The concordance probability estimates (CPE) were computed[14], because the c-statistic seems to overestimate the true concordance probability, especially if the censoring proportion is high. Since the CPE is a consistent estimate, it is a better measure in the context of using predictions from Cox regression models.

Calibration and external validation of the new risk score

To assess model calibration (or how closely the predicted

probabilities reflect actual risk), the Hosmer-Lemeshow calibration statistic, as modified by D'Agostino *et al*[15], comparing observed and predicted risk was implemented.

In addition, the new risk model was validated in a cohort of 85 independent patients from "Calixto Garcia" Hospital who were stratified into 2 risk (R) groups: R $\leqslant$ 8 and R > 8. Within each risk group the survival was calculated using the Kaplan-Meier procedure and the observed-predicted survivals were compared using the log-rank test.

Analyses were performed with the use of SAS software, version 9.1 (SAS Institute).

RESULTS

A total of 180 patients were examined for eligibility, and 172 were included in the study. The reasons for non-participation were: 3 patients with HCC, 3 with repeated alcohol use, and 2 with severe infection disease. The period of recruitment lasted from May 2003 to February 2004. One hundred and forty one patients completed the follow-up period. Thirty one patients died during the study, 29 liver-related and 2 unrelated to liver disease (myocardial infarction). One hundred and seventy patients were included in the outcome analyses.

The patients' clinical and serological features are summarized in Table 1.

In the derivation data set, the median follow-up period was 56 wk (range, 4-104 wk). The CP median score was 7 (range, 5-14) with 61% of the patients being CP class B and C. The MELD and BioCliM median scores were 17 (range, 8-42) and 7.7 (range, 5.7-13.6), respectively. During follow-up, 29 patients (17%) died. The 4-, 12-, 24-, 52- and 104-wk survival rates were 98%, 98%, 90%, 89% and 83%, respectively.

The patients of the validation group were followed for a median of 58 wk (range, 8–104 wk) during which 13 died. The 4-, 12-, 24-, 52- and 104-wk survival rates were 96%, 95%, 88%, 84% and 83%, respectively. The CP median score was 7 (range, 5-14) with 65% of the patients being CP class B and C. The MELD and BioCliM median scores were 18 (range, 9-43) and 7.9 (range, 6-13.8), respectively.

None of the patients in the derivation or validation groups underwent liver transplantation during the follow-up period.

Overall survival according to single prognostic factors

Univariate analysis for 104-wk overall survival: Univariate analysis using Cox proportional hazards models showed that serum levels of creatinine, bilirubin, cholesterol, albumin, prothrombin time, partial thromboplastin time, ascites, spontaneous bacterial peritonitis, encephalopathy and bleeding esophageal varices were significantly associated with survival (Table 2).

Multivariate analysis for 104-wk overall survival: Multivariate Cox regression analysis included those variables independently related to survival resulting from univariate analysis. The selected variables were available in all patients that entered the forward stepwise model. Of the candidate variables, only ascites, encephalopathy, bleeding esophageal varices and serum creatinine were independently predictive of survival (Table 3).

Table 2 Association of baseline characteristics with mortality in 170 cirrhotic patients, results from univariate Cox proportional hazards models

Variables	*P*	Hazard ratio	95% CI for Hazard ratio
Age (yr)	0.68	0.56	0.36-1.06
Sex (male)	0.54	0.44	0.89-1.26
Etiology (viral)	0.66	0.58	0.40-1.11
ALT (IU/L) ($\log_n$ value)	0.85	0.84	0.34-1.12
AST (IU/L) ($\log_n$ value)	0.43	0.90	0.56-1.34
ALT/AST ratio	0.64	0.87	0.50-1.21
Platelet count ($\times 10^9$/L) ($\log_n$ value)	0.54	0.89	0.52-1.30
Prothrombin time (s)[1] ($\log_n$ value)	0.01	2.23	1.24-4.89
INR for prothrombin time ($\log_n$ value)	0.03	1.99	1.13-3.96
Partial thromboplastin time (s)[2] ($\log_n$ value)	0.04	1.78	1.10-3.23
Albumin (mg/dL) ($\log_n$ value)	0.001	3.12	1.89-5.23
Bilirubin (mmol/L) ($\log_n$ value)	< 0.001	3.89	2.12-6.14
Creatinine (mmol/L) ($\log_n$ value)	< 0.001	3.95	2.18-6.56
Cholesterol (mmol/L) ($\log_e$ value)	0.03	1.83	1.34-3,42
Ascites	< 0.001	4.05	2.27-6.33
Spontaneous bacterial peritonitis	0.001	3.05	2.10-5.07
Encephalopathy	< 0.001	4.50	2.90-6.50
Bleeding esophageal varices	< 0.001	4.78	3.11-7.11

CI: Confidence interval; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase. Hazard ratios (95% CI) for quantitative variables are expressed for 1 relevant unit increase of log. INR: International normalized ratio. [1]Prothrombin time (s): Value in seconds. [2]Partial thromboplastin time (s): Value in seconds.

The estimated hazard risk for ascites suggested that the risk of death for uncontrolled ascites was 10.2 times greater than for those with absent or controlled ascites. The risk of death in those patients with relapsing bleeding and uncontrolled encephalopathy increased 3.25 times compared to those without bleeding or with non-relapsing bleeding, and 2.5 times compared to those with absent or controlled encephalopathy. In terms of impact in prognosis, the ascites (hazard ratio (HR), 10.2) and serum creatinine (HR, 3.99) were the most important prognostic factors.

Model derivation and development

In the model derivation cohort, 11 potential variables selected from the univariate analysis ($P < 0.05$) were calculated for model inclusion. Of these only 5 were included in the model. The likelihood ratio statistic showed the significance of the addition of each variable separately to a predictive model that included ascites only (Table 3). The χ^2 statistic was progressively increased with the addition of creatinine, bleeding esophageal varices, hepatic encephalopathy, and bilirubin. The c-statistic in the model that included only ascites was 0.76, based on the c-statistic for censored data. When creatinine, BEV, HE and bilirubin were added to the model, the c-statistic was improved to 0.83, 0.85, 0.89, and 0.90, respectively. In the same context,

Table 3 Contributions of different variables to survival prediction at 104 wk, results from multivariate Cox regression models[1]

Variable	Variable χ^2	Regression coefficient	Hazard ratio	95% CI for Hazard ratio		*P* value	c-statistic	BIC
Ascites	53.90	2.310	10.2	3.78	28.1	< 0.0001	0.76	2014.15
+ Ln (creatinine)	63.43	1.370	3.99	1.57	10.9	0.006	0.83	1988.15
+ BEV	65.71	1.195	3.25	1.01	9.77	0.048	0.85	1970.65
+ HE	68.91	0.909	2.50	0.915	6.88	0.070	0.89	1961.89
+ Ln (bilirubin)[2]	70.11	0.349	1.46	0.66	3.33	0.427	0.90	1951.77

[1]Estimated from Cox proportional hazards models. [2]Biochemical (bilirubin and creatinine) and Clinical (ascites, encephalopathy and bleeding esophageal varices) Model; BEV: Bleeding esophageal varices; HE: Hepatic encephalopathy; BIC: Bayesian Information Criterion. Ln was used to normalize distributions and improve the fit for individual predictors. Hazard ratio for quantitative variables are expressed for 1 relevant unit increase of log. + indicates the addition of each variable separately to the model with ascites only. χ^2 is the likelihood ratio statistic for each group of variables when added to the model. The risk prediction was based on data from the model derivation cohort (n = 170) at 104 wk follow-up.

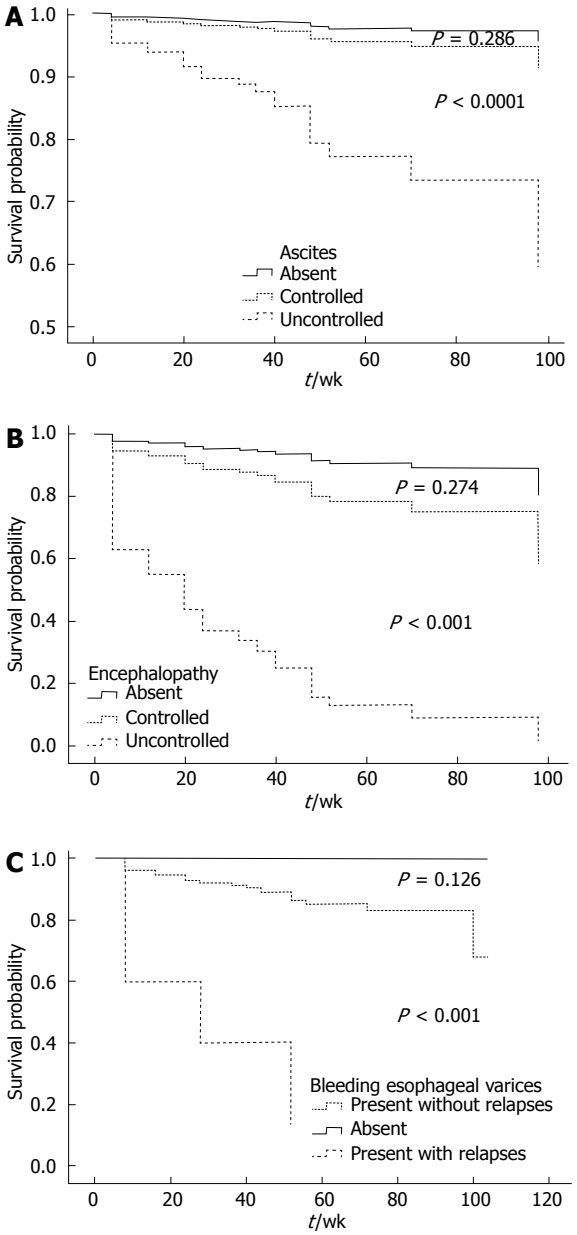

Figure 1 Kaplan-Meier estimated survival curves for clinical variables. A: Ascites; B: Encephalopathy; C: Bleeding esophageal varices.

the combination of ascites, creatinine, BEV, HE and bilirubin revealed the smallest BIC value (1951.77), thus, in the derivation set, the model with the combination of clinical and biochemical variables appeared to improve the risk prediction.

Computational formula for 104-wk risk using best-fitting model

The regression coefficients of the formula for calculating the new risk score (biochemical and clinical model) were selected from a Cox regression model[16] and are reported in Table 3.

The risk scores for individual patients were calculated using the following equation: [1.370 × $\log_e$ (creatinine mmol/L) + 0.349 × $\log_e$ (bilirubin mmol/L) + 2.310 × (ascites: 0 if absent or medically controlled and 1 if uncontrolled) + 0.909 × (encephalopathy: 0 if absent or medically controlled and 1 if uncontrolled) + 1.195 × (bleeding esophageal varices: 0 if absent or present without relapses and 1 if present with relapses). The clinical variables were coded depending on the clinical response to medical treatment. The variables grouped together as "absent or medically controlled" (ascites and encephalopathy) and "absent or present without relapses" (bleeding esophageal varices) have been so grouped because their survival was similar in each one of them (Figure 1). The missing values were imputed for survival modeling.

Survival probabilities were derived from the Cox proportional hazards model: $S(t) = S_0(t)^{\exp(R-R_o)}$. S(t) is the survival probability in wk, $S_0(t)$ the baseline survival function, R the individual risk score and R_0 the risk score of the average patient in the series. For example, the 12-wk survival probability is calculated as: $S_{(12\ wk)} = 0.981^{\exp(BioCliM\ score-7)}$, where 0.981 is the 12-wk baseline survival and 7 is the reference BioCliM score. To ease its use, the score was multiplied by 100.

Predictive models for 12-, 52- and 104-wk survival

Comparison of the c-statistic values among the CP, MELD and BioCliM scores was performed. All scoring systems were found to have diagnostic accuracy in predicting survival. The BioCliM score, however, showed to have better discriminative power in predicting short- (12 wk), intermediate- (52 wk) and long-term survival (104 wk) than the rest of the scores (Figure 2).

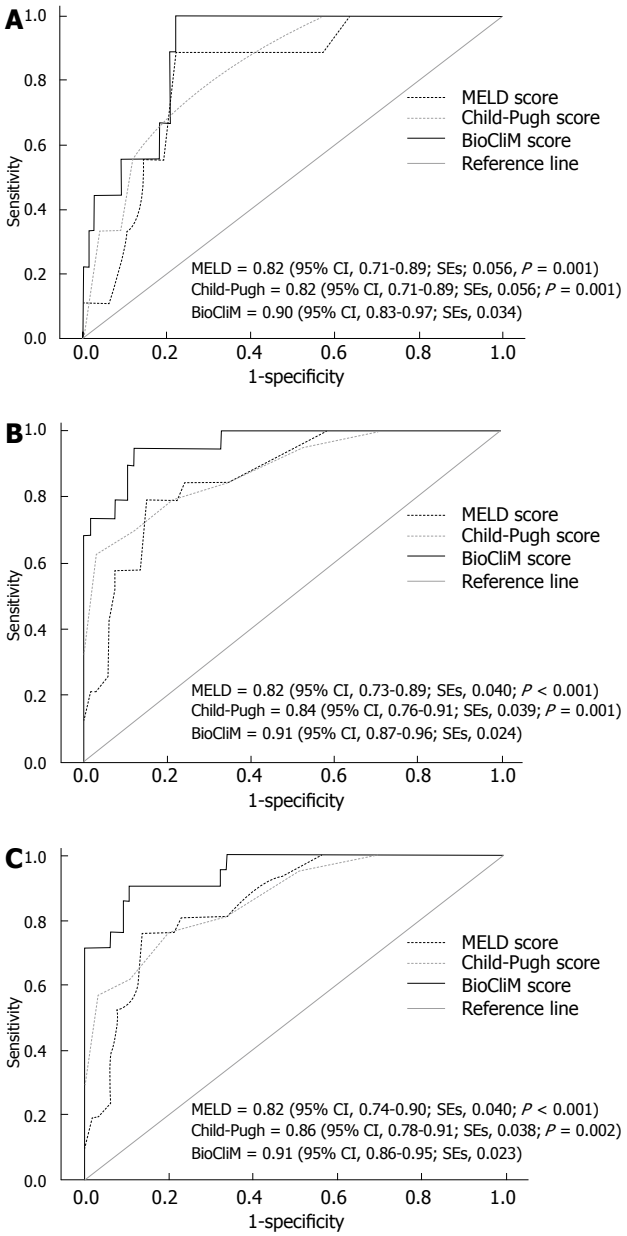

Figure 2 Comparison of the c-index values of the MELD, Child-Pugh and BioCliM scores for 12- (A), 52- (B) and 104-wk (C) survival. SE indicates standard errors. The different values were compared with BioCliM score using the bootstrap method.

The c-statistic for the CP and MELD scores were almost identical for 12-wk survival (0.82 and 0.82), and slightly higher for CP as compared with MELD for 52-wk (0.84 and 0.82) and 104-wk (0.86 and 0.82) survival.

We used an alternative way of computing the concordance probability for a censored outcome to estimate the true concordance probability in samples with a high censored proportion. The concordance probability estimates for the CP (CPE, 0.71; SE, 0.042), MELD (CPE, 0.74; SE, 0.043) and BioCliM (CPE, 0.78; SE, 0.050) models were lower at 12 wk in comparison with those obtained using the standard c-statistic value. Finally, the CPE at 12 wk was consistently higher for BioCliM as compared with CP and MELD scores.

Discrimination and model validation

The Hosmer-Lemeshow statistic (H-L) is a measure of the discrepancy between the observed and predicted risk. A better calibrated model would have a smaller discrepancy between the observed and predicted and thus a smaller H-L statistic.

A significant *P* value for the H-L statistic indicates a significant deviation between predicted and observed outcomes. Figure 3 compares the calibration of the BioCliM, MELD and CP scores in predicting the probability of death at 104 wk. The H-L statistic was 4.69 for the BioCliM score, 17.06 for the MELD score and 14.23 for the CP score, indicating a good calibration for all models; however, this analysis clearly shows that BioCliM is better calibrated.

Figure 4 illustrates the observed and expected Kaplan-Meier survival curves for each score in 2 patient subgroups divided according to risk score as low risk (R $\leqslant$ 8) and high risk (R > 8), selected from the "Calixto Garcia" Hospital. Using a cutoff value of 8 (risk score) to predict probability of survival within 104 wk, the sensitivity and specificity of the BioCliM score was 90% and 87%, respectively. Median survival was 104 wk and 47 wk for low- and high-risk groups, respectively. There were no significant differences between the observed and expected survival curves in the stratified risk groups (low risk, $P = 0.61$; high risk, $P = 0.77$). Thus, the BioCliM score allowed accurate prediction of survival in the cirrhotic patient validation group.

Survival according to the BioCliM score

The differences in the short-, intermediate- and long-term survival between patients with low risk ($\leqslant$ 8), and high risk (> 8) scores were compared (Figure 5).

Overall survival rates were significantly different between low-risk and high-risk patients ($P < 0.0001$). The 12-wk survival rates were 98% and 64% for low and high risk, respectively. For low and high risk, 1-year survival rates were 97% and 3%, and 2-year survival rates were 95% and 0%, respectively. Patients with a high risk score had the highest risk of mortality compared to patients with low values. Patients with a BioCliM score of $\geqslant$ 8 had a median survival of < 47 wk in comparison to patients with a median survival of 104 wk for patients with a BioCliM score of < 8.

DISCUSSION

The most widely used prognostic model to predict survival in cirrhotic patients has been the CP score. It is an important tool for the prognostic evaluation of cirrhotic patients and the current organ allocation policy. It has, however, several drawbacks such as the subjectivity of clinical parameters, limited discriminative capability and variability in the measurements of laboratory parameters[17,18]. Current CP score modifications by adding new variables or utilizing sophisticated measures did not improve its accuracy to predict survival[19-25]. A relatively new score, the MELD,

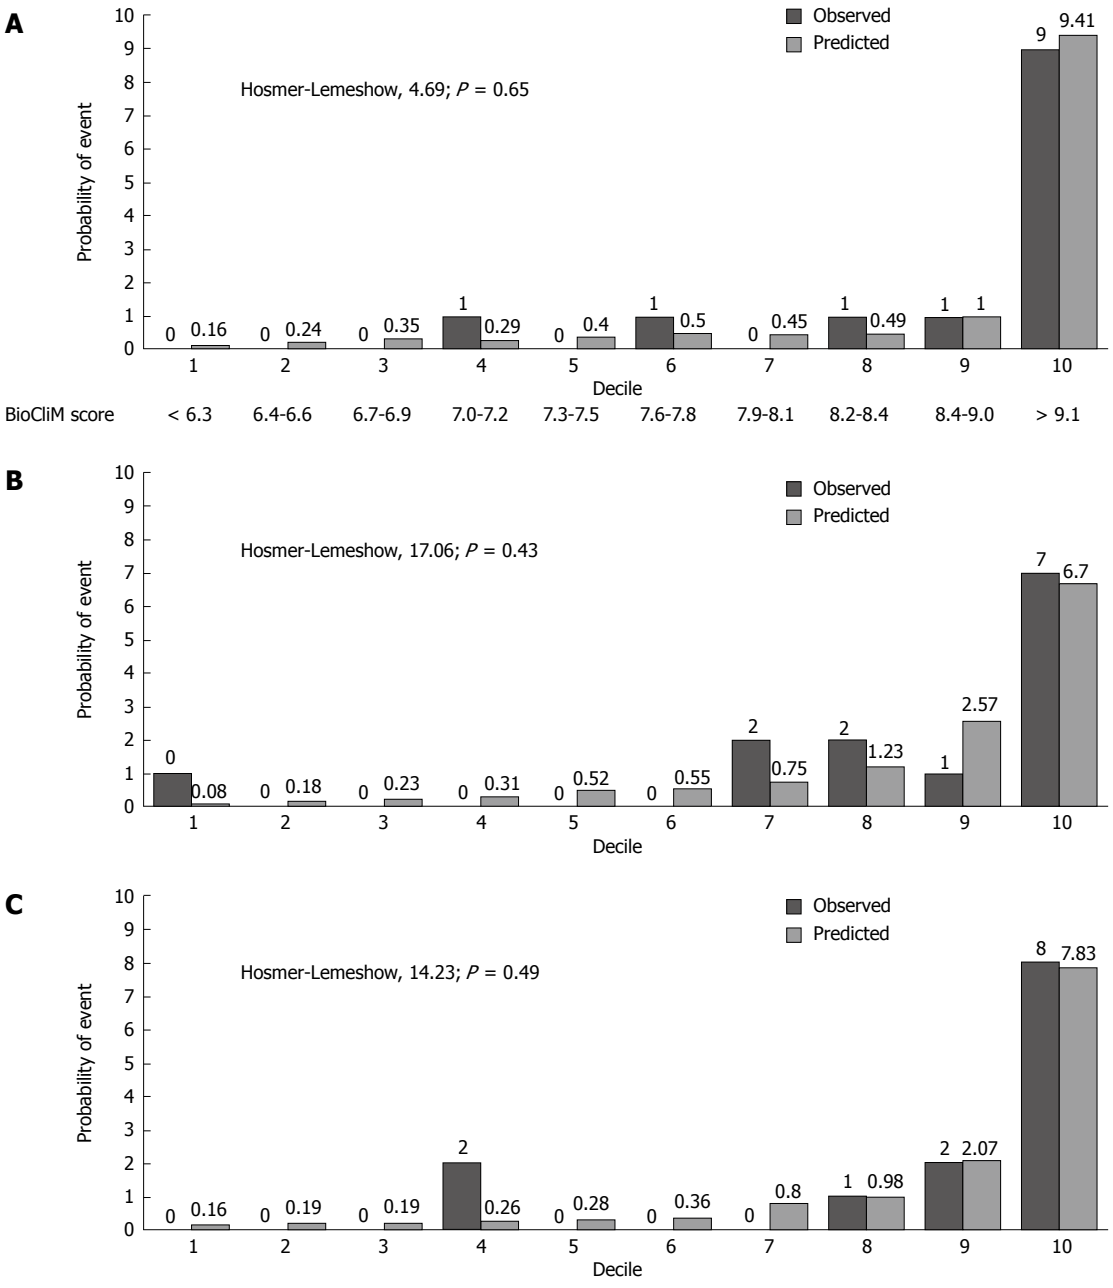

Figure 3 Observed and predicted probability of events at 104 wk. A, B and C shows the observed and predicted probability of death according to BioCliM, MELD and Child-Pugh scores in 10 groups (deciles) of patients, respectively. A significant *P*-value for the Hosmer-Lemeshow statistic indicates a significant deviation between predicted and observed outcomes.

has been instituted in patients with end-stage liver disease awaiting liver transplantation. MELD has shown an advantage over CP by using continuous objective variables that are not open to observer interpretation and are appropriately weighted according to their impact on prognosis[3,4,26]. Its ability to predict mortality, however, has been found to be similar or slightly superior to the traditional CP score[27-30]. These controversies suggest that a better predictive model is necessary to predict survival in cirrhotic patients.

In our study, the baseline characteristics were comparable with similar studies evaluating survival in cirrhotic patients[31-36]. Furthermore, all clinical and biochemical variables included in the CP and MELD scores were associated with survival in univariate analysis. Multivariate Cox proportional hazards analysis identified serum creatinine, ascites, encephalopathy and bleeding esophageal varices as independent prognostic factors for overall survival. The strongest predictors of mortality were ascites and serum creatinine. In our proposed model, ascites, encephalopathy and variceal bleeding were evaluated depending on medical treatment response, and the diagnosis and treatment of each of these was based on the most recent published guidelines[10-12,37]. The used nomenclature appeared to be more uniform and less subjective than the commonly applied classification into CP or MELD scores[2-4].

The major finding of this prospective study is that the BioCliM score, which is based on a combination of 3 clinical indices (ascites, encephalopathy and bleeding

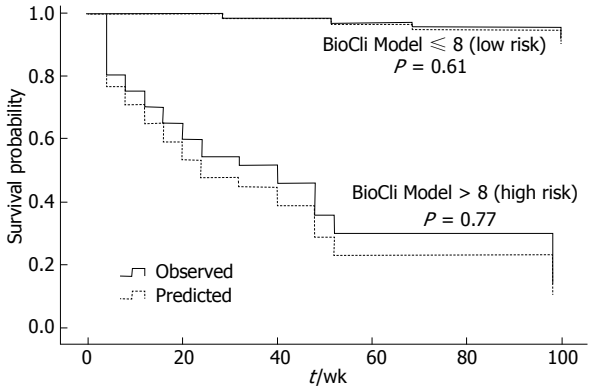

Figure 4 Observed and expected 104-wk survival curves for the BioCliM score. Survival of 85 independent patients from the "Calixto Garcia" Hospital who were stratified according to their risk score into two risk groups (low-risk ⩽ 8 and high-risk > 8). The observed and predicted BioCli Model survival curves were compared using log-rank test. The observed and expected survival was similar for the low- and high-risk groups.

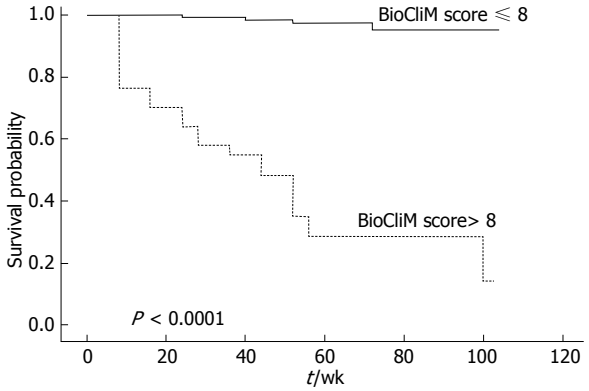

Figure 5 Kaplan-Meier estimated survival curves for the BioCli Model score.

esophageal varices) and 2 biochemical parameters (creatinine and bilirubin), is able to accurately predict short-term (12 wk), intermediate-term (52 wk) and long-term (104 wk) mortality in cirrhotic patients. Our results showed that the BioCliM score is superior to the CP and MELD scores in ranking patients according to their risk of death. In addition, the BioCliM score showed a sustained discriminative power to predict survival through the different evaluated periods (12-104 wk). Our data further support, as well as previous findings, that the MELD score is not significantly superior to the CP score in predicting survival in patients with hepatic cirrhosis[25,27-30]. Theoretically, the MELD score is undoubtedly more objective and robust than the CP score for the previously mentioned reasons; however, a major limitation of the MELD score is the poor discriminative power to predict survival among patients whose clinical course is often affected by other factors which are excluded by the model[38]. Recent studies have demonstrated that ascites, encephalopathy and hyponatremia are important independent predictors of early pretransplant mortality, especially for patients with low MELD scores[8,9,39,40], thus affecting the consideration for an expedited liver transplant under the "sickest first" model. In consequence, as the MELD score does not reflect the presence of ascites and encephalopathy, these patients need to be allocated separately for liver transplantation if MELD is used to prioritize organ allocation. By contrast, the BioCliM scale is able to accurately predict survival in patients with clinical complications of portal hypertension, thus the BioCliM score could be recommended in the individual management of these patients. Further studies are needed to validate its prognostic accuracy in patients undergoing liver transplantation.

Possibly the most important study limitations were the relatively small sample size, the poor geographic diversity of the patients included (single and tertiary center) and the major drawbacks of the MELD score related to wide variability of laboratory parameters such as serum creatinine and bilirubin[28,41,42].

In conclusion, both the CP and MELD scores can accurately predict short-term survival in cirrhotic patients, while the BioCliM score appears to have great discriminative power for short- (4 and 12 wk), intermediate- (24 and 52 wk) and long-term (104 wk) survival. In contrast to the MELD score, the use of the BioCliM score in patients with ascites, encephalopathy and variceal bleeding could significantly increase survival predictive values in patients with end-stage liver disease.

COMMENTS

Background

The Child-Pugh and Model for End-stage Liver Disease (MELD) scores are important tools for the prognostic evaluation of cirrhotic patients and the current organ allocation policy. These have, however, several drawbacks such as the subjectivity of clinical parameters, limited discriminative capability and variability in the measurements of laboratory parameters. The current evidence suggests that a better predictive model is necessary to predict survival in cirrhotic patients.

Research frontiers

The clinical complications of portal hypertension such as ascites, encephalopathy, spontaneous bacterial peritonitis (SBP) and gastrointestinal bleeding are not considered in the MELD score, probably underestimating that they may have a direct association with the severity of liver disease. The classification applied to the clinical complications of portal hypertension (ascites, encephalopathy, variceal bleeding and SBP) in the MELD score does not clearly reveal the different grades of severity of liver disease and its clinical response to medical treatment. Therefore, its utility in the prognostic model could be limited. In this study, the authors have evaluated a new paradigm for clinical variables, depending on the severity and medical treatment response and how they have an influence, as prognostic factors, in the survival of cirrhotic patients.

Innovations and breakthroughs

Recent reports have demonstrated that ascites, encephalopathy and hyponatremia are important independent predictors of early pretransplant mortality, especially for patients with low MELD scores, thus affecting the consideration for an expedited liver transplantation under the "sickest first" model. In consequence, as the MELD score does not reflect the presence of

ascites and encephalopathy, these patients need to be allocated separately for liver transplantation if MELD is used to prioritize organ allocation. By contrast, the new biochemical and clinical model is able to accurately predict survival in patients with clinical complications of portal hypertension; thus the BioCliM score could be recommended in the individual management of these patients.

Applications

In contrast to the MELD score, BioCliM is able to accurately predict survival in patients with clinical complications of portal hypertension, thus the BioCliM score could be recommended in the individual management of these patients. Further studies are needed to validate its prognostic accuracy in patients undergoing liver transplantation.

Terminology

BioCliM is a new biochemical and clinical model that is able to accurately predict survival in patients with end-stage liver disease.

Peer review

The authors examined the prognostic value and predictive capability of a new prognostic model in patients with end-stage liver disease. A less subjective nomenclature to assess the clinical complications of portal hypertension was evaluated in combination with biochemical variables to determine their influence as prognostic factors of survival in cirrhotic patients. The biochemical and clinical model was shown to accurately predict survival in patients with clinical complications of portal hypertension and it appeared to have great discriminative power for short- (4 and 12 wk), intermediate- (24 and 52 wk) and long-term (104 wk) survival.

Abstract

AIM: To investigate hepatitis C virus (HCV) seroprevalence in Tunisian patients with diabetes mellitus and in a control group.

METHODS: A cross-sectional study was conducted to determine the HCV seroprevalence in 1269 patients with diabetes (452 male, 817 female) and 1315 non-diabetic patients, attending health centers in Sousse, Tunisia. HCV screening was performed in both groups using a fourth-generation enzyme immunoassay.

RESULTS: In the diabetic group, 17 (1.3%) were found to be HCV-infected compared with eight (0.6%) in the control group, although the difference was not significant (P = 0.057). Quantitative PCR was performed in 20 patients. Eleven patients were positive and showed HCV genotype 1b in all cases.

CONCLUSION: Frequency of HCV antibodies was low in patients with diabetes and in the control group in central Tunisia, with no significant difference between the groups.

INTRODUCTION

In recent years, a positive association between hepatitis C virus (HCV) infection and diabetes mellitus (DM) had been reported in a number of clinical studies[1-4]. It is now clear that hepatitis C conveys a risk for developing DM, in particular type 2[5-7]. Moreover, several studies have found a high prevalence of anti-HCV antibodies among patients with diabetes, especially those with type 2 DM[8-13]; however, some authors have not observed an association between HCV infection and diabetes[14-16]. Since effective therapy has become available for HCV, it may be worthwhile to determine virus prevalence in patients with and without diabetes, in order to decide whether a programme for screening should also focus on type 2 diabetes. The aim of the present study was to investigate HCV seroprevalence in Tunisian patients with DM and in a control group.

MATERIALS AND METHODS

Patients

During March 2003, we conducted a cross-sectional study of all consecutive patients with diabetes aged > 16 years who were attending the Departments of Internal Medicine, Infectious Diseases and Endocrinology of Farhat Hached Hospital, and primary health care centers in the region of Sousse, Tunisia. Sample size calculation was

based on a 2% HCV seroprevalence estimation with an 80% precision rate and a 95% confidence level. The formula for sample size determination yielded a total of 1223 patients with diabetes. Types 1 and 2 diabetes were defined on the basis of a history of therapy with oral hypoglycemic agents or insulin at the date of inclusion. Patients older than 40 years of age, and treated by oral hypoglycemic agents or switched from insulin were considered to have type 2 diabetes. A control group of non-diabetic patients were recruited from the same centers at the same time. Patients who had corticosteroid-induced diabetes were excluded. Informed consent was obtained from all participants, and the study was approved by Farhat Hached Hospital ethics committee.

Data collection

Data were recorded by using a questionnaire that collected information on demographic and clinical features of DM and risk factors for HCV infection. Blood samples were collected from all patients for HCV serology. Those who were positive for anti-HCV antibodies were called, and liver function tests, glucose blood level, HCV quantitative RNA and HCV genotyping were performed.

Laboratory methods

Serological testing for anti-HCV antibodies was performed by using a fourth-generation ELISA (Murex; Abbot Laboratories, France) according to the manufacturer's instructions. HCV RNA qualitative and quantitative testing (Amplicor; Roche Molecular Systems, Branchburg, NJ, USA) and HVC genotyping were performed at Pasteur Cerba Laboratoire, Cergy Pontoise, France). HVC genotyping was performed by RT-PCR on a segment from the core region and by hybridization of this fragment with oligonucleotide-specific probes. The assay was designed to recognize the 1a, 1b, 2a, 2b, 3, 4, 5 and 6 HCV genotypes.

Statistical analysis

Data were analyzed, using SPSS version 13.0 software (Chicago, IL, USA). A descriptive analysis was followed by bivariate analysis using the χ^2 test for comparison of the two groups, with a 5% statistical significance level. A multivariate analysis with logistic regression was used to determine predictive variables associated with seroprevalence among the significant factors found by bivariate analysis. ORs and 95% CI were calculated for these variables.

RESULTS

Our study included 1269 patients with diabetes and 1315 non-diabetic patients. In patients with diabetes, 1148 (90.5%) and 121 (9.5%) had type 2 and type 1 DM respectively; 284 (22.5%) were treated by insulin. The mean duration of DM was 8.4 years (1-35 years). Furthermore, history of surgery and hospitalization, and scarification were found to be more frequent in patients with diabetes. Patients in the control group were much younger than those with diabetes; the main demographic and clinical characteristics of both groups are shown in Table 1.

Table 1 Epidemiological features of the study population in patients with diabetes and control group *n* (%)

Anti-HCV antibodies (+)	16 (1.4)	8 (0.6)	2.31 (1.01-5.90)	0.04

Antibodies against HCV were detected in 25 patients (1%) among the entire population studied (both diabetic and non-diabetic groups). In the diabetes group, 17 (1.3%) were found to be infected with HCV compared with eight (0.6%) control patients. No significant difference was found between DM patients and the control group ($P = 0.057$) (Table 1). Moreover, anti-HCV seropositivity was detected in 16 (1.4%) of the type 2 DM sub-group, which was significantly higher than that in the control group ($P = 0.04$) (Table 2). However, in multivariate analysis, this difference between seroprevalence of HCV in type2 DM and controls was not confirmed.

Quantitative PCR was performed in 20 patients: 13 with diabetes and seven without, was and a positive result

was obtained in eight and three patients, respectively. All patients were infected by genotype 1b HCV. All non-diabetic patients who were positive for HCV antibodies underwent liver function and blood glucose testing, but no new DM was discovered.

DISCUSSION

To the best of our knowledge, this is the first study in which HCV infection prevalence was evaluated in Tunisian patients with diabetes. Similar to blood donors in whom anti-HCV antibodies were low (0.5%-1.8%)[17-21], in our study HCV infection prevalence in the diabetes, type 2 DM, and control groups was 1.3%, 1.4% and 0.6%, respectively. Despite a high frequency of scarification, history of surgery and hospitalization in patients with diabetes and the type 2 DM subgroup, circumstances which increase risk of HCV infection, prevalence of anti-HCV antibodies was not significantly more frequent in the diabetes group ($P = 0.057$). Moreover, comparing type 2 DM patients to the control group, although a significant difference in HCV infection prevalence was observed in type 2 DM patients ($P = 0.04$), this was not confirmed by logistic regression analysis. Therefore, we cannot establish the diabetic population as a group at high risk for HCV infection. Our findings did not confirm other studies that have reported increased HCV seroprevalence in patients with diabetes[10,22-26]. In a case-control study conducted in the USA, 4.2% of 594 patients in a cohort with diabetes were found to be infected with HCV compared with 1.6% of control patients (377 patients with thyroid diseases)[27]. Other studies have reported an increased HCV seroprevalence, varying from 8% to 11% in European diabetic populations compared with 1%-2% HCV seroprevalence in the general population[10,28-30]. However, in a descriptive Greek study of patients with diabetes without a control group, HCV antibodies were detected in only seven cases, and this prevalence (1.65%) was similar to that in the general population[14].

In conclusion, our study confirms a low prevalence of anti-HCV antibodies in Tunisian patients with diabetes, and may argue against diabetes as a risk factor of HCV infection in this area. Further studies, possibly multicenter, prospective and case-control, are needed to establish the temporal relationship between HCV infection and DM.

COMMENTS

Background

Several studies have found a high prevalence of anti-hepatitis C virus (HCV) antibodies among patients with diabetes mellitus (DM), especially those with type 2 DM. However, some authors have not observed an association between HCV infection and diabetes. Since effective therapy has become available for HCV, it may be worthwhile to determine the prevalence of HCV in patients with and without diabetes, to decide whether a programme for screening should also focus on type 2 diabetes patients.

Research frontiers

The literature is still contradictory about high prevalence of HCV infection in type 2 DM. The prevalence of HCV infection is still unknown in Tunisia. In this study, the authors demonstrated that this prevalence was similar in the general population.

Innovations and breakthroughs

The study confirmed a low prevalence of anti-HCV antibodies in Tunisian patients with diabetes, and may disprove diabetes as a risk factor for HCV infection in this area.

Applications

The low prevalence of HCV infection in type 2 DM in this study argues against the systematic assessment of HCV antibodies in this population.

Peer review

The present manuscript describes a comparative analysis of HCV prevalence in diabetic and non-diabetic populations in central Tunisia. Although its findings are negative, they are interesting because of the relatively large sample size. This is an interesting small epidemiological study on the association between diabetes and HCV prevalence in central Tunisia.

Abstract

AIM: To examine whether a dose-up to 900 mg of ursodeoxycholic acid (UDCA) decreases transaminases in hepatitis C patients.

METHODS: From January to December 2007, patients with chronic hepatitis C or compensated liver cirrhosis with hepatitis C virus (HCV) (43-80 years old) showing positive serum HCV-RNA who had already taken 600 mg/d of UDCA were recruited into this study. Blood parameters were examined at 4, 8 and 24 wk after increasing the dose of oral UDCA from 600 to 900 mg/d.

RESULTS: Serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), and gamma-glutamyl transpeptidase (GGT) levels were significantly decreased following the administration of 900 mg/d as compared to 600 mg/d. The decrease in ALT from immediately before the dose-up of UDCA to 8 wk after the dose-up was 14.3 IU/L, while that for AST was 10.5 IU/L and for GGT was 9.8 IU/L. Platelet count tended to increase after the dose-up of UDCA, although it did not show a statistically significant level (P = 0.05). Minor adverse events were observed in 3 cases, although no drop-outs from the study occurred.

CONCLUSION: Oral administration of 900 mg/d of UDCA was more effective than 600 mg/d for reducing ALT, AST, and GGT levels in patients with HCV-related chronic liver disease.

INTRODUCTION

Current treatment for chronic hepatitis C virus (HCV) infection is based on the administration of pegylated interferon (IFN) alone or in combination with other anti-viral agents such as ribavirin or protease inhibitors. However, these treatments are not completely effective in all patients with HCV genotype 1 and high viral load or in patients with liver cirrhosis[1-4]. Ursodeoxycholic acid (UDCA) was identified in 1902 from polar bear bile by Hammarsten and was isolated and crystallized by Shoda[5]. UDCA is used worldwide for the treatment of primary biliary cirrhosis (PBC) and chronic liver diseases[6-14]. Up to 2006, a dose of 150 mg/d of UDCA was approved as the standard treatment for hepatic protection in patients with chronic viral hepatitis by the public health insurance agency of Japan. However, this dosage is not effective for the treatment of chronic hepatitis[15]. A randomized, controlled-dose study of UDCA for chronic hepatitis C (CH-C) patients reported that UDCA administered at a dose of 600 or 900 mg/d resulted in greater decreases in the serum levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), and gamma-glutamyl

transpeptidase (GGT) compared to 150 mg/d, which was the dose recommended by the Japanese national health insurance policy at that time; however, the results with doses of 600 mg/d or 900 mg/d were similar. In contrast, 600 mg of UDCA, which is the maximum administration dose in PBC or other biliary system diseases such as gallstones, was used ambiguously in CH-C patients[16].

To determine the effect of 900 mg/d of UDCA for CH-C, the present study was conducted primarily as a dose-up trial from 600 mg/d to 900 mg/d in hepatitis C patients, with changes in ALT levels as the primary endpoint.

MATERIALS AND METHODS

Patients

From January to December in 2007, patients with CH-C or compensated liver cirrhosis with HCV (mean age 65.8, range 43 to 80 years) who tested positive for serum HCV-RNA were recruited into this study. All the enrolled patients had already received 600 mg/d of UDCA, and showed over 40 IU/L of ALT at the two points in the 4 wk prior to dose-up of UDCA. Patients were excluded from the study if they had received antiviral treatment with interferon with or without ribavirin or anticancer treatment for hepatocellular carcinoma (HCC). Patients with other malignancies diagnosed within 24 wk before the observation period or patients treated with corticosteroids and/or immunosuppressive drugs were also excluded. Patients with decompensated cirrhosis, hepatitis B, autoimmune liver disease, alcoholic or drug-induced liver injury, malignant tumors and biliary disorders were excluded. Patients receiving intravenous glycyrrhizin were enrolled in this study. However, when the dose or frequency of administration of glycyrrhizin was changed, this was defined as the study endpoint. Written informed consent was obtained from each patient before enrollment into the study.

Methods

After the 4-wk observation period, the dose of UDCA (Urso®, Mitsubishi Tanabe Pharma Corp., Osaka, Japan) was increased from 600 mg/d to 900 mg/d. Serum ALT was measured as a primary endpoint of liver function, and AST and GGT as secondary endpoints, using conventional methods. Blood samples were taken at the start of the observation period, at 0, 4, 8 and 24 wk after initiation of treatment, and at the final observation period. Serum concentrations of ALT, AST, GGT, albumin, total bilirubin and platelet counts were measured. CT and ultrasonography for HCC screening was carried out every 12 wk or 24 wk. Compliance with UDCA administration and adverse effects were determined by patient interview or confirmation of drug diaries.

Statistical analysis

Changes in AST, ALT, GGT, total bilirubin, albumin, and platelet count were analyzed by paired Student's *t*-test. $P < 0.05$ was considered significant.

Table 1 Patient characteristics before beginning the study (mean ± SE)

	Total (n = 32)
Mean age (range)	65.8 ± 2.6 (43-80)
Gender (male)	18 (56)
Liver cirrhosis (%)	7 (22)
Controlled hepatocellular carcinoma (%)	4 (12)
Glycyrrhizin administration (%)	6 (19)
AST (IU/L)	66.5 ± 4.1
ALT (IU/L)	57.1 ± 3.4
GGT (IU/L)	44.2 ± 2.1
Total bilirubin (mg/dL)	0.76 ± 0.5
Serum albumin (g/dL)	4.0 ± 0.1
Platelet count (× 1000/μL)	14.5 ± 1.0
HCVRNA (KIU/mL)	1309 ± 469
HCV genotype (1b/non 1b/not decided)	24/6/2

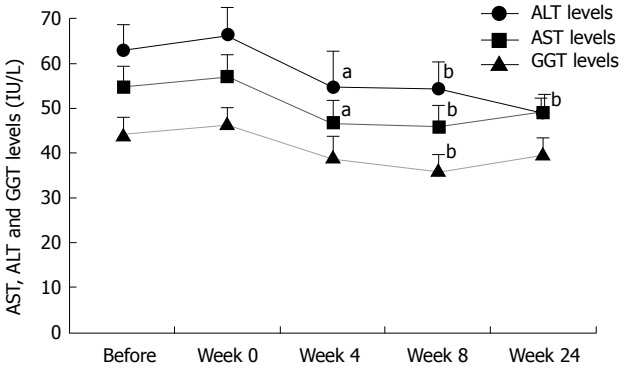

Figure 1 Changes in serum alanine aminotransferase (ALT) levels, serum aspartate aminotransferase (AST) levels and serum gamma-glutamyl transpeptidase (GGT) levels in patients before and during dose-up to 900 mg/d. Data are expressed as mean ± SD. $^aP < 0.05$, $^bP < 0.01$; paired *t*-test compared to week 0 in each parameter.

RESULTS

We enrolled 32 patients to this study. Patient characteristics are described in Table 1. In seven patients with liver cirrhosis, five patients were estimated as Child A and the others as Child B. Three patients with a history of HCC had been clinically diagnosed by dynamic computed tomography as having a complete response to trans-catheter arterial embolization and/or percutaneous radiofrequency ablation 24 wk or more before the start of the observation period. Compliance rate with UDCA administration was over 95%.

Changes in AST, ALT and GGT by dose-up of UDCA

Serum ALT, AST and GGT levels before and after the start of 900 mg of UDCA are shown in Figure 1. Serum ALT, AST and GGT levels were significantly decreased at 4, 8 and 24 wk after dose-up to 900 mg/d. The decrease (decreasing rate, %) in ALT levels before and 8 wk after dose-up to 900 mg of UDCA was 14.3 IU/L (22.1%) as shown in Figure 1. The decrease in AST and GGT were 10.5 IU/L (19.1%), and 9.8 IU/L (22.1%), respectively (Figure 1).

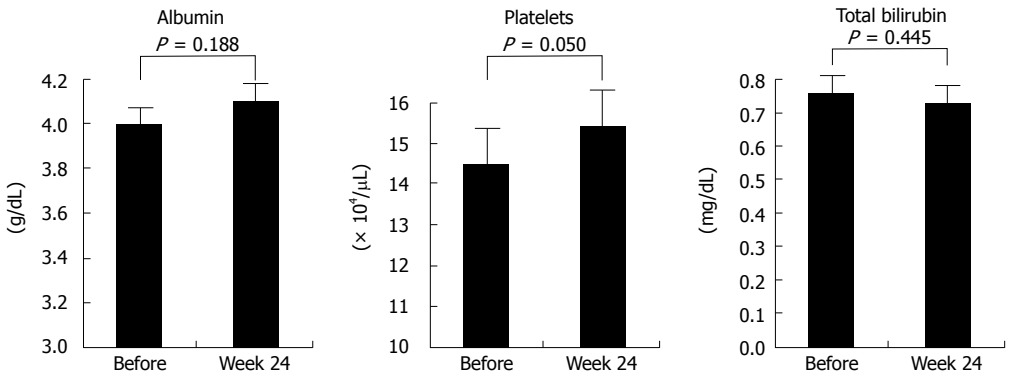

Figure 2 Changes in serum albumin, platelet count, and total bilirubin levels in chronic hepatitis C patients before and 24 wk after beginning the dose-up to 900 mg/d.

Changes in serum concentrations of albumin, total bilirubin and platelet count

Serum albumin level changed from 4.0 g/dL to 4.1 g/dL at 24 wk after the dose-up of UDCA. Platelet count changed from 145 000 to 154 000/μL, and total bilirubin changed from 0.76 to 0.73 mg/dL, although the difference did not reach a statistically significant level (P = 0.05, Figure 2). Serum HCV-RNA level did not change during the study period.

Safety

The number of adverse events during the administration of 900 mg UDCA, totaled three (9.4%), mild diarrhea in two patients and mouth discomfort in one patient. None of these adverse events influenced compliance with UDCA. Although HCC recurrence was detected in one patient at just 24 wk after dose-up of UDCA, this lesion was completely treated with percutaneous radiofrequency ablation.

DISCUSSION

The results of this study revealed that the dose-up trial of UDCA from 600 mg/d to 900 mg/d improved biochemical markers such as serum AST, ALT and GGT as early as the first or second dose-up week and continued to improve biochemical markers up to 24 wk after dose-up of UDCA was initiated. In addition, platelet count tended to increase following this dose-up therapy. These results suggested that 900 mg of UDCA can improve liver function tests in patients with chronic hepatitis C who have already received 600 mg of UDCA. In this study, the frequency of adverse events was lower than those in previous reports[15-18]. A possible reason for this is that patients enrolled in this study were not naïve to UDCA and may have quickly gotten used to the administration of UDCA.

In the natural course of CH-C, patients with normal serum aminotransferase levels show a slow fibrosis progression and a low incidence of HCC. Rino *et al*[19] demonstrated that the mode of reduction therapy and ALT levels were the most important factors, by multivariate analysis, to affect HCC development in patients with HCV-related cirrhosis of Child A classification followed for over 10 years. In addition, a previous study of postoperative patients with HCC found that recurrence was more frequent among patients with high serum ALT levels over 80 IU/L[20]. Moreover, using multivariate analysis in the Inhibition of Hepatocarcinogenesis by Interferon Therapy (IHIT) study, the risk of HCC after interferon treatment without virological response was strongly influenced by ALT levels, and the odds ratio of HCC in sustained virological responders was the same as that in sustained biochemical responders[21]. Therefore, high dose UDCA possibly reduced the occurrence and recurrence of HCC through the reduction of serum ALT level.

The anti-inflammatory mechanism of UDCA was considered to cause a reduction in the cytotoxicity of hydrophobic bile acids, stimulation of hepatobiliary secretion, suppression of NF-kB-dependent transcription by binding to the glucocorticoid receptor, and a decrease in proinflammatory cytokine-induced transcription of phospholipase A2[22-28].

The long-term effects of UDCA therapy in CH-C patients have not been fully elucidated[29]. Changes in liver histology following UDCA administration may not be clear from short-term observation periods. In this study, the dose-up treatment with 900 mg/d UDCA for 24 wk tended to increase serum platelet counts. In patients with hepatitis C virus-related chronic liver diseases, platelet counts reflect histological findings. When the platelet count is low in the patient, progression of liver fibrosis is suggested[30-33]. It is necessary to show histologically the morphological hepatic tissue changes in future studies.

In conclusion, oral administration of high dose 900 mg UDCA, despite the absence of an anti-viral effect, shows beneficial effects in reducing the activity of chronic hepatitis or cirrhosis.

COMMENTS

Background

Administration of pegylated interferon alone or in combination with anti-viral agents has improved the treatment for chronic hepatitis C, but is not very effective in some patients-especially those with hepatitis C virus (HCV) genotype 1 and high viral load or liver cirrhosis. Such patients may benefit from therapies which reduce liver inflammation and fibrosis.

Research frontiers

Researchers assessed the effect of ursodeoxycholic acid (UDCA) on serum liver enzyme levels in patients with chronic hepatitis C or compensated liver cirrhosis with HCV. Serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), and gamma-glutamyl transpeptidase (GGT) levels were significantly decreased with 900 mg/d compared with 600 mg/d.

Innovations and breakthroughs

Increasing the oral UDCA dose to 900 mg/d was effective in reducing ALT, AST, and GGT levels. Adverse effects were reported in 3 cases (9.4%), but none of these adverse effects influenced UDCA compliance.

Applications

The study results suggest that patients with HCV genotype 1 and high viral load or liver cirrhosis may benefit from oral UDCA therapy.

Peer review

This manuscript demonstrates that raising the UDCA dose from 600 mg/d to 900 mg/d improves liver chemistries including AST, ALT, and GGT over a 6 mo period. The authors then suggest that this may lead to suppression of fibrosis in a HCV population. Also, this research suggests that UDCA is safe at this dose. This is novel in a Japanese HCV cohort and the methods are quite straightforward. While not particularly novel, it does suggest that higher dose UDCA can improve liver chemistries.

Abstract

AIM: To investigate the spatial distribution patterns of anorectal atresia/stenosis in China.

METHODS: Data were collected from the Chinese Birth Defects Monitoring Network (CBDMN), a hospital-based congenital malformations registry system. All fetuses more than 28 wk of gestation and neonates up to 7 d of age in hospitals within the monitoring sites of the CBDMN were monitored from 2001 to 2005. Two-dimensional graph-theoretical clustering was used to divide monitoring sites of the CBDMN into different clusters according to the average incidences of anorectal atresia/stenosis in the different monitoring sites.

RESULTS: The overall average incidence of anorectal atresia/stenosis in China was 3.17 per 10000 from 2001 to 2005. The areas with the highest average incidences of anorectal atresia/stenosis were almost always focused in Eastern China. The monitoring sites were grouped into 6 clusters of areas. Cluster 1 comprised the monitoring sites in Heilongjiang Province, Jilin Province, and Liaoning Province; Cluster 2 was composed of those in Fujian Province, Guangdong Province, Hainan Province, Guangxi Zhuang Autonomous Region, south Hunan Province, and south Jiangxi Province; Cluster 3 consisted of those in Beijing Municipal City, Tianjin Municipal City, Hebei Province, Shandong Province, north Jiangsu Province, and north Anhui Province; Cluster 4 was made up of those in Zhejiang Province, Shanghai Municipal City, south Anhui Province, south Jiangsu Province, north Hunan Province, north Jiangxi Province, Hubei Province, Henan Province, Shanxi Province and Inner Mongolia Autonomous Region; Cluster 5 consisted of those in Ningxia Hui Autonomous Region, Gansu Province and Qinghai Province; and Cluster 6 included those in Shaanxi Province, Sichuan Province, Chongqing Municipal City, Yunnan Province, Guizhou Province, Xinjiang Uygur Autonomous Province and Tibet Autonomous Region.

CONCLUSION: The findings in this research allow the display of the spatial distribution patterns of anorectal atresia/stenosis in China. These will have important guiding significance for further analysis of relevant environmental factors regarding anorectal atresia/stenosis and for achieving regional monitoring for anorectal atresia/stenosis.

INTRODUCTION

Anorectal atresia/stenosis is a congenital malformation characterized by absence of continuity of the anorectal canal or of communication between rectum and anus, or narrowing of anal canal, with or without fistula, to neighboring organs[1]. Its incidence is rated high amongst gastrointestinal tract malformations. Incidence relates not only to genetic factors but also to environmental factors, especially spatial differences. There is, however, very little information available in literature about the spatial distribution patterns of anorectal atresia/stenosis in China.

Since 1986 China has been using the hospital-based Chinese Birth Defects Monitoring Network (CBDMN) to dynamically monitor severe congenital malformations such as anorectal atresia/stenosis[2]. We conducted this research to divide monitoring sites of the CBDMN into different clusters using two-dimensional graph-theoretical clustering analysis of the incidences of anorectal atresia/stenosis. Consideration was given to the similarities of the incidences of anorectal atresia/stenosis and the adjacent spatial relationships among different monitoring sites. This paper will present the spatial distribution patterns of anorectal atresia/stenosis and hopes to provide clues for research on its etiology.

MATERIALS AND METHODS

Objects

Research subjects were all perinatal fetal births more than 28 wk of gestation and neonates up to 7 d of age monitored in hospitals in the monitoring sites of the CBDMN from 2001 to 2005. They included live births, fetal deaths, stillbirths and those neonates who died within the first 7 d in these hospitals.

Monitoring hospitals

Using the hospital-based guidelines for monitoring birth defects in developing countries, as recommended by World Health Organization (WHO), the CBDMN gathered data from about 460 hospitals in this hospital-based network. These hospitals - all of them above the county level - were located in 138 cities (138 monitoring sites) of 31 different provinces, municipal cities, and autonomous regions in China. The selection of monitoring sites used the method of stratified sampling based on the combination of geographical location, economic development level and infant mortality rate. The spatial distribution of monitoring sites is in accordance with the distribution of nationwide births. The nationwide program covers approximately 450 000-500 000 births annually through all monitoring hospitals.

Information collection

The monitoring staff all received technical training on the case ascertainment of birth defects and the reporting of register forms. The monitoring hospitals collected the basic monthly information about the fetuses and neonates from units of delivery, pediatric and pathology quarterly reports and filled in the "Quarterly Form for Perinatal Births". The monitoring staff in these hospitals filled in the "Registration Card for Births with Congenital Malformations" regarding the cases of diagnosed anorectal atresia/stenosis. All the forms were required to be handed over to the provincial birth defects monitoring offices; these would be reported to the National Center for Birth Defects Monitoring after scrutiny. The specific monitoring methods and quality control measures complied with those in reference[3].

Inclusion and exclusion criteria

The perinatal births diagnosed as having anorectal atresia/stenosis with reference to criteria in Code Q42.1 and Code 42.3 in ICD-10 were included in this research. According to the criteria authorized by the International Clearing house for Birth Defects Surveillance and Research (ICBDSR), cases of mild stenosis which did not need correction and ectopic anus were excluded.

Spatial distribution analysis

The Excel Package was used to build the database of data of anorectal atresia/stenosis by monitoring sites. The ArcView GIS 3.2 was applied to spatially display the average incidences of anorectal atresia/stenosis in different provinces, municipal cities, and autonomous regions.

Two-dimensional graph-theoretical clustering: The graph is a set of vertices and edges that connect pairs of vertices in the space[4-6]. According to the basic requirements for clustering the two-dimensional ordinal samples, the similarities of the disease-related variables between members of the same cluster and their disparities between members of different clusters need to be maintained. The connectivity of the geographic units within the cluster also needs to be conserved. The weighted connected graph was supposed to be G = (V, E, D), in which (1) V represents the set of the locations of the geographic units (referred to monitoring sites in this research), (2) E represents the initial location connection matrix $B^{(0)}$ (Formula 1), the set of the adjacent relationships among different monitoring sites, and (3) D represents the initial disease-related distance matrix $D^{(0)}$ (Formula 2), the weights between different vertices in the tree algorithm in the graph theory. Based on the weighted connected graph G = (V, E, D), minimum spanning trees (MST) which were of biogeographic significance[7,8] were constructed by the Kruskal MST algorithm[9]. The two vertices with the minimum distance measures were selected and connected. One of the remaining vertices was selected and connected with the one of the two connected vertices to which it showed the minimum distance measured. The other remaining vertices were connected consecutively with those vertices already connected in the same manner until all the vertices were interconnected. The whole process was completed by the DPS7.05 software package[10].

$B^{(0)} = (b_{ik}^{(0)})_{n \times n}$; $i, k = 1, 2, ..., n$ (Formula 1)

$D^{(0)} = (d_{ik}^{(0)})_{n \times n}$; $i, k = 1, 2, ..., n$ (Formula 2)

Where $b_{ik}^{(0)}$ is the labeling of location connection between the monitoring site i and the monitoring site k. The value of $b_{ik}^{(0)}$ is 1 if the two monitoring sites are adjacent, while it is 0 when the two monitoring sites are not. $d_{ik}^{(0)}$ is the similarity distance between the incidence of the monitoring site i and that of the monitoring site k.

The MST was deconstructed by the method of "necks" in the graph theory[11]. Specific steps processed were as follows: (1) calculating the "branches": All n vertices were interconnected by (n-1) edges. Two of these vertices were connected only by one edge and the others were connected by at least two edges, which thus formed a chain without circuits, called the "branch". The branch with the most edges was called the main branch (or diameter) of the MST; (2) calculating the "subsidiary main branch". Starting from any vertex in the main branch of MST, the branch with the most edges, other than the main branch, was separated out and called the subsidiary main branch. The number of edges of the subsidiary main branch was called the "depth" of the vertex; (3) identifying "necks". The task was twofold: (Ⅰ) to appoint an integer "a" (that is > 1), and (Ⅱ) to find the subsidiary main branch of every vertex with a depth ≥ a in the main branch. The edges, which connected the vertices with the depth of 0 in the main shared parts of every subsidiary main branch, were called the "neck"; and (4) the necks were deleted in the graph to deconstruct the MST into parts so that the monitoring sites in the graph were divided into different clusters accordingly.

The layer of the deconstructed MST was added to the Administrative Boundary Layer of the 1:4M-scale Topographic Database of the National Fundamental Geographic Information System of China to formulate the two-dimensional MST-based cluster graph. The clustering results were used to make another cluster map for visual observation. This process was performed by the ArcView GIS 3.2 package software.

RESULTS

A total of 2670367 perinatal births were monitored from 2001 to 2005 all over China. Eight hundred and forty six cases of anorectal atresia/stenosis were found, equating to a total average incidence of 3.17 per 10000. See Table 1 for the average incidences of anorectal atresia/stenosis in different provinces, municipal cities or autonomous regions. The top five incidences appeared in Liaoning (4.89 per 10000 births), Zhejiang (4.83 per 10000 births), Guangdong (4.78 per 10000 births), Chongqing (4.59 per 10000 births) and Beijing (4.10 per 10000 births).

Spatial distribution

Regarding the geographic division standard for Eastern, Middle and Western China from the National Bureau of Statistics of China in 2003[12], the areas (provinces, autonomous regions, or municipal cities) with the highest average incidences of anorectal atresia/stenosis were concentrated in Eastern China, while the areas with the lowest average incidence of less than 1.99 per 10000 were mostly located in Western China (Figure 1).

Results of the two-dimensional graph-theoretical clustering

The MST was constructed with consideration to the similarities of average incidences of anorectal atresia/stenosis and the spatial connectivity between different monitoring sites (Figure 2). According to the "neck" calculation method in the graph theory, when the integral constant, a, was designated as 2, the monitoring sites were divided into 6 clusters of different areas.

Regarding the average incidences of anorectal atresia/stenosis in different provinces, municipal cities and autonomous regions from 2001 to 2005, the monitoring sites were grouped into 6 clusters. Cluster 1 comprised the monitoring sites in Heilongjiang Province, Jilin Province, and Liaoning Province; Cluster 2 was composed of those in Fujian Province, Guangdong Province, Hainan Province, Guangxi Zhuang Autonomous Region, south Hunan Province,

north Hunan Province, north Jiangxi Province, Hubei Province, Henan Province, Shanxi Province and Inner Mongolia Autonomous Region; Cluster 5 consisted of those in Ningxia Hui Autonomous Region, Gansu Province and Qinghai Province; and Cluster 6 included those in Shaanxi Province, Sichuan Province, Chongqing Municipal City, Yunnan Province, Guizhou Province, Xinjiang Uygur Autonomous Province and Tibet Autonomous Region (Figure 3).

DISCUSSION

Anorectal atresia/stenosis is one of the most common malformations in the gastrointestinal tract. Due to pathological changes in the anus and rectum, one-third of the perinatal births with anorectal atresia/stenosis suffer from defecation difficulties of varying degrees of severity following surgery. Most of these births need life-long treatment that severely compromises the quality of life and psychological development in particular. This situation is a burden not only to these babies, but also to their entire families and even to society as a whole in China[13-17]. Some researchers[18-22] suggested that mothers' contact (when they are pregnant) with environmental pollutants could increase their risk of giving birth to babies having congenital malformations. The current research found that the areas with the highest incidences of anorectal atresia/stenosis were concentrated in Eastern China, especially in Liaoning, Zhejiang and Guangdong. With a solid industrial and agricultural base, economic conditions in Eastern China flourish. Most manufacturing plants and industrial factories (including marine-aquatic industries) are located in Eastern China. It is known that these factories are responsible for water pollution and other industrial pollution at a level that is deemed severe. Perhaps mothers in Eastern China have babies with more congenital malformations because of the mothers' severe exposure to these physical and chemical pollutants when they are pregnant. In addition, the regional differences in awareness and uptake of available health care for pregnant woman, infrastructure of monitoring hospitals and diagnosis at a technical level were also factors likely to explain some of the observed geographical variation in anorectal atresia/stenosis. In Western China, limited at economic and cultural levels, most pregnant woman have weak awareness and uptake of health care, which means they do not actively seek antenatal care, so there is the probability of under-reporting of cases, resulting in the lower incidence. As to the health services, in the less developed western regions, the maternal and child healthcare facilities may lack necessary infrastructure, and the technical levels of monitoring staff may be limited, which may also result in the lower detection of congenital malformation.

Cluster analysis is an exploratory data analysis tool for solving classification problems. Assuming the samples as the vectorial points in hyperspace, the object of cluster analysis is to sort the samples into clusters so that the degree of association is strong between members of the same cluster and weak between members of different

clusters. It has widespread application because of its advantage of definite classification. In analysis of spatial distribution structures of disease, both the similarities and the adjacent relationships of geographic units of the same cluster are of interest to researchers[23]. The traditional cluster analysis cannot meet all the requirements. Nevertheless, the two-dimensional graph-theoretical clustering model systematically (1) combines the concept of the two-dimensional constrained spatial hierarchical clustering and the MST method in the graph theory; (2) utilizes the spatial analysis measures of Geographic Information System (GIS) in combination with the tree algorithm to divide the geographic units into clusters. This model allows researchers to consider the similarities as well as the spatial connectivity between different units in the same cluster. This is of significance in (1) analyzing the similarities of different geographic units, (2) demonstrating the spatial distribution of the disease, and (3) identifying the boundaries of the spatial heterogeneity of the disease. Luo *et al*[24] combined the principal component analysis and two-dimensional graph-theoretical clustering to identify the evaluation method for land consolidation priority. Cao *et al*[25] divided the national corn reserve regions based on the two-dimensional graph-theoretical clustering, providing references for application of regional corn reserve technology and for the formation of guidelines for macro-regional corn reserve technology. Few researchers, however, have reported on the use of two-dimensional graph-theoretical clustering as applied to study the spatial distribution of congenital malformations.

This research utilized the two-dimensional graph-theoretical clustering to divide monitoring sites of the CBDMN into different clusters of areas based on average incidences of anorectal atresia/stenosis. The findings in this research will have important guiding significance for further analysis of relevant environmental factors regarding anorectal atresia/stenosis and for allowing regional monitoring for anorectal atresia/stenosis. On the one hand, the congenital malformations relate not only to genetic factors, but also correspond with the influence of other conditions: geographic environment, climate, economic development and even cultural development[26-30]. The results from the two-dimensional graph-theoretical clustering will enable epidemiologists to determine which environmental factors affect the incidence of anorectal atresia/stenosis in each cluster of areas by considering their respective environmental characteristics. On the other hand, although these data showed high incidence of anorectal atresia/stenosis in Eastern China and low incidence in Western China, it is true that different areas within Eastern China and Western China have their own demographic, economic and environmental characteristics. Large-scale monitoring cannot obtain detailed influential factors of anorectal atresia/stenosis in any given region. The results in this research provide an approach for researchers to monitor relevant environmental influential factors for incidence of anorectal atresia/stenosis regionally. By dividing the monitoring sites of the CBDMN into different clusters, the detailed relevant environmental risk factors for anorectal atresia/stenosis in different geographic units can be collected within the same cluster to allow regional monitoring.

The current research took account of the adjacent relationship between different monitoring sites rather than different provinces, autonomous regions or municipal cities, which guaranteed the requirements for geographic divisions for this study. However, if different monitoring sites in the same province were incorporated into different clusters after two-dimensional graph-theoretical clustering, the monitoring work at the provincial level would be subjected to increased difficulties.

ACKNOWLEDGMENTS

We thank monitoring hospitals of the CNBDMN for data collection of anorectal atresia/stenosis. We also thank Mary Meyer and Steven Pan, who polished the paper with meticulous efforts.

COMMENTS

Background

The incidence of anorectal atresia/stenosis is high amongst gastrointestinal tract malformations. It relates not only to genetic factors but also to environmental factors, especially spatial differences. However, very little information available in literature about the spatial distribution patterns of anorectal atresia/stenosis in China.

Innovations and breakthroughs

This is the first study to report the spatial distribution of anorectal atresia/stenosis in China using two-dimensional graph-theoretical clustering considering simultaneously the similarities as well as the spatial connectivity between different units in the same cluster.

Applications

The findings will have important guiding significance for further analysis of relevant environmental factors of anorectal atresia/stenosis and for allowing regional monitoring for anorectal atresia/stenosis.

Terminology

Anorectal atresia/stenosis: a congenital malformation characterized by absence of continuity of the anorectal canal or of communication between rectum and anus, or narrowing of anal canal, with or without fistula to neighboring organs. Two-dimensional graph-theoretical clustering: a cluster method of combining the concept of the two-dimensional constrained spatial hierarchical clustering and the MST method in the graph theory, and utilizing the spatial analysis measures of geographic information system (GIS) in combination with the tree algorithm to divide the geographic units into clusters.

Peer review

The study is based on 460 hospitals from 138 cities across China, and is an interesting paper on the geographical distribution of anorectal atresia/stenosis across China.

Abstract

AIM: To construct *p27mt* recombinant adenovirus, transfect the colorectal cell line Lovo and observe the effects of *p27mt* on Lovo cell apoptosis and cell cycle inhibition.

METHODS: We constructed recombinant adenovirus containing *p27mt* by homologous recombination in bacteria. The colorectal cancer cell line Lovo was infected with recombinant replication-defective adenovirus Ad-p27mt, and expression of *p27mt* was determined by Western blotting; the inhibitory effect of *p27mt* on Lovo cells was detected by cytometry. Cell cycle was determined by flow cytometry. DNA fragment analysis identified the occurrence of apoptosis.

RESULTS: The recombinant adenovirus which already contained *p27mt* target gene was successfully constructed. When multiplicity of infection was $\geqslant$ 50, the infection efficiency was 100%. After transfection of Lovo cells with Ad-p27mt the cells had high *p27* expression which was identified by immunoblotting assay. PI staining and flow cytometry showed that 77.96% of colorectal cancer cells were inhibited in phase G_0/G_1, while in the Ad-LacZ group and blank control group, 27.57% and 25.29% cells were inhibited in the same phase, respectively. DNA fragment analysis, flow cytometry and TUNEL assay demonstrated that *p27mt* is able to induce apoptosis in colorectal cancer cells.

CONCLUSION: *p27mt* has an obvious blocking effect on colorectal cancer cell cycle, and most cells were inhibited in phase G_0/G_1. Therefore, *p27mt* can induce apoptosis in colorectal cells.

Key words: Apoptosis; Cell cycle; Colorectal cancer; *p27mt*; Recombinant adenovirus

INTRODUCTION

p27Kip1 (*p27*) is a cyclin dependent kinase inhibitor (CDKI), whose specific late G_1 destruction allows progression of the cell across the G_1/S boundary. The protein was ubiquitinated by S-phase kinase-interacting protein-2 (Skp2) following its specific phosphorylation, and was subsequently degraded by the 26S proteasome[1]. There was a direct relationship between the low level of *p27* and rapid proliferation occurring in several benign states and in many malignancies. It has been reported that *p27* levels were markedly reduced in several malignancies, such as those of the skin[2], liver[3], bladder[4], thyroid[5], breast[6], prostate[7] and endometrium[8]. In some of the tumors studied, a strong correlation was found between the low level of *p27*, the aggressiveness of the disease and poor prognosis of the patients[6]. Interestingly, *p27* in all these tumors was of the wild-type species (*p27wt*), and its regulation has been attributed to phosphorylation of Thr-187 and subsequent

ubiquitination[9]. Overexpression of *p27 via* adenoviral gene transfer could suppress cancer cell growth regardless of *p27* mutation[10]. Montagnoli *et al*[11] showed that the ubiquitination of *p27* did not occur in *p27mt* with Thr-187 to Ala [p27 (T187A)]. Sheaff *et al*[12] showed that the transfection of p27 (T187A) plasmid caused a G_1 block, which was both resistant to and not modulated by cyclin E/Cdk2. On the basis of these observations of *p27* regulation and the nature of the *p27* tumor suppressor gene, we constructed Adenovirus expressing *p27mt* (Thr-187/Pro-188 to Met-187/Ile-188) to infect the colorectal cancer cell line Lovo, and then investigated its expression and functional significance in the cell proliferation and apoptosis of Lovo cells, by which we aimed to discuss novel methods of gene therapy in colorectal cancer.

MATERIALS AND METHODS

Main reagents

The restriction endonucleases such as *Age* I , *Nhe* I , *Kpn* I , *Pac* I and *Pme* I were purchased from New England Biolabs Co. *Hin*dⅢ, *Eco*RI, λDNA *Hin*dⅢ marker, 200 bp DNA ladder, dNTP, Tag enzyme and T4 DNA ligase were purchased from Huamei Biological Co. (China). The Western blotting kit was purchased from KPL Co. (USA). The rat anti-human *p27kip1* multi-antibody was purchased from Santa Cruz Co. (USA). The horseradish peroxidase (HRP) labeled sheep anti-rat IgG monoclonal antibody was purchase from Zhongshan Co. (China). The *p27mt* primer was designed and synthesized by Beijing Saibaisheng Biological Co. (China). The fetal bovine serum (FBS) was purchased from Hangzhou Sijiqing Biological Engineering Materials Co. (China). The liposome (polyfect) was purchased from Qiagen Co. (USA). Trypsin, DMEM culture medium, Hepes and Cscl were purchased from Sigma Co. (USA).

Plasmid, strain, adenovirus and cell lines

The pORF9-p27mt plasmid was purchased from Invivogen (USA). The pAdeasy-1 plasmid, pBluescript Ⅱsk (+), Ad293 cell, *E. coli* BJ5183 and XL10-gold were purchased from Stratagene (USA). The LacZ recombinant adenovirus (Ad-LacZ with titer 7.15×10^{15}/L)[13] and DH5α were gratefully provided by Doctor Wang Jianing, Clinical Research Institute, Yunyang Medical College. The Lovo cell line was purchased from Type Culture Collection Center, Wuhan University.

Main equipment

This equipment included a high speed freezing centrifuge (Universal 32R, Germany), the ultraspeed freezing centrifuge (Tokyo Cp80max, Japan), inverted phase contrast microscope (Nikon TE2000-u, Japan), CO_2 culture box (CB150#00-17611, wtb-binder), PCR machine (Biometra. Germany), ultraviolet spectrophotometer (Auriud CE2401, UK), Coulter Epics XL flow cytometer (Beckman Co., USA), high speed table-top centrifuge and a water bath shaking table (China).

Construction and identification of p27mt recombinant adenovirus

After pORF9-p27mt was digested by *Age* I and *Nhe* I enzymes, the 619 bp fragment was recycled and subcloned into pBluescript ⅡSK (+) which was digested by *Xma* I and *Xba* I enzymes, thus obtaining pBluescript-p27mt. Then pBluescript-p27mt was digested by *Not* I and *Kpn* I enzymes, and the 699 bp fragment was recycled and inserted into the shuttle plasmid vector pShuttle-CMV which was digested by the same enzymes, thus the transfer plasmid pShuttle-CMV-p27mt was obtained. The competent *E. coli* was transformed by the adenoviral framework plasmid pAdeasy-1. According to the ampicillin-resistant gene, the BJ5183 containing pAdeasy-1 was picked out and prepared into the ultra-competence BJ5183 containing pAdeasy-1. Then, the ultra-competence BJ5183 was transformed by transfer plasmid pShuttle-CMV-p27mt which was digested by *Pme* I enzyme and dephosphorylated by alkaline phosphatase. A little DNA from the transformed clone bacterial plasmid was taken out and the suspect DNA of the recombinant adenovirus plasmid was chosen according to the size of the plasmid in agarose electrophoresis. If the chosen DNA was identified as the correct DNA by digestion of *Pac* I enzyme, then the recombinant adenovirus plasmid pAdeasy-1-p27mt could be prepared. Recombinant adenovirus plasmid DNA was excised by *Pac* I , then transfected by Ad293 *via* liposome polyfect mediation, where the change in cells at different times after transfection was determined. When it appeared that 90% had cell lesions, scratch 293 cells from the culture bottle were vortexed three times at -80℃ to +37℃ to lyse the cells, then centrifuged and the supernatant containing the virus was collected, the 293 cells were reinfected with the above virus and proliferation of the virus occurred at a large scale. Purification of recombinant adenovirus was similar to the method of Cortin *et al*[14]. After purification the adenovirus underwent dialysis, test virus titers were detected using an ultraviolet spectrophotometer. Fifty microliter of purified adenovirus liquid, 100 g/L SDS 20 μL, PBS 430 μL, were assayed at absorbance values of A_{260} and A_{280}, then the granule numbers and purity of adenovirus were determined. If $A_{260} = 10^{15}$pfu/L and $A_{260}/A_{280} > 1.3$ this indicated that the purity was relatively high when virus titers (pfu/L) = $A_{260} \times$ dilution $\times 10^{15}$. PCR identification of recombinant adenovirus Ad-p27mt was carried out. Recombinant adenovirus genome DNA from the high titer virus storage liquid served as a template. Using primer toward the reporter gene *p27mt*, the PCR reaction parameters were: pre-denaturation at 95℃ for 5 min, denaturation at 94℃ for 20 s, annealing at 56℃ for 30 s, elongate at 72℃ for 30 s, 30 cycles, elongate at 72℃ for 10 min. Primer 1: 5'CCTAGAGGGCAAGTACGAGTG3'; Primer 2: 5'GAAGAATCGTCGGTTGCAGGTCGCT3'.

Detection of p27mt gene expression

Lovo cells were incubated in 100 mL/L FCS and RPMI-1640 culture medium at 37℃ in a 50 mL/L CO_2 culture box until the cells spread to 70%-80% of the area and were used in the following experiment.

Lovo cells taken from the 15 cm culture flask were infected with Ad-LacZ according to an Multiplicity of infection (MOI) of 20, 40, 50 and 100 and then incubated for another 48 h. The cells were then fixed by 5 mL/L glutaral for 15 min and washed three times with PBS,

X-gal staining solution (20:1) was added. The cells were then incubated at 37℃ in the 50 mL/L CO_2 culture box for 4-24 h. The blue-stained cells, i.e. the positive cells in which the LacZ gene was expressed, were observed under the microscope and the percentage of positive cells was calculated.

Lovo cells taken from the 75 cm culture flask were infected with Ad-p27mt (MOI 50) and Ad-LacZ (MOI 50), respectively. After incubation in the same conditions for 48 h, the cells were digested by 0.5 g/L trypsin, collected and washed twice with PBS. After lysis by 500 μL 1 × SDS-PAGE cell lysis solution and boiling for 5 min, the cells were centrifuged, the supernatant was collected and then detected by Western blotting.

Cycle detection and apoptosis of cells infected with Ad-p27mt by flow cytometry

Lovo cells cultured in the 75 cm culture flask were infected with Ad-p27mt (MOI 50). After incubation for 48 h, the cells were digested by 0.5 g/L trypsin, collected and then washed twice with PBS. The cell concentration was adjusted to 10^9/L with PBS. One hundred microliter of cell suspension was taken out and mixed with 200 μL DNA-PREP™ LPR and placed at room temperature in the dark for 3 min. The cell suspension was then mixed with 1000 μL DNA-PREP stain (PI staining). The cell cycle phase and apoptosis were detected by a Coulter Epics XL flow cytometer 15 min later. Ad-LacZ (MOI 50) group and normal controls (Lovo cells cultivated without adenovirus) were used as control groups.

Apoptosis by DNA fragment analysis

The cells in the three groups (Ad-p27mt and Ad-LacZ for 48 h and the normal control), were collected and centrifuged at 1000 r/min for 5 min. The supernatant was discarded, and 500 μL of cell lysis solution [1% Np40, 20 mmol/L EDTA, 50 mmol/L Tris-HCl (pH7.5)] and 10 μL protease K were added to the cell sediment. Following incubation in a water bath (56℃) for 1-2 h and extraction with phenol and chloroform, DNA was precipitated by dehydrated alcohol. After washing once with 700 mL/L alcohol, 200 μL TE was added to lyse the DNA. Then RNase (final concentration 50 μg/mL) was added and placed at 37℃ for one night. The DNA was electrophoresed in 10 g/L agarose gel and the results were observed under an ultraviolet lamp.

Detection of cell apoptosis by the TUNEL method

1×10^4 cell suspension was inoculated into a 60 mm dish with a cover glass (washed and high-pressure sterilized). Each of the Ad-p27mt group and the normal control were inoculated into 6 glasses and incubated for 24 h. The glasses were then taken out and washed twice with 1 × PBS and fixed with methanol and freezing acetic acid (3:1) for 30 min. The next procedure was carried out according to the kit instructions. One thousand cells were counted on each glass and the average number of apoptotic cells was determined. Then the apoptotic index (AI), i.e. the number of apoptotic cells in every 100 cancer cells, was calculated.

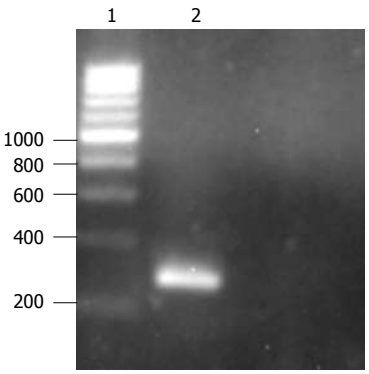

Figure 1 Identification of Ad-p27mt by PCR. 1: 200bp marker; 2: Ad-p27mt.

Statistical analysis

One way-ANOVA was used in processing the measured data, which were expressed as mean ± SD. χ^2 test was adopted in the calculation of enumeration data.

RESULTS

PCR identification of the recombinant adenovirus Ad-p27mt

The pathologically changed 293 cells and the culture fluid were collected, frozen and thawed three times and centrifuged. Five millilitre of the supernatant was taken out and added to 1 mg protease K, 2 mL 1% SDS, 10 mmol/L EDTA and 20 mmol/L Tris-HCl for 2 h. After centrifugation, the supernatant was extracted with phenol and chloroform. After precipitation with dehydrated alcohol, the viral DNA was collected. Then forward and reverse primers were added and the PCR reaction was carried out. The 275 bp target gene was amplified, which showed that the recombinant adenovirus already contained the *p27mt* target gene (Figure 1).

X-gal chemical staining

After Lovo cells were infected with Ad-LacZ, the adenovirus-mediated gene transfer rate was evaluated by X-gal staining. The results showed that the infection efficiency could reach 100% when MOI was larger than 50, which indicated that recombinant adenovirus could effectively transfer the gene to Lovo cells *in vitro* (Figure 2).

The expression of p27 protein was evaluated after Lovo cells were infected with human mutant p27 recombinant adenovirus in vitro

After Lovo cells were infected with Ad-p27mt (MOI 50) for 24 h, these cells were collected and lysed using 1 × SDS × PAGE cell lysis solution. After boiling at 100℃ for 5 min, the cells were centrifuged. The supernatant was collected and the protein was detected by the TMB system Western blotting kit (KPL, USA). After staining with TMB stain, a high expression of 27 KD protein was observed in the Ad-p27mt group while only slight expression (endogenous expression) was observed in the Ad-LacZ group and the normal control group. This showed that the *p27mt* recombinant adenovirus constructed in the present study could express *p27mt* gene in Lovo cells and the protein could also be expressed at a high level in Lovo cells (Figure 3).

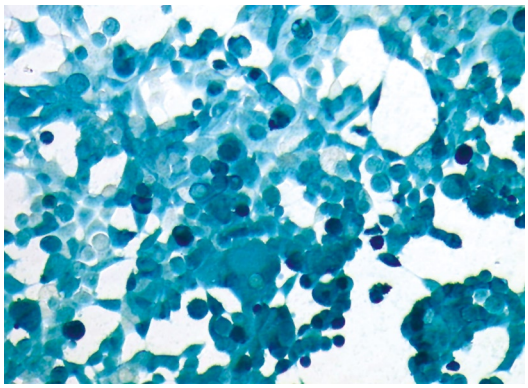

Figure 2 X-gal chemical staining detected the infection efficiency of Ad-p27mt (MOI 50).

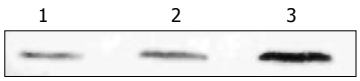

Figure 3 Western blotting of expressed p27 protein. 1: Non-infected Lovo cells; 2: Ad-lacZ infected Lovo cells; 3: Ad-p27mt infected Lovo cells.

Apoptosis of colorectal cancer cells induced by Ad-p27mt

After Lovo cells were treated with Ad-p27mt, Ad-LacZ and without virus for 24 h, apoptosis was observed by flow cytometry and was repeated six times. The average value of hypodiploid cells was: 41.0%, 4.67% and 1.96%, respectively. After statistical analysis, there was a significant difference among the three groups, ($P < 0.01$) (Figure 4).

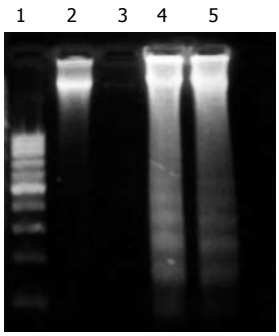

Figure 5 Determination of cell apoptosis by DNA fragment analysis. 1: Marker; 2: Blank group; 3: Ad-lacZ group; 4, 5: Ad-p27mt group.

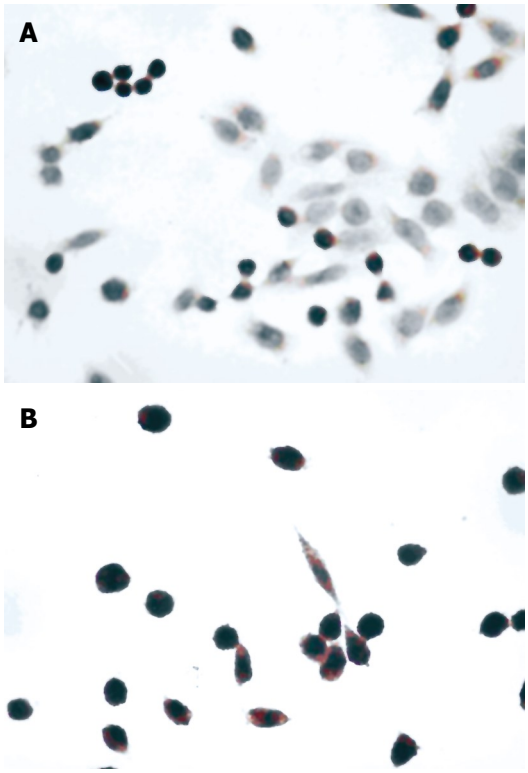

Figure 6 Detection of cell apoptosis by the TUNEL method. A: Blank group; B: Ad-p27mt.

Detection of DNA fragments

The results of DNA electrophoresis showed that the gene bands were intact in the Ad-LacZ and normal control group, while there were obvious 180-200 bp diploid "trapezia" bands in the Ad-p27mt infected group, which was in concordance with the characteristic changes of apoptosis (Figure 5).

Detection of cell apoptosis by the TUNEL method

The nuclei of apoptotic cells were dark stained, the cytoplasm was concentrated and the cells had shrunk. The AI of the Ad-p27mt and the control group were (82.6% ± 3.2%) and (5.0% ± 3.5%), respectively and showed a significant difference ($P < 0.05$). This demonstrated that Ad-p27mt could obviously induce apoptosis in colorectal cancer cells (Figure 6).

Table 1 The effect of Ad-p27mt on the cell cycle of Lovo cells (mean ± SD)

Group	G_0/G_1	S	G_2/M
Blank group	25.29 ± 1.04	41.12 ± 1.19	33.34 ± 1.55
Ad-LacZ group	27.57 ± 0.45[b]	38.21 ± 0.44[b]	34.22 ± 0.92[b]
Ad-p27mt group	77.96 ± 2.20[d]	8.98 ± 0.17[d]	13.06 ± 2.35[d]

Hypodiploid cells were not included ([b]$P < 0.01$ *vs* Ad-LacZ group, [d]$P < 0.01$ *vs* Blank group).

The effect of exogenous p27mt on the cell cycle (Table 1)

The cell cycle of Lovo cells after the various treatments are shown in Table 1. It can be seen that in the Ad-LacZ and blank control groups, the number of cells in the G_0/G_1 phase decreased gradually and the percentage of cells in the S phase increased, which indicated that the transition time of the cell cycle was shortened and cell proliferation was active. However, the percentage of cells in the G_0/G_1 phase decreased and the percentage of cells in the S phase increased and the cell cycle was arrested in the G_0/G_1 phase in the Ad-p27mt group, which was significantly different from the blank and Ad-LacZ groups ($P < 0.01$).

DISCUSSION

Currently, functional reconstruction of anti-oncogenes is a reasonable strategy for tumor gene therapy. p27 protein degradation is mainly caused by phosphorylation of the 187th threonine of *p27* which is mediated by ubiquitin[15-17]. Park *et al*[18,19] replaced the 187th threonine and the 188th praline of the wild-type *p27* with methionine and isoleucine, respectively, by which the target phosphorylation site of CDK would be protected from phosphorylation, and thus the mutant *p27* was prepared. These authors constructed a replication-deficient recombinant adenovirus which carried *p27mt* and *p27wt*, respectively and proved that the inhibition and apoptotic effects in cancer cells was more obvious in the mutant *p27 (p27mt)* than in the wild-type *p27 (p27wt)*.

This study constructed a replication-deficient recombinant adenovirus which successfully carried *p27mt* (Ad-p27mt). Ad-p27mt was then transfected into Lovo cells. When the MOI ⩾ 50, the infection efficiency was 100%. Using Western blotting, high expression of *p27* was observed, and using FACS, the rate of apoptosis was up to 41.0% in the Ad-p27mt group which was significantly different compared to the control group ($P < 0.01$). DNA analysis showed a 180-200 bp DNA ladder, and using the TUNEL technique, the apoptotic index was sharply upregulated to 82.6% which was significantly different compared to the control group ($P < 0.05$). These results showed that *p27mt* is an important gene and is related to the incidence of colorectal carcinoma. The downregulation of *p27* may be the main cause of cell differentiation dysfunction and apoptosis dysfunction. Mutant *p27* promoted the expression of *p27* in Lovo cells, which led to apoptosis in tumor cells. This may be a potential new therapy for colorectal carcinoma.

The concentration of cyclin/CDK is the key factor for cells passing the G_1-S threshold. Cell cycle analysis showed that the cleavage of tumor cells was stopped at the G_1 stage by *p27mt* suppressing the activity of the cyclin/CDK kinase. Hurteau *et al*[20] reported that the accumulation of *p27* played a role in the cell cycle arrest mechanism at the initiation of cell differentiation. A related report[21] in China showed that the *p27* gene suppressed DNA replication and protein synthesis and reduced cell mitosis division and inhibited cell generation.

In our study, apoptosis of colorectal carcinoma cells was successfully induced by the application of the mutant gene p27. The apoptosis rate was significantly higher than that of wild-type p27 reported in our previous study[21], which serves as a very useful experimental support for tumor suppression function reconstruction in the gene therapy of colorectal carcinoma. The efficacy of this method *in vivo* and the mechanism of apoptosis should be determined in future studies.

We thank Dr. Xiao-Jun Yang for his excellent technical assistance.

COMMENTS

Background

Along with the improvement in living standards and a change in diet, there has been a gradual increase in the incidence of colorectal cancer in China. However, no effective therapeutic modalities are available for this condition. Gene therapy for the restoration of *p27* expression is a promising therapy. A mutant type *p27* gene, with a mutation of Thr-187/Pro-188 to Met-187/Ile-188, can inhibit degradation of p27 protein by the ubiquitin-mediated pathway. Inhibition of mutant *p27* (*p27mt*) in tumor cells was stronger than that in wild-type *p27* (*p27wt*), which was demonstrated by cells arresting in the G_0/G_1 phase. In addition, the apoptosis promoting activity of *p27mt* was also stronger. However, few studies on the *p27* gene in colorectal cancer have been reported.

Research frontiers

p27, as a cyclin-dependent kinase inhibitor, tumor suppressor gene, and promoter of apoptosis, has been widely investigated in malignancies such as skin, liver, bladder, thyroid, breast, prostate and endometrium cancer. However, the apoptotic bioactivity of *p27mt* has not been studied in colorectal cancer.

Innovations and breakthroughs

The study indicates that Ad-*p27mt* has a strong apoptosis inducing bioactivity as well as a cell cycle inhibitory effect in colorectal cancer *in vitro*.

Peer review

This is a nice article. This *in vitro* effect of *p27mt* should be examined *in vivo* to determine the safety and efficacy.

Abstract

AIM: To investigate the protein and mRNA expression of semaphorin 5A and its receptor plexin B3 in gastric carcinoma and explore its role in the invasion and metastasis of gastric carcinoma.

METHODS: Expression of semaphorin 5A and its receptor plexin B3 in 48 samples of primary gastric carcinoma, its corresponding non-neoplastic mucosa, and matched regional lymph node metastasis was assayed by reverse transcription-polymerase chain reaction (RT-PCR), real-time RT-PCR and Western blotting.

RESULTS: The protein and mRNA expression of semaphorin 5A and its receptor plexin B3 increased gradually in non-neoplastic mucosa, primary gastric carcinoma and lymph node metastasis ($P < 0.05$). Moreover, the expression of semaphorin 5A was closely correlated with that of plexin B3.

CONCLUSION: Semaphorin 5A and its receptor plexin B3 play an important role in the invasion and metastasis of gastric carcinoma.

Key words: Semaphorin 5A; Plexin B3; Gastric carcinoma; Invasion; Metastasis

INTRODUCTION

Gastric cancer is the leading cause of cancer-related death in some Asian countries including China and Japan. Despite the advances in treatment and research efforts over the past few decades, the outcome of gastric cancer remains poor. The overall 5-year survival rate of gastric cancer patients is 5%-15% in the United States and most other Western countries, largely because many gastric cancers are diagnosed at an advanced stage. The aggressive nature of human gastric carcinoma is related to a variety of intracellular events, including activation of various oncogenes, inactivation of tumor suppressor genes. Therefore, great attention has been given to endogenous factors of tumors, which appear to be responsible for tumor cell growth, progression, and invasion. Identification of such endogenous factors not only leads to a better understanding of the carcinogenesis and development of gastric cancer, but also provides new strategies for developing agents that specifically suppress this process.

Semaphorins are the products of a large family of genes currently containing more than 30 members, all of which share a conserved N-terminal domain called the "sema" domain, a segment of approximately 400-500 amino acids[1]. Based on sequence similarity and distinctive structural features, these genes have been grouped into eight subclasses[1-8], of which classes 3-7 are the products of vertebrate semaphorins. Plexins

are identified as the best characterized semaphorin receptors, which are segregated into four sub-families containing nine members. It has been shown that some vertebrate semaphorins belonging to classes 4-7 can bind directly to plexins and activate plexin-mediated signal transduction[2,3]. These semaphorins and plexins have been originally characterized as constituents of the complex regulatory system responsible for the guidance of axons during the development of the central nervous system[4,5]. However, a growing body of evidence suggests that certain semaphorins, through interacting with its receptors, play a regulatory role in the occurrence and development of tumor[6-9]. Semaphorin 5A is a member of class 5 semaphorins. Plexin B3, belonging to class B plexin subfamily, is a receptor for semaphorin 5A[10]. However, it is unclear whether semaphorin 5A exerts certain biological functions in the progression of human cancers including gastric carcinoma through plexin B3.

In the present study, we investigated the protein and mRNA expression of semaphorin 5A, plexin B3 in primary gastric carcinoma as well as in its corresponding non-neoplastic mucosa and matched regional lymph node metastasis, and preliminarily analyzed their relation with the invasion and metastasis of gastric cancer.

MATERIALS AND METHODS

Patients and specimens

Forty-eight advanced gastric adenocarcinoma (TNM stage Ⅲ-Ⅳ) patients (28 male and 20 female) with lymph node metastasis diagnosed by postoperative pathology were investigated in this study. Their mean age was 58.7 years (range 45-68 years). The patients received neither chemotherapy nor radiation therapy prior to tumor resection and provided their consent for use of tumor tissue. Tissue blocks of non-neoplastic mucosa (> 5 cm away from the edge of tumor), primary tumor and its corresponding metastatic lymph nodes were obtained within 30 min after they were removed from the patients. Each block was cut into two pieces, one for routine pathologic diagnosis and the other for molecular analysis. Samples were frozen in liquid nitrogen immediately and stored at -260℃ until use.

Reverse transcription-polymerase chain reaction (RT-PCR)

Tissues were lysed using Trizol reagent (Invitrogen, Carlsbad, CA), and total RNA was isolated using chloroform and isopropyl alcohol according to the manufacturer's instructions. After RNA was quantified, 1-5 μg of RNA was annealed to Oligo (dT) at 65℃ for 5 min and cooled at room temperature. Using a proSTAR first strand RT-PCR kit (Stratagene, La Jolla, CA, USA), reverse transcriptase and dNTPs were added to the RNA-Oligo (dT) mixture and the reaction was performed at 42℃ for 1 h. Each single-strand cDNA was used for subsequent PCR amplification of semaphorin 5A, plexin B3 and β-actin with the latter used as a quantitative control. PCR was carried out in a reaction volume of 25 μL under the following conditions: an initial denaturation at 95℃ for 5 min, followed by 30 cycles at 94℃ for 30 s, at 55℃ for 50 s, at 72℃ for 40 s, and a final extension at 72℃ for 5 min on an authorized thermal cycler. The primer sequences used amplification are 5'-CTCAGTCGCTGTGAGCG TTAT-3' and 5'-CAGATGTTGGACCGCCAAATA-3' for semaphorin 5A, 5'-TCTGCTGCTGCGGTTCTG-3' and 5'-CCTCTCCACCATCTGCTTGTAG-3' for plexin B3, 5'-CGCACCACTGGCATTGTCAT-3' and 5'-TTC TCCTTGATGTCACGCAC-3' for β-actin, respectively. The primer sequences were synthesized by Beijing Genomics Institute (China). The PCR products were resolved in 1.5 % agarose gels and visualized by staining with ethidium bromide. To quantify the PCR products, bands representing the amplified products were analyzed by Quantity One Analysis Software (BIO-RAD Co., USA).

Real-time PCR

The reaction mixture volume was made up to 50 μL. Quantitative RT-PCR was performed using SYBR GreenER qPCR SuperMix reagents (Invitrogen) and a Bio-Rad iCycler. Relative transcript quantities were calculated using the ΔΔCt method with β-actin as the endogenous reference gene amplified from the samples. PCR conditions were as follows: an initial melting step at 95℃ for 1 min followed by 35 cycles at 95℃ for 90 s, at 60℃ for 30 s, at 72℃ for 30 s, and a final extension at 72℃ for 10 min. The primers used for RT-PCR are 5'-GGTACTGTTCTAGCGACGGC-3' and 5'-ATACTTGGGTTCGGGGTTGT-3' for semaphorin 5A, 5'-AAAGCCACCGAGGAGCCAGAA-3' and 5'-ACTTGACGGCGATGGGGATG-3' for plexin B3, 5'-TGACGTGGACATCCGCAAAG-3' and 5'-CTGGA AGGTGGACAGCGAGG-3' for β-actin, respectively.

Western blotting

Frozen specimens were homogenized in a lysis buffer [50 mmol/L Tris-HCl (pH 7.5), 150 mmol/L NaCl, 1 mmol/L EDTA, 0.25 % sodium deoxycholate, 1 % Triton X-100, 0.1 % sodium dodecyl sulfate (SDS), 1 mmol/L NaF, 1 mmol/L Na_3VO_4], and protease inhibitors (10 mg/L aprotinin and 1 mmol/L phenylmethylsulfonyl fluoride) were added to obtain total protein. An equal amount of protein, quantified with a bicinchoninic acid protein assay kit (Pierce Biotechnology, Rockford, IL, USA), was subjected to 10% SDS-polyacrylamide gel electrophoresis, and transferred to polyvinylidene difluoride membrane. The membranes were blocked with 5 % nonfat milk in Tris buffered saline with Tween 20 [TBST, 50 mmol/L Tris-HCl (pH 7.6), 150 mmol/L NaCl, 0.1 % Tween 20] for 2 h at room temperature, and subsequently incubated with primary anti-rabbit polyclonal antibody (anti-semaphorin 5A diluted at 1:400 and plexin B3 diluted at 1:500 and β-actin diluted at 1:2000 were purchased from Santa Cruz Biotechnology) in a blocking buffer at 4℃ overnight. Following a

A: A representative result (left panel) and summary (right panel) of semaphorin 5A and plexin B3 expression in 48 samples of primary gastric carcinoma (Ca) and its corresponding nonneoplastic mucosa (M) as well as matched regional lymph node metastasis (L) examined by RT-PCR. The expression of β-actin was used as an internal control; B: Real time RT-PCR for relative expression levels of semaphorin 5A and plexin B3 in 48 samples of primary gastric carcinoma (Ca) and its corresponding nonneoplastic mucosa (M) as well as matched regional lymph node metastasis (L).

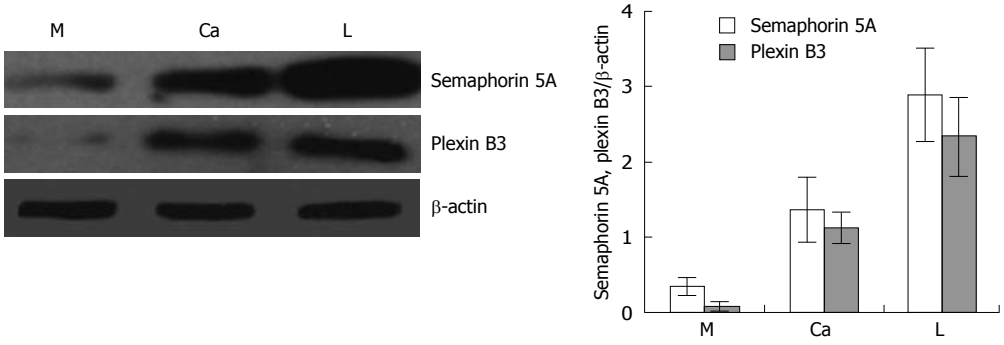

Figure 2 A representative result (left panel) and summary (right panel) of semaphorin 5A and plexin B3 protein expression in 48 samples of primary gastric carcinoma (Ca) and its corresponding nonneoplastic mucosa (M) as well as matched regional lymph node metastasis (L) examined by Western blotting. The expression of β-actin was used as an internal control.

washing with TBST, the membranes were incubated with horseradish peroxidase-conjugated rabbit anti-mouse secondary antibody (1:1000, Dako, Glostrup, Denmark) for 2 h at room temperature. The membranes were washed with TBST, and protein bands were visualized with enhanced chemiluminescence according to its manufacturer's instructions (KPL, Gaithersburg, USA). β-actin bands were taken as a loading control. Protein quantity was analyzed using the UTHSCSA Image Tool 3.0. Target protein expression was evaluated using the relative intensity ratio of target protein/loading control.

Statistical analysis

Results were expressed as mean ± SD. Statistical differences between different groups were assessed by ANOVA using SPSS12.0 statistical software. $P < 0.05$ was considered statistically significant.

RESULTS

Semaphorin 5A and plexin B3 mRNA expression

To infer the status of semaphorin 5A and plexin B3 in the invasion and metastasis of gastric carcinogenesis, we evaluated the mRNA expression of semaphorin 5A and plexin B3 using semi-quantitative RT-PCR in 48 samples of primary gastric carcinoma tissue and its corresponding non-neoplastic mucosa as well as matched regional lymph node metastasis. A representative result of RT-PCR for semaphorin 5A and plexin B3 expression is shown in Figure 1A. The expression of semaphorin 5A and plexin B3 mRNA gradually increased in nonneoplastic mucosa, primary gastric carcinoma and lymph node metastasis ($P < 0.05$). Moreover, the expression of semaphorin 5A was closely correlated with that of plexin B3. To confirm the RT-PCR result of semaphorin 5A and plexin B3, we performed real-time RT-PCR analysis in 20 samples of cDNAs from primary gastric cancer and non-neoplastic mucosa as well as matched regional lymph node metastasis. Similar results were observed (Figure 1B).

Semaphorin 5A and plexin B3 protein expression

The expression levels of semaphorin 5A, and plexin B3 were also measured by Western blotting in primary gastric carcinoma tissue and its corresponding nonneoplastic mucosa as well as matched regional lymph node metastasis. A representative result of Western blotting for the expression of semaphorin 5A and plexin B3 is shown in Figure 2. After normalization with β-actin, the expression of Semaphorin 5A and plexin B3 protein gradually increased in non-neoplastic mucosa, primary gastric carcinoma and lymph node metastasis ($P < 0.05$), which was consistent with the result from RT-PCR analysis.

DISCUSSION

Semaphorin 5A is a member of class 5 semaphorins which are anchored to cell membranes and characterized by seven type 1 thrombospondin repeats. Plexin B3,

belonging to class B plexin subfamily, was identified as a specific and functional receptor for semaphorin 5A. Semaphorin 5A and plexin B3 have been originally characterized as constituents of the complex regulatory system responsible for the wiring of neural networks during the development of the central nervous system, and subsequently found to participate in the activities outside of the nervous system such as migration of neural crest cells and heart development to name but a few examples[11,12]. However, very little is known about the expression and role of semaphorin 5A and plexin B3 in human cancers including gastric carcinoma. A random p-element insertion screen has been used to identify genes that modulate tumor progression and tumorigenicity in Drosophila study[13]. One of the genes identified in this screen is the Drosophila homologue of semaphorin 5C, with which semaphorin 5A shares a high sequence similarity[13]. In addition, experiments performed by Paolo Conrotto and co-workers revealed that semaphorin 5A, through plexin B3, stimulates the tyrosine kinase activity of Met and RON which has been shown to play a role in tumor progression[14,15]. Most importantly, there is cumulative evidence that certain semaphorins and their receptors implicated in axonal path finding in the developing nervous system are expressed in multiple types of cancer cells, modulate the behavior of cancer cells, promote tumor angiogenesis and progression by multiple mechanisms[16]. Taken together, these observations implicate that semaphorin 5A may play a role in the development and progression of human tumors by interacting with plexin B3.

To explore whether semaphorin 5A and plexin B3 are associated with the invasion and metastasis of gastric cancer and exert certain biological functions outside of the nervous system, we investigated the protein and mRNA expression of semaphorin 5A and plexin B3 in primary gastric carcinoma and its corresponding nonneoplastic mucosa as well as matched regional lymph node metastasis by RT-PCR and Western blotting assay. Our experimental results showed that the protein and mRNA expression level of semaphorin 5A was the lowest in normal gastric mucosa, moderate in primary gastric carcinoma, and the highest in lymph nodes with metastatic gastric carcinoma, respectively ($P < 0.05$). In contrast, plexin B3 and semaphorin 5A had a similar expression pattern, suggesting that the expression of plexin B3 is closely correlated with that of semaphorin 5A. These findings demonstrate that the expression of semaphorin 5A and its receptor plexin B3 increased gradually with gastric cancer procession, indicating that semaphorin 5A may play an important role in the invasion and metastasis of gastric carcinoma through plexin B3, displaying a novel expression and function of semaphorin 5A and plexin B3 outside of the nervous system. To our knowledge, this is the first report on the expression of semaphorin 5A and plexin B3 mRNA and protein in gastric carcinoma, and the functional role of semaphorin 5A and plexin B3 in the invasion and metastasis of gastric cancer.

In conclusion, semaphorin 5A and plexin B3 expression increases significantly with gastric carcinoma progression, and semaphorin 5A and plexin B3 may be involved in the processes of gastric cancer invasion and metastasis. Therefore, the novel expression and function of semaphorin 5A and plexin B3 outside of the nervous system not only add more knowledge about semaphorin 5A and plexin B3, but also shed some lights on the pathogenesis of gastric carcinoma, and probably represent a new therapeutic target for gastric carcinoma.

COMMENTS

Background

Gastric carcinoma is one of the most common malignant tumors in China. Invasion and metastasis are the main cause of cancer-related death. Therefore, it is necessary to investigate the mechanism underlying invasion and metastasis of malignant tumors. Semaphorin 5A and its receptor plexin B3 have been originally described in the nervous system, and are important in axon migration and proper central nervous system development. However, very little is known about the expression and role of semaphorin 5A and plexin B3 in human cancers including gastric carcinoma.

Research frontiers

Experiments were performed to study the expression of semaphorin 5A and plexin B3 in gastric carcinoma and its relation with tumor invasion and metastasis. This study showed that the expression of semaphorin 5A and plexin B3 increased gradually in non-neoplastic mucosa, primary gastric carcinoma, and lymph node metastasis, suggesting that the expression of semaphorin 5A and plexin B3 is closely correlated to the invasion and metastasis of gastric cancer.

Innovations and breakthroughs

This is the first report on the expression of semaphorin 5A and plexin B3 in gastric carcinoma, and the relation of semaphorin 5A and plexin B3 with the invasion and metastasis of gastric cancer.

Peer review

The authors studied the expression of semaphorin 5A and plexin B3 in gastric carcinoma and its relation with tumor invasion and metastasis, and showed that the expression level increased gradually in non-neoplastic mucosa, primary gastric carcinoma, and lymph node metastasis, and was positively related to tumor invasion and metastasis, which can be used in research of gastric carcinoma, and provide a new target for gastric carcinoma treatment.

Abstract

Heterotopic pancreas is a congenital anomaly characterized by ectopic pancreatic tissue. Treatment of heterotopic pancreas may include expectant observation, endoscopic resection or surgery. The aim of this report was to describe the technique of ligation-assisted endoscopic mucosal resection (EMR) for resection of heterotopic pancreas of the stomach. Two patients (both female, mean age 32 years) were referred for management of gastric subepithelial tumors. Endoscopic ultrasound in both disclosed small hypoechoic masses in the mucosa and submucosa. Band ligation-assisted EMR was performed in both cases without complications. Pathology from the resected tumors revealed heterotopic pancreas arising from the submucosa. Margins were free of pancreatic tissue. Ligation-assisted EMR is technically feasible and may be considered for the endoscopic management of heterotopic pancreas.

INTRODUCTION

Heterotopic pancreas (HP), also known as pancreatic rest, was first described in 1727 when it was found in an ileal diverticulum[1]. It refers to an uncommon congenital anomaly characterized by the presence of ectopic pancreatic tissue far from the pancreas and without any anatomical or vascular communication with this organ. It occurs in 2% of the general population[2] and is more common in males than females[3]. HP may occur throughout the gastrointestinal tract but has a proclivity for involving the stomach and proximal small intestine. Most affected patients are asymptomatic although a minority may present with a variety of symptoms, most common being epigastric pain[2]. Options for treatment for heterotopic pancreas in the stomach include surgery[2-4], endoscopic resection[5-8] or conservative management. This report describes the first two cases of HP treated with band ligation-assisted endoscopic mucosal resection (EMR).

CASE REPORT

Case 1

A 49-year-old white female presented to her primary gastroenterologist with abdominal bloating and constipation. She was report anemic and found to have heme-occult positive stools. Work-up included a computer tomography (CT) scan of the abdomen and pelvis, colonoscopy and esophagogastroduodenoscopy (EGD). CT revealed small liver cysts but no other abnormalities. Colonoscopy demonstrated two small polyps that were removed. EGD showed a small, firm, umbilicated subepithelial antral mass. The mucosa overlying the mass was biopsied and showed chronic gastritis with no submucosal tissue present. The patient was referred to our endoscopy unit for upper endoscopic ultrasonography (EUS) of the antral lesion.

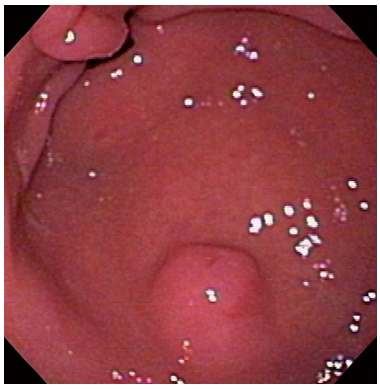

Figure 1 Endoscopic view of heterotopic pancreas of the stomach showing a medium-sized subepithelial nodule with central umbilication and normal overlying mucosa. The pylorus is visible distally.

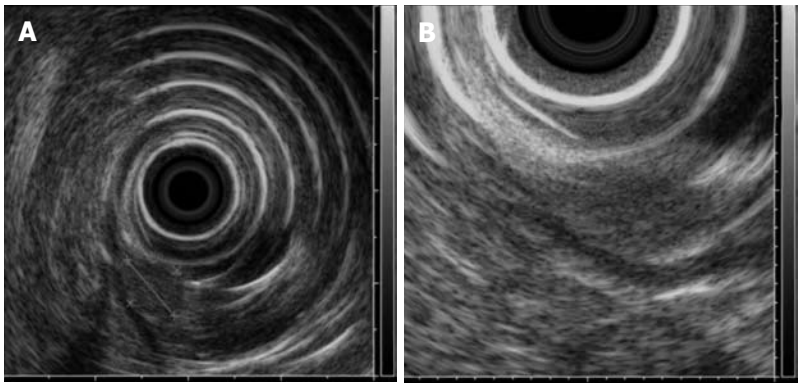

Figure 2 Radial EUS images. A pancreatic rest showing an 8 mm × 6 mm hypoechoic subepithelial mass appearing to involve the mucosa (A) and submucosa (B). The tumor was confirmed as submucosal in origin after resection without involvement of the mucosa.

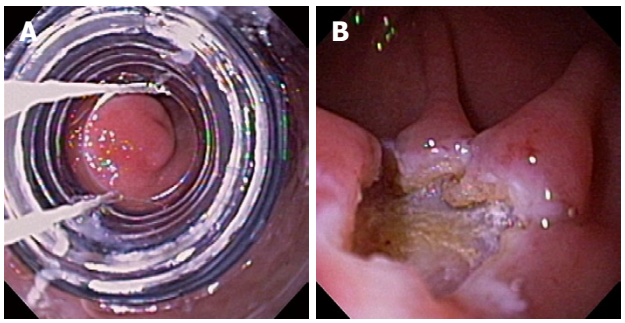

Figure 3 Ligation-assisted EMR of pancreatic rest. The banding device was positioned over the target lesion (A), suction was applied and a band was deployed. The lesion was then resected using electrocautery snare. Residual ulcer is shown (B).

She denied abdominal pain, nausea, vomiting, overt gastrointestinal bleeding or weight loss. Her physical examination revealed a healthy middle-aged white female in no apparent distress. Her abdominal examination was normal without tenderness. Prior to EUS, she was informed that the lesion most likely represented a pancreatic rest and that if suspected diagnosis was confirmed, then conservative management would be reasonable. Nevertheless, the patient expressed her preference for resection of the mass if possible. Informed consent was obtained and sedation was performed using a combination of intravenous midazolam and propofol. Initial EGD confirmed a single medium-sized subepithelial nodule along the greater curvature of the gastric antrum (Figure 1). The patient was then placed into the right lateral decubitus position and water was instilled into the distal stomach. Radial endosonography (GF-UE160-AL5; Olympus America Inc., Center Valley PA; USA) revealed a well-defined hypoechoic lesion from the deep mucosa/submucosa that measured 8 mm × 6 mm in maximal diameter (Figure 2A and B). There was no evidence of peritumoral adenopathy. Ligator-assisted EMR (Duette Multi-Band Mucosectomy; Cook Medical Inc., Winston-Salem, NC; USA) of the tumor was successfully performed using one band (Figure 3). The residual ulcer was closed using three endoclips (Resolution Clip; Boston Scientific Inc., Natick MA; USA). There were no complications. Surgical pathology from the resected specimen revealed heterotopic pancreatic tissue confined to the submucosa (Figure 4).

Case 2

A 15-year-old white female presented to her primary gastroenterologist with left upper quadrant abdominal pain. EGD showed a small subepithelial antral mass. The mucosa overlying the tumor was normal and biopsies showed only mild gastritis. The patient was then referred for an upper EUS. She denied nausea, vomiting, overt gastrointestinal bleeding or weight loss. Physical examination including abdominal examination was normal. Prior to EUS, review of endoscopic pictures from outside EGD suggested a pancreatic rest. Information was provided to the patient and parents that if suspected diagnosis was confirmed, then conservative management would be reasonable. Nevertheless, the patient and parents both expressed preference for tumor resection, if possible. Initial EGD confirmed a single medium-sized subepithelial nodule along the greater curvature of the prepyloric stomach (Figure 5). The patient was then placed into the right lateral decubitus position and water was instilled into the distal stomach. Radial endosonography revealed a well-defined 9 mm × 7 mm hypoechoic lesion from the deep mucosa and submucosa (Figure 6). The outer endosonographic borders were well defined. Ligator-assisted EMR of the tumor was successfully performed using one band (Figure 7). There were no complications. The resected specimen was submitted for pathologic examination, which revealed the presence of HP tissue confined to the submucosa with negative margins.

DISCUSSION

Heterotopic pancreas (HP), also known as pancreatic rest, is most often detected as an incidental finding during routine upper endoscopy. The typical endoscopic appearance in the stomach is as a firm round or oval umbilicated subepithelial nodule along the greater curvature situated

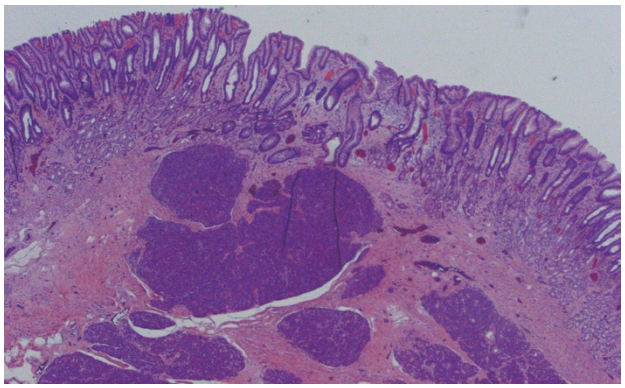

Figure 4 Photomicrograph of the resection specimen showing pancreatic tissue within the gastric submucosa (HE, × 10).

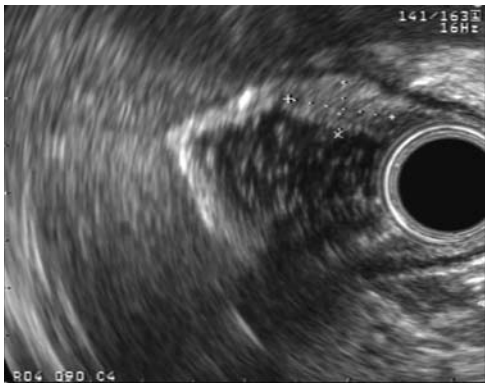

Figure 6 Radial EUS images of a pancreatic rest showing a 9 mm × 7 mm hypoechoic subepithelial mass appearing to involve the deep mucosa and submucosa. The tumor was confirmed as submucosal in origin after resection without involvement of the mucosa.

Figure 7 Ligation-assisted EMR of pancreatic rest.

several centimeters proximal to the pylorus. Most patients are asymptomatic, but symptoms may rarely occur due to the irritative effect of the hormones and enzymes secreted by the HP at a particular site[3]. Histologically, pancreatic rests vary from resembling the normal pancreas (acini, ducts and islets of Langerhans) to widely separated ducts within a muscular stroma[4,9]. Hence, complications in HP resemble those seen with the pancreas itself including acute pancreatitis[10,11], pancreatic cancer[12], cystic degeneration[13] and islet cell tumors[14]. Other rare reported complications include gastrointestinal bleeding[15], gastric outlet obstruction[16], jaundice[13] and abscess formation[10]. Asymptomatic HP can generally be followed expectantly with treatment reserved for patients who are symptomatic, have enlarging lesions or to ensure diagnostic certainty. Both pancreatic rests in these two patients were incidentally discovered during EGD for investigation of anemia and left upper quadrant pain, respectively. Nevertheless, removal was requested by both patients to ensure the suspected pre-procedural diagnosis.

The diagnosis of HP is not straightforward. Although umbilication is characteristic, the specificity of this endoscopic finding for HP remains unknown. The typical EUS image of a pancreatic rest in the stomach is a hypoechoic, heterogeneous submucosal mass, although the muscularis propria and mucosa may be occasionally involved. A ductal structure may also be discernible within the lesion. Although these endosonographic findings are suggestive of HP, the accuracy of EUS for the diagnosis of subepithelial tumors (other than gastrointestinal stromal tumors such as HP) is limited[7,17]. This fact is illustrated in our cases as the mucosa was incorrectly predicted to be involved in both patients.

Since HP is usually a submucosal tumor, pinch mucosal biopsies are invariably non-diagnostic. Nevertheless, Shalaby *et al*[18] reported a case of esophageal HP diagnosed with biopsies obtained with a jumbo forceps. Teixeira[19] has described the use of ethanol injection to create an artificial ulcer that then facilitated the removal of sufficient submucosal tissue to establish the diagnosis of HP. Goto *et al*[20] reported a case of esophageal HP diagnosed by EUS-guided FNA. Historically, the diagnosis of HP was often made by histological examination of surgical specimens. Some authors believe that it is difficult to obtain a definitive diagnosis of HP preoperatively[21] and therefore advocate surgical resection[3].

Although there are some reports of surgical resection of HP[2-4], EMR may be an attractive, less invasive option for resection of accessible lesions. However, there have only been a few reports[5-8] that describe the use EMR for HP resection (Table 1). Two groups have described the use of cap-assisted EMR[5,6]. The "inject, lift and cut", or "strip biopsy" EMR technique[7] was reported for the resection of 6 HP submucosal masses. Finally, Sun *et al*[8]

Table 1 Literature summary of HP cases treated with EMR

Author	Yr	Number of tumors	Mean tumor size (mm)	Tumor location	EMR technique	Follow-up[1] (mo)

EMR: Endoscopic mucosal resection; NR: Not reported. [1]All cases with reported follow-up were without any recurrence.

studied the use of EUS-guided injection and the "inject and cut" EMR technique for the resection of 16 upper gastrointestinal submucosal tumors, two of which were gastric HP tumors. Ligation-assisted EMR may be more operator-friendly than the other EMR techniques. It requires neither saline injection nor snare prepositioning, and the concept of tissue capture is similar to the familiar variceal ligation technique. The current series, to our knowledge, is the first to describe the use of ligation-assisted EMR for gastric HP. This technique permitted a histologic confirmation of the suspected diagnosis and in both cases achieved a margin-negative resection without complication.

Abstract

Meckel's diverticulum (MD) is the most frequent congenital abnormality of the small bowel and it is often difficult to diagnose. It is usually asymptomatic but approximately 4% are symptomatic with complications such as bleeding, intestinal obstruction, and inflammation. The authors report a case of a 7-year-old boy with a one-year history of recurrent periumbilical colicky pain with associated alimentary vomiting, symptoms erroneously related to a cyclic vomiting syndrome but not to MD. The clinical features and the differential diagnostic methods employed for diagnosis of MD are discussed.

Key words: Meckel diverticulum; Abdominal pain; Recurrent subocclusive episodes, Diagnostic imaging

Peer reviewer: Dr. Lee Bouwman, Leiden University Medical Centre, Department of surgery, Albinusdreef 2, PO Box 9600, 230 RC Leiden, The Netherlands

INTRODUCTION

Meckel's diverticulum (MD) occurs in about 2% of the population, making it the most prevalent congenital abnormality of the gastrointestinal tract. It can be asymptomatic or mimic common abdominal disorders. We report a case of a child with an intraoperative diagnosis of MD, with a long history of recurrent abdominal pain and vomiting misdiagnosed as a cyclic vomiting syndrome.

CASE REPORT

A 7-year-old boy was referred with a one-year history of periumbilical colicky pain with associated alimentary vomiting. The frequency of the episodes increased from one per month to weekly and then daily vomiting. The pain usually spontaneously disappeared within a few hours. During the weeks before our visit, the painful episodes lasted longer and were reported to occur also at night. The child lost one kilogram in one month. No diarrhoea was reported, the boy was rather constipated. Previous medical investigations, abdominal ultrasonography and plain abdominal film were negative.

Neither abdominal tenderness, nor liver or spleen enlargement, nor abdominal masses were identified at palpation. Intestinal bacterial overgrowth and celiac disease were excluded by laboratory tests. Complete blood cell count, electrolytes, glycemia, blood ammonia, renal and hepatic function, pancreatic enzymes, C-reactive protein, erythrocyte sedimentation rate, and gamma globulins were within normal ranges.

A plain abdominal film was unremarkable, and a small bowel enema indicated normal transit and normal appearance of the intestinal loops. An abdominal ultrasound (US) revealed a supravesical anechoic mass of about 4 cm × 3 cm × 2 cm, with fluid inside (Figure 1).

Pelvic magnetic resonance imaging (MRI) confirmed the presence of the 4 cm mass, located above and behind the bladder, slightly to the right of the midline, with liquid content (Figure 2).

With the suspicion of a mesenteric cyst or an intestinal duplication, the child underwent an exploratory laparoscopy. The intraoperative macroscopic finding was that of MD. Diagnosis was confirmed by histological features.

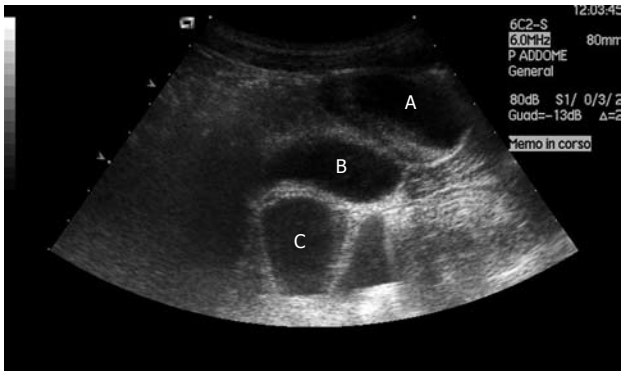

Figure 1 Abdominal ultrasound: anechoic oval supravesical lesion with fluid-fluid level (A); bladder (B); bowel (C).

Figure 2 Abdominal MRI; T1 weighted sequence with fat-suppression (SPIR) after contrast medium, saggital plane: hypointense oval supravesical lesion with air-fluid level and thin enhanced wall (A); bladder (B); rectum (C).

DISCUSSION

MD is the most common congenital anomaly of the gastrointestinal tract. The "rule of two" can remind us of some of its main features: occurs in 2% of the population; usually discovered before 2 years of age; occurs within 2 feet of the ileocecal valve; is 2 inches long and 2 cm in diameter[1]. It is the result of an incomplete atrophy of the omphalomesenteric duct. The location of the diverticulum is on the antimesenteric border of the small intestine, most frequently between 30 cm and 90 cm from the ileocecal valve; there can be a fibrous connection to the umbilicus, as the remnant of the partially obliterated vitelline duct.

MD is a true diverticulum, composed of all layers of the intestinal wall, and is lined by normal small intestine epithelium. Gastric heterotopias can be found in roughly 50% of cases, and pancreatic, duodenal, colonic, or biliary mucosa have rarely been reported.

MD can be silent all through a lifetime: clinical symptoms arise from complications (MD carriers have a 4% lifetime risk of developing a complication)[2]. Hemorrhage is the result of peptic ulceration of the ileal mucosa next to an acid-producing gastric mucosal heterotopia: the presentation of the blood loss varies from recurrent minimal intestinal bleeding, to a massive, shock-producing hemorrhage, and it is usually painless. Diverticulitis can mimic an acute appendicitis: pain is frequently localized in the midline or slightly to the right and, as in appendiceal disease, inflammation can progress until perforation. The diverticulum can invert into the ileal lumen and become the starting point of an ileo-ileal or ileo-ileo-colic intussusception: symptoms can not be discriminated from those ascribed to idiopathic intussusception, even though the onset of the former is described to occur at an earlier age. A further mechanism by which MD can produce intestinal obstruction is to turn around a fibrous remnant: symptoms may vary from intermittent recurrent subocclusive episodes, as in our patient, to frank occlusion with strangulation features if a complete volvulus occurs[3]. "Littre hernia" occurs when a MD protrudes into a potential abdominal opening such as umbilical, inguinal, or femoral, and can be accompanied in some cases by entrapment, inflammation, and necrosis[1]. Tumors are reported in 0.5% to 3% of symptomatic diverticula in adulthood (carcinomas in one third of the cases)[3].

Preoperative diagnosis of a complicated MD can be challenging and often difficult to establish because clinical symptoms and imaging features overlap with those of other disorders causing acute abdominal pain or gastrointestinal bleeding[4].

Initially, our case was misdiagnosed as a cyclic vomiting syndrome and a functional abdominal pain, since neither inflammatory nor bleeding clinical features were present, and laboratory tests were substantially within normal ranges. If any bleeding episode had been reported, a 99mTc-pertechnetate scintigraphy would have been indicated: the principle is that a bleeding diverticulum consists of ulcerated ectopic gastric mucosa that can be revealed with 99mTc-pertechnetate. This concentrates in gastric tissue leading to a reported sensitivity of between 60% and 80%[5].

The progressive worsening of painful episodes, however, prompted us to exclude causes of pain and vomiting requiring surgery, such as intestinal malrotation, which was ruled out by a normal small bowel enema. It is reported in the literature that enteroclysis may be of help in detecting MD but in our case the diverticular image was missed[6].

The US findings of a cyst supported the suspicion of a surgery-indicated cause for the painful episodes, but other gut malformations such as mesenteric cysts or enteric duplications, both of which can present with subocclusive symptoms, were taken into account in the differential diagnoses of our child. US and computed tomography are reported in the literature to be valuable radiological investigations in MD patients without the classical history of painless hemorrhage[7,8].

Complicated MD has a spectrum of radiological features which may help in the preoperative investigations, but are not always diagnostic[7-9]. Our rationale in choosing MRI as a second-line radiological examination lay in the fact that we needed a better anatomical definition of what we suspected was a pelvic mass, without further irradiation of the child: there is no evidence for the use of MRI to detect MD in the literature. Final diagnosis is almost always done at surgery: exploratory laparoscopy is recommended because it affords the possibility of simultaneous surgical resection, which is the definitive cure of a symptomatic MD[10].

In conclusion, Although MD is the most prevalent congenital abnormality of the gastrointestinal tract, it is often difficult to diagnose. The diagnosis of MD should be considered in children with intestinal bleeding, unexplained recurrent abdominal pain, and nausea and vomiting suggestive of cyclic vomiting syndrome.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Articles: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; (13) Guidelines: To introduce Consensuses and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice in gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words). Available from:http://www.wjgnet.com/wjg/help/8.doc

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/14.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc*.
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.
Biology: *H pylori*, *E coli*, *etc*.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/10.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/9.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

INTRODUCTION

World Journal of Gastroenterology is an international, open-access, peer-reviewed, and multidisciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

Abstract

The classic view on the pathogenesis of drug-induced liver injury is that the so-called parent compounds are made hepatotoxic by metabolism (formation of neo-substances that react abnormally), mainly by cytochromes P-450 (CYP), with further pathways, such as mitochondrial dysfunction and apoptosis, also playing a role. Risk factors for drug-induced liver injury include concomitant hepatic diseases, age and genetic polymorphisms of CYP. However, some susceptibility can today be predicted before drug administration, working on the common substrate, by phenotyping and genotyping studies and by taking in consideration patients' health status. Physicians should always think of this adverse effect in the absence of other clear hepatic disease. Ethical and legal problems towards operators in the health care system are always matters to consider.

Key words: Drug-induced liver injury; Cytochrome P-450; Drug metabolism; Pharmacogenomics; Herbal remedies

INTRODUCTION

Drug metabolism is the major determinant of drug clearance and the factor most frequently responsible for inter-individual differences in drug pharmacokinetics. Most adverse hepatic reactions require metabolism of the drug to form reactive metabolites and free radicals (indirect toxicity), that subsequently lead to fatal insults, sensitization to the lethal effects of the innate immune system, or haptenization eliciting an immunoallergic response of the adaptive immune system. Besides licensed drugs, herbal and natural supplements are recognized as causing hepatotoxicity with increasing frequency as patients turn more and more to alternative medicine[1].

Many environmental and developmental factors can interact with each other and with genetic factors to affect drug response and the metabolic activation or inactivation of drugs generally used in medical practice.

Oxidation, reduction and hydrolysis are the main pathways along drug metabolism before excretion. The most important enzyme system of phase I metabolism is the cytochrome P-450 (CYP) system, a microsomal superfamily of isozymes that catalyze the oxidation of many drugs. The electrons are supplied by NADPH/CYP reductase, a flavoprotein that transfers electrons from NADPH (the reduced form of nicotinamideadenine dinucleotide phosphate) to CYP. Multiple forms of CYP enzymes play important roles in the oxidation of structurally diverse xenobiotics. CYP3A (about 30% of total CYP) and CYP2C (about 20% of total CYP) enzymes are major forms. Human cytochrome CYP3A subfamily members (mainly CYP3A4) mediate the metabolism of many marketed drugs (amiodarone, amlodipine, clarithromycin, cyclosporine, erythromycin, lovastatin, nifedipine, tamoxifen, terfenadine, verapamil, R-warfarin) and thus play a critical role in drug metabolism. Furthermore, P-glycoprotein and CYP3A are frequently co-expressed in the same cells and share a large number of substrates and modulators[2].

Other important human drug-metabolizing enzymes are CYP1A2 (caffeine, estradiol, lidocaine, tacrine, theophylline, verapamil, R-warfarin), CYP2C9 (diclofenac, phenytoin, piroxicam, tetrahydrocannabinol, tolbuta-

mide, S-warfarin), CYP2C19 (diazepam, hexobarbital, S-mephenytoin, omeprazole, pentamidine, propranolol, R-warfarin), and CYP2D6 (codeine, debrisoquine, dextromethorphan, encainide, haloperidol, metoprolol, mexiletine, paroxetine, phenothiazines, propanolol, risperidone, sertraline, tricyclic antidepressants, venlafaxine) as highlighted by commonly used probe cocktails[3,4]. The expression of drug metabolizing enzymes, mainly CYP, shows significant interspecies differences and variability among human individuals (polymorphic or inducible enzymes) which makes the accurate prediction of the metabolism of various compounds in humans difficult. For example, patients who metabolize certain drugs rapidly may require higher, more frequent doses to achieve therapeutic concentrations; patients who metabolize certain drugs slowly may need lower, less frequent doses to avoid toxicity, particularly for drugs with a narrow interval of safety.

HEPATOTOXICITY: GENERAL CONCEPTS

Several key issues need to be addressed to study drug induced liver injury (DILI), that is, what metabolites will be formed (metabolic profile); which enzymes are involved and to what extent; whether drug metabolism will be affected directly (drug-drug interactions) or indirectly (enzyme induction) by the administered compound. Drug metabolism studies are routinely performed in laboratory animals, but they are not sufficiently accurate to predict the metabolic profiles of drugs in humans. In fact, hepatotoxicity due to idiosyncratic reactions cannot be detected by conventional animal toxicity studies. Furthermore, predisposing factors in humans such as ethanol-induced metabolic sensitivity to acetaminophen hepatotoxicity do not exist in the animal model. Interspecies differences in bioavailability, distribution and metabolism may also explain a number of false positives and false negatives. There is clearly a need to better understand the drug metabolism enzyme profile of the most commonly used non-rodent species, i.e. the dog and the monkey. Some false negative results may be related to insufficient (not in the pharmaceutical industry) exposure of the animals either because the doses tested were too low or because intestinal absorption was poor. Many of these issues can now be addressed by the use of relevant human *in vitro* models, which may speed up the understanding of drug toxicity. Human hepatocytes are the closest *in vitro* model to the human liver and they are one of the few models which can produce a metabolic profile of a drug which is very similar to that found *in vivo*. However, the use of human hepatocytes is restricted, because limited access to suitable tissue samples prevents their use in high-throughput chemical and genetic screens[5]. Comparative studies on liver microsomes and cells from animal species, including humans, are very useful for demonstrating species differences in the metabolic profile of a given drug and are of great value in the selection of animal species for later pharmacokinetic and toxicological studies[6].

CYP-engineered cells (or microsomes from CYP-engineered cells, for example, Supersomes) have made the identification of CYPs involved in the metabolism of a drug candidate more straightforward and much easier[7]. However, the screening of substances acting as potential CYP inducers can be conducted only in cellular systems fully capable of transcribing and translating CYP genes.

EPIDEMIOLOGY AND CLINICAL ASPECTS OF DRUG INDUCED LIVER INJURY

Drug hepatotoxicity has been evaluated in case histories, surveys based on retrospective record reviews, and spontaneous adverse drug reactions reported to national pharmacovigilance systems, but in relatively few epidemiologic studies. Approximately 1 in 100 patients develops DILI during hospitalisation. DILI is frequently missed and, therefore, DILI detection by diagnosis will result in misleadingly low incidence rates[8]. Unfortunately, patients with drug-induced hepatocellular jaundice have an 11.7% chance of progressing to death or transplantation[9].

DILI cases have been reported to constitute approximately 6% of all out-patients and 3% of referrals and to occur more often in women[10]. The incidence of drug-induced hepatitis is higher in patients over 40 years of age[11]. Acute liver failure or injury not clearly attributable to other known causes occurred in the order of 1 per 10 000 person -years among diabetic patients treated with oral hypoglycemic drugs or insulin[12].

The long term outcome of drug-related liver disease is unknown. To study the natural history of histologically proved drug-induced hepatotoxicity, 44 patients with liver biopsies coded as drug-related liver disease were identified from hospital records. Initial histology showed acute hepatitis in 6, chronic hepatitis in 20, and cholestasis in 18. At a median of 5 years follow-up, one third of patients had persistent significant abnormalities in their liver blood tests. Factors predicting persistence or development of chronic liver disease were fibrosis and continued exposure to the drug[13]. To identify and quantify the risk of acute liver injury associated with individual drugs, authors reviewed and integrated all the published epidemiologic research on the subject. Participants were selected according to their use of selected agents [nonsteroidal antiinflammatory drugs (NSAIDs), antibiotics, acid-suppressing drugs, other drugs suspected of being hepatotoxic] during the study period. Among the agents, authors found a group of important hepatotoxic drugs, including chlorpromazine and isoniazid, with an associated incidence rate of acute liver injury greater than 100/100 000 users. Agents with less risk but greater than 10/100 000 users were amoxicillin-clavulanic acid and cimetidine[14].

DILI with an incidence rate of near 1 per 100 000 encloses a spectrum of clinical disease ranging from no symptoms with mild biochemical abnormalities to fatal, fulminant hepatitis. The majority of adverse liver reactions are idiosyncratic in nature; in fact, about 10% of all acute liver failure cases are attributed to this type of reaction. They can occur in some instances up to three months after the causative medication was last taken.

The diagnosis of DILI is prevalent clinically, and based primarily on history, that is, exclusion of other hepatic diseases (hepatitis A, B, C, Epstein-Barr virus, cytomegalovirus, ischemia, and biliary tract disease), high likelihood of suspicion based on a strict cause-effect sequence, the duration of latency to symptomatic presentation, the presence of immune-mediated hypersensitivity (hypereosinophilia, fever and rush) and the response to drug withdrawal. Re-challenge is not advised in cases with a hypersensitivity basis, although this is the most definitive means of diagnosis. Some of the hypersensitivity cases are associated with autoantibodies to CYP, which can be used to confirm the diagnosis; for example, halothane is associated with anti-CYP2E1, anticonvulsants are associated with CYP3A4, dihydralazine hepatitis is associated with anti-CYP1A2, and tienilic acid (a diuretic drug withdrawn from the market because of hepatic failure) is associated with anti-CYP2C9. In the cases of metabolic idiosyncrasy, careful reintroduction of the offending drug may be accomplished without recurrence of the liver disease but should be done only when the drug is absolutely necessary and with careful monitoring. In some instances, liver biopsy can be of help, showing characteristic features, but it usually is not necessary and tells more about prognosis than etiology.

DILI can be of hepatocellular (increase of both the transaminases, alanine-aminotransferase/aspartate-aminotransferase), cholestatic (predominant rise in serum alkaline phosphatase and/or γ-glutamyl-transferase, GGT) or mixed type. Negative prognostic factors are an elevated serum bilirubin level and high ammonia levels with a mortality of approximately 10%[15]. A further less favourable index is a marked hypoprothrombinemia. Overall, chronic liver injury may occur in up to 5%-6% of the patients on some drugs, even though the putative offending substance is withdrawn[16].

LIVER HISTOLOGY

As previously emphasized, the pathogenesis of drug- or toxin- induced liver injury usually involves the participation of "toxic metabolites" that either elicit an immune response or directly affect the biochemical processes or functions of the cell[17]. Although the same basic process determines the DILI appearance, the histopathological liver changes in these cases vary, including: (a) necrosis, which commonly occurs in acinar zone 3, (b) abundant neutrophil and/or eosinophil infiltration, (c) hepatocytic and/or canalicular cholestasis with little or no inflammation, (d) microvesicular steatosis mixed with macrovesicular steatosis, and (e) presentation of epitheloid cell granuloma. There are no significant differences in liver histopathology between acute and chronic DILI groups, except that the fibrosis and the ductular proliferation are different.

DAMAGE MECHANISMS

Drug metabolites can be free radicals or electrophilic chemicals that undergo or promote a variety of chemical reactions, such as the depletion of reduced glutathione; covalent binding to proteins, lipids, or nucleic acids; or induction of lipid peroxidation. All of these have consequent direct effects on cellular organelles such as mitochondria, the endoplasmic reticulum, the cytoskeleton, microtubules, or on the nucleus. They may also indirectly influence cellular structures through the activation and inhibition of signaling kinases, transcription factors, and gene-expression profiles. The subsequent intracellular stress leads to cell death caused by either cell shrinkage and nuclear disassembly (apoptosis) or swelling and lysis (necrosis). Liver injury is characterized by hepatocyte death; that is the main event, although bile duct epithelium or sinusoidal endothelial cells may also be involved.

CYP-mediated Biotransformation: the common substrate

While several CYPs are involved in the synthesis of bile acids and steroid hormones and the metabolism of fatty acids, retinoic acid, prostaglandins and eicosanoids, a limited number of CYPs (15 in humans) are primarily involved in xenobiotic metabolism. The xenobiotic-metabolizing CYPs are found in families 1-4. Since a single CYP can metabolize a large number of structurally diverse compounds these enzymes can collectively metabolize chemicals found in the diet, environment and administered as drugs. While metabolism of xenobiotics such as drugs is required to efficiently eliminate them from the body, as noted earlier, certain chemicals are metabolically activated to reactive derivatives that cause cell toxicity and cancer. Among these, the CYPs that metabolically activate toxicants and carcinogens are limited to some forms including CYP1A1, CYP1A2, CYP1B1, CYP2A6, CYP2C9, CYP2E1, and to a limited extent the CYP3A subfamily.

ATP depletion

Acetaminophen overdose causes liver injury by mechanisms involving glutathione depletion, oxidative stress and mitochondrial dysfunction. Acetaminophen-induced decreases in mitochondrial reduced glutathione and ATP content, and cytosolic leakage of cytochrome c are attenuated by cyclosporin A, suggesting that mitochondrial oxidative stress and ATP depletion resulting from mitochondrial permeability transition (MPT) are the principal mechanisms involved in acetaminophen-induced liver injury[18].

The role of ATP-depletion-dependent necrosis has further been ascertained. Recently, using TUNEL labeling and caspase 3 activation, it was observed that acetaminophen induced the MPT and ATP-depletion-dependent necrosis or caspase-dependent apoptosis as determined, in part, by ATP availability from glycolysis[19].

Binding to nuclear or cytoplasmatic constituents

Inducers can increase the bioactivation of drugs that contribute to hepatotoxicity *via* reactive intermediates. Nuclear receptors are key mediators of drug-induced changes in the expression of drug clearance pathways. However, species differences in nuclear receptor activation make the

prediction of CYP induction in humans from data derived from animal models problematic. Drugs have the capacity to alter nuclear receptor expression (modulators) and/or serve as ligands for the receptors (agonists or antagonists), and thus can have synergistic or antagonistic effects on the expression of drug-metabolizing enzymes and transporters. Co-administration of drugs that are nuclear receptor agonists or antagonists can lead to severe toxicity, a loss of therapeutic efficacy or an imbalance in physiological substrates, providing a novel molecular mechanism for drug-drug interactions[20].

RNA interference

Authors suggested that the lack of p53 response may confer a growth advantage on preneoplastic hepatocytes and may be an important factor in hepatic tumor promotion by 2-acetylaminofluorene and other genotoxic compounds. Inhibition of RNA polymerase Ⅱ driven transcription by DNA lesions may constitute one of the mechanisms leading to accumulation of the tumor suppressor p53[21].

Oxidative stress and lipid peroxidation

Redox signals are important in the modulation of cell function. Reactive oxygen species (ROS) generation influences many signaling proteins, interfering with molecular and biochemical processes responsible for cell differentiation, proliferation and death. Protein kinase (PKC) is a crucial signaling protein which is subject to redox regulation and controls these responses. ROS are products of normal cellular metabolism and are recognized to be harmful or beneficial to living systems. The harmful effect of ROS is termed oxidative stress and it occurs when there is an overproduction of these species or a deficiency of antioxidants. Enzymatic systems that contribute to ROS formation in the liver include CYP monooxygenases and NADPH oxidase. In the healthy liver, hepatocytes produce low amounts of ROS and Kupffer cells are well equipped to release ROS in response to infection. Antioxidants such as superoxide dismutase and catalase efficiently remove ROS surplus to maintain the normal cell homeostasis. Different stimuli are able to modify the redox state of liver cells modulating signal transduction pathways able to trigger many aspects of liver pathologies. In a recent study, evidence of the central role of PKC as a redox-sensitive molecule implicated in the pathogenesis and progression of toxic liver diseases was provided[22].

The free radicals initiate lipid peroxidation by attacking polyunsaturated fatty acids in membranes, setting off a free radical chain reaction sequence. Lipid peroxidation is known to cause membrane disruption, resulting in the loss of membrane integrity and leakage of microsomal enzymes. By-products of lipid peroxidation include reactive aldehydes that can form protein and DNA adducts and may contribute to hepatotoxicity and carcinogenicity, respectively. Natural antioxidants, including glutathione, are capable of quenching the lipid peroxidation reaction[23].

Immune-mediated hypersensitivity

Because liver undergoes continuous exposure to xenobiotics, it possesses a variety of local immune mechanisms to face these challenges. In the liver there are both innate and adaptive immune cells, including tissue macrophages (KC), natural Killer (NK) cells, and non-NK (NKT) cells, which account for nearly 50% of intrahepatic leukocytes[24]. KC produce various cytokines and other mediators, including prostanoids, nitric oxide and ROS that play roles in promoting and regulating hepatic inflammation. Furthermore, KC represent a major population of antigen-presenting cells (APCs) having an important role in the balance between the induction of immunity and tolerance within the liver. It has been demonstrated that freshly isolated liver NK cells spontaneously induce the cytotoxicity of various cell lines, whereas NKT cells are cytotoxic in the presence of interleukin (IL)-2[25]. This cytotoxicity is further enhanced by IL-12 and IL-18, which are produced by activated KC. Another function ascribed to NK and NKT cells is their ability to produce high levels of T helper (Th) 1 and Th2 cytokines upon stimulation[26]. NK cells have been shown to represent a major source of interferon (IFN)-γ in many types of liver disease[27]. NKT cells produce either IFN-γ or IL-4, or in some cases both cytokines, depending on the differentiation state of the cells and the stimuli[25]. It has also been demonstrated that IL-4 produced by NKT cells may be associated with the initiation and regulation of Th2 responses. Various mechanisms have been suggested to explain this tolerance[28], such as immune deviation, active suppression and apoptosis of activated T cells. Regarding immune deviation, it has been shown that Th2 cytokine production is preferentially maintained when adoptively transferred Th1 and Th2 cells are recovered from the liver. It has also been reported that liver sinusoidal endothelial cells (LSEC) are capable of selectively suppressing IFN-γ-producing Th1 cells while concurrently promoting the outgrowth of IL-4-expressing Th2 cells[29]. Good evidence suggests that hepatic dendritic cells are also important in the induction of tolerance, rather than the activation of T-cell responses. It has been further demonstrated that although LSEC are capable of presenting antigens to T cells, LSEC-activated $CD4^+$ or $CD8^+$ T cells fail to differentiate into Th1 cells or cytotoxic effector cells, respectively[30]. Most drugs are not chemically reactive but can be activated metabolically to reactive species which, after binding to cellular macromolecules, become immunogenic and can elicit an effective immune response. Immune-mediated mechanisms have been proposed for idiosyncratic reactions observed with sulfonamides, halothane and phenytoins. Presentation of drug-protein adducts by professional cells to Th lymphocytes, and/or a direct association between the drug and major histocompatibility complex (MHC) proteins of hepatocytes could be involved in the activation of the immune system. As a consequence of this, drug-directed antibodies and/or T-lymphocytes able to recognize drug-derived haptens arise which are responsible for the clinical manifestations of hepatitis. Drug-directed antibodies can be detected in sera of allergic patients by solid-phase immunoassays. Sensitized T-lymphocytes can be shown by hapten-induced cell proliferation experiments and by the early expression of CD69 antigen[31]. Despite the

possible detection of drug-specific antibodies, it is difficult to directly prove the pathogenic role of the adaptive immune system in DILI, partly because of the lack of animal models. A difficulty in developing animal models is the fact that the default response of the liver to antigens is immunological tolerance. This could also explain the relatively low occurrence of this type of DILI in human beings.

Inflammation

A recent paper emphasizes the imbalance between Th1 cells producing cytokines associated with a cell-mediated response and Th2 cells associated with an antibody response, leading to a shift in immune response to one that may participate in DILI during administration of certain drugs, especially in subjects with genetic polymorphisms in drug-metabolizing enzymes. In fact, several cases of DILI related to administration of drugs appear to be initiated or intensified by respiratory inflammation states, which stimulate sometimes dysregulated production of IFN-γ and/or other proinflammatory cytokines/growth factors. This ends up in down-regulation of various induced and constitutive isoforms of CYPs and other enzymes involved in the metabolism of several drugs, thus having an important impact on the alterations in bioactivation and detoxication processes. DILI may eventually be prevented by screening methods that can identify genetic polymorphisms of drug-metabolizing enzymes and gene polymorphisms or RNA-expression profiles of some proinflammatory cytokines before patients take any drug[32].

Apoptosis

Although CYP-generated reactive metabolites can cause hepatocyte apoptosis, the mechanism of this effect has only recently been elucidated. Male rat hepatocytes were incubated with skullcap diterpenoids. This treatment decreased cellular glutathione and protein thiols and increased cellular Ca^{2+}. This activated Ca^{2+}-dependent tissue transglutaminase formed a cross-linked protein scaffold, and also opened the mitochondrial permeability transition pore, causing outer mitochondrial membrane rupture, increased cytosolic cytochrome c, activation of procaspase 3, internucleosomal DNA fragmentation, and ultrastructural features of apoptosis. Cell death was increased by a CYP3A inducer (dexamethasone) increasing glutathione depletion. In contrast, cell death was prevented by decreasing CYP3A activity (with troleandomycin), preventing glutathione depletion (with cysteine), blocking Ca^{2+}-modulated events (with calmidazolium), preventing mitochondrial permeability transition (with cyclosporin A), or inhibiting caspase 3 (with acetyl-Asp-G u-Va-Asp-a dehyde). Both calmidazolium and cyclosporin A also prevented the increase in cytosolic cytochrome c and procaspase 3 activation[33].

Calcium homeostasis imbalance

When glutathione and other antioxidants are depleted, however, opportunities for lipid peroxidation are enhanced. Weakened cellular membranes allow sufficient leakage of Ca^{2+} into the cytosol to disrupt intracellular Ca^{2+} homeostasis. High Ca^{2+} levels in the cytosol activate Ca^{2+}-dependent proteases and phospholipases that further increase the breakdown of the membranes. Similarly, the increase in intracellular Ca^{2+} can activate endonucleases that can cause chromosomal damage and also contribute to cell death. Sustained cell regeneration and proliferation following cell death may increase the likelihood of unrepaired spontaneous, lipid peroxidation- or endonuclease-derived mutations that can lead to cancer.

FACTORS INFLUENCING PATIENT SUSCEPTIBILITY TO HEPATOXICITY

Determination of DILI also includes an individual susceptibility. This susceptibility is governed by genetic, pre-existing and environmental factors. Predisposing factors are generally thought to be important to somehow explain the unpredictability of the phenomena through which substances turn into hepatotoxins, and consist of ethnic and racial factors, CYP polymorphisms, concomitant liver diseases, age, nutritional status and diet, gender and pregnancy.

Ethnic and racial factors

These factors have important implications for susceptibility to acetaminophen hepatotoxicity following overdosage especially in a small subgroup showing extensive metabolic activation. An exemplary study indicates markedly reduced metabolic activation of acetaminophen in Africans. These ethnic differences in acetaminophen metabolism may be related to genetics even though environmental factors, including differences in diet and protein intake, should not be excluded. There were no ethnic differences in the sulphate conjugation of acetaminophen, but the mean fractional recovery of the glucuronide conjugate in Caucasians was less than in Africans[34].

Concomitant chronic liver diseases

In liver diseases, pharmacokinetics are generally impaired. Pathogenetic factors include alterations in intestinal absorption, plasma protein binding, hepatic extraction ratio, liver blood flow and portal-systemic shunting, biliary excretion, enterohepatic circulation, and renal clearance. The key point is, however, the reduction of functional hepatic mass that may have complex effects on drug clearance, particularly biotransformation. Net results for an individual drug are unpredictable and do not correlate well with the type of liver damage, its severity, or liver laboratory test results. Thus, no general rules are available for modifying drug dosage in patients with liver disease. Recently, NonAlcoholic Fatty Liver Disease (NAFLD) has been found to be a fertile soil for the development of hepatotoxicity. With NAFLD now linked to obesity and metabolic syndrome, the impact of this observation should not be overlooked[35].

Oxidative stress has been detected in patients affected by alcohol abuse, hepatitis C virus (HCV) infections, iron overload and chronic cholestasis[36]. Alcohol-induced liver

disease (ALD) has been associated with the synergistic induction of oxidative stress by alcohol metabolites, iron accumulation and antioxidant depletion[37].

HCV infection may generate oxidative stress by chronic inflammation and by disruption of glutathione efflux. Therefore, oxidative stress is not only a consequence of chronic liver injury but it also contributes to fibrogenesis and it appears as a key player in the pathogenesis of hepatic diseases. Vitamin E could prevent the decrease in O_2 uptake[38].

But what is the role of stress in determining hepatotoxicity? Its regulation of several enzymatic systems which are involved in the biotransformation of xenobiotics in the liver was recently investigated in a study using restraint stress as a stress model in animals. The results demonstrated that stress suppressed total basal CYP content of one third of animals and basal ethoxyresorufin 7-dealkylase activity. On the other hand, restraint stress increased total CYP content in 1,4-bis[2-(3,5-dichloropyridyloxy)]benzene-treated mice, while slightly suppressing PROD activity. In addition, CYP2E1 dependent p-nitrophenol hydroxylation was suppressed by stress in the same animals and cytosolic aldehyde dehydrogenases were not affected. Although stress had no effect on basal CYP2A5 activity, the inducibility of this hepatic activity increased 2-fold after stress exposure. In addition, a slight suppression in liver glutathione content was found. Northern blot analysis revealed that restraint stress had a relatively suppressive effect on control CYP1A2 expression in the liver. In conclusion, stress was found to significantly interfere with the expression processes of some CYP450s[39].

Age

Increased risk of DILI may result from age-related changes in pharmacokinetics or pharmacodynamics. Overall hepatic metabolism of many drugs through the CYP enzyme system decreases with aging. For drugs with decreased hepatic metabolism, clearance typically decreases by 30%-40%. Theoretically, maintenance drug doses should be decreased by this percentage; however, the rate of drug metabolism varies greatly from person to person, and individual titration is required. Risk of any adverse effect and obviously of DILI increases exponentially with the number of drugs used, partly because multiple drug therapy reflects the presence of many diseases and increases risk of drug-disease and drug-drug interactions.

Nutritional status and diet

Increasing evidence implicates dietary factors in the progression of diseases, including certain cancers, diabetes and obesity. Diet also regulates the expression and function of CYP genes which impacts on drug elimination and may also significantly affect disease pathogenesis. Upregulation of CYPs 2E1 and 3A4 occurs after feeding of experimental diets that are high in fats or carbohydrates; these diets also promote hepatic lipid infiltration, which is a component of the metabolic syndrome that characterizes obesity. Increased availability of lipid substrates for CYPs can enhance free radical production and exacerbate tissue injury. Similar processes may also occur in other models of experimental disease states that exhibit a component of altered nutrient utilization. Food-derived chemicals, including constituents of cruciferous vegetables and fruits, modulate CYP expression and the expression of genes that encode cytoprotective phase Ⅱ enzymes. Certain dietary indoles and flavonoids activate CYP1A expression either by direct ligand interaction with the aryl hydrocarbon receptor (AhR) or by augmenting the interaction of the AhR with xenobiotic response elements in CYP1A1 and other target genes. Other dietary chemicals, including methylenedioxyphenyl (MDP) compounds and isothiocyanates also modulate CYP gene expression. Apart from altered CYP regulation, a number of dietary agents also inhibit CYP enzyme activity, leading to pharmacokinetic interactions with coadministered drugs. A well described example is that of grapefruit juice, which contains psoralens and possibly other chemicals that inactivate intestinal CYP3A4. Decreased presystemic oxidation by this CYP increases the systemic bioavailability of drug substrates and the likelihood of drug toxicity. Dietary interactions may complicate drug therapy but inhibition of certain CYP reactions may also protect the individual against toxic metabolites and free radicals generated by CYPs. Chemicals in teas and cruciferous vegetables may also inhibit human CYP enzymes that have been implicated in the bioactivation of chemical carcinogens. Thus, food constituents modulate CYP expression and function by a range of mechanisms, with the potential for both deleterious and beneficial outcomes[40].

As previously emphasised, obesity is considered an important risk factor for DILI. Paradoxically, earlier studies have shown highly exaggerated mechanism-based liver injury by thioacetamide (TA) in rats following moderate diet restriction (DR). The objective of this significant study was to investigate the mechanism of higher liver injury of TA in DR rats. When male rats were maintained on DR (35% of ad libitum diet for 21 d), the total hepatic CYP was increased 2-fold along and there was a 4.6-fold increase in CYP2E1 protein, which corresponded with a 3-fold increase in CYP2E1 activity as measured by chlorzoxazone hydroxylation. To further test the involvement of CYP2E1, 24 and 18 h after pretreatment with pyridine (PYR) and isoniazid (INZ), specific inducers of CYP2E1, rats received a single administration of 50 mg of TA/kg. TA liver injury was > 2.5- and > 3-fold higher at 24 h in PYR + TA and INZ + TA groups, respectively, compared with the rats receiving TA alone. Pyridine pretreatment resulted in significantly increased total CYP content accompanied by a 2.2-fold increase in CYP2E1 protein and 2-fold increase in enzyme activity concordant with increased liver injury of TA, suggesting mechanism-based bioactivation of TA by CYP2E1. Hepatic injury of TA in DR rats pretreated with diallyl sulfide (DAS), a well known irreversible *in vivo* inhibitor of CYP2E1, was significantly decreased (60%) at 24 h. Carbon tetrachloride (CCl_4), a known substrate of CYP2E1, caused less liver injury and greater animal survival, confirming inhibition of CYP2E1 by DAS pretreatment[41].

Gender

Some authors clarified this issue, studying 50 patients diagnosed with active tuberculosis infection with normal pretreatment liver laboratory tests; they were monitored clinically as well as biochemically in a prospective cohort analysis. Antitubercular drug-induced hepatotoxicity was found more often in females (OR 4.2). Younger patients were also at a higher risk (OR 2.75). Nutritional status, assessed by body mass index and serum albumin level, was the next most common predisposing factor[42].

PHENOTYPING AND GENOTYPING STUDIES

The genetic polymorphisms of human drug metabolizing enzymes have been firmly established. Based on the metabolic handling of certain probe drugs, the population can be divided into two phenotypes: the rapid acetylator/extensive metabolizer (EM) and slow acetylator/poor metabolizer (PM). For some authors, a quadrimodal behaviour is possible, that is, poor, intermediate, extensive and ultrarapid.

These polymorphisms have provided useful tools to study the relationship between genetically determined differences in the activity of drug metabolizing enzymes and the risk for adverse drug reactions and certain types of chemically-induced diseases.

With regard to the susceptibility of the two phenotypes, DILI can be anticipated for the following scenarios: (1) the drug toxicity is caused by the parent compound and the elimination of the drug proceeds exclusively *via* the polymorphic enzyme, there being no alternate pathways of biotransformation available. Thus the poor metabolizer phenotype will be more prone to such a type of toxicity since, at the same level of exposure, this phenotype will accumulate the drug as a result of impaired metabolism; (2) the polymorphic pathway is a major route of detoxification, so impairment of this pathway shifts the metabolism to an alternate pathway *via* which a reactive intermediate is formed. In such a situation the PM phenotype constitutes a major risk factor for toxicity (i.e. INZ hepatotoxicity); the toxicity is mediated by a reactive intermediate generated by a polymorphic enzyme. Hence EMs are at a much higher risk than PMs of developing toxicity or cancer (for example, smokers)[43].

A further problem with PMs that the same dose of drug could yield a sustained plasma concentration. Poor metabolism is especially problematic with drugs that have a narrow therapeutic index like debrisoquine, phenformin or captopril. It has been estimated that psychiatric patients with CYP2D6 deficiency encounter more adverse drug incidents than those who are EMs[44].

With estimates of the percentage of pharmaceuticals that are subject to metabolism by the CYP in excess of 80%, the relative activities of these enzymes in various subpopulations and even in individual patients can have important ramifications in matters ranging from dose selection to prediction of toxicity to suitability of a new chemical entity for continued drug development.

As previously emphasized, CYP1A2, 2C9, 2C19, 2D6 and 3A are the major isoforms responsible for the metabolism of more than 90% of marketed drugs. Polymorphism of drug metabolism represents an important source of interindividual and interethnic variation in drug response.

CYP2D6, CYP2C9 and CYP2C19 are three polymorphic CYP enzymes. The EM phenotype occurs when there is at least one wild type allele at the relevant gene locus. The PM phenotype occurs when both alleles of either CYP2D6 or CYP2C19 carry inactivating mutations and give rise to synthesis of enzyme with impaired activity or no synthesis of enzyme at all.

Phenotyping is often based on high-performance liquid chromatography (HPLC) such as the determination of the dextromethorphan/total dextrorphan molar ratios as metabolic ratios (MRs) in plasma samples collected at 3 h after oral administration of 30 mg dextromethorphan hydrobromide. In this situation PMs and extensive EMs can be identified distinctly. To determine the real-time activity of the CYP isozymes, specific probe drugs can be employed. Recently, the use of multiple probe drugs, that is, a 'cocktail' approach, has become popular in pharmacogenetic studies as this provides a high-throughput approach in evaluating CYP isozyme activities. A number of cocktails (from five to six drugs) have been described in the literature.

These include the Pittsburgh cocktail, GW cocktail, Cooperstown cocktail and Karolinska cocktail. So far most of the analytical methods for these cocktails usually require a separate HPLC, gas chromatography (GC) or liquid chromatography/mass spectrometry (LC/MS) technique for each probe drug and its metabolite.

Recently, a fast gradient LC/MS method for the simultaneous determination of CYP substrates and metabolites in the GW cocktail was reported[45]. However, this cocktail has several practical limitations. First of all, the use of diclofenac as a CYP2C9 marker is undesirable due to its variable absorption in humans. Secondly, the use of mephenytoin is inconvenient as this drug is no longer commercially available in many parts of the world; besides, its sedative side effect is prominent, especially in PMs. Thirdly, chlorzoxazone, a probe drug in the cocktail, can significantly inhibit the CYP3A-mediated first-pass metabolism of midazolam in the gut and its use for the present purpose is not recommended.

A rapid LC/tandem MS method has been developed for the determination of six CYP probe substrate metabolites including acetaminophen for CYP1A2, 4-hydroxytolbutamide for CYP2C9, 5-hydroxyomeprazole for CYP2C19, dextrorphan for CYP2D6, 6-hydroxychlorzoxazone for CYP2E1 and dehydronifedipine for CYP3A4[46].

What is the clinical importance of studying the CYP polymorphisms? It has been shown that the cholesterol-lowering effect as well as the efficacy and tolerability of simvastatin is influenced by CYP2D6 genetic polymorphism[47]. Because the different HMG-CoA reductase in-

hibitors differ with respect to the degree of metabolism by the different CYP enzymes, genotyping may help to select the appropriate HMG-CoA reductase inhibitor and the optimal dosage during the start of the treatment and will allow for more efficient individual therapy, also taking in account the eventual DILI. To clarify this point, CYP polymorphisms of fluvastatin were studied.

More than the hepatotoxicity, the pharmacokinetics of both enantiomers of fluvastatin depended on the CYP2C9 genotype with a 3-fold mean difference in the active enantiomer and even greater differences in the inactive enantiomer. Differences in plasma concentrations were not reflected in cholesterol lowering after 14 d of fluvastatin intake in healthy volunteers[48]. In fact, the authors did not find any evidence to support CYP2C9 and CYP2C19 genetic polymorphisms as predictable potential risk factors for DILI[49].

PREDICTING VARIABILITY IN PHARMACOKINETICS

Obviously, it is impossible to genotype all individuals due to the cost, even though for some drugs it should be taken into serious consideration because a single serious incident (hepatic failure) could lead to an excessive health care involvement (liver transplantation). Several examples have been reported.

CYP2C19 is highly polymorphic, with variations in both the expression of mRNA and enzyme, plus actual differences in the protein coding region that give rise to differing rates of catalysis. As with most polymorphisms, there appear to be differences in expression in different ethnic groups. For example, the frequency of PMs among Asians is nearly 20% of Caucasians[50]. The proton pump inhibitor omeprazole and related ulcer drugs are oxidized by CYP2C19, and PMs show a better response to these drugs[51].

Not all drug interactions are genetically determined. In some cases, an inhibitor can block metabolism of a drug and produce the same effect as would poor metabolism. In retrospect, every marketed drug is a relatively successful drug in terms of the limited problems associated with widespread use, the deaths of some individuals notwithstanding-as in the case of "ultra" rapid metabolizers-or, more commonly, arising from enzyme induction. A classic example involves CYP3A4 and 17α-ethynylestradiol, the estrogenic component of oral contraceptives. Similarly, hyperforin, a potent CYP inducer found in the herbal medicine St. John's wort, greatly increases the expression of CYPs that metabolize drugs used for AIDS treatment and organ transplantation. Cases for enhanced drug toxicity due to elevated levels of CYPs are probably less clear; however, CYP3A4 converts the antidiabetic drug troglitazone into toxic products, although the mechanism of toxicity is still unclear. Troglitazone has since been removed from the market. In any event, the drug development process now incorporates a variety of *in vitro* studies designed to predict bioavailability, inhibition of CYP reaction, and the effects of any induction prior to consideration of clinical trials. Conclusively, genotyping can provide useful information about the expected behavior of a drug.

HAS CYP A ROLE IN THE "DIRECT" HEPATOTOXICITY?

CCl_4 is a well-known model compound for producing chemical hepatic injury. CYP is an important monooxygenase in biology. Recent research investigated CYP protein expression in the *in vivo* hepatotoxicity of rats induced by CCl_4. In this experiment, CCl_4 was administered to male rats, and their livers at 24 h post-dosing were studied using proteomic analysis. Blood biochemistry and histopathology were examined to identify specific changes. At the same time, a novel acetylation stable isotopic labeling method coupled with LTQ-FTICR MS was applied to disclose the changes in CYP expression amounts. The quantitative proteomics method demonstrated its correlation coefficient was 0.9998 in a 100-fold dynamic range and the average ratio of the labeled peptides was 1.04, which was very close to the theoretical ratio of 1.00 and the standard deviation (SD) of 0.21. With this approach, 17 CYP proteins were identified and quantified with high confidence. Among them, the expression amounts of 2C11, 3A2, and 2 E1 were down-regulated, while those of 2C6, 2B2, and 2B1 were up-regulated[52].

AN EXAMPLE OF DAMAGE MECHANISMS

CCl_4 continues to provide an important service today as a model substance to elucidate the mechanisms of action of hepatotoxic effects such as fatty degeneration, fibrosis, hepatocellular death, and carcinogenicity. CCl_4 is activated by CYP2E1, CYP2B1 or CYP2B2, and possibly CYP3A, to form the trichloromethyl radical, CCl_3*. This radical can bind to cellular molecules (protein, lipid, nucleic acids), impairing crucial cellular processes such as lipid metabolism, leading to fatty degeneration (hepatic steatosis). Adduct formation between CCl_3* and DNA is thought to possibly induce hepatic cancer. This radical can also react with O_2 to form the trichloromethylperoxy radical CCl_3OO*, a highly reactive species, also called ROS. CCl_3OO* initiates the chain reaction of lipid peroxidation, which attacks and destroys polyunsaturated fatty acids, in particular those associated with phospholipids. This affects the permeabilities of mitochondrial, endoplasmic reticulum, and plasma membranes, resulting in the loss of cellular Ca^{2+} sequestration and homeostasis, which can contribute heavily to subsequent cell damage. Among the degradation products of fatty acids are reactive aldehydes, especially 4-hydroxynonenal, which bind easily to functional groups of proteins and inhibit important enzyme activities. CCl_4 intoxication also leads to hypomethylation of cellular components; in the case of RNA the outcome is thought to be inhibition of protein synthesis, and in the

case of phospholipids it plays a role in the inhibition of lipoprotein secretion. None of these processes per se is considered the ultimate cause of CCl_4-induced cell death; it is by cooperation that they achieve a fatal outcome, provided the toxicant acts in a high single dose, or over longer periods of time at low doses. At the molecular level CCl_4 activates tumor necrosis factor (TNF)-α, nitric oxide, and transforming growth factor (TGF)-α and -β in the cell, processes that appear to direct the cell primarily toward (self-)destruction or fibrosis. TNF-α pushes toward apoptosis, whereas TGF-β appears to direct toward fibrosis. IL-6, although induced by TNF-α, has a clearly antiapoptotic effect, and IL-10 also counteracts TNF-α action. Thus, both interleukins have the potential to initiate recovery of the CCl_4-damaged hepatocyte. Several of the above-mentioned toxicological processes can be specifically interrupted with the use of antioxidants and mitogens, respectively, by restoring cellular methylation, or by preserving calcium sequestration. Chemicals that induce CYPs that metabolize CCl_4, or delay tissue regeneration when co-administered with CCl_4 will potentiate its toxicity thoroughly, while appropriate CYP inhibitors will alleviate much of the toxicity. O_2 partial pressure can also direct the course of CCl_4 hepatotoxicity. Pressures between 5 and 35 mmHg favor lipid peroxidation, whereas the absence of O_2, as well as a partial pressure above 100 mmHg, both prevent lipid peroxidation entirely. Consequently, the location of CCl_4-induced damage mirrors the O_2 gradient across the liver lobule. Mixed halogenated methanes and ethanes, found as so-called disinfectant by-products at low concentrations in drinking water, elicit symptoms of toxicity very similar to CCl_4, including carcinogenicity[23].

TOTAL DOSE OF DRUG

Among drugs that are feared of inducing hepatoxicity, mainly when taken for a very long period, statins are largely under-dosed, but they do in rare cases cause significant liver injury whereas antiretroviral therapy is associated with hepatotoxicity in 10% of treated patients[16].

In a previous study, liver morphology was examined in 41 patients with vitamin A hepatoxicity. Cirrhosis was found in 17, mild chronic hepatitis in 10, noncirrhotic portal hypertension in 5, and "increased storage" alone in nine cases. During a mean follow-up period of 4.6 years, six patients died of causes related to the liver disease. A precise appraisal of drug consumption was obtained in 29 cases. Among them the total cumulative intake was highest in patients with cirrhosis ($423 \pm 103 \times 10^6$ IU) and significantly lower in those with noncirrhotic liver disease (88.5 ± 41; $P < 0.02$). The smallest continuous daily consumption leading to cirrhosis was 25 000 IU during 6 years, whereas higher daily doses (⩾ 100 000 IU) taken over 2.5 years resulted in similar histological lesions. It was concluded that prolonged and continuous consumption of doses in the low "therapeutic" range can result in life-threatening liver damage[53].

Recently, an interesting paper, reporting data from both USA and Sweden, showed a clear relationship between daily doses of oral prescription medications and idiosyncratic DILI, particularly as regards daily doses > 50 mg/d[54].

INDUCTION AND INHIBITION OF CYP ACTIVITY

The possible pharmacokinetic consequences of enzyme induction depend on the localization of the enzyme. They include decreased or absent bioavailability for orally administered drugs, increased hepatic clearance or accelerated formation of reactive metabolites, which is usually related to local toxicity. The toxicological consequences of enzyme induction in humans are fortunately rare, and appear to be mainly limited to hepatoxicity in ethanol-type induction[55].

Diclofenac sodium (DF-Na) is an NSAID used in various aspects of inflammatory disease. The effects of phenobarbital (PB) on metabolism and toxicity of DF-Na *in vitro* and the potential mechanism of DF-Na induced hepatotoxicity have been examined. The decline of CYP 3A was partially reversed by CYP inducer PB, and the maximum induction of CYP 3A was 2.2-fold over control after continuous exposure of hepatocytes to 2 mmol/L PB for 48 h. These findings suggest that the hepatotoxicity and metabolism of DF-Na in rat hepatocytes are increased when hepatic CYP 3A activity is increased[56]. Itraconazole and fluconazole, two antifungal drugs with potent inhibitory effect on CYP, induce hepatotoxicity clinically, but the mechanism underlying the hepatotoxicity is unknown. Pretreatment with SKF 525A, an inhibitor of CYPs, induced more severe hepatotoxicity with both itraconazole and fluconazole *in vivo*[57].

THE IMPACT OF DILI ON DRUG DEVELOPMENT

The inability to predict if a metabolically bioactivated compound will cause toxicity in later stages of drug development or post-marketing is of great importance. One approach for improving the predictive success of compound toxicity could be to compare the gene expression profile in preclinical models dosed with novel compounds to a gene expression database generated from compounds with known toxicity.

A current study[58] in mice utilized a known hepatotoxic compound N-methylformamide and its two analogs labeled with deuterium at different positions to block metabolic oxidation at the formyl [d (1)] and methyl [d (3)] moieties. The data set generated from the different groups of animals enabled authors to determine which gene expression changes were attributed to the bioactivating pathway. The metabolic pathway leading to the production of reactive methyl isocyanate resulted in distinct expression patterns that correlated with histopathologic findings. There was a clear correlation between the expression of certain genes involved in the cell cycle/apoptosis and inflammatory pathways and

the presence of reactive metabolite. These genes may serve as potential genomic biomarkers of hepatotoxicity induced by soft-electrophile-producing compounds. However, the robustness of these potential genomic biomarkers will need to be validated before being adopted into the drug discovery screening process.

AN OPINION ABOUT WIDELY USED DRUGS

Although liver injury has been associated with the "statins", the frequency of such toxicity is lower than that of the control population and the value of biochemical monitoring remains unproved[59]. Clinicians may be concerned about prescribing statins to patients with chronic liver disease, but there is little evidence to suggest that DILI from statins is increased in these patients. Thus, we should prescribe statins for the same indications in patients with chronic liver disease as in patients without, but with closer monitoring[60].

HERBAL REMEDIES AND OTHER DIETARY SUPPLEMENTS

A dietary supplement is defined as any product in pill or liquid form containing a herb, vitamin, amino acid or mineral that complements the normal diet. Indeed, every agency regulates dietary supplements differently from drugs, i.e. only ensuring quality control and good manufacturing processes but not standardization of the active ingredients. Dietary supplements are commonly used primarily because they are widely available and can be bought without consulting a physisician. However, a few supplements are now proven to be safe and useful complements to standard drugs. The supplement may have unlisted ingredients, which may be inert or harmful, or it may contain variable amounts of active ingredients, especially when whole herbs are ground or made into extracts. Most herbal products are mixtures of several substances, and which ingredients are active is not always known. Additional areas of concern include stability of supplements (especially herbal products) once manufactured, use of dietary supplements instead of conventional drugs, toxicity in children and the elderly, and interactions between supplements and drugs. Patients may not think to disclose or may wish to conceal their use of dietary supplements. For this reason, the patient's history should periodically include explicit questions about past and recent consumption of dietary supplements. Recently the use of herbal preparations as remedies for various medical conditions has been increasing rapidly. In one study, 38.9% of patients with chronic liver disease were found to use some sort of herbal preparation[61].

Efficacy and safety of medicinal plants naturally represent the object of interest for pharmacologists, and it is surely this aspect which gives the most important information on herbal medicine use[62].

Many plants have been studied and results published showing variable degrees of efficacy. Toxicity aspects of some of the most frequently used plants are now well known[63].

Among others, a recent report emphasizes the potentially severe hepatotoxicity of Kava which has recently led to the retraction of Kava-containing drugs by the pharmacovigilance authorities in Germany[64]. Authors reported two cases of acute liver injury along with the intake of greater celandine (*Chelidonium majus*), a well-known herbal remedy frequently used for irritable bowel syndrome. All other possible causes of acute liver damage were excluded in both patients. In one patient, cholestatic hepatitis recurred rapidly after involuntary re-exposure. Both patients fully recovered after the withdrawal of greater celandine. The two cases add to the existing database about the potential hepatotoxicity of drugs containing greater celandine and raise the question whether the approval of this drug should be re-evaluated in the light of a lack of evidence for a therapeutic benefit[65].

SOME CONSIDERATIONS ON CAUSALITY ASSESSMENT

Many methods have been proposed to assess the individual causality between a drug treatment and the occurrence of adverse drug events (ADRs), including hepatoxicity. Briefly, these methods may be classified into the following approaches, i.e. expert judgement, probabilistic methods and algorithms.

In expert judgement or global introspection (GI), an expert expresses a judgement about possible drug causation after having taken into account all the available and relevant information on the considered case.

Theoretically, it is possible to apply pre-existing Causality Assessment Methods (CAMs) to the assessment of causality in cases with diagnostic difficulties.

We have historical scales such as Naranjo probability scale[66], Danan's international consensus criteria[67], Maria's and Victorino's scales[68] or Beers criteria for ADRs[69] to make such events predictable and often preventable. Still, on the basis of a global score, four categories of preventability of ADRs ("preventable", "potentially preventable", "unclassable", "not preventable") were proposed by other researchers[70].

Standards are lacking for validation of drug CAMs. An original model has been proposed using a positive rechallenge as an external standard[71]. The GI approach suffers from marked subjectivity leading to poor reproducibility and intra- and inter-rater disagreements. A study confirms that experts express marked disagreements when assessing drug causality independently. The agreement rate was lower for intermediate levels of causality, especially when strong evidence was lacking for confirming or ruling out drug causality[72]. Probabilistic methods are usually regarded as the most rigorous[73]. The probabilistic approach is based on the Bayes theorem and makes it possible to directly assess the odds of drug causation. However, these methods are rather troublesome to routinely use because information for

assessing the probability of drug causation is rarely available. Unlike the Bayesian approach, algorithms have appealing simplicity and are much more widely used for the operational assessment of ADRs. The main reason for their use is to increase inter- and intra-rater agreement. The overall observed agreement between algorithm and GI was moderate although poorly different from chance, confounding variables being a shortcoming of algorithms ability in assessing causality[74].

Drawbacks of animal models

The doubtful assumption that animal models are reasonably predictive of human outcomes has provided the basis for their widespread use in toxicity testing and in biomedical research aimed at developing cures for human diseases. To investigate the validity of this assumption, comprehensive bibliographic databases were searched for published systematic reviews of the human clinical or toxicological utility of animal experiments. In 20 reviews in which clinical utility was examined, the authors concluded that animal models were either significantly useful in contributing to the development of clinical interventions, or were substantially consistent with clinical outcomes, in only two cases, one of which was contentious. These reviews failed to clearly demonstrate utility in predicting human toxicological outcomes; consequently, animal data may not generally be assumed to be substantially useful for these purposes. Possible causes include interspecies differences, the distortion of outcomes arising from experimental environments and protocols, and the poor methodological quality of many animal experiments. What is more, very few reviews existed in which the majority of animal experiments were of good methodological quality. The poor human clinical and toxicological utility of most animal models for which data exists, in conjunction with economic costs, justify a perplexity on animal models[75].

In numerous cases, researchers are simply not aware of the limitations of the animal experiment as such. For example, many animal experiments are dramatically "under-powered", that is, carried out with groups that are too small to allow conclusions to be drawn from the outcome. This stands in marked contrast to *in vitro* experiments where replicate experiments usually represent no major problem. Since *in vitro* models are generally more prone to artefacts due to the numerous variables, for example, of cell culture, the key requirement for their application is their validation and quality control. Sadly, many methods, even if published in the scientific literature, are little standardised and reproducible. Due to limitations in space, many scientific journals cannot publish detailed methodological descriptions. However, nowadays a supplementary central deposit of methods could easily be linked to the respective article[76].

ETHICAL AND LEGAL PROBLEMS ABOUT DRUG-INDUCED LIVER INJURY

Patients should be especially cautious about combining multiple drugs, and tell their doctor about any drugs or other substances they are taking, including prescription and over-the-counter medications, recreational drugs, herbal remedies, and nutritional supplements. Health care professionals are encouraged to report all ADRs, mainly hepatoxicity, and to pay much more attention in prescribing and administering drugs.

Pharmacovigilance is a key step in discovering DILI. But, it is also concerned with pharmacological, pathological, epidemiological and legal respects, other ADRs and interactions as well as problems relating to ineffectiveness, inappropriate use, dependence or poisoning. Physicians should always think of this ADR in the absence of other clear hepatic disease.

LIVER DISEASES POTENTIALLY CAUSED BY DRUGS

Acute hepatitis

Dose-dependent: Acetaminophen[77,78], salicylates[79], (high doses i.e. > 2 g/d).

Dose-independent: Acebutolol[80], allopurinol[81], carbamazepine[82], cimetidine[83], dantrolene[84], diclofenac[79], ethambutol[85], ethionamide[86], enflurane[87], phenelzine[88], phenindione[89], phenobarbital[90], phenytoin[91], phenylbutazone[79], halothane[92], ibuprofen[79], indomethacin[79], isoniazid[85], ketoconazole[93], labetalol[94], maprotiline[95], metoprolol[96], mianserin[97], naproxen[79], para-aminosalicylic acid[98], piroxicam[79], pyrazinamide[85], quinidine[99], penicillins[100], ranitidine[101], sulfonamides[102], sulindac[79], tricyclic antidepressants[103], trimethoprim-sulfamethoxazole[104], valproic acid[105], verapamil[106].

Acute fatty liver

Adrenocortical steroids[107], phenytoin[108], salicylates[79].

Fatty liver

Amiodarone[109], asparaginase[110], ibuprofen[79], indometacin[79], ketoconazole[111], methyldopa[112], naproxen[79], nifedipine[113], acetaminophen[77], perhexeline[114], rifampicin[85], sulindac[79], tetracyclin[115], valproic acid[116], zidovulin[117].

Cholestatic syndrome

Amoxicillin/clavulanate[118], azathioprine[119], captopril[120], carbamazepine[121], carbimazole[122], cephalosporins[123], chlordiazepoxide[124], chlorpropamide[125], cloxacillin[126], cyclosporine[127], danazol[128], disopyramide[129], enalapril[130], erythromycin[131], flecainide, flucoxacillin[132], flurazepam[133], flutamide[134], gold[135], griseofulvin[136], glyburide[137], imipramine[138], haloperidol[139], ketoconazole[140], megestrol[141], mercaptopurine[119], methimazole[142], methyltestosterone[143], nifedipine[144], nitrofurantoin[145], norethandrolone[146], nonsteroidal anti-inflammatory drugs[79], oral contraceptives[147], phenothiazines[148], phenytoin[149], penicillamine[150], propoxyphene[151], sulfonamides[152], tamoxifen[153], thiabendazole[154], tolbutamide[155], tricyclic antidepressants[156], troleandomycin[157], verapamil[158].

Liver granulomas

Allopurinol[159], aspirin[79], carbamazepine[160], chlorpromazine[161], diltiazem[162], gold[163], hydralazine[164], nitrofurantoin[165], penicillin[166], phenylbutazone[79], phenytoin[167], pyrazinamide[168], quinidine[169], sulfasalazine[170].

Chronic liver disease

Acetaminophen (in chronic use or at high doses)[79], dantrolene[171], isoniazid[172], methyldopa[173], phenytoin[174].

Liver cirrhosis/fibrosis

Methotrexate[175], nitrofurantoin[176], terbinafine[177].

Liver tumors

Anabolic steroids[178], danazol[179], oral contraceptives[178], testosterone[178], thorotrast[180].

Vascular reactions

Anabolic steroids[181], azathioprine[182], cyclophosphamide/cyclophosphamide combination[183], dacarbazine[184], oral contraceptives[185], thioquanine[186], vincristine[187].

Fulminant hepatitis and hepatic failure

Lamotrigine[188], nimesulide[189], carbamzepine and levetiracetam[190], isoniazid[191], clarithromycin[192], ecstasy[193].

LIVER DISEASES EVENTUALLY CAUSED BY DIETARY SUPPLEMENT (MAINLY IN OBESE PATIENTS)

Germander (Teucrium chamaedrys) extracts, widely used in Europe in the last decades as a weight loss agent, cause DILI probably mediated by furano neoclerodane diterpenoids[194]. Chaparral (creosote bush, greasewood, or Larrea tridentata) is a desert shrub traditionally used by Native Americans for treatment of several ailments. More recently, preparations of chaparral leaves have been marketed for use as weight loss agents. Reports of chaparral hepatotoxicity were first seen in 1992. The mechanism of chaparral toxicity is unclear but may involve its active ingredient, nordihydroguaiaretic acid[195]. Kava (kava kava, awa, or kew), derived from the dried root and rhizome of Piper methysticum, has recently been marketed as an anxiolytic and mood enhancer. Recent series from Europe have described more than 30 cases of kava-associated hepatic injury, including five cases leading to OLT. The mechanism of hepatic injury appears to be immune-mediated, with CYP2D6 deficiency perhaps being a risk factor[196]. *Ma huang* (from Ephedra sinica and other Ephedra species) is a traditional Chinese extract used for treatment of asthma, nasal congestion, and fever. Recent Western marketing has focused on the stimulatory effects of *Ma huang*, which contains 0.15%-2% of ephedrine-like alkaloids by weight. Although most adverse effects of *Ma huang* are cardiovascular or neurological (e.g. hypertension, stroke, myocardial infarction, seizures, and psychosis), 4% of reports mentioned acute hepatitis. *Ma huang* contains phytochemicals which are thought to modify its toxic activity[197]. In addition to the above supplements, liver injury has been attributed to other botanical agents. The pyrrolizidine alkaloids found in comfrey leaves and Heliotropium, Senecio, and Crotalaria species are known to cause veno-occlusive disease of the liver *via* a toxic effect[198]. Mixtures of valerian and skullcap (Valeriana officinalis and Scutellaria lateriflora) have induced hepatitis *via* alkylating agents. LipoKinetix, was marketed as a dietary supplement for weight loss. Following reports of seven cases of severe hepatotoxicity associated with its use, the FDA moved to remove it from the market in November 2001. Hepatic injury appears to be due to an idiosyncratic reaction, perhaps related to phenylpropanolamine[199]. Among other weight loss agents, usnic acid should be suspected in cases of severe hepatotoxicity[200].

For further details about the topics of this report, we advise the readers to consider the review by Bleibel *et al*[201] and/or to connect to: http://www.fda.gov/cder/guidance/7507dft.htm.

Abstract

Thyroid hormones define basal metabolism throughout the body, particularly in the intestine and viscera. Gastrointestinal manifestations of dysthyroidism are numerous and involve all portions of the tract. Thyroid hormone action on motility has been widely studied, but more complex pathophysiologic mechanisms have been indicated by some studies although these are not fully understood. Both thyroid hormone excess and deficiency can have similar digestive manifestations, such as diarrhea, although the mechanism is different in each situation. The liver is the most affected organ in both hypo- and hyperthyroidism. Specific digestive diseases may be associated with autoimmune thyroid processes, such as Hashimoto's thyroiditis and Grave's disease. Among them, celiac sprue and primary biliary cirrhosis are the most frequent although a clear common mechanism has never been proven. Overall, thyroid-related digestive manifestations were described decades ago but studies are still needed in order to confirm old concepts or elucidate undiscovered mechanisms. All practitioners must be aware of digestive symptoms due to dysthyroidism in order to avoid misdiagnosis of rare but potentially lethal situations.

Key words: Hypothyroidism; Hyperthyroidism; Gastrointestinal motility; Intestine; Liver; Viscera

INTRODUCTION

Thyroid hormones act on almost all organs throughout the body and regulate the basal metabolism of the organism[1]. The gut and viscera are not spared, and disturbances in thyroid function have numerous gastrointestinal manifestations, the true incidence of which is unknown[2]. Digestive symptoms or signs may also reveal clues to thyroid disease and, when ignored or underestimated, diagnosis may be delayed and serious consequences may occur[3-5]. Additionally, patients with dysthyroidism are at an increased risk of developing specific pathologies in the digestive system, whether due to thyroid hormone disturbances or associated with a particular thyroid disease[6-17].

Thyroid interactions with the gastrointestinal system have been widely reported but the literature lacks an exhaustive report on different consequences of dysthyroidism. Gastrointestinal motor dysfunction has been widely accepted as the main cause of symptoms but many complex phenomena have not yet been completely elucidated[4,11,18-21]. This review aims to gather up-to-date knowledge about the effects of dysthyroidism on the gut and viscera.

HYPERTHYROIDISM

As thyroid hormones act on almost all organs within the gastrointestinal tract (gut and viscera), hyperthyroidism induces several symptoms and signs, and causes different biologic and metabolic derangements. Digestive symptoms may represent the only manifestations of hyperthyroidism. A lack of cardinal features of the disease and the presence of persistent abdominal pain, intractable vomiting, weight loss and altered bowel habits are designated as apathetic hyperthyroidism[22].

Esophagus and stomach

Dysphagia is a rare manifestation of hyperthyroidism and can have an acute or chronic pattern[3]. It may be related to direct compression from goiter or to altered neurohormonal regulation[23,24]. Excess thyroid hormone may cause myopathy which involves striated muscles of the pharynx and the upper third of the esophagus[23]. Subsequently, the oropharyngeal phase of deglutition is predominantly impaired and patients are predisposed to nasal regurgitation and aspiration pneumonia. Correction of the endocrine disorder is believed to reverse dysphagia[3,23,24].

In the esophagus, thyroid hormone excess increases the propagation velocity of contractions[25]. Thyrotoxic patients may frequently complain of chronic dyspeptic symptoms such as epigastric pain, fullness and eructation[2]. Tachygastria has been incriminated in upper gastrointestinal symptoms but the true mechanism is not yet fully understood[19,20]. Vomiting is rarely intractable and may involve neurohormonal mediators along with direct action[26]. Studies have yielded variable, even contradictory results concerning gastric emptying in thyrotoxicosis[18,19,27,28]. A significant increase in the dominant electrical frequency and dysrhythmia was shown through a myoelectrical activity study[19,20] but lack of correlation between electrogastrography (EGG) findings and gastric emptying by scintigraphy may be the result of intervening factors such as a smooth muscle disorder, electro-mechanical dissociation, pylorospasm or incoordination of the antrum and duodenum[20,29]. Hypergastrinemia found in hyperthyroidism may also influence gastric and intestinal motility[30].

Intestine and colon

Appetite increase is common but may not be adequate to maintain weight in severe disease[31]. Up to 25% of patients with hyperthyroidism have mild-to-moderate diarrhea with frequent bowel movements[22,32]. Some degree of fat malabsorption is usually present and may reach 35 g/d[33]. Intestinal hypermotility in thyrotoxicosis reduces small bowel transit time, especially when diarrhea is present[18]. Increased appetite and excessive fat-rich food intake may contribute to excessive fecal fat[34]. Moreover, diarrhea may be related to a hypersecretory state within the intestinal mucosa[22,35]. The adrenergic system may contribute to diarrhea as suggested by correction of transit in hyperthyroid patients treated with the β-adrenergic antagonist propranolol[36]. A reduction in mixing of food with digestive secretions may also contribute to decreased fat absorption. Alterations in intestinal absorptive function are still a matter of debate, as absorption may be increased for glucose[34,37] but decreased for calcium[38]. Anorectal physiology is impaired in hyperthyroidism; when compared to controls, mean anal resting and squeeze pressures are lower as is the rectal threshold of sensation[39].

Liver

Increases in aspartate aminotransferase and alanine aminotransferase in 27% and 37%, respectively, of hyperthyroid patients have been reported[40]. These disturbances are attributed to a hypoxic state with disproportionately increased liver activity compared to blood flow[41]. Mild elevation of alkaline phosphatase is encountered in up to 64% of patients with hyperthyroidism[42-44]. This elevation is not specific to the liver since a high turnover in bones may contribute. Elevations of γ-glutamyl transferase and bilirubin do not exceed 20% of normal values[44]. Increases in liver enzymes and hepatic injury related to anti-thyroid therapy is well documented[45]. Mild histological changes are common[46], but cases of fulminant hepatic failure with centrizonal necrosis have been described[46,47]. Long term untreated hyperthyroidism can ultimately lead to cirrhosis[48]. Quantitative 99mTc-HIDA cholescintigraphy in hyperthyroid rats without a gallbladder showed accelerated bile flow to the duodenum[21].

Hyperthyroidism and associated gastrointestinal diseases

Ch'ng *et al*[6] found that patients with Grave's disease were at a 5-fold added risk of developing celiac disease when compared to sex- and age-matched controls. In such cases, celiac disease may contribute to diarrhea and malabsorption. Thyrotoxicosis has been reported in 3.8% of patients with ulcerative colitis while the incidence of ulcerative colitis in hyperthyroid patients varies around 1%[17]. Thyroid disease may exacerbate ulcerative colitis symptoms or alter the response to therapy. Moreover, a positive correlation between Grave's disease and ulcerative colitis has been reported[12], but a common autoimmune origin could not be proven[11]. Isolated instances of an association between Grave's disease and Crohn's disease have been reported, but a common pathogenesis is still to be identified[16]. Primary biliary cirrhosis in association with hyperthyroidism is extremely rare and has only described as isolated case reports[8]. One study showed a prevalence of pernicious anemia of 5% in thyrotoxic patients, mainly resulting from Grave's disease[49], but parietal cell antibodies have been found in up to 30% of patients[50].

HYPOTHYROIDISM

Hypothyroidism occurs mostly secondary to an autoimmune disease or as a consequence of therapy for hyperthyroidism. It manifests throughout the body with decreased metabolic functions. It is biochemically characterized by the accumulation of glycosaminoglycans, mainly hyaluronic acid, in soft tissues[51]. Interstitial edema predominating in the skin and muscles (including the heart and intestinal muscular layer) will follow. Clinical presentation of the disease is related to the severity of the disease (biochemical derangement) but harbors significant individual variation[52]. Gastrointestinal manifestations are not rare and involve different digestive organs.

Esophagus and stomach

Severe hypothyroidism may lead to disturbances in esophageal peristalsis. When the proximal portion is involved, myxedema causes oropharyngeal dysphagia[53] while esophagitis and hiatal hernia occur when the

distal esophagus is altered[22,54]. Esophageal motility disorders, reduced velocity and amplitude of esophageal peristalsis and a decrease in lower sphincter pressure all contribute to dysphagia[55]. Although it represents an extremely rare cause of dyspepsia, hypothyroidism should be investigated when all exploratory methods are negative[56]. A gastric myoelectrical study led by Gunsar *et al*[19] showed a positive correlation between dyspepsia and hypothyroid scores. Additionally, gastric dysmotility is significantly more frequent in hypothyroid patients and is a result of muscle edema and altered myoelectrical activity[57]. Despite a few contradictory results[58], the hypothyroid state seems to delay gastric emptying[19,59]. Phytobezoar due to hypothyroidism has also been reported[60]. Achlorhydria in hypothyroidism may be related to subnormal serum gastrin[61]. Finally, hypothyroidism is associated with a decrease in duodenal basal electrical rhythm[62].

Intestine and colon

Appetite is usually reduced, but weight gain may reach 10% because of fluid retention[31]. Vague abdominal discomfort and bloating may be erroneously attributed to functional bowel disease[2]. The effect of hypothyroidism on the gastrointestinal tract seems to be multifactorial with possible alterations in hormone receptors, neuromuscular disorders and myopathy caused by infiltration of the intestinal wall. Reduction of peristalsis in hypothyroidism is the main pathophysiologic process[62], and constipation remains the most frequent gastrointestinal complaint[22]. Up to 15% of patients have fewer than 3 bowel movements weekly[2]. Moreover, thyroid hormone deficiency may influence transepithelial flux transport by inhibiting Cl^-/HCO^{3-} anion exchange with a subsequent effect on intestinal motility[35]. Although rare, severe cases of hypothyroidism lead to ileus and colonic pseudo-obstruction with fecal impaction and megacolon[63,64]. Inadvertent surgery in these situations is harmful and may be lethal[5]. Absorption of specific substances may be decreased but the total quantity absorbed is usually normal or increased due to an extended time in bowel transit[31,65]. Diarrhea in the hypothyroid state is mainly the result of increased bacterial growth secondary to bowel hypomotility[66,67]. Exceptionally, hypothyroidism may be the cause of gastrointestinal bleeding refractory to usual treatments[68], most probably by means of acquired coagulopathy[69]. Deen *et al*[39] found that the anorectal physiology is altered in hypothyroid states. While maximal anal resting and squeeze pressures are normal, the threshold for rectal sensation is higher and the maximal tolerable volume is diminished when compared to controls.

Liver

Liver function tests are mildly disturbed in almost 50% of patients with hypothyroidism despite normal histological findings[22]. Decreased hepatic metabolism in hypothyroidism is reflected by reduced oxygen consumption[70] and causes a significant decrease in gluconeogenesis[71] and urea nitrogen production[72]. Myxedema ascites in hypothyroidism is rare and may be a long-standing overlooked and/or isolated sign of the disease[73]. The serum-to-ascites albumin gradient is usually > 1.1 g/dL with a high protein content[4,73]. Although considered to be the result of hypothyroidism-related chronic right-heart failure[74,75], it is mainly attributed to increased permeability of vascular endothelium[4,76]. Patients with a common bile duct stone and gallbladder stone have, respectively, 7-fold and 3-fold increases in the frequency of hypothyroidism[77]. This may be related to the triad: hypercholesterolemia, hypotonia of the gallbladder and reduced bilirubin excretion. Experiments in rats confirmed a thyroxine effect on bile composition[78,79], decreased hepatocytic bile salt excretion in hypothyroid state[80] and relaxation of the sphincter of Oddi[81]. Moreover, Laukkarinen *et al*[21] confirmed that bile flow to the duodenum was reduced in hypothyroid rats.

Hypothyroidism and associated gastrointestinal diseases

Compared to the general population, patients with autoimmune thyroiditis have an almost 5-fold increased risk of developing celiac disease[14,15,82,83]. Valentino *et al*[7] showed that as many as 43% of patients with Hashimoto's thyroiditis carry cellular markers for celiac disease. The prevalence of thyroid antibodies is extremely high in patients with pernicious anemia (57%)[13], and the prevalence of overt pernicious anemia among patients with primary hypothyroidism is 12%[31]. An association between hypothyroidism and primary biliary cirrhosis is well documented and ranges from 5% to 20%[9,10,84]. Among patients with primary biliary cirrhosis, antithyroid antibodies were present in 20%[10]. The coexistence of Hashimoto's thyroiditis and Crohn's disease is rare and the etiological background remains to be elucidated[16,85].

CONCLUSION

Dysthyroidism, whether in excess or deficiency, has clinical manifestations within different portions of the digestive tract and viscera. Whether these are related to hormone level disturbances alone or are associated with a specific thyroid disease, the underlying pathophysiology is often complex and not yet fully elucidated in current studies. Although most frequent manifestations are well known, some situations are often underdiagnosed, leading to serious illness and death.

Digestive diseases related to thyroid hormone abnormalities or associated with particular thyroid diseases must be recognized by most, if not all practitioners. Much research requires to be performed in order to add to our understanding of the scientific background of the older empirical works.

Abstract

Developing countries shoulder a considerable burden of gastroenterological disease. Infectious diseases in particular cause enormous morbidity and mortality. Diseases which afflict both western and developing countries are often seen in more florid forms in poorer countries. Innovative techniques continuously improve and update gastroenterological practice. However, advances in diagnosis and treatment which are commonplace in the West, have yet to reach many developing countries. Clinical guidelines, based on these advances and collated in resource-rich environments, lose their relevance outside these settings. In this two-part review, we first highlight the global burden of gastroenterological disease in three major areas: diarrhoeal diseases, hepatitis B, and *Helicobacter pylori*. Recent progress in their management is explored, with consideration of future solutions. The second part of the review focuses on the delivery of clinical services in developing countries. Inadequate numbers of healthcare workers hamper efforts to combat gastroenterological disease. Reasons for this shortage are examined, along with possibilities for increased specialist training. Endoscopy services, the mainstay of gastroenterology in the West, are in their infancy in many developing countries. The challenges faced by those setting up a service are illustrated by the example of a Nigerian endoscopy unit. Finally, we highlight the limited scope of many clinical guidelines produced in western countries. Guidelines which take account of resource limitations in the form of "cascades" are advocated in order to make these guidelines truly global. Recognition of the different working conditions facing practitioners worldwide is an important step towards narrowing the gap between gastroenterology in rich and poor countries.

Key words: *Helicobacter pylori*; Developing countries; Gastrointestinal diseases; Health care delivery; Practice guidelines

INTRODUCTION

Despite political rhetoric, foreign aid, and increased global wealth, the disparity between the developing and developed world is more evident than ever before.

Recently, the economic successes of China and India have lessened poverty for millions of people. Nevertheless, these countries aside, international inequality in income has continued to rise over the past two decades[1].

Nowhere is this inequality clearer than in the arena of health. A child born in Angola in 2006 has a 26% chance of dying before its fifth birthday. In the UK, that risk is 0.6%. In 2006, the life expectancy for a woman from the United States of America was 80 years. If she was instead living in Zambia, her life expectancy declines to just 43 years[2].

In this review, we examine some of the main challenges in developing countries, and discuss potential and existing solutions. Our definition of developing countries is that set out by the International Monetary Fund; "countries with low levels of output, living standards, and technology; per capita GDPs are generally below $5000 and often less than $1500"[3]. The converse, developed countries, will be referred to as "western countries" for clarity. In common practice, these include most of Europe, North America, Japan and Australasia[3] (Figure 1).

The focus of the review will be on gastroenterological problems which head the global disease burden. Although challenges such as war, inadequate water and sanitation, and economic failure all undoubtedly impact on global health, it is beyond the scope of this article to discuss these factors in detail. Moreover, whilst problems such as unstable governments, sectarian violence, and environmental catastrophe undeniably compound health issues, they are by no means confined to developing countries.

In the first part of this review, we will focus on three significant areas of gastroenterological disease which highlight particular problems in developing countries: diarrhoea, hepatitis B and *Helicobacter pylori* (*H pylori*).

The second part of the review will consider the implementation of clinical services in developing nations, encompassing the health workforce, endoscopy services, and the relevance of resource-blind guidelines.

GASTROENTEROLOGICAL DISEASE BURDEN OF DEVELOPING COUNTRIES

Diarrhoeal diseases

The global burden of diarrhoeal diseases outweighs any of the more complex diseases seen in gastroenterology clinics. Every year, there are an estimated 1.5 billion episodes of diarrhoea worldwide[4]. These episodes result in the deaths of approximately 2.2 million people, mostly children in developing countries[4]. This mortality rate has improved from the early 1980s, when diarrhoea is estimated to have caused 4.5 million deaths in children alone[5]. However, it is still the third leading cause of death in under-5 years old, after neonatal causes and pneumonias[6].

Developing countries bear the brunt of this burden. Diarrhoea causes 17.9% of deaths in low-income countries compared to 1.6% in high income countries[6]. Most of these cases are due to the lack of safe water, sanitation and hygiene. Only 34% of people in low-income countries have access to adequate sanitation[6]. As mortality rates from diarrhoea are now so low in western countries, the scale of disease is often expressed in terms of financial costs instead: hospitalisation rates and doctors' consultation time[7]. However, these can be overused resources in the West, and are thus poor comparison measures between countries.

Figure 1 Distribution of countries as per International Monetary Fund (IMF) definitions of economic development (IMF statistical database[3]: reproduced with kind permission of IMF).

Diarrhoeal diseases are caused by a wide variety of pathogens. In 1991, the World Health Organization (WHO) performed a case-control study of the aetiology of diarrhoea in children under 36 mo of age, in five countries: China, India, Mexico, Myanmar and Pakistan. The pathogens most strongly associated with disease were rotavirus, Shigella species and enterotoxigenic *Escherichia coli*[8]. These enteric pathogens, with cholera and typhoid fever, have been identified as the highest priorities for vaccination development by WHO[9].

Diarrhoeal episodes are usually acute and self-limiting. However, they can cause fluid and electrolyte loss from the small intestine so severe that it results in death from dehydration. In some cases, diarrhoea can become persistent: usually defined as lasting at least 14 d[10]. There is evidence that persistent diarrhoea in children can lead to malnutrition[11,12], growth stunting[13,14], and effects on cognitive function[15,16]. A Brazilian study found that children with persistent diarrhoea in the first 2 years of life scored significantly lower on intelligence tests at age 6-10 years, even when controlling for maternal education and helminthic infection[16].

In the late 1980s, oral rehydration therapy (ORT) transformed the management of acute diarrhoea. Physiological studies conducted during the 1950s and 1960s identified the co-transport of sodium and glucose in the small intestine[17-19], which were then harnessed into the oral rehydration solution (ORS) developed at the International Centre for Diarrhoeal Diseases Research in Bangladesh in 1968[20]. WHO adopted and started distribution of a standard ORS in 1975, and set up the WHO Programme for Diarrhoeal Control in 1979[21].

ORT has been heralded as one of the most important therapeutic advances of the past century and has undoubtedly contributed towards the reduction in global child mortality rates described above[22,23] (Figure 2). However it has not reduced the morbidity associated with diarrhoea. Neither stool volume nor

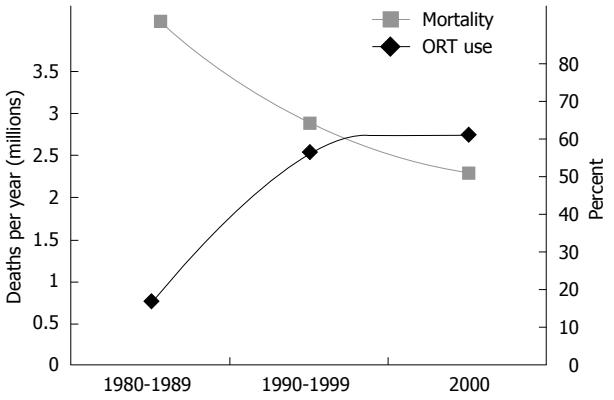

Figure 2 Association between coverage of oral rehydration therapy (ORT) use and mortality rates from diarrhoea in selected countries (from Podewils *et al*[23], 2004. Reproduced with kind permission of Elsevier).

duration of illness are significantly reduced with ORT use, and there may even be a paradoxical increase in stool volume. Therefore, further research has been performed on modifying ORT formulations, including the development of amino acid-containing, starch-based, and reduced sodium solutions. Glutamine, an amino acid, stimulates sodium absorption in experimental models of cholera and rotavirus diarrhoea[24-27]. However, there is conflicting evidence on the efficacy of glutamine containing ORT[20,28], and it is not recommended over WHO ORS at present. The rationale for starch-based solutions (either rice or cereals) is that the polysaccharides would provide more glucose at the intestinal mucosa without the large osmotic load of glucose-based formulations. In addition, they provide nutrition early in the illness. Cereal-based formulations have been shown to reduce total fluid requirements and duration of illness, and are recommended over standard ORS in patients with cholera (but not for non-cholera diarrhoea)[28]. Although cereal-based ORT should be more accessible in rural locations, one study showed that mothers found it more time-consuming to prepare and used standard ORT in preference[29]. In 2003, WHO modified its ORS formulation to contain a reduced amount of sodium and glucose. This hypotonic solution has been associated with less vomiting, decreased stool volume, and reduced need for intravenous fluids[30], and has been recommended for patients with non-cholera diarrhoea. However, concerns have been raised that exclusion of cholera can be difficult in under-resourced areas and use of this formula will lead to hyponatremia in these patients[31]. Clearly, there is still research to be done into the definitive formulation of ORT.

Despite the efficacy of ORT, uptake in developing countries can be variable[32,33]. Difficulties include remembering the correct quantities of ingredients involved in preparing an ORT and high levels of illiteracy[34-36]. Continued effort is required to provide ongoing education at a community level in order to bring about long-term changes[37-40].

More recently, it has been shown that zinc deficiency complicates a significant proportion of diarrhoeal cases[41]. Zinc is not stored in the body, and may be lost from the intestine during diarrhoea[42]. It has a role in immune function[43], however the physiological mechanism linking zinc deficiency with diarrhoea has not yet been elucidated. Several meta-analyses have shown that zinc replacement in acute and persistent diarrhoea reduces both the duration and severity of diarrhoea[43,44], and short (14 d) courses prevent further diarrhoea for 2-3 mo[45]. The WHO has recently recommended that zinc supplementation should be given to all children with acute diarrhoea persisting for at least 14 d[29]. Zinc supplementation has also been shown to significantly reduce the duration of lower respiratory infections[46], the second largest cause of child mortality worldwide.

Universal clean water, hygiene, and sanitation would be the ultimate solution to the global burden of diarrhoea, however in their continued absence, considerable interest has been shown in a more immediate intervention to prevent diarrhoea: vaccination. Of all the pathogens mentioned above, rotavirus is the leading cause of severe diarrhoea in children worldwide. By age 5 years, virtually all children will have been infected by rotavirus, and one in 293 children will have died from it. More than 80% of deaths from rotavirus infection occur in developing countries[47,48]. It also causes a significant financial burden in western countries. Each year in the United States, there are more than 400 000 consultations and up to 70 000 hospital admissions due to rotavirus[49]. Therefore, there has been substantial investment in the development of vaccines against rotavirus infections, both for western and developing countries.

In 2000 and 2001, China introduced a monovalent lamb-derived live attenuated oral vaccine[50]. However, the efficacy of this vaccine is not known, as it was not tested against placebo in the final stages. The focus of research in other countries has been on developing a vaccine against multiple rotavirus serotypes, in order to provide heterotypic protection[48]. The first multivalent live oral reassortant vaccine developed was RotaShield, which was highly effective in field trials in the United States, Finland and Venezuela[51-54]. It was included in the USA immunisation programme in 1998[55], however several cases of intussusception were reported, and the vaccine was subsequently withdrawn[56]. This risk was estimated to be only one per 10 000 vaccinated infants[57], however trials in Ghana, Bangladesh, and India were also stopped at that time, and it was thus not possible to do a risk-benefit analysis for developing countries[48]. Two further rotavirus vaccines have since come onto the market; Rotateq, a human-bovine live-attenuated oral vaccine, and Rotarix, a human live-attenuated oral vaccine. Trials in medium and high-income countries have produced good efficacy results for both these vaccines[58,59], however more trials are needed in developing countries. A large commitment to funding from donor countries will also be required to further reduce global child mortality from diarrhoea.

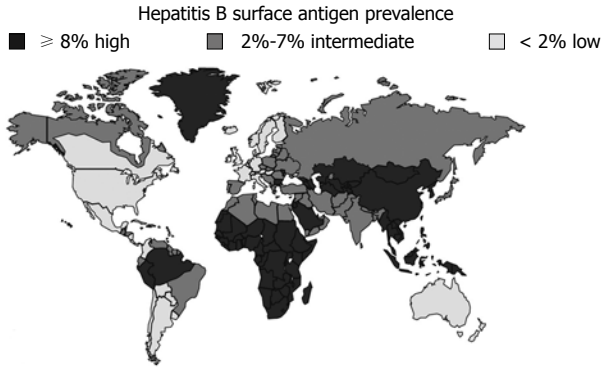

Figure 3 Geographical distribution of the prevalence of chronic hepatitis B virus infection, 2002 (from Mast *et al*[67], 2004. Reproduced with kind permission of Elsevier).

Hepatitis B virus (HBV)

Hepatitis B is the foremost hepatological health problem in the developing world. Up to two billion people worldwide have serological evidence of past or present HBV infection, and 360 million have chronic infection[60,61]. Through its long-term sequelae of liver cirrhosis and hepatocellular carcinoma (HCC), HBV causes 500 000-700 000 deaths each year[60] and is an accessible target for cancer prevention on a massive scale. Although hepatitis C virus (HCV) is increasing in importance, particularly in the western world, HBV is still estimated to account for 50%-55% of HCC worldwide compared to 25%-30% for HCV[62-64].

HBV varies in its prevalence worldwide. Countries can be divided by their level of endemicity, which is based on the percentage of the general population that is seropositive for HBsAg (chronic carriers). Countries with high endemicity have more than 7% seropositivity levels, intermediate 2%-7%, low 0.5%-2% and very low endemicity countries have < 0.5% seropositivity[65,66] (Figure 3[67]). Developing nations make up the bulk of high endemicity countries, including much of sub-Saharan Africa and South East Asia. Notable pre-vaccination examples include the Gambia, where 36% of children were chronic carriers[68], and Taiwan, with 15%-20% chronic carriage in the general population[69-71].

Of particular relevance to developing countries, the likelihood of acquiring chronic HBV infection depends on the age of acquisition of the virus[60,72,73]. For children under 1 year, the risk of chronic infection is 90%. For 1-5 years old, the risk is 30% and for children older than 5 years and adults, the risk decreases to only 6%. This feature accounts for most of the disparity in prevalence outlined above.

The main modes of transmission also vary between countries of high and low endemicity. In high endemicity countries, and in stark contrast to the West, perinatal and horizontal transmission (exposure from close household contacts or play with other children) are the dominant modes[66,74]. In these countries, 70%-90% of the population show serological evidence of previous or current HBV infection. In lower endemicity countries, HBV transmission is mainly limited to high risk groups, such as intravenous drug users and healthcare workers, or is acquired sexually. Although not the main transmission mode, healthcare-acquired infections can assume greater importance in developing countries due to lack of resources for disposable equipment and sterilisation, or lack of awareness of infection control practices[65,75]. However, blood products in most parts of the world are now screened for HBsAg[76].

Chronic infection is responsible for the main burden of disease associated with HBV. Approximately 20% of chronic carriers will die prematurely from cirrhosis leading to liver failure or HCC[77]. Although therapies are available which can suppress HBV replication or modulate the immune reaction, these are expensive and not widely available in much of the developing world. There is currently no therapy which results in virus eradication.

Therefore, the emergence of a plasma-derived vaccine against HBV in the early 1980s was a significant event. This was the world's first cancer prevention vaccine and the first vaccine to prevent a sexually transmitted disease, both functions now echoed by the recently licensed human papillomavirus vaccines. Most current vaccines are produced by recombinant technology[65], and the vaccine prevents HBV infection in 90%-100% of people who produce sufficient antibody responses[78]. It is also highly effective as post-exposure prophylaxis in cases of possible perinatal transmission, even where HBV immunoglobulin co-administration is not possible[79]. Current consensus is that booster doses are not necessary to maintain immunity[60]. Finally, although susceptible to freezing, present vaccines are heat stable, a great advantage in developing countries where access to cold storage facilities is often difficult[60].

In 1992, WHO's Global Advisory Group of the Expanded Programme on Immunization recommended that all highly endemic countries included hepatitis B vaccination into their national childhood immunisation programs by 1995, and all other countries by 1997[80,81]. As of 2006, more than 160 countries had implemented universal hepatitis B vaccination[82]. Several western countries with very low endemicity, such as the United Kingdom, have chosen to pursue a policy of targeted vaccination of high-risk groups rather than universal vaccination[83].

In countries which implemented universal childhood vaccination early on, such as Taiwan, the Gambia, and Malaysia, HBV vaccination was found to be very effective, both in terms of disease prevention and health costs[66,84]. The ultimate goal of these programmes is to prevent the long-term consequences of cirrhosis and HCC, therefore it will be some years before a complete evaluation can be carried out on the first vaccinated cohorts. However, indicators such as HBV seroprevalence and hospital records of acute HBV infections, provide early evidence of their successful impact.

In Malaysia, where universal vaccination was introduced in 1990, HBsAg seroprevalence among children aged 7-12 years decreased from 1.6% in 1997 to

0.3% in 2003[85]. In the Gambia, where HCC is the most common tumour in men[86], vaccination was introduced progressively between 1986 and 1990. Childhood HBsAg seroprevalence has since decreased from 10% in 1986 to 0.6% in 1991[87-89]. Similar declines have been shown in Senegal, China, Indonesia, and Thailand[90].

The best example of the effectiveness of a HBV vaccination programme is probably Taiwan, which had very high levels of chronic carriage in the pre-vaccination era[91]. Over 90% of the population under the age of 40 years had been infected by HBV[92]. Universal infant vaccination was introduced in Taiwan in 1984, one of the first regions to do so[91,93]. 15 years after implementation, HBsAg seroprevalence amongst children 1-15 years decreased from 9.8% in 1984 to 0.7%[94]. In addition, the incidence of fulminant hepatitis amongst infants also decreased. The average mortality from fulminant hepatitis in infants between 1975 and 1984 (pre-vaccination) and from 1985-1998 (post-vaccination) was 5.36 and 1.71 per 100 000 infants, respectively[95].

These evaluations show that HBV can be effectively prevented through a universal vaccination programme. As humans are the only known natural host of the virus, it is feasible that vaccination could eradicate HBV from the world. The major obstacle to global coverage of HBV vaccination is funding. Although the cost of monovalent HBV vaccines had decreased from approximately US $3.00 per dose in 1990 to US $0.30 per dose in 2001[96]. the cost is still higher than the other vaccines included in the extended programme on immunization (e.g. measles, oral polio) which cost between US $0.06 to 0.10 per dose. Several manufacturers have produced combination vaccines containing hepatitis B antigen which allow the addition of hepatitis B vaccine into existing childhood immunisation programmes, however again these are expensive and beyond the capacity of many developing countries.

The Global Alliance for Vaccines and Immunization (GAVI) was founded in 1999 to address this funding gap. GAVI is a consortium between WHO, the World Bank, UNICEF, the Bill and Melinda Gates Foundation, governments of both developing and developed nations, and the vaccine industry[97]. By 2007, it had provided funding for 67 countries out of 69 eligible for support towards the introduction of HBV vaccination programmes[98]. As a result, global three dose vaccine coverage has nearly doubled since 1999 (Figure 4[82]). However, the millions currently infected with HBV in the developing world carry an impending disease burden that will be substantial in the near future.

H pylori infection

It is estimated that 50% of the world's population is infected by *H pylori*[99]. Although most infections are not associated with clinical disease, a significant proportion will go on to develop some of the commonest problems in gastroenterology: gastritis, peptic ulcer disease, and gastric cancer[100-103]. Although less than one percent of infected persons will develop gastric cancer, this is the fourth most common malignancy in the world[104]. It is

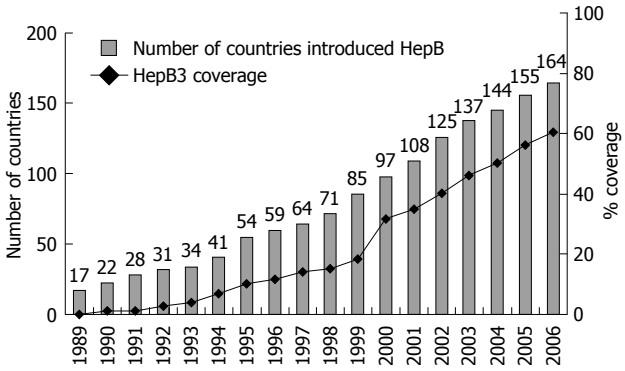

Figure 4 Graph showing number of countries who have introduced hepatitis B vaccination programme and global infant three dose vaccine coverage ("HepB3") (reproduced with kind permission of World Health Organisation).

Table 1 Estimated *H pylori* infection prevalence globally (reproduced with kind permission of World Gastroenterology Organisation)

Country/region	Estimated prevalence of *H pylori* infection (%)
Mexico, Central/South America	70-90
Africa	70-90
Asia	50-80
Eastern Europe	70
Western Europe	50-30
United States and Canada	30
Australia	20

these strong disease associations which establish *H pylori* infection as a leading gastroenterological public health problem.

There are distinct differences in the pattern of *H pylori* infection between developing and western countries. The prevalence of infection in the West has been declining for some years, however it is still very high in developing countries[99], with the majority of the global burden of infection found here (Table 1[105]). This is not surprising, given that risk factors for the infection include low socio-economic status, crowded living conditions, several children sleeping in one bed, large number of siblings and unclean water-all conditions common in the developing world[106-110]. Low education levels have also been positively associated with *H pylori* infection in several studies[111-113]. Prevalence levels in developing countries are therefore associated with the circumstances induced by poverty-and are unlikely to follow the decreasing trend of the western world without alleviation of this factor.

Another marked difference between *H pylori* infection in developing and western countries is the age at acquisition of the infection. Individuals tend to be infected much younger in developing countries than in western countries. In many developing countries, the prevalence of infection exceeds 50% by 5 years of age[114]. In a study of Bangladeshi children, the prevalence of *H pylori* infection was 42% by 2 years of age. Another study of Gambian children using the

diagnostic ^{13}C-urea breath test (UBT) found prevalence levels of over 75% in the second year of life[115] (although very young ages may produce false positive results in the UBT[116]). Comparative studies in western countries show prevalences ranging from 6% in Finland[117], 11% in Scotland[118], 13% in Germany[119], and 23% in Italy[120,121].

Epidemiological studies support person-to-person transmission, which is likely to be *via* faecal-oral and oral-oral routes[122]. The oral-oral route is supported by the finding that pre-mastication of food (the chewing of food by mothers before feeding their babies) is associated with increased prevalence of *H pylori* in infants[106,123,124]. Pre-mastication of food is a common practice in both South-East Asia and Africa. Water sources have also been implicated as a potential mode of transmission, possibly through faecal contamination. An early Peruvian study showed that children living in households with a municipal water supply had a markedly higher risk of *H pylori* infection compared to those who had access to well water[125]. This was supported by findings from a study in Bolivia which found that children living in families using containers which prevented direct contact with this drinking water were significantly less likely to have *H pylori* infection compared to families without this container[126]. Iatrogenic transmission through contaminated endoscopes has been documented both in western and developing countries[127-129], and may be a particular problem in those countries where lack of resources hinders full disinfection procedures[130].

Worldwide, 90% of duodenal ulcers and up to 70% of gastric ulcers are associated with *H pylori* infection[100]. However, peptic ulcer disease is more likely to be reported in western countries, whereas gastric carcinoma is the more common disease association in developing countries[131] In 1994, the International Agency for Research into Cancer designated *H pylori* as a Class I Carcinogen[132].

It is hypothesized that the global variance in disease presentation is related to the age of acquisition of *H pylori* infection[101,122,133]. Infections acquired early in childhood, as in most developing countries, may cause persistent chronic low-grade inflammation which is linked with gastric cancer. Conversely, infections acquired later in life or in adulthood are associated with a more acute inflammatory response and thus ulcer disease.

However, differing incidence rates of gastric cancer globally has led to the description of the "African enigma": that despite a high prevalence of *H pylori* infection, this region has a relatively low incidence of gastric cancer[114,134]. However, this description has been disputed as the average life expectancy on the continent is low (51 years in 2006)[6]. Therefore, individuals may die of other causes before an age at which gastric cancer would become apparent. Indeed, a recent review by Agha *et al*[135] of endoscopy studies carried out on the continent found that *H pylori*-associated peptic ulcers and gastric cancer occurred at similar rates to Western levels.

H pylori infection can have significant sequelae in children in developing countries in addition to the long-term effects of chronic inflammation. Acute *H pylori* infection induces hypochlorhydria, which can be persistent[136-138]. Hypochlorhydria is associated with an increased risk of diarrhoeal diseases, as the gastric acid barrier is effective against many enteric pathogens[139,140]. Therefore, children infected with *H pylori* may be more likely to suffer from diarrhoeal diseases, both acute and persistent[140-143]. In fact, similar findings of malnutrition and decreased growth to those described above for diarrhoeal diseases have been shown in children infected with *H pylori*[142,144-146].

Spontaneous remission of *H pylori* is rare. For symptomatic infections, eradication is usually achieved by a course of antibiotics (typically clarithromycin, amoxicillin or metronidazole) combined with a proton-pump inhibitor[147]. There are other regional guidelines which recommend specific combinations, some of which are directed towards cost issues[148,149]. However, low-cost options may not be as effective as more expensive regimes and may necessitate repeat treatment, leading to higher costs overall[105]. In addition, although eradication may be achievable in western countries with a 7 d regime, treatments of 14 d may be required in developing countries. A study from Brazil showed eradication rates of only 50% if therapy was less than 10 d[150]. Subsequently, a meta-analysis showed a 12% higher eradication rate for 14 d *versus* 7 d regimes[151]. This must be balanced against the likelihood of patient compliance to a complex regime of drugs for 2 wk.

Unfortunately, eradication has been increasingly affected by antibiotic resistance levels worldwide. Many antibiotics are available "over the counter" in developing countries, i.e. not subject to prescription from a doctor. Metronidazole is also used to treat common enteric infections such as amoebiasis and giardiasis: often empirically. Metronidazole resistance is an increasing problem worldwide, although may not affect eradication as much as clarithromycin resistance[114,147]. Antibiotic resistance is the main reason for treatment failure. If sensitivity testing is available, this should guide choices for local first-choice and rescue therapy[105,147].

Re-infection rates after eradication can be as low as 1% in western countries[114]. Given the much greater prevalence of *H pylori* infection in developing countries, it is not surprising that re-infection rates there are also markedly higher. Studies from Chile and Bangladesh have found re-infection rates of around 13%[152,153]. It was difficult, however, to distinguish re-infection from recrudescence in these studies[114].

These issues highlight the need for a vaccine against *H pylori*. As for HBV, there is a need for both preventative and therapeutic vaccines, with the preventative vaccine used primarily on young children in high prevalence areas. Rupnow *et al*[154] modelled the population impact of a prophylactic vaccine. For a typical developing country, they found that with continuous vaccination, *H pylori*-attributable gastric cancer would decrease from 31.8 per 100 000 to 5.8 per 100 000 by 2100. Unfortunately, the current status of *H pylori* vaccines is disappointing. A number of trials have been conducted examining the safety and immunogenicity of various

formulations including recombinant urease, killed whole cells, and live vectors expressing *H pylori* antigens[155]. However, the vast majority of these showed low immunogenicity. Further research is needed to elucidate the mechanism of immune protection and the role of adjuvants.

In conclusion, *H pylori* infection is recognised as a significant public health problem in developing countries. Both antibiotic resistance and re-infection rates threaten the efficacy of existing eradication therapy. Definitive treatment in the form of both prophylactic and therapeutic vaccines is urgently needed in order to alleviate the burden of disease associated with this bacterium.

DELIVERY OF CLINICAL SERVICES IN DEVELOPING COUNTRIES

The first part of this review described three major gastroenterological diseases in the developing world: diarrhoeal disease, hepatitis B, and *H pylori*. Given this burden of gastroenterological disease, specialists in gastroenterology and hepatology are particularly important in developing countries. However, as in most specialities, there is a shortage of trainees.

Mass education and vaccination programmes against diarrhoeal infections, HBV, and potentially *H pylori*, all require immense resources for delivery. Dissemination of the ORT message requires health workers trained in education and prepared to work in remote areas. The consequences of HBV and *H pylori* infection are optimally treated by specialist referral and endoscopy services. However, one of the most limiting factors in the delivery of clinical services in developing countries is the severe lack of trained healthcare personnel.

Health workers

WHO estimates that there is a global shortage of 4.3 million healthcare workers. Africa alone needs an estimated 1.5 million more health workers in order to provide just basic health services[156]. For many years, the strengthening of national health systems and training of personnel have not been included as part of international aid programmes[157]. Staff have been mainly trained intensively for a particular programme's focus, with little integration into a comprehensive national system of health workers.

The result is an uneven distribution of health workers, inverse to the world's health needs. The Americas, including Canada and the United States, have 10% of the global burden of disease, yet almost 37% of the world's health workers. Sub-Saharan Africa, conversely, has more than 24% of the disease burden, yet has only 3% of health workers and less than 1% of the world's financial resources[156]. Ethiopia, for example, has two doctors per 100 000 population. The UK has more than 230 per 100 000[2] (Figure 5[156]). Fifty-seven countries are estimated to have critical shortages of health workers: 36 in sub-Saharan Africa[156].

Figure 5 Geographical distribution of countries with a critical shortage of health service providers (doctors, nurses and midwives) (reproduced with kind permission of World Health Organisation).

There is also a great imbalance within countries. Many hospitals and medical centres are centred in urban areas, whilst populations of many developing countries are still predominantly rural. In both developing and western countries, highly skilled workers can resist rural postings, as there is a higher quality of life and opportunity for money in the urban areas[157,158]. In Malawi, 85% of the population live in rural areas[2]. However, out of Malawi's 156 public sector doctors, 81 are working in central hospitals[159,160]. This leaves many districts without any doctors at all.

There is a general perception that economic migration by skilled health professionals is the main cause of the global shortage. There has been debate in western countries over the ethics of wealthy, more developed countries with a relative density of health workers accepting highly skilled medical migrants from countries with a severe need and valuable investment in their initial training[161]. It is estimated that the UK has saved some £65 million in training costs between 1998 and 2002 by recruiting Ghanaian doctors[162], whilst Ghana has lost £35 million of its training investment to the UK. However, although migration certainly plays a part, it is not the major factor. If Ethiopia had all the doctors it had trained over the last 30 years, there would still only be approximately ten doctors per 100 000 population[157]. The total number of African-born doctors and nurses working in Organisation for Economic Co-operative and Development countries account for less than 12% of the estimated shortages in Africa[163]. (While migration may not account for overall shortages in medical manpower its effects appear to be especially felt among highly trained specialists. In some developing countries almost 100% of specialists leave the country; most never to return).

There are not enough healthcare professionals being trained in developing countries to sustain the needs of the population. Ethiopia produces about 200 doctors per year for 75 million population[164]. The UK produces 6000 per year for 60 million people. Two thirds of Sub-Saharan African countries have only one medical school, whilst some still have none[165]. This inadequate production of health professionals, combined with the accumulative effects of migration and losses due

to the HIV/AIDS epidemic (44 Malawian nurses died in 1999-44% of the annual number trained)[166] have resulted in the severe shortages seen today.

There are several reasons for this low production rate of health workers. Foremost of these, inevitably, is funding. WHO estimates that it would cost $26.4 billion dollars to train the extra 1.5 million health workers needed for the African region, not including provision for future salary costs[156]. Any extra training or production of healthcare workers would require great motivation by donor agencies and governments to provide sustainable funding. Firstly, there is a high rate of student and teacher attrition. Students often find it difficult to find sufficient funding for tuition fees, even with government subsidies. Students who have received poorer quality secondary education may struggle with a medical course, and there is often little support available. Health worker shortages inevitably affect teacher numbers, with remaining lecturers shouldering an increased workload[157].

Once qualified, new graduates are faced with difficult working conditions. Lack of resources can lead to poor job satisfaction and high levels of HIV seropositivity make practical procedures hazardous[156,158]. There has also been a tendency to focus on pre-service training to produce health workers, compared to postgraduate education. Opportunities for specialisation and career progression are few[167]. For example, in Malawi, only 5% of medical specialists and 8% of paediatric posts are filled[159,160]. Salaries which are not adequate to cover living costs make posts in western countries very appealing. In 2004, a junior doctor in Malawi earned approximately £1900 per annum[160]. Basic annual pay for a pre-registration house officer in the UK is £21 000[168]. Indeed, there may be strong family pressures to take a job overseas and provide valuable remittances for those who remain in the country. Some countries have actively embraced health worker migration as a source of revenue. The Philippines operates a managed migration policy and is now the largest provider of registered nurses working overseas[158]. However, 30 000 nurse posts are currently unfilled in the Philippines[158].

The consequences of all these factors on a medical specialty are amply illustrated by the situation in gastroenterology. The world-wide burden of digestive illness is tremendous; for example, digestive cancers, collectively, are the most common malignant diseases. Furthermore, while infectious diseases, as illustrated in the first section, represent a major and persisting challenge for developing nations, urbanization and westernization now threaten to inflict the gastroenterological problems of the West, such as those related to obesity[169] on these already underserved populations. In addition, in certain developing countries prevalence rates for gastroenterological disorders which are very rare in the West, such as gall bladder and biliary cancer, are high and a public health issue. Yet many African countries possess not a single gastroenterologist. Though some would argue that more basic medical care should be the priority in these countries, the World Gastroenterology Organisation (WGO) would counter that to deprive these countries of the expertise that specialists and sub-specialists can provide is condescending, to say the least. If nothing else, such expertise is needed to assist in health care provision planning. It should come as no surprise, therefore, that the many advances in the field of gastroenterology which have so dramatically advanced patient care and improved mortality and morbidity in the West, have not been evenly bestowed on the world's population; some areas of our planet have barely felt the impact of advances in diagnostics and therapeutics. A very striking example is provided by the failure of the laparoscopic era which has so revolutionized digestive surgery elsewhere to even dawn in many African countries. Lack of resources is certainly a factor but lack of skilled personnel is also contributory. Similarly, in many African countries none save for the most privileged have access to diagnostic services, such as endoscopy and ultrasound, that would be deemed routine elsewhere.

More global attention has been paid to the issue of health worker shortages over the last few years. The World Health Report in 2006[156] was dedicated to the health worker crisis. The Global Workforce Alliance, which is hosted by WHO, was set up later in 2006 in order to collate and implement effective strategies to tackle the shortages. In 2008, the first Global Forum on Human Resources for Health was held in Uganda.

Given the urgency of the problem, there is a consensus that innovative solutions are needed rather than simply increasing the number of medical training places. One approach, which has been successful in several developing countries, has been to shift away from a western-style distribution of health workers. Low- and medium-level workers, such as community workers and nursing auxiliaries, can be more appropriate for the needs of the population rather than dependence on high-level workers such as doctors and nurses[157]. Not only is there a greatly reduced training time for these lower-level workers, but more workers can be produced for the same training investment and salary costs are lower. In addition, these workers do not have internationally recognised qualifications, and therefore are less likely to emigrate[157,158]. Although high-level workers are still needed for supervision, some countries have had great success in achieving basic health coverage with community workers.

In 1994, Pakistan created the Lady Health Worker (LHW) cadre, aiming to train 100 000 female community health workers by 2005[157]. These workers are recommended by their community, usually in rural and urban slum areas, and are trained for 15 mo in the prevention and treatment of common illnesses. An evaluation of the scheme in 2002 found that populations served by a LHW are more likely to adopt antenatal care, receive medical assistance at birth, and use family planning services[170]. In Malawi, there is a high rate of trauma associated with farming and road traffic accidents, but only nine orthopaedic surgeons[171]. Orthopaedic clinical officers (OCO) are specifically

trained over 18 mo to be able to fulfil most of the orthopaedic roles required in rural district hospitals, including the conservative management of fractures and dislocations, and some external fixation methods. Since the programme began in 1985, it has trained 117 OCOs, who now manage an estimated 80% to 90% of the orthopaedic workload in Malawi[171]. Indeed, a reliance on western-style models of health workforces has meant that in sub-Saharan Africa low and mid-level workers make up only 7% of the workforce, compared to around 20% in Brazil and Iran[172].

It has also been commented that western models of medical curricula may not be appropriate for countries with an urgent need for health workers. A 5-year course with a strong focus on basic sciences may be a luxury in developing countries with high levels of communicable diseases and limited resources. The St Paul's Millennium Medical School in Ethiopia was set up by the government as part of its aim to increase the national production of doctors to 1000 per year[157]. Here, the curriculum has been cut down from 5.5 to 3.5 years, with an emphasis on practical skills, in order to better prepare graduates for their 5 years service in rural hospitals (Professor Gordon Williams, Dean of St Paul's, personal communication).

Internationally, there have been several bilateral agreements which aim to promote ethical recruitment in response to criticism of western countries' active recruitment of foreign health workers. The UK-South Africa Memorandum of Understanding was signed in 2003 and aims to decrease the efflux of South African health workers through efforts to offer time-limited placements as alternatives and to promote UK self-sufficiency[173]. Norway is also developing a policy which will invest in health worker development projects, whilst increasing the number of national training places to encourage self-sufficiency[173]. Changes under the new UK career progression scheme Modernising Medical Careers is also likely to have an effect on international recruitment. For all training posts, UK graduates and those from the European Economic Area are prioritised over international medical graduates[174]. Although prompted by efforts to improve NHS stability and secure training places for all UK graduates rather than ethical concerns, this policy is likely to decrease the attractiveness of the UK medical job market abroad.

If health workers increasingly remain in their home country, further training must be made available in order to provide adequate numbers of specialists and promote more advanced skills. For gastroenterology specialist training, the main advocate is the WGO. The current objectives of WGO are enshrined in its mission statement: "to promote, to the general public and health care professionals alike, an awareness of the world wide prevalence and optimal care of digestive disorders through the provision of high quality, accessible and independent education and training", which signals the commitment of WGO to address two challenges: firstly, providing the gastroenterologist of the future with an optimal training and, secondly, and most pertinent to this review, bringing the benefits of digestive health care to those who currently struggle or, indeed, fail to achieve access to it. The primary emphasis of WGO, therefore, is on education and training; these objectives are achieved through three distinctive, though closely inter-related, programmes: Training Centres, Train-the-Trainers, and Global Guidelines (described later in review).

Figure 6 Map showing location of World Gastroenterology Training Centres worldwide (reproduced with kind permission of World Gastroenterology Organisation).

Training Centres most directly address the issue of training specialists in gastroenterology or individuals with additional expertise in gastroenterology to serve previously underserved areas. Each centre represents a direct collaboration between local experts, international faculty and several national and regional societies from Europe and North America to deliver regionally relevant training to those who have limited, or in some cases, no access to such opportunities. Our centres in South Africa, Morocco, Egypt, Bolivia, Pakistan, Thailand, Mexico City and Fiji (Figure 6) provide training of variable duration to several hundred young and aspiring gastroenterologists and digestive surgeons from underserved nations in their region. In some of these instances, such as in the centres in Soweto and Suva, the focus is on providing training opportunities to young doctors from areas where little or no gastroenterological expertise exists (in these cases Sub-Saharan Africa and Oceania, respectively). More recently, WGO has established partnerships with centres in Italy, Chile, Argentina, and Brazil to provide more advanced training opportunities to the young doctor who has already completed basic training.

Activities at these training centres are supported by other linked WGO programmes. Train-the-Trainers courses are uniquely devoted to bringing the very latest in educational techniques to those who will train the gastroenterologists of the future, including those who teach and train at our Training Centres. These networks should be accessible to all who seek to train in our specialty, thereby, ensuring the highest standards of care for those who suffer from digestive disorders through the world.

Clinical services

The limiting effect of the shortage of trained health workers and specialists can be seen in the central clinical service of gastroenterology: endoscopy.

In western countries, endoscopy services have

Figure 7 Cut Foley urethral catheter reloaded unto the Opti-vu cap for variceal band ligation at the Endoscopy Unit of Jos University Teaching Hospital, Nigeria.

become such a routine procedure that facilities are readily available, even in some primary care centers. However, in developing countries, services are only available in so-called "centers of excellence" and are rudimentary in most circumstances. They often comprise of direct viewing fibre-optic endoscopes only and are mostly restricted to diagnostic gastroscopies.

This difference is not surprising due to the numerous challenges posed by establishing endoscopy units, including training needs, adequate disinfection facilities and equipment. There is also a lack of awareness amongst most healthcare professionals of the usefulness of therapeutic endoscopy.

While the overall picture looks bleak, there have been some attempts by developing country gastroenterologists to establish endoscopy services. Variceal haemorrhage from portal hypertension is associated with high mortality in most West African countries, due to the lack of endoscopic banding facilities[175]. The Endoscopy Unit at Jos University Teaching Hospital in Nigeria has recently started to perform oesophageal variceal banding and injection sclerotherapy. It costs approximately $300 USD for a single use variceal band ligator, which is vastly prohibitive for most developing country workers. Therefore, the gastroenterologists working at the Endoscopy Unit have modified the normal variceal banding technique by cutting size 14 Foley urethral catheters to size and reloading these on previously used Opti-vu caps (Figure 7). Although not optimal practice, this has reduced the cost to only $30 per session. The modified technique has allowed much greater uptake of the procedure, with improved clinical outcomes. If such interventions become widespread nationally, it has the potential to markedly improve the prognosis in complications of end-stage liver disease, which currently carries a significantly burden in Nigeria.

The training programme for Nigerian gastroenterologists in endoscopic therapies has been bolstered by Royal College of Physicians educational bursaries, which have allowed visits to the UK and reciprocal visits to Nigeria. The Tropical Health and Education Trust also provides training for frontline health workers in the poorest settings, and develops the institutional capacity of local health institutions. This is achieved by focusing on the goals of local health care specialists in individual hospitals, clinics and primary health care projects and offering specialist support and training from UK-based health professionals on a one-to-one basis. Finally, the World Organization of Digestive Endoscopy has set up training centres in Cairo, Egypt and Soweto, South Africa with the aim of improving the management of gastrointestinal disorders in sub Saharan Africa.

It is evident that effective clinical services can exist in developing countries despite being tailored to available resources. Difficulty in adhering to western-defined standards should not necessarily inhibit medical action with benefit to the population.

Guidelines and cascades

Numerous guidelines are produced annually by prestigious medical bodies. The vast majority of these outline "gold standard" practice and are aimed at physicians in resource-rich environments. As such, they are inaccessible and irrelevant for many clinicians in developing countries. As in the case of endoscopy above, many clinicians in developing countries have to "make do" with available resources: in full knowledge that this falls below the gold standard. However, by failing to acknowledge this situation and providing the "next-best option", western guidelines may be preventing the dissemination of knowledge and evidence to its full global audience[176-179].

In order to make guidelines more applicable to differing resource environments, the concept of "cascades" have been developed[177,180]. A cascade is a collection of related diagnostic and treatment options arranged hierarchically in terms of conditions and available resources. Whilst guidelines should continue to summarise best known practice, they could also include alternatives for clinicians with limited funding. These alternatives are usually on the basis of cost, but could also take account of local availability, technology, and infrastructure. Cascades can range from a simple list of options (Table 2) to more complex parallel diagnostic and treatment pathways (Figure 8). In this way, they transform guidelines from being "resource-blind" to "resource-sensitive". Inevitably, cascades are more heavily based on empirical evidence than gold standard options. Research funding is usually spent on trying to improve on best practice-rather than the practicalities of delivery in developing countries. However, with strong involvement from experienced clinicians in developing countries, a consensus is usually reached. More widespread use of cascades in guidelines may also motivate research into the best options for resource-limited services.

Several organizations are now using cascades regularly in their work. The WGO is aiming to include cascades in all of its new guidelines, and has so far published on *H pylori*, acute diarrhoea, treatment of oesophageal varices, colorectal cancer, and hepatitis B[105,181-184]. To aid dissemination, most WGO guidelines are available in at

Table 2 Cascade for treatment of oesophageal varices (reproduced with kind permission of WGO)

least four languages; downloads of non-English versions now account for more than 50% of website traffic. The Asian Pacific Consensus on the msanagement of *H pylori* was an early piece of work produced in response to the need for regional guidelines which took account of resource limitations[149]. A programme which uses cascades in response to the urgent need for improved early detection and basic treatment of breast cancer in developing countries is the Breast Health Global Initiative[185,186]. This is an international alliance of health organizations, government agencies, and leading clinicians, which recognises the inflexibility of western-developed screening programmes and aims to produce evidence-based and economically feasible guidelines for medium and low resource regions.

CONCLUSION

The first part of this review has described the disparity between developing and developed countries for three prominent public health problems: diarrhoeal diseases, hepatitis B, and *H pylori*. In this second section, we have considered some of the major obstacles developing countries face in the delivery of gastroenterological services. Increased investment into health workers worldwide is long overdue. Using endoscopy as an example, some of the current difficulties in clinical services implementation in developing countries were highlighted. Finally, guidelines which acknowledge and adapt to the reality of resource limitations would greatly improve information delivery worldwide.

Ultimately, however, perhaps the most important factor needed to improve healthcare in developing countries is the alleviation of poverty. A report in 2001 from the Commission on Macroeconomics and Health[187] showed a negative correlation between the infant mortality rate of a country and the rate of growth of their gross domestic product-the lower the mortality rate, the faster the growth of the economy. An improved economy would allow more investment in sanitation, housing, water quality: all factors which would effectively reduce the prevalence of the diseases discussed above. Until then, however, we must increase recognition of the varying situations facing gastroenterological colleagues worldwide.

Abstract

CD74 is a protein whose initial role in antigen presentation was recognized two decades ago. Recent studies have revealed that it has additional functions as a receptor for macrophage migration inhibitory factor and as a receptor for an important human pathogen, *Helicobacter pylori* (*H pylori*). The role of CD74 as a receptor is important because after binding of migration inhibitory factor or *H pylori*, NF-κB and Erk1/2 activation occurs, along with the induction of proinflammatory cytokine secretion. This review provides an up-to-date account of the functions of CD74 and how it might be involved in inflammation and cancer within the gastrointestinal tract.

Key words: CD74; Invariant chain; Cancer; Inflammation; *Helicobacter pylori*; Gastrointestinal tract

INTRODUCTION

CD74, also known as the invariant chain or Ii, is a non-polymorphic glycoprotein that has diverse immunological functions. The most well-known function of CD74 is regulating the trafficking of class Ⅱ major histocompatibility complex (MHC) proteins in antigen presenting cells. More recently, CD74 expression has been examined in cell types other than antigen presenting cells (APCs), such as epithelial cells[1]. Some studies also suggest that CD74 might be expressed independently of class Ⅱ MHC, indicating additional functions[2]. Various studies have indicated that CD74 is highly expressed in inflammatory disorders and cancers. It also acts as a receptor for macrophage migration inhibitory factor (MIF) and facilitates adhesion of *Helicobacter pylori* (*H pylori*) to gastric epithelial cells (GECs)[3,4]. CD74 expression is increased during *H pylori* infection, chronic inflammatory conditions of the gastrointestinal (GI) tract, and gastric and colon cancers. One critical function it has in carcinogenesis is to act as an accessory signaling molecule for cell proliferation. This molecule is particularly important in the complex immunological mechanisms of the gastrointestinal tract and in the link between chronic inflammation and carcinogenesis in the GI tract.

THE ROLE OF CD74 IN ANTIGEN PRESENTATION

CD74 was initially characterized for its role in regulating class Ⅱ MHC folding and intracellular sorting and has been studied in most detail in APCs. Newly synthesized CD74 self-assembles as a trimer and this trimer serves as a scaffold onto which class Ⅱ MHC molecules assemble. CD74 blocks the peptide binding cleft of class Ⅱ MHC and prevents premature binding of antigenic peptides. Upon endocytosis of antigens, CD74 directs the class Ⅱ MHC complex to the endosomal pathway using two di-leucine-based signals[5]. Within an endosomal compartment CD74 is digested, leaving just one residual peptide, CLIP (amino acids 91-99), blocking the peptide binding cleft of class Ⅱ MHC. A class Ⅱ MHC-like molecule, HLA-DM, then binds to the class Ⅱ MHC and CLIP is released leaving the peptide binding cleft open for antigenic peptide binding. Class Ⅱ MHC molecules with bound peptides are then exported to the surface of the

antigen presenting cell (APC) for presentation of foreign peptides to T cells. CD74 plays a crucial role in antigen presentation, as class Ⅱ MHC processing and regulation cannot properly occur in the absence of CD74.

In addition to APCs, other cells of the gastrointestinal tract, such as epithelial cells, express class Ⅱ MHC proteins and CD74 and act as APCs, which is an unusual trait of the GI tract. We have previously shown that gastric epithelial cells express class Ⅱ MHC proteins and are capable of processing antigens for presentation to T cells[6,7]. Expression of class Ⅱ MHC and the potential for antigen presentation have also been shown in intestinal epithelial cells. In one elaborate study by Hershberg *et al*, the trafficking of these molecules in epithelial cells was followed in a polarized manner outlining a functional system for antigen presentation[8]. Another important group of cells that express class Ⅱ MHC proteins are the subepithelial intestinal myofibroblasts (IMF)[9,10]. These cells are α-smooth actin positive stromal cells that exist in the lamina propria of the gut[11]. They also act as antigen presenting cells and play an important role in inflammatory diseases and carcinogenesis by releasing cytokines and growth factors and interacting with the immune cells of the lamina propria.

In conventional APCs, CD74 surface expression is low as CD74 is proteolytically removed in endosomes, as we and others[12,13] have shown. However, gastric epithelial cells express readily detectable levels of CD74 on the surface. When we examined human gastric biopsy sections by immunohistochemistry for epithelial expression of CD74, gastric biopsy samples from 44 random patients stained with anti-CD74 monoclonal antibodies (mAb) showed the expression of CD74 in the epithelium. In the samples that were positive for *H pylori* or had gastritis, CD74 staining was heavily increased[14]. This was corroborated by confocal microscopy studies of gastric epithelial cells grown as a polarized monolayer where expression was higher on the apical side of the cells[1].

CD74 ISOFORMS

CD74 is post-translationally glycosylated and exists in different isoforms. As evidence for this, our previous studies showed proteins with different mobilities when immunoprecipitated and subjected to gel electrophoresis[1]. After chemical deglycosylation, only the isoforms that result from alternative translation initiation or splicing were observed. The most common isoform is 33 kDa (p33), but p35, p41 and p43 isoforms also exist[15]. The p35 isoform contains a longer cytoplasmic tail due to the use of an alternative translation initiation site, while the p41 isoform results from alternative splicing, and p43 has both. Both the p33 and p35 isoforms appear to function in regulating class Ⅱ MHC antigen presentation. However, the p41 isoform might also play an important role in T cell selection in the thymus[16]. An important posttranslational modification of CD74 commonly seen is the addition of a glycosaminoglycan side chain, chondroitin sulfate. This isoform has been reported to act as an accessory protein during T cell activation through interaction with CD44 on T cells[17].

CD74 AS A RECEPTOR

CD74 has begun to emerge as a more versatile molecule beyond its well-known function of regulating class Ⅱ MHC trafficking. Multiple studies have revealed that cell surface expression of CD74 is not always dependent on class Ⅱ MHC[2,18]. This was found to be true in studies of colorectal mucosa and different types of lymphocytes by immunohistochemistry, immunoprecipitation, and a mutant cell line that did not express class Ⅱ MHC products. The expression of cell surface CD74 in the absence of class Ⅱ MHC suggests alternative functions for CD74 apart from antigen presentation.

CD74 as a cytokine receptor

Recently, CD74 has emerged as an integral component of a receptor complex for macrophage MIF[3]. MIF is a versatile cytokine-like molecule that mediates both innate and adaptive immunity, plays a role in chronic inflammation, and has also been linked to carcinogenesis. MIF is expressed by the GI tract during inflammatory conditions, *H pylori* infection, and cancers, suggesting the importance of this interaction[19-21]. *H pylori* utilizes a type Ⅳ secretion system to inject the CagA protein into GECs, which we have shown induces MIF production[19] (Figure 1). CagA has also been shown to induce NF-κB activation and IL-8 production[22]. This protein is not only important in inflammation by increasing proinflammatory cytokine production, such as IL-8, but is also associated with gastric cancer[23]. The current model of this receptor complex suggests that CD44 is required in order for MIF to induce signaling events[24]. This model might require the chondroitin sulfate modified isoform of CD74, since CD44 has been shown to bind only to this isoform thus far.

Another study has suggested that CD74 complexes with CXCR2, an interleukin-8 (IL-8) receptor, which is commonly expressed on macrophages and functions to recruit leukocytes to sites of infection[25]. CXCR2 is also expressed by the gastric epithelium[26]. Since gastric epithelial cells are central players in the inflammatory response, IL-8 may act via the gastric epithelium in various processes associated with gastric inflammation linked

to *H pylori* infection. The role of CXCR2 on the CD74 receptor complex has only recently been suggested and should be further investigated.

CD74 as a bacterial receptor

CD74 is an interesting example of a host cell receptor usurped by a pathogen because *H pylori* uses it to adhere to gastric epithelial cells (GECs). *H pylori* is a gram-negative spiral bacterium that colonizes the human gastroduodenal mucosa. Infection with *H pylori* usually begins in childhood and persists for decades if untreated. *H pylori* is recognized as a major contributor to chronic gastritis and peptic ulcer formation and is strongly associated with gastric carcinoma and lymphoma[27,28]. Due to the strength of the evidence supporting an association between adenocarcinomas of the gastric mucosa and *H pylori* infection, *H pylori* was classified as a class I carcinogen by the International Agency for Research on Cancer in affiliation with the World Health Organization[29]. Gastric cancer remains among the most common forms of cancer and is the second deadliest cancer worldwide. Gastric cancer accounts for approximately 700 000 deaths annually worldwide and in the US there are 24 000 new cases and 14 000 deaths annually[30]. The prevalence rates of *H pylori* seropositivity and the incidence of gastric cancer are highly associated within several populations from various countries. For instance, seropositivity can be as high as 80%-100% in some age groups in some countries or in minorities with lower incomes in the United States[31]. These groups have the highest risk of developing gastric cancer and/or gastric ulcers. Thus, *H pylori*-associated diseases represent a significant global and domestic problem and result in considerable morbidity, mortality, and societal costs.

H pylori adhesion to the gastric epithelium is important in successful colonization of the gastric mucosa. Adherent strains survive in the gastric mucosa, reach high bacterial densities, and can re-colonize, whereas non-adherent strains are cleared[32]. These observations support the notion that adhesion is essential in *H pylori* persistence and disease induction. An assortment of molecules on epithelial cells have been proposed as receptors for *H pylori* adherence including carbohydrate moieties [such as Lewis^b (Le^b) blood group antigen and sialyl-dimeric-Lewis^x (Le^x)], lysophospholipid, and other structures[33-35]. Our studies have indicated that *H pylori* also utilizes CD74 to attach to gastric epithelial cells (GEC)[4]. The binding of *H pylori* to CD74 on gastric epithelial cells was confirmed by a series of independent approaches. For instance, blocking of CD74 with antibodies significantly reduced the binding of *H pylori* to gastric epithelial cells. Immunoprecipitation revealed that *H pylori* predominantly binds to the 33 kDa isoform of CD74, but further investigation is needed to test for attachment to the CS modified isoform. As *H pylori* has been reported to bind to various glycoconjugates, including glycosaminoglycans[36], this isoform of CD74 might contribute to the overall interaction of *H pylori* with the host gastric epithelium. We also revealed that urease is the protein on *H pylori* that binds to CD74[37]. This interaction is particularly interesting because many bacteria express urease, so the possibility exists that there might be wider applications of this type of interaction with CD74 depending on urease sequence variation between bacteria.

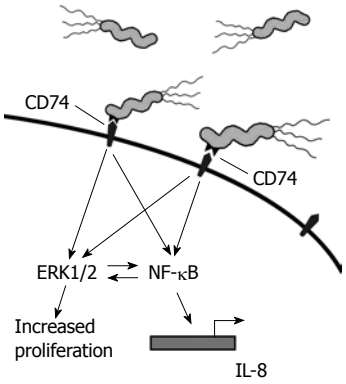

Figure 2 *H pylori* binds to CD74 on gastric epithelial cells and induces Nf-κB and Erk1/2 activation and IL-8 production.

After adhesion of *H pylori* to GEC, the expression of cell surface CD74 is increased[14]. We further showed that CD74 expression increases in gastric epithelial cells of infected humans and a recent study confirmed that this increase in CD74 expression also occurred in a mouse model of *H pylori* infection[38]. Upon *H pylori* binding to CD74, NF-κB activation occurs resulting in the production of proinflammatory cytokines, including IL-8. IL-8 plays a major role in the proinflammatory immune response to *H pylori* infection, therefore, the interaction of *H pylori* with the gastric epithelial cells might be of critical importance in the immune response to infection.

THE ROLE OF CD74 IN SIGNALING EVENTS

The role of CD74 in signal transduction was initially hypothesized when it was found to be phosphorylated and associated with proteins that coordinate various signal transduction pathways[39-41]. Interestingly, the observation that CD74 deficient mice have a defect in B cell development that results in decreased levels of follicular B cells provided insights into the important role of signals delivered through CD74 in B cell development. The cytosolic domain of CD74 alone was noted to induce B cell maturation by activation of NF-κB[42]. CD74 appears to promote B cell survival; therefore, it has been implicated in B cell neoplasms such as gastric mucosa-associated lymphoid tissue (MALT) lymphomas associated with *H pylori* infection.

Our studies have shown that the interaction of *H pylori* with CD74 on GECs induces NF-κB activation and IL-8 production, as shown in Figure 2. MIF has also been shown to bind to CD74[3]. One study outlines a role for CD44 in CD74 signaling. CD44 was required to initiate ERK1 and ERK2 signaling after MIF binding to CD74. Cells deficient in CD44 or transfected with truncated CD44 were not able to induce ERK signaling[24]. In B cells, MIF binding to CD74 led to AKT, Syk, and NF-κB activation, and proliferation in a CD44-dependant manner[43]. CXCR2 has also been shown to complex with

CD74 on monocytes[25]. This study also illustrated that MIF bound directly to CXCR2 and induced monocyte arrest. This study further showed that MIF might interact with CXCR4 on T cells and induce effector T cell arrest. However, it is not yet clear how CD44 is involved in the complexing of CD74 with CXCR2 and what signaling may be induced through CXCR4 since CXCR2 and CXCR4 are G protein-coupled receptors.

Other studies suggest that MIF signaling may also occur by non-receptor mediated endocytosis in addition to the above described receptors[44]. In this proposed mechanism, endocytosed or endogenous MIF interacts with the Jun activation domain-binding protein (Jab1), which is a transcriptional activator for AP-1[45]. Activation of AP-1 might affect cell cycle events by inducing degradation of the cyclin dependent kinase inhibitor, which is a tumor suppresser gene.

THE ROLE OF CD74 IN GI INFLAMMATION

CD74 is highly expressed in inflammatory disorders. We have shown it to be expressed on the gastric epithelium and up-regulated during *H pylori* infection[14]. Others have shown expression to be increased in ulcerative colitis, where overexpression was shown in DNA microarray profiles[46]. Additionally, CD74 is increased during inflammation associated cancers, such as gastric and colon[47,48]. Concurrently, MIF is highly expressed during many inflammatory conditions of the GI tract. We and others have shown that production is increased during *H pylori* infection[19,49]. MIF is also highly expressed during inflammatory bowel disorders (IBD), such as ulcerative colitis and Crohn's disease, where it is induced by intestinal bacteria[50]. In one study, elevated MIF levels were found in Crohn's disease patients at approximately six times higher levels than in healthy controls. Crohn's disease is an inflammatory bowel disorder where the immune system attacks part of the GI tract, and is accompanied by chronic inflammation. Also, this group went on to study MIF in murine colitis where they found colitis to be dependent on continuous MIF production, as evidenced by the protection from colitis by MIF-deficient mice or blocking MIF with monoclonal antibodies in mice with established colitis leading to reduced inflammation.

MIF or *H pylori* binding to CD74 induces NF-κB and subsequent cellular responses, such as the secretion of proinflammatory cytokines. MIF also increases inflammatory responses by overriding glucocortocoid suppression of inflammatory immune responses, including cytokines such as IL-1, IL-6, IL-8, and TNF-α[51]. One of the major proinflammatory cytokines produced after engagement of CD74 and receptor complexing is IL-8. IL-8 is a chemoattractant for neutrophils to a site of inflammation or infection. Upon arrival, they endocytose the antigen and form a phagosome in which reactive oxygen species and hydrolytic enzymes are released. While this process is crucial in fighting infections, it might also exacerbate inflammation in *H pylori* infection and inflammatory bowel disease[52-54]. In another study of glucocortocoid resistant ulcerative colitis, MIF was found to increase IL-8 production through the p38 MAPK pathway with isolated lamina propria mononuclear cells from patient biopsies[55]. When MIF was blocked with monoclonal antibodies after prednisolone treatment, activation of the p38 pathway and IL-8 decreased.

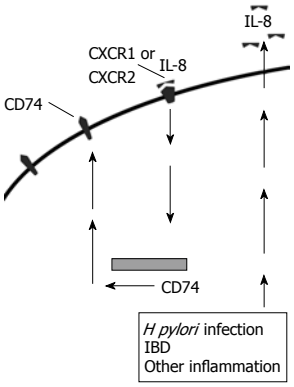

Figure 3 IL-8 produced by epithelial cells binds to CXCR1 and CXCR2 and up-regulates CD74 expression in an autocrine manner.

MIF might also contribute to inflammation by regulating Toll Like Receptor 4 (TLR4) expression on immune cells. TLR4 engagement by ligands such as bacterial LPS leads to proinflammatory cytokine production. This mechanism might be especially important in IBD, in which intestinal bacteria are a major contributor to the induction of the strong inflammatory response. In an *in vivo* study in mice, TLR4 expression in colonic tissue was not seen in MIF knockout mice, although it was in wild-type mice[56]. When the MIF knockout mice were administered rMIF, TLR4 expression was restored and further increased in colonic mice. In a human study of macrophages, neutralizing MIF or deleting the MIF gene resulted in decreased expression of TLR4 and a decreased response to LPS and gram negative bacteria; in broader experiments a decreased response to staphylococcal toxic shock and septic shock was demonstrated[57]. In addition, these cells did not respond well to LPS or gram negative bacteria and had a decreased expression of TLR4. The role of this receptor in the inflammation seen during *H pylori* infection is not clear because although *H pylori* LPS has been suggested to induce only weak responses, there are some studies suggesting it might contribute to the overall immune response to *H pylori*[58,59].

In addition to the role IL-8 plays in inflammation, we have previously shown that IL-8 increases expression of CD74 by gastric epithelial cells, both at the cell surface and mRNA levels[14] (Figure 3). Similarly, we found increased CD74 expression *in vivo*. Most of the *H pylori* infected samples and the samples with gastritis for reasons other than *H pylori* infection had much higher expression of CD74 than uninfected samples not exhibiting signs of gastritis. Other studies have further shown the expression of CD74 increased in ulcerative colitis and Crohn's Disease[46]. Increased CD74 expression could then go on to intensify inflammation by providing more free receptors for MIF or *H pylori* attachment.

THE ROLE OF CD74 IN GI CANCERS

CD74 has a strong link to carcinogenesis, as does MIF.

This ligand/receptor combination might be an important link between chronic inflammation and carcinogenesis. CD74 expression and MIF production have been shown to be increased during *H pylori* infection and gastric cancer[14,47]. High expression has also been noted in colon cancer along with highly increased serum concentrations of MIF in patients with colorectal cancers[60,61]. The contribution of CD74 to carcinogenesis is multifaceted. High levels of CD74 expression associated with class Ⅱ MHC expression might prevent tumor antigen presentation by blocking the peptide binding cleft and preventing antigenic peptide binding for presentation to T cells, rendering tumors less immunogenic. One study suggested this to be the case with colon neoplasms where expression was even increased from low to high grade neoplasms[48]. Chronic inflammation and IL-8 production leads to a prolonged increase in CD74 expression, which might not only decrease antigen presentation, but also exacerbate IL-8 production upon engagement by MIF or *H pylori*. MIF binding to the CD74 receptor complex also promotes proliferation of epithelial cells[19,62]. Long term increased proliferation overtakes natural cell cycle events and sets the stage for carcinogenesis.

MIF binding to CD74 might contribute to carcinogenesis in chronic conditions through the up-regulation of proinflammatory cytokines, including IL-8, which up-regulates CD74 and has its own mechanisms leading to increased proliferation, tumor growth, and angiogenesis. MIF or IL-8 binding to their receptors on epithelial cell surfaces induces the shedding of EGFR ligands in a mellatoprotease-dependent manner, and activation of EGFR through engagement of these ligands[63]. We and others have shown that this pathway is activated during *H pylori* infection[62,64,65]. Additionally, we found that EGFR expression is up-regulated in gastric epithelial cells during *H pylori* infection by MIF and IL-8" after the word infection. The EGFR is highly expressed in various cancers and is involved in pro-inflammatory responses and pro-carcinogenic events, including cell proliferation, migration, and invasion. Expression and activation of this receptor is well-documented in gastric and intestinal cancers[66,67]. One study suggests a correlation between EGFR expression on tumor cells, proliferation, and prognosis in gastric cancer[68]. Another study showed that treatment with antisense RNA for EGFR inhibited gastric tumor growth in a mouse model[69]. Blocking EGFR or its ligands is being studied in order to develop more effective treatments for GI cancers.

MIF also increases epithelial cell proliferation after binding to CD74. One way MIF might affect proliferation and cell cycle events is by regulating p53 tumor suppressor. Numerous cell cycle and apoptosis genes are controlled by p53. We have shown that phosphorylation of the p53 is decreased after MIF binding to CD74[19]. Others have shown that MIF can interact directly with p53 and prevent translocation to the nucleus where it becomes activated and acts as a transcription factor for apoptotic genes[70]. When p53 is blocked from transport to the nucleus, apoptotic pathways are decreased and proliferation increases. Suppression of p53 in macrophages results in a more robust inflammatory response, implying a further link between p53 and inflammation[71].

CONCLUSION

CD74 is a much more versatile molecule than originally thought, playing many important roles in the immune system. Of crucial importance is the role it plays in class Ⅱ MHC processing and the regulation of antigen presentation. This is important in the GI tract because epithelial cells and subepithelial myofibroblasts express CD74 and act as antigen presenting cells. Furthermore, the expression of CD74 on the cell surface might increase chronic inflammatory responses important in both *H pylori* infection and IBD. As a receptor for MIF, CD74 also plays and crucial role in chronic inflammation and might represent a major link between chronic inflammation and carcinogenesis in gastric and intestinal cancers. Development of therapeutics for cancer involving blocking CD74 might provide effective treatments for GI cancers.

Abstract

AIM: To observe the protective effect of *Radix Astragali* injection on immune organs (lymph nodes, spleen and thymus) of rats with obstructive jaundice (OJ) and its mechanism.

METHODS: SD rats were randomly divided into sham-operation group, model control group and *Radix Astragali* treatment group. On days 7, 14, 21 and 28 after operation, mortality rate of rats, pathological changes in immune organs, expression levels of Bax and nuclear factor (NF)-κB p65 proteins, apoptosis indexes and serum tumor necrosis factor (TNF)-α level in spleen and thymus were observed, respectively.

RESULTS: Compared to model control group, the number of dead OJ rats in *Radix Astragali* treatment group decreased ($P > 0.05$). The TNF-α level (27.62 ± 12.61 *vs* 29.55 ± 18.02, 24.61 ± 9.09 *vs* 31.52 ± 10.95) on days 7 and 21, the pathological severity score for spleen [0.0 (0.0) *vs* 0.0 (2.0) on days 7 and 14 and for lymph nodes [0.0 (1.0) *vs* 1.0 (2.0), 1.0 (0.0) *vs* 2.0 (1.0)] on days 21 and 28, the product staining intensity and positive rate of Bax protein in spleen [0.0 (0.0) *vs* 1.0 (2.0), 0.0 (1.0) *vs* 2.0 (1.5) and thymus [0.0 (0.0) *vs* 1.0 (2.0), 0.0 (1.0) *vs* 2.0 (1.5)] on days 14 and 28, the apoptotic indexes [0.0 (0.0) *vs* 0.0 (0.01)] in spleen and thymus [0.0 (0.0) *vs* 0.0 (0.01) on days 14 and 21 were significantly lower in *Radix Astragali* treatment group than in model control group ($P < 0.05$).

CONCLUSION: *Radix Astragali* has protective effects on immune organs of OJ rats by relieving the pathological changes in immune organs, reducing TNF-α level and inhibiting Bax expression and apoptosis in spleen and thymus.

INTRODUCTION

Obstructive jaundice (OJ) is a kind of common clinical manifestation. The pathogenesis and treatment of OJ have been a hot topic in medical field for a long time[1-3]. Since

systemic inflammatory response syndrome and multiple organ dysfunction syndrome were studied in recent years, immune function impairment concomitant with OJ has gradually attracted wide attention and is considered as a cause of death in OJ patients[4-7]. Therefore, one of the important approaches to treatment of OJ is to restore the functions of immune organs[8-10].

Development and utilization of traditional Chinese medicine have good prospects in therapy for OJ since it has a lower cost, more extensive pharmacological effects and fewer side effects. *Radix Astragali,* dried root of *Astragalus membranaceus*, is sweet in taste with a warm property and mainly produced in Inner Mongolia Autonomous Region, Shanxi, Gansu and Heilongjiang Provinces of China. The raw *Radix Astragali* can be used to consolidate the exterior of body. *Radix Astragali* can regulate sweating, warm muscles, strengthen striae, invigorate Qi (vital energy), and alleviate heat in muscles due to Qi deficiency. *Radix Astragali* can also be used in treatment of chicken pox or other diseases with vesicular-papules due to inadequate "dispersing of the evils". *Radix Astragali* invigorates Qi, ascends the Yang-Qi, protects Qi and consolidates the exterior of body, promotes diuresis, relieves edema (generalized swelling of the body), supports Qi to promote skin wound/ulcer healing and tissue/muscle regeneration. *Astragalus* injection is made of extraction from *Radix Astragali*. Since *Astragalus* injection contains polysaccharide, saponin, flavone and trace elements, it has a variety of pharmacological effects and increases the immunity and protects the liver and kidneys[11-15]. It has been shown that cellular immune function decreases in OJ rats[16], which can be successfully treated with *Astragalus* injection.

At present, studies about the effects of *Astragalus* injection on immune organs during OJ are not available. This study was to investigate the protective effect of *Astragalus* injection on immune organs of OJ rats and its mechanism. The results may provide an experimental basis for its application in clinical practice.

MATERIALS AND METHODS

Materials

Healthy male SD rats of clean grade, weighing 270-330 g, were provided by Laboratory Animal Research Center, Zhejiang University of Traditional Chinese Medicine (China). Sodium pentobarbital was purchased from Sigma Corporation (USA). *Radix Astragali* injection (10 mL vial contains active components equivalent to 20 g of the original medicine) was purchased from Chiatai Qingchunbao Pharmaceutical Co, Ltd (China). Serum tumor necrosis factor (TNF)-α ELISA kits were purchased from Shanghai Senxiong Technological Company (China). Anti-nuclear factor (NF)-κB P65 and anti-Bax antibodies were purchased from Santa Cruz Biotechnology, Inc (USA). TUNEL assay kits were purchased from Takara Bio Inc (Jingdu, Japan).

Animal grouping and preparation of OJ models

One hundred and eighty OJ rats, enrolled in this study, were randomly divided into sham-operation group, model control group, and treatment group (n = 60), which were further subdivided into 7, 14, 21 and 28 d groups (n = 15) according to the time after operation. After the rats were anesthetized with intraperitoneal injection of 2.5% sodium pentobarbital (0.2 mL/100 g), their abdominal cavity was opened to identify and dissociate the common bile duct along the hepatoduodenal ligament. The proximal end of the common bile duct of rats in the model control and treatment groups was double-ligated with surgical threads, the common bile duct was cut off, and a layered suture of the abdominal wall was performed to close the abdominal cavity. The common bile duct of rats in the sham-operation group was dissociated but not ligated, and a layered suture of the abdominal wall was also performed to close the abdominal cavity. Rats in the treatment group received intraperitoneal *Radix Astragali* injection at a dose of 0.75 mL/100 g per day, while those in the sham-operation and model control groups received an equal volume of physiological saline solution until the end of 7-, 14-, 21- and 28-d observation periods in the corresponding groups.

Determination of experimental parameters

Mortality rates of rats in different groups were recorded. Rats were killed after anesthesia with sodium pentobarbital in batches, serum was collected to measure TNF-α level by ELISA, and pathological changes in immune organs (lymph nodes, spleen and thymus) were observed. Pathological severity of immune organs was scored according to related standards. Tissues of spleen, thymus and lymph nodes were cut into sections, but the sections of lymph node were not stained. Changes in expression levels of Bax and NF-κB P65 proteins, as well as apoptosis index of spleen and thymus were observed, respectively.

Immunohistochemical staining of Bax and NF-κB P65 proteins in intestinal mucosa

Envision two-step method was used to detect the expression levels of Bax and NF-κB P65 proteins in intestinal mucosa. The staining intensity was evaluated according to the extent of cell coloration: "-" represents negative staining; "+" represents mild staining with positively stained cells showing a yellow pigment; "++" represents moderate staining with positively stained cells showing a brown pigment; "+++" represents intense staining with positively stained cells showing a dark brown pigment; (-) indicates no positive cells; (+) indicates less than 25% of positive cells; (++) indicates 26%-50% of positive cells; and (+++) indicates over 50% of positive cells, each of which was scored as 0, 1, 2 and 3 points, respectively.

Detection of apoptotic index in intestinal mucosa with TUNEL staining

DNA nicking in tissue sections was observed with *in situ* end-labeling (TUNEL) staining. In brief, sections were

Table 1 Comparison of serum TNF-α levels in different groups (ng/L, mean ± SD)

Group	7 d	14 d	21 d	28 d
Sham-operation group	12.89 ± 1.63	12.25 ± 3.37	14.21 ± 3.24	15.61 ± 4.84
Model control group	29.55 ± 18.02[b]	34.10 ± 8.94[b]	31.52 ± 10.95[b]	57.66 ± 12.99[b]
Treatment group	27.62 ± 12.61[a,b]	27.20 ± 9.34[b]	24.61 ± 9.09[a,b]	39.01 ± 9.62[b]

[a]$P < 0.05$ *vs* model control group; [b]$P < 0.01$ *vs* sham-operation group.

baked at 60℃ for 30 min, deparaffinaged, and washed with Milli-Q for 5 min. Tissue was processed with protease K (10 μg/μL) at room temperature for 15 min and washed with phosphate-buffered saline (PBS) for 5 min. A 3% H_2O_2 solution was used to block endogenous peroxydase for 5 min, washed twice with PBS, 5 min each time. Thirty microliters of reaction solution at freezing condition (TdT enzyme : labeling safe buffer = 1:10) was added, incubated at 37℃ for 90 min, and washed twice with PBS, 5 min each time. Fifty microliters of anti-FITC HRP conjugate was added, incubated at 37℃ for 30 min, and washed twice with PBS, 5 min each time. DAB was colored, washed with Milli-Q, counterstained with hematoxylin, and washed with water after differentiation till it became blue. The DAB was routinely dehydrated and mounted onto neutral gum. Apoptotic index was calculated following the equation: Apoptotic index = apoptotic cell count/total cell count × 100%.

Statistical analysis

Data were input into the Excel sheet and read into SPSS 15.0 for further analysis. Normal data were expressed as mean ± SD while abnormal data were expressed as median (interquartile range). Analysis of variance and pairwise comparison were used for normal data, whereas abnormal data were subjected to non-parametric tests, of which Kruskal-Wallis H test was used for pairwise comparison and Mann-Whitney *U* test was used for multiple comparisons. Yates' χ^2 test was used for inter-group comparisons of mortality rates.

RESULTS

Comparison of mortality rates

All rats in the sham-operation group were alive after operation. Two rats in the model control group and one rat in the treatment group died on day 7 after operation. Four rats in the model control group and three rats in the treatment group died on day 14 after operation. Four rats in the model control group and four rats in the treatment group died on day 21 after operation. Seven rats in the model control group and six rats in the treatment group died on day 28 after operation. The total mortality rate of rats in the model control and treatment groups on day 28 was significantly higher than that of rats in the sham-operation group ($P < 0.001$). No significant difference was found in mortality rate between the model control and treatment groups.

Comparison of serum TNF-α levels

The serum TNF-α level was significantly lower in sham-operation group than in model control and treatment groups at different time points after operation ($P < 0.01$), and was significantly lower in treatment group than in model control group on days 7 and 21 after operation ($P < 0.05$, Table 1).

Pathological changes in spleen

In the sham-operation group, the morphology of spleen was normal with no gross pathological changes under light microscope.

In the model control group, the size of spleen increased by 1.2-1.5 folds and the texture of spleen became fragile with no change in color on day 7 after operation. The spleen became enlarged with a thickness of above 0.6 cm and a deeper color and its texture became fragile on day 14 after operation. The spleen was 4 cm × 1 cm × 1 cm in size and its texture became fragile with a purple black color on days 21 and 28 after operation. Under light microscope, the spleen of all rats was grossly normal on day 7 after operation. Fusion, enlargement or spotty necrosis of follicular germinal center in the white pulp of spleen, hyperplasia of fibrous tissue in sinus, and arteriolar sclerosis in spleen of most rats were observed on day 14 after operation. The spleen of few rats was grossly normal. Fusion, enlargement or spotty necrosis of follicular germinal centers in the white pulp of spleen, hyperplasia of fibrous tissue in sinus, and arteriolar sclerosis in spleen of few rats were seen on days 21 and 28 after operation. The spleen of some rats was grossly normal (Figure 1A).

In the treatment group, no significant difference was found in pathological changes at all time points after operation compared to the model control group. Under light microscope**,** no significant difference in pathological changes was noted at each time point after operation. The spleen of most rats was grossly normal. Arteriolar sclerosis in spleen of few rats was seen (Figure 1B).

The pathological scoring standards for spleen are listed in Table 2. The pathological scores were significantly lower for sham-operation group than for model control group on day 14 after operation ($P < 0.05$), and were significantly lower for treatment group than for model control group on days 7 and 14 after operation ($P < 0.05$, Table 3).

No significant difference was found in product staining intensity and in positive rate of NF-κB protein in spleens of all groups (Table 3).

The product staining intensity and positive rate of Bax protein were significantly lower in sham-operation and treatment groups than in model control group on day 28 after operation ($P < 0.05$, Table 3).

The apoptosis index was significantly lower in sham-

operation group than in model control group on days 7, 14 and 28 after operation ($P < 0.05$), and was significantly lower in treatment group than in model control group on day 14 after operation ($P < 0.05$, Table 3).

Pathological changes in lymph nodes

In sham-operation group, the gross morphology of lymph nodes was normal. Under light microscope, no significant difference was observed in pathological changes at different time points after operation. The morphology and structure of lymph nodes were grossly normal. Enlargement of follicular germinal centers and hyperplasia of sinus cells were seen in few rats (Figure 2A).

changes were found in the texture of lymph nodes at all time points after operation. Under light microscope, no significant difference in pathological changes was observed at all time points after operation. Enlargement of follicular germinal centers and hyperplasia of sinus cells were seen in most rats and few rats showed no obvious pathological changes in lymph nodes with spotty necrosis in the mantle zone and germinal centers on days 7, 14, 21 and 28 after operation (Figure 2B).

In the treatment group, no significant difference in pathological changes was observed at all time points after operation compared to the model control group. Under light microscope, no obvious difference was found in lymph node pathological changes at all time points after operation. In most rats, enlargement of lymph nodes in germinal centers and hyperplasia of cells in lymph sinus were observed with spotty necrosis of lymph nodes in the mantle zone and germinal centers of (Figure 2C).

The pathological scoring standards for lymph nodes have been described elsewhere[17]. The pathological score was significantly lower for sham-operation group than for model control group on days 7, 14 and 21 after operation ($P < 0.05$). The pathological score was significantly lower for sham-operation group than for treatment group on day 7 after operation ($P < 0.05$) and was significantly lower for treatment group than for model control group on days 21 and 28 after operation ($P < 0.05$, Table 4).

Pathological changes in thymus

In sham-operation group, no significant difference was found in thymus pathological changes at all time points after operation compared to model control group, and the thymus tissue of all rats was grossly normal (Figure 3A).

In model control group, the thymus of rats was mildly shrunken on day 7 after operation, moderately shrunken and jaundiced on day 14 after operation, and severely shrunken and jaundiced on days 21 and 28 after operation. Under light microscope, no significant difference was noted in thymus pathological changes at all time points after operation. The thymus tissue of most rats was grossly normal. An obscure boundary between thymus cortex and medulla was occasionally seen. The thymus tissue was grossly normal on day 14 after operation. The thymus pathological changes were similar on days 14, 21 and 28 after operation (Figure 3B).

In treatment group, no significant difference in thymus pathological changes was observed on days 7 and 14 after operation compared with model control group. The thymus became mildly jaundiced with no obvious shrinkage on days 21 and 28 after operation. Under light microscope, the thymus tissue of most rats was grossly

normal. An obscure boundary between thymus cortex and medulla was seen in few rats (Figure 3C).

The pathological scoring standards for thymus have been described elsewhere [18]. No significant difference was observed in pathological scores for different groups (Table 5).

No significant difference was found in product staining intensity and positive rate of NF-κB protein in thymus of different groups (Table 5).

The product staining intensity and positive rate of Bax protein were significantly lower in sham-operation group than in model control group on days 7, 21 and 28 after operation ($P < 0.05$), in sham-operation group than in treatment group on day 7 after operation ($P < 0.05$), and in treatment group than in model control group on days 14 and 28 after operation ($P < 0.05$).

The apoptosis index for thymus was significantly lower in sham-operation group than in model control group on days 21 and 28 after operation ($P < 0.05$), and in treatment group than in model control group on days 14 and 21 after operation ($P < 0.05$).

DISCUSSION

It has been shown that the incidence rate of endotoxemia in OJ patients is as high as 39.3%[19], which is mainly

due to insufficient intestinal bile salt that leads to excessive multiplication of intestinal bacteria and decreased inactivation of endotoxins. Since the function of reticuloendothelial system is inhibited, gut-derived endotoxins are not effectively eliminated. As a result, large amounts of endotoxin enter into the blood resulting in endotoxemia. Endotoxin is a main factor for immune function impairment during OJ since it can directly stimulate Kupffer cells to release inflammatory mediators, including oxygen free radicals, TNF-α, IL-6 and IL-8, and thereby aggravates the inflammatory response of body[19-24]. TNF-α is the most important factor for mediating toxic effects of endotoxin. Excessive release of TNF-α can induce multiple organ injuries. We speculate that immune function impairment results from the damage to immune organs. The results of this study show that the serum TNF-α level and pathological scores for spleen and lymph nodes were significantly lower in sham-operation and treatment groups than in model control group, suggesting that TNF-α is involved in OJ-induced damage to immune organs, and *Astragalus* injection can significantly lessen the toxic effects of TNF-α on and improve the pathological changes in immune organs. We think that *Astragalus* injection exerts, to a certain degree, its protective effects on immune organs by suppressing the production of TNF-α. Although no statistically significant difference was observed in pathological scores for thymus, the pathological changes in thymus of *Astragalus* treatment group showed varying degrees of improvement compared with model control group. In model control group, the thymus showed varying degrees of jaundice and atrophy at all time points after operation, and an obscure boundary between the thymus cortex and medulla in parts of thymus tissue under light microscope. In contrast, the thymus in treatment group became jaundiced with no atrophy on days 21 and 28 after operation, and the boundary between the thymus cortex and medulla was obscure in few parts of thymus tissue under light microscope, suggesting that *Astragalus* has protective effects on immune organs.

NF-κB p65, a protein that is extensively distributed in cytoplasm of many cells, can regulate gene transcription in nuclei. It is a member of Rel family of transcriptional regulatory proteins and is involved in gene expression regulation of many inflammatory factors. When the body is under stress, NF-κB p65 is activated and binds to specific κB gene sequences, and thereby promotes gene transcription and protein synthesis of pro-inflammatory molecules, causes strong expression of inflammatory cytokines such as TNF-α and IL-6mRNA, accelerates toxic effect on cells in multiple organs, eventually leading to multiple organ dysfunction. Based on the expression levels of NF-κB p65 protein in spleen and thymus, we speculate that *Astragalus* has no inhibitory effects on the expression of NF-κB p65 protein in spleen and thymus of OJ rats.

Apoptosis is a self-protective strategy employed by the body for removal of the destroyed cells through initiating programmed gene expression under certain pathophysiological conditions[25]. In contrast to cell necrosis, apoptosis is an active and spontaneous process and does not induce dramatic inflammatory reaction. However, apoptosis as a mode of cell loss can also induce functional impairment of immune organs. Bax, a soluble protein encoded by a recently discovered apoptosis-promoting gene, shares the same protein family as Bcl-2 and is able to promote cell apoptosis[26,27]. In this study, the expression level of Bax protein was higher in spleen and thymus of model group than in those of sham-operation group. As a result, the apoptosis index was increased and pathological injury was aggravated, suggesting that Bax protein is involved in physiological or pathological cellular apoptosis of spleen and thymus. After treatment with *Astragalus* injection, the pathological changes in immune organs were improved and the expression level of Bax protein in spleen and thymus, apoptosis index and pathological scores for spleen and thymus were significantly lower in treatment group than in model control group, indicating that *Astragalus* injection can down-regulate the expression of Bax protein, suppress cell apoptosis and exert protective effects on immune organs.

In summary, *Astragalus* injection can improve pathological changes in immune organs, reduce serum TNF-α level, down-regulate expression of Bax protein in spleen and thymus, and suppress cell apoptosis, thereby exerting its protective effects on immune organs of OJ rats. Since *Astragalus* has diverse pharmacological actions, low cost and few side effects, it has a better application prospect and economic value.

COMMENTS

Background

Obstructive jaundice (OJ) is a kind of common clinical manifestation. The pathogenesis and treatment of OJ have been a hot topic in medical field for a long time. As systemic inflammatory response syndrome and multiple organ dysfunction syndrome were studied in recent years, immune function impairment concomitant with OJ has gradually attracted wide attention and is considered as a cause of death in OJ patients. Therefore, one of the important approaches to treatment of OJ is to restore the functions of immune organs.

Research frontiers

Development and utilization of traditional Chinese medicine have good prospects in therapy for OJ since it has lower cost, more extensive pharmacological effects and fewer side effects. Since *Astragalus* injection contains polysaccharide, saponin, flavone and trace elements, it has a variety of pharmacological effects and plays an important role in increasing the immunity of body and protecting the liver and kidney. This study demonstrated that *Radix Astragali* could exert its protective effects on immune organs of OJ rats by relieving the pathological changes in immune organs, reducing tumor necrosis factor (TNF)-α level, and inhibiting Bax expression and apoptosis in spleen and thymus.

Innovations and breakthroughs

At present, no studies about the effects of *Astragalus* on immune organs during OJ are available. In the present study, we investigated the protective effect of *Astragalus* injection on immune organs of OJ rats and its mechanism, which may provide an experimental basis for its application in clinical practice.

Applications

Astragalus has diverse pharmacological actions, low cost and few side effects, and thus can be applied in clinical practice.

Terminology

Nuclear factor (NF)-κB p65, a protein that is extensively distributed in cytoplasm of many cells, is able to regulate gene transcription in nuclei. TNF-α

is a most important factor for mediating the toxic effects of endotoxins. Bax, a soluble protein encoded by a recently discovered apoptosis-promoting gene, shares the same protein family as Bcl-2 and is able to promote cell apoptosis.

Peer review

The manuscript describes the protective effects of *Radix astragali* injection on immune organs of rats with OJ. *Radix astragali* injection could reverse elevated TNF-α level, and spleen, thymus and lymph node lesions. Bax immunoreactivity and apoptosis could be observed after obstructive jaundice. This manuscript is largely descriptive by providing novel insights into the mechanism underlying the beneficial effect *of Radix astragali* on obstructive jaundice.

Abstract

AIM: To examine the effect of alisol B acetate on the growth of human gastric cancer cell line SGC7901 and its possible mechanism of action.

METHODS: The cytotoxic effect of alisol B acetate on SGC7901 cells was measured by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Phase-contrast and electron microscopy were used to observe the morphological changes. Cell cycle and mitochondrial transmembrane potential ($\Delta\Psi m$) were determined by flow cytometry. Western blotting was used to detect the expression of apoptosis-regulated gene Bcl-2, Bax, Apaf-1, caspase-3, caspase-9, Akt, P-Akt and phosphatidylinositol 3-kinases (PI3K).

RESULTS: Alisol B acetate inhibited the proliferation of SGC7901 cell line in a time- and dose-dependent manner. PI staining showed that alisol B acetate can change the cell cycle distribution of SGC7901, increase the proportion of cells in G0-G1 phase and decrease the proportion of S phase cells and G2-M phase cells. Alisol B acetate at a concentration of 30 μmol/L induced apoptosis after 24, 48 and 72 h incubation, with occurrence rates of apoptotic cells of 4.36%, 14.42% and 21.16%, respectively. Phase-contrast and electron microscopy revealed that the nuclear fragmentation and chromosomal condensed, cells shrank and attachment loss appeared in the SGC7901 treated with alisol B acetate. Apoptosis of SGC7901 cells was associated with cell cycle arrest, caspase-3 and caspase-9 activation, loss of mitochondrial membrane potential and up-regulation of the ratio of Bax/Bcl-2 and inhibition of the PI3K/Akt.

CONCLUSION: Alisol B acetate exhibits an anti-proliferative effect in SGC7901 cells by inducing apoptosis. Apoptosis of SGC7901 cells involves mitochondria-caspase and PI3K/Akt dependent pathways.

INTRODUCTION

Gastric cancer is one of the most common malignancies in mankind and its incidence and mortality rank first in China[1]. Recent data indicate that the mortality of gastric cancer in China is tending to increase and it severely threatens the health and life of people[2]. At present, the management of gastric cancer mainly includes surgery and chemotherapy, but the curative effect of the existing chemotherapeutic drugs is not good enough and they have numerous side effects. Therefore, it has become a focus to search the drugs capable of preventing and treating gastric cancer and other malignancies.

Herbal medicines are an important source of novel agents with pharmaceutical potential. Alisol B acetate is a major ingredient isolated from *Alismatis rhizoma* and has been used for urological diseases in traditional Chinese medicine. In recent years, the pharmacological characterization of alisol B acetate has been identified and several biological activities have been defined, such

as the inhibitory effects on lipopolysaccharide[3], the inhibition of complementary activity[4,5] and antibody-mediated allergic reaction[6]. Furthermore, it has been demonstrated that alisol B acetate induces cell death in hepatoma and leukemia cells[7,8]. Later studies have shown that alisol B acetate induces Bax nuclear translocation and apoptosis in human hormone-resistant prostate cancer PC-3 cells[9].

However, no detailed data are available about the role and mechanisms of alisol B acetate in gastric carcinoma. In order to understand the role and mechanisms of alisol B acetate in the treatment of gastric carcinoma, we investigated the effect of alisol B acetate on the growth of human SGC7901 cells and the underlying intracellular signal transduction pathways involved in regulating apoptosis. We found that alisol B acetate-induced apoptosis is accompanied by the modulation of the Bcl-2 family, mitochondrial dysfunction and activation of caspases; in SGC7901 cells, alisol B acetate induced apoptosis *via* the mitochondrial death pathway; and the apoptosis induced by alisol B acetate was sensitized through inhibition of the PI3K/Akt signaling pathway.

MATERIALS AND METHODS

Materials

Gastric adenocarcinoma cell line (SGC7901) was obtained from our laboratory. Alisol B acetate was purchased from Wako Pure Chemical Industries (Osaka, Japan). Methyl thiazolyl tetrazolium (MTT), propidium iodide (PI), Tris-HCl, and Triton X-100 were obtained from Sigma Chemical Company (St. Louis, USA). Monoclonal antibodies to Bax, Bcl-2, Apaf-1 caspase-3 and caspase-9 were purchased from Santa Cruz Biotechnology Incorporation (Santa Cruz, CA, USA). PVDF membrane was obtained from Bio-Rad (CA, USA). Phospho-Akt (Thr308), Akt, PI3K antibodies were procured from Cell Signaling Technology (Beverly, MA, USA).

Cell culture and treatment with alisol B acetate

Cells were cultured in RPMI-1640 medium supplemented with 10% fetal bovine serum, 100 U/mL penicillin and 100 μg/mL streptomycin at 37℃ humidified atmosphere containing 5% CO_2. The chemical compounds (alisol B acetate) were dissolved in dimethyl sulfoxide (DMSO), and diluted to appropriate concentrations with culture medium. The final concentration of DMSO in the culture medium did not exceed 0.1%.

MTT assay

Cells were plated at a density of 2×10^3/well in 96-well plates. Twenty-four hours later, cells were treated with alisol B acetate at different final concentrations from 10 to 80 μmol/L for 24 h or at 30 μmol/L concentration for the indicated time courses. Control cell cultures were treated with DMSO. After addition of test compounds, 20 μL MTT was added to each well. Four hours later, 100 μL of DMSO was added to each well after the medium was removed. Finally, absorbance was detected with an enzyme calibrator at 570 nm and cell viability= (A of study group/A of control group) × 100%. Experiments were done in triplicate. There were six wells for each concentration.

Morphological changes examined by phase-contrast and electron microscopy

Phase-contrast microscopic studies: SGC7901 cells were grown in 35 mm sterile petri plates and treated with various doses of alisol B acetate for 24 h. Morphological changes were observed under phase-contrast microscope.

Electron microscopy: Cells were cultured with alisol B acetate at a concentration of 30 μmol/L for 24, 48 and 72 h, then fixed with 2% paraformaldehyde/2% glutaraldehyde in 0.1 mol/L phosphate buffer (pH 7.4), followed by 1% osmium tetroxide. After dehydration, thin sections were stained with uranyl acetate and lead citrate for observation under a JEM 100 CX electron microscope (JEOL, Peabody, NY, USA).

Flow cytometric analysis of cell cycle

Cells were seeded in 6-well plates and treated with alisol B acetate at 30 μmol/L concentration for 24, 48 and 72 h. DMSO (0.1%)-treated cells served as control. After treatment, media were discarded. The adherent cells were washed with PBS, and 300 μL trypsin was added for 5 min at room temperature to detach the cells. Then, the cell suspension was centrifuged at 1500 r/min for 5 min at room temperature. Decanting of all the supernatant was followed by adding 1 mL of 70% methanol to the pellet. After incubation at 4℃ for at least 12 h, prior to the samples being analyzed by the flow cytometry (FCM) (Becton Dickinson), 1 mL of cold PI stain solution (20 g/mL PI, 20 g/mL RNase A, and 0.1% Triton X-100) was added to the mixture and it was incubated for 15 min in darkness at room temperature. The samples were analyzed by FCM (BD FACS CantoTM). The results were analyzed by Mod Fit LT 3.0 software.

Analysis of mitochondrial membrane potential

Changes of mitochondrial membrane potential were monitored by determination of the fluorescence of Rhodamine (Rh)-123. Cells were treated with or without alisol B acetate for the indicated time courses. At the end of treatment, the cells were finally harvested. Rh-123 was added to 1×10^6 cells in 5 mL complete growth medium to a final concentration of 5 g/L and cells were incubated at 37℃ in the dark for 30 min to allow Rh-123 uptake. Rh-123 loaded cells were washed with ice cold PBS and re-suspended in PBS. Changes in mitochondrial transmembrane potential as a result of mitochondrial perturbation were measured after staining with Rh-123[10]. Ten thousand events were examined by a FACSCAN flow cytometer and data were analyzed with the Macintosh Cell Quest software.

Western blotting analysis

After being treated with alisol B acetate for the indicated periods, the cells were washed with PBS and lysed in a buffer containing 20 mmol/L Tris-HCl, 150 mmol/L NaCl, 1% Triton X-100, 1.5 mmol/L $MgCl_2$, 1 mmol/L $NaVO_3$, 100 mmol/L NaF, 10% glycerol, 1mmol/L EGTA, 10 mmol/L sodium pyrophosphate, and 1 mmol/L phenylmethylsulfonyl fluoride, pH 7.5. Cell lysates were centrifuged at 12000 × *g* for 60 min at 4℃. The protein concentrations were determined using Bio-Rad protein assay (Bio-Rad Laboratories, USA). After SDS-PAGE, proteins were transferred to PVDF membranes for 2 h at 80 mA. The PVDF membrane was treated with TBST containing 50 g/L skimmed milk at room temperature for 2 h, followed by incubation with the first antibodies caspase-3, caspase-9, Apaf-1, Bcl-2, Bax, Akt, P-Akt, PI3K, respectively, at 4℃ overnight. After being washed with TBST for 30 min, the corresponding secondary antibody was added and incubated at room temperature for 1 h. The membrane was then washed three times for 15 min each with TBST and visualized with diaminobenzidine. Quantification of protein was detected with a Lumivision IMAGER (Aisin Seiki, Aichi). Each value represents the mean of triple experiments, and is presented as the relative density of protein bands normalized to β-actin.

Statistical analysis

Data were expressed as mean ± SD. Statistical correlation of data was checked for significance by ANOVA and Student's *t* test. Differences with $P < 0.05$ were considered significant. These analyses were performed using SPSS 11.0 software.

RESULTS

Alisol B acetate inhibited SGC7901 cell proliferation

To investigate the growth inhibition effects of alisol B acetate, the cells were treated with various concentrations of alisol B acetate for 24 h and 30 μmol/L for 8, 16, 24, 48 and 72 h. As shown in Figure 1A, cell viability was decreased remarkably after the cells were treated with 30, 50, 70 and 80 μmol/L alisol B acetate for 24 h. Only a minor inhibition of SGC7901 cell growth was observed in the presence of 20 μmol/L alisol B acetate. Growth was inhibited by more than 40% in cells exposed to 30 μmol/L alisol B acetate after 24, 48 and 72 h. Alisol B acetate had significant growth inhibitory effects on SGC7901 cells in a dose- and time-dependent manner. A concentration of 30 μmol/L alisol B acetate was used in all further experiments.

Alisol B acetate induces apoptosis

SGC7901 cells were treated with alisol B acetate (0, 30, 50 and 70 μmol/L) for 24 h, and phase-contrast microscopy revealed that some cells became round, blunt and smaller in size; light refraction was increased; and cells became detached and suspended in the medium, especially with 50 and 70 μmol/L alisol B acetate. In the control group, cells were regular in morphology and grew fully in patches and confluently, rarely sloughing off (Figure 2).

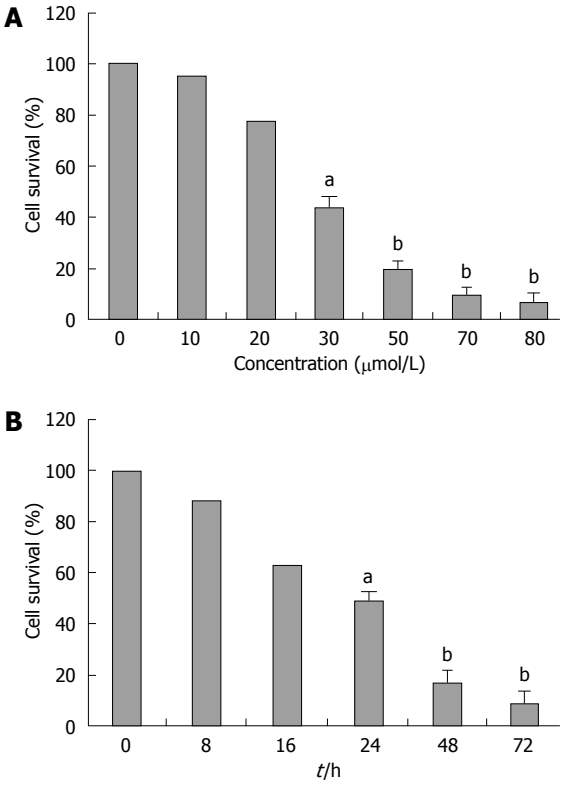

Figure 1 Effect of alisol B acetate on survival of SGC7901 cells. Cells were incubated in the absence or presence of various concentrations of alisol B acetate for 24 h (A), or at 30 μmol/L for different incubation times (B). $^aP < 0.05$, $^bP < 0.01$ *vs* control group (unpaired Student's *t* test).

The ultrastructural and morphological changes were also observed under electron microscope. As shown in Figure 3B and C, nuclear fragmentation, chromosome condensation and cell shrinkage were visible. Subsequent formation of apoptotic bodies were also observed (Figure 3D).

FCM with only PI staining showed (Figure 4) that treatment of SGC7901 cells with 30 μmol/L alisol B acetate for 72 h resulted in a higher number of cells in the G0/G1 phase (79.61%) compared with the control (40.46%). This increase was coupled with the decreased percentage of cells in S phase. After 72 h treatment, the percentage of S phase in alisol B acetate -treated cells was 16.55%, whereas 48.45% in the control cells. In addition, flow cytometric analysis also revealed the effect of alisol B acetate on the induction of apoptosis. As shown in Figure 4, the percentage of the sub/G1 fraction in alisol B acetate-treated cells was increased in a time-dependent manner, indicative of apoptotic cell death.

Alisol B-induced apoptosis is associated with mitochondrial pathways

Mitochondria played a major role in apoptosis triggered by many stimuli. The early loss of mitochondrial membrane potential is a hallmark of apoptosis[11]. We examined the effect of alisol B acetate on mitochondrial

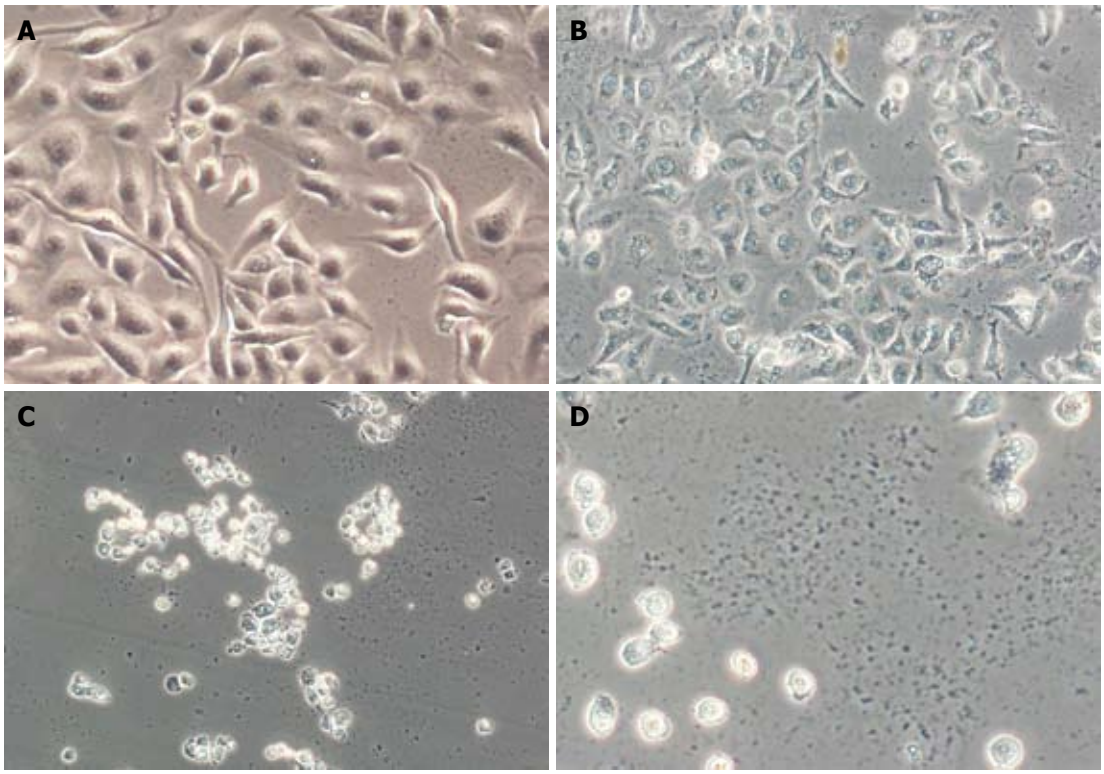

Figure 2 Morphology of SGC7901 cells exposed to alisol B acetate for different concentrations observed under phase-contrast microscope. A: Controls; B-D: SGC7901 cells were treated with 30, 50 and 70 μmol/L alisol B acetate for 24 h.

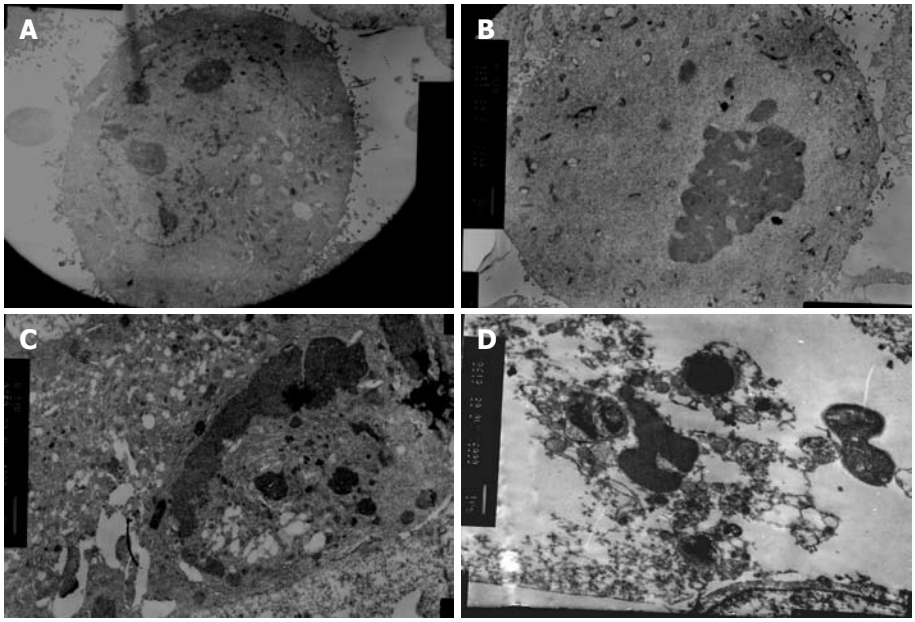

Figure 3 Morphological changes observed under electronic microscope. A: Control; B-D: Cells were incubated with 30 μmol/L alisol B acetate for 24, 48 and 72 h.

membrane potential by means of the potential sensitive Rh-123. After treatment of SGC7901 cells with 30 μmol/L alisol B acetate for 12, 24, 48 and 72 h, flow cytometric data revealed that disruption of mitochondrial membrane potential was 17.75%, 29.87%, 43.32% and 70.00%, respectively, while it was only 4.05% in the control group. The data demonstrated that alisol B acetate induced a time-dependent decrease in mitochondrial membrane potential, indicating the participation of mitochondria-related mechanism (Figure 5).

Up-regulation of Apaf-1 and Bax, activation of caspase-3 and caspase-9

To investigate the mechanism underlying apoptosis induced by alisol B acetate, we tested the effect of this compound on Bcl-2, Bax levels, two important regulators of apoptotic signaling pathways[12]. As shown in Figure 6, Western blotting analysis revealed that alisol B acetate -induced apoptosis did not alter Bcl-2 expression, but resulted in a time-dependent up-regulation of Bax expression, with a maximal up-

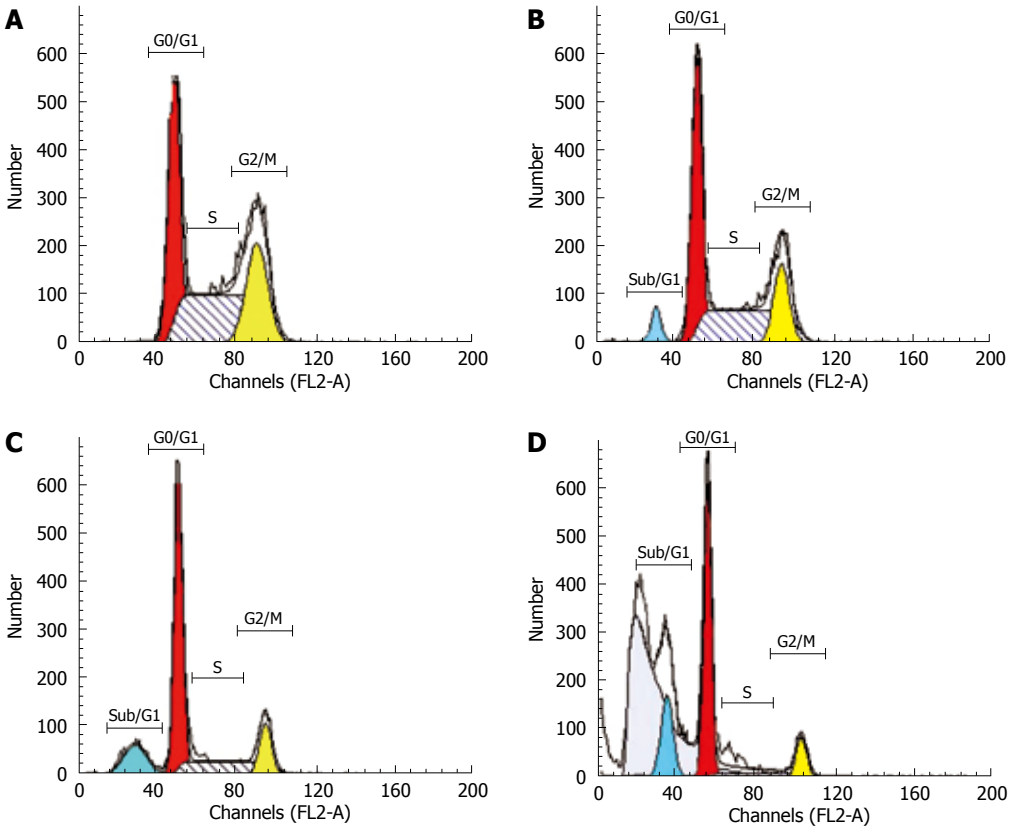

Figure 4 Effect of alisol B acetate on cell cycle distribution of SGC7901 cells. SGC7901 cells were treated with 0.1% DMSO (A) or with 30 μmol/L alisol B acetate for 24 h (B), 48 h (C), or 72 h (D). The cells were collected sequentially and stained with PI and analyzed by FCM.

regulation at 72 h after treatment that was associated with increased levels of Apaf-1, and activated caspases-3 and caspase-9. These results suggest that alisol B acetate induces SGC7901 apoptosis, at least partly, through up-regulation of pro-apoptotic Bax, resulting in up-regulation of the Bax/Bcl-2 ratio and activation of caspase-3 and caspase-9.

Effects of alisol B acetate on PI3K/Akt pathway

Akt, a major downstream target of PI3K, may be the best-characterized kinase known to promote cellular survival[13] and is dysregulated (mainly overexpressed) in a wide spectrum of human cancers, including gastric, hepatoma, and ovarian cancers[14-16]. To determine whether regulation of the Akt signal pathway is necessary for alisol B acetate-induced apoptosis, we investigated the expression of PI3K and Akt after treatment with 30 μmol/L Alisol B acetate. As shown in Figure 7, the levels of PI3K and phosphorylated Akt are time-dependently decreased in response to alisol B acetate. PI3K and phosphorylated Akt were rapidly decreased at 24 h, while the total Akt protein levels remained constant during alisol B acetate treatment. Therefore, these results suggested that Akt/PKB is associated with the survival of SGC7901 gastric cancer cells and inhibition of the PI3K/Akt signaling pathway increased the apoptosis induced by the alisol B acetate.

DISCUSSION

Apoptosis plays an important role in developmental processes, maintenance of homeostasis, and elimination of the damaged cells. Accumulated data indicate that many anticancer drugs can cause the death of tumor cells through the induction of apoptosis[15,17]. Alisol B acetate induces cell apoptosis in hepatoma and leukemia cells[7,8]. However, the effects of alisol B acetate on human gastric cells are still unclear. Therefore, the purpose of the present study was to find out the molecular mechanism of alisol B acetate underlying human gastric cancer cell line SGC7901.

In the present study, we first demonstrated that SGC7901 cells treated with alisol B acetate showed a dose- and time-dependent inhibition of the proliferation. Nuclear fragmentation, chromosome condensation, cell shrinkage and formation of apoptotic bodies were also observed. Flow cytometric analysis revealed that alisol B acetate treatment results in an increase of apoptotic cells. These results suggest that alisol B acetate-induced apoptosis contributes to the growth inhibition of SGC7901 cells.

Mitochondrion plays a critical role in apoptosis induced by some drugs[11]. The mitochondrial death pathway is associated with changes in the permeability of the outer mitochondrial membrane, the collapse of membrane potential[18,19]. Mitochondrial membrane permeability is mainly controlled by the Bcl-2 family of proteins, through regulation of the formation of apoptotic protein-conducting pores in the outer mitochondrial membrane[20-22]. Members of the Bcl-2 family proteins can be divided into two subfamilies; one is anti-apoptotic protein such as Bcl-2 and Bcl-X_L, the other is pro-apoptotic protein such as Bax, Bad, and Bid[23]. The expression of Bcl-2 and Bax is significantly involved in the balance of pro-apoptotic and anti-apoptotic signals at the mitochondrial level[24].

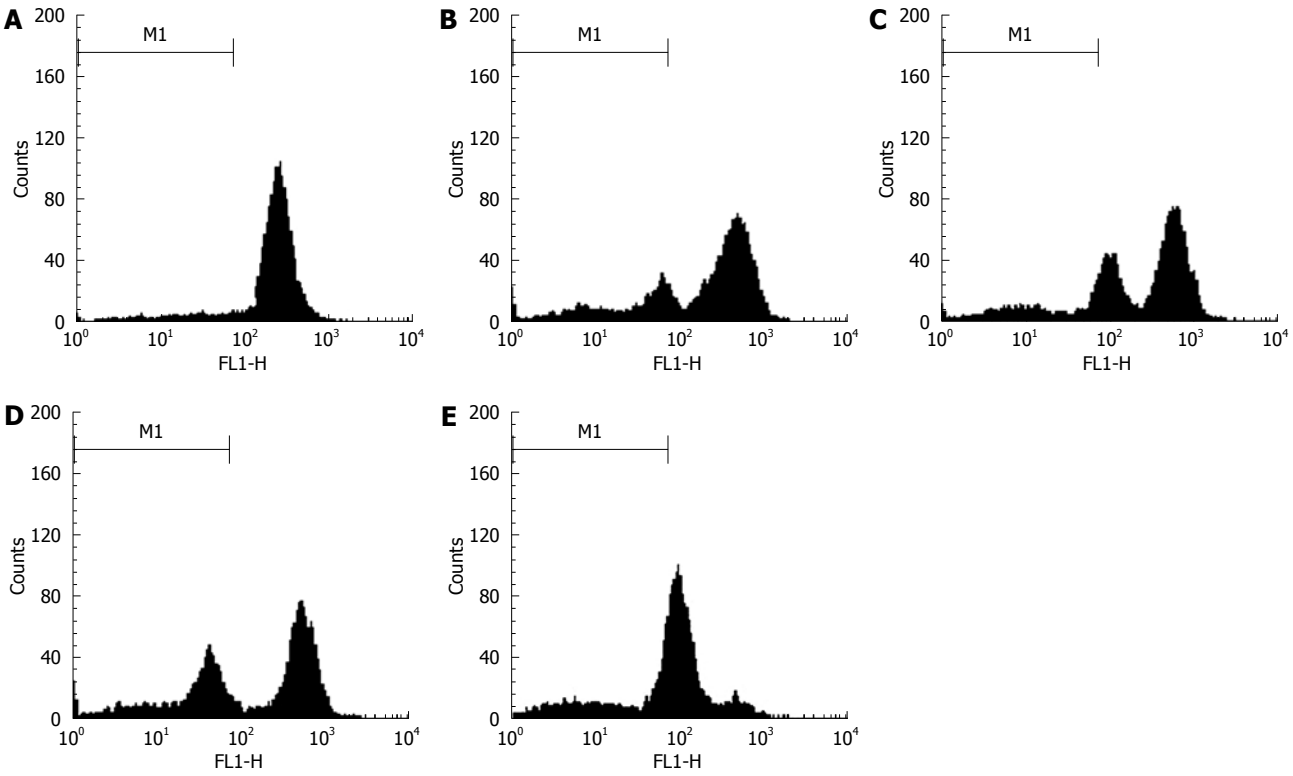

Figure 5 FCM analysis of mitochondrial membrane potential in human SGC7901 cells with 30 μmol/L alisol B acetate for various time periods. The zero concentration was defined as control. The percentage of cells stained with Rh-123 was determined by FCM as described in the Materials and Methods. A: Control; B-E: 12, 24, 48 and 72 h.

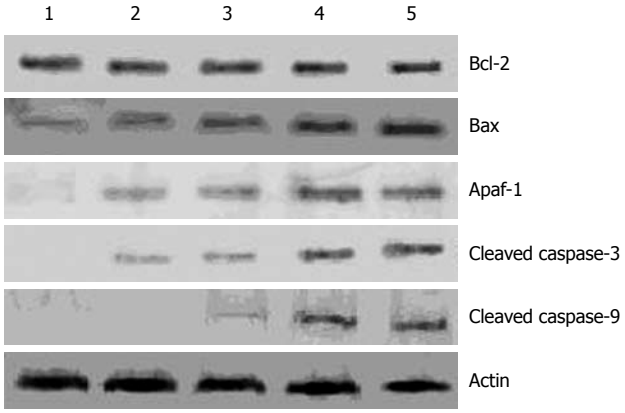

Figure 6 Effect of Alisol B acetate on the expression of Bcl-2, Bax, Apaf-1, cleaved caspase-3 and caspase-9. SGC7901 cells were treated with 30 μmol/L alisol B acetate for 12, 24, 48 and 72 h. The cells were collected and lysed. Western blotting analysis was conducted and probed with antibodies to Bcl-2, Bax, Apaf-1, caspase-3 and caspase-9. Lanes (from left to right): Control cells; 12 h; 24 h; 48 h; 72 h.

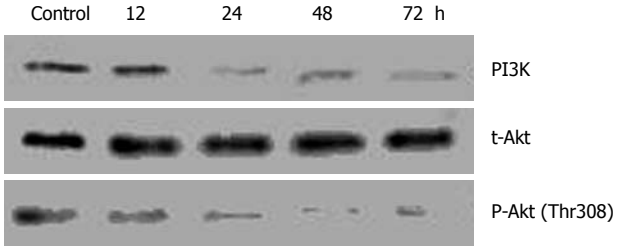

Figure 7 Effect of alisol B acetate on PI3K/Akt activation in SGC7901 cells. SGC7901 cells were treated with 0.1% DMSO (A) or 30 μmol/L alisol B acetate for 12, 24, 48 and 72 h. Western blotting analysis for PI3K, t-Akt and P-Akt was performed using specific antibodies with β-actin as a loading control.

The ratio of Bax/Bcl-2 is critical for the induction of apoptosis and this ratio determines whether cells will undergo apoptosis[25,26]. An increase in the ratio of Bax/Bcl-2 stimulates the release of cytochrome c from mitochondria into the cytosol. The cytosolic cytochrome c then binds to Apaf-1, leading to the activation of caspase-9, caspase-3 and poly (ADP-ribose) polymerase[27,28]. Thus, we examined the effect of alisol B acetate on Bax, Bcl-2 and mitochondrial membrane potential. In our experiments, alisol B acetate increased pro-apoptotic Bax expression without affecting Bcl-2 expression, leading to up-regulation of the ratio between pro-apoptotic (Bax) and anti-apoptotic (Bcl-2). This may be responsible for the concomitant execution phase of apoptosis that we observed, which included disruption of mitochondrial membrane potential.

Caspases, a family of cysteine proteases, are integral parts of the apoptotic pathway. Caspase-9 is the apical caspase in the intrinsic or mitochondria-initiated apoptosis pathway and requires the release of cytochrome C from the mitochondria as well as interactions with Apaf-1[18]. Activation of caspase-3 correlated with activation of caspase-9. Caspase-3 in particular, when activated, has many cellular targets[29]. During apoptosis, caspase-3 is one of the key executioners of apoptosis in response to various stimuli[30]. In many studies, it has been determined that a variety of chemotherapeutic agents induce apoptosis through the activation of caspases[15]. Previous studies have observed that alisol B

acetate induces apoptosis in human hepatoma Hep3B cells and human hormone-resistant prostate cancer PC-3 cells through an increase of caspase-3 and caspase-9 activity[7,9]. Consistent with an increase in the ratio of Bax/Bcl-2 and disruption of mitochondrial membrane potential, this study showed that alisol B acetate resulted in a time dependent up-regulation of Apaf-1, and activation of caspase-9 and caspase-3.

According to the present data, alisol B acetate may first increased the ratio of Bax/Bcl-2, which leads to disruption of mitochondrial membrane potential, and then activates mitochondria-mediated downstream molecular events including cytochrome c release and sequential activation of caspase-9 and caspase-3. These results demonstrated that a mitochondrial damage-mediated caspase pathway might be involved in alisol B acetate -induced apoptosis of SGC7901 cells.

The PI3K pathway regulates several cellular processes, including proliferation, growth[31], apoptosis[32] and cytoskeletal rearrangement. Akt, a major downstream target of PI3K, was originally reported as the cellular counterpart of the viral oncogene, which was amplified in gastric adenocarcinoma[14]. Overexpression of Akt isoforms has now been reported in ovarian, breast, prostate, and pancreatic cancers[16,33-35]. In addition, Akt activity is increased in cancers where the PTEN tumor suppressor is mutated[36]. In recent years, a number of cancer researchers have focused on the central importance of the PI3K/Akt pathway, and therapeutic strategies that target the PI3K/Akt pathway are now being developed[15,37]. PI3K consists of p85 regulatory subunit and a p110 catalytic subunit. Akt is activated by recruitment to the plasma membrane though direct contact of its Plecpstrinhomology domain with PIP3, and phosphorylation at Thr308 and Ser473. Thr308 is phosphorylated by the 3-phosphoinositide-dependent protein kinase PDKI[38]. Through its interaction with proteins in the Bcl-2 family such as BAD, Bax, Bcl-X_L and their downstream effectors, Akt provides a survival signal to the cell[39]. Additionally, Akt blocks cytochrome C release from the mitochondria through regulation of Bcl-2[40] and inhibits the catalytic activity of a pro-death protease, caspase 9 through phosphorylation[41].

In our study, we evaluated the effect of alisol B acetate on the PI3K/Akt pathways by measuring the PI3K and total Akt protein and sequential expression levels of phospho-Akt. We observed that alisol B acetate markedly inhibited PI3K and phospho-Akt after 24 h of treatment. No additional reduction in PI3K and phospho-Akt levels was seen when treatment was prolonged to 72 h and the total Akt protein levels remained constant throughout the course of the experiment. Meanwhile, our data showed that alisol B acetate treatment up-regulates Bax protein and down-regulates mitochondrial membrane potential. Furthermore, our data also showed activation of caspase-9 and caspase-3 in alisol B acetate-treated groups. Inhibition of PI3K/Akt signaling pathway is possibly preceded by modulations in Bax protein, leading to mitochondrial damage and activation of caspase-9, caspase-3 in favor of apoptosis.

In conclusion, we have demonstrated that alisol B acetate significantly induces apoptosis. This apoptotic response is associated with the up-regulation of the ratio of Bax/Bcl-2, loss of mitochondrial membrane and caspase activation. Moreover, the inhibition of PI3K/Akt pathway may play an important role in alisol B acetate-induced apoptosis. Therefore, we believe that alisol B acetate might be a promising molecule in cancer chemoprevention or chemotherapy; and further efforts to explore this therapeutic strategy are necessary.

COMMENTS

Background

Alisol B acetate is a major ingredient isolated from Alismatis rhizome. In recent years, alisol B acetate has shown various biological activities, including inhibitory effects on lipopolysaccharide, the inhibition of complementary activity, antibody-mediated allergic reaction and anti-tumor effects. However, its molecular mechanisms in the anti-tumor effects have not been well documented.

Research frontiers

Studies have confirmed that many Chinese herbs have anti-tumor properties and induce apoptosis. In the process of cell apoptosis induced by drugs, mitochondria plays a great role. phosphatidylinositol 3-kinases (PI3K)/Akt pathway is important in the development and proliferation of various human cancers. In recent years, a number of cancer researchers have focused on the importance of the PI3K/Akt pathway, and therapeutic strategies that target the PI3K/Akt pathway are being developed. In the present work, the authors investigated the effect of alisol B acetate on human SGC7901 cell proliferation, mitochondrial and PI3K/Akt signaling pathways.

Innovations and breakthroughs

The present study shows that alisol B acetate induces apoptosis and decreases proliferation in human gastric cancer cells. It was shown for the first time that alisol B acetate induced human gastric cancer apoptosis by modulation of the Bcl-2 family, loss of mitochondrial membrane potential, activation of caspases and inhibition of PI3K/Akt pathway.

Applications

The data of this article demonstrate the anti-cancer properties of alisol B acetate as well as its mechanism of action. By knowing the mechanism of action of alisol B acetate, it may provide a new therapeutic option, as a potential anticancer agent in the treatment of gastric cancer.

Terminology

PI3K is a major regulator of cell proliferation located in the Akt upstream, and together PI3K and Akt define a signal transduction pathway important in the pathogenesis of many different cancer types. Alisol B acetate is a natural herbal substance.

Peer review

This is a carefully performed study with novel findings that alisol B acetate has the potential for therapeutic application in gastric cancer. It examines the effect of alisol B acetate on the growth of human gastric cancer cell line and its possible mechanism of action. This paper is well-written. The experiments were well-designed and well-executed.

Abstract

AIM: To determine the effect of ethnicity on the severity of reflux esophagitis (RE) and its complications.

METHODS: A retrospective search of the endoscopy database at the University of Florida Health Science Center/Jacksonville for all cases of reflux esophagitis and its complications from January 1 to March 31, 2001 was performed. Inclusion criteria were endoscopic evidence of esophagitis using the LA classification, reflux related complications and self-reported ethnicity. The data obtained included esophagitis grade, presence of a hiatal hernia, esophageal ulcer, stricture and Barrett's esophagus, and endoscopy indication.

RESULTS: The search identified 259 patients with RE or its complications, of which 171 were non-Hispanic whites and 88 were African Americans. The mean ages and male/female ratios were similar in the two groups. RE grade, esophageal ulcer, stricture and hiatal hernia frequency were likewise similar in the groups. Barrett's esophagus was present more often in non-Hispanic whites than in African Americans (15.8% *vs* 4.5%; $P < 0.01$). Heartburn was a more frequent indication for endoscopy in non-Hispanic whites with erosive esophagitis than in African Americans (28.1% *vs* 7.9%; $P < 0.001$).

CONCLUSION: Distribution of RE grade and frequency of reflux-related esophageal ulcer, stricture and hiatal hernia are similar in non-Hispanic whites and African Americans. Heartburn was more frequently and nausea/vomiting less frequently reported as the primary endoscopic indication in non-Hispanic whites compared with African Americans with erosive esophagitis or its complications. African Americans have a decreased prevalence of Barrett's esophagus compared with non-Hispanic whites.

INTRODUCTION

Multiple studies suggest that the frequency of gastroesophageal reflux disease (GERD) complications such as erosive esophagitis, stricture and Barrett's esophagus (BE) is significantly lower in the US minority populations compared with non-Hispanic whites (nHw)[1-6]. Two studies from Veterans Affairs Medical Centers observed that severe GERD affected older nHw more commonly than non-whites[2,3]. Both of these investigations used the Department of Veterans Affairs patient treatment file as the data source.

Two groups of investigators have attempted to determine the frequency of GERD complications between ethnic groups seen at their institutions[7,8]. In one study[7], African Americans (AA), nHw and Asians significantly differed in heartburn prevalence, while the other[8] indicated that AA and nHw had equivalent heartburn prevalence rates. Both studies revealed that AA had decreased rates of erosive esophagitis compared with nHw. The prevalence of BE was only assessed in one investigation with the overwhelming majority seen in nHw.

Regarding BE, limited data exists about the prevalence of this entity in the United States minority populations. Initial studies compared non-Hispanic whites with African Americans. These revealed a predominant presence of BE in nHw when compared with AA[7-9]. In contrast, a report from the National Cancer Institute indicated that the incidence of esophageal adenocarcinoma is increasing in AA[10]. BE is considered the precursor lesion of esophageal adenocarcinoma, therefore one could speculate that the incidence of BE might also be increasing within the AA population.

There is minimal data evaluating the prevalence of GERD complications in any defined general population other than non-Hispanic whites[11,12]. The goal of this study is to compare the severity of reflux esophagitis and its complications in AA and nHw patients who underwent endoscopy at our institution.

MATERIALS AND METHODS

Patient population

A retrospective search of the endoscopy laboratory report database was performed to determine the total number of patients having upper gastrointestinal endoscopy (EGD) at the University of Florida Health Science Center/Jacksonville from 1 January to 31 March 2001. Inclusion criteria were endoscopic evidence of reflux esophagitis, esophageal stricture and/or ulcer, BE, and self reported ethnicity. Exclusion criteria were previous diagnostic EGD, history of non-GERD esophageal condition with the potential to cause esophageal injury (acquired immunodeficiency syndrome, esophageal infections, caustic ingestion, and thoracic radiation), and absence of demographic information within the patient record. The study was approved by the Institutional Review Board of the University of Florida Health Science Center/Jacksonville.

Symptom evaluation

Indication for EGD was recorded on the individual reports by all endoscopists. If multiple indications were listed, the first indication listed was used at the primary reason for performing the procedure. Patients with an indication such as follow-up of any previously noted esophageal lesion were not included in the analysis.

Classification of endoscopic findings

Esophagitis was graded using the Los Angeles system[13,14]. This scheme categorizes mucosal injury as follows: grade A defined as one or more mucosal breaks no longer than 5 mm which do not extend between the tops of two mucosal folds; grade B defined as one or more mucosal breaks more than 5 mm long that do not extend between the tops of two mucosal folds; grade C defined as one or more breaks that are continuous between the tops of two or more mucosal folds but involve < 75% of the esophageal circumference; and grade D defined as one or more mucosal breaks that involve at least 75% of the esophageal circumference. Four-quadrant biopsy specimens were taken at 2 cm intervals from any visible length of columnar lined esophagus to assess the presence of histologic BE. Biopsy sections were then stained with Alcian blue to detect the presence of specialized intestinal metaplasia, the characteristic feature of BE.

Esophageal stricture was defined as a narrowing of the esophageal lumen, which either did not allow passage of a 9 mm endoscope or allowed distal passage of the endoscope with difficulty. The length of the narrowing was measured using the 5 cm endoscope length markings as a reference. Hiatal hernia was defined as the presence of gastric mucosa above the level of the esophageal hiatus. The hernia length was measured using the 5 cm markings as a reference. Hiatal hernia length was considered small if < 2 cm, medium from 2 to 5 cm, and large if greater than 5 cm. The hernia was defined as sliding if the stomach re-entered the abdominal cavity during the endoscopy. Esophageal ulcer was defined as an excavation of the esophageal mucosa of at least 3 mm wide. The ulcer margin had to be raised from the base by at least 1 mm. Location of the ulcer was noted as distal, mid or proximal esophagus.

Table 1 Demographic data of the study population

	AA (n = 88)	nHw (n = 171)
Male/female (%)	38/62	48/52
Age range (yr)	26-101	18-90
Mean age (mean ± SD)	58.5 ± 16.9	55.8 ± 14.5

P = NS for all, NS represents not significant.

Statistical analysis

All values of esophagitis distribution frequency, presence of stricture, esophageal ulcer, hiatal hernia, BE and procedure indication were reported as percentage present for each group. Student's t-test was used for comparisons between groups. Differences between groups will be considered significant if $P < 0.05$. Data analysis was performed using JMP 5.0 for Windows (SAS Institute Inc., Cary, NC).

RESULTS

Demographics of the study population

During the study period, 716 patients had an EGD and 259 of the 716 patients met the criteria for study inclusion. Of the study group, 171 (66%) were nHw and 88 (34%) were AA. Males comprised 48% of the nHw and 38% of the AA groups, respectively. The groups were similar in age and gender distribution (Table 1).

Indication for endoscopy

Table 2 illustrates the indication for EGD between ethnic groups. Heartburn was noted as the primary indication significantly more frequently in nHw than in AA patients (nHw 28.1% and AA 8%; $P < 001$). Nausea and/or vomiting were noted significantly more frequently in AA than nHw patients (nHw 2.9% and AA 9%; $P < 0.04$). Other indications for the procedure were similar between ethnic groups.

Table 2 Indication for endoscopy by ethnicity *n* (%)

Indication	88 AA patients	171 nHw patients	*P* value
Heartburn	7 (8)	48 (28.1)	< 0.001
Dysphagia	14 (15.9)	37 (21.6)	NS
Upper GI bleeding	22 (25)	25 (14.6)	NS
Nausea/vomiting	8 (9.1)	5 (2.9)	< 0.040
Abdominal pain	15 (17)	31 (18.1)	NS
Abnormal X-ray	3 (3.4)	4 (2.3)	NS
Anemia	8 (9.1)	10 (5.9)	NS
Weight loss	4 (4.5)	2 (1.2)	NS
Other	7 (8)	9 (5.3)	NS

Reflux esophagitis grade distribution

Of the 259 patients, 204 had evidence of reflux esophagitis on EGD. Of those with esophagitis, 76 were AA and 128 were nHw. The distribution of esophagitis grade among those with esophagitis in both ethnic groups is illustrated in Table 3. There was no difference observed between the two groups regarding the severity of erosive esophagitis seen.

Table 3 Distribution of reflux esophagitis grade by ethnicity

Ethnicity	LA classification grade			
	A	B	C	D
AA (%) (*n* = 76)	63.2	18.4	7.9	10.5
nHw (%) (*n* = 128)	71.1	12.5	7.0	9.4

P = NS.

Table 4 Prevalence of other endoscopic findings by ethnicity *n* (%)

	AA patients	nHw patients	*P* value
Hiatal hernia	18 (20.4)	39 (22.8)	NS
Stricture	2 (2.2)	10 (5.8)	NS
Ulcer	7 (7.9)	12 (7)	NS
Endoscopic Barrett's esophagus	4 (4.5)	27 (15.8)	< 0.01
Histological Barrett's esophagus	0 (0)	9 (5.3)	0.03

Prevalence of other esophageal findings

Table 4 demonstrates the prevalence of hiatal hernia and endoscopic complications of GERD observed between ethnic groups. With regard to presence of hiatal hernia, esophageal stricture and ulcer, no difference was observed between the groups. However, endoscopic and histologic BE were present significantly more frequently in nHw than AA patients (endoscopic BE: nHw 15.8% and AA 4.5%, $P < 0.01$; histologic BE: nHw 5.8% and AA 0%, $P < 0.04$).

DISCUSSION

The current study comparing the spectrum of reflux esophagitis between nHw and AA patients was designed to test the hypothesis that reflux esophagitis severity and its complications vary between nHw and AA at EGD. The results indicate that the distribution of severity and reflux related complications, other than BE, are similar between AA and nHw patients. This similarity in reflux esophagitis severity, presence of hiatal hernia and complications of reflux esophagitis (except for BE) observed between ethnic groups has not been previously described[2,7,8]. Also, the primary indication for the diagnostic procedure (heartburn in nHw and upper GI bleeding in AA) revealed differences between AA and nHw patients not noted previously. Both of these factors provide insight into reflux disease within the Unites States as a whole and specifically in the African American community.

Similarities and differences in reported GERD symptoms between ethnicities have been reported previously[7,8]. Spechler and colleagues noted that AA complained, understood and met predefined criteria for heartburn more frequently than was observed in either nHw or Asian patients in the metropolitan Boston area. However, El Serag and associates observed that the occurrence of weekly heartburn and/or regurgitation was no different between AA, nHw and a multiethnic group who were all employees at the Houston VA Medical Center. Complicating this further was the use of a survey (GERQ) in the investigation of El Serag *et al* to assess GERD symptoms, which had only been previously validated in nHw or Spaniards[15,16]. It is well recognized that medical communication differs between AA and nHw[17]. Using a tool not validated in African Americans might have led to underestimation of the prevalence of reflux symptoms in that group. This is also suggested by the difference in clinical indication for EGD observed between AA and nHw in the present investigation.

The difference observed in the prevalence of endoscopic BE between AA and nHw in the present investigation corresponds with previous reports in the literature[7,18,19]. The prevalence of histologically confirmed BE among nHw patients is also consistent with the single publication that specifically addressed that issue[19]. The finding that endoscopic BE was only confirmed in 1/3 of cases strongly supports the need for histology in assessing BE.

There are limitations of this investigation that should be recognized. Only those who were referred and presented for EGD were eligible for inclusion in this study. As suggested by previous reports[7,8], AA patients may have not been referred for endoscopy as frequently. This could have led to an underestimation of reflux-related endoscopic disease in that group. The effect of obesity was not accounted for in our study. Multiple studies have indicated an association linking increasing body mass index and presence of reflux symptoms in women, in addition to existence of obesity as a likely risk factor in males[20,21]. A negative association between *H pylori* presence and GERD symptoms is well established[22]. Unfortunately, biopsies of the antrum were not routinely taken in our study, therefore the presence and impact of *H pylori* colonization could not be adequately assessed.

In summary, the results of this study indicate that AA have a similar distribution of esophagitis severity and complications from GERD when compared with nHw. However, the presence of Barrett's esophagus is more common in nHw than AA. Also, it appears that AA and nHw patients with reflux esophagitis and its complications on endoscopy have different indica-

tions for EGD. The reasons for the observed difference in procedure indication and the development of histologic Barrett's esophagus between racial groups are not currently known. However, our data suggests that ethnicity may influence both symptoms leading to endoscopy and the development of BE, a premalignant change in the esophagus due to GERD. Further ethnic-specific investigations are needed to completely understand the lower prevalence of Barrett's esophagus between African Americans and non-Hispanic whites.

COMMENTS

Background

There is minimal data evaluating the prevalence of gastroesophageal reflux disease (GERD) complications in any United States general population other than non-Hispanic whites (nHw). Presently, it is thought that such complications occur less frequently in African Americans (AA) than non-Hispanic whites.

Research frontiers

Barrett's esophagus is a well-recognized complication of GERD and is the principal risk factor for esophageal adenocarcinoma. It is well known that Barrett's esophagus is more frequently discovered in nHw than in other United States ethnic groups. However, differences in other GERD associated conditions between ethnic groups have not been well evaluated. In this study, the authors demonstrate reflux esophagitis and its complications, except for Barrett's esophagus, occur in an equal distribution between AA and nHw patients.

Innovations and breakthroughs

Recent reports have highlighted discrepancies in the prevalence of Barrett's esophagus. However, minimal data exists on the frequency of reflux esophagitis and its complications in communities with a significant component of African Americans. This is the first study to report that reflux esophagitis and its complications, other than Barrett's esophagus, occur at a similar frequency in nHw and AA. In addition, indication for the index endoscopy appears to be different in the above ethnic groups.

Applications

By understanding GERD and its complications among ethnic groups in the United States, this study might indicate future avenues for investigation to prevent the development of Barrett's esophagus and esophageal adenocarcinoma.

Terminology

Barrett's esophagus is the antecedent neoplastic lesion associated with the development of esophageal adenocarcinoma. Incidence of esophageal adenocarcinoma is 3-4 times more frequent in non-Hispanic whites than African Americans.

Peer review

In this paper the authors evaluated the effect of ethnicity on the severity of reflux esophagitis. It deals with an important subject. However, as an endoscopic study, it is limited by lack of information regarding body mass index, access to medication, type of medication used for GERD and socioeconomic status of the different ethnic groups seen.

Abstract

AIM: To identify risk factors to help predict which patients are likely to fail to appear for an endoscopic procedure.

METHODS: This was a retrospective, chart review, cohort study in a Canadian, tertiary care, academic, hospital-based endoscopy clinic. Patients included were: those undergoing esophagogastroduodenoscopy, colonoscopy or flexible sigmoidoscopy and patients who failed to appear were compared to a control group. The main outcome measure was a multivariate analysis of factors associated with truancy from scheduled endoscopic procedures. Factors analyzed included gender, age, waiting time, type of procedure, referring physician, distance to hospital, first or subsequent endoscopic procedure or encounter with gastroenterologist, and urgency of the procedure.

RESULTS: Two hundred and thirty-four patients did not show up for their scheduled appointment. Compared to a control group, factors statistically significantly associated with truancy in the multivariate analysis were: non-urgent *vs* urgent procedure (OR 1.62, 95% CI 1.06, 2.450), referred by a specialist *vs* a family doctor (OR 2.76, 95% CI 1.31, 5.52) and office-based consult prior to endoscopy *vs* consult and endoscopic procedure during the same appointment (OR 2.24, 95% CI 1.33, 3.78).

CONCLUSION: Identifying patients who are not scheduled for same-day consult and endoscopy, those referred by a specialist, and those with non-urgent referrals may help reduce patient truancy.

INTRODUCTION

Patient absenteeism from scheduled outpatient appointments is a major problem for all ambulatory clinics. Failure to attend an appointment results in inefficiency because the vacant appointment interval is often not used by another patient. This typically results in ongoing expenditures without concomitant reimbursement thereby decreasing appropriate resource utilization. This is particularly important for endoscopic procedures where a specific interval is scheduled and appropriate preparation is required for each patient. If a patient does not attend the prearranged endoscopy time, often the time is simply absorbed into the rest of the day without an appropriate substitute being found.

There are a number of maneuvers that various clinics have used in an attempt to decrease truancy from endoscopic appointments. Some sites notify all patients within a few days of their scheduled time, others will insist that the patient themselves confirm their appointment, other sites even "over-book" the endoscopy unit to account for a small percentage that will not appear on their scheduled day. Various methods such as telephone[1] or text message[2] reminders and mailed pre-procedural pamphlets[3] have been used successfully to decrease truancy from endoscopic appointments. Very little research has been devoted to enhancing our

understanding of why patients do not appear at their scheduled appointments, and that which has been done has demonstrated conflicting results[4-8].

Research based in adolescent outpatient clinics have found that telephone reminders the day before the scheduled appointment help to reduce "no-show" rates[9]. Other studies have shown that such reminder systems do not improve patient attendance rates[10,11]. One prospective study found that previous non-attendance for an outpatient appointment was the strongest predictor of future non-attendance behavior[8]. There has been limited research into the explanations or reasons for patient absenteeism for scheduled gastroenterology appointments[12]. If patients could be identified as "high-risk" for absenteeism, then specific targeted efforts could be developed to ensure their appropriate appearance at their procedure. The objective of this study is to identify risk factors that may help predict which patients are the most likely to be truant for a scheduled elective endoscopic procedure.

MATERIALS AND METHODS

This study involved all consecutive patients scheduled to undergo an elective esophagoduodenoscopy (EGD), flexible sigmoidoscopy or colonoscopy in a single Canadian tertiary care, gastroenterology clinic (hospital based) in the year 2003. A retrospective chart review was performed to identify all patients who did not appear for their scheduled outpatient endoscopic procedure and they were compared to a control group (randomly selected patients from the same time period who did show at their appointment) to generate predictors of patient absenteeism. It was felt that it was unnecessary, and in fact not practical, to assess all patients during the entire year that did appear for their examination. By using a random sample (selected from a similar time period as the truant group) comparison between the two groups was deemed statistically appropriate. Patients referred from other hospitals and those undergoing endoscopic retrograde cholangiopancreatography (ERCP) or endoscopic ultrasound (EUS) were excluded.

The factors analyzed included gender, age, duration of time on a waiting list, time of day of procedure (07:30-10:00, 10:00-12:30, 12:30-15:00), day of the week, type of procedure, referring physician (family physician *vs* other specialist), distance to hospital (divided into regional areas), whether the patient went direct to the endoscopy suite for a consult and endoscopy during the same appointment without consulting the gastroenterologist in his/her outpatient clinic prior to the procedure, urgency of the procedure (urgent procedures were defined as patients who were bleeding or who had radiological abnormalities warranting an endoscopic procedure) and whether the patient was undergoing a repeat procedure by the previous gastroenterologist or surgeon. Univariate analysis was then performed to determine independent associations of each factor to patient "no-shows". Odds ratios (OR), 95% confidence interval (95% CI) and their respective *P*-values were generated. Following this, multivariate analysis was performed using logistic regression analysis. Only factors that were statistically significant in multivariate analysis were reported in the model. The SPSS software package for Windows (Release 15.0.0-6 Sept 2006; SPSS Inc., Chicago, IL, USA) was used for statistical analysis. Ethics approval was obtained through St Paul's Hospital, University of British Columbia to conduct the study.

Table 1 Prevalence of patient characteristics among patient's who were and were not truant for scheduled endoscopic procedure

Factor		Number of patients (*n*)		
		Control group[1]	No-show	Total patients evaluated
Urgent procedure	No	219	198	417
	Yes	99	50	149

New patient	No	153	135	288
	Yes	161	133	294

[1]Control group refers to a random sample of patients during the same interval who appeared at their appointment as scheduled; GP: General practitioner; Flex-sig: Flexible sigmoidoscopy.

RESULTS

Table 1 shows the prevalence of patient characteristics that were analyzed as potential predictive factors for truancy for scheduled endoscopic procedure. The absenteeism rate was 3.6% (n = 234) overall, 2.6% for colonoscopy, 2.9% for EGD and 4.3% for flexible sigmoidoscopy. Of the 234 patients, 50% were scheduled for colonoscopy, 35% for EGD and 15% for flexible sigmoidoscopy.

Univariate analysis was performed on each factor to determine the possibility of independent associations with patient "no shows" (Table 2, Figure 1) In the

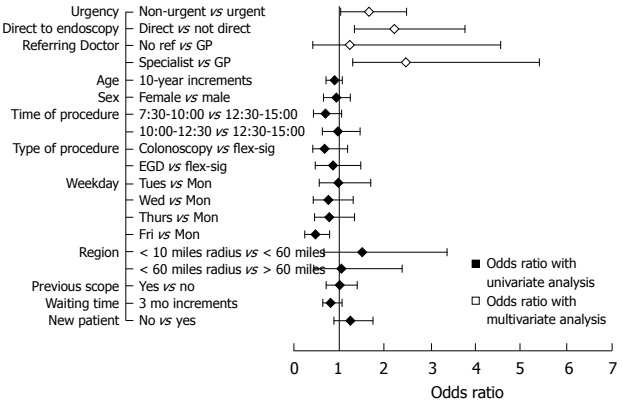

Figure 1 Predictive value for patient absenteeism of variables assessed in univariate (black lines) and multivariate (white lines) analyses. Three factors were statistically associated with patient absenteeism in the multivariate analysis: (1) patients referred for non-urgent *vs* urgent procedures (OR 1.62, 95% CI 1.06, 2.50); (2) patients referred by a specialist *vs* a family doctor (OR 2.76, 95% CI 1.38, 5.52); and (3) patients undergoing office-based consult prior to endoscopy *vs* consult and endoscopic procedure during the same appointment (OR 2.24, 95% CI 1.33, 3.78). In the univariate analysis, patients were more likely to show up for their scheduled appointment on Fridays, however, this was not significant in the multivariate analysis. GP: General practitioner; Flex-sig: Flexible sigmoidoscopy.

univariate analysis, a significant trend was determined towards truancy in those non-urgently referred (OR 1.79, 95% CI 1.2-2.6) and those referred from specialists (as opposed to family physicians) (OR 2.1, 95% CI 1.2-3.9). Interestingly, in the univariate analysis, having their procedure performed on Friday (as opposed to Monday to Thursday) was protective against truancy (OR 0.493, 95% CI 0.28-0.87).

Multivariate analysis was then performed to determine which factors were most associated with a positive outcome (Table 3, Figure 1). In the multivariate analysis three factors were statistically significant determinants in predicting "no shows": (1) patients referred to the clinic for a non-urgent compared to urgent procedures (OR 1.624, 95% CI 1.06, 2.45); (2) patients referred by a specialist compared to those referred by a family doctor (OR 2.76, 95% CI 1.31, 5.524); (3) patients who had an office-based consult prior to the endoscopy as compared to those who went direct to the endoscopy suite for a consult and procedure during the same appointment (OR 2.244, 95% CI 1.33, 3.78). In the multivariate analysis, day of the week the procedure was performed was no longer significant. Figure 1 summarizes the findings of the univariate analysis and the significant factors on the multivariate analysis.

Table 3 Multivariate analysis of patient characteristics and their predictive value for patient absenteeism from scheduled endoscopic procedure

	Comparison	OR	95% CI	*P*-value
Urgency	Non-urgent *vs* urgent	1.624	1.056, 2.497	0.027
Direct to endoscopy	Not direct *vs* direct	2.244	1.331, 3.783	0.002
Referring physician	Specialist *vs* GP	2.763	1.383, 5.519	0.058
	No referral *vs* GP	1.228	0.321, 4.706	0.666

DISCUSSION

There are many factors that are critical in maintaining the efficiency of an endoscopy unit. Many of these factors, such as emergency procedures, equipment failures and sedation difficulties are virtually impossible to predict. The multitasking, late physician is another major cause of an inefficient endoscopy unit and likewise, he/she is admittedly difficult to modify. On the other hand, truancy among patients who fail to attend their scheduled appointment is something that, in theory at least, has the capacity to be controlled.

We have determined the absenteeism rate in our endoscopy unit to be 3.6%, which encompassed 4.3% of flexible sigmoidoscopies, 2.6% of colonoscopies and 2.9% of upper endoscopies. This study was not

designed to compare the absenteeism rates between the different procedures; however, when compared, these rates are not statistically different. We determined three factors that resulted in a patient being considered "high risk" for truancy. It has become common for patients to have a consultation and endoscopy at the same time, just prior to the endoscopy (particularly for screening colonoscopies), and we have found that these patients are more likely to attend their appointment than those who have been previously seen in an office setting by the physician. At present, in our setting, we do not use physician assistants, however, all patients scheduled for a consult and endoscopic procedure at the same time are called by a secretary with subsequent explanation of the preparation and procedure. Those patients who continue to have additional questions that cannot be answered by the secretary are scheduled for an office visit prior to the procedure. The practice of "direct to endoscopy" has become commonplace and we note that this practice has indeed apparently minimized our truancy rates. It should also be recognized that in our Canadian system, many patients are booked for their endoscopic procedures weeks to months in advance and yet, despite this, we still have improved attendance rates for those patients that are booked directly to endoscopy, possibly demonstrating a more motivated patient group. It does confirm that this practice at least results in appropriate attendance to endoscopy and that these patients are compliant with their appointment.

The second factor found to be associated with absenteeism from endoscopy was referral from a specialist rather than a family physician. This is logical in that family physicians are very accustomed to referring patients to a specialist and have an organized system to arrange it. On the other hand, many specialists' offices are very adept at accepting referrals but not nearly as organized when it comes to referring a patient to another specialist. In addition, patients referred from other specialists often tend to have multiple health issues and more likely to be at a more acute state of illness. Just the fact that they have multiple health problems may put them at risk for absenteeism from their scheduled endoscopic appointment. This is another group of patients that can relatively easily be targeted as "high risk" for absenteeism and steps taken to ensure confirmation of their appointment.

The last group of patients who are more likely not to attend their appointments are those with non-urgent reasons for endoscopy. We defined urgent as those patients with bleeding or radiological abnormalities requiring endoscopic assessment. These patients are more likely to attend their procedure as opposed to the truly elective patient. This is logical in that typically, these patients have been told that there is a high likelihood that an abnormality is present and tissue confirmation is critical. These patients are therefore concerned enough to ensure their attendance at their endoscopic examination.

An Australian study demonstrated that patients with previous history of non-attendance were more likely not to attend[8], we have not found that in this study. This may be because if a patient doesn't attend the endoscopy clinic at a scheduled time, typically, the physician will not arrange another endoscopy until another office visit has been completed and an explanation for truancy extracted. A pediatric study demonstrated that social factors (social class, unmarried parents, poorer housing) played a larger role in increasing truancy than other factors such as severity of disease[13]. Due to the nature of this study, assessment of social factors was not performed.

There are several limitations of our study. It is retrospective and contains the usual limitations inherent within this study design. On the other hand, there is presently very limited data available from the literature to determine who is at high risk for truancy from endoscopy units. Many endoscopic sites have instituted measures to limit truancy such as calling all patients by phone or mailing reminders prior to the endoscopic examination to ensure their attendance[1-3,7,14]. Some of these measures are labor intensive with associated cost expenditures. Additionally, most patients attend their clinic appointment and in theory, don't require a reminder. If a select group of patients could be targeted then a limited reminder protocol might be considered. Before we embarked upon any campaign to decrease truancy rates, we felt it was critical to determine what factors were important in this area. Ideally, if we could isolate several factors, steps could be undertaken to improve the system and then re-evaluate after institution of an improved management strategy.

Another limitation of our study is the fact that it applies only to the dataset of our institution and our patients. Its general, applicability may be questioned; however, our site is very similar to many tertiary care centers. Many patients come directly to the endoscopy unit without prior consultation, procedures are performed in large numbers with rapid turnover, the endoscopic rooms and time are the critical elements to the efficiency of any unit. As a tertiary care center with a wide base of referrals, it would appear that our unit is, in fact, similar to many other endoscopic units throughout the world and therefore, our results could likely be replicated elsewhere.

A final limitation of the study is the fact that we have excluded patients who were transferred from other hospitals as well as those scheduled for ERCP and EUS. These patients are more complex with a myriad of other issues (including the acuity of illness) and we felt that the group we needed to concentrate on was those in whom we perform most of the standard, elective endoscopic examinations.

In summary, we found that patients with a non-urgent condition, those referred from a specialist and those who do not have a consult and procedure at the same time are more likely to be absent from their scheduled endoscopic procedure than those without these characteristics. With this information, endoscopy units can hopefully modify their clinical practices to reduce patient truancy. Studies aimed at improving

efficiency in endoscopy units should be aware of these "high-risk" patients to enhance appropriate resource utilization by decreasing absenteeism.

COMMENTS

Background

Patient absenteeism of outpatient procedures is a major problem for all ambulatory clinics.

Research frontiers

Identifying patients who may not present for scheduled endoscopy may help gastroenterologists to reduce patient truancy.

Innovations and breakthroughs

Previous studies have shown that patients at highest risk for truancy are those with a history of truancy; and methods to enhance patient attendance at clinics (i.e. telephone reminders, mailed reminders) have had mixed results.

Applications

Identifying patients who are not scheduled for same-day consult and endoscopy, those referred by a specialist rather than a family physician, and those with non-urgent reasons for referral may help gastroenterologists to reduce patient truancy.

Peer review

This manuscript is of enough interest and describes original work that merits its publication in WJG.

Abstract

AIM: To determine the composition of both fecal and duodenal mucosa-associated microbiota in irritable bowel syndrome (IBS) patients and healthy subjects using molecular-based techniques.

METHODS: Fecal and duodenal mucosa brush samples were obtained from 41 IBS patients and 26 healthy subjects. Fecal samples were analyzed for the composition of the total microbiota using fluorescent *in situ* hybridization (FISH) and both fecal and duodenal brush samples were analyzed for the composition of bifidobacteria using real-time polymerase chain reaction.

RESULTS: The FISH analysis of fecal samples revealed a 2-fold decrease in the level of bifidobacteria (4.2 ± 1.3 *vs* 8.3 ± 1.9, $P < 0.01$) in IBS patients compared to healthy subjects, whereas no major differences in other bacterial groups were observed. At the species level, *Bifidobacterium catenulatum* levels were significantly lower (6 ± 0.6 *vs* 19 ± 2.5, $P < 0.001$) in the IBS patients in both fecal and duodenal brush samples than in healthy subjects.

CONCLUSION: Decreased bifidobacteria levels in both fecal and duodenal brush samples of IBS patients compared to healthy subjects indicate a role for microbiotic composition in IBS pathophysiology.

Key words: Irritable bowel syndrome; Gut microbiota; Bifidobacteria; *Bifidobacterium catenulatum*

INTRODUCTION

Irritable bowel syndrome (IBS) is a common gastrointestinal disorder characterized by abdominal pain or discomfort and altered bowel function. Alterations in psychosomatic factors, gastrointestinal motility, visceral hypersensitivity and microbiotic composition have been suggested to play a role in the pathophysiology of IBS[1]. Alterations in fecal and small intestinal microbiotic composition in IBS patients have been reported and studies revealed a somewhat higher bacterial count in jejunal juice of IBS patients and lower numbers of fecal coliforms, lactobacilli and bifidobacteria than in healthy subjects[2,3]. More specifically, molecular-based methods showed that in IBS patients levels of members of the *Clostridium coccoides* subgroup, *Lactobacillus*, *Collinsella* and *Bifidobacterium catenulatum* groups are different from that of healthy subjects[4,5]. These differences in the fecal microbiotic composition may underlie

symptom generation by promoting abnormal colonic fermentation[6]. However, mucosa-associated bacteria might be more relevant in the symptom generation of IBS, since fecal and jejunal juice samples are only representing the composition of luminal microbiota. Alterations in luminal bacteria composition may change the commensal microbiota and affect the microbiota adhering to the mucosa. Microorganisms adhering to the intestinal wall are more likely to affect the host's immune, physiological or neuronal system or vice versa. The composition of luminal and mucosa-associated bacteria are not the same since the micro-environments are different at the surface of the intestinal epithelium and the lumen[7,8]. Therefore, we aimed to determine the composition of fecal luminal and mucosa-associated microbiota in IBS patients using molecular identification and quantification techniques.

MATERIALS AND METHODS

Subjects

Twelve male and 29 female IBS patients included in this study fulfilled the Rome Ⅱ criteria for IBS and were categorized as diarrhea predominant (IBS-D), constipation predominant (IBS-C) or alternating IBS subgroup (IBS-A)[9]. The IBS population consisted of 14 IBS-D subjects, 11 IBS-C subjects and 16 IBS-A subjects. The control group consisted of 8 male and 18 female healthy subjects from the general population, devoid of GI symptoms or major abdominal surgery. The healthy subjects were significantly ($P < 0.001$) younger (31 ± 2.06 years) than the group of IBS patients (42 ± 2.12 years). Subjects taking medication known to influence bacterial composition and gastrointestinal motility, especially antimicrobial medications and/or probiotics were excluded from the study. The Human Ethics Committee of the University Medical Centre Utrecht approved the study and all subjects gave written informed consent.

Sampling

To obtain small intestinal mucosa-associated material a sterile cytology brush (Uno-Brush, Prince Médical, Ercuis, France) sheathed in a sterile catheter was placed through the endoscope biopsy channel and advanced under direct vision out beyond the endoscope tip[10]. The duodenal mucosa was brushed three times and then pulled back into the sheath of the catheter. The catheter was removed and the brush was immediately cut off the catheter and placed into a sterile tube in liquid nitrogen and stored at -80℃ until analysis. Fecal samples, obtained before endoscopy, were collected and stored at -80℃ until further handling.

Fluorescent in situ hybridization (FISH) analysis of fecal samples

The total number of bacteria present in the fecal samples was determined with the EUB 338 probe which targets all bacteria[11]. FISH analysis was essentially performed as described previously with the genus-specific probes listed in Table 1[12]. Approximately 0.5 g of homogenized feces was suspended in 4 mL of 0.2 mm-pore-size-filtered PBS and 0.5 mL 37% formaldehyde and thoroughly mixed by vortexing for 3 min. After incubation for 4 h at 4℃ the suspension was vortexed again for 2 min. Debris was removed by a short spin at 80 *g* for 1 min. In an eppendorf tube, 300 μL of the supernatant was collected and the fixed cells were washed twice with PBS. For FISH analysis of the *Lactobacillus-Enterococcus* group the cells were first permeabilized by resuspending the pellet in 100 μL Proteinase-K solution (180 kU/L) (Sigma-Aldrich, Zwijndrecht, The Netherlands) and incubated for 10 min at 37℃. The cells were washed as described above and resuspended in 300 μL PBS/ethanol (1:1 v/v). After one hour of storage at -20℃, the cell suspension was diluted 1:10 in hybridization buffer at the required temperature for hybridization, and 5 ng labeled probe was added. Cells were hybridized for 16 h at the prescribed hybridization temperature. After resuspension in 4 mL washing buffer, cells were filtered on a 0.2 mm pore size Isopore polycarbonate membrane filter (Millipore Corporation) and washed with 5 mL of 50℃ washing buffer. Filters were mounted on microscope slides with Vectashield (Vector Laboratories, Burlingame, CA, USA), and hybridized cells were counted visually using an Olympus BX60 epifluorescence microscope using a FITC or Cy3-specific filter. All microscopic counts were determined in duplicate, with a minimum of 300 cells counted per assay.

DNA extraction and polymerase chain reaction (PCR) amplification of fecal and duodenal brush samples

Brush and fecal samples were thawed on ice cooled water. DNA was extracted using the DNeasy Tissue kit (Qiagen, Venlo, The Netherlands) or the Fast DNA Spin kit (Qbiogene, Irvine, USA) from the brush and fecal samples respectively. The eluted DNA samples were stored at -20℃. The integrity of the isolated DNA was determined visually after electrophoresis on a 1.0% agarose gel containing ethidium bromide.

Real-time PCR

Quantification of *Lactobacilli* genera and species

specifically belonging to bifidobacteria was performed using a 5'nuclease (TaqMan) assay as described previously[13,14]. Briefly, a 20 μL PCR amplification mixture containing 10 μL TaqMan Fast Universal Master Mix (Applied Biosystems, Nieuwerkerk a/d IJssel, The Netherlands), optimized concentrations of primers and probes and 2.0 μL isolated DNA was prepared. The temperature profile for the amplification consisted of 20 s at 95℃ and 45 cycles of 1 s at 95℃ and 20 s at 60℃ (ABI 7900 HT Fast; Applied Biosystems, Nieuwerkerk a/d IJssel, The Netherlands). The percentages of the different bacteria were subsequently calculated as described by Liu *et al*[15,16].

Statistical analysis

FISH results with microbial numbers below the detection limit (8.3×10^5/g) were excluded from statistical analysis. Nonparametric FISH microbiota data were compared using Mann-Whitney tests or Kruskal-Wallis test for subgroup analysis. Independent samples *t*-test was used to compare differences in real-time PCR microbiota data between IBS patients and healthy subjects. One-way ANOVA with Bonferroni correction was used for analysis of microbiota in the IBS subgroups.

P-values less than 0.05 were considered statistically significant. All statistical analysis was performed using commercially available software (SPSS 12.0.1 for Microsoft Windows). Data are expressed as mean ± SE.

RESULTS

Characterization of the fecal microbiota of IBS patients and healthy subjects

The mean percentages of all bacterial groups measured are presented in Table 2. The results show that *F. prausnitzii*, *E. rectale*/*C. coccoides* and bifidobacteria are the most abundant groups in both IBS patients and healthy subjects. The levels of bifidobacteria were significantly lower ($P < 0.05$) in IBS patients (4.2% ± 1.3%) than in healthy subjects (8.3% ± 1.9%). No significant differences were observed between IBS-D, IBS-C and IBS-A subgroups. The *C. lituseburense* group was detected in significantly lower levels ($P < 0.01$) in IBS patients compared to healthy subjects; however, *C. lituseburense* reached the detection limit only in 14 healthy subjects and 18 IBS patients. The proportions of *Lactobacillus* spp, *C. coccoides*, *C. histolyticum*, *C. difficile*, *Bacteroides* and *F. prausnitzii* showed no differences between IBS patients and healthy subjects. This set of probes covered 44% and 32% of the total fecal microbiota in the healthy subjects and IBS patients, respectively. The low coverage is predominantly due to low counts in Bacteroides.

Characterization of the fecal bifidobacteria microbiota of IBS patients and healthy subjects

In healthy subjects, the proportion of bifidobacteria identified as *Bifidobacterium catenulatum* (19.31% ± 2.5%) was significantly ($P < 0.001$) higher compared to IBS patients (6.24% ± 0.6%). The low proportion of *B. catenulatum* was consistent in all IBS subgroups (Table 3, Figure 1A). The proportions of the other species (*Bifidobacterium adolescentis*, *Bifidobacterium bifidum* and *Bifidobacterium longum*) were not significantly different between healthy subjects, IBS patients and IBS subgroups. Low levels of *B. bifidum* were detected in fecal samples of all subjects as compared to the other *Bifidobacterium* species and as compared to the *B. bifidum* level in duodenal samples (Tables 3 and 4). The bifidobacterial species covered by these Q-PCR assays were only 43% and 29.5% of the total bifidobacteria population for healthy subjects and IBS patients, respectively.

Table 2 FISH analysis of the composition of the fecal microbiota of HS, IBS patients and IBS subgroups

[b]$P < 0.001$ *vs* HS. Data are expressed as percentage, mean ± SE.

Characterization of the duodenal microbiota of IBS patients and healthy subjects

In healthy subjects, *B. catenulatum* level as percentage of total bifidobacterial load (17.04% ± 2.3%) was significantly ($P < 0.001$) higher when compared to IBS patients (4.85% ± 0.5%). The significantly lower proportion of *B. catenulatum* was observed in all IBS subgroups (Table 4, Figure 1B). The levels of *B. adolescentis, B. bifidum* and *B. longum* as percentage of total bifidobacterial load were comparable between healthy subjects, IBS patients and IBS subgroups (Table 4). With the set of probes used, the total percentage of bifidobacteria of the bifidobacterial load which could be detected is 46% for healthy subjects and 31% for IBS patients.

Characterization of B. catenulatum in age-matched IBS patients and healthy subjects

Since the patients and healthy subjects were not matched, the age difference between the healthy subjects and IBS patients may be a confounding factor. In a subset of the subjects, 19 IBS patients (33 ± 2.8) matched for age

Table 4 Duodenal mucosa-associated bifidobacteria in HS, IBS patients and IBS subgroups

	HS	IBS	IBS-A	IBS-D	IBS-C
B. catenulatum	17.04 ± 2.3	4.85 ± 0.5[b]	5.26 ± 0.9[b]	4.26 ± 0.7[b]	5.04 ± 1.0[b]
B. adolescentis	15.68 ± 2.3	13.90 ± 1.4	14.66 ± 2.7	14.58 ± 1.7	12.21 ± 3.0
B. bifidum	6.09 ± 0.9	5.13 ± 0.8	5.36 ± 1.7	4.43 ± 1.1	5.68 ± 1.3
B. longum	6.88 ± 1.3	7.27 ± 0.8	5.84 ± 1.3	9.01 ± 1.6	6.88 ± 1.40

[b]$P < 0.001$ *vs* HS. Data are expressed as percentage, mean ± SE.

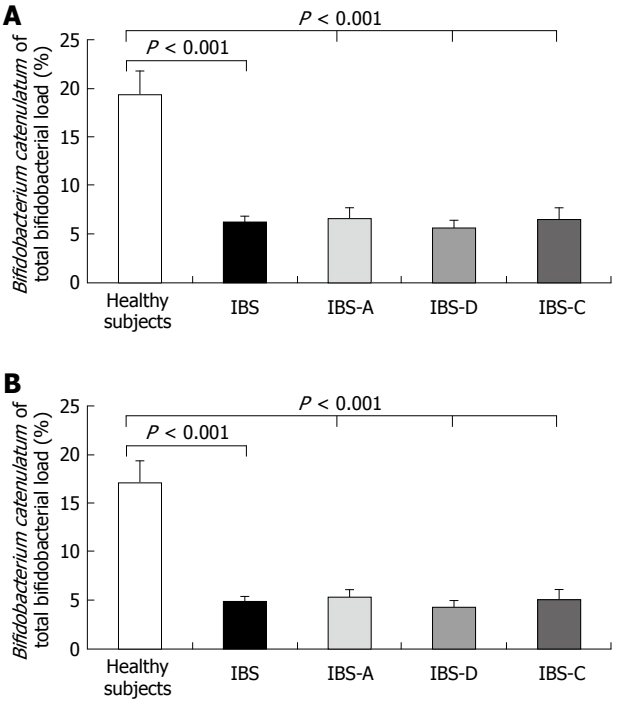

Figure 1 Percentage of *Bifidobacterium catenulatum* as percentage of total bifidobacterial load in fecal samples and duodenal samples of healthy subjects, IBS patients and IBS subgroups (mean ± SE). A: Fecal samples; B: Duodenal samples.

with 19 healthy subjects (33 ± 2.7), decreased levels of *B. catenulatum* were also shown in duodenal as well as in fecal samples of the IBS patients. The mean percentage of *B. catenulatum* of total bifidobacterial load in duodenal samples was significantly ($P < 0.001$) lower in IBS patients (5.48% ± 0.60%) compared to healthy subjects (17.19% ± 2.43%). Percentage of *B. catenulatum* of total bifidobacterial load in the fecal samples was significantly ($P < 0.001$) lower in IBS patients (6.98% ± 0.69%) compared to healthy subjects (19.50% ± 2.67%).

DISCUSSION

Composition of gastrointestinal microbiota is known to be relatively stable and composed of permanent, the so-called core phyla, and transient species which contribute to gastrointestinal health and disease[17-19]. The presence of beneficial microbes in the intestine prevents colonization by potentially pathogenic microbes, referred to as colonization resistance[20,21]. Imbalances in the microbiota are characterized by a decrease in beneficial anaerobic bacteria and increases in aerobic bacteria, fungi and harmful anaerobic bacteria[20].

In this study, we showed, using FISH analysis, that IBS patients have significantly lower fecal levels of bifidobacteria but no differences in the other major bacterial groups. Previous studies have also shown microbial alterations in fecal samples of IBS patients using both culturing and molecular-based techniques[2,4]. Using culturing techniques, Balsari *et al*[2] have already shown in 1982 a decrease in bifidobacteria, coliforms and lactobacilli in IBS patients. Using molecular-based techniques decreased *B. catenulatum*, *C. coccoides*, *Lactobacillus* and *Collinsella* counts in the fecal samples of IBS patients were found[4,5]. These studies were limited to the fecal flora. We broadened the study by examining bifidobacteria levels in duodenal mucosa-associated samples.

Differences in microbiotic composition between luminal and mucosa-associated bacteria have been shown[7,22-25]. The different micro-environment of the epithelium compared to the lumen might lead to a different microbiotic composition[7,26]. Bacteria that attach to the mucosa may exert greater influence on innate immune processes in the intestine[24,27]. In addition, the adhesion of non-pathogenic bacteria to the epithelial surface may contribute to the barrier that effects host resistance to pathogenic bacteria[24].

In this study, we showed that the percentages of *B. bifidum* of the total bifidobacterial counts were lower in the fecal samples than in the duodenal mucosa-associated samples in both IBS patients and controls. This might be due to high hydrophobicity of *B. bifidum* which is related to its ability to adhere to surfaces[28,29]. Furthermore, *B. catenulatum* counts were decreased in duodenal mucosa-associated samples as well as in fecal samples of IBS patients compared to controls. The effect of *B. catenulatum* on the health of the host is unknown. However as a group, bifidobacteria are considered beneficial for the host, as they produce lactic and acetic acids that decrease pH and inhibit the growth of potential pathogenic bacteria[30-32].

Moreover, *Bifidobacterium* spp prevent diarrhea and intestinal infections, alleviate constipation and stimulate the immune system[31]. The lower levels of bifidobacteria might be epiphenomenal or develop as a consequence of altered gastrointestinal motility or genetic makeup of IBS patients rather than being the cause of IBS symptoms[31].

Since the patients and healthy subjects were not matched, the age difference between the healthy subjects and IBS patients might have been a confounding factor. It was reported that elderly (> 65 years old) have lower fecal levels of *B. catenulatum*[33,34]. The elderly were not included in our study. The effect of the age difference between healthy subjects (mean age 32 years) and IBS patients (mean age 42 years) on *B. catenulatum* levels is not known. However, in age-matched IBS patients and healthy subjects statistically significantly decreased levels of *B. catenulatum* were also seen in duodenal as well as in fecal samples of the IBS patients.

An imbalanced microbiotic composition may lead to a different fermentation pattern, especially with an increased hydrogen production resulting in bloating[6,35].

Both antibiotics and probiotics have been shown to reduce IBS symptoms, which further suggests that microbial imbalance may underlie symptom generation in IBS patients[36-40]. Previously, a therapeutic trial suggested that particular *B. infantis* species were efficacious in the treatment of IBS symptoms[41]. No effects of *B. infantis* on stool consistency or frequency could be observed which implies that this therapeutic approach may be applicable to all IBS patients irrespective of their stool pattern[41]. *B. breve* in combination with *L. plantarum* has been shown to decrease pain and the severity of symptoms in IBS patients[42]. Prebiotics, oligofructose and inulin might reduce symptoms in IBS-C patients as they selectively stimulate bifidobacteria which results in increased stool frequency[43].

In conclusion, lower bifidobacteria levels were found both in duodenal mucosa-associated samples as well as in fecal samples of IBS patients when compared to healthy subjects. Specifically, *B. catenulatum* was found to be reduced in duodenal mucosa-associated bacteria as well as in the feces of IBS patients. The relevance of specific *Bifidobacterium* spp in relation to IBS symptoms is unknown; however modulation of the gut microbiota by means of prebiotics or bifidobacteria-containing probiotics to restore a balanced microbiotic composition may have a therapeutic role.

COMMENTS

Background

Alterations in fecal and small intestinal microbiotic composition in irritable bowel syndrome (IBS) patients have been reported and studies revealed a somewhat higher bacterial count in jejunal juice of IBS patients and lower numbers of fecal coliforms, lactobacilli and bifidobacteria than in healthy subjects.

Research frontiers

The aim of the study was to determine the composition of both fecal and duodenal mucosa-associated microbiota in IBS patients and healthy subjects using molecular-based techniques.

Innovations and breakthroughs

Decreased bifidobacteria levels in both fecal and duodenal brush samples of IBS patients compared to healthy subjects indicate a role for microbiotic composition in IBS pathophysiology.

Peer review

The authors investigated the fecal and duodenal mucosal-associated microbiota in patients with IBS. This topic is of interest since, as the authors mentioned, alterations in intestinal flora have been suggested as a potential etiological factor in the pathogenesis of this disorder.

Abstract

AIM: To study glutamine synthetase (GS) activity and glutamate uptake in the hippocampus and frontal cortex (FC) from rats with prehepatic portal vein hypertension.

METHODS: Male Wistar rats were divided into sham-operated group and a portal hypertension (PH) group with a regulated stricture of the portal vein. Animals were sacrificed by decapitation 14 d after portal vein stricture. GS activity was determined in the hippocampus and FC. Specific uptake of radiolabeled L-glutamate was studied using synaptosome-enriched fractions that were freshly prepared from both brain areas.

RESULTS: We observed that the activity of GS increased in the hippocampus of PH rats, as compared to control animals, and decreased in the FC. A significant decrease in glutamate uptake was found in both brain areas, and was more marked in the hippocampus. The decrease in glutamate uptake might have been caused by a deficient transport function, significantly and persistent increase in this excitatory neurotransmitter activity.

CONCLUSION: The presence of moderate ammonia blood levels may add to the toxicity of excitotoxic glutamate in the brain, which causes alterations in brain function. Portal vein stricture that causes portal hypertension modifies the normal function in some brain regions.

Key words: Portal hypertension; Glutamine synthetase; Glutamate uptake; Frontal cerebral cortex; Hippocampus; Rat

Glutamine synthetase activity and glutamate uptake in hippocampus and frontal cortex in portal hypertensive rats. *World J Gastroenterol* 2009; 15(23): 2893-2899 Available from: URL: http://www.wjgnet.com/1007-9327/15/2893.asp DOI: http://dx.doi.org/10.3748/wjg.15.2893

INTRODUCTION

Two major complications appear in severe liver failure: hepatic encephalopathy (HE) and portal hypertension (PH), but the mechanism involved in the production of brain damage is still unclear.

PH is found in patients with cirrhosis, and in portal vein thrombosis, it is characterized by an increase in splanchnic blood flow and pressure, caused by abdominal blood flow resistance, secondary to important liver parenchyma alterations (fibrosis or cirrhosis). Normally, the liver splanchnic blood must reach, through the liver, the hepatic veins and finally the vena cava[1]. As a result

of increased splanchnic blood flow, collateral vein shunts appear and abdominal circulation avoids the damaged liver parenchyma to reach the systemic circulation[2].

HE in acute and chronic liver disease is a complex syndrome, associated frequently with hyperammonemia. Increases in blood brain barrier (BBB) permeability present in PH, allow ammonia ions and other neurotoxic substances to penetrate brain tissue[3-6]. Hyperammonemia is caused by a defect in the liver parenchyma that forms urea from intestinal nitrogenic substances, and vein shunts from the splanchnic circulation carry it into the general circulation[7].

According to Erceg *et al*[8], chronic hyperammonemia, with or without liver failure, impairs the glutamate-nitric oxide-cGMP pathway in the brain and reduces extracellular cGMP in the brain. This function is associated with a decreased ability of rats to learn a Y maze conditional discrimination task. It has been suggested that a decrease in extracellular cGMP is involved in impaired learning ability and intellectual function.

Ammonia is a well-known toxic substance for the central nervous system (CNS), especially when levels exceed the antitoxic capacity of the brain cells. Glutamate plays an important role in cellular metabolism, and contributes to normal excitatory neurotransmission in the brain. When this function is not accomplished effectively, and either ammonia or glutamate are not sufficiently detoxified, their concentrations increase pathologically, neuron and astrocyte functions deteriorate, and damage and even cell death can result[9]. It has been shown clearly that acute ammonia toxicity and liver failure lead to excitotoxicity as a result of activation of N-methyl-D-aspartate (NMDA) receptors in the brain[10], and that blocking these receptors can lead to ammonia-induced death[11]. In contrast, chronic hyperammonemia leads to down-regulation of signal transduction pathways associated with these receptors, which contributes to cognitive impairment[8].

The glutamine/glutamate cycle participates in cell metabolism, and has important relevance in normal and pathological functions. When this cycle does not function adequately, CNS functional damage can appear, and even cellular death can be produced[12]. To accomplish the transformation to ammonia and glutamate into glutamine, the brain depends on the activity of the enzyme glutamine synthetase (GS) in astrocytes. This is associated with correct function of the glutamate transporters, to provide an adequate uptake, release and metabolism of ammonia and glutamate[13]. Therefore, the importance of correct function of the glutamine/glutamate cycle during this detoxifying step in brain is clear.

The aim of the present study was to analyze the participation of GS activity and glutamate uptake in the hippocampus and cerebral frontal cortex (FC), using a prehepatic PH rat model, with the intention to mimic the two major complications that appear in chronic liver failure. By using this model, it may be possible to understand more clearly the defense mechanism of the brain against the two toxic substances, ammonia and the excitatory neurotransmitter glutamate.

MATERIALS AND METHODS

Animals and surgical procedures

Male Wistar rats with an average weight of 240 g were used. The animals were placed in individual cages, with free access to food (standard laboratory rat chow) and water, and a 12-h light cycle: 8.00-20.00 h. Special care for perfect air renewal was taken. PH was obtained by calibrated stenosis of the portal vein, according to the method of Chojkier and Groszmann[14]. Rats were lightly anesthetized with ether and then a midline abdominal incision was made. The portal vein was located and isolated from the surrounding tissues. A ligature of 3.0 silk sutures was placed around the vein, and snugly tied to a 20-gauge blunt-end needle placed alongside the portal vein. The needle was subsequently removed to yield a calibrated stenosis of the portal vein. Fourteen days after portal vein ligation, animals exhibit an increase in portal pressure. Sham-operated rats underwent the same experimental procedure, except that the portal vein was isolated but not stenosed. Animals were placed in individual cages and allowed to recover from surgery. Animals were sacrificed by decapitation at 14 d after portal vein stricture.

Experiments were carried out in accordance with the US National Institutes of Health Guide for the Care and Use of Laboratory Animals (NIH publication Nº 80-23/96) and local regulations. All efforts were made to minimize suffering of animals and to reduce the number of animals used.

Portal pressure measurement

Fourteen days after the corresponding operation, the rats were anesthetized with intraperitoneal sodium pentobarbital (40 mg/kg). Portal pressure was measured through a needle placed in the splenic pulp, and maintained in place by cyanoacrylate gel. The needle was cannulated to a polyethylene catheter (50) filled with a heparinized saline solution (25 U/mL), and connected to a Statham Gould P23ID pressure transducer (Statham, Hato Rey, Puerto Rico), coupled to a Grass 79D polygraph (Grass Instruments, Quincy, MA, USA).

GS activity

GS activity was assessed as described by Rowe *et al*[15], with some minor modifications. Fourteen days after portal vein stricture, rats were sacrificed by decapitation and the FC and hippocampus were incubated in 500 μL HEPES-Tris buffer, which contained 140 mmol/L NaCl, 5 mmol/L KCl, 2.5 mmol/L $CaCl_2$, 1 mmol/L $MgCl_2$, 10 mmol/L HEPES, 10 mmol/L glucose (adjusted to pH 7.4 with Tris base) for 30 min at 37℃. After incubation, each brain region was homogenized in 200 μL 10 mmol/L potassium phosphate, pH 7.2. Reaction mixtures contained 150 μL brain region homogenate and 150 μL stock solution (100 mmol/L imidazole-HCl buffer, 40 mmol/L $MgCl_2$, 50 mmol/L β-mercaptoethanol, 20 mmol/L ATP, 100 mmol/L glutamate and 200 mmol/L hydroxylamine, adjusted to pH 7.2) Tubes were incubated at 37℃ for 15 min.

The reaction was stopped by adding 0.6 mL ferric chloride reagent (0.37 mol/L $FeCl_3$, 0.67 mol/L HCl and 0.20 mol/L trichloroacetic acid). Samples were placed for 5 min on ice. Precipitated proteins were removed by centrifugation at 10000 *g*, and the absorbance of the supernatants was read at 535 nm against a reagent blank. Under these conditions, 1 μmol γ-glutamylhydroxamic acid gave an absorbance of 0.340. GS specific activity was expressed as μmol γ-glutamylhydroxamate per hour per milligram of protein.

Preparation of tissue samples for glutamate uptake

As described for the GS activity assay, at 14 d after portal vein stricture, animals were killed by decapitation. The brain was removed from the cranial cavity, and the FC and hippocampus were dissected onto a Petri dish at 0℃, according to the method of Glowinski and Iversen[16], and homogenized with a glass-PTFE homogenizer in 15 volumes of 0.32 mol/L sucrose. The homogenates were centrifuged at 800 *g* for 10 min, the pellet was discarded, and the supernatant was centrifuged at 20000 *g* for 20 min. The pellet (P2 = crude synaptosomal fraction) was suspended with a glass-PTFE homogenizer in fresh 0.32 mol/L sucrose, and again centrifuged at 20000 *g* for 20 min. The procedure was repeated three times, and the resulting pellet was suspended and used in uptake experiments within 5 h after preparation.

Glutamate uptake procedure

Uptake experiments were carried out using fresh synaptosomal fractions that originated from 20 mg of tissue of FC and hippocampus (wet weight) per 1 mL incubation medium. This consisted of 125.0 mmol/L NaCl, 3.5 mmol/L KCl, 1.5 mmol/L $CaCl_2$, 1.2 mmol/L $MgSO_4$, 1.25 mmol/L KH_2PO_4, 25 mmol/L $NaHCO_3$, 10 mmol/L HEPES and 10 mmol/L D-glucose, pH adjusted to 7.4. The tissue was first incubated for 5 min at 30℃, as described by Takarada *et al*[17], followed by the addition of 10 nmol/L radiolabeled substrate of [^{3}H] L-glutamate, and subsequent incubation for 5-30 min (time course study). The incubation was terminated by vacuum-filtration through Whatman glass fiber-filters (type D) and rapid washing, three times, with isotonic saline solution (at 2-4℃). The radioactivity on the filters was measured using liquid scintillation counting. Parallel experiments were always performed without incubation as time zero, to obtain radioactivity not specifically taken up into brain preparation for the radiolabeled substrate used in this experiment.

Protein content was estimated by the technique of Lowry *et al*[18] using bovine serum albumin as a standard.

Drugs, chemicals and radiolabeled compounds

[^{3}H] L-Glutamate (specific activity: 52.0 Ci/mmol) was from Perkin Elmer NEN Life Science Inc. (Boston, MA, USA). Plasma ammonia concentration was determinate by the Ammoniac Enzymatic UV kit (Biomerieux, France). All other chemicals and reagents were analytical grade and obtained through regular commercial sources.

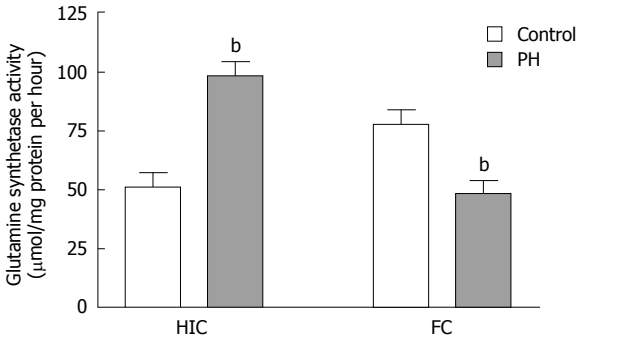

Figure 1 GS activity in the hippocampus and FC. Values are the mean ± SE in eight experiments. $^bP < 0.01$ compared with respective control group. HIC: Hippocampus.

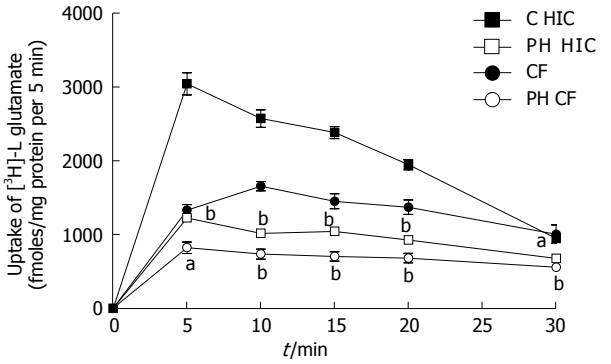

Figure 2 Time course of [^{3}H] L-glutamate uptake in FC and hippocampus. Synaptosomes were incubated with [^{3}H] L-glutamate at 10 nmol/L substrate concentration, for > 30 min, in the presence of 125 mmol/L NaCl at 30℃. Values are the mean ± SE in six or seven separate experiments done in triplicate. $^aP < 0.05$; $^bP < 0.01$ compared with respective control group. C: Control group; PH: Portal hypertension group.

Statistical analysis

The uptake was estimated with Graph Pad Prism 3.1 software (San Diego, CA, USA). Data of uptake activity were presented as the mean ± SE, and were analyzed by one-way analysis of variance, followed by Tukey test[19]. Student's *t* test was used to assess differences between paired groups. $P < 0.05$ was considered as significant.

RESULTS

In these experiments using prehepatic portal hypertensive animals, with almost normal liver function (2-2.5 times normal values), we found a significant increase in hippocampal GS activity, as compared to sham-operated animals ($P < 0.001$) (Figure 1). On the contrary, in FC, a significant decrease in the enzyme activity was documented ($P < 0.001$), in comparison with control rat brains (Figure 1).

The uptake of [^{3}H] glutamate occurred in a temperature-dependent manner and increased with incubation time up to 5 min, with a plateau thereafter at 30 min. Glutamate uptake in the hippocampus and FC showed that, at 30℃, [^{3}H] L-glutamate was taken up into synaptosomes in a time-dependent manner. Its level reached a plateau after 20 min in the presence of Na^+ ions (Figure 2), and remained linear with time for about 2-3 min in the hippocampus and FC, in PH and

sham-operated rats. The uptake of [^{3}H] L-glutamate was temperature- and Na^+-dependent in both regions studied. Time course experiments verified that the uptake of this excitatory amino acid was essentially linear up to 2-3 min at the respective incubation temperature (Figure 2).

The portal hypertensive rat, with almost normal liver function (only moderately increased aspartate aminotransferase and alanine aminotransferase activity and blood ammonia), was shown to have morphological and functional alterations of GS and glutamate uptake in astrocytes and neurons.

There was a significant decrease in glutamate uptake in the portal hypertensive group, as compared to the sham-operated rats, in the hippocampus ($P < 0.001$) and FC ($P < 0.05$) (Figure 2). We found a more pronounced decrease in glutamate uptake in the hippocampus. [^{3}H] L-Glutamate uptake was concentration-dependent at 30℃ and was dramatically suppressed at 2℃ (data not shown). At 30 min, we observed a decline in [^{3}H] L-glutamate uptake in the two regions, which might have been caused by the metabolic changes in the glutamine/glutamate cycle.

Liver homogenates obtained from both groups of animals showed no biochemical alterations and no histological damage (data not shown).

Portal pressure was 8.5 ± 0.5 mmHg in the sham-operated group and 12.5 ± 0.8 mmHg in the PH group ($P < 0.01$).

Plasma ammonium level was 23 ± 9 μmol/L in the control group and 79 ± 15 μmol/L in the PH group, which corresponded to an increase of 243% ($P < 0.01$).

DISCUSSION

PH is responsible for severe circulatory derangements in the splanchnic and systemic circulation, and brain damage results from HE, as a consequence of acute and chronic liver failure. In particular, HE is responsible for severe and often lethal outcomes in these diseases. The HE can be characterized by a wide spectrum of neuropsychiatric abnormalities.

In the present study of prehepatic portal hypertensive rats, we demonstrated different activities of GS and glutamate uptake in the hippocampus and FC. We observed that the activity of GS increased in the hippocampus of PH rats compared to control animals, while there was a decrease in the FC. There was a moderate increase in ammonia concentration.

Using fresh synaptosomal fractions from the FC and hippocampus, we found that glutamate uptake was decreased significantly in PH rats, with a more marked decrease in the hippocampus. In the presence of 125 mmol/L NaCl, uptake of this radiolabeled amino acid occurred in a temperature-dependent manner, and increased with incubation time up to 2-3 min, with a plateau thereafter at 30 min. These results suggest that there are biochemical differences between the brain regions, possibly caused by the toxic metabolic action of ammonia, glutamate, and perhaps glutamine, on the rat brain.

The morphological alterations in the liver parenchyma in chronic disease and in portal vein thrombosis create collateral veins that shunt splanchnic blood flow to the systemic circulation, in an attempt to overcome the increased pressure of portal vein flow. This phenomenon modifies the normal physiology of several organs, including the CNS, and transports intestinal toxins directly to the brain.

In previous experiments with this rat model, alterations in the CNS have been documented, including BBB permeability modifications[5,20]. The impact of PH on the BBB has been demonstrated in rats, in which, 40 d after portal vein stricture, the BBB recovers its function associated to normalize portal pressure and the impermeability to dyes[20].

Glutamate is a major excitatory neurotransmitter, and any alteration in the glutaminergic pathway must modify brain function. Normally, glutamate is synthesized in brain tissue from glucose.

Butterworth *et al*[21], studied the brain in liver failure, glutamate, some other amino acids and neurotransmitters, such as serotonin and dopamine, that are involved in the development of HE. Glutamate uptake and transport are important steps in protecting CNS cells from glutamate excitotoxicity[22,23].

As the removal of ammonia in the brain is linked to the metabolism of glutamate in astrocytes, damage to these cells has been described in PH animals, which involves glutamate uptake and clearance[24].

Rapid clearance of neurotransmitters released from synapses, especially glutamate, acts to limit its signaling and prevents its harmful over-stimulation[25]. It has been well established for several decades that hyperammonemia leads to reduced glutamate uptake, which is caused by a reduced amount and function of glutamate transporters[26-28]. Moreover, it has been shown recently that reduced glutamate transporters and increased extracellular glutamate are responsible for hypokinesia in rats with HE and hyperammonemia[29].

GS plays a central role in the metabolic regulation of the excitatory neurotransmitter glutamate and in the detoxification of ammonia. GS is located mainly in astrocytes. It has been suggested that glutamate can regulate GS brain distribution[30]. This enzyme is responsible for the protection of neurons against excess ammonia and glutamate, by metabolizing both substances into glutamine. Approximately 85% of ammonia is converted to glutamine[31,32]. In addition, glutamate from neurons can be reconverted into glutamine[33]. Astrocytes play a key role in the pathogenesis of ammonia-induced neurotoxicity and HE. Schliess *et al*[34] have found that ammonia induces protein tyrosine nitration in cultured rat astrocytes, which is sensitive to the NMDA receptor antagonist MK-801. Actually, the production of reactive nitrogen intermediates and protein tyrosine nitration may alter astrocyte function and contribute to ammonia neurotoxicity[34].

Acute intoxication with large doses of ammonia leads to CNS cell damage. The main mechanism for ammonia elimination in the brain is its reaction with glutamate to form glutamine. This reaction is catalyzed by GS and consumes ATP[35]. It has observed that GS activity and

glutamine content in the brain are modulated by NMDA receptors and nitric oxide.

There are two main types of hyperammonemia: (1) chronic moderate hyperammonemia, as occurs in liver cirrhosis, which leads to altered cerebral function, and is responsible for the neurological alterations in different hyperammonemic states, and also for some of the neurological alterations in liver disease and HE; and (2) acute intoxication with large doses of ammonia, which may lead to rapid death of animals or patients. This situation can occur in acute liver failure.

Direct toxic effects of glutamine on CNS cells have been demonstrated in isolated mitochondria, which shows that elevated accumulation of glutamine has injurious effects on these cells[36].

Isolated rat cerebral mitochondria treated with high glutamine concentrations (5 mmol/L), as present in acute hyperammonemic rats, show swelling and mitochondrial permeability transition (MPT)[37]. Murthy *et al*[38] have shown that ammonia alone does not induce MPT, but that its metabolism to glutamine is necessary to produce this alteration. Mitochondrial swelling, as a result of the presence of high levels of glutamine and ammonia, is known to stimulate the uptake of glutamine[39].

The addition of glutamine to cultured astrocytes induces MPT development and the formation of free radicals[40]. Hence, glutamine synthesis, from ammonia and glutamate in astrocytes, represents an important process in brain ammonia detoxification, but also can produce negative effects.

The increased activity of GS in the FC, as seen in this PH rat model, may represent a response to moderate increases in ammonia. However, in the hippocampus, we observed decreased activity of GS, which may correspond to an increase in glutamate, caused by decreased uptake and a prolonged toxic effect.

The astrocyte is the brain cell that is directly involved in HE. It participates in chronic porto-systemic encephalopathy, with ultrastructural alterations in the brain. Astrocyte mitochondria are included in this pathophysiological mechanism in the hippocampus[41] and alterations in its respiratory chain, and show ultrastructural damage. By using proton magnetic resonance, Häussinger[42] has shown that brains from HE patients have an increase in glutamine/glutamate signaling. Structural and functional alterations in cultured astrocytes, when their exposure to different ammonia concentrations is modified, suggest the possibility that HE may constitute a primary gliopathy[43].

The mechanisms that produce brain damage in chronic encephalopathy may include the following. (1) Increased ammonia in the brain, which is associated with an increase in glutamate, caused by its reduced uptake, which leads to altered metabolic pathways and functional and morphological damage to the mitochondria in the hippocampus and FC; and (2) The hippocampus possesses a fundamental function in behavioral patterns on memory and spatial mechanisms among other functions. Therefore, it is possible that hippocampus suffers more readily from toxicity than the FC, which also participates in this process, but with minor involvement.

It is possible that the results obtained in the hippocampus in PH rats are indicative of its plasticity, which provokes, during toxic insult, changes in the expression of its enzymes, which maintain the functional equilibrium during this pathological situation. In the mammalian brain, this region is fundamental for the encoding of recent and past experience, including spatial and non-spatial information[41]. The FC has an efficient adaptative mechanism, not described in the hippocampus; its structure perhaps suffers more damage when toxic substances, such as ammonia, glutamate and glutamine are not detoxified efficiently. It may be that, in patients with cirrhosis, these mechanisms can participate in memory processes and behavioral alterations. It might be that the extracellular glutamate that arises from impairment of the glutamate/glutamine cycle in PH participates in the pathogenesis of HE. Furthermore, in PH, increases in ammonia and glutamate and/or glutamine may participate in oxidative stress that is induced by a glutamate-mediated pathway.

Warren and Schenker[44] have demonstrated that inhibition of GS by methionine sulfoximine decreases the death rate in rats intoxicated with ammonia. They found fewer metabolic alterations in HE, including brain edema, less astrocyte swelling, and a decrease in ammonia-induced reactive oxygen species. These experiments demonstrate the negative role that glutamine can play in the pathophysiology of HE[39,45-47]. In liver failure, brain edema, intracranial hypertension, neurotransmitter derangements and neurological symptoms represent the cerebral repercussions of distant liver parenchymal toxicity.

Our results from a PH rat model showed that two different brain regions had different responses in terms of GS activity and glutamate uptake. The BBB in these animals showed an increase in its permeability, apparently as a result of increased portal pressure, because when pressure returned to normal, the BBB recovered its permeability[20]. Also, an increase in astrocyte number, associated with an increase in endothelial cells (angiogenesis), has been documented previously[48].

Finally, it is clear that a partial stricture of the portal vein is capable of modifying functions in two brain regions, the hippocampus and FC. The different changes observed are difficult to explain. Perhaps, further experiments with PH models, using blockers and antagonist of glutamate uptake are needed to explain these results.

COMMENTS

Background

To analyze the participation of glutamine synthetase (GS) activity and glutamate uptake in the hippocampus and cerebral frontal cortex (FC), using a rat model of prehepatic portal hypertension (PH), with the intention of mimicking the two major complications that appear in chronic liver failure: hepatic encephalopathy (HE) and PH.

Research frontiers

In this field, the research hotspots are how to use prehepatic PH rats and how to study the different activities of GS and glutamate uptake in the hippocampus and FC.

Innovations and breakthroughs

This study determinate the uptake of [^{3}H] L-glutamate by synaptosomes of rat cerebral cortex. That provides accurate and reproducible data and can be employed to measure kinetic parameters, and this study determinate GS activity to maintain a stable glutamate/glutamine ratio in the brain.

Applications

Using the PH model, it is possible to understand more clearly the mechanism of toxicity and defense of the brain against two toxic substances: ammonia and the excitatory neurotransmitter glutamate.

Terminology

The extracellular actions of glutamate are limited by glutamate-specific Na^+-dependent transporters that remove glutamate, mostly by taking it up into astrocytes. Astrocytes convert glutamate into glutamine and pass it back to neurons, where it can be converted into glutamate and used to replenish the neurotransmitter stores in synaptic vesicles.

Peer review

The authors have used a rat model of PH and have analyzed the activity of GS and the uptake of glutamate by synaptosomes in the hippocampus and FC 14 d after surgery. The paper seems to be important for understanding HE. The whole paper is relatively easy to read and understand.

Abstract

AIM: To evaluate the maximal-outer-diameter (MOD) and the maximal-mural-thickness (MMT) of the appendix in children with acute appendicitis and to determine their optimal cut-off values to diagnose acute appendicitis.

METHODS: In total, 164 appendixes from 160 children between 1 and 17 years old (84 males, 76 females; mean age, 7.38 years) were examined by high-resolution abdominal ultrasound for acute abdominal pain and the suspicion of acute appendicitis. We measured the MOD and the MMT at the thickest point of the appendix. Patients were categorized into two groups according to their medical records: patients who had surgery (surgical appendix group) and patients who did not have surgery (non-surgical appendix group). Data were analyzed by MedCalc v.9.3. The rank sum test (Mann-Whitney test) was used to evaluate the difference in the MOD and the MMT between the two groups. ROC curve analysis was used to determine the optimal cut-off value of the MOD and the MMT on diagnosis of acute appendicitis.

RESULTS: There were 121 appendixes (73.8%) in the non-surgical appendix group and 43 appendixes (26.2%) in the surgical appendix group. The median MOD differed significantly between the two groups (0.37 cm *vs* 0.76 cm, $P < 0.0001$), and the median MMT also differed (0.15 cm *vs* 0.33 cm, $P < 0.0001$). The optimal cut-off value of the MOD and the MMT for diagnosis of acute appendicitis in children was > 0.57 cm (sensitivity 95.4%, specificity 93.4%) and > 0.22 cm (sensitivity 90.7%, specificity 79.3%), respectively.

CONCLUSION: The MOD and the MMT are reliable criteria to diagnose acute appendicitis in children. An MOD > 0.57 cm and an MMT > 0.22 cm are the optimal criteria.

INTRODUCTION

Since Puylaert[1] described the role of ultrasound (US) as a diagnostic method for acute appendicitis in 1986, the diagnosis of acute appendicitis has become more dependent on the use of US, especially in the doubtful cases for the clinicians. Because of the smaller trunks and thinner subcutaneous fat layer in children compared to adults, US evaluation of the appendix is easier in children. According to previous reports[1-4], radiologists have used several US findings to diagnose acute appendicitis. Among these findings, the maximal outer diameter (MOD) of the appendix was regarded as the most reliable measurement. When the MOD is > 0.6 cm, radiologists suggest the presence of acute appendicitis is indicated.

However, the MOD may be larger than 0.6 cm without acute inflammation. The concern is that the

MOD may be exaggerated by the presence of intra-luminal materials such as gas, feces and fluid[5-7]. To decrease the false positive rate of the MOD criterion, some radiologists have recently attempted to determine another size criterion, the maximal mural thickness (MMT) of the appendix[8-10].

The purpose of this study was to evaluate the diagnostic value of the MOD and the MMT measurements of the appendix in children with clinical suspicion of acute appendicitis and to determine the optimal cut-off values of these measurements in diagnosis of acute appendicitis.

MATERIALS AND METHODS

Among the abdominal US of the children who visited our institute for acute abdominal pain and the suspicion of acute appendicitis between July 2004 and November 2008, we selected 160 children who had a visible appendix on US. These children were aged 1-17 years (84 males, 76 females; mean age, 7.38 years).

After receiving informed consent, the children were examined by experienced radiologists with three different US units (iU22, Philips Medical Systems, Andover, MA, USA; HDI 5000 SonoCT, Philips Medical Systems, Best, The Netherlands; ATL HDI 5000, Philips Medical Systems, Andover, MA, USA). The appendix was scanned from the base to the tip under graded compression using a high resolution transducer (9-12 MHz linear transducer or a 5-8 MHz sector transducer). Then the MOD and the MMT were measured at the thickest point in the cross-sectional image (Figure 1). The MOD was defined as the distance between the outer hyperechoic borders of the the appendix, and the MMT was defined as the distance from the hyperechoic luminal interface to the outer hyperechoic border. Intra-luminal contents including fluid, gas, feces, stones or nothing were recorded.

The medical records of the patients were traced till the symptoms were resolved. We categorized the patients into two groups: patients who had surgery (surgical appendix group) and patients who recovered without surgery (non-surgical appendix group). Data were analyzed by MedCalc v.9.3 software (MedCalc, Mariakerke, Belgium). We used the rank sum test (Mann-Whitney test) to evaluate the difference in the MOD and the MMT between the two groups and used ROC curve analysis to determine the optimal cut-off values of the MOD and the MMT for diagnosing acute appendicitis.

RESULTS

The MOD and the MMT of 164 appendixes in 160 children were included in this study. Forty-four children underwent an appendectomy. The pathological diagnoses were 15 cases of acute appendicitis (without any comment), six cases of acute early appendicitis, 13 cases of acute suppurative appendicitis, six cases of acute gangrenous appendicitis, two cases of acute gangrenous appendicitis with perforation, one case of acute necrotizing appendicitis and one case of congestion. As congestion did not contain any inflammatory cells, the case of congestion was re-classified in the non-surgical appendix group. The case of congestion was finally diagnosed with Crohn's disease in the ileum and cecum. As a result, there were 121 appendixes (73.8%) in the non-surgical appendix group and 43 appendixes (26.2%) in the surgical appendix group.

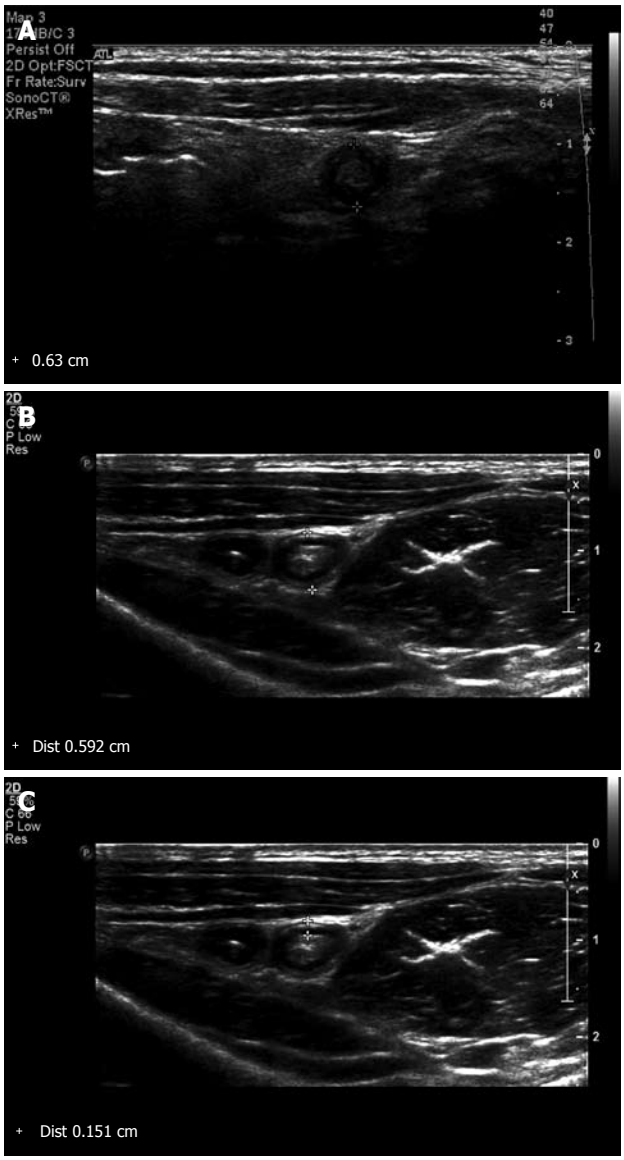

Figure 1 Measurement of MOD and MMT of an appendix in the cross-sectional image. The MOD (A) of the appendix of a 10-year-old boy who had surgery for acute appendicitis. The MOD (B) and the MMT (C) of the appendix of a 7-year-old boy who had a normal appendix in spite of acute abdominal pain.

Because each reference interval of the MOD and the MMT rejected normality ($P < 0.0001$ in each case), the Mann-Whitney test was used for the statistical analysis.

The range of the MOD was 0.20-1.45 cm in all patients, 0.20-0.69 cm in the non-surgical appendix group and 0.42-1.45 cm in the surgical appendix group. The median MOD of 0.37 cm (95% CI: 0.29-0.45 cm) in the non-surgical appendix group was significantly different ($P < 0.0001$) from the median MOD of 0.76 cm (95% CI: 0.69-0.90 cm) in the surgical appendix group. The data comparison graphs between the two groups were presented in Figure 2A.

The range of the MMT was 0.08-0.58 cm in all patients, 0.08-0.49 cm in the non-surgical appendix group

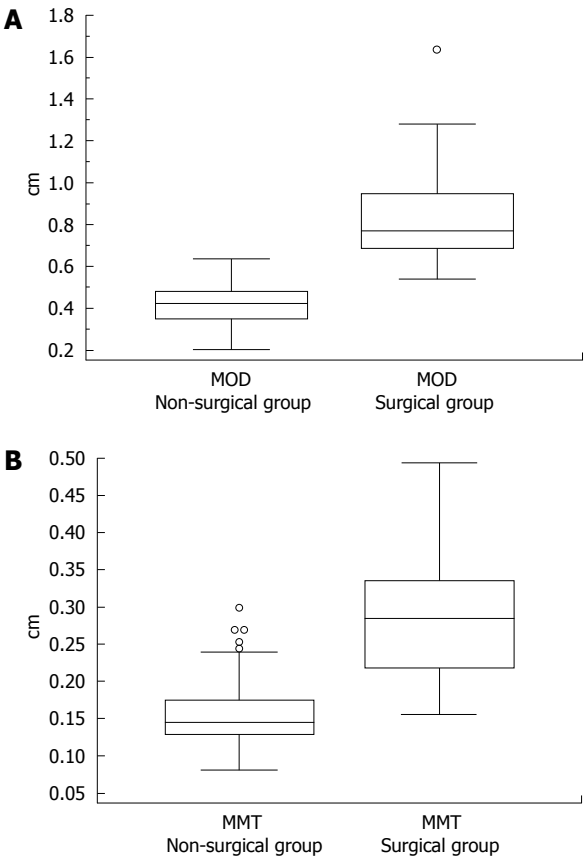

Figure 2 Data comparison graphs of MOD (A) and MMT (B) in box-and-whisker plots. The median MOD and the median MMT were significantly different ($P < 0.0001$) between two groups.

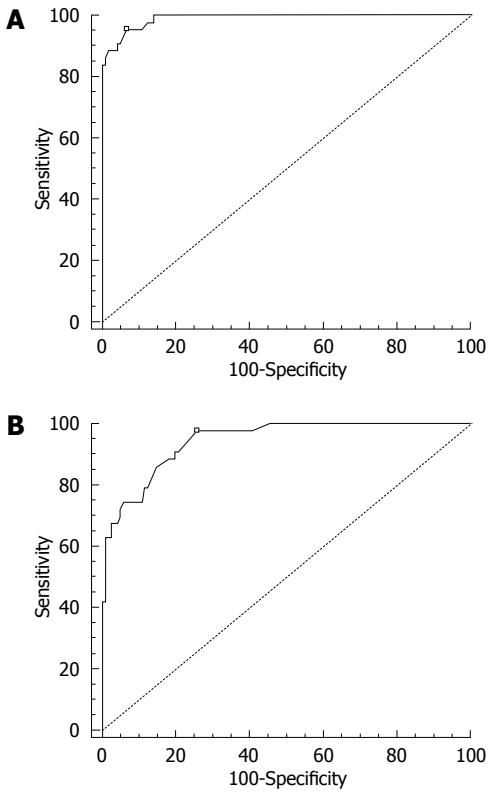

Figure 3 ROC curves of MOD (A) and MMT (B). The optimal cut-off points are marked as white square boxes on the graphs.

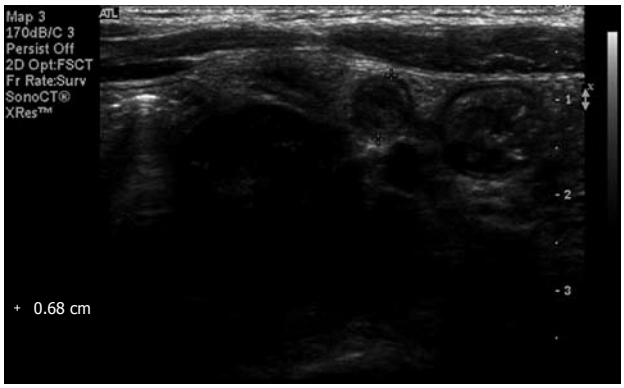

Figure 4 Cross-sectional image of a distended normal appendix in a 7-year-old boy. The MOD of the appendix was 0.65 cm. The intra-luminal hyperechogenicity was due to gas and fecal materials. We diagnosed this as normal appendix, and the symptoms spontaneously resolved.

and 0.10-0.58 cm in the surgical appendix group. The median MMT of 0.15 cm (95% CI: 0.13-0.17 cm) in the non-surgical appendix group was significantly different ($P < 0.0001$) from the median MMT of 0.33 cm (95% CI: 0.30-0.38 cm) in the surgical appendix group. The data comparison graphs between the two groups were presented in Figure 2B.

By ROC curve analysis, the optimal cut-off MOD was 0.57 cm with 89.6% sensitivity, 93.2% specificity and a 13.1 positive likelihood ratio (Figure 3A). The optimal cut-off MMT was 0.22 cm with 84.6% sensitivity, 95.8% specificity and a 20.1 positive likelihood ratio (Figure 3B).

DISCUSSION

According to previous reports[1-4,11], the diagnosis of acute appendicitis by US is based on the following findings; the MOD of the appendix > 0.6 cm; the appendix cannot be compressed with manual pressure by the examiner; the cross-sectional shape of the appendix is round rather than oval; there is an absence of gas in the appendiceal lumen; and there is hyperperfusion of the appendiceal wall on a Doppler study. However, the most credible criterion, the MOD, may be exaggerated and inaccurate in certain conditions (Figure 4)[5-7].

Earlier, Park *et al*[10] suggested that the MMT may have a role as a useful adjunctive measurement, especially for patients with fecal-impacted, non-inflammatory appendixes. As well as this study, there have been several research studies measuring the MMT in children. Simonovský[8] reported that the difference in the normal appendiceal MMT between a group of young children and adolescents and an adult group was marginally significant ($P = 0.042$). In addition, the investigator stated that an MMT < 3 mm should be regarded as normal in children aged six years or younger. Wiersma *et al*[9] also reported the sizes of the MOD and the MMT of a normal appendix in children as 0.21-0.64 cm and 0.11-0.27 cm, respectively. However, they studied only normal appendixes.

In our study, we examined data for both diseased and disease-free appendixes on a large scale, and we compared the MOD and MMT between the surgical appendix and the non-surgical appendix. In a statistical

analysis, both the MMT and the MOD had diagnostic value for acute appendicitis in children.

In addition, we were able to obtain the optimal cut-off MOD and MMT values for diagnosing acute appendicitis in pediatric patients. By ROC curve analysis, the optimal cut-off MOD was 0.57 cm with 89.6% sensitivity, 93.2% specificity and a 13.1 positive likelihood ratio. The optimal cut-off MMT was 0.22 cm with 84.6% sensitivity, 95.8% specificity and a 20.1 positive likelihood ratio. Considering that literature during the last three years has reported that the sensitivity and the specificity for diagnosis of acute appendicitis with US were 80%-100% and 86.5%-100%[10,12-19], our study showed acceptable sensitivity and specificity. While we expected that the MMT would be more sensitive than the MOD, the MMT was less sensitive but more specific than the MOD. We presumed that the MMT could only decrease the false positive ratio of the MOD and could not affect the false negative ratio as the MOD was more sensitive. Therefore, in children, an MOD > 0.57 cm suggests the presence of acute appendicitis and an MMT > 0.22 cm enhances the possibility of having acute appendicitis.

There were several limitations to this study. At first, because our data were obtained only from visible appendixes on US, cases of perforated appendicitis were excluded. Secondly, we categorized patients according to the results of surgery, and therefore cases of chronic or abortive appendicitis may be categorized in the non-surgical appendix group. Thirdly, because the examiner was not one radiologist, inter-observer variance still exists.

In conclusion, the MOD and the MMT are reliable criteria for diagnosis of acute appendicitis in children. An MOD > 0.57 cm and an MMT > 0.22 cm are the optimal criteria.

COMMENTS

Background

US became a reliable modality for diagnosing acute appendicitis, especially in doubtful cases for clinicians. When the maximal outer diameter (MOD) of the appendix is larger than 0.6 cm, radiologists suggest the presence of acute appendicitis. However, because the MOD may be larger than 0.6 cm without acute inflammation, the maximal mural thickness (MMT) of the appendix has been evaluated as another size criterion.

Research frontiers

Dr. Wiersma and colleagues in Juliana Children's hospital in The Netherlands reported the sizes of the MOD and the MMT in the normal appendix. Dr. Park and colleagues in Kwandong University Myongji Hospital in South Korea suggested that the MMT may play a role as a useful measurement for the fecal-impacted, non-inflammatory appendix. However, they included only normal appendixes. The authors examined data from both diseased and disease-free appendixes on a large scale to evaluate the MMT and the MOD and to determine the optimal cut-off values of these measurements in the diagnosis of acute appendicitis in children.

Applications

The MOD and the MMT are reliable criteria for diagnosing acute appendicitis in children. An MOD > 0.57 cm and an MMT > 0.22 cm are the optimal criteria.

Peer review

The authors demonstrated the usefulness of measurements of MOD and MMT in diagnosing pediatric acute appendicitis. They compared the MOD and MMT between surgical and non-surgical appendix groups and showed significant differences between the two groups. They also determined optimal cut-off value of MOD and MMT for diagnosis of acute appendicitis. The manuscript was well organized and well written.

Abstract

AIM: To share our surgical experience and the outcome of limited pancreatic head resection for the management of branch duct intraductal papillary mucinous neoplasm (IPMN).

METHODS: Between May 2005 and February 2008, nine limited pancreatic head resections (LPHR) were performed for IPMN of the pancreatic head. We reviewed the nine patients, retrospectively.

RESULTS: Tumor was located in the uncinate process of the pancreas in all nine patients. Three patients had stents inserted in the main pancreatic duct due to injury. The mean size of tumor was 28.4 mm. Postoperative complications were found in five patients: 3 pancreatic leakages, a pancreatitis, and a duodenal stricture. Pancreatic leakages were improved by external drainage. No perioperative mortality was observed and all patients are recorded alive during the mean follow-up period of 17.2 mo.

CONCLUSION: In selected patients after careful evaluation, LPHR can be used for the treatment of branch duct type IPMN. In order to avoid pancreatic ductal injury, pre- and intra-operative definite localization and careful operative techniques are required.

Key words: Limited pancreatic head resection; Branch duct type; Intraductal papillary mucinous neoplasm

INTRODUCTION

Branch duct type intraductal papillary mucinous neoplasm (IPMN) has a low malignant potential and is more frequently located in the head of the pancreas[1-4]. When this lesion is located in the pancreatic head, the conventional treatment for IPMN has been pancreaticoduodenectomy (PD). Also, partial pancreatic resection is feasible as a treatment for small branch duct type IPMN, which shows less aggressive behavior.

In recent years, some surgeons have advocated limited pancreatectomy for management of benign IPMN and regarding this the following procedures have been reported in several papers: inferior head resection of the pancreas[5], partial pancreatic head resection[6], uncinate process resection[7,8], single branch resection of the pancreas[9], and ductal branch oriented minimal pancreatectomy[10]. It had been expected that there would be advantages of minimal pancreatic parenchymal loss and prevention of functional insufficiency by performing limited pancreatectomy. However, recommendations and reports of postoperative complications and clinical outcomes following these procedures have been limited. Therefore we report a single center surgical experience and short-term outcome of limited pancreatic head resection (LPHR) for the management of branch duct type IPMN.

MATERIALS AND METHODS

From May 2005 to February 2008, a retrospective review

was undertaken of 12 patients who underwent partial pancreatectomy for IPMN at our institution, among whom, nine patients underwent LPHR. In-hospital clinical course and method of operation, postoperative complications and follow-up data were analyzed.

Assessment of the tumor location was carried out before surgery using computed tomography (CT) in all nine cases, upon suspicion of IPMN.

Additional evaluations were routinely performed with endoscopic retrograde cholagiopancreatography (ERCP) or magnetic resonance cholagiopancreatography (MRCP) for evaluating the pancreatic duct, which were confirmed during surgery through direct visualization of lesion by dissection of pancreas head and intraoperative ultrasonography (IOUSG). All pancreatectomies were performed by a single surgeon. Pancreatic parenchymal control was performed using bipolar coagulator for fine dissection and easy bleeding control. All nine resected tumors were examined by a single pathologist with regard to resection margin and tumor characteristics during operation. The definition of postoperative pancreatic leakage was in accordance with the International Study Group on Pancreatic Fistula (ISGPF) definition[11].

Indication for limited pancreatectomy

Prior to 2005, PD was the standard treatment for IPMN of the pancreas head. Sugiyama *et al*[12] reported that size > 30 mm and presence of mural nodules were the strongest predictors of malignancy in branch duct IPMN. But our previous study revealed that many of < 30 mm resected branch duct IPMN were malignant[13]. For these reason, under 30 mm-sized branch duct IPMN were resected at our center, and < 20 mm lesions were observed with close follow-up. Since 2005, LPHR procedure was tried for those lesions > 20 mm, mainly located in the uncinate process in which the main pancreatic duct was intact on imaging study, and branched IPMN was suspected on pancreatogram.

Operative procedure

Pancreatic head was exposed by omentectomy and superior mesenteric vein (SMV) branch ligation such as in PD. After the exposure, exploration of the lesion and main pancreatic duct was carried out using IOUSG. Preoperative or intraoperative pancreatic stents were not used before resection. Bipolar coagulator was used for fine dissection of pancreas head.

RESULTS

Clinical findings

The mean age of the patients was 63 years (range: 42-72 years), with six male patients. Six patients presented clinical symptoms and incidental lesions were found in three patients.

All nine patients underwent multidetector abdominal CT, four of nine patients underwent MRCP, and another five patients underwent ERCP. All nine tumors were located in the uncinate process, and two patients had another lesion in the tail portion of the pancreas. Five patients were confirmed IPMN by imaging studies, another four patients were suspected IPMN or other cystic neoplasm including mucinous cystic neoplasm (MCN). Clinical profiles are summarized in Table 1.

MRCP finding

Three quarters of the cases of MRCP showed connection between the main pancreatic duct and the cystic lesion in the uncinate process (Figure 1). These findings aroused suspicion of branched type of IPMN, and LPHR was planned.

LPHR

Uncinate process resection or ductal branch-oriented

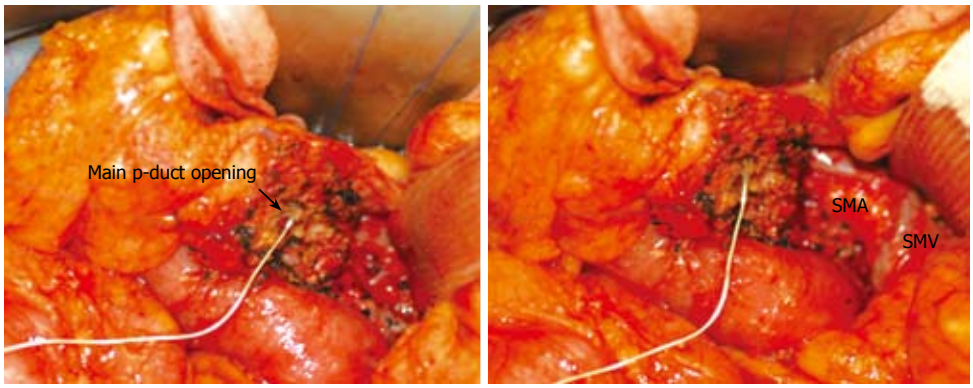

Figure 2 Main pancreatic duct was torn during uncinate process resection (arrow).

minimal pancreatectomy[7,10] were performed in six patients. Single-branch resection[9] was performed in three patients. Two of nine patients underwent additional distal pancreatectomy for pancreatic tail IPMN. The Wirsung duct was damaged in three of the six patients who underwent uncinate process resection or ductal branch-oriented minimal pancreatectomy in which internal silastic stents were inserted and primary repair was carried out (Figure 2). After pancreatectomy, we confirmed the pathologic diagnosis with resection margin.

Pathology

The mean tumor size was 28.4 mm (range 20-42 mm). All nine tumors were confirmed as intraductal papillary mucinous adenoma and resection margins were free of tumor.

Postoperative course

The mean number of hospital days was 21.1 d (range: 8-48 d). There was no mortality and five morbidities. Pancreatic leakage occurred in three patients, two of which involved injured pancreatic duct during operation and an inserted silastic internal pancreatic stent. The third ductal injury was not detected during operation. Pancreatic leakage was detected on postoperative days 4 and 5 respectively. One patient was discharged on postoperative day 32 with a Jackson-Pratt (JP) drain which was removed on day 62 after drain amylase was normalized. Another patient with re-exploration at diagnosis of leakage showed severe inflammation, because of which an external drain (sump drain) was added. Both patients were discharged at postoperative day 43 after removal of the drain. In the case of non-injury of the pancreatic duct, drain amylase increased after operation but normalized at postoperative day 15. One pancreatitis and one duodenal stricture were observed. Duodenal stricture was improved after gastrojejunostomy. The mean follow-up time was 17.2 mo during which there were no recurrences or metastases.

DISCUSSION

Despite the small number of cases included in this study, to our knowledge this study and evaluation of the nine cases of LPHR for branched IPMN is so far the largest amongst related studies. It can be said that partial pancreatic head resection can be a better treatment option than conventional PD for branch duct IPMN on pancreas head under free resection margin. PD may present as surgical overkill for benign and low-grade malignant tumors such as branch duct type IPMN of the pancreatic head. Such procedures result in a significant loss of normal pancreatic parenchyma with subsequent impairment of exocrine and endocrine pancreatic functions[14-16]. Resection of the distal bile duct in patients undergoing PD requires a bilio-enteric anastomosis, which increases the risk of ascending cholangitis and subsequent intrahepatic abscesses[17]. Following PD, the incidence of diabetes mellitus varies between 15% and 40%[18,19]. It can be noted in reports of recent papers that there is unchanged endocrine and exocrine pancreatic function following segmental pancreatic resection[20-22].

Ventral pancreatectomy was performed for management of cystic tumor as limited pancreatic head resection in 1993[23]. This procedure resected too great a width of normal pancreas for a small lesion and reconstructed pancreatic duct and bile duct by entric-anastomosis. Thereafter, pancreatic duct preserving procedures were reported, such as inferior pancreatic head resection, and uncinate process resection[5,7,8]. More minimal pancreatic head resections were performed such as single branch resection of the pancreas, and ductal branch-oriented minimal pancreatectomy[9,10].

Pancreatic leakage is one of the most frustrating complications after limited pancreatic resection. Although this study showed no mortality, three cases of pancreatic leakages occurred. Three pancreatic injuries were found during pancreatectomy. Firstly, the main pancreatic duct was injured after pancreatic dissection from the superior mesenteric vein (SMV) where mucin leaked from a small ductal opening in which a stent was inserted. Secondly, due to ductal tearing, the main pancreatic duct opening was widened during which a stent was inserted through the opening site. Lastly, minutely injured duct was repaired without stent insertion, without leakage after operation. Sata *et al*[9] experienced pancreatic leakages which were managed by the insertion of an endoscopic naso-pancreatic drainage tube. In segmental pancreas resection, pancreatic leakage rates reach up to 40%[20-22].

Generally, benign branch duct type IPMN in the pancreas head, especially the uncinate process, does not involve the main pancreatic duct. However IPMN too close to the main duct, or a large mass, need to be carefully evaluated. For safe dissection during operation without injuring the main pancreatic duct, pre- or intra-

operative pancreatic duct evaluation is crucial. IOUSG or MRCP were insufficient for detecting the pancreatic duct or distance of duct to mass during operation. Although all nine patients had IOUSG performed, three pancreatic injuries occurred. Takada *et al*[7] applied preoperative pancreatic duct stents guided by ERCP, during which the patients did not experience pancreatic leakage. They mentioned that the purpose of the stent was intraoperative identification of pancreatic duct with protection against iatrogenic injury, and postoperative drainage for minimizing pancreatic fistula. Yamaguchi *et al*[10] proposed the placement of a main duct tube for preventing transient stenosis of pancreatic duct. However in this study, preoperative stents were not applied. We speculated that the pancreatic drainage tube produced a pancreatitis.

LPHR does not necessitate anastomosis between the pancreatic duct, bile duct and the bowel. A disadvantage of LPHR was the higher rate of leakage (33.3%). In order to avoid pancreatic ductal injury, preoperative or intraoperative definite localization and careful surgical techniques were important. If the pancreatic duct was injured during operation, internal drainage procedure was necessary. If the disadvantage of ductal injury can be overcome, LPHR can be a useful procedure for the treatment of branch duct type IPMN in selected patients.

COMMENTS

Background

Branch duct type intraductal papillary mucinous neoplasm (IPMN) has a low malignant potential. Limited pancreatectomy is advocated for those lesions, thereby reducing the risk of functional insufficiency and morbidity in extensive resection.

Innovations and breakthroughs

Recommendations and reports of clinical outcomes following limited pancreatic head resection procedures were limited. Several case reports have been published. Despite the small number of cases included in this study, evaluation of the nine cases of limited pancreatic head resections (LPHR) for branched IPMN is so far the largest amongst related studies.

Applications

Disadvantage of LPHR was the higher rate of leakage. If the disadvantage of ductal injury can be overcome, LPHR can be a useful procedure for the treatment of branch duct type IPMN in selected patients.

Peer review

This interesting paper explores the possibility of limited resections for branch duct-type IPMN. But, three of 9 patients also developed a pancreatic fistula; a rate that is also higher than after pancreaticoduodenectomy.

Abstract

AIM: To evaluate the influence of preoperative biliary drainage on morbidity and mortality after surgical resection for ampullary carcinoma.

METHODS: We analyzed retrospectively data for 82 patients who underwent potentially curative surgery for ampullary carcinoma between September 1993 and July 2007 at the Singapore General Hospital, a tertiary referral hospital. Diagnosis of ampullary carcinoma was confirmed histologically. Thirty-five patients underwent preoperative biliary drainage (PBD group), and 47 were not drained (non-PBD group). The mode of biliary drainage was endoscopic retrograde cholangiopancreatography (n = 33) or percutaneous biliary drainage (n = 2). The following parameters were analyzed: wound infection, intra-abdominal abscess, intra-abdominal or gastrointestinal bleeding, septicemia, biliary or pancreatic leakage, pancreatitis, gastroparesis, and re-operation rate. Mortality was assessed at 30 d (hospital mortality) and also long-term. The statistical endpoint of this study was patient survival after surgery.

RESULTS: The groups were well matched for demographic criteria, clinical presentation and operative characteristics, except for lower hemoglobin in the non-PBD group (10.9 ± 1.6 *vs* 11.8 ± 1.6 in the PBD group). Of the parameters assessing postoperative morbidity, incidence of wound infection was significantly less in the PBD than the non-PBD group [1 (2.9%) *vs* 12 (25.5%)]. However, the rest of the parameters did not differ significantly between the groups, i.e. sepsis [10 (28.6%) *vs* 14 (29.8%)], intra-abdominal bleeding [1 (2.9%) *vs* 5 (10.6%)], intra-abdominal abscess [1 (2.9%) *vs* 8 (17%)], gastrointestinal bleeding [3 (8.6%) *vs* 5 (10.6%)], pancreatic leakage [2 (5.7%) *vs* 3 (6.4%)], biliary leakage [2 (5.7%) *vs* 3 (6.4%)], pancreatitis [2 (5.7%) *vs* 2 (4.3%)], gastroparesis [6 (17.1%) *vs* 10 (21.3%)], need for blood transfusion [10 (28.6%) *vs* 17 (36.2%)] and re-operation rate [1 (2.9%) *vs* 5 (10.6%)]. There was no early mortality in either group. Median survival was 44 mo (95% CI: 34.2-53.8) in the PBD group and 41 mo (95% CI: 27.7-54.3; P = 0.86) in the non-PBD group.

CONCLUSION: Biliary drainage before surgery for ampullary cancer significantly reduced postoperative wound infection. Overall mortality was not influenced by preoperative drainage.

Key words: Ampullary carcinoma; Preoperative biliary drainage; Postoperative complications

INTRODUCTION

In patients with ampullary cancer who undergo surgical resection, obstructive jaundice is associated with a higher risk of postoperative complications than in non-jaundiced patients[1]. The impact of jaundice on postoperative morbidity and mortality is well known. However the routine use of preoperative biliary

drainage (PBD) remains controversial. The potential advantages of preoperative stenting include improved nutritional, metabolic and immune function and the possibility of reduced postoperative morbidity and mortality[1]. Opponents of PBD argue that it increases infective complications and morbidity[2,3]. However, there are certain clinical situations such as acute suppurative cholangitis and severe malnutrition in which urgent biliary drainage is indicated and can be life-saving[4]. It is not clear whether the procedure itself or its complications influence the morbidity after surgical resection. The optimal duration of preoperative drainage also remains unknown. Although several reports have been published, there are still no clear guidelines regarding the use of PBD in these patients. We analyzed our patients to assess the influence of PBD on postoperative outcome following pancreaticoduodenectomy (PD) for ampullary tumors.

MATERIALS AND METHODS

We reviewed retrospectively the records of all patients who underwent definitive surgery for carcinoma involving the ampulla of Vater between and September 1993 and July 2007 at the Singapore General Hospital, a tertiary care referral and teaching hospital.

Ampullary cancer was defined as a tumor arising from the ampulla, with evidence of invasion and histopathological signs of neoplasia. In the case of large tumors with involvement of adjacent duodenum or pancreas, the tumor was classified as ampullary if it was centered on the ampulla. Cancers of pancreatic, duodenal and choledochal origin were excluded.

Details of patients who underwent PD (Whipple's operation) or pylorus-preserving pancreaticoduodenectomy (PPPD) for ampullary tumors were entered into a database that included patient characteristics, details of biliary stenting, procedure-related infective complications, surgery, morbidity and mortality. The operations were performed in the Department of Surgery, Singapore General Hospital.

Morbidity

Pancreatic leakage was diagnosed when > 50 mL of drainage fluid, with a serum amylase concentration > 3 times the upper limit of normal was obtained on or after postoperative day 5, or when pancreatic anastomotic disruption was demonstrated radiologically[3]. Wound infection was defined as spontaneous or surgically released purulent discharge that was positive for bacterial growth on culture. Bile leakage was defined as a bilirubin concentration in the drainage fluid that exceeded that in the serum, which resulted in a change of clinical management or the occurrence of a bilioma that required drainage. Infectious morbidity was defined as any complication with evidence of associated localized or systemic infection indicated by fever, leukocytosis and positive culture.

Intra-abdominal or gastrointestinal bleeding was defined as bleeding with either hemodynamic instability or patients who required > 2 U blood transfusion or who required re-operation. Intra-abdominal abscess was defined as purulent discharge with positive cultures from abdominal drains placed at surgery, or as fluid collection that required a drainage procedure. Delayed gastric emptying was defined as inability to tolerate a regular diet for more than seven postoperative days, the need for nasogastric tube drainage for seven or more days postoperatively, or the need for tube reinsertion after removal.

Mortality

Hospital deaths were defined as those that occurred within 30 d of operation or as a direct result of postoperative complications. Late mortality was defined as mortality after 30 d during the follow-up period.

Pathological data

Pathological data were obtained from the patients' medical records and the surgical pathology files. Histological grade, type and the presence of malignant change were noted.

Statistical analysis

Results were expressed as medians and ranges or as numbers and percentages of patients. Two-tailed *t* test and χ^2 test were used for data analysis. SPSS version 13.0 statistical software was used (Chicago, IL, USA) for analysis. Differences were considered statistically significant at $P < 0.05$. The major statistical endpoint of this study was patient survival. Event time distributions for this endpoint were estimated using the method of Kaplan and Meier[5] and compared using the log-rank statistic.

RESULTS

Eighty-two patients were included in the study. Seventy-nine had Whipple's operation and three had PPPD for ampullary tumors. Forty patients (48.8%) were male and 42 (51.2%) were female. Thirty-five (42.7%) patients underwent preoperative biliary plastic stent insertion. There were no inherent differences between the two groups with regard to the decision to proceed with PBD stent insertion. Demographics of the 82 patients with ampullary cancer are summarized in Table 1. The two groups were comparable with regard to sex, age, stage and grading of the ampullary cancer, and diabetes mellitus. Patients who underwent PBD had a significantly higher level of hemoglobin (11.8 ± 1.5 g/dL) on preoperative laboratory evaluation compared with non-stented patients (10.9 ± 1.6 g/dL) ($P < 0.05$). The majority of biliary stents were placed endoscopically, with two patients having percutaneous transhepatic biliary drainage. Numbers were too small to undergo statistical analysis between the types of biliary decompression; thus, "stents" included all patients who underwent PBD. The time interval between biliary drainage and surgery was 39 d (range: 10-89 d). There was a decrease in bilirubin in all patients, with the mean reduction being 47.6 μmol/L. All patients were given intravenous antibiotics at the time of surgery.

Table 1 Patient variables in the PBD and non-PBD groups

	PBD	Non-PBD	Significance
Patients	35	47	
Median age (yr)	65 (23-84)	62 (38-84)	0.91
Sex ratio (M/F)	14/21	26/21	0.28
Mean serum bilirubin	112.4 ± 116.1	91.6 ± 110.2	0.39
Mean hemoglobin	11.8 ± 1.5	10.9 ± 1.6	0.03
Diabetes mellitus	7	12	0.66
Mean albumin	30.5 ± 5.7	31.1 ± 6.2	0.77

Table 2 Morbidity and mortality in the two groups

Morbidity	PBD	Non-PBD	Significance
Sepsis	10	14	0.91
Wound infection	1	12	0.01
Intra-abdominal bleeding	1	5	0.36
Intra-abdominal abscess	1	8	0.09
Gastrointestinal bleeding	3	5	0.95
Bile leakage	2	3	0.73
Pancreatic leakage	2	2	0.73
Delayed gastric emptying	6	10	0.85
Reoperation	1	5	0.36
Hospital death	0	0	0.00
Late mortality	10	13	0.15

All postoperative complications and subpopulation analyses between PBD and non-PBD groups are shown in Table 2. Postoperative sepsis occurred in 29.3% (24/82) of the patients. Six patients had postoperative bleeding that required re-exploration. There were 13 (15.7%) patients with wound infection (one in the PBD and 12 in the non-PBD group), and analysis demonstrated a significantly higher occurrence of wound infection in the non-PBD group ($P = 0.01$).

Tumor grading and histology

Of the 82 infiltrating carcinomas, 21 (25.6%) were well-differentiated, 49 (59.8%) were moderately differentiated, and 12 (14.6%) were poorly differentiated. The most common histological type was intestinal (52/82, 63.4%), followed by pancreaticobiliary (22/82, 26.8%) and colloid (3/82, 3.7%). Five carcinomas had a histological type that was classified as "other".

Mortality and survival

There were no hospital deaths in either group. Twenty-three patients died (28%) during the study period. Median survival was 44 mo (95% CI: 34.2-53.8) in the PBD group and 41 mo (95% CI: 27.7-54.3; $P = 0.86$) in the non-PBD group. There was no significant difference in terms of survival between the groups (Figure 1).

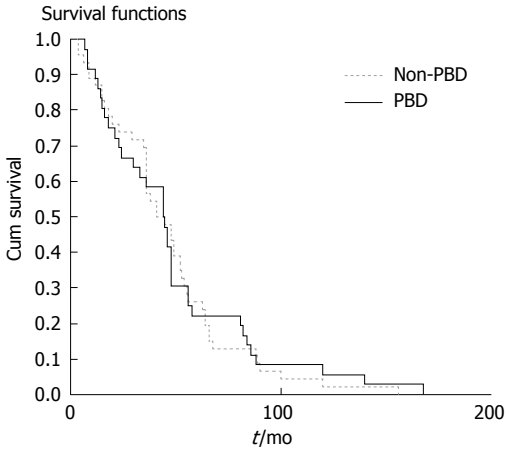

Figure 1 Survival functions for PBD and non-PBD groups.

DISCUSSION

Ampullary tumors share a similar clinical presentation in which jaundice is the predominant symptom. The main initial objectives in these patients are to obtain a precise diagnosis and resolution of jaundice. In an attempt to reach these goals, many treatment modalities have been proposed and applied in recent years. All have been oriented to the necessity of reducing jaundice preoperatively and to preventing perioperative complications, in most cases caused by cholestasis. We found an increase in the rate of wound infection in the perioperative period in the non-PBD group. Malnourishment and malignant obstructive jaundice predispose a patient to wound dehiscence by slowing healing, and increasing the rate of wound infection. A study by Irvin *et al*[6] has suggested that malignant disease may be an important factor in the pathogenesis of wound complications in patients with jaundice. Wound dehiscence or incisional hernia occurred in 59.1% of patients with obstructive jaundice that resulted from malignant disease, but patients with jaundice caused by biliary stones or benign pathology did not develop these complications.

Other factors have been confirmed as having a significant effect on the development of postoperative wound infection, in terms of patient characteristics including diabetes and anemia[7]. Patients with diabetes are more susceptible to wound infection because of impaired neutrophil chemotaxis and phagocytosis. In our series, 25% of non-PBD patients had diabetes compared to 20% in the PBD group, which, although not statistically significant, may have influenced the outcome of surgery. Furthermore the non-PBD group had a hemoglobin level that was significantly lower than that in the PBD group. Impaired wound healing in patients with obstructive jaundice has also been postulated to be caused by an altered immune response, with elevated tumor necrosis factor α activity secondary to circulating endotoxemia[8].

Grande *et al*[9] have compared wound healing in the presence and absence of obstructive jaundice. They used prolyl hydroxylase activity as a marker for collagen synthesis, and found it to be significantly elevated in patients who underwent biliary drainage for benign or malignant biliary obstruction. These patients had better wound healing.

Three common methods of PBD are percutaneous, endoscopic and surgical instrumentation. The endoscopic insertion of a stent through the papilla is a method of draining an obstructed biliary system during endoscopic retrograde cholangiopancreatography (ERCP). In animal studies comparing internal and external biliary drainage, animals undergoing internal drainage experienced

increased survival[10,11], decreased sepsis[12], renal failure[11], and more rapid recovery of immune function[13,14], compared with those undergoing external drainage. Endoscopic biliary drainage is now considered an effective, if not the preferable, treatment for the palliation of malignant biliary tract obstruction[15,16].

To the best of our knowledge, this is the first study to analyze ampullary cancer in the context of PBD. Previous studies have looked at peri-ampullary cancer. Trede and Schwall's[17] retrospective analysis of 150 patients with jaundice undergoing partial or total pancreatectomy revealed a complication rate of 31% and four deaths in 68 patients with no drainage, compared with 17% complications and one death in 82 patients with PBD. Evidence in support of preoperative biliary drainage comes from a prospective randomized trial by Lygidakis *et al*[18], which assigned 38 patients to either PBD (15 ± 2 d) by endoscopic internal stenting, or no PBD. The authors reported a 16% complication rate and no deaths in 19 patients undergoing PBD, compared with 70% complications and two deaths in 19 patients without drainage. Although this difference was highly significant, the investigators scored positive intraoperative blood and bile cultures as a complication. The clinical relevance of such findings is not clear. Smith *et al*[19] have identified prospectively 155 patients who underwent partial PD and found no survival difference between PBD and non-PBD groups. However, the authors concluded that the presence of jaundice at the time of resection had an adverse impact on early postoperative survival. Therefore, preoperative resolution of jaundice following biliary stenting predicted more favorable early survival outcome.

In contrast, a prospective randomized study by Lai *et al*[20] revealed no significant benefit in patients undergoing PBD, and included a wide variety of pathologies, but details of specific complications were not delineated clearly. Choi *et al*[21] have shown that PBD compromised hepatic excretory function, as represented by a slow rate of decrease in serum bilirubin. Limongelli *et al*[22] have revealed that PBD predisposes to a positive intraoperative bile culture, which increases the risk of developing infectious complications and wound infection after pancreatic surgery. Povoski *et al*[23] have reviewed retrospectively 240 consecutive cases of PD. Postoperative morbidity and mortality rates were higher in the PBD group, and they have suggested that PBD should be avoided whenever possible in patients with potentially resectable pancreatic and peripancreatic lesions. Therefore, based on data that, at best, provide mixed results, why should the patients still undergo PBD? First, most patients with ampullary cancer at the time of diagnosis have symptomatic jaundice with pruritus, and some degree of abdominal pain. To some extent, it is hoped that stenting will provide symptomatic improvement. Second, patients who present with acute cholangitis require prior PBD before undergoing definitive surgery.

In contrast, endoscopic biliary drainage before surgery is not a widely accepted procedure among pancreatic surgeons. Potential disadvantages of PBD include those inherent to ERCP such as pancreatitis, bleeding, cholangitis and duodenal perforation. In addition, endoscopic biliary stenting has been shown to generate a severe inflammatory reaction in the bile duct[24], which may make surgical resection more difficult. This was not substantiated by our study, with its comparable mortality and significantly reduced wound infection in the PBD group.

In conclusion, our experience confirms that PBD in patients with obstructive jaundice due to ampullary cancer results in a reduction in wound infection following surgical resection compared with patients not undergoing PBD. Morbidity other than wound infection and mortality were similar with or without PBD. We believe that a detailed prospective randomized trial including a cost analysis in a well-defined and well-matched group of patients undergoing operation for ampullary cancer is warranted, to further evaluate the effectiveness of routine preoperative PBD.

COMMENTS

Background

The effectiveness of preoperative biliary drainage (PBD) in pancreaticoduodenectomy is still extensively debated because of the various conflicting postoperative outcomes, which include benign or malignant, pancreatic or peripancreatic, and ampullary or periampullary lesions.

Research frontiers

The impact of jaundice on postoperative complications is well recognized. However, whether PBD with improvement of jaundice affects surgical outcomes remains controversial.

Innovations and breakthroughs

This is believed to be the first study to investigate the impact of PBD in resectable ampullary cancer patients. Other studies have shown mixed results with regard to postoperative morbidity and mortality amongst ampullary and periampullary cancer.

Applications

The authors conducted the study amongst 82 patients with ampullary cancer and 35 of them had PBD, with a significant reduction in postoperative wound infection rate. A further randomized prospective control study should be conducted in resectable ampullary cancer patients undergoing PBD to look into this positive outcome.

Peer review

This paper addresses an important clinical issue: whether preoperative biliary drainage influences the outcome of resectional surgery for ampullary carcinoma. The results are presented reasonably clearly. The discussion compares the outcomes of this study with other relevant studies and explores the possible reasons for the findings.

Abstract

AIM: To investigate whether microproteinuria could be used as an early and sensitive indicator to detect calcineurin inhibitor (CNI)-related nephrotoxicity after liver transplantation.

METHODS: All liver transplant recipients with normal serum creatinine (SCr) and detectable microproteinuria at baseline were included in this study. The renal function was monitored by the blood clearance of ^{99m}Tc-diethylenetriaminepentaacetic acid every 6 mo. Microproteinuria, SCr and blood urea nitrogen (BUN) were measured at entry and at subsequent follow-up visits. The patients were divided into different groups according to the mean values of glomerular filtration rate (GFR) at the follow-up time points: Group 1, GFR decreased from baseline by 0%-10%; Group 2, GFR decreased from baseline by 11%-20%; Group 3, GFR decreased from baseline by 21%-40%; Group 4, GFR decreased from baseline by > 40% and/or SCr was increasing.

RESULTS: A total of 143 patients were enrolled into this study (23 females and 120 males). The mean follow-up was 32 mo (range 16-36 mo). Downward trends in renal function over time were observed in the study groups. SCr and BUN increased significantly only in Group 4 patients ($P < 0.001$). β2-microglobulin (β2m) and α1-microglobulin (α1m) significantly increased with the subtle change of renal function in recipients who were exposed to CNI-based immunosuppression regimens. The reductions in GFR were closely correlated with elevated α1m ($r^2 = -0.728$, $P < 0.001$) and β2m ($r^2 = -0.787$, $P < 0.001$).

CONCLUSION: β2m and α1m could be useful as early and sensitive indicators of CNI-induced nephrotoxicity.

INTRODUCTION

Calcineurin inhibitors (CNIs) have improved survival significantly after liver transplantation, but nephrotoxicity is an adverse effects common to both cyclosporine and tacrolimus[1-3]. Deterioration of renal function with CNI therapy has been widely reported in liver transplant

recipients[4-6]. A recent analysis of 36 849 liver transplant recipients performed in the United States between 1990 and 2000 revealed an 18.1% incidence of chronic renal failure after 5 years, with CNI dose and duration of exposure correlated with subsequent renal damage[7].

The monitoring of transplant patients, however, is still dependent on somewhat old methodologies: serum creatinine (SCr) levels, total urine output, blood urea nitrogen (BUN), or calculated glomerular filtration rate (GFR). However, these tests are particularly problematic as they do not have sufficient specificity, sensitivity, or accuracy to allow appropriate and timely interventions[8]. Additionally, CNIs are characterized by a narrow therapeutic index, so renal damage is often irreversible when these indices become abnormal, or the indices can still fluctuate in the normal range while renal insufficiency is obvious. Given these limitations, more and more transplant specialists are looking to emerging fields, such as proteomics and metabolism, to improve the current situation. Microproteinuria, as a hallmark of reflecting early changes in the glomeruli and proximal tubular function, can be used as an accurate predictor to monitor early changes in renal function[9,10].

The aim of this prospective study was to find out whether microproteinuria could be used as an early and sensitive indicator to monitor CNI-related nephrotoxicity in liver transplant recipients. It was approved by the Ethics Committee at the West China Hospital, Sichuan University.

MATERIALS AND METHODS

From April 2005 to December 2008, 423 adult patients underwent liver transplantation in our hospital. CNI-based immunosuppression regimens comprising a CNI (cyclosporine A or tacrolimus) + azathioprine + prednisone were delivered to recipients after transplantation. All patients who received a CNI-based regimen for immunosuppression after liver transplantation were potential candidates for this study. Recipients receiving CNI therapy without interruption after liver transplantation, with normal SCr at baseline and detectable microproteinuria in fresh urine were all included in this study. If death occurred within 3 mo posttransplantation or renal dysfunction was caused by non-CNI drugs (such as antibiotics or antivirals), or by other means during follow-up period, the recipients were excluded from the study.

Follow-up protocols were performed once every month for the first 6 mo after liver transplantation, once every 2 mo during months 7-12, and once every 6 mo after 1 year. At each time point, the patient contributed a urine sample which was correlated with the measurements from blood samples. Midstream fresh urine samples were collected and not centrifuged. Measurements of microproteinuria including α1-microglobulin (α1m), β2-microglobulin (β2m), immunoglobulin, microalbumin and transferrin were performed immediately with a Dade Behring array nephelometry system (Dade Behring Inc, USA). SCr (picric acid method) was measured by a Modula clinical chemistry analyzer (Roche Diagnostics, Roche, Switzerland). GFR was measured every 6 mo by the Gates method (PHILIPS Helix SPX-6D SPECT, Holland) which analyzed the blood clearance of ^{99m}Tc-diethylenetriaminepentaacetic acid (DTPA) (5 mCi, from the China Institute of Atomic Energy, radiochemical purity 95%). As consent for a renal biopsy was difficult to obtain, this was performed only when clinically indicated, especially in patients with increasing SCr (an indication of progressive deterioration in renal function).

The actual GFR is considered to be the best overall index of renal function in health and disease[11].Therefore, we chose the actual GFR as the criteria for renal function in this study. The patients were divided into 4 groups according to the mean values of GFR at every 6-mo follow-up: Group 1, GFR declined from baseline by 0%-10%; Group 2, GFR declined from baseline by 11%-20%; Group 3, GFR declined from baseline by 21%-40%; Group 4, GFR declined from baseline by > 40% and/or SCr was increasing.

The normal concentrations of individual proteins present in the urine are illustrated by maximum values[12,13], and are significantly different between different laboratories[12-14]. The normal reference values of microproteinuria provided by Dade Behring, Inc. are: microalbumin < 30 mg/L, α1m < 12.0 mg/L, β2m < 0.20 mg/L, immunoglobulin < 9.6 mg/L, and transferrin < 1.9 mg/L. According to the values determined in 500 Chinese healthy individuals in our laboratory, the normal values used in this study for microalbumin were < 19 mg/L, α1m < 12.5 mg/L, β2m < 0.22 mg/L, immunoglobulin < 20.0 mg/L, and transferrin < 2.2 mg/L.

Statistical analysis was performed by SPSS 13.0 (SPSS Inc., Chicago, IL). Differences in microproteinuria, serum creatinine and BUN were tested with the one way ANOVA test for multiple comparisons. Data were expressed as mean ± SD, or median (range). The Kruskal-Wallis rank sum test (individual comparisons were done by the Wilcoxon rank sum test) and correlation analyses were used in this study. A *P*-value less than 0.05 indicated statistical significance.

RESULTS

A total of 143 liver transplant patients were recruited into this study. Of these, 16 withdrew during the follow-up period. The reasons for withdrawal were infection in 3 patients, acute rejection in 2, use of non-CNI drugs in 4, uncontrolled hypertension in 3, abnormal liver function in 2, and 2 patients died. There were 23 females and 120 male, aged 21-68 years. The grafts and recipients were blood group identical in 127 cases and compatible in 16 cases. The mean follow-up was 32 mo (range 16-36 mo). The primary disease of the 143 recipients included diffuse ischemic intrahepatic biliary stenosis in 8, Caroli disease in 7, Budd-Chiari syndrome with liver cirrhosis in 4, liver cirrhosis after hepatitis B in 56, postoperative liver failure after right lobe hepatectomy caused by hepatic trauma in 4, Wilson disease in 11, α1-antitrypsin deficiency in 2, echinococcus disease of the liver in

[a]$P < 0.05$, *vs* group 1; [c]$P < 0.05$, *vs* group 2. Group 1: GFR declined from baseline by 0%-10%; Group 2: GFR declined from baseline by 11%-20%; Group 3: GFR declined from baseline by 21%-40%; Group 4: GFR declined from baseline by > 40% and/or SCr was increasing.

4, hepatolithiasis in 3, hepatocellular carcinoma in 38, and cholangiocarcinoma in 6. All hepatocellular cancer patients met the UCSF criteria (a single tumor ⩽ 6.5 cm in diameter, or 2 or 3 tumors, none exceeding 4.5 cm in diameter and whose sum of tumor diameters did not exceed 8 cm). The demographic data of these patients are shown in Table 1. There were 102 (71.3%) recipients in Group 1, 35 (24.5%) in Group 2, 6 (4.2%) in Group 3, and none in Group 4 at baseline. At entry into this study, all recipients had normal levels of BUN, SCr, and GFR with detectable microproteinuria in fresh urine. There were no significant differences in body mass index, or pre-transplant MELD score.

Through measurements of GFR by the blood clearance of ^{99m}Tc-DTPA at entry into the study and at the follow-up visits, we found there was a downward trend in renal function over time, and the reductions in GFR were significantly different across all groups (Table 2). The value of GFR was 97.4 ± 12.7 mL/min per 1.73 m^2 in Group 1 (decreased 7.3% ± 2.6% from baseline), and 85.6 ± 17.9 mL/min per 1.73 m^2 in Group 2 ($P < 0.001$ *vs* Group 1) (decreased 16.7% ± 10.1% from baseline), and

62.3 ± 20.5 mL/min per 1.73 m^2 in Group 3 ($P < 0.001$ *vs* Group 1; $P < 0.001$ *vs* Group 2) (decreased 32.5% ± 12.9% from baseline). In Group 4, the value of GFR was 49.6 ± 13.2 mL/min per 1.73 m^2 ($P < 0.001$ *vs* Group 1; $P < 0.001$ *vs* Group 2; $P = 0.002$ *vs* Group 3) (decreased 52.4% ± 20.8% from baseline). The SCr significantly increased only in Group 4 (173.7 ± 28.5 umol/L) when compared with the other groups ($P = 0.017$ *vs* Group 1, $P = 0.021$ *vs* Group 2, $P = 0.035$ *vs* Group 3). Similar trends were found for BUN. However, the urinary β2m ($P < 0.01$) and α1m ($P = 0.043$) were significantly different between the 4 groups of patients. This study also indicated that microalbumin, immunoglobulin and transferrin had no significant differences in the 4 groups of patients.

In Group 1, the mean level of urinary α1m at entry and at subsequent follow-up visits was 22.6 ± 21.1 mg/L, which was significantly lower than that in Group 2 (38.9 ± 25.4 mg/L, $P < 0.001$), and in Group 3 (42.3 ± 35.9 mg/L, $P < 0.001$). In Group 4, the level of urinary α1m (65.1 ± 30.4 mg/L) was significantly higher than that of all the other groups ($P < 0.001$ *vs* Group 1; $P < 0.001$ *vs* Group 2; $P = 0.002$ *vs* Group 3). The findings in this study suggested that the increase in urinary α1m occurred long before the elevation of SCr or BUN, and the reductions in GFR were closely correlated with the increases in α1m ($r^2 = -0.728$, $P < 0.001$). The urinary α1m, as a marker of tubular damage, was sensitive in assessing subtle changes in renal function caused by CNI nephrotoxicity.

The mean level of urinary β2m during follow-up visits was 0.2 ± 0.1 mg/L in Group 1, 0.4 ± 0.2 mg/L in Group 2 ($P = 0.041$ *vs* Group1) and 1.0 ± 1.3 mg/L in Group 3 patients ($P < 0.001$ *vs* Group 1; $P < 0.001$ *vs* Group 2). The level of urinary β2m in Group 4 patients (4.2 ± 2.5 mg/L) was further increased compared to other subgroups ($P < 0.001$ *vs* Group 1; $P < 0.001$ *vs* Group 2; $P < 0.001$ *vs* Group 3). The urinary β2m concentration gradually increased from Group 1 to Group 4. The results of this study showed that the increase in urinary β2m, as a marker of tubular epithelial cell dysfunction, occurred long before the elevation of SCr or BUN, and was also closely correlated with the reduction in GFR ($r^2 = -0.787$, $P < 0.001$). The urinary β2m was also sensitive for detecting subtle changes in renal function in patients exposed to CNI-based immunosuppression regimens. Additionally, monitoring both β2m and α1m could improve the sensitivity and specificity of measurement of CNI-related nephrotoxicity.

DISCUSSION

The tremendous success of CNIs in reducing acute rejection episodes and early immunologic graft injury has not been accompanied by a benefit in long-term recipient survival[15,16]. CNI nephrotoxicity in liver transplantation is a significant concern and appears to be progressive over time when CNI exposure is maintained[17]. Microproteinuria has been used as an early marker of nephrotoxicity to detect small changes in the function of tubular epithelial cells in many pathological conditions[10]. The persistence of microproteinuria may result from drug toxicity or pretransplant renal diseases after liver transplantation. Therefore, recipients with normal serum creatinine at baseline and detectable microproteinuria were selected as subjects in this study.

Follow-up data of this study demonstrated that there was a downward trend in renal function over time, with the persistence of microproteinuria. The urinary concentration of β2m and α1m significantly increased with the subtle change in renal function in all study groups, but the levels of SCr and BUN significantly increased only when renal function was severely reduced by CNI nephrotoxicity (in Group 4, renal function declined 52.4% ± 20.8 % from baseline). A similar study also found microproteinuria occurred long before the elevation of SCr[18]. The subsequent reductions in GFR were closely correlated with elevated α1m ($r^2 = -0.728$, $P < 0.001$) and β2m ($r^2 = -0.787$, $P < 0.001$) in the study groups. The results of this study were similar to another report[19], indicating that tubular epithelial dysfunction defined by elevation of tubular injury biomarkers (β2m or α1m) was very common when CNI exposure was maintained. Additionally, as β2m is unstable in fresh urine, fewer patients were found to have β2m in the urine than α1m in this study. This problem can partly be overcome by maintaining the urine pH value (by adding basic buffer to the urine) to prevent the degradation of β2m. This study suggested that urinary β2m and α1m are sensitive urinary markers for detecting CNI-related nephrotoxicity in liver transplant recipients.

In conclusion, monitoring of patients with SCr requires a higher laboratory effort and the use of gender-specific cut-off values. Measurement of microproteinuria is easily available, non-expensive, and convenient in daily clinical practice. The urinary β2m or α1m can be used as an early, sensitive and simple diagnostic indicator for detecting CNI-related renal dysfunction. Furthermore, it should be used as the screening method after liver transplantation to prevent the progressive deterioration of subclinical renal dysfunction.

ACKNOWLEDGMENTS

The authors are grateful to the staff of the Liver Transplantation Division for collection of the clinical materials, and to Mrs. Fang Liu, Mrs. Yang-Juan Bai and Mr. Jiang-Tao Tang for their skillful technical assistance. Special thanks to the staff of the Department of Clinical Laboratory for processing the urine samples and to staff of the Department of Nuclear Medicine for performing the GFR measurements.

COMMENTS

Background

Deterioration of renal function with calcineurin inhibitor (CNI) therapy has been widely reported in liver transplant recipients. Monitoring of renal function, however, is still dependent on somewhat old technologies: serum creatinine (SCr), blood urea nitrogen (BUN), total urine output. Whether microproteinuria could be used as an early and sensitive indicator to monitor CNI-related nephrotoxicity in liver transplant recipients has not been unequivocally addressed.

Research frontiers

Measurement of SCr, BUN, and total urine output are particularly problematic, as they do not have sufficient specificity, sensitivity, or accuracy to allow appropriate and timely prevention of the deterioration of renal function. In this field, the research goal is to identify more sensitive indicators in the early diagnosis of CNI-related nephrotoxicity in liver transplant recipients.

Innovations and breakthroughs

Recent reports have highlighted that nephrotoxicity of CNIs contributes to renal function deterioration in liver transplant recipients. This is the first study to investigate whether microproteinuria could be used as an early and sensitive indicator to monitor CNI-related nephrotoxicity in liver transplant recipients.

Applications

By using β2-microglobulin (β2m) and α1-microglobulin (α1m) as markers for early diagnosis of CNI-related nephrotoxicity, this study may present a future screening method for preventing the progression of CNI-related renal dysfunction in liver transplant recipients.

Terminology

Microproteinuria: it is a hallmark of the early changes in glomerular and proximal tubular function and includes α1m, β2m, immunoglobulin, microalbumin and transferrin.

Peer review

Microproteinuria was studied in these study groups at entry and at subsequent follow-up visits and was correlated with glomerular filtration rate. It revealed that microproteinuria could be used as an early and sensitive indicator to monitor CNI-related nephrotoxicity in liver transplant recipients. This manuscript is very interesting and may present a future screening method to prevent the progression of CNI-related subclinical renal dysfunction after liver transplantation.

Abstract

We present a case of a transsexual patient who underwent a partial pelvectomy and genital reconstruction for anal cancer after chemoradiation. This is the first case in literature reporting on the occurrence of anal cancer after male-to-female sex reassignment surgery. We describe the surgical approach presenting our technique to avoid postoperative complications and preserve the sexual reassignment.

Key words: Sex reassignment; Pelvic surgery; Anal cancer

INTRODUCTION

Pelvic surgery after male to female sex reassignment implies a particular surgical approach: firstly, anatomic variations during resection can be considerable; secondly, although genital reconstruction is an essential target for patients, it is a difficult operation especially after chemoradiation. We present a case of a transsexual patient who underwent a partial pelvectomy and genital reconstruction for anal cancer.

CASE REPORT

A 63 year-old patient presented with rectal bleeding and anal pain. In 1982, she was submitted to male-to-female sex reassignment surgery according to the technique described by Meyer *et al*[1] consisting of penile disassembly followed by vaginoplasty using all penile components except the corpora cavernosa.

Physical examination on January 2006 revealed an anal ulcer and a biopsy showed evidence of a squamous carcinoma. Clinical staging at diagnosis indicated an involvement of the inguinal lymph nodes (T2N2M0, stage Ⅲ B anal cancer[2]).

Concurrent chemoradiation was administered according to the following scheme: the radiation field included the primary tumour and inguinal lymph nodes; a total of 45 Gy in 25 fractions was administered at the primary tumour and a total of 30.6 Gy at the inguinal fields. Each chemotherapy cycle lasted 38 d and consisted of oxaliplatin 180 mg/m^2 on days 1, 19 and 38 and xeloda 1300 mg/m^2 concurrently to radiotherapy. A radiotherapy boost was also administered either on the primary tumour or the inguinal lymph nodes.

Clinical evaluation six weeks after the completion of chemoradiation showed a complete clinical response. At one year follow-up, CT scan showed local recurrence involving the anal sphincter, neo-vagina and bladder neck. A surgical approach was planned in collaboration with reconstructive surgery in order to preserve sex reassignment.

The surgical approach consisted of two parts.

Figure 1 Elliptical skin islands and flaps preparation.

Figure 2 Reconstruction after one month.

During the abdominal portion of the procedure, the rectum was mobilized, and the posterior bladder wall and the seminal vesicles were exposed. During the pelvic portion of the procedure the excision was completed. The perineal skin incision included the neo-vagina and urethra. The rectum and the anus were removed en bloc with the bladder neck, neo-vagina, seminal vesicles and prostate. The bladder neck was sutured, and sovrapubic cystostomy and the colostomy were performed.

Following the excision, a loss of substance of 20 cm × 15 cm resulted. An elliptical skin island up to 15 cm × 6 cm was outlined over the proximal two-thirds of the gracilis muscle of each thigh, according to a technique previously described by our group[3] (Figure 1). The anterior margin of the incision lay on a line drawn between the pubic tubercle and the semitendinosus tendon. The gracilis tendon was identified distally, and the tendinosus insertion divided. The posterior incision was made down to the muscle. The flap was then elevated from distal to proximal on the thigh. The vascular supply of the flap was the medial femoral circumflex artery, which enters the gracilis muscle 7-10 cm below the pubic tubercle. Once the pedicle was identified and preserved, the proximal muscle was dissected. The entire myocutaneous flap was tunnelled through the subcutaneous skin bridge into the vaginal defect and exteriorized through the introitus. The bilateral flaps were sutured to each other at the midline. The neovagina was shaped into a pouch and then inserted into the pelvic space that left after the exenteration. The proximal end of the neovagina was sutured to the introitus. The result after one month is presented in Figure 2.

The postoperative course was complicated by the occurrence of urinary leak, successfully treated with bilateral temporary nephrostomy.

The histology confirmed a locally advanced squamous carcinoma of the anus. Surgical margins were involved. The patient is free of disease at 8 mo follow-up.

DISCUSSION

This is the first case in literature reporting on the occurrence of anal cancer after male-to-female sex reassignment surgery. We tried to achieve two important targets: (1) to avoid postoperative complications of extended surgery after chemoradiation. In fact, perineal reconstruction with gracilis muscle flaps proved very useful in preventing the primary postactinic healing delay. Immediate perineal reconstruction is helpful in avoiding delayed complications due to radiotherapy, namely tissue sclerosis and irreversible damage to irradiated tissues. Gracilis flap transposition ensures a persistent vascular contribution to the irradiated perineal tissues, increasing local oxygenation and leading to more rapid recovery of the surgical wound. In addition to the vascular advantages, the gracilis muscular flap, fixed to the pelvic floor, prevents dead spaces and thus reduces the incidence of seromas. Extended perineal surgery can subvert the architecture of the pelvic floor reducing the sustaining forces and leading to herniation into the perineal space. We would like to point out that the muscular gracilis flap is crucial to compensate for the lack of perineal support after this operation. Once the defect is closed, no further procedure is needed to treat the above mentioned complications in unreconstructed patients, allowing patients to recover quickly and possibly receive adjuvant therapies. (2) to reconstruct the sexual reassignment. This point may not be essential for the surgeon who often assumes that radical surgery is the only target of the operation, but it remains an important issue for patients.

In conclusion, this is the first case in literature reporting on surgical treatment of locally advanced anal cancer after male-to-female sex reassignment surgery. Surgical reconstruction is a reasonable and helpful option to avoid severe complications and preserve sexual reassignment.

Abstract

Heart failure may lead to subclinical circulatory disturbances and remain an unrecognized cause of ischemic liver injury. We present the case of a previously healthy 40-year-old bodybuilder, referred to our Intensive-Care Unit of Hepatology for treatment of severe acute liver failure, with the suspicion of toxic hepatitis associated with anabolic steroid abuse. Despite the absence of symptoms and signs of congestive heart failure at admission, an anabolic steroid-induced dilated cardiomyopathy with a large thrombus in both ventricles was found to be the underlying cause of the liver injury. Treatment for the initially unrecognized heart failure rapidly restored liver function to normal. To our knowledge, this is the first reported case of severe acute liver failure due to an unrecognized anabolic steroid-induced cardiomyopathy. Awareness of this unique presentation will allow for prompt treatment of this potentially fatal cause of liver failure.

INTRODUCTION

In the absence of a sudden and profound reduction in systemic blood pressure, heart failure is frequently forgotten in the differential diagnosis of acute hepatitis[1]. However, it has long been recognized that ischemic liver injury may follow subclinical circulatory disturbances, particularly in patients with pre-existing passive hepatic congestion, and present as acute hepatitis[2]. Here, we report the first case of severe acute liver failure due to an unrecognized anabolic steroid-induced cardiomyopathy.

CASE REPORT

A 40-year-old male bodybuilder was transferred to our Intensive-Care Unit of Hepatology for treatment of severe acute liver failure. The patient had a history of anabolic steroid abuse over the last 10 years, self-administered in cycles of 6-10 wk, with a 2-3 wk suspension period between cycles. The most frequently used anabolic steroids were: methandrostenolone, stanozolol and oxymetholone (oral); and nandrolone decanoate, testosterone enanthate and trenbolone enanthate (intramuscular). Notably, he used massive doses of all anabolic steroids, including trenbolone enanthate (500-700 mg per week). There was no history of alcohol abuse or acetaminophen intake. He had no family history or past personal history of liver or cardiovascular diseases. The patient was in good physical condition until approximately one month prior to admission, when he experienced increasing fatigue, decreased exercise tolerance and general malaise. Although he stopped exercising and self-administrating the drugs, these symptoms continued to progress and he subsequently developed anorexia, recurrent vomiting, right upper-quadrant abdominal pain and progressive jaundice in the 4 d prior to admission. No history of dyspnea, orthopnea, paroxysmal nocturnal dyspnea or edema could be elicited. At initial evaluation in the patient's local hospital, laboratory

Figure 1 The patient was an athletic young male, with significant jaundice, in no acute distress and able to lie flat.

testing revealed an increase in serum transaminases (aspartate aminotransferase, 7897 IU/L; alanine aminotransferase, 7125 IU/L), coagulopathy (international normalized ratio, 3.3; factor V, 15%), hyperbilirubinemia (total bilirubin 6.8 mg/dL), high ammonia levels (73 umol/L) (normal, 11-32), acute renal failure (creatinine, 3.8 mg/dL), hyponatremia (126 mmol/L) and high lactate dehydrogenase (LDH) level (7140 IU/L). An abdominal ultrasound revealed hepatomegaly and patent flow of the inferior vena cava and hepatic veins. By the end of the first day, the patient was transferred to our Intensive-Care Unit of Hepatology, with the suspicion of anabolic steroid-induced toxic hepatitis.

On transfer, the patient appeared to be an athletic young male in no acute distress and was able to lie flat (Figure 1). Blood pressure was 96/60 mmHg, pulse was 120 beats/min, and respiratory rate was 26 breaths/min. He was conscious with no signs of hepatic encephalopathy. Additional findings on physical examination included generalized jaundice, no evidence of jugular venous distension, clear lung fields and distant heart sounds. He had an enlarged tender liver and no stigmata of chronic liver disease. His extremities were warm, with slight pretibial edema. Laboratory data were similar to those on admission, with markedly depressed values of factor V (15%) and factor Ⅶ (6%). Free testosterone and delta 4-androstenedione concentrations were elevated. Acetaminophen level was undetectable. Serology of known hepatotropic viruses was negative. Antinuclear antibodies were undetectable and serum copper and ceruloplasmin were normal. On chest X-ray, the cardiothoracic index was augmented with clear lung fields. The case was presented to our liver transplantation centre. After correction of hyponatremia with saline, in an attempt to obtain a mildly hyperosmotic state and prevent cerebral edema[3], symptoms and signs of congestive heart failure became evident, with pulmonary congestion and elevated central venous pressure. Echocardiogram showed a dilated cardiomyopathy with an estimated ejection fraction of 15% and a large thrombus in both ventricles. A diagnosis of severe toxic cardiomyopathy associated with anabolic steroids was made after ruling out other causes of non-ischemic dilated cardiomyopathy, including infectious, autoimmune and metabolic causes. With aggressive therapy for cardiac failure with dopamine, dobutamine and watchful diuresis, the patient's liver function improved dramatically. There was a rapid fall in serum transaminases and LDH levels. Four days after admission, the international normalized ratio was < 2.0 and low-molecular weight heparin therapy was started. Serial echocardiograms showed the disappearance of the intraventricular thrombus and improvement in left ventricular function (the fractional shortening increased up to 25%). Coronary angiography disclosed no lesions. After a 16-d hospitalization, the patient was discharged with oral anticoagulation. He his presently in the New York Heart Association functional class Ⅱ, working as a nightclub security agent. However, not enough time has elapsed since treatment to assess full recovery of pathological changes and heart performance.

DISCUSSION

Although the diagnosis of ischemic liver injury can be straightforward in the presence of a clinically evident hemodynamic insult, heart failure may also lead to subclinical circulatory disturbances and remain an unrecognized cause of liver injury[1,2]. Remarkably, in a recent report only around one-half of the patients with ischemic liver injury had been in a state of shock[4]. Isolated cases of unrecognized cardiomyopathy as the cause of severe ischemic liver injury have been reported in the recent literature[5-7]. In these cases, as in our patient, a cardiomyopathy lacking many of the symptoms and signs of congestive heart failure was the cause of the ischemic liver injury, with striking clinical and laboratory evidence of severe liver failure, leading to the possibility of liver transplantation as a rescue therapy. Our patient was an athlete without a history or clinical evidence of heart disease on presentation, and was referred to our Intensive Care Unit of Hepatology for treatment of severe acute liver failure. Several features led to a delay in the diagnosis of the underlying heart disease. Firstly, he was an athletic young male with none of the classic cardiovascular risk factors. Secondly, anabolic steroids are known hepatotoxic drugs[8,9], with only a few reports of severe cardiac toxicity in the literature[10,11]. Thirdly, for unclear reasons, symptoms of congestive heart failure were initially absent; theoretically, the severity of his right-sided heart failure in combination with a low output state may account for this[6]. Finally, cardiac and hepatic diseases share many similar clinical features, such as fatigue, decreased exercise tolerance, hepatomegaly and edema. This case highlights the fact that ischemic injury of the liver should always be considered in the differential diagnosis of acute hepatitis[1]. Retrospectively, some features may have suggested an ischemic rather than a viral or toxic cause of liver injury, including an early massive rise in LDH levels-a ratio of serum alanine aminotransferase to LDH of less than 1.5 may suggest ischemic injury[12]; and a concomitant early rise in the serum creatinine level (additional evidence of end-organ hypoperfusion)[13]. Chest X-ray also revealed

cardiomegaly, despite no evident pulmonary congestion. The rapid fall in serum transaminases after therapy for cardiac failure is characteristic of ischemic liver injury[13].

The medical history of this patient was significant for chronic self-administration of massive doses of anabolic steroids, including trenbolone enanthate, a strictly underground long-active steroid. Although anabolic steroids are associated with significant liver toxicity[8], toxic hepatitis induced by anabolic steroids with predominantly hepatocellular injury is extremely rare[9]. More frequently reported hepatotoxic effects include cholestatic liver injury[8], development of hepatic adenomas[14] and peliosis hepatis[15]. There have been a few reports of severe cardiovascular events associated with anabolic steroid abuse, including cases of severe dilated cardiomyopathy in otherwise young healthy patients[10,11]. Experimental studies[16,17] and non-invasive imaging studies in bodybuilders[18] have demonstrated a dose-dependent impairment of myocardial function after long-term anabolic steroid therapy. It has been proposed that increased fibrosis of the myocardium may be mediated by aldosterone-like effects[10]. The reversibility of such myocardial effects after discontinuation of the drugs is still unknown[18]. A partial recovery of left ventricular function a few months after cessation of anabolic steroid abuse has been reported in two body builders[10].

Anabolic steroid consumption is becoming more widespread and their adverse effects, including cardiovascular and hepatic toxicity, are expected to increase in the years to come[8,10,11]. To the best of our knowledge, this is the first reported case of severe liver failure due to an unrecognized anabolic steroid-induced cardiomyopathy. Awareness of this unique presentation will allow for prompt treatment of this potentially fatal cause of liver failure.

Abstract

Adrenal pseudocysts are rare cystic masses that arise within the adrenal gland and are usually non-functional and asymptomatic. Adrenal pseudocysts consist of a fibrous wall without a cellular lining. We report a patient with a 9 cm, left-sided suprarenal cystic mass who presented with abdominal discomfort of 2 years' duration. A 38-year-old woman was referred to our service for evaluation of abdominal discomfort and gastrointestinal symptoms. Routine laboratory tests were within normal limits. An abdominal computed tomography scan showed a 9 cm × 8 cm × 8 cm well-defined cystic lesion displacing the left kidney. Magnetic resonance imaging showed a cystic lesion with low signal intensity on the T1-weighted image and high signal intensity on the T2-weighted image. A laparoscopic left adrenalectomy was performed to diagnose the lesion. The final pathology showed an adrenal pseudocyst without a cellular lining. The patient had no postoperative complications and she was discharged four days after surgery.

INTRODUCTION

Adrenal pseudocysts are rare lesions that arise within the adrenal gland, most of which are non-functional and asymptomatic. The majority of adrenal pseudocysts are located in the suprarenal area. Preoperatively, larger cysts might be difficult to distinguish from cysts of renal or pancreatic origin. Adrenal pseudocysts consist of a fibrous wall without a cellular lining. We report a case of a patient with a 9 cm, left-sided suprarenal cystic mass who presented with abdominal discomfort of two years' duration.

CASE REPORT

A 38-year-old woman was admitted to our service with a two-year history of abdominal discomfort, anorexia, and nausea. She had no history of trauma and had undergone a laparoscopic unilateral salpingoophorectomy. A physical examination revealed no palpable abdominal masses and no tenderness in the abdomen. Routine laboratory tests were within normal limits. An abdominal computed tomography scan showed a 9 cm well-defined cystic lesion displacing the left kidney (Figure 1). The cystic lesion appeared to arise from the retroperitoneum. For further evaluation of the cystic lesion, magnetic resonance imaging was carried out and the cystic lesion showed low signal intensity on the T1-weighted image and high signal intensity on the T2-weighted image (Figure 2). There were no findings of suspected malignancy on the radiological image. We decided to perform a laparoscopic resection of the cystic lesion to relieve long-lasting gastrointestinal symptoms and to diagnose the lesion.

The patient was placed in the right lateral decubitus, flexed at the waist. A 12-mm trocar was inserted in the umbilical region *via* an open incision. Three other operating ports were placed along the left costal margin, as shown in Figure 3. The second 10-mm trocar was

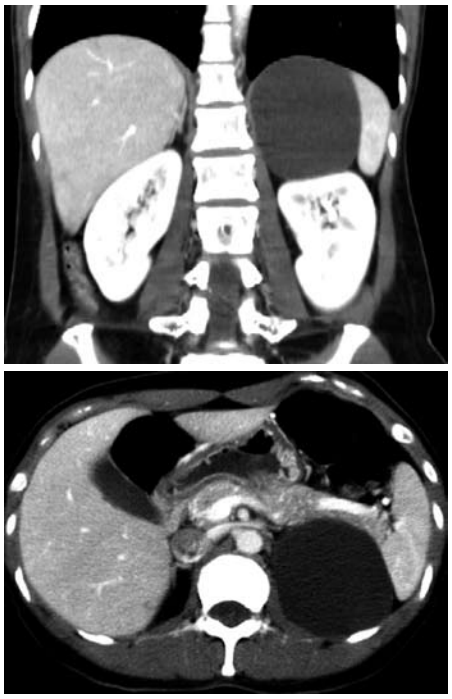

Figure 1 An abdominal computed tomography scan showing a 9 cm well-defined cystic lesion, which abuts the spleen, kidney and pancreas tail.

introduced on the anterior axillary line. The third 5-mm trocar was introduced on left side of the second trocar and placed under the costal margin. The fourth 5-mm trocar was introduced in the posterior axillary line and was used for a retractor. The splenic flexure of the colon was mobilized from the left paracolic gutter to the inferior pole of the spleen. The splenorenal ligament was divided to allow the spleen and tail of the pancreas to rotate medially, exposing the left retroperitoneum. At that time, a smooth, well-capsulated cystic mass, measuring 9 cm × 8 cm × 8 cm, arising from the left adrenal gland was found. The superior, medial and lateral border of the lesion was first dissected from neighboring tissue with a LigaSure (Valley Lab, Boulder, CO). The dissection proceeded inferiorly to expose and ligate the left adrenal vein. The adrenal vein was identified and divided with a 2.5-mm endoscopic vascular stapler (Ethicon). The adrenal cystic lesion, completely freed, was placed in a surgical bag (Endocatch; Ethicon). The cystic contents were aspirated with a needle and were a thin, yellowish fluid. The specimen was extracted *via* the 10-mm port side by enlarging the incision from 1 to 2.5 cm. The operative time was 110 min and the blood loss was 50 mL. Gross appearance showed a thin-walled, yellowish, 6 cm × 3 cm × 3 cm unilocular adrenal lesion (Figure 4). Histological examination showed an adrenal pseudocyst without an epithelial or endothelial lining (Figure 5). The patient had no postoperative complications and she was discharged four days after surgery. The abdominal pain and gastrointestinal symptoms resolved after surgery.

DISCUSSION

Adrenal cysts are classified as a cystic degeneration of adrenal neoplasms, true cysts, pseudocysts, and infectious cysts[1-3]. Among adrenal cysts, the most common types are epithelial cysts and pseudocysts. True cysts are lined with endothelial or mesothelial cells[4]; however, adrenal pseudocysts are devoid of an epithelial or endothelial lining, arise within the adrenal gland, and are surrounded by a fibrous tissue wall. Infectious cysts are most commonly caused by *Echinococcus*[5].

Adrenal pseudocysts are rare and account for 32% to 80% of all adrenal cysts[3,6-9]. Adrenal pseudocysts are often found incidentally on imaging studies or at the time of autopsy. The majority of adrenal pseudocysts are found because of their size-related symptoms[6-8]. Symptoms include gastrointestinal disturbance, early satiety, and a palpable abdominal mass. Patients can present with acute abdominal findings if intracystic hemorrhage or rupture occurs[10].

The etiology of adrenal pseudocysts is unknown; however, several mechanisms have been proposed to account for their occurrence, including cystic degeneration of a primary adrenal neoplasm, degeneration of a vascular neoplasm, and malformation and hemorrhage of adrenal veins into the adrenal gland[1-3,6,7,11]. The etiology of our patient's pseudocyst was indeterminate.

Due to the wide use of the diagnostic imaging modalities, the detection rate of adrenal cystic lesions is increasing. However, preoperative confirmatory diagnosis of a large adrenal cyst can be very difficult, because of the indistinct boundary with surrounding organs and adhesion to neighboring organs[12].

The differential diagnosis of adrenal pseudocysts includes splenic, hepatic, and renal cysts, as well as mesenteric or retroperitoneal cysts, urachal cysts, and

Figure 3 Placement of the laparoscopic trocar and operative ports. A 12-mm trocar was placed in the periumbilical region, and three other operating ports were placed in the abdomen (arrows). The photograph was taken eight months after surgery.

solid adrenal tumors[12,13]. Adrenal pseudocysts must be differentiated from other benign or malignant lesions originating from the adrenal gland or the kidney unilaterally[14-17]. In addition, an exact diagnosis is clinically important because an adrenal cyst > 6 cm carries an increased risk of adrenal malignancy. The reported incidence of malignancy in adrenal cystic lesions is approximately 7%[18,19].

Typically, radiological findings of adrenal cysts reveal thin walls filled with watery fluid and occasional calcifications[20,21]. Often, the inferior wall of the cyst is concave or flat, conforming to the shape of the upper pole of the renal contour.

On computed tomography scan, the present cyst could not be differentiated from a renal or adrenal lesion. The CT scan was not definitive, therefore an MRI was obtained. The adrenal gland was not visualized by the MRI scan and the cystic mass was thus considered to be of pancreatic rather than adrenal origin. The cystic mass could not be differentiated from a retroperitoneal mucinous cystic neoplasm. We chose the laparoscopic approach because of the time involved, the anticipated minimal blood loss, the acceptable rate of complications, and the excellent postoperative quality of life. There

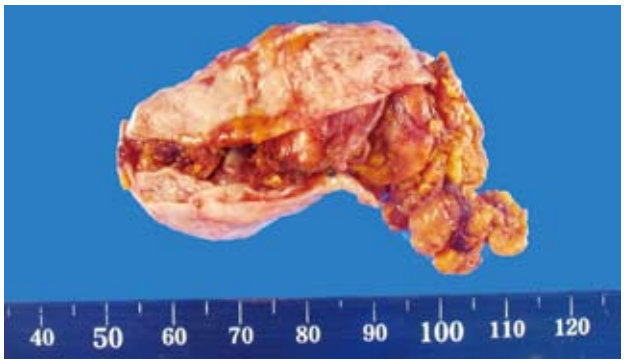

Figure 4 Gross appearance of the 6 cm × 3 cm × 3 cm adrenal cystic lesions. The cystic lesion adheres to adrenal gland tissue.

are few reports of a case of retroperitoneal mucinous cystadenomas treated by laparoscopic surgery[22-24].

During the laparoscopic procedure, we found that the cystic mass had arisen from the left adrenal gland, not the pancreas. We believed that this cystic mass was an adrenal cyst and removed it completely by laparoscopic surgery.

The choice of treatment for adrenal pseudocysts depends on several factors, including endocrine function, symptoms, size, and correct differentiation from an adrenal cyst.

Surgical excision is indicated in the presence of symptoms, suspicion of malignancy, an increase in size, the occurrence of complications, or detection of a functioning adrenal cyst, and can be managed by open surgery or a laparoscopic approach[12,25-27]. Kalady *et al*[28] recommended that adrenal cysts > 6 cm should be approached using an open procedure because of concerns about potential malignancy. In the case of giant pseudocysts, most authors prefer an open adrenalectomy, because the laparoscopic approach is not sufficient to control such large masses with active internal bleeding[29]. However, several reports demonstrate that laparoscopic adrenalectomy for large (> 6 cm) adrenal lesions is surgically feasible and can be applied for any adrenal disease, including benign and potentially malignant lesions[25,30-32].

This case was sufficiently instructive to point out that adrenal cystic lesions can be radiologically mistaken for renal cysts or cystic neoplasms.

This is a rare report of an adrenal pseudocyst mimicking a retroperitoneal mucinous cystic neoplasm, which was treated by laparoscopic resection. Although adrenal pseudocysts might be misdiagnosed as retroperitoneal mucinous cystic neoplasms, a laparoscopic approach to cystic lesions in the suprarenal area should be the initial choice.

Abstract

Severe acute hepatitis of unknown etiology is difficult to treat and often progresses to subacute fulminant hepatitis or late-onset hepatic failure. A 45-year-old well-nourished, healthy man had progressive fatigue and his liver function tests showed severe liver dysfunction. The etiology of sever acute cholestatic hepatitis was unknown. The liver function tests normalized gradually, which excluded high persistent total bilirubin after starting on predonine. A liver biopsy showed chronic active hepatitis with mild fibrosis (A2, F1). Oral Inchinko-to, a Chinese herbal medicine, at 7.5 g daily was prescribed. The treatment was effective with no adverse effects. We present a successfully treated case and discuss hepatoprotective and choleretic effects of Inchinko-to.

Key words: Acute cholestatic hepatitis; Etiology; Inchinko-to; Herbal medicine

INTRODUCTION

Treatment of severe acute hepatitis of unknown etiology is difficult, and the disease often progresses to subacute fulminant hepatitis or late-onset hepatic failure[1]. Several studies have reported on the effectiveness of Inchinko-to, a Chinese herbal medicine used to treat liver disorders and jaundice in Japan[2-5]. Successful treatment of acute hepatic failure of unknown etiology with Inchinko-to has been reported[6].

We treated a patient who suffered from severe acute cholestatic hepatitis of unknown etiology with Inchinko-to. The treatment was effective with no adverse effects. We report and discuss the case.

CASE REPORT

The patient was a 45-year-old man, who had fatigue, vomiting, slight fever, and noticed that his urine had been darker than usual for 1 mo before visiting the clinic. He began to suffer from severe fatigue and loss of appetite, and thus visited the clinic. On physical examination, his skin was dark yellow, without a palpable liver. Liver function tests revealed severe liver dysfunction (Table 1). He was a well-nourished, healthy man with a history of duodenal ulcer. He did not drink alcohol and had no history of blood or blood products transfusion or the use of any drugs, including herbal medicine. He was exposed to no known environmental hazards. His older brother had non-alcoholic steatohepatitis and underwent surgery for rectal carcinoma. Abdominal ultrasonography showed a severely swollen gallbladder and normal intra- and extrahepatic bile ducts; the liver shape and architecture were normal. Upper endoscopy showed an edematous narrowing at the post-bulbar portion of the duodenum and a duodenal ulcer scar in the duodenal bulb.

He was admitted to the hospital. Ursodeoxycholic acid (UDCA) was started at 600 mg daily. Tests for hepatitis A, B, C, and E viruses, Epstein-Barr virus and cytomegalovirus were all negative. Autoantibodies were negative, including anti-mitochondrial, smooth muscle, antinuclear, and perinuclear anti-neutrophil cytoplasmic antibody. Gamma globulin was within the normal limits. The hemolytic complement activity (CH50) was elevated slightly. Abdominal computed tomography showed a severely swollen gallbladder, normal intra- and extrahepatic bile ducts, and normal liver shape and architecture (Figure 1, top). Magnetic resonance imaging showed an edematous,

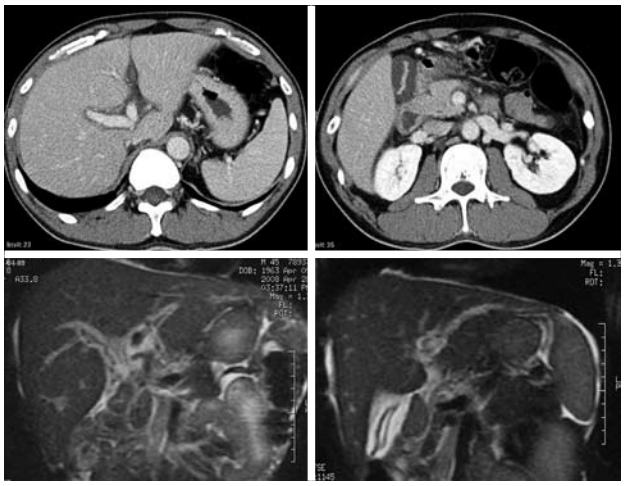

Figure 1 Abdominal CTs and MRIs on admission. Abdominal CTs showing normal liver shape and architecture, normal intra-and extrahepatic bile ducts, and a severely swollen gallbladder (top); MRIs showing a normal liver, bile duct, an edematous, thickened gallbladder wall, and periportal edema (bottom).

thickened gallbladder wall, periportal edema, slight ascites, and a normal liver, bile duct, and pancreatic duct (Figure 1, bottom). Based on these findings, the patient was diagnosed with severe acute cholestatic hepatitis of unknown etiology. The total bilirubin level continued to rise, and so the patient was started on predonine 20 mg daily on 7 May 2008. The serum aspartate aminotransferase, alanine aminotransferase, and lactate dehydrogenase levels normalized gradually, while the total bilirubin remained high. Oral Inchinko-to at 7.5 g daily was prescribed on 17 May 2008. He was weaned from predonine. Subsequently, the total bilirubin level began to decrease (Figure 2). A liver biopsy showed chronic active hepatitis with mild fibrosis (A2, F1).

The patient was discharged. He is currently well at 12 mo after UDCA and Inchinko-to treatment.

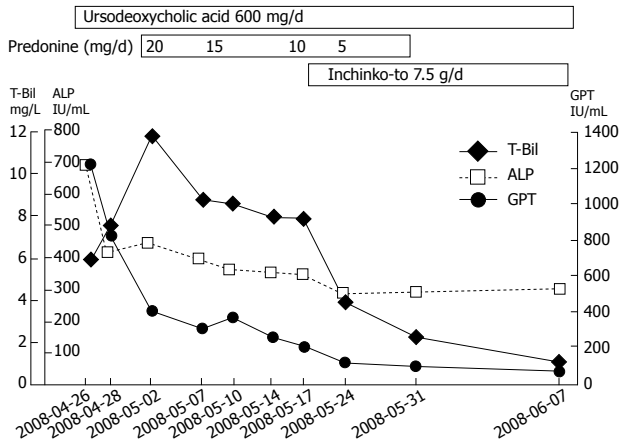

Figure 2 Clinical course of the patient.

DISCUSSION

Without evidence of a virus infection, autoimmune disease, alcohol or drug use, blood or blood products administration, and environmental hazards, the patient was considered to have severe acute cholestatic hepatitis of unknown etiology. Initially, predonine was prescribed for suspected autoimmune hepatitis with a high total bilirubin level[7]. The increasing total bilirubin was thought to suggest progression to subacute fulminant hepatitis[1]. Inchinko-to, a Chinese herbal medicine, has been used clinically for various liver diseases in Japan and China[2-5].

Recent experimental studies have clarified the molecular mechanism of hepatoprotective and choleretic effects of Inchinko-to and its ingredients, and have provided a good rationale for its clinical application to a wide variety of liver diseases, although there is no sound evidence with prospective randomized clinical studies[8-13]. The ingredients of Inchinko-to are genipin, 6,7-dimethylesculetin, capillin, capillene, and capillarisin[2,14,15]. Therefore, we decided to give Inchinko-to to our patient who suffered from severe acute cholestatic hepatitis of unknown etiology. The treatment was effective with no adverse effects.

The death of liver cells in hepatitis is thought to involve apoptosis[16]. Fas/FasL-mediated cytotoxicity is critical to hepatic injury, particularly fulminant hepatitis[17]. Genipin markedly suppressed liver apoptosis/injury in a lethal fulminant hepatitis model[9] and improved acute liver dysfunction by the suppression of tumor necrosis factor-α production[10]. In addition, capillin and capillene inhibit liver cell apoptosis induced by transforming growth factor[8].

Cholestasis results in hepatic and systemic accumulation of potentially toxic bile acids, resulting in liver damage and jaundice[18]. The altered expression of specific hepatocellular transport systems and profound changes in the cytoskeleton of the hepatocytes are associated with cholestatic liver disease[18]. In particular, the impairment of canalicular transport systems has a major role in the pathogenesis of acquired forms of intrahepatic cholestasis[18]. Inchinko-to exerts potent choleretic effects *via* a bile-acid-independent mechanism of multidrug-resistance-associated protein 2 mediation and glutathione content modulation[11-13] by genipin, and of constitutive

androstane receptor activation by 6,7-dimethylesculetin[12]. The marked reduction in bilirubin level after Inchinko-to administration in our case suggested that Inchinko-to and its ingredients stimulated and restored the impaired canalicular transport systems.

UDCA was also used in this case and it has been reported to be effective in cases of chronic liver disease[19] and prolonged cholestasis of acute hepatitis[20]. The therapeutic benefit of UDCA in the treatment of cholestasis may result from a combination of cytoprotective, antiapoptotic, immunomodulatory, and choleretic effects[21]. The choleretic effects of UDCA are medicated by up-regulation of canalicular transporter protein levels[22], and inhibit apoptosis by modulating mitochondrial function[23]. No apparent effect was observed on liver function tests in our case soon after the administration of UDCA. Therefore, the combination of Inchinko-to and UDCA possibly worked synergistically in improving the acute cholestatic hepatitis in this case.

Finally, our success in treating a patient with acute cholestatic hepatitis of unknown etiology supports a previous study[6], and suggests its efficacy in treating such liver disease. Our findings warrant a further clinical trial.

ACKNOWLEDGMENTS

We thank Associate Professor Hitoshi Takagi, Gunma University Graduate School of Medicine and Assistant Director Yoichi Kon, Gunma Cancer Center, Ota, Gunma, Japan, for helpful advice regarding the diagnosis and treatment.

Abstract

We report a case of hepatic angiomyolipoma with uncommon clinical features. A 56-year-old man presented with a hepatic tumor in the caudate lobe. The tumor was hypoechoic on ultrasonography, showed early-phase hyperattenuation on enhanced computed tomography and did not absorb iron on superparamagnetic iron oxide-enhanced magnetic resonance imaging. Hepatocellular carcinoma was highly suspected, and the patient underwent hepatic resection. Histologically, the tumor was mainly composed of smooth muscle cells and contained small amounts of adipose cells and blood vessels. On immunohistochemical staining, the smooth muscle cells were positive for a melanocytic cell-specific monoclonal antibody. In cases with uncommon features of angiomyolipoma, it is quite difficult to distinguish angiomyolipoma from hepatocellular carcinoma.

INTRODUCTION

Hepatic angiomyolipoma (HAML) was first reported by Ishak[1]. It is a rare benign tumor which is composed of a heterogeneous mixture of adipose cells, smooth muscle cells and vessels, and can be treated conservatively if spontaneous hemorrhage or malignant change does not occur[2-4]. The radiological features of HAML depend on the relative proportions of adipose cells[5]. For this reason, preoperative diagnosis of HAML is occasionally difficult, and it is not easy to differentiate from hepatocellular carcinoma (HCC). Herein, we report a case of HAML which was difficult to differentiate from HCC.

CASE REPORT

A 56-year-old Japanese man was admitted to our hospital for further examination of a liver tumor in the caudate lobe. He had no history of liver disease or hepatitis and did not drink heavily. Hepatitis B surface antigen and anti-hepatitis C antibody were negative. Serum levels of transaminase, α-fetoprotein and des-γ-carboxy prothrombin were within the normal range. On ultrasonography, the tumor was hypoechoic (Figure 1A). Enhanced computed tomography (CT) showed a hepatic mass with early-phase hyperattenuation and late-phase hypoattenuation, measuring 4.2 cm × 4.0 cm in the caudate lobe (Figure 1B and C). Magnetic resonance imaging (MRI) revealed hypointensity on T1-weighted images, hyperintensity on T2-weighted images and hyperintensity on diffusion weighted images (Figure 1D-F). The tumor did not absorb iron on superparamagnetic iron oxide-enhanced (SPIO) MRI

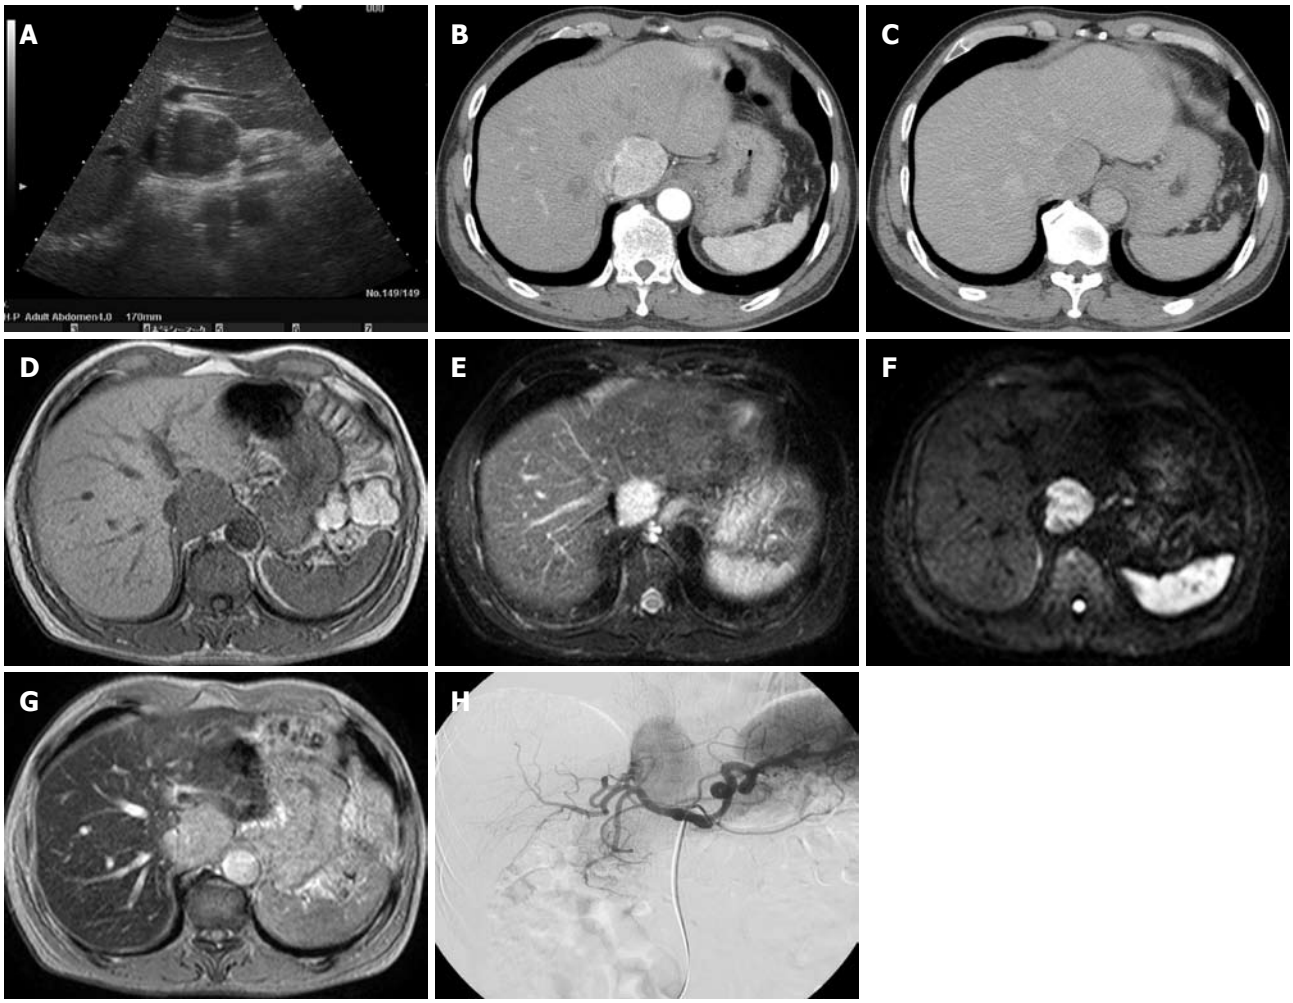

Figure 1 Images. A: The tumor was hypoechoic on ultrasonography, measuring 4.2 cm × 4.0 cm; B-C: Enhanced computed tomography showed a tumor with early-phase hyperattenuation and late-phase hypoattenuation; D-F: Magnetic resonance imaging showed a tumor with hypointensity on T1-weighted, hyperintensity on T2-weighted images and hyperintensity on diffusion weighted images; G: The tumor did not absorb iron on superparamagnetic iron oxide-enhanced MRI; H: On angiography, the tumor was shown as a circumscribed hypervascular mass.

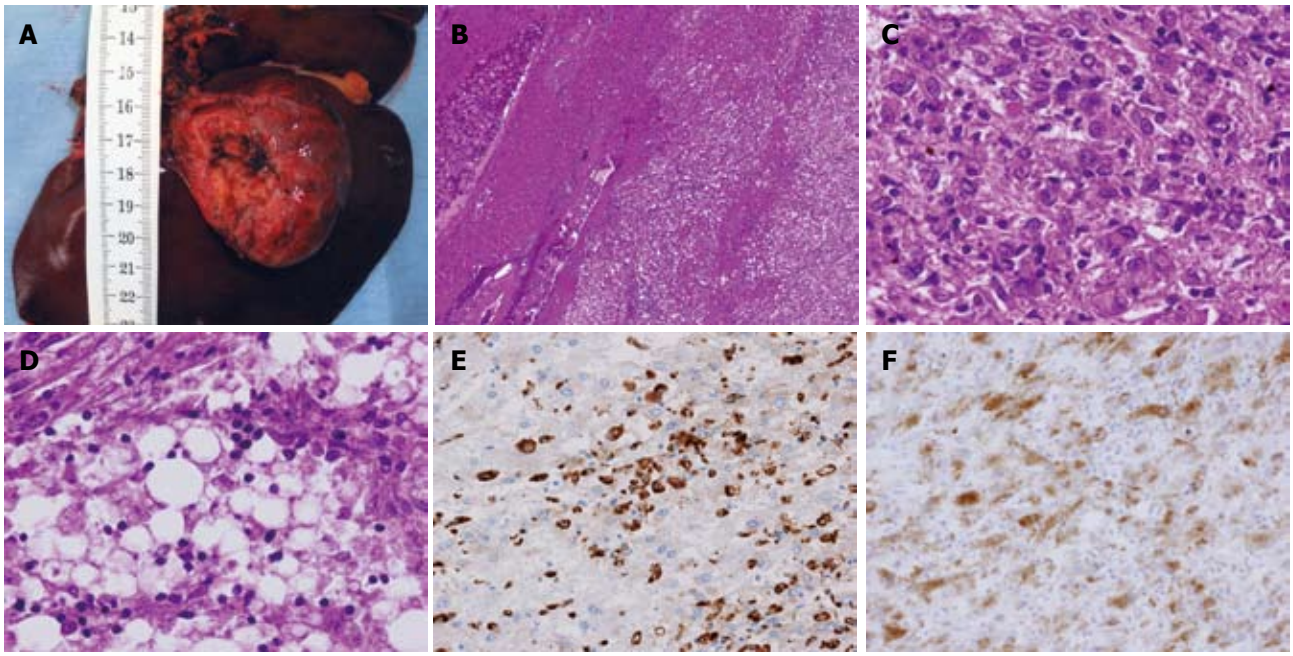

Figure 2 HAML. A: The tumor occupied a large area of the caudate lobe; B-D: The histological features of the tumor showed that it was mainly composed of smooth muscle cells (B: HE stain, × 4; C: HE stain, × 40) and a small number of adipose cells (D: HE stain, × 40); E, F: Immunohistochemically, the tumor was positive for CD68 (E: CD68, × 20), and HMB-45 (F: HMB-45, × 100).

(Figure 1G). On angiography, the tumor was shown as a circumscribed hypervascular mass (Figure 1H). HCC was highly suspected on radiological imaging. Resection of the left lobe with the tumor in the caudate lobe was performed. The tumor measured 6.0 cm in diameter, and the surface of the tumor was gray and white. Histologically, the tumor was mainly composed of smooth muscle cells and contained small amounts of adipose cells and blood vessels (Figure 2A-D). On immunohistochemical staining, the tumor was negative for desmin and S-100, but positive for actin and CD68, and the smooth muscle cells were positive for a melanocytic cell-specific monoclonal antibody (HMB-45) (Figure 2E and F). This tumor was diagnosed as HAML.

DISCUSSION

Recently, the concept of perivascular epithelioid cell tumor (PEComa) which was proposed by Bonetti et al in 1992 has gained wide acceptance[6]. PEComa is defined as a mesenchymal tumor composed of histologically and immunohistochemically distinctive perivascular epithelioid cells. Immunohistochemically, the tumors are consistently immunoreactive for HMB-45, a monoclonal antibody for melanoma. AML is considered a part of PEComa[7]. Smooth muscle cells of HAML stain positively for HMB-45. This finding is useful for the diagnosis of HAML, because liver tumors other than angiomyolipoma are negative for HMB-45[8].

In radiological diagnosis, HAML typically shows high echo on ultrasonography, early-phase hyperattenuation on enhanced computed tomography, hyperintensity on T2-weighted magnetic resonance imaging and a circumscribed hypervascular mass on angiography[9]. The soft tissue component (smooth muscle cells and vessels) is considered to be enhanced by the intravenous administration of contrast material[10]. However, the imaging features of HAML vary because of variations in the proportion of adipose cells, smooth muscle cells and vessels. In particular, the number of adipose cells varies between 10% and 90%[11]. HAML consisting of a small number of adipose cells shows low echo on ultrasonography and early-phase hyperattenuation on enhanced CT. These findings are similar to the imaging features of HCC[12]. On the other hand, there are no reports regarding the radiological features of SPIO MRI on HAML. SPIO contrast material, which is taken up by the reticuloendothelial system and depresses the signal of normal liver at T2-weighted imaging, is useful for the detection of hepatic tumors[13]. In our case, HAML was positive for CD68 stain, which is a Kupffer cell-related marker; however the signal at T2-weighted imaging on SPIO MRI was depressed similar to HCC. Thus, SPIO-MRI was not useful for differentiating HAML from HCC in our case.

HAML shows various histological patterns. According to the line of differentiation and the predominance of tissue components, the tumors are subcategorized into mixed, lipomatous ($\geqslant$ 70% fat), myomatous ($\leqslant$ 10% fat), and angiomatous types. The mixed type is the most common, but tumors with a small number of adipose cells such as the myomatous type, which are rare, show widely variable patterns in morphology[14]. In this study, we classified the HAML in our case as the myomatous type.

In conclusion, HAML is a benign tumor and requires no surgical treatment. However, the diagnosis is difficult because it has various histological patterns. In the myomatous type, the radiological findings including SPIO-MRO are similar to those of HCC. Hepatic tumors without obvious risk factors for HCC should be distinguished from HAML.

Abstract

AIM: To analyze the MEDLINE-indexed publications in gastroenterology specialty journals from 2001 to 2007. Special attention was paid to specific types of articles, the number of publications for individual authors and the author count in each journal.

METHODS: The bibliographic entries of papers belonging to journals listed under the subject heading of "gastroenterology" were downloaded from MEDLINE on the PubMed web site. The analysis was limited to journal articles published between January 1, 2001 and December 31, 2007. The analytical dimensions of an article included journal, publication year, publication type, and author name (the last name and initials).

RESULTS: According to MEDLINE, 81561 articles were published in 91 gastroenterology journals from 2001 to 2007. The number of articles increased from 9447 in 2001 to 13340 in 2007. Only 12 journals had more than 2000 articles indexed in MEDLINE. The "*World Journal of Gastroenterology*" had the largest number of publications (5684 articles), followed by "*Hepato-Gastroenterology*" (3036) and "*Gastrointestinal Endoscopy*" (3005). Of all the articles published, reviews accounted for 17.2% and case reports for 15.4%. Only 3739 randomized controlled trials (4.6% of all articles) were published and their annual number increased from 442 in 2001 to 572 in 2007. Among 141741 author names appearing in the articles of gastroenterology journals, 92429 had published only in one journal, 22585 in two journals, 9996 in three journals, and 16731 in more than three journals. The "*World Journal of Gastroenterology*" had the greatest number of authors (17838), followed by "*Gastroenterology*" (12770), "*Digestive Diseases and Sciences*" (11395), "*American Journal of Gastroenterology*" (10889), and "*Hepatology*" (10588).

CONCLUSION: Global gastroenterology publications displayed a continuous growth in the new millennium. The change was most striking in certain journals. Regular bibliometric analyses on the trends and specific topics would help researchers publish more efficiently and allow editors to adjust the policy more accurately.

INTRODUCTION

Gastroenterology is a highly competitive and productive field of medical research. Researchers in this field usually have a stronger need for bibliographic information than those in other fields. In the past few years, several bibliometric researches have been devoted to the global research trend[1], the research output in specific regions[2,3] and countries[4-6], and the share of author origins in specific journals[7-9] in gastroenterology. However, there still seemed to be a lack of a comparative overview of all gastroenterology specialty journals in the world.

The aim of the current study was to analyze the publications in gastroenterology journals in the new millennium, based on MEDLINE which is freely offered over the internet by the National Library of Medicine in the United States of America. Special attention was paid to specific types of articles, e.g. randomized controlled trials. Because researchers might not publish solely in

one journal during a period of several years, a new analytical method was also proposed to calculate the share of authors publishing in only one journal among all authors in each journal. This new indicator may serve as another dimension to author origins in a journal.

MATERIALS AND METHODS

Journal selection and data sources

The specialty journals of gastroenterology were limited to those listed under the subject heading of "gastroenterology" in MEDLINE. The master file of journals in MEDLINE was first downloaded (ftp://ftp.nlm.nih.gov/online/journals/lsi2008.xml, accessed on September 8, 2008) and a total of 141 gastroenterology journals were identified. Due to cessation of publication and name changes, not all journals were still available.

The bibliographic entries of papers belonging to selected journals were downloaded from MEDLINE on the PubMed web site (http://www.ncbi.nlm.nih.gov/sites/entrez/, accessed on September 8, 2008). The downloading consisted of journals with a Perl script. The retrieval was limited to papers published since 2001. The format type of the retrieval was MEDLINE.

Study design

One bibliographic record with the MEDLINE format contains pairs of tags and data, e.g. PMID-14647050 and AU-Lee SD, where PMID (PubMed unique identifier) and AU (author) are tags. Some types of tags, e.g. AU, PT (publication type) and MH (medical subject headings term), might appear more than once in one record. Some types of tags are not obligatory and might not be present in every record.

The downloaded datasets with MEDLINE format were merged and transformed into one single file with the structure of entity-attribute-value (EAV)[10] for further efficient processing, where entity stood for the PMID of a paper, attribute for the tag, and value for the data. For example, the pair "AU-Lee SD" in the paper of "PMID-14647050" would be converted into "14647050 [tab] AU [tab] Lee SD".

From the EAV file, the numbers of papers in each journal during the years of coverage were first calculated. The processing was limited to papers categorized as "journal article" in the publication type field. In addition, only papers published between January 1, 2001 and December 31, 2007 were included in this analysis.

The articles were also counted according to their publication type. An article might not contain only one publication type. For articles with the publication type of randomized controlled trial, their distribution in journals over the years was computed.

In computing the productivity of individual researchers in all gastroenterology journals, the methods of "total author counting"[11] was adopted. Each author of an article was recognized as having written one article, and then the number of articles authored or coauthored by each researcher during the 7-year period was counted.

Because an author's full name has been indexed in MEDLINE since 2002 and one fifth of the original publications did not contain the full author name[12], authors in the current study were identified according to the conventional author indexing of MEDLINE, i.e. last name, up to two initials of first and middle names, and/or a suffix abbreviation. Different authors with the same last name and initials would not be specifically differentiated in aggregate statistics. However, the name ambiguity would be considered in listing the most prolific authors.

For each journal, the total number of authors who had published in the journal during the 7-year period was calculated as the denominator and then the number of authors who had never published in other gastroenterology journals during the 7-year period was computed as the numerator. The fractional number for each journal might suggest the breadth of author origins.

Statistical analysis

The programming scripts with Perl version 5.10.0 (http://www.perl.com/) were written for downloading and computing. As a popular computer language since the internet era, Perl belongs to the open source software and can be freely downloaded and distributed for use. The National Library of Medicine also provides examples of Perl scripts for use of Entrez programming utilities from PubMed.

Only descriptive statistics, frequency in count and percentage, were displayed.

RESULTS

According to MEDLINE, 81 561 articles were published in 91 gastroenterology journals from 2001 to 2007 (Table 1). The number of articles increased from 9447 in 2001 to 13 340 in 2007. The "*World Journal of Gastroenterology*" had the largest number of publications (5684 articles), followed by "*Hepato-Gastroenterology*" (3036) and "*Gastrointestinal Endoscopy*" (3005). Only 12 journals had more than 2000 articles indexed in MEDLINE. By comparing the situations in 2001 and in 2007, the "*World Journal of Gastroenterology*" had the highest growth rate of publications (5.0-fold increase), followed by "*BMC Gastroenterology*" (2.3-fold), "*Revista de Gastroenterologia de Mexico*" (2.2-fold), "*International Journal of Colorectal Disease*" (2.0-fold), and "*Inflammatory Bowel Diseases*" (2.0-fold). The highest absolute growth was also claimed by "*World Journal of Gastroenterology*" (867 more articles), followed by "*Journal of Gastroenterology and Hepatology*" (208), "*Zhonghua Ganzangbing Zazhi* (*Chinese Journal of Hepatology*)" (200), and "*Digestive Diseases and Sciences*" (180). In contrast, 21 journals had fewer publications in 2007 than in 2001.

As to the publication type of these articles, reviews accounted for 17.2% (14 005 articles) of all articles from 2001 to 2007 and case reports 15.4% (12 539) (Table 2). There were only 3739 randomized controlled trials (4.6% of all articles) among 4627 clinical trials (5.7%). The annual number of randomized controlled trials increased from 442 in 2001 to 572 in 2007. Randomized controlled trials were most frequently published in "*Alimentary Pharmacology & Therapeutics*" (536 articles), followed by

"*American Journal of Gastroenterology*" (278), "*Gastrointestinal Endoscopy*" (186), "*Surgical Endoscopy*" (183), "*World Journal of Gastroenterology*" (176), and "*Gastroenterology*" (171). Among these journals, the "*World Journal of Gastroenterology*" had the greatest increase in randomized controlled trials: from 5 in 2001 to 34 in 2007 (detailed data not shown in tables).

If only the last name and initials of the authors were considered, 141 741 author names appeared in the articles of gastroenterology journals from 2001 to 2007. The "*World Journal of Gastroenterology*" had the greatest number of authors (17 838), followed by "*Gastroenterology*" (12 770), "*Digestive Diseases and Sciences*" (11 395), "*American Journal of Gastroenterology*" (10 889), and "*Hepatology*" (10 588) (Table 2). Among all authors, 82 174 had published only one article, 22 192 two articles, 10 672 three articles, and 26 703 more than three articles. On the other hand, 92 429 authors had published only in one journal, 22 585 in two journals, 9996 in three journals, and 16 731 in more than three journals. The share of authors publishing only in one journal among all authors of the journal was generally higher in journals with apparently narrower research fields or locality, e.g. "*Eksperimental'naia i Klinicheskaia Gastroenterologiia* (*Experimental & Clinical Gastroenterology*)" (95.5%), "*Revista de Gastroenterologia del Peru*" (84.0%), "*Eating and Weight Disorders*" (81.0%), "*Revista de Gastroenterologia de Mexico*" (79.4%), and "*Journal of Health, Population, and Nutrition*" (78.0%) (Table 2).

The top 10 prolific researchers in these gastroenterology journals are listed in Table 3. They were from seven institutions in six countries: three in the USA, four in Europe, and three in Asia. Only two of the top-ranked researchers were surgeons (Masatoshi Makuuchi and Markus W Buchler).

DISCUSSION

The current study demonstrated the most recent trend in publications from gastroenterology specialty journals worldwide. Gastroenterology publications have continued to prosper in the new millennium, not merely due to the expanded coverage of MEDLINE or the growth of a single journal. The number of randomized controlled trials has also increased, but their growth rate has slightly lagged behind that of other articles. Numerous researchers participated in gastroenterology publications; a substantial number of the authors were active in research and had multiple publications. Gastroenterology journals thus showed diverse authorships in which many authors of a journal also published in other specialty journals.

The current study chose MEDLINE as the data source because of its open access and international visibility. To compare the "quality" of scientific publications, people have adopted the controversial citation statistics and "impact factor" in recent years. Because the quantity of citations has increased tremendously and the databank of citations is not freely open to the public, the monopolized data from the black box cannot be extensively verified. Normally, most researchers just need a quick orientation in the field of interest, e.g. the features of journals, the most prolific authors or facilities, or the hottest subjects. Such requests can be easily satisfied by free MEDLINE after processing, without resorting to commercial databases which most individual researchers around the world can hardly afford.

Despite collective growth since 2001, the increases and decreases in individual gastroenterology journals could be observed. Among all journals, the "*World Journal of Gastroenterology*" was most striking. Not only had it published the greatest number of articles since 2003, but it had also attracted the most authors. Along with quantitative growth, the "*World Journal of Gastroenterology*" also had more randomized controlled trials. According to an earlier bibliometric analysis on the "*World Journal of Gastroenterology*", the author origins of the Journal had become more diverse by geographic distribution since 2003. From the analysis in the current study, the majority

of authors in the "*World Journal of Gastroenterology*" did not only publish in this Journal during the study period. Both of these facts indicated that the "*World Journal of Gastroenterology*" had established its position in international gastroenterology publications.

The global research community has frequent fervent disputes about the quality of journal articles[13]. There appears to be a growing discontent about the misuse of the impact factor in hiring, promoting and grant-awarding. Researchers usually consider several factors when choosing a journal to publish their research results. A research article should be judged by its content, and not merely by the journal in which it was published. That is, the impact of an individual article should not be evaluated by the journal impact factor. The function of the academic journal as an effective platform for scientific communication can never be overestimated. Time will show which editorial team acts best.

The major limitation in the current study was the separation of distinct authors. The ambiguity of author names is an unresolved problem of bibliometric research[14]. Although MEDLINE started to index full author names in 2002, the problem still remains. Not every journal print author names in full. Besides, not every author spells their forename consistently in different articles. For example, Buchler MW appeared as Markus W Buchler, Markus-W Buchler, and Markus Wolfgang Buchler. Most cases of ambiguity existed in authors of East Asian origin. Because of homonymous features in Chinese/Japanese/Korean characters, a lot of distinct authors might share the same full name spelled in Latin letters. Therefore, the share of exclusive authors (never publishing in other journals) in each journal in the current study represented only the lowest estimate.

In conclusion, global gastroenterology publications demonstrated a continuous growth in the new millennium. The change was most striking in certain journals. Regular bibliometric analyses on the trends and specific topics would help researchers publish more efficiently and allow editors to adjust the policy more accurately.

ACKNOWLEDGMENTS

The author thanks Professor Tzeng-Ji Chen for his professional advice.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Articles: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; (13) Guidelines: To introduce Consensuses and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice in gastroenterology and hepatology.

The WJG Press and Baishideng

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials. gov sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words). Available from:http://www.wjgnet.com/wjg/help/8.doc

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/14.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc*.
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.
Biology: *H pylori*, *E coli*, *etc*.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office
World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/10.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/9.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

INTRODUCTION

World Journal of Gastroenterology is an international, open-access, peer-reviewed, and multidisciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

Abstract

Acute pancreatitis is an acute inflammatory disease of the pancreas which can lead to a systemic inflammatory response syndrome with significant morbidity and mortality in 20% of patients. Gallstones and alcohol consumption are the most frequent causes of pancreatitis in adults. The treatment of mild acute pancreatitis is conservative and supportive; however severe episodes characterized by necrosis of the pancreatic tissue may require surgical intervention. Advanced understanding of the pathology, and increased interest in assessment of disease severity are the cornerstones of future management strategies of this complex and heterogeneous disease in the 21st century.

Key words: Acute necrotizing pancreatitis; Systemic inflammatory response syndrome; Surgery; Pancreatectomy; Minimal surgical procedures

INTRODUCTION

The death of Alexander the Great (356-323 BC) at the age of 33 has been ascribed to acute necrotizing pancreatitis secondary to rich food and heavy alcohol consumption[1].

In 1856, the great French physiologist Claude Bernard (1813-1878) demonstrated the capacity of pancreatic secretions to digest proteins, carbohydrate and fat[2]. However, the first review on acute pancreatitis (AP) was published by Reginald Huber Fitz (1843-1913) in 1889[3]. In his observation of 53 patients with clinical signs of AP, he believed that the disease was a complication of gastroduodenitis causing inflammation of the biliary duct.

Nevertheless, only in late 19th century did Chiari propose pancreatic autodigestion as the main pathological mechanism of the disease[4]. This theory facilitated the understanding of the late 19th and early 20th century clinicians in the pathophysiology of AP. In 1901, Eugen Opie proposed the "common channel hypothesis", which was based on the assumption that a gallstone lodged in the ampulla could occlude both the common bile duct (CBD) and the pancreatic duct. The obstruction caused the formation of a common channel that would allow reflux of bile into the pancreatic duct with activation of pancreatic enzymes and pancreatitis[5,6].

The pathophysiology and treatment of AP has been intensely studied during the last century and our aim is to review recent evidence and achievements in the diagnosis and treatment of this serious condition at the beginning of the 21st century.

EPIDEMIOLOGY

AP is a growing problem in Europe, posing significant medical, surgical and financial sequelae[7]. A recent systematic review presented trends in incidence of the first attack of AP using data from 12 longitudinal studies[8]. The mean age of the first attack was in the 6th decade. This outcome can be explained by an increasing

incidence of gallstone pancreatitis among white women over the age of 60 years[9,10]. The most common causes were gallstones (11%-56%), idiopathic (8%-44%) and alcohol (3%-66%). However, occult microlithiasis is probably responsible for most cases of idiopathic AP[11].

Gallstone AP was found to be more common in female subjects, alcohol pancreatitis more common amongst men and idiopathic pancreatitis similar in both sexes.

The incidence of AP has been reported to be markedly increasing[8,12,13]. The explanation of this increased incidence could be explained by the routine testing of pancreatic enzymes in patients presenting with abdominal pain at emergency departments, and in over-diagnosis in cases of non-specific increases in enzymes due to other causes. Another explanation is an increase in the incidence of gallstone disease and obesity in the population.

Although fatalities associated with AP have decreased over time from 15%-20% to below 5%, the population mortality rate has remained unchanged with increasing age associated with higher mortality[14-16]. A correlation with duration of disease was also shown with 65% of the deaths occurring in the first 14 d and 80% within 30 d[17].

Overall, severe AP (SAP) occurs in 10%-20% of patients and despite improvements in critical care between 10% and 25% of patients with SAP die[18,19].

PATHOPHYSIOLOGY

The pathogenesis of AP is caused by an inappropriate activation of trypsinogen to trypsin. Once activated these enzymes are responsible of autodigestion of pancreatic tissues resulting in necrosis of the acini and pancreatic islets with interstitial fat necrosis and necrotizing vasculitis[20].

These pathological changes in the pancreatic gland are responsible for releasing active pancreatic enzymes into the bloodstream and stimulating the production of inflammatory cytokines such as interleukin-1, interleukin-6 and interleukin-8 from neutrophils, macrophages and lymphocytes. The release of those interleukins and tumor necrosis factor-α (TNF-α) from macrophages triggers an inflammatory cascade which leads to the systemic inflammatory response syndrome (SIRS)[21]. SIRS may develop into acute respiratory distress syndrome or multiorgan dysfunction syndrome. This systemic inflammatory response to pancreatic injury marks the "first or early phase" of the natural course of SAP, which normally characterizes the first 14 d of the disease[21,22]. In this phase, organ failure is common and often is not associated with infection[23]. The "second or late phase" which starts 14 d after the onset of the disease, is marked by infection of the gland, necrosis and septic systemic complications causing a significant increase in mortality[24]. Infection of the necrotic pancreas occurs in the 8% to 12% of the patients with AP and in 30% to 40% of patients with necrotizing pancreatitis, and it is considered the most important risk factor of necrotic pancreatitis[25,26].

DIAGNOSIS

Abdominal pain together with elevation of plasma levels of pancreatic enzymes is the cornerstone of diagnosis. The pain normally is generalized in the upper abdomen and occurs suddenly without a prodrome. The pain, which tends to last a few days, is often radiated in a bandlike manner to the lower thoracic region of the back. Nausea and vomiting normally appear in about 90% of patients and can be severe. Physical signs of severe disease such as ecchymoses in the flank (Gray-Turner's sign) or in the periumbilical region (Cullen sign) occurs in less than 3% of patients, and have been associated with a mortality of 37%[27]. Pancreatic enzymes are released into the circulation during an acute attack. Levels peak early, and decline over 3-4 d. As a consequence, the diagnosis should not rely on arbitrary levels 3 or 4 times greater than normal, but levels should be interpreted in light of the time since the onset of abdominal pain.

Enzymes released by acinar cells during an attack of AP are amylase and lipase, and their concentration in the serum is used to confirm the diagnosis[28]. The half-life of elevated amylase is shorter than that of lipase: the diagnosis using plasma lipase has slightly superior sensitivity and specificity and greater overall accuracy than amylase.

There are more specific tests in detection of AP, such as urinary trypsinogen activation peptide (TAP), serum and urinary trypsinogen[29-32], but these are less widely available.

Other laboratory tests can exclude metabolic causes such as hypercalcemia and lipid disorders.

AETIOLOGY

In order to optimize the instant management and prevent recurrence of AP it is essential identify the aetiology.

In the Western world, biliary tract disease (38%) and alcoholism (36%) are accountable for the majority of cases of AP[33]. However, in up to 10% of cases, the cause of AP remains unknown (idiopathic AP).

Gallstones

In patients with no history of alcohol consumption, an increased level of serum alanine aminotransferase up to 3 times its normal value is indicative of gallstone pancreatitis.

Gallstone pancreatitis, in most cases, is caused by gallstones passing into the bile duct and temporarily lodging at the sphincter of Oddi. However, duct obstruction can also be localized in the pancreatic duct. Although not completely proven, it is thought that duct obstruction leads to increased pancreatic duct pressure with subsequence injury to acinar cells and activation of digestive enzymes. It is supposed that only gallstones with a diameter up to 5 mm can migrate distally into the biliary duct whilst gallstones with a diameter of 8 mm or more remain in the gallbladder[34].

However, a biliary aetiology should not be excluded when liver function tests are normal since 15%-20% of patients with biliary AP can have normal concentrations of hepatic enzymes[35].

In cases where a biliary aetiology is suspected, the first line of investigation should be a trans-abdominal ultrasound (T-A US). The value of US lies in its ability to demonstrate gallbladder stones and dilatation of the CBD as well as other pathology unrelated to the pancreas. In the case of high clinical suspicion of a biliary cause of AP with normal T-A US, magnetic resonance cholangiopancreatography or endoscopic US should be performed in order to visualize the presence of microlithiasis or other causes of duct obstruction.

Alcohol

Alcohol consumption is the second cause of AP. Although the acinar cell is considered the main target of damage by ethanol, there is not an accepted explanation for why some patients are more predisposed to developing AP than others who consume similar quantities of alcohol. The pathogenesis of alcohol pancreatitis can be explained by a combination of environmental and genetic factors. Genetic studies have suggested that, in hereditary pancreatitis, mutation of the cationic trypsinogen gene and serine peptidase inhibitor, Kazal type 1 (SPINK1) genes can promote AP in the presence of alcohol[36].

Post-ERCP acute pancreatitis

The risk of developing AP after endoscopic retrograde cholangiopancreatography (ERCP) is around 5%[37]. The main risk factors for post-ERCP AP include female gender, presence of periampullary diverticulum, and procedure-related factors such as a cannulation time of more than 10 min and major papilla sphincterotomy. However, the risk of developing asymptomatic hyperamylasemia, which appears in 35%-70% of patients, seems to be linked with procedure-related factors[38].

Trauma

Abdominal trauma causes an elevation of amylase and lipase levels in 17% of cases and clinical AP in 5% of cases. Pancreatic injury occurs more often in penetrating injuries (e.g. from knives, bullets) than in blunt abdominal trauma (e.g. from steering wheels, horses, bicycles). Blunt injury may crush the gland across the spine, leading to a ductal injury in that location[39].

Drug-induced pancreatitis

Drug-induced pancreatitis is considered a rare event (0.1%-2%) and is normally mild and self-limiting. In the literature, the true incidence of drug-induced AP is not known since the evidence is derived mainly from case reports and the diagnosis is always challenging because of the difficulty in distinguishing the effects of drugs from other causes of AP[40].

Drugs strongly associated with AP include azathioprine, sulfonamides, sulindac, tetracycline, valproic acid, didanosine, methyldopa, estrogens, furosemide, 6-mercaptopurine, pentamidine, 5-aminosalicylic acid compounds, corticosteroids, and octreotide.

Infections

Infections are accountable for less than 1% of all AP and tend to be milder than biliary and alcohol-induced AP[41]. Viral infections such as Epstein-Barr, coxsackie virus, echovirus, varicella-zoster and measles are the most common causes of infectious AP especially in children.

Bacterial causes include *Mycoplasma pneumoniae*, *Salmonella typhosa*, *Leptospira*, *Campylobacter* and *Mycobacterium tuberculosis*.

Worldwide, ascariasis can cause AP by migration of worms in and out of the duodenal papillae.

Hereditary pancreatitis

Hereditary pancreatitis is an autosomal dominant gain-of-function disorder related to mutations of the cationic trypsinogen gene (*PRSS1*), which has an 80% penetrance. Mutations in this gene cause premature conversion of trypsinogen to active trypsin causing pancreatic autodigestion. This genetic syndrome is associated with a high risk of developing chronic pancreatitis at a young age and of developing pancreatic cancer[42].

Mutations in the SPINK1 gene, which blocks the active binding site of trypsin, rendering it inactive, are associated with acute and chronic pancreatitis. Patients who have severe SPINK1 mutations normally develop chronic pancreatitis in childhood[43].

In patients with mild CFTR gene mutations, an increased risk of developing acute and chronic pancreatitis has been observed in comparison with the general population.

Hypercalcemia

Hypercalcemia and primary hyperparathyroidism can lead to AP. Hypercalcemia, which causes less than 1% of all cases of pancreatitis, normally appears with excessive doses of vitamin D, familial hypocalciuric hypercalcemia and total parenteral nutrition.

Hypertriglyceridemia

AP usually does not occur until serum triglyceride levels reach 1000 mg/dL. Hypertriglyceridemia causes about 2% of AP and it is normally associated with type I , Type Ⅱ and Type V hyperlipidemia. The triglyceride level should be measured as soon as clinical presentation of AP appears since this level tends to decline during hospitalization because of fasting and Ⅳ fluid resuscitation.

Acquired hypertriglyceridemia can appear in adults because of alcoholism, obesity and poorly controlled diabetes mellitus.

In order to prevent recurrent attacks of AP, the patient should be placed on a low-fat diet, a regular exercise regimen, and tight control of diabetes, with use of lipid-lowering drugs such as statins.

Developmental abnormalities of the pancreas

The pancreas develops from two buds stemming from the alimentary tract of the developing embryo.

Pancreas divisum is a failure of the dorsal and ventral pancreatic ducts to fuse during embryogenesis and it occurs in about 5%-7% of the healthy population. Pancreatitis appears only in 5% of patients with pancreas divisum and it is thought to be the result of ductal hypertension caused

Table 1 Ranson's criteria for prediction of severity of acute pancreatitis

On admission	During initial 48 h
Age > 55 yr	Hemoglobin falls below 10 mg/dL
White cell count < 16×10^9/L	Blood urea nitrogen increases by > 5 mg/dL
Lactate dehydrogenase > 350 U/L	Calcium < 8 mg/dL
Aspartate aminotransferase > 250 U/L	PaO_2 < 60 mmHg (8 kPa)
Glucose > 200 mg/dL	Base deficit > 4 mEq/L
	Fluid sequestration > 6 L

PaO_2: Arterial partial pressure of oxygen.

Table 2 Glasgow (Imrie) severity scoring system for acute pancreatitis

Age > 55 yr
White cell count > 15×10^9/L
PaO_2 < 60 mmHg (8 kPa)
Serum lactate dehydrogenase > 600 U/L
Serum aspartate aminotransferase > 200 U/L
Serum albumin < 32 g/L
Serum calcium < 2 mmol/L
Serum glucose > 10 mmol/L
Serum urea > 16 mmol/L

by a narrow duct at its papillary origin.

Sphincter of Oddi dysfunction (SOD) is suspected clinically by recurrent episodes of epigastric or right upper quadrant pain that last 30 min or longer and that are not relieved by bowel movements or by antiacids[44]. SOD can lead to AP by causing increased pancreatic ductal pressure. However, SOD is a controversial cause of AP especially in patients without elevated sphincter pressures on manometry.

Tumor

Obstruction of the pancreatic ductal system by a tumor can increase the intraduct pressure and causing AP in proximately 14% of patients suffering from pancreatic tumors.

Pancreatic ductal carcinoma, ampullary carcinoma, islet cell tumor, solid pseudotumor of the pancreas, sarcoma, lymphoma, cholangiocarcinoma, or metastatic tumor can cause AP.

In addition, a pancreatic cystic neoplasm, such as intraductal papillary-mucinous neoplasm (IPMN), mucinous cystadenoma, or serous cystadenoma, can also cause AP[45].

Postoperative

AP may occur in the postoperative period of various surgical procedures. The mechanism of this pancreatitis includes transient intraoperative hypotension or pancreatic trauma by intraoperative manipulation. Postoperative AP is often a difficult diagnosis to confirm, and it has a higher complication rate than pancreatitis associated with other etiologies.

Autoimmune pancreatitis

This relatively newly described entity is an extremely rare cause of AP. The diagnosis of autoimmune pancreatitis has to be confirmed by specific radiological and histological findings. Radiologically, there is a focal mass in the pancreatic head on computed tomography (CT) scan and irregular narrowing of the proximal pancreatic duct on ERCP.

Patients normally have an elevated Ig G4 level in the serum and infiltration of IgG4-containing plasma cells in the pancreas. It normally occurs in young people who also suffer from inflammatory bowel disease, primary sclerosing cholangitis, primary biliary cirrhosis and Sjogren's syndrome. The therapy of choice is based on steroids.

PREDICTION OF SEVERITY

Although, the majority of patients have a mild episode of AP, it is difficult to identify the patients who are at risk of developing severe disease on admission to the hospital.

There is agreement that there is still a need for an early objective measure of severity. Clinical examination in the first 24 h of admission although specific, lacks sensitivity and hence is unreliable and should be supported by objective measures[46].

Although there is no ideal single serum marker for predicting severity, C-reactive protein (cut-off of 150 mg/L) is a useful indicator of necrosis with a sensitivity and specificity of 80% but is required to be measured more than 48 h after the onset of symptoms[47-49].

Different markers of severity shown to be useful on admission are serum procalcitonin and urinary TAP and trypsinogen-2[50], serum interleukins-6 and -8 and polymorphonuclear elastase at 24 h after admission[51].

The severity of the inflammatory response to pancreatic injury and the presence of organ failure are normally assessed by scoring systems. Multi-factorial scoring systems based on clinical and laboratory findings such as the Ranson's score, Glasgow Score and the Acute Physiology and Chronic Health Evaluation Ⅱ (APACHE Ⅱ) are considered accurate predictors of the severity of AP[52,53].

In 1974, John Ranson selected 11 prognostic signs based on statistical analysis of 43 parameters gathered retrospectively from 450 AP patients. Five of these criteria are measured on admission and the remaining 11 are measured 48 h post admission (Table 1).

The Glasgow severity scoring system considered 9 variables and can be applied from admission although it is not complete for 48 h[54] (Table 2).

Developed in 1985, the APACHE Ⅱ score has been used to predict severity in AP patients[55]. APACHE Ⅱ measures 12 physiological variables and additional points are added based on patient age and on severe baseline chronic diseases. Measuring APACHE Ⅱ score daily can allow an assessment of progression of the disease[56].

Other markers should also be considered such as body mass index (BMI) since obesity has been shown to increase

Table 3 Modified multiple organ dysfunction score

Organ system involved	Score				
	1	2	3	4	5
Cardiovascular PAHR (beats/min)	⩽ 10	10-15	30-15	20-30	> 30
Respiratory PaO_2/FiO_2 (mmHg)	> 300	300-225	150-225	75-150	< 75
Renal creatinine (μmol/L)	< 100	100-200	200-350	350-500	> 500
Neurological glasgow coma score	15	14-13	12-10	9-7	⩽ 6

Hepatic bilirubin (μmol/L)	< 20	20-60	60-120	120-240	> 240

PAHR: Pressure-adjusted heart rate [heart rate × (right atrial pressure/mean arterial pressure]; FiO_2: Fraction of inspired oxygen.

the risk of systemic complications and mortality[57]. This has led to a modification of the APACHE II scoring system which includes up to 2 points for obesity[58]. This system is called APACHE-O and although Johnson and colleagues have reported its superiority in predicting outcomes, other authors have not confirmed these results[59].

Although these scoring systems can help the physician in a first assessment of the patient, the most important distinction in terms of prediction of severity is the presence of severe manifestations of the disease such as evidence of SIRS and presence of organ failure.

Mofidi, in a recent retrospective study of 259 patients admitted with AP, showed that the mortality rate was significantly higher in patients who developed or had persistent SIRS at 48 h after admission (25.4%) than in patients who had transient SIRS (8%) or no SIRS in the first 48 h (0.7%)[60].

Therefore, immediate assessment should include clinical evaluation particularly of any cardiovascular, respiratory and renal compromise, BMI, chest X-ray and different acute diseases scores. The presence of any single and/or multiple organ failure has been increasingly recognized as an important variable for predicting mortality from AP. The most common organ dysfunction scores used for critically ill patients are the Multiple Organ Dysfunction Score (MODS) and the Sequential Organ Failure Assessment (SOFA)[61,62] (Tables 3 and 4).

Since the SOFA score uses the mean arterial pressure and therapeutic interventions with vasopressors, its outcome prediction for cardiovascular dysfunction is considered better than the MODS[63].

Since the mortality in the presence of pancreatic necrosis increases from 1% to 10%-23%, the importance of early detection of pancreatic necrosis is not to be overlooked[64]. Contrast-enhanced CT has been considered the "gold standard" for the diagnosis of pancreatic necrosis[65,66].

However, it is not clear how soon the full extent of the necrotic process occurs, but it is at least 4 d after onset of the symptoms, and early CT may therefore underestimate the final severity of the disease. Finally, unless some management decision is required based on the extent of necrosis (for example use of prophylactic antibiotics), CT for staging is unlikely to materially affect the management of patients with AP during the first week of the illness. If CT staging of AP is required, the CT severity index (CTSI) as proposed by Balthazar should be used (Table 5). Recent studies demonstrated that AP patients with a CTSI higher than 5 had 8 times higher mortality. Moreover, they were 17 times more likely to have a prolonged hospital course and were 10 times more likely to require necrosectomy than their counterparts with CT scores < 5[67]. There is also evidence that the site of pancreatic necrosis is an important prognostic factor with a worse outcome observed in patients with necrosis affecting the head of the pancreas[68]. The finding of free intraperitoneal fluid and extensive peri-pancreatic fat stranding have also been demonstrated to be associated with worse outcomes.

Although CT is useful in detecting pancreatic necrosis, it is not able to detect a super-infection of necrosis in the later stage of the disease unless gas bubbles are seen within the necrotic area[69].

Patients with persisting organ failure, or in whom new organ failure develops, and in those with persisting pain and signs of sepsis, will require evaluation by dynamic contrast enhanced CT. CT evidence of necrosis correlates well with the risk of other local and systemic complications.

Since pancreatic necrosis commonly remains stable in appearance, a follow-up CT scan at 3 to 4 wk is not normally considered[70].

MANAGEMENT OF MILD AP

In most cases AP is mild and its initial management is directed towards maintenance of adequate organ perfusion in order to reduce the systemic complications caused by the pancreatic injury. This consists of fluid resuscitation, analgesia, oxygen administration, antiemetics and repeated evaluation of the patient's vital signs with the intention of identifying early manifestations of organ dysfunction.

Since fluid loss in mild pancreatitis can be significant, appropriate fluid resuscitation is a crucial part of the management in order to improve the microcirculation of the pancreas (Figure 1).

As a marker of third-space losses, hemoconcentration has been associated with a higher probability of developing pancreatic necrosis and organ failure[71]. Moreover, patients who experienced a worsening or a lack of improvement of their hemoconcentration after 24 h of fluid resuscitation have a higher chance of developing necrotizing pancreatitis[72]. Therefore, all patients with AP should receive very close clinical monitoring with emphasis on vigorous fluid resuscitation. Rehydratation has to be monitored with the help of invasive monitoring such as a Foley catheter and a central line to measure the urine output and central venous pressure, respectively. Patients who have borderline cardiac dysfunction or respiratory failure may require a Swann-Ganz catheter. Crystalloids are preferred to colloids in most instances. However, electrolyte disturbances and fluid overload can

Table 4 Sequential organ failure assessment score (SOFA)

Organ system involved	Score				
	1	2	3	4	5
Cardiovascular	No hypotension	MAP < 70 mmHg	Dopamine or dobutamine (any dose)	Dopamine > 5 μg/kg per min or adrenaline (epinephrine) < 0.1 μg/kg per min or noradrenaline (norepinephrine) < 0.1 μg/kg per min	Dopamine < 0.1 μg/kg per min or > 15 μg/kg per min or adrenaline > 0.1 μg/kg per min or noradrenaline > 0.1 μg/kg per min
Respiratory PaO_2/FiO_2 (mmHg)	> 400	400-300	300-200	200-100[1]	≤ 100[1]
Renal creatinine (μmol/L)	< 100	100-200	200-350	350-500	> 500
Neurological glasgow coma score	15	14-13	12-10	9-7	≤ 6
Haematological platelet count ($\times 10^9$/L)	> 150	150-100	100-50	20-50	≤ 20
Hepatic bilirubin (μmol/L)	< 20	20-60	60-120	120-240	> 240

[1]These values are calculated with ventilatory support. MAP: Mean arterial pressure; SOFA: Sequential organ failure assessment, and is calculated as the sum of the scores for the individual organs.

Table 5 Acute pancreatitis graded with CT and CT severity index table

Grade	CT finding	Points	Necrosis		Severity index
			Percentage	Additional points	
A	Normal pancreas	0	0	0	0
B	Pancreatic enlargement	1	0	0	1
C	Pancreatic inflammation and/or peripancreatic fat	2	< 30	2	4
D	Single peripancreatic fluid collection	3	30-50	4	7
E	Two or more fluid collections and/or retroperitoneal air	4	> 50	6	10

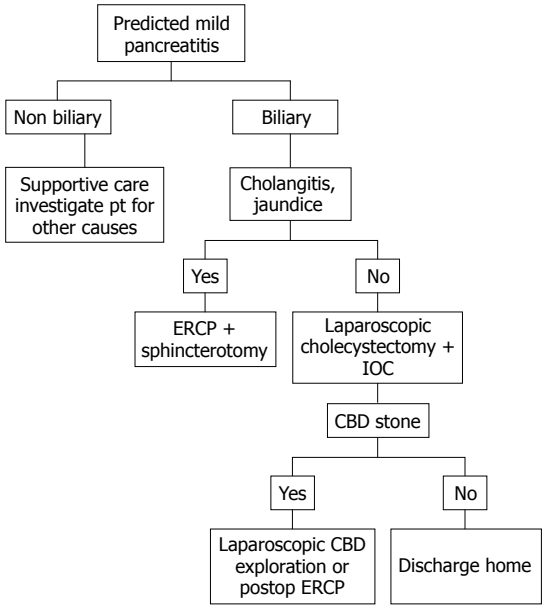

Figure 1 Algorithm for management of mild acute pancreatitis. IOC: Intraoperative cholangiography; CBD: Common bile duct.

be serious complications of fluid resuscitation especially in patients who have developed cardiovascular dysfunction or acute respiratory distress syndrome.

Adequate pain control is essential. Parenteral analgesia is usually needed with an advantage in using patient-controlled analgesia. Opiates are normally used including morphine and meperidine. Since there are no studies directly comparing the effects of meperidine or morphine on sphincter of Oddi manometry, morphine seems to provide more benefit by offering a longer duration of action and fewer side effects[73].

Supplemental oxygen is required in all patients. The oxygen saturation should be maintained at 95% or higher with supplemental oxygen administered by nasal cannula or by a face mask in order to prevent pancreatic necrosis.

The role of activated protease in producing organ failure is not clear. Although antiprotease treatment has been successful in experimental pancreatitis, it has not been shown to offer a survival benefit, but only a reduction of the incidence of complications in human disease[74,75].

Since cytokines could play an important role in AP, many agents have been used in experimental animals to ameliorate or prevent the inappropriate activation of the immune systems.

Anti-TNF-α antibody has been shown to reduce the induction of further cytokines by inflammatory cells but the peak TNF-α production appears to be within 1 or 2 h of the onset of disease. This action can compromise the use of TNF-α blockers in the clinical setting since the presentation and diagnosis of disease occurs after the peak of TNF-α production[76-78].

The role of calcium channel signaling in cytokine release and systemic organ injury in AP has been reported in one animal study. In this study, Hughes demonstrated that calcium channel blockers were associated with a dramatic reduction of TNF-α release with an improvement in overall survival from 40% to 80% between untreated rats and animals pre-treated with diltiazem, respectively[79].

An interleukin-1 receptor antagonist has been shown to be associated with decreased severity of pancreatitis in animal models, however these results have not been translated into clinical practice so far[80,81].

Since acute lung injury in AP results in an up-regulation of vascular adhesion molecule-1 (VCAM-1) cell surface receptor expression on pulmonary vascular endothelium, and neutrophil sequestration, experimental studies showed that blocking VCAM-1 decreased lung injury in AP[82,83]. It is believed that a VCAM-1 antagonist can offer a therapeutic option to improve the systemic manifestation and therefore the prognosis of AP.

Administration of monoclonal antibodies directed against the adhesion molecule, junctional adhesion molecule C expressed by endothelial cells showed a significant reduction in secretion of inflammatory cytokines, and in acinar cell necrosis[84].

Recently, there have been reports considering 5-fluorouracil treatment more effective compared to single inflammatory cytokine blockers in modulation of inflammatory mediators in experimental AP[85]. However, although the last decade has seen an increase in experimental studies on cytokines, the clinical treatment of the disease remains unchanged.

MANAGEMENT OF SAP: "EARLY PHASE"

SAP is defined by the Atlanta classification as an AP with local and/or systemic complications[86]. Some patients develop pancreatitis-associated organ failure during the early phase of the SAP[87].

The initial management of SAP is supportive based on fluid resuscitation, analgesia and enteral nutrition.

All patients should have thrombo-prophylaxis with low molecular weight heparin; however the decision to begin stress ulcer prophylaxis is still debatable.

SAP induces a catabolic state. Hence, early nutritional support is essential in order to avoid malnutrition.

An important issue in the early treatment of SAP is the optimal delivery of nutrition. After initial enthusiasm towards parenteral nutrition (PN), recent guidelines advise early enteral nutrition (EN) through a nasojejunal tube[88]. Patients with AP are characterized by loss of the gut barrier function which is involved in both local and systemic infectious complications[89]. In a meta-analysis analyzing 5 randomized control trials since 1997, Petrov *et al*[90] showed that EN, compared to PN, had a statistically significant lower risk of infection and mortality. Although there are studies supporting a lower infection rate when the tube is positioned in the jejunum, Eatock *et al*[91] demonstrated that nasogastric feeding is as good as nasojejunal feeding.

Although the role of probiotics in AP has been investigated in different clinical trials and meta-analyses, in a recent randomized controlled trial Besselink *et al*[92] showed that, in patients with predicted SAP, probiotic prophylaxis did not reduce the risk of infectious complications and was even associated with an increased risk of death.

Although the main management in the early phase of SAP is advocated to be mainly conservative and supportive in order to avoid organ dysfunction, there are conditions such as gallstone pancreatitis for which early endoscopic or surgical intervention has to be sought.

The benefits of ERCP with sphincterotomy (ES) has been studied in 3 randomized trials[93-95] and 2 meta-analyses[96,97]. Patients with predicted mild acute biliary pancreatitis (ABP) in the absence of cholangitis have not shown benefits from an early ERCP.

The decision on management of patients with predicted severe ABP is still debatable. The most recent United Kingdom guidelines recommend that urgent therapeutic ERCP should be performed within 72 h of admission in all patients with predicted severe ABP, whether or not cholangitis is present[98].

However, a recent meta-analysis by Petrov *et al*[97] demonstrated that early ERCP with or without ES had no beneficial effect in patients with predicted mild or severe ABP without cholangitis. The conclusion of this study was partially supported by the 2007 guidelines of the American Gastroenterology Association which stated that early ERCP in patient with severe ABP without signs of acute cholangitis is still not uniformly accepted in the literature[99].

However, optimal timing of laparoscopic cholecystectomy (LC) in patients with ABP is still contentious. In mild ABP, LC with operative cholangiography has been considered the definitive treatment[100].

Early laparoscopic cholecystectomy (ELC) can be performed as soon as the serum amylase decreases and symptoms improve[101].

Heinrich *et al* recently analyzed 4 prospective trials evaluating the optimal timing for surgery and concluded that ELC should be preferred in patients with mild to moderate ABP while in patients with severe ABP who did not have surgery for necrotizing pancreatitis, cholecystectomy appears to be favorable after full recovery[101-105].

MANGEMENT OF SAP: "LATE PHASE"

The main life-threatening event which characterizes the late phase of SAP is infection of the necrotic pancreatic parenchyma. Infection tends to occur in 10% to 50% of patients with necrotizing pancreatitis and develops 2-3 wk after the onset of symptoms[26,106-108]. The mortality increases from 5%-25% in patients with sterile necrosis to 15%-28% when infection occurs[24,107,109-112].

The infection is thought to be caused by translocation of enteric flora from the small and large bowel, since gram-negative bacteria such as *Escherichia coli* has been the most common species isolated. The use of antibiotic prophylaxis has changed the microbiology in favor of gram-positive and fungal organisms such as *Staphylococcus* species and *Candida*[113-116].

The debate on prophylactic antibiotics in sterile necrotic pancreatitis is still open. Since 1991, when Bradley introduced the concept of conservative treatment of sterile necrotic pancreatitis with the use of antibiotics, different randomized, controlled trials were conducted in order to investigate the beneficial effects of antibiotic therapy[117]. Initial studies were conducted with imipenem, ciprofloxacin and metronidazole[118-121].

These studies showed that antibiotic prophylaxis in

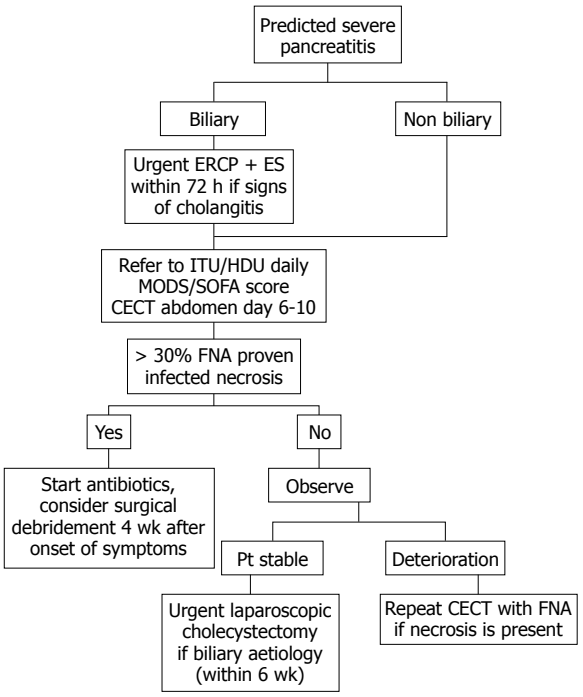

Figure 2 Algorithm for management of severe acute pancreatitis. ERCP: Endoscopic retrograde cholangiopancreatography; ES: ERCP with sphincterotomy; Pt: Patient; MODS: Multiple organ dysfunction score; SOFA: Sequential organ failure assessment; CECT: Contrast-enhanced computed tomography; FNA: Fine needle aspiration.

SAP is capable of reducing the incidence of bacterial infection of pancreatic necrosis but it was unable to improve hospital mortality.

Two placebo-controlled, double-blind trials by Isenmann and Dellinger demonstrated a lack of significant benefit of prophylactic antibiotics on infection and surgical intervention rates[122,123]. However, a recent Cochrane meta-analysis, which included the Isenmann study, showed a reduction in mortality with the use of β-lactams, although there was no evidence of a reduction in the pancreatic necrosis infection rate[124].

Despite the requirement for further multicenter double-blind studies, the use of prophylactic antibiotics in patients with proven necrotic pancreatitis on CT has been advocated. β-lactam agents are preferred to quinolones and the length of the therapy has to be at least 2 wk (Figure 2).

SURGICAL INTERVENTION

Surgery is considered the gold standard treatment for proven infected pancreatic necrosis[125].

Since Bradley has introduced the concept of conservative treatment in non-infected pancreatic necrosis, the timing of surgical intervention has changed substantially[117]. In the past, early surgical intervention was advocated and had a mortality rate up to 65%[126,127]. Recent studies demonstrated the benefit of postponing surgical intervention in reducing the mortality rate to 27%, allowing the immune system to demarcate the pancreatic necrosis[128,129].

The IAP (International Association of Pancreatology) Guidelines recommend that a patient with infected necrotic pancreatitis has to undergo surgery in the 3rd or 4th wk after the onset of symptoms[88]. However, postponing surgical intervention in necrotic pancreatitis can lead to prolonged use of antibiotics and an increased antibiotic resistance and higher incidence of *Candida* infection[130,131].

In a recent retrospective study, Besselink strongly advised avoidance of surgical intervention in the first 14 d even in the presence of multiple organ failure, and withholding of necrosectomy until day 30[132].

The aim of surgical management is to remove all the pancreatic tissue with necrosis in order to reduce the release of inflammatory mediators. Necrosectomy and drainage of infected acute necrotizing pancreatitis can be performed with different approaches such as radiological, endoscopical and surgical intervention.

Radiologic necrosectomy

Since Freeny presented the first series of patients with infected necrotic pancreatitis treated with only CT-guided percutaneous catheter drainage in 1998, this approach has not been considered very successful in debriding thick necrotic pancreatic tissue[133-135]. However, a combination of percutaneous catheter drainage and intensive care support can offer an alternative to surgery[136]. In unstable patients, percutaneous catheter drainage can be successful in draining pus and reducing the systemic manifestations of sepsis and in doing so, prepare the patient for surgery[133].

The placement of the catheter can be obtained through an anterior or retroperitoneal approach. To achieve an adequate drainage of the thick pancreatic necrotic collection, catheters with multiple side holes with a minimum diameter of 12-14 Fr are required[137]. Percutaneous drainage can lead to suprainfection of the pancreatic collection due to colonization of the indwelling catheter. However, clinical infection has been shown to be unlikely if all material is drained within 2-3 d.

Endoscopic necrosectomy

The endoscopic approach with the help of endoscopic US (EUS) has been reported to be effective in recent retrospective studies[138-141]. This technique can be considered as a natural orifice transluminal endoscopic surgery (NOTES) procedure since it employs a transenteric access route.

The most common access is through the posterior wall of the stomach under EUS and under Doppler imaging in order to avoid vascularized areas. The procedure is normally performed under sedation and requires good endoscopic skills.

Initially, a trans-gastric puncture under EUS guidance is performed using a 19-gauge needle through which a guidewire is passed into the cavity and coiled multiple times under fluoroscopic vision. The tract is dilated by a dilator which is passed over the guide and further dilatations can be done using 10-15 mm balloons. This dilation will allow an optimal insertion of the upper endoscope into the pancreatic cavity. The necrosectomy

is performed using different devices such as polypectomy snare, transparent cap baskets and different graspers.

The debridement of necrotic tissue is followed by copious irrigation with normal saline solution. A pig-tail drain inserted into the cavity and a nasocystic drain are used for continuous lavage. The lavage has to be repeated until all the necrotic material is removed[139,140]. The use of antibiotics is advised until the nasocystic drain has been removed.

Although optimal necrosectomy is normally achieved with multiple sessions, in a recent retrospective study which included 6 consecutive patients, Mathew *et al*[139] demonstrated that complete removal of necrotic tissue can be achieved with a single procedure. In this study none of the patients had procedure-related complications; however injury to visceral and vascular structures must be borne in mind as potential life-threatening complications.

Recent data from the literature indicated that the endoscopic approach could be a safe and effective modality for management of infected pancreatic necrosis with potentially lower morbidity than the traditional surgical approach. However, the data was from small prospective studies and multicenter prospective randomized trials are needed to clarify the role of the endoscopic approach in necrotic pancreatitis.

Surgical necrosectomy

The aim of surgery is to control the focus of infection through removal of necrotic tissue. This is based on preserving the endocrine and exocrine functions of the pancreas and allowing postoperative removal of retroperitoneal debris and exudates.

Until recently, necrosectomy was generally performed only by an open route. In order to achieve postoperative continuous drainage of debris, 4 different techniques have been advocated[142]: (1) open necrosectomy with open packing and planned re-laparotomy[143-149]; (2) open necrosectomy with planned re-laparotomy, staged and repeated lavage[150-153]; (3) open necrosectomy with continuous lavage of the lesser sac and retroperitoneum[153-161]; (4) open necrosectomy with closed packing[162].

Open necrosectomy with open packing and planned re-laparotomy: The abdominal cavity is filled with non-adherent packing. Successive laparotomies are performed every 48 h for further debridement which can be performed in intensive care under sedation. The abdomen is closed with drains when granulation tissue appears.

Open necrosectomy with planned re-laparotomy, staged and repeated lavage: After a primary necrosectomy repeated debridement is performed on alternate days until all necrotic tissue has been replaced by granulation tissue. To improve the surgical access some surgeons use an abdominal wall zip.

Open necrosectomy with continuous lavage of the lesser sac and retroperitoneum: Primary necrosectomy is followed by continuous closed lavage of the retroperitoneum. The procedure is based on insertion of 2 or more double 20-24 French drains and a single lumen 28-38 French silicone rubber on each side of the abdomen and placed with the tip at the tail of the pancreas. The smaller lumen of the drains is used for the inflow of the lavage and the larger lumen for the outflow. At least 35-50 L lavage are requested in the first days. Drains can be removed after 2-3 wk.

Open necrosectomy with closed packing: After the removal of the necrotic tissue, the residual cavity is filled with gauze-packed Penrose drains and suction drains. Drains are removed after 7 d.

Of these techniques open necrosectomy with closed continuous lavage of the lesser sac and the retroperitoneum seems to have the lowest mortality and it is the most common approach used by surgeons.

In specialized centers, open surgical management of infected necrosis can reduced the mortality from 80% to 10%-20%. This high mortality has induced surgeons to find a new, less invasive approach in order to reduce the activation of an inflammatory response in patients who are already seriously ill.

MINIMAL INVASIVE SURGICAL APPROACH

Over the last 2 decades, the role of minimal invasive surgical approaches to necrotic pancreatitis has increased. Minimal invasive techniques can be classified under 2 groups: (1) video-assisted retroperitoneal debridement (VARD) and (2) laparoscopic transperitoneal debridement (LTPD).

VARD

This approach was first described by Carter *et al*[163] in 2000 using an operative nephroscope inserted over an 8 Fr pigtail catheter, positioned under CT guidance. Since this initial experience, different studies have performed necrosectomy through a retroperitoneal approach using a rigid nephroscope or zero degree laparoscope.

This technique is performed by placing the patient in a supine position with his left flank elevated. A subcostal or intercostal incision is made to follow the retroperitoneal drains up to the necrotic area which is opened bluntly through digital examination. Necrotic tissue is debrided by a ring forceps and a suction device. A 10 mm laparoscope and a long 10 mm trocar are inserted through the retroperitoneal wound. Under laparoscopic vision, the remaining necrotic tissue is removed by laparoscopic graspers. Two surgical drains are inserted into the necrotic cavity via the incision[164-170].

Recently, Bucher *et al*[170] described a new technique based on a single laparoscopic port in order to avoid repeated necrosectomies. Using a 5 mm laparoscope with a 30 degree optic, a 12 mm trocar was placed in the drain tract. Through this big trocar, 5 mm instruments were used simultaneously with the 5 mm laparoscope. The necrotic cavity was dilated by insufflation with CO_2 at a

pressure of 8 mmHg in order to avoid potential bacterial translocation. At the end the procedure, the cavity was inspected with a 30 degree 10 mm laparoscope. Among 8 patients who underwent this new procedure only one did not have a successful debridement and had repeated necrosectomy.

The VARD approach has the great advantage of avoiding peritoneal contamination but is limited in necrosis extraction, and the need for repeated sessions is quite common. Other limitations of VARD are its low ability in detecting colonic ischemia, and in performing cholecystectomy or insertion of a feeding jejunal tube at the time of debridement[141].

LTPD

Cuschieri described for the first time the technique of laparoscopic infracolic necrosectomy with irrigation of the lesser sac as a valid alternative to open necrosectomy[171].

Although this laparoscopic technique has been described in the literature through case reports since 2002[172-175], only recently Parehk reported a retrospective study on hand-assisted laparoscopic surgery for pancreatic necrosectomy[174]. This study described 18 patients with necrotizing pancreatitis who underwent laparoscopic necrosectomy using an infracolic approach to access the lesser sac with a hand access port in order to enlarge the window in the transverse mesocolon and to bluntly remove the necrotic tissue. The outcomes were encouraging with mean length of stay of 16.3 d after the procedure and a reduction in the incidence of major wound complications.

This technique gives a better exposure of the lesser sac, left paracolic gutter and head of the pancreas, apparently overcoming the main limitation of the retroperitoneal approach in not debriding necrotic tissue completely. On the other hand the transperitoneal approach carries the risk of peritoneal contamination with infected necrosis.

Despite the use of less invasive techniques, complications following debridement of necrotic pancreatic tissue are still common. Pancreatic or enterocutaneous fistulae occur in 30% of patients and it seems related to the severity and extent of the underline necrosis[176]. Fistulae should be managed conservatively initially, deferring surgical closure of fistulae until pancreatitis is completely resolved. Other early complications are wound infection and wound dehiscence which seems less common with the minimal invasive approach. Postoperative bleeding is normally treated through an endovascular procedure with the help of an interventional radiologist.

Late complications such as pancreatic insufficiency and development of organized sterile necrosis are also common[177].

CONCLUSION

Although most patients with AP will have a benign outcome, it is crucial to assess the patient using multi-factorial scoring systems and inflammatory markers in order to evaluate the severity of the condition.

Early management should be conservative, based on fluid resuscitation with a focus on maintaining optimal organ perfusion. Managing the patient in the ICU should be contemplated when patients show signs of clinical deterioration.

A CT scan should be performed at least 48 h after the onset of symptoms and is considered the gold standard for diagnosis of necrotic pancreatitis. As part of the conservative intensive treatment, nasojejunal feeding is recommended in order to reduce bacterial translocation.

In ABP, early ERCP in patients without signs of acute cholangitis is not recommended. Infected necrotizing pancreatitis is the main indication for surgical debridement. The best time of surgery is 3-4 wk after the onset of the condition.

The last 2 decades have seen the emergence of new minimal invasive approaches in performing surgical debridement. However, no randomized controlled studies have been published in comparing different techniques.

Nevertheless, the results of the PANTER trial, a prospective multi-institutional randomized study comparing VARD versus open laparotomy, are still awaited[178].

Abstract

Systemic abnormalities often occur in patients with liver disease. In particular, cardiopulmonary or renal diseases accompanied by advanced liver disease can be serious and may determine the quality of life and prognosis of patients. Therefore, both hepatologists and non-hepatologists should pay attention to such abnormalities in the management of patients with liver diseases.

Key words: Systemic abnormality; Risk of surgery; Drug dosage; Liver disease

INTRODUCTION

Systemic abnormalities are often seen in liver disease, possibly because of the following characteristics of the liver as an organ[1]. (1) The liver is the key organ for the metabolism of protein, carbohydrate and fat. The liver produces many proteins, including coagulation factors. (2) The liver is a major organ for drug metabolism and the removal of hormones and other substances. (3) The liver is frequently invaded by various pathogens, and hepatitis virus infection causes not only serious liver diseases, but also exhibits extrahepatic manifestations through either immunological or non-immunological mechanisms. (4) The liver has a high blood flow supplied from the portal vein and the hepatic artery, leading to changes in portal, systemic or cardiopulmonary circulation in severe or advanced liver disease. (5) The liver is a major hematopoietic organ in the fetus and produces hematopoietic growth factors such as thrombopoietin[2].

In this review, in addition to systemic abnormalities often found in liver disease, dosage adjustment of drugs and risks of surgery in patients with liver disease are summarized. These factors should always be considered in the diagnosis or management of patients with liver disease.

CARDIOPULMONARY SYSTEM IN LIVER DISEASES

Patients with advanced liver disease have mild hypoxemia attributable to an alteration in ventilation-perfusion matching[3]. When a patient with liver disease exhibits dyspnea in the absence of detectable primary cardiopulmonary disease, hepatopulmonary syndrome (HPS) or portopulmonary hypertension (PPHTN) should be considered[4]. Clinical features and diagnostic criteria for HPS and PPHTN are shown in Table 1.

Hepatopulmonary syndrome

HPS is defined as the triad of liver disease, pulmonary gas exchange abnormalities leading to arterial deoxygenation and evidence of intrapulmonary vascular dilatation (IPVD)[4-7]. Although the mechanism for the development of HPS is complex and unclear, ventilation-perfusion mismatch and enhanced production of nitric oxide in the lung have been proposed as the predominant mechanisms[7].

A diagnosis of HPS requires demonstration of IPVD and an increased alveolar-arterial oxygen difference (AaDO2) (> 15 mmHg[8] or > 20 mmHg[6,9])

Table 1 Difference between HPS and PPHTN modified from Rodríguez-Roisin *et al*[4]

	HPS	PPHTN
Prevalence	11%-32% of patients with liver cirrhosis	2% of patients with portal hypertension
Pathogenesis	Increased intrapulmonary shunting	Unknown
Intrapulmonary vascular dilatations	(+)	(-)
Pulmonary arterial hypertension	(-)	(+)
Symptom	Dyspnea, platypnea	Dyspnea on exertion, syncope, chest pain
Clinical manifestations	Cyanosis	No cyanosis
	Orthodeoxia	Accentuated pulmonary component of Ⅱs
	Spider nevi	Systolic murmur, edema
ECG findings	None	RVH, RBBB, right axis deviation
Arterial blood gas levels	Moderate-to-severe hypoxemia (< 60-80 mmHg)	No/mild hypoxemia
Chest radiography	Normal	Cardiomegaly, hilar enlargement
CEE	Positive finding; left atrial opacification for > 3-6 heart beats after right atrial opacification	Usually negative finding
^{99m}TcMAA shunting index	⩾ 6%	< 6%
Pulmonary hemodynamics	Normal/low PVR	Elevated PVR mPAP > 25 mmHg at rest or > 30 mmHg with exercise
OLT	Indicated in severe stages	Only indicated in mild-to-moderate stages

HPS: Hepatopulmonary syndrome; PPHTN: Portopulmonary hypertension; RVH: Right ventricle hypertrophy; Ⅱs: Second heart sound; ECG: Electrocardiography; RBBB: Right bundle-branch block; $AaPO_2$: Alveolar arterial oxygen gradient; CEE: Contrast-enhanced echocardiography; ^{99m}TcMAA: Technetium-99m-labelled macroaggregated albumin; PVR: Pulmonary vascular resistance; mPAP: Mean pulmonary artery pressure; OLT: Orthotopic liver transplantation.

on breathing of air at room temperature and pressure. In order to diagnose IPVD, trans-thoracic contrast-enhanced echocardiography[4], technetium-99m-labeled macroaggregated albumin scanning[10] and pulmonary arteriography are useful. HPS is reported to occur in 11%-32% of patients with chronic liver disease, mainly among those with liver cirrhosis[11-15]. HPS patients who experience severe hypoxemia at rest should receive continuous long-term low-flow oxygen therapy, although no data on its long-term effectiveness is available. Complete resolution of HPS following orthotopic liver transplantation (OLT) has been observed in > 80% of reported cases[16]. At present, OLT appears to be the most effective therapy for patients with HPS.

Portopulmonary hypertension

PPHTN refers to pulmonary arterial hypertension that is associated with portal hypertension. PPHTN should be suspected in hypoxemic patients without pulmonary vascular dilatation[4,7,17]. The most common symptoms are dyspnea on exertion, syncope and chest pain. Although the cause of PPHTN is unknown, it has been reported that vasoactive substances could reach the pulmonary circulation at abnormally high concentrations owing to portosystemic shunts or decreased hepatic metabolism, leading to the pathological pulmonary vascular lesions exhibited in PPHTN[4,18]. Severe PPHTN is a contraindication of OLT, which can result in perioperative death from acute right ventricular failure[19,20]. Therefore, it is very important to distinguish between HPS and PPHTN in patients who are candidates for liver transplantation[4,7,21].

Idiopathic pulmonary fibrosis

Chronic hepatitis C virus (HCV) infection has been associated with a variety of extrahepatic complications, and an association between idiopathic pulmonary fibrosis (IPF) and HCV infection has been reported[22]. Studies undertaken in Japan and Italy suggest that the incidence of anti-HCV antibody positivity in patients with IPF is significantly higher than in those without IPF[22,23]. Arase *et al*[24] reported that the cumulative rate of IPF development is 0.9% at 20 years after HCV infection, which is significantly higher than that after hepatitis B virus (HBV) infection.

Coronary artery disease

It has been reported that atherosclerosis-related coronary artery disease (CAD) is less frequent in patients with liver cirrhosis than in controls matched with cirrhotic patients according to age, sex or cigarette smoking[25-28]. The prevalence of myocardial infarction was found to be significantly lower in cirrhotic patients than that in non-cirrhotic patients (1.7% *vs* 6.4%)[28]. The mechanisms of this protective effect on coronary atherosclerosis are unclear, but it may be associated with liver-related cholesterol metabolism and hematologic changes in cirrhotic patients. In contrast to the reported effect of cirrhosis on CAD, Alyan *et al*[29] demonstrated that HCV infection is an independent predictor of increased coronary atherosclerosis when patients with severe liver disease and cirrhosis are excluded from the analysis. It is thus suggested that the incidence of coronary atherosclerosis in patients with liver disease could be influenced by the severity of the liver disease and by hepatitis virus infection.

Recently, nonalcoholic steatohepatitis (NASH) has become well known as one of the leading causes of cirrhosis, and NASH is known to be strongly related to insulin resistance[30]. Kadayifci *et al*[31] reported that the prevalence of all CAD risk factors and metabolic syndrome was significantly higher in NASH-related cirrhotic patients than in cirrhotic patients with other etiologies.

High cardiac output and increased circulatory volume

In patients with advanced cirrhosis, cardiac output and circulatory volume are increased because systemic vascular peripheral resistance is reduced and oxygen consumption is decreased by arteriovenous shunting[32,33]. However, it is also known that these circulatory changes rarely result in heart failure.

Cardiomyopathy

Dilated and hypertrophic cardiomyopathies associated with HCV infection have been reported[34-36]. Although HCV has been isolated from the myocardium of patients with myocarditis and cardiomyopathy[37], there are conflicting reports on the incidence of HCV infection in these patients[38-41]. International epidemiological studies examining the incidence of HCV infection in patients with non-ischemic cardiomyopathy should be conducted. Some HLA haplotypes have been identified in a particular population of patients with HCV-associated cardiomyopathy, suggesting that genetic predisposition may be involved in the development of the disease[42]. Although the mechanisms of myocardial damage by HCV have not been characterized, HCV core protein may damage the myocardium either directly or indirectly through immunological mechanisms[43-45]. The treatment of chronic hepatitis C with interferon is sometimes contraindicated in patients with myocardial dysfunction[46]. Therefore, understanding and assessing cardiomyopathy as an extrahepatic manifestation of HCV infection is important.

ENDOCRINE SYSTEM IN LIVER DISEASES

Because the liver is involved in the synthesis and metabolism of many kinds of hormones, various abnormalities of circulating hormone levels are found in patients with advanced liver disease. HCV infection is known to be linked to some endocrine disorders.

Diabetes mellitus

Type-2 diabetes mellitus is present in more patients with chronic HCV infection than in those with HBV infection (21% and 12% in the United States, 23.6% and 9.4% in the United Kingdom, respectively)[47-50]. The association between HCV infection and diabetes mellitus is thought to be responsible for insulin resistance, which is shown to be directly induced by HCV core proteins[51]. Insulin resistance is also reported to be closely associated with the progression of fibrosis[52]. Diabetes mellitus is considered to increase the risk of the development of hepatocellular carcinoma and to increase mortality[53,54]. The monitoring of blood glucose should be performed on patients with chronic HCV infection, and in particular on those with advanced fibrosis, and appropriate treatment may be required when diabetes mellitus is diagnosed. The treatment of diabetes should be performed carefully owing to existing liver damage and hepatotoxicity of oral hypoglycemic drugs, particularly in cirrhotic patients. Oral hypoglycemic drugs, like biguanides which improve insulin resistance, for advanced liver diseases may be useful because insulin resistance is considered to be the main cause of glucose intolerance in patients with advanced liver disease[55]. α-glucosidase inhibitors may also be effective, because they reduce the absorption of glucose from the intestine and improve postprandial hyperglycemia[56]. Insulin treatment should be carefully performed in cirrhotic patients, because insulin resistance is increased and the metabolism of insulin decreases as liver diseases advance[55].

Thyroid disease

Thyroid disease often accompanies chronic HCV infection, particularly in elderly women (13% in patients with HCV infection)[56]. Anti-thyroid autoantibodies are also found in patients with chronic HCV infection (0% in men and 14.7% in women)[57]. Interferon-α therapy has been independently associated with the development of thyroid disorders[58,59]. Therefore, thyroid function or anti-thyroid autoantibodies should be evaluated before and during anti-viral treatment with interferon. Furthermore, thyroid cancer is also reported in patients with chronic HCV infection, particularly in those with thyroid autoimmunity[60,61].

Nonalcoholic fatty liver disease (NAFLD)

NAFLD is the most common cause of chronic liver disease in the western world, and NAFLD is known to be accompanied by type-2 diabetes and hyperlipidemia in about 30% of patients[62]. In addition, endocrine disorders such as hypopituitarism or hypothyroidism have been associated with NAFLD (the prevalence is reported to be 2.3% and 15% in NAFLD cases, respectively), although the precise mechanism for this association is unknown[62-64]. Patients with NAFLD accompanied by hypopituitarism may be susceptible to central obesity, dyslipidemia and insulin resistance, leading to disease progression.

HEMATOLOGICAL ABNORMALITIES IN LIVER DISEASES

Erythrocyte abnormalities

About 50%-75% of patients with chronic liver disease develop anemia by various mechanisms[65] including hemodilution, hypersplenism, myelosuppression caused by viral infection or hemolysis (by either immunological or non-immunological mechanisms). Alcoholism has a close association with low dietary intake of folate and vitamin B12, and is known to inhibit the absorption of both nutrients from the gut leading to macrocytic anemia[66,67]. Alcoholic liver cirrhosis is associated with spur cell hemolytic anemia[68], although a recent report revealed that this can also be induced by NASH[69]. Other anemia-causing factors found in liver diseases include hemolysis in Wilson disease, alcoholic liver disease (Zieve syndrome), pregnancy (HELLP syndrome) and myelosuppression followed by viral hepatitis[65].

Leukocyte abnormalities

Leukocytopenia, especially neutropenia, is often found in advanced chronic liver disease. Although splenic sequestration of leukocytes due to hypersplenism or serum hematopoietic progenitor inhibitory factors has been thought to be the main mechanism causing leukocytopenia[70,71], a shortened neutrophil lifespan caused by increased apoptosis may also be responsible[72]. Lymphocytopenia is also often found in patients with liver cirrhosis, possibly due to malnutrition[73]. In contrast, HCV infection can cause monoclonal proliferation of B lymphocytes leading to the induction of various autoimmune disorders[74], and an increased association with the development of non-Hodgkin's lymphoma has been reported[75]. Interestingly, the functional maturation of B lymphocytes has been proven to occur in the livers of patients with hepatitis C[76].

Platelet abnormalities

Patients with chronic liver disease show a reduction in both number and function of platelets[65], and platelet count is shown to decrease with disease progression, especially in the case of HCV infection. The aspartate aminotransferase to platelet ratio index has recently been reported to be a useful predictor of the progression of liver fibrosis in HBV infection[77] and recurrent HCV infection after liver transplantation[78]. The mechanisms responsible for the decrease in platelet count in chronic liver disease include splenic platelet sequestration due to hypersplenism[79] and a reduced level or activity of thrombopoietin[80], which is a hematopoietic factor for thrombocytes produced by mature hepatocytes[2]. In chronic HCV infection, bone marrow suppression by HCV itself[81], or immune-mediated destruction of platelets through production of anti-platelet antibody or formation of immune complexes[81], has been reported to be the cause of thrombocytopenia. Because platelet-associated immunoglobulin (Ig) G is found in as many as 88% of hepatitis C patients[82], it is not unusual for hepatitis C patients with thrombocytopenia to be diagnosed with idiopathic thrombocytopenic purpura.

With regard to platelet function, deficiency in platelet aggregation[83] or platelet-vessel wall interaction[84] has been reported in patients with cirrhosis, resulting in a tendency to bleed profusely.

Recently, the platelet count to spleen diameter ratio has proven to be effective for ruling out the presence of esophageal varices[85]. Therefore, platelet count is an important parameter for assessing disease progression and the presence of complications in advanced liver disease.

Abnormal coagulation

Because most coagulation factors are only synthesized in the liver[86], liver damage can easily lead to abnormal coagulation or a tendency to bleed profusely. Moreover, disseminated intravascular coagulation (DIC) is often seen in seriously ill patients with conditions including sepsis, malignancies and liver failure. Since both liver failure and DIC present with prolonged prothrombin time (PT), it is sometimes difficult to distinguish the two. It has been reported that a decrease in factor Ⅷ (not synthesized in the liver) and decreasing fibrinogen levels and platelet counts over time could indicate DIC accompanying liver failure rather than liver failure alone[87]. Levels of factor V are also reported to be useful for distinguishing the two conditions, since they are < 10% of normal levels in DIC and 10%-40% of normal levels in cirrhosis[87]. Vitamin K deficiency can also cause prolonged PT, but in contrast to liver failure and DIC, it leads to near normal levels of factor V[87].

In addition to prolonged PT, liver diseases are associated with hyperfibrinolysis[88], dysfibrinogenemia[89], endothelial dysfunction[90] and low count and/or decreased function of platelets[81,83], which all increase the risk of profuse bleeding in patients with advanced liver diseases.

GASTROENTEROLOGICAL ABNORMALITIES IN LIVER DISEASES

The liver has a unique anatomical characteristic in that a large amount of blood is supplied directly to the organ from the intestines *via* the portal vein. Consequently, various complications of the gastrointestinal tract are seen in advanced liver diseases.

Portal hypertensive gastropathy and esophageal varices

In a recent large-scale study, 37% of patients with HCV infection and advanced fibrosis in the liver were found to have portal hypertensive gastropathy (PHG)[91]. Biochemical markers of liver disease severity such as low serum albumin, high bilirubin or low platelet count may be correlated with the prevalence of PHG[91]. The presence of PHG may be predictive of esophageal varices[91], and low platelet count could be an indicator of the development of varices[92]. Some previous reports suggested that patients with primary biliary cirrhosis (PBC) may develop esophageal varices at a relatively early stage of the disease when other symptoms related to cirrhosis are not exhibited[93,94]. In recent studies, it has been recommended that PBC patients with a decreased platelet count (140 000-200 000/mm^3) should be screened for esophageal varices[95,96]. Nonselective beta-blockers may be effective for the treatment of PHG[92].

Pancreatic and biliary cancer

In a recent report, it was found that past exposure to HBV may be associated with the development of pancreatic or biliary tract cancer[97,98]. Anti-HBc antibody tests were positive in 7.6% of pancreatic cancer cases and 3.2% of controls[97], and a 2.4-fold increased risk of extrahepatic bile duct cancer in chronic HBV infection was reported[98]. HBV DNA integration in these tissues may have a pathogenetic influence. However, it is debatable whether the risk of biliary or pancreatic cancers is increased by HCV infection[98,99].

SKIN LESIONS IN LIVER DISEASES

Vascular spiders and palmar erythema are well known as skin lesions in patients with liver cirrhosis[100]. These skin lesions are thought to be related to excess estrogen, although the level of serum estrogen has been reported to be normal in patients with liver cirrhosis[100,101].

Chronic hepatitis infection is thought to be associated with various extrahepatic manifestations such as cutaneous lesions[102,103], including mixed cryoglobulinemia, porphyria cutanea tarda (PCT), lichen planus (LP), pruritus and urticaria. When these skin lesions are found, hepatitis virus infection should be considered.

Mixed cryoglobulinemia

Mixed cryoglobulin contains both a polyclonal IgG and a monoclonal IgM rheumatoid factor, and about 80% of mixed cryoglobulinemia is associated with HCV infection. Diagnosis of mixed cryoglobulinemia is made by skin palpable purpura, low serum complement levels and detection of circulating cryoglobulin[104-107]. Palpable purpura is a major finding suggestive of vasculitis. It is reported that a reduction in HCV load by treatment with interferon[108-110] could decrease serum cryoglobulin levels and improve skin lesions.

Porphyria cutanea tarda

PCT is caused by reduced activity of the enzyme uroporphyrinogen decarboxylase, and exposure to the sun can induce the development of skin erythema, vesicles and bullae[111]. A strong association between sporadic PCT and HCV infection has been reported, and a systematic review showed HCV infection in about 50% of patients with sporadic PCT[112]. Chronic HCV infection may impair porphyrin metabolism and cause sporadic PCT, but the mechanism for this is unclear.

Lichen planus

Although LP is a relatively rare skin disorder, it can be seen in patients with chronic liver diseases, particularly those with HCV infection[113]. It has been reported that anti-HCV antibodies are present in 10%-40% of these patients, but the relationship between HCV infection and LP is still uncertain[113,114]. During interferon treatment for chronic HCV infection, the development or exacerbation of LP has been reported[115]. In contrast, the improvement of oral LP in HCV-infected patients treated with interferon has also been reported[116].

Gianotti-crosti syndrome (GCS)

GCS is characterized by a symmetric papular eruption, which is mainly observed on the cheeks, buttocks and extensor surfaces of the forearms and legs[117]. GCS usually occurs in association with several viral infections, and acute HBV infection has been reported to be one of the most common causes of GCS in infants and young children[118,119]. It is, however, reported that GCS rarely occurs in adults[120].

RENAL DISEASES ASSOCIATED WITH LIVER DISEASES

Renal diseases in patients with liver disease can be classified into two major categories by etiology. One is hepatitis virus-associated nephropathy including membranous nephropathy, membranoproliferative glomerulonephritis (MPGN) and mesangioproliferative glomerulonephritis[121-123]. The other is hepato-renal syndrome (HRS), which is a serious complication of advanced liver cirrhosis[124]. When a patient with chronic liver disease has proteinuria and/or hematuria, hepatitis virus-associated nephropathy should be considered (Figure 1)[122].

Hepatitis virus-associated nephropathy

HBV infection may be directly associated with a variety of renal diseases, including membranous nephropathy and MPGN[121,125]. The diagnosis is based on an assessment of the status of HBV replication (HBeAg/Ab and HBV DNA levels)[126], laboratory findings (urinalysis and liver function test) and a kidney biopsy, although it is sometimes difficult to detect the deposition of viral antigens in the kidney by routine immunohistochemical analysis. HBV-associated nephrotic syndrome due to membranous nephropathy is not uncommon in children, and spontaneous recovery has been reported, which is often associated with seroconversion of HBeAg to anti-HBe[127]. In adults, on the other hand, spontaneous resolution is relatively uncommon and antiviral therapy may be effective[128].

HBV-related MPGN is characterized by the deposition of antigen-antibody complexes in the mesangium and subendothelial space. Antiviral therapy with interferon[129,130] or lamivudine[131] has been reported to induce remission in HBV-associated MPGN.

HCV infection is more often associated with renal diseases such as mixed cryoglobulinemia, MPGN and membranous nephropathy[122] than is HBV infection. The prevalence of MPGN in patients with HCV infection is higher than that of patients with HBV infection[123]. A high incidence of mixed cryoglobulinemia (35%-90%) has been reported in patients with HCV infection[132-134]. Mixed cryoglobulinemia is a systemic vasculitis and can frequently cause renal disease. MPGN associated with mixed cryoglobulinemia is the predominant type of glomerulonephritis, and the incidence of MPGN in patients with mixed cryoglobulinemia is approximately 30%[123,135,136]. The pathogenesis of HCV-related cryoglobulinemic MPGN is unknown, but the glomerular damage may be caused by the deposition of immune complexes of HCV, and IgG and IgM rheumatoid factors[135]. The clinical manifestations of renal diseases may include hematuria, nephritic range proteinuria and renal insufficiency. HCV-infected patients should be screened for proteinuria, hematuria, hypertension and renal function, as well as for cryoglobulinemia, complement and rheumatoid factors[124]. A kidney biopsy should be performed when

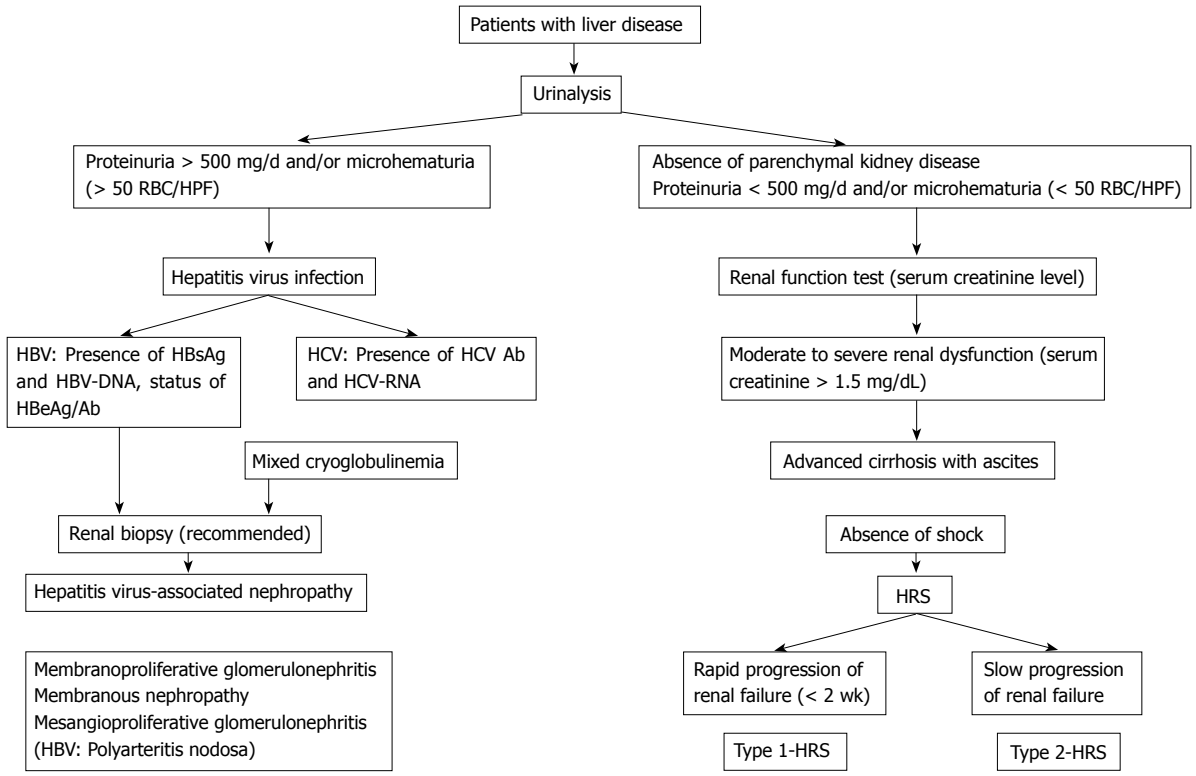

Figure 1 Diagnostic strategy for renal disorders found in patients with liver disease. RBC: Red blood cell; HPF: High power field; HBV: Hepatitis B virus; HCV: Hepatitis C virus.

Table 2 New diagnostic criteria for hepatorenal syndrome in cirrhosis[146]

Cirrhosis with ascites
Serum creatinine > 133 μmol/L (1.5 mg/dL)
No improvement of serum creatinine level (decrease to ≤ 133 μmol/L) after at least 2 d with diuretic withdrawal and volume expansion with albumin. The recommended dose of albumin is 1 g/kg of body weight per day up to a maximum of 100 g/d
Absence of shock
No current or recent treatment with nephrotoxic drugs
Absence of parenchymal kidney disease as indicated by proteinuria > 500 mg/d, microhematuria (> 50 red blood cells per high-power field) and/or abnormal renal ultrasonography

significant proteinuria and/or impaired renal function are observed (Figure 1).

There have been many reports on beneficial responses of patients with HCV-induced renal disease to antiviral therapy with interferon[137-139]. Improvements in both serum cryoglobulin levels and plasma creatinine concentration have been reported in patients who exhibited undetectable levels of serum HCV RNA after interferon therapy. A recently developed combination therapy involving pegylated interferon and ribavirin improved the rate of sustained virologic clearance. It has also been reported that this combination regimen improved HCV-associated mixed cryoglobulinemia[140,141], although the efficacy of ribavirin is limited when renal insufficiency is complicated. Recently, the effectiveness of anti-CD20 chimeric monoclonal antibody (rituximab) in the treatment of cryoglobulinemic glomerulonephritis has been reported[142].

HRS

HRS involves renal failure in patients with severe liver disease in the absence of any identifiable renal pathology[124,143,144]. The incidence of HRS in patients with cirrhosis and ascites is 18% and 39% after 1 and 5 years of follow-up, respectively[145]. New criteria for a diagnosis of HRS were reported by the International Ascites Club in 2007 (Table 2)[146]. HRS may be classified into two types: type-1 HRS is characterized by a rapid progression of renal failure (within 2 wk) with the mortality rate at 2 wk being about 80%. In contrast, the degree of renal failure is less severe in patients with type-2 HRS, and median survival is around 4-6 mo[144]. Type-1 HRS is often induced by a precipitating event, in particular spontaneous bacterial peritonitis[147]. HRS is related to renal vasoconstriction following a reduction of effective circulating volume due to peripheral vasodilation[148]. OLT is the ideal treatment for cirrhotic patients with HRS, but the survival rate after OLT is lower in those patients than in patients without HRS (60% *vs* 70%-80% at three years)[149]. The combined use of vasoconstrictors and albumin is one of the most useful options in treatment of patients

with HRS[150].

The diagnostic strategy for hepatitis virus-associated nephropathy and HRS is shown in Figure 1.

NUTRITIONAL ABNORMALITIES IN LIVER DISEASES

Protein-energy malnutrition is often found in patients with liver cirrhosis, and is reported to have an incidence as high as 30%-90%[151]. Malnutrition has been reported to be associated with survival and surgical outcome in cirrhotic patients, and nutritional intervention such as supplementation of branched-chain amino acids (BCAA) could improve patient outcome[152,153]. Hypermetabolism, which is indicated by increased resting energy expenditure, has been reported to be associated with malnutrition, and the measurement of energy metabolism could thus be used to predict the prognosis of liver cirrhosis[154,155]. Hypermetabolism may be explained by increased α-adrenergic activity[156], and further investigation is required to determine whether the administration of beta-blockers is effective for the treatment of malnutrition in patients with liver cirrhosis.

The administration of BCAA has been reported to not only reduce malnutrition and improve energy metabolism, but also to improve the liver function and quality of life of patients with cirrhosis[157-159]. However, BCCA supplementation may be harmful because glucose intolerance can be exhibited by cirrhotic livers[55]. The administration of BCAA and α-glucosidase inhibitors in combination may improve the therapeutic effects[160].

In addition, hepatic glycogen stores decrease in patients with liver cirrhosis because of liver atrophy, leading to the development of a severe catabolic state after fasting. Late evening snacks including BCAA are recommended in order to avoid such problems during the night-time[158,159].

NERVOUS SYSTEM IN LIVER DISEASES

Liver diseases frequently affect the nervous system.

Hepatic encephalopathy

Hepatic encephalopathy (HE) is a major complication of chronic liver diseases with neuropsychiatric manifestations ranging from sleep disturbance to deep coma. The swelling of astrocytes and oxidative stress induced by ammonia, inflammatory cytokines, benzodiazepines and hyponatremia have been regarded as essential causes of HE[161]. Psychometric tests such as the number connection test may be effective for assessing HE[162], and neuropsychiatric function should be carefully evaluated in patients with chronic liver diseases including alcoholic liver disease and Wilson disease (WD). Minimal hepatic encephalopathy (MHE) occurs in 30%-80% of cirrhotic patients, which could be a serious problem because of the associated impaired quality of life[161,163]. For the management of patients with HE, removal of precipitating causes, such as gastrointestinal bleeding, excessive protein intake, hypokalemic alkalosis, infection, constipation (which can all increase blood ammonia levels), hypovolemia, hypoglycemia, hypoxia and the administration of sedatives, is important. Lactulose is the most effective therapy for HE so far, and has been reported to even be effective for patients with MHE[164].

Polyneuropathy and neurocognitive dysfunction

Nervous system disorders such as neuropathy, fatigue and depression are often associated with chronic HCV infection, even without advanced cirrhosis[165-167]. Mixed cryoglobulinemia in HCV causes peripheral neuropathy as a moderate axonal sensory polyneuropathy[168], and chronic sensory polyneuropathies were found in 13% of HCV infected patients with cryoglobulinemia in southern Italy[169]. In addition, paresthesia has been found in about 20% of patients with chronic HCV infection, particularly among those with cryoglobulinemia[170,171]. The therapeutic response to antiviral treatment for neuropathies is generally unsatisfactory[172]. Furthermore, fatigue or depression is found in many patients with chronic HCV infection, with incidences of about 50% and 35%, respectively[173-175]. These neurocognitive dysfunctions have been characterized epidemiologically or pathophysiologically in chronic HCV infection[166,167,176], and may be explained by the neuroinvasion of HCV, because HCV has been reported to be found in monocytes/microglia of the central nervous system[176,177]. However, antiviral treatment with interferon, particularly interferon-α, is known to exacerbate depression[178].

Guillain-Barre syndrome

Guillain-Barre syndrome accompanying hepatitis virus infection, which is primarily associated with HBV and rarely with HCV or hepatitis A virus, has also been reported[179-181]. Immune complexes have been found in the serum of these patients, which may be the cause of the development of the disease.

Autonomic and sensory nerve dysfunction

Autonomic and sensory nerve dysfunction presenting as reduced 24 h heart rate variability and lower current perception threshold has also been reported to be common in patients with PBC, particularly those suffering a severe form of the disease for a long period[182]. Peripheral sensory nerve dysfunction may contribute to hyperesthesia, leading to the itching that is a characteristic symptom of PBC[182].

Wilson disease

WD is an autosomal recessive inherited disorder of copper metabolism, resulting in excessive accumulation of copper in virtually all organs, especially in the liver. The clinical spectrum of liver diseases in WD is broad from asymptomatic with only mild biochemical

abnormalities, chronic active hepatitis, liver cirrhosis to fulminant hepatitis[183]. Copper accumulation is also remarkable in the cornea (Kayser-Fleischer rings) and brain in patients with WD. The patients show various neuropsychiatric symptoms such as dysarthria, dyspraxia, ataxia, a tremor-rigidity syndrome and psychoses, and progressive extrapyramidal neurological disorder is the typical sign of neurologic WD[183,184]. The initial neurological symptoms usually develop in mid-teenage years or in the twenties and are frequently misdiagnosed as behavioral problems associated with puberty[184].

BONE DISEASE ASSOCIATED WITH LIVER DISEASES

Metabolic bone disease is a common complication of chronic liver disease, particularly in patients with end-stage liver disease due to cholestatic disorders such as PBC. It has been reported that osteoporosis occurs in approximately 20%-30% of patients with PBC[185,186], and older age and severity of the disease were the main risk factors for osteoporosis[187]. Moreover, there were 2-fold relative increases in the risk of bone fractures in patients with PBC compared with the general population[188]. Although the mechanisms responsible for osteoporosis in liver diseases are not well understood, cirrhotic patients show reduced osteoid thickness, osteoblast surfaces and bone formation rate, suggesting the presence of an osteoblast defect[189].

In post-liver transplantation populations, osteoporosis is known to be a major complication[190]. Several studies suggest that bone loss is remarkable within the first year after liver transplantation. The etiology is multifactorial, consisting of both preexisting low bone mineral density associated with underlying liver disease and post-transplantation factors[190]. High-dose corticosteroids and immunosuppressive agents such as cyclosporine A are thought to contribute to bone loss[191]. Although few prospective studies are available, vitamin D and calcium supplementation are generally recommended for those patients[192].

ARTHROPATHY IN LIVER DISEASES

Arthralgia or arthritis is often seen in patients with liver diseases, and it is not rare that arthropathy may be the first presentation of the disease[193]. In acute viral hepatitis, especially in HBV infection, patients may show polyarthralgia or polyarthritis during the prodromal period and immune complex is thought to be responsible for the pathogenesis[194]. Similar arthropathies are seen in patients with chronic hepatitis C, autoimmune hepatitis, PBC, hemochromatosis or WD[193]. Arthralgia or arthritis is reported to be the most common extrahepatic manifestation in patients with hemochromatosis, autoimmune hepatitis and PBC. Polyarthralgia is also the most common symptom of mixed cryoglobulinemia[195], which often occurs secondary to HCV infection.

SEXUAL DYSFUNCTION IN LIVER DISEASES

Erectile dysfunction (ED) is frequently problematic in patients with chronic liver diseases such as hemochromatosis[196], alcoholic liver disease[197] or liver transplant patients[198], leading to worsening of quality of life in those patients. Hypogonadism or protein malnutrition found in patients with advanced liver disease may induce ED[199,200]. Removal of causative factors such as iron or ethanol, or administration of testosterone may improve ED in such patients[197,198]. ED is also more frequent in patients with chronic HCV infection than in control subjects (39% *vs* 14%, respectively) probably due to a direct effect of HCV on neurovascular and hormonal systems (i.e. low testosterone levels)[201]. Successful antiviral treatment such as interferon plus ribavirin may improve such sexual dysfunction in patients with chronic HCV infection[202].

DOSAGE ADJUSTMENT OF DRUGS IN LIVER DISEASES

The liver is the main organ of biotransformation and elimination of drugs. Thus, liver diseases could affect drug metabolism, resulting in abnormally high concentrations of drugs in the body.

Drug elimination by the liver may be determined mainly by first-pass effect, hepatic metabolism and biliary extraction. In addition, since the liver produces most plasma proteins, decreased liver function could influence the binding of drugs to plasma proteins, leading to changes in the distribution and elimination of such drugs[203].

The first-pass effect of each drug is variable and drugs with high first-pass effects are listed in Table 3[204]. The serum concentration of these drugs could easily be elevated by a decrease in hepatic blood flow (especially portal blood flow) or total hepatocyte mass. For drugs with a high first-pass effect, both initial dose and maintenance dose should be reduced in cirrhotic patients if the drug is orally administered.

Drug metabolism in the liver largely depends on the activity of the cytochrome P (CYP) 450 enzymes, which is known to be affected in different ways in patients with cirrhosis. The activities of CYP3A, 1A and 2C19 are reported to be substantially reduced, whereas those of CYP2D6, 2C9, 2B and 2E1 are also reduced, but to a lesser extent[205]. The severity of liver cirrhosis is estimated using Child-Pugh (C-P) classification, and patients with C-P grade A show mild to moderate deterioration of CYP activities. On the other hand, patients with C-P grade B or C are shown to have prominent reduction in CYP activity. Therefore, the doses of drugs mainly metabolized by CYP 3A, 1A or 2C19 in the liver may need to be reduced in these patients (Table 3)[206]. Moreover, cirrhotic patients often have impaired renal function, despite a normal serum

Table 3 Drugs that may need to be administered at reduced doses in patients with liver cirrhosis[187]

Drugs with high first-pass effect	Drugs metabolized mainly by		
	CYP 1A2	CYP3A4	CYP2C9
Amitriptyline	Acetaminophen	Quinidine	Diclofenac
Bromocriptine	Caffeine	Amiodarone	Ibuprofen
Diltiazem	Mexiletine	Lidocaine	Mefenamic acid
Flumazenil	(R)-Warfarin	Midazolam	Tolbutamide
Fluorouracil	Imipramine	Diazepam	Phenytoin
Imipramine	Theophylline	Amitriptyline	Phenobarbital
Isosorbide dinitrate	Propranolol	Imipramine	(S)-Warfarin
Labetalol	Tamoxifen	Carbamazepine	Losartan
Lidocaine	Estradiol	(R)-Warfarin	Piroxicam
Morphine		Erythromycin	
Nifedipine		Clarithromycin	
Pentazocine			
Propranolol			
Verapamil			

creatinine level[207]. Therefore, creatinine clearance should be measured or estimated in cirrhotic patients to determine the appropriate dose of drugs with predominant renal excretion.

RISK OF SURGERY IN PATIENTS WITH LIVER DISEASES

Patients with liver diseases face relatively high risks during surgery, and these risks could be increased according to the progression of liver disease. A decrease in hepatic blood flow during anesthesia or surgery is thought to be mainly responsible for postoperative liver damage, and Cowan *et al*[208] reported that a major reduction in hepatic blood flow occurs after the induction of anesthesia, but not during or after surgery.

In acute viral hepatitis, as well as acute alcoholic hepatitis, the risk of surgery might be extremely high. Therefore, surgery should be avoided unless the situation is life-threatening[209]. In contrast, surgery on patients with chronic hepatitis can generally be considered safe[210], and there have been no deaths or complications reported in patients with chronic hepatitis C undergoing laparoscopic cholecystectomy[211]. In patients with liver cirrhosis, complications and mortality rates of surgery are high[212], especially if one or more of the following factors apply to the patient: elevated bilirubin, prolonged PT, ascites, decreased albumin, encephalopathy, portal hypertension, elevated creatinine concentration, intraoperative hypotension and emergent surgery[213]. The outcome of surgery also depends on the invasiveness or duration of the operation[214]. There are two scores for the assessment of the progression of liver cirrhosis: the model for end-stage liver disease (MELD) score and the C-P grade[215]. Both scores are useful for assessing the risk of surgery, and C-P classification was reported to be useful in stratifying the risk of death. Two studies showed that patients in class A had mortality rates of about 10%, those in grade B had mortality rates of around 30%, and those in grade C had mortality rates above 70%[216,217]. A recent study in Italy also reported similar mortality rates of surgery for patients with liver cirrhosis (C-P grade A; 7.1%, C-P grade B; 23%, C-P grade C; 84%)[218]. Teh *et al*[219] recently reported that MELD score, age and American Society of Anesthesiologists class are important predictors for the risk of postoperative mortality in patients with cirrhosis. Interestingly, they also reported that the risk was not associated with the type of surgery performed. For MELD, operation risks increase according to the score, and one report showed that a MELD score $\geqslant$ 14 or plasma hemoglobin levels < 10 g/dL were independent predictors of poor outcomes in patients undergoing abdominal surgery excluding hepatic surgery[220]. For patients undergoing laparoscopic cholecystectomy, a preoperative MELD score of 8 was linked to high morbidity, and was suggested as the cutoff value for avoiding the operation in patients with liver cirrhosis[221]. However, Schiff *et al*[222] recently reported that preoperative platelet levels and PT (international normalized ratio) are more important factors for the safety of cholecystectomy than C-P grade.

In patients undergoing cardiac surgery, the risk of mortality or complications may be high when a cardiopulmonary bypass is performed on patients with chronic liver disease[223]. In general, the mortality of cirrhotic patients with C-P grade A is low, but that of patients exhibiting C-P grade B for a long period and that of all patients with C-P grade C is high, especially when open heart surgery is performed. Therefore, open heart surgery should be avoided for patients with C-P grade C, and cardiac operation on the beating heart is recommended for patients with C-P grade B[224]. The results of another study led to the recommendation that patients with a C-P score > 7 avoid cardiac surgery involving cardiopulmonary bypass[225].

In summary, surgery should be avoided for patients with acute hepatitis. However, surgery is generally safe for patients with chronic hepatitis and cirrhotic patients with C-P grade A. The risks are elevated for cirrhotic patients with C-P grade B or C, or patients with a MELD score of $\geqslant$ 8, though this might vary according to the type of surgery performed. Other predictive factors for safe surgery are platelet count and PT, both of which are markers for the tendency to bleed profusely and for the progression of liver disease.

CONCLUSION

Liver diseases often cause systemic abnormalities, and it is not uncommon that these complications, rather than the liver disease itself, determine the quality of life and prognosis of patients. Therefore, both hepatologists and non-hepatologists should always pay attention to the abnormalities caused by liver diseases, and should be concerned with their management in addition to the actual treatment of the liver disease itself.

Abstract

Eosinophilic colitis (EC) is a rare form of primary eosinophilic gastrointestinal disease with a bimodal peak of prevalence in neonates and young adults. EC remains a little understood condition in contrast to the increasingly recognized eosinophilic esophagitis. Clinical presentation of EC is highly variable according to mucosal, transmural, or serosal predominance of inflammation. EC has a broad differential diagnosis because colon tissue eosinophilia often occurs in parasitic infection, drug-induced allergic reactions, inflammatory bowel disease, and various connective tissue disorders, which require thorough searching for secondary causes that may be specifically treated with antibiotics or dietary and drug elimination. Like eosinophilic gastrointestinal disease involving other segments of the gastrointestinal tract, EC responds very well to steroids that may be spared by using antihistamines, leukotriene inhibitors and biologics.

INTRODUCTION

Primary eosinophilic gastrointestinal disease (EGID), originally described by Kaijser in 1937[1], is a rare spectrum of gastrointestinal disorders characterized by inflammation rich in eosinophils, without evidence of known causes for eosinophilia, such as parasitic infection, drug reaction, or malignancy[2]. The disease can affect any segment or combination of segments of the gastrointestinal tract from the esophagus to the rectum, giving rise to various clinical presentations including eosinophilic esophagitis (EE), eosinophilic gastritis, eosinophilic gastroenteritis, and eosinophilic colitis (EC). Since secondary eosinophilic inflammation may occur in numerous gastrointestinal disorders such as IgE-mediated food allergy, gastroesophageal reflux disease, and inflammatory bowel disease, the true incidence and prevalence of primary EGID remains largely unknown. A recently established world-wide-web registry found that EGID mainly affects the pediatric population, although it has been reported in patients up to 68 years of age[3]. In the past few years, EE has been increasingly recognized as a distinct condition that affects about 1% of the population, and accounts for dysphagia and food impaction that remain non-responsive to traditional anti-reflux management, both in pediatric and adult gastroenterology[4]. Accordingly, several excellent reviews on EE have recently been published[4-6]. In contrast, EC represents the least frequent manifestation of EGID whether or not it presents with disease in other segments of the gastrointestinal tract[3]. EC appears to have a bimodal distribution that affects neonates with a relatively high prevalence and a separate group of young adults with no gender preference[2].

CLINICAL PRESENTATION

EGID in general has three hallmarks including peripheral eosinophilia (typically in the range of 5% to 35%), segmental eosinophilic infiltration of the

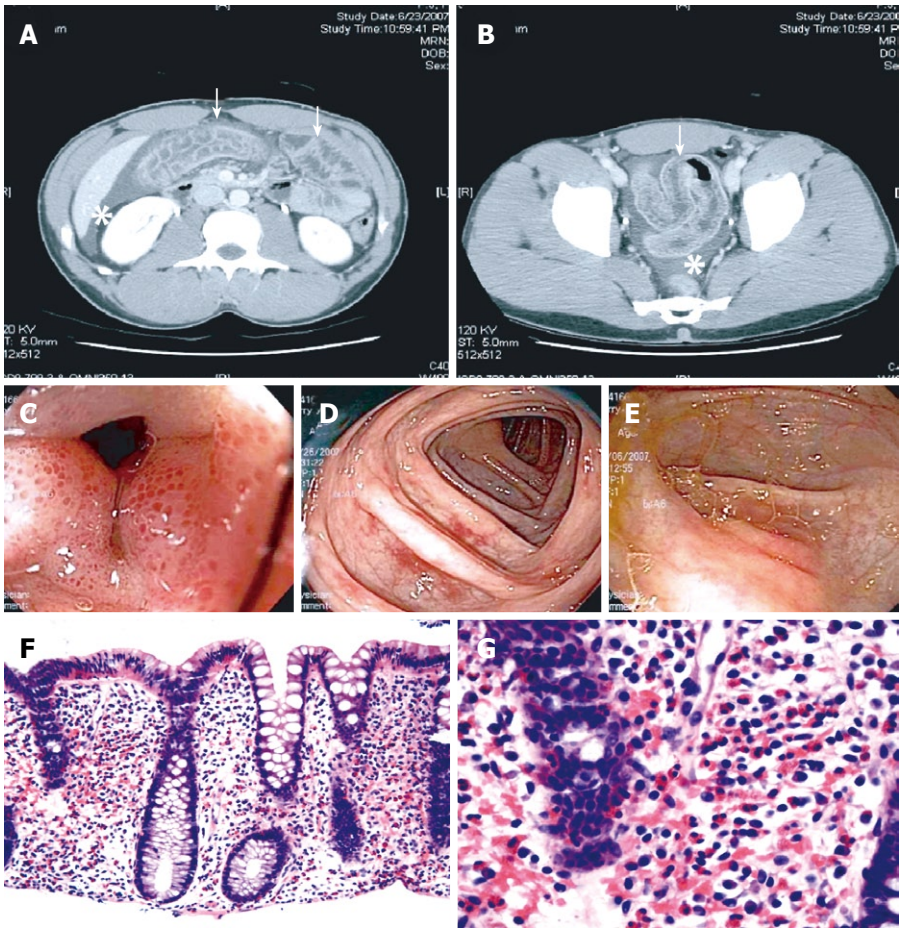

Figure 1 Diagnostic findings in EC. Representative images from a case of a previously healthy 30-year-old man with recurring episodes of abdominal pain, non-bloody diarrhea, and peripheral eosinophilia; extensive workup confirming EC by exclusion; and excellent response to short-term steroid therapy. A and B: Abdominal CT shows circumferential colon wall thickening (arrows) and moderate ascites (asterisks); C-E: Colonoscopy reveals patchy areas in the colon with mucosal edema and punctate erythema; F and G: Histology indicates markedly increased tissue eosinophilia in all examined segments of the colon. HE stains, magnification 100 × and 400 ×, respectively.

gastrointestinal tract, and functional abnormalities[7,8]. Importantly, up to 23% of patients with primary EGID have no peripheral eosinophilia[7]. Symptoms and signs of EGID are usually non-specific and, depending on the affected segment, include abdominal pain, nausea, vomiting, diarrhea, gastrointestinal bleeding, obstruction, malabsorption, weight loss, and ascites. In 1970, Klein *et al*[9] subdivided the disease based on the layer of intestinal wall most extensively infiltrated by eosinophils, to distinguish mucosa-predominant, muscularis-propria-predominant, and serosa-predominant forms of EGID.

The above classification provides good correlation of the physical symptoms and signs with the pathological findings, and it is also applicable to EC. Thus, mucosa-predominant disease shows evidence of mucosal dysfunction, such as protein-losing enteropathy, malabsorption, and diarrhea. Transmural disease is recognized by symptoms of intestinal obstruction and bowel wall thickening on imaging studies. Finally, serosal involvement is distinguished by the presence of eosinophilic ascites, with up to 88% eosinophils seen on fluid analysis[10]. Accordingly, while mucosal EC results in diarrhea[11], the transmural form has been associated with volvulus[12], intussusception[13,14], and even perforation[15,16], and involvement of the intestinal serosa may manifest with ascites[17], which was also illustrated by a case that we have encountered recently (Figure 1).

DIAGNOSTIC CRITERIA AND DIFFERENTIAL DIAGNOSIS

The diagnosis of EGID is made from the presence of gastrointestinal symptoms, peripheral eosinophilia, endoscopic and histological findings, and eosinophilic ascites, with no well-defined causes of eosinophilia on thorough evaluation[8]. A multidisciplinary task force has recently reached consensus on the diagnostic criteria of EE, including the presence of more than 15 eosinophils per high-power field in the esophageal squamous mucosa[6]. No such consensus exists for EC, although most authors have used a diagnostic threshold of 20 eosinophils per high-power field. Of note, normal values for tissue eosinophils vary widely between different segments of the colon, ranging from < 10 eosinophils per high-power field in the rectum to > 30 in the cecum[5], thus location of the biopsy is critically important for interpretation of findings.

More or less prominent tissue eosinophilia in the colon may result from a number of conditions (Table 1) and EC remains therefore a diagnosis of exclusion. Colonoscopic biopsies obtained from patients with inflammatory bowel disease, in particular with Crohn's colitis, often show severe tissue eosinophilia[18]. Parasitic infection of the colon with pinworms, roundworms, or whipworms may lead to marked eosinophilic infiltration, and repeated stool or serological testing may be needed to reveal this specific etiology[19-23]. Drug-induced EC has been de-

EC: Eosinophilic colitis; HES: Hypereosinophilic syndrome.

scribed in response to clozapine[24], carbamazepine[25], rifampicin[26], non-steroidal anti-inflammatory agents[27,28], tacrolimus[29], and gold[30]. EC has also been associated with autoimmune connective tissue disease including scleroderma, dermatomyositis and polymyositis[11,31,32], as well as with allogeneic bone marrow transplantation[33] and the rare Tolosa-Hunt syndrome that features inflammatory ophthalmoparesis[34]. The idiopathic hypereosinophilic syndrome (HES) may also affect the colon, but this rare condition presents with sustained and marked peripheral eosinophilia with end-organ damage that extends beyond the gastrointestinal tract (e.g. heart and skin)[35].

ETIOLOGY AND PATHOGENESIS

The etiology of primary EGID remains largely unknown. Several studies have suggested a relationship with specific food allergies; indeed, about 75% of affected patients have a history of allergy or atopy[2]. Cow's milk and soy proteins are the foods most frequently implicated in the infantile form of EC, although the condition has been described in infants exclusively breast-fed or given protein hydrolysate formulas[2]. Even less is known about the potential causes of the adult form of primary EC. A case report by Inamura *et al*[36] has demonstrated accumulation of mast cells in the colon interstitium after immunohistochemical staining for mast cell tryptase, which suggests the pathogenic role of IgE, while other observations suggest that EC may not be an IgE-mediated disease. Thus, colonic T cells in an animal model have been shown to transfer oral antigen-induced diarrhea to naive mice through a STAT6-dependent mechanism[37]. Specific eosinophil chemoattractants, such as interleukin-5 and eotaxins, may also have a pathogenic role in EC[38]. While EE may develop without other gastrointestinal involvement when experimental animals are sensitized and challenged in the lung, direct exposure of the gastrointestinal mucosa seems to result in multisegmental disease[39].

TREATMENT

No prospective randomized controlled trials exist to date on specific therapy for EC or any other forms of primary or idiopathic EGID. Therapeutic efforts have been based on case reports and small case series. Corticosteroid therapy has formed the backbone for initial management, and it has proven to be the most effective instrument for symptom control in EC[2,40,41]. Up to 90% of cases will respond within 2 wk of treatment, when a slow taper is initiated. However, relapse is frequent and requires recurrent courses or leads to steroid dependence. A role for budesonide has been demonstrated, particularly in disease of the right colon and ileum[42]. It must be emphasized that efforts to rule out parasitic or drug-induced EC are important since empiric treatment with corticosteroids may aggravate the patient's condition, or at least, it may be avoidable. The beneficial effect of elimination and elemental diets has been limited to cases with specific food allergies, especially in treating neonatal disease[43].

Approaches to avoid steroids by using alternative medications have been directed mostly to more prevalent forms of EGID, and expertise about their need and efficacy in EC has been limited. Antihistamine therapy in EGID appears to be gaining prominence. Ketotifen, an H1 antihistamine not yet available in US, has been shown to decrease symptoms as well as tissue eosinophilia[44,45]. The leukotriene inhibitor montelukast, an agent that blocks the action of potent eosinophil chemoattractant leukotriene D4, by competitively antagonizing its receptor expressed on eosinophils, has also been found to be helpful in EGID[46,47]. Mast cell stabilizers, such as cromolyn, are effective by inhibiting release of mast cell mediators such as histamine H1, platelet activating factor, and leukotoxin[48]. More recently, the role of biologics in EGID has also been studied, with favorable outcomes reported by using monoclonal antibodies targeting interleukin 5 (mepolizumab) and IgE (omalizumab)[49,50].

CONCLUSION

In summary, EC is a rare manifestation of the EGID spectrum, which does not appear to be increasing in prevalence, in contrast to recent trends seen in esophageal disease. This dichotomy suggests a disparate pathophysiology of EC, with the possibility that EC itself is a heterogeneous entity. While the pediatric form of EC often subsides without intervention, or upon withdrawal of atopic stimuli, the adult form may relapse and require short-term steroid therapy. Importantly, EC needs to be included in the differential diagnosis of many conditions with primary or secondary involvement of the gastrointestinal tract.

Abstract

"Psychosocial stress" is an increasingly common concept in the challenging and highly-demanding modern society of today. Organic response to stress implicates two major components of the stress system, namely the hypothalamic-pituitary-adrenal axis and the sympathetic nervous system. Stress is anamnestically reported by patients during the course of disease, usually accompanied by a decline in their overall health status. As the mechanisms involving glucocorticoids and catecholamines have been deciphered, and their actions on immune cell function deeper understood, it has become clear that stress has an impact on hepatic inflammatory response. An increasing number of articles have approached the link between psychosocial stress and the negative evolution of hepatic diseases. This article reviews a number of studies on both human populations and animal models performed in recent years, all linking stress, mainly of psychosocial nature, and the evolution of three important liver-related pathological entities: viral hepatitis, cirrhosis and hepatocellular carcinoma.

Key words: Stress; Chronic viral hepatitis; Cirrhosis; Carcinoma; Hepatocellular; Liver pathology

INTRODUCTION

Over time, stress has received a number of definitions in the scientific literature, more or less accurate or complete. One of the most commonly accepted psychological definitions has been that stress occurs when demands from the environment challenge an individual's adaptive capacity, or ability to cope[1]. Several life-changing or threatening events are considered to be "stressors"; factors that are either acute or chronic based on the duration of their interaction. Both have been associated with several immune system dysfunctions, whether or not the individual is affected by an acute or chronic disease[2].

Once an individual is subjected to such a stressor, specific pathways within the brain lead to the activation of the hypothalamic-pituitary-adrenal (HPA) axis as well as the central sympathetic outflow. This constitutes the stress response, releasing key peripheral mediators-glucocorticoids and catecholamines[3].

For a long time, it was suggested that stress influenced hepatic blood flow by inducing vasospasm and centrilobular hypoxia, leading to liver damage[4,5]. In more recent years, as the understanding of stress mediators has improved, the effect that stress has on the onset and development of liver damage during acute and chronic liver diseases has gained a new dimension[3,6].

This article reviews an important part of current literature on the effects of stress on the status of three major interrelated hepatic conditions: viral hepatitis, cirrhosis and hepatocellular carcinoma. We tried to cover the physiological aspects of the stress system and its relationship with several cellular pathways, the immune system effectors and the level of cellular alteration at the hepatic level.

THE HPA AXIS AND CENTRAL SYMPATHETIC NERVOUS SYSTEM

Physiology and interactions with immune-mediated inflammation

The HPA axis and the systemic sympathetic and adrenomedullary system are the key components of

the stress system. Their main function is to maintain basal and stress-related homeostasis[7,8]. They respond to several signaling molecules, such as cytokines produced by immune-mediated inflammatory reactions, tumor necrosis factor (TNF)-α, interleukin-1 (IL-1), and interleukin-6 (IL-6)[7-9].

Corticotrophin-releasing hormone (CRH) and noradrenergic neurons of the central stress system innervate and stimulate each other[7-10]. By using specific receptors, CRH stimulates norepinephrine secretion, while in turn norepinephrine stimulates CRH secretion primarily through α_1-noradrenergic receptors[7,8,10]. An ultrashort negative-feedback loop also exists for both CRH and norepinephrine, down-regulating their production. The serotonergic and cholinergic systems stimulate CRH, arginine vasopressin (AVP), and noradrenergic neurons whilst being inhibited by the opioid-peptide and γ-aminobutyric acid-benzodiazepine systems existing in the brain. Hypothalamic CRH neurons are inhibited by centrally secreted substance P while AVP neurons remain unaffected. Substance P also stimulates the central noradrenergic system[11-13].

CRH-induced secretion of proopiomelanocortin-derived and several other opioid peptides concurs with stress system activation[14,15] which enhances overall analgesia[7,8]. CRH also stimulates corticotrophin secretion through the corticotrophs of the anterior pituitary[16-18]. Adrenal medulla hormones, especially corticotrophin, are principal regulating factors of glucocorticoid secretion[19-23].

All key hormones secreted by HPA components play different roles in the modulation of the immune response and the development of the inflammatory reaction.

Some leukocyte functions are influenced by glucocorticoids, as they suppress cytokine immune activation by inhibiting the production of cytokines and other inflammation mediators, as well as causing resistance to cytokines[7,8,24,25]. The functionality of Type 1 helper T lymphocytes is suppressed whilst eosinophil apoptosis is stimulated. Adhesion molecule expression is inhibited along with their specific receptors[26], while the acute phase reaction is being potentiated[27]. The pituitary hormones, corticotrophin and β-endorphin[28,29], have immunopotentiating and proinflammatory properties. Additionally, β-endorphin produced at inflammatory sites is a potent local analgesic[30].

The hypothalamus exerts a regulatory effect over the HPA axis through CRH and AVP secretion. Their proinflammatory effects have been studied both *in vitro* and *in vivo*[31-38]. CRH concentrations remain high at inflammatory sites, while remaining undetectable in plasma samples obtained concurrently[31]. Rapid catabolism, uptake or binding are thought to be primary mechanisms which prevent CRH from remaining active in the systemic circulatory system[31,39,40]. In addition to the HPA axis, the central sympathetic nervous system is directly connected with the modulation of the stress response. Stimulation of the locus coeruleus-norepinephrine system activates the central nerve pathways, thus influencing peripheral sympathetic outflow[3,4]. This triggers catecholamine release from autonomic nerve endings and from the adrenal medulla[4]. Catecholamines can influence the hepatic inflammatory response by altering hemodynamics[3]. Recently, catecholamine receptors were discovered on immunocompetent cells, thus it is believed that catecholamines can directly influence the immune response[3,6].

STRESS AND CHRONIC VIRAL HEPATITIS

In recent years, a number of studies have established an increasingly clear link between psychosocial or psychophysical stress, personality types and the development of viral hepatitis. Both human clinical trials[41-46] and animal model studies[47-52] were devised in order to prove the interaction between the two.

A clinical trial, performed by Nagano *et al*[41] indicated a positive correlation between psychosocial stress and the severity of chronic hepatitis C. Type 1 personality subjects, due to the nature of their personality traits (low sense of control, object dependence of loss, unfulfilled need for acceptance and altruism) are highly likely to be affected by chronic psychosocial stress. Type 1 personality and psychosocial stress were positively linked to the severity of chronic hepatitis C. Stress was measured using a Stress Inventory questionnaire and a personality evaluation was devised using items from the Grossarth-Maticek theory (according to this theory, type-1 personality subjects are positively associated with malignant neoplasms and chronic diseases)[42]. Patients were divided into three groups depending on the severity of chronic hepatitis C, measured by liver function laboratory parameters (ALAT values, platelet count, albumin and total bilirubin levels). Ultimately, two distinct groups resulted by unifying the 2nd and 3rd initial groups, as their values were similarly elevated. Platelet count and serum albumin levels were positively correlated with hepatitis C severity, both of them being strongly correlated with elevated stress scores. ASAT values strongly correlated with both levels of stress and the presence of type 1 personality traits.

Kunkel *et al*[43] investigated the connections between depression scores, psychosocial stressors, social support, and biological markers of dysfunction of a group of 50 Korean immigrants with chronic viral hepatitis B. Several indicators of liver function, including hepatic transaminases, albumin levels, and prothrombin times (PT) were measured during routine clinic follow-up visits and were correlated with scores obtained from the short form Beck Depression Inventory (BDI-sf). Higher BDI-sf scores were significantly associated with elevated transaminases ($P < 0.001$). Both PT and decreased albumin levels were not significantly correlated with increased BDI-sf scores.

Both studies excluded patients with decompensated cirrhosis, malignant disease, coronary heart disease, stroke, co-infection or interferon treatment.

Clinical studies suggest that chronic psychosocial

stress affects antibody response after hepatitis B vaccination[43,44]. A higher score in stress inventory questionnaires given to the test subjects was positively correlated with a weaker immune response, when administering the same antigen dose[44,46].

Psychosocial stress has intricate relationships with inflammatory and fibrosing changes of the liver during the course of hepatitis[47]. Kaji et *al*[48] reported that serum levels of transaminases increased due to stress in the galactosamine-injured liver of rats. Several animal models have suggested that inflammation-related HPA-activated pathways are influenced by stress.

Psychophysical stress simulated by inescapable foot-shock induced elevations of glucocorticoids (GCs), exacerbating α-galactosylceramide-triggered apoptosis through proliferation of liver natural killer T (NKT) cells and up-regulating the expression of Fas antigen on hepatocytes. GC directly elevates Fas antigen expression, probably through intracellular signal cascades[49]. Several other studies[50,51] established that *in vivo* administration of dexamethasone, an exogenous GC, enhanced the number of liver α-galactosylceramide-activated Vα14 natural killer T cells in mice. As NKT cells play an important immunological role in liver homeostasis[52,53] as well as in hepatocyte apoptosis through their Fas-ligand coated surface[54-56], it is clear that GC elevations during stress negatively influence the pathological state of the liver.

Tamada *et al*[57] found in mice the increased production of IL-4-hepatic NK1.11 T cells after exogenous administration of dexamethasone, thus demonstrating that these cells are resistant to glucocorticoid-induced apoptosis. Their study suggested that the process may play a role in determining the hepatic Th1/Th2 balance in times of stress or during GC therapy.

GCs downregulate expression of endothelial cell adhesion molecules, thus producing inhibitory effects on neutrophil recruitment in liver[3,58]. Increased circulating endogenous GC levels hence decrease hepatic neutrophil chemotaxis, as well as lymphocyte recruitment[58].

GCs inhibit IL-6 and TNF-α at transcriptional and translational levels[59,60]. Endogenous corticosterone, at normal or stress levels, induces IL-6 and TNF-α in an *in situ* liver perfusion, which lead to the conclusion that GCs have additional non-suppressive effects[60].

STRESS AND LIVER CIRRHOSIS

Psychosocial stress *per se* may exaggerate inflammatory and fibrosing change in the cirrhotic liver[3,6,47].

Nagano *et al*[41] included in their clinical test a subset of patients affected by cirrhosis. They found the same positive correlation between psychosocial stress and liver injury, as ALAT values strongly correlated with high stress scores in the cirrhosis cohort.

Tanaka *et al*[61] conducted a long-term follow-up study determining risk factors for malignant transformation of cirrhotic lesions in Japanese patients. His study also demonstrated a possible link between the presence of stress and precipitating indicators for cirrhosis.

Several animal studies were conducted, outlining important cellular mechanisms that link stress response of the sympathetic nervous system, as well as alterations of the HPA axis responsiveness, with liver inflammation in cirrhosis.

Electric foot shock stress exacerbated liver injury in rats treated with carbon tetrachloride[62]. Alterations of the HPA axis responsiveness, as well as elevated plasma cytokine levels, accompany experimental chronic liver disease in mice. Elevated TNF-α and IL-6 levels, coupled with liver injury, decrease hypothalamic mRNA and protein expression of CRH. When mice are exposed to psychological stress, HPA axis functions abnormally, suffering defective activation and significant attenuation in the resultant release of GCs, compared to control groups[63].

NKT cell activity was linked with fibrosing and inflammatory damage in cirrhosis[64]. Epinephrine and norepinephrine, *via* several subtypes of adrenoceptor (AdR), cause expansion of liver NKT cells[49-52,65,66], production of IL-6 from hepatocytes and TNF-α[3,6,49] from Kupffer cells, as well as impairment of hepatic blood flow (HBF). GCs inhibit the production of IL-10, IL-6, TNF-α, PGE_2 leukotrienes and nitric oxide[3,6,61,66] from Kupffer cells. Two mechanisms are involved, a direct one (affecting the stability of mRNA and gene transcription) and an indirect one, by inhibiting the production of the nuclear factor (NF)-κB and the activator protein (AP)-1.

Tjandra *et al*[67] suggested that psychosocial stress itself can influence the course of hepatic inflammation, by directly altering IL-6 and TNF-α production.

Also, Kitamura *et al*[68] studied how immobilization stress can induce increased IL-6 mRNA expression in the liver, as well as an elevation of the plasma IL-6 level. He made a clear distinction between IL-6 produced within hepatocytes and that produced in non-parenchymal cells, using immunohistochemical techniques.

This distinction was further demonstrated by an *in vitro* experiment, using primary cultured rat hepatocytes[68]. This study also explored the effect sympathetic nervous system mediators such as epinephrine and norepinephrine have on TNF-α and IL-6 produced by Kupffer cells and hepatocytes. An increase in norepinephrine is mediated through α_1-, α_2- and β_1- adrenergic receptors, leading to an increased production of pro-inflammatory cytokines[68-72].

Nakajima *et al*[73] discovered that patients with liver cirrhosis and decreased NKT cell activity were at a higher risk of developing hepatocellular carcinoma than those with normal natural killer cell activity.

INFLUENCE OF STRESS ON HEPATOCELLULAR CARCINOMA (HCC) PROGNOSIS

The effects psychosocial stress has on immune suppression in patients with malignant metaplasia are well

established[74]. However, its effects on hepatocarcinoma are yet to be determined. It has been hypothesized that several psychosocial factors, including stress, may account in part for rapid hepatocarcinoma development. Biobehavioral models were suggested in order to demonstrate this interaction[74,75]. Cancers with a strong immune-mediation component, such as HBV-related HCC are believed to be the most appropriate[75].

Several studies proved the correlation between stress and progression of various types of cancer in humans[76-79]. In these studies, positive correlations were found between stress and the grade of dysplasia[76], overall survival[77,78] and cancer recurrence[79].

By using this knowledge, psychological intervention was used as a tool to improve immune functioning and to reduce progression[80-82]. Similar studies were conducted by Spiegel *et al* who observed extended survival in patients affected by cancer after group therapy and other forms of stress-relieving techniques[83].

Carcinoma is associated with high concentrations of TNF-α. Stress, as outlined in several studies, directly influences TNF-α, IL-1, and IL-6 expression[59-61,66-68], in turn influencing the activity of NKT cells[48,50,51]. As a result, stress and depression can influence tumor progression at a cellular level.

Several animal models demonstrated relationships between stress, immune reactivity and tumor growth, by influencing IL-2 production, plasma L3T4 antigen and elevating GCs[74,75].

Liu *et al*[83] demonstrated in a recent study that survival time of mice affected by HCC is greatly reduced when subjected to social isolation stress. He compared the titer of antibody to sheep red blood cell (SRBC), as well as IL-2 levels, and survival time between two groups. Individuals exposed to isolation stress positively correlated with a lower survival time as well as with negatively altered serum values of both SRBC antibodies and IL-2.

Psychosocial stress was also linked to increased DNA damage, alterations in DNA repair and inhibition of apoptosis[84-88].

Sivonova *et al*[84] studied how academic stress during student examinations positively affects oxidative stress and induces direct DNA damage. Single strand breaks of DNA as well as sensitivity to lipid oxidation and the antioxidant status were studied on examination day, as well as at a random time between examinations. They found that in stressful conditions oxidative damage to DNA as well as sensitivity to lipid oxidation were significantly increased ($P < 0.05$), while plasma antioxidant activity was severely decreased ($P < 0.05$), in comparison to the control group of non-stressed individuals.

Glaser *et al*[85,86] proved the association between rotational stress and low concentrations of O6-methyltransferase, an enzyme linked to DNA repair induced in response to carcinogen damage. Their animal study was conducted on forty-four rats to whom dimethylnitrosamine was administered. The group was divided into two, half being randomly assigned to a rotational stress condition[85].

In a study regarding psychological stress, Tomei *et al*[89] found that cellular death decreased during examination compared with a control group, after phorbol ester (tumor promoter through activation of protein kinase C[90]) inhibition of radiation-induced apoptosis. This goes on to demonstrate that stress, having a negative impact on apoptosis, serves as a tumoral proliferation promoter.

CONCLUSION

As seen above, stress has been identified in recent years as an important factor in the progression and outcome of several important liver pathologies. It influences the immune system and several intra- and inter-cellular mechanisms. Comprehensive models that try to integrate these complex mechanisms are being developed.

From a clinical perspective, a better understanding of how stress alters hepatic inflammation would provide additional tools for the management of important liver diseases. It would influence the quality of life of patients by shortening hospitalization times and ensuring a correct therapeutic approach.

For a better understanding of the relationship between stress and liver pathology, we suggest that further studies on both human and animal models be conducted. Comprehensive clinical trials could be devised, which would test positive correlations between elevated stress scores and a number of both serological and imaging parameters assessing disease in hepatic patients. Animal studies should investigate immunohistochemical and genetic alterations at cellular level in the liver of stress-challenged hepatic-impaired rodents.

Abstract

AIM: To test whether oral L-81 treatment could improve the condition of mice with diabetes and to investigate how L-81 regulates microsomal triglyceride transfer protein (MTP) activity in the liver.

METHODS: Genetically diabetic (*db*/*db*) mice were fed on chow supplemented with or without L-81 for 4 wk. The body weight, plasma glucose level, plasma lipid profile, and adipocyte volume of the *db*/*db* mice were assessed after treatment. Toxicity of L-81 was also evaluated. To understand the molecular mechanism, HepG2 cells were treated with L-81 and the effects on apolipoprotein B (apoB) secretion and mRNA level of the MTP gene were assessed.

RESULTS: Treatment of *db*/*db* mice with L-81 significantly reduced and nearly normalized their body weight, hyperphagia and polydipsia. L-81 also markedly decreased the fasting plasma glucose level, improved glucose tolerance, and attenuated the elevated levels of plasma cholesterol and triglyceride. At the effective dosage, little toxicity was observed. Treatment of HepG2 cells with L-81 not only inhibited apoB secretion, but also significantly decreased the mRNA level of the MTP gene. Similar to the action of insulin, L-81 exerted its effect on the MTP promoter.

CONCLUSION: L-81 represents a promising candidate in the development of a selective insulin-mimetic molecule and an anti-diabetic agent.

Key words: Pluronic L-81; *db*/*db* mice; Animal models; diabetes; Microsomal triglyceride protein

INTRODUCTION

Pluronic® surfactants or poloxamers are synthetic copolymers based on ethylene oxide and propylene oxide. They are synthesized by controlled addition of propylene oxide to the two hydroxyl groups of propylene glycol[1]. Pluronic surfactants are widely used in industries as defoaming and antifoaming agents in dishwashing, antifreeze, cutting and grinding fluids, water treatment, *etc.* They are also being investigated as drug delivery vectors[2] and cancer therapies[3]. Pluronic L-81

(L-81) contains 10% hydrophilic and 90% hydrophobic polyoxyethylene residues with a molecular weight of 2750.

L-81 has profound effects on the lipid metabolism of the intestine and the liver. Chronic feeding of rats with L-81 greatly reduced the lymphatic lipid transport from their intestine, without affecting the digestion and absorption of lipid into enterocytes. The absorbed lipid was however accumulated in the enterocytes, suggesting that L-81 interferes with lipoprotein assembly and/or exit of lipoproteins from the mucosal cells[4]. L-81 inhibits chylomicron formation but not very low density lipoprotein (VLDL) assembly in the intestine[5]. On the other hand, L-81 effectively inhibits VLDL and low-density lipoprotein (LDL) secretion in hepatocytes[6]. Assembly of VLDL in hepatocytes depends very much on the endoplasmic reticulum-residing protein microsomal triglyceride transfer protein (MTP). There is evidence that L-81 inhibits MTP activity in hepatocytes[7]. Consistent with these molecular effects, rodents fed with L-81 exhibited obvious weight loss, which is reversible upon withdrawal of the compound in the diet[4,8]. Because the inhibitory effect of L-81 on lipid transport is rapid and readily reversible, it is an attractive drug for controlling obesity.

Obesity, defined as a body mass index exceeding 30 kg/m^2, is epidemic in many developed countries. For instance, more than 50% of the adults in the USA are either overweight or obese[9]. Obesity is a strong risk factor for the development of insulin resistance and type 2 diabetes[10]. The risk of developing type 2 diabetes increases in parallel with increasing severity of overweight and obesity[11]. On the other hand, weight reduction is associated with a decreased incidence of type 2 diabetes[12]. Obesity is also strongly associated with cardiovascular diseases and cancers[13]. Clearly, it would be of great clinical benefit if effective prevention and treatments for obesity and associated type 2 diabetes were established.

Although L-81 is a potent anti-obesity drug, its potential in alleviating obesity-induced insulin resistance and type 2 diabetes has not been fully explored. Here we aimed to test whether L-81 could ameliorate diabetic symptoms using a mouse model of type 2 diabetes, *db/db* mice. *db/db* mice have a mutant leptin receptor which results in high plasma triglyceride and cholesterol levels. *db/db* mice develop significant obesity, fasting hyperglycemia and hyperinsulinemia within 6 wk of age[14]. We also investigated the possibility that L-81 affects MTP activity through transcription regulation.

MATERIALS AND METHODS

Cell culture and measurement of apoB secretion rates in HepG2 cells

HepG2 cells were obtained from the American Type Culture Collection (ATCC) and maintained in basal medium (MEM supplemented with 1.5 g/L sodium bicarbonate, 2 mmol/L glutamate, 2 mmol/L sodium pyruvate) with 10% FBS. In a typical experiment, cells were seeded into 6-well (35 mm) culture plates, allowed to grow to 70% confluence, and then incubated with 3 mL of either the control medium (basal medium supplemented with 3% BSA) or experimental media (control medium plus test substances) at 37℃ for the indicated time. At the end of the experiments, media were collected and analyzed for apolipoprotein B (apoB) and apoA-I by ELISA as described previously[15].

Measurement of human MTP and actin mRNA levels

Total RNA was isolated from HepG2 cells by the guanidinium thiocyanate method and the relative levels of the MTP large subunit and β-actin mRNA were determined by the DNA excess solution hybridization assays as described previously[15].

MTP promoter construct, transfection and reporter assay

The promoter-luciferase construct (MTP-250) which contains a 336-bp fragment encompassing position -250 to +86 of the human MTP promoter was generated by PCR as described in our earlier study[16] and cloned into promoterless pGL3-Basic vector (Promega, Madison, WI). For transfection, HepG2 cells were grown overnight (70% confluent) in 6-well plates and washed twice with serum-free medium. DNA-lipofectAMINE 2000 complexes, containing 1 μg MTP promoter-firefly luciferase construct, 0.1 μg pRL-SV40 renilla luciferase control vector, and 2 μg lipofectAMINE 2000 (Invitrogen) in 200 μL serum-free medium in each well, were allowed to form at room temperature for 30 min. The cells were then overlaid with the complex for 6 h at 37℃. After 16 h of recovery in complete culture medium, the cells were washed twice with serum-free medium, and experimental media with or without the indicated concentration of Pluronic L-81 were subsequently added. After 24 h, the cells were washed twice with ice-cool PBS and treated with passive lysis buffer (Pormega, Madison, WI). The lysates were assayed for both luciferase activities using the Dual-luciferase assay kit (Pormega, Madison, WI) according to the manufacturer's instructions. Luciferase activities were determined by Lumat LB 9507 luminometer (Berthold).

Animals and L-81 treatment

Male and genetically diabetic BKS·Cg-m +/+ Lepr^{db} (*db/db*) mice and their non-diabetic littermates C57BLKS/J (BKS) (5-6 wk of age; n = 3 mice per group) were obtained from Jackson Laboratories (Bar Harbor, ME). They were housed in environmentally controlled conditions with a 12-h light/dark cycle. Mice were fed a standard rodent chow diet (powdered) and water *ad libitum* in sterile cages. Animals were gathered together for 2 wk before the commencement of the experiment. Pluronic L-81 was kindly provided by BASF Corporation (Parsippany, NJ). To prepare food with the indicated amount of L-81 for treatment, L-81 was first dissolved in ethanol and sprayed on the powdered chow. The food was then air-dried to remove the carrier ethanol before it was used to feed the mice. Various parameters of the

mice including body weight, food and water intake were monitored on a regular basis as indicated.

Animal blood sampling, metabolic measurements, intraperitoneal glucose tolerance test (IPGTT), and histological analysis

Animals (n = 3 mice per group) were fasted for 5 h before blood was sampled from the retro-orbital sinus. Plasma glucose, insulin, adiponectin, triglycerides, cholesterol, alkaline phosphatase (ALP), alanine aminotransferase (ALT) levels were measured using standard enzyme assay kits. For IPGTT, mice were first fasted for 5 h and then received an intraperitoneal administration of glucose (2 g/kg). Blood glucose levels were determined using the One-touch Ultra Blood Glucose Monitoring System (LifeScan Inc) from the tail blood samples at 0 (before glucose administration), 30, 60, 90, and 120 min after glucose administration. Tissues were collected and fixed in 10% phosphate-buffered formalin for histological analysis. Paraffin-embedded tissues were sectioned (5 μm thick) and stained with hematoxylin and eosin (HE) using standard procedures.

Statistical analysis

For each animal experiment, C57 lean mice and *db/db* mice (n = 3 mice per group) were either untreated (control) or treated with different concentrations of L-81 or 0.005% rosiglitazone (rosig). The experiment was performed 3 times to obtain data with statistical significance. Data shown were obtained from at least 3 independent experiments and presented as mean ± SD. One-way analysis of variance (ANOVA) was used to compare multiple experimental groups. Differences were considered to be statistically significant when $P < 0.05$.

RESULTS

L-81 treatment induced weight loss and ameliorated diabetes

The nonionic surfactant L-81 has been shown to be an effective weight-reducing drug in rats[4,8]. We observed a similar effect in *db/db* mice. Thus, while *db/db* mice weighed 40 g on average at 5-6 wk of age, and their weight continued to increase during observation, mice treated with 1% or 1.5% L-81 for 30 d lost weight to a small extent (n = 3 mice per group) (Figure 1A and B). Their plasma total cholesterol and plasma triglycerol (TG) were also reduced by L-81 treatment (Figure 1C and D). Examination of their epididymal fat pads revealed that adipocytes in mice treated with L-81 were smaller than in the *db/db* controls, although they were still larger than those in C57 lean control mice (Figure 1E). These data showed that L-81 is, as already found in rats, a hypolipidemic agent in *db/db* mice.

While the weight control effect of L-81 is well documented, its implication in diabetes control is less well understood. So we asked, given the fact that L-81 is effective in control of obesity, is it able to ameliorate diabetes? To answer this we measured some diabetic parameters in L-81 treated *db/db* mice. In this study, we compared L-81 with rosig, a peroxisome proliferator-activated receptor gamma (PPAR-γ) agonist and an anti-diabetes drug[17].

Hyperphagia and polydipsia are two common symptoms of diabetes. We first observed whether a 4-wk L-81 treatment could affect the feeding and drinking behaviors of the mice. Compared with lean controls, *db/db* mice ingested about 2 g more food and 4 g more water per day. Inclusion of 1% or 1.5% L-81, or 0.005% of rosig in their diet could reduce their food and water intake to the lean control level (Figure 2A and B).

Fasting plasma glucose levels of the mice were measured at the beginning and the end of a 21 d treatment period. As shown in Figure 2C, *db/db* mice exhibited elevated fasting blood glucose levels of about 25 mmol/L, as compared with 10 mmol/L in lean controls. Twenty one days of rosig or L-81 treatment reduced this parameter to near the lean control level (Figure 2C). *db/db* mice have a typical diabetic blood glucose profile after glucose injection (Figure 2D). Rosig or L-81-treated mice showed improved glucose tolerance, thus their blood glucose level started to drop slightly or stopped increasing at 30 min after injection (Figure 2D). However, the levels were never as low as in lean control mice.

db/db mice are insulin-resistant and therefore have an elevated plasma insulin level[14]. We found that *db/db* mice treated for 21 d with rosig or L-81 exhibited a lowered plasma insulin concentration (Figure 2E). The effects of rosig and L-81 were comparable. Rosig effectively increased the plasma level of adiponectin, an adipocytokine responsible for increasing tissue sensitivity to insulin. This, however, was not observed in L-81 treated mice (Figure 2F). Taken together, oral L-81 treatment can effectively improve diabetic symptoms in the *db/db* mouse model.

L-81 inhibited MTP transcription

L-81 treated cells show decreased activity of MTP. However MTP purified from those cells exhibited normal TG transfer activity[7], suggesting that L-81 does not affect MTP activity post-translationally. We have shown previously that MTP activity is largely controlled at the transcription level[15]. We therefore wished to address the possibility that L-81 controls MTP activity by modulating the transcription of the MTP gene. To do this we transiently transfected a MTP promoter-luciferase reporter construct as previously described[16] into HepG2 and treated the cells with L-81.

As shown in Figure 3A, the expression of luciferase driven by the full-length MTP promoter (-612 to +86) was reduced by about 25% in the presence of 1% L-81. This figure agrees with that observed previously[7]. Given that MTP plays an essential role in the assembly and secretion of apoB-containing lipoproteins, we tested the effect of L-81 on apoB secretion in HepG2 cells. As shown in Figure 3B, L-81 dose-dependently inhibited the apoB secretion in HepG2 cells, while no significant changes were observed in apoA-I secretion. By examining the cell morphology, lactate dehydrogenase activity (a marker of necrosis), and total cellular proteins

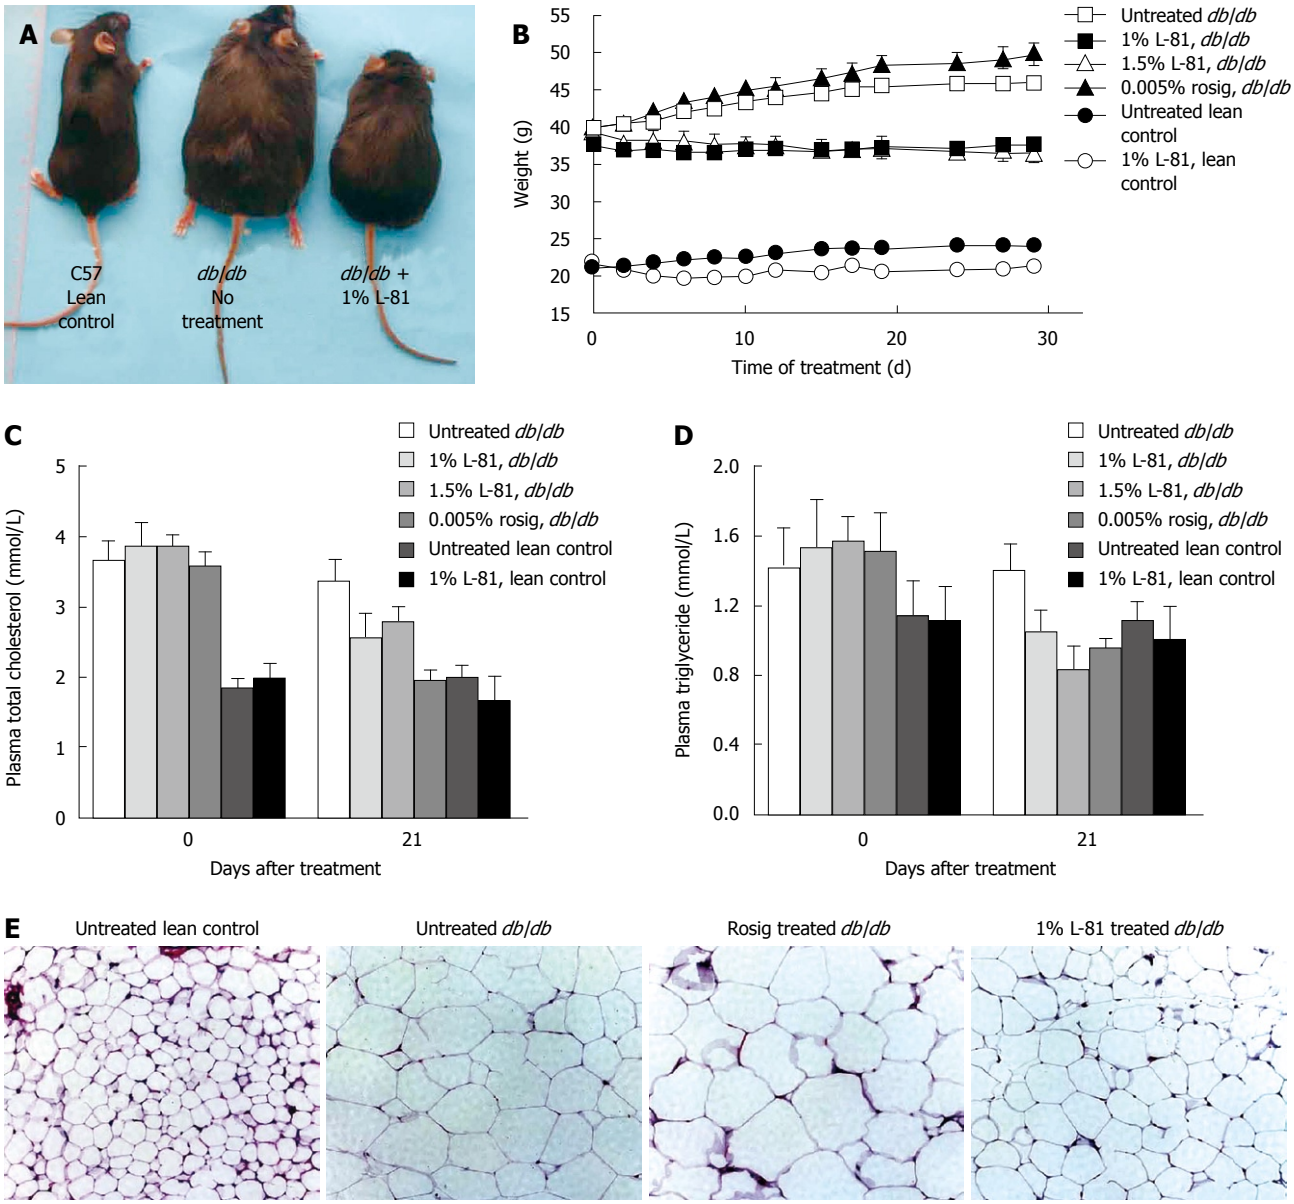

Figure 1 L-81 reduced obesity. A: Body appearances of lean control (left), untreated db/db (middle), and db/db mice fed with chow sprayed with 1% L-81 (right); B: Weight of *db/db* mice or lean control mice receiving different drug treatments over an observation period of 30 d (n = 3 in each group); C: Plasma total cholesterol and (D) plasma triglyceride level of mice treated with the indicated drugs; E: The size of adipocytes in epididymal fat pads of mice treated with the indicated drugs as observed under 100 × magnification.

in HepG2 cells, we also determined that *in vitro* L-81 treatment (0-3 μmol/L) had little or no cytotoxic effect on the cells (data not shown). Taken together, these results demonstrated that L-81 causes a reduction of apoB secretion in HepG2 cells at least partly *via* the inhibition of MTP expression.

To locate the sequence element responsible for mediating the inhibitory effect of L-81 on MTP promoter, we transfected HepG2 cells with various MTP promoter/luciferase reporter deletion constructs (see Figure 3A), and their relative promoter activities were determined from the cells treated with 1% L-81. It was found that the inhibitory effect of L-81 (and insulin) persists up to the deletion construct MTP-115 (Figure 3A), suggesting that L-81 (and insulin) responsive sequence resides between -102 and -115. A mutation of promoter sequence -102 to -108 [where a hepatocyte nuclear factor (HNF)-1 site is located] abolished the inhibitory effect, suggesting that this region is responsible for mediating the inhibition. Either deletion or mutation of the HNF-1 site caused an almost complete shutdown of the MTP promoter activity (Figure 3A), indicating that this site is involved not only in the regulation but also in the basal expression of the MTP gene.

L-81 caused no detectable toxicity to the liver

Pharmacological inhibition of MTP transcription has been explored as a means of treating dyslipidemia. It is believed that by interfering with hepatic and intestinal VLDL packaging, MTP transcription inhibitors would reduce the plasma level of VLDL. Many MTP transcription

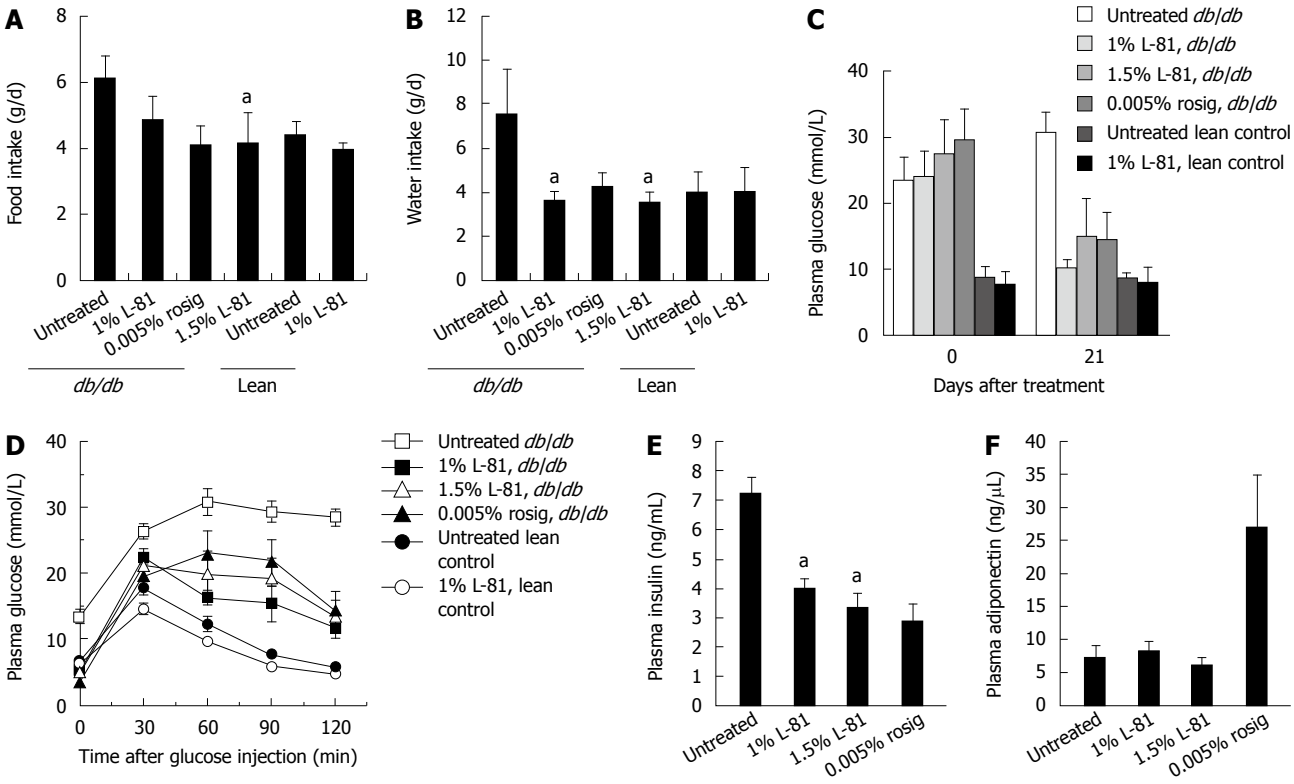

Figure 2 L-81 ameliorated diabetes. A: Food intake and (B) water intake of mice fed on a chow diet, with or without the indicated drugs (n = 3 in each group); C: Fasting plasma glucose levels of lean control mice or *db/db* mice treated with L-81 or rosig before and after a 21 d treatment of the indicated drugs; D: Glucose tolerance of mice treated with the indicated drugs. Mice injected with glucose had their blood glucose level monitored by Onetouch Ultra Blood Glucose Monitoring system; E: Plasma insulin level of *db/db* mice treated with the indicated drugs for 4 wk; F: Plasma adiponectin level of db/db mice treated with the indicated drugs for 4 wk. $^aP < 0.05$ compared with untreated control.

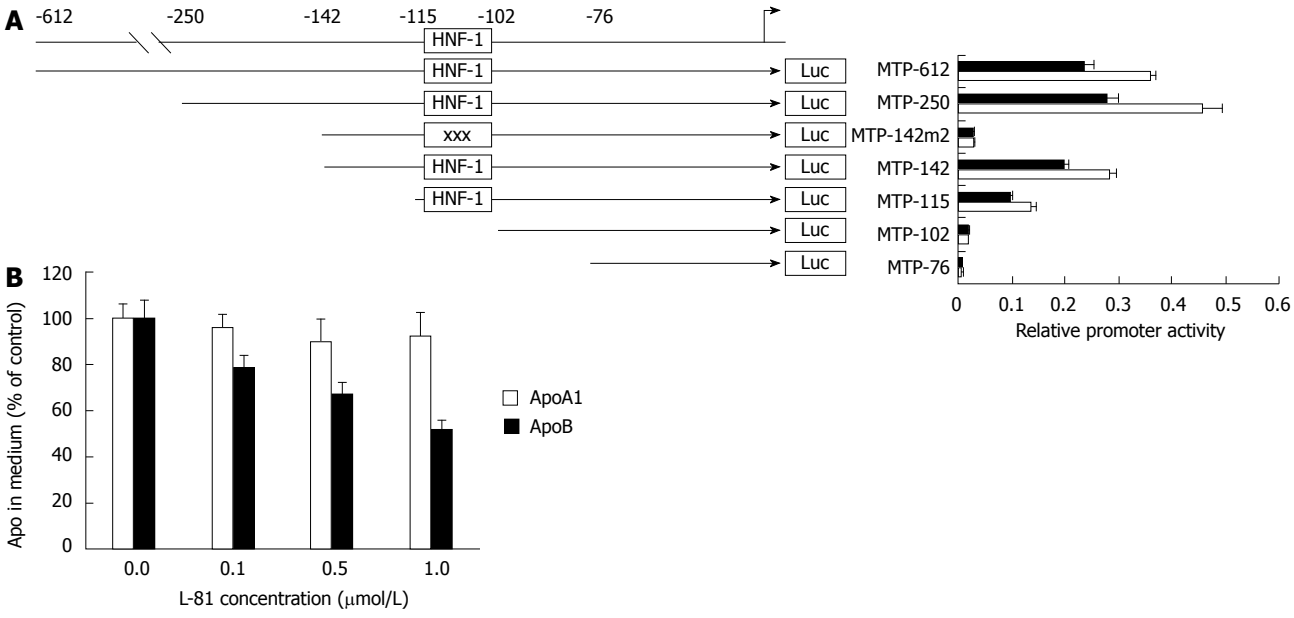

Figure 3 L-81 regulated MTP transcription. A: The human MTP promoter was linked with luciferase reporter. Deletion or mutation constructs of MTP promoter-luciferase were transfected into HepG2 cells. The cells were treated with (black bars) or without (white bars) 1% L-81 in the medium. The luciferase activity in the cell lysate was measured. xxx = disabling mutations; B: L-81 inhibited apoB secretion in HepG2 cells. HepG2 cells were treated with the indicated concentration of L-81. The concentration of apoA-I and apoB in the culture medium were measured and normalized against the untreated control.

inhibitors have been developed and put into clinical trials. However, from the clinical trial data, it is obvious that MTP transcription inhibitors very often cause hepatosteatosis (fatty liver)[18]. We were hence concerned whether L-81's MTP transcription inhibitory effect would lead to hepatosteatosis and a decline of liver function.

To check whether L-81 treatment caused any gross hepatic injury, we measured the plasma ALT level of

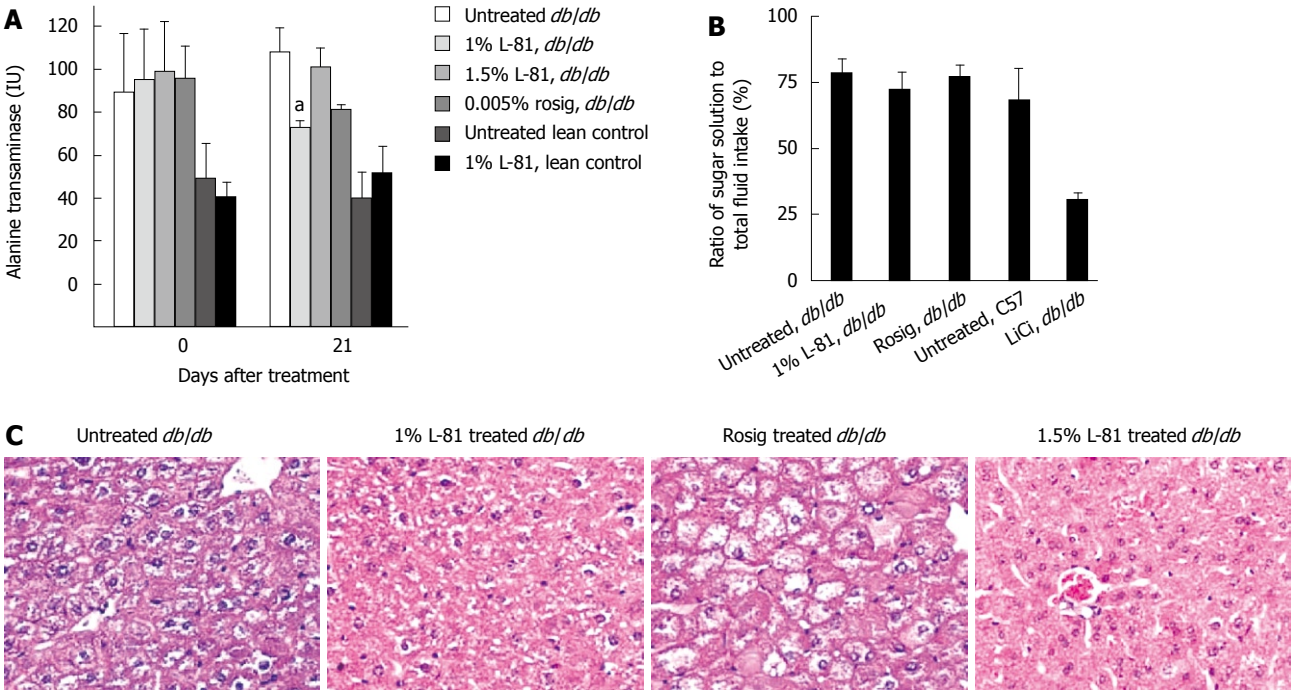

Figure 4 L-81 was not toxic to the liver. A: Plasma ALT level of mice treated with the indicated drugs; B: CTA test of mice treated with the indicated drugs; C: Histological examinations of db/db mice treated with indicated drugs. $^{a}P < 0.05$ compared with untreated *db/db*.

db/db C57L mice after 21 d of L-81 treatment. In lean control mice, the presence of L-81 in the diet did not cause any significant difference in the plasma ALT level, indicating that L-81 did not induce liver injury (Figure 4A). Interestingly, we found that while *db/db* mice generally have a higher level of plasma ALT than C57L lean control mice, L-81 treatment did not result in any significant difference (Figure 4A). Histological examination of the livers of the mice revealed that L-81 treatment caused neither an enlargement of the liver nor any microscopic damage to the liver (Figure 4C).

Conditioned taste aversion (CTA) is a commonly used test to assess whether a particular substance or treatment would render animals ill. L-81 treated mice consumed 72% of their total fluid intake as saccharin in the 2-bottle test, a ratio comparable to that of the untreated *db/db* mice (Figure 4B). Treatment with rosig gave a similar response (Figure 4B). In contrast, administration with lithium chloride produced a robust CTA (Figure 4B). Taken together, we have not observed any toxicity associated with L-81 treatment.

DISCUSSION

The prevalence of obesity is now escalating globally and insulin resistance resulting from the increased fat mass has been identified as a key factor that could drive parallel increases in T2DM[19]. The prevalence of T2DM has reached a pandemic situation in which it is estimated to affect > 6% of the world population. Clinically, patients with T2DM display not only an elevated level of blood glucose, but also an elevated level of plasma lipids. These abnormal levels of circulating lipids are the primary cause of severe macrovascular diseases with poor prognosis, which is responsible for 80% of diabetic mortality and 75% of all hospitalizations for diabetic complications[20]. Indeed, diabetes is recognized as a coronary heart disease "risk equivalent", and the risk of myocardial infarction in diabetic patients is equal to those of non-diabetic patients with known cardiac diseases[21]. Thus, new therapeutic strategies for the treatment of diabetes should not aim only to lower blood glucose level, but also to address diabetes-associated lipid disorders.

Our present study provides evidence for the first time that L-81 is not only a potent lipid-lowering compound but also an anti-diabetic agent in *db/db* mice. L-81 normalizes the levels of plasma lipids and reduces fat mass, and thereby attenuates obesity which is essentially linked to insulin resistance and a number of serious diabetes-associated macrovascular disorders such as coronary, cerebral and peripheral artery diseases[20]. The ability of L-81 to attenuate obesity may play an important role in mediating its antidiabetic effects in *db/db* mice. In fact, the relationship between obesity and insulin resistance/T2DM has been linked in a cause and effect association, as weight loss or gain correlates closely with increasing or decreasing insulin sensitivity, respectively[22-24].

Moreover, L-81 significantly improved fasting glycemic control and glucose tolerance in *db/db* mice. It also reduced hyperphagia and polydipsia, which are symptoms of diabetes mellitus. Remarkably, L-81 caused neither hepatotoxicity nor apparent sickness during the course of treatment. The fact that treatment with L-81 decreased food intake in the *db/db* mice is likely to be an element of the therapeutic action of L-81. Earlier studies showed that L-81 treatment did not affect food

consumption in lean mice[8,25]. Our data on the lean mice are consistent with this previous observation. Compared with rosig, a PPAR-γ agonist[17] and a well marketed anti-diabetic drug, L-81 exhibited comparable potency in lipid and glycemic control without eliciting overt weight gain which is the side effect of the former[26,27].

Consistent with previous studies, we observed that treatment with L-81 led to an accumulation of lipid stored in intestinal villi. Since the turnover rate of the intestinal epithelial lining is rapid, the excess lipids may be excreted together with obsolete cells. It is believed that the intestine is the principal site of action of L-81 when the drug is included in the diet[8,25]. Functionally, L-81 impairs the transepithelial lipid flux during fat absorption and arrests the trafficking of apoB-containing lipoproteins within the enterocytes, which leads to a cytosolic and endoplasmic reticulum lipid accumulation and thereby prevents the absorption of lipids[4,28,29]. This action appears to be selective and does not affect other lipid metabolism such as fatty acid synthesis, cholesterol re-esterification, and more importantly the absorption of other nutrients[4,5,29,30]. Taken together, our present results indicate that L-81 exhibits prominent antidiabetic activities in the diabetic *db/db* mice and suggest that L-81 may represent a new class of anti-diabetic agent conferring both efficacy and safety.

MTP exists in the lumen of the endoplasmic reticulum as a heterodimer with protein-disulfide isomerase and plays a pivotal role in the assembly and secretion of the apoB-containing lipoproteins[31]. Our *in vitro* studies showed that L-81 treatment induced a significant reduction in apoB secretion of HepG2 cells, at least partly *via* the inhibition of MTP gene expression. We also found that the expression of MTP transcripts in the liver of L-81-treated mice was significantly decreased, supporting our *in vitro* data which demonstrated that L-81 could reduce MTP expression. These results indicated that attenuation of the MTP gene expression by L-81 may partially contribute to the improvement of the lipid profiles in diabetic *db/db* mice. Moreover, we showed that L-81 inhibited MTP promoter activity, in a similar fashion as insulin, in L6 cells with an enforced expression of HNF-1α, suggesting that L-81 mimics insulin action and exerts an inhibitory effect on the MTP gene *via* the same HNF-1 element.

We have previously shown that the consensus HNF-1 element is functionally equivalent to the slightly modified HNF-1 element found on the MTP promoter in mediating the negative insulin response[32]. This finding implies that the HNF-1-mediated negative insulin response is not only limited to the MTP gene but also to other genes containing the HNF-1 binding motif. In addition to the MTP gene, the transcription of other HNF-1-containing genes may be elevated under diabetic conditions, which could potentially result in abnormal lipid and glucose metabolism and elevated plasma triglyceride, cholesterol and glucose levels. Thus, compounds like L-81 that can mimic the insulin effect and suppress the transcription of MTP and other HNF-1-containing genes should provide relief to these syndromes. Since HNF-1α contributes to the transcriptional regulation of many rate-limiting steps in gluconeogenesis and also binds to genes whose products are central to normal hepatic functions, including carbohydrate synthesis and storage, lipid metabolism, detoxification, and synthesis of serum proteins[33], the potential regulation of these genes by L-81 warrants further investigation in order to gain more insight into the mechanisms of L-81 action.

COMMENTS

Background

Obesity is common in many developed countries; more than 50% of the adults in the USA are either overweight or obese. The risk of developing type 2 diabetes and cardiovascular diseases increases in parallel with increasing severity of obesity. Therefore, it is crucial to establish effective prevention and treatments for obesity and its associated type 2 diabetes.

Research frontiers

Pluronic L-81 (L-81) effectively inhibits absorption of dietary lipids from the intestine, and secretion of very low density lipoprotein (VLDL) and low density lipoprotein (LDL) from the liver. In this study, the authors demonstrated that oral L-81 treatment can alleviate diabetes symptoms in a mouse model of diabetes (*db/db* mice) and suppress apolipoprotein B (apoB) secretion and microsomal triglyceride protein (MTP) gene transcription in HepG2 cells.

Innovations and breakthroughs

Although L-81 is a potent anti-obesity drug, its potential in alleviating obesity-induced insulin resistance and type 2 diabetes has not been fully explored. This is the first study to report that L-81 has anti-diabetic effects on *db/db* mice, and it mimics the action of insulin by reducing the transcription of the MTP gene.

Applications

By elucidating the molecular mechanism of the anti-diabetic actions of L-81, this study provides the basis for the development of L-81 as a selective insulin mimetic and anti-diabetic agent in the future.

Terminology

Pluronic® surfactants are synthetic copolymers based on ethylene oxide and propylene oxide. They have been widely used in industries as defoaming and antifoaming agents in dishwashing, antifreeze, cutting and grinding fluids. L-81 contains 10% hydrophilic and 90% hydrophobic polyoxyethylene residues with a molecular weight of 2750.

Peer review

The authors investigated the anti-diabetic actions of a nonionic surfactant, L-81, in a mouse model of diabetes. They found that L-81 markedly ameliorated the diabetes symptoms in *db/db* mice by reducing their body weight and plasma glucose, cholesterol and triglyceride levels. Similar to the action of insulin, L-81 was found to inhibit apoB secretion and MTP gene transcription in HepG2 cells. The results are important and lay down the foundation of developing L-81 as an anti-diabetic drug.

Abstract

AIM: To study the methods of preparing the magnetic nano-microspheres of Fe_2O_3 and As_2O_3/Fe_2O_3 complexes and their therapeutic effects with magnetic fluid hyperthermia (MFH).

METHODS: Nanospheres were prepared by chemical co-precipitation and their shape and diameter were observed. Hemolysis, micronucleus, cell viability, and LD_{50} along with other *in vivo* tests were performed to evaluate the Fe_2O_3 microsphere biocompatibility. The inhibition ratio of tumors after Fe_2O_3 and As_2O_3/Fe_2O_3 injections combined with induced hyperthermia in xenograft human hepatocarcinoma was calculated.

RESULTS: Fe_2O_3 and As_2O_3/Fe_2O_3 particles were round with an average diameter of 20 nm and 100 nm as observed under transmission electron microscope. Upon exposure to an alternating magnetic field (AMF), the temperature of the suspension of magnetic particles increased to 41-51℃, depending on different particle concentrations, and remained stable thereafter. Nanosized Fe_2O_3 microspheres are a new kind of biomaterial without cytotoxic effects. The LD_{50} of both Fe_2O_3 and As_2O_3/Fe_2O_3 in mice was higher than 5 g/kg. One to four weeks after Fe_2O_3 and As_2O_3/Fe_2O_3 complex injections into healthy pig livers, no significant differences were found in serum AST, ALT, BUN and Cr levels among the pigs of all groups ($P > 0.05$), and no obvious pathological alterations were observed. After exposure to alternating magnetic fields, the inhibition ratio of the tumors was significantly different from controls in the Fe_2O_3 and As_2O_3/Fe_2O_3 groups (68.74% and 82.79%, respectively; $P < 0.01$). Tumors of mice in treatment groups showed obvious necrosis, while normal tissues adjoining the tumor and internal organs did not.

CONCLUSION: Fe_2O_3 and As_2O_3/Fe_2O_3 complexes exerted radiofrequency-induced hyperthermia and drug toxicity on tumors without any liver or kidney damage. Therefore, nanospheres are ideal carriers for tumor-targeted therapy.

Key words: Liver cancer; Magnetic fluid hyperthermia; Nanoparticle; As_2O_3

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors in China, and the incidence has increased in recent years. Current therapeutic options remain unsatisfactory for most patients. Surgical resection has been recognized as the most effective method for the treatment of hepatocarcinoma, but it is only indicated for a small number of hepatocarcinoma patients[1,2]. Therefore, it is crucial to identify a new method to treat hepatocarcinoma.

In recent years, radiofrequency-induced hyperthermia has increasingly attracted attention for the generation of heat in a desired zone, even in tumors deeply located inside a patient's body. During exposure to alternating

magnetic field (AMF), magnetic particles can absorb energy and transform it into heat at temperatures of 42-45℃, at which tumor cells are very sensitive[3]. In addition, the use of magnetic nanospheres, which can carry the magnetic particles into the tumor cells very easily, can greatly enhance the effects of the thermotherapy. In our research, we attempted to prepare a kind of new magnetic material that contained As_2O_3. We transformed the energy of the radio waves into heat to kill tumor cells and explored the therapeutic effects of nanospheres for the treatment of hepatocarcinoma.

MATERIALS AND METHODS

Materials

As_2O_3 and dimethyl sulfoxide (DMSO) was purchased from Sigma. RPMI-1640 medium was obtained from GIBCOL-BRL. Newborn calf serum was from Si-Ji-Qing Biotechnology Co. (China). HEPES, Trypsin and methyl thiazolyl tetrazolium (MTT) were purchased from AMRESCO. The transmission electron microscope (TEM) used was a H-600 model (Hitachi, Japan) and the scanning electron microscope (SEM) model was JEOL JSM-6360LV (Japan). The energy dispersive spectrometer (EDS) was purchased from Thermo NORAN Vantage (USA).

L929 cells (human fibroblast cell line) and SMMC-7721 cells (human liver cancer cell line) were purchased from the Institute of Biochemistry and Cell Biology, Shanghai Institute of Biological Sciences, Chinese Academy of Sciences.

BALB/C nude mice (male, 10-wk-old) were purchased from the Lakes Animal Experimental Center of the Institute of Biochemistry and Cell Biology, Shanghai Institute of Biological Sciences, Chinese Academy of Sciences.

Methods

Preparation and characteristics of Fe_2O_3 and As_2O_3/Fe_2O_3 nanoparticles: Fe_2O_3 magnetic nanoparticles were prepared according to the method previously described[4]. Fe_2O_3 magnetic nanoparticles were added into a solution of As_2O_3 (0.01 mg/mL, pH = 5, adjusted by acetic acid) under a condition of supersonic dispersion. After 30 min at 80℃, the products were centrifuged at 2000 r/min for 10 min, rinsed twice by absolute alcohol, and then dried in a vacuum. The diameter and composition of Fe_2O_3 and As_2O_3/Fe_2O_3 were examined under TEM and EDS.

A heating test was performed to detect the thermodynamic characteristics of the magnetic particles. Various doses of Fe_2O_3 and As_2O_3/Fe_2O_3 particles were decentralized in 0.9% NaCl. The concentrations of Fe_2O_3 were 2, 4, 6 and 8 g/L. Two milliliters of nanoparticle fluid was then added to a flat-bottomed cuvette to reach a level of 5 mm from the bottom of the cuvette and in the center of the hyperthermia-coil of a high frequency electromagnetic field. The output electric current was 300 A, and the fluid was heated for 1 h with temperature measurement at 5 min intervals.

Biocompatibility study of Fe_2O_3 nanoparticles: MTT assay, hemolytic test, and micronucleus assay were performed to test the *in vitro* cytotoxicity of Fe_2O_3 nanoparticles. To perform the MTT assay, L929 cells were cultured in RPMI-1640 media supplemented with 10% heat-inactivated calf serum, penicillin (100 U/mL) and streptomycin (100 mg/mL) and grown in the presence of 5% CO_2 at 37℃. Cells were seeded in a 96-well plate and treated with 200 μL Fe_2O_3 nanoparticle fluid at various concentrations (100%, 75%, 50% and 25%) for 48 h and with 5 μmol/L of As_2O_3 as a positive control. Subsequently, 20 μL (5 g/L) MTT was added to the cells in each well and incubated for 4 h at 37℃. Culture media was discarded and 150 μL of DMSO was added and subjected to vibration for 10 min. The absorbance (A) value was measured at a wavelength of 493 nm. The cell relative growth rate (RGR) was calculated as follows: (A of experimental group/A of control group) × 100%.

For the hemolytic test, 50 mL of Fe_2O_3 and As_2O_3/Fe_2O_3 was centrifuged at 2000 r/min for 10 min 3 times, then suspended and incubated at 37℃, and after 30 min a liquid-extract was obtained. Ten milliliters of 0.9% NaCl and 10 mL of double distilled water were used as negative (0% hemolysis) and positive (100% hemolysis) controls, respectively. Each group contained three tubes. Diluted anticoagulated rabbit blood (0.2 mL) was added to each tube, which had been pre-heated at 37℃ for 30 min. Contents of all the tubes were incubated in a water bath at 37℃ for 60 min. All tubes were centrifuged at 2500 r/min for 5 min and the supernatant was taken to estimate free hemoglobin. Absorbance was measured and recorded at 540 nm. In general, the optical density was 0.8 ± 0.3 in positive control groups and was no more than 0.03 in negative control groups. The hemolysis rate (HR) was calculated as follows: HR (%) = (A of experimental group - A of negative control group)/(A of positive control group - A of negative control group) × 100%.

For the micronucleus assay, 60 mice were randomly divided into six groups, with five females and five males in each group. Animals were injected intraperitoneally with 100 g/L of Fe_2O_3 or As_2O_3/Fe_2O_3 (40 mg/kg) twice at a 24 h interval. The negative group (with 0.9% NaCl) and positive group (with CT × 40 mg/kg) were set as control groups. Six hours after the second injection, all the mice were killed. The thighbone marrows were extracted for smears, methanol-fixed for 5 min, then dyed with Giemsa for 15 min. For each smear, 1000 polychromatic erythrocytes (PEC) were counted, and the number of PEC containing micronucleus was calculated (MN). Poisson distribution verified the statistical difference of each group.

We also studied the *in vivo* histotoxicity of nanoparticles. The Kun Ming mice were divided into 15 groups randomly with five females and five males in each group. Various amounts of 100 g/L Fe_2O_3 and As_2O_3/Fe_2O_3 nanoparticles were intraperitoneally injected into each mouse of seven groups at 1.25, 1.75, 2.5, 3.5, 5,

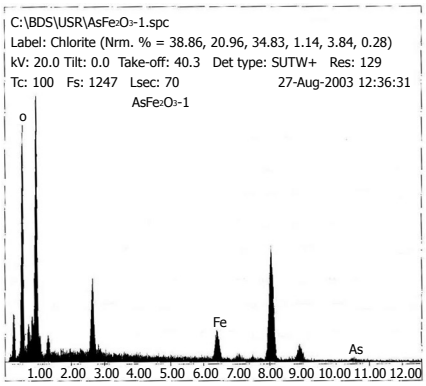

Figure 2 EDS results of As_2O_3/Fe_2O_3.

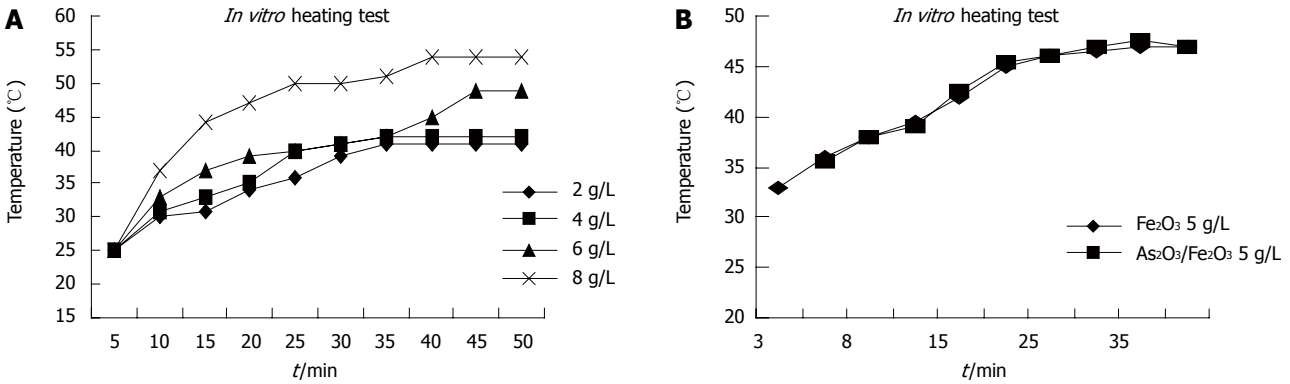

Figure 3 Thermodynamic test. A: Various doses of Fe_2O_3; B: The concentration of Fe_2O_3 is 5 g/L.

7.07 and 10 g/kg according to their weight. The negative control group was injected with the same volume of 0.9% NaCl, and the mice were observed in the following 15 d. The median lethal dose (LD_{50}) was evaluated by the Karber method.

Sixteen healthy pigs were divided randomly into four groups (control group, Fe_2O_3 low dose, Fe_2O_3 high dose, and the As_2O_3/Fe_2O_3 group). Fe_2O_3 or As_2O_3/Fe_2O_3 (10 g/L) was injected into the liver of pigs in the experimental groups. Four pigs from each group were killed from 1 to 4 wk after injection. Serum AST, ALT, BUN and Cr were measured. Livers were harvested and dissected into 1 mm^3 specimens. Subsequently, the samples were fixed in 4% glutaraldehyde and were prepared into ultrathin sections (60 nm) to be examined under TEM and EDS.

Therapeutic effect of As_2O_3/Fe_2O_3 in combination with MFH on xenograft liver cancer

Inhibition of SMMC-7721 cell proliferation was measured by MTT assay according to the method described above. Xenograft tumors were induced in the subcutaneous tissue around the right shoulder of nude mice with SMMC-7721 cells. Once the tumor diameter increased to 0.2-0.4 cm, mice were divided into 6 groups: (1) the control (sterile 0.9% NaCl); (2) As_2O_3 (5 μmol/L As_2O_3); (3) Fe_2O_3 (5 g/L Fe_2O_3); (4) As_2O_3/Fe_2O_3 (5 g/L Fe_2O_3); (5) $Fe_2O_3$with hyperthermia; and (6) As_2O_3/Fe_2O_3 with hyperthermia. Each group contained eight mice. They were injected into the tumors at 1/2 of the volume of the tumor. The tumors of the mice in groups 5 and 6 were exposed to a high-frequency alternating magnetic field and irradiated for 30 min. The treatment was given three times at 24 h intervals. After 45 d, all the mice were killed. The weight and volume inhibitory rates of the tumor were calculated as follows: IW = (1 - the weight of tumor of experimental group/ the weight of tumor of control group) ×100%; Iv = (1 - the volume of tumor of experimental group/the volume of tumor of control group).

Statistical analysis

Values were expressed as mean ± SD. The data were analyzed with SPSS 11.5 and SAS 10.0 software packages. Differences in the results were considered statistically significant when $P < 0.05$.

RESULTS

Characteristics of Fe_2O_3 and As_2O_3/Fe_2O_3 nanoparticles

Under TEM, the nanospheres appeared to be roughly spherical, brown particles that could be suspended stably in water with good dispersibility. The diameter of Fe_2O_3 particles was about 20 nm, and the diameter of As_2O_3/Fe_2O_3 particles was about 100 nm as shown in Figure 1. The EDS result verified that the nanoparticles contained magnetic particles and As_2O_3 (Figure 2).

Figure 3A shows the thermodynamic tests of various

$lgLD_{50}$ = 1-0.15 (2.2-0.5) = 0.745, Sm = 0.0414, As_2O_3/Fe_2O_3 Lg LD_{50} and its 95% CI: 0.745 ± 1.96 × 0.0414 = 0.745 ± 0.0811, As_2O_3/Fe_2O_3 LD_{50} and its 95% CI: 5.56 g/kg (4.56-6.70 g/kg).

doses of magnetic nanoparticles. Fe_2O_3 particles were decentralized in 0.9% NaCl and exposed to a high-frequency alternating electromagnetic field (output current equal to 300 A) for 60 min. The temperature rose rapidly within 5 min and slowly continued to increase from 5-40 min, and remained stable after 40 min. The temperature of the magnetic fluid (MF) rose from 41℃ to 51℃, depending on the different concentrations. The results showed that Fe_2O_3 nanoparticles had good power absorption capabilities in the high-frequency alternating electromagnetic field, and had strong magnetic responsiveness. We selected a suitable temperature range (42-46℃) for tumor hyperthermia[5] by adjusting the concentration of Fe_2O_3. We chose a concentration of 5 g/L for Fe_2O_3, and at this concentration, the temperature rose to 46℃ in MFH (Figure 3B).

Biocompatibility study of Fe_2O_3 and As_2O_3/Fe_2O_3 nanoparticles

MTT assay: The RGR of L929 cells treated with 25%, 50%, and 100% of liquid-extract of Fe_2O_3 were 102.63%, 96.39%, and 95.35%; for As_2O_3/Fe_2O_3 were 93.64%, 38.29%, and 27.26%, respectively. The value of the As_2O_3 group (5 μmol/L) was 30.12% (Table 1). The results corresponded to the cellular morphological changes observed under an inverted microscope.

$lgLD_{50}$ = 1-0.15 (2.1-0.5) = 0.76, Sm = 0.04, Fe_2O_3 Lg LD_{50} and its 95% CI: 0.76 ± 1.96 × 0.04 = 0.76 ± 0.079, Fe_2O_3 LD_{50} and its 95% CI: 5.75 g/kg (4.80-6.90 g/kg).

Hemolytic test: The Absorbance of each group was observed at 545 nm. As shown in Table 2, the HR of Fe_2O_3 and As_2O_3/Fe_2O_3 nanoparticles was 0% and 0.77%, which is far less than the standard 5% that indicates a hemolytic reaction.

Micronucleus assay: The MN formation rates of Fe_2O_3, As_2O_3/Fe_2O_3, the negative control and the positive control groups were 0.28%, 0.26%, 0.24%, and 24.1%, respectively (Table 3).

Median lethal dose (LD_{50}) determination: The mice receiving various doses were observed over the subsequent 15 d and the experimental animals died in succession. The LD_{50} was evaluated by the Karber method. The LD_{50} of mice receiving Fe_2O_3 and As_2O_3/Fe_2O_3 were 5.75 g/kg and 5.56 g/kg, respectively (Tables 4 and 5).

Biocompatibility study in pigs: One to four weeks after injection of Fe_2O_3 and As_2O_3/Fe_2O_3 into healthy pig livers, no significant differences were found in serum AST, ALT, BUN and Cr levels among pigs of all groups (P > 0.05), and no obvious pathological alterations were observed (Table 6). EDS examination revealed that in the As_2O_3/Fe_2O_3 complex group, numerous black

nanosized As_2O_3/Fe_2O_3 complexes had accumulated in the liver tissue of pigs.

Therapeutic effect of Fe_2O_3 and As_2O_3/Fe_2O_3

Morphological changes of apoptotic SMMC-7721 cells: The morphological changes of SMMC-7721 cells after treatment were observed under inverted microscopy. As shown in Figure 4, cells in the control and the Fe_2O_3 groups exhibited a normal shape, clear edge, and no cell fragmentation (Figure 4A). In the groups of As_2O_3, the As_2O_3/Fe_2O_3, the Fe_2O_3 and As_2O_3/Fe_2O_3 combined with MFH, the SMMC-7721 cells became small and global. Some shrunk and even a portion of the cells were suspended, which revealed the typical changes associated with apoptosis (Figure 4B-D). The results showed that both As_2O_3 (5 μmol/L) and MFH (at 46℃) could damage liver cells by inducing apoptosis.

Inhibition of SMMC-7721 cell proliferation after treatment with Fe_2O_3 and As_2O_3/Fe_2O_3 combined with MFH: The results of MTT assay are shown in Figure 5. The cell survival rates of cells treated with Fe_2O_3 and As_2O_3/Fe_2O_3 combined with MFH were 19.66% and 19.95%, respectively, which was statistically different from the negative group ($P < 0.01$). So, the therapeutic effect of nanosized As_2O_3/Fe_2O_3 complexes in combination with MFH on SMMC-7712 cells is much better than that of As_2O_3 or Fe_2O_3 nanoparticles alone.

***In vivo* inhibitory effect of Fe_2O_3 and As_2O_3/Fe_2O_3 combined with MFH on xenograft liver cancer in nude mice:** Animal experiments showed that tumors in the experimental groups became smaller (Figure 6). The mass and volume inhibitory ratio of the As_2O_3/Fe_2O_3 combined with MFH were IM = 82.79% and IV = 83.56%, respectively, which was much higher than that of the other groups (Table 7). Compared with control and experimental groups, each group was markedly different from the controls ($P < 0.01$). Histological examination in the As_2O_3/Fe_2O_3 group revealed that there was an accumulation of black nanosized As_2O_3/Fe_2O_3 particles at the stroma in the margin of the tumors. Many of the tumor cells disappeared at the site adjacent to this accumulation, and a necrotic zone was found surrounding the material (Figure 6).

DISCUSSION

As_2O_3, a traditional Chinese medicine, plays an important role in the treatment and research for human cancers such as acute promyelocytic leukemia (APL), myeloid leukemia, gastric cancer, breast cancer, neuroblastoma and esophageal carcinoma, as well as head and neck cancers[6-8], however, there are many limitations to its use due to its form. Patients treated with As_2O_3 suffered from acute and chronic side effects such as gastrointestinal reactions, which are often severe or fatal[9-11]. Moreover, it has been generally considered to be an extremely effective environmental cocarcinogen for some human malignancies, especially for skin and lung cancer[12]. Therefore, enhancing the curative effect and reducing the toxicity of As_2O_3 by changing its form is of great importance.

Hyperthermia for tumor therapy has been a long-standing modality. At present, thermotherapy is commonly used clinically with such applications as radiofrequency, microwave and lasers, all of which have many limitations for tumor hyperthermia. In 1997, Jordan[13] discovered that a nanoscaled magnetic fluid could be absorbed with much higher power in an alternating magnetic field, and used to treat disease or tumors. This treatment is named "Magnetic Fluid Hyperthermia (MFH)". MFH has a high ability to target and localize thermogenic actions. Therefore,

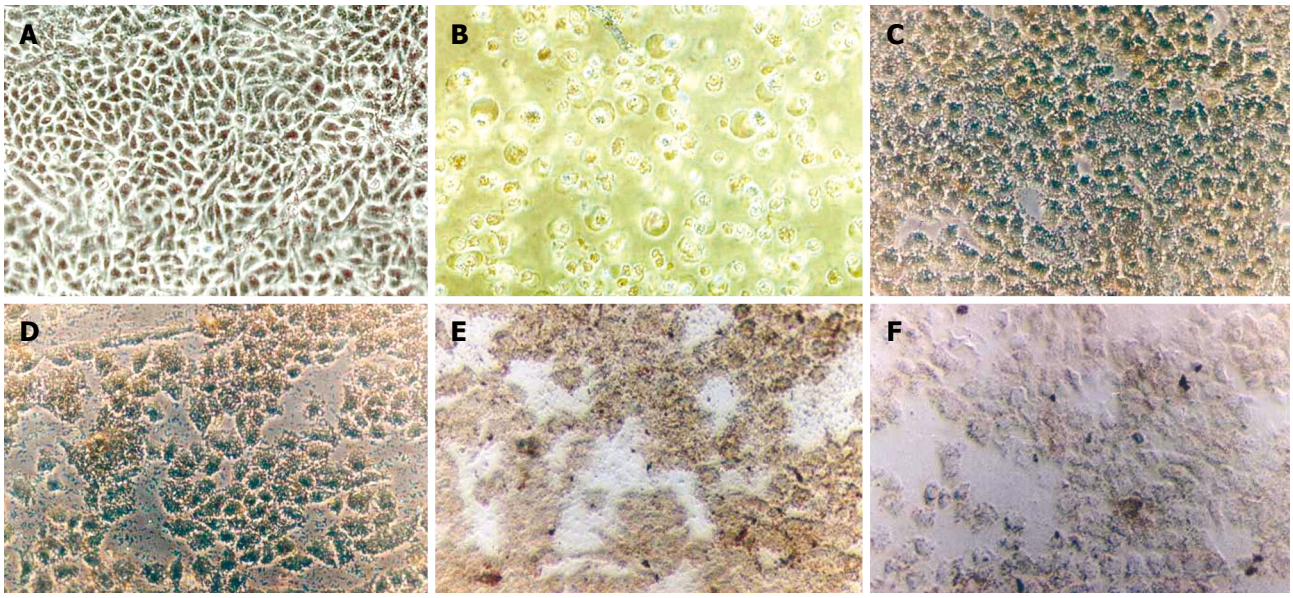

Figure 4 Inverted microscopy of SMMC-7721 cells treated by different methods. A: Negative control group; B: As_2O_3 (5 μmol/L) group; C: Fe_2O_3; D: As_2O_3/Fe_2O_3 group; E: Fe_2O_3 combined with MFH group; F: As_2O_3/Fe_2O_3 combined with MFH group (× 200).

($^bP < 0.01$ *vs* negative group).

Figure 6 Morphological changes of tumors from tumor-bearing nude mice treated by various methods. 1: Control; 2: As_2O_3; 3: Fe_2O_3; 4: As_2O_3/Fe_2O_3; 5: Fe_2O_3 combined with MFH; 6: As_2O_3/Fe_2O_3 combined with MFH.

tissue without magnetic particles would not be damaged.

Nanoparticles combined with MFH may be a potential method to treat tumors. In our study, As_2O_3/Fe_2O_3 complexes were prepared as a new magnetic material. Observed under TEM, they are round or elliptical, disperse well and are about 100 nm in diameter. In addition, they have good power absorption capabilities in a high-frequency alternating electromagnetic field. The temperature can rapidly reach 46℃ within 5 min, which can kill tumor cells while having little effect on normal cells.

However, the biomaterials would be in direct contact with tissues and cells when introduced into the body, so their biocompatibility had to be evaluated before they could be applied in a clinic setting. Many studies have shown that some materials show signs of toxicity when their diameters are reduced to nanoscale[14]. Therefore, the potential hazards and bio-safety of Fe_2O_3 microspheres should be particularly observed when they are applied to tissues. Biomaterials must not only have long-term stability in biotic conditions, but also have no harmful effects on tissues, blood or the immune system. In our work, referring to ISO10993-1992 and other international standards[15-17], we evaluated the nanoparticles using an *in vitro* cytotoxicity test, hemolytic test, a micronucleus experiment, by calculating the LD_{50}, and an *in vivo* study. MTT results showed that Fe_2O_3 nanoparticles had no significant effect on cellular proliferation when treated with various doses of extracted liquids of Fe_2O_3 nanoparticles. The cytotoxicities were 0 grade (RGR > 75%) indicating that there was no evidence of cytotoxicity. The results of the hemolytic test demonstrated that the hemolytic rate of the liquid-extracts of Fe_2O_3 and As_2O_3/Fe_2O_3 were 0.% and 0.77%, far less than 5%. This finding indicated that Fe_2O_3 had no hemolytic reaction when in direct contact with blood and was consistent with the requirement of hemolytic tests for biomaterials. Genotoxicity and

carcinogenicity tests answer the most complicated questions about biomaterials. The micronucleus assay is a rapid detection method to evaluate whether a biomaterial would damage chromosomes or interfere with cellular mitosis. This method can rapidly monitor acute and/or chronic genotoxicity, and does not require cultured cells[18]. In our study, we compared Fe_2O_3 groups with the negative control group and found no significant difference ($P > 0.05$) in the micronucleus formation rate. However, when we compared these groups with the positive control group, the result was significantly different ($P < 0.05$).

Therefore, Fe_2O_3 nanoparticles were not carcinogenic or mutagenic. However, the results of the acute toxicity test revealed that Fe_2O_3 nanoparticles intraperitoneally injected into the mice had low toxicity. The LD_{50} was equal to 5 g/kg, which is in the "no toxicity" category according to the standard of acute toxicity gradation of WHO. The LD_{50} of Fe_2O_3 for the mice was 5.75 g/kg with a 95% confidence interval of 4.8-6.9 g/kg. So, Fe_2O_3 also belonged to the "no toxicity" category and had a wide safety value margin. When we injected Fe_2O_3 into livers of healthy pigs, no significant differences in serum AST, ALT, BUN and Cr levels were found among pigs of all groups ($P > 0.05$), and no obvious pathological alterations were observed. From the results of our experiment, we believe that Fe_2O_3 demonstrated no toxic effects, is a highly biocompatible material and may be suitable for further applications in tumor hyperthermia.

We studied the therapeutic effect of Fe_2O_3 and As_2O_3/Fe_2O_3 combined with MFH on liver cancer *in vitro* and i*n vivo*. We injected Fe_2O_3 and As_2O_3/Fe_2O_3 into the tumor tissues instead of the normal tissue boundary of the tumor. Thus, the nanoparticles were delivered into the desired zone. This method allows thermogenic action to be administered locally, even in tumors located deep inside bodies, while minimizing heating of normal tissue around the tumor[19,20]. Compared with As_2O_3/Fe_2O_3 groups, As_2O_3/Fe_2O_3 combined with MFH had a better inhibitory effect on xenograft liver tumors, which indicates that MFH had a significant therapeutic effect. Much to our surprise, As_2O_3/Fe_2O_3 combined with MFH was the best therapeutic agent among all the groups tested. This result revealed that As_2O_3/Fe_2O_3 combined with MFH had two functions: chemotherapy of As_2O_3 and thermotherapy of magnetic Fe_2O_3 nanoparticles.

In conclusion, As_2O_3/Fe_2O_3 combined with MFH is a new biomaterial with low toxicity. However, we must acknowledge that our studies have limitations, and more researches should be carried out in the future. Although there is still a long way to go before the technology can be applied to clinical treatment, this method may develop into a new approach for the treatment of liver cancer and other solid tumors.

COMMENTS

Background

Hepatocellular carcinoma is one of the most common malignant tumors in China, and has a low recovery rate, so it is necessary to search for a new method to treat liver tumors.

Innovations and breakthroughs

Nanoparticles combined with magnetic fluid hyperthermia (MFH) have become a potential method to treat tumors. In this study, As_2O_3/Fe_2O_3 complexes were found to have two functions, chemotherapy of As_2O_3, and thermotherapy of magnetic Fe_2O_3 nanoparticles.

Applications

As_2O_3/Fe_2O_3 combined with MFH is a new biomaterial with good therapeutic effects on liver cancer. This preparation may be developed into a new agent for the treatment of liver cancer and other solid tumors.

Terminology

MFH is a method that can target and localize thermogenic actions. Therefore, the tissue surrounding the tumor without magnetic particles would not be damaged.

Peer review

The manuscript describes the therapeutic potential of nanosized As_2O_3/Fe_2O_3 complexes in combination with MFH on liver cancer cells. The authors analyzed the toxicity and therapeutic potentials of various concentrations of Fe_2O_3 and As_2O_3/Fe_2O_3. Interestingly, they found significant antitumor effects of those compounds against xenograft tumors of liver cancer cells when combined with magnetic fluid hyperthermia. The data are important and promising.

Abstract

AIM: To investigate the 152 cases of paragangliomas resected over the past 32 years in West China Hospital clinicopathologically.

METHODS: All cases of paragangliomas diagnosed at the Department of Gastrointestinal Surgery and Department of Pathology, West China Hospital, China were reviewed. The pathological documents were supplied by the Department of Pathology, West China Hospital, and other necessary data were extracted from the hospital records. The statistical analyses were performed by survival analysis (Kaplan-Meier method), descriptive statistical analyses and χ^2 analysis.

RESULTS: The neuroendocrine marker vimentin was found to be selectively expressed in the benign tumors, and there were significant differences in the expression of those markers in both benign and malignant tumors. The survival analysis revealed that survival correlated significantly with the malignancy, metastasis and nodal status.

CONCLUSION: Vimentin may be useful in the differential diagnosis between malignant and benign tumors. The difference in the expression of this marker in the tumors could be a clue to the future clinical diagnosis. The malignancy, metastasis and the nodal status may predict the prognosis of this disease.

INTRODUCTION

Paragangliomas (also known as extra-adrenal pheochromocytomas) are rare neuroendocrine neoplasms which are derived from paraganglia, a diffuse neuroendocrine system dispersed from the skull base to the pelvic floor, and these tumors are observed in patients of all ages. Some of the tumors (named as functional paragangliomas) have been discovered to originate, synthesize, store and secrete catecholamines, which leads to elevated levels of urine/serum catecholamines and the typical clinical symptoms such as episodic headache (72%), sweating (69%), and palpitations (51%). The tumors, which can arise in any area of the body containing embryonic neural crest cells, are mainly composed of chromaffin cells[1,2]. Because of their rarity, little information is available regarding the natural history of these tumors and patient outcome after resection, and especially regarding the diagnosis of malignant tumors. We present a review of 152 cases of resected paragangliomas in our single hospital over a greater than 30-year period and review the relevant literature.

MATERIALS AND METHODS

In this study, data were supplied by West China Hospital, Sichuan University (Department of Pathology, Department of Gastrointestinal Surgery and other relevant departments). From April 1976 through December 2007,

152 patients with paragangliomas (also referred to as extra-adrenal pheochromocytomas) underwent resection at the West China Hospital, Sichuan University. Demographics, survival time, tumor location, surgical treatment, pathological documents and other relevant data were extracted from hospital records and pathological reports. Patient confidentiality was ensured in all cases.

For the purpose of this study, malignant tumors were defined as those associated with identified lymph node metastases, distant metastases, vascular invasion, tumor necrosis and other identified malignant behaviors. The tumor histology was defined and classified as described in the pathological reports. Mortality and survival was calculated based on last follow-up or death. Statistical analyses included survival analysis (Kaplan-Meier method), descriptive statistical analyses and χ^2 analysis. Survival rates were compared using log-rank tests. $P < 0.05$ was considered as statistically significant.

RESULTS

A total of 152 cases of extra-adrenal paraganglioma who underwent resection were identified in West China Hospital, Sichuan University. Amongst these cases were: tumors located in retroperitoneum (85 cases), urinary bladder (6 cases), vertebral canal (7 cases), mediastinum (8 cases), mesostenium (2 cases), lung (3 cases), neck (20 cases, including 8 cases of glomus jugulare tumor, 16 cases of carotid body tumor and 1 case of peripharyngeal tumor), and the rest were tumors located in intracalvarium, liver, supraclavicular fossa, vaginal wall, spermatic cord, sacral bone, greater omentum, nasal cavity, mouth floor, rectum and orbital cavity, respectively. The median age of the 152 patients at the diagnosis was 43 years (range; 8-82 years). Eighty-nine patients were men and 64 patients were women. Of these cases, 30 tumors (19.74%) were diagnosed as malignant paragangliomas, including 6 cases of lymph node metastases, 4 cases of distant metastases (3 cases in femur, 1 case in thoracic vertebra), 1 case of recurrence, 22 cases of local invasion (including vascular invasion), and 2 cases were accompanied by other malignant diseases (rectal cancer and neuroblastoma).

Amongst these 152 cases, paragangliomas from various sites were examined for a host of neural and neuroendocrine markers by immunohistochemistry including neurone specific enolase (NSE), S-100 protein, synaptophysin (Syn), chromogranin A (CgA), Cytokeratin (CK), and vimentin: the results are shown in Table 1. NSE was found to be expressed in nearly all the paragangliomas (benign and malignant), and there was no significant difference between benign or malignant tumors ($P = 0.805$). S100, Syn and CgA were found to be expressed in most of the paragangliomas; again no significant difference was found between benign or malignant tumors. CK was found to be expressed in some of the cases, but no significant difference was identified between benign or malignant tumors as the $P = 0.077$. Vimentin was found to be selectively expressed in benign tumors, and a significant difference between benign and malignant paragangliomas was observed ($P = 0.007$), which may be useful in differentially diagnosing between the malignant and benign tumors. In benign tumors, there was a significant difference in the expression of those markers ($P < 0.001$), and the same result could also be found in the malignant tumors ($P < 0.001$). The difference of the expression of those markers in the tumors could be a clue to the future investigation of the diagnosis.

Table 1 Expression of markers in paragangliomas by immunohistochemistry

Markers	Positive rate in benign groups (%)	Positive rate in malignant groups (%)
NSE	99.0	100.0
S100	84.6	71.4
Syn	85.9	95.0
CgA	92.7	88.2
CK	22.2	5.3
Vimentin	76.9	12.5

The overall 5-year survival in all the 152 cases was 88.82%, while in the malignant group of 30 cases, the five-year survival was 43.33%. The median survival in malignant cases was 50 mo. It could be observed that survival correlated significantly with malignancy ($P < 0.001$, Figure 1A). Furthermore, in the malignant group, survival correlated significantly with the presence of metastasis ($P < 0.001$, Figure 1B), the nodal status ($P < 0.001$, Figure 1C), but not with the local invasion ($P = 0.708$, Figure 1D). The survival analysis revealed a significant correlation between survival and the malignancy, metastasis and the nodal status, which may predict the prognosis of this disease.

DISCUSSION

Histologically, paragangliomas are characterized by a honeycomb pattern in which well-circumscribed nests (Zellballen) of round-oval or giant multinucleated neoplastic cells with cytoplasmic catecholamine granules are surrounded by S-100-positive supratentorial cells. Pleomorphism, mitotic figures, and bizarre nuclear forms (which do not necessarily reflect a higher grade of malignancy) may also be seen. There are no standardized histological criteria for differentiating malignant and benign paragangliomas and pheochromocytomas, and they are considered malignant only when cells with neoplastic characteristics are found in areas in which paraganglionic tissue is normally absent. Also, those tumors that contain large numbers of aneuploid or tetraploid cells, as determined by flow cytometry, are more likely to recur[1,3]. Paragangliomas are of two types, sympathetic and parasympathetic. The tumors usually have their origin in adrenal medulla, the organs of Zuckerkandl, the carotid body, aorticopulmonary, intravagal, *etc*[4,5] (Figure 2).

The paraganglioma cells are discovered to be characterized by the presence of neuroendocrine markers, including neurone specific enolase (NSE), S-100 protein,

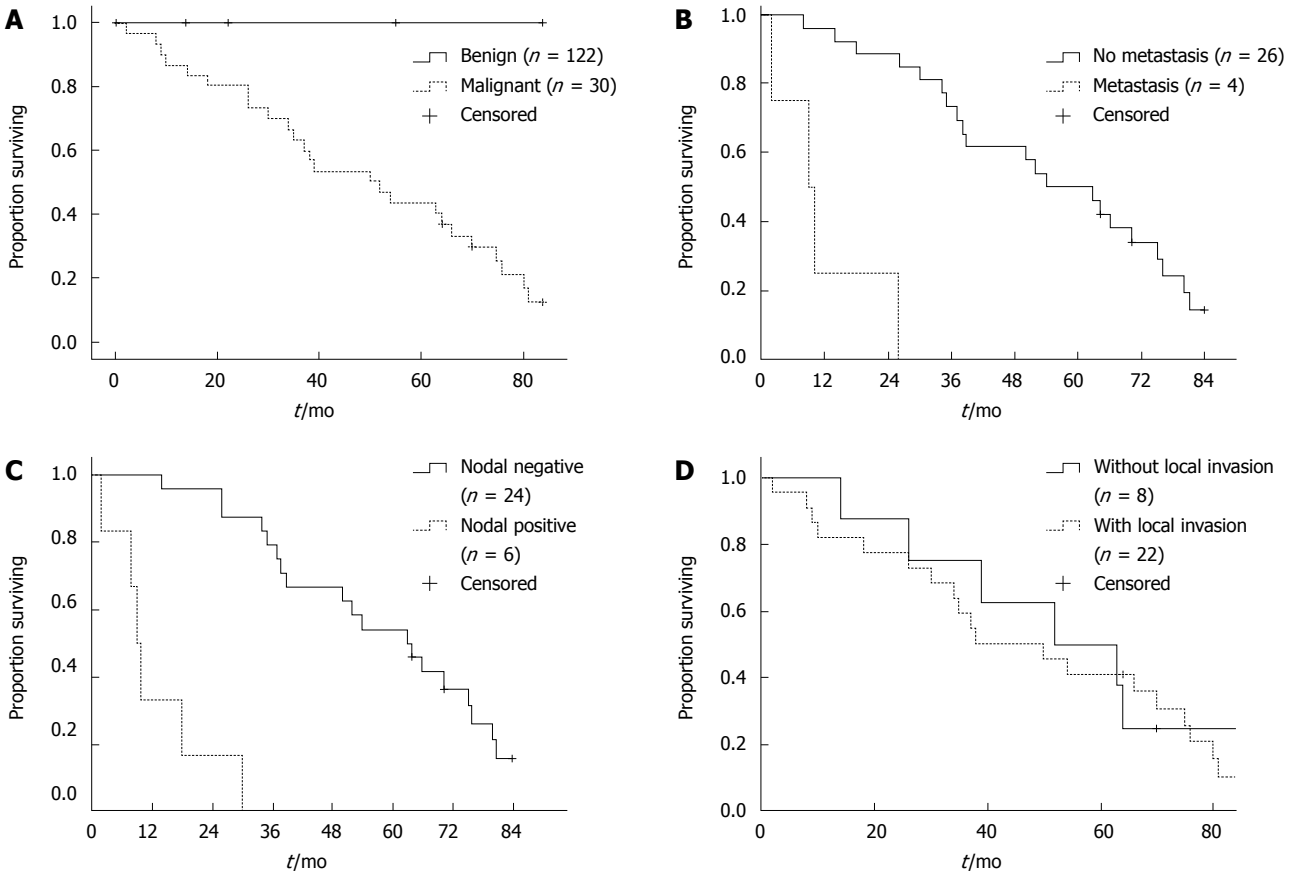

Figure 1 Survival of patients undergoing resection of paraganglioma. Stratified by A: Malignancy ($P < 0.001$); B: Metastasis ($P < 0.001$); C: Nodal status ($P < 0.001$); D: Local invasion ($P = 0.708$).

synaptophysin (Syn), chromogranin A (CgA), Cytokeratin (CK), vimentin, PGP9.5 and CD56, *etc*. The tumor has multiple synthetic activities, and in spite of its heterogeneity, chromogranin A and synaptophysin are the most common neuropeptides synthesised, as they are associated with the presence of neuroendocrine storage granules[6]. The presence of some of these markers in the paragangliomas, as well as their differential expression between the benign and malignant tumors, has been confirmed in our study which may suggest that an immunophenotypic analysis could be useful in the diagnosis of this disease (Figure 3).

Paragangliomas and pheochromocytomas are embryologically related tumors, sharing a neural-crest origin, several clinical features, and an overlapping genetic profile, although they do show variability as to site, histology, and biology. The occurrence of these tumors in familial settings, their association with hereditary syndromes, and their genetic alterations revealed that some cases are familial[7,8]. Multiple endocrine neoplasia type 2 (MEN2), neurofibromatosis type 1 (NF1) and von Hippel Lindau (VHL) syndrome subtypes 2A, 2B, and 2C account for about 10% of cases; the genes involved being the RET proto-oncogene and the NF1 and VHL tumor suppressor genes, respectively. However, with the identification of the familial paraganglioma syndromes, characterized by mutations in the subunits of the succinic dehydrogenase (SDH) enzyme (Table 2, Note: The

Table 2 Classification and characteristics of familial paraganglioma syndromes[8]

		Adrenal	Extra-adrenal Sympathetic	Parasympathetic
Familial paraganglioma 1	SDHD	+	+	+
Familial paraganglioma 3	SDHC			+
Familial paraganglioma 4	SDHB	+	+	+

syndromes were named in the order in which they were identified)[8], it now appears that over 30% of cases are associated with an inherited genetic disposition[8-10]. In our investigation, a very high malignancy rate of 19.74% was obtained, which may suggest that a significant proportion of these patients may have underlying familial SDH gene mutations. This finding also urges us bear in mind the gene mutation test for paraganglioma cases in following investigations. In many previous studies, it has been found that some malignant paraganglioma showed both loss of 8p and gain of 11q13, suggesting these alterations could be markers of malignancy. Furthermore, it has been confirmed that mutations of the SDH and loss of heterozygosity (LOH) on chromosome 11 result in a small fraction of sporadic and almost all familial forms of paraganglioma. The development of paraganglioma in diverse anatomical locations in subjects with SDHB, SDHC, and SDHD germline mutations indicates

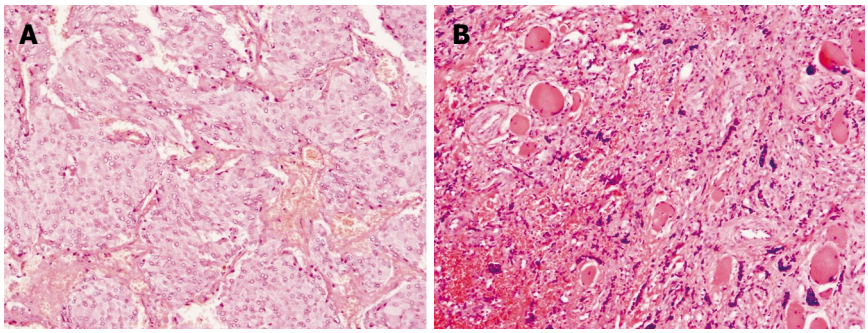

Figure 2 The histologic analysis of paraganglioma. The hematoxylin-eosin stain of chief (type 1) cells arranged in one of the typical cell nests in a retroperitoneal benign tumor (A), and in a femur metastasis (B), (× 50).

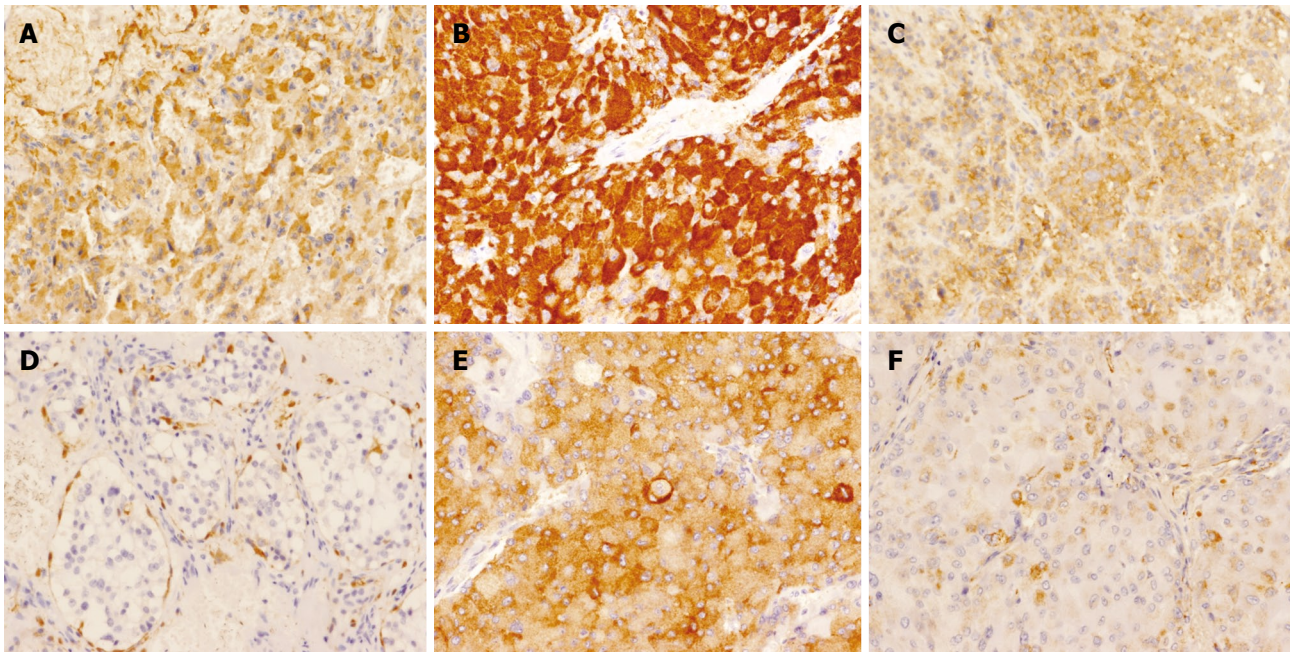

Figure 3 The immunohistochemistry analysis of paraganglioma. The immunolabeling test shows that peripheral to the cell nests are the stellate sustentacular (type 2) cells, intensely brown after S-100 immunolabeling (D), and in some cases CK (A, CgA (B), NSE (C), Syn (E) and vimentin (F) are also positive for paraganglioma, (× 100).

that the paraganglionic system throughout the body is a target for paraganglioma. Thus, the possibility of mitochondrial SDH germline mutations should be raised in the differential diagnosis of all paragangliomas. Whether certain subunit mutations are more strongly associated with a given anatomical location, hormonal activity, malignancy, age at onset, tumor multiplicity, and tumor size remains to be established. Hereditary paraganglioma is closely tied in with germline mutations affecting genes encoding for the SDH enzyme system, which is a heterotetrameric complex with functions in the Krebs cycle related to the oxidation of succinate to fumarate leading to ATP production. The catalytic subunits of SDH are encoded by the genes SDHD, SDHB, SDHC, and SDHA. SDHD encodes the smallest subunit of SDH. SDHA and SDHB are anchored to the mitochondrial inner membrane through membrane-spanning subunits encoded by SDHC and SDHD. A large number of mutations (approx 30) in hereditary paraganglioma have been described for SDHD and SDHB each[3,11,12]. Germline mutations in SDH genes are associated with the development of paraganglioma in diverse anatomical locations, a finding that has important implications for the clinical management of patients and genetic counseling of families. Consequently, patients with paraganglioma and a SDH germline mutation should be diagnosed as potentially hereditary, regardless of family history, anatomical location, or multiplicity of tumors.

In the past, studies involving biochemical measurements of urine/plasma catecholamines were found to have appropriate sensitivity and specificity for detecting catecholamine-secreting functional paragangliomas. Among all the tests studied, measurements of plasma free metanephrines were found to have the best predictive value for excluding or confirming a pheochromocytoma or functional paraganglioma[13,14]. As for those nonfunctional paragangliomas, because they are a heterogeneous group of tumors, using a single test may not be reliable, and a combination of tests may result in higher diagnostic accuracy. Furthermore, scintigraphy with iodide 131-labeled metaiodobenzylguanidine (MIBG 131) is found to be useful, not only for noninvasive diagnosis of paragangliomas, but also for palliative treatment in cases for which other types of treatment have been unsuccessful[15]. Positron emission tomography (PET)-scanning with [18F]-fluorodeoxyglucose, [11C]-

hydroxyephedrine, or 6-[18F] fluorodopamine may help to identify conventionally undetectable tumors[16-19]. For the diagnosis of malignancy in paraganglioma, the clinical and histological features predictive of malignancy are still poorly defined for this type of tumor; the level of serum catecholamines does not necessarily correlate with the malignancy of the tumor. In most previous literature, immunohistochemistry has not been of use for refining the diagnosis of malignant potential, though some malignant tumors may express fewer or different peptides than benign. S100-positive sustentacular cells are often sparse in malignant tumors, although this test is not 100% sensitive[3,6,20]. The only absolute criterion for malignancy is the presence of metastases to sites where chromaffin tissue is not usually found. However, some other features of the tumor may indicate the malignant characteristic, including recurrence, gross local invasion, vascular or capsular invasion, tumor necrosis, malignant histological pattern and cellularity[21]. Also, some evidence suggests that multifactorial scoring systems can help to histopathologically discriminate tumors which pose a significant risk of metastasis from those that do not. In 2002, Thompson[22] proposed the PASS system (Pheochromocytoma of Adrenal Scaled Score), which scores multiple microscopic findings (Table 3). A PASS of < 4 accurately identified all histologically benign and clinically benign tumors. A PASS of $\geqslant 4$ correctly identified all tumors that were histologically malignant. In our study, vimentin was found to be selectively expressed in benign tumors, which may be useful in the differential diagnosis between the malignant and benign tumors. However, in the PASS system as Thompson[22] proposed, vimentin has not been involved and scored as a neuroendocrine marker in the diagnosis of this disease. In order to confirm the value of vimentin, following investigations should involve more cases and areas, more precise testing techniques such as the quantitation test of RNA and protein should be involved, as well. If the diagnostic value of vimentin could be confirmed in the future, vimentin should indisputably be added into the PASS system.

Due to the rarity of this disease, the outcomes of survival analysis in different research studies are not highly coherent. In benign cases, most studies showed that the 5-year survival rate is above 95%; recurrences occur in less than 10% of cases. Whereas, due to the lower incidence of malignant paragangliomas, there are single case reports rather than larger scale case studies and clinical controlled randomized tests, and the exact survival in the malignant cases is difficult to approach. Similar to our study, the value has been found to be 43.33%. The survival in malignant cases was thought to be related to the familial circumstance, the stage of the disease at the diagnosis, the therapeutic methods and follow-up after the surgery, which has also been identified by our study[23,24]. In our study, it was also confirmed that the survival in malignant cases was obviously lower than the benign group as previously reported in many articles. Furthermore, it was revealed that the non-chromaffin site metastases and nodal metastases distinct from local invasion played an important role in the progression and prognosis of this disease, which may help in the estimation of survival in each case and moreover offer individualized therapy for each patient. This result also means that following studies should investigate the possible unique mechanism of metastasis and nodal invasion of this disease, so that the method to prevent this progress may be found.

COMMENTS

Background

Paraganglioma is a rare neuroendocrine neoplasm. This disease usually originates from a diffuse neuroendocrine system dispersed from the skull base to the pelvic floor. Paraganglioma is observed in patients of all ages. Some of the tumors (named as functional paragangliomas) have been discovered to originate, synthesize, store and secrete catecholamines, which leads to elevated levels of urine/serum catecholamines and the typical clinical symptoms such as episodic headache (72%), sweating (69%), and palpitations (51%). Due to the rarity of this disease, the natural history of these tumors, patient outcome after resection, and especially the diagnosis of malignant tumors are still under investigation.

Research frontiers

Nowadays, there are no standardized histological criteria for differentiating malignant and benign paragangliomas, and they are considered malignant only when cells with neoplastic characteristics are found in areas in which paraganglionic tissue is normally absent. The paraganglioma cells are discovered to be characterized by the presence of neuroendocrine markers, including neurone specific enolase (NSE), S-100 protein, synaptophysin (Syn), chromogranin A (CgA), Cytokeratin (CK), vimentin, PGP9.5 and CD56, *etc*. The differential expression of those markers between the benign and malignant tumors and the value of them in the differential diagnosis are broadly discussed.

Innovations and breakthroughs

A Pheochromocytoma of Adrenal Scaled Score (PASS) system was proposed for making the differential diagnosis between malignant cases and benign cases. This system scores multiple microscopic findings such as tumor necrosis, high cellularity, cellular monotony, vascular invasion, *etc*. The differential expression of some markers between the benign and malignant tumors has been confirmed in many studies, which may suggest that immunophenotypic analysis could be useful in the diagnosis of this disease.

Applications

In the study, vimentin was found to be selectively expressed in benign tumors, which may be useful in the differential diagnosis between the malignant and benign tumors. The high malignancy rate of 19.74% may suggest that a significant proportion of these patients have underlying familial SDH gene

mutations. This finding may also attract more attention to the gene mutation test for paraganglioma cases in following investigations. The survival data may help clinicians to estimate the survival in each case and moreover offer individualized therapy for each patient.

Terminology

Paraganglioma (also known as extra-adrenal pheochromocytoma) is a rare neuroendocrine neoplasm which is derived from paraganglia, a diffuse neuroendocrine system dispersed from the skull base to the pelvic floor. Vimentin is a member of the intermediate filament family of proteins. Intermediate filaments are an important structural feature of eukaryotic cells. They, along with microtubules and actin microfilaments, make up the cytoskeleton. Although most intermediate filaments are stable structures, in fibroblasts, vimentin exists as a dynamic structure.

Peer review

This manuscript provides relevant data on the rare condition of paraganglioma, especially in the west region of China, which has significant usefulness for clinicians and pathologists alike. The finding about the differential expression of vimentin may be important in the diagnosis of this disease. The survival analysis may help the clinicians to make clinical decisions.

Abstract

AIM: To investigate the effect of heme oxygenase-1 (HO-1) expression on immune liver fibrosis induced by cobalt protoporphyrin (CoPP) in rats.

METHODS: An immune liver fibrosis model of rat was established by administering human serum albumin (HSA). The rats were divided into CoPP, liver fibrosis and normal control groups. Rats in the CoPP group received intraperitoneal CoPP concurrently with HSA. Expression of HO-1 protein was observed by Western blotting and immunohistochemistry. Hematoxylin and eosin (HE) staining was performed to assess fibrosis proliferation and distribution, proliferation extent of fibroblasts, and alterations in hepatocytes and inflammatory cells. Type Ⅰ and Ⅲ collagens were detected with Van Gieson's (VG) staining and Foot's reticular fiber staining, respectively. In addition, spindle-shaped cells existing at perisinusoidal locations beyond portal and septa areas were investigated with HE staining.

RESULTS: Western blotting and immunohistochemistry showed that the expression of HO-1 protein was higher in the CoPP group than in the liver fibrosis group ($P < 0.05$). Compared with the liver fibrosis group, the serological index of hepatic fibrosis in the CoPP group decreased significantly ($P < 0.05$). HE, VG and Foot's staining revealed that administration of CoPP reduced the extent of hepatic fibrosis. The levels of serological indicators and the number of spindle-shaped cells at perisinuous locations beyond the portal and septa areas were reduced in the CoPP group. Only a few inflammatory cells were seen around the portal areas and central veins in the CoPP group.

CONCLUSION: Increased endogenous HO-1 may suppress liver fibrosis by protecting liver cells, inhibiting inflammatory cell infiltration and hepatic stellate cell transformation.

INTRODUCTION

Heme oxygenase-1 (HO-1) and heme degradation products of biliverdin, bilirubin, CO and free iron play an important role in many physiological and pathological processes, such as liver ischemia-reperfusion injury, liver transplantation, and acute liver injury[1-5]. In the present study, we investigated the effects of HO-1 expression on immune liver fibrosis induced by cobalt protoporphyrin (CoPP) in rats.

MATERIALS AND METHODS

Animals

Healthy male Sprague-Dawley rats, weighing 220-270 g,

were obtained from the Laboratory Animal Center of Dalian Medical University.

Reagents

CoPP injections were prepared by dissolving the compound in 0.2 mmol/L NaOH, adjusting its pH value to 7.4 with 1 mmol/L HCl, and diluting it with 0.9% NaCl to a final concentration of 1 mg/mL, as previously described[6]. Twenty percent human serum albumin (HSA) injection (Instituto Grifols, S.A. Barcelona, Spain), Freunds' incomplete adjuvant (Santa Cruz Biotechnology, Santa Cruz, CA, USA), protoporphyrin IX cobalt chloride (Sigma, St Louis, MO, USA), rabbit anti-HO-1 (Boster Biological Technology, Wuhan, China), and anti-mouse IgG, anti-rabbit IgG (Zhong Shan Golden Bridge Biotechnology, Beijing, China) were used in the study.

Animal model and grouping

Animals were divided randomly into a liver fibrosis group (n = 20), a CoPP group (n = 20), and a normal control group (n = 12). An immune liver fibrosis rat model was established as previously described[7]. Rats were allergized with HSA, and then injured by injecting albumin into the tail vein (2.5 mg per rat each time and increased gradually to 4.5 mg, twice weekly for 6 wk). Rats in the CoPP group received intraperitoneal CoPP (5 mg/kg) concurrently with HSA administration.

Sample collection

Rats were attacked by HSA for 6 wk, fasted for 12 h, and then weighed. Three percent sodium pentobarbital injection (2 mL/kg) was used as an anesthetic agent. Four milliliters of blood was collected from the eyeball of rats and stored at -20℃. Livers were removed from the rats, fixed in a 10% neutral formalin solution, embedded in paraffin, and preserved at -80℃.

Western blotting

One milliliter of lysate containing 20 mmol/L Tris (pH 7.5), 150 mmol/L NaCl, 1%Triton X-100, 1 mmol/L phenylmethanesulfonylfluoride, was added to 100 mg liver tissue. The mixture was homogenized by centrifugation at 12000 r/min for 3-5 min at 4℃, and the supernatant was separated. After SDS-PAGE, the sample was transferred to a polyvinylidine fluoride membrane and stained with 3,3' diaminobenzidine. The sample was incubated with primary antibody (rabbit-anti-mouse HO-1 monoclonal antibody, 1:100) and secondary antibody (peroxidase-labeled sheep-anti-rabbit antibody, 1:100), with β-actin as an internal reference.

Immunohistochemical analysis

Paraffin-embedded liver tissue was cut into sections, which were routinely stained with HE. Cells in good condition were stained using an immunohistochemical method (streptavidin-peroxidase method), after dewaxing, hydration, inactivation, incubation with primary antibody (rabbit-anti-mouse HO-1 monoclonal antibody; 1:150) and secondary antibody (biotin-labeled sheep-anti-rabbit antibody; 1:100), and mounting. The primary antibody was administered with PBS to serve as a negative control. Yellow material in the cytolymph was considered to be a positive cell. Five high-power microscopic fields were randomly chosen per slice. The percentage of positive cells increased as the intensity of staining increased in every field. Ultimately, the average of five fields was used to compare differences between groups.

Measurement of biochemical indicators

Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels were measured with an automatic biochemical analyzer.

Measurement of liver fibrosis indicators

The levels of serum hyaluronic acid (HA), laminin (LN), type Ⅲ procollagen (PC Ⅲ) and type Ⅳ collagen (Ⅳ-C) were measured using a gamma radioimmunoassay counter.

Pathological analysis

Proliferation and distribution of liver fibrous tissue, proliferation of fibroblasts and changes in liver cells, portal areas and central veins were observed by HE staining[8]. Spindle-shaped cells existing at the perisinuous location beyond the portal and septal areas were counted. The proliferation degree of type Ⅰ and Ⅲ collagen was observed with Van Gieson's (VG) and Foot's staining, respectively[8].

Statistical analysis

Data analysis was performed using SPSS 10.0 software (Chicago, IL, USA). Analysis of variance (ANOVA) or Wilcoxon statistical methods were used to determine statistical significance. The results were expressed as mean ± SD. $P < 0.05$ was considered statistically significant.

RESULTS

Western blotting for HO-1 expression

The HO-1 protein expression level was significantly higher in the liver fibrosis group than in the normal control group ($P < 0.01$) and higher in the CoPP group than in the liver fibrosis group ($P < 0.05$, Figure 1).

Immunohistochemistry

Liver cells were not or only slightly stained in the normal control group (Figure 2A). Liver cells and mesenchymal cells were diffusely and unevenly stained in the liver fibrosis group (Figure 2B) and diffusely but strongly stained in the CoPP group (Figure 2C). Compared with the liver fibrosis group, the staining intensity and scope increased significantly in the CoPP group. The score for HO-1 protein expression was 0.80 ± 0.79 in the normal control group, 4.00 ± 1.31 in the liver fibrosis group, and 5.52 ± 1.15 in the CoPP group. The score for HO-1 protein expression was significantly higher in the CoPP group than in the liver fibrosis group ($P < 0.05$).

CoPP reduced the degree of liver fibrosis

The level of serological indicators was significantly

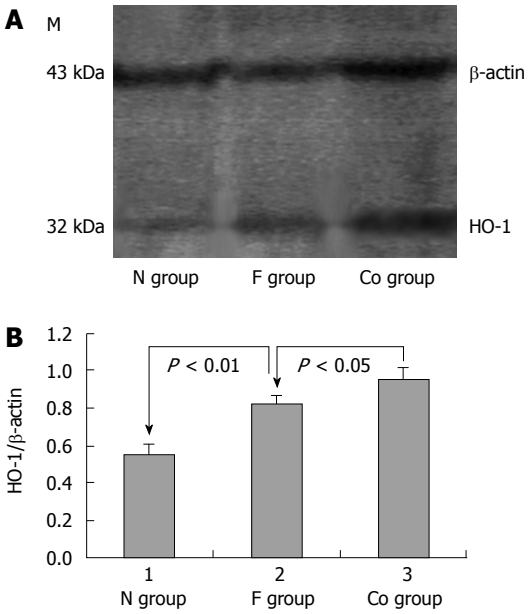

Figure 1 Western blotting of HO-1 protein expression (A) and densitometric analysis of HO-1/β-actin expression (B) in rat liver tissue.

higher in the liver fibrosis group than in the normal control group ($P < 0.01$), and significantly lower in the liver fibrosis group than in the CoPP group ($P < 0.05$, Table 1). The structure of hepatic lobules seemed integral without fibrous hyperplasia, and some collagen fibers were observed in the portal areas of the normal control group (Figure 3). Significant fibrous hyperplasia and fibrosis extension in the portal areas with fibroblast proliferation, widened lobular septa with more fiber deposition, and formation of fibrous septa were found in the liver fibrosis group (Figure 3). Compared with the liver fibrosis group, fibrous hyperplasia was significantly reduced and fine fibers were seen occasionally and distributed mainly in the portal areas of the CoPP group. The number of fibroblasts was also decreased in the CoPP group (Figure 3). Compared with the normal control group, there was a significant increase in fibrosis and hyperplasia of fibroblasts, and type Ⅰ and Ⅲ collagens in the liver fibrosis group ($P < 0.01$). The extent of fibrosis was lower in the CoPP group than in the liver fibrosis group (Table 2).

Mechanism underlying the effect of HO-1 on immune liver fibrosis

Injection of HSA increased serum ALT and AST levels ($P < 0.01$). The serum ALT and AST levels were lower in the CoPP group than in the liver fibrosis group ($P < 0.05$, Table 3). Rat liver cells were relatively uniform, yet most were swollen with a small amount of fatty degeneration and few nuclei were strongly stained and dissolved in the liver fibrosis group. In the CoPP group, most liver cells were normal. Only a small number were swollen and no degeneration of cells was observed, suggesting that HO-1 expression can protect impaired hepatocytes at a certain extent. The number of spindle-shaped cells was 37.2 ± 4.7 in the normal control group, 55.2 ± 3.5 in the liver fibrosis group, and 50.6 ± 3.6 in the CoPP group ($P < 0.01$). Meanwhile, the number of spindle-shaped cells, which were confirmed by electron microscopy to be activated hepatic stellate cells (HSCs), was reduced in the CoPP group. In the liver fibrosis group, a large number of inflammatory cells infiltrated the portal areas. Most of them were lymphocytes, and a small number were neutrophils. A small number of inflammatory cells were observed in the CoPP group.

DISCUSSION

Many chronic liver diseases progress to liver fibrosis[9]. The core aspect of the occurrence and development of hepatic fibrosis is to activate HSCs and transform them into myofibroblast-like cells[10,11]. Various factors result in hepatic fibrosis. Interactions between cells, cells and matrix, or transmitters and matrix, constitute a complex network that underlies the occurrence and development of liver fibrosis[12]. If the cause could be suppressed and the network systems could be impeded, hepatic fibrosis or cirrhosis could be effectively prevented.

Heme is catalyzed into CO, biliverdin and free iron

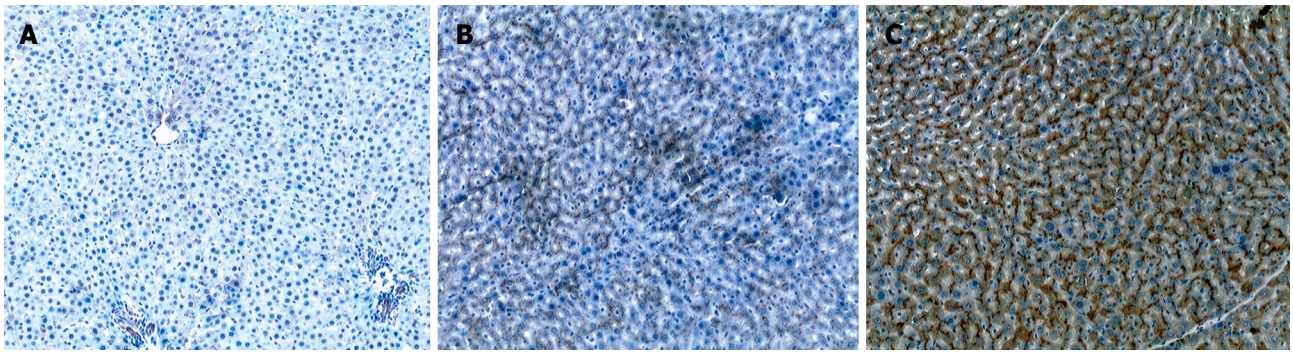

Figure 2 HO-1 protein expressions in rat liver tissue of normal control group (A), liver fibrosis group (B), and CoPP group (C) (× 100).

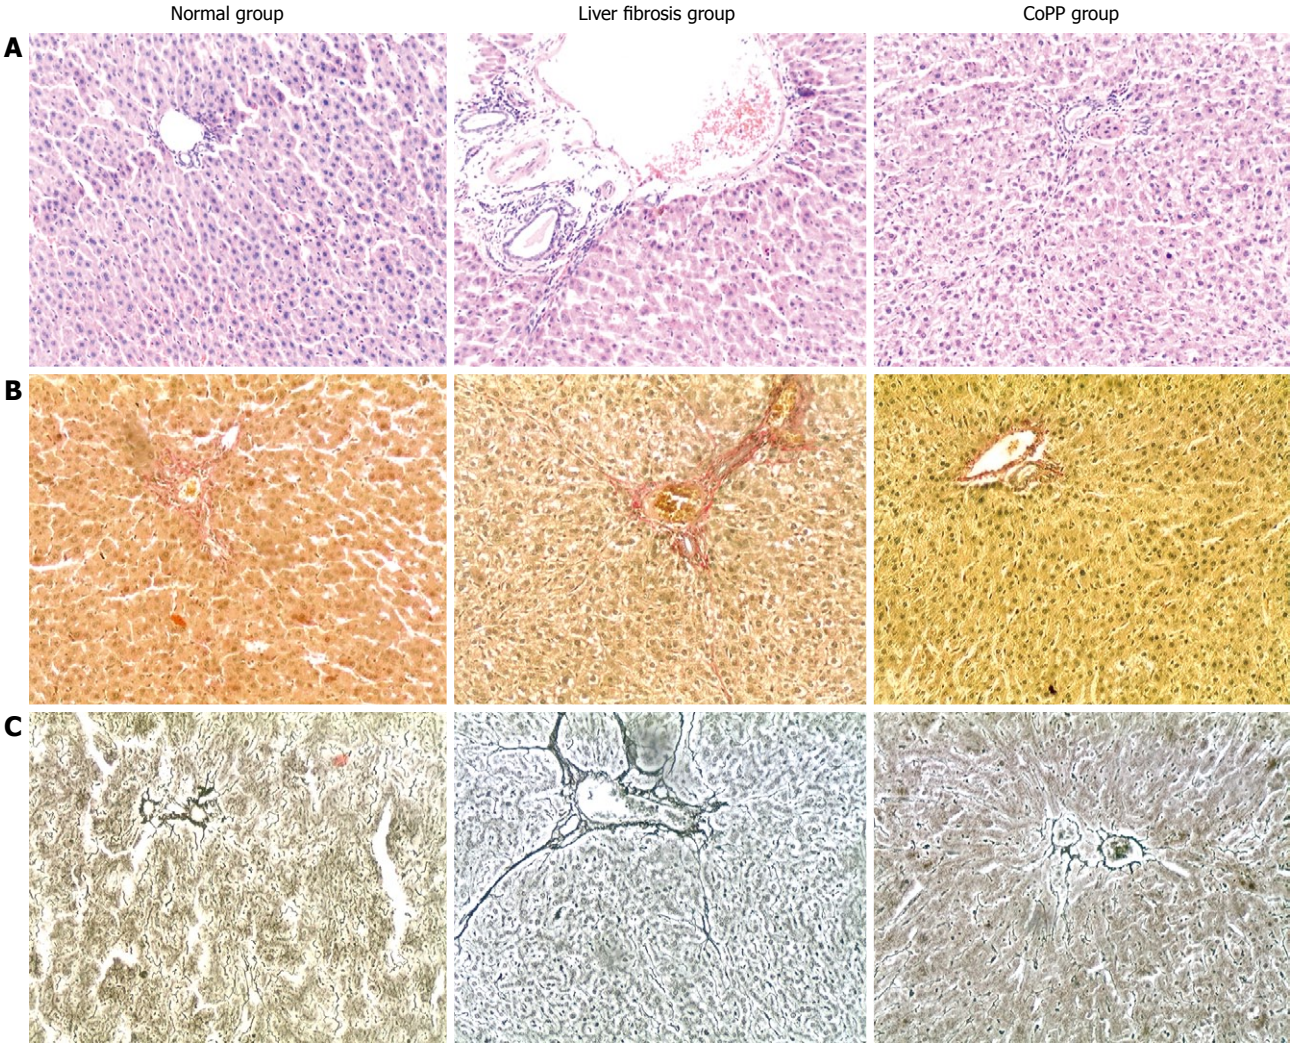

Figure 3 HE staining (A), VG staining (B), and Foot's staining (C) for liver tissues from rats in different groups (× 100).

by HO-1, a rate-limiting enzyme in heme metabolism. HO-1 expression can be induced by various stress factors, such as oxidative stress, inflammatory factors and heavy metals. In addition, some protoporphyrins, especially CoPP, can increase HO-1 expression *in vivo*. HO-1, as a protective protein *in vivo*, plays a vital role in many aspects, such as anti-oxidative stress, anti-inflammation, anti-cell proliferation, and regulation of cytokine expression.

HO-1 is only expressed in Kupffer cells (KCs) of normal liver tissue. In hepatic cirrhosis, however, it is expressed mainly in KCs and fibroblasts[13,14]. HO-1 can inhibit HSC proliferation and type I collagen mRNA expression in cultured human liver fibroblasts. When the adeno-associated-virus-mediated HO-1 gene is injected into portal veins of rats with micronodular cirrhosis induced by CCl_4, HO-1-transduced HSCs can reduce type I collagen transcription, proliferation ability and macrophage infiltration, thus improving the biochemical function of the liver[15,16].

The main cause for chronic liver disease in China

is hepatitis B virus (HBV) infections HBV cannot be used to establish animal models of liver fibrosis. Some scholars believe that rat models of immune liver fibrosis induced by HSA have some similarities in morphology and pathogenesis to liver fibrosis caused by HBV[17]. Therefore, it is of great significance to study the effects of HO-1 on immune liver fibrosis.

In the present study, HO-1 protein expression was observed in the CoPP group. Type Ⅲ collagen was significantly increased early in hepatic fibrosis. Type Ⅰ collagen fibers are mainly distributed at the fibrous septa, while type Ⅲ collagen fibers are associated with the reticular fibers[18,19]. In addition, serum HA, PC Ⅲ, LN and Ⅳ-C levels are closely correlated with liver fibrosis[20,21], indicating that increased HO-1 expression can suppress the occurrence and development of liver fibrosis.

We investigated preliminarily the effect of HO-1 expression on immune liver fibrosis induced by CoPP in rats. When liver cells were destroyed, the membrane permeability was increased and the mitochondria were damaged, and the activity of AST and ALT was elevated. The extent of damage to liver cells is consistent with the level of enzymatic activity[22]. Compared with the liver fibrosis group, serum AST and ALT levels were significantly increased in the CoPP group, indicating that HO-1 protects liver cells. Wen *et al*[23] have established a liver injury model induced by D-galactosamine and lipopolysaccharide (LPS), and found that pretreatment with hemoglobin increases HO-1, reduces damage to the liver, and lowers serum ALT and AST levels, thus improving liver disease. Nakahira *et al*[24] have shown that HO-1 activity inhibited by tin-protoporphyrin can lead to severe liver damage and significantly increased ALT levels. Moreover, CO also exerts protective effects on liver cells. Amersi *et al*[25] have shown that CO can protect liver cells, the AST levels were significantly lower, and the liver structure was normal without swelling or necrosis in the experimental group. Both biliverdin and bilirubin are antioxidants. When biliverdin is transformed into bilirubin, it can strengthen the oxidative capacity, while bilirubin protects the lipid bimolecular layer of the cell membrane[26], suggesting that HO-1 protects liver cells by consuming oxygen molecules and reducing oxygen free radicals, and prevents the peroxidation of free radicals in membrane lipids and maintains membrane integrity and normal physiological functions.

A high HO-1 expression level induced by CoPP plays an important role in reduction of the inflammatory response of liver cells. During inflammatory responses, local blood flow is reduced and leukocytes adhere to activated endothelial cells, thus releasing enzymes and causing cell injury. The key step is adhesion between leukocytes and endothelial cells. Selectin and cell adhesion factors are also involved in the process.

Anti-inflammatory effects of HO/CO are achieved by reducing the expression of adhesion molecules[27]. Macrophages are also activated in inflammatory responses, and produce arachidonic acid substances, tumor necrosis factor-α (TNF-α), and other inflammatory mediators that act on the liver and cause liver injury. LPS can stimulate KCs to generate inflammatory mediators. CO may prevent the expression of inflammatory cytokines [i.e. TNF-α and interleukin (IL)-1β][28], inhibit the secretion of IL-2[29], and reduce T-cell proliferation, thus achieving an anti-inflammatory effect. In addition, CO can increase the expression of anti-inflammatory cytokine IL-10, which can induce HO-1 expression, allowing HO-1 to produce more CO[30]. Thus, a reduction of inflammation induced by HO-1 is achieved by decreasing the activation of KCs, which suppresses the migration and adhesion of leukocytes, and inhibits the release of inflammatory mediators, finally relieves the inflammatory damage to endothelial cells.

A high HO-1 expression level induced by CoPP can inhibit the transformation of HSCs to fibroblasts. In the present study, the number of spindle-shaped cells was decreased in the CoPP group and increased in the liver fibrosis group. Most of these cells were activated HSCs, indicating that HO-1 can inhibit HSC activation. The fibroblasts of α-smooth muscle that express actin are transformed from dormant HSCs to live epithelial or matrix cells. Irrespective of its origin, the activity of fibroblasts is associated with cytokines and chemotactic factors secreted by macrophages[31]. Normal liver cell membranes have a contact-inhibition effect on the proliferation of HSCs and KCs. When liver cells are damaged, destruction of the cell membrane leads to loss of the contact-inhibition effect on HSCs, thus leading to activation of HSCs. The more HSCs are activated, the more cytokines are secreted (including insulin-like growth factor-1). Finally, the feed-forward cycle prevents the reversal of liver fibrosis. In short, HO-1 may inhibit the activation of HSCs.

In conclusion, HO-1 inhibits liver fibrosis and is closely related to other liver diseases. Further study is needed to elucidate its protective effect on immune liver fibrosis.

COMMENTS

Background

Heme oxygenase-1 (HO-1) and heme degradation products are involved in acute liver injury. However, their influence on chronic liver injury is still unclear.

Research frontiers

There are still many unclear or confusing problems about the development and progression of liver cirrhosis. These problems result in difficulties in the treatment of cirrhosis. It is of great significance to study the effects of HO-1 on immune liver fibrosis. The expression of HO-1 induced by drugs may provide a promising way to treat successfully liver fibrosis.

Innovation and breakthroughs

By establishing a model of immune liver fibrosis in rats, the authors investigated the effect of HO-1 induced by cobalt protoporphyrin (CoPP), which may provide a new treatment modality for liver fibrosis.

Applications

The expression of HO-1 induced by drugs in target organs may provide a promising way to treat liver fibrosis.

Terminology

HO-1 stands for heme oxygenase-1, which is a rate-limiting enzyme. It is also known as heat shock protein 32, and is susceptible to various stress factors such as oxidative stress, inflammatory factors, and heavy metals. In addition, some protoporphyrins, especially CoPP can increase HO-1 expression *in vivo*.

Peer review

The study is interesting. The authors showed that increased expression of

HO-1 could suppress liver fibrosis, thus providing a new treatment modality for liver fibrosis.

Abstract

AIM: To identify prognostic factors for survival in patients with liver failure treated with a molecular adsorbent recirculating system (MARS).

METHODS: MARS is a liver-assisting device that has been used in the treatment of liver failure to enable native liver recovery, and as a bridge to liver transplantation (LTX). We analyzed the 1-year outcomes of 188 patients treated with MARS, from 2001 to 2007, in an intensive care unit specializing in liver disease. Demographic, clinical and laboratory parameters were recorded before and after each treatment. One-year survival and the number of LTXs were recorded. Logistic regression analysis was performed to determine factors predicting survival.

RESULTS: The study included 113 patients with acute liver failure (ALF), 62 with acute-on-chronic liver failure (AOCLF), 11 with graft failure (GF), and six with miscellaneous liver failure. LTX was performed for 29% of patients with ALF, 18% with AOCLF and 55% with GF. The overall 1-year survival rate was 74% for ALF, 27% for AOCLF, and 73% for GF. The poorest survival rate, 6%, was noted in non-transplanted patients with alcohol-related AOCLF and cirrhosis, whereas, patients with enlarged and steatotic liver had 55% survival. The etiology of liver failure was the most important predictor of survival ($P < 0.0001$). Other prognostic factors were encephalopathy ($P = 0.001$) in paracetamol-related ALF, coagulation factors ($P = 0.049$) and encephalopathy ($P = 0.064$) in non-paracetamol-related toxic ALF, and alanine aminotransferase ($P = 0.013$) and factor V levels ($P = 0.022$) in ALF of unknown etiology.

CONCLUSION: The etiology of liver disease was the most important prognostic factor. MARS treatment appears to be ineffective in AOCLF with end-stage cirrhosis without an LTX option.

Key words: Molecular adsorbent recirculating system; Prognostic factors; Acute liver failure; Acute-on-chronic liver failure; Liver transplantation

Survival predictors in patients treated with a molecular adsorbent recirculating system. *World J Gastroenterol* 2009; 15(24): 3015-3024 Available from: URL: http://www.wjgnet.com/1007-9327/15/3015.asp DOI: http://dx.doi.org/10.3748/wjg.15.3015

INTRODUCTION

Since its introduction in 1993, molecular adsorbent recirculating system (MARS) albumin dialysis[1,2] has been a subject of research, with the hope of using it to treat effectively patients with rapidly failing liver function. Even though MARS treatment cannot fully compensate for the synthetic and metabolic functions of a normal liver, it has been used as a bridging treatment to sustain the patient until a suitable graft becomes available, or the native liver recovers. MARS treatment has also been used for patients who have a contraindication to transplantation or when a suitable organ is not available.

While the effect of MARS treatment on patient outcome, and laboratory and clinical parameters has been investigated widely in various uncontrolled case series, only a handful of randomized studies have been published[5-9]. Thus, we are still searching to identify which patients are most likely to benefit from this treatment, and to determine whether MARS treatment does in fact improve survival in patients with liver failure. It is crucial to identify not only those patients who have a good possibility of benefiting from MARS treatment, but also those for whom MARS treatment is a futile tool that serves only to prolong suffering when death is imminent.

The aim of this prospective observational study was to identify prognostic factors associated with survival in MARS-treated patients with life-threatening liver failure.

MATERIALS AND METHODS

This was an uncontrolled, prospective, single-center, observational study of 188 consecutive patients who underwent MARS treatment in a liver-disease-specialized intensive care unit (ICU) from May 2001 to March 2007. Four patients were treated before LTX, and then later on after LTX because of graft failure. All patients were categorized into four main groups according to the etiology of liver failure: acute liver failure and injury (ALF), acute-on-chronic liver failure (AOCLF), liver graft failure (GF), or liver failure of miscellaneous etiology. For the final analysis of results, these groups were further divided into subgroups according to specific etiology (Figure 1). Our tertiary liver-disease-specialized ICU is the only transplantation center in Finland.

Patients included in the ALF group required ICU admission and had rapid development of hepatic synthetic dysfunction[10], with or without encephalopathy, and no previous history of liver disease. AOCLF was defined as previously well-compensated chronic liver disease in which an acute decompensation of liver function developed rapidly, as a result of various secondary causes[11]. Graft failure included early (primary dysfunction or non-functioning graft) and late (primarily chronic rejection) dysfunction. The miscellaneous etiologies group contained patients with acute hemorrhagic pancreatitis with ALF, ischemic injury to the liver following myocardial infarction, multiple trauma including injury to the liver, and post-liver resection hepatic failure.

Monitoring and standard medical therapy

All patients received the same standard medical therapy. Blood pressure was monitored *via* arterial and central venous catheters; a Swan-Gantz catheter was used if necessary. All potentially nephro- and hepatotoxic medications were discontinued. Mean arterial pressure was maintained above 65 mmHg with fluid resuscitation and vasoactive medication (primarily noradrenaline infusion). Surveillance for infection and prophylactic antibacterial and antifungal therapy was administered. The level of consciousness was monitored closely and sedatives were avoided in non-intubated patients. If the grade of hepatic encephalopathy was $\geqslant$ 3 according to the West Haven

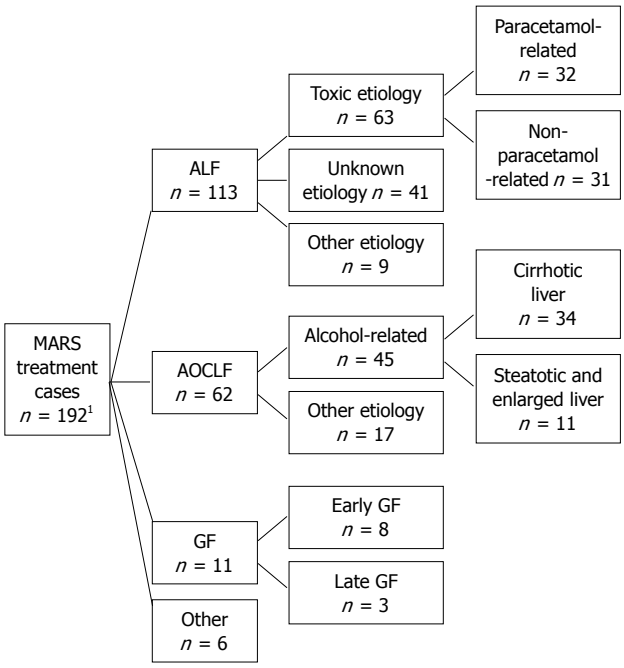

Figure 1 Distribution of liver failure etiologies in MARS-treated patients. [1]192 MARS treatment cases and 188 patients were included in this study. Four patients were treated at two different time points, first due to the primary liver failure, and second for graft failure following LTX.

criteria[12], the patient was usually sedated, intubated, and mechanically ventilated. A standard regimen of lactulose and proton pump inhibitors was used, and the target blood glucose level was normoglycemia, which was maintained with glucose and insulin infusion. *N*-acetylcysteine was used when necessary. Enteral nutrition was employed if possible. Urinary output was monitored and fluid resuscitation with furosemide infusion was used if necessary. Laboratory assessment of coagulation parameters was performed daily and clotting abnormalities were corrected only in cases of active bleeding, or an invasive procedure. Specific antidotes and drug therapies such as silibinin[13] and corticosteroids were used if deemed necessary.

MARS treatment initiation criteria

The criteria for initiating MARS treatment and treatment protocols are summarized in Table 1. In some patients, MARS treatment was commenced in the absence of encephalopathy, particularly in ALF patients who had ingested a lethal amount of toxin or if laboratory parameters indicated progressive liver failure despite the best possible standard medical therapy. As a general rule, we treated only the first exacerbation of chronic alcoholic liver disease.

In the MARS apparatus, the flow rate was 150 mL/min in the blood and albumin circuit and 500 mL/min in the dialysis circuit with bicarbonate buffered dialysate. Ultrafiltration was adjusted to control intravascular volume balance. Anticoagulation was used if permitted by the coagulation status and platelet count of the patient; dalteparin or epoprostenol were used most often. A detailed description of the operational systems of the MARS machine can be found in our previous study[14].

Table 1 Indications for MARS and treatment protocols

Etiology	MARS treatment initiation criteria	Treatment protocol
ALF	Rapid deterioration of hepatic synthetic function and clinical condition despite standard medical therapy and (one of the following criteria)	Twenty-two hours sessions daily until the native liver recovers
	Ingestion of a lethal dose of a known hepatotoxin (mushroom, paracetamol, iron, *etc*)	A suitable transplant organ is found
	Patient fulfills the criteria for highly urgent Ltx	Irreversible organ damage occurs
AOCLF	Rapid deterioration of hepatic synthetic function and clinical condition despite standard medical therapy and (two of the following criteria)	Eight hours sessions based on the daily assessment of the surgeon and anesthesiologist until the patient's clinical condition improves
	Hyperbilirubinemia, bil > 400 μmol/L	A suitable transplant organ is found
	Hepatorenal syndrome type 1	Irreversible organ damage occurs
	Progressive hepatic encephalopathy (grade ⩾ 2)	
GF	No set criteria; depends on the assessment of the transplant surgeon and anesthesiologist	No set protocol; based on the daily assessment of the surgeon and anesthesiologist

ALF: Acute liver failure; AOCLF: Acute-on-chronic liver failure; GF: Graft failure.

Table 2 Demographic, clinical, and treatment data at the beginning of MARS treatment

Characteristic	All patients	ALF			AOCLF		Graft failure
		Toxic	Unknown cause	Other	Alcohol-related	Other

MELD score	32 (5-52)	27 (5-48)	32 (23-50)	27 (23-46)	39 (17-52)	36 (27-44)	26 (20-47)
Mean encephalopathy grade before treatment (± SD)	1.8 (1.5)	1.6 (1.6)	2.0 (1.4)	2.4 (1.7)	1.5 (1.4)	1.9 (1.6)	2.0 (1.9)
Mean encephalopathy grade after treatment (± SD)	1.4 (1.6)	1.4 (1.7)	1.5 (1.7)	1.4 (1.6)	1.1 (1.5)	1.9 (1.8)	1.3 (1.7)
P	< 0.001	NS	0.05	0.04	0.02	NS	0.059

All demographic values are expressed as median (range) or percentage of patients (number of patients). Encephalopathy grades are expressed as mean ± SD). NS: Non-significant.

Measurements and data collection

For all MARS-treated patients, detailed information regarding the patient and treatment session was collected prospectively on a specially designed data collection sheet. Demographic data and clinical parameters were recorded at the beginning and end of each treatment. Baseline measurement was performed at the beginning of the first MARS session. The endpoint was the end of the last MARS session, death, or LTX. At both time points, blood samples were analyzed for cell counts, coagulation factor levels, plasma levels of liver enzymes, bilirubin, ammonium ion, urea, creatinine, blood gases, and electrolytes. The value furthest from the normal range of each measured variable during treatment was not included in the present analysis. The model for end-stage liver disease (MELD) score was calculated according to the standard formula by the United Network for Organ Sharing (UNOS)[15-17] at ICU admission. Survival at 1-year and need for LTX were recorded.

Statistical analysis

All data were analyzed with SPSS for Windows version 15.0 (SPSS, Chicago, IL, USA). The Wilcoxon signed rank test was used for repeated scale measurements before and after treatment within groups. The Mann-Whitney *U* test was applied when scale measurements were compared between groups. The Pearson χ^2 and Fisher exact tests were used to compare outcomes and binominal results between groups. $P \leqslant 0.05$ was considered statistically significant.

Stepwise binary logistic regression analysis was performed to determine factors predicting survival in each etiological subgroup. Variables analyzed included all collected demographic, clinical and treatment-related variables (Table 2) and all laboratory parameters at baseline (Table 3). Missing laboratory values were replaced with the median value of that laboratory result in all patients. The median was used instead of the mean because of the skewed distribution of most results. Special attention was given to variables that changed during MARS treatment and parameters that differed between transplant-free survivors and non-survivors/transplanted patients. The odds ratio (OR) and 95% confidence interval (CI) for each predictive variable were calculated. The best combination

All laboratory values are expressed as median (range). NH_4-ion: Ammonium ion (normal range: 36-86 mmol/L); AST: Aspartate aminotransferase; γ-GT: gamma glutamyltransferase; FV: Coagulation factor Ⅴ (normal range: 80%-120%); AT3: Antithrombin Ⅲ (normal range 80%-120%); TT (%): Thrombin time (normal range, 70%-130%) (includes coagulation factors Ⅱ, Ⅶ, Ⅹ).

of significantly predictive variables was selected using the R^2 score and Hosmer-Lemeshow goodness of fit test.

RESULTS

Baseline characteristics of MARS-treated patients

Our study population consisted of 113 patients with ALF, 62 with AOCLF, 11 with GF, and six with miscellaneous liver failure (Figure 1). In total, 192 MARS treatment cases were included in this study. Four patients were treated before LTX and afterwards because of graft failure. These treatment sessions were categorized separately as individual cases, first according to the primary liver failure etiology, and later on as graft failure cases. In 30% (58/192) of all treated cases, alcohol was either partly (mixed intoxication, *n* = 13) or directly (chronic alcoholic-liver disease, *n* = 45; graft failure caused by alcohol, *n* = 1) related to liver failure. The median number of MARS treatments per patient was two (range: 1-13), and the median duration of one session was 16.5 h (range 4-22.5 h). Contraindications to LTX prior to MARS treatment were present in 35% (67/192) of cases and included substance abuse, serious psychiatric illness, patient decision, serious concomitant disease (e.g.

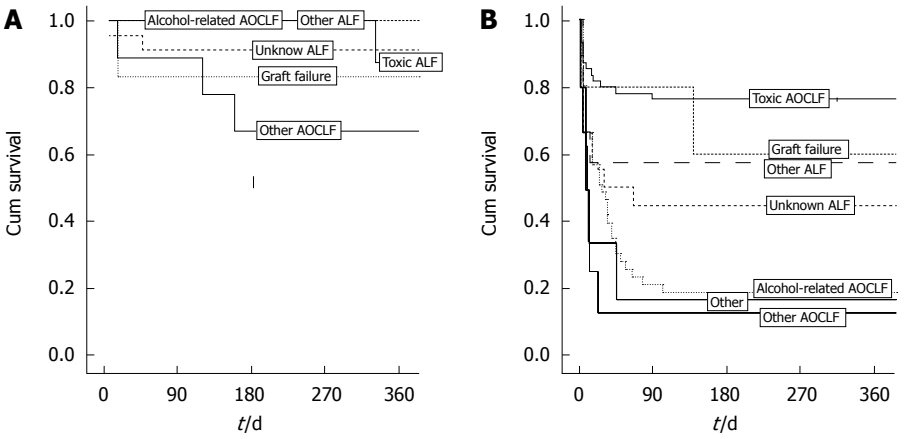

Figure 2 Kaplan-Meier cumulative survival for transplanted (A) and non-transplanted (B) MARS-treated patients with different causes of liver failure.

malignancy), and age > 80 years. In addition, 18 patients became untransplantable during MARS treatment: six because of serious, uncontrollable infections, and 12 because of multiorgan failure or brain death.

Etiologic subgroups differed significantly at baseline with respect to demographic data, clinical condition, and severity of liver failure (Table 2). The percentage of patients who required vasoactive medication and those with renal insufficiency were higher in the AOCLF and GF than in the ALF group. The highest median MELD scores were observed in association with alcohol-related AOCLF (39; range 17-52) and the lowest in association with ALF caused by toxicity (27; range 5-48) and GF (26; range 20-47) (Table 2). Encephalopathy grade decreased significantly in most subgroups during treatment. Changes in laboratory values during MARS treatment are presented in Table 3.

Outcome and characteristics of the subgroups

Kaplan-Meier 1-year survival curves for MARS-treated transplanted and non-transplanted patients are presented in Figure 2. The 1-year survival rate of all transplanted patients was 86% (43/50).

Patients with ALF: Patients with ALF were categorized into three subgroups according to etiology: toxic, unknown, and other (Figure 1). The toxic ALF subgroup was further subdivided into paracetamol-related and non-paracetamol-related intoxication caused by other drugs and toxins (e.g. *Amanita phalloides* or herbal products). The "other ALF" subgroup included patients with pregnancy-related ALF, Budd-Chiari syndrome, acute seropositive hepatitis, and hepatic trauma. A detailed analysis of the outcomes in these patients with ALF can be found in our previous study[18].

The 1-year overall survival rate of all ALF patients was 74% (84/113). The 1-year survival of transplanted ALF patients was 91% (30/33). The percentage of transplanted patients was 3% (1/32) of those with paracetamol-related ALF, 23% (7/31) of those with non-paracetamol-related ALF, 56% (23/41) of those with unknown-etiology ALF, and 22% (2/9) of those with other-etiology ALF. One-year survival rates of the transplanted and non-transplanted patients are shown in Figure 2. Six ALF patients died while waiting for a suitable graft. Half of these patients were non-encephalopathic at the initiation of MARS treatment.

Patients with AOCLF : All AOCLF patients were Child-Pugh class C and had a median MELD score of 36 (range 17-52). In 24% (11/45) of alcohol-related AOCLF and 12% (2/17) of other-etiology AOCLF patients, the liver was still enlarged and showed signs of steatosis.

In the alcohol-related AOCLF group, two abstinent patients received transplants. In other-etiology AOCLF, nine patients received transplants. The 1-year survival rates of non-transplanted and transplanted patients were, respectively, 19% (8/34) and 100% (2/2) in alcohol-related AOCLF, and 13% (1/8) and 67% (6/9) in other-etiology AOCLF.

In the alcohol-related AOCLF subgroup, the 1-year survival rate in non-transplanted patients with enlarged livers and signs of steatosis was significantly higher than in the other patients [55% (6/11) *vs* 6% (2/32); $P = 0.002$]. Both of these groups were comparable at baseline. The median MELD scores were 35 (range 24-48) in those with enlarged livers and steatosis and 39 (range 17-52) in the other patients.

Graft failure patients: In GF patients, 1-year survival rate was 73% (8/11). Four patients with early GF and two with late GF underwent retransplantation. The 1-year survival rates of non-retransplanted and retransplanted patients were, respectively, 50% (2/4) and 75% (3/4) in early GF, and 100% (1/1) and 100% (2/2) in late GF.

Miscellaneous etiology patients: All six patients in the subgroup with miscellaneous-etiology AOCLF had a contraindication to LTX. Only one patient with acute pancreatitis and ALF survived 1 year, and all other patients died within 2 mo of ICU admission.

Prognostic factors predicting 6-mo survival

The etiology of liver failure was highly significant in predicting patient outcome ($P < 0.0001$). The alcohol-related AOCLF subgroup with contraindications to LTX had the highest percentage of non-surviving patients.

In survival analysis, groups were divided into two categories: (1) transplant-free survivors, and (2) non-survivors and transplant recipients. At baseline, within the

ALF group, the non-survivors and transplant recipients differed significantly from the transplant-free survivors in several clinical and laboratory parameters, including MELD score and levels of bilirubin, ammonium ion, and coagulation factors (Table 4).

In the AOCLF group, transplant-free survivors compared with non-survivors and transplant recipients had similar baseline values, except coagulation factor V and antithrombin Ⅲ plasma levels differed significantly (Table 4).

Factors predictive of survival were tested separately using stepwise binary logistic regression analyses in each etiological subgroup. The unwanted or negative endpoint was defined as death within 6 mo or LTX. All demographic and clinical parameters and laboratory values before MARS treatment presented in Tables 2 and 3 were included in these analyses. Additionally, in the toxic etiology subgroup, the analysis of the causative drug or poison was taken into account as an independent prognostic factor.

In the paracetamol-related toxic ALF subgroup, the only significant predictor of survival was the grade of hepatic encephalopathy at the beginning of treatment (OR, 0.345; 95% CI, 0.154-0.774; $P = 0.001$). Based on the equation below, hepatic encephalopathy grades from 0 to 4 predicted the probability (p) of survival at 6 mo to be, respectively, 98%, 94%, 85%, 65% and 40%. The positive predictive and negative predictive values, and the overall predictive accuracy based on the equation and the data were 92%, 57% and 84%, respectively. The sensitivity and the specificity were 67% and 89%, respectively.

$p = 100 \times [1/(1 + e^{-(3.831\text{-HE}*1.064)})]$.

In the non-paracetamol-related toxic ALF subgroup, significant predictors of survival were thrombin time, (TT) (OR, 1.103; 95% CI, 1.000-1.217; $P = 0.049$), and hepatic encephalopathy grade at the beginning of treatment (OR 0.562; 95% CI, 0.305-1.035; $P = 0.064$). The predicted probability (p) of survival at 6 mo was approximated by inserting the patient's variables into the equation given below. For example, a TT of 21% and encephalopathy grade of 2 predicted a survival probability of 45%. The positive predictive and negative predictive values and the overall predictive accuracy based on the equation and the data were 76%, 79% and 77%, respectively. The sensitivity and the specificity were 73% and 81%, respectively.

$p = 100 \times [1/(1 + e^{-(1.120 + \text{TT}*0.098\text{-HE}*0.577)})]$.

In the unknown etiology ALF subgroup, significant predictive factors for survival were coagulation factor V levels (OR, 1.052; 95% CI, 1.007-1.099; $P = 0.02$) and alanine aminotransferase ALT plasma levels (OR, 1.001; 95% CI, 1.000-1.001; $P = 0.013$). The predicted probability (p) of survival at 6 mo was approximated by inserting the patient's ALT and factor V levels (FV) into the equation given below. For example, an ALT value of 550 U/L and FV value of 33% gave a 6-mo survival probability of 6.5%. The positive and negative predictive

values and the overall predictive accuracy based on the equation and the data were 60%, 86% and 83%, respectively. Referring to the data, the sensitivity and the specificity of the equation were 94% and 38%, respectively.

$p = 100 \times [1/(1 + e^{-(-4.894 + ALT*0.001 + FV*0.051)})]$.

We were unable to find significant predictive variables in other etiological subgroups.

DISCUSSION

To the best of our knowledge, the present study of 188 patients represents the largest number of MARS-treated patients with liver failure investigated thus far in a single treatment unit. This is also believed to be the first attempt to examine prognostic factors predicting survival in different etiological subgroups of MARS-treated patients with liver failure. Prognostic and treatment efficacy estimations are becoming increasingly more important in today's ICU management, as the number of patients and per-patient costs continue to increase. In 2001, when we began using MARS therapy, it was unclear which patients would benefit from the treatment. The only available data on MARS at the time were from a few small studies conducted on patients with AOCLF[19-24]. Therefore, data with the planned protocol were collected prospectively from every MARS-treated patient in our ICU.

In AOCLF, some randomized studies[5,6,8,22] and small case series of MARS-treated patients[25-27] have reported favorable effects. However, conflicting reports have also emerged[28]. In review articles, MARS has been considered an effective and safe treatment[29,30], although in an early meta-analysis, it did not significantly reduce mortality[31]. In contrast to these studies, ours did not reveal any beneficial effect of MARS treatment on the outcome of AOCLF, except as bridging therapy. One reason that might explain this difference is patient selection. Our criteria for initiation of MARS therapy included at least two of the following: hyperbilirubinemia, hepatorenal syndrome, and encephalopathy. In the aforementioned studies, enrolled patients were in better clinical condition prior to treatment, which makes a direct comparison of results challenging. Also, in most other studies, follow-up time was significantly shorter than 1 year.

In the present study, we found that in the subgroup of non-transplanted patients with alcohol-related AOCLF, Child-Pugh class C, and no signs of hepatic steatosis or enlargement, the mortality was very high (94%). This suggests that MARS treatment in these patients was not beneficial, as it did not seem to improve the final outcome. Recently, a study by Wolff *et al*[32] led to a similar conclusion. Considering the poor survival results in patients with alcohol-related AOCLF, one might argue that MARS treatment should have been commenced earlier in the course of the disease, to benefit the patient. The optimal timing of MARS treatment in AOCLF was, and still is, unknown and requires further investigation. As most of our patients with AOCLF had end-stage cirrhosis, the regenerative capacity of the native liver was probably non-existent and the benefit of MARS treatment was only in bridging the patient to LTX. Furthermore, we were able to find a subgroup of patients with alcohol-related AOCLF with significantly better survival: patients with enlarged livers and signs of steatosis seemed to benefit more from MARS treatment, and had a significantly higher transplantation-free survival rate, even though all other baseline laboratory and clinical values were similar to those in other cirrhotic patients.

The 1-year survival rate of all transplanted patients was high (86%) in our study. Particularly in transplanted patients with ALF, the overall 1-year survival rate of 91% was significantly higher than the 1-year survival rates of 67%-83% that have been reported by western transplantation registers[15,33,34] and studies[35,36] in the past decade. This finding might be attributable to the observed improvement in many clinical and laboratory parameters in patients with AOCLF or ALF during MARS treatment. Additionally, the grade of encephalopathy decreased significantly in most patients. The fact that these patients were, therefore, in better clinical condition prior to LTX might contribute to the high overall survival of transplanted patients. The favorable effect of MARS treatment on laboratory parameters, as we observed, has also been reported in many small, uncontrolled studies[26,27,37-44]. However, the improvement in laboratory values alone might be only temporary and does not necessarily predict a favorable outcome. However, as noted in other studies, MARS treatment also seems to stabilize the patient hemodynamically and prevent the worsening of encephalopathy[18,19,41,45,46], thus helping to bridge the patient successfully to LTX.

The main goal of our study was to identify prognostic factors that could predict survival and help in the selection of patients for MARS treatment. Based on our data, we built mathematical prediction models to estimate the 6-mo survival probability of MARS-treated patients. The most important factor for survival and spontaneous recovery was the etiology of the liver disease. In both toxic ALF subgroups, the grade of encephalopathy prior to MARS treatment was a prognostic factor, and in the subgroup of non-paracetamol-related ALF, coagulation factor levels were prognostic as well. In the subgroup of unknown-etiology ALF, ALT levels and coagulation factor V levels were prognostic, but surprisingly, encephalopathy grade was not. In other liver failure subgroups, we were unable to detect variables that would accurately predict survival. MELD score was not included in this analysis because the target of this study was not to compare outcomes to previously investigated prognostic criteria, such as early lactate[47], the Clichy criteria[48], and the King's College criteria[49] for non-MARS treated patients with ALF, and the Child-Pugh class[50,51] or MELD score[15,52-54] for patients with AOCLF.

Thrombin time and factor V activity level were significant predictive factors in patients with non-paracetamol-related and unknown-etiology ALF, respectively. These factors emerged as predictive despite the fact that, in our ICU, treatment is usually started with intensive replacement of coagulation factors, to enable

the safe placement of a large-bore dialysis catheter. At the measurement of all baseline laboratory variables, the replacement therapy had already been administered to most patients. Additionally, calculation of the MELD score necessitates the use of the international normalized ratio (INR), and therefore, most patients scored much lower than they would have without prior coagulative therapy. Our results concurred with previous studies that factor V level[48,55] and prothrombin time[49] are significant predictors of survival in patients with ALF. Also, in our predictive model for unknown-etiology ALF, high plasma levels of ALT (which is released into the bloodstream from injured hepatocytes) correlated with improved survival. High serum ALT levels might reflect the initial stage of acute liver injury. As the condition progresses, there is less liver tissue to be destroyed, and thus the ALT levels fall, and the liver's capacity for spontaneous recovery and the probability of transplantation-free survival diminish. The simultaneous plunge in factor V levels further reflects the declining synthetic capacity of the remaining liver mass.

In the present study, the grade of hepatic encephalopathy at the beginning of treatment was a predictive factor of survival in the toxic-etiology ALF subgroup. In these patients, treatment was initiated in the absence of encephalopathy if the patient had ingested a lethal amount of toxin, such as *Amanita* mushrooms. This early treatment might improve the prognosis of these patients. Still, despite ICU and MARS treatment, three originally non-encephalopathic patients with ALF died while waiting for a suitable graft. This finding further emphasizes the importance of early referral and prompt commencement of treatment in a specialized unit[56,57]. In previous studies with non-MARS-treated patients with ALF, encephalopathy grade[49] as well as other clinical, serological and physical variables have been reported as predictors of survival[48,49,55,58-62].

Yuan *et al*[63] have reported recently on a study of the prognostic factors for early (30-d) mortality in MARS-treated patients scheduled for LTX. The study included a heterogeneous group of 50 patients with liver failure regarded and analyzed as one group. In Yuan's study, 68% of patients were transplanted compared to 25% of our patients. The 30-d postoperative survival was 82% in transplanted and 50% in non-transplanted patients. These 30-d survival figures correspond remarkably well with our respective 1-year outcome results (86% survival for transplanted and 47% survival for non-transplanted patients). The prognostic factors that correlated with early postoperative mortality in Yuan's study were sequential organ failure (SOFA) score, creatinine, INR, tumor necrosis factor-α, and interleukin-10. Encephalopathy grade was not considered significant in this analysis[63].

One of the limitations of our study is that it represents a very specific population and distribution of patients with liver failure in Finland. As the etiological factors and causative agents behind ALF and AOCLF vary between countries, the applicability of our results to other scenarios is probably reduced. In addition, there is also a likely selection bias associated with the acceptance of patients with AOCLF for MARS treatment. In Finland, alcohol-related AOCLF is a fairly common condition; these patients are usually treated in basic medical wards and not referred to our unit because chronic alcohol abuse with diagnosed cirrhosis is usually considered a contraindication to ICU treatment. Furthermore, the specificity and especially sensitivity of our predictive models were far from optimal. Ideally, a good prognostic tool would accurately, easily and cheaply predict the patient's survival probability and the need for LTX in the very early stages of the disease. In the real world, however, prognostic calculations can never predict the fate of an individual patient with 100% accuracy, as there are always exceptions to the rule, special circumstances, and multiple factors that were not considered in the prognostic model. At best, such calculations can be used as aids and facilitators, but not as substitutes, for the physician's clinical assessment.

In conclusion, the present study showed that, despite ICU and MARS treatment, patients with AOCLF and end-stage cirrhosis do not seem to benefit from MARS treatment without the possibility of LTX. In patients with alcohol-related AOCLF, we now use MARS treatment only with those whose liver is still enlarged and steatotic, with recovery capacity. The grade of encephalopathy and levels of coagulation factors were not consistently significant prognostic factors in all liver failure groups treated with MARS.

COMMENTS

Background

Rapidly failing liver function is a medical emergency that carries a high risk of mortality. Molecular adsorbent recirculating system (MARS) treatment is an extracorporeal albumin dialysis apparatus that has been used in the treatment of liver failure to enable native liver regeneration or as a bridge to liver transplantation (LTX).

Research frontiers

The impact of MARS treatment on outcome as well as clinical and laboratory variables has been investigated widely in small non-randomized studies. However, prognostic factors predicting survival in MARS-treated patients have only been explored in one study so far. The current hotspot of the research is to determine which patient groups actually benefit from MARS treatment. Another interesting question is whether there are patient groups that do not gain from MARS and should not be treated.

Innovations and breakthroughs

The prognostic factors predicting survival in MARS-treated patients have only been explored in one previous study by Yuan *et al*. That study comprised 50 patients with a heterogeneous etiological background and a follow-up of 30 d. The present study contained 188 patients with a heterogeneous etiological distribution. However, prognostic factors were searched for with logistic regression analysis in each etiological subgroup independently. In addition the follow-up time was 1 year. In the present study, the etiology of liver failure was the most important predictor of survival. In acute liver failure (ALF) with toxic etiology (e.g. paracetamol), the grade of encephalopathy before MARS treatment was a significant prognostic factor. In ALF of unknown etiology, coagulation factor V and liver enzyme alanine aminotransferase levels were prognostic. According to the authors results, the MARS treatment of a cirrhotic patient with an acute-on-chronic liver failure (AOCLF) is not meaningful in terms of prognosis if the patient is not eligible for transplantation.

Applications

MARS treatment appears to be a safe and effective treatment in ALF patients and those chronic liver disease patients who are eligible for LTX.

Terminology

MARS is an extracorporeal albumin dialysis machine that removes water-

soluble and albumin-bound toxins from the patient's blood. ALF is defined as rapid deterioration of liver synthetic and metabolic function in a person with no previous liver disease. AOCLF is a condition in which a previously stable patient with chronic liver disease experiences a rapid deterioration of liver function caused by some triggering event (e.g. gastrointestinal bleeding, infection or ingestion of alcohol). Cirrhosis is a consequence and the histological hallmark of chronic liver disease. It is characterized by the replacement of normal liver cells by scar tissue and eventually it leads to liver failure. Hepatic encephalopathy is a potentially reversible neuropsychiatric disorder presenting as a decreased level of consciousness associated with liver failure

Peer review

This is a well-written paper which has high clinical relevance. This was a unique single-center study of a large population of patients with ALF or AOCLF.

Abstract

AIM: To determine whether new cut-off values for alanine aminotransferase (ALT) and baseline hepatitis B virus (HBV) DNA levels better differentiate HBeAg(-) chronic hepatitis B (CHB) patients from inactive chronic carriers.

METHODS: Ninety-one patients [32 HBeAg(+) CHB, 19 inactive carriers and 40 HBeAg(-) CHB] were followed up for 2 years and were tested for HBV DNA levels by a PCR-based assay. ALT was tested twice during the last 6 mo using new cut-off values: ULN (upper limit of normal) 30 IU/L for males, 19 IU/L for females. Diagnostic accuracy, sensitivity, specificity, positive and negative predictive values were calculated by discriminant analysis.

RESULTS: When using the revised ALT cut-off values, the lowest optimal HBV DNA level that differentiated HBeAg(-) CHB patients from inactive carriers was 50 000 copies/mL. The diagnostic accuracy of HBV DNA to determine inactive carriers with a cut-off of 50 000 copies/mL was similar to the previously recommended cut-off of 100 000 copies/mL (91%). HBV DNA levels were lower than the cut-off value in 95% of inactive carriers and in 28% of HBeAg(-) CHB patients. With ALT < 30 IU/L in men and < 19 IU/L in women and HBV DNA levels < 100 000 copies/mL, the risk of CHB is 5%. On the other hand, if ALT values were > 30 IU in men and > 19 IU in women and baseline HBV DNA levels were > 100 000 copies/mL, the risk is 86%.

CONCLUSION: New cut-off values for ALT together with HBV DNA levels proposed by AASLD (American Association for the Study of Liver Diseases) and NIH (National Institute of Health) consensus seem appropriate to characterize inactive carriers.

Key words: Alanine aminotransferase; Chronic hepatitis B; Hepatitis B antigens; Viral DNA

INTRODUCTION

In the natural history of chronic hepatitis B virus (HBV) infection, sero-conversion from HBeAg(+) to HBeAg(-) and anti-HBe antibody (+) leads to low HBV replication and to normalization of aminotransferases[1]. Such changes have long been considered a reliable clinical indicator of passage to an inactive and innocent state of chronic hepatitis B[1]. However, 2 clinical forms of HBeAg(-) chronic hepatitis B exist after sero-conversion. The first form is the "inactive carrier state" which comprises an absence of HBeAg, a lack of symptoms, persistently normal alanine aminotransferase (ALT) and low or undetectable HBV DNA (< 100 000 copies/mL) levels. The second form is described as "HBeAg(-) chronic hepatitis B", and comprises an absence of HBeAg, presence of symptoms, elevated ALT and a high HBV DNA

level (> 100 000 copies/mL). Differentiation between these 2 forms of chronic hepatitis B is difficult when HBV DNA levels are between 10 000 and 100 000 copies/mL and the distinction depends on the sequential determination of ALT activity[2]. Indeed, patients with HBeAg(-) chronic hepatitis B demonstrate wild fluctuations in serum ALT and 20%-30% of these patients with histologically documented chronic hepatitis have normal ALT at the time of presentation[3]. Consequently, patients with HBeAg(-) chronic hepatitis B with normal liver enzymes may be misdiagnosed as being in an inactive chronic carrier state and thus be denied treatment by mistake.

ALT is the most commonly used enzyme in the evaluation of liver disease. Recently, it has been suggested that the upper normal limit (ULN) for ALT should be decreased to 30 IU/L for men and 19 IU/L for women[4]. Minimal increases in serum ALT levels, although within the classic normal range, have also been reported to be significantly associated with increased risk of liver-related mortality in the general population[5]. Moreover, a recent study showed that chronic hepatitis B patients with normal serum ALT levels were also at risk of development of cirrhosis and hepatocellular carcinoma[4,6]. Therefore, chronic hepatitis B patients with normal ALT levels may be at risk of progressive liver disease. The determination of a more reliable cut-off value for ALT activity is very important.

PCR assays allow the detection of very low serum HBV DNA levels (100 copies/mL)[6], and are more powerful tests than hybridization techniques[7]. An arbitrary serum HBV DNA level of 100 000 copies/mL has been proposed by the United States National Institute of Health (NIH) workshop[8] to differentiate HBeAg(-) chronic hepatitis B from the inactive carrier state. However, a study from France found that 98% of inactive carriers had HBV DNA levels < 100 000 copies/mL at presentation and 97% of patients had HBV DNA levels persistently below 100 000 copies/mL during a 1-6 year follow-up. A study from Greece reported that a cut-off value of 100 000 copies/mL would lead to misclassification of 13% of their patients with HBeAg(-) chronic hepatitis B and possible denial of treatment. The researchers suggested a HBV DNA cut-off level of 30 000 copies/mL to be more appropriate for differentiating the inactive carrier state from HBeAg(-) chronic hepatitis B[9,10]. A study from the United States found that no HBV DNA cut-off value existed for differentiating inactive carriers from patients with HBeAg(-) chronic hepatitis B[11]. Thus, the appropriate HBV DNA value for differentiating inactive chronic carriers from patients with HBeAg(-) chronic hepatitis B remains to be determined.

HBV DNA levels at baseline have been associated with an increased risk of cirrhosis and hepatocellular carcinoma[12-14]. Moreover, Yuen *et al*[13] reported an increased risk of complications as well as increased mortality from liver disease in patients with a prolonged low level of viremia (10 000-100 000 copies/mL). An important question is whether the use of new cut-off values for ALT (30 U/L in men and 19 U/L in women) and baseline HBV DNA levels better differentiates HBeAg(-) chronic hepatitis B patients from inactive chronic carriers. In the current study, we evaluated whether the combination of the revised cut-off values for ALT and the baseline HBV DNA levels correctly predicted the classification of patients with HBeAg(-) chronic hepatitis B.

MATERIALS AND METHODS

One hundred and ninety patients with HBeAg(-) chronic hepatitis B infection were recruited and studied retrospectively. Inclusion criteria were: HBsAg(+), HBeAg(-) for at least 6 mo. Patients with fatty liver, alcohol use > 30 g/d, obesity (BMI > 28), hepatocellular carcinoma, hepatitis C, hepatitis D and HIV viral co-infection were excluded. Patients with decompensated liver disease including bilirubin level > 1.5 mg/dL (25.6 μmol/L), prothrombin time > 15 s or INR > 1.7, albumin level < 3.4 g/dL, ascites, bleeding esophageal varices or hepatic encephalopathy were also excluded. 59 patients were enrolled. Thirty two patients with HBeAg(+) chronic hepatitis B were added to the study population for comparison. All patients with HBeAg(-) chronic HBV infection had baseline ALT determined at the first visit. During follow-up (12-24 mo), all patients had serum ALT determined at 3 and 6 mo intervals and underwent liver biopsy in cases of increased ALT activity at least twice (ULN for ALT values 40/30 were used). Patients were classified into HBeAg(-) chronic hepatitis B if they had increased ALT activity, HBV DNA > 100 000 copies/mL and histological findings compatible with chronic hepatitis. On the other hand, patients with HBeAg(-) chronic hepatitis B infections were classified into the inactive chronic carriers if they had persistently normal ALT values at the first visit and through follow-up, and HBV DNA < 100 000 copies/mL. Patients with normal ALT values were followed up with ALT measured every 3-6 mo for the first 2 years and every 12 mo thereafter. No patient received antiviral or immunosuppressive therapy during the study period. Standard biochemistry was performed by Olympics analyzer (Hamburg, Germany). ULN for ALT were: 40 U/L in men and 30 U/L in women for the old normal range and 30 U/L in men and 19 U/L in women for the new normal range[7]. Patients with increased ALT and HBV DNA < 100 000 copies/mL (n = 7) and histological findings compatible with chronic hepatitis were incorporated into the HBeAg(-) chronic hepatitis B group. The rare cases with persistently normal ALT, and HBV DNA > 100 000 copies/mL (n = 4) were not classified because of the very small number of patients. All serum samples were processed in the same laboratory using the same methods and the same reference values. Virology tests, including HBsAg, HBeAg, anti-HBe antibody, anti-HBS antibody, and anti-HB core antibody, anti-HDV antibody, anti-HCV antibody, and anti-HIV antibody, were evaluated by commercially available enzyme immunoassays. Serum HBV DNA was measured by a sensitive quantitative PCR assay (Amplicor HBV monitor test, Roche Diagnostic Systems, Branchburg, NJ)

Table 1 Baseline characteristics of 91 patients with chronic hepatitis B virus infection

Patient characteristics	HBeAg (+) Chronic hepatitis B *n* = 32	HBeAg(-) hepatitis B		[1]*P*
		Inactive carriers *n* = 19	HBeAg(-) chronic hepatitis *n* = 40	
Gender (M/F)	23/9	17/2	30/10	0.001
Age	32 ± 11	39 ± 10	39 ± 10	0.010
BMI	24.9 ± 2.5	25.1 ± 2.6	25.9 ± 2.0	0.300
Histological grade	4.6 ± 1.9 (4-12)	ND	4.4 ± 1.2 (4-18)	0.500
Histological stage	1.3 ± 1.4 (0-6)	ND	1.1 ± 1.3 (0-6)	0.500
ALT (IU/L)	118 (16-190)	24 (16-30)	52 (20-116)	0.001
AST (IU/L)	71 (11-142)	26 (16-34)	38 (17-143)	0.001
HBV DNA (median, copies/mL)	1.9×10^{11}	4150	2×10^{5}	0.001

Values are median, or mean ± SD. [1]Comparison between 3 groups. ND: Not done. Every 19 IU/mL of HBV DNA equals 100 copies/mL. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; HBV: Hepatitis B virus.

with sensitivity levels of 200 copies/mL[15]. An arbitrary value of 100 copies/mL was assigned to samples with undetectable HBV DNA for statistical comparison. Liver histology for inflammation and fibrosis stage was performed according the classification of Ishak[16].

Statistical analysis

Statistical analysis was performed using the Winstat program. Results are presented as median (range) or mean ± SD. The Mann-Whitney test and Kruskal-Wallis test for non-parametric data were used for comparison between 2 and among 3 groups, respectively. The Spearman test was used for the correlation between 2 quantitative variables. The diagnostic validity of a single baseline measurement of serum ALT, aspartate aminotransferase (AST), and HBV DNA levels, and the validity of the combined new normal range for ALT and HBV DNA levels were tested regarding correct classification of HBeAg(-) into those with HBeAg(-) chronic hepatitis B or those who were inactive carriers. Cut-off levels for ALT were ULN values. Cut-off levels for HBV DNA, were 5000, 50 000 and 100 000 copies/mL respectively[15,16]. The percentage of cases correctly classified by each diagnostic test as well as sensitivity, specificity, and positive and negative predictive values were calculated by discriminant analysis. The likelihood ratio was calculated according to the formula (LR+ = sensitivity/1-specificity), LR- = (1-sensitivity/specificity). In all cases, tests of significance were two-tailed, with a significance level less than 0.05. The study was approved by an institutional ethics committee and each patient signed an informed consent form.

RESULTS

Patients with HBeAg(-) chronic hepatitis B were older than the HBeAg(+) patients (39 ± 10 *vs* 32 ± 11, $P < 0.001$). Men were predominant in all groups. The 91 patients with chronic HBV infection were classified as: 32 HBeAg(+) patients, 19 who were inactive chronic carriers and 40 patients determined to have HBeAg(-) chronic hepatitis B. Baseline ALT values were within the normal range according to the new cut-off values (30 U/L in men and 19 U/L in women) in 24 patients (40%) and were increased in 60% of the 59 patients with HBeAg(-) chronic hepatitis B infection. Demographic, histological and laboratory characteristics are presented in Table 1. Baseline ALT levels were lower in patients with HBeAg(-) than HBeAg(+) chronic hepatitis B (median 32 U/L, mean 52 ± 29.8 U/L *vs* median 52 U/L, mean 118 ± 44.9 U/L, $P < 0.01$). There was no difference in inflammatory grade (4.4 ± 1.2 *vs* 4.6 ± 1.9, $P < 0.5$) or fibrosis stage (1.1 ± 1.3 *vs* 1.3 ± 1.4, $P < 0.5$) between HBeAg(-) and HBeAg(+) chronic hepatitis B patients. No cases of bridging fibrosis or early cirrhosis were documented.

Median HBV DNA levels were lowest in the inactive chronic carriers, intermediate in the HBeAg(-) chronic hepatitis B patients, and highest in HBeAg(+) chronic hepatitis B patients ($P < 0.001$, Table 1). Serum HBV DNA was less than 50 000 copies/mL in 95% of inactive chronic carriers and undetectable (< 200 copies/mL) in 20% of them.

A baseline serum HBV DNA cut-off level of 50 000 copies/mL could correctly classify 91% of HBeAg(-) patients, achieving better classification than baseline traditional ALT (40 U/L in men and 30 U/L in women) and AST enzyme cut-off levels. The diagnostic accuracy of the HBV DNA cut-off of 50 000 was similar to the commonly proposed serum HBV DNA cut-off of 100 000 copies/mL, but much better than the latest recent proposition of 5000 copies/mL or 1000 copies/mL (Table 2). The cut-off value of 50 000 copies/mL also performed better than 5000 copies/mL in the subgroup of patients with the new ALT cut-off values (30 U/L in men and 19 U/L in women), achieving correct classification in 91% of cases. When using ALT × 1.3 combined with HBV DNA cut-off of 50 000 copies/mL, we increased the diagnostic accuracy from 80% to 85% (Table 3).

A serum HBV DNA cut-off level at 50 000 copies/mL alone had better sensitivity, specificity, and positive or negative predictive values for discrimination between patients with HBeAg(-) chronic hepatitis B and inactive chronic carriers as compared with any other single variable [HBV DNA with a cut-off at 5000 copies/mL, ALT and AST level (Table 2)]. Multivariate discriminant analysis showed that all single variables could classify our patients into HBeAg(-) chronic hepatitis B and inactive carrier state, but the standardized canonical discriminant function co-efficiency was higher for serum HBV DNA with a cut-

off at 50000 copies/mL ($f = 0.76$) than for serum with a cut-off 5000 ($f = 0.69$) or ALT level ($f = 0.44$). Using cross validation in univariate discriminant analysis, if the cut-off was set at 50000 copies/mL, serum HBV DNA could correctly classify 80% of the patients with HBeAg(-) chronic hepatitis B infection, and could correctly classify 85% if the cut-off was set at 50000 copies/mL combined with ALT × 1.3 above the new ULN (30 U/L in men and 19 U/L in women). ALT and AST could correctly classify only 78% and 58% of cases, respectively (Table 2). Of the 5 patients with HBeAg(-) chronic hepatitis B and HBV DNA cut-off levels < 50000 copies/mL, 4 patients (95%) were inactive chronic carriers. All inactive carrier patients had normal baseline AST as well as normal new ALT values. Similarly, all patients with chronic hepatitis B with normal ALT levels initially, also had normal AST values initially. A serum HBV DNA level at 50000 copies/mL could correctly classify 91% of these cases similar to the correct classification of 91% achieved by HBV DNA of 100000 copies/mL, and more than the 75% achieved by HBV DNA < 20000 copies/mL and the 70% by HBV DNA < 5000 copies/mL (Table 2). If ALT values were > 30 U/L in men and > 19 U/L in women and baseline HBV DNA levels were > 100000 copies/mL, the likelihood (odds) of having HBeAg(-) chronic hepatitis B is raised by 16 relative to the previous probability of disease, with a diagnostic accuracy of 95%, a negative predictive value of 86%, a positive predictive value of 100%, a sensitivity of 92%, and a specificity of 100% (Table 4).

Within the HBeAg(-) chronic hepatitis B group, patients with elevated baseline ALT (> 30 U/L in men and 19 U/L in women) had a significantly higher median serum HBV DNA level compared with those patients with normal baseline ALT values (median 96053 copies/mL, mean 870000 copies/mL *vs* median 16202 copies/mL, mean 370000 copies/mL, $P < 0.01$). There was less overlap in HBV DNA levels between HBeAg(-) chronic hepatitis B patients and inactive carriers when the new normal range for ALT was used. Serum HBV DNA levels did not correlate with age, gender or histology but correlated well with the new ALT levels in all patient populations ($r = 0.42$, $P < 0.001$) and to a lesser extent ($r = 0.3$, $P < 0.01$) in patients with HBeAg(-) chronic hepatitis B (Figure 1).

DISCUSSION

New medical treatment has proven effective for patients with chronic hepatitis B; therefore early and definitive

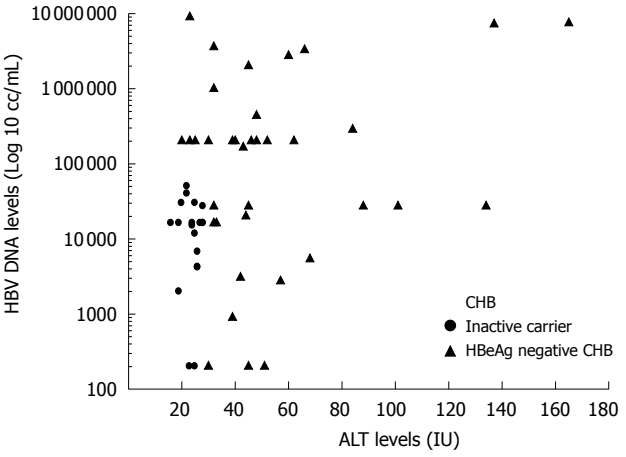

Figure 1 Correlation between ALT values and HBV DNA serum levels in inactive carriers and in HBeAg(-) chronic hepatitis B (r = 0.3, P < 0.01). CHB: Chronic hepatitis B. Every 19 IU/mL of HBV DNA equals 100 copies/mL.

detection is crucial[3]. Decreasing the ULN values for ALT levels significantly increases the ability to detect HBeAg(-) chronic hepatitis B. The results of the present study indicate that if ALT values are < 30 U/L in men and < 19 U/L in women with baseline HBV DNA levels < 100 000 copies/mL, the likelihood of being diagnosed with HBeAg(-) chronic hepatitis B is 5%. On the other hand, if ALT values are > 30 U/L in men and > 19 U/L in women with HBV DNA levels > 100 000 copies/mL, the likelihood of HBeAg(-) chronic hepatitis B diagnosis is 86%. The results indicate also that HBV DNA cut-off levels of 100 000 copies/mL as proposed by the NIH workshop[8] to characterize inactive carriers seems appropriate, and that HBV DNA cut-off levels lower than 50 000 copies/mL do not add to the diagnostic accuracy of HBeAg(-) chronic hepatitis B.

In HBeAg(-) chronic hepatitis B, ALT levels can flare with an intervening period of normal values, can continue to increase without flare, or demonstrate intermittent flares superimposed on a continuous elevation[17,18]. The majority of our patients belonged to the first profile. The current study is in keeping with the work of Martinot-Peignoux *et al*[9] who showed that HBV DNA levels remained stable with a median of 1000-10 000 copies/mL in 85 inactive carriers followed for 1-6 years, and only 2% had HBV DNA levels > 100 000 copies/mL, supporting the NIH recommendation. However, the Martinot-Peignoux study did not include patients with HBeAg(-) chronic hepatitis B and the proportion of patients with HBV DNA < 50 000 copies/mL was not reported, thus a direct comparison with our findings cannot be made. Moreover, compared with the Martinot-Peignoux study, a stricter definition of inactive chronic carrier was used in the current study, using the new normal range for ALT (30 U/L in men and 19 U/L in women) and lower HBV DNA levels. Reports from Greece found that 13% of 134 patients with HBeAg(-) chronic hepatitis B had serum HBV DNA levels < 100 000 copies/mL, indicating that a cut-off of 100 000 copies/mL could lead to misclassification of these patients and possible denial of treatment[19]. The authors suggested that a cut-off HBV DNA levels of 30 000 copies/mL might be more appropriate for differentiating inactive HBsAg carriers from patients with HBeAg(-) chronic hepatitis B. The Greek study used old values for normal ALT levels (40 U/L in men and 30 U/L in women) and was based on serum HBV DNA levels taken at admission. In the present study, levels < 50 000 copies/mL did not add to the diagnostic accuracy of the classification of HBeAg(-) chronic hepatitis B. The current work is also in agreement with the finding of Chu *et al*[11] that HBV DNA values above 100 000 copies/mL would exclude 95% of inactive carriers but also 22% of HBeAg(-) chronic hepatitis patients if testing of ALT was performed at admission and again after 6 mo. More recently, Degertekin & Lok[20] concluded that a cut-off 5000 copies/mL is more appropriate for differentiating inactive carriers from HBeAg(-) chronic hepatitis B patients. Our study contrasts with the Degertekin & Lok study in that HBV DNA cut-off levels of 5000 copies/mL did not improve diagnostic accuracy for differentiating HBeAg(-) chronic hepatitis patients from inactive carriers. Given the variable natural history of chronic hepatitis B viral infection and variable genotype and mutations, it is possible that this threshold level might differ from one population to another and may vary with time depending on the host immune status and other exogenous factors[21].

HBV viremia was detected in the vast majority of patients with HBeAg(-) chronic hepatitis B, and the 50 000 copies/mL cut-off also performed better than 5000 copies/mL in the subgroup of patients with new normal ALT levels, achieving correct classification in 91% of cases[22]. Using ALT × 1.3 above the new cut-off limit combined with a HBV DNA cut-off of 50 000 copies/mL increased the diagnostic accuracy from 80% to 85%. With this threshold level, it is possible to identify individuals with very low risk of progressive liver disease, in whom current treatment offers no benefit and who may require less frequent monitoring. This depends on host factors such as CD4 immune response, viral factors such as HBV genotypes and mutation in the core promoter and precore regions and environmental factors such as alcohol consumption[21].

More than 90% of our subjects belonged to the ethnic Druze religious group and were infected > 40 years ago. Thus our data may not be applicable to individuals with adult-acquired HBV infection or with perinatal acquired HBV infection but who are younger than 40 years old[23]. Long term longitudinal studies of inactive carriers have reported that 15%-24% developed HBeAg(-) chronic hepatitis and 20%-30% had moderate to severe inflammation while up to 20% had advanced fibrosis or cirrhosis[24-26]. Moreover, *post hoc* analysis of phase Ⅲ clinical trials of entecavir have confirmed that patients with < 2 ULN of the old ALT values (40 U/L in men and 30 U/L in women) at pretreatment were less likely to undergo HBeAg seroconversion or to have detectable serum HBV DNA[22].

Our results do not confirm previously reported data that single AST measurement is better than serum HBV DNA or ALT levels for the differentiation between HBeAg(-) patients with active and inactive liver dis-

ease[26]. In contrast, we found that that the new baseline cut-off for ALT levels (30 U/L in men and 19 U/L in women) clearly performs better than AST in achieving correct classification of HBeAg(-) chronic hepatitis B, 78% and 58%, respectively (Table 2). ALT, a biochemical marker of inflammation, showed a greater increase in HBeAg(+) patients when compared with HBeAg(-) chronic hepatitis B patients, suggesting that HBeAg has immunomodulatory action[27]. There was no correlation between serum HBV DNA and histological grade in either HBeAg(-) or HBeAg(+) chronic hepatitis B patients, in agreement with previous reports of HBV DNA levels and histological severity in HBeAg(-) chronic hepatitis B patients[28]. In addition, we found no correlation between HBV DNA levels and the pattern of histological inflammation (portal, periportal necrosis, and interlobular or confluent necrosis).

Limitations of our study are: (1) lack of genotype sequencing in order to identify HBV mutants; however reports on the relationship between precore and core promoter variants, serum HBV DNA levels and liver diseases are inconclusive[29-31]; (2) HBV DNA levels may vary widely with time and any classification of HBeAg(-) chronic hepatitis B may subsequently change. Therefore, longitudinal evaluation of HBV DNA levels was not performed in the current study[31]; (3) the small number of patients; (4) a short period of follow up; (5) the absence of histology in the healthy carrier group.

In conclusion, with new cut-off values for ALT (30 U/L in men and 19 U/L in women), there may be less overlap in HBV DNA levels between inactive carriers and HBeAg(-) chronic hepatitis B patients. The HBV DNA cut-off levels of 100 000 copies/mL proposed by the NIH workshop to characterize inactive carriers, is accurate[8]. HBV DNA cut-off levels < 50 000 copies/mL do not improve diagnostic accuracy for differentiating between HBeAg(-) chronic hepatitis B patients from inactive carriers. Longer follow-up and repeated determination of HBV DNA and ALT serum levels are required to definitively exclude HBeAg(-) chronic hepatitis B and to classify a patient into the inactive carrier state.

COMMENTS

Background

Two clinical forms of HBeAg(-) chronic hepatitis B exist after hepatitis Be antigen seroconversion. The first form is the "inactive carrier state" which comprises absence of HBeAg, a lack of symptoms, persistently normal alanine aminotransferase (ALT), and low or undetectable hepatitis B virus (HBV) DNA (< 100 000 copies/mL) levels. The second form is described as "HBeAg(-) chronic hepatitis B", and includes the absence of HBeAg, the presence of symptoms, elevated ALT and high HBV DNA levels (> 100 000 copies/mL). Differentiation between these 2 forms of chronic hepatitis B is difficult when HBV DNA levels are between 10 000 and 100 000 copies/mL and the distinction depends on the sequential determination of ALT activity. Consequently, patients with HBeAg(-) chronic hepatitis B with normal liver enzymes according to the old ALT values (ALT 40 IU/L for men and 30 IU/L for women) may be misdiagnosed as inactive chronic carriers.

Innovations and breakthroughs

The study indicates that lower baseline ALT cut-off values (ALT 30 U/L in men, 19 U/L in women) in combination with a baseline HBV DNA level (> 100 000 copies/mL) better differentiate HBeAg(-) chronic hepatitis B patients from inactive chronic carriers.

Applications

The clinical application is that many patients misdiagnosed as inactive carriers may now benefit from antiviral treatment.

Peer review

The study is interesting from a clinical point of view and that the authors studied different cut-off values for baseline HBV DNA and ALT levels to better classify HBeAg(-) subjects into chronic hepatitis patients and inactive chronic carriers.

Abstract

AIM: To evaluate the effectiveness of simethicone in enhancing visibility and efficacy during colonoscopy.

METHODS: A prospective, double-blind, randomized, placebo-controlled study was conducted. One hundred and twenty-four patients were allocated to receive 2 doses of sodium phosphate plus 240 mg of tablet simethicone or placebo as bowel preparation. Visibility was blindly assessed for the amount of air bubbles and adequacy of colon preparation. Total colonoscopic time, side effects of the medication, endoscopist and patient satisfaction were also compared.

RESULTS: Sodium phosphate plus simethicone, compared to sodium phosphate plus placebo, improved visibility by diminishing air bubbles (100.00% *vs* 42.37%, $P < 0.0001$) but simethicone failed to demonstrate improvement in adequacy of colon preparation (90.16% *vs* 81.36%, $P = 0.17$). Endoscopist and patient satisfaction were increased significantly in the simethicone group. However, there was no difference in the total duration of colonoscopy and side effects of the medication.

CONCLUSION: The addition of simethicone is of benefit for colonoscopic bowel preparation by diminishing air bubbles, which results in enhanced visibility. Endoscopist and patient satisfaction is also increased.

Key words: Simethicone; Colonoscopy; Bowel preparation

INTRODUCTION

Colonoscopy is considered to be the gold standard investigation for assessing colonic lesions; but many factors, such as the quality of bowel preparation, endoscopist, and patient factors, may affect the diagnostic accuracy and therapeutic safety[1-5]. Inadequate bowel preparation has been reported in 10%-75% of colonoscopic examinations[1,3]. The ideal preparation for colonoscopy should be safe, acceptable to patients with negligible discomfort, and it should take effect on rapid cleansing[2-4]. Unfortunately, none of the preparations meets all of the requirements[2-4]. Several studies have evaluated the efficacy and side effects of regimens for bowel preparation[3-14]. In 2006, three medical organizations (the American Society for Gastrointestinal Endoscopy, the American Society of Colon and Rectal Surgeons, and the Society of American Gastrointestinal and Endoscopic Surgeons) suggested that polyethyleneglycol (PEG) should be a gold standard for colonoscopic bowel preparation (Grade IA), and aqueous sodium phosphate (NaP) was an alternative regimen to PEG solution (Grade IA)[2]. This consensus also stated that adjunctive therapy, such as bisacodyl, metoclopramide, and simethicone, was shown to improve the quality of bowel preparation[2].

Simethicone is an oral antifoaming agent that reduces bloating, abdominal discomfort, and abdominal pain by promoting the clearance of excessive gas along the gastrointestinal tract[15]. Chemically, simethicone is a mixture of polydimethylsiloxanes that works by reducing the surface tension of air bubbles and causing the coalescence of small bubbles into larger ones that pass more easily with belching or flatulence[15]. Simethicone is not absorbed into the bloodstream and is, therefore, considered relatively safe[15]. Its use prior to diagnostic procedures such as gastroscopy[16], transabdominal ultrasound[17,18], anorectal ultrasound[19], computed tomography scan[20] and capsule endoscopy has been increasingly reported[21,22].

The presence of air bubbles along the colonic surface can prevent the clear visualization of the whole colon. Simethicone works as an adjunct to bowel preparation with the purpose of diminishing foam formation and improving visualization during colonoscopy[23-28]. However, most of the previous studies that demonstrated enhanced quality of bowel preparation used PEG for the bowel preparation regimen[23-28]. Furthermore, only liquid simethicone was used as an adjunct therapy in these studies[23-28]. The benefit of simethicone in improving colonic bowel preparation, however, was not explored in previous studies[23-28]. Moreover, other factors such as time of colonoscopy, endoscopist, and patient satisfaction have never been mentioned[23-28]. Although some endoscopists already use simethicone prior to performing colonoscopic examination in daily practice, the adjunctive use of simethicone in the standard bowel preparation regimen has not been uniformly accepted so far. We aimed to evaluate the beneficial effect of oral simethicone on bowel preparation, as compared to NaP alone, with regard to the degree of visibility and the quality of bowel preparation. We selected NaP solution as a bowel preparation regimen because of its tolerability. Based upon three medical consensuses, NaP solution is suggested to be an alternative bowel preparation with equal potency to PEG solution[2]. The addition of oral simethicone to the bowel preparation regimen before colonoscopy is more practical and more convenient than on-demand simethicone spraying due to time savings and prompt, clear visualization. Furthermore, the addition of simethicone may reduce the total colonoscopic time. The primary endpoint of this study was to compare the efficacy of simethicone to placebo in terms of the amount of air bubbles remaining and bowel preparation quality. The success rate and duration of colonoscopy, endoscopist satisfaction, and patient acceptability were the secondary endpoints.

MATERIALS AND METHODS

Protocol

A double-blind, randomized, placebo-controlled study was conducted between January 1, 2007 and December 31, 2007. The inclusion and exclusion criteria were shown in Table 1. All patients were instructed to consume a low-residual liquid diet one day prior to the date of the procedure. At the beginning of the study, they were allocated to receive 2 doses of either 45 mL of NaP plus 240 mg of tablet simethicone or 45 mL of NaP plus identically appearing placebo the evening before and the morning of the day of the procedure. During colonoscopy, we used meperidine and midazolam as the sedation regimen. Colonoscopic examinations were performed by 8 investigators (5 staff and 3 fellows). The details of the colonoscopic findings were recorded on DVDs. Endoscopic visibility was assessed for the amount of air bubbles and the adequacy of colon preparation by a single investigator who was blind as to the types and details of bowel preparation. Five areas of the colon (rectosigmoid, descending, transverse, ascending, and cecum) were graded for the amount of air bubbles. The amount of intraluminal air bubbles was classified into four grades as shown below[24]: Grade 0 = No or minimal scattered bubbles; Grade 1 = Bubbles covering at least half the luminal diameter; Grade 2 = Bubbles covering the circumference of the lumen; Grade 3 = Bubbles filling the entire lumen.

Table 1 Inclusion and exclusion criteria

Inclusion criteria
Adults aged 18-70 years of age scheduled for colonoscopy at the gastroenterological unit
Exclusion criteria
Renal insufficiency (Cr ⩾ 2 mg/dL)
Uncontrolled congestive heart failure (NYHC Ⅲ-Ⅳ)
Massive ascites
Myocardial infarction within 6 mo
Pregnancy
Coagulopathy
History of colonic surgery
Colonic obstruction
History of anti-flatulence and/or other laxative agent use within 1 wk
Refusal to participate in the study

The re-defined grading was classified by following the more practical report by Sudduth *et al*[24]. The most frequent grading was selected to represent the overall grading; for example, if the grade was 0, 0, 0, 1, 1 the patient was assigned an overall grade of 0. If there were several equal grades, the grading that was closest to the final grading would be selected. For example, when the grading was 0, 0, 1, 1, and 2, grade 1 was selected. Grades 0 and 1 were re-defined as the diminishing of air bubbles; grade 2 and 3 were re-defined as the failure to diminish air bubbles[24]. The adequacy of colon preparation was graded as follows[28]: Excellent = Small amounts of clear liquid; Good = Residual liquid stool, all mucosa seen; Adequate = Some particulate matter, > 90% of mucosa seen; Poor = Substantial particulate matter or solid stool, < 90% of mucosa seen; Unacceptable = Solid stool throughout the colon.

Excellent, good, and adequate were grouped and re-defined as acceptable for adequacy of colon preparation; poor and unacceptable were grouped and re-defined as unacceptable for adequacy of colon preparation. The

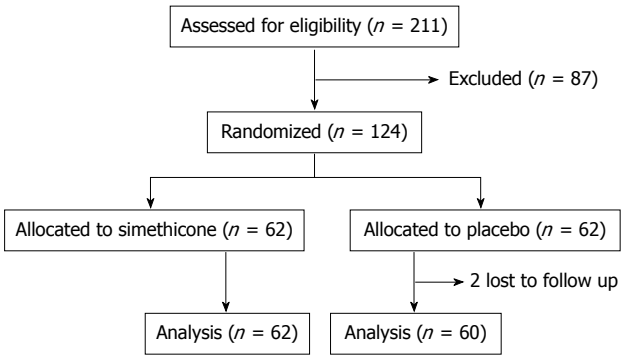

Figure 1 Patient disposition.

success rate, total duration of colonoscopy, side effects of medication, endoscopist satisfaction, and patient satisfaction were compared between the two groups. Endoscopist satisfaction was evaluated for air bubbles and adequacy of colon preparation by a self-rated questionnaire with a 4-degree scale ranging from very poor to very good[10]. The side effects of the bowel preparation regimens were recorded. Patient satisfaction was scored with a Visual Analog Scale, ranging from 0-10, where 0 represented "very poor" and 10 represented "excellent" [10]. The study was registered in the national clinical trials database (ClinicalTrials.gov identifier NCT00615303) and was approved by the Hospital Ethics Committee. The study was conducted according to the Helsinki Declaration guidelines.

Statistical analysis

The sample size was calculated based on the result of a previous study that revealed that simethicone improved colonic visibility by decreasing air bubbles (97.0% *vs* 75.0%). The calculated sample size of each group was 59 patients. Mean (SD) or median (range) was used to describe continuous data. Frequency (%) was used to describe categorical data. Independent *t* tests (or Mann-Whitney test) were used to compare the continuous characteristics and outcomes of interest data. Chi-square test (or exact test) was used to compare the categorical characteristics and outcomes of interest data. All analyses were performed using STATA version 9.0. $P < 0.05$ was accepted as statistically significant.

RESULTS

Two hundred and eleven patients were initially scheduled for colonoscopy. Eighty-seven patients were excluded because of failure to meet the inclusion criteria (10 patients did not give consent to the study, 38 patients with renal insufficiency received PEG instead of NaP solution, 12 patients had massive ascites, 8 patients had coagulopathy, 14 patients had a history of colonic surgery, and 5 patients had a history of colonic obstruction) (Figure 1). One hundred and twenty-four patients were recruited to the study. Two patients in the placebo group were lost to follow-up. Clinical characteristics of the study patients are shown in Table 2. There were no significant differences between the two groups. Mean age of both groups together was 57 years, and the proportion of male to female was 50 (41.0%): 72 (59.0%). The colonoscopic examination was not completed in 2 patients (1 from each group). Seventy-one (58.2%) and 51 (41.8%) patients underwent colonoscopy due to the presence of gastrointestinal symptoms and for screening purposes, respectively. The details of the endoscopic findings did not differ between the simethicone and placebo groups (Table 3).

NaP plus simethicone improved endoscopic visibility significantly by diminishing air bubbles more than NaP plus placebo, both when each segment of the colon was

considered separately and also when the colon was analyzed as a whole (100.0% *vs* 42.4%, $P < 0.0001$) (Table 3). Nevertheless, simethicone failed to decrease the amount of residual fecal material (90.2% *vs* 81.4%, $P = 0.17$) (Table 3). Endoscopist and patient satisfaction in simethicone group was higher than that in the placebo group (79.0% *vs* 32.8%, $P < 0.0001$ and 8.7 ± 1.8 *vs* 7.6 ± 1.9, $P = 0.002$) (Table 4). However, there was no difference in the total duration of colonoscopic examination between the simethicone and placebo groups (25.1 ± 13.1 *vs* 27.3 ± 12.9 min, $P = 0.27$). The issue of who performed the procedure did not affect the study result. Adverse drug reactions such as nausea and vomiting, abdominal pain, fatigue, and sleep disturbance were not significantly different between the two groups. Nausea and vomiting was found to be the most common side effect in this study (Table 5).

Table 5 Side effects of bowel preparation (%)

Abdominal pain	5 (12.5)	6 (14.0)
Fatigue	2 (5.0)	1 (2.3)
Sleep disturbance	0	1 (2.3)

DISCUSSION

Colonoscopy is one of the most accurate investigations for colorectal screening and for assessing colonic lesions in patients who present with gastrointestinal symptoms such as hematochezia, diarrhea, or constipation. The quality of colonoscopy depends on multiple factors such as the redundancy of the colon, patient discomfort, and the type of bowel cleansing regimen. Inadequate bowel cleansing can impair visualization and colonic lesions. It may also prolong the duration of colonoscopy and increase patient discomfort. Previous studies were done to evaluate the efficacy of various bowel preparation regimens; however, the ideal bowel preparation regimen has not yet been found. PEG and NaP have been incorporated in the standard recommendations as bowel preparation for colonoscopy[2,3].

Simethicone is one of the adjunct therapies that can improve the quality of bowel preparation[23-28]. In this study, we report that the addition of simethicone to NaP is superior to the standard colonic bowel preparation with NaP alone, in terms of diminishing air bubbles and increasing patient acceptance to bowel preparation regimen. The endoscopic visibility was acceptable in 100.0% of patients in the simethicone group while it was found in only 42.4% in the placebo group. However, simethicone failed to raise the quality of colon preparation to a satisfactory level. Previous studies showed that simethicone improved the visibility of colonoscopy[23-28]. Sudduth *et al*[24] evaluated the efficacy of simethicone and NaP in 86 patients. The study revealed that simethicone improved colonic visibility by decreasing air bubbles (97.0% *vs* 75.0%, $P < 0.05$). Shaver *et al*[23] assessed the benefit of adding simethicone to Golytely in 120 patients. The study showed that simethicone decreased colonic foam (100.0% *vs* 67.0%, $P < 0.005$) and residual stool (5.3% *vs* 38.9%, $P < 0.05$)[23]. Compared to previous studies, we found more air bubbles along the gastrointestinal tract without clear explanation. Using NaP solution as a bowel preparation regimen instead of PEG may be one of the factors related to this. The addition of simethicone to bowel preparation did not yield any benefit in terms of bowel preparation adequacy.

The improvement in patient satisfaction with the bowel preparation regimen, which was never evaluated in previous papers, was reported here; although it was statistically significant, it may not be clinically relevant. Improving patient satisfaction in the simethicone group may be due to the fact that simethicone reduces gas and abdominal discomfort during colonoscopy. Patient satisfaction may encourage patient willingness to undergo repeated colonoscopy in the future. Simethicone is not absorbed into the bloodstream, and is therefore considered relatively safe with very few reports of bloating, constipation, diarrhea, gas, and heartburn[15]. In this study, the number of other side effects (e.g. nausea and vomiting, abdominal pain, fatigue and sleep disturbance) were equally distributed in both groups. These side effects may also be caused by NaP solution. Although simethicone improved visibility by decreasing air bubbles, we did not find any decrease in the total duration of colonoscopy. Moreover, the completion rate of colonoscopy between the two groups was not different. Patient factors (e.g. the length and redundancy of the colon), requirement of additional procedures (e.g. polypectomy and mucosal biopsy), and experience of the endoscopist are possible confounding factors that may lengthen the colonoscopic time.

The results of our study have some limitations. Firstly, there was no improvement of adequacy of colon preparation, and residual fecal materials were still present after the addition of simethicone. Secondly, we did not investigate other clinically important endpoints such as the reduction of missed lesions or interval neoplasm because there may be other factors, such as endoscopist factors, colonoscopic withdrawal time, and bowel preparation regimen that could affect the result of the study. Larger studies with different protocol designs are needed to answer these questions.

Air bubble reduction results in markedly enhanced visibility and, possibly, improvement in the quality of the colonoscopy. Endoscopist and patient satisfaction is also increased in the simethicone group. Thus, simethicone may be considered to be an adjunct therapy to NaP bowel preparation regimen in clinical practice.

COMMENTS

Background

Colonoscopy is considered to be the gold standard investigation for colonic lesions. Sodium phosphate (NaP) is one of the bowel preparation regimens for colonoscopy; however, air bubbles can impair visibility during the examination.

Research frontiers

Simethicone is an oral antifoaming agent. The presence of air bubbles along the colonic surface can impede the clear visualization of the whole colon. This article aims to evaluate the effectiveness of simethicone in enhancing visibility and efficacy during colonoscopy.

Innovations and breakthroughs

The use of simethicone as an adjunct to the bowel preparation regimen has been studied and the quality of the bowel preparation was found to be increased. However, all of the previous studies used PEG plus simethicone as a bowel preparation regimen and only liquid simethicone was selected as an adjunct therapy. Furthermore, a decrease in haziness was still questionable. Colonoscopy duration and the satisfaction of the endoscopist and the patient have never been explored.

Applications

The addition of simethicone to NaP solution is of benefit for colonoscopic bowel preparation by diminishing air bubbles, resulting in enhanced visibility. Endoscopist and patient satisfaction is also enhanced after simethicone addition. Thus, simethicone should be considered as an adjunct to NaP solution for bowel preparation.

Peer review

This manuscript entitled "Improving Quality of Colonoscopy by adding Simethicone to Sodium Phosphate Bowel Preparation" shows outcomes of a prospective randomized control trial for additional benefit of simethicone for colon preparation. This study is well constructed and the study protocol itself is quite acceptable, but the outcomes show only a modest benefit of simethicone.

Abstract

AIM: To present a series of cases with symptomatic acute extensive portal vein (PV) and superior mesenteric vein (SMV) thrombosis after splenectomy treated by transjugular intrahepatic approach catheter-directed thrombolysis.

METHODS: A total of 6 patients with acute extensive PV-SMV thrombosis after splenectomy were treated by transjugular approach catheter-directed thrombolysis. The mean age of the patients was 41.2 years. After access to the portal system *via* the transjugular approach, pigtail catheter fragmentation of clots, local urokinase injection, and manual aspiration thrombectomy were used for the initial treatment of PV-SMV thrombosis, followed by continuous thrombolytic therapy *via* an indwelling infusion catheter in the SMV, which was performed for three to six days. Adequate anticoagulation was given during treatment, throughout hospitalization, and after discharge.

RESULTS: Technical success was achieved in all 6 patients. Clinical improvement was seen in these patients within 12-24 h of the procedure. No complications were observed. The 6 patients were discharged 6-14 d (8 ± 2.5 d) after admission. The mean duration of follow-up after hospital discharge was 40 ± 16.5 mo. Ultrasound and contrast-enhanced computed tomography confirmed patency of the PV and SMV, and no recurrent episodes of PV-SMV thrombosis developed during the follow-up period.

CONCLUSION: Catheter-directed thrombolysis *via* transjugular intrahepatic access is a safe and effective therapy for the management of patients with symptomatic acute extensive PV-SMV thrombosis.

Key words: Mechanical thrombectomy; Portal vein; Splenectomy; Superior mesenteric vein; Thrombolysis; Thrombosis

INTRODUCTION

Portal vein (PV) and superior mesenteric vein (SMV) thrombosis is an uncommon but lethal complication occurring after splenectomy[1,2]. The incidence of this type of complication ranges from 1.6% to 11% in some series[3] and from 6.3% to 10% in others[4,5]. Although many patients with PV and SMV thrombosis may be asymptomatic, the consequences of these thromboses can be severe, and include mesenteric ischemia and variceal bleeding, with a mortality rate of 5%-37%[2]. There are no uniform protocols for the

effective treatment of PV-SMV thrombosis following splenectomy, including duration of anticoagulation therapy and the potential effectiveness of prophylactic perioperative antiplatelet agents[6-9]. However, to avoid lethal complications, appropriate treatment should be performed as soon as possible, especially in patients with SMV involvement[4,6].

Recently, endovascular interventional techniques have been recognized as promising alternatives for the treatment of PV-SMV thrombosis. Case reports of the successful treatment of PV-SMV thrombosis include intra-arterial infusion of thrombolytics *via* the superior mesenteric artery (SMA) by the transfemoral artery[10,11], thrombolysis *via* a transjugular intrahepatic approach[12-14], and percutaneous transhepatic mechanical or pharmacologic thrombolysis[15-17]. The aim of the present study is to report the clinical outcome of 6 patients with acute symptomatic PV and SMV thrombosis after splenectomy who were treated with transjugular intrahepatic portal access aspiration thrombectomy and catheter-directed thrombolysis at our hospital.

MATERIALS AND METHODS

The study was approved by the institutional review board at our hospital. The potential risks and benefits of the procedure were explained, and informed consent was obtained from each patient.

Patients

Between March 2001 and October 2007, using the transjugular intrahepatic approach, we treated 6 patients (1 woman, 5 men) with a mean age of 41.2 years (range 32-52 years) who had symptomatic extensive PV and SMV thrombosis after open splenectomy. All 6 patients had acute abdominal symptoms of less than 3 wk (range, 3-16 d; average, 8.5 d).

Of these patients, four underwent splenectomy due to liver cirrhosis with portal hypertension, gastroesophageal variceal bleeding, and hypersplenism; splenectomy was performed in two patients due to portal hypertension and gastroesophageal variceal bleeding, caused by splenic vein occlusion. These 2 patients had a history of pancreatitis. All 6 patients had marked splenomegaly. The pre-splenectomy platelet count was less than $100 \times 10^3/mm^3$ ($3.5\text{-}6.5 \times 10^3/mm^3$; reference range, $100\text{-}300 \times 10^3/mm^3$), and in the normal range in 2 patients. The interval between the onset of symptoms of PV-SMV thrombosis and splenectomy was 11 to 35 d (median, 20.5 d).

All 6 patients initially presented with abdominal pain of insidious onset associated with nausea; 3 had distension, 3 had diarrhea, 2 had low-grade fevers, 1 had vomiting, and 1 had heme-positive stools. All patients were hemodynamically stable, and no clinical signs of peritonitis were noted at abdominal examination (Table 1).

Diagnostic evaluation

On admission, increased platelet count ($340\text{-}660 \times 10^3/mm^3$) was observed in 4 patients (Table 1). Increased white blood cell count ($12.5 \pm 1.5 \times 10^3/mm^3$; range, $11.5\text{-}14.0 \times 10^3/mm^3$) was found in 3 patients. Increases in transaminases (AST, 60-80 IU, reference range, 5-40 IU; ALT, 65-110 IU, reference range, 5-40 IU) were seen in 3 patients. Normal values were detected for thrombin time, serum D-dimer, C-reactive protein, serum D-lactate, and amylase. A workup for hypercoagulable states (factor V leiden, protein C and S deficiency, antithrombin Ⅲ deficiency, and lupus anticoagulant) yielded normal results.

Ultrasonography (US) and computed tomography (CT) were performed in all 6 patients. All patients had SMV thrombosis extending into the main portal vein which was confirmed by the imaging study.

General management

All patients were treated initially with bowel rest and nasogastric suction, intravenous fluid administration, broad-spectrum prophylactic antibiotics (including ampicillin, gentamycin, and metronidazole), and intravenous heparin adjusted to maintain the activated partial thromboplastin time ratio between 2.0 and 2.5 times the control.

Systemic anticoagulation after the diagnosis of PV and SMV thrombosis was assessed for 2 d in 4 cases and 3 d in 2 cases, however, the symptoms continued in 4 patients with worsening abdominal pain in 2 patients. After discussions with the surgery and medicine departments, and given the lack of clinical and radiographic suspicion for ischemic bowel, these patients were referred to the interventional radiology department for catheter-directed thrombolysis to achieve rapid restoration of PV-SMV flow. The mean time from admission to our institute to treatment with catheter-directed thrombolysis was 3.5 d, with a range of 2.5-5 d.

Indications and contraindications to interventional radiological thrombolysis

In our hospital, catheter-directed thrombolysis was employed in patients with acute and subacute PV and SMV thrombosis, with severe symptoms, and with persistent symptoms or worsening of symptoms despite anticoagulation.

Contraindications to interventional thrombolysis included mesenteric infarction, recent gastrointestinal bleeding, recent stroke, and primary or metastatic central nervous system malignancies.

Endovascular techniques

Before the transjugular approach was attempted, the portal system was studied with indirect portography obtained during the venous phase following iodinated contrast medium injections into the SMA and the splenic artery. Angiography revealed patent superior mesenteric and splenic arteries. Venous phase confirmed complete thrombosis of the SMV and PV.

The transjugular approach was carried out according to the technique previously described[12-14] by using US and fluoroscopic guidance of the portal vein puncture. Following infiltration of local anesthesia, a Rosch-Uchida

Table 1 Summary of clinical data

No. of patients	Age (yr)/sex	Symptoms	Etiologies of splenectomy	Platelet count at admission ($\times 10^3$/mm^3)	Onset of symptoms postoperative day
1	40/M	Fever, abdominal pain, distension, and nausea	Cirrhosis, portal hypertension, and variceal bleeding	540	16
2	43/M	Epigastric pain, diarrhea, fever, and nausea	Cirrhosis, portal hypertension, variceal bleeding, hypersplenism	280	14
3	38/F	Abdominal pain, nausea, distension, and vomiting	Portal hypertension, variceal bleeding	660	11
4	42/M	Abdominal pain, diarrhea, and nausea	Cirrhosis, portal hypertension, variceal bleeding, hypersplenism	360	19
5	32/M	Abdominal pain, distension, nausea, heme-positive stools	Cirrhosis, portal hypertension, variceal bleeding, hypersplenism	240	35
6	52/M	Abdominal pain, nausea, and diarrhea	Portal hypertension, hypertension, variceal bleeding, hypersplenism	340	28

set (Cook, Bloomington, IN, USA) was used to gain access to the portal vein branch. Once the catheter was placed inside a portal branch, the thrombus could be traversed with the aid of a 4 Fr Cobra catheter (Cordis, the Netherlands) and a hydrophilic guidewire (Terumo, Japan). After reaching distal branches of the SMV, the Cobra catheter was exchanged for an 8 mm diameter angioplasty balloon catheter (Boston Scientific, MA, USA), to open up a channel, and then a 10-Fr Rosch-Uchida sheath (Cook) was put into the portal trunk. A bolus of 3000 IU of heparin was injected *via* a peripheral venous catheter.

Through the 10-Fr sheath, an angled 8-Fr guiding catheter (Cordis) was used to aspirate as much of the thrombus as possible from the SMV and PV with a Luer-Lok 60-mL syringe. The aspiration procedure was performed from distal to proximal clots in 8-12 cycles (10 ± 2). Simultaneously, a 5-Fr pigtail catheter (Cordis) was used to fragment the thrombus with "spinning technique"[16] and an injection of urokinase (TIANJIN Biochemical Pharmaceutical Co., LTD, China) 200 000-300 000 IU using a hand-pulse spray technique.

Following the mechanical aspiration procedure, a 4-Fr multiple side-hole catheter (Angiodynamics, Queensbury, NY, USA) was placed with the tip in the SMV, and then continuous thrombolytic therapy was started with urokinase 50 000 IU/h. Heparin infusion was given simultaneously *via* a peripheral venous catheter, at a dose of 1000 IU/h. The adequacy of anticoagulation was adjusted to maintain the activated partial thromboplastin time between 2.0 and 2.5 times the control, during treatment and throughout hospitalization. During the prolonged infusion of thrombolytics, patients had PV-SMV venographic follow-up *via* the infusion catheter every 24 h. Color Doppler ultrasound scan (CDUS) assessment of PV and SMV patency was performed at 24, 48, and 72 h, 1 wk following the procedure, and at discharge.

Termination of the infusion of thrombolytics was based on clinical and radiographic findings. The catheter infusion of thrombolytics was discontinued after the patients' symptoms (i.e. abdominal pain, distention, and diarrhea) had improved sufficiently that they were able to begin oral intake, and the repeated venography demonstrated good flow from the SMV into the portal vein, and no relapse of the thrombosis. The patients were then placed on chronic anticoagulation with warfarin adjusted to maintain an International Normalized Ratio of 2-3 after discharge.

Follow-up US was performed at patient discharge, every 2-3 mo in the first year, and every 4-6 mo in the second year. Follow-up CT was carried out at patient discharge, and then every 3 mo for 1 year and then every 6-12 mo thereafter.

Technical success was defined as successful catheterization of the portal vein, removal of the majority clots, and restoration of flow in the trunk of PV and SMV. Clinical success was defined as relief of symptoms and bowel resection was not required after the procedure. Minor complications were defined as no therapy or normal therapy without consequence.

RESULTS

Technical success

Technical success was achieved in all 6 patients. No complications, such as hemorrhage or contrast extravasation were observed during the procedures. Direct venography of PV-SMV after access to the portal vein confirmed extensive thrombosis in the PV and SMV with poorly formed collateral drainage (Figures 1 and 2).

Using pigtail catheter fragmentation, local urokinase injection, and manual aspiration thrombectomy of the PV-SMV thrombosis resulted in removal of clots $\geqslant$ 60% (60%-80%) in all 6 patients (Figures 3 and 4). Restoration of partial flow in the main PV and SMV was documented on immediate follow-up direct portal venography.

After mechanical thrombolysis, continuous thrombolytic therapy *via* the indwelling infusion catheter in the SMV was performed for three to six days (4.5 ± 1.5 d). The mean total dose of urokinase *via* the catheter infusion was 5.8 million IU (range, 3.6-7.2 million). At completion of indwelling catheter infusion of thrombolytics a near complete lysis of clots (removal of clots greater than 90%) was observed in 4 patients and a partial lysis with a degree of residual thrombus less than 20% was observed in 2 patients, which were confirmed by repeated venography *via* the infusion catheter at the SMV.

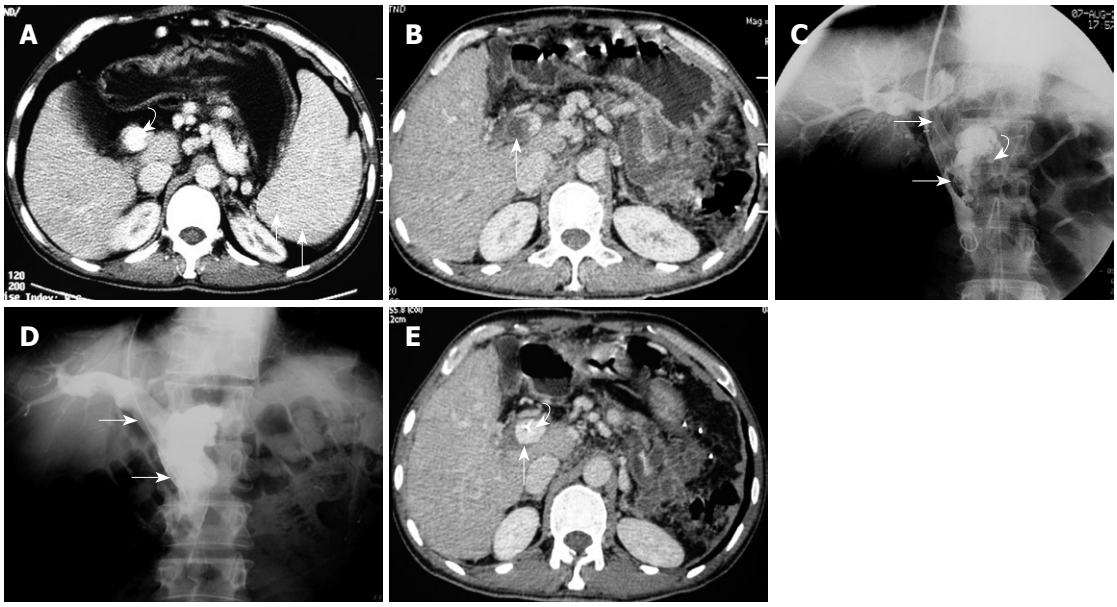

Figure 1 Case 1: A 40-year-old man with low-grade fever, abdominal pain, distension, and nausea for 12 d. He had undergone splenectomy 4 wk previously. A: Selected axial image from before open splenectomy contrast-enhanced CT shows splenomegaly (arrows) and patent portal vein (curved arrow); B: Selected axial image from admission contrast-enhanced CT, on postoperative day 28, shows massive thrombus within the PV (arrow); C: Pre-treatment direct venography *via* transjugular approach access to the portal vein shows massive thrombosis of the PV extending into the SMV (arrows). Note the stump of the splenic vein (curved arrow); D: Follow-up direct portal venography *via* the infusion catheter, obtained 5 d after the catheter infusion of thrombolytics, shows patency of the main PV-SMV (arrows); E: CT image at the same level as in Figure 1B obtained 5 d after the interventional procedure, before the infusion catheter removal, shows the wide patent main PV (arrow). Note the infusion catheter within the PV (curved arrow).

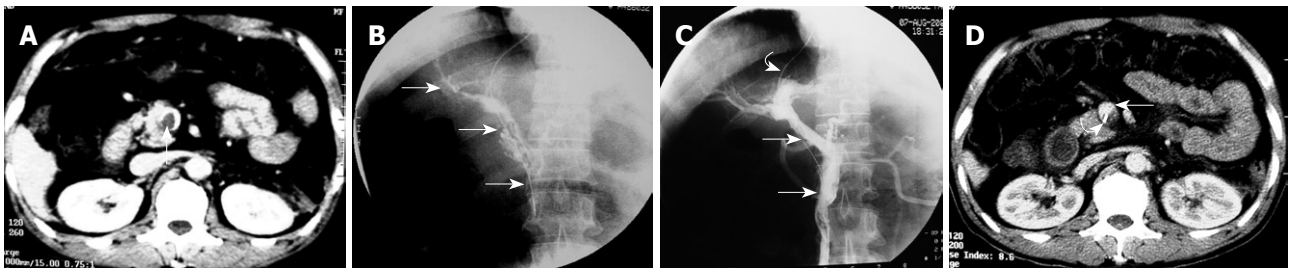

Figure 2 Case 2: A 43-year-old man with epigastric pain, diarrhea, fever, and vomiting for 1 wk. He had undergone splenectomy 3 wk previously. A: Selected axial image from admission contrast-enhanced CT, on postoperative day 21, shows thrombus (arrow) within the SMV; B: Pre-treatment direct venography *via* transjugular approach access to the portal vein shows extensive thrombosis of the SMV extending into the main PV and intrahepatic branches (arrows); C: Follow-up direct portal venography *via* the infusion catheter (curved arrow), obtained 6 d after the catheter infusion of thrombolytics, shows patent PV and SMV with only minimal residual wall thrombus (arrows); D: CT image at the same level as in Figure 2A obtained 6 d after the catheter infusion of thrombolytics, before the infusion catheter removal, shows the wide patent SMV (arrow) with only minimal residual wall thrombus. Note the infusion catheter within the SMV (curved arrow).

Clinical improvement

Sufficient clinical improvement was seen in all 6 patients after 12-24 h of the mechanical thrombolysis procedure, characterized by a progressive reduction in abdominal pain, nausea, diarrhea, and distention. The patients continued to improve clinically during thrombolysis *via* the indwelling infusion catheter in the SMV. Oral intake was started at 3-5 d (4 ± 1.0 d) after abdominal pain, nausea, distention, and diarrhea was completely resolved. No patient required bowel resection after the procedures. No thrombotic, hemorrhagic, or infectious complications were noted during hospitalization. All 6 patients were discharged within 6-14 d (8 ± 2.5 d) of admission.

Contrast-enhanced CT was obtained in all 6 patients before discharge. The images demonstrated almost complete disappearance of PV-SMV thrombosis in 4 patients, and partial recanalization of the PV and SMV with residual thrombus (less than 20% compared to pre-treatment) in 2 patients. Three patients had abnormal AST and ALT values at admission, which returned to normal at discharge.

Follow-up

The mean duration of follow-up after hospital discharge was 40 ± 16.5 mo (range, 15-62 mo). All 6 patients are alive at writing, and no recurrent episodes of PV and SMV thrombosis developed during the follow-up period. Chronic anticoagulation with oral warfarin was initiated in all 6 patients at least 6 mo (6-12 mo) after hospital discharge. During the 15-62 mo follow-up period, US and contrast-enhanced CT confirmed the patency of the PV-SMV, without cavernous transformation of the PV or extrahepatic collaterals.

The platelet count returned to the normal range in

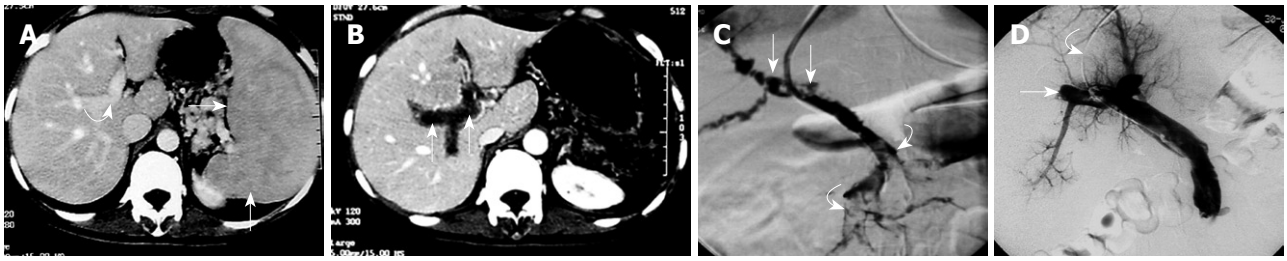

Figure 3 Case 3: A 38-year-old woman with abdominal pain, nausea, distension, and vomiting for 3 d. She had undergone splenectomy 2 wk previously. A: Selected axial image from before open splenectomy contrast-enhanced CT shows splenomegaly (arrows) and patent portal vein (curved arrow); B: Selected axial image from admission contrast-enhanced CT, on postoperative day 14, shows extensive thrombus within the PV (arrows); C: Pre-treatment direct venography *via* transjugular approach access to the portal vein showing extensive PV (arrows) and SMV (curved arrows) thrombosis, without collateral drainage; D: Follow-up direct portal venography *via* the infusion catheter (curved arrow), obtained 5 d after the catheter infusion of thrombolytics, shows patent PV and SMV with residual thrombosis within the intrahepatic portal venous branches (arrow).

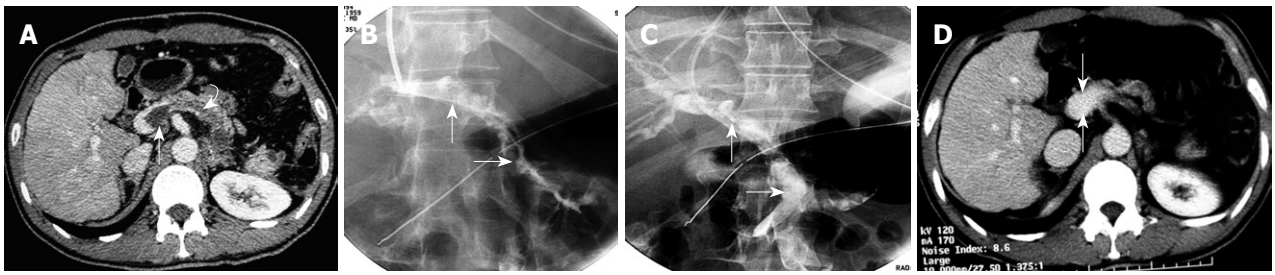

Figure 4 Case 4: A 42-year-old man with abdominal pain, diarrhea, and nausea for 2 wk. He had undergone splenectomy 4 wk previously. A: Selected axial image from admission contrast-enhanced CT demonstrates massive thrombus within the proximal of SMV (arrow) and the stump of the splenic vein (curved arrow); B: Pre-treatment direct venography *via* transjugular approach access to the portal vein showing extensive PV-SMV thrombosis (arrows), without collateral drainage; C: Immediate follow-up direct portal venography after catheter fragmentation and aspiration of the PV-SMV thrombosis, shows 75% reduction of thrombosis in the SMV and PV (arrow). The catheter infusion of thrombolytics was continued for 4 d and further improvement was confirmed by CT follow-up; D: Contrast-enhanced CT image at the same level as in Figure 4A obtained 5 d after completion of the interventional procedure shows a wide patent SMV (arrows).

four patients. Long term oral aspirin was given at a dose of 100 mg/d to 2 patients because their platelet count was > $300 \times 10^3/mm^3$ ($380 \times 10^3/mm^3$, $460 \times 10^3/mm^3$, respectively, at the last examination).

DISCUSSION

Although the exact mechanisms of PV-SMV thrombosis formation after splenectomy remain unclear, altered platelet function as well as transient thrombocytosis after splenectomy, a decrease in portal blood flow and pressure, and stasis of blood in the stump of the splenic vein appear to predispose to PV-SMV thrombosis[6,18]. Ikeda *et al*[4] reported that patients with PV-SMV thrombosis after splenectomy had a significantly heavier splenic weight than those without PV-SMV thrombosis, suggesting that a large splenic mass is a possible risk factor for post-splenectomy PV-SMV thrombosis. Stamou *et al*[7] reported that a platelet count of more than $650 \times 10^3/mm^3$ and greater spleen weight (> 650 g) was associated with the development of portal system thrombosis. In our cases, marked splenomegaly was present in all 6 patients. In addition, a significant increase in platelet count was found in 4 patients at admission. However, we can not draw any conclusions due to our very small group of patients and lack of a control group.

Medical and surgical options are of limited value in extensive PV-SMV thrombosis[1,2]. In symptomatic PV-SMV thrombosis patients, treatment depends on the presence or absence of clinical and CT peritoneal signs. An emergency laparotomy with resection of necrotic bowel is necessary in the former condition and anticoagulant and/or thrombolytic therapy in the latter condition. The advantage of surgical embolectomy is that it allows for direct inspection of the bowel at the time of embolectomy and resection of necrotic bowel, if necessary. However, it is often difficult to remove all the thrombus from the small branches of the mesenteric veins. Often, adjuvant thrombolytic therapy is necessary and can be associated with a high risk of bleeding in the postoperative patient[19,20]. Systemic anticoagulant and/or thrombolytic therapy is of limited value in extensive PV-SMV thrombosis, as it has low efficacy and is time consuming[2].

In patients with acute or subacute symptomatic PV-SMV thrombosis, endovascular interventional treatment has been reported with encouraging initial results[10-17]. With this approach, PV-SMV thrombosis can be managed by pharmacologic thrombolysis and/or mechanical thrombectomy. For pharmacologic thrombolysis, possible routes of treatment include indirect intra-arterial infusion of thrombolytic agents *via* the SMA[10,11] and direct access to the portal vein, by the transjugular[12-14] or transhepatic routes[15-17]. Mechanical thrombectomy techniques include balloon angioplasty, thrombectomy devices, aspiration thrombectomy, stent placement, and TIPS creation[14,15].

Indirect thrombolytic therapy *via* the SMA is less technically demanding and has been described for its potential benefits in infusing thrombolytic agents into small mesenteric venous branches[10,11]. However, this approach does not allow direct infusion into the thrombus, may result in lytic agents diverting through patent branches and collaterals, and possible prolongation of the total infusion time *via* the SMA[12], which may result in an increased risk of bleeding. Direct access to the portal vein by a transjugular or transhepatic route directly targets the PV-SMV thrombosis, leading to fast removal of the thrombus and flow improvement, and an improvement in the patient's symptoms[14,15].

Percutaneous transhepatic access is technically relatively easy and allows the maneuver of mechanical devices compared with transjugular intrahepatic access. Usually, this approach is suitable for the removal of larger clots within the trunk of the PV and SMV. The drawbacks of the percutaneous transhepatic route include the development of intraperitoneal or subcapsular hepatic hemorrhage[16,21]. This is likely to occur given that the transhepatic route for mechanical thrombectomy of splanchnic venous thrombosis requires traversing the hepatic capsule and is followed by thrombolysis and possibly systemic anticoagulation.

Our 6 patients with acute extensive PV-SMV thrombosis after splenectomy treated with the transjugular intrahepatic approach demonstrates the feasibility of this route to the management of this challenging illness. The transjugular approach access to the portal vein is generally performed with the creation of a transjugular intrahepatic portosystemic shunt; this approach is usually indicated for patients with cirrhosis with portal hypertension caused by portal vein thrombosis[13,14]. Compared to the percutaneous transhepatic approach, the transjugular intrahepatic approach does not require traversing the hepatic capsule, and thus would eliminate the risk of subcapsular hemorrhage[12,14]. Furthermore, the transjugular intrahepatic approach is safer in patients with anticoagulation. In addition, based on our experience with the TIPS procedure, we opted for this approach to treat an extensive acute PV-SMV thrombosis. Although we did not observe any complications in our 6 patients with the transjugular approach, significant intra-abdominal bleeding is a potential serious complication[22].

Mechanical thrombectomy devices and aspiration thrombectomy are feasible and effective in the re-establishment of portal and mesenteric circulation in patients with acute extensive thrombosis[12,21]. Good results have been obtained with thrombectomy devices such as the Arrow-Trerotola, Oasis, Amplatz thrombectomy, and AngioJet, although the clinical experience with these thrombectomy devices in PV-SMV thrombosis is limited[12,23,24]. We did not use mechanical thrombectomy devices in our small series because these devices were unavailable at that time in our angiographic laboratory. Aspiration of the fresh thrombus with a large lumen catheter has also been reported[14,25]. The advantages of this technique are that a large-lumen catheter is generally available in standard angiography laboratories, is of low cost compared with the various thrombectomy devices, and is an easy device which can be as effective as the various thrombectomy devices in removing thrombus from a vessel[16,25].

In patients with acute extensive thrombosis of the PV-SMV, mechanical thrombectomy could initially be used to debulk the thrombus, and pharmacologic thrombolysis would probably still be necessary in most cases to treat residual thrombosis and to treat thrombus in the small and peripheral veins[16,23]. The combination of aspiration and local pharmacological thrombolysis *via* a direct access to the portal system is more effective and significantly decreases the treatment time in patients with extensive PV-SMV thrombosis compared to indirect and direct thrombolysis infusion alone[12,23,24]. In our 6 cases, aspiration thrombectomy associated with indwelling catheter infusion of thrombolytics into the SMV was effective, resulted in a rapid improvement in symptoms, recanalization of the SMV, resolution of symptoms, and resumption of oral nutrition.

Combining thrombolytic infusion with anticoagulation would appear to increase the risk of bleeding and hemorrhage[26,27]. A study by Ouriel *et al*[26] described the complication rates for patients with lower-extremity arterial or venous occlusions treated with local urokinase or rt-PA. Overall, 15% required transfusion and 1.2% developed intracranial hemorrhage, which was fatal in 8 of 9 cases. In our series, no bleeding complications occurred. This may have resulted from the relatively low dose infusion of urokinase *via* the catheter in the SMV, no simultaneous peripheral venous infusion of urokinase, and careful monitoring of the coagulation status during treatment. As for thrombolytic agents, we prefer urokinase to rt-PA (recombinant tissue plasminogen activator), because it is similarly active on thrombus dissolution but appears to be safer, being associated with a lower incidence of hemorrhagic complications[26]. In addition, urokinase is generally available in our institution, and is less costly than rt-PA.

Interventional endovascular thrombectomy and direct thrombolysis can offer a non-surgical alternative for the treatment of extensive PV-SMV thrombosis[10-17]. However, this can only be performed in a select group of patients who do not present with bowel ischemia and infarction, or who are not at risk for bleeding, and who have persistent symptoms or worsening of symptoms despite anticoagulation[1,2]. Minimally symptomatic or asymptomatic patients with PV-SMV thrombosis may best be treated with systemic anticoagulation only. Prompt surgical intervention should be undertaken if the patient's condition deteriorates or clinical signs of peritonitis develop during the interventional treatment[2]. In this small group, we chose interventional procedures to treat these patients because systemic anticoagulation was ineffective and because the SMV was involved. The results obtained in our series of patients can be considered satisfactory. All 6 patients showed a patent SMV and PV, without recurrent episodes, during a mean follow-up of 40 mo.

The limitations of this study include the lack of a control group, randomization, and uniformity of

evaluation and treatment. Because of the small sample size, no statistically significant conclusions could be drawn regarding treatment with respect to dosages of thrombolytic agent or heparin, techniques, or underlying risk factors. This is partly related to the low incidence of the illness as well as the natural evolution of therapeutic techniques during the last 10 years.

In summary, the combination of catheter fragmentation of clots, aspiration thrombectomy, and indwelling catheter infusion of thrombolytics *via* transjugular intrahepatic access to the portal system, is a safe and effective therapy for the management of patients with acute extensive PV-SMV thrombosis. Because of the small size of the study and other factors, the ability to generalize the results is limited.

COMMENTS

Background

Thrombosis of the portal vein (PV) and superior mesenteric vein (SMV) is considered a possible cause of death after splenectomy. The reported incidence of PV-SMV thrombosis after elective open splenectomy ranges from 6.3% to 11%. Although many patients with PV-SMV thrombosis may be asymptomatic, the consequences of these thromboses can be severe, including mesenteric ischemia and variceal bleeding, with a mortality rate of 5%-37%. There are no uniform protocols for the effective treatment of PV-SMV thrombosis following splenectomy.

Research frontiers

The treatment of symptomatic acute thrombosis of the PV and SMV is controversial. Due to unsatisfactory results obtained in some cases with medical treatment, as well as the difficulty in performing surgical procedures in some cases, new possibilities, such as percutaneous techniques, have been investigated.

Innovations and breakthroughs

The authors report 6 patients with acute extensive PV-SMV thrombosis after splenectomy treated with transjugular approach catheter-directed thrombolysis, which demonstrated the feasibility of this route in the management of this challenging illness. Compared to the percutaneous transhepatic approach, the transjugular approach does not require traversing the hepatic capsule, and thus eliminates the risk of subcapsular hemorrhage. In addition, the transjugular approach is safer in patients with anticoagulation. Secondly, this is the first study to report on the efficacy of the combination of aspiration thrombectomy with an indwelling catheter infusion of thrombolytics into the SMV, which resulted in a rapid improvement in symptoms, recanalization of the SMV, and resolution of symptoms. Finally, the combination of thrombolytic infusion with anticoagulation can be associated with a high risk of bleeding. In the authors' series, no bleeding complications occurred. This may have resulted from the relatively low dose infusion of urokinase *via* the catheter in the SMV, no simultaneous peripheral venous infusion of urokinase, and careful monitoring of the coagulation status during treatment.

Applications

Interventional endovascular thrombectomy and direct thrombolysis can offer a non-surgical alternative for the treatment of extensive PV-SMV thrombosis. This technique can be performed in patients who do not present with bowel ischemia and infarction, or who are not at risk for bleeding, and have persistent symptoms or worsening of symptoms despite anticoagulation.

Terminology

Endovascular interventional techniques for the treatment of thrombosis include intra-vascular pharmacologic thrombolysis and mechanical thrombectomy. Catheter-directed intra-vascular thrombolysis can directly target the thrombus, leading to fast removal of the thrombus and flow improvement, and an improvement in symptoms. Interventional mechanical thrombectomy techniques include balloon angioplasty, thrombectomy devices, aspiration thrombectomy, stent placement, and TIPS creation.

Peer review

This study reports 6 patients that were treated with techniques of interventional radiology to restore patency of portal venous thrombosis (extending to the mesenteric vein) that developed after being submitted to surgical splenectomy. The authors report a 100% success rate of the technique without side effects. Although the size of the series is small, the results can be considered satisfactory and is encouraged.

Abstract

AIM: To identify and compare the profile of Ca^{2+} channel subunit expression in INS-1 and rat pancreatic β cells.

METHODS: The rat insulin-secreting INS-1 cell line was cultured in RPMI-1640 with Wistar rats employed as islet donors. Ca^{2+} channel subunit expression in INS-1 and isolated rat β cells were examined by reverse transcription polymerase chain reaction (RT-PCR). Absolute real-time quantitative PCR was performed in a Bio-Rad iQ5 Gradient Real Time PCR system and the data analyzed using an iQ5 system to identify the expression level of the Ca^{2+} channel subunits.

RESULTS: In INS-1 cells, the L-type Ca^{2+} channel 1C subunit had the highest expression level and the TPRM2 subunit had the second highest expression. In rat β cells, the TPRC4β subunit expression was dominant and the expression of the L-type 1C subunit exceeded the 1D subunit expression about two-fold. This result agreed with other studies, confirming the important role of the L-type 1C subunit in insulin-secreting cells, and suggested that non-voltage-operated Ca^{2+} channels may have an important role in biphasic insulin secretion.

CONCLUSION: Twelve major Ca^{2+} channel subunit types were identified in INS-1 and rat β cells and significant differences were observed in the expression of certain subunits between these cells.

Key words: L-type calcium channels; Expression profile; Insulin-secreting cells; Rats; pancreatic β cell; Reverse transcription-polymerase chain reaction

INTRODUCTION

Recent theories portray type 2 diabetes mellitus (T2DM) as a heterogeneous disorder. In addition to insulin resistance, clinical studies in humans and animals have documented a variety of defects in β cell function[1], and most researchers agree that both insulin secretion impairment and insulin resistance contribute to the fully established disease[2]. Insulin produced by pancreatic islet β cells efficiently regulates glucose homeostasis in humans and other mammals. These cells are electrically excitable, and couple changes in blood glucose concentration to insulin release *via* electrical signals.

Glucose-stimulated insulin secretion is biphasic, with about a 10 min first phase and a several hour second phase[3]. Intracellular Ca^{2+} signals play a pivotal role in β cell function and, as insulin secretion is the most important role of these cells, knowledge of the intricacies of the signals involved in excitation-secretion coupling is important in understanding both normal β cell function and related pathological states. It has been reported that both voltage-dependent and non-voltage-operated Ca^{2+} channels are involved in these processes. The voltage-dependent Ca^{2+} channels include L-type, T-type, N-type and R-type channels[4,5]; the non-voltage-operated Ca^{2+} channels include ryanodine-sensitive Ca^{2+} channels[6-8],

transient receptor potential channels (TRP)[9-11], and inositol 1,4,5-trisphosphate (IP_3)-sensitive channels[12], the latter mobilizing Ca^{2+} from the endoplasmic reticulum. Impaired first-phase insulin secretion is an early feature of T2DM, whereas second-phase insulin secretion deteriorates with progression of the disease. A genetic study has indicated that polymorphisms in R-type channels in humans are associated with T2DM and impaired insulin secretion[13]. Moreover, most Ca^{2+} channels consist of various subunits which participate in different physiologic functions in different species or sub-cloned cell lines[12]. For example, T-type Ca^{2+} channels have little or no expression in rodents, but can be detected in humans[14]. Thus, the above suggests that Ca^{2+} channel subunits may be suitable candidates as pathogenetic factors in diabetes.

Considering the essential functions of Ca^{2+} signals for insulin secretion and the various Ca^{2+} channel subunits in β cells, a systemic identification of Ca^{2+} channel subunit expression in β cells is necessary to further the understanding of their functions in regulating insulin secretion and to find potential new therapy targets for T2DM. The aim of this study was to detect the expression profile of six voltage-dependent Ca^{2+} channel subunits, including L-type (α1C, D, S and 1F subunits), R-type (α1E subunit), and N-type (α1B subunit), and nine non-voltage-operated Ca^{2+} channel subunits including Ryr1, Ryr2, TRPC1, TRPC4α, TRPC4β, TRPM2, IP_3R1, IP_3R2 and IP_3R3, in an INS-1 cell line, and to compare the identified subunits with those detectable in rat primary pancreatic β cells. The INS-1 rat cell line was employed as a model of pancreatic β cells because INS-1 cells show susceptibility to glucotoxicity, similar to β cells.

MATERIALS AND METHODS

Cell culture

INS-1 cells lines were glucose-responsive and a gift from Professor Tao Xu (Institute of Biophysics, Chinese Academy of Sciences, P. R. China) and were cultured in RPMI-1640 medium containing 11.2 mmol/L glucose, 100 mL/L fetal calf serum, 2 mmol/L L-glutamine, 1 mmol/L sodium pyruvate[15], 100 000 U/L penicillin, 100 mg/L streptomycin, and 50 mmol/L β-mercapto-ethanol, in a fully humidified atmosphere containing 50 mL CO_2 per liter air at 37℃.

Preparation of rat pancreatic β cells and identification by reverse transcription-polymerase chain reaction (RT-PCR)

Pathogen-free, inbred, male Wistar rats weighing 300-350 g were used as islet donors. The animals were maintained on standard rat chow and acidified water *ad libitum*. For islet retrieval, individuals were sacrificed by cervical dislocation and the pancreas was quickly removed. Pancreatic islets were isolated using a standard collagenase digestion[16,17]. Briefly, islets were separated from exocrine tissue by centrifugation over a discontinuous dextran gradient after digestion with 0.5 g/L collagenase V (Sigma C9263) for 30 min, and further purification by handpicking under a microscope. Islets were collected and washed twice in phosphate-buffered saline and dispersed as single cells by mechanical shaking in 4 mL of Hank's solution (Ca^{2+} and Mg^{2+} free) before filtering the cell mixture over a 35 μm pore size filter (BD Falcon) and diluting to 200 mL. This preparation was divided into 20 mL per tube, and cDNA was synthesized from the total isolated RNA, as described below.

To distinguish glucagon-producing-cells from insulin-producing-cells, specific primer pairs were designed from the insulin and glucagon genes in GenBank. The sequences were: insulin-F, AAACAGCACCTTTGTGG TTCTCA; insulin-R, GTGCCACTTGTGGGTCCTCC; glucagon-F, TCGTGGCTG GATTGTTTG; and glucagon-R, TGGCGTTTGTCTTCGTTTAT. The PCR procedure was: the insulin gene at 95℃ for 30 s, 59℃ for 30 s, 72℃ for 30 s, and 35 cycles; and the glucagon gene at 95℃ for 30 s, 53℃ for 30 s, 72℃ for 30 s, and 35 cycles.

RT-PCR and absolute real-time quantitative PCR analysis

Total RNA was extracted from INS-1 cells and rat pancreatic β cells using the RNeasy Mini Kit (Qiagen, Germany) according to the manufacturer's instructions. One microliter aliquot of the RNA was incubated with Oligo (dT) 18 at 70℃ for 5 min, and then put on ice. RNase inhibitor (1 μL), 100 μmol/L dNTPs, 0.01 mol/L dithiothreitol, and 200 U of M-MLV reverse transcriptase (Promega, USA) were added to the mixture (20 μL final volume), incubated at 42℃ for 50 min, and then incubated at 85℃ for 5 min. Table 1 summarizes the primer pairs used for the amplification of Ca^{2+} channel subunits, PCR was performed in a standard 50 μL reaction volume, and the resulting products were visualized by Golden view after 3% agarose gel electrophoresis in TAE buffer (40 mmol/L Tris-acetate, 2 mmol/L EDTA, pH 8.5).

The expression levels of the subunits were quantified by absolute real-time quantitative PCR with the Bio-Rad iQ5 Gradient Real Time PCR system and all reactions performed in a 25 μL reaction volume containing 12.5 μL of 2xSYBR Green Master mix (Bio-Rad, USA), 1 μL of each primer pair (10 μmol/L), and 1 μL of cDNA templates. The products of PCR were cloned into the pGEM-T easy vector using the pGEM-T easy cloning kit (Promega, USA). Five microliters LB-broth cultures containing single colonies were grown up overnight at 37℃ with shaking at 200 r/min and the resulting plasmids were purified. Plasmid DNA was solubilized in 50 μL TE buffer and the sequences of the cloned products confirmed by DNA sequencing. Purified plasmid clones were quantified by Eppendorf Biophotometer and the copy number calculated as follows: 6.02×10^{23} (copies/mol) × DNA amount (g)/[DNA length (bp) × 660 (g/mol per becquerel)].

Based on the copy number and concentration of the plasmid DNA, the precise number of molecules added to subsequent real-time PCR runs was calculated, thus

[1]These three subunits were not identified in INS-1 and rat β cells.

providing a standard for specific cDNA quantification. All samples were prepared as 1:10, 1:100, and 1:1000 dilutions and each reaction at different dilutions performed in triplicate. The standard curve and data analysis were produced using Bio-Rad iQ5 software.

RESULTS

Preparation of rat pancreatic β cells and identification by RT-PCR

An average of 300-500 islets were produced from each rat, with about 1000 cells per islet and composed of 70% β cells. In the first 10 cDNA templates analyzed, six templates only expressed the insulin gene, three expressed the glucagon gene, and the last one expressed neither. The cDNA whose glucagon gene was positive was considered to be from contamination by alpha islet cells and could be ignored and, thus, the others were chosen as templates for analysis of β cell Ca^{2+} channel subunit expression.

Expression of Ca^{2+} channels subunits in INS-1 and rat pancreatic β cells

RT-PCR was performed to identify the expression of Ca^{2+} channel subunits in INS-1 and rat pancreatic β cells. Of the 15 subunit types, 12 types were amplified from INS-1 and rat pancreatic β cells and their identities confirmed (Figure 1A). Three types, not identified in either INS-1 or rat pancreatic β cells, were the L-type α1F, S and Ryr1 subunits. Under the same reaction conditions, these three were identified in cDNA from heart and skeletal muscle because these sources

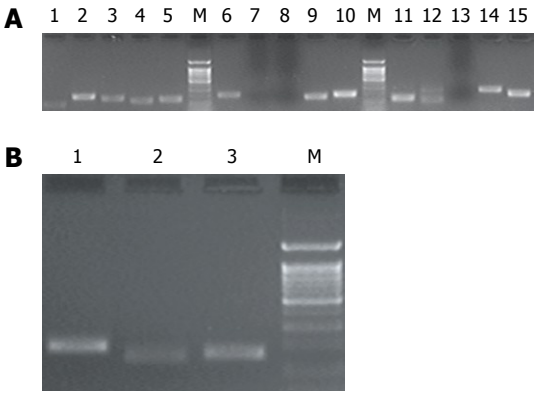

Figure 1 The Ca^{2+} channel subunits expression profile in INS-1 and rat β cells. A: 12 of 15 Ca^{2+} channel subunits in rat pancreatic β cells. 1-5: Separately represent subunits TRPC1, TRPC4α, TRPC4β, TRPM2, and L-α1C; 6-10: Separately represent subunits L-α1D, L-α-S, L-α1F, IP_3R1, and IP_3R2; 11-15: IP_3R3, R-α1E, Ryr1, Ryr2, and N-α1B; M: 100 bp ladder marker, (bottom band, 100 bp; the expression profile of INS-1 is the same as for rat β cells, not shown); B: L-α-S, L-α1F, and Ryr1 expressed in rat heart and skeletal muscle. 1-3: L-α-S (cDNA of skeletal muscle), L-α1F (heart), and Ryr1 (cDNA of skeletal muscle); M: 100 bp ladder marker; bottom band of M, 100 bp.

are composed of multiple tissues, including muscles, blood vessels, and nerve fibers (Figure 1B). It was found that 12 subunit types were expressed in INS-1 and rat pancreatic β cells (Table 2): L-type (α1C, α1D subunits), R-type (α1E subunit), and N-type (α1β subunit) preferentially in INS-1 cells; Ryr2, TRPC1, TRPC4α, TRPC4β, TRPM2, IP_3R1, IP_3R2, and IP_3R3 preferentially in β cells.

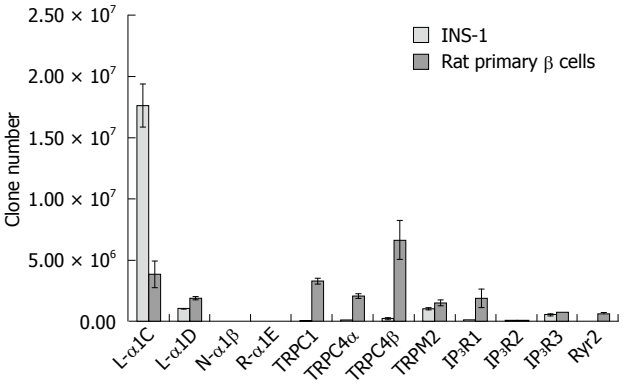

Figure 2 Expression level of 12 Ca^{2+} channel subunits in INS-1 and rat primary β cells.

mRNA level of Ca^{2+} channel subunits in INS-1 and rat pancreatic β cells

Melt curve analysis of all subunits revealed that there was a single peak at the expected melting temperature for PCR applications. The absolute real-time quantitative PCR analyses showed (Table 2, Figure 2) that, in INS-1, L-type α1C subunits were dominant and were expressed significantly more than other subunits. The R-α1E subunit was expressed at a very low level as in the β cells. In the latter cells, the expression levels of subunits were relatively similar, but the expression of Ryr2, TRPC1, TRPC4α, TRPC4β, TRPM2, and IP_3R1 were significantly higher than in INS-1.

DISCUSSION

As important regulatory factors in insulin secretion, Ca^{2+} channels have potential as targets for developing new T2DM therapies. Considering the variety of Ca^{2+} channel subunits present in different cell clones and species, the aim of this study was to perform a systematic identification of Ca^{2+} channel subunits in INS-1 and rat pancreatic β cells. Collectively, 12 of 15 subunit types were found to be expressed in INS-1 and primary rat islet β cells. The L-type α1C subunit expression exceeded that of α1D 10-fold in INS-1 cells, but only 2-fold in the β cells. These results were similar to recent research in INS-1 832/12 cells which confirmed that α1C subunit expression exceeded that of the α1D subunit by two-fold and that the α1C subunit had a critical role in insulin secretion[18]. The L-type α1C subunit performs a special function in the first phase of insulin secretion and glucose tolerance. In mice, α1C subunit deficiency decreased the whole-cell Ca^{2+} current by about 45% and abolished the first phase of insulin secretion, resulting in glucose intolerance[19]. In the present study, L-type α1C subunits were dominant among all subunit expressions, which was in accordance with its important biological function in both INS-1 and rat β cells. The L-type α1D subunit's roles in insulin secretion or proliferation were not confirmed until recently[18,20-22].

The expression of the non-voltage-operated Ca^{2+} channel subunits Ryr2, TRPC1, TRPC4α, TRPC4β, and IP_3R1 in rat β cells exceeded those in INS-1 by 10-fold and TRPM2 expression was not significantly different between the β cells and INS-1. These results suggested that non-voltage-operated Ca^{2+} channels may have a greater role in regulating insulin secretion in comparison with voltage-dependent Ca^{2+} channels. The expression level of the TRPC4β subunit was dominant in the β cells and, as a member of the TRPC subfamily, TRPC4 shows four protein motifs (M1-M4) characteristic of the TRPC sub-family[23]. Specifically, TRPC4β lacks 84 amino acids in the C-terminus, which corresponds to putative binding sites for calmodulin and IP_3 receptors in TRPC4α. The ionic channels formed by TRPC4 appear to be Ca^{2+}-permeable, but there is a considerable discrepancy in the degree of Ca^{2+} selectivity. Studies with mice lacking TRPC4 suggest an important role for TRPC4 in supporting Ca^{2+} entry[24]. The defect in Ca^{2+} entry in TRPC4-/- mice appears to be associated with a reduction in arterial vasorelaxation, vascular permeability in the lung, and neurotransmitter release from thalamic dendrites[25]. Though the expression levels of subunits observed here were not absolutely coupled with their functions, the present results suggested that TRPC4β may be performing some functions in insulin biphasic secretion and that further clarification is needed.

The insulin-secreting INS-1 cell line was established by dispersion of a radiation-induced insulinoma from NEDH rats in 1992[15]. INS-1 cells can respond to glucose and are generally considered to be a β cell model, but an important drawback to this cell line is its polyclonal nature reflected by the presence of glucose-responsive and glucose-unresponsive subpopulations[26]. As was demonstrated here, there was a significant difference in the levels of expression of Ca^{2+} channel subunits between INS-1 and β cells, which probably reflected differences in the intracellular metabolism and/or secretory pathways. Taken together, these INS-1 cells may not have represented an exclusively insulin-producing β cell line.

The present study systematically identified the expression profile of Ca^{2+} channel subunits in INS-1 cells and rat pancreatic β cells and quantitatively characterized them by direct comparison. These results will be helpful in advancing the understanding of Ca^{2+} channel subunits and their roles related to insulin secretion.

ACKNOWLEDGMENTS

We thank Professor Tao Xu (Institute of Biophysics, Chinese Academy of Sciences, China) for kindly providing us with INS-1 cell lines.

COMMENTS

Background

The proportion of people with type 2 diabetes has increased throughout the world. It is now recognized that abnormal insulin secretion precedes the onset of type two diabetes. Ca^{2+} channels have important roles in the progress of insulin secretion by β cells.

Research frontiers

Ca^{2+} channels are composed of several subunits and mainly control Ca^{2+} influx through different mechanisms because of different patterns of subunit composition. In islet β cells, the expression profile of these subunits has not

been systematically investigated. In this study, the authors systematically identified the expression of Ca^{2+} channels in primary β cells and INS-1, an insulin-secreting rat cell line.

Innovations and breakthroughs

This is the first study to report the expression profile of Ca^{2+} channel subunits in primary rat pancreatic β cells and INS-1. Furthermore, the real time PCR data suggested that the INS-1 cell line was not an ideal β cell bioelectrical model.

Applications

By understanding which types of Ca^{2+} channels are expressed in rat β and INS-1 cells, this study may have advanced the understanding of the possible functions of various Ca^{2+} channels in insulin secretion and provided clues to the physiopathology of diabetes.

Terminology

Ca^{2+} channels provide pores for the passive diffusion of ions across biological membranes, in particular Ca^{2+}. β cells are the unique cells of insulin production, and the INS-1 is an insulin-secreting cell line established by dispersion of a radiation-induced insulinoma from NEDH rats in 1992.

Peer review

This is an interesting study, the authors identified the expression profile of Ca^{2+} channel subunits in the INS-1 cell line and rat pancreatic β cells, by reverse transcription polymerase chain reaction.

Abstract

AIM: To measure the normal space between the posterior wall of the vagina and the anterior wall of the respectively rectum using computed tomography (CT) and reveal its were relationship to rectocele.

METHODS: A total of twenty female volunteers without rectocele were examined by CT scan. We performed a middle level continuous horizontal pelvic scan from the upper part to the lower part and collected the measurement data to analyze the results using *t*-test.

RESULTS: Twenty volunteers were enrolled in the study. The space between the posterior wall of the vagina and the anterior wall of the rectum was measured at three levels (upper 1/3, middle, lower 1/3 level of vagina). The results showed that the space from the posterior wall of the vagina to the anterior wall of the rectum at the upper 1/3 level and the middle level was 3.896 ± 0.3617 mm and 4.6575 ± 0.3052 mm, respectively. When the two groups of data were compared, we found the space at the upper 1/3 level was shorter than at the middle level ($P < 0.01$). Moreover, at the lower 1/3 level the space measured was 10.058 ± 0.4534 mm. The results revealed that the space at the lower 1/3 level was longer than that at the middle level ($P < 0.01$).

CONCLUSION: These measurement data may be helpful in assessing rectocele clinical diagnosis and functional outcomes of rectocele repair.

INTRODUCTION

Rectocele (herniation of the anterior rectal wall into the posterior wall of vagina) is a common problem in women. Nichols and Genadry[1] and Pucciani[2] divided rectocele into those with chronic evacuation difficulty and normal genital position (type 1, distension rectocele) and those associated with genital organ prolapse (type 2, displacement rectocele). It has been suggested that these two types have different anatomical, clinical, and therapeutic methods. In the past few decades, several techniques have been proposed for treating rectocele. In some mild cases, conservative management succeeded. If conservative management failed to relieve symptoms, surgical treatment was advocated. Endorectal rectocele repair has been performed by colorectal surgeons[3-5]. However, after endorectal repair difficult evacuation has been reported[6,7]. Transvaginal rectocele repair has been performed mainly by gynecologists using posterior colporrhaphy[8,9]. These methods included plication of the levator muscles, strengthening of the rectovaginal septum and closure of the specific defect of the rectovaginal facia. Transvaginal repair has been criticized because of sexual discomfort. The aim of the present study was to measure the normal spaces between rectum and vagina using computed tomography (CT). To our knowledge, data on the normal space between rectum and vagina was lacking. This information should prove beneficial not only to rectocele repair but also to the correction of genital organ prolapse.

MATERIALS AND METHODS

Twenty female volunteers without rectocele were examined by CT (SIEMENS SOMATOM spirit, JAPAN) scan in Tianjin HongQiao hospital. Their mean age were 42.5 years (range 32-48 years). They were placed in the supine position, and received continuously horizontal pelvic scan from the upper part of the vagina to its lower part. This scanning was performed with a slice thickness of 8.0 mm and collimation of 4.0 mm. We used CT to reconstruct the images on three planes (upper, middle, lower level of the vagina) and measured the vertical space from the posterior wall of the vagina to the anterior wall of the rectum. We collected the measurement data and used *t*-test to analyze the results.

RESULTS

We measured the space between the posterior wall of the vagina and the anterior wall of the rectum of the volunteers at three levels (upper 1/3, middle, lower 1/3 level of the vagina) and collected data. The data was divided into three groups. The first group was measured at the upper 1/3 level of the vagina (Figure 1A), the second group was acquired at the middle level of the vagina (Figure 1B) and the third group was measured at the lower 1/3 level of the vagina (Figure 1C). The two-samples mean *t*-test was used to study differences between groups. Table 1 showed the data describing the distance between the posterior wall of the vagina and the anterior wall of the rectum at three levels (upper 1/3, middle, lower 1/3 level of the vagina). Table 2 presented the comparison of space size between the upper 1/3 level of the vagina and the middle level of the vagina and the comparison of space size between the middle level of the vagina and the lower 1/3 level of the vagina. Data was expressed as mean ± SD, and statistical significance was considered present when $P < 0.01$. In Table 2, the results showed the space from the posterior wall of the vagina to the anterior wall of the rectum was longer at the middle level of the vagina than at the upper 1/3 level of vagina ($P < 0.01$) and was shorter at the middle level of the vagina than at the lower 1/3 level of the vagina ($P < 0.01$).

DISCUSSION

Rectocele is defined as herniation of the anterior rectal wall into the posterior vaginal wall. Rectoceles may be classified according to their position (low, middle, high); size (small < 2 cm, medium 2-4 cm, large > 4 cm); degree (type 1, type 2). The classifications of position and size are pure an anatomical description. However, the degree type could lead surgeons to make different decisions for management, which were proposed by Nichols and Pochak[1] and Pucciani[2]. Although it was a well-known fact that rectocele results from the weakness of the rectovaginal septum, there was a long-standing debate about the rectovaginal septum because of several early anatomical studies unable to determine the presence of rectovaginal septum. In 1970, Nichols *et al*[10] were able to identify a definitive anatomical and histological facial structure between the rectum and vagina in all dissections. Delancey[11,12] confirmed the fibers of rectovaginal septum ran vertically and blended with the muscular wall of the vagina. He also demonstrated the presence of some other posterior vaginal wall supporting structures which include the endopelvic facia, levator anti muscle and perineal membrane. In our study, we measured the distance between the posterior wall of the vagina and the anterior wall of the rectum (Tables 1 and 2). The results showed the distance becomes wider leading from top to bottom (Figure 1). The data also revealed that the rectovaginal septum becomes gradually thicker leading from top to bottom because the septum is the main portion between the gap from vagina to rectum. Based on these

Table 1 Data on the space between the vagina and the rectum at three levels (mm)

Table 2 Comparison of the space difference at the upper 1/3 level of the vagina, the middle level of the vagina and the lower 1/3 level of the vagina

	Group 1 (n = 20)	Group 2 (n = 20)	Group 3 (n = 20)	*P* value
mean ± SD (mm)	3.896 ± 0.3617	4.6575 ± 0.3052	10.058 ± 0.4534	$P < 0.01$

measurement findings, it seemed that the higher position rectocele occurred more easily.

Although the true incidence of rectocele in the general population is uncertain, it has been found in 20%-80% of women referred to pelvic floor clinics[13]. The difficulties in diagnosis are not only because early rectocele is asymptomatic, but also because the dominant symptoms of rectocele are complex. Shorvon and colleagues[14] defined the rectocele depth exceeding 1 cm as pathological rectocele. At this stage, it is possible that patients have no sensation of difficulty in evacuation, constipation and so on. As a result , some early rectocele patients may be neglected. This study investigated the size of the normal space between the posterior wall of the vagina and the anterior wall of the rectum (Table 1). The study may be useful in the early diagnosis of rectocele by comparison of the patient's data with normal data.

The surgical indications for rectocele repair are controversial. Most surgeons advocated operative repair if the quality of life of the patient was affected, for instance they had a large symptomatic rectocele and failed to empty sufficiently. Surgery for rectocele repair included several different techniques using different approaches, ranging from the endorectal to the perineal or vaginal route[15,16]. Endorectal rectocele repair was developed by Sullivan[17]; it's advantages included an ability to deal with coincident anorectal pathology (in particular hemorrhoids and anterior mucosal rectal prolapse), with a definitive defect-specific septal repair and excision of the redundant rectal mucosa. The transperineal rectocele repair was described by Watson[18]; this method has been used to restore the anatomical pelvic floor structures and repair the rectovaginal septum. The traditional transvaginal approach was developed further into posterior colpoperineorrhaphy by Helgar. This surgery technique was used for all forms of genital and related rectal prolapse. However, this procedure destroyed the perineal body and created a tight band inside the vaginal introitus. We also observed the perineal body at the lower 1/3 level of the vagina (Figure 1C), which joined together the distal part of transvaginal septum. It is obvious that the whole perineal body is an important pelvic floor supporting structure. However, all these surgery techniques have been reported to produce some postoperative symptoms. For example, the difficult evacuation has been reported with endorectal repair. Transvaginal repair and transperineal repair have also been criticized because of sexual discomfort. A combination of the three surgery techniques was popularized recently. This produced a strong rectovaginal septum to avoid rectocele and also eliminated postoperative symptoms. Furthermore, the anatomical restoration of normal space between the rectum and vagina is key to resolving complex postoperative symptoms, e.g. difficult evacuation, sexual discomfort and so on. There is limited measurement data available relating to the space between the rectum and the vagina, which can be helpful for surgeons in assessing clinical diagnosis and functional outcomes of different types of rectocele repair. The present study provides measurement data on the normal space between rectum and vagina which may be useful for assessing clinical diagnosis of rectocele and functional outcomes of rectocele repair.

COMMENTS

Background

Rectocele is a common problem in females. In the past few decades, several techniques have been proposed for treating rectocele. However, it is difficult to diagnose rectocele early because there is no data on the normal size of the space between the rectum and vagina. There are several different techniques available for repair of rectocele, but they are associated with some postoperative symptoms. This study may be helpful for surgeons in assessing clinical diagnosis and functional outcomes of different types of rectocele repair.

Research frontiers

Surgery for rectocele repairs includes several different techniques using different approaches, ranging from the endorectal to the perineal or vaginal route. Nowadays a combination of the three surgery techniques is popular, which not only produces a strong rectovaginal septum to avoid rectocele but also eliminates postoperative symptoms.

Innovations and breakthroughs

This study revealed that the rectovaginal septum becomes gradually thicker going from top to bottom. Furthermore, based on these measurement findings, surgeons could assess clinical diagnosis and functional outcomes of different types of rectocele repair.

Terminology

Rectocele can be defined as herniation of the anterior rectal wall into the posterior vaginal wall.

Peer review

The manuscript is simple, but important for colorectal surgeons, gynecologists and general surgeons who daily manage this disease.

Abstract

AIM: To investigate immunosuppressive agents used to treat inflammatory bowel disease (IBD) in East China.

METHODS: A retrospective review was conducted, involving 227 patients with IBD admitted to Sir Run Run Shaw Hospital, College of Medicine, Zhejiang University from June 2000 to December 2007. Data regarding demographic, clinical characteristics and immunosuppressants usage were analyzed.

RESULTS: A total of 227 eligible patients were evaluated in this study, including 104 patients with Crohn's disease and 123 with ulcerative colitis. Among the patients, 61 had indications for immunosuppressive agents use. However, only 21 (34.4%) received immunosuppressive agents. Among the 21 patients, 6 (37.5%) received a subtherapeutic dose of azathioprine with no attempt to increase the dosage. Of the 20 patients that received immunosuppressive agent treatment longer than 6 mo, 15 patients went into remission, four patients were not affected and one relapsed. Among these 20 patients, four patients suffered from myelotoxicity and one suffered from hepatotoxicity.

CONCLUSION: Immunosuppressive agents are used less frequently to treat IBD patients from East China compared with Western countries. Monitoring immunosuppressive agent use is recommended to optimize dispensation of drugs for IBD in China.

Key words: Inflammatory bowel disease; Immunosuppressive agents; Azathioprine

INTRODUCTION

Inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), is a chronic disorder of the gastrointestinal tract. There have been no large scale epidemiological studies on the incidence and prevalence of IBD in China, but reports indicate that rates are increasing. According to data collected from multiple hospitals, the prevalence rate of UC and CD can be speculatively estimated to be $11.6/10^5$ and $1.4/10^5$, respectively; however, the numbers may be underestimated[1]. An investigation from one hospital showed that the definitive cases of IBD during the past 10 years have increased five-fold[2].

Immunosuppressive agents, such as Azathioprine (AZA), play an essential role in drug therapy of IBD. Evidence-based medicine has shown that immunosuppressive agents can control active inflammation, allow for the withdrawal of steroids, and ultimately maintain long-term remission of IBD[3-5]. However, great interpatient variability has been found when assessing the efficacy and toxicity of these drugs. In the treatment of active disease, about 2/3 of the patients achieve remission, but this results is not achieved in approximately 15% of cases, and serious

drug toxicity leads to cessation of therapy in 9%-28% of patients, such as myelotoxicity and hepatotoxicity[6,7]. Uncertainty regarding the risk of interpatient variability and serious drug toxicity prevent the use of AZA and other immunosuppressants, and therefore affects the quality of care in IBD patients. Domestically, the paradox is quite a problem. Currently, there are no reports about the status of usage of AZA and other immunosuppressive agents in Chinese IBD patients.

Sir Run Run Shaw Hospital is a teaching hospital affiliated to Zhejiang University, China. Together with 12 other large hospitals and numerous smaller district hospitals, it provides health care to 48 million people living in Zhejiang Province in eastern China. Our IBD study group has set up an IBD database to collect IBD patients' data in East China. The purpose of the current study was to do a retrospective study of the therapeutic status of immunosuppressive agents, such as AZA used in patients with IBD in hospitals, to investigate the therapeutic implications of IBD in eastern China, to arouse the attention of clinicians, to apply immunosuppressive drugs optimally and to enhance the quality of therapy delivered to IBD patients.

MATERIALS AND METHODS

Subjects

IBD patients admitted to Sir Run Run Shaw Hospital, College of Medicine, Zhejiang University, from June 2000 to December 2007, were enrolled in this study.

The diagnosis of IBD was confirmed by the criteria established by Chinese Society of Gastroenterology[8] in 2000 and the guidelines issued by the Clinical Services Committee of the British Society of Gastroenterology (BSG)[9] in 2004. Patients not under the care of a gastroenterologist were excluded.

Data collection

A retrospective review was performed. Clinical data on demographic information, clinical characteristics of IBD patients, as well as endoscopic, radiologic, surgical and pathological records, confirmed diagnoses, duration and severity of disease, and use of immunomodulatory agents were collected from the inpatient and follow-up clinic visit records and collated in an IBD database.

Statistical analysis

The data were expressed as mean values, and the enumeration data were expressed by percentages. All statistical analyses were performed by SPSS V 13.0 (Statistical Product and Service Solutions).

RESULTS

Patient characteristics

According to the inclusion and exclusion criteria, 104 patients with CD and 123 patients with UC were enrolled in the study. All the patients were Han Chinese.

UC was categorized by extent, activity and severity of disease. Extent of disease at diagnosis was defined macroscopically by the proximal limit of inflammation at colonoscopy and was divided into the following four categories: (1) Proctitis, inflammation confined to the rectum only; (2) Distal colitis, inflammation involving to the rectum and sigmoid colon; (3) Left-sided colitis, inflammation extending the rectum to and including the splenic flexure; (4) Extensive colitis, inflammation proximal to the splenic flexure.

Patients with Crohn's disease were classified by age of onset, disease location and behaviour according to the Vienna classification[10]. Disease activity was assessed using the Harvey-Bradshaw index (HBI) for CD and the Sutherland index for UC. Active disease was defined as a HBI value $\geqslant$ 5 or a Sutherland index $\geqslant$ 3. Severity was broadly divided into mild, moderate or severe according to the Truelove & Witts' criteria for UC and the criteria established by the Chinese Society of Gastroenterology for CD.

Severe UC was defined as the passage of $\geqslant$ 6 bloody stools daily with one or more of the following criteria: temperature > 37.8℃, pulse > 90/min, haemoglobin < 10.5 g/dL, or erythrocyte sedimentation rate (ESR) > 30 mm/h[11].

Mild CD was defined when the patient had no fever, abdominal tenderness, abdominal mass and obstruction, while severe CD was defined when the patient had persistent high fever, weight loss, nausea, vomiting, abdominal pain, diarrhea, anemia, and complications. Characteristics of the patients and the information about the location of disease are given in Table 1.

Table 1 Clinical characteristics of the study population

	Crohn's disease	Ulcerative colitis
Number of patients	104	123
Female	42 (40.4%)	56 (45.5%)
Age (yr)	36 (13-70)	45 (15-80)
Disease duration (yr)	4.8 (0.5-24)	5.5 (0.5-23)
Non-smoking	82 (78.8%)	90 (73.2%)
Severity, *n* (%)		
Mild	24 (23.1)	62 (50.4)
Moderate	51 (49)	42 (34.1)
Severe	29 (27.9)	19 (15.5)
Disease distribution, *n* (%)		
Small intestine	44 (42.3)	
Ileum and colon	17 (16.3)	
Colon	40 (38.5)	
Upper digestive tract	3 (2.9)	
Disease distribution (UC), *n* (%)		
Distal colon		41 (33.3)
Left side colon		24 (19.5)
Systemic or pan-colon		58 (47.2)
History of any intestinal operation	46 (44.2)	5 (4.1)

Of the 227 patients, 61were administered immunosuppressant agents. Among these patients 27 (44.3%) were steroid-dependent (refers to a relapse when the steroid dose is reduced below 20 mg/d, or within 6 wk of stopping steroids), 6 (9.8%) were steroid-refractory (refers to active disease in spite of an adequate dose and duration of prednisolone > 20

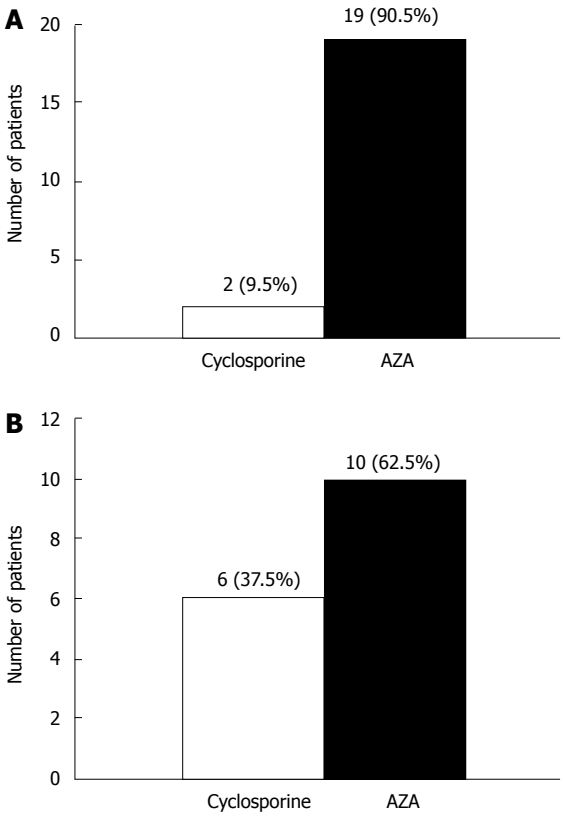

Figure 1 Drug therapeutic status of IBD patients who received immunosuppressant therapy. A: Twenty one IBD patients; B: AZA therapeutic status of 16 IBD patients.

mg/d for more than 2 wk) and 28 (45.9%) had post-surgery fistulating CD. Twenty-one patients (21/61, 34.4%) received immunosuppressive agents (19 cases with AZA, two cases with cyclosporin) as shown in Figure 1A. The mean dose of AZA was 1.47 mg/kg per day (range 0.83-2.22 mg/kg per day). A suboptimal dose of AZA was defined as a dose less than 1.5 mg/kg per day in the absence of myelotoxicity or hepatotoxicity. AZA-related myelotoxicity is defined as WBC $< 3.0 \times 10^9$/L or neutrophil $< 1.5 \times 10^9$/L, while AZA-related hepatotoxicity is defined as ALT and/or GGT levels greater than 5 times the upper normal limit, or ALP levels greater than 3 times the upper normal limit, excluding viral hepatitis. When withdrawing AZA or reducing the dose, the above indexes recover to normal. According to this criterion, among the 19 patients treated with AZA, there were two with myelotoxicity and one with hepatotoxicity, before the clinician adjusted the dosage. The other 16 residual cases received AZA therapy, and six of those cases (37.5%) received subtherapeutic therapy, with no attempt to increase this dosage (Figure 1B).

Therapeutic circumstances and adverse reactions in patients receiving immunosuppressant therapy

Of the 21 patients administered immunosuppressant therapy, 21 patients maintained these regimen for more than 6 mo, and one patient withdrew from drug without a recommendation by a clinician 3 mo later.

The effectiveness of the immunosuppressant therapy (disease remission) is defined as follows: for Crohn's disease, the HBI value was less than five or for UC the Sutherland index was less than three. According to this definition, of the 20 patients who received immunosuppressant therapy for more than 6 mo, 15 (75%) patients went into remission, four (20%) patients had no benefit and one (5%) relapsed.

According to the definitions of AZA-related myelotoxicity and hepatotoxicity, four (20%) patients suffered from myelotoxicity (two cases occurred within 3 mo after receiving AZA therapy; one case each occurred one and two years after drug therapy) and one (5%) patient suffered from hepatotoxicity.

DISCUSSION

IBD, which includes CD and UC, is a complicated disease of the digestive tract. In recent years, because of the rapid development of evidence-based medicine, the therapy guidelines of IBD in China and abroad have been updated constantly. Reddy *et al*[12] analyzed the therapeutic condition of American patients with IBD according to the American College of Gastroenterology (ACG) practice guidelines[13,14]. They found that the dose of aminosalicylic acid agents was not adequate and enema therapy and immunosuppressive agents were not applied effectively[13,14]. With the lack of relative data in China, we carried out this study to reflect the current therapeutic condition of patients with IBD in eastern China.

Although glucocorticoids are effective in the induction of remission for IBD, more than 20% of patients may be steroid-refractory or become steroid-dependent[15-17]. Meta-analyses showed that glucocorticoids are not effective for medical maintenance. The frequency and severity of well-recognized adverse effects also preclude their long-term use.

Immunosuppressive agents such as AZA can induce and maintain remission of IBD and have steroid sparing effects in patients who are steroid dependent or who have refractory IBD[7,18-20].

In our study, the use of immunosuppressive agents was restricted to a minority of IBD patients (19.6%) who adapted to use these drugs, which is distinctly less frequent compared with that in Western countries. Furthermore, more than half of the patients did not receive recommended doses of AZA. We found that the percentage of serious drug toxicity was 5/20 in AZA therapy. Because of the lack of data from large-scale studies in China, the adverse reaction rate of AZA in Han nationality Chinese with IBD is not clear. Results of our study are consistent with the conclusions reported outside of China[21].

At present, many researchers presume that interpatient and interracial variability, which are based on thiopurine methyltransferase (TPMT) gene polymorphisms and enzyme activity, exist and affect the efficacy and toxicity of AZA. Whether TPMT gene

polymorphisms and enzyme activity have their own characteristics in this Han Chinese population, and how they affect the efficacy and toxicity of drug still remains to be seen. Because large-scale studies in China are not available, we do not have relevant data about TPMT gene polymorphisms and enzyme activity, relative studies about the efficacy and toxicity of drugs when given with TPMT, relevant screening methods for high risk groups before using drug or relative monitoring methods for the efficacy and toxicity of drug. Serious drug toxicities, such as myelotoxicity and hepatotoxicity, deter the use and prevent achieving the optimal dose of immunosuppressive agents by clinicians. Experience abroad has shown that AZA can be safely used for treatment of IBD[22-24].

Recently, TPMT and its genotype have been applied to predict the efficacy and toxicity of drugs, which can provide some guidance for clinicians and reduce the incidence of drug toxicity in Western countries[25-29]. Meanwhile, studies have shown that examining TPMT enzyme activity may decrease the overall medical cost in Europe and America[30,31].

Therefore, developing a study of TPMT polymorphisms and enzyme activity in Han nationality Chinese with IBD and clarifying the correlation between the efficacy and toxicity of drugs and TPMT will provide theoretical evidence for the clinical application of immunosuppressive agents, such as AZA. Developing techniques to examine TPMT polymorphisms and enzyme activity, as well as concentrations of AZA's metabolites, will be helpful to screen patients in high risk groups, reduce the incidence of toxicity because of drugs, improve the rationality and reliability of pharmacotherapy, setup an individualization of therapeutic schedules, and broaden the therapeutic modalities for IBD patients.

ACKNOWLEDGMENTS

The authors thank the patients for their participation in this study, and acknowledge the contribution of all the doctors and nurses in the GI department of the Sir Run Run Shaw Hospital for collecting the data.

COMMENTS

Background

Immunosuppressive agents are well established in the treatment of inflammatory bowel disease. The goals of using this class of medication are to control active inflammation, allow for the withdrawal of steroids, and ultimately to maintain long-term remission of inflammatory bowel disease (IBD).

Research frontiers

Immunosuppressive agents, such as Azathioprine (AZA), play an essential role in the pharmacotherapy of IBD. Evidence-based medicine proved that immunosuppressive agents such as AZA can induce and maintain remission of IBD and have steroid sparing effects in patients who are steroid dependent or who have refractory IBD. However, experience abroad has shown great interpatient variability in the efficacy and toxicity of these drugs.

Innovations and breakthroughs

The use of immunosuppressive agents in IBD patients in China has not been reported. The authors designed this study to address this problem and provide data to improve the quality of IBD treatment in China.

Peer review

This is an important study and interesting topic, especially for an Asian readership.

Abstract

AIM: To observe the hepatic injury induced by carbon dioxide pneumoperitoneum in rats and to explore its potential mechanism.

METHODS: Thirty healthy male SD rats were randomly divided into control group (n = 10), 0 h experimental group (n = 10) and 1 h experimental group (n = 10) after sham operation with carbon dioxide pneumoperitoneum. Histological changes in liver tissue were observed with hematoxylin-eosin staining. Liver function was assayed with an automatic biochemical analyzer. Concentration of malonyldialdehyde (MDA) and activity of superoxide dismutase (SOD) were assayed by colorimetry. Activity of adenine nucleotide translocator in liver tissue was detected with the atractyloside-inhibitor stop technique. Expression of hypoxia inducible factor-1 (HIF-1) mRNA in liver tissue was detected with *in situ* hybridization.

RESULTS: Carbon dioxide pneumoperitoneum for 60 min could induce liver injury in rats. Alanine aminotransferase and aspartate aminotransferase were 95.7 ± 7.8 U/L and 86.8 ± 6.9 U/L in 0 h experimental group, and 101.4 ± 9.3 U/L and 106.6 ± 8.7 U/L in 1 h experimental group. However, no significant difference was found in total billirubin, albumin, and pre-albumin in the three groups. In 0 h experimental group, the concentration of MDA was 9.83 ± 2.53 μmol/g in liver homogenate and 7.64 ± 2.19 μmol/g in serum respectively, the activity of SOD was 67.58 ± 9.75 nu/mg in liver and 64.47 ± 10.23 nu/mg in serum respectively. In 1 h experimental group, the concentration of MDA was 16.57 ± 3.45 μmol/g in liver tissue and 12.49 ± 4.21 μmol/g in serum respectively, the activity of SOD was 54.29 ± 7.96 nu/mg in liver tissue and 56.31 ± 9.85 nu/mg in serum, respectively. The activity of ANT in liver tissue was 9.52 ± 1.56 in control group, 6.37 ± 1.33 in 0 h experimental group and 7.28 ± 1.45 (10^{-9} mol/min per gram protein) in 1 h experimental group, respectively. The expression of HIF-1 mRNA in liver tissue was not detected in control group, and its optical density difference value was 6.14 ± 1.03 in 0 h experimental group and 9.51 ± 1.74 in 1 h experimental group, respectively.

CONCLUSION: Carbon dioxide pneumoperitoneum during the sham operation can induce hepatic injury in rats. The probable mechanisms of liver injury include anoxia, ischemia reperfusion and oxidative stress. Liver injury should be avoided during clinical laparoscopic operation with carbon dioxide pneumoperitoneum.

INTRODUCTION

Along with the utilization of laparoscope in surgery,

more and more patients can recover with less injuries and complications. However, laparoscopic operation is always limited due to exposure of the organs. Although carbon dioxide pneumoperitoneum is a desirable method to assist in exposing abdominal organs, the high pressure of carbon dioxide in abdominal cavity has some potential side effects, such as impairment of liver, kidney and heart functions[1-3]. Some researches revealed that the continuous high pressure from carbon dioxide during laparoscopic operation can result in ischemia injury in multiple organs, and the longer the operation lasts, the severer the injury is[2]. One of the important reported mechanisms of liver injury is ischemia reperfusion[1,2]. This study was to observe whether sham operation with carbon dioxide pneumoperitoneum causes liver injury and to explore its probable mechanism.

MATERIALS AND METHODS

Animals

Thirty healthy male SD rats were randomly divided into control group (n = 10), 0 h experimental group (n = 10), and 1 h experimental group (n = 10) after sham operation with carbon dioxide pneumoperitoneum. All experimental rats received sham operation for 1 h. Rats in the two experimental groups accepted carbon dioxide pneumoperitoneum during operation. The pressure of carbon dioxide was 15 mmHg. Liver tissue and serum were collected for further test.

Reagents

Oligo-nucletide probe of hypoxia inducible factor 1 (HIF-1) mRNA was produced by Shanghai Shenneng Biotechnology Company (China). ^{3}H-ADP and atractyloside (ATR) were obtained from Sigma Company (USA).

Methods

All rats were anaesthetized with pentobarbital sodium muscular injection. Rats in the two experimental groups received carbon dioxide pneumoperitoneum for 1 h during sham operation. Rats in the control group only underwent sham operation for 1 h. Blood samples and liver tissues were taken immediately from rats in 0 h experimental group and control group, and from rats in 1 h experimental group after sham operation, respectively. Liver function was detected with an automatic biochemistry analyzer. Histological changes in liver tissue were observed with hematoxylin-eosin (HE) staining under optical microscope. Concentration of malonyldialdehyde (MDA) in liver homogenate and serum was measured by thio-barbituric acid colorimetry using a spectrophotometer at the wave length of 532 nm and expressed as μmol/g. Activity of superoxide dismutase (SOD) was detected by xanthine oxidase colorimetry and expressed as nu/mg. Mitochondria in liver tissue were isolated by centrifugation. Activity of ANT in liver tissue was detected with the ATR-inhibitor stop technique. Mitochondria were initiated by adding ^{3}H-ADP and terminated after 12 s by adding ADR. Radioactivity in each group was measured and activity of ANT was expressed as 10^{-9} mol/min per gram protein. Expression of HIF-1 mRNA in liver tissue was detected with *in situ* hybridization (ISH). The results of ISH were quantified with an electronic computer and shown as absorbance (A) value.

Statistical analysis

Experimental data were expressed as mean ± SD. All data were analyzed by t test using SPSS 10.0 statistical software.

RESULTS

Liver function

Liver function in the two experimental groups was disturbed obviously compared with the control group (Table 1). After sham operation with carbon dioxide pneumoperitoneum, the level of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) was 86.8 ± 6.9 U/L and 95.7 ± 7.8 U/L respectively in 0 h experimental group A, which was higher than that in control group (P < 0.05). The level of AST and ALT was 106.6 ± 8.7 U/L and 101.4 ± 9.3 U/L respectively in 1 h experimental group, which was higher than that in control group (P < 0.05). No significant difference was observed in the levels of total bilirubin (TB), albumin (A) and pre-albumin (Pre-A) between the two experimental groups.

MDA concentration and SOD activity in liver homogenate and serum

In control group, the concentration of MDA in liver homogenate and serum was 4.69 ± 1.31 μmol/g and 3.98 ± 1.05 μmol/g, respectively. After sham operation with carbon dioxide pneumoperitoneum, the concentration of MDA in liver homogenate and serum was significantly elevated in the two experimental groups (Table 2), indicating that liver is more susceptible to hypoxia injury. The activity of SOD in control group was 80.56 ± 12.43 nu/mg in liver homogenate and 75.66 ± 11.35 nu/mg in serum, respectively. The activity of SOD in liver homogenate and serum was significantly decreased in the two experimental groups (P < 0.05), demonstrating that more oxygen radicals are produced in the two experimental groups and SOD is consumed after elimination of oxygen radicals.

Histological changes in liver tissue

Liver samples were embedded in paraffin, stained with HE and then observed under an optical microscope. The livers of control group showed a normal lobular architecture with central veins and radiating hepatic cords, indicating that sham operation with routine anesthesia does not cause histopathological damage to liver. Mild hepatic fatty degeneration and necrosis were found in livers of the two experimental groups

Table 1 Changes in liver function (mean ± SD)

Group	TB (μmol/L)	ALT (U/L)	AST (U/L)	A (g/L)	Pre-A (mg/L)
Control	24.5 ± 5.1	48.5 ± 8.2	45.6 ± 7.7	38.5 ± 4.2	203.5 ± 76.4
0 h experimental group	23.1 ± 3.7	95.7 ± 7.8[a]	86.8 ± 6.3[a]	37.4 ± 3.1	195.8 ± 41.5
1 h experimental group	25.8 ± 3.5	101.4 ± 9.3[a]	106.6 ± 8.7[a]	40.6 ± 3.9	182.9 ± 58.4

[a]$P < 0.05$ *vs* control group.

Table 2 MDA concentration and SOD activity in liver homogenates and serum (mean ± SD)

Group	MDA (liver) (μmol/g)	SOD (liver) (nu/mg)	MDA (serum) (μmol/g)	SOD (serum) (nu/mg)
Control group	4.69 ± 1.31	80.56 ± 10.43	3.98 ± 1.05	75.66 ± 9.35
0 h experimental group	9.83 ± 2.23[a]	67.58 ± 9.75[a]	7.64 ± 2.39[a]	64.47 ± 10.23[a]
1 h experimental group	16.57 ± 3.45[a]	54.29 ± 7.96[a]	12.49 ± 4.21[a]	56.31 ± 9.87[a]

[a]$P < 0.05$ *vs* control group.

Table 3 Activity of ANT in mitochondria of liver (mean ± SD)

Group	ANT (10^{-9} mol/min per gram protein)
Control group	9.52 ± 1.76
0 h experimental group	6.37 ± 1.23[a]
1 h experimental group	7.21 ± 1.05[a]

[a]$P < 0.05$ *vs* control group.

(Figure 1A). The hepatic injury was more severe in 1 h experimental group B than in 0 h experimental group, suggesting that carbon dioxide pneumoperitoneum can cause hepatic injury (Figure 1B).

Activity of ANT in mitochondria of liver

In control group, the activity of ANT was 9.52 ± 1.56 (10^{-9} mol ADP/min per gram protein). In 0 h experimental group A, it was only 6.37 ± 1.33 ($P < 0.05$ compared with control group), indicating that energy metabolism in mitochondria of liver is damaged by carbon dioxide pneumoperitoneum. One hour after carbon dioxide pneumoperitoneum, the activity of ANT was slightly increased (7.21 ± 1.05) compared with control group ($P < 0.05$). However, it was lower in 1 h experimental group than in control group, indicating that energy metabolism in mitochondria of liver is recuperated to some extent after sham operation with carbon dioxide pneumoperitoneum (Table 3).

Expression of HIF-1 mRNA in liver tissue

No expression of HIF-1 mRNA was found in liver tissue from control group, indicating that sham operation without carbon dioxide pneumoperitoneum does not cause hypoxia stimulation in liver (Figure 2A). The expression of HIF-1 mRNA was significantly increased in the two experimental groups. The *A* value for HIF-1 mRNA was 6.14 ± 1.03 in 0 h experimental group and 9.51 ± 1.74 in 1 h experimental group ($P < 0.05$). Brown positive particles of HIF-1 mRNA, mainly located in cytoplasm of liver cells, were more in stromal cells than in hepatocytes (Figure 2B). Whether the stromal cells are hepatic stellate cells or endotheliocytes remains unknown. The expression of HIF-1 mRNA was increased more significantly in 1 h experimental group compared with 0 h experimental group, indicating that there exists persistent hypoxia stimulation in liver after carbon dioxide pneumoperitoneum (Figure 2C).

DISCUSSION

Laparoscopic operation, performed frequently in recent years, has many advantages over conventional surgery, such as less injuries and complications. Thus patients who accept laparoscopic operation can recover with a shorter healing time and less operative scars. However, exposure of organs is always not enough. Carbon dioxide pneumoperitoneum is a desirable method to assist in exposing abdominal organs. Some researches have shown that it has some potential side effects, such as impairment of liver, kidney, and heart functions[1-4]. It has been reported that the continuous high pressure from carbon dioxide during laparoscopic operation can result in ischemia injury of multiple organs, and the longer the operation lasts, the severer the injury is[5,6].

In this study, 1 h after sham operation with carbon dioxide pneumoperitoneum, the serum ALT and AST levels were increased while the levels of TB, A and Pre-A were not significantly changed. Since the half life of albumin is 14 d, the reduced albumin level can demonstrate the chronically impaired synthetic function of liver. However, the half life of prealbumin is only 2 d, and accordingly, a low level of prealbumin in serum indicates acute impairment of liver synthetic function. This study showed that liver function injury was not severe enough to cause hypoproteinemia. However, more susceptible markers of the liver function, ALT and AST, demonstrated mild impairment of liver function. It has been shown that necrosis of even a few hepatocytes results in a high level of transaminase[7-10]. In HE stained liver samples, fatty degeneration was found in some hepatocytes, indicating that ischemia or anoxia occurs during sham operation with carbon

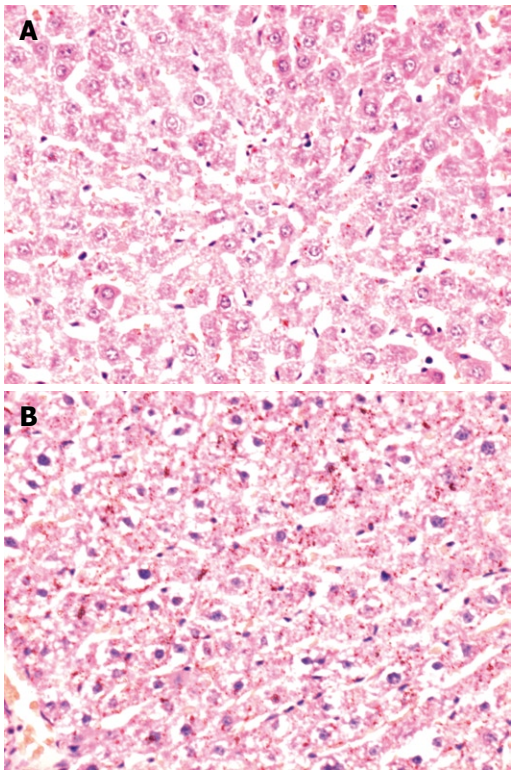

Figure 1 Liver injury in 0 h experimental group (A) and 1 h experimental group (B).

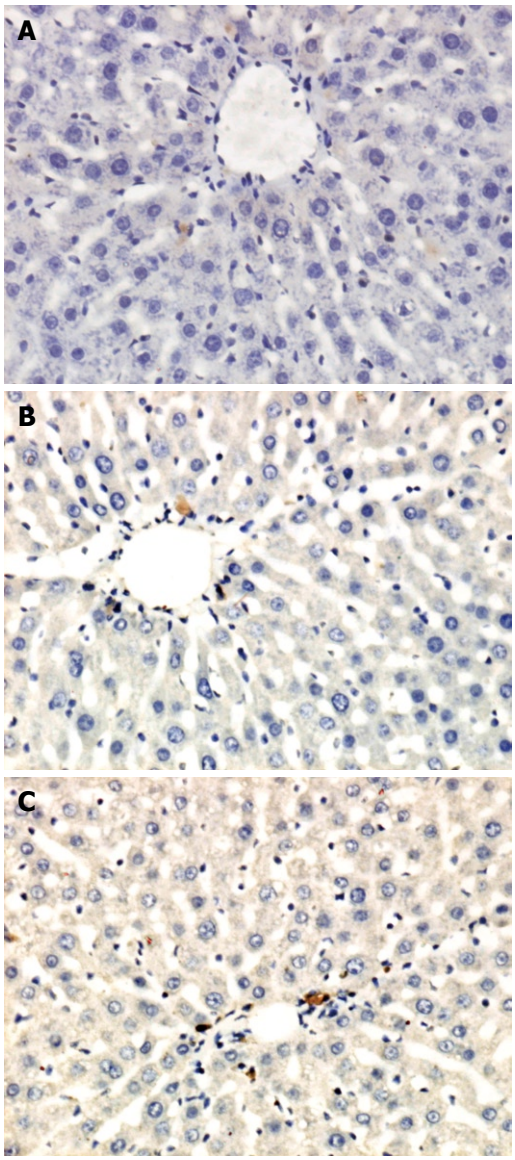

Figure 2 Expression of HIF-1 mRNA in liver tissue from control group (A), 0 h experimental group (B), and 1 h experimental group (C).

dioxide pneumoperitoneum[11]. The elevated expression level of HIF-1 mRNA in liver homogenate further indicates that anoxia injury is induced by carbon dioxide pneumoperitoneum. MDA is the end product of lipid peroxidation. The concentration of MDA in liver homogenate or serum is a direct marker for the level of oxygen radicals. SOD is one of the important scavenger enzymes of oxygen radicals. The activity of SOD would decrease after oxygen radicals are cleaned. In this study, the concentration of MDA was elevated and the activity of SOD was reduced in liver homogenate and serum, indicating that the number of oxygen radicals is increased after carbon dioxide pneumoperitoneum. Since liver is a motochondria-abundant organ, it is more susceptible to hypoxia than other organs. In this study, the activity of ANT, a marker of energy metabolism in mitochondria[12], was reduced after carbon dioxide pneumoperitoneum. The activity of ANT was mildly elevated 1 h after carbon dioxide pneumoperitoneum compared with the control group. It has been shown that blood-supply is obviously decreased in portal vein during carbon dioxide pneumoperitoneum[13]. In addition, hypercapnemia is related to ischemia injury of abdominal organs, while high pressure during operation and immediate relief of carbon dioxide after operation can induce ischemia reperfusion injury of multiple organs and apoptosis of hepatocytes after carbon dioxide pneumoperitoneum[14,15]. In this study, hepatic injury in rats and the possible mechanism of carbon dioxide pneumoperitoneum were elicited. Since pathophysiological changes in rats are not always identical as those in human beings, injury of carbon dioxide pneumoperitoneum should be observed closely in clinical practice. Although impairment of liver function usually does not cause severe complications, it should be alleviated or avoided especially in patients with preceding liver diseases during sustaining laparoscopic operation[16-20]. It has been shown that liver injury is pressure-dependant[21]. The pressure of carbon dioxide used in pneumoperitoneum is 10-12 mmHg, which is higher than that (7-10 mmHg) in the port system[22]. The higher pressure from carbon dioxide influences the systemic and portal blood flow dynamics[23-26], and causes apoptosis of hepatocytes[27,28]. A shorter time or a lower carbon dioxide pressure in pneumoperitoneum might help to alleviate liver injury. Stepwise increasing carbon dioxide insufflation might also be an ischemic preconditioning method to reduce liver injury[29]. Further study is needed on the precise mechanism of carbon dioxide pneumoperitoneum and more effective methods should be found to avoid liver injury[30].

COMMENTS

Background

Along with the utilization of laparoscope and carbon dioxide pneumoperitoneum in surgery, potential side effects of carbon dioxide pneumoperitoneum have been noticed in recent years.

Research frontiers

Some researches have shown that carbon dioxide pneumoperitoneum can induce impairment of liver, kidney, and heart functions. Apoptosis of hepatocytes was observed in this study.

Innovations and breakthroughs

This study showed mild injury of liver function in rats. At the same time, the expression level of hypoxia inducible factor-1 mRNA in liver tissue was increased as an evidence of anoxia in liver.

Peer review

This describes liver injury caused by carbon dioxide pneumoperitoneum in experimental rats. Although the injury does cause significant complications in rats, close attention should be paid to hepatic injury or other injury in clinical practice. The results of this study are of practical values.

Abstract

Iatrogenic perforation of esophageal cancer or cancer of the gastroesophageal (GE) junction is a serious complication that, in addition to short term morbidity and mortality, significantly compromises the success of any subsequent oncological therapy. Here, we present an 82-year-old man with iatrogenic perforation of adenocarcinoma of the GE junction. Immediate surgical intervention included palliative resection and GE reconstruction. In the case of iatrogenic tumor perforation, the primary goal should be adequate palliative (and not oncological) therapy. The different approaches for iatrogenic perforation, i.e. surgical versus endoscopic therapy are discussed.

Key words: Esophageal cancer; Esophageal perforation; Emergency surgery; Stent therapy

INTRODUCTION

Iatrogenic perforation of cancer of the esophagus or the gastroesophageal (GE) junction is a potentially life-threatening complication. Its incidence has increased most likely because of more aggressive palliative endoscopic therapy[1], and the current widespread use of endoscopic ultrasound (EUS) for accurate preoperative staging[2]. Therapy and management, i.e. conservative versus surgical treatment remains controversial, with successful early outcome being described for both approaches[3,4]. Irrespective of the treatment, iatrogenic (or spontaneous) perforation of the tumor has been shown to be a strong negative predictive factor for long-term survival. Therapy should therefore focus on the immediate and efficient control of the perforation (such as drainage, stenting or resection), and on a satisfactory quality of life rather than on oncologically adequate treatment.

CASE REPORT

An 82-year-old man was referred to our department with perforation of a subtotal stenosing adenocarcinoma of the GE junction. Previous symptoms were vomiting and weight loss of 6 kg in the last 6-8 wk. In the initial computed tomography (CT) scan, no signs of distant metastases were present. The patient had a history of tuberculosis 40 years ago, and CT revealed massive pleural calcifications. He was on oral anticoagulation therapy because of paroxysmal supraventricular tachycardia. To complete the staging, EUS was performed after endoluminal dilation of the tumor and passage into the stomach. EUS demonstrated an uT3 stage with suspicious lymph nodes. Following the EUS procedure, the patient developed severe abdominal pain. Subsequent CT showed air in the distal mediastinum, as well as in the retroperitoneal and intraperitoneal space (Figure 1A and B). After referral, the patient presented in a reduced general condition with acute abdomen, and signs of sepsis (tachycardia, hypotension and tachypnea). Infection signs were slightly increased: C-reactive protein 0.6 mg/dL (normal < 0.5 mg/dL), leukocytes 11.0 G/L (normal 4-9 G/L). As a result of the clinical symptoms, free intra-abdominal air, and subtotal stenosing tumor, we decided against initial endoscopic intervention and for immediate

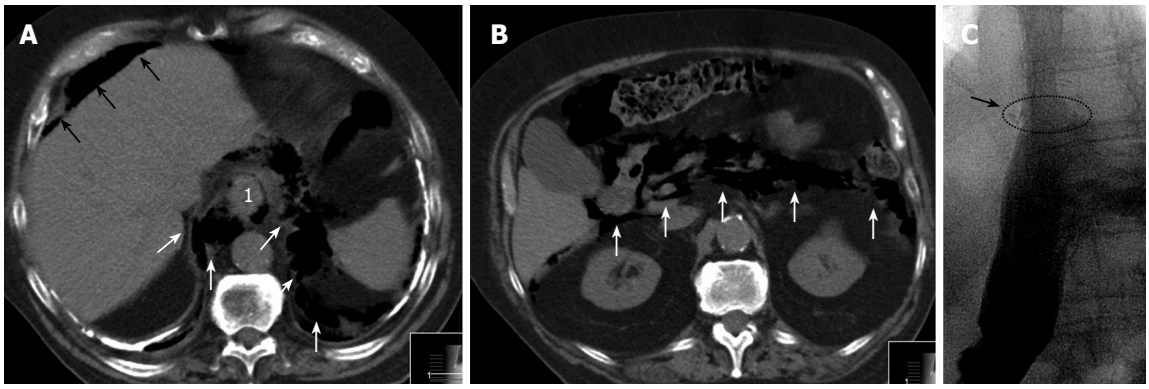

Figure 1 Pre- and postoperative radiographs. A and B: CT scan of the abdomen revealing free intra-abdominal air (A, black arrows) and massive mediastinal (A, white arrows) and retroperitoneal (B, white arrows) air. [1]Depicts the tumor localization at the GE junction; C: Water-soluble contrast medium swallowed after GE reconstruction (end-to-side esophago-gastrostomy) without evidence of anastomotic stenosis or leakage. The circle (arrow) points to the level of the anastomosis.

explorative laparotomy (10 h after the EUS procedure).

Intraoperatively, the tumor was localized exactly at the GE junction, with a dorsal perforation just proximal to the tumor. The tumor was removed completely by resection of the cardia and 5 cm of the distal esophagus. For reconstruction, a partial proximal gastric tube was constructed (20-25 cm in length with a diameter of 4-5 cm) using linear staplers (50 mm Proximate Linear Cutter; Ethicon Endo-Surgery, Inc., Cincinnati, OH, USA). The gastric antrum was opened from the ventral aspect and a circular stapler (25 mm CEEA circular stapler; Covidien Autosuture, Mansfield, MA, USA) was introduced to anastomose the distal esophagus with the proximal ventral portion of the gastric tube. Since the small bowel mesentery was rather short and not mobile, we decided against total gastrectomy and esophagojejunal reconstruction in this emergency situation. An oncological lymph node dissection was not carried out in this elderly and multimorbid patient.

The postoperative course was uneventful. The patient received intravenous antibiotics (imipenem/cilastatin, 3 × 500 mg/d), but no antifungal agent, for 7 d. A water-soluble contrast medium swallow on postoperative day 7 showed no signs of stenosis or anastomotic insufficiency (Figure 1C). The patient was put on full diet following this examination, and was discharged on postoperative day 14. On a further follow-up visit after 4 wk, the patients did not complain of reflux or dysphagic symptoms. Final histopathological examination revealed a perforated pT3 adenocarcinoma of the GE junction. The case was discussed interdisciplinarily, and no additive/palliative therapy was initiated because of the low WHO performance status of 2-3.

DISCUSSION

Perforation in patients with potentially curative resectable cancer of the esophagus or GE junction reduces dramatically the chance of long-term survival. Immediate therapy should target the potential septic focus either by drainage and stenting the lesion, or by resection. Secondary considerations include oncologically adequate treatment and reconstruction of the GE passage that offers the best quality of life.

The approach of conservative versus surgical therapy in cases of iatrogenic perforation has shifted more towards conservative therapy, together with the development of novel endoscopic stenting possibilities[1]. The question of whether iatrogenic perforations are best managed by surgery or endoscopy has recently been addressed by two large studies. Di Franco *et al*[5] have examined 48 patients with iatrogenic perforation of esophageal cancer. Sixteen patients were treated by oncological esophagectomy, and 32 were treated conservatively because of advanced disease in 17 and poor performance status in 15. The authors demonstrated that all patients in the resection group died of recurrent disease and more than half of them died within the first year after surgery. The difference in survival between the resected and non-resected group of patients was not significant. Similarly, Jethwa *et al*[6] have analyzed 83 iatrogenic perforations during diagnostic endoscopy, of which, 27 were managed by surgery. The median survival in the whole cohort was 72 d. There was a trend for longer survival in patients undergoing surgery. However, the high 30-d mortality of nearly 40% and the poor survival in the surgical and non-surgical group shows that even rapid surgical treatment often fails to change the natural course of the disease at this stage. Together, both studies suggest that the primary approach to perforated esophageal cancer should be conservative.

However, under certain conditions, the conservative approach is not feasible; e.g., the perforation is too extensive for adequate stent therapy, or, as in our case, the tumor is (subtotal) stenosing, making successful stent therapy exceedingly difficult. Other indications for a surgical approach include extensive peritonitis or mediastinitis that cannot be drained adequately by interventional drainage placement. Irrespective of the indication for surgery, it should entail the least invasive measure that offers the greatest chance of immediate survival and the best quality of life for the remaining time period. Thus, whenever possible, the esophago-intestinal continuity should be re-established.

In the present case, we opted for reconstruction using an end-to-side esophago-gastrostomy. Limited resection of the cardia and the distal esophagus has been described

particularly for early tumors of the GE junction. While this procedure is safe and effective, and does not seem to result in postgastrectomy symptoms or microgastria[7], other reports have highlighted the long-term risk of reflux esophagitis when using esophagogastrostomy for reconstruction[8]. Other options include the Merendino procedure or total gastrectomy with esophago-jejunostomy reconstruction[9]. However, while the former one would seem too time consuming and technically demanding in an emergency situation[8], the latter requires an adequate mobile jejunum, and there is evidence of an early clinical benefit from formation of a gastric reservoir[9].

In conclusion, the management of esophageal perforation in the context of an underlying malignancy demands an individual approach that depends upon the site and etiology of the perforation. Irrespective of the therapeutic approach, the prognosis after tumor perforation is dismal. Therefore, the best palliative procedure has to be chosen, which is in most instances, a conservative one with drainage and stenting, or limited surgery with re-establishment of the esophago-intestinal continuity.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Articles: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; (13) Guidelines: To introduce Consensuses and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice in gastroenterology and hepatology.

The WJG Press and Baishideng

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words). Available from:http://www.wjgnet.com/wjg/help/8.doc

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/14.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc*.
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.
Biology: *H pylori*, *E coli*, *etc*.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,
Ocean International Center,
No.62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
Telephone: +86-10-59080039
Fax: +86-10-85381893
E-mail: wjg@wjgnet.com
http://www.wjgnet.com

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/10.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/9.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
