### Abstract

**AIM:** To determine the distribution and frequencies of the genotypes and haplotypes of the genes encoding for the glucocorticoid receptor (GR), the tumor necrosis factor (TNF)- $\alpha$  and the interleukin (IL)-10 in childhood Crohn's disease (CD) and to assess the impact of the corresponding DNA variants on clinical and disease phenotypes.

**METHODS:** Ten variants in GR, TNF- $\alpha$  and IL-10 were genotyped in 113 childhood CD cases and 95 healthy subjects, both of French-Canadian origin.

**RESULTS:** For the GR polymorphisms (R23K and N363S) and IL-10 variants in the 5'flanking region (-1082 G > A, -819 T > C and -592 A > C), no difference was observed in allele and genotype frequencies between CD patients and controls. At the haplotype level, we found three IL-10 haplotypes previously described in Caucasians (GCC, ACC and ATA) and three novel haplotypes only present in IBD patients. When we analyzed the haplotype distribution with the anatomical location of the disease, the GCC haplotype was associated with the colonic and the ACC haplotype with the terminal ileum location, respectively. The genotyping of five polymorphisms in the promoter

region of the TNF- $\alpha$  gene (-1031 T > C, -863 A > C, -857 T > C, -308 A > G and -238 A > G) revealed a significant overrepresentation of homozygous -1031 CC among CD patients (OR = 9.9) and an association with the colonic location. For TNF- $\alpha$ , eleven haplotypes were inferred, including two frequent ones, TCCGG and CACGG, which were significantly observed more frequently in controls and cases, respectively.

**CONCLUSION:** This is one of the first studies investigating the association between haplotype structure and disease location in a CD pediatric cohort. Our results will help to increase our understanding of the genetic determinants of childhood CD.

Sanchez R, Levy E, Costea F, Sinnett D. IL-10 and TNF- $\alpha$  promoter haplotypes are associated with childhood Crohn's disease location. *World J Gastroenterol* 2009; 15(30): 3776-3782 Available from: URL: <http://www.wjgnet.com/1007-9327/15/3776.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.3776>

### INTRODUCTION

Inflammatory bowel diseases (IBD) represent a complex genetic disease that is defined by at least two major disorders: Crohn's disease (CD) and ulcerative colitis. These diseases are distinct in terms of disease extension, localization, behaviour and the occurrence of extra-intestinal manifestations<sup>[1]</sup>. The incidence of IBD is bimodal, with the first peak occurring in the second and third decades of life and the second peak between the fifth and seventh decades. However, in North America, IBD also occurs during childhood or adolescence in up to 25% of patients<sup>[2]</sup>. Recent studies suggest that genetic predisposition may play an important role. For instance, the NOD2/CARD15 gene (chromosome 16)

and the IBD5 locus (chromosome 5) are associated with susceptibility to CD in adults<sup>[3]</sup>. Although initial studies suggested that the association of CARD15 with susceptibility to CD was higher for pediatric-onset disease, recent work with children suggests that this association in pediatric cases is roughly comparable to adult-onset disease. Furthermore, the association between the IBD5 locus and the risk of CD is weaker for children than for adults<sup>[3]</sup>. Despite extensive research, the etiology of childhood IBD is still unknown, but the immune-mediated chronic intestinal inflammation results from complex interactions between genes conferring susceptibility, exogenous or endogenous triggers, and environmental factors. In this study, we investigated the association between DNA variants in genes encoding for the glucocorticoid receptor (GR), the tumor necrosis factor (TNF)- $\alpha$  and the interleukin (IL)-10 and childhood CD phenotypic and clinical features. We found significant associations between IL-10 and TNF- $\alpha$  promoter haplotypes and disease location.

## MATERIALS AND METHODS

### Subjects

Incident cases of CD ( $n = 113$ ), ranging from 5 to 20 years old, were diagnosed in the Division of Gastroenterology of Ste-Justine Hospital, Montreal, Canada. The criteria for inclusion in this group were: (1) Complete clinical history; (2) Caucasians of French-Canadian origin residing in the Province of Quebec as judged by their names, languages and places of birth; (3) Availability of biological material. Patient characteristics are given in Table 1. The control group ( $n = 95$ ) was composed of unrelated healthy French-Canadian individuals who had agreed to donate their blood on an anonymous basis and to provide the information on their geographic origin, age, and gender. The targeted population was the one served by Ste-Justine Hospital, and our requests were addressed to parents and/or children that visited the Hospital for non-gastroenterological conditions.

The French-Canadian population represents a suitable model for genetic epidemiological studies because of its relative homogeneity in terms of genetics, socio-demographics and history<sup>[4,5]</sup>. The Ste-Justine's Institutional Review Board approved the research protocol and informed consent was obtained from all participating individuals and/or their parents.

### Genotyping

Genomic DNA was isolated from peripheral blood cells using standard methods (GENTRA Kit). Individuals were genotyped for TNF- $\alpha$  (-1031 C > T, -863 A > C, -857 T > C, -308 A > G, -238 A > G), IL-10 (-1082 G > A, -819 T > C, -592 A > C) and GR (R23K G > A and N363S A > G) polymorphisms by allele specific oligonucleotide (ASO) hybridization assay, as described in Labuda *et al*<sup>[6]</sup>. Briefly, primers flanking the polymorphic sites were used to amplify PCR products that were dot-blotted in duplicate on nylon membranes and assayed for the ab-

sence or presence of a specific mutation by hybridization with ASO for both alleles in parallel experiments. Samples with known genotypes were interspersed among study samples (positive controls) to ensure genotyping accuracy. For each experiment, the genotypes were read manually by two independent individuals and only concordant readings were accepted. To detect potential genotyping errors, Hardy-Weinberg equilibrium was tested. The oligonucleotides and assay conditions used for ASO are given in the supplementary materials (Table 2).

### Haplotype solving and linkage disequilibrium (LD) analysis

Haplotypes were inferred for all sites with minor allele frequency > 5% using the software PHASE, v. 2.1.1<sup>[7,8]</sup>. The LD statistics D and D' were both computed for each pair of single nucleotide polymorphisms (SNPs) with the software Arlequin v. 2.0<sup>[9]</sup>.

### Haplotype networks

The NETWORK 4.1.1.2 program was used to infer the likely genealogical history between the most frequent haplotypes using the Median-Joining (MJ) algorithm<sup>[10]</sup>. In an MJ network, circles represent distinct haplotypes and are scaled to reflect the frequency of these haplotypes. The branches connect the haplotypes and indicate the mutational steps between the haplotypes. The MJ network was generated only for IL-10 and TNF- $\alpha$  haplotypes.

### Statistical analysis

The chi-squared test was used to examine the differences in the distribution of genotypes between cases and controls.

The level of significance was calculated by Fisher's exact test (two-sided). Odds ratios (OR) were given with 95% confidence intervals (CI). Log linear analysis was used to include potential confounding factors in the analysis (age and gender). All analyses were performed using the SPSS statistical package (version 11.0.1). A proportional test was done to compare the association of various genotypes and haplotypes with different anatomical disease locations.

## RESULTS

Using PCR ASO hybridization assays, we genotyped 10 SNPs in *GR*, *IL-10* and *TNF- $\alpha$*  genes in 113 CD children and 95 healthy subjects, all of French-Canadian origin. All SNPs tested were in Hardy-Weinberg equilibrium in the control group, although no homozygous genotypes were observed for the *GR* minor alleles.

<sup>1</sup>The SNP positions within a haplotype are the following: R23K G > A, N363S A > G. n: Number of chromosomes.

For *GR*, we genotyped two SNPs in the exon 2, a G > A substitution, resulting in an amino acid change from arginine to lysine in the codon 23 (R23K), and an A > G substitution, resulting in an asparagine to serine change at codon 363 (N363S). The observed allele frequencies were consistent with those reported elsewhere for Caucasian populations<sup>[11-14]</sup>. The distribution of the alleles and genotypes did not differ between control and patient groups (supplementary materials, Table 3). Using the genotyping data, we were able to infer three haplotypes, including the major one GG (94%) and two minor ones, GA and AG, both at 3% (supplementary materials, Table 4). No significant differences were observed between the distribution of these haplotypes among cases and controls. No association was found between any *GR* genotypes and haplotypes and any clinical or phenotypic features (data not shown).

For *IL-10*, we genotyped three SNPs in the 5' flanking region of *IL-10*: -1082 G > A, -819 T > C and -592 A > C. The frequencies and the distribution of the alleles and genotypes were similar in CD patients and controls (Table 5) and similar to those reported in other Caucasian populations<sup>[15,16]</sup>. However, we found that the homozygous

ATA	27	24

<sup>1</sup>The SNP positions within a haplotype are the following: -1082 G > A, -819 C > T, -592 C > A. *n*: Number of chromosomes.

GG genotype at the SNP -1082 G > A was significantly associated ( $P = 0.008$ ) with the colonic localization of the disease. No other significant associations were found at the genotype level. Using the genotyping data, we inferred 5 haplotypes, including 3 frequent ones and 2 rare ones, found only in CD patients (Table 6). The three most frequent haplotypes (GCC, ACC and ATA) were previously described in other Caucasian populations<sup>[15-18]</sup>. The haplotype GCC was statistically significantly associated with the ileo-colonic ( $P = 0.01$ ) and colonic ( $P = 0.01$ ) locations, whereas the haplotype ACC was significantly associated with the terminal ileum ( $P = 0.01$ ) and upper digestive tract ( $P = 0.032$ ) (Figure 1). We estimated pair-wise LD and found a strong LD ( $D' = 0.989$ ,  $r^2 = 0.93$ ) between -819 T > C and -592 C > A, but a weak LD between -1082 G > A and -819 T > C ( $D' = 1.0$ ,  $r^2 = 0.27$ ) (data not shown). These results confirmed the putative independent role for the -1082 G > A variant. Altogether, these results suggest an important role for the SNP -1082 G > A in determining disease location.

For TNF- $\alpha$  we genotyped five SNPs in the promoter region: -1031 T > C, -857 T > C, -863 A > C, -308 A > G and -238 A > G. The allelic and genotypic frequencies are shown in Table 7. The homozygous CC genotype for the

**Figure 1** Distribution of haplotypes by disease location. A: IL-10 haplotypes; B: TNF- $\alpha$  haplotypes. The percentage of each haplotype according to disease location is indicated at the right of the corresponding haplotype, as described in Tables 6 and 8.

SNP -1031 T > C was significantly overrepresented in CD patients (11%,  $P = 0.008$ ) when compared to controls (1%) suggesting an increased risk of disease (OR = 9.9, 95% CI: 1.1-78). Although not significant, we also observed differences for the SNP -863 A > C, with the allele A present in 28% of cases and 19% of controls. The -1031 CC homozygotes were associated ( $P = 0.02$ ) with the colonic region and the heterozygote CT with the terminal ileum location ( $P = 0.03$ ). For SNPs -308 A > G and -238 A > G, both homozygous GG genotypes were associated with the upper digestive tract ( $P = 0.008$  and  $P = 0.05$ , respectively), whereas the heterozygous GA was associated with the terminal ileum location ( $P = 0.008$  and  $P = 0.05$ ). Using the genotyping data, we inferred eleven haplotypes (Table 8), including 3 major ones (H1, H3 and H7). These results were similar to those reported by Bennet *et al*<sup>[19]</sup> in myocardial infarction (MI) patients. The haplotype H1 (TCCGG) was more frequent in the control group (56%), suggesting a protective effect (OR = 0.69, 95% CI: 0.49-0.99,  $P = 0.04$ ) when compared with patients (48%), whereas the haplotype H7 (CACGG) was more frequent in CD patients (25%), suggesting an increased risk effect (OR = 1.64, 95% CI: 1.05-2.56,  $P = 0.03$ ) when compared with the control group (17%). The SNPs -1031 T > C and -863 A > C might explain this effect because the other three SNPs are shared by both haplotypes. Furthermore, the haplotype H3 (TCCAG) was observed more frequently in cases with terminal

<sup>1</sup>The homozygous -1031 CC is associated with an increased risk of disease (OR = 9.9, 95% CI: 1.3-78,  $P$  = 0.008); <sup>2</sup>The homozygous -1031 CC is associated ( $P$  = 0.02) with the colonic region; the heterozygous -1031 CT is associated with the terminal ileum location ( $P$  = 0.03); the homozygous -308 GG ( $P$  = 0.008) and -238 GG ( $P$  = 0.05) with the upper digestive tract.

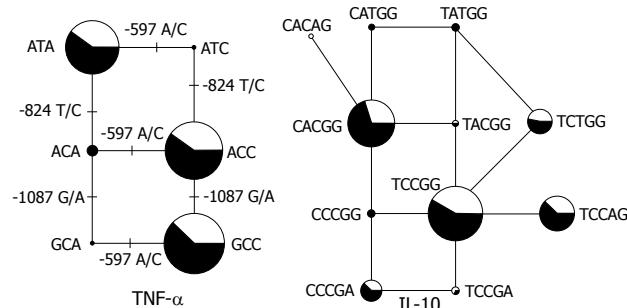

ileum localization ( $P$  = 0.015), whereas the haplotypes H6 (CCCGA) and H7 (CACGG) were overrepresented in the colonic region ( $P$  = 0.02) and in the upper digestive tract ( $P$  = 0.02), respectively (Figure 1).

To gain knowledge about the history of each SNP found in a given haplotypes and possibly about their functional impact, we built haplotype networks (Figure 2). For IL-10, the network suggests that the haplotype GCC was derived from the ancestral haplotype ACC (based on chimpanzee sequence), while the third major haplotype ATA was probably created through a recombination event involving one of the rare haplotypes (ATC or ACA) (Figure 2). The haplotype network for TNF- $\alpha$  was more complex because its promoter region of TNF- $\alpha$  underwent numerous recombination and mutation events. Indeed, five SNPs in a 1 kb region led to the inference of eleven distinct haplotypes: one major haplotype (H1) with a frequency of 56%, four intermediate ones (H3, H4, H6 and H7) with frequencies ranging from 4% to 17%, and six rare ones, with frequencies below 1% (Figure 2). The ancestral haplotype, ACCGG (based on the chimpanzee sequence), was not found, suggesting that the major haplotype (TCCGG) appeared very soon in human history. This could suggest a positive selection supporting a key role for the SNP-1031 T > C.

<sup>1</sup>SNP positions within a haplotype are the following: -1031 T > C, -863 C > A, -857 C > T, -308 G > A, -238 G > A; <sup>2</sup>OR = 0.69, 95% CI: 0.49-0.99; <sup>3</sup>OR = 1.64, 95% CI: 1.05-2.56. n: Number of chromosomes.

**Figure 2** TNF- $\alpha$  and IL-10 haplotype networks. The haplotype networks were drawn using the Phylogenetic Network Analysis Software NETWORK 4.1.1.2<sup>[10]</sup>. Left: IL-10 haplotypes are named as listed in Table 6; Right: TNF- $\alpha$  haplotypes are named as listed in Table 8. The area of the circle is proportional to the overall haplotype frequency, while colors indicate the distribution among CD patients (black) and controls (white). The solid lines connecting each haplotype represent single mutations occurring without recombination, and correspond to the maximum parsimony tree for this network. "ANC" designates the ancestral promoter haplotype derived from chimpanzee DNA analysis.

## DISCUSSION

In the present study, we determined the allelic and genotypic distribution of SNPs and the corresponding haplotypes in the GR, TNF- $\alpha$  and IL-10 genes among CD children and healthy controls, all of French-Canadian origin.

Genes encoding for immunoregulatory molecules clearly constitute important candidate susceptibility loci for IBD, and a number of recent studies have highlighted the central roles played by IL-10 in orchestrating the immune response. With regard to the IL-10 promoter SNPs (-1082 G > A, -819 C > T, -592 C > A), we found three promoter haplotypes (GCC, ACC and ATA), previously described in Caucasians, and two haplotypes (ACA, ATC) only present in CD children. We found that children carrying the haplotypes GCC (OR = 2.0, CI = 1.08-3.69) and ACC (OR = 2.5, CI = 1.02-6.2) were at increased risk of developing the disease at the ileo-colonic and terminal ileum locations, respectively. Conversely, a protective effect was noted when carrying haplotype GCC against the terminal ileum (OR = 0.34, CI = 0.12-0.96)

and the upper digestive tract ( $OR = 0.4$ ,  $CI = 0.17\text{--}0.91$ ) locations, while the ACC haplotype protected against the ileo-colonic location ( $OR = 0.49$ ,  $CI = 0.26\text{--}0.93$ ). These observations suggest that the SNP -1082 G > A plays an important role in determining disease location. The functional impact of this SNP has been shown in other studies: the -1082 GG genotype was the most important genetic factor in the regulation of high constitutive IL-10 expression (mRNA levels) and high IL-10 serum levels (protein basal expression)<sup>[18]</sup>; the homozygous -1082 AA was associated with decreased IL-10 production in CD patients and controls<sup>[17]</sup>; and the -1082 G > A was implicated in the production of IL-10 in whole blood samples stimulated with LPS for 24 h<sup>[18]</sup>.

TNF- $\alpha$  is a multifunctional cytokine involved in the promotion of inflammatory responses and plays a critical role in the pathogenesis of inflammatory, autoimmune and malignant diseases<sup>[20]</sup>. The functional changes in intestinal mucosa of patients with IBD lead to an increased secretion of proinflammatory cytokines in small and large bowel lamina propria. In fact, TNF- $\alpha$  levels are elevated in serum, mucosa and stool of patients with IBD and the infusion of monoclonal anti-TNF- $\alpha$  antibodies is a highly effective treatment against IBD<sup>[21]</sup>. Intestinal phagocytes or activated macrophages secrete ample amounts of TNF- $\alpha$ , which play an essential role in the pathogenesis of IBD. Variability in the capacity to produce TNF- $\alpha$  seems to be genetically determined<sup>[22]</sup>. For the TNF- $\alpha$  promoter SNPs (-1031 T > C, -863 A > C, -857 T > C, -308 A > G and -238 A > G), we found that children carrying at least one -1031 C allele were associated with the disease in certain locations, i.e. the colon in the case of the homozygous -1031 CC ( $P = 0.02$ ), and the terminal ileum in the case of the heterozygous -1031 TC ( $P = 0.03$ ). For SNPs -308 A/G and -238 A/G, both homozygous GG genotypes were associated with the upper digestive tract ( $P = 0.008$  and  $P = 0.05$ , respectively), whereas the heterozygous GA ( $P = 0.008$  and  $P = 0.05$ , respectively) was associated with the terminal ileum location. The promoter allele -308 A was reported to be associated with greater TNF- $\alpha$  transcription *in vitro*<sup>[23]</sup>. There are some studies confirming the association between the SNP -308 G > A and susceptibility to IBD<sup>[24,25]</sup> and others showing no association between any of the SNPs tested (-308 A > G, -857 T > C and -238 A > G) and IBD<sup>[16,26,27]</sup>. Furthermore, among the eleven TNF- $\alpha$  promoter haplotypes resolved, TCCGG was more frequent in the control group whereas CACGG was overrepresented in CD children. Also the CACGG haplotype increased the risk of developing the disease in the upper digestive tract ( $OR = 2.4$ ,  $CI = 1.12\text{--}5.1$ ).

In several inflammatory diseases, variations in glucocorticoid sensitivity have been reported to be associated with SNPs in the GR gene<sup>[13,28-30]</sup>. In this study we found no evidence of independent involvement of GR allelic variants (R23K and N363S) and CD phenotypic and clinical parameters, despite the reported correlations of the variants N363S with glucocorticoid hypersensitivity<sup>[13]</sup> and R23K with decreased response to

dexamethasone<sup>[29]</sup>.

In conclusion, this is one of the first studies assessing the impact of candidate gene haplotypes and disease location in childhood CD. The fact that certain associations were observed for given haplotypes rather than at individual SNPs reflects the benefit of haplotype-based analysis. Our results highlight the importance of knowing the haplotype structure because haplotypes potentially capture more genetic diversity than single-locus genotypes and therefore serve as better hallmarks to understand complex traits. Finally, one of the limitations of studying pediatric CD is that a relative small number of patients are available for study. Because of the small sample size, this report should be considered as exploratory and further studies are required to confirm these genetic associations with childhood CD.

## COMMENTS

### Background

Crohn's disease (CD) is a chronic inflammatory bowel disease that affects more than half a million North Americans. The deregulated expression of the glucocorticoid receptor (GR) and the cytokines interleukin (IL)-10 and tumor necrosis factor (TNF)- $\alpha$  plays a crucial role in the pathogenesis of inflammatory diseases. Single nucleotide polymorphisms (SNPs) in the promoter regions of TNF- $\alpha$ , IL-10 and GR genes may influence the expression of these genes, thereby modulating the susceptibility to CD. This study assesses the impact of specific SNPs and haplotypes on the risk of developing childhood CD.

### Research frontiers

Some variants in the promoter region of genes may affect either the expression or activity levels of proteins and therefore may be mechanistically associated with CD risk. Although several gene loci have been associated with susceptibility to CD in adults, the etiology of childhood CD is still unknown. The current study is one of the first studies assessing the impact of candidate gene's haplotypes and disease location in childhood CD. Furthermore, it highlights the importance of haplotype structures as better hallmarks than single-locus phenotypes to understand the genetics underlying complex traits.

### Innovations and breakthroughs

It is important to investigate the genetic variation in susceptibility to CD and identify markers that will facilitate identification of individuals at risk of developing this disease. Although no significant association was found between GR (R23K and N363S) polymorphisms and risk of CD, TNF- $\alpha$  promoter SNPs and IL-10 and TNF- $\alpha$  promoter haplotypes were overrepresented in children with CD and were associated with specific disease location.

### Applications

This is one of the first studies investigating the association between haplotype structure and disease location in a CD pediatric cohort. The results of this study will help us to further understand the genetic determinants of childhood CD. Future studies in larger pediatric cohorts and further analysis of the biological function of the identified variants are required to understand the role of TNF- $\alpha$  and IL-10 polymorphisms and related haplotypes in determining the risk of CD.

### Peer review

The distribution and frequencies of the genotypes and haplotypes of the genes encoding for TNF- $\alpha$ , IL-10 and GR and the impact of the corresponding variants on risk of CD in a childhood French-Canadian cohort was studied. The results show that polymorphisms in the TNF- $\alpha$  promoter region as well as specific TNF- $\alpha$  and IL-10 haplotypes are associated with the risk of CD, at least in this study population.

## Abstract

**AIM:** To elucidate the efficacy and safety of a split dose of midazolam in combination with meperidine for colonoscopy.

**METHODS:** Eighty subjects undergoing outpatient colonoscopy were randomly assigned to group A or B. Group A ( $n = 40$ ) received a split dose of midazolam in combination with meperidine. Group B ( $n = 40$ ) received a single dose of midazolam in combination with meperidine. Outcome measurements were level of sedation, duration of sedation and recovery, degree of pain and satisfaction, procedure-related memory, controllability, and adverse events.

**RESULTS:** Group A had a lower frequency of significant hypoxemia ( $P = 0.043$ ) and a higher sedation score on withdrawal of the endoscope from the descending colon than group B ( $P = 0.043$ ). Group B recovered from sedation slightly sooner than group A ( $P < 0.002$ ). Scores for pain and memory, except insertion-related memory, were lower in group A one week after colonoscopic examination ( $P = 0.018$  and  $P < 0.030$ , respectively). Poor patient controllability was noted by the endoscopist and nurse in group B ( $P = 0.038$  and  $P = 0.032$ , respectively).

**CONCLUSION:** Split dose midazolam in combination with meperidine resulted in a safer, more equitable sedation status during colonoscopic examination and a

## INTRODUCTION

Colonoscopy is one of the most commonly performed medical procedures worldwide. Although recent advances in endoscopy have improved endoscope imagery and flexibility, colonoscopy remains a difficult and lengthy endoscopic procedure that causes the patient considerable discomfort or pain. Most gastroenterologists use moderate sedation for colonoscopy. Under deep sedation, patients may develop inadequate spontaneous ventilation and may require assistance to maintain a patent airway. In addition, constant repositioning of such patients because of their poor cooperation may exhaust nurses or assistants<sup>[1-7]</sup>.

Although several agents are available for inducing moderate sedation, the combination of a benzodiazepine and an opiate (midazolam and meperidine) is most commonly used<sup>[3,7-9]</sup>. The use of propofol is increasing in clinical practices because practitioners believe that it shortens the duration of sedation and recovery<sup>[10-15]</sup>. However, many endoscopic units, especially in Korea, are hesitant to use this agent because it frequently results in deep sedation. Moreover, it is doubtful whether it is suitable for colonoscopic procedures because of poor patient control<sup>[2,4,16]</sup>. A modified administration of a conventional combination of sedatives such as midazolam and meperidine may be safer and have a more positive outcome than propofol, especially for colonoscopic procedures, the duration of which

is greater and more variable than that of upper gastrointestinal endoscopy.

The objective of this study was to compare the efficacy and safety of split dose midazolam in combination with meperidine with conventional single dose midazolam in combination with meperidine.

## MATERIALS AND METHODS

### **Patients**

This study was a randomized, controlled clinical trial and involved 80 consecutive outpatients who presented for colonoscopy at the Armed Forces Capital Hospital in Korea. Patients were considered eligible to participate if they were 18 years of age or older and were scheduled for colonoscopy only. Associated medical illnesses were graded according to the American Society of Anesthesiologists' Physical Status Classification (ASA grade). Exclusion criteria included ASA risk Class 3 or higher, history of a colonic surgical procedure, inpatient status, chronic use of benzodiazepines or opiates, sleep apnea, liver cirrhosis, pregnancy, willingness to undergo unsedated colonoscopy, and allergies to soybeans or eggs. A total of 86 patients were invited to participate. Six of these patients were excluded because the colonoscopy was aborted due to poor preparation. Thus, 80 patients gave their informed consent and completed the study. All colonoscopies were performed by one gastroenterologist who had 6 years of colonoscopy experience. The sedative agents were administered by one nurse. The study was blinded to the endoscopist and recovery nurse, but not to the sedating nurse. Sedation endpoints were drowsiness, facial relaxation, slurred speech, and tolerance to insertion of the colonoscope. Patients were randomly assigned to one of the two groups for sedation according to a table of random numbers. All patients received 50 mg of meperidine intravenously prior to administration of midazolam. Patients in group A (split dose midazolam and meperidine) initially received 2.5 mg (< 70 kg b.w.) or 3 mg (> 70 kg b.w.) of midazolam intravenously. A second dose of midazolam (< 70 kg b.w., 1.5 mg; > 70 kg b.w., 2 mg) was administered immediately after ileal intubation. Patients in group B (single dose midazolam and meperidine) initially received 4 mg (< 70 kg b.w.) or 5 mg (> 70 kg b.w.) of midazolam intravenously. Placebo administration of saline was performed after ileal intubation in group B. Supplemental doses of midazolam or meperidine were not administered to ensure that consistent doses were used during the trial. The times at which sedation and colonoscopic insertion were initiated, the distal ileum was intubated, and the colonoscope was withdrawn from the anus were recorded.

### **Assessment of safety**

The endoscopist and registered nurse who administered the sedative agent were certified in advanced cardiac life support. An endoscopy technician was present to assist the endoscopist with technical maneuvers. All patients were continuously monitored for heart rate

(three-lead electrocardiogram), oxygen saturation (pulse oximetry), and mean arterial blood pressure (serial blood pressure measurements every 5 min). Significant oxygen desaturation was defined as an oxygen saturation of less than 90% for more than 15 s. Supplemental oxygen (2 L/min via a nasal cannula) was administered for any episode in which  $\text{SaO}_2$  was less than 85% or oxygen saturation was less than 90% on three separate occasions. Oxygen desaturation and the need for supplemental oxygen were recorded as significant outcomes. Heart rate was monitored continuously using pulse oximetry and bradycardia was defined as a heart rate of less than 60 beats per minute or a heart rate 25% below baseline. Blood pressure was measured before and after the procedure.

### **Assessment of sedative efficacy and recovery**

After sedation was initiated, the assistant responsible for measuring sedation level was brought into the room. The assistant was unaware of the protocol concerning delivery of the sedative. The degree of sedation was assessed using a sedation score (5 = not arousable, 4 = arousable to stimuli, 3 = arousable to command, 2 = drowsy, 1 = awake). The sedation score was recorded twice for each patient: on advancing the endoscope into the descending colon and on withdrawing it from the descending colon. Patients were transferred to the recovery area immediately after the procedure if their vital signs were stable. The time taken to recover from sedation was assessed using a modified Aldrete score at 5, 10, and 30 min after the procedure. The modified Aldrete score is an established postanesthetic recovery score that takes into account respiration and circulation parameters, and patient consciousness and activity<sup>[17]</sup>. The score ranges from 0 to 10, the latter indicating that the patient is fit for discharge.

### **Patient assessment**

When the patients were contacted by phone or visited one week after the procedure, they were asked to fill out a questionnaire using a 10-point visual analog scale to grade the amount of pain, overall satisfaction, and memory of specific aspects of the procedure (insertion of the colonoscope, withdrawal of the colonoscope, and intentional position changes on ileal intubation). This was conducted by an investigator blinded to the protocol of study.

### **Endoscopist and assistant nurse assessment**

The endoscopist's and assistant nurse's evaluations of the patient's controllability were obtained immediately after the procedure using a 10-point visual analog scale.

### **Statistical analysis**

On the basis of a previous study<sup>[18]</sup>, assuming that the split dose group will have a mean procedure-related pain score of 8.0/10.0 with a 1% reduction in pain, a sample size of 37 per group was required to detect the difference with a power of 90% and a type I error of 0.05 (PS Power and Sample Size Calculations, Version

3.0; Biostatistics Department, Vanderbilt University, Nashville, TN). Descriptive data are presented as the number of patients (%) or as the mean  $\pm$  SD. Continuous data were compared using the unpaired Student's *t* test, and categorical variables were tested using the corrected chi-square method. The criterion for statistical significance was  $P < 0.05$ .

## RESULTS

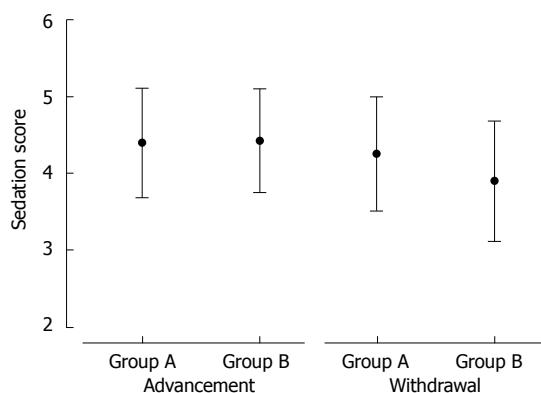

Demographic data and procedure indications for the subjects are presented in Table 1. There were no significant differences among the groups in age, gender, body mass index, or procedure indication. Patients who received single dose midazolam had a significantly shorter time from onset of sedation to initiation of endoscopy than those who received split dose midazolam ( $P = 0.003$ ,  $0.89 \pm 0.31$  vs  $1.18 \pm 0.49$ ). There was no difference in the total duration of the procedure and the time of ileal intubation between patients in both groups. The frequency of a significant drop in oxygen saturation was higher in group B than in group A ( $P = 0.043$ , 20% vs 5%). There was no difference between the groups in terms of a significant drop in mean arterial blood pressure or a significant alteration in heart rate (Table 2). Reversal agents were needed in two cases. However, no patient experienced severe cardiopulmonary complications. There was a significant difference between the sedation scores in group A and B at the time at which the scope was advanced into the descending colon. However, the sedation score in group A was significantly higher than that in group B on withdrawal of the endoscope from the

descending colon ( $4.25 \pm 0.74$  vs  $3.9 \pm 0.78$ ,  $P = 0.043$ ) (Figure 1). Table 3 shows recovery status according to the modified Aldrete score. Recovery from sedation was slightly sooner for group B than for group A, 5 min ( $4.28 \pm 1.06$  vs  $5.75 \pm 0.95$ , respectively,  $P < 0.001$ ), 10 min ( $6.55 \pm 0.50$  vs  $7.00 \pm 0.68$ , respectively,  $P < 0.001$ ), and 30 min ( $8.73 \pm 0.85$  vs  $9.32 \pm 0.69$ , respectively,  $P < 0.001$ ) after the procedure. Moreover, the interval from removal of the endoscope to discharge was longer for group A than group B ( $37.1 \pm 6.87$  min vs  $33.8 \pm 5.75$  min, respectively,  $P = 0.022$ ). The patients' recollection of pain during colonoscopy and satisfaction with the procedure at one week after the procedure are shown in Table 4. One week after the colonoscopic examination, all scores for pain and memory except for insertion-related memory were lower for group A than for group B. The endoscopist and the assistant nurse reported that group B was more difficult to control during the procedure than group A ( $P = 0.038$  and  $P = 0.032$ , respectively) (Figure 2).

**Figure 2** Visual analog scale on patient controllability reported by the endoscopist and assistant nurse.

## DISCUSSION

This study is the first to compare the safety and efficacy of split dose midazolam in combination with meperidine with that of single dose midazolam in combination with meperidine for conscious sedation during colonoscopy. Although propofol is used increasingly during routine colonoscopy, nonanesthesiologists are hesitant to use propofol because of its known potential to cause transient apnea or general anesthesia, for which there is no reversal agent<sup>[2,4,19]</sup>.

There is a widespread belief among endoscopists that, for colonoscopy, sedation with the combination of a benzodiazepine and a narcotic is superior to sedation with either agent alone. A recent uncontrolled prospective study of a cohort of patients sedated using a combination of midazolam and meperidine reported that unintended deep sedation occurred in 11% of colonoscopies<sup>[11]</sup>. Our aim was to identify a practical and alternative sedation method based on the combination of a benzodiazepine and meperidine. Most endoscopists prescribe single dose midazolam at the time of initiating the colonoscopy without adequately monitoring the patient's sedative status or the amount of additional sedative administered. Endoscopists routinely prescribe additional administration of a sedative when patients are severely agitated or experience pain, but there are no coherent guidelines for this practice. Moreover, the small painful response of patients during the procedure tends to be neglected by endoscopic unit staff. This randomized study was designed to evaluate the promising effect of a divided dose of midazolam on sedation status.

Midazolam is known to produce retrograde amnesia as well as anterograde amnesia<sup>[20]</sup>. Because of the long duration of colonoscopic procedures, it is thought that single dose midazolam administration results in uneven distribution of the sedative effect during the procedure. Moreover, administration of a single full dose of midazolam is associated with the risk of hypoxemia and paradoxical reactions such as hostility, rage, and physical violence, especially during the initial part of the procedure. For these reasons, an alternative method is required to ensure adequate

moderate sedation for the duration of colonoscopy. Our study showed that the sedative efficacy of the split dose was superior to that of the single dose at the time of withdrawal of the endoscope. Although there was no serious cardiopulmonary depression in either group, the split dose reduced the frequency of a drop in oxygen saturation, unlike the single dose. Split dose midazolam treatment is a stable, sustainable, and safe sedation method for colonoscopy. Unfortunately, the post endoscopic sedation-related recovery of the split dose group was delayed according to the Aldrete score. It seems inevitable that additional administration of sedative will affect the recovery of patients.

The split dose method induced sleep by the end of the colonoscopic procedure and was associated with loss of memory of the events that occurred during colonoscopy 1 wk later. It seems that split dose midazolam administration and the subsequent post endoscopic sleep played a role in the amnesia. This should be considered for moderate sedation even if the main concern is to facilitate rapid recovery to ensure fast turnover at the endoscopic unit.

Initial excessive sedation to ensure easy patient control during colonoscopy seems to be undesirable at the time of advancement of the endoscope. Our study suggests that less sedation should be administered during advancement of the endoscope and more sedation with the moderate agent should be administered during endoscope withdrawal. Regrettably, the satisfaction score in our study was not different between the groups. This seems to have been caused by an inadequate number of subjects because the sampling size was calculated on the basis of pain score in a previous report. Hence, further study with a larger number of subjects should be considered.

In summary, our study shows that a split dose of midazolam in combination with meperidine is superior to a single dose of midazolam in combination with meperidine with respect to safety, equable sedation status, procedure-related pain, and unpleasant memory, but results in a longer recovery time.

## COMMENTS

### Background

For conscious sedation during colonoscopy, the modified administration of a conventional sedative combination such as midazolam and meperidine may be safer and have a more positive outcome than propofol.

### Research frontiers

Researchers assessed the efficacy of various premedications such as propofol, midazolam, meperidine or fentanyl on moderate sedation during the colonoscopic procedure.

### Innovations and breakthroughs

Split dose midazolam in combination with meperidine led to a lower frequency of significant hypoxemia and a higher sedation score on withdrawal of the colonoscope. One week after colonoscopic examination, scores for pain and memory were lower in patients who received split dose midazolam compared to those who received single dose midazolam.

### Applications

A split dose of midazolam in combination with meperidine is superior to a single dose of midazolam in combination with meperidine with respect to safety, equable sedation status, procedure-related pain, and unpleasant memory.

**Peer review**

This is a randomized study to compare the safety and efficacy of split dose midazolam in combination with meperidine with that of single dose midazolam in combination with meperidine for conscious sedation during colonoscopy. This manuscript suggested that split dose midazolam treatment is a stable, sustainable, and safe sedation method for colonoscopy compared with the administration of single dose midazolam.

### Abstract

**AIM:** To investigate acute transient hepatocellular injury in patients with cholelithiasis and cholecystitis but no evidence of choledocholithiasis.

**METHODS:** The medical records of patients with cholelithiasis who underwent cholecystectomy between July 2003 and June 2007 were retrospectively reviewed. Imaging studies to detect common bile duct (CBD) stones were performed in 186 patients, who constituted the study population. Biochemical liver tests before and after surgery, and with the presence or absence of CBD stones were analyzed.

**RESULTS:** In 96 patients with cholelithiasis and cholecystitis without evidence of CBD stones, 49 (51.0%) had an alanine aminotransferase level elevated to 2-3 times the upper limit of normal, and 40 (41.2%) had an elevated aspartate aminotransferase level. Similar manifestations of hepatocellular injury were, as would be expected, even more obvious in the 90 patients with CBD stones. These markers of hepatocellular injury resolved almost completely within 2 wk to 1 mo after cholecystectomy. Compared to 59 patients with histologically less severe cholecystitis

### INTRODUCTION

Although viral hepatitis is quite prevalent in Taiwan, viral infection is by no means the only cause of acute hepatitis<sup>[1]</sup>. One setting in which there may be acute inflammation of the liver parenchyma is the presence of common bile duct (CBD) stones and cholangitis, situations in which liver tests have been widely studied<sup>[2-4]</sup>. We have found few investigations, however, of biochemical evidence of hepatocellular injury (hepatitis) in patients with cholelithiasis and cholecystitis who do not have CBD stones.

Hepatocellular injury is indicated by increases in serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT). The severity of such injury may be reflected in decreased hepatic production of

certain products such as albumin and clotting factors. Inflammation or damage to the biliary tract is signaled by an increase in alkaline phosphatase (ALK-P), which is sometimes confirmed by measuring gamma-glutamyltransferase. Serum bilirubin levels may be elevated in both biliary tract and hepatocellular diseases. Discussion of this topic is therefore often confusing when the general term is used rather than the names of particular biochemical markers of interest.

We designed this study to address the specific question of how often hepatocellular injury occurs in patients with cholelithiasis and cholecystitis in the absence of CBD stones, as opposed to cases where CBD stones/obstruction were found. We also wanted to see if there was any correlation between the degree of hepatocellular injury and the severity of the cholecystitis.

## MATERIALS AND METHODS

We retrospectively reviewed the medical records of patients admitted to Mackay Memorial Hospital, Taipei, from July 2003 to June 2007 who underwent cholecystectomy for cholelithiasis associated with cholecystitis (acute or chronic). Of 1168 such records, we retrieved those of patients who had undergone either preoperative endoscopic retrograde cholangiopancreatography (ERCP) or magnetic resonance cholangiopancreatography (MRCP) or intra-operative cholangiography. The imaging procedures were done to determine whether CBD stones were present in patients who had either sonographic evidence of a dilated CBD and/or biochemical evidence suggesting biliary tract obstruction. The cholecystectomized patients who had biochemical or sonographic evidence suspicion of a CBD disorder but refused to undergo invasive imaging such as ERCP, were not included in the study. Patients with viral hepatitis (that is, hepatitis A, hepatitis B or C virus infection), alcoholic liver disease, drug-related hepatitis, metabolic liver disease, autoimmune hepatitis, pancreatitis, or a previous history of ERCP with endoscopic sphincterotomy for removal of CBD stones were excluded. The liver tests analyzed for this study included AST, ALT, ALK-P, and total and direct bilirubin. The peripheral leukocyte count was also recorded. All the patients had stones in the gallbladder as demonstrated by sonography, and also in the operative specimens. Cholecystitis was diagnosed and its severity graded on the basis of the pathology examination as either gangrenous or simple cholecystitis.

### Statistical analysis

The Student *t*-test was used to analyze differences between groups. We compared the liver tests (including AST, ALT, ALK-P, direct bilirubin and total bilirubin) in patients with cholelithiasis or cholecystitis who underwent cholecystectomy with or without CBD stones. We also compared the liver tests in patients with a histological diagnosis of gangrenous vs simple cholecystitis, but only in those without evidence of CBD stones.  $P < 0.05$  was considered significant.

## RESULTS

Of all 1168 records, 186 patients (92 males, 94 females) met the study inclusion criteria. The number of patients with cholelithiasis and abnormal liver function tests was more than 186. However, as the aim of our study was to ensure the status of the CBD, we only included patients whose CBDs were evaluated using imaging procedures. In the included 186 patients, a total of 226 imaging procedures for evaluation of CBD were performed, with 114 instances of ERCP, three of MRCP, and 109 of intra-operative cholangiography. CBD stones were found in 90 patients. It was very remarkable that few MRCPs were done in comparison to ERCPs and intra-operative cholangiographies. It was because of a limitation of the medical insurance system in Taiwan. Cholecystectomy was performed urgently in 154 patients and electively in 32 (Table 1). The method of cholecystectomy was laparoscopic in 142 and conventional in 44. In patients who underwent an urgent procedure, acute right upper quadrant or epigastric pain had been present for no more than 2 d prior to surgery. Those undergoing elective surgery had had at least one recent episode of pain typical of biliary tract disease and had been deemed to have symptomatic cholelithiasis.

Most of the liver tests were abnormal, not only in patients with stones both in the gallbladder and the CBD, but also in patients with stones limited to the gallbladder. However, the mean values in patients with CBD stones were significantly higher than those in patients without evidence of CBD stones. Of the 96 patients without evidence CBD stones, 49 (51.04%) had an elevated ALT, averaging 2-3 times the upper limit of normal. A slightly lower proportion (41.67%) also had an elevated AST. The highest AST was 670 IU/dL and the highest was ALT 566 IU/dL. Mild elevations of serum total bilirubin and ALK-P were also present in 27% and 23%, respectively, of these patients (Table 2). Among these 96 patients, 82 patients were seen for follow-up 2 wk to 1 mo after cholecystectomy, by which time the mean values of the liver tests had almost returned to normal, with only the mean ALT still slightly elevated, but already much lower than the preoperative level (Table 3).

There were 74 patients who had cholelithiasis and cholecystitis without evidence of CBD stones and who underwent urgent cholecystectomy. The gallbladder histology revealed gangrenous cholecystitis in 15 patients. The only significant differences between that group and the 59 patients with simple cholecystitis were a higher bilirubin level ( $1.14 \pm 1.27$  mg/dL vs  $2.66 \pm 1.97$  mg/dL,  $P < 0.001$ ) and white cell count ( $9480 \pm 4681/\mu\text{L}$  vs  $12840 \pm 5273/\mu\text{L}$ ,  $P = 0.018$ ). The aminotransferase and ALK-P levels did not differ significantly between the two groups (Table 4).

## DISCUSSION

Hepatocellular injury in patients with cholecystitis is usually attributed to injury related to CBD stones. However,

we have demonstrated that patients with cholecystitis and cholelithiasis but without evidence of CBD stones may also have elevated serum aminotransferase levels. Although the liver test abnormalities in such patients in our study were milder on average than in those with CBD stones, the highest ALT (566 IU/L) and total bilirubin (9.3 mg/dL) levels were still quite striking.

Pathologically, liver changes such as chronic cholestasis or portal-portal linking fibrosis are a common finding in patients with cholelithiasis with CBD stones. However, other non-specific changes in liver histology are also found in patients without CBD stones<sup>[5]</sup>. In our study, hepatocellular injury (diagnosed clinically by elevation of aminotransferases and bilirubin levels) was common regardless of whether or not CBD stones were present. The incidence was higher and the aminotransferase elevations were more marked in those with stones<sup>[6]</sup>, but a substantial proportion of patients without CBD stones also had some degree of hepatocellular injury. In most patients, the AST, ALT, and bilirubin levels had almost returned to normal 2 wk to 1 mo after cholecystectomy (Table 3). This hepatocellular injury appeared to be a transient, reactive phenomenon secondary to cholecystitis associated with cholelithiasis, whether or not there had been stones in the CBD. This kind of hepatocellular

injury, even showing relatively high serum levels of aminotransferases and bilirubin, should not be an obstacle to preparation of these patients for surgical intervention. Its activity is transient and mild. It needs no further management and will resolve spontaneously as expected, assuming the diseased gallbladder is removed.

There are two main origins of ALK-P: the liver and bone. An elevated serum ALK-P found to originate from the liver, particularly if it persists for a period of time, suggests prolonged cholestasis<sup>[7]</sup>. In our patients in whom no CBD stones were identified, the mean serum ALK-P was not significantly elevated (Table 2), implying that they had no obvious biliary obstruction before operation. In general, there are two distinct patterns of liver injury: one is hepatocellular damage demonstrated clinically by elevated levels of the aminotransferases but with a relatively normal ALK-P; the other is that of cholestasis with an ALK-P elevated out of proportion to the aminotransferases. It is not difficult to understand why hepatocellular damage, and hence elevations of the aminotransferase levels, would occur in the presence of CBD stones. Higher biliary tree pressures can lead to impaired bile secretion, retention of bile acids, and consequent apoptosis or necrosis of hepatocytes<sup>[7]</sup>. However, the exact mechanism of hepatocellular damage in cholecystitis associated with cholelithiasis but without choledocholithiasis is not fully understood. Presumably such patients have normal biliary pressure. Free radical reactions in the human gallbladder have been demonstrated to occur in cholecystitis, suggesting that oxidative stress may partially account for liver injury<sup>[8,9]</sup>. It may also be that inflammation in the gallbladder induces inflammation in the closely apposed neighboring liver tissue. However, elevation of aminotransferases could not be explained based on the proximity effect

**Table 4 Comparison of basic data between gangrenous cholecystitis and simple cholecystitis in patients who underwent urgent surgery (total 74 patients) (mean  $\pm$  SD)**

Variable	Gangrenous cholecystitis (15)	Simple cholecystitis (59)	P-value	95% CI	
				Lower	Upper
Age	64.9 $\pm$ 11.8	56.1 $\pm$ 16.4	0.053	-17.83	0.13

WBC (3400-10000/ $\mu$ L)	12840.0 $\pm$ 5273.9	9480.2 $\pm$ 4681.3	0.018	-6128	-591.6

alone since it bears no relation to prognosis of severe acute cholecystitis<sup>[10]</sup>. On the other hand, severity of acute cholecystitis also had no significant influence on the level of serum aminotransferases<sup>[11]</sup>.

Jaundice is a common feature of patients with CBD stones<sup>[12]</sup>. In fact, it is not a rare manifestation of gallbladder disease without evidence of CBD stones; the difference is that in the latter, the serum total bilirubin level is usually less than 4 mg/dL<sup>[13,14]</sup>. In our patients without evidence of CBD stones, the mean total bilirubin level of 1.5 mg/dL was comparable with reports in the literature. However, the highest value of up to 9.3 mg/dL means that hyperbilirubinemia beyond the so-called 'mild degree' will not always suggest a complicated condition of gallstone disease.

Peng *et al*<sup>[11]</sup> documented that the severity of inflammation in cholecystitis with CBD stones did not influence the level of aminotransferases and bilirubin. However, the severity of inflammation was defined as acute attack or not. In our study, the definition of severity is based on the gallbladder histology (simple or gangrenous cholecystitis). In patients with gangrenous cholecystitis, while aminotransferase levels were not particularly elevated, the mean serum bilirubin was significantly higher than that in patients with simple cholecystitis (Table 4). Diabetes mellitus and leukocytosis have been associated in some studies with gangrenous cholecystitis, but hyperbilirubinemia has not<sup>[15-17]</sup>. However, these studies did not exclude patients with CBD stones, which may have skewed the comparison between those with and without a gangrenous gallbladder. For this comparison, we also analyzed only patients without evidence of CBD stones and found that leukocytosis as well as hyperbilirubinemia were associated with more severe, i.e. gangrenous, cholecystitis.

There could be the possibility that small stones passed through the duct during biliary colic so as to result in biochemical liver function abnormalities. Our results seemed not to favor this proposal. Firstly, ERCP (most of our patients underwent ERCP examination) is so far the most reliable (both sensitivity and specificity are over 95%) and widely applicable imaging procedure to evaluate the CBD, even in the elderly<sup>[18,19]</sup>. Our judgment of further management for the patients mainly depended on these evaluations. Secondly, small stones

that pass through the duct, especially stones less than 0.5 cm in diameter, may induce pancreatitis<sup>[20]</sup>. We excluded patients with pancreatitis to reduce this possible confounding factor. Finally, the averaged normal ALK-P levels in the group without evidence of CBD stones also argues against transient stone passage as a cause of the hepatocellular injury.

The limitation of our study is that it was a retrospective observation. We selected patients who underwent image evaluation of the CBD because of suspicion of biliary obstruction from abnormalities in biochemical liver function and/or sonography. The elevated aminotransferase levels in the group of patients may have resulted in a falsely high incidence of hepatocellular injury induced by gallbladder disease without CBD stones. However, regardless of the pathophysiology and true occurrence rate, the abnormal biochemical liver function of almost all the patients resolved rapidly and spontaneously after cholecystectomy. This phenomenon implied that the transient hepatocellular injury was brought about by symptomatic gallstones with cholecystitis even in the absence of CBD stones.

We observed persistently high liver enzymes in one patient who was subsequently found to have cancer of the Ampulla of Vater. This suggests that if there is incomplete postoperative resolution of the abnormal tests, residual or additional pathology should be investigated. However, in the absence of other symptoms, it would be reasonable to wait for 1 mo to see if the hepatocellular injury resolves before initiating more invasive studies such as ERCP.

## COMMENTS

### Background

Acute hepatocellular injury is a commonly encountered phenomenon in patients with cholelithiasis and concomitant common bile duct (CBD) stones. However, in clinical practice, it seemed to occur also in cholelithiasis patients without evidence of CBD stones. Its incidence and final outcome necessitated clarification.

### Research frontiers

Abnormal liver function tests for predicting CBD stones have been well discussed, however, the relationship between liver function and cholelithiasis/cholecystitis alone is not well understood.

### Innovations and breakthroughs

In this study, the authors studied a phenomenon of hepatocellular injury in patients with cholelithiasis without evidence of concomitant stones in the CBD. It was transient and resolved spontaneously after cholecystectomy.

## Applications

This kind of hepatocellular injury, even showing relatively high serum levels of aminotransferases and bilirubin, should not be an obstacle to preparation of such patients for surgical intervention. The abnormalities will be expected to recover spontaneously and need no further investigation or treatment unless they persist for more than 1 mo.

## Peer review

This is an interesting paper addressing an acute transient hepatocellular injury which is often presented but ignored. The article is well balanced and the discussion is clear and exhaustive.

(42.5 mo vs 26.5 mo,  $P = 0.035$ ) compared to those in the control group, despite the fact that no significant difference in 5-year OS rate was observed (54.4% vs 48.3%,  $P = 0.137$ ). Multivariate analysis showed the distance of tumor from the anal verge, pretreatment serum carcinoembryonic antigen level, pathologic TNM stage and LVI were the major factors affecting OS.

**CONCLUSION:** Neoadjuvant radiotherapy does not reduce LVI significantly; however, the prognostic meaning of LVI has changed. Patients with LVI may benefit from neoadjuvant radiotherapy.

## Abstract

**AIM:** To investigate the meaning of lymphovascular invasion (LVI) in rectal cancer after neoadjuvant radiotherapy.

**METHODS:** A total of 325 patients who underwent radical resection using total mesorectal excision (TME) from January 2000 to January 2005 in Beijing cancer hospital were included retrospectively, divided into a preoperative radiotherapy (PRT) group and a control group, according to whether or not they underwent preoperative radiation. Histological assessments of tumor specimens were made and the correlation of LVI and prognosis were evaluated by univariate and multivariate analysis.

**RESULTS:** The occurrence of LVI in the PRT and control groups was 21.4% and 26.1% respectively. In the control group, LVI was significantly associated with histological differentiation and pathologic TNM stage, whereas these associations were not observed in the PRT group. LVI was closely correlated to disease progression and 5-year overall survival (OS) in both groups. Among the patients with disease progression, LVI positive patients in the PRT group had a significantly longer median disease-free period (22.5 mo vs 11.5 mo,  $P = 0.023$ ) and overall survival time

## INTRODUCTION

Currently, the treatment of rectal cancer has stepped into a new era of multimodality therapy<sup>[1]</sup>. Neoadjuvant therapy, including preoperative radiotherapy (RT) or radiochemotherapy (RCT), has become a standard regimen for locally advanced rectal cancer<sup>[2]</sup>. There have been growing concerns in recent years about the pathologic evaluation of rectal cancer after neoadjuvant therapy, since the pathologic stage (ypTNM) is now significantly different from its original meaning<sup>[3,4]</sup>. Due to neoadjuvant therapy, a considerable number of patients experience tumor regression or downstaging, and a minority of patients experience a complete pathologic response (CPR)<sup>[5]</sup>. However, the problem is that there are still few favorable pathological indicators to reflect and predict the clinical consequence of rectal cancer after neoadjuvant therapy.

Lymphovascular invasion (LVI) has been widely acknowledged as a useful independent pathological indicator for predicting prognosis, as well as a good index to guide postoperative therapy in colorectal cancer. Patients with LVI usually have a higher chance of disease progression and poorer prognosis<sup>[6-8]</sup>. The NCCN (National Comprehensive Cancer Network) guideline recommended LVI as a high risk factor of disease advance for colon cancer after surgery<sup>[9]</sup>. For rectal cancer, LVI is also a crucial high risk factor for recurrence post transanal local resection<sup>[10]</sup>. However, it has still to be established whether LVI has the same predictive meaning and clinical significance for patients with rectal cancer undergoing preoperative radiation. Does the biological behavior of the cancer cells involved in the blood or lymphatic vessels change after radiation? This is the issue we focus on.

## MATERIALS AND METHODS

### Clinical data

Data from all consecutive patients with resectable rectal carcinoma treated in our hospital from January 2000 to January 2005 were collected retrospectively. Among them, we selected eligible patients according to the following criteria: (1) resectable rectal cancer 12 cm or less from the anal verge; (2) evaluated by endorectal ultrasound (ERUS) or magnetic resonance imaging (MRI) before treatment; (3) histologically identified primary carcinoma of the rectum; (4) no clinical evidence of distant metastases; (5) transabdominal radical resection based on the principle of total mesorectal excision (TME); (6) R0 resection.

Exclusion criteria were: (1) patients who underwent concurrent RCT; (2) patients with CPR after neoadjuvant radiotherapy; (3) patients with synchronous tumors or history of other malignant tumors within 5 years; (4) familial adenomatous polyposis (FAP) and hereditary non-polyposis colorectal carcinoma (HNPCC); (5) died of complications or other non-cancer related reasons.

In total 325 patients were included (Table 1). All included patients were divided into a preoperative radiotherapy (PRT) group ( $n = 103$ ) and a control group ( $n = 222$ ), according to whether or not they underwent neoadjuvant radiation. There was no statistically significant difference in the gender, age, tumor location, preoperative serum carcinoembryonic antigen (CEA) level, pathologic stage and LVI between the two groups (Table 1). The conditions of histological differentiation and pretreatment stage (by imaging) were better in the control group, which implied a potentially better prognosis of patients in the control group. But the following multivariate analysis demonstrated that these two factors were not the major factors affecting the clinical consequence, so we considered the patients in the two groups to be comparable. Furthermore, we believe it more reasonable to investigate the influence of LVI on clinical consequence under the same pathologic stage rather than the same pretreatment stage in the

two groups, so it was inevitable that the pretreatment stage of the PRT group was later because of tumor-downstaging after neoadjuvant radiotherapy.

### Pretreatment evaluation

All included patients underwent ERUS or MRI to evaluate the tumor size, invasion depth and extent, and the involvement of pararectal lymph nodes. In total 280 patients (86.2%) were evaluated by ERUS and 45 patients (13.8%) by MRI. Serum CEA was measured and abdominal CT and chest radiography were also routinely performed before treatment.

### Neoadjuvant therapy

We adopted neoadjuvant radiation with a total dose of 30 Gy (30 Gy/10 fractions), recommended by the

Chinese Anti-Cancer Association (CACA)<sup>[11]</sup>, based on some high-level clinical evidence<sup>[12,13]</sup>. Surgery was performed 2-3 weeks after full dose radiation.

### Surgery

All included patients underwent radical resection strictly according to the principles of TME<sup>[14]</sup>, regardless of abdominoperineal resection (APR) or low anterior resection (LAR). In addition, 11 patients underwent combined resection (CR) involving partial or total resections of some pelvic organs; all resection margins were identified as negative by pathologic examination.

### Pathologic evaluation

All slides of postoperative specimens were stained with hematoxylin and eosin (HE) and were reviewed by one senior pathologist who was blind to the prognosis of patients. The available criteria for the histologic diagnosis of LVI included<sup>[15]</sup>: presence of tumor cells within lymphatic or vascular space; identification of endothelial cells lining the space; the presence of an elastic lamina surrounding the tumor; and attachment of tumor cells to the vascular wall.

Tumor regression was mostly in the form of fibro-inflammatory changes or necrosis replacing neoplastic glands. Mucin pools were also seen sometimes, as another type of degeneration post radiotherapy. Comparison between the pathologic T stage and clinical T stage (by imaging) was made to identify tumor-downstaging in the PRT group<sup>[16]</sup>.

### Postoperative therapy

All patients in the PRT group were given postoperative chemotherapy for 6-8 cycles, using the standard regimens based on 5-FU or capecitabine, such as FOLFOX, CapeOX or capecitabine alone. In the control group, only patients with lymph node involvement or with the pathologic T3 or T4 stage were given adjuvant chemotherapy, with the same regimens as were used in the PRT group. Notably, 95% (76/80) of LVI positive patients underwent postoperative adjuvant chemotherapy, while only 4/58 LVI positive patients in the control group were not given postoperative chemotherapy due to the early TNM stage. Therefore, our results concerning prognosis involved the influence of postoperative chemotherapy.

For the patients with disease progression, three patients with resectable liver metastasis underwent partial liver resection and one patient with solitary lung metastasis underwent lung wedge resection. Two patients with resectable local recurrence underwent APR. Other patients with disease progression underwent systematic chemotherapy or support therapy.

### Follow up

Patients were followed at 3 mo intervals for the first two years and then at 6 mo intervals for the next three years. Evaluations consisted of physical examination, serum CEA, a complete blood count, and blood chemical analysis. Proctoscopy, abdominal ultrasonography, CT of

the abdomen and pelvis, and chest radiography were also routinely used every 6-12 mo, according to the NCCN guideline<sup>[19]</sup>. Follow up time ranged from 3 to 96 mo, and the median follow up time was 72 mo. We chose 5 years as a time terminal for evaluation of outcomes. The follow up rate was 86.5% (281/325), with 44 inconclusive patients.

### Statistical analysis

Statistical analyses were performed using SPSS 16.0 statistical software. The categorical variables were analyzed with the Pearson chi-squared or Fisher's exact test, as appropriate. The Kaplan-Meier survival curve was used to estimate the proportion of patients surviving or remaining disease-free at each time interval. Disease free survival (DFS) and overall survival (OS) curves were compared between groups using the Wilcoxon's test for time-to-event parameters. Disease-free periods were compared using a log-rank test. Multivariate Cox proportional hazards regression was used to analyze the major factors affecting overall survival. All statistical tests were 2-sided, and the level of significance set at 5%.

## RESULTS

### The distribution and related factors of LVI

The overall positive rate of LVI was 24.6% (80/325), with no statistically significant difference in distribution between the PRT and control groups (21.4% and 26.1% respectively,  $P = 0.353$ ) (Table 1). Within the PRT group, LVI was not significantly reduced in patients with tumor-downstaging (Table 2). In the control group, LVI strongly correlated with histological differentiation and pathologic T and N stages whereas these associations were not observed in the PRT group (Table 2).

### The influence of LVI to clinical consequence

To get credible statistical results, we merged the local recurrence and distant metastasis to disease progression data because of the limited number of local recurrences in the PRT group. LVI was significantly associated with disease progression in both groups (Table 3): 38.5%-43.2% of LVI positive patients developed recurrence or metastasis, whereas 15.6%-17.6% of LVI negative patients progressed finally ( $P < 0.05$ ). LVI was also strongly correlated with DFS and OS: patients with LVI had lower rates of 5 year DFS and OS in both groups (Table 3, Figure 1A and B).

However, the influence of LVI on prognosis was not same in the two groups (Figure 2A and B). Among the patients with disease progression, LVI positive patients in the PRT group had a longer disease-free period and survival time than those in the control group (the median DFS time was 22.5 and 11.5 mo respectively,  $P = 0.023$ ; the median OS time was 42.5 and 26.5 mo respectively,  $P = 0.035$ ). There were no statistically significant differences in the 5 year DFS rate (54.4% vs 44.8%,  $P = 0.099$ ) and OS rate (54.4% vs 48.3%,  $P = 0.137$ ). For LVI negative patients, neither DFS nor OS showed significant differences between the two groups

**Table 2** The relevance of LVI and pathologic factors

		LVI		Positive rate (%)	P value
		Present	Absent		
PRT	ypT	T1	1	5	16.7
		T2	6	31	16.2
		T3	14	44	24.1
		T4	1	1	50.0
ypN	N0	9	54	14.3	0.057
	N1	9	15	37.5	
	N2	4	12	25.0	
Histological differentiation	High	1	3	25.0	0.998
	Moderate	15	55	21.4	
	Poor	5	19	20.8	
	Mucinous and signet	1	4	21.0	
Downstaging	Yes	7	34	17.1	0.388
	No	15	47	24.2	
Control	pT	T1	0	11	0
		T2	8	50	13.8
		T3	49	98	33.3
		T4	1	5	16.7
	pN	N0	15	103	12.7
		N1	15	37	28.8
		N2	28	24	53.8
Histological differentiation	High	7	22	24.1	0.015
	Moderate	34	122	21.8	
	Poor	11	16	40.7	
	Mucinous and signet	6	4	60.0	

(the median DFS time was 14.0 and 15.0 mo respectively,  $P = 0.980$ ; the median OS time was 29.8 and 34.0 mo respectively,  $P = 0.247$ ).

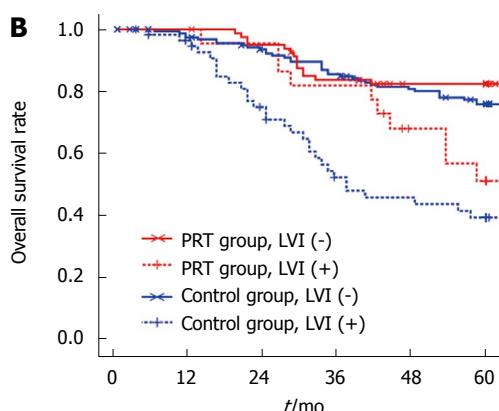

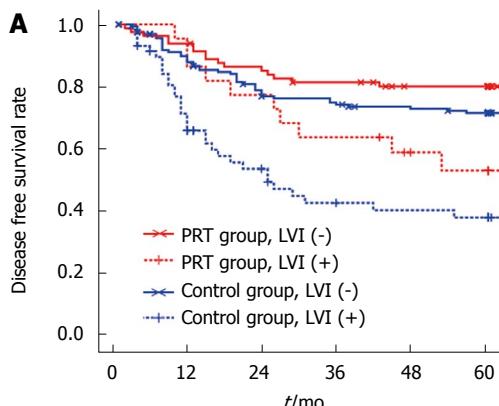

### The factors influencing prognosis

Multivariate analysis demonstrated that the distance of the tumor from the anal verge, pretreatment serum CEA level, pathologic TNM stage and LVI were the major factors affecting the 5 year OS (Table 4) whereas gender, age, neoadjuvant radiotherapy, tumor-downstaging, histological differentiation and pretreatment stage were not significantly associated with long-term survival.

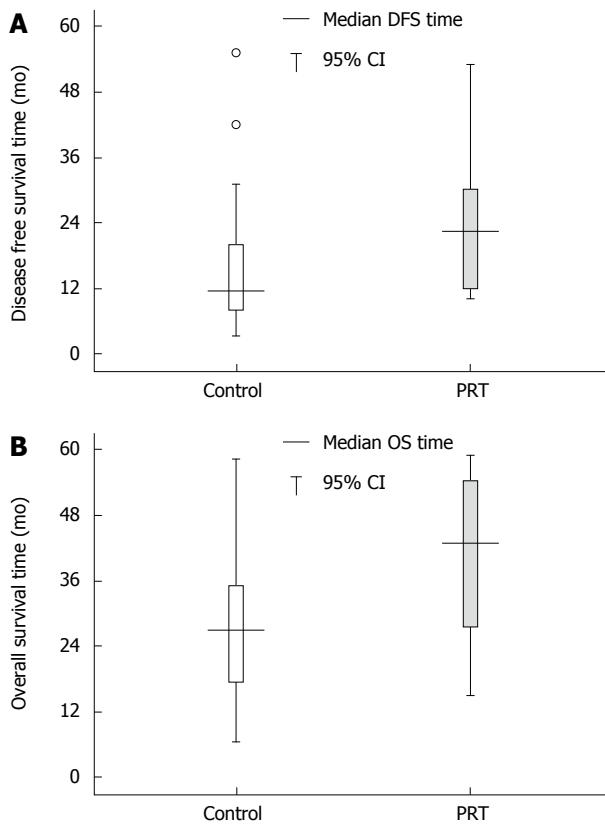

## DISCUSSION

Strictly speaking, lymphovascular invasion implies involvement of vascular and lymphatic vessels. However, histological distinction between larger lymphatic and smaller venous channels may not always be possible. Therefore, the term lymphovascular is used to refer to any or all of these structures<sup>[17]</sup>. LVI could be recognized clearly on HE-stained slides, despite the fact that some reports indicate using immunohistochemical stains with CD31 and D2-40 may improve the diagnosis<sup>[18,19]</sup>.

LVI has long been recognized as a favorable independent pathological indicator for predicting the prognosis of patients with colorectal cancer, which is usually associated with a poor consequence<sup>[6-8]</sup>. However, most studies concerning LVI were made in patients not given neoadjuvant therapy. Although several authors mentioned

**Figure 1** K-M plot of DFS (A) and OS (B) for LVI between the two groups. The LVI negative patients had a significantly higher 5-year DFS rate ( $P < 0.05$ ) and OS rate ( $P < 0.01$ ) than LVI positive patients in both groups ( $P < 0.05$ ).

**Figure 2** Stem and Leaf plot for comparison of DFS time (A) and OS time (B) for LVI positive patients between the two groups. Among the 42 (A) and 40 (B) LVI positive patients with disease progression, the patients in the PRT group had a longer median DFS time ( $P < 0.05$ ).

**Table 3** The association of LVI and prognosis

	PRT		P	Control		P
	Present	Absent		Present	Absent	
Disease progression (%)	Yes	10 (38.5)	16 (61.5)	0.014	32 (43.2)	42 (56.8) < 0.01
	No	12 (15.6)	65 (84.4)		26 (17.6)	122 (82.4)
5-year DFS rate	%	54.5 (12/22)	80.2 (65/81)	0.020	44.8 (26/58)	73.2 (120/164) < 0.01
5-year OS rate	%	54.5 (12/22)	82.7 (67/81)	< 0.010	48.3 (28/58)	78.0 (128/164) < 0.01

**Table 4** Multivariate analysis of OS by COX model (backward elimination)

Variable	Hazard ratio	95% CI	P value

Serum CEA level	1.334	1.027-1.732	0.031
pTNM stage	1.347	1.198-1.514	< 0.01
LVI	0.450	0.292-0.692	< 0.01

in their studies that LVI correlated with awful prognosis in patients undergoing neoadjuvant therapy<sup>[20,21]</sup>, there have been very few studies that specifically investigated the difference in LVI after neoadjuvant therapy compared to LVI after surgery directly. Our study was undertaken to illuminate such differences.

Despite the fact that preoperative radiation may lead to some histological changes, such as tumor regression or even a complete response<sup>[3,22,23]</sup>, our study found that preoperative radiotherapy alone did not significantly reduce the occurrence of LVI: at the same pathologic stage, the positive rates of LVI in the two groups were not significantly different (21.4% vs 26.1%, P = 0.353). Even for patients with tumor-downstaging, who could be considered sensitive to radiation, the LVI positive rate was not significantly reduced which implied the killing effect of X-rays to cancer cells involved in the vessels may be limited. Perhaps the addition of concurrent chemotherapy may work on LVI more effectively, which will be our continuing work based on the results from the current study. However, the influence of radiochemotherapy on LVI is more complicated, so we chose radiotherapy alone as the first step.

However, the behavior of tumor cells involved in the vessels somewhat changed after radiation. Our results demonstrated that the disease progression of patients with LVI in the PRT group was significantly delayed, which suggested that the aggression of those tumor cells in the blood or lymphatic vessels may have been significantly weakened by X-ray, though they were not completely eliminated. Currently, it is generally believed that radiation can cause DNA damage and chromosome aberrations, leading to an abortion of cell mitosis and proliferation, as well as inducing cell apoptosis<sup>[24,25]</sup>. Therefore, we inferred that the tumor cells involved in the vessels may be partly killed or inhibited by neoadjuvant radiotherapy so that disease progression was delayed and the survival time was prolonged.

At present, the issue about who would benefit from

neoadjuvant therapy is still being debated. Some authors believe that only patients with a good response to radiation could benefit from neoadjuvant therapy<sup>[3,16,26,27]</sup>. Our study demonstrated patients with LVI could gain a prolonged disease-free period and survival time from neoadjuvant radiotherapy. Thus, LVI positive patients may also benefit from neoadjuvant radiotherapy in a sense.

## ACKNOWLEDGMENTS

The authors appreciate Dr. Sarah in department of Pathology, UCLA for her excellent professional and language support.

## COMMENTS

### Background

Currently, neoadjuvant therapy has become a standard protocol for locally advanced rectal cancer. Although some studies have demonstrated that lymphovascular invasion (LVI) after neoadjuvant therapy is a high risk factor for recurrence, there have been very few studies that specially addressed the meaning of LVI after neoadjuvant therapy. The study is designed to compare the difference in LVI between patients undergoing neoadjuvant radiotherapy and those undergoing surgery directly.

### Research frontiers

The pathologic evaluation of the rectal cancer after neoadjuvant therapy is the hotspot most oncologists and scholars focus on.

### Innovations and breakthroughs

The study specifically addresses the meaning of LVI in rectal cancer after neoadjuvant radiotherapy; furthermore, they are first to report the difference in LVI after neoadjuvant radiotherapy.

### Applications

They demonstrated that patients with LVI could gain a prolonged disease-free period and survival time from neoadjuvant radiotherapy which provides significant evidence and reference for the application of neoadjuvant radiotherapy.

### Terminology

Lymphovascular invasion: a morphological concept which refers to the presence of tumor cells within lymphatic or vascular vessels, representing strong aggression of tumor cells.

### Peer review

The manuscript, reported by Du et al, investigates, in a retrospective cohort study, the difference in LVI after neoadjuvant therapy compared to LVI after surgery directly. This manuscript is well presented and gives us an interesting result. The patient's cohort is important.

The prevalence of *PTCH1a* TRR methylation was investigated in 170 gastric cancer tissue samples and the adjacent normal tissues by MSP. The correlation of *PTCH1a* TRR methylation with *PTCH1* expression or with patients' clinical features was analyzed.

**RESULTS:** Methylation of *PTCH1a* TRR was observed in AGS cells and a subset of gastric cancer tissues (32%, 55/170), while no methylation amplification products were observed in any normal tissues by MSP. The methylation of *PTCH1a* TRR was correlated negatively with *PTCH1* expression (Spearman's  $r = -0.380$ ,  $P = 0.000$ ). However, methylation of *PTCH1a* TRR was not related to the gastric cancer patients' clinical features, such as sex, age of onset, clinical stage, lymph node metastasis or histological grade. The methylation of *PTCH1a* TRR in AGS cells was almost converted to non-methylation after 5-Aza-dC treatment, which increased *PTCH1* expression ( $5.3 \pm 2.5$  times;  $n = 3$ ) and apoptosis rate ( $3.0 \pm 0.26$  times;  $P < 0.05$ ;  $n = 3$ ).

**CONCLUSION:** Methylation of *PTCH1a* TRR is present in a subset of gastric cancers and correlated negatively with *PTCH1* expression. This may be an early event in gastric tumorigenesis and a new treatment target.

## INTRODUCTION

The hedgehog (HH) pathway plays a critical role in embryonic development, tissue polarity and

carcinogenesis. In the HH pathway, Sonic HH binds to the receptor PTCH1, which is encoded by the *PTCH1* gene. This liberates the Smoothened protein, which allows glioma-associated oncogene homolog 1 zinc finger protein (GLI) and MYCN transcription factors to turn on target genes, including the *PTCH1* gene itself, in a negative feedback loop as a tumor suppressor gene. More recently, abnormal activation of the HH pathway has been reported in subsets of human basal cell carcinoma<sup>[1]</sup>, medulloblastoma<sup>[2]</sup>, pancreatic cancer<sup>[3-5]</sup>, lung cancer<sup>[6]</sup>, prostate cancer<sup>[7]</sup> and gastrointestinal cancer<sup>[8-10]</sup>.

Gastric cancer is one of the most common cancers worldwide, and has high mortality. Patients with gastric cancer usually present at late stages and have a poor prognosis. Loss-of-function mutation of *PTCH1* gene participates in the abnormal activation of the HH pathway, which occurs frequently in some cases of human basal cell carcinoma<sup>[11]</sup> and medulloblastoma<sup>[12]</sup>, but it has never been observed in gastric cancer<sup>[13]</sup>. Loss-of-function of tumor suppressor gene is also known to result from methylation of the transcriptional regulation region (TRR). Recently, several studies have argued that *PTCH1* TRR methylation is involved in tumorigenesis<sup>[14-17]</sup>; however, none has been reported in gastric cancer. Previous studies have shown that the *PTCH1* gene has three major isoforms in the first exon, *PTCH1a*, *PTCH1b* and *PTCH1c* that code for different N-sequence *PTCH1* proteins, *PTCH1-l*, *PTCH1-m* and *PTCH1-s*, respectively, and expression of each is regulated by its own independent TRR<sup>[18]</sup>.

The present study analyzed the methylation of *PTCH1a* TRR in gastric cancer cell line AGS and some gastric cancer tissue samples. We showed that methylation of *PTCH1a* TRR took place in a subset of gastric cancers, and was correlated negatively with *PTCH1* gene expression. It was not related to the patients' clinical features of gastric cancer, which suggested that the methylation of *PTCH1a* TRR might be an early event in gastric tumorigenesis.

## MATERIALS AND METHODS

### Gastric cancer patients' tissue samples and cell line

All the tissue samples were obtained from Shanghai Xinhua Hospital with hospital ethics board approval. One hundred and seventy gastric cancer tissue samples were collected from radical gastrectomy, to analyze the methylation of the *PTCH1* gene, and its expression. All patients gave informed consent for their specimens to be studied. The tumor and adjacent macroscopically normal tissue samples were preserved in liquid nitrogen immediately after being resected. Only the samples in which the proportion of tumor cells was > 70% and adjacent normal tissues with no inflammation or tumor infiltration were selected. Patients' clinical features were recorded, including sex, age of onset, clinical stage, lymph node metastasis, and histological grade. Gastric cancer cell line AGS was obtained from the American Type Culture Collection (ATCC, Rockville, MD, USA) and cultured under recommended conditions.

### DNA/RNA isolation

Frozen tissue in liquid nitrogen was pulverized for subsequent DNA isolation using the Blood and Cell Culture DNA kit (Qiagen, Hilden, Germany) or RNA isolation with TRIzol (Gibco-BRL, Glasgow, UK) according to the protocols of the manufacturers.

### Relative quantitative (RQ) RT-PCR

Total RNA (2.5 µg) was treated with DNase RQ1 (Promega, Madison, WI, USA) to remove trace amounts of genomic DNA contamination, and converted to cDNA using the oligo (dT) primer system (TaKaRa, Dalian, China), in a total volume of 50 µL. Aliquots of the reaction mixture were used for quantitative PCR amplification with ABI7500 (Applied Biosystems, Foster City, CA, USA) using SYBR Premix EX TagTM (TakaRa). PCR was run for 30 cycles of denaturation at 95°C for 5 s, annealing at 55°C for 20 s, and elongation at 72°C for 20 s. Gene expression was quantified by the comparative CT method, with normalizing CT values to the housekeeping gene β-actin. After amplification, melting curve analysis was performed to ensure the products' specificity. The RQ value of *PTCH1* expression in the samples was calculated in comparison with a calibrator (the expression level of pooled adjacent normal tissue samples). To ensure experimental accuracy, all reactions were performed in triplicate. The primer sequences for the gene amplification are shown in Table 1.

### Methylation-specific PCR (MSP) and bisulfite sequencing PCR (BSP)

Bisulfite modification, MSP and BSP were performed as described before<sup>[19,20]</sup>. The primers of MSP and BSP are shown in Table 1. One microgram of genomic DNA was treated using the EZ DNA Methylation Kit (Zymo Research, Orange, CA, USA) according to the manufacturer's instructions. For MSP, 1 µL modified DNA was amplified using MSP primers that specifically recognized the methylated or unmethylated DNA after bisulfite conversion. CpGenome Universal Methylated DNA (S7821) and CpGenome Universal Unmethylated DNA (S7822) (Chemicon Company, Temecula, CA, USA) were used as control DNA for methylated and unmethylated detection, respectively. Amplification products were visualized by UV illumination on 3% low-range ultra-agarose gel (Bio-Rad Laboratories, Hercules, CA, USA) that contained ethidium bromide. For BSP clone sequence analysis, the PCR products were subcloned into a pMD-18-T vector (TaKaRa). Ten clones were sequenced for cell line AGS and some gastric cancer tissues.

### 5-Aza-2'-deoxycytidine (5-Aza-dC) treatment

Cells were plated at a density of  $3 \times 10^4$  cells/cm<sup>2</sup> in a six-well plate on day 0. The demethylating agent 5-Aza-dC (Sigma-Aldrich, Deisenheim, Germany) was added on days 1, 2 and 3 to maintain its concentration as 1 µmol/L in fresh medium. Cells were harvested on

day 4 for RNA and DNA extraction. Control cells were incubated without the addition of 5-Aza-dC.

#### Analysis of cell cycle and apoptosis by flow cytometry

About  $1 \times 10^6$  AGS cells were centrifuged at 1000 r/min for 5 min to remove the culture solution. Cell cycle was measured by propidium iodide (PI) staining (final concentration 100 µg/mL, 0.01 mol/L PBS, pH 7.4; R&D System, Abingdon, UK) and flow cytometry (Becton Dickinson, Fullerton, CA, USA). Meanwhile, cell apoptosis rate was measured by annexin V/PI double staining (R&D Systems) and flow cytometry.

#### Immunohistochemistry

Sections of 3 µm were dried for 30 min at 72°C, deparaffinized in xylene, and rehydrated in a decreasing ethanol series. Endogenous peroxidase activity was blocked with 3% H<sub>2</sub>O<sub>2</sub> in methanol for 30 min and endogenous biotin with a blocking kit (SP-2001; Vector Laboratories, Burlingame, CA, USA). Antigen retrieval was performed by autoclaving for 10 min at 120°C in 10 mmol/L citrate buffer, pH 6.0. Sections were blocked for 30 min in a protein block (X0909; Dako, Carpinteria, CA, USA), and incubated overnight at 4°C with diluted goat polyclonal antibody directed against human PTCH1 protein (sc-6149, 1:100; Santa Cruz Biotechnology, Santa Cruz, CA, USA). After washing the sections with PBS that contained 0.1% Tween 20, biotinylated secondary antibodies were added for 30 min at room temperature. After extensive rinsing and incubation with avidin-biotin, immunoperoxidase antibody staining was visualized with the 3,3' diaminobenzidine system (Nichirei, Tokyo, Japan), and the sections were counterstained with Mayer's hematoxylin. The application of primary antibody to tissue sections was omitted in negative controls.

#### Statistical analysis

Statistical analysis was carried out using SPSS version 14.0 (SPSS, Chicago, IL, USA). Differences were considered statistically significant at  $P < 0.05$ . The nonparametric correlations of PTCH1 expression with methylation were analyzed with Spearman's test. Differences in the clinicopathological parameters between positive and negative PTCH1a TRR methylation were determined with the  $\chi^2$  test.

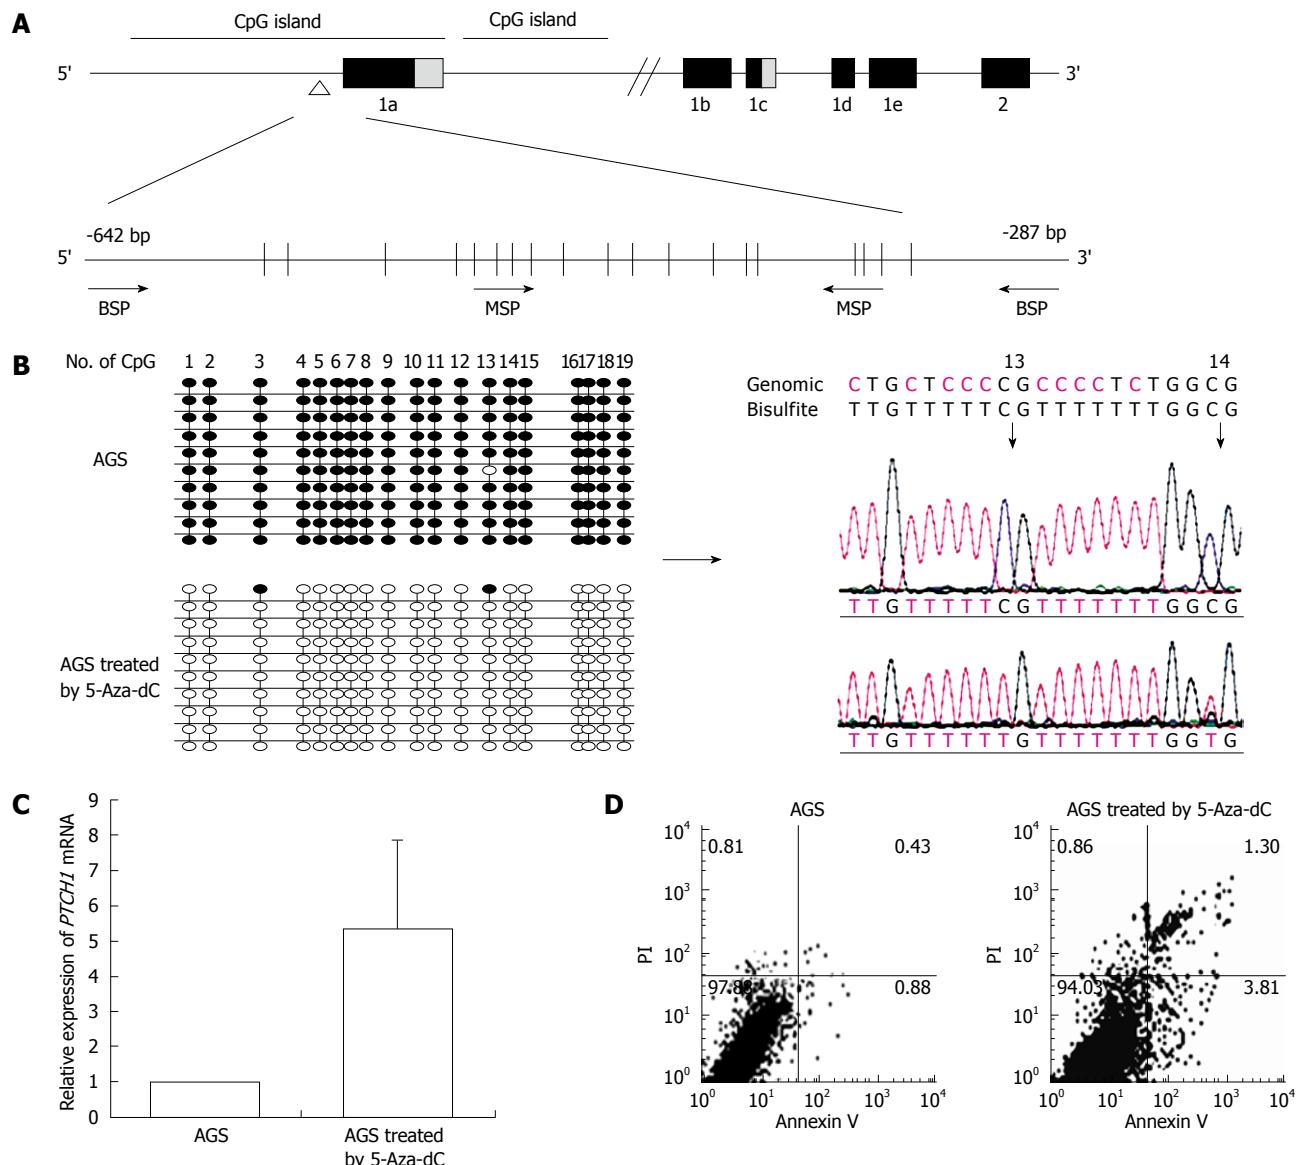

## RESULTS

#### PTCH1a TRR methylation and PTCH1 gene expression in gastric cancer cell line AGS

According to National Center for Biotechnology Information, PTCH1 gene has three mRNA transcripts. We analyzed the CpG island at -3950 bp upstream and +2050 bp downstream from the transcription initiation site of PTCH1a (designated as 0) by the methylation analysis software Methyl Primer Express v1.0 (Applied Biosystems). As shown in Figure 1A, two CpG islands exist in this region. One is -1139 to +860 bp and the other is +875 to +1692 bp. The region from -643 to -355 bp in the first CpG island that contained 19 CpG sites was chosen for the BSP and MSP primer amplifications. The MSP up-primer contained the fifth to eighth CpG sites, while the down-primer contained the sixteenth to eighteenth CpG sites. The methylation level of PTCH1a TRR in gastric cancer cell line AGS treated with 5-Aza-dC after 72 h was measured through BSP clone sequences. As shown in Figure 1B, almost all the CpG sites were methylated in the untreated cells, while almost all of them were converted to unmethylated after treatment with 5-Aza-dC. The RQ value of PTCH1 expression increased by  $5.3 \pm 2.5$  times ( $P < 0.05$ ,  $n = 3$ ) (Figure 1C). The cell cycle had no significant alteration after treatment (data not shown), by PI staining. However, as shown in Figure 1D, the apoptosis rate increased significantly by  $3.0 \pm 0.26$  times ( $P < 0.05$ ,  $n = 3$ ) by annexin V/PI double staining. These results indicated that the PTCH1a TRR was highly methylated in AGS cells, and became unmethylated after 5-Aza-dC treatment, which substantially increased PTCH1 expression and induced more apoptosis.

#### PTCH1a TRR methylation in gastric cancer tissues

In order to investigate the prevalence of PTCH1 TRR methylation in gastric cancer tissues, detection of PTCH1a TRR methylation in 170 gastric cancer tissues was performed by MSP. If the methylation amplification products appeared after electrophoresis in the investigated sample, PTCH1 TRR was predicted to be methylated. The prevalence of PTCH1a TRR methylation was 32% (55/170) in gastric cancer tissues, while no methylation amplification products were observed in any normal tissues (data not shown). Part

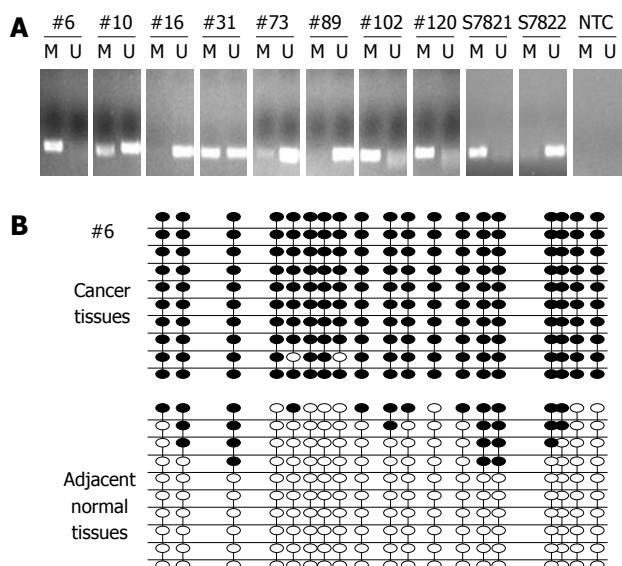

**Figure 1 Analysis of methylation and expression of *PTCH1a* in gastric cancer cell line AGS.** A: Illustration of *PTCH1a* TRR and topology of MSP and BSP primers. BSP detection region contained 19 CpG sites, and MSP up-primer and down-primer contained four and three CpG sites, respectively. The detection amplicon is indicated by the empty triangle; B: Alteration of *PTCH1a* TRR methylation in gastric cancer cell line AGS treated with 5-Aza-dC. Genomic DNA from untreated AGS cells and those treated with 5-Aza-dC (1  $\mu$ mol/L) were analyzed by BSP at day 4. The left column indicates alterations of the 19 CpG sites contained in the BSP amplicon through 10 cloned sequences after 5-Aza-dC treatment. The right column displays part of the sequence of the methylated and unmethylated clones. Black dot, methylated; white dot, unmethylated; C: Alteration of *PTCH1* expression in gastric cancer cell line AGS treated with 5-Aza-dC. *PTCH1* gene expression in AGS cells treated with 5-Aza-dC (1  $\mu$ mol/L) at day 4 was detected by real-time PCR relative to untreated AGS cells. Expression of *PTCH1* gene was enhanced significantly in the treated AGS cells compared with untreated ( $P < 0.01$ ,  $n = 3$ , independent tests). Box, mean; bar, SD; D: Analysis of apoptosis of AGS cells treated with 5-Aza-dC. The rate of apoptosis in AGS cells treated with 5-Aza-dC (1  $\mu$ mol/L) at day 4 was significantly higher compared to untreated cells ( $P < 0.01$ ,  $n = 3$ ). The representative analysis of AGS cell apoptosis by annexin V/PI method is shown.

of the representative MSP amplification products electrophoretogram is shown in Figure 2A. To further confirm the fact of *PTCH1a* TRR methylation, we chose gastric cancer tissue sample #6 with a positive methylation amplification product, and the pool of adjacent normal tissues ( $n = 12$ ) for BSP clone sequencing. As shown in Figure 2B, almost all of the 19 CpG sites in 10 clones exhibited methylation in cancer tissues, while very few CpG sites in adjacent normal tissues did. These results demonstrated that the methylation of *PTCH1a* TRR did exist in a subset of gastric cancer tissues.

#### Correlation between methylation of *PTCH1a* TRR and *PTCH1* expression in gastric cancer tissues

We analyzed the correlation between methylation of *PTCH1a* TRR and *PTCH1* expression. As shown in Figure 3, there was a significant difference in *PTCH1* mRNA expression between methylated and unmethylated gastric cancer tissues. High expression had a negative correlation with high methylation (Spearman's  $r = -0.380$ ;  $P = 0.000$ ). To further determine this negative correlation, the *PTCH1* protein was examined in four representative samples by immunohistochemistry. As shown in Figure 4, two samples (#3 and #5) with

**Figure 2** Methylation of *PTCH1a* TRR in gastric cancer tissues. A: Methylation of *PTCH1a* TRR in gastric cancer tissues ( $n = 170$ ) using MSP. MSP results from eight representative patients (#) are shown. The DNA bands in lanes labeled with M represent the products amplified with the methylation-specific primers, while DNA bands labeled with U represent the products amplified with the non-methylation-specific primers. CpGenome Universal Methylated DNA (S7821) and the CpGenome Universal Unmethylated DNA (s7822) were used as controls for methylation and non-methylation. Water was used as non-template control (NTC); B: Genomic DNA of gastric cancer tissues and its corresponding normal tissues from a representative patient (#6) was analyzed by BSP. Methylation patterns of the 19 CpG sites contained in the BSP amplicon through 10 clone sequence analyses in cancer tissues, and corresponding normal tissues are shown. Black dot, methylation; white dot, non-methylation.

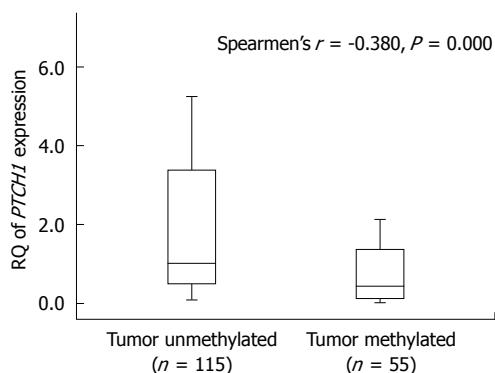

visible unmethylated products by MSP were positive for *PTCH1* protein and had higher RQ value of *PTCH1* mRNA expression, while another two samples (#7 and #10) with visible methylated products by MSP were negative for *PTCH1* protein and had lower RQ value of *PTCH1* mRNA expression. Samples #3 and #7 were well-differentiated, while #5 and #10 were poorly differentiated. Notably, this was further proof that a subset of gastric cancer tissues were characterized by methylation of *PTCH1a* TRR, along with lower expression of the *PTCH1* gene.

#### Relationship between *PTCH1a* TRR methylation in gastric cancer tissues and clinical features

We analyzed statistically the relationship between the methylation of *PTCH1a* TRR in gastric cancer tissues and clinical features. As shown in Table 2, there was no correlation between the methylation of *PTCH1a* TRR and clinical features, including sex, age of onset, clinical stage, lymph node metastasis, and histological grade. These data suggest that methylation of *PTCH1a* TRR is an early event in gastric tumorigenesis.

## DISCUSSION

The methylation of tumor suppressor gene plays an important role in the tumorigenesis of gastric cancer. *PTCH1* gene is a known tumor suppressor gene in

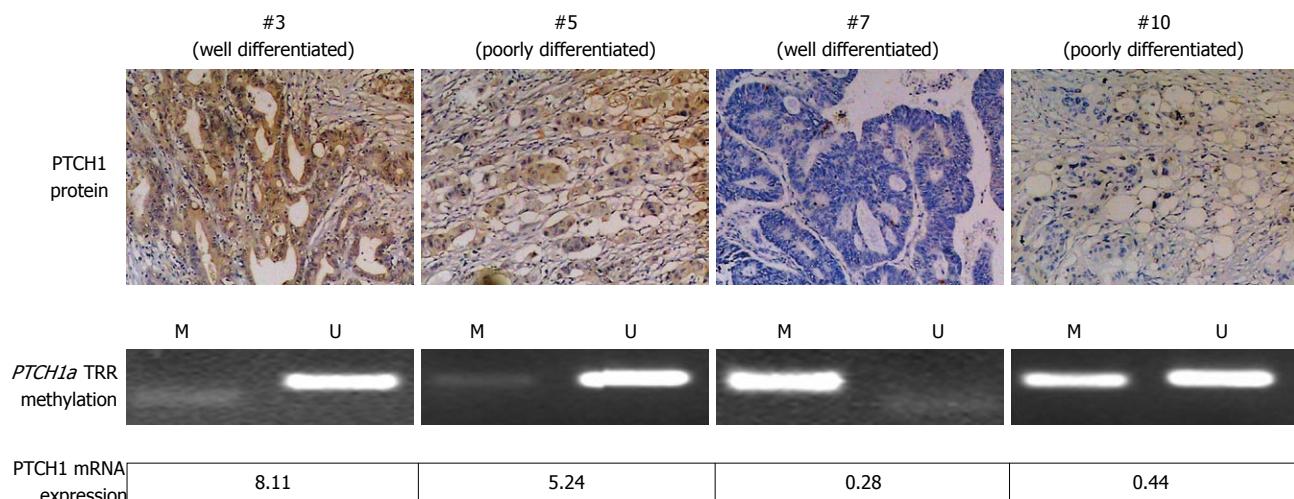

**Figure 3** Correlation between methylation of *PTCH1a* gene TRR and expression of *PTCH1* in gastric cancer tissues. Box plot illustrating the loss of *PTCH1* gene expression in relation to the methylation of *PTCH1a* gene TRR in human gastric cancer tissues ( $n = 170$ ). The Y axis indicates the RQ value of *PTCH1* gene mRNA expression was calculated in comparison with a calibrator (the expression level of pooled adjacent normal tissue samples). Horizontal lines: Group medians; Boxes: 25%-75% quartiles; Vertical lines: Range, peak and minimum.

the HH pathway. Loss of function mutation and epigenetic regulation has been found in many kinds of tumors<sup>[3,6,13,14]</sup>.

*PTCH1* gene has three main isoforms of the first exon, *PTCH1a*, *PTCH1b*, and *PTCH1c*, which code for different N-sequence *PTCH1* proteins PTCH1-l, PTCH1-m and PTCH1-s, respectively<sup>[18]</sup>. Each expression is regulated by its own independent TRR. Although it has been reported that PTCH1-l and PTCH1-m have the same effect on inducing apoptosis and suppressing GLI-mediated transcription, only the methylation analysis of *PTCH1b* TRR has been reported by some research groups. Cretnik *et al*<sup>[17]</sup> have reported that methylation of *PTCH1b* TRR (-1593 bp, transcription initiation site of *PTCH1b* as 0) occurs in ovarian tumors (dermoids and fibromas) compared to healthy controls, but not in basal cell carcinoma. Wolf *et al*<sup>[14]</sup> have demonstrated methylation

**Figure 4 Correlation of PTCH1 mRNA and protein expression with methylation of PTCH1a TSS.** Expression of PTCH1 genes, as well as methylation of PTCH1a TSS are displayed in four representative gastric cancer tissue samples (#3, #5, #7 and #10). PTCH1 protein expression was detected by immunohistochemical staining (original magnification,  $\times 100$ ). Methylation of PTCH1a TSS was detected by MSP. The RQ value of PTCH1 gene mRNA expression was calculated in comparison with a calibrator (the expression level of pooled adjacent normal tissue samples). The well-differentiated tissue sample #3 and the poorly differentiated tissue sample #5 showed non-methylated products by MSP, positive expression of PTCH1 protein, and higher RQ value of PTCH1 mRNA expression. The well-differentiated tissue sample #7 and poorly differentiated tissue sample #10 showed methylated products by MSP, negative expression of PTCH1 protein, and lower RQ value of PTCH1 mRNA expression.

of PTCH1b TSS (-776 to +1238 bp, transcription initiation site of PTCH1b as 0) in breast cancer cell lines and tissues, which has a negative correlation with PTCH1 expression. However, Pritchard *et al*<sup>[15]</sup> have found that there is no methylation of PTCH1b TSS (-983 bp, transcription initiation site of mRNA1b as 0) in primary medulloblastoma.

In the present study, we analyzed the methylation status of PTCH1a TSS. We selected the upstream regulation region of PTCH1a (-643 to +355 bp, transcription initiation site of mRNA1b as 0) as the target region to be analyzed because this region was in the CpG island that appeared nearest to the transcription initiation site of PTCH1a gene, according to the software analysis. In order to investigate the methylation status in a number of gastric cancer tissues, the BSP colon sequence method was used to identify the suitable CpG sites for the MSP primer design. We found that the upstream regulatory sequence of PTCH1a gene was methylated in the gastric cancer cell line and a subset of gastric cancer tissues, and this methylation correlated with low expression of the PTCH1 gene. Nagao *et al*<sup>[18]</sup> have reported that the expression of these three isoforms is regulated by GLI transcription factors, one in exon 1a and the other between exons 1a and 1b, in the vicinity of which methylation is found in ovarian tumors<sup>[17]</sup>. However, we found methylation at -441 bp upstream of the GLI binding site in exon 1, and the methylation of this target region was correlated negatively with PTCH1 gene expression. These results suggest that CpG island methylation in the TSS of PTCH1a gene plays a role in the regulation of not only PTCH1a transcription, but also downstream PTCH1b and PTCH1 transcription.

Several recent studies have demonstrated that activation of the HH signaling pathway is involved in gastric

tumorigenesis<sup>[21-25]</sup>. However, PTCH1 gene expression has not been investigated extensively, especially in normal gastric tissues. Ma *et al*<sup>[26]</sup> have reported that PTCH1 mRNA expression was detected by hybridization in about 64% (63/99) of gastric cancer tissues but not in normal gastric tissues (0/18). Many other studies have shown by immunohistochemistry that PTCH1 gene expression was present in the fundic glandular epithelium of the stomach<sup>[8,24]</sup>. We found that adjacent normal tissues expressed PTCH1 gene, along with being unmethylated, which confirms that PTCH1 gene expression is present in normal gastric tissues.

Berman *et al*<sup>[13]</sup> have found that the PTCH1 gene was expressed in six human gastric cancer cell lines including AGS, which indicates that the Hedgehog signaling pathway is activated not by mutation, but by ligand expression. The expression of PTCH1a and PTCH1b genes was equally active in terms of suppressing GLI-mediated transcription, as a negative feedback for regulation of the HH signaling pathway, and induction of apoptosis<sup>[18]</sup>. We found that the demethylation reagent 5-Aza-dC reversed the methylation of PTCH1a gene, enhanced PTCH1 gene expression, and induced apoptosis. Our results implied that the enhanced expression of PTCH1 gene that resulted from demethylation strengthened the negative feedback function of PTCH1, which provided a new target for treating gastric cancer.

Previous studies have found that a high level of aberrant DNA methylation exists in *Helicobacter pylori* (*H. pylori*)-infected gastric mucosa and is possibly associated with gastric cancer risk<sup>[27,28]</sup>. Others have shown that *H. pylori* infection might affect the HH pathway that is involved in gastric carcinogenesis<sup>[29,30]</sup>. These results suggest that the methylation of PTCH1a TSS in gastric cancer may be triggered by *H. pylori* infection in the early

course of carcinogenesis. This will be studied in our laboratory in the future.

We demonstrated that methylation of *PTCH1a* TRR was present in a subset of gastric cancers. To the best of our knowledge, this phenomenon has not been observed or reported by any research group to date. Methylation of *PTCH1* was correlated negatively with *PTCH1* gene expression and was not related to clinical features of gastric cancer, which suggested that the methylation of *PTCH1a* TRR is an early event in gastric tumorigenesis. Downregulation of *PTCH1a* gene methylation may provide a new therapy for gastric cancer characterized by *PTCH1a* TRR methylation.

## COMMENTS

### Background

Abnormal activation of the hedgehog (HH) pathway has been reported in subsets of human basal cell carcinoma, medulloblastoma, pancreatic cancer, lung cancer, prostate cancer and gastrointestinal cancer. Although loss-of-function mutation in the *PTCH1* gene participates in the abnormal activation of the HH pathway, several studies have argued that the *PTCH1* transcriptional regulation region (TRR) methylation is involved in tumorigenesis. However, none has been reported in gastric cancer.

### Research frontiers

Previous studies have shown that the *PTCH1* gene has three major isoforms in the first exon, *PTCH1a*, *PTCH1b* and *PTCH1c* that code for different N-sequence *PTCH1* proteins *PTCH1-I*, *PTCH1-m* and *PTCH1-s*, respectively. Expression of each is regulated by its own independent TRR. The present study analyzed the methylation of *PTCH1a* TRR in gastric cancer.

### Innovations and breakthroughs

The present study showed that methylation of *PTCH1a* TRR is present in a subset of gastric cancers, and correlated negatively with *PTCH1* gene expression. It was not related to the clinical features of gastric cancer, which suggests that methylation of *PTCH1a* TRR is an early event in gastric tumorigenesis. To the best of our knowledge, these phenomena have never been observed or reported by any research group to date.

### Applications

By understanding that the methylation of *PTCH1a* TRR might be an early event in gastric tumorigenesis, this study may provide a new therapy for gastric cancer that is characterized by *PTCH1a* TRR methylation.

### Terminology

The HH pathway plays a critical role in embryonic development, tissue polarity and carcinogenesis. In the HH pathway, the receptor *PTCH1* is encoded by the *PTCH1* gene as a tumor suppressor gene, and plays a role in negative feedback regulation of activation of the HH pathway. Methylation of TRR can induce the loss of gene expression. Thus, methylation of *PTCH1a* TRR might be an early event in gastric tumorigenesis.

### Peer review

The authors detected the methylation of *PTCH1a* TRR in gastric cancer cell line AGS and 170 gastric cancer tissue samples and adjacent normal tissues, and analyzed the correlation of *PTCH1a* TRR methylation with *PTCH1* expression and clinical features. They revealed that the methylation of *PTCH1a* TRR correlated negatively with *PTCH1* expression. However, the methylation of *PTCH1a* TRR was not related to the clinical features of gastric cancer, such as sex, age of onset, clinical stage, lymph node metastasis, and histological grade. The results are interesting and may represent a molecular mechanism of gastric carcinogenesis.

## Abstract

**AIM:** To determine the effect of hammerhead ribozyme targeting connective tissue growth factor (CCN2) on human hepatic stellate cell (HSC) function.

**METHODS:** CCN2 hammerhead ribozyme cDNA plus two self-cleaving sequences were inserted into pTriEx2 to produce pTriCCN2-Rz. Each vector was individually transfected into cultured LX-2 human HSCs, which were then stimulated by addition of transforming growth factor (TGF)- $\beta$ 1 to the culture medium. Semi-quantitative RT-PCR was used to determine mRNA levels for CCN2 or collagen I, while protein levels of each molecule in cell lysates and conditioned medium were measured by ELISA. Cell-cycle progression of the transfected cells was assessed by flow cytometry.

**RESULTS:** In pTriEx2-transfected LX-2 cells, TGF- $\beta$ 1 treatment caused an increase in the mRNA level for CCN2 or collagen I, and an increase in produced and secreted CCN2 or extracellular collagen I protein levels. pTriCCN2-Rz-transfected LX-2 cells showed decreased basal CCN2 or collagen mRNA levels, as well as produced and secreted CCN2 or collagen I protein. Furthermore, the TGF- $\beta$ 1-induced increase in mRNA or protein for CCN2 or collagen I was inhibited partially in pTriCCN2-Rz-transfected LX-2 cells. Inhibition of

CCN2 using hammerhead ribozyme cDNA resulted in fewer of the cells transitioning into S phase.

**CONCLUSION:** Endogenous CCN2 is a mediator of basal or TGF- $\beta$ 1-induced collagen I production in human HSCs and regulates entry of the cells into S phase.

## INTRODUCTION

Activation of hepatic stellate cells (HSCs) is a central event in the pathobiology of hepatic fibrosis<sup>[1,2]</sup>. In response to chronic liver injury, quiescent HSCs undergo gradual phenotypic changes that result in their trans-differentiation into  $\alpha$ -smooth muscle actin (SMA)-positive, proliferative, myofibroblast-like cells. In the injured liver, activated HSCs are responsible for producing much of the excess extracellular matrix, including fibrillar collagen<sup>[1,2]</sup>. At the molecular level, this process is driven by a variety of growth factors, cytokines and matricellular proteins. While transforming growth factor (TGF)- $\beta$  has received special attention because of its potent fibrogenic effects *in vivo* and its ability to stimulate fibrogenic pathways in HSCs<sup>[3]</sup>, targeting of this molecule for therapeutic intervention is problematic because of its other important actions in the liver, including tumor suppression and immune modulation. However, a potentially more attractive target is connective tissue growth factor (CCN2), which appears to mediate many of the fibrogenic properties of TGF- $\beta$ <sup>[4]</sup>.

CCN2 was discovered as a TGF- $\beta$ -immediate early gene in 1989<sup>[5]</sup> and numerous studies since then have described an intimate relationship between these molecules in many fibrotic diseases, including those of the liver<sup>[6]</sup>. CCN2 is recognized increasingly as a central player in hepatic fibrosis and may offer new options for prognosis, diagnosis and therapy<sup>[7]</sup>. Previously, we have shown that exposure of HSCs to CCN2 induces cell adhesion, migration and proliferation, the latter of which is associated with transient induction of c-fos and activation of the extracellular signal-regulated kinase 1/2 signaling pathway<sup>[8-10]</sup>. In addition, CCN2 induces expression of  $\alpha$ -SMA and type I collagen in HSCs, consistent with a role in activation and fibrogenesis<sup>[8]</sup>. We have shown that adhesive signaling by CCN2 in HSCs increases expression of collagen type I, fibronectin, and tissue inhibitor of metalloproteinase (TIMP)-1, and decreases expression of caspase 8 and hepatocyte growth factor<sup>[11]</sup>. CCN2 also stimulates survival pathways in activated HSCs<sup>[12]</sup>. These data suggest that CCN2 drives both fibrogenic and anti-apoptotic pathways in activated HSCs and reinforce the notion that CCN2 is a potential novel therapeutic target in liver fibrosis.

We and others have shown that CCN2 mRNA and protein are expressed increasingly during progressive activation of cultured primary rat HSCs, or in response of the cells to stimulation by TGF- $\beta$ , vascular endothelial growth factor, lipid peroxidation products, acetaldehyde or platelet-derived growth factor-BB<sup>[8,13-16]</sup>. We have shown further that CCN2 promoter activity is enhanced in a Smad7-dependent fashion by TGF- $\beta$  in primary rat HSCs transfected with the CCN2 promoter, luciferase reporter construct<sup>[10]</sup>, and that CCN2 production in the HSCs is stimulated by TGF- $\beta$ <sup>[6]</sup>. We recently showed that TGF- $\beta$ -induced CCN2 promoter activity in activated mouse HSCs requires Smad and Ets-1 elements in the CCN2 promoter<sup>[16]</sup>, as described for normal fibroblasts or mesangial cells<sup>[17-20]</sup>. However, CCN2 promoter activity in activated HSCs is uniquely antagonized by ALK4/5/7 inhibition<sup>[16]</sup>. CCN2 gene regulation in activated HSCs is distinct from that of scleroderma, which is independent of Smad/ALK5-mediated TGF- $\beta$  signaling, but is dependent on endothelin-1<sup>[17,21,22]</sup>, or pancreatic cancer, which depends on activated ras/MEK/ERK rather than TGF- $\beta$  or endothelin-1<sup>[23]</sup>.

Surprisingly, there is no information regarding the role of basal or TGF- $\beta$ -induced CCN2 in the function of human HSCs. In the present study, we investigated the effect of a hammerhead ribozyme that targets CCN2 on TGF- $\beta$ 1-induced collagen I synthesis or cell-cycle progression in the LX-2 human HSC line, which was generated originally by spontaneous immortalization of primary human HSCs in low-serum conditions<sup>[24]</sup>.

## MATERIALS AND METHODS

### Reagents

Dulbecco's Modified Eagle's Medium (DMEM),

Lipofectamine<sup>TM</sup> 2000 and TRIzol were from Life Technologies (Carlsbad, CA, USA). Fetal bovine serum (FBS) was obtained from Hyclone (Logan, UT, USA). Human TGF- $\beta$ 1 was purchased from PeproTech (Rocky Hill, NJ, USA). The human HSC line, LX-2, was a kind gift of Dr. Scott Friedman (Mount Sinai Hospital, New York). pTriEx2 vector was obtained from Novagen (Gibbstown, NJ, USA). *Xba*I and *Nco*I were from Toyobo (Osaka, Japan). Avian myeloblastosis virus and Taq DNA polymerase were from Promega (Madison, WI, USA). ELISA kits for human CCN2 or collagen I were from, respectively, USCN Life Science and Technology Co. (TX, USA) or Cosmo Bio (Tokyo, Japan).

### Ribozyme design and recombinant plasmid construction

The mRNA sequence of human CCN2 (NCBI, gi: 98986335) was scanned for potential hammerhead ribozyme cleavage sites using proprietary design software developed by the Shanghai Institute of Biological Chemistry of the Chinese Academy of Sciences. Of the five potential hammerhead ribozyme cleavage sites, one site located at 896 of CCN2 mRNA was identified with optimal secondary folding. A 34-mer hammerhead ribozyme cDNA that targeted at the C-U-A at position 896 of CCN2 mRNA (sense: 5'-CTTCTCCTGATGAGTCCTGAGGACG AAAGCCTG-3'; antisense: 5'-CAGGCTTCGTCCTC ACGGACTCATCAGGAGAAG-3'), plus two self-cleaving sequences, were synthesized chemically and inserted into pBluescript II SK9(-) cloning vector. Both pTriEx2 and pBluescript II SK9(-) were linearized with *Xba*I and *Nco*I individually, and the digested products were ligated using T4 DNA ligase. The resulting vector, termed pTriCCN2-Rz, (in which synthesis of the ribozyme was driven by the chicken  $\beta$ -actin promoter and the cytomegalovirus enhancer) was confirmed by DNA sequencing.

### Cell culture and transfection

LX-2 cells were allowed to grow at 37°C for 2 d in DMEM that contained 10% FBS, 100 U/mL penicillin and 100  $\mu$ g/mL streptomycin. The cells were digested with 0.25% trypsin, and washed with Hank's Balanced Salt Solution (without  $\text{Ca}^{2+}$  or  $\text{Mg}^{2+}$ ). The cells were then cultured in either 20  $\times$  100-mm cell culture dishes for RNA isolation and determination of cell-cycle progression, or 12-well plates for measurement of production and secretion of CCN2 or collagen I. Prior to transfection, the cells were grown in DMEM that contained 2.5% FBS for 24 h, followed by DMEM that contained 0.1% FBS for another 24 h. Cells were transfected with vectors using Lipofectamine<sup>TM</sup> 2000 reagent under serum-free conditions for 4 h. The transfected cells were incubated for another 24 h in the presence or absence of 20 ng/mL TGF- $\beta$ 1.

### Semi-RT-PCR

Total RNA was extracted from cultured LX-2 cells using TRIzol reagent. An optimal RNA template (0.8  $\mu$ g)

was generated by semi-quantitative RT-PCR using a UNOII thermocycler (Biometra, Germany). The expression of mRNA for human CCN2, collagen  $\alpha$ 1 (I), or  $\beta$ -actin was examined by RT-PCR using the following forward and reverse primers: CCN2 forward, 5'-CCTGGTCCAGACCACAGAGT-3'; CCN2 reverse, 5'-ATGTCTTCATGCTGGTGCAG-3'; collagen  $\alpha$ 1 (I) forward, 5'-CCTCAAGGGCTCCAACGAG-3'; collagen  $\alpha$ 1 (I) reverse, 5'-TCAATCACTGTCTGCCCA-3';  $\beta$ -actin forward, 5'-GTCCTCTCCAAAGTCCACAC-3';  $\beta$ -actin reverse, 5'-GGGAGACCAAAAGCCTTCAT-3'.

Briefly, 0.8  $\mu$ g RNA was reverse transcribed using Moloney murine leukemia virus reverse transcriptase in the presence of oligo(dT) and dNTP, followed by amplification of cDNA (1  $\mu$ L), using Taq DNA polymerase in a final volume of 50  $\mu$ L that contained 1 mmol/L MgCl<sub>2</sub>, 0.2  $\mu$ mol/L of each dNTP, and 0.5  $\mu$ mol/L of each primer. Amplification conditions were 94°C for 30 s, 58°C for 30 s, and 72°C for 1 min, over 32 cycles. Amplification products were visualized on ethidium-bromide-stained agarose gels. Image analysis of the individual transcripts was carried out using Gel-Pro 3.2 software (Media Cybernetics, Bethesda, MD, USA). Data were expressed as the gray-scale ratio of either CCN2 mRNA or collagen  $\alpha$ 1 (I) mRNA relative to that of  $\beta$ -actin mRNA.

### **CCN2 or collagen I ELISA**

CCN2 or collagen I levels were measured in cell lysates or conditioned medium of serum-starved, cultured LX-2 cells in the absence or presence of 20 ng/mL TGF- $\beta$ 1 for 24 h using a sandwich ELISA following the manufacturer's instructions for each kit. Briefly, microtiter wells were pre-coated for 2 h (CCN2) or 30 min (collagen I) at 37°C, with 100  $\mu$ L of each standard, or 1:20 dilutions of LX-2 cell lysates or conditioned medium supernatant. The plates were then developed by addition of biotinylated anti-CCN2 antibody or anti-collagen I antibody, followed by avidin-conjugated horseradish peroxidase. The color reaction was developed using tetramethylbenzidine substrate solution and measured by its absorbance at 450 nm using a Model 550 plate reader (BioRad, Hercules, CA, USA).

### **Flow cytometry**

LX-2 cell-cycle progression was determined by resuspending the cells at 1  $\times$  10<sup>6</sup> cells/mL in PBS, fixing the cells with 75% ethanol overnight, and then staining the cells with 0.1  $\mu$ g/mL propidium iodide in a 0.1% sodium citrate/0.1% Triton X-100 solution for 30 min at room temperature in the dark, in the presence of 0.2 mg/mL RNase. Analysis of cellular DNA content after cell staining with propidium iodide was performed by flow cytometry at an excitation wavelength of 488 nm. The distribution of cells in three major phases of the cycle (G0/G1, S, G2/M) was analyzed using CellQuest software (BD Biosciences, San Jose, CA, USA).

### **Statistical analysis**

The values reported represent the mean  $\pm$  SD of the

measurements of at least four different experiments. Photographs of RT-PCR products are representative of at least three independent experiments. Statistical analysis of the data was performed using SPSS for Windows version 11 (SPSS, Chicago, IL, USA). The Student *t* test was used for paired data that were normally distributed, and *P* < 0.05 was considered significant.

## **RESULTS**

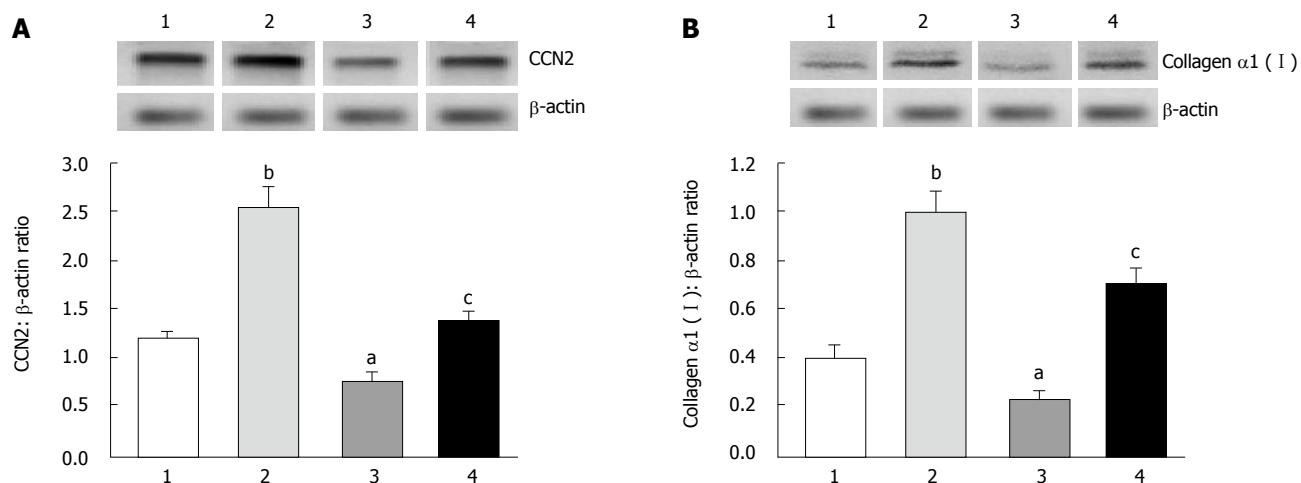

### **Effects of hammerhead ribozyme on CCN2 mRNA and protein expression in cultured LX-2 cells**

Previous studies have demonstrated that the LX-2 cell line contains CCN2 mRNA<sup>[25]</sup>, a feature that is characteristic of the activated HSC phenotype<sup>[6]</sup>. Since many TGF- $\beta$  pro-fibrogenic activities are mediated by CCN2<sup>[26]</sup> and TGF- $\beta$  stimulates collagen production in LX-2 cells<sup>[24]</sup>, we examined the functional relationship between TGF- $\beta$  and CCN2, utilizing hammerhead ribozymes designed to cleave CCN2 mRNA in the cells. Initial experiments were performed in which the LacZ reporter gene was inserted downstream of CCN2 hammerhead ribozyme cDNA in pTriCCN2-Rz, and into the downstream multiple cloning site of pTriEx2, to investigate the transcriptional activity of both vectors. When histochemical X-gal staining was performed on cell cultures transfected with either pTriEx2 or pTriCCN2-Rz individually, about 30% of the cells were positive for each vector (data not shown), and this transfection efficiency was sufficient to assess subsequently the functional effect of the hammerhead ribozyme that targeted CCN2.

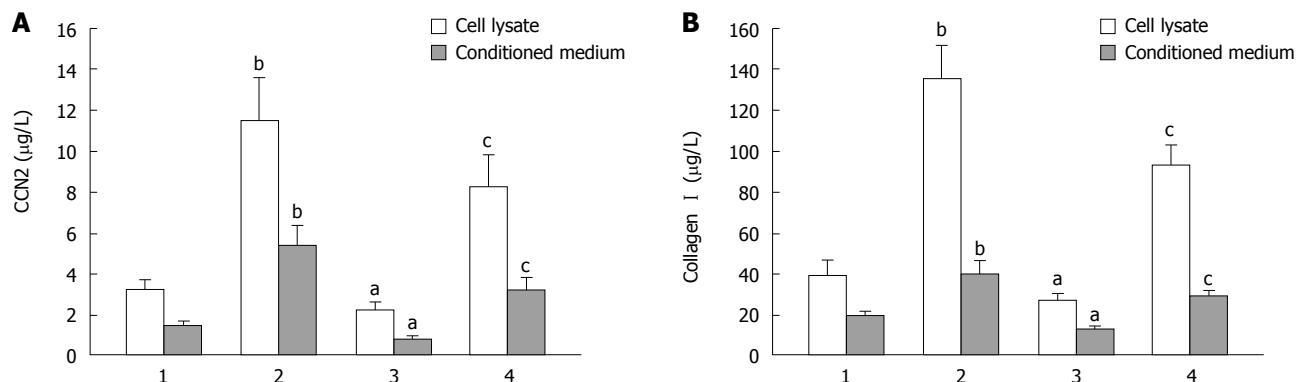

CCN2 mRNA and protein in pTriEX-2-transfected LX-2 cells were present under basal growth conditions and there was an approximately 2.5- and 3.5-fold increase, respectively, in CCN2 transcript and protein levels (*P* < 0.01, paired *t* test) after stimulation of the cells with TGF- $\beta$  for 24 h (Figures 1A and 2A). In contrast, after transfection with the pTriCCN2-Rz vector, the LX-2 cells demonstrated reduced constitutive expression of CCN2 mRNA and protein (*P* < 0.05) under baseline conditions and moreover, the stimulation of CCN2 mRNA and protein (*P* < 0.05) in response to TGF- $\beta$  was attenuated substantially (*P* < 0.05). These data confirmed the ability of the hammerhead ribozymes to target CCN2 mRNA and to block CCN2 production and secretion, thus allowing for its function in LX-2 cells to be further explored.

### **Effects of hammerhead ribozyme on TGF- $\beta$ 1-induced collagen I mRNA and protein expression in cultured LX-2 cells**

Under basal conditions, pTriEx-2-transfected LX-2 cells produced collagen  $\alpha$ 1 (I) mRNA and the amount of this transcript was enhanced two-fold by TGF- $\beta$  treatment (*P* < 0.01; Figure 1B). On the other hand, under basal conditions, pTriCCN2-Rz-transfected LX-2 cells produced approximately 60% of the level of collagen  $\alpha$ 1 (I) mRNA as control cells (*P* < 0.05). Whereas TGF- $\beta$  treatment of pTriCCN2-Rz-transfected

**Figure 1** Effect of CCN2 hammerhead ribozyme on basal or TGF-β-induced mRNA expression of CCN2 or collagen α1 (I). The figure shows the RT-PCR reaction products (upper panel) and the densitometric scans (lower panel) for (A) CCN2 mRNA or (B) collagen α1 (I) after transfection of LX-2 cells with pTriEx2 (lanes 1 and 2) or pTriCCN2F-Rz (lanes 3 and 4) under basal conditions (lanes 1 and 3), or after stimulation with 20 ng/mL TGF-β1 for 24 h (lanes 2 and 4). <sup>a</sup>P < 0.05 vs lane 1; <sup>b</sup>P < 0.01 vs lane 1; <sup>c</sup>P < 0.05 vs lane 2.

**Figure 2** Effect of CCN2 hammerhead ribozyme on basal or TGF-β-induced protein production or secretion of CCN2 or collagen I. The figure shows the protein levels of CCN2 (A) or collagen I (B) in cell lysates or conditioned medium measured by ELISA after transfection of the cells with pTriEx2 (lanes 1 and 2) or pTriCCN2F-Rz (lanes 3 and 4) under basal conditions (lanes 1 and 3), or after stimulation with 20 ng/mL TGF-β1 for 24 h (lanes 2 and 4). <sup>a</sup>P < 0.05 vs lane 1; <sup>b</sup>P < 0.01 vs lane 1; <sup>c</sup>P < 0.05 vs lane 2.

LX-2 cells resulted in stimulation of the amount of collagen α1 (I) mRNA, the level attained was only 70% of that seen in TGF-β-stimulated control cells ( $P < 0.05$ ; Figure 1B). Essentially identical results were obtained when cell lysates or conditioned medium from the cells were tested by ELISA, in that basal and TGF-β-stimulated collagen I protein production and secretion was attenuated significantly in pTriCCN2F-Rz-transfected LX-2 cells as compared to those transfected with pTriEx-2 ( $P < 0.05$ ; Figure 2).

### Effects of hammerhead ribozyme on LX-2 cell-cycle progression

We next used flow cytometry to assess the effect of basal CCN2 expression on LX-2 cell-cycle progression. As shown in Table 1, after pTriCCN2F-Rz transfection, a relatively higher proportion of cells were in the G0/G1 phase ( $P < 0.05$ ) and a lower proportion were in S phase ( $P < 0.05$ ), as compared to pTriEx2-transfected cells. This showed that endogenous CCN2 played a role in the G0/G1 → S transition in LX-2 cells. To verify that

this difference was not caused by greater cytotoxicity of pTriCCN2F-Rz than pTriEx2, the viability of transfected LX-2 cells was verified by trypan blue exclusion assay. Less than 3% of the pTriEx2- or pTriCCN2F-Rz-transfected cells stained blue, and there was no difference in the frequency of trypan-blue-positive cells between pTriEx2 and pTriCCN2F-Rz transfection (data not shown). Moreover, comparable amounts of β-actin mRNA were amplified from pTriEx2- or pTriCCN2F-Rz-transfected cells (Figure 1).

### DISCUSSION

In the present study, a recombinant vector, pTriCCN2F-Rz, bearing hammerhead ribozyme cDNA plus two self-cleaving sequences that targeted the 896 site of CCN2 mRNA, was constructed and transfected into the LX-2 human HSC line. The hammerhead ribozyme blocked CCN2 mRNA transcription and protein production in LX-2 cells and inhibited basal or TGF-β1-induced transcription and production of collagen I in LX-2 cells.

**Table 1 Distribution of cell-cycle phases in pTRIEx2- or pTriCCN2-Rz-transfected LX-2 cells**

Vector	G0G1 (%)	S (%)	G2M (%)
pTRIEx2	60.64 ± 2.26	27.53 ± 1.76	11.83 ± 1.36
pTriCCN2-Rz	80.45 ± 3.12 <sup>a</sup>	10.83 ± 1.02 <sup>b</sup>	8.27 ± 0.68

<sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01 compared with pTRIEx2.

That the knockdown achieved in these experiments was only partial was likely attributable to the transfection efficiency of 30%, but even so, the data clearly showed a CCN2-dependency of basal or TGF-β-stimulated collagen I production in activated human HSCs. This finding, coupled with the ability of hammerhead ribozyme targeting of CCN2 to attenuate the rate of HSC proliferation, suggest that it is a useful therapeutic strategy in fibrosis of the liver and possibly, of other organ systems.

In recent years, the relationship between CCN2 and TGF-β in fibrogenic pathways has been explored using blocking strategies that exploit the targeting of CCN2 mRNA with antisense oligonucleotides or small interfering RNA (siRNA)<sup>[27]</sup>. The use of CCN2 antisense oligonucleotides has helped to establish the importance of CCN2 for TGF-β-induced collagen production in a variety of cell types including kidney mesangial cells, NRK cells, corneal fibroblasts, and conjunctival fibroblasts<sup>[28-33]</sup>. In *in vivo* animal models, CCN2 antisense oligonucleotides have proven effective in reducing matrix expansion or fibrosis in the skin or kidney<sup>[34-36]</sup>, and scarring around breast implants<sup>[37]</sup>. However, while CCN2 antisense therapy in CCl<sub>4</sub>-induced liver fibrosis is associated with reduced expression of mRNA for CCN2 or collagen, fibrous deposits are not reduced, an effect that has been attributed to high expression of TIMP-1<sup>[38]</sup>.

Insight into fibrogenic mechanisms has also been obtained from experiments that employ CCN2 siRNA technology that relies on short dsRNA for gene silencing, and shows improved potency and specificity as compared to antisense oligonucleotides<sup>[27]</sup>. CCN2 siRNA was effective in blocking collagen synthesis in scleroderma fibroblasts<sup>[39]</sup>, glucose-induced matrix production in vascular smooth muscle cells<sup>[40]</sup>, or TGF-β-stimulated collagen production in dermal fibroblasts, osteoblasts or rat HSCs<sup>[41-43]</sup>. Plasmids expressing short hairpin RNA, which are easier to produce and more effective than some traditional siRNA approaches, have been shown to disrupt CCN2 gene expression in cultured rat HSCs, and to cause marked attenuation in the production of collagen III and IV, laminin, and hyaluronic acid<sup>[44]</sup>. Finally, *in vivo* studies have shown that CCN2 siRNA delivery to rats is an effective anti-fibrotic therapy in renal allografts after transplantation or in livers after exposure to N-nitrosodimethylamine<sup>[45,46]</sup>. In mice, an HSC-specific targeting strategy has been employed for CCN2 siRNA therapy in CCl<sub>4</sub>-induced hepatic fibrosis<sup>[27]</sup>.

Additional approaches for antagonizing the

production or action of CCN2 have been described, such as those employing pharmacological inhibitors or neutralizing antibodies<sup>[27]</sup>. However, pharmacological inhibitors are not necessarily specific to CCN2, while the use of neutralizing antibodies or antisense oligonucleotides relies on a stoichiometric and relatively inefficient 1:1 complex formation with their respective CCN2 protein or RNA target. Since, in our studies, the CCN2 ribozyme acted catalytically by binding and cleaving its target RNA, whereupon the fragments were released and the cycle was repeated numerous times, this mode of CCN2 antagonism was considerably more efficient than other methods. On the other hand, since the hammerhead ribozyme motif cleaves the phosphodiester bond downstream of a NUY triplet (where N is any base and Y is any base except G), a potential drawback to the use of ribozymes in some applications is the availability of this required NUY cleavage site in the target RNA molecule.

We conducted these studies with LX-2 cells because they are viable in serum-free media, demonstrate many of the hallmarks of activated HSCs, and because human HSCs have not been studied previously in the context of CCN2 mRNA inhibition. Our data support the potential use of hammerhead ribozyme in targeting CCN2 in fibrotic livers since, in the presence or absence of added TGF-β, it reduced collagen synthesis and secretion by the cells, and reduced the frequency of S-phase cells, even though the cells were constitutively activated and had a high basal proliferative rate. This latter observation is of interest because we are aware of only one other report in which a CCN2 hammerhead ribozyme has been developed, and this has been shown to block TGF-β-mediated proliferation of dermal fibroblasts<sup>[47]</sup>. Thus, our data suggest that targeting CCN2 mRNA will likely cause anti-fibrogenic and anti-proliferative effects within the activated HSC population in fibrotic liver.

## ACKNOWLEDGMENTS

We thank Dr. Scott Friedman for his support and for providing the LX-2 cells.

## COMMENTS

### Background

Fibrosis is a debilitating pathology that can occur in many different organs and affects millions of people around the world. It is characterized by excessive collagen deposition that can prevent essential organs from functioning properly, and can ultimately lead to organ failure. In the liver, a cell type called the hepatic stellate cell (HSC) is responsible for producing much of the collagen that contributes to hepatic fibrosis, and recent evidence suggests that connective tissue growth factor (CCN2) is an important molecule that drives collagen production in these cells.

### Research frontiers

There is much optimism that antagonism of CCN2 may be a novel and effective means of preventing or reversing fibrosis. Methods for preventing the production or action of CCN2 are at the forefront of research in this area, and it is important to examine the various options available so that rational therapeutic approaches can be developed.

### Innovations and breakthroughs

Previously, it has been shown that transforming growth factor (TGF)-β is potent

fibrogenic molecule *in vivo* and can stimulate fibrogenic pathways in HSCs. However, TGF- $\beta$  plays essential roles in the liver, such as tumor suppression and immune modulation, such that targeting of this molecule for therapeutic intervention is problematic. Since CCN2 acts downstream of TGF- $\beta$  in fibrogenic cascades and mediates many of the fibrogenic properties of TGF- $\beta$ , it is becoming accepted that CCN2 is a more appropriate molecule to target than TGF- $\beta$ . Recently, methods have begun to emerge that achieve antagonism of CCN2 mRNA through the use of blocking cDNA or RNA sequences. In the present study, the authors used this type of blocking approach in a human HSC line, LX-2, to prevent CCN2 mRNA transcription and protein production, to inhibit basal or TGF- $\beta$ 1-induced transcription and production of collagen I, and to reduce the number of actively dividing cells. The innovative features of these studies involve the use of human HSCs and the delivery of the antisense molecule in the form of a hammerhead ribozyme, which has a more efficient blocking action than some other conventional antisense methods. Their data show that the anti-fibrotic properties of CCN2 hammerhead ribozyme are caused by a reduction of collagen production and cell proliferation.

### Applications

The study results suggest that CCN2 hammerhead ribozyme may have utility as a therapeutic agent for treating hepatic fibrosis *in vivo*.

### Terminology

HSCs are a minor and quiescent cell type in the liver that usually reside in the space of Disse, but which undergo activation after hepatic injury to produce large quantities of fibrillar collagens, which are deposited as insoluble fibrous matrix. TGF- $\beta$  is a multifunctional molecule that has immunomodulatory and tumor-suppressive actions in the liver, but which also is fibrogenic through its stimulation of CCN2 transcription.

### Peer review

In this study Gao and Brigstock have focused on CCN2 that is considered to mediate many TGF- $\beta$ -induced fibrotic reactions, to develop potential treatment of liver fibrosis, because TGF- $\beta$ -targeting therapeutic intervention has been found to be problematic because of side effects in the liver. The authors examined the effects of CCN2 gene-targeting blocking on the TGF- $\beta$ -dependent activation of LX-2 cells, utilizing the hammerhead ribozyme method to suppress CCN2 gene expression. Recombinant vector pTriCCN2-Rz was prepared by inserting CCN2 hammerhead ribozyme cDNA plus two self-cleaving sequences into pTriEx2 vector, and transfected LX-2 cells together with a null vector, pTriEx2. The collagen type I synthetic and proliferative activities were assessed at the gene and protein levels, and compared between the cells transfected with pTriCCN2-Rz and pTriEx2 vectors. As a result, the authors were able to demonstrate the expected attenuation of collagen synthesis activity by CCN2-Rz transfection not only in the TGF- $\beta$ -treated cells, but also in the control cells. Introduction of pTriCCN2-Rz gene also suppressed the entry of the cells into the S phase.

cytokine that plays a role in the pathogenesis of inflammatory bowel disease. The introduction of anti-TNF- $\alpha$  agents for the treatment of ulcerative colitis (UC) has been delayed because contrary to Crohn's disease (CD), UC has classically been considered a T helper cell type 2 (Th2) disease, for which the role of TNF- $\alpha$  is less relevant than that of other cytokines such as interleukin (IL)-10 and IL-5<sup>[1]</sup>. However, other more recent studies have shown that TNF- $\alpha$  may play a major role in the etiopathogenesis of UC, justifying the use of anti-TNF- $\alpha$  therapies<sup>[2]</sup>.

Infliximab (IFX) is presently the only biologic therapy employed in the treatment of moderate-to-severe UC<sup>[3]</sup>. With increased use of IFX in UC, cases of intolerance or adverse reaction to this drug are expected. In these clinical situations and based on the data and experience from CD, adalimumab (ADA) is likely to be the next biologic drug to be used in UC. There are currently very few data published regarding the efficacy of ADA in UC. Moreover, the data are short-to-medium term, and there is no evidence of its long-term efficacy.

We report on two patients with moderate-to-severe UC who, due to adverse reactions to IFX, have been under therapy with ADA for two years. Clinical remission and mucosal healing are described.

### Abstract

Infliximab (IFX) is currently the only biologic therapy used in the treatment of moderate-to-severe ulcerative colitis (UC). In the years to come, more biologic therapies will have a role in the management of moderate-to-severe UC. We report on two patients with steroid-dependent UC who, due to adverse reactions to IFX, have been under therapy with adalimumab for two years. Both patients received concomitant immunosuppressive treatment. Long term clinical remission and mucosal healing are described.

### INTRODUCTION

Tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) is a proinflammatory

### CASE REPORT

#### Case 1

A 55-year-old male was diagnosed with ulcerative pancolitis in 2003. In 2005 he developed steroid dependence and treatment with azathioprine 2.5 mg/kg was started with clinical response for 1 year. In October 2006, the patient presented both clinical (8 bloody stools per day) and endoscopic relapse (3 points on the Mayo endoscopic subscore). After performing viral serologies, chest X-ray and Mantoux test, treatment with IFX 5 mg/kg was started. At the second dose, he developed a generalized skin rash on both trunk and extremities requiring drug discontinuation. On this basis and after requesting compassionate use, ADA treatment was started with an induction dose of 160 mg at week 0 followed by 80 mg at week 2 and then 40 mg every 2 wk thereafter as maintenance therapy. The patient had a very good clinical response, with normalization of stools after 2 mo. From the onset of treatment and over the subsequent two year period the patient has experienced no new flare and remains in clinical remission. A

**Figure 1 Colonoscopy.** A: Case 1 at 2 years of adalimumab treatment; B: Case 2 at 2 years of adalimumab treatment.

colonoscopy performed at 2 years from onset of ADA therapy showed no evidence of disease activity and complete mucosal healing (Figure 1A).

### Case 2

A 29-year-old woman with a previous diagnosis of rheumatoid arthritis was diagnosed with ulcerative pancolitis in 2004. After one year she developed steroid-dependency and treatment with azathioprine 2.5 mg/kg was started. Despite this treatment, she was readmitted to the hospital in March 2006 for a severe relapse. A colonoscopy was performed showing diffuse continuous mucosal disease and multiple erosions with signs of bleeding (2 points on the Mayo endoscopic subscore). Given these findings, it was decided to start treatment with IFX 5 mg/kg after performing the standard pretreatment evaluation for biologic therapies (viral serologies, chest X-ray and Mantoux test). On the second dose of IFX, the patient experienced an adverse drug reaction with difficulty breathing and edema of the face and glottis requiring drug discontinuation. Treatment with ADA was initiated with an induction dose of 160 mg at week 0, followed by 80 mg at week 2 and then 40 mg every 2 wk thereafter as maintenance therapy. The patient did not have any adverse drug reaction, corticosteroids were completely withdrawn and a marked improvement was observed in intestinal and articular symptoms. A colonoscopy performed at 2 years after starting ADA treatment showed absence of acute disease, no friability, and signs of healing, with findings compatible with 0 points on the Mayo endoscopic subscore (Figure 1B).

### DISCUSSION

Currently, IFX is the only biologic therapy approved for UC treatment, although in the not very distant future other biologic agents will be employed for treatment of this disease. As occurred in CD, ADA is likely to be the next biologic drug that will be used in UC, although only case reports<sup>[4]</sup> or very limited studies have been published to date. These studies only included patients with loss of response or intolerance to IFX. The few data published are from a French group who, in a first study, reported their short-term experience in 10 patients with UC who had loss of response or intolerance to IFX<sup>[5]</sup>. They evaluated the efficacy of ADA at 4 wk after two doses (160 mg at week 0 and 80 mg at week 2) and observed that patients showed improvement, and that among patients with no response two subsequently underwent colectomy. This same group has recently published medium-term data (median follow-up 42 wk) from 13 ADA-treated patients who had loss of response or intolerance to IFX<sup>[6]</sup>. During this period, 46% of patients underwent colectomy, with no differences being observed between the group of patients with loss of response or intolerance. Recently another open-label study has shown 50% response at week 24 in UC patients treated with AD<sup>[7]</sup>.

Our aim in reporting these two cases is to provide information on the clinical and mainly endoscopic long-term efficacy of ADA. Mucosal healing seems to be an important new therapeutic target in inflammatory bowel disease and the complete mucosal healing reported in our two cases seems to confirm the expectations created for ADA in UC, in that it seems to be a reasonable alternative in cases of intolerance or adverse reaction to IFX<sup>[8]</sup>.

Both patients received concomitant treatment with thiopurinic immunosuppressants. The studies conducted in CD do not provide sufficient evidence to recommend the routine long-term use of immunosuppressants in all patients treated with ADA, but concomitant use of immunosuppressant and ADA in UC should be evaluated in depth in controlled clinical trials.

The present study is a series of only two cases and solid conclusions cannot be drawn from its findings. We only aim to show that in the presence of severe UC, in patients with an adverse reaction to IFX, ADA treatment is a possible and safe alternative that can maintain long-term clinical and endoscopic remission.

endoscopic clipping for colonic diverticular bleeding: A rare complication. *World J Gastroenterol* 2009; 15(30): 3817-3818 Available from: URL: <http://www.wjgnet.com/1007-9327/15/3817.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.3817>

## INTRODUCTION

Diverticular bleeding is one of the most common causes of lower-GI bleeding. It has been reported that endoscopic clipping is effective in diverticular bleeding<sup>[1-3]</sup>. However, we wish to report the rare complication of sepsis caused by endoscopic clipping for colonic diverticular bleeding.

## CASE REPORT

We herein report the rare complication of sepsis caused by endoscopic clipping for colonic diverticular bleeding. A 78-year-old man with a 12-h history of near syncope and painless hematochezia was admitted to our hospital. Following the transfusion of 4 U of blood and continued hematochezia, a colonoscopy was performed. Active bleeding was seen as continuous arterial spurting from a single diverticulum located in the middle ascending colon. This diverticulum was seamed by four endoclips. The next day, the patient became febrile with a temperature of 39.2°C. Laboratory data included a white blood cell count of 18100/mm<sup>3</sup> and a C-reactive protein level of 3.4 mg/dL. He was diagnosed with sepsis since *Escherichia coli* was detected in the blood culture. Antibiotics were started. Four days later his fever had improved and laboratory data improved 9 d later.

The next day, the patient became febrile with a temperature of 39.2°C. Laboratory data included a white blood cell count of 18100/mm<sup>3</sup> and a C-reactive protein level of 3.4 mg/dL. He was diagnosed with sepsis since *Escherichia coli* (*E. coli*) was detected in the blood culture. Antibiotics were started. Four days later his fever improved and his laboratory data improved 9 d later.

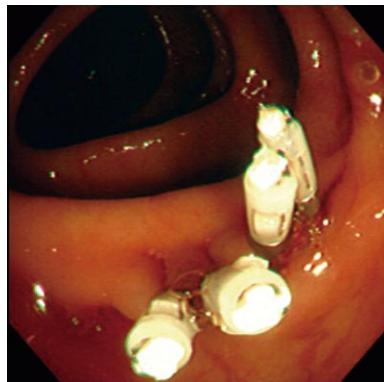

## DISCUSSION

Although diverticular bleeding episodes are often self-limiting, massive hemorrhage requiring therapeutic intervention occurs in a significant number of patients. Endoscopic clipping and other endoscopic therapies have been the treatment of choice in such cases<sup>[1-4]</sup>.

Normally, hemoclips are placed on and around the

**Figure 1** Continuous arterial spurting from a single diverticulum located in the middle ascending colon.

**Figure 2** The diverticulum was seamed by four endoclips.

visible vessel and immediate hemostasis is completed<sup>[1-4]</sup>. However, we seamed the diverticulum itself using endoclips because of difficulty in recognizing the visible vessel due to massive arterial spurting. The next day, the patient developed sepsis. This was probably because *E. coli* was present in the diverticulum which then invaded blood vessels.

It is important that hemoclips are placed on and around the visible vessel if possible, because it can alert the endoscopist to be mindful of potential hazards such as the one we encountered. However, hemoclips would appear to pose a risk of perforation when applied to the thin dome of a diverticulum.

### INTRODUCTION

Duodenal diverticulum is a disease entity that was first described in 1710 by Chromel. Most duodenal diverticula are diagnosed incidentally, 2% to 5% at barium study of gastrointestinal tract, 12% to 27% at endoscopy, and 22% in autopsy cases. Only 5% to 10% of patients with duodenal diverticula suffer from clinical symptoms. However, less than 1% of patients require treatment for various complications such as perforation, hemorrhage, and biliary/pancreatic/gastrointestinal obstruction.

Here, we report a patient who presented with duodenal obstruction after successful selective transcatheter arterial embolization (TAE) for a duodenal diverticular hemorrhage.

### CASE REPORT

A 69-year-old woman was admitted with abrupt onset of dull abdominal pain and vomiting. She had hypertension, did not drink alcohol, smoke, or use non-steroidal anti-inflammatory drugs. She had visited the department of internal medicine complaining principally of melena two years prior to admission. At that time, initial serum hemoglobin was 12.2 g/dL, and endoscopic evaluation, including gastroscopy and colonoscopy, showed no specific findings except for erosive gastritis. Computed tomography (CT) images showed a large duodenal diverticulum, however it was decided to merely observe the diverticulum because it did not cause any symptoms (Figure 1).

When she arrived at the emergency room this time, an intraabdominal bulging mass was palpated in the right upper quadrant of her abdomen. Her hemoglobin level was 7.9 g/dL and a CT scan showed an acute duodenal diverticular hemorrhage, large surrounding retroperitoneal hematoma, and an arterial pseudoaneurysm. The arterial pseudoaneurysm was thought to be the cause of the acute hemorrhage (Figure 2A). A superior mesenteric arteriogram

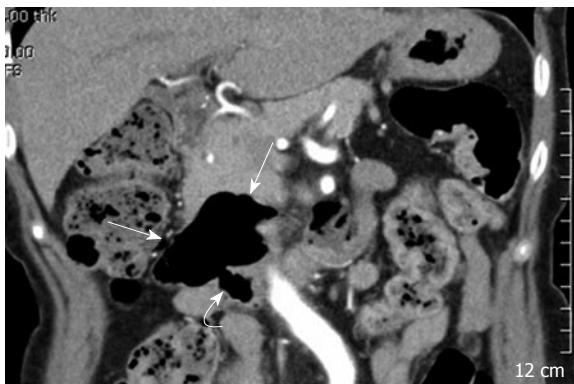

### Abstract

We present a 69-year-old woman with a duodenal obstruction after successful selective transcatheter arterial embolization (TAE) for a duodenal diverticular hemorrhage. Two weeks after TAE, the patient showed abrupt symptoms of duodenal obstruction. Resolving hematomas after successful selective transcatheter arterial embolization should be thoroughly observed because they might result in duodenal fibrotic encasement featuring inflammatory duodenal wall thickening, duodenal deformity, dysmotility, and finally obstruction.

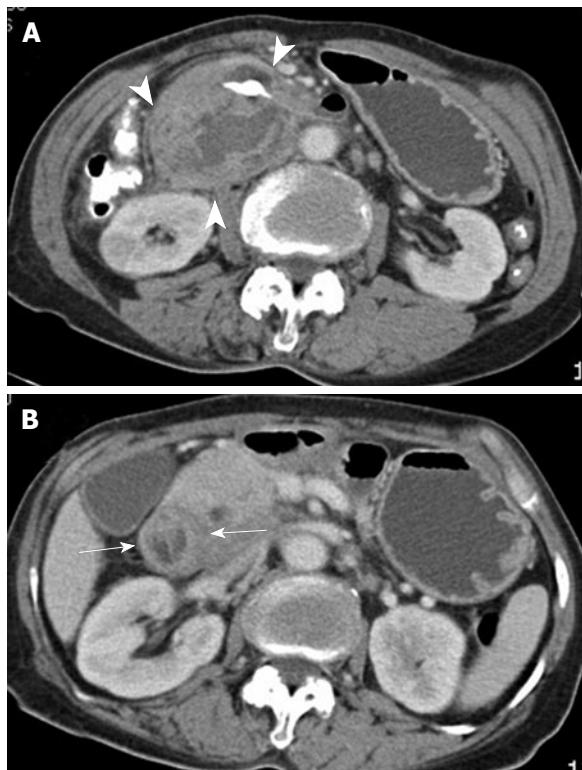

**Figure 1** Computed tomography (CT) image two years before the admission shows an approximately 6 cm sized silent diverticulum (arrows) originating from the proximal third portion of the duodenum (curved arrow).

**Figure 2** Diagnostic images on admission. A: An approximately 7 cm sized acute duodenal diverticular hemorrhage (curved arrow) and surrounding large retroperitoneal hematoma (arrows) around the duodenum on contrast enhanced CT image; B: The causative arterial pseudoaneurysm (arrow) on superior mesenteric arteriogram; C: Barium leakage into the large hemorrhagic duodenal diverticulum (arrows) and another small silent diverticulum (curved arrow) in the duodenal third portion on upper gastrointestinal barium study.

(Figure 2B), showed that the arterial pseudoaneurysm was in a duodenal branch of the anteroinferior pancreaticoduodenal artery and transcatheter glue embolization was performed in a superselective way using a Histoacryl (N-butyl-2-cyanoacrylate)-Lipiodol

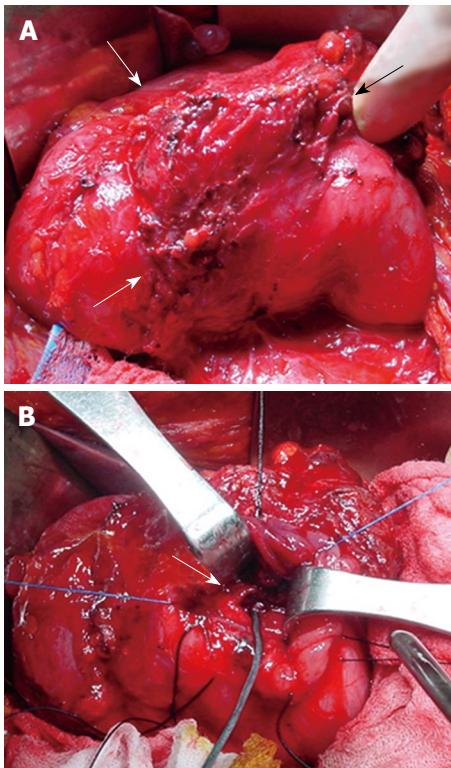

**Figure 3** CT images when the patient complained of gastrointestinal obstruction 2 wk after admission. A: Previously noted large duodenal diverticular hemorrhage and retroperitoneal hematoma were decreased in size (arrowheads); B: However, marked edematous bowel wall thickening is newly visualized in the duodenal second and third portions (arrows).

mixture. A post-embolization arteriogram showed successful embolization of the pseudoaneurysm.

Gastroscopy and an upper gastrointestinal barium study performed on the seventh day after the embolization revealed a huge diverticulum at the mesenteric border of the duodenal third portion, about 10 cm distal from the ampulla. The duodenal lumen was compressed by the duodenal diverticulum and surrounding hematoma. Another small diverticulum was identified at about 10 cm distal to the complicated diverticulum. There was no evidence of further active bleeding from the upper gastrointestinal tract or any ischemic changes to the duodenum. The duodenal passage was intact (Figure 2C).

Two weeks after admission, the patient showed gastrointestinal symptoms of obstruction (epigastric distension and postprandial bilious vomiting). A follow-up CT scan showed a decrease in the duodenal diverticular and the retroperitoneal hematoma; however, marked edematous duodenal wall thickening and luminal narrowing had developed in the duodenal second and third portions, suggesting duodenal deformity resulting from peridiverticular fibrosis (Figure 3). Despite the conservative treatment with total parenteral nutrition (TPN) and Levin tube drainage, the patient's symptoms of obstruction did not improve. Furthermore, TPN was no longer possible because of repeated central line sepsis. Therefore, a laparotomy was performed 24 d after the admission.

**Figure 4 Intra-operative findings.** A: A hard duodenal diverticulum filled with old hematoma, which was covering about 10 cm of the duodenal second portion, with severe peridiverticular fibrosis (arrows); B: The diverticular opening at the 3rd portion of the duodenum (arrow).

During the laparotomy, we found a hard duodenal diverticulum filled with a blood clot, which covered about 10 cm of the duodenal second portion. In addition, severe peridiverticular fibrosis and deformity were found to be causing duodenal second portion stricture. Through a longitudinal duodenotomy, a diverticular opening was identified at the 3rd portion of the duodenum that was more than 10 cm away from the ampulla of Vater. Neither dissection nor resection of the diverticulum was possible due to dense adhesion. Instead, suture ligation of the diverticular opening, with hematoma evacuation and gastrojejunostomy, was performed (Figure 4).

After the operation, she suffered from delayed gastric emptying, which caused symptoms such as postprandial bilious vomiting. However, the symptoms improved dramatically after several weeks of conservative treatment and, open discharge, she retained the ability to tolerate any meal without bleeding.

## DISCUSSION

We have presented a patient with duodenal obstruction after successful selective TAE for a duodenal diverticular hemorrhage. There are few reports on duodenal obstruction caused by duodenal stenosis from retroperitoneal or duodenal fibrotic encasement, while a few other reports describe the obstruction caused by intraluminal diverticular stone, bezoar, and ingested foreign bodies around diverticulum<sup>[1-3]</sup>. To the best of our knowledge, this is the first case report of duodenal

diverticular hemorrhage complicated by duodenal obstruction after TAE.

Only 5% to 10% of patients with duodenal diverticula suffer from clinical symptoms, of which 1% or less require treatment for various complications such as perforation, hemorrhage, and biliary/pancreatic/gastrointestinal obstruction<sup>[1,4]</sup>. In our patient, the patient suffered from both hemorrhage and obstruction. After a CT scan and from laboratory findings, we found that the symptoms of obstruction were caused by the diverticular hemorrhage and a surrounding retroperitoneal hematoma, which compressed the duodenal lumen. Angiography showed that the origin of the hematoma was the arterial pseudoaneurysmal rupture on the anterior wall of the duodenal diverticulum.

Use of arteriography to diagnose duodenal diverticular bleeding was first reported by Miller *et al*<sup>[5]</sup> in 1970. Since then, angiography and endoscopy have become the most useful modalities for diagnosing and managing gastrointestinal bleeding, suggesting TAE as the treatment of choice of duodenal diverticular hemorrhage<sup>[6,7]</sup>. However, due to the complex vascular anatomy of duodenum, TAE must be done with extreme caution. Pancreatitis, ischemic damage, and rebleeding have been reported as possible complications after superselective TAE. In our patient, the patient didn't suffer from any of these complications after the superselective TAE, and bleeding control was successful with no change in hemoglobin level during the follow-up period after the intervention. However, two weeks after admission, symptoms of obstruction were abruptly aggravated. CT, an upper gastrointestinal barium study, and gastroscopy suggested stricture of the second portion of the duodenum caused by duodenal wall thickening with deformity and dysmotility, which resulted from peridiverticular fibrosis, not by ischemic damage from the embolization. Therefore, great care should be taken after the TAE, not only to detect pancreatitis and rebleeding, but also for the symptoms of obstruction, so that the patient can be managed appropriately and timely.

According to previous reports, duodenal obstruction due to fibrotic encasement of the duodenum in most cases is self-limited by the end of the first month of treatment of nasogastric suction and total parenteral nutrition<sup>[8]</sup>. However, the patient suffered from repeated central line sepsis, therefore we concluded that the conservative treatment had failed and we decided to operate.

Various operations are considered for diverticulum based on the symptoms and operative field findings<sup>[1,9,10]</sup>. Surgical management of duodenal obstruction in duodenal diverticulum includes diverticulectomy through duodenotomy or duodenal resection with primary end-to-end anastomosis. However, inflamed duodenal diverticulum might cause adhesions, making it difficult to dissect, especially when the diverticulum is located in the second portion of the duodenum. The diversion of the upper gastrointestinal tract might be better than complete dissection and resection of the diverticulum, possibly preventing CBD or AoV injury. Therefore, a diversion procedure is more suggestive when there is severe inflammation or friability of the tissue. In

our patient, the diverticular opening was in the 3rd portion of the duodenum; however, due to severe dense adhesions and fibrosis of the duodenum, only suture ligation of diverticular opening and gastrojejunostomy were performed.

In conclusion, selective TAE should be considered as the first line treatment for duodenal diverticular hemorrhage. Complications of peridiverticular and retroperitoneal fibrosis around the resolving hematoma could happen after successful TAE; therefore the resolving hematoma should be thoroughly observed. In addition, conservative treatment should be considered before surgery to relieve the duodenal obstruction resulting from duodenal fibrotic encasement after a duodenal diverticular hemorrhage. If surgery is necessary, gastrointestinal diversion could be done instead of complete resection in cases with severe inflammation or tissue friability.

## Abstract

A 48-year-old Indian male with alcoholic liver cirrhosis was admitted after being found unresponsive. He was hypotensive and had hematochezia. Esophagogastroduodenoscopy (EGD) showed small esophageal varices and a clean-based duodenal ulcer. He continued to have hematochezia and anemia despite blood transfusions. Colonoscopy was normal. Repeat EGD did not reveal any source of recent bleed. Twelve days after admission, his hematochezia ceased. He refused further investigation and was discharged two days later. He presented one week after discharge with hematochezia. EGD showed non-bleeding Grade 1 esophageal varices and a clean-based duodenal ulcer. Colonoscopy was normal. Abdominal computed tomography (CT) showed liver cirrhosis with mild ascites, paraumbilical varices, and splenomegaly. He had multiple episodes of hematochezia, requiring repeated blood transfusions. Capsule endoscopy identified the bleeding site in the jejunum. Concurrently, CT angiography showed paraumbilical varices inseparable from a loop of small bowel, which had herniated through an umbilical hernia. The lumen of this loop of small bowel opacified in the delayed phase, which suggested variceal bleeding into the

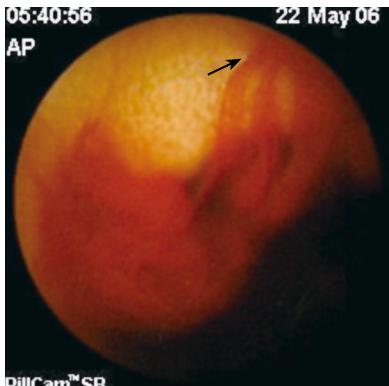

## INTRODUCTION

Bleeding jejunal varices can be difficult to diagnose and manage. We present a case of obscure overt gastrointestinal hemorrhage secondary to jejunal varices, detailing the extensive investigations and unconventional management.

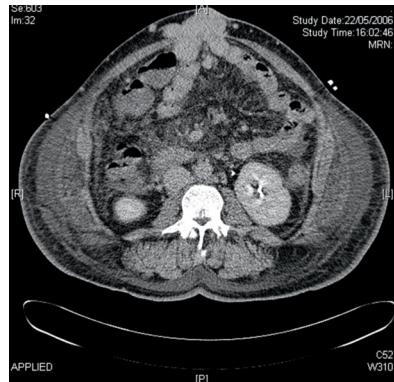

## CASE REPORT

A 48-year-old Indian male with alcoholic liver cirrhosis had been treated for ascites and encephalopathy for the prior 6 years. Variceal endoscopic ligation was performed 5 years previously for bleeding esophageal varices. In the same year, he underwent a laparotomy for repair of an incarcerated umbilical hernia. He defaulted follow-up thereafter.

Regarding the current episode, he was admitted after being found unresponsive. He was hypotensive

**Figure 1** Capsule endoscopy identified the bleeding site (arrow) in the jejunum.

**Figure 2** CT angiography showed variceal bleeding into the small bowel.

**Figure 3** Percutaneous paraumbilical embolization *via* caput medusae was performed.

and digital rectal examination showed hematochezia. His hemoglobin was 7.4 g/dL on admission. Esophago gastroduodenoscopy (EGD) showed small esophageal varices, and a 2 cm clean-based ulcer in the duodenal bulb. He continued to have hematochezia and anemia despite blood transfusions. Colonoscopy was normal up to the cecum. Repeat EGD again did not reveal any source of recent bleed. Twelve days after admission, his hematochezia ceased, and his hemoglobin was 8.4 g/dL. He refused further investigation and was discharged two days later.

He subsequently presented one week after discharge, complaining of abdominal pain and hematochezia for two days. His blood pressure was 120/80 mmHg, and heart rate was 110 beats/min. There was no encephalopathy. He had mild ascites. Digital rectal examination showed hematochezia. Hemoglobin was 4 g/dL, platelets  $63 \times 10^9/L$ , prothrombin time was 22 s and albumin 15 g/L. Diagnosis was Child's C alcoholic liver cirrhosis with possible variceal bleed. He was treated with IV esomeprazole, IV somatostatin and IV ceftriaxone and was transfused with fresh frozen plasma and packed cells. Emergency EGD showed non-bleeding Grade 1 esophageal varices and a clean-based duodenal ulcer. Colonoscopy was normal. Abdominal computed tomography (CT) showed liver cirrhosis with mild ascites, paraumbilical varices, and splenomegaly. He continued to have multiple episodes of hematochezia, requiring repeated blood transfusions.

Capsule endoscopy (Figure 1) identified the bleeding site in the jejunum. Concurrently, CT angiography was also carried out, having been negative on two prior episodes of hematochezia. However, the third

CT angiography (Figure 2), performed during active hematochezia, showed paraumbilical varices inseparable from a loop of small bowel which had herniated through an umbilical hernia. The lumen of this loop of small bowel opacified in the delayed phase, which suggested variceal bleeding into the small bowel. Portal vein thrombosis was present.

A decision was made for percutaneous paraumbilical embolization *via* caput medusae to be carried out on day 9 of hospitalization. The caput medusae near the umbilicus was punctured. When there was good return of blood, the guidewire was introduced and it was noted to pass freely into a vein. The guidewire was manipulated into the superior mesenteric and the splenic vein. Injection of contrast demonstrated the anatomy of the portovenous system clearly. The catheter tip was then positioned peripherally so that injection of contrast opacified only the veins near the ventral hernia leading into the caput. Three steel coils were placed into this vein. At the end of the study, injection of contrast under pressure did not demonstrate any retrograde flow, indicating that it was occluded (Figure 3).

Following the embolization, the hematochezia stopped. The patient remained well and somatostatin was stopped on day 12 of hospitalization. His hemoglobin rose to 9.0 g/dL and he was discharged. However, he defaulted subsequent follow-up.

## DISCUSSION

Obscure gastrointestinal bleeding (OGIB) is categorized into obscure overt and obscure occult bleeding based on the presence or absence of clinically evident bleeding<sup>[1]</sup>. Gastroscopy and colonoscopy should be repeated in OGIB, as a bleeding source can be identified on repeat endoscopies in some patients<sup>[2]</sup>. When repeat upper and lower endoscopies are negative, the small intestine should be investigated. Diagnostic accuracy for such investigations is limited mainly by the difficulty of performing adequate studies in this uncommon condition. In a meta-analysis, capsule endoscopy was shown to be superior to push enteroscopy and small bowel barium radiography for diagnosing clinically significant small bowel pathology in patients with OGIB, with incremental yields of 30% and 36%, respectively<sup>[3]</sup>. In a prospective study comparing capsule endoscopy with double-balloon enteroscopy in 35 patients with OGIB,

small-bowel abnormalities were detected using capsule endoscopy in 80% of cases, compared with 60% using double-balloon enteroscopy. The authors suggested that although the detection rate of capsule endoscopy was superior, the procedures were complementary, and that an initial diagnostic capsule endoscopy might be followed by therapeutic double-balloon enteroscopy<sup>[4]</sup>. In a prospective study of patients with lower gastrointestinal hemorrhage, sensitivity, specificity, and positive and negative predictive values of CT angiography for detection of colonic angiodysplasia were 70%, 100%, 100% and 57%, respectively, using colonoscopy and conventional angiography as reference standards<sup>[5]</sup>. A prospective study reported the diagnostic yield for OGIB of capsule endoscopy and CT enteroclysis to be 50% and 12.5%, respectively<sup>[3,6]</sup>. In another prospective study, diagnostic yield for OGIB of capsule endoscopy and MR enteroclysis was 36% and 0%, respectively<sup>[3,7]</sup>.

Capsule endoscopy, being relatively non-invasive, was a suitable investigation for this patient. CT angiography relies on an actively bleeding lesion to identify the bleeding site with the added advantage that CT scanning can visualize intra-mural and extra-intestinal disease. CT or MR enteroclysis use intravenous contrast and either neutral or positive ionic oral contrast delivered through a nasoenteric tube. The volume control distends the small bowel and the multi-sensor CT or MR with fine cuts provides sufficient detail to visualize intra-mural and extra-intestinal disease. Having more than one investigative procedure that use different methodologies increases the chances of success. There was overt and often profound gastrointestinal bleeding, making CT angiography a good candidate.

Once diagnosis is secured, then selection of a therapeutic approach is needed. This may indeed be challenging, balancing between risk and benefit in the context of the patient's general state of health. In the situation of this patient, variceal bleeding of the small bowel seemed most likely. A triad of portal hypertension, hematochezia without hematemesis, and previous abdominal surgery characterizes small intestinal varices<sup>[8]</sup>. Prior abdominal surgery predisposes the development of ectopic varices in adhesions. Possible physiological explanation could be the network of fine communication between the posterior abdominal wall and the parietal surface of the viscera, arising in the embryo due to the juxtaposition of the developing systemic and visceral venous plexus<sup>[9]</sup>. The patient had previous hernia repair, therefore satisfying the above-mentioned triad characteristic of small intestinal varices.

Options available for the treatment of jejunal varices include surgery, transjugular intrahepatic porto-systemic shunt (TIPS), enteroscopy and percutaneous embolization. Surgical treatment options for small intestinal variceal bleed include resection of the affected area of bowel, direct ligation of the bleeding varix, and re-anastomosis or portosystemic shunt insertion, which are associated with significant risk in a patient with advanced cirrhosis. TIPS with or without trans-catheter embolization of the varices is an alternative to laparotomy in some cases<sup>[10]</sup>.

Uncontrolled bleeding from ectopic varices located in rectum, colon, ileum, jejunum, duodenum, and stoma have been treated with TIPS successfully in 90% of patients<sup>[10]</sup>, and this is the option recommended for prevention of rebleeding from gastric and ectopic varices (including intestinal, stomal, and anorectal varices) by the American Association for the Study of Liver Diseases<sup>[11]</sup>.

As the patient had severe coagulopathy and extensive paraumbilical varices, surgery was deemed to be of high risk. He was not an optimal candidate for TIPS as he had portal vein thrombosis. Double-balloon enteroscopy was a suitable alternative, but this would have been a prolonged procedure, with increased technical difficulty posed by the expected large amount of blood in the small bowel. As such, percutaneous embolization was attempted first. Embolization using steel coils, gel foam, thrombin, collagen or autologous blood clot aims to occlude the feeding vein to the ectopic varices. Steel coils are available in a variety of sizes, allowing occlusion of large veins without difficulty, leading to a permanent focal occlusion, and are therefore the preferred embolic materials. Percutaneous embolization has been reportedly performed via the transjugular or transhepatic route. However, as he had portal vein thrombosis, these approaches were not straightforward. Unconventional approaches had to be considered. He had extensive caput medusae, and this provided us with an alternative and more direct access to the portal circulation.

The percutaneous paraumbilical embolization via caput medusae used to treat our patient has not been previously described, and could be a possible therapeutic option for cirrhotics with portal vein thrombosis and bleeding small intestinal varices not suitable for surgery. There is a case report of a patient with jejunal varices treated successfully with embolization<sup>[12]</sup>. A 79-year-old woman developed melena 2 years post-jejunal resection for a jejunal varix. Abdominal angiography revealed recurrence of the jejunal varix around the hepaticojjunostomy. She underwent a surgical procedure with intra-operative portography, and embolization of the jejunal varix. Our patient, in addition to having previous abdominal surgery, also had severe coagulopathy, which made any surgical approach a high risk procedure.

In summary, for this cirrhotic patient with portal vein thrombosis and previous abdominal surgery, ectopic jejunal varices were found to be the source of OGIB by the combination of CT angiography and capsule endoscopy. However, portal vein thrombosis precluded the recommended therapeutic choice, TIPS, and we used percutaneous embolization with coils via the paraumbilical approach as an unconventional and successful solution.

### Abstract

Mesenteric panniculitis is a rare, benign and chronic fibrosing inflammatory disease that affects the adipose tissue of the mesentery of the small intestine and colon. The specific etiology of the disease is unknown. The diagnosis is suggested by computed tomography and is usually confirmed by surgical biopsies. Treatment is empirical and based on a few selected drugs. Surgical resection is sometimes attempted for definitive therapy, although the surgical approach is often limited. We report two cases of mesenteric panniculitis with two different presentations and subsequently varying treatment regimens. Adequate response was obtained in both patients. We present details of these cases as well as a literature review to compare various presentations, etiologies and potential treatment modalities.

### INTRODUCTION

Mesenteric panniculitis is an acute benign fibrosing

and inflammatory condition that involves the adipose tissue of the mesentery. It was first described by Jura in 1924 as "retractile mesenteritis" and further labeled as "mesenteric panniculitis" by Odgen later in the 1960s. Currently, it has several names: sclerosing mesenteritis, mesenteric lipodystrophy, mesenteric sclerosis, retractile mesenteritis, mesenteric Weber-Christian disease, liposclerotic mesenteritis, lipomatosis and lipogranuloma of the mesentery<sup>[1]</sup>. It can be categorized according to three pathological changes: chronic nonspecific inflammation, fat necrosis and fibrosis<sup>[2]</sup>. This varied terminology has caused considerable confusion, but the condition can now be evaluated as a single disease with two pathological subgroups. If inflammation and fat necrosis predominate over fibrosis, the condition is known as mesenteric panniculitis, and when fibrosis and retraction predominate, the result is retractile mesenteritis. The overall presence of some degree of fibrosis makes the pathological term sclerosing mesenteritis more accurate in most cases<sup>[3]</sup>.

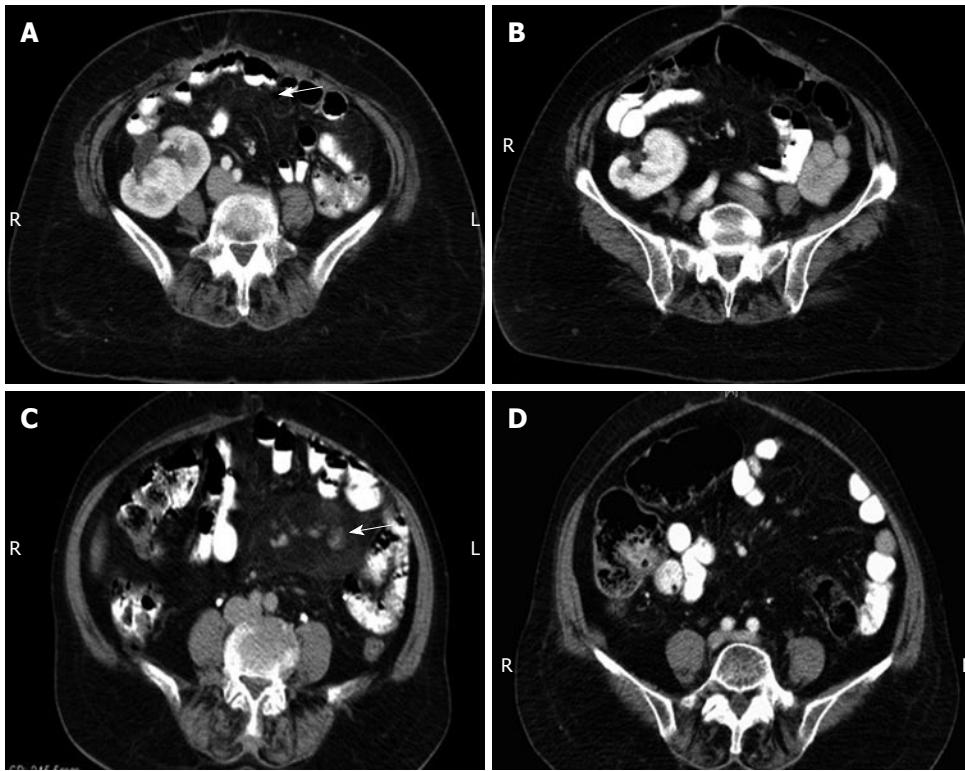

### CASE REPORT

#### Case 1

A 68-year-old female patient was admitted to our hospital with a 1-wk history of recurrent, right-sided abdominal pain, moderate in intensity, which lasted for many hours, and was associated with nausea but not vomiting. She had no change in bowel habits and was passing flatus and stools.

Her past medical history included hypertension for 10 years, dyslipidemia and diffuse diverticulosis with recurrent episodes of diverticulitis that necessitated left partial colectomy with primary anastomosis 4 years ago. As a result of disease progression, she underwent open total colectomy with an ileorectal anastomosis. She presented at 6 wk after surgery. Her medication history included valsartan, propranolol, fenofibrate, laxatives, antispasmodics and fibers. She had no known allergies, no significant family history, and a review of her systems was unremarkable.

Upon physical examination, the patient appeared well, in no acute distress and had stable vital signs. The remainder of the examination was unremarkable, except for moderate tenderness upon superficial and deep palpation of the abdomen (right quadrant, and a feeling of an ill-defined mass. Her laboratory profile was normal.

**Figure 1 High resolution computed tomography scan.** A: Smooth thickening evident between small bowel loops suggestive of a large inflammatory mass (arrow); B: Almost total disappearance of the inflammatory mass; C: A mass in jejunal compartment suggestive of mesenteric panniculitis. arrow shows a 9 mm lymph node; D: Complete disappearance of the previously described mass.

Computed tomography (CT) of the abdomen was performed using reconstructed slice thickness of 5 mm after oral and intravenous (*iv*) contrast administration, which showed a focal increase in density of the mesenteric fat with stranding in the supra-umbilical region, which was most probably inflammatory in origin and suggestive of mesenteric panniculitis (Figure 1A). This finding was surprising, especially in the light of a previous laparotomy a few weeks before, which revealed a clean abdomen.

The patient was started on prednisone 40 mg daily and was followed-up closely. Her symptoms gradually decreased in intensity and pain disappeared totally within 8 wk. Follow up CT 3 mo later showed a decrease in the mesenteric mass by 80%-90% (Figure 1B). However, she could not tolerate the steroids much longer because of peripheral neuropathy and hyperglycemia, therefore, she was switched to colchicine 100 mg daily orally.

Her status was reassessed 6 mo later, and CT showed persistence of the positive response and absence of the mass. Currently, she has been off treatment for 6 mo without recurrence of any symptoms.

### Case 2

A 74-year-old female patient presented to our care because of a chronic history of abdominal discomfort. Her symptoms were episodic and included discomfort that lasted a few minutes, which was associated with vomiting and followed by syncope of a few seconds duration. She had no abdominal pain, no change in bowel habits or hematochezia and no weight loss.

Her past medical history was significant for hypertension, herniated vertebral disc, peptic ulcer disease and diverticulosis. At the time of presentation, the patient was taking perindopril, levothyroxine and risedronate. She had no known allergies to any medication or substance, and no significant family history. A review of her systems was notable for nausea and occasional vomiting.

Upon physical examination, she appeared well, in no acute distress and had stable vital signs. Laboratory data revealed a normal complete blood count, blood chemistry and coagulation profile. Upper gastrointestinal endoscopy was performed and showed mild non-erosive gastritis with a positive urease test for *Helicobacter pylori*.

Spiral CT of the abdomen and pelvis, using a reconstructed slice thickness of 5 mm after oral and iv contrast administration showed a hazy, veil-like hyperattenuation of the mesenteric root and leaves, primarily seen in the jejunum. The radiological picture was highly suggestive of mesenteric panniculitis (Figure 1C). Interspersed subcentimetric mesenteric lymph nodes were also seen. The largest one was located in a lower jejunal mesenteric leaflet of the left lower quadrant, and reached 9 mm in the short axis. The rest of the examination was normal.

Treatment was started with 40 mg prednisone once daily and she was discharged home. She had an excellent response that was demonstrated in her follow-up CT scan 2 mo later. The previously described increased density of the peri-pancreatic and mesenteric fat caused by panniculitis was no longer present. The

mesenteric fat showed normal density with no evidence of inflammation or retroperitoneal or mesenteric adenopathy.

At this time, she had no abdominal complaints. She was still taking the same dose of steroids. Three months later, she was readmitted with acute herpes zoster infection. Treatment had to be aborted and prednisone was slowly tapered until discontinuation, and no other treatment was initiated. She was followed-up closely with no recurrence of symptoms and persistent radiological remission, as shown by CT repeated at 2 mo after steroid discontinuation (Figure 1D).

## DISCUSSION

Mesenteric panniculitis is a rare inflammatory condition that is characterized by chronic and nonspecific inflammation of the adipose tissue of the intestinal mesentery. So far, 130 cases have been reported in the literature under several names: retractile mesenteritis, sclerosing mesenteritis, liposclerotic mesenteritis, isolated lipodystrophy of the mesentery, mesenteric lipomatosis, and lipogranuloma of the mesentery, and mesenteric manifestations of Weber-Christian disease<sup>[4,5]</sup>. Most studies have indicated that the disease is more common in men, with a male/female ratio of 2-3:1, and several reports have indicated it to be more common in Caucasian men. Incidence increases with age, and pediatric cases are exceptional, probably because children have less mesenteric fat when compared to adults<sup>[6]</sup>.

The pathogenic mechanism of mesenteric panniculitis seems to be a nonspecific response to a wide variety of stimuli. Although various causal factors have been identified, the precise etiology remains unknown. Emory *et al*<sup>[2]</sup> have reported a series in which 84% of patients had a history of abdominal trauma or surgery. Furthermore, the disease is related to other factors, such as mesenteric thrombosis, mesenteric arteriopathy, drugs, thermal or chemical injuries, vasculitis, avitaminosis, autoimmune disease, retained suture material, pancreatitis, bile or urine leakage, hypersensitivity reactions, and even bacterial infection<sup>[6,7]</sup>. Other factors, such as gallstones, coronary disease, cirrhosis, abdominal aortic aneurysm, peptic ulcer, or chylous ascitis, have also been linked to this disease<sup>[8]</sup>. More recent studies have shown a strong relationship between tobacco consumption and panniculitis<sup>[7]</sup>.

Retractile mesenteritis has been associated with a number of malignant diseases such as lymphoma, lung cancer, melanoma, colon cancer, renal cell cancer, myeloma, gastric carcinoma, chronic lymphocytic leukemia, Hodgkin's disease, large cell lymphoma (giant-cell carcinoma), carcinoid tumor, and thoracic mesothelioma<sup>[2,6,7,9-11]</sup>.

In over 90% of cases, mesenteric panniculitis involves the small-bowel mesentery, although it may sometimes involve the sigmoid mesentery<sup>[10]</sup>. On rare occasions, it may involve the mesocolon, peripancreatic region, omentum, retroperitoneum or pelvis<sup>[12]</sup>.

The mean clinical progression is usually 6 mo,

**Table 1 Differential diagnosis of mesenteric panniculitis**

Reaction to adjacent cancer or chronic abscess
Retroperitoneal sarcoma

ranging from 2 wk to 16 years. The disease is often asymptomatic. When present, clinical symptoms vary greatly, and may include anorexia, abdominal pain, abdominal fullness, nausea, pyrexia, and weight loss<sup>[11]</sup>. On occasions, the disease may also present with merely a single or multiple palpable masses. Exceptionally, rectal bleeding, jaundice, gastric outlet obstruction, and even acute abdomen have been reported<sup>[2,9,12]</sup>. Such a wide variety of manifestations means that a large number of illnesses must be considered for differential diagnosis, therefore, careful assessment by the treating physician is strongly advised (Table 1).

Histologically, the disease progresses in three stages<sup>[6]</sup>. The first stage is mesenteric lipodystrophy, in which a layer of foamy macrophages replaces mesenteric fat. Acute inflammatory signs are minimal or non-existent; the disease tends to be clinically asymptomatic and prognosis is good. In the second stage, termed mesenteric panniculitis, histology reveals an infiltrate made up of plasma cells and a few polymorphonuclear leukocytes, foreign-body giant cells, and foamy macrophages. Most common symptoms include fever, abdominal pain, and malaise. The final stage is retractile mesenteritis, which shows collagen deposition, fibrosis, and inflammation. Collagen deposition leads to scarring and retraction of the mesentery, which in turn, leads to the formation of abdominal masses and obstructive symptoms. The exact diagnosis is often difficult and is usually made by finding one of three major pathological features: fibrosis, chronic inflammation, or fatty infiltration of the mesentery. To some extent, all three components are present in most cases<sup>[13]</sup>.

Blood tests tend to be within the normal range. Neutrophilia, increased erythrocyte sedimentation rate or anemia have been reported occasionally in the retractile mesenteritis stage<sup>[6]</sup>.

Some reports even go as far as stating that few or none of the patients with mesenteric panniculitis can be diagnosed correctly before operation<sup>[4,14]</sup>. However, with the advent of imaging technology like high-resolution CT or magnetic resonance imaging, distinguishing mesenteric panniculitis from other mesenteric diseases with similar imaging features such as carcinomatosis, carcinoid tumor, lymphoma, desmoid tumor, and mesenteric edema seems possible and feasible<sup>[15,16]</sup>. The imaging appearance of mesenteric

panniculitis varies depending on the predominant tissue component (fat necrosis, inflammation, or fibrosis)<sup>[17]</sup>. It is visualized usually as a heterogeneous mass with a large fat component and interposed linear bands with soft tissue density in cases of mesenteric panniculitis, or as a homogeneous mass of soft tissue density in cases of retractile mesenteritis. Colonoscopy is usually unrevealing, since mesenteric panniculitis is extrinsic to the bowel. Paracentesis that reveals inflammatory cell populations without mitotic figures can also aid diagnosis.

Mesenteric panniculitis resolves spontaneously in most cases, however, palpable masses may often be found between 2 and 11 years after diagnosis, especially in patients with associated comorbidity<sup>[6]</sup>. In such cases, several types of treatment have been proposed but no consensus has been established. In general, treatment has been reserved for symptomatic cases. Incidental masses may be observed and left untreated. Therapy is individualized on a case by case basis. Treatment may be attempted with a variety of drugs including steroids, thalidomide, cyclophosphamide, progesterone, colchicine, azathioprine, tamoxifen, antibiotics and emetine, or radiotherapy, with different degrees of success<sup>[18-20]</sup>. Surgery may be attempted if medical therapy fails or in the presence of life-threatening complications such as bowel obstruction or perforation<sup>[5]</sup>.

Our two cases showed different presentations: one was chronic and compatible with most published data, and the other was post-surgical, which makes it a very rare occurrence. Two different treatment regimens were used successfully in both cases. This should encourage us to review our approach to those cases that are always considered to be surgical, and leave room for medical treatment, which may be more effective than previously noted.

In conclusion, mesenteric panniculitis is a rare clinical entity that occurs independently or in association with other disorders. Diagnosis of this nonspecific, benign inflammatory disease is a challenge to gastroenterologists, radiologists, surgeons and pathologists. CT features of the disease, usually highly suggestive, have recently been delineated clearly. Open biopsy seems rarely necessary. There is no standardized treatment, and it may consist of anti-inflammatory or immunosuppressive agents. We recommend resection only when the advanced inflammatory changes become irreversible or in cases of bowel obstruction. Overall prognosis is usually good and recurrence seems to be rare.

### Abstract

We present a rare case of a 45-year-old woman who presented with epigastric pain associated with early satiety and weight loss. Imaging revealed a large intra-abdominal mass in the epigastrium. Despite intensive investigations, including ultrasound scanning, computed tomography, upper gastrointestinal endoscopy, and percutaneous biopsy, a diagnosis could not be obtained. A histological diagnosis of cavernous hemangioma arising from the gastro-splenic ligament was confirmed after laparoscopic excision and histological examination of the intra-abdominal epigastric mass.

### INTRODUCTION

Cavernous hemangiomas are congenital hamartomatous lesions that originate from the mesodermal tissues, which are composed of large dilated blood vessels and contain large blood-filled spaces that are caused by dilation and thickening of the walls of the capillary loops. They have been reported in different organs, including the liver, colon, retroperitoneum, spleen, adrenal glands, soft tissues, bone, central nervous system, and mediastinum<sup>[1]</sup>. However, it is extremely rare for these tumors to originate from the mesentery<sup>[2]</sup> or omentum<sup>[3]</sup>. In this case report, we present the clinical presentation, diagnosis and treatment of a cavernous haemangioma that arose from the gastro-splenic ligament.

### CASE REPORT

A 45-year-old woman presented with sudden-onset epigastric pain of 2 h duration after eating a meal. She described her pain as a dull ache that radiated to the back, which was associated with early satiety, retching, vomiting and recent weight loss of approximately 6.35 kg. Her past medical history included laparoscopic cholecystectomy and uterine fibroid embolization. She was taking regular omeprazole for dyspepsia. Upon examination, she had neither jaundice nor anemia, and her vital signs were within normal limits. She had no supraclavicular lymphadenopathy. The abdominal examination revealed epigastric tenderness with no guarding or rigidity, and fullness in the left upper quadrant. Her initial laboratory blood results including liver function tests, amylase and full blood count were within normal limits. An abdominal ultrasound scan revealed a large 10.5 cm × 7.5 cm × 6.5 cm solid mass in the epigastrium anterior and to the left of the tail of the pancreas, and a mildly enlarged spleen, normal liver, pancreas and kidneys, and a fibroid uterus with an intrauterine device *in situ*. The ultrasonic appearance of the epigastric mass was not typical of a gastrointestinal stromal tumor (GIST) or lymphoma. Subsequent computed tomography (CT) of the chest and abdomen showed a well-circumscribed mass of mixed attenuation in the left upper abdomen, which was probably related to the stomach, and measured 10 cm in maximum diameter (Figure 1). In order to rule out gastric cancer, she underwent upper gastrointestinal endoscopy that

**Figure 1** Computed tomography appearance of a well-circumscribed mass of mixed attenuation in the left upper abdomen, that was probably related to the stomach, and measured 10 cm in maximum diameter.

showed mild reflux oesophagitis and a normal stomach. The diagnosis remained unclear despite an ultrasound-guided biopsy of the epigastric mass, which showed ectatic lymphovascular vessels with a fibrous stroma, with no evidence of malignancy upon histology.

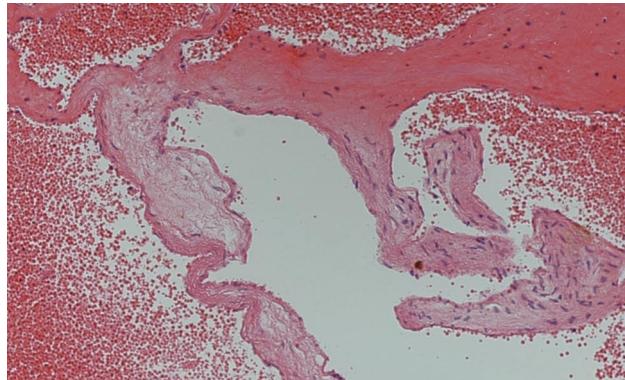

Laparoscopic excision of the intra-abdominal epigastric mass was performed. The intraoperative findings showed that the encapsulated mass, which was related to the omentum and gastro-splenic ligament, was adherent to but not directly invading the anterior wall of the stomach. The mass was dissected off the anterior wall of the stomach, and was mobilized from the omentum and gastro-splenic ligament with laparoscopic LigaSure Advance™ device (Covidien Ltd). The mass with an intact capsule was delivered through a Pfannenstiel incision in the suprapubic region. The microscopic specimen showed a hemorrhagic lesion that consisted of numerous thick-walled blood vessels filled with blood, surrounded by fibrosis and a few adjacent, benign-looking simple ductules, which were characteristic of cavernous hemangioma (Figure 2).

The patient was discharged 2 d postoperatively with no complications.

## DISCUSSION

Cavernous hemangiomas of the omentum and mesentery are extremely rare. These tumors frequently are asymptomatic and discovered incidentally at imaging, surgery or autopsy, but can have serious consequences. The clinical presentation of such a lesion varies depending on its location. Our patient presented with symptoms of abdominal pain, vomiting, early satiety and weight loss. In other case reports, these lesions presented as intermittent abdominal pain and dyspepsia<sup>[3]</sup>, palpable abdominal mass<sup>[2,4]</sup>, or acute abdomen caused by ruptured omental cavernous hemangioma<sup>[5]</sup>, ruptured mesoappendix cavernous hemangioma<sup>[6]</sup>, or an infected greater omental cavernous hemangioma<sup>[7]</sup>.

The diagnosis of such lesions can be challenging, and ultrasonography and CT have been used. Ultrasound scanning reveals a solid mass with a heterogeneous multinodular appearance, whereas CT reveals a

**Figure 2** Numerous thick-walled blood vessels lined by endothelial cells and containing red blood cells. Appearance was characteristic of cavernous hemangioma (HE,  $\times 100$ ).

homogenous or a heterogeneous mass<sup>[6]</sup>, or a mixed picture<sup>[4]</sup>.

Magnetic resonance imaging of cavernous hemangioma typically shows a uniform high signal intensity on T2-weighted images<sup>[3,4]</sup>, but occasionally shows heterogeneous signal intensity on T2-weighted images, as a result of fibrosis, hemorrhage or calcification<sup>[8]</sup>, or low signal intensity in T2-weighted images because the tumor is mainly occupied with old blood<sup>[2]</sup>. In hindsight, this resectable lesion should not be biopsied percutaneously, as it may spread the tumor through other anatomical planes, as in the case of malignant GIST. In addition, a small needle biopsy may produce a poor cellular yield, and the quality of the sample may not be adequate to make an accurate diagnosis. In this case of cavernous hemangioma, a biopsy may potentially cause a rupture or bleeding of the tumor.

In patients with gastrointestinal bleeding of obscure origin who are transfusion-dependent, wireless capsule endoscopy or double-balloon enteroscopy may allow examination of the entire small bowel and successful identification of hemangioma within the bowel lumen. Willert *et al*<sup>[9]</sup> have reported successful endoscopic treatment of multiple cavernous hemangioma during double-balloon enteroscopy of the small bowel. However, in our case report of cavernous hemangioma located at the gastro-splenic ligament, capsule endoscopy and double-balloon enteroscopy were unlikely to have been beneficial, as the lesion was located extraluminally. On the other hand, endoscopic ultrasound may help to characterize the extent of vascularity of the hemangioma, and allow selection of cases for endoscopic mucosal resection of cavernous hemangioma in the wall of the esophagus<sup>[10]</sup> or stomach<sup>[11]</sup>.

The treatment for cavernous hemangioma is surgical excision, and recurrence after complete resection has never been reported. Laparoscopic excision of this vascular lesion is feasible, and has the advantages of less pain and quicker recovery following surgery.

In conclusion, cavernous hemangioma of the omentum or mesentery is a rare tumor that can be very difficult to diagnose preoperatively, despite advanced

imaging techniques. As a result, it should be included in the differential diagnosis of any mass that arises in the mesentery or omentum. Surgical excision and histological examination may offer the only means of diagnosis.

### TO THE EDITOR

Patients with negative hepatitis B surface antigen (HBsAg) and positive antibody to hepatitis B core antigen (anti-HBc) but no antibody to hepatitis B surface antigen (anti-HBs) have traditionally been described as having occult hepatitis B virus (HBV) infection<sup>[1]</sup>. The recent article by Pérez-Rodríguez *et al*<sup>[2]</sup> in the issue of the *World J Gastroenterol* (March 14, 2009) described these patients as "anti-HBc alone", none of them was positive for serum HBV DNA. Of note, 10 of the 30 patients tested were taking lamivudine or tenofovir when the tests were performed. Furthermore, "anti-HBc alone" was associated with factors such as young age and HCV infection. They concluded that HBV DNA determination should not be performed in every "anti-HBc alone" patient, but only in those with unexplained clinical or analytical signs of liver injury.

Patients with prior exposure to HBV may subsequently clear their serum HBsAg, and become anti-HBc positive. Anti-HBs may be positive or negative, as anti-HBs may fall over time. Some authors considered patients with anti-HBc but no anti-HBs as having occult HBV infection<sup>[1,3-6]</sup>. Consequently, in a portion of these patients, HBV DNA may be detected. Biologically, it would be difficult to explain why this should not be the case in HIV patients as reported by Pérez-Rodríguez and colleagues<sup>[2]</sup>. It is uncertain what the authors meant when they considered that patients with defective immune response (anti-HBc) would have undetectable HBV DNA. On the contrary, if one considers that these HIV patients may have defective immune response (i.e. immunodeficiency), one might expect a higher HBV DNA level. We performed a similar study in lymphoma patients, who were HBsAg negative, anti-HBc positive, and tested for anti-HBs and HBV DNA at diagnosis ( $n = 89$ ). Among the 27 "anti-HBc alone" patients, who were anti-HBs negative as defined by the authors, 2 (7.4%) had a detectable HBV DNA level,

### Abstract

Hepatitis B virus (HBV) infection is endemic in various parts of the world. A proportion of patients have resolved prior exposure to HBV, as evidenced by the clearance of circulating hepatitis B surface antigen and the appearance of antibody to hepatitis B core antigen (anti-HBc), which could produce protective antibody to hepatitis B surface antigen (anti-HBs). With time, anti-HBs in some patients may become negative. Such patients are described as having occult HBV infection or "anti-HBc alone". In the context of immunodeficient patients, such as HIV patients or lymphoma patients undergoing immunosuppressive immunotherapy, the lack of protective anti-HBs may increase the risk of hepatitis B reactivation. Serum HBV DNA testing may be necessary in "anti-HBc alone" patients, to detect patients at a high risk of developing HBV infection allowing appropriate prophylactic management.

**Key words:** Hepatitis B virus; Human immunodeficiency virus; Antibody to hepatitis B core antigen; Hepatitis B virus DNA; Viral hepatitis

**Peer reviewer:** Dariusz M Lebentszjn, Associate Professor, 3rd Department of Pediatrics, Medical University of Białystok, 17 Waszyngtona Str, Białystok 15-274, Poland

as compared to the negative results by Pérez-Rodríguez *et al*<sup>[2]</sup>. Although our results were observed in lymphoma patients, it is difficult to explain why this should be different in HIV patients. Interestingly, even among the 63 lymphoma patients with positive anti-HBs, 2 (3.2%) had detectable HBV DNA.

The negative HBV DNA results reported by Pérez-Rodríguez *et al*<sup>[2]</sup> could be confounded by the fact that 10 patients were on anti-viral agents, suppressing HBV DNA levels. It is also uncertain whether administration of anti-viral agents could have an impact on HBV DNA load, thus it will be important to re-examine the HBV profile of patients with HIV at diagnosis, prior to the usage of anti-viral agents, particularly lamivudine (which suppresses HBV) to confirm the results reported by the authors.

Furthermore, HBV DNA tests were not conducted for all "anti-HBc alone" patients due to non-medical reasons as reported by Pérez-Rodríguez *et al*<sup>[2]</sup>. Due to the relatively small number of patients tested ( $n = 30$ ), more patients need to be followed up.

It has also been reported that "anti-HBc alone" is associated with young age, which is consistent with the earlier findings<sup>[7]</sup>. However, this paper did not provide a biological explanation for the higher prevalence of the defective immune pattern observed in younger patients. Notably, the median age of our 27 patients was 69.3 (range 17.6-83.6) years whereas the mean age of the 59 lymphoma patients with negative HBsAg, positive anti-HBc and anti-HBs was 63.9 (range 24.2-86.5) years. Contrary to the results reported by Pérez-Rodríguez *et al*<sup>[2]</sup>, we observed a higher median age in lymphoma patients with the "anti-HBc alone" pattern.

In conclusion, it is important to verify the author's observations in a proportion of newly diagnosed HIV

patients, prior to the usage of anti-viral agents, particularly lamivudine (which could suppress HBV DNA levels) to confirm the results reported by the authors. Testing of HBV DNA in "anti-HBc alone" patients may be necessary.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*) ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systematically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Articles: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities on basic research and clinical practice.

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, PubMed Central, Digital Object Identifier, CAB Abstracts and Global Health. ISI, Thomson Reuters, 2008 Impact Factor: 2.081 (32/55 Gastroenterology and Hepatology).

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[12,21]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) =  $8.6 \pm 24.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *argI*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *KboI*, *KpnI*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

**Editorial Office**

**World Journal of Gastroenterology**

Editorial Department: Room 903, Building D, Ocean International Center,

No.62 Dongsihuan Zhonglu, Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

**Language evaluation**

The language of a manuscript will be graded before it is sent for revision.

- (1) Grade A: priority publishing;
- (2) Grade B: minor language polishing;
- (3) Grade C: a great deal of language polishing needed;
- (4) Grade D: rejected. Revised articles should reach Grade A or B.

**Copyright assignment form**

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

**Responses to reviewers**

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

**Proof of financial support**

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

**Links to documents related to the manuscript**

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

**Science news releases**

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

**Publication fee**

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

World Journal of Gastroenterology  
Volume 15 Number 31 August 21, 2009

### INTRODUCTION

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### EDITORS FOR THIS ISSUE

Responsible Assistant Editor: *Xiao-Fang Liu*  
Responsible Electronic Editor: *Yin-Ping Lin*  
Proofing Editor-in-Chief: *Lian-Sheng Ma*

Responsible Science Editor: *Lin Tian*  
Proofing Editorial Office Director: *Jian-Xia Cheng*

#### NAME OF JOURNAL

*World Journal of Gastroenterology*

#### RESPONSIBLE INSTITUTION

Department of Science and Technology of Shanxi Province

### Abstract

Baishideng's goal over the next few years is to edit and publish high-quality articles through the open-access model, to maximize the benefits to members of the editorial board, authors and readers, as well as achieving social and economic benefits.

### INTRODUCTION

Beijing Baishideng BioMed Scientific Co., Ltd was established on November 20, 2007. Its predecessor was The WJG Press, and its main task is to edit and publish biomedical journals. The predecessor to the currently published *Shijie Huaren Xiaohua ZaZhi* (*World Chinese*

*Journal of Digestology*) was the *Xin Xiaohuabingxue ZaZhi* (*New Journal of Gastroenterology*), which was launched in Shanxi on January 15, 1993. The predecessor of the weekly publication *World Journal of Gastroenterology* was the *China National Journal of New Gastroenterology*, which was launched in Shanxi on October 1, 1995. We are also preparing to publish the *World Journal of Hepatology*, *World Journal of Gastrointestinal Oncology*, *World Journal of Diabetes*, *World Journal of Gastrointestinal Endoscopy*, *World Journal of Stem Cells*, *World Journal of Gastrointestinal Surgery*, *World Journal of Gastrointestinal Pathophysiology*, and *World Journal of Gastrointestinal Pharmacology and Therapeutics* which will be launched successively in Beijing after September 15, 2009. Our goal is to edit and publish high-quality articles through the open-access (OA) model<sup>[1]</sup>, to maximize the benefits to members of the editorial board, authors and readers.

### MAXIMIZATION OF THE PERSONAL BENEFITS OF EDITORIAL BOARD MEMBERS

Our editorial board comprises 1126 invited experts in 60 countries, which means that we have access to outstanding scientists around the world, because first-class publications require a first-class editorial team<sup>[2,3]</sup>. Member of the editorial board should: (1) have attained a high level of scholarship and respect in their respective fields; (2) have a rigorous academic attitude and integrity; (3) participate actively in academic conferences and activities; (4) carry out peer review of six articles for the journal every year; and (5) write a commentary article or organize a series of "Highlight" articles for the journal every 2 years. Maximization of the interests of members of the editorial board is mainly reflected in the following.

#### Members of the editorial board review articles

(1) Responsibility to their own fields. A member of the editorial board rigorously evaluates a manuscript within a specified time; (2) Responsibility to the author. After agreeing to peer review a manuscript, a member of the editorial board makes a scientific evaluation of its accuracy, clarity, importance and its contribution to the scientific community; and (3) Responsibility to the journal. When a member of the editorial board cannot complete the review within the time set by the journal, he/she should decline the review and explain the reason.

Once a member of the editorial board agrees to review a manuscript, he/she is under an obligation to send their comments to the editorial department within the specified time. If the member of the editorial board cannot complete the review on time, he/she should inform the editorial department and ask whether to return the unreviewed manuscript or request for an extension of time. When a member of the editorial board receives a manuscript involving an apparent conflict of interest with his/her own research work or point of view, the member of the editorial board should decline to review the manuscript and explain the specific conflict of interest. The most common conflict of interest is private or professional relationships between the member of the editorial board and the organization undertaking the research or the author(s) that may affect the impartiality of the review, or competition between the member of the editorial board and those undertaking the research. When a member of the editorial board cannot return a reviewed manuscript to the editor for some reason, he/she can recommend one or two peer reviewers familiar with the topic of the paper to help the editor process the manuscript accurately and quickly. As a qualified member of the editorial board, he/she must abide by certain rules, deal with problems fairly and impartially, and avoid abuse of his/her position<sup>[4]</sup>. We publish all relevant information, including the conclusion of the peer review and the name and organization of the reviewer, along with the article. This is to control the quality of the peer reviewers, editors and publishers, ensure that each article is published after peer review, and reflect peer reviewers' responsibility.

#### **Members of the editorial board publish commentary articles**

Almost all the 1126 members of the *WJG* editorial board are leaders in their own fields. To mobilize the enthusiasm of the editorial board and maximize their interest in the journal, we set ourselves the following tasks. (1) We publish a list of members of the editorial board at a fixed location in the printed and online editions of each issue of the journal; (2) We express thanks to members of the editorial board whose reviewed manuscripts have been accepted, publish relevant information such as the name and organization of the reviewer along with the author's article, and send a PDF copy of the article to them; (3) We also express thanks to members of the editorial board whose evaluated manuscripts have been rejected; (4) We send a summary list of articles published to members of the editorial board each year, and invite them to write commentary articles for the coming year; and (5) We offer 50 US dollars for the author of every "Highlight" or "Observation" article. However, the majority of the members of the editorial board do not take the payment for articles solicited. A Canadian member of the editorial board, Professor H Freeman, University of British Columbia, said at the outset of the "Observation" articles that: "We need the spirit of Bethune to run *WJG* successfully"<sup>[5]</sup>. Professor Freeman has published 20 commentary articles in the observation column of which he is the chief editor. Scientists contribute to the

international community and they do not publish articles for economic gain. *WJG* published a variety of 1203 articles in issues 1-48 in 2008, of which there were 265 commentary articles written by members of the editorial board, which accounted for 22.08% of the published output. According to Journal Citation Reports published from 2006-2007 for *WJG* included in the Science Citation Index Expanded, the top three categories that contributed published articles in terms of the average number of times cited were reviews (8.63), editorials (6.24) and highlights (5.83)<sup>[6]</sup>.

#### **Members of the editorial board are ambassadors for the journal**

From 2007 to 2009, the editorial board of *WJG* had 1126 members in 60 countries. Where there are members of the *WJG* editorial board, there are also authors and readers of *WJG*. We decide on candidate members of the editorial board according to their citations in the ISI Web of Knowledge. Whether a person can be finally accepted as a member of the editorial board depends mainly on his/her resumé and job title. Only experts holding a rank higher than associate professor can serve as members of the *WJG* editorial board. International members of the editorial board are ambassadors who help with the global dissemination of our journals. They are also liaison officers who recommend persons in the same field as their own to contribute to *WJG*.

### **MAXIMIZING THE BENEFIT TO AUTHORS OF PUBLISHING ARTICLES**

One of the biggest advantages of open access publishing is that people around the world can have immediate access to peer-reviewed articles *via* the internet. This provides a new platform for the international community to have equitable access to the latest scientific developments, and to play a positive role in advancing scientific knowledge.

#### **Qualifications of authors for publishing articles**

We require authors to declare that they all meet the eligibility criteria below, no author who meets these criteria has been left out, and contributors and sponsors have been duly thanked. The eligibility criteria for authors proposed by the international committee of medical journal editors are<sup>[7]</sup>: (1) authors must have made a significant contribution to the concept and design of the research and the acquisition, analysis and interpretation of data; (2) draft articles and critically revise the article for important intellectual content; and (3) approve the final version of the article to be published.

#### **Editing and publishing quality of published articles**

Whether the editorial department of the journals receives high-quality international articles hinges on many factors. The editing and publishing quality of every article published in the journal needs to be guaranteed. Our approach is as follows. (1) We give our journals an international appeal, e.g. containing the word "World"

in the title, to attract international authors to contribute articles; (2) We accept online contributions, so that authors can submit a manuscript from any place that has an internet connection. The system replies automatically or the editorial department returns acknowledgement of the manuscript within 24 h; (3) Members of the editorial board participate in online peer review, which generally takes 2-4 wk; (4) Reject manuscripts or send those that are accepted back to the authors for revision; (5) Edit and ReleaseProcess manuscripts in a scientific manner; (6) Authors revise their articles; (7) Formal acceptance or rejection of manuscripts; (8) In processing manuscripts, the language editor solves common errors, including grammar, syntax, spelling, punctuation and logic; (9) Return manuscripts to the author for final revision; (10) The editorial director organizes the production; (11) Electronic editing and production, including redrawing of charts, graphs and automatic checking by the software Heima; (12) The electronic editor in charge carries out editing and typesetting; the science editor in charge carries out proofreading, including Heima proofreading; (13) The author carries out proofreading; (14) The editorial director and editor-in-chief carry out proofreading; (15) Produce and proofread films; (16) Printing; (17) Create the online edition; (18) The editorial director checks the online edition; and (19) Release the online edition. Every aspect of every article published through the above process is original. For example, charts and graphs are re-drawn, references are re-formatted using software, and Word documents are converted into XML format automatically to avoid human errors. In the entire process from editorial personnel receiving the manuscript to online publishing, we put service and quality first, and aim to establish the reputation of the journal so as to attract international contributors.

### **Comments accompanying original articles**

The accompanying comments for each article are written in an easy-to-understand manner to enable professional scientists, the public and media to understand more broadly the relevance of the article, and to play a role in promoting science to a wider audience. Accompanying comments cover the following. (1) Background information: summarizes relevant background that will give readers a better understanding of the article in an easy-to-understand manner to enable professional readers, the public and the media to understand more broadly relevant knowledge of the article and have a better understanding of the meaning of the article; (2) Research and development: aims to help readers understand how the article relates to the key areas of research in the field; (3) Relevant reports: references to other relevant papers that may help with understanding the article, or as pointers to wider reading on the subject of the article; (4) Inventory of innovations: summarizes the innovative aspects of the article, so that readers can see how the new study differs from and is related to previous work; (5) Main points of application: summarizes the practical applications of the article, and how it may improve existing or develop future applications. Hopefully, this may lead to the article being

cited extensively; (6) Glossary: a simple, straightforward and clear explanation of the terms in the article that are important for its understanding, as many readers may not be familiar with these terms or have a full understanding of them; and (7) Peer review: the editorial department summarizes the opinions of the peer reviewers, to demonstrate the significance of the article.

### **The core interests of authors in publishing articles**

Members of the editorial board publish a wide range of commentary articles in the form of invited papers. The purpose of these is to comment on the status quo, progress and problems in fast-developing fields, in an attempt to play a role in guiding clinical or basic research. Other contributing authors submit original articles for publication. The purpose of these is to report the latest developments in scientific research, which are innovative, of a high standard, and have considerable scientific significance in their own field. The core interests and values main purpose of members of the editorial board and contributing authors in publishing articles is to disseminate their peer-reviewed research results around the world, and hopefully, to have them cited by others in the same field, thereby contributing to scientific progress. If journal articles written by members of the editorial board and contributing authors do not achieve the above-mentioned core interests and values, the science editor and peer reviewer's judgment of the quality of the article will be considered to be at fault, which is caused mainly by subjectivity and bias. In this case, subjectivity means that all manuscripts are evaluated by peer reviewers based on their own expertise. Academic research can be controversial, and within a given subject area, the opinions of peer reviewers may be not be exactly same and may even be diametrically opposed. Some peer reviewers are relatively tolerant, while others are relatively harsh. These are all important factors affecting peer reviewers' opinions. Therefore, the review of manuscripts cannot be completely free of subjective assumption. Bias refers to non-academic influencing factors that result from the peer reviewers' different preferences or prejudices, including the authors' nationality, mother tongue, sex and organization for which they work<sup>[4]</sup>. *WJG* published 2506 articles in 2006-2007, of which 1963 (78.33%) have been cited in another 1597 journals. The self-citation rates for articles in *WJG* in 2006 and 2007 were 22.16% and 11.34%, respectively<sup>[6]</sup>.

### **International profile of articles published**

It is very disappointing for an author to see no reaction after his/her article is published in a journal. A major reason for this is the particular journal's lack of international profile. High-quality journals are an important indicator of a country's achievement in terms of scientific and technological research, therefore, we aim to create high-quality academic journals of global significance to increase our international profile. Influential high-quality scientific journals are an important platform for academic exchange around the world and an effective vehicle for cultivating innovative talent. They

also provide authoritative leadership in their particular discipline and give a lead in developing new areas of research<sup>[8]</sup>. To achieve these ends, we have adopted an OA publishing model with the following objectives. (1) Release the online edition of *WJG* on time. Up to July 12, 2009, the number of visits was 33947050, the maximum number of times an article was viewed was 50454, and the maximum number of times an article was downloaded in PDF format was 7653; (2) Upload PubMed abstracts on time. From 1998 to 2009, PubMed included 7977 articles from *WJG*. The number of visits by international readers in October 2008 was 76358; (3) Upload PMC full texts on time. From May 1, 2009 to June 11, 2009, 689 articles were included. The number of dedicated IP addresses visiting articles was 31491; the number of times articles were downloaded was 22133; and the number of times XML articles were viewed was 35479; (4) Upload EurekAlert! press releases on time. A total of 198 *WJG* scientific press releases were published from 2007 to 2009. The number of times press releases were viewed was 441128; and the maximum number of times a single press release was viewed was 4126. Through the above methods, *WJG* has increased greatly its international profile and has attracted more contributions from international authors. *WJG* published 1203 articles in issues 1-48 in 2008, which originated from 62 countries, and international authors accounted for 70.25% of the articles published. Editing and publishing high-quality articles and distributing them on time to various media is one of the important methods of increasing the international profile of the authors' work. We award 500 RMB to the electronic editor in charge of each issue for publishing on time and have achieved significant results, thus ensuring on-time publication of each issue in various media.

## MAXIMIZING THE BENEFITS TO READERS BY OBTAINING KNOWLEDGE

At present, universities and scientific research institutions have to spend vast sums of money to obtain access to academic scientific papers, and many small institutions cannot afford the high fees for access licenses. Implementation of the open access model around the world can increase the access of researchers and the general public to information about achievements in scientific research. The research report compares three kinds of publishing models. The open access model has the greatest advantage because research institutions or those funding the research have paid the publishing

costs, therefore, papers can be obtained free of charge<sup>[9]</sup>. The competitive edge of scientific journals depends on the commitment and loyalty of readers. The more readers, the bigger the market share for any given journal. We must establish a reader-centered service so that they accept and come to value our journals<sup>[10]</sup>. We make the online edition of 7977 articles published by *WJG* available to readers around the world. The full text of the articles is available for free download and > 20000 visits are received from readers each day. Readers around the world currently can read and download the latest articles published by *WJG* free of charge, through PubMed and PMC of the United States National Library of Medicine.

## CONCLUSION

The only way for Baishideng to achieve a lasting reputation and continue to develop is to publish high-quality articles and make the full text freely available around the world. This will allow us to develop a commercial publishing model that maximizes the interests of the editorial board, authors and readers.

## Abstract

Polymorphonuclear (PMN) cell count in the ascitic fluid is essential for the diagnosis and management of spontaneous bacterial peritonitis (SBP). To date, PMN cell count is routinely performed by traditional manual counting. However, this method is time-consuming, costly, and not always timely available. Therefore, considerable efforts have been made in recent years to develop an alternative test for a more rapid diagnosis and monitoring of SBP. The use of urinary reagent strips was proposed to achieve an "instant" bedside diagnosis of SBP. A series of reports evaluated the urine strip test for SBP diagnosis and reported promising results. However, a recent large multicenter study revealed a surprising lack of diagnostic efficacy of the urine screening test for SBP diagnosis. Another method, more recently proposed as an alternative to the manual PMN count, is the measurement of lactoferrin in ascitic fluid, but the data available on the diagnostic value of this test are limited to a single study. However, both urinary reagent strips and ascitic lactoferrin tests are qualitative methods and need, therefore, to be further confirmed by standard cytology of the ascitic fluid. To date, the only quantitative method proposed as a valid alternative to manual PMN counting is automated blood cell counters, commonly used in all laboratories for blood cell counting. Data available in the literature on the diagnostic performance of this method are limited but very promising, and this tool seems to have the potential to replace the manual counting method.

## INTRODUCTION

Spontaneous bacterial peritonitis (SBP) is a frequent and severe complication of decompensated cirrhosis. Since its first description in the 1970s, when the mortality rate exceeded 80%, a significant and substantial improvement in the prognosis of SBP has been noted. In more recent prospective studies the mortality rate was reported to be around 20%<sup>[1-3]</sup>. The widespread use of diagnostic paracentesis, as well as the prompt initiation of empiric antibiotic therapy, based on the results of ascitic polymorphonuclear (PMN) cell count, has contributed to an improvement in the survival of these patients.

## DIAGNOSIS AND TREATMENT OF SBP

The percentage of SBP in hospitalized cirrhotic patients with ascites ranges between 10% and 30%<sup>[4-9]</sup>, whereas the prevalence of SBP among outpatients with cirrhosis is markedly lower (approximately 3.5%)<sup>[10]</sup>. Four practical guidelines and experts' consensus reports on the diagnosis and management of SBP are currently available<sup>[11-14]</sup>, all of which suggest that the diagnosis of SBP should be based on PMN cell count in the ascitic fluid. The detection of a PMN cell count greater than 250 cells/mm<sup>3</sup> is highly suspicious of SBP and provides an indication to initiate empirical antibiotic treatment. Only a few SBP patients, in fact, have typical symptoms suggestive of peritoneal infection such as fever, abdominal pain and a high blood leukocyte count. More often, SBP is suspected when the patient develops signs of hepatic

encephalopathy or a rapid impairment of renal function without any apparent precipitating factor. In addition, in a significant percentage of cases, SBP may be completely asymptomatic and the diagnosis is made only by diagnostic paracentesis. The presentation of SBP recently observed in a consecutive series of hospitalized patients<sup>[15]</sup> is reported in Table 1. Following hospitalization of any cirrhotic patient with newly diagnosed ascites, even in the absence of symptoms or if admitted for other reasons, a diagnostic paracentesis is therefore advised, aimed at investigating the presence of SBP. To rule out the possible presence of SBP, a paracentesis tap should also be repeated in all ascitic cirrhotic patients with gastrointestinal bleeding or hepatic encephalopathy, and whenever patients develop clinical symptoms and signs of infection, renal impairment or an unexplained worsening of their clinical condition<sup>[11]</sup>.

Following the diagnosis of SBP, ascitic fluid collection and blood cultures should be carried out before initiating antibiotic administration. The commonest organisms isolated in patients with SBP include *Escherichia coli*, Gram-positive cocci (mainly *Streptococcus* species) and *Enterococci*. These organisms account for approximately 70% of all cases of SBP<sup>[16,17]</sup>. Antibiotic therapy, however, should not be delayed to the moment when microbiological results are available; with conventional culture techniques, the ascitic fluid culture may be negative in up to 60% of patients with SBP<sup>[11]</sup>. Antibiotic therapy should instead be initiated empirically immediately after evidence of SBP at diagnostic paracentesis, without the need to wait for identification of the causative organism and *in vitro* susceptibility. Cefotaxime is the antibiotic most extensively investigated in patients with SBP<sup>[18-20]</sup>, since it covers 95% of the flora isolated from the ascitic fluid and achieves high ascitic fluid concentrations during therapy<sup>[12,21]</sup>. The dose of cefotaxime is 4.8 g/d given intravenously for a minimum of five days. Other studies<sup>[22-26]</sup> have evaluated the efficacy of cephalosporins (such as ceftriaxone and ceftazidime) administered once daily; although data are still limited, they appear to be as effective as cefotaxime. The association between amoxicillin and clavulanic acid also proved to be as effective as cefotaxime, with a similar security profile<sup>[27,28]</sup>. In patients with uncomplicated SBP (i.e. no gastrointestinal bleeding, hepatic encephalopathy or renal failure), oral treatment with ofloxacin or other quinolones for eight days can be administered<sup>[29]</sup>. An intravenous → oral step-down schedule with ciprofloxacin (switch therapy) allows completion of the antibiotic treatment at home, once the patient is discharged. This regimen was recently shown to be as efficacious but more cost-effective than intravenous cefotaxime<sup>[30]</sup>. With the regimen described above, the resolution of SBP is achieved in approximately 90% of cases and 30-d survival is at least 80%<sup>[11]</sup>.

The empirical antibiotic treatment chosen should be continued until symptom resolution or should be modified according to the results of the microbiological test. However, since SBP is often asymptomatic and the ascitic fluid culture outcome is often negative, once again the PMN cell count should be considered as a diagnostic

**Table 1 Signs and symptoms of SBP at the time of hospital admission in a recently published paper<sup>[15]</sup>**

tool to objectively demonstrate the efficacy of the ongoing antibiotic treatment and, finally, resolution of the infection. According to the International Ascites Club guidelines published in 2000<sup>[11]</sup>, a diagnostic paracentesis should be repeated after two days during antibiotic therapy to assess treatment response. A PMN cell count reduction greater than 25% of the initial value was in fact suggested as the main criterion for establishing the efficacy of the antibiotic and the need for switching the therapy. This recommendation is very important, since there have been suggestions that the type and etiology of bacterial infections in cirrhosis may have changed during recent years<sup>[31,32]</sup>. An increasing incidence of SBP caused by Gram-positive bacteria in cirrhotic patients with ascites has been observed by different authors<sup>[33,34]</sup>. In addition, an increased frequency of bacteria resistant to multiple antibiotics was shown<sup>[35]</sup>. Our recent study<sup>[15]</sup> reported that, in clinical practice, a switch from cefotaxime to another antibiotic was necessary in more than 40% of SBP cases, thus supporting the possibility that the microbial etiology of SBP, as well as sensitivity to antibiotic therapy, is changing. A method aimed at objectively establishing resolution of the infection would be extremely useful; once again, the PMN cell count in the ascitic fluid obtained at diagnostic paracentesis was revealed to be the most reliable tool.

## THE DETERMINATION OF PMN CELLS IN THE ASCITIC FLUID

Unfortunately, in clinical practice, ascitic PMN cell count is not always possible within a few hours, thus causing an unacceptable delay in the diagnosis and treatment of this potentially fatal infection. At present, PMN cell count is routinely performed by a traditional hematological method with a light microscope in a manual counting chamber. For this method, 10 mL of ascitic fluid are collected in tubes containing ethylenediaminetetraacetic acid (EDTA) and centrifuged at 1500 r/min for 10 min. Nine milliliters of the supernatant are discharged and 40 µL of the remaining ascitic fluid are diluted with 800 µL of Turk's fluid, gently shaken and used to fill the counting chamber. The cells are counted (40 × objective) in one of the nine large squares and the number of white blood cells per cubic millimeter calculated. Another 10 mL sample of ascitic fluid is used for the PMN percentage determination (100 × objective), after centrifugation and May Grünwald-Giemsa staining. This method is presently considered the

“gold standard” for the evaluation of ascitic PMN count, but this procedure is laborious and time-consuming. This results in the laboratory often providing the PMN count too late in the day, or sometimes even on the next day, when the patient may have progressed from an early stage to a fatal stage of infection. Moreover, the manual method is not always timely available in all hospitals, especially in those small patient care units with limited laboratory facilities, and the method cannot frequently be performed on an emergency basis (at night or on week-ends). This manual system, therefore, often delays the initiation of antibiotic therapy and may expose patients to a higher risk of death.

On the basis of these considerations, considerable efforts have been made in recent years to develop an alternative test for a more rapid diagnosis of SBP. This represents an interesting and promising area of investigation, which could determine the further optimization of SBP management and further improvement in its prognosis. The use of urinary reagent strips—which identify leukocytes by detecting their esterase activity *via* a colorimetric reaction—was proposed to achieve an “instant” bedside diagnosis of SBP. Their employment was tested for the rapid diagnosis of bacterial meningitis, pleural or synovial infections, thus suggesting that they could also be used for the rapid diagnosis of SBP. The first study<sup>[36]</sup>, published in 2002, involved 72 cirrhotic patients, nine of whom had SBP, reported a sensitivity and a specificity of 100% for the urinary strips in the diagnosis of SBP. After this successful result, in the following years a number of

reports<sup>[37-51]</sup> evaluated the urine strip test for the diagnosis of SBP (Table 2). These studies reported promising and encouraging results, with the sensitivity of urinary strips for the diagnosis of SBP ranging between 85% and 100% and the specificity between 90 and 100%. These published studies were, however, limited by the small number of SBP episodes and were restricted to one or two centers. Therefore, the need to validate this method in a larger population of cirrhotic patients in a multicenter study arose. A prospective multicenter (70 centers) study with a total of 2123 paracenteses performed in 1041 patients was published in 2007 by Nousbaum et al<sup>[52]</sup>. Surprisingly, this paper did not confirm the good and promising results of the previous studies, but confirmed a very high specificity for reagent strips in the diagnosis of SBP, and revealed a poor sensitivity of this test (45%). This study, therefore, reported the lack of diagnostic efficacy of the urine screening test and the authors concluded that a routine cytological examination remains mandatory for the diagnosis of SBP. After initial great enthusiasm, the use of reagent strips for SBP diagnosis has been disappointing.

Another method, more recently proposed as an alternative to the manual PMN count, is the measurement of lactoferrin in ascitic fluid. Lactoferrin is released by PMN leukocytes on the activation of these cells and its presence in body fluids is proportional to the flux of neutrophils. It was therefore hypothesized that its use could also be useful in the detection of SBP. The data available on the diagnostic value of this test for SBP diagnosis are limited to a single study<sup>[53]</sup>. This study, in

which ascitic fluid lactoferrin was measured in a total of 218 ascites samples, reported that the sensitivity and specificity of the assay for SBP diagnosis were 95% and 97%, respectively. However, the quantitative lactoferrin assay used in this study is not commercially available. Qualitative and rapid tests are already commercially available for bedside measurement of lactoferrin concentration in the stool (to distinguish inflammatory from non-inflammatory bowel conditions). The authors hypothesized that qualitative tests able to detect lactoferrin levels in excess of a predetermined level for bedside diagnosis can easily be developed and with limited costs. They concluded that, although further confirmatory studies are needed, ascitic fluid lactoferrin could serve as an initial screening test for the detection of SBP in cirrhotic patients.

It is important to underline that both urinary reagent strips and ascitic lactoferrin tests are qualitative methods and need, therefore, to be further confirmed by standard cytology of the ascitic fluid. These tests could merely be a screening modality providing only a presumptive diagnosis, but they do not have the potential to replace the manual counting method. Moreover, a qualitative test does not have applicability in the clinical management of SBP, since a reduction of more than 25% of the initial PMN cell count value is, according to the current guidelines, the criterion to establish the efficacy of the ongoing antibiotic treatment. To date, the only quantitative methods proposed as a valid alternative to manual PMN counting are automated blood cell counters, commonly and largely used in all laboratories for blood cell counting. They offer accurate and rapid differential counts of leukocytes, including PMN cells. The published data available on the diagnostic performance of this method are limited but very promising (Table 3). The first study<sup>[54]</sup>, which tested an automated cell counter for the diagnosis of SBP, was published in 2003 by our group. This study, in which 130 ascitic fluid samples obtained from 74 cirrhotic patients were analyzed, demonstrated that the use of an automated cell counter provides an accurate determination of ascitic fluid PMN and has a reliable diagnostic accuracy when compared with manual counting. In fact, the automated blood cell counter had a sensitivity of 94% and a specificity of 100%, while positive and negative predictive values were 100% and 99.1%, respectively (Table 3). These findings were also confirmed by Cereto *et al*<sup>[55]</sup> (Table 3). More recently, a further study<sup>[56]</sup>, in which we analyzed 112 samples of ascitic fluid, showed that the manual and automated meth-

ods had good agreement not only in the first diagnostic paracentesis, but also in those performed during the follow-up. These results suggested that the automated cell counter is a useful and reliable tool not only for the diagnosis of SBP, but also in its management for monitoring the therapeutic efficacy of antibiotic treatment, as well as for establishing resolution of the infection. The use of automated PMN counting may provide several advantages for the diagnosis and management of SBP: it is commonly available in all patient care units, it is routinely accessible in emergencies (i.e. at night or on weekends) and provides the results in a few minutes, thus allowing the clinician to quickly decide whether to start empiric antibiotics or to change the ongoing antibiotic therapy. Finally, it is important to remember that all this involves a very low cost (only €1.38 for a single ascitic cell determination). Another, although less important, advantage of the automated cell counting method over urinary reagent strips, the manual method and the ascitic lactoferrin test, is that it is possible to precisely assess the amount of PMN in bloody (for a traumatic tap or a condition inducing bleeding) ascitic fluid. With the other methods, the amount of PMN derived directly from the blood spilled over into the ascitic fluid cannot be differentiated from the amount of PMN due to the infection. A correction factor of 1 PMN per 250 red blood cells has been proposed<sup>[11]</sup>, because this is the maximum expected ratio of PMN to red blood cells normally present in the peripheral blood. With automated cell counters, a measure of the amount of red blood cells and PMN in both the peripheral blood and the ascitic fluid can be obtained simultaneously. The amount of ascitic PMN due to the infection can therefore be calculated by the real PMN-to-red blood cells ratio in the blood and by the real erythrocytes and PMN number in the ascitic fluid.

## CONCLUSION

Although further confirmatory data are needed, automated cell counters offer a reliable, easier and quicker PMN count, they may also considerably simplify the diagnostic approach and clinical management of SBP and should be routinely adopted. The automated method has the potential to be an optimal substitute for manual PMN counting and could definitely replace it.

inexpensive, and associated with the lowest complication rate. When the size and/or location of the tumor limits standard endoscopic resection, a number of different transanal approaches are used to remove adenomatous polyps in the lower rectum, but adenomas in the middle or upper rectum are difficult to remove using standard transanal excision (TE) instruments. Different techniques have been developed for the removal of rectal adenomas that are not amenable to removal during colonoscopy.

### TE

TE of lower rectal adenoma, first reported by Parks<sup>[2]</sup>, is one of the most frequently adopted approaches for excision of rectal polyps of any dimension, situated as far as 6 cm from the anal verge, and has very few complications, and low recurrence and mortality. In a review of the literature, bleeding after TE was present in up to 10% of the patients, perforation in up to 6%, and anal stenosis in up to 5%, with a mortality rate of 2%<sup>[3-6]</sup>. Recurrence is variable, at 3%-50% for adenoma from adenoma, and up to 3% for carcinoma from adenoma. In a long series of 117 procedures, Sakamoto *et al*<sup>[7]</sup> treated 27% of patients for residual disease and 30% for recurrence, with a 10% rate of serious complications. In a recent study, Pigot *et al*<sup>[8]</sup> obtained better results: they resected apparently benign rectal adenomas from 207 consecutive patients with a 3.6% recurrence rate, eight postoperative complications, and one death. Specific recurrence-free probability was 99.5% at 1 year, 96% at 5 years, and 95% at 10 years.

In the middle and upper third of the rectum, benign lesions are difficult to reach transanally, and standard radical surgical options, such as posterior trans-sphincteric resection, and low anterior resection can be offered to the patient; however, they have been associated with high morbidity, such as anastomotic leakage, sexual dysfunction, and fecal and urinary incontinence.

### Abstract

Transanal excision (TE), endoscopic transanal resection (ETAR) and transanal endoscopic microsurgery (TEM) can be used to remove adenomatous polyps. However, their use is limited by the size or location of the tumor. TE is limited to the lower rectum, TEM offers better access to lesions in the middle and upper rectum, and ETAR is used less frequently than it deserves for resection of rectal lesions.

### INTRODUCTION

The risk of carcinoma developing in a colorectal polyp of 1 cm or larger is 2.5% and 8% at 5 and 10 years, respectively<sup>[1]</sup>. This potential for malignancy of adenomatous colorectal polyps is an indication for their excision and the first-line treatment is endoscopic removal during the diagnostic procedure, which is safe, relatively

### POSTERIOR APPROACH

The posterior approach (represented by a combination of coccyx removal and partial sphincter division) has been progressively abandoned. It was indicated for extensive lesions in the anterior rectal wall at a distance of 8-10 cm from the anal verge. Variable rates of complications and very high rates of recurrence have been reported. In a

review of 360 cases treated for benign and malignant lesions, fecal fistula was the most frequent complication in 5%-70% of patients and fecal incontinence in 5%-25%<sup>[3,9]</sup>. Adenoma recurrence rate was up to 33% and a stoma was necessary in 20%-70% of patients, as a temporary stoma to avoid fecal fistula or as a therapeutic stoma after its appearance<sup>[3,9]</sup>.

## ENDOSCOPIC TRANSANAL RESECTION (ETAR)

ETAR was first described in 1977 by Lindenschmidt *et al*<sup>[10]</sup> and has been used in the resection of rectal adenoma. A review of 304 cases (464 procedures) from seven studies, most of them in the United Kingdom, with probable double recording of patients (Table 1), suggests that ETAR is valuable in the resection of rectal adenoma with low morbidity and mortality. This technique has shown low recurrence, however, it is impossible to know if the resection is complete and the margins are free of tumor after various procedures in the same patient from whom the adenoma is resected piecemeal. ETAR does not require surgical assistance, anesthesia, extreme positioning, new technology or special training. Nevertheless, this technique provides limited resection of mesorectal fat and lymph nodes,

limited histopathological information regarding extent of resection, and poor local disease control.

## TRANSANAL ENDOSCOPIC MICROSURGERY (TEM)

TEM has been used successfully in the management of rectal adenoma and in selected cases of rectal carcinoma, since it was introduced by Professor Buess in 1984<sup>[18]</sup>. It has been suggested that TEM enables local excision of adenomas up to 24 cm from the anal verge, and offers a minimally invasive alternative to TE, radical surgery and recurrence from previously used endoscopic resection, with superior endoscopic magnification and illumination, accuracy and complete resection, and secure suture closure.

TEM has produced satisfactory results, with better recurrence rates and low morbidity and mortality. In one of the largest studies of adenoma resection using TEM, the authors reported a 3.4% early postoperative complication rate and 1.2% and 7% recurrence rates after 1 and 5 years, respectively, in a series of 286 cases<sup>[19]</sup>. In a review of 1682 adenoma resection procedures from 18 studies (Table 2), an average of 11% of the patients were found to have residual adenoma in the surgical margin, 6.3% had recurrence, and the complication rate was up to 11% during a follow-up period of 12 mo in one series, and > 24 mo in the rest of the studies.

The histologically positive resection margin is highly significant in terms of local recurrence rates after adenoma resection. In a review of 18 studies with a minimum follow-up of 12 mo (Table 2), I have found that residual adenoma in the surgical margin varied from 0% to 37.3%. However, the recurrence rate was 0%-15%, predominantly in cases with positive or uncertain resection margins. In three large series, it has been found that adenoma recurrence rate is high in the incompletely resected group (37.7%, 46% and 25%) compared with that in patients with free histological margins after adenoma resection (4.3%, 3% and 3.7%, respectively)<sup>[28,33,34]</sup>. In another two studies, adenoma extending to the surgical margin of locally excised polyps was found in 25%<sup>[21]</sup> and 30.7% of cases<sup>[38]</sup>. The latter was a large series of 238 patients (226 patients treated by TEM and 12 by TE). It is remarkable that, with such high positive-residual-margin rates, the recurrence rates in these studies were only 5.6% after 33 mo follow-up<sup>[21]</sup> and 3.6% after 67.5 mo follow-up<sup>[38]</sup>, which are lower

than the rates reported in studies with lower positive-residual-margin rates. Røkke *et al*<sup>[31]</sup> did not observe adenoma recurrence after 12 mo follow-up in a series of patients in whom the residual adenoma in surgical margin was 10%.

Even for recurrent adenoma, TEM has now become an important alternative treatment. Five series have reported the use of TEM in the treatment of recurrent adenoma or residual disease without further recurrence<sup>[25,26,32,33,35]</sup>.

In five studies that have compared adenoma resection with TEM and another procedure, the lower or similar recurrence, residual tumor and early complication rates favor TEM resection<sup>[22,38-40]</sup>. Late complication rates were higher after TEM because of the increased incidence of transient incontinence in the postoperative period<sup>[39,40]</sup>. Recently, Moore *et al*<sup>[41]</sup> have compared rectal adenoma excision with TEM and TE, and concluded that TEM is more effective than the other technique, because they found a significantly higher rate of clear margin with less fragmented specimens after TEM, with low complication and recurrence rates.

## CONCLUSION

The transanal approach is a feasible, frequently used technique with few complications and low recurrence and mortality, but its use is limited to the lower rectum. The posterior approach with coccygeal resection, with or without sphincter section, can be mentioned only anecdotally in colorectal surgery. Probably very few surgeons are using it because of its high morbidity and recurrence and the use of colostomy. ETAR is a forgotten minimally invasive technique. It is a simple and safe method and technical expertise has already been acquired on urological conditions such as bladder and prostate tumors; however, it is used less frequently than it deserves for resection of rectal lesions. This is probably because few colorectal surgeons have much enthusiasm for the multiple sessions and piecemeal resection using a resectoscope. TEM offers better access to lesions in the middle and upper rectum, with superior endoscopic magnification and better illumination, superior visualization and pneumorectum, with accurate and complete resection allowing better histological analysis, and secure suture closure. The benefits of TEM are: few complications; low recurrence and mortality; less postoperative pain and use of analgesia; shorter time to the patient being able to walk, sit, eat and defecate; shorter hospital stay; and avoidance of colostomy. These benefits can compensate for the high price of the instruments.

### INTRODUCTION

Globally, one half of the nearly 1 million patients diagnosed with colorectal cancer annually will develop liver metastases during the course of the disease<sup>[1,2]</sup>. Autopsy findings suggest that approximately 50% of patients who die of colorectal cancer have liver metastases, which are the only site of metastatic disease in approximately 20%-30% of patients<sup>[3]</sup> and the cause of death in most of these patients<sup>[4]</sup>. In other types of cancer, liver metastases are a sign of distant dissemination, and surgery is not a curative option<sup>[5]</sup>. In colorectal cancer, however, portal vein drainage from the gastrointestinal tract to the liver favors metastasis to the liver without systemic dissemination<sup>[5]</sup>. Surgery therefore provides a potentially curative treatment option for patients with resectable liver disease<sup>[6]</sup>, in contrast with palliative chemotherapy for those with unresectable disease.

One of the most important recent advances in the management of advanced colorectal cancer is the concept of downstaging initially unresectable disease using chemotherapy so that more patients become eligible for potentially curative surgery. Current treatment guidelines<sup>[4]</sup> and substantial research highlight the importance of increasing the rates of secondary resection in initially unresectable disease. The addition of active targeted therapies, such as cetuximab and bevacizumab, to chemotherapy may further increase secondary resection rates. This article summarizes the current data on secondary resection of initially unresectable liver metastases of colorectal cancer using currently available systemic therapy regimens.

### HOW RESECTABILITY MAY BE ACHIEVED

Reported 5-year survival rates following hepatic resection generally range from 25% to 40% (Figure 1)<sup>[7-9]</sup>, though

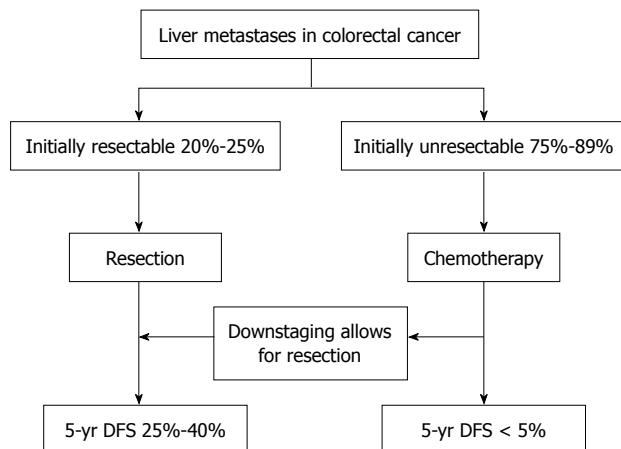

### Abstract

Surgery is the only curative option for patients with liver metastases of colorectal cancer, but few patients present with resectable hepatic lesions. Chemotherapy is increasingly used to downstage initially unresectable disease and allow for potentially curative surgery. Standard chemotherapy regimens convert 10%-20% of cases to resectable disease in unselected populations and 30%-40% of those with disease confined to the liver. One strategy to further increase the number of candidates eligible for surgery is the addition of active targeted agents such as cetuximab and bevacizumab to standard chemotherapy. Data from a phase III trial indicate that cetuximab increases the number of patients eligible for secondary hepatic resection, as well as the rate of complete resection when combined with first-line treatment with the FOLFIRI regimen. The safety profiles of preoperative cetuximab or bevacizumab have not been thoroughly assessed, but preliminary evidence indicates that these agents do not increase surgical mortality or exacerbate chemotherapy-related hepatotoxicity, such as steatosis (5-fluorouracil), steatohepatitis (irinotecan), and sinusoidal obstruction (oxaliplatin). Secondary resection is a valid treatment goal for certain patients with initially unresectable liver metastases and an important end point for future clinical trials.

**Figure 1** Breakdown of the incidence of liver metastases of colorectal cancer and expected outcomes with current treatment.

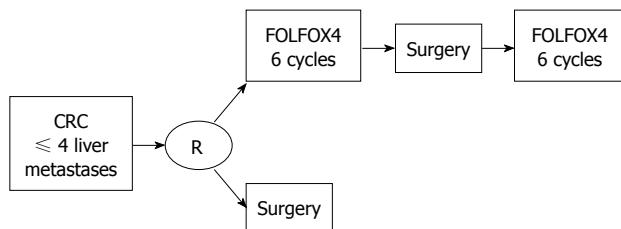

rates exceeding 50% have been observed in some studies<sup>[1,10,11]</sup>, and these outcomes may be improved by the use of preoperative or postoperative chemotherapy or both<sup>[12,13]</sup>. In a recent phase III trial, hepatic resection was compared with resection plus perioperative chemotherapy (6 cycles of FOLFOX4 before and 6 cycles after surgery) (Figure 2). Perioperative chemotherapy increased 3-year survival rates significantly in eligible patients (36.2% vs 28.1%) and resected patients (42.4% vs 33.2%), compared with surgery alone<sup>[2]</sup>.

Unfortunately, 80%-90% of patients with liver metastases are considered to have unresectable disease at the time of diagnosis<sup>[4,7]</sup>. For them, modern chemotherapy and biologic agents afford median survival times hovering around 15 to 20 mo (Figure 1)<sup>[14-20]</sup>.

Curative surgery remains an option if initially unresectable disease can be downstaged to allow for potentially definitive, ie, secondary, resection. Reported resectability rates after chemotherapy vary widely, depending on the patient population and definition of resectability. In unselected patients with unresectable liver metastases treated with chemotherapy, resection rates of 1% to 26% have been reported<sup>[21]</sup>. Higher resection rates (approximately 24%-54%) have been seen in patients with disease confined to the liver<sup>[21]</sup>.

Outcomes following secondary resection are comparable to those observed after primary resection, making resectability a high-priority therapeutic goal. In a study of 872 patients with colorectal liver metastases, 701 (80%) were deemed to have unresectable disease. Of these patients, 95 (13%) ultimately underwent secondary resection after downstaging with chemotherapy. The 5-year survival rate in patients undergoing secondary resection was the same as that in patients undergoing primary resection at the same institution for initially resectable disease (34%)<sup>[7]</sup>.

As investigators attempt to refine the use of resectability and collect information about resection as a clinical endpoint, a rough positive indicator of potential improvement in resectability rates is tumor shrinkage activity. It is therefore unsurprising that conversion to resectability correlates with response to

**Figure 2** Schema of the EORTC 40983 of perioperative chemotherapy<sup>[2]</sup>.

chemotherapy<sup>[21]</sup>. A retrospective review of 305 patients treated with preoperative irinotecan- or oxaliplatin-based chemotherapy followed by resection of liver metastases showed that pathologic response to chemotherapy is an independent predictor of survival<sup>[22]</sup>. Importantly, these findings support an aggressive approach in which optimal management aims to put curative options within reach by tailoring systemic therapy to achieve the highest response rate possible, particularly in patients with borderline resectable disease.

## SECONDARY RESECTION FOLLOWING STANDARD CHEMOTHERAPY

### Oxaliplatin- and irinotecan-based regimens

Several combinations of 5-fluorouracil and leucovorin with either oxaliplatin or irinotecan have established efficacy and are accepted as standard treatment for advanced colorectal cancer<sup>[4,14,15,17,22,23]</sup>. These regimens can also lead to secondary resection in some patients with initially unresectable liver metastases. In unselected populations with advanced colorectal cancer, oxaliplatin-based therapy produces secondary resection rates of 15%-22% and complete resection rates (R0) of 9%-13% (Table 1)<sup>[14,23-25]</sup>. Among patients treated with irinotecan-based regimens, approximately 9% become eligible for surgery and 7% will achieve complete resection (Table 2)<sup>[14,23,26-28]</sup>.

Comparative data from several studies suggest that oxaliplatin-based regimens may be more effective than irinotecan-based regimens in converting unresectable disease to resectable disease<sup>[14,29,30]</sup>, although this finding has not always been consistent<sup>[23]</sup>. Importantly in these studies, median survival times for resected patients reach 42-47 mo.

Higher resection rates have been reported in studies of selected patients, such as those with liver metastases only. In a phase II trial evaluating FOLFOX4 in patients with unresectable metastases confined to the liver, response rate was 60% and surgery was possible in 40% of patients<sup>[25]</sup>. Of the 17 patients who underwent surgery, 14 were free of residual disease (R0). The median survival was 26 mo. Additional studies have evaluated irinotecan-based regimens in selected patient populations; resection rates were generally 30%-40%<sup>[26-28]</sup>.

### FOLFOXIRI

More recently, several groups have evaluated the

combination of 5-fluorouracil, oxaliplatin, and irinotecan (FOLFOXIRI)<sup>[16,31,32]</sup>, with the rationale of maximizing concurrent exposure to multiple active agents<sup>[14,33]</sup>. In a preliminary study in 39 patients with unresectable liver metastases, the response rate was 64% and secondary surgery was possible in 23 patients (59%)<sup>[32]</sup>. Of these patients, 84% achieved R0 resection.

Two randomized trials have compared FOLFOXIRI with FOLFIRI as first-line therapy for patients with initially unresectable advanced colorectal cancer<sup>[16,31]</sup>. Although the first study, of 283 patients, found no significant difference between the two treatment groups in response or survival<sup>[31]</sup>, the second study, involving 244 patients, found that FOLFOXIRI significantly increased response rates (60% vs 34%) and median survival (22.6 mo vs 16.7 mo)<sup>[16]</sup>. Both studies, however, showed that FOLFOXIRI increased secondary resection rates compared with FOLFIRI. Significantly more patients treated with FOLFOXIRI in the first study were eligible for secondary resection (14 vs 6)<sup>[31]</sup>. This included 14 patients with liver metastases (11 vs 3), of whom 11 achieved R0 resection (9 vs 2). In the second study, the rate of R0 secondary resection was significantly greater with FOLFOXIRI (15% vs 6%) overall and in those with liver metastases only (36% vs 12%)<sup>[16]</sup>.

Both randomized trials reported increased toxicity with FOLFOXIRI compared with FOLFIRI, including higher incidences of alopecia, diarrhea, neutropenia, and neurotoxicity, a factor to weigh against the benefits achieved<sup>[16,31]</sup>. Further investigation is needed to identify new strategies for increasing rates of secondary resection without increasing toxicity associated with standard chemotherapy agents.

## IMPROVING ON STANDARD CHEMOTHERAPY: ADDITION OF BIOLOGICS

Two monoclonal antibodies are approved for use in advanced colorectal cancer that have been shown to improve outcomes when combined with chemotherapy. Combining these agents with standard chemotherapy may represent a safe and effective strategy for increasing the proportion of patients eligible for potentially curative surgery.

### Cetuximab

Cetuximab blocks the activity of the epidermal growth factor receptor (EGFR) and is approved for use in the United States in combination with irinotecan in patients with irinotecan-refractory disease, or as monotherapy for patients who have failed both irinotecan- and oxaliplatin-based chemotherapy. Adam *et al*<sup>[34]</sup> assessed the ability of cetuximab-based therapy to downstage patients with unresectable disease and liver metastases refractory to prior chemotherapy to become eligible for surgery with curative intent. A total of 151 patients were treated either completely at the Paul Brousse Hospital (PBH, *n* = 133) or referred to PBH for hepatectomy after receiving cetuximab-based therapy elsewhere (*n* = 18). Of the 151 patients, 27 underwent surgery, of whom 20 had received cetuximab plus irinotecan; four, cetuximab plus oxaliplatin; and one, all three agents. Two-thirds of patients who underwent surgery had had at least two prior chemotherapy regimens. Of the 133 patients treated completely at PBH, 9 (7%) underwent surgery, which is encouraging, considering these were heavily pretreated and refractory patients.

<sup>1</sup>FOLFOX4 or XELOX. PFS: Progression-free survival in the study arm; FOLFIRI: Irinotecan plus infusional 5-fluorouracil/leucovorin (5-FU/LV); IFL: Irinotecan, fluorouracil, and leucovorin; CT: Chemotherapy.

In the first-line setting, an initial phase I / II trial of 21 patients with unresectable, EGFR-expressing disease who received cetuximab plus 5-fluorouracil, leucovorin, and irinotecan found a 67% response rate with median survival of 33 mo<sup>[19]</sup>. Five patients (24%) were eligible for secondary resection. A phase II study evaluated first-line cetuximab plus FOLFOX4 in 43 patients with unresectable, EGFR-expressing disease<sup>[35]</sup>. Confirmed responses were seen in 72% of patients and the disease control rate was 95%. Ten patients (23%) underwent potentially curative surgery and nine (21%) had no evidence of residual disease after surgery. Overall, the median survival was 30 mo.

A randomized phase II trial comparing FOLFOX4 with or without cetuximab (the OPUS trial) found that cetuximab significantly increases response rates in patients with good performance status when added to standard first-line chemotherapy (49.0% vs 36.8%)<sup>[36]</sup>. Resection rates were higher with cetuximab (6.5% vs 3.6%), as were R0 resection rates (4.7% vs 2.4%)<sup>[36]</sup>. Cetuximab was associated with an increase in skin reactions, infusion-related reactions, and hypomagnesemia, but no exacerbation of oxaliplatin-related toxicities.

The CRYSTAL study (*n* = 1198) investigating the addition of cetuximab to FOLFIRI was the first phase III trial to demonstrate that adding a therapeutic monoclonal antibody to standard chemotherapy may improve secondary resection rates (Table 3)<sup>[37-40]</sup>. Cetuximab significantly increased the overall secondary resection rate (6% vs 2.5%), and boosted the rate of complete resection (R0) 3-fold [4.3% vs 1.5%; odds ratio 3.0 (95% CI 1.4-6.5)]. As expected, higher rates of R0 resection were seen in the subgroup of patients with disease confined to the liver (approximately 20% of patients in each arm), for whom the addition of cetuximab also appeared to increase R0 resection rates compared with FOLFIRI alone (9.8% vs 4.5%) and was associated with a significant increase in progression-free survival (median, 11.4 mo vs 9.2 mo)<sup>[37]</sup>.

The second key finding of CRYSTAL revealed that the benefit from cetuximab was concentrated in the subgroup of patients with wild-type K-RAS on their tumors (64.4% of the initial evaluable population); this population experienced a reduction in the risk of

progression of 32% (HR = 0.68, *P* = 0.017), and 16% higher response rate (59.3% vs 43.2%, *P* = 0.0025)<sup>[42]</sup> compared with those with mutant K-RAS. The effect on patients with disease confined to the liver was also dramatic, with the response rate reaching 77% in the population with K-RAS wild type<sup>[41]</sup>.

These promising observations have propelled more focused investigation on the role of cetuximab as a conversion or downstaging agent. The CELIM study was a randomized phase II study (*n* = 111) in which patients with unresectable liver metastases received cetuximab with either FOLFOX or FOLFIRI. Of 106 patients evaluable for efficacy, a response rate of 74% was reported in both arms combined, 79% in those with K-RAS wild-type tumors. Confirmed response (by second CT scan according to RECIST criteria or by resection) rate was 62% in both arms combined, 70% in those with K-RAS wild-type tumors. The rate of resection was an encouraging 46%, and 34% of patients achieved R0 resections. Nineteen of 75 patients (25%) with unresectable disease at enrollment had resectable disease after 16 wk of therapy (*P* = 0.021)<sup>[42]</sup>.

### **Bevacizumab**

Bevacizumab binds to vascular endothelial growth factor (VEGF) and is approved for use in combination with 5-fluorouracil-based chemotherapy as first- or second-line treatment for metastatic colorectal cancer. This agent has been shown to improve outcomes when added to first-line chemotherapy for advanced colorectal cancer, increasing response rates by approximately 10% compared with chemotherapy alone and producing median survival rates of approximately 17-24 mo<sup>[20,38,43]</sup>. Nonrandomized trials evaluating the combination of bevacizumab and oxaliplatin-based chemotherapy as neoadjuvant therapy in patients with resectable disease have also produced promising results<sup>[13,44]</sup>.

Data from phase III trials suggest that bevacizumab does not increase secondary resection rates when added to standard chemotherapy (Table 3), both for irinotecan-based and oxaliplatin-based therapy, although the resected patients in bevacizumab are low to extract any firm conclusion<sup>[38,39]</sup>.

A non-randomized, uncontrolled phase IV study

(first BEAT) prospectively collected data on resection rates following bevacizumab plus various chemotherapy regimens as first-line treatment for advanced colorectal cancer. Of the 1914 evaluable patients, 215 (11.2%) underwent surgery after receiving systemic therapy and 170 (8.8%) achieved R0 resection. Preliminary data suggest a 2-year survival rate of 44% in the entire patient population and 82% in those who achieved R0 resection<sup>[40]</sup>.

Based on the findings described above, it appears that bevacizumab does not compromise the feasibility of secondary resection of metastatic disease; it is unclear, however, whether adding bevacizumab has the potential to improve upon the resectability rates achieved with chemotherapy alone<sup>[40]</sup>.

## THE ROLE OF LOCAL THERAPIES IN THE MANAGEMENT OF LIVER METASTASES

Local treatments may be combined with surgery with the potential to improve upon the therapeutic benchmarks achieved with surgery alone. Abdalla *et al*<sup>[1]</sup> reported on the use of radiofrequency ablation (RFA), alone or in combination with surgery in 158 patients in whom R0 resection was not possible. Outcomes were far superior for the 190 patients who underwent complete resection, with roughly double survival rates at 4 years (65% vs 22%-36% with RFA alone or RFA plus surgery). RFA seemed to offer a modest advantage over palliative chemotherapy only.

Stereotactic body radiation (SBRT) is a local treatment approach that may enhance outcomes in patients with liver metastases<sup>[45]</sup>, but it is too early to determine its relative efficacy compared with other modalities. A recent retrospective comparison of outcomes after surgery, RFA, or SBRT in patients whose liver disease recurred after initial partial resection, revealed equivalent outcomes across the three approaches<sup>[46]</sup>; well-controlled prospective comparisons are lagging.

Finally, selective internal radiation therapy (SIRT), using Yttrium-90 microspheres<sup>[47]</sup>, is also a feasible technology awaiting validation in this disease setting.

## TREATMENT DECISIONS, TOXICITY, FEASIBILITY AND OTHER CONCERNS

Considering the importance of achieving resectability as a therapeutic goal, its accurate assessment is key to delineate management strategies, and the availability of increasingly sophisticated diagnostic tests may help optimize evaluation approaches. Positron-emission tomography combined with computed tomography (PET-CT) with [<sup>18</sup>F]-fluoro-2'-deoxy-D-glucose (FDG) has an important role in staging patients with colorectal cancer, and in ruling out extrahepatic metastases in advanced disease, although prior chemotherapy may lower its sensitivity<sup>[48]</sup>. MRI is used for further evaluation of the liver in patients with metastatic colorectal cancer. A 2008 study of 20 consecutive patients with colorectal

cancer compared whole-body MRI *vs* PET-CT for staging of lymph nodes and distant metastases. Results suggested a preference for PET-CT in diagnosing lymph nodes, but a trend toward superiority for whole-body MRI in detecting metastases in liver, brain, and bone<sup>[49]</sup>. Finally, intraoperative ultrasound (IOUS) is a standard method to determine resection margin and identify previously undetected tumors<sup>[50-52]</sup>. Contrast-enhanced IOUS offers greater sensitivity, increasing identification of new metastatic lesions by approximately 20%<sup>[50,53,54]</sup>, and allows more time to find new metastases intraoperatively<sup>[51]</sup>. Zalinski *et al*<sup>[55]</sup> developed a new marking technique to help identify resection margins intraoperatively following preoperative chemotherapy: coils are placed behind the deep margin of lesions using a guide needle and CT or ultrasound guidance prior to systemic chemotherapy. The coils are then easily detected during surgery.

The relevance of resectability in disease prognosis recently became clearer. Patients with resectable metastases either hepatic or extrahepatic (but not both) had a 5-year overall survival rate of 54%, compared with 13% for patients with both resectable hepatic and extrahepatic disease and 0% for unresectable metastases, regardless of location<sup>[56]</sup>. The authors proposed the inclusion of resectability as a criterion to stratify stage IV colorectal cancer.

The degree of optimization of downstaging strategies in routine clinical practice, however, remains unclear. In a recent review of managed care records of nearly 500 patients with colorectal cancer who underwent hepatic resection, only 20% had received preoperative chemotherapy<sup>[57]</sup>. It is not known how many patients initially diagnosed with unresectable liver metastases are re-evaluated by a liver surgeon after first-line therapy to determine whether the patient's resectability status has changed. Several authors have emphasized the importance of a multidisciplinary approach to the management of colorectal liver metastases and close cooperation among radiologists, medical oncologists, and surgeons with expertise in liver resection<sup>[4,7,58]</sup>.

### Chemotherapy-related hepatotoxicity

Due to recent advances in surgical techniques and postoperative care, the safety of hepatic resection for colorectal liver metastases has improved considerably<sup>[1]</sup>. Despite the trend toward increasing extensiveness of resection, surgical mortality rates remain less than 5%<sup>[8,59]</sup>. In addition, use of portal vein embolism (PVE), a well-established and well-tolerated procedure, has been shown to reduce the risk of postoperative liver failure, with a low rate of complications in resection of colorectal liver metastases<sup>[60,61]</sup>.

However, systemic therapy may be associated with liver injury and affect surgical outcomes. Chemotherapy is known to cause pathologic changes in normal liver tissue, modifying gross appearance and impairing parenchymal hemostasis and regenerative capacity<sup>[2,12,62]</sup>. The impact of these effects on clinical outcomes in patients undergoing hepatic resection is unclear. In the EORTC 40983 trial

**Table 4** Liver injury by chemotherapy regimen<sup>[12]</sup>

Other	0	100	NS	8	92	NS	0	100	NS

<sup>1</sup>Rubbia: Brandt grade 2 or 3; <sup>2</sup>Kleiner score ≥ 4; <sup>3</sup>Presence of liver injury characteristic; comparison of each chemotherapy group vs no chemotherapy. FU: Fluorouracil; IRI: Irinotecan; OX: Oxaliplatin; NS: Not significant.

(Figure 2), six cycles of preoperative chemotherapy did not increase the rate of surgical mortality compared with surgery alone. Chemotherapy was associated with an increase in reversible postoperative morbidity that was generally within the expected range for hepatic resection (25% vs 16%)<sup>[2]</sup>. Karoui *et al*<sup>[63]</sup> retrospectively compared outcomes following hepatic resection in 45 patients who received preoperative chemotherapy and 22 who received no preoperative chemotherapy. Treatment with chemotherapy was associated with an increase in postoperative morbidity. Interestingly, morbidity correlated with the number of cycles of preoperative therapy given (≥ 6 cycles vs < 6 cycles), but not the type of chemotherapy used.

Others have reported that different chemotherapy regimens cause different types of liver injury, with varying effects on clinical outcomes (Table 4)<sup>[12]</sup>. Treatment with 5-fluorouracil-based treatment has been associated with an increase in steatosis, which is associated with increased postoperative morbidity<sup>[58,64]</sup>. In addition, longer duration of 5-fluorouracil-based therapy (≥ 9 cycles vs 1–8 cycles) was associated with significantly increased incidence of sinusoidal injury (42% vs 26%; P = 0.017) and postoperative liver insufficiency (11% vs 4%; P < 0.035), and was an independent predictor of postoperative liver insufficiency (P = 0.031; odds ratio, 3.90)<sup>[65]</sup>. Irinotecan has been associated with steatohepatitis, which in turn was correlated with increased mortality following hepatic resection, particularly due to liver failure<sup>[12]</sup>. Oxaliplatin therapy does not induce steatosis or steatohepatitis, but increases the risk of developing vascular lesions and sinusoidal obstruction syndrome; a clear link between these effects and postoperative morbidity or mortality rates has not been established<sup>[12,66]</sup>.

Given the varying effects of different chemotherapy agents on liver tissue, both the efficacy and safety of available regimens should be considered when selecting an appropriate regimen for use in an individual patient. It also is advisable limiting the number of cycles of preoperative chemotherapy in order to avoid extensive liver injury, and to perform surgery as soon as possible after achieving resectability.

#### Cetuximab and hepatic outcomes

The most common adverse event associated with cetuximab treatment is skin reactions. Less common but potentially serious adverse events include infusions

reactions, cardiopulmonary arrest, and hypomagnesemia.

There is little data specifically on the effects of cetuximab on the liver in this setting. In Adam *et al*<sup>[34]</sup>, nine patients who became eligible for surgery after cetuximab-based therapy had evidence of liver injury, but this was not attributable to cetuximab. Overall, one patient died postoperatively and approximately 50% of patients had surgical complications.

The addition of cetuximab does not appear to increase the incidence of adverse events typically associated with oxaliplatin-based therapy, such as neutropenia, diarrhea, fatigue, or neurotoxicity<sup>[35,36]</sup>. In the CRYSTAL trial, the addition of cetuximab to FOLFIRI in the first-line setting did not increase all-cause mortality rates, and there were no deaths attributed to cetuximab. Patients who received cetuximab and FOLFIRI had higher incidences of diarrhea and cetuximab-related skin reactions<sup>[37]</sup>.

#### Bevacizumab and hepatic outcomes

Treatment with bevacizumab is associated with increased incidence of hypertension and relatively low rates of certain potentially serious events, such as bleeding, gastrointestinal perforation, and arterial thromboembolism<sup>[20,38,40]</sup>. Recent results have found that bevacizumab reduces the incidence of oxaliplatin-related sinusoidal injury, although the exact mechanism for this effect is unknown<sup>[44,65]</sup>. It has been suggested that the antiangiogenic effects of bevacizumab can interfere with hepatic regeneration and wound healing, which is relevant to its use in the perioperative setting<sup>[13,67]</sup>. To avoid surgical morbidity, it is currently recommended to stop bevacizumab therapy at least 6 wk before surgery and resume treatment 28 d or more after surgery, provided that all incisions have healed completely<sup>[4,13,67]</sup>. Reddy *et al*<sup>[68]</sup> reported that complications are more prevalent in patients who undergo surgery within 8 wk of stopping bevacizumab, compared with those who discontinue bevacizumab more than 8 wk before surgery (62.5% vs 30.4%). In a study of preoperative chemotherapy plus bevacizumab, Gruenberger *et al*<sup>[13]</sup> reported that when bevacizumab was discontinued about 5 wk before surgery, the resulting rates of complications were similar to that achieved in a historical control group of patients who received chemotherapy alone. Whether the need to discontinue bevacizumab for several weeks perioperatively hinders its ability to allow for complete resection is unknown.

**Table 5 Secondary resection in patients with initially unresectable liver metastases**

Improve patient selection through early and continued consultation in a multidisciplinary team approach, including close cooperation among a radiologist, medical oncologist, and surgeon with experience in liver resection  
 Conduct surgical evaluation at baseline and, if disease is initially unresectable, reevaluation at intervals during therapy to determine if conversion to resectability has been achieved  
 Set appropriate goals of therapy (best response, conversion to resectable disease, or palliation)  
 Determine length of therapy, with consideration for the risk of potential toxicities  
 Consider the safety profile of individual agents and the risks of overtreatment, including hepatotoxicity  
 If the treatment goal is conversion to resection, treat to resectability and not to best response

## CONCLUSION

The use of systemic therapy to downstage unresectable liver metastases to achieve resectability offers a curative option with long-term outcomes similar to those achieved with primary resection. Therefore, secondary resection is a valid treatment goal for certain patients with initially unresectable liver metastases and an important end point for future clinical trials (Table 5).

Refinement of available first-line treatment options may increase secondary resection rates. Because response rates correlate with secondary resection rates, aggressive approaches that increase the likelihood of preoperative response seem warranted. The blurring of first-line therapy and neoadjuvant therapy underscores the need for clear definitions of treatment approach, ie, curative versus palliative, and the goals of therapy, e.g. best response, conversion to resectable disease, and palliation. Multidisciplinary involvement in the management of the patient is essential to implement a continued surgical evaluation approach as patients with borderline resectable/unresectable disease undergo systemic treatment.

The benefits of aggressive chemotherapy to downstage liver metastases should be weighed against the potential increase in adverse events, particularly those related to liver injury and surgical outcomes. Different chemotherapy agents have different effects on the liver. To avoid excessive liver injury and postoperative complications, the safety profile of individual agents should be considered when selecting a preoperative regimen; the duration of preoperative chemotherapy should be kept to a minimum; and surgery should be performed as soon as resectability has been achieved.

The addition of targeted therapies to current first-line chemotherapy platforms may improve secondary resection rates. The two leading candidates for this approach are cetuximab and bevacizumab. Data from a randomized trial indicate that cetuximab increases secondary resection rates when added to irinotecan-based therapy. The addition of cetuximab to preoperative chemotherapy does not appear to increase hepatotoxicity or mortality compared with chemotherapy alone. When discontinued at least 6 wk before surgery and reinitiated at least 28 d after surgery, bevacizumab also appears to be a safe treatment option in this setting, and there is some evidence to suggest that bevacizumab may reduce the risk of sinusoidal injury. Current studies evaluating cetuximab, bevacizumab, and both in combination are

underway and will help to further refine their role in the preoperative setting.

The invasive front dominant type was associated with histologic type and advanced stage. MMP7 positivity was correlated with LN $\gamma 2$  or LN $\beta 3$  expression but not with clinicopathological characteristics. Active MMP7 detected by casein zymography was correlated with depth of invasion and advanced stage. Downregulation of MMP7 expression by siRNA resulted in a significant decrease in biliary tract cancer cell invasion *in vitro*.

**CONCLUSION:** Our results suggest that LN $\gamma 2$  and LN $\beta 3$ , in conjunction with MMP7, play a key role in the progression of biliary tract cancer.

Overexpression of  $\beta 3/\gamma 2$  chains of laminin-5 and MMP7 in biliary cancer. *World J Gastroenterol* 2009; 15(31): 3865-3873 Available from: URL: <http://www.wjgnet.com/1007-9327/15/3865.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.3865>

## Abstract

**AIM:** To clarify the clinicopathological significance of laminin-5  $\gamma 2$  (LN $\gamma 2$ ) and  $\beta 3$  (LN $\beta 3$ ) chains and MMP7 expression in biliary tract cancer.

**METHODS:** We analyzed the association between immunohistochemically detected LN $\gamma 2$ , LN $\beta 3$ , and MMP7 expression in biliary tract cancer and clinicopathological characteristics. Activity of MMP7 was analyzed by casein zymography. An *in vitro* invasion assay after treatment with MMP7-specific siRNA was performed.

**RESULTS:** LN $\gamma 2$  expression was predominantly observed in carcinoma cells at the invasive front. LN $\gamma 2$  expression was seen in 57% of patients with biliary tract cancer, and was associated with depth of invasion, histologic type, and advanced stage. The expression pattern of LN $\beta 3$  was classified into two types: invasive front dominant type (38%) and diffuse type (28%).

## INTRODUCTION

Despite recent advances in diagnosis and treatment, the prognosis of patients with biliary tract cancer is still poor. Surgical resection is possible in only a small proportion of patients<sup>[1,2]</sup>. Consequently, elucidating the biological characteristics of these carcinomas has become necessary to improve the prognosis of patients and to devise better treatment strategies.

Laminins are components of the extracellular matrix (ECM) that contribute to the architecture of the basal lamina surrounding the epithelial cells and mediate cell adhesion, growth, migration, proliferation, and differentiation. Laminins are heterotrimeric glycoproteins composed of three different polypeptide

chains ( $\alpha$ ,  $\beta$  and  $\gamma$ ) arranged in a cruciform structure. A separate gene encodes each polypeptide chain and different combinations of these chains lead to the 15 different laminin isoforms<sup>[3-5]</sup>. Laminin-5/laminin-332 (LN5), consists of  $\alpha_3$ ,  $\beta_3$ , and  $\gamma_2$  chains, which are encoded by three distinct genes (*LAMA3*, *LAMB3*, and *LAMC2*, respectively)<sup>[6]</sup>. LN5 has been shown to promote the adhesion, migration, and scattering of a variety of cultured cells, mainly through integrin  $\alpha_3\beta_1$ , more strongly than other ECM proteins<sup>[7]</sup>. Moreover, in hepatocellular carcinoma (HCC), LN5 reportedly plays an important role in epithelial-mesenchymal transition through down-regulation of E-cadherin and translocation of  $\beta$ -catenin into the nuclei<sup>[8]</sup>.

Expression of the three subunits of LN5 is regulated differentially in cancer cell lines and in normal and malignant tissues including HCC<sup>[9-11]</sup>. Indeed, LN $\gamma_2$  has been shown to be secreted as a single subunit in gastric cancer<sup>[12]</sup>. Several lines of evidence suggest that the tumor-derived LN $\gamma_2$  contributes to invasion of tumor cells. LN $\gamma_2$  expression has been immunohistochemically detected in various types of carcinomas, such as HCC, colorectum, stomach, and esophagus<sup>[9,12-16]</sup>. It is notable that LN $\gamma_2$  has been predominantly detected at the invasive front, where tumor cells with the most aggressive phenotype are localized<sup>[17]</sup>.

Degradation of ECM components is mostly controlled by proteolytic enzymes called matrix metalloproteinases (MMPs)<sup>[18]</sup>. Specific cleavage of LN5 ( $\gamma_2$  subunit at residue 587) by MMP2 has been shown to induce migration of breast epithelial cells<sup>[19]</sup>. This altered form of LN5 was found in tumors and in tissues undergoing remodeling, but not in quiescent tissues. LN5 is also converted into a migration-promoting substrate by MT1-MMP<sup>[20]</sup>. MMP7, also known as matrilysin, is a “minimal domain MMP” that exhibits broad proteolytic activity against components of the ECM and non-ECM<sup>[18]</sup>. MMP7 is often overexpressed at the invasive front in various types of human cancer and is associated with cancer progression<sup>[21,22]</sup>. Both LN $\gamma_2$  and MMP7 are targets of the Wnt/ $\beta$ -catenin pathway<sup>[23,24]</sup>.

Although there are only a few reports regarding LN $\beta_3$  expression in human cancer, coexpression of LN $\gamma_2$  and LN $\beta_3$  has been reported in HCC, squamous cell carcinoma of the tongue and colorectal carcinoma and basal cell carcinoma of the skin<sup>[9,25,26]</sup>. It has recently been reported that human LN5 is a ligand for MMP7 and that a specific cleavage occurs in its  $\beta_3$  chain<sup>[27]</sup>. These results are interesting because MMP7 is overexpressed in HCC and colorectal carcinoma<sup>[18,28]</sup>. However, expression of LN5 and MMP7 in biliary tract cancer has not been clearly addressed.

To clarify the possible involvement of LN5 and MMP7 in the progression of biliary tract cancer, we immunohistochemically analyzed these expressions in 61 primary biliary tract cancer. Activity of MMP7 was analyzed by casein zymography. An *in vitro* invasion assay of biliary tract cancer cell lines after treatment with MMP7-specific siRNA was performed.

## MATERIALS AND METHODS

### **Cell lines and tissue samples**

Human bile duct cancer cell lines (TFK-1, HuH-28, and MEC) were obtained from Cell Resource Center for Biomedical Research, Tohoku University. Bile duct cancer cell line TKKK and gallbladder carcinoma cell lines TGBC1TKB, TGBC2TKB, and TGBC14TKB were purchased from Riken Cell Bank (Tsukuba, Japan). Cells were cultured in RPMI1640 or DMEM supplemented with 10% fetal bovine serum. Formalin-fixed, paraffin-embedded sections of 61 biliary tract carcinomas (30 extrahepatic bile duct carcinomas, 18 gallbladder carcinomas, 13 carcinomas of the ampulla of Vater) were used for immunohistochemically. Sections containing the most invasive part of each tumor were used. Fresh specimens of extrahepatic bile duct carcinoma ( $n = 10$ ), gallbladder carcinoma ( $n = 7$ ), and carcinoma of the ampulla of Vater ( $n = 3$ ) were obtained from patients who had undergone surgical treatment. Specimens were immediately frozen in liquid nitrogen at the time of surgery and stored at -80°C. Each tissue specimen was used for casein zymography. Histopathological features of the specimens were classified according to the pathological tumor-node-metastasis (TNM) classification system of the International Union Against Cancer. Informed consent was obtained from each subject and the institutional review committee approved the experiments.

### **Semi-quantitative reverse transcriptase-PCR (RT-PCR) and real-time RT-PCR**

Semi-quantitative RT-PCR was carried out as described previously<sup>[29]</sup>. Total RNA was extracted from cell lines using TRIzol reagent (Invitrogen, Carlsbad, CA, USA) following the manufacturer's instructions. cDNA was synthesized from 1  $\mu$ g of total RNA using SuperScript III reverse transcriptase (Invitrogen) with random hexamers. PCR was performed using primers specific for the *LAMA3*, *LAMB2* and *LAMC2* gene and the *glyceraldehyde-3-phosphate dehydrogenase* (*GAPDH*) gene. *GAPDH* served as an internal control of the reaction. Standard curves for semiquantitative RT-PCR were drawn as described previously<sup>[30]</sup>. All reactions were carried out at least in duplicate and controlled without reverse transcriptase. PCR products were electrophoresed in 2% agarose gels. Real-time RT-PCR was performed using the TaqMan real-time PCR system as described previously<sup>[31]</sup>.

### **Immunohistochemistry**

Immunohistochemistry was carried out as described previously<sup>[32]</sup>. The antibodies used were as follows: anti-LN $\alpha_3$  rabbit polyclonal antibody (1/100 dilution, Santa Cruz, CA, USA), anti-laminin5 ( $\gamma_2$  chain) mouse monoclonal antibody (1/50 dilution, Chemicon, Temecula, CA, USA), anti-LN $\beta_3$  rabbit polyclonal antibody (1/100 dilution, Santa Cruz), and anti-MMP7 mouse monoclonal antibody (1/50 dilution, Daiichi Fine Chemical, Takaoka, Japan). Normal mouse or rabbit

immunoglobulins were substituted for each primary antibody as negative controls. Cytoplasmic expression was defined as positive when immunoreactivity was observed in more than 10% of carcinoma cells. We defined the cells at the deepest invading part of the tumor as the invasive front.

### Casein zymography

Casein zymography was performed as previously described with some modifications<sup>[28]</sup>. Tissue extracts were electrophoresed on 8% polyacrylamide gel containing 1 mg/mL casein. After electrophoresis, gels were washed in 2.5% Triton-X 100 and incubated for 48 h at 37°C in 50 mmol/L Tris-HCl (pH 7.4), 10 mmol/L CaCl<sub>2</sub>, 1 mmol/L ZnCl<sub>2</sub>, and 0.02% NaNO<sub>3</sub>, followed by staining with 0.1% Coomassie brilliant blue.

### siRNA transfection

siRNA transfection was performed as described previously<sup>[33]</sup>. Levels of MMP7 inhibition were analyzed by RT-PCR and Western blotting. siRNA-transfected cells were used for the *in vitro* invasion assay.

### In vitro invasion assay

Assays were performed by the modified Boyden Chamber method as described previously<sup>[34]</sup>. Assays were also performed with 250 ng/mL of TIMP1, an MMP inhibitor. The results were presented as means  $\pm$  SD for each sample.

### Statistical analysis

Expression was assessed for associations with clinicopathological parameters using the chi-square two-tailed test or Fisher's exact test. A *P* value  $< 0.05$  was considered statistically significant. A *P* value between 0.05 and 0.10 was considered as a trend toward an association.

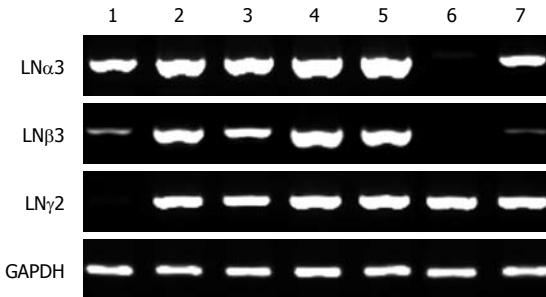

## RESULTS

### Expression of LN $\alpha$ 3, LN $\beta$ 3 and LN $\gamma$ 2, and MMP7 in cell lines

Expression levels of LN $\alpha$ 3, LN $\beta$ 3 and LN $\gamma$ 2, and MMP7 in cancer cell lines were analyzed using semi-quantitative RT-PCR (Figure 1). LN $\alpha$ 3 mRNA was detected in all seven cell lines but at very low levels in TGBC-14TKB. LN $\beta$ 3 mRNA was detected in six cell lines but at very low levels in MEC and TKKK. LN $\gamma$ 2 mRNA was detected in all seven cell lines but at very low levels in MEC. TFK-1, HuH-28, TGBC-1TKB, and TGBC-2TKB expressed considerable amounts of all 3 chains of LN5. MMP7 mRNA was detected in all seven cell lines. There were no significant correlations between these expression patterns and characteristics of the cell lines. Similar data were observed by real-time RT-PCR (data not shown).

### Overexpression of LN $\gamma$ 2, LN $\beta$ 3, and MMP7 in biliary tract cancer tissues

Expression of LN $\alpha$ 3 was detected in normal basement

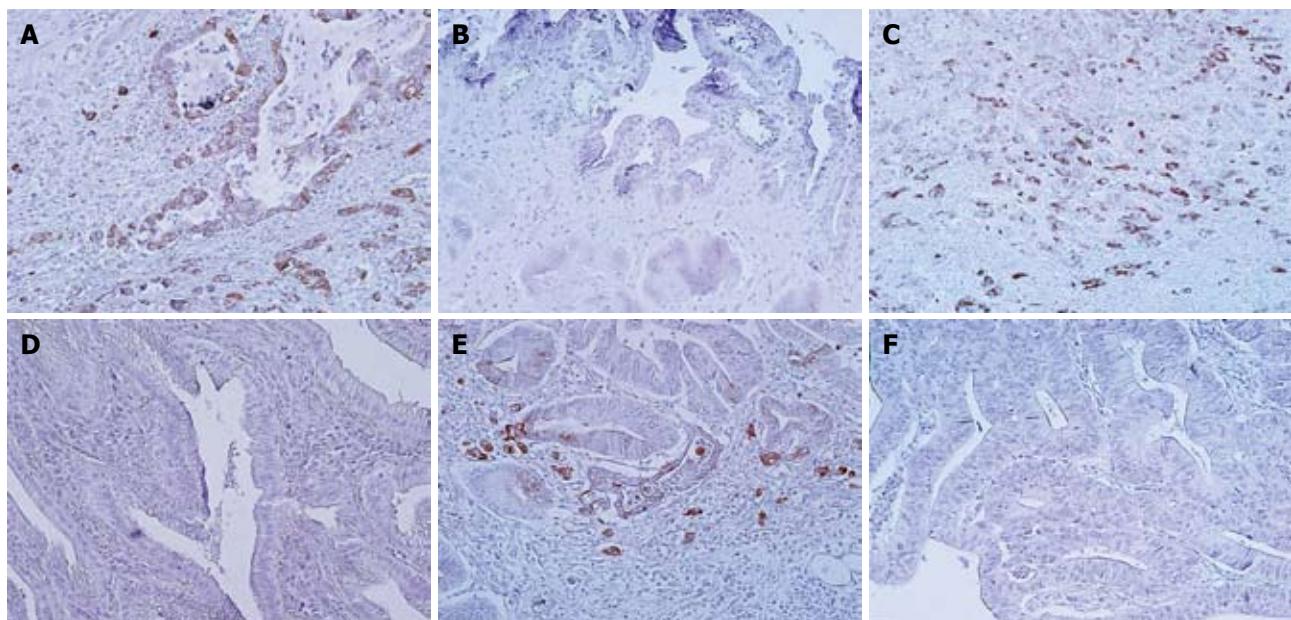

**Figure 1** RT-PCR analysis of the LN $\alpha$ 3, LN $\beta$ 3, LN $\gamma$ 2 genes in biliary tract cancer cell lines. 1: MEC; 2: TFK-1; 3: HuH28; 4: TGBC1TKB; 5: TGBC2TKB; 6: TGBC14TKB; 7: TKKK.

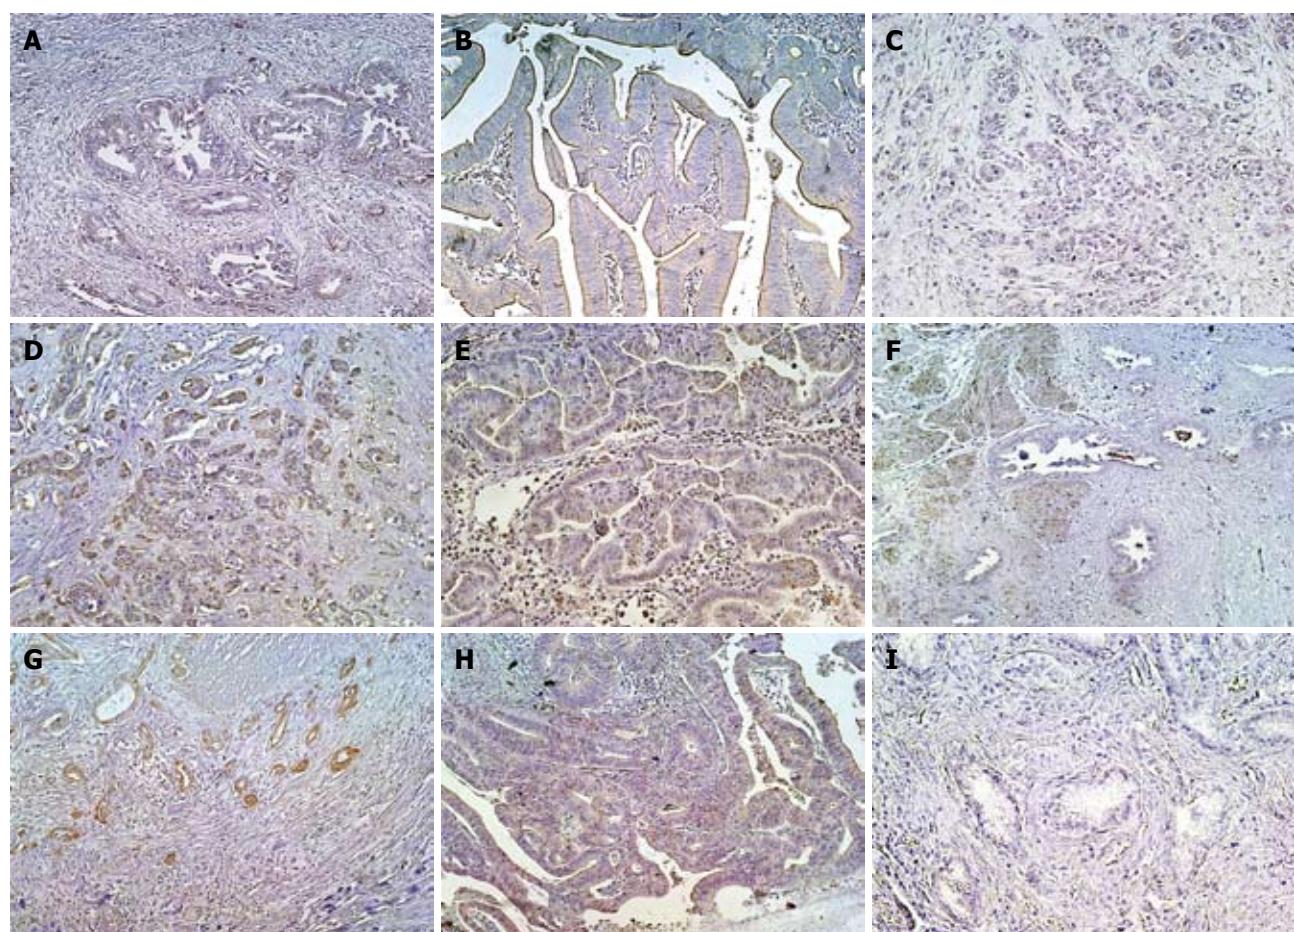

membranes but not in carcinoma cells (data not shown). Figure 2 shows representative results of immunohistochemistry for LN $\gamma$ 2 in biliary tract cancer. In carcinoma tissues, the cytoplasm of carcinoma cells was stained for LN $\gamma$ 2 at levels much stronger than those in normal basement membranes. The cytoplasmic immunoreactivity was often more intense at the invasive front. Cancer cells budding or dissociating from the tumor nests showed intense cytoplasmic staining. Sections with immunostaining signals in over 10% of carcinoma cells, which were observed in 35 (57%) of 61 cases, were judged to be positive for LN $\gamma$ 2. LN $\gamma$ 2 positivity was 67% in extrahepatic bile duct cancer, 50% in gallbladder cancer, and 46% in carcinoma of the ampulla of Vater. Figure 3 shows representative results of immunohistochemistry for LN $\beta$ 3 in biliary tract cancer. In carcinoma tissues, the cytoplasm of carcinoma cells was stained for LN $\beta$ 3 at levels much stronger than those in normal basement membranes. The expression pattern of LN $\beta$ 3 was classified into 2 patterns: invasive front dominant pattern and diffuse pattern. The invasive front dominant pattern and diffuse pattern were observed in 23 (38%) and 17 (28%) of 61 cases, respectively. Positivity for invasive front dominant pattern and diffuse pattern was 47% and 17% in extrahepatic bile duct cancer, 28% and 39% in gallbladder cancer, and 31% and 38% in carcinoma of the ampulla of Vater. Figure 4 shows representative results of immunohistochemistry for MMP7 in biliary tract cancer tissues. MMP7 immunoreactivity was intense at the invasive front in several cases. In general, MMP7 immunoreactivity was diffuse rather than invasive front dominant like LN $\gamma$ 2. Sections with immunostaining signals in over 10% of carcinoma cells, which were observed in 42 (69%) of 61 cases, were judged to be positive for MMP7. MMP7 positivity was 80% in extrahepatic bile duct cancer, 50% in gallbladder cancer, and 69% in carcinoma of the ampulla of Vater.

### Association of LN $\gamma$ 2, LN $\beta$ 3, and MMP7 expression with clinicopathological characteristics

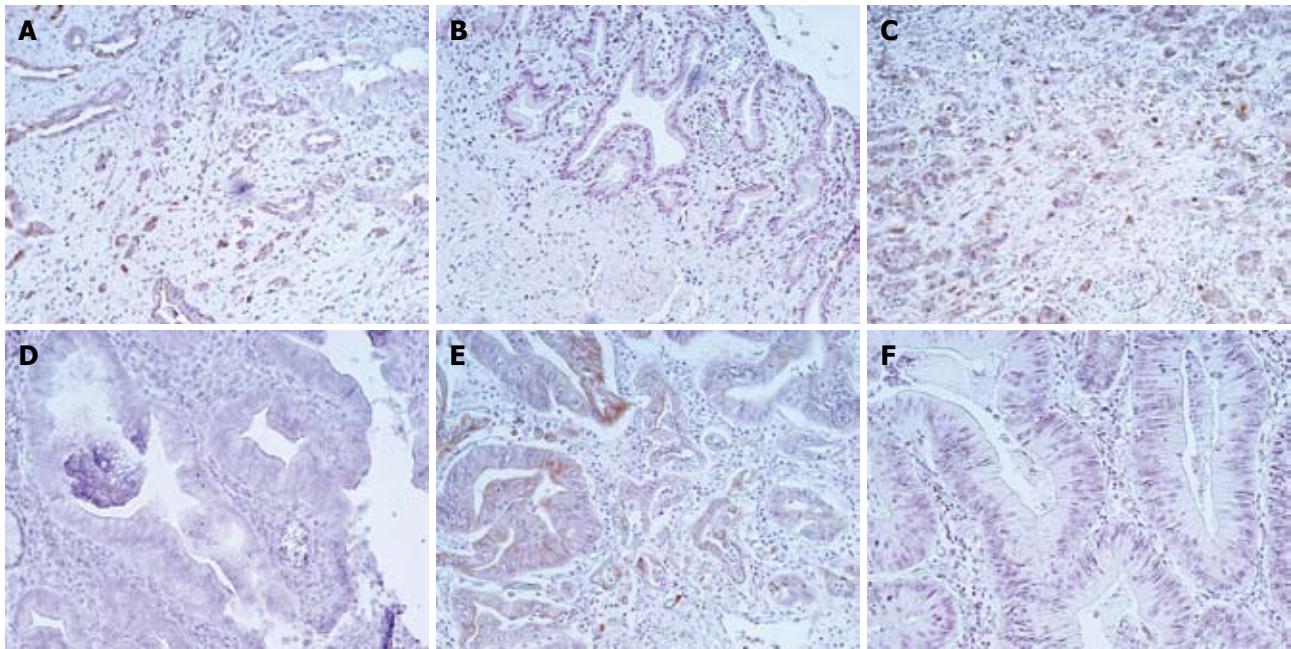

The relationship between LN $\gamma$ 2 positivity and clinicopathological characteristics is summarized in Table 1. LN $\gamma$ 2 positivity was significantly correlated with histologic type (less differentiated type), depth of invasion

**Figure 2 LN $\gamma$ 2 expression in biliary tract cancer tissues.** A, B: Extrahepatic bile duct cancer tissues; A: Moderately differentiated tubular adenocarcinoma positive for staining. Note that LN $\gamma$ 2 is strongly positive in tumor cells at the invasive front; B: Papillary adenocarcinoma negative for staining; C, D: Gallbladder cancer tissues; C: Moderately differentiated tubular adenocarcinoma positive for staining; D: Well differentiated tubular adenocarcinoma negative for staining; E, F: Carcinoma tissues of the ampulla of Vater; E: Moderately differentiated tubular adenocarcinoma positive for staining. Note that LN $\gamma$ 2 is strongly positive in tumor cells at the invasive front; F: Well differentiated tubular adenocarcinoma negative for staining.

**Figure 3 LN $\beta$ 3 expression in biliary tract cancer tissues.** A-C: Extrahepatic bile duct cancer tissues; A: Well differentiated tubular adenocarcinoma positive for invasive front dominant staining; B: Papillary adenocarcinoma positive for diffuse staining; C: Moderately differentiated tubular adenocarcinoma negative for staining; D-F: Gallbladder cancer tissues; D: Moderately differentiated tubular adenocarcinoma positive for invasive front dominant staining; E: Papillary adenocarcinoma positive for diffuse staining; G-I: Carcinoma tissues of the ampulla of Vater; G: Well differentiated tubular adenocarcinoma positive for invasive front dominant staining; H: Well differentiated tubular adenocarcinoma positive for diffuse staining; I: Well differentiated tubular adenocarcinoma negative for staining.

**Figure 4 MMP7 expression in biliary tract cancer tissues.** A, B: Extrahepatic bile duct cancer tissues; A: Moderately differentiated tubular adenocarcinoma positive for staining. Note that MMP7 is strongly positive in tumor cells at the invasive front; B: Papillary adenocarcinoma negative for staining; C, D: Gallbladder cancer tissues; C: Moderately differentiated tubular adenocarcinoma positive for staining; D: Well differentiated tubular adenocarcinoma negative for staining; E, F: Carcinoma tissues of the ampulla of Vater; E: Moderately differentiated tubular adenocarcinoma positive for staining. Note that MMP7 is strongly positive in tumor cells at the invasive front; F: Well differentiated tubular adenocarcinoma negative for staining.

(invasion into serosa), and advanced stage. The relationship between LN $\beta$ 3 positivity and clinicopathological characteristics is summarized in Table 2. LN $\beta$ 3 invasive front dominant pattern was significantly correlated with histologic type (less differentiated type) and advanced stage. There was a tendency that lymph node metastasis was more frequently observed in cases with LN $\beta$ 3 invasive front dominant pattern than in other cases ( $P = 0.063$ ). The relationship between MMP7 positivity and clinicopathological characteristics is summarized in Table 3. MMP7 positivity was not significantly correlated with clinicopathological characteristics. The expression of LN $\gamma$ 2, LN $\beta$ 3 invasive front dominant pattern, and MMP7 were correlated with each other (Tables 4–6).

#### MMP7 activity detected by zymography

Using casein zymography, the levels of secreted matrilysin were analyzed (Figure 5). Nontumorous tissues secreted neither latent (28 kDa) nor activated (19 kDa) MMP7 activity. Latent and activated forms of MMP7 were detected in 16 (80%) and 12 (60%) of 20 carcinoma tissues, respectively. The activity was eliminated by the addition of the metalloproteinase inhibitor EDTA (data not shown). The activated form but not the latent form was correlated with depth of invasion and advanced stage.

#### Suppression of cancer cell invasiveness by MMP7

##### siRNA treatment

*In vitro* invasion assays after treatment with specific siRNA for the MMP7 gene were carried out to assess the direct role of the expression of MMP7 in cancer

## DISCUSSION

In the current study, LN $\gamma$ 2 positivity in carcinoma cells at the invasive front was immunohistochemically observed in 57% of patients with biliary tract cancer, and was associated with histologic type (less differentiated type), depth of invasion, and advanced stage. LN $\beta$ 3 invasive front dominant pattern was immunohistochemically observed in 38% of patients with biliary tract cancer, and was associated with histologic type (less differentiated type) and advanced stage. These results suggest that LN $\gamma$ 2 and LN $\beta$ 3 expression in carcinoma cells at the invasive front contributes to the more aggressive phenotype of carcinoma cells, resulting in the progression of biliary tract cancer.

Preferential expression of LN $\gamma$ 2 and LN $\beta$ 3 in carcinoma cells at the invasive front and its correlation with tumor progression suggest that these molecules play a role in the acquisition of a migrating and invading epithelial cell phenotype that is a prerequisite for malignancy<sup>[13]</sup>. Also in metastatic HCC, LN5 was mainly distributed along the tumoral advancing edge<sup>[9]</sup>. The mechanism underlying the preferential distribution of LN $\gamma$ 2 and LN $\beta$ 3 at the invasive front in cancer is not known. It is known that activation of cancer-related genes in carcinoma cells affects their associated stromal cells. Certain stromal cell populations lying close to carcinoma cells may be induced to assist the invasion process by signals sent out by the cancer cells, stimulating the synthesis of gene products that facilitate cancer cell invasion and migration<sup>[35]</sup>. Interactions of carcinoma cells with stromal cells or with the surrounding extracellular matrix at the invasive front may result in an accumulation of LN $\gamma$ 2 and LN $\beta$ 3 at the invasive front, where they may play a direct role in tumor invasion processes<sup>[19]</sup>.

Although there are only a few reports regarding LN $\beta$ 3 expression in human cancer, coexpression of LN $\gamma$ 2 and LN $\beta$ 3 has been reported in HCC, squamous cell carcinoma of the tongue, colorectal carcinoma and basal cell carcinoma of the skin<sup>[9,25,26]</sup>. Sordat *et al*<sup>[14]</sup> reported that the heterodimer of the LN $\gamma$ 2 and LN $\beta$ 3 chains is accumulated in the cytoplasm of dissociating (or budding) tumor cells from neoplastic tubules of colon carcinomas. Since LN $\gamma$ 2 and LN $\beta$ 3 were not always coexpressed in biliary tract cancer, further analysis is necessary to elucidate the mechanism of overexpression and localization of LN $\gamma$ 2 and LN $\beta$ 3 in biliary tract cancer. LN5 reportedly plays an important role in epithelial-mesenchymal transition through downregulation of E-cadherin and translocation of  $\beta$ -catenin

**Figure 6** *In vitro* invasion assay with or without TIMP1 (250 ng/mL) in TFK-1 and siRNA transflectants. Each column indicates the means of three experiments; <sup>b</sup>*P* < 0.01.

into the nuclei<sup>[8]</sup>. It will be interesting to address this issue in biliary tract cancer in the near future.

In contrast to preferential expression of MMP7 in carcinoma cells at the invasive front in various carcinomas, the expression pattern of MMP7 was diffuse in biliary tract cancer. The mechanism underlying the differential distribution of MMP7 in carcinomas needs to be further analyzed. MMP7 positivity was not significantly correlated with clinicopathological characteristics. However, the expression of LN $\gamma$ 2, LN $\beta$ 3 invasive front dominant pattern, and MMP7 were correlated with each other. It has been suggested that the controlled up-regulation of gene products is one of the characteristics of invading cancer cells and that these gene products have functions crucial for the invasive phenotype of cancer cells<sup>[13]</sup>. It is notable that limited proteolysis of LN $\beta$ 3 by MMP7 increases the cell motility activity of LN5 in colon carcinoma cells<sup>[27]</sup>.

The activated form but not the latent form of MMP7 was correlated with depth of invasion and advanced stage, suggesting that active MMP7 plays an important role in the progression of biliary tract cancer. The implication of up-regulation of MMP7 expression in tumor progression was further substantiated by the *in vitro* invasion analysis. We revealed that down-regulation of MMP7 expression by siRNA resulted in a significant decrease in biliary tract cancer cell invasion *in vitro*, suggesting that up-regulation of MMP7 contributes to the more invasive phenotype of biliary tract cancer cells. Taken together, our results suggest that LN $\gamma$ 2 and LN $\beta$ 3, in conjunction with MMP7, play a key role in the progression of biliary tract cancer.

## COMMENTS

### Background

Biliary tract cancers are relatively rare human malignancies involving the gallbladder and/or the bile ducts, but the prognosis is poor. Understanding the molecular biological features of biliary tract cancer progression is necessary for improving the prognosis. The potential role of laminin-5 (LN5) and MMP7 in human cancer is receiving increasing attention.

### Research frontiers

Altered expression patterns of LN5, especially the LN $\gamma$ 2 chain, and MMP7 have been correlated with tumor behavior, such as invasiveness, vascularization, metastatic potential, and patients' poor prognosis. However, expression of LN5

and MMP7 in biliary tract cancer has not been clearly addressed. In this study, the authors demonstrate that LN $\gamma$ 2, LN $\beta$ 3, and active MMP7 play a key role in the progression of biliary tract cancer.

### Innovations and breakthroughs

This is the first study to report that invasive front dominant expression of LN $\gamma$ 2 and LN $\beta$ 3, and active MMP7 play a key role in the progression of biliary tract cancer. Furthermore, our *in vitro* studies suggest that MMP7 plays an important role in biliary tract cancer cell invasion.

### Applications

Detection of LN $\gamma$ 2, LN $\beta$ 3, and active MMP7 could be molecular markers for tumor aggressiveness in biliary tract cancer. Understanding how LN $\gamma$ 2, LN $\beta$ 3, and active MMP7 are induced and how their expression is blocked may represent a future strategy for therapeutic intervention in the treatment of patients with biliary tract cancer.

### Terminology

**Laminin:** A heterotrimeric glycoprotein composed of three different polypeptide chains ( $\alpha$ ,  $\beta$  and  $\gamma$ ), is a component of the extracellular matrix (ECM) that contributes to the architecture of the basal lamina surrounding the epithelial cells and mediates cell adhesion, growth, migration, proliferation, and differentiation. **LN-5/LN-332:** LN5, consists of  $\alpha$ 3,  $\beta$ 3 and  $\gamma$ 2 chains, and is involved in cell adhesion, migration, and scattering. Altered expression of LN-5 plays an important role in cancer. **MMP7:** Degradation of ECM components is mostly controlled by proteolytic enzymes called MMP. MMP7, also known as matrylsin, is a minimal domain MMP that exhibits broad proteolytic activity against components of the ECM and non-ECM.

### Peer review

This paper reports the expression of LN-5 chains and MMP-7 in biliary cancer. The authors showed that LN $\gamma$ 2 and LN $\beta$ 3, in conjunction with MMP7, play a key role in the progression of biliary cancer. The study sounds interesting and confirms the role of LN-5 and MMP7 in human cancer.

p27 expression was enhanced following 15d-PGJ<sub>2</sub> treatment in a dose-dependent manner in MGC803 cells. Interestingly, we also found that small interfering RNA for PPAR- $\gamma$  inhibited growth and induced apoptosis in MGC803 cells. The inhibition of PPAR- $\gamma$  function may be a potentially important and novel modality for treatment and prevention of gastric carcinoma.

**CONCLUSION:** A PPAR- $\gamma$  agonist inhibited growth of human gastric carcinoma MGC803 cells by inducing apoptosis and G<sub>1</sub>/G<sub>0</sub> cell cycle arrest with the involvement of survivin, Skp2 and p27 and not via PPAR- $\gamma$ .

## Abstract

**AIM:** To investigate whether peroxisome proliferator-activated receptor  $\gamma$  (PPAR- $\gamma$ ) is expressed in human gastric carcinoma and whether PPAR- $\gamma$  is a potential target for gastric carcinoma therapy.

**METHODS:** PPAR- $\gamma$  protein in gastric carcinoma was examined by immunohistochemistry. In the gastric carcinoma cell line MGC803, PPAR- $\gamma$ , survivin, Skp2 and p27 protein and mRNA were examined by Western blotting and real-time reverse transcription-polymerase chain reaction, respectively; proliferation was examined by MTT; apoptosis was examined by chromatin staining with Hoechst 33342 and fluorescence activated cell sorting (FACS); and cell cycle was examined by FACS; the knockdown of PPAR- $\gamma$  was done by RNA interference.

**RESULTS:** A high level of expression of PPAR- $\gamma$  was observed in human gastric carcinoma and in a human gastric carcinoma cell line MGC803. The PPAR- $\gamma$  agonist 15-deoxy- $\Delta$ 12,14-prostaglandin J<sub>2</sub> (15d-PGJ<sub>2</sub>) inhibited growth, and induced apoptosis and G<sub>1</sub>/G<sub>0</sub> cell cycle arrest in MGC803 cells in a concentration-dependent and time-dependent manner. The effect of 15d-PGJ<sub>2</sub> on MGC803 cells was not reversed by the selective and irreversible antagonist GW9662 for PPAR- $\gamma$ . Furthermore, survivin and Skp2 expression were decreased, whereas

## INTRODUCTION

Gastric carcinoma is the second most common cancer in the world and kills more than 600 000 people annually<sup>[1]</sup>. At present, the management of gastric carcinoma mainly includes surgery and chemotherapy, but the curative effect of the existing chemotherapeutic drugs is not effective and they have numerous side effects. Many studies have been performed to search for therapeutic targets and drugs capable of preventing and treating gastric carcinoma and other malignancies.

Peroxisome proliferator-activated receptors (PPARs) are nuclear hormone receptors, initially described as molecular targets for compounds, which induce peroxisomal proliferation<sup>[2]</sup>. Up to now, 3 different isotypes of PPARs have been identified in various species, being the products of distinct genes and generally designated as PPAR- $\alpha$ , PPAR- $\beta/\delta$ , and PPAR- $\gamma$ <sup>[2,3]</sup>. PPAR- $\gamma$  has been extensively studied. Similarly to other

members of the nuclear receptor gene family, PPAR- $\gamma$  is an agonist-activated transcription factor<sup>[3,4]</sup>. PPAR- $\gamma$  heterodimerizes with retinoid X receptor to bind to the PPAR response element, leading to the transcription of downstream genes<sup>[5]</sup>. Several specific agonists have been found, such as the thiazolidinediones (including pioglitazone, rosiglitazone, and troglitazone), 15-deoxy- $\Delta$ 12,14-prostaglandin-J<sub>2</sub> (15d-PGJ<sub>2</sub>), and certain polyunsaturated fatty acids. GW9662 has been shown to be a selective and irreversible antagonist of PPAR- $\gamma$ , and irreversibly binds within the agonist binding domain through covalent modification of a cysteine residue<sup>[6]</sup>.

PPAR- $\gamma$  is predominately expressed in adipose tissue and plays a central role in adipocyte differentiation and insulin sensitivity<sup>[7]</sup>. Recent studies have shown that, in addition to its classic role, PPAR- $\gamma$  is implicated as a putative therapeutic target for cancer in a variety of tumors as several observations suggest that stimulation of PPAR- $\gamma$  function may inhibit carcinogenesis and tumor cell growth<sup>[8,9]</sup>. However, the exact role of PPAR- $\gamma$  on carcinogenesis and tumor cell growth is still unclear<sup>[10-14]</sup>. Recent investigations by Morita *et al*<sup>[15]</sup> and Konturek *et al*<sup>[16]</sup> have shown that PPAR- $\gamma$  is implicated in *Helicobacter pylori*-related gastric carcinogenesis, and that PPAR- $\gamma$  agonists may have potential in a cancer therapeutic role.

We here demonstrate that PPAR- $\gamma$  may be involved in gastric carcinogenesis, and that the inhibition of PPAR- $\gamma$  may be of benefit in the treatment of gastric carcinoma.

## MATERIALS AND METHODS

### Chemicals

PPAR- $\gamma$  agonist, 15d-PGJ<sub>2</sub> and antagonist GW9662 were purchased from Cayman chemical (Ann Arbor, M1). Other drugs were reagent grade.

### Tissue samples

One hundred and thirty eight samples of surgically-resected primary gastric carcinoma tissues, 138 samples of paired adjacent mucosa (2-5 cm from the margin of the gastric carcinoma) and 138 samples of paired normal mucosa (histologically proven) at the surgical margin (at least 5 cm from the margin of the gastric carcinoma) tissues were obtained from the First Affiliated Hospital of Inner Mongolia Medical College in China from October 2004 to January 2005. All gastric carcinoma patients underwent total or subtotal gastrectomy, and no patient received any treatment for cancer before surgery. The patient series included 111 males and 27 females with a mean age of 58.5 years and a median age of 60 years (range, 36-78). After surgery, the gastric specimens were fixed in 10% neutral buffered formalin and embedded in paraffin for immunohistochemistry. The clinical stage of all gastric carcinoma specimens were determined according to new TNM criteria published by the Union International Centre Cancer in 1997. All pathological diagnoses were performed by 2 independent pathologists.

### Immunohistochemical staining of PPAR- $\gamma$

Sections of paraffin-embedded tissues (4  $\mu$ m) were

mounted on glass slides. The intracellular expression of PPAR- $\gamma$  was detected using a PPAR- $\gamma$  specific mAb (sc-7372, E-8, Santa Cruz Biotechnology, CA) with standard non-biotin horseradish peroxidase (HRP) 2-step immunostaining (Zymed) according to the manufacturer's instructions. The immunoreactive products were visualized using 3,3'-diaminobenzidine (DAB)/H<sub>2</sub>O<sub>2</sub>.

### Cell culture and treatment with PPAR- $\gamma$ agonists and antagonists

We used the human gastric carcinoma cell line MGC803 from Beijing Tumor Institute. It was maintained in RPMI1640 containing 10% fetal bovine serum (FBS) at 37°C under 5% CO<sub>2</sub>. A PPAR- $\gamma$  agonist or antagonist were added at the time of replating.

### Cell survival assay

Gastric carcinoma cells were treated with a PPAR- $\gamma$  agonist or antagonist dissolved in DMSO for 8, 18 and 24 h in culture medium in 96-well plates. MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide, Sigma] solution was then added to the well with gentle pipetting. After 4 h, the supernatant was removed after centrifugation at 1000 r/min for 5 min at room temperature, and 180  $\mu$ L DMSO was added to each well to solubilize the crystal products by shaking for 10 min. Absorbance at 570 nm was measured with an ELISA reader. The negative control had medium without serum and cells, and was used as the zero point of absorbance. Cell vitality of the control group was 100%. The inhibitory rate (IR) of cells was calculated according to the equation as follows: IR (%) = [1 - ( $A_{570}$  nm absorbance in 15d-PGJ<sub>2</sub> treated group/ $A_{570}$  nm absorbance in control group)]  $\times$  100%. Each assay was performed in triplicate.

### Apoptosis analysis

Apoptosis was analyzed by 2 different methods. First, chromatin staining with Hoechst 33342 was carried out. Briefly, MGC803 cells treated with 15d-PGJ<sub>2</sub> were cultured on Laboratory-Tek Chamber Slides for 24 h. The cells were then fixed with methanol for 10 min and rinsed. Chromatin staining was done with Hoechst 33342 (Sigma) to detect nuclear condensation. Secondly, cell apoptosis was measured by fluorescence activated cell sorting (FACS) using the Annexin-V FITC Apoptosis Detection Kit according to the manufacturer's protocol. The apoptotic rate was calculated as the percentage of annexin V-positive and propidium iodide (PI)-negative cells divided by the total number of cells in the gated region. The data was pooled from 3 independent experiments.

### Cell cycle examination

The effect of 15d-PGJ<sub>2</sub> on the cell cycle was examined with PI staining by FACS using Epics-XL (Beckman Coulter).

### Western blotting analysis

Cell total protein was extracted from MGC803 cells using

CytoBuster™ Protein Extraction Reagent (Novagen). The concentration of the protein was determined with Coomassie brilliant blue G-250. Cell total protein (50 µg) was separated by 12% SDS-PAGE. After electrophoresis, the proteins were transferred to a polyvinylidene fluoride membrane, blocked overnight in Tris buffered saline with 10% skim milk at 4°C. PPAR- $\gamma$  (Santa Cruz), Skp2 (Zymed), p27 (Santa Cruz) and  $\beta$ -actin (Santa Cruz) were detected using primary mouse mAb, and survivin (Santa Cruz) was detected using primary rabbit polyclonal Ab at a dilution of 1:2000, followed by HRP-conjugated anti-mouse IgG or anti-rabbit IgG at a dilution of 1:1500. Immunocomplexes were visualized using DAB.  $\beta$ -actin was used as the internal control.

#### **Reverse transcription-polymerase chain reaction (RT-PCR)**

Total RNA was extracted from MGC803 cells using TRIzol reagent (Gibco, USA). The resultant RNA samples were quantified using a spectrophotometer at a wavelength of 260 nm. The integrity of the isolated RNA samples was analyzed electrophoretically on agarose gel, followed by staining in ethidium bromide. An aliquot of 2 µg of total RNA from each sample was reversely transcribed and amplified using RT-PCR Enzyme Mix Kit (Sino-American Biotechnology Co.). For detection of human PPAR- $\gamma$  mRNA, a combination of a sense primer (5'-TCTCTCCGTAATGGAAGACC-3') and an antisense primer (5'-GCATTATGAGACATCCCCAC-3') were used. The reverse transcription was performed for 1 h at 37°C and amplification was done by initial denaturation at 95°C for 2 min, 40 cycles of amplification (95°C for 40 s, 55°C for 50 s, and 72°C for 50 s) and a final extension step of 7 min at 72°C was carried out in a 30 µL mixture containing 2 µg of total RNA, 25 pmol/L each of the sense and antisense primers, 2.0 mmol/L MgCl<sub>2</sub>, 0.1 mmol/L dNTP, 1.5 µL 20 × buffer without Mg<sup>2+</sup>, 2 µL RT-PCR Enzyme Mix and double-distilled H<sub>2</sub>O.  $\beta$ -actin sense primer, 5'-ATCTGGCACACACCTTC TACAATGAGCTGCG-3', and antisense primer 5'-CGTCATACTCCTGCTGCTGATCCACATCTGC -3' were used. The reverse transcription was done for 1 h at 37°C and amplification was performed by initial denaturation at 94°C for 5 min, 35 cycles of amplification (95°C for 15 s, 60°C for 1 min, and 72°C for 30 s) and a final extension step of 7 min at 72°C was carried out in a 30 µL mixture containing the same components as above. The length of the  $\beta$ -actin PCR product was 838 bp and was the internal control. The PCR reaction products were separated electrophoretically in a 2% agarose gel and stained with ethidium bromide for 40 min at 80 V, and observed and photographed. All primers were synthesized by Shanghai Sangon Biological Engineering Technology and Service Co., Ltd.

#### **Construction of small interfering RNA (siRNA) expression vectors**

To further elucidate the effect of PPAR- $\gamma$  in gastric carcinoma, we applied the siRNA targeting approach. We used shRNA™ vector (provided by Wuhan Genesil

Biotechnology Co., Ltd.) in which shRNA expression is driven by the U6 RNA promoter to produce small and hair RNA transcripts. We generated 3 different shRNA™ vectors and an empty vector used as a control. The oligonucleotides 5'-GATCCGAACAGAT CCAGTGGTTGCTTCAAGA-CGGCAACCACT G G A T C T G - T T C T T T T T G T C G A C A - 3', 3'-GCTTGTCTAGGTACCAACGAAGTTCTGC CGTTGGTGACCTAGACAAGAAAAACAG CTGTTCGA-5' were used to generate anti-heparanase shRNA™ pSi1, and oligonucleotides 5'-GATCCGTAAA-GTGGAGCCTGCATCTTC AAGACGGATGCAGGCTCCACTTGATTTT TGTCGACA-3', 3'-GCAGTTCACCTCGGACGTAG AAGTTCTGCCTACGTCCGAGGTGAAACTAAAA AACAGCTGTTCGA-5' were used to generate anti-heparanase shRNA™ pSi2. Oligonucleotides 5'-GATCCG-ACAAACCTGCTACAAGCCCTCAAGAC GGG-GCTTGTAGCAGGTTGTCTTTTGT CGACA-3', 3'-GCTGTTGACGATGTTCG GGAAGTTCTGCCCGAACATCGTCCAACAGAA AAAACAGCTGTTCGA-5' were used to generate anti-heparanase shRNA™ pSi3.

#### **Transfection**

For the transfection, pSi1, pSi2 and pSi3 (1.0 µg) were added to RPMI1640 medium (without FBS) containing cation liposome vector (2.0 µL) and allowed to incubate for 20 min at room temperature to produce the transfection mixture. The transfection mixture was then added to the cells ( $1 \times 10^5$  per dish) in the serum-free medium. Six hours after the start of transfection, the medium was changed to RPMI1640 medium containing 10% FBS. RNA interference effect was examined by RT-PCR, Western blotting and MTT assay. Cell apoptosis determination was carried out at the final step.

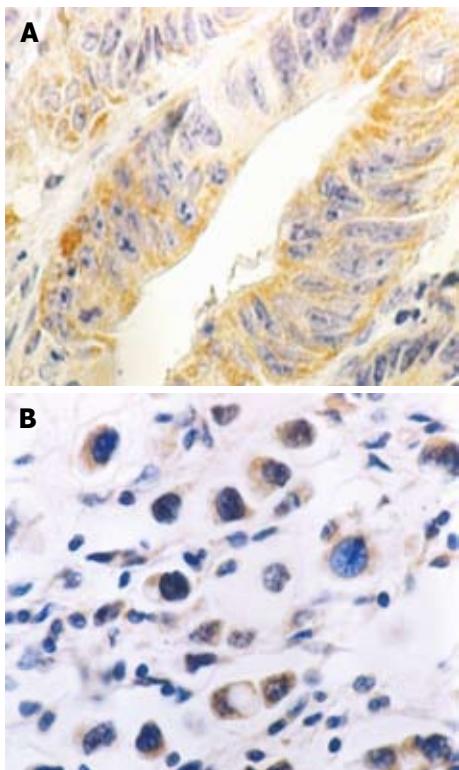

#### **Statistical analysis**

The results were expressed as mean  $\pm$  SD. Statistical analysis was performed using the Student's *t*-test,  $\chi^2$  test or one-way ANOVA and subsequent Fisher's LSD test.  $P < 0.05$  was considered statistically significant. Statistical analysis was performed using SPSS11.0 software.

## **RESULTS**

#### **Enhanced PPAR- $\gamma$ expression in gastric carcinoma tissue and MGC803 cells**

The positive rate of PPAR- $\gamma$  protein expression was significantly higher in gastric carcinoma (75.0%) than in paired mucosa adjacent to gastric carcinoma (27.5%) and in normal gastric mucosa at the surgical margin of gastric carcinoma (13.0%) ( $P < 0.001$ ). Mucosa adjacent to gastric carcinoma had significantly higher expression than normal gastric mucosa at the surgical margin of gastric carcinoma ( $P < 0.05$  and  $P < 0.001$ ) (Figure 1). The rate of PPAR- $\gamma$  protein expression was positively associated with histologic type and negatively associated with invasive depth, vessel invasion, lymph node metastasis, distant metastasis and clinical stage

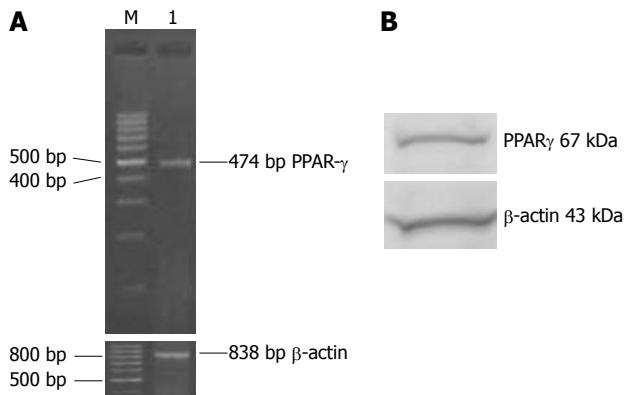

**Figure 1** Peroxisome proliferator-activated receptor- $\gamma$  (PPAR- $\gamma$ ) protein in the cytoplasm of gastric carcinoma cells by immunohistochemistry (3,3'-diaminobenzidine and hematoxylin staining  $\times 400$ ). A: Well differentiated gastric carcinoma; B: Poorly differentiated gastric carcinoma.

**Table 1** Correlation of PPAR $\gamma$  protein expression in gastric carcinoma with clinicopathological features

Clinicopathological features	<i>n</i>	PPAR $\gamma$ protein		$\chi^2$	<i>P</i>
		+	-		
Histologic subtype	138			24.663	0.000
Intestinal type	63	60	3		
Diffuse type	75	44	31		
Depth of invasion	138			1.183	0.277
Serosal	24	16	8		
Out of serosa	114	88	26

Lymph node metastasis	138			0.309	0.578
Absent	36	28	8		
Present	102	76	28		
Distant metastasis	138			0.535	0.464
Absent	126	96	30		
Present	12	8	4		
Clinical stage <sup>1</sup>	126			0.017	0.897
I - II	39	30	9		
III-IV	87	61	26		

<sup>1</sup>Because clinical staging could not be performed because of the lack of accurate records about lymph nodes, data of 12 cases were not included in the statistical analysis.

( $P < 0.05$ ) of gastric carcinoma. The rate of PPAR- $\gamma$  protein expression was significantly higher in intestinal-type gastric carcinoma (95.2%) than in diffuse-type gastric carcinoma (58.7%) ( $P < 0.001$ ) (Table 1). Both PPAR- $\gamma$  mRNA and protein showed positivity in the human gastric carcinoma cell line MGC803 (Figure 2).

**Figure 2** PPAR- $\gamma$  mRNA and protein expression in gastric carcinoma cell line MGC803. A: PPAR $\gamma$  mRNA expression examined in MGC803 cells by reverse transcriptase-polymerase chain reaction. M: 100 bp DNA marker and 500 bp was the brightest; 1: MGC803 cells. #### Effect of 15d-PGJ<sub>2</sub>, GW9662 and 15d-PGJ<sub>2</sub> + GW9662 on growth of MGC803 cells

Treatment with a concentration of 0.01, 0.1 and 1  $\mu\text{mol/L}$  15d-PGJ<sub>2</sub> did not affect MGC803 cell growth. The inhibition of proliferation of MGC803 cells by 5, 10, 20, 30, and 40  $\mu\text{mol/L}$  15d-PGJ<sub>2</sub> was significantly higher than that of 0  $\mu\text{mol/L}$  ( $P < 0.001$ ) (Table 2). Correspondingly, inhibition was also enhanced with increasing 15d-PGJ<sub>2</sub> concentrations. Inhibition was  $5.98\% \pm 1.41\%$ ,  $13.64\% \pm 0.69\%$ , and  $34.64\% \pm 0.99\%$  after 8, 18, and 24 h, respectively, following 30  $\mu\text{mol/L}$  15d-PGJ<sub>2</sub> addition. It was significantly higher at 18 h than 8 h ( $P < 0.001$ ), and it was significantly higher at 24 h than 18 h ( $P < 0.001$ ); it was enhanced over a prolonged time. Thus 15d-PGJ<sub>2</sub> inhibited proliferation of MGC803 cells in a concentration-dependent and time-dependent manner (Figure 3A). The proliferation inhibition rate of MGC803 cells by GW9662 treatment for 24 h, showed no difference between 0.01, 0.1 and 1  $\mu\text{mol/L}$  and 0  $\mu\text{mol/L}$  concentrations (all  $P > 0.05$ ). Inhibition of proliferation was significantly higher at 2.5 and 5  $\mu\text{mol/L}$  compared to 0  $\mu\text{mol/L}$  (all  $P > 0.05$ ). The proliferation inhibition rate of MGC803 cells by 15d-PGJ<sub>2</sub> and GW9662 combination treatment for 24 h showed no difference between the 0.01, 0.1 and 1  $\mu\text{mol/L}$  GW9662 and 5, 10, 20, 30 and 40  $\mu\text{mol/L}$  15d-PGJ<sub>2</sub> combination groups and the 5, 10, 20, 30 and 40  $\mu\text{mol/L}$  15d-PGJ<sub>2</sub> group (Table 3).

#### Effect of 15d-PGJ<sub>2</sub> on apoptosis of MGC803 cells

15d-PGJ<sub>2</sub> is capable of inducing MGC803 cell apoptosis as seen by morphological observation (Figure 4) and flow cytometry (Figure 5). The apoptosis rate of MGC803 cells of 5, 10, 20, 30, and 40  $\mu\text{mol/L}$  15d-PGJ<sub>2</sub> was significantly higher than that of 0  $\mu\text{mol/L}$  ( $P < 0.001$ ) (Table 1); it was enhanced with increasing concentrations of 15d-PGJ<sub>2</sub>. The apoptosis rate was  $6.58\% \pm 0.62\%$ ,  $15.99\% \pm 1.73\%$ , and  $38.23\% \pm 1.36\%$  at 8, 18 and 24 h, respectively, following 30  $\mu\text{mol/L}$  15d-PGJ<sub>2</sub> addition, and increased with time. Thus, 15d-PGJ<sub>2</sub> induced

**Table 2** Effect of various concentrations of 15-deoxy- $\Delta$ 12,14-prostaglandin-J2 (15d-PGJ<sub>2</sub>) on proliferation, apoptosis and cell cycle of gastric carcinoma MGC803 cells after 24 h [(mean  $\pm$  SD) %]

MGC803 cell apoptosis in a concentration-dependent and time-dependent manner (Figure 3B).

#### Effect of 15d-PGJ<sub>2</sub> on cell cycle of MGC803 cells

15d-PGJ<sub>2</sub> at 30  $\mu$ mol/L significantly increased the proportion of MGC803 cells in the G<sub>0</sub>/G<sub>1</sub> phase ( $P < 0.001$ ) and significantly decreased the proportion in the S and G<sub>2</sub>/M phases ( $P < 0.001$  and  $P < 0.01$ , respectively) (Figure 6).

#### Effect of 15d-PGJ<sub>2</sub> on survivin, Skp2 and p27 expression in MGC803 cells

Survivin and Skp2 protein were decreased and p27 protein was increased as the concentration of 15d-PGJ<sub>2</sub> increased as shown by Western blotting (Figure 7).

#### Effect of knockdown of PPAR- $\gamma$ by RNAi

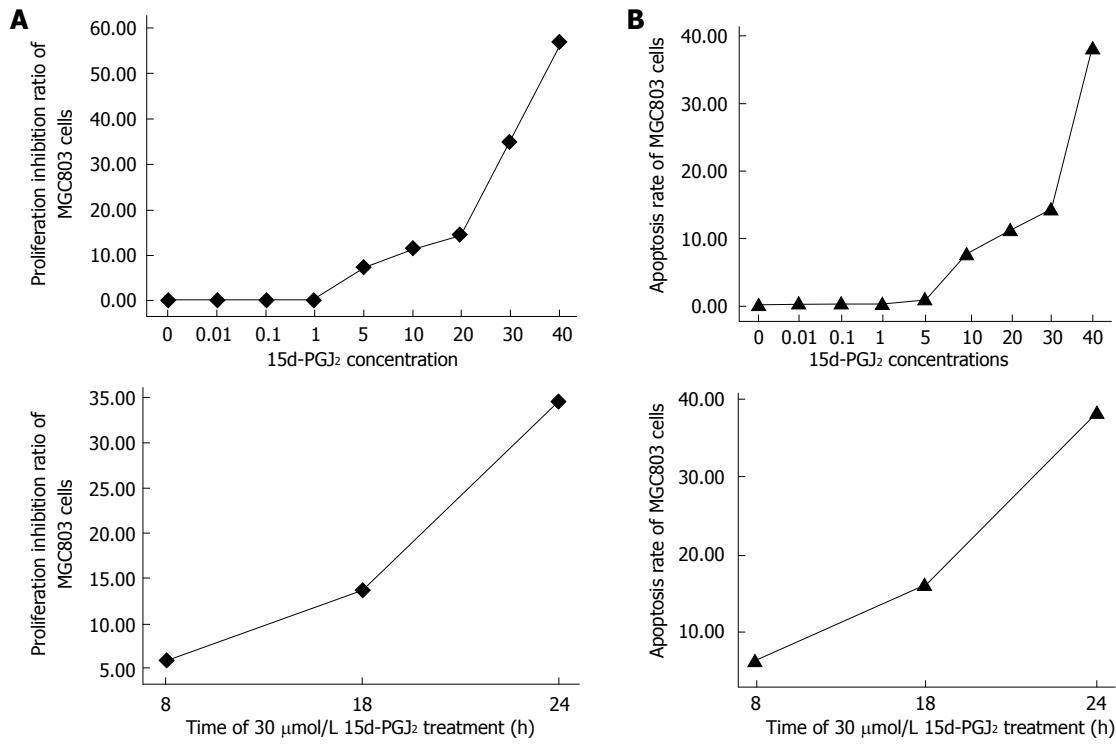

To examine whether the inhibitory effect of PPAR- $\gamma$  agonist 15d-PGJ<sub>2</sub> on the growth of MGC803 cells was via a PPAR- $\gamma$  specific pathway and influenced PPAR- $\gamma$  expression in the tumor cells, we used the RNAi approach for PPAR- $\gamma$ . Efficiency of transfection approximate 80% was evaluated by fluorescence microscopy 48 h after transfection of a vector containing the gene encoding green fluorescent protein (Figure 8). MGC803 cells were transiently transfected with pSi1, pSi2 and pSi3 or empty vectors by cation liposome vector, and the cells were tested for PPAR- $\gamma$  expression 48 h later. Of the cells transfected with pSi1, pSi2 and pSi3, pSi1 was most effective in silencing PPAR- $\gamma$  mRNA and

protein expression in MGC803 cells, as determined by semiquantitative RT-PCR (Figure 9A) and Western blotting (Figure 9B). PPAR- $\gamma$  specific RNAi effectively decreased PPAR- $\gamma$  mRNA and protein level in the MGC803 cells and showed inhibition of cell growth (Figure 10A) and induction of cell apoptosis (Figure 10B).

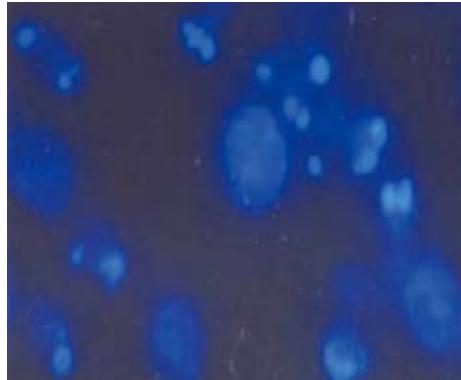

## DISCUSSION

Recently, the potential of PPAR- $\gamma$  as a target for the prevention and treatment of cancer has been widely studied<sup>[17]</sup>. However, the potential therapeutic role of PPAR- $\gamma$  agonists has been questioned, based on contradictory results. In experiments using animal models of colon cancer, PPAR- $\gamma$  agonists increased the development of colon tumors<sup>[10]</sup>. This contradictory result was supplemented by a recent report using transgenic mice that expressed a constitutive active form of PPAR- $\gamma$  in mammary glands, and showed that PPAR- $\gamma$  signaling accelerated tumor development in mammary glands<sup>[18]</sup>. The actual role of PPAR- $\gamma$  in cancer has been complicated by recent findings that PPAR- $\gamma$  agonists affect cancer cells independent of PPAR- $\gamma$ <sup>[19-22]</sup>, and silencing of PPAR- $\gamma$  and PPAR- $\gamma$  antagonists have been shown to inhibit cancer cell growth<sup>[13,14]</sup>. To date, the role of PPAR- $\gamma$  in gastric carcinogenesis remains unclear.

In the present study, PPAR- $\gamma$  was found to be expressed at higher levels in gastric carcinoma than in paired mucosa adjacent to gastric carcinoma, and in both tissues the PPAR- $\gamma$  levels were higher than in their

**Figure 3** 15d-PGJ<sub>2</sub> inhibited proliferation (A) and induced apoptosis (B) of MGC803 cells in a concentration-dependent and time-dependent manner.

**Figure 4** Morphological changes of MGC803 cells 24 h after treatment with 30  $\mu\text{mol/L}$  15d-PGJ<sub>2</sub>. Cell shapes were observed by fluorescence microscopy (Hoechst 33342 staining,  $\times 400$ ). Nuclear chromatin condensation, marginalization of nuclear chromatin and half moon formation, nuclear fragments with bright chromatin and apoptotic bodies were easily identified in some cells.

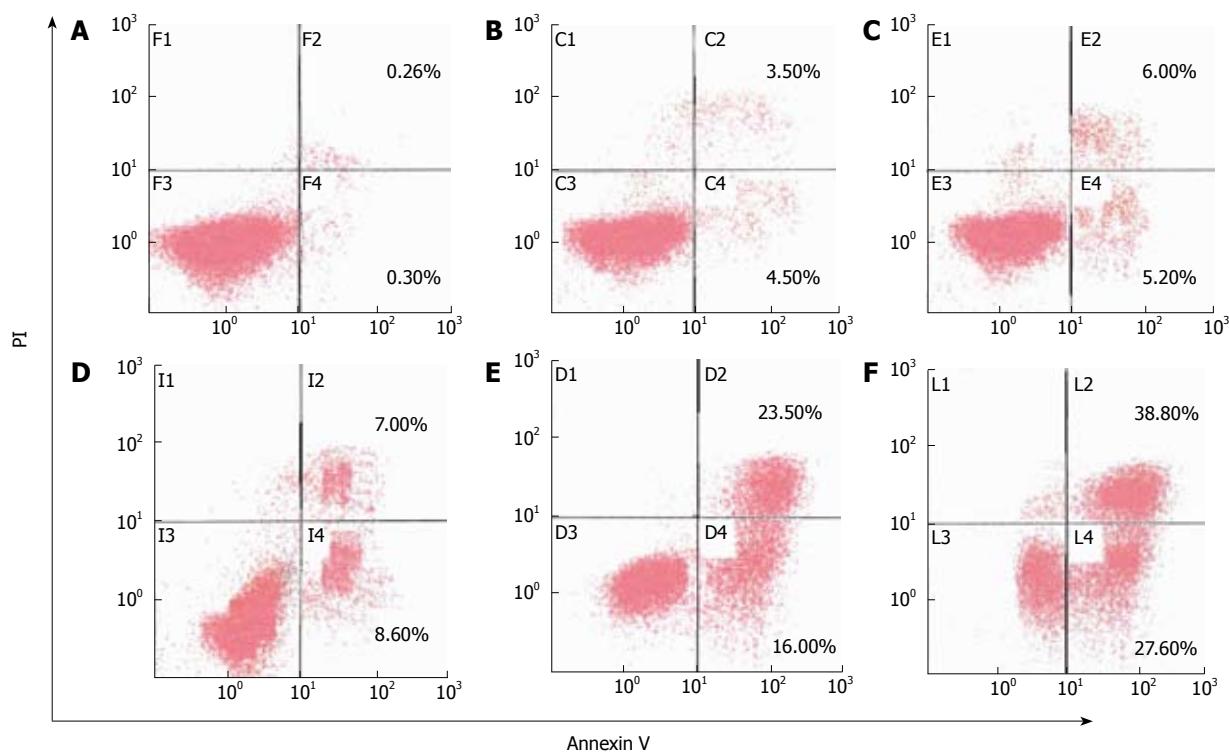

paired normal gastric mucosa at the surgical margin of the gastric carcinoma. Similar effects were also observed in gastric cancer in another study<sup>[16]</sup>. In addition, we used the siRNA approach to confirm the effect of PPAR- $\gamma$  on gastric carcinoma. The result showed that silencing PPAR- $\gamma$  clearly inhibited the growth and induced apoptosis of MGC803 cells. Similar effects were also observed in other cancers such as hepatocellular carcinoma<sup>[13]</sup>. These results indicated that PPAR- $\gamma$  may be involved in gastric carcinogenesis.

Here, we clearly showed that the PPAR- $\gamma$  agonist 15d-PGJ<sub>2</sub> inhibited growth of cultured gastric cancer MGC803 cells, and our study also demonstrated that the PPAR- $\gamma$  antagonist GW9662 did not interfere with this effect and that 2.5  $\mu\text{mol/L}$  GW9662 inhibited growth of

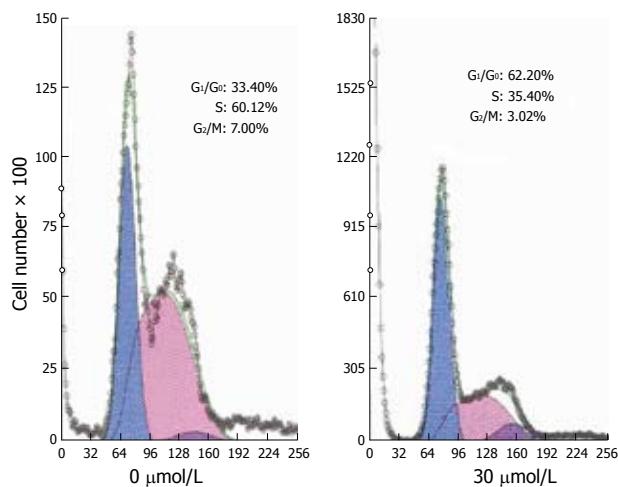

MGC803 cells. Furthermore, PPAR- $\gamma$  siRNA markedly inhibited the growth of MGC803 cells in our study. These results indicated that 15d-PGJ<sub>2</sub> inhibited growth of cultured gastric carcinoma MGC803 cells by a PPAR- $\gamma$ -independent pathway. These results also suggested that PPAR agonists may be useful in the chemoprevention or chemotherapy of gastric malignancies. Additionally, some recent studies reported that the biological effect of PPAR- $\gamma$  agonists is independent of PPAR- $\gamma$ <sup>[19,23-28]</sup>, but other research concluded that 15d-PGJ<sub>2</sub> inhibited growth of cancer cells and gastric cancer cells by activating the PPAR- $\gamma$  pathway<sup>[29-32]</sup>. What is the reason for the discrepancies between our data and the data found in other reports? This may be attributed to the fact that some investigators did not study the effect of PPAR antagonists on tumor cell growth and on the effect of PPAR agonists, as they only used PPAR agonists.

The inhibition of growth of cultured gastric cancer MGC803 cells by PPAR- $\gamma$  agonists is mainly a result of apoptosis, as evidenced by the data for nuclear condensation by chromatin staining with Hoechst 33342 and annexin V-FITC staining through FACS analysis. Mechanisms may exist by which apoptosis is induced by PPAR agonists. Furthermore, the inhibition of cell growth and induction of apoptosis by PPAR- $\gamma$  agonists were time- and concentration-dependent.

Survivin is an inhibitor of apoptosis, and is expressed during embryonal development but lacks expression in terminally differentiated adult tissues. Interestingly, it becomes re-expressed in transformed cell lines and in a variety of human tumors, and deserves growing attention as “an ideal target” for cancer therapy. Survivin is involved in the control of apoptosis and directly inhibits caspase 3 and 7 activities. Survivin is mostly

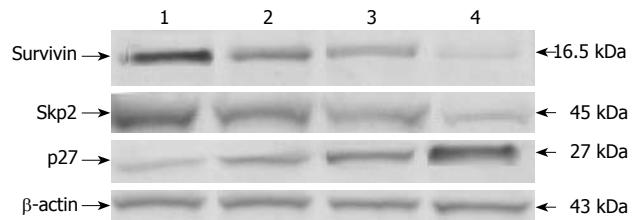

**Figure 5 Apoptosis rate of MGC803 cells detected by flow cytometry 24 h after treatment with 15d-PGJ<sub>2</sub> at various concentrations. A: 0 μmol/L; B: 5 μmol/L; C: 10 μmol/L; D: 20 μmol/L; E: 30 μmol/L; F: 40 μmol/L.**

**Figure 6 Cell cycle distribution of MGC803 cells by flow cytometry 24 h after treatment with 15d-PGJ<sub>2</sub> at various concentrations.** 15d-PGJ<sub>2</sub> at 30 μmol/L could significantly increase the proportion of cells in the G<sub>0</sub>/G<sub>1</sub> phase ( $P < 0.001$ ) and decrease the proportion in the S and G<sub>2</sub>/M phases in MGC803 cells ( $P < 0.001$  and  $P < 0.01$ ).

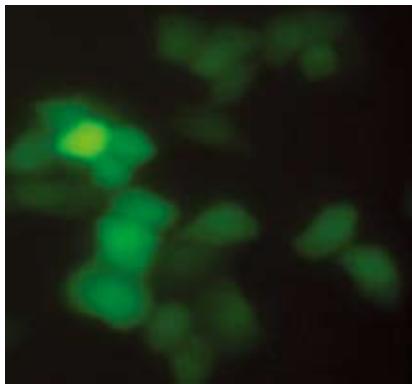

expressed in cell cycle G<sub>2</sub>/M and lacks expression in G<sub>1</sub>/G<sub>0</sub><sup>[33]</sup>. During tumorigenesis, survivin expression is negatively correlated with apoptosis but positively correlated with proliferation and angiogenesis<sup>[34]</sup>. Our study showed that the levels of survivin protein were decreased with the increase in 15d-PGJ<sub>2</sub> concentration, and were inversely associated with the apoptosis induced by 15d-PGJ<sub>2</sub>. These data suggest that 15d-PGJ<sub>2</sub> may inhibit survivin expression to induce apoptosis in gastric carcinoma MGC803 cells.

Our study showed, by flow cytometry, that 15d-PGJ<sub>2</sub>

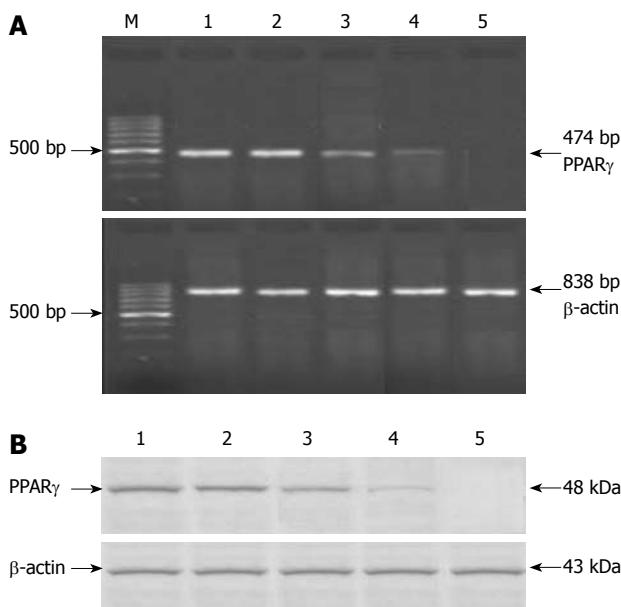

**Figure 7 Survivin, Skp2 and p27 protein expression by Western blotting in MGC803 cells 24 h after treatment with 15d-PGJ<sub>2</sub> at various concentrations.** Lane 1: 0 μmol/L; Lane 2: 5 μmol/L; Lane 3: 20 μmol/L; Lane 4: 30 μmol/L. Survivin and Skp2 protein decreased and p27 protein increased with increasing concentrations of 15d-PGJ<sub>2</sub>.

induced MGC803 cell arrest in the G<sub>1</sub>/G<sub>0</sub> cell cycle phase and reduced the percentage of cells in the S and G<sub>2</sub>/M cell cycle phases. This may be another reason for inhibition of the growth of gastric carcinoma MGC803 cells by 15d-PGJ<sub>2</sub>. Additionally, this may be in part the reason that 15d-PGJ<sub>2</sub> reduced the level of survivin, although we cannot exclude the possibility that 15d-PGJ<sub>2</sub> may have a direct effect on survivin expression. In eukaryotes, progression of the cell cycle is controlled by interactions between cell cycle control proteins (cyclins) and their catalytically active cyclin-dependent kinases (CDKs). The activity of each cyclin-CDK complex is in turn regulated by several different mechanisms, the most important being negative regulation by CDK inhibitors<sup>[35]</sup>. p27 is an inhibitor of cyclin E-CDK2 and cyclin A-CDK2, which drive cells from the G<sub>1</sub> phase to the S phase of the cell division cycle<sup>[36,37]</sup>, and p27 is expressed at its highest level in the G<sub>1</sub>/G<sub>0</sub> phase. The amount of p27 is mainly regulated by posttranslational

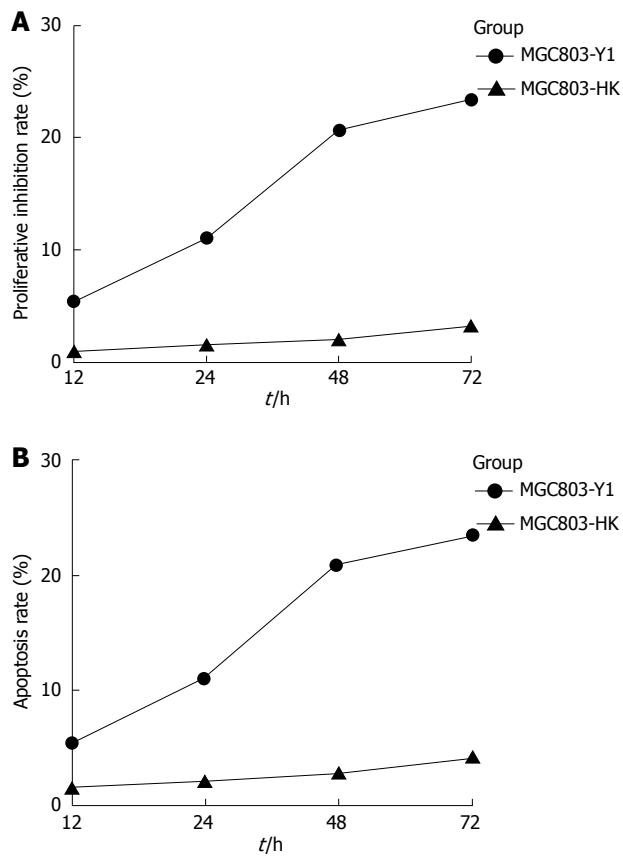

**Figure 8** Human gastric carcinoma MGC803 cells observed by fluorescence microscopy 48 h after pSi1 transfection.

**Figure 9** PPAR $\gamma$  after pSi transfection. A: PPAR $\gamma$  mRNA expression in various cells detected by RT-PCR 48 h after transfection; B: PPAR $\gamma$  protein expression in various cells 48 h after transfection as detected by Western blotting. Lane M: 100 bp DNA marker, 500 bp was the brightest; Lane 1: MGC803-N (normal MGC803 cells); Lane 2: MGC803-HK (MGC803 cells transfected by empty vector); Lane 3: MGC803-pSi3 (MGC803 cells transfected by pSi3 vector); Lane 4: MGC803-pSi2 (MGC803 cells transfected by pSi2 vector); Lane 5: MGC803-pSi1 (MGC803 cells transfected by pSi1 vector). The effect of pSi1 was best in silencing PPAR $\gamma$  mRNA and protein expression in MGC803 cells.

ubiquitin-proteasome-mediated proteolysis<sup>[38]</sup>. The cell cycle-dependent degradation of p27 is dependent on phosphorylation at Thr<sup>187</sup> in the late G<sub>1</sub> phase by CDK2, and Thr<sup>187</sup> phosphorylation is a necessary prerequisite for the sequential addition of ubiquitin molecules by a ubiquitin ligase complex, SCF<sup>Skp2</sup>, composed of Skp1, Cull, Rbx1, and the F-box protein Skp2<sup>[37]</sup>. Polyubiquitination of p27 then targets p27 for degradation in the proteasome, thus removing the p27 cell cycle “brake”, allowing cells to transition from G<sub>1</sub> to the S phase<sup>[39]</sup>. Some investigations have shown that Skp2 is a specific substrate-recognition subunit of SCF<sup>Skp2</sup>, the expression of Skp2 is required for the ubiquitination and subsequent degradation of p27 *in vitro* and *in vivo*<sup>[40-42]</sup>, and Skp2 knockout cells exhibit p27 at high levels<sup>[43]</sup>.

**Figure 10** Proliferative inhibition and apoptosis rate of MGC803-Y1 and of MGC803-HK cells after transfection. The proliferative inhibition (A) and apoptosis (B) rate of MGC803-Y1 cells was higher than that of MGC803-HK cells at 12-72 h after transfection.

Skp2 levels are cell cycle regulated, and Skp2 accumulates during the S phase. Inappropriate expression of Skp2 in G<sub>0</sub> cells can promote S phase entry concomitant with loss of p27. Recently, the targeted disruption of Skp2 resulted in an accumulation of p27, and cell cycle arrest in the G<sub>1</sub> cycle. The level of Skp2 protein was decreased, whereas the level of p27 protein was increased with increasing concentration of 15d-PGJ<sub>2</sub> treatment when examined by Western blotting. These data suggested that 15d-PGJ<sub>2</sub> induced MGC803 cell arrest in G<sub>1</sub>/G<sub>0</sub> by Down-regulating Skp2 expression and upregulating p27 expression. Furthermore, these results suggested that 15d-PGJ<sub>2</sub> may interfere with ubiquitin-proteasome-mediated proteolysis in gastric carcinoma cells.

In conclusion, our study suggests that PPAR- $\gamma$  may be involved in gastric carcinogenesis, and that 15d-PGJ<sub>2</sub> may inhibit the growth of human gastric carcinoma MGC803 cells by inducing apoptosis and G<sub>1</sub>/G<sub>0</sub> arrest, with the involvement of survivin, Skp2 and p27, but *via* a PPAR- $\gamma$ -independent pathway.

## COMMENTS

### Background

Many efforts have been made to search for therapeutic targets and drugs capable of preventing and treating gastric carcinoma and other malignancies. Peroxisome proliferator-activated receptors (PPARs) are nuclear hormone receptors, initially described as molecular targets for compounds, which induce peroxisomal proliferation.

## Research frontiers

Three different isotypes of PPARs have been identified in various species, being the products of distinct genes and generally designated as PPAR- $\alpha$ , PPAR- $\beta/\delta$ , and PPAR- $\gamma$ . PPAR- $\gamma$  is one that has been extensively studied. As with other members of the nuclear receptor gene family, PPAR- $\gamma$  is an agonist-activated transcription factor. PPAR- $\gamma$  heterodimerizes with retinoid X receptor to bind to the PPAR response element, leading to the transcription of downstream genes.

## Innovations and breakthroughs

Several specific agonists have been found, such as the thiazolidinediones (including pioglitazone, rosiglitazone, and troglitazone), 15-deoxy- $\Delta$ 12,14-prostaglandin-J<sub>2</sub> (15d-PGJ<sub>2</sub>), and certain polyunsaturated fatty acids. GW9662 has been shown to be a selective and irreversible antagonist of PPAR- $\gamma$ , and irreversibly binds within the agonist binding domain through covalent modification of a cysteine residue.

## Applications

By understanding how PPAR- $\gamma$  affects the growth of cells, this study may represent a future strategy for therapeutic intervention in the treatment of patients with gastric carcinoma.

## Terminology

PPAR- $\gamma$  receptors are nuclear hormone receptors, which induce peroxisomal proliferation. 15d-PGJ<sub>2</sub> is a specific agonist. Peroxisomal proliferation is thought to be crucial in gastric carcinoma.

## Peer review

PPAR- $\gamma$  receptors are nuclear hormone receptors. The authors examined whether PPAR- $\gamma$  may affect gastric carcinogenesis, and 15d-PGJ<sub>2</sub> may inhibit the growth of MGC803 cells by inducing apoptosis and G<sub>1</sub>/G<sub>0</sub> arrest, but through a PPAR- $\gamma$ -independent pathway. The result may be useful in treatment of gastric carcinoma.

### Abstract

**AIM:** To analyze the correlation between CD14 rs2569190/C-159T single nucleotide polymorphism (SNP) and disease progression in chronic hepatitis C.

**METHODS:** Liver biopsy specimens from a total of 137 and 349 patients with chronic hepatitis C were separately evaluated with respect to necroinflammatory activity (grading) and architectural changes (staging). In one group, further histological lesions characteristic for hepatitis C, hepatitis C virus subtypes, and biochemical parameters of liver disease were also investigated. Samples of genomic DNA were genotyped for the respective SNP by 5'-nuclease assays using fluorescent dye-labeled allele-specific probes.

**RESULTS:** Genotype distribution did not deviate from the Hardy-Weinberg equilibrium. In the first group, patients homozygous for the variant allele T were found to be younger than C allele carriers ( $39.6 \pm 12.5$  vs  $45.7 \pm 11.5$ ,  $P = 0.008$ ). Among the histological lesions studied, portal lymphoid aggregates were more frequently observed among TT homozygotes than among C carriers ( $21/37$  vs  $32/100$ ,  $P = 0.008$ ). The presence of portal lymphoid aggregates was closely correlated with hepatic inflammation ( $P = 0.003$ ) and with bile duct damage ( $P < 0.001$ ). The degree of fibrosis, in contrast, was not found to be related to the **CD14** gene C-159T polymorphism.

**CONCLUSION:** The data suggest a possible relationship between CD14 C-159T polymorphism and the formation of portal lymphoid aggregates, but not liver fibrosis progression in chronic hepatitis C.

### INTRODUCTION

Hepatitis C virus (HCV), which currently infects about 3% of the world's population (an estimated 210 million people), is a major cause of chronic viral liver disease<sup>[1]</sup>. Chronic hepatitis C is characterized by mostly mild hepatic inflammatory activity which does, however, hold a significant risk of proceeding to liver cirrhosis and hepatocellular carcinoma<sup>[2]</sup>. Further characteristic histological alterations may include steatosis, bile duct lesions, and portal lymphoid aggregates<sup>[3-5]</sup>. While steatosis, for instance, has been shown to be associated with HCV subtype infection and is suggested to be modulated by HCV proteins<sup>[4,6]</sup>, progression of fibrosis in chronic hepatitis C has been attributed to age, gender, or alcohol consumption<sup>[7]</sup>, and to host genetic factors<sup>[8]</sup>. Different genetic backgrounds have also been found to be associated with the susceptibility to HCV subtype infection<sup>[9,10]</sup>.

As a result of its anatomic links to the gut, the liver is constantly exposed to gut-derived bacterial products, e.g. lipopolysaccharides (LPS), which are suggested to be important cofactors in toxin- or ethanol-induced liver disease by exacerbating ongoing injury<sup>[11]</sup>. Endotoxemia arises from increased translocation of endotoxins from the gut lumen because of altered intestinal permeability and decreased hepatic clearance capacity<sup>[12]</sup>.

Hepatocytes and Kupffer cells, the resident liver macrophages which play a major role in the clearance of systemic bacterial infection, express the membrane-associated form of the endotoxin receptor CD14 (mCD14) at low levels in comparison to peripheral blood monocytes (reviewed by Schwabe *et al.*<sup>[12]</sup>). Moreover, sinusoidal endothelial cells and activated hepatic stellate cells, the main fibrogenic cell type in the injured liver, also express mCD14<sup>[12,13]</sup>. mCD14 is anchored by glycoprophosphatidyl inositol, being part of a cell surface receptor complex which additionally contains the dimerized Toll-like receptor 4 and MD-2 (reviewed by Pålsson-McDermott & O'Neill<sup>[14]</sup>). Furthermore, it also localizes with TLR3, the double-stranded RNA (dsRNA) receptor, in intracellular compartments enhancing dsRNA sensing and TLR3 signalling<sup>[15,16]</sup>. In addition to the membranous form, a soluble form of CD14 lacking the glycoprophosphatidyl inositol anchor is thought to modulate LPS responses *via* local stimulatory (promoting) and systemic anti-inflammatory (competing) mechanisms<sup>[17]</sup>.

Recently, a single nucleotide polymorphism (SNP) within the *CD14* gene, rs2569190/C-159T, has been demonstrated to be associated with the risk of developing liver cirrhosis, but not steatosis or less advanced stages of fibrosis, in patients with alcohol-induced liver disease (ALD)<sup>[18-20]</sup>. These results were attributed to the finding that, *in vitro*, the T allele is more actively transcribed than the C allele<sup>[21]</sup>, leading consequently to the assumption that the TT carriers' hepatic cells may be prone to enhanced inflammatory reactions after endotoxin exposure. The relationship between rs2569190 TT genotype and liver disease progression, however, was not observed in a study by von Hahn and colleagues, in which the variant allele T was alternatively shown to be solely associated with cryptogenic chronic liver disease<sup>[22]</sup>.

The current study aimed to investigate, in two different cohorts, whether the variant position rs2569190/C-159T within the *CD14* gene is associated with hepatitis C liver disease manifestations, and allowed replicated analysis as is demanded for genetic association studies<sup>[23]</sup>.

## MATERIALS AND METHODS

### Ethics

The study was approved by the local ethical committee and conformed to the ethical guidelines of the 2000 Declaration of Helsinki. Patients gave their informed consent.

### Patients

A total of 137 mainly Caucasian chronic hepatitis C patients (mean age  $44.0 \pm 12.0$  years, median 42 years) who consulted the Liver Unit of the Department of Gastroenterology and Endocrinology at the University Medical Center Goettingen (UMG), Germany, between 1993 and 2006 were enrolled. The chronic nature of infection was proven by detection of HCV-specific antibodies and HCV RNA in the patients' sera using a highly sensitive nested reverse transcription polymerase chain reaction (RT-PCR) over a period of at least 6 mo as described<sup>[24]</sup>.

As part of routine clinical evaluation, liver biopsy procedures were performed and liver disease was confirmed in the course of a defined histological evaluation as described below. Biochemical liver disease parameters, i.e. serum activities of alanine aminotransferase (ALT), aspartate aminotransferase (AST), and  $\gamma$ -glutamyl transferase ( $\gamma$ -GT) were recorded in parallel. Patients with concomitant non-hepatitis C viral infections and those with continued alcohol or other drug abuse were excluded.

Samples and data from another 349 chronic hepatitis C patients (mean age  $45.8 \pm 13.5$  years, median 45 years) were kindly provided by the German Network of Competence for Hepatitis (Hep-Net)<sup>[25]</sup>.

### Determination of HCV genotype

HCV genotyping was performed for the 137 patients (UMG group) using the Innolipa HCV II line probe assay (Innogenetics, Ghent, Belgium).

### Histological evaluation

Before the start of therapy, liver biopsies were taken from patients for histological evaluation. In brief, sections (5–10  $\mu\text{m}$ ) from formalin-fixed and paraffin-embedded liver biopsies were stained with hematoxylin-eosin, trichrome, and Prussian blue. According to Desmet and colleagues, necroinflammatory activity (grading, score 1 to 3), and structural alterations (staging, score 0 to 4) were scored separately<sup>[26]</sup>. Other lesions typical of hepatitis C such as degree of steatosis (score 0 to 3), the presence or absence of portal lymphoid aggregates, and the presence or absence of bile duct damage were studied additionally as previously described<sup>[14]</sup>. Hep-Net samples were independently scored by two experienced pathologists according to the German guidelines with regard to inflammation activity and fibrosis progression<sup>[25,26]</sup>.

### Isolation of genomic DNA

Genomic DNA (gDNA) was purified from peripheral blood mononuclear cells (PBMCs) using the QIAamp DNA Mini Kit following the blood and body fluid spin protocol (Qiagen, Hilden, Germany). The concentration and the purity of the DNA isolated from PBMCs were determined spectrophotometrically by reading the absorbance levels at 260 and 280 nm. The integrity of gDNA was ascertained through electrophoresis using a 0.6% agarose gel. Alternatively, when PBMCs were not available, gDNA was purified from a 2 mL sample of serum by means of the QIAamp DNA Blood Midi Kit (Qiagen, Hilden, Germany) following the manufacturer's instructions.

### SNP genotyping by 5'nuclease assay

gDNA (10 ng derived from PBMCs or an aliquot corresponding to 12.5  $\mu\text{L}$  serum) was amplified in a total volume of 20  $\mu\text{L}$  by real-time PCR using the TaqMan<sup>®</sup> Universal Master Mix (Applied Biosystems, Darmstadt, Germany) and 36  $\mu\text{mol/L}$  of primers each (*CD14*: forward 5'-CTAGATGCCCTGCAGAATCCTT-3', reverse 5'-CCCTTCCTTGAAATATTGCA-3'). Allelic discrimination was achieved by adding 8  $\mu\text{mol/L}$  differentially fluorescence dye-labeled allele-specific minor

groove binder probes (CD14: VIC 5'-CCTGTTACGG TCCCCCTG-3', FAM 5'-CTGTTACGGCCCCCT-3'). Reactions and analyses were carried out in the sequence detection system ABI prism 7000 (Applied Biosystems, Darmstadt, Germany) according to the supplier's instructions.

### Statistical analysis

Quantitative parameters were described by mean and standard deviation or median and inter-quartile range, and the Kolmogorov-Smirnov test was applied to investigate whether these distributions were Gaussian. The UMG group and Hep-Net group were compared regarding age using the parametric independent samples *t*-test.

For describing the ordinal and nominal scaled parameters such as gender, HCV subtype, hepatitis activity, fibrosis, steatosis, portal lymphatic aggregates, and bile duct damage, absolute frequencies and percentages were determined.  $\chi^2$  tests were applied to investigate the association of these parameters with the genotype or minor allele frequency (MAF).

To avoid bias, data were also stratified by age (< 44 years, and ≥ 44 years), and parameters which showed significant correlations to the genotype in the univariate analysis were also analyzed using multivariate logistic regression. The results of stratifying and logistic regression were noted in the text and/or the tables where necessary.

All tests were performed two-sided and the level of significance was set at 0.05. The test results were interpreted in an exploratory way because no alpha adjustment for multiple testing was carried out. Statistical analyses were performed with the assistance of Medistat GmbH, Kiel, Germany, using PASW 17 for Windows (SPSS Inc., Chicago, IL).

## RESULTS

### Epidemiological characteristics

A total of 137 and 349 patients with chronic hepatitis C (UMG and Hep-Net groups, respectively) were genotyped for the bi-allelic SNP within the *CD14* gene,

rs2569190/C-159T. The variant allele T in the first group was found to be about as frequent as the wild-type C allele leading to a CC:CT:TT genotype distribution of 30:70:37 and a T allele frequency of 0.526 (Table 1). Hep-Net patients followed a distribution of 109:170:70 leading to a lower MAF of 0.444 (Table 2). MAFs were close to that given for Caucasians in public databases. The genotype distribution in both groups followed the Hardy-Weinberg equilibrium (Tables 1 and 2, respectively).

No significant difference was found between UMG and Hep-Net patients' regarding gender and age ( $\chi^2$  test,  $P = 0.781$ , independent samples *t*-test,  $P = 0.177$ , respectively). Epidemiological analysis revealed no significant relationships between the patients' CD14 rs2569190 genotype and gender (Tables 1 and 2). However, when analyzing patients' age with regard to the studied SNP genotypes, the UMG patients homozygous for the variant allele T were found to be on average 6.1 years younger than C carrier patients (mean age,  $45.7 \pm 11.5$  years) at the time of liver biopsy taken before the start of therapy (Table 1). This observation, however, was absent in Hep-Net patients (Table 2).

Similar to the European population, most UMG patients were infected with HCV subtype 1b, followed by 1a and 3a. No significant difference was found between the distribution of HCV type 1 and non-type 1 infections among the three SNP genotypes (Table 1).

### Biochemical parameters

Before the start of therapy, AST, ALT, and  $\gamma$ -GT serum activities were recorded for UMG patients as indicators of liver injury in chronic hepatitis C. The median levels of AST and ALT showed an increase from the wild-type to the variant type (Table 3). The number of TT patients with markedly elevated serum ALT activities, i.e. greater than two-fold the upper normal limit, was found to be markedly higher than the number of TT patients with normal ALT activities yielding a slightly increased T allele frequency among patients with markedly elevated ALT ( $\chi^2$  test,  $P = 0.044$ ) (Table 3). However, after stratification by age, this was no longer significant (data not shown).

**Table 2** Epidemiological characteristics of chronic hepatitis C patients with regard to CD14 rs2569190 genotype (Hep-Net group)

<sup>1</sup> Number of patients with elevated/normal ALT	11/19	38/32	23/14	0.171 <sup>a</sup>	0.583/0.462
γ-GT (median, IQR)	35.5, 13.8-58.8	27.0, 14.0-56.3	32.0, 15.5-53.5		
<sup>1</sup> Number of patients with elevated/normal γ-GT	10/20	19/51	11/26	0.934 <sup>a</sup>	0.513/0.531

AST: Aspartate aminotransferase. Upper normal limit is 19 U/mL for males, and 15 U/mL for females; ALT: Alanine aminotransferase. Upper normal limit is 23 U/mL for males, and 19 U/mL for females; γ-GT: γ-glutamyltransferase. Upper normal limit is 28 U/mL for males, and 18 U/mL for females; IQR: Inter-quartile range. <sup>1</sup>Markedly elevated serum activities of transaminases (> two-fold the upper normal limit) were considered; <sup>2</sup>χ<sup>2</sup> test was applied; <sup>a</sup>C carriers vs TT. After stratification by age, all P-values were non-significant.

### Hepatitis C disease activity and progression

Liver biopsy specimens were taken before the start of an interferon-based therapy and evaluated histologically. Hep-Net patients had higher frequencies of advanced degrees of hepatitis activity and fibrosis progression (Tables 4 and 5) (χ<sup>2</sup> test, P < 0.001 for both parameters). Both UMG and Hep-Net patients showed no correlation between their CD14 C-159T genotype and hepatitis activity or fibrosis (Tables 4 and 5, respectively). Other lesions typical and more characteristic of hepatitis C, namely the degree of hepatic steatosis, the presence or absence of lymphoid aggregates and bile duct damage, were additionally studied in UMG patients. With regard to the degree of steatosis and bile duct damage, no significant association with CD14 C-159T genotype distribution could be found (Table 4). T allele homozygous patients, however, were found to have portal lymphoid aggregates more frequently than C carriers (21/37 vs 32/100, respectively, χ<sup>2</sup> test, P = 0.008) (Table 4).

To avoid spurious findings, a separate analysis was carried out to identify other factors which might underlie the formation of portal lymphoid aggregates. No relationship was found between the presence or absence of portal lymphoid aggregates and sex, age, HCV subtype, biochemical parameters, the stage of fibrosis, or the degree of steatosis (logistic regression analysis, data not shown). In accordance with previous studies, however, a significant relationship between the presence of portal lymphoid aggregates and hepatic inflammatory activity (χ<sup>2</sup> test, P = 0.003) and bile duct damage (χ<sup>2</sup> test, P < 0.001) was found<sup>[3,5,27]</sup>. Nevertheless, even in the subgroups which had portal lymphoid aggregates with other lesions, a shift towards the T allele was always observed: 15 TT and 13 CT among the 32 patients who

had both a high grade of hepatitis activity and portal lymphoid aggregates: (MAF = 0.672 compared to 0.481 for the remaining patients); 13 TT and 17 CT among the 35 patients who presented with both bile duct damage and portal lymphoid aggregates: (MAF = 0.614 compared to 0.495 for the others) (data not shown).

### DISCUSSION

Among chronic hepatitis C patients, no evidence was found for a relationship between the endotoxin receptor CD14 rs2569190/C-159T genotype and the progression of liver fibrosis. This finding was obtained by analyzing two different patient cohorts, one derived from the UMG (n = 137) (Table 4), the other from the Hep-Net, a Germany-wide collection of samples (n = 349) (Table 5). It is in line with previous findings on Caucasian patients<sup>[20,22]</sup>.

By considering the sum of the evidence, the situation of chronic liver disease resulting from HCV infection appears to be different from the situation of chronic liver disease resulting from alcohol consumption: whereas in ALD, progression of fibrosis was shown to be associated with TT genotypes<sup>[18-20]</sup>, in chronic hepatitis C it did not appear to be related to this genetic variation.

Of note, a recent report found the influence of an environmental factor on the association of rs2569190/C-159T and total serum IgE levels in Russian children<sup>[28]</sup>. Depending on the *Helicobacter pylori* (*H pylori*) infection status, seronegative or seropositive, the T allele was associated with a decreased or an increased IgE serum concentration, respectively<sup>[28]</sup>. The observation of the lack of an association of rs2569190/C-159T genotype with chronic hepatitis C disease progression, but an

association with ALD and the dependency of the association on *H pylori* infection status for an atopy-related parameter, suggests that LPS sensitivity depends on both genetic and environmental factors (gene-environment interaction).

The lack of an association between this CD14 SNP and liver disease progression in chronic hepatitis C patients, is also in accordance with a finding by Huang *et al*<sup>[29]</sup> who, by functional genomic scanning, identified seven SNPs within seven genes which carry the most relevant risk for developing cirrhosis in Caucasian hepatitis C patients, with CD14 not being among them.

In contrast, a significantly higher frequency of rs2569190 T homozygote hepatitis C patients was found among patients with portal lymphoid aggregates (Table 4). As with lymphocyte infiltrations, primary follicles and secondary follicles in the lymph nodes, portal lymphoid aggregates have been described to

occur in various patterns ranging from vague lymphoid aggregation to round defined follicles to well-formed follicles with clearly identifiable germinal centers<sup>[30]</sup>. Their presence has been attributed to the participation of the host's immune system in liver disease pathogenesis<sup>[3,5]</sup>. To our knowledge, even today, the etiology and relevance of this manifestation for disease development and/or progression remains unclear. The presence of portal lymphoid aggregates was the only histological manifestation found to be related to CD14 rs2569190/C-159T genotypes (Table 4). As reported in other studies, the presence of portal lymphoid aggregates was found to be closely correlated with bile duct damage and the degree of inflammatory activity<sup>[3,5,27]</sup>, but not with sex, age<sup>[3,4]</sup>, or HCV subtype<sup>[4]</sup>. The finding of a correlation between portal lymphoid aggregates and HCV subtype 1b infection in Chinese<sup>[3]</sup> but not European patients is obviously related to a different

HCV subtype distribution. The comparison between subtype 1b- and type 2-infected patients, as is possible among Chinese patients, cannot be carried out among European patients because of the low proportion of type 2 infections. Portal lymphoid aggregates have also usually been found in the early stages of liver disease and to have disappeared in cirrhosis<sup>[27,31]</sup>. Thus, our finding of a positive association of TT status and the presence of portal lymphoid aggregates, on the one hand, and the absence of an association with disease progression, on the other hand, are concordant with that observation.

The relationship between TT genotype and younger age in the UMG group (Table 1) was neither observed among the patients from the Hep-Net group (Table 2) nor among patients from another German study<sup>[20]</sup>. In contrast to what might have been expected, these three cohorts do differ in demographic and clinical features. For instance, as outlined, the Hep-Net group comprised a higher proportion of patients with greater degrees of hepatic inflammatory activity and also more advanced stages of fibrosis than the UMG group (Tables 4 and 5). The cohort studied by Meiler *et al*<sup>[20]</sup> was found to differ significantly in age from the Hep-Net group and both in age and gender distribution from the UMG group (data not shown). Von Hahn's cohort was similar to the UMG and Hep-Net groups with regard to gender distribution, however, further demographic analysis, i.e. association of genotypes and age, was not given<sup>[22]</sup>.

In conclusion, in contrast to what was reported for ALD, our analyses did not reveal an increased risk for chronic hepatitis C patients, homozygous for the CD14 C-159T T allele, to develop more pronounced fibrosis but suggested a relationship of this variation in the formation of portal lymphoid aggregates.

## ACKNOWLEDGMENTS

The authors thank all physicians of the Department of Gastroenterology and Endocrinology, UMG, who were involved in the patients' care for their kind cooperation, PD Dr. Stefan Schweyer for his help in histological evaluation of patients' liver biopsies, and Waltraut Kopp for expert technical assistance. Sincere thanks are given to PD Dr. Margarete Odenthal, Institute of Pathology, University of Cologne, for valuable discussions on the manuscript and also to the German Network of Competence for Hepatitis (Hep-Net) for kindly facilitating the use of hepatitis C patients' material and data. Thanks are also given to Ulrike Schulz, Medistat, for professional statistical analyses.

## COMMENTS

### Background

Progressive hepatic fibrosis develops in patients with chronic liver diseases irrespective of etiology and with a marked inter-individual variability. Different host genetic backgrounds have been shown to act as co-factors in promoting ongoing liver disease progression exacerbated by gut-derived bacterial lipopolysaccharides (endotoxins).

### Research frontiers

The variant allele T of a well-known single nucleotide polymorphism (SNP) in

the endotoxin receptor CD14 gene has been reported to be associated with increased alcohol-related liver cirrhosis. In this study, the authors show that the T allele is correlated with the presence of portal lymphoid aggregates rather than being associated with fibrosis progression in chronic hepatitis C virus (HCV) infection.

### Innovations and breakthroughs

Recent reports have shown a lack of an association between the T allele and liver fibrosis progression in the context of chronic HCV infection. Genetic association studies, however, require to be replicated. Apart from performing an analysis in two different cohorts, this study is the first to expand the analysis to further histological lesions typical of HCV infection with regard to CD14 rs2569190/C-159T.

### Applications

Understanding the mechanisms underlying chronic hepatocellular injury in hepatitis C is important for therapy applications. This study argues for a possible relationship of CD14 rs2569190 T allele in the formation of portal lymphoid aggregates, the presence of which has been attributed to the host's immunological participation in liver disease pathogenesis. Moreover, it excludes a possible role of the variation in promoting fibrosis progression.

### Terminology

Liver fibrosis is the excessive accumulation of extracellular matrix proteins including collagen. Cirrhosis is the last stage of fibrosis. A SNP is a variation of one base in the DNA; the nucleotide observed is different from the norm at this position. It occurs with a frequency of > 1% in the normal population. Portal lymphoid aggregates are defined as a densely packed collection of small lymphocytes within the portal tract without or with the formation of a germinal center. Lipopolysaccharide is the main component of the outer cell wall of gram-negative bacteria.

### Peer review

This is a valuable population-based association study, which is useful for examining a well-known genetic variation with a role in a common multifactorial disease that may have a strong environmental component. In contrast to the situation in alcoholic liver cirrhosis, the SNP rs2569190/C-159T is not related to chronic HCV-induced fibrosis progression, but to another histological feature, namely, the presence of portal lymphoid aggregates.

Saccharomyces cerevisiae (gASCA), anti-laminaribioside (ALCA), anti-chitobioside, anti-mannobioside, anti-OMP antibodies and major NOD2/CARD15 mutations. Thirty out of 82 CD patients enrolled at the time of diagnosis were re-evaluated for the same antibodies after longstanding gluten-free diet (GFD).

**RESULTS:** 65.9% of the CD patients were positive for at least one of the tested antibodies at the time of the diagnosis. Except anti-OMP and ALCA, anti-microbial antibodies were exclusively seen in untreated CD; however, the overall sensitivity was low. Any glycan positivity (LR+: 3.13; 95% CI: 2.08-4.73) was associated with an increased likelihood ratio for diagnosing CD. Significant correlation was found between the levels of anti-glycan and anti-endomysial or anti-transglutaminase antibodies. Anti-glycan positivity was lost after longstanding GFD. Anti-glycan antibody titers were associated with symptoms at presentation, but not the presence of NOD2/CARD15 mutations. Patients with severe malabsorption more frequently had multiple antibodies at diagnosis ( $P = 0.019$ ).

**CONCLUSION:** The presence of anti-glycan antibodies in CD seems to be secondary to the impaired small bowel mucosa which can lead to increased antigen presentation. Furthermore, anti-glycan positivity may be considered an additional marker of CD and dietary adherence.

### Abstract

**AIM:** To determine the prevalence of a new set of anti-glycan and anti-outer membrane protein (anti-OMP) antibodies in a Hungarian cohort of adult Celiac disease (CD) patients.

**METHODS:** 190 consecutive CD patients [M/F: 71/119, age: 39.9 (SD: 14.1) years], 100 healthy, and 48 gastrointestinal controls were tested for glycan anti-

## INTRODUCTION

Celiac disease (CD) is a genetically determined chronic inflammatory disorder with autoimmune components induced by exposure to gluten<sup>[1]</sup>. The clinical presentation of the disease is highly variable and little is known about the factors that determine the type of symptoms. The inflamed and damaged small bowel mucosa as well as the clinical symptoms shows recovery in most affected subjects after a complete removal of gluten from their diet<sup>[2]</sup>. The presence of different autoantibodies is a typical feature of CD; however, the exact mechanism behind their production and potential role in the disease pathogenesis has not yet been fully understood<sup>[3]</sup>. Tissue transglutaminase 2 (TG2) is the main autoantigen of anti-endomysial antibodies (EMA) and anti-TG2/EMA are commonly used for screening and diagnosing CD<sup>[4]</sup>. More recently antibodies directed against synthetic deamidated gliadin peptides have also been suggested as a reliable tool for diagnosing CD<sup>[5]</sup>. Most of the other antibodies do not appear to have either high sensitivity or specificity for CD, but they may be associated with specific clinical presentations or extra-intestinal manifestations<sup>[6]</sup>. As a sign of the cytoskeleton and intercellular tight junction involvement, a high prevalence of IgA anti-actin antibodies was also reported which strongly correlated with the degree of villous atrophy, appearing in more severe forms of the disease<sup>[7]</sup>. Furthermore, production of anti-actin antibodies was gluten dependent. After strict adherence to gluten-free diet (GFD), they become undetectable within several months indicating that their appearance follows mucosal injury<sup>[8,9]</sup>. Similarly, also the occurrence of anti-zonulin antibodies was associated with active CD and disappearing during remission<sup>[10]</sup>.

The presence of serological responses to various microbial antigens [e.g. phosphopeptidomannan cell-wall component of anti-Saccharomyces cerevisiae (ASCA), outer membrane porin C transport protein of the *Escherichia coli* (OmpC) or the *Pseudomonas fluorescens* associated protein I2] is characteristic of Crohn's disease and has been intensively studied for its clinical value in this patient group<sup>[11]</sup>. The occurrence and magnitude of the seroreactivity are associated with complicated small bowel disease and the need for surgical intervention<sup>[12,13]</sup>. More recently, antibody formations against different glycans, which are common structures in the glycocalyx of pathogenic yeast and bacteria<sup>[14]</sup>, have also been reported in this patient group. Our group demonstrated that with the use of anti-glycan (g)ASCA and a panel of novel anti-glycan antibodies [anti-mannobioside (AMCA), anti-laminaribioside (ALCA), and anti-chitobioside (ACCA)], gave the same conclusions. Additionally, we evaluated the performance of all four anti-glycan antibodies and the traditional combination of ASCA IgG and IgA. Both panels equally identified 59.4% of all Crohn's disease patients. Eighty percent of these identified cases were the same patients while the remaining 10%-10% were detected by only one of the panels<sup>[15]</sup>.

Despite the fact that the exact mechanism behind antibody formation or their possible relevance in the

pathogenesis still needs to be elucidated, current data suggest that these markers are not an epiphenomenon related to the inflamed, leaky bowel mucosa<sup>[16-18]</sup> but reflect a loss of tolerance toward bacterial and fungal flora<sup>[19]</sup>. Furthermore, the anti-microbial antibodies might represent genetic susceptibility because patients who have positive antibodies often carry mutations in the NOD2/CARD15 gene<sup>[11,20,21]</sup>.

Anti-microbial antibody formation has also been reported in CD. ASCAs remain the most widely investigated antibodies<sup>[22-26]</sup> in this patient group but increasing experimental data are available on newly discovered antibodies such as anti-I2 or anti-OmpW (*Bacteroides caccae* TonB-linked outer membrane protein)<sup>[27,28]</sup>. The frequency of ASCA varied from 27% to 59% in various studies, owing to the differences in the number and the age of the patients as well as the commercial assays used for antibody detection. The frequency of seropositivity and serum levels of these antibodies clearly decreased during GFD.

We hypothesized that newly discovered inflammatory bowel disease (IBD)-associated antibodies (including anti-glycan antibodies and anti-OMP) may also be of importance in CD and aimed to determine the prevalence of these antibodies in a Hungarian cohort of adult CD patients in relation to clinical presentation, GFD and NOD2/CARD15 mutations.

## MATERIALS AND METHODS

### **Patients**

One-hundred and ninety consecutive, unrelated Hungarian adult patients with biopsy-proven CD (male/female: 71/119, mean age: 39.9 years, SD: 14.1) and 66 of their first degree relatives (siblings, mean age: 37.7 years, SD: 13.9) were investigated. The diagnosis of CD was based on small bowel biopsy showing severe villous atrophy with crypt hyperplasia (Marsh type III lesions)<sup>[29]</sup> and elevated serum levels of antibodies against transglutaminase (TGA) and endomysium (EMA). IgA and IgG class EMA were investigated on human umbilical cord substrate using indirect immunofluorescence method as previously described<sup>[30]</sup>. TGA were measured by enzyme-linked immunosorbent assay (ELISA) using human recombinant antigen expressed in *Escherichia coli*<sup>[31,32]</sup>.

Of the 190 patients, 82 patients' sera were obtained at the time of diagnosis (Group CD1) and in 30 of these 82 patients further serum samples were re-evaluated for the same antibodies after adherence to long-standing GFD. The median follow-up period between these blood samplings was 28.5 mo [interquartile range (IQR): 18-52]. In the 108 remaining cases the diagnosis of CD had been established prior to this study and they adopted a strict GFD. These 108 patients were divided into two separate groups according to their current TGA and EMA status and dietary compliance at the time of the sampling. Thirty-three patients still had positive EMA and TGA results (Group CD2) and the median duration was here 3.5 mo (IQR: 1-11). The adequate compliance was indicated by reduced antibody titers as compared to those at diagnosis. The remaining 75 patients had

negative EMA and normal TGA titers (Group CD3), median follow up: 21 mo (IQR: 6-85).

Detailed clinical data concerning the clinical presentation of CD at diagnosis were classified as follows: (1) severe generalized malabsorption (presence of at least four of the following five symptoms: diarrhea, abdominal distension, weight loss, anemia, hypoproteinemia); (2) non-specific gastrointestinal symptoms that did not compromise the general condition (diarrhea, constipation, bloating, recurrent abdominal pain or vomiting, esophageal reflux); (3) iron deficiency anemia without major gastrointestinal complaints; (4) dermatitis herpetiformis; (5) silent disease (population screening); (6) other (autoimmune diseases, reduced bone mineral density, liver disease, brain disease). Patients were assigned to one of these major presentation types in a prospective manner, based on clinical and routine laboratory results at diagnosis.

The control group consisted of 100 healthy, ethnically similar, blood donor individuals (male/female: 47/53, mean age: 36.6 years, SD: 9.1) who had normal findings on a thorough medical examination, blood pressure measurements, and routine laboratory tests. A second non-celiac gastrointestinal disease control group consisted of 48 patients with irritable bowel syndrome/diverticulosis without inflammation (male/female: 21/26, mean age 40.4 years, SD: 16.1). In controls, CD was excluded by the negativity of EMA and TGA. None of the control subjects had a family history of CD. Further comparisons were made with the previously published Crohn's disease cohort we investigated for the same antibodies earlier<sup>[15]</sup>.

The study protocol was approved by the Regional and Institutional Committee of Science and Research Ethics of the University of Debrecen (DEOEC RKEB/IKEB: 2600-2007). Informed consent was obtained from all patients and controls.

#### **Anti-microbial antibody assays**

gASCA IgG, AMCA IgG, ALCA IgG, ACCA IgA (IBDX®, Glycominds Ltd., Lod, Israel), ASCA IgG, ASCA IgA and OMP IgA (QUANTA Lite™ OMP PLUS, INOVA Diagnostics, San Diego, CA) were measured in sera according to the manufacturers' protocols. The results were presented as arbitrary units, which were calculated based on sample and calibrator optical density. Cut-off levels used for the determination of positivity were according to the manufacturers' guidelines: 50, 100, 60 and 90 U/mL for gASCA IgG, AMCA IgG, ALCA IgG, ACCA IgA, respectively, and 25 U/mL for ASCA IgG, ASCA IgA and OMP IgA.

#### **Detection of NOD2/CARD15 mutations**

One-hundred and thirty-four CD patients and 100 healthy control subjects were eligible for NOD2/CARD15 mutation analysis. Major NOD2/CARD15 mutations (SNP8, 12 and 13) were determined as previously described<sup>[13]</sup> by denaturing high-performance liquid chromatography (dHPLC, Wave DNA Fragment Analysis System, Transgenomic Limited, UK). Sequence variation, observed in the dHPLC profile, was sequenced on both

strands to confirm the alteration. Sequencing reactions were performed with the ABI BigDye Terminator Cycle Sequencing Kit v1.1 (Applied Biosystems, Foster City, CA) and samples were sequenced on an ABI Prism 310 Genetic Analyzer (Applied Biosystems, Foster City, CA).

#### **Statistical analysis**

Variables were tested for normality with Shapiro Wilk's  $W$  test.  $t$ -test with separate variance estimates,  $\chi^2$ -test,  $\chi^2$ -test with Yates correction and likelihood ratio (LR) test were calculated to evaluate differences between various groups of CD patients and controls, as well as within subgroups of CD patients, as appropriate. Sensitivities, specificities, positive and negative likelihood ratios were calculated to determine the predictive power of gASCA, AMCA, ALCA, ACCA, OMP or the combination of these markers in distinguishing between CD and controls. Spearman's rank order correlation was calculated to test the association between anti-glycan/OMP and TGA levels. Two-sided  $t$ -test for independent samples with separate variance estimates and ANOVA with post hoc Scheffe test were used to analyze the association between anti-glycan antibody titers and clinical symptoms at diagnosis. A  $P$  value of  $< 0.05$  was considered as significant. For statistical analysis, SPSS15.0 (SPSS Inc, Chicago, IL) was used with the help of a statistician (Dr. Peter Vargha).

## **RESULTS**

#### **Presence of anti-glycan and anti-OMP antibodies at the time of diagnosis of celiac disease**

The frequency and the mean titers of gASCA IgG, AMCA IgG, and ACCA IgA were significantly higher at the time of diagnosis of CD than in healthy and non-celiac gastrointestinal control groups (Table 1, Figure 1). However, the frequency of ALCA IgG and anti-OMP IgA positivity and also the mean titers in the patients were similar to those in control groups. No difference was found between healthy subjects and GI controls based on the presence of these antibodies. For that reason, we only used the healthy subjects as a control group in the subsequent comparisons.

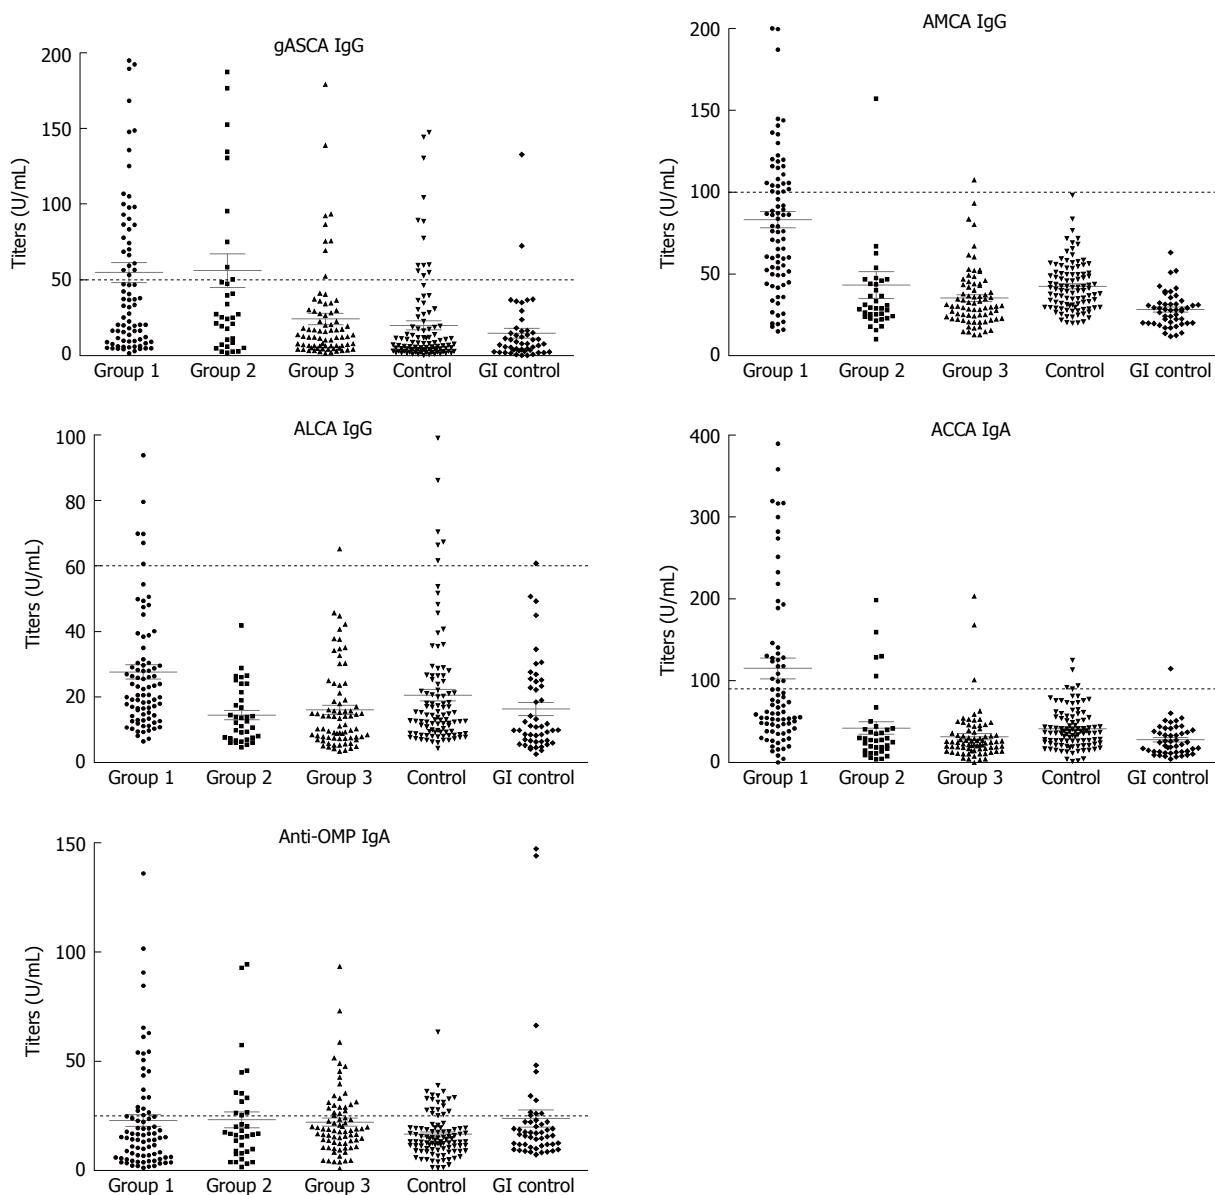

When calculating the sensitivity and specificity of the different markers based on the cut-off values suggested by the manufacturer, 65.9% of the CD patients were positive for at least one of the tested anti-microbial antibodies at the time of diagnosis. Except ALCA, all anti-glycan antibodies were specific for untreated CD. However, the overall sensitivity was low (gASCA: 39.0%, AMCA: 35.4%, ACCA: 37.8%). The above association was further tested by using the LR test. The sensitivity, specificity, positive and negative LR between CD at diagnosis and controls are presented in Table 2. Compared to healthy controls, gASCA, AMCA, and ACCA were associated with a moderate increase in the likelihood of CD, respectively. The positivity of any anti-glycan antibody significantly increased the likelihood for untreated CD (Table 2).

Detailed clinical data on the symptoms at the time

**Table 1 Frequency of anti-microbial antibodies in 190 patients with celiac disease and in control groups n (%)**

	Group 1	Group 2	Group 3	Control	GI control
n	82	33	75	100	48
TGA IgA (U/mL) (median; IQR)	54.3 (20.2-100.0)	32.2 (9.9-73.1)	2.7 (2.2-3.7)	-	-
gASCA IgG positive	32 (39.0) <sup>b,f,j</sup>	12 (36.3) <sup>d,i,l</sup>	10 (13.3)	14 (14)	2 (4.2)

**Table 4 Occurrence of multiple antibody responses to microbial antigens in untreated celiac disease patients in relation to the number of responses against microbial antigens n (%) (n = 78)**

	0	1	2 to 4	Total
Severe malabsorption	7 (22)	8 (25)	17 (53)	32 (40)
Non-specific gastrointestinal symptoms	13 (38)	12 (35)	9 (27)	34 (44)
Iron deficiency anemia	6 (67)	3 (33)	0	9 (12)
Others	2	0	1	3 (4)
Total	28 (36)	23 (29)	27 (35)	78 (100)

P = 0.019 by  $\chi^2$ -test. Clinical data were not available for 4 patients.

of diagnosis in Group CD1 was available in 78 patients out of 82. Of the 78 patients, 32 (41%) presented with severe malabsorption, 34 (43.6%) with non-specific or minor gastrointestinal symptoms, 9 (11.5%) with iron deficiency anaemia, and 3 (3.9%) with other symptoms. The titers of the anti-glycan antibodies varied according to the presenting symptoms (Table 3) by 2-sided *t*-test for independent samples with separate variance estimates. If the above association was tested by ANOVA and post hoc Scheffe-test only the association for gASCA ( $P = 0.027$ ) and AMCA ( $P = 0.03$ ) remained significant. Moreover, the clinical presentations of CD were distributed differently according to serological response (Figure 2, Table 4). Patients with severe malabsorption more frequently had multiple antibodies ( $P = 0.019$ ) while in those with non-specific gastrointestinal symptoms or iron deficiency anaemia no seroreactivity or reactivity against only one glycan components was more commonly seen (Table 4). Out of the CD patients with multiple antibodies positivity, 65.4% were diagnosed because of malabsorption, which was significantly higher than in CD patients with another serotype group (0 = 26.9%, or 1 = 34.8%,  $P = 0.019$ ) (Figure 2).

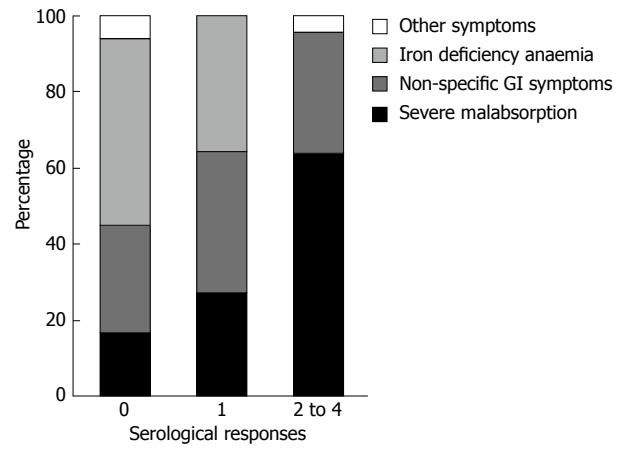

#### Correlation between anti-glycan and anti-OMP antibodies and TGA or EMA

A significant correlation was found between anti-glycan and TGA levels ( $P_{\text{gASCA}} < 0.001$ ,  $R = 0.39$ ;  $P_{\text{AMCA}} = 0.01$ ,  $R = 0.28$ ;  $P_{\text{ALCA}} = 0.006$ ,  $R = 0.23$ ;  $P_{\text{ACCA}} < 0.0001$ ,  $R =$

**Table 3 Association between the titer of anti-microbial antibodies and the leading clinical symptoms at the time of celiac disease presentation (in Group 1, n = 78)<sup>1</sup>**

	Malabsorption	Non-specific gastrointestinal	Anaemia
n	32	34	9
gASCA IgG	54.8 (16.4-99.4) <sup>b</sup>	21.3 (7.1-76.5)	12.2 (8.8-36.7)
AMCA IgG	90.3 (59.5-115.9) <sup>b</sup>	73.8 (52.3-104.4) <sup>a</sup>	44.1 (25.1-55.0)
ALCA IgG	20.6 (16.7-31.2) <sup>b</sup>	23.7 (16.5-39.1) <sup>a</sup>	12.8 (9.9-15.2)

<sup>1</sup>Detailed clinical data were not available for 4 patients, data of 3 patients with other symptoms are not shown; <sup>a</sup> $P < 0.005$ , <sup>b</sup> $P < 0.01$ , between patients with non-specific gastrointestinal symptoms or malabsorption and anaemia by *t*-test for independent samples with separate variance estimates.

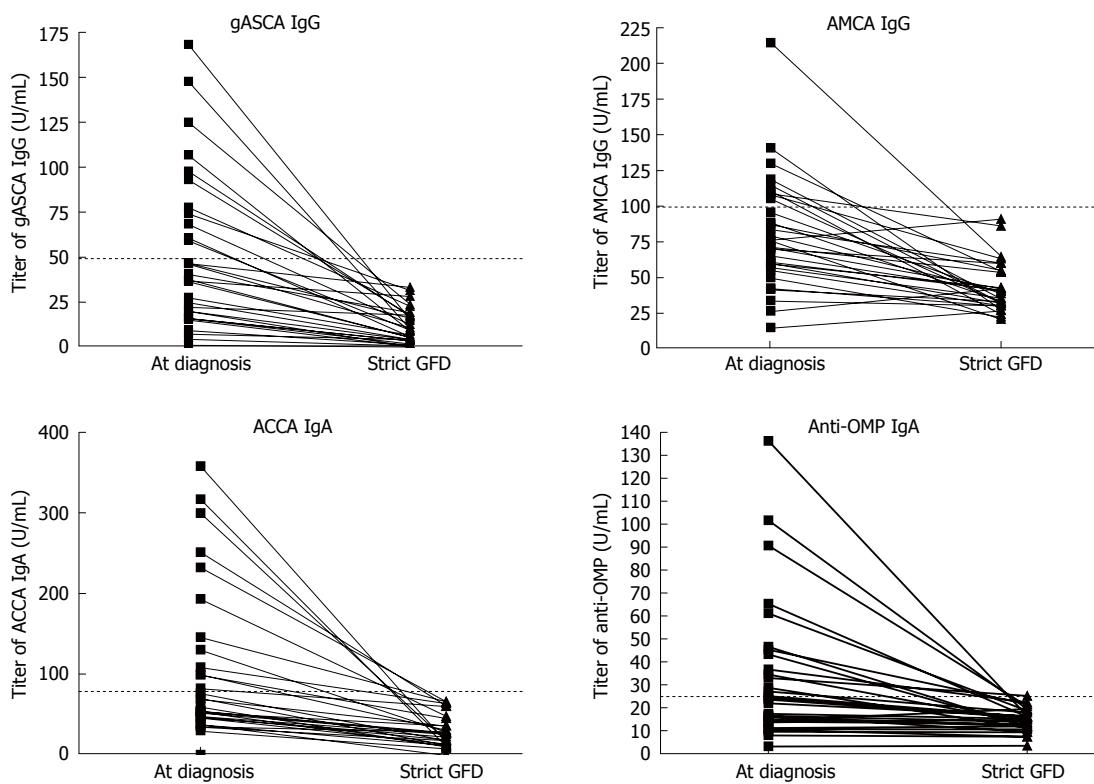

**Figure 2 Clinical presentation of celiac disease according to serological response.**

0.53;  $P_{\text{antiOMP}} = 0.001$ ,  $R = 0.25$  by Spearman's rank order correlation). Similarly, a positive association was found between EMA IgA and gASCA ( $P < 0.001$ ), AMCA ( $P < 0.001$ ), ACCA ( $P < 0.0001$ ), or any-glycan ( $P < 0.0001$ ) but not with anti-OMP positivity.

#### The effect of strict gluten-free diet on anti-glycan and anti-OMP antibody positivity

In the group of 30 patients who were evaluated both at diagnosis and following a long term GFD (subgroup of Group CD1), initial positivity for anti-glycan antibodies (gASCA in 12, AMCA in 9, and ACCA in 11 patients) observed at diagnosis was lost after GFD. The titer of each antibody decreased significantly after adherence to GFD ( $P < 0.001$  for each). Anti-OMP antibody positivity behaved similarly, with all but one of 14 patients positive at diagnosis becoming negative after GFD. The one patient who did not become negative during a 135 month-long period of GFD did in fact decrease during GFD from 33.2 to a borderline positive value of 25.4 units (a positive result is defined as  $\geq 25$  units).

The level of the different antibodies was also significantly lower after GFD ( $P < 0.001$  for each). Figure 3 shows individual anti-glycan and anti-OMP antibody titers at the time of diagnosis and their changes

**Figure 3** Individual anti-glycan and anti-OMP antibody titers at the time of the diagnosis and their variations after successful adherence of to the gluten-free diet (GFD). Mean follow up period of 49 [10-159] mo ( $n = 30$ ). Dotted lines show cut-off values for positivity.

after successful adherence of to the GFD.

The frequency of antibodies directed against glycans and the mean antibody titers were significantly lower in patients with successful adherence to GFD (Group CD3) than in untreated patients (Group CD1) (Table 2, Figure 1) and did not differ statistically from healthy controls.

#### Prevalence of NOD2/CARD15 mutations and their association with antibody titers and symptoms at presentation

The prevalence of NOD2/CARD15 mutation in CD (19/134, 14.2%) did not differ from that in the control group (16/100, 16%). Additionally, we did not observe any association between symptoms at presentation or anti-glycan antibody positivity and the presence of NOD2/CARD15 variants (data not shown).

#### DISCUSSION

This is the first report to investigate the complex associations between a panel of new serological markers, clinical presentation of the disease, and NOD2/CARD15 status in a relatively large cohort of CD patients. Furthermore, direct comparison between the anti-microbial responses in this CD group and our similarly tested previous Crohn's disease cohort<sup>[15]</sup> can be made to add new pieces to the puzzle of the anti-microbial antibody formation.

In this study, we demonstrated that the presence of anti-glycan antibodies (gASCA, ACCA, and AMCA) are associated with CD at the time of diagnosis. However

the prevalence of ALCA and anti-OMP did not differ from the results in the control group. The rate of gASCA positivity (39%) at the time of diagnosis of CD was comparable to the results in CD patients in previous studies<sup>[22-26]</sup>. Based on previous results a sample size of 42-66 celiac patients and controls would have been needed to confirm the above difference with an alpha error of 5% and a statistical power of 95%. In fact, in the present study, for celiac disease at diagnosis the alpha error was 3% and the statistical power 97%.

We could not concur with the findings of Candelli *et al*<sup>[26]</sup> and Barta *et al*<sup>[33]</sup>, which showed significant differences in the prevalence of ASCA IgG between CD and Crohn's diseases. In contrast, no significant difference was noted between the two groups (39% vs 50.5%,  $P = 0.091$ ). In the present study, except ALCA, the occurrence of other anti-glycan antibodies and their median titers in CD at diagnosis was also similar to those observed in Crohn's disease<sup>[13,34]</sup> (celiac disease gASCA: 33.1 U/mL, AMCA 79.3 U/mL, ALCA 21.5 U/mL, ACCA 68.4 U/mL vs Crohn's disease gASCA: 48.3 U/mL, AMCA 55.5 U/mL, ALCA 25.4 U/mL, ACCA 46.2 U/mL). In addition, the positivity rate for any anti-glycan antibody was also comparable in these patient groups (CD vs Crohn's disease: 65.9% vs 59.4%,  $P = \text{NS}$ ). In addition, sensitivity, specificity, positive and negative likelihood ratios in celiac disease are comparable to that observed in Crohn's disease. Consequently, in patients with gastrointestinal symptoms, the presence of gASCA, AMCA, or ACCA may not only suggest underlying Crohn's disease but may also be associated with untreated CD. At the same time, and based on our

results, ALCA and anti-OMP proved to be specific but relatively non-sensitive markers for Crohn's disease.

Current data advocate that in both CD and Crohn's disease patients have a primary defect in intestinal permeability that is also shared by a subgroup of relatives. In CD, it is also apparent that the exposure to gluten results in mucosal inflammation and the consequent tissue damage further abrogating the primary gut barrier defect, while gluten removal resolves the enhanced intestinal permeability<sup>[35,36]</sup>. These gliadin-induced mechanisms are proposed to be the cause of the anti-microbial antibodies formation in the disease and is strongly supported by the association found between anti-glycan markers and TGA or EMA in the present study and also that the antibody status is substantially altered following the introduction of GFD. gASCA and other positive anti-glycan antibodies were entirely lost in our cohort of CD patients, after strict adherence to long-term GFD. These results are concordant with previous findings<sup>[20,22]</sup>. In the study of Mallant-Hent *et al*<sup>[24]</sup>, ASCA IgG or IgA positivity disappeared in a substantial number but not the all of the 111 patients on a strict GFD (from 28.8% to 8.1%). A possible explanation for this difference could be that the mean follow up period after GFD was longer in our study [49 (10-159) mo vs 33 (range 3-113) mo]. These results suggest that as the period of strict GFD increases, so is the greater disappearance of antibody positivity, which will supposedly lead to entire mucosal healing in the small intestine. The higher prevalence of ASCA in adults compared to children further underlines the important role of long-lasting inflammation and consequently antigen exposure in the formation of anti-microbial antibodies.

In the present study, we also established that the kinetics of antibody disappearance is variably sensitive to the length of GFD. Of the anti-glycan antibodies, AMCA and ACCA declined most rapidly, right after the TGA titer started to diminish. In Group CD2, the prevalence of these antibodies had already changed as compared to Group CD1, from approximately 36% to 11%, while the frequency of gASCA and anti-OMP remained unchanged. Among those CD patients who adopted a strict GFD, the duration of GFD was the shortest in this group. In the group of patients with a successful response to GFD (Group CD3), the frequency of gASCA as well as AMCA and ACCA was also lower. At the same time, the overall frequency of anti-OMP did not change, either in group CD2 or in CD3 (Table 1). We showed however, that the level of anti-OMP clearly declined to normal in 13 of the 14 anti-OMP positive CD patients when specific patients in group CD1 were followed (Figure 2). The explanation of this supposedly inconsistency may be that the mean follow-up in both groups CD2 and CD3 was significantly shorter than in those in group CD1 participating in intra-individual longitudinal monitoring, suggesting that anti-OMP requires the longest time to disappear completely and this occurs long after the normalization of TGA and EMA. The differences in the evolution of anti-OMP and anti-glycan antibodies in IBD has also justified our findings in this patient group<sup>[15]</sup>.

We evaluated the possible relationship between sero-

logical response and the clinical presentation of the disease. Patients with multiple seroreactivity to glycans, more commonly presented with severe malabsorption as compared to those without any reactivity against any glycan at all (63% vs 22%,  $P = 0.019$ ), and accounted for 53% of all malabsorption cases. Among the patient groups, the TGA titer reached the highest value (115.9 U/mL vs others: 60.9 U/mL,  $P = 0.016$ ) in those presenting with malabsorption, further supporting enhanced intestinal permeability as a likely component involved in antibody formation. It is well known that the intestinal damage is most pronounced in the malabsorption cases and TGA is a good marker for tissue injury<sup>[37]</sup>. We must note however, that the number of subjects in different clinical presentation groups were limited, thus further studies with a larger cohort of CD patients are needed to confirm these findings.

Recent data suggest that the presence of anti-microbial antibodies might be linked to genetic susceptibility. In patients with Crohn's disease an association was found between antimicrobial formation and the carriage of mutations in innate immunity receptor genes (NOD2/CARD15 or toll-like receptor)<sup>[15,20]</sup>. However, in the absence of NOD2 variants in our Crohn's patients' cohort, the gASCA and the any-glycan positivity was also reasonably high (43.5% and 53.7%, respectively). Furthermore, among CD patients in the present study we found that these antibodies occur with the same frequency and magnitude as in patients with Crohn's disease, albeit the occurrence of NOD2/CARD15 mutation was significantly lower. These findings - alongside with the fact that there is no association between TLR4 variants and CD<sup>[38,39]</sup> - do not support the primary role of genetic predisposition in antibody formation. Nevertheless, the presence of NOD2/CARD15 was associated with an increased antibody formation in Crohn's disease and an apparent link was also reported between increased permeability and NOD2/CARD15 3020insC mutation<sup>[40]</sup>. We did not observe any association between anti-glycan antibody positivity and the presence of NOD2/CARD15 variants in CD. However, the limited number of subjects carrying NOD2/CARD15 mutations might not have allowed us to recognize significant differences in serological response in this patients group. An inheritable trait of anti-microbial antibody formation is unlikely in CD, since we did not find a higher prevalence of ASCA (9.1% vs 14%) and anti-OMP (12.1% vs 20%) as compared to the controls in the 66 unaffected, first-degree relatives (siblings) of this cohort.

On the basis of significant similarity in the qualitative and quantitative serological response in the two patients' groups, we hypothesize a similar mechanism for the formation of the anti-microbial antibody formation in both celiac disease and Crohn's disease. The presence of serological response might be the reflection of the sustained exposure to the constituent of the gut microflora due to the enhanced bacterial translocation. The known predisposing factors for bacterial translocation, such as bacterial overgrowth in the small bowel (secondary to intestinal dysmotility)<sup>[41-43]</sup>, the damage to the integrity of the gut

mucosa (secondary to alterations of the local intestinal microvasculature)<sup>[44,45]</sup>, which results in reduced oxygen delivery and an increased formation in oxygen radicals<sup>[46]</sup> as well as the upregulation of the proinflammatory cytokines, such as tumor necrosis factor  $\alpha$ , interleukin-17 or interferon gamma in active lesions<sup>[47]</sup>, and the defective mucosal immunological defense<sup>[21,48]</sup> are all typical features in both clinical conditions. The significance of the enhanced bacterial translocation out of the small bowel in the anti-microbial antibody formation is further supported by the fact that the presence of the serological response among patients with Crohn's disease is mainly characteristic for those with complicated (stricture or penetrating) small bowel involvement and is rarely observed in the isolated colonic disease or in patients with ulcerative colitis. At the same time, the recovered gut barrier function protects against the invasion of microbes or their components leading to the cessation of anti-microbial antibody formation. In CD, this process may be justified by the observation that the serological response is a temporary phenomenon. As a result of the discontinuation of gliadin exposure and the subsequent mucosal healing, the antibodies disappear completely. Confirming this aspect of our hypothesis is much more complicated in Crohn's disease. First of all, the pathogenetic processes are not only multifaceted but also less characterized as compared to CD. The complete elimination of the causative agents is not possible. Moreover, no such reliable serological markers are available reflecting the extent of gut inflammation as TGA and anti-actin IgA antibodies in CD. Finally, in terms of the complete loss of microbial seroreactivity, the long-lasting complete remission (without mucosal inflammation) is mandatory but rarely reached in patients with Crohn's disease as compared to CD patients adhering to a strict GFD. In this point of view, findings reporting a lack of solid correlation between disease activity and the presence or the magnitude of seroreactivity<sup>[17,49]</sup> in Crohn's disease can not be in opposition to our hypothesis any more. The advent of the new biological treatments might answer this unresolved question, since the complete mucosal healing in Crohn's disease can be achieved with this therapy in a greater proportion of cases than with classical drugs. At this moment, however, no data from prospective studies are available addressing the effect of the biological therapy on antibody stability. Our data also call for additional basic research to explore the exact mechanism of immune responses to commensal enteric bacteria as well as the possible clinical significance of the bacterial translocation in the pathogenesis or the complications of these diseases as it is well established in other clinical conditions such as liver cirrhosis, acute pancreatitis or sepsis<sup>[50]</sup>.

In conclusion, our results suggest that ASCA and other anti-glycan antibodies may be considered as additional markers for CD and adherence to a GFD. Furthermore, the presence and the magnitude of response to microbial components is associated with a more severe clinical course but not with mutations in NOD2/CARD15. This seroreactivity may be the consequence of the enhanced bacterial translocation through the impaired small bowel mucosa.

## COMMENTS

### Background

Anti-microbial antibody formation has been reported in celiac disease. Relatively high positivity rates were observed for the conventional antibodies, for example, anti-Saccharomyces cerevisiae (ASCA), anti-OmpW, and anti-I2, and they were known to decrease after a successful gluten free diet.

### Research frontiers

Newly discovered inflammatory bowel disease-associated antibodies (including anti-glycan antibodies and anti-OMP) may also be of importance in celiac disease, however, not studied thus far in the published literature. The presence of anti-microbial antibodies in relation to clinical presentation of the disease and NOD2/CARD15 mutations was also not investigated.

### Innovations and breakthroughs

Anti-glycan antibody positivity is a common feature of celiac disease at the time of diagnosis and is lost after long-term gluten-free diet. The positivity rate and titers at diagnosis are as high as observed in Crohn's disease. The presence of anti-glycan antibodies is associated with the presenting symptoms, especially with severe malabsorption but not with mutations in NOD2/CARD15. We did not find a higher prevalence of anti-microbial antibodies in the unaffected, first-degree relatives of this patient cohort.

### Applications

The data may add new pieces to the puzzle of the anti-microbial antibody formation and also assist to re-evaluate recently proposed mechanisms. Serological response to various microbial antigens might be considered a universal marker of the enhanced translocation of the gut microflora through the impaired small bowel mucosa both in celiac and Crohn's disease patients.

### Terminology

Serology markers: anti-endomysial antibodies, synthetic deamidated gliadin peptides, antibodies against microbial antigens such as cell wall component of *Saccharomyces cerevisiae*, outer membrane porin C transport protein of the *Escherichia coli* (OmpC) or the *Pseudomonas fluorescens* associated protein (I2). anti-glycan antibodies: glycan-ASCA (gASCA), anti-mannobioside (AMCA), anti-laminaribioside (ALCA), anti-chitobioside (ACCA).

### Peer review

Papp et al studied the prevalence of antimicrobial antibodies in celiac disease patients. The most relevant finding is that anti-glycan antibody titers were associated with symptoms at presentation and their positivity was lost after longstanding gluten free-diet as well as patients with multiple anti-glycan antibodies at diagnosis had more frequently severe malabsorption.

### Abstract

**AIM:** To investigate the differences in injury patterns caused by arterial, venous or arteriovenous mesenteric occlusion.

**METHODS:** Male Wistar rats were separated equally into four groups. Occlusion was performed by clamping the superior mesenteric artery (A), the mesenteric vein (V) or both (AV) for 30 min, followed by 60 min of reperfusion. A control group received sham surgery only. Intestinal sections were examined for histological damage and serum tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), endothelin-1 (ET-1), P-selectin, antithrombin III (ATIII) and soluble intracellular adhesion molecule-1 (ICAM-1) concentrations were measured.

**RESULTS:** All groups showed significant mucosal injury compared to controls. Furthermore, mucosal injury was significantly more severe in the V and AV groups

compared to the A group ( $3.6 \pm 0.55$ ,  $3.4 \pm 0.55$  and  $2 \pm 0.71$ , respectively,  $P = 0.01$ ). ICAM-1 was similarly elevated in all groups, with no significant differences between the groups. P-selectin levels were significantly elevated in the V and AV groups but not the A group ( $1.4 \pm 0.5$  ng/mL,  $2.52 \pm 0.9$  ng/mL and  $0.02 \pm 0.01$  ng/mL, respectively,  $P = 0.01$ ) and ET-1 was significantly elevated in the A and V groups but not the AV group ( $0.32 \pm 0.04$  pg/mL,  $0.36 \pm 0.05$  pg/mL and  $0.29 \pm 0.03$  pg/mL, respectively,  $P = 0.01$ ) compared to sham controls. ATIII levels were markedly depleted in the V and AV groups, but not in the A group ( $29.1 \pm 5.2$  pg/mL,  $31.4 \pm 21.8$  pg/mL and  $55.8 \pm 35.6$  pg/mL, respectively,  $P = 0.01$ ), compared to controls. Serum TNF- $\alpha$  was significantly increased in all groups compared to sham controls ( $1.32 \pm 0.87$  ng/mL,  $1.79 \pm 0.20$  ng/mL and  $4.4 \pm 0.69$  ng/mL, for groups A, V and AV, respectively,  $P = 0.01$ ), with higher values in the AV group.

**CONCLUSION:** Different patterns of response to ischemia/reperfusion are associated with venous, arterial or arteriovenous occlusion. Venous and arteriovenous occlusion was associated with the most severe alterations.

### INTRODUCTION

Acute mesenteric ischemic disease can be either arterial or venous in etiology. Acute arterial ischemia results

from reduced blood flow caused by mesenteric artery thrombosis or embolism, leading to bowel necrosis and high mortality<sup>[1]</sup>. Mesenteric vein occlusion is usually due to thrombosis, is less common than arterial occlusion and carries a lesser risk of bowel necrosis and therefore reduced mortality<sup>[2,3]</sup>. Greater knowledge of the differences between these conditions would aid the search for therapeutic interventions, and also expand our understanding of ischemia/reperfusion (I/R) pathophysiology. This information would also be relevant for transplantation and aortic reconstruction procedures, which are invariably related to periods of I/R<sup>[4]</sup>.

The intestine is very susceptible to ischemic injury. Ischemia causes mucosal damage through the production of substances like oxygen-derived free radicals, pro-inflammatory cytokines such as tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and the complement system<sup>[5]</sup>. The pattern of injury has been found to be different after experimental arterial or venous occlusion of the mesenteric circulation followed by reperfusion. Generally, the histological injury grade is thought to be greater after venous occlusion, even though energy metabolism is altered to a lesser extent than in arterial occlusion<sup>[6]</sup>. However, another study found that venous congestion alone could not cause reperfusion injury, while arterial occlusion could do so easily<sup>[7]</sup>. This issue could be resolved if the differences between the injury response to these two situations could be found.

During I/R, endothelial functions are altered, resulting in microcirculatory dysfunction which modulates mucosal integrity<sup>[8]</sup>. Endothelial injury and increased vascular permeability also occur<sup>[9]</sup>. The vascular endothelium regulates vascular tone, leukocyte adhesion and the coagulation cascade, among other factors. Endothelial function serum marker levels such as intracellular adhesion molecule-1 (ICAM-1), endothelin-1 (ET-1) and coagulation factors have also been found to be altered after I/R. One study showed that ET-1 modulates intestinal I/R injury in rats<sup>[10]</sup>, while another showed that ICAM-1 is overexpressed, possibly contributing to injury by promoting leukocyte infiltration<sup>[11]</sup>. Another adhesion molecule, P-selectin, is also thought to modulate intestinal I/R injury, through complement deposition and leukocyte interaction<sup>[12]</sup>. Intestinal I/R also causes hemostatic alterations, namely coagulation induction, thrombin generation, and fibrin deposition, which correlate with the extent of injury<sup>[13]</sup>.

In this study we evaluate the possibility that arterial, venous and arteriovenous occlusion, followed by reperfusion, might cause different types of response to I/R injury in the intestine. These differences were investigated by measuring ET-1, antithrombin III (ATIII), soluble ICAM-1 and P-selectin serum concentrations, soluble markers of endothelial function, as well as by measuring TNF- $\alpha$ , a cytokine that plays a central role in I/R injury.

## MATERIALS AND METHODS

### **Animal procedures**

Animal procedures were performed in accordance with

the proper use and care of laboratory animals, approved by the ethics committee of our institution. Experiments were performed on 20 male Wistar rats weighing 200–250 g. Animals were maintained under standard conditions, such as stable room temperature (24 ± 3°C), a 12 h light/12 h dark cycle, and access to commercial rat pellets and water *ad libitum*.

### **Animal model**

Briefly, after pentobarbital sodium anesthesia (Anestesal, Pfizer Inc, Mexico) (35 mg/kg, i.p), a midline laparotomy was performed, and the small intestine was externalized and wrapped in humid gauze. Animals were placed under a heating lamp in order to preserve core body temperature at (37°C). The cecum was occluded using a 2-0 nylon suture to prevent collateral blood flow, and ischemia was induced by obstructing either the superior mesenteric artery, the mesenteric vein before its union with the portal system, or both, with microvascular clamps for 30 min (ischemia), and removed to allow 60 min reperfusion. Immediately after clamping the mesenteric vessels, the intestines were returned to the peritoneal cavity where they remained for the entire duration of the procedure. Occlusion was confirmed by loss of pulsation and characteristic red dark coloring of the intestine in the venous group, or pale pink coloring and loss of pulsation in the arterial group.

Rats were divided in four groups ( $n = 5$ ). The first group received only sham surgery (Sham), where laparotomy was performed but intestines were only manipulated but not made ischemic. Group A was subjected to arterial occlusion and reperfusion as described above. Group V was subjected to venous occlusion and reperfusion as described above. Group AV was subjected to both arterial and venous occlusion and reperfusion as described above.

### **Morphological examination**

Immediately after concluding the reperfusion period, rats were sacrificed by exsanguination from the aorta and tissue samples were obtained and fixed in 10% neutral buffered formalin overnight. Samples were then embedded in paraffin, and 4 µm-thick sections were stained with hematoxylin and eosin (H/E) and examined under a light microscope by a blinded pathologist. The Chiu score of mucosal injury was used to evaluate the degree of histological damage<sup>[14]</sup>. The scale consists of values from 0 to 5, where 0 is normal mucosa; 1, development of sub epithelial (Gruenhagen's) spaces; 2, extension of the sub-epithelial space with moderate epithelial lifting from the lamina propria; 3, extensive epithelial lifting with occasional denuded villi tips; 4, denuded villi with exposed lamina propria and dilated capillaries; and 5, disintegration of the lamina propria, hemorrhage, and ulceration.

### **Inflammatory cell infiltration**

Under light microscopy, H/E stained tissue samples were analyzed for leukocyte infiltration by a blinded pathologist. The predominant type was recorded in both mucosa and

muscular layers, and intensity of infiltration was quantified with a numerical scale with values from 0 to 3, where 0, no infiltration; 1, mild infiltration; 2, moderate infiltration and 3, severe infiltration. Two slides and five high power fields per slide were examined and averaged.

#### **Serum levels of ET-1, AT<sub>III</sub>, P-selectin, ICAM-1 and TNF- $\alpha$**

At the end of the reperfusion period 3 mL of blood was obtained from each rat and left to clot for serum acquisition. Serum levels of ET-1 were determined using a rat ET-1 EIA kit (Immuno-Biological Laboratories, Japan). Serum levels of AT<sub>III</sub> were determined using a rat AT<sub>III</sub> ELISA kit (GenWay Biotech, USA). Serum levels of soluble ICAM-1 were determined using a quantikine rat sICAM-1 ELISA kit (R & D Systems, USA). Serum levels of P-selectin were determined using a quantikine rat P-selectin ELISA kit (R & D Systems, USA). These were used as markers of endothelial function. Serum concentrations of TNF- $\alpha$  were determined using a rat TNF- $\alpha$  Elisa kit (PeproTech, Mexico).

#### **Statistical analysis**

SPSS 11.0 statistical software (SPSS Inc. Software, Chicago, Illinois, USA) was used to analyze data using one-way analysis of variance (ANOVA) and with the Tukey-Kramer post-hoc test so as to determine comparisons between the groups, and differences between the groups, respectively. The relationships between the variables studied were determined by the calculation of Pearson correlation coefficients. All values are expressed as mean  $\pm$  SD and  $P < 0.05$  was considered statistically significant.

## **RESULTS**

#### **Morphological examination**

The sham group showed normal intestinal mucosa (Chiu score  $0.2 \pm 0.45$ ). All occlusion groups had significantly higher injury scores compared to the sham group (Figure 1,  $P < 0.01$ ). Groups V and AV had the highest injury scores ( $3.6 \pm 0.55$  and  $3.4 \pm 0.55$ , respectively), showing severe epithelial lifting and severe capillary congestion (Figure 1), with no difference observed between these two groups. However, both the AV and V groups had significantly higher scores compared to group A ( $2 \pm 0.71$ ,  $P < 0.01$ ), which showed moderate lifting and very little congestion.

#### **Inflammatory cell infiltration**

Compared to the sham group ( $1.2 \pm 0.45$ ), groups V and AV ( $2.6 \pm 0.55$  and  $2.6 \pm 0.55$ ) both had a significantly higher leukocyte infiltration intensity (Figure 1,  $P < 0.05$ ). Group A ( $2 \pm 0.7$ ) was not statistically different from either the V or sham group. The infiltrate type was similar in all groups, and was composed mostly of neutrophils, with few macrophages or lymphocytes observed.

#### **Serum markers of endothelial function**

The sham group had soluble P-selectin serum concentrations of  $0.83 \pm 0.47$  ng/mL. In group A the levels remained

**Table 1 Pearson's correlation coefficient between the variables studied**

	<b>TNF-<math>\alpha</math></b>	<b>ET-1</b>	<b>P-selectin</b>	<b>ICAM-1</b>	<b>AT<sub>III</sub></b>
Chiu Score	0.715 <sup>a</sup>	0.714 <sup>b</sup>	0.552 <sup>a</sup>	0.608 <sup>b</sup>	-0.633 <sup>a</sup>
TNF- $\alpha$	x	0.26	0.646 <sup>b</sup>	0.337	-0.534 <sup>a</sup>
ET-1		x	-0.015	0.655 <sup>b</sup>	-0.409
P-selectin			x	0.044	-0.275
ICAM-1				x	-0.532 <sup>a</sup>

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ . Data are presented as correlation coefficients ( $r$ ).

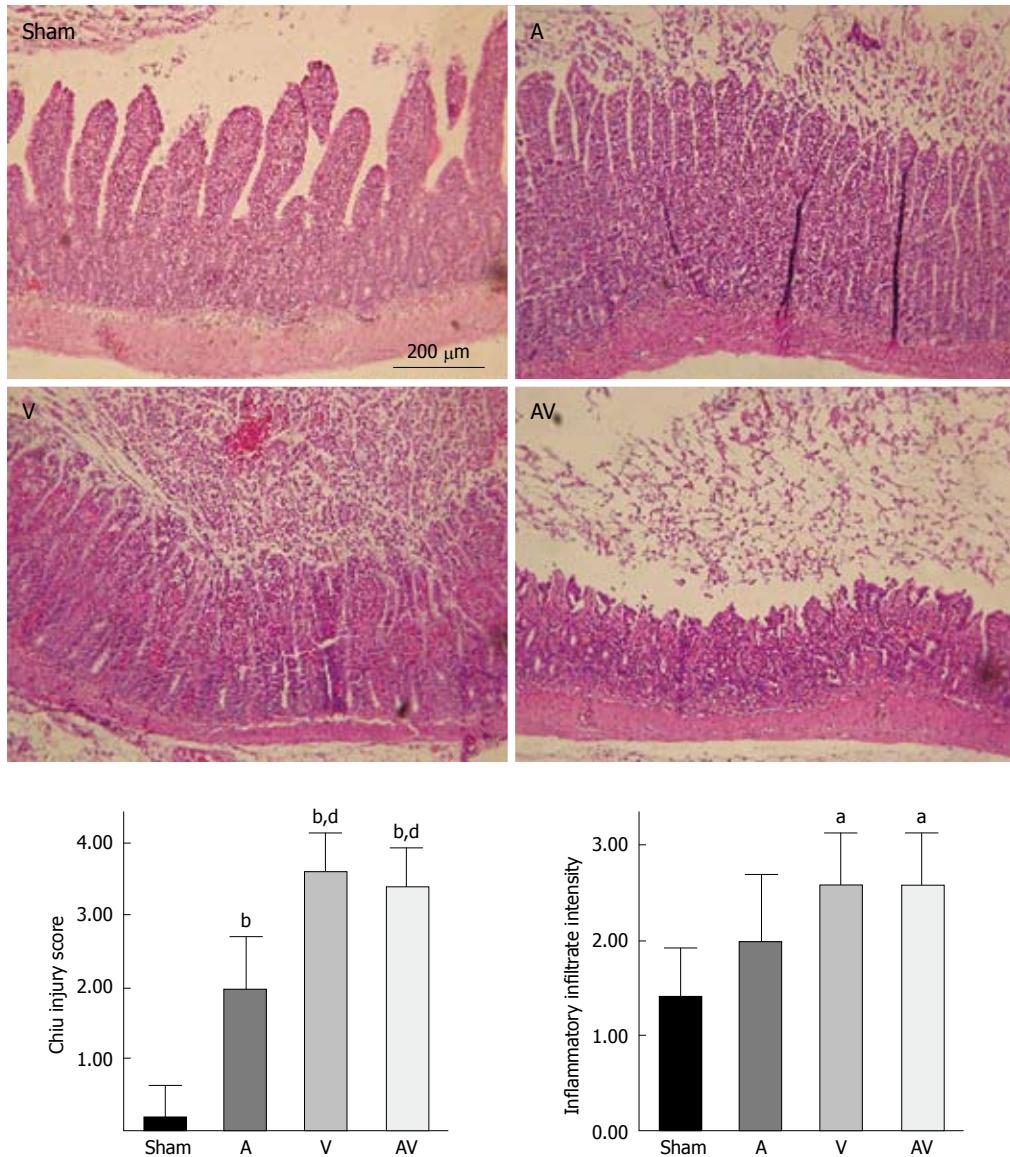

barely detectable, and were not statistically different to the sham group ( $0.02 \pm 0.01$  ng/mL). Groups V and AV had significantly higher values compared to the sham group ( $1.4 \pm 0.5$  ng/mL and  $2.52 \pm 0.9$  ng/mL, respectively,  $P < 0.01$ ), with the latter being significantly higher than the former ( $P < 0.05$ , Figure 2). AT<sub>III</sub> serum concentrations were significantly depleted in groups V and AV compared to the sham group ( $29.1 \pm 5.2$  pg/mL and  $31.4 \pm 21.8$  pg/mL vs  $85.3 \pm 17.4$  pg/mL, respectively,  $P < 0.01$ ), while in group A they remained within the sham group range ( $55.8 \pm 35.6$  pg/mL). However, there was no difference between the V or AV groups (Figure 2). No difference was found between ET-1 levels in the sham and AV groups ( $0.23 \pm 0.01$  pg/mL vs  $0.29 \pm 0.03$  pg/mL, respectively, Figure 2). Levels in both the A and V groups were significantly elevated compared to the sham group ( $0.32 \pm 0.04$  pg/mL and  $0.36 \pm 0.05$  pg/mL, respectively,  $P < 0.01$ ), with levels in the V group also being significantly higher than in that in the AV group, but not the A group. Finally, all groups had significantly elevated soluble ICAM-1 serum concentrations compared to the sham group (A:  $569.2 \pm 170.8$  pg/mL, V:  $529 \pm 191.5$  pg/mL and AV:  $483.9 \pm 41.6$  pg/mL vs  $194 \pm 38.9$  pg/mL, respectively,  $P < 0.01$ ), but no differences were found between each of these three groups (Figure 2). In summary, venous and arteriovenous occlusion elevated P-selectin, and depleted AT<sub>III</sub>, to a greater extent than arterial occlusion only. Venous and arterial occlusion, but not arteriovenous occlusion, elevated ET-1 levels compared to sham groups, with no differences between them. ICAM-1 levels were elevated in all groups compared to the sham group, with no differences between them.

#### **TNF- $\alpha$ serum concentrations**

The sham group had TNF- $\alpha$  serum concentrations of  $0.11 \pm 0.14$  ng/mL. In groups A, V and AV the levels were significantly increased compared to sham controls ( $1.32 \pm 0.87$  ng/mL,  $1.79 \pm 0.20$  ng/mL and  $4.4 \pm 0.69$  ng/mL, respectively,  $P < 0.01$ , Figure 2). TNF- $\alpha$  serum concentrations were significantly higher in the AV group compared to both the A and V group, with no differences observed between these two groups.

#### **Linear correlations between variables**

Linear correlations were observed between the systemic concentrations of endothelial function markers, TNF- $\alpha$  and injury scores. These correlations are shown in Table 1. All the measured variables, except for AT<sub>III</sub>, showed a significant positive correlation with the histological injury score. AT<sub>III</sub> showed a significant negative correlation with

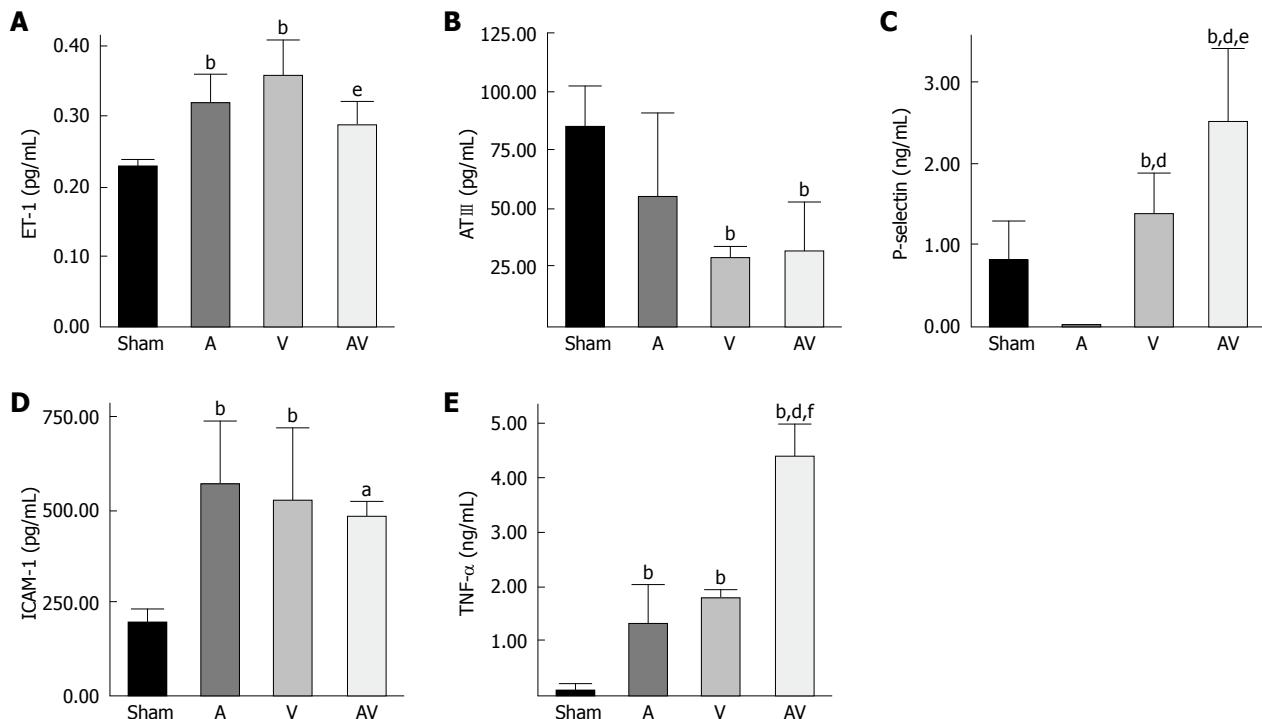

**Figure 1** Histological findings (H & E) and injury scores. A: Arterial occlusion and reperfusion group; V: Venous occlusion and reperfusion group; AV: Both arterial and venous occlusion and reperfusion group. <sup>a</sup>P < 0.05 vs sham; <sup>b</sup>P < 0.01 vs sham; <sup>c,d</sup>P < 0.01 vs A.

the injury score ( $r = 0.608$ ,  $P < 0.01$ ). TNF- $\alpha$  was the variable most strongly correlated with injury score ( $r = 0.715$ ,  $P < 0.01$ ).

## DISCUSSION

Ricci *et al*<sup>[15]</sup> found greater mortality in rats after intestinal arterial versus arteriovenous occlusion. However, Yano *et al*<sup>[16]</sup> found that the degree of intestinal damage due to venous occlusion was greater than the damage resulting from both arteriovenous and arterial occlusion, with no difference between the latter two procedures. Greater intestinal hemorrhage has also been observed after venous occlusion compared with arterial occlusion<sup>[6]</sup>. Other studies confirmed these findings, showing that venous occlusion could induce intestinal injury as early as within 5 min, while arterial occlusion could not even at longer time periods<sup>[17]</sup>. Some of the molecular bases of these differences have been investigated. Venous congestion has been shown to induce increased levels of inflammatory

cytokines, in a similar way to arterial occlusion<sup>[18]</sup>. However, in one I/R study, intestinal malonyldialdehyde levels (as an index of free radicals) were found to be higher in venous occlusion compared to arterial occlusion, despite no obvious difference in tissue injury<sup>[19]</sup>. In other organs, such as the kidney, renal vein occlusion has been found to induce a stronger inflammatory response (TNF- $\alpha$ , free radicals, but not ICAM-1), neutrophilic infiltration, and greater functional damage, compared to arterial occlusion<sup>[20]</sup>. In our study, I/R due to venous occlusion was shown to cause greater damage to the intestinal mucosa than arterial occlusion alone, in agreement with the previous studies. However, we found no difference between the type or the intensity of injury between venous and arteriovenous occlusion. Arterial occlusion caused limited but significant histological damage and was associated with little leukocyte infiltration. The pro-inflammatory cytokine TNF- $\alpha$  is one of the main orchestrators of the inflammatory response and a key mediator of injury during I/R<sup>[21]</sup>. In our study,

**Figure 2** Serum concentrations of endothelial function markers and TNF- $\alpha$ . A: ET-1 serum concentrations; B: ATIII serum concentrations; C: P-selectin serum concentrations; D: Serum levels of soluble ICAM-1; E: TNF- $\alpha$  serum concentrations.  $^aP < 0.05$  vs sham;  $^bP < 0.01$  vs sham;  $^dP < 0.01$  vs A;  $^eP < 0.05$  vs V;  $^fP < 0.01$  vs V.

TNF- $\alpha$  levels were significantly elevated after all three occlusion methods, with the highest levels observed in the arteriovenous occlusion group. TNF- $\alpha$  concentrations were strongly correlated to injury intensity.

Intestinal I/R affects the microvasculature, endothelial cells, and endothelial cell function<sup>[8]</sup>. ET is a vasoactive substance which induces intense vasoconstriction of blood vessels, and its activation is thought to play an important part in the development of these microvascular changes<sup>[22]</sup>. ET-1 participates in intestinal I/R injury by modulating leukotriene production<sup>[10]</sup>. Additionally, it has been demonstrated that ET-1 is involved mainly in post-reperfusion induced vasospasm and damage, and ET receptor antagonists are able to protect against mucosal injury<sup>[23]</sup>. In agreement with previous reports, we found that I/R due to arterial occlusion induces elevations in ET-1 levels, and further, we demonstrated that venous occlusion has a similar outcome, although there was a tendency for higher levels in the venous occlusion group. Surprisingly, ET-1 elevation was not present when both arterial and venous occlusion was performed simultaneously. Other factors capable of explaining this result might be at play. It is known that reductions in perfusion pressure during mesenteric ischemia cause diminished arteriolar resistance and vasodilation as a compensatory mechanism<sup>[24]</sup>. While venous occlusion alone causes severe congestion and increased intravascular pressure, arterial occlusion alone might only cause reduced inflow perfusion with normal outflow. Supporting this idea, Tsunada *et al*<sup>[18]</sup> reported a more pronounced reduction of blood flow and increased subsequent flow recovery after reperfusion with arterial occlusion, compared to venous occlusion. We speculate

that arteriovenous occlusion might balance inflow and outflow alterations, resulting in intravascular pressure and tone equilibrium, possibly explaining the absence of ET-1 activation which we observed. Further experiments are required to assess this possibility and the role of ET-1 in regulating post-ischemic vascular tone.

P-selectin is an adhesion molecule which modulates endothelial-leukocyte interactions. During intestinal I/R, P-selectin mRNA expression is upregulated in the microvascular endothelium<sup>[25]</sup> and P-selectin immunoreactivity is increased in the intestinal mucosa<sup>[26]</sup>. I/R studies have shown that P-selectin blockade or genetic deficiency result in diminished intestinal mucosa damage after I/R in rodent models, further supporting the idea that P-selectin participates in the pathophysiology of I/R injury<sup>[27,28]</sup>. In our study, I/R in the arteriovenous occlusion group caused higher elevations of soluble P-selectin serum concentrations than in the venous occlusion group. Moreover, arterial occlusion was unable to alter these values compared to the sham group. P-selectin levels were also found to be correlated to histological injury scores.

The coagulation cascade is promoted by I/R<sup>[13]</sup>. AT III is an endogenous anticoagulation molecule produced in lung, liver and endothelium which limits thrombin formation. Thrombin activation and the formation of thrombin-antithrombin complex is increased after intestinal I/R, contributing to cytokine production and inflammatory injury<sup>[29]</sup>. Furthermore, these alterations would theoretically result in endogenous ATIII depletion. One rodent study found that ATIII levels were indeed depleted after intestinal I/R, and that they were restored by protective therapy<sup>[30]</sup>. Additionally, ATIII

administration can protect the intestinal mucosa against I/R injury<sup>[31]</sup>. We found that I/R due to both venous and arteriovenous occlusion caused ATIII depletion whereas arterial occlusion alone did not. In our study, a negative correlation between ATIII levels and injury scores was observed, suggesting that depleted ATIII levels are indeed reflective of damage intensity. A possible explanation for our results is that the microvascular congestion and venous stasis caused by the venous occlusion component promotes the coagulation cascade to a greater extent than the arterial component during ischemia and reperfusion. Indeed, temporal and histological differences have been found to exist between thrombus generation in arterial and venous endothelium<sup>[32]</sup>. While stasis seems to be a more important factor in veins, impaired laminar flow and plaque formation seem to be essential for arterial thrombus generation<sup>[33]</sup>. Furthermore, studies have shown that decreased levels of ATIII after major surgery can predict higher complication and mortality rates<sup>[34]</sup>. Therefore, the differences in ATIII depletion between arterial or venous mesenteric ischemia might be of clinical relevance. The physiopathological consequences of these results warrant further investigation.

ICAM-1 is another adhesion molecule that mediates leukocyte reactivity and adhesion to endothelium. Intestinal I/R is also associated with an upregulation of ICAM-1 and subsequent leukocyte infiltration<sup>[35]</sup>. Systemic ICAM-1 activity is also upregulated, possibly contributing to multisystem failure and remote organ injury<sup>[11]</sup>. Serum levels of ICAM-1 have been shown to be markedly elevated after intestinal I/R, and low serum concentrations are associated with beneficial outcomes after the administration of protective agents<sup>[36]</sup>. The inhibition of ICAM-1 with monoclonal antibodies is able to reduce the intensity of the functional and morphological alterations in the intestine subjected to I/R<sup>[37,38]</sup>. In our study, we found that soluble ICAM-1 serum concentrations were elevated by intestinal I/R, in agreement with the previous reports. However, there was no difference between any of the occlusion methods employed, suggesting that soluble ICAM-1 is non-specifically elevated in arterial, venous or arteriovenous I/R.

In conclusion, we showed that a different pattern of response to I/R characterize different forms of mesenteric occlusion methods. Venous occlusion seems to cause more severe tissue damage and changes in P-selectin and ATIII depletion compared to arterial occlusion. This suggests that these molecules are sensitive to changes in the intensity of the histological injury and therefore might be partly responsible for some of the pathophysiological differences between venous and arterial occlusion. Arteriovenous occlusion showed greater tissue damage and TNF- $\alpha$  levels compared to arterial occlusion alone, but only differences in P-selectin and ET-1 were found between them. Finally, arterial occlusion was related to the least severe changes compared to controls, and ICAM-1 values were not different between the different I/R groups.

We discussed the possibility of these differences being dependent on local microvascular factors, but since

serum concentrations are indicative of the systemic state, the explanation could lie in differences in the systemic consequences of the occlusion methods employed. Studies on the local and remote tissue expression of these molecules would be helpful in clarifying these issues. However, our results confirm that there are differences in the inflammatory responses associated with venous, arterial or arteriovenous occlusion that could partly explain the molecular bases of the clinical differences between these conditions.

## ACKNOWLEDGMENTS

We would like to thank Jose Luis Vazquez Juarez, MVZ, for providing animals and ensuring their care. We would also like to thank the staff at the Liver Unit, UANL, for management of the serum samples.

## COMMENTS

### Background

Intestinal ischemia can occur when blood flow from the mesenteric vasculature is obstructed. Obstructions can be embolic, atherosclerotic or vasospastic in etiology. Mesenteric veins or arteries can be affected. Ischemia and reperfusion also takes place in transplant procedures and states of hypoperfusion (shock). The pathophysiological differences between venous, arterial or total ischemia of the intestine are not fully understood. In this study, the aim was to investigate these differences using a rat model.

### Research frontiers

Ischemia/reperfusion is an important topic of research. The molecular mediators responsible for ischemia/reperfusion injury could be modulated to improve transplantation outcomes.

### Innovations and breakthroughs

In this study, it is demonstrated that venous, arterial or arteriovenous occlusion followed by reperfusion, cause different patterns of injury and serum elevations of inflammatory markers.

### Applications

To understand the pathophysiological bases of ischemia/reperfusion injury could lead to novel treatments, specifically tailored for conditions of venous, arterial or total ischemia.

### Peer review

This is a very interesting study which examines changes in rat intestinal histology and inflammatory serum cytokine markers subsequent to arterial, venous or concomitant arterial and venous occlusion and reperfusion. The authors demonstrated the differences in injury patterns caused by arterial, venous or arteriovenous mesenteric occlusion. This study is well-investigated and has a novel finding.

overloading of CCh promoted fluid secretion in 15 of 20 CHs. This promotion was classified into four patterns, which were eventually related to the categories of CH: Overall sustained phase was continuously raised (*Yin*-nourishing, fluid production-promoting and heat-clearing agents); The sustained secretion rose to reach a maximum then decreased (*Qi*-enhancing agent); Sustained secretion rose to reach the highest maximum and was then sustained with a slight decline (swelling-reducing, phlegm-resolving and pus-expelling agents); Stimulation of salivary secretion without any added stimulants. Addition of CCh raised the fluid secretion to reach the highest maximum then sharply decreased to a lower sustained level (blood activating agent).

**CONCLUSION:** The present findings lead to the conclusion that various CHs have different promotional effects directly on the salivary gland.

### Abstract

**AIM:** To determine whether Chinese herbs (CHs) relieve xerostomia (dry mouth) by increasing salivary secretion.

**METHODS:** The submandibular glands of Wistar rats were surgically isolated and perfused arterially with buffered salt solution. After control perfusion, recording started 5 min prior to the start of stimulation. After fluid secretion was induced by 0.2 μmol/L carbamylcholine (CCh) in the perfusate for 10 min, Chinese herb (CH) was added in the perfusion for 5 min. CCh was then overloaded at 0.2 μmol/L in the perfusion for 20 min. The volume of salivary fluid secretion was recorded by a computer-controlled balance system.

**RESULTS:** Saliva secretion formed an initial ephemeral peak at 30 s followed by a gradual increase to a sustained level. CH alone induced no or little saliva in all types of CH selected. During perfusion with CH,

### INTRODUCTION

Xerostomia (dry mouth) is caused by salivary hypo-function (reduction in salivary fluid secretion). Severe xerostomia induces speech difficulty, infection of the oral cavity and is associated with systemic disease<sup>[1]</sup>. Salivary hypofunction is associated with aging and with various diseases including diabetes, hypertension, dehydration, drugs, radiation therapy, autoimmune diseases, irradiation, sarcoidosis and many other renal, neurologic and skin diseases<sup>[2]</sup>. Xerostomia may be transient and/or reversible as in the case of medications but relatively permanent in

the case of autoimmune diseases, damage due to radiation therapy and aging. The present therapeutic procedures for xerostomia are limited and include the supplemental use of artificial saliva and the use of stimulants such as pilocarpine and cevimeline.

Therapeutic use of muscarinic agents is sometimes avoided due to underlying diseases. The use of artificial saliva may bother patients during talking. Clinical research on the gene transfer of aquaporin has recently taken place<sup>[3,4]</sup>, and is still in progress.

For thousands of years, Traditional Chinese Medicine (TCM) has been used in the treatment of xerostomia. TCM does not follow the western style of diagnosis such as whether the symptom is primary or secondary, but is based on the classical theory-Syndrome Differentiation and Treatment. However, both ancient and contemporary practitioners of TCM have no standard classification of xerostomia symptoms, because all herbalist doctors have their own understanding and clinical experiences of syndrome differentiation and herb-choice. Following a comparison of the types of classifications, we can summarize xerostomia symptoms and classify them as follows: Yin-deficiency and thin fluid-deficiency; Yin-deficiency and dryness-heat; lack of activation due to Qi-deficiency; internal block of blood stasis; accumulation of damp-heat; phlegm accumulating with blood stasis<sup>[5-7]</sup>.

In order to choose herbs, all herbalist doctors obey the principle of therapy "Supply the deficiency, Reduce the excess". Because all practitioners of Chinese Medicine have their own preferences for particular herbs, overall, they are likely to choose herbs for xerostomia as follows: *Qi*-enhancing agents, Body fluid-regenerating agents, *Yin*-nourishing agents, Heat-clearing agents, Dampness-eliminating agents, Blood-activating agents, and Phlegm-resolving agents<sup>[8-11]</sup>.

Several thousand types of Chinese herbs are now in clinical use. By combining our previous findings<sup>[12]</sup> with reports by other herbalist doctors, we chose the following twenty herbs: *Yuzhu* (YZ, *Rhizoma polygonati odorati*<sup>[13,14]</sup>), *Shihu* (SH, *Herba dendrobii*<sup>[15,16]</sup>), *Shashen* (SS, *Radix glehniae*<sup>[17,18]</sup>), *Maimendong* (MD, *Radix ophiopogonis*<sup>[10,18]</sup>), *Tianmendong* (TD, *Radix asparagi*<sup>[17,18]</sup>) as *Yin*-nourishing agents; *Gegen* (GG, *Radix puerariae*<sup>[5]</sup>), *Wumei* (WM, *Fructus mume*<sup>[10,19]</sup>) as Body fluid-regenerating agents; *Shengdihuang* (SD, *Radix rehmanniae*<sup>[19,20]</sup>), *Xuanshen* (XS, *Radix scrophulariae*<sup>[17,18]</sup>), *Chishao* (CS, *Radix paeoniae rubra*<sup>[5,21]</sup>) as Heat-clearing agents; *Huangqi* (HQ, *Radix astragali*<sup>[8,14]</sup>), *Tai Zi Shen* (Tzs, *Radix pseudostellaris iae*<sup>[8]</sup>), *Gancao* (GC, *Radix glycyrrhizae*<sup>[18,22]</sup>) as *Qi*-enhancing agents; *Danshen* (DS, *Radix salviae miltiorrhizae*<sup>[17,18]</sup>) as Blood-activating agents; *Zaoci* (ZJC, *Fructus gleditsiae abnormalis*<sup>[19]</sup>), *Tianhuafen* (THF, *Radix trichosanthis*<sup>[20,23]</sup>), *Ziyuan* (ZY, *Radix asteris*<sup>[24,25]</sup>) as Phlegm-resolving agents; *Taoren* (TR, *Semen persicae*<sup>[13,24]</sup>), *Chuanshanjia* (CSJ, *Squama manis*<sup>[23]</sup>) as Body mass-softening and resolving agents; *Dandiquionyu* (DDQY<sup>[26]</sup>) as a mixture.

However, the effects of these CHs have not been evaluated quantitatively and their mechanisms have not been widely investigated. In particular, it is unknown

whether the effects of these CHs act directly on the salivary glands or indirectly via neural or hormonal controls.

The present study examines whether these CHs have a direct effect on the salivary gland to increase salivary fluid secretion. Effective CHs can induce fluid secretion solely or accelerate fluid secretion by muscarinic agents such as carbachol. For this purpose, we used isolated and arterially perfused submandibular salivary glands from rats. The results provided us with quantitative data on how much CHs can accelerate salivary secretion.

## MATERIALS AND METHODS

### Materials

Granular extracts of the Chinese herbs (CHs): YZ, SH, SS, MD, TD, SD, XS, CS, GC, WM, HQ, Tzs, GG, DS, TR, ZJC, ZY, THF and CSJ were provided by Tian Jiang Pharmaceutical Co., Ltd., Jiang Yin, China. The preparations were in strict standard control according to the industry standards.

Just before each experiment, the extract equivalent to 10 g of each CH was dissolved in distilled water by ultrasonic wave concussion. After centrifugation at 5000 r/min for 10 min, the supernatant was collected and adjusted to 0.5 g/mL as the CH stock solution. Before use, the stock solution was diluted 100 times into the perfusate to obtain a final concentration of 5 g/L. Then, this CH-containing perfusate was filtered through a 0.22 µm pore size filter (Sterivex-GV, Millipore, MA, USA). The clinical dose of CH ranges from 10 to 50 g/person because the recipe is a mixture of several CHs (each CH dose is 5 g). For experimental convenience, we used an average dose of 25 g/animal for each experiment. Assuming that all CHs will move to the systemic circulation (5 L for 60 kg body weight), the concentration of CHs in the blood will be 5 g/L. We took this as the concentration of CH in the perfusion buffer.

DDQY has been proved effective in promoting saliva secretion. The ingredients of DDQY are as follows: *RenShen* 5 g, *ShengDi* 20 g, *FuLing* 10 g, *DanShen* 15 g, *MaiDong* 10 g. All the ingredients were added with 200 mL distilled water and were decocted twice for half an hour each time and the solution after each decoction was mixed and filtered. The final solution obtained was 96.7 mL. For convenience, we blended the solution with distilled water until the CH concentration of the stock solution was 0.5 g/mL. All the above ingredients were provided by JingQuan Group Chinese Traditional Medication Decoction Pieces Co., Ltd., AnHui, China.

Salts, glucose, carbamylcholine chloride (carbachol, CCh) were from Sigma, MO, USA. A fluorine-fiber tube (EXLONTM) was purchased from Iwase Co. Ltd. (Atsugi, Japan).

### Methods

Wistar rats were fed a standard pellet diet and water *ad libitum*. The rats were anesthetized with pentobarbitone sodium (50 mg/kg body weight, by intraperitoneal injection). The submandibular glands (120-180 mg) were surgically isolated as previously described<sup>[12]</sup> and the

attached sublingual gland was removed after ligation of the feeding arteries, draining vein and sublingual duct. The extralobular main duct from the submandibular gland was cannulated with a fluorine-fiber tube (0.3 mm × 0.5 mm O.D.) for sampling. The artery distal to the glandular branch was cannulated with a stainless steel catheter (26G) connected to the infusion line for perfusion. The vein from the gland was cut free. The gland was isolated and transferred to an organ bath (37°C), where the arterial catheter was connected to the perfusion apparatus. The drained venous effluent was continuously removed.

The glands were perfused arterially at a rate of 2 mL/min using a peristaltic pump (Cole-Palmer) to supply enough oxygen even without a specific oxygen carrier during the secretory period<sup>[12]</sup>. The perfusion fluid was a buffered salt solution of the following composition (mmol/L): Na<sup>+</sup>, 145; K<sup>+</sup>, 4.3; Ca<sup>2+</sup>, 1.0; Mg<sup>2+</sup>, 1.0; Cl<sup>-</sup>, 148.3; glucose, 5.0. This solution was buffered at pH 7.4 with 10 mmol/L HEPES. The solution was prepared from stock solutions for each experiment and placed in a reservoir where it was equilibrated with 100% oxygen at 37°C.

To measure fluid secretion rate, the ductal cannula was filled with perfusate buffer and the tip placed under the water surface in a cup on an electronic balance (minimum digit was 0.1 mg, Shimadzu AEG-220), avoiding any contact with the bottom of the cup. Then, when salivary secretion started, the cumulative secreted mass could be measured. Cumulative weight was automatically measured every 3 s and transferred to a computer. The rate of fluid secretion was calculated from time-differentiation of the cumulative volume of saliva assuming a saliva specific gravity of 1.0.

Following control perfusion for longer than 20 min, recording was started 5 min prior to the start of stimulation. Fluid secretion was induced by the addition of 0.2 μmol/L carbamylcholine (CCh) in the perfusate. Following control stimulation with CCh for 10 min, CCh was removed from the perfusion line by perfusion with control perfusate for 5 min. Then only the CH was added to the perfusion for 5 min. This was to observe the effect of only the CH. After CH perfusion for 5 min, CCh was overloaded at 0.2 μmol/L in the perfusion for 20 min. To observe the accelerative effect of the CH, the dose of CCh used was 0.2 μmol/L to induce a moderate fluid secretion (c.f. 1.0 μmol/L is a supramaximal dose). The digital noise was smoothed by taking the moving average of every 11 data sets.

### Statistical analysis

To reduce the variance among individual glands, the value of the flow rate was shown as mean ± SE. The statistical significance of the changes were assessed by double-tailed Student's *t*-test in a comparison between the control values (4.95–5 min) and the data sets obtained at 19.95–20 min, 24.95–25 min, 29.92–30 min and 34.95–35 min, along the time course. The induction of salivary secretion

by CH only was determined by a comparison between the data-sets at 9.95–10 min and 14.95–15 min. *P*-value < 0.1 were considered statistically significant.

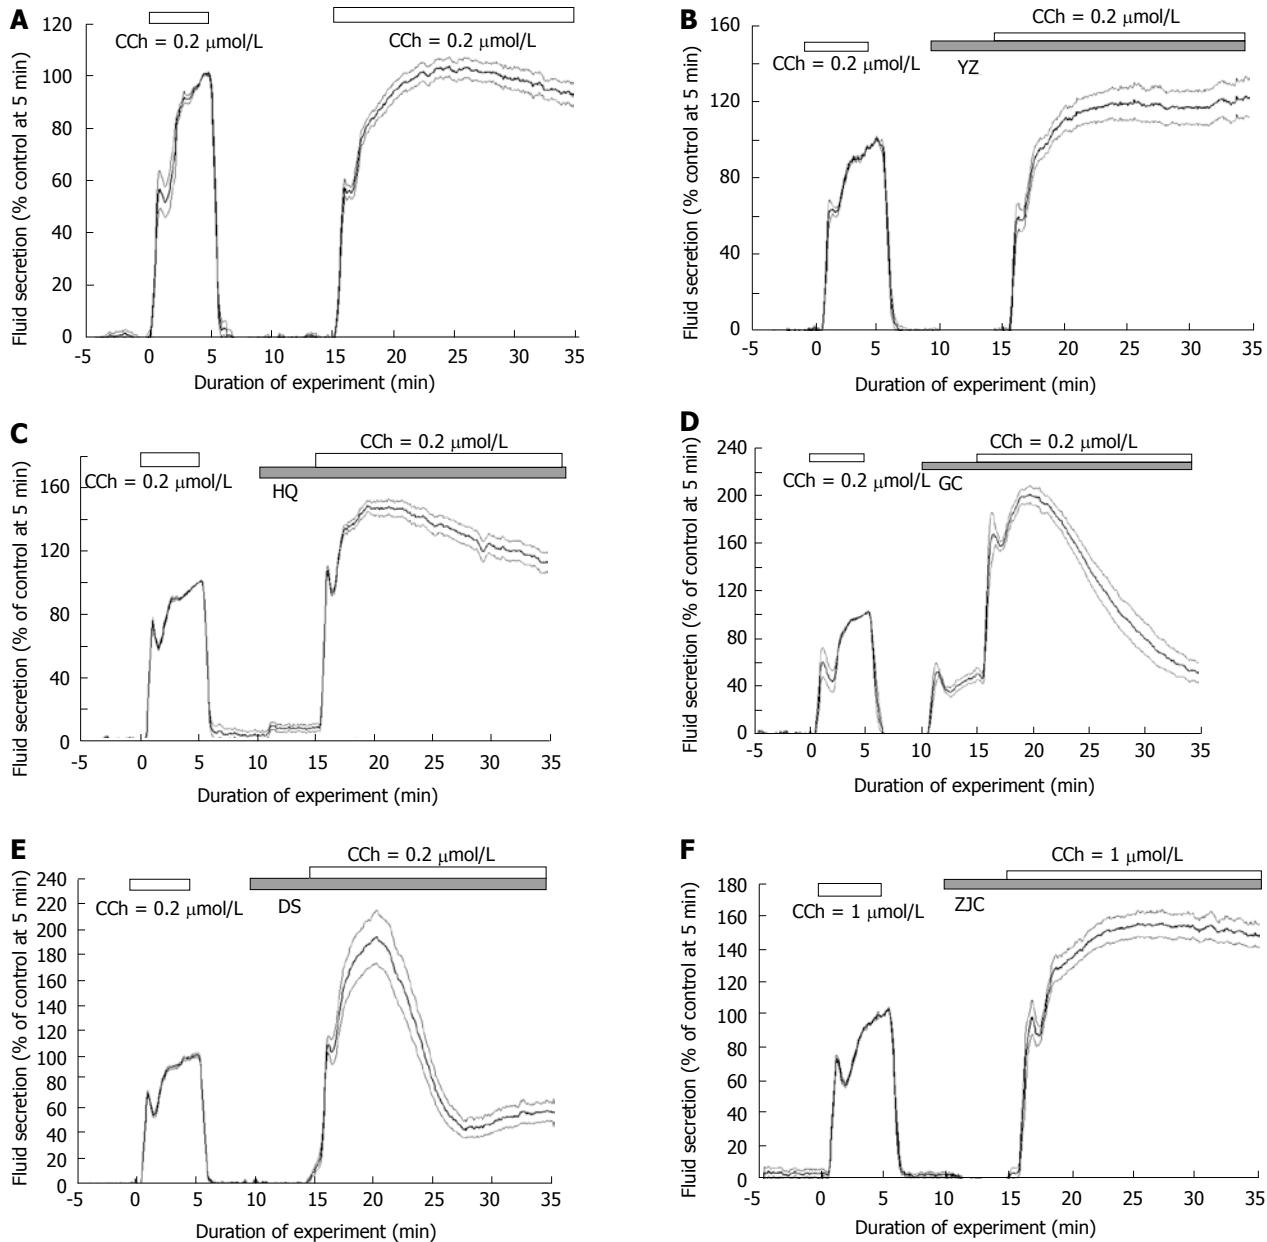

## RESULTS

### **Control stimulation with CCh**

The isolated perfused rat submandibular gland had almost no spontaneous fluid secretion. To standardize secretion in each gland, carbachol (CCh) stimulation was applied for 5 min. This initial phase included an initial transient increase and a pre-sustained stage of fluid secretion around 5 min from the start of CCh stimulation ( $71.4 \pm 8.5 \mu\text{L/g}$  per min). After washing with CCh for 5 min, CHs were applied for 5 min to check if the single application of the CH could induce fluid secretion. The period of 5 min allows the CHs and secretagogues to fully circulate in the gland. Because physiological neural reflex stimulation was applied to the gland under circulation of CH, we overloaded CCh on the CH circulated gland to determine the promotional effect of CH. Figure 1A shows the CCh-induced fluid secretion without addition of CHs. A single application of CCh showed a sustained plateau phase with a slight hump after the initial phase of secretion. For statistical examination of the promotional effect we compared how much the percentage of fluid secretion changed at 5, 10, 15 and 20 min from the start of the second CCh stimulation. The control stimulation of CCh showed no statistical difference to that of the 5-min value for the first stimulation (Figure 1A, *P* > 0.05).

### **Yin-nourishing agents**

YZ, SH, SS, MD and TD induced no secretion on single application (Figure 1B). Pre-loading of YZ did not increase the initial transient response to CCh (Figure 1B and Table 1). The initial transient peak ( $37.2 \pm 12.7 \mu\text{L/g}$  per min at 16.2 min, *n* = 6) and the maximal response ( $68.1 \pm 12.4 \mu\text{L/g}$  per min at 23.7 min) were similar to control values ( $36.9 \pm 7.0 \mu\text{L/g}$  per min at 1.1 min) and the value at 4.85 min ( $71.6 \pm 7.6 \mu\text{L/g}$  per min). Pre-loading of MD and TD increased the secretory response to CCh (Table 1). The initial transient peak ( $50.9 \pm 5.4 \mu\text{L/g}$  per min at 16.2 min, *n* = 6;  $41.4 \pm 6.0 \mu\text{L/g}$  per min at 17.55 min, *n* = 5) was higher than the control response to CCh ( $36.9 \pm 7.0 \mu\text{L/g}$  per min at 1.1 min;  $36.6 \pm 12.5 \mu\text{L/g}$  per min at 1.55 min), and the maximal response ( $82.2 \pm 6.1 \mu\text{L/g}$  per min at 23.05 min;  $73.2 \pm 3.6 \mu\text{L/g}$  per min at 27.2 min) was also higher than the control response to CCh ( $72.3 \pm 7.7 \mu\text{L/g}$  per min at 23.05 min;  $64.1 \pm 10.7 \mu\text{L/g}$  per min at 5.35 min). During CCh stimulation, fluid secretion was maintained at a higher level. On the other hand, pre-loading of SH did not change the responses to CCh. Pre-loading of SS decreased the responses to CCh (Table 1). The initial transient peak ( $25.3 \pm 5.8 \mu\text{L/g}$  per min at 16.4 min, *n* = 6) and the maximal response ( $43.8 \pm 5.3 \mu\text{L/g}$  per min at 27.35 min) were lower than the control value ( $45.4 \pm 6.1 \mu\text{L/g}$  per min at 1.1 min) and the value at 5.3 min ( $70.4 \pm 11.5 \mu\text{L/g}$  per min).

**Figure 1** Time course of fluid secretion during stimulation. A: 0.2  $\mu\text{mol/L}$  carbamylcholine (CCh); B: YZ + 0.2  $\mu\text{mol/L}$  CCh; C: HQ + 0.2  $\mu\text{mol/L}$  CCh; D: GC + 0.2  $\mu\text{mol/L}$  CCh; E: DS + 0.2  $\mu\text{mol/L}$  CCh; F: ZJC + 0.2  $\mu\text{mol/L}$  CCh. The values (%) were normalized by the value at 5 min from the first CCh stimulation (indicated by an open bar on the top of the graph). After washing the CCh for 5 min, Chinese herbs (CHs) were added in perfusion (indicated by a shaded bar). After another 5 min, the second CCh stimulation was added (an open bar, in Figure 1A without CH) to CHs perfusion. The second CCh stimulation was applied (open bar). The values for fluid secretion were statistically unchanged at 5, 10 and 15 min after the start of the second stimulation. The overall sustained phase was continuously raised. The average values (bold line,  $n=16$  from 8 glands in A;  $n=12$  from 8 glands in B;  $n=12$  from 6 glands in C;  $n=10$  from 5 glands in D;  $n=12$  from 6 glands in E;  $n=10$  from 5 glands in F) and the mean of standard error (mean  $\pm$  SE, thin line) are shown.  $n$ : The number of sampling points.

### Body fluid-regenerating agents

GG and WM did not induce secretion on a single application. Pre-loading of GG decreased the responses to CCh (Table 2). The initial transient peak ( $45.5 \pm 8.8 \mu\text{L/g}$  per min at 16.5 min,  $n=6$ ) was lower than the control initial transient peak ( $59.3 \pm 7.9 \mu\text{L/g}$  per min at 1.1 min). The maximal response ( $68.2 \pm 13.4 \mu\text{L/g}$  per min at 21 min) was also lower than the control response at 5 min ( $83.0 \pm 11.4 \mu\text{L/g}$  per min). After reaching a maximum, the flow rate was slowly decreased to  $52.9 \pm 16.0 \mu\text{L/g}$  per min at 35 min even during sustained stimulation. Thus, GG did not show a promotional effect on CCh-induced fluid secretion. Pre-loading of

WM increased the secretory response to CCh (Table 2). The initial transient peak ( $61.3 \pm 16.2 \mu\text{L/g}$  per min at 16.2 min,  $n=6$ ) was higher than the control response ( $53.9 \pm 16.1 \mu\text{L/g}$  per min at 1.1 min), and the maximal response ( $89.8 \pm 15.6 \mu\text{L/g}$  per min at 25.95 min) was also higher than the control response ( $72.3 \pm 7.7 \mu\text{L/g}$  per min at 5.4 min). During CCh stimulation, the fluid secretion was maintained at a higher level ( $83.2 \pm 10.2 \mu\text{L/g}$  per min at 35 min).

### Heat-clearing agents

SD, XS and CS did not induce secretion on a single application. Pre-loading of SD and XS decreased the

t-tests between the control and the values at a fixed time during addition of CH on CCh stimulation are shown <sup>b</sup>P < 0.1, <sup>a</sup>P < 0.05 vs FS at 4.95-5 min, <sup>c</sup>P < 0.05 vs FS at 9.95-10 min. GG: *Gegen*; WM: *Wumei*; SD: *Shengdihuang*; CS: *Chishao*.

responses to CCh (Table 2). The initial transient peak of SD ( $34.4 \pm 7.5 \mu\text{L}/\text{g}$  per min at 16.2 min, n = 5) and XS ( $42.9 \pm 7.9 \mu\text{L}/\text{g}$  per min at 16.2 min, n = 6) were similar to or lower than the control values ( $34.7 \pm 7.3 \mu\text{L}/\text{g}$  per min at 1.15 min;  $61.0 \pm 13.6 \mu\text{L}/\text{g}$  per min at 1.15 min), whereas the maximal response of both SD and XS ( $56.9 \pm 7.6 \mu\text{L}/\text{g}$  per min at 24.5 min;  $61.2 \pm 14.2 \mu\text{L}/\text{g}$  per min at 21.5 min) were lower than the control maximal value ( $72.3 \pm 7.7 \mu\text{L}/\text{g}$  per min at 5.1 min;  $81.0 \pm 15.2 \mu\text{L}/\text{g}$  per min at 5 min). The response gradually declined during stimulation. Thus, SD and XS did not show a promotional effect on CCh-induced fluid secretion. On the other hand, pre-loading of CS increased the secretory response to CCh (Table 2). The initial transient peak ( $57.9 \pm 7.4 \mu\text{L}/\text{g}$  per min at 17.2 min, n = 6) was higher than the control response ( $44.7 \pm 8.5 \mu\text{L}/\text{g}$  per min at 1.25 min), and the response increased  $86.0 \pm 8.7 \mu\text{L}/\text{g}$  per min at 20 min, which was also higher than the corresponding response to single stimulation with CCh ( $66.6 \pm 10.8 \mu\text{L}/\text{g}$  per min at 5 min). During CCh stimulation, fluid secretion continued to increase to the highest value,  $109.2 \pm 9.9 \mu\text{L}/\text{g}$  per min at 35 min.

### Qi-enhancing agents

HQ did not induce statistically significant fluid secretion (comparison between the values at 10 min and 12 min). Pre-loading of HQ enhanced the secretory response to

CCh (Figure 1C and Table 3). Both the initial transient peak ( $85.9 \pm 6.8 \mu\text{L}/\text{g}$  per min at 16 min, n = 6) and the maximal response ( $116.9 \pm 5.1 \mu\text{L}/\text{g}$  per min at 19.4 min) were higher than the control CCh stimulation ( $60.9 \pm 7.3 \mu\text{L}/\text{g}$  per min at 1 min and  $80.3 \pm 5.7 \mu\text{L}/\text{g}$  per min at 5.15 min, respectively). After reaching a maximum, fluid secretion declined slowly to a similar level to that of the control response (Figure 1C and Table 3). *Taizishen* (Tzs) did not induce secretion on a single application. Pre-loading of Tzs increased the secretory response to CCh (Table 3). Both the initial transient peak ( $71.1 \pm 16.2 \mu\text{L}/\text{g}$  per min at 17.25 min, n = 5) and the maximal response ( $104.9 \pm 13.7 \mu\text{L}/\text{g}$  per min at 24.05 min) were higher than the control CCh stimulation ( $43.5 \pm 6.3 \mu\text{L}/\text{g}$  per min at 1.2 min and  $72.2 \pm 7.8 \mu\text{L}/\text{g}$  per min at 5.05 min, respectively). After reaching a maximum, fluid secretion declined gradually. *Gancao* (GC) induced a significant secretion even on a single application (Figure 1D) with an initial transient peak ( $27.0 \pm 4.7 \mu\text{L}/\text{g}$  per min at 11.5 min, n = 5) and sustained secretion ( $25.6 \pm 4.6 \mu\text{L}/\text{g}$  per min at 15 min). Pre-loading of GC promoted the secretory response to CCh (Figure 1D and Table 3). Both the initial transient peak ( $85.1 \pm 13.2 \mu\text{L}/\text{g}$  per min at 16.65 min) and the maximal response ( $102.3 \pm 14.4 \mu\text{L}/\text{g}$  per min at 19.4 min) were higher than the control CCh stimulation ( $39.0 \pm 3.5 \mu\text{L}/\text{g}$  per min at 1.15 min and  $62.6 \pm 7.8 \mu\text{L}/\text{g}$  per min at 5.15 min, respectively). After fluid secretion increased to reach a value double the level of stimulation without GC,

The control and the values at a fixed time during addition of CH on CCh stimulation are shown <sup>b</sup>P < 0.1, <sup>a</sup>P < 0.05 vs FS at 4.95-5 min. ZJC: Zaojoci; ZY: Zi-yuan; TR: Taoren; CSJ: Chuanshanjia.

secretion then declined gradually to half the maximal value (24.0 ± 5.3 μL/g per min at 35 min).

### Blood-activating agents

DS induced significant secretion even on a single application (Figure 1E) with a long delay of 3-4 min (8.0 ± 2.9 μL/g per min at 15 min, n = 6) and then increased markedly to a maximum and thereafter declined (data are not shown, as the overload of CCh was started at 15 min in the present series of experiments). Pre-loading of DS promoted the secretory response to CCh (Figure 1E and Table 3). Both the initial transient peak (76.2 ± 11.5 μL/g per min at 16.05 min) and the maximal response (124.0 ± 17.5 μL/g per min at 19.3 min) were higher than the control CCh stimulation (52.1 ± 10.0 μL/g per min at 1.05 min, 72.3 ± 12.6 μL/g per min at 5.15 min) as shown in Figure 1E. Fluid secretion then increased to reach a value double the level of stimulation without DS, and declined gradually to half this value (36.6 ± 6.1 μL/g per min at 35 min).

### Phlegm-resolving agents

ZJC did not induce secretion on a single application (Figure 1F). Pre-loading of ZJC increased the secretory response to CCh (Figure 1F, Table 4). The initial transient peak (60.9 ± 7.1 μL/g per min at 16.8 min, n = 5) and the maximal response (99.1 ± 11.8 μL/g per min at 25.3 min) were higher than the control CCh stimulation (45.2 ± 7.0 μL/g per min at 1.2 min, 65.8 ± 12.5 μL/g per min at 5.25 min) as shown in Figure 1F. Fluid secretion tended to decline gradually (93.9 ± 11.8 μL/g per min at

35 min) during stimulation. THF and ZY did not induce secretion on a single application. Pre-loading of THF and ZY (Table 4) increased the secretory response to CCh. The initial transient peak (45.1 ± 9.8 μL/g per min at 16.25 min n = 6; 55.7 ± 11.0 μL/g per min at 16.55 min, n = 6) were higher than the control CCh stimulation (43.3 ± 13.2 μL/g per min at 1.15 min, 45.3 ± 9.3 μL/g per min at 1.2 min); the maximal response (77.0 ± 11.0 μL/g per min at 26.3 min; 86.9 ± 9.7 μL/g per min at 28.95 min) was also higher than the control CCh stimulation (65.4 ± 15.4 μL/g per min at 5.15 min, 63.9 ± 10.6 μL/g per min at 5.3 min). Fluid secretion tended to decline gradually (73.2 ± 10.0 μL/g per min at 35 min; 80.5 ± 8.0 μL/g per min at 35 min) during stimulation.

### Body mass-softening and resolving agents

TR and CSJ did not induce secretion on a single application. Pre-loading of TR increased the secretory response to CCh (Table 4). The initial transient peak (47.6 ± 8.6 μL/g per min at 16.4 min, n = 5) was higher than the control CCh stimulation (43.5 ± 6.3 μL/g per min at 1.1 min). However, the maximal response (66.1 ± 8.6 μL/g per min at 1.1 min) was similar to the control CCh stimulation (71.8 ± 7.6 μL/g per min at 5.25 min). Fluid secretion was sustained at the same level during stimulation. Pre-loading of CSJ did not increase the secretory response to CCh (Table 4). The initial transient peak (38.3 ± 8.6 μL/g per min at 16.65 min, n = 5) was similar to the control response (39.0 ± 3.5 μL/g per min at 16.65 min), and the maximal response (53.3 ± 12.7 μL/g per min at 25.75 min) was lower than the control response (71.8 ± 7.4 μL/g per min at 5.2 min). Because the

control values for fluid secretion in response to CCh were lower in the series using CSJ, the percentage change ( $118.8 \pm 8.0\%$  at 25 min) showed promotion by CSJ (Table 4).

### **Herb mixture**

DDQY did not induce secretion on a single application. Pre-loading of DDQY increased the secretory response to CCh. The initial transient peak ( $40.9 \pm 9.8 \mu\text{L/g}$  per min at 16.35 min,  $n = 5$ ) and the maximal response ( $78.0 \pm 7.9 \mu\text{L/g}$  per min at 27.45 min) were higher than the control CCh stimulation ( $25.9 \pm 4.7 \mu\text{L/g}$  per min at 1.45 min,  $51.3 \pm 8.7 \mu\text{L/g}$  per min at 5.25 min). Fluid secretion tended to decline gradually ( $74.2 \pm 4.7 \mu\text{L/g}$  per min at 35 min) during stimulation.

## **DISCUSSION**

### **Selection of CHs which possibly increase salivary fluid secretion**

Disorders of salivary secretion are the result of various causes and mechanisms in modern medicine, while in TCM, saliva is a body fluid and its deficiency is related to the deficiency of *Yin*-fluid, the vigor of internal heat and the dysfunctional distribution of *Yin*-fluid. TCM regards the body as a whole, and holds that the normal secretion of saliva needs the generational effect of *Qi* as well as its promotional effect. Once there is dysfunctional secretion of body fluid, the oral cavity cannot be moistened, and new pathologic features such as phlegm and excessive fluid will occur, leading to stagnation, which incurs another secondary injury which we call internal block (e.g. blood stasis),

In the treatment of secretion disorders, Body fluid-regenerating, *Yin*-nourishing, and Heat-clearing agents are commonly used and are reported in the literature<sup>[9,10]</sup>. *Qi*-enhancing agents are often prescribed simultaneously<sup>[8]</sup>. In chronic patients with a long disease course, Blood-activating agents are usually used, and sometimes even stasis-resolving<sup>[17,18]</sup>, hard mass-softening and block-dispelling agents<sup>[19,23]</sup>. In conclusion, the therapeutic concept of TCM is to identify suitable herbs which can resolve the pathologic status of patients so as to reach a new balance, which is called Syndrome Differentiation and Treatment.

### **Classification of responses**

It is interesting to find in our experiments that the promotional patterns of CH on secretion were classified into four patterns, which were eventually related to the categories of CH: overall sustained phase was continuously raised (*Yin*-nourishing, fluid production-promoting and heat-clearing agents). Although they belong to different CH types, they are closely correlated in the TCM theory, that is, *Yin*-nourishing and fluid production-promoting agents are similar in function, while heat-clearing agents can reserve body fluid which is reduced by internal heat; Sustained secretion rose to reach a maximum then decreased, this pattern was observed in HQ and TZS. These are *Qi*-enhancing agents; Sustained secretion rose to reach the highest

maximum then was sustained with a slight decline (swelling-reducing, phlegm-resolving and pus-expelling agents). These 3 types of herbs have one thing in common, in that they all aim to dispel pathologic features inside the body. It is possible that they may have a similar promotional pattern; Stimulation of salivary secretion without any added stimulants. The addition of CCh promoted fluid secretion to reach the highest maximum then inhibited secretion to a lower sustained level (blood activating agent DS and GC). GC, a *Qi*-enhancing herb, is usually used as a conciliatory agent, and is quite different from the common *Qi*-enhancing agents such as HQ.

The present findings at an organ level lead to the conclusion that various CHs have different promotional mechanisms and target sites. There are scientific essences in the TCM theory and its herb classifications, however further investigations are needed, including dose-dependency of the promotional pattern of each CH.

### **CHs which did not show potential in promoting salivary fluid secretion**

The isolated and arterially perfused salivary gland can induce fluid secretion either by neural stimulation and/or by arterial application of secretagogues. If there is no stimulation then no secretion occurs. In the present study, SH, XS, GG, SS, and DH did not show any potential in promoting fluid secretion in the salivary gland. This suggests no salivary promotional effects directly on the salivary glands by SH, XS, GG, SS, and DH. However, we have to examine the dose-response of these CHs, then we might expect to see that these CHs have indirect effects on the neural system and/or hormonal system, and indirectly affect salivary fluid secretion.

### **Possible mechanisms for the promotion of salivary fluid secretion by CHs**

Fluid secretion by salivary glands has been recognized as the transcellular movement of electrolyte/water at secretory endpiece cells (or acinar cells). Recently, the paracellular component of fluid secretion was also taken into account. The initial fluid secretion in response to CCh is estimated mainly due to transcellular fluid movement, whereas 60%-70% of fluid secretion is due to the paracellular component during the sustained stimulation period 1 min after the start of stimulation<sup>[27]</sup>. The initial transient peak of fluid secretion is thought to be due mainly to transcellular fluid secretion. Whereas, fluid secretion during the sustained phase depends both on transcellular and paracellular components.

One possible mechanism for the promotion through transcellular movement is activation of receptors to increase cytosolic  $\text{Ca}^{2+}$  which is mobilized from  $\text{Ca}^{2+}$  store/ $\text{Ca}^{2+}$  entry. In addition, the activation of transporters for  $\text{Cl}^-$  entry is possible.  $\text{Cl}^-$  channels allow  $\text{Cl}^-$  release across luminal membrane, and the activation of  $\text{Na}^+/\text{K}^+$  ATPase can increase  $\text{Na}^+$ -coupled  $\text{Cl}^-$  entry. The activation of unknown receptors can also play a role in these possible mechanisms.

In paracellular mechanisms, opening of junctional complexes is possible. In addition, increases in unknown

driving forces related to paracellular fluid transport needs further study.

Research to clarify the mechanisms of promotion is tightly linked to the search for control points of fluid secretion mechanisms. We could check cytosolic  $\text{Ca}^{2+}$  and  $\text{Na}^+$ -coupled  $\text{Cl}^-$ -entry in transcellular mechanisms by measuring the ouabain sensitive component of oxygen consumption. We could also determine the junctional complexes in paracellular mechanisms by measuring the secretion of fluorescent dye which cannot enter the cell. These possible mechanisms require further study.

## COMMENTS

### Background

Xerostomia (dry mouth) is caused by salivary hypofunction (reduction in salivary fluid secretion). Traditional Chinese Medicine (TCM) has been used in the treatment of xerostomia. The aim of the present study was to determine if Chinese herbs (CHs) had a direct effect on the salivary gland to increase salivary fluid secretion.

### Research frontiers

The present therapeutic procedures for xerostomia are limited and include the supplemental use of artificial saliva and the use of stimulants. TCM is an effective therapy with few side effects. However, there is little research on the effects of CHs on salivary secretion. Our study aims to identify the effects of CHs on salivary secretion.

### Innovations and breakthroughs

By combining our previous findings with reports by other herbalist doctors, we chose twenty herbs and used isolated and arterially perfused rat submandibular salivary glands to examine if CHs had direct effects on the salivary gland to increase salivary fluid secretion. The results provided us with quantitative data how much CHs could accelerate salivary secretion.

### Applications

The quantitative results of this study showed how much CHs could accelerate salivary secretion. This information could possibly provide a theoretical guide for choosing herbs to relieve xerostomia in TCM practices.

### Peer review

The manuscript by Murakami et al, describes the results of studies on the effect of several types of traditional Chinese herb remedies, commonly used to relieve the effects of dry mouth disease (xerostomia), on salivary fluid secretion in the perfused rat submandibular salivary gland. It has some merits as it addresses the problem of xerostomia, a condition affecting quite a large segment of the world population including millions of elderly women.

### Abstract

**AIM:** To study the levels of serum soluble intercellular adhesion molecule-1 (sICAM-1), plasma D-lactate and diamine oxidase (DAO) in patients with inflammatory bowel disease (IBD), and the potential clinical significance.

**METHODS:** Sixty-nine patients with IBD and 30 healthy controls were included in this study. The concentration of sICAM-1 was detected with enzyme-linked immunosorbent assay, the level of D-lactate and DAO was measured by spectroscopic analysis, and the number of white blood cells (WBC) was determined by routine procedure.

**RESULTS:** The levels of sICAM-1, DAO, and WBC in IBD patients were significantly higher than those in the control group ( $P < 0.01$ ). sICAM-1 in IBD patients was found to be closely related to the levels of DAO and D-lactate ( $212.94 \pm 69.89$  vs  $6.35 \pm 2.35$ ,  $P = 0.000$ ), DAO  $212.94 \pm 69.89$  vs  $8.65 \pm 3.54$ ,  $P = 0.000$ ) and WBC ( $212.94 \pm 69.89$  vs  $7.40 \pm 2.61$ ,  $P = 0.000$ ), but no significant difference was observed between patients with ulcerative colitis and patients with Crohn's disease. The post-treatment levels of sICAM-1, D-lactate and WBC were significantly lower than before treatment

(sICAM-1  $206.57 \pm 79.21$  vs  $146.21 \pm 64.43$ ,  $P = 0.000$ ), (D-lactate  $1.46 \pm 0.94$  vs  $0.52 \pm 0.32$ ,  $P = 0.000$ ) and (WBC  $7.24 \pm 0.233$  vs  $5.21 \pm 3.21$ ,  $P = 0.000$ ).

**CONCLUSION:** sICAM-1, D-lactate and DAO are closely related to the specific conditions of IBD, and thus could be used as a major diagnostic index.

### INTRODUCTION

The barrier function of the intestinal mucosa is of vital importance in inflammatory bowel diseases (IBD). Analysis of this function provides an important basis in the diagnosis of intestinal mucosal barrier dysfunction. Therefore, the importance of a timely, correct assessment of intestinal mucosal barrier function cannot be overestimated in judging the patient's disease state, estimating the prognosis and determining a comprehensive treatment program. However, direct observation of the intestinal barrier function involves many difficulties, so observation mostly needs to be made indirectly.

D-lactate, a metabolic end product of gastrointestinal bacteria, can be produced by many of these bacteria. As mammals do not have an enzyme system capable of its decomposition, D-lactate will enter the blood when the intestinal barrier function is damaged, and as they do

not have D-lactate dehydrogenase, a rise in the level of D-lactate can be detected when the permeability of the intestinal mucosa is increased. Therefore, examination of peripheral blood can reveal the degree of damage of the intestinal mucosa and the change in its permeability<sup>[1]</sup>. Diamine oxidase (DAO) is a highly active intracellular enzyme in the cytoplasm of the upper chorial cells of the intestinal mucosa. In cases where the intestinal mucosal epithelial cells and barrier function are damaged, the release of DAO is increased, and DAO enters the extracellular space, lymphatic vessels and bloodstream, thus increasing the level of DAO in the plasma. As the activity of DAO is stable, its concentration in the blood can reflect the damage and restoration of the intestinal cavity<sup>[2]</sup>.

Overactivation of leukocytes is an important pathological process of IBD. The stagnation and infiltrative exosmosis of leukocytes depend on the expression and function of the intracellular adhesion molecules (ICAMs) of leukocytes and endotheliocytes at the inflammatory location.

ICAMs are a type of glycoprotein synthesized by cells and assembled on the cell surface or secreted to the cell epimatrix, and can promote the adhesion between cells or between cells and the epimatrix. The role of ICAM-1, belonging to the immunoglobulin superfamily, in the development of IBD, has been receiving more and more attention in recent years. The ICAM-1 of normal tissues is usually expressed at low levels in vascular endothelial cells, and in mononuclear macrophagocytes in the intestinal mucosal lamina propria and lymph. In the intestinal tissues of patients with IBD, the expression and distribution of ICAM-1 is significantly increased and is closely related to the degree of inflammation of the tissues<sup>[3]</sup>. The adhesive molecules in vascular endothelial cells, leukocytes or other cells can be swallowed into the cells, or peel off into the blood circulation, becoming soluble intercellular adhesion molecule-1 (sICAM-1). The post-translation product of the mRNA of some cells, are possibly not expressed on the cellular surface, but are directly secreted into the blood and is thus another important source of sICAM-1<sup>[4,5]</sup>. The increase in sICAM-1 in the serum is a marker of the damage or activation of endotheliocytes. Therefore, the level of the sICAM-1 in the serum is a significant index in the detection of some diseases<sup>[6,7]</sup>.

In this research, sICAM-1, D-lactate and DAO of 69 patients with IBD were measured quantitatively with the objective of assessing their changes and clinical significance.

## MATERIALS AND METHODS

### Materials

**Subjects:** Test group including 69 patients, aged 18-60 years, with IBD hospitalized in our department [41 cases of ulcerative colitis (UC), 27 males and 13 females; 19 cases of Crohn's disease (CD), 11 males and eight females]. All patients were diagnosed by enteroscopy and were given the standard treatment set by the National

Symposium on IBD, 2000 for 15 d before reassessment. Thirty healthy blood donors are used as control group.

**Reagents and apparatus:** Human serum sICAM-1 enzyme-linked immunosorbent assay (ELISA) kit (purchased from Boehringer Mannheim, Germany); D-lactate standard solution and D-lactic acid dehydrogenase, O-dianisidine, cadaverine dihydrochloride, horseradish peroxidase and DAO standard solution (all purchased from Sigma). The following analytical reagents were prepared in the laboratory: methotrexate injection (purchased from Zhejiang Wanma Pharmaceutical Ltd.); sulfasalazine tablets (purchased from Shanghai Sanwei Pharmaceutical Ltd.); superoxide dismutase and myeloperoxidase kit (purchased from Nanjing Jiancheng Biological Institute).

**Major analysis apparatus:** 721 spectrophotometer (Shanghai Sophisticated Scientific Instruments Ltd.).

### Methods

A 3 mL sample of venous blood was collected from each subject of the test and control groups. After the sample was injected into dry test tubes and the serum was separated centrifugally, the serum was stored at -20°C for examination.

The level of sICAM-1 in the serum was detected with an ELISA, the plasma level of D-lactate was determined, after the plasma was deproteinized with perchloric acid, using enzyme-coupled UV-spectrophotometry<sup>[8]</sup>; the serum DAO was determined by spectrophotometry as by Luk *et al*<sup>[2]</sup>; the number of white blood cells (WBC) was detected routinely.

### Statistical analysis

All the data are presented as mean ± SD. Statistical methods used included the *t*-test, analysis of variance and linear correlation analysis. Statistical software SPSS (version 10.0) was employed for data analysis.

## RESULTS

### Comparison between the test group and the control group

As is shown in Table 1, the levels of sICAM-1 (206.57 ± 79.21 vs 107.25 ± 52.41), D-lactate (1.46 ± 0.94 vs 0.82 ± 0.47), DAO (9.91 ± 5.64 vs 2.04 ± 0.95), and WBC (7.24 ± 2.33 vs 4.82 ± 1.46) in IBD patients were significantly higher than those of the control group (*P* < 0.01).

### Comparison of WBC, sICAM-1, DAO and D-lactate between the 49 UC cases of UC and 19 CD cases

As is shown in Table 2, no distinct difference was demonstrated in the levels of all four substances in the UC group and CD group (*P* > 0.05). Analysis of the levels of WBC, sICAM-1, DAO and D-lactate of the test group demonstrated that sICAM-1 was related to the levels of DAO, with the correlation coefficient being 0.321 and *P* < 0.01, and also to the level of D-lactate, with the correlation coefficient being 0.412, and *P* < 0.01.

**Table 1 Comparison of the values of WBC, serum sICAM-1, DAO and plasma D-lactate between the test IBD group and control group (mean  $\pm$  SD)**

Group	n	WBC ( $\times 10^9/L$ )	sICAM-1 (ng/mL)	DAO (U/mL)	D-lactate ( $\mu\text{g/mL}$ )
Test	69	7.24 $\pm$ 2.33	206.57 $\pm$ 79.21 <sup>a</sup>	9.91 $\pm$ 5.64 <sup>a</sup>	1.46 $\pm$ 0.94 <sup>a</sup>

Post-treatment	5.21 $\pm$ 3.21	146.21 $\pm$ 64.43 <sup>a</sup>	6.42 $\pm$ 2.18 <sup>a</sup>	0.52 $\pm$ 0.32 <sup>a</sup>

<sup>a</sup>P < 0.01 vs pre-treatment.

### Comparison of WBC, sICAM-1, DAO and D-lactate of the test group before and after treatment

The levels of WBC, sICAM-1, DAO and D-lactate of the test group were examined after the subjects were treated and the IBD was shown to be improved substantially by clinical symptoms and enteroscopy. As is shown in Table 3, the post-treatment levels of sICAM-1 (206.57  $\pm$  79.21 vs 146.21  $\pm$  64.43), D-lactate (1.46  $\pm$  0.94 vs 0.52  $\pm$  0.32), DAO (9.91  $\pm$  5.64 vs 6.42  $\pm$  2.18) and WBC (7.24  $\pm$  2.33 vs 5.21  $\pm$  3.21) were significantly lower than before treatment (P < 0.01).

## DISCUSSION

In case of an acute attack of IBD, the structure and function of the intestinal mucosa of the patient can be seriously damaged, resulting in intestinal barrier dysfunction and thus release of intestinal bacteria, and may even induce multi-organ failure thus endangering life.

Presently, whether IBD is active is comprehensively judged primarily from clinical symptoms, erythrocyte sedimentation rate, C-reactive protein, endoscopic observations and pathology. This method can, in most cases, determine the activity of IBD quite accurately. However, for a small number of patients, those with the disease in the early stage and those with recurrence of the disease, the biochemical features are not conspicuous enough and endoscopic examination fails to display the acute activity of IBD, thus missing the opportunity of treatment because of the lack of a timely diagnosis; therefore, working out a set of monitoring indexes which are more

sensitive is of substantial importance to clinical work.

The permeability of the intestinal mucosa has been used for the assessment of the development and prognosis of some diseases, such as CD, UC, etc. The prospective research by Tibble *et al*<sup>[9]</sup> showed that 12 mo's duration of the alteration in intestinal mucosal permeability worsens the disease, with the sensitivity and specificity being 84% and 61%, respectively. In addition, this index can also be used in prediction of the recurrence of the disease. The multi-parameter regression analysis of 47 cases of intensive care patients<sup>[9,10]</sup> demonstrated that the intestinal mucosal permeability is the only index which can predict the development of multi-organ function failure syndrome in critical patients.

Injury is a process of inflammation, during which the adhesion of leukocytes and the damage to intestinal endothelial cells will increase the level of DAO and D-lactate. In this study, the serum DAO and D-lactate of the 69 patients with IBD before treatment were higher than those of the control group (P < 0.01), but no distinct difference was observed between the UC group and the CD group. The levels of DAO and D-lactate after treatment saw a marked decline. This offers proof to the fact that the levels of DAO and D-lactate, which reflect the changes in the disease condition, increase with activity of IBD but decline when the damage to the intestinal mucosa is restored after treatment.

Sans *et al*<sup>[11]</sup> found that sICAM-1 increased in the inflammatory intestinal mucosa of patients with IBD and was related to the concentration of sICAM-1 in the blood. The research by Mack *et al*<sup>[12]</sup> revealed that when

the expression of endotheliocyte ICAM-1 was lowered, the interaction between endotheliocytes and leukocytes weakened, thus alleviating the inflammatory activity. Taniguchi *et al*<sup>[13]</sup> relieved the symptoms of colitis induced by dextran sulphate sodium by adopting preventive treatment using anti-ICAM-1 monoclonal antibody.

In our research, it was found that the content of DAO and D-lactate of IBD patients were markedly higher than those of the control group, showing that damage to a certain degree existed in the intestinal mucosa of IBD patients in the acute stage ( $P < 0.01$ ), and the permeability increased. In addition, the post-treatment content of both DAO and D-lactate decreased, indicating that the permeability had somewhat improved.

It was also demonstrated in the research that the IBD patients' leukocyte number and sICAM-1 level before treatment were markedly higher than those of the control group ( $P < 0.01$ ) but markedly declined after treatment ( $P < 0.01$ ). This testified to the fact that the sICAM-1 level was obviously related to the condition of the disease. The research on anti-intracellular adhesion molecule monoclonal antibody in the treatment of IBD also pointed to the role of sICAM-1 in IBD.

To sum up, the tissue damage caused by the adhesion between leukocytes and endotheliocytes is one of the common pathologies in IBD produced by bacteria and cytokines. As high expression of sICAM-1 is the important molecular basis for the increase of the adhesion between leukocytes and endotheliocytes, blocking this adhesion has become an effective preventive and therapeutic method; therefore, sICAM-1, DAO and D-lactate in the serum can be utilized as important monitoring indexes in the treatment of IBD, and sICAM-1 may be a promising molecular indicator of the activity of IBD.

## COMMENTS

### Background

The barrier function of the intestinal mucosa is of vital importance in inflammatory bowel diseases (IBD). Detection of this function provides an important basis in the diagnosis of intestinal mucosal barrier dysfunction.

### Research frontiers

The importance of a timely correct assessment of the intestinal mucosal barrier function cannot be overestimated in judging the patient's disease state, estimating the prognosis and determining a comprehensive treatment program. However, direct observation of the intestinal barrier function involves many difficulties, so the observation mostly needs to be made indirectly.

### Innovations and breakthroughs

Presently, whether IBD is active is comprehensively judged primarily from clinical symptoms, erythrocyte sedimentation rate, C-reactive protein, endoscopic observations and pathology. This method can, in most cases, determine the activity of IBD quite accurately. However, for a small number of patients, those with the disease in the early stage and those with recurrence of the disease, the biochemical features are not conspicuous enough and endoscopic examination will fail to display the acute activity of IBD, thus missing the opportunity of treatment because of the lack of a timely diagnosis; therefore, determination of a set of monitoring indexes which are more sensitive is of substantial importance to clinical work.

### Applications

Serum soluble intercellular adhesion molecule-1 (sICAM-1), plasma D-lactate and diamine oxidase can be used as very important diagnostic indices, and sICAM-1 may be a useful molecular marker of the activity of IBD.

### Peer review

In this manuscript, Song *et al* report that serum levels of sICAM-1, D-lactate, and diamine oxidase are increased in IBD patients. Although the sample numbers tested seem to be relatively low, I feel that this manuscript contains potentially attractive data that would be of benefit to both clinical and basic scientific fields of IBD.

excluded from the study. The colonoscopy attendance rate was 23.04% (428/1858) during the first 12 mo without intervention, and 37.69% (539/1430) during the second 12 mo with intervention ( $P < 0.001$ ). Logistic regression analysis showed that the intervention was more effective among subjects with only objective barriers (OR: 34.590, 95% CI: 23.204-51.563) or subjects with some specific high-risk characteristics: first-degree relatives diagnosed with CRC (OR: 1.778, 95% CI: 1.010-3.131), personal history of intestinal polyps (OR: 3.815, 95% CI: 1.994-7.300) and positive result for immunochemical fecal occult blood testing (OR: 2.718, 95% CI: 1.479-4.996).

**CONCLUSION:** The barrier-focused telephone or on-site consultation intervention appears to be a feasible means to improve colonoscopy attendance among nonadherent high-risk subjects for CRC screening in China.

### Abstract

**AIM:** To increase attendance for colonoscopy among nonadherent high-risk individuals for colorectal cancer (CRC) screening in China.

**METHODS:** During the first 12 mo without intervention, only 428 of the 2398 high-risk subjects attended a scheduled colonoscopy examination. The 1970 subjects who did not attend for CRC screening were enrolled in the present study. Prior barrier investigation was performed to ascertain the reasons for nonadherence. A barrier-focused intervention program was then established and implemented among eligible nonadherent subjects by telephone interviews and on-site consultations. The completion rates of colonoscopy during the first 12 mo without intervention and the second 12 mo with intervention were compared. Variations in the effect of the intervention on some high-risk factors and barrier characteristics were analyzed using logistic regression.

**RESULTS:** 540 subjects who were not eligible were

### INTRODUCTION

In 2002, colorectal cancer (CRC) was the fourth most common cancer diagnosed worldwide in men and the third in women, over 1 000 000 new cases were diagnosed, and more than 500 000 deaths resulted<sup>[1]</sup>. CRC screening can reduce mortality and incidence<sup>[2-5]</sup>. Data from 1991 to 2004 for the United States show that advances in prevention, early detection, and treatment of cancer have resulted in an approximately 14% decrease

in overall cancer mortality, with remarkable declines for lung, colorectal, breast and prostate cancer<sup>[6]</sup>. This evidence demonstrates that changes in lifestyle and/or cancer screening have been responsible for the decline in cancer mortality and incidence. The data from Chinese CRC screening practice have also shown decreased mortality and incidence rate in Jiashan and Haining<sup>[7,8]</sup>. A two-step screening method has been recommended for community-based CRC screening in China: immunochemical fecal occult blood testing (iFOBT) and investigation by questionnaire of high-risk factors, followed by colonoscopy examination.

Although attendance rate for colonoscopy examination is crucial to the screening effect, it has remained disappointing in our urban CRC screening. Low attendance for CRC screening has also been found in other urban areas in China<sup>[9]</sup>. Therefore, it is necessary to establish effective CRC screening intervention methods to increase attendance. The reasons for low attendance<sup>[10-16]</sup> can be categorized into subjective or objective barriers. In this study, we evaluated the effects of a barrier-focused intervention program on colonoscopy attendance among nonadherent high-risk subjects undergoing community-based CRC screening in an urban area.

## MATERIALS AND METHODS

### **CRC screening protocol in China**

The protocol for CRC mass screening in China is as follows<sup>[17]</sup>. Primary screening: subjects aged 40-74 years, who are positive for one or more of the following items are considered to be at high-risk for CRC: (1) immunochemical fecal occult blood testing (iFOBT); (2) first-degree relatives (FDRs) with CRC; (3) personal history of cancer or colorectal polyps; (4) two or more of the following items: (I) chronic diarrhea; (II) chronic constipation; (III) mucous and bloody stools; (IV) personal history of appendicitis or appendectomy; (V) personal history of chronic cholecystitis or cholecystectomy<sup>[18]</sup>; (VI) history of psychiatric trauma (e.g. divorce or death of relatives). Secondary screening: subjects who are considered to be at high risk for CRC should undergo colonoscopy examination.

### **Enrollment**

From the end of July 2006, we conducted population-based CRC screening according to Chinese screening guidelines in Xiacheng District, Hangzhou, China. All participants provided written informed consent. The 2398 subjects who were positive for the questionnaire and/or iFOBT were regarded as the high-risk population and were invited to follow-up colonoscopy. Only 428 (17.85%) high-risk subjects had attended a scheduled colonoscopy examination by the end of July 2007. The remained 1970 nonadherent high-risk subjects who did not attend colonoscopy examination were enrolled as the target population for our intervention. The cost of screening and intervention were supported by our research funding.

**Table 1 Main barriers to colonoscopy among high-risk subjects (*n* = 407)**

Barriers	<i>n</i> (%)
Subjective barriers	
"I am not at risk for CRC": no symptoms	185 (45.45)
Fear of finding cancer and subsequent surgery	10 (2.46)
Fear of some complications related to colonoscopy	9 (2.21)
Other personal health concerns <sup>1</sup>	9 (2.21)
Embarrassment	2 (0.49)
Total	215 (52.83)
Objective barriers	
Intolerance of pain or discomfort	112 (27.52)
Busy on working days	50 (12.29)
Intolerance of bowel preparation or diet control	14 (3.44)
Inconvenience and complexity of colonoscopy procedure	14 (3.44)
Transportation problems	2 (0.49)
Total	192 (47.17)

<sup>1</sup>Subjects preferred to focus on current health problems, such as diabetes, and fractures. CRC: Colorectal cancer.

### **Barrier investigation**

To obtain in-depth information about the reasons for nonadherence, we selected 500 subjects from the target population and conducted questionnaire surveys by telephone or on-site interviews about the barriers to adherence. The questionnaires contained some acknowledged barrier options. Barriers were classified as subjective or objective. Only the most influential barrier was recorded. Four hundred and seven valid questionnaires were obtained. Table 1 lists the main barriers among high-risk nonadherent subjects.

### **Population classification**

We planned to classify the target population into three groups for later evaluation of intervention effects. (1) Subjects with one or more subjective barriers (such as "I am not at risk for CRC"), with or without objective barriers. At least, the subjective barriers prevented them from attending colonoscopy examination. (2) Subjects with one or more objective barriers (such as intolerance of pain), without subjective barriers. They recognized the screening benefits but the objective barriers prevented them attending. (3) Subjects who simply forgot about or missed their colonoscopy examination. They were prepared to undergo colonoscopy.

### **Establishment and implementation of intervention**

Based on the results of barrier investigation, a barrier-focused intervention program was established. The program included general and special measures. The general measures were performed among all eligible subjects and the special measures were performed selectively on each subject according to his/her specific barriers (Table 2). For subjects with subjective barriers, an explanation and education were used. For subjects with only objective barriers, the aim was mainly to adopt definite goals to improve objective conditions. For subjects without barriers, only general measures were used.

The intervention program was started at the end

**Table 2** Barrier-focused intervention program

Barriers	Special measures	General measures
Subjective barriers	Explanation and education	
"Not at risk for CRC": no symptoms	Explain benefits and importance of screening, and give results of previous screening	Answering questions about the screening
Fear of finding cancer	Explain that early detection of CRC leads to good prognosis	Reminding of upcoming appointments
Fear of complications or perforation	Explain that complications in colonoscopy examination are rare	Arranging on-site consultations from the physician and epidemiologists if necessary
Embarrassment	Ensure that the patient's confidence will be well protected	Providing guidance
Objective barriers	Improving objective condition	
Intolerance of pain	Arranging painless colonoscopy <sup>1</sup>	
Lack of time on working days	Arranging examination at weekends	
Intolerance of bowel preparation	Simplifying bowel preparation	
Inconvenience and complexity of colonoscopy procedure	Providing guidance	

<sup>1</sup>Painless colonoscopy: Intravenous general anesthesia was performed during colonoscopy.**Table 3** Baseline characteristics of eligible subjects (*n* = 1430)

Characteristics	<i>n</i> (%)
Age (yr)	
40-59	687 (48.04)
60-74	743 (51.96)
Sex	
Male	511 (35.73)
Female	919 (64.27)

With subjective barriers	646 (45.17)
With objective barriers	714 (49.93)
Without barriers	70 (4.90)

<sup>1</sup>Positive for questionnaire refers to having ≥ 2 of the following six items: (1) chronic diarrhea; (2) chronic constipation; (3) mucous or bloody stools; (4) personal history of appendicitis or appendectomy; (5) personal history of chronic cholecystitis or cholecystectomy; (6) history of psychiatric trauma. iFOBT: Immunochemical fecal occult blood testing.

of August 2007. The 1970 subjects received a series of telephone interviews or on-site interviews. The prevention care managers carried out the following: (1) explained the study purpose and obtained consent; (2) assessed eligibility by inquiring about patient disease history, and it was suggested that those with a disease history should be evaluated by specialists to make sure that they would tolerate the colonoscopy examination; (3) identification of the specific individual barriers to colonoscopy; (4) implementation of intervention measures predesigned to reduce these barriers; (5) arranged on-site consultations, during which the oncology physician and epidemiologists answered questions and tried to persuade subjects to participate in the colonoscopy examination; and (6) scheduled the colonoscopy appointments if the subjects consented.

The prevention care managers reminded the subjects by telephone 2 d ahead of the examination and provided guidance on the day of examination. Colonoscopy was

performed by gastroenterologists in the endoscopy units of local hospitals, and the results were retrieved via manual review of the medical records.

The intervention process was terminated in the following situations: (1) the subject attended a scheduled colonoscopy; (2) the subject definitely refused our invitation; and (3) the subjects were lost to follow-up after at least three calls. The intervention program was terminated at the end of August 2008.

### Statistical analysis

The  $\chi^2$  test was used to evaluate statistical differences between the colonoscopy completion rates. Logistic regression analysis was used to evaluate the variation in the effects of the intervention on different characteristics of barriers and among subgroups with different high-risk factors. All data were analyzed using SPSS version 16.0.

## RESULTS

### Baseline characteristics

Five hundred and forty subjects were excluded from the study because of death (*n* = 16), medical unfitness to undergo colonoscopy (*n* = 154), movement from the community (*n* = 260), or other reasons (*n* = 110). Table 3 provides the baseline characteristics.

### Intervention effect

Twenty-five subjects were lost to follow-up during the intervention, and we assumed that these subjects refused the colonoscopy invitation. The above 540 subjects were excluded from the study. The colonoscopy attendance rate was 23.04% (428/1858) during the first 12 mo without intervention, and 37.69% (539/1430) during the second 12 mo with intervention ( $P < 0.001$ ). Among the eligible 1430 subjects, attendance rate post-intervention was 5.11% (33/646) for subjects with subjective barriers, 62.32% (445/714) for those with objective barriers, and 87.14% (61/70) for those with no barriers.

As shown in Table 4, the intervention was more effective for subjects with only objective barriers (OR:

FDRs: First-degree relatives.

34.590, 95% CI: 23.204-1.563) and those without barriers (OR: 132.421, 95% CI: 59.709-293.681), compared to those with subjective barriers. The intervention was also more effective for subjects with FDRs diagnosed with CRC (OR: 1.778, 95% CI: 1.010-3.131), personal history of intestinal polyps (OR: 3.815, 95% CI: 1.994-7.300) or positive results for iFOBT (OR: 2.718, 95% CI: 1.479-4.996).

## DISCUSSION

In previous studies on CRC screening intervention, higher attendance was achieved by some intervention practices such as health-care-provider-directed intervention<sup>[19]</sup>, telephone support<sup>[20,21]</sup>, psychoeducational intervention<sup>[22,23]</sup>, tailored guidance<sup>[24,25]</sup>, patient-physician communication<sup>[26]</sup>, motivational interviewing<sup>[27]</sup>, physician reminder<sup>[28,29]</sup>, community volunteers<sup>[30]</sup>, and mailed brochure<sup>[31]</sup>. However, one-sided intervention methods may not achieve a satisfactory effect among nonadherent high-risk subjects.

In this study, we first identified the main barriers to colonoscopy examination, and then established a multifaceted barriers-focused intervention program that targeted objective and subjective barriers. The results indicated that the intervention program effectively increased the completion rate of colonoscopy among nonadherent high-risk subjects. The attendance rate of colonoscopy screening significantly increased during the intervention compared with the first 12 mo without intervention (23.04% vs 37.69%, *P* < 0.001), which reduced more effectively the mortality and incidence in the screening area, because more positive lesions were detected<sup>[2,32]</sup>. Moreover, the targeted subjects during the intervention were nonadherent and did not respond to the examination invitations during the first 12 mo, which

made the intervention more difficult.

There were several barriers for any one subject, which made evaluation of each specific intervention measure complicated and inaccurate. We simplified the evaluation by classifying the target population into three behavioral groups according to their respective barriers. Colonoscopy completion rate in the population with objective barriers was higher than that in those with subjective barriers (62.32% vs 5.11%), which indicates that measures that target objective barriers are more effective. The colonoscopy completion rate in the population without barriers was as high as 87.14%, which indicates that only general intervention measures achieve satisfactory results among these individuals. Logistic regression also showed that the intervention was more effective for subjects with objective barriers and with no barriers compared to those with subjective barriers. Intervention measures that target subjective barriers should be improved to further increase the uptake rate.

Previous studies on barriers to CRC screening have noted that younger age is a predictor of receiving a physician recommendation for screening<sup>[33,34]</sup>. However, in our study, logistic regression showed that there was no significant difference in intervention effects between middle-aged (40-59 years) and aged (60-74 years) populations. This may have resulted from the differences between our study population and those of previous studies in terms of ethnicity, socioeconomic status and other sociodemographic characteristics.

Our findings suggested that several high-risk factors were associated positively with intervention effect. The intervention was more effective among subjects with a history of intestinal polyps. Most of these subjects had been advised by their physicians to take regular examinations, which may have contributed to their higher compliance with our intervention. Subjects with positive results for iFOBT showed better compliance. The perceived value of different high-risk factors may explain partially the variation in intervention effect. According to the medical knowledge of high-risk subjects, some items in the questionnaire (e.g. personal history of appendicitis or appendectomy, history of psychiatric trauma) seem to be less specific to CRC than iFOBT is. This may reduce the perceived importance of questionnaire investigation and cause the subjects to consider iFOBT more valuable in CRC screening. However, further investigation is needed to confirm this explanation. The poor compliance of subjects with positive questionnaire results highlighted the importance of tailoring education programs to address questionnaire investigation of CRC. Poor participation in CRC screening in FDRs of patients with CRC has been reported previously<sup>[35]</sup>. In our study, the subjects with FDRs diagnosed with CRC showed slightly better compliance. The possible reason was that the physicians who diagnosed and treated the index patients also explained the increased risk for the FDRs and advised CRC screening to increase their awareness and attendance.

Our study had several strengths: (1) we recruited

nonadherent high-risk subjects among whom intervention for colonoscopy examination has not been widely studied before; (2) the sample number was large, the consent rate was high, and few were lost to follow-up; and (3) the community setting of the study provided ready access to the subjects.

There were also some limitations to the study: (1) there was no comparison group, and one group pre- and post-test was studied; (2) it did not have saturation coverage of the communities, and it may not have included completion of all colonoscopy examinations, because the duration of the intervention was short; and (3) the population classification was based on self-reported barriers, which may have potential bias.

In summary, this barrier-focused intervention in nonadherent high-risk subjects may increase colonoscopy attendance in urban CRC screening. We found that our intervention in individuals with subjective barriers was not as effective or practical as in those with objective barriers. The next steps are to modify the intervention methods to better overcome subjective barriers. The ultimate goal is to apply the multifaceted barriers-focused intervention to other urban CRC screening regions in China.

## ACKNOWLEDGMENTS

We thank Professor Shu Zheng for helpful suggestions and review of earlier versions of this paper. We also thank the endoscopy physicians in local hospitals for performing the colonoscopy. We appreciate the previous work for the screening carried out by the local Center for Disease Control and Prevention and the community.

## COMMENTS

### Background

Colonoscopy examination is regarded as the gold standard for mass screening of colorectal cancer (CRC). Although attendance rate for colonoscopy examination among high-risk populations is crucial for screening success, it has remained disappointing for CRC screening. Therefore, it is necessary to establish effective screening intervention methods to increase colonoscopy compliance.

### Research frontiers

In previous studies on CRC screening intervention, higher attendance was achieved by some intervention practices such as health-care-provider-directed intervention, or telephone support. However, one-sided intervention methods may not achieve a satisfactory effect among nonadherent high-risk subjects. Many studies have reported that subjective or objective barriers prevent high-risk subjects from undergoing colonoscopy examination, which indicates that barrier-focused intervention might be effective. However, such barrier-focused intervention has not been reported previously.

### Innovations and breakthroughs

This is believed to be the first study to establish a barrier-focused intervention program and evaluate its effects on colonoscopy attendance in CRC screening. Moreover, in this study, nonadherent high-risk subjects were recruited, among whom, intervention for colonoscopy examination has not been widely studied before.

### Applications

The study suggests that barrier-focused intervention is an effective method and may be used to increase colonoscopy attendance in other CRC screening regions.

### Terminology

Barrier-focused intervention in CRC screening is an intervention method that

aims to increase colonoscopy attendance by removing the barriers that prevent the subjects from undergoing colonoscopy examination. Barrier-focused intervention must be tailored or individualized because every subject may have different barriers.

### Peer review

The authors performed barrier-focused intervention to increase colonoscopy attendance among nonadherent high-risk populations in China. The colonoscopy attendance rate was 23% during the first 12 mo without intervention and 38% during the second 12 mo with intervention. The authors concluded that the barrier focused telephone or on-site consultation intervention appears to be a feasible means to improve colonoscopy attendance among nonadherent high-risk populations for CRC screening. Improving colonoscopy attendance in CRC screening is an important issue, and the results of this study are interesting.

### Abstract

**AIM:** To investigate the long-term effect of the number of resected lymph nodes (LNs) on the prognosis of patients with node-negative gastric cancer.

**METHODS:** Clinical data of 211 patients with gastric cancer, without nodal involvement, were analyzed retrospectively after D2 radical operation. We analyzed the relationship between the number of resected LNs with the 5-year survival, the recurrence rate and the post-operative complication rate.

**RESULTS:** The 5-year survival of the entire cohort was 82.2%. The total number of dissected LNs was one of the independent prognostic factors. Among patients with comparable depth of invasion, the larger the number of resected LNs, the better the survival ( $P < 0.05$ ). A cut-point analysis provided the possibility to detect a significant survival difference among subgroups. Patients had a better long-term survival outcomes with LN counts  $\geq 15$  for pT1-2,  $\geq 20$  for pT3-4, and  $\geq 15$  for the entire cohort. The overall recurrence rate was 29.4% within 5 years after surgery. There was a statistically significant, negative correlation between the number of resected LNs and the recurrence rate ( $P < 0.01$ ). The post-operative complication rate was 10.9% and was not significantly correlated with the number of dissected LNs ( $P > 0.05$ ).

**CONCLUSION:** For node-negative gastric cancer, sufficient number of dissected LNs is recommended during D2 lymphadenectomy, to improve the long-term survival and reduce the recurrence. Suitable increments of the dissected LN count would not increase the post-operative complication rate.

### INTRODUCTION

Gastric cancer is a common malignancy worldwide. Despite its declining incidence, mortality of gastric cancer remains high<sup>[1]</sup>. It is generally accepted that a higher survival rate benefits from a standardized pattern of lymph node dissection<sup>[2-4]</sup>. Many studies favor an extended lymphadenectomy at the time of potentially curative gastrectomy for node-positive gastric cancer, and the risk of long-term death tends to decrease when the number of resected lymph nodes increases to about 25<sup>[5-7]</sup>. However, there are few studies on how many nodes should be removed and examined when performing a radical gastrectomy for node-negative gastric cancer. Therefore, the aim of this retrospective study was to evaluate the long-term effect of the number of resected lymph nodes (LNs) on the prognosis of patients with node-negative gastric cancer.

### MATERIALS AND METHODS

#### Materials

Between January, 1995 and March, 2004, 211 patients diagnosed with primary gastric cancer were treated with curative resection at the Department of Oncology,

Affiliated Union Hospital of Fujian Medical University, Fuzhou, China. The surgical procedure was defined as curative when no grossly visible tumor tissue (metastasis or LN involvement) remained after resection and when the resection margins were histologically normal. There were 164 males and 47 females whose age ranged from 29 to 84 years ( $57.4 \pm 11.3$  years). All patients received a D2 dissection according to the Japanese Classification of Gastric Carcinoma<sup>[8]</sup>. Lymph nodes were meticulously dissected from the en bloc specimens, and the classification of the dissected LNs was determined by specialist surgeons who reviewed the excised specimens after surgery, based on the Japanese Classification of Gastric Carcinoma<sup>[8]</sup>. All resected lymph nodes were proven to be without nodal involvement. The tumors' size was  $4.2 \pm 2.1$  cm. Patients were divided according to the primary site of gastric cancer: 75 upper third (U) tumors; 40 middle third (M) tumors; and 96 lower third (L) tumors. Based on the Japanese Classification of Gastric Carcinoma<sup>[8]</sup>, there were 69 at stage pT1, 58 at stage pT2, 62 at pT3 and 22 at pT4. As far as the histological grades were concerned, there were 55 differentiated and 156 undifferentiated cases. Total gastrectomy, proximal subtotal gastrectomy and distal subtotal gastrectomy were carried out in 99, 15 and 97 cases, respectively. A total of 4649 LNs were taken for histological examination, and the median number of LN per patient was 22 (range, 6-48; mean  $22.7 \pm 7.0$ ). Routine follow-up consisted of physical examination, laboratory tests (including measurement of carcinoembryonic antigen, CA19-9 and CEA levels), chest radiography, and abdominopelvic ultrasonography or computed tomography (CT). At the early stage (pT1), patients were followed every 6 mo during the first 2 years, and then yearly beyond the third year; at more advanced stages (pT2 or greater), follow-up was every 3 mo during the first year, every 6 mo or yearly beyond the second year, for a total of 5 years. Endoscopy was performed every 6 mo or yearly. All surviving patients were followed for more than five years. The survival time was the time from diagnosis until the last contact, the date of death, or the date that the survival information was collected. The rate of follow-up visits was 92.9%, with 196 cases involved.

## Methods

Patients were stratified into five groups, based on the total number of LNs removed, as follows: < 15 LNs (18 cases), 15-19 LNs (49 cases), 20-24 LNs (63 cases), 25-29 LNs (44 cases) and  $\geq 30$  LNs (37 cases). The statistical analysis was performed with the Statistical Package for Social Science (SPSS), version 13.0 for Windows. Actuarial survival was determined via the Kaplan-Meier method, with univariate comparisons between groups through the log-rank test. Cox regression was used for multivariate analysis, with a backward elimination model for all covariates. Spearman rank correlation coefficient was used to analyze the relationship between the number of dissected LNs and recurrence rate. The correlation between the number of resected LNs and post-operative complication rate was analyzed with logistic regression model. Significance of differences was assumed at  $P < 0.05$ .

## RESULTS

### Univariate survival analysis

The five-year overall survival rate of the entire cohort was 82.2%. The clinicopathological variables tested in the univariate analysis are shown in Table 1. Factors influencing the 5-year survival rate were tumor size ( $P = 0.033$ ), depth of invasion ( $P < 0.001$ ) and number of resected LNs ( $P < 0.001$ ). The covariates age ( $P = 0.431$ ), gender ( $P = 0.170$ ), tumor location ( $P = 0.432$ ), pathological types ( $P = 0.645$ ) and type of gastrectomy ( $P = 0.640$ ) had no significant influence on the survival.

### Multivariate survival analysis

Multiple survival analysis was calculated by the Cox's proportional hazard regression model. The prognostic

	20-24	23	8 (34.8)		
	25-29	16	4 (25.0)		
	≥ 30	19	3 (15.8)		

<sup>1</sup>Significance of differences was assumed at P < 0.01; <sup>2</sup>Recurrence within 5 years after surgery.

factors considered at univariate analysis were analyzed first by stepwise regression, including tumor size, depth of invasion and number of resected LNs. As a result, there were two independent, statistically significant prognostic parameters: depth of invasion ( $P = 0.032$ ) and number of resected LNs ( $P < 0.001$ ). The risk ratios and their 95% confident interval were listed in Table 2.

#### Impact of total LN counts by univariate survival analysis

The five-year survival, based on T category, showed considerable variations with increasing counts of resected LNs. An obvious trend toward better survival was observed for higher numbers of resected LN (Table 3).

#### Cut-point survival analysis

A cut-point analysis was performed to determine the numeric LN value that determines the greatest actuarial survival difference between pT1-2 and pT3-4 subgroups. We selected the ability to detect differences between groups based on the magnitude of the log-rank test  $\chi^2$  statistic. Results for all relevant cut points and stage subgroups are listed in Table 4. The cut-point analysis yielded the greatest survival difference at the levels of 15 (pT1-2), 20 (pT3-4) and 15 (entire cohort).

#### Impact of the number of resected LNs on recurrence rate

Within 5 years after surgery, a recurrence was confirmed by clinical, radiological examination or reoperation in 62 patients, with an overall recurrence rate of 29.4%. The number of patients with peritoneal and lymph nodes recurrence were 28 and 13 respectively. The most common site of haematogenous recurrence was the liver, occurring in 12 patients. Other patterns of recurrence were bone recurrence in 5 patients and lung recurrence in 4 patients. The relationship between the number of resected LNs and recurrence rate was analyzed by Spearman rank correlation coefficient (Table 5). For either pT1-2 or pT3-4 subgroups, there was a statistically significant, negative correlation between the number of dissected LNs and the recurrence rate ( $P < 0.01$ ).

#### Correlation between number of resected LNs and post-operative complication rate

Twenty-three of the 211 patients (10.9%) experienced postoperative complications. These included pancreatitis (4 cases), anastomotic leakage (3), intra-abdominal abscess (4), postoperative ileus (1), stenosis (3), countercurrent esophagus (2), pancreatic leakage (2) and pneumonia (4). Logistic regression analysis revealed that the number of dissected LNs was not significantly correlated with the post-operative complication rate ( $P = 0.214$ ).

## DISCUSSION

It is commonly regarded that lymph node metastases is one of the most important prognostic factors in patients with gastric cancer after curative operation<sup>[9,10]</sup>. Bruno *et al*<sup>[11]</sup> pointed out that patients with node-negative gastric cancers have clinicopathological features similar to those with early gastric cancer and they showed also how those patients have a better prognosis than those with node-positive gastric carcinoma. The 5-year survival rate of patients with node-negative gastric carcinoma was 89.5%, based on the work by Wu *et al*<sup>[12]</sup>, whereas, based on our present data, this rate is

82.2%. The only potentially curative treatment for this disease is complete surgical resection, with an en bloc LN dissection. D2 lymph node dissection can increase the long-term survival of gastric cancer patients with lymph node metastases and it has become a standard surgical procedure for curative treatment in Korea and Japan<sup>[13]</sup>. D2 lymph node dissection requires not only a specific anatomical extension (i.e. it must include both perigastric and suprapancreatic nodes), but also a certain number of resected LNs (at least 15). The number of dissected LNs is closely related to the postoperative pathologic staging and the prognostic assessment. Bouvier *et al*<sup>[14]</sup> investigated 749 cases with gastric cancer, and the results showed that the risk of misclassification became significant, with an error rate of 47.1% in the pathology reports, when fewer than 10 lymph nodes were examined. They concluded that, in the latter cases, staging is not reliable. Karpeh *et al*<sup>[15]</sup> reviewed 1038 patients with gastric cancer who had undergone gastrectomy with curative intent. They found that removal of  $\geq 15$  LNs appears to provide a considerable survival advantage, in comparison with the removal of  $< 15$  LNs. In an attempt to improve staging accuracy, it was recommended that a minimum of 15 lymph nodes be examined. Based on our data, the median number of total LNs examined was 22 (mean  $22.7 \pm 7.0$ ) per patient. In addition, the number of LNs dissected emerges as one of the most important prognostic indicators. Our present study shows that, with comparable depth of invasion, patients with a larger number of dissected LNs have a better survival rate ( $P < 0.05$ ), consistent with the results of Smith *et al*<sup>[16]</sup>. The contribution of negative LN counts to the prognosis of patients is partly due to LN micrometastases. In patients without LN metastases identified by HE staining, about 20% had LN micrometastases<sup>[17]</sup>. Thus, it can be concluded that an extended lymphadenectomy contributes to decrease the number of residual tumor cells, leading to better prognosis. However, it is unclear how many LNs need to be removed in a D2 dissection in patients with node-negative gastric cancer. Giuliani *et al*<sup>[18]</sup> suggested that patients with node-negative gastric cancer should undergo adequate lymphadenectomy to permit examination of  $\geq 23$  LNs, which would allow accurate identification of prognostic variables. From the cut-point analysis, we suggest that, to be adequate, the resection, at the time of a D2 radical dissection, should involve 15 LNs for pT1-2 and 20 LNs for pT3-4, and this based on an accurate survival estimates in patients with node-negative gastric cancer.

Despite improved prognosis, as a result of early diagnosis, radical operations and the development of adjuvant therapy<sup>[9,19,20]</sup>, death from gastric cancer is still almost entirely due to recurrent disease. About 5% of patients with early gastric cancer and 50% of patients with advanced gastric cancer die with recurrent disease, as reported by Böhner *et al*<sup>[21]</sup>. In a large set of follow-up data from Japan, among 14 000 patients with recurrent gastric cancer, the rate of loco-regional recurrence following potentially curative resection was 25.6%<sup>[22]</sup>. This

may be due to the insufficient anatomical extension of the dissection at the time of the first surgery, including an insufficient gastrectomy or insufficient lymphadenectomy. The randomized Dutch gastric carcinoma study compared D1 and D2 lymphadenectomy and appeared to observe a significant reduction of the loco-regional recurrence rate after a more extended lymphadenectomy: following D1 lymphadenectomy, 36% of patients died with local recurrence, compared with 27% when a D2 lymphadenectomy was performed ( $P < 0.05$ )<sup>[23]</sup>. Our present study shows that the overall recurrence rate is 29.4% within 5 years after surgery. The Spearman rank correlation coefficient analysis revealed that there was a statistically significant, negative correlation between the number of dissected LNs and the recurrence rate ( $P < 0.01$ ). A lower recurrence rate was observed in cases with higher total LNs, indicating that a sufficient lymphadenectomy contributed to reduce the number of residual tumor cells. While correlating the number of dissected LNs with the post-operative complication rate, Zilberstein *et al*<sup>[24]</sup> did not find any difference between the average number of dissected LNs in patients with and without complications. These authors suggested that the higher morbidity and mortality rates were not due to the extended lymphadenectomy. Those rates may be more likely correlated with the level of experience in gastroesophageal surgery, with the presence of an appropriate learning curve for radical gastrectomy and with the experience in the management of postoperative complications. The post-operative complication rate in our study was 10.9% and the logistic regression analysis showed that the number of dissected LNs did not correlate with the post-operative complication rate ( $P > 0.05$ ). According to our results, it appears that a suitable increment of the number of dissected LN would not increase the post-operative complication rate if the surgery is performed by a trained surgical team.

## COMMENTS

### Background

Many studies have favored an extended lymphadenectomy at the time of a potentially curative gastrectomy for node-positive gastric cancer, and the risk of long-term death tends to decrease when the number of resected lymph nodes increases to about 25. However, few studies have assessed the relative contribution of the number of total resected lymph nodes to the outcome in patients with node-negative gastric cancers.

### Research frontiers

It is generally accepted that a higher survival rate benefits from a standardized pattern of D2 radical dissection, which requires the removal of Group 1 and Group 2 lymph nodes (LNs). The number of dissected LNs is strongly correlated with patients' survival.

### Innovations and breakthroughs

The authors retrospectively reviewed 211 patients with node-negative gastric cancer, who were treated with D2 radical resection at a hospital in Fujian between 1995 and 2004, to assess how the number of dissected LNs may affect their survival rate.

### Applications

The authors suggest that importance should be attached to removing a sufficient number of LNs in order to improve the long-term survival and reduce the recurrence rate of patients with node-negative gastric cancer. Moreover, suitable increments of the number of dissected LNs would not increase the post-operative complication rate.

**Peer review**

The authors are to be congratulated on this paper, recording the effect of the number of lymph nodes resected in a large number of patients (211) with node negative gastric cancer and a remarkable survival rate of 82.2% at 5 years. The number of lymph nodes resected influenced the prognosis of the patients with node negative gastric cancer. This finding has important information for gastrointestinal surgeons.

graphic characteristics, acute rejection rates, liver and renal function test results, or the number of potentially interacting medications administered between the two groups. The tacrolimus dosage requirements in group S were significantly lower than group N at 2 wk ( $2.8 \pm 0.4$  mg/d vs  $3.6 \pm 0.7$  mg/d,  $P = 0.006$ ), 3 wk ( $2.9 \pm 0.7$  mg/d vs  $3.9 \pm 0.8$  mg/d,  $P = 0.008$ ), 4 wk ( $2.9 \pm 0.8$  mg/d vs  $3.9 \pm 1.0$  mg/d,  $P = 0.023$ ) and 2 mo ( $2.8 \pm 0.7$  mg/d vs  $3.8 \pm 1.1$  mg/d,  $P = 0.033$ ). Tacrolimus 12-h trough concentrations were similar between the two groups at all times except for 2 wk post-transplantation, when the concentrations were significantly greater in group S recipients than in group N recipients ( $11.3 \pm 4.8$  ng/mL vs  $7.0 \pm 3.8$  ng/mL,  $P = 0.026$ ).

**CONCLUSION:** SFS grafts recipients have significantly decreased tacrolimus dosage requirements compared with non-SFS grafts recipients in AALDLT during the first 2 mo post-surgery.

## INTRODUCTION

With the shortage of cadaveric donor organs, living donor liver transplantation (LDLT) is generally accepted for end-stage liver disease. In LDLT, the graft size is inevitably small and requires regeneration, especially in small-for-size (SFS) grafts. Various studies have indicated that liver regeneration and function return rapidly in both donor and recipient after transplantation<sup>[1-3]</sup>. However, several studies have shown that living donor liver transplant

**RESULTS:** There were no differences in the demo-

recipients required smaller doses of tacrolimus compared with deceased donor liver transplant patients<sup>[4,5]</sup>, which indicated that liver regeneration could affect the metabolism of tacrolimus in LDLT. The liver is a large metabolic pool which metabolizes many drugs including immunosuppressive drugs in humans. Tacrolimus, a calcineurin inhibitor, is predominantly metabolized in the liver by cytochrome P450 3A4 (CYP3A4)<sup>[6]</sup>. Kishino *et al*<sup>[7]</sup> reported that inter- and intra-individual variations in CYP3A4 activity were caused by differences in the actual ratio of graft volume (GV) to standard liver volume (SV) and donor age. Furthermore, Fukatsu *et al*<sup>[8]</sup> reported that graft hepatic weight was significantly correlated with clearance of tacrolimus. One possible explanation for the high variability of the optimal tacrolimus dose and its pharmacokinetics is the difference in graft size. In recent years, LDLT in adult patients with SFS grafts has become increasingly accepted<sup>[9]</sup>. However, questions related to this technique have arisen: What are the tacrolimus dosage requirements in SFS grafts which require adequate liver regeneration? Does liver regeneration of SFS grafts have any impact on tacrolimus metabolism? Are there any differences in tacrolimus dosage requirements between SFS grafts and non-SFS grafts in LDLT? The answers to these questions are unknown because there are few studies on tacrolimus dosage requirements in LDLT with SFS grafts in the existing literature. Hence, the purpose of this study was to determine the tacrolimus dosage requirements and blood concentrations in adult-to-adult right lobe living donor liver transplantation (AALDLT) recipients with SFS grafts.

## MATERIALS AND METHODS

### Inclusion and exclusion criteria

Patients were included in this analysis if they were 18 years or older, had their transplantation performed at West China Hospital, received tacrolimus as basic immunosuppression and were followed up for at least 6 mo post-surgery. Exclusion criteria: (1) Patients receiving dual liver grafts. (2) Patients who had undergone combined liver and kidney transplantation. (3) Patients who were followed up for less than 6 mo and who were lost to follow up. (4) Patients who underwent retransplantation. And (5) patients who received cyclosporine as basic immunosuppression.

### Recipients and donors

According to the inclusion and exclusion criteria, the study enrolled 54 AALDLT recipients and 54 donors who underwent right lobe hepatectomy at West China Hospital of Sichuan University during January 2007 and October 2008.

The 54 donors consisted of 34 males and 20 females. Donor age ranged from 19 to 53 years (mean, 30.9 ± 8.5 years). The relationships of the donors to the respective patients were: four fathers, three mothers, 11 offspring, 16 brothers, eight sisters, five wives, two husbands and five friends.

All the recipients underwent LDLT using right lobe graft without a middle hepatic vein. Of the 54 recipients, 45

(83.3%) were male and 9 (16.7%) were female. The average age of the recipients was 43 (27-64) years. Indications for transplantation were: chronic hepatitis B with liver cirrhosis (18 cases); fulminant hepatic failure (six cases); hepatocellular carcinoma (28 cases) and other causes (two cases). The pre-transplantation MELD scores of the recipients were 1-13 in 30 patients, 14-24 in 16 patients, and ≥ 25 in eight patients.

According to the GRBW, the 54 AALDLT recipients were divided into two groups: group S (GRBW < 0.8%), eight cases and group N (GRBW ≥ 0.8%), 46 cases. Written informed consent was obtained from both donors and recipients before surgery, and all the AALDLTs were approved by the Ethics Committee of West China Hospital.

### Immunosuppression protocols

Basic postoperative immunosuppression consisted of corticosteroids and tacrolimus (Prograf; Fujisawa, Osaka, Japan). Supplemental immunosuppression consisted of mycophenolate mofetil (for benign diseases) or azathioprine (for malignant diseases). Initial steroid tapers consisted of 1000 mg of intravenous (IV) methylprednisolone intraoperatively, followed by a 7-d taper (50 mg Q6h day 1, 40 mg Q6h day 2, 30 mg Q6h day 3, 20 mg Q6h day 4, 20 mg Q8h day 5, 10 mg Q6h day 6 and 10 mg Q8h day 7) to 20 mg of oral prednisone once daily. The corticosteroid was withdrawn from all patients within 3 mo after transplantation. Initial suspected or biopsy-proven rejections were treated with two 500-mg IV methylprednisolone boluses on consecutive days, followed by a 7-d taper to 20 mg of oral prednisone once daily.

Severe or steroid-resistant rejections were treated with a 7- to 14-d course of muromonab-CD3 (Orthoclone OKT3; Orthobiotech Products, Raritan, NJ, USA). Initial tacrolimus doses were 0.05-0.1 mg/kg per day divided into twice-daily dosing. Tacrolimus doses were adjusted to achieve a target 12-h trough concentration of 10-15 ng/mL for the first 3 mo post-transplantation, followed by 5-10 ng/mL thereafter. Tacrolimus 12-h trough concentrations were analyzed by the IMx assay (Abbott Laboratories, Chicago, IL, USA).

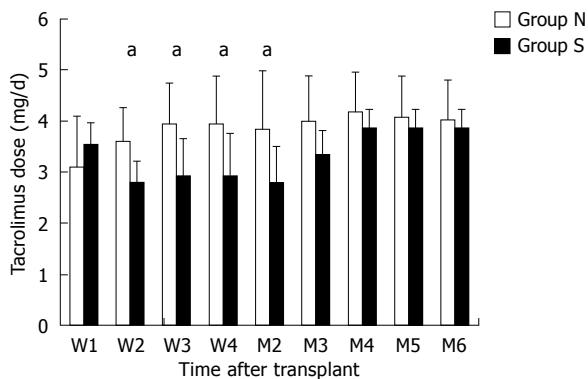

### Data collection

Tacrolimus daily doses and 12-h trough blood levels were recorded in both group S and group N at the following intervals after transplantation: weeks 1, 2, 3 and 4 and months 2, 3, 4, 5 and 6. At each interval, serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin (TB), albumin (Alb), and creatinine (Cr) levels were recorded. Tacrolimus 12-h trough concentrations, AST, ALT, TB, Alb and Cr were measured twice weekly in the first month post-surgery, and weekly from month 2 to 6. At each interval, values recorded for dose, level, and respective liver function and kidney function test results represent the mean value over the past days. Meanwhile, acute rejection rates and the number of potentially interacting medications were determined at each interval in the two groups. Body weight was also recorded for each patient at each interval.

**Table 1 Patient demographics**

	<b>Group S</b>	<b>Group N</b>	<b>P</b>

### Statistical analysis

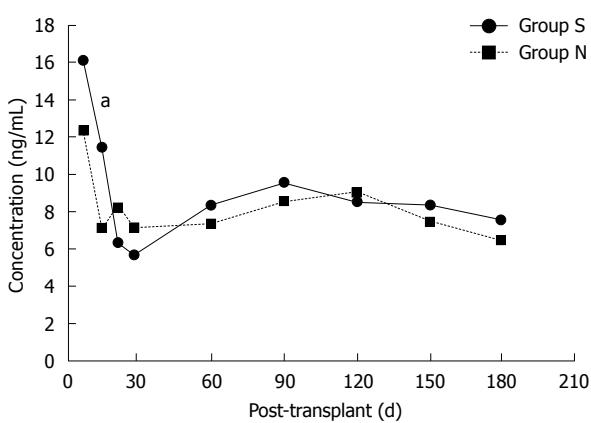

Quantitative descriptive data were expressed as mean ± standard deviation (SD) or median (minimum to maximum). Qualitative descriptive data were expressed as percentages. Fisher's Exact,  $\chi^2$ , Student's *t* and rank tests were used for statistical analysis. Tacrolimus doses and 12-h trough concentrations were compared weekly for the first month post-transplantation. For months 2-6 post-transplantation, tacrolimus doses and 12-h trough concentrations were compared monthly. ALT, AST, TB, Alb, and Cr were also compared between the two groups over the 6-mo period. All statistical analyses were performed using SPSS version 16.0 for Windows statistical software (SPSS Inc., Chicago, IL, USA). Differences with a *P* value < 0.05 were considered significant.

## RESULTS

The demographics of group S and group N cohorts are listed in Table 1. There were no differences between the two groups with regard to recipients' age, donors' age, sex, and MELD score. In addition, there were no differences between the two groups in indications for transplantation or number of treated rejection episodes. There were no

**Table 2 Medication interactions**

differences between the two groups with regard to the number of patients administered an interacting drug, total number of courses of an interacting drug, or duration of therapy (Table 2). Mean body weight for SFS grafts recipients undergoing AALDLT was slightly higher (66.6 kg) than for non-SFS grafts recipients undergoing AALDLT (61.7 kg, *P* = 0.244 not significant). The proportion of group S who underwent Roux-en-Y anastomosis was greater than that in group N, however, not statistically significant (12.5% vs 7%, *P* = 0.484).

Tacrolimus dosage requirements for each group over the first 6 mo post-transplantation are shown in Figure 1. There was no significant difference in doses during the first week. The tacrolimus dosage requirements in group S were significantly lower than those in group N at 2 wk ( $2.8 \pm 0.4$  mg/d vs  $3.6 \pm 0.7$  mg/d, *P* = 0.006), 3 wk ( $2.9 \pm 0.7$  mg/d vs  $3.9 \pm 0.8$  mg/d, *P* = 0.008), 4 wk ( $2.9 \pm 0.8$  mg/d vs  $3.9 \pm 1.0$  mg/d, *P* = 0.023) and 2 mo ( $2.8 \pm 0.7$  mg/d vs  $3.8 \pm 1.1$  mg/d, *P* = 0.033). At 3, 4, 5 and 6 mo post-transplantation, there was no statistically significant difference between the two groups with regard to tacrolimus dosage requirements.

Despite having lower dosage requirements at 2, 3 and 4 wk and 2 mo post-transplantation, tacrolimus 12-h blood concentrations were not significantly different between the two groups except for week 2 post-transplantation ( $11.3 \pm 4.8$  ng/mL vs  $7.0 \pm 3.8$  ng/mL, *P* < 0.05, Figure 2). In

**Table 3** Liver function and kidney function test values

	Month					
	1	2	3	4	5	6

addition, there were no significant differences between the two groups with regard to ALT, AST, TB, Alb, or Cr over the entire study period (Table 3).

## DISCUSSION

LDLT has emerged as an effective alternative strategy to overcome donor organ shortage. In recent years, LDLT in adult patients with SFS grafts has become increasingly accepted<sup>[9]</sup>. With SFS grafts, it is considered that reduced functional liver mass is a necessity for adequate liver regeneration. Nevertheless, the liver is a large metabolic pool which metabolizes many drugs including immunosuppressant drugs in humans. Tacrolimus (FK506) is a potent immunosuppressive agent that is widely used in organ transplantation<sup>[10]</sup>. Because FK506 has serious side-effects (such as nephrotoxicity, hypertension and neurotoxicity) and a narrow therapeutic window (5–20 ng/mL)<sup>[11]</sup>, the desired blood concentration should be achieved as soon as possible. However, tacrolimus dosage requirements and blood concentrations in LDLT with SFS grafts have not yet been reported.

Ours results indicated that tacrolimus dosage requirements were substantially reduced in AALDLT recipients with SFS grafts compared with non-SFS grafts recipients during the first 2 mo post-transplantation despite having similar 12-h trough concentrations. Beyond 2 mo post-transplantation, dosage requirements between the two groups were similar.

The reason for the relatively low tacrolimus dosage requirements in SFS grafts recipients during the first 2 mo post-transplantation is not clear. However, there are several possibilities. We analyzed pharmacokinetic variables between group S and group N (such as absorption, volume of distribution, and clearance) to explain the dosage requirement difference. Tacrolimus dosage requirements may be reduced by increased absorption, decreased volume of distribution, or decreased clearance. Neither increased absorption nor decreased volume of distribution in group S was a possible explanation. The only difference in group S and group N that could impact on absorption was the greater proportion of AALDLT recipients with a Roux-en-Y anastomosis. The proportion of group S who

underwent Roux-en-Y anastomosis was greater than that in group N (12.5% vs 7%), but this was not statistically significant ( $P = 0.484$ ). Moreover, a Roux-en-Y anastomosis is associated with decreased immunosuppressive absorption<sup>[12]</sup>. The volume of distribution of immunosuppressants was larger rather than smaller in group S because of their heavier body weight (SFS grafts recipients were 4.9 kg heavier than non-SFS grafts recipients).

Another explanation for the lower tacrolimus dosage requirements in group S might be reduced immunosuppressive clearance, which may be explained by two possible mechanisms. The first possible mechanism is that as the graft size in group S was smaller than in group N, it did not meet the demands of metabolism. SFS grafts have a relatively small liver mass because the GRBW is less than 0.8% and severe ischemic injuries caused by decreased hepatic arterial inflow or even hepatic artery thrombosis can occur<sup>[13-15]</sup>. Fukatsu *et al*<sup>[8]</sup> reported that graft hepatic weight was significantly correlated with clearance of tacrolimus in adult patients who had undergone LDLT, and Sugawara *et al*<sup>[16]</sup> reported that the optimal tacrolimus dose was best correlated with GV/SV ratio. Lee *et al*<sup>[17]</sup> reported that the clearance of tacrolimus was related to GRWR and the clearance of tacrolimus was decreased in patients with a small graft. Kishino *et al*<sup>[18]</sup> reported that the mean  $T_{1/2}$  of tacrolimus in patients with SFS grafts (GV/SV ratio: smaller than 50%) was significantly ( $P < 0.05$ ) longer than that in patients with GV/SV larger than 51%. These results suggest that graft size is important and could influence the clearance of tacrolimus. The reason why graft size can influence the clearance of tacrolimus is not very clear. CYP3A4 content and activity in liver grafts may partially explain the problem. Tacrolimus is mainly metabolized by CYP3A4 in the liver and intestine<sup>[6,19]</sup>. Powis *et al*<sup>[20]</sup> reported that CYP3A4 content and activity in human liver tissue decreased rapidly after surgical removal, and Kishino *et al*<sup>[7]</sup> reported that inter- and intra-individual variations in CYP3A4 activity were caused by differences in GV/SV ratio and donor age. In other words, the reduced CYP3A4 content and lower CYP3A4 activity in SFS liver grafts could partially explain the difference in tacrolimus dosage requirements between group S and group N.

Another explanation for reduced immunosuppressive clearance in SFS liver grafts may be related to several cytokines and growth factors. Several studies<sup>[21,22]</sup> have revealed that a SFS liver graft retained the capacity to regenerate faster by modulation of the expression pattern of HGF, IL-6 and TGF- $\beta$ 1 immediately after LDLT and both the regeneration rates and the levels of cytokines and growth factors were higher in SFS liver grafts than normal sized liver grafts. These markers have also shown an ability to decrease cytochrome P450 3A activity in the liver in both mice and humans<sup>[23-25]</sup>, which may decrease its ability to metabolize drugs. In other words, there were many more cytokines and growth factors (such as HGF, IL-6) in SFS liver grafts, which could decrease the clearance of tacrolimus.

In order to eliminate the impact of drug interactions, the potential medications which could affect tacrolimus level were determined in the two groups. It was noted in several studies that fluconazole, felodipine and lansoprazole could elevate tacrolimus blood level by inhibiting the activity of CYP3A4<sup>[26-28]</sup>. In the present study, the majority of patients in both groups were administered interacting drugs in the first month post-transplantation. However, there were no differences between the two groups with regard to the number of patients administered an interacting drug, total number of courses of an interacting drug, or duration of therapy. As a result, the impact of drug interactions was balanced in the two groups.

To make a rough determination of hepatic function and kidney function in group S and group N, we measured serum AST, ALT, TB, Alb, and Cr levels at each interval post-transplantation in both groups of patients. AST, ALT, and TB reflected the hepatic metabolic function while Alb was responsible for the synthetic function of the liver. AST, ALT, and TB levels were slightly greater at almost all follow-up intervals and Alb level was slightly lower in group S in the first 3 mo post-transplantation, although there was no statistical significance. This could not explain the difference in tacrolimus dosage requirements between group S and group N, however, more sensitive measures of hepatic function, i.e. galactose, caffeine, indocyanine green and monoethylglycinexylidide clearance test, should be performed to confirm the hypothesis.

There are several limitations to this study. Firstly, the sample size was small in group S. In addition, we did not study tacrolimus pharmacokinetics in this analysis which may have strongly affected the difference in the tacrolimus dosage requirements between the two groups.

In conclusion, AALDLT recipients with SFS grafts have significantly decreased tacrolimus dosage requirements compared with non-SFS grafts recipients during the first 2 mo post-surgery, in spite of having similar tacrolimus concentrations. We recommend that relatively low initial doses of tacrolimus should be administered to these patients.

## COMMENTS

### Background

Several studies have shown that living donor liver transplant recipients required smaller doses of tacrolimus compared with deceased donor liver transplant patients, which indicated that liver regeneration could affect the metabolism of tacrolimus in living donor liver transplantation (LDLT). However, there are few studies in the existing literature on tacrolimus dosage requirements in LDLT with small-for-size (SFS) grafts which require adequate liver regeneration.

### Research frontiers

In recent years, LDLT in adult patients with SFS grafts has become increasingly accepted. The administration of immunosuppressants for SFS grafts has not been explicitly reported due to limited studies. In this field, the research goal was to determine the optimal initial tacrolimus dose for LDLT recipients with SFS grafts.

### Innovations and breakthroughs

Several studies have shown that living donor liver transplant recipients required smaller doses of tacrolimus compared with deceased donor liver transplant patients. This is the first study to compare tacrolimus dosage requirements in

patients who received a graft with adequate hepatic mass and patients who received a SFS graft in LDLT.

### Applications

This study revealed that relatively low initial doses of tacrolimus should be administered to patients who receive a SFS graft in LDLT, which is a good guideline to follow for the rational administration of tacrolimus in future LDLT recipients with SFS grafts.

### Terminology

SFS graft: SFS liver graft, this is generally considered when a graft has a graft-recipient body weight ratio (GRBW) less than 0.8% in LDLT. GRBW: Graft-recipient body weight ratio.

### Peer review

The current paper is well-written and informative.

### INTRODUCTION

The primary effect of non-selective non-steroidal anti-inflammatory drugs (NSAIDs) is to inhibit cyclooxygenase (prostaglandin synthase), thereby impairing the ultimate transformation of arachidonic acid to prostaglandins, prostacyclin, and thromboxanes. The extent of enzyme inhibition varies among the different NSAIDs. At least two isoforms of cyclooxygenase enzymes have been described. While cyclooxygenase-1 (COX-1) is constitutively expressed in most normal tissues, cyclooxygenase-2 (COX-2) expression is predominantly induced during inflammation and tissue injury<sup>[1]</sup>. Most of the side effects associated with the use of non-selective NSAIDs are thought to be due to inhibition of COX-1. Therefore, selective COX-2 inhibitors have been developed in order to minimize some of the NSAID-associated adverse effects. Celecoxib is a widely used COX-2 inhibitor with high levels of patient acceptability and satisfaction, which may result from its combination of efficacy and relatively benign adverse effect profile. The daily recommended adult dose ranges between 100 and 800 mg/d for various clinical indications including osteoarthritis, ankylosing spondylitis, rheumatoid arthritis, chemoprevention of familial polyposis, primary dysmenorrhea, and acute pain<sup>[2]</sup>.

Recent reports described liver injuries in association with COX-2 inhibitors ranging from acute liver failure<sup>[3-6]</sup> to varying degrees of transient cholestatic<sup>[7-10]</sup> and/or hepatocellular injuries<sup>[11,12]</sup>. We report a case of celecoxib-associated acute cholestatic hepatitis progressing to liver failure requiring transplantation.

### Abstract

Selective cyclooxygenase-2 (COX-2) inhibitors are widely used due to their efficacy and good safety profile. However, recent case reports have described varying degrees of liver injuries associated with the use of COX-2 inhibitors. We report the case of a patient who developed acute cholestatic hepatitis progressing to hepatic failure requiring liver transplantation, following a 3-d course of celecoxib for treatment of generalized muscle aches and pains. The clinical presentation, the laboratory data, as well as the liver histopathology were supportive of the putative diagnosis of drug induced liver injury.

### CASE REPORT

A 52-year-old Caucasian female was in her usual state of health until she developed generalized muscle aches and pains 1 d after performing yard work. Over the next 3 d, she took a total of eight 200 mg-tablet of the prescription drug Celecoxib. On the 3rd day, she developed fatigue, loss of appetite, intense pruritus and dark-brown (“coke”) colored urine. The patient’s symptoms progressively worsened over the next 3 d, and 1 wk after the use of

**Table 1** Laboratory values

AST: Aspartate aminotransferase (17-59 IU/L); ALT: Alanine aminotransferase (21-72 IU/L); AP: Alkaline phosphatase (38-126 IU/L); GGT: Gamma glutamyl transpeptidase (0-65 IU/L); Bil: Total bilirubin (0.2-1.3 mg/dL); INR: International normalized ratio (0.8-1.2).

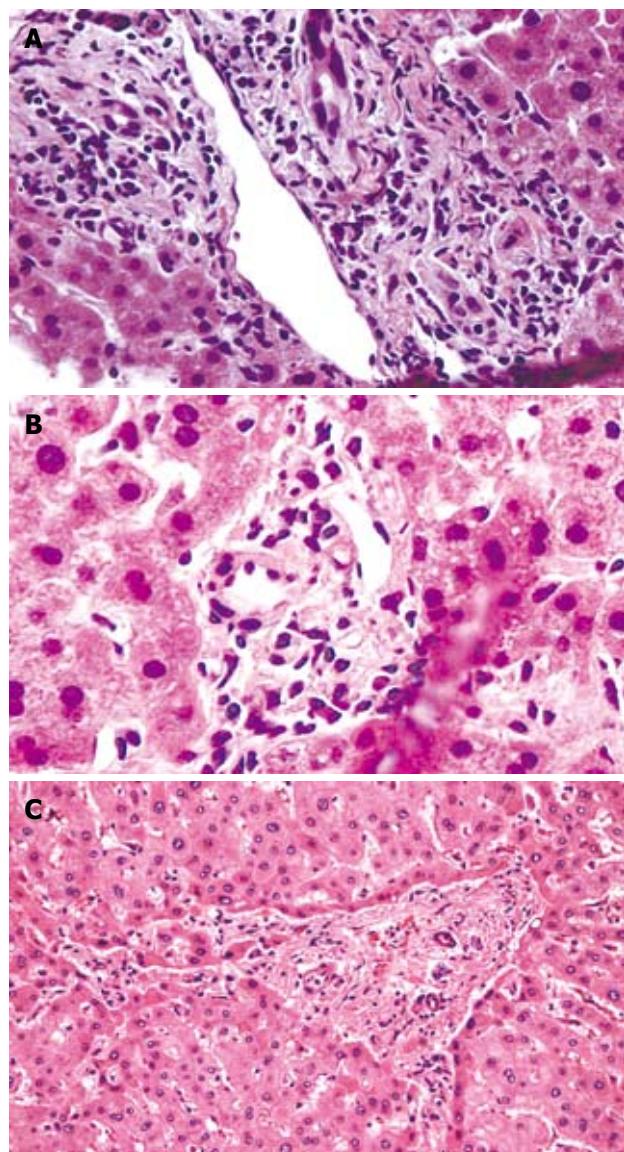

celecoxib, she presented to the local emergency room. She denied abdominal pain, nausea, vomiting, but did endorse a weight loss of five pounds.

The patient worked as a registered nurse. Past medical history was positive for a needle stick injury from an HIV/HCV co-infected patient one year earlier, for which she was evaluated at employee health. Her liver function tests (LFTs) were normal (Table 1), and the serologies for HIV, hepatitis B and C were negative at the time of needle stick and at subsequent follow-up visits at three, seven and 10 mo. The patient was single and not sexually active. She denied any alcohol intake, smoking, use of aspirin, or over the counter medications, herbals, and illicit drugs. She denied recent travel or sick contacts.

On physical exam, she was afebrile and jaundiced with mild right upper quadrant tenderness. Initial laboratory studies revealed abnormal LFTs with predominantly cholestatic pattern (Table 1). Serum urea nitrogen and creatinine levels were normal. Blood count differential was notable for peripheral eosinophilia with an absolute eosinophil count of 760/mL. Platelets count, INR and serum albumin were within normal limits.

Repeat testing at a 2-wk follow-up revealed worsening LFTs (Table 1). Antibodies to hepatitis A, B and C and Epstein-Barr virus, Cytomegalovirus and Herpes simplex virus were negative. Iron studies, an autoimmune panel (Anti-nuclear antibodies, anti-smooth muscle antibodies, liver-kidney-microsomal antibodies and immunoglobulins), anti-mitochondrial antibodies, alpha-one anti-trypsin, and ceruloplasmin were within normal limits. A CT scan of abdomen with intravenous contrast revealed normal liver morphology with no focal lesions and no biliary duct dilatation; the hepatic and portal veins were patent. Ultrasound guided liver biopsy showed ductopenia with lobular foam cell change and cholestasis along with periportal fibrosis and no evidence of bridging fibrosis (Figure 1A and B). The patient was started on 500 mg of ursodiol twice daily, oral fat-soluble vitamins, and prednisone 40 mg daily, tapered progressively over 2 wk for presumed drug induced liver injury (DILI).

On a return visit 2 wk later, the patient showed no improvement in her symptoms and was complaining of

**Figure 1** Hepatic histology. A: Relatively large portal tract containing bile ducts with increased nuclear to cytoplasmic ratio, eosinophilic transformation of the cytoplasm, nuclear hyperchromasia, and uneven nuclear spacing; B: Small portal tract containing the hepatic artery and portal vein, but there is no bile duct. Five of twelve interlobular portal tracts in this biopsy lacked bile ducts; C: Hepatectomy specimen: loss of interlobular bile ducts in most of the small portal tracts, more advanced portal and periportal fibrosis with short fibrous septa. (Haematoxylin & Eosin stain,  $\times 100$ ).

worsening pruritus and an additional 10-pound weight loss. Lab tests at this time revealed a total bilirubin of 35 mg/dL and acute renal failure with BUN of 89 and creatinine of 7.5 (Table 1). The patient was admitted to the medical intensive care unit. She was challenged with intravenous fluids with improvement in her creatinine to 3.9 mg/dL. However, the patient's clinical condition continued to deteriorate with a new development of lethargy. The INR increased to 3.4 despite subcutaneous injections of Vitamin K, and the total bilirubin peaked at 51 mg/dL. The patient underwent orthotopic liver transplantation, 54 d after the initial ingestion of celecoxib.

Sections through the hepatectomy specimen showed severe intrahepatic cholestasis, prominent ductopenia,

and degenerative changes of the duct epithelial cells involving most of the small bile duct branches; the large bile ducts showed little to no evidence of duct injury. More advanced portal and periportal fibrosis was noted (Figure 1C). The postoperative course was uneventful. On follow-up visits at 1 and 6 mo, the patient remained clinically stable and had normal LFTs (Table 1).

## DISCUSSION

Many NSAIDs and COX-2 inhibitors have been associated with hepatotoxicity varying from transient cholestatic<sup>[7-10]</sup> and hepatocellular injury<sup>[11,12]</sup> to fulminant hepatic failure<sup>[3-6]</sup>. The incidence of COX-2-associated hepatotoxicity is extremely difficult to estimate accurately and the current literature is based on case reports of side effects. Several cases of liver injury associated with celecoxib use have been reported. Self-limited cholestatic hepatitis was reported in most of the cases with resolution of symptoms after stopping celecoxib<sup>[7-10]</sup>.

Liver failure associated with COX-2 inhibitor use has been reported with Nimesulide and rofecoxib<sup>[3-6]</sup>. Fulminant liver failure requiring orthotopic liver transplantation after celecoxib use has been recently reported in one case<sup>[3]</sup>. To our knowledge, our case is the second documented case of celecoxib-induced liver failure requiring liver transplantation. Interestingly, our patient developed a liver injury after a 3-d course of celecoxib when compared to the 2-wk course in the other reported case of celecoxib-induced liver failure<sup>[3]</sup>.

Several factors support the diagnosis of drug-induced liver injury (DILI) secondary to celecoxib as the most likely etiology for our patient's liver failure. These include: the acute presentation following celecoxib use; the significant eosinophilia in the blood and on the liver biopsy; and finally, the exclusion of other etiologies for liver failure.

To further assess the likelihood of DILI, we used the Roussel Uclaf Causality Assessment Method/Council for International Organizations of Medical Sciences (RUCAM/CIOMS) scoring system<sup>[13]</sup>. The criteria for scoring include: time to onset of the reaction, course of the reaction, risk factor(s) for drug reaction, concomitant drug(s), non drug-related causes, previous information on the drug, and response to re-administration. Using this system, the causality of the drug in our case is classified as "probable", with a score of 8. A more recent DILI diagnostic scale uses temporal relationship between drug intake and the onset of clinical picture, exclusion of alternative causes, extrahepatic manifestations, intentional or accidental re-exposure to the drug, previous reports in the literature of cases of DILI associated with the drug<sup>[14]</sup>. On a scale of -6 to 20, the probability of the diagnosis of DILI is expressed as: definite  $\geq 17$ , probable = 14-17, possible = 10-13, unlikely = 6-9, and excluded  $\leq 6$ . Our patient scored 15, hence the likelihood of DILI is "probable".

The underlying mechanisms for NSAIDs-induced

liver injury are poorly understood. The adverse effects are due to either host dependent idiosyncratic reactions or dose dependent intrinsic reactions. Idiosyncratic reaction, which is the most common type, is mediated by either an immunological mechanism or abnormalities in drug metabolism<sup>[15]</sup>. The etiology of DILI in our patient is most likely an idiosyncratic reaction as she developed her symptoms after taking a relatively short course of celecoxib, well within its recommended daily adult dose.

In conclusion, we present a case of cholestatic hepatic injury following a short course of celecoxib progressing to liver failure and requiring liver transplantation. Clinicians should be aware that despite its better safety profile for gastrointestinal side effects compared to nonselective NSAIDs, celecoxib may be associated with severe hepatotoxicity.

Combined hepatocellular and cholangiocellular carcinoma presenting with radiological characteristics of focal nodular hyperplasia. *World J Gastroenterol* 2009; 15(31): 3940-3943 Available from: URL: <http://www.wjgnet.com/1007-9327/15/3940.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.3940>

## INTRODUCTION

The two major subtypes of primary liver cancer are hepatocellular carcinoma (HCC) and cholangiocarcinoma (CC). Combined hepatocellular and cholangiocellular carcinoma (cHCC-CC) is a rare tumor type containing unequivocal elements of both HCC and CC that are intimately mixed<sup>[1,2]</sup>. It accounts for 1.0%-14.2% of all primary liver carcinomas<sup>[3]</sup>. Initial misdiagnosis was reported in several patients. The main diagnostic techniques for cHCC-CC include serum markers, imaging and histological analysis.

## CASE REPORT

A 47-year-old woman, who was admitted to the radiology department of our hospital, presented with a 2 mo history of general illness, slight weight loss and a palpable mass in the right upper abdomen. Ultrasound and contrast-enhanced computed tomography (CT) of the abdomen were performed in another hospital. Ultrasound of the upper abdomen revealed a heterogeneous hypoechoic tumor in the liver. The CT scan showed a heterogeneous contrast-enhanced mass in segments 5 and 6 of the liver. Her past medical history included an appendectomy and hepatitis B positivity for more than 15 years. She was considered a so called healthy carrier of hepatitis B.

Magnetic Resonance Imaging (MRI) was performed in our hospital. On MRI a focal liver lesion inferior in the right lobe was visualized. The mass was homogeneous hypointense on T1 (Figure 1C and G) and slightly hyperintense on T2 (Figure 1A and B). The dynamic contrast-enhancement with gadolinium chelate (Magnevist®, Baeyer HealthCare Pharmaceuticals, Düsseldorf, Germany) established a relatively hypervasculature heterogeneous nature with late enhancement of the central scar (Figure 1D-H). The contrast-enhancement

## Abstract

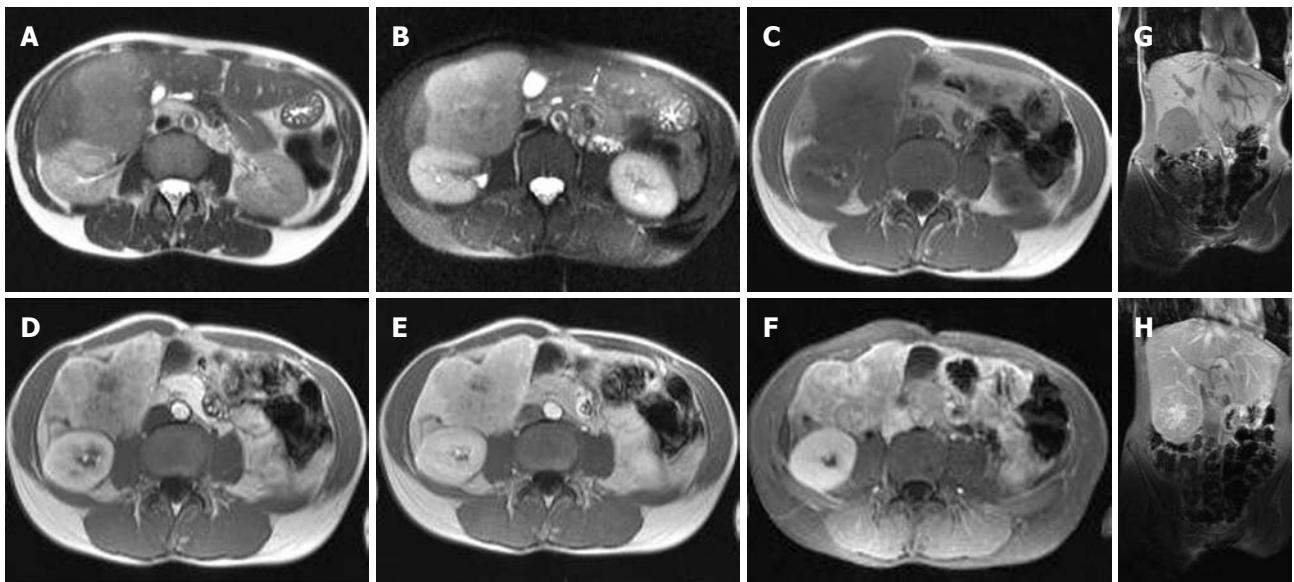

Combined hepatocellular and cholangiocellular carcinoma (cHCC-CC) is a rare tumor type containing unequivocal elements of both hepatocellular carcinoma and cholangiocarcinoma that are intimately mixed. Although these tumors are usually considered to be more related to hepatocellular carcinoma than to cholangiocarcinoma, they sometimes, in contrast to hepatocellular carcinoma, contain a significant amount of fibrous stroma. This might in some cases explain atypical radiological features. We report a case of a cHCC-CC in a 47-year-old female that resembled focal nodular hyperplasia on Magnetic Resonance Imaging. Correlation of imaging and serum levels of  $\alpha$ -fetoprotein and CA19.9 can help to make the correct diagnosis preoperatively.

**Figure 1 MRI images of combined hepatocellular and cholangiocellular carcinoma.** Axial T2 (A) and T2 fat saturated (B) MRI images showed a slightly well circumscribed lesion. The mass is hyperintense in comparison to the normal liver. Axial T1 (C) MRI images demonstrated a hypointense lesion. Early arterial (D), late arterial (E) and venous (F) MRI images displayed a hypervascular heterogeneous enhancement with central scar. The coronal T1 (G) image showed a hypointense lesion, while the coronal T1 MRI image after Gadolinium contrast (H) demonstrated a heterogeneous early enhancement of the lesion with delayed uptake in the scar.

**Figure 2 Histopathological images of combined hepatocellular and cholangiocellular carcinoma.** A: Nests of tumor cells with trabecular architecture, reminiscent of hepatocellular differentiation, separated by bands of fibrous tissue; B: Focally tumor cells formed glandular structures with mucinous secretory material, compatible with cholangiocellular differentiation.

and morphologies were consistent with focal nodular hyperplasia. Laboratory results, however, revealed an elevated  $\alpha$ -fetoprotein level of 154 000 ng/mL.

Right hepatectomy was performed. A white firm tumoral mass of 8.5 cm in diameter and one satellite

nodule of 1 cm were identified during macroscopic examination of the resection specimen. The non-tumoral liver did not display signs of cirrhosis macroscopically. Microscopically, the tumor consisted of nests of tumor cells separated by broad bands of fibrous tissue, focally resembling a fibrous scar (Figure 2A). In most tumor cell nests, tumor cells displayed a trabecular growth pattern. Trabecular structures were several cell layers thick, in contrast to normal liver tissue in which trabeculae are only 1 to 2 layers in thickness. Focally, however, glandular structures containing secretory material were observed (Figure 2B). Tumor cells arranged in trabecular structures displayed positivity for HepPar1 and  $\alpha$ -fetoprotein and immunohistochemistry with a polyclonal anti-CEA antibody revealed the presence of canalicular structures. These features are consistent with hepatocellular differentiation. Where tumor cells formed glandular structures, the presence of neutral mucin could be demonstrated. The secretory material displayed alcian blue positivity and was positive in a PAS-diastase reaction, compatible with cholangiocellular differentiation. Moreover, areas of glandular differentiation displayed positivity for CA19.9 and MUC1, while areas of hepatocellular differentiation were negative. In addition, positivity for CK7 and CK19 was observed in areas of glandular growth pattern, while areas with trabecular growth pattern displayed most often only positivity for CK8 and CK18. These histological features together with the immunohistochemical profile are consistent with a diagnosis of cHCC-CC.

## DISCUSSION

cHCC-CC is a rare primary liver tumor type containing unequivocal elements of both hepatocellular carcinoma and cholangiocarcinoma<sup>[1,2]</sup>. It accounts for 1.0%-14.2% of

all primary liver carcinomas<sup>[3]</sup>. In 1949, the first description of cHCC-CC was reported by Allen *et al*<sup>[4]</sup>. Some studies found that this tumor type is more frequently diagnosed in patients with chronic hepatitis and liver cirrhosis<sup>[5]</sup>, although this could not be confirmed in other studies<sup>[1]</sup>. Most studies report that patients with cHCC-CC show similar clinical and pathological features as hepatocellular carcinoma patients, including a mean age onset in the sixth decade, male predominance, a high incidence of hepatitis B virus infection, underlying chronic liver disease and elevated serum  $\alpha$ -fetoprotein levels<sup>[6]</sup>. Several reported patients were initially misdiagnosed<sup>[7]</sup>. Various factors, such as an atypical enhancing pattern on imaging, the small size of one of the components, and the presence of a tumor composed of intermediate tumor cells, were found to be the causes of misdiagnosis<sup>[8]</sup>. The tumor remains usually generally clinically silent and patients present with advanced illness<sup>[6]</sup>. A simultaneous elevation of serum levels of CA 19-9 and  $\alpha$ -fetoprotein in patients with a liver mass on imaging may suggest the presence of cHCC-CC<sup>[7]</sup>. Ultrasound usually demonstrates a round or ovoid hypoechoic mass with a central hyperechoic area<sup>[9]</sup>. On contrast-enhanced CT, cHCC-CC lesions are divided into 3 classes of enhancement patterns. The first group of lesions, namely cHCC-CC resembling hepatocellular carcinoma, shows hyperenhancement in the early phase and hypoenhancement in the late phase due to washout of contrast (Type I lesions). The second group, Type II lesions, demonstrates peripheral enhancement in the early as well as in the late phase. Type III lesions present an area of hyperenhancement in the early phase and an area of slight delayed enhancement in the late phase<sup>[10]</sup>. The cHCC-CC lesions resembling cholangiocarcinoma, however, enable low attenuation in the arterial phase and low, iso- or high attenuation in the venous phase<sup>[11]</sup>. Preoperatively cHCC-CC is, however, usually only considered when a liver tumor has CT features of both hepatocellular carcinoma and cholangiocellular carcinoma<sup>[12]</sup>. In addition, Toh *et al*<sup>[13]</sup> reported a hypodense tumor with vague contrast enhancement associated with elevation of  $\alpha$ -fetoprotein levels and multiple regional lymphadenopathies as a cHCC-CC. Finally, cHCC-CC has also been reported as presenting as a hypervascular tumor associated with increased serum CEA and CA 19-9<sup>[14]</sup>.

On MRI, cHCC-CC has been reported to show low signal intensities on T1-weighted images and high signal intensities on T2-weighted images<sup>[15]</sup>. In the arterial phase, it has been described that the T1-weighted images describe an enhancing mass nearly isointense to the surrounding parenchyma with a central necrotic non-enhancing zone<sup>[10]</sup>.

Final diagnosis of cHCC-CC can only be made by histological examination. Extensive sampling of tissue is required in order not to miss the diagnosis in case one of the tumor compounds represents only a minor component of the tumor. Surgery is the only effective treatment for this tumor. The median survival time following cHCC-CC surgery has been reported to be 48 mo<sup>[17]</sup>. Partial hepatectomy with lymph node dissection can result in 5-year survival rates exceeding 50% in

patients with early stage disease<sup>[18]</sup>. Prognostic factors of poor outcome of cHCC-CC are distant metastasis, major vascular branch invasion, regional lymph node involvement, bilobar distribution, multiple tumors, tumor necrosis and ascites<sup>[19]</sup>.

In conclusion, preoperative diagnosis of cHCC-CC remains difficult. It is of great importance to choose appropriate imaging, such as MRI, in combination with serum  $\alpha$ -fetoprotein and CA 19.9 levels. In addition, extensive tissue sampling is required in order to not miss this diagnosis in cases where one of the two components is of small size. Most studies show that this tumor type has similar geographical distribution and age and sex distribution as hepatocellular carcinoma. Some authors, however, have reported a worse prognosis as compared to patients with pure hepatocellular carcinoma.

### Abstract

X-linked agammaglobulinaemia (XLA) is a humoral immunodeficiency syndrome characterized from childhood by the absence of circulating B lymphocytes, absent or reduced levels of serum immunoglobulin and recurrent bacterial infections. For many affected patients, regular treatment with immunoglobulin is life saving. Hepatitis C viral (HCV) infection acquired through contaminated blood products is widely described in this patient cohort. The natural history of HCV infection in patients with XLA tends to follow a more rapid and aggressive course compared to immunocompetent individuals. Furthermore, standard anti-viral therapy appears to be less efficacious in this patient cohort. Here we report the cases of two brothers with XLA who contracted HCV through contaminated blood products. They were treated with a six month course of Interferon alpha-2b and Ribavirin. We report a sustained virologic response five years after completing treatment.

### INTRODUCTION

Infection with the hepatitis C virus (HCV) is characterized by low grade hepatitis which may progress to cirrhosis and hepatocellular carcinoma over many years. The mortality associated with HCV infection is adversely affected by several factors including: the age of the patient at initial infection, ongoing alcohol consumption, intra-venous drug abuse and the viral genotype<sup>[1,2]</sup>. Furthermore, the natural history of HCV infection in immunocompromised patients appears to follow a more aggressive course leading to rapid development of cirrhosis and hepatocellular carcinoma.

X-linked agammaglobulinaemia (XLA) is an inherited immunodeficiency disease caused by mutations in the gene coding for Bruton's tyrosine kinase (BTK) and occurs with a frequency of 1 in 250 000 males<sup>[3]</sup>. Abnormal gene expression prevents B lymphocyte differentiation and maturation in the bone marrow leading to absence of circulating antibody-producing plasma cells<sup>[4]</sup>. Furthermore, abnormalities in T cell function have been demonstrated in patients with XLA<sup>[5]</sup>. The diagnosis of XLA may be made clinically when the following criteria are met: recurrent bacterial infections in a male infant, absence of circulating peripheral B cells and more than one male in the family affected in different generations.

Early reports of HCV infection in hypogammaglobulinaemic patients suggest a severe and rapidly progressive course<sup>[6-9]</sup>. Initial attempts at treatment with interferon alpha demonstrated poor efficacy in maintaining virologic response and made little impact on the mortality and morbidity of those with a rapidly progressive course. Here we report the cases (diagnosis, management and follow-up) of two brothers with XLA who acquired HCV infection through infected blood products.

### CASE REPORT

C.D. and J.D. are brother's aged 27 and 30 years,

respectively. They both suffered from recurrent lower respiratory tract infections as infants. Their younger brother died of pseudomonal meningitis and septicaemia as an infant. Their clinical history raised suspicion for an underlying immunodeficiency syndrome, which was confirmed when both brothers were found to be deficient in serum B cells and immunoglobulin in early childhood. Genotyping for BTK mutation was carried out and a diagnosis of XLA was established in each case. Subsequently, their cousin, who had a similar clinical history, was also diagnosed with XLA.

Both brothers were commenced on gammaglobulin infusions in 1985. This was comprised of fresh frozen plasma pooled from donors, which was not initially screened for viral contaminants. In 2002, routine biochemical analysis revealed raised liver function tests in J.D. and a full liver screen was carried out. Initial screening tests for anti-HCV including Ortho HCV ELISA Test System and Recombinant Immunoblot Assay-3 were negative. Subsequently, PCR for HCV RNA was carried out and was positive for HCV genotype 3 infection. C.D. was then screened and also found to be HCV antibody negative, but PCR positive for genotype 3 infection. The baseline viral loads were 1723102 copies/mL and 52352 copies/mL for J.D. and C.D., respectively. Neither brother had risk factors for HCV infection other than their previous treatment with intravenous gammaglobulin. The results of a full infectious, metabolic and auto-immune liver screen were otherwise negative in both patients. The baseline clinical data for each patient is summarized in Table 1.

Both patients underwent a liver biopsy, which showed chronic active hepatitis. J.D. had stage 1 fibrosis with mild to moderate inflammatory activity, while C.D. had stage 0 fibrosis with mild inflammation. Both brothers were treated with a 24-wk of Pegylated Interferon alpha-2b and Ribavirin which they completed in June, 2003. There were no significant complications during treatment. Both patients were treated with antibiotics for respiratory tract infections during treatment, but did not require admission to hospital. Their viral load became undetectable 4 wk into therapy and both patients remain PCR negative five years post treatment. J.D. currently receives 35 g of Flebogamma and C.D. receives 40 g, every 3 wk, which is well tolerated by both.

## DISCUSSION

Immunoglobulin therapy is widely used for the treatment of immune deficiency syndromes. Unfortunately, several outbreaks of HCV infection secondary to immunoglobulin replacement therapy have been documented in recent times. Although the true prevalence of HCV infection is difficult to estimate in this population, large studies estimate the incidence at approximately 8.3%, a number far greater than that in the immunocompetent population<sup>[10]</sup>. Unfortunately, the diagnosis of HCV in this high risk population remains problematic for several reasons. Firstly, the poor sensitivity of traditionally used screening tests including measurement of serum

**Table 1 Baseline clinical data for both patients**

	Age at diagnosis (yr)	Baseline viral load (copies/mL)	Baseline ALT (IU/L)	Liver histology	Treatment	Time to PCR negative (wk)
C.D.	27	52352	37 (< 42)	Mild inflammation	Peg-Interferon alpha-2b + Ribavirin	< 4
J.D.	30	1723102	87 (< 42)	Stage 1 fibrosis + moderate inflammation	Peg-Interferon alpha-2b + Ribavirin	< 4

aminotransferase and detection of anti-HCV antibody means that a diagnosis of HCV infection will be missed unless PCR for viral RNA is carried out. Secondly, as there is no set of international guidelines or recommendations for screening this patient cohort, there is wide variation in the screening tests employed between different centers. Finally, despite significant developments regarding viral safety for immunoglobulin preparations, clear product documentation is often absent, making early detection of HCV infection and identification and tracing of exposed individuals difficult.

The clinical course of HCV infection in patients with hypogammaglobulinaemia is unclear. Some reports suggest a rapidly progressive course with poor patient outcomes<sup>[8,11]</sup>, while others demonstrate the more usual, slowly progressive course, at least in the short term<sup>[12,13]</sup>. A less aggressive clinical course has been observed in patients with XLA compared with those with combined variable immunodeficiency<sup>[14]</sup>, although this remains a source of debate<sup>[15]</sup>. The variability between different trials remains unexplained. The duration of infection remains as an important predictor of patient outcome. Undoubtedly other co-morbidities including alcohol consumption, intra-venous drug abuse and co-infection with hepatitis B (HBV) adversely impact on the clinical course also. It is noteworthy that Italian patients appear to follow a more benign course following HCV infection than other populations<sup>[13,16]</sup>, suggesting a role of HCV viral load and genotype in the genesis of liver disease.

Early attempts to treat HCV infection with interferon- $\alpha$  monotherapy in patients with primary immunodeficiency have been disappointing<sup>[6,8]</sup>. However, more recent data demonstrates sustained virologic responses (SVRs) of 54%<sup>[13]</sup>, and between 35%-40% approximately<sup>[14,15]</sup>, in similar patients with acute and chronic HCV infection respectively. Due to the small number of patients involved, it is difficult to determine the influence of viral load and viral genotype on treatment response. Improved treatment outcomes are seen however in patients with a shorter duration of infection and when combination therapy (Interferon and Ribavirin) is used. The excellent treatment response seen in our patients may relate to multiple factors including a favourable genotype, the young age of each patient, minimal liver fibrosis and the absence of other co-morbidities. The duration of infection is unknown as the infected batch was never identified. Although patients are considered to have achieved SVR when they remain PCR

negative six months post completion of treatment, we delayed the reporting of our patients in case of late relapse.

In conclusion, our report raises a few important points. Firstly, all patients who received intravenous immunoglobulin during periods when routine screening was not carried out, should be tested for HCV infection. The importance of measuring HCV RNA rather than looking for HCV antibodies in this patient cohort can not be overstated. Indeed, serological tests failed to make a diagnosis of active HCV infection in both our patients. Secondly, the successful outcome of treatment in both patients highlights the limited role of humoral immunity in the mechanisms of HCV clearance. Finally, despite pessimistic initial reports, the diagnosis and treatment of HCV infection in patients with XLA can lead to excellent long-term outcomes.

### Abstract

Lymphangioma usually occurs in children and usually involves the skin. Mesenteric lymphangioma is extremely rare in adults. Typically, lymphangioma appears on computed tomography (CT) as a lower attenuation of a cystic mass, however, some cases appear to be a solid mass. We describe the CT and 18F-FDG positron emission tomography/CT appearance in a case of jejunal and mesenteric cavernous lymphangiomatosis mimicking metastasis in an adult patient with rectal cancer.

### INTRODUCTION

Gastrointestinal and mesenteric lymphangioma or lymphangiomatosis are extremely rare in adults<sup>[1-3]</sup>. A lymphangioma usually appears as a partially septated, cystic mass on imaging studies including ultrasound, computed tomography (CT), and magnetic resonance imaging (MRI). CT is a basic imaging modality for detecting and evaluating various malignancies. Occasionally, lymphangioma may appear as a solid or infiltrative soft tissue mass on CT because of its microcystic nature or if there is intracystic debris or hemorrhage. The non-cystic appearance of mesenteric lymphangioma may be confused on CT with metastasis or a malignant tumor, especially in patients with malignancy. 18F-FDG positron emission tomography (PET)/CT may have an important role for staging malignancy because hypermetabolic tumor cells actively uptake 18F-FDG<sup>[4]</sup>. This report describes the CT and 18F-FDG PET/CT appearance of a mesenteric and jejunal lymphangiomatosis mimicking metastasis in an adult patient with rectal cancer.

### CASE REPORT

A 71-year-old man was referred for evaluation of a rectal cancer detected on colonoscopy and CT during an evaluation of hematochezia. He had a 5-year history of taking medication for underlying angina. Rectal examination showed a hard mass in the rectum. The standard laboratory tests were normal. Rectal cancer was seen as segmental and irregular wall thickening in the distal rectum with several enlarged perirectal lymph nodes on contrast-enhanced CT (Figure 1A). The soft-tissue density of the nodular mass and hazy attenuations in the jejunal mesentery (Figure 1B) were overlooked initially on either CT scans or on surgery. The patient underwent laparoscopic abdominal transanal resection and ileostomy. Adjuvant chemotherapy and ileostomy closure were performed during the year following surgery. Follow-up, contrast-enhanced CT revealed nodular jejunal and adjacent mesenteric masses in contrast to the barium-filled jejunum; the masses measured approximately 8 cm × 6 cm in width (Figure 1C). Under the suspicion of mesenteric and jejunal wall metastasis from the rectal cancer, 18F-FDG PET/CT was performed, but no remarkable FDG uptake was seen (Figure 1D).

**Figure 1** A 71-year-old man with rectal cancer and mesenteric lymphangioma. A, B: Contrast-enhanced, coronal CT images show irregular and concentric rectal wall thickening (arrow heads), a nodular soft-tissue-density mass, and hazy strands in the jejunal mesentery (arrows); C: Follow-up, contrast-enhanced, coronal CT obtained one year after laparoscopic rectal cancer resection, reveals clear demarcation of the jejunal nodular lesions and infiltrative soft tissue masses in the adjacent mesentery. No remarkable jejunal obstruction was found; D: 18F-FDG PET shows no 18F-FDG uptake in the jejunum or mesenteric lesions; E: The cut section of the jejunum reveals a dark-red, multiloculated, cystic lesion measuring 8.0 cm × 5.0 cm in the mucosa to the subserosa; F, G: Histopathologic view of the tumor shows numerous, multiloculated, cystically dilated lymphatic spaces lined by attenuated endothelium in the entire jejunal wall (HE stain,  $\times 40$ ) and adjacent mesentery (HE,  $\times 20$ ).

Pathological examination of a resected segment of the jejunum revealed a macroscopic, dark red, multiloculated cystic lesion measuring 8.0 cm × 5.0 cm from the mucosa to the subserosa (Figure 1E). Microscopically, it showed numerous multiloculated, cystically dilated spaces lined by attenuated endothelium and involved mucosa to subserosa. In the focal area, ectatic spaces appeared to dissect through the muscularis propria of the small intestine. Proteinaceous, fluid-containing lymphocytes seen in the cystic spaces revealed that the channel originated in the lymphatic system. The stroma was composed of a delicate meshwork of collagen punctuated by lymphoid aggregates (Figure 1F). Immunohistochemical staining for CD34 showed positivity in the endothelial cells of the tumor (Figure 1G). The diagnosis of cavernous lymphangioma involving the jejunum and mesentery was established. The patient had an uneventful postoperative course and was discharged one week after surgery.

## DISCUSSION

Lymphangioma or lymphangiomatosis affect the skin, the covering of various organs and areas except of the brain. About 90% are diagnosed within the first two years of their existence<sup>[1,2]</sup>. In adults, gastrointestinal tract involvement of mesenteric lymphangioma is very rare, the distal ileal mesentery is most frequently involved<sup>[3]</sup>. The etiology of lymphangiomas is still unclear. They are considered to be a congenital dysplasia of lymphatic tissue and abnormal development of the lymphatic vessels during fetal life<sup>[5,6]</sup>. The macroscopic appearance of lymphangioma is a cystic mass with partial septations

and its histological characteristics are endothelial-lined, dilated, communicating lymphatic channels containing a variable amount of connective tissue and smooth muscle fiber<sup>[5,7]</sup>. Lymphangiomas are generally classified as simple capillary, cavernous, and cystic according to the size of lymphatic space and the nature of the lymphatic wall<sup>[8,9]</sup>. Cavernous lymphangioma is composed of dilated lymphatic vessels and lymphoid stroma and is connected with the adjacent normal lymphatics. Alternatively, cystic lymphangioma is composed of various-sized lymphatic spaces and has no connection with the adjacent normal lymphatics. However, as cystic lymphangiomas may have a cavernous area, clear differentiation between cystic and cavernous lymphangioma is not always possible<sup>[9,10]</sup>.

Most intra-abdominal lymphangiomas are of cystic form and generally appear as a thin-walled, multiseptated, cystic mass with or without intracystic debris. Although these lymphangioma characteristics may appear in typical, multiseptated, cystic masses on images including ultrasound and CT, some lymphangiomas may appear to be solid masses because they contain intracystic debris or hemorrhage or due to the microcystic nature of cavernous lymphangiomas. MRI is advantageous for detecting fluid-filled cystic lesions as it may reveal the cystic nature of cavernous lymphangiomas that appear as solid masses on CT<sup>[11]</sup>. In our patient with rectal cancer, multiple nodular mesenteric masses infiltrating into the jejunum and adjacent mesentery were found. Because we did not suspect the microcystic nature of cavernous lymphangiomas, MRI was not performed to differentiate a microcystic tumor mimicking a solid mass.

As 18F-FDG is an analogue of glucose, its uptake

within viable tumor cells is in proportion to the rate of glycolysis. Therefore, as 18F-FDG PET/CT can detect hypermetabolic tumor cells, it can be widely used for the detection, staging, and management of various malignant tumors<sup>[4]</sup>. In our patient, as 18F-FDG PET/CT revealed no remarkable 18F-FDG uptake within the solid, mass-like lesions in the jejunal and adjacent mesentery, we were able to exclude the possibility of metastasis from the underlying rectal cancer.

The clinical symptoms of gastrointestinal and mesenteric lymphangiomas vary from being asymptomatic to acute abdominal symptoms such as obstruction or bleeding, according to the size and the localization of the tumor<sup>[10,12,13]</sup>. The treatment of choice is complete surgical resection. Because lymphangioma is benign in nature, the prognosis is usually good despite the possibility of tumor recurrence. As Goh *et al*<sup>[14]</sup> reported a 100% recurrence rate, complete lymphangioma resection is important in order to prevent tumor recurrence.

In conclusion, rarely occurring, cavernous mesenteric lymphangioma in adults occasionally appears on CT as a solid mass and it may be confused with metastasis in patients with malignancies. Therefore, 18F-FDG PET/CT may be helpful in excluding the presence of metastasis.

## INTRODUCTION

Preduodenal portal vein (PDPV) is a rare congenital anomaly which was first described by Knight in 1921<sup>[1]</sup>. Clinically, 50% of the patients present with symptoms related to intestinal obstruction, but only in a few is the obstruction directly caused by the PDPV<sup>[2-4]</sup>. In the majority of cases, the obstruction is thought to be caused by associated anomalies such as duodenal diaphragm, intestinal malrotation, and annular pancreas. In the remaining 50%, PDPV is asymptomatic and diagnosed incidentally on preoperative investigation or during surgery for other diseases<sup>[2-4]</sup>. Patients with symptoms directly associated with PDPV or resulting from associated anomalies often require correction of the intestinal obstruction<sup>[2-5]</sup>.

Scoliosis is a well known anomaly in the pediatric orthopedic field. In patients with severe scoliosis, a surgical correction is often needed. The hallmark of surgical treatment is thought to be early intervention before the development of large curvatures<sup>[6]</sup>. Recent orthopedic surgery for scoliosis has evolved to include the routine use of spinal instrumentation to achieve a good result.

No reports have been published regarding patients

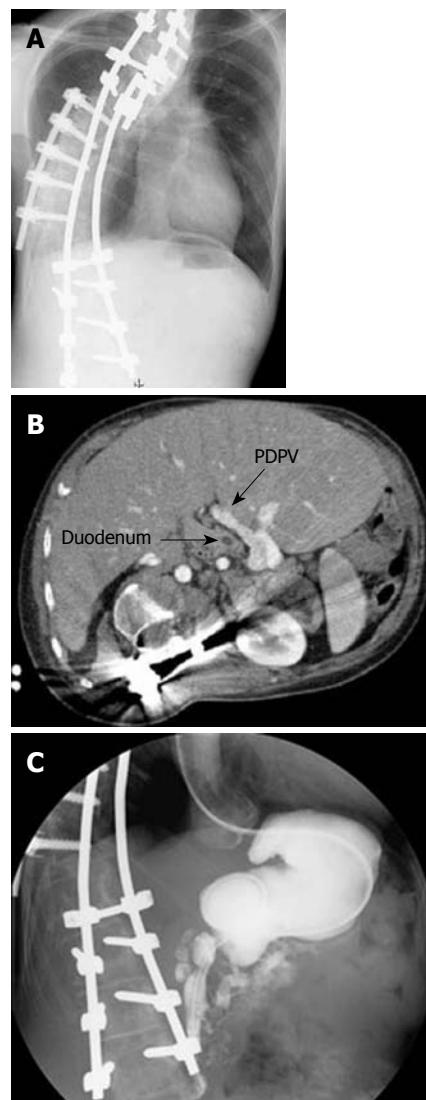

with PDPV associated with severe scoliosis. We experienced one male patient with malnutrition resulting from PDPV and a previously performed operation for scoliosis. An improvement in the quality of life (QOL) was found after being treated with a combination of a gastrojejunostomy, with both Braun's anastomosis and a side-to-side anastomosis between the duodenal second portion and jejunum, and nutritional support. Therefore, we herein report and discuss the clinical course of this patient and his treatment.

## CASE REPORT

A 22-year-old male patient with PDPV presented with duodenal stenosis, ranging from the first to the second portions. Frequent vomiting had occurred at 1 year of age. Therefore, fundoplication had been performed at 2 years of age in another hospital. However, he had occasionally suffered from vomiting since the fundoplication. In addition, he gradually developed severe scoliosis over time. Therefore, he underwent surgery twice for scoliosis at 21 and 22 years of age. After the orthopedic operations, he developed malnutrition because of severe vomiting during a 6-mo period. In another hospital, the cause of the vomiting was investigated, and found to be the result of widespread duodenal stenosis.

On admission to our department, an X-ray film showed a spine with a large curve to the right side although it was corrected by previous orthopedic surgery (Figure 1A). Abdominal computerized tomography (Figure 1B) and a gastrointestinal contrast study (Figure 1C) revealed that the stenosis was associated with both the PDPV and the previously performed operation for scoliosis. In addition, his nutritional condition at admission was extremely poor (body mass index: 11.4). Furthermore, he also had diabetes associated with dysfunction of Vater's sphincter. We therefore introduced nutritional support using both parenteral and enteral nutrition by jejunal feeding tube at first. Two months later, the blood sugar was well controlled by insulin therapy. During nutritional support with insulin therapy for 6 mo, his nutritional condition gradually improved (Figure 2). Six months later, his nutritional condition was observed to have returned to the normal level for his age (body mass index: 18.2, Figure 2).

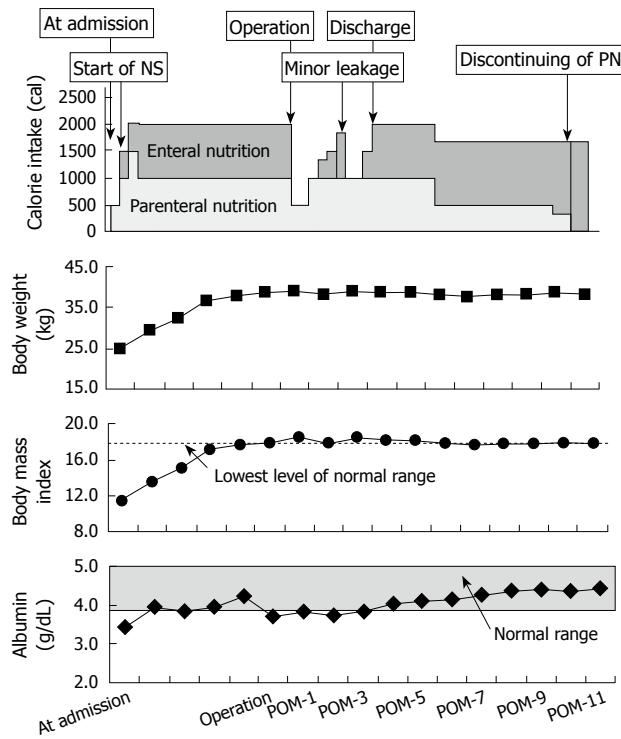

Thereafter, an operation was performed. The operative findings showed that the PVPD had induced the severe stenosis of the duodenal first portion, and that the stenosis widely ranging from the second to third portions was a result of stretching by the corrected spine (Figure 3A). No intestinal malrotation was found. The liver was confirmed to be a symmetrical liver. The head of the pancreas was found to be attached to the stenosis of the first duodenal portion. However, the pancreas did not surround any portions of the duodenum. Although the second portion was mildly dilated after performing mobilization of the duodenal second portion, neither the first nor third duodenal portion was dilated (Figure 3B). Therefore, a gastrojejunostomy with Braun's anastomosis was selected and performed (Figure 3B). In addition, a side-to-side anastomosis between the duodenal second

**Figure 1** Images at admission. A: Plain X-ray film. Although the spine was corrected by a previous orthopedic operation, a severe scoliosis with right side protrusion was found at admission; B: Abdominal CT scan. The preduodenal portal vein (PDPV) was found to be located in the anterior side of the duodenum; C: Contrast study of the upper gastrointestinal tract. A contrast study of the duodenum showed a stenosis ranging from the second to third portions. In addition, the contents flowed to both the dilated main pancreatic duct and common bile duct.

portion and jejunum was performed to allow smooth passage of the duodenal contents (Figure 3B).

The postoperative course was uneventful except for slight leakage at the site of anastomosis. Regarding his diabetes, he required insulin therapy for the control of blood sugar. The postoperative contrast study showed that duodenal passage in the second portion improved and that most of the contents in the stomach flowed smoothly into the connected jejunum through the gastrojejunostomy. Two months later, he could eat a normal volume of solid food by mouth (Figure 2). Three months later, he was discharged, using both feeding by mouth and home parenteral nutrition with insulin therapy, and was again able to attend university (Figure 2). Seven months after discharge, he no longer required home parenteral nutrition. Unfortunately, an improvement in his diabetes

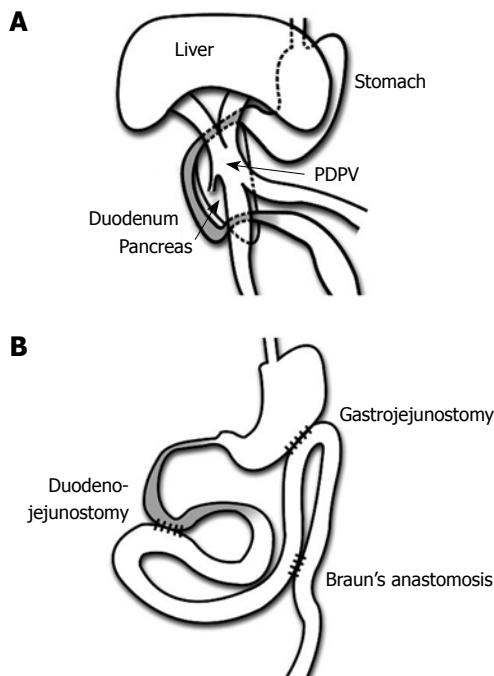

**Figure 2 Clinical course of our patient.** This figure shows the clinical course of our patient during the period from admission to the cessation of parenteral nutrition. After the preoperative nutritional support using both parenteral and enteral nutrition for 6 mo, an improvement in body weight and body mass index was seen. After the operation, the calorie intake from parenteral nutrition was gradually reduced. The postoperative anthropological markers were maintained. NS: Nutritional support; POM: Postoperative months.

was not observed after the operation and therefore he has needed to continue insulin therapy.

## DISCUSSION

In general, a PDPV without associated anomalies may be the cause of duodenal stenosis in the first or second portion if symptoms related to PDPV occur<sup>[1-5,7,8]</sup>. Therefore, in such patients, an operation including duodenoduodenostomy, is thought to be required for the smooth passage of duodenal contents<sup>[1-5,7,8]</sup>. However, in this patient with PDPV, the stenosis ranged from the first to the third portions of the duodenum. This may be why duodenal stenosis in this patient was also associated with severe scoliosis. He had needed an operation for severe scoliosis but the surgery was not thought to be good for duodenal passage because the duodenum was stretched longitudinally to the spinal axis. After the orthopedic operation, his symptoms had further deteriorated. The first portion of the duodenum was thought to be anchored to both the thick pedicle of the PDPV and the head of the pancreas, and stretched to the hepatic side before the orthopedic operation. Therefore, the orthopedic operation may have induced excessive stretching of the duodenum, resulting in the duodenal stenosis, ranging from the second to third portions, in addition to the stenosis of first portion arising from the PDPV.

In this patient, the long-term symptoms related to

**Figure 3 Operative findings and performed procedures in our patient.** A: Operative findings. The PDPV was found to induce the severe stenosis of the duodenal first portion and the stenosis ranging from the second to third portions was the result of stretching by spinal correction. No intestinal malrotation was found. The liver was confirmed to be a symmetrical liver. The head of the pancreas was found to be attached to the stenosis of the first duodenal portion. The duodenum is colored gray in this figure; B: Performed procedures. A gastrojejunostomy with Braun's anastomosis was performed for the stenosis in the first portion. In addition, a duodenojjunostomy between the duodenal second portion and jejunum was performed for smooth passage of the duodenal contents. The duodenum is also colored gray in this figure.

PDPV, including frequent vomiting, induced malnutrition. In addition, the duodenal stretching after the orthopedic operation also contributed to the malnutrition. In general, if the severe symptoms are thought to be related to PDPV, duodenoduodenostomy is performed first<sup>[1,7,8]</sup>. However, in this patient, we preceded surgery with the recovery of his nutritional condition using both parenteral and enteral nutrition, since his nutritional condition had been very severe at admission. Although the time required for the nutritional recovery was long, the operation for the duodenal stenosis was performed smoothly, leading to a good postoperative clinical course. Therefore, in a specific case with severe malnutrition as in this report, nutritional support may precede the operation for severe duodenal stenosis.

In cases where duodenoduodenostomy is performed for duodenal stenosis resulting from PDPV, recent studies recommend the loose overbridging duodenoduodenostomy in order not to compress the blood flow of the portal vein<sup>[9]</sup>. In this patient, we could not perform the loose overbridging duodenoduodenostomy for stenosis of the duodenal first portion because the stenosis was widespread. Therefore, a gastrojejunostomy with Braun's anastomosis was performed. In addition, a side-to-side anastomosis between the duodenal second portion and the jejunum was performed to allow smooth passage of the duodenal contents, including the pancreatic juice and

bile, because Kocher's duodenal mobilization did not result in enough improvement of the stenosis ranging from the second to third portions. As no patient with a clinical course similar to our patient had been reported in the literature, we were uncertain which operations were the best choice for this patient. However, based on the postoperative clinical course in our patient, the operations we performed resulted in an improvement in the patient's QOL. Therefore, such a combination of operations is thought to be one choice for severe widespread duodenal stenosis.

small ectopic pancreas developing into jejunojejunal intussusception: A rare cause of ileus. *World J Gastroenterol* 2009; 15(31): 3954-3956 Available from: URL: <http://www.wjgnet.com/1007-9327/15/3954.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.3954>

### INTRODUCTION

Ectopic pancreas is not an extremely rare pathological condition<sup>[1-3]</sup>. It is defined as the presence of pancreatic tissue lacking anatomical and vascular continuity with the pancreas<sup>[1]</sup>. It occurs most commonly in the stomach, duodenum, and jejunum and has been reported in other locations, including the ileum, Meckel's diverticulum, colon, gall bladder, umbilicus, fallopian tube, mediastinum, spleen, and liver<sup>[2]</sup>. The majority of the cases have been found incidentally at laparotomy performed for other abdominal diseases. When an ectopic pancreas is found incidentally during surgery for other abdominal conditions, resection should be considered because of the risk of late clinical problems. This disease occasionally develops symptoms such as bleeding, vomiting or abdominal pain due to pancreatitis<sup>[2,3]</sup>. Even if symptoms are present, the preoperative diagnosis of ectopic pancreas in the small bowel appears to be difficult. Malignant transformation can occur in the ectopic pancreas tissue as well as in the tissue of a normally located pancreas. However, the incidence of malignant change in the ectopic pancreas has been estimated to be less than that of the normal pancreas itself<sup>[3]</sup>. Ectopic pancreas rarely occurs as intestinal invagination leading to ileus in adults<sup>[4]</sup>. Here, we describe a rare case of small jejunal ectopic pancreas that led to jejunojejunal intussusception and ileus.

### CASE REPORT

The patient was a 62-year-old Japanese man. He was admitted to our hospital complaining of intermittent abdominal pain of several months' duration that was increasing in both magnitude and frequency. He had not had previous abdominal surgery and had been in good health. No specific family history was identified. His body temperature was 36.8°C, blood pressure was 132/76 mmHg, and radial pulse rate was 62 beats/min and regular. He had neither anemia nor jaundice. A neurological examination revealed no abnormal findings.

### Abstract

Intussusception is rare in adults. We describe a 62-year-old man with jejunal ectopic pancreas that led to jejunojejunal intussusception and ileus. The patient was admitted to our hospital because of intermittent abdominal pain. Plain abdominal radiography showed some intestinal gas and fluid levels. Abdominal CT scan demonstrated a target sign suggesting bowel intussusception. Jejunography using a naso-jejunal tube showed an oval-shaped mass about 15 mm in diameter with a smooth surface in the jejunum, which suggested a submucosal tumor (SMT), and edematous mucosa around the mass. Partial jejunal resection was carried out and the resected oval-shaped tumor, 14 mm × 11 mm in size, was found to be covered with normal jejunal mucosa. The tumor was histologically diagnosed as type III ectopic pancreas according to the classification proposed by Heinrich. Abdominal pain resolved postoperatively. This case reminds us that jejunal ectopic pancreas should be included in the differential diagnosis of intussusception caused by an SMT in the intestine.

**Figure 1** Jejunography using a naso-jejunal tube showed an oval-shaped mass in the jejunum (arrow) and edematous mucosa around the mass.

**Figure 2** Macroscopic findings of the tumor. A 14 mm x 11 mm oval-shaped submucosal tumor covered with normal mucosa was observed.

**Figure 3** Histological findings of the tumor. The localized tumor was composed of proliferating ducts and proliferation of smooth muscle bundles without mitotic figures. However, both exocrine acini and endocrine elements were lacking (HE,  $\times 100$ ).

Laboratory tests showed hemoglobin concentration of 14.6 g/dL, a red blood cell count of  $441 \times 10^4/\mu\text{L}$ , a white blood cell count of  $10300/\mu\text{L}$  (normal range:  $4000-8000/\mu\text{L}$ ), and a platelet count of  $19.5 \times 10^4/\mu\text{L}$ . Biochemical tests were within normal limits. Plain abdominal radiography showed some intestinal gas and fluid levels. Abdominal CT scan demonstrated a target sign suggesting bowel intussusception and dilated small bowel. Subsequent jejunography using a naso-jejunal tube showed an oval-shaped mass 15 mm in diameter with a smooth surface in the jejunum, which suggested a submucosal tumor (SMT), and edematous mucosa around the mass (Figure 1). Based on these findings, the patient was diagnosed with intussusception due to intestinal SMT. The patient underwent a laparotomy. At laparotomy, a small solid tumor that was 60 cm distal to the Treitz's ligament was palpable and the small bowel around the tumor was edematous. Liver and spleen were normal. There was no evidence of mesenteric or retroperitoneal lymphadenopathy, ascites or peritoneal disease. The resection of jejunum with 2 cm margins and an end-to-end anastomosis was performed. The resected oval shaped tumor, 14 mm x 11 mm in size, was covered with normal jejunal mucosa and no ulcer or erosion was seen on the mucosal surface (Figure 2). Opening of the rudimentary pancreatic duct was not detected. Histologically, the mass was distributed from submucosa to smooth muscle layer and was composed of proliferating ducts and proliferation of smooth muscle bundles without mitotic figures

(Figure 3). However, both exocrine acini and endocrine elements were lacking. Based on the above findings, this tumor was diagnosed as jejunal ectopic pancreas (type III ectopic pancreas according to the classification proposed by von Heinrich<sup>[5]</sup>). The postoperative course was uneventful. As a result of this treatment, the patient's abdominal pain resolved postoperatively.

## DISCUSSION

Ectopic pancreas is defined as the presence of pancreatic tissue lacking anatomical and vascular continuity with the pancreas<sup>[1]</sup>. It occurs most commonly in the stomach, duodenum, and jejunum and has been reported in other locations, including the ileum, Meckel's diverticulum, colon, gall bladder, umbilicus, fallopian tube, mediastinum, spleen, and liver<sup>[2]</sup>. Ectopic pancreas occurs in 0.25%-13.7% of patients based on both autopsy and surgical series; approximately 70% of all such tissues are found in the stomach, duodenum, and jejunum<sup>[2]</sup>. When an ectopic pancreas is found coincidentally during surgery for other abdominal conditions, resection should be considered because of the risk of late clinical problems. Although this disease occasionally develops symptoms such as bleeding, vomiting or abdominal pain due to pancreatitis<sup>[2,3,6,7]</sup>, intestinal obstruction or intussusception is rare<sup>[4,8,9]</sup>. No invagination case caused by ectopic pancreas had been observed in a series of 53 invaginations, reported by Ong *et al*<sup>[10]</sup>. Ectopic pancreas in the small intestine may rarely be fatal; however, Hitosugi *et al*<sup>[11]</sup> reported a sudden death case (11-year-old Japanese female) caused by intestinal obstruction due to jejunal ectopic pancreas (about 4 cm in diameter). Adult intussusception represents 5% of all cases of intussusception and accounts for only 1%-5% of intestinal obstructions in adults<sup>[12]</sup>. In contrast with intussusception in children, nearly all adult cases have primary causes such as a polyp, an SMT or a malignant tumor that needs to be resected<sup>[13,14]</sup>. In the present case, the small SMT (ectopic pancreas) in the jejunum caused ileus due to intussusception.

The preoperative diagnosis of ectopic pancreas in the small bowel appears to be difficult. However, there are some recent reports describing ectopic pancreas in the small bowel discovered by double-balloon enteroscopy or capsule endoscopy<sup>[15-17]</sup>. In spite of using double-balloon enteroscopy, endoscopic diagnosis is rarely

conclusive on endoscopic biopsies because the lesion locates mainly in the submucosal layer and the biopsy is often not deep enough to reach the submucosal tumor tissue. In the present case, the diagnosis could not be confirmed preoperatively although we knew that bowel intussusception due to small SMT might cause ileus. Because of the suspicion of ileus due to jejunal tumor, the patient underwent laparotomy; thus, double-balloon enteroscopy was not performed in the present case.

This disease is treated in principle by surgical resection if bowel intussusception or ileus occurs<sup>[4]</sup>. Moreover, physicians should be aware that ectopic pancreas in the small bowel may associate with endocrine tumor or carcinoma<sup>[18-21]</sup>. However, ectopic pancreas in the small intestine is usually benign. Ectopic pancreas in the small intestine is rarely fatal and patients remain asymptomatic in their daily lives, except for when bleeding, bowel intussusception, obstruction or pancreatitis occurs. Therefore, it is likely that there are patients with latent small bowel ectopic pancreas which may be incidentally discovered in the future, as a result of advances in diagnostic imaging, such as improved CT, MRI, capsule endoscopy and double-balloon enteroscopy.

In conclusion, we have reported a very rare case of jejunal ectopic pancreas that led to jejunoojejunal intussusception. Thus, it is necessary to be aware that a jejunal ectopic pancreas may cause jejunoojejunal intussusception even though the likelihood is small. This etiology should be suspected in a patient with chronic atypical abdominal pain.

### INTRODUCTION

Vesical diverticula are herniations of the bladder mucosa and submucosa through the muscular wall of the bladder<sup>[1]</sup>. They are often asymptomatic and are discovered incidentally during an examination for other reasons<sup>[1,2]</sup>. Some patients present with urinary tract infections, obstruction, gallstones, or frequent voiding caused by diverticula, especially when they are large and empty poorly. The common causes of large bowel mechanical obstruction in adults are malignant tumors, diverticular disease, and volvulus. Extrinsic obstruction secondary to distension of a giant vesical diverticulum is rare. To our knowledge, this is the fourth report of a vesical diverticulum causing disrupted defecation or intestinal obstruction in the English medical literature since 1957<sup>[3-5]</sup>. We report an unusual case of large bowel obstruction caused by a giant bladder diverticulum. In addition, this is the largest vesical diverticulum reported in the literature.

### Abstract

Vesical diverticula frequently result from bladder outlet obstructions. However, giant vesical diverticula which cause acute abdomen or intestinal obstruction are very rare. Our review of the English medical literature found 3 cases of bladder diverticula which caused gastrointestinal symptoms. Here, we present a 57-year-old man with a giant diverticulum of the urinary bladder who complained of abdominal pain, nausea and vomiting, constipation, no passage of gas or feces, and abdominal distension for 3 d. A 20 cm × 15 cm diverticulum was observed upon laparotomy. The colonic obstruction was secondary to external compression of the rectum against the sacrum by a distended vesical diverticulum. We performed a diverticulectomy and primary closure. Twelve months postoperatively, the patient had no difficulty with voiding or defecation.

### CASE REPORT

A 57-year-old man was admitted to the general surgery department with abdominal pain, nausea and vomiting, constipation, no passage of gas or feces, and abdominal distension for 3 d. The relevant physical examination revealed a distended abdomen, decreased bowel sounds, diffuse sensitivity on palpation of the abdomen, and empty rectal ampulla. Laboratory investigations showed a blood urea nitrogen level of 31 mg/dL, a creatinine level of 1.1 mg/dL, and a C-reactive protein level of 35 mg/L. The blood cell count revealed leukocytosis at 16500/µL, a hemoglobin level of 13.5 g/dL, and a platelet count of 423000/µL. Other serum parameters, including prostate specific antigen (PSA, 1.9 ng/mL), were within normal limits. Computed tomography (CT) showed a 15 cm × 10 cm low density cystic lesion with smooth contours located in the presacral region, pushing the rectum to the right and the sigmoid colon and bladder superiorly (Figure 1A and B). The patient had a history of trauma because of a traffic accident 4 years previously, and

The first three references present cases of bladder diverticula which caused gastrointestinal symptoms. CT: Computed tomography; EDS: Ehlers-Danlos syndrome; TUR-P: Transurethral prostatectomy; USG: Ultrasonography.

**Figure 1** Computed tomography showed a 15 cm × 10 cm low density cystic lesion with smooth contours located in the presacral region, pushing the rectum to the right and the sigmoid colon and bladder superiorly (A and B).

because of this diagnostic laparotomy was performed and a few sutures were placed in the bladder. As the patient had symptoms of acute abdomen, laparotomy was performed.

During laparotomy, the mass was found to be a diverticulum originating from the posterosuperior region

**Figure 2** No significant pathology was observed on intravenous pyelography 3 mo postoperatively.

of the bladder. The colonic obstruction was secondary to external compression of the rectum against the sacrum by a distended vesical diverticulum. The diverticulum measured approximately 20 cm × 15 cm and was difficult to mobilize by dissecting its delicate attachments to the anterior rectal wall. The diverticular orifice was approximately 1-1.5 cm in diameter. A diverticulectomy and primary closure were performed. Postoperatively, the bladder was catheterized for 10 d. Three months postoperatively, the patient's urinary frequency and constipation had disappeared. An intravenous pyelography (IVP) showed no significant pathologic findings (Figure 2). The patient had no difficulty in voiding nor had constipation 12 mo postoperatively.

## DISCUSSION

We described a rare cause of a giant vesical diverticulum causing mechanical bowel obstruction in an adult patient. We summarized the characteristics of the 12 cases of "giant bladder diverticulum" which we found in the literature in the Table 1<sup>[3-11]</sup>. Three of the cases

caused intestinal obstruction<sup>[3-5]</sup>. The bladder is a hollow muscular organ that stores and evacuates urine. The normal bladder can store approximately 350-400 mL of urine. A diverticulum is an abnormal sac or pouch protruding from the wall of a hollow organ. Most bladder diverticula are primary, congenital, or secondary to outflow obstruction or neurogenic bladders<sup>[12-14]</sup>. Congenital diverticula usually occur in areas where there is insufficient muscle, typically at the ureterovesical junction, or between bundles of hypertrophied muscle. They are usually asymptomatic and are discovered incidentally. Occasionally, a diverticulum may produce urinary obstruction as a result of compression of the urethra, or urinary tract infection arising from retention of urine within the diverticulum<sup>[8,15]</sup>. In this case, only minimal obstruction caused by the pressure on the ureters was observed. No obstruction of the urethra developed. Although diverticula generally develop from the ureteral orifices in the bladder, in this case the diverticulum was located in the posterosuperior region of the bladder distant from the orifices.

In this patient, the diverticulum was in the same location as previous trauma. Because of this and since trauma is known to be one of the etiologic factors for acquired diverticula, we believed that this diverticula had occurred as a result of the previous trauma.

The indications for surgery are persistent or recurrent urinary infection, the presence of a stone or tumor in the diverticulum<sup>[16,17]</sup>, a vesicocutaneous fistula<sup>[18]</sup>, lower urinary tract symptoms, and voiding symptoms or vesicoureteral reflux<sup>[19]</sup> resulting from the diverticulum or ureteral obstruction<sup>[6,12]</sup>. In this case, laparotomy was indicated by the normal IVP results and CT scan showing a mass exerting pressure on the ureters and rectum. Vesical diverticula are a common pathology of the urinary bladder, generally secondary to cervico-urethral obstruction. Shaked *et al*<sup>[5]</sup> presented a case of bladder distention and diverticulum arising from obstruction caused by a prostate adenoma. In their case, they reported that colonic obstruction occurred because the colon was packed between the sacrum and bladder. In our case, although the bladder diverticulum was large, no obstruction was observed because the diverticulum developed from the posterosuperior part of the bladder. This was reflected in the PSA and transrectal ultrasonography results.

In conclusion, there are several reported cases of bladder distention and diverticula causing colonic obstruction. For this reason, although rare, bladder pathology should be considered in patients with obstruction of the rectosigmoid region.

## INTRODUCTION

With the increased number of living donor liver transplantation (LDLT) patients, some special complications have become apparent. Central pontine myelinolysis (CPM) is a severe nervous system complication following liver transplantation<sup>[1-3]</sup>. To date, no studies have been performed addressing CPM occurrence and treatment following LDLT. This study aimed to report the clinical manifestations and treatment of three patients diagnosed with CPM following LDLT from January 2005 to November 2007. The three donors in this study were lineal relatives of these patients. No organs were used from prisoners and no subjects were prisoners at the time of data collection.

## CASE REPORT

### Case one

This patient was a 51-year-old female diagnosed with chronic, type B hepatitis, hepatic decompensation, and hepatic encephalopathy. Her blood type was B/Rh (-). Pre-operative examination revealed the following parameters: total bilirubin (107.9 μmol/L), direct bilirubin (53.6 μmol/L), aspartate aminotransferase (595 IU/L), glutamate-pyruvate transaminase (600 IU/L), and serum cholesterol (0.18 mmol/L). Blood electrolytes, Child-Turcotte-Pugh score, and MELD score are shown in Table 1. In November 2005, the patient underwent adult-to-adult LDLT with a right lobe graft. The donor was the patient's son, whose blood type was B/Rh (+). Electrolytes were re-examined in the intensive care unit (Table 1). Post-operative immunosuppressive regimen was administered. The patient was treated with cyclosporine A (250 mg, twice daily), 0.75 g mycophenolic acid (oral)

## Abstract

We analyzed the clinical manifestations and experiences of diagnosing and treating central pontine myelinolysis following living donor liver transplantation. The clinical data of three patients with central pontine myelinolysis following living donor liver transplantation from January 2005 to November 2007 were retrospectively analyzed at the West China Hospital, Sichuan University, China. The three patients developed hyponatremia prior to surgery. Case 1 suffered locked-in syndrome following surgery, and received a large dose of gamma globulin, and subsequently recovered. Case 2 was in a coma for three days, and received hyperbaric chamber treatment. This patient remained in a mild coma for six months following surgery. Case 3 developed consciousness disturbances, gradually went into a coma following surgery, and died due to pulmonary infection. Central pontine myelinolysis is a severe complication in patients following living donor liver transplantation. Large-dose gamma globulin treatment, as well as hyperbaric oxygen, might be effective therapeutic methods.

Special therapy	Gamma globulin (i.v.)	Hyperbaric oxygen treatment	No

twice daily, and methylprednisolone (iv). Subsequent, cyclosporine A blood concentration was shown to be 180-250 mg/L. At 6 h after surgery, the patient was conscious, and the tracheal cannula was removed. On day one after surgery, the patient maintained clarity, answered questions with short sentences, exhibited locomotor activities, and drank water. On day three after surgery, the patient presented with decreased spontaneous speech, slowed actions, could not answer a simple question correctly, had indistinct pronunciation, and bucked while drinking water. On day five after surgery, the patient had stable vital body signs, clear consciousness, spontaneous eye opening, ocular movement, but did not exhibit spontaneous speech, spontaneous limb activities, or reaction to pain stimulation. Physical examination showed increased tension of limb muscles, muscle force 0°, decreased deep and superficial sensations, bilateral Babinski sign (+), and an Expanded Disability Status Scale score of 9.5. Skull nuclear magnetic resonance was subsequently performed and the findings are displayed in Figure 1. The patient was diagnosed with “locked-in syndrome” induced by CPM, and was administered citicoline (0.5 g daily *via* intravenous drip) and a large dose of gamma globulin (0.5 g/kg daily for ten days, iv). Oral cyclosporine A was not administered. On day twelve after surgery, the patient pronounced monosyllables, performed light limb activities with grade III muscle force, but was still not able to swallow. On day fourteen after surgery, the patient was conscious, producing longer utterances, pronounced indistinctly and slowly, demonstrated increased autonomic activities, bucked during swallowing, and presented with an Expanded Disability Status Scale score of 6. Three months after surgery, the patient presented with normal liver function,

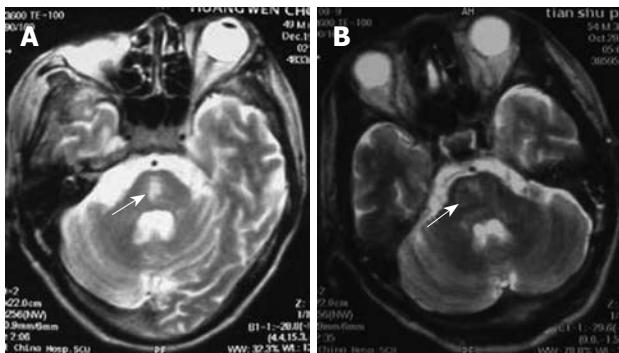

**Figure 1** Magnetic resonance imaging displayed high-signal intensity on T2-weighted images of the central pons 7 d after surgery (arrow).

clear consciousness, normal diet, self-care, slow speech rate, and slow motor reactions.

### Case two

This patient was a 54-year-old male diagnosed with chronic severe hepatitis (type B), hepatic encephalopathy, and hepatorenal syndrome. His blood type was O/Rh (+). Pre-operative examination revealed the following parameters: total bilirubin (280 μmol/L), direct bilirubin (158.6 μmol/L), aspartate aminotransferase (269 IU/L), glutamate-pyruvate transaminase (188 IU/L), serum cholesterol (1.24 mmol/L), and serum creatinine (263.7 μmol/L). Blood electrolytes, Child-Turcotte-Pugh score, and MELD score are presented in Table 1. In March 2006, the patient received adult-to-adult LDLT with a right lobe graft. The donor was the patient’s brother, whose blood type was O/Rh (+). Electrolytes were re-tested in the intensive care unit (Table 1).

Post-operative immunosuppressive regimen was administered. The patient received tacrolimus (FK506, 2 mg twice daily, oral), 0.75 g mycophenolic acid (oral, twice daily), and methylprednisolone (iv). Subsequent tacrolimus blood concentration was found to be 6.5-8 ng/mL. At 11 h after surgery, the patient was conscious, and the tracheal cannula was removed. The patient had stable vital body signs, poor mental state, and little spontaneous speech. On day two after surgery, the patient presented with lethargy, eye-opening reaction to powerful stimulation, and indistinct pronunciation. On day three after surgery, the bilateral pupils reacted poorly to light reflex and were equal in size and shape. The patient suffered from moderate coma, with decreased muscular tension, Babinski sign of the right side (+), Babinski sign of the left side (-), and a Glasgow-Pittsburgh score of 20. On day 6 after surgery, the patient received a tracheotomy, and respiration was supported by a respirator due to pulmonary infection. CPM was diagnosed with skull magnetic resonance imaging (Figure 2A). On day ten after surgery, the patient developed moderate coma, with good recovery of liver function. Following hyperbaric chamber treatment (2 h, once per day, for 14 d), the patient presented with good light reflex in both pupils, mild coma, increased autonomic activities, improved tension of limb muscles, and a Glasgow-Pittsburgh score of 26. At six months, the patient suffered from mild coma, but exhibited good liver function.

**Figure 2** Magnetic resonance imaging displayed high-signal intensity on T2-weighted images of the central pons 9 d (A) and 8 d (B) after surgery (arrows).

### Case three

This patient was a 47-year-old male diagnosed with chronic severe hepatitis (type B), upper gastrointestinal bleeding, and hepatorenal syndrome. His blood type was B/Rh (+). Pre-operative examination revealed the following parameters: total bilirubin (197.4 μmol/L), direct bilirubin (116.5 μmol/L), aspartate aminotransferase (141 IU/L), glutamate-pyruvate transaminase (107 IU/L), serum cholesterol (1.07 mmol/L), and serum creatinine (207.7 μmol/L). Blood electrolytes, Child-Turcotte-Pugh score, and MELD score are presented in Table 1. In August 2007, the patient received adult-to-adult LDLT with a right lobe graft. The donor was the patient's wife, whose blood type was B/Rh (+). Electrolytes were re-measured in the intensive care unit (Table 1). Post-operative immunosuppressive regimen was performed. The patient was treated with zenapax (containing daclizumab), 0.75 g mycophenolic acid (oral, twice daily), and methylprednisolone (iv). At 9 h following surgery, the patient was conscious, and the tracheal cannula was removed. The patient received hemofiltration due to worsened renal function. At 1 wk, the patient was conscious, displayed autonomic activities, reduced speech, low speech sound, and could provide correct answers to simple questions. Both pupils exhibited good light reflexes and normal ocular fundus, and were equal in size and shape. Tendon reflexes were symmetric and active, with pathological sign (-). Muscular tension of the upper limbs was increased, with flexion deformity and grade II muscle force, but muscular tension of the lower limbs was decreased. On day 8 after surgery, the patient went into a coma, opened eyes when powerfully stimulated, could not pronounce or perform autonomic limb activities, and presented with normal liver and kidney function. CPM was diagnosed using skull magnetic resonance imaging (Figure 2B). On day 14 after surgery, the patient suffered from mild coma and received a tracheotomy, his respiration was supported by a respirator due to pulmonary infection. Subsequently, the patient developed severe sepsis and multiple organ failure, and died at twenty-three days following surgery.

### DISCUSSION

CPM is a severe complication of the nervous system

following liver transplantation, with high mortality and disability rates<sup>[4-6]</sup>. CPM is difficult to diagnose, due to the various clinical manifestations, and precise epidemiological data are lacking. From January 2005 to December 2007, 3/184 patients at the Center for Liver Transplantation, West China Hospital, Sichuan University, China undergoing living donor liver transplantation were diagnosed with CPM, with an occurrence rate of 1.63%.

CPM following liver transplantation is due to multiple factors. (1) Severe hyponatremia, especially during rapid correction of chronic hyponatremia: patients who develop CPM following liver transplantation suffer from severe hyponatremia prior to transplantation. However, not all hyponatremia patients develop CPM<sup>[7]</sup>. Rapid correction of hyponatremia, as well as larger alterations in plasma osmotic pressure, influences CPM occurrence<sup>[1]</sup>. Increased serum sodium (> 15 mmol/L) within 24 h has also been closely associated with CPM occurrence<sup>[1]</sup>. (2) Neurotoxicity of cyclosporine A and tacrolimus can induce or aggravate CPM. Cyclosporine A-related motor aphasia patients were shown to develop CPM, as diagnosed by skull magnetic resonance imaging<sup>[8,9]</sup>. (3) Severe damage to liver function prior to surgery is associated with CPM occurrence, especially in patients with hepatic encephalopathy and hypcholesterolemia. (4) Hemorrhage, infection, vascular complications, and impaired graft function following liver transplantation can result in CPM occurrence. Immune factors might participate in CPM pathogenesis, such as myelin sheath antibody formation<sup>[10,11]</sup>. In the present study, these three cases developed severe hyponatremia prior to surgery. Serum sodium ion concentration increased by > 20 mmol/L, and plasma osmotic pressure was greatly altered 6-8 h after surgery. These factors were responsible for CPM occurrence. Living donor liver transplantation is an elective procedure. Thus, there should be ample opportunity to correct serum sodium before surgery. A large number of blood products and synthetic colloids should be infused into patients during the peri-operative period, such as erythrocyte suspension, fresh frozen plasma, platelets, cryoprecipitate, hetastarch, and succinylated gelatin. These liquids contain many sodium salts, which increase serum sodium within a short period of time. More attention should be paid to regulating serum sodium during the peri-operative period to avoid adverse outcomes due to rapid correction of hyponatremia. It is also important for anesthesiologists to correct serum sodium very slowly during surgery. In case 1, the post-operative immunosuppressive agent was cyclosporine A. The blood drug concentration ranged between 180-250 mg/L. In case 2, the post-operative immunosuppressive agent was tacrolimus, and the blood drug concentration ranged between 6.5-8 ng/mL. Although blood drug levels were not significantly increased, severe liver disease-induced metabolic disturbances could lead to brain glial cell damage. It seems that critically ill patients with end-stage liver disease may have an organic mental syndrome. Any insult such as calcinerin inhibitors under these circumstances may cause further damage resulting in CPM.

The clinical manifestations of CPM are multi-faceted following liver transplantation, and include

mental disorder, cortical blindness, pseudobulbar palsy, aphasia, ataxia, visual hallucination, epileptic seizure, locked-in syndrome, and coma<sup>[12-14]</sup>. Case 1 was diagnosed with locked-in syndrome, meaning that the bilateral corticospinal tract and corticobulbar tract were blocked surrounding the pontine abducent nucleus. The characteristics of this syndrome include quadriplegia and anarthria, with preservation of consciousness. Patients retain vertical eye movement, and can facilitate non-verbal communication. Few patients with this syndrome have been reported, especially in LDLT. Cases 2 and 3 suffered from coma. Magnetic resonance imaging has proven to be a good diagnostic method for CPM. Positive diagnosis has not been detected in many patients using magnetic resonance imaging following the onset of clinical symptoms. This was associated with abnormal imaging manifestations following clinical symptoms.

To date, there remains a lack of effective therapeutic methods for CPM. The present methods primarily attempt to nourish brain cells, improve cerebral metabolism, and reduce immunosuppressive concentrations. In addition, gamma globulin has been injected intravenously into CPM patients, resulting in improved scores on the Expanded Disability Status Scale<sup>[10,11]</sup>. In the present study, case 1 was treated with a large dose of gamma globulin and was tested according to the Expanded Disability Status Scale. Case 2 received hyperbaric oxygen treatment and underwent Glasgow-Pittsburgh Score testing. Case 1 presented with improved (> 36%) scores on the Expanded Disability Status Scale following treatment. This might be correlated to treatment with large-dose gamma globulin which destroys myelin sheath-related antibodies by decreasing toxic substances in the myelin sheath and by accelerating remyelination. Case 2 presented with improved (30%) scores on the Glasgow-Pittsburgh Score following treatment. This might be correlated to hyperbaric oxygen, which reduced myelin sheath destruction, accelerated cell regeneration, and decreased edema in the injured regions. However, we cannot thoroughly assess the outcomes of these two methods, due to the limited number of cases.

CPM, a life-threatening illness, is difficult to diagnose and treat, and presents with a poor prognosis following living donor liver transplantation. More attention should be directed to the risk factors for CPM to avoid clinical complications, and to continue the search for an effective therapeutic method.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*) ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastrolesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systematically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Articles: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities on basic research and clinical practice.

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports/Science Edition, Index Medicus, MEDLINE, PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, PubMed Central, Digital Object Identifier, CAB Abstracts, and Global Health. ISI, Thomson Reuters, 2008 Impact Factor: 2.081 (32/55 Gastroenterology and Hepatology).

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

#### REFERENCES

##### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[12,21]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

##### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

##### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg13.5396].

##### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) =  $8.6 \pm 24.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *argI*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *KboI*, *KpnI*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

**Editorial Office**

**World Journal of Gastroenterology**

Editorial Department: Room 903, Building D, Ocean International Center,

No.62 Dongsihuan Zhonglu, Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

**Language evaluation**

The language of a manuscript will be graded before it is sent for revision.

- (1) Grade A: priority publishing;
- (2) Grade B: minor language polishing;
- (3) Grade C: a great deal of language polishing needed;
- (4) Grade D: rejected. Revised articles should reach Grade A or B.

**Copyright assignment form**

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

**Responses to reviewers**

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

**Proof of financial support**

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

**Links to documents related to the manuscript**

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

**Science news releases**

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

**Publication fee**

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

### INTRODUCTION

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

## INTRODUCTION

Idiopathic achalasia is a rare primary motility disorder of the esophagus. The classical features are incomplete relaxation of a frequently hypertensive lower esophageal sphincter (LES) and a lack of peristalsis in the tubular esophagus. These motor abnormalities lead to dysphagia, stasis, regurgitation, weight loss, or secondary respiratory complications. Although major strides have been made in understanding the pathogenesis of this rare disorder, including a probable autoimmune mediated destruction of inhibitory neurons in response to an unknown insult in genetically susceptible individuals, a definite trigger has not been identified. The diagnosis of achalasia is suggested by clinical features and confirmed by further diagnostic tests, such as esophagogastroduodenoscopy (EGD), manometry or barium swallow. These studies are not only used to exclude pseudoachalasia, but also might help to categorize the disease by severity or clinical subtype. Recent advances in diagnostic methods, including high resolution manometry (HRM), might allow prediction of treatment responses. The primary treatments for achieving long-term symptom relief are surgery and endoscopic methods. Although limited high-quality data exist, it appears that laparoscopic Heller myotomy with partial fundoplication is superior to endoscopic methods in achieving long-term relief of symptoms in the majority of patients. However, the current clinical approach to achalasia will depend not only on patients' characteristics and clinical subtypes of the disease, but also on local expertise and patient preferences.

## Abstract

Idiopathic achalasia is a rare primary motility disorder of the esophagus. The classical features are incomplete relaxation of a frequently hypertensive lower esophageal sphincter (LES) and a lack of peristalsis in the tubular esophagus. These motor abnormalities lead to dysphagia, stasis, regurgitation, weight loss, or secondary respiratory complications. Although major strides have been made in understanding the pathogenesis of this rare disorder, including a probable autoimmune mediated destruction of inhibitory neurons in response to an unknown insult in genetically susceptible individuals, a definite trigger has not been identified. The diagnosis of achalasia is suggested by clinical features and confirmed by further diagnostic tests, such as esophagogastroduodenoscopy (EGD), manometry or barium swallow. These studies are not only used to exclude pseudoachalasia, but also might help to categorize the disease by severity or clinical subtype. Recent advances in diagnostic methods, including high resolution manometry (HRM), might allow prediction of treatment responses. The primary treatments for achieving long-term symptom relief are surgery and endoscopic methods. Although limited high-quality data exist, it appears that laparoscopic Heller myotomy with partial fundoplication is superior to endoscopic methods in achieving long-term relief of symptoms in the majority of patients. However, the current clinical approach to achalasia will depend not only on patients' characteristics and clinical subtypes of the disease, but also on local expertise and patient preferences.

## CLINICAL PRESENTATION

The hallmark of achalasia (Greek: failure to relax) is dysphagia for solids and liquids in up to 100% and 97% of patients, respectively<sup>[1-3]</sup>. As a result of stasis and retention of food and liquids in the esophagus, patients frequently experience weight loss (30%-91%), chest pain (17%-95%), regurgitation (59%-64%), and nocturnal cough (11%-46%)<sup>[1]</sup>. Difficulty with belching might result from alteration of the upper esophageal belch reflex<sup>[4]</sup>. Patients might frequently complain of heartburn. Although heartburn is the cardinal symptom

of gastroesophageal reflux, which is the antithesis of achalasia, it occurred with a frequency of 72% in one study, even after the onset of dysphagia<sup>[5]</sup>. The sensation of heartburn in patients with achalasia might be explained by retention of acidic or noxious food contents or by lactate production from bacterial fermentation within the esophagus<sup>[6]</sup>. Hiccups can also occur, and probably result from esophageal distention and stimulation of afferent vagal fibers<sup>[7]</sup>. The distribution of symptoms can differ in the population studied. Chest pain occurs predominantly in younger patients (mean age 40 years) and appears to improve over time<sup>[8]</sup>. However, neither manometric, nor radiographic findings predict the occurrence of retrosternal pain. Most symptoms do not appear to have a specific gender distribution, although in Iranian patients, chest pain appeared to be more common among females<sup>[9]</sup>. Physicians need to be aware of the spectrum of symptoms of achalasia, because diagnostic delays for years after the onset of symptoms appear to be due to misinterpretation of typical findings, rather than atypical presentations<sup>[10]</sup>.

The most common extraesophageal manifestations of achalasia are pulmonary complications. Structural or functional pulmonary abnormalities occur in more than half of patients and might be due to recurrent aspiration or tracheal compression from a dilated esophagus<sup>[11]</sup>. In cases of extreme dilation and distortion of the cervical esophagus, a “bull frog neck” appearance can develop, leading to tracheal obstruction above the larynx and associated stridor<sup>[2]</sup>. Although some investigators have observed delayed gastric emptying or gallbladder dysfunction in patients with achalasia<sup>[12-14]</sup>, others were unable to confirm these observations<sup>[15]</sup>, and it still remains elusive whether a selective defect of vagal ganglionic neurons might affect other parts of the gastrointestinal tract as well.

## DIAGNOSIS AND CLINICAL VARIANTS

A number of tests are available to confirm the diagnosis of achalasia, once the clinical suspicion arises. Radiographic studies, EGD and esophageal manometry are the primary tools of investigation. Although EGD appears normal in 44% of patients with achalasia<sup>[11]</sup>, it might show esophageal dilatation and retention of food or secretions. During inversion of the endoscope in the stomach, tight adherence of the distal esophagus with downward motion of the gastroesophageal junction upon endoscope advancement can sometimes be visualized. However, despite the commonly elevated LES pressure, the esophagogastric junction can usually be traversed easily, and firm resistance should raise the suspicion of neoplastic infiltration or other causes of pseudoachalasia. Pseudoachalasia can mimic all endoscopic, radiographic and manometric findings of achalasia and has a broad differential diagnosis of neoplastic and non-neoplastic causes, which have been recently reviewed<sup>[16,17]</sup>. Infiltration of the esophageal myenteric plexus by neoplastic cells or paraneoplastic processes have been suggested in patients with a

**Table 1 Manometric variants of achalasia**

Standard Manometry
Vigorous achalasia (high amplitude esophageal body contractions)
A short segment of esophageal body aperistalsis
Retained complete deglutitive LES relaxation with aperistalsis
Intact transient LES relaxation with aperistalsis
High resolution manometry (patients with impaired EGJ relaxation)
Type I : Minimal esophageal pressurization
Type II : Esophageal pressurization > 30 mmHg
Type III : Esophageal spasm

LES: Lower esophageal sphincter; EGJ: Esophagogastroduodenoscopy.

malignant etiology<sup>[16]</sup>. A shorter duration of symptoms and older age at presentation should raise a suspicion of pseudoachalasia, which often requires further testing with endoscopic ultrasound or CT scan to rule out malignancy<sup>[17]</sup>. In our view, a simple and non-invasive initial test to differentiate between primary and secondary achalasia is transabdominal ultrasonography, which often allows a clear visualization of the gastric cardia and its surrounding structures<sup>[18]</sup>. However, a negative ultrasound does not always exclude pseudoachalasia, and CT or other cross-sectional imaging should be added if clinical suspicion remains strong.

A barium esophagogram (barium swallow) is the most commonly used initial diagnostic study. It classically shows a typical smooth tapering of the distal esophagus (“bird’s beak”) with proximal dilation of the esophagus and lack of peristalsis during fluoroscopy. The value of obtaining a timed barium esophagogram in patients with achalasia lies in its potential to monitor the success of therapeutic interventions and to detect disease recurrence prior to the development of symptoms<sup>[19]</sup>. The timed barium swallow is performed by having the patient drink 100-250 mL of barium in an upright position and by taking radiographs one, two and five minutes after the last swallow. The distance from the distal oesophagus to the top of the barium column, as well as the maximal esophageal width, are measured for comparison before and after treatment.

Manometry remains the diagnostic modality with the highest sensitivity and should be part of the diagnostic evaluation in all patients with achalasia. Three cardinal features support the diagnosis of classic achalasia: Aperistalsis of the smooth muscle portion of the esophagus, incomplete LES relaxation and elevated LES resting pressure. As mentioned above, manometric variants of achalasia have been described (Table 1). Vigorous achalasia is a variant characterized by aperistaltic, simultaneous esophageal contractions with higher average amplitudes (> 37 mmHg)<sup>[20]</sup>. It has been suggested that vigorous achalasia might present an earlier form of achalasia, in which esophageal contractions against the outflow obstruction at the LES are still maintained. However, vigorous achalasia appears to be independent of age of onset and symptom duration, and is not associated with return to normal peristalsis after surgical myotomy<sup>[21,22]</sup>. Although it has been suggested that patients with vigorous achalasia might show better success with botulinum toxin injection than patients with classic

achalasia<sup>[23]</sup>, this has minor clinical relevance, because other treatment options are superior in most cases. Therefore, it remains unclear whether dividing patients into those with “vigorous achalasia” and “classic achalasia” has any clinical implications. Despite such reservations, physicians need to be aware that achalasia might present with a spectrum of manometric findings that might not meet all of the criteria specified above (Table 1)<sup>[24]</sup>. Their significance lies in the recognition that these sometimes confusing manometric findings are consistent with achalasia when combined with additional clinical data supportive of the diagnosis. As mentioned for the timed barium swallow, manometry also plays a role in monitoring treatment response and predicting treatment success of pneumatic dilatation, as discussed below.

The recent introduction of HRM with pressure topography plotting into the diagnostic armory has brought a renaissance to the classification of idiopathic achalasia into variants with possible clinical implications. A retrospective study by Pandolfino *et al*<sup>[25]</sup> described three distinct variants, with type I exhibiting minimal esophageal contractility without pressurization, type II with absent peristalsis but compartmentalized, pan-esophageal pressurization, and type III with lumen obliterating spasm. The authors showed that pan-esophageal pressurization (type II) had the best overall treatment response, whereas type III predicted a poor treatment response to all types of therapy. Further prospective studies are needed to confirm these interesting early results.

## TREATMENT

Treatment of idiopathic achalasia remains strictly palliative. In view of the suspected autoimmune mechanism of the disease, it appears surprising that no study has systematically addressed the use of immunosuppressive therapy in an attempt to prevent disease progression<sup>[26]</sup>. Therefore, current treatment modalities are primarily directed at relieving distal esophageal obstruction and consist of pharmacologic therapy, endoscopic treatment with pneumatic dilation or botulinum toxin injection, and surgery. The appropriate choice of therapeutic options depends on multiple factors, such as the patient’s characteristics, clinical presentation, local expertise and patient preferences, but should be based on the best available evidence.

Pharmacological therapy is directed at achieving a reduction of LES pressure by the use of smooth muscle relaxants, such as calcium channel blockers (e.g. nifedipine 10-30 mg sublingually 30-45 min before meals), nitrates (e.g. isosorbide dinitrate 5 mg sublingually 10-15 min before a meal) or phosphodiesterase 5 inhibitors<sup>[27,28]</sup>. The main limitations of these agents are their short duration of action, limited improvement of dysphagia despite documented LES relaxation, or the frequent occurrence of side effects, such as peripheral edema, headaches or hypotension, which especially occur with calcium channel blockers and nitrates. Their use is, therefore, limited to symptomatic relief in patients who have very early disease, or as a temporary measure

for patients who are awaiting a more definite treatment option, or are high risk for more invasive options<sup>[29]</sup>.

Endoscopic options of treatment include disruption of the LES by pneumatic dilation or botulinum toxin injection. Botulinum toxin is a potent neurotoxin that leads to a blockade of the release of acetylcholine from excitatory motor neurons. In a landmark study, Pasricha *et al*<sup>[30]</sup> showed that endoscopic injection of botulinum toxin into the area of the LES lead to symptomatic improvement in patients with achalasia, which was accompanied by reduced esophageal retention over a period of 6 mo. One randomized controlled trial (RCT) has shown that the two commercially available formulations of botulinum toxin are equally effective, but need to be given in different dosages because of variable potency<sup>[31]</sup>. The treatment effect of one of these formulations (Botox® Allergan Inc, Irvine, California, USA) might be maximized when a repeated injection of 100 IU is given one month after the first injection<sup>[32]</sup>. In contrast, a lack of an initial symptomatic response and residual LES pressure  $\geq 18$  mmHg after botulinum toxin are associated with a poor overall response<sup>[33]</sup>. The best results of botulinum toxin have been achieved in patients with vigorous achalasia, older patients and patients whose LES pressures do not exceed  $\geq 50\%$  of the upper limit of normal<sup>[23,34]</sup>. However, the use of botulinum toxin is limited by its lack of long-term efficacy with recurrence rates of approximately 50% after one year and universal symptomatic relapse at two years<sup>[35,36]</sup>. Two recent meta-analyses concluded that although botulinum toxin has an excellent safety profile, it seems slightly less effective than pneumatic dilatation in the short-term and is clearly inferior in the long-term for the treatment of achalasia<sup>[37,38]</sup>.

Pneumatic dilatation has been used for the treatment of patients with achalasia for more than half a century and is currently considered the most effective non-surgical treatment for achalasia<sup>[39,40]</sup>. A number of different pneumatic dilators with variable balloon compliance have been used in clinical trials. Currently, the low-compliance polyethylene pneumatic dilator (Rigiflex®, Boston Scientific, Boston, MA, USA) appears to be the most widely used. Although pneumatic dilators from other manufacturers are available (e.g. Cook Medical, Bloomington, IN; USA or Hobbs Medical, Stafford Springs CT, USA; HCDD, latex balloon, Rüsch Inc, Germany), only limited comparative data exist, which have not shown a difference in efficacy or safety<sup>[41,42]</sup>. Using a graded approach with the polyethylene balloon dilator, with increasing diameters from 3.0 to 4.0 cm, a 93% response rate was achieved over a mean follow up period of four years with a relatively low complication risk<sup>[43]</sup>. The most feared complication of pneumatic dilation is perforation, which occurred in 1.6% of patients in a meta-analysis with 1065 patients in experienced hands<sup>[39,40]</sup>. Studies assessing the long-term efficacy of pneumatic dilation have shown that a permanent treatment success can only be achieved in 40%-60% of patients after a follow up of  $\geq 15$  years<sup>[44-46]</sup>. Although one study showed that “on demand” repeat dilations may again lead to remission in the majority of patients<sup>[47]</sup>, others have shown that longer lasting treatment effects cannot be expected

from such therapy<sup>[48]</sup>.

Predictors of treatment failure with balloon dilation appear to be younger age (< 40 years), male gender, pulmonary symptoms and failed response to one or two initial dilations<sup>[49-52]</sup>. In contrast older age appears to be associated with favorable outcomes of pneumatic dilation. Manometric findings that predict poor outcome are high initial LES pressures (e.g. > 15-30 mmHg) or a reduction of LES pressure < 50% after the first dilation<sup>[50,52,53]</sup>. Manometry should, therefore, be routinely performed pre- and post-interventionally.

With the advent of minimally invasive laparoscopic approaches, surgery has evolved from an ancillary procedure, used when pneumatic dilation failed, to the favored primary approach by many surgeons and gastroenterologists in a majority of patients with achalasia<sup>[54]</sup>. The goal of surgery is to alleviate the esophageal obstruction by myotomy of the LES. To prevent secondary gastroesophageal reflux, the procedure has usually been combined with some type of fundoplication procedure. The superiority of surgical myotomy over pneumatic dilation was suggested by three recent meta-analyses in the English and Chinese literature that mostly considered retrospective cohort studies<sup>[38,39,55]</sup>. Although both pneumatic dilation and surgical myotomy have a substantial risk of subsequent need of interventions (repeated pneumatic dilation, surgical myotomy or esophagectomy) over a period of 10 years, the probability was significantly smaller in the latter group (56% vs 26%, respectively) in one study<sup>[56]</sup>. To date, only one RCT with data on long-term follow-up has been published by Csendes *et al*<sup>[57]</sup> comparing myotomy followed by 180° Dor fundoplication to pneumatic dilation with a Mosher bag. Although this study has been criticized because of potentially technique-related suboptimal results in the pneumatic dilation group, it still remains the best available evidence to date. The authors showed good response after a five year follow up period for 95% of surgically treated patients vs 65% of patients in the pneumatic dilation group. However, very late results in the surgical group showed that clinical deterioration occurs, reducing the surgical success rate to 75% after a mean follow up of 15.8 years<sup>[58]</sup>. Of the patients with poor surgical results, 92% resulted from complications of severe reflux disease and not from incomplete myotomy. A number of trials have, therefore, investigated the benefit of anti-reflux procedures in addition to myotomy. In a prospective RCT, reflux symptoms were reduced from 47.6% with laparoscopic Heller myotomy alone to 9.1% when a Dor fundoplication was added<sup>[59]</sup>. In another RCT, laparoscopic myotomy with Dor fundoplication was equally effective as a myotomy with “floppy” Nissen fundoplication in controlling reflux, but dysphagia rates were significantly higher in the latter group (2.8% vs 15%, respectively;  $P < 0.001$ )<sup>[60]</sup>. With success rates of 47%-82% at 10 years, laparoscopic Heller myotomy with partial fundoplication appears to have evolved into the surgical procedure of choice<sup>[39,61,62]</sup>. A recent single center RCT compared laparoscopic cardiomyotomy with partial Toupet fundoplication to pneumatic dilation in patients with newly diagnosed achalasia. Similar to

the Csendes study, it also showed significantly fewer treatment failures in the surgical arm after a period of 12 mo<sup>[63]</sup>. Another head to head multicenter RCT has been ongoing for a number of years, but publication is still pending<sup>[64]</sup>.

Predictors of a negative outcome with surgical myotomy were severe preoperative dysphagia, lower preoperative LES pressures of < 30-35 mmHg, progressive esophageal body dilation with flask type or sigmoid esophagus, and preoperative endoscopic treatment in some studies<sup>[61,65-68]</sup>. However, other studies showed treatment responses even in (selected) patients with dilated esophageal bodies or sigmoid esophagus, and in patients who previously failed pneumatic dilation<sup>[48,69,70]</sup>. The effect of surgical myotomy on chest pain remains controversial, and patients should be aware that this symptom might not reliably improve after either pneumatic dilation or surgery<sup>[8]</sup>. Occasionally, a temporary placement of self-expanding metal stents (SEMS) has been suggested as a possible means of dilation or as a bridge to surgery<sup>[71,72]</sup>. However, because no information with regard to its long-term effectiveness exist and complications might be frequent and potentially severe<sup>[73]</sup>, stent treatment for achalasia cannot be recommended at the present time.

Finally, it should not be forgotten that for patients not responding to any one of the above mentioned therapies, subtotal esophageal resection with gastric pull-up remains as a viable treatment option. Although such therapy is extremely invasive and associated with a high post-operative morbidity, favorable long-term results with significant improvement of symptoms can be achieved, even if endoscopic therapy or surgical myotomy have persistently remained unsuccessful<sup>[74]</sup>.

## COMPLICATIONS AND PROGNOSIS

Complications in patients with achalasia might occur from the natural course of the disease (e.g. aspiration, squamous cell carcinoma, and megaesophagus), from iatrogenic interventions (e.g. perforation after balloon dilation, or postoperative complications after myotomy), or from the late consequences of a successful intervention (e.g. reflux related complications, such as strictures or adenocarcinoma).

As a result of the natural course of the disease, structural parenchymal pulmonary disease occurs in 33% of patients with achalasia, probably from chronic microaspiration. Furthermore, delayed diagnosis, or ineffective intervention, might lead to progressive dilation of the esophagus and the development of a megaesophagus. This complication occurs in 10% of patients at a median of 18-21 years after the onset of symptoms and might require esophagectomy in the most severe cases<sup>[75,76]</sup>.

In addition, treatment modalities carry their own inherent risks. As previously mentioned, the main risk of pneumatic dilation is perforation, which occurs at a mean of 1.6% (range from 0%-8%), even in experienced hands<sup>[39]</sup>. The risk of perforation appears to be highest during initial dilation, as opposed to subsequent

**Table 2** Predictors of treatment response in achalasia

Treatment option	Positive predictors	Negative predictors
Botulinum toxin injection	Vigorous achalasia Older patients	Initial LES pressure $\geq 50\%$ of the upper limit of normal Lack of clinical response or residual LES pressure $\geq 18$ mmHg after initial botulinum toxin treatment
Pneumatic dilatation	Older patients	Male Gender Pulmonary symptoms Failed response to 1-2 initial dilations High initial LES pressure ( $> 15-30$ mmHg) <sup>1</sup> Reduction of LES pressure $< 50\%$ after the first dilation
Myotomy	Younger patients (< 40 yr)	Severe preoperative dysphagia Lower preoperative LES pressures of $< 30-35$ mmHg <sup>1</sup> Esophageal body dilation (flask type or sigmoid esophagus) Preoperative endoscopic treatment (in some studies)

<sup>1</sup>Pressure values show considerable inter-study variability, depending on techniques used by different authors. Therefore, the pressure values shown in the table only reflect estimates based on the available literature.

dilations<sup>[77]</sup>. Although the perforation risk of laparoscopic myotomy is smaller with 0.7% (range 0%-8%), the overall rate of postoperative complications is 6.3%, with a periprocedural mortality of 0.1%<sup>[39]</sup>. As a result of endoscopic or surgical treatment, reflux esophagitis occurred in approximately 10% of patients in our own prospective cohort, even though 43% of patients received acid suppressing medications<sup>[76]</sup>. Reflux esophagitis was more commonly observed after surgical myotomy with Dor fundoplication (14%) than after pneumatic dilation (5%), possibly indicating more effective disruption of the LES. Late reflux complications, such as esophageal stricture occurred in half of these patients.

The most feared complication of achalasia is esophageal cancer. A recent review of the available literature reported a mean prevalence of esophageal cancer of 3% in patients with achalasia, indicating a fifty-fold increased risk over the general population<sup>[78]</sup>. Squamous cell carcinoma appears to occur most commonly, and probably results from stasis, causing bacterial overgrowth and production of nitrosamines, which in turn lead to chronic inflammation, dysplasia and cancer<sup>[79]</sup>. In addition, adenocarcinoma may result from long-standing reflux after successful treatment<sup>[80,81]</sup>. Although insufficient data are available to make evidence-based surveillance recommendations, many experts support a strategy of surveillance for cancer or reflux complications. Accordingly, the latest ASGE guideline suggests that it would be reasonable to consider such a strategy after 15 years of symptoms<sup>[82]</sup>. Annual follow up surveillance intervals have been suggested at least by one author<sup>[77]</sup>. Patients should be kept on a liquid diet three to four days before the surveillance endoscopy and an esophageal lavage should be considered immediately before the procedure to optimize visualization. Despite the described cancer risk and frequent long-term complications, patients with achalasia do not appear to experience a significant compromise of their overall life expectancy<sup>[76]</sup>.

## CONCLUSIONS AND FUTURE PERSPECTIVES

Achalasia is an idiopathic disorder, likely caused by

autoimmune mediated destruction of inhibitory neurons in response to an unknown, possibly viral, insult in genetically susceptible individuals. Physicians should be aware of typical and atypical presentations of achalasia to avoid diagnostic delays. Standard diagnostic work-up should include an EGD, timed barium swallow and manometry. Additional testing may become necessary if pseudoachalasia is suspected. The appropriate choice of therapy depends on multiple factors, including local expertise, patient preferences, and known predictors of treatment failures (Table 2). Based on the current evidence, we prefer laparoscopic myotomy in combination with partial fundoplication in young patients (< 40 years) with low surgical risk as the primary treatment option. In older patients, or those who want to avoid surgery, pneumatic dilation produces good long-term results, unless the first one to two dilations are unsuccessful, or LES pressure is not adequately decreased. Botulinum toxin might be especially useful in very old patients, or those with major comorbidities, because of its excellent safety profile. Subsequent treatments should be based on symptom recurrence. Pharmacological therapy should be reserved for patients awaiting a more definite treatment option. For patients not responding to any one of the above mentioned therapies, or patients with megaesophagus, esophageal resection remains a viable option.

In the future, well designed prospective studies are needed to identify optimal treatment options for different subgroups of patients with idiopathic achalasia. The advent of new exciting diagnostic methods, such as HRM, may aid in predicting treatment responses and warrants further investigation. Finally, with growing insight into the pathophysiology of this disease, novel treatment options that aim at preventing the late stages of the disease might evolve.

Effect of perioperative blood transfusion on clinical outcomes in hepatic surgery for cancer. *World J Gastroenterol* 2009; 15(32): 3976-3983 Available from: URL: <http://www.wjgnet.com/1007-9327/15/3976.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.3976>

## INTRODUCTION

Improvements in surgical techniques, in pre- and post-operative care, and increased experience have improved the safety of liver resections for hepatocellular carcinoma (HCC), and these procedures frequently can be carried out without blood transfusions<sup>[1-5]</sup>. By contrast, riskier hepatectomies, including posterior resections with reconstruction of the vena cava or resection of the caudate lobe, represent complex procedures which could require perioperative blood transfusion. Transfusion of allogenic blood has been reported to be associated with potentially devastating complications such as transmission of human immunodeficiency virus and hepatitis, transfusion reactions, increased postoperative infection rate, and increased incidence of recurrences for certain cancers<sup>[6]</sup>. Moreover, pulmonary oedemas occurring during or after a blood transfusion appear as the most frequent serious immediate incidents: they include transfusion-associated circulatory overload and transfusion-related acute lung injury (TRALI)<sup>[6]</sup>. Transfusion of allogenic whole blood products has been shown to induce variations in certain immune functions<sup>[7,8]</sup>, such as reduced NK cell activity, T lymphocyte blastogenesis, and increased suppressor T lymphocyte activity, which may be of great relevance for host resistance to infection and the spread of neoplastic cells. But, the adverse effects of allogeneic whole blood transfusion on cancer recurrence and survival rates<sup>[9-12]</sup>, regardless of innumerable published studies, continue to be debatable, since as many studies can be found that invalidate<sup>[13-18]</sup> as those that substantiate<sup>[19-27]</sup> this hypothesis.

Recent advances in surgical techniques to control blood loss and transfusion need<sup>[28-32]</sup>, and the growing vast experience with hepatic resections, have been

## Abstract

Allogeneic blood transfusion during liver resection for malignancies has been associated with an increased incidence of different types of complications: infectious complications, tumor recurrence, decreased survival. Even if there is clear evidence of transfusion-induced immunosuppression, it is difficult to demonstrate that transfusion is the only determinant factor that decisively affects the outcome. In any case there are several motivations to reduce the practice of blood transfusion. The advantages and drawbacks of different transfusion alternatives are reviewed here, emphasizing that surgeons and anesthetists who practice in centers with a high volume of liver resections, should be familiar with all the possible alternatives.

responsible for a remarkable reduction in the use of blood and blood products during surgery. Despite these efforts, allogeneic blood transfusion rates during hepatic resections have been reported at 40% to 80% depending upon the magnitude of the resection<sup>[3]</sup>. Furthermore, even though the introduction of the hepatic inflow occlusion technique introduced by Pringle<sup>[33]</sup> and selective and/or intermittent inflow occlusion have been very effective at reducing blood loss during hepatic resection, back bleeding from the hepatic veins and their tributaries during the Pringle manoeuvre can still be unpredictable, severe, and unexpected<sup>[34]</sup>.

This paper outlines the current perspectives on blood transfusion in hepatic resection, focusing on allogeneic blood transfusion, intraoperative autotransfusion, preoperative autologous blood donation, and intraoperative isovolemic hemodilution.

## ALLOGENEIC BLOOD TRANSFUSION

New measures to reduce transfusion errors have recently been defined by Regan *et al*<sup>[35]</sup>. The incidence of allogeneic blood transfusion is high in patients with cirrhotic livers undergoing liver resections for HCC, and for that reason it is vital to determine whether these transfusions stimulate tumor recurrence. The postoperative recurrence of HCC associated with perioperative blood transfusion has been supported<sup>[36]</sup> and disputed<sup>[37]</sup>. Furthermore the relationship between perioperative allogeneic blood transfusions, recurrence free survival, and the immunologic profiles of patients with HCC who have undergone curative liver resections has been investigated<sup>[38]</sup>. These studies have shown that in transfused patients, the CD4 levels are decreased by 90 postoperative days, whereas the CD8 levels are elevated during 14-90 d after surgery, as compared with nontransfused patients. Postoperative levels of the CD57+NK-cell subset and PHA responses in the transfused group are elevated as compared with the nontransfused group, and the PHA response of the transfused patients is significantly increased at seven postoperative days. Recurrence free survival seems not to be affected by perioperative blood transfusions.

All these studies suggest the significance of perioperative blood transfusion as an independent prognostic variable in terms of recurrence, survival, complications, and death. Patients who need preoperative, intraoperative, or postoperative transfusions are generally those with large lesions that either require a tri-segmentectomy, or are too close to the vena cava. On the other side, patients who do not need blood transfusions tend to have smaller, more peripheral lesions that can be resected under close hemostatic control. This suggests that patients with large HCC (with poor prognosis) are more likely to receive blood, and possible other factors should be taken into consideration for a more accurate evaluation. In regard to survival, for instance, the margin of resection, evidence of metastatic disease, liver failure or other perioperative complications should always be reviewed.

## INTRAOPERATIVE AUTOTRANSFUSION

Intraoperative autotransfusion [also known as autologous blood salvage or intraoperative blood salvage (IBS)] is a medical procedure involving recovering blood lost during surgery and re-infusing it into the patient. Different medical devices have been developed to assist in salvaging the patient's own blood in the perioperative setting. IBS is widely used in a variety of surgical procedures, including cardiovascular, orthopedic, and gynecologic procedures, and emergency medical situations<sup>[39-41]</sup>, but IBS in oncologic patients has not been widely studied. IBS has been cited as a contraindication<sup>[42]</sup> because of the potential risk of disseminating metastasis. This concept was introduced firstly by Yaw *et al*<sup>[43]</sup> who demonstrated tumor cells in processed blood that passed through filters in the Bentley autotransfusion device. Other studies support that IBS can be safely used in patients with cancer<sup>[44-46]</sup>. Because the Haemonetics cell saver processes blood by centrifuge-based washing after filtration, the risk of reinfusion of malignant cells seems to be lower than by the Bentley system. Clinical evidence of dissemination of cancer cells caused by IBS has not been reported, and several studies show no correlation between the presence of malignant cells and their subsequent dissemination<sup>[47,48]</sup>. The haemonetics cell saver was employed by Fujimoto *et al*<sup>[49]</sup> as an intraoperative scavenger of blood in patients undergoing hepatectomy for HCC. In this study autotransfusion was shown to be safe and effective, and the pattern and frequency of recurrence suggest that autotransfusion is not responsible for recurrence or metastasis. Hashimoto *et al*<sup>[50]</sup> showed that IBS in living liver donors undergoing liver resection for graft procurement offered the advantage of reduced blood loss during parenchymal transection.

At the present time, the processes used to assist in salvaging the patient's own whole blood in the perioperative setting can be categorized into three general types: (1) Cell processors and salvage devices that wash and save red blood cells (RBCs), i.e. "cell washers" or RBC-savers; (2) Direct transfusion; (3) Ultrafiltration of whole blood. Cell processors are red cell washing devices that collect anticoagulated shed or recovered blood, wash and separate the RBCs by centrifugation, and reinfuse the RBCs. RBC washing devices can help remove byproducts in salvaged blood such as activated cytokines, anaphylatoxins, and other waste substances that may have been collected in the reservoir suctioned from the surgical field. However, they also remove viable platelets, clotting factors, and other plasma proteins essential for homeostasis. Direct transfusion is a blood salvaging method associated with cardiopulmonary bypass circuits or other extracorporeal circuits that are used in surgery such as coronary artery bypass grafts, valve replacement, or surgical repair of the great vessels. Hemofiltration or ultrafiltration devices constitute the third major type of blood salvage appearing in operating rooms. In general, ultrafiltration devices filter the patient's anticoagulated whole blood. The filtration process

removes unwanted, excess non-cellular plasma water, low molecular weight solutes, platelet inhibitors and some particulate matter through hemoconcentration, including activated cytokines, anaphylatoxins, and other waste substances making concentrated whole blood available for reinfusion. Hemofiltration devices return the patient's whole blood with all the blood elements and fractions including platelets, clotting factors, and plasma proteins with a substantial Hb level. Presently, the only whole blood ultrafiltration device in clinical use is the *Hemobag*.

Concerns about possible contamination of autologous RBC with cancer cells responsible for metastasis still continues to limit the use of IBS in cancer patients. This is despite the fact that no evidence has been reported showing an increase in metastasis or a decrease in patient survival, regardless of the obvious demonstration that salvaged blood is contaminated with viable tumor cells which are not washed out of the RBC layer during IBS. Total elimination of the risk of reinfusion of cancer cells by irradiation has been proposed by Hansen<sup>[51]</sup>, who has been able to show that IBS with blood irradiation is safe as it provides efficient elimination of contaminating cancer cells, does not compromise the quality of RBC, and is very effective in saving blood resources. The effectiveness of this procedure has been shown on a large number of oncologic patients<sup>[52]</sup>.

## PREOPERATIVE AUTOLOGOUS BLOOD DONATION

Evidence that allogeneic transfusion may lead to a potential risk of postoperative infections, and the increased demand for blood with a declining population of qualified, willing, and healthy donors, give reason for the current support for preoperative autologous transfusion (PAD)<sup>[53,54]</sup>. The overall benefits of PAD have been assessed in both randomized trials and cohort studies<sup>[55]</sup>. Assuming that the donor is not bacteremic at the time of donation and/or there are no clerical errors resulting in the accidental transfusion of the wrong unit of blood, the patient is also protected against hemolytic, febrile or allergic transfusion reactions; alloimmunization to erythrocyte, leukocyte, platelet or protein antigens; and graft-versus-host disease (GVHD). An additional benefit is that erythropoiesis may be stimulated by repeated phlebotomies, thereby enabling the patient to regenerate hemoglobin at an accelerated rate after surgery.

PAD programs are not without some disadvantages. Perhaps the most important is that autologous blood is considerably more expensive than allogeneic blood. This problem is compounded by the fact that current reimbursement programs of most of the National Health systems around the world either deny the medical necessity of PAD or ignore the well-documented increase in cost<sup>[56]</sup>. Moreover, the blood that is not transfused to the intended recipient (approximately 50% of donated blood) is generally wasted rather than being transfused to other patients<sup>[57]</sup>. This wastage of blood

and the costs of administering autologous programmes result in collection expenses that are higher than those for allogeneic transfusion.

Patients undergoing PAD may donate a unit (450 ± 45 mL) of blood as often as twice weekly, until 72 h before surgery. Under normal conditions, patients conventionally donate once weekly. Oral iron supplements are routinely prescribed. This iatrogenic blood loss is accompanied by a response in endogenous erythropoietin (EPO) levels that, although increased significantly over basal levels, remain within the normal range. The erythropoietic response that occurs under these conditions is therefore modest<sup>[58]</sup>. With routine PAD, erythropoiesis of 220-351 mL (11%-19% RBC expansion)<sup>[59,60]</sup> or the equivalent of 1-1.75 blood units, occurs in excess of basal erythropoiesis, which indicates the efficacy of this blood conservation practice.

The use of autologous blood deposits for cancer patients undergoing elective surgical procedures has been studied by Lichtiger<sup>[61]</sup>, who was able to show that the majority (132/182) of his patients (with head and neck, neurosurgical, gastrointestinal and colorectal, adrenal, gynecologic, soft tissue and bone, breast, and genitourinary tumors) underwent surgery using only autologous transfusions. Kajikawa *et al*<sup>[62]</sup> evaluated the benefit of autologous blood transfusion and the effect of recombinant human erythropoietin (rh-EPO) on preoperative autologous blood donation for hepatectomy in patients with cirrhosis. Their study shows that autologous blood transfusion yields clinically superior results for hepatectomy in patients with cirrhosis when compared with homologous transfusion. In addition preoperative rh-EPO administration minimizes presurgical decreases in hematocrit (HCT) caused by autologous blood donation<sup>[62]</sup>. Likewise preoperative autologous blood donation in combination with rh-EPO therapy markedly reduces the requirements for homologous blood transfusion during hepatic resections<sup>[63]</sup>.

Other studies on patients undergoing hepatic resection have shown that the predeposition of autologous blood decreased the need for homologous transfusions from 56% to 38%. A further reduction in the transfusion rate of 25% could have been possible if all patients had donated 2 U of autologous blood<sup>[64]</sup>.

To determine if predonation of autologous blood impacts upon transfusion practice and clinical outcome following liver resection, clinical records of 379 consecutive patients undergoing hepatic resection for metastases of colorectal cancer were identified from the prospective hepatobiliary database and reviewed by Chan *et al*<sup>[65]</sup>. No conclusion could be drawn from their data concerning the influence of allogeneic transfusion on tumor recurrence, since their study was not a randomized trial comparing allogeneic blood transfusion with autologous transfusion. Data from their study however demonstrated that PAD alone is insufficient to alter the rate of tumor recurrence or disease-specific survival. Furthermore major hepatic resections using current surgical techniques can be performed safely with low blood loss so that transfusion is required for only a minority

of patients. PAD may further reduce the need for allogeneic blood. Autologous blood transfusion is safe after storage and it has advantages if compared with homologous blood transfusion with regard to postoperative liver function and survival rate after hepatectomy for HCC<sup>[66]</sup>.

In a recent study, Hirano *et al*<sup>[67]</sup> have shown that their autologous blood program, with IBS and preoperative blood donation, reduces the volume of banked blood needed and improves the prognosis of patients undergoing hepatectomy for HCC.

## INTRAOPERATIVE ISOVOLEMIC HEMODILUTION

Acute isovolemic hemodilution (ANH) is another possible alternative to allogeneic blood transfusions, which was introduced in the early 1970s<sup>[68]</sup>. The procedure implies the removal of blood from the patient immediately before operation and the simultaneous replacement with appropriate volume of crystalloid or colloid fluids. ANH will reduce the HCT so that blood shed during the operative procedure will result in less RBC mass loss. The amount of blood removed varies between one and three units (450-500 mL constitutes 1 U), although larger volumes may be withdrawn safely in certain circumstances. The removed blood is then reinfused as autologous whole blood after the major blood loss portion of the procedure is completed. The blood withdrawn is anticoagulated and maintained at room temperature, in the operating room, for up to 8 h. It is reinfused into the patient as needed during, or after, the surgical procedure. ANH can be used as the only blood preservation technique, or it can be combined with preoperative autologous donation, blood salvage, or both.

Hemodilution could be classified according to the target HCT as mild ( $HCT \geq 30\%$ ), moderate ( $30\% < HCT \geq 20\%$ ), or severe ( $HCT < 20\%$ )<sup>[16]</sup>. The target HCT with ANH is variable but is often around 25%-30%. Severe hemodilution (e.g. 20%) is likely to be more efficacious with regards to blood conservation, but the risks are greater, particularly for patients with preexisting medical conditions such as coronary heart disease<sup>[69]</sup>.

ANH should be taken into consideration for patients with good initial HCTs who are assumed to be deprived of more than two units of blood (900-1000 mL) during surgery. This technique works better in healthy, young adults, but it has been successfully employed in children and elderly patients. ANH has been used in vascular, orthopedic, and in some general surgical procedures. In addition, Jehovah's Witnesses patients accept this technique with the modification that we keep the blood moving and in direct contact with the patient's vascular system. Some Jehovah's Witnesses will agree to ANH if the blood is maintained in a closed circuit continuous flow system<sup>[70]</sup>.

ANH is contraindicated in cardiac disease, since the main compensatory mechanism for the induced anemia is an increase in the cardiac output, when renal function

is impaired, since large amounts of infused fluids need to be excreted, and when baseline hemoglobin is below 110 mg/L (11 g/dL). Furthermore low concentrations of coagulation proteins, inadequate vascular access, and the absence of appropriate monitoring capability indicate that ANH should not be used<sup>[71]</sup>.

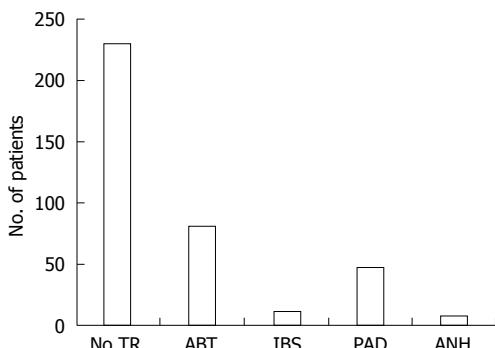

In the last 20 years several groups reported the use of ANH during major hepatic resections<sup>[72-76]</sup>, and the overall conclusion is that ANH, in selected patients, is a safe and effective technique that appears to reduce the number of patients requiring homologous blood transfusion as well as the number of units transfused per patient. Furthermore, Jehovah's Witnesses with hepatic tumors represent a major problem for liver surgeons to achieve good outcome, in fact these patients, because of their religious beliefs, refuse transfusion of blood and blood products. In order to avoid transfusion Barakat *et al*<sup>[75]</sup> have recently described the use of ANH in a Jehovah's Witness who underwent a combined left trisegmentectomy and caudate lobectomy to treat a large intrahepatic cholangiocarcinoma.

ANH is considered a simple and inexpensive procedure, and has the advantage that fresh autologous blood is readily available. Numerous studies of its efficacy, however, have produced conflicting results, perhaps because of the heterogeneity of the surgeries in which it was used, differences in study protocol, and differences in the definition of outcome variables<sup>[77,78]</sup>.

## DISCUSSION

Liver resection is still the mainstay of treatment for patient with HCC. Even though improved surgical techniques and anesthesia have remarkably decreased the mortality rates of liver resections, morbidity rates, remain high. One of the major risks of hepatectomy is large-volume blood loss, which necessitates perioperative blood transfusion. The possible consequences of homologous blood transfusion are well known and include noninfectious risks such as transfusion reactions, transient immunodeficiency, transfusion-associated GVHD, and TRALI<sup>[79-84]</sup>. Thus there are conclusive motivations to reduce blood loss during surgery and, as a consequence to lessen blood transfusion. It has been clearly shown that transfusion has a significant negative effect on perioperative mortality, complications, and length of hospital stay, even if it is difficult to demonstrate that transfusion is the only factor that decisively affects the outcome. The magnitude of the surgical procedure has always to be considered the most critical factor. It is intuitive that anterior, small, marginal atypical resections are quite different to complicated posterior large resections which include reconstruction of resected vena cava.

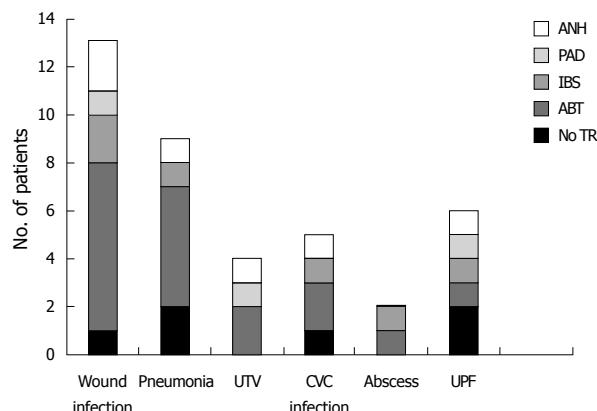

An association between transfusion and postoperative complications has been shown in preclinical models<sup>[85,86]</sup> and in clinical studies<sup>[87-91]</sup>. The review of 378 consecutive elective liver resections performed in our institution shows that 62% of the patients were not transfused, and the remaining 38% received blood products delivered with different procedures (Figure 1).

**Figure 1 Transfusion procedures in 378 patients undergoing liver resection.** No TR: Not transfused (62%); ABT: Autologous blood transfusion (21%); IBS: Intraoperative blood salvage (3%); PAD: Preoperative autologous blood donation (12%); ANH: Acute normovolemic hemodilution (2%, seven of the eight pts were Jehovah's Witnesses). Data from the Department of Surgical Sciences, University of Insubria, Varese, Italy.

Infectious complications (wound infections, pneumonia, urinary tract infections, central venous catheter infections, abscesses, and undiagnosed postoperative fever) have been more frequent in the transfused group of patients (33 vs 7). Most of the infections complications (18) have been recorded in the patients receiving autologous blood transfusions, the most frequent being wound infections (7) and pneumonia (5). Our results confirm the observation of Alfieri *et al*<sup>[92]</sup> who in a series of 254 liver resections found a significant association between blood transfusions and development of complications. More recently, Kooby *et al*<sup>[93]</sup> have been able to show that perioperative blood transfusion is a prognostic factor for the development of complications in univariate and multivariate analysis. Transfused patients had twice as high a chance of developing major complications and four times the risk of perioperative death. Transfused patients also had a higher incidence of infectious complications (17% vs 13%,  $P = 0.03$ )<sup>[93]</sup>.

Despite these results and studies, it is still debatable whether transfusion is the only and independent factor related to short term outcome, and specifically the only determinant of postoperative infectious complications. Is the transfusion itself and not the reason for the transfusion the cause of postoperative morbidity? Intraoperative hypotension, complexity of operation (extended hepatectomies vs lesser resections), duration of anesthesia, age, stage of the neoplastic lesion, degree of liver dysfunction, nutritional status, and possible neoadjuvant treatment, are all factors which could interfere with some aspects of the complex immunologic response. Furthermore, timing of the transfusion and the circumstances necessitating transfusions have been proposed as the real determinants of prognosis<sup>[94]</sup>. Today we are not able to conclude that transfusion is the factor producing the infectious complication, and the correlation we found of transfusion with complications should not be interpreted as a direct cause and effect relationship. The infectious complications are different in the transfused and non-transfused patients, but we cannot say for sure

**Figure 2 Details of postoperative infectious complications (44 pts, 11.6%) occurred in 378 patients undergoing liver resections and correlated to transfusion procedures.** UTV: Urinary tract infection; CVC: Central venous catheter; UPF: Undiagnosed post-operative fever. Data from the Department of Surgical Sciences, University of Insubria, Varese, Italy.

that immunologic irregularities are what produces the difference.

In recent years, we have had the occasion to carry out seven major liver resections on Jehovah's Witnesses with large tumors. The management of Jehovah's Witnesses with HCC, or any other type of liver tumor, entails a multidisciplinary, adapted plan in harmony with their religious beliefs to achieve good outcome<sup>[95]</sup>. This approach enabled us to perform the surgical procedure respecting their religious conviction, and authorized us to anticipate that ANH could be considered a safe alternative for use in selected cases in which allogeneic blood transfusion is considered of high risk. This approach, in our series, has been associated with a relative high incidence of infectious complications, if compared with other autologous blood transfusion procedures (Figure 2).

## CONCLUSION

A substantial discrepancy is apparent in transfusion practice for elective surgery, and even more so for liver resections<sup>[96]</sup>. Reducing unneeded exposure to blood components by blood saving measures is essential in patients undergoing elective surgery. A publication for anesthesiologists reviews good transfusion practices in surgical patients<sup>[97]</sup>.

Perioperative blood transfusion has been described as one of the risk factors for poor outcome after liver resection. This seems particularly verifiable for infectious complications. The postoperative recurrence of HCC associated with perioperative blood transfusion has been the subject of controversy due to conflicting results. Although allogeneic blood transfusion may have immunosuppressive effects, perioperative blood transfusions seem not to influence the cancer free survival rate in patients with HCC. Even if there is no evidence of one transfusion procedure which prevails over the others, surgeons who practice in Centers with high volume of liver resections should be familiar with

all the possible alternatives (ABT, IBS, PAD, ANH), since each of them, when blood products are needed, have a place depending upon the different clinical pattern.

Finally, maintaining a low central venous pressure has been shown recently to be effective in reducing blood loss during partial liver resections. Moreover antifibrinolytic drugs have proved to be effective in reducing blood loss during liver transplantation<sup>[98]</sup>.

### INTRODUCTION

The gastric pathogen, *Helicobacter pylori* (*H pylori*), is a member of the epsilon-bacteria. This microaerophilic, Gram-negative bacterium colonizes the human stomach<sup>[1]</sup>. It is estimated that over half of the human population are infected by *H pylori*<sup>[2]</sup>. The infection causes mucosal inflammation, atrophy, ulceration and cancer<sup>[3,4]</sup>. Five strains of *H pylori* and a number of related bacteria have been sequenced. Genomics, evolutionary studies and population genetics have advanced our understanding of this bacterium.

### GENOMIC FEATURES

In 1997, *H pylori* strain 26695 was firstly sequenced<sup>[5]</sup>. It was isolated from an English patient with chronic gastritis. The chromosome of strain 26695 is circular and composed of 1667867 base pairs. The average GC content is approximately 39%. In the initial annotation, it has 1590 open reading frames that are possibly protein-coding<sup>[5]</sup>, in addition to the RNA coding genes (2 copies of 16S rRNA and 23S rRNA genes, 36 tRNA genes). Later analysis of the genome sequence suggested a smaller number of ORFs in strain 26695<sup>[6]</sup>. The ongoing studies have found genes that were neglected in the initial analysis. A general secretion machinery is widely present in bacteria, which functions in secretion of outer membrane proteins from the inner membrane and delivery of proteins to extracellular environments<sup>[7]</sup>. The initial annotation revealed a partial general secretion machinery because it lacked SecE in 26695<sup>[5]</sup>. A further analysis of the genome sequences with GeneMark, Glimmer and BlastX found a small open reading frame between nusG and rmpG (HP1203-HP1204)<sup>[8]</sup>. It has a high homology and structural similarity to the SecE protein in related bacteria. Therefore, strain 26695 has a complete general secretion machinery, which is consistent with the fact that the bacterium is capable of protein secretion. In addition, small RNA genes are universally present in bacteria<sup>[9]</sup>. The tmRNA gene (*ssrA*) has been found in *H pylori*, which encodes a functional RNA molecule and a small peptide that is involved in

### Abstract

Genomic sequences have been determined for a number of strains of *Helicobacter pylori* (*H pylori*) and related bacteria. With the development of microarray analysis and the wide use of subtractive hybridization techniques, comparative studies have been carried out with respect to the interstrain differences between *H pylori* and inter-species differences in the genome of related bacteria. It was found that the core genome of *H pylori* constitutes 1111 genes that are determinants of the species properties. A great pool of auxillary genes are mainly from the categories of *cag* pathogenicity islands, outer membrane proteins, restriction-modification system and hypothetical proteins of unknown function. Persistence of *H pylori* in the human stomach leads to the diversification of the genome. Comparative genomics suggest that a host jump has occurs from humans to felines. Candidate genes specific for the development of the gastric diseases were identified. With the aid of proteomics, population genetics and other molecular methods, future comparative genomic studies would dramatically promote our understanding of the evolution, pathogenesis and microbiology of *H pylori*.

Dong QJ, Wang Q, Xin YN, Li N, Xuan SY. Comparative genomics of *Helicobacter pylori*. *World J Gastroenterol* 2009;

quality control of translation<sup>[10]</sup>. In addition, *H pylori* also possesses a sRNA gene encoding the RNA component of Rnase P and the 4.5S RNA gene which is involved in secretion<sup>[11,12]</sup>.

In 1999, strain J99 was sequenced which was isolated from an American patient with a duodenal ulcer<sup>[6]</sup>. Compared to strain 26 695, it has a slightly smaller circular chromosome (1 643 831). The overall genomic organization, gene order and predicted proteomes of the sequenced strains are very similar. The predicted open reading frames are less in strain J99, amounting to 1495. There are 1406 genes shared by both strains, but 86 open reading frames are absent from strain 26 695. Both strains contain a complete *cag* pathogenicity island that codes for a type IV secretion system which delivers the CagA cytotoxin protein into gastric epithelial cells<sup>[13]</sup>. Comparison of the two genomes reveals the occurrence of translocation and inversion events. A 83 kb inversion contains most of the strain specific genes. This region was named a plasticity zone since it has a much lower GC content (35%) than the rest of the genome.

In 2006, a chronic atrophic gastritis *H pylori* strain, HPAG1, was sequenced<sup>[14]</sup>. It was isolated from an 80 year-old female patient who was enrolled in a Swedish case-control study of gastric cancer<sup>[15]</sup>. Similar to the sequenced strains 26 695 and J99, HPAG1 is a type 1 strain that contains *cagA* and a virulent allele of *vacA*<sup>[15]</sup>. The genome of HPAG1 (1 596 366 bp) is the smallest in the three sequenced strains. A total of 1536 open reading frames were predicted. Of these, 43 genes are only present in HPAG1. Analysis revealed that 29 genes that are found in both J99 and 26 695 were missing from HPAG1. If genes in a strain are absent from other strains, they are called strain-specific genes. The comparison of three sequenced *H pylori* strains shows that the majority of strain-specific genes are functionally unknown. Another group of strain-specific genes is composed of genes of the R-M system (restriction-modification). They encode proteins involved in DNA restriction or modification. Other strain-specific genes include those encoding outer membrane proteins and *cag* proteins.

*H pylori* strain G27 was sequenced recently<sup>[16]</sup>. It was originally isolated from an Italian patient<sup>[17]</sup> and has been used widely in *H pylori* research. This strain is naturally transformable<sup>[18]</sup>, capable of delivering CagA into epithelial cells in culture<sup>[19,20]</sup>, and capable of adapting to variable environments<sup>[21]</sup>.

The G27 genome has a similar size to the other three sequenced strains. It is 1 652 983 bp long and has a GC content of 38.9%. 1515 open reading frames was predicted. In addition, G27 also contains one 10032 bp AT rich (65.2%) plasmid resembling that found in strain HPAG1<sup>[14]</sup>. The plasmid encodes 11 genes. In agreement with the previous report<sup>[6]</sup>, the *cag* pathogenicity island of G27 is disrupted by a transposon. This, however, does not seem to interfere with any of the open reading frames or to the delivery of CagA into host cells. Unlike strain 26 695, there is a single plasticity region in G27 which contains a large number of *H pylori* specific genes.

It is predicted that strain G27 has 58 genes that are not found in 26 695, J99, or HPAG1.

The *H pylori* Shi470 genome has also been sequenced by Washington University Medical School. It is 1.61 Million bp long and contains approximately 1609 predicted genes. The sequences are available on the university website (<http://hpylori.ucsc.edu>).

The finding of strain-specific genes from the comparison of the sequenced strains is in agreement with the earlier studies which demonstrated the high diversity of the *H pylori* genome<sup>[22-24]</sup>. No identical strains of *H pylori* have been found in their genetic types unless they are isolated from a family<sup>[25-27]</sup>. *H pylori* has great mutation and recombination capacities. Analysis of the genomic sequences failed to identify a complete mismatch repair system controlling the confidentiality of replication, despite the presence of a homology of MutS<sup>[28,29]</sup>. This results in a high mutation rate of *H pylori*. Examination of 29 clinical isolates revealed that approximately 1/4 of them had mutator phenotype with higher mutation frequencies than Enterobacteriaceae mismatch-repair defective mutants<sup>[30]</sup>. In another study, examination of paired strains isolated from a patient at different times suggested a mutation rate of  $4.1 \times 10^{-5}$ , which is comparable to that of *E. coli* mutator<sup>[31]</sup>. *H pylori* is naturally competent for transformation<sup>[32]</sup>. Nonrandomly distributed repetitive sequences are found in the genome, which leads to frequent recombination events<sup>[33]</sup>. The recombination rate (recombination events starting at any particular nucleotide) is estimated to be  $6.9 \times 10^{-5}$ <sup>[34,35]</sup>. High levels of recombination and mutation could explain the observed genomic diversity in *H pylori*.

## DETERMINATION OF THE CORE GENOME OF *H PYLORI*

Inter-strain diversity, represented by variations in number and contents of genes, chromosomal rearrangements and allelic diversities, is not unique to *H pylori*<sup>[36]</sup>. This has been noted in a number of other bacterial species. For *H pylori*, each strain contains many strain-specific genes<sup>[7,14]</sup>. It has been proposed that a particular bacterial species contains a core set of genes and the auxiliary genes<sup>[37]</sup>. The core genome contains genes that are present in all or nearly all of the strains. It determines the properties that are characteristic of the species. The auxiliary genes are present in some of strains. They are determinants of the biological properties unique to some of the strains. Salama *et al*<sup>[38]</sup> firstly explored the core set of genes in *H pylori*. A total of 15 strains of *H pylori* mainly isolated from Western countries were examined using a microarray method<sup>[38]</sup>. It was found that 1281 genes were common to all the examined strains, therefore constituting the core genome of *H pylori*. Considering the limited number of strains examined and the fact that *H pylori* is highly prevalent in human, could these genes represent the actual core set of the *H pylori* species? Additionally, these strains were only isolated from Western individuals. In fact, molecular typing of global strains has found that the modern population of *H pylori* divides into five major

groups, hpEurope, HpAfrica1, hpafrica2, hpEastAsia and hpAsia2<sup>[39,40]</sup>. They are possibly derived from different ancestral groups. Gressmann *et al*<sup>[41]</sup> further examined 56 globally representative strains of *H pylori*. The number of the genes in the core set of *H pylori* was diminished to 1150. The author concluded through a calculation that the core genome of *H pylori* only consists of 1111 genes.

The auxiliary set of genes in *H pylori* amounts to 22%-27% of the genome<sup>[14,41]</sup>. In agreement with the findings from the whole genome sequencing of *H pylori* strains, the auxiliary genes consist of those coding for functionally unknown proteins, cag protein, outer membrane proteins and proteins of DNA metabolism<sup>[7]</sup>.

Candidate genes specific for development of gastric diseases.

The long term clinical outcomes of the *H pylori* infection are diverse. The infected gastric mucosa may develop inflammation, atrophy, intestinal metaplasia, ulceration, cancer and MALT lymphoma<sup>[1,3,4]</sup>. Genes in the auxiliary set are specific only for some strains. Do they play roles in the determination of the final outcome of an infected individual? *H pylori* broth culture filtrates cause the formation of intracellular vacuoles in mammalian cells<sup>[42]</sup>. The protein which has the vacuolation activity was purified and named VacA (Vacuolating cytotoxin). Despite of the universal presence of the *vacA* gene in *H pylori*, some strains do not cause the vacuolation of epithelial cells. This is attributed to the mosaic structure of *vacA*<sup>[42]</sup>. A signal region in the N-terminal and a mid region of *vacA* are polymorphic. The signal region affects the vacuolating activity of the cytotoxin: a 12 amino acid extension on the s2 form blocks the activity, although not all s1 forms have the cytotoxic activity<sup>[43]</sup>. The mid region is a determinant of the cell specificity of VacA<sup>[44]</sup>. There are three *vacA* genotypes, s1/m1, s1/m2 and s2/m2 in *H pylori*. The association of s1/m1 strains with severe diseases has been observed in some studies. A recent study found an intermediate region (i-region) of *vacA* between the signal region and the mid region that also contributes to the levels of vacuolating activity<sup>[45]</sup>. The genotype i1 was more frequently found in gastric cancer associated *H pylori* than the i2<sup>[45]</sup>. Strains possessing *vacA* i1 are strongly associated with peptic ulcer<sup>[46]</sup>. Another protein has been found to be co-present in almost all of the strains possessing the vacuolating activity<sup>[47]</sup>. The protein was named as cytotoxin-associated gene A (*cagA*) protein. The gene is present in the majority of strains. Those possessing the vacuolating activity and the CagA expression are called type I strains, or virulent strains<sup>[48]</sup>. The presence of *cagA* is generally the marker for a large DNA region called *cag* pathogenicity island<sup>[49]</sup>. Proteins produced by the *cag* island make up a type IV secretion system which delivers CagA into the epithelial cells<sup>[50,51]</sup>. The type IV secretion system locates across the inner and outer membrane and forms a pilus-like structure at the surface<sup>[51,52]</sup>. The CagL protein is a specialized adhesin that is targeted to the pilus surface<sup>[53]</sup>. Through an arginine-glycine-aspartate motif, it binds to and activates integrin  $\alpha 5\beta 1$  receptor on gastric epithelial cells. This interaction triggers CagA delivery into target cells<sup>[54]</sup> and activation of Src of gastric epithelial

cells<sup>[55]</sup>. Translocated CagA remains associated with the host membrane and becomes tyrosine phosphorylated on carboxyl-terminal repeat motifs (Glu-Pro-Ile-Tyr-Ala, or EPIYA motifs)<sup>[56,57]</sup> by members of the Src family of protein tyrosine kinases such as c-Src, Fyn, Lyn, and Yes<sup>[58]</sup>. Phosphorylated CagA interacts with SHP-2<sup>[59]</sup>, which thereafter activates a number of phosphatases inducing alteration of signaling pathways. This alters the spreading, migration, adhesion, polarity and cytoskeletal structures of epithelial cells<sup>[60-63]</sup>. A large European study, demonstrated that *cagA* positive strains are significantly associated with the development of gastric cancer<sup>[64]</sup>. The *cag* island is thus an important determinant of the clinical outcomes of the *H pylori* infection. Most *H pylori* strains, and almost all in certain geographical locations, however, are virulent (that is they expressing CagA and VacA). Are there any other genomic differences associated with the clinical outcomes?

Comparison of the genomic contents of different strains has found genes that are potentially disease-specific. Peptic ulcer disease frequently occurs in humans with severe, or even lethal complications. The disease may also affect children. Oleastro *et al*<sup>[65]</sup> reported the study of the genomic comparison of a *H pylori* strain isolated from a child presenting with duodenal ulcer and a strain from a sex and age matched child with gastritis. It was found that genes jhp0562 and jhp0870 are more frequently seen in children with peptic ulcer than in those with gastritis. Both genes are located in the plasticity zone. Jhp0562 encodes a putative LPS glycosyltransferase involved in LPS biosynthesis<sup>[66]</sup>, whereas jhp0870 codes for an outer membrane protein. LPS and outer membrane proteins play roles in the induction of an inflammatory response from the gastric mucosa<sup>[66,67]</sup>. Whether jhp0562 and jhp0870 contribute to the development of ulceration in children deserves further study. Other genomic comparison studies have found that the *cag* island and a 670 bp-long DNA fragment that is partially homologous to the hydrolase kinase gene are potentially associated with peptic ulcer diseases<sup>[68]</sup>. Gastric mucosa infected by *H pylori* develops inflammation, and gradually become atrophic. Mucosal atrophy is an important stage in stomach carcinogenesis. A thorough examination of the genome of 6 strains from atrophic gastritis found a set of 121 "ChAG-associated" (ChAG, chronic atrophic gastritis) genes<sup>[14,69]</sup>. They are universally present in these 6 strains but absent from 56 globally derived strains of *H pylori*<sup>[69]</sup>. Their putative roles in the development of atrophy and promotion of carcinogenesis are yet to be studied. Intestinal metaplasia of gastric mucosa is a precancerous lesion. *H pylori* in the patient with intestinal metaplasia is likely associated with progression into gastric cancer. Comparison of a cancer strain and a duodenal ulcer strain of *H pylori* found a novel sequence named Clone P32 with homology to GepA in *Dichelobacter nodosus*<sup>[70]</sup>. Examination of strains from diverse gastric diseases demonstrated that Clone P32 is inversely associated with intestinal metaplasia. Gastric B cell lymphoma of mucosa associated lymphoid tissue is highly associated with the *H pylori* infection<sup>[1]</sup>. Eradication of the bacterium leads to the alleviation of the disease. Comparing

the genome of a strain from gastric B cell lymphoma with that from gastritis revealed that jhp0950 encoding a *H pylori* specific protein of unknown function was potentially associated with the development of the disease<sup>[71]</sup>. It was present in about 3 quarters of strains from gastric lymphoma, but only present in about half of strains from gastritis, duodenal ulcer or gastric adenocarcinoma. If other virulent factors were taken into account, the odds of having gastric MZBL among patients harbouring JHP950, *iceA1* (coding for a restriction enzyme), and *sabA* (coding for a major adhesin) "on" strains were 10 times higher than for the others<sup>[72]</sup>. Although these genes are specific for strains from a specified disease, it is uncertain whether they are pathogenic for a particular disease. Actually, different gastric diseases greatly differ in a variety of environmental factors that have potential impacts on the biological behaviors and genetics of the bacterium. For example, secretion of gastric acid is varied in different diseases<sup>[73]</sup>. Therefore, further studies are required to say that a gene is specific for the pathogenesis of a particular disease.

## INTRA-HOST EVOLUTION OF THE *H PYLORI* GENOME

It is believed that the *H pylori* infection is usually acquired in childhood<sup>[74]</sup>. The bacterium is transmitted from parents to their children with a bias of mother to children transmission<sup>[75,76]</sup>. Once the infection is established, the bacterium persists in the host for decades unless eradicated with antibiotics. Transmission of bacteria to a new host is a major barrier for bacterial spreading. It may affect the bacterial genome contents. Four healthy adults were experimentally infected with *H pylori*. Examination of isolates form 15 d or 90 d postinfection demonstrated that their genomic contents were identical to the challenging strain<sup>[77]</sup>. A similar result was found in a study of experimental infected mice<sup>[78]</sup>. These findings suggest that for *H pylori*, transmission does not cause any alteration of the gene components of the genome, or, in the other words, the establishment of the *H pylori* infection does not require the involvement of novel genes. Further evidence supporting this conclusion comes from a study of the analysis of the strains from a mother and her three children<sup>[75]</sup>. Microarray analysis demonstrated that the genomic contents of isolates from the mother were identical to those from the children. *H pylori* persists in the human stomach for decades, probably from childhood. It may experience a variety of ecological alterations, which may in turn have large impacts on the genome of the organism. The output of gastric acid alters with aging and with infection by *H pylori*. Alterations of the constituents and the quantity of the gastric mucus underneath which the bacterium resides are observed during the course of the *H pylori* infection. The gastric epithelial cells may undergo metaplasia and changes in surface proteins, which affect adhesion and the supply of nutrients. The gastric mucosa may produce immune and inflammatory products against

the bacterium. The co-infection with other microbes is also frequent seen in the stomach. These alterations may affect genomic contents of *H pylori*. Kraft et al<sup>[79]</sup> examined paired strains of *H pylori* with respect to their genomic contents using the microarray method. Paired strains were isolated from the same patients at an interval from 3 to 36 mo. Of 21 pairs of strains examined, 4 pairs showed differences in their genomic contents, suggesting the occurrence of evolutionary events. These included a complete deletion and a partial loss of the *cag* pathogenicity island, a replacement of an open reading frame of unknown function with the restriction-modification system HpyAIV, an acquisition of 14 genes in the plasticity zone, a duplication of the *ceuE* genes (HP1561/HP1562) and a truncation of tandem arranged *ackA* and *pta* genes resulting in the formation of pseudogenes. A study has compared 2 pairs of strains obtained from the same patients at an interval of 4 years<sup>[69]</sup>. The patients had progressed from atrophic gastritis to cancer. Six genes were absent, including 3 genes involved in DNA repair, an outer membrane protein and two hypothetical proteins. Nine genes were gained, including a ligase, a metalloprotease, a tRNA formyltransferase, a putative ribonuclease, a restriction enzyme and four hypothetical genes. The comparison suggests that with the progression of the atrophy to cancer, the bacterium may have a propensity for losing its diversifying capacity. Findings from these studies demonstrate that *H pylori* may acquire or lose genes during the intra-host colonization<sup>[80]</sup>. The genes involved fall into the same categories as the strain specific genes. This was further supported by the results from the comparison of the sequenced strain J99 with isolates obtained 6 years later<sup>[81]</sup>. These comparative studies of the *H pylori* genome draw a picture of the genomic changes during the cycle of invasion, colonization and transmission to a new host. It appears that invasion into a new host has little effect on the gene composition of the genome. This indicates that the current genome of *H pylori* has sufficient capacities for permitting bacterial invasion into a human host or even into a host of different species under experimental conditions. Once the infection is established, the bacterium has to cope with the dynamic changes of the ecology during the long-term coexistence with the host. Genomic diversifications, or gain and/or loss of genes, occur in response to these changes. The diversifications involve genes that are mainly those strain specific genes observed from comparative studies of unrelated strains of *H pylori*. Intra-host evolution of *H pylori*, thus, results in the creation of a pool of genes that are generally needed by some strains. This pool of genes can be considered as the auxiliary set of genes of *H pylori*.

## COMPARATIVE STUDIES OF *H PYLORI* AND ITS RELATED BACTERIA

Since the isolation of *H pylori*, a number of closely related bacteria have been identified, constituting a

new bacterial genus named Helicobacter genus<sup>[82,83]</sup>. Bacteria within this genus have been shown to colonise the gastrointestinal tract of mammals. Many of these Helicobacter species are involved in the pathogenesis of gastrointestinal diseases<sup>[82,83]</sup>. Phylogenetic analysis has shown that the *helicobacters* can be separated into two clusters<sup>[84]</sup>. Gastric species that colonise the stomach of mammals form a cluster. Species that inhabit the intestine and biliary tracts cluster together to form the enterohepatic cluster. In addition to *H. pylori*, the genome sequences have been determined for several other *helicobacters*, including *H. mustelae* from ferret, *H. acinonychis* from large felines (cheetahs, lions and tigers)<sup>[85]</sup>, *H. hepaticus* from mice which causes hepatoma<sup>[86]</sup>, and *Wolinella succinogenes* from cattle<sup>[87]</sup>.

General genomic features of these *helicobacters* are listed in Table 1, which also includes information for several species of *campylobacter*<sup>[88-91]</sup>. Of these related bacteria, the size and GC content of *H. acinonychis* are most similar to those of *H. pylori*<sup>[85]</sup>. Comparison of 612 orthologues that are present in both *H. acinonychis* and *H. pylori* found that they differ at only few of their amino acids. The Blast scores against *H. pylori* of most coding sequences in *H. acinonychis* are very high. These findings lead to the conclusion that a host jump has occurred from human to felines<sup>[85]</sup>. This event probably occurred 100 000 years ago. More studies are required to confirm this conclusion considering that universally accepted criteria to identify a host jump event are currently unavailable. The study also found a set of fragmented genes and newly acquired genes in *H. acinonychis*. These genes include a set of genes encoding outer membrane proteins and a cluster of genes encoding proteins for sialylation of bacterial surface carbohydrates. It has been suggested that these genes are probably beneficial for the bacterium to evade host immune defenses<sup>[92]</sup>.

Information from comparative genomics has greatly enhanced our understanding of the microbiology, physiology, evolution and pathogenesis of *H. pylori*. Candidate genes specific for the development of the gastric disease, particularly gastric cancer have been identified. Considering the striking diversities in the

*H. pylori* genome which are intensified by intra-host evolution, further studies exploring these genes must take account of them.

### Abstract

**AIM:** To determine the accuracy of 1.5-T magnetic resonance imaging (MRI) in the evaluation of gastric wall invasion and perigastric lymph node metastasis in gastric adenocarcinoma.

**METHODS:** Twenty resected gastric specimens containing 20 tumors were studied with a 1.5-T MR system using a commercial head surface coil. MR scanning was performed with a T1 weighted image (TR/TE = 500/20), and a T2 weighted image (TR/TE = 2500/90). MR findings were compared with pathologic findings.

**RESULTS:** A T1-weighted image demonstrated three layers in the normal gastric wall. All of the gastric tumors were well demonstrated by lesions and location. In a MRI findings of gastric wall invasion, there was 1 case of T1, 7 of T2, 11 of T3. Pathologic results of resected specimens included 3 cases of pT1, 4 of pT2, and 12 of pT3. The accuracy of T staging with MRI was 74% (14 of 19). MRI findings of lymph node me-

tastasis included 6 cases of N0, 13 cases of N1. The accuracy of the N staging with MRI was 47% (9 of 19).

**CONCLUSION:** MRI has a high diagnostic accuracy in the evaluation of the T staging of gastric cancer *in vitro* and thus potentially enables preoperative histopathologic staging.

### INTRODUCTION

The preoperative staging workup of gastric carcinoma is performed mainly with computed tomography (CT). CT has been a favored method for preoperative evaluation and staging in patients with gastric carcinoma<sup>[1-3]</sup>. Parallel advances in CT equipment and scanning techniques have reduced scanning time and decreased motion artifacts. Simultaneously, rapid IV contrast administration with an automatic power injector has improved contrast enhancement of the gastric wall and gastric cancer. Helical CT has advantages over conventional CT, including faster scanning time and fewer respiratory misregistration artifacts in a single breath-hold<sup>[4]</sup>. However, CT is limited, particularly in the diagnosis of lymph node metastasis, peritoneal metastasis, and small hematogenous metastasis<sup>[5,6]</sup>.

Endoscopic sonography has been reported to be the most accurate technique for the T staging of gastric carcinoma because it can define five layers of the gastric

wall. But this technique cannot evaluate other factors such as liver metastasis and peritoneal seeding<sup>[7]</sup>. In addition, endoscopic sonography is an invasive technique dependent on the operator.

Magnetic resonance imaging (MRI) has not become popular for staging because of a number of limitations, including motion artifacts, lack of a stable contrast medium, and the high cost<sup>[8,9]</sup>. However, continuous technical improvements have been made in MRI of the abdomen, thereby reducing motion artifacts and improving image quality. These improvements include breath-hold fast imaging techniques, placement of abdominal binders, administration of antiperistaltic agents, and the use of phased array coils<sup>[10]</sup>. *In vitro* studies using 1.4-7-T MR systems have shown that MRI allows the depiction of gastric wall layers and therefore, technically permits the evaluation of the local tumor stage of gastric carcinomas<sup>[11-13]</sup>.

The purpose of this study was to assess the accuracy of the evaluation of gastric carcinomas and lymph node metastasis *in vitro* by using gastrectomy specimens that were studied with 1.5-T MRI.

## MATERIALS AND METHODS

### Subjects

Over a period of 13 mo, a total number of 20 consecutive patients with histopathologically proven gastric carcinoma underwent subtotal or total gastrectomy. There were twenty resected gastric specimens that were obtained from the patients who were diagnosed with gastric carcinoma histologically by fiberoptic biopsy. The patients underwent subtotal or total gastrectomy. They consisted of fourteen men and six women [mean age, 53 years: 34-77 years (14 men, 6 women)]. Nineteen subtotal gastrectomy specimens and one total gastrectomy specimen was obtained and used in this study.

### Specimen preparation

We needed to distend the gastric specimens for MRI. During their operations, all the stomachs were not opened for the purpose of this study. To distend the stomach of the specimens, the duodenal resection border was sealed with a continuous suture before the specimen was filled with saline solution. The specimens were then placed in a plastic box that had been filled with 5-6 L of saline solution.

The proximal portion of the gastrectomy specimen was hanged at the cap by strings. The box was capped and placed in the head coil of a 1.5-T MRI (SMT 1.5 scanner, Shimazu Co., Tokyo, Japan). Then the MR examination was performed. The study protocol was approved by the Institutional Review Board, and agreement was obtained from each patient before surgery.

### MRI protocol

The MRI obtained in this study was based on the following multisection spin echo sequences for T1-weighted images, repetition time (TR) ms/echo time (TE) ms = 500/20, and for T2-weighted images, 2500/90.

Two numbers of excitation were applied in this scanning. The matrix size was 256 × 256. Slice thickness was 5 mm and the intersection gap was 1 mm. Field of view was 20 cm. MR scans of the gastrectomy specimen were taken along the axial and sagittal planes. A head coil was used for scanning.

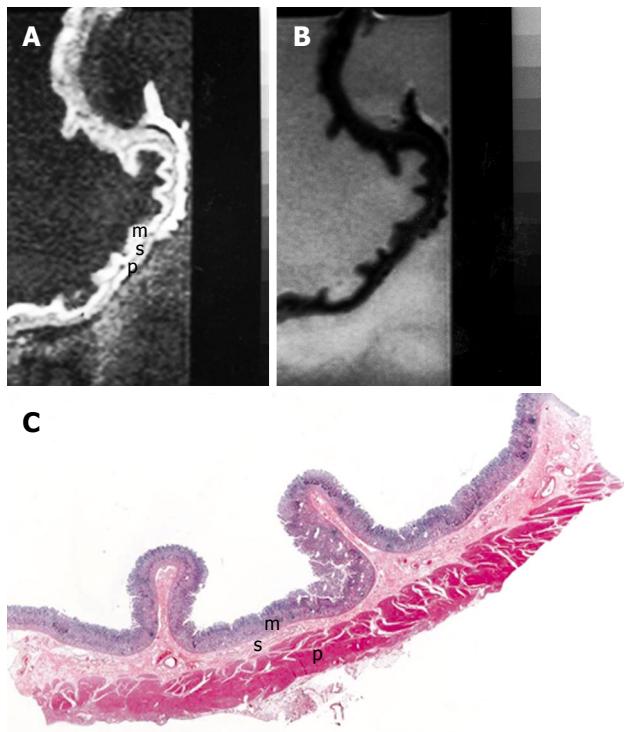

### Image analysis

The MR images of 20 resected gastric specimens were analyzed by two radiologists (H.S and S.K with 3 and 10 years of abdominal CT and MRI experience, respectively) in consensus before the results from the pathologic examination were available. The number of visible wall layers and their specific signal intensity (SI) characteristics were examined. Wall-layer correlation was made on the basis of the layer thickness of the visible layers in MRI compared with the ones visible in histology. The presence of a tumor, defined as destruction of the normal gastric wall layers, was noted. The tumors were examined for variations in SI. The depth of infiltration was evaluated according to earlier publications<sup>[12,13]</sup>. A normal gastric wall was identified as having 3 layers. In terms of scanning direction and degree of distention of the wall, a gastric wall that was more than 1 cm thick or that showed an abrupt change of pattern from normal to pathologic was considered abnormal. The location, gross appearance, size and degree of serosal invasion of tumors were evaluated. Location was classified according to four areas: antrum, body, body and antrum, and fundus. Gross appearance was classified into four categories by Bormann's classification for advanced gastric carcinoma<sup>[14]</sup>. T and N staging were based on the TNM system developed by the American Joint Committee on Cancer (AJCC)<sup>[15]</sup>. Early gastric cancer was evaluated according to the Japanese Research Society for Gastric Cancer<sup>[16]</sup>. The degree of tumor invasion in the gastric wall according to the T stage was measured as follows: T1 meant that MR showed obliteration of SI within the thickened mucosal layer and second submucosal layer, T2 meant that thickening of the gastric wall and obliteration of the third layer of muscularis propria, and T3 meant irregular SI in the outer margin of the third layer.

We counted the total number of lymph nodes which were located in the perigastric area. A lymph node of > 8 mm at the short axis was considered to be pathologic<sup>[17]</sup>. N staging of lymph nodes was performed. N0 is defined as no regional lymph node metastasis, N1 as metastasis in one to six regional lymph nodes, N2 as metastasis in seven to 15 regional lymph nodes, N3 as metastasis in more than 15 regional lymph nodes. Results of MR images were compared with findings in pathologic specimens and a report made by pathologists.

### Histologic preparation

Immediately after the MR examination of resected gastric specimens, the specimens were transferred to the department of pathology. The time interval between resection and fixation of the specimens was 2-3.5 h. The pathologist was not informed of the findings of

**Figure 1 MRI and histology of normal gastric wall.** A: T1-weighted (500/20) sagittal image of resected gastric wall showed three layers. The inner layer corresponds to the mucosa (m) and the middle layer to the submucosa (s). The outer layer basically consists of the muscularis propria (p) from which the serosa cannot be differentiated; B: T2-weighted (2500/90) MRI showed low SI on mucosa and muscularis propria and relatively high SI on submucosa; C: Light microscopic section of normal gastric wall obtained from the greater curvature site of stomach body showed three layers which are compatible with inner mucosal layer (m), middle submucosa layer (s) and outer muscularis propria and serosal layer (p) (HE stain; original magnification,  $\times 1$ ).

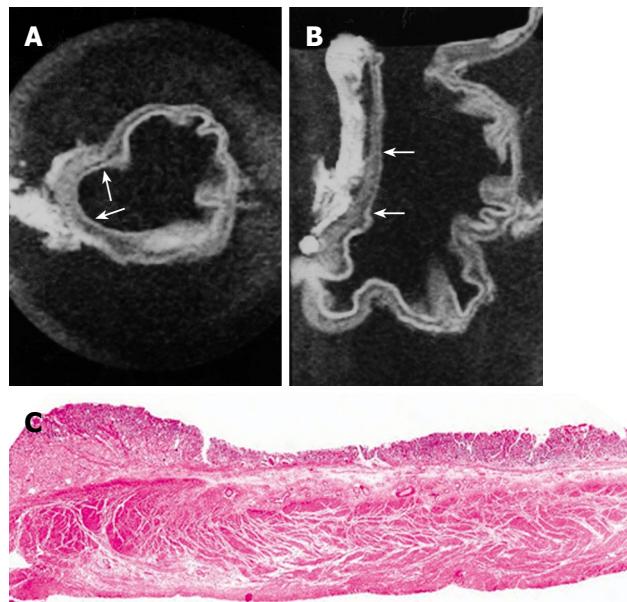

the MRI. The gastrectomy specimens were cut in planes corresponding to MRI imaging planes. The location, gross appearance, tumor size, and the histologic depth of invasion were determined for each specimen. The gastric carcinomas were staged according to the American Joint Committee on Cancer<sup>[15]</sup>. The diagnosed early gastric carcinomas (EGCs) were evaluated<sup>[16]</sup>. Finally, the histopathological staging of the specimens were compared with the staging by MRI. The depth of tumor invasion was decided according to the T factor of the TNM classification. Invasion of the mucosa or submucosa is classified as pT1, invasion of the muscularis propria as pT2, and tumor penetration of the serosa as pT3.

All the lymph nodes in the perigastric area of the specimens were counted and examined. Lymph nodes were stained with hematoxylin-eosin and examined by a light microscope for metastasis. Correlation between MR staging of lymph node metastasis and pathologic staging were performed by AJCC protocol<sup>[15]</sup>.

## RESULTS

### SI characteristics of normal gastric wall

On MRI, two to three layers with different SI in the normal gastric wall can be depicted. However, there was

**Figure 2 MRI and histology of early gastric cancer.** A: T1-weighted (500/20) axial image showed depression of gastric wall and obliteration of submucosal low SI (arrows); B: T1-weighted sagittal MRI showed depressed mucosa with tumor invasion to submucosa layer (arrows); C: Light microscopic section showed depressed mucosa with tumor invasion to submucosa (HE stain; original magnification,  $\times 1$ ).

a mainly three-layered structure (multilayered pattern) of the gastric wall by MRI. The inner layer showed an increase of SI and was 1–3 mm thick on the T1-weighted images. The second had a lower SI with thickness that varied at different sites in the same individual. The outer layer showed a slightly higher SI.

On T2-weighted images, the inner and outer layers regularly had a low SI, and the middle layer a high SI. On the basis of the comparison, the inner layer corresponds to the mucosa, the middle to the submucosa and the outer to the muscularis propria and serosal layers (Figure 1).

### Detection of primary tumor

MRI of gastric carcinoma on resected specimens showed as follows: two cases of Bormann's type 1 carcinoma (polypoid type), seven cases of Bormann's type 2 (ulcerative type), six cases of Bormann's type 3 (ulcerative type with infiltration), and four cases of Bormann's type 4 (infiltrating type). One case of early gastric carcinoma with type IIc was observed, whose lesion was seen as a depression of the mucosa with thinning of the gastric wall on axial and sagittal scannings (Figure 2). Gross pathologic findings showed tumor lesions as follows; two cases of Bormann's type 1, four of Bormann's type 2, nine of Bormann's type 3, four of Bormann's type 4. One case of early gastric carcinoma with type IIc was proved upon histologic examination.

In terms of the classification of gross appearance in the nineteen lesions detected as advanced gastric carcinoma, the accuracy of MRI in the Bormann's type classification was 89% (16 of 19). Differentiation between Bormann's type 2 and type 3 lesions was

**Table 1 Magnetic resonance imaging (MRI) and pathologic correlation of tumor invasion in gastric wall**

Diagnosis at histologic examination					
Diagnosis' at MR	pT0	pT1	pT2	pT3	Total
T0					
T1		1			1
T2		2	3	2	7
T3			1	10	11
	3	4	12		19

erroneous in three lesions.

The location of gastric carcinoma was also identified on the MR images. There were nine cases of gastric carcinoma involvement in the gastric antrum, three cases in the stomach body, seven cases in the antrum and the body, one case involving the entire stomach. Upon gross specimen examination, there was no difference between them and the MRIs.

#### Depth of tumor invasion

Degree of invasion was evaluated in the nineteen cases of advanced gastric carcinoma (Table 1). MRIs of gastric carcinoma in resected specimens showed various findings, including thickening of the gastric wall with irregularity in the mucosal SI obliteration, thickening of the gastric wall with first and second layer SI obliteration, diffuse thickening of the gastric wall with third layer SI obliteration and irregularity with ulceration as well.

T1-weighted images showed intermediate SI in regions affected by gastric carcinoma compared to the surrounding normal mucosa and muscularis propria SI. T2-weighted images showed low SI in the gastric carcinoma. Most tumors had a homogenous SI. However, in some cases necrosis and calcification caused an inhomogeneous SI. It is not possible to differentiate between the muscularis propria, subserosa, and serosa. The reason for this inability was that we considered the subserosa and serosa as being located on the outer border of the joint layer representing the muscularis propria, subserosa, and serosa. If an infiltration was visible, the tumor was classified as T2 as long as it did not reach the outer border. Penetration of the external margin meant at once infiltration of the serosa, and the tumor was staged as a T3 carcinoma. A tumor infiltrating the subserosa without penetrating the serosa was still considered T2, according to the AJCC<sup>[5]</sup>. The MRI findings of gastric wall invasion included 1 case of T1, 7 of T2 (Figure 3), and 11 of T3 (Figure 4). Pathologic results of resected specimens included 3 cases of pT1, 4 of pT2, and 12 of pT3. Differentiation between T1 and T2 classifications was not difficult in cases displaying a distinction between three layers. However, two cases of pT1 were over staged as T2. One case of pT2 was over staged as T3. Two cases of pT3 were understaged as T2. Differentiation between T2 and T3 lesions was difficult due to the outer muscularis propria and serosal layer's thinness and could not always be demonstrated by MRIs. The level of accuracy

**Table 2 MRI and pathologic correlation of lymph node metastasis**

Diagnosis at histologic examination				
Diagnosis at MR	pN0	pN1	pN2	Total
N0	2	3	1	6
N1	4	7	2	13
N2	6	10	3	19

in determining the T factor according to the TNM classification was 74% (14 of 19 lesions).

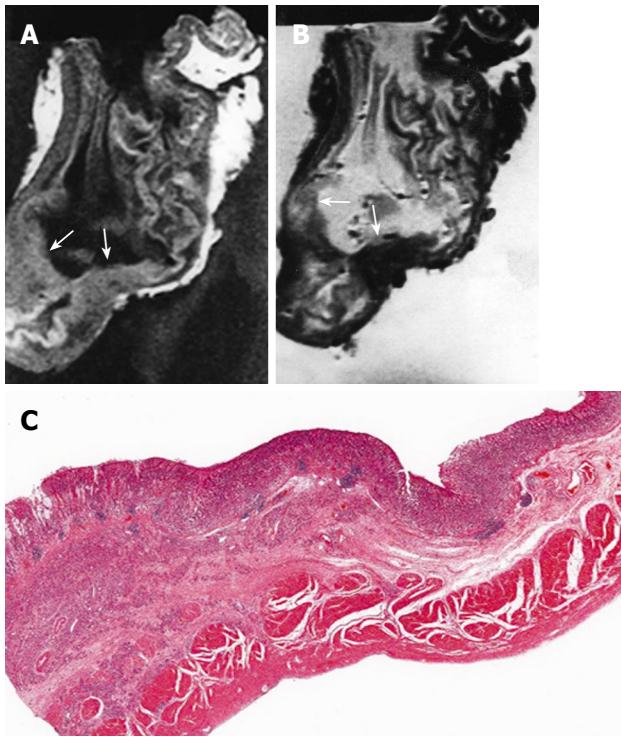

#### Regional lymph node metastasis

The lymph nodes presented with intermediate SI on T1-weighted images, intermediate SI on T2-weighted images. The sizes were measured as being from 0.35 cm to 3.5 cm. We counted 34 lymph nodes in the MRIs. Only 1 lymph node was measured as less than 0.8 cm on its short axis and the other 33 lymph nodes were measured as more than 0.8 cm on their short axis.

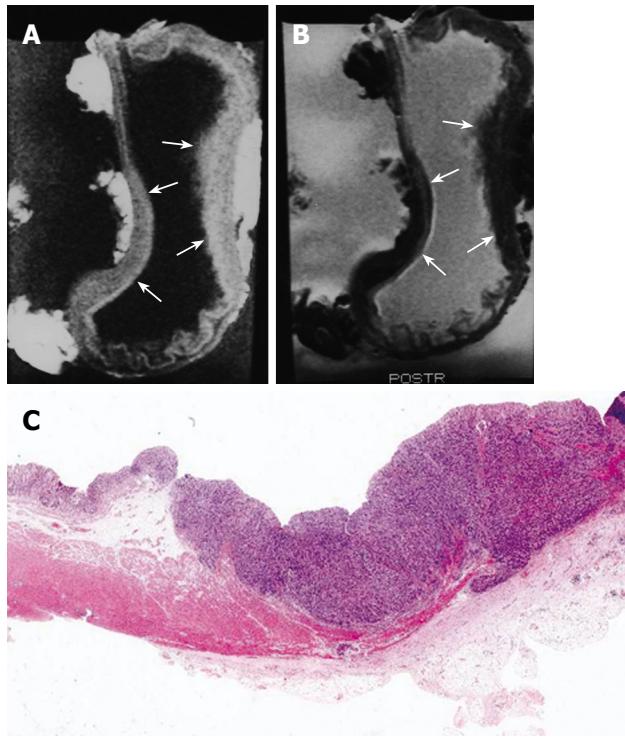

One hundred forty lymph nodes were removed from 19 cases of resected gastric specimens. The short axis of resected nodes proved malignant upon pathologic examination ranging from 0.3 to 3.5 cm. Overall metastasis was found in 60 lymph nodes. Degree of lymph node metastasis was also evaluated in 19 cases of gastric carcinoma (Table 2). MRI findings of lymph node metastasis included 6 cases of N0, and 13 of N1 (Figure 5). Pathologic findings of lymph node metastasis included 6 cases of pN0, 10 of pN1 and 3 of pN2 (Figure 6). Four cases of pN0 were over staged as N1 on the MR images. Three cases of pN1 were understaged as N0. Three cases of pN2 were understaged as N1 and N0. The accuracy of N staging by MRI was 47% (9 of 19).

## DISCUSSION

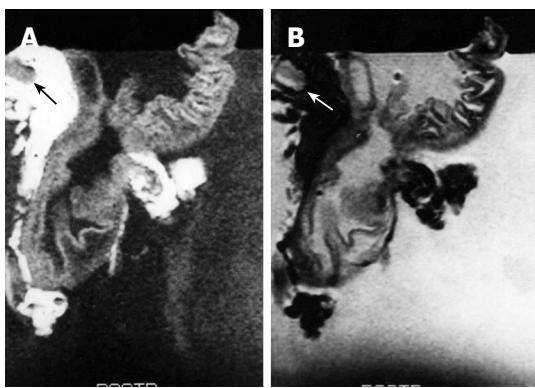

Imaging modalities, such as CT and endoscopic sonography are performed for the staging of gastric carcinoma. However, the accuracy of staging gastric carcinoma is still controversial in any diagnostic modality and a definitive diagnostic modality has not been established yet. Preoperative staging of gastric carcinoma is limited by the fact that available imaging modalities do not enable accurate evaluation of depth of infiltration of the gastric wall<sup>[18-21]</sup>. CT imaging is still evaluated for gastric wall invasion and staging of gastric carcinoma. However, the results of CT in local tumor staging are also insufficient, particularly because no reliable anatomic layer differentiation of the gastric wall can be achieved<sup>[20]</sup>. Without depiction of the wall layers, a secure distinction between T1, T2 and T3 tumors cannot be achieved. Results of early studies concerning CT diagnosis of gastric carcinoma were encouraging; however, findings in later articles were pessimistic about the ability of CT to enable staging of gastric carcinoma<sup>[7,9]</sup>. Recently, spiral CT has been founded to be more accurate than previous CT studies<sup>[22,23]</sup>.

**Figure 3 MRI and histology of T2 gastric cancer.** A: T1-weighted (500/20) sagittal image showed diffuse thickening of gastric wall with obliteration of mucosa, submucosa and muscularis propria SI in antrum and lower body, while preserved outer marginal SI (arrows); B: T2-weighted (2000/90) sagittal MRI showed ill defined lesion with minimal increased and same SI compared to surrounding normal gastric wall (arrows); C: Light microscopic section demonstrate proper muscle invasion of gastric cancer (HE stain; original magnification,  $\times 1$ ).

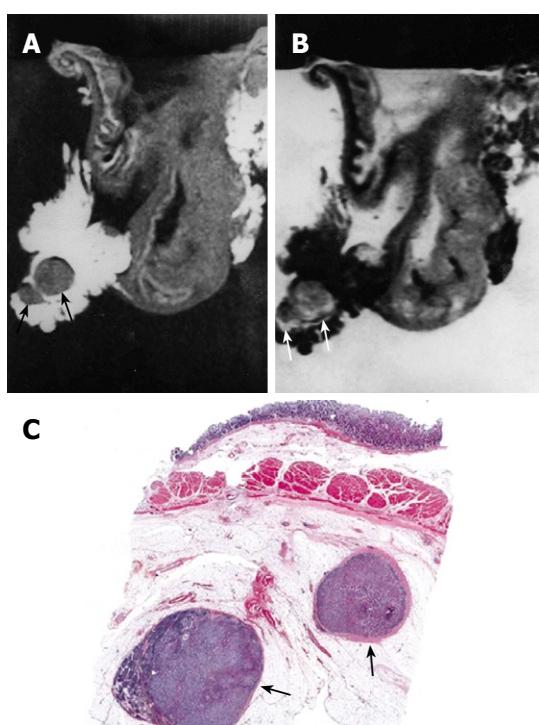

**Figure 4 MRI and histology of T3 gastric adenocarcinoma.** A: T1-weighted (500/20) sagittal image showed thickening of gastric wall with all three layer SI change in lesser and greater curvature site of stomach body (arrows); B: T2-weighted (2000/90) sagittal MRI showed minimal increase of SI on lesion site and poor delineation of gastric wall SI at outer layer margin compared to normal gastric wall (arrows); C: Light microscopic section showed extension of tumor invasion to serosal layer (HE stain; original magnification,  $\times 1$ ).

**Figure 5 MRI of N1 gastric adenocarcinoma.** A: T1-weighted (500/20) MR image showed single lymph node on lesser curvature site of stomach body (arrow); B: T2-weighted (2000/90) MRI showed intermediate signal SI of lymph node (arrow).

Endoscopic sonography is effective for detection of lymph node involvement in the perigastric area<sup>[24]</sup>. Moreover, Botet *et al*<sup>[7]</sup> reported the accuracy of the N factor and overall staging with endoscopic sonography to be 78% (39 of 50), which is significantly higher to that examined with the conventional dynamic CT technique. However, there are limitations to endoscopic sonography in the evaluation of distant perigastric lymph node metastasis. Another problem is that endoscopic sonography is invasive and the results are

**Figure 6 MRI and histology of N2 gastric adenocarcinoma.** A: T1-weighted (500/20) MRI showed two lymph nodes in lesser curvature site of stomach antrum (arrows). Eight lymph nodes are detected in total in perigastric area (not shown); B: T2-weighted (2000/90) MRI showed intermediate SI in the lymph nodes (arrows); C: Light microscopic section showed two lymph nodes in lesser curvature site of gastric antrum (arrows) (HE stain; original magnification,  $\times 1$ ).

highly operator-dependent.

Interest in the use of MRI for the staging of gastric carcinoma is increasing, but most clinical studies stage the local tumor situation without the differentiation of gastric wall layers<sup>[4,8-10]</sup>. Studies that use depiction of gastric wall layers as a basis for local tumor staging and lymph node metastasis are rare<sup>[13,25]</sup>.

The high quality of soft-tissue imaging of MR systems enables the depiction of anatomic wall layers. Auh *et al*<sup>[11]</sup> studied the gastric wall using an experimental 4.7-T system whereas Lubienski *et al*<sup>[12]</sup> used an experimental 2.4-T system. Both groups proved that the depiction of gastric-wall layers is technically possible. Auh *et al*<sup>[11]</sup> depicted 3 layers whereas Lubienski *et al*<sup>[12]</sup> was able to differentiate 4 layers and correlated them to the mucosa, lamina muscularis mucosa, submucosa and muscularis propria. Typically 3 gastric wall layers are visible. The inner layer corresponds to the mucosa and lamina muscularis mucosa and the middle layer to the submucosa. The outer layer showed the same SI as the muscularis propria in the study of Lubinski's *et al*<sup>[12]</sup> study and therefore mainly consisted of muscle tissue and serosal layers. Palmowski *et al*<sup>[13]</sup> demonstrated that a reliable depiction of gastric-wall layers can be achieved by a conventional 1-T MRI. As no subserosa and serosa could be depicted, it must be presumed that they were located on the outer side of the third layer. So the third layer represented the muscularis propria, subserosa, and serosa together<sup>[13]</sup>. We could demonstrate that the inner and outer layers as hyperintense and the middle layer as hypointense at 1.5-MRI. When the three layers were depicted in the gastric wall, the mucosa and the muscularis propria were clearly different from the intervening submucosal layer on T1-weighted images. The distinction among the layers is based mainly on the lower SI of the submucosa compared with that of the mucosa or muscularis propria. The difference between the three layers was also depicted in the T2-weighted images.

In this study, gastric carcinomas appeared as masses with destruction of the normal structure of the gastric wall or diffuse thickening of the gastric wall and showed intermediate SI compared to surrounding normal gastric walls on T1-weighted images and low SI on T2-weighted images. Both sequences were useful for tumor localization and complement each other because some carcinomas in the study could only be recognized by deviating signal behavior in one of the 2 sequences. In our study, signal characteristics of the carcinoma depending on the MR sequence were not analyzed. Palmowski *et al*<sup>[13]</sup> reported that carcinomas show an intermediate SI on T1-weighted images, a low SI on T2-weighted images and a high SI on opposed phase images. Opposed phase images were not obtained in our study, but Dux *et al*<sup>[25]</sup> demonstrated that opposed phase images show a very high SI in gastric tumors and insisted that this was useful for the staging of gastric carcinoma. In this study, the infiltration of gastric carcinoma was correctly defined in 74% of the cases. This was not different from that of CT images that had an accuracy rate of 50%-85% and that of MR images

that had an accuracy rate of 73%<sup>[4,7,26]</sup>. Yamada *et al*<sup>[27]</sup> reported that gastric specimens that were imaged after fixation in formalin and then MR imaged could also depict early gastric carcinoma. In this study, one case of early gastric carcinoma was depicted on MRI with a shallow depressed wall. This was made possible by adequate distention of the resected stomach with saline. To our knowledge, this is the first MRI depiction of early gastric carcinoma using gastric specimens without fixation in formalin. In this study, unfortunately, cases with pathologic T4 were not included because most patients who were diagnosed as T4 on preoperative imaging studies did not undergo surgery.

The evaluation of lymph node metastasis on MRIs had some limitation in this study, since the size criteria was used only on MRIs and there was no trial of contrast enhancement because of *in vitro* study of gastric carcinoma. Lymph node borders and signal intensity were not also evaluated for diagnosis of lymph node metastasis. But some cases of lymph nodes showed intermediate SI on T1 and T2-weighted images in the tumor infiltration region and this was correctly correlated with the histology. One-to-one pathologic-to-radiologic correlation on each lymph node was not performed in our study. According to Dux *et al*<sup>[25]</sup> study, lymph nodes showed a high SI on opposed phased images. MRI had low rate in depicting lymph node metastasis, with an accuracy of 47%. However, the result was similar to the other reports<sup>[25,27]</sup>. Further study is needed to increase accuracy in the finding of lymph node metastasis in gastric carcinoma.

In conclusion, the present study demonstrated that MRI can reliably depict several anatomical layers of the gastric wall and also MRI of gastric carcinoma could enable accurate diagnosis of location, gross appearance, degree of gastric wall invasion of the tumors and delineation of regional lymph node metastasis. A clear image of the tumor can be achieved. Therefore, an evaluation of the local tumor stage of gastric carcinoma and perigastric lymph node metastasis based on morphologic criteria is technically possible. This study, using a conventional 1.5-T MRI in combination with standard sequences, demonstrated the potential of MRI in the staging of gastric carcinomas. Although the result obtained in N-staging was not acceptable, it should be explored further. However, we were able to show not only MR findings of gastric wall invasion but also perigastric lymph node involvement in the gastric carcinoma. The results of our study cannot, at this time, be transferred to clinical practice, because conventional imaging acquisition techniques do not provide an image quality comparable to that of those taken of *in vitro* specimens. Advances in the variation of sequence techniques, as well as application of ultrafast imaging techniques, may in the future allow preoperative staging of gastric carcinomas by MRI.

## COMMENTS

### Background

The preoperative staging workup of gastric cancer is performed mainly with

computed tomography (CT). Magnetic resonance imaging (MRI) has not become popular for staging because of a number of limitations, including motion artifacts, lack of a suitable oral contrast medium, and the high cost. However, continuous technical improvements have been made in MRI of the abdomen, thereby reducing motion artifacts and improving image quality.

### Research frontiers

MRI has not yet reached clinical importance because of some limitations. However, *in vitro* studies using experimental 2.4-4.7-T MR systems have shown that MRI allows the depiction of gastric wall layers and therefore technically permits the evaluation of the local tumor stage of gastric cancer.

### Innovations and breakthroughs

MRI in the staging of gastric cancer is not usually applied in clinical practice. Its results are the same or inferior to CT in accuracy. There are many MRI *in vitro* and clinical imaging gastric cancer studies. *In vitro* MRI systems demonstrate well gastric wall layers and tumor invasion well and MRI has shown tumor invasion and lymph node metastasis in some clinical studies as well. However, normal gastric wall depiction and tumor invasion of the gastric wall are important to tumor staging, as are demonstrations of perigastric lymph node metastasis. The authors studied resected gastric specimens for the accurate depiction of normal gastric walls, tumor invasion and lymph node metastasis using 1.5-T MRI.

### Applications

The study results suggest that MRI could be useful in gastric wall invasion in the staging of gastric cancer. However, further study in the staging of lymph node metastasis is still needed.

### Peer review

The authors successfully demonstrated normal gastric wall layers and tumor invasion in their *in vitro* study using 1.5-T MRI. The results suggest that MRI is a potential diagnostic tool in the staging of gastric cancer.

## Abstract

**AIM:** To assess the efficacy of intramuscular diclofenac and fluid replacement for prevention of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis.

**METHODS:** A prospective, placebo-controlled study was conducted in 80 patients who underwent ERCP. Patients were randomized to receive parenteral diclofenac at a loading dose of 75 mg followed by the infusion of 5-10 mL/kg per hour isotonic saline over 4 h after the procedure, or the infusion of 500 mL isotonic saline as placebo. Patients were evaluated clinically, and serum amylase levels were measured 4, 8 and 24 h after the procedure.

**RESULTS:** The two groups were matched for age, sex, underlying disease, ERCP findings, and type of treatment. The overall incidence of pancreatitis was 7.5% in the diclofenac group and 17.5% in the placebo group (12.5% in total). There were no significant differences in the incidence of pancreatitis and other variables between the two groups. In the subgroup analysis, the frequency of pancreatitis in the patients without sphincter of Oddi dysfunction (SOD) was significantly lower in the diclofenac group than in the control group ( $P = 0.047$ ).

**CONCLUSION:** Intramuscular diclofenac and fluid replacement lowered the rate of pancreatitis in patients without SOD.

## INTRODUCTION

Pancreatitis is the most common complication of endoscopic retrograde cholangiopancreatography (ERCP), with a reported incidence of 1%-10% in most prospective studies<sup>[1-9]</sup>. The generally accepted criteria for the diagnosis of post-ERCP pancreatitis were proposed in 1991 during a consensus workshop. These criteria include new onset of pancreatic-type abdominal pain associated with at least a threefold increase in serum amylase or lipase occurring within 24 h after ERCP, and the pain symptoms need to be sufficiently severe to require admission to the hospital or to extend the length of stay of patients who are already hospitalized<sup>[1,10]</sup>.

There have been numerous theories about the mechanisms of pancreatitis. The most widely accepted theory is that mechanical trauma to the papilla or pancreatic sphincter, caused during instrumentation, creates transient obstruction of outflow of pancreatic juice<sup>[1]</sup>. Another theory suggests that the increased hydrostatic pressures in the pancreatic duct caused by injection of contrast or saline could cause injury to the pancreatic duct or parenchyma<sup>[1]</sup>.

Risk factors reported for ERCP-induced pancreatitis include a history of pancreatitis<sup>[11]</sup>, difficult cannulation<sup>[2]</sup>, repeated injection of the pancreatic duct<sup>[11]</sup>, pancreatic acinar opacification<sup>[12]</sup>, sphincter of Oddi dysfunction (SOD)<sup>[3,13]</sup> and precut or needle-knife endoscopic sphincterotomy<sup>[9,13,14]</sup>.

Cellular events that lead to pancreatitis involve an inflammatory process with premature activation of trypsin in acinar cells<sup>[15,16]</sup>. Phospholipase A<sub>2</sub> is believed to play a critical role in the initial inflammatory cascade of acute pancreatitis by regulating a number of pro-inflammatory mediators, including arachidonic acid products and platelet-activating factors<sup>[17]</sup>. Prevention or interruption of this cascade may prevent development of pancreatitis and its consequences. Although drug development has been impressive, the availability of effective drugs in the prevention and management of pancreatitis remains limited<sup>[15]</sup>.

Chemoprevention of pancreatitis still remains a debated question. Pharmacological prevention of pancreatitis after ERCP has been the topic of several investigations in recent years.

Diclofenac, a potent inhibitor of phospholipase A<sub>2</sub> activity, administered immediately after the procedure, is effective at preventing pancreatitis<sup>[9,18]</sup>. Advantages of this prophylaxis are the low cost and the possibility of "on-demand" treatment. Addition of non-steroidal anti-inflammatory drugs (NSAIDs) has also been shown to have beneficial effects in experimental acute pancreatitis<sup>[19]</sup>.

The aim of this study was to evaluate the efficacy of intramuscular (IM) diclofenac and fluid replacement for the prevention of pancreatitis in all eligible patients who underwent ERCP at our medical center.

## MATERIALS AND METHODS

The study described in this report was approved by the ethics committee of Suleyman Demirel University School of Medicine, Isparta, Turkey. Between August 2006 and April 2008, 91 patients fulfilled the inclusion criteria, 80 of whom were included in the final analysis. Patients were excluded from study participation if they had a contraindication for diclofenac, including patients with recently diagnosed peptic ulcer disease, renal failure, those who had taken an NSAID during the preceding week, those who developed acute pancreatitis during the 2 wk before ERCP, those with a history of chronic pancreatitis, and those who did not agree to participate in the study. Entry to the study was restricted to patients advised to have endoscopic retrograde cholangiography with or without pancreatography for extrahepatic cholestasis and/or impaired liver function tests.

A prospective, placebo-controlled trial was conducted in 80 patients who underwent ERCP. The patients received 75 mg IM diclofenac and intravenous (IV) isotonic saline at a rate of 5-10 mL/kg per hour for 4 h or an inert placebo (500 mL IV isotonic saline) immediately after ERCP. At the end of each procedure, the researchers recorded the details of the maneuvers performed, including the total time of the procedure, the number of attempts at cannulation, the number of pancreatic duct cannulations, the final diagnosis, and whether a sphincterotomy, a needle-knife papillotomy, or stent placement were performed. We did not use pancreatic duct stenting for prevention of pancreatitis.

Patients were sedated with IV midazolam. Xylocaine spray was used as a local anesthetic.

Serum amylase was determined 4 h after ERCP. If the 4-h serum amylase level was < 3 times the upper normal limit and there was no clinical evidence of acute pancreatitis at that time, patients were allowed free oral fluids and a diet. If the 4-h serum amylase level was > 3 times the upper normal limit and the patient exhibited pain or nausea and vomiting, then the patient was kept fasting and IV crystalloid fluids with opiate analgesics were prescribed. The following 8 h and 24 h blood tests were repeated for serum amylase and the patients were interviewed and examined for clinical evidence of acute pancreatitis. Acute pancreatitis was defined as serum amylase > 3 times the upper limit of normal associated with epigastric pain, back pain, and epigastric tenderness. Patients with persistent signs and symptoms of pancreatitis after 48 h underwent contrast-enhanced computed tomography.

Pancreatitis was graded as mild, moderate, or severe. Sphincter of Oddi dysfunction (SOD) was defined according to the Milwaukee Biliary Group Classification<sup>[20]</sup>.

The instruments used were cannula, sphincterotome, guidewire, and stone basket (Boston Scientific, Natick, MA, USA).

## Statistical analysis

Data were summarized by descriptive statistics. The  $\chi^2$  square and Fischer's exact tests were used to compare categorical patient data. The Mann-Whitney U test and Student's *t* test were used to compare continuous variables. Two-tailed *P* < 0.05 were considered to indicate significance.

## RESULTS

A total of 80 patients were eligible for the study. Forty patients received 75 mg diclofenac and isotonic saline replacement (diclofenac group), and 40 received inert parenteral fluid replacement (control group). No patients discontinued the study medication because of adverse effects. Overall, the baseline characteristics were consistent across all treatment groups (Table 1). The mean ages of patients in the diclofenac and control groups were  $60.3 \pm 16.1$  years and  $59.3 \pm 14.4$  years, respectively. There were 15 women in the diclofenac group and 22 in the control group. Similarly, there were no statistically significant differences between the groups considering the procedures, and factors that might increase the risk of pancreatitis, including single or repeated pancreatic duct injection, SOD, younger age, female sex and precut endoscopic sphincterotomy (Table 2). Although the frequency of pancreatitis in the patients with SOD did not differ between the diclofenac and control groups, it was statistically significant between groups when the patients with SOD was excluded (*P* = 0.047). The most frequent indication for ERCP was bile duct stone in the diclofenac (57.5%) and control (27.5%) group. Post-endoscopic bleeding

**Table 1 Characteristics of patients in the diclofenac and control groups<sup>1</sup>**

	Diclofenac group (n = 40)	Control group (n = 40)	P
Variables			
Age (yr) <sup>2</sup>	60.3 ± 16.1	59.3 ± 14.5	0.766

Others <sup>4</sup>	9 (22.5)	10 (25.0)	

<sup>1</sup>All data were presented as [n (%)] and comparisons were made with  $\chi^2$  or Fisher's exact test unless otherwise stated. <sup>2</sup>Data was presented as (mean ± SD) and comparison was made with Student's *t* test. <sup>3</sup>Data were presented as [median (interquartile range)] and comparisons were made with Mann-Whitney *U* test. <sup>4</sup>Primary sclerosing cholangitis, hydatid cysts communicating with the bile ducts, Mirizzi syndrome, and postoperative complications. Post-ERCP: Post-endoscopic retrograde cholangiopancreatography; SOD: Sphincter of Oddi dysfunction.

because of sphincterotomy was observed in three of 75 sphincterotomy patients (3.75%). All the bleeding was seen during the procedure. No case of delayed bleeding occurred. Two of three bleeding episodes in the control group and one in the diclofenac group were self-limited and stopped during endoscopy without intervention.

Pancreatitis occurred in 10/80 patients (12.5%), three of whom (7.5%) belonged to the diclofenac group and seven (17.5%) belonged to the control group (Table 1). Four and eight hours after endoscopy, the mean ± SE serum amylase level was 283.15 ± 82.74 IU/L and 308.34 ± 96 IU/L in the control group and 223.95 ± 35.45 IU/L and 218.39 ± 35.44 IU/L in the diclofenac group. Twenty-four hours after endoscopy, the mean ± SE serum amylase level was 231.56 ± 57.73 IU/L in the control group and 161.82 ± 31.03 IU/L in the diclofenac group (Table 3). In the diclofenac group, the mean values of amylase were low but the statistical difference was not significant ( $P > 0.01$ ).

## DISCUSSION

The number of ERCP procedures performed annually worldwide has increased dramatically over the past 25 years. Pancreatitis occurs in 1%-10% of patients but may approach ≥ 25% depending on the presence of other risk factors<sup>[15]</sup>.

Several mechanical and pharmacological interventions have been evaluated in the prevention of pancreatitis. The availability of effective drugs and strategy of chemoprevention are unresolved issues in the pharmacological prophylaxis of pancreatitis. Previous

**Table 3 Serum amylase level (mean ± SE, IU/L) following ERCP in diclofenac and control groups**

Group	Amylase 4 h	Amylase 8 h	Amylase 24 h
Diclofenac	223.95 ± 33.45	218.39 ± 35.44	161.82 ± 31.03
Control	283.15 ± 82.74	308.34 ± 96	231.56 ± 57.73

There were no statistically significant differences.

studies on reducing the incidence of pancreatitis have targeted reduction of pancreatic secretion, prevention of intra-acinar trypsinogen activation, interruption of the inflammatory cascades, relaxation of the sphincter of Oddi, and prevention of infection<sup>[21]</sup>.

An ideal agent is highly effective in reducing pancreatitis, is safe for the patient, well tolerated, relatively affordable, and does not have a prolonged administration time<sup>[1]</sup>. Various pharmacological agents (such as nifedipine, glucagon, calcitonin, lidocaine, nitroglycerine, antibiotics, steroids, allopurinol, interleukin-10, and heparin) have been tried, but have met with disappointing results in preventing pancreatitis in randomized controlled trials<sup>[1,22-34]</sup>.

Only two agents seem to offer any clinical benefit: the protease inhibitor gabexate mesilate<sup>[35-37]</sup> and the antisecretory agent somatostatin may be efficacious in preventing pancreatitis when given by continuous IV infusion<sup>[34,38,39]</sup>. Since these agents require continuous and prolonged IV infusion, they are not suited for same-day outpatient ERCP<sup>[34]</sup>.

Several prospective randomized studies have shown that pancreatic stents have a beneficial role for prevention of pancreatitis in high-risk patients, including biliary and pancreatic sphincterotomy for SOD<sup>[40-42]</sup>, biliary balloon dilation for stone<sup>[43]</sup> and precut biliary sphincterotomy<sup>[21]</sup>. Although pancreatic stenting is

often beneficial, the down sides include the difficulty of stent insertion in patients with small or tortuous ducts and the follow-up required for stent removal. A simple prophylactic medication would be highly desirable<sup>[21]</sup>.

NSAIDs may prevent pancreatitis by inhibiting prostaglandin synthesis and interrupting the inflammatory cascade of pancreatitis<sup>[34]</sup>.

In the report by Sotoudehmanesh *et al*<sup>[15]</sup>, eligible patients undergoing ERCP ( $n = 490$ ) were randomized to receive a 100-mg indomethacin rectal suppository ( $n = 245$ ) or placebo ( $n = 245$ ) just prior to ERCP, and rates of post-procedure pancreatitis were assessed. Pancreatitis occurred in 7/221 (3.2%) patients in the indomethacin group and in 15/221 (6.8%) of those receiving placebo ( $P = 0.06$ ), with an overall pancreatitis rate of 5% (22/442).

Montaño Loza *et al*<sup>[45]</sup> have reported a randomized prospective clinical trial that compared indomethacin with placebo in the prevention of pancreatitis. They enrolled patients undergoing ERCP for suspected bile duct obstruction rather than selecting for a high-risk cohort. Rectal indomethacin (100 mg) or placebo was administered prior to ERCP. Seventy-five patients were randomized to each group, a sample size that was calculated a priori to detect a 15% reduction in pancreatitis. The overall incidence of pancreatitis was 10.7%. The incidence of pancreatitis was 16% (12/75) in the placebo group and 5.3% (4/75) in the indomethacin group. This difference was statistically significant, with a  $P$  value of 0.034. All pancreatitis cases in both groups were categorized as mild<sup>[44,45]</sup>.

Diclofenac, an NSAID, inhibits phospholipase A<sub>2</sub>, which is thought to play a critical role in the early inflammatory cascade. In addition, it strongly inhibits neutrophil/endothelial attachment, thus preventing accumulation of neutrophils at the site of tissue damage<sup>[46]</sup>, and inhibits the expression of nitric oxide synthase, an enzyme associated with inflammation and cell damage<sup>[47]</sup>. It is a cheap, widely available agent with a short, easy method of administration.

Murray *et al*<sup>[9]</sup> have conducted a single-center, prospective, randomized, double-blind, placebo-controlled study to determine if a single dose of rectally administered 100 mg diclofenac, given after ERCP, reduced the incidence of pancreatitis. Of 220 patients, 110 received rectal diclofenac, and the others, an inert placebo. Pancreatitis occurred in 6.4% of patients in the diclofenac group and in 15.5% of those receiving placebo ( $P = 0.049$ ). This difference was statistically significant. Also, the drug was not effective in the subgroup of patients with SOD, the very group at highest risk<sup>[9]</sup>.

Khoshbaten *et al*<sup>[18]</sup> have reported a randomized controlled study that compared 100 mg rectal diclofenac with placebo in 100 patients who underwent high-risk ERCP. To select high-risk cases, only those undergoing pancreatography (with or without cholangiography) were enrolled. The study drug or placebo was administered on arrival in the recovery area. The overall incidence of pancreatitis was 15%. The incidence of pancreatitis

in the placebo group was 26% (13/50), whereas the incidence of pancreatitis in the diclofenac group was 4% (2/50). This difference was statistically significant, with  $P < 0.01$ . No patients in this clinical trial developed necrotizing pancreatitis or required surgical intervention<sup>[18,44]</sup>.

We showed that, in the diclofenac group, pancreatitis was seen less than in the control group, but this was not statistically significant. The absence of the statistical difference may have been caused by the small number of patients.

A number of risk factors for post-ERCP pancreatitis have been identified by a multitude of studies that have different study designs, have examined different candidate predictor variables, and have taken place in a variety of settings<sup>[15]</sup>. The impact of some of these associations has been supported by large, multicenter prospective trials, while others have been suggested in smaller series and by clinical experience. Risk factors that have been recognized as independent predictors in more than one study include: younger age, female sex, pancreas divisum, SOD, prior ERCP-induced pancreatitis, difficulty of cannulation, and pancreatic duct injection<sup>[15]</sup>. None of the patients in our study had pancreas divisum or prior ERCP-induced pancreatitis. Also, there was no significant difference in the incidence of pancreatitis when comparing diclofenac with placebo, in patients with younger age, female sex, SOD, pre-cut sphincterotomy and twice or more pancreatic duct cannulation ( $P > 0.01$ ). In our study, subgroup analysis showed that diclofenac significantly decreased the frequency of pancreatitis only in the patients without SOD. All the cases of pancreatitis were mild and the patients were discharged from the hospital within several days without any complication.

Acute pancreatitis is an unstable disease that causes intravascular fluid loss because of local and systemic inflammation. Clinical improvement can be achieved by fluid infusion. Fluid resuscitation is the most important treatment during the first 72 h after onset of acute pancreatitis. Therefore, the two goals of early phase fluid resuscitation are amelioration of tissue hypoxia and prevention of complications<sup>[48]</sup>.

In our study, IV isotonic saline was given to the diclofenac group in the initial 4 h (5-10 mL/kg per hour) after ERCP. Five hundred milliliters isotonic saline was given to the control group to keep the IV line open. Although the importance of fluid management in acute pancreatitis is known, there have not been so many studies about the prophylactic effects of this approach.

In conclusion, our study showed that parenteral diclofenac and hydration tended to prevent post-ERCP pancreatitis, but the finding was not statistically significant. In the whole group, diclofenac did not prevent the occurrence of pancreatitis but, according to the subgroup analysis, in patients without SOD, it significantly prevented pancreatitis. For this reason, further studies are required on the efficacy of this treatment with other doses and combinations of diclofenac and hydration that might prevent pancreatitis.

## COMMENTS

### Background

Pancreatitis is the most common complication of endoscopic retrograde cholangiopancreatography (ERCP). Pharmacological prevention of pancreatitis after ERCP has been the topic of several investigations in recent years.

### Research frontiers

Various pharmacological agents have been tried but have met with disappointing results in preventing pancreatitis in randomized controlled trials. Non-steroidal anti-inflammatory drugs may prevent pancreatitis by inhibiting prostaglandin synthesis and interrupting the inflammatory cascade of pancreatitis. The importance of fluid management in acute pancreatitis is known, but there have not been many studies about the prophylactic effects of this approach.

### Innovations and breakthroughs

The overall results of this study showed that parenteral diclofenac and fluid replacement had no beneficial effect on the prevention of pancreatitis. Although diclofenac and fluid replacement did not prevent the occurrence of post-ERCP pancreatitis, the rate of pancreatitis was lower in those patients without sphincter of Oddi dysfunction (SOD) who received diclofenac. To prevent post-ERCP pancreatitis, further studies should be carried with the other doses and combinations of diclofenac and hydration in a larger group of patients.

### Applications

This study was designed to evaluate the efficacy of prophylactic intramuscular diclofenac and fluid replacement for the prevention of post-ERCP pancreatitis.

### Peer review

This study aimed to find a pharmacological way for preventing post-ERCP pancreatitis. The results show that prophylactic intramuscular diclofenac and fluid replacement has no benefit except in patients without SOD.

### Abstract

**AIM:** To investigate the proficiency level reached in laparoscopic splenectomy using the learning curve method.

**METHODS:** All patients in need of splenectomy for benign causes in whom laparoscopic splenectomy was attempted by a single surgeon during a time period of 6 years were included in the study ( $n = 33$ ). Besides demographics, operation-related variables and the response to surgery were recorded. The patients were allocated to groups of five, ranked according to the date of the operation. Operation duration, complications, postoperative length of stay, conversion to laparotomy and splenic weight were then compared between these groups.

**RESULTS:** There was a significant difference regarding operation times between the groups ( $P = 0.001$ ). An improvement was observed after the first 5 cases. The learning curve was flat up to the 25th case. Following the 25th case the operation times decreased still further. There was no difference between the groups regarding the other parameters.

**CONCLUSION:** Unlike the widely accepted "L" shape, the learning curve for laparoscopic splenectomy is a horizontal lazy "S" with two distinct slopes. Privileges may be granted after the first 5 cases. However proficiency seems to require 25 cases.

### INTRODUCTION

Laparoscopic splenectomy has become the gold standard intervention for the removal of the spleen, especially for benign causes. However, the organ's high anatomic location, fragility and generous blood supply makes the procedure an advanced laparoscopic operation<sup>[1,2]</sup>. Furthermore, unlike patients with gall bladder stones, patients who need splenectomy for benign disorders are rare. These factors may prohibit the laparoscopic surgeon from becoming proficient in laparoscopic splenectomy. Measuring the expertise and setting a minimum number of procedures to be performed in order to be accepted as proficient in this rather rare operation has proved difficult.

One method for quantifying the level of expertise is to split the study population arbitrarily into two, as early and late experience<sup>[3,4]</sup>. Several variables are then compared between the two groups. A more sensitive method is to depict the learning curve. The learning curve may be briefly defined as the repetition of the procedure until it is learned<sup>[5]</sup>. In this study, we aimed to define the learning curve for laparoscopic splenectomy based on the experience of a single surgeon.

### MATERIALS AND METHODS

All patients with laparoscopically attempted splenectomy, operated on by a single surgeon (TZN), were included in this study. The time period was from November 2002 to January 2008. During this time span 33 patients (23 female) with a mean  $\pm$  SD age of  $43.4 \pm 18.4$  years were operated. Operative indications were immune thrombocy-

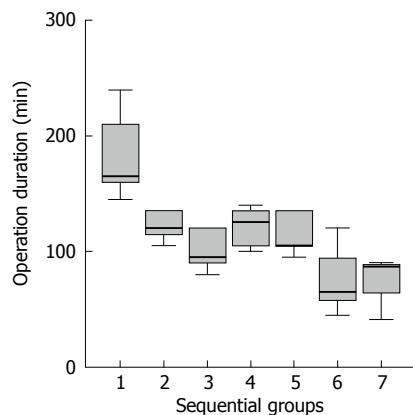

topenic purpura (ITP) ( $n = 27$ ), hemolytic anemia ( $n = 3$ ), thalassemia ( $n = 2$ ), and hydatid cyst ( $n = 1$ ). Besides demographics, associated disorders, the size of the spleen (long axis) as measured with preoperative ultrasonography, duration of surgery, the volume of gas used, additional procedures during operation, conversions to laparotomy, amount of intra/postoperative blood loss and blood products transfused, presence of accessory splenic tissue, complications, morsellated splenic weight, length of hospital stay, early and late success in hematological disorders and thrombocytosis in the long term were recorded.

Patients with hematological diseases were referred from the hematology clinic with resistant or persistent disease. The hydatid cyst patient had a type 3, 7-cm cyst in the spleen. He had percutaneous treatment for type 1 and 2 cysts located in the liver.

All patients received vaccination against encapsulated bacteria within 2 wk prior to operation. For ITP cases, the patients received pulse steroid or intravenous immunoglobulin therapy before the operation in order to increase the thrombocyte count to at least  $50\,000/\text{mm}^3$ . General anesthesia was used. A nasogastric tube was placed routinely. A lateral approach was used for the operation<sup>[6-8]</sup>. The patient was placed in a 70-80° right lateral position with reverse Trendelenburg for the table. The table was flexed 20-25° at the kidney rest to increase the left flank space. Following skin preparation and draping, the table was tilted to the left in order to obtain an approximately supine position for the initial insufflation. Four trocars, each 5 cm apart, were placed along an imaginary left subcostal incision with the most medial on the midline and most lateral on the left anterior axillary line. The table was again tilted to the original position. The 30° optic was introduced through the middle of the lateral 3 trocars. The stomach was manipulated through the most medial 4th trocar. The dissection was started from the inferior pole using clips and ultrasonic dissector for vascular control. Hilar vessels were controlled in the same manner, sometimes utilizing intracorporeal silk ligatures for the large-sized vessels. A vascular stapler was not used routinely: it was deemed necessary for only one patient with large-sized vessels. Lastly, short gastric vessels were controlled. After separating the lateral connections, the spleen was placed in a retrieval bag and was morsellated and removed through the lateral 10 mm trocar. The piecemeal specimen was weighed and sent for pathological assessment.

Patients were usually started on oral feeding the next day and discharged or transferred to the hematology clinic the following day. Hemoglobin and thrombocyte counts were studied on the first postoperative week and 3rd postoperative month to assess the early and late response to splenectomy for hematological diseases. Response to the surgery was defined as hemoglobin level greater than 100 g/L for hemolytic anemia and thrombocyte count of more than  $150\,000/\text{mm}^3$  for ITP. Thrombocytosis is defined as a thrombocyte count of more than  $600\,000/\text{mm}^3$ .

General descriptive characteristics of the group

**Figure 1** The learning curve for laparoscopic splenectomy based on the operation times. Groups are formed according to the date of the operation.

were expressed as mean  $\pm$  SD and percentages where necessary. In order to define the learning curve, patients were divided into groups of five ranked according to the date of operation (the last group consisted of 3 patients). Dichotomous variables such as rate of complications and conversion to laparotomy were compared between groups by  $\chi^2$  analysis. Continuous variables such as the duration of operation, the amount of gas used, splenic weight and length of hospital stay between ranked groups were compared using the ANOVA technique.  $P < 0.05$  was accepted as significant. All analyses were performed using SPSS version 13.0 (SPSS, Chicago, Illinois).

## RESULTS

In 18 (54.5%) patients the size of the spleen was less than 12 cm. The size was in the range of 12-20 cm in 14 (42.4%) patients and over 20 cm in one patient (3.0%). One third of the patients ( $n = 10$ ) had additional systemic diseases, diabetes mellitus ( $n = 4$ ) being the most common.

The immediate preoperative thrombocyte count for ITP cases was  $60\,960 \pm 77\,440/\text{mm}^3$ . Hemoglobin level for hemolytic anemia and thalassemia cases was  $92 \pm 38\text{ g/L}$ .

Only one patient (3%) was converted to laparotomy. In this patient (12th case, 3rd group) the spleen was large, over 20 cm and weighed 1 040 g. Hemorrhage could not be controlled and the case was converted at the 105th min. Erythrocyte suspension (5 units) was transfused to 3 hemolytic anemia patients (9.1%) during the perioperative period. Thrombocyte transfusion was not needed.

The mean operation duration for the whole group was  $120.2 \pm 46.2$  min. There was a significant difference between ranked groups regarding operation time ( $P = 0.001$ ). The last two groups' operation time, i.e. after the 25th case, was less than the first 5 cases according to the Bonferroni post hoc test (Figure 1).

Accessory spleens were detected and removed in 5 patients (15.2%). The average amount of CO<sub>2</sub> used was  $137.5 \pm 80.7\text{ L}$ . There was no difference between ranked groups regarding CO<sub>2</sub> use ( $P = 0.119$ ). Postoperative complications were observed in 3 patients (one atelectasis,

one wound infection and one suture reaction). Early and late success rates were 83.9% and 81.0%, respectively, and were not significantly different between the groups. Thrombocytosis was observed in 5 patients (15.2%). Antiaggregant therapy with salicylic acid was instituted for these patients.

## DISCUSSION

There has been a rush for minimal access surgery with the introduction of laparoscopic cholecystectomy in the 1980s. However, the surgical community was not technically prepared for this uncontrolled demand. Although weekend courses, seminars and hands-on courses were held worldwide, minimal access surgery education was less than optimal<sup>[9-11]</sup>. Surgical societies, not wishing to repeat these mistakes, started regular courses for both basic and advanced laparoscopic procedures. Universities and teaching hospitals included these procedures in their curricula. Several societies advocated a minimum number of procedures to be set to grant privileges to perform an operation<sup>[12]</sup>.

It is difficult to define a point when mastery of a procedure is reached. Subjective assessment in this regard is unreliable and several objective methods have been devised for this task. One simple method is to compare the early with late experience. For this, a chronologically-ranked patient population is divided in two<sup>[4]</sup>. Markers of expertise such as operation time, complication rate, conversion rates (in case of laparoscopy), time to oral feed and cost are then compared between these arbitrarily separated groups. The learning curve, which is more sensitive, usually is a graphic representation of the expertise level reached for a particular procedure/process. The cases are individually ranked on a chronological basis and are placed on one axis of the graph. The above-mentioned variables are depicted on the other axis. The initial slope of the curve is usually steep where the learning process is fast and with each case performance increases. After a while, the slope flattens and no major improvement can be observed following a certain number of the procedures. The point, the nth case, where the curve starts to flatten is accepted as the instance where the procedure is learnt. Even after this point minor improvement in performance is detected, albeit the difference is usually not significant. A variation of this technique is to allocate patients into small groups and compare these groups with regard to determined variables. Similarly there is a point when a significant difference cannot be observed, which is accepted as the number of procedures needed to perform to reach proficiency.

Since the first report of laparoscopic splenectomy by Delaitre, this procedure has become the preferred treatment for the removal of the spleen<sup>[13-15]</sup>. However, this being one of the advanced laparoscopic procedures and due to the relatively rare occurrence of the conditions requiring splenectomy, the procedure is difficult to master.

Several studies have defined the minimum number of laparoscopic splenectomies to be performed for proficiency. Operation time is the most used variable

as it is easier to calculate and validate. In the study by Rege and Joehl, these authors suggested that an improvement occurred with the first 15-25 patients<sup>[3]</sup>. In a review generally comparing the results of initial and late experience for laparoscopic procedures, it was determined that 20 laparoscopic splenectomies were sufficient for mastery<sup>[5]</sup>. In the study by Peters *et al*<sup>[16]</sup>, a minimum of 20 laparoscopic splenectomies were deemed necessary for ITP surgery proficiency. Regarding pediatric surgery, 20 cases, similarly, were declared to be the threshold for proficiency<sup>[17]</sup>.

However, there are some design limitations of the above-mentioned studies. In the reports by Rege and Chan the patient populations were split in two; an initial first 15, and those that came later<sup>[3,4]</sup>. The cut-off point was chosen arbitrarily and compared only two groups, i.e. the initial and late experience, which may decrease the sensitivity as stated previously. Further, in order to document an accurate progress and exclude personal variations, the performance of a single surgeon should be recorded. If other surgeons' experiences are included, the investigated parameters may differ according to the individual's skill. Among the above-mentioned studies, the experience of a single surgeon was assessed in only one report<sup>[17]</sup>. Among the rest of the reports, either senior residents gradually started to perform the operations or different hospitals/surgeons were included in the analyses<sup>[3,16,18]</sup>. The concern about inclusion of low-volume surgeons in such assessments has also been previously stated<sup>[19,20]</sup>. Although Cordera *et al*<sup>[20]</sup> have attempted some 42 laparoscopic splenectomies, rightfully they have not calculated a learning curve due to inclusion of several surgeons. Another potential source of bias is the introduction of new devices or technology during the study period. For instance, an ultrasonic dissector was introduced during the latter course of the study in one report<sup>[4]</sup>.

In our study the experience of a single surgeon was assessed to exclude personal variations in skill. In order to eliminate the possible confounding effects of the mechanical set-up, standard techniques and instruments were used during the course of the study. Instead of comparing the arbitrary initial and late experience we have assessed the differences between sequential multiple groups. Twenty to twenty-five laparoscopic splenectomies were cited to be the minimum number for mastery of the procedure in the literature. However, it is common knowledge that privileges are granted with far less experience of this relatively rare operation. Usually 3 to 5 laparoscopic splenectomies, arbitrarily defined, are accepted to be sufficient<sup>[3]</sup>. However, there is no evidence in the literature supporting this figure. We provide the first evidence that 5 laparoscopic splenectomies could be accepted as the minimum number for the general curricula. There is a dual curve in our study of the learning process (Figure 1). Progress is rapid with the first 5 cases and then the curve steadies up to the 25th case. At that point there is again a significant increase in the performance i.e. a decrease in the operation time.

We have shown that the learning curve for laparo-

scopic splenectomy is not a smooth "L" but has two distinct slopes. With the first 5 cases the novice may be granted privileges for performing laparoscopic splenectomy on an individual basis. Past the 25th case the surgeon could be accepted as an expert in the field. Although unlikely, it is yet to be shown that any further improvement could be observed after this level.

## COMMENTS

### Background

Laparoscopic revolution resulted in some controversies regarding the education in advanced laparoscopic surgery. In order to assess the level of expertise and to grant privileges in surgery, a learning curve of the procedure is used.

### Research frontiers

Laparoscopic splenectomy has become the gold standard intervention for the removal of the spleen, especially for benign causes. In this study, the authors have investigated the proficiency level reached in laparoscopic splenectomy using the learning curve method.

### Innovations and breakthroughs

Unlike the widely accepted "L" shape, the learning curve for laparoscopic splenectomy is a horizontal lazy "S" with two distinct slopes. Privileges may be granted after the first 5 cases. However, proficiency seems to require 25 cases.

### Applications

The authors have shown that the learning curve for laparoscopic splenectomy is not a smooth "L" but has two distinct slopes. With the first 5 cases the novice may be granted privileges for performing laparoscopic splenectomy on an individual basis. Past the 25th case the surgeon could be accepted as an expert in the field.

### Terminology

The learning curve is a graphic representation of the expertise level reached for a particular procedure. This is briefly defined as the repetition of the procedure until it is learned. Reaching proficiency is defined by measuring the expertise and setting a minimum number of procedures to be performed in order to be accepted as proficient.

### Peer review

It is an interesting topic for the readers. It should be accepted for publication.

### Abstract

**AIM:** To evaluate the clinical characteristics of splenic marginal-zone lymphoma (SMZL) following antigen expression and the influence of therapeutic approaches on clinical outcome and overall survival (OS).

**METHODS:** A total of 30 patients with typical histological and immunohistochemical SMZL patterns were examined. Splenectomy plus chemotherapy was applied in 20 patients, while splenectomy as a single treatment-option was performed in 10 patients. Prognostic factor and overall survival rate were analyzed.

**RESULTS:** Complete remission (CR) was achieved in 20 (66.7%), partial remission (PR) in seven (23.3%), and lethal outcome due to disease progression occurred in three (10.0%) patients. Median survival

of patients with a splenectomy was 93.0 mo and for patients with splenectomy plus chemotherapy it was 107.5 mo (Log rank = 0.056,  $P > 0.05$ ). Time from onset of first symptoms to the beginning of the treatment (mean 9.4 mo) was influenced by spleen dimensions, as measured by computerized tomography and ultra-sound ( $t = 2.558$ ,  $P = 0.018$ ). Strong positivity (++) of CD20 antigen expression in splenic tissue had a positive influence on OS (Log rank = 5.244,  $P < 0.05$ ). The analysis of factors interfering with survival (by the Kaplan-Meier method) revealed that gender, general symptoms, clinical stage, and spleen infiltration type (nodular vs diffuse) had no significant ( $P > 0.05$ ) effects on the OS. The expression of other antigens (immunohistochemistry) also had no effect on survival-rate, as measured by a  $\chi^2$  test ( $P > 0.05$ ).

**CONCLUSION:** Initial splenectomy combined with chemotherapy has been shown to be beneficial due to its advanced remission rate/duration; however, a larger controlled clinical study is required to confirm our findings.

Splenectomy with chemotherapy vs surgery alone as initial treatment for splenic marginal zone lymphoma. *World J Gastroenterol* 2009; 15(32): 4009-4015 Available from: URL: <http://www.wjgnet.com/1007-9327/15/4009.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.4009>

### INTRODUCTION

Splenic marginal-zone lymphoma (SMZL) is an indolent B-cell lymphoma, generally presented with splenomegaly, and frequent involvement of the bone marrow and

peripheral blood. The typical immunophenotypic profile is: IgM+, IgD+/-, cytoplasmic Ig-/+; pan B antigens+, CD5-, CD10-, CD23-, CD43-/+; and cyclin D1-. It is characterized by micronodular infiltration of the spleen with marginal-zone differentiation<sup>[1-4]</sup>. An SMZL variant with villous lymphocytes (SMZL + VL) has been previously described as "splenic lymphoma with villous lymphocytes", and included into the FAB classification of chronic B-cell leukemias<sup>[5]</sup>. Lymphomas of the marginal zone are recognized as separate clinical phenomena amongst B-cell NHL in the REAL classification. Thus, SMZL was divided from other marginal zone lymphomas, such as mucosa associated lymphoid tissue (MALT) lymphoma or nodal B-type marginal zone lymphoma, and accepted by WHO classification in 2001 as a distinct clinical and pathohistological (PH) entity<sup>[6-9]</sup>. According to more recent data, SMZL and SMZL with or without villous lymphocytes (SMZL ± VL) are two phases (tissue and leukemic) of the same disease<sup>[10,11]</sup>.

Typical genetic abnormalities in SMZL are deletions at 7q22-7q32<sup>[8]</sup>. The majority of SMZL patients have good long-time survival. Standard prognostic factors cannot differentiate patients into groups with poor or high-quality clinical outcomes. However, several immune-mediated events, such as hemolytic anemia and thrombocytopenia, as well as the presence of the serum monoclonal component, could be predictive factors for survival-rate. Splenectomy is considered the first-line treatment for SMZL patients<sup>[12,13]</sup>. Even if this therapy results just in partial remission (PR), surgery-response is usually sufficient to correct (pan) cytopenia and also to improve the patient's quality of life and overall survival-rate. The presence of SMZL in peripheral lymph nodes and extranodal locations is uncommon. Thus, the spleen is considered the site of lymphoma origin, even if there were regional enlargements of the lymph nodes<sup>[9-11]</sup>. The frequency of mutation in the 5' non-coding region of the *bcl-6* gene has been used as a marker of germinal center derivation, which might be used to establish the molecular heterogeneity<sup>[14-16]</sup>. Therefore, SMZL is a primary disease of the spleen, with subsequent bone marrow (BM) and peripheral blood (PB) involvement<sup>[17-19]</sup>. The diagnosis is based on the spleen PH, in accordance with clinical data. Incorporation of immunophenotypic profiles and molecular characteristics into BM and PB morphology, improves the diagnostic validity. SMZL is an indolent lymphoma, although there is a small subset of patients with an aggressive clinical course<sup>[20-22]</sup>. Studies on this entity have been aggravated by the fact that the disease is very rare<sup>[23]</sup>.

The purpose of this pilot study is to show PH features, as well as clinical data and follow-up in splenectomy with chemotherapy vs surgery alone treated SMZL ± VL patients.

## MATERIALS AND METHODS

### **Patients**

The study group included 30 patients with SMZL ± VL. Splenectomy plus chemotherapy was applied to 20 patients, while splenectomy as a single treatment-option

was performed for ten patients. The follow-up time was 12 years (1994-2006). Diagnosis was established and confirmed after initial splenectomy with consecutive PH and immunohistochemical (IHC) analysis, only upon consensus of two independent hematopathologists. Criterion of SMZL + VL was more than 20% of such lymphocytes in the peripheral blood<sup>[1]</sup>. Clinical stage (CS) was determined according to the Ann Arbor staging classification<sup>[24]</sup>. The following clinical characteristics were analyzed: sex, age, constitutional "B" symptoms, CS, and time from the onset of first symptoms to the beginning of treatment. Thereafter, complete blood count and standard biochemical analyses were done as follows: serum iron (sFe), ferritin, lymphoma activity parameters: lactate dehydrogenase (LDH) and beta-2-microglobulin (β-2M), serum paraprotein presence (M-component), virological analysis (hepatitis B, C and HIV markers). The size of the spleen was determined by ultrasound (US) or computerized tomography (CT). Its weight in grams was also measured after spleen removal.

### **Histology and immunohistochemical analyses**

Diagnosis was based on analysis of tissue samples (spleen, lymph node, and BM) according to criteria of WHO classification system. All tissue samples were fixed in B5, processed by standard methods, embedded in paraffin, cut by a microtome (4 μm sections) and stained by classical staining methods: hematoxylin eosin (HE), Giemsa and reticulin (Gordon-Sweet).

Immunostaining was performed using a labeled streptavidin-biotin procedure with monoclonal antibodies (DAKO, Glostrup, Denmark). The relevant antibodies used in routine diagnosis were: LCA, EMA, IgD, IgM, CD20, CD79-α, CD5, CD23, CD43, CD10, bcl-2, CD3, Cyclin D-1, and Ki-67.

The strength of CD20 antigen (Ag) expression was graduated semi-quantitatively as strong (+++), moderate (++) or weak (+) according to cell positivity, almost in all cells, more than 50%, and in less than 50% of cells, respectively. For other antigens, expression was graded as, positive (+) or negative (-), whilst Ki-67 expression was evaluated numerically as a percentage of positive cells. Splenic marginal zone areas were selected, focusing in all cases on the areas with the highest growth fraction. Preparations of spleen, lymph nodes and BM were analyzed by standard light microscopy.

### **Drug-treatment**

The initial treatment in all (30) patients was splenectomy. The CHOP (cyclophosphamide, hydrodoxorubicine, vincristin, and prednisolone) protocol was applied in nine (45.0%) cases. Fludarabine containing regimens (FMD - fludarabine, mitoxantrone, dexamseone; and FMC - fludarabine, mitoxantrone, cyclophosphamide) were used in 11 (55.0%) cases. The decision to give additional chemotherapy was made according to the presence of constitutional "B" symptoms at presentation and lymphadenopathy. Two types of applied treatment (splenectomy alone or splenectomy with chemotherapy) in a 3-year follow-up period were analyzed for every patient.

### Statistical analysis

Among descriptive analysis, the arithmetical mean and standard deviation were used for parametric data and the median was used for description of non-parametric data. For the parametric analytical model, we applied Student's *t*-test. For non-parametric analytical models, we used Pearson's  $\chi^2$  tests, Fisher's exact test, Kolmogorov-Smirnov's test, and Kaplan-Maier's method for analysis of OS. For significance,  $\alpha$  errors of 0.05 were chosen in all methods. SPSS version 6.0 for Windows was used to create a database. Statistical analyses were completed within the statistics package of the Institute of Medical Statistics and Information Technology, School of Medicine, Belgrade.

## RESULTS

### Patient's characteristics

There were 11/30 (36.7%) males and 19/30 females (63.3%). The mean age was 58 years (range, 33-76). Performance status according to the Eastern Cooperative Oncology Group (ECOG) scale was 0 = 18%, 1 = 56%, and 2 = 26%. SMZL was diagnosed in 18 patients (60.0%), and SMZL + VL was found in 12 (40.0%) cases. The patients' general clinical features and hematological characteristics included in this study are summarized in Table 1.

Furthermore, HIV 1 and 2 antibodies were all negative (100%). Hepatitis B antibodies were also negative in all patients. Hepatitis C antibodies were positive in only one case (3.3%).

The mean sFe level was 7.24  $\mu\text{g/L}$  (range, 2.20-16.2). Decreased values below absolute in relation to gender were recorded in 19 (63.3%) patients, and normal were reported in 11 (36.7%) subjects. Relative iron deficiency might be explained in two ways. Firstly, iron resorption was reduced due to loss of appetite with an increase of passive intestinal hyperemia on account of splenomegaly. Secondly, more intensive loss of the same oligo-element was stimulated by hemorrhage, (most often occult). Ferritin levels were within normal limits in relation to gender in all subjects.

### Immunohistochemical findings

A total of 30 (100%) patients with typical histological and immunohistochemical splenic marginal zone lymphoma pattern were examined (Figure 1).

Immunohistochemical analysis revealed that none of the positive expressing antigens had a significant influence on disease outcome, as assessed using a  $\chi^2$  test with the following confirmed results: CD79-alfa ( $\chi^2 = 5.074$ ,  $P > 0.05$ ), CD20 ( $\chi^2 = 4.046$ ,  $P > 0.05$ ), CD43 ( $\chi^2 = 0.910$ ,  $P > 0.05$ ), IgD ( $\chi^2 = 2.503$ ,  $P > 0.05$ ), IgM ( $\chi^2 = 1.147$ ,  $P > 0.05$ ), bcl-2 ( $\chi^2 = 3.667$ ,  $P > 0.05$ ), and Ki-67 ( $\chi^2 = 2.503$ ,  $P > 0.05$ ). Moreover, Ki-67 positivity varied from 5%-35%, with following distributions: 5%-15%, 15%-25%, and 25%-35% in nine (30.0%), 14 (46.7%) and seven patients (23.3%), respectively.

Using the long rank test in the Kaplan Mayer method of survival showed that among all antigens, only CD20 antigen had some impact on OS. Namely, among three groups of patients according to CD20 positivity (strong,

moderate, weak), median survival was 113 mo, 83 mo, and only 43 mo, respectively (Log rank = 5.244,  $P < 0.05$ ).

### Prognostic factor analysis and overall survival

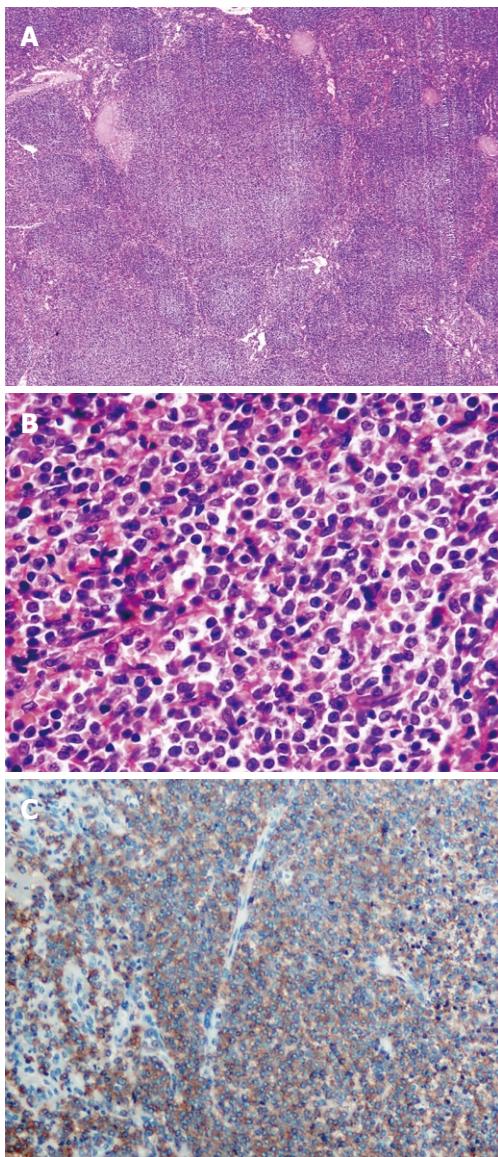

In this study, all the patients were splenectomized at the beginning of treatment. Therapeutic splenectomy, i.e. as the only curative modality in 10 (33.3%) patients was performed. Splenectomy with chemotherapy (different protocols) was done in the remaining 20 (66.7%) patients. After a mean three-year follow-up, the outcome was as follows: 20 (66.7%) patients had complete remission (CR), seven (23.3%) had partial remission (PR), and three (10.0%) died due to disease progression.

Out of 10 patients having undergone splenectomy only, eight (80.0%) had CR and two (20.0%) had significant PR (76 mo). In addition, all CR were stable after five years (60 mo). No patient with spleen rupture, a rare but possible complication, was reported.

Out of those receiving chemotherapy after splenectomy (20 patients), CR was achieved in 11 (55.0%) patients. The CHOP protocol was used in nine (45.0%) cases, and FMD or FMC were used in 11 (55.0%) cases. Ultimately, the mode of treatment was not a factor interfering with OS of our patients. Median survival of patients with splenectomy only was 93.0 mo and in patients with splenectomy and chemotherapy it was 107.5 mo (Log rank = 0.056,  $P > 0.05$ ).

The cumulative survival of patients included in this study is presented in Figure 2.

As shown, after 120 mo of follow-up, the incidence of survival was constant (about 77%). Time from onset

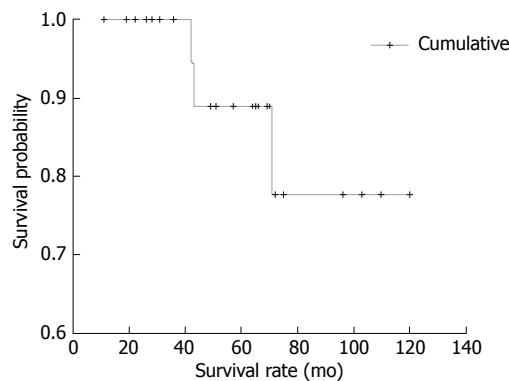

**Figure 1 SMZL-splenic tissue.** A: Nodular infiltration (HE,  $\times 40$ ); B: Neoplastic cells with monocyte-like morphology (HE,  $\times 400$ ); C: Immunohistochemistry for CD20 $^{+}$ , brown staining in lymphoma cells (streptavidin-biotin,  $\times 200$ ).

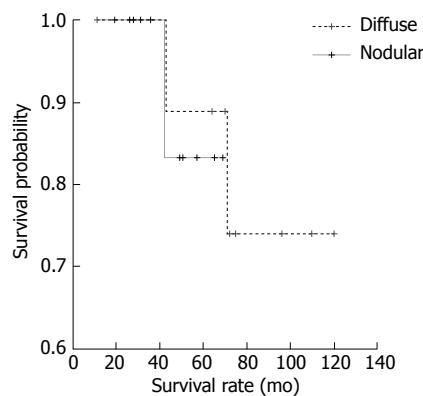

of first symptoms to the beginning of treatment (mean 9.4 mo, range 1-84) was influenced by spleen dimension, as measured by CT and US, and was significantly shorter in patients with higher spleen dimensions ( $t = 2.558$ ,  $P = 0.018$ ). The highest mean values of segmented neutrophil percentage were found in subjects who reached CR, and conversely, the lymphocyte percentage mean values were lowest in those who achieved CR ( $P = 0.026$ ).

Spleen dimensions measured by CT also correlated with clinical stage ( $P = 0.034$ ).

The analysis of factors interfering with survival, as measured by the Kaplan-Meier method, revealed that gender was not a factor affecting the length of survival (Log rank = 0.643,  $P > 0.05$ ). Further analysis of such factors showed that the presence of "B" symptoms also had no effect on survival (Log rank = 0.141,  $P > 0.05$ ). Moreover, CS was not a factor affecting patient survival (Log rank = 0.560,  $P > 0.05$ ). Similarly, the type of spleen infiltration (nodular vs diffuse) was not a factor

**Figure 2** Cumulative survival of patients investigated (with constant incidence of survival after 120 mo).

**Figure 3** Patients' survival with different type of spleen infiltration (nodular vs diffuse).

**Table 2** Results of Cox regression method and significance of compared factors of treatment outcome in our patients

Variables	Score	df	P
Gender	0.244	1	0.621
Age	0.657	1	0.418
Time from the onset of B symptoms to treatment	13.906	10	0.177
CS	0.557	2	0.757
Spleen infiltration (nodular vs diffuse)	0.009	1	0.923
Mode of treatment	0.089	1	0.900

affecting the survival of patients (Log rank = 0.021,  $P > 0.05$ ), as shown in Figure 3.

Finally, the analysis of lethal outcome predictors by the Cox regression model included the role of factors that could have any effect on such an outcome (Table 2). As illustrated, none of the studied factors appeared to be significant for predicting treatment outcome in our group of patients.

## DISCUSSION

Splenic marginal zone lymphoma is a relatively rare entity with a slight male predominance. In our group of patients there was higher incidence of female - 19 (63.3%), in relation to male - 11 (36.7%), as compared to other studies<sup>[25,26]</sup>. The mean patients' age was 58.2 years, which agreed with the fact that splenic lymphoma is a

disease of older age<sup>[1,7]</sup>.

A majority of the SMZL cases studied carried a non-mutated bcl-6 gene<sup>[14]</sup>. The frequency of these mutations in normal spleen confirms previous findings on the hypermutation IgVH process in normal B-cell populations<sup>[27,28]</sup>. This data supported the existence of molecular heterogeneity in this entity. It also favored the hypothesis that, in spite of initial morphological observations, a significant proportion of SMZL cases could derive from an non-mutated naive precursor, which is different from those of the marginal zone, and possibly located in the mantle zone of splenic lymphoid follicles. Thus, the marginal zone differentiation of these tumors could be related more to the splenic microenvironment than to the histogenetic characteristics of the tumor<sup>[20]</sup>.

Considering PH findings, in our group there were 18 patients (60.0%) with SMZL, and 12 (40.0%) with SMZL + VL. The largest number of patients had advanced disease in clinical stage IV + V (86.7%). The shortest time of the onset of first symptoms to the beginning of treatment was one month, and the longest was 84 mo. The average was 9.4 mo it was correlated with spleen dimension, as measured by CT and US. It was significantly shorter in patients with higher spleen dimensions. SMZL is a slow-course disease and is detected in progressive phase in the highest percentage<sup>[7,20]</sup>. In accordance with this, Thieblemont found BM infiltration in 95% of patients<sup>[11]</sup>. Almost all (97%) patients had clinical stage III and IV, as reported in the large cohort of patients published by Arcaini<sup>[25]</sup>, with a similar proportion of about 90% of BM infiltration in a series of 129 patients<sup>[30]</sup>. It was apparent that the majority of patients in our study were in clinical stage IV.

Splenomegaly lasted approximately 9.4 mo before diagnosis (interval of 1-36 mo), referring to a study in 1999<sup>[26]</sup>, which is similar with our results. Another study on 18 patients established an average pre-treatment presence of symptoms to be four months (two-six month interval)<sup>[31]</sup>. Similarly, a series of 17 patients reported pre-treatment duration of symptoms varying from several days to four months with a mean time of 2.1 mo<sup>[9]</sup>.

The finding that spleen dimension correlated with clinical stage, as well as with the time from onset of first symptoms to the beginning of treatment, is rational since the dominant tumor mass is in the spleen. The maximal weight of the spleen measured intraoperatively was 8000 g and minimal weight was 450 g (mean = 2235.7 g). Such a finding suggested that there was at least one a case with a huge splenomegaly, rarely seen in foreign literature<sup>[23,26]</sup>. The pattern of spleen infiltration (nodular vs diffuse) was not significant for OS in our group of patients. According to the literature, 85% of patients with relapsed or progressive disease have nodal involvement, with a relatively low frequency of nodal involvement at initial diagnosis<sup>[25]</sup>. This emphasizes the care necessary in sorting nodal involvement of SMZL from primary nodal MZL, and the necessity of differential diagnosis with additional molecular markers.

We found that 27 (90.0%) patients manifested a lower or higher degree of anemia. Anemia is strongly characteristic of spleen lymphoma. It occurs due to

hypersplenism rather than BM infiltration<sup>[1,7]</sup>. In a series of 81 patients reported by Thieblemont, 44 with spleen lymphoma had anemia and of these, 13 had Coombs-positive hemolytic anemia<sup>[11]</sup>. Similar results, with about half of the patients being anemic, were published for a large group of 309 patients<sup>[25]</sup>.

Despite the presence of anemia (Hb ≤ 110 g/L) in about 30% of patients with SMZL ± VL with mean value of hemoglobin 118 g/L<sup>[30]</sup>, the percentage of anemic cases in our patients was significant higher, due to the predominance of advanced clinical stage. Leukocytosis and leukocytopenia were found in about a third of the patients, whilst half of the patients had neutropenia and lymphocytosis. Such percentage of cells, rather than platelet count, in our patients was of no prognostic value regarding the survival period. A higher rate of achieving CR was found in patients with higher initial segmented neutrophil count and with a lower level of lymphocytes at presentation.

The distribution of serum paraprotein has varied from 8%<sup>[25]</sup>, which was comparable to our results, to as much as 46%<sup>[11]</sup>. In a third large series of 129 patients with spleen lymphoma, paraprotein was present in 22% of patients, with the highest concentration of 25 g/L, but without any prognostic value<sup>[30]</sup>. Contrastingly, Arcaini reported that the presence of paraprotein had prognostic value in terms of shorter time to disease progression<sup>[32]</sup>.

The established positivity of hepatitis C virus antibodies varied from 1%<sup>[11]</sup>, which was similar to our results, to 19%, while hepatitis B virus antibodies were detected in 5% of cases<sup>[25]</sup>.

Serum LDH is an important activity parameter of aggressive disease, while in low-aggressive ones, its increase can designate the transformation of disease to more severe form<sup>[18]</sup>. In our study group, this parameter was within referential limits in 72% of patients, which suggested low-grade disease status. On the other hand, Chacon reported about 60% patients with significantly elevated LDH<sup>[23]</sup>.

In our patients, β-2M was predominantly elevated (83.3%), ranging from 2.38 to 7.4 μg/L. The results are in accordance with the established fact that this parameter is increased in SMZL as a negative prognostic marker<sup>[33,34]</sup>.

Regarding the type and outcome of treatment, our results indicated that the use of adjuvant chemotherapy following the splenectomy had no influence on OS rate, as reported in published series so far<sup>[1,7,23]</sup>. This finding is in accordance with the fact that the use of alkylating drug therapy yields a rate of response of about 44%, but complete remissions are rare, probably due to the existing BM infiltration<sup>[1,7]</sup>. Until now, the treatment of SMZL has been controversial. In all large series, a significant group of patients received no therapy. These patients do not seem to have worst outcome than those initially treated. For these reasons, and assuming that SMZL is an indolent disease, some authors recommend a “watch and wait” approach<sup>[23]</sup>. Although, in general SMZL behaves as an indolent disease, there is a significant group of patients who died from the disease in a relatively short time period. The role of chemotherapy is still a matter of debate. One

of the striking findings is the relatively low percentage of patients who attain CR after chemotherapy, because of the presence of BM involvement after chemotherapy<sup>[23]</sup>. The literature presents diverse chemotherapy regimens for SMZL. Generally, splenectomy leads to somatic compensation of patients, rendering it impossible for local relapse in the spleen, prevents continuous dissemination from the primary tumor site, and mostly corrects cytopenias, creating better conditions for chemotherapy<sup>[35]</sup>.

SMZL is a relatively indolent disease, but in some cases it displays more aggressive behavior, which should stimulate the search for predictive biologic factors and alternative therapies. Early splenectomy combined with chemotherapy in properly stratified patients at presentation has been shown to be beneficial because of improvement in remission rate/duration and superior OS. However, there was no statistical significance, probably due to the limited number of patients. Thus, the evaluation of these therapeutic approaches requires larger, randomized, and controlled clinical studies.

## COMMENTS

### Background

Splenic marginal-zone lymphoma (SMZL) is a relative uncommon low-grade lymphoma and primary disease of the spleen, with bone marrow and peripheral blood involvement. The existence of molecular heterogeneity in this entity gave additional results in favor of the hypothesis that, in spite of initial morphological observations, most SMZL cases could derive from a non-mutated naive precursor, different from those of the marginal zone, and possibly located in the mantle zone of splenic lymphoid follicles. Thus the marginal zone differentiation could be related more to the splenic microenvironment than it is to the histogenetic characteristics of the tumor. Until now, standard prognostic factors could not differentiate patients into groups with poor or favorable clinical outcome.

### Research frontiers

Despite the evaluation of different prognostic factors, the treatment of SMZL is still controversial. However, several immune-mediated events, such as hemolytic anemia and thrombocytopenia, as well as the presence of the serum monoclonal component, could be predictive factors for survival-rate. Splenectomy is considered the first-line treatment. Even when this therapy results in partial remission, the response to the surgery is usually sufficient to correct cytopenia and also to improve the patient's quality of life, as well as overall survival-rate.

### Innovations and breakthroughs

SMZL is an indolent lymphoma, although there is a small subset of patients with an aggressive clinical course. Despite this fact, there have been significant groups of patients who have received no therapy, with only a "watch and wait" approach being adopted to their indolent clinical course. Early splenectomy combined with consecutive chemotherapy leads to somatic compensation of patients, renders it impossible for local relapse in the spleen, prevents continuous dissemination from the primary tumor site, commonly corrects cytopenias, and improves the survival-rate.

### Applications

This data shows that early splenectomy combined with chemotherapy at presentation leads to some improvements in duration of overall survival, although with no statistical significance, probably due to the limited number of patients. Therefore, future approaches will need well controlled and larger clinical studies.

### Peer review

In this manuscript, the authors delivered some interesting data on clinical-pathological features and clinical outcomes of 30 SMZL patients. They confirm that early splenectomy, at the beginning of treatment, combined with chemotherapy is helpful to prevent disease recurrence. The data presented might be beneficial for clinical treatment of patients with SMZL.

### Abstract

**AIM:** To test whether the expression and activity of H,K-ATPase in parietal cells would be affected by cigarette smoke extract.

**METHODS:** Extracts of cigarette smoke were administered into mice by gastric gavage (5 mg/kg body weight/day) for 3 d or in drinking water for 7 or 14 d. For the latter, each day a mouse consumed 5 mL water containing extracts of two cigarettes, on average. Control littermate mice received only vehicle. To compare the amount of H,K-ATPase in control and smoke-treated mice, the stomach was processed for Western blotting and immunohistochemical analysis using monoclonal antibodies specific for  $\alpha$ - or  $\beta$ -subunits of H,K-ATPase. The *p*-nitrophenylphosphatase activity assay was used as a measurement for K-dependent H,K-ATPase activity.

**RESULTS:** Probed transblots showed an increase in the amount of H,K-ATPase in smoke-treated mice which was confirmed by immunohistochemistry and was found to be due to increased amounts of protein per parietal cell rather than an increased parietal cell number. The increase in the amount of H,K-ATPase was associated with an enhancement of its enzymatic activity. K-dependent activity in control and smoke-treated mice was significantly different (respectively, 0.12  $\mu$ mol/mg vs 0.27  $\mu$ mol/mg per minute,  $P < 0.05$ ).

### INTRODUCTION

Cigarette smoking is a major worldwide health problem. According to the World Health Organization, smoking is the largest preventable cause of premature death worldwide. It is a common habit among teenagers, adults, and even health professionals<sup>[1]</sup>. In addition to the well known adverse effects of smoking on cardiovascular and respiratory systems, some studies have shown that smoking is a major risk factor for some gastrointestinal diseases<sup>[2-4]</sup>. Several clinical and epidemiological studies have provided evidence suggesting that smokers are more susceptible to peptic ulcer disease and respond to anti-ulcer drugs less efficiently than non-smokers<sup>[4-9]</sup>. In experimental animals, some studies have shown that cigarette smoking potentiates the damaging effects of ethanol or corticosteroids on the gastric mucosa<sup>[10,11]</sup>.

The mechanisms by which cigarette smoking adversely affects the gastric mucosa have not been fully elucidated. It has been shown that free radical production, infiltration of neutrophils, stimulation of angiotensin II production, down-regulation of epidermal growth factor and reduction of gastric blood flow play an important role in the harmful effects of smoking<sup>[7,12-14]</sup>. However, it is not

known whether cigarette smoking or nicotine adversely affects some other factors that may influence the integrity of the gastric mucosa. The hydrochloric acid secreted by parietal cells is one of the main aggressive factors that play an important role in gastric mucosal damage and the pathogenesis of peptic ulcer disease<sup>[15,16]</sup>. The major protein involved in this process of acid secretion is the proton pump or H,K-ATPase. It is not known whether the H,K-ATPase of gastric parietal cells is altered by cigarette smoking.

In the stomachs of rodents and humans, parietal cells are scattered throughout the gastric glands, made of pit, isthmus, neck and base regions (Figure 1). They develop from epithelial progenitors which are anchored in the isthmus region<sup>[17-19]</sup>. During their development, parietal cells concomitantly synthesize the catalytic  $\alpha$ - and regulatory  $\beta$ -subunits of H,K-ATPase<sup>[20]</sup>. Following their maturation in the isthmus, parietal cells bidirectionally migrate to become scattered throughout the glandular regions of the gastric epithelium. In mice, the turnover time of parietal cells averages 54 d. Old parietal cells undergo progressive physiological deterioration and eventually die and are eliminated at the luminal surface by extrusion into the gastric lumen or deep at the gland bottom by phagocytosis via a neighboring healthier glandular cell or an invasive connective tissue macrophage<sup>[21]</sup>.

In the cytoplasm of parietal cells, both  $\alpha$ - and  $\beta$ -subunits of H,K-ATPase are targeted to the membranes of tubulovesicles. Upon stimulation by histamine, acetylcholine, or gastrin, the tubulovesicles translocate from the cytoplasm to the apical and canalicular membranes of the parietal cell. Therefore, expansion of the canalicular system and elongation of the microvilli are features of a stimulated parietal cell. H,K-ATPase of the apical and canalicular membranes of stimulated parietal cells utilizes ATP generated by the numerous large mitochondria to pump protons into the lumina of canaluli and gastric glands in exchange for potassium<sup>[22]</sup>. While much research is directed to discover new inhibitors of gastric H,K-ATPase, little is known about the extrinsic factors involved in its dysregulation.

Since smokers are more susceptible than nonsmokers to developing peptic ulcer disease and more likely to experience delays in ulcer healing, and since parietal cells are considered a key player during the pathogenesis and healing of this disease, we hypothesized that smoking alters H,K-ATPase, the major protein of the parietal cell which is responsible for acid secretion. Therefore, the aim of this study was to test whether the expression and activity of H,K-ATPase of parietal cells would be affected in animals administered with cigarette smoke extract.

## MATERIALS AND METHODS

### Preparation of cigarette smoke extracts

The method of Shin *et al*<sup>[23]</sup> was slightly modified to prepare ethanol and aqueous extracts of cigarette smoke. The smoke of burning red Marlboro cigarettes (Philip Morris, Inc., Richmond, VA, USA) was bubbled into ethanol or water by using a vacuum system. The ethanol

extract was allowed to evaporate and the precipitate was dissolved in 0.1% dimethyl sulfoxide (DMSO).

### Animals and experimental design

The procedures follow experiment in this study were in accordance with the guidelines for the care and use of laboratory animals and were approved by the Animal Research Ethics Committee of the Faculty of Medicine and Health Sciences, UAE University. In this study, C57BL mice of both sexes were used at two different age groups. (1) Young adult 8-wk-old mice ( $n = 12$ ) received the ethanol smoke extract, 5 mg/kg body weight/day, *via* oro-gastric gavage needle on 3 consecutive days. (2) Weaning-age mice (3-wk-old,  $n = 32$ ) received the aqueous smoke extract in their drinking bottles which were made freely accessible for 7 or 14 continuous days. Fresh extract-containing water was used daily. It was estimated that every day, on average, each weaned mouse consumed 5 mL of water containing smoke extract of two cigarettes. For both age groups of smoke-treated mice, weight- and sex-matched littermate (8- or 3-wk-old) mice were used as controls and received only vehicle (0.1% DMSO or water, respectively). One day after treatment, each pair of smoke-treated and control littermate mice was killed by an overdose of ether. The stomachs were immediately removed and processed for biochemical and immunohistochemical analyses.

### Mucosal homogenate preparation

Gastric mucosal homogenates were prepared as previously described<sup>[20,24]</sup>. Part of the oxytic mucosa of the stomach was scraped, minced and then homogenized on ice-cold hypotonic buffer (pH 6.7) containing 113 mmol/L mannitol, 37 mmol/L sucrose, 0.4 mmol/L EDTA, 5 mmol/L piperazine-N,N'-bis(2-ethanesulfonic acid)-tris (hydroxymethyl) aminomethane. The crude homogenate was centrifuged at a low speed (35 g) for 5 min to remove unbroken cells and tissues. To obtain pellets enriched in H,K-ATPase, some solubilized crude homogenates of control and smoke-treated mice were centrifuged at a higher speed (25000 g) for 2 h. Portions of the low-speed supernatants and the re-suspended high-speed pellets of control and smoke-treated mice were processed for measurement of protein concentration using Bradford's method and then quantification of H,K-ATPase using Western blotting.

### Western blotting analysis

Portions of the homogenates or re-suspended pellets of control and smoke-treated mice were solubilized in buffer containing 1% SDS, 0.5 mol/L urea, 5% 2-mercaptoethanol, 0.25 mmol/L EDTA, 10% glycerol, 0.0025% bromophenol blue, and 30 mmol/L Tris-HCl, pH 6.8 and run through 8% or 10% acrylamide<sup>[20]</sup>. Proteins were subsequently electro-transferred onto nitrocellulose membranes (Schleicher & Schuell Bioscience, Dassel, Germany) and probed with mouse monoclonal antibodies specific for the  $\alpha$ - (97 kDa) or  $\beta$ - (60-80 kDa) subunits of H,K-ATPase (Medical & Biological Laboratories Co., Woburn, MA, USA) at a

dilution of 1:2000. After washing, blots were incubated with horseradish peroxidase-conjugated goat anti-mouse immunoglobulin (Ig) G (Jackson ImmunoResearch Laboratories Inc., West Grove, PA, USA) at 1:10 000 dilution. To control equal loading of proteins in both smoke-treated and control mice, anti- $\beta$ -actin antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA) was used at 1:2000 dilution. Bands of protein-antibody complexes were visualized using SuperSignal West Pico chemiluminescence detection kit (Thermo Fisher Scientific, Rockford, IL, USA) and their relative intensities were quantified by densitometry using the Scion Imaging program for Windows (version  $\beta$  4.0.3.2; developed by Scion, Frederick, MD, USA). Data were expressed as means in arbitrary units and the level of significance of differences between control and smoke-treated groups were determined by using the Student's *t* test.  $P < 0.05$  was taken as significant.

#### **Light microscopic and immunohistochemical analyses**

Pieces of the oxytic regions of the stomachs of control and smoke-treated mice were fixed in Bouin's solution and embedded in paraffin. For general histology, some sections (5  $\mu\text{m}$ ) were stained with hematoxylin-eosin or periodic acid Schiff technique. Adjacent sections were used for immunohistochemical analysis using antibodies specific for the  $\alpha$ - or  $\beta$ -subunits of the gastric H,K-ATPase. Antigen-antibody binding sites were visualized by using fluorescein isothiocyanate (FITC)-labeled donkey anti-mouse IgG (Jackson ImmunoResearch Laboratories Inc., West Grove, PA, USA).

To measure the intensity of H,K-ATPase immunolabeling of the cells, image analysis was performed on probed gastric mucosal tissue sections of some control ( $n = 4$ ) and smoke-treated littermate mice ( $n = 4$ ) using the Scion Imaging program as previously described<sup>[20]</sup>. Probed sections were examined at 40  $\times$  magnification with an Olympus microscope and photographed with a DP-70 digital camera with the option of fixed manual exposure to ensure equal exposure of control and smoke-treated tissue sections. Digitalized TIFF images of immunolabeled parietal cells were stored at a resolution of 300 dpi. Labeled parietal cells cut through their nuclei were only considered for measurement by using the freehand tool and drawing a line around the periphery of the cell. The number of cells examined per animal ranged from 20 to 35. Following measurement of the immunostaining intensity of various cells in one section, the background intensity was subtracted. Quantitative results of the optical density were reported in arbitrary units corresponding to immunostaining intensity which is indicative of the amount of H,K-ATPase in the sectioned cells. For each stained cell examined, the area was also measured and expressed in arbitrary units. Data are presented as mean  $\pm$  SE.

#### **Enzymatic activity assay**

In some experiments, the gastric mucosa of control and smoke-treated mice were homogenized and briefly centrifuged at low speed as mentioned above. Some of

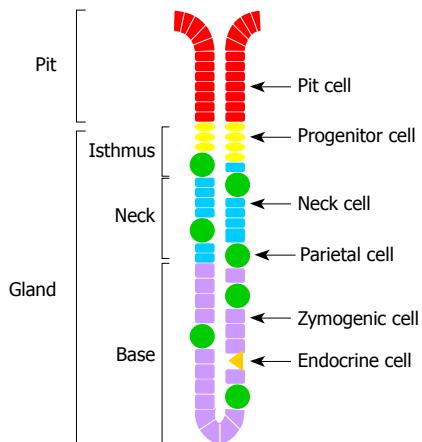

the supernatant was processed by the Bradford method for measurement of protein concentration and the remainder for K<sup>+</sup>-dependent  $p$ -nitrophenylphosphatase ( $p$ NPPase) activity assay which was used as an index of H,K-ATPase activity<sup>[20]</sup>. The  $p$ NPPase activity was measured at 37°C in buffer containing 7.5 mmol/L Tris-HCl (pH 7.5), 3.5 mmol/L MgSO<sub>4</sub>, 30 mmol/L sucrose, and 0.02 mmol/L EDTA. To eliminate the contribution of Na,K-ATPase, 0.1 mmol/L ouabain was included in the incubation buffer. The K-dependent and Na-dependent  $p$ NPPase activity was assayed with 20 mmol/L KCl and NaCl in the buffer, respectively. The reaction was initiated by the addition of 5 mmol/L sodium  $p$ -nitrophenyl phosphate and terminated by 1.5 mL of 0.5 mol/L NaOH. Liberated  $p$ -nitrophenol was read at 410 nm by a Beckman Du 70 spectrophotometer. The K-dependent  $p$ NPPase activity was obtained from the difference of the values obtained with and without 20 mmol/L KCl. The enzymatic activity was expressed in micromoles per milligram protein per minute. Student's *t* test was used to compare values in control *vs* smoke-treated mice.

## **RESULTS**

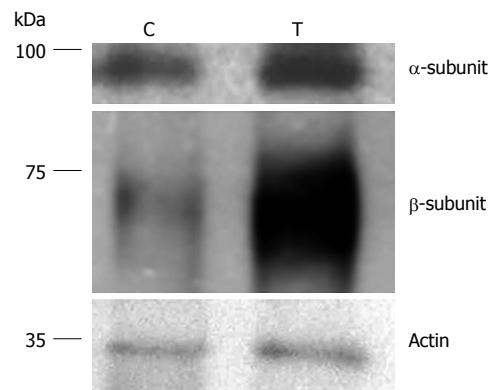

In the present study, extracts of cigarette smoke were administered to adult and weaned mice in two different modes: (1) aqueous extract in drinking water, and (2) ethanol extract *via* orogastric gavage needle. These two different modes of administration showed more or less similar effects on gastric H,K-ATPase. However, when the smoke extract was introduced with the drinking water, a duration-dependent effect was noted. The 7-d exposure of the gastric mucosa to smoke extract in the drinking water produced no significant difference between control and smoke-treated mice. When the duration of administration of smoke-containing drinking water was doubled, a significant difference was noted in the H,K-ATPase of smoke-treated *vs* control mice.

#### **Effect of cigarette smoke extract on the amount of H,K-ATPase**

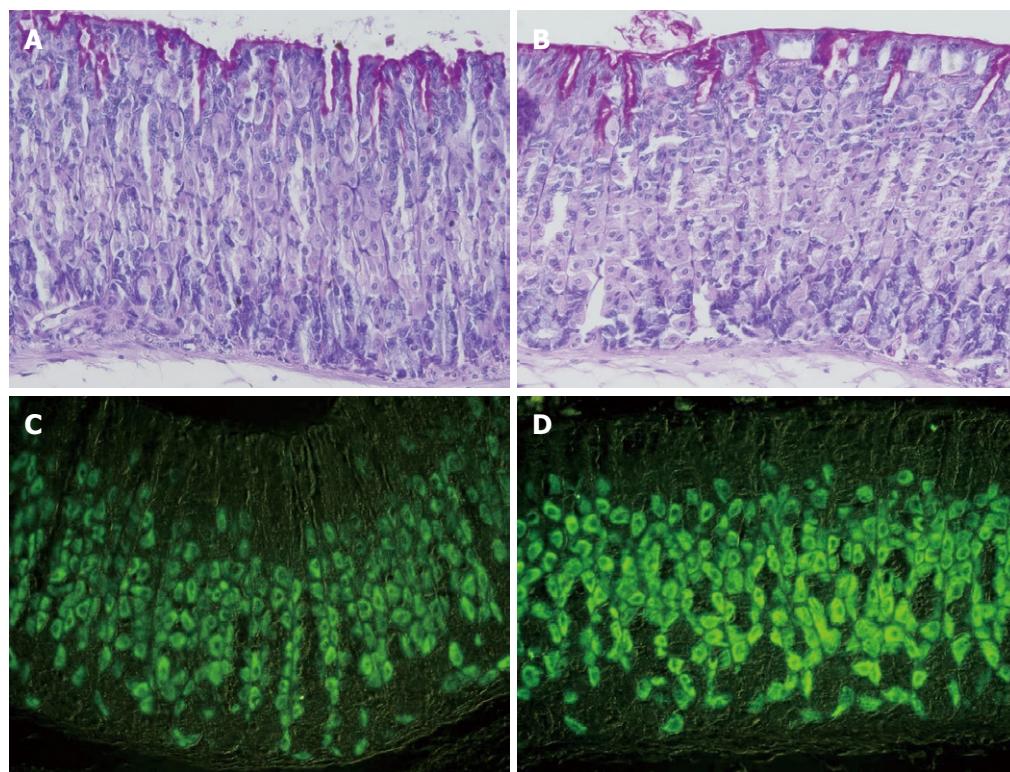

Proteins of the mucosal homogenates of mice treated with ethanol or aqueous extracts of cigarette smoke and their control littermates were separated on polyacrylamide gels and transblotted on nitrocellulose membranes. Probing of the membranes with antibodies specific for the  $\alpha$ - or the  $\beta$ -subunits of H,K-ATPase revealed an increase in the amount of this protein in smoke-treated mice (Figure 2). Densitometric analysis of the protein bands of H,K-ATPase showed that the amounts of both the  $\alpha$ - and  $\beta$ -subunits were significantly increased. It was estimated that the percent increase of the  $\alpha$  subunit averaged 220% and the percent increase of the  $\beta$  subunit averaged 350%. However, it should be noted that in the case of aqueous extract-treated mice, there was a dose/duration-dependent effect on H,K-ATPase expression. While the 7-d-treatment showed no significant difference as compared with control littermate mice (data not shown), 14 d of treatment showed a significant increase in the amount of H,K-ATPase ( $P < 0.05$ ).

**Figure 1** Schematic drawing of the structural unit of the gastric epithelium showing the pit and three glandular regions and the scattered H,K-ATPase-containing parietal cells.

**Figure 2** Representative transblots showing protein expression of the  $\alpha$ - and  $\beta$ -subunits of H,K-ATPase in control (C) and smoke-treated (T) mice. Note the differences in the intensity of the protein bands in control vs smoke-treated samples. Ten micrograms of proteins were loaded per lane. Beta actin was detected by a mouse monoclonal antibody and used as a loading control.

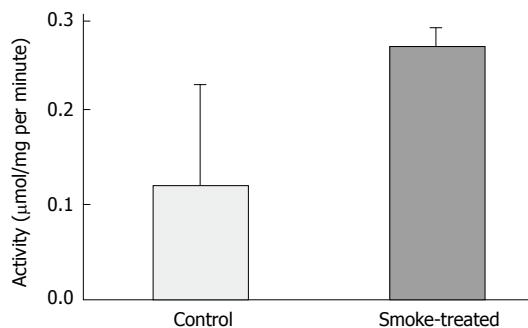

**Figure 3** Gastric mucosal tissue sections of control (A, C) and smoke-treated (B, D) mice. A and B demonstrate the gastric mucosae of control and treated mice stained with periodic acid-Schiff and hematoxylin. No difference is noted in parietal cells of control and treated tissues. Immunohistochemical labeling of parietal cells in the gastric mucosa of control (C) and smoke-treated (D) mice with antibodies specific for H,K-ATPase  $\beta$ -subunit. Labeled parietal cells are distributed throughout the gastric glands. Note the difference in the labeling intensity of parietal cells in control vs smoke-treated mice,  $\times 400$ .

#### **Effect of cigarette smoke extract on the immuno-labeling of parietal cells**

To test whether the increase in the amount of H,K-ATPase is due to an increase in parietal cell number or due to an increase in the amount of protein per cell, oxytic mucosal tissue sections of control and smoke-treated mice were probed with antibodies specific for the  $\alpha$ - or  $\beta$ -subunit of H,K-ATPase. To eliminate the possible variations in immunostaining conditions, stomach tissues obtained from smoke-treated and their littermate sex and weight-matched control mice were

processed simultaneously and embedded in the same paraffin blocks. Tissue sections of control and treated mice were de-waxed and immuno-probed together on the same slides.

Microscopic examination demonstrated the usual pattern of distribution of labeled parietal cells in both control and smoke-treated tissues (Figure 3). Parietal cells were scattered throughout the mucosa of all tissues examined. Counts of parietal cells in control and smoke-treated tissues showed no significant difference. The number of H,K-ATPase-labeled parietal cells averaged

**Figure 4 Analysis of the enzymatic activity of the H,K-ATPase of gastric mucosae in control and smoke-treated mice.** Note the increased activity in the cigarette smoke-treated homogenate.

12.3 cells per gland in control mice and 11.7 cells in the gland of smoke-treated mice. However, when the intensity of the immuno-labeling was compared in control and smoke-treated tissues, an apparent difference was noted. In general, immuno-stained cells of smoke-treated tissues appeared darker than in control tissues (Figure 3). This difference reflected an increase in the amount of H,K-ATPase per cell after treatment with cigarette smoke extract. Quantification of the intensity of H,K-ATPase immunostaining confirmed this difference. Measurements of parietal cell density in each pair of control and smoke-treated mice showed that the percentages of increase in staining intensity after smoke treatment are highly significant ( $P < 0.001$ ) and varied from 150% to 200%. In all mice examined, a similar staining pattern was obtained with antibodies specific for the  $\alpha$ - and  $\beta$ -subunits.

#### **Effect of cigarette smoke extract on the activity of the proton pump**

To test whether the increase in the expression of H,K-ATPase protein is associated with a change in its enzymatic activity, some of the mucosal homogenates were processed for *p*NNPase activity assay. The results indicated that while the enzymatic activity in control tissues averaged 0.12  $\mu\text{mol}/\text{mg}$  per minute, smoke-treated tissues showed more than 2-fold increased activity, 0.27  $\mu\text{mol}/\text{mg}$  per minute ( $P < 0.05$ , Figure 4).

## **DISCUSSION**

The present study demonstrates that cigarette smoke extract enhances the expression and activity of H,K-ATPase in the oxyntic mucosa of the mouse stomach which may explain the susceptibility of smokers to development of peptic ulcer disease.

The pathogenesis of peptic ulcer disease involves several factors including enhanced acid secretion, which is regarded as one of the major ulcerogenic factors. Acid secretion is also considered the primary target of contemporary drug therapy for peptic ulcer disease.

The available data concerning the effects of cigarette smoking on gastric acid secretion are controversial. Clinical studies showed that smoking may stimulate<sup>[25-28]</sup>, inhibit<sup>[29,30]</sup> or have no effect<sup>[31,32]</sup> on gastric acid secretion. Such disparity between studies may be explained, in part,

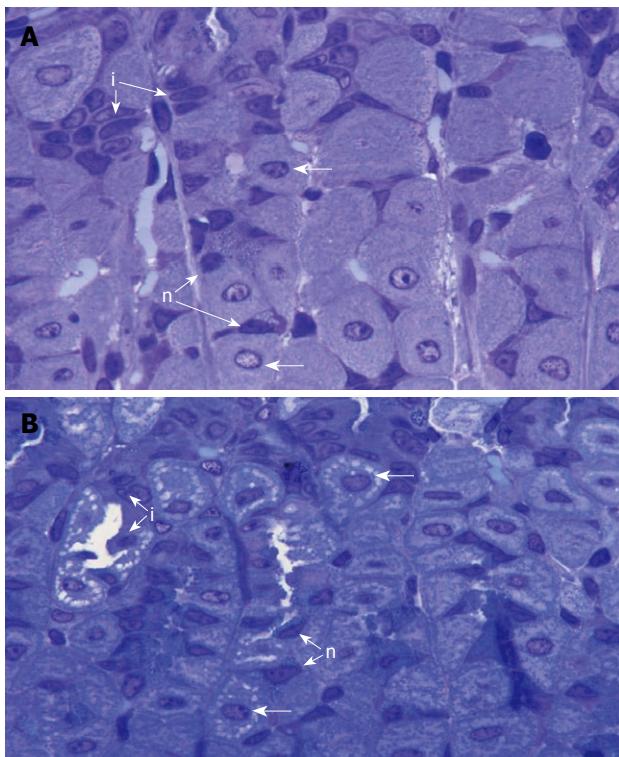

by the differences in nicotine content and number of cigarettes used, and by the lack of adequate controls due to marked individual variability of basal gastric secretion. In the current study, we did not intend to measure acid secretion, but the plan was to dissect the event down stream and examine the major enzyme of the parietal cell, H,K-ATPase, which is responsible for acid secretion.

Nicotine is one of the main constituents of cigarette smoke responsible for the adverse effects of smoking. The effect of nicotine on gastric acid secretion is also controversial. Several lines of evidence have suggested that it has a stimulating effect. Nicotine administered to rats for 10 d caused an increase in gastric secretory volume and acid output. This finding was attributed to increased muscarinic receptor sensitivity, and consequently, basal acid secretion<sup>[33]</sup>. Lindell *et al*<sup>[34]</sup> also noted that nicotine administration enhances gastric acidity and impairs postprandial gastric neutralization in humans. Likewise, nicotine treatment abolishes in a dose-dependent manner the depressing effect of ethanol on acid secretion in rats<sup>[35]</sup> and significantly stimulates basal gastric acid output in cats<sup>[36]</sup>. *In vitro* study demonstrated that nicotine could exert direct stimulatory effects on parietal cells and potentiate the histamine-mediated response in the isolated cell model<sup>[36]</sup>.

Some other studies showed contrasting findings. In one study, the gastric acid secretion stimulated by intravenous pentagastrin was completely inhibited by nicotine<sup>[37]</sup>. Another study also showed that acid output together with gastric secretory volume one hour after vagal stimulation induced by modified sham feeding was lower in human subjects on smoking than non-smoking days<sup>[38]</sup>. Based on the contrasting nature of evidence, the effect of nicotine or smoking on gastric acid secretion remained elusive.

The present study supports the view that smoking enhances gastric acid secretion by up-regulating the expression and activity of H,K-ATPase. Based on previous studies, the mechanism by which the smoke extract affected the acid secreting parietal cells could be a combination of receptor mediated and direct effects on the parietal cell.

Therefore, the present study provides an answer to some questions which were raised by some epidemiological studies. Why are cigarette smokers more susceptible to development of peptic ulcer disease? Why is recurrence of peptic ulcer more common in smokers than non-smokers? Why is the healing of peptic ulcer disease delayed in smokers? As an answer to these questions, we hypothesized that H,K-ATPase in the parietal cells is more aggressive in smokers than non-smokers. Then we tested this hypothesis by using an ethanol or aqueous extract of cigarette smoke, which were previously found to be rich in nicotine by various chromatography techniques<sup>[39]</sup>. The extract was administered to mice orally and three methods were carried out to characterize the anticipated alteration of the gastric H,K-ATPase. First, Western blotting analysis of homogenates obtained from the gastric mucosae of control and smoke-treated mice showed an increase in the amount of H,K-ATPase in the 3-d-treated adult mice and 14-d-treated weaning-age mice. However, when the

**Figure 5** Semithin (0.5-micron-thick) sections of the gastric mucosae of control (A) and smoke-treated (B) mice stained with toluidine blue to demonstrate the isthmus and neck regions of the gastric glands. The large numerous parietal cells (horizontal arrows) are separated by progenitor or isthmal cells (i) and neck cells (n). Note that, in the smoke-treated tissue but not control tissue, there are pale areas in the cytoplasm of parietal cells which represent expanded lumen of the intracellular canalicular system,  $\times 1000$ .

weaned mice were treated for only 7 d with half the dose, there was no significant change in the amount of H,K-ATPase as compared to their control littermates. Therefore, there is a duration- and dose-dependent effect of cigarette smoke extract in weaning-age mice. During this age, the developing gastric glands undergo compartmentalization into isthmus, neck and base regions<sup>[40]</sup>. In these developing glands, parietal cells might not have acquired all the machinery to respond to an extrinsic stimulus and therefore a longer duration of treatment with cigarette smoke extract is needed. Second, immunohistochemical analysis of gastric parietal cells using antibodies specific for their H,K-ATPase revealed an enhancement in the immunostaining of parietal cells of the smoke-treated mice. Since tissues of these treated mice and their weight- and sex-matched littermate control mice were processed together, embedded in the same tissue blocks and immuno-probed simultaneously on the same slides, the differences in immunostaining intensity were taken to represent an increase in the amount of H,K-ATPase per parietal cell. Third, the proton pump activity, measured by *p*NPPase assay was enhanced in the gastric mucosal homogenates of smoke-treated mice compared to control mice.

The question was raised whether the increased amount and activity of H,K-ATPase was associated with the translocation of tubulovesicles into the canalicular membranes. Some gastric mucosal tissues obtained from three pairs of smoke-treated and control mice were fixed in a Kar-

novesky's solution and processed for Araldite embedding and semithin sectioning. Microscopic examination of parietal cells located in the isthmus and neck regions of the gastric glands (known to be involved in acid secretion<sup>[41]</sup>) revealed that those of the smoke treated mice tend to acquire stimulated morphology with expanded canalicular system as compared to those of control mice (Figure 5).

In conclusion, the present study demonstrates a possible explanation for the susceptibility of smokers to develop peptic ulcer disease. Therefore, we propose the following scenario. It seems that smokers develop parietal cells with an increased amount and activity of H,K-ATPase and tendency to acquire an extended canalicular system. Accordingly, parietal cells of smokers are enhanced to produce much acid upon stimulation and their gastric and duodenal mucosae become more vulnerable to development of peptic ulcer disease.

## COMMENTS

### Background

Clinical, epidemiological and experimental studies have shown that smokers are more susceptible to peptic ulcer disease and respond to anti-ulcer drugs less efficiently than non-smokers. Parietal cells are targets for anti-ulcer drugs and their inhibition is an important modality for peptic ulcer treatment.

### Research frontiers

Parietal cell activation may be associated with gastric mucosal injury and peptic ulcer disease. Since smoking is a predisposing factor to peptic ulcer, it is hypothesized that cigarette smoke extract may cause activation of gastric parietal cells. In this study, the authors demonstrated that over-expression of the gastric proton pump could be a possible mechanism for the susceptibility of smokers to peptic ulcer disease.

### Innovations and breakthroughs

Previous reports have demonstrated the role of epidermal growth factors, blood flow, neutrophils, angiotensin II, and free radicals in the adverse effects of smoking on the gastrointestinal mucosa. In this study, the authors have demonstrated an additional possible effect of smoking on the expression and activity of the gastric proton pump.

### Applications

By understanding how smoking may alter the biological features of the gastric mucosa, this study may help in improving the current preventive and therapeutic modalities of peptic ulcer disease.

### Terminology

The proton pump or H,K-ATPase is the major protein of parietal cells responsible for acid secretion. It is the main target for anti-ulcer drugs. Better understanding of the biological features of these cells and defining factors responsible for the regulation or dysregulation of their proton pump is important for designing new modalities for prevention and treatment of peptic ulcer disease.

### Peer review

The authors used a smoking extract to study parietal cell H,K-ATPase expression and activity. It is a very interesting study.

Joo I, Kim HC, Chung JW, Jae HJ, Park JH. Risk factors for rebleeding after angiographically negative acute gastrointestinal bleeding. *World J Gastroenterol* 2009; 15(32): 4023-4027 Available from: URL: <http://www.wjgnet.com/1007-9327/15/4023.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.4023>

## INTRODUCTION

Acute non-variceal gastrointestinal bleeding accounts for approximately 20% of emergency room visits and 5% of admissions<sup>[1]</sup>. Although endoscopy (including the use of upper endoscopy and colonoscopy) has been used as a first-line treatment option in patients with gastrointestinal bleeding<sup>[2,3]</sup>, angiographic intervention can be used as a safe diagnostic and treatment method in patients with gastrointestinal bleeding that is refractory to endoscopic treatment<sup>[4-6]</sup>.

Angiography requires a bleeding rate of 0.5-1 mL/min for detection. When neither extravasation nor vascular abnormality such as pseudoaneurysm is found, the bleeding site cannot be embolized selectively. Thus, intermittent bleeding is likely to result in a negative angiographic study<sup>[7,8]</sup>. The incidence of rebleeding in patients with negative initial angiography has been reported in up to 60% of cases<sup>[9]</sup>. However, little is known about the predictive factors for rebleeding, to determine if further investigations should be performed. The aim of this retrospective study was to identify the factors related to rebleeding in patients with gastrointestinal bleeding and normal angiographic findings.

## MATERIALS AND METHODS

From January 2000 to July 2007, 341 patients with acute non-variceal gastrointestinal bleeding were referred to the angiography unit of our institution for possible transcatheter arterial embolization. We excluded 193 patients as they had active bleeding detected by angiography, and these patients received selective or empirical embolization. Among 148 patients with negative findings upon initial angiography, 20 were

## Abstract

**AIM:** To identify possible predictive factors for rebleeding after angiographically negative findings in patients with acute non-variceal gastrointestinal bleeding.

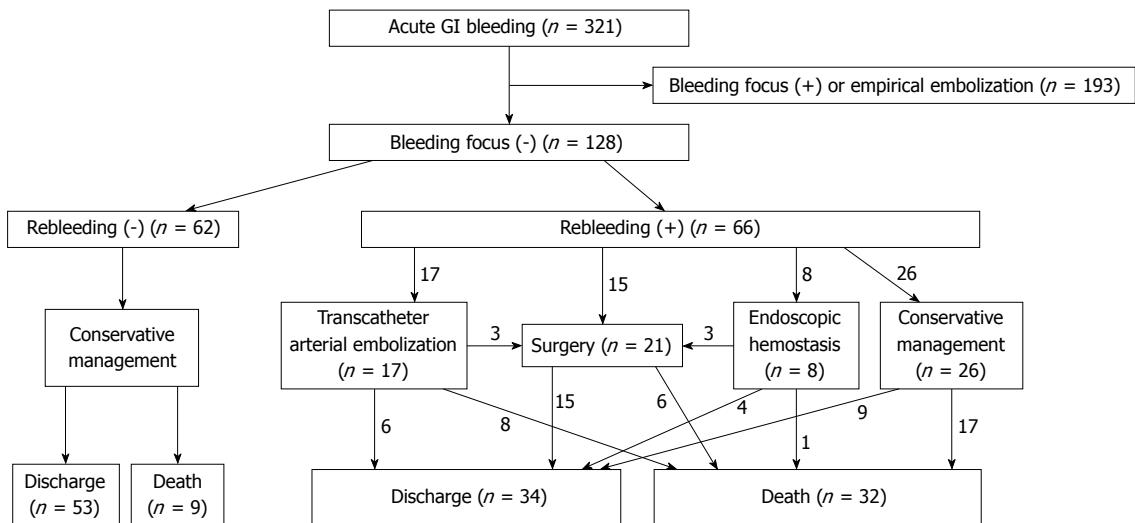

**METHODS:** From January 2000 to July 2007, 128 patients with acute non-variceal gastrointestinal bleeding had negative findings after initial angiography. Clinical and laboratory parameters were analyzed retrospectively.

**RESULTS:** Among 128 patients, 62 had no recurrent gastrointestinal bleeding and 66 had recurrent gastrointestinal bleeding within 30 d. As determined by the use of multivariate analysis, an underlying malignancy, liver cirrhosis and hematemesis were significant factors related to recurrent gastrointestinal bleeding.

**CONCLUSION:** Clinical factors including underlying malignancy, liver cirrhosis, and hematemesis are important predictors for rebleeding after angiographically negative findings in patients with acute non-variceal gastrointestinal bleeding.

**Key words:** Angiography; Gastrointestinal hemorrhage; Predictive factor

**Figure 1** Flow diagram of patient outcome.

excluded because of limited medical records or suspected variceal gastrointestinal bleeding. A total of 128 patients (94 male, 34 female; age range, 18–85 years, mean age, 57.8 years) who had no active bleeding detected by initial angiography were included in this study. Approval was obtained from the ethical board committee of Seoul National University Hospital and patient informed consent was waived because of the retrospective nature of the study.

Clinical and laboratory parameters were reviewed retrospectively. The variables assessed included the following: patient age, sex, history of hematemesis, hematochezia or melena, shock, hemoglobin level, platelet count, prothrombin time, partial thromboplastin time, recent surgery, potential bleeding diatheses (liver cirrhosis or chronic renal failure), underlying malignancy, use of nonsteroidal anti-inflammatory drugs, and use of other antiplatelet agents or anticoagulants at the time of evaluation. Rebleeding was confirmed by endoscopy or surgery, and was clinically defined as: (1) fresh hematemesis; (2) fresh melena with systolic blood pressure < 100 mmHg; (3) a decrease in hemoglobin level of > 4 g/dL within 24 h; and (4) a requirement of two more red blood cell transfusions within 24 h.

The univariate association between clinical and laboratory variables and rebleeding was examined using Fisher's exact test for categorical variables and the *t* test for continuous variables. Variables with *P* < 0.25 as determined by univariate analysis were subjected to multiple logistic regression analysis with the use of a backward stepwise method. For univariate and multiple logistic regression analysis, *P* < 0.05 was regarded as statistically significant. Statistical analyses were performed using commercially available software (SPSS for Windows version 10.0 (Chicago, IL USA). All reported *P* values were two tailed.

## RESULTS

Before the initial angiography examination, endoscopy

was performed in 97 patients, endoscopic hemostasis was attempted in 18 patients, tagged red blood cell scintigraphy was performed in 21 patients, and a computed tomography (CT) scan was obtained for 40 patients. After initial angiography with negative findings, endoscopy was performed in 81 patients, endoscopic hemostasis was attempted in eight patients, tagged red blood cell scintigraphy was performed in 18 patients, a CT scan was obtained for 18 patients, and surgical treatment was performed in 21 patients.

The location of bleeding was the esophagus (*n* = 3), stomach (*n* = 31), duodenum (*n* = 25), small intestine (*n* = 12), colon (*n* = 13) and unknown (*n* = 44). The cause of bleeding was a benign ulcer (*n* = 50), gastrointestinal tumor (*n* = 7), ischemic enteritis (*n* = 3), radiation colitis (*n* = 2), iatrogenic injury (*n* = 2), angiodysplasia (*n* = 2) and undetermined (*n* = 62).

Among 128 patients who had no active bleeding detected by angiography, 62 had no recurrent gastrointestinal bleeding and 66 had recurrent gastrointestinal bleeding. Figure 1 documents the clinical course of the 128 patients. For the 66 patients with rebleeding, 40 received interventions including surgery, transcatheter arterial embolization and endoscopic hemostasis. The 4-wk mortality rate was 48% (32/66) for patients with rebleeding and 15% (9/62) for those without rebleeding. Among 41 expired patients, the cause of death was uncontrolled bleeding in 11, pneumonia or sepsis in 13, aggravation of the underlying malignancy in 10, cardiac failure in one, hepatic failure in one, and unknown in five.

Based on univariate analysis, the hemoglobin level, partial thromboplastin time, use of antiplatelet medication, underlying malignancy, presence of liver cirrhosis and shock were significant factors related to recurrent gastrointestinal bleeding. Based on multivariate analysis, underlying malignancy (*P* = 0.002, OR = 3.81), liver cirrhosis (*P* = 0.017, OR = 4.81) and hematemesis (*P* = 0.042, OR = 2.59) were significant factors related to recurrent gastrointestinal bleeding (Table 1).

## DISCUSSION

Acute non-variceal gastrointestinal bleeding is one of the common emergency conditions for inpatients as well as outpatients<sup>[1]</sup>. Superselective angiography and transcatheter embolization have been used widely for upper and lower gastrointestinal bleeding refractory to endoscopic therapy<sup>[4,5]</sup>. In the case of failure of endoscopic management caused by a large number of blood clots or poor bowel preparation, angiography may be the choice of diagnostic or therapeutic method<sup>[4]</sup>. The angiographic procedure can provide accurate localization of the bleeding focus and immediate hemostasis, and localization of the bleeding site prior to surgery can prevent “blind” bowel resection. In addition, the use of angiography is less invasive than surgery, and is a good option for poor surgical candidates<sup>[10]</sup>. Recently, the use of improved techniques and instruments has decreased the number of complications such as bowel ischemia within an acceptable range<sup>[5,6]</sup>.

Unfortunately, blood extravasation is not always visualized. In recent reviews of angiographic findings, blood extravasation or intraluminal blush was seen in 40%-60% of angiographic cases of non-variceal upper

gastrointestinal bleeding<sup>[1,7,8]</sup>. There have been many studies of patients with normal angiograms, but a gold standard for management has not been determined. Some suggest that, in the case of negative angiographic findings in patients with intermittent or slow flow bleeding, use of nuclear scintigraphy seems reasonable to help confirm and localize the lesion<sup>[11,12]</sup>. The use of CT angiography may add to the detection of intermittent bleeding with possible better localization of the source and etiology of the bleeding. Ettorre *et al*<sup>[13]</sup> have shown a detection rate of 72% in patients with obscure gastrointestinal bleeding, in whom endoscopic and nuclear imaging failed to localize the bleeding site. The use of angiography has been reported with intra-arterial or intravenous injection of vasodilators, heparin, and even thrombolytic drugs to improve the rate of positive angiographic findings in occult lower gastrointestinal bleeding, although these modifications have been considered provocative<sup>[14-16]</sup>. Some investigators have suggested that blind embolization of the left gastric artery after endoscopic localization can show a decrease in the rebleeding rate<sup>[17]</sup>. As a result of the safety of the procedure, empiric embolization of the upper gastrointestinal tract for acute bleeding has been recommended when guided by endoscopic findings.

We expect that determination of the predictive factors for rebleeding may help in the selection of patients for further work-up or treatment, and consequently, may increase the success rate and decrease the rate of complications. Several studies have demonstrated clinical and endoscopic factors including liver cirrhosis, recent surgery, hypovolemic shock, hematemesis, large ulcer size, non-bleeding visible vessel, and the presence of an adherent clot on an ulcer base as significant predictive factors for the recurrence of hemorrhage in patients with peptic ulcer<sup>[18,19]</sup>. In our study, underlying malignancy, liver cirrhosis and hematemesis were significant factors related to recurrent gastrointestinal bleeding. As we did not perform endoscopy in all patients, and the study population was heterogeneous, including upper and lower gastrointestinal bleeding, endoscopic factors were not included in the analysis.

Rebleeding rates reported in the literature vary from 7% to 25% in patients with peptic ulcer or lower gastrointestinal bleeding<sup>[18-20]</sup>. In our study, the incidence of rebleeding within 1 mo was 52% (66/128). We think that the rebleeding rate was high because many severely ill patients were included in our study population.

The mortality rate in our study was 48% for patients with rebleeding and 15% for those without. Since there are many variables, we cannot state that the rebleeding itself affected mortality. However, prediction of rebleeding seems to have a relation to the prediction of prognosis.

This study had some limitations. First, the variable diagnostic and therapeutic modalities were performed without a settled sequence or principle. Most of the patients (120/128) received variable transfusions of red blood cells, fresh frozen plasma or platelet concentrate before angiography. Tagged red blood cell scintigraphy was performed in 21 patients and CT angiography in 40. Endoscopy was performed in 97 patients and 18 underwent endoscopic treatment. The selection of endoscopy or angiography in acute gastrointestinal bleeding is not well established. In our retrospective review, in cases in which postoperative CT showed an active bleeding focus, or the condition of the patient was inappropriate for endoscopy, angiography was performed as the first-choice method for diagnosis and treatment of acute gastrointestinal bleeding. Second, patients were enrolled in the study from only a single referral hospital. Many of the patients were elderly and had numerous medical problems. These conditions may have influenced the relatively high rebleeding rate and high mortality rate. Third, although the clinical features of upper gastrointestinal bleeding are quite different from lower gastrointestinal bleeding, both upper and lower gastrointestinal bleeding were included in this study population, as we could not determine the location of the bleeding site in 44 of 128 patients.

In conclusion, clinical factors including underlying malignancy, liver cirrhosis, and hematemesis are important predictors of recurrent bleeding after negative angiographic findings in patients with acute non-variceal gastrointestinal bleeding.

## COMMENTS

### Background

Acute non-variceal gastrointestinal bleeding is a common emergency condition. Superselective angiography and transcatheter embolization have been used widely for gastrointestinal bleeding. Unfortunately, blood extravasation is not always visualized.

### Research frontiers

To predict the risk of gastrointestinal rebleeding after negative angiography may be important clinically. However, little is known about the predictive factors for rebleeding, to determine if further investigations should be performed.

### Innovations and breakthroughs

This study is believed to be the first to establish predictive factors for rebleeding after angiographically negative gastrointestinal bleeding.

### Applications

Determination of the predictive factors for rebleeding may help in the selection of patients for further work-up or treatment, and consequently, might increase the success rate and decrease the rate of complications.

### Peer review

This study evaluated retrospectively the risk factors for gastrointestinal rebleeding after negative angiography.

### Abstract

**AIM:** To identify the distribution of hepatitis B virus (HBV) subgenotype and basal core promoter (BCP) mutations among patients with HBV-associated liver disease in Indonesia.

**METHODS:** Patients with chronic hepatitis (CH, n =

61), liver cirrhosis (LC, n = 62), and hepatocellular carcinoma (HCC, n = 48) were included in this study. HBV subgenotype was identified based on S or preS gene sequence, and mutations in the HBx gene including the overlapping BCP region were examined by direct sequencing.

**RESULTS:** HBV genotype B (subgenotypes B2, B3, B4, B5 and B7) the major genotype in the samples, accounted for 75.4%, 71.0% and 75.0% of CH, LC and HCC patients, respectively, while the genotype C (subgenotypes C1, C2 and C3) was detected in 24.6%, 29.0%, and 25.0% of CH, LC, and HCC patients, respectively. Subgenotypes B3 (84.9%) and C1 (82.2%) were the main subgenotype in HBV genotype B and C, respectively. Serotype adw2 (84.9%) and adrq+ (89.4%) were the most prevalent in HBV genotype B and C, respectively. Double mutation (A1762T/G1764A) in the BCP was significantly higher in LC (59.7%) and HCC (54.2%) than in CH (19.7%), suggesting that this mutation was associated with severity of liver disease. The T1753V was also higher in LC (46.8%), but lower in HCC (22.9%) and CH (18.0%), suggesting that this mutation may be an indicator of cirrhosis.

**CONCLUSION:** HBV genotype B/B3 and C/C1 are the major genotypes in Indonesia. Mutations in BCP, such as A1762T/G1764A and T1753V, might have an association with manifestations of liver disease.

## INTRODUCTION

Hepatitis B virus (HBV) infection is associated with a diverse clinical spectrum of liver damage ranging from asymptomatic carriers, chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma (HCC)<sup>[1]</sup>. HBV, a member of the *hepadnaviridae*, is a relaxed circular double-stranded DNA virus, and is currently classified into 8 genotypes (A to H), which reflect its geographical distribution<sup>[2,3]</sup>. For instance, HBV genotype A is prevalent in Europe, Africa, and India<sup>[4]</sup>. HBV genotypes B and C are predominant in most parts of Asia, including China, Japan, and Indonesia<sup>[4-10]</sup>. Genotype D is common in the Mediterranean area, the Middle East and India, whereas genotype E is localized in sub-Saharan Africa<sup>[4,11-13]</sup>. Genotype F and H are only identified in Central and South America<sup>[4,14,15]</sup>. Genotype G has been found in France, Germany, and the United States<sup>[4,16-18]</sup>.

Besides the differences in geographical distribution, there is growing evidence that the HBV genotype may also influence the clinical outcomes of liver disease. Among Asian patients who constitute approximately 75% of HBV carriers worldwide, it has been shown that HBV genotype C is more commonly associated with severe liver disease and the development of cirrhosis and HCC than HBV genotype B<sup>[19-23]</sup>. However, most of these studies were carried out in Taiwan and Japan, thus can not be generalized even for Asian countries.

In addition to HBV genotype, mutations in the core promoter, precore or HBx gene have been shown to have an association with severe liver disease. For instance, many studies have revealed that the double mutation in BCP (A1762T/G1764A) is associated with an increased risk of severe liver disease including HCC, and can be used as a prediagnostic biomarker of HCC<sup>[24-28]</sup>. The predominant mutation in the precore region of HBV which involved a G-to-A change at nucleotide 1896, and resulted in a premature stop codon at codon 28, was proved to be associated with increased HCC risk<sup>[23,28-30]</sup>. In addition, among HBV carriers, the A1762T/G1764A mutation is more frequently found in genotype C than genotype B<sup>[19,31]</sup>. However, an independent study on a comparison of HBV genotype C from Vietnam and Japan showed mutations at different positions in the core promoter/precore region of HBV<sup>[32]</sup>, indicating that the effect of mutation on liver carcinogenesis may not be universal. In addition, some mutations in HBx protein, in particular for HBV genotype C, have been shown to be significantly associated with HCC. A Serine-to-Alanine mutation at codon 31 (S31A) in HBx protein<sup>[33]</sup>, a Proline-to-Serine mutation at codon 38 (P38S) in HBx protein of HBV genotype C<sup>[34]</sup>, and some other particular mutations in HBx protein were found to be associated with increased risk of HCC<sup>[35]</sup>. Those studies, however, were independently carried out in different

countries (China Taiwan, Japan, and Korea), and resulted in three different results.

Despite various reports about the effect of HBV genotype and/or mutations on liver disease progression, the virological significance on liver carcinogenesis is not yet fully elucidated. In particular for Indonesia, some reports had been published regarding the distribution of HBV genotype<sup>[7-10,36]</sup>, and only one study reported samples from CH, LC, and HCC<sup>[8]</sup>. Moreover, to the best of our knowledge there is no report on the distribution of BCP mutations and their possible association with clinical manifestations of liver disease. Thus, the aims of the present study were to identify the distribution of HBV genotype/subgenotype and BCP mutations in patients with different clinical status, and to investigate the association of HBV genotype/subgenotype or BCP mutations and liver disease progression in Indonesia.

## MATERIALS AND METHODS

### Samples

Serum samples were obtained from 171 patients with HBV-associated liver disease, comprising 61 CH patients (mean age  $37.8 \pm 13.0$  years; male/female: 40/21), 62 LC patients (mean age  $50.2 \pm 11.6$  years; male/female: 44/18), and 48 HCC patients (mean age  $49.6 \pm 10.4$  years; male/female: 43/5). CH was defined as persistent seropositivity for HBsAg for at least 6 months. LC was diagnosed by liver function tests and ultrasonography. The diagnosis of HCC was on the basis of ultrasonography as well as an elevated serum  $\alpha$ -fetoprotein (AFP) level ( $\geq 200$  ng/mL), or liver biopsy samples by needle aspiration for samples in which the AFP level was low. Sera of CH, LC, and HCC patients were collected from Cipto Mangunkusumo Hospital, Gatot Soebroto Hospital, Klinik Hati, Jakarta, Siloam Hospital Lippo Karawaci, Tangerang, Mataram General Hospital, Mataram, and Wahidin Sudirohusodo Hospital, Makassar, from May 2006 until November 2008. All sera were hepatitis B surface antigen (HBsAg)-positive as determined by a commercially available enzyme-linked immunosorbent assay kit (Abbott Laboratories, Chicago, IL, USA). Blood samples were collected from each patient at the time of their clinical evaluation, separated into sera and stored at -70°C until viral DNA extraction. The study was approved by the Institutional Ethic Committee and informed consent was obtained from each patient.

### Viral DNA extraction and PCR amplification

HBV DNA was extracted from 200  $\mu$ L serum using the QIAamp DNA blood mini kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions, and 80  $\mu$ L of eluted DNA was stored at -70°C until use. Full S gene was amplified by PCR with primers Fgp2 and Rgp2 (Table 1). The following cycling parameters were used for 40 cycles of PCR: denaturation at 95°C (30 s), annealing at 55°C (45 s) and elongation at 72°C (2 min). When the PCR amplification was negative, a nested PCR was carried out to amplify the preS region.

**Table 1** Primers used in this study

Primer	Nucleotide sequence (5'→3')	Position	Polarity	Reference
Full S				
Fgp2	CGCCATGGGAGGTTGGTCTTCAAACCTCG	2848-2873	Forward	This study

Primers HBPr134 and HBPr135 (Table 1) were used as previously described for the first-round 35 cycles of PCR by the following cycling parameters<sup>[2]</sup>: denaturation at 95°C (1 min), annealing at 48°C (30 s) and elongation at 72°C (1 min). The second-round PCR was then performed using primers HBPr94 and HBPr134 (Table 1) with the same conditions as the first-round PCR except for annealing at 56°C (30 s). Similarly, HBx gene was amplified using primers Fgp3 and Rgp3 (Table 1). The cycling parameters were the same as that for S gene amplification, except with an elongation time of 1 min. A nested PCR was performed for PCR negative samples using primers HB1 and HB3 for the first round PCR [35 cycles: denaturation at 95°C (1 min), annealing at 48°C (30 s) and elongation at 72°C (1 min)] and using primers HB2 and HB3 for the second round PCR with the same parameters as the first-round PCR, but the annealing temperature was 46°C, as described previously<sup>[37]</sup>. Both sets of primers could amplify the full HBx gene. All PCR reactions were carried out by the PCR Core System (Promega, Madison, WI, USA). The PCR products were visualized on 1% agarose gel stained with ethidium bromide and purified using Wizard® SV Gel and the PCR Clean-Up System (Promega, Madison, WI, USA).

#### Analysis of HBV genotype/subgenotype, serotype and HBx mutations

Nucleotide sequences of the PCR fragments were determined with the BigDye Terminator v3.1 Cycle Sequencing kit (Applied Biosystems, Foster City, CA, USA) and the appropriate primers, and sequenced with 3130xl DNA sequencer (Applied Biosystems). All HBs and HBx gene sequences were edited manually and were aligned with reference sequences retrieved from GenBank, using the ClustalW program incorporated in Bioedit v7.0. HBV genotypes/subgenotypes were determined based on the homology in the S or preS gene. Phylogenetic trees were constructed by the neighbor-joining method. HBV serotypes were deduced on the basis of predicted amino acid sequences of HBsAg<sup>[3,38,39]</sup>.

#### Statistical analysis

All statistical analyses were performed using SPSS 15.0

software for Windows (SPSS Inc., Chicago, IL, USA) and MedCalc® version 10.1.0.0 for Windows (MedCalc Software, Broekstraat, Mariakerke, Belgium). Significance differentiations for continuous variables were analyzed using *t*-test analysis. While the categorical variables were analyzed using the Fisher's exact test and chi-square test. *P* < 0.05 were considered significant.

## RESULTS

#### **HBV genotypes/subgenotypes distribution and clinical diagnosis**

Only HBV genotype B and C were detected in the samples, which were respectively distributed in 73.7% and 26.3% of the samples (Table 2). Among HBV genotype B, subgenotypes B2, B3, B4, B5 and B7 were identified, although subgenotype B3 was the major subgenotype identified (84.9% of all genotype B or 62.6% of total samples). HBV subgenotypes B2 and B4 were only found in CH and LC, respectively. HBV subgenotype B5 was found in LC and HCC, while subgenotype B7 was detected in all different clinical diagnoses of the samples. On the other hand, among HBV genotype C, subgenotypes C1, C2, and C3 were found, but subgenotype C1 was dominant (82.62% of all genotype C or 21.6% of total samples). HBV subgenotype C1 was distributed in all samples, but subgenotype C2 and C3 were not detected in HCC samples. Based on statistical analysis, there was no significant association between HBV genotype/subgenotype and a clinical diagnosis of liver disease (Table 2). Serotype distribution demonstrated that adw2 was the major serotype (62.6%) in the samples, followed by adrq+ (24.6%) (Table 2). Other serotypes such as adw, adw3, ayw, ayw1, and ayr were also found in a small number of the samples. Similar to genotype results, no association between serotype and clinical status of the liver disease was observed (Table 2).

#### **HBx and basal core promoter mutations**

Initially, amino acid sequences of HBx from the samples were aligned and compared with reference sequences of amino acids retrieved from GenBank (accession no. BAA23459 and BAD86602 for HBV genotype B and C,

respectively). Several amino acid changes were observed in both HBV genotype B and C. The prevalence of four amino acid substitutions (T118N, I127N/T/S, K130M and V131I) in HBV genotype B were significantly different between CH and LC, and three of them (T118N, K130M and V131I) showed a significant difference in prevalence between CH, LC and HCC, but none of them was significantly different between LC and HCC (Figure 1, Table 3). In contrast, none of the amino acid substitutions showed any significant difference in prevalence in the different clinical status in HBV genotype C (data not shown).

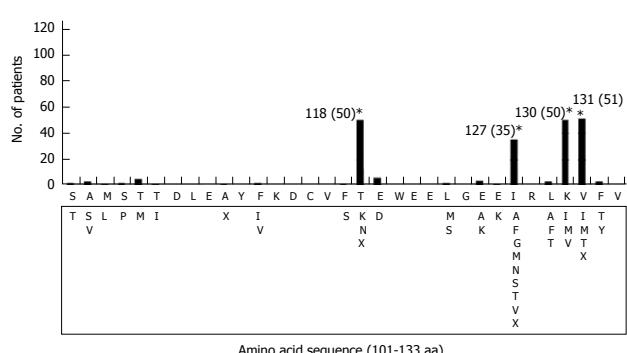

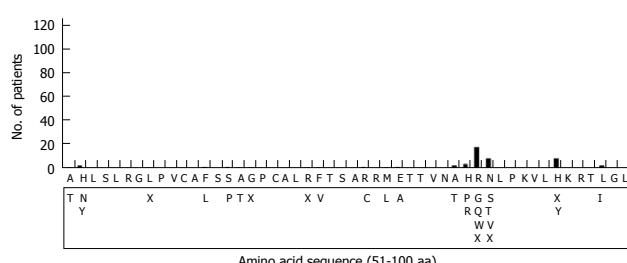

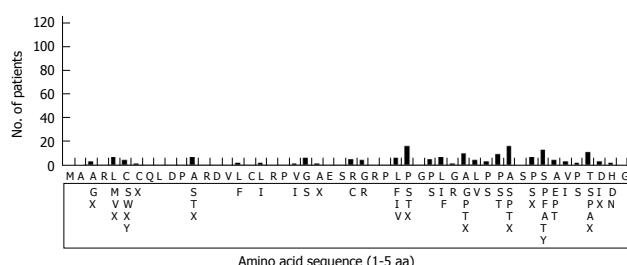

The four substituted amino acids located in BCP region, the corresponding nucleotides (C1726A/T1727(C/T) corresponding to T118N, T1753V corresponding to I127N/T/S, and A1762T/G1764A corresponding to K130M and V131I) were analyzed (Table 4). Mutations at positions 1762 and 1764 (corresponding to K130M

and V131I amino acid substitutions), either as a double mutation or an independent mutation, were significantly higher in LC and HCC than CH. Particularly, the double mutation (A1762T/G1764A) which was found in 19.7%, 59.7% and 54.2% of CH, LC and HCC, respectively ( $P < 0.001$ ). There was no significant difference in the prevalence of the double mutation between HCC with and without cirrhosis (41.7% and 58.3%). Analysis of the nucleotide at position 1753 showed that a T-to-V (A/G/C) mutation (corresponding to I127N/T/S amino acid substitutions) was significantly higher in LC (46.8%) compared with CH (18.0%) and HCC (22.9%) ( $P = 0.004$ ), suggesting that this mutation could be an indicator of liver cirrhosis. Moreover, the prevalence of T1753V mutation was also not significantly different between HCC with cirrhosis (16.7%) and that without cirrhosis (25.0%) (data not shown).

In addition, C1726A/T1727 (C/T) mutations

**Figure 1** Distribution and frequencies of the amino acid mutations in the 133 amino acids of HBx protein of HBV genotype B observed in the present study. Reference sequence of HBV genotype B (accession no. BAA23459) is shown at the top and mutations are shown below the reference sequence. Stars indicate the major substitutions observed and values in parentheses are number of patients with respective mutation.

(corresponding to T118N substitution) were significantly higher in CH (39.3%) than in LC (12.9%) and HCC (22.9%). These results suggested that these mutations were reversely associated with severity of liver disease. In another words, single nucleotide polymorphisms (SNPs) in C1726/T1727 have an association with liver disease manifestations. The distribution of SNPs in 1726/1727

is shown in Table 5. In HBV genotype B, most of nucleotides in 1726 were A or C. The percentage of 1726A was significantly higher in CH (52.2%) than in LC (20.5%) and HCC (33.3%) ( $P = 0.009$ ), while 1726C was more prevalent in LC (79.5%) and HCC (66.7%) than in CH (41.3%) ( $P = 0.001$ ). On the other hand, most of the nucleotides in 1727 were T, however there was no significant difference in the percentage of 1727T in CH (95.7%), LC (88.6%), and HCC (97.2%) ( $P = 0.279$ ). These results suggested that SNP in 1726, but not in 1727, of HBV genotype B was associated with the development of liver disease. In contrast, no association between SNP in the same positions in HBV genotype C and progression of liver disease was observed (Table 5).

### Comparison of BCP and HBx mutations between genotype B and C

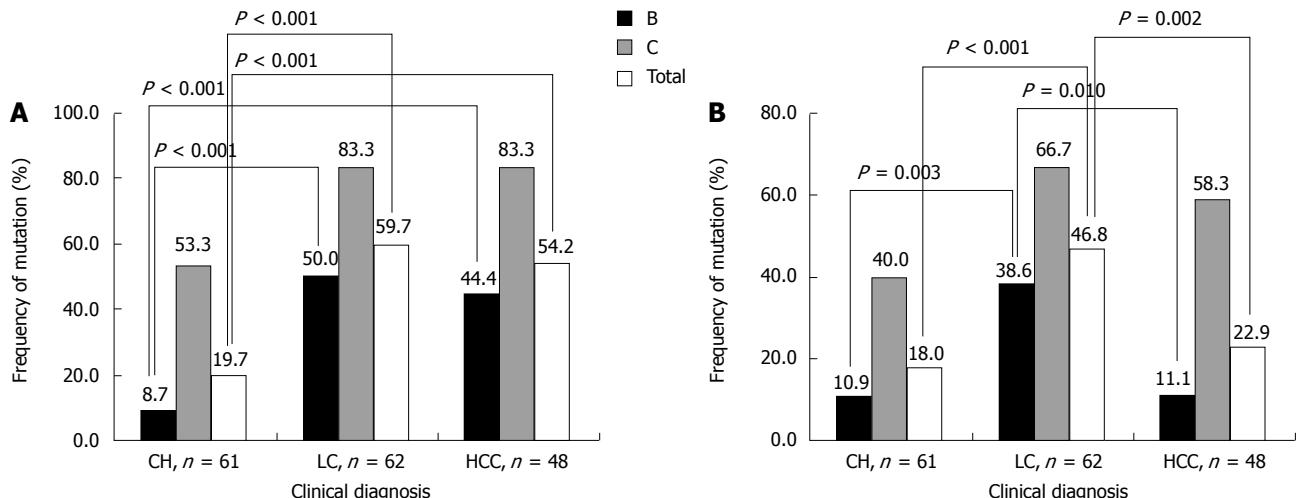

The percentage of cases with A1762T/G1764A mutation was significantly higher in genotype C than genotype B, regardless of clinical status: 53.3% vs 8.7% in CH, 83.3% vs 50.0% in LC, and 83.3% vs 45.5% in HCC (Figure 2A). From an analysis of total samples of these two genotypes, it was shown that the percentage of A1762T/G1764A mutation in genotype C was higher than that of genotype B (73.3% vs 33.3%,  $P < 0.001$ ). Similar to the results of A1762T/G1764A mutation, T1753V mutation also showed a significantly different distribution between genotypes C (55.6%) and B (20.6%) with  $P < 0.001$  (Table 6 and Figure 2B). When T1753V mutation was observed in each clinical status, its prevalence in HBV genotype C and B were 40.0% vs 10.9% in CH, 66.7% vs 38.6% in LC, and 58.3% vs 11.1% in HCC. In contrast, C1726A/T1727(C/T) mutation was more frequent in HBV genotype B (31.7%) than genotype C (6.7%) ( $P = 0.002$ ).

## DISCUSSION

Identification of viral as well as host factors associated with the development of severe liver disease including HCC may have important clinical implications in the management of patients with HBV infection. Many studies have suggested that HBV genotype might play

**Figure 2** The prevalence of A1762T/G1764A (A) and T1753V (B) mutations in the samples with different clinical diagnoses. The number on each histogram represents the percentage of each mutation in each group. P values between the groups are shown respectively.

an important role in the development of severe liver diseases. However, it is also widely accepted that HBV genotypes appear to show varying geographic patterns in their distribution which means the association between HBV genotype and the severity of liver disease may differ from one region to another. For instance, studies from Taiwan and Japan demonstrated that HBV genotype C is associated more with severe liver disease than HBV genotype B<sup>[19-23]</sup>. Since HBV genotype B and C are the main genotypes transmitted in these areas, the investigators compared between genotype B and C. However, another study from Alaska showed that there was a significant association between HBV genotype F and the development of HCC among native Alaskan people<sup>[40]</sup>. This means that the association between HBV genotype and severity of liver disease could be different, depending on the area and the genotype of HBV transmitted in that particular area. From this study, a cross-sectional analysis of subjects from several

different centers in Indonesia, it was found that HBV genotype B was the major genotype and no association between HBV genotype as well as serotype and clinical status of liver disease was observed. Analysis of data from a prospective cohort study, however, is needed to further elucidate the association between HBV genotype and manifestations of liver disease in Indonesian HBV carriers.

Many studies have demonstrated that virus mutations, including mutations of HBx protein, BCP, and precore are linked to the severity and outcome of HBV infection. A study from Taiwan reported that the amino acid substitution at codon 31 of HBx protein (S31A) was frequently found in HCC patients and was predicted to have an association with HCC development<sup>[33]</sup>. A Japanese group also reported that a mutation at codon 38 (P38S) of HBV genotype C was associated with HCC development<sup>[34]</sup>. Recently, it was reported that mutations in HBx protein (V5M/L, P38S, H94Y, I127T/N, K130M

**Table 6 Comparison of core promoter mutations in HBV genotype B and C**

and V131I) from Korean patients are linked with severity of liver disease<sup>[35]</sup>. HBx protein analysis of samples in the present study showed that I127N/T/S, K130M and V131I amino acid substitutions are associated with severe liver disease, especially with liver cirrhosis (Table 3). However, no association between S31A as well as P38S mutations and liver disease progression was found, which is different from previous studies in Taiwan, Japan, and Korea<sup>[33-35]</sup>.

It is well known that the double mutation (A1762T/G1764A) in BCP is associated with an increased risk of liver disease. For instance, the frequency of double mutation (A1762T/G1764A) increased with advancing clinical status in Taiwanese patients [3%, 11%, 32% and 64% in asymptomatic carriers (AC), LC, CH, and HCC groups, respectively]<sup>[24]</sup>. A recent report from China has also demonstrated that the incidence of double mutation increased along with the progression of liver disease; the percentage of the double mutation was 33%, 56% and 85% in CH, LC, and HCC groups, respectively<sup>[31]</sup>. In Indonesian patients, however, the A1762T/G1764A double mutation was increased in CH from 19.7% to 59.7% in LC and was slightly decreased in HCC (54.2%) (Table 4). These results suggest that the double mutation is associated with severe liver disease. In addition, analysis of the nucleotide at position 1753 showed that a T-to-V (A/G/C) mutation increased to 46.8% in LC from 18.0% in CH, but dramatically decreased in HCC (22.9%) (Table 4), suggesting that this mutation is associated with liver cirrhosis rather than HCC. In contrast, analysis of sera or plasma from Japanese subjects with AC, CH, LC and HCC infected with HBV genotype C showed that the percentage of T1753V mutation increased with progression of liver disease<sup>[41]</sup>. It is also reported that T1753V mutation was higher in HCC (53.2%) compared with LC (18.8%) and CH (9.8%)<sup>[31]</sup>. These results were inconsistent with the present study, particularly in LC and HCC. These discrepancies might be associated with HCC status; most of HCC cases in the present study were without cirrhosis. Another possibility is that most of the samples analyzed in the previous reports were HBV genotype C, whereas most of samples in the present study were HBV genotype B.

The most interesting finding of the present study is the association of SNP at position 1726 of HBV

genotype B, but not genotype C, and severity of liver disease. Since HBV genotype B is the major genotype in Indonesia, this finding is important for the management and prevention of HBV carriers from developing more advanced disease such as liver cirrhosis and HCC in Indonesia. This association, however, has to be confirmed by analyzing more samples. A comparison of mutation prevalence between HBV genotype B and C showed that the percentage of T1753V and A1762T/G1764A mutations were higher in genotype C than in genotype B (Table 6). These results are in accordance with previous findings from Taiwan and China<sup>[20,31]</sup>.

In summary, the present study demonstrated that HBV genotype B and C were detected among HBV-associated liver disease patients in Indonesia, and genotype B was predominant. It was found that HBV genotype, as well as the serotype, might not be associated with an increased risk of HCC. The A1762T/G1764A and T1753V mutations in BCP can be used as an indicator for progression of liver disease in Indonesian patients.

## COMMENTS

### Background

Hepatitis B virus (HBV) genotype, mutations in the core promoter, precore or HBx gene have been shown to have an association with severe liver disease. The aims of the study were to identify the distribution of HBV subgenotype and basal core promoter (BCP) mutations among patients with HBV-associated liver disease in Indonesia, and analyze the possible association between HBV genotype and/or BCP mutations and severity of liver disease among Indonesian patients.

### Research frontiers

Although there were some reports on the distribution of HBV genotype in Indonesia, the association between HBV genotype and/or BCP mutations and liver disease progression has not been investigated. Therefore it is important to have information not only related to the distribution of HBV genotype/subgenotype and BCP mutations in patients with different clinical status, but also the association of HBV genotype/subgenotype and/or BCP mutations and liver disease progression in Indonesia.

### Innovations and breakthroughs

The present study demonstrated that only HBV genotype B and C were detected among HBV-associated liver disease patients in Indonesia, and genotype B was predominant. It was found that HBV genotype, as well as the serotype, might not be associated with an increased risk of hepatocellular carcinoma (HCC). The double mutation (A1762T/G1764A) was associated with progression of liver disease, while T1753V mutation could be used as an indicator of liver cirrhosis rather than HCC. In addition, SNP in 1726 has an association with manifestations of liver disease.

### Applications

The double mutation (A1762T/G1764A) can be used for the prediction of severe liver disease including cirrhosis and HCC, whereas the T1753V mutation is a predictor of liver cirrhosis in Indonesian patients. In addition, SNP in 1726 can also be used for the prediction of liver disease severity.

### Terminology

HBs; HBs gene encode the surface protein of HBV that consist of preS1, preS2, and S. HBx; HBx gene encode functional X protein. BCP; BCP can be

considered a part of HBx gene that regulate the core gene expression.

#### Peer review

The study provides a identify HBV subgenotype and basal core promoter (BCP) mutations distribution among HBV-associated liver disease patients in Indonesia. The work is of theoretical and practical importance.

cystic lesions and main pancreatic ducts (MPDs) were significantly larger in malignant IPMNs compared with those of the benign IPMNs ( $P < 0.05$ ). The combined-type IPMNs had a higher rate of malignancy than the other two types of IPMNs ( $P < 0.05$ ). Tumors with mural nodules and thick septa had a significantly higher incidence of malignancy than tumors without these features ( $P < 0.05$ ). Communication of side-branch IPMNs with the MPD was present in nine cases at pathologic examination. Seven of them were identified from CTA and MPVR or CR images. From comparison with the pathological diagnosis, the sensitivity, specificity, and accuracy of MDCT in characterizing the malignancy of IPMN of the pancreas were determined to be 100%, 87.5% and 95%, respectively.

**CONCLUSION:** MDCT with CTA and MPVR or CR techniques can elucidate the imaging features of IPMNs and help predict the malignancy of these tumors.

## Abstract

**AIM:** To retrospectively evaluate the imaging features of pancreatic intraductal papillary mucinous neoplasms (IPMNs) in multi-detector row computed tomography (MDCT).

**METHODS:** A total of 20 patients with pathologically-confirmed intraductal papillary mucinous neoplasms (IPMNs) were included in this study. Axial MDCT images combined with CT angiography (CTA) and multiplanar volume reformations (MPVR) or curved reformations (CR) were preoperatively acquired. Two radiologists (Tan L and Wang DB) reviewed all the images in consensus using an interactive picture archiving and communication system. The disputes in readings were resolved through consultation with a third experienced radiologist (Chen KM). Finally, the findings and diagnoses were compared with the pathologic results.

**RESULTS:** The pathological study revealed 12 malignant IPMNs and eight benign IPMNs. The diameters of the

## INTRODUCTION

Intraductal papillary mucinous neoplasms (IPMNs) of the pancreas, defined by the World Health Organization (WHO), are a broad spectrum of neoplasms arising from the pancreatic duct epithelia and characterized by cystic dilatation of the main and/or branch pancreatic ducts, and occasionally by the presence of mural nodules (papillary excrescence or protuberances)<sup>[1-6]</sup>. According to

the site and extent of involvement, IPMNs are classified into three subtypes: main duct type, branch duct type, and combined-type (mixed type) with both main and branch duct lesions<sup>[2,7,8]</sup>. Although an IPMN is a rare tumor, the increasingly common use of imaging techniques has contributed to the identification of an increasing number of the lesions, even in entirely asymptomatic cases<sup>[9-13]</sup>.

According to the International Guidelines for management of IPMN<sup>[2]</sup>, magnetic resonance imaging (MRI) along with magnetic resonance cholangiopancreatography (MRCP) is referred to as the best imaging modality to outline the gross appearance of IPMN. However, computed tomography (CT) is still the mainstay in the evaluation of patients with IPMNs of the pancreas. Improvements in CT such as the evolution of post-processing techniques in multi-detector row CT (MDCT), have enhanced the capability of CT in the evaluation of abnormalities of the pancreatic parenchyma and the pancreatic ducts in patients with IPMNs<sup>[10]</sup>. Axial CT images combined with multiplanar volume reformations (MPVR) or curved reformations (CR) and CT angiography (CTA) with maximum intensity projection should display the imaging features of IPMNs in more detail. Recent studies assessed the capability of MDCT in defining the invasiveness of the IPMN and in evaluating the resectability of IPMNs<sup>[14,15]</sup>. The IPMN can evolve through all biological stages, from slight dysplasia to carcinoma. As one of the few surgically curable pancreatic tumors, accurate preoperative prediction of malignancy remains one of the major issues in the optimal treatment of IPMNs, and it also influences the outcome of the resection<sup>[16,17]</sup>.

The present study retrospectively assessed the imaging findings of IPMNs with MDCT and evaluated the capabilities of MDCT with emphasis on the postprocessing techniques to predict the malignancy of IPMNs.

## MATERIALS AND METHODS

### Patient population

Between December 2005 and March 2008, IPMN of the pancreas was diagnosed in 31 cases at our institution based on surgico-pathological examination. Of these 31 cases, 20 patients [11 male, 9 female; mean age, 62 years (range, 41-81 years)] who underwent MDCT within a month prior to surgery were recruited into this study. At our hospital, surgical planning requires that most patients in whom IPMN of the pancreas is suspected undergo MDCT including CTA and MPVR or CR processing rather than dynamic MRI with MRCP for evaluation of the extent of the disease and the relationship between affected parts of the pancreas and surrounding vessels and organs. The lesions revealed by the subsequent pathological examinations were divided into three subtypes: benign adenoma, noninvasive carcinoma including borderline malignancy and carcinoma *in situ*, and invasive carcinoma in accordance with the WHO classification. A borderline lesion was defined as a tumor which was not overtly malignant but had some foci of severe cellular atypia, indicating that it should be treated as malignant. Thus, an IPMN considered at imaging to be malignant could include a borderline malignancy, carcinoma *in situ*, and invasive carcinoma on pathology

in this study. The mean interval between the imaging and surgery was 22 d (range, 10-31 d). Institutional Review Board approval and waiver of informed consent for this retrospective study were obtained.

### CT techniques

All CT examinations were performed with a 4- or 16-slice MDCT scanner (Lightspeed QX/I or Lightspeed 16; GE Medical Systems, Milwaukee, Wis). The parameters applied in the CT scan were as follows: a tube voltage of 120 kVp, a tube current of 280 mA, and tube rotation time of 0.5-0.8 s. Prior to administration of contrast agents, non-enhanced CT of the upper abdomen was performed with 10 mm slice thickness and 10 mm spacing. Non-ionic contrast materials with an iodine concentration of 300 mgI/mL were injected into the antecubital vein at a rate of 3-4 mL/s with an 18-20-gauge cannula for all the patients. In addition, 40 mL dextrose was administered at the same rate immediately after the administration of contrast agents. The pancreatic phase of dual phased CT was started at 35 s after the initiation of contrast material injection, whereas the venous phase was performed afterwards with a delayed time of 65-70 s. For the pancreatic phase, a slice thickness of 1.25 mm and a table speed of 11.25 mm/s were utilized while a slice thickness of 5 mm and a table speed of 18.75 mm/s were employed for the venous phase. Axial images were retrospectively reconstructed at a 50% overlap, using a 1.25 mm slice thickness, and 0.625 mm spacing.

In all patients, CTA and 2-dimensional (2D) MPVR or CR images were generated from the source axial images at a commercially available dedicated workstation (ADW 4; GE Medical Systems) by a radiologist (Zhao YE).

### Image analysis

Two radiologists (Tan L and Wang DB) reviewed all the images in consensus at an interactive picture archiving and communication system workstation. The readers were aware of the diagnosis of an IPMN but were blinded to the findings of surgery and pathological examination. In cases of interobserver disagreement, final decisions were made through consultation with a third experienced radiologist (Chen KM).

Each reader recorded the following items: (1) the largest diameter of the cystic lesion; (2) the largest diameter of the main pancreatic duct (MPD); (3) classification of the tumors as main duct type, branch duct type, and combined type (mixed type). The main duct type was diagnosed when dilatation of the MPD had increased its diameter to more than 5 mm. The presence of one or multiple cystic lesions in the pancreatic parenchyma, without dilatation of the MPD, indicated that a branch duct-type tumor was present. The combined type was diagnosed when the pancreas contained one or more cystic lesions and the diameter of the dilated MPD was more than 5 mm; (4) locations of the lesions: in the head or uncinate process, the body, or the tail of the pancreas. Diffuse involvement was denoted when the lesion involved the entire gland; (5) internal solid structures: presence or absence of mural nodules and thick septa; (6) other findings including vascular involvement, lymph node enlargement,

**Table 1 Relationship between imaging findings on MDCT and surgico-pathological diagnosis of pancreatic IPMNs**

MDCT findings	Surgical and pathological results		<i>P</i>
	Benign ( <i>n</i> = 8)	Malignant ( <i>n</i> = 12)	
Largest diameter of cystic lesion	21.6 ± 10.3 mm	43.5 ± 16.5 mm	< 0.05
Caliber of main pancreatic duct	3.3 ± 1.6 mm	7.5 ± 5.5 mm	< 0.05
Morphologic type			< 0.05
Branch duct	4	1	
Combined	2	10	
Main duct	2	1	
Location of cystic lesion			> 0.05
Head and uncinate	4	10	
Body	0	1	
Tail	2	0	
Diffuse	2	1	
Solid structures inside lesion			< 0.05
Mural nodules and thick septa	2	10	
No mural nodules or thick septa	4	1	

MDCT: Multi-detector row computed tomography; IPMNs: Intraductal papillary mucinous neoplasms.

and duodenal involvement, as well as dilatation of the bile duct and distant metastasis. All the imaging diagnoses were compared with the surgico-pathological outcomes.

### Statistical analysis

The unpaired Student's *t*-test was used to assess the differences in the largest diameters of the cystic lesion and MPDs between the benign and malignant groups. Fisher's exact test was used to evaluate the differences in classification, location, and internal solid structures between the benign and malignant tumors confirmed by pathology. The sensitivity, specificity, and accuracy of the MDCT diagnosis for IPMNs of the pancreas were calculated. *P* < 0.05 was considered statistically significant. Statistical analysis was performed with SPSS 13.0 computer software (Chicago, IL, USA).

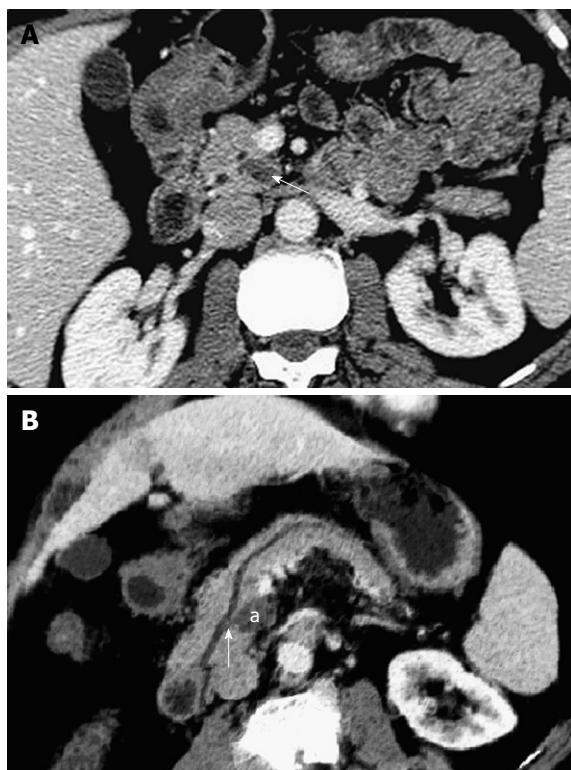

## RESULTS

### Pathologic results

Five patients (5 of 20, 25%) had invasive carcinoma, whereas seven patients (7 of 20, 35%) had a noninvasive carcinoma (including three borderline lesions and four carcinoma *in situ*). Both of these lesions were regarded as malignant in this study. The lesions in the other eight patients (8 of 20, 40%) were classified as benign IPMNs by pathology. Among the 12 malignant IPMNs, two patients had duodenal involvement with one also having vascular involvement, another two patients had regional lymph node metastasis on surgico-pathological examination, and one patient only had vascular involvement.

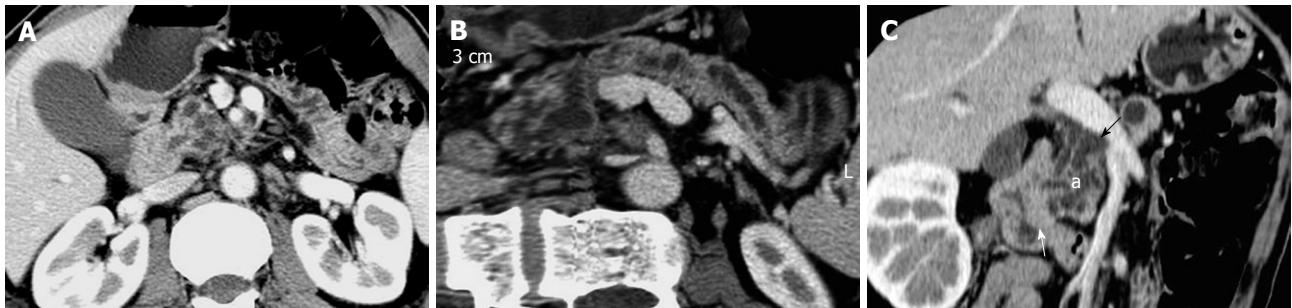

### Imaging features of IPMNs compared with surgico-pathological results

The imaging features of IPMNs at MDCT are summa-

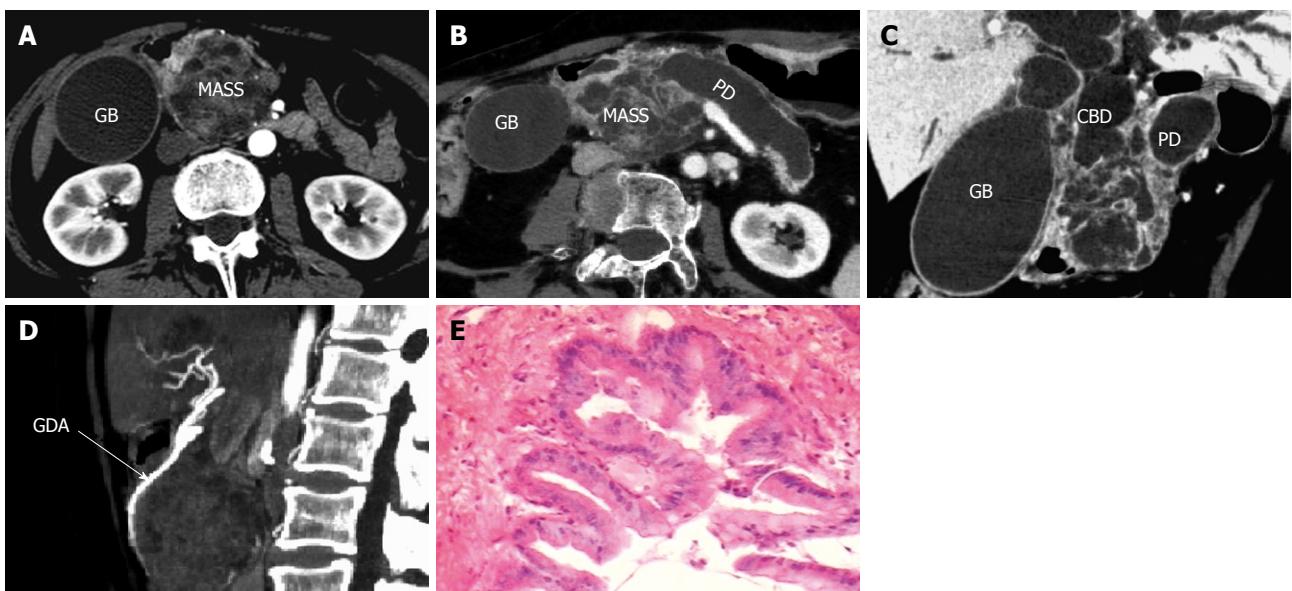

**Figure 1 Pathologically confirmed benign branch-duct-type IPMN in a 47-year-old woman with abdominal discomfort for about 6 mo. A:** There was a 2-cm cystic mass (white arrow) in the uncinate process of the pancreas at the axial abdominal MDCT image; **B:** The cystic mass (a) in the posterior pancreatic parenchyma was demonstrated with a communication (white arrow) between the mass and the main pancreatic duct which was slightly dilated in the curved reformed (CR) image.

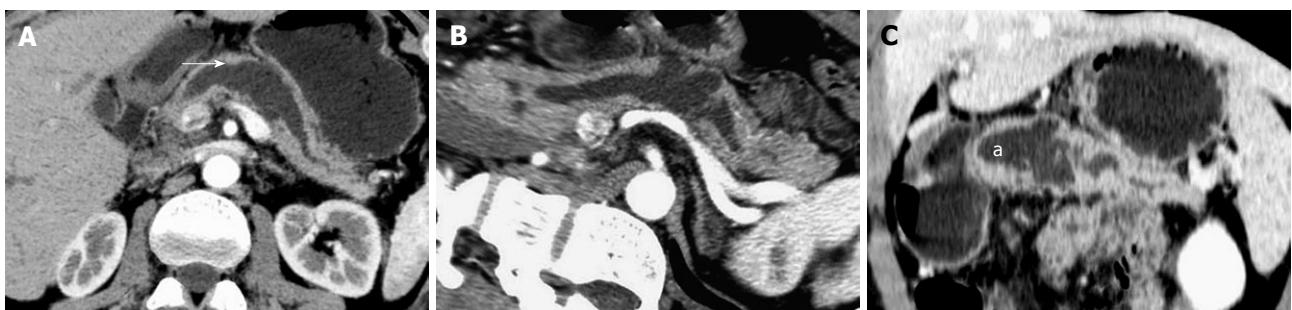

rized in Table 1. The largest diameters of the cystic lesions were 21.6 ± 10.3 mm and 43.5 ± 16.5 mm for benign and malignant IPMNs, respectively. A statistically significant difference has been demonstrated between the sizes of the lesions of benign and malignant IPMNs (*P* < 0.05). The mean diameter of most dilated segments of MPD was 3.3 ± 1.6 mm in patients with benign IPMNs, and 7.5 ± 5.5 mm in patients with malignant IPMNs. The diameter of the MPD was significantly larger in patients with malignant IPMNs compared with that of benign cases (*P* < 0.05) (Figure 1). Based on MDCT findings, five patients (5 of 20, 25%) were classified as branch duct type, three patients (3 of 20, 15%) as main duct type, and 12 patients (12 of 20, 60%) as combined type. With pathognomonic correlation, malignant IPMNs presented in one of the five patients with branch duct type, one of three patients with main duct type, and 10 of the 12 patients with combined type. Significant correlation was shown between the type of ductal involvement and the pathological results. The combined type also had a higher rate of malignancy (*P* < 0.05) (Figure 2). Three combined-type cases had accompanying marked dilatation of the biliary tracts including extrahepatic and intrahepatic bile ducts (Figure 3). The pancreatic head and uncinate process were the most common locations of IPMNs, accounting for 70% (14 of 20). Malignant IPMNs presented in 10 of these 14 patients with an incidence of 83.3% (10 of 12) among all the malignant cases. Only one malignant IPMN identified

**Figure 2 Pathologically confirmed malignant combined-type IPMN in a 41-year-old man with abdominal and back pain for about 2 years.** A: A 4 cm cystic mass with multiple septa arising from the pancreatic head was revealed in the axial MDCT image; B: Besides the cystic mass in the pancreatic head, the profile of the main pancreatic duct, which was severely dilated, was depicted on the CR image; C: The cystic lesion (a) in the pancreatic head invaded the duodenum and main portal vein resulting in the duodenal wall thickening (white arrow) with marked enhancement and irregular narrowing (dark arrow) of the vessel in the multiplanar volume reformation (MPVR) image.

**Figure 3 Pathologically confirmed malignant combined-type IPMN in a 65-year-old man with jaundice and abdominal pain for about 1 year.** A: An 8 cm cystic and solid mass (MASS) was seen in the axial arterio-phased MDCT image with contrast agents. The gallbladder (GB) was distended; B: The heterogeneous mass was shown with severe dilatation of the main pancreatic duct (PD) and the gallbladder (GB) in the CR image; C: The profile of the dilatation of pancreatobiliary system (CBD, common bile duct) was entirely depicted in the MPVR image; D: The gastroduodenal artery (GDA) showed irregularity as a result of infiltration of the tumor; E: The tumor consisted of papillary proliferations of tall columnar mucin-producing epithelium. Atypical epithelium characterized by enlarged nuclei (HE,  $\times 150$ ).

**Figure 4 Pathologically confirmed malignant combined-type IPMN in a 55-year-old man with abdominal pain for 1.5 years.** A: A 3 cm  $\times$  10 cm longitudinally cystic mass in the pancreatic body was shown with a mural nodule (white arrow) in the axial MDCT images; B: The classification of combined type for this case was accurately defined by the CR image; C: The profile of the cystic mass (a) and dilatation of the branch duct and the upstream pancreatic duct were identified in the MPVR images.

by MDCT was located at the body of the pancreas (Figure 4), whereas the IPMNs arising from the pancreatic tail in two cases were both benign and verified by pathology. The other three (3 of 20, 15%) cases had diffuse lesions,

and one of these (33.3%) was malignant. Among 17 branch duct-type and combined-type lesions, mural nodules and thick septa were seen in 12 cases (Figure 4). Ten of these 12 were referred to as malignant IPMNs on pa-

thology. Tumors with mural nodules and thick septa had a significantly higher incidence of malignancy than tumors without them ( $P < 0.05$ ).

No distant metastasis was revealed on MDCT in any of the patients. Vascular invasion was revealed in two patients from CTA images (Figure 2), and was proven by surgico-pathological studies. Lymph node enlargement was seen in three patients on axial CT images, but one was a false-positive when compared with the results of pathological examination. Two patients had duodenal involvement depicted by MPVR images and confirmed by pathological examination (Figure 2), and one of these had vascular involvement. Vascular involvement was also detected in another case. Communication of side-branch IPMNs with the MPD was present in nine cases at pathological examination. Seven of these (77.7%, 7 of 9) were identified from CTA and MPVR images (Figure 1).

From a comparison with the pathological outcomes, the sensitivity, specificity, and accuracy of MDCT in characterizing the malignancy of IPMN of the pancreas were determined to be 100%, 87.5% and 95%, respectively.

## DISCUSSION

After the first report of IPMN in 1982, this tumor entity has been increasingly recognized over the past decades as a result of the markedly improved imaging modalities<sup>[18,19]</sup>. IPMNs mainly occur in the 6th to 7th decades of life, affecting males slightly more frequently than females. IPMNs account for 0.5% of all pancreatic neoplasms found at autopsy, 7.5% of clinically diagnosed pancreatic neoplasms, and 16.3% of surgically resected pancreatic neoplasms<sup>[20]</sup>. The IPMN was histologically defined by the WHO as “intraductal mucin-producing neoplasm with tall columnar mucin-containing epithelium with or without papillary projections, involving the MPD and/or major side branches”<sup>[21]</sup>. The IPMN is also believed by some to follow the so-called “adenoma-carcinoma” sequence<sup>[19]</sup>. Sohn et al<sup>[22]</sup> reported that there appears to be a lag time of approximately 5 years in the progression from adenoma to invasive carcinoma and that progression to invasive carcinoma occurs relatively quickly once moderate dysplasia is found. Kawai et al<sup>[17]</sup> reported that the malignancy rate of IPMNs was 48% while it was 67% in the study conducted by Lopez Hänninen et al<sup>[23]</sup>. In our study, the malignancy rate was 60% (12 of 20). The treatment decision with regard to IPMN is often based on the patient’s age at presentation, the lesion location in the pancreas, the extent of ductal involvement, and also the presence or absence of malignant features<sup>[24]</sup>. Since most of the main duct IPMNs will progress into invasive carcinomas, the resection of main duct IPMNs and mixed variant IPMNs is recommended if the patient is a good surgical candidate with a reasonable life expectancy<sup>[25,26]</sup>. Currently, the cross-sectional imaging studies including MDCT and MRI with MRCP play a crucial role in structuring the treatment protocol for the patients with IPMNs.

Since the MDCT is widely used in clinical practice, more and more IPMNs are detected. Because of the overproduction of mucus, MPD dilatation can occur both proximal and distal to the tumor. In our study,

most (14 of 20) of the IPMNs were located at the head and uncinate process of the pancreas, but there was no statistically significant differences in the distribution of the lesion locations because of the bias resulting from the small size of the patient population in this group. However, the cystic lesions in the pancreatic parenchyma and the diameter of the MPD in malignant IPMNs presented with significantly larger sizes than the benign IPMNs ( $P < 0.05$ ). More combined-type IPMNs were malignant than the other two subtypes ( $P < 0.05$ ). The MDCT features most specific for a malignant IPMN were mural nodules and thick septa inside the lesion (10 of 20) in this group as indicated in the literature<sup>[27,28]</sup>. Thinner-slice reformed CTA and MPVR or CR images showed other malignant signs clearly, including vascular invasion, lymph node enlargement, and duodenal involvement, as well as dilatation of the common bile duct and common hepatic duct (Figure 3). Ogawa et al<sup>[15]</sup> reported that the sensitivity, specificity, and accuracy for identifying malignancy were 83%, 81% and 82% and for identifying pancreatic parenchymal invasion were 90%, 88% and 89%, respectively. According to the International Consensus Guidelines for management of IPMN, the branch duct IPMNs are benign more frequently than the main duct IPMNs<sup>[2]</sup>. The data in this study also complied with this rule. However, compared with the published series from Europe, Japan, and the USA<sup>[9,29-32]</sup>, the main duct IPMN had a lower rate of malignancy (1 of 3) in the present study, whereas the combined-type IPMNs demonstrated malignancy in more cases (10 of 12) on pathology. The sensitivity, specificity, and accuracy of MDCT in characterizing the malignancy of IPMNs were 100%, 87.5% and 95%, respectively. They were a little bit higher than the data in the published literature<sup>[2,15]</sup>. This could be explained possibly by the bias generated by the small number of purely main duct IPMNs and the limited size of the entire patient population in this group. Moreover, because of the limited cases of IPMN recruited in the present study, we considered the noninvasive carcinoma including borderline malignancy and carcinoma *in situ*, and invasive carcinoma together as a malignancy for analysis. On the other hand, this strategy without separation of the noninvasive and invasive carcinoma should be quite reasonable in the clinical context since progression from noninvasive malignancy to invasive carcinoma occurs relatively quickly once moderate dysplasia is found<sup>[22]</sup>. To some extent, the noninvasive carcinoma including borderline malignancy and carcinoma *in situ* should attract as much attention as invasive carcinoma in this setting where even the benign adenoma can progress to carcinoma in only 5 years<sup>[22]</sup>. Therefore, more prospective studies with a big IPMN population are required in order to reveal the more accurate profile of Chinese patients in the future.

Compared with the combined type IPMNs, patients with the branch-duct type IPMN without malignant features can be managed by follow-up examinations instead of surgery, particularly when the patient refuses surgery, or when the patient is in poor condition with other severe concomitant disease<sup>[33]</sup>. Thus, the imaging

modalities such as MDCT could be valuable in deciding whether the patient should undergo surgery or follow-up in most cases. The presence of communication of the pancreatic cystic lesion with the MPD is one of the most reliable findings for the diagnosis of branch duct IPMN<sup>[34]</sup>. With routine transverse CT scanning of the pancreas, the communicating duct is not easily seen. MPVR or CR images can markedly increase the chance of identification of the interaction.

Normally, IPMNs have a better outcome and prognosis compared to pancreatic ductal adenocarcinomas. The overall 5-year survival rate has been reported to exceed 80% for noninvasive IPMNs and 50% for the invasive malignant IPMNs<sup>[19]</sup>. Therefore, correct evaluation of IPMN is extremely important as a recent analysis has suggested that this entity is one of the few surgically curable pancreatic neoplasms<sup>[18]</sup>. Prior investigations showed MRI with MRCP was useful for assessment of IPMN as a noninvasive approach<sup>[23,35,36]</sup>. However, its spatial resolution is not as high as that of CT. Moreover, MDCT scanning is fast enough to acquire all necessary imaging data during a single breath-hold in which much thinner sliced images can be generated. It is less subject to respiratory motion and partial-volume effects than MRI<sup>[37,38]</sup>. Since most of the patients are elderly, the abovementioned characteristics of MDCT seem to be important for patients with IPMNs. With CTA and MPVR or CR images using 3D or 2D modes in different planar directions, MDCT can show the lesion itself, the surrounding structures, and the nearby vessels, as well as the bile duct during one set of CT scans. The reformed images of bile ducts were similar to the MRCP image (Figure 3). Dilatation of the bile ducts and the enlarged gallbladder could be clearly depicted. With the postprocessing techniques, CTA and MPVR or CR images can be generated with more details about the IPMN and the surrounding parenchyma or adjacent vessels.

In conclusion, MDCT scanning with CTA and MPVR or CR techniques can help predict malignant IPMN by differentiating the various types of ductal involvement and demonstrating the mural nodules and thick septa of the lesion, the MPD dilatation of the combined subtypes, the size of the cystic lesion as well as the involvement of surrounding structures. MDCT can be referred to as the diagnostic tool of choice for accurate evaluation of IPMN before treatment.

## COMMENTS

### Background

Intraductal papillary mucinous neoplasm (IPMN) mainly occurs in the 6th to 7th decades of life, affecting males slightly more frequently than females. IPMN accounts for 0.5% of all pancreatic neoplasms found at autopsy, 7.5% of clinically diagnosed pancreatic neoplasms, and 16.3% of surgically resected pancreatic neoplasms. The increasingly common use of imaging techniques has contributed to the identification of an increasing number of the lesions, even in entirely asymptomatic cases.

### Research frontiers

Accurate preoperative evaluation of an IPMN is extremely important for the clinician involved in the diagnosis and further evaluation and intervention, as it is one of the few surgically curable pancreatic neoplasms. However, main duct and combined type IPMNs are more likely to be malignant with biological aggressiveness. A noninvasive imaging approach is the tool of choice for

assessing an IPMN of the pancreas preoperatively and can provide accurate information for planning treatment protocols. Although magnetic resonance imaging with magnetic resonance cholangiopancreatography is referred to as the best imaging modality to outline the gross appearance of IPMNs, computed tomography (CT) is still the mainstay in evaluation of patients with IPMNs of the pancreas. Moreover, multi-detector row CT (MDCT) scanning is fast enough to acquire all the necessary imaging data during one single breath-hold in which much thinner sliced images can be generated for reformations.

### Innovations and breakthroughs

There is limited published literature concerning the prediction of malignancy of IPMNs of the pancreas. In this series, the combined-type IPMNs had a higher rate of malignancy than the other two types of IPMNs ( $P < 0.05$ ). The diameters of the cystic lesion and main pancreatic duct (MPD) were significantly larger in malignant tumors compared with those of benign IPMNs ( $P < 0.05$ ). Tumors with mural nodules and thick septa had a significantly higher incidence of malignancy than tumors without these features ( $P < 0.05$ ). In comparing with the pathological results, the sensitivity, specificity, and accuracy of MDCT in characterizing the malignancy of IPMN of the pancreas were determined as 100%, 87.5% and 95%, respectively. The imaging findings were predictive of the malignancy of the IPMNs.

### Applications

Based on their research, MDCT scanning with CT angiography (CTA) and MPVR or CR techniques can help predict malignant IPMN by differentiating the various types of ductal involvement and demonstrating the mural nodules and thick septa of the lesion, the MPD dilatation of the combined subtypes, the size of the cystic lesion as well as the involvement of surrounding structures. MDCT can be referred to as the diagnostic tool of choice in accurate evaluation of IPMN before treatment.

### Terminology

IPMN: histologically defined by the World Health Organization as an "intraductal mucin-producing neoplasm with tall columnar mucin-containing epithelium with or without papillary projections, involving the MPD and/or major side branches"; MDCT: multiple detectors applied to CT. This modality can improve the scanning speed and spatial resolution dramatically. Furthermore, MDCT is intrinsically suitable for CTA scanning.

### Peer review

The authors evaluated the predictive factors for the presence of malignancy associated with IPMN based on their own data. It is well organized and an overall theoretical analysis is given. The conclusions are scientifically reliable and valuable.

### Abstract

**AIM:** To evaluate the safety and long-term prognosis of conservative resection (CR) for benign or borderline tumor of the proximal pancreas.

**METHODS:** We retrospectively analyzed 20 patients who underwent CR at the Second Affiliated Hospital of Zhejiang University School of Medicine between April 2000 and October 2008. For pancreaticojejunostomy, a modified invagination method, continuous circular invaginated pancreaticojejunostomy (CCI-PJ) was used. Modified continuous closed lavage (MCCL) was performed for patients with pancreatic fistula.

**RESULTS:** The indications were: serous cystadenomas in eight patients, insulinomas in six, non-functional islet cell tumors in three and solid pseudopapillary tumors in three. Perioperative mortality was zero and morbidity was 25%. Overall, pancreatic fistula was present in 25% of patients. At a mean follow up of 42.7 mo, all patients were alive with no recurrence and no new-onset diabetes mellitus or exocrine dysfunction.

**CONCLUSION:** CR is a safe and effective procedure for patients with benign tumors in the proximal pancreas, with careful CCI-PJ and postoperative MCCL.

### INTRODUCTION

Pancreaticoduodenectomy (PD) and distal pancreatectomy (DP) are standard operations for tumors located in the proximal portion of the pancreas. However, these standard techniques are associated with a significant risk of long-term endocrine and exocrine impairment. Recently, there has been increased interest in conservative surgery in an attempt to preserve as much as possible the pancreatic parenchyma and integrated upper digestive system anatomy. For patients with benign or low-grade malignant tumors, conservative resection (CR) such as central pancreatectomy or enucleation has been investigated to maintain the normal upper digestive system anatomy, and to reduce the risk of development of exocrine and endocrine functional insufficiency. Although CR of the proximal pancreas may be more appropriate and less time-consuming, it has not been used widely previously because of its high morbidity, especially pancreatic fistula. The focus of this study was to evaluate the safety and outcomes of CR for benign or borderline tumors of the head, neck and proximal part of the pancreas.

### MATERIALS AND METHODS

Twenty patients with benign or borderline tumors

localized in the head, neck and proximal part of the pancreas, who were treated with central pancreatectomy ( $n = 11$ ) and enucleation ( $n = 9$ ), between April 2000 and October 2008, were analyzed retrospectively. Data on preoperative, intraoperative and postoperative care were collected and maintained on a secure database. Preoperative parameters included demographics, clinical presentation, and exocrine and endocrine evaluation. Preoperative imaging modalities such as abdominal spiral contrast CT and ultrasound imaging were used to evaluate the suitability for surgical resection in all cases. Intraoperative details including operative time, total blood loss, transfusion and the method of surgery were recorded. Postoperative events and clinical outcomes such as surgical complications, mortality, pathological data and long-term follow-up were recorded carefully.

Postoperative pancreatic fistula was defined as drainage of  $> 50$  mL per 24 h of fluid, with amylase content  $> 3$  times serum amylase activity for  $> 10$  d after operation<sup>[1,2]</sup>. Perioperative mortality was defined as death in the hospital or within 30 d. Delayed gastric emptying (DGE) was defined to be present when nasogastric intubation was maintained for  $\geq 10$  d, combined with at least one of the following: vomiting after removal of the nasogastric tube, reinsertion of nasogastric tube, or failure to restore oral feeding<sup>[3]</sup>. Fasting glucose blood level was used for the diagnosis of new-onset diabetes<sup>[4]</sup>. Exocrine insufficiency was defined as steatorrhea and weight loss requiring pancreatic enzymes supplementation.

### Indications for CR of the pancreas

CR was indicated for benign or low-grade malignant lesions localized in the proximal pancreas, especially in young patients. Simple enucleation was used when the tumor was near or at the surface of the pancreas. Great care had to be taken to avoid the main pancreatic duct injury and obtain complete excision during surgery, otherwise central pancreatectomy was chosen. Central pancreatectomy was indicated when the tumor was deeply embedded in the pancreatic parenchyma without clear margin, and was not suitable for enucleation. The distal remnant of the pancreas was kept at least 5 cm in length.

### Surgical technique for central pancreatectomy

Central pancreatectomy was performed as reported previously<sup>[5-7]</sup>. After transecting the pancreas by electrocautery to the left and right of the tumor, the main pancreatic duct was ligated using a 3-0 silk suture, and the proximal pancreatic stump was oversewn with 3-0 polypropylene in a continuous running fashion. Reconstruction of the distal pancreatic remnant was accomplished with a retrocolic Roux-en-Y pancreaticojejunostomy. For pancreaticojejunostomy, a modified invagination method, continuous circular invaginated pancreaticojejunostomy (CCI-PJ), was used. The remnant of the pancreas was dissected for about 1-3 cm from the cut edge, and several small veins running between the pancreas and the splenic vein

had to be divided and ligated. The pancreatic stump was invaginated into the jejunum, and a single-layer continuous circular anastomosis with 3-0 polypropylene was performed between the full thickness of the resected jejunum and the body of the pancreas. The largest silicon stent that could be passed into the main pancreatic duct was used in all these patients. Finally, four 24-F drainage catheters were placed near the pancreatic anastomosis.

### Postoperative management

Antibiotics were used prophylactically for 5 d after operation, but octreotide was not used routinely. Parenteral nutrition and early enteral feeding were administered. Enteral feeding usually began gradually on postoperative day 3. The fluid from the drain tube placed near the pancreatic anastomosis was monitored routinely for volume and amylase level. For those patients with pancreatic fistulas, modified continuous closed lavage (MCCL) was performed as reported in our previous study<sup>[8]</sup>. A long 6/8-F silicon tube was inserted into each of the 24-F drainage catheters and pulled out from the lateral part of the catheter about 3-5 cm to the external end. The drainage catheter was connected with a drainage pack. A high volume (20-50 L/d) of normal saline was infused through the silicon tube and eventually ran out into the drainage pack through the same rubber catheter. The lavage volume and duration was adjusted according to the appearance and quality of the outflowing liquid.

### Statistical analysis

Results are presented as mean  $\pm$  SD. Statistical analysis was performed using SPSS version 15.0 statistical software. Student's *t* test was used for comparison of two independent samples. Categorical variables were compared using the  $\chi^2$  or Fisher exact test.  $P < 0.05$  was considered statistically significant.

## RESULTS

The characteristics of CR patients are summarized in Table 1. Eight patients had serous cystadenoma, six had insulinoma, three had solid pseudopapillary tumors, and three had non-functional islet cell tumors. Each tumor was resected with clear margins, as determined by intraoperative frozen section and confirmed by final pathological examination. Mean tumor diameter was 2.9 cm (range 0.8-10.0 cm). Mean operating time was 236.5 min (range 75-405 min). The mean intraoperative blood loss was 350 mL (range 100-1200 mL). Three patients (15%) required intraoperative blood transfusion. The mortality was zero and morbidity was 25%. Overall occurrence of pancreatic fistula was 25% and DGE was 20%. Compared with 12 cases of PD for benign tumors in the proximal pancreas during the same period in our hospital, the characteristics did not differ significantly between the two groups. The mortality was zero and the morbidity was 25% in both groups.

It should be pointed out that, among five cases of

CR: Conservative resection; DGE: Delayed gastric emptying.

fistula from 20 CR operations, there were two from nine enucleations and three from 11 central pancreatectomies. Fistula after enucleation usually healed within 7-15 d, by multiple drainage without special intervention. However, in one case of enucleation for a 10-cm solid pseudopapillary tumor located at the head of the pancreas, a small rupture in the main pancreatic duct was found during surgery, and it was repaired by primary suturing with 5-0 polypropylene. The volume of drainage came up to > 1 L/d at the early stage after operation. With MCCL, the fistula healed 15 d later. In the three fistulas from 11 central pancreatectomies, two cases presented with clinically significant pancreatic fistulas that required further medical intervention (Table 1).

After a postoperative follow up of 42.7 mo (range 6-100 mo), all patients were alive without tumor recurrence. No patients developed new-onset diabetes mellitus. However, two cases of new-onset diabetes developed in the PD group. None experienced clinical exocrine insufficiency or required pancreatic enzyme supplements, and three patients needed exocrine substitution in the PD group. Exocrine function of the pancreas was better preserved in the CR than PD group ( $P < 0.05$ ).

## DISCUSSION

For tumors located in the head, neck and proximal pancreas, standard or extended pancreatectomy, such as PD, DP and extended DP, which involves resection of a notable amount of normal parenchyma, has been indicated for benign lesions. It has been reported that the rates of new-onset diabetes mellitus and exocrine insufficiency after PD were 10%-40% and 22%-60% respectively<sup>[7,9-12]</sup>. Previous reports have shown that 72% of patients became insulin dependent after subtotal left pancreatectomy, whereas 85%-95% resection caused diabetes in all patients<sup>[13,14]</sup>. Besides pancreatic parenchyma, the integrated upper digestive and biliary anatomy also plays a key role in maintaining consequent digestive, immunological and coagulative function and neurohormonal regulation of insulin activity<sup>[15]</sup>. In addition, Reid-Lombardo *et al*<sup>[16]</sup> have reported that the 5- and 10-year cumulative probability of biliary stricture after PD for benign lesions was 8% and 13%; that is why, in recent years, CR, such as central pancreatectomy and enucleation, has been investigated with great interest. In the present study, with a mean of 42.7 mo follow-up, there was no new-onset diabetes mellitus

<sup>1</sup>Central pancreatectomy; <sup>2</sup>Thirty two central pancreatectomies and 14 enucleations; <sup>3</sup>Twenty one central pancreatectomies and 15 enucleations.

and pancreatic exocrine insufficiency, which is the same as previously reported<sup>[17-23]</sup>. Moreover, in our study, the mean age of patients was only 45.3 years old. For these young patients with benign pancreatic disease, CR might be much more significant in achieving good quality of life, because CR can avoid long-term anastomotic complications and pancreatic insufficiency.

However, conservative pancreatectomy has not been used widely to date because of its high morbidity rate, especially pancreatic fistula. It has been reported that the morbidity rate of CR ranged from 35% to 63% (Table 2), which is much higher than that for PD and DP<sup>[6,7,22-25]</sup>. In our study, the morbidity rate of CR was 25%. Overall pancreatic fistula rate was 25%, and DGE rate was 20%.

The pancreatic fistula rate in our study was a little better than that reported since 2000 (Table 2), which has ranged from 30% to 63%<sup>[6,7,22-25]</sup>. In our study, although fistula developed in five of 20 patients, only two with clinically significant fistula required further intervention. According to our experience here, CCI-PJ and efficient MCCL might be responsible for lower morbidity in CR. With CCI-PJ, the stump of the pancreas and the cut edge of the jejunum could be connected closely with polypropylene sutures, which were used for anastomosis of the blood vessels. After postoperative pancreatic fistula has been diagnosed clinically, postoperative MCCL with a high volume of normal saline (20-50 L/d) was necessary to control the pancreatic fistula effectively. The advantage of MCCL compared with general lavage is that there was no concern about the imbalance between ingoing and outgoing fluids because the small silicon tube for irrigation was placed at the tip of the large catheters for outgoing fluid. With MCCL, most patients with pancreatic fistula recover without further surgical intervention.

In conclusion, CR for benign or borderline tumors of the proximal pancreas could be performed safely with careful CCI-PJ and postoperative MCCL. It is useful for preserving long-term pancreatic function.

## COMMENTS

### Background

In recent years, there has been a marked increase of incidentally discovered benign or borderline tumor of the pancreas using advanced diagnostic imaging techniques. The resection of benign lesions located in the proximal portion of

the pancreas traditionally has been accomplished by pancreaticoduodenectomy and distal pancreatectomy. These extended resections result in removal of normal pancreatic tissue, which increased the risk of loss of exocrine and endocrine function.

### Research frontiers

Conservative pancreatic resection including pancreatic enucleation and central pancreatectomy has evolved as a means of preserving as much as possible the pancreatic parenchyma and integrated upper digestive system anatomy. In the present study, the authors evaluated the safety and long-term prognosis of patients who underwent conservative resection (CR) for benign or borderline tumors of the proximal pancreas.

### Innovations and breakthroughs

CR for benign or borderline tumors of the proximal pancreas could be performed safely with careful continuous circular invaginated pancreaticojejunostomy and postoperative modified continuous closed lavage (MCCL). It is effective for preserving long-term pancreatic function.

### Applications

CR is a safe and reasonable technique for benign tumors or lesions of low malignant potential in the proximal pancreas. To obtain good results, careful patient selection and experience in pancreatic surgery are of paramount importance in this setting.

### Terminology

Central pancreatectomy, also known as middle pancreatectomy, is a segmental resection of the pancreas. Dagradis and Serio performed the first central pancreatectomy with an oncological indication in 1984. The main advantage of this operation is that it permits preservation of most of the pancreatic parenchyma, extrahepatic bile duct, duodenum, and spleen.

### Peer review

The article is well written and demonstrates the results of CR of benign tumor of the proximal pancreas. CR is a procedure that offers benefits for benign and low-grade malignant pancreatic tumors, because it allows preservation of endocrine and exocrine functions. A lower risk of typical postoperative complications following pancreatectomy is especially important in young patients, which is stressed by authors of this study. A presented method (MCCL) of management in patients with pancreatic fistula may be useful for other researchers.

change in liver pathology. The volume of the spleen was enlarged 2-fold after ligation, and the sinus of the spleen was enlarged due to congestion. Significant sinus endothelial cell proliferation was observed, but no evidence of hypersplenia was found on hemogram and biochemical examination.

**CONCLUSION:** These findings suggest that a satisfactory prehepatic PHT rat model can be obtained by partial ligation of the portal vein, and this PHT rat model was stable for at least 10 wk.

## Abstract

**AIM:** To study the stability of portal hypertension (PHT) caused by partial ligation of the portal vein ligation (PVL) in a rat model.

**METHODS:** Thirty male adult Wistar rats were divided into two groups: 10 in Group I received a sham operation; and 20 in Group II received partial PVL. Portal vein pressure (PVP) was measured at four time periods: before ligation, 2 wk, 6 wk and 10 wk post-surgery. Portal venography, blood sampling and liver and spleen pathological examinations were conducted at 10 wk after surgery.

**RESULTS:** The PVP was  $9.15 \pm 0.58$  cmH<sub>2</sub>O before ligation, and increased to  $17.32 \pm 0.63$  cmH<sub>2</sub>O 2 wk after PVL. By repeat measurement of the PVP in each rat, it was shown to remain elevated for 10 wk. There were no significant differences in the pressure measurements at 2 wk, 6 wk and 10 wk. Varices were found mainly in the mesenteric vein 2 wk after PVL, which were more obvious later, while these manifestations were similar at week 6 and week 10. Portal venography demonstrated the varices and collaterals. There was no significant

## INTRODUCTION

A rat model of prehepatic portal hypertension (PHT) produced by partial portal vein ligation (PVL) is an important tool in studying PHT. The PVL model has been used to study alterations in the splanchnic circulation and in the pathophysiology of the hyperdynamic circulation after ligation<sup>[1,2]</sup>. However, from the literature almost all of these studies were carried out around 2 wk after PVL; and are rarely reported beyond this time period. It is suspected that elevated portal vein pressure (PVP) can last for a longer period of time. The aim of this study was to determine the stability of artificially elevated PVP using rigidly controlled experiments. Furthermore, we used this

model to evaluate the effect of a newly designed splenohepatopexy in PHT treatment.

## MATERIALS AND METHODS

Thirty male Wistar rats weighing 280–320 g (average 302 g) were kept under temperature controlled conditions and an artificial 12-h light-dark cycle. They were allowed standard chow and water *ad libitum*. All animals and procedures were approved by the Ethics Committee of the Animal Experiment Center of Capital Medical University.

Animals were randomized into two groups: Ten rats in Group I had a sham operation; and twenty rats in Group II had partial portal-vein ligation. PVP was measured at four time periods: before ligation, 2 wk, 6 wk, and 10 wk after surgery. Portal venography was performed in rats at 10 wk. Other parameters measured included: weight and volume of spleen, hemogram, biochemical parameters and pathologic examination of the liver and spleen.

### Model establishment

Animals were anesthetized with intramuscular administration of 2% pentobarbital solution. The model was established according to Harvoldsen and Myking<sup>[3,4]</sup>. A 1.5 cm midline incision was made and the portal vein was exposed. The diameter of the portal vein was measured by Vernier calipers at the point where the ligation would be carried out. A No.4 silk thread was placed around the portal vein together with a pre-placed 21G blunt-tipped needle lying along the portal vein. By tying the ligature snugly beyond the left gastric vein, and then pulling out the needle, a stenosis of the portal vein with a constriction corresponding to the thickness of the pre-placed needle was left behind.

### PVP measurement

After anesthesia, a midline incision was made. A segment of the mesenteric branch vein was cannulated with a 24-g cannula needle, and the tip of the cannula was advanced just into the trunk of the superior mesenteric vein. The PVP was recorded, *via* a pressure transducer, by the BL-420E+ biophysical function experiment system (manufactured by Taimeng Technology Limited Company, Chengdu, China). Pressure measurement lasted for 3 min, and the average value was regarded as the PVP. To maintain stable anesthesia, the measurement was started 20 min after the injection of pentobarbital.

### Portal venography

A midline incision was made after anesthesia; the ileocolic vein was cannulated with a 20-g cannula, and the tip of the cannula was advanced into the lower part of the portal vein just above the entrance to the splenic vein. Seventy-six percent meglumine diatrizoate was injected at a speed of 2 mL/5 s, and the intrahepatic and extrahepatic portal vein system could be seen.

### Blood samples and liver, spleen pathological examination

At week ten, blood samples from the rats were obtained

**Table 1 PVP changes (cmH<sub>2</sub>O), (mean ± SD)**

Groups	wk-0	wk-2	wk-6	wk-10
G- I (SO, n = 10)	9.15 ± 0.58	9.22 ± 0.49	9.27 ± 0.43	9.21 ± 0.49
G- II (PVL, n = 16)	9.21 ± 0.63	17.32 ± 1.77 <sup>a</sup>	17.36 ± 1.93 <sup>a,b</sup>	16.82 ± 2.20 <sup>a,b</sup>

Portal vein pressure (PVP) changes at four time periods were compared. <sup>a</sup>P < 0.001 vs value of G- I ; <sup>b</sup>P < 0.001 vs value of wk-2 in G- II. wk-0: before ligation; wk-2, wk-6, wk-10: 2 weeks, 6 weeks and 10 weeks post-surgery, respectively.

for hemogram and biochemical examination. Both liver and spleen biopsy were taken for pathological examination, (using Hematoxylin-eosin staining). The rats were sacrificed at the end of the experiment.

### Statistical analysis

The data were expressed as mean ± SD. Repeated analysis of variance was used to compare the differences between groups by SPSS 11.5 software. Values of P < 0.05 were considered significant.

## RESULTS

### Constriction rate of the portal vein

The average diameter of the portal vein before ligation was 2.40 ± 0.18 mm, and the outer diameter of the 21-g needle was 0.80 mm. According to the formula, the constriction rate = (1 -  $\Delta r^2 / \Delta R^2$ ) × 100%<sup>[5]</sup> = 88.9%.

### Survival rate of animals

None of the rats in Group I died, while 4 rats in Group II died after PVL. The survival rate was 80% (16/20). Three rats died within 24 h of ligation, the other rat died between 24 and 48 h after surgery. Autopsy found severe congestion of the mesenteric and splenic veins, as well as marked cyanosis of the gut and spleen. No mortality occurred after this period.

### PVP

Partial ligation of the portal vein resulted in an immediate increase in PVP up to 25–30 cmH<sub>2</sub>O. Two weeks after surgery, PVP dropped to about 17.32 cmH<sub>2</sub>O, which was about twice the value of the control (P < 0.01). The pressure at week 6 and week 10 was maintained at a similar level, with no significant difference compared with the value for week 2. PVP in Group II was significantly higher than that in Group I. (Table 1 and Figure 1).

### Varices and collateral circulation after PVL

**Gross observations:** In Group I, in the mesenteric vein, there was no distortion, no varices and no visible collaterals. In Group II, in the mesenteric and gastric veins, varices were found mainly in the mesenteric vein 2 wk after PVL, and collaterals could be seen mainly between the spleen and left kidney. The left adrenal vein was markedly engorged. Collaterals could also be seen between the inferior mesenteric vein and the posterior peritoneum (Figures 2 and 3). Collateral

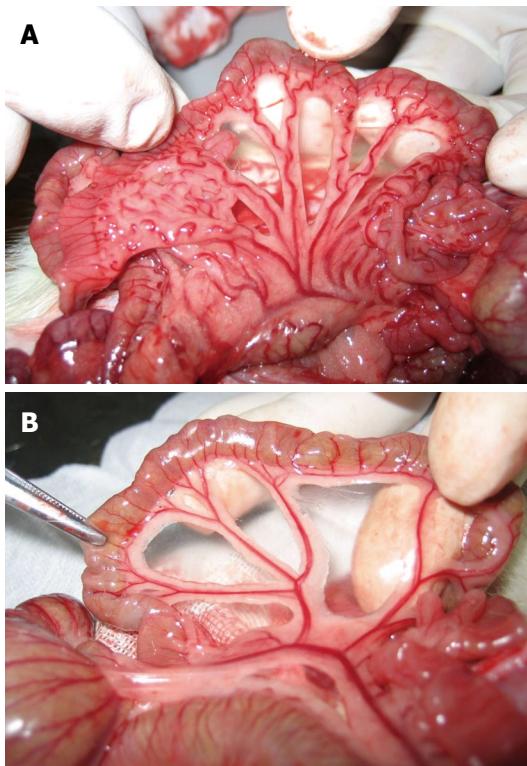

Figure 2 Changes in the mesenteric vein. A: There was no distortion, no varices, no visible collaterals in the mesenteric vein before portal vein ligation; B: Varices were found mainly in the mesenteric vein 2 wk after portal vein ligation.

vessels were found in the porta hepatis in some rats. These manifestations were more obvious later, and were similar at week 6 and week 10. The spleen was markedly enlarged 2 wk after surgery with some white fibrin deposits on the splenic capsule.

#### Portal venography

**Group I:** An angiographic study revealed normal mesenteric and portal vein image patterns in control rats. The intrahepatic portal vein was shown as tree twig branches. There was only a little contrast medium in the mesenteric vein and the splenic vein. After ligation of the portal vein, images of the superior and inferior mesenteric veins and the splenic vein appeared simultaneously, but no collateral circulation could be seen (Figure 4).

**Group II:** At week 10, portal venography showed the mesenteric vein with varices and collaterals, and a lot of

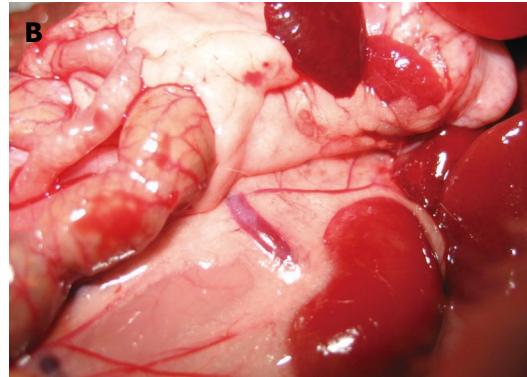

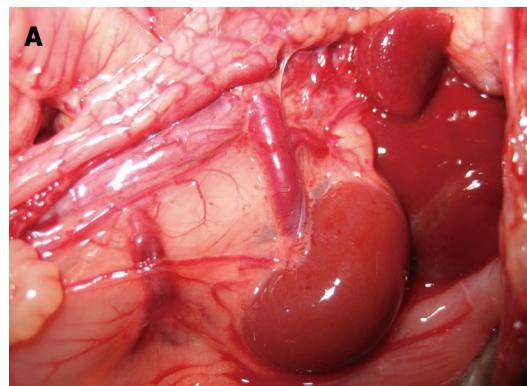

Figure 3 Collaterals after PVL. A: In the control rat, the left renal vein was thin and of normal size, no collaterals could be seen between the spleen and the left kidney; B: Collaterals could be seen mainly between the spleen and the left kidney 10 wk after PVL. The left adrenal vein was markedly engorged. The collaterals could also be seen between the inferior mesenteric vein and the posterior peritoneum.

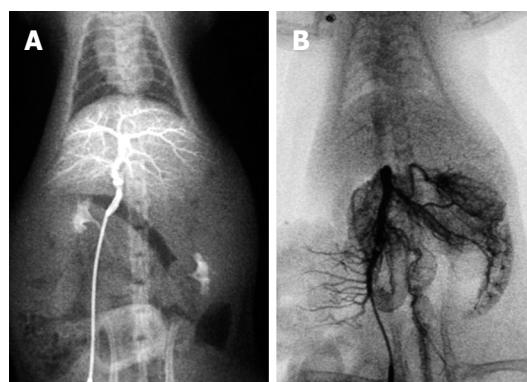

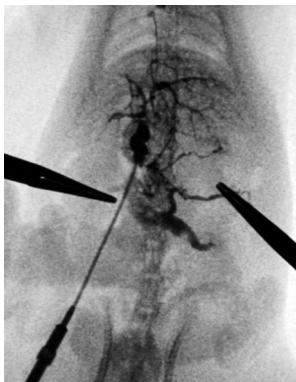

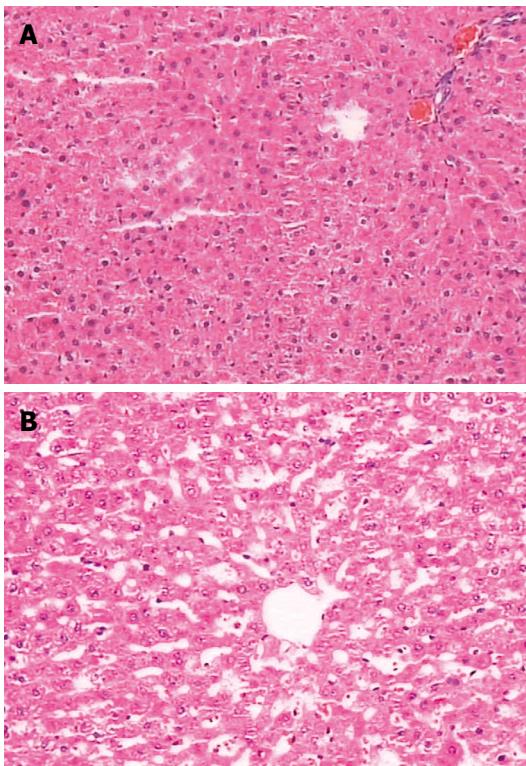

Figure 4 Portal venography in control rat. A: The intrahepatic portal vein was shown as tree twig branches. the contrast medium was seen in the vena cava, which indicated the establishment of the collateral circulation. These observations were not seen in the control rats. Following PVL, the left adrenal vein was clearly seen and had an enlarged diameter, while this vein was not seen in the control group. On continuous observation, some contrast medium was seen in the portal vein system which diffused via the left adrenal vein into the left renal vein and the vena cava. Additionally, collateral vessels between the inferior mesenteric vein and the

**Figure 5** At week 10, portal venography showed the mesenteric vein with varices and collaterals. A lot of contrast medium was seen in the vena cava, which indicated the establishment of the collateral circulation. These observations were not seen in the control rats. The left adrenal vein after PVL was clearly shown with an enlarged diameter, while this vein was not seen in the control group.

**Figure 6** There were no significant changes in liver pathology. A: Pathologic image of rat in Group- I ; B: Image of Group- II .

posterior peritoneum were also seen in the angiograph. No obvious esophageal varices were found. Contrast medium in the liver decreased significantly (Figure 5).

#### Splenic volume

The splenic volume was slightly increased when the weight of the animal increased in Group I , and was almost twice the original size in Group II after PVL. The difference in volume in Group II was significantly different from that in Group I ( $P < 0.01$ ) (Table 2).

#### Hemogram and biochemical parameters

There were no significant differences between Group I and II in hemogram and biochemical parameters. No evidence of hypersplenia was found.

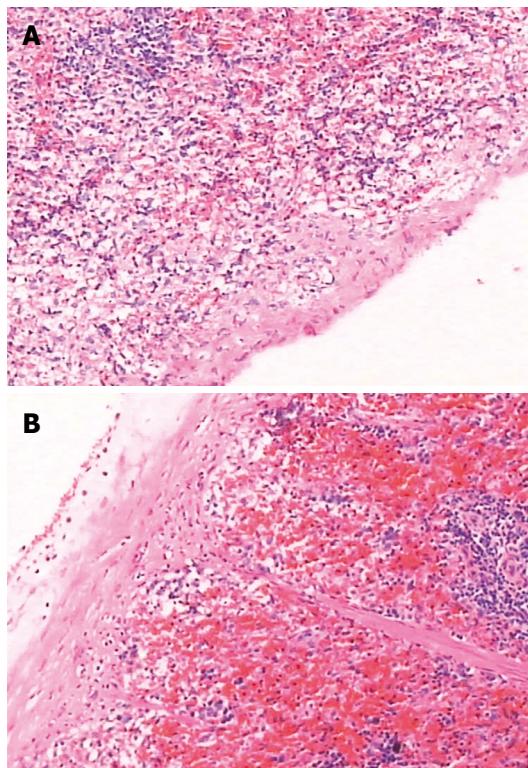

#### Pathology study

There was no significant change in liver pathology. The

## DISCUSSION

The rat model of PHT produced by partial PVL is an important tool in studying PHT. It is fast, economic, simple and repeatable. Some authors have applied the model to the study of alterations in splanchnic circulation and the pathophysiology of the hyperdynamic circulation<sup>[1]</sup>. However, most of these studies were short-term experiments, which were carried out 2-3 wk after ligation. There are few reports of long-term experiments, two months or more after ligation. Some authors even doubt the long-term stability of the model, and are concerned that PVP will drop to the normal level due to establishment of the collateral circulation. For experiments on the surgical treatment of PHT,

such as spleno-hepatopexy, a long-term stable model is needed. The aims of the present study were to prove the stability of the PHT rat model under rigidly controlled experimental conditions, and to prove that this model is suitable for evaluating the effect of our newly designed spleno-hepatopexy for PHT treatment. For spleno-hepatopexy, a peripheral cut on the surface of the spleen and the same on the liver are made which adhere together, it is hoped that the high pressure blood in the spleen will diffuse into the liver through the collateral circulation instead of porto-systemic venous shunting to allow detoxification of the liver.

In our experiment, the PVP value before ligation and in control animals was within the same range as that found by other investigators<sup>[4,6,7]</sup>. The establishment of a partial PVL resulted in instant congestion in the portal vein system, and the PVP immediately increased to 25-30 cmH<sub>2</sub>O. At week 2 after surgery, following compensation by the animal itself, the pressure dropped to about 17 cmH<sub>2</sub>O. In subsequent observations from week 2 to week 10, the elevated PVP value was maintained at the increased level of about 17 cmH<sub>2</sub>O, which was about twice the level before ligation.

Several factors affected the results of these experiments. The portal vein constriction rate is a critical factor in rat survival in the PHT model. After complete portal vein ligation, the portal vein system was suddenly blocked, and this resulted in a serious blood deficiency in the circulation, and the rat died within one hour. For partial ligation, the survival rate following PVL was positively related to the constriction rate<sup>[4]</sup>. We obtained different constriction rates by using different-sized needles. With a 26-g (diameter = 0.45 mm) or a 23-g needle (diameter = 0.6 mm), all the rats died within 1-2 h after ligation. Using a 22-g needle (diameter = 0.7 mm), mortality was about 80%, which was obviously not acceptable for these experiments. Using a 21-g needle (diameter = 0.8 mm), the constriction rate was 88.9%, and the mortality dropped to 20%-30%, and was acceptable for this model of PTH. By decreasing the constriction rate using a 19-g needle (diameter = 1.0 mm), the survival rate was increased, but the PVP did not reach an ideal level to meet the experimental demand.

Constriction of the portal vein resulted in increased resistance in the portal vein, and therefore increased PVP. The resistance of the portal vein was mainly determined by the constriction rate of the portal vein in the experiment. Other factors such as the thickness of the thread were also important. We tried different sizes of thread in our preliminary experiments, including 3-0, 1-0 and No.1, No.4 and No.7 silk. For thin thread less than No.1, the PVP was unstable, and the pressure was usually low, because the resistance of a tube is positively related to the obstructive length. However, for thread thicker than No.7 silk, it was difficult to make a tight knot on such a small portal vein of nearly 1.0 mm. Eventually, we selected the No.4 thread and obtained satisfactory results. Some authors use triple-ligation on the portal vein to obtain the PVL model. Additionally, right ligation against the portal vein axis is also quite

important. The strength used for ligation is important and should be the same in every experiment. Too much strength could damage the portal vein, which may result in thrombosis, while too little strength would be too loose and inaccurate for standard constriction. Cleaning the surrounding tissue next to the portal vein is also useful to reduce errors in constriction diameter.

There have been different reports on the PVP level after PVL. Orda *et al*<sup>[8]</sup> induced PVL in a rat model with an elevated pressure for 2-3 wk, which then dropped to normal. This was thought to be due to a large amount of collateral circulation formation. Cantly<sup>[9]</sup> summarized the previous experience and thought that simple ligation or application of a meroid constrictor to the portal vein could only maintain a high pressure for 4-6 wk. He designed a method of using the ameroid constrictor accompanied by portal lymph node ligation, and hence a high portal pressure could be maintained for about 12 months. Myking *et al*<sup>[3]</sup> and Halvorsen *et al*<sup>[7]</sup> performed serial experiments on the PVL rat model, and successfully elevated PVP for 12 mo after simple ligation, and was considered a stable and repeatable rat model.

The difference in results in the literature might be due to multiple factors, e.g. the animal strain and body weight. In a very low weight rat, a stable elevated pressure is difficult to maintain<sup>[3]</sup>. With regard to the constriction rate, this might be influenced by the size of the needle, the thickness of the thread, and the design of the experiments.

In the PVL model of Myking and Halvorsen<sup>[3,7]</sup>, only one pressure measurement was carried out for each rat. In our experiment, four measurements were carried out for each rat. By this method, we could observe the PVP changes in every rat, which was much more accurate and reliable than a single measurement. Following surgery, there was little adhesion in the rat abdominal cavity except at the local area of ligation or puncture. Because the mesenteric vein branch can be used repeatedly, multiple measurements were possible for each rat.

The peak PVP level after PVL was usually 24 h post-surgery<sup>[10]</sup>. Under natural compensation, the collateral circulation is established to release the high pressure. It was proved that the collateral circulation could be observed two days after PVL, and was fully established 3-4 wk post-surgery<sup>[10]</sup>. The diverted volume of portal vein blood flow was about 95%<sup>[3]</sup>. In our experiments, we also observed that varices appeared in the mesenteric vein 2 wk after surgery. The collateral vessels between the spleen and left kidney, between the inferior mesenteric vein and the posterior peritoneum, and at the site of porta hepatis were also observed at this time, but were more apparent at 6 wk after ligation. The manifestations at week 10 were similar to those at week 6. Portal venography further proved the establishment of the collateral circulation. The left adrenal vein was significantly enlarged and became an important shunting vessel between the splanchnic circulation and the systemic circulation.

Some researchers<sup>[1]</sup> have studied the splanchnic and

systemic hemodynamics in the PVL rat model. They found that, after 2 wk of PVL, the rats with portal hypertension and greater than 93% portal-systemic shunting had an increase in portal venous inflow of 50%, and a concomitant 40% decrease in splanchnic arteriolar resistance. Cardiac index was elevated by 50%, and total peripheral resistance was decreased by 40%. The resistance to portal blood flow in portal vein-constricted rats was similar to that in control rats, indicating that the hyperdynamic portal venous inflow, and not resistance, was the mainstay of the elevated portal venous pressure. Some researchers<sup>[10]</sup> have suggested that many vessel-activated substances which accumulate in the systemic system, without inactivation by the liver, were the direct cause of the hyperdynamic circulation. Therefore, it is considered that, in the early period of PVL, portal vein obstruction is the direct cause of elevated PVP, but with the subsequent establishment of the collateral circulation, the hyperdynamic circulation becomes the important factor in maintaining the elevated pressure. Although portal-systemic shunting can reach to more than 90%, the PVP can still maintain an elevated level.

Other features of the PVL portal hypertensive rat model were noted: Hepatic function remained normal, which is similar to the clinical manifestation of PHT. Although the spleen volume increased almost 2-fold due to enlargement and congestion of splenic sinusoids, proliferation of sinus endothelial cells, hypersplenism was not shown by hemogram, which was similar to findings in the dog PHT model<sup>[5]</sup>. The reason for this may be due to species and anatomy differences to that in humans, or may be due to the short observation period.

In conclusion, portal vein partial ligation increases PVP to around twice the normal value and can be maintained for more than 10 wk. This method can provide a satisfactory model for investigating the surgical treatment of PHT.

## COMMENTS

### Background

Portal hypertension (PHT) is a serious disease in children. In about half of children with PHT it is prehepatic. However, the results of surgery for PHT are unsatisfactory. To investigate and to improve the results of surgery, a long-term stable animal model of PHT is needed. Partial portal vein ligation is a good method of producing a prehepatic PHT rat model. The technique is fast and economic. However, researchers have had different experiences in the long-term stability of the model. Some authors have suggested that the portal vein pressure (PVP) would drop to normal 2 wk after ligation, but others think that the models would be stable for more than a year.

### Research frontiers

Several types of PHT animal models have already been established. But focusing on the long-term stability of these models it is still a frontier of research.

### Innovations and breakthroughs

In their experiments, the prehepatic PHT rat model was proved to be stable for more than 10 wk. The anatomic features of this model were described in detail. Moreover, it is interesting that almost no adhesion in the abdominal cavity and no blood thrombosis in the mesenteric vein were found after repeated operations. Thus, it is possible to measure the PVP repeatedly in one rat, providing a better comparison in the same animal. This is superior to the method commonly used, i.e. a single measurement in each experimental rat.

### Applications

The prehepatic PHT rat model is quite useful in the study of PHT, as the alterations in the splanchnic circulation and the pathophysiology of the hyperdynamic circulation can be studied. It is a fast and economic model and can be widely used in this research field. In addition, it can also be used in clinical research, e.g. a new design for spleno-hepatopexy, and to explore new surgical techniques for PHT in children.

### Terminology

**Portal hypertension:** A series of syndromes with abnormal circulation and increased blood pressure in the portal system. According to its pathology, PHT can be divided into three types, prehepatic, intrahepatic and posthepatic.

**Varices:** Abnormally dilated/stretched veins, frequently caused by the development of portal collateral vessels as a result of portal hypertension. It often occurs in the portal system, such as the mesenteric vein and the splenic vein. The most clinically important varices in humans are found in the esophagus and stomach-submucosal varices of the lower esophagus or gastric fundus sub-mucosa.

**Spleno-hepatopexy:** Is a newly designed surgical procedure which allows communication of the spleen with the liver to establish a compensatory collateral circulation by-pass which crosses over the blockage of the portal vein. Thus, the blood in the distal portal system may be drawn into the liver, instead of into the systemic circulation allowing liver detoxification. This surgical technique would be beneficial for patients with prehepatic portal hypertension, especially in children.

### Peer review

The study by Dr. Wen et al, examines the natural history of portal hypertension in a rat model subjected to partial portal vein occlusion. It may be worth the authors effort as the paper provides valuable information on a common animal model of portal hypertension.

## Abstract

**AIM:** To analyze the differences and relevance of Yes-associated protein (YAP) and survivin, and to explore the correlation and significance of their expression in gastric carcinoma and precancerous lesions.

**METHODS:** The PV9000 immunohistochemical method was used to detect the expression of YAP and survivin in 98 cases of normal gastric mucosa, 58 intestinal metaplasia (IM), 32 dysplasia and 98 gastric carcinoma.

**RESULTS:** The positive rates of YAP in dysplasia (37.5%) and gastric carcinoma (48.0%) were significantly higher than that in normal gastric mucosa (13.3%),  $P < 0.01$ . The positive rates of survivin in IM (53.4%), dysplasia (59.4%) and gastric carcinoma (65.3%) were significantly higher than in normal gastric mucosa (11.2%),  $P < 0.01$ . Survivin expression gradually increased from 41.7% in well differentiated adenocarcinoma through 58.3% in moderately differentiated adenocarcinoma to 75.6% in poorly differentiated adenocarcinoma, with significant Rank correlation,  $r_s = 0.279$ ,  $P < 0.01$ . The positive rate of survivin in gastric carcinoma of diffused type (74.6%) was significantly higher than that in intestinal type (51.3%),  $P < 0.05$ . In gastric carcinoma with lymph

## INTRODUCTION

Yes-associated protein (YAP) is a type of cellular adaptor protein and transcriptional co-activator, which was initially isolated by Sudol *et al*<sup>[1]</sup> in 1994, as a result of its binding to the Src family member non-receptor tyrosine kinase YES (Yes kinase-associated protein). In biological conditions, YAP was described as a target of the Hippo (Hpo)-Salvador-Warts pathway and was phosphorylated by the pathway to negatively regulate growth by simultaneously inhibiting proliferation and promoting apoptosis. In recent years, some investigators have found YAP to be overexpressed and highly activated in hepatic cancers and mammary cancers<sup>[2-4]</sup>, suggesting its carcinogenicity. Survivin is a new member of the inhibitor of apoptotic protein (IAP) family, and was initially cloned by the cDNA of effector cell protease receptor-1 in the human genomic library in 1997<sup>[5]</sup>. Many

investigations have found survivin to be overexpressed in most common tumors, but almost never in normal tissues<sup>[6]</sup>. The overexpression of survivin was closely related to tumorigenesis and progression, and was one of the strongest apoptotic inhibitors identified. In tumors, lack of, or mutation of, any factor(s) in the Hpo signaling pathway can lead to dephosphorylation and activation of YAP, which then induces a high expression of Ki67, c-myc, SOX4, H19, AFP, BIRC5/survivin, BIRC2/cIAP1 and other cellular proliferation-related genes and inhibitors of apoptosis. Of note is the massive induction (30-fold) of BIRC5/survivin, leading to breakdown in the balance of cellular proliferation and apoptosis, and an increase in the occurrence and development of tumors<sup>[7]</sup>.

Gastric cancer is one of the malignant diseases with the highest incidence and mortality rates, but its pathophysiology remains to be clarified. We measured the expression level of YAP and survivin in normal gastric mucosa, precancerous lesions and gastric carcinoma using an immunohistochemical (IHC) method in order to analyze the significance and correlations of these two factors with gastric tumorigenesis.

## MATERIALS AND METHODS

### Clinicopathological data

We collected gastric carcinoma specimens from the First Affiliated Hospital of China Medical University: 98 cases of gastric carcinoma, including 29 cases of early gastric carcinoma (EGC) and 69 cases of advanced gastric carcinoma (AGC), with matched normal gastric mucosa, 58 cases of intestinal metaplasia (IM), and 32 cases of dysplasia (DYS). There were 66 males and 32 females, mean age 60 years. Gross types were as follows: EGC cases: 18 cases of type I + IIc, 10 cases of type III, one case of extensive superficial type; AGC cases: seven cases of Borrmann I + II, 62 cases of Borrmann III + IV. According to the World Health Organization histological classification of GC, the 98 cases were classified as follows: two papillary adenocarcinoma, 12 well differentiated adenocarcinoma, 25 moderately differentiated adenocarcinoma, 41 poorly differentiated adenocarcinoma, two undifferentiated adenocarcinoma, seven signet ring cell carcinomas and nine mucinous adenocarcinoma.

### Tissue microarray construction and IHC staining

Samples were fixed in 10% formalin, embedded in paraffin, cut into 4  $\mu$ m thick sections and constructed in blocks for tissue microarray. All the samples were evaluated by two experienced pathologists for diagnosis.

Expression of YAP and survivin in gastric carcinomas, precancerous lesions and normal gastric mucosa were detected using an IHC method. A PV-9000 kit was purchased from Beijing Zhongshan Golden Bridge Biotechnology Company. Anti-human rabbit YAP polyclonal antibody was purchased from the Cell Signaling Technology Company (working dilution 1:25). Anti-human rabbit polyclonal antibody survivin (ready to use)

was purchased from Fuzhou Maixin Company (China). All procedures were implemented according to the manufacturer's instructions. For negative controls, sections were treated with 0.01 mol/L phosphate-buffered saline instead of primary antibodies.

### IHC staining evaluation

YAP was specifically located in the cytoplasm and nucleus of carcinoma cells; survivin was specifically located in the cytoplasm of carcinoma cells. Staining intensity (A) was classified as 0 (negative), 1 (weak), 2 (moderate) and 3 (strong). The percentage of positive cells (B) examined in 200 cells were divided into 0 (< 5%), 1 (5%-25%), 2 (26%-50%), 3 (51%-75%) and 4 (> 75%). According to the product of A and B, the IHC result was classified as 0, negative (-); 1-4, weakly positive (+); 5-8, moderately positive (++) and 9-12, strongly positive (+++).

### Statistical analysis

Statistical analysis was performed using SPSS 11.5 Package,  $\chi^2$  test, Fisher's exact test and Kendall's  $\tau_{ab}$  test were used to differentiate the rates of different groups and test the correlation between the two factors.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Expression of YAP in normal gastric mucosa, IM, DYS and gastric carcinoma

The positive rates of YAP presence in dysplasia (37.5%) and gastric carcinoma (48.0%) were significantly higher than that in normal gastric mucosa (13.3%),  $P < 0.01$ ; there was no statistically significant difference between YAP expression in the normal gastric mucosa and IM (16/58, 27.6%), dysplasia and gastric carcinoma,  $P > 0.05$ . YAP expression showed an increasing trend from well differentiated adenocarcinoma (4/12, 33.3%), through moderately differentiated adenocarcinoma (11/25, 44.0%) to poorly differentiated adenocarcinoma (24/41, 58.5%), although without significant Rank correlation. The positive rate of YAP expression showed an increasing trend from gastric carcinoma without lymph node metastasis (5/17, 29.4%), to gastric carcinoma with lymph node metastasis (24/52, 46.2%), though without statistical significance,  $P > 0.05$ . There was no significant correlation of the expression of YAP with patients' gender, age, Borrmann's classification of gastric carcinoma or Lauren classification,  $P > 0.05$  (Tables 1 and 2, Figure 1).

### Expression of survivin in normal gastric mucosa, IM, DYS and gastric carcinoma

The positive rates of survivin in IM (53.4%), dysplasia (59.4%) and gastric carcinoma (65.3%) were significantly higher than that in normal gastric mucosa (11.2%),  $P < 0.01$ . The expression level gradually increased from well differentiated adenocarcinoma (41.7%), through moderately differentiated adenocarcinoma (58.3%) to poorly differentiated adenocarcinoma (75.6%), with significant Rank correlation,  $r = 0.279$ ,  $P < 0.01$ .

The positive rate of survivin in gastric carcinoma of diffused type (74.6%) was significantly higher than that in intestinal type (51.3%),  $P < 0.05$ . In gastric carcinoma with lymph node metastasis (76.9%), the positive rate of survivin was significantly higher than that in the group without lymph node metastasis (41.2%),  $P < 0.01$ . There was no relationship between gastric carcinoma and sex, age and gross type of carcinoma (Tables 3 and 4, Figures 2-4).

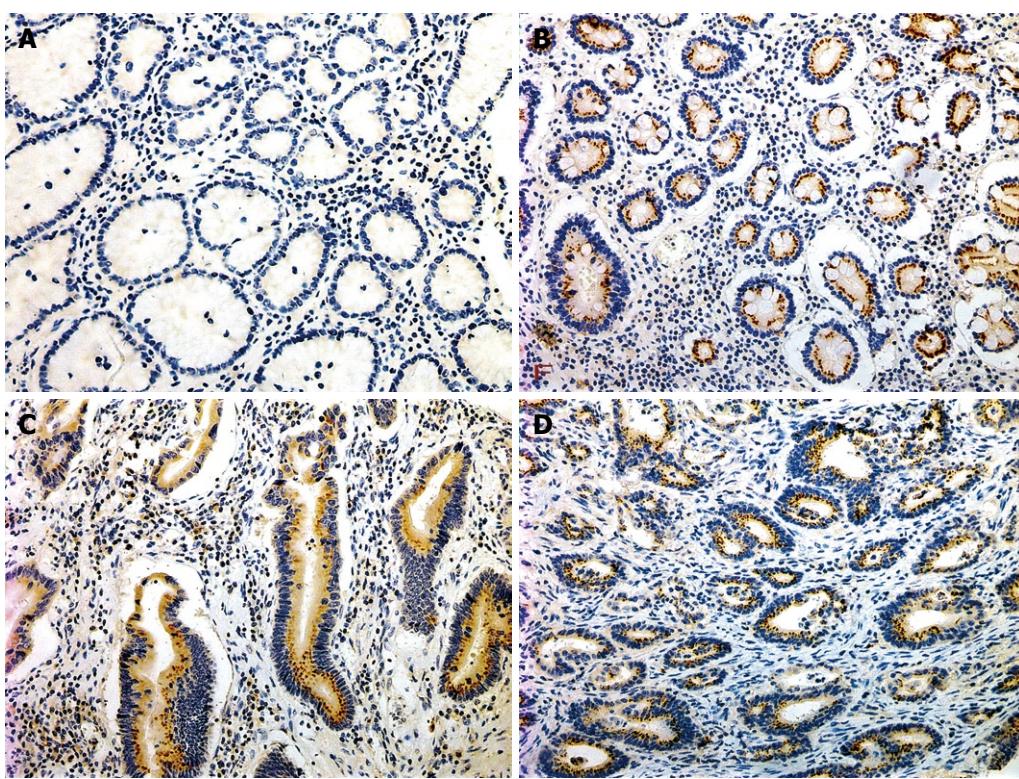

## DISCUSSION

The Hpo pathway was originally identified in *Drosophila* as a potent regulator of inhibition of cell growth and promotion of apoptosis. The pathway consists of a tumor suppressor kinase cascade which negatively regulates growth and results in inactivation of a transcriptional co-activator, Yorkie (Yki)<sup>[8]</sup>. The human ortholog of Yki,

YAP, has a 31% sequence homology and similar biologic activity. YAP is a 65 kDa phosphoprotein which is rich in proline. In biological conditions, YAP is phosphorylated by the Hpo signaling pathway, and is highly conserved with other components of this pathway, regulating the balance between cell proliferation and apoptosis to maintain the steady-state of the cellular environment<sup>[2,9,10]</sup>. Dysregulation of any factor(s) in this pathway can lead to tumorigenesis. Overholtzer *et al*<sup>[9]</sup> introduced the YAP gene by retroviral infection into the immortalized, but non-tumorigenic, human mammary epithelial cell line MCF10A and found that overexpression of YAP induced epithelial-to-mesenchymal transition, suppression of apoptosis, growth factor-independent proliferation, and anchorage-independent growth in soft agar, which suggests that YAP contributes to malignant transformation in cancers, and supports the potential significance of this pathway in human cancer.

**Figure 1 Expression of Yes-associated protein (YAP) in normal gastric mucosa (A), intestinal metaplasia (B), dysplasia (C) and gastric carcinoma (D). IHC PV9000,  $\times 200$ .**

**Figure 2 Expression of survivin in normal gastric mucosa (A), intestinal metaplasia (B), dysplasia (C) and gastric carcinoma (D). IHC PV9000,  $\times 200$ .**

Zhao *et al*<sup>[2]</sup> evaluated YAP expression in 115 cases of human hepatocellular carcinoma (HCC) samples by IHC staining of tissue microarrays. Among the 115 cases of human HCC samples examined, 54% showed strong YAP staining, while 95% of normal liver tissue samples (40 out of 42 cases) showed very weak staining, indicating a significant difference in YAP levels between normal and cancerous tissues. Similar observations were made in prostate cancer tissues. Up to now, we

have found only one report on the expression and role of YAP expression in gastric carcinoma, where YAP expression in 78 normal gastric mucosa was 14%, while in 55 gastric carcinomas and 92 gastric metastatic disease the expression was 30% and 35% respectively, significantly higher than that in normal gastric mucosa<sup>[11]</sup>. Our IHC investigation found that the expression of YAP in DYS and gastric carcinoma was significantly higher than in normal gastric mucosa, suggesting that an

abnormality of the Hpo pathway leads to overexpression of YAP, resulting in malignant transformation of the gastric mucosa. We speculate that YAP may play an important role as a tumorigenic factor and early gastric tumorigenic molecule during gastric carcinogenesis.

Survivin is a new member of the IAP family, and has been implicated to have a role in protection from apoptosis and regulation of mitosis<sup>[12]</sup>. The survivin gene has been located on the 17q25 chromosome, encoding a 16.5 kDa protein. Survivin is characterized by a unique structure with a single BIR on the N terminal and an  $\alpha$ -helix structure on the C terminal; the BIR structure is thought to play a role during anti-apoptosis, while the helix structure may participate in the microtubule binding structure<sup>[13,14]</sup>. Data from a large analysis of human transcripts revealed survivin as the fourth most highly expressed protein in human cancer tissue compared with normal tissue<sup>[15-18]</sup>. Xiao et al<sup>[19]</sup> found that the positive rates of survivin expression in tumors with metastases (in lymph node metastasis 86.2%, liver metastasis

100% and ovarian metastasis 100%) were significantly higher than that in tumors without metastasis (64.3%). Our data indicated that the positive rates of survivin in IM, atypical hyperplasia and gastric carcinoma were significantly higher than that in normal gastric mucosa. The expression level gradually increased from well differentiated adenocarcinoma, through moderately differentiated adenocarcinoma to poorly differentiated adenocarcinoma, with significant Rank correlation. The positive rate of survivin in gastric carcinoma of the diffused type was significantly higher than that in the intestinal type. In gastric carcinoma with lymph node metastasis, the positive rate of survivin was significantly higher than that in the group without lymph node metastasis, indicating that survivin may be involved in the occurrence, development and lymph node metastasis of gastric carcinoma. Survivin can act as a prognostic and predictive indicator for gastric carcinoma patients.

Dong et al<sup>[7]</sup> used microarray analysis to identify YAP-induced genes in murine livers. Selected genes

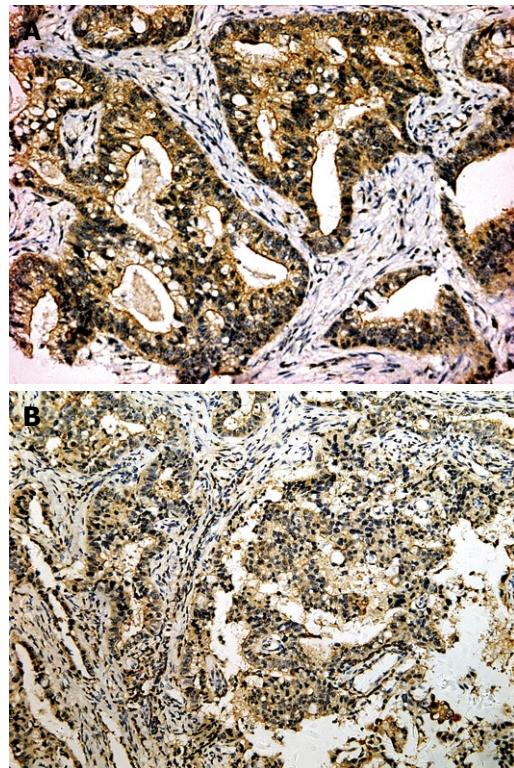

**Figure 3** The expression of survivin in gastric carcinoma without lymph node metastasis (A,  $\times 200$ ) and with lymph node metastasis (B,  $\times 100$ ). IHC PV9000.

from the microarray analysis were validated by real-time quantitative polymerase chain reaction analysis. YAP induced the transcription of many genes which are normally associated with hepatocyte proliferation, such as Ki67, c-myc, SOX4, H19, and AFP. It also induced the expression of several negative regulators of apoptosis, such as the IAP family members BIRC5/survivin and BIRC2/cIAP1, and the BCL2 family gene MCL1. Of note is the massive induction (30-fold) of BIRC5/survivin. To determine whether cIAP1 and YAP might cooperate during tumorigenesis,  $p53^{-/-}$ , myc liver progenitor cells were infected with either YAP and control vector or YAP plus cIAP1 and assayed for their ability to form tumors *in vivo*. Tumors arising from  $p53^{-/-}$ , myc hepatoblasts coexpressing cIAP1 and YAP grew faster than those expressing either oncogene alone, suggesting that they may collaborate to contribute to tumorigenesis and progression<sup>[20]</sup>.

Our investigation found that the expression of YAP and survivin in gastric carcinoma were positively correlated, and we speculate that YAP may induce a high expression of cell proliferation-related factors and apoptotic inhibitors, such as Ki67, cIAP1 and survivin. Survivin may participate in gastric carcinogenesis, progression and metastasis by inhibiting apoptosis of gastric carcinoma and regulating cellular mitosis. Whether YAP and survivin collaborate to contribute to gastric carcinogenesis and progression require further study.

Previous reports have found that YAP was an activator of cell death in mammalian cells. YAP was shown to activate apoptosis in response to DNA damage by

**Figure 4** The expression of survivin in primary gastric carcinoma (A) and relevant lymph node metastasis (B). IHC PV9000,  $\times 200$ .

interacting with p73 in several cancer cell lines<sup>[21,22]</sup>. This is in direct contrast to the results of our investigation and other previous reports. The roles of YAP in biological and pathological conditions remain to be clearly defined.

## COMMENTS

### Background

Yes-associated protein (YAP) is a type of cellular adaptor protein and transcriptional co-activator. In recent years, some investigators have found YAP to be overexpressed and highly activated in hepatic cancers and mammary cancers, suggesting its tumorigenicity. Survivin is a new member of the inhibitor of apoptotic protein (IAP) family, which was initially cloned by the cDNA of the effector cell protease receptor-1 in the human genomic library in 1997. The authors measured the expression of YAP and survivin in normal gastric mucosa, precancerous lesions and gastric carcinoma using an immunohistochemical method, to analyze the significance and correlations of the two factors with gastric carcinogenesis.

### Research frontiers

The Hippo (Hpo) pathway was originally identified in Drosophila as a potent regulator of inhibition of cell growth and promotion of apoptosis. The pathway consists of a tumor suppressor kinase cascade which negatively regulates growth and results in inactivation of a transcriptional co-activator, Yorkie (Yki). The human ortholog of Yki, YAP, has a 31% sequence homology and similar biologic activity. YAP is a 65 kDa phosphoprotein, rich in proline. In biological conditions, YAP is phosphorylated by the Hpo signaling pathway, and is highly conserved with other components of this pathway, regulating the balance between cell proliferation and apoptosis to maintain the steady-state of the cellular environment.

### Innovations and breakthroughs

Previous reports have found that YAP was an activator of cell death in mammalian cells. YAP was shown to activate apoptosis in response to DNA damage by interacting with p73 in several cancer cell lines. This is in direct contrast to the results of their investigation and other previous reports.

### Applications

The authors investigation found that the expression of YAP and survivin in

gastric carcinoma were positively correlated. They speculate that YAP may induce a high expression of cell proliferation-related factors and apoptotic inhibitors, such as Ki67, cIAP1 and survivin. Detecting YAP and survivin together may help in early diagnosis of gastric carcinoma. Whether YAP and survivin collaborate to contribute to gastric tumorigenesis and progression requires further study.

#### Peer review

The investigation found that the expression of YAP and survivin in gastric carcinoma were positively correlated, and the authors speculated that YAP may induce a high expression of cell proliferation-related factors and apoptotic inhibitors, such as Ki67, cIAP1 and survivin. Survivin may participate in gastric carcinogenesis, progression and metastasis by inhibiting apoptosis of gastric carcinoma cells and regulating cellular mitosis. The study is interesting and is worth further exploration.

### Abstract

**AIM:** To evaluate different standard liver volume (SLV) formula and verify the applicability of the formulae for Chinese adults.

**METHODS:** Data from 70 cases of living donor liver transplantation (LDLT) performed at our transplantation centers between January 2008 and April 2009 were analyzed. SLV was estimated using our recently reported formula [the Chengdu formula: SLV (mL) = 11.5 × body weight (kg) + 334] and other reported formulae used for Chinese adults. Actual intraoperative liver volumes were obtained from a review of the patients' medical records.

**RESULTS:** The actual right liver volume was not significantly different from the estimated right liver volume determined by the Chengdu formula, but was significantly smaller than estimates using the Heinemann, Urata, Vauthey, and Lee formulae ( $P < 0.01$ ), and significantly larger than estimates using the Fan formula ( $P < 0.05$ ).

**CONCLUSION:** The Chengdu formula was demonstrated to be reliable by its application in LDLT.

### INTRODUCTION

Living donor liver transplantation (LDLT) has been used to alleviate the shortage of available liver donors. Accurate estimation of the standard liver volume (SLV) of the living donor and recipient is crucial. Overestimation of the donor's SLV may result in excessive hepatic resection leading to liver failure, while underestimation of the recipient's SLV may result in small-for-size graft syndrome<sup>[1-5]</sup>. Since 2001, our transplant centers have carried out 212 LDLTs. We estimated the SLV using computed tomography (CT) or reported formulae. However, there was a difference between these estimates and the actual liver volumes (ALVs) for Chinese adults. Recently, we developed a new formula (named the Chengdu formula) to estimate SLV using data from 115 LDLTs<sup>[6]</sup>. The formula is: SLV (mL) = 11.5 × body weight (kg) + 334. Using this formula, the SLVs were evaluated in 76 cases of LDLT performed from January 2008 to April 2009. Its accuracy was compared to that of other internationally reported formulae<sup>[7-10]</sup> to assess which formula is the most accurate for Chinese adults.

### MATERIALS AND METHODS

#### Patient selection

The data from 76 living donors were analyzed. Inclusion criteria were: (1) a healthy adult donor, aged 19-59 years; (2) right liver graft without middle hepatic vein; (3) adult-to-adult LDLT; (4) single donor; (5) no history of long term drinking. Exclusion criteria: (1) donor age < 18 or > 60 years; (2) left hepatic graft or left lateral lobe graft; (3) double donor grafts; (4) adult-to-child transplant; (5) donors who were hepatitis B or C carriers<sup>[11-14]</sup>.

#### Clinical data

Data of preoperative donors included age, sex, height

**Table 1** Reported formulae for ESLV

Author	Report date	Formula	Material used (race, number)
Urata et al <sup>[7]</sup>	1995	ESLV = 706.2 × BSA + 2.4	CT Volumetry (Japanese, 96)
Heinemann et al <sup>[8]</sup>	1999	ESLV = 1072.8 × BSA - 345.7	Autopsy (Caucasian 1332)
Vauthey et al <sup>[9]</sup>	2002	LV = 18.51 × BW + 191.8	CT volumetry (Western, 292)
Lee et al <sup>[5]</sup>	2006	ESLV = 691 × BSA + 95	LDLT (Korea, 311)
Fan et al <sup>[4]</sup>	2000	ESLW = 218.32 + BW × 12.29 + gender × 50.74 (M = 1, F = 0)	LDLT (Chinese, 159)
Chengdu <sup>[6]</sup>	2009	ESLV = 334.024 + 11.508 × BW	LDLT (Chinese, 115)

ESLV: Estimated standard liver volume; BSA: Body surface area; BW: Body weight; CT: Computed tomography; LDLT: Living donor liver transplantation.

**Table 2** Donor characteristics

Age (yr)	32.21 ± 10.07 (19-59)
Gender (Male:Female)	53:17
Body weight (kg)	62.97 ± 8.41 (42-87)
Body height (cm)	167.31 ± 8.15 (148-185)
Body mass index (kg/m <sup>2</sup> )	22.23 ± 2.44
Body surface area (m <sup>2</sup> ) by DuBois formula	1.7082 ± 0.14
Body surface area (m <sup>2</sup> ) by Mosteller formula	1.7081 ± 0.14
Total liver volume on CT (mL)	1189.53 ± 114.75
Right lobe graft volume on CT without MHV	658.98 ± 81.14
Right lobe volume without MHV to total liver volume on CT (%)	55.4 ± 3.7
Actual right liver volume (mL)	578.58 ± 72.33

MHV: Middle hepatic vein.

(BH, measured to the nearest 1 cm), body weight (BW, measured to the nearest 0.5 kg), and body surface area (BSA) calculated using the DuBois formula: BSA (m<sup>2</sup>) = BW (kg) 0.425 × BH (cm) 0.725 × 0.007184 or the Mosteller formula: BSA (m<sup>2</sup>) = square root BH (cm) × BW (kg)/3600. From the diaphragm to the superior mesenteric artery plane, the entire liver image was scanned using a 7 mm thick layer. In the Leonardo workstation, the LV was measured by venous phase images<sup>[15,16]</sup>. All preoperative CT examinations of donors were performed by a single radiologist and all donor procedures were performed by the same surgical unit. The volume of the grafts was measured by a 3 L beaker using a drainage method intraoperatively and the error was less than 10 mL<sup>[17,18]</sup>.

Right liver graft without middle hepatic vein reconstruction from a living donor was performed as described, with temporary occlusion of the right portal vein (PV) and right hepatic artery and use of ultrasonography to guide parenchymal transection. The right hepatic duct, right hepatic artery, right portal vein branch, and right hepatic vein were transected approximately 2-3 mm from the confluence<sup>[19,20]</sup>, leaving the donor's main PV and confluence intact. The graft was flushed with University of Wisconsin solution through the PV and hepatic artery<sup>[21,22]</sup>.

The volume of 70 livers was calculated using the Chengdu standard LV formula<sup>[6]</sup> as described above. The estimated right LV (ERLV) was obtained by multiplying the SLV by the proportion of the LV contributed by the right lobe on CT. The actual right LV (ARLV) was obtained by intraoperative measurement. The difference

between the ERLV and ARLV was statistically evaluated.

The formulae of Heinemann et al<sup>[8]</sup>, Urata et al<sup>[7]</sup>, Vauthey et al<sup>[9]</sup>, Lee et al<sup>[5]</sup>, and Fan et al<sup>[4]</sup> in addition to our own formula<sup>[6]</sup> were used to determine the estimated SLV (ESLV) of our donor livers. The previously reported formulae are shown in Table 1. For each liver, we calculated the difference between the ALV and volume estimated by each formula (ELV).

### Statistical analysis

After testing for normal distribution (kurtosis and skewness tests), descriptive statistics were calculated and data were expressed as means ± SD for age (year), BW (kg), BH (cm), body mass index (BMI), and BSA. The ERLV-ARLV and the ELV-ALV were compared by the 2-sided paired-samples *t*-test. *P* < 0.05 was considered statistically significant. All statistical analyses were performed using the SPSS (version 13.0) program.

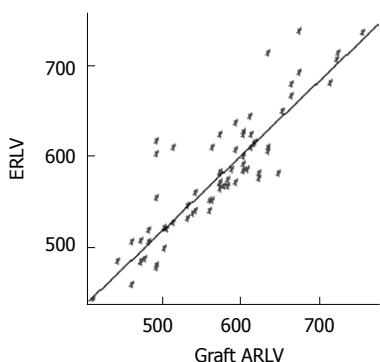

## RESULTS

Seventy donors (all Chinese; 53 men and 17 women; mean age, 32.21 ± 10.07; range, 19-57 years) met the selection criteria. All donors were related to the recipients.

The characteristics of donors are shown in Table 2. All donors were considered healthy on the basis of BMI. All but one donor with a BMI of 17 kg/m<sup>2</sup> had a BMI of 18-28 kg/m<sup>2</sup>. The mean volume of the right lobe on CT was 658.98 ± 81.14 mL and represented 55.4% ± 3.7% of the whole liver on CT.

The mean ELV and mean ERLV using the Chengdu standard formula were 1058.70 ± 96.74 mL and 586.15 ± 67.17 mL, respectively. The mean ARLV was 578.58 ± 72.33 mL. Differences for individual donors between ERLV and ARLV were not significant (*t* = -1.882, *P* = 0.064). A plot of the relationship of ARLV to the ERLV calculated using the Chengdu formula is shown in Figure 1.

The mean total LV determined preoperatively on CT was 1189.53 ± 114.75 mL. The mean RLV on CT without the middle hepatic vein was 658.98 ± 81.14 mL, and 55.4% ± 3.7% of the total LV. The ALV calculated from the volume of the graft and the ratio of the RLV to the total LV on CT (%) was 1050.10 ± 107.41 mL. The Heinemann, Urata, Vauthey, and Lee formulae significantly overestimated the LV (*P* < 0.01), while the Fan formula significantly underestimated the LV (*P* <

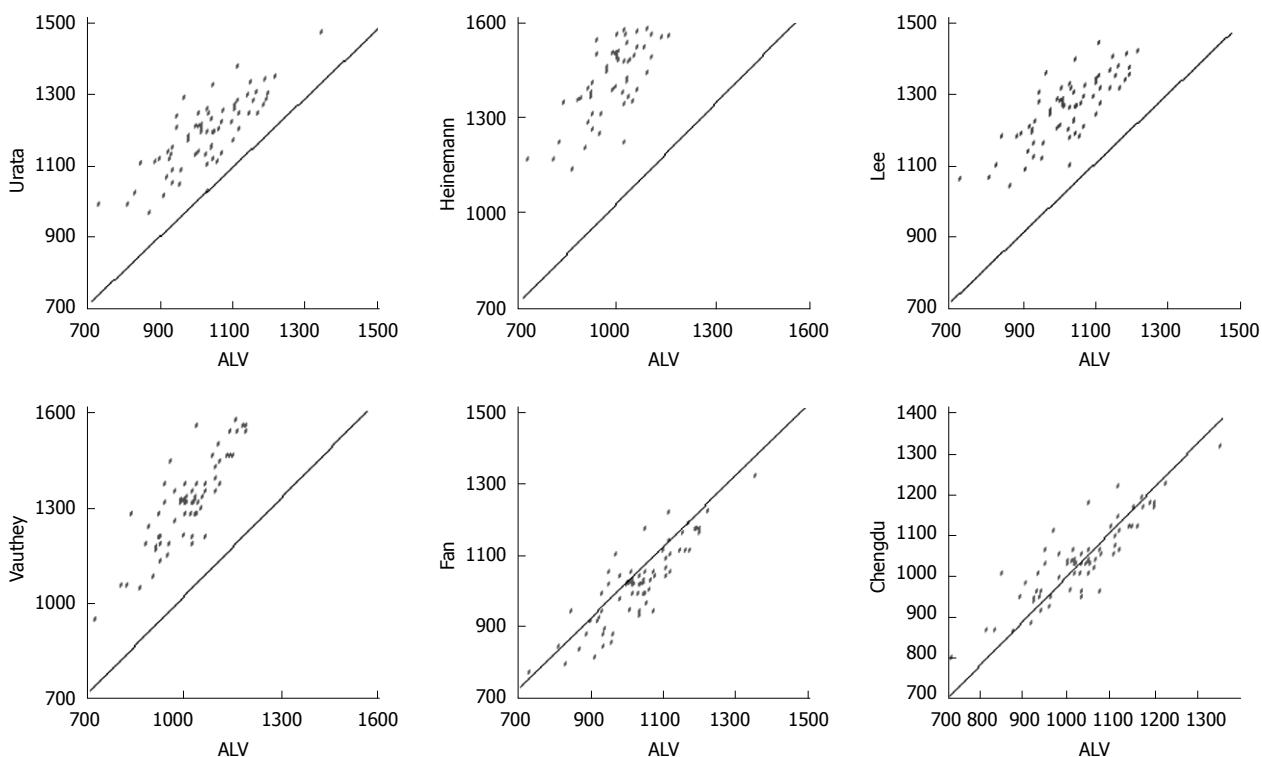

**Figure 1 Correlation between actual right liver volume (ARLV) and estimated right liver volume (ERLV) by the Chengdu formula.** When both were the same, a dot would be on the linear line.

**Table 3 Statistical analysis of estimated LV by each formula**

Formula	mean $\pm$ SD	t	P-value
Urata	1208.73 $\pm$ 99.92	-20.91	P < 0.01
Heinemann	1486.85 $\pm$ 151.78	-40.84	P < 0.01
Vauthey	1357.40 $\pm$ 155.60	-32.44	P < 0.01
Lee	1275.36 $\pm$ 97.77	-29.87	P < 0.01
Fan	1034.28 $\pm$ 111.61	2.465	P = 0.016
Chengdu	1058.70 $\pm$ 96.74	-1.417	P = 0.161
ALV	1050.10 $\pm$ 107.41	ND	ND

ALV: Actual liver volume; ND: Not determined.

**Figure 2 Correlation between actual liver volume (ALV) and estimated liver volume (ELV) by each formula.** When both were the same, a dot would be on the linear line. Formulae of Urata, Heinemann, Vauthey, and Lee overestimated LV with respect to ALV. The Fan formula underestimated LV and the Chengdu formula gave a good estimate of ALV.

0.05). There was no significant difference between ALV and ELV using the Chengdu formula (Figure 2).

## DISCUSSION

CT has become a standard method for assessing liver graft volume in living donors. Estimation of LV by CT (compared to actual volume) has a margin of error of 5%-25%<sup>[23,24]</sup>. In the present study, all donors had preoperative CT assessment of LV (mean total LV, 1189.53  $\pm$  114.75 mL and mean volume of right lobe graft without middle hepatic vein, 658.98  $\pm$  81.14 mL). The actual volume of the right liver was 578.58  $\pm$  72.33 mL. In the present study, the LV on CT was 10%-20% higher than the ALV<sup>[25-27]</sup>. The reasons may be as follows: (1) Preoperative CT measurement is carried out under normal blood flow conditions. Perioperatively, liver resection interrupts the blood supply causing a loss of liquid volume, collapse of supporting structures, and thereby reduction in the volume

of the liver. (2) Sources of error (partial volume effect, inter-observer variation, and respiratory movements) may account for this difference<sup>[28]</sup>.

The difference between the ERLV (using our formula) and ARLV was compared to the difference between ERLV, calculated using the formulae of Heinemann, Urata, Vauthey, Lee, and Fan, and ARLV in our 70 donors. The Heinemann, Urata, Vauthey, and Lee formulae overestimated LV (P < 0.01)<sup>[29]</sup>. The reasons may include: ethnic differences (patients in Europe and the United States were Caucasian). All except the Sheung Tat Fan and Chengdu formulae were used to estimate LV from CT LV or autopsy LV. Estimates of LV by CT were 5%-25% higher than the ALV<sup>[30]</sup>.

Statistical analysis showed that the Fan formula tends to underestimate LV. The weight and height of the donors in our study were higher than those in the Hong Kong group. This may be one of the reasons both results are very close (Table 3). Above all, we believe that

the Chengdu formula was demonstrated to be reliable by its application in LDLT. We were limited to use of single center data in the present study, but we hope to improve the formula by using national multicenter data in the future<sup>[31]</sup>.

## COMMENTS

### Background

With development of living donor liver transplantation (LDLT), especially improvement of right graft adult-to-adult LDLT, the danger of donating has been paid more and more attention. The exact liver volume is not only relevant for the recipient, but also for the donor to avoid dangerous life-threatening residual liver volumes.

### Research frontiers

Scholars of different countries established several standard liver volume (SLV) formulae from clinical data. The authors estimated the SLV using computed tomography or reported formulae. However, there was a gap between these estimates and the actual liver volumes for Chinese adults. Recently, they developed a new formula (named the Chengdu formula) to estimate SLV using data from 115 LDLTs.

### Innovations and breakthroughs

With the Chengdu formula, the SLVs were evaluated in 76 cases of LDLT performed from January 2008 to April 2009. Its accuracy was compared to that of other internationally reported formulae to assess which formula is the most accurate for Chinese adults.

### Applications

With national multicenter data in the future, the Chengdu formula for SLV can be improved. It may then be applied to the evaluation of donors for LDLT.

### Terminology

Standard liver volume: normal liver volume without disease affecting the volume of liver.

### Peer review

Very interesting manuscript dealing with a very hot topic: determination of optimal size matching between graft and recipient in LDLT by means of race-adapted calculation of liver volumes. The recently published liver volume formula for Chinese people (Chengdu formula) has been demonstrated to be more reliable than others and therefore it should be adopted especially in this particular form of LT.

## INTRODUCTION

Parvovirus B19 is a common infection that often occurs in childhood, with 50% of adolescents having antibodies to the virus by 15 years of age<sup>[1]</sup>. The infection is transmitted by respiratory droplets and through blood products derived from viremic donors. Most acute infections in children do not result in symptoms, but the clinical presentation can range from erythema infectiosum to non-specific febrile symptoms. In adults, a polyarthropathy that can resemble rheumatoid arthritis or systemic lupus erythematosus has been reported, particularly in middle aged women<sup>[2]</sup>. In patients with hemoglobinopathies the infection can cause a clinically relevant drop in hemoglobin, which may require transfusion. In the immunocompromised patient, this infection can result in bone marrow suppression and transient mild transaminase elevations commonly occur. In children there have been several reports of severe acute hepatitis and acute liver failure, which are most often self-limited<sup>[1]</sup>. There is, however, at least one reported case of parvovirus B19 induced fulminant hepatic failure in a child that required urgent liver transplantation<sup>[3]</sup>.

The majority of published cases of parvovirus B19 induced hepatitis in adults have suggested that hepatic involvement by the virus is less severe than in the pediatric population<sup>[4]</sup>. We report the case of a 55-year-old immunocompetent woman with no previous history of liver disease who developed fulminant hepatic failure secondary to acute infection with parvovirus B19 and required urgent liver transplantation.

## Abstract

Parvovirus B19 induced acute hepatitis and hepatic failure have been previously reported, mainly in children. Very few cases of parvovirus induced hepatic failure have been reported in adults and fewer still have required liver transplantation. We report the case of a 55-year-old immunocompetent woman who developed fulminant hepatic failure after acute infection with Parvovirus B19 who subsequently underwent orthotopic liver transplantation. This is believed to be the first reported case in the literature in which an adult patient with fulminant hepatic failure associated with acute parvovirus B19 infection and without hematologic abnormalities has been identified prior to undergoing liver transplantation. This case suggests that Parvovirus B19 induced liver disease can affect adults, can occur in the absence of hematologic abnormalities and can be severe enough to require liver transplantation.

## CASE REPORT

A 55-year-old immunocompetent woman who was born in Canada presented to her family physician and subsequently a local emergency room with a two week history of fatigue, general malaise, nausea with emesis,

anorexia, dark urine and pruritus. She was noted to be jaundiced and complained of mild arthralgias in her upper extremities. One week prior to developing these symptoms, she was a passenger on a commercial airplane flight and assisted an ill jaundiced passenger who had vomited. She was a retired registered nurse with no risk factors for viral hepatitis. She denied the use of herbal remedies and acknowledged minimal alcohol consumption. On initial assessment, she was afebrile with marked icterus, no hepatosplenomegaly or ascites and mild asterixis.

Initial laboratory investigations revealed a hemoglobin 161 g/L (normal: 115-155 g/L), white blood cell count  $6.6 \times 10^9/L$  (normal:  $4 \times 10^9$ - $11 \times 10^9/L$ ), platelet count  $236 \times 10^9/L$  (normal:  $150 \times 10^9$ - $400 \times 10^9/L$ ), creatinine 62  $\mu\text{mol}/L$  (normal: 40-95  $\mu\text{mol}/L$ ), aspartate aminotransferase 1838 U/L (normal: 10-38 U/L), alanine aminotransferase 1398 U/L (normal: 20-65 U/L), alkaline phosphatase 304 U/L (normal: 50-160 U/L),  $\gamma$ -glutamyl transpeptidase 179 U/L (normal: 10-55 U/L), direct bilirubin 166  $\mu\text{mol}/L$  (normal: 0-5  $\mu\text{mol}/L$ ) and total bilirubin 359  $\mu\text{mol}/L$  (normal: 0-18  $\mu\text{mol}/L$ ), international normalized ratio 1.9 (normal: 0.9-1.1), partial thromboplastin time 34 s (normal: 24-34 s), albumin 29 g/L (normal: 35-48 g/L). Hepatitis A IgG was positive and IgM was negative, hepatitis B surface antigen was negative and hepatitis C serology was negative and investigations excluded hepatitis E. Acetaminophen level was < 66  $\mu\text{mol}/L$  (normal: < 66  $\mu\text{mol}/L$ ). An urgent abdominal ultrasound demonstrated a normal appearing liver with no focal lesions.

Two days after admission to a local hospital she was transferred to the regional liver transplantation centre for assessment. On arrival, she remained icteric and demonstrated evidence of mild hepatic encephalopathy and ascites. Her liver enzymes continued to deteriorate and her liver function tests became increasingly abnormal. Her Model for End-stage Liver Disease (MELD) score was 28<sup>[5]</sup>. Further investigations revealed a serum ceruloplasmin of 301 mg/L (normal: 215-540 mg/L), IgA 3.24 g/L (normal: 0.7-4.0 g/L), IgG 13.4 g/L (normal: 6.7-15.2 g/L), IgM 1.09 g/L (normal: 0.4-2.3 g/L). The patient's anti-nuclear antibody, anti-smooth muscle antibody and anti-mitochondrial antibody were negative and iron studies were within normal limits. Serology for human immunodeficiency virus and cytomegalovirus were negative, Epstein Barr virus IgG was positive and IgM was negative. Serology for parvovirus B19 was positive, with both IgG and IgM being detected by ELISA (Biotrin).

Five days after transfer, she was placed on the waiting list for liver transplantation. Ten days after transfer she developed worsening encephalopathy and was moved to the top of the transplant list. Twelve days after her transfer she underwent an orthotopic liver transplant. One day post-transplant she was extubated and by the following day she was transferred to the solid organ transplant ward in stable condition.

Histopathologic analysis of the explanted liver

demonstrated massive hepatic necrosis consistent with viral induced fulminant hepatitis. A sample of the explanted liver was ground up with a mortar and pestle in a 2 mL volume of Minimal Essential Medium. After clarifying by centrifugation, the preparation was extracted for nucleic acid using the EasyMag platform (from bioMerieux). The extracted DNA was then tested by a parvovirus specific PCR using the forward primer CCAGGAATGACTACAAAAGGCAAATAC and the reverse primer GGTAATGCAGGGTTCTTG. The reaction was carried out for 40 cycles, each consisting of 95°C for 0 s, 52°C for 30 s and 72°C for 30 s. The PCR products were analyzed by electrophoresis on agarose gel containing ethidium bromide and visualized under UV light. A band corresponding to a 191 base pair amplicon, diagnostic for Parvovirus B19, was seen. The finding of Parvovirus B19 by PCR in the explanted liver therefore confirmed the serological diagnosis of acute Parvovirus B19 infection.

## DISCUSSION

Parvovirus B19 has been proposed as a causative agent of hepatitis, hepatitis-associated anemia and acute liver failure. There are several cases reported in the literature of patients with abnormal liver biochemistry, with and without associated anemia, caused by acute infection with parvovirus B19. One small series reported detectable parvovirus B19 DNA by polymerase chain reaction in liver tissue from 4 of 6 (67%) pediatric patients with acute liver failure accompanied by hepatitis-associated anemia and in 2 of 4 (50%) of those with acute liver failure in isolation<sup>[6]</sup>. Viral DNA was not detected in any of the patients' sera. A second small series found that parvovirus DNA was detected in 5 of 6 (83%) livers from patients with idiopathic non-A-E acute liver failure with hepatitis-associated anemia, 2 of 3 (67%) livers in patients with isolated acute liver failure and 1 of 6 (17%) livers from patients with acute liver failure of known non-parvovirus etiology<sup>[7]</sup>. So *et al*<sup>[8]</sup> (2007) have recently published a case report describing an 11-year-old boy who presented with fulminant hepatic failure secondary to acute parvovirus B19 infection who required urgent liver transplantation.

The majority of the available literature regarding acute parvovirus B19 induced fulminant hepatic failure has described cases involving children. Despite this, however, there are several published reports of acute parvovirus B19 infection in adults associated with the development of acute hepatitis<sup>[8-11]</sup>. Interestingly, in virtually every case reported the patients have had a complete and spontaneous remission. This has led to speculation that the syndrome in adults is not only less common than in children, but that it has a much less severe course with better patient outcomes. The case described in this report appears to be the first reported in which an adult patient has been recognized as having acute parvovirus B19 induced fulminant hepatic failure prior to liver transplantation. There remains a

remote possibility that she acquired the infection in childhood and that this acute episode was precipitated by an immune response to viral reactivation. In any event, it demonstrates that adults may also develop fulminant hepatic failure in the absence of hematologic abnormalities and may ultimately require liver transplantation as a potential life saving intervention.

It is worth noting that the notion of parvovirus B19 as a cause of acute viral hepatitis is not universally accepted and that there is also literature published that questions this association. A small study by Wong *et al*<sup>[12]</sup> documented the presence of parvovirus B19 DNA in the liver tissue of 4 of 15 (27%) patients with acute hepatitis as compared to 3 of 22 (14%) patients with non-viral liver disease. They concluded that no difference exists in the prevalence of parvovirus B19 in liver tissue in patients with acute liver failure or hepatitis-associated anemia as compared to those with chronic hepatitis B and C infection. Despite this study's findings, evidence continues to mount in favour of parvovirus B19 as a causative agent of acute hepatitis and fulminant hepatic failure.

In conclusion, there is growing evidence that Parvovirus B19 may cause acute viral hepatitis, which can result in fulminant hepatic failure requiring liver transplantation. Although this infection is most commonly acquired in childhood, adults who become acutely infected can develop liver dysfunction as a result. The liver disease can occur independently from the often-associated hematologic abnormalities, as illustrated by the case described in this report. Fulminant hepatic failure induced as a result of acute infection with parvovirus B19 remains a rare clinical entity, however it may be underreported due to infrequent testing that results from a lack of awareness about this syndrome. A wider recognition of parvovirus B19 as a potential cause of severe liver disease is expected to augment our ability to make a definitive diagnosis of the etiology underlying such severe clinical presentations.

### INTRODUCTION

Alcoholic liver disease (ALD) represents a common cause of morbidity and mortality in Europe and United States, its clinical manifestations ranging from fatty liver to end-stage cirrhosis. In this context, acute alcoholic hepatitis (AAH) is a serious complication, with a short-term mortality rate exceeding 50% in most severe cases<sup>[1-4]</sup>. Liver biopsy maintains its pivotal role in diagnosing AAH, in predicting its outcome and in the selection of patients suitable for treatment: steatosis, ballooning degeneration, Mallory bodies, perivenular polymorphonuclear inflammation and "chicken-wire" fibrosis represent the most frequent findings<sup>[5]</sup>.

In the setting of AAH, imaging studies do not confirm the presence of ALD, but can be used to evaluate hepatic parenchymal changes. Ultrasonography (US) scan, computed tomography (CT) scan, and magnetic resonance imaging (MRI) can be used to diagnose fatty changes, cirrhosis or neoplastic diseases of the liver.

On MRI, specific features suggestive for alcoholic cirrhosis versus virus-induced cirrhosis include a higher volume index of the caudate lobe, smaller size of regenerative nodules of the liver and more frequent visualization of the right posterior hepatic notch<sup>[6]</sup>. On US liver scan, the presence of "pseudoparallel channel signs" and of low hepatic artery resistivity index (RI) at duplex Doppler investigation have both been reported in AAH<sup>[7-9]</sup>. A "pseudotumoral" hepatic pattern at CT scan has also been reported in this setting, even if only scanty data are available<sup>[10]</sup>. Advanced fibrosis can be

### Abstract

In acute alcoholic hepatitis (AAH), a "pseudotumoral" appearance of the liver parenchyma on computed tomography (CT) scan has been reported. The main findings are hypervascularized areas closely similar to those observed in large hepatocellular carcinomas. We report a case of a patient affected by AAH with an unusual appearance of these "pseudotumoral" areas on CT scan, close resembling a metastatic cancer rather than a primary hepatocellular carcinoma. In fact, in contrast with previous reports, the picture was characterized by the presence of many inhomogeneous, hypoattenuated areas highlighted during both pre- and post-contrast phases. Moreover, we report the first description of "pseudotumoral" lesions on ultrasound scan. This patient was successfully treated with corticosteroids, even if many controversies still exist regarding their efficacy in this setting.

determined using transient elastography<sup>[11]</sup>.

The present case report refers to an AAH patient with unusual pseudotumoral US and CT scan hepatic pattern, with favourable clinical course after alcohol withdrawal and steroid treatment.

## CASE REPORT

A 33-year-old man, immigrating from Bangladesh, was referred to our Gastrointestinal Unit on August 9, 2007 because of marked asthenia, nausea, vomiting, abdominal pain and weight loss of 11 kg (from 66 to 55 kg for 170 cm of height) during the previous month. Blood arterial pressure was 105/70 mmHg and heart rate 80 beats per minute. The state of consciousness was normal and the physical examination revealed a painful hepatomegaly, with the lower hepatic edge 20 cm below the right costal margin. His past history revealed heavy smoking, accounting for a lifetime packet sum of 1800, and daily alcohol intake of 60 g until 2005; alcohol intake was then denied until hospital admission. His laboratory tests are reported in Table 1 (left column). Past or current HBV, HCV and HIV infections were ruled out by determining HBsAg and anti-HBc (tested with commercial electrochemiluminescence immunoassay kits-Elecys HBsAg, anti-HBc; Roche Diagnostics, GMBH, Manheim, Germany), anti-HCV (Innotest-HCV-Ab IV; Innogenetics, Ghent, Belgium) and anti-HIV (tested with chemiluminescence immunoassay, Ag/Ab Combo-Architect, Abbott, Chicago, Illinois, USA). Serological and stool tests for parasitic infections were negative. Anti-nuclear, anti-mitochondrial and anti-LKM antibody were searched for by indirect immunofluorescence performed on 4 µm cryostat sections from rat liver, kidney and stomach tissues, at a sera dilution of 1:40. ECG and chest X rays were negative. US liver scan revealed a severe derangement of hepatic structure, characterized by multiple micro- and macronodular hyperechoic lesions; the biliary tree was not dilated and there were no signs of portal hypertension. Color-Doppler examination showed intrahepatic arterial dilation with pseudoparallel channel sign and low hepatic artery RI (Figure 1). At total body CT scan there was a marked liver enlargement, and multiple hypoattenuated areas were noted both with and without contrast medium (Figure 2); a diagnosis of metastatic liver disease was made. Transient elastography (Fibroscan®) was also performed and the observed value of 75 kPa (normal value < 8.0) was consistent with advanced liver fibrosis. Upper gastrointestinal tract endoscopy revealed esophageal varices (F1) and portal hypertensive gastropathy. To better define hepatic lesions, US-guided liver biopsy was obtained from both hypoattenuated areas and the surrounding parenchyma, and specimens routinely stained. At histology, main findings included a diffuse fibrosis surrounding regenerating nodules, intrasinusoidal collagen deposition, perivenular polymorphonuclear infiltration, focal fatty infiltration and ballooning degeneration with Mallory bodies, all features consistent with a final diagnosis of AAH on

**Table 1** Biochemical characteristics of the patient

Parameters (reference value)	August 9, 2007	November 22, 2007	November 12, 2008
Haemoglobin (g/dL) (13-16)	12.7	12.2	12

cirrhosis, with "pseudotumoral" areas. In the meantime, careful re-evaluation of usual daily alcohol intake, extended to patient's friends, allowed to estimate an actual daily intake of 250 g for many years.

According to a Maddrey's discriminating factor of 63, we instituted a treatment consisting in the daily administration of 40 mg of prednisolone, rapidly followed by clinical and laboratory improvement. The regimen was slowly tapered down and at the following clinical observation in November 2007, the patient was asymptomatic, he had stopped drinking, his body weight had increased by 13 kg (from 55 to 68) and his physical examination revealed a dramatic reduction in liver size, with the lower hepatic edge at 5 cm below the right costal margin. Laboratory tests at that time are summarized in Table 1 (central column). Moreover, a new determination of the transient liver elastography indicated a value of 51 kPa, accounting for a decrease of 24 kPa as compared to the previous measurement. A further control, performed on November 11, 2008, showed the complete normalization of both physical findings and blood tests (Table 1, right column). Interestingly, at this time, the score at transient elastography was 8.5 kPa. As mean corpuscular volume of red blood cells was unusually "normal" (86 fL, with reference value of 84-94 fL) in the setting of AAH, and, also considering the ethnic origin of the patient, we investigated a possible underlying hemoglobinopathy by HPLC (high performance liquid chromatography), analysing different Hb fractions (Variant, Bio-Rad, Milan, Italy). Findings were consistent with a heterozygous state for HbE.

## DISCUSSION

The present case report concerns a patient with AAH superimposed to established cirrhosis, with "pseudotumoral" hepatic areas. This unusual finding was first

**Figure 1** US scan showing a large hypoechoic area compared to surrounding parenchyma (A) and the image of “parallel channel” sign (B). Color-Doppler demonstrates the “pseudoparallel channel” sign, characterized by dilated intrahepatic arterial branch with an adjacent portal venous tract, and the low hepatic artery RI (C, D).

**Figure 2** CT scan showing a wide hypovascularized area in the pre-contrast phase (A) that remains hypovascularized during both early (B) and late (C) arterial phases.

described in two reports<sup>[9,10]</sup>, possibly involving the same single case. More recently, Colli *et al*<sup>[12]</sup> described both the CT and histological characteristics of “pseudotumoral” hepatic areas in five patients with AAH. These focal lesions were described as hypoattenuated areas when compared to the surrounding parenchyma, during the pre-contrast phase, becoming hyperattenuated during the post-contrast and late arterial phases, respectively, a pattern consistent with hypervasculated areas possibly related to a high-grade tissue regeneration. Interestingly, such lesions were closely similar to those observed in cases of large hepatocellular carcinoma<sup>[13]</sup>, accounting for possible misdiagnosis. Differently from what previously reported, in this case the finding of many inhomogeneous, hypoattenuated areas highlighted during both pre- and post-contrast phases was more similar to metastatic cancer rather than to primary hepatocellular carcinoma and was responsible for the initial misdiagnosis of hepatic metastases. This led to further

investigations, including a liver biopsy, which provided the correct diagnosis of AAH, ruling out any malignancy. This picture differs from the previously reported AAH CT pattern.

Occasionally, focal areas of normal parenchyma in an otherwise diffuse fatty liver may simulate mass lesions, described as “pseudolesions”, that may pose a difficult diagnostic problem<sup>[14]</sup>. These areas usually present a vascularisation similar to the surrounding parenchyma: in the present case, instead, the lesions appeared clearly different in each vascular phase, as compared to the liver. Moreover, pseudo-tumoral hepatic lesions were described in a variety of other benign conditions, such as inflammatory pseudotumors, parasitic infestations, tuberculosis infection, or areas of focal sparing in diffuse processes<sup>[15-19]</sup>, conditions ruled out in our patient.

An additional interesting finding, in the present case, was the presence of a typical alcohol-related duplex-Doppler image, called “pseudoparallel channel sign”,

reported in patients with AAH by Sumino *et al*<sup>7</sup> and characterized by dilated intrahepatic arterial branch with an adjacent portal venous tract. A dilation of hepatic artery, with increased peak systolic velocity, has also been described by Han *et al*<sup>9</sup>, who assumed that in AAH the presence of liver fibrosis increases sinusoidal resistance, blocking sinusoidal blood flow and ultimately portal blood flow in a retrograde manner. Therefore, in order to maintain hepatic perfusion, there is a dilation of hepatic artery leading to increased blood flow. A further interesting Doppler finding in this patient was the low hepatic artery RI, whose role in diagnosing AAH remains however controversial. Colli *et al*<sup>8</sup> reported a statistically significant decrease of hepatic artery RI in patients with AAH, as compared to both healthy and cirrhotic patients, a finding in contrast with the cirrhotic pattern observed in our patient. The possible relevance of the hepatic artery RI in AAH has also been challenged by Han *et al*<sup>9</sup>, who reported a high variability of this sign in patients with liver disease, accounting for a lack of a clear-cut distinction between AAH and cirrhosis.

To assess the severity of underlying liver disease and to properly take care of the patient, we assessed three main prognostic models, all validated for AAH [i.e. Maddrey's discriminating factor (mDF), model for end-stage liver disease and Glasgow for acute alcohol hepatitis score (GAHS)]<sup>[20-22]</sup>. Our case scored a total of 63, 14 and 9, respectively, compared to reference values of 32, 21 and 9. A mDF  $\geq 32$  and a GAHS score  $\geq 9$  identify patients with a very poor prognosis who have been reported to have had a good clinical response to corticosteroids<sup>[23]</sup>. Based on an mDF of 63 and a GAHS of 9, a corticosteroid regimen was instituted and then slowly progressive tapered down, on the basis of progressive clinical, laboratory and radiological improvement. At present, prognostic scores for AAH may orient the patient management, even if the use of steroids in this setting has recently been challenged by pertinent metanalytic data<sup>[24]</sup> while other treatments, such as anabolic steroids, pentoxifylline and infliximab, are still under investigation<sup>[25-27]</sup>.

To complete the liver disease staging and to obtain data useful in the follow up, our patient underwent also a transient elastography (FibroScan®). Values obtained in this case were very high, indicating not only a possible advanced fibrosis of the liver, but also confirming recent reports suggesting that transient elastography can be influenced by other parameters, such as the degree of necroinflammatory activity, especially during acute hepatitis<sup>[28]</sup>.

To summarize, in patients with AAH, "pseudotumoral" hepatic areas can appear at CT scan not only as hypervascular lesions similar to HCC, as previously described, but also as hypoattenuated lesions during all contrast phases, closely similar to liver metastases. This feature has to be carefully considered to avoid misdiagnosis.

forated Meckel's diverticulum. *World J Gastroenterol* 2009; 15(32): 4075-4076 Available from: URL: <http://www.wjgnet.com/1007-9327/15/4075.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.4075>

### INTRODUCTION

Celiac disease is an autoimmune enteropathy often seen in gluten sensitive patients<sup>[1]</sup>. It has two presentations in adults, namely the classical (diarrhea-predominant) type and the silent type<sup>[2]</sup>. The silent group includes atypical presentations. Some initiating factors, such as gluten overload, surgery, giving up smoking, and infections can trigger the disease, which can become apparent in an abrupt manner<sup>[3,4]</sup>.

Meckel's diverticulum is a common congenital anomaly of the small bowel. Ulcer, hemorrhage, intussusception, intestinal obstruction, perforation, and, very rarely, vesicodiverticular fistulae and tumors are complications of these diverticula<sup>[5]</sup>. We present a case of Meckel's diverticula that was diagnosed as celiac disease after surgery. This is the first reported case of Celiac disease that has been diagnosed after an ileal resection rather than upper abdominal surgery.

### Abstract

Celiac disease can be triggered by upper abdominal surgery, such as vagotomy, oesophagectomy, pancreaticoduodenectomy, and gastrojejunostomy. Here we report a case of a 24 year-old woman who developed celiac disease after an ileal resection for perforated Meckel's diverticula. This is the first reported celiac case that has been triggered, not by upper abdominal surgery, but after ileal resection for Meckel's diverticula.

### CASE REPORT

A 24 year-old woman applied to the emergency service with abdominal pain, nausea, and vomiting. She did not have any bowel movements or flatus and her abdominal pain worsened after her hospitalization. There was tenderness and guarding on abdominal palpation. Her initial laboratory tests revealed a leukocytosis score of 14000/mm<sup>3</sup>.

Due to her worsening abdominal pain and a white blood cell count that progressively increased to 16.000/mm<sup>3</sup>, urgent surgery was performed for an acute abdomen. Perforated Meckel's diverticula, located 80 cm proximal to the ileocecal valve, were observed during the operation. Ten centimeters of small bowel segment including the Meckel's diverticulum was resected and an end-to-end anastomosis was performed. Pathological investigation of the surgical specimen revealed perforated Meckel's diverticula and segmental ileal resection. The patient was discharged 4 d after the surgery without any complications.

**Figure 1** Diffuse villous atrophy in the duodenum (HE,  $\times 10$ ).

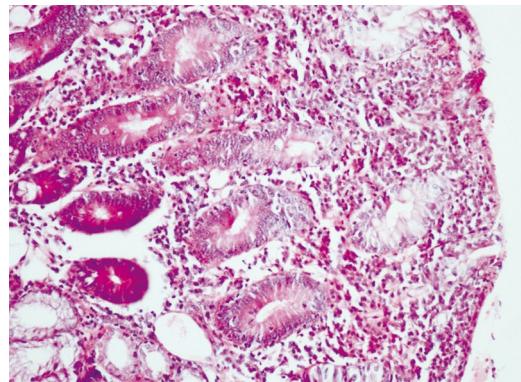

Twenty days after the discharge, the patient applied to the gastroenterology clinic with complaints of abdominal pain, flatulence and a loose stool 4-times/d. Her laboratory examination revealed Hb:10 g/dL, WBC: 5400/mm<sup>3</sup>, Plt: 458.000/mm<sup>3</sup>, vitamin B12: 119 ng/mL (180-914), AST: 14 U/L (5-45), ALT: 14 U/L (5-45), and ALP: 260 U/L (80-270). An upper gastrointestinal endoscopy was performed for her anemia, which showed antral gastritis and scalloping of duodenal mucosal folds. Endoscopic duodenal biopsy revealed diffuse atrophic villi with an increase in intraepithelial lymphocytes suggesting celiac disease (Figures 1 and 2). For confirmation of Celiac disease, gluten antibodies were determined as follows: anti-gliadin IgA, 88.2 U/mL (0-12); anti-gliadin IgG > 100 U/mL (0-12); anti-endomysial IgA antibody, (+++); anti tissue transglutaminase IgG, 51.2 U/mL (0-10); and anti tissue transglutaminase IgA, > 200 U/mL (0-10). Gluten was removed from the diet and thereafter her complaints of abdominal pain, flatulence, and diarrhea resolved. Her laboratory tests after a 2-mo gluten free diet were; Hb 12.2 g/dL and vitamin B12: 461 ng/mL (180-914).

## DISCUSSION

Celiac disease is an autoimmune enteropathy seen in gluten sensitive patients. It is a common genetic disorder with a prevalence of 1%-2%<sup>[6]</sup>. The disease can manifest itself by different clinical presentations. There are gastrointestinal symptoms, diarrhea and weight loss in the classical type, while extra intestinal findings are most common in the atypical or subclinical form<sup>[2-4]</sup>.

Our patient could have been in the silent form of the disease that became overt after the triggering effect of surgery. There are celiac disease patients in the literature that were triggered by upper gastrointestinal surgery, such as vagotomy, oesophagectomy, pancreaticoduodenectomy, and gastrojejunostomy<sup>[7-10]</sup>. Our case is the first report of celiac disease being triggered by ileal surgery.

The autoimmune activation mechanism triggered by the surgery is not yet known. However, it has been postulated that raised intestinal permeability might be involved in the pathogenesis of celiac disease<sup>[11]</sup>. Andersen

**Figure 2** Increased intraepithelial lymphocytes in the duodenum (HE,  $\times 50$ ).

et al<sup>[12]</sup> have shown by a triple sugar test that bowel permeability is increased in ileostomy patients. Perhaps this hyperpermeability could be the triggering factor in our patient. Another possible mechanism for the emergence of post-operative Celiac disease in our patient could be antigenic overload secondary to postoperative changes<sup>[9]</sup>.

Early diagnosis of Celiac disease in the postoperative period is important to prevent complications. A clinician should be aware of Celiac disease when the patient has refractory diarrhea, anemia, weight loss, and hypoalbuminemia after ileal surgery, not just after upper gastrointestinal surgery.

## Abstract

Cholecystocolonic fistula (CF) is an uncommon type of internal biliary-enteric fistulas, which comprise rare complications of cholelithiasis and acute cholecystitis, with a prevalence of about 2% of all biliary tree diseases. We report a case of a spontaneous CF in a 75-year-old diabetic male admitted to hospital for the investigation of chronic watery diarrhea and weight loss. Massive pneumobilia demonstrated on abdominal ultrasound and computerized tomography, along with chronic, bile acid-induced diarrhea and a prolonged prothrombin time due to vitamin K malabsorption, led to the clinical suspicion of the fistula. Despite further investigation with barium enema and magnetic resonance cholangio-pancreatography, diagnosis of the fistulous tract between the gallbladder and the hepatic flexure of the colon could not be established preoperatively. Open cholecystectomy with fistula resection and exploration of the common bile duct was the preferred treatment of choice, resulting in an excellent postoperative clinical course. The incidence of biliary-enteric fistulas is expected to increase due to the parallel increase of iatrogenic interventions to the biliary tree with the use of endoscopic retrograde cholangio-pancreatography and the increased rate of cholecystectomies performed. Taking into account that advanced imaging techniques fail to demonstrate the fistulas tract in half of the cases, and that CFs usually present with non-specific symptoms, our report

could assist physicians to keep a high index of clinical suspicion for an early and valid diagnosis of a CF.

## INTRODUCTION

Internal biliary-enteric fistulas (IBFs) are very rare, comprising 0.4%-1.9% of all biliary tract diseases<sup>[1-3]</sup>. IBFs are detected in only 0.2%-0.9% of all biliary tract operations<sup>[4-6]</sup>. Depending on the site of communication with the extrahepatic biliary tree, several types of fistulas are recognized (cholecystoduodenal, choledochoduodenal, cholecystogastric, cholecysto-choledochal, cholecystocolonic, cholecystoduodenocolic)<sup>[1,2]</sup>. Peptic ulcer and malignancies of the stomach, gallbladder, pancreas, duodenum, colon and bile ducts have been identified as etiologic factors, with cholelithiasis being the predisposing factor<sup>[2]</sup>. Iatrogenesis may be responsible for an increasing incidence of IBFs in the near future<sup>[2]</sup>, as the use of endoscopic retrograde cholangio-pancreatography (ERCP) and the rate of cholecystectomies performed annually increase.

A cholecystocolonic (otherwise cholectystocolonic) fistula (CF) is an uncommon type of IBF, which forms a communication between the gallbladder and the hepatic flexure of the transverse colon (Figure 1)<sup>[7]</sup>. Theoretically, fistula formation was part of the natural history of acute cholecystitis prior to the era of cholecystectomy and antibiotics<sup>[8]</sup>. Its frequency among other types of IBF

ranges between 8% and 13.6%<sup>[1,9,10]</sup>. CFs are associated with several severe complications, such as acute cholangitis, biliary peritonitis and biliary cirrhosis<sup>[3,11,12]</sup>, leading to a global mortality rate between 10% and 15%<sup>[4,9,10]</sup>.

Since Courvoisier first discussed spontaneous biliary fistulas in 1890<sup>[5]</sup>, several authors have described interesting case-reports of CF in the literature<sup>[13-38]</sup>. However, diagnosis still remains a challenge, mainly because: (1) CF presents with varying and non-specific symptoms; (2) CF is very rare and is kept last in differential diagnosis; and (3) even advanced imaging techniques fail to demonstrate the fistulas tract in almost half of the cases<sup>[1,2,13]</sup>.

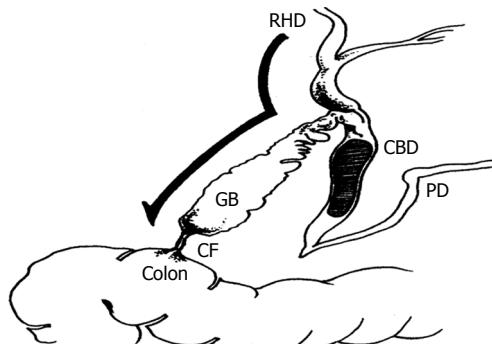

In this paper, we report a case of a spontaneous CF and review the literature. The aim of this paper is to elaborate on the clinical manifestation of a CF and describe the pathophysiological mechanisms. In conclusion, we suggest that the triad of pneumobilia, chronic diarrhea and malabsorption of vitamin K could assist physicians to keep a high index of clinical suspicion for CF, leading to an early and valid diagnosis.

## CASE REPORT

A 75-year-old male patient was referred to our university hospital for the investigation of chronic diarrhea and weight loss. The patient reported suffering from watery diarrhea of 3-4 bowel movements daily, lasting longer than 18 mo, and weight loss of 15 kg. The patient reported having no fever, nausea, vomiting, jaundice or abdominal pain. Medical history revealed the presence of mild diabetes mellitus type 2, which was controlled by diet, and a long-lasting smoking habit. The patient had already been subjected to colonoscopy prior to his admittance. Biopsies, including the terminal ileum, had been unrevealing. Routine laboratory tests of total white blood cell (WBC) count, erythrocyte sedimentation rate (ESR), aminotransferase levels and electrolytes had also been found within normal.

On admission, the patient was afebrile. No pathological signs were found on physical examination. Laboratory investigation demonstrated alkaline phosphatase of 228 IU/L (normal range 35-120 IU/L),  $\gamma$ -glutamyl transpeptidase of 120 IU/L (normal: 10-45 IU/L), C-reactive protein of 6.51 mg/dL (normal: 0-0.5 mg/dL) and a prolonged prothrombin time (PT) of 20.3 s (normal: 12.2 s), that was returned to normal after parenteral administration of vitamin K (10 mg subcutaneously). Total and differential WBC counts, haemoglobin, platelet count, ESR, aminotransferase levels, bilirubin, total protein, albumin and electrolytes ranged within normal values. Fecal examination included negative stool culture and negative examination of stool for ova and parasites. Stool examination for fat was negative, but fat determination of 24 h stool was unavailable.

Ultrasonographic examination of the liver and the extrahepatic biliary tree demonstrated pneumobilia and moderate dilatation of the intrahepatic bile ducts, with a normal common bile duct and a thick-walled gallbladder (Figure 2). Enhanced CT of the abdomen confirmed

**Figure 1 Schematic demonstration of a cholecystocolic fistula (modified from Benage et al<sup>[7]</sup>). GB: Gallbladder; CBD: Common bile duct; RHD: Right hepatic duct; PD: Pancreatic duct; CF: Cholecystocolic fistula.**

**Figure 2 Ultrasonographic examination revealing pneumobilia and moderate dilatation of the intrahepatic bile ducts, with a normal common bile duct and a thick-walled gallbladder.**

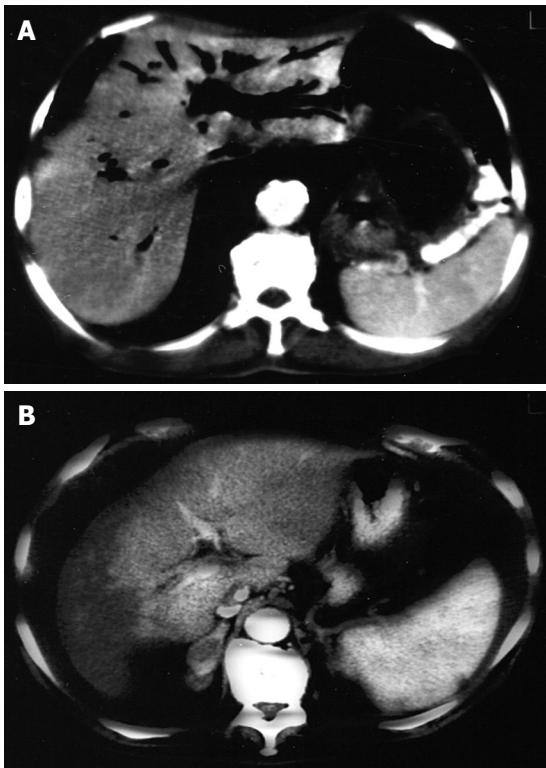

massive pneumobilia and absence of common bile duct dilatation (Figure 3A). Furthermore, the presence of air was detected in the gallbladder, which was neighboured to the hepatic flexure of the colon (Figure 3B). Neither the following barium enema nor the MR cholangio-pancreatography were able to detect any fistulous tract between the gallbladder and the colon.

The patient was subsequently referred to surgery for diagnostic laparotomy. During surgery a fistulous tract from the fundus of the gallbladder to the hepatic flexure of the colon was detected, along with an impacted large gallstone near Vater's villa. Cholecystectomy with fistula resection and bilio-enteric anastomosis after gallstone removal was undertaken. The patient had an excellent postoperative clinical course. Diarrhea stopped, and he regained his weight within a 6 mo period.

## DISCUSSION

We report a case of a spontaneous CF in a male diabetic patient, due to asymptomatic cholelithiasis. A combined triad of strong clues (pneumobilia, chronic, bile acid-induced diarrhea and malabsorption of fat-soluble vitamin K) provided high clinical suspicion for a CF, which was only confirmed during diagnostic laparotomy.

Several authors have reported their own experience of CFs<sup>[2,7,9,13-38]</sup>. Table 1 summarizes patients' demographics,

**Figure 3** Computed tomography scan. A: Massive pneumobilia ("air cholangiogram"); B: Presence of air detected in the gallbladder.

etiological factors, clinical presentation, presence of pneumobilia, means of fistula visualization and treatment option preferred. CF occurs mostly in the elderly, with a female preponderance<sup>[3,9]</sup>. In our case and in more than 90% of all cases, cholelithiasis is the main etiologic factor. Cholelithiasis may cause either recurrent episodes of acute cholecystitis/cholangitis or asymptomatic chronic calculous cholecystitis. The sequence of events that lead to the formation of the fistula include gallbladder inflammation, mechanical erosion by gallstones and gangrenous changes of both the gallbladder wall and the wall of the adjacent colon<sup>[14,17,39]</sup>. The gallstone found in the common bile duct in our patient could have affected the formation of the fistula by increasing the pressure in the biliary tree and thus enhancing the mechanical erosion of the gallbladder by another gallstone or gallstones that could easily have escaped through the fistulous tract.

CF usually has a benign clinical course, remaining asymptomatic for a long time, and can only be found incidentally<sup>[24,26,28]</sup> or be suspected by the presence of unexplained pneumobilia in patients with a history of episodes of right upper quadrant (RUQ) pain<sup>[17,22]</sup>. In other cases, varying symptoms are identified like fever, nausea and vomiting, attacks of abdominal pain localized mainly in the RUQ and jaundice<sup>[15,19,23,36]</sup>. These symptoms are non-specific and cannot be directly attributable to the fistula but rather to the main etiologic factor, cholelithiasis. In these cases, clinical presentations of acute cholecystitis, cholangitis or acute/chronic pancreatitis predominate.

A more specific symptom of a CF is chronic diarrhea<sup>[2,9,13,14,21,24,27,32,35]</sup>. CFs alter the normal enterohepatic

circulation of bile acids, leading to chronic watery diarrhea. This is a type 1, bile acid-induced diarrhea, which results from the stimulation of colonic mucosa by bile acids and the subsequent colonic secretion of water and electrolytes<sup>[35,40,41]</sup>. In other cases, especially when hepatic synthesis of bile acids is reduced, bypass of the distal ileum allows bile acids to escape absorption, leading to steatorrhea<sup>[7,9,35,36]</sup>. Bile salts are needed for micelle formation and subsequent absorption of fat and fat-soluble vitamins, while protein absorption is not affected. Fat malabsorption resulting from impaired micelle formation is not as severe as malabsorption resulting from pancreatic lipase deficiency, because fatty acids and monoglycerides can form lamellar structures, which to a certain extent can be absorbed<sup>[42]</sup>. Theoretically, malabsorption of fat-soluble vitamins (A, D, K and E) may be marked, because micelle formation is required for their absorption. However, malabsorption of fat-soluble vitamins A and E has never been reported in the literature, while malabsorption of vitamin D has only been described in one female patient with CF and osteoporosis/osteomalacia<sup>[7]</sup>. The deficiency of those vitamins has to be marked to provide clinical symptoms, and laboratory evaluation is difficult and outside routine clinical practice. On the other hand, vitamin K deficiency can easily be detected by a prolonged PT and can be fixed with parenteral administration.

Rare complications of CF reported in the literature are ectopic gallstone in the colon with obstruction<sup>[29,30,34,37,38]</sup> or hemorrhage of the lower gastrointestinal tract<sup>[20]</sup>, and extraperitoneal abscess with sepsis due to ascending contamination by colon bacteria<sup>[18,20,43]</sup>.

Barium enema<sup>[2,9,13,21,24,26,27,32]</sup>, <sup>99m</sup>Tc scintigram<sup>[24,43]</sup>, CT<sup>[29,44]</sup>, MRCP and ERCP<sup>[7,13-15,17,19,21,22,35,36]</sup> have all been used in order to demonstrate the fistula. However, non-visualization of the fistulous tract occurs in almost half of the cases<sup>[1,2,13,44]</sup>, and, subsequently, patients are subjected to exploratory laparotomy. The presence of pneumobilia, detected by plain abdominal films, abdominal ultrasound or CT, may provide presumptive evidence for the existence of a biliary-enteric fistula, but it is non-specific<sup>[2,45]</sup>. Other radiological features include a small atrophic gallbladder adherent to neighboring organs or a shrunken thick-walled gallbladder around gallstones<sup>[2,44]</sup>.

Open cholecystectomy with fistula resection and exploration of the common bile duct is the treatment of choice mostly preferred in order to avoid attacks of cholecystitis and/or cholangitis. However, successful cases using the laparoscopic approach are increasingly reported in the literature<sup>[15,23,26,28,31-33]</sup>. In non-surgical patients, either conservative treatment with antibiotics and supplementation of fat-soluble vitamins<sup>[9,16]</sup>, or ERCP sphincterotomy<sup>[36,46]</sup> to reduce biliary pressure are suggested.

In conclusion, especially in patients with a history of gallstone disease, the presence of chronic watery diarrhea and vitamin K malabsorption, combined with the radiological finding of pneumobilia, form a pathognomonic triad. Either internists/gastroenterologists

## INTRODUCTION

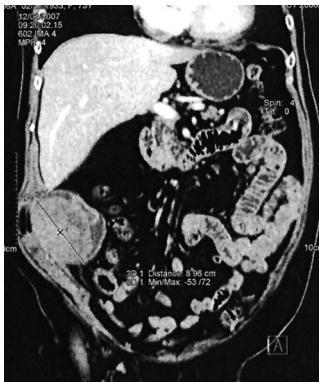

Appendicitis was recognized as a surgical disease when Reginald Heber Fitz correctly pointed out that the frequent abscesses in the right iliac fossa were often due to perforation of the veriform appendix, and he referred to the condition as appendicitis<sup>[1]</sup>. Since that discovery and the development of various surgical incisions and appendectomy techniques, many early and late postoperative complications and coincident conditions have become evident. One of these complications is a postoperative abdominal wall mass in the region of McBurney's muscle-splitting incision. The diagnosis and management of abdominal wall masses after open appendectomy are challenging because various conditions such as appendectomy-related, primary-local (appendectomy-unrelated) and primary-systemic could be the cause of abdominal wall masses postoperatively. This report presents the first known case of a suture granuloma with intra-abdominal extension as a cause of an abdominal wall mass after open (muscle-splitting) appendectomy.

## CASE REPORT

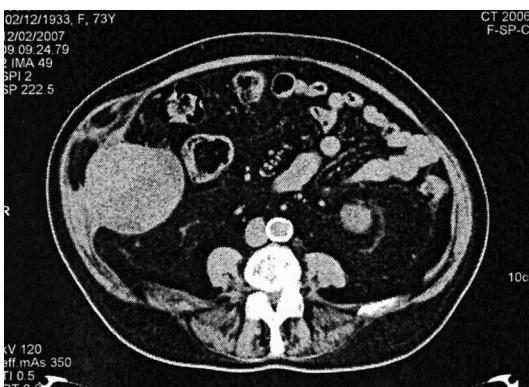

A 75 year-old woman presented with a slightly painful palpable mass in the right lower abdomen lasting for 6 mo. The pain in the right lower quadrant was described as continuous, nonradiating, mild and non-disturbing. There was no nausea or vomiting. Body temperature

## Abstract

Most complications after appendectomy occur within ten days; however, we report the unusual case of a suture granuloma 12 years after open appendectomy. The afebrile 75-year-old woman presented with a slightly painful palpable mass in the right lower abdomen. There was no nausea or vomiting and bowel movements were normal. She lost 10 kg during the 3 mo before presentation. The patient had undergone an appendectomy 12 years previously. Physical examination revealed a tender mass, 10 cm in diameter, under the appendectomy scar. The preoperative laboratory findings, tumor markers and plain abdominal radiographs were normal. Multi-slice computed tomography scanning showed an inhomogenous abdominal mass with minimal vascularization in the right lower abdomen 8.6 cm × 8 cm × 9 cm in size which communicated with the abdominal wall. The abdominal wall was thickened, weak and bulging. The abdominal wall mass did not communicate with the cecum or the ascending colon. Complete excision of the abdominal wall mass was performed *via* median laparotomy. Histopathological examination revealed a granuloma with a central abscess. This case report demonstrates that a preoperative diagnosis of abdominal wall mass after open appendectomy warrants the use of a wide spectrum of diagnostic modalities and consequently different treatment options.

**Figure 1** CT scan of the abdominal wall mass in the right lower abdomen protruding into the abdominal cavity dislocating small bowel loops.

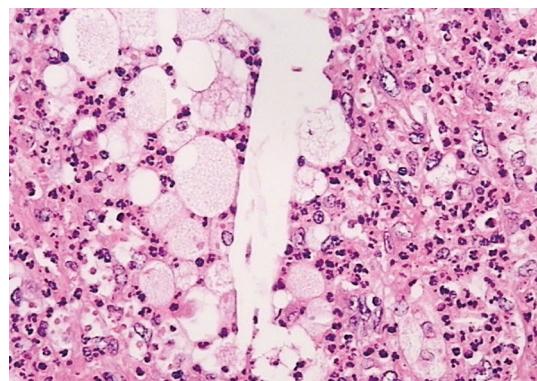

**Figure 2** CT scan of the lower abdomen showing the abdominal wall mass with thickened and bulging abdominal wall and no communication with the cecum.

was 36.8°C and bowel movements were normal. She lost 10 kg during the 3 mo before presentation. The patient had undergone open appendectomy (muscle-splitting incision) 12 years previously. Five years ago she had undergone vaginal hysterectomy with bilateral salpingo-oophorectomy for uterine leiomyomata. Following surgery the patient was in good health and without any symptoms or complaints. She did not take any medications. Physical examination revealed a slightly tender mass, 10 cm in diameter, under the appendectomy scar in the right lower abdomen. The swelling was elastic and poor in mobility. Other resistances were not found, and the rest of the physical examination was normal.

Preoperative laboratory findings and plain abdominal radiographs were normal. Tumor markers were as follows: CEA = 2.42 µg/L; AFP 1.24 µg/L; CA19.9 = 4.89 kU/L and CA 125 = 5.80 kU/L. Abdominal ultrasonography demonstrated a low-echoic mass lesion 8 cm × 8 cm just lateral to the cecum and in communication with the lateral abdominal wall. No peristalsis or communication with the bowel lumen was observed. Esophagogastroduodenoscopy revealed chronic gastritis and colonoscopy revealed sigmoid diverticulosis and normal mucosa in the cecum with normal ileocecal valve. Multi-slice CT scanning showed an inhomogenous abdominal mass with minimal vascularization in the right lower abdomen

**Figure 3** Excised abdominal wall mass.

**Figure 4** Histological image showing the abscess with polymorphonuclear leukocytes, histiocytes and cholesterol crystals (central part of the photograph). (HE,  $\times 400$ ).

which was 8.6 cm × 8 cm × 9 cm in size and communicated with the abdominal wall. The abdominal wall was thickened, weak and bulging (Figure 1). There was no communication between the cecum and the abdominal wall which was also confirmed by previous colonoscopy (Figure 2). From these findings an abdominal wall tumor was suspected and elective surgery was performed.

After a midline laparotomy and adhesiolysis, the greater omentum was detached from the mass in the right lower abdomen which was located intraperitoneally. There was no free intraperitoneal fluid or fibrin deposits. The elastic mass was adherent to the abdominal wall and there was no communication with the small and large bowel, retroperitoneal or vascular structures. After partial omentectomy, the mass was completely extirpated from the abdominal wall (Figure 3). Histopathological examination revealed a foreign-body granuloma with a central abscess (Figure 4). The patient's early postoperative course was uneventful and she left hospital on the 10th postoperative day. On several control examinations during the first 18 mo, the patient was completely symptomless.

## DISCUSSION

This case represents an unusual complication of a suture granuloma with intra-abdominal extension as a cause of an abdominal wall mass 12 years after open appendectomy.

To our knowledge (Medline search 1962-2007) this is the third case of such a complication after appendectomy. Abdominal wall abscesses after appendectomy were diagnosed by Matsuda *et al*<sup>[2]</sup> 11 years postoperatively and by Ichimiya *et al*<sup>[3]</sup> 25 years postoperatively.

A unique feature in our case was the intra-abdominal extension of the abdominal wall suture granuloma with a central abscess which complicated definitive diagnosis.

Since the development of various surgical incisions and appendectomy techniques, many early and late postoperative complications and coincident conditions have become evident. One of these complications is a postoperative abdominal wall mass in the region of McBurney's muscle-splitting incision. Morbidity associated with appendectomy can be as high as 25% in complicated cases<sup>[4]</sup>. Morbidity can be divided into early and late complications. Early complications are more common and mostly include wound hematoma, seroma, abscess or intra-abdominal abscess due to persistence of cavities between the muscle layers and the subcutaneous tissue which encourages fluid collections<sup>[5]</sup>. These complications can then result in cystic formations or masses that can simulate a tumor of the abdominal wall, if they are not readily resolved. For this reason, a meticulous surgical technique, careful hemostasis and placement of suction drains in the subcutaneous tissue are recommended, principally in obese patients<sup>[6]</sup>. Late complications are rare and can include obstruction due to adhesions, postoperative hernia or progression of inflammatory bowel disease not evident at operation for suspected appendicitis. Most of these complications can present as an abdominal mass. An abdominal mass as a primary pathology or postoperative finding always makes precise preoperative diagnosis difficult. A complete list of differential diagnoses of late presenting abdominal wall masses after open appendectomy is shown in Table 1.

Several points should be stressed. Firstly, abdominal wall masses could be: (1) appendectomy-related; (2) primary; (3) posttraumatic; and (4) related to other interventions in the surrounding area for other pathologic conditions. Thus, history taking and physical examination are crucial. The time interval from appendectomy is essential because it determines the difference between early and late complications of appendectomy. Furthermore, symptoms and signs of unrelated diseases (local or systemic) should be confirmed or ruled out (abdominal wall tumors, extension of intra-abdominal malignancy, endometriosis, lymphoproliferative disorders *etc*). Confirmation of invasive interventions in the surrounding area is very important. Open/laparoscopic surgery for intra-abdominal malignancy/infectious diseases, percutaneous or laparoscopic biopsy or percutaneous fine-needle aspiration for malignant hepatobiliary disease could be the cause of abdominal wall port site or incisional metastases or abscesses.

Secondly, by delineating the peritoneal line, the intraperitoneal or extraperitoneal location of the lesion can be determined. This is important for several reasons. First, the entrance into the peritoneal cavity

**Table 1 Differential diagnosis of late presentation abdominal wall masses after open appendectomy**

Suture granuloma

Extension from intestinal actinomycosis
Abdominal wall (hematogenous)

could be avoided during surgery if the lesion is located extraperitoneally. Also if the abscess is the cause (acute or chronic) then the extraperitoneal route avoids spillage of contents into the abdominal cavity thus eliminating the possibility of intra-abdominal abscess as a postoperative complication.

Generally, early postoperative masses are easier to diagnose and treat, while late postoperative abdominal wall masses could be of various etiologies that warrant the use of a wide spectrum of diagnostic modalities and consequently different treatment options. All these facts signify the importance of preoperative diagnosis. Thus, abdominal ultrasound, contrast-enhanced multi-slice CT and other diagnostic modalities should be used according to clinical findings. It is concluded that late postoperative abdominal wall masses after open appendectomy can be of various etiologies that warrant

the use of a wide spectrum of diagnostic modalities and consequently different treatment options.

### TO THE EDITOR

In the Letter to the Editor by Lobb<sup>[1]</sup>, the author has hypothesized that the putative hepatotoxicity of the dietary supplement, Hydroxycut, may be due to one of its components, namely hydroxycitric acid (HCA) derived from *Garcinia cambogia*. However, it is important to note that, of the 14 different formulations of Hydroxycut that have been marketed, only 8 contain HCA. In general, these products are cocktails containing up to 20 different ingredients. In the case studies cited by the author<sup>[1]</sup>, information is not provided regarding the specific Hydroxycut products that were used in each of the case reports. This is of concern given that of the numerous ingredients present in these products, no specific reason was given for identifying HCA as the putative hepatotoxic agent other than as the possible hepatotoxic agent in some of the previous case reports. Because of the name of this product line, it is understandable that a possible word association might be made with HCA. Can the reported hepatotoxicity of these products (assuming it is correct) be attributed to an ingredient or combination of ingredients? No information or discussion was presented regarding the potential hepatotoxicity of any of the other ingredients or combinations of ingredients, and it is distracting to make inferences without sound research support.

The importance of the issues raised above is underscored by the numerous animal<sup>[2-8]</sup> and human<sup>[5,9-12]</sup> studies on the safety and efficacy of HCA (as Super CitriMax, HCA-SX). Regrettably, none of these studies was referenced and discussed by the author of this Letter to the Editor<sup>[1]</sup>. In experimental animal studies at up to 25X the human equivalency dose of HCA, no reports are available on hepatotoxicity or other adverse effects. A HCA dose of 2500 mg/kg, equivalent to 150 000 mg in a 60 kg individual, had no adverse effect in the tested animals<sup>[2-4]</sup>.

### Abstract

Although a number of cases of hepatotoxicity are associated with the use of Hydroxycut weight management products, it has been alleged that their effects are primarily due to the presence of hydroxycitric acid (HCA, as Super CitriMax) in the formulations. However, while these products contain up to 20 different ingredients, some do not contain HCA. Case studies reported to date have not considered in depth the literature on the numerous animal and human studies that have been conducted on the safety and efficacy of HCA. No HCA-associated hepatotoxicity or treatment-related adverse effects have been reported in these studies, and thus it is premature to make the assumptions presented in the recent case studies regarding Hydroxycut. If it is established in well controlled studies that the use of these formulations with and/or without HCA can result in the occurrence or progression of hepatotoxicity, additional studies should be conducted to characterize the causative factor(s).

**Key words:** Hydroxycitric acid; Super CitriMax; Hydroxycitric acid-SX; *Garcinia cambogia*; Hydroxycut; Liver failure; Hepatotoxicity; Safety and efficacy

**Peer reviewer:** Xiao-Ming Yin, MD, PhD, Associate Professor of Pathology, Associate Director, Division of Molecular Diagnostics, Department of Pathology, University of Pittsburgh School of Medicine, Scaife Hall, 7th Fl, Room S739, 3550

Soni *et al*<sup>[5]</sup> have summarized the results of 15 HCA human clinical studies, 14 of them were double blind and placebo controlled, and one was a single arm, open trial. No treatment-related adverse effects have been reported in any of these studies. These authors concluded that HCA at a level up to 2800 mg/d is safe for human consumption. The combined data strongly suggest that HCA itself is not the culprit with respect to the case studies reporting hepatotoxicity associated with Hydroxycut use. In the Health Hazard Report on Hydroxycut by Mozersky *et al*<sup>[13]</sup>, the Board noted that it did not know what ingredient(s) present in these products can cause hepatotoxicity, assuming the products are indeed the causative agents. More studies are needed before a definitive conclusion can be made.

Interestingly, several animal studies have suggested that HCA may have hepatoprotective<sup>[14,15]</sup> and chemoprotective<sup>[16]</sup> properties. In addition, Kaats<sup>[17]</sup> has recently conducted a 60-d study on 25 human subjects using a product containing 4600 mg/d of HCA. The results showed no evidence of adverse effects and indicated hepatoprotection based on decreasing values for the hepatic enzymes, aspartate aminotransferase (AST) and alanine aminotransferase (ALT).

It should be noted that the dried fruit of *Garcinia cambogia*, a source of HCA, has been consumed for centuries throughout Southeast Asia<sup>[18]</sup> and is in the USDA's list of Perennial Edible Fruits<sup>[19]</sup>. Consistent with the above findings, HCA (as Super CitriMax) has been generally recognized as safe (GRAS) by the Burdock Group, one of the nation's leading food ingredient safety and toxicology groups.

Finally, a key issue that was not discussed by Lobb<sup>[1]</sup> is the possibility that other co-consumed substances, such as acetaminophen, alcohol, or a wide range of prescription drugs, may have been responsible for the hepatotoxicity. The referenced case study by Shim and Saab<sup>[20]</sup> does in fact note that acetaminophen was consumed along with aspirin. Acetaminophen toxicity is the leading cause for calls to Poison Control Centers in the United States and results in almost 500 deaths annually due to acute liver failure<sup>[21]</sup>.

There is no question that issues exist with respect to the regulation, quality control, and appropriate safety and efficacy studies of supplements, just as there are issues with numerous drugs, including acetaminophen, that cause extensive morbidity and mortality.

However, to point an accusatory finger at an ingredient that has been extensively studied and for which no adverse effects have been reported in animal and human studies, is counterproductive.

Given the widespread use of dietary supplements in the USA as well as in other countries, it is imperative that sound science should be used in the evaluation of the potential negative as well as the positive effects of these products. With respect to the potential negative effects of some of these products, an important step forward in this regard is the current requirement for adverse event reporting. However, it is important to note

that these reports typically reflect the associations, rather than the clear-cut cases of causality. When the associations are noted, they should be rigorously examined, and if the supplements are found to be the causative factors for the pathology reported, the true agents need to be firmly identified, along with the dose at which the negative effects are induced.

### TO THE EDITOR

We read with great interest the recent article by Liu *et al*<sup>[1]</sup> published in the April issue of the "World Journal of Gastroenterology" comparing the results of transcatheter arterial embolization and open surgical hemostasis in the treatment of patients with massive pancreaticojejunal anastomotic hemorrhage after pancreateoduodenectomy. We have several comments. Transcatheter embolization is now accepted as the salvage treatment of choice for acute bleeding from the upper gastrointestinal tract. Many published studies have confirmed the feasibility of this approach and the high technical and clinical success rates, ranging from 91% to 100% and from 63% to 100%, respectively, in all case-series including more than 10 patients over the last decade<sup>[2,3]</sup>. First, we are surprised in this study that 6 (35.3%) of the 17 patients had no angiography prior to additional open surgical hemostasis. In our experience, arteriography plays the primary role in the initial investigation of active gastrointestinal bleeding after pancreateoduodenectomy and should be the first step of investigative procedure in such situations, even in hemodynamically unstable patients. It was reported that the gastroduodenal artery stump is one of the main sources of pancreaticojejunal anastomotic hemorrhage after pancreateoduodenectomy<sup>[3]</sup>, as confirmed in this study. Selective angiography of the celiac trunk and common hepatic artery allows in the majority of cases to detect extravasation of contrast medium. However, it is usually difficult to catheterize the gastroduodenal artery stump. Then, we think that coil embolization of the common or proper hepatic artery on either side of the bleeding point ("sandwich technique") is preferable to prevent retrograde filling<sup>[4]</sup>. It seems unlikely that this technique was used by the authors, probably explaining recurrent bleeding in 2 (20%) of the 10 patients treated with transcatheter arterial embolization. Liver failure rarely occurs when hepatic artery embolization is achieved with this technique. However, verification of portal venous flow and the absence of underlying liver disease prior to embolization are required. When

### Abstract

Massive pancreaticojejunal anastomotic bleeding, mainly from the gastroduodenal stump, is one of the most common complications of pancreateoduodenectomy. Selective angiography should be systematically the first step of investigative procedure in such situations. Phacoarteriography may be used if the bleeding point is not spontaneously identified, and allows safe and effective treatment with transcatheter arterial embolization compared to blind open surgical hemostasis. Coil embolization of the common or proper hepatic artery on either side of the bleeding point with "sandwich technique" is then the preferred technique to prevent retrograde filling. Surgery should be performed only as a last resort.

Loffroy R, Guiu B. Arterial embolization is the best treatment for pancreaticojejunal anastomotic bleeding after pancreateoduodenectomy. *World J Gastroenterol* 2009; 15(32): 4090-4091 Available from: URL: <http://www.wjgnet.com>

the celiac trunk and common hepatic arteriograms are negative, selective catheterization of the superior mesenteric artery must be performed routinely to increase the probability of visualizing active bleeding, because the inferior pancreaticoduodenal artery sometimes supplies the pancreaticojejunal anastomosis. Furthermore, intraarterial anticoagulants, vasodilators, or fibrinolytic agents may be used during angiography to directly elicit contrast medium extravasation, thereby significantly facilitating embolization. In conclusion, we agree with the authors about the safety and efficacy of transcatheter arterial embolization for the treatment of acute hemorrhage after pancreatectoduodenectomy. Angiography should be performed first in such situations. In most cases, embolization obviates the need for surgery and is associated with lower complications and mortality rates than open surgical hemostasis.

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*) ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastrolesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systematically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Articles: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities on basic research and clinical practice.

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[12,21]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Patent** (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc, assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) =  $8.6 \pm 24.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *argI*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *KboI*, *KpnI*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

**Editorial Office**

**World Journal of Gastroenterology**

Editorial Department: Room 903, Building D, Ocean International Center,

No.62 Dongsihuan Zhonglu, Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

**Language evaluation**

The language of a manuscript will be graded before it is sent for revision.

- (1) Grade A: priority publishing;
- (2) Grade B: minor language polishing;
- (3) Grade C: a great deal of language polishing needed;
- (4) Grade D: rejected. Revised articles should reach Grade A or B.

**Copyright assignment form**

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

**Responses to reviewers**

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

**Proof of financial support**

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

**Links to documents related to the manuscript**

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

**Science news releases**

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

**Publication fee**

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
