65.37/9.27). FCM with PI staining demonstrated that the apoptosis rates of HepG2 cells treated with 3.0, 10.0 and 30.0 μmol/L ADFMChR for 48 h were 5.79%, 9.29% and 37.8%, respectively, and were significantly higher when treated with 30.0 μmol/L ADFMChR than when treated with 30.0 μmol/L ChR (16.0%) ($P < 0.05$) and were similar to those obtained with 30.0 μmol/L 5-FU (41.0%). DNA agarose gel electrophoresis showed that treatment of HepG2 cells with 10.0 μmol/L ADFMChR for 48 h and 72 h resulted in typical DNA ladders which could be reversed by 10.00 μmol/L GW9662, a blocker of PPARγ. Western blotting analysis revealed that after 24 h of treatment with 3.0, 10.0, 30.0 μmol/L ADFMChR, PPARγ and Bax protein expression in HepG2 cells increased but Bcl-2 and NF-κB expression decreased; however, pre-incubation with 10.0 μmol/L GW9662 could efficiently antagonize and weaken the regulatory effect of 3.0, 30.0 μmol/L ADFMChR on PPARγ and NF-κB protein expression in HepG2 cells.

CONCLUSION: ADFMChR induces apoptosis of HepG2 cell lines by activating PPARγ, inhibiting protein expression of Bcl-2 and NF-κB, and increasing Bax expression.

INTRODUCTION

Human liver carcinoma is the fifth most common cancer in the world and is responsible for > 600 000 deaths

annually[1]. The majority of patients with hepatocellular carcinoma die within 1 year after the diagnosis. At present, the treatment of hepatocellular carcinoma mainly includes surgery and chemotherapy, but the curative effects of the existing chemotherapeutic drugs are not good enough and they have numerous side effects. Therefore, searching for highly efficient antitumor drugs remains a hot research area.

Peroxisome proliferator-activated receptor γ (PPARγ) is a member of the nuclear hormone receptor superfamily; a ligand-dependent transcription factor that plays an important role in lipid and glucose metabolism[2,3]. In recent years, over-expression of PPARγ has been found in a variety of tumor cells and PPARγ agonists can induce apoptosis[4,5]. It has been reported that chrysin (ChR) and its derivatives activate PPARγ to inhibit COX-2 and iNOS activity through various pathways distinguished from thiazolidones[6].

Chrysin (5,7-dihydroxy flavone, ChR) is a kind of flavonoid with pharmacological activities and is widely distributed in the plant kingdom. It has been demonstrated that ChR can markedly inhibit the growth of human thyroid cancer cells[7], and has an effect on the inhibition of proliferation and induction of apoptosis in human myeloid leukemia cells as well[8,9]. Comte *et al*[10] reported that, through alkylation, the hydrophobicity of ChR is increased, its KD value decreased, and its binding affinity towards P-glucoprotein (P-gp) enhanced. We confirmed that a series of B-ring trifluoromethylated derivatives of ChR markedly inhibited the growth of HT-29 and SGC-7901 cell lines[11] and that 5, 7-dihydroxy-8-nitrochrysin (NOChR) had an inhibitory effect on subcutaneously transplanted primary Lewis lung carcinoma in mouse and its spontaneous metastasis in a dose-dependent manner[12]. Our previous study showed that the suppressive effect of 5-allyl-7-gen-difluoromethylenechrysin (ADFMChR) on proliferation of the CoC1 cell line was stronger than that of ChR[13]. However, whether ADFMChR has antitumor effects on human liver carcinoma is unknown.

In this study, we aimed to investigate whether ADFMChR induces apoptosis of HepG2 cell line by activation of PPARγ and whether NF-κB, Bcl-2 and Bax are involved in this mechanism, thereby providing a new opportunity for research with regard to the pharmaceutical prevention and cure of human liver cancer.

MATERIALS AND METHODS

Cell lines and cell culture

HepG2 cells and L-02 cells were purchased from the China Center for Type Culture Collection (CCTCC) and were cultured in RPMI-1640 medium with 10% fetal bovine serum. Antibiotics added were 100 units/mL penicillin and 100 μg/mL streptomycin (Life Technologies, Inc) at 37℃ in a 5% CO_2 incubator.

Medicines and chemical reagents

ADFMChR was synthesized in the Medical College, Hunan Normal University as previously described[14]; with a molecular weight of 344 ku, characteristic yellow crystals and purity of 99.0%, its molecular formula is $C_{19}H_{14}O_4F_2$. ADFMChR was dissolved in dimethyl sulfoxide (DMSO), diluted with phosphate buffer solution (PBS), and finally prepared as 2 mmol/L storage solution after filtration sterilization. RPMI-1640, ChR, MTT and DMSO were purchased from Sigma Company. 5-fluorouracil (5-FU) was from Jinghua Pharmaceutical Corporation Ltd, Nantong. Ladder Apoptotic DNA Ladder Detection Kit was purchased from Bodataike Company, Beijing. Mouse anti-human Bcl-2 monoclonal antibody, mouse anti-human NF-κB monoclonal antibody, mouse anti-human Bax monoclonal antibody and rabbit anti-human PPARγ polyclonal antibody were purchased from Santa Cruz Biotechnology, Inc (U.S.A).

MTT assay

HepG2 cells or L-02 cells were seeded in a 96-well plate at a density of 1.0×10^4 cells/well as previously described[15]. Drugs of different concentrations were added to each well and cultured for 48 h, followed by incubation with 5 mg/L MTT for 4 h. The supernatant was removed after centrifugation. Finally, 100 μL of DMSO was added and absorbance at 490 nm wavelength (A_{490}) was measured by means of Enzyme-labeling instrument (EX-800 type). Relative cell proliferation inhibition rate (IR) = (1 - average A_{490} of the experimental group/average A_{490} of the control group) × 100%.

Flow cytometry (FCM) with propidium iodide (PI) staining

HepG2 cells were treated with serum-free medium for 24 h, followed by treatment with media containing 3.0, 10.0, 30.0 μmol/L ADFMChR, 30.0 μmol/L ChR and 30.0 μmol/L 5-FU for 48 h, respectively. Cells were collected and prepared as a single cell suspension by mechanical blowing with PBS, washed with cold PBS twice, fixed with 700 mL/L alcohol at 4℃ for 24 h, stained with PI and cell apoptosis was detected using FCM (American BD Company, FACS420).

DNA agarose gel electrophoresis

As previously described[16], cells were cultured with 10.0 μmol/L ADFMChR and 10.0 μmol/L ADFMChR plus 10.0 μmol/L GW9662, a PPARγ antagonist, for 0, 24, 48 and 72 h, respectively. Cells were washed twice with PBS and DNA was extracted with an Apoptotic DNA Ladder Detection Kit according to the manufacturer's instructions. The extracted DNA was kept at 4℃ overnight. Then 8.5 μL of DNA sample was mixed with 1.5 μL of 6 × Buffer solution, electrophoresed on 20.0 g/L agarose gel containing ethidium bromide at 40 V, and observed through DBT-08 gel image analysis system.

Western blotting analysis

As previously described[17], cells were treated with 3.0, 10.0, 30.0 μmol/L ADFMChR and 30.0 μmol/L ChR for 24 h, respectively. Cells were collected, washed three times with PBS, lysed in cell lysis buffer containing 0.1 mol/L NaCl, 0.01 mol/L Tris-Cl (pH 7.6), 0.001 mol/L

EDTA (pH 8.0), 1 μg/mL Aprotinin, 100 μg/mL PMSF, and then centrifuged at 13000 × *g* for 10 min at 4℃. The extracted protein sample (25 μg total protein/lane) was added in the same volume of sample buffer and subjected to denaturation at 100℃ for 10 min, then electrophoresed on 100 g/L or 60 g/L SDS-PAGE at 100 mA for 3 h, and finally transferred onto PVDF membrane. The PVDF membrane was treated with TBST containing 50 g/L skimmed milk at room temperature for 2 h, followed by incubation with the primary antibodies PPARγ, NF-κB, Bcl-2 and Bax (1:500 dilution), respectively, at 37℃ for 2 h or at 4℃ overnight. After being washed with TBST for 30 min, the corresponding secondary antibody was added and incubated at room temperature for 1 h. The membrane was then washed three times for 15 min each with TBST. Fluorescence was visualized with enhanced chemiluminescence (Amersham, Arlington Heights, IL). The results were analyzed with Image analyzer and the product of area and optical density was expressed as integral absorbance (IA).

Statistical analysis

Experimental data in each group were presented as mean ± SD. Analysis of variance was performed with SPSS software for windows 15.0 by using one way ANOVA and pairwise comparison with Student's *t* test. $P < 0.05$ was considered statistically significant.

RESULTS

Determination of proliferation of HepG2 and L-02 cell lines by MTT assay

MTT assay showed that ADFMChR markedly inhibited proliferation of HepG2 cells in a dose-dependent manner (Figure 1), with little effect on growth of L-02 cells, and when IC_{50} were measured as 8.45 μmol/L and 191.55 μmol/L, respectively, the potency of ADFMChR to HepG2 cells was found to be similar to 5-fluorouracil (5-FU, IC_{50} was 9.27 μmol/L). The selective index of ADFMChR cytotoxicity to HepG2 cells was 22.67 (191.55/8.45), higher than 5-FU (SI was 7.05 (65.37/9.27).

Analysis of the effect of ADFMChR on apoptosis of HepG2 cell lines by FCM with PI staining

FCM with PI staining demonstrated that the apoptosis rates of HepG2 cells treated with 3.0, 10.0 and 30.0 μmol/L ADFMChR for 48 h were 5.79%, 9.29% and 37.8%, respectively, and were significantly higher when treated with 30.0 μmol/L ADFMChR than when treated with 30.0 μmol/L ChR (16.0%) ($P < 0.05$) and were similar to those obtained with 30.0 μmol/L 5-FU (41.0%) (Figure 2).

Detection of ADFMChR-induced apoptosis of HepG2 cells by agarose gel electrophoresis

DNA agarose gel electrophoresis showed that treatment of HepG2 cells with 10.0 μmol/L ADFMChR for 48 h and 72 h resulted in typical DNA ladders, which could be eliminated or attenuated by treating with 10.0 μmol/L ADFMChR plus 10.0 μmol/L GW9662 for 48 h and 72 h (Figure 3).

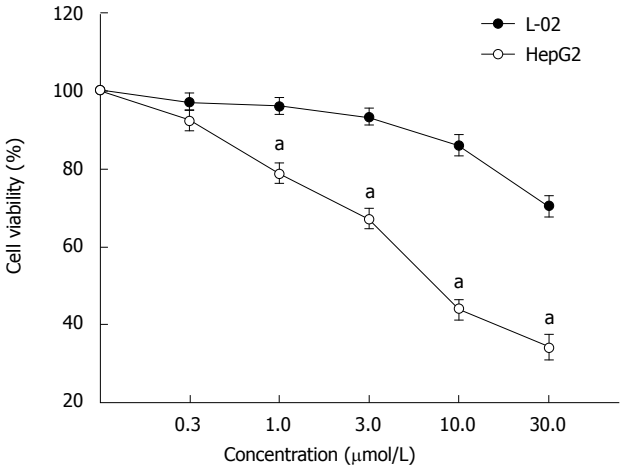

Figure 1 ADFMChR selectively inhibited proliferation of HepG2 cells. $^aP < 0.05$ *vs* treatment with ADFMChR in the same concentration to L-02 cells (mean ± SD, $n = 9$).

Analysis of the effect of ADFMChR on PPARγ, NF-κB, Bax and Bcl-2 protein expression of HepG2 cell line

Western blotting analysis showed that the relative densities of PPARγ, NF-κB, Bcl-2 and Bax protein bands of HepG2 cells treated with 3.0, 10.0, 30.0 μmol/L ADFMChR for 24 h were 109.3%, 126.4%, 147.7% and 92.9%, 89.0%, 72.4% and 94.1%, 85.5%, 77.3% and 106.8%, 116.3%, 125.7% of the HepG2 cells not treated with ADFMChR, respectively ($P < 0.05$) (Figure 4). This indicates that ADFMChR can increase the PPARγ and Bax protein expression and decrease NF-κB and Bcl-2 protein expression.

Effect of GW9662 on regulation of PPARγ and NF-κB protein expression by ADFMChR

Western blotting analysis demonstrated that when HepG2 cells were pre-incubated with 10.0 μmol/L GW9662, a blocker of PPARγ, for 30 min, the effects of 3.0, 30.0 μmol/L ADFMChR on PPARγ protein expression and NF-κB protein expression were antagonized or weakened (Figure 5), suggesting that the effects of ADFMChR on up-regulation of PPARγ protein expression and down-regulation of NF-κB protein expression were associated with the activation of PPARγ.

DISCUSSION

Tumorigenesis and tumor progression are strongly associated with abnormal apoptosis. A number of antitumor drugs exert their therapeutic effects by inducing or promoting apoptosis. Enhancing the antitumor effect of existing anticancer drugs, but not to increase its toxicity, is the aim of current anticancer research. There is evidence to support the concept that luteolin, apigenin and chrysin have great potential to be developed into novel cancer preventative agents[18].

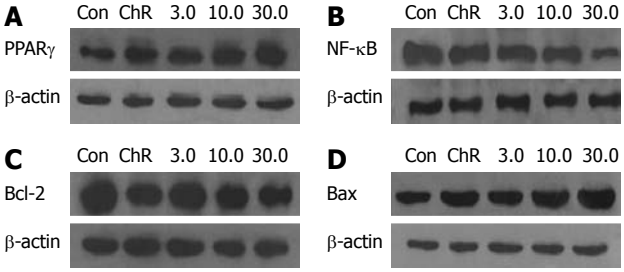

Figure 4 Western blotting analysis showing regulation of PPARγ (A), NF-κB (B), Bcl-2 (C) and Bax (D) protein expression in HepG2 cells by ADFMChR. (mean ± SD, $n = 3$).

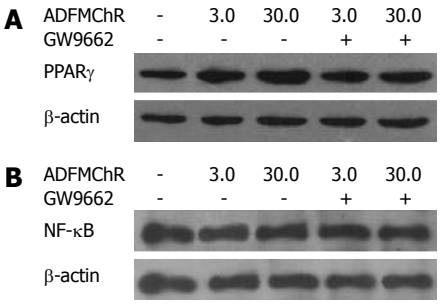

Figure 5 PPARγ antagonist GW9662 blocked the effects of ADFMChR on PPARγ and NF-κB protein expression in HepG2 cells. A: PPARγ; B: NF-κB. HepG2 cells were pretreated with 10.0 μmol/L GW9662 for 30 min, then exposed to 3.0, 30.0 μmol/L ADFMChR for 24 h, respectively (mean ± SD, $n = 3$).

Our previously research showed that ADFMChR potently inhibited the proliferation of ovarian cancer CoC1 cells in a dose-dependent manner[19], and could induce apoptosis of SMMC-7721 cells *in vitro*, with its mechanism possibly associated with G1 phase cell cycle arrest[20]. Li *et al*[19] and Xu *et al*[21] found that the ability of ADFMChR to induce induction of apoptosis in CoC1 cells may be mediated by activation of PPARγ, sequentially accompanied by reducing NF-κB and Bcl-2 levels and increasing Bax expression. Our experiment was to investigate the apoptosis of human liver carcinoma HepG2 cell line induced by ADFMChR and to provide experimental evidence for its application as an antitumor drug.

Apoptosis usually results in typical morphological and biochemical characteristics, including condensed chromatin in cells, appearance of apoptotic bodies, presence of hypodiploid peak in FCM analysis and DNA ladder bands on agarose electrophoresis[22,23]. In

this study, treatment of HepG2 cells with ADFMChR resulted in formation of DNA ladder bands and the appearance of marked hypodiploid peak. Thus, this experiment suggested that ADFMChR can induce apoptosis of human liver carcinoma HepG2 cell line *in vitro*.

PPARγ is a kind of ligand-activated nuclear transcription factor belonging to a nuclear receptor superfamily and has been implicated in metabolic diseases and is associated with cell proliferation, differentiation and apoptosis[24]. NF-κB inhibits apoptosis, promotes cell survival and reduces the expression of Bcl-2[25]. Chen *et al*[26] confirmed that PPARγ ligands may markedly inhibit NF-κB expression and reduce Bcl-2 expression leading to inhibited cell growth and induction of apoptosis of colonic cancer HT-29 cell line by activation of PPARγ. Liang *et al*[6] have recently shown that ChR is activated in different ways with thiazolidinones, and PPARγ inhibits activation of cyclooxygenase-2 (COX-2) and inducible nitric oxide synthase. 8-bromo-7-methoxychrysin (BrMChR) or 5,7-dihydroxy-8-nitrochrysin (NOChR) induce apoptosis of SGC2-7901 cell line by activating PPARγ[27,28]. In order to find out whether ADFMChR decreases NF-κB and Bcl-2 protein expression to induce apoptosis of HepG2 cells by activation of PPARγ, we pre-incubated HepG2 cells with GW9662, a selective antagonist of PPARγ, and observed the effect of ADFMChR on apoptosis and PPARγ and NF-κB protein expression of HepG2 cells. Our results showed that preincubation with GW9662 could effectively antagonize ADFMChR-induced apoptosis of HepG2 cells and down-regulation of NF-κB protein expression, suggesting that apoptosis of HepG2 cells induced by ADFMChR is dependent on activation of PPARγ.

Apoptosis is a complex process involving several genes, such as Bcl-2, Bax, and great attention has been given to the Bcl-2 family. The Bcl-2 family can positively and negatively regulate apoptosis[29]. Bcl-2 and Bax are two members of the Bcl-2 family, and play different roles in programmed cell death[30]. When Bax is over-expressed in cells, apoptosis in response to death signals is accelerated, leading to its designation as a death agonist[31]. When Bcl-2 is over-expressed it heterodimerizes with Bax and death is repressed[31]. Therefore, the ratio of Bcl-2 to Bax is important in determining susceptibility to apoptosis[30]. The results in this study confirmed that Bcl-2 expression in non-treated HepG2 cells was higher than in those treated with 3.0, 10.0, 30.0 μmol/L ADFMChR for 24 h; in contrast, Bax expression was lower. Thus, the ratio of Bcl-2 to Bax in HepG2 cells treated with ADFMChR was lower than that of non-treated HepG2 cells, which indicated that ADFMChR-induced HepG2 cells apoptosis was associated with down-regulation of Bcl-2 expression, up-regulation of Bax expression and reduction of the ratio of Bcl-2 to Bax.

In summary, ADFMChR possesses stronger anti-hepatic cancer effect *in vitro* than parent compound ChR, and was similar to 5-FU, and it exerts its apoptotic effect by activation of PPARγ, down-regulation of NF-κB and Bcl-2 protein expression, up-regulation of Bax protein expression, and reduction of the ratio of Bcl-2 to Bax. ADFMChR might be a promising candidate for the development of antitumor drugs.

COMMENTS

Background

Human liver carcinoma is the fifth most common cancer in the world. Unfortunately, the disease is often diagnosed at a late stage. For these patients, medical treatments, including chemotherapy, chemoembolization, ablation, and proton beam therapy, are not adequate. Most patients show disease recurrence that rapidly progresses to the advanced stages with multiple intrahepatic metastases and their 5-year relative survival rate is only 7%. Clearly, there is an urgent need for new therapies for this disease.

Research frontiers

Enhancing the antitumor effect of existing anticancer drugs, but not to increase its toxicity, is the aim of current anticancer research. Natural compounds have been extensively studied and have shown anti-carcinogenic activities by interfering with the initiation, development and progression of cancer through the modulation of various mechanisms including cellular proliferation, differentiation, apoptosis, angiogenesis, and metastasis. Flavonoids are a group of polyphenolic substances widely distributed in the plant kingdom and present in human diets. Previous reports have shown that flavonoids (such as chrysin, apigenin) could inhibit the proliferation and induce apoptosis in tumor cells. In this study, the authors demonstrate that 5-allyl-7-gen-difluoromethylenechrysin (ADFMChR) could induce apoptosis of human liver carcinoma HepG2 cells *in vitro* by activation of PPARγ.

Innovations and breakthroughs

Recent research has shown that chrysin and its derivatives possess a strong anticancer effect. This is the first study to report that ADFMChR, the derivative of chrysin, has a greater suppressive effect on proliferation of HepG2 cells than that of chrysin, and induces apoptosis of HepG2 cells. These data support the idea that ADFMChR has great potential to be developed into novel cancer preventative agents.

Applications

This finding may provide a molecular basis for the clinically observed cancer-preventive effects of 5-allyl-7-gen-difluoromethylenechrysin (ADFMChR) and new clues for research about pharmaceutical prevention and cure of human liver carcinoma.

Terminology

ADFMChR, a Chrysin derivative, which was taken as the principle compound to design and synthesize, was prepared by alkylation, methylation, and gen-difluoromethylation of chrysin, and was found to have stronger anticancer activities than parent compound chrysin.

Peer review

The authors demonstrate that the effects of ADFMChR on induction of apoptosis in HepG2 cells may be associated with activation of PPARγ, sequentially accompanied by inhibition of protein expression of NF-κB and Bcl-2 and reduced ratio of Bcl-2 to Bax. The results provide a new idea for cure of human liver carcinoma.

Abstract

AIM: To investigate the association of variations in the cyclooxygenase-2 (COX2) and uridine diphosphate glucuronosyltransferase 1A6 (UGT1A6) genes and non-steroidal anti-inflammatory drugs (NSAIDs) use with risk of colon cancer.

METHODS: NSAIDs, which are known to reduce the risk of colon cancer, act directly on COX2 and reduce its activity. Epidemiological studies have associated variations in the *COX2* gene with colon cancer risk, but others were unable to replicate this finding. Similarly, enzymes in the *UGT1A6* gene have been demonstrated to modify the therapeutic effect of NSAIDs on colon adenomas. Polymorphisms in the *UGT1A6* gene have been statistically shown to interact with NSAID intake to influence risk of developing colon adenomas, but not colon cancer. Here we examined the association of tagging single nucleotide polymorphisms (SNPs) in the *COX2* and *UGT1A6* genes, and their interaction with NSAID consumption, on risk of colon cancer in a population of 422 colon cancer cases and 481 population controls.

RESULTS: No SNP in either gene was individually statistically significantly associated with colon cancer, nor did they statistically significantly change the protective effect of NSAID consumption in our sample. Like others, we were unable to replicate the association of variants in the *COX2* gene with colon cancer risk ($P > 0.05$), and we did not observe that these variants modify the protective effect of NSAIDs ($P > 0.05$). We were able to confirm the lack of association of variants in *UGT1A6* with colon cancer risk, although further studies will have to be conducted to confirm the association of these variants with colon adenomas.

CONCLUSION: Our study does not support a role of COX2 and UGT1A6 genetic variations in the development of colon cancer.

INTRODUCTION

Almost 150 000 new colorectal cancer cases are estimated to be diagnosed in 2008, resulting in almost 50 000 deaths (National Cancer Institute-www.cancer.gov). Colon adenomas (polyps) are a well established precursor of colon cancer. The genetic and environmental factors that cause the development of colon adenomas or their subsequent progression into cancer are not entirely known. Genetics are known to be a large risk factor for colon cancer, and indeed having a family history of colon cancer increases your risk of developing it yourself substantially. However, the known genetic susceptibility loci for colon cancer make up only a small fraction of this risk.

Cyclooxygenase-2 (COX-2) is a pro-inflammatory enzyme that converts arachidonic acid to prostaglandins. COX2 has been shown to be upregulated in a high proportion (about 86%) of human colorectal cancer[1]. Numerous additional findings have indicated a likely role for the cycloxygenases and inflammation in the development of colon cancer[2].

Non-steroidal anti-inflammatory drugs (NSAIDs), including aspirin and ibuprofen, act directly on COX2 as well as other targets to reduce activity. A substantial body of epidemiologic and randomized clinical trial evidence suggests that regular NSAID use and selective COX-2 inhibitors reduce the risks of colorectal cancer or the recurrence of adenomatous polyps[3], which is, at least in part, attributed to their known anti-inflammatory effects. The *COX-2* gene is thus a good candidate gene for colorectal carcinogenesis and its genetic variants may affect the susceptibility to the development of this colorectal cancer by altering the effects of this enzyme on the inflammatory response. To date, a few studies have evaluated a limited number of polymorphisms in the *COX2* gene in relation to risk of colorectal cancer and adenomatous polyps[4-7]. The findings have yielded inconsistent results, with some[4-6], but not all[7], reporting an association with the risk of colorectal cancer or polyps. Additionally, a sib-pair study of colon neoplasia with relatively small sample size found no linkage to the *COX2* locus[8].

Furthermore, genetic variation in the uridine diphosphate glucuronosyltransferase 1A6 (*UGT1A6*) gene have been associated with differences in aspirin metabolism, and those with the less frequent variants have a 30%-50% lower enzyme activity[9]. Additionally, a few studies have examined the association of genetic polymorphisms in *UGT1A6*, a rate-limiting enzyme directly involved in aspirin metabolism, and their interactions with aspirin or NSAIDs in relation to colorectal cancer and polyps[10-13]. Although two studies of colon cancer observed no association with genetic variants in *UGT1A6*[12,13], two studies of colon adenomas identified variants in *UGT1A6* that modified the protective effect of aspirin[10,11]. Others have identified variants that influence the risk of adenoma recurrence[14]. To further investigate the role of *COX2* and *UGT1A6* in relation to the risk of colon cancer, we tested nine tag single nucleotide polymorphisms (SNPs) in *COX2* and two functional SNPs in *UGT1A6*[13] in a population-based case-control study of colon cancer.

MATERIALS AND METHODS

Study population

The details of the present study have been described elsewhere[15]. Briefly, colon cases (n = 422) were identified through the population-based Surveillance, Epidemiology and End Results (SEER) Kentucky Cancer Registry, and 481 population controls living in Kentucky were recruited *via* random digit dialing. Participants donated a blood sample for genetic analyses and completed a detailed self-administered lifestyle risk factor questionnaire that included information on NSAID use. Participation rates were 72.2% for cases and 62.5% for controls. All participants provided written informed consent. The study was approved by the Institutional Review Boards of the University of Kentucky, Lexington, and Case Western Reserve University/University Hospitals Case Medical Center.

Genotyping

We assessed the common genetic variation (SNPs with minor allele frequencies > 5%) of *COX-2* that spanned about 2 kb upstream of the transcription start site and about 1 kb downstream of the 3' untranslated region. Seven tag SNPs for COX-2 were selected to predict unmeasured SNPs ($r^2 > 0.8$) using publicly available genotype data for European populations from the International HapMap project (www.hapmap.org) and the Perlegen and Seattle SNP projects (http://gvs.gs.washington.edu/GVS). One common SNP, -899 G/C (rs20417), that was previously associated with colorectal cancer[9], and rs689470, which was previously associated with prostate cancer[16], were also included. Two functional non-synonymous SNPs [rs1105879 (R184S) and rs2070959 (T181A)] in UGT1A6[13] were selected. Genotyping was performed using the Taqman allelic discrimination assay with genotyping error < 0.1%, as described previously[15].

Statistical analyses

We evaluated the association between *COX-2* and *UGT1A6* genotypes and colon cancer risk using multivariate unconditional logistic regression models. Each SNP was evaluated assuming dominant, additive and recessive modes of inheritance. For all SNPs, the allele with the lower frequency was coded as the risk allele. For the dominant model, individuals with at least one copy of the risk allele were coded as 1, others were

coded as 0. For the recessive model, only those with two copies of the risk allele were coded as 1. In the additive model, individuals were coded with the number of risk alleles they possessed (0, 1 or 2). In our base models, we adjusted for age, gender, and race. For these analyses, age was defined as age at diagnosis for cases and age at recruitment for controls. We further controlled for family history of colorectal cancer, body mass index (BMI), regular NSAID use, alcohol consumption, smoking, and intensity of recreational physical activity in the 20 s, for those with available data. Regular NSAID use was defined as having reported intake of at aspirin or ibuprofen at least twice a week for a period of one month or longer.

To evaluate potential effect modification of NSAID use, we tested for multiplicative interaction by including the main effects and a cross-product term of SNP × NSAID use in the logistic regression models. All *P*-values were two-sided, and all analyses were undertaken with SAS software (version 9.1; SAS Institute, Inc., Cary, North Carolina).

RESULTS

The characteristics and genotypic distributions of this predominantly Caucasian study population are summarized in Table 1. All SNPs were found to be in Hardy-Weinberg equilibrium both in controls alone and in the entire sample. We found no statistically significant association between any of the nine *COX2* SNPs and two functional *UGT1A6* SNPs and colon cancer risk, regardless of the mode of inheritance (Table 2).

We further explored potential effect modification of the association by regular NSAID use, and found no evidence for interaction of any SNP (Table 2) in either gene ($P > 0.05$).

Since others[10] have reported that UGT1A6 variants modify the therapeutic effects of aspirin in a population of women only, we stratified our analyses by gender. We found very little differences in results with nothing significant in females or males only as well (results not shown).

DISCUSSION

In our analysis, we examined potential effect modification by regular NSAID use rather than aspirin alone, as other groups have done, due to the smaller number of aspirin alone users. To account for this, we repeated our analysis using aspirin use only (115 cases and 157 controls), and the results did not change materially (not shown), with no significant findings. However, the lack of association with aspirin alone may be due to the small sample size and thus lack of statistical power.

Our study had over 90% power to detect an OR ⩾ 1.75 at a two-sided $\alpha = 0.05$ for the polymorphisms studied here, and over 80% power to detect an OR ⩾ 1.60, assuming a dominant model of inheritance and allele frequency of 0.1. While we did comprehensively capture the common genetic variation across the *COX2* gene, we only evaluated two putative functional SNPs in *UGT1A6*, and were limited in our ability to make direct conclusions about the effect of other genetic variants in *UGT1A6*. It is possible that these variants have smaller effects on colorectal cancer susceptibility or the therapeutic effects of NSAID use that we were unable to detect with this study.

Table 1 Population characteristics *n* (%)

	Case (*n* = 422)	Control (*n* = 481)	*P*[1]

[1]*P*-value of significance difference between cases and controls in χ^2 test (discrete variables and genotypes) or *t*-test (continuous); [2]Age at diagnosis for cases, and age at questionnaire completion for controls; [3]Family history of first-degree relatives with colorectal cancer.

It is important to note that NSAID use was based on self-report. Individuals may not accurately recall duration or frequency of NSAID intake. Nevertheless, our finding of a protective effect of NSAID use (OR = 0.69, 95% CI = 0.50-0.96, $P = 0.02$) is in agreement with its well-documented association with colon cancer[17], lending credibility to our questionnaire data.

In conclusion, this moderately large population-based case-control study did not detect a direct association between variants in the *UGT1A6* and *COX2* genes and risk of colon cancer nor an effect modification by NSAIDs. The results of our study are in line with the two studies of colon cancer showing null results[12,13]. Taken together with the studies showing an association with polyps[10,11], our results suggest genetic variation of *UGT1A6* may affect the early stages of colon tumorigenesis, but has little influence on the progression from adenomatous polyps to colon cancer, although we are unable to test that hypothesis directly.

Table 2 Odds ratios for individual SNPs and SNP by NSAID use interactions

COMMENTS

Background

Colon cancer accounts for almost 150 000 cancer cases and 50 000 deaths in the United States alone. Non-steroidal anti-inflammatory drug (NSAID) use has been well known to reduce the risk of colon cancer.

Research frontiers

It is unclear how individual variation influences the protective effect of NSAIDs. Cyclooxygenase-2 (*COX2*) and uridine diphosphate glucuronosyltransferase 1A6 (*UGT1A6*) are two genes that have been proposed to modify the effect of NSAIDs on colon cancer risk. *COX2* is a direct target of NSAIDs and UGT1A6 variations have been shown to alter the metabolism of aspirin, a common NSAID.

Innovations and breakthroughs

This study has provided further insight into the role of the *COX2* and *UGT1A6* genes in colon cancer risk.

Applications

Since genetic variation often accounts for differences in an individual's response to preventive or therapeutic drugs, it is important to understand the relationship between genes, the drugs and the intended outcome. NSAIDs have been suggested as a chemopreventive agent for individuals at high risk of colon cancer. It is thus important to identify those individuals who would most benefit from the use of NSAIDs. This study found that, while other genes may predict enhanced benefit of NSAID use for colon cancer prevention, *COX2* and *UGT1A6* do not.

Terminology

COX2 and *UGT1A6* are two genes involved in NSAID metabolism. Since NSAIDs, including aspirin and ibuprofen, are known to be protective for colon cancer, it has been hypothesized that these genes would influence and individual's response to NSAID use with respect to colon cancer risk.

Peer review

The authors examined the association of *COX2* and *UGT1A6* polymorphisms

and risk of colon cancer. They also evaluated the effect of variations in these genes on the protective effect of NSAIDs. They did not find an association with any variant examined and risk of colon cancer nor did they find they these variants altered NSAID effects. This study gives further evidence that these genes are not directly involved in colon cancer carcinogenesis.

Abstract

AIM: To clarify which method has accuracy: 2nd generation contrast-enhanced ultrasound or biopsy of portal vein thrombus in the differential diagnosis of portal vein thrombosis.

METHODS: One hundred and eighty-six patients with hepatocellular carcinoma and portal vein thrombosis underwent in blinded fashion a 2nd generation contrast-enhanced ultrasound and biopsy of portal vein thrombus; both results were examined on the basis of the follow-up of patients compared to reference-standard.

RESULTS: One hundred and eight patients completed the study. Benign thrombosis on 2nd generation contrast-enhanced ultrasound was characterised by progressive hypoenhancing of the thrombus; in malignant portal vein thrombosis there was a precocious homogeneous enhancement of the thrombus. On follow-up there were 50 of 108 patients with benign thrombosis: all were correctly diagnosed by both methods. There were 58 of 108 patients with malignant thrombosis: amongst these, 52 were correctly diagnosed by both methods, the remainder did not present malignant cells on portal vein thrombus biopsy and showed on 2nd generation contrast-enhanced ultrasound an inhomogeneous enhancement pattern. A new biopsy during the follow-up, guided to the area of thrombus that showed up on 2nd generation contrast-enhanced ultrasound, demonstrated an enhancing pattern indicating malignant cells.

CONCLUSION: In patients with hepatocellular carcinoma complicated by portal vein thrombosis, 2nd generation contrast-enhanced ultrasound of portal vein thrombus is very useful in assessing the benign or malignant nature of the thrombus. Puncture biopsy of thrombus is usually accurate but presents some sampling errors, so, when pathological results are required, 2nd generation contrast-enhanced ultrasound could guide the sampling needle to the correct area of the thrombus.

Key words: Hepatocellular carcinoma; 2nd generation contrast enhanced ultrasound; Contrast enhanced sonography; Malignant thrombosis; Portal vein biopsy

INTRODUCTION

About 20% of patients at first access visit to a specialized centre for the care of hepatocellular carcinoma (HCC)[1] are in need of differential diagnosis between be-

nign portal vein thrombosis (PVT) or malignant thrombosis. The nature of the thrombus can have a significant impact on treatment. In particular, because the prevalence of tumor recurrence is nearly 100%, patients who have HCC and proven neoplastic vascular thrombus are not candidates for any treatment[2-5]. Malignant PVT can occur in patients with cirrhosis, with or without the presence of parenchymal HCC, because there is the possibility of intravascular first growth of this neoplasm[6]. Thrombi have been studied in an effort to determine imaging characteristics that could be used to distinguish benign from malignant thrombi[7-11]. Unfortunately, the imaging characteristics tend to overlap, in particular on computer tomography (CT) or magnetic resonance imagine (MRI) exams only the feature of thrombus-tumor continuity is widely accepted as a reliable indicator of thrombus malignancy[12,13]. In patients where percutaneous ablation of HCC is the therapy of choice, the technique of reference throughout the world for differentiating benign from malignant PVT is percutaneous fine needle biopsy (FNB) of the thrombus[14]. Given the obvious clinical utility of a reliable non-invasive technique for diagnosis of malignant PVT, the limitation of previous imaging studies and an opportunity at our institutions to perform a reasonably large prospective study with cytopathologic correlation in all patients, we undertook an investigation to compare Contrast-Enhanced Sonography (CEUS) and portal vein FNB of thrombus in differentiating benign from malignant thrombosis.

MATERIALS AND METHODS

The study protocol which was fully concordant with ethical principles of the Declaration Helsinki was approved by the institutional ethic committee. A written informed consent was obtained from each patient.

Patients

From January 2001 to February 2006, we enrolled consecutively 256 cirrhotic patients with HCC and PVT (Table 1). The major part of these patients were not eligible for surgical resection/liver transplantation, the others refused intervention. We restricted analysis only to patients without direct contiguity between the thrombus and HCC and considering also the patients drop out on follow-up we completed the study in 108 patients. Clinical and ultrasonography (US) details of these patients are displayed in Table 2.

Study design

Diagnosis of HCC was made according to the guidelines drawn up the Barcelona 2000 EASL Conference[15]. These guidelines suggest that in a liver cirrhosis setting HCC may be diagnosed by coincidental findings in at least two imaging modalities (spiral CT and Doppler US or MRI) that should reveal arterial hypervascularity or in the case of combined criteria (spiral CT with alfa-fetoprotein levels > 400 ng/mL). US guided biopsy should be performed in those cases in which the above-mentioned criteria are not satisfied[15]. Pathological diagnosis of HCC was made according to the International Working Party criteria[16]. The thrombi were detected on routine sonographic and CT examination. Spiral CT was performed in a range of one month before or after color Doppler US. In patients after diagnosis of HCC, in order to characterize PVT, we performed both CEUS and portal FNB; according to the results of portal FNB patients were evaluated for potential percutaneous ablation of HCC. Study design is displayed in Figure 1. Patients underwent first CEUS then portal FNB on the same occasion carried out by two separate operators; the operator that performed PVT FNB was blinded to the results of CEUS. Patients without malignant cells on FNB underwent percutaneous treatment; the others underwent supportive care. Results of baseline CEUS were evaluated in blind fashion on the basis of the evolution

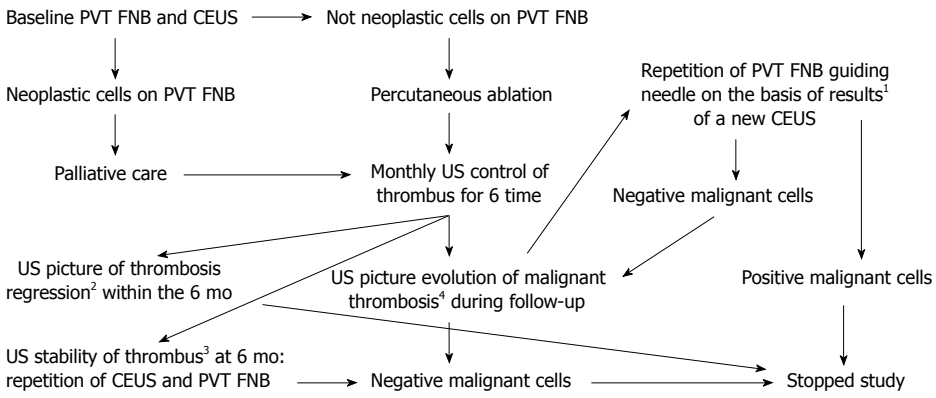

Figure 1 Study design. PVT FNB: Portal vein thrombus fine needle biopsy; CEUS: 2nd generation Contrast-Enhanced US (CEUS) of thrombus; [1]Guiding needle on portion of thrombus showing on CEUS precocious iso or hyperenhancement pattern; [2]No increase in size and distribution with preservation of vessel wall or recanalization/shrinkage, or disappearance of a PVT within the 6 mo of follow-up were accepted as proof of a benign portal vein thrombus; [3]No change in feature of thrombus and in the diameter of the segment of involved vein at 6 mo of follow-up; [4]Increase in size with infiltration of perivascular parenchyma and interruption of vessel wall was US features indicative of malignant thrombosis.

of thrombus on follow-up and were not decisive for the therapeutic management of patients. All patients after CEUS and PVT FNB were followed up for 6 mo; they underwent monthly US examination by an operator that was blinded to CEUS and PVT FNB initial results. We considered as the reference standard of benign or malignant thrombosis the US evolution of thrombus in combination with concordant cytology on new PVT FNB: i.e. no increase in size and distribution with preservation of vessel wall or recanalization/shrinkage, or disappearance of a PVT within the sixth months of follow-up were accepted as proof of a benign portal vein thrombus. However, in cases of stability of thrombi with no change in diameter of the segment of involved vein at 6 mo of follow-up, patients were resubmitted to CEUS and PVT FNB; in absence of malignant cells at this cytological examination, thrombus was definitively considered benign. Our reference standard of malignant thrombosis was increase in size on US, with or without infiltration of perivascular parenchyma and interruption of vessel wall at any time point during the follow-up. In the presence of such evolution of the US picture, CEUS and PVT FNB were repeated with guidance of the needle biopsy to thrombus areas with enhancing pattern allowing for the search for malignant cells; in presence of these, patients stopped the follow-up and thrombus was definitively considered malignant. Patients that died on follow-up without definitive diagnosis were considered drop outs. Specimens were obtained with a 22-Gauge Chiba needle in all patients; needles are manufactured with a removable occlusive stylet. The same biopsy technique described by others[14] was used in all patients. A positive result was considered if the biopsy specimen contained hepatocytes that had malignant features.

Baseline and contrast-enhanced harmonic ultrasound

An Aloka-Prosounds-5500-model equipped with a multifrequencies 2-6 MHz sector probe, was used. Contrast-enhanced imaging was performed according to the protocol used for the Bracco-SonoVue preclinical trial[17]. Examination was performed with low acoustic power (mechanical index under 0.01). SonoVue (BR1; Bracco, Milan, Italy)[18,19] consisted of sulfur-hexafluoride (SF_6) vapor-filled and phospholipid-stabilized microbubbles with a diameter uniformly smaller than 8 μm; these microbubbles circulate in the intravascular space crossing pulmonary and systemic capillary circulation[20,21]. 2.5 mL of contrast-agent were administered for each patient. Thanks to its ability to avoid destruction of bubbles, the low mechanical index technique allows identification of the entire vascular phase of contrast agent perfusion, consisting of the arterial phase (15-30 s after injection of agent), the portal phase (30-60 s after injection of agent) and the late parenchymal phase[22-24]. Positive arterial enhancement of the thrombus was defined as a greater hyperechogenicity of the vascular bed-occupying lesion in comparison to the surrounding liver parenchyma detected during the arterial phase. Two independent highly experienced readers firstly performed off-site assessments of the videotapes in a computer-generated randomised order. The readers were blinded to all clinical and pathological information as to the nature of the analysed thrombi.

Statistical analysis

Sensitivity, specificity, positive and negative predictive values of CEUS and PVT FNB were obtained for diagnosis of the nature of the thrombus; we considered as reference standard the US picture evolution of thrombus on follow-up, with a new PVT FNB as above decrypted accordingly to obtain definitive cytological confirmation.

RESULTS

On follow-up we identified 58 of 108 patients (53.7%) with malignant thrombosis and 50 (46.3%) with benign thrombosis. Figure 2 displayed results of combined tests: in 50 of 56 patients without malignant cells on first PVT FNB, benign PVT was characterized on CEUS by a diffuse homogeneous hypoenhancing pattern and this appearance was persistent compared with the adjacent liver, also during late phase (Figure 3A-C). In the follow up of

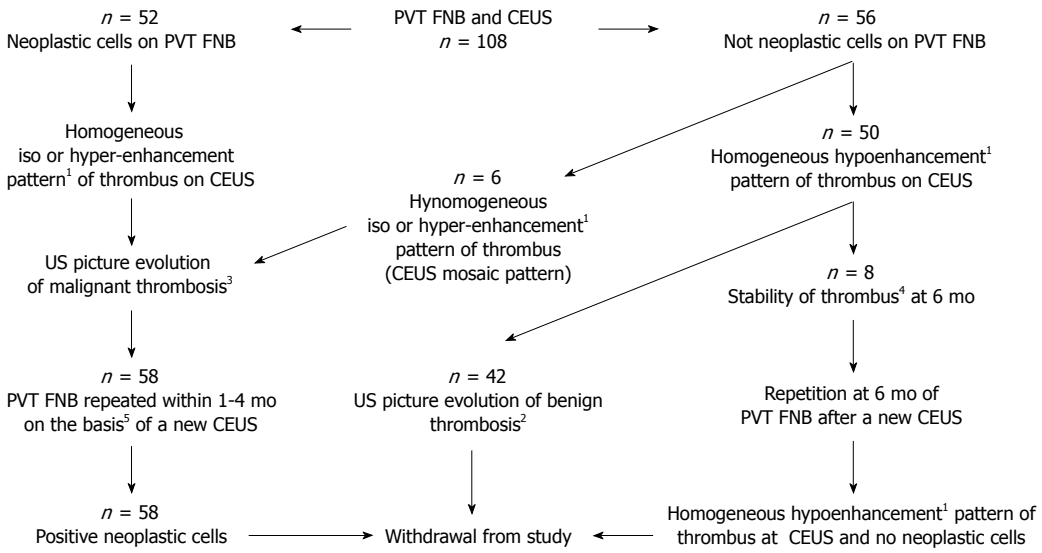

Figure 2 Summary of combined test results. [1]Iso, hyper, or hypoenhancement pattern of thrombus compared to the surrounding parenchyma; [2]Reference standard of benign thrombosis is a US evidence of evolving thrombus: no increase in size or distribution with vessel wall preservation or recanalization/shrinkage, or disappearance of a PVT within the 6 mo of follow-up were accepted as evidence of a benign portal vein thrombus; [3]Us image of evolution, indicating malignant thrombosis: increase in size with infiltration of perivascular parenchyma and interruption of vessel wall was US features of malignant thrombosis; [4]No change in thrombus image and in the diameter of the segment of vein involved at 6 mo of follow-up; [5]PVT FNB were repeated guiding the needle to the thrombus territories with enhancing pattern.

these patients we observed 16 spontaneous disappearances of thrombi after treatment of HCC, 26 recanalization with shrinkage of thrombi and 8 cases of stability of thrombi with no change in diameter of the segment of involved vein. These benign PVT patients were resubmitted to CEUS and PVT FNB at 6 mo with the same combined results as at the start (Figure 2). In 6 patients of 56 without malignant cells on FNB (false negative on PVT FNB), CEUS showed no homogeneous arterial enhancement of some small portions of thrombus. On follow-up the thrombus of these patients showed intravascular spread with growth in maximal diameter of the involved segments of the portal branch from a mean of 8 mm to a mean of 14 mm, with interruption of the vessel wall in 3 patients; we repeated CEUS and guided a new portal FNB to areas of thrombus that showed an enhancing pattern, obtaining positive results for malignant hepatocytes. The islands of neoplastic tissue were located at baseline CEUS as corresponding to the anterior wall of right branch in 1 case, corresponding to and mainly in the centre of the vessel in 3 cases, and corresponding to the posterior wall of left portal branch in 2 cases; they measured between 9 mm and 15 mm in length. In all 6 cases there was a complete thrombosis, involving the portal trunk and both branches, which measured in length between 18 mm and 27 mm. We retrospectively called the CEUS appearance of these cases "mosaic picture" of neoplastic thrombus (Figure 4A and B).

There were 52 patients (Figure 2) with the presence of malignant cells on the baseline portal FNB: these showed on follow-up growth in diameter and intravascular spread of PVT within 1-4 mo. The repetition of PVB FNB in all these patients, with an US picture evolution of malignant thrombosis on the basis of a new CEUS, always confirmed the diagnosis (not false-negative). Typical malignant PVT had an unequivocal appearance at CEUS: during the arterial phase intense and diffuse homogeneous contrast enhancement (Figure 5A and B) was seen, followed or not by a washout of contrast material from the thrombus; the appearance was iso or hyperechoic in arterial phase and hypo or isoechoic during the late phase (Table 3). Sensitivity, specificity, positive and negative predictive value of PVT FNB and CEUS were the same for both, respectively: 89.6%, 100%, 100%, 89.2%. These

Table 3 Contingent tables

Group	Results
Patients studied on follow-up	108
Malignant thrombosis	58 (53.7%)
Benign thrombosis	50 (46.3%)
Presence of neoplastic cells on PVT FNB[1]	
True positive	52 (48.1%)
False positive	0
Not neoplastic cells on baseline PVT FNB	
False negative	6[2] (5%)
True negative	50 (46.3%)
Iso-hyper-enhancement pattern[1] on CEUS and mosaic pattern	
True positive	58
Precocious isoenhancement pattern	21
Precocious hyperenhancement pattern	31
Mosaic pattern[3]	6
False positive	0
Hypoenhancement patternc on CEUS	
False negative	0
True negative	50 (46.3%)

Sensitivity, specificity, positive and negative predictive value of CEUS: All 100%. [1]Iso-hyper-hypoenhancement pattern of thrombus respect to surround parenchyma; [2]False negative patients on portal vein FNB were the same with mosaic pattern on CEUS; [3]Hynomogeneous iso-hyperenhancement of thrombus.

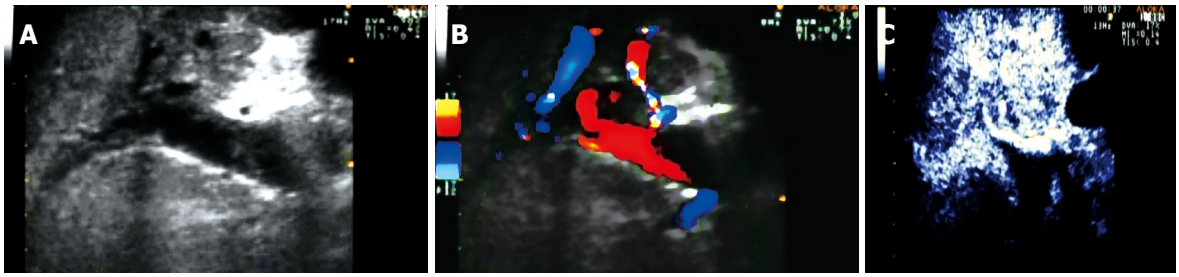

Figure 3 Benign thrombus. A: On sonography lumen of portal vein is partially filled with hypoechoic material representing occlusive thrombus; B: Color Doppler ultrasound reveals color signals only within a portion of portal lumen; C: Contrast-enhanced sonography scan during portal phase reveals uniformly non-enhancing area within portal vein, perfectly reproducing the benign thrombus.

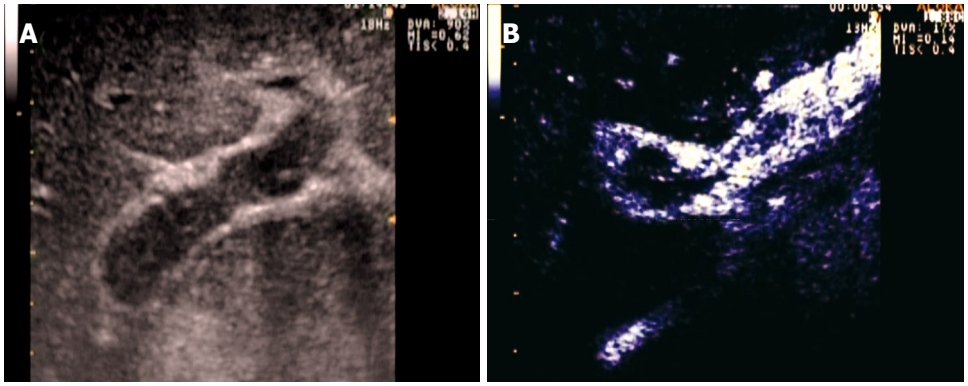

Figure 4 Malignant mosaic thrombus. A: Sonography scan reveals isoechoic area within portal lumen representing thrombus; B: Contrast enhanced sonography scan during late arterial phase reveals thrombus as predominantly enhancing area, indicative of arterial neovascularization (malignant thrombosis) with some non-enhancing areas of the thrombus (mosaic pattern).

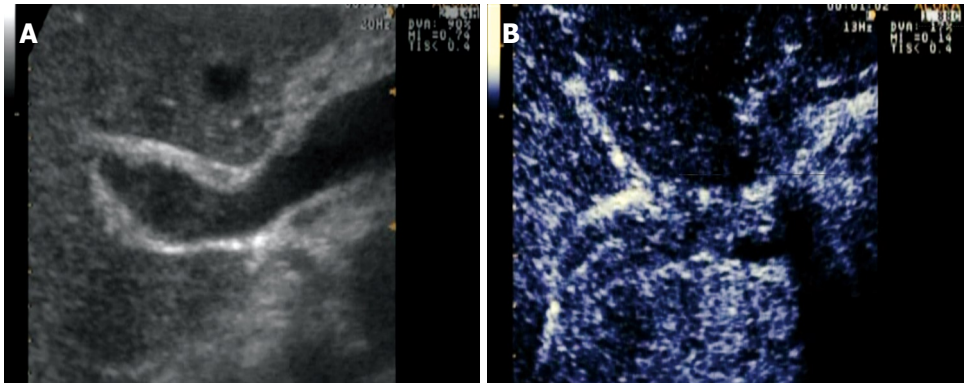

Figure 5 Malignant thrombus. A: sonography reveals echogenic area (thrombus) within vessel lumen; B: during arterial phase of contrast-enhanced sonography the diffusely enhanced area representing thrombus with internal neovascularity.

values coincided for both techniques because, as shown in Table 3, the false-negative patients on baseline CEUS and PVT FNB were the same. On the other hand, if we retrospectively admitted the mosaic picture of enhancement (the picture of the 6 false-negative patients on CEUS) as an alternative, but possible, picture of appearance of malignant PVT on CEUS, and considering that prospectively no false-positive or false-negative results were given, 100% of sensitivity and specificity were obtained for this technique.

DISCUSSION

In previous studies, we[25] and others[26] have described the usefulness and superiority of contrast-enhanced sonography with respect to sonography and color Doppler sonography in the detection and characterisation of thrombus. Here our study differs in two points: (1) we systematically compared in blinded fashion the validity of portal FNB with respect to contrast enhancement of portal thrombus; (2) we excluded from our study patients with evidence of continuity between thrombus and tumor tissue (most of patients in study of Rossi *et al*[26]) a feature considered diagnostic of malignant thrombosis both on sonography[26], and on helical TC/MRI imaging[12,13].

CT remains the primary imaging technique for staging HCC and identifying PVT[27]. MRI also appears to be a promising tool[28]. Although the capacity for CT to show main or lobar PVT is well established, controversy surrounds radiologists' ability to use CT to consistently differentiate between malignant and simple thrombi[3,7,27]. This reluctance to stage possible portal vein invasion by CT/MRI alone has perhaps been appropriate given the lack of a formal study in the literature that compares the imaging characteristics of proven benign and malignant thrombi. It was shown that tumor thrombus neovascularity may also be identified, with variable accuracy, by color Doppler

sonography[29-34]. Now the use of CEUS permits us to study in real time micro-vascular architecture of each thrombus, searching for global arterial enhancement typical of HCC neovascularity. The interpretation of results is based on general characteristics of enhancing/hypoenhancing of thrombus after administration of contrast ultrasound agent. The sensitivity of CEUS is better with respect to Doppler sampling of intrathrombus vessels; there are in fact technical limits of Doppler sampling due to the small diameter of vessels of the microvascular architecture of neoplastic tissue[35].

We deduced that homogeneous hypoenhancement of the thrombus on CEUS with respect to the surrounding parenchyma is diagnostic for benign thrombosis. Significantly, benign PVT does not show enhancement at any time after ultrasound contrast agent administration. The homogeneous enhancement of thrombus on CEUS must be considered diagnostic for malignant thrombosis. In particular, the appearance of malignant PVT can be precociously hyperechoic or isoechoic with respect to the surrounding parenchyma: this picture could be due to diffuse arterialization of surrounding liver parenchyma, a pathophysiological phenomenon secondary to the same thrombosis.

In our study, in order to obtain an accurate differential diagnosis as to the nature of a PVT, we utilized as gold-standard methods the prospective evaluation of the thrombus with, in most cases, a concordant cytology on PVT FNB repetition. We in fact were uncertain about the validity of using only baseline portal FNB to determine diagnosis because of the not optimal sensitivity of the method. The possibility of sampling error could result in both false-positive and false-negative diagnoses for malignant PVT. Because a benign thrombus does not contain hepatocytes, specimens that include cells from the periportal hepatic parenchyma or hepatocytes picked up during passage of the biopsy needle through the liver could lead to false-positive diagnoses of malignant tumor. We prevented false-positive diagnoses by using a biopsy needle with an occlusive stylet, keeping the stylet tightly seated until the needle tip was detected inside the portal vein and performing the biopsy under continuous sonographic visualization with the needle tip kept within the lumen of the portal vein at all times during passages. In our study no diagnosis of malignant tumor on FNB PVT was false-positive indicating that the invasive procedure is maximally specific. False-negative diagnoses for malignant cells could be produced if the portion of a malignant portal vein thrombus from which a specimen was obtained failed to contain malignant hepatocytes. We tried to prevent false-negative diagnoses by performing the biopsy on the portal vein thrombus by sampling the longest possible segment of a portal vein thrombus. We obtained anyway 6 false-negative results for malignant thrombi. In all 6 cases the appearance on CEUS was as an inhomogeneous enhancement of the thrombus; we called the CEUS appearance of these cases "mosaic-picture" of neoplastic thrombus. We were unhappy about the false-negative results of portal FNB derived from sampling the non-neoplastic portion of the thrombus; we repeated portal FNB within 1-4 mo guiding the biopsy on results of the CEUS (FNB of enhancing part of thrombus) and obtained malignant cells. We supposed that the echotexture of malignant thrombus on CEUS was not homogeneous in these 6 patients because there were some occult islands of neoplastic tissue in the thrombus that after administration of ultrasound contrast agent showed as enhancing patterns with respect to the diffuse hypoenhancing of the remaining benign thrombus. Probably in these cases the phenomena of benign thrombosis was superimposed on the initial neoplastic invasion of the portal vein. So CEUS of portal vein thrombi appears as a diagnostic procedure more accurate than "blind" portal FNB in the diagnosis of malignant thrombosis with regard to the possibility of giving a panoramic vision of the thrombus without the sampling-error of "blind" portal FNB. So it is reasonable, when cytology confirmation of malignant thrombosis is needed, that portal FNB can be guided on the result of CEUS in order to reduce false-negative results due to casual sampling.

In conclusion, CEUS of portal thrombus is more accurate than biopsy of thrombus for making the differential diagnosis as to the nature of the thrombus. CEUS of portal thrombus is a reliable diagnostic tool for assessing non-invasively the nature of the PVT. This procedure is usually accurate but presents some sampling errors linked to the 'blind' biopsy of the thrombus.

COMMENTS

Background

About 20% of patients at first access visit to a specialized centre on the care of hepatocellular carcinoma need differential diagnosis between benign portal vein thrombosis (PVT) or malignant thrombosis. Patients who have hepatocellular carcinoma and proven neoplastic vascular thrombus are not candidates for any treatment: in these cases the prevalence of tumor recurrence is nearly 100%.

Research frontiers

The world technique of reference for differentiating benign from malignant PVT is the invasive percutaneous fine needle biopsy (FNB) of the thrombus. Given the obvious clinical utility of a reliable non-invasive technique for the diagnosis of malignant PVT, the authors undertook an investigation to compare Contrast-Enhanced Sonography (CEUS) and portal vein FNB of thrombus for differentiating benign from malignant thrombosis.

Innovations and breakthroughs

For the first time, the authors systematically compare in blinded fashion the validity of portal FNB with respect to non-invasive contrast enhancement of portal thrombus in order to differentiate benign from malignant thrombosis.

Applications

CEUS of portal thrombus is more accurate than biopsy of thrombus for making differential diagnosis of the nature of the thrombus. CEUS of portal thrombus is a reliable diagnostic tool for assessing non-invasively the nature of PVT.

Terminology

CEUS consists of an ultrasound exam which is performed after parenteral administration of an ultrasound contrast. The CEUS in this study consists of sulfurhexafluoride (SF_6) vapor-filled and phospholipid-stabilized microbubbles with a diameter uniformly smaller than 8 μm; these microbubbles circulate in the intravascular space crossing pulmonary and systemic capillary circulation.

Peer review

This paper addresses the value of II Generation CEUS in non-invasive differential diagnosis of benign from malign portal vein thrombosis. The manuscript is interesting.

Abstract

AIM: To compare creatinine clearance (Ccr) with estimated glomerular filtration rate (eGFR) in preoperative renal function tests in patients undergoing hepatectomy.

METHODS: The records of 197 patients undergoing hepatectomy between August 2006 and August 2008 were studied, and preoperative Ccr, a three-variable equation for eGFR (eGFR3) and a five-variable equation for eGFR (eGFR5) were calculated. Abnormal values were defined as Ccr < 50 mL/min, eGFR3 and eGFR5 < 60 mL/min per 1.73 m^2. The maximum increases in the postoperative serum creatinine (post Cr) level and postoperative rate of increase in the serum Cr level (post Cr rate) were compared.

RESULTS: There were 37 patients (18.8%) with abnormal Ccr, 31 (15.7%) with abnormal eGFR3, and 40 (20.3%) with abnormal eGFR5. Although there were no significant differences in the post Cr rate between patients with normal and abnormal Ccr, eGFR3 and eGFR5 values, the post Cr level was significantly higher in patients with eGFR3 and eGFR5 abnormality than in normal patients (P < 0.0001). Post Cr level tended to be higher in patients with Ccr abnormality (P = 0.0936 and P = 0.0875, respectively).

CONCLUSION: eGFR5 and the simpler eGFR3, rather than Ccr, are recommended as a preoperative renal function test in patients undergoing hepatectomy.

Key words: Estimated glomerular filtration rate; Creatinine clearance test; Hepatectomy; Renal function test

INTRODUCTION

The outcome of hepatic resection has improved dramatically during the last 20 years, along with improvements in surgical techniques and perioperative management[1]. Operative mortality is now reportedly less than 1% at most institutions in Japan[2]. However, hepatectomy is associated with intraoperative blood loss, and postoperative complications such as liver failure, infection, bile leakage, ascites, and pleural effusion[3]. Uncontrolled ascites, pleural effusion and intraoperative blood loss disturb blood circulation, leading to dysfunction of not only the liver but also the kidney[4]. Therefore, for appropriate patient selection, it is necessary to evaluate preoperative liver and renal function accurately.

Glomerular filtration rate (GFR) is the most important and comprehensive index of renal function. GFR is measured by inulin clearance, but this takes > 2 h, and requires repeat collection of blood and urine every 15 min[5]. GFR is rarely measured in a clinical setting because of its intricacy. On the other hand, creatinine clearance (Ccr) has been measured clinically by a simple

method as a preoperative renal function test[6,7]. Although Ccr yields an approximate value for GFR, it is usually higher than the GFR as a result of secretion of 10%-15% of the creatinine into urine in the uriniferous tubule[8].

In 1999, Levey *et al* first reported a prediction equation known as modification of diet in renal disease (MDRD) for estimation of GFR on the basis of age, sex, race, serum creatinine, albumin and blood urea nitrogen (BUN) level for individuals of caucasian and black ethnicity[8]. MDRD has now been accepted as a standard method for evaluation of renal function in North America and Europe. This was a breakthrough for estimation of GFR because of its simplicity and ease of calculation. As a result of differences in physique between caucasian and black individuals, unique variables for estimating GFR in Japanese subjects have been investigated[9]. For this purpose, in 2008, two new equations for estimated GFR (eGFR) were devised on the basis of multiple regression analysis from inulin clearance data of 763 Japanese patients with chronic kidney disease and healthy controls[10]. These were: the three-variable equation for eGFR (mL/min per 1.73 m^2) = $194Cr^{-1.094} \times Age^{-0.287}$ (× 0.739; if the patient is female); the five-variable equation for eGFR (mL/min per 1.73 m^2) = $142Cr^{-0.923} \times Age^{-0.185} \times Alb^{0.414} \times BUN^{-0.233}$ (× 0.772; if the patient is female).

However, no studies have evaluated the usefulness of eGFR as a preoperative renal function test parameter. If eGFR is superior to Ccr as a preoperative renal function test, then eGFR should replace Ccr because of its simplicity of measurement. In this study, we retrospectively calculated the preoperative three-variable and five-variable equations for eGFR, and compared the results with Ccr, to clarify their superiority as a preoperative renal function test in patients undergoing hepatectomy.

MATERIALS AND METHODS

Patients

At Dokkyo Medical University, a total of 211 hepatic resections were performed for hepatobiliary disease between August 2006 and August 2008. Of these patients, 14 who were on hemodialysis, or for whom the results of preoperative Ccr were not available, were excluded. A total of 197 patients who underwent hepatectomy alone or hepatectomy plus combined surgery such as splenectomy, Hassab's operation, gastrectomy and colectomy for hepatocellular carcinoma (HCC), metastatic liver tumor, biliary malignancy and other benign disease were included in this study. There were 147 men and 50 women, with a mean age of 65.0 ± 10.0 years.

Measurements

Preoperative Ccr was measured by the 24-h method in all patients. The indocyanine green retention rate at 15 min (ICGR15) was also performed before hepatectomy. Serum creatinine, BUN and albumin levels were examined before hepatectomy, and 1, 2, 3, 5, 7, 14, 21 and 28 d after hepatectomy. The preoperative three-variable equation for eGFR (eGFR3) and the five-variable equation for eGFR (eGFR5) were calculated using the new formulas for Japanese patients[10]. The maximum serum creatinine and BUN levels after hepatectomy (post Cr, post BUN) were determined, and the postoperative rate of increase in the serum creatinine level (post Cr rate) was calculated by the following formula using the preoperative serum creatinine level (pre Cr) and post Cr. Post Cr rate (%) = (post Cr - preCr) × 100/post Cr.

Abnormal Ccr was defined as < 50 mL/min according to the New York Heart Association criteria[11,12], and groups with abnormal eGFR3 and eGFR5 were defined as < 60 mL/min per 1.73 m^2 according to the stage of chronic kidney disease[13].

Surgical procedures

Indications for hepatectomy were determined using the criteria of Makuuchi[14]. Portal embolization (PE) before hepatectomy was indicated in patients undergoing major hepatectomy when the estimated liver volume after hepatectomy was not sufficient to tolerate surgery (remnant liver volume < 40%)[15,16]. Transcatheter arterial embolization (TAE) was performed preoperatively in patients with massive HCC in order to occlude arterio-portal shunts. Preoperative biliary drainage was carried out in patients with obstructive jaundice. Liver resection was performed when the serum total bilirubin level was < 2.0 mg/dL. Simultaneous hepatectomy plus splenectomy, or Hassab's operation, were indicated for control of portal hypertension, esophageal and gastric varices, and thrombocytopenia (platelet count < $5.0 \times 10^4/mm^3$) in patients with HCC and liver cirrhosis[17]. The liver parenchyma was transected by the crush method using a Pean forceps or Cavitron Ultrasonic Aspirator while employing the intermittent Pringle maneuver. After resection of the liver tumors and subsequent hemostasis, the cut liver surface was coated with fibrin glue. The abdomen was then closed after placing drains around the cut liver surface. Major hepatectomy was classified as removal of one Couinaud segment or more, and minor hepatectomy as removal of less than one Couinaud segment.

Statistical analysis

Data were expressed as median (range). Non-parametric data were evaluated by χ^2 test and Kruskal-Wallis test between groups showing normal and abnormal values of Ccr, eGFR3 and eGFR5. Parametric data including post Cr and post Cr rate were compared among groups with normal and abnormal Ccr, eGFR3 and eGFR5 values using the Mann-Whitney *U* test. Correlations between Ccr or post Cr and eGFR3 and eGFR5 were analyzed using Pearson's correlation coefficient. Differences at $P < 0.05$ were considered to be significant.

RESULTS

Liver resections were performed for malignant disease in 180 patients and for benign disease in 17 patients. Malignant disease included 117 HCCs, 40 metastatic liver tumors, 16 biliary malignancies, three

Preoperative treatment (-:+)	134:26	32:5	0.6804

Hepatitis virus indicates hepatitis B, C, B + C; Preoperative treatment indicates biliary drainage, TAE and portal vein embolization.

cholangiocarcinomas and four other malignancies. Benign lesions included three giant hepatic cysts, three biliary cyst adenomas, three donors of living-related liver transplantation, two cases of hepatolithiasis, two of massive hemangioma, two of cholecystitis, and two cases of regenerative nodules. There were no significant differences in diseases between the groups with normal and abnormal Ccr, eGFR3 and eGFR5 values (Table 1).

Clinical background characteristics of the Ccr, eGFR3 and eGFR5 groups are shown in Tables 2-4, respectively. The median ages of patients with abnormal Ccr and eGFR5 values were significantly greater than those of patients with normal values. There were no significant differences in sex, height, weight, viral infection, $ICGR_{15}$, or frequency of preoperative treatment between the groups with normal and abnormal Ccr, eGFR3 and eGFR5 values.

Thirty-seven patients (18.8%) had abnormal Ccr, 31 (15.7%) had abnormal eGFR3, and 40 (20.3%) had abnormal eGFR5 values. Preoperative serum Cr and BUN levels, Ccr, eGFR3 and eGFR5 in all the patients

eGFR3: Estimating glomerular filtration rate calculated by 3 factors; $ICGR_{15}$: Indocyanine green retention rate at 15 min.

Table 4 Background characteristics on eGFR5

	Normal eGFR5 group (n = 157)	Abnormal eGFR5 group (n = 40)	P
Age (yr)	65 (30-82)	71 (55-85)	0.0003
Sex (male:female)	119:38	28:12	0.4521
Height (cm)	161.5 (133.9-182.7)	158.5 (138.0-173.0)	0.0751
Weight (kg)	59.7 (33.0-95.6)	58.4 (44.0-93.0)	0.5478
Hepatitis virus (-:+)	75:82	16:24	0.3788
$ICGR_{15}$ (%)	13 (3-74)	14 (1-31)	0.6363
Preoperative treatment (-:+)	130:27	36:4	0.2644

with abnormal parameters were significantly worse than those in all the normal patients. Although there were no differences in serum albumin levels between the groups that had normal and abnormal Ccr and eGFR3, the serum albumin level was significantly decreased only in the group with eGFR5 abnormality (Table 5). The correlation between Ccr and eGFR5 was stronger than that between Ccr and eGFR3 (Figure 1).

Surgical details of the patients are shown in Table 6. Seventy-three patients underwent extensive hepatectomy. Among these patients, 28 (14.2%) underwent extended lobectomy, and 19 (9.6%) underwent lobectomy. According to the Couinaud classification, 26 patients (13.2%) underwent bisegmentectomy, and 37 (18.8%) underwent segmentectomy. Eighty-seven patients (44.2%) underwent partial hepatectomy. Although intraoperative blood loss in the patients with eGFR5 abnormality was significantly greater than that of normal patients, there were no significant differences in other surgical background factors, such as operation time, Pringle time, and type of surgical treatment between patients who were normal and abnormal for Ccr, eGFR3 and eGFR5.

Although neither operative nor hospital deaths were recorded, three patients (1.52%) required hemodialysis after hepatectomy because of multiple organ failure (two cases) and enterocolitis. Hepatic failure occurred in two patients. Postoperative results are shown in Table 7. Post Cr and post BUN of patients with eGFR3 and eGFR5 abnormalities were significantly higher than in normal patients, but post Cr and post BUN in patients with Ccr abnormality were not significantly higher than those in

Table 5 Preoperative measurements

in normal patients.

Figure 2 shows the correlation between Ccr, eGFR3 and eGFR5 and post Cr. Although a weak correlation between post Cr and Ccr was observed, there were significant correlations between post Cr and eGFR5, and the correlation between post Cr and eGFR5 was higher than that between post Cr and eGFR3. Post Cr rates of patients with Ccr, eGFR3 and eGFR5 abnormality were not significant (Table 7).

DISCUSSION

As a preoperative renal function test, it is ideal to measure GFR by inulin clearance, but this is not practical in a clinical setting. Although the easiest renal function test to perform is measurement of serum creatinine level, use of this parameter alone is not recommended because it is affected by various factors such as muscle mass, sex, age, diet, and renal tubule function[9,13]. Therefore, Ccr has been measured routinely in patients undergoing major surgery for a long time. Determination of Ccr requires timed urine collection and blood sampling. Twenty-four-hour urine collection is especially inconvenient for patients with neurogenic bladder or the elderly. On the other hand, eGFR3 and eGFR5 require only a single blood sample, and can be estimated on the basis of age, sex, serum creatinine, BUN and albumin without the need for urine collection. If eGFR3

Table 7 Postoperative measurements

	Post Cr (mg/dL)	Post BUN (mg/dL)	Post Cr rate (%)
Overall (n = 197)	0.87 (0.43-8.43)	18 (7-97)	11.3 (0-88.1)
Normal Ccr (n = 160)	0.85 (0.43-5.71)	17 (7-81)	11.0 (0-88.1)
	P = 0.0936	P = 0.0875	P = 0.8253
Abnormal Ccr (n = 37)	0.95 (0.50-8.43)	20 (10-97)	12.3 (0-79.4)
Normal eGFR3 (n = 166)	0.83 (0.43-5.71)	17 (7-81)	11.4 (0-88.1)
	P < 0.0001	P = 0.0033	P = 0.4575
Abnormal eGFR3 (n = 31)	1.17 (0.70-8.43)	21 (11-97)	9.0 (0-79.4)

	P < 0.0001	P < 0.0001	P = 0.8950
Abnormal eGFR5 (n = 40)	1.14 (0.70-8.43)	23 (11-97)	11.5 (0-79.4)

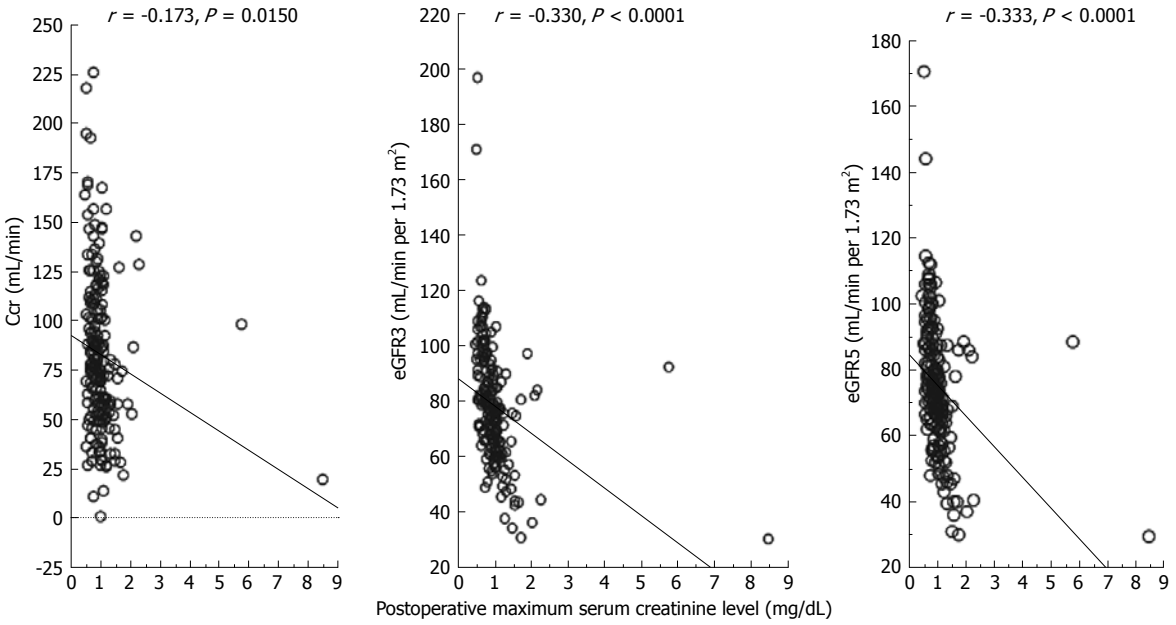

Figure 2 Relationship of the maximum increase in post Cr level to measured Ccr and eGFR.

and eGFR5 are superior to Ccr for preoperative renal function testing, there would be certain advantages in terms of clinical effort and cost.

The results of this study demonstrated that 24-h urine collection for measurement of Ccr no longer appears necessary on a routine basis for estimation of preoperative renal function. In fact, there were no significant differences in the post Cr or BUN level after hepatectomy between patients who had normal and abnormal preoperative Ccr values (Table 7). Post Cr and BUN levels in patients with eGFR3 and eGFR5 abnormalities were significantly higher than those in normal patients. In addition, the correlations between post Cr and eGFR3, and eGFR5 were significant, but that between post Cr and Ccr was not significant (Figure 2). These results indicate that eGFR3 and eGFR5 are superior to Ccr for predicting post renal dysfunction.

In this study, the post Cr rate after hepatectomy was also evaluated in patients who had normal and abnormal Ccr, eGFR3 and eGFR5 values, and no significant differences were evident (Table 7). We have already reported that hepatectomy can be performed safely without rapid and progressive deterioration of renal function in patients with non-uremic renal failure (Ccr of > 20 but < 50 mL/min)[6]. The factors affecting the post Cr rate after hepatectomy are preoperative liver function ($ICGR_{15}$ > 20%), intraoperative blood loss and operation time, and not preoperative renal dysfunction (data not shown).

In this study, eGFR5 differentiated 40 patients with preoperative renal dysfunction among 197 patients more sensitively than Ccr or eGFR3. There was a stronger positive correlation between Ccr and eGFR5 than between Ccr and eGFR3 (Figure 1). Although the equation for eGFR5 is a little complex, eGFR5 is more suitable than eGFR3 for patients undergoing hepatectomy. Since serum albumin level is one of the factors that reflects liver preservation, patients with HCC and liver cirrhosis frequently have lower levels of serum albumin. In fact, in this study, preoperative serum albumin levels ranged from 2.1 to 4.4 g/dL, with a median value of 3.3 g/dL. Thus, eGFR5 appears to be a more acceptable parameter for accurate preoperative evaluation of renal function in hepatectomy patients presenting a wide range of serum albumin levels.

To the best of our knowledge, this is the first retrospective study to have compared Ccr and eGFR as a preoperative renal function test in patients undergoing

hepatectomy. Since equations for eGFR in individuals of caucasian, black and Japanese ethnicity have been established, eGFR is now almost universally available. We suggest that eGFR3 and eGFR5 are useful as preoperative renal function parameters in patients undergoing hepatectomy worldwide.

In conclusion, we recommend eGFR5 using serum albumin level as a preoperative renal function test in patients undergoing hepatectomy. Ccr is no longer recommended as a first-choice preoperative renal function test.

COMMENTS

Background

Although creatinine clearance (Ccr) has been measured clinically by a simple method as a preoperative renal function test, Ccr is not strictly equal to glomerular filtration rate (GFR). Recently, an equation for estimated GFR (eGFR) for Japanese individuals has been postulated. It has been accepted that eGFR is equal to measured GFR in chronic kidney disease. However, there have been no previous studies regarding the reliability of eGFR as a preoperative renal function test.

Research frontiers

If eGFR is superior to, or equal to Ccr as a preoperative renal function test, eGFR should replace Ccr because of its simplicity of measurement. The authors retrospectively compared Ccr and eGFR as a preoperative renal function test in patients undergoing hepatectomy.

Innovations and breakthroughs

eGFR is useful as preoperative renal function parameters in patients undergoing hepatectomy. Ccr is no longer recommended as a first-choice preoperative renal function test.

Applications

Although Ccr has been used as preoperative renal function test, eGFR should replace Ccr as a routine preoperative renal function test in various surgical fields.

Terminology

eGFR is estimated GFR which is calculated from age, sex, serum creatinine value (eGFR3), or adding serum albumin concentration and BUN value (eGFR5).

Peer review

This is a well-written paper on normal and sensitive parameters of renal function, i.e. eGFR3 and eGFR5 as predictors of renal function after hepatectomy. These parameters seem easy to determine, accurate and well-associated with the stage of kidney disease. The study seems well-designed and performed, original in concept and statistically valid.

Abstract

AIM: To verify that CD markers are available for detecting cancer stem cell populations and to evaluate their clinical significance in colon cancer.

METHODS: Immunohistochemistry for CD133, CD24 and CD44 was performed on the tissue microarray of 523 colorectal adenocarcinomas. Medical records were reviewed and clinicopathological analysis was performed.

RESULTS: In colorectal adenocarcinoma, 128 of 523 cases (24.5%) were positive and 395 cases (75.5%) were negative for CD133 expression. Two hundred and sixty-four of 523 cases (50.5%) were positive and 259 cases (49.5%) were negative for CD24 expression. Five hundred and two of 523 cases (96%) were negative and 21 cases (4%) were positive for CD44 expression. Upon clinicopathological analysis, CD133 expression was present more in male patients (P = 0.002) and in advanced T stage cancer (P = 0.024). Correlation between CD24 expression and clinicopathological factors was seen in the degree of differentiation (P = 0.006). Correlation between CD44 expression and clinicopathological factors was seen in the tumor size (P = 0.001). Survival was not significantly related to CD133, CD24 and CD44 expression.

CONCLUSION: CD markers were related to invasiveness and differentiation of colorectal adenocarcinoma. However, CD expression was not closely related to survival.

Key words: CD133; CD24; CD44; Colon cancer stem cells; Colorectal adenocarcinoma

INTRODUCTION

Colorectal adenocarcinoma is the second most common type of cancer and a major cause of cancer-related morbidity and mortality in the Western world[1]. The incidence of colorectal cancer has increased from 5.8% in 1980 to 10.3% in 2000 in South Korea, in part because of Westernization of the diet[2].

Countless treatment protocols, including chemotherapy and radiation, have been applied to colorectal cancer and a number of studies have identified conventional prognostic factors[3]. However, a complete cure of colorectal cancer has not been accomplished despite numerous efforts. Recently, the prospective identification of colon cancer stem cells

has received major attention because of their potential for colon cancer treatment[4,5]. Current colon cancer treatment modalities target proliferating cells, but colon cancer stem cells are thought to be slowly cycling cells; therefore, they may escape present targeted interventions because they are not actively proliferating. This may be one of the most important reasons behind colon cancer treatment failure and recurrence. It is important to validate *in vitro/in vivo* colon cancer stem cell findings in clinical samples. This will be a critical step toward the development of effective targeted colon cancer treatment, but thus far, no data are available on the clinical implications of the suggested colon cancer stem cells in clinical samples.

Recently, several CD markers have been identified as solid cancer stem cell markers. CD133, also known as PROML1 or prominin, is a stem cell surface antigen that has been recently identified as a potential cancer stem cell marker in brain, colon and prostate cancer[4-7]. CD44, also known as homing cell adhesion molecule, is a cell surface glycoprotein expressed on lymphocytes, monocytes and granulocytes, which has been identified as a stem cell marker in breast and head and neck cancer[8,9]. CD24, a cell surface marker, is a single chain sialoglycoprotein with a molecular mass of 42 kDa. CD24- and CD44-expressing pancreatic cancer cells show cancer stem cell characteristics[10]. Here, we report the identification of CD133-, CD24- and CD44-positive tumor cells in colon tumor sections by an immunohistochemistry-based technique, and discuss the findings in conjunction with clinicopathological data.

MATERIALS AND METHODS

Patients and specimens

This retrospective study consisted of a consecutive series of 523 colorectal adenocarcinomas with complete histopathological data available. Patients were diagnosed and treated at the Hanyang University Hospital, Seoul, Korea, from January 1991 to August 2001. There were 295 male and 228 female patients, with ages ranging from 17 to 87 years (mean, 59.0 years). The adenocarcinomas were located in the cecum (n = 18), ascending colon (n = 77), hepatic flexure (n = 12), transverse colon (n = 26), splenic flexure (n = 4), descending colon (n = 24), sigmoid colon (n =112), and rectum (n = 250). Their sizes ranged from 0.3 to 15 cm (mean, 5.7 cm).

All tissue samples were formalin-fixed and paraffin-embedded. Hematoxylin and eosin (HE)-stained slides, pathological reports, and other medical records were reviewed to confirm the diagnosis and clinicopathological parameters, including age, gender, tumor location, tumor size, depth of invasion, lymph node metastasis, distant metastasis, American Joint Committee on Cancer (AJCC) stage, Dukes' stage, degree of differentiation, lymphovascular invasion and patient survival.

Tissue microarray (TMA) construction

The most representative area was carefully selected and marked on an H&E-stained slide. The TMA was assembled using a tissue-array instrument (AccuMac arrayer; ISU ABXIS Co. Ltd., Seoul, Korea) that consisted of thin-walled stainless steel punches and stylets used to empty and transfer the needle content. The assembly was held in an X-Y position guide equipped with semiautomatic micrometers, with a 1-mm increment between individual samples and a 3-mm punch depth stop device. Briefly, the instrument was used to create holes in a recipient block with defined array cores. A solid stylet, which closely fits the needle, was used to transfer the tissue cores into the recipient block. Taking into account the limitations of the representative areas of the tumor, we used triplicate 1-mm diameter tissue cores from each donor block.

HE and immunohistochemical staining

Multiple 4-μm sections were cut with a Leica microtome. Sections were transferred to adhesive-coated slides. One section was routinely deparaffinized with standard xylene and hydrated through graded ethanol in water, stained with HE, and covered with a coverslip. For immunohistochemical staining, the TMA slides were dewaxed by heating at 55℃ for 30 min and by three 5-min washes with xylene. Tissues were rehydrated by a series of 5-min washes in 100%, 90% and 70% ethanol and phosphate buffered saline (PBS). Antigen retrieval was performed by microwaving the samples for 4 min 20 s at full power in 250 mL 10 mmol/L sodium citrate (pH 6.0). Endogenous peroxidase activity was blocked with 0.3% hydrogen peroxidase for 20 min. The primary polyclonal rabbit anti-CD133 antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA) was diluted 1:200 using goat serum and incubated at room temperature for 1 h. The primary monoclonal mouse anti-CD24 antibody (Santa Cruz Biotechnology) was diluted 1:50 and the primary monoclonal mouse anti-CD44s antibody (Neomarkers, CA, USA) was diluted 1:100. After three 2-min washes with PBS, the sections were incubated with a biotinylated goat secondary antibody for 30 min (DAKO, Carpinteria, CA, USA). After three 2-min washes with PBS, horseradish peroxidase-streptoavidin (DAKO) was added to the section for 30 min, followed by another three 2-min washes with PBS. The samples were developed with 3,3'-diaminobenzidine substrate (Vector Laboratories, Burlington, Ontario, Canada) for 1 min and counterstained with Mayer's hematoxylin. The slides were dehydrated following a standard procedure and sealed with coverslips. We used the glioblastoma tissue as a positive control of CD133, the tonsillar lymphoid tissue as a positive control of CD24, and the tonsillar mucosal epithelial tissue as a positive control of CD44. Negative controls were performed by omitting CD133, CD24 and CD44 antibodies during the primary antibody incubation. The representative sections of CD133, CD24 and CD44 immunostaining are shown in Figure 1.

Interpretation of CD133, CD24 and CD44 expression

CD133, CD24 and CD44 expression was evaluated

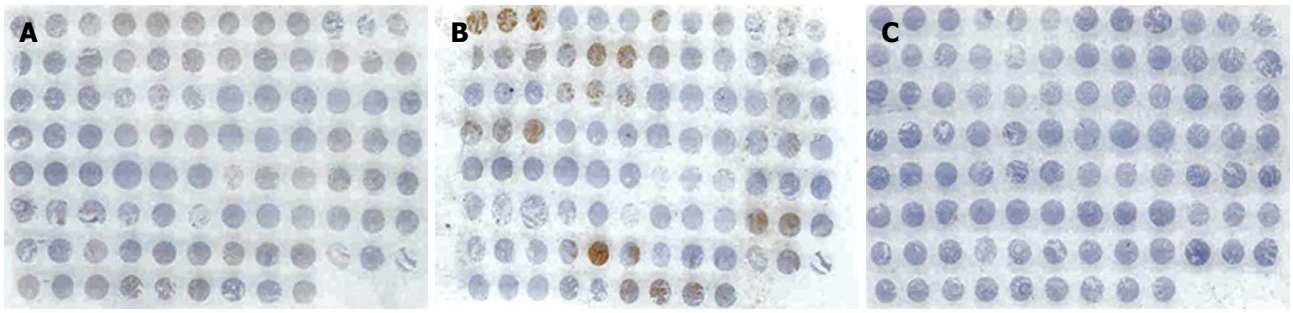

Figure 1 Representative photograph of the TMA slides with immunohistochemical staining. A: CD133; B: CD24; C: CD44.

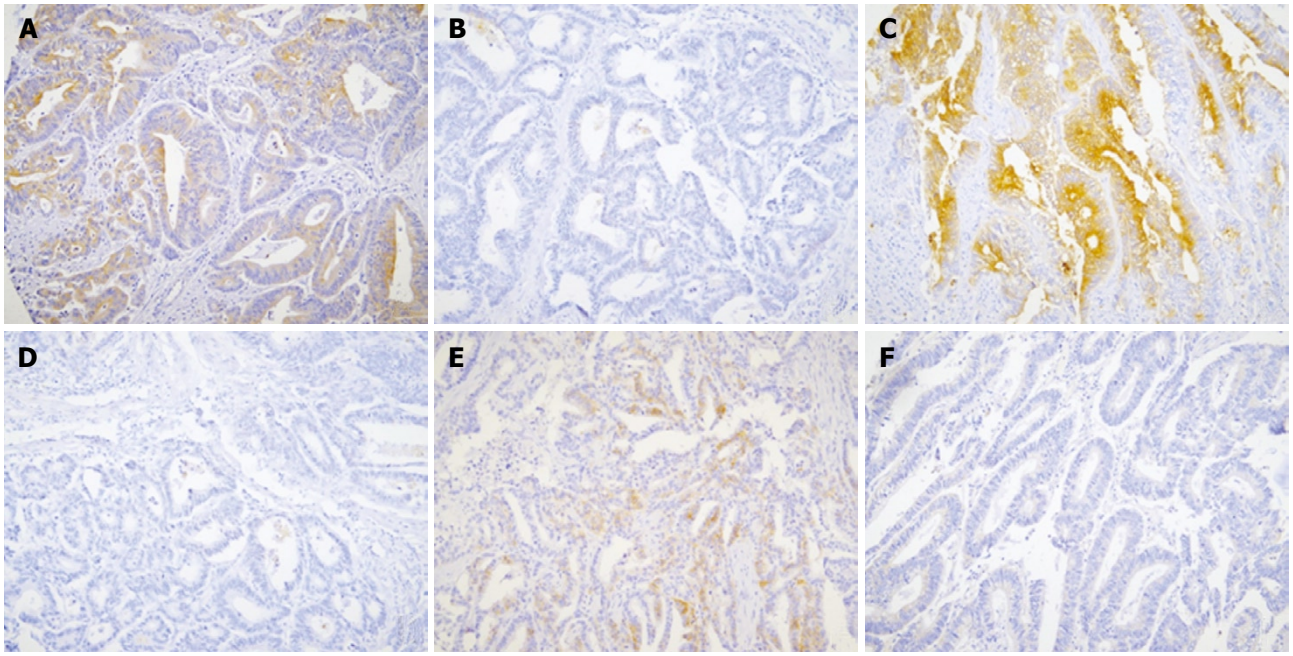

Figure 2 Representative photographs of CD marker expression in colorectal adenocarcinoma. Positive staining (A) and negative staining (B) for CD133. Positive staining (C) and negative staining (D) for CD24. Positive staining (E) and negative staining (F) for CD44.

semi-quantitatively by two independent pathologists (Paik SS and Song YS), in a blinded fashion without knowledge of clinical and pathological information. The sections were scanned at high magnification to assess the positivity of staining in tumor cells. We regarded the staining as positive in cases with cytoplasmic positivity. In cases of discrepant assessments, slides were reinvestigated by both pathologists under a multi-head microscope and an agreement was obtained.

Statistical analysis

Statistical analysis was performed using SPSS version 12.0 software (SPSS, Chicago, IL, USA). The χ^2 test was used to examine the association between CD133, CD24 and CD44 expression and various clinicopathological characteristics, including age, gender, tumor location, tumor size, TNM category, AJCC stage, Dukes' stage, degree of differentiation, and lymphovascular invasion. The Kaplan-Meier method was used to calculate overall survival curves. Univariate survival analysis with the log-rank test was used to compare the difference between the survival rates of the patients' subgroups. Multivariate survival analysis with Cox's proportional hazard regression model was used to evaluate the independent prognostic factors. A difference of $P < 0.05$ between groups was considered significant.

RESULTS

Pattern of CD marker expression in colorectal adenocarcinoma

CD marker expression was evaluated in colorectal adenocarcinoma. One hundred and twenty-eight of 523 cases (24.5%) were positive and 395 cases (75.5%) were negative for CD133 expression (Figure 2A and B). Two hundred and sixty-four of 523 cases (50.5%) were positive and 259 cases (49.5%) were negative for CD24 expression (Figure 2C and D). However, 21 of 523 cases (4%) were positive and 502 cases (96%) were negative for CD44 expression (Figure 2E and F).

Correlation of CD marker expression and clinicopathological parameters in colorectal adenocarcinoma

Upon clinicopathological analysis, CD133 expression

Table 1 Correlation between CD133 and CD24 expression and clinicopathological factors in colorectal cancer (*n* = 523)

was present more in male patients (P = 0.002) and in advanced T stage cancer (P = 0.024) (Table 1). Correlation between CD24 expression and clinicopathological factors was seen in the degree of differentiation (P = 0.006) (Table 1). Correlation between CD44 expression and clinicopathological factors was seen for the tumor size (P = 0.001) (data not shown).

Correlation of CD marker expression and patient overall survival

We examined the effect of CD marker expression on clinicopathological prognostic factors in colorectal adenocarcinoma. A significant prognostic influence of age, histological grade, AJCC stage, lymphatic invasion and vascular invasion on overall survival was found by univariate and/or multivariate analyses. However, no impact of CD133, CD24 and CD44 expression on overall survival was observed in univariate and multivariate survival analyses. Kaplan-Meier survival curves and log-rank tests showed no significant correlation between patient survival and CD133, CD24 and CD44 expression (P = 0.774, P = 0.775 and P = 0.636, respectively) (Figure 3).

DISCUSSION

Cancer stem cells have recently been proposed to

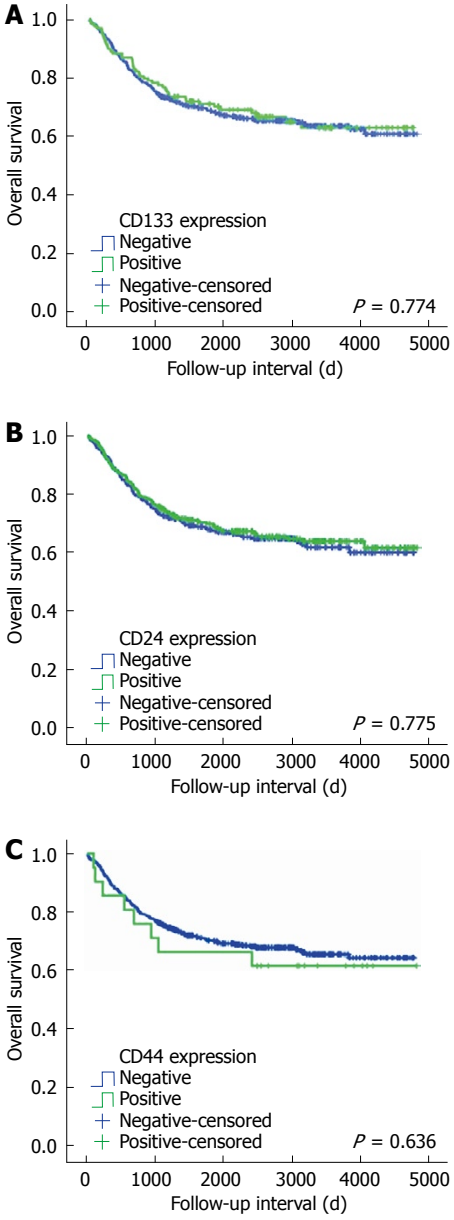

Figure 3 Cumulative survivals according to CD133 (*P* = 0.774) (A), CD24 (*P* = 0.775) (B) and CD44 (*P* = 0.636) (C) expression in colorectal cancer patients (Kaplan-Meier method).

be the cancer initiating cells that are responsible for tumorigenesis and for contributing to cancer resistance in leukemia[11]. Compared to leukemia, evidence for the existence of cancer stem cells in solid tumors has been more difficult to obtain for several reasons. Cells within solid tumors are less accessible, and functional assays suitable for detecting and quantifying normal stem cells from many organs have not yet been developed, and the cell surface markers required to isolate such cells have not been identified fully. However, there have been some impressive studies in this area recently. Advances have been made in identifying and enriching cancer stem cells in several solid tumors, including breast, brain and colon cancers[4-6,8-10].

Lapidot *et al*[12] have shown that leukemia-initiating stem cells present in the peripheral blood of acute myelogenous leukemia (AML) patients can induce AML when transplanted into severe combined immunodeficient mice. In 2003, Al-Hajj *et al*[8] isolated human breast cancer stem cells that can cause breast cancer in non-obese diabetic/severe combined immunodeficient (NOD/SCID) mice through serial transplantations, which suggests a capacity for self-renewal. The following year, Singh *et al*[6] have found evidence of stem cell involvement in brain cancer. Recently, O'Brien *et al*[4] have demonstrated that CD133-positive colon-cancer-initiating cells in the human colon cancer specimen generate tumors in the renal capsule of pre-irradiated NOD/SCID mice. More recently, cells have been isolated from human prostate cancer patients, which can produce serially transplantable prostate tumors in NOD/SCID mice[10]. Even though definitive cancer stem cell markers have not been found in all the previously mentioned studies, these studies have revealed that only a small subset of cells in different tumor types is capable of tumor formation and several candidate stem cell markers have been evaluated. While CD133, CD24 and CD44 have been tested as cancer stem cell markers for serial transplantation studies in various cancers, their prognostic value has not been elucidated clearly[4-10].

CD133, which is one of the most important cancer stem cell markers[4-7], was stained fairly well in 24.5% of our colon cancer patients. In terms of clinicopathological parameters, CD133 expression was related to gender and T stage. The present study revealed that male gender was positively related to CD133 expression. T0 and T1 colon cancers showed lower incidence of CD133 protein expression compared to advanced colon cancer.

CD24, another important cancer stem cell marker, was expressed in 50.5% of the colon cancer patients. Correlation between CD24 expression and clinicopathological factors was seen in degree of differentiation. CD24 consists of a small protein core comprising 27 amino acids, which is extensively glycosylated and is bound to the membrane via a phosphatidylinositol anchor[13-15]. Several reports have shown that CD24 can be expressed on several solid tumors such as small cell lung cancer, neuroblastoma, rhabdomyosarcoma and renal cell cancer[16,17]. Lim *et al*[18] have reported that CD24 expression is related to lymph node metastasis in colon cancer. Weichert *et al*[19] have shown that cytoplasmic CD24 expression in colorectal cancer is independently correlated with shortened patient survival. We have not seen any positive correlation between CD24 expression and nodal status and patient survival.

CD44 is an unique adhesion molecule and several studies have revealed that CD44 is overexpressed at the mRNA and protein levels in colon cancer[20,21]. In our study, large tumors bigger than 5.5 cm showed more frequent CD44 expression, which indicated that CD44 expression was related to clinical tumor burden.

Our results in human colon cancer specimens showed various expression patterns of CD markers. This is believed to be the first trial to verify the

relationship between well-known prognostic factors of colon cancer and conventional cancer stem cell markers. Tumor invasiveness and differentiation were identified as clinicopathological factors related to cancer stem cell markers, especially CD133 and CD24.

For further study, other colon stem cell markers which are related to patient survival should be found for clinical application of colon cancer stem cells. Several studies have indicated that pleuripotency-related factors, including Oct3/4, are related to cancer development[22-24]. Beside CD markers, other cancer stem cell markers may help distinguish cancer stem cells from cancer cells.

In summary, we have presented some evidence that several conventional clinical factors were related to cancer stem cell markers in colorectal adenocarcinoma. However, CD133, CD24 and CD44 expression did not show a close relationship with the survival outcome of colorectal adenocarcinoma. These results warrant further careful and well-designed studies of colon cancer stem cells as markers for clinical application.

COMMENTS

Background

Colorectal adenocarcinoma is the second most common type of cancer and a major cause of cancer-related morbidity and mortality in the Western world. Countless treatment protocols including chemotherapy and radiation have been applied to colorectal cancer treatment and a number of studies have identified conventional prognostic factors. Recently, the prospective identification of colon cancer stem cells has received major attention because of their potential for colon cancer treatment.

Research frontiers

This study focused on the identification of CD133-, CD24- and CD44-positive tumor cells in colon tumor sections by an immunohistochemistry-based technique, and the findings are discussed in conjunction with clinicopathological data.

Innovations and breakthroughs

Results in human colon cancer specimens showed various expression patterns of CD markers. This is believed to be the first trial for verifying the relationship between well-known prognostic factors of colon cancer and cancer stem cell markers. Tumor invasiveness and differentiation were identified as clinicopathological factors related to cancer stem cell markers.

Applications

The authors have presented some evidence that several conventional clinical factors were related to cancer stem cell markers in colorectal adenocarcinoma. However, CD133, CD24 and CD44 expression did not show a close relationship with survival. These results warrant further careful and well-designed studies of colon cancer stem cells as markers for clinical application.

Terminology

CD133, also known as PROML1 or prominin, is a stem cell surface antigen that has been identified recently as a potential cancer stem cell marker in brain, colon and prostate cancer. CD44, also known as homing cell adhesion molecule, is a cell surface glycoprotein expressed on lymphocytes, monocytes and granulocytes, which has been identified as a stem cell marker in breast and head and neck cancer. CD24, a cell surface marker, is a single chain sialoglycoprotein with a molecular mass of 42 kDa.

Peer review

The authors have presented some evidence that several conventional clinical factors were related to cancer stem cell markers in colorectal adenocarcinoma. This study is modestly reported with respect to a careful and large study. The approach needs to be encouraged, despite the relatively negative nature of the study with respect to the utility of the markers as a prognostic markers.

Abstract

AIM: To evaluate the efficacy of cola treatment for gastric phytobezoars, including diospyrobezoars.

METHODS: A total of 17 patients (range: 48 to 78 years) with symptomatic gastric phytobezoars treated with cola and adjuvant endoscopic therapy were reviewed. Three liters of cola lavage (10 cases) or drink (7 cases) were initially used, and then endoscopic fragmentation was done for the remnant bezoars by using a lithotripsy basket or a polypectomy snare. The overall success of dissolving a gastric phytobezoars with using three liters of cola and the clinical and endoscopic findings were compared retrospectively between four cases of complete dissolution by using only cola and 13 cases of partial dissolution with cola.

RESULTS: After 3 L of cola lavage or drinking, a complete dissolution of bezoars was achieved in four patients (23.5%), while 13 cases (76.5%) were only partially dissolved. Phytobezoars (4 of 6 cases) were observed more frequently than diospyrobezoars (0 of 11) in the group that underwent complete dissolution (P = 0.006). Gender, symptom duration, size of bezoar and method of cola administration were not significantly different between the two groups. Twelve of 13 patients with residual bezoars were completely treated with a combination of cola and endoscopic fragmentation.

CONCLUSION: The rate of complete dissolution with three liters of cola was 23.5%, but no case of diospyrobezoar was completely dissolved using this method. However, pretreatment with cola may be helpful and facilitate endoscopic fragmentation of gastric phytobezoars.

Key words: Gastric phytobezoars; Diospyrobezoars; Cola; Dissolution; Clinical efficacy

INTRODUCTION

Bezoars are hard masses or concretions of indigestible food, vegetable fiber or hair that are found in the gastrointestinal (GI) tract, usually in the stomach. Although the incidence of bezoars is unknown, the reported incidence is about 0.4%[1]. Bezoars are usually classified into four types according to their composition: phytobezoars, trichobezoars, medication bezoars and lactobezoars. Dissolution therapy with proteolytic or cellulase enzymes[2], endoscopic fragmentation or aspiration and surgery have been proposed as the treatment options for bezoars, and these treatments have a wide range of efficacy[3]. Ingestion of persimmons is considered the most common cause of phytobezoars in some countries[4,5]. Because of their hard consistency, endoscopic therapy with fragmentation or enzymatic dissolution is challenging and sometimes mechanical fragmentation cannot be accomplished.

Recently, dissolution bezoars with cola has been described to be one of the effective treatment options for the treatment of gastric phytobezoars. However,

only commentaries on individual cases or small number of cases have been reported on the cola dissolution of phytobezoars[6-12]. To elucidate the efficacy of cola for dissolving phytobezoars, further evaluations with large number cases are needed. Here, we report the clinical results of 17 consecutive patients with gastric phytobezoars, including diospyrobezoars, who were initially treated by three liters of cola gastric lavage or drink.

MATERIALS AND METHODS

The medical records of 17 patients with gastric phytobezoars treated by cola gastric lavage at Korea University Hospital, Seoul, between 2002 and 2008 were retrospectively reviewed. Diagnosis and classification of gastric bezoars were based upon clinical and endoscopic findings. Diospyrobezoar was diagnosed by history of eating persimmons and the endoscopic typical characteristics such as cemented seeds of persimmon or hard consistency or darkish-brown color. The size of each bezoar was grossly estimated as occupied percentage of the lumen of the stomach. The patients' median age was 63 years (range: 48-78). Seven patients had a long-standing history of diabetes mellitus (DM), four had a history of arterial hypertension (AHT) and the other patients had no significant past or concurrent diseases. On the initial endoscopic evaluation, 11 cases had darkish-brown colored diospyrobezoar and 6 cases had bright brown or yellow colored phytobezoars (Table 1). After diagnosing the bezoar, two nasogastric tubes (16 F) were placed for performing gastric cola lavage. One tube was used for the continuous administration of cola, and the other for natural drainage. A lavage with three liters of cola was performed over 12 h. All the procedures were done after obtaining informed consent from all the patients. Among the 17 patients, 8 patients drank the three liters of cola as they had refused to have the nasogastric tube inserted (Table 2). The nine patients with nasogastric tubes were kept in the recumbent position to prevent aspiration. The patients with DM had blood glucose monitoring by a glucometer. One day after the lavage with three liters of cola (or after drinking the same amount of cola), second-look endoscopic examinations were performed for assessing the bezoar. The status of the bezoars was then described, i.e. whether or not the bezoar remained in place, and whether it had changed its size and consistency. When the bezoar had disappeared, we considered this as complete dissolution. When it had a decreased size and a softened consistency by palpation with the biopsy forcep, then the response was considered as partial dissolution. If no change of the size and consistency was observed, then this was considered as lack of response. As the result of the initial administration of cola, patients were divided into two groups, i.e with either complete dissolution or partial dissolution. The clinical and endoscopic features and the method of cola administration were then retrospectively compared between two groups.

The endoscope we used was an Olympus GIF Q 260 or a H 260 (Olympus, Tokyo, Japan). If a residual bezoar was observed, then endoscopic fragmentation was done using a lithotripsy basket (GML-90-26-180, Medi-Globe, Achenmuhle, Germany) or a polypectomy snare (SD-5L-1, Olympus, Japan) (Figure 1A and B). Finally, fragmented bezoars were crushed and retrieved with a biopsy forcep or a pentagon grasping forcep (Figure 1C and D). After the procedures, all the patients were advised to drink an additional 3 L of cola. Re-examination endoscopy was done one day after the procedures. All the endoscopic procedures were performed by three expert endoscopists.

Fisher exact test and the Mann-whitney *U* test were used for the comparison of clinical, endoscopic, and method of administration of cola. $P < 0.05$ were regarded as statistically significant.

RESULTS

After lavage with (or drinking) 3 L of cola, a complete

dissolution was observed in four patients (23.5%), whereas 13 cases were partially dissolved with cola, i.e. their size was grossly decreased and their consistency was more softened than that observed before treatment (Figure 1A and B). The clinical characteristics of patients

with complete dissolution (CD) and partial dissolution (PD) are compared and summarized in Table 2. The complete dissolution was observed in 4 out of 6 cases of phytobezoars, but no complete dissolution was noted in diospyrobezoars ($P = 0.006$). Other parameters, including age, gender, size of bezoar, endoscopic findings and the method of cola administration, were not different between the two groups (Table 3). Among the 13 cases with residual bezoars, eleven were completely treated with one endoscopic session and additional drink of three liters of cola. Four patients (case 13, 14, 15, 17) needed two endoscopic sessions to completely disrupt the bezoar.

Thirteen out of 14 (91.6%) patients were completely cured with a combination of cola and endoscopic treatment. The mean endoscopic procedure time was 44.53 ± 18.56 min and the mean number of used accessories was 2.07 ± 1.02. No procedure-

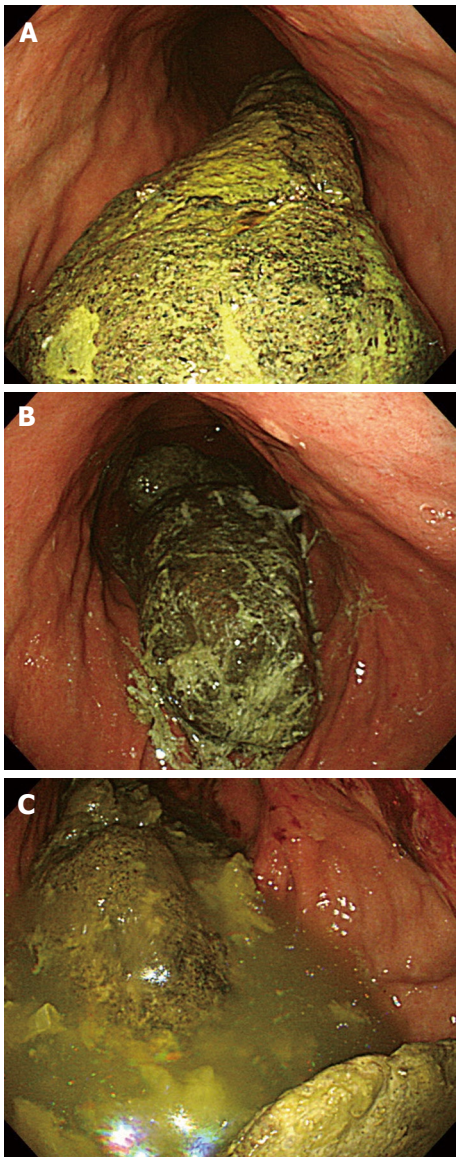

Figure 2 Endoscopic views of huge diospyrobezoar. A: Initial endoscopic view. Endoscopic view of huge dark brownish colored diospyrobezoar in the stomach (Case 17). B: Endoscopic view of one day after 3 L of cola lavage. The size was decreased and some fragmentation was observed. C: Endoscopic view of 4th day. The residual bezoar still remained with fragmentation (total amount of administrated cola was 9 L).

related complications developed, such as hemorrhage, perforation and small bowel obstruction. The mean hospital stay of all patients was 3.52 ± 1.32 d.

In another patient (case 17), the decreased size and softened consistency of the bezoar was observed after an initial lavage with three liters of cola lavage, but the endoscopic breakage failed (Figure 2A and B). So, 100 mL of cola were directly injected into the bezoar using an endoscopic needle and six additional liters of cola were administered orally for two days. On the fourth day, the bezoar still remained in place, with only partial resolution (Figure 2C). Because the patient refused an additional endoscopic treatment with cola, the bezoar was removed by surgery.

DISCUSSION

The treatment modalities for gastric bezoars include endoscopic therapy with fragmentation, medical treatment by enzymatic dissolution and surgery[13]. Various endoscopic methods and instruments for breaking up bezoars have been reported, including lithotripsy with basket[14], endoscopic suction removal with large-channel endoscopy[15], polypectomy snare[16] and biopsy forceps. However, these procedures are time-consuming. Furthermore, procedure-related complications may develop, such as bleeding, overtube-associated complications and intestinal obstruction caused by the fragmented, residual bezoars. In addition, chemical dissolution usually requires a long period of time and complications may develop, such as electrolyte imbalance, gastric ulcer and bleeding. The reported efficacy of chemical dissolution is variable[3,17].

Recently, Ladas *et al*[6] reported a five cases of gastric phytobezoars successfully dissolved by lavage with three liters of cola. Since then, there were six reports written in English and describing the treatment of gastric bezoars with cola. However, reports on cola dissolution have been limited to individual case reports. Methods and results are summarized in Table 4.

In this series, we report the clinical results of 17 gastric phytobezoars treated with cola. To our knowledge, this is largest study ever on this topic. The therapeutic efficacy of a lavage with three liters of cola (or of drinking the same amount), to achieve the complete dissolution of bezoars, was only 23.5%. Compared with previous reports, our success rate is very low. The reason for this low therapeutic efficacy of cola may be due to the fact that most cases of our series were diospyrobezoars (13 out of 17 cases, 76.4%), and in fact we failed to observe the complete dissolution of diospyrobezoars using cola alone.

Diospyrobezoars following ingestion of persimmon are formed by the agglutination of the tannins in the

skin of the fruit. Because of their hard consistency, endoscopic therapy with fragmentation or enzymatic dissolution is challenging and sometimes mechanical fragmentation cannot be accomplished. In a previous report, the efficacy of the combination of endoscopic fragmentation and pharmacotherapy was 80%[18]. There are four reports of cases in whom the complete dissolution of diospyrobezoars was carried out with cola (Table 4). The direct injection of small amounts of cola directly into the phytobezoars is also rapidly effective and safe[6,7,9]. However, in our experience, this technique was not effective for complete dissolving huge disopyrobezoar (case 17). So, in case of diospyrobezoars, complete dissolution might not be achieved with cola use alone.

Another reason for the low therapeutic efficacy may be the relatively short duration of cola administration. There were two successful dissolution cases with daily cola drinking for longer durations (7 d[10] and 3 mo[18]). A prolonged administration may have changed our clinical results, but it may also have induced metabolic disturbances due to the cola's high caloric content. Also, a longer administration time may prolong the *nil per os* time and the length of hospital stay. So, we used the short duration of cola and combined it with the endoscopic fragmentation.

Cola alone could not dissolve completely all gastric phytobezoars. However, in our series, softened-consistency or decreased size was observed in all residual bezoars. So, endoscopic fragmentation and retrieval of the bezoars could be easily performed. Except for four cases, all the procedures were completed in only one session, with relative short procedure time. As the bezoars' consistency was softened, disruption of accessories was prevented. So, these techniques are cost-effective when considering the length of the hospital stay, the number of endoscopic sessions and the used accessories. Also, using additional cola after endoscopic disruption may be helpful preventing small bowel obstruction due to daughter fragments.

Cola's mechanism of dissolution of bezoars is not well understood. The suggested mechanisms are: (1) the mucolytic effect of $NaHCO_3$, (2) the digestion of the bezoar by CO_2 bubbles and (3) the cola's acidity, which is similar to that of gastric acid[6].

In conclusion, the complete dissolution rate using three liters of cola was 23.5%, but no case of diospyrobezoars was completely dissolved. However, pretreatment with cola may be helpful and facilitate endoscopic fragmentation of gastric phytobezoars. A combination therapy of gastric phytobezoars with cola and endoscopic fragmentation is cost-effective and decreases the number of endoscopic sessions and accessories that are used as well as the hospital stay.

COMMENTS

Background

Ladas *et al* have first reported a case series of gastric phytobezoars that were successfully dissolved with cola lavage along with oral maintenance. Since then, there were several reports of gastric bezoar cases successfully treated only with cola.

Innovations and breakthroughs

The efficacy of cola for dissolving bezoars was very low compared with previous reports. There was no case of completely dissolved diospyrobezoar with cola. However, the use of cola for dissolving bezoars was cost-effective.

Applications

This study may suggest that dissolving gastric bezoars with cola alone is not the best treatment modality, especially for diospyrobezoars.

Peer review

The study evaluated the efficacy of cola treatment for gastric phytobezoars. The study is well written and perhaps the largest experience todate.

Abstract

AIM: To determine if TSPAN1 overexpression is associated with clinicopathological and prognostic factors in human colorectal adenocarcinoma.

METHODS: Total RNA was extracted in 20 human adenocarcinoma tissues for TSPAN1 mRNA assay by RT-PCR. Eighty-eight specimens of human colorectal adenocarcinoma were surgically removed. TSPAN1 protein levels in cancer tissues were determined by immunohistochemistry using a polyclonal antibody against self-prepared TSPAN1. The correlation between TSPAN1 expression and the clinicopathological factors and the overall survival rate was analyzed by univariate and multivariate assay.

RESULTS: TSPAN1 mRNA was detected in 90.0% (18/20) of cancerous tissues. The light density of TSPAN1 mRNA expression levels was 0.89 ± 0.30 in adenocarcinoma by gel-image system. TSPAN1 protein expression was detected in 78.41% (69/88) and weakly expressed in 40% normal colorectal tissues. There were significant differences between colorectal adenocarcinoma and normal control epithelium ($P < 0.05$). TSPAN1 protein expression in colorectal cancerous tissue was significantly correlated with the histological grade, cell expression PCNA, lymph nodal metastasis and TNM staging of the disease. Patients with TSPAN1 protein overexpression had a significantly shorter survival period than that in patients with TSPAN1 protein negative or weak expression, respectively ($P < 0.05$). Furthermore, by multivariate analysis, TSPAN1 protein expression demonstrated an independent prognostic factor for human colorectal cancers ($P < 0.05$, relative risk 0.755; 95% confidence interval 0.302-1.208).

CONCLUSION: The expression of *TSPAN1* gene is increased in colorectal carcinoma, suggesting that TSPAN1 might serve as an independent prognostic factor for the colorectal adenocarcinoma patients.

Key words: TSPAN1; Colorectal adenocarcinoma; Semi-quantitative RT-PCR immunohistochemistry; Prognosis

INTRODUCTION

The colorectal carcinoma is one of the most common malignant neoplasms, ranking the fourth frequency in men and third in women[1]. Although the prognosis has slightly improved in the past years, colorectal cancer is still the second and third major common cause of

cancer related death in men and women in the United States, respectively[2]. The incidence of colorectal cancer is the fourth in malignant tumor ranking in China, and it is increased dramatically in developing regions[3,4]. The colorectal cancer is thought to result from a combination of environmental factors, diet, lifestyle, chronic inflammation and accumulation of specific genetic alterations. The pathogenesis and development of colorectal cancer involve multi-genes and multi-steps. Ogino *et al*[5] showed the occurrence of colorectal cancer involved in a series of gene mutations, microsatellite instability (MSI) and 18q loss of heterozygosity (LOH). The other molecules studied include MST1 (Mammalian sterile 20-like kinase)[6]. Replication protein (RPA)[7], ELAV-like protein Huk and COX-2[8], α-catenin, β-catenin[9] α-ligatin, β-ligatin, Rho-a[10], *etc*. In fact, an established cascade of events leading to colorectal cancer development and progression is described by Vogelstein. The alteration of expression of these molecules often showed an obvious correlation with pathologic grading and clinical staging in colorectal cancer, which can be used as a biomarker for assessing prognosis. Currently, the assessment of prognosis is mainly based on pathological features of the tumor which is valuable to the triage of patients who will benefit from adjuvant therapy. The clinical pathological staging is the most popular standard prognostic approach for predicting the clinical outcome of colorectal cancer patients[11,12]. The prognosis of colorectal cancer is closely related to the tumor TNM stages. However, patients with similar stages of the disease have various outcomes. Therefore, there is a need to identify useful prognostic molecular markers in guiding treatment decisions and/or in developing more effective treatments. TSPAN1 (GenBank Accession No. AF065388) is a new member of TM4SF[13], which is located at chromosome 1 p34.1. It encodes a 241 amino acid protein. TSPAN1 was reported as a tumor-related gene recently[13-17]. In several studies, TSPAN1 gene over-expression was detected in liver cancer[14], prostate cancer[15], gastric carcinoma[16] and cervix cancer[17]. It has been proposed that TSPAN1 plays a role in cell mitosis and/or cause cell abnormal differentiation. In this study, we examined fresh tumor tissues and histological sections of colorectal adenocarcinoma to determine the expression of TSPAN1 mRNA and protein, and analyzed the relationship between the gene expression and clinicopathological parameters. The result suggests that overexpression of TSPAN1 is correlated to the prognosis of colorectal cancer patients.

MATERIALS AND METHODS

Specimen

A total of 88 patients with colorectal adenocarcinoma, diagnosed and treated from January 1998 to April 2000 were investigated in this study. Of the 88 cases evaluated, 46.6% (41 cases) were rectum cancers, 30.1% (27 cases) were sigmoid colon cancers, 6.8% (6 cases) were descending colon cancers, 2.3% (2 cases) were transverse colon cancers and 13.6 % (12 cases) were ascending colon cancers. The median age at the time of diagnosis was 62.2 years (range, 37-85). There were 50 male patients, 38 female patients. None of them had received chemotherapy or radiotherapy before diagnosis. After surgery, these patients with TMN stage Ⅱ took oral 5-fluorouracil and patients with stage Ⅲ-Ⅳ were subjected to 5-fluorouracil-based systemic chemotherapy. In order to avoid bias, each case was diagnosed by two pathologists.

The clinicopathological data were determined according to the WHO classification and TNM cancer staging[11,12,18]. The average size of the tumor was 4 cm (range from 1.5 to 7.6 cm), 54.5% (48 cases) were cauliflower/polyp type and 45.45% (40 cases) were ulcer/sclerotic type. Adenocarcinomas were graded predominantly on the basis of the extent of glandular appearances, and divided into well (lesions exhibit glandular structures in > 95% of the tumor, grade 1, 15.9% or 14 cases), moderate (lesions have 50%-95% glands, grade 2, 44.31% or 39 cases) and poor differentiation (lesions have 5%-50% glands, grade 3, 39.77% or 35 cases). Tumor limited in submucosa (T1) and muscularis propria (T2) as stage Ⅰ accounted for 32.95% (29 cases), tumor invaded through muscularis propria into subserosa or into non-peritonealized pericolic or perirectal tissues (T3) and tumor directly invades other organs or structures and/or perforates visceral peritoneum (T4) as stage Ⅱ accounted for 29.54% (26 cases), and the tumor with metastasis in 1-3 regional lymph nodes (N1-3) in any T as stage Ⅲ and the tumor with distant metastasis (M) in any T and N as stage Ⅳ, Ⅲ and Ⅳ accounted for 37.5 % (33 cases). Vascular invasion in 26 cases (29.55%) demonstrated that vessel wall was occlusive or infiltrating damaged up to the complete destruction with a surrounding fibroinflammatory reaction[19-21]. Such clinicopathological factors as perineural invasion and desmoplasia reaction were observed and analyzed as well. The proliferation level of cancer cells was evaluated based on the expression of PCNA in tumor parenchymas.

Semiquantitative reverse transcription-polymerase chain (RT-PCR)

Twenty cases of fresh colorectal cancer specimens were stored in -70℃ refrigerator immediately after dissection for semi-quantitative RT-PCR with co-amplification of TSPAN1 gene and an internal control β-actin. Briefly, total RNA from tumor tissues was extracted with TRLZOL reagent and the reverse transcription was performed with Rneasy Kit (Clontech, CA, USA) according to previously published protocols[14]. A 50 μL PCR reaction contains approximately 50 ng of human colorectal cancer ds-cDNA; 40 mmol/L Tricine-KOH, pH9.2; 15 mmol/L KOAc; 3.5 mmol/L Mg $(OAc)_2$; 0.2 μmol/L 5' TSPAN1 primer (5'-CAG-TTC-CCT-CTT-TCA-GAA-CTC-ACT-G-3'); 0.2 μmol/L 3' TSPAN1primer (5'-ATC-CAC-CCA-GAG-GCT-CTG-CTG-ATT-TCA-CCT-3'); 0.1 μmol/L 5' β-actin primer (5'-TTA-CAC-CCT-TTC-TTG-ACA-AAA-CCT-A-3');

0.1 μmol/L 3' β-actin primer (5'-CAA-AAG-CCT-TCA-TAC-ATC-TCA-AGT-3'); 0.2 mmol/L each of dATP, dGTP, dCTP and dTTP; and 1 μL of Advantage™ cDNA Polymerase Mix (50X; contains KlenTaq-1 and Deep Vent polymerases). The PCR cycling was as follows: PCR tubes were preheated at 94℃ for 20 s; then run 30 cycles at 96℃ for 6 s (denature); 60℃ for 20 s for annealing and 72℃ for 1 min for extension, in a DNA thermal cycle 9600 (PE Biosystems, CA, USA). PCR products were applied to electrophoresis on 1% agarose gel analysis; the expected *TSPAN1* gene was a band at 1159 bp. TSPAN1 expression was evaluated by calculating the average ratios of light density using symmetry computerized gel imaging system[14].

Immunohistochemistry

All 88 adenocarcinoma samples were routinely fixed in 40 g/L formaldehyde solution and embedded in paraffin. After slicing into 4 μm thick sections, immunohistochemistry was performed using Dako Elivision TM Plus Two-step System (PV-6000 kit, Zymed, Co., USA.). To detect the TSPAN1 and PCNA expressions in colorectal adenocarcinoma tissues, the sections were dewaxed in xylene and rinsed in alcohol and graded alcohol/water mixtures. Sections were then submitted to antigen retrieval treatment in a pressure cooker. The tissues were boiled in 0.01 mol/L, pH 6.0 citric acid buffer to retrieval antigen for 5 min. They were then treated with 0.3% hydrogen peroxide in absolute methanol to inhibit endogenous peroxidase activity for 15 min at room temperature. After blocking of background staining with diluted normal calf serum, sections were incubated overnight at 4℃ with polyclonal antibodies against TSPAN1 (antibody prepared with the help of American San Francisco gene biotechnology company) and PCNA (PC10, No. 40780708, DAKO, USA), respectively. Subsequent reaction proceeded using a two step assay, immunoreaction was visualized with peroxidase-3,3'-diaminobenzidine (DAB). Finally, sections were lightly counterstained with Mayer's haematoxylin and mounted. The negative controls were set by omitting the primary antibodies. The positive controls were the hepatocellular carcinoma with positive expressions of TSPAN1. In addition, 10 specimens from the marginal normal mucosa of tumor were used as normal controls[16].

Evaluation of immunohistochemical staining

All sections were blindly analyzed by two experienced pathologists under light microscope. Based on the estimated percentages of positive parenchyma cells and/or the immunostaining intensity, which was determined by comparing the immunoreactivity of the positive controls that were included in each experiment, staining results were divided into four categories: (-) tissues specimens: positive parenchyma cell with less than 5% of the cancer tissues and/or weakly stained; (+) tissue specimens: positive parenchyma cell with less than 25% of the cancer tissues and/or weakly stained; (++) tissues specimens: positive parenchyma cell with less than 50% of the cancer tissues and/or moderately stained, and (+++) tissue specimens: positive parenchyma cell with more than 75% of the cancer tissues and/or strongly stained[14,16].

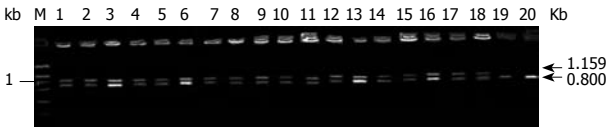

Figure 1 Analysis of TSPAN1 and β-actin mRNA expression in 20 cases of colorectal adenocarcinoma. TSPAN1 and β-actin mRNA expressions were detected in 20 cases of colorectal adenocarcinoma tissues by semi-quantitative RT-PCR. The upper bands were TSPAN1 and the lower bands were β-actin. Lane M: 200 ng of 1 kb size ladder (New England BioLabs); Lanes 1-20: Colorectal adenocarcinoma tissues.

Statistical analysis

Association between *TSPAN1* gene expression and other clinicopathological factors of the tumor were assessed by the Fisher's exact test (two-sided) for categorical variables and χ^2 test were used to compare ordinal variables. The grading-related data was analysed by Spearman test. Overall survival was defined as the period from the date of diagnosis to the date of death. Survival curves were determined according to the Kaplan-Meier method, and compared using Log-rank test statistical differences. Multivariate survival analysis was performed with SPSS version 11.0 Software (Chicago, IL, USA).

RESULTS

RT-PCR detection of TSPAN1 mRNA expression

Total RNA was extracted from 20 cases of colorectal adenocarcinoma tissues. RT-PCR analysis of TSPAN1 mRNA expression was then performed. The positive rate of TSPAN1 mRNA expression was 90% (18/20) in the colorectal adenocarcinoma (Figure 1), and the relative amount of TSPAN1 mRNA levels in cancer tissues was assessed based on the β-actin control. The relative amounts of TSPAN1 mRNA were 0.89 ± 0.30.

Immunochemistry detection of TSPAN1protein expression

TSPAN1 was mainly presented in cytoplasm and located at membrane as well. In the normal control epithelium, 3 cases presented a weakly positive staining of TSPAN1, and only 1 case presented moderately positive expression (Figure 2A). We observed TSPAN1 protein expression in 78.41% (69/88) cases of tumors, in which 17.39 % (12/69) was displayed as strong expressed (+++), 44.93% (31/69) as moderately expressed (++), and 37.68% (26/69) as weakly expressed (+). There were significant differences between colorectal adenocarcinoma and normal control epithelium ($P < 0.05$), (Figures 2B-E).

Correlation with clinicopathological parameters

To investigate the role of TSPAN1 expression in colorectal cancer, we examined the correlation of

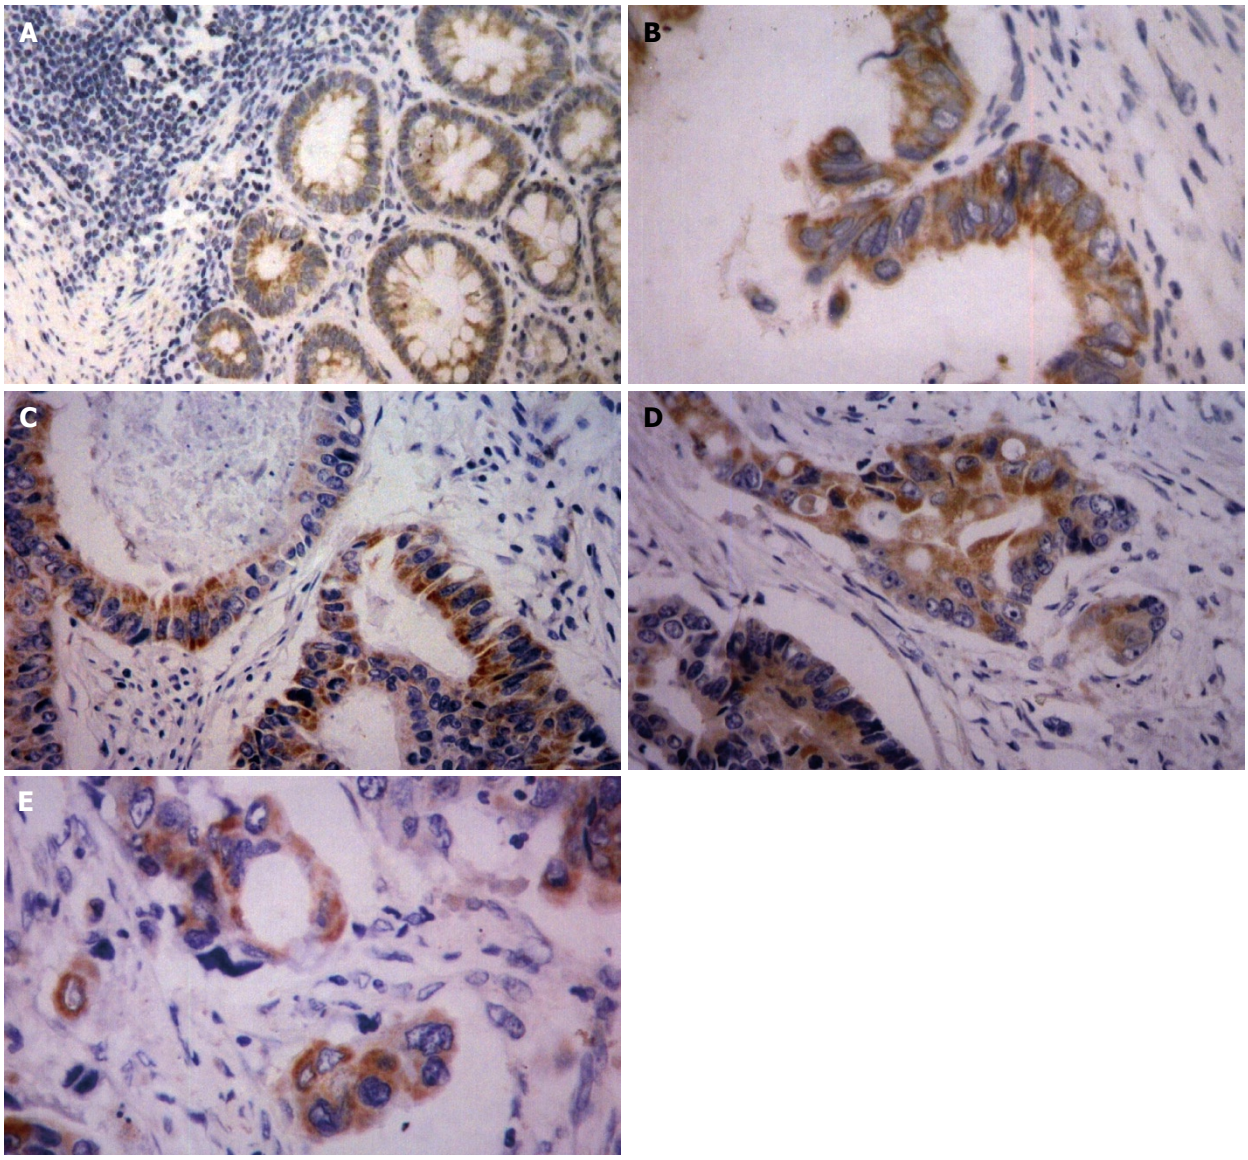

Figure 2 TSPAN1 expression in normal tissues (A), colon cancer tissues (B, C), rectal cancer tissues (D, E). Paraffin section of human colorectal carcinoma tissues was stained with anti-TSPAN1 polyclonal antibody by immunohistochemistry. A: TSPAN1 weakly expressed in the cytoplasm. (× 100). B, C: TSPAN1 was located in the cytoplasm with yellow granulation. (× 200). D, E: Cancer nest showed positive TSPAN1 expression and vascular invasion. (× 200).

TSPAN1 expression with the clinicopathological features (Table 1). We found a positive correlation with histological grade, PCNA expression, nodal metastasis and TNM stages (P = 0.001, 0.015, 0.008 and 0.002, respectively). TNM staging of colorectal cancer is more important for patient's prognosis evaluation. The five-year survival rate of TMN stage 1 is more than 95%, while it is less 10% in patients with TNM stage Ⅲ-Ⅳ. From Table 1, it can be found that the TSPAN1 expression rate and intensity in early TNM stage were lower than in late TNM stage cancer tissues. In addition, TSPAN1 expression was not associated with vascular invasion, perineural invasion and desmoplasia.

Correlation with patients' survival rate

Within a period of 60 mo of the follow-up, 24 cancer-related deaths occurred, 3 of the deaths come from 9 patients with TSPAN1 negative tumors, and 21 from 33 patients in the TSPAN1 positive group. In the entire cohort, the overall survival rate of patients with TSPAN1 negative tumors were significantly higher than that of those with TSPAN1 positive tumors (63.64% *vs* 33.33%; log-rank test: χ^2 = 15.48, P = 0.001). Kaplan-Meier estimated the overall survival rate based on cell TSPAN1 expression in the patients with a follow-up period of 60 mo (Figure 3). To compare with other clinicopathological factors, the effects of histologic grades, node status, PCNA expression, TNM stages, vascular invasion or perineural invasion on the patients' survival were also analysed with univariate log-rank test. As shown in Table 2, the factors of cellular differentiation, node status, PCNA expression, TNM stages had a significant effect on the overall survival rate (P = 0.03, 0.001, 0.0003 and 0.002, respectively). Furthermore, univariate survival analysis was performed to investigate possible prognostic impact of TSPAN1 in

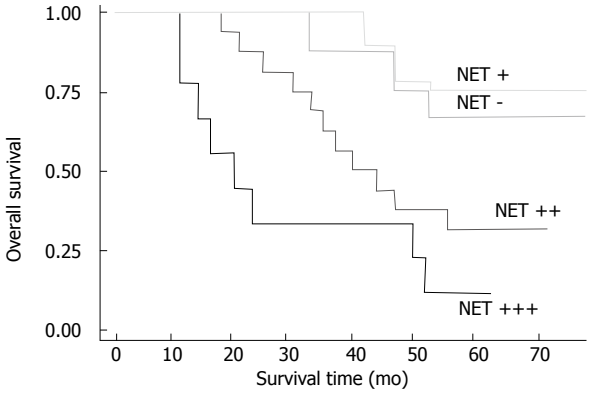

Figure 3 Overall 5-year survival curve of colorectal adenocarcinoma patients with TSPAN1 negative (-) and TSPAN1 positive (+, ++, +++) for the entire cohort (*P* = 0.001) was estimated by Kaplan-Meier test. Survival rate in TSPAN1 expression groups (++, +++) were obviously lower than that of weak expression (+) or negative (-) group, respectively ($P < 0.05$). There was no significant difference of survival rates between TSPAN1 negative group (-) and TSPAN1 weak expression group (+).

colorectal cancer. As shown in Table 2, the expression of TSPAN1 correlated with a worsening of the survival probability, which was statistically significant. This was also confirmed by a multivariate survival analysis including above factors (Table 3). All of these results suggested that TSPAN1 expression in tumors was an independent prognostic factor for colorectal adenocarcinoma patients (relative risk = 0.755; 95% confidence interval: 0.302-1.208 $P = 0.001$).

DISCUSSION

Many studies reported that TSPAN1 mRNA and protein were expressed in human normal tissues and carcinomas[13-17]. Serru detected TSPAN1 expression in various cell lines by RT-PCR including cervical cancer, lung cancer, squamous carcinoma, colorectal cancer and breast cancer cells[13]. Wollscheid *et al*[17] detected TSPAN1 mRNA level by RT-PCR and TSPAN1 protein by immunohistochemistry in cervical cancer and found that the gene was expressed in CIN Ⅲ, cervical squamous cell carcinoma and adenocarcinoma,

especially in all undifferentiated cervical carcinoma and adenocarcinoma. They thought *TSPAN1* gene expression correlated to cell proliferation and may be used as a marker for cervical cancer prognosis. However, *TSPAN1* gene expression in human colorectal cancer tissues has not been reported so far. In this study, we for the first time demonstrated that TSPAN1 mRNA and protein were extensively expressed in 90% and 78% human colorectal cancer tissues, respectively. Our results revealed that epithelial cells of the normal colon or rectum displayed a slight expression of TSPAN1 antigen (Figure 2A). There was significant difference between cancer tissues and normal control. The results are consistent with most other reported data[12-14] and suggest that the TSPAN1 expression is a specific marker for malignant transformation.

In colorectal cancer, the presence of many tumor-associated antigens and their relationship with clinical pathological parameters have been described[22-23]. PCNA, a major marker for cell proliferation, is highly expressed in most tumors[24]. In this study, the finding of a significant positive correlation between TSPAN1 and PCNA expression provided further evidence to support a potential role of TSPAN1 in tumor proliferation process (Table 1). The colorectal cancer development may hence relate to the accumulation of TSPAN1 protein in tumor cells. Similarly, our previous study found that TSPAN1 expression correlated with tumor proliferation maker Ki67 expression in human gastric carcinomas[16].

Currently, the TNM stage represents the main tool for identifying prognostic differences among patients with colorectal cancer. The reported 5-year survival rate is 95% for stage Ⅰ patients, 67% for stages Ⅱ, and 9.4% for stage Ⅲ and Ⅳ patients[25]. In our prospective 5-year follow-up study, the overall survival rate was 83.3% for stage Ⅰ patients, 62.5% for stage Ⅱ patients, and 13.6% for stage Ⅲ and stage Ⅳ patients (Table 2). Similarly, we showed that there was a significant correlation between the overall survival rate and the disease stages. Our study revealed that there was a statistically significant association between TSPAN1 expression and the various stages of colorectal cancer, in which TSPAN1 positive staining was seen in 63.64% patients with shorter survival time (Table 3). The univariate and multivariate analyses suggested that TSPAN1 status, PCNA expression, tumor stages and nodal status were strong predictors for the final clinical outcome (Table 3). Likewise, another study in our lab also showed that TSPAN1 expression was significantly correlated with the metastasis and poor prognosis of gastric carcinoma[16]. Increasing TSPAN1 protein expression was found associated with more advanced stages of cervical carcinoma[17]. All these findings suggest that TSPAN1 over-expression status might yield unfavorable prognosis for some types of cancers. Identifying those patients with high-risk colorectal cancers by TSPAN1 expression detection would be of great benefit for improving the treatment strategies. By the way, other reports displayed that vascular invasion and perineural invasion were correlated with a poor prognosis[19-21], but in this study we found no direct effect on tumor prognosis.

Colorectal carcinoma is one of the most common cancers in western world and in China, however its molecular mechanism is still unclear. To understand the specific regulation of gene expressions between colorectal cancer and non-cancer tissues and know the genes or proteins characteristics will delineate the molecular changes and obtain useful diagnostic marker. We have demonstrated that TSPAN1 was expressed in majority of human colorectal carcinomas in the current study. TSPAN1 expression, measured by immunohistochemistry in the tumor tissues, may be a candidate gene for diagnosis and prognosis of colorectal carcinoma. The overexpression of TSPAN1 in cytoplasm is associated with higher tumor grade, metastasis, proliferation, and more advanced stages and poor prognosis in colorectal adenocarcinoma patients, suggesting a tumor-related gene role of TSPAN1 in human colorectal cancer development.

The authors thank Mrs Lu for her help in collecting survival data.

COMMENTS

Background

The colorectal cancer results from a combination of environmental factors, diet, lifestyle, chronic inflammation and accumulation of specific genetic alterations. TSPAN1 (GenBank Accession No. AF065388) is a new member of TM4SF located at chromosome 1 p34.1. It encodes a 241 amino acid protein. TSPAN1 was reported as a tumor-related gene recently.

Research frontiers

TSPAN1 gene over-expression was detected in liver cancer, prostate cancer, gastric carcinoma and cervix cancer. It has been proposed that TSPAN1 plays a role in cell mitosis and/or cause cell abnormal differentiation.

Innovations and breakthroughs

In this study the authors examined fresh tumor tissues and histological sections of colorectal adenocarcinoma to determine the expression of TSPAN1 mRNA and protein, and analyzed the relationship between the gene expression and clinicopathological parameters, and found that overexpression of TSPAN1 is correlated to prognosis of colorectal cancer patients.

Applications

Testing TSPAN1 expression in tissues would be a useful tool to evaluate the prognosis of patients with colorectal cancer.

Peer review

The authors examined the expression of Net-1 in colorectal tissues, a novel gene whose function has yet to be understood so far. This study is of some clinical significance.

Abstract

Jejunoileal bypass (JIB), popular in the 1960s and 1970s, had remarkable success in achieving weight loss by creating a surgical short bowel syndrome. Our patient had an unusual case of liver disease and provided no history of prior bariatric surgery. Later, it was recognized that he had a JIB in the 1970s, which was also responsible for the gamut of his illnesses. Patients with JIB are often not recognized, as they died of complications, or underwent reversal of their surgery or a liver-kidney transplant. Early identification with prompt reversal, and the recognition and treatment of the life-threatening consequences play a critical role in the management of such patients.

Key words: Jejunoileal bypass; Bariatric surgery; Weight loss; Obesity; Morbid obesity

INTRODUCTION

Bariatric surgery is one of the few proven methods that cause durable weight loss. Failure of conservative means of producing permanent weight reduction in patients with morbid obesity, led to the introduction of operative approaches, such as jejunoileal bypass (JIB), which became popular in the late 1960s and early 1970s[1].

At that time, JIB was the most effective surgical intervention for achieving and maintaining weight loss. Typically, 35 centimeters of proximal jejunum was anastamosed, end-to-side or end-to-end, to the terminal 10 centimeters of ileum[2] (Figure 1). It was presumed that patients undergoing this procedure would experience continued hyperphagia, but would accomplish weight loss due to malabsorption[3]. As a result of JIB, patients whose preoperative weight was over 157 kg lost a mean of 58 kg at the end of 1 year[2].

However, JIB surgery has long been abandoned as a method of weight reduction surgery because of serious short and long-term complications. The number of patients who currently retain a jejunoileal bypass is small, as most patients have died or undergone reversal of their operation or conversion to a different bariatric procedure[3]. Recognition of previous JIB and understanding of its metabolic consequences are essential in the proper management of these patients.

CASE REPORT

A 64-year-old male was admitted on a regular basis for tense ascites (requiring serial large volume paracentesis) attributed to underlying advanced liver disease of unclear etiology. It was presumed to be the result of steatohepatitis from nonalcoholic fatty liver disease and/or chronic hepatic congestion due to decreased cardiac function.

The patient had a prior history of morbid obesity (191 kg, BMI 62) and cholecystectomy. His physical examination was remarkable for jaundice, abdominal ascites, spider angioma in the upper chest, gynecomastia and splenomegaly.

He had numerous other medical problems including multiple kidney stones with three previous lithotripsy interventions, progressive kidney disease requiring hemodialysis, a 30-year history of intermittent loose

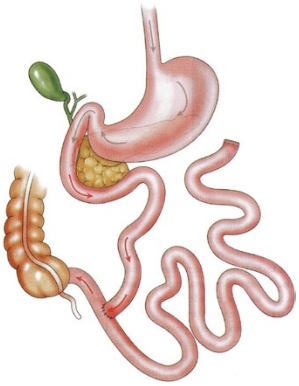

Figure 1 Jejunoileal bypass. A surgical short bowel syndrome created by bypassing more than 90% of the functioning small intestine.

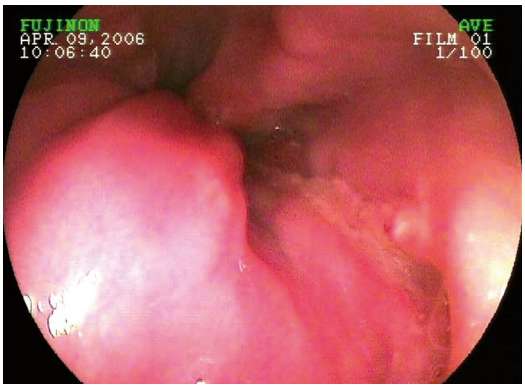

Figure 3 Upper endoscopy showing grade I esophageal varices, as a result of portal hypertension.

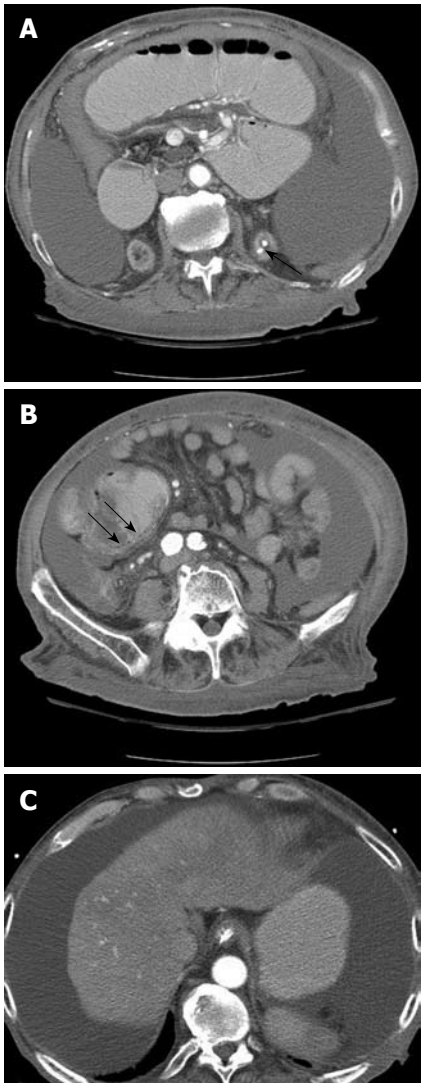

Figure 2 CT scan of the abdomen. showing stones in the left kidney (A, arrow), pneumatosis intestinalis (B, arrow) and shrunken nodular liver with abdominal ascites (C).

Table 1 Laboratory investigations

BUN/Creatinine (normal = 8-26/0.9-1.3)	34/8.2
Albumin (normal = 3.5-5.0)	1.9
Prothrombin time/INR (normal = 11.9-14.3/< 1.0)	25.3/2.4
ALT/AST (normal = 15-41/14-63)	45/41
Platelet count (normal = 140-400)	129
Serum albumin ascites gradient	2.3
Hepatitis profile (A, B, C)	Negative

BUN: Blood urea nitrogen; INR: International normalized ratio; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase.

stools, arthritis, fatigue, paresthesias, progressive loss of night vision, joint pains, slurred speech, incoordination and weakness.

On further questioning, the patient and family revealed that he had "weight loss surgery" in the 1970s at another facility. However, an upper endoscopy showed an intact pylorus, which raised suspicion of possible previous JIB surgery. His archived medical records were then obtained and it revealed that the patient indeed had a jejunoileal bypass performed in 1974.

Initial laboratory evaluation is noted in Table 1. Further evaluation revealed deficiency of all fat-soluble vitamins. The markers of other causes of chronic liver disease (viral hepatitis B and C, antinuclear antibody, anti-smooth muscle antibody, anti-mitochondrial antibody, ceruloplasmin, iron and ferritin) were negative. Stool studies showed findings consistent with steatorrhea. Computed tomography imaging of his abdomen revealed nephrolithiasis, pneumatosis intestinalis, a shrunken and nodular liver with abdominal ascites, and osteopenia (Figure 2). Upper endoscopy, as in Figure 3, revealed esophageal varices, portal hypertensive gastropathy and no evidence of prior gastric bypass.

He underwent a transjugular liver biopsy that showed portal fibrosis (stage 2, grade 1) with specimen fragmentation. A repeat transjugular liver biopsy with hepatic hemodynamic measurements was performed, with a hepatic portal venous gradient at 7 mmHg (normal, 1-4 mmHg), the wedge pressure was 23 (normal, 4-13 mmHg) and the hepatic vein pressure was 16 mmHg (normal, 2-10 mmHg) - findings consistent with portal hypertension.

The patient declined reversal of JIB and did not wish evaluation for liver-kidney transplantation. He is currently being managed symptomatically by hospice care.

The complications of JIB are summarized in Table 2 above[4].

Table 2 Complications of jejunoileal bypass

Problem	Mechanism	Manifestations in this patient
Steatohepatitis Possible cirrhosis	Amino acid deficiency	Advanced liver disease with portal hypertension
Renal oxalosis	Excess oxalate absorption; Oxalate not bound by calcium	Multiple kidney stones and three previous lithotripsy interventions; Progressive kidney disease due to suspected oxalate nephropathy requiring lifelong hemodialysis
Fat soluble vitamin deficiency	Malabsorption; Steatorrhea	Serum levels: Vitamin A = 17 (360-200 mg/L) Vitamin D ⩽ 10 (22-67 pg/mL) Vitamin E = 3 (5.5-17.0 mg/L) Vitamin K ⩽ 0.03 (0.1-.2 ng/mL)
Gallstones	Bile acid loss; Mobilization of cholesterol	Previous cholecystectomy for symptomatic cholelithiasis
Enteritis	Bacterial overgrowth	30 years of diarrhea and steatorrhea Pneumatosis intestinalis
Arthritis	Bacterial toxin; Autoimmune	Bilateral knee and shoulder pain
Fatigue syndrome	Vitamin deficiency; Multifactorial	Marked fatigue, bed-ridden status
Bypass encephalopathy	Possible deficiency; Possible D-lactic acid deficiency	Slurred speech, incoordination and weakness
Bypass dermatitis	Possible antigen-antibody complex (enteric bacteria)	Cutaneous urticarial rash

CONCLUSION

Although jejunoileal bypass was effective and reliable, it was associated with severe complications such as renal failure (37%), diarrhea (29%) and consequent electrolyte imbalances, calcium oxalate nephrolithiasis (29%), liver disease (10%), fat-soluble vitamin deficiencies, malnutrition and death[5]. The most severe early complication of JIB was acute liver failure (7%)[5]. Our patient exhibited nearly all of the known metabolic complications described in the literature (Table 2).

Of the various types of bariatric procedures, JIB is particularly devastating because of its dramatic complications, and is no longer used for the management of morbid obesity. A number of studies[6-8] highlighted the high complication rates even after a decade and sometimes lifelong, difficulty maintaining satisfactory follow-up and the need for frequent revision surgery making it an unacceptable procedure performed remotely on any major scale.

Today, this procedure is a formidable diagnostic challenge because it was a surgery of the olden days (1960s and 1970s), old records may not be available and upper endoscopy may be essentially normal. Most patients have either died or had conversion to a different bariatric procedure. The importance lies in early identification based on clinical history, with prompt reversal and the recognition and treatment of the life-threatening metabolic consequences.

Abstract

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world. This case documents an unusual metastatic presentation of HCC in the humerus. Preoperative palliative arterial embolization of the tumor was performed to arrest severe tumor bleeding caused by the biopsy. Embolization turned out to be useful also in limiting/preventing potential uncontrolled bleeding during subsequent amputation.

Key words: Hepatocellular carcinoma; Humerus; Upper arm; Metastasis; Embolization

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world[1]. The most frequent sites of extrahepatic metastases of HCC are the lungs, lymph nodes, bones, and adrenal glands[2], whereas the extremities, and especially the humerus, are very rare metastatic sites. Here we report an interesting case of humerus metastasis of HCC with severe hemorrhage after biopsy.

CASE REPORT

A 74-year-old man with a background of alcoholism and smoking initially presented with pain on the right side of the chest. Clinical examination revealed mild hepatomegaly and pallor. An abdominal ultrasound showed the presence of a solid mass in the right lobe of the liver, measuring 5.2 cm × 6.5 cm, with heterogeneous echotexture (Figure 1A). Computed tomography (CT) imaging of the abdomen confirmed the presence of a lesion in segment Ⅷ of the liver, with central areas of necrosis (Figure 1B). An additional, smaller focal lesion was found also in segment Ⅶ of the liver (Figure 1C). Both lesions showed typical imaging characteristics of an HCC. Notably, a thrombosis of the portal vein was also present (Figure 1D), which presented a contraindication for chemoembolization of the HCC. The patient was discharged.

After 4 mo, the patient was referred again with progressive painful swelling of the left upper arm and superficial ulceration. An X-ray showed a destructive lesion of the left humerus, associated with a bulging soft tissue component (dimensions 5.5 cm × 4 cm). The diaphysis of the humerus was completely destroyed for a length of 4 cm (Figure 2A and B). Magnetic resonance imaging (MRI) clearly demonstrated a large osteolytic lesion (coronal dimensions 6.2 cm × 5 cm) in the left humerus space, with complete destruction of the bone (Figure 2C and D). The tumor reached the surface of the skin. A surgical biopsy was performed to sample tissue from the ulcerated mass. However, massive bleeding developed from the biopsy site immediately after excision. Because the hemorrhage could not be stopped by electrocauterization, it was decided to perform an arterial embolization on the assumption that possible HCC metastases would typically be hypervascularized. A 5 French cobra catheter was advanced from the femoral artery into the left axillary artery and a selective

A: Round but inhomogeneous tumor with hyper- and hypo-echoic appearance in the sonography (diameter 6 cm, arrow); B: Axial multidetector CT contrast image at the arterial phase demonstrated a tumor lesion in the right upper lobe (arrow). Dimension 7 cm × 6.5 cm × 60 cm with hyperdense periphery and hypodense centre (latter areas of necrosis); C: Additional 1.4 cm × 1 cm × 1 cm hyperintense lesion in segment Ⅶ of the liver (arrow); D: Partial thrombosis of the portal vein (arrow).

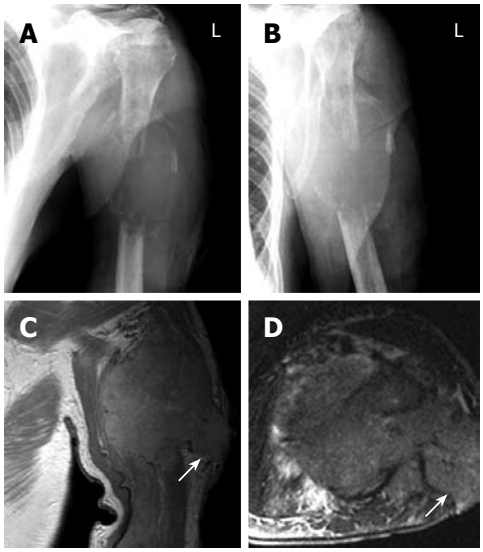

Figure 2 X-Ray (A, B) and MR imaging (C, D) of HCC metastasis at the humerus. A and B: Destructive lesion in the left humerus associated with a bulging soft tissue component, 5.5 cm × 4 cm in dimension; C: Coronal noncontrast PD-weighted (TR/TE, 1920/12) image demonstrating a soft tissue tumor (coronal dimension 6.2 cm × 5 cm) with complete destruction of the humerus, the tumor reached the surface with ulceration (arrow); D: Axial noncontrast TIRM sequences (TR/TE, 7400/92) show the edematous tumor in the centre of the extremity and the lateral tumor branch to the surface (arrow). In this region, a biopsy was taken which was followed by massive hemorrhage.

arteriogram was obtained. Injection of contrast medium showed a hypervascular, destructive tumor of the humerus (Figure 3A). Extravasation of the contrast medium indicated the presence of hemorrhage (Figure 3B). Afterwards, multiple accessible feeding branches were reached with superselective catheterization using a tracker catheter, and embolized with Bead Block (size 300-500 μm, Terumo Europe, Leuven, Belgium). Follow-up angiographies during embolization showed stasis of flow within the tumor. At

A: Catheter angiography of the axillary artery reveal a round hypervascular tumor; B: Selective angiography of a tumor feeding vessel as side of application of Bead Block (size 300-500 μm, Terumo Europe, Leuven, Belgium) for embolization; C: After embolization of main parts of the tumor, at this status no areas of bleeding detectable but small parts of the tumor still perfused; D: Final treatment with amputation of the left upper extremity.

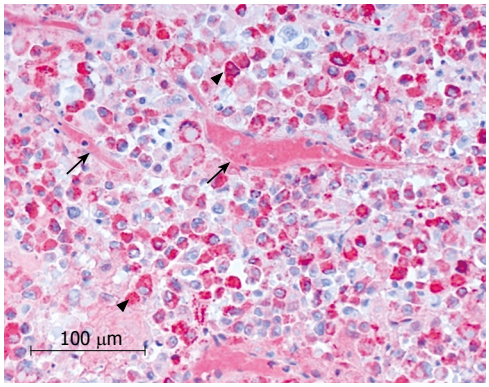

Figure 4 Neoplastic cells of HCC metastasis were diffusely stained by hepatocellular antigen (for instances, see arrowheads), destroyed bone areas within the tumor are visible (arrows).

the end, partial tumor embolization was achieved. The medial parts of the tumor remained perfused, since not all the small-sized branches of this region could be accessed or localized (Figure 3C). However, bleeding was successfully stopped. There were no postprocedural complications. On the following day, amputation of the left arm was deemed necessary since an alternative treatment, e.g. osteosynthetic stabilization of the destroyed humerus, was not achievable (Figure 3D). Thus, *a posteriori* the embolization proved useful also as a measure to prevent uncontrolled hemorrhages during amputation.

The histopathological evaluation of the biopsy confirmed the diagnosis of metastasis from the liver HCC (Figure 4).

DISCUSSION

This report describes an unusual case of massive metastasis of a HCC carcinoma to the upper arm, with partial

destruction of the humerus. To the best of our knowledge, no such cases have been reported in the literature to date. Also, while bone metastases of HCC usually manifest as multiple lesions, no other bone metastases were detected in this case.

The prognosis of HCC patients with extrahepatic metastasis is generally poor[3]. It is estimated that 30%-78% of HCC show metastases at autopsy[4]. HCC spreads mainly *via* the hematogenous route, causing intra- and extra-hepatic metastases that are generally hypervascular and, if located in the bone, osteolytic. Hypervascularity should be taken into account before biopsy excisions since the procedure can cause an uncontrolled hemorrhage, as reported here and by Chen *et al*[5] who described a life-threatening hemorrhage from a sternal metastasis of HCC. In the present case, the marked size of the tumor in the upper arm did not allow us to distinguish whether the metastasis had primarily localized in the muscle or in the bone. However, intramuscular HCC metastases are extremely rare[6,7], possibly because of the contractile action of muscle, its local pH environment, and/or the accumulation of lactic acid. Also, skeletal muscle produces tumor suppressors which may contribute to the rarity of metastases in the muscles[8]. A study with 194 autopsies of malignant tumors showed that macro- or micro-metastases of skeletal muscle were present only in 34 cases (17.5%)[9]. Metastases of HCC are clearly more frequent in the bone but, unlike the present humerus case, their most common sites are the vertebrae, the pelvis, and the ribs. In turn, bone metastases of HCC are commonly characterized by expansive soft tissue masses with bone destruction, as in the present case.

To date, only a few reports are available concerning arterial embolization of bleeding HCC metastases. This procedure can support treatment to reduce the tumor size[10] or to reduce the severity of the symptoms (e.g. pain or bleeding). Wallace *et al*[11] reported that patients with bone metastases who underwent embolization had a reduction of pain for 4-9 mo. In our case, the goal of embolization was to control the bleeding following biopsy excision. A posteriori, a benefit was also the containment/prevention of potential bleeding during amputation. Amputation became necessary because of the advanced tumor size and the degree of bone destruction.

In conclusion, this case documents an unusual metastatic presentation of HCC in the humerus. Preoperative palliative arterial embolization of the tumor was performed to arrest severe tumor bleeding caused by the biopsy. Embolization turned out to be useful also in limiting/preventing potential uncontrolled bleeding during subsequent amputation.

Abstract

Iatrogenic bile-duct injury post-laparoscopic cholecystectomy remains a major serious complication with unpredictable long-term results. We present a patient who underwent laparoscopic cholecystectomy for gallstones, in which the biliary injury was recognized intraoperatively. The surgical procedure was converted to an open one. The first surgeon repaired the injury over a T-tube without recognizing the anatomy and type of the biliary lesion, which led to an unusual biliary mal-repair. Immediately postoperatively, the abdominal drain brought a large amount of bile. A T-tube cholangiogram was performed. Despite the contrast medium leaking through the abdominal drain, the mal-repair was unrecognized. The patient was referred to our hospital for biliary leak. Ultrasound and cholangiography was repeated, which showed an unanatomical repair (right to left hepatic duct anastomosis over the T-tube), with evidence of contrast medium coming out through the abdominal drain. Eventually the patient was subjected to a definitive surgical treatment. The biliary continuity was re-established by a Roux-en-Y hepatico-jejunostomy, over transanastomotic external biliary stents. The patient is now doing well 4 years after the second surgical procedure. In reviewing the literature, we found a similar type of injury but we did not find a similar surgical mal-repair. We propose an algorithm for the treatment of early and late biliary injuries.

INTRODUCTION

Laparoscopic cholecystectomy (LC) has emerged as a gold standard of cholecystectomy and is the commonest laparoscopic surgical procedure performed by many surgeons worldwide. Unclear anatomy of the biliary tract and acute cholecystitis are associated with an elevated risk of bile duct injuries. These are serious surgical complications and are sometimes unrecognized during the procedure. A clear interpretation of the biliary anatomy as well as a good surgical experience are prerequisites for a definitive surgical repair. Primary surgical repair and further misinterpretation of the biliary anatomy with consequent mal-repair of the biliary tract injury are very unusual conditions. We present here a case of biliary tract injury that was recognized during LC but that was submitted to a mal-repair surgical procedure causing difficult problems of correct interpretation and management for the definitive surgical repair.

CASE REPORT

A 45-year-old woman was admitted to the referring hospital with symptomatic gallbladder stones for elective LC. She had not undergone any previous operations. Cholecystectomy was reported to be difficult by the operating surgeon. He reported that she had acute cholecystitis, and the biliary anatomy was not clear. During the operation he recognized that he caused a biliary injury, and for this reason he decided to convert

the intervention to open surgery. He completed the cholecystectomy, and performed a repair of the biliary injury over a T-tube, according to his interpretation of the injury. He did not perform a cholangiogram before the repair, but the post-repair intraoperative cholangiogram was interpreted as a good repair. An infra-hepatic drain was inserted. During the first postoperative day, the abdominal drain brought out 500 mL of bile and the T-tube drained 100 mL of a similar fluid. On the following days, the abdominal drain brought 800-1000 mL of bile daily and the T-tube brought 40-60 mL daily. During the next 2 wk, the output through the drains did not decrease, and the treating surgeon asked to transfer the patient to our hospital, with a diagnosis of biliary fistula. The referring surgeon had an average experience in laparoscopic surgery. Past medical history revealed a non-insulin-dependent diabetes mellitus on oral medication.

In our hospital, the patient appeared pale, mildly dehydrated, not jaundiced and with normal vital signs. She was in the average weight range. The abdominal examination revealed a right sub-costal scar, two scars from the trocars, and two drains (an abdominal drain and the other was a T-tube) that both contained bile. She did not look septic.

The laboratory results showed: hemoglobin 10 g/dL; white blood cell count 11 300/mm^3; K^+ 3.2 meq/L; Na^+ 132 meq/L. Liver enzymes and bilirubin were within the normal range.

Abdominal US showed normal liver size and echogenicity, without intra-hepatic biliary dilatation, a small sub-hepatic collection, and sub-hepatic multiple clips. The distal part of the biliary tree was not identified.

A T-tube cholangiogram (Figure 1) was done in our hospital, which showed a grade Ⅳ Bismuth injury, with the T-tube limbs within the left and right hepatic ducts. The biliary contrast medium appeared immediately through the abdominal drain, and the distal part of the biliary tree was not shown. These findings (mal-placed T-tube and fistula) suggested a plan for the definitive biliary surgical repair. We did not perform magnetic resonance cholangiography (MRC), because the patient already had a T-tube, and also she had a sub-hepatic collection.

Informed consent was obtained from the patient and her family. She was given a prophylactic third-generation cephalosporin, which was continued for 24 h postoperatively. She was shifted to insulin therapy from the day she was admitted to our hospital, which was continued until she returned to her normal diet, on postoperative day 7. The intraoperative finding was a Bismuth grade Ⅳ injury that was repaired by right and left hepatic duct end-to-end anastomosis over a T-tube, performed by the referring surgeon. During exploration, we found an absence of the biliary confluence and the common hepatic duct, which may have indicated a misinterpretation by the first surgeon of the common hepatic duct as the cystic duct, therefore, he excised this region altogether with the gallbladder. Multiple clips on the distal biliary tree (common bile duct) were found.

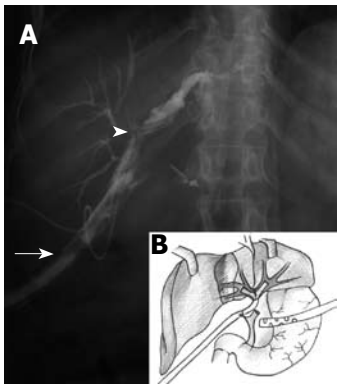

Figure 1 T-tube cholangiography. A: Postero-anterior T-tube cholangiogram showing biliary tract mal-repair (arrowhead indicates the T-tube, arrow indicates the tube drain); B: Schematic diagram of the cholangiogram.

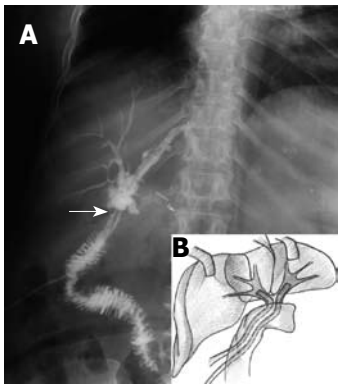

Figure 2 T-tube cholangiography. A: Postero-anterior view of the T-tube cholangiogram, which was done in our hospital, after the definitive surgical repair of the biliary tract injury (arrow: two intra-bilio-jejunal stents); B: Schematic diagram of the cholangiogram.

We also noted a bile leak from the posterior wall of the anastomosis that was performed previously over the T-tube. The T-tube was removed and a Roux-en-Y hepatico-jejunostomy over two trans-anastomotic stents was then performed (Figure 2). The patient had a good postoperative recovery without complications. The trans-stents' cholangiogram performed on postoperative day 10 showed patent anastomosis without leakage. The stents were closed and the patient was discharged. The tubes were removed after 2 mo. The patient was followed up by clinical examination, liver enzymes and abdominal ultrasound (US), every 3 mo for the first year, every 6 mo for the second year, and then every year thereafter. In her final follow-up visit in August 2008, she was in good condition, 4 years after our surgical repair. She did not have any wound complications, neither in the early nor in the late postoperative period.

DISCUSSION

Misinterpretation of biliary anatomy was the main cause of biliary mal-repair. The hard task was to understand this mal-repair carried out by the referring surgeon, and then to perform a definitive biliary repair. The only possible explanation was that the referring surgeon misinterpreted the left hepatic duct as the common bile duct. This was very hard to recognize from the first radiological study, performed in the referring hospital, in which the contrast medium spilled out into the abdominal drain, and it was interpreted incorrectly as the common bile duct. As a result of the poor quality of this radiological study, we performed another T-tube cholangiogram and discussed the case with our

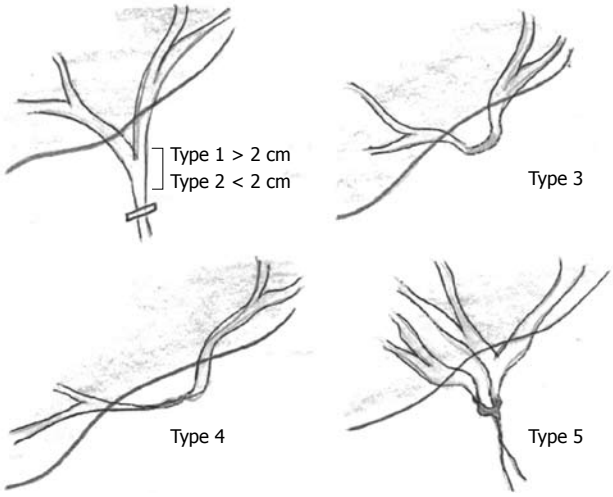

Figure 3 Bismuth classification of biliary injuries.

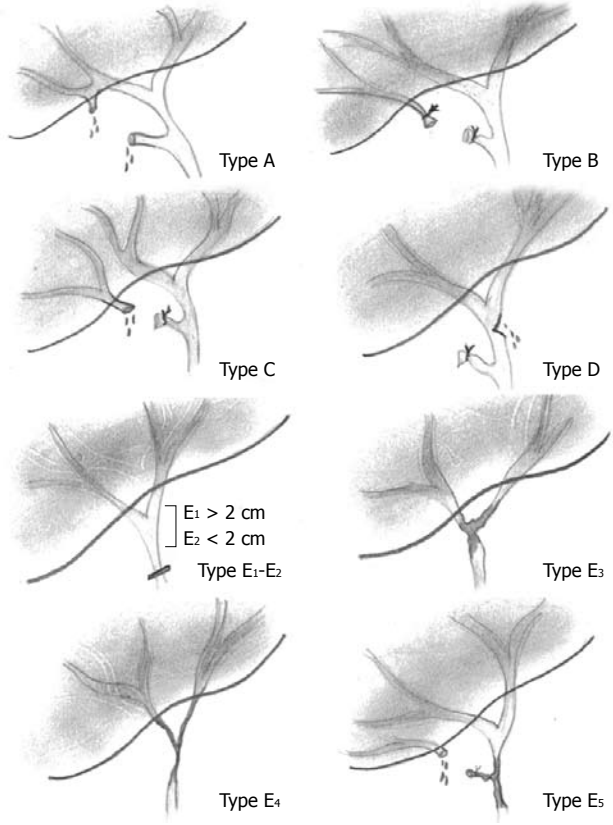

Figure 4 Strasberg classification of biliary injuries.

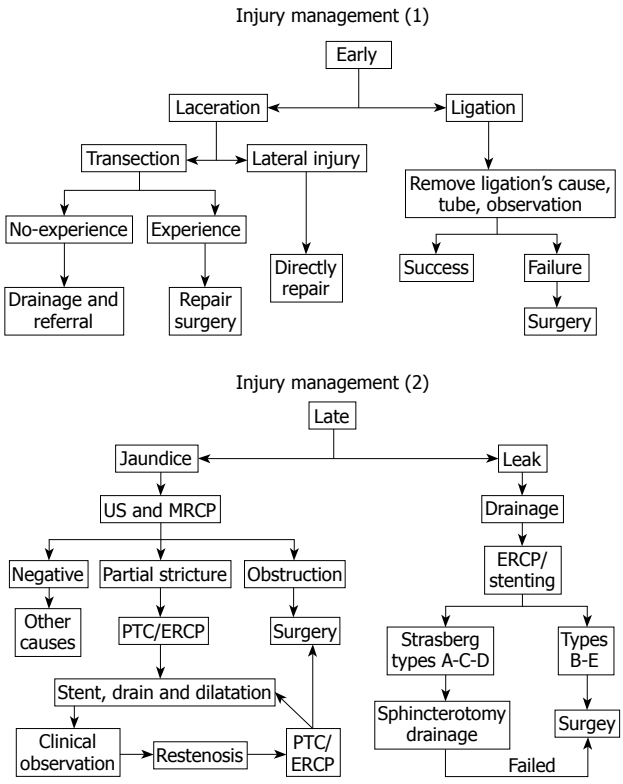

Figure 5 Our suggested flow chart for the management of early and late presentations of biliary injuries. PTC: Percutaneous transhepatic cholangiography; ERCP: Endoscopic retrograde cholangiopancreatography.

radiologist, who confirmed our suspicion of the mal-repair. Although this kind of injury is well known (Bismuth type Ⅳ), we could not find a similar case of mal-repair in the English literature.

The incidence of biliary tract injury ranges from 0.2% to 0.8% worldwide, and even an experienced surgeon can cause such injury[1-5]. There is more than one classification for biliary injury, but the most widely used for surgical purposes are the Bismuth and Strasberg classifications (the later includes the former).

Our patient presented with grade Ⅳ Bismuth or Strasberg E Ⅳ biliary injury, which required surgical treatment. Figures 3 and 4 show drafts for both Bismuth and Strasberg classifications[4,6,7].

The referring surgeon tried to repair the injury immediately during the first operation. The identification of injury during surgery is reported to be between 15% and 50% of cases. Although primary repair is possible, and can be done laparoscopically, it should only be performed by an experienced surgeon. If this is not the case, drainage and referral to an experienced surgeon is the rule[2,3,8-10]. Poor identification of the anatomical features of the hepatic triangle represents the commonest cause of injury[3]. Bismuth noted that the level of the stricture found during repair was one level higher than the level of injury identified during the first operation[7]. During the re-operation for failed repair, the level of stricture has been reported to be even higher[11].

In our case, we re-established the biliary continuity by a Roux-en-Y hepatico-jejunostomy, after trimming the previous biliary anastomosis, over two stents inserted into the right and left hepatic ducts. A postoperative tube cholangiogram is shown in Figure 4. Different methods of repair have been reported by different surgical teams[5,7,12]. Percutaneous and endoscopic retrograde cholangiopancreatography (ERCP) interventions can both be used in the management of biliary injuries, but under different conditions than ours[13]. We recommend, in cases that present with suspected stricture, to start with MRCP as the procedure of choice to identify the anatomy and the type of injury. In our specific case, the patient already had a drain in her biliary system, and she also had a biliary leak, therefore, it was appropriate to

use these drains for delineating the biliary anatomy by a tube cholangiogram.

We propose an algorithm (Figure 5) for the treatment of early and late biliary complications. We consider complications that appeared during the first month postoperatively as early (usually leaks), and those presenting after one month as late complications (usually strictures).

Bile duct injuries are serious surgical complications. A major study led by Cameron showed post-repair mortality of 1.7%, with a similar percentage of patients dying before repair, as a result of sepsis. The study of Cameron also showed a complication rate after repair of 42.9%, despite an early referral to a specialist center[12]. Long-term outcome after repair showed good results in > 90% of cases[8].

In conclusion, biliary tract injuries are sometimes difficult to recognize, even for experienced surgeons. In the absence of an experienced surgeon, it is mandatory to limit the surgical manipulation to simple drainage, and to refer the patient to a more specialized center, in order to give the best chance for definitive treatment.

Abstract

Schwannoma is a well-described, benign nerve sheath tumor of the soft tissue, but is rare in the gastrointestinal tract. Gastrointestinal schwannomas are often incidentally discovered as small polypoid intraluminal lesions. In this report, we describe the clinicopathologic and immunohistochemical features of a distinctive neural mucosal polyp composed of a diffuse cellular proliferation of uniform bland spindled cells in the lamina propria that entraps the colonic crypts. Immunohistochemical analysis revealed strong and diffuse positivity for the S-100 protein. To avoid confusion of these solitary colorectal polyps containing pure spindled Schwann cell proliferation in the lamina propria with neural lesions that have significant association with inherited syndromes, it is better to use the designation "mucosal Schwann hamartoma".

INTRODUCTION

Schwannoma is a common soft tissue tumor, but it appears to be rare among spindle cell mesenchymal tumors of the gastrointestinal tract[1-4]. Colorectal schwannomas are uncommon, and are incidentally discovered as small polypoid intraluminal lesions, often with mucosal ulceration, during colonoscopy screening. Gastrointestinal schwannomas have characteristic histological features that are different from their soft tissue counterparts, such as the presence of a reactive lymphoid peripheral cuff, the absence of encapsulation and degenerative changes[5-7]. The tumors are mainly situated in the muscularis propria of the digestive wall. Rectal bleeding, colonic obstruction, and abdominal pain are the most common presenting symptoms. The separation of GI stromal tumors (GISTs) from gastrointestinal schwannoma is clinically important because the former group have a high risk of malignant behaviour[8-11], while the second are benign. Recently the designation "mucosal Schwann cell hamartoma" has been proposed for lesions containing diffuse pure Schwann cell proliferation in the lamina propria, which entrap adjacent crypts, to avoid confusion with the neural lesions that are associated with inherited syndromes such as von Recklinghausen's neurofibromatosis[12]. In this study, we report a case of a colorectal polyp comprising diffuse Schwann cell proliferation in the lamina propria that belongs to the entity proposed.

CASE REPORT

Clinical presentation

A 60-year-old woman with no personal history of malignancy underwent a colonoscopy during the workup of occult blood in the stool. She had no family history of colon cancer and no history of familiar adenomatous polyposis, multiple endocrine neoplasia type Ⅱb, neurofibromatosis type Ⅰ, or Cowden syndrome.

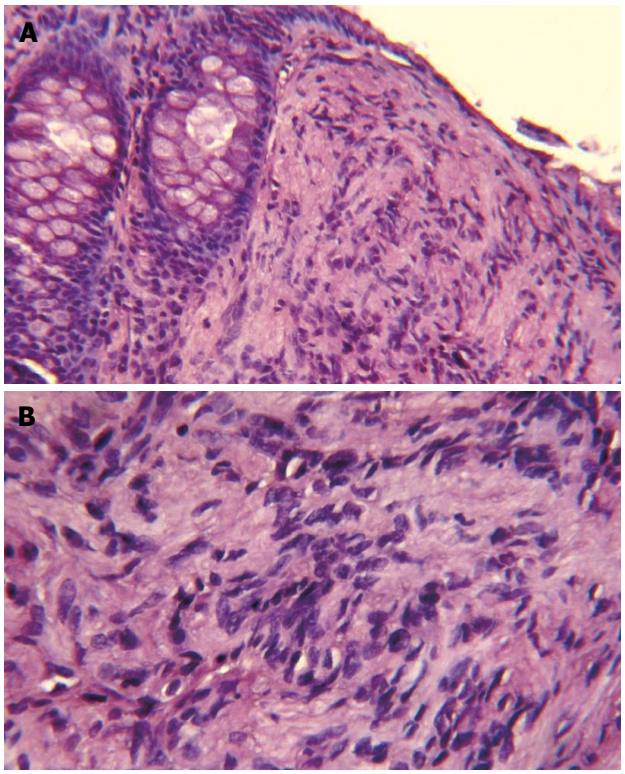

Figure 1 Histological features of the lesion. Low- (A) and high (B)-power magnification of haematoxylin and eosin stained tissue sections of colorectal mucosa. A diffuse, Schwann cell proliferation in the lamina propria, which entraps colonic crypts is visible. Cytologically, the lesions are composed of uniform bland spindle cells with elongated nuclei, dense eosinophilic cytoplasm, and minimal intervening stroma with vague Verocay bodies.

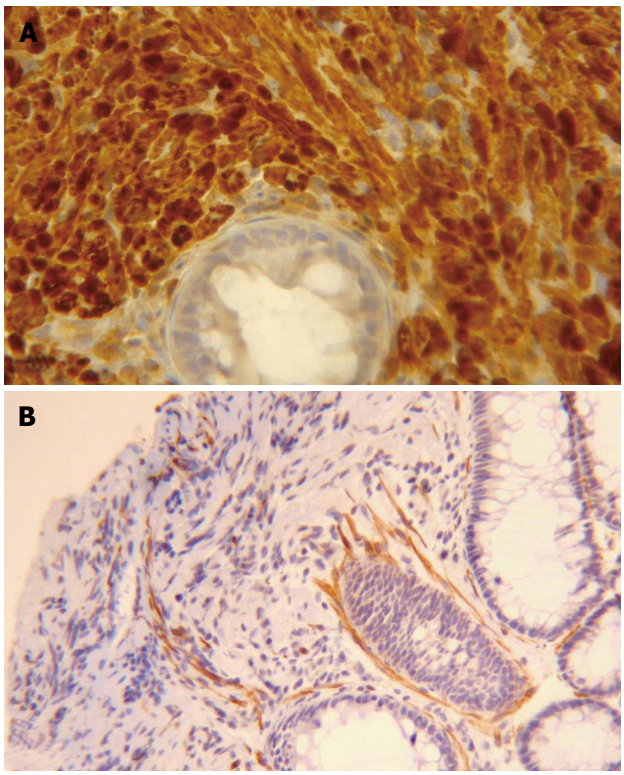

Figure 2 Immunohistochemical staining. The lesion consists of a pure population of Schwann cells, as shown by the diffuse immunoreactivity for the S-100 protein (A). Only scattered myoepithelial cells and vascular structures were highlighted by the immunostaining for α-smooth muscle actin (B).

Endoscopic and microscopic findings

Endoscopic examination showed a small sessile polyp of 0.5 cm in diameter without mucosal ulceration in the rectosigmoid colon. A biopsy was obtained. Hematoxylin and Eosin stained histologic sections showed a diffuse cellular proliferation of uniform spindle cells with elongated, tapering nuclei, and indistinct cell borders, arranged in whorls and vague Verocay bodies, entrapping adjacent crypts (Figure 1). The epicenter of the lesion was located in the lamina propria without involvement of the muscularis mucosae. No nuclear atypia, pleomorphia, or mitoses were seen. The immunohistochemical analysis demonstrated that all the cells were extensively and strongly positive for the S-100 protein (Figure 2A). Cells were negative for CD117 (KIT), α-smooth muscle actin (1A4) (Figure 2B), and CD34 (QBEND/10). Scattered mild chronic inflammation with the rare appearance of mast cells was present in the background.

DISCUSSION

Schwannoma (or neurilemoma) is an encapsulated nerve sheath tumour, common in the soft tissue. In the gastrointestinal tract schwannomas are rare and non-encapsulated, although well circumscribed[3]. They may appear as a small intramucosal nodular lesion, polypoid lesions, or poorly demarcated transmural proliferations[13]. According to the reports of Hou *et al*[7] and Daimaru *et al*[1] schwannomas were more frequently found in the stomach than in the colon or rectum. Miettinen and colleagues[3] and Lewin and colleagues[14], have described and characterized the largest series of colorectal schwannomas. Spindle cells variants have been found to be the most frequent, but epithelioid and plexiform schwannomas have also been described.

Herein we described a case of colorectal polyp in a female patient discovered during colonoscopy for the workup of occult blood in the stool. Histological examination of the polyp revealed a poorly circumscribed proliferation of uniform bland spindle cells, arranged in whorls and with a poorly formed area suggestive of Verocay bodies. The epicenter of the lesion was in the lamina propria, without involvement of the muscularis mucosae. Cellular spindle cell proliferation was interspersed between colonic crypts. No peripheral lymphoid aggregates, nuclear atypia nor mitosis were seen. The proliferated cells were strongly S-100 positive, and CD117, α-smooth muscle actin and CD34 negative, corresponding to the Schwann cell phenotype.

Mucosal neural polyps with similar features to our case have been recently described by Gibson *et al*[12], and we agree with author's proposal of the new and interim designation of "mucosal Schwann cell hamartoma" for this lesion, to avoid confusion with the gastrointestinal neural lesions that have significant associations with inherited syndromes[15-17]. Our case should not be considered as an intramucosal schwannoma, although qualitatively composed exclusively of Schwann cells, because

it presents peculiar histological features: the lack of circumscription, the absence of a peripheral lymphoid cuff[5], and crypt entrapment. Solitary ganglioneuromas and perineuriomas might predominantly involve the mucosa but the population of ganglion cells and the positivity for epithelial membrane antigen (EMA) are distinctive features. In contrast to neurofibromas, the polyp evaluated in our study was cytologically uniform, and, based on diffuse immunoreactivity for S-100 protein, seems to be composed essentially of a pure population of Schwann cells. Moreover, CD34 and neurofilament are useful stains for the differential diagnosis, because neurofibromas typically demonstrate a significant subpopulation of CD34-positive stromal cells and scattered axons.

Leiomyomas might also be encountered arising in association with the muscularis mucosae of the colon. They express desmin, calponin, and caldesmon but lack S-100 protein[14].

It is important in the GI tract to recognize GI stromal tumors (GISTs), which might pursue a malignant course. GISTs might have neural differentiation but they are typically reactive with c-kit/CD117 antibodies, and originate from or differentiate into the interstitial cells of Cajal with activating mutations in the KIT24-27 and PDGFRa genes[7-10].

In conclusion, the lesion we have encountered should be categorized as a mucosal Schwann cell hamartoma. Accurate histological differential diagnosis of this kind of lesion has clinical relevance, not only for immediate patient management, but also because it might provide the first clue to the existence of inherited tumor syndromes (searching for ganglion cells), which will have broader implications for the patient's family and potentially important consequences for genetic counselling.

Abstract

Fibrosing cholestatic hepatitis (FCH) is a variant of viral hepatitis reported in hepatitis B virus or hepatitis C virus infected liver, renal or bone transplantation recipients and in leukemia and lymphoma patients after conventional cytotoxic chemotherapy. FCH constitutes a well-described form of fulminant hepatitis having extensive fibrosis and severe cholestasis as its most characteristic pathological findings. Here, we report a case of a 49-year-old patient diagnosed with small-cell lung cancer who developed this condition following conventional chemotherapy-induced immunosuppression. This is the first reported case in the literature of FCH after conventional chemotherapy for a solid tumor. In addition to a detailed report of the case, a physiopathological examination of this potentially life-threatening condition and its treatment options are discussed.

INTRODUCTION

Hepatitis B virus (HBV) is a well-known pathogen which can cause fulminant hepatitis in some patients undergoing cytotoxic chemotherapy. Patients who have completely recovered from acute hepatitis can harbor a latent HBV infection for decades[1].

Fibrosing cholestatic hepatitis (FCH) is a recognized unique variant of viral hepatitis which was originally reported in 1991 by Davies *et al*[2] in HBV-infected recipients of liver allografts. Other authors have also reported FCH cases in HCV-infected recipients after liver transplantation[3] and in renal[4], cardiac[5] or bone marrow transplanted patients[6] as well as in patients with acquired immunodeficiency syndrome[7]. FCH has additionally been reported secondary to hepatitis C allograft reinfection[8].

However, to our knowledge only 3 cases of FCH have been reported after conventional cytotoxic chemotherapy. Nonetheless, all of them were diagnosed with non-solid tumors (acute myelogenous leukemia[9], acute lymphoblastic leukemia[10] and low grade non-Hodgkin's lymphoma[11]). FCH is associated with extremely high mortality[12].

We report a case of a patient diagnosed with small-cell lung cancer who developed FCH under chemotherapy-induced immunosuppression.

CASE REPORT

This is a case of a 49-year-old male with a 38 pack-year smoking history and a past medical history of hepatitis B. He had not received previous blood transfusions. At the time of admission, the patient presented with pain in the right hemithorax. Initial investigations included thoracic X-ray, thoracic computed tomography (CT) and positron emission tomography (PET)-CT imaging demonstrating right pleural effusion, right upper lobe

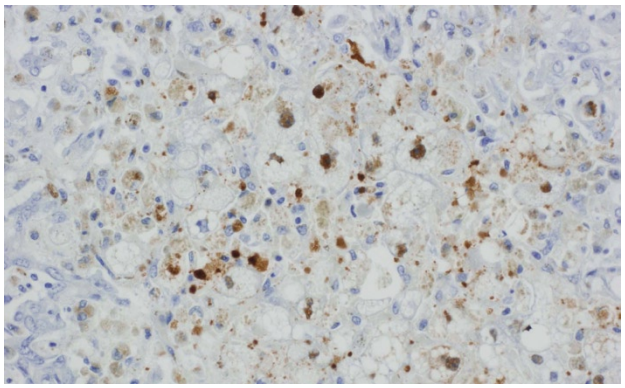

Figure 1 Liver necropsy stained with antibody against hepatitis B core antigen. FCH is also characterized by massive expression of hepatitis B core antigen (nuclear and cytoplasmic).

atelectasia, mediastinal adenopathies and liver and bone metastases. After a bronchoscopy-guided biopsy, he was diagnosed with extensive-disease small-cell lung cancer. The patient accepted chemotherapy and a combination regimen of cyclophosphamide 400 mg/m^2 (days 1-3), adriamycin 40 mg/m^2 (day 1), cisplatin 100 mg/m^2 (day 2), vincristine 2 mg (day 3) and etoposide 100 mg/m^2 (days 1-3) was administered. After the first cycle, the patient presented with grade Ⅳ febrile neutropenia in spite of pegfilgrastim prophylaxis. For this reason, a 20% dose reduction was applied on the second cycle. Doses were escalated to the original levels in the third cycle, during which the patient presented with elevation of glutamic oxalacetic transaminase (GOT) (232 UI/mL) and glutamic pyruvic transaminase (GPT) (639 UI/mL).

Following the third cycle, a PET-CT scan showed a radiological complete response. In contrast, the patient showed persistent elevation of transaminases (GOT: 198 UI/mL; GPT: 400 UI/mL).

After administration of the fourth cycle, he developed grade 4 thrombocytopenia and neutropenia. A complete serological study was performed demonstrating hepatitis B reactivation (HBsAg, HBeAb and HBcAb IgG positive). Despite treatment with the nucleoside analogue entecavir and methylprednisolone, the hepatitis progressed towards acute hepatic failure (GOT: 1879 UI/mL; GPT: 2663 UI/mL; total bilirubin: 42 mg/dL; direct bilirubin: 37 mg/dL; indirect bilirubin: 5 mg/dL; prothrombin time: 10%). A liver biopsy was not performed, due to thrombocytopenia and clotting time elevation.

The patient was transferred to the Intensive Care Unit and received plasma exchange, vasoactive drugs and wide spectrum antibiotics (piperacillin-tazobactam). In spite of these therapies, he died a month after the last chemotherapy cycle from acute liver failure.

The autopsy showed residual tumor in the mediastinum and peribronchial nodes, a hepatic reaction and fibrosing cholestatic hepatitis. The microscopic study revealed marked hepatocyte degeneration, whereas the immunohistochemical analysis demonstrated hepatocytes diffusely stained for HBsAg following both intracytoplasmic and cytoplasmic membranous patterns and nuclear and intracytoplasmic HBcAg staining patterns (Figure 1). Serum levels of HBV DNA polymerase were 17 857 100 UI/mL.

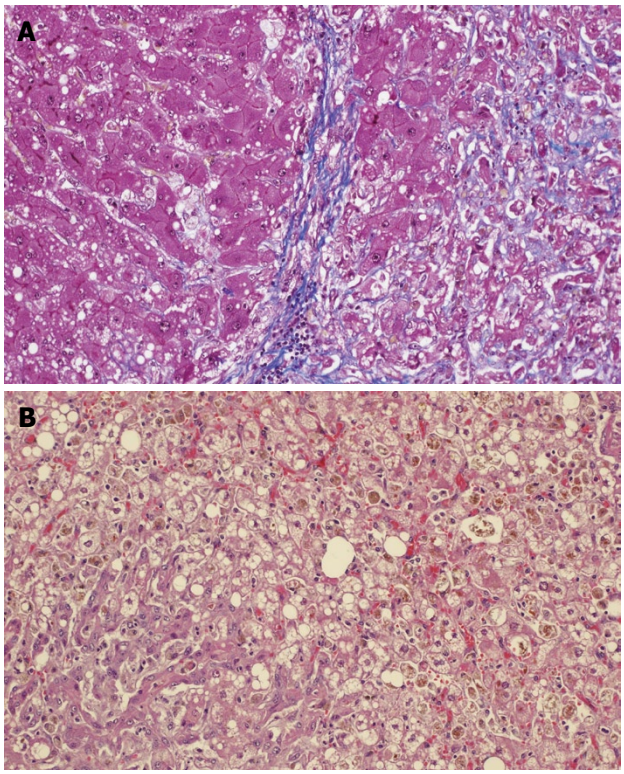

Figure 2 Liver necropsy. A: Stained with Mason trichromic; B: Stained with eosin-hematoxylin. FCH is characterized by marked hepatocellular swelling, lobular disarray and cholestasis, with only mild or no portal or lobular inflammation, combined with acute cholangiolitis and fibrosis surrounding the cholangioles.

DISCUSSION

To our knowledge, this is the first reported case of FCH after conventional cytotoxic chemotherapy treatment in a patient diagnosed with a solid tumor. There have only been 3 case reports published of FCH patients who had received conventional chemotherapy for hematological malignancies. FCH is a subtype of viral hepatitis in HVB-infected patients which is associated with extremely high mortality.

Degeneration of hepatocytes with minimal infiltration of inflammatory cells (which is clearly distinguishable from other fulminant hepatitis), extensive fibrosis and severe cholestasis are the most characteristic pathological findings. Liver parenchymatous changes include hepatocyte swelling and cholestasis with marked ductular reaction[13] (Figure 2A and B).

Although the ultimate physiopathological mechanism in this condition remains elusive[14], the extremely high levels of viral replication, the massive HBcAg and HBsAg expression in the liver and the non-significant inflammatory component suggest a direct HBV cytopathologic effect. The accumulation of viral antigens in the endoplasmic reticulum damages vital cell functions leading to cell death[13]. Although specific treatment protocols are lacking, a few case reports

have described a clinical benefit after administration of ganciclovir/foscarnet antiviral therapy[15] in these patients. Additionally, other reports describe the efficacy of lamivudine, a nucleoside analog reverse transcriptase inhibitor, in the treatment of chronic hepatitis[12] and in prophylaxis of chronic hepatitis and FCH[16]. Moreover, lamivudine has been recommended by some authors for the prophylaxis of HBV hepatitis in carrier subjects undergoing cytotoxic chemotherapy for lymphoid malignancies[17], although no data from clinical trials are available.

This case report suggests that viral analysis might be indicated in patients presenting with solid tumors before initiating intensive chemotherapy regimens. In addition, prophylactic lamivudine should be considered in HVB chronic infection carrier patients (HBsAg positive and/or HBcAb IgG positive) in this setting.

Abstract

Crohn's disease (CD) is a chronic relapsing and remitting autoinflammatory disorder of the gastrointestinal tract that has many intestinal and extraintestinal complications. The purpose of treatment is long-term remission, reduction of complications, and improvement of patients' quality of life. In many cases, this can be quite challenging and it is necessary to have a well thought out management strategy. We present the case of a 38-year-old woman with fistulizing CD that manifested as diffuse abdominal pain and bloody diarrhea accompanied by arthralgia. In addition, there were ulcerative lesions surrounded by cutaneous inflammation and erythema on her extremities, indicative of pyoderma gangrenosum. The patient was treated with high doses of parenteral methylprednisolone without any improvement and was started on adalimumab. A positive response to adalimumab therapy was observed: after 2 mo of therapy, the ulcerative skin lesion healed completely and the enterogastric fistula was closed after 5 mo adalimumab treatment. Adalimumab might be a suitable initial as well as maintenance therapy in patients with complicated CD.

INTRODUCTION

Crohn's disease (CD) is characterized by fissuring ulcers and segmental transmural inflammation of the gastrointestinal tract. The ileum is frequently involved in chronic inflammatory diseases; however, these can occur in any part of the digestive tract, from mouth to anus. Fistulas are the major and most common complications of the disease. The cumulative risk of any kind of fistula is 33% after 10 years and 50% after 20 years from the first appearance of the disease, as exemplified by a population-based study[1]. Although CD predominantly affects the gastrointestinal system, it is also associated with several extraintestinal manifestations. The most common extraintestinal disorders associated with inflammatory bowel disease (IBD) include dermatologic, ophthalmologic, musculoskeletal and hepatobiliary diseases; however, practically every organ system could be involved. These extraintestinal disorders can significantly contribute to morbidity and consequently impair the overall life quality of the patient considerably more than bowel-related symptoms.

Treatment is very complex and includes antibiotics and various immunomodulators. Surgery may be needed for therapy-refractory cases. The increasing number of advanced biological treatments for IBD offers new possibilities for the management of IBD associated with extraintestinal manifestations[2].

We report a case of successful adalimumab usage for CD complicated by enterocutaneous fistula, which also constituted an effective alternative treatment for pyoderma gangrenosum.

CASE REPORT

A 38-year-old woman presented with a 20-year history of CD, numerous complications and frequent relapses. Previously she had undergone several corrective gastrointestinal surgeries for perirectal fistulas. She carried a stoma since 1997 following left hemicolectomy and Hartmann's procedure. She continued to receive maintenance 5-aminosalycilate (mesalamine) and budesonide therapy. Corticosteroid therapy and combined antibiotic/antimycotic treatment were used intermittently for increased disease activity resulting in moderate clinical response. The patient was unable to tolerate azathioprine.

In February 2004, she developed erythema nodosum on her extremities, which was resolved by corticosteroid-antibiotic treatment. The patient was referred to our department for further examination and management in November 2004, when she developed asymmetric oligoarthritis that responded well to treatment with a corticosteroid and maintenance methotrexate, resulting in remission for 6 mo. In 2005, the patient was treated with intravenous pulse cyclophosphamide for moderate to severe disease activity as a rescue therapy.

The patient remained in remission for 6 mo. In January 2007, she was admitted to our hospital again because of increased weakness, mild ulcerative skin lesions, and abdominal pain with bloody diarrhea. Additionally, she had arthralgia but no fever. Her blood tests showed a white cell count of 8.97×10^9 cells/L, a platelet count of 289×10^9 cells/L, a C reactive protein level of 68.57 mg/L, a hematocrit of 36 and an increased erythrocyte sedimentation rate (64 mm/h). Immunologic evaluation did not show B-cell/immunoglobulin disorders or antibody positivity. Upon physical examination, she had some small, red papules on her extremities with ulcerations on their surface that were characterized by pyoderma gangrenosum (Figure 1). In addition, we also found diffuse abdominal tenderness and an abdominal mass located in the periumbilical region. Her urine and chest X-rays were normal. Abdominal computed tomography (CT) showed a moderately enlarged spleen as well as thickened and inflamed bowel walls that are characteristic of CD (Figure 2). The inflamed bowels were surrounded by fat stranding, and CT also showed multiple enterocolic fistulas. Upper endoscopic examination revealed an enterogastric fistula from the corpus of the stomach to the stoma. Surgical correction was not an option because the patient did not agree to surgery. The patient received infliximab (Remicade; Schering-Plough) therapy as well as maintenance methotrexate therapy but there was no significant improvement in her symptoms and in her test results.

Following a failed course of infliximab (because of lack of response), adalimumab (Humira; Abbott Laboratories) was proposed as an alternative treatment. Adalimumab was administered subcutaneously at a dose of 80 mg/wk for the first 2 wk followed by 40 mg/wk afterwards. In addition, the patient was treated for a limited period with high doses of parenteral methylprednisolone and a combined antibiotic treatment. After 2 mo of therapy, the skin ulcers were completely healed. Subjective clinical improvement could be seen after 3 mo of therapy. The patient did not experience any adverse effects. After 5 mo of therapy contrast radiography of the bowel passage showed significant improvement. A 3-4 cm long, narrow and blind fistula originating from the stomach could be seen but it was not connected to the bowel. Nevertheless, the duodenum and jejunum were moderately inflamed and the terminal ileum was intact without inflammatory signs.

Figure 1 Small, red papules on the extremities with ulcerations.

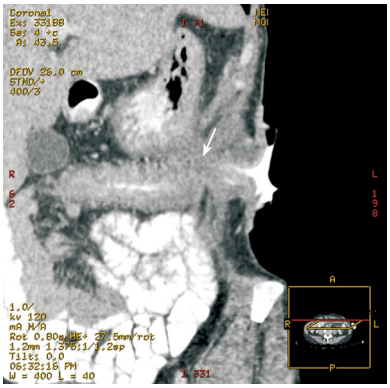

Figure 2 Enterogastric fistula from the corpus of the stomach to stoma on abdominal computed tomography (white arrow).

DISCUSSION

Up until now the use of adalimumab for fistulizing CD with extraintestinal manifestations has been reported in only a few cases. We reported a case of a woman with CD complicated by fistulas and pyoderma gangrenosum. The patient was successfully treated with adalimumab.

Extraintestinal manifestations of IBD can be diagnosed before, simultaneously with, or after the diagnosis of IBD is made. These symptoms occur in 21%-36% of IBD cases. It is important to distinguish complications of IBD from secondary diseases as they demand different and specialized therapies. The recognition of symptoms can be difficult since these extraintestinal symptoms can also be the primary manifestations of IBD[3,4].

The connection between different extraintestinal symptoms and IBD is unclear. The shared and unique epitopes in the human colon, eye, joint and biliary epithelium may suggest an immune mediated process.

Pyoderma gangrenosum is one of these inflamma-

tory cutaneous manifestations and it is independent of disease activity. This ulcerative cutaneous condition can either be associated with systemic inflammatory diseases (in at least 50% of cases) or it can occur alone. The diagnosis is made by excluding other causes of cutaneous ulcerations that are similar in appearance, including infection, malignancy, vasculitis, collagen vascular diseases, diabetes, and trauma. Treatment is relatively difficult. Currently, systemic immunosuppressants, often prednisone, are the mainstay of therapy. Long-term therapy with these agents is often required and can expose patients to possible adverse effects.

The treatment of IBD with extraintestinal manifestation has advanced in parallel to our increasing understanding of its pathomechanism[5-9]. One of the most well recognized proinflammatory mediators involved in the pathogenesis of IBD is tumor necrosis factor α (TNF-α). It is known that high levels of TNF-α have been associated with the development of intestinal inflammation in CD. The current evidence suggests that TNF-α blocking agents such as infliximab, adalimumab, and certolizumab pegol are effective maintenance therapy in CD. TNF-α blocking agents bind with TNF-α molecules thereby neutralizing the biological activity of TNF-α, resulting in the reduction of intestinal inflammation.

On other hand, treatment strategies for fistulizing CD are usually controversial. External fistulas are more responsive to medical therapy than internal fistulas in patients with CD. Combined treatment with antibiotics and immunomodulators may be a suitable initial therapy for CD patients with external fistulas. TNF-α blocking agents can also be used as an additional therapy in the treatment of corticosteroid dependent, refractory cases or in complicated extraintestinal manifestations[10].

This case report demonstrates the potential efficacy of adalimumab in the management of complicated fistulizing CD and/or pyoderma gangrenosum. Further studies into the use of adalimumab in this patient subgroup with CD are warranted.

Abstract

We describe a 15-mm scirrhous hepatocellular carcinoma (HCC) in a 60-year-old man with B-type cirrhosis. Ultrasound disclosed a 15-mm hypoechoic nodule in segment 7. Contrast-enhanced US revealed heterogeneous, not diffuse, hypervascularity in the early phase and a defect in the Kupffer phase. Contrast-enhanced computed tomography (CT) revealed a heterogeneous hypervascular nodule in the early phase and a low-density area in the late phase. Magnetic resonance imaging (MRI) revealed iso- to hypointensity at T1 and high intensity at T2-weighted sequences. Contrast-enhanced MRI also revealed a heterogeneous hypervascular nodule in the early phase and washout in the late phase. Super-paramagnetic iron oxide-MRI revealed a hyperintense nodule. CT during hepatic arteriography and CT during arterial portography revealed heterogeneous hyperattenuation and a perfusion defect, respectively. Based on these imaging findings the nodule was diagnosed as a mixed well-differentiated and moderately-differentiated HCC. Histologically, the nodule was moderately-differentiated HCC characterized by typical cytological and structural atypia with dense fibrosis. Immunohistochemically, the nodule was positive for heterochromatin protein 1 and alpha-smooth muscle actin, and negative for cytokeratin 19. From the above findings, the nodule was diagnosed as scirrhous HCC. Clinicians engaged in hepatology should exercise caution with suspected scirrhous HCC when imaging studies reveal atypical findings, as shown in our case on the basis of chronic liver disease.

INTRODUCTION

According to World Health Organization (WHO) classifications, hepatocellular carcinoma (HCC) with diffuse fibrosis is subclassified as scirrhous-type HCC (SHCC)[1]. Histologically, it is characterized by diffuse fibrosis along the sinusoid-like blood spaces with varying degrees of atrophy of tumor trabeculae. Preoperative images by computed tomography (CT) and magnetic resonance imaging (MRI) are, however,

often misdiagnosed as those of cholangiolocellular carcinoma (CCC), HCC-CCC, and metastatic carcinoma due to heterogeneous enhancement in the early phase and prolonged enhancement in the late phase attributed to abundant fibrous stroma. Moreover, imaging studies for the diagnosis of SHCC, such as contrast-enhanced ultrasound (US), CT during hepatic arteriography (CTA) and CT during arterial portography (CTAP) have so far not been described. Here, we present a case of moderately differentiated SHCC that histologically manifested as typical cytological and structural atypia with dense fibrosis, whereas imaging studies with contrast-enhanced CT, MRI, US, CTA and CTAP revealed a mixed well-differentiated and moderately-differentiated HCC.

CASE REPORT

A 60-year-old man with B-type liver cirrhosis was admitted in November 2007 for further examination of a 15-mm hypoechoic nodule in segment seven (S7). The patient had no history of alcohol, blood transfusion or drug abuse. On admission, physical examination showed no remarkable abnormalities. Hepatitis B virus was positive for surface antigen and for envelope antibody, and negative for envelope antigen (HBeAg). The amount of HBV deoxyribonucleic acid was less than 2.6 log copy/mL. Laboratory studies disclosed the following abnormal values: platelets $5.3 \times 10^4/\mu L$ (normal, 14-34), aspartate aminotransferase 44 IU/L (0-38), alkaline phosphokinase 864 IU/L (115-359), thymol turbidity 7.7 U (0-4), zinc sulfate turbidity test 14.8 U (2-12), and γ-globulin 29.3 g/dL (10.6-20.5). The levels of tumor markers were as follows: alpha-fetoprotein (AFP) 3.8 ng/mL (< 10), protein induced by vitamin K absence 71 mAU/mL (0-40), CA19-9 39.4 U/mL (0-37), and CEA 4.78 ng/mL (0-5).

US disclosed a 15-mm hypoechoic nodule in S7. Contrast-enhanced CT revealed a heterogeneous, not diffuse, hypervascular nodule in the early phase and a low-density area in the late phase (Figure 1A and B). MRI revealed iso- to hypointensity at T1 and high intensity at T2-weighted sequences. Contrast-enhanced MRI revealed a heterogeneous hypervascular nodule in the early phase and washout in the late phase (Figure 2A and B). Super-paramagnetic iron oxide-MRI revealed a hyperintense nodule. Contrast-enhanced US revealed heterogeneous hypervascularity in the early phase and a defect in the Kupffer phase (Figure 3A and B). CTA and CTAP revealed heterogeneous hyperattenuation and a perfusion defect, respectively (Figure 4). Based on these imaging findings, the nodule was diagnosed as a mixed well-differentiated and moderately differentiated HCC. Histologically, the nodule was moderately-differentiated HCC characterized by typical cytological and structural atypia with dense fibrosis (Figure 5A and B). Immunohistochemically, the nodule was positive for heterochromatin protein 1 and alpha-smooth muscle actin (α-SMA) (Figure 5C and D), and negative for cytokeratin 19 (CK19). From the above findings, the nodule was diagnosed as SHCC. We conducted radiofrequency ablation for the SHCC and the nodule was completely ablated. Local recurrence has not been observed over a period of 15 mo.

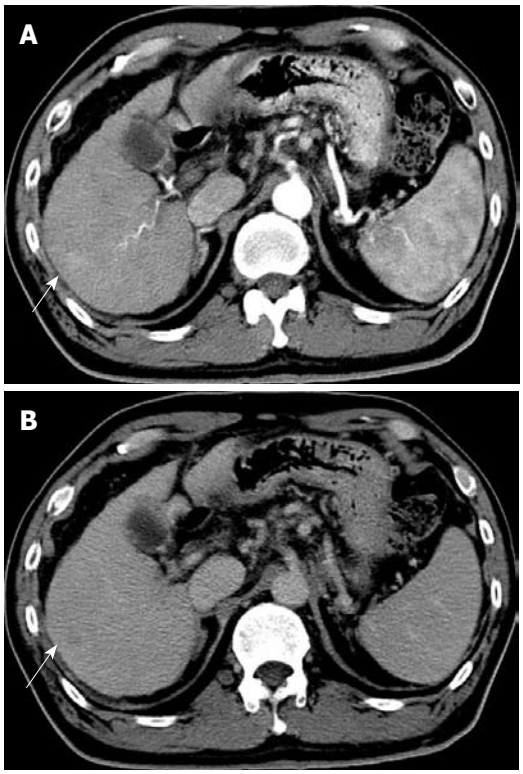

Figure 1 Contrast-enhanced CT. Heterogeneous, not diffuse, hypervascular nodule in the early phase (A) (arrow), and a low-density area in the late phase (B) (arrow).

DISCUSSION

The clinical background of SHCC is not significantly different from that of non-SHCC with regard to age, gender, positive rates to hepatitis viruses, AFP levels, Child-Pugh classification, and the stage of tumor-node-metastasis. In both morbidities, over 60% of cases are associated with chronic hepatitis rather than with liver cirrhosis. HCC patients with liver cirrhosis and liver dysfunction tend not to undergo surgery. In our case, resection was not carried out because of poor liver function attributed to liver cirrhosis.

With no clear pathological definition of SHCC, in particular a standard for the degree of the fibrosis for diagnosing the disease, its rate varies between 0.2% and 4.2%[2,3]. Regarding terminology, SHCC is often confused with "sclerosing hepatic carcinoma" that is used to designate a variety of tumors with sclerotic change and hypercalcemia arising in non-cirrhotic livers[4]. Sclerosing hepatic carcinoma does not, however, constitute a distinct histopathological entity; some of these tumors appear to be HCC, others CCC. Therefore, sclerosing hepatic carcinoma has been deleted from the WHO classification[1]. Kurogi *et al*[5] have defined SHCC as a tumor with diffuse fibrous changes in almost the entire area of the largest cross-section of the tumor and a mean fibrotic area of 39% compared with only 4.6%

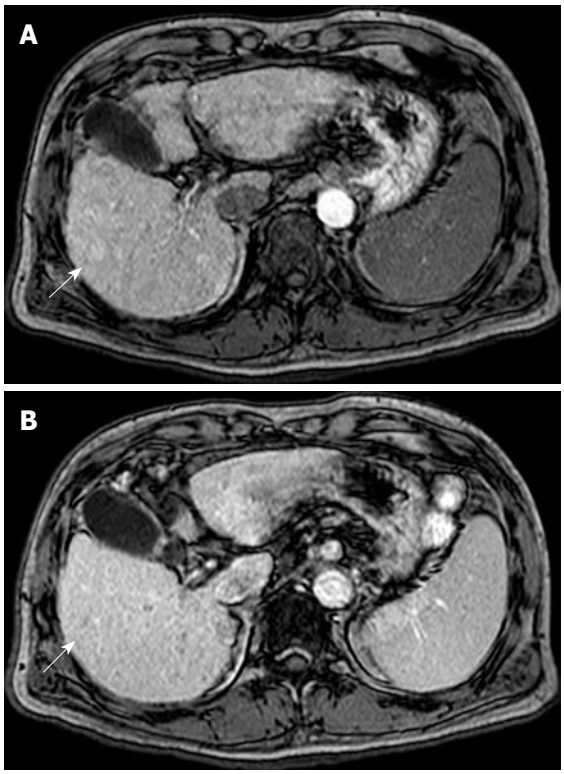

Figure 2 Contrast-enhanced MRI. A heterogeneous hypervascular nodule in the early phase (A) (arrow), and washout in the late phase (B) (arrow).

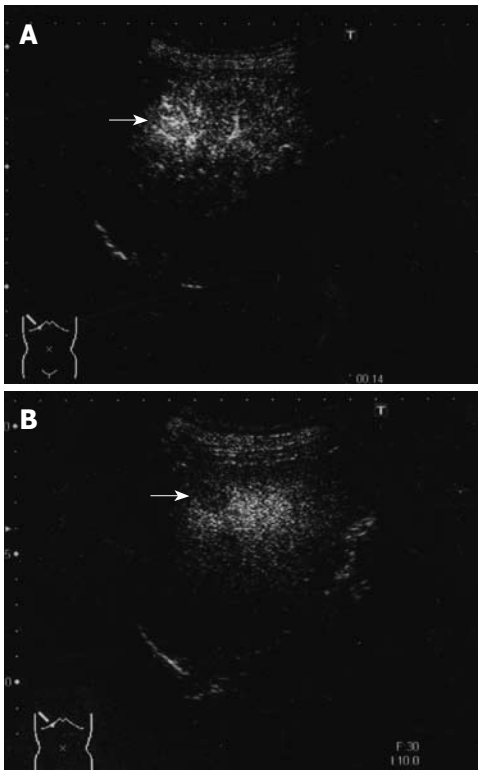

Figure 3 Contrast-enhanced US. Heterogeneous hypervascularity in the early phase (A) (arrow), and defect in the Kupffer phase (B) (arrow).

in non-SHCC.

SHCC is characterized by stellate fibrosis (84%), no encapsulation (absence of capsule) (100%), no necrosis and hemorrhage (100%), intratumoral portal tracts (80%), remarkable lymphocyte infiltration (84%), clear cell change (84%), and hyaline bodies (52%). The number of α-SMA-positive myofibroblast-like cells (activated stellate cells) in the tumor is about three times that in non-SHCC[5].

SHCC is occasionally misdiagnosed as fibrolamellar carcinoma (FLC) because of the presence of lamellar fibrosis. FLC is common in young adults and usually arises in the liver without any underlying chronic liver disease. Histologically, FLC is characterized by polyhedral, deeply eosinophilic neoplastic hepatocytes with round nuclei and distinct nucleoli, many of which contain intracytoplasmic hyaline globules and distinct pale bodies, and fibrosis arranged in a lamellar fashion around the neoplastic hepatocytes[6,7]. Conversely, although SHCC occasionally presents with lamellar fibrosis, the cancer cells being different from those of FLC, it is common in older patients with associated chronic hepatitis or liver cirrhosis[5]. Accordingly, it is not difficult to differentiate SHCC from FLC. In our case, the nodule was not diagnosed as FLC, clinically or histologically.

The US pattern was mostly hypoechoic, and contrast-enhanced CT and MRI revealed mostly heterogeneous hypervascularity in the early phase. The most characteristic feature of the imaging studies was prolonged enhancement in the late phase. Incidentally, imaging studies such as contrast-enhanced US, CTA and CTAP have, so far, not been described for use in the diagnosis of SHCC. Misdiagnosis by imaging studies is more frequent in SHCC than non-SHCC. Of 25 cases of SHCC, nine (36%) have been diagnosed as CCC, combined HCC-CCC, and metastatic carcinoma characterized by abundant fibrous stroma, the misdiagnosis being attributed to the prolonged enhancement of the tumor in the late phase and heterogeneous enhancement in the arterial phase on contrast-enhanced CT[5].

Figure 4 Heterogeneous hyperattenuation at CTA (arrow).

In our case, contrast-enhanced CT, MRI, US revealed heterogeneous hypervascularity in the early phase; the nodule was not misdiagnosed as CCC or HCC-CCC because the imaging findings showed no prolonged enhancement in the late phase. The nodule was misdiagnosed as well-differentiated and moderately-

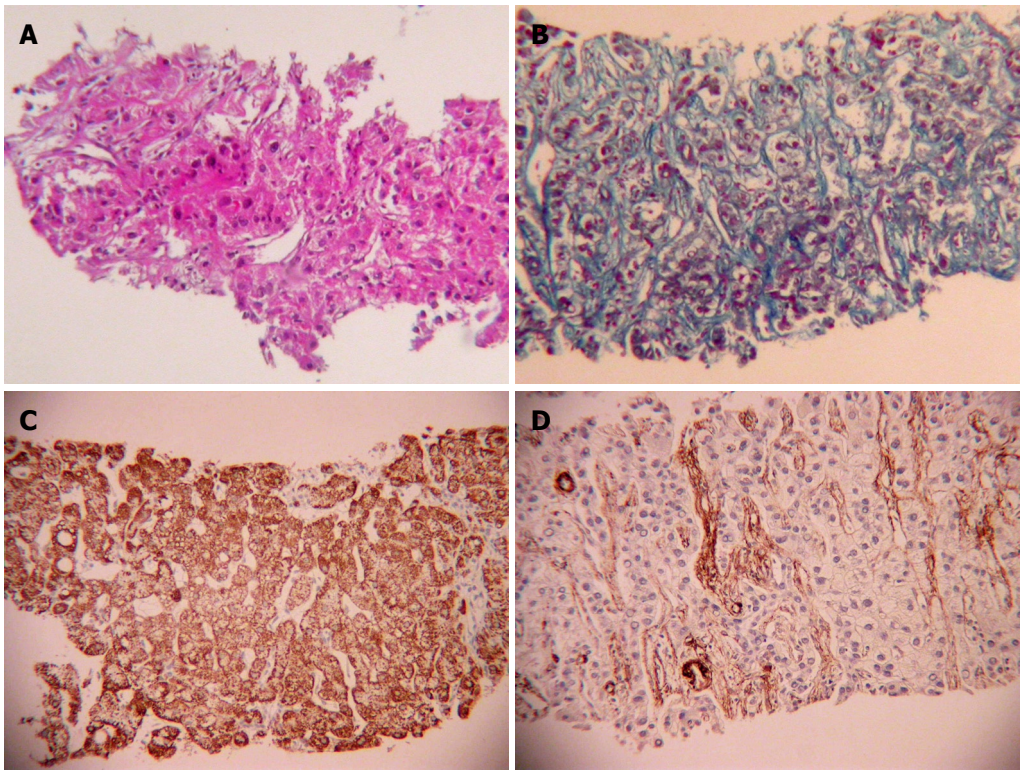

Figure 5 US-guided biopsy. Moderately-differentiated HCC characterized by typical cytological and structural atypia with dense fibrosis (HE stain) (A), (Mallory-Azan stain) (B). Positive for Hp1 (C) and α-SMA (D).

differentiated HCC on contrast-enhanced CT, MRI and US, which showed heterogeneous hypervascularity in the early phase and washout in the late phase; CTA and CTAP showed heterogeneous hypervascularity in the arterial and perfusion defect in the portal phases. Immunohistochemically, the nodule was negative for CK19 and, therefore, not CCC. Although contrast-enhanced US, CTA and CTAP did not indicate SHCC, these modalities are very effective in showing the heterogeneous vascular component, washout and perfusion defect of the nodule and contribute to precise diagnosis.

Clinicians engaged in hepatology should exercise caution with suspected SHCC when imaging studies reveal atypical findings, as shown in our case on the basis of chronic liver disease.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Articles: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; (13) Guidelines: To introduce Consensuses and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice in gastroenterology and hepatology.

The WJG Press and Baishideng

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words). Available from:http://www.wjgnet.com/wjg/help/8.doc

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/14.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc*.
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.
Biology: *H pylori*, *E coli*, *etc*.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office
World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/10.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/9.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

INTRODUCTION

World Journal of Gastroenterology is an international, open-access, peer-reviewed, and multidisciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

Abstract

Hepatitis C virus (HCV) has been recognized to be both a hepato- and lymphotropic virus. HCV lymphotropism represents an essential lap in the pathogenesis of virus-related autoimmune and lymphoproliferative disorders, ranging from clonal expansion of B-cells with organ- and non-organ-specific autoantibody production up to overt non-Hodgkin's lymphoma along a continuous step-by-step model of B-cell lymphomagenesis, where the intermediated mixed cryoglobulinemia could be considered as a stage of suppressible antigen-driven lymphoproliferation. HCV infection of lymphoid cells could set up privileged reservoirs able to interfere with the host viral clearance efficiency and may be implicated in viral recurrence after apparently successful antiviral therapy. The HCV long-lasting extrahepatic replicative state generates an abnormal systemic immunological response, easily detectable by searching simple laboratory and clinical parameters, mainly represented by vasculitis-like skin features and hypocomplementemia. The presence or absence of this hypersensitivity pattern seems to correlate with the antiviral response and could be identified as a novel immunological cofactor. Further research is required to fully verify the real impact on therapeutic choice/regimen.

Key words: Hepatitis C virus; Lymphotropism; Natural history; Antiviral therapy; Immunological co-factor

INTRODUCTION

Hepatitis C virus (HCV) infection has been currently identified as the leading cause of chronic liver disease, including cirrhosis and hepatocellular carcinoma, in Western countries. However, despite its large diffusion (with over 170 million of people infected world-wide), the lack of symptoms during the acute phase, together with the indolent course of the disease over time, hampers the difficulties to assess the natural history of the disease. This complexity can also be argued from the wide heterogeneity of disease complications' rate observed when different methodological approaches were used. Moreover, the progression of the disease could also be dramatically affected by many variables related to the host, the virus and the environment. The global socioeconomic burden of HCV is magnified by hundreds of thousands of infections identified every year. Finally, in the last few years, the long-term outcome of the infected subjects has been deeply modified by the use of efficient antiviral therapy.

HCV has been recognized to be both hepato- and lymphotropic virus; HCV lymphotropism represents an essential lap in the pathogenesis of virus-related immunological disorders[1], being responsible for poly-oligoclonal expansion and consequent wide organ- and non-organ-specific autoantibody production, including rheumatoid factor (RF) and cryo- and non-cryoprecipitable immune complexes.

IMMUNOLOGICAL MECHANISMS

HCV, belonging to the Flaviviridae family, is a positive single-stranded RNA virus, without a DNA intermediate of replication, unable to integrate into the host genome[2].

Otherwise, HCV affects cellular functions modulating the immune response, cell proliferation or apoptosis, so facilitating the clonal B-lymphocyte spread[3-5]. HCV may exert an antigen-driven chronic stimulus on the immune system through several viral proteins[6]. An important pathogenetic step is the interaction between the HCV envelope protein E2 and the CD81 molecule, a fairly ubiquitary tetraspanin present on both hepatocytes and B-cells surface[7], ending up to a strong and sustained polyclonal stimulation of B-cell compartment. CD81 is a part, on the B-cell, of a complex with CD21, CD19 and Leu 13; such complex lowers the threshold for B-cell activation by bridging antigen-specific recognition and CD21-mediated complement recognition[8]. Then, the interaction between HCV-E2 and CD81 could increase the frequency of VDJ rearrangement in antigen reactive B-cells[4,5,9], with possible bcl-2 proto-oncogene activation[4,5]. Again, the latter stage could be secondary to t(14; 18) translocation alone, repeatedly observed in B-cells of HCV-infected individuals, particularly in those with type Ⅱ mixed cryoglobulinemia (MC)[4,6]. Bcl-2 proto-oncogene is able to inhibit apoptosis, leading to abnormal B-cell survival[6]. Besides, the prolonged B-cell survival could prompt, in presence of additional factors (genetic, epigenetic, hormonal and immunological), other genetic aberrations up to overt non-Hodgkin's lymphoma (NHL), as late complication of the MC syndrome[1,9]. The critical question remains whether HCV replication occurs in normal B-cells and is directly lymphomagenic or is lymphomagenesis a stochastic process accompanying HCV-driven proliferation of B-cells[10]. At all, given its biological characteristics, HCV may be involved in several autoimmune and lymphoproliferative disorders, and the multifaceted HCV syndrome can fit in a continuous step-by-step model of B-cell lymphomagenesis, whereby MC could be viewed as marker of antigen-driven lymphoproliferation and frank NHL as loss of antigen-dependence[11].

CLINICAL IMPLICATIONS

At this point, the most scheming and open issue is the definite weight placed on the HCV natural history by its lymphotropism. Firstly, HCV infection of lymphoid cells could condition HCV persistence. In fact, lymphoid cells, and particularly long-living subsets and/or bone-marrow elements, may represent privileged reservoirs able to interfere with host viral clearance efficiency, by impairing the capability of immune response and/or by facilitating selection of distinctive viral variants[12]. Nowadays, it remains indefinite how infection of the immune cells by HCV may alter their functions, although impairment in the allostimulatory capability of HCV-infected dendritic cells derived from patients with chronic hepatitis C has been reported[13]. Interestingly, the entity of this extrahepatic reservoir seems to be correlated with the length of infection[12] and may be implicated in HCV recurrence after apparently successful antiviral therapy[1], the peripheral blood mononuclear cells (PBMC) being a potential viral tank resistant to interferon (IFN). In fact, in several researches PBMC infection appeared as a negative factor of patient on-IFN response[14-18] or predictive for relapse off-IFN monotherapy[15,18-20] or -combined (plus ribavirin) antiviral treatment[21]; on the other hand, such prognostic value was not observed in other studies and is still a controversial question[22-25]. Previous literature data report sustained response (SR) in a near 10% of patients with chronic HCV infection after IFN alone. Classical predictors of response include viral load and genotype, as well as histological (fibrosis score) and metabolic[26] features or alcohol as cofactor. Also the immunological background is associated with antiviral response, the cellular immune functions being essential to the elimination of HCV-infected hepatocytes. A basal low T-helper type 1 and type 2 ratio predicted a higher SR rate in a Japanese cohort[27]. Nevertheless, the immunological pattern remains poorly explored. Conflicting data have been reported on the prevalence of MC in chronic HCV patients, ranging from less than 5% up to 50 %[28,29]. In most cases type M immunoglobulins with RF activity have been found in cryoprecipitates[30], inducing the deposition of immune complexes in small vessels (vasculitis)[31]. The MC-related clinical manifestations, including purpura, arthralgias and weakness, and complications, as glomerulonephritis, neuropathic lesions, B-cell NHL, reflect a systemic involvement that may lessen the chance of viral eradication. In a recent effort[32], it was retrospectively confirmed that this immunological phenotype, also labelled as type Ⅲ or hypersensitivity disorder, is significantly associated with a higher risk of viral persistence after IFN monotherapy, with skin involvement and hypocomplementemia being independent predictors of lack of response; conversely, this study suggested that in the absence of common negative predictors, such as this last immunological cofactor, SR could be reached also by a therapeutic approach based on IFN monotherapy. What practical implications does HCV lymphotropism suggest? No factor is currently available to predict the productive HCV infection of PBMC, but such event is likely to be time-dependent during the natural history of HCV infection. In other words, we observe the serological response and the clinical effects of a long-lasting extrahepatic replicative state, i.e. an abnormal immunological status. This picture can be easily detected by looking for cryoglobulins, RF, antinuclear antibody, complement fractions, circulating immune complexes (C1q protein and C1q binding), mono-oligoclonal gamma-globulin expansion or vasculitis-related clinical manifestations including skin lesions (palpable purpura or hyperpigmented macule of the lower limbs), sensory-motor peripheral neuropathy (gait impairment associated with paresthesia and cramps), arthralgias, as well as urinary changes suggestive of glomerular derangement, i.e. microalbuminuria (in the absence of hypertension and diabetes), all variously combined (at least four out of the above mentioned laboratory and clinical parameters)[32]. This approach is reliable and less expensive or hard than direct detection of HCV in PBMC. The antiviral therapy (IFN plus ribavirin) significantly counteracts the

exaggerated immune response, also independently from the viral outcome[33], through different mechanisms: IFN could affect the intrahepatic T-cell response and inhibit interleukin (IL) 10 production[34], meanwhile ribavirin suppresses IL 10, IL 12 and tumor necrosis factor-alpha[35]; since the hypersensitivity disorders are the expression of a polyclonal activation of B-cells, due to stimulation by T-cells, it could be hypothesized that the changes induced by the combined therapy in the cytokine pattern determine a down-regulation of the mechanism of stimulation T-cells/B-cells. Sometimes, polyclonal B-cell hyperactivity partially escapes from the immune modulation effects of the antiviral treatment, so that the immunological spectrum persists after HCV clearance and suppression of the antigenic stimulus[33]. On the other hand, the undetectability of serum HCV RNA does not mean complete viral clearance, since genomic material has been found in PBMC of SR patients[12], and, therefore, an ongoing immune-stimulation cannot be excluded; interestingly, in those same patients with occult PBMC infection, a persistence of the MC syndrome, even if to a lesser degree with respect to the pre-treatment period, was observed, suggesting a potential advantage of using a prolonged course of antiviral treatment to obtain a sufficient consolidation. The discovery of occult HCV infection has challenged the paradigm that apparent complete resolution of hepatitis C, either spontaneously or therapeutically-induced, would be indicative of eradication of HCV[36]; persistent HCV replication in hepatocytes and PBMC would likely drive the continuous antigenic stimulation of the immune system in immunocompetent patients, which, in turn, allows the host to keep this silent infection under relative control[37]; again, such prolonged HCV replication associated with the chronic presentation of HCV antigens by infected B-cells and monocytes could contribute to the immune tolerance of HCV, thus supporting even further HCV persistence[37]. Finally, negativization of anti-HCV antibody, unrelated to an immunosuppression context, occurs in a percentage of long-term (on average 4 years) SR patients showing a weaker CD4+-specific HCV reactivity; such lessened immunological spur could mirror a full disappearance of the minimal, residual viral amounts, although the potential localization of a further load within PBMC, without release of viral particles into the serum, cannot be ruled out[38]. Only a prolonged follow-up will be able to verify the definitive clearance.

In conclusion, the treatment of hepatitis C is expensive, often demanding, from the patients' perspective, and difficult as far as the decision about whom, when and for how long to treat. Another predictor of response to antivirals is recognized, as immunological cofactor, i.e. the HCV lymphotropism. Further studies are warranted to evaluate alternative antiviral schedules depending on the presence or the absence of this additional cofactor.

Abstract

The incidence of early gastric cancer (EGC) with duodenal invasion is extremely low, although advanced gastric cancer that arises in the antrum occasionally invades the duodenum. We investigated the clinicopathological features of EGC with duodenal invasion and provided strategies for clinical management. A Medline search was performed using the keyword "early gastric cancer" and "duodenal invasion". Additional articles were obtained from references within the papers identified by the Medline search. We revealed that EGC with duodenal invasion was of the superficial spreading type of tumor. Tumors > 60 mm in size invaded the duodenum more extensively, and the distance of duodenal invasion from the pyloric ring was further in the elevated type than in the depressed type of tumor. There was no significant difference between the length of duodenal invasion and the histological type of the tumor. Gastric cancer located adjacent to the pyloric ring, even if cancer invasion was confined to the mucosa or submucosa, was more likely to invade the duodenum. The present study reveals that the elevated type of EGC is associated with more extensive duodenal invasion when the tumor size is > 60 mm, thus highlighting the importance of identification of duodenal invasion in these cases. We also reveal that sufficient duodenal resection with a cancer-free distal surgical margin should be performed in cases of duodenal invasion.

Key words: Duodenal invasion; Early gastric cancer; Gastrectomy; Superficial spreading type; Tumor differentiation

INTRODUCTION

Early gastric cancer (EGC), which is defined as a lesion confined to the mucosa or the submucosa, regardless of the presence of lymph node metastasis, has a good prognosis with surgical treatment. However, a small number of patients experience recurrence of EGC after resection. Sano *et al*[1] have reported that, in a study of 1475 patients with EGC treated with surgery, 1.4% experienced disease recurrence. The incidence of recurrence of EGC was shown to be significantly higher in the patient group with submucosal, node-positive and undifferentiated tumors. Furthermore, some rare cases show distant metastasis, such as in liver, lung, or bone, even though the depth of cancer invasion is confined to the mucosa[2]. Sufficient resection margins are necessary to prevent recurrence of EGC, because inadequate resection that does not maintain surgical margins free of cancer can lead to disease recurrence. Duodenal invasion by gastric cancer is encountered in 11.9%-23.8% of all patients with cancer in the gastric antrum[3-5]. However, EGC with duodenal invasion is rare amongst cases of advanced gastric cancer[6]. There have been very few case reports of this type of cancer. Since the literature on this subject consists mostly of isolated case reports, the clinicopathological features of EGC with duodenal invasion remain unclear. We attempted to elucidate the clinicopathological features of patients with EGC extended to the duodenum, and discuss the possible mechanisms underlying this rare condition and practical surgical strategies.

PATIENTS AND CLINICOPATHOLOGICAL PRESENTATION

We reviewed 41 patients who underwent surgical resection for EGC with duodenal invasion between

1975 and 2008. Thirty-eight cases were identified in the available literature using a Medline search and Japan Centra Revuo Medicina by use of the keywords "early gastric cancer" and "duodenal invasion". Additional articles were obtained from references within the papers identified by the searches. Three cases were patients treated in our hospital. Data on age, gender, tumor location, tumor type, tumor size, depth of invasion, lymph node metastasis, histological type, and preoperative diagnosis of duodenal invasion for each patient were obtained. The clinicopathological features of the 41 reported cases are listed in Table 1. Of the 41 patients analyzed, the mean age of patients was 63.2 years (range, 44-84 years), and there was a slight male predominance, with a male-to-female ratio of 16:13. The average diameter of tumors was 51.6 mm (range, 10-130 mm). The average distance of duodenal invasion was 7.9 mm (range, 1.0-38 mm). The case with the maximal distance of duodenal invasion was one of our cases. All patients had undergone curative tumor resection. There was no lymph node metastasis in cases in which the tumor was confined to the mucosa, whereas of the 25 patients in which the tumor had invaded the submucosa, four had lymph node metastasis. There was no lymphatic or venous invasion or distant metastasis.

The Mann-Whitney *U* test was used to assess correlations among the mean values for each group. The Pearson χ^2 test was applied to qualitative variables. All values are expressed as mean ± SD. $P < 0.05$ was considered significant.

EFFECT OF TUMOR INVASION DISTANCE

Table 2 shows the results of univariate analysis of the distance of duodenal invasion from the pyloric ring in relation to eight selected variables: age, gender, gross appearance, tumor size, depth of invasion, histological type, lymph node metastasis, and preoperative diagnosis

Table 2 Clinicopathological characteristics of EGC with duodenal invasion

Characteristics	No. of patients	Length of duodenal invasion (mm)	*P* value
Age (yr)			0.276
< 60	13	7.2	
> 60	16	11.7	
Gender			0.029
Male	16	5.3	
Female	13	15.2	
Gross appearance			0.046

Diffuse	13	5.1	
Lymph node metastasis			0.006
Negative	32	8.9	
Positive	4	3	
Preoperative diagnosis of duodenal invasion			0.001
Possible	8	24.3	
Impossible	16	3.6	

of duodenal invasion. The distance of duodenal invasion by EGC was 4.5 mm for depressed type tumors, 11.4 mm for elevated type tumors, 5.3 mm for tumors with a diameter < 60 mm, and 14.8 mm for tumors with a diameter > 60 mm. These results revealed a positive correlation between more extensive duodenal invasion and elevated type tumors with a size > 60 mm.

In advanced gastric cancer, the rate of metastasis to the lymph nodes was high when the distance of duodenal invasion was > 10 mm[7]. By comparison, we found lymph node metastasis in only four cases of EGC, and in each of these, invasion had reached the submucosa and the distance of duodenal invasion was < 10 mm. This result suggests that there is a strong positive correlation between the incidence of lymph node metastasis and submucosal invasion, regardless of the distance of duodenal invasion.

PREOPERATIVE DIAGNOSIS OF EGC WITH DUODENAL INVASION

Generally, preoperative diagnosis of malignant invasion to the duodenum is difficult[8,9], because spread of gastric cancer to the duodenum is often infiltrative and invades directly through the submucosal or subserosal layer[10-12]. Most of these cases are advanced gastric cancer[13]. In EGC, gastroenteroscopic examination is a reliable technique for identifying the area of cancer infiltration[14]. It is necessary to accurately define the tumor margin in order to determine the resection line. However, it is occasionally difficult to accurately determine the margin of the tumor in the vicinity of the pyloric ring by endoscopy[15-17]. This is because the pyloric ring is a narrow lumen, making it difficult to observe the tumor, and it can be deformed by ulcers, mucosal atrophy, and metaplastic changes. Moreover, pyloric movement caused by strong peristalsis and reflux of bile prevent the satisfactory observation of the lesion on the pyloric ring[15].

Duodenal invasion by EGC was diagnosed preoperatively by esophagogastroduodenoscopy (EGD) or barium meal examination in only eight cases (Table 1). The mean distance of duodenal invasion was 24.3 mm in the group in which a preoperative diagnosis was possible, whereas it was 3.6 mm in the group in which a preoperative diagnosis was not possible. There was a significant difference between the two groups (Table 2). In these cases, the distance of duodenal invasion was greater for elevated or mixed type tumors > 10 mm in diameter. Of the nine cases in which the distance of duodenal invasion was > 10 mm, there was only one case in which a preoperative diagnosis of duodenal invasion was not possible. By comparison, no case could be diagnosed preoperatively where the distance of duodenal invasion was < 10 mm. These results suggest that a preoperative diagnosis of duodenal invasion is related to tumor type and size. Kuwata *et al*[18] have reported that radiological diagnosis of duodenal invasion is more useful in the elevated type than in the depressed type of tumor, and that the compression method gives a more accurate diagnosis than the double-contrast method. Furthermore, despite extensive preoperative examination, determination of the tumor margin is often not possible in patients with a superficial spreading type of gastric cancer[19-22]. Thus, a satisfactorily precise diagnostic approach to assess the extent of tumor invasion has not been established.

MECHANISMS OF DUODENAL INVASION BY EGC

The border between the stomach and the duodenum is not clinically obvious. Brunner's glands can be considered as the start of the duodenum for the clinicopathological assessment of duodenal invasion by gastric cancer[3,13]. When gastric cancer directly invades the mucosal layer, the Brunner's glands remain intact, even when surrounded by cancer cells[3]. For this reason, it is thought that Brunner's glands prevent direct cancer invasion from the gastric mucosa to the duodenal mucosa. In a study of 141 patients with gastric carcinoma with duodenal invasion, there was only one case of intramucosal carcinoma[3]. In the case of a lesion caused by an ulcer, it is speculated that destruction of the mucosal structure of the duodenum by an ulcer located in the pylorus allowed gastric cancer to invade the duodenum[23]. In another case in which endoscopic mucosal resection (EMR) had been performed previously for gastric cancer in the area of the pyloric ring, it is thought that destruction of the gastroduodenal mucosal microanatomy by EMR allowed carcinoma cells to invade the duodenal mucosa[24].

The superficial spreading type of EGC is characterized by wide and superficial spreading activity of the

cancer compared with a more limited depth of vertical invasion[25]. According to Yasui *et al*[26], EGC is classified as a superficial spreading type of tumor when the product of the longest diameter of the tumor and the diameter perpendicular to it is > 25 cm^2. Our study has revealed that gastric cancer with duodenal invasion is most often the superficial spreading type. Relations between the superficial spreading tumor and duodenal invasion of EGC may refer to multiple occurrence of cancer[27]. Previous authors have reported that the superficial spreading type accounted for 5.46%-11.0% of all EGC[19-22], whereas it accounted for 27.0% of EGC cases with duodenal invasion (Table 3). Duodenal invasion was more extensive in superficial spreading cancer lesions (16.3 mm) than in small-sized cancer lesions (5.4 mm). In both of these groups, there was no significant difference in the gross appearance, depth of invasion, histological type, or the incidence of lymph node metastasis. Taken together, these results suggest that the superficial spreading type of gastric cancer adjacent to the pyloric ring may have the potential to invade the duodenum.

STRATEGY FOR SURGICAL TREATMENT OF EGC WITH DUODENAL INVASION

The outcome of surgical treatment for EGC is generally considered to be satisfactory[1,28]. If EGC is treated with the appropriate surgical strategy, the outcome of treatment is excellent, even in patients with duodenal invasion[29]. However, Kakeji *et al*[30] analyzed 95 patients with duodenal invasion by gastric cancer, including advanced cases, and found that tumor spread into the duodenum was limited to within 2 cm in 76% of the patients and to within 3 cm in 81% of the patients. Therefore, for patients with advanced gastric cancer with duodenal invasion, gastrectomy with resection of 3-4 cm of the duodenum and sufficient lymph node dissection is recommended.

Recent advances in endoscopic and laparoscopic surgery now offer a better quality of life to patients with EGC[31]. Although the 5-year survival rate for EGC is ⩾ 90%[32], complete surgical extirpation of gastric cancer with a sufficient resection margin from the tumor, and removal of metastatic lymph nodes, is necessary for good prognosis in all EGC cases, including those with duodenal invasion[1,29,31,32]. Previous reports have revealed that the prognosis of gastric cancer patients is affected mostly by depth of invasion, followed by lymph node metastasis and tumor location[33,34]. Tumor size in gastric cancer is a reliable prognostic factor that might be a suitable candidate for use in the staging system[35]. However, tumor size is not an independent prognostic factor[36]. Tumor diameter > 3.5 cm has been identified as an independent factor for the occurrence of lymph node metastasis[33]. Our review revealed that many cases of EGC with duodenal invasion had larger tumors, with an average diameter of 51.6 mm, than cases without duodenal invasion. Among the cases of EGC with duodenal invasion, there was no cancer recurrence because suitable surgical resection had been performed. It is necessary for surgeons to identify a suitable resection line for the distal margin for preoperative diagnosis of duodenal invasion. In cases in which there is further extension of the tumor toward the duodenum, it may be necessary to determine a resection line using intraoperative EGD[37].

The indistinct tumor margins characteristic of superficial spreading tumors in EGC can lead to discrepancies in tumor area between surgical findings and pathological diagnosis[20,22]. Kasakura *et al*[19] have reported that, despite extensive preoperative examination, determination of the tumor margin was not possible in 26 of 59 patients with superficial spreading cancer. Furthermore, the number of metastatic lymph nodes was greater than with the common tumor type[21]. Accordingly, gastrectomy with extensive lymph node dissection with wide and sufficient surgical margin seems to be a most appropriate treatment for the superficial spreading type of EGC, including those cases with duodenal invasion. Based on these findings, treatment of superficial spreading type EGC, in which the distal margin is near the pyloric ring, should focus on attaining a satisfactory margin from the tumor.

CONCLUSION

Gastric cancer located adjacent to the pyloric ring, even if cancer invasion is confined to the mucosal or submucosal layer, has the potential for duodenal invasion, and surgeons should be aware of this possibility. The present study indicates that EGC of the elevated type with a tumor size > 60 mm correlates positively with more extensive duodenal invasion. Our findings highlight the importance of identification of duodenal invasion by pre- and intra-operative closed observation, and reveal that the resection line in cases of duodenal invasion should be performed with a cancer-free margin.

Abstract

Non-classical manifestations of autoimmune hepatitis can delay diagnosis and treatment. Our aims were to describe the clinical phenotypes that can confound the diagnosis, detail scoring systems that can ensure their recognition, and outline advances in treatment that can improve their outcome. Prime source and review articles in English were selected through Medline from 1970-2008 and assimilated into personal libraries spanning 32 years. Acute severe or asymptomatic presentations and atypical histological findings, including centrilobular zone 3 necrosis and concurrent bile duct changes, are compatible with the diagnosis. Cholangiographic abnormalities may be present in children and adults with the disease, and autoimmune hepatitis must be considered in patients without autoantibodies or with antimitochondrial antibodies and no other cholestatic features. Asymptomatic patients frequently become symptomatic; mild disease can progress; and there are no confident indices that justify withholding treatment. Two diagnostic scoring systems with complementary virtues have been developed to evaluate patients with confusing features. Normal liver tests and tissue constitute the optimal end point of treatment, and the first relapse is an indication for long-term azathioprine therapy. Cyclosporine, tacrolimus and mycophenolate mofetil are promising salvage therapies, and budesonide with azathioprine may be a superior frontline treatment. We conclude that the non-classical phenotypes of autoimmune hepatitis can be recognized promptly, diagnosed accurately, and treated effectively.

INTRODUCTION

Autoimmune hepatitis was initially perceived as a self-perpetuating, inflammatory liver disease in young amenorrheic women with hirsutism, acne and cirrhosis[1-3]. The validity of this classical phenotype was subsequently strengthened by technological advances that excluded a viral cause for the condition[4] and by studies that implicated perturbations of the immune system in its pathogenesis[5-8]. The clinical phenotype expanded as the concept of autoimmunity was applied broadly to liver diseases of unknown cause and as the requirement for 6 mo of disease activity was eliminated from its definition[9,10]. Autoimmune hepatitis still lacks an etiological agent and disease-specific laboratory test, but its designation now applies to patient populations far more diverse and numerous than the original patients with "lupoid hepatitis"[11].

Autoimmune hepatitis must be considered in all individuals with acute and chronic hepatitis of undetermined cause and with graft dysfunction after liver transplantation[11]. Acute[12-15], acute severe[16-19],

and asymptomatic[20-22] forms have been described; progression to cirrhosis may be indolent and unsuspected[23-25]; transitions between active and inactive disease may occur spontaneously[26,27]; concurrent immune diseases may obscure the diagnosis[28,29]; serological markers may be variably expressed and absent at presentation[30-32]; histological findings may include centrilobular zone 3 necrosis[33-37] or concurrent biliary changes[38-42]; and different ethnic groups may have non-classical clinical phenotypes[43-47]. The identification of autoimmune hepatitis in diverse clinical situations is critical since prompt institution of corticosteroid therapy can be life-saving[48-50].

Corticosteroids alone or a lower dose in combination with azathioprine induce clinical, laboratory and histological improvement in 80% of patients within 3 years[51,52]. Ten- and twenty-year survivals exceed 80%[24], and hepatic fibrosis is reduced or prevented[53-56]. These therapeutic successes are counterbalanced against adverse outcomes that justify the continued pursuit of new drugs and regimens. Nine percent of treated patients deteriorate despite compliance with corticosteroid schedules (treatment failure)[57,58]; 13% develop treatment-related side effects that compel premature withdrawal of medication (drug toxicity)[59]; and 9% improve but not to a degree to justify discontinuation of the medication (incomplete response)[59]. Furthermore, 50%-86% of patients who enter remission relapse after drug withdrawal and require re-treatment[27,51,60-64].

The diagnostic criteria of autoimmune hepatitis have been codified by an international panel[9,10], and scoring systems can establish the diagnosis in difficult cases[9,10,65,66]. The re-definition of treatment goals[67-70] and the revision of current treatment strategies[71-75] promise to improve results. The emergence of powerful immunosuppressive agents, mainly from the transplantation arena, promises to strengthen the treatment repertoire[76,77], and the clarification of critical pathogenic pathways make site-specific molecular interventions feasible[76,78,79]. The clinical spectrum of autoimmune hepatitis has expanded, but the diagnostic instruments and therapeutic options have also improved.

The objectives of this review are to describe the non-classical clinical phenotypes of autoimmune hepatitis, detail the diagnostic instruments that can ensure their recognition, and introduce the evolving treatment strategies. Classical syndromes are the cornerstones of clinical practice, but variations from the classical are its realities. The changing spectrum of autoimmune hepatitis and its treatment underscores the importance of the disease and the vigor of the investigative effort that it has generated.

NON-CLASSICAL CLINICAL PHENOTYPES

Autoimmune hepatitis is defined as a self-perpetuating inflammation of the liver of unknown cause that is characterized by interface hepatitis on histological examination, hypergammaglobulinemia, and autoantibodies[80]. The diagnosis has great latitude since no features are disease-specific. The phenotypes that satisfy the definition of autoimmune hepatitis but are outside the boundaries of classical disease have acute severe presentations, few or no symptoms, atypical histological findings, absent or variant serological markers, concurrent cholangiographic changes, male gender, and non-Caucasian backgrounds.

Table 1 Non-classical phenotypes of autoimmune hepatitis

Non-classical phenotype	Salient features
Acute severe disease	Corticosteroids effective in 36%-100%[49] Protracted treatment can be complicated by infection[49] High mortality if no better within 2 wk of therapy[85] MELD score ⩾ 12 identifies 97% of treatment failures[58]
Asymptomatic mild hepatitis	Common (25%-34%) but unstable state[20-22,87-89] Symptoms develop in 26%-70%[20,21] Progression possible if untreated[20-22,87] Improves quickly with therapy[22]
Atypical histological features	Centrilobular necrosis is an early acute form[18,33-37,92] Transition to interface hepatitis possible[35] Coincidental biliary changes lack cholestatic profile[41] Fatty changes may co-exist[58,94]
Absent or variant serological markers	Seronegativity possible in 13%[31] Other features and treatment outcome similar[31,32,100] Non-standard autoantibodies possible[101-104] Conventional autoantibodies may be expressed later[30] Screen for celiac disease[105-108]
Concurrent cholangiographic changes	Abnormal cholangiograms in 44% with CUC[116] Poor outcome if biliary changes and CUC[121-124] MRC abnormalities in 8% adults without CUC[117] MRC abnormalities may be associated with fibrosis[119]
Male gender	0.2-0.5 cases/100 000 per year[127,128] Low frequency of concurrent immune diseases[130-132] No diversity of HLA DRB1*04 alleles[130-132] Better survival than women[136]
Non-Caucasian	Cholestatic features may be common[45,141-143] Male predominance possible[47] Socioeconomic factors important[137,138,146,147]

MELD: Model of End Stage Liver Disease; MRC: Magnetic resonance cholangiography; CUC: Chronic ulcerative colitis; HLA: Human leukocyte antigen.

Acute severe presentations

The diagnosis of autoimmune hepatitis is no longer restricted by a time requirement for disease activity[9,10]. An acute severe or fulminant presentation can reflect *de novo* inflammation[12-15] or the spontaneous exacerbation of a previously unsuspected chronic disease[81]. An acute or abrupt onset occurs in 40% of patients with autoimmune hepatitis[14,81,82], whereas an acute severe presentation is rare[83] (Table 1).

The acute form can be differentiated from the chronic form by laboratory features [higher serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels, total serum bilirubin concentration, and serum γ-glutamyl transpeptidase level] and by histological findings (more frequent centrilobular zone 3 necrosis with plasmacytic infiltration and bile duct injury), but its recognition in individual cases relies mainly on an awareness that acute severe autoimmune hepatitis is possible[84].

Corticosteroid therapy suppresses inflammatory

activity in 36%-100% of patients with acute severe presentations[49], whereas delay in treatment can result in a poor outcome[51,83] (Table 1). Immediate survival and the need for urgent transplantation depend on the rapidity and nature of the response to corticosteroids[50,85,86]. Failure to improve at least one laboratory abnormality reflective of liver inflammation or function, especially a pre-treatment hyperbilirubinemia, within 2 wk indicates that liver transplantation should be considered[85]. Relentless pursuit of an unachievable benefit from corticosteroid therapy can be complicated by infection and the lost opportunity for a successful transplantation[49].

The Model of End Stage Liver Disease (MELD) can be used to identify individuals with autoimmune hepatitis who are likely to fail corticosteroid therapy and require liver transplantation[58] (Table 1). MELD scores $\geqslant$ 12 points at presentation have a sensitivity of 97% and specificity of 68% for treatment failure, and patients with such scores warrant close scrutiny and preparedness for liver transplantation. A MELD score $\geqslant$ 12 points at presentation captures all problematic patients, but it does not preclude their salvation through prompt and vigorous corticosteroid treatment.

Asymptomatic mild presentations

Autoimmune hepatitis is asymptomatic in 25%-34% of patients at presentation[20-22], and retrospective analyses have estimated that 25%-85% of individuals have mild disease[20-22,87-89] (Table 1). These presentations contrast with those described in the classical treatment trials in which selection criteria focused on severe symptomatic and immediately life-threatening disease[51,90,91]. Treatment guidelines have been promulgated for the individuals with severe disease, but they remain arbitrary and inconsistent for those with mild disease[80]. These difficulties reflect in part the lack of a codified definition of mild autoimmune hepatitis and uncertainty about its natural history.

Untreated mild autoimmune hepatitis has a better outcome than severe disease, but it does not have a benign prognosis (Table 1). Cirrhosis develops in 49% of untreated patients within 15 years[87]; liver failure and hepatocellular carcinoma are possible[22]; asymptomatic patients become symptomatic in 26%-70% of instances[20,21]; and 10-year mortality exceeds 10%[21,22]. Spontaneous resolution is possible, but untreated patients with mild autoimmune hepatitis improve less commonly (12% *vs* 63%, $P = 0.006$) and more slowly than treated patients, and they have a lower 10-year survival (67% *vs* 98%, $P = 0.01$)[22].

A "safe" subset of patients with non-aggressive autoimmune hepatitis who require no therapy cannot be reliably identified, and the clinical threshold for starting corticosteroid therapy cannot be so high that all patients with mild or asymptomatic disease are excluded (Table 1). Mild autoimmune hepatitis can improve spontaneously, and this prospect may dampen therapeutic zeal, especially if measured against the possibility of serious treatment-related complications[22]. A dictum to do no harm, however, that focuses more concern on the treatment than the disease may be incorrect.

The aggressive potential of mild autoimmune hepatitis at presentation, the inability to predict outcome by clinical parameters, the expected rapidity of the treatment response, and the safety of current treatment regimens favor a proactive management strategy[22]. Until randomized clinical trials are performed comparing treatment against no treatment, the management strategy in patients with mild disease should lean toward conventional therapy. Mild asymptomatic autoimmune hepatitis is a non-classical phenotype, but it should not be regarded or managed as a different disease.

Atypical histological features

The histological hallmark of autoimmune hepatitis is interface hepatitis, but other histological findings are compatible with the disease[9,10] (Table 1). Centrilobular zone 3 necrosis (Figure 1) is probably an early form of autoimmune hepatitis that is detected mainly in patients with an acute onset[18,33-37,92]. Successive liver tissue examinations have disclosed transition of the centrilobular zone 3 pattern of necrosis to that of typical interface hepatitis during the course of the disease[35]. This non-classical finding may suggest an acute viral or toxic injury, but the diagnosis of autoimmune hepatitis should not be discounted.

Concurrent biliary changes, including isolated destructive cholangitis (Figure 2), may also be found in patients with otherwise classical autoimmune hepatitis[38-42] (Table 1). These patients do not have a cholestatic clinical or laboratory profile, and successive tissue examinations have not disclosed persistence or progression of the biliary injury[41]. The biliary changes probably reflect collateral damage associated with an exuberant inflammatory process rather than a transition state to a cholestatic disease or variant syndrome. The biliary changes should not alter the diagnosis or the treatment strategy.

Fatty changes (Figure 3) may also be present at accession or after corticosteroid therapy[58,93,94] (Table 1). Non-alcoholic fatty liver disease (NAFLD) is a common finding in the general population, and it may be associated with autoantibodies and hypergammaglobulinemia[94-97]. Both conditions can co-exist, and corticosteroid therapy can ameliorate the autoimmune hepatitis and intensify the NAFLD[58,94]. The presence of coincidental fatty change should not discourage the diagnosis or treatment of autoimmune hepatitis, but it compels an accurate diagnosis. Worsening of the laboratory indices during therapy justifies liver tissue examination and reassessment of the treatment strategy[58,94]. Progressive fatty change can be a cause of treatment failure[58].

Absent or atypical serological markers

Antinuclear antibodies (ANA), smooth muscle antibodies (SMA), and antibodies to liver kidney microsome type 1 (anti-LKM1) are the classical serological markers of autoimmune hepatitis[98,99]. These antibodies are not pathogenic or disease-specific, and their expression can vary in individual cases and in different geographical

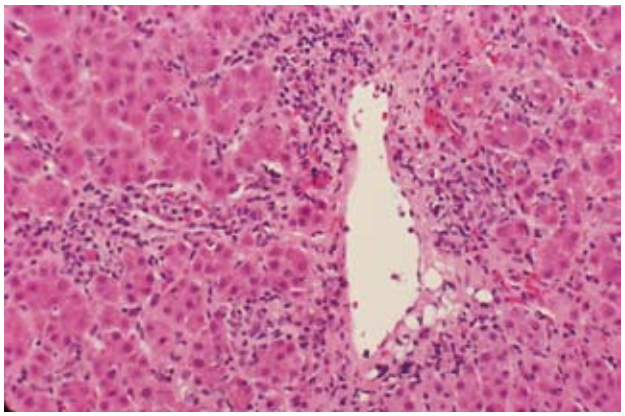

Figure 1 Centrilobular zone 3 necrosis. Inflammation and hepatocyte drop out are present around a terminal hepatic venule in conjunction with hepatic plate thickening, architectural disorganization, and rosette formation. Centrilobular (perivenular) zone 3 necrosis can be an early acute form of autoimmune hepatitis that can transform to interface hepatitis (HE, × 200).

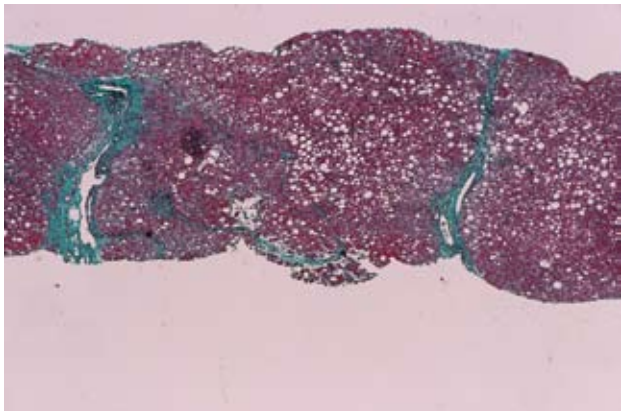

Figure 3 Steatosis. Macrovesicular steatosis is the predominant histological feature after corticosteroid treatment. Fatty changes may be present before or during corticosteroid treatment and perpetuate or extend the laboratory indices of liver inflammation (Trichrome stain, × 40).

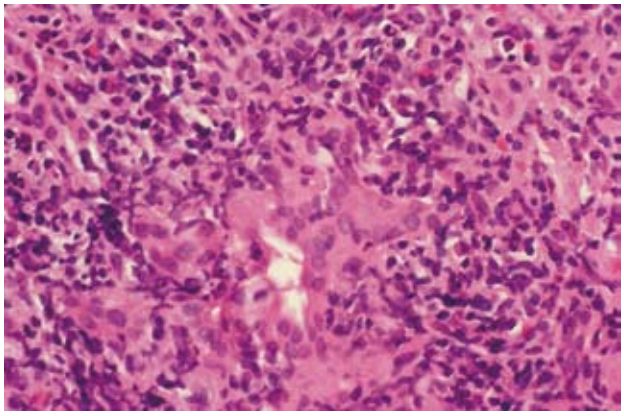

Figure 2 Concurrent pleomorphic cholangitis. Lymphocytes and histiocytes surround, infiltrate and damage an interlobular bile duct. Bile duct injury in the absence of cholestatic clinical and laboratory manifestations may represent collateral injury that is transient (HE, × 400).

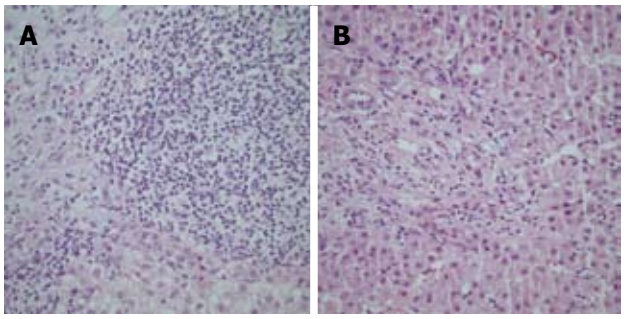

Figure 4 Histological features of a Turkish patient with the "overlap syndrome" (autoimmune hepatitis and primary biliary cirrhosis) characterized by heavy portal infiltration with lymphocytes and plasma cells (A) and bile ductular proliferation and ductopenia (B) (HE, × 200).

regions and ethnic groups. Thirteen percent of white North American adults with classical features of autoimmune hepatitis lack ANA, SMA, and anti-LKM1[31] (Table 1).

Seronegative patients with autoimmune hepatitis have a non-classical phenotype, and they constitute an "autoantibody-negative autoimmune hepatitis"[31,32,100]. These patients are indistinguishable from those with classical disease, including their HLA profiles, and they also respond to corticosteroid therapy[31,32,100] (Table 1). Twenty percent may express non-standard autoantibodies, such as antibodies to soluble liver antigen (anti-SLA)[101,102] or atypical perinuclear anti-neutrophil cytoplasmic antibodies (atypical pANCA)[103,104], and others may express SMA, ANA or both later in their course[30]. Some corticosteroid-responsive patients remain seronegative throughout their disease, and they may await discovery of their signature autoantibody[31,32,100]. All such patients must be screened for celiac disease by testing for immunoglobulin A antibodies to tissue transglutaminase or endomysium[105-108].

Antimitochondrial antibodies (AMA) can be present in 8%-35% of patients with otherwise classical autoimmune hepatitis, and they define another non-classical serological phenotype[108-112]. These coincidental AMA are not associated with cholestatic features, histological findings of biliary injury, or different response to corticosteroid therapy[110-113]. They may persist for as long as 27 years in the absence of primary biliary cirrhosis (PBC)[111]; they may disappear spontaneously; or they may appear late in the course of the disease without apparent clinical relevance[112]. Severe inflammatory activity may result in modification of the mitochondrial antigens through oxidative stress and facilitate the production of AMA which in turn can disappear when the inflammatory stress subsides[114]. AMA in the absence of cholestatic laboratory or histological features should not dissuade the diagnosis of autoimmune hepatitis or compel a different treatment strategy. The "serological overlap" with PBC does not constitute a hybrid disease or pathological process in transition.

Concurrent cholangiographic changes

Concurrent cholangiographic changes have been described in children[115] and adults[116,117] with autoimmune hepatitis, and these findings constitute another non-classical clinical phenotype (Table 1). The

emergence of magnetic resonance cholangiography (MRC) as a safe, effective and non-invasive mechanism by which to assess the biliary system[118] has indicated that cholangiographic changes that resemble primary sclerosing cholangitis (PSC) occur in 8% of adults with autoimmune hepatitis[117]. These changes occur predominately in women who typically lack inflammatory bowel disease, and they are associated with histological features that reflect increased lobular activity rather than biliary injury[117].

The nature and significance of the biliary changes by MRC remain unclear since most adults with these changes respond to corticosteroid therapy[117]. The possibility of a disease process other than typical PSC or an unusual but nonspecific biliary distortion induced by fibrosis cannot be discounted (Table 1). Recent prospective studies have indicated that while adults with autoimmune hepatitis have a high frequency of intrahepatic biliary changes by MRC (24%), the occurrence of PSC is rare (2%)[119]. Furthermore, the frequency of biliary changes by MRC in adults with autoimmune hepatitis is similar to that in patients with cirrhosis of a non-biliary and non-autoimmune nature. Hepatic fibrosis rather than the nature of the liver disease may be the most important parameter independently associated with the biliary changes[119].

Cholangiographic abnormalities by endoscopic or intrahepatic cholangiography are present in 44% of adults with autoimmune hepatitis and inflammatory bowel disease[116,120], and patients with these changes are typically refractory to corticosteroid therapy[121-124] (Table 1). This is the non-classical phenotype that has immediate clinical relevance, and its discovery impacts on the diagnosis, treatment, and outcome. Biliary studies should be performed mainly in adult patients with inflammatory bowel disease or recalcitrance to corticosteroid therapy[121,125]. Not all biliary changes have independent pathological significance or clinical importance[126].

Male gender

Autoimmune hepatitis does occur in white northern European men[127,128], and its development in this gender constitutes another non-classical phenotype (Table 1). Women with autoimmune hepatitis outnumber men with the disease by more than three-fold[129], and estimates of the incidence of autoimmune hepatitis in northern European men ranges from 0.2-0.5 cases per 100 000 persons per year[127,128]. The existence of an important clinical distinction between men and women with autoimmune hepatitis is still unsettled, but clearly the experiences over the decades have not identified a striking difference between the genders.

White North American women with autoimmune hepatitis are distinguished from men with autoimmune hepatitis and the same ethnicity by having higher frequencies of concurrent immune diseases (34% *vs* 17%, $P = 0.05$) and HLA DRB1*04 (49% *vs* 24%, $P = 0.007$)[130-132] (Table 1). Women with HLA DRB1*04 also have higher frequencies of concurrent immune diseases than women without HLA DRB1*04 (52% *vs* 22%, $P < 0.000001$) as do men with HLA DRB1*04 compared to men without HLA DRB1*04 (26% *vs* 4%, $P = 0.002$)[129,132]. These findings suggest that the clinical phenotype is driven by the genetic predisposition of the host as well as the gender[129,133].

Retrospective surveys have suggested gender-based differences in disease behavior and treatment outcome, but results have been discrepant[134-136]. Differences in age at presentation (39 years *vs* 49 years, $P = 0.06$) and the frequency of relapse after drug withdrawal (71% *vs* 55%, $P = 0.06$) have not reliably distinguished men from women with autoimmune hepatitis. The higher frequency of HLA A1-B8-DRB1*03 in men who relapse (50% *vs* 23%, $P = 0.003$) and greater mortality in women than men ($P = 0.02$) have been contrasting features in some experiences, and these findings require further examination[135,136] (Table 1).

The principal clinical concern related to gender is that the diagnosis of autoimmune hepatitis might be overlooked in men. Gender may be a surrogate marker that signifies different antigenic exposures, hormonal effects on immune responsiveness, chromosomal imbalances that favor loss of self-tolerance, and genetic predispositions for immunocyte activation[132]. The diagnosis of autoimmune hepatitis in men should trigger the same treatment strategies and monitoring schedules as in women.

Non-Caucasians

Racial background can affect the clinical phenotype of autoimmune hepatitis, and diagnostic criteria developed mainly in white northern European and North American populations may not apply in different ethnic groups and geographical regions (Table 1). Black North American patients have cirrhosis at presentation more commonly than white North American patients (85% *vs* 38%)[43,137,138]. Japanese patients typically have mild, late onset disease[139]. South American patients are younger than white North American counterparts, and they have more severe laboratory abnormalities at presentation[140]. Alaskan natives have a higher frequency of acute icteric disease, asymptomatic illness, and advanced fibrosis at accession than non-native patients[44]. Aboriginal North Americans have disproportionately high frequencies of immune-mediated disorders, cholestatic features, and advanced disease at presentation[141-143]. African, Asian and Arab patients have a higher frequency of biliary changes on histological examination than white northern European patients[45], and patients from Somalia are frequently men with rapidly progressive disease[47] (Table 1).

The variations in clinical phenotype suggest that genetic background and geographical location affect occurrence and behavior of the disease[129,133]. Indigenous etiological agents or population-dependent genetic factors may modulate susceptibility to autoimmune hepatitis, determine targets of the immune response, and affect the vigor of the inflammatory reaction[144,145]. Socioeconomic status, healthcare access, and quality of care are other factors that must be analyzed when assessing discrepancies

in disease occurrence and outcome among different racial groups[137,138,146,147] (Table 1).

TURKISH PERSPECTIVE

The importance of recognizing the diverse manifestations of autoimmune hepatitis in different regions and ethnic groups is illustrated by the appearance and behavior of the disease in Turkey. Autoimmune hepatitis in this region has a character that aligns with the disease of white northern Europeans and North Americans, but it can be difficult to recognize if only the western phenotype is considered.

Autoimmune hepatitis is a relatively rare disorder in Turkey when compared with chronic viral hepatitis, but it is still the most common autoimmune liver disease[148,149]. Its high prevalence in women is not unusual, but its 9:1 female-to-male ratio[148,149] exceeds the female propensity (3:1 female-to-male ratio) in North America[129]. The age of occurrence in adults (age ranges, 18-59 years; mean age, 42 years) is as broad as elsewhere[150], but there are many patients with signs of hepatitis who are negative for viral markers and the conventional autoantibodies[149]. These patients are typically designated as having "cryptogenic chronic hepatitis", but they respond well to treatment with corticosteroids and azathioprine. Other liver diseases must be carefully excluded, especially in men and those who lack the conventional autoantibodies, and the diagnosis must be supported by the demonstration of compatible liver enzyme abnormalities, serum immunoglobulin G (IgG) elevation, and histological findings. The presence of periportal lymphoplasmacytic infiltration in liver tissue is an important clue to the diagnosis, and all patients in whom there is a suspicion of autoimmune hepatitis should undergo liver tissue examination.

As in other regions, the features of autoimmune hepatitis may be intermixed with those typical of other liver diseases, especially the cholestatic disorders ("overlap syndromes"), and the diagnosis must be secured by expert histological interpretation and cholangiographic studies (Figure 4)[148,151,152]. In Turkey, as elsewhere, liver tissue examination is the most important tool in directing the diagnosis, and a second examination of the liver tissue after institution of treatment provides a comparison that can support or change the original impression.

Concurrent immune diseases, such as autoimmune thyroiditis[153], celiac disease[154], Sjogren syndrome[155], autoimmune diabetes[155], and various rheumatic conditions[156], can accompany the autoimmune hepatitis of Turkey, but unlike the disease in other regions, the liver disease in Turkey can frequently be linked to different triggers, including indigenous infections [prolonged hepatitis A virus (HAV) infection[157] and brucellosis[158]] and medicinal agents (Echinacea[159], doxycycline[158], estrogen[160], cyproterone acetate[160], and ornidazole[161]). A genetic basis for the liver disease and its immune manifestations has not been well studied in Turkey, but the classical HLA phenotype, A1-B8-DRB1*03, of western countries does not appear to be an important susceptibility factor in this area[162].

Corticosteroid therapy remains the mainstay of treatment in Turkey, but azathioprine, ursodeoxycholic acid and budesonide have been added to the list of available and effective drugs. Combination therapy is the preferred regimen, and budesonide is gaining favor over prednisolone in combination with azathioprine. An example of tailoring the treatment strategy to the population base is the practice of maintaining individuals in remission on low dose prednisolone (4 mg on alternate days) either alone or in combination with azathioprine long-term. By recognizing the regional variations in the clinical phenotype and tailoring therapy to suit the prevalent disease behavior, autoimmune hepatitis in different regions and ethnic groups can be diagnosed promptly and treated successfully in a cost-effective, low risk manner.

NEW DIAGNOSTIC INSTRUMENTS

New diagnostic instruments have evolved that have the flexibility to accommodate atypical features of autoimmune hepatitis and the sensitivity and specificity to ensure accurate diagnosis of the non-classical phenotypes. A diagnostic scoring system that was promulgated mainly as a research tool in 1993[9] was revised in 1997[10] to exclude cholestatic syndromes. A simplified diagnostic scoring system was added in 2008 to ease clinical application[65], and both systems can now be exploited to strengthen the diagnosis in difficult cases[66].

Original revised diagnostic scoring system

The revised original diagnostic scoring system developed by the International Autoimmune Hepatitis Group (IAIHG) evaluates 13 clinical components and renders 27 possible grades[10] (Table 2). It is a comprehensive template that grades each component of the disease, including gender, laboratory manifestations of liver inflammation and cholestasis, the conventional autoantibodies, viral markers, epidemiological risk factors such as drug or alcohol exposures, HLA phenotype, concurrent immune diseases, novel autoantibodies, and individual histological features. It also grades the treatment response, and a score can be rendered before and after treatment.

A pre-treatment score of 10 points or higher or a post-treatment score of 12 points or higher indicates the likelihood of autoimmune hepatitis[10] (Table 2). No single test or finding defeats or ensures the diagnosis of autoimmune hepatitis if other components are sufficiently strong to outweigh it. The Receiver Operating Characteristic (ROC) curve for the revised original scoring system shows that the minimum pre-treatment score of 10 points has a sensitivity of 100% and a specificity of 73% for autoimmune hepatitis. A pre-treatment score of 15 points or higher has a specificity of greater than 90% for autoimmune hepatitis[66].

The principal virtues of the revised original scoring

Table 2 Revised original pre-treatment scoring system[10]

Variable	Result	Points	Variable	Result	Points
Gender	Female	+2	HLA	DR3 or DR4	+1
AP:AST (or ALT) ratio	> 3	-2	Immune disease	Thyroiditis, colitis, others	+2
	< 1.5	+2			
γ-globulin or IgG level above normal	> 2.0	+3	Other markers	Anti-SLA, actin, LC1, pANCA	+2
	1.5-2.0	+2			
	1.0-1.5	+1			
	< 1.0	0			
ANA, SMA, or anti-LKM1 titers	> 1:80	+3	Histological features	Interface hepatitis	+3
	1:80	+2		Plasmacytic	+1
	1:40	+1		Rosettes	+1
	< 1:40	0		None of above	-5
				Biliary changes	-3
				Other features	-3
AMA	Positive	-4	Treatment response	Complete	+2
				Relapse	+3
Viral markers	Positive	-3			
	Negative	+3			
Drugs	Yes	-4	Pretreatment aggregate score		
	No	+1	Definite diagnosis		> 15
			Probable diagnosis		10-15
Alcohol	< 25 g/d	+2	Post-treatment aggregate score		
	> 60 g/d	-2	Definite diagnosis		> 17
			Probable diagnosis		12-17

AP: AST (or ALT) ratio: Ratio of alkaline phosphatase level to aspartate or alanine aminotransferase level; Anti-SLA: Antibodies to soluble liver antigen; Anti-LC1: Antibodies to liver cytosol type 1; pANCA: Perinuclear anti-neutrophil cytoplasmic antibodies; IgG: Immunoglobulin G; ANA: Antinuclear antibodies; SMA: Smooth muscle antibodies; Anti-LKM1: Antibodies to liver/kidney type 1; AMA: Antimitochondrial antibodies; HLA: Human leukocyte antigen.

Table 3 Simplified scoring system of the International Autoimmune Hepatitis Group[65]

Variable	Result	Points
Autoantibodies		
ANA or SMA	≥ 1:40	+1
ANA or SMA	≥ 1:80	+2
Antibodies to liver kidney microsome type 1	≥ 1:40	+2
Antibodies to soluble liver antigen	Positive	+2
Immunoglobulin level		
Immunoglobulin G	> UNL	+1
	> 1.1 ULN	+2
Histological findings		
Morphological features	Compatible	+1
	Typical	+2
Viral disease		
Absence of viral hepatitis	No viral markers	+2
Pretreatment aggregate score		
Definite diagnosis		≥ 7
Probable diagnosis		6

ULN: Upper limit of normal.

system are that it ensures the systematic assessment of all key features of the disease and it is not compromised by a missing or atypical feature[66]. The revised original diagnostic scoring system is most useful in evaluating patients with few or atypical findings of autoimmune hepatitis, including the variant syndromes, because of its comprehensive nature. It quantifies the strength of the diagnosis, and it is a valuable research tool that ensures comparable study populations within clinical trials.

Simplified diagnostic scoring system

The simplified diagnostic scoring system eases clinical application by evaluating only 4 clinical components, and it has been validated in diverse ethnic groups and liver diseases[65] (Table 3). The simplified scoring system is based on the presence and level of autoantibody expression by indirect immunofluorescence, serum IgG concentration, compatible or typical histological features, and the absence of viral markers. It does not grade treatment response.

The ROC curve for the simplified scoring system shows that a minimum score of 6 points has a sensitivity and specificity of 90% for the diagnosis of autoimmune hepatitis[66] (Table 3). Scores of 7 points or higher are nearly 100% specific for the diagnosis of autoimmune hepatitis with only a small decrease in sensitivity. The virtues of the simplified scoring system are the ease of its clinical application, and its combined high sensitivity and specificity for the diagnosis[66]. It is especially useful in excluding autoimmune hepatitis in patients with other distinct conditions who have confusing concurrent immune features. The revised original scoring system has greater sensitivity for the diagnosis, whereas the simplified system has superior specificity and accuracy.

NEW TREATMENT STRATEGIES

New treatment strategies for autoimmune hepatitis are evolving as current regimens are being used more effectively and new drugs are being exploited in selected situations. The non-classical phenotypes of autoimmune hepatitis are managed in the same fashion as the classical phenotypes, and they benefit similarly from these advances.

Table 4 Therapeutic advances in autoimmune hepatitis

Advance	Nature	Attribute
Improved current therapy	Initial therapy until resolution of liver tests and tissue	Prevention of relapse after drug withdrawal[70]
	Long-term azathioprine therapy after relapse or incomplete response	Prevention of disease progression[71,73,125]
	Pretreatment vaccination for viruses	Protection against morbidity of concurrent viral infection[74]
New drugs	Calcineurin inhibitors (cyclosporine, tacrolimus)	Salvage therapy[150-157]
	Purine antagonists (6-mercaptopurine, mycophenolate)	Salvage therapy[161-166]
	Budesonide (combined with azathioprine)	Effective and safe front line therapy[75]
Potential molecular interventions	Synthetic blocking peptides	Block autoantigen presentation[186,187]
	Cytokine manipulations	Promote anti-inflammatory effects[188]
	T cell vaccination	Eliminate cytotoxic liver-infiltrating clone[189]
	Oral tolerance (high or low dose regimen)	Reduce immune response (low dose) or induce anergy (high dose)[190,191]
	Mesenchymal stem cells (human bone marrow-derived)	Replace damaged hepatocytes[200]

Improvements in current treatment strategies

The ideal end point of initial corticosteroid therapy has now been defined[67-70]; the treatment adjustments after relapse and incomplete response have been formalized[71-73]; and vaccination against hepatitis A (HAV) and hepatitis B (HBV) viruses prior to therapy has been proposed[74]. These improvements constitute advances in the current treatment regimens (Table 4).

Corticosteroid therapy should be continued until the clinical, laboratory and histological features of autoimmune hepatitis have fully resolved (Table 4)[67-70]. Relapse after drug withdrawal is the most common management problem in autoimmune hepatitis, and this occurrence can be reduced by continuing treatment until liver tests and tissue are normal[59,70,163]. Patients who sustain remission after treatment withdrawal have better laboratory indices and liver tissue examinations at the time of drug withdrawal than patients who relapse, and treatment until complete resolution of the inflammatory features is the ideal end point of therapy.

Sixty percent of patients who achieve an ideal treatment end point still relapse after drug withdrawal, and 40% of treated patients are unable to achieve full resolution of their disease[70]. The relentless pursuit of an ideal but unachievable treatment end point in these individuals can result in drug-related side effects[59,62]. Patients with relapse after drug withdrawal, incomplete response to conventional treatment, and drug intolerances must be managed differently[125].

Repeated relapse and re-treatment is associated with a progressive increase in the cumulative frequencies of cirrhosis, requirement for liver transplantation, and death from hepatic failure[64]. The preferred management strategy after the first relapse is to institute treatment with long-term fixed dose azathioprine (Table 4)[71,73]. Prednisone and azathioprine are re-started until clinical and laboratory resolution is achieved. The dose of azathioprine is then increased to 2 mg/kg daily as the dose of prednisone is withdrawn. Azathioprine is then continued indefinitely as a chronic maintenance therapy. Eighty percent of patients are able to sustain remission in this fashion over a 10 year period of observation. Patients who improve during treatment but not to a degree to satisfy remission criteria (incomplete response) can also be managed by this regimen[125].

Vaccination against HAV and HBV is an important adjunct to conventional treatment (Table 4). Susceptibility to infections with HAV (51%) and HBV (86%) is high in patients with autoimmune liver disease, and the incidence of these infections is 1.3-1.4 per 1000 person-years[74]. Vaccination frequencies are only 11% for HBV and 13% for HAV in these patients, and the response to the HBV vaccine is poor or absent in most individuals vaccinated during immunosuppressive therapy[74]. These observations suggest that pre-treatment vaccination for HAV and HBV is under-utilized in autoimmune liver disease and that outcomes can be improved by early vaccination to prevent viral super-infection and mortality.

Advances in pharmacological options

Treatment options have increased in autoimmune hepatitis as new drugs with targeted immunosuppressive actions have been used empirically[76,164] and a third generation corticosteroid has been evaluated by randomized clinical trial[75]. None of these treatments has been incorporated into standard management algorithms, but they constitute an evolving armamentarium that promises to improve outcomes by either interrupting critical pathogenic pathways or eliminating intolerances to the current medications.

The calcineurin inhibitors (cyclosporine[165-169] and tacrolimus[170-172]) have been used as frontline and salvage therapies in children[173-175] and adults[165-172] with autoimmune hepatitis, and these multiple small clinical experiences have supported their efficacy and tolerance (Table 4). Additional clinical trials are necessary to determine their target population, dosing schedule, and safety profile.

The purine antagonists (6-mercaptopurine[176] and mycophenolate mofetil[177-181]) have also been effective in some patients refractory to conventional corticosteroid regimens (Table 4). 6-mercaptopurine has reduced disease activity in patients unresponsive to azathioprine, and should be considered as a salvage therapy[176]. Intolerances to azathioprine based on thiopurine methyltransferase deficiency contraindicate its use, and the drug should not be administered to patients with

azathioprine-related side effects[182].

Mycophenolate mofetil is independent of the thiopurine methyltransferase metabolic pathway, and several small experiences have indicated that it can be effective in problematic patients[177-181] (Table 4). Improvement occurs in 39%-84% of patients who tolerate the drug, but the intention to treat is thwarted in 34%-78% of patients because of drug intolerances (nausea, vomiting, pancreatitis, rash, alopecia, deep venous thrombosis, diarrhea and failure to normalize liver tests)[180,183,184]. Mycophenolate mofetil is another promising alternative drug in the treatment of autoimmune hepatitis, but only a minority of problematic patients may reap its benefits[183-185].

Budesonide is a third generation corticosteroid that has been used empirically as frontline[186-188] and salvage[189] therapy in autoimmune hepatitis (Table 4). Its high first-pass clearance by the liver and its breakdown to inactive metabolites promised to improve efficacy and safety compared to conventional corticosteroid regimens[190]. Its advantage, however, was never fully realized until it was evaluated by randomized clinical trial in 203 treatment-naïve patients with autoimmune hepatitis[75]. Budesonide in combination with azathioprine has been found to be superior to prednisolone and azathioprine in normalizing the serum ALT level (47% *vs* 18%, $P < 0.00001$) and reducing the frequency of steroid-related side effects (28% *vs* 53%, $P = 0.0001$) after 6 mo of treatment[75]. The frequency of histological improvement and the durability of the results are unknown, but the findings suggest that budesonide may be an alternative, more effective, and safer frontline regimen than a prednisone-based schedule. Budesonide has not been effective as a salvage therapy in patients with severe disease on long-standing corticosteroid treatment[189], and corticosteroid-induced side effects are still possible, especially in patients who have been treated previously with prednisone[189] or who have cirrhosis[189,191].

Various other drugs (cyclophosphamide[192], methotrexate[193], rapamycin[194], rituximab[195], intravenous immunoglobulin[196], deflazacort[197], and ursodeoxycholic acid[198]) have been proposed for use in autoimmune hepatitis, and their number reflects the need for better salvage therapies in the treatment of autoimmune hepatitis (Table 4). Prospective and scientifically rigorous collaborative studies are needed to expand the therapeutic repertoire and comprehensive analyses are required to demonstrate that these incremental improvements in outcome are cost-effective[199,200].

Site-specific molecular inventions, including antigen-blocking synthetic peptides[201,202], cytokine manipulations[203], T cell vaccination[204], and oral tolerance regimens[205,206], become feasible when the critical pathogenic mechanisms of the disease are clarified[207-209], and confident animal models of the human disease are developed[210-214] (Table 4). Mesenchymal stem cells from human bone marrow that can differentiate into functional hepatocytes have the potential to rescue individuals from liver failure, reduce reliance on whole organ transplantation, and obviate the complications of whole organ rejection and drug toxicity[215] (Table 4). The treatment options for autoimmune hepatitis are already plentiful and effective, but the drive for further improvement must be continuous and vigorous.

CONCLUSION

Autoimmune hepatitis can have acute severe or asymptomatic presentations, centrilobular zone 3 necrosis, concurrent bile duct damage or non-alcoholic fatty changes on histological examination, absent or atypical serological markers, cholangiographic abnormalities, and variable clinical phenotypes related to gender or ethnicity. These non-classical manifestations do not alter the management strategy, but they require prompt recognition and confident diagnosis. The revised original diagnostic scoring system of the IAIHG is useful in evaluating patients with few or atypical findings of autoimmune hepatitis because of its comprehensive nature. The simplified diagnostic scoring system is useful in excluding autoimmune hepatitis in patients with other distinct conditions who have confusing concurrent immune features because of its high specificity. Current treatment regimens have been improved by pursuing resolution of liver tests and liver tissue prior to drug withdrawal, instituting long-term azathioprine therapy after the first relapse, and vaccinating against HAV and HBV prior to treatment. Cyclosporine, tacrolimus, 6-mercaptopurine, and mycophenolate mofetil are promising salvage therapies, whereas budesonide in combination with azathioprine may be a superior frontline therapy to prednisone and azathioprine.

Abstract

AIM: To evaluate the possible role of Tribble 3 (TRB3) in a rat model of non-alcoholic fatty liver disease (NAFLD) and its signal transduction mechanism.

METHODS: Thirty Sprague-Dawley rats were randomized into three groups: normal control group, non-alcoholic fatty liver group A (fed on a high-fat diet for 8 wk) and group B (fed on a high-fat diet for 16 wk). To determine the degree of hepatic steatosis in rats of each group, livers were stained with hematoxylin and eosin, and evaluated; real-time fluorescent quantitative reverse transcriptase-polymerase chain reaction was performed to measure the expression levels of TRB3 mRNA; and Western blotting analysis was done to determine the expression levels of protein kinase B (Akt) and phosphorylated protein kinase B (p-Akt-Thr308, p-Akt-Ser473).

RESULTS: Hepatic steatosis was evident in both NAFLD groups: mild to moderate hepatic steatosis occurred in group A, mainly as mild steatosis. Moderate to severe hepatic steatosis occurred in group B, mainly as severe steatosis. The expression level of TRB3 mRNA in group B was significantly higher than in the control group (122.28 ± 95.37 *vs* 3.06 ± 2.33, $P = 0.001$) and group A (122.28 ± 95.37 *vs* 5.77 ± 4.20, $P = 0.001$). There was no significant difference in the expression levels of Akt (1.03 ± 0.53 *vs* 1.12 ± 0.77, $P = 0.729$) and p-Akt-Thr308 (0.82 ± 0.45 *vs* 0.92 ± 0.38, $P = 0.592$) between group A and the control group. The expression level of Akt and p-Akt-Thr308 in group B was significantly lower than in group A (Akt 0.41 ± 0.16 *vs* 1.12 ± 0.77, $P = 0.008$; p-Akt-Thr308 0.47 ± 0.19 *vs* 0.82 ± 0.45, $P = 0.036$) and the control group (Akt 0.41 ± 0.16 *vs* 1.03 ± 0.53, $P = 0.018$; p-Akt-Thr308 0.47 ± 0.19 *vs* 0.92 ± 0.38, $P = 0.010$). The expression level of p-Akt-Ser473 in group A was significantly higher than in group B (1.48 ± 0.50 *vs* 0.81 ± 0.39, $P = 0.041$) as well as the control group (1.48 ± 0.50 *vs* 0.45 ± 0.26, $P = 0.003$).

CONCLUSION: TRB3 blocks insulin signaling by inhibiting Akt activation, which contributes to insulin resistance. It may be an important factor in the occurrence and development of NAFLD.

Key words: Non-alcoholic fatty liver disease; Rat; Tribble 3; Protein Kinase B; Insulin resistance

INTRODUCTION

Three pseudo kinases of the Tribble family[1,2] have been recognized recently, which include Tribble 1 (TRB1), TRB2 and TRB3. Different from the typical kinase domain structure, tribbles lack a conventional ATP binding site and activity domain of protein kinases. Thus, no kinase activity by tribbles has been detected. They are classified as members of the family of pseudo-kinases[3]. TRB3 is a mammalian homolog[4] of *Drosphila* tribbles and is also called a neuronal cell death-inducible putative protein kinase gene in rodents. TRB3 is located

on the 20p13 region of the human chromosome[5]. Its full-length translated region in mRNA is 1074 bp, its protein product is made of 358 amino acids and it is a kind of nucleoprotein.

Studies indicate that TRB3 is involved in many biological processes, including insulin resistance (IR), blocking of insulin signaling pathway[6], endoplasmic reticulum stress responses[7] and the regulation of cell growth and differentiation[8,9]. Du *et al*[6] have found that the expression of hepatic TRB3 increased in a rat model of diabetes. It inhibits the activation of the Akt/PKB signaling pathway by insulin, resulting in IR. TRB3 inhibits the phosphorylation of Thr-308 and Ser-473 by binding with them, thus inhibiting the activity of Akt. Then, the insulin signaling pathway is blocked.

Research by Chitturi *et al*[10] indicates that IR exits in about 98% of patients with non-alcoholic fatty liver disease (NAFLD). IR is possibly of key importance in inducing NAFLD. Therefore, any factor related to IR may play an important role in the development of NAFLD. Therefore, TRB3 may not only be a cause of IR, but also an important factor in the occurrence and development of NAFLD. Rat models of NAFLD have been developed by feeding them a high-fat diet. The objective was to study the expression of TRB3 mRNA using reverse transcriptase-polymerase chain reaction (RT-PCR) in rat models of NAFLD, and to evaluate the role of TRB3, using Western blotting analysis, in the occurrence and development of NAFLD.

MATERIALS AND METHODS

Animals

Thirty healthy Sprague-Dawley rats weighing 210-260 g (15 male and 15 female) were purchased from Shanghai Slac Laboratory Animal Co. Ltd., Chinese Academy of Sciences. The rats were fed normal food for 1 wk.

Reagents

The materials for the high-fat-diet rat models and the reagents for pathological tests were all purchased from Shanghai Lanji Technology Development Co., Ltd.; Trizol and SYBR Green I were purchased from Invitrogen. Akt (A444) antibody, p-Akt (S473) antibody and p-Akt (T308) antibody were obtained from Bioworld. Actin and horseradish peroxidase (HRP)-labeled goat anti-rabbit IgG (H + L) were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA). PVDF membranes were supplied by Millipore. Diaminobenzidine was purchased from Sigma. DEPC-treated Water, TBE and loading buffer were obtained from Shanghai Gene and Biotech Co., Ltd. Taq enzyme and random primers were supplied by Takara Biotechnology (Dalian) Co., Ltd. RNase inhibitor, dNTP, Moloney murine leukemia virus and TEMED were procured from Promega. DTT, SDS, Tris, Glycin, N, N'-Methylene bisacrylamide and acrylamide were obtained from Amresco. BSA was acquired from the Huamei Biotech Company (packaged separately after being imported). Protein markers were purchased by the Shanghai Institute of Biochemistry, Chinese Academy of Sciences. Methyl alcohol was purchased from the Sinopharm Reagent Group (Shanghai, China).

Apparatus

Applied Biosystems 7500 Real-Time PCR System, Vertical Electrophoresis Tank, Electrophoresis Apparatus PAC3000 and Semi-Dry Transfer Unit were purchased from Bio-Rad; high-speed freezing centrifuge, Centrifuge 5417R, was purchased from Eppendorf; Gel Imaging System (GIS)-2008 was purchased from Shanghai Tanon Science & Technology Co., Ltd.; electronic balance BP310P was from Sartorius; pipettes were from Gilson; glass homogenizer was from Ningbo Scientz Scientific Instruments Research Institute; UV-VIS Spectro Photometer Unico UV-2000 was from Unico (Shanghai) Instruments Co., Ltd.; ultrapure water system from Millipore; and ultrasonic cell disruption system Soniprep150 from SANYO.

Animals

The rats were divided into three groups according to random number tables. The control group (n = 10) was fed on a normal diet; NAFLD groups (n = 20) were fed on high-fat diet, which was prepared by adding 10% lard and 2% cholesterol to the normal diet. Group A (n = 10) was fed on high-fat diet for 8 wk and group B (n = 10) was fed on high-fat diet for 16 wk. All the rats lived in an air-conditioned room at room temperature at 18-23℃ and 60% humidity. All the rats were fed *ad libitum* and had free access to water.

Histopathology

According to the schedule of the experiment, the rats were anesthetized with 2.5% pentobarbital sodium solution (1.5 mL/kg), injected into the abdominal cavity after an overnight fasting. They were sacrificed after blood samples were taken from the inferior vena cava, and the livers were removed immediately. Serum and liver paraffin embedded tissue sections were prepared according to routine methods. The liver specimens were fixed in a neutral formalin solution. The tissue sections were hematoxylin and eosin (HE), and the HE-stained sections were examined under a light microscope for the evaluation of hepatic steatosis.

Measurements for observation indexes

Fluorescent quantitative RT-PCR for measurement of TRB3 mRNA expression levels: RNA extraction and cDNA synthesis: The Trizol method was used to extract total RNA from tissues and an UV-VIS Spectrophotometer was used to determine the purity and concentration. Two micrograms of total RNA was reverse transcribed into cDNA.

Real-time fluorescent quantitative PCR: The SYBR

Table 1 Expression levels of TRB3 mRNA, Akt, p-Akt-Thr308, p-Akt-Ser473

Group	Case	TRB3 mRNA (10^{-5})	Akt	p-Akt-Thr308	p-Akt-Ser473
Control	10	3.06 ± 2.33	1.03 ± 0.53	0.92 ± 0.38	0.45 ± 0.26

B	10	122.28 ± 95.37[b]	0.41 ± 0.16[b]	0.47 ± 0.19[b]	0.81 ± 0.39[c]

[b]$P < 0.01$ *vs* control group/group A; [c]$P < 0.05$ *vs* group A.

Green I dye method was adopted. GADPH and TRB3 were amplified by reverse transcription. After gel electrophoresis of amplified products, a fully-automatic Gel Imaging System was used to analyze mRNA expression to compare the intensity between the groups. All the results were normalized to GADPH. The GADPH primers were used as follows: upstream primer: 5'-ACCACAGTCCATGCCATCAC-3', downstream primer: 5'-TCCACCACCCTGTTGCTGTA-3'. The length of the amplified product was 440 bp. The TRB3 primers were used as follows: upstream primer: 5'-TCA TCTTGCGCGACCTCAA-3', downstream primer: 5'-TCCACCACCCTGTTGCTGTA-3'. The length of the amplified product was 296 bp. Thirty-six cycles of pre-degeneration at 95℃ for 2 min, degeneration at 95℃ for 10 s, annealing at 50℃ for 10 s, and extension at 72℃ for 45 s were used for all experiments.

Western blotting analysis for the expression levels of total Akt and phosphorylated Akt (p-Akt-Thr308, p-Akt-Ser473): Equal samples of tissue were prepared and put into protein extracts to be ground as plasm form. Then the plasm was high-speed centrifuged under freezing conditions for protein extraction. The protein concentration was determined according to the fixed steps. The protein samples (30 μL) were subjected to SDS-PAGE electrophoresis, transferred to PVDF membranes, and shaken on a rotary shaker at room temperature for 2 h. After that, a TBST buffer solution was used to wash the membrane three times. Then, Akt-related antibodies (Akt1, p-Akt-Thr308, p-Akt-Ser473) were incubated at 4℃ overnight under constant shaking on a rotary shaker. After three washes with TBST buffer solution, HRP-labeled goat anti-rabbit IgG (H + L) was incubated at room temperature while shaking on a rotary shaker for 2 h. NBT/BCIP reagent was applied for color development. The membrane was rinsed with deionized water. All the procedures were repeated three times. β-actin was chosen as an internal control. The GIS was used for data analysis, and statistical analysis was used to detect differences between samples and the internal control.

Statistical analysis

SPSS11 software was used for the statistical analysis. All the statistical data were expressed as mean ± SD for single factor analysis of variance and paired comparisons were performed by the least-square deconvolution method. Two-tailed tests ($\alpha = 0.05$) were used for statistical treatment. $P < 0.05$ was considered a significant difference.

RESULTS

Histopathological changes

A high-fat diet causes obvious hepatic steatosis in rats, which was evident for both model groups. Mild to moderate hepatic steatosis occurred in group A, mainly as mild steatosis. Moderate to severe hepatic steatosis occurred in model group B, mainly as severe steatosis. Mild hepatic steatosis tissue was defined as hepatic steatosis that accounted for 30%-50% of the total liver cells in the microscopic field; for moderate hepatic steatosis, liver cells with hepatic steatosis accounted for 50%-75% of the total liver cells; and for severe hepatic steatosis tissues, liver cells with hepatic steatosis accounted for over 75% of the total liver cells. In portal areas, severe inflammation featured infiltration of large numbers of diffuse lymphocytes and neutrophils, destroyed limiting plates and hepatic lobules were infiltrated by inflammatory cells that surrounded liver cells (Figure 1).

Fluorescent quantitative RT-PCR for measurement of TRB3 mRNA expression levels

We adopted real-time fluorescent quantitative RT-PCR methods to measure the expression levels of TRB3 mRNA in rats (Figure 2A-C). The relation ($r = 0.99$) between amplified results of PCR and Ct value of standard samples is shown in Figure 2C. From the melting curve, no primer dimer formation was detected during the PCR reaction (Figure 2B). We found that the expression level of TRB3 mRNA in group B was significantly higher than in the control group (122.28 ± 95.37 *vs* 3.06 ± 2.33, $P = 0.001$) and group A (122.28 ± 95.37 *vs* 5.77 ± 4.20, $P = 0.001$). There was no significant difference (5.77 ± 4.20 *vs* 3.06 ± 2.33, $P = 0.914$) in the expression levels of TRB3 between group A and the control group (Figure 3, Table 1). All these data indicate that a simple hepatic steatosis pathomorphism showed no significant difference between group A and the control group for the expression of TRB3 mRNA. As the time to set up the model increased, the degree of hepatic steatosis was raised. When the model deteriorated to show evidence of a fatty hepatitis pathomorphism, the expression of TRB3 mRNA was significantly higher.

Western blotting analysis for the expression levels of total Akt and phosphorylation Akt (p-Akt-Thr308, p-Akt-Ser473)

The protein bands of Akt p-Akt-Thr308 and p-Akt-

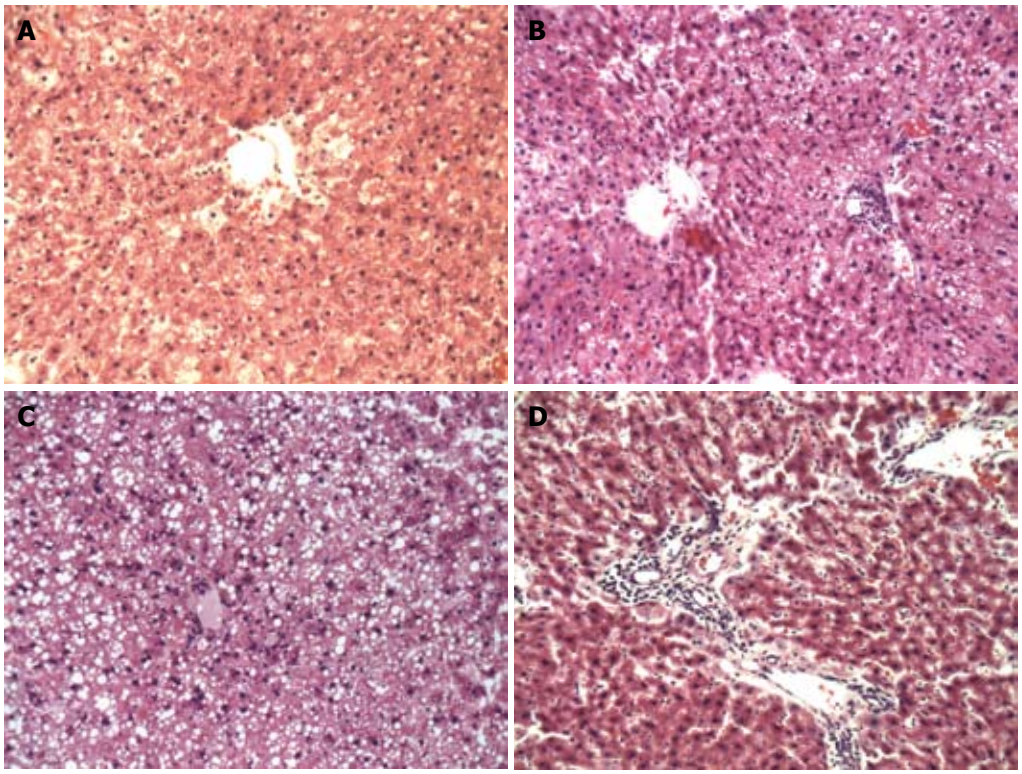

Figure 1 The degree of hepatic steatosis in each group. A: In group A, mild hepatic steatosis was observed on histological examination (HE, × 200); B: In group A, moderate hepatic steatosis was observed (HE, × 200); C: In group B, hepatocytes showed severe hepatic steatosis. Liver cells with hepatic steatosis accounted for over 75% of the total liver cells (HE, × 200); D: In group B, hepatocytes showed severe steatosis along with portal inflammation (HE, × 200).

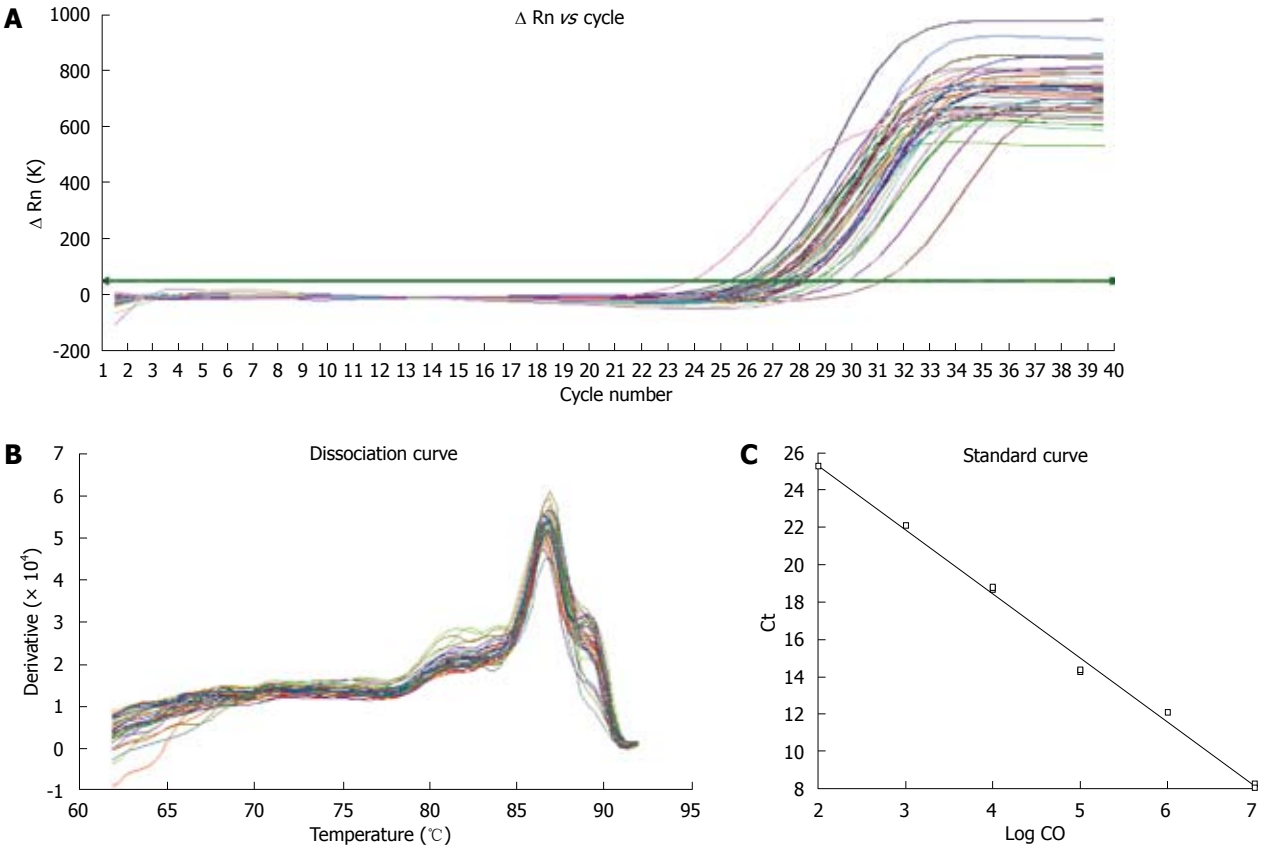

Figure 2 Fluorescent quantitative PCR for measurement of TRB3 mRNA expression levels. Real-time PCR was used for absolute quantification analysis. A: Amplification curve with the threshold value set in the exponential growth phase; B: Melting curve showing no primer dimer in PCR reaction; C: Standard curve for the relation (r = 0.99) between amplified results of PCR and Ct value of standard samples was in accordance with the requirements of real-time PCR. The intensities of fluorescent signals indicated the variation of product concentrations.

Ser473 are shown for each group. There was no significant difference in the expression levels of Akt (1.03 ± 0.53 *vs* 1.12 ± 0.77, P = 0.729) and p-Akt-Thr308 (0.82 ± 0.45 *vs* 0.92 ± 0.38, P = 0.592) between group A and

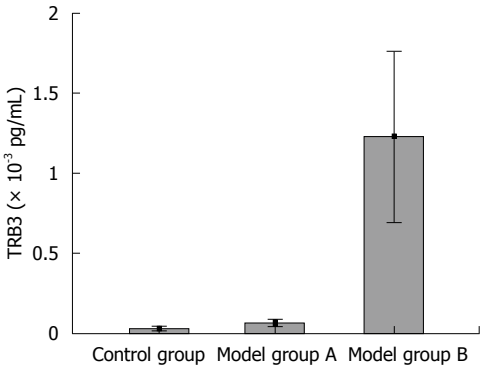

Figure 3 Comparison of TRB3 expression levels among the three groups. The TRB3 mRNA expression level in group B was significantly ($P < 0.01$) higher than in the control group and group A. There was no significant difference ($P > 0.05$) between group A and the control group.

the control group. However, the expression levels of Akt and p-Akt-Thr308 in group B was significantly lower than in group A (Akt 0.41 ± 0.16 *vs* 1.12 ± 0.77, $P = 0.008$; p-Akt-Thr308 0.47 ± 0.19 *vs* 0.82 ± 0.45, $P = 0.036$) and the control group (Akt 0.41 ± 0.16 *vs* 1.03 ± 0.53, $P = 0.018$; p-Akt-Thr308 0.47 ± 0.19 *vs* 0.92 ± 0.38, $P = 0.010$). The expression level of p-Akt-Ser473 in group A was significantly higher than in group B (1.48 ± 0.50 *vs* 0.81 ± 0.39, $P = 0.041$) as well as the control group (1.48 ± 0.50 *vs* 0.45 ± 0.26, $P = 0.003$) (Table 1). All these data indicate that a simple hepatic steatosis pathomorphism does not produce a significant difference between the model group and the control group in the expression of total Akt. As the rats were exposed to longer periods of a high-fat diet, the degree of hepatic steatosis was increased. When the rats deteriorated to a fatty hepatitis pathomorphism, the expression of total Akt, p-Akt-Thr308 and p-Akt-Ser473 was significantly lower than the simple fatty liver disease modeled by group A and the control group.

DISCUSSION

NAFLD has increased in recently years, and is one of the major causes for cryptogenic cirrhosis[11,12]. The pathogenesis of NAFLD is complicated. There is an interaction between genetic susceptibility and multiple metabolic disorders involved in the disease. The pathophysiologic basis of the condition is mainly insulin resistance and oxidative stress. No perfect theory exists for all its clinical manifestations[13,14]. At present, IR along with hepatocyte fatty degeneration is believed to be a key factor in the occurrence and development of fatty liver disease[15,16]. Research indicates[10] that IR exits in about 98% of patients with NAFLD. IR is probably of key importance for the induction of NAFLD. Therefore, any factor related to IR may play an important role in NAFLD.

Studies indicate that TRB3 is involved in many biological processes, including IR and blocking of the insulin signaling pathway[6,17]. In this study, we generated a rat model of NAFLD using a high-fat diet. Group A modeled simple fatty liver, and we continued to feed the rats with the high-fat diet. Simple hepatic steatosis produced no significant difference between the model group and the control group in the expression of TRB3 mRNA. As the rats were exposed to longer periods with the high-fat diet, the extent of hepatic steatosis was raised. When the condition of the rats deteriorated to a fatty hepatitis pathomorphism (group B), the expression of TRB3 mRNA became significantly higher. This result indicates that TRB3 is involved in the occurrence and development of NAFLD.

On the basis of recent research, through this study, we made further efforts to discover the possible mechanism of TRB3 involved in the occurrence and development of NAFLD. One study has shown that IR is related to the insulin signaling pathway phosphoinositide 3-kinase/protein kinase B (PI3-K/PKB)[18]. Akt is a key protein[19] in the PI3-K insulin signaling pathway. Two of its sites need to be phosphorylated[20,21] for its normal physiological function. One site is Thr-308, located in the kinase domain, and the other one is Ser-473, located in hydrophobic motif of the regulatory domain. After the binding of insulin and its receptors in the cell membrane, the upstream signaling proteins in this pathway are activated step by step. Thr-308 and Ser-473[22,23] phosphorylation sites for Akt are activated, and then endocytose from membrane to cytoplasm, which starts a cascade of reactions of the downstream related substrate proteins. Through this process, insulin contributes to glycogen synthesis, glucose transport, glycolysis and the inhibition of gluconeogenesis[24]. The quantity of Akt decreases and its activity changes in rats with IR[25]. Ijuin *et al*[26] have found that TRB3 may inhibit the signal transduction of insulin-activated PI3-K in CHO cells, which suggests that TRB3 affects insulin signal transduction and inhibits uptake and utilization of glucose by cells. Du *et al*[6] and Matsushima *et al*[27] have found that in the hepatic cells of TRB3 transgenic rats, TRB3 inhibited the phosphorylation and activation of Thr-308 and Ser-473 of Akt, but did not affect the protein expression of Akt. Therefore, TRB3 may decrease glucose tolerance and cause blood glucose elevation. The phosphorylation of substrate proteins like glycogen synthase kinase-3β by Akt was inhibited, and glycogen synthesis and the function of insulin on glucose metabolism was also lowered. TRB3 plays an important role in IR. TRB3 gene knockouts may increase the sensitivity of hepatic cells to insulin stimulation. The activity of Akt may be enhanced, and blood glucose levels may be lower[28]. The above mentioned studies indicate that TRB3 could block the insulin signaling pathway through inhibiting Akt activation[6]. Since TRB3 inhibits the phosphorylation of Thr-308 and Ser-473 by binding with them, it inhibits the activity of Akt. As a result, the insulin signaling pathway is blocked. Our results also support this hypothesis. When the pathomorphism was simple hepatic steatosis, there was no significant difference between the model group and control group in the expression of TRB3

mRNA. The expression level of total Akt did not change much either. As the degree of hepatic steatosis was raised and deteriorated to fatty hepatitis, the expression of total Akt, p-Akt-Thr308 and p-Akt-Ser473 was significantly lower than that in the simple fatty liver model group.

The data for p-Akt-Ser473 in Table 1 show that in mild steatosis (group A), expression levels are much greater than control while in severe steatosis (group B), levels go back to the control value. We assume that the complex regulation of active molecules *in vivo* may lead to another pathway. Balendran *et al*[29] have shown that 3-phosphoinositide-dependent protein kinase-1, Akt and protein-kinase-C-related kinase-2 interact with each other after the phosphorylation of Thr308, which can be converted into 3-phosphoinositide-dependent protein kinase-2 (PDK2) and modify Ser473. Kroner *et al*[30] have found that the existence of PDK2 can be proven by the complex relationship between Thr308 and Ser473, which is phosphorylated independently. A study by Ferguson *et al*[31] has shown that Akt can be activated in a PI3-K-independent pathway. Therefore, this interesting phenomenon is worthy of further study.

In conclusion, TRB3 can block the insulin signaling pathway by inhibiting the activation of Akt[32,33], and contributing to IR. Therefore, TRB3 may be an important factor in the occurrence and development of NAFLD. This study provides an experimental basis for future studies about the role of TRB3 in NAFLD. The control of the expression level of TRB3 in liver may become a new target for NAFLD therapy.

COMMENTS

Background

Tribble 3 (TRB3) is involved in many biological processes, including insulin resistance (IR), blocking of the insulin signaling pathway, endoplasmic reticulum stress responses, and the regulation of cell growth and differentiation. Any factor related to IR will play an important role in the development of non-alcoholic fatty liver disease (NAFLD). Therefore, the authors of this study investigated the relationship between TRB3 and IR, and aimed to establish its importance in the occurrence and development of NAFLD.

Research frontiers

The study is the first to evaluate the role of TRB3 with IR in NAFLD. The potential effect of TRB3 is likely to block the insulin signaling pathway through inhibiting Akt activation. TRB3 may play an important role in the occurrence and development of NAFLD.

Innovations and breakthroughs

This study explained one of the possible mechanisms of IR, which could produce a potentially facilitative effect on the occurrence and development of NAFLD.

Applications

This study provides an experimental basis for future studies on the role of TRB3 in NAFLD. The control of the expression level of TRB3 in liver may become a new target for therapy for NAFLD.

Peer review

In the present study, the authors tested the effect of TRB3 in NAFLD in rats, and found a facilitative effect in the occurrence and development of NAFLD.

Abstract

AIM: To investigate the association between individual or combined use of non-steroidal anti-inflammatory drugs (NSAIDs) or statins and colorectal cancer risk.

METHODS: In a population-based case-control study in women, we examined the association between NSAIDs and statin use and the risk of colorectal cancers. We further investigated whether the use of statins modifies the protective effect of NSAIDs. Female cases (n = 669) of colorectal cancer aged 50-74 years were identified from a statewide registry in Wisconsin during 1999-2001. Community control women (n = 1375) were randomly selected from lists of licensed drivers and Medicare beneficiaries. Medication use and risk factor information were gathered during a structured telephone interview. A multivariable logistic regression model was used to calculate odds ratio (OR) and 95% confidence interval (CI).

RESULTS: Overall, NSAIDs users had a 30% reduction in risk of colorectal cancer (95% CI: 0.56-0.88). Statin use was not associated with colorectal cancer risk (OR = 1.17, 95% CI: 0.74-1.85), regardless of structural type (lipophilic or hydrophilic), duration of use, or recency. There was no evidence of an interaction between NSAIDs and statins and colorectal cancer risk (P-interaction = 0.28).

CONCLUSION: Although our results confirm the inverse association between NSAIDs use and colorectal cancer risk, they do not support a risk reduction in statin users, or an interaction effect of combined NSAIDs and statin use.

Key words: Non-steroidal anti-inflammatory drugs; Statin; Colorectal cancer; Cancer prevention; Chemoprevention

INTRODUCTION

There is strong evidence for a reduced risk of colorectal cancer in regular users of non-steroidal anti-inflammatory drugs (NSAIDs)[1,2] and some promising but inconsistent observational data regarding a role of statins in this risk[3-11]. An interaction between the use of NSAIDs and statin on the risk of colorectal cancer is suggested by both *in vivo* and *in vitro* studies[5,12,13].

NSAIDs induce apoptosis in colon cancer cells[14,15]. By blocking cyclooxygenase enzymes, they also inhibit prostaglandin production, which is known to promote tumor angiogenesis and cell proliferation[1]. Statins have anti-neoplastic effects through both HMG-CoA (3-hydroxy-3-methyl-glutaryl-CoA) dependent and independent processes[13,16,17]. Inhibition of the prenylation of cell signaling proteins, as well as the anti-inflammatory and anti-oxidative properties of statins, are thought to be responsible for their anti-cancer effects[16]. Augmentation of sulindac or celecoxib induced apoptosis by Lovastatin in colon cancer cell lines and

the increased activation of caspase-3, a pro-apoptotic protein, in combined statin and NSAIDs use[12,18], suggest a synergistic anti-cancer effect. These observations have also been supported by some observational data[5].

The purpose of this study was to investigate the effects of NSAIDs and statin use in relation to colorectal cancer in a population-based case-control study in women. We also investigated whether the use of statins modified the relationship between NSAIDs and statins.

MATERIALS AND METHODS

Female cases (n = 669) of colorectal cancer aged 50-74 years were identified from the Wisconsin cancer reporting system, the statewide tumor registry, during 1999-2001. Registry reports included stage, histology and limited treatment information. Of the 1038 eligible cases, 170 (16.4%) were deceased, 19 (1.8%) were not contacted due physicians' disapproval, 22 (2.1%) could not be located and 154 (14.8%) declined to participate, resulting in a 65% response rate. We also excluded four cases with unreliable interviews. Community control (n = 1375) women were randomly selected to match the age distribution of cases from two sampling frames: lists of licensed drivers (age < 65 years) and Medicare beneficiaries (age ⩾ 65 years). Women were ineligible as controls if they reported a history of colorectal cancer. The response rate for controls was 79%.

Structured telephone interviews were conducted to obtain information regarding medication use, including NSAIDs and statins, and other factors (Table 1). We considered the most commonly used statins that were approved by the Food and Drug Administration from 1995 through 2000. Having ever used NSAIDs or statins was confined to subjects who reported using the medications for at least 30 d. We defined the duration of each period of NSAIDs or statin use. Use of these preparations within one year before the reference year was considered as current use. We categorized statins according to whether they were lipophilic (simvastatin, lovastatin and fluvastatin) or hydrophilic (pravastatin), as it has been suggested that the anti-cancer activity of statins might be limited to the ones with lipophilic structure[16].

Odds ratios (OR) and 95% confidence intervals (CI) were calculated from multivariable logistic regression models to estimate the associations between NSAIDs and statins with the risk of colorectal cancer. We also evaluated possible interaction between NSAIDs and statin use by including a cross-product term of "ever use" of these medications in the regression model. We adjusted for the potential confounding factors (Table 1) by including them in the multivariate models.

RESULTS

Overall, 657 cases of colorectal cancer and 1342 controls were included in the analysis (Table 1). The prevalence of regular NSAIDs use in the sample was 33% (20% aspirin and 13% non-aspirin, 26% current users). The prevalence of statin use was 7% (6% current users, 5% lipophylic and 2% hydrophylic) (Table 2).

[1]Control percentages were age-adjusted to the cases age distribution. In this table, percentages are based on excluding unknowns in that category.

Those who had ever used NSAIDs had a 30% decrease in colorectal cancer risk (OR = 0.70; 95% CI: 0.56-0.88) compared to those who had never used NSAIDs. The risk reduction was statistically significant in current users but not in former users and there was no trend for increasing duration (P = 0.75).

Having ever used statins was not associated with colorectal cancer risk (OR = 1.17; 95% CI: 0.74-1.85) regardless of the type of statin (lipophilic or hydrophilic). Neither long term (> 3 years) nor current statin use were associated with risk.

Having ever used both NSAIDs and statins was not associated with colorectal cancer risk (OR = 0.96; 95% CI: 0.49-1.78). The association between NSAIDs use and colorectal cancer risk was not modified by use of statins (P-interaction = 0.28) (data not shown).

DISCUSSION

Our finding of a 30% reduced risk of colorectal cancer with NSAIDs use is consistent with the current evidence. The observed colorectal cancer risk reductions range from 20% to 40%, possibly due to the heterogeneity of study designs[1].

In contrast to our findings on NSAIDs use, we did not observe an association between statin use and colorectal cancer risk. This association has been examined in secondary analyses of randomized controlled trials that

did not show a risk reduction among users[19]. The small number of colorectal cancer cases should be considered while interpreting these trial results as they were designed to measure cardiovascular outcomes. Observational studies have also produced inconsistent findings. While two case-control studies[5,10] reported risk reduction in long term statin users, other studies[3,4,6,9,10] did not show such an inverse association[20-25]. In a large case-controlled study[10] of 1953 cases and 2015 controls, a 50% reduction in colorectal cancer risk (OR = 0.53; 95% CI: 0.38-0.74) was observed in long term statin users (more than 5 years).The difference between databases from which the cases and controls were selected might have influenced the results. In their study, all the incident cases from northern Israel were included, while controls were recruited from a health maintenance organization, possibly making them more likely to have a healthier life style. In another population-based case-controlled study conducted in Germany[5] (537 cases and 612 controls), a 35% risk reduction (OR = 0.65; 95% CI: 0.43-0.99) was observed among statin users. However, after adjustment for NSAIDs use, the estimate did not remain statistically significant.

We also did not find any combined effect for NSAIDs and statins. To our knowledge, only two other population-based studies[3,5] have looked at the combined effect of NSAIDs and statins on colorectal cancer risk. While one[5] suggested a stronger risk reduction in combined users than we hypothesized, neither found evidence of a statistically significant interaction between NSAIDs and statin use (*P* interactions = 0.37 and 0.21, respectively).

Statin use was uncommon in our study subjects, which may have limited our ability to detect a true reduced risk. However, in another study from our group[26], with a similar design and population, a significant reduction in breast cancer risk was observed only among regular users of fluvastatin, which also had low prevalence of use. Statins are relatively new medications, therefore examining outcomes like adenomatous polyps as an intermediate step in colorectal cancer development might be a reasonable approach to evaluate both individual and combined effect of statins on colorectal cancer risk. Our study was restricted to women, but there are no reported gender effects on the association of drugs with colorectal cancer risk. The availability of detailed information, control for potential confounding factors, and reliable exposure measurements are the major strengths of our study.

In conclusion, these results support the inverse association between NSAIDs use and colorectal cancer risk in women, especially in current users. We did not detect an association between colorectal cancer risk and statin use, regardless of type (lipophilic *vs* hydrophilic), recency or duration of use. Further, there was no interaction effect of combined NSAIDs and statin use.

COMMENTS

Background

The use of non-steroidal anti-inflammatory drugs (NSAIDs) such as Aspirin is known to be inversely associated with risk of developing colorectal cancer. Some studies have suggested such an association with the use of the commonly used lipid lowering drugs, statins. There is also some experimental data suggesting a synergistic effect for these two popular drug families against colorectal cancer risk.

Research frontiers

While NSAIDs have some possible protective effect against colorectal cancer, they are not yet approved for routine use for this purpose, mainly because of their potentially fatal side effect, bleeding. Finding another protective agent that works synergistically with NSAIDs, allowing a decreased NSAIDs dose, could lower the incidence of the side effect whilst preserving the desired effect; cancer prevention. The promising evidence indicating such an effect for statins is exciting, because these drugs are a hot topic for different preventive strategies, especially in cardiovascular diseases.

Applications

The study results confirm the previously known inverse association between NSAIDs use and colorectal cancer risk.

Peer review

This is a retrospective case-controlled study investigating if NSAIDs or/and statins have chemopreventive effects in women with regard to colorectal cancer (CRC). It is well known that regular users of NSAIDs are at less risk of developing gastrointestinal cancers, including CRC. This paper supports this hypothesis.

Abstract

AIM: To compare the performance of different types of abdominal drains used in bariatric surgery.

METHODS: A vertical banded Roux-en-Y gastric bypass was performed in 33 morbidly obese patients. Drainage of the peritoneal cavity was performed in each case using three different types of drain selected in a randomized manner: a latex tubular drain, a Watterman tubulolaminar drain, and a silicone channeled drain. Drain permeability, contamination of the drained fluid, ease of handling, and patient discomfort were evaluated postoperatively over a period of 7 d.

RESULTS: The patients with the silicone channeled drain had larger volumes of drainage compared to patients with tubular and tubulolaminar drains between the third and seventh postoperative days. In addition, a lower incidence of discomfort and of contamination with bacteria of a more pathogenic profile was observed in the patients with the silicone channeled drain.

CONCLUSION: The silicone channeled drain was more comfortable and had less chance of occlusion, which is important in the detection of delayed dehiscence.

Key words: Bariatric surgery; Contamination; Drains; Gastric leak; Patency; Peritonitis

INTRODUCTION

Most of the immediate complications occurring after bariatric surgery are due to technical errors that may go unrecognized[1]. Among them, intraoperative bleeding and dehiscence of anastomoses, although infrequent, are the most feared complications. Dehiscence occurs at a frequency of 1% to 4.4% of cases, resulting in significant morbidity and eventually even death. The early detection of this complication could reduce morbidity and mortality[2-4].

Resources for the early diagnosis of dehiscence during the postoperative period are limited. The clinical signs and symptoms are difficult to interpret and imaging exams, when they can be performed, may yield false results due to excess body weight.

Over the last three decades, efforts have been made to investigate the effectiveness of prophylactic drainage of the peritoneal cavity in controlled randomized clinical trials[5-8]. Although there are no evidence-based data justifying the use of drains in various situations, including bariatric surgery, most services routinely use them for the early identification of fistulae and their treatment[9].

Different types of drains are available but the search is ongoing for the ideal model. A closed-system model of a silicone drain was recently produced, with multiple channels in its intra-abdominal portion and vacuum

aspiration (Blake®-Ethicon), which has been used in various operations including bariatric surgery[10-16].

The objective of the present study was to assess the patency of three different types of abdominal drains used in bariatric surgery.

MATERIALS AND METHODS

During the period from January to September 2007, 33 morbidly obese patients were selected for surgical treatment by banded Roux-en-Y gastric bypass. The patients were divided into three groups according to the type of drain employed in the peritoneal cavity. The study was approved by the Research Ethics Committee of the hospital and all patients gave written informed consent to participate.

The type of drain used was selected at random: Group 1, closed-system latex tubular drain with multiple holes and without aspiration; Group 2, Watterman drain consisting of two No. 16 Levin catheters with multiple holes wrapped with a No. 4 Penrose tube (open system) (Figure 1); Group 3, silicone drain with multiple channels (Blake®Ethicon) 24 Fr connected to a 300 mL J-Vac® reservoir (Ethicon) under continuous vacuum. All drains were left in place for seven days after surgery.

Before removal of the drain, the patient received 120 mL of a methylene blue solution by the oral route in order to test for the presence of possible anastomosis dehiscence of staple lines. No radiological test was applied. For the evaluation of drain permeability, the daily output of each drain was recorded over a postoperative period of seven days.

Microbiological and antimicrobial analysis of the intraperitoneal end of the drains was performed on the seventh postoperative day during the interruption of drainage. In order to obtain peritoneal fluid the drains were punctured in their external portion. The end of each drain located in the peritoneal cavity was also sent for analysis. Both procedures were carried out under rigorous asepsis.

Subjective evaluation of the comfort of each drain was performed using a questionnaire which was completed by the patient on the day of drain removal. The information obtained referred to pain at the drain site and to pain during drain removal (graded from 0 to 5), ease of handling and discomfort with the presence of odors.

Groups were compared by one way analysis of variance (ANOVA) and then paired for application of the Tukey post-test. The level of significance was set at 5%.

RESULTS

All patients who underwent surgery were evaluated. Mean patient age, weight and BMI were 37.1 years, 138.20 kg and 51.42 kg/m^2, respectively. The characteristics of the groups studied were similar (Table 1).

All patients had a favorable postoperative course without major complications. There was no extravasation of methylene blue during the tests carried out on the seventh postoperative day. However, the intraperitoneal end of the Watterman drain in a group 2 patient was stained blue at the time of removal. A No. 16 Levin catheter was immediately introduced in this patient in order to maintain patency. No significant drainage occurred on subsequent days and the patient's course was favorable.

Day 7	$P < 0.05$	$P < 0.05$	$P > 0.05$

P value obtained by the Tukey post-test.

Drain output

No difference in collected fluid volume was observed up to the second postoperative day. Starting on the third day, the silicone channeled drain showed significantly greater drainage compared to the others (Table 2) and this difference persisted up to the 7th postoperative day. No difference in collected volume was observed between the tubular latex drain and the tubulolaminar (Watterman) drain (Table 3).

Microbiological analysis

Microbiological evaluation of the fluid from the peritoneal cavity collected through the various drains revealed that nine patients with the silicone channel drain had a positive culture, with the bacteria most frequently detected being *Staphylococcus* spp., *Proteus* spp. and *Klebsiella* spp.; for the

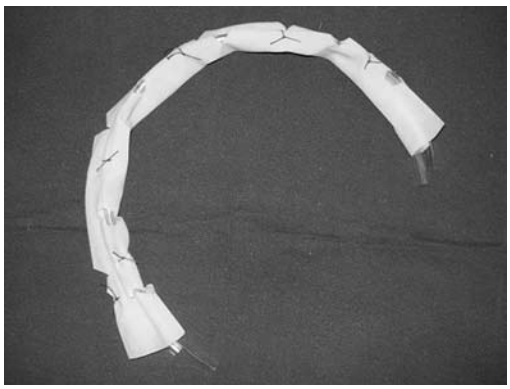

Figure 1 Watterman drain.

latex tubular drain all cultures were positive and the most frequent bacteria were *Enterobacter* spp., *Enterococcus* spp., *Proteus* spp. and *Pseudomonas* spp.; all the cultures of the tubulolaminar Watterman drains were also positive and the most frequent bacteria were *Serratia* spp., *Morganella* spp., *Proteus* spp. and *Enterobacter* spp..

Microbiological evaluation of the drain end located in the peritoneal cavity showed a similar frequency of culture positivity and similar bacterial species identified in the peritoneal fluid for all drains (Table 4).

Subjective evaluation

Drain handling and emptying of the collecting bag were considered easy for all drain types. The tubular latex drain was considered to be the most painful and the silicone channeled drain was considered to present fewer unpleasant odors (Table 5).

DISCUSSION

Drainage of body cavities has been practiced in medicine for a long time. During the last three decades, surgeons have made efforts to investigate the value of prophylactic drainage after abdominal surgery in controlled randomized clinical trials[8,9]. The utility of closed suction drains after gastrointestinal procedures

has long been debated. Although there is some data against the use of prophylactic drains, bariatric surgeons often use them for a variety of reasons: as an early alert to the presence of leakage and hemorrhage, and as a resource for the treatment of these complications[16].

It was not the subject of this work to study the benefits or disadvantages of the presence of drains or how often they are used. For this type of study, a greater number of patients must be evaluated. Although there is a lack of consensus regarding prophylactic drainage in gastric surgery[9], at our institution, we always use tubular closed drains without suction in gastrointestinal procedures and, in accordance with many bariatric centers, prophylactic drains are routinely used in bariatric surgery. On the other hand, the effectiveness of a tubular closed drain without suction is very low for prolonged postoperative periods and may impair the diagnosis and treatment of fistulae after bariatric surgery, especially those with delayed occurrence[5]. In an experimental study, the tubular drain was found to be obstructed early, 24 to 48 h after its introduction, due to envelopment by the omentum and penetration of omental fringes into the draining orifices. Contamination around the drain has also been observed, causing washing for relief of obstruction to be risky[6].

Early studies have demonstrated that the persistence of serous drainage after obstruction of drains placed in the peritoneal cavity originates from a reaction by the organism to the presence of a foreign body, in this case the drain itself[7]. The migration of bacteria into the peritoneal cavity through the drain has also been reported[6,7].

In general, tubular closed drains tend to result in lower infection rates compared to laminar open catheters. On the other hand, laminar open drains are less frequently obstructed[11]. Thus, it is pertinent to look for an alternative way of keeping drains permeable for a prolonged period of time in order to facilitate the diagnosis and management of fistulae after bariatric surgery, especially those occurring in a delayed manner.

In the present study, the performance of the latex tubular drain without suction was similar to that of the Watterman model, which functions as a tubulolaminar drain, also without suction. There was no difference in terms of drained volume, culture positivity or diversity of the bacterial species isolated. Subjective evaluation revealed that the tubulolaminar drain had an unpleasant odor when dressings were changed compared with the tubular drain, which was more painful when handled.

The silicone channeled closed drain with vacuum and without multiple perforations had some advantages over the two more traditional models, such as a lower incidence of obstruction and pain at the site of insertion, as well as easy handling, and represents a more recent alternative that deserves to be evaluated in view of the additional costs[12].

In the present study, a persistently greater volume of daily drainage was observed with the silicone channeled closed drain, suggesting lower obstruction rates. A lower incidence of pain and fewer unpleasant odors were also recorded. Bacterial contamination by the retrograde route occurred in 81% of cases, however, the bacteria most frequently identified had a less pathogenic profile compared to the other two types of drain.

Thus, we can conclude that the silicone drain with multiple channels has a more prolonged permeability, and is recommended as an alternative for drainage of the peritoneal cavity after bariatric surgery. This recommendation is made in view of the fact that dehiscence can manifest in a delayed manner, as we experienced a patient with staple line dehiscence on the seventh postoperative day.

COMMENTS

Background

With the current increase in bariatric surgery, some complications such as, intraoperative bleeding and dehiscence of anastomoses, although infrequent, are matters of concern. The resources for the early diagnosis of these complications are limited. Drainage of the peritoneal cavity may result in the early identification and treatment of fistulae. Different types of drains are available but the search is ongoing for the ideal model.

Research frontiers

A closed-system model of a silicone drain, with multiple channels in its intra-abdominal portion (Blake®Ethicon) was recently produced. This silicone channeled closed drain with vacuum had some advantages over the two more traditional models, such as a lower incidence of obstruction and pain at the site of insertion, as well as easy handling.

Innovations and breakthroughs

This silicone drain (Blake®Ethicon) is being used by a great number of surgeons around the world and for a wide variety of surgical procedures such as cardiothoracic surgery, transplantation and bariatric surgery

Applications

This study suggests that the silicone drain is a good alternative for drainage of the peritoneal cavity after bariatric surgery, if the surgeon decides to drain it.

Terminology

Bariatric surgery is carried out in severely obese patients with the objective of reducing body weight and the comorbidity related to obesity. Dehiscence is any rupture or opening of surgical sutures. Drains are a device by which a channel or open area may be established for the exit of fluids or purulent material from a cavity, wound, or infected area.

Peer review

The authors compared the performance of different types of abdominal drains used during bariatric surgery. This article is interesting and well written.

Abstract

AIM: To study the effect of celecoxib (CXB) on diethylnitrosamine activation through the regulation of cytochrome P450 in a hepatocarcinogenesis model.

METHODS: Six-week-old male Sprague-Dawley rats were randomly divided into five groups, a non-treated group (NT), a diethylnitrosamine-treated group (DEN), a DEN+CXB-treated group (DEN+CXB), and CXB 8 d-treated and CXB 32 d-treated groups. The effects of celecoxib on the enzymatic activities of CYP1A1, 2A, 2B1/2, and 2E1 were assessed in hepatic microsomes 24 h after DEN administration. Changes in CYP1A1 and CYP2B1/2 protein expression were also evaluated. The rate of DEN metabolism was measured by the production of the deethylation metabolite acetaldehyde, and the denitrosation metabolite nitrite.

RESULTS: DEN+CXB administration produced a significant increase in the enzymatic activities of CYP2B1/2 and 1A1, whereas it did not change the activities of CYP2A and 2E1, compared to that of the DEN group. CXB treatment for eight days did not produce a significant effect on enzymatic activity when compared to the NT group; however, when it was administered for prolonged times (CXB 32 d group), the enzymatic activities were increased in a similar pattern to those in the DEN+CXB group. The observed increase in the enzymatic activities in the DEN+CXB group was accompanied by an increase in the CYP2B1/2 protein levels; no changes were observed in the levels of CYP1A1. *In vitro*, CXB increased the denitrosation of DEN, a pathway of metabolic detoxification. The addition of SKF-525A, a preferential inhibitor of CYP2B, abrogated the denitrosation of DEN.

CONCLUSION: These results suggest that the mechanism of action of CXB involves enhancement of the detoxification of DEN by an increasing denitrosation *via* CYP2B1/2.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common tumors, with about one million new cases per

year worldwide. Despite progress in early diagnosis and novel therapies, the overall survival of HCC patients has not been significantly improved over the last three decades. Therefore, preventive strategies are of paramount importance and need to be actively explored in order to reduce the incidence of this disease[1].

Numerous epidemiological studies have demonstrated that long-term use of cyclooxygenase-2 (COX-2) specific inhibitors, such as celecoxib (CXB), are associated with a reduced incidence of several types of cancer[2]. Studies in rodents have shown that CXB inhibits the development of chemically induced cancers, including colon, skin, urinary bladder, and breast[3-6]. The proposed mechanisms for the effects of CXB in these models include inhibition of cell proliferation, reduction of angiogenesis and induction of apoptosis[7]. Recently, we have demonstrated that CXB acts as a chemopreventive agent against the development of preneoplastic lesions induced by diethylnitrosamine (DEN), 2-acetylaminofluorene and partial hepatectomy in the modified resistant hepatocyte (MRH) model[8]. However, the exact mechanism of action by which CXB decreases liver preneoplastic lesions remains unclear, because there was no evidence of apoptosis or of changes in COX-2 expression or PGE2 production after CXB treatment. The observed reduction in proliferation markers was not sufficient to explain the reduced number of preneoplastic lesions, thus other mechanisms must be involved in the CXB effect, probably during the initial stages of hepatocarcinogenesis.

In the MRH model, DEN bioactivation is required to produce preneoplastic lesions and subsequently HCC[9]. The metabolic activation of DEN occurs during the first hours after administration, *via* cytochrome P450 (CYP)-dependent α-hydroxylation, which results in an ethylating agent capable of forming DNA adducts. The CYP1A1/2, 2B, 2A1/2 and 2E1 subfamilies are the major enzymes involved in the bioactivation of DEN[9-11]. In addition to the activation reaction, a denitrosation reaction may also occur, which results in nitrite production. Nitrite formation is an alternative pathway for the formation of an alkylating intermediate, and represents a carcinogen detoxification pathway[12-14]. These two pathways of DEN metabolism could occur in parallel, and although some studies suggest that both pathways are catalyzed by the same CYP enzyme, the participation of distinct isoforms must be considered. In the absence of CYP inducers, the predominant reaction is activation; nevertheless, when specific isoforms are induced, the two mechanisms compete with each other, favoring the DEN detoxification pathway[9,14].

Since there is no information in the literature about CYP regulation by CXB as a chemopreventive mechanism, the aim of this study was to determine the effect of CXB on DEN activation by affecting CYP regulation in the MRH model. These data demonstrate that the preferential modulation of CYP2B1/2 by CXB enhances DEN detoxification, which therefore blocks the initiation of the hepatocarcinogenic process.

MATERIALS AND METHODS

Materials

DEN was purchased from Sigma Chemical Co. (St. Louis, MO). Ethoxy- and pentoxy-resorufin were purchased from Molecular Probes, Inc. (Eugene, OR). Electrophoresis reagents were purchased from Bio-Rad (Hercules, CA). The monoclonal anti-rat CYP1A1 antibody was purchased from Oxford Biochemicals Research, Inc. (Oxford, MI). The monoclonal anti-rat CYP2B1/2 antibody was kindly provided by Dr. Colin Jefcoate (University of Wisconsin-Madison, Dept. of Pharmacology, Madison, WI). The horseradish peroxidase-conjugated goat anti-mouse IgG antibody was acquired from Pierce Protein Research Products (Rockford, IL).

Experimental diet

CXB was extracted from the commercial drug Celebrex® (Pfizer, Mexico City, Mexico). The identity and purity of the molecule was above 99%, as determined by nuclear magnetic resonance analysis in the Department of Chemistry at CINVESTAV (Mexico City, Mexico). Diet 5001 containing 1500 ppm of CXB was prepared by Purina Test Diet (Richmond, IN).

Animals

Six-week-old male Sprague-Dawley rats were purchased from Harlan Industries (Mexico City, Mexico). Rats were fed ad libitum and housed in a controlled environment with a 12 h light/dark cycle, 50% relative humidity and a temperature of 21 ± 2℃. All experiments were performed according to the guidelines established by the Institutional Animal Care Committee in agreement with Mexican Official Norm NOM-062-ZOO-1999.

Experimental procedure

After acclimation, the rats were separated into five treatment groups (Figure 1). In the non-treated (NT) group, rats were fed with 5001 basal diet and sacrificed eight days after the beginning of the experiment; the DEN and DEN+CXB groups received a single intraperitoneal dose of DEN (200 mg/kg) and were sacrificed 24 h later. The DEN group was fed the basal diet. The DEN+CXB group was pretreated with CXB from seven days before DEN administration until sacrifice. The CXB 8 d and CXB 32 d groups were treated only with CXB for the indicated times. Animals were sacrificed by cervical dislocation and the livers were then removed and processed to obtain microsomes, as described by Mayer *et al*[15].

Enzymatic activities

Alkoxyresorufin metabolism assays: Microsomal *O*-dealkylation of 7-ethoxy-(EROD, CYP1A1) and 7-pentoxy-resorufin (PROD, CYP2B1/2) were measured fluorometrically at 37℃ using 530 and 585 nm excitation and emission wavelengths, respectively[16,17].

***p*-Nitrophenol hydroxylase (PNPH) assay:** The

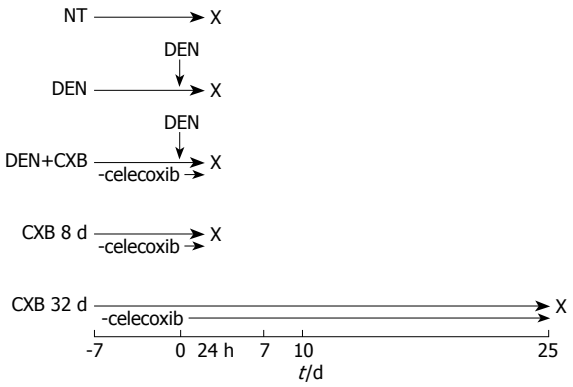

Figure 1 Schematic representation of CXB administration in the hepatocarcinogenesis model. In the NT group, rats were maintained on a basal diet. DEN and DEN+CXB groups were treated with DEN. The CXB diet was given from 7 d before DEN administration until sacrifice, indicated with X ($n = 4$).

activity of CYP2E1 was measured by the formation of 4-nitrocatechol, which was determined spectrophotometrically at 546 nm[18].

7α-Testosterone hydroxylation: The activity of CYP2A1 was determined in microsomal suspensions obtained from treated and control rats as previously described[19]. Protein concentration was determined by Lowry's method[20] using bovine serum albumin as a standard.

Immunoblotting

Microsomal proteins (15 and 30 μg/lane for CYP2B1/2 and CYP1A1, respectively) were separated by 10% SDS-PAGE. Proteins were blotted onto PVDF membranes. These membranes were blocked overnight at 4℃ with 100 mmol/L glycine, 1% BSA and 5% non-fat dry milk in a PBS-1% Triton X-100 solution. Then, membranes were challenged with anti-rat CYP1A1 or 2B1/2 antibodies for 1 h at room temperature, followed by incubation with a horseradish peroxidase-conjugated secondary antibody for 1 h at room temperature. The specific protein bands were visualized by chemiluminescence (Santa Cruz Biotechnology, Inc.) and exposure to radiographic film. Densitometric analysis of bands was carried out using Sigma Gel software (Jandel Scientific, San Rafael, CA).

In vitro biotransformation of DEN by rat hepatic microsomes

The rate of DEN metabolism in control and CXB-treated rat hepatic microsomes was measured by the production of both a deethylation metabolite, acetaldehyde, and a denitrosation metabolite, nitrite, as previously described[12,14,21]. The enzymatic assay was performed in a final volume of 1 mL TMP buffer (50 mmol/L Tris-HCl, 10 mmol/L $MgCl_2$, 150 mmol/L KCl, pH 7.0) containing 0.5 mg rat hepatic microsomal protein, 1.2 mmol/L NADPH and 50 mmol/L DEN. Reactions were initiated by adding DEN and incubating at 37℃ for 30 min, and were then stopped by adding 0.1 mL 25% $ZnSO_4$ and 0.1 mL saturated $Ba(OH)_2$ in an ice bath. Samples were vortexed and centrifuged at 5000 *g* for 10 min. One-hundred microliter aliquots of supernatant were used for nitrite measurements using a specific colorimetric assay kit (Cayman Chemical Co., Ann Arbor, MI), according to the manufacturer's instructions. Acetaldehyde production was determined by HPLC in a Waters Liquid Chromatography model 600 using an Xterra C18 phase reverse column (3.9 mm × 150 mm), as previously described[21]. As a control for CYP2B1/2-specificity, these assays were carried out in the presence of 50 mmol/L SKF-525A.

Statistical analysis

Data are presented as mean ± SD. Analysis of variance and the Bonferroni test were used to assess statistical differences among the tested groups, and the level of significance was set at $P < 0.05$. All statistical analyses were performed using SigmaStat software version 3.1 (Systat Software, Inc., Point Richmond, CA).

RESULTS

CXB modulates the enzymatic activity of CYPs

To determine whether the chemopreventive effect of CXB is associated with changes in the enzymatic activities of some CYPs, the activities of CYP1A1, CYP2A1, CYP2B1/2 and CYP2E1 were determined 24 h after DEN administration (Table 1). Eight days of CXB treatment did not produce a significant effect on any of the evaluated enzyme activities. DEN treatment significantly decreased the CYP1A1 and CYP2A1 activities by 66% and 58%, respectively, whereas CYP2B1/2 and CYP2E1 activities were increased 3.6- and 2.5-fold, respectively, in comparison to the NT group. When CXB was administered in combination with DEN (DEN+CXB group), the CYP1A1 activity was increased 3.5-fold and the CYP2B1/2 activity was increased 9-fold over the DEN group. Compared with the NT group, the increase in CYP2B1/2 activity was 33-fold, while no significant changes were observed for CYP1A1 activity. On the other hand, the DEN+CXB treatment had no influence on the activities of CYP2E1 and CYP2A1 (Table 1). Interestingly, the prolonged treatment with CXB (CXB 32 d group) produced an increase in the majority of the enzymatic activities analyzed: CYP1A1, CYP2B1/2 and CYP2E1. These results suggest that pretreatment with CXB in combination with the administration of DEN elicited a preferential induction of CYP1A1 and 2B1/2 enzymatic activities, with the 2B1/2 isoforms induced to a greater degree.

Celecoxib induces the expression of CYP2B1/2 but not CYP1A1

To determine whether the increases observed in the enzymatic activities of CYP1A1 and 2B1/2 were related to increases in protein levels, these isoforms were analyzed by immunoblotting. In the DEN-treated group, there were no significant differences in the protein expression of CYP1A1 and CYP2B1/2 compared to the NT group. The pretreatment with CXB in the DEN+CXB group significantly increased CYP2B1/2 protein expression (2.5-fold), but it had no significant effect on CYP1A1 protein expression compared to the DEN group (Figure 2).

Table 1 Effect of celecoxib on hepatic microsomal enzyme activities in a hepatocarcinogenesis assay

Treatment	Alkoxyresorufin *O*-dealkylation activity (pmol resorufin/min per mg protein)		Testosterone hydroxylase activity (pmol of product/min per mg protein)	*p*-Nitrophenol hydroxylase activity (nmol 4-nitrocatechol/min per mg protein)
	EROD (CYP1A1)	PROD (CYP2B1/2)	7α-OHT (CYP2A1/2)	PNPH (CYP2E1)
NT	13.1 ± 0.5	2.0 ± 0.5	129.2 ± 18.9	0.38 ± 0.07
CXB 8 d	13.3 ± 4.3	4.2 ± 2.2	ND	0.53 ± 0.16
DEN	4.5 ± 1.3[a]	7.3 ± 3.2[a]	54.2 ± 19.2[a]	0.97 ± 0.14[a]
DEN+CXB	15.9 ± 4.8[b]	65.9 ± 35.4[a,b]	66.0 ± 5.9[a]	0.80 ± 0.25[a]
CXB 32 d	54.5 ± 11.3[a]	114.2 ± 23.2[a]	151.5 ± 29.5	1.40 ± 0.44[a]

Male rats were treated with a single dose of DEN (200 mg/kg) *ip* and sacrificed 24 h after administration (DEN and DEN+CXB groups). The CXB diet was provided 7 d before DEN treatment and until sacrifice (8 d). The CXB 8 d and CXB 32 d groups received only a CXB-containing diet. [a]Significantly different from the NT group; [b]From the DEN group, according to the Bonferroni test ($P < 0.05$). Values shown are the mean ± SD from $n = 4$. ND: Not determined.

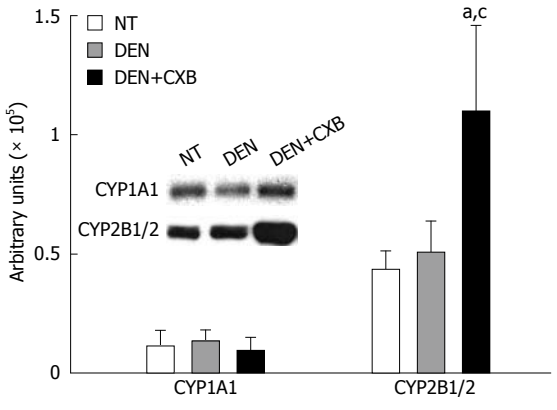

Figure 2 Immunodetection of hepatic microsomal CYP isoforms from DEN- and/or CXB-treated rats. Microsomal proteins (15 and 30 μg/lane for CYP2B1/2 and CYP1A1, respectively) were separated by SDS-PAGE and tested for different CYPs using specific anti-rat CYP antibodies. The bands in the inset box correspond to CYP2B1/2 and CYP1A1 protein detected in the NT, DEN and DEN+CXB groups. The graphic represents the densitometric analysis of the CYP amounts in the experimental groups. [a]$P < 0.05$, *vs* NT group; [c]$P < 0.05$ *vs* DEN group, Bonferroni test. $n = 4$ for all groups.

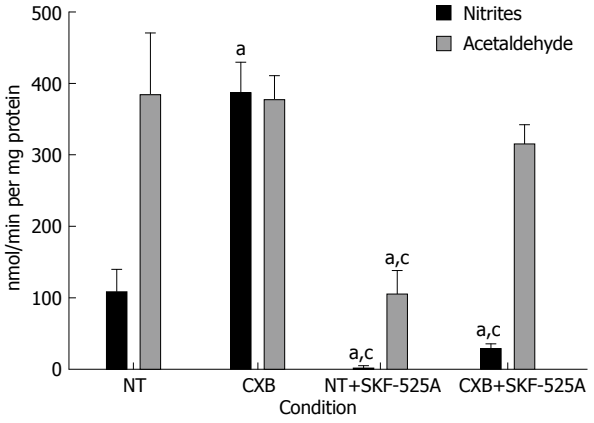

Figure 3 *In vitro* metabolism of DEN in non-treated and CXB-treated rat hepatic microsomes. The denitrosation rate was measured by the production of nitrites, and the deethylation rate was measured by the production of acetaldehyde in the presence or absence of SKF-525A. Values are presented as mean ± SD. [a]$P < 0.05$, *vs* NT group; [c]$P < 0.05$ *vs* CXB group. Bonferroni test, $n = 4$ for all groups.

In summary, these results show that CXB differentially affects these two isoforms; the increase in the protein expression of CYP2B1/2 suggests that the regulation might be at the transcriptional level, while in the case of CYP1A1, CXB seems to regulate only the enzymatic activity.

CXB favors detoxification by denitrosation of DEN

To explore whether regulation of the CYP isoforms by CXB induces the detoxification pathway of DEN as a chemopreventive mechanism, nitrite and acetaldehyde yields were measured in the microsomes of non-treated and CXB-treated rats. We used rat microsomes treated with CXB for 32 d, where the pattern of induction of enzymatic activities was similar to the pattern observed in the DEN+CXB group (with preferential induction of the 2B1/2 isoform), because the eight days of CXB treatment did not produce significant changes in the enzymatic activities.

Microsomes of non-treated rats showed a production of acetaldehyde that was 3.5-fold higher than that of nitrites, which suggests that the predominant route for the DEN metabolism is deethylation, leading to the bioactivation of the carcinogen.

Microsomes obtained from CXB-treated rats showed a 3.6-fold increase in the rate of denitrosation of DEN, while there was no effect on DEN deethylation. This result indicates an induction of the detoxification pathway of the carcinogen. To confirm whether this effect resulted from induction of the enzymatic activity of CYP2B1/2 by CXB, we included SKF-525A in the assay, a CYP inhibitor that acts preferentially on this isoform. Inhibition of CYP2B1/2 resulted in a 98% reduction in nitrite production in the microsomes isolated from non-treated animals, and a 95% reduction in the microsomes of CXB-treated rats, suggesting that CYP2B1/2 was involved in the denitrosation of DEN under basal conditions (NT animals) and CXB-induced conditions. The deethylation rate in non-treated rat microsomes decreased 73%, and no statistically significant changes were observed in the rat microsomes treated with CXB. One possible explanation for this result is that CYP2E1 and 1A1 are minimally affected by SKF-525A and could be responsible for the acetaldehyde production under these conditions (Figure 3).

DISCUSSION

CXB has shown to have anticancer effects in several

experimental models, including the MRH model, where it showed a striking chemopreventive activity by inhibiting liver preneoplastic lesions in rats[8]. Although that study demonstrated a reduction in proliferation markers and in the nuclear translocation of NF-κB, the exact mechanism of action remains unclear[8].

Altered expression of CYP genes is a common feature in hepatic preneoplastic and neoplastic lesions induced by various carcinogens, including DEN[22]. Therefore, DEN metabolism *via* hepatic microsomal CYPs provides molecular targets for chemoprevention. This study demonstrates that the chemopreventive effect of CXB in the modified resistant hepatocyte model is mediated by changes in DEN metabolism *via* CYP regulation. CXB treatment for 8 d did not induce significant changes in enzymatic activities; however, when it was administered for 32 d or in combination with DEN, CXB strongly enhanced the enzymatic activity of CYP2B1/2. Moreover, CXB treatment increased the nitrite levels, which have been proposed to result from the DEN detoxification pathway[12,13]. This finding supports the explanation that the chemopreventive activity of CXB is carried out by reducing carcinogen-induced DNA damage, thus preventing the initiation of hepatocarcinogenesis. We propose that the effect of CXB is due to the preferential induction of CYP2B1/2. This hypothesis is reinforced by *in vitro* results, where the increase in DEN denitrosation elicited by CXB was inhibited by the addition of SKF-525A, an inhibitor of several CYP isoforms including 2B1/2B2, 3A1/2 and 2A, whereas CYP2E1 and 1A are less affected[23]. The deethylation rate was not affected by the inhibitor, suggesting that CYP2E1, and possibly CYP1A, could be the main isoforms involved in this pathway.

According to a previous report, the enzymatic activity of CYP2E1 increased with DEN treatment[24]. This is congruent with the participation of this isoform in DEN metabolism[10,24]. However, CXB did not have any effect on this increase, suggesting that there is no contribution of CYP2E1 to the chemoprotective effect of CXB. On the other hand, CXB reversed the effect of DEN on CYP1A1-specific EROD activity. A decrease in the CYP1A1 enzyme activity in preneoplastic lesions induced by DEN has been previously reported[25]. Induction of CYP1A1 has been related to chemoprevention[26]; thus, the induction of this isoform by CXB could explain its chemopreventive effect, but comparing the levels of enzymatic activity induced reveals that its participation is probably minor compared to CYP2B1/2. Additionally, CYP2A was not affected by CXB, and considering that it is partially affected by SKF-525A, this isoform could be involved in the deethylation reaction of DEN, although to a lesser extent than CYP2E1.

This is the first report that describes the effect of CXB on hepatic CYP regulation. Other chemoprotectors have been shown to act in a similar way. For example, among their multiple effects, diallyl sulfide, indole-3-carbinol, *d*-limonene and bicyclol induced the enzymatic activity of several CYP isoforms, including CYP2B1/2[21,26]. In particular, the effect of bicyclol on CYP2B1 was associated with an increase in the denitrosation rate of DEN[21]. In that case, bicyclol reduced the Km values for denitrosation below the values of deethylation, which may be attributed to the induction of specific CYPs. According to these results on DEN metabolism, the chemopreventive CXB effect in the MRH model could be similar to that of bicyclol[21], mediated mainly by the 2B1/2 isoform. Isoforms of the 1A, 2A, 2B and 2E CYP families share a broader overlap in substrate selectivity. In addition, a single enzyme can bind a variety of substrates, multiple substrates, and/or generate multiple products from a single substrate, which makes it difficult to discriminate between these possibilities in *in vivo* systems[27,28]. Further studies are required to clarify the mechanism by which CXB induces the denitrosation of DEN, and whether this is generated simply by the preferential induction of isoforms or by other effects.

In summary, the modulation of several hepatic CYPs by CXB modifies the bioactivation of DEN, favoring detoxification *via* denitrosation. This pathway may constitute an additional mechanism of action to explain the chemoprotective effects of CXB at the initiation stage in this hepatocarcinogenesis model.

ACKNOWLEDGMENTS

We thank Dr. Angelina Flores and Sonia Sánchez for their aid in the extraction of celecoxib, Dr. Víctor Pérez and Isabel Wens for their helpful assistance with HPLC-based determinations, and Patricia Vázquez, Evelia Arce and Sergio Hernández for their technical support. We also thank Maria Antonieta López, Rafael Leyva, Manuel Flores, Ricardo Gaxiola and UPEAL Chairman Dr. Jorge Fernández at UPEAL-CINVESTAV for the animal handle and care.

COMMENTS

Background

Celecoxib, a non-steroidal antiinflammatory drug, is associated with a reduced incidence of several types of cancer, including hepatocellular carcinoma. Study of the mechanism of action has been possible by means of animal models. In the modified resistant hepatocyte model, celecoxib has shown a chemoprotector effect in the development of liver preneoplastic lesions; however, the action mechanism has not been defined completely.

Research frontiers

Diethylnitrosamine bioactivation is a crucial event in the initiation stage of the modified resistant hepatocyte model, a process dependent on hepatic cytochrome P450 (CYP). Therefore, modulation of liver CYP provides molecular targets for chemoprevention. This study demonstrates that the chemopreventive effect of celecoxib is mediated by changes in diethylnitrosamine metabolism *via* CYP regulation.

Innovations and breakthroughs

Recent investigations have demonstrated several mechanisms through which celecoxib exerts its chemoprotector effect. However, this is the first report that describes the capacity of celecoxib to modulate liver CYP expression and explains how the preferential induction of CYP2B1/2 activates the detoxification pathway by increasing nitrite formation. These effects represent an additional mechanism to elucidate the chemopreventive activity of celecoxib.

Applications

This study contributes to the understanding of the mode of action of celecoxib, which may represent a future strategy for therapeutic intervention in the treatment of patients with a high risk of suffering hepatocellular carcinoma.

Terminology

CYP is hepatic microsomal protein involved in the phase I metabolism. Celecoxib is a nonsteroidal anti-inflammatory drug that specifically inhibits cyclooxygenase-2. Diethylnitrosamine is a carcinogen initiator used in the modified resistant hepatocyte model.

Peer review

The authors examined the capability of celecoxib to modulate CYP as part of its chemopreventive mechanism in the modified resistant hepatocyte model. The results suggest that celecoxib favors the diethylnitrosamine detoxification and contribute to clarifying the chemopreventive mechanism in the chemical hepatocarcinogenesis of rat.

Abstract

AIM: To prospectively investigate the efficacy of the revised Vienna Classification for diagnosing colorectal epithelial neoplastic lesions in cold biopsy specimens.

METHODS: Patients were selected for inclusion if they had colorectal epithelial lesions that were not considered suitable for direct endoscopic resection. These included colorectal polyps ⩾ 10 mm and lesions suspected of being carcinomas capable of invading the colorectal submucosa or beyond, including strictures, based on the cold biopsies obtained from each lesion prior to resection. We investigated the relationship between diagnoses based on cold biopsy samples using the revised Vienna Classification and resected specimens of the same lesions, and the therapeutic implications of diagnoses made using the revised Vienna Classification. The same cold biopsy specimens were also examined using the Japanese Group Classification guidelines, and compared with the resected specimens of the same lesions for reference.

RESULTS: A total of 179 lesions were identified. The sensitivity, specificity, positive and negative predictive values of the revised Vienna Classification for distinguishing between intramucosal lesions and submucosal invasive carcinomas in cold biopsy specimens was 22.2%, 100%, 100%, and 71.4%, respectively, and for distinguishing between intramucosal lesions and those invading the submucosa or beyond was 59.7%, 100%, 100%, and 37.6%, respectively. The sensitivity, specificity, positive and negative predictive values of the Japanese Group Classification for distinguishing between intramucosal lesions and submucosal invasive carcinomas in cold biopsy specimens was 83.3%, 91.4%, 83.3%, and 91.4%, respectively, and for distinguishing between intramucosal lesions and those invading the submucosa or beyond was 95.1%, 91.4%, 97.9%, and 82.1%, respectively. A total of 137 of 144 carcinomas that had invaded the submucosa or beyond and three high-grade intraepithelial neoplasias were diagnosed as "carcinoma" using the Japanese Group Classification system.

CONCLUSION: The revised Vienna Classification for cold biopsy specimens has high positive predictive value in the diagnosis of colorectal carcinoma invasive to the submucosa or beyond.

INTRODUCTION

Considerable discrepancies have been reported between diagnoses of colorectal epithelial neoplastic lesions made by Western and Japanese pathologists from endoscopic cold biopsies and resected specimens of the same

lesions[1,2]. Japanese pathologists have distinguished five groups of lesions within the spectrum of colorectal epithelial neoplasia for cold biopsy specimens [Japanese Group Classification (JGC)], namely: normal or benign changes (inflammation/hyperplasia) without atypia [Group 1 (G1)]; non-neoplastic lesions with atypia resulting from inflammation, hyperplasia or regeneration [Group 2 (G2)]; neoplastic lesions with low-grade atypia, including adenomas with mild or moderate atypia and lesions difficult to diagnose as neoplastic or non-neoplastic [Group 3 (G3)]; neoplastic lesions strongly suspected of carcinoma, including adenomas with severe atypia [Group 4 (G4)]; and definite carcinoma [Group 5 (G5)], irrespective of intramucosal or submucosal invasion[3,4]. This different criterion for the diagnosis of "colorectal carcinoma" may be the reason why there are fewer discrepancies between diagnoses from cold biopsies and resected specimens by Japanese pathologists.

In the clinical setting, cold biopsies are required to facilitate management decisions for large and/or advanced lesions. The therapeutic implications of resecting adenomatous polyps equal to or larger than 10 mm ($\geqslant$ 10 mm) should be considered carefully because these polyps are at risk of becoming submucosal invasive carcinomas[5]. Compared to the endoscopic diagnosis of colorectal polyps including submucosal invasive carcinomas, the endoscopic diagnosis of more advanced colorectal carcinomas rarely presents a problem and can be referred for surgical resection[6]. However, histopathologic confirmation of these lesions from cold biopsy specimens should always be sought. Discrepancies between diagnoses based on cold biopsies and resected specimens of the same lesions are more likely to occur for these large and/or advanced lesions because cold biopsy-based diagnoses are subject to the limitations of superficiality and sampling errors[3]. In contrast, direct endoscopic resection (ER) without prior cold biopsy of small (< 10 mm) colorectal polyps is feasible and histopathologic examination of completely resected lesions enables adequate diagnosis and appropriate treatment, therefore, cold biopsies for small polyps are not mandatory.

Diagnostic discrepancies do not matter to patients if Western and Japanese physicians understand the implications of their respective pathology reports and apply management strategies that are appropriate to the needs of their patients[7]. However, continued attempts to unify Western and Japanese reporting systems are desirable because merging the terminologies of these systems will help codify the advantages of each into a language that is universally understood[8].

To overcome the differences between the conventional Western criteria and the JGC, the Vienna Classification attempted to combine the basic concepts of the conventional Western criteria, which emphasizes that invasion is an indicator of metastatic potential, with the strong points of the JGC, which values consistency between diagnoses of cold biopsy and resected specimens[2,9]. In the revised Vienna Classification (rVC), histopathologic diagnoses are classified into five categories according to neoplastic severity and depth of invasion. This classification also distinguishes between epithelial neoplastic lesions limited to the mucosa and those invading the submucosa[2].

To examine the efficacy of the rVC for diagnosing colorectal polyps $\geqslant$ 10 mm, and colorectal lesions suspected of being carcinomas invasive to the submucosa or beyond, including strictures, we prospectively compared the diagnoses from cold biopsy specimens using the rVC guidelines with the diagnoses from resected specimens of the same lesions using the World Health Organization (WHO) classification[10]. We investigated the value of the rVC system for distinguishing intramucosal lesions from those capable of invading the submucosa or beyond, with special reference to distinguishing between intramucosal lesions and submucosal invasive carcinomas because of the different therapeutic implications among these lesions. In addition, the same cold biopsy specimens were examined using the JGC guidelines and the resulting diagnoses compared to those obtained from the resected specimens of the same lesions, graded according to the WHO classification.

MATERIALS AND METHODS

Patients

In total, 5465 colonoscopies, sigmoidoscopies or proctoscopies were performed prospectively on 3719 patients at the Toho University Ohashi Medical Center, Tokyo, Japan, between January 2001 and December 2003. The study was approved by the Toho University Ohashi Hospital ethics committee. Signed informed consent was obtained from all participating patients. This study was performed in accordance with the Helsinki Declaration.

Inclusion/exclusion criteria

Patients were selected for inclusion in this study if they had colorectal epithelial lesions that were not considered suitable for direct ER. These included colorectal polyps $\geqslant$ 10 mm and lesions suspected of being carcinomas capable of invading the colorectal submucosa or beyond, including strictures, based on the cold biopsies obtained from each lesion prior to resection. The histopathologic diagnosis of each cold biopsy specimen was compared with the final histopathologic diagnosis of each resected lesion. Exclusion criteria included: no epithelial lesions; polyps < 10 mm; polyps $\geqslant$ 10 mm and lesions suspected of being carcinomas invasive to the submucosa or beyond, including strictures, but with no cold biopsy specimens; the inability to compare the histopathologic diagnosis of cold biopsy specimens with the final histopathologic diagnosis of the resected lesion; carcinoid tumors; familial adenomatous polyposis; inflammatory bowel disease; local recurrence after resection for epithelial neoplastic lesions; and the inability to give informed consent.

Endoscopic evaluation

All lesions were diagnosed macroscopically using

conventional colonoscopes (CF-200I, 230I, or 240I; Olympus Co, Ltd, Tokyo, Japan) by endoscopists who had performed more than 500 colonoscopic procedures by direct visualization. If necessary, the lesions were then delineated using 0.1% indigo carmine solution. Polyps and early colorectal carcinomas were classified as Ⅰp (pedunculated type), Ⅰsp (semipedunculated type), Ⅰs (sessile type), Ⅱa (superficial elevated type), Ⅱb (superficial flat type), or Ⅱc (superficial depressed type) according to the criteria outlined by the Japanese Society for Cancer of the Colon and Rectum[4]. Early colorectal carcinoma was defined as carcinoma with invasion limited to the mucosa or submucosa, regardless of the presence or absence of lymph node metastases[1,4]. Lesions that had become invasive carcinomas and had advanced into the muscularis propria or beyond were classified as exophytic/fungating, endophytic/ulcerative, diffusely infiltrative/linitis plastica, or annular according to the WHO classification[10].

Measurements of lesions and tissue sampling

The size of each lesion was estimated *in situ* by using a fully opened standard biopsy forcep (8 mm) (FB-24Q-1; Olympus) adjacent to the lesion, and measured after resection. The cold biopsies were performed using the same forceps (FB-24Q-1; Olympus). The number of cold biopsy specimens and the areas biopsied were dependent on the discretion of each endoscopist; if possible, specimens were obtained from different areas, and included the edges and the center of the lesion.

Treatment modality

Treatment modality was dependent on the size of the lesion, the endoscopic assessment of the depth of invasion and the degree of stricture, and on factors such as the patient's age and morbidity. This was also aided by the histopathologic diagnoses from cold biopsy specimens according to the JGC as routinely practiced.

Histopathologic evaluation

The cold biopsy specimens were fixed with 10% buffered formalin, embedded in paraffin, and stained with hematoxylin and eosin. The only clinical information available to the examining pathologists was that the specimen in question represented a biopsy/biopsies of a colorectal epithelial lesion. All cold biopsy specimen slides were examined independently by two experienced pathologists, and all discrepancies were resolved by a conjoint review of the slides in question. Histopathologic type and grade was evaluated according to the WHO classification[10]. Histopathologic diagnosis of each cold biopsy specimen was made using both the rVC and JGC guidelines[2-4]. If more than one cold biopsy specimen was taken, the most advanced diagnosis was taken as the final diagnosis of the lesion. After resection, tissue samples of the entire lesion were cut from resected specimens that had been fixed in 10% buffered formalin, embedded in paraffin, and stained with hematoxylin and eosin. The histopathologic diagnoses of resected specimens were made for each lesion using the WHO classification[10]. The relationship between the diagnoses of cold biopsy specimens using the rVC and JGC guidelines, and the depth of invasion in resected specimens of the same lesions was investigated.

Statistical analysis

The sensitivity and specificity, and positive and negative predictive values were all calculated with 95% confidence intervals (CI)[11]. The varying proportion of categorical variables between two groups (i.e. intramucosal lesions *versus* submucosal invasive carcinomas, and intramucosal lesions *versus* those invading the submucosa or beyond) was tested by Fisher's exact test. Statistical significance was defined as $P < 0.05$.

RESULTS

Clinicopathologic data

One patient with subserosal invasive transverse colon carcinoma with three cold biopsy specimens was excluded from the analysis because all three specimens showed necrotic tissue only. There were 171 patients (93 men, 78 women; mean age, 66.9 years; range, 33-93) with 179 lesions. A single lesion was found in 165 (96.5%) cases with five (2.9%) and one (0.6%) patients having two or four lesions, respectively. Ten lesions were located in the cecum (5.6%), 34 in the ascending colon (19.0%), 25 in the transverse colon (14.0%), 11 in the descending colon (6.1%), 46 in the sigmoid colon (25.7%), and 53 in the rectum (29.6%). Eight lesions were classified as Ⅰp (4.5%), seven as Ⅰsp (3.9%), 20 as Ⅰs (11.2%), 13 as Ⅱa (7.3%), six as Ⅱa + Ⅱc (3.4%), seven as exophytic/fungating (3.9%), 63 as endophytic/ulcerative (35.2%), and 55 as annular (30.7%). The lesions ranged from 10 to 180 mm in diameter (mean, 46.8 mm). No carcinomas < 10 mm invading the submucosa or beyond were found. Ileocecal resection ($n = 7$), right hemicolectomy ($n = 40$), partial resection of the transverse colon ($n = 6$), left hemicolectomy ($n = 5$), partial resection of the descending colon ($n = 3$), sigmoidectomy ($n = 32$), anterior resection ($n = 37$), abdominoperineal resection ($n = 7$), subtotal colectomy ($n = 4$), Hartmann's procedure ($n = 3$), transsacral resection ($n = 1$), transanal resection ($n = 4$), and ER ($n = 30$) procedures were performed.

Histopathologic diagnoses of cold biopsy specimens from 179 lesions

A total of 404 cold biopsy specimens were obtained from 179 lesions, ranging from one to six specimens per lesion (mean, 2.3). Five inadequate specimens [exudative material (2); granulation tissue (2); necrotic tissue (1)] were excluded; therefore, 399 cold biopsy specimens were included in the analysis. The histopathologic type and grade of each cold biopsy specimen was classified as follows: four non-neoplastic lesions; one indefinite neoplastic lesion; 31 low-grade intraepithelial neoplasias; 55 high-grade intraepithelial neoplasias; 69 well-differentiated adenocarcinomas; 16 moderately differentiated adenocarcinomas; and three poorly differentiated adenocarcinomas.

Table 1 Relationship between the histopathologic diagnoses of cold biopsy specimens using the revised Vienna Classification and the depth of invasion in resected specimens of the same lesions

Invasion depth[1]	The revised Vienna Classification								Total (%)
	C1	C2	C3	C4.1	C4.2	C4.3	C4.4	C5	
Non-N	2	0	0	0	0	0	0	0	2 (1.1)
LGIN	0	0	12	0	0	0	0	0	12 (6.7)
HGIN	0	0	16	2	1	0	2	0	21 (11.7)
Submucosa	0	0	2	1	0	3	8	4	18 (10.1)
MP or beyond	2	1	1	0	6	4	30	82	126 (70.4)
Total (%)	4 (2.2)	1 (0.6)	31 (17.3)		57 (31.8)			86 (48.0)	179 (100)

C: Category; Non-N: Non-neoplastic; LGIN: Low-grade intraepithelial neoplasia; HGIN: High-grade intraepithelial neoplasia; MP: Muscularis propria. [1]The histopathologic diagnoses of resected specimens were made using the World Health Organization classification. The comparison of two groups (intramucosal lesions (i.e. Non-N, LGIN and HGIN) *versus* submucosal invasive carcinomas) tested by Fisher's exact test showed $P = 0.01$. The comparison of two groups (intramucosal lesions *versus* those that had invaded the submucosa or beyond) tested by Fisher's exact test showed $P < 0.001$.

G: Group. [1]The histopathologic diagnoses of resected specimens were made using the World Health Organization classification. The comparison of two groups [intramucosal lesions (i.e. Non-N, LGIN and HGIN) *versus* submucosal invasive carcinomas] tested by Fisher's exact test showed $P < 0.0001$. The comparison of two groups (intramucosal lesions *versus* those that had invaded the submucosa or beyond) tested by Fisher's exact test showed $P < 0.0001$.

Relationship between the diagnoses of cold biopsy specimens made under the rVC guidelines and the depth of invasion in resected specimens

The histopathologic diagnoses of 399 cold biopsy specimens made using the rVC guidelines were as follows: 51 for C1; one for C2; 50 for C3; four for C4.1; 14 for C4.2; 28 for C4.3; 98 for C4.4; and 153 for C5. The final rVC diagnoses for the 179 lesions included four C1 lesions, one C2 lesion, 31 C3 lesions, 57 C4 lesions, and 86 C5 lesions. Table 1 shows the relationship between the final histopathologic diagnoses of the cold biopsy specimens using the rVC criteria and the depth of invasion in resected specimens of the same lesions. The resected specimens were diagnosed as follows: 35 intramucosal lesions (two non-neoplastic lesions; 12 low-grade intraepithelial neoplasias; 21 high-grade intraepithelial neoplasias); 18 submucosal lesions; and 126 lesions in the muscularis propria or beyond. The sensitivity of the rVC system to distinguish intramucosal lesions from submucosal invasive carcinomas was 22.2% (95% CI, 3.0%-41.4%), with a positive predictive value of 100%. Specificity and negative predictive value were 100% and 71.4% (95% CI, 58.8%-84.1%), respectively. The comparison of two groups (intramucosal lesions *versus* submucosal invasive carcinomas) tested by Fisher's exact test showed $P = 0.01$. The sensitivity of the rVC system to distinguish intramucosal lesions from lesions invasive to the submucosa or beyond was 59.7% (95% CI, 51.7%-67.7%), with a positive predictive value of 100%. Specificity and negative predictive value were 100% and 37.6% (95% CI, 27.7%-47.4%), respectively. The comparison of two groups (intramucosal lesions *versus* those that had invaded the submucosa or beyond) tested by Fisher's exact test showed $P < 0.001$.

Relationship between the diagnoses of cold biopsy specimens made under the JGC guidelines and the depth of invasion in resected specimens

Histopathologic diagnoses of 399 cold biopsy specimens made using the JGC criteria were as follows: 51 specimens in G1; one in G2; 50 in G3; four in G4; and 293 in G5. The final diagnoses for the 179 lesions using the JGC guidelines were as follows: four G1 lesions; one G2 lesion; 31 G3 lesions; three G4 lesions; and 140 G5 lesions. Table 2 shows the relationship between the final histopathologic diagnoses of the cold biopsy specimens using the JGC guidelines and the depth of invasion in resected specimens of the same lesions. The histopathologic diagnoses made for the 179 resected specimens are described in the section above. The sensitivity of the JGC system to distinguish intramucosal lesions from submucosal invasive carcinomas was 83.3% (95% CI, 66.1%-100%), with a positive predictive value of 83.3% (95% CI, 66.1%-100%). Specificity and negative predictive value were 91.4% (95% CI, 82.2%-100%) and 91.4% (95% CI, 82.2%-100%), respectively. The comparison of two groups (intramucosal lesions *versus* submucosal invasive carcinomas) tested by Fisher's exact test showed $P < 0.0001$. The sensitivity of

the JGC system to distinguish intramucosal lesions from lesions invasive to the submucosa or beyond was 95.1% (95% CI, 91.6%-98.7%), with a positive predictive value of 97.9% (95% CI, 95.5%-100%). Specificity and negative predictive value were 91.4% (95% CI, 82.2%-100%) and 82.1% (95% CI, 70.0%-94.1%), respectively. The comparison of two groups (intramucosal lesions *versus* those that had invaded the submucosa or beyond) tested by Fisher's exact test showed $P < 0.0001$. Three high-grade intraepithelial neoplasias and 137 of 144 carcinomas that had invaded the submucosa or beyond were diagnosed as "carcinoma" (G5) under the JGC guidelines.

DISCUSSION

From a therapeutic point of view, the most important histopathologic distinction in cold biopsy specimens taken from colorectal epithelial neoplastic lesions is whether there is evidence of invasion into the submucosa (or beyond). Histopathologic confirmation of lesions using cold biopsy specimens are ideal for predicting the therapeutic implications of colorectal epithelial neoplasia that cannot be treated by direct ER. We have shown that the rVC system had a high positive predictive value (100%) in diagnosing submucosal invasive carcinomas and carcinomas that had invaded the muscularis propria or beyond from cold biopsy specimens. These results may provide both patients and physicians with valuable information that will facilitate management decisions.

In cases of colorectal polyps, Livstone *et al*[12] reported 13 discrepancies (26%) between the diagnoses from single fractional biopsies and the final diagnoses of colonic lesions in 42 patients with 50 colonic polyps (0.8 to 4.5 cm in diameter). Of these discrepancies, four carcinomas invasive to the submucosa or beyond were found; adenomatous epithelium was detected in the fractional biopsies from two cases and normal colonic epithelium in the other two cases[12]. Pugliese *et al*[13] reported that among 53 patients with 59 colorectal polyps ($\geqslant$ 5 mm), seven cases had carcinomas that had invaded the submucosa or beyond, and four of these had been underestimated from the cold biopsy specimens. Gondal *et al*[14] reported that among 442 patients with a total of 532 colorectal adenomas ($\geqslant$ 2 mm) biopsied by flexible sigmoidoscopy and removed by colonoscopy, the assessment of the intraepithelial neoplasia status was changed in 51 adenomas (10%), and 38 (7%) of these had been underestimated from the cold biopsy diagnoses compared with the diagnoses based on polypectomy samples. Of these lesions, 389 (73%) were < 10 mm in diameter. In addition, four carcinomas invading the submucosa or beyond had been underestimated as being low-grade or high-grade intraepithelial neoplasias[14].

These observations suggest that cold biopsy-based diagnoses underestimate histopathologic diagnoses of the resected lesions in some cases of colorectal epithelial neoplastic lesions. In our study, the rVC system underestimated the distinction between intramucosal lesions and submucosal invasive carcinomas in 26.4% (14/53) of lesions. The sensitivity of the rVC system for distinguishing between intramucosal lesions and submucosal invasive carcinomas was poor (22.2%). Therefore, histopathologic examination of completely resected lesions was essential for the adequate diagnosis and appropriate treatment of the colorectal polyps including submucosal invasive carcinomas[15].

Overall, the rVC system had a high specificity (100%) for the histopathologic diagnoses of carcinomas invasive to the colorectal submucosa or beyond, whereas the sensitivity was poor (59.7%). The rVC system underestimated the distinction between intramucosal lesions and lesions that invaded the submucosa or beyond in 32.4% (58/179) of lesions. The poor sensitivity and high underestimation rate of the rVC system was caused by the high prevalence (80.4%) of submucosal or beyond invasive colorectal carcinomas in our cohort, and because the pathologists used invasion of the submucosa or beyond as an obligatory criterion for the diagnosis of carcinoma.

Direct ER without prior cold biopsy of small (< 10 mm) lesions is usually feasible and histopathologic examination of completely resected lesions enables adequate diagnosis and appropriate treatment. Therefore, cold biopsies for small lesions are not needed and our cases did not include these lesions. Under the JGC criteria, 137 of 144 carcinomas that invaded the submucosa or beyond were diagnosed as "carcinoma" (i.e. G5). The diagnostic criteria for colorectal carcinoma according to the JGC guidelines appear to attach more importance on nuclear features and glandular structures, and the presence of evident invasion into the submucosal layer is not considered mandatory[1]. Therefore, although the cold biopsy forceps were usually capable of sampling intramucosal lesions only, the diagnosis of "carcinoma" was possible under the JGC guidelines. For the same reason, distinguishing between intramucosal lesions and those invasive to the submucosa or beyond, or overestimating intramucosal lesions as those invasive to the submucosa or beyond was not a problem under the rVC guidelines, whereas three high-grade intraepithelial neoplasias were diagnosed as "carcinomas" using the JGC system.

Lesions can be diagnosed as low-grade dysplasia in the West and as carcinomas in Japan due to the differences in interpreting nuclear and structural features[1]. Japanese pathologists consider these features as clues for the diagnosis of carcinoma, but Western pathologists either do not take these features into consideration (such as rounded nuclei and variable shape of glands) or do not attach similar importance to these features with regard to the severity of dysplasia (such as marked hyperchromatism of nuclei and enlarged prominent nucleoli)[1]. These different histopathologic interpretations of the nuclear and structural features of lesions between Western and Japanese pathologists require further investigation.

The use of the rVC guidelines for cold biopsy specimens has a high positive predictive value in diagnosing carcinomas invasive to the colorectal

submucosa or beyond. However, it is of limited value in predicting the depth of invasion assigned to the resected specimens, especially for the diagnosis of submucosal invasive carcinomas. This should be supplemented by endoscopic assessment of the depth of invasion.

COMMENTS

Background

Large differences have been found between Western and Japanese pathologists in their diagnosis of colorectal epithelial neoplastic lesions. To overcome the differences between the conventional Western and the Japanese criteria, the Vienna Classification attempted to combine the basic concepts of the conventional Western criteria, which emphasizes that invasion is an indicator of metastatic potential, with the strong points of the Japanese criteria, which values consistency between diagnoses from cold biopsies and resected specimens. In the revised Vienna Classification, histopathologic diagnoses are classified into five categories according to neoplastic severity and depth of invasion. However, the efficacy of the revised Vienna Classification for diagnosing colorectal epithelial neoplastic lesions has not been reported.

Research frontiers

Diagnostic discrepancies do not matter to patients if Western and Japanese physicians understand the implications of their respective pathology reports and apply management strategies that are appropriate to the needs of their patients. However, continued attempts to unify Western and Japanese reporting systems are desirable because merging the terminologies of these systems will help codify the advantages of each into a language that is universally understood.

Innovations and breakthroughs

This is the first report investigating the efficacy of the revised Vienna Classification for diagnosing colorectal epithelial neoplastic lesions in cold biopsy specimens.

Applications

The revised Vienna Classification of colorectal epithelial neoplastic lesions seeks to be more closely in tune patient management, however, it should be emphasized that cold biopsy-based diagnoses are subject to the limitations of superficiality and sampling errors.

Peer review

The authors prospectively investigated the efficacy of the revised Vienna Classification for diagnosing colorectal epithelial neoplastic lesions in cold biopsy specimens. The studies are well done, and the manuscript is well written.

Abstract

AIM: To clarify the characteristic features of biliary lesions in patients with autoimmune pancreatitis (AIP) and compare them with those of primary sclerosing cholangitis (PSC).

METHODS: The clinicopathological characteristics of 34 patients with sclerosing cholangitis (SC) associated with AIP were compared with those of 4 patients with PSC.

RESULTS: SC with AIP occurred predominantly in elderly men. Obstructive jaundice was the most frequent initial symptom in SC with AIP. Only SC patients with AIP had elevated serum IgG4 levels, and sclerosing diseases were more frequent in these patients. SC patients with AIP responded well to steroid therapy. Segmental stenosis of the lower bile duct was observed only in SC patients with AIP, but a beaded and pruned-tree appearance was detected only in PSC patients. Dense infiltration of IgG4-positive plasma cells was detected in the bile duct wall and the periportal area, as well as in the pancreas, of SC patients with AIP.

CONCLUSION: SC with AIP is distinctly different from PSC. The two diseases can be discriminated based on cholangiopancreatographic findings and serum IgG4 levels.

Key words: Autoimmune pancreatitis; IgG4; Primary sclerosing cholangitis; Sclerosing cholangitis

INTRODUCTION

Autoimmune pancreatitis (AIP) is a unique form of pancreatitis in which autoimmune mechanisms are suspected of being involved in the pathogenesis. AIP has many clinical, radiological, serological and histopathological characteristics: (1) elderly male preponderance; (2) initial symptom is frequently painless obstructive jaundice; (3) occasional association with impaired pancreatic endocrine or exocrine function, and various extrapancreatic lesions; (4) favorable response to steroid therapy; (5) radiological findings of irregular narrowing of the main pancreatic duct and enlargement of the pancreas; (6) serological findings of elevated serum γ globulin, IgG, or IgG4 levels, along with the presence of some autoantibodies; and (7) histopathological findings of dense infiltration of T lymphocytes and IgG4-positive plasma cells with fibrosis and obliterative phlebitis in the pancreas[1-3]. Bile duct stenosis occurs frequently with AIP, and the major initial symptom in AIP patients is obstructive jaundice. The lower portion of the common bile duct is frequently stenotic. However, when AIP patients develop stenosis in the intrahepatic bile duct, the cholangiographic appearance is similar to that of primary sclerosing cholangitis (PSC)[4,5]. PSC is a progressive disease involving the intra- and extra-hepatic bile ducts. Despite therapy, PSC sometimes leads to liver cirrhosis. However, since AIP patients respond well to steroid therapy, it is necessary to discriminate between sclerosing cholangitis (SC) associated with AIP and PSC. This study aimed

to clarify the characteristic features of biliary lesions in AIP patients and compare them with those of PSC.

MATERIALS AND METHODS

Study patients

Over a 27-year-period, 43 patients (36 male and 7 female, average age 66.4 years) at Tokyo Metropolitan Komagome Hospital were diagnosed with AIP based on the following clinicopathological criteria: irregular narrowing of the main pancreatic duct on endoscopic retrograde pancreatography (n = 43), pancreatic enlargement on ultrasonography (US) or computed tomography (CT) (n = 42), presence of autoantibodies (n = 22), elevated serum IgG4 level in excess of 135 mg/dL (n = 31), characteristic histological findings in the pancreas (n = 12), and responsiveness to steroid therapy (n = 32). In the 43 AIP patients, 34 had SC (lower bile duct in 34, and intrahepatic bile duct in 4). During the same time, 4 patients were diagnosed with PSC according to appropriate criteria[6].

Methods

The stenotic portion of the bile duct was examined by endoscopic retrograde cholangiopancreatography and/or magnetic resonance cholangiopancreatography, and wall thickening of the bile duct in which stenosis was not obvious on cholangiography was assessed on CT and US. Two experienced gastroenterologists retrospectively reviewed these imaging findings without information on the patients. Extrapancreatic lesions, including sclerosing sialadenitis, sclerosing cholecystitis, and retroperitoneal fibrosis, were evaluated on physical examination, CT, and US. Serum IgG4 levels were measured in 30 AIP patients and 2 PSC patients. Histological examination and immunostaining with anti-IgG4 antibody were performed on specimens of the extrahepatic bile duct (6 AIP patients and 1 PSC patient) and liver (3 AIP and 2 PSC patients).

Statistical analysis

Statistical differences between the two groups were analyzed first by the Kruskal-Wallis H-test, followed by Mann-Whitney's U-test if significant. Other analyses were performed using Fisher's exact test. In all tests, $P < 0.05$ was considered statistically significant.

RESULTS

Clinical features

Men were significantly more commonly affected by SC with AIP than by PSC. Patients' age at diagnosis was significantly older in those with SC with AIP. Among the initial symptoms, obstructive jaundice was the most frequently observed in SC with AIP. Elevated serum IgG4 levels were frequent in SC patients with AIP, but not in the 2 PSC patients examined. Sclerosing diseases were frequently associated with SC with AIP. Ulcerative colitis was present in only 2 young PSC patients (Table 1). Thirty-two SC patients with AIP were treated with steroid therapy, and all of them showed a good response. All PSC patients were treated with ursodeoxycholic acid, and 1 patient underwent steroid therapy for associated ulcerative colitis. Cholangiographic findings progressed gradually in three PSC patients, and one patient ultimately required liver transplantation. All SC patients with AIP had a favorable outcome without liver failure.

Table 1 Clinical differences between sclerosing cholangitis with autoimmune pancreatitis and primary sclerosing cholangitis

	SC with AIP	PSC	P value
Average age (yr)	63.8	39.2	< 0.01
Male/Female	29/5	1/3	< 0.05
Obstructive jaundice +/-	30/4	0/4	< 0.01
Elevated serum IgG4 +/-	26/30	0/2	
Associated sclerosing disease +/-	20/14	0/4	< 0.05

SC with AIP: Sclerosing cholangitis with autoimmune pancreatitis; PSC: Primary sclerosing cholangitis.

Figure 1 Endoscopic retrograde cholangiography of a patient with autoimmune pancreatitis showing a relatively long stricture of the hepatic hilar bile duct.

Cholangiopancreatographic findings

On pancreatography, narrowing of the main pancreatic duct was detected in all SC patients with AIP, but no abnormal findings were detected in any of the PSC patients. On cholangiography, the intrahepatic bile duct was involved in all PSC patients, but was involved in only four SC patients with AIP (Figure 1). Segmental stenosis of the lower bile duct was observed in all SC patients with AIP, but was not detected in any of the PSC patients. Extensive involvement of the bile duct, showing widespread wall thickening of the middle and upper bile duct where stenosis was not obvious on cholangiography, was detected only in 14 SC patients with AIP, although there was no significant difference between the two groups. A diffusely distributed, beaded and pruned-tree appearance and diverticular formation were detected only in PSC patients (Figure 2 and Table 2). A long stricture was detected in the hepatic hilar region in all 4 SC patients with AIP involving the intrahepatic bile duct.

Histological and immunohistochemical findings

In PSC, the hilar bile duct displayed diffuse fibrosis with moderate lymphoplasmacytic infiltration. The liver of PSC patients showed features of biliary cirrhosis, and fibro-obliterative lesions characterized by onion skin-like periductal fibrosis with predominantly lymphocytic infiltration were observed around the intrahepatic bile

Table 2 Cholangiopancreatographic differences between sclerosing cholangitis with autoimmune pancreatitis and primary sclerosing cholangitis

	SC with AIP	PSC	*P* value
Narrowing of the main pancreatic duct +/-	34/0	0/4	< 0.01
Stenosis of the intrahepatic bile duct +/-	4/30	4/0	< 0.01

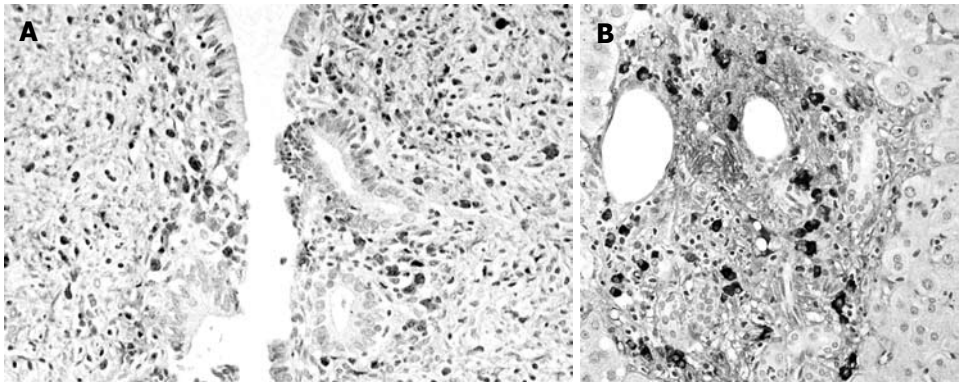

Figure 3 IgG4-immunostaining of the bile duct (A) and liver (B) of a patient with autoimmune pancreatitis. Dense infiltration of IgG4-positive plasma cells was detected in the bile duct wall (A) and the periportal area of the liver (B).

duct. However, infiltration of IgG4-positive plasma cells was not detected in the bile duct or liver.

The histological findings of SC associated with AIP included transmural fibrosis and dense lymphoplasmacytic infiltration of the bile duct wall, along with lymphoplasmacytic infiltration and fibrosis in the periportal area of the liver. Compared with PSC, lymphoplasmacytic infiltration was denser, the degree of fibrosis was less severe, and the onion skin-like appearance was not observed. Dense infiltration of IgG4-positive plasma cells was detected in the bile duct wall (Figure 3A) and the periportal area (Figure 3B), as well as in the pancreas, of patients with AIP.

DISCUSSION

SC is a heterogeneous disease that may be associated with choledocholithiasis, biliary tumor, or infection. SC of unknown origin is called PSC. PSC is progressive despite conservative therapy and involves the intra- and extrahepatic bile ducts, resulting in liver cirrhosis. The effect of steroid therapy is questionable, and liver transplantation currently provides the greatest hope for a possible cure. It occurs among patients in their 30 and 40 s and is frequently associated with inflammatory bowel disease[7,8]. Pancreatograms are not abnormal in most cases[9].

However, an analysis of 192 PSC patients in Japan found that their characteristics differed from those in Western counties, with regard to age distribution and the incidence of complications[10]. In that analysis, the patients were predominantly men, and two peaks in age distribution at diagnosis (20-30 years and 50-70 years) were identified. Compared to younger patients, those aged 40 years or older displayed a lower incidence of associated ulcerative colitis, whereas the incidence of chronic pancreatitis was higher.

SC is frequently associated with AIP, and occurs predominantly in elderly men. The major initial symptom of SC with AIP is obstructive jaundice, which differs from PSC. The most prominent feature on cholangiography for SC with AIP was stenosis of the lower bile duct. When stenosis is found in the intrahepatic or the hilar hepatic bile duct, the cholangiographic appearance is very similar to that of PSC[4,5]. However, a long stricture was detected in the hepatic hilar region in SC patients with AIP, instead of the beaded and pruned-tree appearance that is frequently observed in PSC. Widespread wall thickening of the middle and upper bile ducts was also detected only in SC patients with AIP.

SC patients with AIP responded dramatically well to steroid therapy and showed a favorable outcome[5,9,11]. Histologically, dense infiltration of IgG4-positive plasma cells was detected in the bile duct wall and the periportal area of SC patients with AIP, but it was not detected in PSC patients. SC with AIP is sometimes associated with sclerosing diseases such as sclerosing sialadenitis, sclerosing cholecystitis, or retroperitoneal fibrosis, and these salivary, gallbladder, and retroperitoneal lesions show similar histological findings to those in the bile duct and pancreas. Furthermore, abundant infiltration of IgG4-positive plasma cells is detected in various organs of AIP patients[12,13]. Therefore, we proposed a new clinicopathological entity, an IgG4-related sclerosing disease, which is histopathologically characterized by extensive IgG4-positive plasma cell and T lymphocyte infiltration of various organs. We also suspect that AIP and SC with AIP is a pancreatic and bile duct lesion of this systemic disease[13-15]. Based on the above findings, SC with AIP should be differentiated from

PSC. In particular, since SC with AIP responds well to steroid therapy, discrimination between the two diseases is necessary before making therapeutic decisions. Clinically, serum IgG4 levels and cholangiopancreatographic findings are useful in differentiating between the two diseases.

Considering the predominance of elderly men, the infrequent association with inflammatory bowel disease, and the frequent association with chronic pancreatitis, many older patients diagnosed with PSC in Japan may actually have SC with AIP.

In conclusion, since SC with AIP is induced by different mechanisms to those in PSC, the condition should be differentiated from PSC. The two diseases can be discriminated based on their cholangiopancreatographic findings and serum IgG4 levels.

COMMENTS

Background

When patients with autoimmune pancreatitis (AIP) develop stenosis in the intrahepatic bile duct, the cholangiographic appearance is similar to that of primary sclerosing cholangitis (PSC). PSC is a progressive disease involving the intra- and extrahepatic bile ducts.

Innovations and breakthroughs

Sclerosing cholangitis with AIP is distinctly different from PSC. Only SC patients with AIP had elevated serum IgG4 levels and responded well to steroid therapy. Segmental stenosis of the lower bile duct was observed only in SC patients with AIP, but a beaded and pruned-tree appearance was detected only in PSC patients. Dense infiltration of IgG4-positive plasma cells was detected in the bile duct wall and the periportal area of SC patients with AIP.

Applications

Sclerosing cholangitis with AIP responds well to steroid therapy. The differential diagnosis between sclerosing cholangitis with AIP and PSC is important to ensure optimal patient treatment.

Peer review

The authors described the characteristic features of biliary lesions in autoimmune pancreatitis patients. The paper is well presented and the result are interesting.

Abstract

AIM: To assess the ability of endoscopic ultrasonography (EUS) to differentiate neoplastic from non-neoplastic polypoid lesions of the gallbladder (PLGs).

METHODS: The uses of EUS and transabdominal ultrasonography (US) were retrospectively analyzed in 94 surgical cases of gallbladder polyps less than 20 mm in diameter.

RESULTS: The prevalence of neoplastic lesions with a diameter of 5-10 mm was 17.2% (10/58); 11-15 mm, 15.4% (4/26), and 16-20 mm, 50% (5/10). The overall diagnostic accuracies of EUS and US for small PLGs were 80.9% and 63.9% ($P < 0.05$), respectively. EUS correctly distinguished 12 (63.2%) of 19 neoplastic PLGs but was less accurate for polyps less than 1.0 cm (4/10, 40%) than for polyps greater than 1.0 cm (8/9, 88.9%) ($P = 0.02$).

CONCLUSION: Although EUS was more accurate than US, its accuracy for differentiating neoplastic from non-neoplastic PLGs less than 1.0 cm was low. Thus, EUS alone is not sufficient for determining a treatment strategy for PLGs of less than 1.0 cm.

Key words: Endoscopic ultrasonography; Neoplastic lesion; Polypoid gallbladder lesion

INTRODUCTION

Polypoid lesions of the gallbladder (GB) are increasingly detected by ultrasonography (US). Indeed, 4%-7% of healthy individuals have been reported to have polyps of the GB[1,2]. The significance of these polypoid lesions is poorly understood, and the appropriate management of these lesions is controversial. Although most GB polyps are benign, some early carcinomas of the GB share the same appearance as benign polyps. Currently, GB polyps larger than 1 cm should be surgically removed because of the increased risk of malignancy[3]. On the other hand, patients with smaller polyps usually require repeated US and follow-up. Distinguishing between non-neoplastic, neoplastic, and potentially malignant lesions is a major diagnostic dilemma, and the therapeutic options for these lesions remain controversial.

Endoscopic ultrasonography (EUS) is considered to be superior to conventional US for imaging GB lesions, because EUS can provide high-resolution images of small lesions with higher ultrasound frequencies (7.5-12 MHz *vs* 3.5-5 MHz)[4,5]. The improved accuracy of EUS in imaging small GB lesions has been previously reported in a surgical series[5-7]. However, polyps with a maximum diameter of less than 10-15 mm are difficult to differentially diagnose in many cases. The present study assesses the predictive value of EUS in the differential diagnosis of small polypoid lesions (maximum diameter, $\leqslant$ 20 mm) of the GB in a surgical series.

MATERIALS AND METHODS

Patients

Between 1996 and 2006, 365 patients underwent EUS for small (maximum diameter, $\leqslant$ 20 mm) polypoid lesions

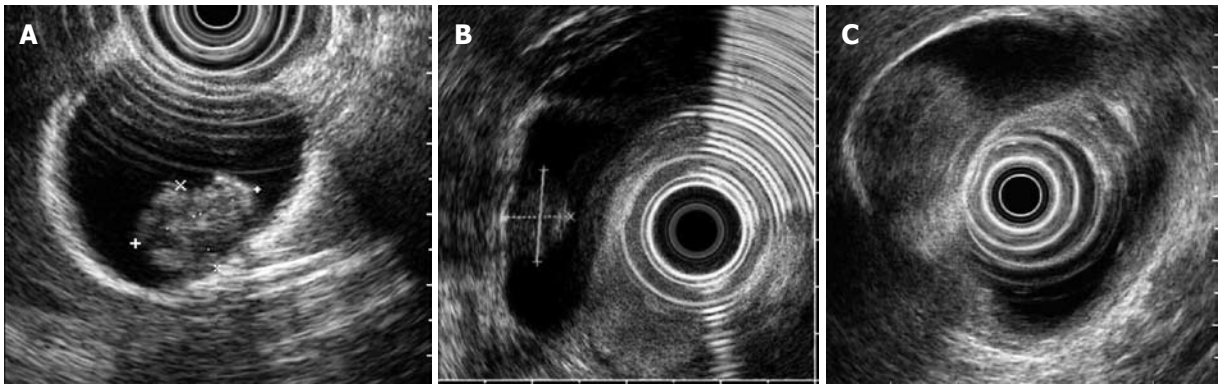

Figure 1 Polypoid lesions of gallbladder. A: Cholesterol polyp of the gallbladder. EUS shows a 13-mm-diameter, granular-surfaced, pedunculated mass with an internal echo pattern characterized by an aggregation of echogenic spots. Histological examination of the surgical specimen showed a cholesterol polyp; B: Adenoma of the gallbladder. EUS shows a 10-mm-diameter, homogeneously isoechoic, pedunculated mass. The histological diagnosis was tubulovillous adenoma with focal high-grade dysplasia; C: Adenocarcinoma of the gallbladder. EUS shows a 19-mm-diameter, smooth-surfaced, heterogeneously echogenic, pedunculated mass. Histological examination of the surgical specimen showed adenocarcinoma.

of the GB detected by transabdominal US. Of these 365 patients, 94 patients who underwent laparoscopic cholecystectomy for GB polyps were enrolled. US was performed as an abdominal screening test for asymptomatic patients or as a detailed examination for patients suspected of having a gastrointestinal disorder because of clinical symptoms. When US revealed polypoid lesions inside the GB, the patient then underwent EUS. In principle, EUS was indicated for polypoid lesions exceeding 5 mm or for potentially neoplastic polyps. Patients with localized adenomyomatosis or diffuse wall-thickening lesions resulting from inflammation were excluded from the study.

Methods

All patients with suspected neoplastic lesions based on EUS underwent surgery. Generally, surgery was not indicated for patients with a EUS diagnosis of non-neoplastic lesions, except for symptomatic cases or patients undergoing combined operations for other abdominal diseases. In our surgical series, the EUS diagnosis was compared with the histopathological diagnosis. Based on the pathological evaluation of specimens obtained upon cholecystectomy, the GB polyps were assigned into two groups: neoplastic (adenoma and carcinoma) and non-neoplastic (cholesterol, inflammatory, and fibrous). In patients with multiple polyps, the size of the largest polyp was measured.

Demographics and EUS findings were prospectively collected at the time of the procedure and were analyzed retrospectively. EUS was performed by one of the authors with knowledge of the ultrasonographic findings. In all cases, the differential diagnosis of polypoid lesions of the GB by EUS and US was made according to the criteria outlined below[5,6].

Cholesterol polyps (Figure 1A) are pedunculated lesions with a granular surface. The internal echo is hyperechoic to isoechoic with a tiny, spotty echo pattern. Relatively large polyps, those greater than 10 mm in diameter, may not give the typical image but may have a spotty echo area. Localized adenomyomatosis is imaged as a sessile echogenic mass containing multiple microcysts or with a comet tail artifact. Neoplastic polyps (adenoma, Figure 1B or carcinoma, Figure 1C) are pedunculated or sessile masses without echogenic spots, multiple microcysts, or comet tail artifacts; the internal echo is hypoechoic to isoechoic and almost homogeneous.

Transabdominal US was performed using a real-time scanner with a 3.5-MHz curved array transducer (SSD-2000; Aloka, Tokyo, Japan). EUS was performed using an echoendoscope with a 7.5-MHz or 12-MHz radial sector scan transducer (GF-UM2, UM3, UM20; Olympus Co., Tokyo, Japan). The GB was visualized from the duodenum and gastric antrum. For sedation, 5 mg of midazolam were administered intravenously.

Statistical analysis

The results were analyzed by Fisher's exact probability test or the Wilcoxon test, as appropriate. Differences were considered significant at $P < 0.05$.

RESULTS

Patient characteristics

Of the 94 patients, 19 had neoplastic lesions and 75 had non-neoplastic lesions. The mean age of the patients with non-neoplastic polyps was 50 ± 12.5 years, and that of patients with neoplastic polyps was 51 ± 11.3 years. Most of the non-neoplastic polyps were cholesterol polyps (56/75, 74.7%). Seventeen polypoid lesions were adenomyomatosis, and two polyps were inflammatory polyps. Adenocarcinoma was found in two patients; and adenomas, in 17. Two of the 17 adenomas contained focal high-grade dysplasia. The prevalence of neoplastic lesions with a diameter of 5-10 mm was 17.2% (10/58); 11-15 mm, 15.4% (4/26), and 16-20 mm, 50% (5/10) (Table 1). The average size of non-neoplastic polyps was 9.8 ± 2.8 mm (5-18). Among neoplastic polyps, the average size of an adenoma without high grade dysplasia, adenoma with high grade dysplasia, and adenocarcinoma were 9.9 ± 3.6 mm (6-17), 12.0 mm (7 and 17), and 19.0 mm (13 and 25), respectively. The average size

of neoplastic polyps including adenoma with high grade dysplasia and carcinoma tended to be larger than neoplastic polyps without high grade dysplasia and non-neoplastic polyps.

Differential diagnosis by EUS and US

Differential diagnosis by EUS and US was successful in 70 (74.5%) and 54 (57.4%) of 94 patients, respectively; the difference between these rates was significant (P = 0.014). When the results of EUS were assessed according to the pathological results (Table 2), cholesterol polyps were correctly identified in 47 of 56 patients (83.9%). The unsuccessful diagnoses included nine cases that were misjudged as adenoma. Adenomyomatosis was correctly identified in 11 of 17 patients (64.7%). Among the six misdiagnosed cases, four were cholesterol polyps and two were neoplastic polyps. Neoplastic polyps were correctly identified in 12 of 19 patients (63.2%). The unsuccessful diagnoses included seven cases misjudged as cholesterol polyps. Five of the seven cases were less than 1.0 cm in size, and another of the cases was 17 mm in size before surgery. EUS showed a homogeneously isoechoic, pedunculated mass, and abdominal CT showed an enhanced polypoid mass of the GB in the arterial phase. Therefore, we diagnosed it as an early cancer. However, this polyp was confirmed to be a cholesterol polyp after cholecystectomy (Figure 2). Of the 19 neoplastic polyps, two were adenocarcinoma, with diameters of 10 and 19 mm, respectively.

Table 3 shows the EUS results categorized according to the size of the polypoid GB lesion (< 10 mm *vs* 10-20 mm). Of the 58 cases with a diameter less than 10 mm, EUS correctly distinguished 84.6% (33/39) of the cholesterol polyps, 36.4% (4/11) of the adenomyomatosis, and 50.0% (4/8) of the neoplastic lesions. Of the 36

	Sensitivity	Specificity	PPV	NPV	Accuracy
EUS					
Overall	66.7	84.2	50.0	91.4	80.9
5-10 mm	44.4	86.0	36.4	89.6	79.7
11-20 mm	88.9	81.5	61.5	95.7	83.3
US					
Overall	47.4	72.0	30.0	84.4	67.0
5-10 mm	20.0	83.3	20.0	83.3	72.4
11-20 mm	77.8	51.9	35.0	87.5	63.9

PPV: Positive predictive value; NPV: Negative predictive value.

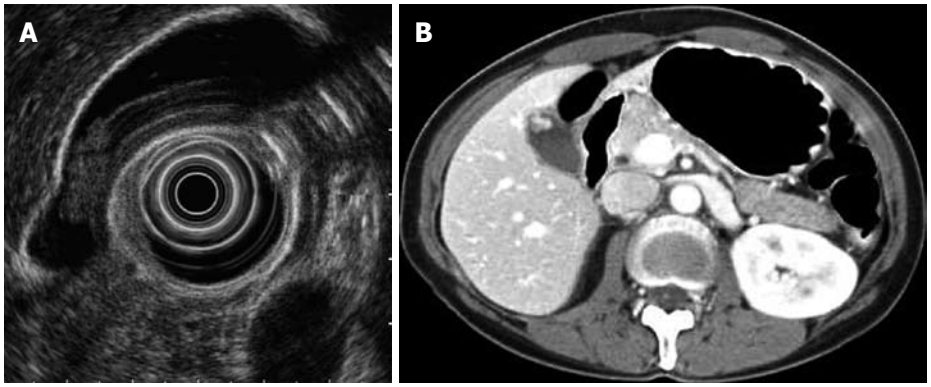

Figure 2 Misjudged case diagnosed as adenoma or carcinoma before surgery. A: EUS shows a 17.5-mm-diameter, homogeneously isoechoic, pedunculated mass; B: Abdominal CT shows an enhanced polypoid mass of the gallbladder in arterial phase. Histological examination of the surgical specimen showed a cholesterol polyp.

cases with polyps greater than 10 mm in diameter, EUS correctly distinguished 82.4% (14/17) of the cholesterol polyps, 87.5% (7/8) of the adenomyomatosis, and 88.9% (8/9) of the neoplastic lesions. The accuracy of EUS in diagnosing neoplastic lesions tended to be lower for polyps greater than 10 mm (79.7%) than for polyps less than 10 mm (83.3%) ($P = 0.12$). There was no significant difference between EUS and US in the diagnosis of cholesterol polyps.

Table 4 summarizes the results of differential diagnoses between neoplastic and benign polyps assessed by EUS and US. The overall sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy for EUS (US) in the diagnosis of neoplastic lesions were 66.7% (47.5%), 84.2% (72.0%), 50.0% (30.0%), 91.4% (84.4%), and 80.9% (67.0%), respectively (Table 5). When the results for relatively smaller polyps (diameter, < 10 mm) and for larger polyps (diameter, > 10 mm) were considered separately, the sensitivity, specificity, PPV, NPV, and accuracy for US were all lower than the values for EUS in both groups. The values for EUS in polyps less than 1.0 cm in diameter were lower than those in polyps greater than 1.0 cm in diameter.

DISCUSSION

Owing to the widespread use of conventional US, an increasing number of polypoid lesions of the GB are being identified. However, it is difficult to make differential diagnoses of polypoid GB lesions by US, CT, and magnetic resonance imaging. In general, factors that increase the probability that a GB polyp will be malignant include age greater than 50 years, a solitary lesion, a polyp greater than 1.0 cm in size, the presence of gallstones, a sessile lesion, and a rapid change in lesion size on serial ultrasonography[8,9]. All of these factors should be taken into consideration when advising patients with a polypoid lesion of the GB (PLG). The correct surgical management of PLGs is controversial. Although it is widely agreed that patients with symptomatic PLGs should be offered cholecystectomy, preferably by the laparoscopic route, the best treatment for an asymptomatic patient is not clear. In cases with a high probability of a malignant lesion, such as a PLG larger than 2 cm, open surgery is preferred to reduce the risk of tumor seeding associated with laparoscopic surgery. For asymptomatic PLGs smaller than 1 cm, follow-up US every 6 to 12 mo is necessary to exclude a rapidly growing malignant tumor[3].

There are a number of reports suggesting that sessile lesions smaller than 1.0 cm have an increased incidence of malignancy compared with those with a stalk[10]. In this study, 10 of 19 (52.6%) neoplastic polyps were pedunculated lesions smaller than 1 cm. Sugiyama *et al*[11] reported that approximately 30% of polyps with a diameter of 11-15 mm were cholesterol polyps and that about 40% of neoplastic polyps were 6-10 mm in diameter. Kubota *et al*[12] found that 57% of cholesterol polyps, 75% of adenomas, and 13% of neoplastic polyps were less than 10 mm in diameter. Thus, for polyps less than 10 mm in diameter, criteria other than size, along with an aggressive work-up, are needed to discriminate between neoplastic and non-neoplastic polyps.

EUS is considered to be superior to conventional US for imaging GB lesions, because EUS can provide high-resolution images of small lesions at higher ultrasound frequencies (7.5-12 MHz *vs* 3.5-5 MHz). Many

studies have investigated the relationship between the neoplastic nature of GB polyps and their morphological characteristics such as the number of polyps, the polyp shape, the diameter of the largest polyp, the echo level and internal echo pattern, and the polyp margin[12-14]. Among these variables, size is the most significant predictor of neoplastic polyps. However, the accuracy of EUS in identifying neoplastic lesions among polyps smaller than 10 mm in our study was only 44.4%, which was significantly lower than the identification rate among polyps greater than 1.0 cm (88.9%, $P < 0.05$).

To overcome the limitation of EUS in the differential diagnosis of neoplastic and non-neoplastic polypoid lesions less than 10-15 mm or less than 20 mm in size, an EUS scoring system has been adopted[7,15]. According to this system, the sensitivity, specificity, and accuracy of the risk for a neoplastic polyp were 81%, 86%, and 83.7%, respectively, for polyps with an EUS score of 6 or greater, whereas the sensitivity, specificity, and accuracy using a 10 mm cut-off diameter were 60%, 64%, and 62.7%, respectively[7]. Based on the EUS scoring system of Sadamoto *et al*[15], the sensitivity, specificity, and accuracy of the risk for neoplasia in polyps with scores of 12 or higher were 77.8%, 82.7%, and 82.9%, respectively. The EUS scoring system will be useful for differentiating between neoplastic and non-neoplastic polyps of the GB, however, the EUS variables used to calculate the score differ between the different EUS scoring systems.

The accuracy of EUS results tend to be lower for polyps smaller than 1 cm than for polyps greater than 1 cm in size. In our study, seven of 11 (63.6%) polyps less than 1.0 cm in size that were determined to be neoplastic by EUS before surgery were confirmed after surgery to be non-neoplastic lesions, including six cholesterol polyps and one adenomyomatosis. Using US, only two of 10 cases were determined to be neoplastic polyps after surgery. Thus, despite its higher accuracy compared with conventional US, EUS could not differentiate malignant from benign polyps smaller than 1.0 cm. No carcinoma was found in polyps less than 1.0 cm in size, but the prevalence of adenoma was 17.2% in our study.

Although EUS was more accurate than US, its accuracy for differentiating malignant from benign PLGs of less than 1.0 cm was low. EUS could not differentiate malignant lesions from benign polyps less than 1.0 cm in size, because such small polyps do not often show findings typical of cholesterol polyps, localized types of adenomyomatosis, or neoplastic lesions. Thus, EUS alone is not sufficient for determining a treatment strategy for PLGs of less than 1.0 cm. Polyps less than 1.0 cm in diameter without typical EUS or US findings should be followed-up by US at intervals of 6-12 mo. Changes in the size or structure of polypoid lesions should prompt reinvestigation with EUS and lead physicians to consider cholecystectomy.

COMMENTS

Background

The distinction between non-neoplastic, neoplastic and potentially malignant lesions is a major diagnostic dilemma and the therapeutic options for small polypoid lesions of the gallbladder remain controversial. Although endoscopic ultrasonography (EUS) was more accurate than ultrasonography (US), its accuracy for differentiating malignant from benign polypoid gallbladder lesions (PLGs) of less than 1.0 cm was low.

Research frontiers

Among many variables, size is the most significant predictor of neoplastic polyps. Although EUS was more accurate than US, its accuracy for differentiating malignant from benign PLGs of less than 1.0 cm was low. Thus, EUS alone is not sufficient for determining a treatment strategy for PLGs of less than 1.0 cm.

Innovations and breakthroughs

Many studies have investigated the relationship between the neoplastic nature of gallbladder (GB) polyps and their morphological characteristics such as the number of polyps, the polyp shape, the diameter of the largest polyp, the echo level and internal echo pattern, and the polyp margin. Among these variables, size is the most significant predictor of neoplastic polyps. However, the accuracy of EUS results tends to be lower for polyps smaller than 1 cm than for polyps greater than 1 cm in size. To overcome the limitation of EUS in the differential diagnosis of neoplastic from benign PLGs, an EUS scoring system has been adopted. The EUS scoring system will be useful for differentiating between neoplastic and non-neoplastic polyps of the GB, however, the EUS variables used to calculate the score differ between the different EUS scoring systems. Thus, EUS alone is not sufficient for determining a treatment strategy for PLGs of less than 1.0 cm.

Applications

The study results suggest that EUS alone is not sufficient for determining a treatment strategy for PLGs of less than 1.0 cm. Thus, new diagnostic criteria of EUS or tools are needed to distinguish between non-neoplastic, neoplastic, and potentially malignant lesions in small PLGs.

Terminology

Neoplastic gallbladder polyps: A neoplastic polyp has the properties of a neoplasm including adenoma and carcinoma. A non-neoplastic polyp does not have the properties of a neoplasm and includes cholesterol, inflammatory and fibrous polyps.

Peer review

Although retrospective, this study involves a large series of patients and describes the role of EUS well. The results suggest that EUS alone is not sufficient for determining a treatment strategy for PLGs of less than 1.0 cm and a new diagnostic approach is needed.

Mucin gene expression in bile of patients with and without gallstone disease, collected by endoscopic retrograde cholangiography. *World J Gastroenterol* 2009; 15(19): 2367-2371 Available from: URL: http://www.wjgnet.com/1007-9327/15/2367.asp DOI: http://dx.doi.org/10.3748/wjg.15.2367

Abstract

AIM: To investigate the pattern of mucin expression and concentration in bile obtained during endoscopic retrograde cholangiography (ERC) in relation to gallstone disease.

METHODS: Bile samples obtained at ERC from 29 consecutive patients, 17 with and 12 without gallstone disease were evaluated for mucin content by gel filtration on a Sepharose CL-4B column. Dot blot analysis for bile mucin apoproteins was performed with antibodies to Mucin 1 (MUC1), MUC2, MUC3, MUC5AC, MUC5B and MUC6. Staining intensity score (0-3) was used as a measure of antigen expression.

RESULTS: MUC1, MUC2, MUC3, MUC5AC, MUC5B and MUC6 were demonstrated in 34.4%, 34.4%, 51.7%, 51.7%, 55.1% and 27.5% of bile samples, respectively. The staining intensity scores were 0.62 ± 0.94, 0.58 ± 0.90, 0.79 ± 0.97, 1.06 ± 1.22, 1.20 ± 1.26 and 0.41 ± 0.73, respectively. Mean mucin concentration measured in bile by the Sepharose CL-4B method was 22.8 ± 24.0 mg/mL (range 3.4-89.0 mg/mL). Mean protein concentration was 8.1 ± 4.8 mg/mL (range 1.7-23.2 mg/mL).

CONCLUSION: High levels of MUC3, MUC5AC and MUC5B are expressed in bile aspirated during ERC examination. A specific pattern of mucin gene expression or change in mucin concentration was not found in gallstone disease.

INTRODUCTION

Mucins are high-molecular-weight glycoproteins containing oligosaccharide side-chains attached to serine or threonine residues of the apomucin backbone by O-glycosidic linkages[1-4]. Several mucin (MUC) genes located on different chromosomes have been sequenced and cloned[5-14]. These genes encode apoproteins with specific tandem repeats of amino acids. Antibodies have been developed against the tandem repeats, enabling the identification of specific mucins by immunohistochemistry.

Mucins can be divided into two classes: gel-forming and membrane-associated. Bile mucin has two main domains: one rich in serine, threonine and proline, which contains the majority of the covalently-bound carbohydrates; and another, nonglycosylated domain, enriched in serine, glutamic acid, glutamine and glycine, which binds hydrophobic ligands such as bilirubin. An increased expression of gel-forming mucin, such as MUC5AC and MUC2, was found in patients with hepatolithiasis[15]. Although bile-duct mucin production has been extensively studied in malignant diseases[16-22], little is known about mucin synthesis and expression in cholelithiasis, choledocholithiasis and cholangitis.

The aim of the present study was to examine mucin concentration and specific expression in bile samples of patients undergoing endoscopic retrograde cholangiography (ERC) for the evaluation

of symptomatic bile duct disease, and to investigate the possible association between mucin expression and the clinical states of gallstone disease.

MATERIALS AND METHODS

Sampling

Twenty-nine patients who underwent ERC due to symptomatic bile duct disease were included in the study. Background data and results for ultrasound examinations and liver function tests were obtained from the files. Bile was collected by aspiration, as completely as possible, after the papilla was cannulated and before proceeding to any other procedures, such as papillotomy or choledochal stone removal. The Institutional Review Board (Ethical Committee) of Rabin Medical Center approved the study.

Bile analysis

To determine mucin concentration in the bile, we used the gel-filtration technique, as previously described[23,24]. Briefly, after centrifugation to remove debris, samples of bile were subjected to gel filtration on Sepharose CL-4B columns (1 × 40 cm). We used the closed-column system of Pharmacia Biotech (Cambridge, MA, USA): peristaltic pump, P-1; columns and adapters, C10; fraction collector, Redifrac and Ultraspec 1000; VV/visible spectrophotometer; and chart reader, 80-2109-03. Samples of 2 mL were applied to the columns and eluted with 10 mmol/L Tris-HCl buffer at pH 8.0. Fractions of 1 mL were collected, and optical density was determined at a wavelength of 280 nm. Findings were correlated with a standard curve of readings of mucin purified from porcine stomach (1% bound sialic acid), purchased from Sigma (St. Louis, MO, USA). The amount of protein was estimated by the Laury method.

Dot blot analysis

Samples were subjected to dot blot analysis on nitrocellulose membranes. Membranes were incubated with monoclonal antibodies to Mucin 1 (MUC1), MUC2, MUC3, MUC5AC, MUC5B and MUC6 (all mouse), followed by incubation with anti-mouse and IgG labeled with biotin. Antibody binding was detected with streptavidin-horseradish peroxide and chemiluminescent reagents (EZ-ECL, Beit-Haemek, Israel). Monoclonal antibodies were purchased from Neomarkers (Fremont, CA, USA). Staining intensity was scored (0-3) as a measure of antigen expression.

Statistical analysis

All results are expressed as mean ± SD. The analyses included descriptive statistics, χ^2 test, Student's *t*-test, and linear regression analysis. $P < 0.05$ was considered significant.

RESULTS

Study population

The study group consisted of 13 men and 16 women aged 64.5 ± 16.8 years (Table 1). A gallstone disease was diagnosed in 17 patients and excluded in 12 patients. The indications for ERC, abdominal ultrasound results, and liver function test results before ERC are presented in Table 1.

ERC: Endoscopic retrograde cholangiography; CBD: Common bile duct; SOL: Space-occupying lesion.

ERC results

The ERC findings are shown in Table 2. Linear regression analysis revealed a positive correlation between the mean common bile duct (CBD) width measured on abdominal ultrasound and ERC. There was also a positive correlation between ultrasound findings of cholelithiasis and ERC findings of dilated CBD; between the presence of a clinical syndrome of cholangitis and ultrasound findings of pancreatitis; and between increased concentrations of serum direct bilirubin and ERC findings of CBD stricture. A wider CBD was demonstrated in patients with evidence of choledocholithiasis on ERC (10.90 ± 4.97 mm) than in patients without CBD stones (7.44 ± 1.98 mm). Information from the ultrasound studies and ERC results was used to stratify the patients into a group with gallstone related disease, and a group without gallstone disease.

Mucin concentration in bile

Mean ± SD mucin concentration in bile, measured by the Sepharose CL-4B method, was 22.8 ± 24.0 mg/mL (range 3.4-89.0 mg/mL). Mean protein concentration was 8.1 ± 4.8 mg/mL (range 1.7-23.2 mg/mL). Mucin concentration in bile was not significantly different between men and women (24.68 ± 27.29 mg/mL *vs* 21.38 ± 21.96 mg/mL), patients younger or older than 70

years (18.87 ± 15.72 mg/mL *vs* 26.59 ± 30.07 mg/mL), and patients with or without choledocholithiasis (22.46 ± 24.94 mg/mL *vs* 23.11 ± 24.29 mg/mL).

Mucin expression in bile

The expression of the mucin genes examined by dot blot analysis is shown in Table 3. Linear regression analysis revealed a positive correlation between MUC5AC and MUC5B expression [MUC5B = 0.273 + (0.874 × MUC5AC); R = 0.845]. There was also a positive correlation between MUC1 expression and papillary enlargement on ERC. The correlation between the expressions of the different MUC genes in bile is shown in Table 4.

Comparison of patients with and without gallstone disease

Summarizing the clinical and imaging data allowed the patients to be stratified into a group with diagnosed gallstone disease (n = 17), and a group with no evidence of gallstone disease (n = 12). There were no significant differences in gender, age, laboratory results, ultrasound finding, indication and results of ERC, except in the presence of gallstone disease (Table 5). Mucin concentration in bile was similar in both groups (21.68 ± 7.87 mg/mL *vs* 24.54 ± 24.10 mg/mL, P = 0.759), as was mucin gene expression (Table 5).

Table 3 Mucin gene expression in bile collected in ERC

Mucin gene	Score mean ± SD (range)	Cases (%)
MUC1	0.62 ± 0.94 (0-3)	34.4
MUC2	0.58 ± 0.90 (0-3)	34.4
MUC3	0.79 ± 0.97 (0-3)	51.7
MUC5AC	1.06 ± 1.22 (0-3)	51.7
MUC5B	1.20 ± 1.26 (0-3)	55.1
MUC6	0.41 ± 0.73 (0-2)	27.5

DISCUSSION

Different mucin genes are expressed in bile, and the role of each is unclear. Bile mucin is derived from pure hepatic bile, gallbladder-concentrated bile, and mucin secreted by the bile duct epithelium. Ko *et al*[25] found that in patients with biliary sludge, mucin concentration was higher in bile collected by ERC than in gallbladder bile. They concluded that the biochemical composition of hepatic bile is modified during residence in the gallbladder, contributing to sludge formation, and that hepatic bile samples are therefore inappropriate for microscopic detection of microlithiasis. However, although the mucin concentration in hepatic bile in the present study was similar to that reported by Ko *et al*[25] (22.8 ± 24.0 mg/mL *vs* 20 ± 30 mg/mL), the concentration of mucin in gallbladder bile in our previous study was 17.5 ± 16.4 mg/mL[26], close to that of hepatic bile and much lower than the 450 ± 290 mg/mL found by Ko *et al*[25]. Thus, our studies do not support the assumption of Ko *et al*[25], and this controversy requires further investigation.

We demonstrated a higher expression of two secretory mucin proteins, MUC5AC and MUC5B, and the membrane-bound protein, MUC3. MUC5AC and MUC5B are both gel-forming mucins that may increase the viscosity of bile in cases of symptomatic bile duct disease. Since we could not find a change in mucin concentration or in these specific genes expressions in bile derived from patients with or without gallstone disease, our findings do not support a role for MUC5AC or MUC5B in the etiopathogenesis of gallstones.

Zen and coworkers described a lipopolysaccharide-induced increase in MUC2 and MUC5AC expression in cultured murine biliary epithelial cells, which was mediated by tumor necrosis factor alpha[27]. They concluded that since lipopolysaccharide is a bacterial component, bacterial infection may be involved in the altered mucin secretion in the intrahepatic biliary tree and, thereby, in the lithogenesis of hepatolithiasis. Wandenhaute and coworkers noted a strong mRNA expression of MUC5B, MUC3 and MUC6, and a weak expression of MUC1, MUC2 and MUC5AC, in biliary epithelial cells[28]. Lee and Liu found that MUC3 and MUC5B were the main mucin genes expressed in the biliary epithelium of stone-containing intrahepatic bile ducts and normal controls[29]. Mucin gene expression

was altered in dysplastic preneoplastic cells.

The main weakness of our study is the absence of healthy controls. We could not compare mucin concentration and gene expression in the cholestatic situation with that of normal bile collected in ERC, since ERC is usually performed with therapeutic intent in symptomatic patients.

In the present study, we observed a positive correlation between MUC1 expression in bile and the expression of all the other mucin genes examined. Wang and coworkers reported a similar result in mice[30]. They described a positive correlation between MUC1 and MUC5AC expression, indicating a gene-gene interaction that might affect the accumulation of mucin gel and cholesterol gallstone formation.

In summary, we could not demonstrate a change in mucin secretion and expression between patients with and without gallstone disease, or support the role of mucin in the etiopathogenesis of biliary sludge or stone formation.

COMMENTS

Background

Secretory mucins are gel-forming and may increase bile viscosity. The biochemical composition of hepatic bile is modified during residence in the gallbladder, contributing to sludge formation. An increased expression of gel-forming mucin, such as MUC5AC and MUC2, was found in patients with hepatolithiasis. Little is known about mucin synthesis and expression in cholelithiasis, choledocholithiasis and cholangitis.

Innovations and breakthroughs

High levels of MUC3, MUC5AC and MUC5B are expressed in bile aspirated during endoscopic retrograde cholangiography examination. A specific pattern of mucin gene expression or change in mucin concentration was not found in gallstone disease.

Applications

Expression of other mucin genes or changes in concentration should be investigated in gallstone disease. The role of mucin synthesis and secretion in gallstone formation is still unknown.

Peer review

The manuscript by Vilkin *et al* describes the analysis of certain members of the Mucin gene family in the bile of patients with and without gallstone disease. The authors demonstrate the presence of Mucin 1 (MUC1), MUC2, MUC3, MUC5AC, MUC5B and MUC6 in the bile of all patients, but there was no correlation to

the presence of gall stones. While this manuscript contains negative data, with no conclusive outcomes, the data is nevertheless important as it disproves a currently regarded theory about the role of mucins in gall stone formation.

Abstract

AIM: To determine the correlation of Adjusted Blood Requirement Index (ABRI) with the 7th day outcome in patients presenting with acute variceal bleeding.

METHODS: All patients presenting with acute variceal hemorrhage (AVH) were included. Patients with previous band ligation, sclerotherapy, gastrointestinal or hepatic malignancies were excluded. Patients were managed as per standard protocol for AVH with terlipressin and band ligation. ABRI scores were calculated using the formula outcome of alive or expired up to the 7th day after treatment. The correlation between ABRI and mortality was estimated and a receiver operative characteristic (ROC) curve was plotted.

RESULTS: A total of 113 patients (76 male; 37 female) were included. On assessment, 18 were in Child's Pugh Class A, 82 in Class B and 13 were in Class C. The median number of blood units transfused ± inter-quartile range was 3.0 ± 2.0. The median ± inter-quartile range for ABRI was 1.3 ± 1.1. The ROC curve of ABRI for expiry showed a significantly large area of 0.848 ($P < 0.0001$; 95% CI: 0.75-0.95). A significant correlation of log transformation of ABRI with an outcome of mortality was present ($P < 0.0001$).

CONCLUSION: ABRI correlates strongly with mortality.

INTRODUCTION

Chronic liver diseases and cirrhosis are now being recognized as an important cause of morbidity and mortality worldwide. Acute variceal hemorrhage (AVH) secondary to cirrhosis is to date the most important cause of mortality in cirrhosis[1]. In Pakistan, hepatitis B and C are the most important causes of cirrhosis[2]. The frequency of varices is very high in cirrhotic patients, nearly 40% of patients with compensated cirrhosis and 60% with decompensated cirrhosis have varices[3]. Due to recent advancements, mortality from AVH has been reduced to 20% from the first variceal bleed[4]. Bleeding from AVH carries a high risk of mortality during the first 5 d, with a gradual decline in risk over the next 4-6 wk[5]. The prediction and evaluation of adequate hemostasis by non-endoscopic methods are desired by treating physicians. Many criteria and definitions to evaluate failure to control and prevent variceal bleeding were developed in the Baveno Consensus Workshops Ⅰ-Ⅲ but failed in clinical application due to cumbersome procedures and calculations[6-10]. Further developments in this subject identified an independent factor the "Adjusted Blood Requirement Index (ABRI)" in the Baveno Workshop Ⅳ[11]. ABRI was developed to determine adequate control or failure to control variceal hemorrhage. An ABRI value of $\geqslant 0.75$ at any point time was defined as a failure to control variceal bleeding[11].

Failure of AVB control leads to increased mortality. Thus ABRI could be used to assess the risk of mortality. A correlation between ABRI and mortality has not been evaluated in a prospectively designed study. We have reported its correlation with outcome in a retrospective analysis previously[12]. As there are no reports of a prospective evaluation of ABRI and its relation to mortality, there is a need to assess this correlation in our settings.

This study was designed to evaluate the correlation between ABRI and outcome at the 7th day after hospital admission as improved or expired in acute variceal bleeding.

MATERIALS AND METHODS

All cirrhotic patients who presented with AVB were included. Informed consent was obtained from all patients. Patients with a history of previous band ligation or sclerotherapy, hepatocellular carcinoma and the presence of peptic ulcer or gastrointestinal (GI) malignancy on endoscopy were excluded. Patients were managed as per standard protocol of acute variceal bleeding[10]. Blood samples were taken for Complete Blood Counts, Prothrombin Time, Liver Function Tests and albumin before the start of therapy. Child's Pugh Class assessment was carried out. All patients were given terlipressin 2 mg *iv* initial dose and followed by 1 mg/6 h for 3 d. The number of blood units transfused was noted and endoscopic variceal band ligation (EVBL) was performed within 24 h of admission. Study endpoint was patient outcome (alive or expired at the 7th day after admission). The ABRI value was calculated using the following formula[11]: ABRI = blood units transfused/[(final hematocrit - initial hematocrit) + 0.01]. Child's Pugh score was calculated using the formula[13] shown in Table 1.

Sample size

Sample size was estimated using the following parameters: Level of Significance (α) = 5%; Power of test (1-β) = 80%; Test value of population proportion (P_0) = 20% (0.2); Anticipated value of population proportion (P_a) = 30% (0.3); Sample size (n) = 109.

Statistical analysis

mean ± SD was calculated for age. Median and inter-quartile range were calculated for the number of blood units transfused and ABRI. Frequencies of gender, Child's Pugh Class and outcome were calculated. ABRI values $\geqslant$ 0.75 were recoded into a new variable as uncontrolled while ABRI values < 0.75 were recoded as controlled and their frequency estimated. χ^2 test was performed for outcome with ABRI control status and Child's Pugh Class was carried out with continuity correction and likelihood ratio applied where indicated. A receiver operative characteristic (ROC) curve of ABRI was plotted for expiry. Log transformation of variable ABRI was carried out as it was not normally distributed and then used for Pearson's Bivariate correlation with outcome. The significance level was set at $P \leqslant 0.05$. SPSS version 17.0 was used for statistical analysis.

Table 1 Child's Pugh score was calculated (using formula)

Parameter	Numerical score		
	1	2	3
Ascites	None	Slight	Moderate to severe
Encephalopathy	None	Slight to moderate	Moderate to severe
Bilirubin (mg/dL)	< 2.0	2-3	> 3.0
Albumin (g/dL)	> 3.5	2.8-3.5	< 2.8
Prothrombin time (prolonged in seconds)	1-3 s	4-6 s	> 6.0

Child's Pugh Class A = 5-6 points; Child's Pugh Class B = 7-9 points; Child's Pugh Class C = 10-15 points.

Table 2 Cross tabulation of ABRI groups with outcome

		Outcome		Total
		Alive	Expired	
ABRI groups	Controlled	27	0	27
	Uncontrolled	67	19	86
Total		94	19	113

RESULTS

A total of 113 patients fulfilling the inclusion/exclusion criteria were inducted. These included 76 (67.3%) male (44.3 ± 11.8 years) and 37 (32.7%) female (44.1 ± 9.4 years). Terlipressin was given to 111 patients (98.2%) immediately on admission. EVBL was performed in 105 (92.9%) patients. The assessment on admission showed that 18 (15.9%) were in Child's Pugh Class A; 82 (72.6%) in Child's Pugh Class B and 13 (11.5%) were in Child's Pugh Class C. The median number of blood transfusions given was 3.0 pints and the inter-quartile range was 2.0. The median ABRI was 1.3 with an inter-quartile range of 1.1. The number of patients with ABRI $\geqslant$ 0.75 was 86 (76.1%) showing a failure to control variceal bleeding according to ABRI criteria. Outcome at the 7th day after admission showed that 94 (83.2%) patients were alive while 19 (16.8%) patients had expired during this period. Cross tabulation of outcome (alive and expired) with ABRI status [controlled (< 0.75) and uncontrolled ($\geqslant$ 0.75)] showed that no patients had expired in the ABRI controlled group (Table 2). χ^2 test with continuity correction gave a significance value of $P = 0.017$. A similar cross tabulation with Child's Pugh Class showed that the highest percentage of patients expired in Child's Pugh Class C while no patients with Child's Class A expired (Table 3). χ^2 test with the Likelihood Ratio gave significant differences in the frequencies of expiry with Child's Pugh Class ($P < 0.0001$). A ROC curve was plotted using expiry as a state variable (Figure 1). The area under the curve was significantly large at 0.848 ($P < 0.0001$; 95% CI: 0.75-0.95). The sensitivity and specificity of the ABRI cutoff value of 0.75 in our study was 100% and 73.4%, respectively. The correlation of

Table 3 Cross tabulation of Child's Pugh Class with outcome

			Outcome		Total
			Alive	Expired	
Child's Pugh Class	Class A	Count	18	0	18
		% within Child's Pugh Class	100.0%	0.0%	100.0%
	Class B	Count	71	11	82
		% within Child's Pugh Class	86.6%	13.4%	100.0%
	Class C	Count	5	8	13
		% within Child's Pugh Class	38.5%	61.5%	100.0%
Total		Count	94	19	113
		% within Child's Pugh Class	83.2%	16.8%	100.0%

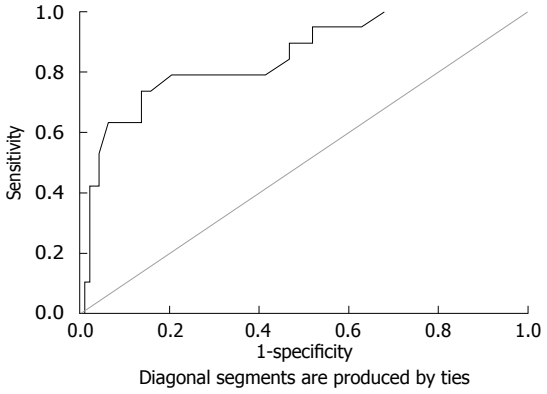

Figure 1 ROC curve of ABRI against expiry.

ABRI with outcome was analyzed by Pearson's Bivariate Correlation test. As the data of ABRI was skewed and not normally distributed its Log_{10} transformation was used. The results showed a significant correlation between ABRI and expiry with $P < 0.0001$.

DISCUSSION

This study showed a significant correlation between ABRI and the 7th day outcome in patients with AVH. This is a very significant finding as it is important to predict the outcome at an initial stage of management and ABRI suggests whether the variceal hemorrhage has been arrested at any point during management. Our study also established its correlation with mortality. Earlier validation studies of ABRI were retrospective[11,12]. The current study is prospective and designed more specifically to assess the correlation of ABRI with mortality which has not been previously studied. The correlation of higher ABRI scores with mortality was significant and this simple to use parameter should be used to assess failure to control bleeding and risk of mortality. The number of units of blood transfused and hematocrit levels, if used alone, are not good criteria to assess variceal bleeding control. We also used pharmacological and endoscopic interventions and the combined effect of these interventions was reflected in the outcome which was also observed in other reports from this region[14]. About 70% of patients rebleeding within 2 years, thus managing the index bleed properly and obliteration of varices can decrease rebleeding[15,16].

Many scoring systems have been derived to predict the outcome of upper GI hemorrhage. The Rockall score is one such scoring system for predicting rebleeding and mortality which also showed good correlation[17,18]. Limitations of the Rockall score are that it is rather difficult to use with the requirement of more parameters as compared to ABRI and it is not variceal bleeding specific, but designed for both variceal and non-variceal bleeding[18,19]. Another popular scoring system, the Child's Pugh score predicts all cause morbidity and mortality in cirrhotic patients but is not specific for variceal hemorrhage[20].

In conclusion, among the many predictive scoring systems in cirrhotic patients, ABRI is specific for variceal hemorrhage and correlates strongly with mortality and is a good indicator of the failure of variceal hemorrhage control.

COMMENTS

Background

In a developing country like Pakistan, hepatitis B and C are the most important causes of cirrhosis. The frequency of varices is very high in cirrhotic patients, nearly 40% of patients with compensated cirrhosis and 60% of patients with decompensated cirrhosis have varices. Mortality from variceal bleeding is still high at 20%. The prediction of mortality risk is difficult and available scores are difficult to calculate and thus do not enjoy wide acceptability and application.

Research frontiers

Adjusted Blood Requirement Index (ABRI) is a score which is used to determine the failure to control variceal bleeding. In this study it was correlated with the outcome of mortality.

Innovations and breakthroughs

Many scoring systems are in use to predict the outcome of upper gastrointestinal hemorrhage. The Rockall score is one such scoring system for predicting rebleeding and mortality but it is rather difficult to use. Another scoring system, the Child's Pugh score predicts all cause morbidity and mortality in cirrhotic patients but is not specific for variceal hemorrhage. The ABRI is a variceal hemorrhage-specific score and is easy to use.

Applications

ABRI: A validated tool to determine variceal bleeding control also correlates well with mortality in such patients.

Peer review

Many scoring systems have been described to predict the prognosis of upper gastrointestinal hemorrhage like Rockall and Child's Pugh but these have limitations. In practice, it is useful to predict the outcome at admission of patients with acute variceal hemorrhage. This study showed a significant correlation between ABRI and expiry. The methodology is correct. This work deserves to be published to stimulate other teams over the world to perform the same study with a large number of patients.

Abstract

AIM: To investigate the effect of pain relief after infusion of ropivacaine at port sites at the end of surgery.

METHODS: From October 2006 to September 2007, 72 patients undergoing laparoscopic cholecystectomy (LC) were randomized into two groups of 36 patients. One group received ropivacaine infusion at the port sites at the end of LC and the other received normal saline. A visual analog scale was used to assess postoperative pain when the patient awakened in the operating room, 6 and 24 h after surgery, and before discharge. The amount of analgesics use was also recorded. The demographics, laboratory data, hospital stay, and perioperative complications were compared between the two groups.

RESULTS: There was no difference between the two groups preoperatively in terms of demographic and laboratory data. After surgery, similar operation time, blood loss, and no postoperative morbidity and mortality were observed in the two groups. However, a significantly lower pain score was observed in the patients undergoing LC with local anesthesia infusion at 1 h after LC and at discharge. Regarding analgesic use, the amount of meperidine used 1 h after LC and the total used during admission were lower in patients undergoing LC with local anesthesia infusion. This group also had a shorter hospital stay.

CONCLUSION: Local anesthesia with ropivacaine at the port site in LC patients significantly decreased postoperative pain immediately. This explains the lower meperidine use and earlier discharge for these patients.

INTRODUCTION

Since 1987, laparoscopic cholecystectomy (LC) has been the favored treatment for gallbladder lesions[1]. Historically, contraindications to LC have included obesity, pregnancy, acute cholecystitis, and cardiovascular disease. With experience gained from laparoscopic surgery, LC has been attempted successfully and has become the procedure of choice in each subgroup of patients[2,3]. A major benefit of laparoscopy in upper gastrointestinal surgery results from avoidance of an upper abdominal incision. LC has proven benefits of less pain and improved pulmonary function tests compared with small-incision cholecystectomy[4-6]. However, assessment of postoperative stay and return to normal activity has shown conflicting results[5-7]. Many trials have assessed methods of reducing pain after LC, and several aspects of pain

after laparoscopy have been addressed[8-11]. These studies have concentrated on the mechanism of pain or focused on gynecological procedures, with an emphasis on the role of non-steroidal anti-inflammatory drugs (NSAIDs)[8]. Some of the reviews have demonstrated the heterogeneity of randomized controlled trials and have concluded that pain after LC is multifactorial[11]. Although, many methods of analgesia produce short-term benefits, this does not equate with earlier discharge or improved postoperative function.

This prospective and randomized controlled trial aimed to clarify the impact of infusion of local analgesia at the port site after LC on pain relief and postoperative outcome.

MATERIALS AND METHODS

From October 2006 to September 2007, 72 patients undergoing LC by the authors (Yeh CN, Yeh TS, and Chao TC) at the Department of Surgery, Chang Gung Memorial Hospital, Taiwan were included in this prospective randomized controlled trial. The study subjects were adult patients who had been referred for elective LC for gallbladder lesions. The diagnostic work-up for patients with gallbladder lesions before LC included history taking, physical examination, abdominal ultrasonography, abdominal computed tomography, and magnetic resonance cholangiopancreatography. The study was approved by the local institutional review board of Chang Gung Memorial Hospital and all patients gave informed consent before taking part in the study.

Randomization and treatment

The randomization was centralized and used a random permuted block design. Eligible patients were aged 20-85 years, not pregnant, and had adequate hematological, hepatic and renal function. The exclusion criteria were as follows: immunosuppressive drug therapy within the previous 6 mo; an immunosuppressive condition, including AIDS; autoimmune disorders; organ transplantation; radiotherapy or chemotherapy within the previous 6 mo; and insulin-dependent diabetes mellitus (type 1). Discharge from the wards was the primary endpoint. Clinical features, laboratory data, operative outcomes, pain score, and analgesic requirement were analyzed and compared between the ropivacaine and saline groups. Hospital stay was defined as the number of days from operation to the actual date of hospital discharge. Surgical mortality was defined as death that occurred within 1 mo after surgery.

Seventy-two patients were included in the study and randomized into a control or local anesthesia with ropivacaine (LA) group. All 72 patients received general anesthesia with the same protocol by one of the authors (Lin CC, anesthesiologist). The LA group received 1.0% ropivacaine 20 mL at the port site after wound closure (6 mL for epigastric port, 6 mL for umbilical port, and 4 mL for each working port). The control group received 0.9% normal saline 20 mL at the port site after wound closure (6 mL for epigastric port, 6 mL for umbilical port, and 4 mL for each working port). Ropivacaine or normal saline was applied to the skin, subcutis, fascia, and parietal peritoneum through the port sites at the end of surgery.

Patient monitoring and testing

A visual analog scale (VAS) with a 10-cm vertical score ranged from "no pain" to "worst possible pain". The VAS was used to assess postoperative pain when the patient awakened in the operating room (about 1 h after surgery), then after 6 and 24 h, and before discharge. The pain score was recorded by the authors (Lee HL, Liu YY, Wang SY, Tsai CY, and Yeh CN). Pain intensity was estimated using a VAS and the amount of analgesics used. The biochemistry data, operative time, hospital stay, and perioperative complications were recorded.

Statistical analysis

All data are presented as the percentage of patients or mean ± SD. Numerical data were compared by independent two-sample t test or paired two-sample t test. Pearson χ^2 test and Fisher exact test were used for nominal variables. All statistical analyses were performed using the SPSS computer software (Chicago, IL, USA). $P < 0.05$ was considered to be statistically significant.

RESULTS

Clinical features, laboratory data, and operative outcomes

Table 1 summarizes the demographic data of patients with gallbladder lesions receiving LC without local anesthesia (control group) and with local anesthesia (LA group). Both groups shared a similar age distribution and sex ratio. The two groups displayed no significant difference in ratio of previous abdominal operation, etiology of disease, and operative indications. The LA group had similar American Society of Anesthesiologists

Table 2 Laboratory data of 72 patients undergoing LC with and without local anesthesia infusion at the port site (mean ± SD)

	Control (n = 36)	LA (n = 36)	P
Hemoglobin (g/dL)	13.4 ± 1.8	14.1 ± 1.7	0.634

grade, operative time, operative blood loss, postoperative drain insertion, and complication rates as the control group. No 30-d mortality occurred in this study. The LA group had a significantly shorter hospital stay than the control group (1.1 ± 0.3 d *vs* 2.8 ± 2.7 d, $P = 0.001$). Table 2 displays the laboratory data of the 72 patients. No significant difference was noted between the two groups.

Evaluation of pain relief

Table 3 and Figure 1 compare the pain intensity and analgesic requirement between the control and LA groups. Both groups achieved gradual pain relief after surgery in terms of VAS for pain and need for analgesics. However, the LA group experienced significantly less pain at 1 and 24 h after surgery and at discharge when compared with the control group. Furthermore, the LA group had less meperidine use at 1 h and total meperidine use after LC. However, there was no significant difference in acetaminophen use between the two groups (Figures 2-4).

DISCUSSION

Postoperative pain associated with LC is less intense and lasts a shorter time than that seen with open cholecystectomy. This explains why patients can be discharged and returned to their normal daily activities earlier[12]. However, as seen in this study, LC is not a pain-free procedure. Pain remains a prevalent complaint of the

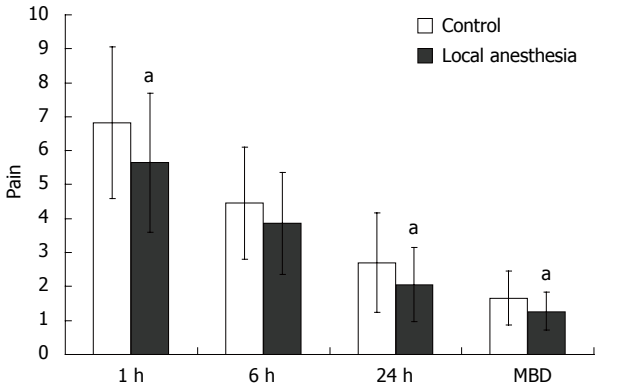

Figure 1 Pain evaluation of LC patients in the LA and control groups. $^aP < 0.05$ compared with the respective patient group at each time point after surgery. Significant difference in pain score was noted between the LA and control groups, except at 6 h after surgery. All data were presented as mean ± SD. MBD: May be discharged.

Significant difference was noted between the LA and control groups at 1 h after surgery. All data were presented as mean ± SD.

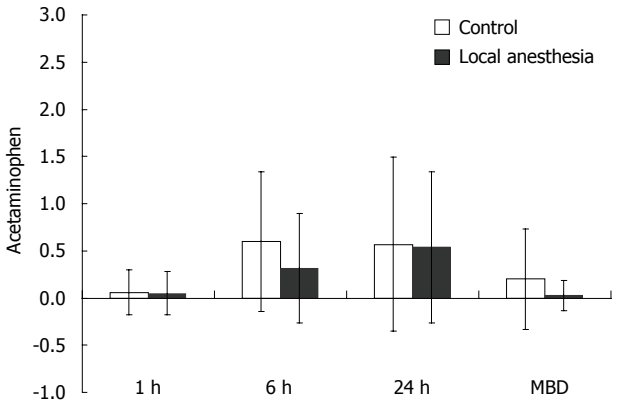

Figure 3 Acetaminophen required for LC patients in the LA and control groups. No significant difference was noted between the LA and control groups after surgery. All data were presented as mean ± SD.

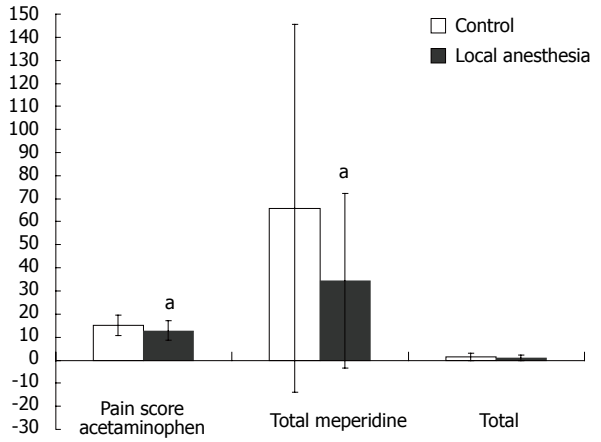

Figure 4 Pain evaluation and total analgesic requirement in LC patients in the LA and control groups. [a]*P* < 0.05 when compared with the respective patient group after surgery. Significant difference was noted for pain and meperidine requirement between the LA and control groups after surgery. All data were presented as mean ± SD.

early postoperative period after LC. This study clearly showed that pain reached a peak within the first few hours following the operation but diminished during the next 2-3 d, demonstrated by the distribution of the pain score and parenteral analgesic requirement. It has been reported that incisional pain is more intense than visceral pain and is dominant during the first 48 h after LC[13].

Several mechanisms have been proposed for generation of pain following laparoscopy: ruptured blood vessels caused by rapid distension of the peritoneum; traumatic traction on the nerves; release of inflammatory molecules; trauma to the abdominal wall, and when the gallbladder is removed from the abdomen; pneumoperitoneum created by use of CO_2; maintenance of high abdominal pressure; irritation of the phrenic nerve; and application of cold CO_2[14]. This explains why no consensus can be reached regarding effective postoperative pain relief in patients undergoing LC, because pain is multifactorial[11]. Although a number of studies have been conducted in an effort to reduce postoperative pain after surgery, the results have varied.

Postoperative pain control is directed at early mobilization, recovery, and discharge. However, pain also plays a major role in the metabolic and endocrine response, and is instrumental in the impairment of postoperative pulmonary function. Various methods have been investigated for reducing postoperative pain, such as local anesthesia[15], intraperitoneal infiltration of local anesthesia[16], preoperative administration of anti-inflammatory drugs[17], utilizing CO_2 at body temperature, applying intrapleural morphine[18], and combined use of NSAIDs and opioids[19].

Our findings indicated that infiltrating ropivacaine after surgery through the port site reduced pain intensity, the number of patients requiring postoperative analgesics, and hospital stay. Administering local anesthesia at the end of surgery offered a longer time delay to the need for analgesics, compared with patients who did not receive postoperative local anesthesia. Furthermore, patients who received local anesthesia at the end of surgery required significantly lower doses of analgesics than patients who did not receive local anesthesia. This is explained by the fact that pain intensity was less among patients who received local anesthesia at the end of the surgery than among those who did not.

Ropivacaine is a new long-acting local anesthetic that was developed after the emergence of bupivacaine-related severe toxicity. The agent is a pure left-isomer and, based on its three-dimensional structure, it has less toxic potential on the central nervous system and the heart[20]. Several clinical studies have evaluated its toxicology and clinical profiles: theoretically and experimentally, some differences can be seen, but reflection of these characteristics in clinical practice has not been evident. However, the reduced toxic potential of the pure left-isomer supports its use in clinical situations in which the risk of systemic toxicity related to overdosing or unwanted intravascular injection is high, such as during epidural or peripheral nerve blocks. Adverse effects associated with the use of local anesthesia, such as allergic reactions and local tissue, cardiovascular, central nervous system and systemic toxicity, were reported as rare in one previous study[20], and we did not observe any adverse effect related to the use of local anesthesia. Generally, the present study confirms earlier evidence that, in patients with gallbladder lesion undergoing LC, local anesthesia infusion is more effective when applied at the end of an operation than at the start.

Local anesthesia with ropivacaine infusion at the port site in LC patients at the end of surgery significantly decreased postoperative pain immediately. This short-term benefit explains the lower parenteral analgesic use and earlier discharge for LC patients with local anesthesia infusion. However, another clinical trial including multiple factors regarding pain after LC should be conducted.

COMMENTS

Background

Although laparoscopic cholecystectomy (LC) is a less painful procedure than open cholecystectomy, patients still felt wound pain after surgery. We tried to improve postoperative pain relief by the use of local anesthesia.

Research frontiers

Local anesthesia is used for postoperative analgesia and is effective. However, there have been few randomized studies performed. Good postoperative pain control will improve quality of life after LC.

Innovations and breakthroughs

Pain after LC may be caused by personal factors, duration of operation, intraperitoneal pressure, and the gallbladder lesion concerned. We used a prospective randomized trial to demonstrate that postoperative pain control improved by adding local anesthesia.

Applications

This local anesthesia procedure can be used routinely in other kinds of laparoscopic surgery to reduce postoperative pain.

Peer review

The authors reported that local anesthesia with ropivacaine infusion was beneficial for LC. The present study was concerned mainly with anesthesia. However, this paper is interesting and instructive for surgeons. The presentation and readability of the manuscript are good.

Abstract

AIM: To detect and evaluate the antibodies against *Helicobacter pylori* (*H pylori*) neutrophil-activating protein (HP-NAP) in patients with gastric cancer and other gastroduodenal diseases.

METHODS: Recombinant HP-NAP was prepared from a prokaryotic expression system in *Escherichia coli*. Serum positivity and level of HP-NAP-specific antibodies in sera from 43 patients with gastric cancer, 28 with chronic gastritis, 28 with peptic ulcer, and 89 healthy controls were measured by rHP-NAP-based ELISA. rHP-NAP-stimulated production of interleukin-8 (IL-8) and growth-related oncogene (GRO_α) cytokines in the culture supernatant of SGC7901 gastric epithelial cells was also detected.

RESULTS: The serum positivity and mean absorbance value of HP-NAP-specific antibodies in the gastric cancer group (97.7% and 1.01 ± 0.24) were significantly higher than those in the chronic gastritis group (85.7% and 0.89 ± 0.14, $P < 0.005$) and healthy control group (27.7% and 0.65 ± 0.18, $P < 0.001$). The sensitivity and specificity of ELISA for the detection of HP-NAP-specific antibodies were 95.5% and 91.5%, respectively. HP-NAP could slightly up-regulate IL-8 production in gastric epithelial cell lines but had no effect on GRO_α production.

CONCLUSION: Infection with virulent *H pylori* strains secreting HP-NAP is associated with severe gastroduodenal diseases, and HP-NAP may play a role in the development of gastric carcinoma. rHP-NAP-based ELISA can be used as a new method to detect *H pylori* infection. The direct effect of HP-NAP on gastric epithelial cells may be limited, but HP-NAP may contribute to inflammatory response or carcinogenesis by activating neutrophils.

INTRODUCTION

Helicobacter pylori (*H pylori*), a microaerophilic Gram-negative bacterium, infects the stomach of more than 50% of human population worldwide and is a major cause of chronic gastritis and peptic ulcer. Furthermore, it is associated with gastric adenocarcinoma and gastric B cell lymphoma. In 1994, the World Health Organization classified *H pylori* infection as a definite (class 1) carcinogen[1]. *H pylori* colonization is followed by infiltration of neutrophils, macrophages and lymphocytes in gastric mucosa. The degree of mucosal damage is closely associated with the extent of

neutrophil infiltration[2-4].

Multiple bacterial virulence factors, such as vacA, cagA and lipopolysaccharide (LPS), can modulate *H pylori*-induced inflammation. *H pylori* neutrophil-activating protein (HP-NAP), a 150-kDa iron-binding protein, is a ball-shaped dodecamer formed by four-helix bundled subunits with its sequence similar to that of bacterioferritins and DNA binding proteins[5,6]. It has been designated as a neutrophil-activating factor because it promotes the adherence of neutrophils to endothelial cells and stimulates production of reactive oxygen species (ROS) in neutrophils by activating nicotinamide adenine dinucleotide phosphate (NADPH) oxidase in plasma membrane[7-11]. Satin *et al*[12] demonstrated that the purified recombinant HP-NAP is chemotactic for human neutrophils and monocytes, induces surface expression of β_2-integrin, which mediates endothelial transmigration, adhesion and accumulation of leucocytes at the site of *H pylori* infection. Recombinant HP-NAP induces the production of ROS by neutrophils *via* a cascade of intracellular activation events, including increased cytosolic calcium and phosphorylation of proteins, leading to the assembly of functional NADPH oxidase on neutrophil plasma membrane. In addition, HP-NAP increases the synthesis of tissue factor and secretion of type 2 inhibitor of plasminogen activator in monocytes[13,14], contributing to the inflammation of gastric mucosa by fibrin deposition. These studies indicate that HP-NAP is a virulence factor relevant to the pathogenic effect of *H pylori*.

It was recently reported that HP-NAP promotes a Th1 immune response by inducing the expression of IL-12 and IL-23 in neutrophils and monocytes, and also elicits an antigen-specific Th1-polarized T cell response in gastric mucosa of *H pylori*-infected patients *in vivo*[15]. It has been shown that HP-NAP is able to shift antigen-activated human T cells from a Th2 to a Th1 cytotoxic phenotype characterized by production of IFN-γ and TNF-α[16]. Additionally, the majority of infected patients have antibodies against this antigen, and vaccination of mice with HP-NAP induces protection against a subsequent challenge with *H pylori*[12]. Therefore, HP-NAP is an immune modulator promoting Th1 immune responses and an important vaccine candidate antigen[17,18].

Since HP-NAP is a powerful stimulant for the production of ROS, mediating damage to DNA and enhancing cell turnover[19], it may be a risk factor for *H pylori*-associated gastric cancer. Currently, it is uncertain whether HP-NAP is related to the occurrence of gastric cancer. Interleukin-8 (IL-8) and growth-related oncogene (GRO_α) are members of the CXC chemokine family that induce neutrophil chemotaxis and activation. It has been shown that IL-8 and GRO_α levels are elevated in *H pylori*-infected gastric mucosa[20]. In addition, *H pylori* water soluble surface proteins up-regulate the expression of IL-8 and GRO_α mRNA and protein by neutrophils[21]. Whether HP-NAP contributes to the inflammatory response or carcinogenesis by up-regulating IL-8 and GRO_α production in *H pylori*-infected gastric mucosa remains unknown. An understanding of the relation between HP-NAP and gastric cancer and the molecular mechanism(s) underlying HP-NAP-induced diseases should lead to improved approaches to the effective control of *H pylori*-associated gastric cancer.

In the present study, recombinant HP-NAP was prepared from a prokaryotic expression system in *Escherichia coli*, and the *napA* gene in 20 *H pylori* clinical isolates from South China was detected by PCR. The seropositivity and level of HP-NAP-specific antibodies in sera from 43 patients with gastric cancer, 28 with chronic gastritis, 28 with peptic ulcer, and 89 healthy controls were measured by rHP-NAP-based ELISA. The production of IL-8 and GRO_α cytokines in culture supernatant from SGC7901 gastric epithelial cells stimulated by rHP-NAP was also detected.

MATERIALS AND METHODS

Preparation of bacterial and gastric epithelial cell lines

H pylori NCTC11639 strain was stored at -70℃ in our department. Bacteria were routinely cultured on Columbia agar plates supplemented with 10% defibrinated sheep blood, 0.004% triphenyltetrazolium chloride, and Dent selective supplement (Oxoid, Basingstoke, UK) at 37℃ for 3 d under a microaerophilic atmosphere containing 50 mL/L O_2, 150 mL/L CO_2 and 800 mL/L N_2. Several colonies were then picked up and inoculated into 20 mL of Brucella broth (Becton Dickinson, Cockeysville, MS) containing 0.1% β-cyclodextrin supplemented with 5% (v/v) fetal calf serum. After 24 h, 2 mL of culture was transferred to 40 mL of fresh medium, and the same process was repeated twice. Finally, 1 mL of the incubated medium containing the bacterial cells, most of which were spiral rather than coccoid, was plated on Brucella agar (Becton Dickinson) containing 10% (v/v) defibrinated sheep blood and cultured at 37℃ for an additional 3 d in a microaerophilic atmosphere containing 50 mL/L O_2, 150 mL/L CO_2 and 800 mL/L N_2. Bacterial cells were harvested, washed twice with cold phosphate-buffered saline (PBS, 25 mmol/L sodium phosphate, pH 7.2, 0.9% NaCl), and then sedimented by centrifugation at 5000 × *g* for 10 min at 4℃. The cell pellet was stored at -80℃.

Human gastric epithelial cells (SGC7901) were cultured at 37℃ in RPMI-1640 (Gibco, USA) containing 10% FBS (Gibco) in a humidified atmosphere containing 50 mL/L CO_2, and plated at 10^6 cells/well in 24-well plates. The medium was changed every 3 d and replaced with RPMI-1640 without serum before experiment.

Collection of serum samples from infected and healthy individuals

H pylori infection was diagnosed by histological examination of endoscopic biopsy specimens and CLO testing. Forty-three serum samples were collected from patients with gastric cancer at Southern Hospital, Guangzhou, China. The age of patients ranged 27-83 years. Twenty-eight serum samples were also collected from patients with peptic ulcer or chronic gastritis at Southern Hospital. The age of patients ranged 28-67 years. Finally, 89 serum samples were collected from healthy blood donors at the age of 18-70 years.

Cloning and purification of NAP

Genomic DNA of *H pylori* was prepared using a Takara kit (Takara, Japan) according to its manufacturer's instructions. The extracted genomic DNA was then used as a template for amplification of the NAP coding region using a Taq DNA polymerase PCR kit (Takara, Japan)[22,23]. Two primer sequences corresponding to the 5' and 3' ends of the coding gene, including *Eco*RI and *Xho*I restriction sites, were used: P1: 5'CCGGAATTCA TGAAAACATTTGAA-3', P2: 5'CCGCTCGAGTTAA GCCAAATGGGC-3'.

The PCR product was cloned into the expression vector pGEX-4T-1 (Amersham Biosciences). The plasmid was then transformed into *E. coli* strain TOP10 (Invitrogen BV, Leek, The Netherlands), and NAP expression was induced with 1 mmol/L isopropyl-β-d-1-thiogalactopyranoside when the cells were grown to the log phase at room temperature. After 4 h, the cells were harvested by centrifugation and washed with ice-cold PBS containing 5 mmol/L EDTA and 2 mmol/L PMSF. All subsequent procedures were performed at 4℃. The NAP-GST fusion protein was purified by glutathione-sepharose 4B column chromatography.

Screening for seropositive individuals with IgG antibodies against *H pylori* in healthy subjects

Anti-*H pylori* IgG antibodies in serum samples were assayed by indirect ELISA using a diagnostic kit (BIOCUP, Shenzhen, China). According to the instructions, serum (l00 μL, diluted 1/100 in PBS) was added to ELISA plates pre-coated with purified *H pylori* antigens in duplicate and incubated for 1 h. Controls consisted of wells with PBS alone, *H pylori* negative and positive serum, which were considered blank, negative and positive controls, respectively. Peroxidase-conjugated anti-human IgG (1/5000) was added and incubated for 30 min, after which the plates were washed with PBS, and color reaction was initiated by the addition of TMB (100 μL). After 10 min, the reaction was terminated by the addition of 1 mol/L H_2SO_4 (100 μL). The plate reader was calibrated to the blank well and the absorbance at 450 nm was read. Cut-off value (C.O.) = 2.1 × Nc (Nc = the mean absorbance value for three negative controls). Samples with absorbance > 0.21 were considered positive. The anti-*H pylori* IgG seropositive individuals were considered to be *H pylori*-infected healthy individuals.

Detection of antibodies against HP-NAP in serum by ELISA

Recombinant HP-NAP was prepared and purified, and ELISA was carried out as previously described[24-27]. Briefly, immunoplates (Nunc, Denmark) were coated with rNAP (5μg/well) and incubated overnight at 4℃. After washed three times with a washing buffer containing PBS (pH 7.2) and 0.1% Tween 20, the plates were blocked with 200 μL of 10% bovine serum in PBS and incubated in a moist chamber for 1 h at 37℃, then washed three times with a washing buffer containing PBS (pH 7.2) and 0.1% Tween 20. One hundred microlitre of serum samples (1:100) from patients or healthy individuals was then added to the microtiter wells, and the plates were incubated at 37℃ for 60 min. After washed with PBS, 100 μL of secondary antibody (goat anti-human IgG-HRP, 1:10 000) was added to each well and incubated for 60 min at 37℃. After washed with PBS, 100 μL of TMB/H_2O_2 substrate was added to the wells and incubated at room temperature for about 10 min. The reaction was terminated by adding 100 μL of 2 mol/L H_2SO_4. The absorbance of each well was read at 450 nm. Samples with absorbance > 0.78 were considered positive. Each sample was tested in duplicate.

Selection of cut-off values for antibodies against HP-NAP in human serum

A receiver operating curve (ROC) was plotted to calculate the cut-off values for antibodies against HP-NAP at a 95% accuracy level[26]. In addition, the cut-off values were determined by mean plus 2 × SD and mean plus 3 × SD, derived from *P* values in healthy individuals.

Detection of the *napA* gene in *H pylori* clinical isolates by PCR

Genomic DNA of 20 *H pylori* clinical isolates was prepared and used as a template for amplification of the NAP coding region with two primer sequences as preciously described[28]. PCR was carried out in a final volume of 60 μL. A preliminary denaturation step at 95℃ for 5 min was followed by 30 amplification cycles, each consisting of denaturation at 94℃ for 30 s, annealing at 50℃ for 30 s, extension at 72℃ for 45 s, and a final extension at 72℃ for 7 min. Then, 10 μL of amplicon was transferred onto a 1.5% (w/v) agarose gel in 1 × TBE buffer, and electrophoresis was performed at 80 V for 30 min in a DNA submarine plate. The gel was then stained with ethidium bromide.

IL-8 and GRO$_\alpha$ production in human gastric epithelial cells stimulated with rHP-NAP

Before use, human gastric epithelial cells (SGC7901) growing in 24-well plates were washed and replaced with RPMI-1640 without serum, and then stimulated with 10 μg rHP-NAP for 12 h and 36 h, respectively. The supernatant was centrifuged to remove particulate debris and stored in aliquots at -70℃. IL-8 and GRO$_\alpha$ concentrations in the culture supernatant were measured by ELISA using a Quantikine immunoassay kit (R&D, USA) according to its manufacturer's instructions. Before detection, the culture supernatant was filtered through a sterile membrane filter (0.22 μm. pore size).

Statistical analysis

Statistical analyses were conducted using the SPSS software package. One-way ANOVA was performed to assess differences among groups. *Post hoc* multiple comparisons between different infectious groups were done by LSD analysis. Comparisons between the seropositivity of anti-HP-NAP antibodies in patients with gastric cancer and other gastroduodenal diseases were done by chi-square test.

RESULTS

Expression and purification of recombinant protein

The gene encoding for HP-NAP was obtained by PCR amplification using genomic DNA extracted from *H pylori* as a template. Agarose gel electrophoresis analysis of the PCR product is shown in Figure 1.

A 435 bp DNA fragment was detected, which corresponded to the size of the HP-NAP gene. The DNA sequence of the hypothetical HP-NAP gene of *H pylori* was determined (data not shown) and submitted to GenBank (accession No. DQ341279). To facilitate purification, HP-NAP was expressed as a GST fusion protein in *E. coli* Top10 cells. Expression of the recombinant NAP-GST was examined by SDS-PAGE. A pronounced band with an approximate molecular weight of 44 kDa appeared in the supernatant of cell lysate after induction but not in control cells, suggesting that the fusion protein can be successfully expressed in bacterial cells (Figure 2).

The purified NAP-GST fusion protein was further confirmed by Western blotting. Serum from *H pylori*-infected patients specifically recognized the recombinant NAP-GST fusion protein, while negative serum did not (Figure 3).

Selection of cut-off values for HP-NAP-specific antibodies

A cut-off value of 0.78 was determined for ELISA of HP-NAP antibodies using ROC analysis (Figure 4). The area under the ROC curve was 0.97. Overall, ELISA yielded a sensitivity of 95.5% (95% confidence interval) and a specificity of 91.5% (95% confidence interval) for the detection of antibodies against HP-NAP in serum.

Comparison between seropositivity for anti-*H pylori* IgG and anti-HP-NAP antibodies in healthy subjects

Anti-*H pylori* IgG seropositivity was detected in 47 of the 89 healthy subjects who were considered *H pylori*-infected healthy individuals. As shown in Table 1, the anti-*H pylori* IgG and anti-HP-NAP seroposivity in healthy individuals was 52.8% (47/89) and 14.6% (13/89), respectively. The anti-*H pylori* IgG seropositivity was much higher than the anti-HP-NAP antibody seropositivity ($P < 0.005$). The anti-HP-NAP antibody seropositivity, however, was 27.7% (13/47) in *H pylori*-infected healthy individuals.

Detection of antibodies against HP-NAP in patients with gastric cancer and other gastroduodenal diseases by ELISA

The seropositivity for antibodies against HP-NAP in gastric cancer and peptic ulcer patients was 97.7% (42/43) and 92.8% (26/28), respectively, while the seropositivity for antibodies against HP-NAP in chronic gastritis patients was 85.7% (24/28). The seropositivity for antibodies against HP-NAP in infected healthy controls was 27.7%. The seropositivity for HP-NAP-specific antibodies in gastric cancer patients was higher than that in chronic gastritis patients ($P < 0.05$) and in infected healthy controls ($P < 0.01$). The difference in the mean absorbance value for antibodies against HP-NAP between groups was also confirmed by one-way

Table 1 Positivity comparison between *H pylori* -specific IgG and HP-NAP-specific antibodies in healthy individuals *n* (%)

	Total number tested	Positivity
HP-specific IgG Abs	89	47 (52.8)
HP-NAP-specific Abs (total healthy persons)	89	13 (14.6)[1]
HP-NAP-specific Abs (infected healthy persons)	47	13 (27.7)

[1]$P < 0.005$ *vs* infected healthy persons; Abs: Antibodies.

Table 2 Demonstration of antibodies against HP-NAP in serum from *H pylori*-infected patients by ELISA *n* (%)

Patient group	Positivity for HP-NAP antibodies	Negativity for HP-NAP antibodies	Absorbance (mean ± 2SD) (cut-off value 0.78)	Range
Gastric cancer group (n = 43)	42 (97.7)	1 (2.3)	1.01 ± 0.24	0.748-1.269
Peptic ulcer group (n = 28)	26 (92.8)	2 (7.1)	0.98 ± 0.32	0.771-1.265
Chronic gastritis group (n = 28)	24 (85.7)	4 (14.3)	0.89 ± 0.14	0.711-1.122
Healthy persons (HP-IgG positive n = 47)	13 (27.7)	34 (72.3)	0.65 ± 0.18	0.451-0.948

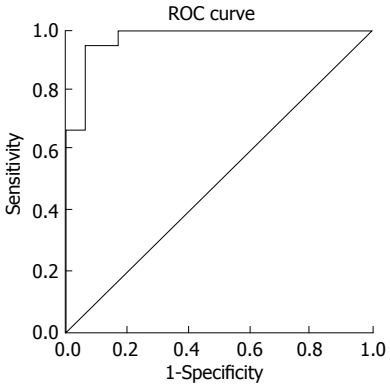

Figure 4 Receiver operating characteristic curve analysis showing the cut-off value for anti-HP-NAP antibodies in serum from patients with gastric cancer, peptic ulcer, chronic gastritis and healthy controls, respectively.

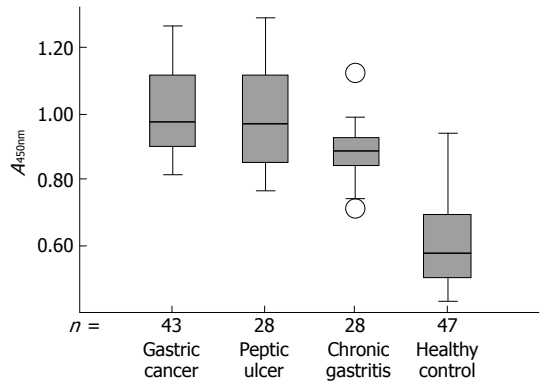

Figure 5 Box plot demonstrating the level of antibodies against HP-NAP in serum from patients with gastric cancer, peptic ulcer, chronic gastritis and healthy controls, respectively. The box plot showing the 5th and 95th percentiles (bars), the 75th and 25th percentiles (boxes), and the median (bars in boxes), respectively. *n*: Number of individuals in each group.

ANOVA analysis (F = 4.014, P = 0.023). The mean absorbance value for anti-HP-NAP antibodies in gastric cancer patients was 1.01 ± 0.24 (range 0.748-1.269), significantly higher than that in chronic gastritis patients (0.89 ± 0.14, range 0.711-1.122, $P < 0.005$) and in infected healthy controls (0.65 ± 0.18, range 0.451-0.948, $P < 0.001$). There was no significant difference, however, in the mean absorbance value for anti-HP-NAP antibodies between patients with gastric cancer (1.01 ± 0.24, range 0.748-1.269) and peptic ulcer (0.98 ± 0.32, range 0.771-1.265) (Table 2).

Box plots of the antibodies against HP-NAP in sera from patients with gastric cancer, peptic ulcer, chronic gastritis, and healthy controls are shown in Figure 5, with the 90th percentile range and 75th and 25th percentiles.

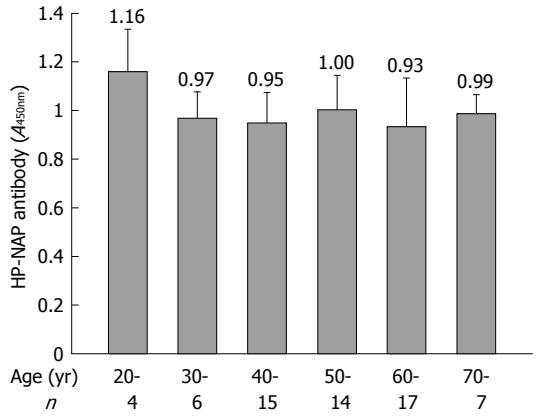

Figure 6 Comparison of HP-NAP antibody levels in different age groups.

Comparison of HP-NAP antibody levels in different age groups

Most *H pylori*-associated diseases occurred in subjects at the ages of 40-70 years (53/63). The mean absorbance value for anti-HP-NAP antibodies was not significantly different in patients at different ages (Figure 6).

Detection of napA gene in all H pylori clinical isolates

The *napA* gene was detected by PCR in 20 *H pylori* clinical isolates. All examined *H pylori* strains carried the *napA* gene. The electrophoresis results of PCR products of the *napA* gene from 8 representative *H pylori* strains are shown in Figure 7.

IL-8 and GROα production in human gastric epithelial cells stimulated with rHP-NAP

The IL-8 and GROα levels in culture supernatant of human gastric epithelial cell line SGC7901 were measured by ELISA, showing that HP-NAP slightly up-regulated the IL-8 production (Table 3) but had no effect on GROα production by gastric epithelial cells (data not shown).

DISCUSSION

HP-NAP, an important virulence factor for *H pylori*, induces adherence of neutrophils to gastric epithelial cells and causes an inflammatory reaction by activating neutrophils. In the present study, we cloned and expressed HP-NAP, which was then used as an antigen to detect HP-NAP-specific antibodies in serum samples. The seropositivity for anti-HP-NAP antibodies was detected in 89 healthy subjects and compared with that for anti-*H pylori* IgG antibodies in the same subjects. Meanwhile,

Table 3 IL-8 level in culture supernatant of human gastric epithelial cell line SCG7901 (pg/mL)

Time (h)	IL-8 level		
	10 μg/mL NAP	1 μg/mL LPS	Control
12	10.10[b]	8.07	3.55
36	30.14[b]	30.54	11.28

[b]$P < 0.01$ *vs* control.

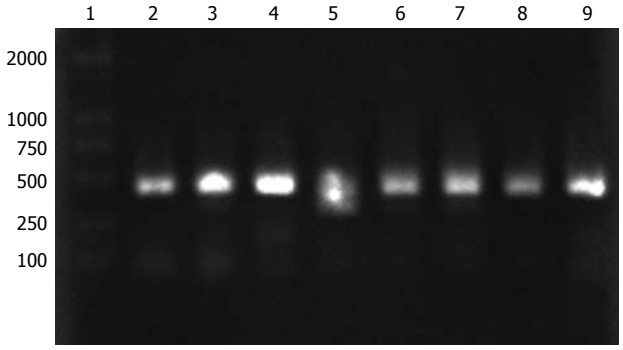

Figure 7 Agarose gel electrophoresis analysis of PCR product of *napA* gene from *H pylori* clinic strains. Lane 1: DL2000 DNA marker; Lanes 2-9: *napA* gene (435 bp) from eight *H pylori* clinic strains.

the seropositivity and levels of HP-NAP-specific antibodies in 43 patients with gastric cancer, 28 with chronic gastritis, 28 with peptic ulcer, were measured by rHP-NAP-based ELISA. Moreover, the *napA* gene in 20 *H pylori* clinical isolates from South China was detected by PCR. The production of IL-8 and GROα cytokines in the culture supernatant of SGC7901 gastric epithelial cells stimulated with rHP-NAP was also detected.

The seropositivity for anti-*H pylori* IgG was 52.8% (47/89) in healthy subjects, which is in agreement with the average prevalence (about 50%-60%) of *H pylori* in the adult Chinese population. The 47 subjects who were serum positive for anti-*H pylori* IgG were considered to be *H pylori*-infected healthy individuals. The seropositivity for anti-HP-NAP antibodies was 27.7% (13/47) in *H pylori*-infected healthy individuals, due to variations in HP-NAP expression in different *H pylori* strains. It has been shown that the neutrophil adhesion-promoting activity in different *H pylori* strains varies considerably[29,30], suggesting that HP-NAP is differently expressed in different *H pylori* strains[31]. Our results also show that the mean absorbance value for anti-HP-NAP antibodies was not significantly different in different age groups. Our work and other studies, however, have found that the *napA* gene is present in all *H pylori* clinical isolates.

H pylori is a clear (class 1) carcinogen. HP-NAP stimulates neutrophils to infiltrate gastric mucosa and subsequently causes ROS production by activating NADPH oxidase in plasma membrane. It was reported that ROS can cause a variety of DNA lesions and produce mutations in mammalian cells[32]. ROS production is significantly decreased in gastric mucosa of patients with *H pylori* successfully eradicated[33]. It has also been shown that HP-NAP can be involved in extravasation of leukocytes, and ROS can play a role in the carcinogenic process in gastric mucosa during chronic *H pylori* infection[34,35], indicating that HP-NAP may be a risk factor for *H pylori*-associated gastric cancer.

In the present study, the seropositivity and mean absorbance value for HP-NAP-specific antibodies in gastric cancer patients (97.7% and 1.01 ± 0.24) were significantly higher than those in chronic gastritis patients (85.7% and 0.89 ± 0.14, $P < 0.005$) and in infected healthy controls (0.65 ± 0.18, range 0.451-0.948, $P < 0.001$). There was no difference, however, in the seropositivity or mean absorbance value for HP-NAP antibodies between the patients with gastric cancer and peptic ulcer, indicating that HP-NAP specific antibodies are correlated with severe gastroduodenal diseases and HP-NAP may contribute to the pathogenesis of *H pylori*-associated gastric cancer. Our results also show that HP-NAP had a strong antigenicity, and the majority of infected patients produced antibodies against HP-NAP.

ELISA for the detection of antibodies against HP-NAP in this study had a sensitivity of 95.5% and a specificity of 91.5%. Since the level of HP-NAP-specific antibodies may be correlated with the severity of *H pylori* infection, ELISA can be used in immunodiagnostic assay for *H pylori*-infection and in screening for a high-risk population with *H pylori*-associated gastric cancer.

In this study, HP-NAP slightly up-regulated IL-8 production by gastric epithelial cell lines, but had no effect on GROα production, suggesting that the direct effect of HP-NAP on gastric epithelial cells may be limited, but HP-NAP may contribute to the inflammatory response or carcinogenesis by activating neutrophils.

In conclusion, infection with virulent *H pylori* strains secreting HP-NAP is associated with severe gastroduodenal diseases and HP-NAP may play a role in the development of gastric carcinoma. rHP-NAP-based ELISA can be used as a new method to detect *H pylori* infection. We have recently developed a monoclonal antibody against HP-NAP, which might be used to detect HP-NAP expression in gastric mucosa. It would be desirable to carry out a comparative analysis to define the characteristic differences in HP-NAP expression between patients with gastric cancer and other gastroduodenal diseases. Further characterization of the interactions between HP-NAP and gastric cancer should aid in the development of novel strategies against *H pylori*-associated gastric cancer.

COMMENTS

Background

Helicobacter pylori (H pylori) infection increases the risk of developing peptic ulcer, gastric adenocarcinoma, and gastric B cell lymphoma. *H pylori* neutrophil-activating protein (HP-NAP), a virulence factor, promotes the adherence of neutrophils to gastric mucosa endothelial cells and stimulates high production of reactive oxygen species (ROS) in neutrophils. Since ROS can mediate DNA damage and enhance cell turnover, HP-NAP may be a risk factor for *H pylori*-associated gastric cancer. To prevent *H pylori*-related cancer, mass screening for and treatment of *H pylori* infection are cost-effective. Whether HP-NAP is related to the occurrence of gastric cancer is still uncertain.

Research frontiers

HP-NAP is a virulence factor for *H pylori* infection and a vaccine candidate antigen. The majority of infected patients have antibodies against this antigen,

and vaccination of HP-NAP in mice can protect against a subsequent challenge with *H pylori*. *H pylori* colonization is followed by infiltration of neutrophils, macrophages and lymphocytes in gastric mucosa. The degree of mucosal damage is closely correlated with the extent of neutrophil infiltration. It has been shown that HP-NAP can be involved in the extravasation of leukocytes, and ROS can play a role in the carcinogenic process of gastric mucosa during chronic *H pylori* infection.

Innovations and breakthroughs

An understanding of the relation between HP-NAP and gastric cancer should lead to improved approaches to the effective control of *H pylori*-associated gastric cancer. Seropositivity and mean absorbance value for HP-NAP-specific antibodies in gastric cancer patients were significantly higher than those in chronic gastritis patients and in infected healthy controls. There was no difference, however, in serum positivity or mean absorbance value for HP-NAP antibodies between patients with gastric cancer and peptic ulcer. These findings indicate that HP-NAP specific antibodies are correlated with severe gastroduodenal diseases and HP-NAP may contribute to the pathogenesis of *H pylori*-associated stomach cancer.

Applications

ELISA used for the detection of antibodies against HP-NAP in this study had a sensitivity of 95.5% and a specificity of 91.5%. Since the level of HP-NAP-specific antibodies may be correlated with the severity of *H pylori* infection, ELISA can be used to screen for a high-risk population with *H pylori*-associated gastric cancer.

Terminology

H pylori, a gram-negative microaerophilic bacterium, causes a long-term mild inflammation of stomach lining and is strongly linked to the development of duodenal and gastric ulcers and stomach cancer. Over 50% of the world's population harbor *H pylori* in their upper gastrointestinal tract, and infection is more prevalent in developing countries.

Peer review

In this study, the authors detected and evaluated the level of antibodies against HP-NAP in patients with gastric cancer and other gastroduodenal diseases. The results suggest that HP-NAP-specific antibodies are correlated with severe gastroduodenal diseases and HP-NAP may contribute to the pathogenesis of *H pylori*-associated stomach cancer. ELISA can be used to screen for a high-risk population with *H pylori*-associated gastric cancer.

Abstract

AIM: To investigate the clinicopathological roles of Bmi1 in esophageal squamous cell carcinoma (ESCC).

METHODS: Quantitative real-time polymerase chain reaction and immunohistochemical staining for Bmi1 were performed in cancerous and adjacent non-cancerous paraffin-embedded esophageal specimens.

RESULTS: The Bmi1 expression level was unaffected by gender and age. The level of Bmi1 mRNA in ESCC was significantly higher than that in the adjacent non-cancerous tissues (2.181 ± 2.158 *vs* 0.931 ± 0.894, $P = 0.0152$), and its over-expression was aggressively associated with lymph node metastasis (3.580 ± 2.487 *vs* 1.703 ± 0.758, $P = 0.0003$), poorer cell differentiation ($P = 0.0000$) and advanced pathological stage (3.827 ± 2.673 *vs* 1.590 ± 0.735, $P = 0.0001$). The patients were divided into high-expression and low-expression groups based on the median expression level of Bmi1 mRNA, and a shorter overall survival time in the former group was observed. Immunohistochemistry for Bmi1 oncoprotein showed diffusely positive, focally positive and negative expression in 44, 16 and 10 of 70 ESCC cases, respectively, compared with three, two and five of 10 adjacent non-cancerous cases ($P = 0.027$). The positive rate of the oncoprotein in samples of histological grade Ⅲ was higher than that of grade Ⅱ ($P = 0.031$), but its expression had no relation to the lymph node metastasis and pathological staging. In 70 ESCC samples, Bmi1 showed high intense expression in the cytoplasm and less or even no expression in the nucleus.

CONCLUSION: Bmi1 was over-expressed in ESCC. Increased Bmi1 mRNA expression was significantly associated with ESCC progression, and the oncoprotein was largely distributed in the cytoplasm of tumor cells.

Association between Bmi1 and clinicopathological status of esophageal squamous cell carcinoma. *World J Gastroenterol* 2009; 15(19): 2389-2394 Available from: URL: http://www.wjgnet.com/1007-9327/15/2389.asp DOI: http://dx.doi.org/10.3748/wjg.15.2389

INTRODUCTION

Esophageal cancer is one of the most frequently occurring malignancies and the seventh leading cause of cancer-related deaths in the world. It exhibits considerable geographic variation, and 95% of tumors are esophageal squamous cell carcinoma (ESCC)[1]. Besides the impact of the environment, the process of esophageal tumorigenesis at the molecular level is related to disorders of cell amplification, differentiation, senescence and apoptosis. The genetic bases underlying esophageal tumorigenesis have been partly understood in the past few years, including a loss of the anti-oncogene p53 and over-expression of epidermal growth

factor receptor or c-Myc[2]. However, other molecular mechanisms involved in esophageal tumorigenesis progress are still largely unknown.

Bmi1, located in 10p11.23, is a member of the polycomb group (PcG) and a component of the polycomb repressive complex 1. It was initially identified as an oncogene cooperating with c-Myc in the generation of lymphomas in double transgenic mice[3-5]. Several lines of evidence imply that Bmi1 plays an important role in the regulation of cell proliferation and senescence and is required for maintenance of adult hematopoietic and neural stem cells[6-9]. *Bmi1* gene amplification is observed mainly in mantle cell lymphomas[10], and recent serial studies have shown that Bmi1 is overexpressed in many somatic solid tumors such as colon carcinoma, non-small cell lung cancer, breast cancer, head and neck squamous cell carcinoma and gastric carcinoma[11-15], and it may be of diagnostic and prognostic relevance. However, to date, no report about the role of Bmi1 in ESCC has been made. The up-regulation of c-Myc and the down-regulation of p53 and p16 in ESCC[2] tissues make it plausible that Bmi1 may play an important role in the initiation and development of ESCC. This study was designed to investigate Bmi1 expression in ESCC tissues and its impact on patients with ESCC.

MATERIALS AND METHODS

Ethics

The use of study specimens for analyses was approved by the Research Ethics Committee of Nanjing Medical University. Informed written consent was obtained from all the patients.

Case selection

From June 1997 to February 2000, 80 ESCC and 15 adjacent non-cancerous paraffin-embedded samples were obtained from the tumor center of Nanjing First Hospital affiliated to Nanjing Medical University. There were 52 male and 28 female patients with a mean age of 60 years (range: 41-82). The patients were given preoperative examination including biopsy for diagnosis, barium X-ray, CT and ultrasonic endoscopy for clinical staging, and no treatment was given before operation. Radical resection was performed in each patient, and all the samples underwent postoperative pathological examination. There were 54 cases of stage Ⅰ-Ⅱ and 26 cases of stage Ⅲ-Ⅳ cancer according to the American Joint Committee on Cancer staging manual (AJCC, 2002)[16]. With regard to postoperative histological results, 16 were well-differentiated, 40 moderately differentiated and 24 poorly differentiated. Another 70 ESCC and 10 non-cancerous paraffin-embedded samples were enlisted from January 2002 to December 2003 in the same institution. There were 48 male and 22 female patients with a mean age of 61 years (range: 38-89). All the patients were assessed for physiological ability and endoscopy and CT scan were performed for clinical staging prior to routine surgery for ESCC. The postoperative pathological examination found 56 cases of stage Ⅰ-Ⅱ and 14 cases of Ⅲ-Ⅳ cancer according to AJCC (2002) pTNM standards[16]. Clinical follow-up after surgery and diagnosis was based on periodic visits (every 3 mo during the first year, every 6 mo the second year, and then yearly until relapse).

RNA extraction and quantitative real-time polymerase chain reaction (PCR)

Real-time quantitative PCR was performed on paraffin-embedded sections from 80 ESCC patients and 15 adjacent non-cancerous samples. Briefly, total RNA was extracted by Recover All Total Nucleic Acid Isolation kit (Ambion), and 10 mg of DNase-treated total RNA was used for reverse transcription with Superscript Ⅲ (Invitrogen, Carlsbad, CA, USA). An aliquot representing 100 ng input RNA was amplified by quantitative real-time PCR using the TaqMan PCR reagent kit and assay-on-demand gene expression products (FAM/Sybr, Foster City, CA, USA). RNA extracted from a non-cancerous lesion in one patient was used as a standard. After reverse transcription, standard cDNA was serially diluted to obtain five standard solutions for use in PCR to generate the reference curve. Sequences of the Bmi1 bidirectional primers were designed using Primer 5.0 rotor-gene 6.0 (Corbett Research) as follows: Bmi1 sense 5'-GTATTCCC TCCACCTCTTCTTG-3', Bmi1 antisense 5'-TGCTGAT GACCCATTTACTGAT-3'. House-keeping gene: β-actin sense 5'-CCTGTACGCCAACACAGTGC-3', antisense 5'-ATACTCCTGCTTGCTGATCC-3'. Quantitative real-time PCR was carried out in a Rotor-Gene 3000 PCR kit (Corbett Research) with 10000 × Syber Green (Molecular Probes). After reverse transcription, standard cDNA was serially diluted to obtain five standard solutions for use in PCR to generate the reference curve. The relative amount of cDNA in each sample was measured by interpolation using the standard curve (Figure 1), and then the relative ratio of Bmi1 to β-actin (housekeeping gene) expression was calculated for each ESCC sample.

Immunohistochemistry

Histopathological evaluation was performed on 4-μm slides stained with hematoxylin and eosin (HE) (Figure 2). Commercially available rabbit monoclonal antibodies against Bmi-1 (1:100, Santa Cruz Biotechnology) were used as primary antibodies. A paraffin section of the ESCC sample was deparaffinized and rehydrated in graded alcohol to water. Antigenic enhancement was performed by submerging in citrate buffer (pH 6.0) and microwaving. Endogenous peroxide activity was quenched by applying 0.3% hydrogen peroxide for 10 min, followed by incubation with 1% BSA to block the non-specific binding. The primary monoclonal anti-Bmi1 antibody was incubated for 60 min at 37℃. After washing, the tissue section was reacted with the biotinylated anti-rabbit IgG, and visualized using a Dako Envision System horseradish peroxidase for monoclonal antibodies. The slides were immersed in the prepared diaminobenzidine solution, which produces a brown precipitate at the level of the antigen-primary antibody. Slides were then counterstained with hematoxylin, dehydrated through alcohols of increasing concentration, placed in xylene, coverslipped using Permount, and

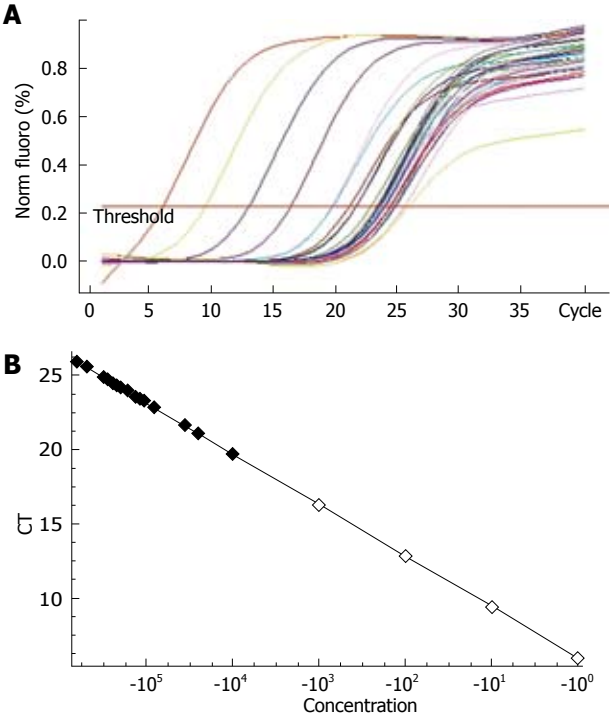

Figure 1 Amplification curve (A) and standard curve (B) of quantitative real-time PCR for Bmi1 mRNA. Total RNA was extracted for subsequent reverse transcription, and standard cDNA was serially diluted to obtain five standard solutions (1×10^{-1}, 1×10^{-2}, 1×10^{-3}, 1×10^{-4}, 1×10^{-5}) for use in PCR to generate the reference curve, slope rate of the straight line (a) = -3.42089, intercept (b) = 5.97517, correlation coefficient (*r*) = 0.9996. The strength of Bmi1 and β-actin was directly generated by the machine.

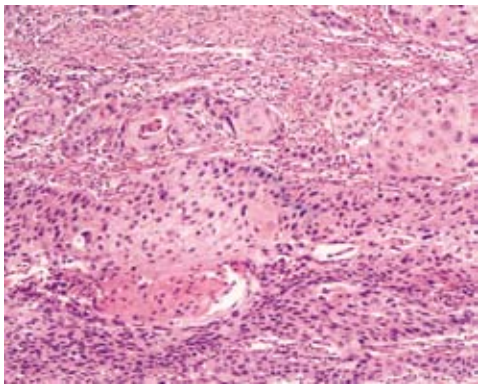

Figure 2 Staining of ESCC tissues. The tumor cells of cancerous tissues were stained as violet in the nucleus and pink in the cytoplasm (× 100).

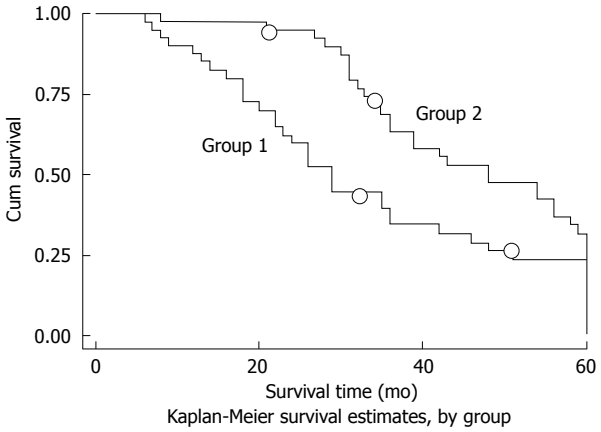

Figure 3 Effects of Bmi1 mRNA expression on prognosis of ESCC patients. Two patients did not complete the 5-year follow-up in each group (small circles). The survival rate was higher in the down-expression group (group 2) than in the up-expression group (group 1), $\chi^2 = 4.41$, $P = 0.0356$.

analyzed under light microscopy. Each section was evaluated by at least two independent professional pathologists, the distribution of Bmi-1 was scored on a semi-quantitative scale, the percentage of positive tumor cells was recorded and divided as follows: negative (< 10% of tumor cells positive), locally positive (10%-50% of tumor cells positive), and diffusely positive (> 50% of tumor cells positive).

Statistical analysis

Data were expressed as mean ± SD and analyzed using the Stata v9.0-CYGiSO bin (Computer Resource Center, USA). The significance of differences among groups was determined by Student's *t* test and χ^2 test or Fisher's exact test. The difference in free survival between groups was analyzed by the Kaplan-Meier method and log-rank test. The starting point for calculating free survival was the date of surgery, and the endpoint was the date of death. Statistical significance was assessed at the two sided 5% level, and *P* values less than 0.05 were considered statistically significant.

RESULTS

Quantitative real-time PCR analysis

Clinical follow-up was made in 76 patients. The comparative expression levels were determined as a ratio between the Bmi1 and the housekeeping gene (β-actin) to correct for variation in the amounts of mRNA. The 5-year survival rate was 37.46%. The Bmi1 mRNA level was higher in the cancerous tissues than that in the non-cancerous tissues (2.181 ± 2.158 *vs* 0.931 ± 0.894, $P = 0.0152$). The Bmi1 expression level was unaffected by gender and age. The expression level of Bmi1 mRNA was much lower at the Ⅰ-Ⅱ stage than that at the Ⅲ-Ⅳ stage, which varied inversely with the differentiation grade, and was lower in cases without metastatic lymph nodes than in those with metastatic lymph nodes (Table 1). Based on the detection of Bmi-1 median expression level (1.085), patients were divided into the down-expression group (Bmi1 mRNA level < 1.085) and the up-expression group (Bmi1 mRNA level > 1.085), and the accumulated survival rate was higher in the former than that in the latter (Figure 3).

Protein analysis

Bmi1 oncoprotein expression was diffusely positive, focally positive and negative in 44, 16 and 10 of 70 ESCC cases, respectively. Compared with three, two and five of 10 adjacent non-cancerous cases, Bmi1 protein was significantly increased in ESCC samples ($P = 0.027$). Analysis of protein localization in ESCC cells was made, and the tumor cells with Bmi1 staining were divided

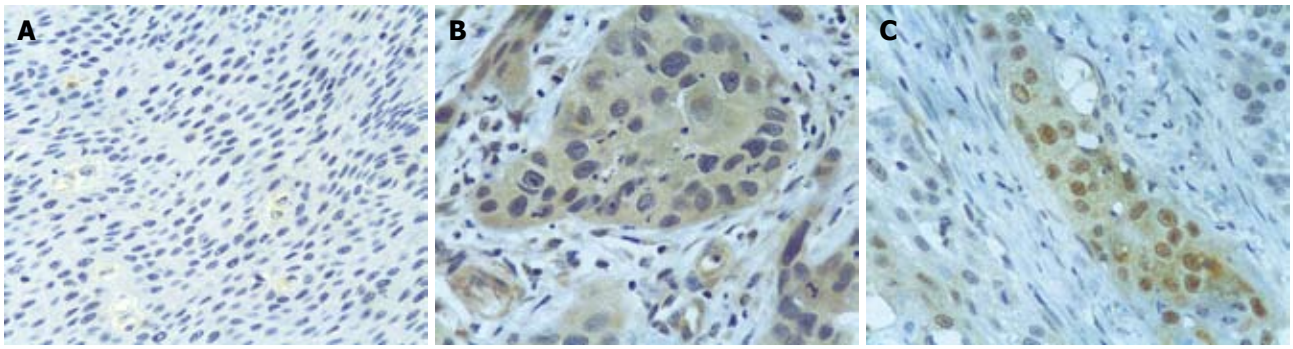

Figure 4 Immunohistochemical staining of ESCC using antibody to Bmi-1. A: Bmi1 protein expression in adjacent non-cancerous tissues (× 400); B: Cytoplasm staining of Bmi1 in ESCC cells (× 400); C: Intense Bmi-1 staining in the nucleus in ESCC cells (× 400). The brown staining under light microscopy indicates positivity.

Table 1 Associations of Bmi-1 mRNA expression in ESCC tissues with clinicopathological characteristics (mean ± SD)

Parameter	Bmi-1 mRNA	*P*
Age (yr)

ESCC was subjected to immunohistochemistry using antibodies to Bmi1. χ^2 test was used to detect the difference between Bmi1 oncoprotein and clinicopathological status.

into three categories, referring to both the nucleus and cytoplasm. In all 70 tested ESCC tissues, Bmi1 presented highly intense expression in both nucleus and cytoplasm with varied degrees, accompanied by less or even no expression in the nucleus, with significant differences (Figure 4). The positivity of the oncoprotein in samples of histological grade Ⅲ was more frequent than that of grade Ⅱ, but no significant differences were observed between other differentiated grades ($P = 0.031$). No relationship was found between the Bmi1 protein expression and lymph node metastases, pathological staging and cell differentiation (Table 2). Clinical follow-up was made in 67 patients. The 5-year survival rate was 40.01%. There was no statistical difference in survival rates between groups according to the Bmi1 expression ($P = 0.1704$).

DISCUSSION

ESCC is a major cause of morbidity and mortality worldwide[1], and it is significant to identify a biological genetic molecular marker related to its pathophysiological processes.

Epigenetic aberrations, the heritable changes in gene expression that occur in chromatin structure including DNA methylation, histone post-translational modifications and nucleosomal remodeling, rather than the DNA sequence, are involved in cancer development[17-20]. Bmi1, the first PcG protein found, is a chromatin modifier implicated in the tumorigenesis through negatively regulating the gene expression such as the INK4A locus, which is thought to regulate p53 and the Rb signaling pathway in cooperation with c-myc[5,6,19,21]. In this retrospective study, we examined the Bmi1 expression and investigated its impact on ESCC patients.

Bmi1 mRNA expression was significantly higher in the ESCC samples than in the adjacent non-cancerous tissues, and so was Bmi1 protein expression, which indicated that Bmi1 plays an important role in the development of ESCC, and has diagnostic value.

Dirks[22] has reported that Bmi1-deficient tumors may be less aggressive because they have fewer stem cells. Bmi1 expression is also found inversely correlated with the differentiation grade of clear cell carcinoma

and is involved in tumor progression[23]. Our data are in agreement with the findings by previous publications that the acquisition of metastatic ability of tumor cells is considered a late event in the evolution of malignant tumors. We found that the Bmi1 mRNA expression was higher in the stage Ⅰ/Ⅱ tissues than in stage Ⅲ/Ⅳ, significantly lower in patients without metastatic lymph nodes, and inversely related to cell differentiation. The oncoprotein was more frequently observed in tissues with poorer differentiation. These results suggest that Bmi1 expression may not be required for initiation of ESCC but is required for its progression. It may be a guide for postoperative therapy and a differentiation marker in ESCC with high malignancy. Furthermore, we discovered that the accumulated survival of patients in the up-expression group was much shorter than that of patients in the down-expression group, which may predict survival in ESCC patients.

It was interesting to note that Bmi1 protein expression was negatively correlated with malignant grade, including lymph node metastasis and advanced pathological stage. This may have been because the samples for protein analysis were obtained at different periods than those for mRNA analysis, which resulted in a different selection bias. Also, the number of lymph nodes resected by different operators varied, and the lymph nodes removed during surgery for pathological diagnosis may have been misdiagnosed as metastatic lymph nodes.

The PcG protein Bmi1 showed abundant nuclear expression in prostate cancer, colorectal cancer and gastric carcinoma[11,15,24]. However, in our study, cytoplasmic staining appeared in most of the tumor cells with less or even no expression in the nucleus alone, which suggests that Bmi1 produces a marked effect on the development of ESCC, mainly in the cytoplasm. This is inconsistent with the PcG pathway activation hypothesis that states that increased Bmi1 expression in cancer cells is associated with elevated levels of H2AubiK119 and H3metK27 histones, which suppress the expression of the INK4a/ARF locus in the nucleus[21].

The mechanisms of Bmi1 up-expression that induce adverse pathological and clinical features in ESCC patients are poorly understood. Some previous studies have shown that Bmi1 expression is a potential escape mechanism and associated with markedly increased likelihood of treatment failure and disease relapse after surgery[25,26]. Qin *et al*[27] have found that down-regulation of Bmi-1 enhances 5-fluorouracil-induced apoptosis in nasopharyngeal carcinoma cells and have suggested that the combination of 5-FU treatment and Bmi-1 depletion might be a potential clinical strategy for cancer chemotherapy.

However, we believe that further investigations on larger series of ESCC patients, including clinical follow-up and novel molecular techniques, are needed to confirm our conclusions. Whether Bmi1 can be used for accurate prediction of ESCC and its potential chemosensitivity to current pharmaceutical treatment needs further study.

COMMENTS

Background

Bmi1, a member of the polycomb group and a component of the polycomb repressive complex1, has been considered as a oncogene involved in many solid and hematological malignant tumors, and it may be of diagnostic and prognostic relevance. However, to date, no report about the role of Bmi1 in esophageal squamous cell carcinoma (ESCC) has been made. However, the up-regulation of c-Myc and the down-regulation of p53 and p16 in ESCC tissues make it plausible that Bmi1 may play an important role in the initiation and progression of ESCC.

Research frontiers

This research, for the first time, investigated the expression of Bmi1 and its clinicopathological role in patients with ESCC.

Innovations and breakthroughs

A significant upregulation of Bmi1 was observed in cancerous tissues in contrast to adjacent non-cancerous paraffin-embedded esophageal specimens at the mRNA and the protein level by quantitative real-time polymerase chain reaction (PCR) and immunohistochemistry. Furthermore, overexpression of Bmi1 positively correlated with lymph node metastases, pathological stage and differentiation grade at the mRNA level.

Applications

Bmi1 may act as a guide for the postoperative therapy and a differentiation marker of ESCC with high malignancy, and for prediction of the survival of ESCC patients.

Peer review

The authors investigated the expression of Bmi1 at the mRNA and protein level in patients with ESCC in comparison with healthy adjacent tissue, by real-time PCR and immunohistochemistry. They observed a significant up-regulation of Bmi1 in tumor tissues in contrast to healthy control tissues. Up-regulation correlated positively with lymph node metastases, stage and histological grading at the mRNA level. However, the histological analysis showed no such correlation. The authors conclude that Bmi1 expression is common in ESCC and may serve as a marker to predict lymph node metastasis and survival in ESCC patients.

Abstract

AIM: To evaluate the impact of alcohol dehydrogenase-2 (ADH2) and aldehyde dehydrogenase-2 (ALDH2) polymorphisms on esophageal cancer susceptibility in Southeast Chinese males.

METHODS: Two hundred and twenty-one esophageal cancer patients and 191 healthy controls from Taixing city in Jiangsu Province were enrolled in this study. ADH2 and ALDH2 genotypes were examined by polymerase chain reaction and denaturing high-performance liquid chromatography. Unconditional logistic regression was used to calculate the odds ratios (OR) and 95% confidence interval (CI).

RESULTS: The ADH G allele carriers were more susceptible to esophageal cancer, but no association was found between ADH2 genotypes and risk of esophageal cancer when disregarding alcohol drinking status. Regardless of ADH2 genotype, ALDH2G/A or A/A carriers had significantly increased risk of developing esophageal cancer, with homozygous individuals showing higher esophageal cancer risk than those who were heterozygous. A significant interaction between ALDH2 and drinking was detected regarding esophageal cancer risk; the OR was 3.05 (95% CI: 1.49-6.25). Compared with non-drinkers carrying both ALDH2 G/G and ADH2 A/A, drinkers carrying both ALDH2 A allele and ADH2 G allele showed a significantly higher risk of developing esophageal cancer (OR = 8.36, 95% CI: 2.98-23.46).

CONCLUSION: Both ADH2 G allele and ALDH2 A allele significantly increase the risk of esophageal cancer development in Southeast Chinese males. ALDH2 A allele significantly increases the risk of esophageal cancer development especially in alcohol drinkers. Alcohol drinkers carrying both ADH2 G allele and ALDH2 A allele have a higher risk of developing esophageal cancer.

Key words: Alcohol dehydrogenase-2; Aldehyde dehydrogenase-2; Gene polymorphisms; Alcohol drinking; Esophageal cancer

INTRODUCTION

There is epidemiological evidence showing that alcohol intake is associated with increased esophageal cancer risk[1]. Acetaldehyde, the oxidative metabolite of ethanol, is recognized to be carcinogenic in animals and suspected to have similar effects in humans[2]. Ethanol is oxidized to acetaldehyde and then to acetate by alcohol dehydrogenase (ADH) and aldehyde dehydrogenase (ALDH), both of which have genetic

polymorphisms. People homozygous for the ALDH2*2 allele (Glu487Lys, Lys or A allele) do not have any ALDH activity. Heterozygous individuals carrying the reference (G) and variant (A) alleles (ALDH2*1/2, or A/G) show only 1/16 of the activity seen in ALDH2*1 homozygotes (G/G)[3-5]. ADH2*2 allele (Arg47His, His or A allele) encodes a superactive subunit of ADH2 and that superactive ADH2*2 homodimer has about a 40 times higher Vmax than the less-active ADH2*1/2*1 form of ADH2[3,4]. Therefore, shortly after alcohol drinking, individuals carrying both variant ADH2 and ALDH2 would accumulate a large amount of aldehyde that cannot be efficiently oxidized to the non-toxic acetic acid. Different combinations of ADH2 and ALDH2 genotypes may influence the individual susceptibility to cancer.

Taixing city, located in the middle part of Jiangsu Province, China, has relatively high incidence and mortality rates for esophageal cancer (in 2005, the age-adjusted mortality rate was 53.66 per 100 000 for esophageal cancer). Our previous study has shown that more than 40% of adult residents in Taixing drink wine and that drinking is a risk factor for esophageal cancer in this area[6]. We have also shown relationships between ALDH2 and the risk of esophageal cancer, but no statistically significant association was found[7]. In this study, we increased the sample size to define the individual and combined roles of ADH2, ALDH2 polymorphisms and drinking habits in the risk analysis for esophageal cancer development in Southeast Chinese males.

MATERIALS AND METHODS

Study subjects

We recruited male patients who were histopathologically diagnosed as having esophageal carcinoma from January 2005 to December 2006. Population-based male controls were recruited from healthy residents in the villages or towns where cases resided. All study subjects have completed a questionnaire administrated by a trained interviewer, covering residential, occupational, social, living style, psychological and economical factors. The interviewer then collected blood samples of subjects from a peripheral vein after obtaining their oral informed consents. The collected blood samples were shipped to the public health center within a day. Buffy coat was then separated and stored at -30℃. We defined a drinker as a person who drinks at least once per week (alcohol intake more than 40 g) and continuously drinks for at least half the year. A few patients and residents refused to participate in our study, but the overall response rate was 97% for patients and 95% for controls, respectively. The Ethics Committee of Jiangsu Provincial Institute of Cancer Research approved this study. Associations could not be assessed in women because of sparse drinking habits.

DNA extraction and genotyping of ADH2 and ALDH2

Whole blood was collected into EDTA-coated tubes and centrifuged for 15 min. The buffy coat layer was isolated. Genomic DNA was extracted from 200 μL of buffy coat using a Qiagen QIAamp DNA blood mini kit (QIAGEN Inc., Valencia, CA). Genotyping of ADH2 and ALDH2 was determined by polymerase chain reaction (PCR) and denaturing high-performance liquid chromatography (DHPLC).

The sequences of primers used in this study are F: 5'-GGGCTTTAGACTGAATAACCTTGG-3' and R: 5'-AGGGAAAGAGGAAACTCCTGAA-3' for ADH2 Arg47His, and F: 5'-TGCTATGATGTGTTTGGAGCC-3' and R: 5'-GGCTCCGAGCCACCA-3' for ALDH2 Glu487Lys. Reactions were carried out in a total volume of 25 μL containing 20 pmol of each primer, 0.25 mmol/L each dNTPs, 2.0 mmol/L $MgCl_2$, 2.5 μL 10 × buffer, 1 IU hotTag polymerase and 0.5 μL genomic DNA. PCR conditions were as follows: denaturation at 95℃ for 7 min, followed by 35 cycles at 95℃ for 30 s, at 62℃ for 30 s, at 72℃ for 30 s, and a final extension at 72℃ for 5 min. The products were denatured at 94℃ for 4 min, and their temperature was declined to 25℃ step by step according to 0.1℃/s.

Transgenomic WAVE DNA fragment analysis system (WAVE-300, Transgenomic, USA) and associated WAVEMAKER software were used for genotyping. An aliquot (5 μL) of the PCR products was directly injected into a DNASep column. The column mobile phase for sample elution consisted of a mixture of buffer A [0.1 mol/L triethylammonium acetate (TEAA)] and buffer B (0.1 mol/L TEAA with 25% acetonitrile). Samples were eluted at a linear gradient of buffer B over a 4.5-min period at a constant flow rate of 0.9 mL/min. For each DNA region, DHPLC conditions were established by a titration analysis at 1-3℃ above and below the mean melting temperature predicted by software simulation. There were three genotypes: namely G/G, G/A, and A/A, for ADH2 Arg47His and ALDH2 Glu487Lys, respectively.

Statistical analysis

All analyses were done with the SAS (version 6.02) and Epi-info (version 6.04) statistical package. Odds ratios (OR) and 95% confidence intervals (CI) were adjusted by unconditional logistic regression analysis. Gene-environment interactions were evaluated by additive model and expressed in terms of synergy index (S) and attributable proportions of interaction (API)[8]. The Mantel-Haenszel χ^2 method was used to test for significant associations between the ADH2 or ALDH2 genotype and cancer risk.

RESULTS

Four hundred and twelve Jiangsu males were enrolled in this study. Numbers of subjects were 221 cases with esophageal cancer and 191 controls (Table 1). The proportional distributions of age, occupation, education, smoking and drinking did not significantly differ between cases and controls, but the proportional distributions

[1]Crude OR; [2]Adjusted odds ratios (ORs) were adjusted for income.

of income (ten years before and recent years) were significant lower in cases than in controls (4.52 and 3.64 for *T* value, $P < 0.01$).

As shown in Table 2, the frequency of ALDH2 G/G, G/A and A/A genotypes were 40.73%, 40.27% and 19.00% in cases and 59.69%, 34.55% and 5.96% in controls respectively. The distribution of the ALDH2 genotypes was significant different between controls and cases ($\chi^2 = 22.30$, $P < 0.01$). The frequency of ADH2 A/A, A/G and G/G genotypes demonstrated no significant differences between cases and controls ($\chi^2 = 4.92$, $P = 0.085$). The allelic distribution of ADH2 and ALDH2 polymorphisms was in Hardy-Weinberg equilibrium ($P > 0.05$).

As for income-adjusted odds ratio, compared with ALDH2 G/G carriers, the OR was 1.70 (95% CI: 1.08-2.68) for G/A carriers, 5.69 (95% CI: 2.51-12.18) for the A/A carriers and 2.19 (95% CI: 1.43-3.34) for the two genotypes combined. Compared with the subjects with ADH2 A/A genotype, subjects with G/G genotypes had an increased OR of 2.78 (95% CI: 1.06-7.29). As for allelic comparison, the OR was 2.15 (95% CI: 1.57-2.95) for ALDH2 A allele and 1.39 (95% CI: 1.01-1.92) for ADH2 G allele carriers.

Table 3 Interaction between ALDH2 and ADH2 genotype and the ORs for esophageal cancer

ADH2	ALDH2	Cases	Controls	OR[1] (95% CI)	OR[2] (95% CI)
A/A	G/G	44	68	1.00	1.00
G/A+G/G	G/G	46	46	1.55 (0.89-2.70)	1.46 (0.79-2.70)
A/A	G/A	40	33	1.87 (1.03-3.40)	1.93 (0.99-3.75)

A/A	A/A	22	7	4.98 (1.91-12.33)	5.28 (1.88-14.83)
G/A+G/G	A/A	20	4	7.73 (2.48-24.13)	12.22 (2.62-56.91)

[1]Crude OR; [2]ORs were adjusted for income.

Regardless of ADH2 genotype, ALDH2G/A or A/A carriers were found to have significantly increased risk of developing esophageal cancer. ALDH2 A/A homozygotes have higher esophageal cancer risk than ALDH2G/A heterozygotes. As compared to the subjects with ADH2A/A and ALDH2 G/G genotypes (double wild type), those with variant alleles for both ADH2 (G allele) and ALDH2 (A allele) had a significantly increased OR. ALDH2 A/A homozygotes who were also carrying ADH2 G allele had the highest OR of 12.22 (95% CI: 2.62-56.91) (Table 3).

The ALDH2 A/A genotype alone showed a moderate increase of esophageal cancer risk in both drinkers and non-drinkers (Table 4). No significant relationship was found in analysis of ADH2 genotypes. Compared with non-drinkers with both ALDH2 G/G and ADH2 A/A genotypes, drinkers with ALDH2 A and ADH2 G alleles showed a significantly elevated risk of esophageal cancer (OR = 8.36, 95% CI: 2.98-23.46)

The OR for esophageal cancer among alcohol drinkers with ALDH2 A allele was markedly increased to 3.05 (95% CI: 1.49-6.25) compared to non-drinkers with ALDH2 G/G genotypes (Table 5). A significant gene-environment interaction between alcohol drinking and ALDH2 was observed for esophageal cancer risk (S = 2.93). The population attributable risk due to alcohol drinking by ALDH2 A allele carriers was estimated to be 41% for esophageal cancer (API = 0.41).

DISCUSSION

Our previous studies showed that drinking was associated with increased esophageal, stomach and liver cancer in Taixing[6]. We also found that it was not ADH2 but ALDH2 polymorphisms that had a significant interaction with heavy alcohol consumption in the development of hepatocellular carcinoma (HCC)[9]. In the present study, both ADH2 G allele and ALDH2 A allele significantly increased the risk of esophageal cancer development. ALDH2 A allele significantly increases the risk of esophageal cancer development

especially in alcohol drinkers. Alcohol drinkers carrying both ADH2 G allele and ALDH2 A allele have a higher risk of developing esophageal cancer.

There is no doubt that the differences in environment exposures/lifestyle influence the genetic susceptibility to cancer. There have been a lot of papers regarding the relationship between ADH2 and ALDH2 polymorphisms and esophageal cancer susceptibility. Chao *et al*[10] found that Chinese alcoholic patients with the ADH G and ALDH2 A allele were more susceptible to esophageal cancer. Many studies found that the inactive ALDH2 genotypes had a significantly increased risk for developing esophageal cancer and that a gene-environment interaction exists between alcohol drinking and the inactive ALDH2 genotypes[2,11-16]. Boonyaphiphat *et al*[17] did not find ALDH2 increased the risk significantly (OR of ALDH G/A 1.57, 95% CI: 0.89-2.76). However, the combined at risk genotypes, ADH A/A and ALDH G/A increased risk by four-fold and heavy drinkers > 60 g/d harboring ADH A/A or ALDH G/A had about an 11-fold increased risk. Our previous study showed no statistically significant association between ALDH2 and esophageal cancer susceptibility[7]. However, in this study with a larger sample size, we found that the ALDH2 A allele showed a moderately increased risk for esophageal cancer as compared with ALDH2 G/G carriers, and significant gene-environment interactions between alcohol drinking and ALDH2 were observed regarding esophageal cancer risk (S = 2.93). The population attributable risk due to alcohol drinking by ALDH2 A allele carriers was estimated to be 41% for esophageal cancer. Yokoyama *et al*[18] also found that an extraordinarily high proportion of excessive risk for esophageal cancer in Japanese males can be attributed to drinking by persons with inactive heterozygous ALDH2 (68.5%). Aldehyde dehydrogenase-2 generates acetic acid from acetaldehyde metabolism and its activity correlates with *in vivo* acetaldehyde concentration. Thus, diminished ALDH2 enzyme activity and consequent higher concentrations of acetaldehyde can be risk factors for esophageal cancer. In this study, we, for the first time, report that ALDH2 A/A homozygotes have higher esophageal cancer risk than ALDH2 G/A homozygotes, which is consistent with the different ALDH2 enzyme activity resulting from A/A and G/G genotypes. Literature has shown that after drinking, the blood acetaldehyde concentrations in those with ALDH2 A/A and G/A were 19- and 6-fold higher than in those with G/G genotype, respectively[19].

In this study, we found the ADH G allele carriers were more susceptible to esophageal cancer, but no association was found between ADH2 genotypes and risk of esophageal cancer when disregarding drinking status. Compared with non-drinkers carrying both ALDH2 G/G and ADH2 A/A, drinkers carrying both ALDH2 A allele and ADH2 G allele showed a significantly higher risk of developing esophageal cancer (OR = 8.36, 95% CI: 2.98-23.46). The inactive ADH2 genotype has also been demonstrated to enhance the risk of esophageal cancer among alcoholics and the general population. The inactive ALDH2 genotype and ADH2 genotype carriers have higher risk of developing esophageal cancer, especially among alcohol drinkers[11,13-18]. These findings conflicts with those demonstrating that the enzyme activity in ADH G allele was much higher than that of A allele. Yoshihara *et al*[20] showed that there were no significant differences in blood ethanol and acetaldehyde concentrations between volunteers with ADH2*1 and without ADH2*1. Thus, the mechanism of the ADH2 polymorphism involved

in esophageal cancer risk may be associated with, not acetaldehyde, but a direct involvement of ethanol.

In summary, this study found that polymorphisms of the ADH2 and ALDH2 genes were significantly associated with the risk of esophageal cancer in Southeast Chinese males. Significant gene-environment interactions between alcohol drinking and ALDH2 were observed in esophageal cancer risk. Significant interactions between ADH2 and ALDH2 polymorphisms were also observed. These findings can provide additional information about the role of alcohol in esophageal cancer risk in Chinese populations. For individuals with ALDH2 A/A or G/A genotypes, reducing alcohol consumption may help lower their risk for esophageal cancer.

We thank the local staff of the Public Health Center of Taixing City for their assistance in data collection.

COMMENTS

Background

Esophageal cancer is the most common cancer in China. There is epidemiological evidence that alcohol intake is associated with an increased esophageal cancer risk. Alcohol dehydrogenase-2 (ADH2) and aldehyde dehydrogenase-2 (ALDH2) have a strong impact on alcohol metabolism. The authors' previous study has shown that more than 40% of adult residents in Taixing drink wine and that drinking is a risk factor for esophageal cancer in this area. However, no statistically significant association between ALDH2 and the risk of esophageal cancer was found. In this study, the authors increased the sample size to define the individual and combined roles of ADH2, ALDH2 polymorphisms and drinking habits in the risk for esophageal cancer development in Chinese males.

Innovations and breakthroughs

The present study showed that polymorphisms of the ALDH2 genes were significantly associated with the risk of esophageal cancer in Southeast Chinese males. Significant gene-environment interactions between alcohol drinking and ALDH2 were observed in esophageal cancer risk. Significant interactions between ADH2 and ALDH2 polymorphisms were also observed.

Applications

This research showed the genetic risk factors and the role of gene-environment interactions in identifying individuals at risk of esophageal cancer, which have certain theoretical and application values for studying the etiology of esophageal cancer and its prevention.

Terminology

ADH2: A zinc-containing enzyme which oxidizes primary and secondary alcohols or hemiacetals in the presence of NAD. In alcoholic fermentation, it catalyzes the final step of reducing aldehyde to alcohol in the presence of NADH and hydrogen. ALDH2: An enzyme that oxidizes aldehyde in the presence of NAD+ and water to acid and NADH. Genetic polymorphisms: The regular and simultaneous occurrence of two or more discontinuous genotypes in a single interbreeding population. The concept includes differences in genotypes ranging in size from a single nucleotide site to large nucleotide sequences visible at a chromosomal level.

Peer review

This study provides more information on the ADH2 and ALDH2 polymorphisms of esophageal cancer in Southeast Chinese males and the findings support the previous results that the risk of esophageal cancer increases in subjects carrying ADH2*1 allele (G allele) and ALDH2*2 allele (A allele) in an overall population, and especially ALDH2*2 allele (A allele) in alcohol drinkers. These epidemiological findings might help construct a prevention strategy against esophageal cancer.

Abstract

AIM: To evaluate the effectiveness and safety of capsule endoscopy (CE) in patients with recurrent subacute small bowel obstruction.

METHODS: The study was a retrospective analysis of 31 patients referred to hospital from January 2003 to August 2008 for the investigation of subacute small bowel obstruction, who underwent CE. The patients were aged 9-81 years, and all of them had undergone gastroscopy and colonoscopy previously. Some of them received abdominal computed tomography or small bowel follow-through.

RESULTS: CE made a definitive diagnosis in 12 (38.7%) of 31 cases: four Crohn's disease (CD), two carcinomas, one intestinal tuberculosis, one ischemic enteritis, one abdominal cocoon, one duplication of the intestine, one diverticulum and one ileal polypoid tumor. Capsule retention occurred in three (9.7%) of 31 patients, and was caused by CD (2) or tumor (1). Two with retained capsules were retrieved at surgery, and the other one of the capsules was spontaneously passed the stricture by medical treatment in 6 mo. No case had an acute small bowel obstruction caused by performance of CE.

CONCLUSION: CE provided safe and effective visualization to identify the etiology of a subacute small bowel obstruction, especially in patients with suspected intestinal tumors or CD, which are not identified by routine examinations.

Key words: Capsule endoscopy; Small bowel obstruction; Capsule retention

INTRODUCTION

Small bowel obstruction is a frequent cause of acute abdomen. The definitive diagnostic rate is not high using traditional radiographic evaluation, such as plain film radiography, abdominal computed tomography (CT), or small bowel follow-through. Some reports have demonstrated that capsule endoscopy (CE) is superior to radiographic examination and push enteroscopy in the investigation of intestinal diseases, especially for obscure gastrointestinal bleeding or suspected Crohn's disease (CD)[1-4]. Although capsule retention is a relatively infrequent complication, small bowel obstruction and strictures have been considered contraindications to CE. It is interesting to note that there is a controversy about this contraindication in the literature. The goal of the present study was to evaluate the safety and effectiveness of CE in patients with small bowel obstruction.

MATERIALS AND METHODS

Subjects

Between January 2003 and August 2008, 31 patients underwent CE for the investigation of small bowel obstruction, who had previously received gastroscopy and colonoscopy, abdominal CT or small bowel follow-

Table 1 Clinical findings and outcomes of CE or surgery

Patient	Gender/age (yr)	Surgical history/ NSAID use	Prior examinations	GI transit time (min)	CE or surgical findings	Follow-up (mo)

EGD: Esophagogastroduodenoscopy; AXR: Abdominal X-ray; MRI: Magnetic resonance imaging; CE: Capsule endoscopy; CTE: CT enterography; SBFT: Small bowel follow-through; US: Ultrasound; CD: Crohn's disease. (±): Suspected positive; (+): Positive; (-): Negative; Not pass: The capsule did not pass the ileocecal valve within the duration of the examination, but was not retained. GI: Gastrointestinal. [1]The patient was lost to follow-up 1 mo after surgery. [2]The follow-up was missed after CE examination.

through more than once. All previous radiological and endoscopic examinations could not identify clear etiology.

Materials

CE (Given M2A, Giving Imaging Ltd, Yoqneam, Israel) measuring 11 mm × 26 mm, which magnify images eight times, has a battery life of 6-8 h. It is used in conjunction with an imaging system including a data recorder and interpretative workstation. Continuous video-images are transmitted at a rate of two frames per second.

Methods

A total of 1121 patients underwent CE between January 2003 and August 2008. Most of them underwent CE for the evaluation of obscure bleeding or suspected CD. We identified 31 patients presenting with symptoms consistent with small bowel obstruction, and abdominal X-ray showed incomplete intestinal obstruction. All the 31 patients who were aware of an increased risk for capsule retention and the possibility for surgery received CE examination, when the symptoms of intestinal obstruction were relieved by conservative management. All the patients gave written informed consent. The medical data were retrospectively analyzed, including age, sex, medical and surgical history, follow-up, and radiographic, routine endoscopic and CE examinations.

RESULTS

The mean age of these 31 patients was 47.12 ± 18.38 years (range 9-81 years); 18 of the subjects were male and 13 were female. Seventeen of them were out-patients, 14 were in-patients, and nine had surgical histories before capsule examinations were performed. All of them had undergone gastroscopy and colonoscopy previously, but the results were negative. Twenty-three of them had undergone CT enterography or small bowel follow-through, and positive or suspected results were found in six cases. Four of the six patients achieved definitive diagnoses by CE examination, surgical or pathological biopsy, and the remaining two were false-positive.

The average gastric emptying time was 43.8 ± 36.1 min (range 4-131 min). In 15 of the 31 patients, the capsule passed the ileocecal valve within the duration of the examination. The mean small bowel transit time (based on 24 patients) was 332.2 ± 86.7 min (range 167-484 min, Table 1). In 28 of the 31 patients, the capsule was evacuated in 3 d. Capsule retention occurred in three

Table 2 Abnormalities detected on CE in patients with small bowel obstruction

Detected abnormalities (12)	Gender/age (yr)	CE retention (time)	Therapy	Post-CE obstructive symptom
CD (4)				
	F/18	No	Medical therapy	None
	M/54	Yes (1 wk)	Surgical resection	None
	M/53	No	Medical therapy	None
	F/65	Yes (6 mo)	Medical therapy	None
Tumor (2)				
Ileal neuroendocrine carcinoma	M/46	No	Surgical resection	None
Jejunal adenocarcinoma	F/52	Yes (2 wk)	Surgical resection	None
Intestinal tuberculosis (1)	F/31	No	Medical therapy	None
Ischemic enteritis (1)	F/67	No	Surgical resection	None
Abdominal cocoon (1)	M/43	No	Surgical resection	None
Intestinal diverticulum (1)	M/60	No	Medical therapy	None
Ileal polypoid tumor (1)	F/59	No	Lost to follow-up	None
Duplication of intestine (1)	M/9	No	Surgical resection	None

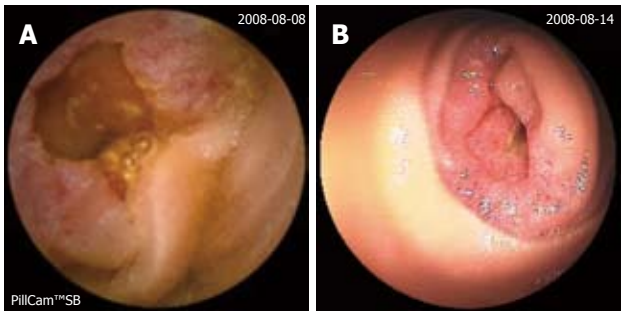

Figure 1 CE and double air-balloon endoscopic images of stenosis. A: CE shows an annuliform mass in the intestine; B: Double air-balloon endoscopy also shows an annuliform mass, but we failed to retrieve the retained capsule.

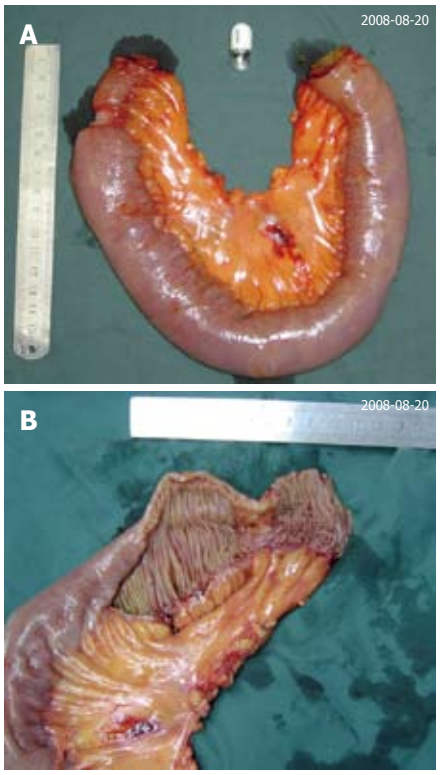

Figure 2 Surgical images of stenosis. A: A retained capsule was removed at surgery; B: An obvious stenosis was caused by jejunal adenocarcinoma.

(9.7%) cases, caused by CD or tumor, of which, were retrieved at surgery, and the other one of the capsules was spontaneously passed the stricture by medical treatment in 6 mo. None of the cases showed any symptoms of acute or subacute obstruction during CE examination.

CE disclosed definitive intestinal disease in 12 (38.7%) of the 31 patients, including four CD, two carcinoma, one intestinal tuberculosis, one ischemic enteritis, one abdominal cocoon, one intestinal duplication, one small-intestinal diverticulum and one ileal polypoid tumor (Table 2). Single or multiple ulcers were found in six patients. In three of the six, CD was diagnosed by CE images and clinical manifestations, and obvious symptom relief was achieved through treatment with mesalazine. In one of the six patients, capsule was retrieved at surgery which had not passed the stricture for 7 d, and the replacement showed CD. In another of the six patients, multiple ulcers were found with CE and double-balloon enteroscopy. CD was firstly considered according to the endoscopic findings and clinical data, but medical treatment with mesalazine did not relieve the patient's symptoms. The later BUS and CT scans showed multiple retroperitoneal lymph node enlargement, meanwhile, the purified protein derivative test was found to be positive. Pathological analysis of biopsy specimens obtained from these lymph nodes indicated tuberculosis. The patient's symptoms were relieved significantly by anti-tuberculosis treatment, therefore, intestinal tuberculosis was diagnosed. The remainder of the six was demonstrated abdominal cocoon at surgery. In one elderly patient, intestinal mucosal erosion and bleeding were found at CE examination. Later, exploratory laparotomy was performed for advanced identification of etiology and therapy, which indicated superior mesenteric artery embolus. In another case, the capsule images presented abnormal intestinal motility and CT scan showed mural thickening of the distal ileum, and finally, ileal neuroendocrine carcinoma was diagnosed by surgery. In a pediatric case, CE also showed abnormal intestinal motility. The child was treated surgically because of failure of medical treatment, which indicated duplication of the intestine. The CE findings in the remaining two cases disclosed diverticulum of the small intestine and ileal polypoid tumor. In a female patient

whose CA199 increased clearly CT, BUS scan or air-barium double contract examination were negative, but CE and double air-balloon endoscopy showed an annuliform mass, which was demonstrated to be jejunal adenocarcinoma at later surgery (Figures 1 and 2).

None of the patients had other risk factors for stricture formation, such as long-term administration of non-steroidal anti-inflammatory drug (NSAIDs) and abdominal radiotherapy. The capsule images were normal in 19 of the 31 cases. Follow-up was missed in three of the 19 cases. An elderly patient in the remaining 16 died of pulmonary infection. Small bowel obstruction did not reappear in the other 15 cases during medical treatment in the follow-up period. However, adhesive ileus could not be excluded in four of the 14 patients who had a history of abdominal surgery. The capsule findings allowed a definitive diagnosis in 12 of the 31 cases: six patients accepted surgical treatment (one CD, two tumors, one ischemic enteritis, one abdominal cocoon, one duplication). Five patients (three CD, one intestinal tuberculosis, one intestinal diverticulum) were treated medically without surgery, and no recurrence of small bowel obstruction was found in these patients during follow-up.

DISCUSSION

CE is a novel diagnostic technique that has been used increasingly for analysis of many disorders of the small intestine, such as occult gastrointestinal bleeding, suspected CD, chronic diarrhea, and protein-losing enteropathy. Although small bowel obstruction has been considered a contraindication to CE, in our series, CE was documented to be very valuable and safe in identifying the etiology of small bowel obstruction, and it was also found to be easy to swallow, painless and well tolerated by these selected patients. CE findings allowed a definitive diagnosis in 12 (38.7%) out of the 31 cases, in which CD (4/31) was the major disease inducing stricture of the intestine. This cause was consistent with that in the study of Chiefetz and Lewis[5]. In contrast, some authors have reported that NSAID-induced stricture was the major cause of capsule retention[6,7]. Recently, Mason *et al*[8] have reported that intestinal mass or radiation enteritis are the main causes of subacute small bowel obstruction. The different causes of stricture may be associated with the indications of the patients.

The incidence of retention is closely related to the selected population. The incidence of retention varies from 0%-21% in the literature as a result of the different populations and indications for examination. The highest published rate (21%) was reported in the study of Chiefetz and Lewis[5], in which CD (2/19 cases) was also noted to be the major cause of retention. In another study with a total of 102 cases[9], the rate of retention was 13% (5/38) in patients with known CD, but only 1/64 cases with suspected CD had a retained capsule. The rate of capsule retention was very low in most studies, especially when the patients were selected without suspected small bowel obstruction or intestinal stricture. In the report of Barkin and Friedman[10], the incidence was 0.75% in a large study of 900 patients who had previously normal small intestines. Most recently, Li *et al*[7] have reported 14 cases of CE retention (1.4%) in 1000 capsule examinations. It was shown that tumors or NSAID strictures were the major etiology of retention in both of these studies. In our highly selected population, capsule retention occurred in 3 of 31 cases (two CD, one tumor).

Recently, dissolving patency capsules have been used in some studies to evaluate intestinal patency in patients with small bowel strictures, before video-CE (VCE). The patency capsule[11] is composed of lactose, remains intact in the gastrointestinal tract for 40-100 h post-ingestion, and disintegrates thereafter. Spada *et al*[12] have reported that 94% (30/34) of cases with small bowel stricture passed the intact or disintegrated capsule in the stools. Expulsion was confirmed in three cases by fluoroscopy, and the remaining patient withdrew consent to the study. In addition, VCE passed uneventfully through the small bowel stricture of all 10 patients who underwent VCE following patency capsule examination. The study of Spada *et al* has suggested that the patency capsule is a safe and effective tool for evaluation of functional patency of the small bowel, even when stricture has been indicated by traditional radiology. In another multicenter study[13], in all the 106 patients with strictures, no acute ileus was induced by Agile patency capsule. However, in the study of Bovin *et al*[14], in one of the 22 cases with suspected obstructive intestinal disease and/or radiological evidence of small-bowel strictures, impaction of an intact capsule led to ileus and emergency surgery. Similarly, in the study of Delvaux *et al*[15], of all 22 patients with known or suspected stenosis, the patency capsule induced a symptomatic intestinal occlusion in three patients, which was resolved spontaneously in one and required emergency surgery in two. It was shown that the start of dissolution at 40 h after ingestion was too late to prevent intestinal occlusion. Furthermore, the patency capsule can not detect stenosis and the etiology of small bowel obstruction.

Capsule retention has been defined as the presence of a capsule in the body for a minimum of 2 wk after ingestion, or when the capsule is retained in the bowel lumen indefinitely, unless targeted medical endoscopy or surgical intervention is initiated[16]. In our series, capsule retention occurred only in three cases, in which one of the capsules was spontaneously passed the stricture by medical treatment in 6 mo, and the other two retained capsules were retrieved at surgery. No acute small bowel obstruction occurred after administration of CE. The reported rate of acute abdomen induced by capsule is low. However, there is a controversy in the literature about the utility of capsule retention. In many studies, patients with a high risk of intestinal stricture were excluded for fear of capsule retention, which may have led to acute intestinal obstruction or surgical emergency. However, in most cases, capsule retention is symptomatic, although some patients accepted surgical therapy, which is safe and identifies or treats the underlying disease. Thus, some authors consider that capsule impaction is a valuable means of detecting significant stenosis that would benefit from

surgical management[5]. In addition, the retained capsule can be retrieved using double-balloon endoscopy[17,18]. Importantly, it is necessary to make the patients aware of the potential need for surgery before CE, although the risk for retention was low.

Based on our results, the most common etiology of small bowel obstruction was CD, followed by tumor. In our selected population, capsule retention was asymptomatic, which did not lead to surgical emergency. It is concluded that CE is a safe and effective tool for detecting etiology and stenosis of patients who have a history of small bowel obstruction, especially for the patients with suspected intestinal tumors or CD, which are not identified by routine examinations. Such results need future confirmation from prospective randomized studies.

COMMENTS

Background

Capsule endoscopy (CE) has been demonstrated to be superior to routine radiological examinations in the investigation of obscure gastrointestinal bleeding or suspected Crohn's disease (CD). Small bowel obstruction or strictures are considered to be a contraindication for CE in many centers. However, the accuracy of radiography in this situation has often been questioned.

Research frontiers

CE is now commonly performed for gastrointestinal bleeding of obscure origin or suspected CD. It is noted that the visualization of patients with suspected small bowel stenosis using traditional radiological methods is associated with high false-negative results and radiation doses. Recently, CE or patency capsule has been performed for suspected intestinal strictures in some studies, mainly for patients with known or suspected CD. However, reports about patients with subacute intestinal obstruction receiving CE are rare in the literature up till now.

Innovations and breakthroughs

At many centers, CE is considered to be contraindicated in suspected obstructive small bowel disease, for fear of capsule retention. In the present study, capsule retention occurred only in three cases (one of the capsules was spontaneously passed the stricture by medical treatment in 6 mo, the other two were retrieved at surgery), and no acute small bowel obstruction occurred after administration of CE. CE can be helpful in diagnosing subacute intestinal obstruction in patients with otherwise negative imaging studies, especially for patients with suspected intestinal tumors or CD.

Applications

CE is helpful in diagnosing subacute intestinal obstruction in patients with negative or uncertain imaging studies, which may become an appropriate indication for performing CE.

Terminology

Subacute small bowel obstruction is diagnosed in patients who present with symptoms consistent with small bowel obstruction, in whom abdominal X-ray shows incomplete intestinal obstruction. CE is a novel diagnostic technique that has been used increasingly for analysis of many disorders of the small intestine, such as occult gastrointestinal bleeding, suspected CD, chronic diarrhea, and protein-losing enteropathy.

Peer review

This paper describes CE in patients with small bowl obstruction. Although today the results of MRI of the intestine mostly offers the best chance of finding stenosis, CE is an interesting technique and should lead to a higher percentage of diagnosis.

Abstract

AIM: To investigate the effect of two-channel gastric electrical stimulation (GES) with trains of pulses on gastric emptying and slow waves.

METHODS: Seven dogs implanted with four pairs of electrodes and equipped with a duodenal cannula were involved in this study. Two experiments were performed. The first experiment included a series of sessions in the fasting state with trains of short or long pulses, each lasted 10 min. A 5-min recording without pacing was made between two sessions. The second experiment was performed in three sessions (control, single-channel GES, and two-channel GES). The stimulus was applied *via* the 1st pair of electrodes for single-channel GES (GES *via* one pair of electrodes located at 14 cm above the pylorus), and simultaneously *via* the 1st and 3rd channels for two-channel GES (GES *via* two pairs of electrodes located at 6 and 14 cm above the pylorus). Gastric liquid emptying was collected every 15 min *via* the cannula for 90 min.

RESULTS: GES with trains of pulses at a pulse width of 4 ms or higher was able to entrain gastric slow waves. Two-channel GES was about 50% more efficient than single-channel GES in entraining gastric slow waves. Two-channel but not single-channel GES with trains of pulses was capable of accelerating gastric emptying in healthy dogs. Compared with the control session, two-channel GES significantly increased gastric emptying of liquids at 15 min (79.0% ± 6.4% *vs* 61.3% ± 6.1%, $P < 0.01$), 30 min (83.2% ± 6.3 % *vs* 68.2% ± 6.9%, $P < 0.01$), 60 min (86.9% ± 5.5 % *vs* 74.1% ± 5.9%, $P < 0.01$), and 90 min (91.0% ± 3.4% *vs* 76.5% ± 5.9%, $P < 0.01$).

CONCLUSION: Two-channel GES with trains of pulses accelerates gastric emptying in healthy dogs and may have a therapeutic potential for the treatment of gastric motility disorders.

INTRODUCTION

Gastrointestinal functional or motor disorders are common, affecting 25% of the United State population[1,2] and 5%-10% of Asian population[3]. The patients often complain of a series of dyspeptic symptoms such as nausea and vomiting[4]. Gastric dysrhythmia has been observed in a variety of gastrointestinal motility disorders, including unexplained nausea and vomiting[4], gastroparesis[4,5], type II diabetes[2,5], early pregnancy[6], gastroesophageal reflux disease[7], after vagotomy and surgery[8] or after bone marrow or stem cell transplant[9]. In these circumstances, the frequency of gastric slow wave becomes either abnormally high (tachygastria) or low (bradygastria). Gastric emptying is delayed in

patients with gastroparesis and in about 30%-65% of patients with functional dyspepsia.

The commonly used medical therapy for gastroparesis is prokinetic agents, such as metoclopramide, cisapride, domperidom and erythromycin[10]. However, there are a considerable number of patients who are refractory to these medical therapeutic agents and side effects also limit their usage. While a number of studies have shown that some prokinetics have anti-dysrhythmic effects, but none of them has been developed for the normalization of gastric dysrhythmia[5,11].

Gastric electrical stimulation (GES) or pacing has been under investigation as a potential therapy for gastrointestinal motility disorders[12,13]. A number of studies have been performed to investigate the effect of gastric pacing, but the majority of them seem to indicate that gastric pacing is able to entrain gastric slow waves[14-20], accelerate gastric emptying in patients with gastroparesis[21,22] or in animal model of gastroparesis[18-20]. Three distinct methods have been used in GES, including long pulse stimulation, short pulse stimulation, and stimulation with trains of short or long pulses. In long-pulse stimulation, the pulse width is in the order of milli-seconds and the stimulation frequency is usually in the vicinity of the physiological frequency of gastric slow wave[23-25]. In short pulse stimulation, the pulse width is substantially shorter and is in the order of a few hundred micro-seconds. The stimulation frequency is usually a few times higher than the physiological frequency of gastric slow wave[12,26]. It has been reported that long-pulse stimulation can normalize gastric dysrhythmia, entrain the slow wave[13,17,25,27,28], accelerate gastric emptying in human beings and dogs, and short-pulse stimulation is effective against nausea and vomiting with no or little effect on gastric dysrhythmia, slow waves, or gastric emptying[18,26]. Trains of pulses are composed of a repetitious train of pulses and are derived from the combination of two signals: a continuous signal with a high frequency (in the order of 5-100 Hz) and a control signal to turn the pulses on and off, such as x seconds "on" and y seconds "off". This kind of stimulation has been frequently used in electroacupuncture[29]. Most previous studies were performed using long- or short-pulse GES in patients and in animal model of gastroparesis. Commercially available implantable stimulators are capable of generating short pulses or trains of pulses but not long pulses that are technically difficult to produce. That is, long pulse GES is practically not feasible or much less feasible than GES of pulse trains and has to be replaced by GES with trains of pulses. Accordingly, it is important to study whether the GES with trains of pulses is able to mimic the functions of long pulse GES. However, to the best of our knowledge, few studies have investigated the effect of GES with trains of pulses on gastric motility, such as gastric slow waves and gastric emptying.

This study was to investigate the effect of GES with trains of pulses on gastric slow waves and gastric emptying in health dogs.

MATERIALS AND METHODS

Animal preparation

Seven healthy female beagle dogs, weighing 14-21 kg, were used in this study. After an overnight fasting, the dogs were anesthetized with 2% sodium thiopental (0.6 mL/kg, intravenous) and underwent abdominal surgery. Their tongue color, pulse rate and breath rate were monitored. Four pairs of stainless steel cardiac pacing wires were implanted on the serosal surface of stomach in an arching line along the greater curvature. The most distal pair was placed 2 cm above the pylorus, and the distance between adjacent pairs of electrodes was 4 cm. The bipolar electrodes in each pair were 0.5 cm apart. The electrodes were affixed to the gastric serosa with an unabsorbable suture in the seromuscular layer of stomach. The wires were brought out through the anterior abdominal wall, channeled subcutaneously along the left side of the trunk, and placed outside the skin for pacing or recording gastric myoelectric activity. Each dog was equipped with a duodenal cannula 20 cm beyond the pylorus for the assessment of gastric liquid emptying. The study was initiated after the dogs were completely recovered from surgery, usually 2 wk after surgery. The Animal Care and Use Committee of the Union Hospital of Tongji Medical College approved the surgical and experimental protocols.

Experimental protocol

The study was composed of two experiments using the following protocols. Experiment 1 was designed to assess the optimal stimulation parameters (lowest stimulation energy) to entrain gastric slow waves in the dogs. The dogs were fasted overnight and received no medication before the study. A 30-min baseline recording was made *via* all electrodes in the stomach. Then, an adjustable multi-channel electrical stimulator (model A300, World Precisio Instruments, Sarasota, Florida) was used for stimulation in a constant current mode, and the stimulus consisted of periodic trains of bipolar pulses with adjustable pulse widths. In order to get effective pacing parameters for the entrainment, a series of sessions with various pacing parameters were performed in the fasting state, 10 min each session. A 5-min recording without pacing was made between two consecutive pacing sessions. The pulse width was gradually increased (0.3 ms, 0.5 ms, 0.7 ms, 0.9 ms, 1 ms, 2 ms, 3 ms, 4 ms …) until entrainment of gastric slow waves was achieved. Other parameters for GES were fixed. The stimulus was delivered *via* the 1st channel for single-channel GES (a train on-time of 3 s and off time of 8 s, a pulse frequency of 30 Hz, an amplitude of 5 mA) or *via* both the 1st and 3rd channels for two-channel (channel one: 3 s-on and 8 s-off, 30 Hz, 2 mA; channel three: the same as channel one except for pulse amplitude of 1.6 mA). With this setting, the frequency of pulse train was about 5.5 trains/min, which is similar to the physiological frequency of gastric slow wave. Time delays among different channels were determined

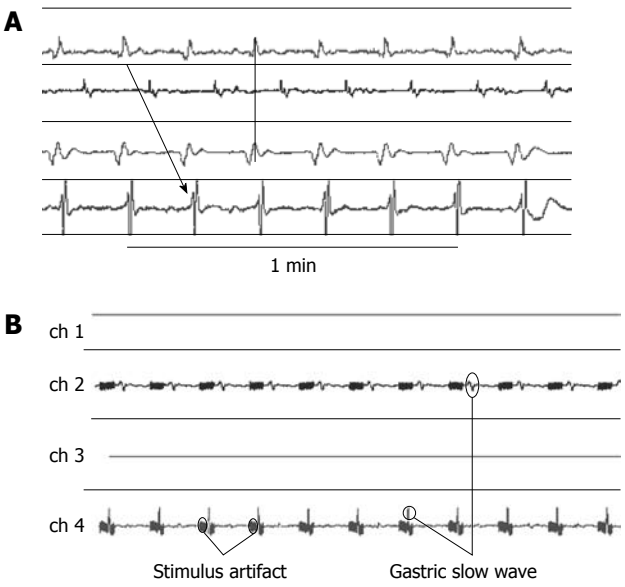

Figure 1 Gastric slow waves at the baseline and with two-channel GES (A), and recordings of gastric slow waves at baseline during 2-channel GES *via* the first and third channels (B).

based on the propagation speed of intrinsic gastric slow waves during the baseline recording. The peak of slow waves occurred simultaneously at the 1st and 3rd channels (a phase shift of 360 degree). Accordingly, stimulation applied in these two channels was synchronic or simultaneous (Figure 1).

Experiment 2 was to investigate the effect of two-channel GES with trains of pulses on gastric emptying. The stimulation parameters were determined as in experiment 1. The study was performed in three sessions (control, single-channel GES, two-channel GES) on three separate days (at least 3 d apart) in a randomized order. Each session consisted of four consecutive 30-min periods of gastric slow wave recordings. During each study session, the dogs were fed with a liquid meal composed of 43 g Nutrison (Nutricia, Holland) and 100 mg phenol red mixed with 100 mL water, immediately after a 30-min baseline recording in the fasting state (the dogs were fasted for 12 h or more). The total volume was 237 mL with a total energy of 250 kcal (6 g fat, 40 g carbohydrate, and 9 g protein). The emptied chyme containing gastric secretion and the ingested liquid meal were collected every 15 min *via* the intestinal cannula for 90 min. The collected volume and the amount of phenol red in each collection were used for the assessment of gastric emptying. Session two was the same as session one, except that GES was performed *via* the 1st channel during the entire postprandial period (Figure 2) with a train on-time of 3 s and off time of 8 s, a pulse frequency of 30 Hz, an amplitude of 5 mA, and width of 4 ms (the optimal pulse width obtained from experiment 1). Session three was the same as session two, except that GES was performed *via* channels one and three (pulse amplitude of 2 mA for channel one and 1.6 mA for channel three). The reduced pulse amplitude in the distal (channel three) stimulation channel was designed to avoid retrograde propagation of stimulation.

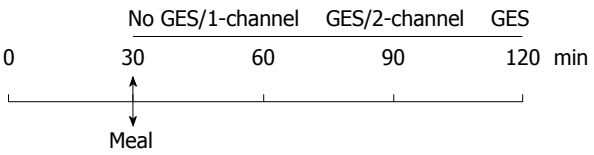

Figure 2 Experiment protocol.

Recording and assessment of gastric slow waves

A multi-channel recorder (AcqknowledgeIII, EOG 100A, Biopac System, Inc. Santa Barbara, CA) was used to record gastric slow waves *via* the serosal electrodes during the entire study. All signals were displayed on a computer monitor and saved on the hard disk with an IBM-compatible 486PC. The low and high cutoff frequencies of the amplifier were 0.05 and 35 Hz, respectively. The most distal recording was used to identify whether gastric slow waves are entrained with GES. Complete entrainment was defined as the frequency of gastric slow waves that was the same as the pacing frequency and phase-locked with the pacing stimulus. The percentage of entrainment of gastric slow waves was defined as the ratio of difference between the recorded slow wave frequency during pacing (f) and the intrinsic frequency before pacing (fi), and the difference between the pacing frequency (fp) and the intrinsic frequency before pacing. It was represented as % of entrainment = (f - fi)/(fp - fi)[28].

Gastric emptying

The test liquid meal contained 100 mg of phenol red as a marker, and gastric emptying was determined by assessment of the amount of phenol red in each collection of gastric effluent as previously described[19]. During the study, the volume of each collection was recorded and a sample of 5 mL was taken and stored in a freezer. At the end of study, these samples were analyzed using a spectrophotometer to detect the amount of phenol red in each sample. Gastric emptying was assessed by calculating the amount of phenol red recovered from each collection of gastric effluent.

Statistical analysis

Results were reported as mean ± SE. The analysis of variance (ANOVA) was used to assess the difference in three sessions of gastric emptying. Paired Student *t* test was used to investigate the differences in gastric emptying between the stimulation and control sessions. $P < 0.05$ was considered statistically significant.

RESULTS

Effect of GES with trains of pulses on gastric slow waves

Gastric slow waves were entrained in each dog with single-channel or two-channel GES using trains of pulses with a greater pulse width. The relation between the entrainment of slow waves and stimulation pulse width is presented in Figure 3. The percentage of entrainment of gastric slow waves with single- or two-channel GES

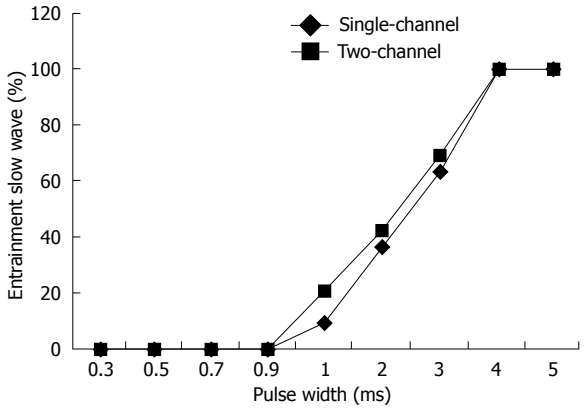

Figure 3 Percentage of slow wave entrainment with GES as a function of stimulation pulse width.

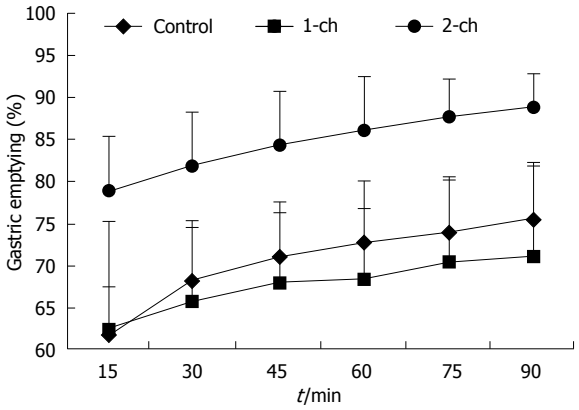

Figure 4 Gastric emptying in the control sessions and sessions with single-channel or two-channel GES. $P < 0.01$ (2-ch *vs* control).

was 7.75% ± 1.62% or 19.25% ± 9.04% at 1 ms, 36.62% ± 5.75% or 42.82% ± 5.45% at 2 ms, 62.34% ± 7.38% or 67.75% ± 9.80% at 3 ms and 100% ± 0% or 100% ± 0% at 4 ms, respectively. A complete entrainment was achieved with GES with a pulse width of 4 ms or greater. Some typical recordings at the baseline and during GES are shown in Figure 1. The entrainment of gastric slow waves usually occurred a few minutes after gastric pacing as demonstrated by the fact that the slow waves were phase-locked with the pacing stimulus a few minutes after the initiation of pacing.

To compare the stimulation energy required to completely entrain the gastric slow waves, the following formula was used for the calculation of stimulation energy (E): E = (cycles/min) × (frequency) × (pulse width) × (amplitude)^2. Accordingly, the minimum energy required by single-channel GES was 16 500 ms × mA^2, whereas that for the two-channel GES was 8421.6 ms × mA^2, which represents about 51.04% of the energy required by single-channel GES or a saving of 48.96% of energy.

Effect of GES with trains of pulses on gastric emptying

Two-channel GES with trains of long pulses (pulse width: 4 ms) could accelerate gastric emptying in the healthy dogs ($P < 0.01$, ANOVA) (Figure 4). Compared with the control session, two-channel GES significantly increased gastric emptying of liquids at 15 min (79.0% ± 6.4% *vs* 61.3% ± 6.1%, $P = 0.001$), 30 min (83.2% ± 6.3 % *vs* 68.2% ± 6.9%, $P = 0.005$), 60 min (86.9% ± 5.5% *vs* 74.1% ± 5.9%, $P = 0.010$), and 90 min (91.0% ± 3.4% *vs* 76.5% ± 5.9%, $P < 0.0037$), respectively, after feeding. However, no significant difference was noted in gastric emptying between single-channel GES and control sessions.

DISCUSSION

In the present study, GES with trains of wider pulses (width ⩾ 4 ms) but not short pulse could entrain gastric slow waves. Two-channel GES but not single-channel GES, significantly accelerated gastric emptying of liquids in healthy dogs.

Most previous studies showed that long pulse GES can entrain gastric slow waves in human beings and animals[19,20,22-25,27]. None of these studies has investigated the effect of GES with trains of pulses on gastric slow waves. It has been shown that GES with trains of short pulses can improve symptoms, such as nausea and vomiting of patients with gastroparesis[24,26], but cannot entrain gastric slow waves or normalize gastric dysrhythmia. In this study, GES with trains of pulses entrained gastric slow waves as long as the width of pulses in the train was 4 ms or greater. The energy required to completely entrain gastric slow waves with two-channel GES was less than that with single-channel GES, which might be due to the fact that each stimulation was responsible for entraining slow waves in a smaller region (about 50%) of the stomach with two-channel GES, compared with single-channel GES.

Conventionally, long-pulse GES is performed using a single pair of electrodes or single-channel GES. It has been reported that single-channel GES with long pulses accelerates gastric emptying in patients with gastroparesis[22] and in animal models of gastroparesis[30], and has no effect on gastric emptying in healthy dogs[18,19,30]. Recent studies on the effect of multi-channel GES on gastric emptying and entrainment of slow waves indicate that multi-channel stimulation with long pulses is more efficient than single-channel stimulation for the entrainment of slow waves, and can accelerate gastric emptying[18-20,31]. It has been shown that four-channel long pulse GES can accelerate gastric emptying in healthy dogs[18], whereas two-channel long pulse GES can normalize vasopressin-induced delayed gastric emptying in dogs[19]. To date, no study is available on the effect of multi-channel GES with trains of pulses on gastric emptying. In the present study, we used single-channel (14 cm above the pylorus) and two-channel (6 and 14 cm above the pylorus) GES to investigate their effect on gastric emptying. Compared with the control session, two-channel but not single-channel GES with trains of pulses significantly accelerated gastric emptying, which is consistent with the previous findings.

It is well known that gastric emptying of liquid and solid occurs separately, involving different areas

of stomach. It is believed that the antrum undergoes orderly peristaltic contractions and acts as a pump, while the proximal segment functions as a reservoir[32]. Gastric emptying demands accommodated motion of the proximal and distal stomach. The motility of stomach follows an orderly pattern in which gastric peristaltic contractions are phase-locked with gastric pacesetter potentials, which sweep distally from the corpus toward the pylorus. It is also known that gastric contractions are controlled by gastric slow waves. Multi-channel GES more accurately mimics the natural propagation and characteristics of gastric slow waves[18,30], thus controlling gastric contractions more effectively.

In this study, two-channel GES with trains of pulses entrained gastric slow waves and accelerated gastric emptying in healthy dogs, suggesting that two-channel GES with trains of pulses might be applicable in treatment of gastroparesis and normalization of gastric dysrhythmia. Technically, it is more feasible to make an implantable stimulator using trains of pulses than using repetitive long pulses due to the current charge balance. Accordingly, GES with trains of pulses is technically more attractive than long pulse GES. Currently, most commercially available implantable stimulators use trains of pulses. However, none of them is able to generate pulses with a width of 4 ms or greater. Therefore, new hardware design and development are needed before two-channel GES with trains of pulses can be used in clinical practice.

In conclusion, entrainment of gastric slow waves is feasible using GES with trains of pulses at a pulse width of 4 ms or greater. Two-channel GES with trains of pulses can accelerate gastric emptying in healthy dogs and may have a therapeutic potential for the treatment of gastric motility disorders.

COMMENTS

Background

Gastric dysrhythmia and delayed gastric emptying have been observed in a variety of gastric motility disorders. Treatment options for such disorders include medical therapy, surgical therapy, and nutritional support.

Research frontiers

Gastric electrical stimulation (GES) or pacing has been under investigation as a potential therapy for gastrointestinal motility disorders. However, few studies are available on the effect of two-channel GES with trains of pulses on gastric slow waves and gastric emptying.

Innovations and breakthroughs

In this study, the authors used single-channel (14 cm above the pylorus) and two-channel (6 and 14 cm above the pylorus) GES to investigate their effect on gastric emptying. Compared with the control session, two-channel but not single-channel GES with trains of pulses significantly accelerated gastric emptying, which is consistent with the previous findings.

Applications

Two-channel GES could entrain gastric slow waves and accelerate gastric emptying in healthy dogs, suggesting that two-channel GES with trains of pulses can be used in treatment of gastroparesis and normalization of gastric dysrhythmia.

Terminology

GES with trains of pulses, composed of a repetitious train of pulses, is derived from the combination of a continuous pulse singal with a high frequency (in the order of 5-100 Hz) and a control signal to turn the pulses on and off, such as x seconds "on" and y seconds "off". This kind of stimulation has been used in electroacupuncture.

Peer review

The authors have demonstrated that entrainment of gastric slow waves is feasible with GES of trains of pulses at a pulse width of 4 ms or greater and two-channel GES with trains of pulses can accelerate gastric emptying in healthy dogs, thus having a therapeutic potential for the treatment of gastric motility disorders.

Abstract

Hereditary fructose intolerance (HFI) is an under-recognized, preventable life-threatening condition. It is an autosomal recessive disorder with subnormal activity of aldolase B in the liver, kidney and small bowel. Symptoms are present only after the ingestion of fructose, which leads to brisk hypoglycemia, and an individual with continued ingestion will exhibit vomiting, abdominal pain, failure to thrive, and renal and liver failure. A diagnosis of HFI was made in a 50-year-old woman on the basis of medical history, response to IV fructose intolerance test, demonstration of aldolase B activity reduction in duodenal biopsy, and molecular analysis of leukocyte DNA by PCR showed homozygosity for two doses of mutant gene. HFI may remain undiagnosed until adult life and may lead to disastrous complications following inadvertent fructose or sorbitol infusion. Several lethal episodes of HFI following sorbitol and fructose infusion have been reported. The diagnosis can only be suspected by taking a careful dietary history, and this can present serious complications.

INTRODUCTION

Hereditary fructose intolerance (HFI) is an autosomal recessive inborn error of metabolism that results from a deficiency of fructose 1-phosphate aldolase in the liver, intestine and kidney.

The estimated incidence is 1 in 20 000 live births[1] and the carrier frequency is 1 in 70, but the prevalence of HFI in adults is unknown. The clinical symptoms were first described by Chambers and Pratt in 1956[2].

Affected individuals fail to metabolize fructose completely in the liver, intestine and kidneys because of deficiency of fructose 1-phosphate aldolase and ingestion of fructose, sorbitol or sucrose causes abdominal pain, vomiting and symptomatic hypoglycemia. The syndrome typically appears in the newborn at the time of weaning from the breast when food containing sucrose or fructose is given. Continued ingestion results in poor feeding, growth retardation, gradual liver and kidney failure acidosis, and eventually death[3]. Affected children soon develop an aversion to all foods and protect themselves by self-imposed fructose and sucrose restriction.

The strict dietary exclusion leads to normal growth and longevity. Nevertheless, complete elimination of this sugar from the diet is difficult to achieve, especially for undiagnosed adults, without professional advice. These people may suffer symptoms throughout life and represent a diagnostic challenge for attending physicians. Furthermore, potentially lethal complications may result from inadvertent infusion of fructose- or sorbitol-containing solutions in a hospital setting[4,5].

CASE REPORT

A 50-year-old German woman presented with a long life history of aversion to sugary foods. She reported being breast fed until the age of 2 years, and her mother said that she refused the usual sucrose-containing formulas. She described nausea, vomiting, diffuse abdominal pain and hypoglycemic symptoms even after the smallest amount of sugar or fruit. Her 2-year-old brother died after receiving an intravenous infusion in hospital, while her parents and three siblings are asymptomatic. She takes no regular medications. On examination, she

Table 1 FTT using 250 mg/kg body weight showing glucose, phosphate, uric acid and magnesium levels in the blood following injection of fructose

Time (min)	Glucose (mg/dL)	Phosphate (mmol/L)	Uric acid (mg/dL)	Magnesium (mmol/L)
0	87	1.000	5.1	0.72
15	67	0.77	6.74	0.84
30	61	0.64	7.74	0.8
45	60	0.80	7.58	0.88
60	68	0.83	7.58	0.91

had mild thoracic scoliosis with no neurological defect. Otherwise, physical examination was unremarkable.

Results of laboratory investigations including full blood count, urea, creatinine, electrolytes, full biochemical profile, amylase lipase and lipid studies, liver function tests and insulin level were within normal ranges. A fructose tolerance test (FTT) using 250 mg fructose per kilogram body weight was performed. At 0, 15, 30, 45 and 60 min after fructose injection, blood samples were taken for analysis of glucose, phosphate, uric acid and magnesium. A typical abnormal FTT was observed after the infusion, i.e. a drop in serum glucose and serum phosphate and rise in serum uric acid and magnesium concentration occurred (Table 1).

Thirty minutes after fructose injection, she developed significant dizziness, sweating, tremor and abdominal pain that were closely observed, and by 60 min her symptoms improved. The diagnosis was further confirmed by histochemical analysis of an endoscopic biopsy specimen from the small intestine, which showed 70% reduction in aldolase B activity in the mucosa, and molecular analysis of leukocyte DNA extracted from a blood sample using PCR amplification revealed that she had inherited two doses of the mutant gene, one from each parent, as the cause of the disease.

DISCUSSION
